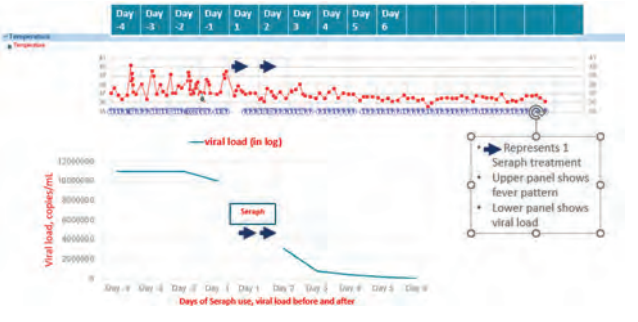
Case Description: A 17 y.o. female s/p deceased donor kidney transplant (txp) for underlying FSGS, on chronic therapy with prednisone, tacrolimus, everolimus, presented 2 years post txp with dysuria, hematuria and fevers. She had AKI (creatinine of 2.3, baseline 0.8), elevated transaminases, and high serum ADV (> 10 million copies/mL). Kidney biopsy showed ADV nephritis with patchy areas of necrotizing interstitial inflammation and abundant viral inclusion bodies. Immunosuppression was discontinued but she remained febrile to 41° C, and had ADV levels >log 7 (> 10 million copies/mL). Cidofovir was not used due to AKI, and the risk of nephrotoxicity. After discussing the risks and benefits treatment with Seraph100 filter was started. She received 2 sessions in-line with continuous renal replacement therapy for a total time of 9 hours. Approximately 18 blood volumes were processed. ADV load decreased from 10 million prior to treatment to 148009 copies/mL (log 5.2) after the 2nd session. Fever curve (Fig 1) and transaminases improved. The ADV load continued to decrease despite not receiving additional sessions & restarting txp meds.

Discussion: Seraph® 100 filter was effective in reducing the ADV load in this adolescent patient with disseminated adenoviral infection post kidney txp, and led to an improvement in her clinical status. She tolerated treatment without significant adverse events. Teaching Point: The Seraph 100 uses heparin coated beads to bind pathogens, and can help debulk the infectious load. More studies are needed in pediatrics on its efficacy.



Clinical, viral response with Seraph

Correlation Between Percentage Donor-Derived Cell-Free DNA (%dd-cfDNA) at Time of Allograft Biopsy and Rejection: Insights from the Multi-Center Pediatric Outcomes of Kidney Care in Renal Allografts (pOKRA) Study

Raja Dandamudi,[1,3] Leslie Walther,[1] Megan Kelton,[2] Margret Kamel,[4] Jodi M. Smith,[2] Vikas R. Dharnidharka.[1,3] *[1]Washington University in St Louis, St Louis, MO; [2]Seattle Children's Hospital, Seattle, WA; [3]St Louis Children's Hospital, St Louis, MO; [4]Emory University, Atlanta, GA.*

Background: The is prospective multi-center observational study to assess the accuracy of % dd-cfDNA as a biomarker for the detection of allograft rejection on simultaneous biopsy, in pediatric kidney transplant patients.

Methods: A total of 48 patients from 3 centers who underwent kidney biopsies within the first year post-transplantation were included in the study. We measured %dd-cfDNA levels using a targeted, multiplex PCR-based method analyzing single nucleotide polymorphisms. Patients were divided into two groups based on the presence or absence of allograft rejection, including subclinical rejection.

Results: We studied 77 samples of plasma %dd-cfDNA levels drawn on the same morning before kidney biopsies from 48 unique patients. Of 77 biopsies, 70 (91%) were surveillance biopsies, whereas 7 (9%) were diagnostic. We had 13 biopsy specimens from 12 patients with biopsy-proven acute rejection and 64 biopsy specimens from 44 patients without biopsy-proven acute rejection. At rejection, the %dd-cfDNA median (IQR) level was significantly higher at 1.2% (IQR, 0.5%-2.0%) than the quiescent group (median, 0.26%; IQR, 0.18%-0.49%). The area under the curve was 0.82 (95% confidence interval 0.70 to 0.93). Using a 1% cutoff, %dd-cfDNA had a specificity of 86 % (95% CI, 75% to 92%) and a sensitivity of 62 % (95% CI, 36% to 82%) in identifying active rejection. At the lower cutoff of 0.5%, %dd-cfDNA had a lower 75% specificity (95% CI, 63% to 84%) but higher 77% sensitivity (95% CI, 50% to 92 %) to discriminate biopsy-proven acute rejection from no rejection.

Conclusions: Prospective multicenter dd-cfDNA% levels timed to biopsy show a high accuracy with biopsy-proven acute rejection in children.

Using Eculizumab for Immediate Recurrence of ANCA Vasculitis in a Pediatric Kidney Transplant

Francis V. Lomanta,[1,2] Joseph R. Sherbotie,[1,2] Caitlin G. Peterson.[1,2] University of Utah, Division of Pediatric Nephrology. *[1]University of Utah Health, Salt Lake City, UT; [2]Primary Children's Hospital, Salt Lake City, UT.*

Introduction: ANCA associated vasculitis (AAV) is associated with poor renal outcomes with 20-30% of patients developing chronic kidney disease and up to 20-35% progressing to end-stage kidney disease. Recent advances have led to increasing interest towards complement inhibition as a potential treatment for AAV. We present a case of disease recurrence after pediatric kidney transplantation and the novel use of Eculizumab to salvage graft function.

Case Description: A 5-year-old Hispanic male with ESKD due to myeloperoxidase antibody positive ANCA vasculitis developed disease recurrence post-kidney transplant. Pre-transplant disease control required multiple rounds of high dose steroids, cyclophosphamide, azathioprine, and rituximab. Transplant induction included thymoglobulin and pulse-dose steroids with rapid taper. Mycophenolate (MMF) and tacrolimus (TAC) was started on POD 1 and 2 respectively. He developed gross hematuria on POD 5 with doubling of his serum creatinine (sCr) on POD 8. Kidney biopsy was done on POD 14 which showed pauci-immune glomerulonephritis and acute tubular necrosis without rejection. He was treated with plasmapheresis, pulse-dose steroids, and a dose of rituximab. Compassionate use of a C5a receptor inhibitor was sought and denied. Eculizumab, a C5 inhibitor was given instead on POD 28. With MMF, TAC, Eculizumab and steroid taper, his sCr improved. Two months later, he was transitioned to Ravulizumab. His kidney function remains stable and he continues to receive infusions without concerns of disease recurrence or serious infections.

Discussion: Previous reports of Eculizumab use for AAV led to our decision to use it for our patient with historically difficult to control AAV. This case illustrates a rare presentation of immediate disease recurrence of AAV in a pediatric kidney transplant and the successful use of C5 blockade. No specific treatment guidelines exist for childhood AAV, currently highlighting the need for further studies to evaluate efficacy and safety of complement inhibitors as treatment for childhood AAV.

Lipoprotein Apheresis in Pediatric Post-Transplant FSGS

Amber J. Kazi, Daryl M. Okamura, Raj P. Munshi, Roberto Gordillo, Andre Dick, Jodi M. Smith, Shina Menon. *University of Washington School of Medicine, Seattle, WA.*

Background: Focal segmental glomerulosclerosis (FSGS) is a common cause of end-stage renal disease (ESRD) in adolescents with a recurrence rate of >30% after transplant (txp). Lipoprotein apheresis (LDL-A) has been successfully used for post-txp FSGS recurrence (r-FSGS). It has also been used for drug resistant primary FSGS and de novo FSGS (d-FSGS) post-txp. We aimed to describe the efficacy and safety of LDL-A in pediatric patients with FSGS post-txp.

Methods: Retrospective, single center study at a tertiary care pediatric hospital. Outcomes were complete remission (CR) defined as Upc < 0.2; partial remission (PR) defined as Upc 0.2-2 and ≥ 50% reduction in proteinuria from baseline. All Upc in mg/mg.

Results: Five patients, age range 7-21 yrs (2 females; 4 r-FSGS, 1 d-FSGS) underwent LDL-A. Those with r-FSGS, 3 episodes were immediately post-txp, and 1 after 40 mths. D-FSGS was diagnosed 16 mths post txp in a patient with ARPKD. Two had a relapse requiring a 2nd course of LDL-A. Each course had 12 sessions using Liposorber® LA-15 system over a period of 9 weeks. Of those with r-FSGS, 3 had CR or PR at a median of 4 weeks after starting LDL-A. Patient 2 had >50% reduction in Upc from 34 (pre LDL-A) to a nadir of 3.3. A clinical relapse with increase in Upc to 11 was noted 4 months after 1st LDL-A. A 2nd course resulted in CR. Patient 3 with d-FSGS also had a >50% reduction in Upc from 15 (pre LDL-A) to a nadir of 2.7. A relapse with AKI (Upc 10.3, serum creatinine 7.3mg/dL) was seen after 11 months. A second course of LDL was attempted but patient did not respond, and was transitioned to chronic hemodialysis. No adverse events related to LDL-A were reported. Patient 3 had central line associated thrombus.

Conclusions: We report successful use of LDL-A in 5 pediatric patients. CR/PR was achieved in all with r-FSGS. In d-FSGS, there was significant decrease in proteinuria but no remission. The therapy was well tolerated with the only adverse event secondary to vascular access. More studies are needed to assess its efficacy in primary and d-FSGS post-txp.

Diabetic Ketoacidosis in Pediatric Kidney Transplant Patient After Treatment for Rejection

Katrina Epperson,[1,2] Susan A. Phillips,[2] Elizabeth G. Ingulli.[1,2] *[1]University of California San Diego, La Jolla, CA; [2]Rady Children's Hospital San Diego, San Diego, CA.*

Introduction: New onset diabetes after transplantation (NODAT) is reported in 3-20% of pediatric kidney transplant (KT) patients. Diabetic ketoacidosis (DKA) has not been reported in a pediatric KT recipient. We report on the first case of DKA in a pediatric KT patient with NODAT after treatment of acute rejection.

Case Description: A 16yo, nonobese, female who received a deceased donor KT 4mos earlier was diagnosed with biopsy-proven acute T-cell mediated Banff class 1B and acute antibody mediated rejection in the setting of elevated creatinine. Her rejection was treated with thymoglobulin (total dose 5 mg/kg) and methylprednisolone (MP, total dose ~20 mg/kg). After her initial dose of MP, she developed hyperglycemia, was diagnosed with NODAT and managed initially with insulin and then with sitagliptin and metformin. Her hemoglobin A1c ranged from 5.3% – 7.1%. A subsequent kidney biopsy 21 months after KT showed acute T-cell mediated Banff class 1B and acute antibody mediated rejection. This episode was treated with MP (~30 mg/kg) followed by oral prednisone 60 mg daily (~1 mg/kg/day). Her hemoglobin A1c was 5.8% and she remained on sitagliptin and metformin. She presented 41 days later with new onset polyuria and polydipsia. She was found to have 3+ urine ketones, blood glucose 427 mg/dL, bicarbonate 12 mmol/L, anion gap 22 mmol/L, pH 7.23, beta-hydroxybutyrate 3.77 mmol/L, C-peptide 0.33 ng/mL, and hemoglobin A1c 12.4%. Her creatinine was at her baseline of 0.77 mg/dL and her trough tacrolimus level was 3.7 ng/mL on 4 mg XR tacrolimus daily. She was receiving prednisone 30 mg daily. Type 1 diabetes autoantibodies were negative: glutamic acid decarboxylase-65 antibody, insulin autoantibody, islet cell antibody 512, and zinc transporter 8 antibody. She was admitted and treated for DKA. Her insulin requirement was ~1.6 units/kg/day.

Discussion: Our patient's NODAT is likely related to intense steroid treatment for rejection and significant insulin resistance. At our center, we have implemented a multidisciplinary pediatric KT and diabetes clinic that promotes communication between providers and with patients. A single clinic visit streamlines care and facilitates management of NODAT. Recognition of the rare complication of steroid induced DKA in pediatric KT recipients is essential to provide prompt diagnosis and management.

Neurocognitive Profile of Pediatric Kidney Transplant Candidates Aged 3 to 17 Years

Lidan Gu, Finola E. Kane-Grade, Christopher J. Anzalone, Danielle Glad, Michael D. Evans, Sarah J. Kizilbash. *University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Pediatric kidney transplant candidates frequently undergo pre-transplant neuropsychological evaluation. However, little is known about the neuropsychological profile of children awaiting a kidney transplant.

Methods: One hundred and one patients aged 3 to 17 years completed pretransplant neuropsychological evaluations at our center. Standardized tests were administered. Correlations between these test scores and age as well as dialysis duration were examined using Pearson Correlations. The effects of the cause of ESKD and race on test performances were evaluated using multivariate analysis of variance (MANOVA), adjusting for dialysis duration and age at testing.

Results: The mean age of our study cohort was 11.1 years (*SD*=4.2). The mean Full-Scale IQ of our cohort was significantly lower than general population at 87.3 (*SD*=16.8) (t= -6.64, p<.001). Age was significantly correlated with reasoning scores (r=.36, p=.003). Dialysis duration was negatively correlated with memory scores as measured by CVLT-C (r=-.323, p=.02) and visual organization scores as measured by the Rey-Osterrieth copy test (r=-.58, p=.003). After adjusting for age at testing and dialysis duration, the cause of ESKD was significantly associated with overall IQ (F(2)=3.3, p=.04) and verbal comprehension (F(2)=3.3, p=.05) performance (see figure). Race (F(1)=7.3, p=.009) and insurance type (F(1)=3.9, p=.05) were also significantly associated with verbal comprehension.

Conclusions: Pediatric kidney transplant candidates are at high risk for developing neurocognitive deficits, including lower overall IQ. Younger patients are at higher risk for abstract reasoning deficits, and patients with long dialysis duration are at higher risk for developing memory and visual organization difficulties. In addition, our results suggest that patients with CAKUT tend to have lower IQ scores versus patients with nephrotic syndrome, and white patients tend to perform better than patients of color on verbal abilities.

Social Determinants of Health and Kidney Transplant Outcomes in Youth

Ashton Chen,[1,2] Gregory B. Russell,[1] Carol Vincent,[1,2] Andrew M. South,[1,2] Kiri W. Bagley.[1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Atrium Health Wake Forest Baptist, Winston-Salem, NC.*

Background: Investigating how social determinants of health (SDoH) affect clinical outcomes is important in achieving health equity. The effect of SDoH on the pediatric transplant recipients is not well understood. Our aim was to investigate the association of adverse SDoH with kidney allograft outcomes in a diverse population of youth from a broad referral area.

Methods: In this single-center retrospective cohort study, data were extracted from the electronic health record using biomedical informatics methods. Inclusion criteria were youth 0-18 years who received a kidney transplant and had post-transplant care at our center from 9/25/2012 to 12/31/2022. Exposures were insurance type (public vs private), distance to transplant center, preferred language, and area deprivation index (ADI). Outcomes were graft survival, time to first biopsy-proven acute rejection (BPAR), and number of BPAR episodes. We used Kaplan-Meier estimates for graft survival and time to first BPAR. Cox proportional hazards regression models estimate the associations of exposures with time-to-event outcomes. For BPAR episodes, a negative binomial regression model, adjusted for time followed, assessed the relationship between outcome and exposure.

Results: Of 78 participants, 37% were female; median age at transplant was 8.5 years [IQR 3,14]; median follow-up was 5.0 years [IQR 4.1,7.0]. Event-free survival at 1 and 5 years was 100% and 92%. Median number of BPAR was 0 [IQR 0-2]. Public insurance, greater distance to transplant center, non-English language, and higher ADI were not associated with higher risk of graft failure or time to first BPAR. However public insurance was associated with greater BPAR episodes on unadjusted analysis [OR 3.33, CI 1.19-9.30] and after adjusting for race [OR 3.07, CI 1.08-8.73].

Conclusions: Several adverse SDoH were not associated with worse graft survival or faster time to BPAR in this interim analysis of pediatric kidney transplant recipients. However, having public insurance was associated with a greater number of BPAR. Public insurance may represent a risk marker for patients with greater healthcare needs and who may experience inequities in care. Ongoing quantitative and qualitative studies will clarify health-related social needs and patient experiences in this population to identify targeted interventions to achieve more equitable and optimal transplant outcomes.

Neighborhood Socioeconomic Deprivation Among Pediatric Kidney Transplant Recipients

Chloe E. Douglas,[1,2] Miranda Bradford,[3] Yue-Harn Ng,[2] Reya H. Mokiao,[1,2] Aaron G. Wightman,[1,2] Rachel M. Engen,[4] Jodi M. Smith.[1,2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Washington School of Medicine, Seattle, WA; [3]Seattle Children's Research Institute, Seattle, WA; [4]University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: Addressing social determinants of health is integral to kidney transplant management, although focus has only recently shifted to neighborhood-level effects. Using data from the Scientific Registry of Transplant Recipients, we describe the association between neighborhood socioeconomic deprivation and graft loss in pediatric kidney transplant recipients.

Methods: US recipients ≤18 years of age at time of listing who underwent kidney transplantation January 1st, 2010, to May 31st, 2022 (n=9,719) were included. Neighborhood deprivation was calculated using patient ZIP codes at time of listing and the Material Community Deprivation Index (MCDI), ranging from 0 (least deprived) to 1 (most deprived). Recipients were stratified into quintiles (Q). Kaplan-Meier and multivariable Cox proportional hazard estimates were calculated.

Results: The median MCDI for the most deprived neighborhoods (Q5) was 0.53 [IQR: 0.47, 0.84] compared to 0.23 [IQR: 0.06, 0.27] in the least deprived (Q1). Black and Hispanic patients were over-represented in the most deprived neighborhoods. As neighborhood deprivation increased, dialysis duration and deceased donation increased, while preemptive transplantation decreased. Recipients living in the most deprived neighborhoods had a 1.67 times greater risk of graft loss compared to the least deprived (CI: 1.42, 1.98).

Conclusions: Pediatric kidney transplant recipients with the highest levels of neighborhood socioeconomic deprivation had a greater risk of graft loss. Increased focus should be placed on contextual effects of neighborhood environment to address health disparities in pediatric kidney transplantation.

Recipient Proximity to Transplant Center in US Pediatric Kidney Transplantation

Chloe E. Douglas,[1,3] Jodi M. Smith,[1,3] James D. Perkins,[3] Aaron G. Wightman,[1,3] Yue-Harn Ng,[3] Rachel M. Engen.[2] *[1]Seattle Children's Hospital, Seattle, WA; [2]University of Wisconsin-Madison, Madison, WI; [3]University of Washington School of Medicine, Seattle, WA.*

Background: Recipient proximity to a transplant center varies greatly among US children with kidney failure. Prior studies of US children listed for kidney transplant demonstrated that less proximity to center was associated with greater risk of death on the waitlist. Using data from the Scientific Registry of Transplant Recipients, we describe the association between recipient proximity to transplant center and candidate evaluation and outcomes in US pediatric kidney transplant recipients.

Methods: US children ≤18 years of age at time of listing who underwent kidney transplantation from January 1st, 2001, to December 31st, 2019 (n=12,113) met inclusion criteria. Proximity to transplant center was calculated using recipient and transplant center ZIP codes at time of listing. Logistic and linear regression, in addition to multivariable Cox proportional hazard models, were utilized to analyze outcomes of interest.

Results: Seventy-five percent of recipients lived within 83 miles of a transplant center at time of listing. A majority of Black recipients (81.8%) lived within 83 miles (≤75th percentile) of a center, compared to 72.3% of white recipients. Twenty-three percent of recipients in the ≥75th percentile had a primary diagnosis of FSGS, versus 28% in the ≤25th percentile. Proportions of pre-emptive transplant and public insurance were similar across strata. There was no significant difference in survival across strata, with those with least proximity to center having no increased risk of graft failure (aHR 0.96, 95% CI: 0.87-1.06). There was no change in odds of living donor transplantation (aOR 1.01, 95% CI: 0.99-1.03) or delayed graft function (aOR 0.98, 95% CI: 0.95-1.02) with each 100-mile increase from center. Residing within the ≥75th percentile at time of listing increased waitlist time by 3% of one year (10.95 days, 95% CI: 0.6-6%).

Conclusions: No meaningful associations between recipient proximity to center and graft survival, waitlist time, living donor transplantation, or delayed graft function were detected. Future efforts should explore the impact of proximity to center on additional aspects of transplant access, recipient well-being, and caregiver burden.

SA-PO391

Distance to Transplant Center and Pediatric Kidney Transplant Outcomes and Access to Care

Sierra Armstrong,[1] Gregory B. Russell,[1] Andrew M. South,[1,2] Ashton Chen.[1,2] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Atrium Health Wake Forest Baptist, Winston-Salem, NC.*

Background: Reliable transportation is necessary for equitable healthcare access. Transportation insecurity poses a barrier to care, contributing to worse health outcomes in chronic disease. However its significance in pediatric transplantation is an area of ongoing investigation. Our aim was to assess the impact of distance to the transplant center on outcomes and post-transplant follow-up care in a geographically diverse cohort of pediatric transplant recipients.

Methods: In a single-center retrospective cohort study, data were extracted from the electronic health record using biomedical informatics methods. Inclusion criteria were youth 0-18 years who received a kidney transplant and had post-transplant care at our center from 9/25/2012–12/31/2022. Our exposure was distance to the transplant center, determined by calculating geodetic distance from participants' residence zip code to the transplant center. Outcomes were graft survival, biopsy-proven acute rejection (BPAR), hospitalization rates, and no-shows and cancelled appointments in the transplant clinic. We used Kaplan-Meier curves and Cox proportional hazards regression to estimate associations of exposures with outcomes.

Results: Of 78 participants, 37% were female; median age at transplant was 8.5 years (IQR 3,14); median follow-up was 5.0 years (IQR 1,7.0). The median distance to the transplant center was 29.0 miles (IQR 13.4,60.1); mean no-show proportion was 8.9% (SD 8.1%); mean cancellation proportion was 26.3% (SD 10.6%). Distance to the transplant center was not associated with higher risk of graft failure, shorter time to first BPAR, higher BPAR, and higher hospitalization rates. Greater distance from the transplant center was associated with a higher proportion of cancelled clinic appointments (p 0.0001, Beta coefficient 1.08 per 10 miles, 95% CI (0.63,1.54)).

Conclusions: Greater distance to the transplant center was associated with more clinic cancellations, which can cause delayed care resulting in negative effects on transplant health. Further study by collecting qualitative data on patient transportation access may help us understand the patient experience and what barriers can be mitigated to reduce appointment cancellations. By collecting qualitative data on patient transportation access in this population, we hope to better inform transplant maintenance and optimize long-term care.

Childhood Opportunity Index and Pediatric Kidney Transplant Health

Jimshad Farooque-Wooden,[1] Kiri W. Bagley,[1,2] Gregory B. Russell,[1] Andrew M. South,[1,2] Ashton Chen.[1,2] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Atrium Health Wake Forest Baptist, Winston-Salem, NC.*

Background: Social Determinants of Health research has become increasingly important. The Childhood Opportunity Index (COI) is a composite of 29 variables affecting child health and well-being related to Health/Environment (HE), Social/Economic (SE), and Education (E). Research exploring the impact of COI on kidney transplant outcomes is lacking. Our aim was to assess association of COI with pediatric kidney transplant outcomes.

Methods: This was a single-center retrospective cohort study of kidney transplant recipients 0-18 years with post-transplant care at our center from 9/25/2012-12/31/2022. Exposures were overall COI and COI domains based on 2015 census tract data from diversitydatakids.org. Outcomes were graft survival, time to first biopsy-proven acute rejection (BPAR), number of BPARs, hospitalization rates, and transplant clinic no-show and cancellation rates. Statistical analyses included Kaplan-Meier, Cox proportional-hazards, and negative binomial regression models.

Results: Of the N=78 participants; median age at transplantation was 8.5 years [IQR 3,14]; median follow-up 5 years [IQR 4.1,7.0]. Event-free survival at 1 and 5 years was 100% and 92%. COI was not associated with graft survival, number of BPAR, hospitalization rates, or cancelled visits. COI-SE was inversely associated with time to first BPAR [p=0.010, HR=1.10, 95% CI 1.02-1.17]. Overall COI and COI-SE were inversely correlated with no-show rates [p=0.039, Beta coefficient=-0.41 per 5 units (95% CI -0.80,-0.02) and p=0.029, Beta coefficient=-0.43 per 5 units (95% CI -0.81,-0.05)]. Higher no-show rates were associated with worse graft survival [p=0.018, HR=1.38, 95% CI 1.06-1.79].

Conclusions: Lower COI-SE was associated with higher no-show rates which was associated with worse graft survival. Higher COI-SE was associated with shorter time to first BPAR, possible due to patients maintaining regular follow-up with more timely BPAR diagnosis. Higher no-show rates in individuals from areas of low COI-SE may

result in delayed BPAR diagnosis, which could increase risk of graft failure. Future study can assess if COI predicts other transplant or kidney disease outcomes. To better understand the effects that lower COI may have at the individual level, questionnaires can be used to identify barriers to care such as affordability, perceived cost, transportation, or ability to attend appointments.

Revisiting Clinical Relevance of Radionucleotide-Based GFR Estimation and Comparison with CKiD U25 eGFR Equation in Pediatric Liver Transplant Patients

Vimal Chadha, Brent Cully, Voytek Slowik. *Children's Mercy Kansas City, Kansas City, MO.*

Background: Renal dysfunction is common in patients with liver transplant recipients and can be present at the time of transplant or develop later during follow-up. Kidney function in these patients is monitored periodically by measuring glomerular filtration rate (GFR). In the absence of appropriate serum creatinine-based estimation equations in the past, GFR measurement by utilizing radionucleotide agent such as diethylenetriamine pentaacetate (DTPA) have been in common practice. The procedure involves IV line placements, radionucleotide agent administration, and blood draws. The value of newer GFR estimating equations such as CKiD U25 (derived form Chronic Kidney Disease in Children Under 25) have not been evaluated in these cases.

Methods: Retrospective analysis of all liver transplant patients since 1995 who had their GFR estimated by radionucleotide (99mTc-DTPA) for kidney function monitoring. The DTPA-GFR was compared with eGFR calculated by creatinine based CKiD U25 equation. All creatinine values were converted to isotope dilution mass spectrometry (IDMS) reference measurement. Patients with any missing data were excluded.

Results: 356 DTPA-GFR measurements (median 4 per patient; range 1 – 9) from 95 patients (57% males; median age at transplant 2.1 years, range 0.45 – 19.2) obtained at a median age of 10 years were available. 53 (15%) serum creatinine values were above the age specific reference range and the eGFR by U25 equation was <90 mL/min for all, while 40 had <90 mL/min, 11 had between 90 – 120, and 2 had >120 mL/min based on DTPA-GFR. 303 serum creatinine values were in normal range and the GFR was >120 mL/min in 94 (31%) by both methods. Of the rest of 209 values, U25 equation classified 147 (90 – 120 mL/min) and 18 (<90 mL/min); while DTPA-GFR classified 115 (90 – 120 mL/min) and 28 (<90 mL/min). The concordance between U25 and DTPA-GFR was ~50% for eGFR 90 – 120 mL/min, and ~15% for <90 mL/min, respectively. Overall, the correlation coefficient "r" between the two methods was 0.45 (p <0.0001).

Conclusions: In the absence of the gold-standard measurement, CKiD U25 equation appears to perform better than DTPA-GFR which is a time consuming, cumbersome and expensive procedure. Addition of serum Cystatin C is likely to further improve the eGFR estimation by CKiD U25 equation.

Preventative Dental Practices and Cardiometabolic Health in Adolescents

Kristal Wong,[1] Srighana Nadella,[2] Mel Mupparapu,[2] Christine B. Sethna.[1]
[1]Cohen Children's Northwell Health Physician Partners Pediatric Nephrology and Kidney Transplant, Queens, NY; [2]University of Pennsylvania School of Dental Medicine, Philadelphia, PA.

Background: Decreased utilization of dental services in adolescence has been linked to cardiometabolic disease in adulthood. The aim was to assess the relationship between preventative dental practices and cardiometabolic health in adolescents.

Methods: Analysis included children aged 13-17 years enrolled in the National Health and Nutrition Examination Survey (NHANES) from 2011-2018 who completed an oral health questionnaire. No dental care was defined as not having a dental visit in the past year. Financial barriers to seeking dental care were assessed among those without dental care. Cardiometabolic outcomes included obesity, elevated blood pressure (BP 120-129/<80 mmHg), hypertensive BP (BP≥130/80 mmHg), dyslipidemia (any abnormal lipid level), glucose intolerance (HOMA-IR), uric acid, glomerular hyperfiltration (estimated glomerular filtration rate [eGFR] ≥140 ml/min/1.72 m^2), and microalbuminuria (urine albumin:creatinine >30 mg/mg). Regression models adjusted for age, sex, self-identified race/ethnicity, household income, food insecurity, health insurance, household education, and body mass index (BMI) z-score examined associations using complex survey design procedures.

Results: Of 2,861 adolescents, 17.6% (0.9%) did not receive dental care in the past year and of those, 20.2% (1.9%) had financial barriers to accessing dental care. Adolescents without dental care had higher odds of overweight/obesity and dyslipidemia. Those with financial barriers had higher levels of non-HDL, lower levels of HDL, and higher odds of dyslipidemia (Table 1).

Conclusions: In a nationally representative population of adolescents, lack of preventative dental practices was associated with cardiometabolic health makers of overweight/obesity and dyslipidemia. In addition, financial barriers to health were associated dyslipidemia.

Dental Caries and Cardiometabolic Health in Adolescents

Kristal Wong,[1] Srighana Nadella,[2] Mel Mupparapu,[2] Christine B. Sethna.[1]
[1]Cohen Children's Medical Center, Queens, NY; [2]University of Pennsylvania School of Dental Medicine, Philadelphia, PA.

Background: Dental caries is the most common chronic disease in the pediatric population. Prior studies suggest that poor oral health may contribute to an increased risk of metabolic syndrome and cardiovascular risk in adulthood. The aim was to assess the association between dental caries and cardiometabolic risk in adolescents.

Methods: Analysis included adolescents aged 13-17 years enrolled in the National Health and Nutrition Examination Survey (NHANES) from 2011-2018 who completed an oral health questionnaire/exam. Untreated caries was defined as having one or more decayed teeth. Severity of dental caries was assessed by the Decayed, Missing, Filled Teeth (DMFT) score in permanent dentition (No caries, DMFT=0). Cardiometabolic outcomes included obesity, elevated BP (BP 120-129/<80 mmHg), hypertensive BP (BP ≥130/80 mmHg), dyslipidemia (any abnormal lipid level), glucose intolerance (HOMA-IR), uric acid, glomerular hyperfiltration (estimated glomerular filtration rate [eGFR] ≥140 ml/min/1.72 m^2), and microalbuminuria (urine albumin:creatinine >30 mg/mg). Regression models adjusted for age, sex, self-identified ethnicity/race, household income, food insecurity, health insurance status, household education, and body mass index (BMI) z-score examined associations using complex survey design procedures.

Results: Of 2,861 adolescents (age 14.97 [0.03] years, 55.3% [1.2%] male), 25.6% (1.3%) had untreated caries and 55.4% [1.3%] had DMFT ≥1. In adjusted models, untreated caries was significantly associated with higher HOMA-IR levels and lower eGFR values. Additionally, DMFT ≥1 was associated with higher odds of elevated BP compared to a DMFT of 0 (Table 1).

Conclusions: In a nationally representative study of adolescents, there was an association between untreated/more severe caries with cardiometabolic markers of BP and glucose intolerance.

Funding: NIDDK Support

Hyperfiltration in Obese Diabetic BTBRob/ob Mice Can Be Measured Transcutaneously

Steffen A. Hettler, Diego O. Pastene, Benito Yard, Bernhard K. Krämer. *Universitat Heidelberg, Mannheim, Germany*.

Background: Transcutaneous assessment of glomerular filtration rate (tGFR) has only been validated in lean mice. At 24 weeks obese diabetic mice display vasodilation of the afferent glomerular arteriole and increased glomerular size, yet do not differ in tGFR values from lean mice. Hence, we questioned if hyperfiltration can be assessed transcutaneously in obese diabetic mice.

Methods: We measured tGFR and FITC-sinistrin plasma clearance simultaneously in obese diabetic BTBR$^{ob/ob}$ and lean non-diabetic BTBR$^{wt/-}$ mice at week 12. At week 24 we assessed tGFR again and used tissue clearing and light sheet microscopy to assess glomerular size and vasodilation of the afferent arteriole in mice that were perfused with an infrared fluorescent dye.

Results: While at week 12 tGFR significantly differed between the groups with a faster clearance in the diabetic BTBR$^{ob/ob}$ mice (both $t_{1/2}$ of FITC-sinistrin (p=0.0081) and calculated GFR (p=0.0069)), no difference was found between diabetic and non-diabetic mice in tGFR at 24 weeks. In line with the increased tGFR, also FITC-sinistrin plasma clearance was significantly increased at week 12 in BTBR$^{ob/ob}$ mice (p=0.0140). At week 24 the diameter of afferent arterioles were significantly larger in BTBR$^{ob/ob}$ vs. BTBR$^{wt/-}$ mice (p=0.0007) and associated with increased glomerular size (p=0.0136).

Conclusions: The results indicate that hyperfiltration can be detected in diabetic mice by tGFR early in the course of disease. In keeping with the findings that no difference in tGFR was found at 24 weeks despite morphological parameters that indicate hyperfiltration, our data might be explained by progressive loss of functional nephrons later in the disease. Accordingly, this will reduce total glomerular filtration while increased glomerular pressure and dilation of the afferent glomerular arterioles (and presumably single nephron glomerular hyperfiltration) remain in nonsclerotic nephrons.

The Genetic Architecture of Diabetic Nephropathy in Mice

Jeffrey B. Hodgin,[1] Mark P. Keller,[2] Markus Bitzer,[1] Alan Attie.[2] [1]*University of Michigan, Ann Arbor, MI;* [2]*University of Wisconsin-Madison, Madison, WI.*

Background: Diabetic nephropathy (DN) is the leading cause of end-stage renal disease in the United States and has a significant impact on human suffering. Leptin-deficient BTBR mice (BTBR$^{ob/ob}$) develop hallmark glomerular features of diabetic kidney disease in humans, whereas leptin-deficient C57BL/6J (B6$^{ob/ob}$) mice do not.

Methods: To identify the genetic loci that underlie this strain difference, we constructed an F2 intercross between BTBR$^{ob/ob}$ and B6$^{ob/ob}$ mice. We isolated kidneys from 460 F2 mice and used them to histologically score percent mesangial matrix and glomerular volume in ~50 glomeruli per mouse, yielding ~45,000 distinct measures in total. The same histological measurements were made in kidneys from B6 and BTBR mice when either lean or obese (*Lep*$^{ob/ob}$) at 4 and 10 weeks of age, allowing us to assess the contribution of strain, age, and obesity on glomerular pathology. All F2 mice were genotyped for ~5,000 single nucleotide polymorphisms (SNPs), ~2,000 of which were polymorphic between B6 and BTBR.

Results: We were able to identify a quantitative trait locus (QTL) on chromosome 7 at ~30 Mbp for percent mesangial matrix, glomerular volume, and mesangial volume. Two podocyte-specific genes in this region, Nphs1 (nephrin) and Kirrel2 (NEPH3 or filtrin), are physically located at the QTL and contain several high-impact SNPs (at splice regions or result in missense variants). Both are members of the immunoglobulin superfamily of cell adhesion molecules and localize to the podocyte slit diaphragm. Futhermore, mutations in these genes have been linked to chronic kidney disease in humans.

Conclusions: Our findings indicate genetic differences in genes known to be crucial to podocyte function and glomerular filtration barrier integrity as drivers of microstructural glomerular changes in diabetic nephropathy. Diabetic nephropathy is likely to be polygenic, with various genes, participating in various pathways, acting synergistically to affect susceptibility to the disease. Our study highlights Nphs1 and Kirrel2 and their role in podocyte function as genes that contributes to susceptibility to diabetic nephropathy and hallmark structural changes in the glomerulus. Genetic testing of a panel of gene variants may identify patients genetically predisposed to podocyte injury in diabetes and guide care to prevent nephropathy in diabetes.

Sexual Dimorphism in Glucose Metabolism in Type 2 Diabetic Mice

Mariana C. de Ponte, Karina Thieme. *Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil.*

Background: The prevalence of non-insulin-dependent diabetes has grown enormously over the last three decades and today this complication is a major global concern. According to the World Health Organization, the percentage of deaths attributed to high blood glucose is greater in males than females. This fact translates to experimental models of type 2 diabetes, in which obese male show increased blood glucose levels in comparison to female, despite the same degree of obesity. However, the mechanisms underlying this observation are still unclear. Thus, the aim of this study is to investigate the sexual dimorphism in glucose metabolism in BTBR WT and ob/ob mice.

Methods: The mice had blood glucose and body weight evaluated every two weeks. At the 16th week of age, euthanasia was performed to collect urine, liver and the kidneys. Albuminuria and gene expression of glucose metabolism enzymes were further performed.

Results: Preliminary data show that BTBR ob/ob mice, independently of sex, presented increased body weight in comparison to corresponding WT mice, but obese male were hyperglycemic than female throughout the experimental protocol. Diabetes and obesity induced albuminuria equally between males and females, which confirms loss of kidney function. In the liver, male and female BTBR ob/ob mice showed decreased *Pck1* and increased *Fbp*1 transcript levels, suggesting alteration of the gluconeogenesis pathway. However, female BTBR ob/ob mice had increased liver *Pkm* transcript levels than the corresponding male. In addition, liver *Pkm* transcript levels positively correlated with the blood glucose levels, which indicates sexual dimorphism in liver glycolysis. In the kidney, increased gene expression of the gluconeogenesis enzymes were observed in obese mice independently of sex, however, *Hk1, Pkm* and *Pfkp* transcript levels were upregulated only in females. Moreover, kidney *Pfkp* transcript levels positively correlated with blood glucose levels, suggesting also sexual dimorphism in kidney glycolysis. Gene expression of glucose transporters in the proximal tubule, SGLT2 and GLUT2, were only affected by obesity and diabetes and not by sex.

Conclusions: Collectively, these data show that there is a sexual dimorphism in gene expression of glycolysis enzymes in both liver and kidney, which may be associated with differences in blood glucose levels of male and female BTBR ob/ob.

TNF-α Pathway and Podocyte Dysfunction in Male and Female BTBR ob/ob Mice

Mariana C. de Ponte, Karina Thieme. *Universidade de Sao Paulo Instituto de Ciencias Biomedicas, Sao Paulo, Brazil.*

Background: Diabetic kidney disease (DKD) is the major cause of chronic kidney disease (CKD) in patients with diabetes. Studies suggest that tumor necrosis factor alpha (TNF-α) pathway signaling is important for DKD progression. TNF-α contributes to glomerular inflammation and injury, however, the mechanisms underlying this dysfunction, especially in podocytes, need to be further elucidated. Thus, the aim of this study is to elucidate how TNF-α may contribute to podocyte dedifferentiation in DKD and whether sexual dimorphism can modulate this process.

Methods: For this, male and female BTBR WT and ob/ob mice, a gold standard model of experimental type 2 diabetes and obesity were studied. The mice were observed up to a period of 16 weeks of age, and at the end of the experimental protocol, urine and kidneys were collected for analysis of albuminuria and gene expression. *In vitro*, immortalized mouse podocytes were treated with TNF-α for gene expression analysis.

Results: Preliminary data show that BTBR ob/ob mice presented elevated blood glucose levels, body weight and albumin excretion in comparison to WT mice. Among these parameters, blood glucose levels were affected by sex, as females were less hyperglycemic than males. In the kidneys, gene expression of TNF-α and TNF-α receptor

type 1 (TNFR1) were not statistically different among groups, but gene expression of TNF-α receptor type 2 (TNFR2) were upregulated in BTBR ob/ob mice independently of the sex. *Snai1* transcript levels were not changed, but there were an effect of sex and obesity on *Snai2* transcript levels. Females have higher gene expression of nephrin and podocin, but obesity reduces the expression of these genes, regardless of sex. *In vitro* experiments show that TNF-α treatment induced increased TNF-α gene expression and decreased *Snai2* transcript levels in podocytes.

Conclusions: In conclusion, these data suggest that BTBR ob/ob mice presented kidney inflammation, podocyte dysfunction and alteration of the cellular dedifferentiation pathway. Sexual dimorphism was observed in the gene expression of podocyte markers and *Snai2* transcript levels. *In vitro*, we confirmed the association of an inflammatory *millieu* with the dedifferentiation and inflammatory response of podocytes.

The Association Between Mechanosensitive Ion Channel Piezo2 Expression and Fibrogenesis in Hypertensive Diabetic Kidney Disease

Rina Oba,[1,2] Go Kanzaki,[2] Takashi Yokoo,[2] Miki Nagase.[1] *[1]Department of Anatomy, Kyorin University School of Medicine, Tokyo, Japan; [2]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage kidney disease, and mechanical forces such as glomerular hyperfiltration are crucial in the pathogenesis and progression of DKD. We previously reported *Piezo2* expression in mouse kidneys and its alteration by dehydration and hypertension, however, the role of Piezo2 in DKD is still unclear. We aimed to elucidate *Piezo2* expression and regulation in mouse models of DKD.

Methods: We used two types of DKD models (high fat diet (HFD) and streptozotocin (STZ)-treated C57BL/6J mouse, and high salt (HS)-treated type 2 diabetic KK-A^y mouse) and non-diabetic control C57BL/6J mice. Blood samples and kidneys were collected at 29 weeks of age in HFD+STZ mice and 19 weeks of age in KK-A^y+HS mice. We examined blood and urine analyses, histopathologic and immunohistochemical evaluations of kidneys, and gene expression analysis. The localization of *Piezo2* expression was identified using in situ hybridization method.

Results: Both DKD models exhibited significant obesity, hyperglycemia, albuminuria, glomerular hypertrophy, mesangial expansion, infiltration of macrophages, and tubular vacuolization compared to control mice. These findings were more severe in KK-A^y+HS mice than in HFD+STZ mice. KK-A^y+HS mice showed hypertension. Fibronectin protein expression was significantly upregulated in the glomerular areas of KK-A^y+HS mice kidneys. In addition, there were no significant differences in interstitial fibrosis between HFD+STZ mice and control mice, whereas severe interstitial fibrosis was observed in KK-A^y+HS mice kidneys. In situ hybridization studies showed no significant difference in *Piezo2* expression between HFD+STZ mice and control mice, but *Piezo2* expression was increased and localized in the glomerular and interstitial regions in KKAy+HS mice. Real-time RT-PCR showed that *Piezo2* and *Fn1* mRNA were increased in KKAy+HS mice compared with control mice. Furthermore, *Piezo2* expression was strongly correlated with *Fn1* expression (ρ=0.92, P<0.001).

Conclusions: Our findings suggest that *Piezo2* expression is upregulated in glomerular and interstitial regions in the advanced stage of DKD with increased glomerular mechanical stress, and *Piezo2* is associated with kidney fibrosis.

Effects of Electronic Cigarette Aerosol Exposure on Kidney Health in Diabetic/Obese Mice

Amna Raja,[1] Dweet G. Chhaya,[1] Arul Veerappan,[1] Christina Awada,[1] Surya V. Seshan,[3] Judith T. Zelikoff,[1] Edgar A. Jaimes.[2] *[1]New York University Grossman School of Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY; [3]Weill Cornell Medicine, New York, NY.*

Background: Diabetes is one of the most important risk factor for chronic kidney disease (CKD) and end stage kidney disease. Tobacco smoking accelerates the progression of CKD of different etiologies including diabetes. However, whether e-cig use also has a deleterious effect on CKD progression is unknown. The aim of this study was to examine whether inhalation exposure of diabetic adult mice to e-cig aerosols, with and without nicotine, changes gene expression linked to kidney injury.

Methods: 7-8-wk-old BTBR obese mice, a model of type II diabetes, were exposed to: 1) filtered air (control); 2) Propylene glycol/ Vegetable glycerin PG/VG (1:1); or 3) PGVG (1:1) + Nicotine (36 mg/ml) for 10-wk (3hr/d; /5d/wk). After euthanasia, kidneys were collected for RNAseq and histology. After RNA extraction, bulk RNAseq was performed, followed by RNAseq libraries preparation with TruSeq Stranded Total RNA kit (Illumina). Libraries were sequenced and aligned against mouse genome. Differential gene expression analysis was performed with DESeq2 R/Bioconductor package. The 2nd kidney from each mouse was fixed in formalin and used to assess kidney injury in PAS-stained slides.

Results: Inhalation exposure of mice to PG/VG + nicotine resulted in gene expression changes in 724 genes, while only 3 genes were differently expressed in the PG/VG group, compared to controls. Kidney injury related genes (i.e., Rorc, Col4a3, EGFR, LRRK2, VDR), cancer related genes (e.g., Adamts1, Ccn1, Ackr3) and immune-regulatory (e.g., Ace2, Rorc, Cxcl6, Ccn1), were upregulated in the PG/VG + nicotine exposed group compared to controls. In the PG/VG only group, pro-inflammatory (Rorc) was upregulated, while inflammation-protective Nr1d and kidney injury-associated Mt1 genes were downregulated. Kidney histology showed mesangial expansion consistent with diabetic nephropathy, which was similar in all 3 exposure groups.

Conclusions: Long-term, repeated exposure of diabetic mice to e-cig aerosols containing nicotine induces significant changes in genes involved in CKD progression, cancer, and inflammation. This groundbreaking study reveals the kidney as a target of e-cig use and opens the door for further research concerning the impact of e-cig use on kidney health.

Novel Drug Screening Strategy to Explore Exosome-Targeted Intervention of Intraglomerular Cross-Talk for Diabetic Kidney Disease

Daisuke Fujimoto, Shuro Umemoto, Takashige Kuwabara, Ryosuke Date, Teruhiko Mizumoto, Yutaka Kakizoe, Yuichiro Izumi, Masashi Mukoyama. *Kumamoto Daigaku Daigakuin Seimei Kagaku Kenkyubu Igakubu, Kumamoto, Japan.*

Background: Exosome (Exo), one of the extracellular vesicles, is an important mediator of intercellular communication in the regulation of physiological and pathophysiological processes. We reported the significance of intraglomerular cellular crosstalk centered on mesangial cells (MC) in the pathogenesis of diabetic kidney disease (DKD). However, the roles of Exo-mediated processes still remain elusive. The aim of this study is to explore novel exosome-targeted therapeutic strategy for DKD.

Methods: We focused on Exo as a possible key factor acting in a paracrine manner in glomeruli and examined the effects of mesangial cell-derived Exo (MC-Exo) on macrophages (Mφ) in culture. In order to identify new therapeutic agents, we established a high-throughput screening assay that can efficiently inhibit Exo-induced inflammation by use of validated library. We further investigated the effects of a candidate agent on DKD in vivo.

Results: MC-Exo stimulation activated NF-κB and increased the mRNA expression of TNFα and IL-1β in Mφ. The effects were significantly enhanced in Exo from MC cultured under high-glucose conditions compared to low-glucose conditions. DiO (fluorescent dye)-stained MC-Exo was colocalized with a cell-impermeant polar tracer, Cascade Blue™ hydrazide in Mφ, confirming that Exo was uptaken into Mφ by endocytosis. Next, from over 3,000 compounds, we screened drug candidates that could specifically and effectively suppress NF-κB activity and exosomal actions with minimum toxicity. Alvespimycin (Alv), an Hsp90 inhibitor, was identified as a final candidate. Treatment of diabetic rats with Alv improved proteinuria and mesangial expansion, along with suppressed mRNA expression of IL-1β and TNFα in glomeruli. Notably, the pre-final list of 28 compounds contained four Hsp90 inhibitors including Alv. Among them, Alv showed the highest inhibitory effect of Exo-uptake by FCM analysis.

Conclusions: Through our unique Exo-targeted drug screening, we successfully discovered alvespimycin, an Hsp90 inhibitor, which may ameliorate diabetic nephropathy. Alv inhibited Exo-uptake of Mφ and suppresses local inflammation in glomeruli, probably independent of Hsp90 blocking mechanisms. Exo-targeted intervention could be a novel and promising strategy for DKD.

SA-PO403

Investigation of Urinary Exosomal miRNA and lncRNA Expression Profiles and ceRNA Network in Diabetic Kidney Disease

Wenbin Tang. *Xiangya Hospital Central South University Department of Nephrology, Changsha, China.*

Background: Diabetic kidney disease (DKD) is one of the major cause of end-stage renal disease (ESRD), it is important to detect diagnostic biomarkers of DKD. This study aims to explore expression profiles of urinary exosomal miRNA and lncRNA in DKD patients, and their possible regulatory mechanism in DKD.

Methods: We performed urinary exosomal miRNA and lncRNA profile in DKD, DM patients and healthy subjects, and analyzed biological functions of differentially expressed miRNAs and lncRNAs. And then we focused on the important mRNA ZEB1/2 which were related to DKD, constructed a ceRNA network.

Results: We identified differentially expressed 47 miRNAs and 61 lncRNAs of urinary exosome in DKD. GO and KEGG analysis showed target genes of miRNAs were involved in Iκ-BK/NF-κB, Wnt, PI3K-Akt pathway, autophagy and oxidation-reduction process. Differential lncRNAs participated in occurrence and development of DKD through peroxisome proliferator-activated receptor, cGMP-PKG pathway, autophagy and platelet activation. Furthermore, We constructed a ceRNA network with differentially expressed miRNAs, lncRNAs, ZEB1, ZEB2, and found that 7 lncRNA-miRNA- mRNA axes could promote the expression of ZEB1/ZEB2, which may play an important role in TIF of DKD.

Conclusions: In conclusion, Urinary exosomal lncRNA-miRNA may involved in the process of TIF in DKD through targeting transcription factor ZEB1/ZEB2, providing new directions to further clarify the pathogenesis and therapeutic targets of DKD.

Comparative Transcriptome Analysis of Spontaneously Diabetic Torii Fatty Rat Undergoing Salt Loading Alone or with Unilateral Nephrectomy

Takahiro Shirozu,[1] Aya Yoshimura,[1] Miwa Sakata,[1] Masanori Kugita,[1] Kanako Kumamoto,[1] Yuko Hata,[1] Eiji Sugihara,[1] Tamio Yamaguchi,[2] Kazuo Takahashi,[1] Shizuko Nagao.[1] *[1]Fujita Health University, Toyoake, Japan; [2]Suzuka University of Medical Science, Suzuka, Japan.*

Background: The Spontaneously Diabetic Torii (SDT) fatty rat is an animal model for type 2 diabetes and obesity. Salt loading and unilateral nephrectomy developed hypertension and diabetic nephropathy in this model early in the disease process. The current study aimed to identify risk factors for diabetic nephropathy and conduct transcriptome analysis using RNA-seq in SDT fatty and Sprague-Dawley (SD) rats.

Methods: Male SDT fatty and SD rats underwent distilled (Cont) or 0.3% NaCl (Salt) water loading from 10 to 20 weeks of age. Body weight, diet and fluid intake, systolic and diastolic blood pressure, blood glucose, and urine albumin level were assessed. Kidney sections were subjected to pathological analyses by H&E, PAS, and sirius red staining to investigate glomerular lesions and fibrosis. Whole kidney extracts underwent RNA-seq to analyze differentially expressed genes (DEGs) between strains, salt loading, and unilateral nephrectomy (Nx) at 9 weeks of age. Gene ontology (GO) analysis was performed on the DEGs using the DAVID analysis tool.

Results: Although no differences in body weight, diet and fluid intake were observed, blood glucose levels were significantly higher in SDT fatty than in SD rats, regardless of loading. Systolic and diastolic blood pressure, urine albumin, and glomerular lesion and fibrosis scores were significantly higher in SDT fatty (Salt) compared to SDT fatty (Cont), SD (Salt), or SD (Cont) rats. Using RNA-seq analyses, comparison of SDT fatty and SD strains showed 864 DEGs in Cont, 1500 in Salt, and 1599 in Salt/Nx. With respect to salt loading effects, in SDT fatty rats there were 481 DEGs in Cont vs. Salt, 365 in Cont vs. Salt/Nx, and 60 in Salt vs. Salt/Nx, whereas in SD rats, there were 57 DEGs in Cont vs. Salt, 167 in Cont vs. Salt/Nx, and 199 in Salt vs. Salt/Nx. GO analysis showed higher expression of genes involved in immune response and extracellular matrix related with inflammation in SDT fatty Salt or Salt/Nx compared to Cont rats.

Conclusions: Salt-treated SDT fatty rats showed elevated expression of inflammatory-related genes. This suggests a potential role of salt in promoting renal pathology in this model.

Oxidative Stress-Related Mitochondrial and Lysosomal Quality Control Mechanisms in Renal Cortex During the Normoalbuminuric Stage of Diabetes Mellitus

Naohito Ishii,[1] Pamela K. Carmines,[2] Naokazu Sato,[1] Yoshifumi Kurosaki,[1] Akemi Imoto,[1] Taro Sugase,[4] Mio Narita,[1] Masanori Yokoba,[1] Takafumi Ichikawa,[1] Tsuneo Takenaka,[3] Masato Katagiri.[1] *[1]Kitasato University, Sagamihara, Japan; [2]University of Nebraska Medical Center, Omaha, NE; [3]International University of Health & Welfare, Minato-ku, Japan; [4]Seiikai Medical Clinic NASU, Ohtawara, Japan.*

Background: Oxidative stress during the normoalbuminuric stage of type 1 diabetes mellitus (DM) damages renal cortical mitochondria. Subsequent mitochondrial autophagy (mitophagy) produces autophagosomes destined for lysosomal degradation; hence, any lysosomes damaged in DM must be either repaired or degraded and removed in order for mitophagy to reach fruition. We aimed to determine if oxidative stress in DM triggers not only renal cortical mitophagy, but also lysosomal repair and elimination through lysosome-selective autophagy (lysophagy).

Methods: Four groups of rats (n=5 per group) received one of the following treatments: 1) STZ group: rats with DM induced by streptozotocin injection (STZ, 65 mg/kg, *i.p.*); 2) Sham group: rats receiving the STZ vehicle; 3) STZ+TLM group: STZ rats treated with telmisartan (TLM, an angiotensin receptor blocker; 10 mg/kg/day in chow); and 4) Sham+TLM group: TLM-treated Sham rats. Two weeks later, blood glucose levels, blood pressure, glomerular filtration rate (GFR), and urinary excretion of albumin and *N*-acetyl-β-D-glucosaminidase (NAG) were measured in each rat. Renal cortex homogenates were assayed for 3-nitrotyrosine (3-NT, an oxidative stress marker measured by HPLC), and Western blot was used to quantify proteins related to mitophagy (PINK1, BNIP3, LC3-II, p62), lysosomal repair (Galectin-3), and lysophagy (LAMP2, FBXO27).

Results: Blood glucose levels were higher in STZ rats than in Sham rats ($P<0.05$) and were unaffected by TLM. Blood pressure, albumin excretion, and NAG excretion were unaltered by STZ or TLM. GFR and renal cortical 3-NT levels were increased in STZ rats ($P<0.05$), and both changes were prevented by TLM ($P<0.05$). STZ rats had increased renal cortical LC3-II, PINK1, Galectin-3, and FBXO27 protein levels compared with Sham ($P<0.05$), with these effects prevented by TLM ($P<0.05$). BNIP3, p62 and LAMP2 levels did not differ among groups.

Conclusions: DM-induced renal cortical mitophagy, lysosomal repair, and lysophagy were blunted by the antioxidant effects of TLM, suggesting that these may be closely related quality control mechanisms triggered by oxidative damage.

Liraglutide's Unveiled Renoprotective Mechanism in Type 1 Diabetes: Insights into Macrophage Polarization

Natalie Youssef, Mohamad Noureldein, Sarah Al Moussawi, Assaad Antoine Eid. Eid's Lab. *American University of Beirut, Beirut, Lebanon.*

Background: Diabetic Kidney Disease is a major complication of type 1 (T1D) and type 2 (T2D) diabetes. While the GLP-1RA liraglutide, has shown promise in protecting the kidneys of individuals with T2D, its effects T1D are not well-studied. Additionally, the underlying mechanism through which liraglutide provides renoprotection in T1D or T2D requires further investigation. Macrophages are known to contribute to the development and progression of DKD. Upon infiltrating the glomeruli, they tend to adopt a pro-inflammatory M1 phenotype rather than an anti-inflammatory M2 phenotype. In addition to inflammation, excessive production of ROS is implicated in DKD progression. This study aims to investigate the renoprotective effects of liraglutide in T1D and examine its influence on shifting macrophage polarization towards the anti-inflammatory M2 phenotype by modulating NADPH oxidase.

Methods: C57/BL6J adult male mice were divided into 3 groups (n=5/group): C group, T1D group (induced by 3 consecutive doses of STZ), and T1D group treated with liraglutide (0.3 mg/kg twice daily). After a 13-week treatment period, the mice were sacrificed, and kidneys were isolated for analysis.

Results: Our results show that liraglutide improves kidney injury in T1D mice manifested by a reduction in kidney hypertrophy, BUN, ACR, proteinuria, glomerular hypertrophy, glomerulosclerosis, as well as glomerular collagen deposition. These findings were associated with decreased expression of inflammatory cytokines, as well as the M1 macrophage specific markers. Moreover, the levels of the anti-inflammatory cytokines were increased, and this was associated by an increase in the M2 macrophage specific markers. Furthermore, liraglutide treatment attenuated ROS production manifested by decreased NADPH oxidase activity through an inhibition of NOX2 and NOX4. Of interest, liraglutide treatment was associated with activation of the NADPH oxidases DUOX isoforms, indicating a more controlled and regulated ROS production, which may be involved in redox signaling and tissue homeostasis.

Conclusions: Our data highlight an anti-inflammatory renoprotective effect of liraglutide. This is manifested by a notable shift in macrophage polarization from the pro-inflammatory M1 phenotype to the anti-inflammatory M2 phenotype, through the modulation of NADPH oxidase activity in T1D.

MiR-200b Induces ZEB1-Mediated Upregulation of Matriptase and Affects Expression of Podocin: A Proposed Mechanism of Podocyte Effacement and Proteinuria in Diabetic Kidney Disease

Ramesh Tati,[1] Janina Müller-Deile,[3,4] Anna Walentinsson,[1] Nina Sopel,[3,4] Miguel Carracedo,[1] Emelie Lassen,[1] Kerstin Ebefors,[2] Magnus Soderberg,[1] Christoph Daniel,[3,4] Pernille B. Laerkegaard Hansen,[1] Mario Schiffer,[3,4] Jenny C. Nystrom,[2,1] Lisa Buvall.[1] *[1]AstraZeneca AB, Mölndal, Sweden; [2]Gothenburg University, Gothenburg, Sweden; [3]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [4]University Hospital Erlangen, Erlangen, Germany.*

Background: Diabetic kidney disease (DKD) is the leading cause of chronic kidney disease and a predominant reason for renal failure. Evidence from previous research indicates that abnormal expression of microRNAs (miRs) links closely to the occurrence and progression of DKD

Methods: Expression of miRs in urine samples from DKD patients and in cultured renal cells stressed with transforming growth factor beta 1 (TGF-β1) was evaluated by TaqMan assay. The emerging miR of interest and its downstream targets were analyzed in human renal sections, in cultured human podocytes and in zebrafish.

Results: Cell free urine screening showed increased abundance of miR-200b in samples from patients with DKD when compared to healthy controls. In situ hybridization confirmed expression of miR-200b in kidney specimens from DKD patients, but was not detected in healthy renal parenchyma. Transcriptome profiling of cultured human podocytes overexpressing miR-200b identified this miR as a regulator of the ZEB1 mediated matriptase (ST14)/ podocin pathway and found TGF- β1 and high glucose (HG) stress to be upstream activators of miR-200b expression in these cells. Immunofluorescence analysis of kidney sections from DKD patients showed increased expression of ST14 and decreased expression of podocin when compared to healthy controls. Furthermore, injection of a miR-200b mimic in zebrafish larvae caused an upregulation of ST14 and was accompanied by phenotypic changes such as edema, proteinuria and podocyte effacement.

Conclusions: Our results show that miR-200b is expressed in glomeruli and found at elevated levels in urine of DKD patients. Stressors such as high glucose or TGF-β1 can activate transcription of miR-200b in human podocytes, leading to increased levels of matriptase, a serine protease previously shown to cleave podocin. The observed decrease in podocin levels in glomeruli from DKD patients, together with the effect of a miR-200b mimic on proteinuria and ultrastructure of the pronephros in zebrafish positions miR-200b as a key regulator that modulates matriptase overactivation in DKD and warrants further studies.

SA-PO408

PACSIN2 Regulates the Inflammatory Response in Diabetic Kidney Disease

Rim Bouslama,[1] Zydrune Polianskyte-Prause,[1] Eero Lehtonen,[1] Yelin Subashi,[1] Sonja Lindfors,[1] Sinem Karaman,[1] Markus Plomann,[2] Sanna H. Lehtonen.[1] Translational Metabolism, Sanna Lehtonen Lab. *[1]Helsingin yliopisto, Helsinki, Finland; [2]Universitat zu Koln, Köln, Germany.*

Background: Diabetic kidney disease (DKD) is associated with hemodynamic and metabolic alterations including chronic low-level inflammation. Podocytes, the glomerular epithelial cells, are damaged by the inflammatory *milieu* in DKD *via* poorly understood mechanisms. Our study identifies protein kinase C and casein kinase substrate in neurons 2 (PACSIN2) as a new regulator of inflammation in the kidney.

Methods: This study relies on PACSIN2 knockout (KO) mice, in which we modeled DKD. We also used isolated human glomeruli and cultured human podocytes. We analyzed samples by quantitative Western blot, and immunofluorescence or immunohistochemical stainings.

Results: At the age of 12 months, compared to controls, PACSIN2 KO mice had paler kidneys, increased albumin to creatinine ratio, and altered glomerular vasculature. This coincided with increased circulating IL6, increased glomerular macrophage infiltration, and disrupted oxidative process in the glomeruli. Treatment of human glomeruli *ex vivo* with IL6 led to increased expression of PACSIN2. In cultured human podocytes, the expression and phosphorylation of PACSIN2 varied in response to inflammatory stimuli. PACSIN2 also interacted with NFkB and GSK3β depending on the stimulus. Diabetic PACSIN2 KO mice were lighter than diabetic controls, had lower glycaemia, lower albuminuria, and excreted less urine per 24h. We found no difference in macrophage infiltration and oxidative damage between diabetic WT and diabetic PACSIN2 KO mice. Nevertheless, the expression of NFkB and GSK3β was increased in glomerular lysates of diabetic PACSIN2 KO mice.

Conclusions: Our results indicate that lack of PACSIN2 alone causes kidney damage and increases inflammation in the glomeruli. In the context of DKD, lack of PACSIN2 improved metabolic and kidney parameters. Our study uncovers PACSIN2 as novel regulator of inflammation and highlights the contextual regulation of the inflammatory response in the glomeruli.

Exploring the Role of CXCL16 in Diabetic Kidney Disease: Insights into Inflammation, Lipid Disorders, and Therapeutic Potential of Curcumin

Aili Cao,[1] Ying Chen,[2] Jun Tao,[1] Xudong Hou.[3] *[1]Department of Nephrology, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Department of Nephrology, Putuo Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China; [3]Shanghai Frontiers Science Center of TCM Chemical Biology, Institute of Interdisciplinary Integrative Medicine Research, Shanghai University of Traditional Chinese Medicine, Shanghai, China.*

Background: Diabetic nephropathy (DN) is a common complication of diabetes characterized by the progressive presence of albumin in the urine and the destruction of glomeruli. Elevated levels of soluble C-X-C chemokine ligand 16 (CXCL16) have been associated with inflammatory and lipid responses, which play a significant role in the development of renal dysfunction in patients with diabetes. However, the precise mechanisms through which CXCL16 affects DN are not yet fully understood.

Methods: To address this, we conducted a comprehensive study to investigate how CXCL16 contributes to podocyte injury in DN.

Results: CXCL16 were associated with abnormal lipid metabolism. The addition of CXCL16 to podocytes led to the formation of lipid droplets, along with increased expression involved in lipid synthesis and storage. CXCL16 treatment inhibited the movement of Nrf2 into the nuclei of podocytes. To explore potential therapeutic approaches, we evaluated the effects of curcumin, a compound known to activate Nrf2, on podocyte senescence and injury. Our results demonstrated that curcumin treatment reduced the accumulation of lipid droplets and mitigated podocyte injury, as evidenced by a decrease in cellular senescence. Importantly, we found that the protective effects of curcumin were inhibited when CXCL16 was reduced by CXCL16 siRNA. Meanwhile, curcumin treatment prevented CXCL16-induced oxidative stress and inflammation, preserved the expression of synaptopodin, and inhibited the abnormal movement of Nrf2. Through molecular modeling and docking analysis, we discovered that curcumin directly targeted a specific region in the CXCL16 protein, blocking its kinase activity. In a mouse model of DN, we validated the therapeutic potential of curcumin.

Conclusions: Taken together, our findings suggest that CXCL16 may serve as a promising therapeutic target for the treatment of DKD.

SA-PO410

Effects of Stimulating and Inhibiting IL11 Pathway in Kidney Fibrosis

Ozlem Senol-Cosar, Matthew M. Rankin, Neelakantan T. Vasudevan, Veeravan Mahadomrongkul, Maria Chiara Magnone, Xiefan Lin-Schmidt, Romer A. Gonzalez-Villalobos. *Janssen Research and Development LLC, Boston, MA.*

Background: IL11 has been widely implicated as a major downstream effector of TGFβ signaling driving fibrogenesis and extracellular matrix deposition in several organs including the kidney. Here, we aimed to test fibrotic effects of IL11 in in vitro and in vivo kidney disease models.

Methods: Primary renal fibroblasts and human precision-cut kidney slices (PCKS) were treated with TGFβ in the absence or presence of anti-IL11 mAb or anti-TGFβ as positive control. Fibrotic gene expression and ECM accumulation were measured with qRT-PCR, ELISA and picrosirius red (PSR) staining. The in vivo effects of IL11 on fibrosis and kidney function were tested on 12-week old db/db-UNX mice subject to daily subcutaneous dosing of recombinant mouse IL11 for 8 weeks (10, 100, 200 ug/kg). The anti-fibrotic effects of anti-IL11 were assessed using unilateral ureteral obstruction (UUO) mice that were treated with single-dose anti-IL11 and anti-TGFβ mAb. Renal tissues were probed for fibrotic marker expression. Kidney function was assessed by serum creatinine, Blood Urea Nitro (BUN), and urine albumin-creatinine ratio (uACR).

Results: In kidney fibroblasts and PCKS, TGFβ induced IL11, Fn1, Col4a1 and Col1a1. However, rhIL11 did not cause increase in fibrotic marker expression in these models. Furthermore, fibrotic marker expression and ECM accumulation were only partially inhibited by anti-IL11 in PCKS whereas no such effect was observed in primary kidney fibroblasts. Chronic administration of rmIL11 in db/db-UNX mice caused an increase in kidney weight, reduction in body weight and upregulated expression of FN, TIMP1 and Col1a1 genes, however no impact on renal function or accumulation of ECM was detectable in the IL11 treated mice. Both IL11 and TGFβ mAbs showed significant reduction in selective fibrotic markers compared to isotype control at Day 3 in UUO kidneys.

Conclusions: We demonstrated that IL11 expression is induced by TGFβ. However, either IL11 by itself or its inhibition failed to significantly impact fibrosis in vitro or kidney function in vivo. Collectively, these data suggest that other factors in renal milieu play a more important role than IL11 to drive fibrosis in the kidney.

NLRP3 Inflammasome Activation Mediated by Lysyl Oxidase-Like 2 in Human Podocytes in Diabetic Condition

Hoon Young Choi,[1,2] Nara Jeon,[1,2] Beom Jin Lim.[1,2] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Gangnam Severance Hospital, Seoul, Republic of Korea.*

Background: Diabetic kidney disease (DKD), a major complication of diabetes mellitus is a most common cause of kidney failure. Sterile inflammation is a hallmark of DKD. The NLR family pyrin domain containing 3 (NLRP3) inflammasome is a mechanism of sterile inflammation known to be activated by metabolic stimuli and reactive metabolites associated with DKD. Recently, lysyl oxidase-like 2 (LOXL2) has been reported to associate with tissue fibrosis, inflammation, and oxidative stress, all of which are implicated in the pathogenesis of diabetes and its complications. In this study, we investigated the expression of LOXL2 in human kidney and podocyte, and its contribution to NLRP3 inflammasome expression in podocyte with high-glucose condition.

Methods: We evaluated the expression of LOXL2 in human kidney using immunoflurorescence staining. Real-time PCR and western blotting analysis for LOXL2 mRNA and protein expression were performed using cultured human immortalized podocytes. After fully differentiated, cultured human podocytes were exposed to high glucose (HG) for 48 hours. Podocyte-specific LOXL2 knock-down cells using CRISPR-Cas9 was generated.

Results: By real-time PCR and immunofluorescence staining, LOXL2 expression was identified in human glomerulus and was significantly increased in that with diabetic kidney disease compared with normal control. mRNA of NLRP3 inflammasome expression was also significantly increased in podocyte with HG condition (6.79±0.32 vs. 1.60±0.26, $P<0.05$). Gene silencing of LOXL2 significantly reduced mRNA and protein expression of NLRP3 inflammasome in immortalized human podocytes with HG compared to controls. Western blot analysis showed that collagen I and phosphorylated Smad2 protein expression were significantly decreased in LOXL2 knock-down podocytes.

Conclusions: Our results showed that NLRP3 inflammasome activation may attenuated by gene silencing of LOXL2 in podocytes in diabetic condition.

SA-PO412

Inhibition of YAP Impairs the Expression and Function of WT1 in Diabetic Podocytes

Jianchun Chen, Xiaoyong Wang, Agnes B. Fogo, Raymond C. Harris. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Podocyte injury and loss are hallmarks of diabetic nephropathy (DN). The molecular mechanisms underlying these phenomena are poorly understood. Yes-associated protein (YAP) is a transcriptional coactivator that regulates cell proliferation, differentiation, and apoptosis. Nuclear YAP in podocytes is crucial for differentiation, cell survival, and structural maintenance. However, the role of YAP in diabetic podocyte injury is unclear

Methods: Inducible podocyte-specific YAP deletion (Yap^{podiKO}) mice and wild-type(Yap^{podWT}) mice were generated by crossing podocin.iCreERT2(+) mice with Yap gene floxed mice. Unilateral nephrectomized (UNX) Yap^{podiKO}, Yap^{podWT}, FVB/NJ mice, and mice with an inactive allele of the Wt1 gene ($Wt1^{CreERT2/+}$) were subjected to streptozotocin injections to induce type I diabetes. Proteinuria and diabetic podocyte injury were assessed. The expression of YAP, TAZ, WT1, TEAD1 and other podocyte-specific proteins in isolated glomeruli was analyzed by immunofluorescent staining or immunoblotting. The expression of these proteins was examined in primary cultured podocytes exposed to 25mM glucose with or without treatment of verteporfin, transfection of YAP siRNA or WT1 siRNA.

Results: In normal human and mouse kidneys, YAP was primarily localized in the nuclei of podocytes. However, diabetic podocytes exhibited increased phosphorylation and cytoplasmic retention of YAP. Diabetic UNX- Yap^{podiKO} and UNX- $Wt1^{CreERT2/+}$ mice were more susceptible to diabetic podocyte injury, as evidenced by earlier proteinuria and severe glomerulosclerosis compared to diabetic UNX-wildtype control mice. In vivo and in vitro studies revealed that YAP is a crucial coactivator of TEAD for Wt1 gene transcription in podocytes, and TEAD1 is an unrecognized downstream target of WT1 in podocytes. In the presence of high glucose, inhibiting YAP in podocytes impaired WT1 expression, and subsequent inhibition of TEAD1 and other wt1 target gene expression may contribute to diabetic podocyte injury.

Conclusions: Constitutively active YAP in podocytes plays a vital role in regulating WT1 gene expression and controlling the transcriptional function of WT1. In diabetic podocytes, inhibition of active YAP impairs WT1 expression, and subsequent inhibition of TEAD1 expression may represent an unrecognized mechanism of diabetic podocyte injury.

SA-PO413

AdipoR1 Is Reduced in Glomeruli in Type 2 Diabetes and Its Depletion in Podocytes in Vitro Impairs Integrin β1 Trafficking, Focal Adhesion Assembly, and Cell Adhesion

Sanna H. Lehtonen,[1] Constanze Schmotz,[1] Jukka P. Tienari,[4] Moin Saleem,[2] Katharina Pfeil,[3] Heiko Bugger,[3] Kirsi H. Pietiläinen,[1] Tuomas Mirtti,[1] Sonja Lindfors.[1] *[1]Helsingin yliopisto Laaketieteellinen tiedekunta, Helsinki, Finland; [2]University of Bristol, Bristol, United Kingdom; [3]Medizinische Universitat Graz, Graz, Austria; [4]HUS-yhtyma, Helsinki, Finland.*

Background: Adiponectin signals *via* adiponectin receptors 1 and 2 (AdipoR1/2) but the role of AdipoR1 in podocyte injury, and the regulation of AdipoR1 expression, remain unknown.

Methods: We carried out immunohistochemical stainings of kidneys of AdipoR1-deficient mice or people with type 2 diabetes (T2D). We treated podocytes with sera from lean and obese people, knocked down AdipoR1 lentivirally and overexpressed miR-221-3p in podocytes. Analyses included integrin endocytosis, adhesion and apoptosis assays.

Results: AdipoR1 and its binding partner APPL are downregulated in glomeruli of people with T2D without kidney disease and reduced AdipoR1 correlates with lowered podocyte number. In cultured podocytes, treatment with sera from obese people and overexpression of miR-221-3p reduce AdipoR1 expression. Expression of miR-221-3p is higher in glomeruli of people with T2D in comparison to controls, and the glomerular expression of miR-221-3p inversely correlates with AdipoR1-positive area. In cultured AdipoR1-knockdown (AdipoR1-KD) podocytes and mice depleted of AdipoR1, CD2AP, P-cadherin and synaptopodin are downregulated. This is coupled with reduced survival signaling and enhanced apoptosis and inflammation. AdipoR1-KD leads to mislocalization of APPL and impaired endocytic trafficking of active integrin β1. Focal adhesion (FA) appearance changes to plaque-like in AdipoR1-KD cells, resulting in increased mean FA area and decreased total cellular number of FAs. The expression of Arp3, which controls FA morphology, is reduced upon AdipoR1 knockdown and the cells show reduced re-adhesion.

Conclusions: Diabetes-associated mir-221-3p reduces AdipoR1 expression in podocytes. Lowered expression level of AdipoR1 in podocytes increases apoptosis and inflammation, impairs trafficking of active integrin β1 and alters FAs and cell adhesion. These alterations may contribute to kidney disease development in T2D.

SA-PO414

Diabetic Kidney Disease: Protein 4.1O Reduces YAP/TAZ Activation and Growth Factor-Induced Podocyte Migration

Eva Koenigshausen,[1] Timo Reisewitz,[1] Nina M. Duelberg,[1] Larissa Matten,[1] Thorsten Wiech,[2] Lorenz Sellin.[1] *[1]Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany; [2]Genome Biologie Cellulaire et Therapeutique, Paris, France.*

Background: FRMD3 has been identified as a candidate gene for diabetic nephropathy and encodes for protein 4.1O. So far, four different protein 4.1O splice variants have been identified. The molecular function of these splice variants is unknown. In diabetic kidney disease growth factor signaling, Yes-associated kinase (YAP, and its paralogue TAZ) translocation into the nucleus and target gene transcription is increased. YAP/TAZ and growth factors have been shown to promote cell migration.

Methods: Human kidney biopsy samples from healthy and diabetic patients were stained for protein 4.1O with immunohistochemistry. HEK293T cells were stimulated with low (5 mmol/l), high (25 mmol/l) glucose concentrations or an osmotic control (5 mmol/l glucose + 19, 5 mmol/l mannitol). RNA was isolated and PCR performed. HEK293T cells expressed protein 4.1O splice variants or the control and were stimulated with low, high glucose or mannitol. After cell lysis, western blot was performed for phospho-YAP 397 and actin. Human podocytes were stably transduced with 4.1O splice variants. For migration assays, human podocytes were stimulated with 1 % FCS and different growth factors as well as its inhibitors.

Results: Protein 4.1O expression is detected in healthy human glomeruli by immunohistochemistry. In diabetic patients with CKD stage 3b to 5 and gross proteinuria protein 4.1O expression seems to be increased in podocytes. High glucose but not its osmotic control leads to enhanced transcription of FRMD3. Under high glucose condition protein 4.1O significantly increases YAP phosphorylation. This effect is abrogated if a splice variant lacking a c-terminal domain is expressed. Protein 4.1O reduces podocyte migration after growth factor stimulation compared to control and other splice variants. Treatment with a growth factor inhibitor does not alter podocyte migration in protein 4.1O and control cells.

Conclusions: Expression of protein 4.1O is increased in human diabetic kidney disease and under high glucose conditions. Protein 4.1O splice variants have differential effects on YAP/TAZ activation and growth factor induced migration. This improved understanding of protein 4.1O splice variant function helps to better understand its role in diabetic nephropathy.

Blocking LFA-1 Reduces Diabetic Kidney Disease in a Mouse Model of Type 2 Diabetes

Jocelyn Cervantes, Farah Kramer, Jenny E. Kanter. *University of Washington, Seattle, WA.*

Background: Diabetic dyslipidemia, characterized by elevated triglyceride-rich lipoproteins (TRLs), is a known risk factor for renal function decline. At the same time, macrophage accumulation has been observed in kidney biopsies in individuals with diabetic kidney disease (DKD). Thus, we wanted to test the role of monocyte infiltration in the progression of diabetic kidney disease.

Methods: BTBR wildtype (WT) and leptin-deficient (OB; diabetic) mice with LDL receptor deficiency were maintained on a high-fat diet to promote human-like dyslipidemia.

Results: OB diabetic mice with human-like dyslipidemia have a dramatic increase in DKD (glomerular size: 4164 ± 385 μm^2 in WT mice and 8299 ± 622 in OB mice, albuminuria to creatinine ratio: 374.3 ± 71.0 μg/mg in WT mice and 4648 ± 1021 in OB mice). This was associated with increased monocyte recruitment, glomerular macrophage accumulation, and glomerular foam cells, suggesting a pathogenic role for macrophages in DKD progression (Mac-2 positive cells per glomerulus in WT mice was 1.0 ± 0.2 and 6.8 ± 0.6 in OB mice). Notably, diabetes increased the expression of the adhesion molecule ICAM-1 in the glomerulus and in isolated kidney endothelial cells (ICAM-1 μm^2 per glomerulus in WT mice was 11.2 ± 3.1 and 54.7 ± 15.0 in OB mice) with a concomitant increase in monocyte binding partner, LFA-1. To test if LFA-1 facilitates monocyte infiltration into the kidney glomerulus and exacerbates DKD injury, we treated WT and OB mice with a control blocking antibody or an anti-LFA-1 blocking antibody (900 μg/week) for 4 weeks. Blocking LFA-1 did not affect blood glucose or lipid levels but resulted in a reduction in glomerular hypertrophy and urinary albuminuria in OB mice (glomerular hypertrophy: 6209 ± 346 μm^2 in control antibody-treated OB mice compared to LFA-1 treated OB mice 4844 ± 251, albumin to creatinine ratio: 1084 ± 157 μg/mg in control-treated OB mice compared to anti-LFA-1 treated OB mice 546 ± 164.0).

Conclusions: Together, these data suggest that diabetes promotes monocyte infiltration into the glomerulus, which in turn contributes to DKD.

The Insulin/Insulin-Like Growth Factor Axis Is Critically Important in the Kidney Podocyte Controlling Gene Transcription and Spliceosome Function

Jenny Hurcombe,[1] Fern Barrington,[1] Frédéric Burdet,[2] Paul T. Brinkkoetter,[3] Gavin I. Welsh,[1] Richard Coward.[1] *[1]University of Bristol, Bristol, United Kingdom; [2]Swiss Institute of Bioinformatics, Lausanne, Switzerland; [3]Universitatsklinikum Koln, Koln, Germany*.

Background: Insulin signalling to the podocyte via the insulin receptor (IR) is crucial for kidney function and insulin-like growth factor 1 (IGF1) signalling through the structurally related insulin-like growth factor 1 receptor (IGF1R) is also known to directly affect the podocyte. Since the IR and IGF1R may act redundantly in some contexts, this study sought to elucidate the role of the insulin/IGF1 axis in podocyte function using mouse and cell culture models deficient in both receptors.

Methods: To examine the effects of combined receptor loss *in vivo*, a transgenic mouse model with conditional inactivation of podocyte IR and IGF1R was generated. *In vitro*, conditionally immortalised genetic IR/IGF1R dual knockout podocytes were characterised using global proteomic and transcriptomic analysis.

Results: Podocyte specific IR/IGF1R knockout mice developed significant albuminuria and a severe renal phenotype with global sclerosis, renal failure and death occurring between 4 and 24 weeks. >90% loss of IR/IGF1R in cultured mouse podocytes was also detrimental resulting in >50% cell death 7 days after gene knockdown. Enrichment analysis of total proteomic data revealed a striking downregulation of gene ontology terms associated with DNA repair, splicing and RNA processing activity in IR/IGF1R knockdown cells. Long-read RNA sequencing was performed to obtain an overview of global splicing differences in the IR/IGF1R knockdown transcriptome and to determine the effect of spliceosome depletion on the transcriptomic profile of these cells. Analysis of this data revealed higher levels of intron retention and an increase in the proportion of transcripts containing premature termination codons in IR/IGF1R knockdown podocytes along with differential expression of fibronectin splice variants.

Conclusions: This work underlines the critical importance of podocyte insulin/IGF signalling and reveals a novel role for this extrinsic hormonal signalling axis in the maintenance of genomic integrity and in RNA processing by regulating spliceosome activity in this cell type.

SA-PO417

Podocyte-Specific Deletion of SHP-1 Restored SUMOylation of Podocin and Reversed the Progression of Diabetic Kidney Disease

Farah Lizotte, Pedro M. Geraldes. *Universite de Sherbrooke, Sherbrooke, QC, Canada*.

Background: Both clinical and experimental data suggest that podocyte injury is involved in the onset and progression of diabetic kidney disease (DKD). Although the mechanisms underlying the development of podocyte loss is not completely understood, critical structure proteins such as podocin have been shown to play a major role in podocyte survival and function. We have reported that SHP-1 (a protein tyrosine phosphatase) expression is increased in podocytes of diabetic mice and glomeruli of patients with diabetes. However, the contribution of SHP-1 in podocytes has not been investigated.

Methods: Conditional podocyte specific SHP-1 deficient mice (Podo-SHP-$1^{-/-}$) have been generated to evaluate the impact of SHP-1 on renal function (albuminuria and GFR) and kidney pathology. Deletion of SHP-1 was performed at 4 weeks of age (prevention group; prior to the onset of diabetes) and after 16 weeks of diabetes (reversibility group). Mice were euthanized at 24 weeks of age for renal function and histology assessment.

Results: Elevated albuminuria and GFR seeing in the diabetic mice were preserved in the diabetic mice with specific podocyte ablation of SHP-1 at 4 weeks of age. Interestingly, late deletion of SHP-1 in podocytes after 16 weeks of diabetes also restored renal function and prevented kidney disease progression. Structural changes such as mesangial cell expansion, glomerular hypertrophy, GBM thickening, podocyte foot process effacement and podocyte loss induced by diabetes were also blunted and even reversed with deletion SHP-1 specifically in podocytes. Moreover, podocyte-specific deletion of SHP-1 at 4 weeks and 20 weeks of age prevented diabetes-induced expression of Coll IV, fibronectin, RhoA, and ROCK1, whereas it restored nephrin, podocin and TRPC6 expression. Mass spectrometry analysis revealed that SHP-1 reduced SUMO2 expression and is association with podocin which was also confirmed by immunoprecipitation and co-immunofluorescence in patients with diabetes kidney disease, while podocyte-specific deletion of SHP-1 allow to maintain podocin integrity and stability in a diabetic context.

Conclusions: Our data uncovered a new role of SHP-1 in the regulation of cytoskeleton dynamics and slit diaphragm protein expression and stability, and specific deletion of SHP-1 contribute to preserve podocyte function and even reverse DKD progression.

GSK3β: A Key Regulator of Glomerular Podocyte Injury in Diabetic Kidney Disease

Mengxuan Chen, Yan Ge, Lance D. Dworkin, Rujun Gong. *The University of Toledo Department of Medicine, Toledo, OH.*

Background: Emerging evidence suggests that glycogen synthase kinase (GSK)3β, a critical transducer downstream of the insulin signaling pathway, acts as a convergent point for myriad pathways implicated in kidney injury, repair, and regeneration. However, its role in the pathogenesis of diabetic kidney disease remains highly controversial and was examined here.

Methods: Conditionally immortalized mouse podocytes were cultured under nonpermissive conditions and exposed to a diabetic milieu containing high ambient glucose and insulin as well as proinflammatory conditions, following GSK3β silencing, ectopic expression of a constitutively active GSK3β mutant (S9A), or treatment with tideglusib, a highly-selective small molecule inhibitor of GSK3β. Podocyte injury was assessed and signaling pathways examined.

Results: Upon diabetic insult, podocytes demonstrated prominent signs of cytopathic changes, marked by loss of homeostatic marker proteins like synaptopodin, increased oxidative stress and apoptosis, and stress-induced premature senescence, as evidenced by increased staining for the acidic senescence-associated-β-galactosidase activity, amplified formation of γH2AX foci, and elevated expression of mediators of senescence signaling, like p21 and $p16^{INK4a}$. Podocyte injury was associated with a reduction in inhibitory phosphorylation of GSK3β, denoting GSK3β hyperactivity. In podocytes overexpressing S9A, diabetic podocytopathy was worsened, concomitant with a desensitized insulin signaling activity, enhanced senescence response, impaired Nrf2 antioxidant response and the ensued exacerbation of oxidative damages. Conversely, GSK3β knockdown potentiated the insulin signaling, reinforced Nrf2 antioxidant response, and suppressed senescence, resulting in an improvement in podocyte injury. This protective effect was mimicked by tideglusib co-treatment, suggesting that GSK3β hyperactivity plays a key role in mediating diabetic podocytopathy.

Conclusions: Our findings suggest that GSK3β hyperactivity contributes to glomerular podocyte injury in diabetic kidney disease.

Photobiomodulation Protects High-Fat Diet-Induced Diabetic Kidney Injury via Inhibition of Inflammation

Ji Bian,[1] Brian Bicknell,[3] Ann Liebert,[2] Xinming Chen,[1] Chunling Huang,[1] Carol A. Pollock.[1] Renal Group. *[1]Kolling Institute, Sydney Medical School, Faculty of Medicine and Health, University of Sydney, Royal North Shore Hospital, Sydney, NSW, Australia; [2]Faculty of Medicine and Health, University of Sydney, Sydney, NSW, Australia; [3]College of Health and Medicine, Australian National University, Canberra, ACT, Australia*.

Background: Innovative therapeutic strategies for DKD are urgently needed due to limitations of current treatments. PBM, using red or near-infrared light to modulate cellular function, has gained increasing interest among available therapeutic strategies for many diseases due to its wide variety of positive effects, such as suppressing inflammation, improving mitochondrial activity, and alleviating oxidative stress, which are all inherent in DKD. However, the potential role of PBM in treating DKD has not yet been explored.

Methods: *In vitro*, human proximal tubular cells (HK2 cells) pre-treated with low dose (4.32 J) or high dose (8.64J) PBM were then incubated with TGF-β1 (2 ng/ml)

for 48 hours with or without PBM irradiation every 24h. *In vivo*, high-fat diet (HFD)-induced DKD mice were treated with low dose (7.2J) or high dose (18J) PBM 3 times per week commencing at 12 weeks of HFD and continue for 12 weeks. SHAM treatment was identical but with laser diodes switched off. Renal function, fibrotic and inflammatory markers were examined.

Results: *In vitro* results showed that TGF-β1 induced overexpression of fibronectin and tumour necrosis factor (TNF-α) ((*P*<0.01) at both mRNA and protein levels, which were significantly reversed by low (*P*<0.05) but not high PBM dose. Moreover, low but not high PBM dose significantly inhibited TGF-β 1-induced phosphorylation of p65 in comparison with the SHAM group. *In vivo*, low but not high PBM dose improved HFD-induced kidney injury with significant decreases in the levels of blood urea nitrogen, 24h albumin, and urine albumin-creatinine ratio (*P*<0.05). Furthermore, HFD-induced overexpression of collagen IV, TNF-α, a-SMA, TGF-β1, F4/80, and CD68 were reversed by low (*P*<0.05) but not high dose of PBM.

Conclusions: PBM exerts its reno-protective effect via inhibiting inflammation in in vitro and in high-fat diet-induced diabetic mice. This effect is biphasic, with PBM above the therapeutic dose showing no improvement in renal function.

C/EBPα Exacerbates Diabetic Nephropathy by Inducing ACSL4-Mediated Ferroptosis in Tubular Cells

Ziru Xia, Xiangchen Gu, Weiming Wang. Weiming Wang's Team. *Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China*.

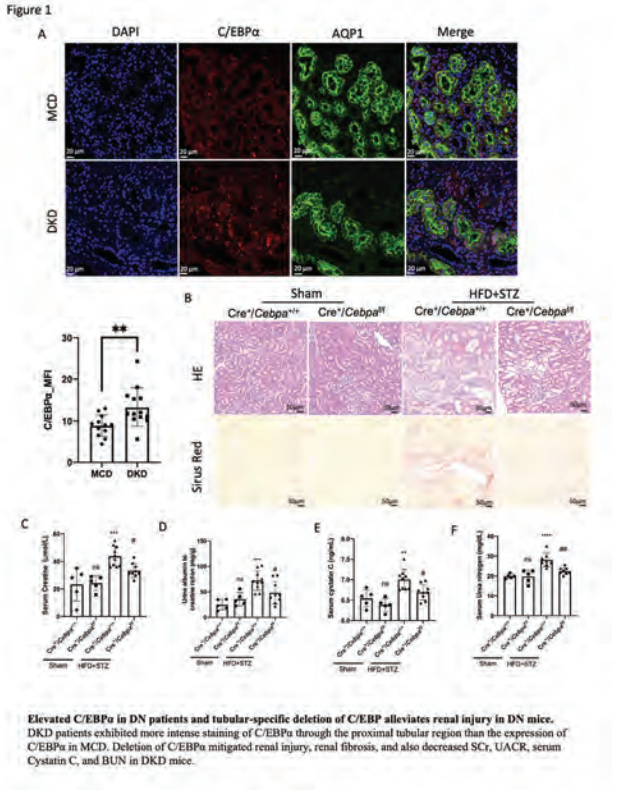
Background: Diabetic nephropathy (DN) is a serious complication of diabetes, leading to the progressive decline of kidney function. In this study, we examined the increased expression of CCAAT/enhancer binding protein alpha (C/EBPα) in DN patients and investigated its potential role in DN pathogenesis.

Methods: Pepck-Cre^{+}/*Cebpa*$^{+/+}$ (WT) and Pepck-Cre^{+}/*Cebpa*$^{fl/fl}$ (KO) mice were streptozotocin (STZ)-induced for diabetes. Renal histopathology, UACR, BUN, SCr, and Cystatin C levels were assessed for renal injury. Kidney tissues were analyzed for ferroptosis markers (GPX4, 4-HNE, MDA). C/EBPα transcriptional activity was examined using CUT&TAG, dual-luciferase, and ChIP-qPCR.

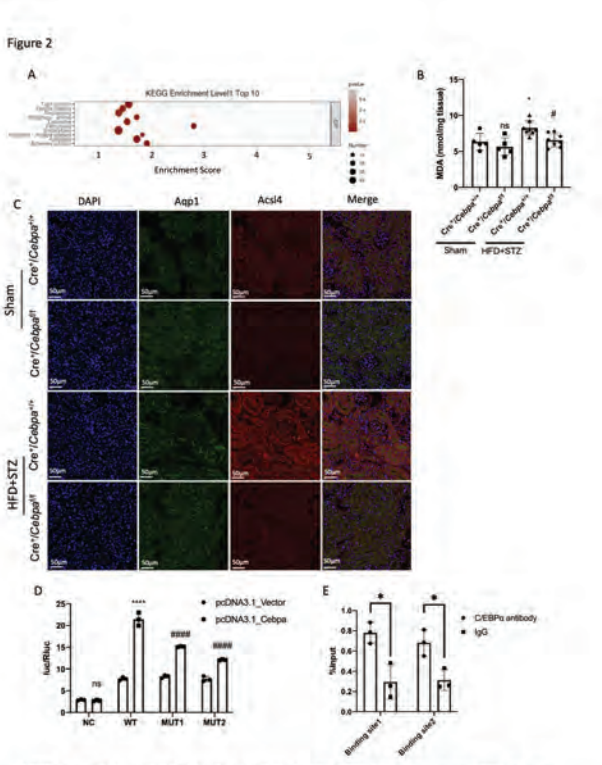
Results: STZ-treated WT mice showed more severe pathological injury, elevated SCr, cystatin C, BUN, and UACR. They also displayed pronounced signs of ferroptosis, including increased MDA, 4-HNE, and reduced GPX4. We further demonstrated that C/EBPα attenuated renal ferroptosis by binding to the TRS of ACSL4, a key enzyme of lipid peroxidation.

Conclusions: We discovered that C/EBPα regulated ACSL4 expression by binding to its TRS, triggering lipid peroxidation and subsequent ferroptosis. And knockout of C/EBPα could alleviate ferroptosis and ameliorate tubular injuries in DN.

Funding: Government Support - Non-U.S.



Elevated C/EBPα in DN patients and tubular-specific deletion of C/EBP alleviates renal injury in DN mice. DKD patients exhibited more intense staining of C/EBPα through the proximal tubular region than the expression of C/EBPα in MCD. Deletion of C/EBPα mitigated renal injury, renal fibrosis, and also decreased SCr, UACR, serum Cystatin C, and BUN in DKD mice.



C/EBPα attenuated ferroptosis by directly upregulating ACSL4. CUT&TAG-sequencing and KEGG pathway enrichment revealed a significant enrichment of genes in the ferroptosis signaling pathway. Knockout of C/EBPα mitigated ferroptosis in DN and decreased the expression of ACSL4. C/EBPα regulated the expression of ACSL4 by binding to its TRS sequence.

SA-PO421

PDIA4 Ameliorates Renal Tubular Pyroptosis via Suppressing IRE1a-sXBP1 Pathway in Diabetic Kidney Disease

Dekun Wang, Xuan Liu, Xiaoyue Tan. *Nankai University, Tianjin, China*.

Background: Accumulating evidences imply the vital role of tubular injury in the pathogenesis of DKD, as well as of ER stress, the regulatory machinery of protein homeostasis. ER stress results in the activation of distinct unfolded protein response (UPR), and the effect of conserved UPR branch IRE1 on the diabetic tubular injury is still elusive.

Methods: We evaluated the activation of IRE1a/sXBP1 and NLPR3 inflammasome, as well as pyroptosis in the high glucose-stressed tubular cells. Furthmore, effects and underlying mechanism of PDIA4 on the activation of IRE1a induced by high glucose were investigated.

Results: We identified the activated IRE1α/sXBP1 and NLRP3 inflammasome, as well as pyroptosis via analyzing the differential genes expression in the diabetic tubules, which was further confirmed in the glucose-stressed tubular cells and biopsy samples from patients of DKD. Consistently, silencing down of IRE1α or administration of IRE1α inhibitor alleviates high glucose-induced NLRP3 inflammasome and pyroptosis. Furthermore, we revealed that PDIA4 suppresses the high glucose-induced tubular IRE1α/sXBP1. Immunoprecipitation and crosslinking assay demonstrated that high glucose promotes the dynamic interaction among PDIA4, Bip and IRE1α. That is, dissociation of Bip with IRE1α and Bip with PDIA4, while increase of PDIA4 with IRE1α. Bond of PDIA4 with IRE1α depends on -CHGC motif, and thus suppresses the activation of IRE1α/sXBP1. Dual-luciferase assay revealed that sXBP1 transcriptionally induces HSC70, hence results in the decrease of PDIA4 via CMA dependent degradation. In vivo, we overexpressed PDIA4 in two mouse models of DKD via injection of AAV9-PDIA4. Our data demonstrated the ectopic overexpression of PDIA4 alleviates the diabetic tubular injury and inflammation reaction, accompanied with the reduced IRE1α/sXBP1 and NLRP3 inflammasome.

Conclusions: Altogether, we revealed that the stress of high glucose activates IRE1α/sXBP1 pathway, NLRP3 inflammasome and pyroptosis in renal tubular cells. XBP1s reduces PDIA4 via induction of HSC70 and thus selective CMA degradation. Reciprocally, PDI4 exhibits inhibitory effect on IRE1α/sXBP1 pathway via bond with oligomerized IRE1α.

Screening for Small-Molecule Inhibitor for KIM-1 and Its Functional Validation in Kidney Fibrosis

Amrendra K. Ajay,[1,2] Yutaro Mori,[1,2] Venkata Sabbisetti,[1,2] Joseph V. Bonventre.[1,2] Bonventre Lab. *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Kidney Injury Molecule-1 (KIM-1) is a glycosylated protein upregulated following proximal tubular injury in humans and mice. With acute and chronic injury, KIM-1 mediates the uptake of apoptotic cells, oxidized lipids, advanced glycation end products (AGEs), and albumin-bound to long-chain fatty acids. Overexpression of KIM-1 causes chronic kidney disease (CKD) in mice.

Methods: We developed a cell-based high throughput functional assay for KIM-1 mediated uptake of DiI labeled ox-LDL and screened 14,414 unique compounds. After setting up a score based on each compound's potential to inhibit cellular ox-LDL uptake, we selected 240 potential hits and cherry-picked them from the primary screening. We performed secondary assays to confirm whether TW-37 quenches the fluorophore or it cleaves the extracellular domain of KIM-1 We employed cell-based binding assays, competitive inhibition assays, and Raman spectroscopy to investigate the binding of recombinant human KIM-1 to a top-hit molecule, TW-37.

Results: We found several hits, with TW-37 as the top hit. TW-37, a second-generation benzene sulfonyl derivative of gossypol, had the highest inhibitory effect on ox-LDL uptake. TW-37 is known to have Bcl2 inhibitory activity; however, Bcl-2 blockade with another specific Bcl-2 inhibitor, ABT-263, did not inhibit KIM-1-dependent ox-LDL uptake, showing that the effects of TW-37 and were not related to Bcl-2 inhibition. TW-37 is not toxic to epithelial cells at concentrations up to 11 μM. Our results from fluorescence quenching experiments confirmed that TW-37 does not quench DiI-fluorophore nor cleave KIM-1. *In silico* docking, experiments revealed a putative TW-37 binding pocket spanning residues 37 to 52 of KIM-1. Raman spectroscopy showed that TW-37 specifically binds to recombinant human KIM-1 and not to the BSA. TW-37 significantly decreased the cellular binding of ox-LDL and BSA-conjugated palmitic acid.

Conclusions: We have identified and characterized TW-37 as an inhibitor of KIM-1 binding. Thus, TW-37 has potential use as a therapeutic for treating kidney disease where chronic KIM-1-mediated uptake of lipid-laden albumin into the proximal tubule contributes to fibrosis and CKD.

SA-PO423

Renal Tubule-Specific Angiotensinogen Knockout Ameliorates Diabetic Kidney Disease in Type 1 Diabetic Akita Mice

Wenxia Yang,[1] Ke Su,[1] Yuchao Pang,[1] Min-Chun Liao,[1] Junzheng Peng,[1] Kana N. Miyata,[2] Janos G. Filep,[3] Julie R. Ingelfinger,[4] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Saint Louis University, Saint Louis, MO; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Massachusetts General Hospital, Boston, MA.*

Background: Angiotensinogen (AGT), the sole precursor of angiotensins in the renin-angiotensin system (RAS), is highly expressed in the renal proximal tubules (RPTs) of mice and patients with diabetic kidney disease (DKD). We reported previously that mice specifically overexpressing *Agt* in RPTs (*Agt*-Tg) develop hypertension and kidney injury. However, the pathophysiological roles of the intrarenal RAS in DKD progression is not well-defined. We investigated whether genetic deletion of *Agt* specifically in renal tubules (RT) could improve kidney injury in type 1 diabetic Akita mice.

Methods: We generated Akita mice with RT-specific *Agt* knockout (Akita Agt^{RT} KO) by crossbreeding Akita $Agt^{lox/lox}$ mice with Agt^{RT} KO (tubule-specific Pax8-Cre) mice. Male Akita Agt^{RT} KO, Akita $Agt^{lox/lox}$, non-diabetic $Agt^{lox/lox}$ and Agt^{RT} KO mice were studied at 20 weeks of age. Physiological data, kidney function, and urinary angiotensin II (Ang II) were assessed. Immunostaining on kidney sections, western blotting (WB) and real-time quantitative PCR (RT-qPCR) were performed to assess protein and gene expression in isolated RPTs.

Results: *Agt* deletion in RT did not significantly affect systolic blood pressure in Akita mice. Fasting blood glucose levels were lower in Akita Agt^{RT} KO vs. Akita mice. Glomerular filtration rate was increased in Akita mice, but was normalized in Akita Agt^{RT} KO mice. The urinary albumin-creatinine ratio (ACR) and Ang II levels were increased in Akita mice, but significantly decreased in Akita Agt^{RT} KO mice. Akita mice exhibited glomerular and tubular hypertrophy, tubular luminal dilation, and necrosis; these abnormalities were markedly attenuated in Akita Agt^{RT} KO mice. Podocyte number (defined by P57 and WT1 staining) was decreased in Akita mice, but was partially restored in Akita Agt^{RT} KO mice. Sodium-glucose cotransporter 2 (SGLT2) expression was lower in Akita Agt^{RT} KO mice than in Akita mice. Urinary glucose excretion was higher in Akita Agt^{RT} KO mice than in Akita mice.

Conclusions: Deletion of *Agt* in RT decreased hyperglycemia, glomerular hyperfiltration, ACR, kidney injury, and SGLT2 expression in Akita mice, demonstrating that inactivation of the intrarenal RAS attenuates DKD progression, at least in part, via down-regulation of SGLT2 expression.

Non-Steroidal Mineralocorticoid Receptor Antagonists (MRAs)-Finerenone Ameliorates Mitochondrial Dysfunction via PI3K/Akt Signaling Pathway in Diabetic Tubulopathy

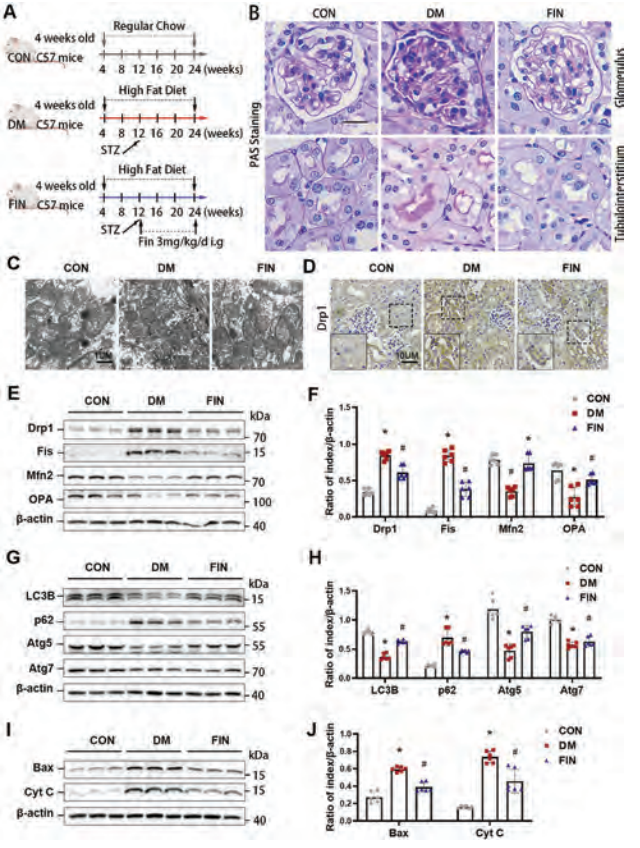
Pei Wang. *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

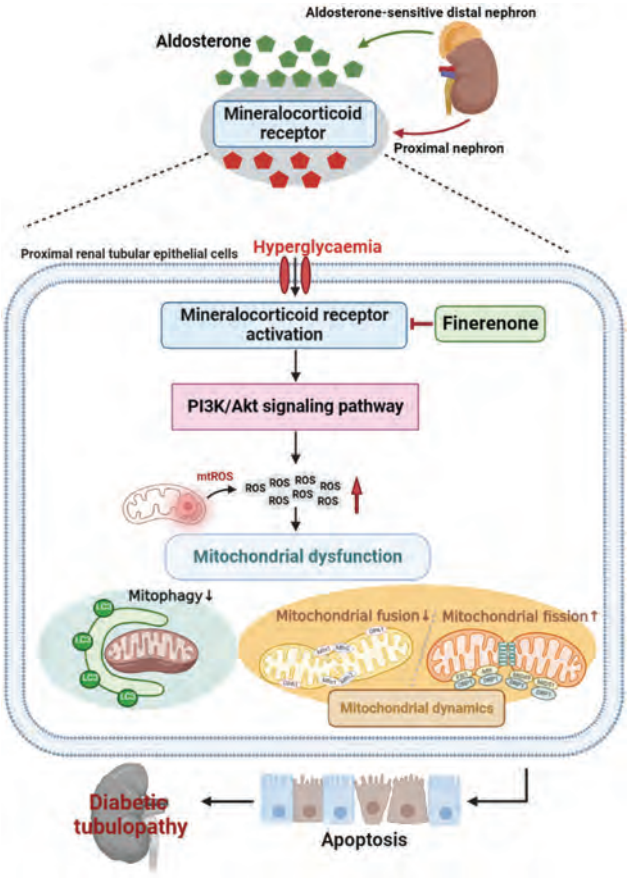
Background: Diabetic tubulopathy (DT) is gradually valued and elucidated as same as glomerular pathology in the pathophysiological perturbations of diabetic kidney disease (DKD). The mitochondria-centric view of DT is emerging as a vital pathological factor in metabolic diseases including DKD. Finerenone (FIN), a novel non-steroidal MRAs, attenuates proteinuria and fibrosis in tubules in DM, but these precise pathomechanisms remain unclear.

Methods: We investigated the role of mineralocorticoid receptor (MR) activation in perturbation of mitochondrial function via PI3K/Akt signaling pathway, including mitochondrial dynamics and mitophagy, under a DM state or hyperglycemia ambience.

Results: *In vivo*, the molecules were examined in kidneys of DM and FIN treatment mice as well. Notably, FIN administration partially attenuated mitochondrial fragmentation, oxidative stress, and apoptosis and restored mitophagy via PI3K/Akt signaling pathway both in HK-2 cells subjected to HG ambience and tubular cells of DM mice.

Conclusions: These results suggest a novel mechanism linking MR activation to mitochondrial dysfunction via PI3K/Akt signaling pathway during tubular injury in the pathogenesis of DKD and it provides evidence support for FIN as a agent for the treatment of DKD.





SA-PO425

Stable Isotope Resolved Mass Spectrometry in Individuals with Type 1 Diabetes Reveals that Diminished Renal Mitochondrial Function Precedes Clinical Diabetic Kidney Disease

Judy J. Baek,[1] Chenchen He,[2] Lynn Ang,[1] Rodica Pop-Busui,[1] Subramaniam Pennathur.[1] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Agilent Technologies Inc, Santa Clara, CA.*

Background: Significant metabolic reprogramming occurs in diabetic kidney disease (DKD). Metabolomics studies of murine models of DKD demonstrate increased glucose metabolism and urinary and kidney lactate production. However, whether such changes occur in individuals with type 1 diabetes (T1D), and the temporal nature of such reprograming with respect to clinical DKD has not been systematically investigated. Stable isotope resolved mass spectrometry using [U-C13] glucose allows dynamic measurement and tracing of relevant glucose-derived metabolic pathways. We performed glycemic clamp study with [U-C13] glucose to evaluate how kidney metabolism is altered in T1D.

Methods: Euglycemic-hyperglycemic clamp studies with [U-13C] glucose were conducted in matched healthy control (HC), and in T1D individuals with established early DKD, and without clinical microvascular complications. All groups had similar estimated glomerular filtration rates (eGFR, CKD-EPI equation). Urine and plasma were collected throughout the course of the clamp study. Blood glucose levels were maintained at 100 mg/dl (±20) for the euglycemic clamp and 300 mg/dl (±20) for the hyperglycemic clamp arms of the study. Urine was analyzed with LC-MS for labeled urinary metabolites which reflect kidney metabolism.

Results: Urinary metabolites in the glycolytic and TCA cycle (mitochondrial) were detected in all three groups. Analysis of the TCA cycle metabolite isotopologues (malate, fumarate and α-ketoglutarate) under hyperglycemic clamp demonstrated significantly increased labeled glucose incorporation into the HC urine in comparison to T1D individuals with and without DKD. Incorporation into citrate and cis-aconitate were significantly elevated in the HC group only versus T1D DKD group.

Conclusions: These metabolic flux labeling studies suggest that T1D results in diminished kidney mitochondrial metabolism, compared to HC under hyperglycemic conditions. This difference was even more pronounced between HC and T1D with DKD. Our data strongly suggests that metabolic changes occur in T1D that results in reduced glucose mitochondrial metabolism, even prior to clinical DKD.

SIRPα Contributions to Muscle Kidney Cross-Talk in Diabetic Kidney Disease

Jiao Wu, Zhaoyong Hu, Sandhya S. Thomas. *Baylor College of Medicine, Houston, TX.*

Background: Fatty acid oxidation (FAO) is a preferred energy source for highly metabolic cells including cardiomyocytes and proximal tubular cells. The kidney is second only to the heart in mitochondrial numbers and oxygen consumption. ATP generation occurs mainly through fatty acid oxidation in the proximal tubular cells. Lipotoxicity has been linked to worsening kidney disease. Specifically, ATP depletion increases lipid accumulation, tubular necrosis and maladaptive repair ultimately leading to kidney dysfunction. Here we examined the role of muscle mediator, signal regulatory protein alpha (SIRPα) and its role in kidney FAO and function. Circulating serum SIRPα has been identified in patients with CKD, therefore we have examined the effects of SIRPα in a diabetic model of kidney disease.

Methods: Control flox mice, muscle (m)-specific and adipose (ad)-specific SIRPα knockout (KO) mice were subjected to a 60% high fat diet and compared to mice on standard chow. Metabolic processes including mRNA, protein expression, and oxygen consumption rates (Seahorse Bioscience) were identified. Triglyceride content was evaluated by triglyceride clearance assay.

Results: Control flox mice display elevated levels of serum SIRPα in response to HFD. mSIRPα KO mice but not adipose-specific SIRPα KO mice exhibit evidence of improved body weight, intracellular insulin signaling in peripheral tissues, and adipokine profile. Additionally, these mice demonstrate less intramuscular fat when compared to control mice on HFD. Also, exogenous SIRPα impaired proximal tubular FAO while reducing ATP production. Finally, kidney tissues in mSIRPα KO mice unlike adSIRPα KO mice displayed improved renal fatty acid oxidation, a reduction in kidney triglyceride content, less kidney fibrosis, and importantly protection against diabetic kidney disease (cystatin C similar to control) despite obesity-induced diet.

Conclusions: These results suggest the importance of the muscles contribution to kidney disease, specifically, myokine SIRPα in exacerbating diabetic kidney disease. Our discoveries provide insight in correcting metabolic defects associated with kidney FAO and to prevent diabetic kidney disease.

SA-PO427

ALCAT1-Mediated Cardiolipin Remodeling Contributes to Podocyte Mitochondrial Dysfunction in Diabetic Kidney Disease

Yanqin Fan, Yiqun Hao, Guohua Ding. *Renmin Hospital of Wuhan University, Wuhan, China.*

Background: Recent studies suggested that mitochondrial damage resulting from abnormal cardiolipin remodeling was associated with the pathogenesis of diabetic kidney disease (DKD). AS a cardiolipin acyltransferase, ALCAT1 was confirmed to be involved in Parkinson's diseases and other aging-related diseases by regulating pathological CL remodeling. The purpose of this investigation was to determine the role of ALCAT1 in DKD.

Methods: We used db/db mice to conduct the in vivo experiments. Double immunolabeling and Western blots (WB) were performed to assess ALCAT1 distribution and expression in glomeruli. Mitochondrial structure was examined by transmission electron microscope (TEM). CL composition was assessed by lipidomics analysis. We cultured conditionally immortalized human podocytes to perform the in vitro studies. Lipidomics, TEM and WB analysis were similar to the in vivo study. Mitochondrial function was evaluated by mitochondrial membrane potential, mitochondrial ROS and ATP. The overexpression plasmids and siRNA were transfected to further investigate the changes of podocyte mitochondrial injury following overexpression or knockdown of ALCAT1.

Results: ALCAT1 expression was increased in glomerular podocytes of db/db mice and high-glucose (HG) cultured podocytes, accompanied by increased oxidized CL (ox-CL) and mitochondrial damage. ALCAT1 deficiency effectively blocked HG-induced ox-CL and podocyte mitochondria damage. In contrast, ALCAT1 upregulation enhanced ox-CL and mitochondria malfunction. Moreover, CL antioxidant SS-31 treatment markedly inhibited mitochondria dysfunction and cell injury. And SS-31 treatment could partly reverse the damage caused by ALCAT1 overexpression. We further found that ALCAT1 could mediate the key regulators of mitochondrial dynamics and mitophagy.

Conclusions: Our results demonstrated that ALCAT1-mediated cardiolipin remodeling played a crucial role in diabetic kidney disease and provided new insights for its treatment.

IL-6-ZIP14-GPX4 Axis Is Involved in Ferroptosis in Diabetic Kidney Disease

Keping Wu, Xiaochang Xu, Enyi Zhu, Yejing Dong, Yimin Zhang. *Sun Yat-Sen University, Guangzhou, China.*

Background: Ferroptosis is caused by lipid peroxidation and iron accumulation. Our previous study have shown that ZIP14 is involved in ferroptosis in Diabetic kidney disease(DKD), but the mechanism is unknown. Interleukin-6 (IL-6) can specifically increase the expression of ZIP14. Thus, we hypothesize that IL-6-ZIP14-GPX4 axis is involved in ferroptosis in DKD.

Methods: Renal biopsies of patients with DKD were collected to detect the changes related to ferroptosis. We induced DKD in 8-week-old male rats with streptozotocin (STZ) and treated with GPX4-Adeno-associated viral (AAV) via tail vein to analyze the degree of renal injury. The expression of GPX4, IL-6 and ZIP14 was detecetd in kidney.

Results: The expression of GPX4 was down-regulated in DKD. While the levels of IL-6 and ZIP14 were up-regulated in kidney of STZ rats. Iron deposition was confirmed in kidney of DKD. The mitochondria of renal biopsy presented reduced mitochondrial volume and missing mitochondrial cristae. The levels of malondialdehyde (MDA), and Fe2+ in STZ group were higher than in the control. While the levels of GSH and SOD were lower than in the control. Over-expression of GPX4 decreased the expression of IL-6 and ZIP14 in kidney of STZ rats. Also, the urine protein-creatinine ratio, and the levels of both MDA and Fe2+ were decreased.

Conclusions: The IL-6-ZIP14-GPX4 axis is involved in ferroptosis in DKD.

Long-Read Sequencing Identifies Loss of Proximal Tubule Spliceosome Gene Srsf7 as a Driver of Inflammation Through Alternative Splicing

Megan L. Noonan, Haojia Wu, Benjamin D. Humphreys. *Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage renal disease worldwide, and SGLT2i have potent reno-protective effects, however the mechanism is unclear. Recently, the mRNA splicing factor *Srsf7* was shown in mice to be downregulated in DKD, and SGLT2i treatment specifically rescued *Srsf7* expression in the S1-segment of the proximal tubule (PT).

Methods: hTERT-RPTECs were treated with control or siRNA against *SRSF7* for 72h, then submitted for long-read (Nanopore) sequencing to more accurately capture alternative splicing. Reads were aligned using minimap2 then quantified with Salmon and analyzed for differential gene expression and differential transcript usage (DTU) using the R packages IsoformSwitchAnalyzeR and bambu.

Results: *SRSF7*-knockdown (KD) efficiency was >80%. Differential gene expression analysis also identified *SRSF7* as a top significantly down-regulated gene. *RSAD2* and *OAS2*, genes involved in viral inflammatory response, were identified as top upregulated genes, which was confirmed by significant increases in both gene and protein expression in *SRSF7*-KD cells. Gene Ontology analysis showed upregulation of biological processes related to viral response, NFkB signaling, and response to interferon, well as enrichment of these hallmark inflammatory pathways by GSEA. Conversely, processes related to cell cycle were downregulated in cells with *SRSF7*-KD, suggesting changes in proliferation. *MKI67* gene expression and BrdU incorporation were decreased in *SRSF7*-KD cells. The genes *SNAPIN*, *LGMN*, and *GGCT* were identified by both computational tools as having alternatively spliced isoforms between control and *SRSF7*-KD cells and were validated using RT-PCR. Genes with alternative splicing were enriched in pathways related to viral response/inflammatory signaling, mRNA alternative splicing, RNA metabolism, and apoptosis.

Conclusions: Decreased *SRSF7* in PT cells drives expression of pro-inflammatory genes and regulates splicing of inflammatory genes. Pro-inflammatory alternative splicing events in the S1 segment may thus drive DKD progression and SGLT2i are reno-protective by promoting an anti-inflammatory S1 transcriptome by rescuing Srsf7 expression.

SGLT2 inhibition Alters Pdk4 and Ces1g Expression in a Mouse Model of Diabetes

Anne Long, Takashi Hato, Amy Zollman, Jessica M. Overstreet, Timothy A. Sutton, Pierre C. Dagher. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Diabetes mellitus (DM) continues to be the major contributor to the development of chronic kidney disease (CKD). SGLT2 inhibitors (SGLT2i) have emerged as an important therapeutic intervention to slow the progression of CKD in patients with and without DM. However, the mechanisms by which SGLT2i confer a protective effect in CKD have not been fully elucidated. To further explore the protective mechanisms of SGLT2i in the kidney, we utilized Riboseq to examine the translatome in a mouse model of type 2 DM following SGLT2i treatment.

Methods: 8-week-old db/db (Kallis strain) and db/m (background control) mice were gavaged with 1mg/kg of dapagliflozin (dapa) or vehicle control daily for 4 weeks. Mice were subsequently euthanized and kidneys were harvested for bulk Riboseq and RNA seq.

Results: Riboseq analysis revealed that SGLT2i treatment of db/db mice significantly decreased kidney expression of pyruvate dehydrogenase kinase 4 (Pdk4). Given that Pdk4 is a known inhibitor of pyruvate dehydrogenase, this suggests SGLT2i alters glucose utilization and energy production in the kidney. Additionally, SGLT2i significantly increased the expression of Ces1g (carboxylesterase 1g) (Figure 1). Ces1g is involved in cholesterol and fatty acid utilization.

Conclusions: To our knowledge, this is the first report of SGLT2i effects on Pdk4 and Ces1g expression in the kidney. These data suggest that the protective effects of SGLT2i may include significant alterations in pathways regulating glucose and lipid metabolism. Ongoing studies will determine if direct manipulation of Pdk4 and/or Ces1g provides kidney protective effects in DM independent of SGLT2i.

Funding: NIDDK Support

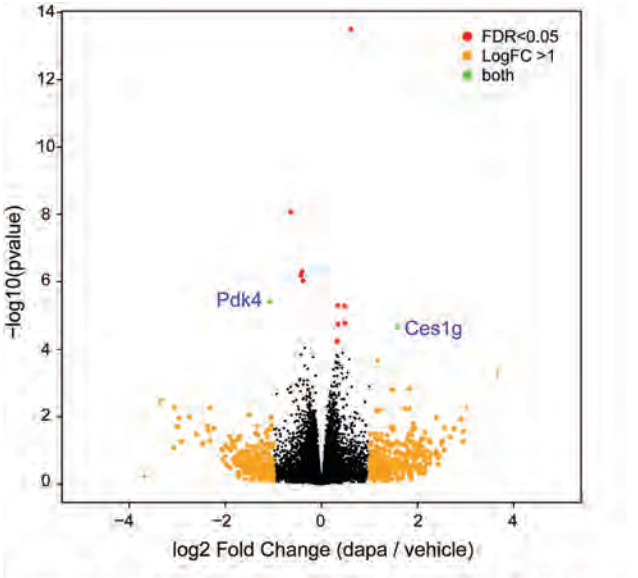

Figure 1: Volcano plot of gene expression in the kidney of db/db mice treated with SGLT2i vs vehicle control (Riboseq). Pdk4 is significantly decreased by SGLT2i. Ces1g is significantly increased by SGLT2i.

Dampening Protein Translation Abrogates the Development of Albuminuria in a Diabetic Mouse Model

Anne Long, Amy Zollman, Takashi Hato, Timothy A. Sutton, Jessica M. Overstreet, Pierre C. Dagher. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Diabetes remains a major cause of chronic kidney disease and end stage kidney disease. The pathophysiologic processes leading to the development of kidney disease in diabetes are poorly understood because it is not common practice to obtain kidney biopsies in diabetic patients without diabetic kidney disease (DKD). We have previously demonstrated that translation, the fundamental process in protein synthesis, is increased in the kidney in a mouse model of diabetes. This increase in translation was observed prior to the onset of DKD. Here we investigate whether direct inhibitors of protein translation, such as tetracyclines, can mitigate the development of proteinuria.

Methods: Db/db mice on a Kaliss strain background which are prone to developing manifestations of DKD over time were used. These mice demonstrate an increase in translation starting as early as eight weeks. Treatment with minocycline (50mg/kg daily x 4 weeks by gavage) was started at 8 weeks and the kidneys were harvested for polyribosomal profiling (PRP). In a parallel set of experiments, 6-week old Db/Db mice (n=10) were treated for up to 10 weeks with minocycline (50mg/kg daily in drinking water) and urine was collected weekly for measurement of albuminuria. Finally, a separate group of Db/Db mice were treated with the SGLT2 inhibitor (dapagliflozin; 1mg/kg, po) for 4 weeks and kidneys were harvested for PRP.

Results: Treatment with minocycline resulted in a 30% reduction in global protein translation as measured by PRP. Fifty percent of the vehicle control treated mice developed significant albuminuria (albumin/creatinine ratio between 0.6-6 μg/μg). In contrast, in all mice treated with minocycline allbumin/creatinine ratios < 0.5 μg/μg. Interestingly, SGLT2 inhibition also resulted in reduction of protein translation as measured by PRP.

Conclusions: Increased protein synthesis in the kidney is a feature of diabetes before the onset of DKD. Pharmacologic strategies to reduce protein synthesis may serve as a new therapeutic avenue to prevent the development of DKD.

The Effect of Altered Branched-Chain Amino Acid (BCAA) Metabolism on Proteinuria and Mesangial Expansion in db/db Mice Treated with SGLT2 Inhibitor

Junichiro Hagita,[1,2] Toshiki Tsuboi,[1] Shoma Tsubota,[1] Sawako Kato,[1] Takuji Ishimoto,[2] Yasuhiko Ito,[2] Tomohito Doke,[1] Shoichi Maruyama.[1] *[1]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [2]Aichi Ika Daigaku Daigakuin Igaku Kenkyuka Igakubu, Nagakute, Japan.*

Background: The protective effect of SGLT2 inhibitors on diabetic kidney disease (DKD) have been reported, however, underlying molecular mechanism remains unclear. Unbiased kidney metabolomics and transcriptome analysis for kidneys treated with SGLT2 inhibitors have been warranted. Although lowering blood glucose levels is believed to have a protective effect on DKD, recent studies have shown that SGLT2 inhibitors modulate branched-chain amino acid (BCAA) transporter expression and mTORC1 function, indicating the role of BCAA metabolism in DKD.

Methods: SGLT2 inhibitor, Tofogliflozin (5mg/kg/day) was given to the db/m and db/db mice for 8 weeks. The blood glucose levels, body weight and food intake were regularly examined. Urinary albumin and creatinine levels were measured. PAS, PAM, and collagen IV were stained in kidney FFPE sections. LC-MS and RNA sequence for kidney tissues was performed. The phosphoS6 (pS6) was stained with Nephrin in frozen kidney tissue to see the mTORC1 activation in mesangial cells. Mes13 were incubated with BCAA, and the levels of collagen IV and proteins associated with mTORC1 activation pathway were examined.

Results: Blood glucose levels were significantly reduced in db/db mice treated with Tofogliflozin compared to db/db mice ($p<0.01$). The proteinuria, mesangial expansion, and collagen IV accumulation were reduced in db/db mice treated with Tofogliflozin. The unbiased metabolomics study identified significant changes in 68 metabolites of kidneys from db/db mice compared to db/m mice ($p<0.05$). Tofogliflozin reversed the changes in 15 out of 68 metabolites. In addition to the metabolites associated with glycolytic or polyol pathways, the levels of BCAA were significantly reduced in kidneys treated with Tofogliflozin ($p<0.05$). The higher levels of collagen IV were confirmed in MES13 treated with BCAA. The protein levels of phosphorylated forms of S6 (pS6) and S6K (pS6K) indicating mTORC1 activation. The higher expression of pS6 in the mesangial region of db/db mice and reduction of their levels in Tofogliflozin-treated db/db mice was confirmed.

Conclusions: Unbiased metabolomics analysis identified the reduction of BCAA levels in kidneys treated with an SGLT2 inhibitor. The higher BCAA levels promote mesangial expansion by modulating mTORC1 activation.

Renal Tubule-Specific NRF2 Deletion Downregulates SGLT2 and Angiotensinogen Expression and Ameliorates GFR and Kidney Injury in Akita Mice

Ke Su,[1] Shuiling Zhao,[1] Wenxia Yang,[1] Yuchao Pang,[1] Min-Chun Liao,[1] Junzheng Peng,[1] Kana N. Miyata,[2] Janos G. Filep,[3] Julie R. Ingelfinger,[4] Shao-Ling Zhang,[1] John S. Chan.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Saint Louis University, Saint Louis, MO; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Massachusetts General Hospital, Boston, MA.*

Background: Nuclear factor erthyroid-2 related factor 2 (NRF2) expression is increased in kidneys of mice and patients with diabetes. We have reported that overexpression of NRF2 in renal proximal tubular cells (RPTCs) increases sodium-glucose co-transporter 2 (SGLT2) and angiotensinogen (AGT) expression and exacerbates dysglycemia and progression of nephropathy in type 1 diabetic (T1D) Akita *Nrf2*$^{-/-}$/*Nrf2*^{RPTC} transgenic (Tg) mice (Diabetes 2021). However, the pathophysiological role of renal NRF2 in the progression of diabetic kidney disease (DKD) is not well understood. We now report the impact of *Nrf2* deletion specifically in renal tubules (RT) of Akita mice on the expression of SGLT2 and AGT in RPTCs in the setting of hyperglycemia and kidney injury.

Methods: Akita RT-specific *Nrf2* knock-out (Akita *Nrf2*^{RT} KO) mice were generated by crossbreeding Akita with *Nrf2*^{RT} KO mice using Pax8-Cre (through crossbreeding male *Nrf2* floxed mice with female RT-specific Cre deleter (Pax8-Cre) mice). Immunostaining on kidney sections, Western blot (WB) and real-time qPCR (RT-qPCR) were employed to assess protein and gene expression in isolated RPTs. Physiological and kidney morphological changes were assessed in male Akita *Nrf2*^{RT} KO, Akita *Nrf2*$^{lox/lox}$, non-diabetic *Nrf2*$^{lox/lox}$ and *Nrf2*^{RT} KO mice at the age of 10 to 20 weeks.

Results: SGLT2 and AGT expression in RPT were significantly lower in Akita *Nrf2*^{RT} KO mice cf. to Akita mice. Glomerular filtration rate (GFR) was increased in Akita mice but was normalized (reversed glomerular hyperfiltration) in Akita *Nrf2*^{RT} KO mice. Fasting blood glucose, glomerular tuft volume, RPTC volume, tubular luminal dilatation, tubular injury score, kidney weight and urinary albumin-creatinine ratio (ACR) were significantly increased in Akita mice vs nondiabetic *Nrf2*$^{lox/lox}$ and *Nrf2*^{RT} KO mice. These abnormalities were greatly reduced in Akita *Nrf2*^{RT} KO mice, except for fasting blood glucose. Fractional excretion of glucose was increased in Akita mice and increased further in Akita *Nrf2*^{RT} KO mice.

Conclusions: Our results show that RT-*Nrf2* deletion ameliorates GFR and kidney injury in Akita mice, indicating renal NRF2 is important in tubuloglomerular feedback via down-regulation of intrarenal SGLT2 and AGT expression.

Residues L667 and L658: Critical Players in the Functional Activation of SGLT2 by MAP17

He Zhou, Solange Abdulnour-Nakhoul, L. Lee Hamm, Nazih L. Nakhoul. *Tulane University School of Medicine, New Orleans, LA.*

Background: Sodium-glucose cotransporter 2 (SGLT2) is crucial for renal glucose reabsorption. Unlike its family member SGLT1, SGLT2 requires an activator protein, MAP17, for its transport activity. However, the mechanism of this unique activation is unclear. A recent cryogenic electron microscope (cryo-EM) study predicted interactive residues on SGLT2-MAP17 complex, but their functional significance requires validation. This study aims to investigate the role of specific SGLT2 amino acid residues in the functional activation of SGLT2 by MAP17 and their effect on glucose transport.

Methods: Five SGLT2 residues predicted to interact with MAP17 were selected based on cryo-EM predictions and aligned sequences of SGLT2 homologues. Mutations (mostly to alanine or cysteine) were designed to assess the effects of side chain and polarity changes. Transport studies were conducted using Xenopus oocytes expressing wild-type SGLT2 (SGLT2-WT) proteins or mutants and co-expressing MAP17. Oocytes were microinjected with mRNA for SGLT2-WT or SGLT2 mutants, and MAP17 mRNA was co-injected. Negative controls included H_2O-injected oocytes and SGLT2-only-injected oocytes. Glucose transport in each oocyte was assessed by perfusing solutions containing 86 mM Na^+ and 20 mM glucose and measuring whole cell currents generated by glucose-activated Na^+ transport using two-electrode voltage clamp.

Results: Three SGLT2 mutations (L667C, L667M, and L658C) significantly inhibited glucose transport compared to SGLT2-WT. Specifically, L667C inhibited transport by 88%, L667M by 72%, and L658C by 70% ($p<0.01$). Notably, mutations F666A, F666Y, M661A, M661C, V665A and V665C did not significantly inhibit SGLT2 activity.

Conclusions: L667C, L667M and L658C mutations inhibited glucose transport potentially by disrupting the interaction between SGLT2 and MAP17, likely through altered hydrophobicity or disulfide bond formation. While other predicted interacting sites have a marginal contribution, L658 and L667 emerge as essential residues, displaying conservation and divergence among species and family members. This study confirmed the effects of cryo-EM predicted residues on SGLT2-MAP17 interaction and identified novel critical amino acids (L667 & L658) for SGLT2 function and MAP17 interaction.

Combination Therapy with Lisinopril and Dapagliflozin Rescues GFR Decline and Glomerular Damage in the KKAy Mouse Model of Diabetic Kidney Disease

Arianne Van Koppen,[1] Andrea R. Nawrocki,[2] Simon A. Hinke,[2] Harry van Goor,[3] Ingeborg M. Bajema,[3] Amélie Dendooven,[4] Tri Q. Nguyen,[5] Matthew D. Breyer,[2] Reinout Stoop.[1] *[1]TNO, Leiden, Netherlands; [2]Janssen Research and Development LLC, Boston, MA; [3]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [4]Universitair Ziekenhuis Gent, Gent, Belgium; [5]Universitair Medisch Centrum Utrecht Afdeling Pathologie, Utrecht, Netherlands.*

Background: We previously showed that male KKAy mice develop DKD with progressive decline of GFR upon high fat diet feeding together with a vasoconstrictor. In this study, efficacy of combination therapy with an ACE-inhibitor (lisinopril) and SGLT2-inhibitor (dapagliflozin) on renal function and histopathology was investigated.

Methods: Male KKAy mice underwent uninephrectomy (UNX). After recovery mice received high fat diet (45% LARD) and 50 mg/L LNNA in drinking water (wk0). At week 4, lisinopril (2.5 mg/kg/day and at week 8 dapagliflozin (5 and 20 mg/kg/day) were started. Body weight, blood glucose, food and water intake and albuminuria were determined regularly. GFR was measured transdermally by FITC-sinistrin clearance. Mice were terminated at week 16 and kidney histology was scored. Non-induced and induced non-treated mice were used as controls.

Results: Treatment of KKAy mice on HFD+LNNA with Dapagliflozin reduced blood glucose immediately. Combination therapy with lisinopril and dapagliflozin (5 mg/kg/day) rescued the progressive GFR decline to levels seen in non-induced chow-controls. Pathology showed that the percentage of healthy glomeruli increased from 14% to 26% after combination therapy (dapa 5). Interstitial fibrosis and tubular atrophy were signficantly reduced by combination therapy.

Conclusions: Male KKAy mice on a HFD and LNNA developed DKD resulting in CKD. Combination therapy with Lisinopril and Dapagliflozin rescued GFR decline and reduced glomerular damage. This indicates that the model is clinically relevant and can be used to study compound efficacy in both early and more advanced stages of DKD.

Funding: Commercial Support - Janssen, BPM, Government Support - Non-U.S.

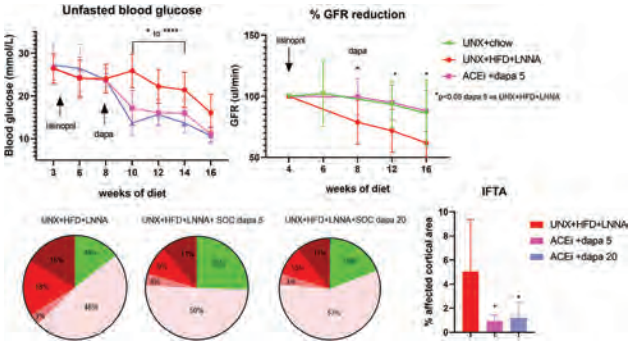

Figure 1: Dapagliflozin decreased blood glucose levels. Combination therapy with Lisinopril and Dapagliflozin rescued GFR decline, glomerular damage and interstitial fibrosis and tubular atrophy.

SA-PO436

Canagliflozin Inhibits Hedgehog Interacting Protein (Hhip)-Mediated Renal Tubular Cell Senescence in Type 1 Akita Mice

Shiao-Ying Chang,[1] Kana N. Miyata,[1,2] Min-Chun Liao,[1] Yuchao Pang,[1] Xin-Ping Zhao,[1] Junzheng Peng,[1] Julie R. Ingelfinger,[3] John S. Chan,[1] Shao-Ling Zhang.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Saint Louis University, Saint Louis, MO; [3]Massachusetts General Hospital, Boston, MA.*

Background: We have recently reported that hedgehog interacting protein (Hhip) activates sodium-glucose cotransporter 2 (Sglt2) expression and promotes tubular senescence-associated secretory phenotype (SASP) in murine diabetic kidney disease (DKD) (*Diabetiologia 2023*). However, the underlying mechanism(s) are poorly understood. Here, we aimed to elucidate the functional impact of the SGLT2 inhibitor, Canagliflozin (Cana) on tubular Hhip-mediated cell senescence in vivo and in vitro.

Methods: Akita renal proximal tubular cells (RPTC)-specific Hhip transgenic (Tg) mice (Akita/Hhip-Tg), Akita/non-Tg and their respective controls (Hhip-Tg or non-Tg) were studied. Cana was administered to Akita mice (Akia/Hhip-Tg vs. Akia/non-Tg) in water (10 or 30 mg/kg/day) from 6 to 20 weeks of age. Primary RPTCs and rat immortalized RPTC cells (IRPTCs) were also employed.

Results: Hhip-Tg mice were fertile and phenotypically normal cf. non-Tg. Compared to respective controls at 20-weeks, both Akita/Hhip-Tg and Akita/non-Tg mice displayed typical DKD dysfunction (hypertension, hyperglycemia, polyuria, increased urinary albumin/creatinine ratio and glomerular filtration rate) and dysmorphology (renal hypertrophy, glomerulosclerosis and tubulopathy). These features were more pronounced in Akia/Hhip-Tg than in Akita/non-Tg. Cana administration ameliorated DKD features in a dose-dependent manner. There was evidence of renal tubular SASP--Heightened β-galactosidase activity was seen in Hhip-Tg cf. non-Tg mice, and its activity was more pronounced in Akita/Hhip-Tg cf. Akita/non-Tg mice. In contrast, Cana more effectively inhibited tubular SASP in kidneys of Akita/non-Tg cf. Akita/Hhip-Tg mice. In IRPTCs, excessive Hhip gene expression through either engineered overexpression or high glucose (25mM D-glucose) stimulation promoted extracellular vehicle (apoptotic bodies and microvesicles)-mediated cellular senescence, and their effects were inhibited by the addition of canagliflozin (500nM).

Conclusions: Canagliflozin appears to be capable of offsetting DKD-related tubulopathy and tubular senescence, possibly, via the inhibition of excessive Hhip delivered extracellularly in DKD.

SA-PO437

Cholesterol 25-Hydroxylase Protects Diabetic Kidney Disease by Regulating ADP Ribosylation Factor 4

Lu Zhang, Zhengying Fang, Jia Fu, Chengguo Wei, Ruijie Liu, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Cholesterol 25-hydroxylase (CH25H) is a cholesterol hydroxylase which is actively involved in lipid metabolism. In kidney, CH25H predominantly expressed in endothelial cells and macrophages, which are renal resident cells and immune cells that have been proved of great importance in context of DKD progression. Intriguingly, the expression of CH25H is upregulated in diabetic mouse. In this study, we determined the effects of CH25H and its product 25HC in DKD.

Methods: C57BL/6J wild type (ch25h$^{+/+}$/lepr$^{+/+}$), ch25h KO (ch25h$^{-/-}$/lepr$^{+/+}$), diabetic (ch25h$^{+/+}$/lepr$^{db/db}$) and DKO (ch25h$^{-/-}$/lepr$^{db/db}$) were utilized in this study. The mice were sacrificed at the age of 24 weeks. C57BLKS/J male lepr$^{db/+}$ and lepr$^{db/db}$ mice were used for 25HC treatment study. In vivo studies were conducted with human umbilical vein endothelial cells and immortalized human podocytes.

Results: CH25H predominantly expressed in glomerular and peritubular endothelial cells. Lepr$^{db/db}$ and STZ-induced diabetic mice have an elevated level of CH25H mRNA level in glomeruli. Global deletion of ch25h in Lepr$^{db/db}$ mice aggravated DKD, showing more albuminuria and worse glomerular hypertrophy and mesangial matrix deposition, and can be alleviated by 25HC treatment. In vivo studies revealed that 25HC binds to a GTP-binding protein Arf4, enhancing its activity by inhibiting the interaction between Arf4 and its GTPase-activating protein Asap1. Interesting, Asap1 expressed mostly in endothelial cells and its expression is increased in the diabetic kidney. In Golgi apparatus, Arf4 activity is required for maintaining essential protein transportation and cellular function, while in cytosol Arf4 inhibits the activity of Aldolase and accumulation of methylglyoxal, thereby preventing cells from death.

Conclusions: Lacking of CH25H aggravated DKD and can be rescued by exogenous supplement of its catalytic product 25HC. 25HC protects DKD by maintaining Arf4 activity via inhibiting Arf4 interaction with its GAP Asap1. Activated Arf4 is required for promoting protein transportation in golgi apparatus and suppressing methylglyoxal production in cytosol, thereby preventing cells from injuries.

SA-PO438

Targeting the LXR/mTOR Signaling Axis: A Novel Therapeutic Strategy for Modulating Autophagy in Diabetic Kidney Disease

Sahar Alkhansa,[1] Rachel Njeim,[1,2] Sarah Al Moussawi,[1] Fuad N. Ziyadeh,[1] Assaad Antoine Eid.[1] *[1]American University of Beirut, Beirut, Lebanon; [2]University of Miami School of Medicine, Miami, FL.*

Background: Autophagy, vital for maintaining kidney homeostasis, is impaired in podocyte dysfunction and diabetes-induced podocyte injury. However, the underlying mechanisms behind autophagy alteration remain poorly understood. Both mTOR complexes and oxidative stress have been implicated as potential key players in diabetes-related autophagy imbalance, yet the mechanisms leading to their alterations are unclear. Additionally, the role of Liver-X-Receptor (LXR) in autophagy and its interaction with other pathways in diabetic kidney disease (DKD) is not well defined. This study aims to elucidate the role of the LXR/mTOR axis in autophagy and its connection to podocyte injury in type 2 diabetes (T2D)

Methods: In vitro experiments were performed using cultured human podocytes while in vivo experiments were conducted using control mice and T2D mice. T2D mice were treated with different pharmacological drugs to inhibit specific components of the mTOR complex: rapamycin for mTORC1, JR-AB2-011 for mTORC2, and PP242 for mTORC1/mTORC2. Another group of T2D mice was treated with T0 to activate LXR. In parallel, control mice were treated with Hydroxychloroquine (HCQ), an autophagy inhibitor, to further investigate the role of autophagy

Results: High glucose levels or hyperglycemia can lead to podocyte injury and dysregulation of autophagy. This is primarily caused by the production of reactive oxygen species (ROS) through NADPH oxidase activation. Additionally, LXR deactivation and mTORC1/mTORC2 activation contribute to these effects. Activation of LXR using T0 restores renal homeostasis by reducing proteinuria, reversing histological and phenotypical changes, and inhibiting NOX4. Moreover, LXR activation improves diabetes-induced autophagy alteration by restoring the expression of LC3B and p62. LXR activation also reduces the activation of both mTORC1 and mTORC2. Furthermore, inhibiting mTORC1, mTORC2, or mTORC1/2 pathways replicates the effects of LXR activation on ROS production and renal injury, but it does not affect the LXR pathway. Conversely, inhibiting autophagy in control mice using HCQ alone is enough to induce kidney injury

Conclusions: This study presents evidence for a novel role of LXR/mTOR in regulating oxidative stress and autophagy during the onset and progression of diabetic kidney disease (DKD)

Phenotypic Features of Advanced Nephropathy in a Murine Model of Metabolic Syndrome: Focus on Sex Differences

Sharma S. Prabhakar. *Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Diabetes nephropathy (DN) which is often an integral part of obesity and metabolic syndrome (MS), is the most cmmon cause of ESRD in most countries. We had originally characterized nephropathy in ZSF rats, a rat model of DN and MS (Prabhakar S, JASN 2007). While male ZSF rats developed advanced features of DN and MS, the phenotypic features of female ZSF rats which have the same genetic background have not been well described. The goals of this study are to examine and compare the expression of MS in male and female ZSF rats at an advanced age.

Methods: Obese ZSF (ZDFxSHHF-fa/facp) model was developed by crossing lean female Zucker Diabetic Fatty (ZDF ./fa) and lean male Spontaneously Hypertensive Heart Failure (SHHF/Mcc-facp, ./fa) rats. Male and female CD rats were used as controls. Rats were monitored from 8th week of life and were fed normal rat chow (CD rats) or high calorie, high fat diet (Purina 5008) in the case of ZSF rats. The present report pertains to data obtained at 46 weeks of age. Blood pressure (BP) was measured by tail cuff plethysmography (Non-Invasive BP measurements using the Kent CODA system). Blood and urine were examined for glucose (Ascensia Contour glucometer) and protein levels. Body weights were measured weekly.

Results: The data here represent the results at 46th week in ZSF and CD rats, Obesity was first evident in ZSF rats at 20 wks but progressed steadily. Male ZSF rats were heavier than female ZSF rats (736±31 vs. 508±44gm p<0.0001) CD male rats were also heavier than female (802±111 vs. 306±31, p<0.0001) Male ZSF and CD rats did not differ significantly in their weights. Male ZSF rats developed significant hypertension compared to female rats (169/126 vs 139/89 p<0.05) CD males and female rats has similar BP (139±102 vs.136±90 mm/Hg p=NS). Proteinuria was was significantly high in male ZSF rats compared to female rats (>2 gm vs.1 gm) while CD rats had trace or no proteinuria. Male ZSF rats developed overt diabetes compared to mild diabetes in female ZSF rats.

Conclusions: These findings indicate that despite having similar genetic make-up, obese ZSF rats displayed major differenes in male and female sexes. In general male rats displayed more florrid features of metabolic syndrome. These observations warrant more intense investigations to explore the etiologic basis and factors to account for such differences between sexes.

KLF2 Agonists as a Novel Therapy for Diabetic Kidney Disease

Lulin Min,[1,2] John C. He,[1,3] Fang Zhong.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [3]James J Peters VA Medical Center, New York, NY.*

Background: Glomerular endothelial cell (GEC) dysfunction is a key event mediating the progression of diabetic kidney disease (DKD). Krüppel-like Factor-2 (KLF2) is induced by flow-mediated shear stress and has endo-protection via its anti-inflammatory, anti-thrombotic activation, and anti-angiogenesis effects. Our key observations : 1) In humans DKD, reduction of KLF2 expression is associated with the progression of DKD. 2) In cultured GECs, we find that KLF2 has anti-inflammatory effects and is a key and direct regulator of eNOS expression. 3) After induction of diabetes or unilateral nephrectomy to induce glomerular hyperfiltration, mice with endothelial cell-specific KLF2 deficiency develop more severe GEC injury and kidney disease as compared to wild type mice.

Methods: We generated an inducible endothelial cell-specific KLF2 overexpression mouse model to test whether overexpression of KLF2 protects GEC injury in DKD mice. We used Limited Rational Design (LRD) approach to design and synthesize KLF2 agonists. We screened KLF2 agonists in cultured GECs by using qPCR assay for eNOS and confirmed by western blot analysis. We utilized the drug affinity responsive target stability (DARTS) method to confirm the interaction of KLF2 agonists with KLF2. We treated db/db mice and BTBR ob/ob mice with KLF2 agonists

Results: Induction of KLF2 expression in endothelial cells in diabetic mice ameliorated albuminuria and glomerular injury with increased glomerular eNOS expression. Screening of KLF2 agonists identified that compound 6 (C-6) had the strongest stimulation on eNOS expression based on qPCR analysis and a dose-dependent stimulatory effect was also confirmed by western blot analysis. By DARTS approach, we confirmed that C-6 had direct interaction with KLF2 without regulation of its mRNA or protein expression, suggesting that C-6 increases the transcription of eNOS via enhancing the binding of KLF2 at eNOS promoter. To test whether C-6 has effects in vivo, we fed both db/db mice and BTBR-ob/ob mice with C-6 at 2.5mg/kg by daily gavage for 8 weeks and found a significant reduction of albuminuria and improvement of glomerular injury in these mice with no obvious toxicity. eNOS expression was also restored in the glomeruli of these diabetic mice by treatment of C-6.

Conclusions: KLF2 has a major protective role against GEC injury in DKD and KLF2 agonists could be developed as potential drugs for treatment of DKD.

Discovery and Development of a Therapeutic Lead Compound for Diabetic Kidney Disease

Rachel Njeim,[1] Haley M. Donow,[2] Judith T. Molina David,[1] Jeffrey D. Pressly,[1] Haley Gye,[1] Sandra M. Merscher,[1] Marc Giulianotti,[2] Alessia Fornoni,[1] Hassan Ali.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Florida International University, Miami, FL.*

Background: Diabetic kidney disease (DKD) is a leading cause of kidney failure worldwide. We previously demonstrated that the accumulation of lipid droplets (LDs) in podocytes leads to lipotoxicity and cell death in DKD. Drugs that lower circulating lipids do not halt DKD progression. However, directly reducing LD accumulation in podocytes was shown to slow disease progression in experimental DKD. We hypothesize that a drug that specifically targets LD accumulation in podocytes will be effective at halting or reversing DKD progression.

Methods: We developed a phenotypic assay using immortalized human podocytes and deployed it to screen a combinatorial library representing over 45 million unique compounds. We performed mechanistic analyses on hit compounds using transcriptomic, proteomic, and phenotypic techniques. We conducted medicinal chemistry to improve drug-like properties and tested one compound in a murine model of DKD.

Results: We identified and synthesized a series of novel compounds that effectively inhibit LD accumulation in podocytes and protect them from injury and cell death. RNAseq analysis revealed that these compounds significantly reduce the expression of genes that mediate tumor necrosis factor (TNF)-signaling, a pathway associated with LD accumulation and podocyte injury, and alter the expression of lysosome-associated membrane glycoprotein (LAMP), a regulator of autophagy. Mechanistic studies demonstrated that these compounds robustly activate autophagy/lipophagy, leading to a significant reduction in LD accumulation in podocytes. We tested one compound with improved drug-like properties in an experimental model of DKD, *db/db* mice, and found that it significantly prevented the progression of DKD, as evidenced by a reduction in albumin-to-creatinine ratios (ACR) and the reduced pathological renal damage associated with DKD.

Conclusions: Our screening assay successfully identified compounds that protect podocytes from LD accumulation by inducing lipophagy. We developed a lead candidate from our initial hit series that demonstrates remarkable efficacy in preventing DKD progression *in vivo*. We are continuing lead optimization efforts toward generating a clinical candidate for testing in a clinical trial.

siRNA Inhibition of Lysophosphatidic Acid Receptor 1 (LPAR1) Attenuates Kidney Fibrosis and Improves Kidney Function in a Rat Model of Hypertensive CKD

Yun Liu, Jingyuan Lee, Fengcheng Xia, Alistair Joseph C. Quimbo, Xing-Xian (Scott) Yu. *Nitto BioPharma Inc, San Diego, CA.*

Background: LPAR1 plays an important role in fibrosis. Its expression is upregulated in kidneys of different injuries. We developed an LPAR1 siRNA-LNP that shows a good kidney cell distribution and improves kidney fibrosis and function in diabetic and Adriamycin-induced models of CKD. Here we demonstrate these efficacies in rats of hypertensive CKD.

Methods: Dahl salt-sensitive rats were fed an 8% high-salt diet for 6 wks and then treated with the LPAR1 siRNA-LNP at 1 or 2 mpk once/wk for 4 wks. A group with an ACEi, Perindopril treatment (Tx) at 3 mpk daily and a combination Tx group was also included in one study. Kidney LPAR1 knockdown, uACR, urine KIM-1 and Cystatin C, kidney hydroxyproline (HP), the expression of the key fibrogenic and inflammatory genes and others were measured. Histological changes were determined.

Results: LPAR1 siRNA Tx caused a dose-dependent reduction in uACR (>80% reduction at 2 mpk), urine KIM-1 and Cystatin C levels (both were nearly normalized at 2 mpk). The Tx also dose-dependently lowered blood pressure (systolic pressure dropped from ~176 to 142 mmHg in the 2 mpk group) and improved animal survival (~50% in control group vs 100% in 2 mpk group). The Tx significantly decreased kidney HP content. Histological analysis found that the Tx improved both glomerular and tubular histology including glomerulosclerosis and tubule-interstitial fibrosis. RNAscope analysis found that Tx at 2 mpk normalized LPAR1 expression. RNAseq analysis indicated that the Tx significantly lowered fibrogenic and inflammatory signaling activities and increased mitochondrial TCA cycle and oxidative phosphorylation activities. RT-PCR confirmed a down-regulation in expression of the key fibrogenic and inflammatory genes including TGFβ, CTGF, Col1a1, Col2a1, RAGE and NF-κβ. Though both LPAR1 siRNA and Perindopril lowered serum creatinine levels to a similar degree, LPAR1 siRNA showed a much better efficacy than the ACEi in improving kidney histology. Combination Tx showed additive effects on serum creatinine and kidney histology.

Conclusions: These data further demonstrated that siRNA inhibition of LPAR1 improves kidney fibrosis and function in rats of hypertensive CKD in addition to other models. Therefore, the LPAR1 siRNA-LNP could be a potential therapeutic for kidney fibrosis.

SA-PO443

Targeting Lysophosphatidic Acid Receptor 1 (LPAR1) with siRNA-Lipid Nanoparticles (siRNA-LNP) Is a Potential Therapeutic Approach for CKD -Associated Kidney Fibrosis

Xing-Xian (Scott) Yu, Yun Liu, Fengcheng Xia, Alistair Joseph C. Quimbo, Jens Harborth, Jingyuan Lee, Jean-Pierre Clamme. *Nitto BioPharma Inc, San Diego, CA.*

Background: LPAR1 plays an important role in tissue fibrosis. Its expression is upregulated in kidneys (K) of different injuries. To explore if siRNA inhibition of its expression could be a therapeutic approach for K fibrosis, we developed a K-targeting LPAR1 siRNA-LNP.

Methods: A series of LPAR1 siRNAs were designed and screened in vitro. The activity of the selected lead siRNA was confirmed in vivo. A series of LNP formulations for delivery of siRNA to K were designed and screened in vivo. Cell distribution of siRNA in K was analyzed with different approaches. The selected lead LPAR1 siRNA-LNP was used to treat mice of DKD or rats of Adriamycin-induced CKD. LPAR1 gene knockdown, serum creatinine, uACR, K hydroxyproline (HP) and histological changes were determined.

Results: In vitro screen identified a lead LPAR1 siRNA of an IC50 ~10pM. The activity was confirmed in vivo. A lead LNP formulation was identified by showing >50% LPAR1 mRNA reduction in mouse K after a dose of 4 mpk and a higher siRNA accumulation in K than in liver or other tissues 24 hr after dosing. FACS analysis found that siRNA was delivered to majority of K cells including podocytes, mesangial cells, endothelial cells in glomeruli, and epithetical and non-epithetical cells in non-glomerulus part. Treatment (Tx) of mice with a single dose of a podocin siRNA-LNP significantly reduced podocin mRNA, further demonstrating the siRNA was delivered into podocytes. RNAscope analysis found that LPAR1 siRNA reduced LPAR1 mRNA level in different K cells. Tx of STZ-induced diabetic mice with LPAR1 siRNA at 4 mpk once a wk for 4 wks lowered K HP levels, and improved K fibrosis and tubular degeneration. Tx of BTBR *ob/ob* mice caused ~20% and 45% reduction in uACR after 3 and 9 wks of Tx, respectively. Tx of rats of Adriamycin-induced CKD at 2 mpk/wk for 4 wks normalized serum creatinine, lowered uACR by 60%, improved glomerulosclerosis, stopped worsening of glomerular atrophy, and reversed glomerular effacement and tubular dilation. The Tx effect lasted for >11 wks.

Conclusions: Above data demonstrated that siRNA inhibition of LPAR1 expression improves K fibrosis accompanied by an improved K function in multiple CKD models. Therefore, the siRNA-LNP could be a potential therapeutic for K fibrosis.

SA-PO444

Renal Cell Type-Associated Therapeutic Effects of Semaglutide in a Mouse Model of Hypertension-Accelerated Diabetic Kidney Disease

Stine T. Bak, Louise Dalbøge, Michael Christensen, Thomas Secher, Henrik H. Hansen, Ida Rune, Lisbeth N. Fink, Mette V. Østergaard. *Gubra, Hoersholm, Denmark.*

Background: Obesity, hyperglycemia and hypertension are critical risk factors for development of diabetic kidney disease (DKD). While emerging evidence suggests that glucagon-like peptide-1 receptor (GLP-1R) agonists improve cardiovascular and renal outcomes in type 2 diabetes patients, their mode of action is presently unclear. Using paired bulk and single-nucleus RNA sequencing (RNAseq), we profiled renal transcriptome signatures of the long-acting GLP-1R agonist semaglutide alone and in combination with the ACE inhibitor lisinopril in a model of hypertension-accelerated, advanced DKD facilitated by adeno-associated virus-mediated renin overexpression (ReninAAV) in uninephrectomized (UNx) female *db/db* mice.

Methods: Seven weeks after ReninAAV administration and six weeks post-UNx, *db/db* UNx-ReninAAV mice were administered (q.d.) vehicle, semaglutide (30 nmol/kg, s.c.) or semaglutide (30 nmol/kg, s.c.) + lisinopril (30 mg/kg, p.o.) for 11 weeks. Endpoints included blood pressure, urine biochemistry, kidney histopathology as well as paired bulk and single-nucleus RNA seq. Cell type deconvolution was performed by referencing expression of treatment-affected genes across all major kidney cell types using single nuclei RNAseq.

Results: Semaglutide robustly reduced hyperglycemia, hypertension and albuminuria concurrent with reduction in glomerulosclerosis severity. Co-administration of lisinopril further ameliorated hypertension and glomerulosclerosis. Gene expression affected by both semaglutide mono- and combination treatment were primarily associated with the immune system and extracellular matrix remodeling. Semaglutide promoted discrete renal gene expression changes in *db/db* UNx-ReninAAV mice with notable suppression of macrophage-associated genes. Combined semaglutide and lisinopril administration resulted in more widespread transcriptome changes in several renal cell types, including macrophages, mesangial cells, podocytes and proximal tubule cells.

Conclusions: Semaglutide improves disease hallmarks in the db/db UNx-ReninAAV mouse model of advanced DKD and improves renal transcriptome signatures. Outcomes were further improved by combined antihypertensive standard-of-care.

SA-PO445

Effects of Nonsteroidal Mineralocorticoid Antagonist (Finerenone) in Western Diet-Induced Kidney Diseases

Komuraiah Myakala,[1] Nataliia V. Shults,[1] Xiaoxin Wang,[1] Kyle E. Korolowicz,[2] Olga C. Rodriguez,[2] Chris Albanese,[2] Moshe Levi.[1] *[1]Georgetown University Medical Center, Washington, DC; [2]Georgetown Lombardi Comprehensive Cancer Center, Washington, DC.*

Background: Mineralocorticoid receptor (MR) overactivation plays a crucial role in the pathogenesis of chronic kidney disease, several cardiovascular and arterial diseases. Recently the non-steroidal MR antagonist Finerenone (FN) was shown to have highly beneficial cardiac and renal protective effects. The purpose of these studies was to determine the mechanisms of the beneficial effects FN in kidney disease in a mouse model of western diet induced obesity and insulin resistance.

Methods: 2-month old C57BL/6J mice fed on low fat (LF) or western diet (WD) were treated with vehicle or FN for 6-months (prevention studies) or after 3 months on the LF or WD at 5 months of age, mice treated with vehicle or FN for 3 months (intervention studies) until they were 8 months old.

Results: Mice fed a Western diet (WD) had increased body weight and kidney weight, whereas Finerenone reduced kidney weight ratio without affecting body weight and blood glucose levels remained unchanged. WD-fed mice had higher plasma levels of TG and TC, reduced by FN. The WD fed mice exhibited significantly increased albuminuria and KIM1 which was decreased with FN. Kidneys of WD-fed mice showed increased expression levels of pro-inflammatory cytokines (MCP1, TGFβ), innate immunity pathways (TLR2, STING, STAT3), and fibrosis marker fibronectin and PAI-1, which were significantly reduced by FN. Interestingly, kidney cholesterol and ceramide levels were markedly increased in WD fed mice, which were reduced by FN. Electron microscopy revealed glomerular basement membrane disruption, podocyte foot process loss, and mitochondrial structural abnormalities in WD-fed mice, all improved by FN.

Conclusions: Our data shows that administration of Finerenone exhibits a renal protective role and prevents the progression of kidney disease in a mouse model of western diet induced obesity and insulin resistance.

Linagliptin Increases Urinary Sodium Excretion via Deactivating Renal Epithelial Sodium Channel (ENaC) in Diabetic Rodents and Patients with Diabetes Mellitus

Goh Kodama, Kensei Taguchi, Sakuya Ito, Kei Fukami. *Kurume Daigaku Igakubu Daigakuin Igaku Kenkyuka, Kurume, Japan.*

Background: About half of patients with diabetes mellitus (DM) develop hypertension, leading to further organ damage. ENaC activation is linked to hypertension. Whereas SGLT2 inhibitors have drawn attention to its renoprotective effect, there are still several anti-diabetic agents available in clinic. However, which agent is the best partner of SGLT2 inhibitors remains unknown. In the present study, we investigated whether linagliptin (LINA), a DPP4 inhibitor, coordinates with SGLT2 inhibitor to attenuate diabetic nephropathy (DM-N) and explored the synergetic effect of LINA in diabetic and hypertensive rodents as well as patients with DM.

Methods: [1] SDT-fatty rats, an obese DM model, were given high salt water and categorized into four groups as followings; Sham, DM-N, DM-N treated with Empagliflozin for 12 weeks (EMPA), DM-N treated with 6-week EMPA followed by 6-week treatment with linagliptin (EMPA + LINA). [2] DOCA/salt mice, an ENaC-activated hypertensive model, were treated with EMPA or EMPA + LINA to investigate if LINA regulates ENaC activation. [3] Cultured distal tubules were treated with high sodium and glucose in the presence of EMPA, LINA, or GLP-1. [4] Urine samples were collected from patients with DM treated with LINA, EMPA, or the combination to investigate urinary sodium excretion.

Results: Tubular injury and renal fibrosis in SDT-fatty rats were improved by EMPA or EMPA + LINA. Along with lowered glucose level, renal dysfunction was attenuated by EMPA or EMPA + LINA. Urinary sodium excretion was increased by combination of the two when compared to EMPA alone. Renal ENaC was reduced with upregulation of Nedd4-2 by EMPA + LINA. Also, combination of the two attenuated hypertension with increase in urinary sodium excretion in DOCA/salt mice. Upregulation of Nedd 4-2 in DOCA/salt mice was prevented by the combination, but not EMPA alone. High sodium and glucose medium increased ENaC expression and suppressed Nedd4-2 expression, both of which were reversed by co-incubation with GLP-1 or LINA. Among the patients with DM, urinary sodium excretion was increased by combination of the two even when compared to EMPA or LINA alone.

Conclusions: LINA can become a potent to prevent the progression of DM-N through deactivating ENaC leading to increased urinary sodium excretion.

SA-PO447

Association of FRMD3 and ACE Gene Polymorphisms with Diabetic Nephropathy and Non-Diabetic Kidney Disease

Juan D. Diaz Garcia, Enrique F. Morales Lopez, Mario Alamilla-Sanchez, Oscar Lara Palafox, Juan Ernesto Muñoz Arellano, Jose L. Ortega. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: FRMD3 and ACE gene polymorphisms have been suggested as an alternative test to differentiate diabetic nephropathy from non-diabetic kidney disease in patients with type 2 diabetes mellitus. This study was conducted to investigate the

relationship between FRMD3 and EA genes. and the clinical features of diabetic nephropathy. Objective: To determine the association of FRMD3 and ACE gene polymorphisms with diabetic nephropathy and non-diabetic kidney disease.

Methods: Patients who already had renal pathology findings were evaluated for ACE and FRMD3 polymorphisms. The subjects were classified into three groups; diabetic nephropathy, diabetic patients with other non-diabetic nephropathy and healthy patients. Polymorphisms of the ACE and FRMD3 genes were analyzed in each group.

Results: In a total of 200 patients from a reference medical center, the prevalence of GG, CG and CC was 45%, 43% and 12% respectively. There were no significant differences in clinical parameters, which consisted of disease duration, proteinuria, and complications in diabetic patients. The G allele was found mainly in patients with diabetic nephropathy (50.5%) while the C allele was found in patients with diabetes and other types of nephropathy (43.9%) ($p = 0.02$). There was a significant association between the CC genotype in patients with diabetes and other types of kidney disease compared to GG ($p = 0.001$). In addition, the C allele was 2.2 times more associated with diabetes and other kidney disease than the G allele ($p = 0.03$). The CC genotype was correlated with the risk of diabetes and other kidney disease than the GG and GC genotypes, with odds ratios of 6.6 and 4.5, respectively ($p = 0.02$).

Conclusions: Regarding the FRMD3 and ACE genes evaluated, the presentation of the C allele, especially homozygous CC, was associated with patients with diabetes and other types of nephropathy in patients with overt proteinuria. Therefore, renal biopsy is suggested in those with the C allele or the homozygous CC genotype.

SA-PO448

Dysregulated miR-936 as a Novel Diagnostic Marker for Diabetic Nephropathy: Meta-Analysis and Validation Study

Gantsetseg Garmaa,[1,2] Stefania Budnuc,[3,4] Tamás Kói,[5,1] Gabor Kokeny.[1] *[1]Semmelweis Egyetem, Budapest, Hungary; [2]Mongolian National University of Medical Sciences, Ulaanbaatar, Mongolia; [3]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [4]Division of Pancreatic Diseases, Heart and Vascular Center, Semmelweis University, Budapest, Hungary; [5]Department of Stochastics, Institute of Mathematics, Budapest University of Technology and Economics, Budapest, Hungary.*

Background: MiRNAs are short non-coding ribonucleic acid molecules that bind to target messenger RNAs, resulting in their degradation and translational repression. They could be used as a diagnostic marker and nucleic acid therapy in chronic kidney disease (CKD).

Methods: We used two consecutive methods to validate miR-936 in diabetic nephropathy (DN). First, investigating potential miRNA in CKD is explored from a meta-analysis of 32 miRNA profiling studies. The enrichment analysis was performed for target genes and molecular pathways utilizing DIANA mirPath v.3 and Reactome. Finally, for the first time, miR-936 was validated by qRT-PCR in kidney biopsy of DN patients and high glucose-induced HK-2 cells.

Results: Urinary miR-936 was one of the most down-regulated from a meta-analysis (Figure 1). The enrichment analysis found dysregulated miRNAs affecting fatty acid biosynthesis and metabolism pathways. MiR-936 was over-expressed in DN patient kidney biopsies (DN, n=3) compared to control kidney tissue (CTL, n=3) but did not reach statistical significance (Mann-Whitney test). HK-2 cells in high glucose (24 hours, 25 mmol/l, n=3) medium increased miR-936 expression by 2-fold (*$p<0.05$ by Kruskal Wallis test), while mannitol, osmotic control (20 mmol/l, n=3) had no effect.

Conclusions: The dysregulation of miR-936 expression in diabetic nephropathy is investigated, which will provide further research on the molecular mechanism of dysregulated miR-936 in diabetic nephropathy.

Label-Free Multimodal Imaging of Diabetic Kidney Disease Tissue

Anthony A. Fung,[1] Sanjay Jain,[2] Lingyan Shi.[1] HuBMAP. *[1]University of California San Diego, La Jolla, CA; [2]Washington University in St Louis, St Louis, MO.*

Background: Accurate biomarker detection without sample destruction is critical for better utilization and preservation of biopsies. We developed a label-free multimodal imaging platform, combining hyperspectral SRS, MPF, and SHG. This approach reduces sample prep, enables the use of smaller biopsies, and details structural and biochemical changes in both 2D and 3D. Several histological stains are produced from the same sample without the need for serial reconstruction, and avoids unintended sample preparation effects such as lipid droplet fusion. Key insights include lipid subtype ratios, mesangial expansion, collagen fibrotic changes, and oxidative stress. Compatible with conventional methods, this platform affirms and deepens our understanding of DN to improve patient outcomes.

Methods: FFPE and fresh frozen renal tissue, subsequently fixed in 4% PFA, were sliced to 200µm and cleared with 8M urea and 0.2% TritonX. These samples were placed on glass slides and sealed under coverglass in water. SRS images used a tunable 500mW pump and 330mW 1031nm Stokes beams with a pixel dwell time of 40µs and a spectral resolution of 15cm-1. SHG was captured using the Stokes beam.

Results: 3D volumetric imaging provided more accurate mesangial volume fractions than single plane measurements, enabling the visualization of this expansion in DN. Relative distribution of ceramides and TAGs, as well as a greater degree of cholesterol esterification were observed in DN tubules. We also observed collagen fiber thickening and disarray, and oxidative stress. Findings were corroborated by routine IHC and IF.

Conclusions: This is the first all-in-one optical platform to visualize lipid subtype dysregulation, collagen thickening and anisotropy, oxidative stress, and mesangial expansion in DN in 2D and 3D. The spatial and chemical resolution afford multiplexed views of DN and maximizes sample utilization while maintaining flexibility.

Funding: NIDDK Support

Long-Term Exposure to Ambient Air Pollutants and Increased Risk of ESRD in Patients with Type 2 Diabetes Mellitus and CKD

Zhi Shang, Yueming Gao, Zhenling Deng, Yue Wang. *Peking University Third Hospital, Beijing, China.*

Background: Limited data have examined the association between air pollution and the risk of end-stage renal disease (ESRD) in patients with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD).

Methods: Data on air pollutants were obtained from the Beijing Municipal Ecological and Environmental Monitoring Center. Long-term exposure to air pollutants during the follow-up period was measured using the ordinary Kriging method. The outcome was defined as the occurrence of ESRD. Multivariate logistic regression analysis was used to estimate the association between air pollution and the risk of ESRD.

Results: 1,738 patients with T2DM and CKD hospitalized in Peking University Third Hospital from January 1, 2013, to December 31, 2021 were enrolled in this study. During a mean follow-up of 41 months, 98 patients developed ESRD. After adjusting for confounders, an increase of 10 $\mu g/m^3$ in $PM_{2.5}$ (odds ratio [OR] 1.19, 95% confidence interval [CI] 1.03–1.36) and PM_{10} (OR 1.15, 95% CI 1.02–1.30) concentration were positively associated with ESRD. An increase of 1 mg/m^3 in CO (2.80, 1.05–7.48) and an

increase of 1 μg/m³ in SO_2 (1.06, 1.00–1.13) concentration were also positively associated with ESRD. Apart from NO_2, all the above air pollutants have additional predictive value for ESRD in patients with T2DM and CKD, with $PM_{2.5}$ performing best.

Conclusions: In patients with T2DM and CKD, long-term exposure to $PM_{2.5}$, PM_{10}, CO, and SO_2 was positively associated with the risk of ESRD.

Funding: Government Support - Non-U.S.

Epidemiology of Diabetic CKD in Rural and Peri-Urban Bangladesh

Mohammad H. Sarker,[1] Md Moshiur Rahman,[2] Hasnat Sujon,[3] Shakila Banu,[1] Mohammod Jobayer Chisti,[1] Asg Faruque.[1] *[1]International Centre for Diarrhoeal Disease Research Bangladesh, Dhaka, Bangladesh; [2]Hiroshima Daigaku Daigakuin Ikei Kagaku Kenkyuka, Hiroshima, Japan; [3]Medizinische Hochschule Hannover, Hannover, Germany.*

Background: Diabetes is often compounded with chronic kidney disease, and both diseases are becoming more prevalent. However, epidemiological data on Diabetic Chronic Kidney Disease (DCKD) is largely lacking in developing countries. We aimed to generate data in evaluating the prevalence of DCKD and associated risk factors in a selected rural community in Bangladesh.

Methods: We recruited study patients from the Mirzapur Demographic Surveillance System by stratified random sampling. We performed fasting blood sugar to screen patients for diabetes, and measured serum creatinine and urine albumin to creatinine ratio followed by a repeat measurement after 3 months to diagnose CKD. The GFR was estimated using the CKD Epidemiology Collaboration equation, and CKD was diagnosed using the Kidney Disease Outcomes Quality Initiative guidelines. Additionally, age, gender, marital status, occupation, educational background, income/month, smoking status, and sleeping hours were acquired during interviews. Physical examinations were performed to determine blood pressure, pulse rate, height, weight, waist circumference, and hip circumference. Moreover, blood samples were collected to measure serum albumin, hemoglobin, total cholesterol and triglyceride Chi-square test was performed for estimation of odds ratios (OR) and their 95% confidence intervals (CI) to determine the strength of association. Variables with *P*-values <0.05 were simultaneously included into the multivariate logistic model and adjusted odds ratio (aOR) and 95% CI were estimated.

Results: The prevalence of DCKD was 7.0% (61 cases of 872 screened participants). In multivariable analysis, associated factors for prevalent DCKD included hypertension (aOR 2.18, 95% CI 1.21-3.94), low serum albumin (aOR 2.24, 95% CI 1.00-5.00), and hypertriglyceridemia (aOR 2.14, 95% CI 1.21-3.79). However, there was no significant association between DCKD and those aged 46 years and more, sleeping duration less than 7 hours per day, present tobacco smokers, abdominal obesity, and hypercholesterolemia.

Conclusions: This epidemiological data on DCKD in rural and peri-urban Bangladesh revealed a 7% prevalence of DCKD. An early detection system to diagnose DCKD and the intervention should be scaled up to curb the risk factors, such as hypertension, low serum albumin, and hypertriglyceridemia.

Improving CKD Screening in Spanish-Speaking Patients with Poorly Controlled Type 2 Diabetes at a Rural Community Health Center

Anna Kenan,[1] Naeemah Munir.[2] *[1]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]Piedmont Healthcare Inc, Siler City, NC.*

Background: The American Diabetes Association (ADA) and Kidney Disease Improving Global Outcomes (KDIGO) consensus recommendations advise that patients with type 2 diabetes (T2DM) undergo annual screening with urine microalbumin creatinine ratio and estimated glomerular filtration rate. Less than half of patients with T2DM receive the recommend screening. This project aimed to increase CKD screening in Spanish-Speaking patients with poorly controlled T2DM (A1c>9) by 5% over 2 months at a community health center in rural North Carolina and evaluated secondary patient-centered outcomes of initiation of sodium glucose cotransporter 2 inhibitors (SGLT2i) and diagnosis with CKD.

Methods: We performed chart review querying for Spanish-speaking patients at SCCHC with T2DM with A1c>9 without a diagnosis of CKD (n=134). We then created a pop-up alert for patients without any CKD screening in the past year. We performed patient outreach to schedule appointments, offer counseling on CKD screening, and pend labs. Finally, we generated a flier for providers summarizing ADA and KDIGO guidelines for CKD screening and initial management.

Results: Only 43% of patients received full screening at baseline. Overall, the number of patients screened for CKD increased by 7%. 85% of patients with alerts in their charts who showed up for appointments received full screening. 50% of patients contacted through patient outreach scheduled an appointment and all patients who were seen in clinic following outreach received full screening. Only 29% of patients for whom the only intervention was provider education recieved complete screening. No diagnoses of CKD were made as a result of screening. There was an increase in prescription of an SGLT2i from 35% to 69% in patients recieving any CKD screening.

Conclusions: The improvement in CKD screening resulting from this project supports the need for pre-visit planning tools that highlight CKD screening, for patient education efforts, and for a one click 'Kidney Profile' lab order. The increased use of SGLT2i in patients recieving full screening supports a correlation between CKD screening and increased risk reduction therapy. Future efforts to increase appropriate CKD diagnosis and patient counseling following screening will be important for empowering patients to prevent disease progression.

SA-PO453

HbA1c-Dependent Projection of Long-Term Renal Outcomes

Thomas Welte,[1,2] Lukas Westermann,[1] Frederic Arnold.[1,3] *[1]Universitatsklinikum Freiburg Innere Medizin, Freiburg im Breisgau, Germany; [2]Friedrich Miescher Institute for Biomedical Research, Basel, Switzerland; [3]Institute for Microbiology and Hygiene, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg, Germany.*

Background: Diabetes mellitus is a major risk factor for the development of chronic kidney disease (CKD). An association between glycated hemoglobin (HbA1c) and decline of kidney function is well established. There is limited data addressing the prognostic value of baseline HbA1c to predict long-term renal outcomes regardless of diabetes status or anti-diabetic therapies.

Methods: In this single-center retrospective observational study, we analyze the effect of glycemic status on renal outcomes in a study population of $N = 19{,}285$ subjects over a median follow-up time of 69 months. The primary endpoint was defined as time to manifestation of moderate CKD (estimated glomerular filtration rate [eGFR] < 60 ml/min/1.73 m²) in subjects with unconstrained kidney function (eGFR > 60 ml/min/1.73 m²) at baseline. The secondary endpoint was defined as time to progression of CKD (eGFR < 30 ml/min/1.73 m²) in subjects with CKD stage III (eGFR 30 - 60 ml/min/1.73m²) at baseline. Endpoints were individually analyzed using interval- and right-censored datasets. For univariate time-to-event analysis, subjects were grouped into four cohorts by median HbA1c at baseline (HbA1c: < 5.7%, 5.7 – 6.5%, 6.5% – 8.5%, ≥ 8.5%). Covariate-adjusted hazard ratios were estimated applying multivariate parametric regression models on continuous HbA1c measures. A Cox proportional hazard based model was established to predict decline of kidney function based on discrete baseline HbA1c levels.

Results: Lowest baseline HbA1c levels were associated with the slowest decline of kidney function, highest baseline HbA1c levels with the fastest decline of kidney function (median time to primary endpoint for HbA1c < 5.7%: 16 years [95% CI: 13.6-17.8]; for HbA1c 5.7 - 6.5%: 14. years [95% CI: 12.4-15.4]; for HbA1c 6.5 - 8.5%: 9.9 years [95% CI: 8.6-11.7]; for HbA1c > 8.5: 7.1 [95% CI: 5,7 - 8,8], $P < 0.0001$). Similar trends were observed for the secondary endpoint. Covariate-adjusted time-to-event analysis confirms a concentration-dependent effect of HbA1c at baseline on both endpoints.

Conclusions: HbA1c is a strong predictor for kidney function decline, regardless of preexisting diabetes status or CKD stage. Lower HbA1c levels are associated with a lower risk of manifestation or progression of CKD.

SA-PO454

Impact of SGLT2 Inhibitor on All-Cause Mortality Among Patients with Type 2 Diabetes with and Without CKD

Abdullah Almuhaiteeb,[1] Mohamed Abu-Farha,[2] Jehad Abubaker,[2] Hamad Ali,[2] Fahd Al-Mulla.[2] *[1]Amiri Hospital, Kuwait City, Kuwait; [2]Dasman Diabetes Institute, Kuwait City, Kuwait.*

Background: SGLT2 inhibitors have been shown to improve survival among patients with chronic kidney disease (CKD) with and without diabetes. The long-term mortality benefit remains unclear. In addition, the existence of CKD among type 2 diabetes mellitus (DM) who are on SLGT-2 inhibitor can influence its mortality benefit. In this study, we wanted to compare mortality benefit among type 2 DM who are taking SGLT2 inhibitors and CKD to patients with normal renal function. We hypothesize that SGLT2 inhibitor should be started prior to the development of renal impairment among patients with type 2 DM.

Methods: In this retrospective study, we included all type 2 diabetes patients who presented to Dasman Diabetes institute for follow up from 2015 until 2022. The patients were divided based upon whether they were taking SGLT2- inhibitor or not and their CKD status. The main outcome was all-cause mortality.

Results: A total of 3569 patients were included. The all-cause mortality unadjusted hazard ratio (HR) for patients who were on SGLT2-inihbitor was 0.61 (95% CI, 0.41-0.89). After Adjusting for AgeGroup, gender, BMI and CKD stage, the adjusted HR ratio was 0.67 (95% CI, 0.45-0.99). The all-cause mortality HR for patients who were on SGLT2-inhibitor was 0.64 (95% CI, 0.43-0.95) which was adjusted for renal impairment. The HR for patients who had renal impairment who did not receive SGLT2 inhibitor was 4.41 (95% CI, 2.94-6.608). Whereas for patients who were on SGLT2 inhibitor and had renal impairment the adjusted HR was 2.82 (95% CI, 1.60-4.99) and 2.37 (95% CI, 1.31-4.27).

Conclusions: Over period of 8 years follow up, SGLT2-inhbitors were associated with lower all-cause mortality. The presence of CKD is associated with reduced survival suggesting that SGLT2 inhibitor should be started prior to the development of renal disease to improve survival. More research required to assess the optimal time to start SGLT2 inhibitor.

SA-PO455

Higher Glycemic Variability Increased the Risk of All-Cause Mortality in Patients with Diabetes Mellitus on Hemodialysis

Bogdan S. Matei,[1] Salmir Nasic,[2,3] Björn Peters,[2,1] Anna Wärme,[4,1] Johan Svensson,[4,5] Hanri Afghahi.[2,1] *[1]Department of Nephrology, Skaraborg Hospital, Skövde, Sweden; [2]Department of Molecular and Clinical Medicine, Institute of Medicine, the Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden; [3]Research and Development Center (FoU) at Skaraborg Hospital, Skövde, Sweden; [4]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [5]Department of Internal Medicine, Skaraborg Hospital, Skövde, Sweden.*

Background: Glycemic (HbA1c) variability has been recognized as an important predictor for the risk of cardiovascular events and all-cause mortality in patients with diabetes mellitus (DM) with and without renal failure. The aim of this study was to examine the association between HbA1c variability, as a measure of long-term glycemic control and the risk of all-cause mortality in patients with DM and HD.

Methods: Data of 2061 patients (collected between 2008 and 2018) with DM type 1 and 2 and HD were analyzed. HbA1c variability before and after HD was defined as the coefficient variation (CV), which was calculated as the ratio between the standard deviation (SD) and the mean of HbA1c. The relationships between HbA1c variability and mortality were examined by Cox models to estimate hazard ratios (HR) with and 95% confidence intervals (CI) in univariate and multivariate analyses, which was adjusted for demographics, laboratory findings and comorbidity. The patients were divided in seven groups, and we used the lowest CV group (CV≤0.5) as the reference group.

Results: During follow-up, 1071 (52%) deaths occurred. Through entire time of study each one unit increase of CV was associated with higher risk of mortality (HR 1.11, CI 1.02-1.23). Data before HD-start showed that 969 (47%) patients had HbA1c variability with CV>1, which increased to 1188 (58%) during HD. Patients in the group with the lowest CV≤0.5 had the best survival and 169 (8%) of these patients died. In a sub-analysis before HD-start, 597 (29%) of the patients had CV≤0.5, but during HD, 405 (20%) of the patients had CV≤0.5. The two groups with highest CV>2.8 had the highest risk of mortality and 305 (15%) of these patients died. In a sub-analysis before HD-start, 268 (13%) of the patients had CV>2.8, but during HD, 449 (22%) of the patients had CV>2.8. In the multivariate Cox analyses, the groups with highest CV (2.8-4.6 and >4.6) were associated with increased risk of mortality (HR 1.98, CI 1.54-2.47 and HR 1.99, CI 1.54-2.57) compared with the reference group.

Conclusions: Glycemic variability should be considered an important risk factor for mortality in patients with DM and HD. In patients with DM andHD, we highly recommend consistent monitoring of glucose homeostasis and regular evaluation of DM treatment.

SA-PO456

Preventing Hypoglycemia in ESRD Patients with Diabetes Mellitus: The Great Challenge

Hira H. Al-adroos. *Riverside Community Hospital, Riverside, CA.*

Background: Patients with end stage renal disease who have coexisting diabetes mellitus are at an increased risk of developing hypoglycemia. With renal failure, patients have decreased renal gluconeogenesis, glucose reabsorption, and insulin clearance. ESRD patients accounted for about one third of all severe hypoglycemia episodes in hospitalized diabetics. Inadequate dose-adjustment of insulin could be a significant factor contributing to higher rates of hypoglycemia in these patients. In this study, we propose to add a text-based warning for physicians when ordering insulin in order to prevent overcorrection of glucose levels in these patients. Our long term goal is to create an individualized insulin sliding scale for patients with ESRD in order to prevent hypoglycemia and its sequelae.

Methods: We conducted an analysis on 1,178 hospitalized patients to evaluate the incidences of hypoglycemia in patients with co-existing diabetes mellitus and end stage renal disease. Our study aimed at understanding whether administering a lower average dose of insulin would decrease the overall number of episodes of hypoglycemia in these patients. The intervention was a text-based electronic reminder for physicians when they ordered insulin. The 2 groups studied were the pre-intervention group from October 2021 to June 2022 and post-intervention group from July 2022 to March 2023. There were 703 patients studied in the pre-intervention period and 474 patients in the post-intervention period.

Results: Upon analysis of the results, it was noted that there was no statistically significant difference between pre and post intervention groups in the number of hypoglycemic episodes. Although not statistically significant, we do see a reduced amount of total hypoglycemic episodes in patients post-intervention who had at least one prior hypoglycemic episode recorded. It should be noted that the cut off for hypoglycemia classification was changed during the course of this study which could have contributed to the lack of statistically significant results.

Conclusions: This study raises attention towards an important complication of end stage renal disease. Recurrent hypoglycemia can further complicate the course of acute illnesses. With the number of hypoglycemic episodes noted to be higher in the pre-intervention group, it is worthwhile to adjust insulin administration for these patients inpatient.

SA-PO457

Accuracy of Real-Time Continuous Glucose Monitoring in Hemodialysis Patients with Diabetes

Yoko Narasaki,[1] Kamyar Kalantar-Zadeh,[2] Seungsook You,[1] Andrea C. Daza Aguilar,[1] Alejandra Novoa-Vargas,[1] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA.*

Background: HD patients with diabetes are at heightened risk of hypo- and hyperglycemia. Traditional glycemic markers (HbA1c) are less reliable in ESKD, and self-monitored blood glucose may not adequately capture glycemic status in HD patients given its infrequent nature. We thus sought to assess the accuracy of continuous glucose monitoring (CGM) as a more frequent (every 5-minutes), convenient, and automated method of glycemic assessment in a prospective HD cohort with diabetes.

Methods: Among 33 HD patients with diabetes hospitalized from 10/2020-5/2021, we conducted simultaneous glucose measurements using CGM measured by Dexcom G6 devices vs. blood glucose levels using capillary fingerstick or venous blood glucose, with the latter measured at least 4 times per day (before each meal and at night), plus every 30 minutes while receiving HD (total of 6-8 measures during HD). We assessed the agreement of CGM vs. blood glucose values using the mean absolute relative difference (MARD), defined as the average of absolute values of relative differences between CGM vs. blood glucose).

Results: The MARD was 19% overall and 18% and 22% during the non-HD and HD periods, respectively. Consensus error grid analysis showed all of sensor values in clinically acceptable zones A (allowable total error region typically associated with no harm) and B (small amount of data slightly outside the no harm zone but unlikely to cause significant harm).

Conclusions: In hospitalized HD patients with diabetes with concurrent CGM and blood glucose measurements, real-time CGM showed clinically acceptable performance and agreement with blood glucose. Further studies are needed to determine whether CGM can improve the glycemic management of HD patients compared to conventional approaches.

Efficacy of Continuous Glucose Monitoring (CGM) in People with Diabetes on Dialysis

Yimeng Zhang, Pushpa Singh, Kavitha Dhevi Krishnasamy Ganapathy, Vijayan Suresh, Muhammad A. Karamat, Srikanth Bellary, Jyoti B. Baharani. *University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Patients with diabetes on dialysis (DM) experience wide variations in glucose levels leading to increased risk of hypoglycaemia. Due to the inaccuracies of HbA1c in dialysis patients, JBDS-IP and KDIGO Diabetes Work Group recommend the use of CGM. We conducted a systematic review to examine current evidence for CGM use and its impact on clinical outcomes.

Methods: Search of MEDLINE and Embase databases was conducted. Clinical or observational trials in adults with DM on dialysis and CGM intervention reporting glycaemic outcomes were included. Data collected included patient characteristics, intervention and glycaemic outcome. Quality was evaluated using the NHLBI assessment tool.

Results: Of the 936 citations identified, 49 duplicates were removed. 887 screened by title and abstract. 9 full texts reviewed and a further 7 excluded due to duplications and failure to meet to selection criteria. Data was extracted for 2 studies (table 1), both 'good' quality, prospective before-and-after interventional studies with no control group. Joubert et al, (2015) showed mean CGM glucose level was 8.3 at baseline and 7.7mmol/L at the end of the CGM period ($p<0.05$). HbA1c decreased from 6.9 to 6.5% at the end of 12 weeks ($p<0.05$). Number of insulin adjustment was higher during the CGM compared to the SMBG period (2.1 vs 1.4, $p<0.05$). Mean CGM was lower on dialysis days (7.6 vs 7.8mmol/L, $p<0.05$). Képénékian et al, (2014) reported after 3 months with CGM-adapted insulin regimen, HbA1c decreased from 8.4 to 7.6% ($p<0.01$). Mean CGM values decreased from 9.9 to 8.9mmol/L ($p=0.05$). The frequency of glucose values >10mmol/L decreased from 41 to 30% ($p<0.05$), without significant increase in hypoglycaemia frequency. Insulin requirements increased from 70 to 82IU/d ($p<0.01$), without significant weight gain.

Conclusions: Evidence demonstrating impact of CGM on glycaemic outcomes in patients with DM on dialysis is lacking. Further trials with bigger sample size and longer follow up are needed to ascertain the benefits of CGM in these patients.

Author (year)	Country	Participant characteristics	Age (years)	Male to female ratio	Sample size	Comparator	Intervention	Outcome - Primary	Outcome - Secondary	Follow up duration

Association of Peripheral Neutrophil Count with Risk of Cardiovascular Mortality Among Adults with Diabetic Kidney Disease: Evidence from NHANES 2005-2010

Ruiyan Xie, Ka Ho Jason Sher, Danting Zhang, Yat Hin Desmond Yap. Dr. Yap, Yat Hin Desmond Team. *Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China.*

Background: Accumulating data shows that chronic inflammation has crucial pathogenic contributions in CKD patients with diabetes, but the contribution of neutrophils count in diabetic kidney disease (DKD) remains elusive.

Methods: We performed a cross-sectional study of 44,494 participants in the National Health and Nutrition Examination Surveys (NHANES) from 2005 to 2020. The prevalence of CKD and diabetes were calculated. The association of peripheral neutrophils count levels with kidney functions in DKD and cardiovascular disease (CVD) mortality were further explored using logistic regression and Cox proportional hazards models.

Results: Among the 2,643 patients with DKD from NHANES, the weighted mean of peripheral neutrophil count level was 4.97. When compared with patients with DKD in the lowest neutrophil count quintile, The highest quintile had the positively association with uACR and negatively relationship with estimated eGFR. During 2,215 person-years of eligible follow-up, 766 deaths (n = 237 deaths from CVD) occurred. In comparison to those in the those in the lowest neutrophil count quintile group, the highest quintile group had the HRs of 1.77 for all-cause mortality and 2.24 for CVD mortality in the fully adjusted model. A linear count-response relationship of peripheral neutrophil count with CVD mortality were also demonstrated (*P=0.002*).

Conclusions: Higher peripheral neutrophil count was significantly associated with an increased risk of cardiovascular mortality and poor kidney function among patients with DKD.

Funding: Private Foundation Support

Diagnosis of Renal and Cardiovascular Injuries in Type 1, Type 2, and Prediabetic Patients Using an Ensemble of Machine Learning and Deep Learning Methods

Diala Jazra,[1] Mariam Rakka,[2,1] Frederic Harb,[3] Celina R. Bou Jaoude,[1] Adrian W. Aboujaoude,[1] Mahmoud Choucair,[1] Assaad Antoine Eid,[4,1] Rouwaida Kanj.[5,1] *[1]American University of Beirut, Beirut, Lebanon; [2]University of California Irvine, Irvine, CA; [3]University of Balamand, Balamand, Lebanon; [4]University of Michigan, Ann Arbor, MI; [5]University of Illinois Urbana-Champaign, Urbana, IL.*

Background: Diabetes is a growing global pandemic with serious complications such as renal and cardiovascular injuries. Diabetic nephropathy, characterized by decreased glomerular filtration rate (GFR) and albuminuria, is a microvascular complication of

diabetes. Cardiovascular disease, which can result in injuries to coronary, cerebrovascular, and peripheral arteries, is a macrovascular complication. Studies have shown that renal and cardiovascular diseases often co-occur in individuals with diabetes, but there is currently no machine learning algorithm that was used to diagnose the existence of both complications simultaneously.

Methods: For this study, a dataset of 273 diabetic patients is obtained from the American University of Beirut Medical Center (AUBMC). Chronic kidney disease is defined as a GFR lower than 60 ml/min and/or an albumin to creatinine ratio greater than 30. Cardiovascular disease outcome is measured by the presence of cardiovascular events such as myocardial infarction, heart failure, arrhythmias and valvulopathies. To balance the class distributions, the synthetic minority oversampling technique (SMOT) is used. The Random Forest and Artificial Neural Network models are employed to analyze the data and evaluate the relevance of each feature using feature importance methods. The grid search method is used to fine-tune the hyperparameters of the models.

Results: The Random Forest model achieved an accuracy of 91%. The Extreme gradient Boosting (XGBoost) feature importance method revealed that the most relevant features, in decreasing order of importance, were urine albumin mg/l, serum creatinine, age, LDL, total cholesterol, heart rate, phosphate, systolic blood pressure, carbon dioxide, and potassium. The Neural Network had 75% accuracy with Grid Search. The lower accuracy could be due to the small sample size (273 patients) for deep learning.

Conclusions: The results of the study show that machine learning can be useful in diagnosing renal-cardiovascular complications in diabetic patients.

SA-PO461

Differentiating Non-Diabetic Kidney Diseases from Diabetic Nephropathy in Type 2 Diabetes Mellitus Patients with Nephrotic Syndrome

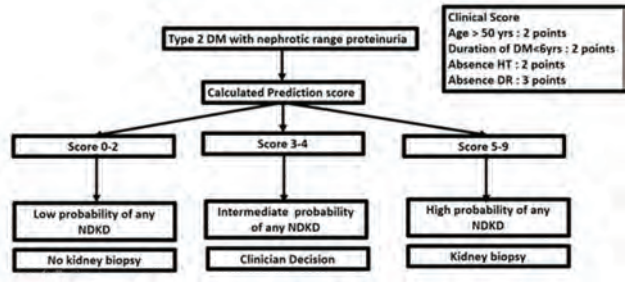
Solos Jaturapisanukul, Punnawit Laungchuaychok, Wanjak Pongsitisak. Vajira Renal-Rheumatology-Autoimmune Disease Research Group. *Navamindradhiraj University, Bangkok, Thailand.*

Background: Nephrotic syndrome (NS) in patients with type 2 diabetes mellitus (T2DM) encompass both diabetic nephropathies (DN) and non-diabetic kidney diseases (NDKD). This study aims to investigate kidney biopsies in T2DM patients who had NS to determine the prevalence of NDKD and analyze characteristic features that are associated with NDKD. The objective is to develop a clinical prediction score that can differentiate any NDKD cases from DN alone.

Methods: This study was done as a single-center, retrospective, cross-sectional observational design, patients diagnosed with T2DM who underwent kidney biopsy due to NS at Vajira Hospital between 2013-2021. All patients received diagnoses of either DN, isolated NDKD, or NDKD superimposed on DN, which were confirmed through pathological examinations. To identify factors correlated with NDKD, a multiple logistic regression analysis was performed. Additionally, a clinical prediction score was developed by assigning weights to the predictors' coefficients in a multivariable logistic model.

Results: A total of 273 patients were enrolled in this study, with 89 patients (32%) DN alone, 69 patients (25%) NDKD superimposed on DN, and 115 patients (42%) NDKD alone. The most prevalent NDKD causes were IgA nephropathy. The absence of diabetic retinopathy (DR) (adj.OR 2.89; 95% CI 1.61-5.2; p<0.001), age>50 years (adj. OR 2.26; 95% CI 1.29-3.93; p=0.004), duration of DM < 6 years (adj.OR 2.02; 95% CI 1.14-3.57; p=0.015), and absence of hypertension (adj.OR 2.058; 95% CI 1.08-3.89; p=0.026) significant associations with NDKD. From these 4 predictors, a prediction score was derived, wherein a score >5 indicated a higher likelihood of NDKD (AUROC of 0.75, 95%CI 0.63-0.86)

Conclusions: The prevalence of any NDKD in T2DM with NS is 67%. No DR, Age > 50 years, duration of DM < 6 years, and absence of hypertension have significant association with NDKD. A new clinical prediction score for distinguishing any NDKD from DN alone can defer kidney biopsy.



Algorithm using Clinical Prediction score

Progression to ESKD in Type 2 Diabetes by Histological Findings: A Retrospective Cohort Study

Karina Haar,[1,2] Frederik Persson,[2] Iain O. Bressendorff,[3] Ditte Hansen,[3,4] Marie Møller,[3] Peter Rossing,[2,4] Rikke Borg.[1,4] PRIMETIME. *[1]Department of Medicine, Zealand University Hospital, Roskilde, Denmark; [2]Steno Diabetes Center Copenhagen, Herlev, Denmark; [3]Department of Nephrology, Copenhagen University Hospital – Herlev and Gentofte, Herlev, Denmark; [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: The risk of progression to end-stage kidney disease (ESKD) varies among individuals with type 2 diabetes (T2D). This study aims to investigate if the risk of progression to ESKD differ by biopsy-proven type of kidney disease.

Methods: We conducted a retrospective cohort study including all adults with T2D in Denmark from 1996-2020 who had a kidney biopsy performed. The individuals were previously classified as having diabetic nephropathy (DN) (n=599), non-diabetic nephropathy (NDN) (n=703), mixed disease (n=165), normal histopathology (n=49), or could not be classified (NC) (n=743). Using high-quality national registry data, the cohort was described with demographic, clinical, and laboratory data and comorbidity. Stratified analysis of progression to ESKD within the type of kidney disease was performed.

Results: The cohort consisted of 68% men with mean age 64.1+11.2 years at biopsy. At the time of biopsy, the DN group had systolic blood pressure (SBP) 144±20 mmHg and a body mass index (BMI) of 30.9±6.2 kg/m^2. They had a median and interquartile range [IQR] estimated glomerular filtration rate (eGFR) 39 [24.0, 59.2] ml/min/1.73m^2 and median [IQR] urine albumin-creatinine ratio (UACR) 2373 [890.2, 4183.5] mg/g. The NDN group had SBP 138±21 mmHg, a BMI of 30.8±6.5 kg/m^2, eGFR 29 [15.0, 58.0] ml/min/1.73m^2, and UACR 766 [95.5, 2394.5] mg/g. The mixed disease group had SBP 147±21 mmHg, a BMI of 31.7±6.1 kg/m^2, eGFR 25 [11.0, 48.0] ml/min/1.73m^2 and UACR 1863 [583.0, 3400.0] mg/g. We found a significant difference in the rate of renal progression ($p < 0.001$). During a median follow-up of 12.8 years, progression to ESKD occurred in 52% with DN, 42% with NDN, 53% with mixed disease, 25% with normal histopathology, and 41% with NC. Time to ESKD from diagnosis of T2D was significantly different within the type of kidney disease ($p < 0.001$); 13.2 [8.0, 17.9] median [IQR] years in DN, 7.8 [4.5, 12.8] years in NDN, 13.0 [7.8, 17.3] years in mixed disease, 6.3 [1.3, 11.1] years in normal histopathology, and 9.2 [5.1, 14.6] years in NC.

Conclusions: In people with T2D, we found the highest rate of ESKD in DN and mixed disease, but with the slowest time to progression. Analyses suggest that the risk of and time until progression to ESKD differs significantly within types of biopsy-proven kidney disease.

SA-PO463

Progression to ESKD in Type 1 Diabetes by Histological Findings

Karina Haar,[1,2] Frederik Persson,[2] Iain O. Bressendorff,[3] Ditte Hansen,[3,4] Marie Møller,[3] Peter Rossing,[2,4] Rikke Borg.[1,4] PRIMETIME. *[1]Department of Medicine, Zealand University Hospital, Roskilde, Denmark; [2]Steno Diabetes Center Copenhagen, Herlev, Denmark; [3]Department of Nephrology, Copenhagen University Hospital - Herlev and Gentofte, Herlev, Denmark; [4]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: Kidney disease in diabetes is a heterogeneous disease. To improve personalized medicine in people with diabetes, it is crucial to identify people at risk of progressing to end-stage kidney disease (ESKD). This study aims to investigate if progression to ESKD differs by biopsy-proven type of kidney disease in people with type 1 diabetes (T1D).

Methods: In this retrospective registry study, we included all Danish adults with T1D from 1996-2020 who had a kidney biopsy performed. The included individuals had diabetic nephropathy (DN)(n=132), non-diabetic nephropathy (NDN)(n=73), mixed disease (n=39), normal histopathology (n=5), or could not be classified (NC)(n=78). Demography, clinical presentation, laboratory values, and prevalence of comorbidity were described by compiling unique national registry data. Within the type of kidney disease, we analyzed progression to ESKD.

Results: The DN group consisted of 71% men with systolic blood pressure (SBP) of 146±21 mmHg and a body mass index (BMI) of 25.1±5.5 kg/m^2. In NDN and mixed disease groups 66% and 59%, respectively, were men. In NDN, mean SBP was 137±18 mmHg and they had a BMI of 24.6±3.5 kg/m^2. Those with mixed disease had a mean SBP of 135±21 mmHg and a BMI of 24.7±3.7 kg/m^2. Median and interquartile range [IQR] estimated glomerular filtration rate (ml/min/1.73m^2) and urine albumin-creatinine ratio (mg/g) were 37 [22.6, 54.1] and 2670 [935.4, 4390.7] in DN, 41 [14.0, 85.0] and 857 [304.5, 3860.5] in NDN, 27 [16.4, 71.8] and 1240 [435.0, 3472.0] in mixed disease, 29 [20.6, 36.5] and 201 [118.0, 984.7] in normal histology, and 35 [12.5, 62.5] and 436 [40.0, 2281.0] in NC, respectively. During a median [IQR] follow-up time of 22.6 [14.5, 30.4] years, 61% with DN advanced to ESKD, compared to 52% with NDN, 59% with mixed disease, and 46% with NC. There were no significant differences between groups. Likewise, there was no significant difference in median [IQR] time to progression of ESKD; 17.4 [12.0, 21.9] years in DN, 14.9 [9.1, 23.0] years in NDN, 19.6 [17.1, 27.4] years in mixed disease, 24.1 [19.3, 26.0] years in normal histopathology, and 18.5 [11.3, 24.8] years in NC.

Conclusions: In people with T1D, retrospective analysis of registry data did not find a significant difference in risk of progression to ESKD or time to ESKD within biopsy-proven type of kidney disease.

Preliminary Results from iBeat Ancillary Study: A Novel Bari Classification of Renal Damage in Diabetic Patients with CKD

Paola Pontrelli,[1] Michele Rossini,[1] Francesca Conserva,[1] Francesco Pesce,[1] Francesco Giorgino,[1] Luigi Laviola,[1] Phillip J. McCown,[2] Edgar A. Otto,[2] Brad A. Godfrey,[2] Steven Sourbron,[3] Kim Gooding,[4] Maria F. Gomez,[5] Matthias Kretzler,[2] Loreto Gesualdo.[1] *[1]University of Bari, Bari, Italy; [2]University of Michigan, Ann Arbor, MI; [3]University of Sheffield, Sheffield, United Kingdom; [4]University of Exeter, Exeter, United Kingdom; [5]Lunds Universitet, Lund, Sweden.*

Background: Renal damage in diabetes is heterogeneous, kidney biopsy remains the gold standard for diagnosis. In this iBEAt sub-study, within the BEAt-DKD project (https://www.beat-dkd.eu/), we aimed to correlate imaging, clinical, molecular and histopathological data to dissect renal damage phenotypes.

Methods: We enrolled 83 patients to perform kidney biopsy (carried out in 64 patients), US and MRI, biofluids and clinical data collection.

Results: According to KDIGO 13 patients were in stage A1, 26 in A2 and 25 in A3, all ranging from G1 to G4. Histological classification by Mazzucco et al (PMID: 11920336) identified 31% of patients with class 1 (diabetic nephropathy-DN); 33% with class 2 (vascular and ischemic glomerular changes); 4% with class 3a (glomerular diseases and DN) and 31% with class 3b (other glomerulonephritis in the absence of DN). Since we observed heterogeneous histological lesions, we here propose a novel classification for diabetic patients with CKD. We recognized 3 different classes (DKD, NDKD, DKD+NDKD) and 6 different phenotypes including: a) in DKD (33%): pure metabolic (7%) and vascular metabolic (26%); b) in NDKD (63%): pure vascular (35%), immunological vascular (IgA, FSGS, MN; 9%), pure immunological (IgAN, FSGS; 19%); c) in DKD+NDKD overlapping phenotypes (4%). We observed differences of uACR (p=0.02) and proteinuria (p=0.005) among the different phenotypes of DKD and NDKD. PAS staining confirmed the increased mesangial expansion in DKD phenotype (p=0.04); vascular wall-to-lumen ratio discriminated vascular vs metabolic (p=0.04) and immunologic damage (p=0.05); renal resistive index discriminated among the phenotypes (p=0.02). We also performed single-cell RNASeq analysis of kidney biopsies mapping more than 61000 nuclei in different cell types, identifying differences between classes and phenotypes along the nephron and the vasculature (i.e. TNNT2 expression in podocytes was associated with vascular damage).

Conclusions: The integration of renal pathology, imaging and molecular data from the same patient has the potential to unlock new diagnostic criteria to address the heterogeneity of renal phenotypes, providing a new classification of renal damage in diabetes.

SA-PO465

Glomerular Crescents Are Associated with the Risk of Kidney Progression in Type 2 Diabetic Kidney Disease

Sohyun Bae,[1] Jong Hyun Jhee,[2] Jung Pyo Lee,[1,3] Tae ik Chang,[4] Jieun Oh,[5] Sung Gyun Kim,[5] Ho Jun Chin,[1,6] Seung Seok Han.[1] *[1]Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Republic of Korea; [2]Department of Internal Medicine, Gangnam Severance Hospital, Seoul, Republic of Korea; [3]Division of Nephrology, Seoul National University Boramae Medical Center, Seoul, Republic of Korea; [4]Department of Internal Medicine, National Health Insurance Service Medical Center Ilsan Hospital, Ilsan, Republic of Korea; [5]Department of Internal Medicine, Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [6]Division of Nephrology, Seoul National University Bundang Hospital, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: Type 2 diabetic kidney disease (T2DKD) is the leading cause of chronic kidney disease and end-stage kidney disease. The heterogeneous phenotype of T2DKD complicates the approach to treating patients. While kidney biopsy is the gold standard for diagnosis, it is not perfect in predicting progression to end-stage kidney disease. Herein, we addressed whether the presence of glomerular crescents was associated with the outcomes in biopsy-proven T2DKD.

Methods: A total of 360 patients who were diagnosed as biopsy-proven DKD in the setting of type 2 diabetes but did not have other crescentic glomerulonephritis from 9 medical centers were reviewed. Hazard ratios (HRs) were calculated using a Cox regression model to evaluate the risk of kidney progression (i.e., ≥50% of decrease in estimated glomerular filtration rates) according to the presence of glomerular crescents.

Results: 11 patients (3.1%) had glomerular crescents in the biopsied tissues. During the follow-up period (median, 18 months; maximum, 18 years), the crescent group had a higher risk of kidney progression than no crescent group with adjusted HR of 2.71 (1.22–6.03) ($P = 0.014$). The relationship with kidney progression was more prominent in patients with high proportion of crescents than in those with low proportion.

Conclusions: The presence of glomerular crescents is associated with progression of T2DKD. Accordingly, histological monitoring of glomerular crescents may be needed to treat patients intensively.

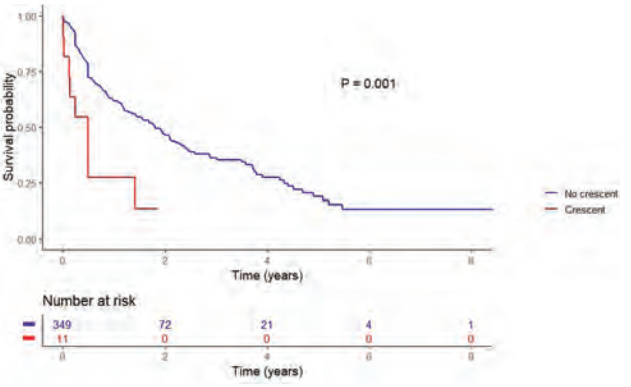

Fig 1. Kidney outcome curves for patients with and without crescents in the biopsied tissues. Kaplan-Meier curve depicted for patients without crescents versus those who had glomerular crescents in the biopsied tissues.

Diversity of Kidney Biopsy Findings Among Diabetic Patients in the Cleveland Clinic Kidney Biopsy Epidemiology Project

Alvin G. Kwon,[1] Hanny Sawaf,[1] Shruti Shettigar,[2] Leal C. Herlitz,[1] Adam Kabuka,[2] Surafel K. Gebreselassie,[2] Shane A. Bobart.[2,1] *[1]Cleveland Clinic Foundation, Cleveland, OH; [2]Cleveland Clinic Florida, Weston, FL.*

Background: Patients with a clinical diagnosis of diabetes without other criteria to prompt kidney biopsy are often treated and managed as diabetic kidney disease (DKD). We sought to describe the spectrum of kidney biopsy findings among patients with diabetes and identify factors associated with finding DKD and non-DKD (NDKD).

Methods: We identified patients with a history of diabetes from the Cleveland Clinic Kidney Biopsy epidemiology project from January 2015 to September 2021 using available ICD-10 code data.

Results: Of 4128 patients with native kidney biopsies, 3503 had ICD-10 code data. We identified 1271 (36.3%) with an ICD-10 coded diabetes. Of these, 462 (36.3%) had DKD alone and 678 (53.3%) had NDKD alone, 105 (8.3%) had both DKD and NDKD and 26 (2.0%) were either normal or non-diagnostic. The most common diagnoses among those with NDKD were FSGS (23.6%), global glomerulosclerosis NOS (12.8%), ATN (8.9%) IgA nephropathy (8.0%) and ANCA vasculitis (7.4%) and membranous nephropathy (4.9%). When comparing types of NDKD between NDKD alone (n=678) and DKD+NDKD (n=105), global glomerulosclerosis NOS was more prevalent in NDKD alone group (13.9%, 5.7%). Oxalate nephropathy and PIGN were more prevalent in DKD+NDKD patients (4.8%, 0.9% and 11.4%, 3.5%, respectively). Aging and White race were positively associated with NDKD compared to DKD alone. (Table)

Conclusions: Of diabetic patients who underwent kidney biopsy, only 36.4% had DKD alone and 63.6% had additional diagnoses on biopsy. Aging had positive association with NDKD than DKD alone. Global glomerulosclerosis NOS, oxalate nephropathy and PIGN had different prevalence in NDKD versus DKD+NDKD. Further analysis is required and ongoing to determine factors associated with alternative diagnoses other than DKD among diabetes patients to guide the use of kidney biopsy in this setting.

Funding: Private Foundation Support

Factors associated with NDKD among diabetes patients in CCKBEP

Multivariable models (NDKD, n=783 vs. DKD alone, n=463)	Non-Diabetic Kidney Diseases OR (95% CI)
Model A	
Gender, female	0.85 (0.67, 1.08)
Age at time of biopsy, per 1 year older	0.020 (0.011, 0.028); beta coefficient
Race, self-identified White	1.42 (1.11, 1.82)
Model B	
Gender, female	0.84 (0.66, 1.06)
Age at time of biopsy, >70 years old	1.94 (1.46, 2.58)
Race, self-identified White	1.44 (1.13, 1.84)

SA-PO467

Diabetic Kidney Disease Phenotypes and Cardiovascular Outcomes

Sophie E. Claudel,[1] Runqi Zhao,[1] Insa M. Schmidt,[1] Sushrut S. Waikar,[1] Anand Srivastava,[2] Ashish Verma.[1] *[1]Boston Medical Center, Boston, MA; [2]University of Illinois Chicago, Chicago, IL.*

Background: Adults with diabetic kidney disease (DKD) have high risk of major adverse cardiovascular events (MACE) and cardiovascular disease (CVD). However, variability in cardiovascular risk across DKD phenotypes remains poorly understood.

Methods: This is a longitudinal analysis of adults with diabetes from two cohorts, the National Health and Nutrition Examination Survey (NHANES, N=5,126) and the UK Biobank (N=27,059). We defined four distinct clinical phenotypes: no DKD (estimated glomerular filtration rate (eGFR)≥60ml/min and urinary albumin-to-creatinine ratio (UACR)<30mg/g), albuminuria only (eGFR≥60mg/ml and UACR≥30mg/g), decreased

eGFR only (eGFR<60ml/min and UACR<30mg/g), and albuminuria plus decreased eGFR (eGFR<60ml/min and UACR≥30mg/g). We used multivariable adjusted Cox proportional hazard models to assess CVD outcomes.

Results: In NHANES, the albuminuria only phenotype and the albuminuria plus decreased eGFR phenotype were associated with a 2.71-fold higher risk of CVD mortality (hazard ratio [HR] 2.71, 95% confidence interval [CI] 1.91-3.85) and a 2.75-fold higher risk (HR 2.75, 95%CI 1.80-4.21) compared to no DKD. In the UK Biobank, the albuminuria-only phenotype had a 2.01-fold higher risk of CVD mortality (HR 2.01, 95%CI 1.75-2.32) and a 1.54-fold higher risk of MACE (HR 1.54, 95%CI 1.41-1.68) compared to no DKD. Moreover, the albuminuria plus decreased eGFR phenotype had a 3.24-fold higher risk of CVD mortality (HR 3.24, 95%CI 2.38-4.40) and a 2.06-fold higher risk of MACE (HR 2.06, 95%CI 1.64-2.59) compared to no DKD. The decreased eGFR phenotype was associated with a 1.65-fold higher risk of CVD mortality (HR 1.65, 95%CI 1.24-2.18) and a 1.30-fold higher risk of MACE (HR 1.30, 95%CI 1.06-1.59) compared to no DKD.

Conclusions: Each DKD phenotype had varying risk of CVD mortality and MACE, indicating distinct clinicopathological characteristics. These findings emphasize the need for tailored management to prevent adverse cardiovascular outcomes in DKD.

Albuminuria Is Associated with Higher Carotid Plaque Volume Quantified by Novel 3D Ultrasound in Type 1 Diabetes

Luis Felipe Ferreira-Divino,[1] Christina G. Poulsen,[1] Viktor Rotbain Curovic,[1] Laerke Urbak,[2] Laurence Rouet,[3] Marie Frimodt-Moller,[1] Tine Hansen,[1] Nikolaj Eldrup,[2] Henrik H. Sillesen,[2] Peter Rossing.[1,4] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Rigshospitalet, Copenhagen, Denmark; [3]Philips Health Technology Innovation, Paris, France; [4]Kobenhavns Universitet, Copenhagen, Denmark.*

Background: Carotid atherosclerosis is associated with progression of kidney disease. Novel 3D ultrasound (3DUS) methods to quantify carotid plaque volume (CPV) may potentially provide more accurate information on carotid atherosclerosis compared to conventional ultrasound methods. We investigated the association between CPV and albuminuria in individuals with type 1 diabetes (T1D) and healthy controls.

Methods: Total CPV (tCPV) was quantified using a novel 3DUS transducer (XL14-3, Philips Healthcare) and calculated as the sum of CPV bilaterally. Individuals with T1D were stratified based on historic albuminuria: normal (30 <mg/g), moderately (30-299 mg/g), or severely increased (≥300 mg/g). tCPV was Ln-transformed in all analyses. Association between tCPV and albuminuria groups was analyzed using linear regression with healthy controls as reference and adjusted for age, sex, systolic blood pressure, smoking, eGFR and LDL-cholesterol. Analyses were repeated solely including the T1D individuals, with the normal albuminuria group as reference, further adjusted for HbA_{1c}. Estimates per one standard deviation increase in Ln-tCPV with 95% confidence intervals are presented.

Results: A total of 120 individuals with T1D and 20 healthy controls were included, 48% were female and mean (±SD) age was 54±15 years. Of the individuals with T1D, 30 had normal, 45 moderately and 45 severely increased albuminuria. Median (IQR) tCPV in each group was: healthy controls 11.6 (6.0-41.6) mm^3, normal 13.0 (1.4-60.9) mm^3, moderately increased 29.2 (17.8-106.1) mm^3, and severely increased 46.3 (10.6-117.5) mm^3 albuminuria. Participants with moderately and severely increased albuminuria had higher tCPV compared to healthy controls after adjustment (0.42, CI [0.01-0.83], p=0.05) and (0.60, CI [0.13-1.06], p=0.01), respectively. Among T1D, individuals with moderately (0.38, CI [0.03-0.72], p=0.03) and severely increased (0.53, CI [0.13-0.94], p=0.01) albuminuria had higher tCPV than individuals with normal albuminuria.

Conclusions: Individuals with T1D and moderately or severely increased albuminuria had higher tCPV, measured with a novel 3DUS method, compared to individuals with normal albuminuria and healthy controls.

SA-PO469

SGLT2 Inhibition Improves Vascular Function in Patients with Type 2 Diabetes: A Double-Blind, Randomized, Placebo-Controlled Crossover Trial

Didde K. Kristensen,[1,2] Steffen F. Nielsen,[1,2] Niels H. Buus,[3,2] Frederik H. Mårup,[3,2] Jesper N. Bech,[1,2] Camilla L. Duus,[1,2] Frank H. Mose.[1,2] *[1]University Clinic in Nephrology and Hypertension, Gødstrup Hospital and Aarhus University, Herning, Denmark; [2]Aarhus Universitet Institut for Klinisk Medicin, Aarhus, Denmark; [3]Aarhus Universitetshospital Afdeling Nyresygdomme, Aarhus, Denmark.*

Background: Sodium glucose co-transporter 2 inhibitors (SGLT2i) reduce cardiovascular events and protect kidney function in patients with type 2 diabetes (DM2). Improved vascular function may be a part of the explanation for this. Vasodilatory capacity in patients with DM2 after SGLT2 inhibition was examined in this study.

Methods: In a double-blind, randomized, placebo-controlled cross-over study, 15 patients with DM2 and preserved kidney function (eGFR > 60 ml/min/1.73 m^2) were included. Participants received four weeks of SGLT2i treatment (empagliflozin 10 mg) and matching placebo in a random order separated by a two-week wash-out period. At the end of each treatment period vascular function was evaluated by venous occlusion plethysmography. Forearm blood flow (FBF) was measured during intra-arterial infusion of acetylcholine (ACh) and sodium nitroprusside (SNP) in increasing concentrations, assessing endothelium-dependent and independent vasodilation, respectively. Repeated measures two-way ANOVA was used to compare absolute FBF between groups.

Results: The majority of participants were male (73 %). Mean age was 68±9 (SD) years (range 49-82), eGFR was 81±10 ml/min/1.73 m^2 and duration of diabetes was 16±9 years. Hypertension was diagnosed in 11 (73 %) participants and 4 (27 %) had cardiovascular disease. Both ACh and SNP dose-dependently increased FBF (Figure 1 and 2). FBF was significantly higher during SNP infusion after empagliflozin treatment as compared to placebo (p=0.004). No difference in FBF was found between empagliflozin and placebo during ACh infusion (p=0.399).

Conclusions: Empagliflozin improves endothelium-independent vasodilatation in patients with DM2, whereas no changes could be observed in endothelium-dependent vasodilation. These results suggest that SGLT2 inhibition positively affects vascular function, however the improvement does not appear to be related to improvement of the endothelial function.

Validation and Application of Serum Urea Nitrogen-Based Protein Intake Assessment Equation in Diabetic Kidney Disease (DKD) Cohort

Qiuling Li, Wenjian Wang. *Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China.*

Background: Our previous studies have established an equation based on serum urea nitrogen in CKD stage 3 patients prospectively, however, its application remains unknown in other stages patients. We aimed to verify the DPI equation in different CKD patients and explored the survival analysis. We applied this equation in our DKD cohort and NHANES cohort.

Methods: We retrospectively collected the clinical data from patients diagnosed with CKD in Guangdong Provincial People's Hospital from January 2015 to September 2022. End points included 50% reduction of eGFR, ESRD, and the occurrence of major cardiocerebrovascular event. We used Maroni's formula as a reference in our research to evaluate the applicability of DPI_{sUCR} equation and prognosis difference in patients with different DPI levels were further analyzed. In application cohort, we retrospectively collected the clinical data from patients diagnosed with DKD in Guangdong Provincial People's Hospital from January 2015 to September 2022 and NHANES cohort from 1999 to 2018 respectively. The endpoint events of different DPI levels were analyzed using the propensity score matching method to further confirm the clinical utility of this equation.

Results: The DPI_{sUCR} equation is more distinguishable in CKD stage 3 patients and DKD cohort, and it's well correlated with the DPI evaluated by Maroni's formula among CKD stage 1~2 and stage 4 patients as well as in DKD patients. Kaplan-Meier analysis showed patients with low DPI (<0.8 g/kg. d) has a better survival prognosis than high DPI (>1.0 g/kg. d) evaluated by DPI_{sUCR} equation or Maroni's formula, especially in CKD stage 3~4 patients. Analysis of data from 820 eligible valid cases in the DKD cohort revealed that, low protein diet improved outcomes. Also, analysis of data from 1723 eligible valid cases in the NHANES cohort revealed that, low protein diet improved outcomes and delay time to endpoint, especially in advanced CKD stage 3~4 patients. In the CKD cohort with diabetes history, restricted protein diets improved outcomes, and although there was a trend, there was no significant difference in results.

Conclusions: The DPI_{sUCR} equation is applicable in CKD stage 1~4 patients and DKD cohorts. Patients with DPI_{sUCR}≤ 1.0 g/kg. d generally have a better prognosis. Our study reveals DPI_{sUCR} equation identify patients with LPD effectively in CKD and NHANES cohort.

Effects of Probiotics and Fibers on Markers of Nephropathy and Endothelial Dysfunction in Persons with Type 1 Diabetes and Albuminuria

Elisabeth B. Stougaard,[1] Ninna H. Tougaard,[1] Viktor Rotbain Curovic,[1] Suvanjaa Sivalingam,[1] Christian S. Hansen,[1] Tine Hansen,[1] Marie Frimodt-Moller,[1] Robert E. Steinert,[2] Frederik Persson,[1] Peter Rossing.[1] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]dsm firmenich, Kaiseraugst, Switzerland.*

Background: Recent data have pointed towards a link between gut microbiota and chronic kidney disease. Defects in the intestinal barrier due to microbial imbalance allow bacterial toxins to pass and cause systemic inflammation damaging the endothelium. Fibers serve as substrate for the beneficial bacterial strains, together with probiotics they have a positive effect on the gut environment, reestablish the microbial symbiosis and thereby strengthen the gut barrier in experimental models. We hypothesized that a supplement of fructo-oligosaccharides and probiotics would strengthen the gut barrier and protect the endothelium and kidneys.

Methods: A randomized, double blind, placebo controlled, crossover study including 41 persons with type 1 diabetes and albuminuria (urinary albumin-to-creatinine ratio (UACR) >30 mg/g) on renin-angiotensin-system blockade. Participants received synbiotic mix and matched placebo for 12 weeks in a random order with 6 weeks of washout. The primary end point was change from baseline to end of period in UACR (3 morning urine samples per visit). Secondary endpoints were: Change from baseline to end of period in endothelial glycocalyx thickness (perfused boundary region) and in inflammatory markers; end-of-period glomerular filtration rate (GFR) and ambulatory systolic blood pressure measured after each treatment period with synbiotic mix versus placebo.

Results: A total of 41 participants were randomized and 35 completed the study. Mean age was 58 (SD 10) years, 73% (n=30) were male, median UACR was 134 (IQR 63-293) mg/g, estimated GFR was 75 (30) ml/min/1.73m^2. There was no significant difference in UACR with a mean relative change (CI 95 %) from baseline to end-of-treatment of -3.0 (-18.4; 15.5) % in the synbiotic group and -12.0 (-29.6; 9.6) % in the placebo group with no significant difference between treatment periods (9.37 (-25.2; 44.0) percentage points; p = 0.60). No significant difference in the secondary end points was demonstrated.

Conclusions: Twelve weeks treatment with a supplement of synbiotic mix had no effect on UACR, perfused boundary region, inflammatory markers, GFR or ambulatory systolic blood pressure in subjects with type 1 diabetes and albuminuria.

Safety and Efficacy of Glucagon-Like Peptide-1 Receptor Agonists (GLP-1RAs) Among Patients with Type 2 Diabetes Mellitus (T2DM) and Advanced CKD and ESKD: A Systematic Review and Meta-Analysis

Pajaree Krisanapan,[1,2] Kanokporn Sanpawithayakul,[2] Pattharawin Pattharanitima,[3] Charat Thongprayoon,[1] Supawit Tangpanithandee,[1] Jing Miao,[1] Michael A. Mao,[4] Iasmina Craici,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Thammasat University Hospital, Khlong Nueng, Thailand; [3]Thammasat University Faculty of Medicine, Khlong Nueng, Thailand; [4]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Evidence supporting the use of GLP-1RAs in T2DM patients and advanced chronic kidney disease (CKD) and end-stage kidney disease (ESKD) is scarce.

Methods: A literature search was conducted using MEDLINE, EMBASE, and Cochrane Database from inception through February 2023. The protocol for this review was registered in the International Prospective Register of Systematic Reviews (CRD 42023398452). Clinical trials and cohort studies reporting safety or efficacy outcomes of GLP-1RAs in adult patients with T2DM and advanced CKD (stage 5 CKD and ESKD) were included. Outcome measures included mortality, cardiovascular, blood glucose, and weight. Adverse events were assessed for safety. Estimates were pooled using random-efffects meta-analysis model.

Results: Eight studies (5 trials and 3 cohort studies) consisting of 27,639 patients with a median follow-up of 3 months (IQR 3, 12) were included in this meta-analysis. There was no difference in one-year mortality outcomes, but one cohort study found a significant long-term reduction in all-cause mortality with GLP-1RAs (HR 0.7; 95% CI 0.6, 0.9). GLP-1RAs significantly reduced cardiothoracic ratio (standardized mean difference, SMD of -1.2%; 95% CI -2.0, -0.4) and pro-BNP (SMD -335.9 pmol/L; 95% CI -438.9, -232.8), but did not significantly decrease systolic blood pressure compared to controls. GLP-1RAs significantly reduced mean blood glucose (SMD -1.1 mg/dL; 95% CI -1.8, -0.3) but not maximum blood glucose, blood glucose fluctuation, or HbA1c. GLP-1RAs resulted in significant weight loss (SMD -2.2 kg; 95% CI -2.9, -1.5). In term of safety, GLP-1RAs were associated with 3.8- and 35.7-time higher risk of nausea and vomiting, respectively, but were not significantly associated with higher risk of hypoglycemia.

Conclusions: Our study provides evidence supporting the safety and efficacy of GLP-1RAs among T2DM patients with advanced CKD and ESKD. While GLP-1RAs may have GI side effects, they demonstrate significant improvement on cardiovascular outcomes, blood glucose control, and weight reduction.

SA-PO473

Effects of Ertugliflozin by Uric Acid Quintile: Observations from VERTIS CV

Vikas Sridhar,[1] Francesco Cosentino,[2] Samuel Dagogo-Jack,[3] Richard E. Pratley,[4] Nilo B. Cater,[5] Margaret Noyes Essex,[5] Mario Maldonado,[6] Yujie Zhao,[7] David Cherney.[1] VERTIS CV Investigators. *[1]Department of Medicine, Division of Nephrology, University Health Network and University of Toronto, Toronto, ON, Canada; [2]Unit of Cardiology, Karolinska Institute & Karolinska University Hospital, Stockholm, Sweden; [3]University of Tennessee Health Science Center, Memphis, TN; [4]AdventHealth Translational Research Institute, Orlando, FL; [5]Pfizer Inc., New York, NY; [6]MSD (UK) Limited, London, United Kingdom; [7]Merck & Co., Inc., Rahway, NJ.*

Background: The sodium–glucose cotransporter 2 inhibitor ertugliflozin (ERTU) lowers serum uric acid (UA) levels. Using data from the VERTIS CV trial (NCT01986881), the impact of ERTU on eGFR and albuminuria was investigated in patients by baseline serum UA levels.

Methods: Patients with type 2 diabetes and atherosclerotic cardiovascular disease were randomized (1:1:1) to ERTU 5 mg, 15 mg (doses pooled for analyses), and placebo (PBO). Patients were categorized by baseline UA quintile (Table). UA over time, eGFR slopes (chronic from Weeks 6 to 260), and the time to first event of progression of albuminuria were analyzed for ERTU versus PBO.

Results: At baseline, there were notable differences by UA subgroup, such as sex, UACR, eGFR and diuretic use (Table). ERTU was associated with reductions in UA over time in all baseline UA subgroups (Fig. A). Treatment with ERTU resulted in a significantly slower rate of yearly eGFR decline in all UA subgroups compared with PBO (P<0.001; Fig. B). ERTU was associated with a reduced risk of albuminuria progression in all UA subgroups compared with PBO (Fig. C; $P_{interaction}$=0.34).

Conclusions: In VERTIS CV, ERTU reduced UA while attenuating eGFR decline and albuminuria progression, irrespective of baseline UA quintile.

Effects of Sotagliflozin on Anemia in Patients with Type 2 Diabetes (T2D) and Stages 3 and 4 CKD

Vikas Sridhar,[1] Michael J. Davies,[2] Phillip Banks,[2] Manon Girard,[2] Amy K. Carroll,[2] David Cherney.[1] *[1]University Health Network, Toronto, ON, Canada; [2]Lexicon Pharmaceuticals Inc, The Woodlands, TX.*

Background: Anemia is frequent in advanced diabetic kidney disease. Sodium-glucose cotransporter inhibitors (SGLTi) consistently increase hemoglobin (Hb) through multiple mechanisms. We examined the effects of sotagliflozin, a dual SGLT1 and SGLT2 inhibitor, on Hb in patients with type 2 diabetes (T2D) and chronic kidney disease (CKD) stage 3 and 4, with and without anemia.

Methods: This was a pooled patient-level data analysis from two studies evaluating the efficacy and safety of sotagliflozin (200 and 400 mg) vs. placebo in patients with T2D and CKD 3 or 4 over 26 weeks. The effect of sotagliflozin on Hb, hematocrit, serum albumin, systolic blood pressure (SBP), body weight and estimated glomerular filtration rate (eGFR) was assessed in patients with anemia (defined as baseline Hb <13 mg/dL for men and <12 mg/dL for women) and without anemia.

Results: In the entire cohort, baseline mean Hb was 12.7 g/dL and sotagliflozin increased Hb from baseline to week 26 by 0.39 g/dL (200 mg; 95% CI 0.21-0.56) and 0.41 g/dL (400 mg; 95% CI 0.24-0.59) vs. placebo (p<0.0001). Of the 1064 patients randomized, 493 (46.3%) patients had anemia at baseline. The effect on Hb with sotagliflozin relative to placebo was more pronounced in patients without anemia over 26 weeks (Figure [doses pooled]). Sotagliflozin (doses pooled) increased odds of anemia resolving (odds ratio 1.95, p=0.017), with a trend towards decreased odds of anemia developing (odds ratio 0.75, p=0.41) over 26 weeks. The effect of sotagliflozin on serum albumin, SBP, body weight, and eGFR was generally consistent between patients with and without anemia. Sotagliflozin was generally well tolerated with similar safety profiles between anemia subgroups.

Conclusions: Sotagliflozin increased Hb in a rapid and sustained manner in patients with T2D and moderate-severe CKD over 26 weeks, and reversed anemia in a population at high risk of anemia.

Funding: Commercial Support - Lexicon Pharmaceuticals, Inc., The Woodlands, TX

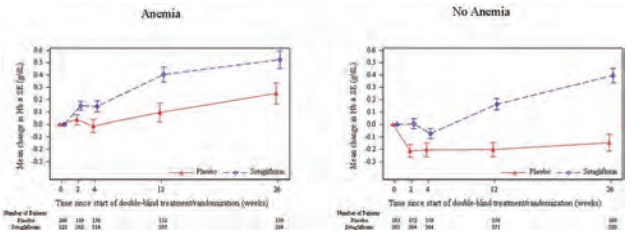

Figure. Mean change in hemoglobin from baseline over 26 weeks by anemia subgroup

SGLT2 Inhibitor Therapy Ameliorates Anemia in Diabetic Kidney Disease

Chuanlei Li, Cheuk-Chun Szeto. *The Chinese University of Hong Kong Faculty of Medicine, Hong Kong, Hong Kong.*

Background: Sodium glucose cotransporter 2 inhibitor (SGLT2i) is a standard treatment for kidney and cardiovascular protection in diabetic kidney disease (DKD). Recent evidence suggests that SGLT2i may enahnce erythropoietin production. We perform a retrospective cohort study to determine the effect of SGLT2i on the hemoglobin level in patients with DKD.

Methods: We reviewed 670 DKD patients started on SGLT2i. Their hemoglobin level and estimated glomerular filtration rate (eGFR) 6 months before the use of SGLT2i, immediately before, and 6 months after the use of SGLT2i were reviewed.

Results: The hemoglobin level had a small but significant increase 6 months after SGLT2 inhibitor treatment from 12.89 ± 1.75 to 13.08 ± 1.94 g/dL (p < 0.0001). The absolute increase in hemoglobin level was 0.19 ± 1.06 g/dL; 274 patients (40.9%) had hemoglobin increase ≥ 0.5 g/dL, and 117 (17.5%) had an increase ≥1.0 g/dL. In contrast, the average hemoglobin level was 13.01 ± 1.75 g/dL 6 months before SGLT2i, which showed a significant decline to the pre-treatment level (p=0.001). The increase in hemoglobin after SGLT2i was most marked in CKD stage 3b (12.26 ± 1.81 to 12.68 ± 1.98 g/dL, p < 0.0001). There was no significant correlation between the change in hemoglobin level and the severity of albuminuria or HbA1c level.

Conclusions: SGLT2i has a small but significant beneficial effect on DKD-related anemia. The clinical impact of this effect deserves further studies.

ESKD-Free Survival Time in Patients with CKD and Type 2 Diabetes (TD2) in FIDELITY

Ajay K. Singh,[1] Stefan D. Anker,[2] Gerasimos Filippatos,[3] Bertram Pitt,[4] Peter Rossing,[5,6] Luis M. Ruilope,[7,8] Christiane Ahlers,[9] Youssef M. Farag,[10] Katja Rohwedder,[11] Luke Roberts,[12] George L. Bakris.[13] *[1]Renal Division, Harvard Medical School, Harvard University, Boston, MA; [2]Department of Cardiology (CVK) of German Heart Center Charité; Institute of Health Center for Regenerative Therapies (BCRT), German Centre for Cardiovascular Research (DZHK) Partner Site Berlin, Charité Universitätsmedizin, Berlin, Germany; [3]National and Kapodistrian University of Athens, School of Medicine, Department of Cardiology, Attikon University Hospital, Athens, Greece; [4]Department of Medicine, University of Michigan School of Medicine, Ann Arbor, MI; [5]Steno Diabetes Center Copenhagen, Herlev, Denmark; [6]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [7]Cardiorenal Translational Laboratory and Hypertension Unit, Institute of Research imas12, Madrid, Spain; [8]CIBER-CV, Hospital Universitario 12 de Octubre, Madrid, Spain; [9]Statistics and Data Insights, Bayer AG, Wuppertal, Germany; [10]Cardiovascular and Renal United States Medical Affairs, Bayer U.S. LLC, Cambridge, MA; [11]Medical Affairs, Bayer AG, Berlin, Germany; [12]Clinical Development, Bayer PLC, Reading, United Kingdom; [13]Department of Medicine, University of Chicago Medicine, Chicago, IL.*

Background: End-stage kidney disease (ESKD) is a major health and economic burden; patients with reduced quality of life are at high risk of cardiovascular mortality. Finerenone significantly reduced the risk of cardiorenal outcomes in patients with chronic kidney disease (CKD) and type 2 diabetes (T2D) in FIDELITY, a prespecified pooled analysis of the FIDELIO-DKD and FIGARO-DKD trials. Here, we estimated the ESKD-free survival time of patients treated with finerenone vs placebo.

Methods: Patients with T2D and CKD (albuminuria and estimated glomerular filtration rate [eGFR] ≥25–90 mL/min/1.73 m²) and on optimized renin–angiotensin system (RAS) inhibition were randomized (1:1) to finerenone or placebo. To estimate the population-level effect of finerenone, the restricted mean survival time for ESKD after 4.5 years of treatment in FIDELITY was extrapolated to 6,425,196 US patients with T2D and CKD according to the US National Health and Nutrition Examination Survey. The cumulative incidence and treatment effects of finerenone vs placebo for time to eGFR <10 mL/min/1.73 m² were also analyzed using a patient-based two-slope model extrapolated to 20 years.

Results: In FIDELITY, finerenone significantly reduced the risk of ESKD vs placebo (hazard ratio [HR]=0.80; 95% confidence interval [CI] 0.64–0.99; *p*=0.040). After 4.5 years of treatment with finerenone, the overall estimated time saved from ESKD for the US patient population vs placebo was 103,260 years (95% CI −3407 to 210,556). Using extrapolations based on 5000 Monte-Carlo simulations for the individual eGFR patient slopes, the cumulative incidence for time to eGFR <10 mL/min/1.73 m^2 showed a risk difference between treatments of −4.5%, −7.6%, −6.7% and −5.6% for 5, 10, 15 and 20 years, respectively, corresponding to a number needed to treat of 22, 13, 15 and 18 patients for finerenone. Treatment effects of finerenone vs placebo for time to eGFR <10 mL/min/1.73 m^2 showed a relative risk reduction of 21% (HR=0.79; 95% CI 0.76–0.82).

Conclusions: Treatment with finerenone and optimized RAS therapy was associated with a delay in time to ESKD in patients with CKD and T2D and may provide patient and healthcare cost-saving benefits.

SA-PO477

Discrepancy Between Lifetime vs. Five-Year Risk Estimates for ESKD in US Adults with Diabetes

Yoshitsugu Obi,[1] Xiaoqian Zhu,[1] Maria Clarissa Tio,[1] Timothy E. Yen,[1] Neville R. Dossabhoy,[1] Tariq Shafi.[2] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Houston Methodist Hospital, Houston, TX.*

Background: The Kidney Failure Risk Equation (KFRE) estimates the short-term (2- or 5-year) risk of ESKD. Misinterpretation of this short-term risk as lifetime risk may lead to patient misunderstanding and suboptimal shared decision-making.

Methods: We analyzed data from 972 US adults aged 35-84 years with diabetes and eGFR 30 to <60 mL/min/1.73 m^2 who participated in the 1999-2020 NHANES. Each sample was weighted to represent the general US population. We used the KFRE to calculate 5-year ESKD risk, and the Swedish National Diabetes Register prediction model (Østergaard, CJASN 2022) to estimate the lifetime ESKD risk where we calibrated baseline hazards for mortality and ESKD based on the national databases. We compared the distribution of lifetime risk across KFRE categories, further stratified by age groups.

Results: The mean age of the study cohort was 71 years, 52% were female, the median HbA1c was 6.8%, and the median duration of diabetes was 15 years. The mean eGFR was 49 mL/min/1.73 m^2, and 53% and 43% had moderate and severe albuminuria, respectively. The 5-year risk of ESKD by KFRE (median 1.2% [IQR, 0.6% to 3.1%]) was consistently lower than the lifetime ESKD risk (median 22% [IQR, 12% to 42%]). This discrepancy was more pronounced in younger patients (**Figure**). For example, within the KFRE 1% to <5% risk category, the median estimated lifetime risk was 21% for age ≥70 years, 43% for age 60-69 years, and 53% for those <60 years.

Conclusions: The KFRE, a short-term ESKD risk estimate, substantially underestimates the lifetime risk of ESKD in patients with diabetes at every risk interval, particularly in the younger populations. Clinicians should consider lifetime ESKD risk estimates, rather than just short-term ESKD risk, when counseling patients with diabetes.

Overall and Interindividual Effect of Four Different Drug Classes on Soluble Urokinase Plasminogen Activator Receptor in Albuminuric Type 1 and Type 2 Diabetes

Viktor Rotbain Curovic,[1] Morten B. Houlind,[4,3] Marjolein Kroonen,[2] Niels Jongs,[2] Tine Hansen,[1] Emilie Zobel,[1] Juliette Tavenier,[4] Jesper Eugen-Olsen,[4] Gozewijn D. Laverman,[5] Frederik Persson,[1] Peter Rossing,[1,3] Hiddo J. Heerspink.[2] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]University Medical Center Groningen, Groningen, Netherlands; [3]Kobenhavns Universitet, Kobenhavn, Denmark; [4]Copenhagen University Hospital - Amager and Hvidovre, Hvidovre, Denmark; [5]Ziekenhuisgroep Twente, Almelo, Netherlands.*

Background: Soluble urokinase plasminogen activator receptor (suPAR) is a biomarker active in multiple inflammatory processes and a risk factor of diabetic nephropathy. We evaluated the effect of four different drug classes on suPAR in type 1 and type 2 diabetes with albuminuria.

Methods: Post hoc analyses of a randomized, open-label, crossover trial including 26 adults with type 1 and 40 with type 2 diabetes with urinary albumin-creatinine ratio (UACR) ≥30 and ≤500 mg/g assigned to 4-week treatments with telmisartan 80mg, empagliflozin 10mg, linagliptin 5mg, and baricitinib 2mg separated by 4-week washouts. Plasma suPAR was measured before and after each treatment. SuPAR change after each treatment was calculated and, for each individual, the best suPAR-reducing drug was identified. Subsequently, the effect of the best individual drug was compared against the mean of the other three drugs. Repeated measures linear mixed-effects models were employed. Finally, treatment effect on UACR was correlated against treatment effect on suPAR, for each treatment and participant, assessed using Pearson's R.

Results: Baseline median (IQR) plasma suPAR was 3.5 (2.9, 4.3) ng/ml. No overall effect on suPAR levels was observed for any one drug. The individual best-performing drug varied, with baricitinib being selected for 20 (30%) participants, followed by empagliflozin for 19 (29%), linagliptin for 16 (24%), and telmisartan for 11 (17%). The individual best-performing drug reduced suPAR by 13.3% (95%CI: 3.7, 22.8; p=0.007). Difference in suPAR response between the individual best-performing drug and the other three was -19.7% (-23.1, -16.3; p<0.001). Baseline levels of suPAR and UACR were significantly correlated (R=0.28, p=0.029), but changes in UACR and suPAR after treatment were not correlated for any drug.

Conclusions: We demonstrated no overall effect of 4-week treatment with telmisartan, empagliflozin, linagliptin, or baricitinib on suPAR. However, individualization of treatment might significantly reduce suPAR levels and this mechanism is independent of UACR response.

Early Use and Effectiveness of Finerenone in US Patients with CKD and Type 2 Diabetes: A FOUNTAIN Platform Analysis

Nikolaus G. Oberprieler,[1] Csaba P. Kovesdy,[2] J. Bradley Layton,[3] Alain Gay,[1] Alfredo E. Farjat,[1] Fangfang Liu,[1] Catherine B. Johannes,[3] Manel Pladevall-Vila,[4] David Vizcaya.[1] *[1]Bayer AG, Leverkusen, Germany; [2]University of Tennessee, Memphis, TN; [3]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC; [4]RTI Health Solutions Barcelona, Barcelona, Spain.*

Background: Based on evidence from clinical trials, finerenone reduces the risk of cardiovascular and renal complications among patients with chronic kidney disease (CKD) and type 2 diabetes (T2D). Evidence from finerenone use in real-world clinical practice is lacking.

Methods: Longitudinal (from July 2021 to latest data available) cohort study using two existing US electronic health record and insurance claim databases. Among individuals with both CKD and T2D, a single cohort of new users of finerenone is described (patient characteristics, comorbidities, comedications, and incidence rates of cardiovascular and renal outcomes, including eGFR and UACR changes over time).

Results: Preliminarily, results from an initial feasibility assessment show a total of 662 new users of finerenone who had a mean (SD) age of 72.1 (8.3) years with 46.6% being female. The most common comorbidities at baseline were hypertension (98.3%), hyperlipidemia (87.5%), peripheral vascular disease (66.8%), neuropathy (53.7%), retinopathy (35.5%), and congestive heart failure (34.4%); 9.9% of individuals had acute coronary syndrome and 6.5% experienced a stroke prior to finerenone initiation. Baseline comedication use was common with 70.5% of individuals using an angiotensin-converting enzyme inhibitor (ACE) or an angiotensin receptor blocker (ARB), 60.2% a beta-blocker, and 50.6% calcium channel blockers (CCB). Furthermore, 90.9% of finerenone users used anti-hyperglycemic medications, including insulins (46.6%), metformin (42.9%), sodium-glucose cotransporter-2 (SGLT2) inhibitors (42.3%), and glucagon-like peptide-1 (GLP-1) receptor agonists (35.2%). Complete results from the full Optum EHR and OM1 Real-World Data Cloud™ databases, including incidence rates of cardiovascular and renal outcomes, will be presented as part of the conference presentation.

Conclusions: Early evidence from patients who receive finerenone as part of clinical practice in the US suggests that finerenone is used independently of demographic and clinical characteristics. Furthermore, this analysis of early adopters suggests that finerenone is used as a complementary treatment option to other renal and cardiovascular protective medication-classes recommended for patients with CKD and T2D.

Comparative Kidney and Cardiovascular Effectiveness of Empagliflozin Compared to Dipeptidyl Peptidase-4 Inhibitors in Patients with Type 2 Diabetes Mellitus

Daniel Edmonston,[1,2] Hillary Mulder,[1] Elizabeth Lydon,[1] Karen Chiswell,[1] Zachary Lampron,[1] Christina M. Shay,[3] Keith A. Marsolo,[1] Hayden Bosworth,[1,2] Neha Pagidipati.[1,2] *[1]Duke Clinical Research Institute, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany.*

Background: Placebo-controlled trials of sodium-glucose cotransporter-2 inhibitors (SGLT2i) demonstrated kidney and cardiovascular benefit for people with type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD). We used real-world data to compare the effectiveness and safety of empagliflozin to dipeptidyl peptidase-4 inhibitors (DPP4i) in patients with T2DM, with and without CKD.

Methods: We used electronic health record data from 20 large US health systems participating in PCORnet©. Using propensity overlap weighting, we compared the effectiveness of empagliflozin vs. DPP4i in patients with T2DM among those newly prescribed these medications between 2016-2020. Primary composite endpoint included first occurrence of 40% eGFR decline, incident ESKD, or all-cause mortality (ACM) through 2 years. We also assessed cardiovascular and safety outcomes.

Results: Among 62,197 patients, 32% initiated empagliflozin and 68% initiated DPP4i. Median follow-up was 1.1 years. Empagliflozin was associated with lower risk of the primary outcome compared to DPP4i (Table). Risk for ACM and a cardiovascular composite of stroke, myocardial infarction, or ACM were also lower in patients prescribed empagliflozin overall and in those with CKD. The difference in heart failure hospitalization risk between groups did not reach statistical significance. Genital mycotic infections and diabetic ketoacidosis were the only safety events more common in patients prescribed empagliflozin. Differences in risk for primary composite, 40% eGFR decline and ACM were also significantly lower in patients with CKD.

Conclusions: In a real-world population with T2DM with and without CKD, empagliflozin is associated with significantly lower risk for kidney and cardiovascular outcomes compared with DPP4i.

Funding: Commercial Support - Boehringer Ingelheim and Lilly

Table. Comparative kidney and cardiovascular effectiveness and safety of empagliflozin compared to DPP4i in patients with T2DM with and without chronic kidney disease: PCORnet®

Interim Results from FINE-REAL: A Prospective Study Providing Insights into the Use of Finerenone in Routine Clinical Settings

Susanne B. Nicholas,[1] Ricardo Correa-Rotter,[2] Nihar Desai,[3] Lixin Guo,[4] Sankar D. Navaneethan,[5] Kevin M. Pantalone,[6] Christoph Wanner,[7] Stefanie Hamacher,[8] Alain Gay,[9] David C. Wheeler.[10] *[1]David Geffen School of Medicine at UCLA, Los Angeles, CA; [2]Department of Nephrology and Mineral Metabolism, Instituto Nacional de Ciencias Médicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [3]Section of Cardiovascular Medicine, Yale School of Medicine, Yale New Haven Hospital, New Haven, CT; [4]Department of Endocrinology, Beijing Hospital, National Center of Gerontology, Institute of Geriatric Medicine, Chinese Academy of Sciences, Beijing, China; [5]Section of Nephrology, Baylor College of Medicine, Houston, TX; [6]Endocrinology and Metabolism Institute, Cleveland Clinic, Cleveland, OH; [7]Department of Medicine, Division of Nephrology, University Hospital Würzburg, Würzburg, Germany; [8]ClinStat GmbH, Huerth, Germany; [9]Medical Affairs & Pharmacovigilance, Pharmaceuticals, Bayer AG, Berlin, Germany; [10]Department of Renal Medicine, University College London, London, United Kingdom*.

Background: Finerenone is a selective, nonsteroidal mineralocorticoid receptor antagonist, which improved kidney and cardiovascular outcomes in patients with chronic kidney disease (CKD) associated with type 2 diabetes (T2D) in phase 3 trials. Finerenone is approved in the European Union, US, China, and several other countries. FINE-REAL (NCT05348733) aims to provide insights on characteristics and treatment patterns of participants treated with finerenone in clinical practice.

Methods: FINE-REAL is a prospective, single-arm, non-interventional study of patients initiated on finerenone as part of their routine care in accordance with their country-approved label. The study, initiated in June 2022, is expected to be completed by January 2028.

Results: As of April 28, 2023, 574 participants have been enrolled. Baseline median UACR is 1,354 mg/g; however, UACR is unreported for 35% of participants (Table). Mean eGFR (mL/min/1.73 m^2 ([SD]) is 53 (23). Uptake of agents acting on the RAAS and of statins is 52% and 24%, respectively. Adverse events have been reported in 72 (12.54%) participants. Hyperkalemia has been reported in 17 (2.96%) participants, with all instances recorded as asymptomatic and none requiring hospitalization. Updated results from a later cut-off date, June 13, 2023, will be presented at the congress.

Conclusions: UACR is not routinely measured in a large proportion of patients in the real-world setting. In general, the uptake of guideline-recommended therapies for CKD associated with T2D is low (RAAS inhibitors and statins). Advocacy for greater adherence to standard of care could improve patient outcomes.

Funding: Commercial Support - The study and this analysis were funded by Bayer AG, Leverkusen, Germany. Predictors and Outcomes of Discontinuation of Glucagon-Like Peptide-1 Receptor Agonists (GLP-1 RAs) in CKD

L Parker Gregg,[1,2] Peter Richardson,[2] Vijay Nambi,[1,2] Michael E. Matheny,[3,4] Salim S. Virani,[5] Sankar D. Navaneethan.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]Vanderbilt University Medical Center, Nashville, TN; [4]VA Tennessee Valley Healthcare System, Nashville, TN; [5]The Aga Khan University, Karachi, Pakistan.*

Background: GLP-1 RAs improve cardiovascular and kidney outcomes in patients with CKD but are underutilized. We aimed to study treatment discontinuation and its associations with patient-level characteristics and death among those with CKD.

Methods: Adults with CKD stages 3-4 were identified from the Veterans Affairs (VA) Corporate Data Warehouse from 2005-2022. Individuals who had an incident prescription for a GLP-1 RA were included, with the date of prescription used as the index date for the analysis. The primary outcome was treatment discontinuation, defined as an interruption in GLP-1 RA prescription for at least 90 days. Cox proportional hazards regression identified factors associated with time to treatment discontinuation and the association of treatment discontinuation with time to all-cause death, treating GLP-1 RA discontinuation as a time-varying covariate.

Results: Of 60,020 individuals who received a GLP-1 RA, 95% were male, 75% were White, 20% were Black, 63% were of age ≥70, and 80% had CKD stage 3a. Discontinuation (at least once) occurred in 28,407 (47%) GLP-1 RA users over a median (IQR) of 1.41 (0.72, 2.59) years of follow up. Black or unreported race, younger age, and concomitant vascular disease were associated with GLP-1 RA discontinuation (**Figure**). There were 9628 deaths. GLP-1 RA discontinuation, included as a time-varying covariate, was associated with all-cause death (HR 2.22 [95% CI 2.11, 2.34], P<0.0001) independent of age, sex, race, CKD stage, medical comorbidities, and concomitant medication use.

Conclusions: In CKD population, discontinuation of GLP-1RA is common and was associated with an increased risk of death. Additional studies exploring the reasons for short-term and long-term discontinuations of these agents are needed.

Increased Risk of Serious Hypoglycemia with Insulin Glargine in Veterans with Type 2 Diabetes: An Emulated Clinical Trial Observational Study

Amara Sarwal,[1,2] Jincheng Shen,[1,2] Ravinder Singh,[1,2] Mckenna R. Nevers,[1,2] Sydney E. Hartsell,[2,1] Guo Wei,[1,2] Robert E. Boucher,[1,2] Azeem M. Mohammed,[2] David Kim,[2] George Bissada,[2] Farahnaz Akrami,[2] Brad Adams,[1,2] Jesse Christensen,[1,2] Tom Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT.*

Background: Serious hypoglycemic events needing medical attention are significant complications of anti-glycemic therapy in type 2 diabetes (T2D), particularly in those with CKD. Therefore we examined the risk of serious hypoglycemic events with insulin glargine (IG) use compared to glucagon-like peptide-1 receptor agonists) GLP1-RA and sodium-glucose cotransporter-2 inhibitors (SGLT2i) in a national cohort of veterans.

Methods: We conducted an active comparator, new user design study of veterans (N = 30165) with T2D with CKD (eGFR < 60) on metformin who then initiated on IG or SGLT2i or GLP1-RA for the first time between 01/01/2018 to 12/31/2021. Those with any previous use of these agents were excluded. Administrative censor date was 03/31/2023. Serious hypoglycemic events needing medical attention were identified from ER/ urgent care visits or hospital discharge diagnosis with ICD10 codes using a validated algorithm. Inverse probability weights (IPW) were developed using propensity scores for the three drug classes. In IPW Cox models, the study drug classes were related to the risk of serious hypoglycemic events.

Results: 38.2% were initiated on IG, 12.7% on GLP1-RA and 49.1% on SGLT2i. Mean eGFR was 79.5± 20.1 ml/min/1.73m^2. There were 972 events over 78594 years follow-up. In IPW Cox regression, compared to GLP1-RA, the IG group had higher risk whereas the SGLT2i group had lower risk (Table 1).

Conclusions: IG is associated with higher serious hypoglycemia risk in CKD. The safety of IG in CKD needs to be reevaluated.

Table 1. Risk of hypoglycemia by drug class and CKD

	Event Rate	HR (95% CI)
Non-CKD (N= 128774)	0.71	
GLP1-RA (N = 16355)	0.52	1.00
Insulin Glargine (N = 49821)	1.09	1.59 (1.39, 1.82)
SGLT2i (N = 62598)	0.42	0.70 (0.60, 0.81)
CKD (N = 30165)	1.24	
GLP1-RA (N = 3787)	1.06	1.00
Insulin Glargine (N = 10901)	1.88	1.49 (1.21, 1.83)
SGLT2i (N = 15477)	0.74	0.67 (0.54, 0.83)

SA-PO484

Increased Mortality Risk with Insulin Glargine in Veterans with Type 2 Diabetes: An Emulated Clinical Trial Observational Study

Amara Sarwal,[1,2] Jincheng Shen,[1,2] Ravinder Singh,[1,2] Mckenna R. Nevers,[1,2] Sydney E. Hartsell,[1,2] Guo Wei,[1,2] Robert E. Boucher,[1,2] Brad Adams,[1,2] Jesse Christensen,[1,2] Tom Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT.*

Background: Insulin glargine (IG) is one of the most commonly used anti-glycemic agents in advanced CKD. However, there is a paucity of data in head to head comparisons of IG with newer agents like glucagon-like peptide-1 receptor agonists (GLP1-RA) and sodium-glucose cotransporter-2 inhibitors (SGLT2i). Therefore we examined the risk of mortality with insulin glargine use compared to GLP1-RA and SGLT2i use in a national cohort of veterans.

Methods: We followed the active comparator, new user design to emulate a trial to compare the effect of initiating on IG or SGLT2i or GLP1-RA among veterans with T2D on metformin who initiated any one of these three between 01/01/2018 to 12/31/2021 (N = 158,939). Those with previous use of these agents were excluded. Administrative censor date was 03/31/2023. Generalized propensity score based inverse probability weighting (IPW) was employed to control confounding in the observational data and facilitate comparisons among the three drug classes. In IPW Cox models, the study drug classes were related to the risk of mortality in those without and with CKD (eGFR < 60).

Results: 38.2% were initiated on IG, 12.7% on GLP1-RA and 49.1% on SGLT2i. 19% had CKD. There were 11,109 deaths over 368,347 patient-years of follow-up in non-CKD and 4,660 deaths over 80,043 patient-years in CKD patients. In IPW Cox regression, compared to GLP1-RA, the IG group had higher mortality risk in both the non-CKD and CKD subgroups whereas the SGLT2i group had lower mortality in the CKD subgroup (Table).

Conclusions: IG is associated with higher mortality risk in both non-CKD and CKD subgroups. These results suggest that the routine clinical use of IG needs to be reconsidered.

Table 1. Mortality events

	Event Rate	HR (95% CI)
Non-CKD (N= 128774)		
GLP1-RA (N = 16355)	1.96	1.00
Insulin Glargine (N = 49821)	4.14	1.70 (1.59, 1.83)
SGLT2i (N = 62598)	2.26	0.95 (0.88, 1.02)
CKD (N = 30165)		
GLP1-RA (N = 3787)	4.80	1.00
Insulin Glargine (N = 10901)	7.91	1.39 (1.26, 1.53)
SGLT2i (N = 15477)	4.31	0.82 (0.74, 0.90)

SA-PO485

Major Adverse Kidney Disease Events in a Real-World Population with Diabetes

Katherine R. Tuttle,[1,2] Lindsey M. Kornowske,[1] Cami R. Jones,[1] Kenn B. Daratha,[1] Alain K. Koyama,[3] Susanne B. Nicholas,[4] Fang Xu,[3] Yoshihisa Miyamoto,[3] Joshua J. Neumiller,[5] Radica Z. Alicic,[1,2] Obidiugwu Duru,[4] Keith C. Norris,[4] Meda E. Pavkov.[3] CURE-CKD Registry. *[1]Providence Health and Services, Spokane, WA; [2]University of Washington School of Medicine, Seattle, WA; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [5]Washington State University, Pullman, WA.*

Background: Assessing risk for major adverse kidney disease events (MAKDE) helps target populations who could benefit from improved chronic kidney disease (CKD) awareness, detection, and intervention. In a real-world population with diabetes, we evaluated the frequency of MAKDE and Kidney Disease Improving Global Outcomes (KDIGO) risk categories during 2013-2020.

Methods: The study population was derived from electronic health records data in the Center for Kidney Disease Research, Education, and Hope (CURE-CKD) Registry at Providence and UCLA Health systems. Demographic and clinical characteristics were obtained for patients aged ≥18 years with diabetes. CKD was defined by eGFR <60 mL/min/1.73 m^2, UACR ≥30 mg/g or UPCR ≥0.15 g/g. MAKDE was defined as a composite of 40% eGFR decline from baseline, eGFR <15 mL/min/1.73 m^2, dialysis, or kidney transplant. Frequency of MAKDE was evaluated by baseline CKD status and KDIGO risk categories.

Results: Among patients with diabetes (N=285,036), 51% (n=144,016) were women and mean age was 61±16 years. At baseline, 21% (n=60,672) had CKD with mean eGFR of 56±24 mL/min/1.73 m^2 and median UACR of 58 (interquartile range [IQR] 33-164) mg/g. Frequency of MAKDE was 27% (16,180/60,672) in those with CKD and 14% (32,112/224,364) in those without CKD. Median follow-up was 2.3 (IQR 1.0-4.0) years. Among patients with CKD who had baseline eGFR and UACR/UPCR measurements, 37% were classified as high or very high KDIGO risk. MAKDE frequency increased by higher KDIGO risk categories (**Figure**).

Conclusions: MAKDE occurred commonly in a real-world population with diabetes. Compared to those without CKD, prevalence of MAKDE was twice as high in patients with CKD and more than one-third of them were in high or very high KDIGO risk categories when both eGFR and UACR/UPCR were measured.

SA-PO486

A Quality Improvement Project to Increase CKD Screening in Diabetics

Ken J. Park, Lisa J. Nakashimada, Eric S. Albright. *Kaiser Permanente Northwest, Portland, OR.*

Background: The ADA recommends that patients with DM should be screened for CKD annually with a urinary albumin (ACR) and serum creatinine (Scr). However, CKD screening remains low at 10-40%. In addition, ACEi or ARB's and SGLT2 inhibitors are under prescribed. We implemented a quality improvement project to increase annual screening for CKD in DM. We were also interested in whether increased CKD screening increased prescribing of ACEi or ARB's, SGLT2-inhibitors, and co-management with nephrology.

Methods: This is a quality improvement project of Kaiser members in the Portland Metro area between ages of 18-85 with DM (~40,000 pts). Patients with ESRD, on hospice or palliative care, <1 yr Kaiser enrollment, living in long term care facility, >66

with frailty and advanced illness, or >81 with frailty were excluded. Auto ordering of Scr and ACR in patients who had not had either lab resulted within the past year was rolled out on May 11, 2022. Providers received an EHR alert at time of visit reminding them that patients were due for labs. Patients also received automated letters, texts, and phone calls on their birthday to go to the lab. Data was collected cross sectionally at the beginning of the month and the percent of patients with Scr and ACR tested within the past year were reviewed monthly. Prescribing of ACEi/ARB, SGLT2-inhibitors, and nephrology co-management within 1 year was also tracked. Trends were reviewed using control charts.

Results: By 10 months after rollout, we saw an increase in ACR and Scr testing from 35% to 71%. We saw a small increase in ACEi or ARB use in patients with DM with hypertension and ACR ≥ 30 mg/gm from mean of 82% to 82.3%. There was no change in percent of patients with renal indication seen by nephrology which stayed around 28%. We saw an increase in SGLT2-inhibitors use in patients with renal indication from 10% to 16%. However, the improvement was occurring prior to rollout of the intervention making it unclear if the increase was a result of an increase in ACR and Scr testing.

Conclusions: Our findings suggest that use of auto ordered labs and automated outreach can result in significant improvement in CKD screening amongst diabetics. We saw a statistically but clinically insignificant increase in ACEi/ARB use after the intervention. We saw a larger increase in SGLT2-inhibitors use although we could not attribute this to increased ACR and Scr testing.

SA-PO487

Prescribing of Sodium Glucose Co-Transporter 2 Inhibitors Among Hispanic/Latino Individuals Within Duke University Health System

Matthew R. Sinclair,[1,2] Yixuan Feng,[1] Clarissa J. Diamantidis,[1] Benjamin A. Goldstein.[3] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Clinical Research Institute, Durham, NC; [3]Duke University Department of Biostatistics and Bioinformatics, Durham, NC.*

Background: Type 2 diabetes (T2D) is a risk factor for cardiovascular disease, chronic kidney disease, and death. Lifetime prevalence of T2D in Hispanic/Latino individuals is over 50%. One medication class, the sodium glucose co-transporter 2 inhibitors (SGLT2is), improve cardiovascular and kidney outcomes among patients with T2D. Unfortunately, recent national evidence shows that racial and ethnic minority individuals with T2D, including Hispanics/Latinos, are less likely to receive SGLT2is compared to non-Hispanic White individuals. Prescribing patterns of SGLT2is within Duke University Health System (DUHS) are currently unknown. We examined prescribing rates and likelihood of SGLT2i prescribing among Hispanic/Latino individuals with T2D within DUHS compared to other races and ethnicities.

Methods: We extracted data from the DUHS electronic health record system to identify adults with T2D eligible to receive an SGTL2i. Starting in January of 2017, we defined eligibility as having a diagnosis code for T2D and an outpatient encounter with a hemoglobin A1C >6.5%. Patients were followed until either receiving an SGLT2i, losing eligibility (i.e., eGFR < 30 or A1C < 6.5%), death, or follow-up through December 31, 2022. We assessed time to SGLT2i prescribing based on race/ethnicity, accounting for competing risks in a subdistribution hazard model.

Results: Among adults with T2D (n = 6,653), Hispanic/Latino individuals had a lower cumulative incidence of SGLT2i prescriptions (10.1%) compared to both non-Hispanic Black (16.3%) and non-Hispanic White (17.5%) individuals (p=0.12). After adjusting for age, sex, type of health insurance, area deprivation index, and comorbidities, there was suggestion of a decreased likelihood of prescribing among Hispanic/Latino individuals when compared to both non-Hispanic Black (adjusted hazard ratio (aHR) 0.77 (95%CI: 0.53 – 1.11)) and non-Hispanic White (aHR 0.77 (95%CI:0.53-1.12)) individuals.

Conclusions: SGLT2is are prescribed at low rates among patients with T2D within DUHS, consistent with national trends. Likelihood of prescribing was lowest among Hispanic/Latino individuals, even after adjustment for key demographics and clinical comorbidities, when compared to their non-Hispanic Black and White counterparts.

SA-PO488

Use of Medicines to Protect Kidney Function Among Patients with Type 2 Diabetes (T2DM) and CKD in the United States

Yun Han,[1] Miao Yu,[1] Michael Heung,[1] William H. Herman,[1] Joseph A. Vassalotti,[3] Fang Xu,[2] Rajiv Saran.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Centers for Disease Control and Prevention, Atlanta, GA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Newer classes of diabetes, kidney, and cardioprotective medicines, such as SGLT2i and GLP1a, have shown better outcomes among diabetic patients. We examined the use of SGLT2i and GLP1a among patients with T2DM and CKD in the US.

Methods: We identified 425,879 patients aged ≥20 years diagnosed with T2DM and CKD (mean age: 73.9 years) from Optum Clinformatics™ data. Medical history and specialist visits in 2019 were defined by ICD codes and provider ID (nephrology, cardiology, and endocrinology). We examined specific medicine use(SGLT2i, GLP1a, ACEIs/ARBs, and statins) in 2020. Combination therapy was defined as the overlapped use of medicines for ≥ 30 days. Logistic regression model was applied to examine factors related to medication use.

Results: SGLT2i use was observed among 5.5% of patients with type 2 diabetes and CKD, with higher usage in CKD stage G1–2 (6.2%) compared with other stages (G3: 4.6%, G4: 2.1%, and G5: 2.8%, $P < .0001$). About 8.0% of patients used GLP1a, with a higher usage in CKD stage G3 (7.9%) compared with early stages and advanced stages (G1–2: 7.5%, G4: 7.1%, and G5: 5.7%, $P < .001$). After adjusting for demographics and other covariates, having endocrinologist visits, being covered by Exclusive Provider Organization plans (compared to Health Maintenance Organization plans), and being covered by Point of Service plans, were found to be significant predictors of using SGLT2i and GLP1a (Table).

Conclusions: We document low use of SGLT2i and GLP1a among diabetic patients with CKD in 2020. Given encouraging results from several recent, large randomized clinical trials, especially with SGLT2i, our study suggests an ongoing need for investigating barriers and disparities in the real-world use of these medicines.

Funding: Other U.S. Government Support

Treatment Utilization and Disease Burden Associated with CKD Progression in Patients with Type 2 Diabetes

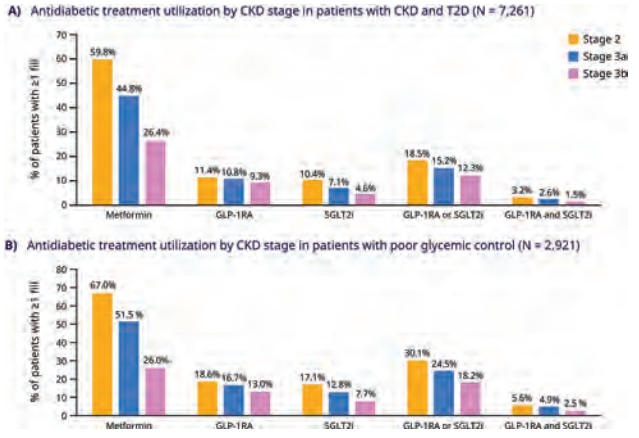
James J. Amamoo,[1] Brenna L. Brady,[3] Josh Noone,[1] Lin Xie,[1] Sherif Mehanna,[1] Helen V. Varker,[3] George L. Bakris.[2] *[1]Novo Nordisk Inc, Plainsboro, NJ; [2]University of Chicago, Chicago, IL; [3]Merative, Cambridge, MA.*

Background: Effective management of type 2 diabetes (T2D) is important for preventing/delaying complications, such as chronic kidney disease (CKD). This real-world, retrospective cohort study examined clinical characteristics and antidiabetic treatment utilization, particularly sodium-glucose cotransporter-2 inhibitors (SGLT2is) and glucagon-like peptide-1 receptor agonists (GLP-1RAs), in patients with CKD and T2D.

Methods: Data were obtained from the Merative™ MarketScan® Explorys Claims-Electronic Health Record Database (January 1, 2016, to September 30, 2021). Patients were aged ≥18 years and had ≥2 estimated glomerular filtration rate (eGFR) values between 15 and 89 mL/min, indicating the same CKD stage within a 90-day period. The first eGFR value qualifying for inclusion was the index date, and patients were continuously enrolled for 6 months pre-index and 12 months post-index. Patients had diagnoses of CKD and T2D in the pre-index period. Treatment utilization was reported by CKD stages 2–3b; all analyses were descriptive.

Results: : A total of 7,261 patients were included (mean ± SD age, 72.4 ± 10.6 years; 56.4% male). Patients had CKD stage 2 (28.0%), 3a (27.4%), 3b (29.5%), or 4 (15.1%). At pre-index, 4.2% and 7.8% of patients received SGLT2is and GLP-1RAs, respectively. At post-index, on average, 43.3% of patients across CKD stages 2–3b received metformin, 10.4% received GLP-1RAs, and 7.3% received SGLT2is; decreasing use of these agents was observed with CKD progression (**Figure**). In a subset of patients with poor glycemic control (glycated hemoglobin >7%; n=2,921), metformin, SGLT2i and GLP-1RA utilization was low; 18.2–30.1% received SGLT2is or GLP-1RAs (**Figure**).

Conclusions: Despite a large number of patients with comorbid CKD and T2D having poor glycemic control, SGLT2i and/or GLP-1RA utilization was low. Improved diabetes management is needed in this patient population.



SA-PO490

Limitations to the Use of Guideline-Directed Medical Therapy (GDMT) in Patients with CKD and Type 2 Diabetes Mellitus (DM) in the Primary Care Setting at an Inner-City Hospital in Bronx, New York

Rosalba Y. Santana De Roberts,[1] Belinda Jim,[2] Vishal Reddy Bejugam,[1] Shiny Teja Kolli,[1] Zin Thawdar Oo,[1] Bruna Taveras Garcia,[1] Shobhit Piplani,[1] Chinweizu D. Okogbaa,[1] Amr W. Aljareh,[1] Chisom Asuzu,[1] Sonam Nihalani.[1] *[1]NYC Health and Hospitals North Central Bronx, New York, NY; [2]New York City Health and Hospitals Jacobi, Bronx, NY.*

Background: In 2022, KDIGO modified its GDMT for CKD and Type 2 DM patients to include SGLT-2 inhibitors (SGLT2i's) along with angiotensin converting enzyme inhibitors or angiotensin receptor blockers (ACEI/ARB) as first-line therapy. However, many patients are discontinued due to adverse effects of an initial decline in estimated glomerular filtration rate (eGFR), frequent yeast infections, urinary tract infections, and euglycemic ketoacidosis. We aimed to study which limitations affect practice patterns in our hospital.

Methods: We conducted a retrospective analysis of patients with CKD and Type 2 DM from the primary care clinics from North Central Bronx Hospital, a community hospital in Bronx, NY, from July of 2019 to July of 2022. Statistical analysis was performed using the SPSS program where dichotomic variables and their relationships were analyzed using Chi square and binary logistic regression.

Results: Out of 419 patients recruited, 66.8% were found to be prescribed an ACEI/ARB, while 20.5% were prescribed SGLT-2i's. A history of hyperkalemia showed a decreased odds ratio (OR) (0.460, 0.28-0.73 CI 95%, P=0.04), whereas a microalbuminuria check showed an increased OR (1.923, 1.2-1.9 95% CI, P=0.04) of an ACEI/ARB prescription respectively. CKD stage was also found to affect ACEI/ARB prescription with more patients been prescribed in stages 2, 3a, 3b (78.2%, 68.6%, 67.9%) and less in patients with CKD stages 4, 5, (55.6%,47.6%), respectively, P= 0.015. In the regression model, the only independent variable found to affect SGLT-2i prescriptions was microalbuminuria, where patients who had a microalbuminuria check within last year were more likely to have been prescribed an SGLT-2i OR=2.5, 1.11-3.12 CI 95%, p= 0.019.

Conclusions: A history of hyperkalemia and advanced CKD stage are limiting factors to prescribing ACEI/ARB, while not checking microalbuminuria are limiting factors to prescribing ACEI/ARB and SGLT-2 inhibitors.

SA-PO491

Change in Urine Albumin-to-Creatinine Ratio (UACR) and Health Care Resource Utilization (HRU) and Costs in Patients with Type 2 Diabetes (T2D) and CKD

Navdeep Tangri,[1] Qixin Li,[2] Yan Chen,[3] Rakesh Singh,[2] Keith A. Betts,[3] Youssef M. Farag,[2] Scott Beeman,[2] Yuxian Du,[2] Sheldon X. Kong,[2] Todd E. Williamson,[2] Aozhou Wu,[3] Brendan Rabideau,[3] Kevin M. Pantalone.[4] *[1]Department of Community Health Services, Max Rady College of Medicine, University of Manitoba, Winnipeg, MB, Canada; [2]Bayer U.S. LLC, Whippany, NJ; [3]Analysis Group Inc, Los Angeles, CA; [4]Department of Endocrinology, Cleveland Clinic, Cleveland, OH.*

Background: UACR is an important measure of kidney damage, but the impact of changes in UACR on HRU and costs in patients with T2D and CKD is unclear.

Methods: We used the Optum electronic health records database (01/2007-09/2021) to identify adult patients with albuminuria, measured by UACR ≥30 mg/g (initial test) after diagnosis of T2D and CKD. UACR change was categorized as increased (>30% change), stable (-30% to 30%), or decreased (<-30%) based on the percent change between the initial test and the last test (between 183-730 days after the initial test). All-cause inpatient (IP) admissions, emergency room (ER) visits, outpatient (OP) visits, and total medical costs were evaluated during the 1 year after the last test. The association of UACR change with HRU was evaluated using Poisson regression, adjusting for key baseline characteristics. Medical costs (2022 USD) were estimated using a unit cost approach based on HRU frequencies.

Results: Among 144,814 patients eligible for the study, 81,084 (56%) had decreased, 31,766 (22%) had stable, and 31,964 (22%) had increased UACR. Compared with patients with stable UACR (IP admissions: 0.18 per-person-per-year [PPPY]; ER visits: 0.31 PPPY; OP visits: 19.13 PPPY; costs: $12,521), those with decreased UACR had similar HRU (IP: 0.17 PPPY; ER: 0.31 PPPY; OP: 19.90 PPPY) and annual medical costs ($12,329), while those with increased UACR had higher HRU (IP: 0.24 PPPY; ER: 0.35 PPPY; OP: 21.20 PPPY) and costs ($15,013). Compared with patients with stable UACR, those with decreased UACR had adjusted incidence rate ratios of 0.97 (95% CI: 0.93-1.01) for IP, 0.97 (0.94-1.01) for ER, and 1.02 (1.01-1.03) for OP. Patients with increased UACR had adjusted incidence rate ratios of 1.22 (1.17-1.28) for IP, 1.10 (1.05-1.15) for ER, and 1.07 (1.05-1.08) for OP compared with patients with stable UACR.

Conclusions: Among patients with T2D and CKD who had albuminuria, increases in UACR were associated with higher HRU and costs compared to patients with stable UACR, while decreases in UACR were associated with similar HRU and costs. Mitigating increases in UACR could yield economic benefits for this patient population.

Cost-Effectiveness Analysis of Dapagliflozin vs. Finerenone for Diabetic Kidney Disease

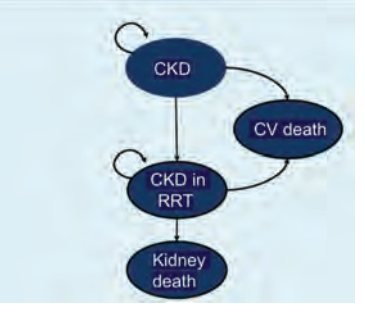
Miriam G. Nava-Vargas,[1,2] Kevin J. Arellano Arteaga,[1,3] Luis A. Camacho-Murillo,[2] Oscar O. Marquez.[1,2] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Regional Valentín Gómez Farias, Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Zapopan, Mexico; [3]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage chronic kidney disease (CKD) worldwide. CKD carries a health problem public health associated with high morbidity, mortality, high costs and low quality of life. It is necessary to implement risk reduction strategies, such as the use of selective sodium- glucose cotransporter inhibitors 2 (iSGLT2) and selective nonsteroidal mineralocorticoid receptor antagonist (MRA), reducing the risk of 20-40% of time to first onset of kidney failure, sustained decrease in eGFR, and renal or cardiovascular death.

Methods: A probabilistic economic model (Markov model) was developed to evaluate the cost-effectiveness of dapagliflozin versus finerenone for CKD. The model compared patients with dapagliflozin 10 mg per day versus finerenona 20 mg per day, added to standard treatment, in a cohort analyzed at 100 years of age. The states of CKD, progression to CKD with renal replacement therapy (RRT) requirement, renal and cardiovascular death were structured. The effect of dapagliflozin was estimated based on DAPA-CKD trial (HR 0.56; 95% CI, 0.45 - 0.68; $p < 0.001$) and the effect of finerenone based on FIDELTY trial (HR 0.77; 95% CI, 0.67–0.88; P = 0.0002). Probabilities, benefits, and costs of previous studies reported in literature were collected; to finally calculate the total costs, years of life gained adjusted for quality of life and the cost-effectiveness ratio.

Results: The total difference in cumulative life years was 3,979 for CKD in favor of dapagliflozin use. An incremental cost-effectiveness ratio, expressed in quality-adjusted life years, of $8,907 dollars was estimated with dapagliflozin versus $14,451 dollars with finerenone.

Conclusions: Dapagliflozina is cost-effective treatment versus finerenone for CKD, total difference $ 5,544 dollars for quality-adjusted life year.



SA-PO493

Overcoming Recruitment Obstacles in a Trial Examining Intradialytic Plantar Electrical Nerve Stimulation in Diabetic Hemodialysis Patients

Abdullah I. Hamad,[1] Bijan Najafi,[2] Myeounggon Lee,[2] Rania A. Ibrahim,[1] Mincy Mathew,[1] Heba M. Ateya,[1] Yoldez Zitouni,[1] Fadwa S. Al-Ali.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Baylor College of Medicine, Houston, TX.*

Background: Recruitment of patients on hemodialysis (HD) into a clinical trial is challenging (HD schedule, post-HD fatigue, polypharmacy, and physical and mental conditions). COVID-19 pandemic added an extra challenge (manpower, funding, and physical distance). We present challenges we faced in screening, recruiting, and retaining patients in our study of intradialytic plantar electrical nerve stimulation (iPENS).

Methods: Our study design is a double-blind, randomized controlled trial. We used iPENS to improve gait, balance and mobility (assessed using wearable sensors) among diabetic patients undergoing HD. Patients received either 1-hour active iPENS or non-functional iPENS during every HD for 12 weeks. Our original target was to recruit 100 patients over 4 year study period.

Results: We screened 540 HD patients in 2018-23. 410 (76%) patients were excluded (mostly non-diabetic and non-ambulatory patients. 130 (24%) patients met the inclusion criteria, but 19 (14.6%) refused to participate (not interested in any extra tasks during HD). 111 patients consented, but 18 (16.2%) of patients dropped (mostly due to COVID-19 interruptions). In the end, 92 patients (17% of the total screened patients) completed the study. Our study faced 11 months interruption related to COVID-19 pandemic. No patients discontinued the study because of extra burden or side effects. Most patients reported positive feedback and experience, with many requesting to continue the intervention beyond the study duration.

Conclusions: Our study was successful in recruiting its target despite its complexity and the challenges it faced. Creating an innovative study design that suits patients' schedules was essential to our success.

Systolic Blood Pressure Modifies the Relationship Between Coronary Artery Calcification and Adverse Kidney Outcome: Results from KNOW-CKD

Young Su Joo,[1,2] Jung Tak Park,[1,2] Tae-Hyun Yoo,[1,2] Kook-Hwan Oh,[3] Shin-Wook Kang,[1,2] Seung Hyeok Han.[1,2] *[1]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [3]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Previous studies have shown that elevated BP and coronary artery calcification (CAC) are risk factors for adverse kidney outcomes. However, the interaction between CAC and BP in relation to CKD progression has not well been studied. In this observational study, we aimed to evaluate whether systolic blood pressure (SBP) could modify the association between CAC and CKD progression in patients with CKD.

Methods: We analyzed 1698 participants with CKD stages G1 to G5 from the KoreaN cohort study for Outcome in patients With Chronic Kidney Disease (KNOW-CKD). Participants with kidney failure with replacement therapy (KFRT) and those with missing data for CAC and SBP were excluded. We categorized the participants according to their 1-year-mean systolic BP as controlled (SBP <120 mmHg) or uncontrolled (SBP≥120 mmHg) and the CAC status (Agatston score=0 or >0 AU). CKD progression was defined as a composite of halving eGFR from baseline value or onset of KFRT.

Results: During 10,023 person-years of follow-up (median 6.2 years), the composite outcome occurred in 689 (40.7%) participants. We found a significant interaction between the Agatston score and SBP for CKD progression (P=0.02). There were 90 (27.5%), 67 (37.0%), 219 (39.5%), and 313 (49.7%) composite outcome events in participants with controlled BP without CAC (group 1), controlled BP with CAC (group 2), uncontrolled BP without CAC (group 3), and uncontrolled BP with CAC (group 4), respectively. In multivariable cause-specific Cox model, the corresponding hazard ratios (95% confidence intervals) for groups 2, 3, and 4 were 1.25 (0.88-1.77), 1.44 (1.12-1.87), and 1.78 (1.35-2.34), respectively, compared with group 1. Sensitivity analysis using a different SBP cutoff of 130 mmHg yielded similar results.

Conclusions: The clinical implication of CAC for CKD progression may be influenced by the status of controlled SBP, and CAC is more strongly associated with adverse kidney outcome when SBP is not adequately controlled.

Are We Dismissing Type 2 Myocardial Infarction (MI) in ESRD? A Serious Note of Concern

Jorge Gutierrez, Chee Yao Lim, Kenneth Johan, Alberto Romero, Pinal Patel, Rahul Zain, Afsheen Afzal, Maria Angela Matabang, Betina Sinanova, Julian Ategeka, Laverne Yip, May Soe, Abdul Wahab, Richa Aggarwal, Vidya Menon. *Lincoln Medical Center, Bronx, NY.*

Background: Patients with ESRD and elevated troponin (cTn) have increased morbidity and mortality. The cTn elevation is often overlooked and categorized as chronic cTn elevation or demand ischemia. We aim to evaluate 30-day readmission and mortality at one year among hospitalized ESRD patients.

Methods: Adult patients with ESRD and elevated cTn admitted from 4/2020 to 4/2022 were included. The 4th Universal Definition of MI and cTn change ≥20% in patients with elevated cTn on admission were used to identify type 1 MI in ESRD. Patients were stratified into 2 groups: type 1 and type 2 MI. 30 days readmission rate and mortality during admission & 1 year were analyzed.

Results: Of the 376 patients hospitalized, 168 were classified as Type 1 or 2 MI and the rest were determined to have chronic elevation of cTn. 24 were classified as type 1 and 144 as type 2. Baseline characteristics were similar between both groups. 30 days readmission rate was 21% in the type 1 group vs 18% in the type 2 (p= 0.745). Mortality during hospitalization was 21% for type 1 vs 9% for type 2 (p= 0.083). Mortality was comparable at 1 year: 29% for type 1 vs 17% in Type 2. Risk of mortality in type 2 MI was higher with heart failure (OR 4.121, p=0.041), afib (OR 6.684, p=0.031) and hemoglobin <8 (OR 9.023, p=0.007). Patients with CVA (OR 0.080, p=0.010), chest pain on admission (OR 0.097, p=0.006), and atypical symptoms (OR 0.079, p=0.016) had better survival.

Conclusions: Type 2 MI is more common among ESRD patients. It has comparable outcomes at one year to type 1, highlighting the importance of strategies to accurately diagnose and risk stratify for better outcomes. Further research in this area, including the role of intervention, will enhance our understanding and improve clinical practices for this vulnerable population excluded in the ISCHEMIA-CKD trial.

SA-PO496

Are We Closing the Loop in Patients with ESRD Too Soon?

Jorge Gutierrez, Kenneth Johan, Chee Yao Lim, Alberto Romero, Pinal Patel, Maria Angela Matabang, Afsheen Afzal, Rahul Zain, Richa Aggarwal, Vidya Menon. *Lincoln Medical Center, Bronx, NY.*

Background: Cardiovascular (CV) disease remains the leading cause of death in ESRD patients. Myocardial infarction (MI) is associated with poorer outcomes compared to the general population. A recent consensus by the Standardized Outcomes in Nephrology Hemodialysis (SONG-HD) group defines MI type I in ESRD patients if they have changes in EKG, symptoms, and a rise or fall of troponin (cTn) within 6 to 12

hours of more than 20% if elevated or more than 50% if normal on admission. We aimed to study the outcomes of patients with ESRD and elevated troponin according to this new consensus.

Methods: This retrospective single center study included patients with ESRD admitted with elevated troponin from April, 2020 to 2022. Patients with a single cTn on admission, repeated cTn less than 6 hours apart from the initial, admitted for cardiac arrest or trauma were excluded. Patients that met criteria for type I MI according to the SONG-HD group consensus were included for the study. Baseline characteristics and mortality up to 1 year were analyzed using descriptive statistics.

Results: After stratifying according to exclusion and inclusion criteria a total of 24 ESRD patients were admitted during this period for type I MI. 4 patients received ACS protocol (ACSP) and PCI within 30 days with a mortality of 0%, 12 patients only ACSP with a mortality of 25% and 8 patients no intervention with a mortality of 50%. 14 patients were documented as type I MI and 10 patients were not due to the lack of guidelines at that time. Out of the 14 patients, 3 received ACSP and PCI within 30 days, with a mortality rate of 0%, 9 only ACSP with a mortality of 11% and 2 received no intervention with a mortality rate of 50%. Out of the 10 patients not identified as type 1 on hospitalization, mortality was 50%.

Conclusions: To date there are no clinical trials about the benefit or harm of revascularization in patients with ESRD. The ISCHEMIA-CKD study reports no benefit in initial invasive strategy when compared to conservative strategy in patients with CKD stage 3 and 4. Though our sample size is small, it brings to light the recurrent question about the role of early cardiac catheterization/PCI among patients with type 1 MI with ESRD while highlighting the importance of early and accurate recognition of type 1 MI in this high risk population.

SA-PO497

Etelcalcetide Use Affects Changes in Agatston Coronary Artery Calcium (CAC) Score in Maintenance Dialysis Patients

Toshiki Doi,[1,2] Kenichi Morii,[1,2] Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Takao Masaki.[2] *[1]Ichiyokai Harada Hospital, Hiroshima, Japan; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: Dialysis patients are known to be at high cardiovascular risk, and the Agatston CAC score, a measure of coronary artery calcification, has been associated with cardiovascular events. Recently, calcimimetics such as etelcalcetide have been used to manage secondary hyperparathyroidism, but their effect on vascular calcification is unknown. Therefore, the present study investigated whether etelcalcetide use affects changes in Agatston CAC scores in maintenance hemodialysis patients.

Methods: This historical cohort study included 192 patients undergoing maintenance hemodialysis who had Agatston CAC score of 100 or higher and were not using calcimimetics other than etelcalcetide. Propensity score matching was performed by age, gender, diabetes mellitus, Ca, iP, and intact PTH. In addition, we examined whether there was a difference in etelcalcetide use and the rate of change in Agatston CAC score after one year.

Results: In the two groups of patients matched for background factors by propensity scores (18 patients each), the Agatston CAC score change was significantly lower in the etelcalcetide use group ($p = 0.0284$).

Conclusions: Etelcalcetide use in maintenance dialysis patients may reduce coronary calcification.

SA-PO498

Empagliflozin in Patients with Acute Heart Failure and Diuretic Resistance: Preliminary Data from the DRIP-AHF-1 Trial

Pedro Marques, Abhinav Sharma, Thomas Mavrakanas. *McGill University Health Centre, Montreal, QC, Canada.*

Background: Diuretic resistance is common in acute heart failure and associated with poor clinical outcomes. Chronic kidney disease (CKD) is a major determinant of diuretic resistance. Association of furosemide with sodium-glucose cotransporter 2 inhibitors can potentially overcome diuretic resistance in acute heart failure patients with CKD.

Methods: This is a prospective, single-arm, observational, open-label clinical trial. Patients admitted with acute heart failure with estimated glomerular filtration rate (eGFR) of 15-45mL/min/1.73m^2 and diuretic resistance, defined as a urinary output (UO)<300mL in the 2 hours post 1-1.5mg/kg IV furosemide, were recruited. These patients received 25mg of empagliflozin 2 hours post a second IV furosemide bolus of 1-1.5mg/kg, administered at least 5 hours after the initial furosemide bolus. Primary outcome is the 3-hour UO post furosemide+empagliflozin on the first day of the study, compared with furosemide alone. Secondary outcomes include fractional excretion of sodium (FENa) and total urinary sodium excretion.

Results: From 32 patients screened, 6 patients met inclusion criteria and consented to participate. Median age was 80 (75-84) years, 67% were male, median ejection fraction was 40 (40-55) % and median baseline eGFR 18 (17-25) mL/min/1.73m^2. All patients had a strong response to furosemide after empagliflozin administration (Table)

Conclusions: Our preliminary data shows that empagliflozin at a dose of 25mg, when added to high dose IV furosemide in patients with acute heart failure, low eGFR and diuretic resistance, is capable of increasing urinary output and urinary sodium excretion.

Funding: Private Foundation Support

Data for the primary and secondary outcomes

Patient number	UO 3h post FST (mL)	UO 3h post Empa+FST (mL)	FENa 3h post FST (%)	FENa 3h post Empa+FST (%)	Na excretion 3h post FST (mmol)	Na excretion 3h post Empa+FST (mmol)
#1	215	290	4.7	7.6	14.4	22.0

SA-PO499

Effect of Renal Denervation on Plasma Adipokines Concentrations in Patients with Resistant Arterial Hypertension

Marcin Adamczak,[1] Beata Czerwienska,[1] Michal Lelek,[2] Damian Gojowy,[1] Katarzyna Mizia-Stec,[2] Andrzej Wiecek.[1] *[1]Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland; [2]1st Department of Cardiology, Medical University of Silesia, Katowice, Poland.*

Background: Adiponectin, leptin and visfatin are synthesized by adipocytes. Adiponectin has anti-diabetic, anti-atherosclerotic, anti-thrombotic, anti-inflammatory, and cardioprotective properties. Leptin has hypertensinogenic properties. Visfatin seems to be a marker of endothelial dysfunction and vascular damage. Renal denervation (RDN), is proposed as method of treatment in patients with resistant arterial hypertension (RAH). This single-center, interventional clinical study aimed to assess the effect of RDN on plasma adipokines (adiponectin, leptin and visfatin) concentration in patients with RAH.

Methods: Eighteen patients (9 women, 9 men) aged 53.2±6.5 years with RAH who underwent RDN using Simplicity catheters (Medtronic, Inc., Northridge, CA) were enrolled in the study. Plasma adiponectin, leptin and visfatin concentration was determined before and 6 months after RDN using: the Human Adiponectin ELISA Kit (Otsuka Pharmaceutical Co, Tokyo, Japan), the Human Leptin RIA HL-81K (Linco Research, Inc., Missouri, USA) and Visfatin c-terminal ELISA Kit (Phoenix Pharmaceuticals Inc., Karlsruche, Germany), respectively.

Results: Systolic and diastolic blood pressure was reduced 6 months after RDN (mean ± standard deviation; 196.6±28.2 and 162.9±15.6; $p<0.001$ as well as 117.9±26.4 and 90.7±8.6 mmHg; $p<0.001$), respectively). Body mass index (BMI) before and 6 months after RDN was similar (mean ± standard deviation, 31.0 ± 4.4 and 31.3±4.4 kg/m^2; $p=0.8$). Plasma adiponectin concentration increased significantly 6 months after RDN (median with interquartile range; 5.78 (3.70;10.47) and 7.58 (5.60;10.64) μg/mL, $p=0.009$). Plasma leptin and visfatin concentration measured before and 6 months after RDN did not change significantly (median with interquartile range; 5.78 (95% CI 27.5 (14.0;39.0) and 22.5 (12.0;32.0) ng/mL; $p=0.13$, as well as 4.45 (3.70;5.00) and 4.70 (4.10;6.00) ng/mL; $p=0.23$, before and 6 months after RDN, respectively).

Conclusions: 1. Renal denervation may increase plasma adiponectin concentration but did not influence plasma leptin and visfatin concentration in patients with RAH. 2. Increased plasma adiponectin concentration may participate in the cardiovascular benefits in these patients, however long term clinical consequences of this observation need further investigations.

Efficacy and Safety of Renal Denervation in the Maintenance Hemodialysis Patients with Hypertension: A Single-Center Study

Yuan Luo, Zhuo Xu, Guiling Wei, Chunfeng Gu, Hong Ye, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Hypertension, a characteristic symptom in patients undergoing maintenance hemodialysis (MHD), is strongly linked to elevated hospitalization and mortality rates. Percutaneous renal denervation is a novel adjunctive treatment for hypertension, and we observed its efficacy and safety in patients undergoing maintenance dialysis.

Methods: Hypertension patients who underwent hemodialysis for more than 3 months were recruited. The eligible patients were between 18 and 70 years old, with office systolic blood pressure ranging from >150 mmHg to <180 mmHg, while concurrently taking three or more stable doses of antihypertensive medications for at least 6 months. Before enrollment, patients underwent a 28-day standardized treatment with antihypertensive medications. Those whose office systolic blood pressure remained between ≥150 mmHg and ≤180 mmHg after the treatment were included. Patients were subjected to follow-up assessments at 1, 3, and 6 months. The primary endpoints were a change in office systolic blood pressure, and changes in antihypertensive medication types and dosages from baseline to 6 months for the renal artery denervation.

Results: Between April 2021 and April 2023, among 26 enrolled patients, 12 patients who fulfilled the qualifying criteria underwent RDN surgery. The average age of the 12 patients was 43.4±10.60 years, with an average duration of dialysis of 2.4±1.14 years. At 3 months, the office systolic blood pressure reduction was -21.1mmHg(SD 5.7). At 6 months, the office systolic blood pressure reduction was -17.3mmHg(SD 3.8). At 6 months, only one patient required a reduction in the dosage of one medication, while the remaining patients maintained consistent types and dosages of medications as prior to the procedure. There were a total of 3 cases of adverse events, with 2 cases of minor hematoma at the femoral artery puncture site and 1 case of rectal bleeding in a patient with hemorrhoids.

Conclusions: At 6 months of follow-up,RDN produced a clinically meaningful blood pressure reduction,independent of concomitant antihypertensive medications. The application of RDN in patients undergoing maintenance hemodialysis is efficacy and safety.

Pooled, 12-Month Renal Safety and Blood Pressure (BP) Reductions Using the Symplicity Spyral Radiofrequency Renal Denervation Catheter

Raymond R. Townsend,[1] Felix Mahfoud,[2] Giuseppe Mancia,[3] David E. Kandzari,[5] Robert Whitbourn,[4] Michael Böhm.[2] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany; [3]Universita degli Studi di Milano-Bicocca, Milano, Italy; [4]St Vincent's Heart Centre, Melbourne, VIC, Australia; [5]Piedmont Heart Institute, Atlanta, GA.*

Background: Renal denervation (RDN) targets the sympathetic nervous system to lower blood pressure (BP). Impact on long-term renal function after RDN is less well known. We report the 12-month BP reductions and renal safety after RDN from the largest existing database, using the latest generation, multi-electrode, radiofrequency (RF) Symplicity Spyral™ catheter.

Methods: A broad spectrum of patients with hypertension were enrolled in the SPYRAL HTN Global Clinical Program, consisting of 4 major studies; SPYRAL First-In-Man, SPYRAL HTN-OFF MED, -ON MED and Global SYMPLICITY Registry (GSR). GSR is an all-comer registry for patients with uncontrolled hypertension, including chronic kidney disease (CKD), whereas patients enrolled in the SPYRAL HTN-OFF and -ON MED trials required to have OSBP ≥150 and <180 mmHg and ODBP ≥90 mmHg. OFF MED patients were required to have a drug washout period prior to treatment and did not take drugs for the first 3 months. ON MED patients were on a stable 1-3 antihypertensive drug regimen for 6 months. All were treated with RF RDN using the Spyral catheter. We pooled reductions in office and 24-h ambulatory BP, safety outcomes include changes in the estimated glomerular filtration rate (eGFR) and renal artery stenosis incidence (>70%, confirmed by angiography).

Results: As of March 2023, 1,539 patients received RF RDN using the Spyral catheter. Patients at baseline were 58±12yrs old, 38.2% female, 30.1% had type 2 diabetes, eGFR was 77.9±24.4mL/min/1.73m^2, 21.6% had CKD stage 3 or more, OSBP was 164±22mmHg and ASBP was 152±17mmHg. 12 months after RDN, OSBP changed by -15.9 ± 23.2 (n=970; p<0.001) and ASBP changed by -10.0±15.7 (n=660; p<0.001). Significant diastolic BP reductions were also observed. eGFR changed minimally by -2.6mL/min/1.73m^2 (n=805; p<0.001). There was no incidence of renal artery stenosis (>70%).

Conclusions: In this large, pooled population of patients receiving RF RDN using the Spyral catheter, there were significant and consistent BP reductions through 12 months. There was no incidence of renal artery stenosis, and eGFR change was consistent with the natural progression of the aging hypertensive population. These data highlight the safety and efficacy of RF RDN as an adjunctive therapy to antihypertensive drugs to treat high BP.

Mineralocorticoid Receptor Antagonist (MRA) Use Among CKD Patients Before and After the Transition to Dialysis: A Real-World Observation from an Integrated Health System

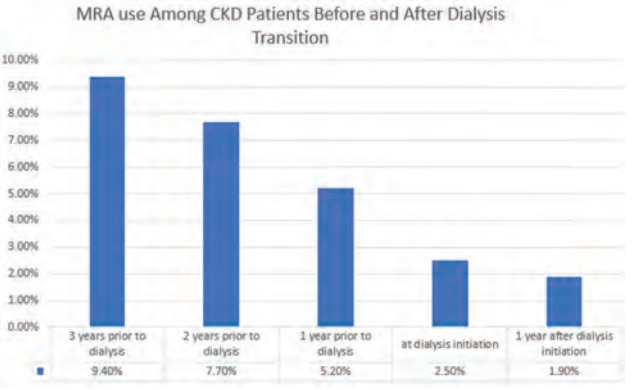
Eric M. Tong, Hui Zhou, Katherine J. Pak, Khalid Namoos, Sally F. Shaw, Jiaxiao Shi, Benjamin Broder, John J. Sim. Southern California Permanente Medical Group. *Southern California Permanente Medical Group, Woodland Hills, CA.*

Background: MRAs may improve outcomes in the end-stage kidney disease (ESKD) population, but their use has been limited due to potential side effects and concerns. Among a large, diverse real-world population of incident ESKD patients, we evaluated MRA use prior to and one year after the transition and its associations with short-term all-cause hospitalizations and mortality.

Methods: A retrospective cohort study within Kaiser Permanente Southern California was performed among CKD patients (eGFR≤45) who transitioned to dialysis between 1/1/2007 and 12/31/2017. MRA (spironolactone and eplerenone) use was defined as two or more pharmacy dispensations. MRA use was evaluated as ever, within 3, 2, and 1 year before dialysis, at dialysis initiation, and 1 year after dialysis. Multivariable logistic regression was performed to assess the patients' characteristics related to the use of MRA.

Results: Among 6,812 CKD patients who transitioned to dialysis, 18.3% used an MRA at any time before dialysis and decreased prior to the initiation of dialysis (Figure 1). Among 5,655 ESKD patients who survived, MRA use was 1.9% at 1 year after dialysis. Dialysis patients on MRA were more likely to be non-Hispanic White (OR: 1.87; 95% CI: 1.12-3.12), Asian (OR: 1.82; 95% CI: 1.07-3.09), on peritoneal dialysis (OR: 1.67; 95% CI: 1.10-2.55), and have uncontrolled hypertension with higher hypertensive medication use. The 1 year RR for hospitalization (1.00; 95% CI: 0.81-1.23) or all-cause mortality (0.99; 95% CI: 0.52-1.88) was not significant among MRA vs. non-MRA users.

Conclusions: MRA use was low (1.9%) after transitioning to dialysis. Uncontrolled hypertension but not heart failure was associated with MRA use. Given potential benefits, MRA use in dialysis may represent an area of focus in managing the dialysis population.



SA-PO503

Impact of Angiotensin-Converting Enzyme Inhibitors and Angiotensin Receptor Blockers on Cardiovascular Events and Mortality in Dialysis Patients: A Meta-Analysis of Randomized Controlled Trials

Muhammed Khaled Elhadi Elfaituri, Taha K. Elfaituri, Hazem Faraj, Ahmed Msherghi. *University of Tripoli Faculty of Medicine, Tripoli, Libya.*

Background: Cardiovascular disease is the leading cause of mortality among patients with end-stage renal disease undergoing dialysis. Angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) are commonly used to manage hypertension in this demographic. Despite their widespread use, the decisive impact of these medications on cardiovascular outcomes and all-cause mortality within the dialysis patient population remains to be fully elucidated. This systematic review and meta-analysis of randomized controlled trials (RCTs) sought to accurately quantify the effect of ACEIs and ARBs on a composite of fatal and non-fatal cardiovascular events, cardiovascular mortality, and all-cause mortality among patients undergoing dialysis.

Methods: A systematic search of PubMed, EMBASE, and the Cochrane Library was conducted up to January 2023, focused on RCTs assessing the effects of ACEIs and ARBs on the specified outcomes in dialysis patients. Two reviewers undertook independent data extraction, and any discrepancies were resolved through consensus. The pooled Odds Ratio (OR) with 95% confidence intervals was calculated using a random-effects model. All statistical analyses were performed using R version 4.0.3 with the metafor and meta packages.

Results: A total of 4 RCTs involving 1,502 patients (755 patients on ACEIs/ARBs and 747 controls) were identified. The results revealed that ACEIs and ARBs were not associated with a significant reduction in the composite of fatal and non-fatal cardiovascular events (OR 0.86, 95% CI 0.57-1.28, I^2=66%), cardiovascular mortality (OR0.78,95%CI0.55-1.12,I^2=0),orall-causemortality(OR0.87,95%CI0.66-1.13,I^2=8%). Notably, heterogeneity was observed among the included studies.

Conclusions: The findings of this meta-analysis of RCTs did not provide clear evidence of a significant benefit of ACEIs and ARBs on cardiovascular outcomes or overall survival in dialysis patients. However, given the heterogeneity observed among the included trials, further, high-quality RCTs are warranted to strengthen these findings. Clinicians should consider this lack of definitive evidence when weighing these medications' potential benefits and risks for patients undergoing dialysis.

SA-PO504

PRN Blood Pressure Medication Use in VA Hospitals

Caleb J. Rowan,[1,2] Dexter Hadley,[3,2] Seonkyeong Yang,[1,2] Ronald I. Shorr,[1,2] Weihsuan Lo-Ciganic,[4,2] Muna T. Canales.[1,2] *[1]University of Florida College of Medicine, Gainesville, FL; [2]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [3]University of Central Florida College of Medicine, Orlando, FL; [4]University of Florida College of Pharmacy, Gainesville, FL.*

Background: Pro Re Nata blood pressure medications (PRNBP) are commonly used to treat inpatient asymptomatic hypertension. Recent studies in non-Veteran populations suggest this may increase risk of ischemic events and in-hospital mortality. To date, the extent and characteristics of PRNBP use in VA hospitals is unknown.

Methods: We obtained National VA Corporate Data Warehouse (CDW) data on medical/surgical floor hospitalizations in FY16-20 lasting ≥ 3 days for Veterans who were not on dialysis and ≥18 years old. We validated an algorithm to identify PRNBP versus no-PRNBP use in VA national data by comparing CDW data with individual chart review (30 charts per group). We applied this algorithm to report the frequency and characteristics of hospitalizations with and without PRNBP use in patients already on scheduled BP medications.

Results: 577,136 hospitalizations (381,896 unique Veterans) met our criteria at national VA hospitals. An algorithm to identify PRNBP use in VA hospitals was 97% sensitive and 100% specific. Using this algorithm, of the 577,136 hospitalizations, 142,506 (24.7%) received PRNBP defined as a one-time or PRN order. 309,126 of the 577,136 hospitalizations had scheduled BP medications (224,001 unique Veterans). We chose the first hospital stay of each unique Veteran as the unit of study (n=204,990); of these, 87,975 received at least one PRNBP during the stay and 117,015 did not. Age and BMI for those with and without PRNBP were similar (mean±SD age: 70.5±11.5 vs

70.5±11.3; BMI: 29.5±6.7 vs 30.1±6.8; standard mean difference (SMD)<0.1). Admission systolic BP was higher in the PRNBP group (mean±SD: 146.4±25.4 vs 137.0±20.8; SMD=0.4) as was mean systolic BP (138.8±17.2 vs 130.7±13.7; SMD=0.5). Stays with PRNBP had median±IQR 2.0±3.0 doses given. Hydralazine and metoprolol were the most common PRNBP (27% each). Length of stay was slightly longer for those who received PRNBP (median±IQR: 6.0±6.0 vs 5.0±4.0; SMD=0.2). Mean baseline serum creatinine was 1.3±0.9 for PRNBP vs 1.2±0.8 for those without PRNBP (SMD=0.09).

Conclusions: The highly sensitive and specific algorithm to identify PRNBP use in VA hospitals found that inpatient PRNBP use was very common and occurred among those with higher admission BP. This cohort is the largest to date to study PRNBP use and will be the basis of future study to examine the clinical outcomes of PRNBP use in VA hospitals.

SA-PO505

Blood Pressure Changes with Intensive Urate Lowering in Uncontrolled Gout Patients with and Without CKD

Brad A. Marder,[1] Richard J. Johnson,[2] Hyon Choi,[3] Katie L. Obermeyer,[1] Brian LaMoreaux,[1] Peter E. Lipsky.[4] *[1]Horizon Therapeutics plc, Deerfiled, IL; [2]University of Colorado, Aurora, CO; [3]Massachusetts General Hospital, Boston, MA; [4]AMPEL BioSolutions LLC, Charlottesville, VA.*

Background: Hypertension rate is high in uncontrolled gout (UCG) patients (pts) and associated with gout and hyperuricemia. In adults, allopurinol had little effect on BP, but intensive urate-lowering with pegloticase reduced systolic (SBP) and diastolic (DBP) BP. BP changes during pegloticase use (MIRROR RCT trial) were examined.

Methods: UCG pts (SU≥7mg/dL, oral ULT failure/intolerance, and ≥1 gout symptom) were randomized 2:1 to oral MTX (15mg/wk) or PBO as cotherapy to pegloticase (8mg biweekly, 52wks). After 2wk MTX tolerance period and 4wk MTX/PBO Run-in, pts began pegloticase+MTX/PBO (Day 1). Sitting BP was measured before MTX (baseline [BL, Wk -6]) and pegloticase (Wk -4, Day1) exposure and every 2wks thereafter. Preinfusion, on-treatment BP data were included. Mean(±SD) change from BL (CFB) was examined by treatment group and BL eGFR (<60, ≥60ml/min/1.73m^2).

Results: 152pts (89% men, 55±13yrs, 14±11yr gout history, 76% tophi, 11±14flares/yr) were randomized (100 MTX, 52 PBO). Groups were similar at BL, including SBP (MTX vs PBO: 133±13 vs 131±15mmHg) and DBP (82±9 vs 83±10mmHg). SBP initially decreased in both groups but more in MTX pts by Wk24 (CFB: -6±16 vs -1±18mmHg). CFB was sustained in MTX pts thru Wk52, but fluctuated after Wk24 in PBO pts (n≤19; **Figure**). In MTX pts, DBP was below BL thru Wk52 (CFB: -2±8mmHg). In PBO pts, DBP first declined, but returned to BL by Wk52 (CFB: +1±12mmHg). Pts with BL eGFR≥60 (SBP: 133±13mmHg, DBP: 83±9mmHg; N=98) and <60 (130±15mmHg, 80±7mmHg; N=46) had similar BP CFB early in treatment but by Wk24 was more pronounced in ≥60 group (trend persisted thru Wk52, **Figure**).

Conclusions: BP decreased during pegloticase therapy in CKD and nonCKD pts. After 6mo, pts cotreated with MTX and without CKD had more pronounced changes. These data support a possible role of urate, and potentially MTX, in regulating BP particularly in nonCKD pts with gout. Further study is needed.

Funding: Commercial Support - Horizon Therapeutics plc

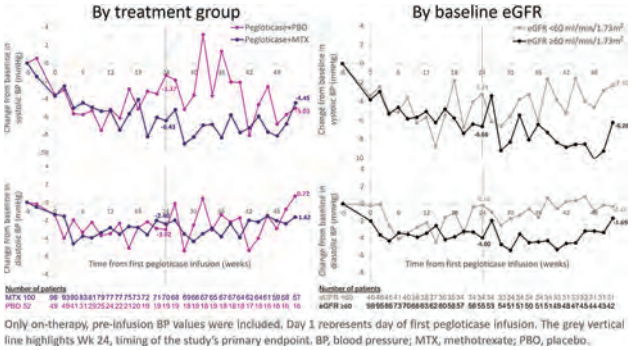

Figure. Mean change from baseline (before MTX, Wk -6) in BP during biweekly pegloticase (8 mg) treatment.

SA-PO506

Sacubitril/Valsartan Improves Cardiac Function in Dialysis Patients

Zaher Armaly. *Nazareth Hospital EMMS, Nazareth, Israel.*

Background: Heart failure is a common disease characterized by activation of adverse neurohormonal systems and high mortality and mortality rate. Noteworthy, cardiovascular diseases are well known complication of CKD, especially in ESRD, where dialysis patients are 7- 8 times more likely to encounter cardiac arrest than the general population. Sacubitril/Valsartan (Sac/Val) is a dual inhibitor/blocker of neprilysin and angiotensin II receptor, which exert cardioprotective effects among patients with reduced and preserved ejection fraction (HFrEF & HFpEF). Unfortunately, the drug is not approved for subjects with advanced CKD and dialysis patients due to safety concern. The current study examined cardiac and renal effects of Sac/Val in dialysis patients.

Methods: The study was approved by the Nazareth Hospital EMMS Human Research Review Committee and carried at Nazareth Hospital. All patients provided informed consent. Thirteen chronic dialysis patients with HFrHF (FE<40%) were recruited. All patients received conventional dialysis regimens (3 sessions a week for HD; daily dialysis for PD) and all received conventional treatment for CHF and other background illnesses. Patients were treated with Sacubitril/Valsartan at incremental doses 2X50 up to 2X200 mg/day and blood samples were collected and ECHO was performed at baseline and after 3 and 6 months after treatment. Also, quality of life was assessed by Cardiomyopathy Questionnaire (Kansas City KCCQ-12) before and after life after Sacubitril/Valsartan adminsitration.

Results: Administration of Sac/Val to dialysis patients with HFrEF for 6 months gradually improved EF independently of morphological changes in cardiac geometry, as was assessed by echocardiography, and hemodynamic alterations. Specifically, EF was 32.1±1.15% at baseline and increase to 41.15±1.78% (P<0.01) and 48.63±4.72 (P<0.005) following 3 and 6 months of treatment with Sacubitril/Valsartan, respectively. This improvment was associated with significanly reduction in pulmonary artery systolic pressure (PASP). Interestingly, the quality of life significantly improved after Sacubitril/Valsartan treatment. No major adverse effects were reported in the present study, supporting the safety of Sacubitril/Valsartan at least in these patients and for the applied follow up period.

Conclusions: Collectively, these findings support the use of Sac/Val as cardio protective agent in dialysis patients with HFrEF.

Funding: Private Foundation Support

SA-PO507

Heart Failure (HF) in the SGLT2 Inhibitor (SGLT2i) and GLP1 Receptor Agonist (GLP1-RA) Era: Does Hypertension (HTN) Matter?

Sydney E. Hartsell,[1,2] Amara Sarwal,[1,2] Jincheng Shen,[1,2] Guo Wei,[1,2] Mckenna R. Nevers,[1,2] Brad Adams,[1,2] Ravinder Singh,[1,2] Robert E. Boucher,[1,2] Tom Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT.*

Background: Whether uncontrolled HTN modifies the potential protective effects of SGLT2-I and GLP1-RA on HF is unknown.

Methods: We conducted an active comparator, new user design study in a national cohort of veterans (N = 129,186) with type 2 diabetes (T2D) on metformin without HF at baseline and initiated on an SGLT2i, GLP1-RA or insulin glargine (IG) for the first time between 1/1/18 and 12/31/21 and followed until 3/31/23. In Cox models, we examined whether the associations of SBP categories with HF risk modified by the drug class.

Results: 13.1% were initiated on GLP1RA, 38.9% on IG and 47.9% on SGLT2i. There were 8,850 HF events over 355,990 person-years. Within each of the drug classes, those with SBP 110 to 130 mmHg had the lowest and > 150 mmHg the highest incidence of HF (Fig). In a multivariable Cox model adjusted for SBP levels, demographics, comorbidity, CKD stages and other variables, compared to GLP1RA, IG had higher risk of HF but SGLT2i had similar risk (Table). In the same model, there was a graded association of SBP levels with the risk of HF (Table). The product interaction term of drug classes and SBP categories was not significant (p = 0.65).

Conclusions: HTN remains a significant risk factor for HF in veterans with T2D initated on SGLT2i or GLP1RA.

HF risk by Drug Class and SBP groups

Predictor	HR (95% CI)
Drugs	
GLP1	Reference
Insulin Glargine	1.19 (1.11, 1.27)
SGLT2i	0.93 (0.87, 0.99)
SBP Groups	
<110	1.20 (1.10, 1.31)

Effect of Baroreflex Activation Therapy on Blood Pressure: A Randomized Sham Clinical Pilot Trial on Behalf of the BAT Team

Daniel Gordin,[1,2] Johan R. Simonsen,[1] Pirkka Vikatmaa,[1] Ilkka T. Tikkanen.[1,2] On Behalf of the BAT Team. *[1]HUS Helsingin yliopistollisen sairaala, Helsinki, Finland; [2]Minerva Foundation Institute for Medical Research, Helsinki, Finland.*

Background: Baroreflex activation therapy (BAT) is a promising treatment option for individuals with resistant hypertension. No randomized sham controlled trials have been done thus far.

Methods: This investigator-initiated randomized, double-blinded sham-controlled pilot trial included five Finnish patients with resistant hypertension. Participants were found eligible if they were 18-70 years old with a daytime systolic ambulatory blood pressure (ABP) of ≥145 mmHg, and/or a diastolic ABP ≥95 mmHg. Patients were on ≥3 antihypertensive drugs including a diuretic. A witnessed drug intake prior to ambulatory blood pressure measurement (ABPM) was implemented. The Barostim Neo System was implanted for modulation of the autonomic nervous system by direct electrical stimulation of the carotid baroreceptors. One month after implantation, all participants were randomized to either 8 months BAT-system on or BAT-system off followed by continuous BAT for all participants (Figure). ABPM was performed per protocol. The primary outcome was defined as a change in systolic ABP after 8 months of BAT, compared to pharmacotherapy.

Results: BAT decreased mean daytime systolic blood pressure by 11.8 mmHg in three participants randomized to BAT, while in the two remaining participants randomized to continuous pharmacotherapy mean systolic daytime blood pressure increased by 8.7 mmHg. When pooling daytime systolic 24-hour ABP, BAT was associated with a 9.2 mmHg lower mean blood pressure (143.5 mmHg [95% CI:142.2-144.9] vs 152.7 mmHg [151.1-154.2], <0.0001). In linear mixed models with the BAT-system's status as a fixed effect, daytime SBP at baseline and after 8 months of follow-up were compared between individuals on BAT and continuous pharmacotherapy. BAT was associated with a reduction in mean daytime SBP of -11.7 mmHg (P<0.0001).

Conclusions: BAT may lower systolic blood pressure in individuals with resistant hypertension. Large-scale studies are needed to support this assumption.

A Clinical Study to Evaluate and Compare the Blood Pressure (BP) Measurements Taken at Peridialysis Time, at Home, and with Ambulatory BP Monitoring (ABPM) Machine in Hemodialysis Patients

Vikas K. Bohra, Rajesh Aggarwal, Blessy S. Bhalla, Mohit M. Kurundwadkar. DrNB Nephrology. *Sri Balaji Action Medical Institute, New Delhi, India.*

Background: The study was conducted to find variability of BP measurements obtained at Peridialysis time & at Home with respect to ABPM which would help in better understanding of HTN & its control in HD patients.

Methods: The observational study was conducted in 50 ESRD patients undergoing HD at our centre. BP measurements were taken at baseline & at 6 months during follow up. For each case, BP measurements were taken at Pre HD, Intradialysis, Post HD at Home with calibrated digital BP machine and compared with 44 hours Ambulatory BP recorded with calibrated ABPM machine. The data was analysed both at baseline & at follow up, to find which BP taken at Pre HD, Intradialysis, Post HD & at Home showed highest agreement with the 44 hr Ambulatory BP.

Results: At baseline 44(88%) of cases at baseline were hypertensive (Average BP ≥130/80mmHg over 44 hr monitoring) based on ABPM. Average Home BP had the least difference with average BP by ABPM [SBP diff (2.88 ± 1.44), DBP diff (1.98 ± 1.17)] followed by Median Intradylitic BP{ SBP diff 3.2 ± 4.69 DBP diff 3.52 ± 3.36}. Both Pre HD & Post HD BP vary widely compared to ABPM. On Bland Altman analysis, range of agreement was narrowest with Home BP{SBP 5.64, DBP 4.58). Peridialysis time BP {Pre HD ((SBP 11.23 to 22.49, DBP 4.15 to 15.93) Median intradialytic(SBP-5.99 to12.39, DBP-3.06 to10.10) & Post HD (SBP-31.24 to 3.44, DBP-18.30 to 2.42)} had wide range of agreement with ABPM. **At 6 month follow up** Average Home BP had the least difference with average BP by ABPM {SBP diff (2.82 ± 1.27), DBP diff (2 ± 1.48)}. Both Pre HD & Post HD BP vary widely compared to ABPM. On Bland Altman analysis, range of agreement was narrowest with Home BP{SBP 4.99, DBP 5.82}. Peridialysis time BP {Pre HD ((SBP 10.33 to 22.39, DBP 4.77 to 17.31) Median intradialytic(SBP-10.55 to 20.55, DBP-3.06 to10.10) & Post HD (SBP-3.44 to10.92, DBP-19.08 to 4.40)} had wide range of agreement with ABPM.

Conclusions: Home BP can be an alternative to ABPM for diagnosing HTN in HD patients considering it to be more practical compared to cumbersome ABPM. At dialysis unit, Median Intradylitic BP may be an alternative to ABPM for diagnosing HTN when home BP measurements are not available. Pre HD & Post HD BP measurements should not be used to make diagnosis & treatment of HTN in HD patients.

SA-PO510

Does Home Blood Pressure Monitoring Improve Blood Pressure in CKD?

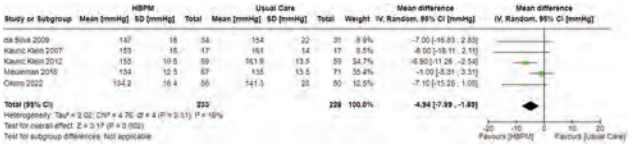
McKenna Eisenbeisz,[1] Nathan Carey,[2] Meenakshi Sambharia,[1] Sadaf Akbari,[1] Reem Mustafa,[3] Diana I. Jalal,[1] Thomas J. Wilkinson.[2] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]University of Leicester, Leicester, United Kingdom; [3]Kansas University Medical Center, Kansas City, KS.*

Background: Uncontrolled hypertension is a well-established risk factor for kidney disease progression, cardiovascular disease, and death in patients with chronic kidney disease (CKD). Home blood pressure monitoring (HBPM) is commonly utilized to optimize blood pressure (BP) control in the general population with hypertension. However, it is unclear whether HBPM improves BP control in CKD. We conducted a systematic review and meta-analysis of studies assessing the efficacy of HBPM in reducing BP in patients with CKD.

Methods: A multi-database search was completed to identify interventional studies that included HBPM as an intervention and included change in BP as an outcome. Additional studies were identified by internet and citation searches. Studies were not limited by country but were restricted to those printed in English.

Results: Of 12,100 abstracts screened, 13 manuscripts met the inclusion criteria and included 883 patients across the spectrum of CKD. Six studies included subjects with pre-dialysis CKD, 4 included subjects on hemodialysis, 2 included transplant patients, and one with a mixture of these groups. Eight out of the 10 manuscripts reported a significant change in systolic BP and 5 reported a significant change in diastolic BP. Two manuscripts reported increased achievement of goal BP. Notably, only 5 studies included a control arm and were included in the meta-analysis. Our results, shown in the **Figure**, indicate that HBPM improves systolic BP. Similar results were obtained for diastolic BP.

Conclusions: While few studies have evaluated if utilization of HBPM is effective in reducing BP in patients with CKD, results of this meta-analysis suggest that HBPM may improve BP control in CKD.



SA-PO511

Apelin Offers Cardiovascular and Renal Benefits in Health and CKD

Fiona A. Chapman, David E. Newby, Neeraj Dhaun. *The University of Edinburgh Centre for Cardiovascular Science, Edinburgh, United Kingdom.*

Background: Chronic kidney disease (CKD) affects 1 in 10 people and cardiovascular disease is its commonest endpoint. Despite standard-of-care, outcomes remain poor and new therapies are needed. Apelin, an endothelium-dependent vasodilator and inotrope, is a potential novel treatment. We examined the cardiovascular and renal actions of apelin in health and CKD.

Methods: Patients with stable, non-diabetic CKD and age- and sex-matched healthy volunteers were recruited to a randomized, double-blind, placebo-controlled study. Subjects received pyroglutamated apelin-13 ([Pyr^1]apelin-13 (1 nmol/min and 30 nmol/min) or placebo on two study visits. Blood pressure, impedance cardiography and pulse wave velocity were examined. Iohexol and para-aminohippurate clearances determined glomerular filtration rate (GFR) and effective renal blood flow (ERBF), respectively. Tubular function was assessed *via* urinary electrolyte and free water excretion.

Results: Twelve patients with CKD and 12 healthy volunteers were recruited. Baseline characteristics are shown in **Table 1.** Compared to placebo, in health and CKD 30 nmol/min [Pyr^1]apelin-13 reduced mean arterial pressure by ~3% and systemic vascular resistance index by ~10-15%, and increased cardiac index by ~10-15% ($p<0.05$ for all comparisons). In health and CKD, 1 nmol/min and 30 nmol/min [Pyr^1]apelin-13 had similar effects on renal endpoints. ERBF increased by ~15% ($p<0.01$ compared to placebo in both groups). In CKD only, GFR fell by ~4 mL/min, filtration fraction by ~3% and proteinuria by ~25% ($p<0.01$ compared to placebo for all). [Pyr^1]apelin-13 promoted natriuresis and free water clearance in health and CKD. Overall, the effects of apelin were prolonged in CKD.

Conclusions: Apelin has cardiovascular and renal benefits in CKD. If maintained long-term these would improve cardiovascular and renal outcomes. Clinical trials of long-acting oral apelin analogues are justified in CKD and other conditions with impaired salt and water balance.

Baseline characteristics

	Healthy volunteers	Chronic kidney disease
Age, years	48±4	48±4
Male sex (%)	8 (67)	8 (67)
Mean arterial pressure, mmHg	90±6	95±8
Systemic vascular resistance index, dynes*cm*cm-5 m2	2548±397	3013±613
Pulse wave velocity, m/s	5.8±0.2	6.6±0.3
Glomerular filtration rate, mL/min	98±5	41±5
Protein:creatinine ratio, mg/g	0	344(141-1273)

SA-PO512

Apelin Increases Forearm Blood Flow in CKD

Fiona A. Chapman, David E. Newby, Neeraj Dhaun. *The University of Edinburgh Centre for Cardiovascular Science, Edinburgh, United Kingdom.*

Background: Chronic kidney disease (CKD) is a global health emergency. It is independently associated with cardiovascular disease. Despite current treatment patients still progress to kidney failure and/or die from cardiovascular causes. There is an unmet need for newer therapies and apelin, an endothelium-dependent vasodilator and potent inotrope, is an attractive therapeutic target. Clinical studies find apelin improves endothelial function in health and heart failure. We examined the local vascular actions of apelin in CKD.

Methods: Patients with stable, non-diabetic CKD and age- and sex-matched healthy volunteers were recruited to a randomised, placebo-controlled study. Baseline blood pressure and pulse wave velocity were measured. Gold-standard venous occlusion plethysmography was used to examine endothelial function in response to incremental intra-arterial doses of acetylcholine (7.5, 15 and 30μg/min, endothelium-dependent vasodilation), sodium nitroprusside (1, 2 and 4μg/min, endothelium-independent vasodilation), and pyroglutamated apelin-13 ([Pyr^1]apelin-13; 0.3, 1, 3, 10, 30 and 100nmol/min). Circulating tissue plasminogen activator (tPA) and plasminogen activator inhibitor-1 assessed endogenous fibrinolysis.

Results: Fifteen patients with CKD (mean age 55±4 years; 53% male) and 15 healthy volunteers (mean age 51±3 years; 67% male) were recruited. In comparison to health, patients with CKD had a higher blood pressure (mean arterial pressure: 102mmHg *versus* 93mmHg, $p<0.05$) and increased pulse wave velocity (7.5±2.2 m/s *versus* 6.0±0.9m/s, $p<0.01$). Similar dose-dependent vasodilation to acetylcholine and sodium nitroprusside was seen in both groups. [Pyr^1]apelin-13 dose-dependently increased forearm blood flow to a maximum of ~30% in both health and CKD ($p<0.01$ compared to baseline for both). Net tPA antigen release increased 20-70 fold in both groups, with a trend to a greater release in CKD.

Conclusions: In optimally managed patients with CKD, apelin promotes vasodilation and may regulate fibrinolysis. If maintained longer-term with systemic treatment, apelin would reduce cardiovascular risk. Systemic studies are needed to investigate the haemodynamic and renal effects of apelin in CKD.

SA-PO513

Relationship Between Iron Deficiency and QTc Prolongation in Japanese Maintenance Hemodialysis Patients

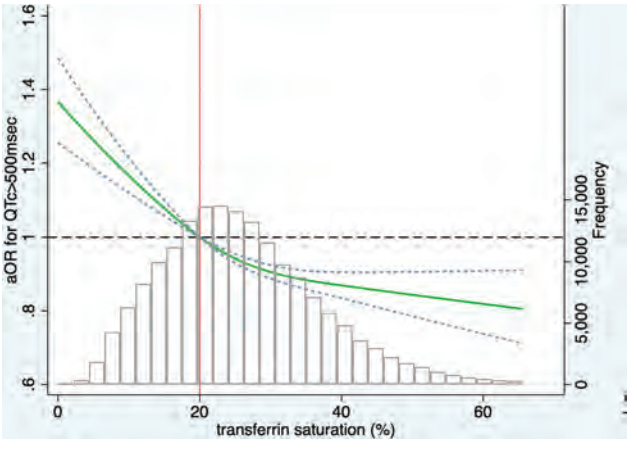
Kiichiro Fujisaki,[1] Sho Sasaki,[4] Toshiaki Nakano,[2] Nobuhiko Joki.[3] *[1]Iizuka Hospital, Iizuka, Japan; [2]Kyushu University, Fukuoka, Japan; [3]Toho University Ohashi Medical Center, Tokyo, Japan; [4]Kyoto University Hospital, Kyoto, Japan.*

Background: QT interval prolongation is a risk factor for fatal arrhythmias and other cardiovascular complications. Causes of QT interval prolongation in hemodialysis (HD) patients is not fully understood. It has also recently been reported that lower transferrin saturation (TSAT), one of the marker for iron deficiency, is associated with cardiovascular complications in patients with CKD. We hypothesize that iron deficiency may be associated with QT interval prolongation in HD patients.

Methods: We identified 175,448 eligible patients from a nation-wide database receiving thrice-weekly HD in Japan. The cross-sectional study was conducted on adult maintenance HD patients enrolled in the 2019 Japanese Society for Dialysis Medicine Annual Survey. Logistic regression analysis was performed with serum ferritin (S-fer) and TSAT as explanatory variable and QTc prolongation (QTc >500 msec) as outcome, adjusted for possible confounding factoes.

Results: A total of 175,448 patients were included in the analysis of this study. The mean QTc (standard deviation) was 451.7 (36.1) msec. 13,343 (7.6%) of subjects have suffered from QTc >500 msec. On multivariate analysis, the adjusted odds ratios [95% confidence interval] for QTc prolongation in the groups with TSAT ≤ 20% and S-Fer >100 ng/mL, TSAT ≤ 20% and S-Fer ≤ 100 ng/mL, TSAT > 20% and S-Fer ≤ 100 ng/mL with the group with S-Fer > 100 ng/mL and TSAT > 20% as the control group, were 1.12 [1.05, 1.20], 1.19 [1.14, 1.25] and 0.99 [0.95, 1.04], respectively. A J-curve relationship was observed between TSAT and QTc prolongation (Figure).

Conclusions: This study suggests that decreased TSAT (≤20%) may be associated with QTc prolongation in maintenance HD patients. Iron deficiency may play some role for prolonging ventricular repolarization time independent of other risks in HD patients.



A J-curve relationship was observed between TSAT and QTc prolongation

Characteristics and Prediction of Tumor Recurrence in Patients with Pheochromocytoma and Paraganglioma: A Single-Center Experience in Taiwan

Yi-Ran Tu,[1] Kun-Hua Tu.[1,2] *[1]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan.*

Background: Both pheochromocytoma and paraganglioma are rare catecholamine-producing neuroendocrine tumors. Surgical resection is the only curative treatment for these tumors. Patients receiving tumor resections, however, still probably encountered tumor recurrence. To our best knowledge, it's still with unclear clinical presentation of these catecholamine-producing tumor and lack of useful parameters to predict recurrence after tumor resection. The aim of this study is to find predictors of tumor recurrence in patients with these two rare neuroendocrine tumors.

Methods: This study was conducted at a tertiary medical center in Taiwan retrospectively. Data collection by chart review was undertaken in a 2000-bed private university hospital in Taiwan between January 2000 and December 2021. In total, 310 patients with pathologic diagnosis of pheochromocytoma or paraganglioma were enrolled.

Results: The study subjects were grouped as PCC and PGL and then further classified to sympathetic PPGLs and parasympathetic PPGLs according to the tumor origin. This study include 156 patients of PCC and 154 patients of PGL which larger tumor size, more symptoms of headache, arrythmia, diaphoresis, anxiety, and mass effects, more comorbidity of hypertension and hyperglycemia, higher urine epinephrine level, and higher renin level were significantly noted in patients with PCC. The other classification of the subjects including 247 patients with sympathetic PPGLs and 63 patients with parasympathetic PPGLs who have significant larger size of tumor, more symptoms of arrythmia, diaphoresis, body weight loss, and chest tightness without ischemic heart disease, and more comorbidity of hypertension and hyperglycemia in the group to sympathetic PPGLs. Of the subjects, there are 14 patients categorized as the

recurrent group, and 289 patients categorized as non-recurrent group. Comparing with non-recurrent group, recurrent group are younger (p=0.03407), and have more genetic ancestry (p=0.02062).

Conclusions: Our study demonstrates the characteristics of PCC and PGL and several clinical parameters such as age and genetic ancestry are associated with tumor recurrence after tumor resection in patients with PCC or PGL. It will help clinician to closely monitor disease status after tumor resection.

SA-PO515

Differences in Cardiovascular Phenotype and Pharmacotherapy Between Patients with ESKD Based on Transplant Eligibility

Sherna F. Adenwalla,[1] James Burton,[1,2] Daniel S. March,[1,2] Rachael Stannard,[3] Matthew Graham-Brown.[1,2] *[1]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [2]NIHR Leicester Biomedical Research Centre, Leicester, United Kingdom; [3]University of Leicester Department of Population Health Sciences, Leicester, United Kingdom.*

Background: Cardiovascular disease (CVD) is a major cause of death in end-stage kidney disease (ESKD) patients, linked to traditional and non-traditional risk factors. The ISCHAEMIA-CKD trial indicated no benefit from early invasive treatment for coronary artery is disease (CAD) in advanced kidney disease. Hence, optimizing conservative medical therapy is crucial. We conducted post-hoc analyses using CYCLE-HD trial data to compare structural and functional heart disease and pharmacotherapy in patients active and not active on the transplant waiting list.

Methods: 130 hemodialysis patients underwent cardiac MRI for comprehensive cardiovascular phenotyping (2015-18). Appropriate comparison tests were used depending on data distribution. If initial testing revealed a significant difference, ANCOVAs were used to adjust for age.

Results: 71/130 patients were active and 59/130 were not active on the transplant list. The 'active' group were younger (53 (40, 61) vs 66 (57, 75) years). 68% vs 79% were male, 69% vs 64% had hypertension, 20% vs 10% had dyslipidemia, 30% vs 48% had diabetes. There were no significant differences in medication use: 15% vs 8% on an ACE inhibitor or ARB, 48% vs 41% on a beta blocker, 50% vs 37% on a calcium channel blocker, 28% vs 32% on aspirin, 45% vs 61% on a statin. After adjusting for age, left ventricular (LV) ejection fraction, global longitudinal, and circumferential strain were significantly lower in the 'not active' group and LV mass index was higher (Table 1).

Conclusions: In this analysis, pharmacotherapy to mitigate CVD was poor irrespective of transplant listing status. CV phenotype was different between those listed and those not listed. Greater attention must be paid to optimising CV pharmacotherapy in both groups of patients to improve CV outcomes.

Table 1: Cardiac MRI characteristics

	Active, n=71	Not active, n=59	p-value*	ANCOVA
LV mass index (g/m²)	58 (48, 77)	60 (52, 76)	*	F= 3.8
Global native T1 (ms)	1269 ± 39	1280 ± 42		F=1.1
PWV (m/s)	7 (6, 9)	9 (7, 13)	*	F=0.0
LV ejection fraction (%)	57 (51, 62)	54 (41, 61)	*	F=8.9*
Global longitudinal strain (%)	-15 (-16, -12)	-13 (-15, -10)	*	F=7.3*
Global circumferential strain (%)	-17 (-19, -14)	-15 (-19, -12)	*	F=5.7*

Comparative Safety and Effectiveness of Statins in Kidney Transplant Recipients

Sunjae Bae,[1] Mark Schnitzler,[2] Krista L. Lentine,[2] Dorry L. Segev,[1] Mara McAdams-DeMarco.[1] *[1]New York University Grossman School of Medicine, New York, NY; [2]Saint Louis University, Saint Louis, MO.*

Background: Recent observational studies suggest that statins are well-tolerated and may lower all-cause mortality in kidney transplant recipients. A specific type of statin may be preferrable over other types, given the unique pathophysiological challenges in this population. We compared the safety and effectiveness outcomes between statins in a national cohort.

Methods: Using the USRDS data, we studied adult kidney transplant recipients in 2006-2018 who started atorvastatin, pravastatin, simvastatin, rosuvastatin, or lovastatin post-transplant. Those who used statins pre-transplant or had the outcome of interest before transplant or statin initiation were excluded. Those who used multiple statins were censored at the initiation of the second statin. We analyzed Medicare institutional claims to ascertain various safety/effectiveness outcomes (see Table 1) and Medicare pharmacy claims to ascertain statin use. Deaths were captured from multiple sources including Social Security and CMS data. We used Cox regressions to compare mortality and the safety/effectiveness outcomes between statins, after adjusting for multiple recipient-, donor-, and transplant-related risk factors.

Results: Our cohort included 16,967 recipients; 7,885 used atorvastatin, 4,065 used pravastatin, 3,617 used simvastatin, 1,207 used rosuvastatin, and 193 used lovastatin. Compared to atorvastatin users, pravastatin users showed lower risk of all-cause mortality (aHR=0.82 [95% CI; 0.72-0.94]), cardiovascular mortality (aHR=0.73 [95% CI; 0.55-0.98]), myocardial infarction (aHR=0.79 [95% CI; 0.62-1.00]), and hemorrhagic stroke (aHR=0.57 [95% CI; 0.33-0.98]). Simvastatin users showed lower risk of all-cause mortality (aHR=0.88 [95% CI; 0.78-0.98]), cardiovascular mortality (aHR=0.75 [0.58-0.97]), and hemorrhagic stroke (aHR=0.55 [95% CI; 0.35-0.86]). Other outcomes did not differ between statins (Table 1).

Conclusions: Pravastatin and simvastatin might be preferrable over atorvastatin in kidney transplant recipients. Further research addressing other cardiovascular risk factors and statin dose is needed.

Funding: NIDDK Support

Comparing Long-Term Blood Pressure Management in Kidney Transplant Patients: Immediate-Release vs. Extended-Release Tacrolimus

Chien-Wen Yang, Debbie L. Cohen. *University of Pennsylvania, Philadelphia, PA.*

Background: Tacrolimus (Tac) is a first-line anti-rejection medication with immediate-release (Tac IR) and extended-release (Tac ER) versions. Hypertension is a common adverse effect of Tac, but the longitudinal blood pressure control between kidney transplant recipients receiving Tac ER and Tac IR has never been studied.

Methods: A retrospective, single-center cohort study used data from the University of Pennsylvania Health System. Adult patients aged 18+ who started tacrolimus immediately after kidney transplantation between January 1st, 2016, and December 31st, 2019, were included. The primary outcome was time-varying systolic and diastolic blood pressure (SBP and DBP) documented through December 31st, 2021. Baseline and time-varying variables were collected, and the secondary outcome was the incidence of hypertensive crisis. Sensitivity analysis was performed using time-constant exposure based on the type of Tac patients received at four months post-transplant. A logistic regression model, a 3-step marginal structural model, and a 2-tailed Fisher's exact test were used for analysis.

Results: 654 patients with 16,382 BP entries were analyzed. Black patients were 2.32 times more likely to receive Tac ER (p=0.001). Patients taking Tac ER had a 1.87 mmHg lower SBP than those taking Tac IR (p=0.009), but no difference in SBP in the sensitivity analysis with a time-constant exposure at a 4-month cutoff. No significant differences were observed in DBP in both the main and sensitivity analyses. A total of 9 patients experienced a hypertension crisis; 8 were on Tac IR, and 1 was on Tac ER. No statistical difference in the occurrence of hypertension crises between the two groups was found.

Conclusions: Post-transplant patients taking Tac ER show a slightly lower SBP than those on Tac IR, without a significant difference in hypertensive crisis incidence.

Funding: Other NIH Support - pharmacoepidemiology T32

Evaluating Mean SBP and DBP in Patients on Tac ER vs Tac IR Through a Marginal Structural Linear Mixed Effects Model

Tac ER vs Tac IR	Coefficient (95% CI)	P value	Intra-cluster Variation
Time varying exposure			
SBP	-1.87 (-3.28, -0.47)	0.009	0.26
DBP	-0.31 (-1.25, 0.64)	0.527	0.37
Sensitivity analysis with 4 months cutoff

DBP	1.53 (-0.40, 3.45)	0.120	0.39

SA-PO518

Association Between Progression of Coronary Artery Calcification and Development of Kidney Failure with Replacement Therapy: Findings from KNOW-CKD Study

Cheol Ho Park,[1] Hyung Woo Kim,[1] Jung Tak Park,[1] Tae ik Chang,[2] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Seung Hyeok Han.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: A higher burden of coronary artery calcification (CAC) is a strong risk factor of adverse cardiovascular and kidney outcomes. However, clinical implications of longitudinal change in CAC remain unknown. Here, we evaluated whether the progression of coronary artery calcification can predict development of kidney failure with replacement therapy (KFRT).

Methods: A total of 1,173 participants with chronic kidney disease (CKD) G1 to G5 without kidney replacement therapy were included from KNOW-CKD (Korean Cohort Study for Outcomes in Patients With Chronic Kidney Disease). Participants were

categorized into 3 groups according to the change in CAC score between baseline and year 4 (non-progressors, ≤0 AU; moderate progressors, 1–199 AU; severe progressors ≥200 AU). The primary outcome was the development of KFRT.

Results: During a follow-up period of 4,690 person-years (median, 4.2 years), the primary outcome occurred in 230 (19.6%) participants. The incidence of KFRT was 37.6, 54.3, and 80.9 per 1000 person-years in non-, moderate, and severe progressors, respectively. In multivariable cause-specific hazard model, the hazard ratios (HRs) for the moderate and severe progressors were 1.77 (95% CI, 1.06–2.95) and 2.52 (95% CI, 1.06–6.00), respectively, compared with non-progressors. A sensitivity analysis using a different definition of CAC progression, with a threshold of 100 AU, also yielded similar results.

Conclusions: The progression of CAC was associated with an increased risk for development of KFRT in patients with CKD.

Additive Risk for Pericardial Effusion of Exposure to Either Hydralazine or Minoxidil and Advanced CKD

Giovanni Zlaket, Hannah T. Jordan, Rosemary Kovacic, Juan Carlos Q. Velez. *Ochsner Health, New Orleans, LA.*

Background: Vasodilatory antihypertensives hydralazine and minoxidil have been linked to the development of pericardial effusion. However, most of the available evidence comes from small cohort studies or case series. Furthermore, because advanced chronic kidney disease (CKD) is associated with uremic pericardial effusion, it is not clear whether hydralazine or minoxidil independently confer a risk for pericardial effusion in advanced CKD. We aimed to examine this question in a large patient database.

Methods: We retrospectively reviewed records of adult patients who underwent transthoracic echocardiography (TTE) between 2017 and 2022 to identify those diagnosed with pericardial effusion. Exposure to either hydralazine or minoxidil within 3 months prior to the TTE was probed, as well as demographic and clinical characteristics, including CKD status. Advanced CKD included stage 4 or 5 CKD or end-stage kidney disease. Cases of mesothelioma or tuberculosis were excluded.

Results: A total of 153,678 unique patients with TTE entered the analysis. Pericardial effusion was found in 1,441 (0.94%). By multivariate logistic regression, exposure to hydralazine [OR 1.58 (CI 1.4–1.8), p<0.0001)], exposure to minoxidil [OR 4.48 (CI 2.8–7.2), p<0.0001)], advanced CKD [OR 2.30 (CI 1.7–3.1), p<0.0001)], coronary artery disease [OR 1.21 (CI 1.1–1.4), p=0.0011)], and female sex [OR 1.33 (CI 1.2–1.5), p<0.0001)], were independently associated with increased risk of pericardial effusion, whereas age, race, diabetes mellitus and hypertension were not. The rate of pericardial effusion was greater in those exposed to vasodilators: 1.4% of hydralazine users (n=24,650) compared to 0.8% of nonusers (n=121,118) (p<0.0001), and 5.4% of minoxidil users (n=354) compared to 0.9% of nonusers (n=153,414) (p<0.0001). Among those with advanced CKD (n=2,337), the incidence of pericardial effusion was overall higher and significantly associated with exposure to either hydralazine (3.3% vs 1.7% for nonusers, p=0.022) or minoxidil (6.5% vs 2.1% for nonusers, p=0.043).

Conclusions: Hydralazine and minoxidil confer an increased risk for pericardial effusion that augments the increased risk associated with advanced CKD. Because these agents are frequently prescribed in advanced CKD, close monitoring is advised.

SA-PO520

Renalism: An Obstacle to Left Heart Catheterization in CKD Patients

Chapman Wei, Ahmad Mustafa, Fasih Sami Siddiqui, Radu C. Grovu, Shahkar Khan, Taqi A. Rizvi, John A. Afif, Gennifer Wahbah Makhoul, Joanne Ling, Nnedindu Asogwa, Nawal Mustafa, Mitchell Weinberg, Elie El-Charabaty, Suzanne E. El Sayegh. *Staten Island University Hospital, Staten Island, NY.*

Background: "Renalism" is the reluctance of clinicians to conduct contrast-based studies such as left heart catheterization (LHC) on individuals with chronic kidney disease (CKD). Non-ST-elevation myocardial infarction (NSTEMI) often requires LHC and delay can lead to increased mortality and adverse cardiovascular outcomes.

Methods: The National Inpatient Sample Database 2016-2018 was used to sample patients presenting with NSTEMI. Baseline demographics and comorbidities were collected using ICD-10-codes. Patients less than 18 years old, missing data, and with end-stage renal disease were excluded. Patients were stratified into CKD 1-2 vs CKD 3-5. 1:1 propensity matching was performed to match the two cohorts. Mortality and cardiovascular outcomes were compared in CKD 3-5 patients who underwent LHC and those who did not.

Results: Of 427,593 NSTEMI patients, 79,284 had CKD 3-5. CKD 3-5 patients were less likely to have LHC and had increased mortality. After matching, CKD 3-5 was independently associated with less LHC. During regression analysis, CKD 3-5 patientsthat underwent LHC were 2.9 times less likely to have in-hospital mortality compared to patients that did not undergo LHC. Additionally, LHC in CKD 3-5 patients was also associated with decreased cardiovascular outcomes and acute kidney injury (p<0.001).

Conclusions: Alteration in practice-based guidelines due to risk of contrast-induced nephropathy leads to less LHC in CKD patients and increased mortality and adverse cardiovascular outcomes. Further studies are needed to evaluate the risks and benefits of contrast-based studies in this patient cohorts.

Outcomes of CKD Stage 3-5 patients that underwent left heart catheterization

Outcomes	P-value	Odds Ratio	Lower 95% CI	Upper 95% CI
Unmatched				
Mortality	<0.001	0.390	0.352	0.432
Acute Kidney Injury	<0.001	0.651	0.626	0.678

Cardiovascular Risk Prediction Improvement Using Algorithm- or Formula-Based Pulse Wave Velocity: Analysis of CARTaGENE

Louis-Charles Desbiens,[1,3] Annie-Claire Nadeau-Fredette,[1,3] Bernhard Hametner,[4] Francois Madore,[1,2] Mohsen Agharazii,[5] Remi Goupil.[1,2] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [3]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [4]Austrian Institute of Technology GmbH, Wien, Austria; [5]Centre Hospitalier Universitaire de Quebec-Universite Laval, Quebec, QC, Canada.*

Background: Carotid-femoral pulse wave velocity (PWV) is the gold-standard measurement for aortic stiffness and a well-established surrogate marker for cardiovascular disease. Faster and less resource-intensive methods to estimate PWV (using either formulas or integrated pulse wave analysis algorithms) have been developed but their incremental predictive value for cardiovascular outcomes remains unclear.

Methods: We studied individuals aged between 40 and 69 from the population based CARTaGENE cohort (Quebec, Canada). Baseline PWV was assessed using a previously described estimation formula (formula- based PWV, or f-PWV; using age, sex, and systolic blood pressure) or estimated with the ARCSolver algorithm from central waveform characteristics obtained with the SphygmoCor device (algorithm-based PWV, or a-PWV). Major adverse cardiovascular events (MACE: cardiovascular mortality, non- fatal stroke, non-fatal myocardial infarction) during a 10-year follow-up were obtained from medico-administrative databases. Cox proportional hazards models were employed to obtain associations between PWV and MACE after adjustment for existing cardiovascular risk prediction scores (ASCVD [from revised pooled cohort equations], SCORE-2).

Results: 17,548 individuals were included and 2,263 experienced a MACE during follow-up. Mean PWV values at baseline were 8.4 ± 1.4 m/s (f-PWV) and 7.9 ± 1.3 m/s (a-PWV). Both f-PWV (HR= 1.52, 95% CI [1.47-1.58]) and a-PWV (HR=1.60 [1.54-1.66]) were predictive of MACE in unadjusted models. The association between a-PWV and MACE remained significant after adjustment for ASCVD (HR= 1.14 [1.08-1.20]) and but not after adjustment for SCORE-2 (HR= 1.06 [1.00-1.13]). In contrast, f-PWV was not associated with increased MACE after adjustment for either prediction score (HR= 1.02 [0.97-1.08] for ASCVD; HR= 0.95 [0.89-1.00] for SCORE-2). Similar trends were observed after stratification for tertiles of baseline cardiovascular risk.

Conclusions: Algorithm-based PWV, but not formula-based PWV, improves cardiovascular prediction beyond what is achievable with recognized prediction tools.

SA-PO522

Rates and Outcomes of Cardiac Surgery for People Receiving Long-Term Dialysis or Kidney Transplantation in Australia

Stephen P. McDonald,[1,6] Dominic Keuskamp,[1,6] Christopher E. Davies,[1,6] Julian A. Smith,[2,5] Robert A. Baker,[3,4] Christopher M. Reid,[2] Jenni Williams-Spence,[2] Lavinia Tran,[2] Kevan Polkinghorne.[2,5] *[1]Australia and New Zealand Dialysis and Transplant Registry, Adelaide, SA, Australia; [2]Monash University, Clayton, VIC, Australia; [3]Flinders University, Adelaide, SA, Australia; [4]Southern Adelaide Local Health Network, Bedford Park, SA, Australia; [5]Monash Medical Centre Clayton, Clayton, VIC, Australia; [6]University of Adelaide, Faculty of Health and Medical Sciences, Adelaide, SA, Australia.*

Background: Rates of coronary artery disease and cardiac valve disorders are higher among people with kidney failure (KF). Cardiac surgery (CS - coronary artery bypass grafting [CABG] and valve replacement surgery) are important treatment options for these, but may carry substantial risks. Utilising data linkage of two registries with national coverage, we examined rates and outcomes of CS among patients receiving long term dialysis or with a kidney transplant.

Methods: Data were linked probabilistically between the Australia & New Zealand Dialysis & Transplant Registry and the Australian & New Zealand Society of Cardiac & Thoracic Surgeons Cardiac Surgery Database. Thirty-day mortality adjusted for risk factors was compared for 3 groups based on status at time of surgery (dialysis / kidney transplant / non-kidney failure [KF]) using multiple logistic regression. The study population included all eligible CS in Australia from 2001-2019.

Results: Demographics are shown in the Table. Crude 30-day mortality was highest among the dialysis group then the transplant and non-KF groups. Mortality progressively improved over time. Adjusted for procedure type and other comorbidites, excess mortality persisted for the KF groups. The odds ratio for 30 day mortality for CS in the dialysis group was 3.4 [2.7-4.2] and for the transplant group was 2.4 [1.4-4.2]. Adjusted analyses

showed increased risk of mortality were seen for valve replacement (vs CABG), urgent surgery, comorbidities and those with greater dialysis vintage. Mortality at 24 months was 32 [29-35]% for the dialysis group and 16 [12-20]% for the transplant group.

Conclusions: Among KF patients requiring CS, early mortality rates are substantially increased, especially when other comorbidities are present or surgery is urgent. While the risks of not operating are not known for these cohort, these data will inform and support careful consideration of the risks of cardiac surgery in this group.

Funding: Government Support - Non-U.S.

	Dialysis	Transplant	Non-KF
Number	1639 (74% male)	353 (75% male)	150741 (73% male)
Age (median (IQR) ; years)	63 (55-71)	64 (55-69)	68 (59-71)
Diabetes (%)	58	44	29
Procedure type (Isolated CABG / Isolated valve replacement / combined)	955/301/244	131/98/55	80606/30754/15298
Unadjusted 30 day mortality [95% CI]	6.5 [5.3-7.8]%	4.5 (26-7.3)%	2.2 (2.1-2.3)%

SA-PO523

Association of CKD and Cardiovascular Disease Risk with All-Cause Mortality: A Mediation Analysis in Chinese Adults

Yang Li. *Zhongshan Hospital Fudan University, Shanghai, China.*

Background: To evaluate the complex relationship of chronic kidney disease (CKD) and cardiovascular disease (CVD) risk with mortality in different age groups and the mediation effect of CVD risk among Chinese adults.

Methods: A total of 7533 participants from the China Health and Nutrition Survey (CHNS) cohort were included in this study. CKD was defined as eGFR <60 mL/min/1.73m^2. Framingham risk score (FRS) was used to assess CVD risk. The interaction, joint association of CVD risk and CKD on mortality, and subsequent mediation effect were evaluated using multivariable Cox regression.

Results: CHNS cohort recorded 266 deaths over a mean follow-up time of 5.04 years. The all-mortality rates among adults with CKD and high CVD risk were significantly higher than healthy controls (22.48 and 21.30 per 1000 person-years). The adjusted hazard ratios (aHR) were 1.70 (95% CI 1.27-2.28) and 1.62 (95%CI 1.26-2.09), respectively. There was a negative interaction between CKD and CVD risk on mortality. The association between CKD and mortality was stronger in low+medium CVD risk group (aHR=1.87, 95% CI 1.20-2 .91). Besides, mortality hazard was highest in CKD patients with high CVD risk (aHR=3.14, 95% CI 1.92-5.14). Mediation analysis showed that CVD risk mediated 33.4% of the effect of CKD on all-cause mortality (p<0.001). After adjusting for the moderator of age, the mediation proportion was 7.2%-10.3%.

Conclusions: Comprehensive strategies including lifestyle modifications, diet restrictions, and cardio-nephrology multidisciplinary treatment for mitigating CVD risk in CKD patients should focus on middle-aged people and early disease detection.

Constipation and Risk of Death and Cardiovascular Events in Hemodialysis Patients

Juyoung Jung,[1,2] Sang-Cheol Park,[3] Hye Min Choi,[1,2] Dong-jin Oh,[1,2] Young Eun Kwon,[1,2] Song in Baeg,[1,2] Hyokyeong Yu.[1,2] *[1]Myongji Hospital, Goyang, Gyeonggi-do, Republic of Korea; [2]Hanyang University College of Medicine, Seongdong-gu, Seoul, Republic of Korea; [3]Artificial Intelligence and Robotics Laboratory, Myongji Hospital, Goyang, Republic of Korea.*

Background: Constipation is common in dialysis patients and primary care. Recent studies have disclosed its independent associations with the increased risk of mortality or cardiovascular disease in the general population. In this study, we aimed to investigate the association of constipation with clinical outcomes using a large cohort of hemodialysis (HD) patients in Korea.

Methods: This retrospective, population-based cohort study used HD quality assessment data from the Korean Health Insurance Review and Assessment (HIRA) during the period between January 2015 and June 2021. Public medical insurance registration is mandatory in Korea, and HIRA is an independent agency that reviews and assesses healthcare benefit costs. Constipation was defined as the number of total prescribed laxatives of ≥ 180 during the baseline one year period. The primary endpoint was evaluated as the development of all-cause mortality and cardiovascular events including myocardial infarction (MI) and stroke. Each event was identified as the relevant International Classification of Disease (ICD)-10 diagnosis as the major diagnostic code and procedural codes for the health insurance claims.

Results: A total of 35,230 patients over the age of 19 years old were included in the study, and the mean follow-up period was 54.2 month. Overall, 25.9% of HD patients were identified as having constipation, which seemed to be higher than the reported 15-20% in the general population. The most frequently used laxatives were lactulose/lactitol. In Cox proportional hazard model, constipation was associated with increased all-cause mortality (hazard ratio [HR], 1.16; 95% confidence interval [CI], 1.09–1.23) and ischemic stroke (HR, 1.16; 95% CI, 1.0.–1.32) after multivariable adjustment for demographics, prevalent comorbidities, and medications. Constipation was not significantly associated with MI and hemorrhagic stroke after multivariable adjustments although the crude cumulative incidence of each was higher in patients with constipation.

Conclusions: Constipation was associated with higher risk of all-cause mortality and incident ischemic stroke independently of known cardiovascular risk factors in prevalent HD patients. Further studies are needed to determine whether constipation serve as one of the indicators of poor health or is a possible causal factor to cardiovascular disease.

SA-PO525

The Role of Blood Pressure Load in Ambulatory Blood Pressure Monitoring in Adults: A Review of Current Evidence

Ophir Eyal, Iddo Z. Ben-Dov. *Hadassah University Medical Center, Jerusalem, Israel.*

Background: In the field of ambulatory blood pressure monitoring (ABPM), the concept of the blood pressure load (BPL), defined as the percentage of readings above a certain threshold, has been in general use since the 1990s. However, the benefits of using this index in adults have not been clearly demonstrated, and accordingly it has not been integrated into the major blood pressure diagnosis and treatment guidelines. In this manuscript, we present the first comprehensive review of the current evidence regarding the possible associations of BPL with target organ damage and clinical outcomes, the major determinants for its role and utility in blood pressure measurement. We put a particular emphasis on studies exploring whether BPL has added benefit to the mean blood pressure indices.

Methods: Our review is based on a search of PubMed for all articles containing the combination of the MeSH term "Blood Pressure Monitoring, Ambulatory" and "blood pressure load" or "BP load", last performed on April 13th, 2023. We also scanned the references from articles found on the PubMed search. We included all the articles for which we could find full text in English examining the associations of BPL as defined above with clinical outcomes or organ damage.

Results: While a couple dozen studies aimed to assess the association of the blood pressure load with target organ damage, the cumulative sample size is small. Almost all of the studies are retrospective, and none are interventional. Though the associations of the BPL with various measures of target organ damage are evident, the available literature fails to demonstrate a clear and consistent added value for the BPL over the mean blood pressure indices.

Conclusions: The BPL has been a part of the ABPM report for more than 3 decades worldwide, yet we have found no previous paper reviewing the evidence for its use. Based on our analysis, we summarize that while the associations of BPL with target organ damage are clear, it is inconclusive whether the addition of BPL to the mean blood pressure indices has any advantage. There is a clear need for further research in this field, including large-scale prospective trials with long-term follow-up to elucidate the possible benefits of incorporating BPL into clinical practice.

SA-PO526

Why We Treat Asymptomatic Blood Pressure Elevations in the Hospital

Muna T. Canales,[1,2] Sandra W. Citty,[1,3] David E. Winchester,[1,2] I. M. Freytes.[1] *[1]VA North Florida South Georgia Veterans Health System, Gainesville, FL; [2]University of Florida College of Medicine, Gainesville, FL; [3]University of Florida Health, Gainesville, FL.*

Background: In the hospital, asymptomatic blood pressure elevations (ABPE) are often treated with Pro Re Nata blood pressure medications (PRNBP). There is no evidence to support this practice, and recent literature suggests it may be harmful. Provider and nursing rationale and motivations for treating ABPE are not well understood.

Methods: We recruited clinical providers and nurses from inpatient non-ICU settings for 1 on 1 semi-structured interviews. Based on the Theoretical Domain Framework Interviews were coded in a rolling fashion by a multidisciplinary group until theme saturation was achieved.

Results: We interviewed 10 providers (years in role): 5 internal medicine/hospitalist physicians (10-22), 1 midlevel provider (8), 4 housestaff (2-7); and 6 nurses (1.7-4 years). Definitions for HTN "emergency" vs "urgency" varied within each group with respect to threshold for definition and for treatment. Providers and nurses felt that treatment varied by patient factors and nursing experience or stress level, while nurses felt there was variability by provider. All noted hospital factors that could affect BP including pain, stress, measurement technique, diet, substance abuse, and missed medications. Most providers felt that using PRNBP would lead to more harm than good, though some noted benefit to titrate scheduled medications, quick nursing response and less calls to doctor. Some providers feared being viewed as negligent by nursing or patients if they did not treat. Factors related to rapid response thresholds and need for MD to push IV medications at the bedside also influence provider and nursing actions. Nurses cited goal of keeping vitals in the normal range using PRNBP. Some providers felt guidelines needed regarding thresholds for treatment of inpatient ABPE. For buy in from providers, education of providers and nursing regarding new literature to support guidelines would be helpful to change practice. A few providers stated that adding alerts in the medical record or penalties to change practice is not desirable while another said alerts would be helpful. Nurses did not feel a need for any change to practice save to make PRNBP more accessible in the computer system.

Conclusions: Education of providers, nursing and patients regarding goals for ABPE with an algorithm for an approach to management may be helpful to optimize treatment of ABPE in the hospital.

Health Care Utilizations and Costs in the Year Following an Incident Major Thrombotic Cardiovascular Event (MTCVE) in Patients with and Without ESKD

Alejandro Victores,[1] Lori D. Bash,[1] Nicholas S. Roetker,[2] Dena Rosen R. Ramey,[1] James B. Wetmore,[2] Marc P. Bonaca.[3] *[1]Merck & Co Inc, Rahway, NJ; [2]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN; [3]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Background: Patients with end-stage kidney disease (ESKD) are at higheran elevated risk of major thrombotic cardiovascular events (MTCVEs) and use moresubstantial healthcare resources than compared to patients without ESKD. There is limited information on costs following MTCVEs in patients with ESKD.

Methods: Cohorts of Medicare fee-for-service beneficiaries aged ≥66 years were created using data from the US Renal Data System (USRDS) for ESKD patients receiving in-center hemodialysis (HD) and a 20% sample of Medicare claims for non-ESKD patients. We included patients experiencing a new MTCVE (myocardial infarction, ischemic stroke, venous thromboembolism, or critical limb ischemia) between 2015-2018. Adjusted all-cause healthcare resource utilization (HCRU) and cost outcomes were assessed for 1 year following the index event.

Results: Table 1 and Figure 1 detail HCRU and costs, respectively, in the year following each type of MTCVE. Patients with ESKD had much higher rates of all-cause hospitalization than non-ESKD patients, with the largest magnitude of difference in patients with VTE. Rates of ICU admissions, inpatient days, emergency and outpatient encounters were significantly higher in ESKD patients even after demographic adjustment. Adjusted costs of care were higher in ESKD patients compared with non-ESKD patients across all encounter and MTCVE types, with some variation in costs attributable to specific encounter types.

Conclusions: In the year after an incident MTCVE, patients with ESKD had significantly higher all-cause HCRU and costs of care than non-ESKD patients who experienced the same type of MTCVE. These differences persisted even after adjustment.

Funding: Commercial Support - Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA

Evaluation of Plasma Sphingolipids as Mediators of the Relationship Between Kidney Diseases and Cardiovascular Events

Benjamin Lidgard,[1] Nisha Bansal,[1] Leila R. Zelnick,[1] Andrew N. Hoofnagle,[1] Amanda M. Fretts,[1] W. T. Longstreth,[1] Michael Shlipak,[2,3] Jason G. Umans,[4] Rozenn Lemaitre.[1] *[1]University of Washington, Seattle, WA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]University of California San Francisco, San Francisco, CA; [4]Georgetown University, Washington, DC.*

Background: Patients with chronic kidney disease (CKD) are at higher risk for cardiovascular events. Sphingolipids are a family of circulating lipids with regulatory and signaling roles that are strongly associated with both eGFR and cardiovascular disease. We examined whether circulating sphingolipids partially mediate the associations between eGFR and cardiovascular events.

Methods: We measured the circulating concentrations of 4 ceramides and 4 sphingomyelins with the fatty acids 16:0, 20:0, 22:0, and 24:0, in plasma from 3,463 participants in the Cardiovascular Health Study without prevalent cardiovascular disease. We tested the adjusted mediation effects by these sphingolipids of the associations between eGFR and incident cardiovascular disease via quasi-Bayesian Monte Carlo method with 2,000 draws, using a Bonferroni-corrected p value for significance of 0.00625.

Results: The mean (±SD) eGFR was 70 (±16) mL/min/1.73 m², and the mean age was 76 (±5) years. Lower eGFR was associated with higher plasma ceramide and sphingomyelin 16:0, and lower ceramides and sphingomyelins 20:0 and 22:0. Lower eGFR was associated with risk of incident heart failure and ischemic stroke, but not myocardial infarction. Five of eight sphingolipids partially mediated the association between eGFR and heart failure. The strongest mediators were ceramide-16:0 (proportion mediated 14%, 95% CI 8-23%) and sphingomyelin-16:0 (proportion mediated 10%, 95% CI 5-17%). No sphingolipids significantly mediated the association between eGFR and ischemic stroke (**Table**).

Conclusions: Plasma sphingolipids partially mediated the association between lower eGFR and incident heart failure. Altered sphingolipids metabolism may contribute to heart failure in patients with CKD.

Funding: NIDDK Support, Other NIH Support - NHLBI: R01 HL128575, and R01 HL111375, Private Foundation Support

Table: Mediation by individual sphingolipids of the associations between eGFR and cardiovascular outcomes using a quasi-Bayesian Monte Carlo method with 2,000 draws

Sphingolipid	Heart failure		Ischemic Stroke	
	Proportion mediated (95% CI)	p-value	Proportion mediated (95% CI)	p-value
Ceramide-16:0	**0.14 (0.08, 0.23)**	**<0.001**	-0.05 (-0.15, 0.00)	0.04
Ceramide-20:0	0.04 (0.01, 0.09)	0.02	0.03 (-0.12, 0.28)	0.54
Ceramide-22:0	**0.04 (0.01, 0.09)**	**<0.001**	0.01 (-0.09, 0.17)	0.58
Ceramide-24:0	0.02 (0.00, 0.05)	0.07	0.01 (-0.05, 0.11)	0.57
Sphingomyelin-16:0	**0.10 (0.05, 0.17)**	**<0.001**	0.00 (-0.17, 0.18)	0.96
Sphingomyelin-20:0	**0.04 (0.01, 0.08)**	**0.002**	0.00 (-0.10, 0.11)	0.95
Sphingomyelin-22:0	**0.07 (0.03, 0.13)**	**<0.001**	0.02 (-0.10, 0.24)	0.55

Plasma Uromodulin and Cardiovascular Outcomes in Adults with Hypertension and CKD

Jesse C. Ikeme,[1,2] Rebecca Scherzer,[1,2] Pranav S. Garimella,[3] Michelle M. Estrella,[1,2] Joachim H. Ix,[3,4] Michael Shlipak.[1,2] *[1]University of California San Francisco, San Francisco, CA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]University of California San Diego, La Jolla, CA; [4]VA San Diego Healthcare System, San Diego, CA.*

Background: Uromodulin (UMOD) is an emerging kidney tubule biomarker that may improve identification of persons at elevated cardiovascular (CV) risk beyond conventional markers. We evaluated the association of plasma UMOD with CV outcomes in CKD.

Methods: This was a secondary analysis of the Systolic Blood Pressure Intervention Trial (SPRINT), in which an intensive systolic blood pressure (SBP) target reduced risk of CV events and mortality. We measured plasma UMOD at baseline in participants with eGFR <60 ml/min/1.73 m² (N = 2302) and evaluated its association with a composite primary outcome of nonfatal myocardial infarction (MI), acute coronary syndrome without MI, acute decompensated heart failure (HF), stroke or CV death. Hazard ratios (HR) were estimated using Cox proportional hazards models adjusted for demographic and clinical variables, including eGFR and albuminuria.

Results: Median follow-up was 3.9 years, mean eGFR was 46 (IQR: 36–55) mL/min/1.73 m² and median plasma UMOD was 17.2 (IQR: 12.3–23.2) ng/ml. In the lowest UMOD quartile, 105 out of 575 (18.3%) experienced the primary outcome compared to 57 out of 575 (9.9%) in the highest. After multivariable adjustment, higher UMOD was not significantly associated with the primary outcome in the overall cohort. Of the component outcomes, each SD higher UMOD was associated with 30% lower risk of stroke (HR 95%CI: 0.51–0.95, p <.01) only. The association of UMOD with the primary and HF outcomes differed by eGFR (p for each interaction <.05) (Figure). Each SD higher UMOD was associated with 24% lower risk of the primary outcome (HR 95%CI: 0.63–0.91) and 33% lower risk of HF (HR 95%CI: 0.51–0.89) in those with eGFR <45 ml/min/1.73 m² (p <.01 for both), but not among those with eGFR ≥45 ml/min/1.73 m².

Conclusions: Higher plasma UMOD in hypertensive persons with CKD is associated with lower risk of stroke and, among those with lower eGFR, lower risk of CV and HF events.

Association of Serum Magnesium with Atrial Fibrillation in Patients Requiring Peritoneal Dialysis

Kenji Nakata,[1] Tatsunori Toida,[2,3] Noriaki Kurita,[3,4] Nobuhiko Joki.[1] *[1]Toho Daigaku Iryo Center Ohashi Byoin, Meguro-ku, Japan; [2]Kyushu Hoken Fukushi Daigaku, Nobeoka, Japan; [3]Fukushima Kenritsu Ika Daigaku Igakubu Daigakuin Igaku Senko, Fukushima, Japan; [4]Fukushima Kenritsu Ika Daigaku Fuzoku Byoin, Fukushima, Japan.*

Background: It has been known that morbidity of atrial fibrillation (AF) in chronic kidney disease is higher than in general population. Age, obesity, diabetes mellitus (DM), and cardiovascular disease, these are thought to be one of the risk factors of AF. Hypomagnesemia is also potential risk factor of AF in hemodialysis patients, while it has not been studied in peritoneal dialysis (PD) patients. Hence, we examined association between of serum magnesium (sMg, mg/dL) with AF.

Methods: A nation-wide, cross-sectional study was performed by using data from Japanese Renal Data Registry, which encompasses a nationwide population dialysis centers, corrected at the end of 2019. The inclusion criteria were as follows: only PD patients, aged≥20. The exclusion criteria were as follows: missing data for Mg and history of AF. Among 332599 dialysis patients, 2366 PD patients were enrolled into this study finally. They were divided three groups according to the lower and upper level of sMg general reference value of 1.8 and 2.6, named low-, normal-, and high-sMg group respectively. Odds ratio (OR) for AF was calculated in each group compared with normal-sMg group by logistic regression analysis. AF was diagnosed by rest 12-leads electrocardiogram.

Results: Mean age was 63±13 years, 65.1% of them were male, 47.8% had DM. Mean sMg level was 2.14±0.58, and 4.3% had AF. In unadjusted model, the odds for AF was significantly increasing in low-sMg group compared with normal-sMg group (OR 2.23, p=0.0003), while high-sMg group did not show significant increment or decrement of OR for AF. After adjusting of confounding variables of age, sex, DM, and current smoker, same trend had seen between low and norml sMg groups.

Conclusions: Hypomagnesemia was closely associated with AF in PD patients. Preventing hypomagnesemia may reduce the incidence of AF in PD patients. We may need to monitor the sMg level regularly and pay attention more to hypomagnesemia to prevent AF in PD patients.

Biomarkers of Kidney Tubule Health and Retinal Microvascular Signs: The Multi-Ethnic Study of Atherosclerosis

Hassan Gorji,[1] Ronit Katz,[2] Jason W. Yang,[1] Stacy M. Meuer,[6] Orlando M. Gutierrez,[3] Mark J. Sarnak,[5] Michael Shlipak,[4] Joachim H. Ix,[1] Rakesh Malhotra.[1] *[1]University of California San Diego, La Jolla, CA; [2]University of Washington, Seattle, WA; [3]The University of Alabama at Birmingham, Birmingham, AL; [4]University of California San Francisco, San Francisco, CA; [5]Tufts Medical Center, Boston, MA; [6]University of Wisconsin-Madison, Madison, WI.*

Background: Both the retina and kidney can be damaged by microvascular disease. Here, we examined the association between biomarkers for kidney tubule health and retinal microvascular signs in persons who participated in The Multi-Ethnic Study of Atherosclerosis (MESA).

Methods: Among 470 MESA participants, we measured 6 plasma biomarkers of kidney tubule health: KIM-1, MCP-1, SuPAR, TNFR 1 and 2, and YKL-40 and 6 urinary biomarkers of kidney tubule health: A-1MG, EGF, IL-18, KIM-1, MCP-1, and YKL-40. Retinal microvascular measurements were assessed from fundus photography: central retinal arteriolar and venular equivalents (CRAE and CRVE, respectively). We used multivariable linear regression models to test the associations between kidney tubule health markers and CRAE and CRVE. Final model was adjusted for age, race, gender, BMI, hypertension, LDL, HDL, smoking, urine albumin, urine creatinine and eGFR.

Results: Mean age was 60±10 years and mean eGFR was 92±13ml/min/1.73m². The prevalence of HTN and current smoking was 36% and 14%, respectively. The mean CRAE and CRVE was 144±14 μm and 214±21 μm, respectively. In adjusted continuous models, each 1 SD higher plasma KIM-1, and urine KIM-1 concentrations were individually associated with narrower CRAE. Each 1 SD higher plasma SuPAR concentrations were individually associated with wider CRAE and CRVE (Figure). There was no significant association between remaining biomarkers and CRAE and CRVE.

Conclusions: In this study of community-living individuals without CKD, diabetes, or CVD, selected kidney tubule health markers are associated with subtle retinal microvascular changes. These findings suggest that microvascular disease may impact the kidney tubules, above and beyond the glomerulus.

Table: Association of plasma and urine biomarkers with retinal microvascular changes among MESA participants.

Subclinical Primary Aldosteronism and eGFR Decline

Gregory L. Hundemer,[1] Mohsen Agharazii,[2] Francois Madore,[3] Remi Goupil.[3] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]Universite Laval, Quebec, QC, Canada; [3]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada.*

Background: Primary aldosteronism (PA), characterized by renin-independent aldosterone secretion, is the most common and modifiable form of secondary hypertension. Overt PA predisposes to disproportionately high rates of cardiovascular and kidney disease, independent of blood pressure (BP). Growing evidence suggests that milder forms of renin-independent aldosteronism (ie, Subclinical PA) are highly prevalent yet their clinical significance remains uncertain.

Methods: Prospective study of 536 participants aged 40-69 yr and on no BP medications from the randomly sampled, population-based CARTaGENE cohort (Canada). Using aldosterone and renin levels from enrollment, we employed multivariable linear regression models to measure the association between the aldosterone-renin ratio (ARR) and eGFR (via the 2021 CKD-EPI$_{Cr/CysC}$ equation) measured at enrollment and after 5-7 years of follow-up.

Results: The mean (SD) age, eGFR, and systolic BP were 55 (7) years, 107 (13) mL/min/1.73m^2, and 132 (11) mmHg, respectively. Higher ARR was successively associated with steeper annual eGFR decline with ARR Tertile 3 having a 74% steeper decline than ARR Tertile 1 (1.18 vs. 0.68 mL/min/1.73m^2/yr, P=0.01; **Fig. 1**). On multivariable linear regression, higher ARR was associated with steeper annual eGFR decline (P=0.03; **Fig. 2**).

Conclusions: In a randomly sampled, population-based cohort of individuals on no antihypertensive medication, Subclinical PA was associated with steeper eGFR decline, independent of BP. Subclinical PA may serve as a potentially modifiable risk factor to prevent or slow CKD.

FIGURE 1: ANNUAL EGFR DECLINE BY ARR TERTILE

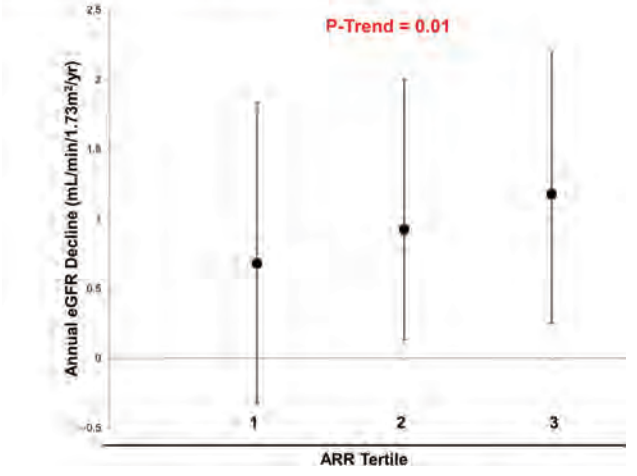

FIGURE 2: ARR AND eGFR ASSOCIATIONS

SA-PO534

Galectin-3 and Mortality in Relation to Vascular Calcification in Incident Hemodialysis Patients

Ji Hwan Kim,[1] Jwa-kyung Kim,[1] Sung Gyun Kim,[1] Jinha Jang,[1] In Soo Kim,[1] Sung Jin Moon.[2] *[1]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [2]Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea.*

Background: Vascular calcification is a recognized risk factor for mortality in hemodialysis patients. Galectin-3 (Gal-3), a key regulator of fibrosis, inflammation, and cell proliferation, has been implicated in adverse outcomes in several pathological conditions such as heart failure and chronic kidney disease. The study aims to determine whether elevated Gal-3 levels may affect vascular calcification and how these effects may contribute to mortality risk in hemodialysis patients.

Methods: Serum Gal-3 was measured in patients from the incident hemodialysis cohort (n=477, age 68.5 ± 12.6 years) and the cut-off value for predicting mortality was estimated by area under the receiver operating characteristic (ROC) curve (AUC). The extent of aortic arch calcification (AAC) was assessed by chest X-ray. We performed a causal mediation analysis to investigate the effect of Gal-3 on mortality via vascular calcification. Mortality data were obtained with a median follow-up of 42 months.

Results: Serum Gal-3 levels were closely associated with age (r=0.131, p=0.004), coronary artery disease history (r=0.117, p=0.010), brain natriuretic peptide levels (r=0.154, p=0.004), high-density lipoprotein (HDL) cholesterol (r=-0.176, p=0.001), high-sensitivity C-reactive protein (hs-CRP) (r=0.183, p=0.002), and AAC score (r=0.249, p<0.001). At a cut-off level of 37.0 ng/mL, the AUC for predicting mortality was 0.718 with sensitivity and specificity of 60.2% and 74.7%, respectively. Multivariate Cox regression analysis showed that higher Gal-3 levels increased all-cause mortality by 2.2-fold (95% confidence interval [CI] 1.38-3.45, p=0.001). The results of the mediation analysis suggested that this association was partially mediated by vascular calcification. Both the indirect effect between Gal-3 and mortality through vascular calcification (β=0.0068, bootstrapped 95% CI 0.0020-0.0138) and the direct effect of the Gal-3 on mortality (β=0.0370, bootstrapped 95% CI 0.0205-0.0594) were significant.

Conclusions: This study suggests a possible mechanism linking serum Gal-3 and increased mortality in hemodialysis patients, providing evidence for a significant role of Gal-3 in vascular calcification.

SA-PO535

Dialysis Transition in Patients with and Without Heart Failure in a CKD Population

Simran K. Bhandari, Katherine J. Pak, Hui Zhou, Sally F. Shaw, Jiaxiao Shi, Benjamin Broder, John J. Sim. *Kaiser Permanente Southern California, Los Angeles, CA.*

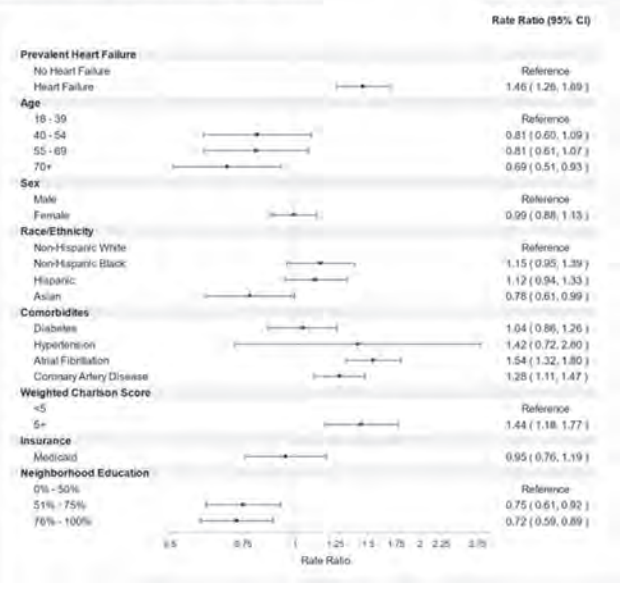
Background: CKD and heart failure (HF) frequently coexist and are associated with worsened outcomes. We sought to compare CKD patients with and without HF who transitioned to dialysis.

Methods: Retrospective study between Jan 2007 and Dec 2018 among incident CKD adult patients who initiated dialysis within Kaiser Permanente. Incident CKD identified as≥2 consecutive eGFR≤45 at least 90 days apart with one prior eGFR≥60. Prevalent HF determined by ICD coding for HF. Dialysis setting (inpatient vs outpatient) and dialysis access (among HD) at initiation were determined for patients with vs without HF. Multivariable logistic regression used to estimate odds ratios (OR) and 95% Cl for inpatient dialysis initiation and catheter use.

Results: 6,812 CKD patients initiated dialysis. 2,498 had HF [71% preserved EF (HFpEF), 20% reduced EF (HFrEF), and 9% unknown EF]. Inpatient dialysis start occurred in 18.5% with HF vs 9.6% without HF. Catheter use at dialysis start occurred in 58.5% with HF vs 51.9% without HF. Inpatient dialysis start OR (95% Cl) were 1.73 (1.30, 2.29), 1.42 (1.22, 1.66), and 1.45 (1.17, 1.79) for HF unknown EF, HFpEF, and HFrEF compared to no HF. Inpatient dialysis start OR were 1.46 (1,26, 1.69), 0.69 (0.51, 0.93), 0.99 (0.88, 1.13), 1.54 (1.32, 1.80), 1.28 (1.11, 1.47), 1.44 (1.18, 1.77), and 0.72 (0.59, 0.89) for HF vs no HF, age>70, female, AFib, CAD, Charlson score>5, and education level 76-100%, respectively. Catheter start OR were 1.04 (0.99, 1.10), 0.85 (0.76, 0.95), 1.04 (0.99, 1.10), 1.21 (1.14, 1.29), 0.98 (0.93, 1.04), 1.20 (1.12, 1.29), and 0.86 (0.79, 0.93) for HF vs no HF, age>70, female, Afib, CAD, Charlson score>5, and education level 76-100%.

Conclusions: HF patients were more likely to start dialysis inpatient. HFrEF was associated with inpatient and catheter at dialysis start. Our findings question whether CKD patients with HF may benefit from earlier and differential dialysis transition strategies.

Forest plot of rate ratios for inpatient dialysis initiation among incident CKD patients (N = 6,812)



SA-PO536

Association of Antihypertensive Medications with Cardiovascular (CV) Outcomes in Patients with CKD

L Parker Gregg,[1,2] Aaron R. Perkins,[3] Hui Yang,[3] Vijay Nambi,[1,2] Susan Hedayati,[4] Sankar D. Navaneethan,[1,2] Carlos A. Alvarez.[3,4] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]Texas Tech University Health Sciences Center School of Pharmacy - Dallas, Dallas, TX; [4]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Angiotensin converting enzyme inhibitors (ACEi) and receptor blockers (ARB) are first line for hypertension in patients with CKD. Whether the second agent prescribed is associated with CV events is less clearly established.

Methods: Using the Veterans Affairs Corporate Data Warehouse, we identified veterans with CKD stages 1-5 based on estimated glomerular filtration rate and albuminuria from 1/1/2010 to 12/31/2016. We selected individuals prescribed an ACEi/ARB as monotherapy for hypertension at or prior to the time of prescription of a second antihypertensive agent (*index date*), grouped by thiazide diuretics (TD), loop diuretics (LD), calcium channel blockers (CCB), and beta blockers (BB). The primary outcome was the composite of hospitalization for heart failure or fatal or non-fatal myocardial infarction or stroke, or revascularization. Inverse probability of treatment weights (IPTW) were generated using generalized boosted methods, and Cox proportional hazards regression assessed associations between medications and CV events.

Results: Of the 328,399 participants, 98,222 (30%) were prescribed TD, 39,202 (12%) LD, 71,091 (22%) CCB, and 119,884 (36%) BB. The mean age was 71 years, 97% were men, 72% were White, and 18% were Black. Compared to the other groups, TD users were younger, more likely to be female, and less likely to have CKD stages 4 or 5. Heart failure was more common among users of LD (36%) and BB (18%) compared to TD (3%). Weighted standardized differences demonstrated that characteristics were balanced between groups after IPTW. There were 111,124 composite CV events. Compared to TD, increased hazard of CV events was seen for LD, CCB, and BB users (**Figure**).

Conclusions: Although residual indication bias cannot be excluded, these data suggest that there may be an increased risk of CV events with LD, CCB, and BB compared to TD in those with CKD. Examination of the reasons to initiate these agents is warranted.

Kidney Function Predicts New-Onset Cardiorenal Events and Mortality in Primary Aldosteronism: Approach of the 2021 Race-Free eGFR Equation

Chun-Fu Lai, Yen-Hung Lin, Vincent Wu. Taiwan Primary Aldosteronism Investigation (TAIPAI) Study Group. *National Taiwan University Hospital, Taipei, Taiwan.*

Background: Individuals with primary aldosteronism (PA) exhibit glomerular hyperfiltration, which may conceal underlying kidney damage. We aimed to investigate whether baseline estimated glomerular filtration rate (eGFR) is associated with cardiovascular outcomes in this population.

Methods: This observational cohort study enrolled 760 coronary artery disease-naïve patients diagnosed with PA between January 1, 2007 and December 31, 2018 (male, 45%; mean age, 52.3 ± 11.9 years). The baseline eGFR was calculated using the 2021 Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation, which includes serum creatinine and cystatin C but omits the race variable. Outcomes were composite cardiovascular events (total death, non-fatal myocardial infarction, and coronary revascularization procedure), all-cause mortality, and adverse kidney events.

Results: During a mean follow-up of 5.8 ± 3.2 years, new-onset composite cardiovascular events occurred in 47 patients, with a crude incidence rate of 10.9 per 1,000 person-years. Multivariable Cox proportional hazards analysis showed that baseline eGFR was independently associated with composite cardiovascular events (hazard ratio [HR], 0.98 [95% CI, 0.97–0.99]). Penalized splines smoothing in multivariable regression analysis demonstrated that the risk of composite cardiovascular events increased negatively and linearly when patients had a baseline eGFR less than 85 mL/min/1.73m^2. Patients with baseline eGFR <85 mL/min/1.73m^2 were independently associated with higher risks of composite cardiovascular events (HR, 2.39 [95% CI, 1.16–4.93]), mortality (HR, 4.63 [95% CI, 1.59–13.46]), and adverse kidney events (sub-distribution HR, 5.96 [95% CI, 3.69–9.62], with mortality as a competing risk). (Figure 1A-C)

Conclusions: Our data support interpreting baseline eGFR as a predictor for new-onset adverse cardiorenal events and emphasizes the importance of the early detection of kidney function impairment in hypertensive patients with PA. We also firstly point to the validity of the 2021 race-free CKD-EPI equation in patents with PA.

Blood Pressure Is Not Controlled to <130/80 mm Hg in Majority of Veterans with High Atherosclerotic Cardiovascular Disease (ASCVD) Risk

Aseel Zghayer,[1,3] Meghan O'Halloran,[3] Zhiping Huo,[3] Frances M. Weaver,[1,3] Ashley M. Hughes,[2] Kevin Stroupe,[1,3] Talar Markossian,[1] Holly J. Kramer.[1,3] *[1]Loyola University Health System, Maywood, IL; [2]University of Illinois Chicago, Chicago, IL; [3]Edward Hines Junior VA Hospital, Hines, IL.*

Background: Blood pressure (BP) control remains the most effective intervention to prevent cardiovascular disease (CVD). The American College of Cardiology/American Heart Association (ACC/AHA) hypertension guideline recommends a BP goal <130/80 mmHg for adults with high CVD risk which includes individuals with existing ASCVD, diabetes mellitus (DM) or chronic kidney disease (CKD). Few studies have examined the proportion of Veterans with CVD, DM or CKD with BP controlled to <130/80 mmHg receiving care within Veterans Affairs patient aligned care teams (PACT).

Methods: Vital sign data were obtained from 98,433 Veterans aged 18 to 85 years with a hypertension diagnosis during a PACT visit within eight Veteran Integrated Service Network 12 medical centers from January 1,2019, through March 1,2020. BP control was examined by high CVD risk (age ≥ 65 years and/or CVD, DM or CKD) and by presence of CVD, DM, CKD based on ICD10 diagnosis codes, or estimated glomerular filtration rate < 60 ml/min/1.73 m^2 on two occasions based 90 days apart prior to the end of the study period. BP control was defined as a systolic BP <130 mmHg and diastolic BP <80 mmHg based on BP recorded during the last PACT clinic visit during the study period.

Results: The mean age was 68.5 years (SD 12.7) and 93% were male. Among the 89,537/98433 Veterans with high CVD risk, BP was controlled to <130/80 mmHg in 37.5% and <140/90 mmHg in 76.5%. Among subgroups, BP was controlled to <130/80 mmHg in 42.8% (5313/12,414) with CKD, 39.8% (13,484/33,880) with diabetes, 45.3% with CVD (13,402/29,584) and in 47.1% (1810/3845) with CKD, DM and CVD. In contrast, BP was controlled to <140/90 mmHg in over 75% of Veterans with CKD, DM and/or CVD. (Figure 1).

Conclusions: The majority of Veterans with high CVD risk did not have BP controlled to < 130/80 mmHg. Strategies are needed to improve BP control in Veterans with high CVD risk.

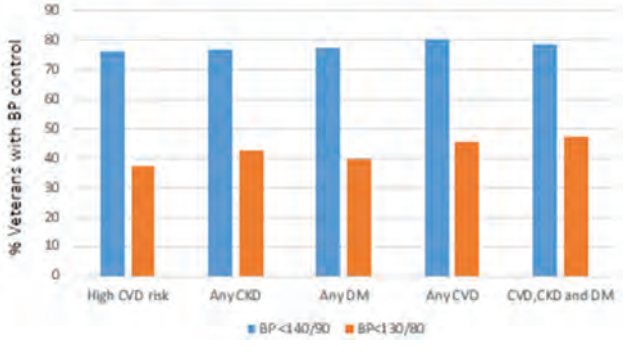

Figure 1.

SA-PO539

Association Between Birth Weight Z-Score and Blood Pressure in Young Adults

Asdis H. Sigurdardottir,[1,2] Olafur S. Indridason,[1] Sigurdur S. Stephensen,[1,2] Vidar O. Edvardsson,[1,2] Thordis J. Hrafnkelsdottir.[1,2] *[1]Landspitali, Reykjavik, Iceland; [2]Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland.*

Background: Low birth weight (BW) has been associated with increased risk of hypertension later in life. The aim of this study was to examine the association between BW weight z-score and blood pressure (BP) indices in healthy young adults.

Methods: Participants were recruited from a cohort of 970 adults aged 20-22-years who participated in a population-based study of BP in 9-10-year-old Icelandic children. All participants underwent 8 resting clinic BP measurements during two separate visits and an ambulatory BP (ABP) measurement. Birth weight and gestational age obtained from the Icelandic Birth Registry were used to calculate BW z-scores based on a standardized growth chart by Niklasson & Albertsson-Wikland. Pearson correlation coefficient and multivariable linear regression were used for analysis.

Results: Of 170 young adults who completed the follow-up study, 102 were women (60%). The mean clinic BP was 120/65 mm Hg in men and 112/66 mm Hg in women. The mean BW for men was 3625±736 g and 3646±592 g for women. A negative correlation was observed between BW z-score and both systolic and diastolic ABP (r= -0.14, p=0.026 and -0.10, p=0.20, respectively). When the sexes were analyzed separately the correlation between BW z-score and systolic ABP was statistically significant only in women (r=-0.24, p=0.014). In women the association between BW z-score and diurnal systolic ABP was significant (r=-0.26, p=0.013) while the correlation with nocturnal systolic ABP was not (r=-0.16, p=0.097). When adjusted for body mass index a significant association was detected between BW z-score and both systolic and diastolic ABP in young women (beta= -1.7, p=0.02 and beta= -1.2, p=0.01, respectively). This association was stronger for both diurnal systolic and diastolic ABP (beta= -1.8, p=0.02, and beta= -1.4, p=0.02), than for nocturnal ABP (beta= -1.4, p= 0.08, and beta= -0.79, p= 0.2). In men, BW z-score did not have a significant association with either ABP (systolic, r=-0.002 p=0.9; diastolic, r=-0.1 p=0.4) or clinic BP (systolic, r=-0.07 p=0.4; diastolic, r=-0.02 p=0.8) at follow-up.

Conclusions: Low BW z-score has a strong association with systolic ABP in young women and this relationship is stronger for diurnal systolic ABP.

SA-PO540

Prevalence of Aldosterone Breakthrough in a Cardiometabolic Clinic and Association with Albuminuria

Ahmed R. Imcaoudene, Caroline Najjar, Pedro Marques, Michael A. Tsoukas, Abhinav Sharma, Thomas Mavrakanas. *McGill University Health Centre, Montreal, QC, Canada.*

Background: Type 2 diabetes (T2D) and chronic kidney disease (CKD) patients have cardiovascular and renal benefits when treated with renin-angiotensin system (RAS) blockers. Some of these patients are known to exhibit a rise in aldosterone levels while on RAS blockers, called aldosterone breakthrough. The aim of our study is to assess the prevalence of aldosterone breakthrough in our clinic and its association with albuminuria.

Methods: Patients from a cardiometabolic clinic with available plasma aldosterone concentration (PAC) levels were screened. Exclusion criteria included: not taking a RAS blocker for at least 10 months, current treatment with a mineralocorticoid receptor antagonist (MRA) and an Aldosterone to renin ratio suggestive of primary hyperaldosteronism. Patients with a PAC>400pmol/L were considered to have aldosterone breakthrough.

Results: 64 patients met the inclusion criteria with 21 (33%) showing aldosterone breakthrough. Patient characteristics are shown in the Table. No significant differences in baseline characteristics were seen in patients with or without aldosterone breakthrough except for higher albuminuria in the breakthrough group. The prevalence of CKD was numerically higher in the breakthrough group. Similar trends were seen when aldosterone breakthrough was defined as a PAC level above the median of our sample.

Conclusions: Aldosterone breakthrough is prevalent in patients from a cardiometabolic clinic and is associated with higher albuminuria. Patients with aldosterone breakthrough can potentially draw more benefit when treated with an MRA.

Baseline characteristics based on the presence or absence of aldosterone breakthrough

Characteristic	Aldosterone breakthrough	No aldosterone breakthrough	p value
Age (years, median [IQR])	67 (64-77)	67 (61-75)	0.58
Sex (male, [n,%])	15 (71)	28 (65)	0.61
Hypertension (n, %)	19 (90)	37 (86)	0.62
Type 2 diabetes (n, %)	20 (95)	40 (93)	0.73
Heart Failure (n, %)	13 (62)	23 (53)	0.52
Chronic kidney disease* (n, %)	16 (76)	22 (51)	0.06
SGLT2i (n, %)	16 (76)	35 (81)	0.63
Albuminuria (mg/g, [median (IQR)])	264 (76-1118)	34 (0-1013)	0.02
PAC (pmol/L, [median (IQR)])	549 (498-839)	227 (151-291)	<0.01

*defined as eGFR<60mL/min/1.73m2

IQR - Interquartile range; PAC - Plasma aldosterone concentration; SGLT2i - sodium-glucoseco-transporter 2 inhibitors.

Low-Grade Albuminuria and Cardiovascular Mortality Among Healthy Adults

Sophie E. Claudel,[1] Sushrut S. Waikar,[1] Insa M. Schmidt,[1] Vasan S. Ramachandran,[2,3] Ashish Verma.[1] *[1]Boston Medical Center, Boston, MA; [2]Boston University School of Public Health, Boston, MA; [3]The University of Texas Health Science Center at Houston School of Public Health - San Antonio Campus, San Antonio, TX.*

Background: Albuminuria is associated with cardiovascular events among adults with underlying cardiovascular disease and diabetes, even at low levels of urinary albumin excretion. We hypothesized that low-grade albuminuria is associated with cardiovascular death among healthy adults.

Methods: We included adults participating in the 1999-2014 National Health and Nutrition Examination Survey (N=18,696). We excluded those with urinary albumin-to-creatine ratio (UACR) >30mg/g, baseline cardiovascular disease, hypertension, diabetes, estimated glomerular filtration rate <60ml/min/1.73m^2, those who were currently pregnant, and those who had received dialysis in the last year. We assessed the relationship between log-transformed UACR and cardiovascular and all-cause mortality using multivariable Cox proportional hazards models. Models were adjusted for age, sex, race or ethnicity, survey year, BMI, insurance, smoking, A1c, systolic blood pressure, total cholesterol, serum albumin, statin use, and eGFR.

Results: Mean age was 38.1 years (standard deviation 14.0) and 53.4% were female. The median length of follow up was 12.2 years [interquartile range 8.4-16.4 years]. In adjusted models, each doubling of UACR was associated with a 34% higher risk of cardiovascular death [HR 1.34 (95% confidence interval (CI) 1.10-1.63)] and a 28% higher risk of all-cause mortality [HR 1.28 (95% CI 1.16-1.41)]. The highest tertile of UACR was associated with an 84% higher risk of cardiovascular death [HR 1.84 (95% CI 1.18-2.89)] and 59% higher risk of all-cause mortality [HR 1.59 (95% CI 1.29-1.97)], compared with the lowest tertile **(Table 1)**.

Conclusions: Higher levels of albuminuria in the "normal" range < 30 mg/g in healthy individuals nevertheless predict cardiovascular and all-cause mortality.

Effect of Intensive Blood Pressure Control on Kidney Outcomes: Long-Term EHR-Based Post-Trial Follow-Up of SPRINT

Paul E. Drawz,[1] Kristin M. Lenoir,[2] Nayanjot Kaur Rai,[1] Nicholas M. Pajewski.[2] *[1]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN; [2]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Intensive blood pressure (BP) lowering in SPRINT produced acute decreases in kidney function and increased the risk of AKI. We evaluated the effect of intensive BP lowering on long-term changes in kidney function using trial data supplemented with outpatient EHR creatinine values.

Methods: SPRINT data were linked with EHR data from 49 (of 102) SPRINT study sites. The primary outcome was the slope of decline in eGFR calculated using trial and outpatient EHR values. Secondary outcomes included a ≥30% decline in eGFR to <60ml/min/1.73m^2 and a ≥50% decline in eGFR in participants with eGFR ≥60 and <60ml/min/1.73m^2 at baseline, respectively.

Results: EHR creatinine values were available for a median of 8.7 years for 3041 participants. The long-term slope of decline in eGFR was -1.09 ml/min/1.73m^2/year (95% CI -1.17 to -1.01) in the standard treatment group and -0.72 ml/min/1.73m^2/year (95% CI -0.80 to -0.64) in the intensive treatment group (P <0.001). Among participants without CKD at baseline, intensive compared to standard treatment was associated with an increased risk of a ≥30% decline in eGFR during the intervention (hazard ratio (HR) 3.29, 95% CI 2.35, 4.60), but not during the post-intervention observation phase (HR 1.09, 95% CI 0.84, 1.42). There was no significant effect of intensive treatment on eGFR decline in those with CKD at baseline. Estimates of kidney outcomes during the intervention period were similar when using SPRINT and EHR creatinine values.

Conclusions: Intensive BP lowering was associated with a lesser slope of decline in eGFR compared with standard BP lowering during long-term follow-up in SPRINT. However, there was no consistent benefit of intensive BP lowering on secondary kidney outcomes.

The Impact of Chronic Fluid Overload, Water Imbalance (Tonicity), and Sodium Toxicity on Mortality of Hemodialysis Patients

Jule Pinter,[1] Bernd Genser,[2] Nicholas C. Chesnaye,[3] Stefan Pfeifer,[1] Kaitlin J. Mayne,[4] Stefano Stuard,[5] Ulrich Moissl,[5] Jeroen Kooman,[6] Kitty J. Jager,[9] Christoph Wanner,[1] Brendan Smyth,[7] Bernard J. Canaud.[8] European Clinical Database5 Study Group. *[1]Julius-Maximilians-Universitat Wurzburg Medizinische Fakultat, Wurzburg, Germany; [2]Universitat Heidelberg, Heidelberg, Germany; [3]Amsterdam Public Health Research Institute, Amsterdam, Netherlands; [4]University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom; [5]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [6]Universiteit Maastricht Faculty of Health Medicine and Life Sciences, Maastricht, Netherlands; [7]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [8]Universite Montpellier Faculte des Sciences de Montpellier, Montpellier, France; [9]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Chronic fluid overload, water imbalance and plasma sodium toxicity (tonicity) contributes to high mortality in hemodialysis-dependent (HD) patients and the interplay remains unclear. In this retrospective cohort, we aimed to determine the dose-response relationship and interplay between cumulative burden of fluid overload (FO) as measured by body composition (BCM)-measurement, plasma and dialysate sodium on all-cause mortality.

Methods: Incident HD-patients with a valid BCM-measurement ≤90 days of renal replacement therapy were eligible. Cumulative exposure was quantified by counting the months spent in exposure status and categorized in deciles or quartiles. Exposure status was defined as FO, hypo and hypernatremia (<135, >145mmol/l) and dialysate sodium ≤138mmol/l. A threshold of 7% defined mild and 13% or 15%, for women and men, severe relative FO. 7% <- normal fluid status was defined as fluid depletion. Hazard Ratios (HR) for defined conditions were estimated from Cox regression frailty model and adjusted for clustering by country and clinics and potential confounding variables.

Results: 68,196 incident HD-patients from 875 clinics in 25 countries were followed-up to ten-years (2010-2020), during which 21,644 patients died. The mortality risk associated with FO increased with cumulative exposure burden, mild FO (>1.1 Liter) showed a steeper increase pattern with HR peaking at 3.28 (95%CI: 3.00 to 3.59) than clinically severe FO (>2.5 Liter) (HR peak 2.47(2.33-2.63) compared to normal fluid status (figure 1).

Conclusions: The effect of FO on mortality is large and mandates a sensitive definition to quantify the risk. The dose-response effect of FO is better assessed using the 7% cut-off definition for mild as compared to severe FO. This suggests that the use of a stricter FO definition, could lead to better control of fluid status and improved outcomes.

Bioelectrical Impedance Parameters as Earlier Predictors of Mortality/ Survival in Ecuadorian Hemodialysis Patients

Juan C. Santacruz, Kevin G. Armijo, Layla N. Baez, Paola K. Arévalo, Maria G. Santacruz, Nairi Seleni N. Sucre Guevara, Paulo Reinoso, Angel C. Santacruz, Veronica Gavilanes. *Clínica de los Riñones Menydial, Quito, Ecuador.*

Background: Bioelectrical impedance analysis (BIA) is a non-invasive test to assess body composition and water distribution. Nutritional and volume disturbances are related with mortality in hemodialysis (HD) population. Few is known about BIA parameters as mortality/survival predictors. The aim of the study was to study BIA parameters as mortality/survival predictors in HD patients.

Methods: Observational-prospective-cohort study from April 2021-2023 in one HD center. BIA analysis was performed in HD patients and parameters significatively related with mortality and survival were identified. ROC curves, regression and correlation analysis were performed in BCM parameters identified.

Results: A total of 115 patients were included, 9 (7,8%) died. Phase Angle (PA) (4.64°±1.11vs3.12°±0.62;p:0.01), Lean Tissue Index (LTI) (12.41Kg/m²±3.14vs9.75Kg/m² ±2.95;p0.02), Intracellular Water (ICW) (15.26L±3.53vs13.23L±4.97;p=0.03) were related with survival. Correlation analysis found positive correlation of PA (p<0.001), LTI (p=0.02) and ICW (p= 0,03) with survival. Age (53.98y±14.75vs70.67y±7.14; p<0.001) and E/I ratio (0.97±0.14vs1.17±0.16;p<0.001) were related with mortality. Age (p=0.002) and E/I ratio (p=0,005) had positive correlation with mortality.

Conclusions: Phase Angle, Intracellular water, E/I ratio, and Lean Tissue Index of a single non-invasive BIA can be used as earlier predictors of survival and mortality in HD patients allowing premature identification and intervention in this group of patients to reduce mortality risk.

Kidney Sodium MRI: Extending the Concept of Residual Kidney Function in Hemodialysis

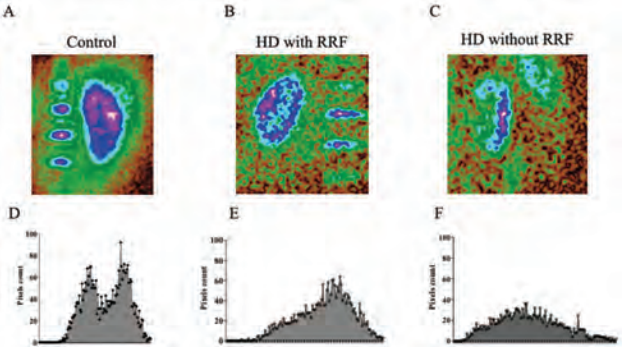
Sandrine Lemoine,[1,2] Alireza Akbari,[2,3] Jarrin D. Penny,[2,3] Christopher W. McIntyre.[2,3] *[1]Hospices Civils de Lyon, Lyon, France; [2]Western University, London, ON, Canada; [3]London Health Sciences Centre, London, ON, Canada*.

Background: It is widely recognized that persistence of even modest amount residual kidney function (RKF) is associated with improved outcomes, in hemodialysis (HD) patients. The concept of RKF, as currently utilized, is exclusively based upon urine volume and small solute clearance-requiring complete interdialytic urinary collection. This makes accurate and consistent assessment measurement challenging and difficult to implement in clinical practice. More importantly it focusses almost exclusively on glomerular function, rather than a more inclusive consideration of overall kidney function to incorporate assessment of renal tubular mass. The aim of this study was to test the feasibility of obtaining useable ^{23}Na-MRI kidney images, in the setting of dialysis dependance (as compared to normal subjects without CKD) and initially describe the associations between directly imaged medullary sodium content and other components of a more conventional approach to the definition of RKF.

Methods: We included 21 healthy volunteers and 17 HD participants, fasted for eight hours prior to their study visit. Urine samples were collected to measure urinary osmolarity, before MRI scan.

Results: Median (IQR) fasting medulla to cortex ratio was significantly higher 1.56 [1.5 – 1.61] in healthy volunteers compared to HD patients 1.22 [1.13 – 1.3], p<0.0001. Medulla to cortex ratio and median urinary osmolarity were correlated (r=0.87, p<0.0001) in the whole population. We found a significant association between HD vintage and medulla to cortex ratio whereas we did not find any association with urine volume. Sodium signal intensity distribution within healthy kidney describes two different peaks-relating to well defined cortex and medulla; whereas HD participants displays only a single peak indicative of the markedly lower sodium concentration.

Conclusions: The application of kidney sodium MRI to the study of RKF in patients receiving maintenance HD is practical and provides a previously unavailable ability to interrogate the function of remnant tubular mass.



SA-PO546

Analysis of Microcirculatory Flow Changes After Hemodialysis

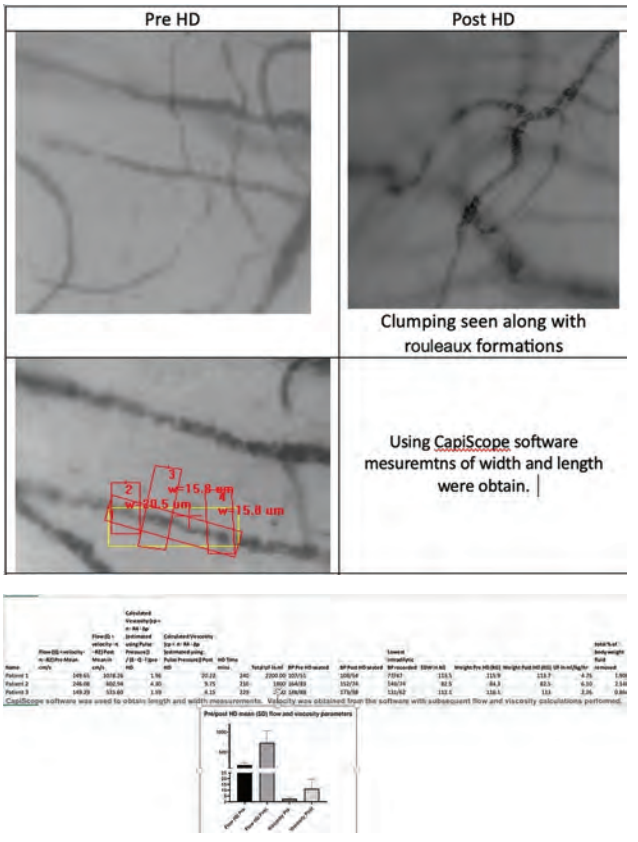
Sylvester Barnes IV,[1,2] Bruce I. Gaynes,[1,2] Robert S. Dieter.[1,2] *[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL; [2]Edward Hines Junior VA Hospital, Hines, IL*.

Background: During HD there appears to be a viscosity change in RBCs which leads to a decrease in their deformability changing to a rouleau formation with concurrent increases in viscosity. Increases in both whole blood and plasma viscosity are corelated with increases in HTN as wells as adverse cardiovascular changes.

Methods: Changes to the microcirculation in HD patients have previously been documented by Bemelmans et al by viewing the sublingual mucosa. Microcirculation impairment is an independent predictor of organ dysfunction and death which can be assessed via capillaroscopy examination. We adapted a commercial orthogonal polarization spectral imaging camera to perform capillaroscopy of the conjunctival tissue bed. Unlike the sublingual mucosa, the bulbar conjunctiva demonstrates hemodynamic features not dissimilar to the cerebral cortex.

Results: Early findings demonstrate a profound abnormality in RBC aggregation and RBC density in the microvasculature post-HD figure 1, along with a calculated increase in viscosity via software analysis (Figure 2). Although the etiology of these findings is unclear, it correlates with the observed increase in cardiovascular events seen among ESRD patients in the immediate days following dialysis.

Conclusions: Although the Fåhraeus–Lindqvist effect predicts viscosity decrease with an increase in microcirculatory flow, our study findings demonstrate that in HD, an increase in flow is proportional to an increase in viscosity. Rouleau formation post-HD is abnormal and is postulated to be responsible for the increase in viscosity noted. The increase in viscosity appears unrelated to UF but to HD itself.



SA-PO547

Changes in the Glymphatic System Before and After Dialysis Initiation in Patients with ESRD

Jiyae Yi, Sihyung Park, Yang Wook Kim, Bongsoo Park, Yoo jin Lee, Changmin Heo, Yeongrok Oh, Byeongo Choi. *Inje University Haeundae Paik Hospital, Busan, Republic of Korea*.

Background: This study evaluated 1) glymphatic system function in patients with end-stage renal disease (ESRD) before dialysis initiation compared to healthy controls, and 2) changes in glymphatic system function after renal replacement therapy including dialysis in patients with ESRD using the diffusion tensor image analysis along the perivascular space (DTI-ALPS) method.

Methods: This prospective study was conducted at a single hospital. We enrolled 14 neurologically asymptomatic patients who initiated hemodialysis or peritoneal dialysis for ESRD, as well as 17 healthy controls. The patients underwent magnetic resonance imaging (MRI) before and 3 months after dialysis initiation, and the DTI-ALPS index was calculated. We compared the DTI-ALPS index before and after dialysis initiation between patients with ESRD and healthy controls.

Results: The DTI-ALPS index differed between patients with ESRD before dialysis initiation and healthy controls (1.342 vs. 1.633, p=0.003) but not between patients with ESRD before and after dialysis initiation (1.342 vs. 1.262, p=0.386). A positive correlation was observed between DTI-ALPS and phosphate levels (r=0.610, p=0.020) in patients with ESRD.

Conclusions: We confirmed glymphatic dysfunction in patients with ESRD but observed no differences before or after dialysis initiation. This may be related to uremic toxins that are not removed by dialysis in patients with ESRD. The results of this study could be used to develop the pathophysiology and treatment of patients with ESRD.

SA-PO548

Near-Infrared Spectroscopy in Hemodialysis

Arslan Mahmood, Andrew A. Moses. *Lenox Hill Hospital, New York, NY.*

Background: Near-infrared spectroscopy (NIRS) is a noninvasive monitoring of cerebral oxygenation commonly used in monitoring for ischemia in surgical patients. Sensors are placed to measure oxygenation in the designated area. Infrared waves pass through a regional area to detect deoxygenation prior to widespread ischemia. During Hemodialysis (HD), ESKD patients are known to have abnormalities in cerebral blood flow, but few studies have looked at changes in cerebral oxygenation during HD in these patients. The aim of this study was to evaluate cerebral regional O2 saturation (rSO2) during HD, and to assess any correlation with vital signs such as blood pressure (BP) and heart rate.

Methods: Six inpatients with ESKD undergoing dialysis were enrolled. We used the FDA cleared device, INVOS PM 7100 patient monitor (K211561) and the INVOS Adult rSO2 sensor (K182868) produced by Medtronic. A sensor was secured on each side of the scalp, to measure temporal lobe oxygenation. NIRS monitor was placed at the beginning of HD and was removed 5 minutes after the session ended. Baseline was established during the first five minutes of the treatment. Desaturation was defined as a 20% or greater relative reduction from baseline local blood oxygen level for at least 1 minute.

Results: Patients' ages ranged from 59-85 years. Baseline rSO2 was adequately obtained in all patients. Desaturation was observed in one out of six patients (Figure). This was a 25% desaturation lasting for 2 minutes and 40 seconds, during which patient was asymptomatic and without change in vital signs. The same patient had a one-time drop in BP to 87/46 but no desaturation was observed during this time. Another patient had a one-time drop in BP to 91/63, without any desaturation observed in this time.

Conclusions: This pilot study was conducted to establish baseline cerebral oxygenation data for ESKD patients undergoing HD. Though a small sample size, this approach has potential to reveal interesting and useful insights to effects of HD on neurological function. We are continuing to gather patients and will use this group to establish norms of NIRS in ESKD patients.

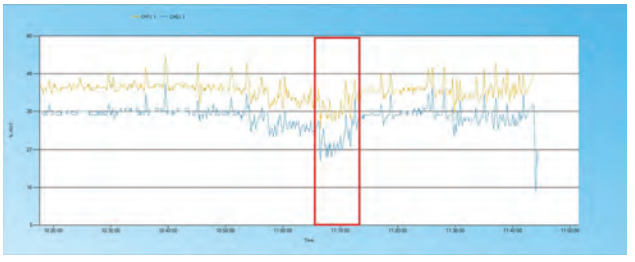


Figure: NIRS data of patient with desaturation marked in red box

SA-PO549

Cerebrovascular Function and Brain Structure in Hemodialysis Patients

Dawn F. Wolfgram,[1] Brian Schmit,[1,3] Wesley Richerson.[2] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Vanderbilt University, Nashville, TN; [3]Marquette University College of Engineering, Milwaukee, WI.*

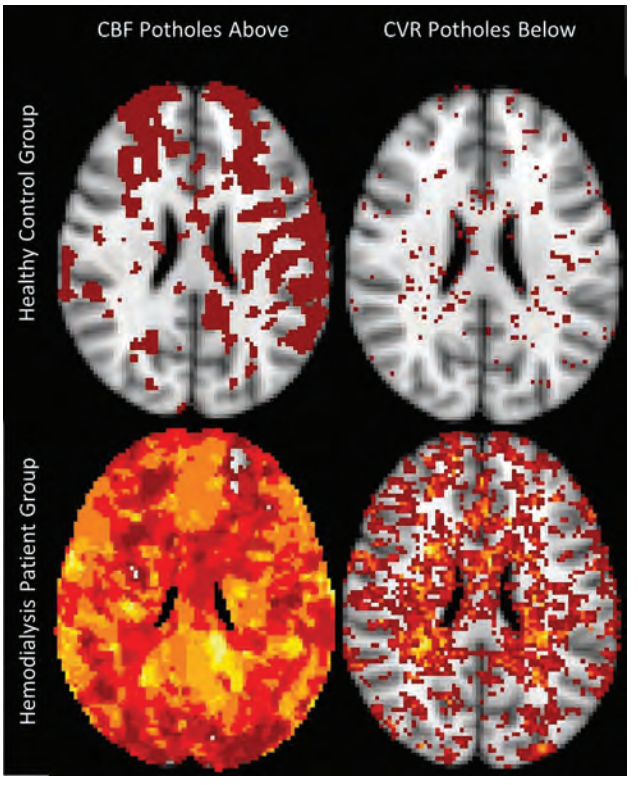
Background: Hemodialysis (HD) patients often have decline in cerebral blood flow (CBF) and cerebral oxygen saturation during HD. Cerebrovascular reactivity (CVR) measured at rest may be able to identify individuals susceptible to intradialytic hypoperfusion and ischemic brain injury. We hypothesized that HD patients would have decreased CVR and increased CBF relative to controls and that decreased CVR would be related to structural brain lesions.

Methods: In 10 HD patients and 10 controls, we measured cortical thickness and white matter hyperintensity (WMH) volume from the T1 and T2 FLAIR respectively, CVR from a breath hold during BOLD CVR fMRI, and arterial transit time and CBF from arterial spin labelling. Differences in these measures between the groups were tested by averaging across the tissue and with a pothole analysis. We correlated cortical thickness and WMH volume with cerebrovascular variables to assess the relationship between brain structure and cerebrovascular health in HD patients.

Results: Compared to controls, the HD cohort had decreased cortical thickness, increased WMH volume (p=0.002, p=0.004), and increased white matter CBF (p=0.02). Pothole analysis demonstrated a greater number of increased gray and white matter CBF voxels (p=0.03, p=0.02) and a greater number of decreased gray and white matter CVR voxels (p=0.02, p=0.01). No significant relationships were found between cortical thickness or WMH volume and CVR or CBF.

Conclusions: HD patients have structural injury with decreased cortical thickness and increased WMH. Notably, HD patients had increased CBF and decreased CVR. However, we did not find that decreased CVR correlated with decreased cortical thickness or increased WHM in this pilot study.

Funding: NIDDK Support, Private Foundation Support



Pothole count of higher CBF and lower CVR. Brighter yellow indictes a greater prevalence of potholes in that location

Early Detection of White Matter Changes Through MRI Brain Diffusion Tensor Imaging (DTI) in ESRD Patients on Hemodialysis

Tushar A. Dighe, Debapriya Saha, Charan B. Bale, Pavan Wakhare, Nilesh Shinde, Akshay R. Kulkarni, Abhijit S. Chavan, Chetan U. Phadke, Anuja P. Makan, Shreeharsh Godbole, Atul Sajgure. *Dr. D.Y. Patil Medical College, Pune, India.*

Background: Neurological complications like stroke and cognition disorders contribute to morbidity and mortality in CKD patients significantly. It has been postulated that neurological adverse events and renal dysfunction in CKD patients are related at the pathogenesis level. Neurological changes in the brain in CKD patients can be detected by Magnetic resonance studies at a stage earlier than overt clinical symptom manifestation.

Methods: After obtaining approval from the Institutional Ethics Committee, 30 patients with end-stage renal disease on hemodialysis and 10 age-matched control persons without kidney disease underwent routine biochemical studies and an MRI brain on a 3T scanner. Fractional Anisotropy and Mean Diffusivity were calculated for corpus callosum genu and splenium, anterior and posterior corona radiata, pons, and cerebellar hemispheres on both sides. Conventional MRI images were evaluated for changes in small vessel disease. Student's unpaired T-test was used to determine if the difference in results were statistically significant.

Results: 18 out of 30 hemodialysis patients and three out of 10 control patients had white matter changes of small vessel disease detectable in conventional MRI sequences. Fractional anisotropy was significantly low for corpus callosum genu ($p<0.003464$ and $p<0.007437$, right and left sides respectively) and anterior corona radiata ($p<0.04272$ and $p<.001653$, right and left sides respectively) in hemodialysis patients than control. No significant difference in fractional anisotropy was noted for other locations. Mean diffusivity was higher at corpus callosum genu and anterior corona radiata in hemodialysis patients than in age-matched controls but did not reach statistical significance ($p>0.05$).

Conclusions: There are white matter changes detectable by DTI imaging in a quantitative manner in anterior corona radiata and corpus callosum genu in hemodialysis patients that is absent in age-matched control persons without renal disease. Further research is needed to use these early quantitative DTI changes to build robust predictive models for prognostication that will lead to comprehensive renal and neurological clinical management in CKD patients.

Intrinsic Prefrontal Functional Connectivity According to Cognitive Impairment in Patients with ESRD

Yeongrok Oh, Bongsoo Park, Yang Wook Kim, Sihyung Park, Yoo jin Lee, Changmin Heo, Jiyae Yi, Byeongo Choi. *Inje University Haeundae Paik Hospital, Busan, Republic of Korea*.

Background: This study aimed to investigate differences in intrinsic prefrontal functional connectivity according to the presence of cognitive impairment in patients with end-stage renal disease (ESRD) using functional near-infrared spectroscopy (fNIRS).

Methods: We prospectively enrolled 37 patients with ESRD who were undergoing hemodialysis for more than six months and had no previous history of neurological or psychiatric disorders. The NIRSIT Lite device was used to acquire fNIRS data, and the NIRSIT Lite Analysis Tool program was used to process the data and generate a functional connectivity matrix. We obtained functional connectivity measures by applying graph theory using BRAPH program from the connectivity matrix using the BRAPH program. All patients with ESRD underwent a Korean version of the Montreal Cognitive Assessment (MoCA-K) to assess their cognitive function.

Results: Of the 37 patients with ESRD, 23 had cognitive impairment, whereas 14 patients showed no cognitive impairment. Intrinsic prefrontal functional connectivity was significantly different between groups. The network measures of the strength, global efficiency, and mean clustering coefficient were lower (4.458 vs. 5.129, p=0.018; 0.397 vs. 0.437, p=0.028; 0.316 vs. 0.421, p=0.003; respectively) in ESRD patients with cognitive impairment than those without cognitive impairment. There were no significant correlations between MoCA-K scores and clinical characteristics.

Conclusions: We demonstrated a significant association between cognitive function and intrinsic prefrontal functional connectivity in patients with ESRD. ESRD patients with cognitive impairment have reduced connectivity and segregation in the prefrontal brain network compared with those without cognitive impairment.

Urea Clearance in a Large-Animal Hemodialysis Benchtop Model Using Nanoporous Silicon Nitride Membranes

Jonathan Ferruzza,[1,2] Maria F. Presti,[1,2] Dean G. Johnson.[2,1] [1]*University of Rochester Medical Center, Rochester, NY;* [2]*University of Rochester, Rochester, NY*.

Background: Over three-quarters of a million Americans live with the daily complications of end-stage renal disease (ESRD), and 71% of those are on some form of hemodialysis (NIH NIDDK 2020). One major shortcoming with current hemodialysis is the non-ambulatory nature of the treatment, with many patients undergoing treatment for four hours, three times a week. Our goal is to make conventional renal replacement therapy more compact, allowing for ambulatory dialysis. To accomplish this, our lab has previously devised and utilized nanoporous silicon nitride (NPN) membranes that demonstrated a 20% urea clearance in a small-animal model (Hill et al., 2020). We modified the NPN membranes for use in a large animal benchtop model by increasing the surface area while maintaining a pore size of 0.35-μm. NPN membranes with a pore size of 35-nm were also developed for testing in the large-animal model with the goal of consistent dialysis of uremic toxins without loss of other important macromolecules and blood components (e.g., albumin and white blood cells).

Methods: The large-animal hemodialysis benchtop model consists of a 500 mL circulating analyte (20 mM urea-spiked 1x phosphate-buffered saline (PBS) or whole heparinized bovine blood) flowing across an NPN membrane counter to 1x PBS, circulating at a rate of 50 mL/min and 120 mL/min respectively. The NPN membranes are contained in a stable 3D-printed housing unit that allows for effective flow-through and the ability to gather transmembrane pressure readings, without damage to the chip. Small samples (~100 μL) were collected from the body of the dialyzed analyte every five minutes for the first thirty minutes, and every fifteen minutes thereafter, over the course of two hours.

Results: The clearance results of the NPN membranes in the dialysis of urea-spiked 1x PBS and blood show a decrease in urea concentration in the analyte over a time of two hours, consistent with that seen in the small-animal model. This data suggests that NPN membranes are effective dialyzers of metabolic waste products, such as urea, in a large-animal model of ESRD.

Conclusions: This study demonstrates the effectiveness of microporous and nanoporous silicon nitride membranes for dialyzing small metabolic waste products in a large-scale animal model.

Impact of Protein Fouling on Middle Molecule Removal During Initial Dialysis Phase

James P. Kennedy,[1] Karlee Emal,[1] Joanie Werner,[1] Chih-Hu Ho,[1] Adam M. Zawada,[2] Skyler Boyington.[1] [1]*Fresenius Medical Care North America, Ogden, UT;* [2]*Fresenius Medical Care Deutschland GmbH, Sankt Wendel, Germany*.

Background: Deposition of plasma proteins to the dialyzer membrane during the initial dialysis phase strongly reduces removal capacity of middle molecules such as β2-microglobulin (β2-m). Hydrophilic membrane modification with polyvinylpyrrolidone (PVP) has been shown to reduce protein fouling and to stabilize dialyzer performance during dialysis treatment. In the present study we investigated the impact of initial protein fouling on middle molecule removal by different dialyzers, including the novel FX CorAL with PVP enriched and stabilized surface of its Helixone *hydro* membrane.

Methods: This *in vitro* study included the following dialyzers: FX CorAL 80 (Fresenius Medical Care), Revaclear 400 (Baxter), Diacap Pro 19H (B. Braun), ELISIO 17H and Cellentia 17H (both Nipro). Protein deposition to the membrane was simulated during a recirculation experiment with bovine plasma for 30 and 60 min. β2-m clearance was determined in a single-pass setup with bovine plasma at three time points (before protein fouling [0min], after 30min and 60min protein fouling). Clearance values were normalized based on the membrane surface size.

Results: Across all five investigated dialyzers, mean β2-m clearance reduced by 18.7% after 30min of plasma recirculation (0min: 35.2±9.3ml/min/m^2; 30min: 28.7±7.5ml/min/m^2). After additional 30min of plasma recirculation, β2-m clearance only slightly decreased (60min: 28.4±7.9ml/min/m^2; -1.1% vs 30min). When comparing the clearance reduction by the different dialyzers, the FX CorAL showed low β2-m clearance decrease while having the highest β2-m clearance values throughout the experiment (0min: 47.2±3.4ml/min/m^2; 30min: 39.8±0.9ml/min/m^2; 60min: 40.0±1.3ml/min/m^2) as compared to Revaclear (0min: p<0.001; 30min: p<0.001; 60min: p<0.001), Diacap Pro (p<0.01; p<0.001; p<0.001), ELISIO (p<0.01; p<0.001; p<0.001) and Cellentia (p<0.001; p<0.001; p<0.001).

Conclusions: Efficient removal of middle molecules while preserving vital proteins such as albumin is pivotal for patients requiring renal replacement therapy. To prevent loss of dialyzer performance during treatment, novel hydrophilic membranes, such as FX CorAL's Helixone *hydro* membrane, has been shown to reduce protein fouling and to stabilize performance during treatment, especially during the initial dialysis phase.

SA-PO554

Hydrophilic Membrane Modification Improves Filtration Characteristics of Dialyzer Membranes

James P. Kennedy,[1] Eva Förster,[2] Saeedeh Saremi,[2] Lukas Theis,[2] Florian Küng,[2] Dirk Delinski,[2] Wenhao Xie,[3] Matthias Faust,[4] Adam M. Zawada.[2] [1]*Fresenius Medical Care North America, Ogden, UT;* [2]*Fresenius Medical Care Deutschland GmbH, Sankt Wendel, Germany;* [3]*Fresenius Medical Care R&D (Shanghai) Co., Ltd., Shanghai, China;* [4]*Saarland University of Applied Sciences, Saarbrücken, Germany*.

Background: While efficient removal of uremic solutes and accumulated water is pivotal for the well-being of patients requiring kidney replacement therapy, the removal capacity of a dialyzer decreases during dialysis treatment due to adsorption of plasma proteins to the membrane. Hydrophilic membrane modification with polyvinylpyrrolidone (PVP) has been shown to reduce protein adsorption and to stabilize permeability of the membrane during treatment. The present study compares water permeability changes of polysulfone membranes, including the PVP enriched and stabilized membrane of the novel FX CorAL dialyzer.

Methods: This *in vitro* study included the polysulfone-based FX CorAL 600, FX CorDiax 600 (both Fresenius Medical Care) and xevonta Hi15 (B. Braun) dialyzers. Protein fouling to the membrane was simulated during a recirculation experiment with bovine milk for 4h. The decrease in filtration flow (Q_F) at constant inlet flow (Q_{IN}, 400ml/min) and transmembrane pressure (TMP, 75mmHg) (setup 1) as well as the increase in TMP at constant Q_F (100ml/min) and Q_{IN} (400ml/min) (setup 2) were continuously determined during recirculation.

Results: Across all dialyzers, Q_F at constant Q_{IN} and TMP decreased strongly in the first 20min and then slowly for the remaining time (20min: -50.8±15.9ml/min; 4h: -66.9±29.2ml/min). Likewise, the TMP at constant Q_F and Q_{IN} increased first strongly and then slowly (20min: +21.9±3.9mmHg; 4h: +39.0±5.9mmHg). The FX CorAL showed the lowest reduction in Q_F (20min: -30.6±8.2ml/min; 4h: -32.6±13.4ml/min) as compared to FX CorDiax (20min: -61.0±3.7ml/min, p=0.001; 4h: -78.2±21.4ml/min, p=0.017) and xevonta (20min: -60.8±3.4ml/min, p=0.001; 4h: -90.0±5.5ml/min, p=0.006). In line, the FX CorAL showed lowest increase in TMP (20min: +18.3±1.5mmHg; 4h: +32.7±2.1mmHg), as compared to the FX CorDiax (20min: +21.7±3.8mmHg, p=0.214; 4h: +39.9±4.8mmHg, p=0.078) and xevonta (20min: +25.8±0.8mmHg, p=0.015; 4h: +44.4±3.0mmHg, p=0.011).

Conclusions: Protein adsorption to the membrane is the major factor for the initial decrease of dialyzer membrane permeability during hemodialysis. Hydrophilic membrane modification with PVP reduces protein fouling and stabilizes the removal capacity of solutes and water during dialysis treatment.

SA-PO555

Uremic Toxins Are Adsorbed by the Model 3 Wearable Artificial Kidney (WAK)

Victor Gura,[1,2] Carlos Orantes,[3] Noble B. Tabibian,[1] Johanna ten Hoeve.[1] [1]*University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA;* [2]*Cedars-Sinai Medical Center, Los Angeles, CA;* [3]*Wearable Artificial Organs Inc., Beverly Hills, CA*.

Background: Elimination of uremic toxins is necessary for effective renal replacement therapy. Previous WAK data showed that its sorbents adsorb beta2 microglobulin, uric acid, hippuric acid, indoxyl sulphate and indoleacetic acid. We aimed to show the WAK3 effectively purifies dialysate from additional toxins.

Methods: Discarded dialysate from 8 dialysis patients was placed in a reservoir and recirculated for 4 hours through the the WAK3 charcoal cartridge. Samples were obtained before and after the fluid passage through the cartridge and analyzed LC-MS. Metabolites

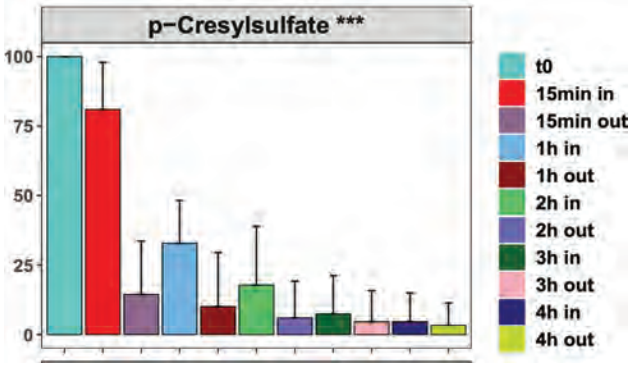
were separated on a LunaNH2 (Phenomenex) HILIC column and detected with a Q Exactive orbitrap mass spectrometer (Thermo Scientific). Statistical analysis was done with a one-way Anova test.

Results: the concentration of ADMA, homocitrulline, homocysteine, kynurenine, p-cresylsulfate, phenol, and phenylacetylglutamine, and methylguanidine in the spent dialysate decreased by 87.93% (p= <0.001) at a dialysate pulse flow rate of 30 ml/min. after 4 hours of recirculation through the WAK sorbent cartridge

Conclusions: The WAK3 effectively adsorbs uremic toxins from dialysate supporting the notion that the device may be effective in treating dialysis patients.

Percentage of toxin removed from dialysate after 4 hours of recirculation through the WAK3 charcoal sorbent

TOXIN	% removed	p-value
Methylguanidine	74.4%	<0.001
ADMA	93.98%	<0.001
Homocitrulline	80.19%	<0.001
Homocysteine	72.33%	<0.001
Kynurenine	97.5%	<0.001
p-Cresylsulfate	96.71%	<0.001
Phenol	95.54%	<0.001
Phenylacetylglutamine	92.85%	<0.001



SA-PO556

Can Oral Potassium Binders Be Added to Dialysate to Improve the Efficacy of Hemodialysis?

Rouzbeh Tehrani,[1] Avrum Gillespie,[2] Juliana Alderfer.[1] *[1]Temple University, Philadelphia, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Background: Can commercially available oral potassium (K+) binders (sodium zirconium cyclosilicate, ZS-9) be added to the dialysate to improve diffuse clearance and reduce dialysate usage while decreasing blood-dialysate K+ gradients?

Methods: This is an in-vitro hemodialysis experiment using 1 liter of freshly collected Li-heparinized porcine blood dialyzed with an average blood flow rate of 30 mL/min and dialysate flow of 50 mL/min, two peristaltic pumps, Fresenius Optiflux hemodialysis membranes, and CitraPure dialysate concentrate (Rockwell Medical). For the potassium management experiment, 5 g of ZS-9 was added to 1 L of dialysate. Dialysate K+ was set to 4 mmol/L for the management of the potassium concentration gradient (delta C_K). ZS-9 leaching to blood was tested by examining blood specimens after 5-hour hemodialysis, using highly concentrated Nano-Slurry (10 to 20 g/l) dialysate and increased transmembrane pressure (reversed), and measuring the reverse filtrate for nanoparticles for turbidity and nanoparticle materials using inductively coupled plasma mass spectrometry.

Results: In experiment 1, blood K+ was 5 mmol/L and dialysate K+ was 4 mmol/L plus ZS-9 (delta C_K=1), by 60 minutes using recirculated dialysate, serum K+ had decreased to 3.5 mmol/L and dialysate K+ 3.0 mmol/L. In experiment 2, the blood K+ was 8 mmol/L and the dialysate 4 mmol/L plus ZS-9 (delta C_K=4), by 60 minutes using recirculated dialysate, the serum potassium was 4 mmol/L. In experiment 3, the starting serum potassium was 8 and the bath was 4 K+, after the addition of ZS-9, potassium dropped to 5.8 at 20 minutes, and then after the addition of ZS-9 at 40 minutes, potassium dropped to 2.5mmol/L and maintained at equilibrium. The addition of ZS-9 in increments was to manage C_K gradient throughout the treatment. No suspended particles and no trace amount of Zr or Si were detected passing through the membrane from dialysate to blood.

Conclusions: The addition of commercially available K+ binder, sodium zirconium cyclosilicate (ZS-9), effectively lowered potassium using recirculated dialysate while maintaining a minimal concentration gradient throughout the treatment. The addition of K+ binders to dialysate can be incorporated into a novel hemodialysis machine that can recirculate dialysate and offer the management of K+ throughout the treatment.

SA-PO557

Can Oral Phosphate Binders Be Added to Dialysate to Improve the Efficacy of Hemodialysis?

Rouzbeh Tehrani,[1] Avrum Gillespie,[2] Juliana Alderfer.[1] *[1]Temple University, Philadelphia, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Background: Can commercially available polymeric phosphate binders, Sevelamer carbonate (SC), be added to the dialysate to improve diffuse clearance and reduce dialysate usage while decreasing blood-dialysate phosphate gradients? Sevelamer carbonate is an orally administered, non-absorbed phosphate-binding anion exchange resin. It is a buffered form of Sevelamer hydrochloride.

Methods: This is an in-vitro hemodialysis experiment using 1 liter of freshly collected Li-heparinized porcine blood with an average blood flow rate of 30 mL/min and dialysate flow of 50 mL/min, two peristaltic pumps, Fresenius Optiflux hemodialysis membranes, and CitraPure dialysate concentrate (Rockwell Medical) which was diluted and the pH adjusted using sodium bicarbonate (Solcart B, B.Braun). For the phosphate experiment, 3 tablets of SC were crushed and added to the dialysate, 2700 mg of active-SC/L. SC leaching to blood was tested by (i) examining blood specimens after prolonged 5-hour hemodialysis, (ii) using highly concentrated SC-added dialysate (5 to 10 g/L) and increased transmembrane pressure, and measuring the reverse filtrate for SC particles.

Results: For the hyperphosphatemia experiment, the start serum phosphorus was 8 mg/dL. After 30 minutes of dialysis, the phosphorus was 5.5 mg/dL. SC was added and the phosphate dropped to 2.5 mg/dL at 100 minutes. SC was then added again and phosphate dropped to 2 mg/dL. No suspended particles were detected passing through the membrane from dialysate to blood.

Conclusions: The addition of Sevelamer Carbonate (SC) effectively lowered phosphate using recirculated dialysate and can be incorporated into a novel hemodialysis machine that can recirculate dialysate, reducing water consumption for both in-center and home hemodialysis. While SC effectively reduced phosphate levels, its addition to the dialysate has been found to influence the dialysate pH. Therefore, careful consideration must be given to pH adjustment when utilizing SC. Maintaining appropriate dialysate pH is crucial for ensuring patient safety and optimizing dialysis outcomes.

SA-PO558

Improving the Efficacy and Efficiency of Hemodialysis by Adding Nanoscale Activated Carbon (Nano-Slurry) Sorbent to the Dialysate

Rouzbeh Tehrani,[1] Avrum Gillespie,[2] Juliana Alderfer.[1] *[1]Temple University, Philadelphia, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Background: Improving the efficacy and efficiency of dialysate for hemodialysis has the potential to improve patient outcomes and reduce waste and energy consumption. Currently, hemodialysis relies mostly on diffusive clearance across a gradient between the patient's blood and the dialysate. We demonstrate that the addition of nanoparticle sorbents to the dialysate can improve the efficiency of hemodialysis and can allow for the reuse of dialysate.

Methods: This is an in-vitro hemodialysis experiment using Li-heparinized porcine blood, two peristaltic pumps, Fresenius Optiflux hemodialysis membranes, and CitraPure dialysate concentrate (Rockwell Medical) which was diluted and the pH was adjusted using medical-grade sodium bicarbonate (Solcart B, B.Braun). One liter of freshly collected porcine blood was dialyzed with an average blood flow rate of 30 mL/min and dialysate flow of 50 mL/min. Nanoscale activated carbon (Nano-Slurry) was tested in this study. The mass of added adsorbents (0.5 to 5 g/l) varied depending on the adsorbent type, targeted blood toxin, and expected removal rate. Absorbent leaching to blood was tested by using highly concentrated Nano-Slurry (10 to 20 g/l) dialysate and increased transmembrane pressure by increasing the dialysate flow rate to 1000 mL/min and measuring the reverse filtrate for nanoparticles by turbidity with a near-infrared turbidity meter.

Results: In the single-pass experiment, creatinine was removed in half the time when using Nano-Slurry dialysate. We then did our recirculated dialysate experiment and the Nano-Slurry, creatinine rapidly equilibrated in the control experiment at 30 minutes whereas, the recirculated Nano-Slurry dialysate continued to remove creatinine at the end of the experiment, 100 minutes. BUN rapidly lowered from 17 mg/dL to 7mg/dL, below the calculated equilibrium at 20 minutes. For the absorbent leaching experiment, the reverse filtrate had turbidity that remained unchanged pre- and post-experiment with a measure of 0.03 NTU.

Conclusions: Nano-Slurry improved the efficiency in both in-vitro single pass and recirculated hemodialysis models. The addition of nanoscale adsorbents improved the efficiency of dialysis and can be incorporated into a novel hemodialysis machine that can recirculate dialysate, reducing water consumption for both in-center and home hemodialysis.

SA-PO559

Animal Models for Studying Protein-Bound Uremic Toxin Removal

Sabbir Ahmed,[1] Joost C. de Vries,[2] Jingyi Lu,[1] Milan H. Verrijn Stuart,[2] Silvia M. Mihaila,[1] Robin W. Vernooij,[2] Rosalinde Masereeuw,[1] Karin G. Gerritsen.[2] *[1]Universiteit Utrecht, Utrecht, Netherlands; [2]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands.*

Background: Protein-bound uremic toxins (PBUTs) are linked with the progression of chronic kidney disease (CKD) and higher morbidity and mortality risks. Conventional dialysis does not effectively remove PBUTs due to their binding to plasma proteins. Therefore, novel approaches to improve PBUT clearance are being developed, but these require validation before clinical trials can be initiated. To gain more insight into suitable CKD animal models we conducted a semi-systemic review to document PBUT concentrations in various models and species.

Methods: The search yielded 1163 records which were included for abstract screening, of which 66 were included for data extraction (Figure 1). All data were extracted by one researcher, after which the data were independently validated by a second researcher. Two specific types of injury were distinguished and analyzed as subgroups for the effect on PBUT levels: nephron loss models (e.g. 5/6th nephrectomy) and tubular damage models (by administration of tubulotoxins, e.g. adenine).

Results: PBUT concentrations were reported in studies using rats (n=43), mice (n=16), dogs (n=3), cats (n=4), goats (n=1), and pigs (n=1). Most studies in rodents reported mean uremic concentrations of plasma indoxyl sulfate (IS) close to or in the range of human ESKD, with the highest concentrations in tubular injury models (121.7 μM (89.3 μM – 154.1 μM); mean (95% CI), n=15 rat studies). Compared to nephron loss models in rats, a greater rise in plasma IS compared to creatinine was found in tubular injury models (factor 11.2 versus 6.3 for nephron loss models), likely due to the fact that tubular secretory function was relatively more affected than glomerular filtration. The small number of studies and heterogeneity of the data reported precluded detailed analysis of large animal models or other PBUTs.

Conclusions: Tubular injury models in rats appear to be suitable models to mimic human ESKD for *in vivo* validation of innovative PBUT-lowering strategies.

A Chronic Intermittent Hemodialysis Pig Model for Functional Evaluation of Dialysis Filters

Shouichi Fujimoto,[1,2] Shushi Yamamoto,[3,4] Hiroshi Umeno,[5] Yusuke Sano,[5] Masahide Koremoto,[6] Yoshimichi Goda,[4,7] Toshihiro Tsuruda,[4] Masao Kikuchi.[2] *[1]Department of Medical Environment Innovation, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [2]Division of Nephrology and Dialysis, University of Miyazaki Hospital, Miyazaki, Japan; [3]Department of Small Animal Clinical Sciences, School of Veterinary Medicine, Rakuno Gakuen University, Ebetsu, Japan; [4]Department of Hemo-Vascular Advanced Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [5]Medical Technology and Material Laboratory, Asahi Kasei Medical Co. Ltd., Fuji, Japan; [6]Product Development Strategy Department, Asahi Kasei Medical Co. Ltd., Tokyo, Japan; [7]Department of Veterinary Medical Science, Faculty of Agriculture, University of Miyazaki, Miyazaki, Japan.*

Background: Performance evaluation of new dialysis filters is primarily performed *in vitro*, which can lead to differences in clinical results. Currently, data on filter performance and safety are available only for actual hemodialysis patients. Herein, we aimed to establish an *in vivo* dialysis model that could be extrapolated to humans.

Methods: A bilateral nephrectomy porcine model of renal failure was established, in which a double-lumen catheter for human dialysis was subsequently placed in the external jugular vein under general anaesthesia, the tip of which was fixed to the back (Fig 1). Hemodialysis was performed every other day in the same manner as in humans, during which various clinical data were evaluated. The utility of hemodiafilters coated with and without vitamin E (V-RA and ABH™) was subsequently compared using this model.

Results: Hemodialysis treatment was successfully performed in bilaterally nephrectomised pigs under the same dialysis conditions as humans (4 h per session, 3 times a week, for 2 weeks). In accordance with human clinical data, regular dialysis alleviated renal failure in pigs, allowing for sufficient activity. The vitamin E-coated filter showed a significantly greater reduction rate of advanced oxidation protein products (AOPP) during dialysis and a lower quantity of fibrinogen adhesion at the first dialysis on postoperative day 1 than ABH (Fig 2).

Conclusions: Herein, we successfully constructed a pig model of chronic hemodialysis that mimics the pathophysiology and dialysis condition of patients undergoing hemodialysis. This model will be useful for evaluating the performance and safety of dialysis filters before market release.

Funding: Commercial Support - Asahi Kasei Medical Co. Ltd.

Amino Acid Loss During a Hemodialysis Session Depending on Membrane Materials

Tomohiro Shirouzu,[1] Tomokazu Maeda,[2] Ikutaro Furuno,[3] Tetsu Miyamoto.[3] *[1]2nd Department of Internal Medicine, University of Occupational and Environmental Health School of Medicine, Kitakyushu, Japan; [2]Kitakyushu General Hospital, Kitakyushu, Japan; [3]Kidney Center, University of Occupational and Environmental Health School of Medicine, Kitakyushu, Japan.*

Background: Dialysis-related factors including nutrient loss during a hemodialysis (HD) session may have an important impact on protein energy wasting especially in elderly or malnourished dialysis patients. In this study, we examined dialysate amino acid (AA) loss during a HD session and compared clear space (CS) of AA among three different membranes including acrylonitrile and sodium methallyl sulfonate blend (AN 69) which has significantly smaller amount of albumin loss.

Methods: In 6 maintenance HD patients (6 women), pre-HD plasma basic 20 AA profiles were analyzed in three consecutive HD sessions (blood flow 200ml/min, 4 hours) with different membranes. Simultaneously, dialysate AA losses in each session are measured by continuous effluent collection (2L/hr) from the drainage line. The membranes studied were: cellulose tri-acetate (CTA), polysulfone(PS), and acrylonitrile and AN 69. All membranes had similar surface area of 1.5 square meters. We measured CS using the pre-dialysis plasma AA concentration and AA losses in dialysate, and compared CS among the three membranes.

Results: The total amino acid (TAA) loss for each HD session was 8.2 (5.9-10.0) g for CTA, 8.0 (6.1-9.5) g for PS, and 7.3 (5.0-8.4) g for AN69 (p=0.32). Average of CS for each AA is 21(16-25) L for CTA, 19(16-27) L for PS, 18(15-24)L for AN69 (p=0.36). Total CS for AA is 400(311-474) for CTA, 362 (302-505) L for PS, 344 (292-451)L for AN69 (p=0.36).

Conclusions: A total of 7 to 8 grams of AA are lost per HD session. No superiority of AN69 for reducing AA loss was not observed in this study.

SA-PO562

Bisphenol Levels in Hemodialyzers

Nadja Grobe,[1] Zahin S. Haq,[1] Xin Wang,[1] Joann Cheng,[2] Gabriela Ferreira Dias,[1] Christoph Moore,[3] Dorothea Piecha,[3] Peter Kotanko,[1,4] Chih-Hu Ho.[5] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]Value Stream Dialyzers, Fresenius Medical Care, Ogden, UT.*

Background: Bisphenol A (BPA)-based materials are widely employed across various industries, including dialysis. As concerns for BPA's health risks rise, bisphenol S (BPS)-based materials are increasingly used. However, BPS safety requires further evaluation. To support thorough risk assessments on bisphenols and their exposure for hemodialysis patients, extractables (E) and leachables (L) from 8 commercially available dialyzers were tested.

Methods: For E, dialysate and blood sides of each dialyzer were incubated statically at 37°C with 95% ethanol (EtOH) and collected after 72 hrs. For L, bloodlines, dialysate and blood sides were filled with 17.2% EtOH and recirculated at 300 mL/min and 37°C for 24 hrs. Bloodline controls were run using the recirculation setup. Bisphenols were quantified by liquid chromatography-mass spectrometry using standard addition and stable-isotope labeled standards.

Results: BPA (0.43 - 32.82 µg/device) and BPS (0.02 - 2.51 µg/device) were detected in E from dialyzers and housings made with BPA- and BPS-containing materials (Figure 1). In L, BPA was only detected in one dialyzer made of BPA-containing membrane and housing material. BPS (0.08 - 1.44 µg/device) was detected in L of dialyzers made with BPS-based materials. BPA/BPS were not detected in bloodline controls, cellulose-based membranes, and in Fresenius Medical Care's FX CorAL 120 dialyzer, a member of the recently FDA-cleared CorAL dialyzer family.

Conclusions: Dialyzers have varied bisphenol amounts based on raw materials and manufacturing process used for housing and membranes. FX CorAL exhibited no detectable bisphenols, as opposed to other dialyzers with synthetic membranes, where varying amounts of bisphenols were detected. To understand the BPS toxicological profile, additional studies should be performed and evaluated as rigorously as BPA.

Revaclear 400	Baxter	PAES/PVP	PC	Steam	0.43	ND	0.27	0.15
Bain B-20HF	Bain	PES	PP	Radiation	ND	ND	2.51	0.62

- PS – polysulfone, PVP – polyvinylpyrrolidone, PP – polypropylene, ND – not detected, PAES – polyarylethersulfone, PC – polycarbonate, PES – polyethersulfone.
- PS and PC are BPA-based materials, PES is BPS-based material, while PVP, PP, cellulose or asymmetric triacetate are neither BPA- nor BPS-based materials.
- Different sterilization processes are indicated.
- 95% ethanol is extractable, 17.2% ethanol is leachable.
- All samples were analyzed in duplicate for three technical replicates.
- For the 95% EtOH extracts, the BPA and BPS amount in extracts of blood side and dialysate side were combined and reported as the total amount in each sample for each dialyzer. For calculating the extraction mass in extractables, the extraction volume and density of 0.8 g/ml for 95% EtOH was used. For leachables, no density adjustment was used as the density of 17.2% EtOH is close to 1 g/ml.

Figure 1: BPA and BPS extraction mass in extractables (E) and leachables (L) of tested dialyzers.

Endotoxin Retentive Performance of the Fresenius FX CorAL Dialyzer

Michael E. Henrie, Chih-Hu Ho. *Value Stream Dialyzers, Fresenius Medical Care, Ogden, UT.*

Background: Many dialyzer innovations focus on improving solute removal or sequestration of target molecules. However, these improvements may impact peripheral dialyzer functions, such as prevention of pyrogenic substances from entering patient blood. This study explored the transmembrane flux and retention of endotoxins for the following dialyzers: FX CorAL 80 and Optiflux F180NRe (Fresenius Medical Care), and Theranova 400 (Baxter International). FX CorAL (F), a new dialyzer featuring novel Helixone hydro membrane, Optiflux (O), a membrane known for endotoxin performance, and Theranova (T), a medium cut-off (MCO) membrane.

Methods: *In-vitro* experiments used culture filtrates of *P.* aeruginosa (ATCC 27853) and *S.* maltophilia (ATCC 13637) spiked into saline to create a solution containing > 200 EU/mL. Dialyzers were challenged under diffusive and convective test configurations, with samples taken during both configurations at 5, 15, 30, and 60 minutes. Samples were analyzed for endotoxin using a kinetic turbidimetric LAL assay with a detection limit of 0.001 EU/mL.

Results: Diffusive transmembrane flux of endotoxin was observed for all dialyzers, with F and O nearly 10^3 lower than T. Maximum diffusive endotoxin concentrations: F = 0.0016 EU/mL; O = 0.0209 EU/mL; T = 30.98 EU/mL. Convective endotoxin flux decreased over time for all dialyzers, with T plateauing higher than O or F. Log reduction values were calculated from convective samples at 60 minutes: T = 1.61; F = 4.26; O = 4.72.

Conclusions: Endotoxin retention of dialysis membrane is a final barrier in the transfer of pathogens to patients. This is an important membrane quality, since endotoxins present in dialysate will contribute to chronic inflammation in patients. FX CorAL demonstrates endotoxin retentive performance similar to Optiflux, and better than Theranova. Improved understanding of endotoxin removal mechanisms may lead to enhanced endotoxin retention in parallel with dialysis membrane development.

Effect of Dialysis Treatment on Structural Brain Connectivity in Patients with ESRD

Byeongo Choi, Yang Wook Kim, Yeongrok Oh, Jiyae Yi, Bongsoo Park, Sihyung Park, Yoo jin Lee, Changmin Heo. *Inje University Haeundae Paik Hospital, Busan, Republic of Korea.*

Background: End-stage renal disease (ESRD) patients are known to have reduced structural and functional brain connectivity associated with cognitive function. However, the effect of dialysis treatment on brain connectivity is not understood. This study was designed to evaluate effects of dialysis treatment on structural brain connectivity in patients with ESRD.

Methods: This prospective study was conducted with 20 ESRD patients with pre-dialysis and 35 healthy controls. The patients underwent T2-weighted and three dimensional T1-weighted magnetic resonance imaging (MRI) before and 3 months after dialysis initiation, and cortical thickness was calculated. We applied a graph theoretical analysis for calculating the structural co-variance network based on the cortical thickness. We compared the cortical thickness and structural co-variance network between ESRD patients with pre-dialysis and healthy controls, and between ESRD patients with pre-dialysis and those with post-dialysis.

Results: The mean cortical thickness in both hemispheres was lower in ESRD patients with pre-dialysis than in healthy controls (2.296 vs. 2.354, p=0.030; 2.282 vs. 2.362, p=0.004; respectively), and it was higher in ESRD patients with post-dialysis than in those with pre-dialysis (2.333 vs. 2.296, p=0.001; 2.322 vs. 2.282, p=0.002; respectively). In analysis of the structural co-variance network, the assortative coefficient was lower in ESRD patients with pre-dialysis than that in healthy controls (-0.062 vs. -0.031, p=0.029), and it was higher in ESRD patients with post-dialysis than those with pre-dialysis (-0.002 vs. -0.062, p=0.042).

Conclusions: We found that there were differences in cortical thickness and structural co-variance network before and after dialysis in ESRD patients. This indicates that dialysis treatment affects structural brain connectivity and will contribute to understand the pathophysiologic mechanism of cognitive function alterations resulting from dialysis treatment in ESRD patients.

SA-PO565

Uromodulin in Kidney Failure

Rita L. McGill, Arlene B. Chapman. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

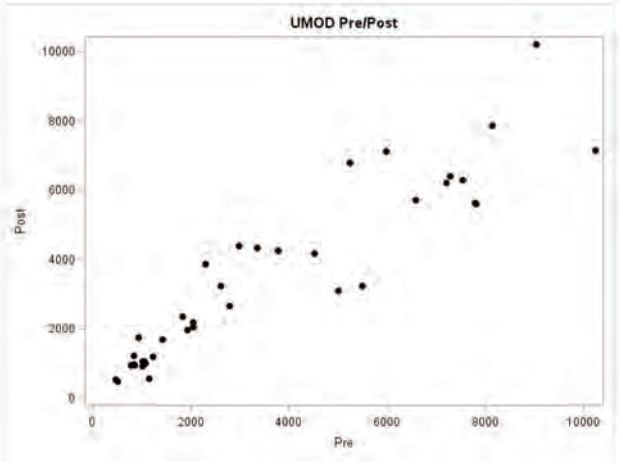
Background: Uromodulin (UMOD) is a 95 kDa glycoprotein produced exclusively by the loop of Henle. UMOD is detectable in urine and blood and levels may represent functional renal tubular mass. To address this question, we measured serum UMOD in chronic dialysis patients to evaluate its potential utility as biomarker of kidney function and to assess its dialyzability.

Methods: Serum samples were obtained immediately before and after hemodialysis through dialysis access and immediately frozen at -20. All samples were assayed undiluted within 6 months, using a sandwich ELISA assay platform (Invitrogen ®; Thermo-Fisher), with assay sensitivity down to 40 pg/mL. Estimated glomerular filtration rate (eGFR) was

determined using the median of all available pre-dialysis eGFR values within a month of the sample collection date. Age, sex, dialysis vintage, and target weight were collected. Descriptive analyses and Spearman correlation coefficients were performed.

Results: Pre- and post-dialysis levels were obtained from 38 individuals. Values were non-normally distributed (Fig1). Median UMOD pre-dialysis was 2450 (IQR=1060- 5981) pg/mL, and post dialysis was 2870 (IQR=1050-5640) pg/mL, with median difference =16 (!QR=-600-470) pg/mL, P=0.8. UMOD>8000 pg/mL were in the 95th percentile. Pre- and post- dialysis UMOD values were highly correlated (R=0.93, P<0.001 and did not correlate with eGFR, age, sex, dialysis vintage or target weight.

Conclusions: Low levels of UMOD are detectable in patients with end stage kidney failure. There is no evidence of removal of UMOD with hemodialysis. Further evaluation of UMOD as a biomarker of potential kidney recovery after acute injury or transplantation or indicator of preserved residual renal function is worth further investigation.



Uromodulin Levels Before and After Hemodialysis

Is the Donnan Equilibrium Still Intact in High-Volume Hemodiafiltration?

Malte Gross,[1] Alfred J. Gagel,[2] Andreas Maierhofer.[2] *[1]Technische Hochschule Ulm, Ulm, Germany; [2]Fresenius Medical Care Deutschland GmbH, Schweinfurt, Germany.*

Background: High convective flow in high-volume hemodiafiltration has raised concerns that intradialytic electrolyte balance might be changed compared to standard HD, requiring adaptions of dialysate electrolyte prescription. The presence of charged proteins in the blood which are too large to penetrate the dialyzer membrane cause an asymmetric small ion distribution governed by the Gibbs-Donnan equilibrium (GDe). Derivations of GDe in most cases ignore the hydrodynamic drag from transmembrane fluid flow. We studied the effect of this flow by numerical simulations in an extended model.

Methods: The Nernst-Planck equation was extended by an advective term taking into account the hydrodynamic transmembrane flow as an additional driving force for ion transport. For the simplest case of two oppositely charged monovalent permeable ions a set of differential equations was derived. This allowed for a numerical calculation of permeable ion concentrations on both sides of the membrane depending on the transmembrane flow speed. The deviation of ion concentrations from their equilibrium values was analyzed for different ion species and concentrations for a large range of transmembrane flow rates.

Results: Even in the case of a non-zero convective flow, equilibrium concentrations are already reached a few nm from the inner membrane boundary, thus still within the membrane pores (cf. Fig. 1). These concentrations differ slightly from what is expected from classical Gibbs-Donnan equilibrium. However, in a typical HDF treatment, where transmembrane flow speed is less than 10^{-5} ms^{-1} this deviation is less than 6 10^{-5} mmol/L.

Conclusions: Even in high volume hemodiafiltration the transmembrane flow has negligible influence on the equilibrium electrolyte concentrations.

Funding: Commercial Support - Fresenius Medical Care Deutschland GmbH

Noninvasive Assessment of Liver Disease and Outcomes in ESKD

Oscar Swift,[1] Malcolm A. Finkelman,[3] Yonglong Zhang,[3] Chadd Javier,[1] Mikky M. Gilbert,[1] Kieran Mccafferty,[2] Jonathan P. Wong,[4] Paul Warwicker,[5] Jean Patrick,[6] Georgia Winnett,[4] Gowrie Balasubramaniam,[4] Richard C. Warburton,[1] Sivakumar Sridharan,[1] Ken Farrington,[1] Enric Vilar.[1] *[1]East and North Hertfordshire NHS Trust, Stevenage, United Kingdom; [2]Barts Health NHS Trust, London, United Kingdom; [3]Associates Of Cape Cod Inc, East Falmouth, MA; [4]Mid and South Essex NHS Foundation Trust, Basildon, United Kingdom; [5]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [6]James Paget University Hospitals NHS Foundation Trust, Great Yarmouth, United Kingdom.*

Background: People with ESKD often exhibit risk factors (diabetes mellitus, obesity and hypertension) for non-alcoholic fatty liver disease (NAFLD) and its progressive form, non-alcoholic steatohepatitis (NASH). NAFLD and NASH both associate with increased cardiovascular risk and by 2030 NASH will be the leading cause of cirrhosis. Little is known about prevalence and clinical outcomes of NAFLD and NASH in ESKD. We report updated interim results from this study non-invasively evaluating liver disease in ESKD.

Methods: This prospective observational study involves 451 prevalent patients with ESKD receiving dialysis for >3 months at 5 UK kidney units. A FibroScan (Echosens) measured hepatic steatosis using controlled attenuation parametrography and fibrosis using transient elastography. Survival analyses were performed using Kaplan-Meier estimates and a Cox regression model for multivariate analysis.

Results: Median patient age was 62. 61% of patients were male. 93% had hypertension, 48% diabetes and 63% hyperlipidaemia. 33% had a BMI of greater than 30kg/m^2. 27% had suspected NAFLD and 12% suspected NASH. There was increased mortality with suspected hepatic fibrosis grades F2-4 (19.1% vs 2.5% in grades F0-1). Kaplan-Meier survival curves are shown in Figure 1. Mortality in participants with suspected hepatic fibrosis grades F3-4 was significantly increased after adjustment for other predictors of survival (Figure 2).

Conclusions: There is significant burden of suspected hepatic steatosis and fibrosis in ESKD. Suspected F3-4 fibrosis is an independent risk factor for mortality in this interim analysis. Strategies to improve liver health in advanced kidney disease may be of benefit.

SA-PO568

The Relationship Between Myocardial Fibrosis and Physical Activity in Individuals Receiving Hemodialysis

Daniel S. March,[1,2] Katherine L. Hull,[2] Matthew Graham-Brown,[1,2] James Burton.[2] On Behalf of the CYCLE-HD Investigators. *[1]University of Leicester, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom*.

Background: Individuals with end stage kidney disease receiving haemodialysis have high levels of myocardial fibrosis, which is thought to contribute to their excess cardiovascular burden. In addition, these individuals are physically inactive, which directly associates with high levels of cardiovascular and all-cause mortality. However, the relationship between physical activity levels and myocardial fibrosis has not previously been explored.

Methods: This is a post-hoc analysis of baseline data from the CYCLE-HD trial. Participants wore an accelerometer on the upper arm for 7 days; average steps per day were calculated by dividing the total number of steps by days worn. Global, septal and non-septal native T1 times (a surrogate of myocardial fibrosis) were acquired using cardiac MRI. Spearman's correlation and multiple linear regression analyses (adjusting for age, gender and diabetes) were performed to investigate associations between steps per day and T1 variables.

Results: Data for 102 participants were included. Mean steps per day were 3180±282. Steps per day had a significant negative correlation with global native T1 (-0.308; P = 0.002), non-septal T1 (-0.287; P = 0.004) and septal T1 (-0.275; P = 0.005). This relationship persisted after adjustment (Table 1).

Conclusions: Increased physical activity defined by average daily step count, associates with lower levels of myocardial fibrosis. Overall the levels of physical activity were low (comparable to levels reported in other studies), however these data indicate that even these levels (below recommended guideline levels) may be beneficial. Longitudinal studies are needed to understand the mechanisms behind these findings.

Table 1. Multiple linear regression showing the association between steps per day, Native T1, Non-septal T1 and Septal T1

	Standardised coefficients β (95% CI)	P-value
Steps per day and CMR (n=102)		
Native T1	-0.004 (-0.007 to -0.001)	=0.003
Non-septal T1	-0.004 (-0.006 to -0.001)	=0.009
Septal T1	-0.004 (-0.007 to -0.001)	=0.007

*There was no significant association between myocardial fibrosis and other variables (age, gender and diabetes) in the regression analyses.

SA-PO569

Assessing Muscle Mass and Radiodensity via Chest CT for Prognostic Insights in Hemodialysis Patients

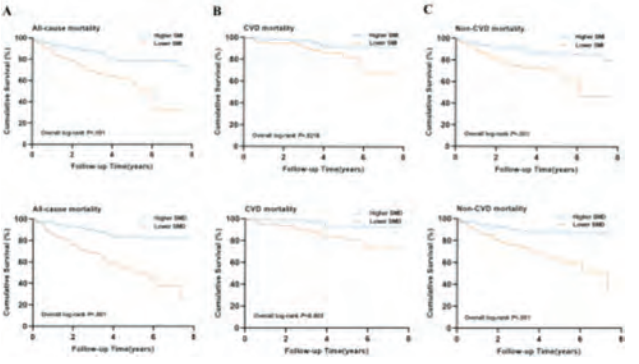
Jianqiang Liu, Zengchun Ye, Hui Peng. *The Third Affiliated Hospital of Sun Yat-Sen University Lingnan Hospital, Guangzhou, China*.

Background: CKD often leads to PEW, which in turn contributes to the development of sarcopenia. This condition is strongly associated with increased mortality. Consequently, evaluating muscle mass in HD patients is of significant clinical relevance. However, the relationship between muscle mass measured by Chest CT and prognosis for HD patients remains unclear.

Methods: Between January 2015 and December 2019, we conducted a retrospective study involving HD patients in a hemodialysis center. Chest CT scans at T12 level were analyzed using segmentation software to assess SMI and SMD.

Results: A total of 303 patients were included, with a mean age of 55.4± 16.6 years and a median follow-up period of 4.6 years. During the follow-up period, 78 deaths occurred. Sex-specific cut-offs of SMI and SMD were determined using maximally selected rank statistics analysis: 96 patients(31.6%) with SMI <30(male) or <24.35(female) cm^2/m^2 and 99 patients(32.6%) with SMD <38.61 (male) or <31.44(female) HU were categorized as having lower SMI and lower SMD, respectively. Patients with lower SMI and lower SMD consistently demonstrated an increased risk of any cause deaths, as evidenced by Kaplan Meier survival curves. After adjusting for confounding factors using mult ivariate Cox proportional risk models, lower SMI and lower SMD were independently associated with a higher risk of all-cause mortality and non-cardiovascular mortality. This association persisted in subgroup analyses and competitive risk model. Adding SMI and SMD to the established risk model improved the C-index from 0.78 to 0.82 (P < 0.001), with similar results observed in NRI and IDI. Decision curve analysis revealed that the prognostic model incorporating both SMI and SMD yielded the highest net benefit for predicting all-cause mortality.

Conclusions: SMI and SMD measurements derived from chest CT-T12 images provide valuable prognostic information, potentially enhancing the criteria for chest CT use in sarcopenia studies among HD patients.



Kaplan-Meier analysis of any cause mortality.

SA-PO570

Association Between Muscle Quality Measured by Computed Tomography and Valvular and Thoracic Aortic Calcification in Maintenance Hemodialysis Patients

Xiaoxu Wang, Bin Wang, Xiaoliang Zhang. *Southeast University Zhongda Hospital, Nanjing, China*.

Background: Extra-coronary calcification (ECC) is independently associated with Cardiovascular disease (CVD). Low muscle mass is known to be related to vascular calcification. We evaluated whether muscle quality measured by computed tomography was associated with the risk of ECC in maintenance hemodialysis (MHD) patients.

Methods: The patients who underwent MHD in our Blood Purification Center from January 1, 2020 to December 31, 2022 were enrolled. Chest computed tomography images were collected and an open-source software 3D Slicer (version 5.0.3) was used to assess muscle quality (by skeletal muscle density, SMD, HU) at L1 level. The whole thoracic aorta calcification scores (TACS) and calcification scores of the 3 segments of thoracic aorta, including ascending thoracic aorta (ATACS), aortic arch (AoACS), and descending thoracic aorta (DTACS) were measured by 3D Slicer. 2-dimensional ultrasonic echocardiography was used to assess the number of calcified valves and patients were divided into 3 groups. We used multivariable linear regression analysis and cumulative logit model respectively to explore relationships between SMD and ECC.

Results: The age of 1076 patients was (57.98±14.49) years old, 59.3% of patients were male and the median dialysis age was 52 (17, 96) months. SMD was significantly negatively associated with TACS (model 1 [adjusted for age and sex]: standardized coefficient [β], -0.38 [95%CI, -0.51 — -0.24, P<0.001]; model 2 [adjusted for all factors in model 1 plus body mass index, smoking status, history of drug usage and past history]: β, -0.39 [95%CI, -0.52 — -0.25, P<0.001]; model 3 [adjusted for all factors in model 2 plus primary disease, dialysis vintage and laboratory results (albumin, interleukin-6, uric acid, et al)]: β, -0.44 [95%CI, -0.60 — -0.29, P<0.001]). Similarly, SMD was negatively correlated with ATACS, AoACS and DTACS. Additionally, increased SMD reduced the

risk of cardiac valve calcification (model 1: odds ratio [OR], 0.92 [95%CI, 0.89 — 0.95, P<0.001]; model 2: OR, 0.91 [95%CI, 0.88 — 0.95, P<0.001]; model 3: OR, 0.90 [95%CI, 0.86 — 0.95, P<0.001]).

Conclusions: This is the first study evaluating the association between skeletal muscle quality and ECC in MHD patients. We identified significant negative associations between muscle quality and specific markers of ECC.

SA-PO571

Intradialytic Plantar Electrical Stimulation Boosts Mobility and Physical Activity in Frail Patients: A Randomized Controlled Trial

Abdullah I. Hamad,[1] Bijan Najafi,[2] Myeounggon Lee,[2] Rania A. Ibrahim,[1] Mincy Mathew,[1] Heba M. Ateya,[1] Yoldez Zitouni,[1] Naima S. Rodriguez,[2] Jaewon Beom,[2] Fadwa S. Al-Ali.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Department of Surgery, Baylor College of Medicine, Houston, TX.*

Background: Frailty is notably pervasive in hemodialysis (HD) patients and contributes to diminished physical activity, poor quality of life, and mortality risk. Our study aimed to assess the efficacy of a targeted intradialytic plantar E-stim intervention to enhance mobility in frail diabetic HD patients.

Methods: Participants randomized into intervention group (IG, n=35) and control group (CG, n=33). IG received plantar E-stim treatment and CG had a non-operational device both for 1 hour with their HD sessions for 12-week period. To assess daily physical activity, participants wore a monitoring pendant for two consecutive days both at the onset of the study and following the 12-week intervention.

Results: The IG and CG showed no significant differences in age, sex, BMI, or frailty rates. Remarkable group x time interaction effects were noted in terms of physical activity (total standing transition: p=0.017; total walking transition: p=0.015) and mobility capacity (total steps: p=0.040) among frail patients. The IG demonstrated notable enhancements in standing (+18.12%, Cohen's d=0.315) and walking transitions (+17.10%, Cohen's d=0.476) from baseline to the 12-week mark. In contrast, the CG displayed a decrease in physical activity (Standing: -14.80%, Cohen's d=0.281; Walking: -23.59%, Cohen's d=0.365). Mobility capacity decline was less in IG (-3.48%, Cohen's d=0.048), while CG saw a significant reduction (-52.85%, Cohen's d=0.644).

Conclusions: This study highlights that intradialytic plantar E-stim substantially enhances both physical activity and mobility, particularly among frail HD patients. Given these findings, it is recommended that E-stim be integrated as an adjunctive measure to routine HD treatment.

Funding: Government Support - Non-U.S.

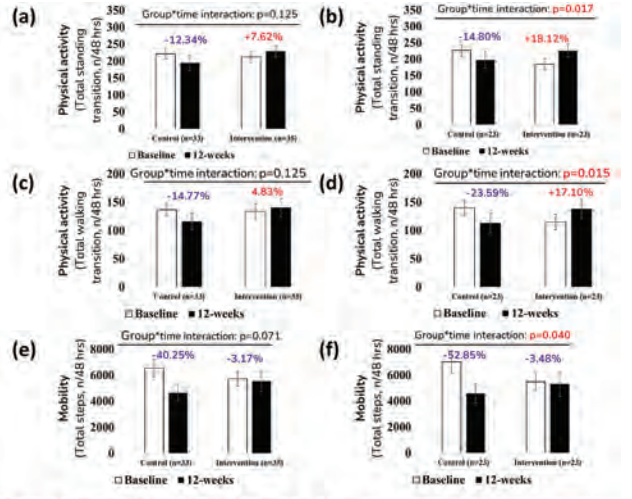

Figure 1. Changes of daily physical activity for 48 hours: (a), (c), and (e) reflect all participants including non-frail patients; and (b), (d), and (f) includes only frail patients.

SA-PO572

Roles of Irisin, a Myokine on Uremic Sarcopenia

Teruyuki Okuma, Seiji Ueda, Hajime Nagasawa, Tomoyuki Otsuka, Yusuke Suzuki. *Juntendo Daigaku, Bunkyo-ku, Japan.*

Background: The prevalence of sarcopenia is high in patients with CKD. Further, sarcopenia is reported to be closely associated not only with reduced physical activity but also with mortality. Recently, it has been noticed that skeletal muscles immediately after exercise secrete bioactive substances called myokines, which are associated with metabolic improvement and muscle mass increase. Irisin, one of the myokines, has been found to play an important role in the maintenance of endothelial function, thus contributing to the development of atherosclerotic vascular diseases. Furthermore, Irisin is known to be decreased in CKD condition and its levels are associated with the severity of atherosclerosis, possibly contributing to the increase in cardiovascular complications in CKD. In this study, we investigated the role of Irisin in uremic sarcopenia.

Methods: In the clinical study, we examined the relationship between serum Irisin and sarcopenia, exercise intensity, and atherosclerosis in 65 hemodialysis patients in our hospital. In vivo study, we performed 5/6 nephrectomy on C57BL/6J mice as a CKD model, and the exercise group received an exercise intervention for 10 weeks. We measured serum Irisin, the expression levels of FNDC5 (a precursor of Irisin) in skeletal muscle, serum creatinine, muscle mass, and grip strength, and evaluated renal lesions, especially endothelial damage by PAS staining and glycocalyx staining.

Results: In dialysis patients, Irisin levels tended to be lower in the patients with low physical performance/activity. The same tendency was also found between Irisin levels and the markers of atherosclerosis such as ABI or Agatston score. In vivo study, the expression levels of FNDC5 were significantly decreased in the skeletal muscle of CKD model mice compared to sham mice. Along with decreased Irisin levels, glomerular endothelial injury assessed by glycocalyx staining and glomerular sclerosis was observed in the CKD model. Exercise intervention significantly not only ameliorated FNDC5 expression and increased serum Irisin levels but also halted progressive renal dysfunction by inhibiting endothelial damage in CKD model mice.

Conclusions: These observations suggest that impaired Irisin release could be a culprit for CVD in CKD, which could be restored by exercise training.

SA-PO573

Sarcopenia with Central Obesity Is Associated with an Increased Risk of All-Cause Mortality in Maintenance Hemodialysis Patients

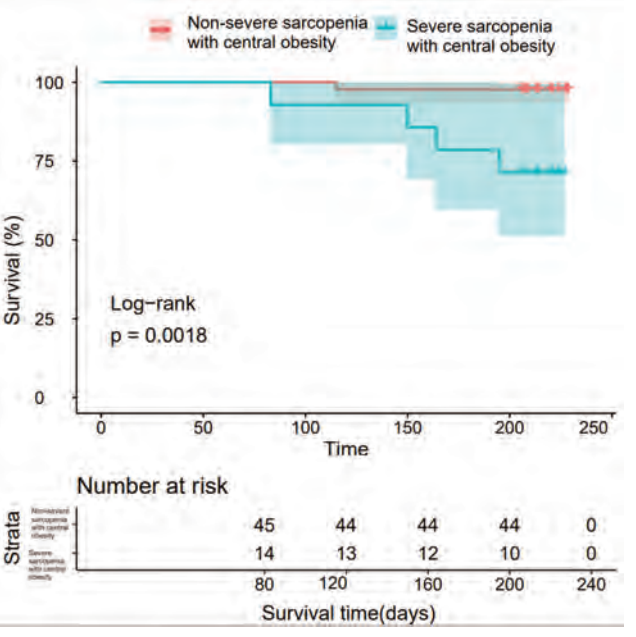
Qirong Song, Sha Fu, Junzhe Chen, Xiaohong Wang, Yuxin Luo, Aiqun Liu, Ying Tang. Nephrology Dept. *The Third Affiliated Hospital of Southern Medical University, Guangzhou City, China.*

Background: Sarcopenia, a common condition found in maintenance dialysis (MHD) patients, is known to be linked to higher rates of illness and death. Several studies have indicated that central obesity can predict cardiovascular mortality in MHD patients. However, there is a knowledge gap regarding the impact of sarcopenia with central obesity on the survival of MHD patients.

Methods: This retrospective, observational, cohort study enrolled MHD patients on Sept 1-31, 2022. The Asian Working Group for Sarcopenia criteria and the waist hip rate (WHR) were used to diagnose sarcopenia with central obesity. Additionally, demographic, body composition, clinical laboratory and body composition by bioimpedance were collected. The primary outcome is all-cause mortality with MHD patient.

Results: A total of 59 MHD patients were included in this study, specifically, the prevalence of sarcopenia was 44.1% and the prevalence of sarcopenia with central obesity was found to be 49.2%. Over a median follow-up period of 214 days, a total of 5 (8.5%) deaths occurred. Univariate Cox regression analyses revealed several factors associated with an increased risk of mortality, including age (HR: 0.055; p=0.098), 5-time chair stand test (HR: 0.044; p=0.029), and severe sarcopenia with central obesity (HR: 2.651; p<0.001). However, in the multivariate analysis, only severe sarcopenia with central obesity remained independently associated with all-cause mortality (HR: 2.734; p=0.015), indicating that severe sarcopenia with central obesity was linked to an increased risk of all-cause mortality in MHD patients.

Conclusions: It is crucial to consider the presence of central obesity when evaluating the correlation between sarcopenia and adverse outcomes in individuals undergoing dialysis.



SA-PO574

Sarcopenia Prevalence According to Short Daily and Conventional Hemodialysis Regimens: Preliminary Findings from the SARC-HD Study

Heitor S. Ribeiro,[1] Marvery P. Duarte,[1] Fábio A. Vieira,[1] Victor M. Baião,[1] Priscila M. Varela,[4] Jacqueline F. Monteiro,[3] Antonio Jose Inda-Filho,[2] Otavio Nobrega.[1] *[1]Universidade de Brasilia, Brasilia, Brazil; [2]Centro Universitario ICESP, Brasilia, Brazil; [3]DaVita Brasil Participacoes e Servicos de Nefrologia Ltda, Rio de Janeiro, Brazil; [4]IdealCor, Brasília, Brazil.*

Background: Sarcopenia is a skeletal muscle disorder characterized by the loss of muscle strength, muscle mass, and performance, and is highly prevalent in patients undergoing hemodialysis (HD). Despite the increasing interest and clinical recognition, there is little understanding of how sarcopenia evolves across users of different modalities of HD regimens. Therefore, we investigated the prevalence of sarcopenia according to short daily and conventional hemodialysis regimens.

Methods: This cross-sectional multicenter study included eight dialysis units in Brasilia, Brazil, and enrolled adult patients undergoing HD for ≥3 months. Muscle strength was evaluated by handgrip strength and five-time sit-to-stand test. Calf circumference was used to estimate muscle mass, and physical performance through the 4-m gait speed test. Stages of sarcopenia were defined according to the revised European Working Group on Sarcopenia in Older People. Patients were stratified according to the hemodialysis regimen, short-daily (5 to 6 sessions/week, duration ~2h30) and conventional (3 sessions/week, duration ~4h).

Results: The study enrolled 258 patients (66% male, 58.3 ± 0.9 years), 45% on conventional HD. The overall prevalence of probable sarcopenia (low muscle strength), sarcopenia, and severe sarcopenia was 26.7%, 26.7%, and 8.5%, respectively. No significant differences were found in the prevalence of sarcopenia, low muscle mass, and low physical performance between patients undergoing short daily and conventional HD (30.3% vs. 22.4%; $P > 0.05$). The low muscle strength was significantly higher in patients undergoing short daily compared to those receiving conventional HD (19.0% vs. 32.0%; $P = 0.024$).

Conclusions: Our multicenter study revealed a high prevalence of sarcopenia; however no significant difference was observed in prevalence between different HD regimens. Nevertheless, patients on short daily regimens had a higher prevalence of low muscle strength. This highlights a potential association between the HD regimen and the primary manifestation of sarcopenia, precisely muscle strength.

SA-PO575

Body Composition and Coronary Artery Calcification in a Prospective Hemodialysis (HD) Cohort: A Substudy of the NIH THYROID-HD Trial

Yoko Narasaki,[1] Matthew J. Budoff,[2] Rachelle Bross,[2] Mackenzie K. Cervantes,[2] Joel D. Kopple,[2] Gregory Brent,[4] Richard Casaburi,[2] Harry B. Rossiter,[2] Shlomit Radom-Aizik,[2] Csaba P. Kovesdy,[3] Andrea C. Daza Aguilar,[1] Seungsook You,[1] Kamyar Kalantar-Zadeh,[2] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]The University of Tennessee Health Science Center, Memphis, TN; [4]University of California Los Angeles, Los Angeles, CA.*

Background: HD patients have a high burden of coronary artery calcification (CAC), which is associated with CV mortality. We examined the relationship of body composition assessed by dual-energy x-ray absorptiometry (DXA) with CAC measured by cardiac CT in a prospective HD cohort.

Methods: In a substudy of the multi-center NIH THYROID-HD Trial, we examined associations of specific DXA body composition metrics (ratios of total body mineral content (BMC)/total mass, total fat mass/total mass, total lean mass/total mass) with elevated CAC Agatston scores (>400 Hounsfield units) in HD patients with upper reference and subclinical hypothyroid range TSH levels (>3.0-10.0mIU/L) using logistic regression. In secondary analyses, we examined the relationship between novel DXA visceral adiposity metrics (trunk/limb fat mass ratio, visceral adipose tissues (VAT) mass, VAT volume, VAT area) and elevated CAC scores.

Results: In 189 HD patients with baseline DXA and CAC measurements, the median (IQR) of CAC scores was 388 (29, 1978). Each +Δ0.02 increase in total BMC/total mass ratio was associated with lower risk of elevated CAC in adjusted analyses: OR (95%CI): 0.14 (0.03, 0.69) (**Fig A**). In unadjusted analyses, higher trunk/limb fat mass ratio (+Δ0.2), VAT mass (+Δ100 g), VAT volume (+Δ100 cm^2), and VAT area (+Δ100 cm^2) were each associated with higher risk of elevated CAC: ORs (95%CIs): 1.26 (1.02, 1.55), 1.12 (1.02, 1.23), 1.11 (1.02, 1.21), and 1.06 (1.01, 1.10), respectively (**Fig B**). While adjusted analyses narrowly missed statistical significance, point estimates showed higher CAC risk with higher VAT values.

Conclusions: In a subcohort of patients from the NIH THYROID-HD Trial, higher BMC/total mass was associated with lower risk of CAC, whereas higher visceral adiposity value was associated with higher CAC risk. Further research is needed to determine if VAT reduction lowers CAC risk in HD patients.

SA-PO576

Body Composition and Its Response to Intradialytic Exercise in Kidney Failure: A Combined Analysis of the PEDAL and CYCLE-HD Randomised Controlled Trials

Khai Ping Ng,[1] Jamie H. Macdonald,[2] Robin Young,[3] Daniel S. March,[4] Matthew Graham-Brown,[5] Tom Mercer,[6] Sharlene A. Greenwood,[7] James Burton,[5] Indranil Dasgupta.[8] *[1]University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; [2]Institute for Applied Human Physiology, Bangor, United Kingdom; [3]University of Glasgow, Glasgow, United Kingdom; [4]University of Leicester, Leicester, United Kingdom; [5]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [6]Queen Margaret University Division of Dietetics Nutrition Biological Sciences Physiotherapy Podiatry and Radiography, Musselburgh, United Kingdom; [7]King's College London Centre for Nephrology Urology & Transplantation, London, United Kingdom; [8]University Hospitals Birmingham NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Patients with kidney failure on hemodialysis (HD) are at high risk of sarcopenia obesity, highlighting the need for effective nutrition and exercise strategies to improve long-term outcomes. This post-hoc analysis of the PEDAL and CYCLE-HD studies aimed to 1) determine the clinical utility of fat tissue index (FTI) and lean tissue index (LTI) in comparison to body mass index (BMI) and 2) assess the effect of a 6-month intradialytic exercise intervention on FTI and LTI compared to usual care.

Methods: BMI, FTI and LTI were *a priory* secondary endpoints in both the PEDAL and CYCLE-HD trials. BMI was classified as per WHO definitions. FTI and LTI were determined by Bioelectrical Impedance Analysis (BIA) and classified as per the MONDO study, that found an FTI of 4-15kg/m^2 and an LTI of 15-20kg/m^2 were associated with best survival.

Results: Across both studies, 298 participants had BIA measurement at baseline; with 209 at baseline and 6-months. Mean age was 58±15 years, 65% male, median HD vintage 1.3 years (IQR 0.5-3.4) and mean BMI of 28.3±6.3kg/m^2. BMI correlated with FTI (r=0.79; p<0.0001). Of those with healthy BMI (n=198), 17% were over-nourished by FTI (>15kg/m^2) and 74% undernourished (LTI <15kg/m^2). Conversely, among those with an FTI of 4-15kg/m^2, 14% were categorised as overweight or obese by BMI. There was no significant correlation between BMI and LTI; 24% had BMI ≥30kg/m^2 and LTI <15kg/m^2 (sarcopenic obesity); only 16% had both FTI of 4-15kg/m^2 and an LTI of 15-20kg/m^2. With intradialytic exercise, there was no significant difference between the groups in change over 6 months for LTI (-0.33, CI -1.08-0.41; p=0.4) or FTI (0.16, CI -0.69-1.00; p=0.7), regardless of compliance.

Conclusions: This study highlighted issues of body composition misclassification using conventional BMI cut-offs in HD patients. Only a minority of patients had both LTI and FTI within the range associated with best survival. The majority of patients had hidden sarcopenia with nearly 75% with normal BMI being sarcopenic. 6-months of intradialytic exercise did not improve body composition, suggesting alternative interventions are required to target fat and lean tissue mass and enhance patients' survival.

SA-PO577

Changes in Modified Creatinine Index Following Bone Fractures in Patients Undergoing Maintenance Hemodialysis

Keisuke Soeda,[1] Hirotaka Komaba,[1] Yosuke Nakagawa,[1] Miho Hida,[3] Takatoshi Kakuta,[2] Masafumi Fukagawa.[1] Division of Nephrology, Endocrinology and Metabolism. *[1]Tokai Daigaku Igakubu Jinnai Bunpu Taisha Naika, Isehara, Japan; [2]Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan; [3]Medical Corporation Kuratakai, Hiratsuka, Japan.*

Background: Previous research has shown associations between lower skeletal muscle mass and a subsequent increased risk of bone fractures in hemodialysis patients. However, limited data exist on whether fractures lead to a loss of muscle mass in this population.

Methods: We analyzed a historical cohort study of 2,292 patients undergoing maintenance hemodialysis in Japan. We compared longitudinal changes in modified creatinine index (mCI) as a surrogate marker of muscle mass in a subcohort of patients who experienced fractures during the 7-year study period and those who did not, matched by propensity score at 1:3. Follow-up started immediately prior to the occurrence of fracture in the fracture group and at study enrollment in the non-fracture group.

Results: During a median follow-up of 5.4 years (IQR, 2.5-7.0 years), 113 patients experienced clinical fractures, among which 84 patients had data on mCI over time. With the use of propensity-score matching, 66 patients who experienced a clinical fracture were matched with 198 patients who did not sustain a fracture. While the mCI remained virtually unchanged in the non-fracture group, there was a progressive decrease in mCI in the fracture group, with a 3.0% decrease from baseline at 1 year and an 8.0% decrease at 5 years. Similar findings were obtained for changes in nutritional indicators such as serum albumin and body mass index.

Conclusions: In patients undergoing maintenance hemodialysis, the occurrence of clinical fractures may lead to a subsequent reduction in muscle mass, as indicated by the modified creatinine index. Whether interventions to prevent muscle mass loss following a fracture improve clinical outcomes warrants further investigation.

SA-PO578

Metabolites Associated with Mortality in Hemodialysis Patients

Solaf Al Awadhi,[1] Eugene P. Rhee,[2] Kendra E. Wulczyn,[2] Sahir Kalim,[2] Dorry L. Segev,[3] Mara McAdams-DeMarco,[3] Sharon M. Moe,[4] Ranjani N. Moorthi,[5] Thomas H. Hostetter,[6] Jonathan Himmelfarb,[7] Timothy W. Meyer,[8] Neil R. Powe,[9] Marcello Tonelli,[10] Tariq Shafi.[1] *[1]Houston Methodist, Houston, TX; [2]Massachusetts General Hospital, Boston, MA; [3]NYU Langone Health, New York, NY; [4]Indiana University School of Medicine, Indianapolis, IN; [5]Indiana University Bloomington, Bloomington, IN; [6]University of North Carolina Wilmington, Wilmington, NC; [7]University of Washington, Seattle, WA; [8]Stanford Medicine, Stanford, CA; [9]University of San Francisco, San Francisco, CA; [10]University of Calgary, Calgary, AB, Canada.*

Background: Uremic toxins contributing to the increased risk of death in hemodialysis patients remain largely unknown. We used untargeted metabolomics profiling to identify plasma metabolite associated with mortality in hemodialysis patients.

Methods: We created a cohort of 465 participants from the Longitudinal US/Canada Incident Dialysis (LUCID) study in which we profiled 498 known plasma metabolites measured on an untargeted platform. We assessed the association between metabolites and 1-year mortality adjusting for age, sex, race, cardiovascular disease, diabetes, BMI, albumin, KT/V, dialysis duration, and country. We used limma, a metabolite-wise linear model with empirical Bayesian inference, and two machine learning models, LASSO and random forest (RF), for analysis. We corrected for batch effects in metabolite abundances using the removal of unwanted variation (RUV) method, and we accouted for multiple testing by false discovery rate (q) below 10%. We defined mortality-metabolite associations as robust if significant in the limma model ($q<0.1$) and at least of medium importance in both LASSO and RF models (metabolite is above the 70th percentile for the variable importance measure).

Results: The mean age was 61 years, 88% were male, 54% had diabetes and 48% had cardiovascular disease. There were 44 deaths (9.5%). The mean duration from dialysis initiation to metabolomic profiling was 62 days. We identified two metabolites significantly associated with 1-year mortality; mesaconate (HMDB0000749) and quinolate (HMDB0000232) ($q<0.1$ and high importance by both LASSO and RF). We identified 29 additional metabolites associated with 1-year mortality ($q\geq0.1$) with high and/or medium importance by both LASSO and RF.

Conclusions: We identified two metabolites significantly associated with an increased 1-year mortality risk in incident hemodialysis patients. Mesaconate is an intermediate in the glutamate degradation pathway and has not been previously designated as a uremic toxin. Quinolate is a product in the kynurenine pathway and has been previously considered as a uremic toxin. Our study identifies additional metabolites that could be further investigated for mechanisms of uremic toxicity and potetial targeted interventions to prevent poor outcomes.

SA-PO579

The Geriatric Nutritional Risk Index (GNRI) to IL-6 ratio as a Predictor of Mortality in a Long-Term Follow-Up of Hemodialysis Patients

Tetsu Miyamoto,[1] Tomohiro Shirouzu,[2] Yoichiro Nagai,[2] Hiroshi Ishida,[2] Ikutaro Furuno,[1] Kazutoshi Nakazono,[2] Emi Hasegawa,[1] Masaharu Kataoka.[2] *[1]Kidney Center, University of Occupational and Environmenttal Health School of Medicine, Kitakyushu, Japan; [2]2nd Department of Internal Medicine, Univiersity of Occupational and Environmental Health School of Medicine, Kitakyushu, Japan.*

Background: Persistent inflammation is an important cause of protein-energy wasting, which is a potent predictor of mortality. Therefore, regular monitoring of inflammatory biomarkers concurrently with nutritional risk screening may be clinically useful for estimating mortality risk in dialysis patients.

Methods: In this multicenter prospective cohort study comprising 325 maintenance hemodialysis patients (38% female; median age, 66 years; age range, 20-91years), we investigated the effect of the ratio of geriatric nutritional risk index (GNRI) to plasma C-reactive protein (CRP), Interleukin-6 (IL-6) and Pentraxin 3 (PTX3) levels on 10-year all-cause mortality. We used Cox proportional hazards models to estimate mortality risk.

Results: A total of 170 (52.3%) patients died during the observation period. When adjusting for age, sex, dialysis vintage, diabetes mellitus and cardiovascular disease, patients with higher log GNRI/IL-6 had a significantly lower mortality risk (Hazard ratio [HR]: 0.58, 95%CI: 0.41-0.82; P=0.002). Higher log GNRI/CRP (HR:0.74, 95%CI:0.62-0.91, P=0.006) and higher log GNRI/PTX3 (HR:0.46, 95%CI:0.22-0.93, P=0.03) are also related to lower mortality risk.

Conclusions: The ratio of GNRI to plasma inflammatory proteins levels, especially the ratio of GNRI to IL-6, may be a useful biomarker for assessing mortality risk in hemodialysis patients. Nutritional risk screening is expected to improve the mortality prediction power of inflammatory biomarkers.

Endothelial Glycocalyx Injury due to Hemodialysis Induces Intradialytic Hypotension

Tomotaka Miura, Keiko Suzuki, Kodai Suzuki, Chihiro Takada, Hideshi Okada. *Gifu University Graduate School of Medicine, Gifu, Japan.*

Background: Hemodialysis (HD) plays a pivotal role in replacing renal function for patients with end-stage renal failure. When the patients undergo hemodialysis, HD complications, such as intradialytic hypotension and arrhythmia, are inevitable. The vascular endothelial glycocalyx, which exists on the inner surface of vascular endothelial cells and maintains vascular homeostasis, has been suggested to be impaired by hemodialysis. However, it is unclear whether the endothelial glycocalyx injury is associated with HD complications.

Methods: We enrolled the patients who underwent outpatient hemodialysis at Gifu Seiryu Hospital between April 2022 and July 2022 (346 hemodialysis sessions). Patients aged <20 years. This single-center retrospective study evaluated the association between syndecan-1, an endothelial glycocalyx dysfunction marker, and complications of hemodialysis. Complication events, as the primary outcome, were defined as intradialytic hypotension, arrhythmia, and subjective symptoms such as chest pain, nausea, general malaise, and leg cramps during HD. Patients undergoing outpatient maintenance HD at Gifu Seiryu Hospital undergo blood tests at the beginning of each month. The GEE model was used to reveal the association between the serum syndecan-1 concentration in pre-HD and hypotension. Age, sex, and BNP were included in the model as covariates to adjust for confounders.

Results: In total, 92 patients were enrolled. The median HD period was 40 months. The most common primary illness was diabetic nephropathy. In pre-HD, the median serum syndecan-1 concentration was 67.7 ng/mL. In post-HD, the median serum syndecan-1 concentration was 98.3 ng/mL. According to the generalized estimating equations (GEE) model adjusted for age, sex, BNP, and amount of water removed per hour, no association was found between serum syndecan-1 concentration in pre-HD and appearance of intradialytic hypotension (odds ratio (OR): 1.001, P<0.741). However, a GEE model using the same adjustment factors showed that the greater the amount of change in serum syndecan-1 concentration before and after HD, the more complications appeared (OR: 1.005, P<0.013).

Conclusions: The study revealed that the quantitative assessment of the endothelial glycocalyx injury by measuring the concentration of serum syndecan-1 during HD is associated with intradialytic hypotension.

SA-PO581

Variability of Troponin I Levels in Patients on Chronic Haemodialysis over One Week

Ivan Durlen, Petar Babic, Ivana Bedalov Crnkovic, Ana Savuk, Lovorka Derek, Ivica Horvatic. *Dubrava University Hospital, Zagreb, Croatia.*

Background: Patients undergoing chronic haemodialysis (HD) have remarkably higher risk for major adverse cardiovascular events. Haemodynamic and volume changes inbetween dialysis sessions lead to constant cardiac burdain and strain which could increase cardiac troponin levels without signs and symptoms of an acute coronary syndrome (ACS). This makes it more difficult to diagnose acute disorders. Primary goal was to evaluate the basal troponin values of HD patients on their first weekly treatment (the highest volume overload) and observe value oscillations during the week.

Methods: Data of 67 patients (24 female, 43 male) undergoing chronic HD programme at Dubrava University Hospital were collected after aquiring informed consent. Troponin levels were measured multiple times during the period of one week, using Beckman Coulter High-Sensitivity Troponin I (hs-cTnI) assay - before every HD session, after the first session that week and the day after the first session, what resulted with 3 to 5 values per patient depending on the dialysis regiment. Upper reference limit (URI) for hs-cTnI is <14.9 ng/L for female patients and <19.8 ng/L for male patients.

Results: Before the first session, mean basal hs-cTnI was 30,6ng/L (range 5,1 ng/L - 211,2 ng/L), with differences in male (34,6ng/L – 75% higher than URI) and female patients (23,8 ng/L – 60% higher than URI). More male patients had hs-cTnI levels in the reference interval, 51% opposed to 36% of female patients. However, more male patients had values higher than 50 ng/L (6 males, 1 female). The highest mean value was measured after the first dialysis session of the week (32,7 ng/L) and the lowest before the last session in the week (25,8 ng/L). A 7-percent rise in mean value was recorded after one dialysis session. The coefficient of variation (CV) was measured for each patient and the mean CV for hs-cTnI values was 19,6% (2% - 67%) with significant difference between female (13,5%) and male (23%) patients.

Conclusions: Our results show that hs-cTnI values were elevated in 54% of patients on chronic HD without signs of ACS with mean value of 30,1 ng/L out of all the measurements. During one week hs-cTnI values were acceptably stabile with variability of 20%. Patient's hs-cTnI mean value could be taken as a personal basal value for comparison when diagnosing ACS.

SA-PO582

Comparative Analysis of Cardiovascular Performance in Hemodialysis and Heart Failure Patients

Hayaan Kamran, Eliott Arroyo, Drake Dillman, Sharon M. Moe, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Patients on hemodialysis (HD) exhibit significant impairment in cardiovascular functional capacity that may be comparable to those with non-CKD associated heart failure. The problem is that to-date, no studies have directly compared cardiovascular functional differences between patients on HD compared with non HD patients with heart failure with reduced ejection fraction (HFrEF) and HF with preserved ejection fraction (HFpEF). We hypothesized that patients on HD exhibit unique exercise ventilatory response patterns compared to those with HFrEF and HFpEF.

Methods: We conducted a cross-sectional analysis of patients on thrice-weekly HD versus HFpEF (EF ≥40%) and HFrEF (EF <40%) patients who underwent cardiopulmonary exercise test (CPET) at Indiana Universtiy. A total of 90 patients (age=55 [13] years; n=30 per group) were included in this analysis.

Results: There were no group differences in age, sex, or diabetes (all p's>0.05). The HD group had a higher prevalence of hypertension (p<0.001), lower hemoglobin (Hgb; p<0.001), and lower beta blocker (BB) use (p<0.001) compared to both HFrEF and HFpEF, and a higher proportion of smokers compared to the HFpEF group (p=0.017). After adjusting for these covariates, peak oxygen uptake (VO_2Peak) was lower in the HD (12.9 [12.0-14.1] mL/kg/min) and HFrEF (13.0 [12.2-14.3] mL/kg/min) groups compared to HFpEF (16.3 [15.5-17.6] mL/kg/min; p=0.028). Percent of heart rate reserve (% HRR) was lower in the HD group (37.8 [31.6-39.8]; p=0.011) compared to both HFrEF (57.0 [20.9-59.1]) and HFpEF (61.0 [54.8-63.0]). Additionally, VE/VCO_2 slope was lowest in the HD group compared to HFpEF and HFrEF (p<0.001). Hgb, smoking, VE/VCO_2 slope, and %HRR were significantly associated with VO_2Peak in the HD group; this differered with sex, race, VE/VCO_2 slope, and %HRR for HFrEF, and sex, BB use, and %HRR for HFpEF.

Conclusions: Patients on HD exhibit similar declines in VO_2Peak as those with HFrEF without significant CKD undergoing evaluation for heart transplant, exemplifying the dramatic effects of CKD on cardiovascular health. Chronotropic incompetence and impaired skeletal muscle reserve may be predominant drivers of impaired VO_2Peak in HD patients, while impaired lung capacity and cardiac output may be predominant drivers in patients with HFrEF and HFpEF.

SA-PO583

Correlation of Cardiac Function by Transthoracic Ultrasound and State of Inflammation in Asymptomatic Young Patients (18-40 Years), with Hemodialysis: A Single-Center Experience

Lizeth Arizpe,[1] Marianela Rodney,[3] Elizabeth Baez,[1] Armando Castillo García,[1] Mario Jimenez Hernandez.[1,2] *[1]Universidad de las Americas Puebla, Cholula, Mexico; [2]HUP, Hospital Universitario BUAP, Puebla, Mexico; [3]Instituto Cardiorenal de Puebla, Puebla, Mexico.*

Background: Cardiac pathology is currently one of the leading causes of mortality worldwide, with chronic kidney disease being a major risk factor for cardiovascular-related deaths, especially in patients undergoing renal replacement therapy. Patients undergoing renal replacement therapy, such as hemodialysis, are subject to frequent changes in volume and persistent systemic inflammation. However, early monitoring and management of heart failure in young patients with chronic kidney disease are often lacking.

Methods: The aim of this observational, descriptive, and cross-sectional study was to evaluate the degree of cardiac dysfunction and inflammatory profile in young, asymptomatic hemodialysis patients, by analyzing their medical records, clinical analysis to evaluate the inflammatory profile of hemodialysis patients and performing a transthoracic echocardiogram.

Results: The study included 24 hemodialysis patients with a median age of 29 years (range 24-38 years) and no history of systemic arterial hypertension or cardiac disease at the time of data collection. There was a direct correlation between anemia and systolic dysfunction (p=0.013), as well as anemia and diastolic dysfunction (p=0.043). In relation with inflammatory profile we founded that elevated levels of ferritin were correlated with a higher degree of diastolic dysfunction (p=0.023), and low ferritin levels were associated with pericardial effusion (p=0.043).

Conclusions: Asymptomatic young patients on hemodialysis present with subclinical cardiac dysfunction associated with metabolic and inflammatory disorders. The presence of pericardial effusion was not associated with elevated inflammatory parameters, therefore detection of pericardial effusion by echocardiography is necessary for adequate control and preservation of cardiac function.

Cardiac Autonomic Innervation Is Decreased in Postmortem Tissue from Individuals with ESKD Compared with Those Without

Qandeel H. Soomro, Valeria Mezzano, Navneet Narula, David M. Charytan. *New York University Grossman School of Medicine, New York, NY.*

Background: Cardiac innervation changes can lead to an imbalance in neural activation and arrhythmias. Although described in other disease states, changes in cardiac innervation have not been studied in ESKD.

Methods: Age and DM matched cases with ESKD and controls without ESKD (10/group) who underwent autopsy at NYU-affiliated hospitals (2012-2020) were identified. Demographic and CV history was collected from autopsy and medical records. Case and controls were selected based on availability of LV anterior wall sections without extensive fibrosis in the area of interest. We performed H&E staining, and immunohistochemistry for S100 (all nerves), Tyrosine hydroxylase (TH, sympathetic nerves) and trichrome staining for fibrosis. Staining and fibrosis were quantified within regions of interest in the epi-, mid- and endocardial ⅓ as density per mm^2 (primary outcome) or fibrosis %.

Results: Mean age: ESKD 66.7 vs. controls 65.6 y, sex: 50% female in both groups and DM was (80% in both groups), whereas 60% were Black in the ESKD group vs. 40% in the control group. All ESKD patients had ischemic heart disease vs. with 30% of controls. Most common cause of death: myocardial infarction (50% in ESKD, 30% controls) followed by pump failure. Overall nerve density was lower in ESKD compared to controls: S100 density in the mid (63.97/mm2 vs. 106.7/mm2, P=0.04) and endocardial (62.6/mm^2 vs. 203.2/mm^2, P=0.003) thirds. Sympathetic nerve density was lower in dual-stained sections, particularly in the endocardial region (65.9/mm^2 vs. 180.6/mm^2, P=0.002). Fibrosis was higher in those with ESKD in all regions (epi= 0.009 vs. 0.005, mid= 0.024 vs. 0.006, endo=0.033 vs. 0.006, P= <0.05 for all). Fibrotic area was not correlated with nerve density (overall and for sympathetic nerves) in regions of interest (P> 0.05 for all).

Conclusions: Reduced overall nerve density and sympathetic innervation observed in ESKD. Further studies are needed to evaluate cardiac innervation patterns in ESKD and its link to arrhythmia.

Automatic Detection of Intradialytic Paroxysmal Atrial Fibrillation and Flutter in Single-Lead ECG

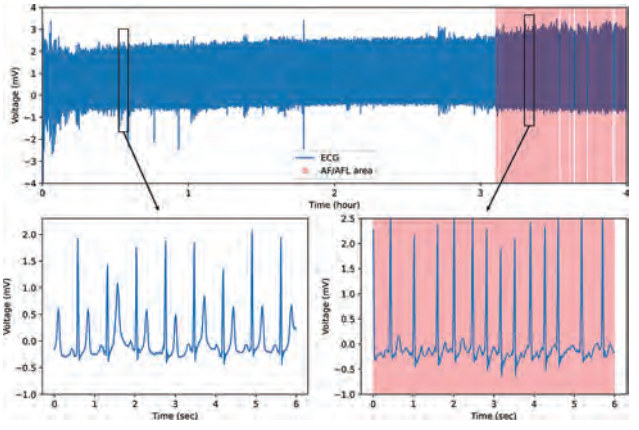
Donghwan Yun,[1,2] Dong Ki Kim,[1,2] Kook-Hwan Oh,[1,2] Seung Seok Han.[1,2] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Jongno-gu, Republic of Korea.*

Background: Intradialytic paroxysmal atrial fibrillation and flutter (AF/AFL) can result in hemodynamic instability and suboptimal dialysis dose. To achieve appropriate prevention and management of intradialytic paroxysmal AF/AFL, the first step is precise detection during hemodialysis session. Herein, we developed a Transformer-based model to automatically segment AF/AFL in single-lead echocardiography (ECG) by self-supervised learning and masked signal modelling.

Methods: To develop a model, we used 11 open source databases containing 5,684-hour ECG signals from 2,017 patients. To validate a model, intradialytic ECG signals were retrieved from 4-hour 30 hemodialysis sessions at Seoul National University Hospital. AF/AFL was defined as ≥10-second duration, and the Swin Transformer model with wide window-size was adopted as a main architecture. The model performance was evaluated with F1 score.

Results: The model achieved F1 scores of 0.9612 and 0.9731 in segmenting AF/AFL and other rhythms, respectively. Throughout cross-database, F1 scores ranged between 0.8889 and 0.9896 depending on the prevalence of AF/AFL. Ablation analysis identified that the performance was attributable to pretraining with masking random signals and unlabeled database. The present model was superior to previous models in detecting AF/AFL particularly when training and testing databases were matched. When applying to intradialytic ECGs, the model showed favorable performance in segmenting AF/AFL areas.

Conclusions: The model with self-supervised learning and masked signal modelling maintains robust performance in various databases, which will help automatic detection of intradialytic paroxysmal AF/AFL.



SA-PO586

Clearance of Cardiac Troponins Depends on Hemodialysis Mode: A Randomized Cross-Over Trial

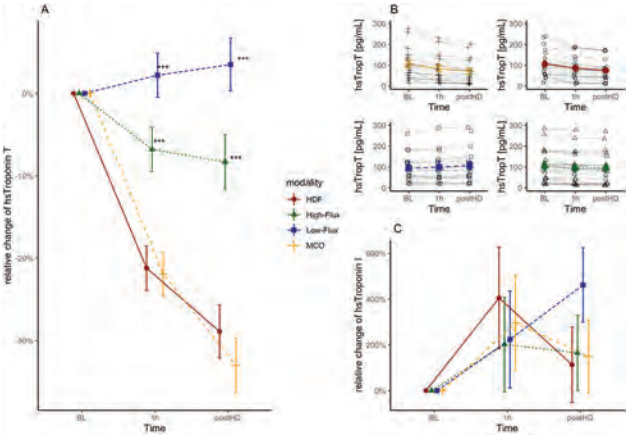
Michael Kolland,[1,5] Jascha Amenitsch,[1,5] Nikolaus Schreiber,[1,5] Noemi E. Ginthör,[1,5] Max Schuller,[1,5] Regina Riedl,[1,2] Peter P. Rainer,[1,3] Daniel Schneditz,[1,4] Tobias Niedrist,[1] Kathrin Eller,[1,5] Benedikt Krietemeyer,[1,5] Alexander R. Rosenkranz,[1,5] Alexander H. Kirsch.[1,5] *[1]Medizinische Universitat Graz, Graz, Austria; [2]Institute for Medical Informatics, Statistics and Documentation, Graz, Austria; [3]BioTechMed Graz, Graz, Austria; [4]Otto Loewi Research Center, Graz, Austria; [5]Department of Internal Medicine, Division of Nephrology, Graz, Austria.*

Background: Diagnosis of acute myocardial infarction (AMI) is difficult in hemodialysis (HD) patients as they less likely present typical features, thus, diagnosis relies on biomarkers. There is inconclusive data on cardiac Troponin (cTn) kinetics during HD without considering membrane characteristics.

Methods: We included prevalent, clinically stable HD patients and measured cTns (cTnT and cTnI) concentrations before, during and after HD with different modalities (low-flux HD, high-flux HD, hemodiafiltration [HDF] and medium cut-off (MCO)-HD). Treatment characteristics were standardized and similar between groups. The primary aim was to compare relative changes of cTns from baseline to after 1 hour of HD (Δ1h) for different dialysis modalities with secondary outcomes including absolute and relative changes of cTns during and after HD, using linear mixed models accounting for subjects, sequence, period and treatment.

Results: Of 20 patients, one patient was excluded because of NSTE-AMI, thus, 19 were included in final analysis. Of those 47.4 % were female (mean age 65.5±13.4 years, median dialysis vintage 19 months (min. 3, max. 165)). Different Δ1h were observed for MCO (least square mean [LSM] -21.9 ± 2.7%) vs. low-flux (+2.2 ± 2.7%, p<0.001) and MCO vs. high-flux (LSM -6.8 ± 2.7%, p<0.001) with no difference for MCO vs. HDF (LSM -21.2± 2.7%, p=0.81). Similar results were observed post HD. For absolute changes, LSM for MCO were -21.2 (± 3.2 pg/mL), -6.4 (± 3.2 pg/mL) for high-flux, -20.2 (± 3.2 pg/mL) for HDF treatment and +2.3 (± 3.2 pg/mL) for low-flux HD after one hour. There was no clear trend in cTnI kinetics.

Conclusions: Standard diagnostic AMI algorithms cannot be applied during HD. A Δ of >20% of cTnT, recommended by the SONG-HD MI group, occurs without evidence of ACS when MCO-HD or HDF are applied.



SA-PO587

Serum Endocan as a Risk Factor for Aortic Stiffness in Patients on Maintenance Hemodialysis

Ho-Hsiang Chang,[1] Yu-Hsien Lai,[1,2] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Endocan is secreted by the activated endothelium and plays a central role in inflammation and endothelial dysfunction, angiogenesis and vascular smooth muscle cell proliferation, it is associated with cardiovascular disease. This cross-sectional study aimed to assess the relationship between serum endocan levels and carotid–femoral pulse wave velocity (cfPWV) in patients on maintenance hemodialysis (HD).

Methods: Blood samples and baseline characteristics were collected from 122 HD patients. Serum endocan concentrations were measured with an enzyme-linked immunosorbent assay kit. Aortic stiffness was defined as a cfPWV of more than 10 m/s, while cfPWV values ≤ 10 m/s defined the control group, according to the ESH-ESC 2018 guideline.

Results: Of the 122 HD patients, aortic stiffness was diagnosed in 53 (43.4%) and higher percentages of diabetes ($p < 0.001$), hypertension ($p = 0.030$), were of older age ($p = 0.007$) and had higher systolic blood pressure ($p = 0.011$) and endocan levels ($p < 0.001$) in those with aortic stiffness than those without. After adjusting for factors significantly associated with aortic stiffness by multivariate logistic regression analysis, serum endocan (odds ratio [OR]: 1.566, 95% confidence interval [CI]: 1.224–2.002, $p < 0.001$), age (OR: 1.040, 95% CI: 1.001–1.080, $p = 0.045$), and diabetes (OR: 4.067, 95% CI: 1.532–10.798, $p = 0.005$) were independently associated with aortic stiffness in patients with chronic HD. Multivariable forward stepwise linear regression analysis also confirmed that the logarithmically transformed endocan level (β =0.405, adjusted R^2 change = 0.152; $p < 0.001$) was an independent predictor of cfPWV values. The area under the receiver operating characteristic (ROC) curve predicting aortic stiffness by serum endocan level was 0.713 (95% CI: 0.620–0.806, $p < 0.001$).

Conclusions: Serum endocan level positively correlates with cfPWV and is also an independent predictor of aortic stiffness in maintenance HD patients.

SA-PO588

The Association Between Adipokines and Cardiovascular (CV) Risk Factors in Hemodialysis Patients

Sarwar Khan, Peter N. Van Buren. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Non-traditional risk factors in cardiovascular (CV) disease among hemodialysis (HD) patients include mineral bone disease and extracellular volume overload. Adiponectin is an adopokine that has an inverse relationship with CV disease in the general population, but studies in HD patients show conflicting results regarding its association with CV morbidity and mortality. We explored associations between adiponectin and leptin with various CV risk factors in a subset of an HD cohort.

Methods: We conducted a cross-sectional study of hypertensive HD patients. We measured adiponectin and leptin with ELISA from frozen plasma obtained in a midweek treatment. BP was measured per HD protocol. And we obtained pre and post HD measurements of ECV with bioimpedance spectroscopy. We conducted Pearson correlation and multiple linear regression analysis to determine associations between adipokines and other clinical variables.

Results: There were 24 participants who had adiponectin levels (mean 12238 [504] ng/mL) with 58% men, 58% Black, and 50% with diabetes. There were no differences in adiponectin based on sex, race or diabetes. Adiponectin correlated negatively with fat free mass (r=-0.51, p=.02) and dry weight (r=-0.44, p=.03). Leptin correlated positively with

fat mass (r=0.7, p=.004) and dry weight (r=0.6, p=.003), but had a negative correlation with ECV bodyweight (r=-0.8, p=.00001). Table 1 shows adiponectin was signficantly associated with dry weight, BP, phosphate, and ADMA (with independent associations of phosphate and ADMA).

Conclusions: Adiponectin was associated with known CV risk factors in a small cohort of HD patients, although phosphate was the only independent predictor. Leptin was associated with anthropometric measurements, consistent with findings from others. The association between phosphate and adiponectin is novel and warrants further investigation.

Funding: NIDDK Support, Veterans Affairs Support

Table 1:Linear regression (univariate and multivariate) analyses using plasma adiponectin as the outcome

	Univariate		Model 1		Model 2	
	Standardized Regression Coefficient	P. Value	Standardized Regression Coefficient	p-value	Standardized Regression Coefficient	P. Value
Phosphate	0.4	0.04	0.4	0.02	0.3	0.05
ADMA	0.4	0.05	0.4	0.02	0.3	0.05

Association of Bioimpedance Parameters with Changes in Blood Pressure During Hemodialysis: A Secondary Analysis of the Frequent Hemodialysis Network (FHN) Daily Trial

Enass Sayed,[1,2] Youssef M. Farag,[3] Katherine S. Ravi,[1,2] Glenn Chertow,[4] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Bayer US, New Jersey, NJ; [4]Stanford University School of Medicine, Stanford, CA.*

Background: Intra-dialytic hypertension (IDHyper) affects 5-15% of patients and is associated with cardiovascular and all-cause mortality. Hypervolemia is thought to be a major etiological factor, yet the association of objective measures of volume with IDHyper is not well described.

Methods: In post hoc analyses of the FHN Daily Trial (n=234), using data from baseline, 1, 4, and 12 months (n=800), random effects regression was used to assess the association of bioimpedance measures of volume and general health (vector length and phase angle) with post-HD SBP (continuous) and any increase in SBP (categorical) from pre- to post-HD. Models were adjusted for randomized group, age, sex, race, BMI, vascular access, HD vintage, hypertension, heart failure, diabetes, residual urea clearance, pre-HD SBP, hemoglobin, phosphorus, and eKt/V.

Results: Mean age was 50 ±14 years; 39% were female; 43% were Black. Shorter vector length (per 50 Ω/m) was associated with higher post-HD SBP (3.1 mmHg; 95%CI 2.0, 4.2; Fig. 1) and higher odds of IDHyper (OR 1.64; 95%CI 1.13, 2.39). The lowest tertile of vector length (vs. highest) was associated with higher post-HD SBP (6.3 mmHg; 95%CI 3.3, 9.3) and a trend toward higher odds of IDHyper (OR 2.09 95%CI 0.81, 5.35). Narrower phase angle (per 1 degree) was associated with higher post-HD SBP (1.0 mmHg; 95%CI 0.3, 1.6), and higher odds of IDHyper (OR 1.33; 95%CI 1.03, 1.72). The lowest tertile of phase angle (vs. highest) was associated with higher post-HD SBP (5.5 mmHg; 95%CI 2.6, 8.4) and higher odds of IDHyper (OR 2.74; 95%CI 1.11, 6.76).

Conclusions: Bioimpedance measures of volume status are independently associated with higher post-HD SBP and risk of IDHyper. Incorporation of bioimpedance measurement at individual HD sessions may help identify a subgroup of patients at risk of IDHyper.

Use of Novel and Conventional Cardiac Biomarkers to Assess Cardiovascular Risk in Hemodialysis Patients

Zachary J. Neronha, Andy Chuu, Frank J. O Brien. *Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Hemodialysis patients experience greatly increased morbidity and mortality. Although the underlying etiology is not completely understood, volume overload likely plays an important role given their elevated risk of cardiovascular disease and especially heart failure. Biomarkers are commonly used to clinically assess volume status in cardiology patients, but cardiac biomarker use in dialysis patients is complicated by an incomplete understanding of biomarker clearance during dialysis and the complex interplay of renal and cardiac causes of volume overload. Here, we investigate a panel of conventional and novel cardiac biomarkers in a group of hemodialysis patients catagorized by their baseline ejection fraction.

Methods: We performed a descriptive, prospective cohort study utilizing a group of hemodialysis patients at the Chromalloy American Kidney Center, an outpatient hemodialysis center in St. Louis, MO serving approximately 150 ESRD patients. Study enrollment was randomized, and consisted of 35 patients seperated into 3 groups with ejection fractions <40%, 40-50%, and >50% based on a recent echocardiogram. The mean age was 62 and 94% were African American. Pre-dialysis blood was drawn to measure NT-proBNP, high-sensitivity troponin T (hsTnT), galectin-3, growth differentiation factor-15 (GDF-15), and soluble ST2 (sST2).

Results: Randomization produced a distribution of patients across the cohorts that was relatively equivalent in age, ethnicity and gender and differed with respect to EF. Preliminary data suggests that within our cohort, ejection fraction influenced novel cardiac biomarker expression. Patients with a lower ejection fraction had biomarker expression more suggestive of volume overload than those with preserved ejection fraction. Those with an EF of >50% also had a high level of cardiac biomarker expression.

Conclusions: Preliminary analysis of the baseline characteristics of this patient cohort suggests cardiac biomarker expression is influenced by ejection fraction. More study is needed to evaluate how cardiac biomarker data varies with volume optimization, and any predictive value it may have for major adverse cardiovascular events. We therefore plan to follow this patient cohort for an additional year to assess any changes in biomarker expression, future adverse events, and the impact of volume optimization on biomarker expression.

SA-PO591

Duration of Hemodialysis as an Amplifier of Thrombolytic Deficit and Oxidative Stress in ESRD

Srdjan Nikolovski,[1] Fakiha Siddiqui,[1] Bhavana Reddy,[1] Debra Hoppensteadt,[1] Bulent Kantarcioglu,[1] Madeline T. Allen,[1] Emily G. Krupa,[1] Jawed Fareed,[1] Vinod K. Bansal.[2] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Medical Center Department of Nephrology, Maywood, IL.*

Background: Thrombo-inflammation and oxidative stress increase as kidney function declines. Additionally, the incidence of thromboembolic events is several times higher in patients with end-stage renal disease (ESRD) on hemodialysis (HD). However, the mechanism underlying the increased risk for thrombotic events has not yet been thoroughly investigated. The aim of this study is to measure the level of biomarkers of thrombo-inflammation and oxidative stress in ESRD patients on HD and to investigate the association of those levels with HD duration.

Methods: In this cross-sectional study, levels of oxidative stress-related, and thrombo-inflammatory biomarkers, as well as blood cell count values were determined in plasma samples of ESRD patients undergoing HD at a single healthcare center. Time between sample collection date and the initiation of HD was correlated with the measured biomarker levels. Commercially available normal human plasma samples were used as a healthy control group.

Results: The study included 96 patients with median age of 64 years (interquartile range-IQR 50-74), and 40 healthy control plasma samples. The median time since initiation of HD in ESRD group was 62 months (IQR 25-94). The levels of tissue-type plasminogen activator (tPA) and functional plasminogen activator inhibitor 1 (PAI-1) were significantly higher in ESRD patients, compared to control group (Med 4.2 vs 0.4 ng/mL and Med 7.0 vs 3.2 IU/mL, respectively). Significant positive correlation of tPA and functional PAI-1 levels was observed with the time spent on HD in months (r=0.32, p=0.03 and r=0.35, p=0.02, respectively). Those biomarkers were entered into age-adjusted logistic regression model showing predictive potential of HD duration on functional PAI-1 levels only (OR 0.32, p=0.03) (Table 1).

Conclusions: Increase of functional PAI-1 during the time spent on HD clearly suggests that the risk of developing thrombotic complications may rise over time due to the increase of fibrinolytic deficit which is modulated by an upregulation of functional PAI-1 in ESRD patients on HD.

Biomarker (unit)	OR	95% CI	p
tPA (ng/mL)	0.130	-0.016 - 0.041	0.388
Functional PAI-1 (IU/mL)	0.323	-0.078 - -0.005	0.028

The CompAct-HD Trial Reports an Acute Complement Activity-Associated Inflammatory Response Within 15 Minutes of Starting Hemodialysis

Andy Herbert,[1] Duha Ilyas,[2] Elizabeth A. Blackburn,[1] Leonard Ebah,[2] Jennifer Mackie,[1] Sandip Mitra.[2] [1]*Invizius Ltd, Motherwell, United Kingdom;* [2]*Manchester Foundation Trust, Manchester, United Kingdom.*

Background: It is well established that kidney patients experience aberrant complement pathway activation. A heightened inflammatory state is thought to contribute to excess cardiac deaths and cardiovascular events in those undergoing hemodialysis (HD). The aim of the CompAct-HD trial is to characterize complement activation and biomarker response to blood-membrane-circuit interaction during HD.

Methods: Six timed intradialytic blood samples were collected in 300 HD patients during a standard treatment with ultrapure water and high flux membranes. Complement activity potential was determined from timepoint 1 and inflammatory biomarkers from timepoints 2 to 6. Highly multiplexed assays enabled us to determine 60 biomarkers of complement activation and inflammation from a single blood sample.

Results: The 6 blood samples for each patient revealed changes in inflammatory biomarkers within 15 minutes (T3, sCD40L, panel A) of starting dialysis. There was a wide range in the magnitude of this response between individuals. Most biomarker levels increased, peaking during the first hour of dialysis and then fell; not always to the level at the start of dialysis. Interrogating the data for sCD40L to remove patients with Alternative Pathway activity in the first and second quartile showed that patients with complement activity above the median experienced a larger median inflammatory response at all time points (panel B).

Conclusions: Patients with an elevated complement activation potential experienced an exaggerated acute intradialytic inflammatory response within 15 mins of HD treatment, which did not always resolve to baseline by the end of the dialysis session.

Immune Response of Heterologous vs. Homologous Prime-Boost Regimens with Adenoviral Vectored and mRNA COVID-19 Vaccines in Immunocompromised Patients

Chang Chu, Bernhard K. Krämer, Berthold Hocher. *Universitatsklinikum Mannheim, Mannheim, Germany.*

Background: Due to rare but major adverse reactions to the AstraZeneca adenoviral ChAdOx1-S-nCoV-19 vaccine (ChAd), German health authorities recommended adults under 60 who received one dose of ChAd, to receive a second dose of the BioNTech mRNA BNT162b2 vaccine (BNT) as a booster. Studies in the general population suggest an enhanced efficacy of the heterologous (ChAd-BNT) compared to the homologous (BNT-BNT) vaccination regimen. However, an analysis of the efficacy in patient populations with a high risk of severe COVID-19 due to acquired immunodeficiency is still missing.

Methods: We therefore compared both vaccination regimens in healthy controls, patients on dialysis and patients with rheumatic diseases concerning the humoral and cellular immune response.

Results: The humoral and cellular immune response differed substantially in healthy controls compared to patients with acquired immunodeficiency. Overall, the most significant differences between the two immunization regimens were found in neutralizing antibodies. These were higher after a heterologous immunization. Healthy controls responded well to both vaccination regimens. However, the formation of neutralizing antibodies was more pronounced after a heterologous immunization. Dialysis patients, on the other hand, only developed an adequate humoral and particularly cellular immune response after a heterologous immunization. Rheumatic patients also - to a weaker extent compared to dialysis patients - benefited from a heterologous immunization.

Conclusions: In conclusion, the heterologous COVID-19 vaccination regimens (ChAd-BNT) seem to have an advantage over the homologous vaccination regimens, especially in immunocompromised patients such as patients with end-stage kidney disease treated with hemodialysis.

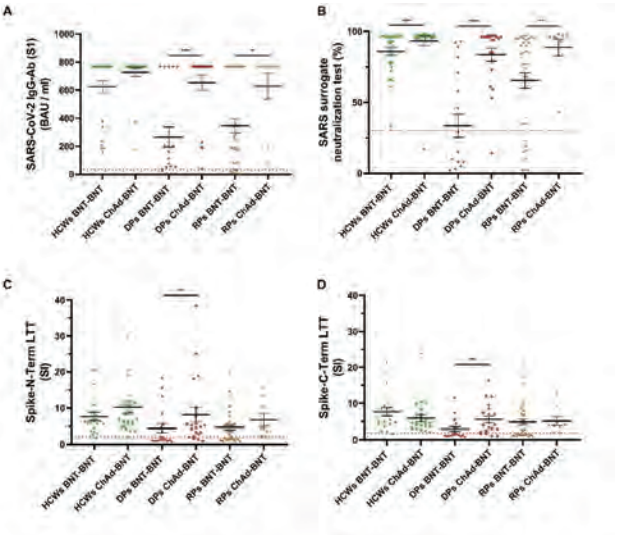

Figure 1. Scatterplots of humoral and cellular response to homologous (BNT-BNT) or heterologous (ChAd-BNT) COVID-19 vaccination regimens in participants with different medical conditions. All plots display geometric means with standard error of the mean (SEM). Statistical significance was assessed by Mann-Whitney U test. *, p<0.05, **, p<0.01, ***, p<0.001. Clinical and Biological Profile and Factors Associated with High Blood Lead Levels in Chronic Hemodialysis Patients in a Western French Guiana Hospital Center

Arriel Makembi.[1,2] [1]*Universite de Kinshasa, Kinshasa, Congo (the Democratic Republic of the);* [2]*Centre Hospitalier de l'Ouest Guyanais Franck Joly, Saint-Laurent-du-Maroni, French Guiana.*

Background: Lead is toxic to the body. Its chronic intoxication combines various clinical and biological disorders that can be life-threatening. In French Guiana, lead poisoning is particularly worrying, as the incidence rate is nearly sixty times higher than in metropolitan France. In chronic hemodialysis patients, lead levels are often higher and can lead to several adverse consequences. Hence, the interest of this study, which is to describe the clinical and biological characteristics of chronic hemodialysis patients with high blood lead levels and to identify the associated factors to draw attention to its screening and the prevention of its complications.

Methods: Descriptive and analytical cross-sectional study that included 65 patients on chronic conventional hemodialysis: with an annual biological assessment in December 2022, including a serum lead assay. The outcome was the notion of hyper lead level, defined by a lead level > 85 µg/l. We described the clinical, biological, and dialytic parameters of patients with hyper lead levels and in logistic regression, we identified the factors that are correlated according to a significance threshold P<0.05.

Results: In total, 54% of patients had hyper lead levels, of which 2/3 were female. They were older, with an average age of 62. No patients had occupational exposure to lead. 94% were hypertensive and half were diabetic. 1/4 had anaemia and all had resistance to erythropoietin. Their ferritin levels were slightly lower, with an average of 721 µg/l. The mean albumin was 30 g/l, pre-albumin was 28 g/l, the mean parathyroid hormone was elevated at 1355 ng/ml, NT-pro BNP at 9144 ng/ml. The mean CRP was 10.8 mg/L. They had collapsed residual diuresis and natriuresis with averages of 150 ml and 12 mmol/24 hours, respectively. There was a significant positive correlation between elevated BLL and young age and negative correlation with female sex, low serum albumin, prealbumin, protein and ferritin levels, and collapsed residual diuresis.

Conclusions: High blood lead levels are common in the Guyanese chronic hemodialysis population in which it is correlated with female sex, malnutrition, iron deficiency and residual poor renal function and probably with resistance to erythropoietin treatment. It is necessary to screen in at-risk populations to prevent complications associated with it.

SA-PO595

Validity and Adequacy of Animal Models in Haemodialysis Research: A Systematic Review

Joost C. de Vries,[1] Kimberley Wever,[2] Marianne C. Verhaar,[1] Karin G. Gerritsen,[1] Merle M. Krebber.[1] *[1]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [2]Radboudumc, Nijmegen, Netherlands.*

Background: With the worldwide dialysis population growing rapidly, there is an urgent need for hemodialysis (HD) innovations. However, before novel HD technologies can be implemented, extensive preclinical testing is required. Currently, there is no consensus on the most suitable animal model (species, type and validation of kidney injury etc.) for HD innovation research, nor are there gold standards for reporting efficiency outcomes.

Methods: This review, registered in PROSPERO (CRD42022307144), involved a systematic search in PubMed and Embase for relevant studies up to February 4th 2022. After removing duplicates, 5723 abstracts were screened for eligibility by three independent reviewers. Inclusion was based on publication of a HD intervention in any animal model with adequate kidney failure. Data from individual reports were subsequently extracted using predefined parameter sheets.

Results: Of the 5723 abstracts screened, 195 records were included as full text and 41 full text articles were included for data-extraction. Data extraction has been completed for all articles, but only qualitative analysis has been conducted thus far. Studies most frequently used dogs (54%), followed by rats (27%), pigs (8%), goats (6%), sheep, and cats (both 2%). Dog studies were primarily conducted before 2010, with a shift towards other large animals observed thereafter. Relevant descriptives such as strain, sex, weight, and age were not systematically reported, with only 4 (9%) records reporting all four parameters and 23 (49%) not reporting two or more. Regarding kidney injury, 42 (89%) studies used an acute kidney injury model, with kidney injury induced via surgery in 43 (91%) studies. One study validated the presence of kidney injury by measuring eGFR, while all other studies reported urea, creatinine, or both parameters. Finally, 30 reports (64%) performed only a single dialysis session per animal.

Conclusions: Use of dogs in HD research has significantly declined over the past decades, potentially due to a shift in public ethical perception. A notable concern is the overall inadequate adherence to the ARRIVE guideline for reporting. Our findings indicate no apparent improvement in reporting quality over time, highlighting the necessity for clear guidelines to drive innovative HD research.

SA-PO596

Hyperammonemia in Multiple Myeloma (MM): Rare but Serious Complication

Erik Mai, Salem Vilayet, Zipporah Krishnasami. *Medical University of South Carolina, Charleston, SC.*

Introduction: MM is characterized by abnormal plasma cell proliferation and clinical manifestations such as hypercalcemia, renal insufficiency, anemia, and bone lesions. Encephalopathy associated with MM can stem from hypercalcemia, hyperviscosity, or uremia. In rare cases, certain myeloma cell lines can cause hyperammonemia which can result in cerebral edema, high intracranial pressure, and high mortality rates. We present a case of hyperammonemic encephalopathy complicating relapsed refractory MM (RRMM) following an autologous stem cell transplant.

Case Description: A 62-year-old African American woman with RRMM following an autologous stem cell transplant presented with bone pain, increasing lethargy and confusion. Laboratory studies showed anemia, thrombocytopenia, low Kappa-Lambda ratio and normal calcium levels. Despite a normal liver function test, she had elevated ammonia levels, peaking at 157.3 umol/L. Her blood gas indicated chronic primary respiratory alkalosis (pH 7.51, PCO_2 23mmHg, HCO_3^- 18mmol/L) due to ammonia-stimulated ventilation. A head CT was negative for acute pathology. Findings were consistent with MM-induced hyperammonemic encephalopathy. Lactulose and rifaximin were started, but her ammonia level remained elevated. To aid in ammonia clearance, she underwent continuous renal replacement therapy (CRRT) at a a dose higher than standard (~35mL/kg/hr), while receiving aggressive chemotherapy (DCEP). After four days, there was an improvement in her ammonia level and mentation, and CRRT was discontinued. However, the patient was readmitted for hyperammonemic encephalopathy and ultimately transitioned to hospice care due to treatment failure.

Discussion: Hyperammonemic encephalopathy should be considered in MM patients with decreased consciousness. The exact mechanism is unclear but may be related to the production of ammonia by myeloma cell lines or to myeloma-related humoral factors which can affect amino acid metabolism leading to hyperammonemia. While rare, this manifestation may indicate an advanced disease state and an unfavorable prognosis. Management lacks consensus, but chemotherapy is crucial. Lactulose and rifaximin may reduce ammonia levels; however, renal replacement therapy is more effective in ammonia clearance and may prevent complications from prolonged hyperammonemia, including cerebral edema.

SA-PO597

A Case of Hepatic Encephalopathy During Hemodialysis

Farid Arman, Pedro D. Mogrovejo Pintado, Mariana A. Chang, Jai Radhakrishnan, Jordan G. Nestor. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Hepatic encephalopathy (HE) is a serious neurological complication of portal hypertension (PH). A variety of dialysis-related factors can increase the risk of HE.

Case Description: A 50-year-old male with a history of nodular regenerative hyperplasia complicated by PH and recurrent ascites despite transjugular intrahepatic portosystemic shunt (TIPS) and kidney failure on hemodialysis (HD), hospitalized 2 times in 2 months for recurrent episodes of altered mental status (AMS) during HD sessions. The etiology of the AMS was suspected to be due to HE after an acute episode of confusion was witnessed during an inpatient HD treatment. Subsequent evaluation during this witnessed episode suggested worsening alkalosis during the course of his treatment (Table 1). Therefore, in subsequent HD treatments, his prescription was modified to lower blood flow rates and use of a lower bicarbonate (HCO3) bath (25 instead of 35). During the following 3 inpatient sessions, there were no more episodes of AMS. He subsequently underwent a TIPS revision which led to a complete resolution of his recurrent episodes of AMS.

Discussion: Ammonia exists in the blood as NH3 and $NH4^+$, but only NH3 can cross the blood brain barrier (BBB). Respiratory and metabolic alkalosis favors the production of NH3, and its CSF concentration can increase 2-3 fold. As a result, we suspect that in patients with PH who have undergone TIPS, HD can augment their risk of HE. Moreover, intradialytic hypotension (IDH) can lead to increased portosystemic shunting and increased ammonia levels. In this individual, the recurrent episodes of AMS occurring exclusively during HD sessions can plausibly be explained by a presumed increase in NH3 levels crossing the BBB and precipitating HE. The use of a lower HCO3 bath (25), and prevention of IDH, successfully temporized the patient while he awaited revision of his TIPS procedure.

	On admission	During AMS episode	Post HD session with HCO3:25 bath
Na	139	141	140
K	4.7	3.2	4.2
Cl	102	97	100
Carbone Dioxide	17	28	21
BUN	48	17	35
Creatinine	5.98	3.1	4.91
pH	7.6	7.65	
PCO2	22	27	

SA-PO598

Hydroxocobalamin-Triggered Blood Leak Detection During Hemodialysis in a Liver Transplant Patient

Mauricio Ostrosky-Frid, Charles T. Owens, Laila S. Lakhani. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Introduction: High-dose intravenous hydroxocobalamin, known as Cyanokit, is routinely administered for vasoplegic shock, a life-threatening complication from cardiac surgery when conventional vasopressors are insufficient to maintain an appropriate mean arterial blood pressure goal. In liver transplant patients, hydroxocobalamin use has become more common for vasoplegia and to decrease time on pressor dependence post-transplant. After liver transplant, some patients with acute kidney injury require continuous renal replacement therapy (CRRT) followed by transition to intermittent hemodialysis (iHD). Hydroxocobalamin is mostly excreted in the urine and has a half-life of 26-31 hours. It also has a deep red color, causing discoloration of body fluids, including urine and dialysis effluent. iHD machines have a light sensor to detect small blood leaks into the effluent as a safety feature to prevent unwitnessed hemolysis or bleeding into the filter. Interestingly, hydroxocobalamin is detected as a blood leak, which halts the hemodialysis procedure. Hydroxocobalamin does not affect CRRT, so patients remain on CRRT for approximately 5 days and then transition to iHD.

Case Description: A 67 year-old male with decompensated NASH cirrhosis and acute kidney injury from hepatorenal syndrome requiring dialysis underwent a liver transplant. He received hydroxocobalamin and was transferred to the SICU where he was started on CRRT briefly, and, given no pressor requirement, iHD was initiated. However, the iHD machine detected hydroxocobalamin as a small blood leak and stopped the procedure. CRRT was restarted. iHD was restarted after another 72 hours and no complications were noted.

Discussion: Hydroxocobalamin-triggered blood leak detection is common and causes increased time on CRRT. Fresenius iHD machine has a photometric sensor consisting of a green and red light transmitter and a photodetector. An alarm is triggered when green light is absorbed by blood and hydroxocobalamin is capable of triggering this alarm. Alternatives to allow for earlier transition to hemodialysis are other iHD machines that have different sensors that do not detect hydroxocobalamin, empirical adjustment of dialysate and blood flow to decrease detection of hydroxocobalamin, and treating intraoperative vasoplegic syndrome with methylene blue instead of hydroxocobalamin, which does not impair iHD.

SA-PO599

Purpuric Rash After Starting Hemodialysis: Not the Immediate Suspect

Etty Kruzel Davila,[1,2] Ashraf Badran,[1] Teuta Zeitun.[1,2] *[1]Galilee Medical Center, Nahariya, Israel; [2]Bar-Ilan University The Azrieli Faculty of Medicine, Ramat Gan, Israel.*

Introduction: Hemodialysis patients are at risk to develop vitamin C deficiency. Several factors can contribute to vitamin C deficiency, including potassium restricted diet, hemodialysis clearance of water soluble vitamins and increased oxidative stress leading to vitamin C utilization. However, clinical manifestation of scurvy is rare or overlooked. Herein, we report a case of scurvy in a hemodialysis patient.

Case Description: A 74-year-old patient with end stage kidney disease due to diabetic nephropathy has been treated with hemodialysis since 2020. During 2022, she was hospitalized several times due to pulmonary edema. A purpuric rash with perifollicular erythema was noted on her lower legs (Figure A). She also complained of gingival bleeding. Laboratory exam demonstrated undetectable vitamin C level (less than 4 mg/L), hypoalbuminemia and elevated CRP. Based on her dermatologic findings and labs results, a diagnosis of scurvy was made. After 2 months of daily vitamin C supplement, her symptoms and rash resolved, without episodes of pulmonary edema. Echocardiography demonstrated improved LV function (EF 35% improved to 45%), suggesting a therapeutic role for vitamin C repletion.

Discussion: Recommendation of Clinical Practice Guidelines for Nutrition in CKD about regular vitamin C supplementation is opinion based. The absence of rigorous recommendation stems from lack of double blind randomized controlled clinical trials that explored the potential beneficial effect of vitamin C supplementation and possible deleterious effect of calcium oxalate supersaturation, accumulation and deposition. This case is a reminder that scurvy can occur in hemodialysis patients and may contribute to cardiovascular complications. A high clinical awareness is warranted in order to diagnose this treatable devastating disease.

SA-PO600

Recurrent Severe Hypersensitivity Reactions Following New Start of Hemodialysis

Colton Jensen, Chidinma Enyinna, Brendan Ferraro, Alison F. Fitzgerald. *University of Vermont, Burlington, VT.*

Introduction: Hypersensitivity reactions are a known complication of dialysis. Most cases are due to ethylene oxide, membrane filters, or medications. We present a case of a patient with recurrent hypersensitivity reactions on dialysis despite numerous changes to his dialysis configuration.

Case Description: A 78 yo male with chronic kidney disease and hypertension presented to our hospital with anuric AKI requiring hemodialysis (HD). A few minutes prior to the end of his first HD session, he developed hypotension for which treatment was stopped. 90 minutes into his second session, he developed hypotension, loss of consciousness (LOC), and ventricular tachycardia, all of which resolved after treatment was stopped. He had no significant electrolyte abnormalities, no ischemic changes on EKG, and his hemoglobin was stable. No other patients who underwent HD that day had a similar reaction. During his next 4 sessions, he developed LOC and hypotension requiring norepinephrine despite switching dialysis machines and reverse osmosis machines, as well as using a hypoallergenic dialyzer (Cellentia-19), priming the circuit with 2 liters of saline, and pre-treatment with diphenhydramine, cimetidine, and prednisone.

His symptoms occurred progressively sooner with subsequent HD sessions and resolved each time with discontinuation of treatment. An IgE level was elevated but an ethylene oxide IgE level, C3/C4, and tryptase were normal. An ethylene oxide IgE level obtained 1 month later was normal. He tolerated treatment with a NxStage machine with gamma sterilized tubing but did not tolerate a subsequent attempt using an Optiflux dialyzer and NovaLine bloodlines. He did tolerate further treatments with a Revaclear dialyzer and Novaline bloodlines. The patient became progressively debilitated with difficult road to recovery. He elected to forgo further HD treatments and opted for comfort-oriented care.

Discussion: This patient developed a constellation of symptoms most consistent with severe anaphylactoid reactions on dialysis. Through a series of trial and error of adjusting different components of his dialysis apparatus, he was found to be non-tolerant of ethylene oxide treated components and tolerant of the gamma irradiated ones. This case demonstrates the potential severity of dialysis reactions and the importance of considering every step and component in evaluating the cause.

SA-PO601

A Unique Case of Dialysis Hypersensitivity Reaction in a Critically Ill Patient on Continuous Renal Replacement Therapy

Nicole Wyatt, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Allergic reactions are well-established life-threatening complications of dialysis, however these reactions pose a diagnostic challenge in critically ill patients on continue renal replacement therapy (CRRT) who may have other severe illnesses confounding the picture. We present a case of a dialysis-related anaphylactic type reaction to a CRRT system sterilized with ethylene oxide (EtO).

Case Description: A 48-year-old male with hypertension and undifferentiated inflammatory arthritis presented with shortness of breath and dark tarry stools. The patient's initial work up was significant for anemia with hemoglobin 4.1 gm/dL and concern for pneumonia. The hospital course was complicated by acute hypoxic respiratory failure requiring mechanical ventilation, septic shock requiring vasopressor support, and AKI secondary to ATN with peak creatinine 4.01 mg/dL from prior baseline 0.94 mg/dL. Nephrology was engaged for initiation of CRRT due to worsening pulmonary edema in the setting of oliguria >72 hours. The patient experienced repeated episodes of severe hypotension upon starting CRRT which required escalation of vasopressor doses. These episodes persisted despite extra rinsing of the filter with albumin and saline. He also experienced repeated episodes of circuit clotting despite anticoagulation with heparin and citrate. There was high suspicion for a dialysis-related reaction to the EtO sterilized CRRT system and the patient was transitioned to intermittent hemodialysis with a steam sterilized system which was tolerated without any complications. He underwent another session without incident and ultimately experienced kidney recovery.

Discussion: This case highlights the importance of having high clinical suspicion for dialysis related reactions, particularly in the ICU setting when the diagnosis may be more challenging. We believe the patient's repeated severe hypotension when starting CRRT was likely due to an IgE mediated hypersensitivity to the EtO sterilized CRRT system. EtO, a chemical known to cause type A dialysis reactions, is no longer used to sterilize most dialyzers however it is important to recognize several CRRT systems as well as dialysis tubing and ancillary components may still use EtO. Due to this, it is imperative to increase provider education and awareness of dialysis reactions particularly in the complex ICU setting.

SA-PO602

Dialysis in Diabetic Ketoacidosis (DKA)? Profound Acidemia in the Setting of Diabetic Ketoacidosis Triggered by Inferior ST-Elevation Myocardial Infarction (STEMI)

Alex Barnes, Ali Mehdi, Laura Ferreira Provenzano. *Cleveland Clinic, Cleveland, OH.*

Introduction: Diabetic ketoacidosis (DKA) is a life-threatening condition that can cause severe acidemia impairing cardiac contractility and vascular tone. The role of bicarbonate therapy remains controversial. We present a case of severe DKA triggered by an myocardial infarction that required continuous venovenous hemodialysis(CVVHD) for severe acidemia.

Case Description: A 32 year old female with poorly controlled Type 1 Diabetes mellitus was brought to the ED unresponsive. Family reported preceding nausea, vomiting, and confusion after heavy alcohol use and skipping insulin. She was hemodynamically stable but obtunded with dry mucous membranes and Kussmaul respirations. VBG showed a pH<6.8, pCO2 16mmHg, bicarbonate<2mmol/L, potassium 6.7mmol/L and lactate 9.9mmol/L. Serum glucose was 1255mg/dL, BHB >4.5mmol/L, and creatinine 2.24mg/dL (baseline 0.7mg/dL). ECG revealed ST elevations in inferior leads. The patient received bicarbonate based crystalloids along with insulin. Two hours later, VBG showed persistent severe academia (pH 6.85) and a rising serum Troponin. Despite improving urine output, given severe acidemia, CVVHD was started (effluent dose: 30ml/kg/hr). The patient's pH normalized and a left heart catheterization was done revealing an 80% thrombotic lesion in the RCA which was stented. Dialysis was continued for 8 hours with careful attention to potassium balance. Kidney function recovered with creatinine dropping to 1.01mg/dL after 24 hours. Overshoot alkalosis with mild alkalemia (pH 7.49) followed and was managed expectantly. Patient was discharged two days thereafter with appropriate follow-up.

Discussion: DKA is a life threatening condition triggered by infections, stroke, malignancy, myocardial infarction, or medical nonadherence. In addition to managing DKA, timely identification of the underlying trigger is critical to patient outcomes. The role of bicarbonate therapy in DKA is controversial and the role of renal replacement therapy in severe cases remains undefined. This case illustrates the use of bicarbonate based fluids and ultimately CVVHD successfully to control the patient's severe metabolic derangement to expedite timely revascularization. Hourly assessments with careful attention to potassium balance and acid base status is critical to this strategy.

SA-PO603

Managing Phosphate Repletion During Continuous Renal Replacement Therapy in the Setting of Severe Hyperbilirubinemia

Jason A. Jones,[1] Ellen E. Im,[1,2] Brian C. Y'Barbo.[1] [1]*Walter Reed National Military Medical Center, Bethesda, MD;* [2]*Uniformed Services University of the Health Sciences, Bethesda, MD.*

Introduction: Continuous renal replacement therapy (CRRT) is commonly used for critically ill patients with acute kidney injury. Among CRRT-associated adverse effects, hypophosphatemia is common. Strategies to prevent or treat hypophosphatemia include protocolized phosphate replacement and use of dialysate/replacement solutions containing phosphate. Most patients on CRRT require phosphate supplementation, particularly after the first 48 hours. Our facility, which uses dialysate without phosphate, has a replacement protocol guided by serum phosphate levels drawn every 6 hours.

Case Description: A patient with acute-on-chronic alcoholic liver disease and hepatorenal syndrome was treated with continuous veno-venous hemodialysis without replacement fluid: Blood flow rate 300 ml/min and dialysate flow rate 29 ml/kg/hr. The patient had severe jaundice with total bilirubin of 35 mg/dL. This rendered the colorimetric assay of serum phosphorus inaccurate and not reportable. Protocolized phosphate replacement based on serum levels became impossible. To measure serum phosphate without bilirubin interference, we measured phosphate levels in the effluent as a surrogate. Simultaneously, we measured serum urea nitrogen (SUN) and effluent dialysate urea nitrogen (EDUN), as a quality control measure to assess dialysate saturation.

Discussion: During CRRT, 90-100% dialysate saturation is assumed to occur for small molecules with sieving coefficients near 1.0, such as urea and phosphate. EDUN (56mg/dL) agreed closely with SUN (52.4mg/dL), demonstrating that effluent dialysate was saturated and in equilibrium with plasma. Dialysate phosphate was 4.6mg/dL. We inferred that dialysate phosphate was reasonably equivalent to serum phosphate and were able to circumvent bilirubin interference with serum phosphate assay. The patient received protocol-driven phosphate replacement, guided by dialysate effluent phosphorous measurements, which ranged between 2.4-5.1mg/dL. The use of effluent phosphorus levels as a serum phosphorus surrogate provides a novel approach for guiding phosphate replacement in patients with severe hyperbilirubinemia. *The views expressed in this abstract are those of the author(s) and do not necessarily reflect the official policy of the Department of Defense or the U.S. Government.*

SA-PO604

Dialyzing or Hemolyzing? A Case of Continuous Renal Replacement Therapy (CRRT) Filter Hemolysis

Tyler Maggio, Iiro Honkanen. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Evidence of hemolysis in the inpatient setting evokes a broad differential. Devices are frequently employed to support vital organ functions that can introduce an additional mechanism for hemolysis that expands the differential. Here we describe a case of hemolysis secondary to filter induced lysis as part of a continuous renal replacement therapy (CRRT) circuit.

Case Description: A 43-year-old man presented with altered mental status, shortness of breath, and hypotension. He had a history of systolic heart failure, CKD stage 4, Type 2 diabetes, and chronic normocytic anemia. Workup was pertinent for worsening ejection fraction with elevated NT-proBNP consistent with cardiogenic shock with AKI on CKD for which he remained oliguric despite diuretic challenge. CRRT was initiated on day 2. On hospital day 16 the hemoglobin dropped to a nadir of 5.9 g/dL that did not respond appropriately to blood transfusions. Plasma free hemoglobin was elevated with undetectable haptoglobin. Direct antibody testing was negative. Liver enzymes, fibrinogen, and platelets were stable. There was concern for intradialytic hemolysis based on amber tinge in the effluent dialysate bag and otherwise unrevealing workup. CRRT pressures were reviewed and within normal ranges and no kinks were identified in the circuit. Plasma free hemoglobin was measured pre and post filter which identified a 20% increase from 1017 to 1282 mg/dL. The CRRT circuit was discontinued with subsequent improvement in serum hemoglobin and normalization in plasma free hemoglobin. No additional evidence of hemolysis was identified. The CRRT circuit was resumed with a new filter from a different lot on hospital day 18 with no further hemolysis observed.

Discussion: Hemolysis is a serious condition that may be associated with worse morbidity and mortality in the setting of severe illness. CRRT access sites as well as the individual components of the circuit serve as potential sources of mechanical hemolysis. Plasma free hemoglobin can be sampled at various points of the circuit to suggest the source of hemolysis. Once an implicated component has been identified, the circuit should be reset with monitoring for improvement of hemolysis. CRRT use is increasing in ICUs, so clinicians should be aware that filter induced mechanical hemolysis is a rare but plausible cause of hemolysis that can be easily corrected.

SA-PO605

Iron Poisoning and the Utility of Continuous Renal Replacement Therapy (CRRT)

Omer Sheikh, Amy Yau, Madeline S. Chung. *The Ohio State University, Columbus, OH.*

Introduction: Iron poisoning is a rare life-threatening condition. The primary method for iron removal remains chelation therapy, and continuous renal replacement therapy (CRRT) should be utilized as an adjunctive therapy. We describe a case on the role of RRT in iron chelation for severe iron poisoning.

Case Description: An 18 Year old man with unremarkable past medical history presented to the hospital with intentional overdose secondary to ibuprofen and iron. He was initiated on chelation agent, deferoxamine, and referred to our center for transplant evaluation. Initial iron profile was significant for an iron level of 320 ug/dL. Peak iron levels of > 3000 ug/dL were seen 3 hours after presentation and trended to < 90 ug/dL 48 hours after presentation. Baseline serum creatinine of 0.5-0.8 mg/dL, and at the time of his presentation was 0.78 mg/dL and so toxicology recommended initiation of CRRT to ensure deferoxamine clearance. Imagining studies did not demonstrate iron deposits in the kidneys. 5 days after ingestion, the patient successfully underwent hepatitis C virus positive orthotopic liver transplant. He was eventually liberated from renal replacement therapy 7 days after initiation.

Discussion: This case highlights the important supportive role of CRRT in the management of iron overdose. Iron poisoning can lead to significant hemodynamic instability, including hypotension and fluid shifts and it can also lead to direct toxic effects. Iron poisoning can also lead to electrolyte derangements such as hyponatremia, hyperkalemia, or metabolic acidosi. In both instances, CRRT helps maintain fluid balance by allowing for precise control of fluid removal, replacement, and electrolyte adjustments. Additionally, chelating agents are mostly excreted in the urine unchanged. In cases where iron chelation therapy is utilized, especially if there is any renal impairment, CRRT can assist in removing the chelating agent from the bloodstream and preventing its accumulation and potential adverse effects. Of note hepcidin and pro-hepcidin have molecular weights of 2.7 KDa and 10 KDa, respectively, and, therefore, may be removed by CRRT, which uses membranes with a cut-off of 35 KDa. Nephrologists should be liberal in the use of CRRT especially if patients are receiving chelation therapy or have any degree of renal insufficiency.

SA-PO606

Ifosfamide-Induced Neurotoxicity Treated with CRRT

Avneet Kaur,[1] Paul T. Merchant,[2] Tarek Ashour.[2] *[1]Government Medical College Patiala, Patiala, India; [2]Cleveland Clinic, Cleveland, OH.*

Introduction: Ifosfamide is an alkylating chemotherapeutic agent with wide application in treatment of multiple gynecological cancers. Encephalopathy is one of the worrisome complications of ifosfamide therapy occurring in about 10-40% of the patients. We discuss a case of a 63-year-old female who developed ifosfamide-induced encephalopathy after an acute kidney injury (AKI).

Case Description: 63 year old female patient with past history of uterine adenocarcinoma. She required multiple lines of chemotherapy, the latest regimen included doxorubicin and ifosfamide. Her clinical course was complicated by obstructive uropathy from the uterine mass and she required bilateral nephrostomy tube insertion. She also had recurrent AKI, severe metabolic acidosis and hypokalemia that was attributed to tubular toxicity from Ifosfamide. Her creatinine partially recovered and remained ~2 mg/dl with eGFR of 27 ml/min. She also had ifosfamide induced neurotoxcity and was successfully treated by IV methylene blue. She was admitted for her 3rd cycle of chemotherapy. On admission, her creatinine was 2.6 mg/dl. Her kidney function initially improved with IV fluids however worsened again and her creatinine peaked at 2.69 mg/dl. Both nephrostomy tubes were patent and kidney ultrasound showed no hydronephrosis. Her hospital course was complicated by altered mental status, CT scan brain showed no acute intracranial findings. She was treated for ifosfamide induced neurotoxicity with IV methylene blue however her mental status worsened, and she was transferred to the ICU. It is also notable that the patient was treated with aprepitant for nausea earlier in her admission and may have contributed to slowed metabolism of ifosfamide and decreased response to methylene blue. She was started on CVVHD given the concern of poor renal clearance of ifosfamide. She received 4 days of CVVHD, her mental status gradually improved, and the dialysis line was removed.

Discussion: This case illustrates the successful use of CVVHD in a patient with suspected ifosfamide neurotoxicity. An acute kidney injury along with use of aprepitant made the patient more prone to accumulation of toxic metabolites, which was not responsive to methylene blue. With increasing therapeutic options for cancer treatment, the nephrologist's role in handling medication side effects will continue to expand.

SA-PO607

A Tale of Two Lines: Line Positioning Affecting Ability to Tolerate CRRT

Devang B. Patel, Juan Carlos Q. Velez, Karthik Kovvuru. *Ochsner Medical Center, New Orleans, LA.*

Introduction: Continuous renal replacement therapy (CRRT) is the modality of choice for delivering dialysis to patients with hemodynamic instability. However few patients have a precipitous drop in blood pressure with initiation of CRRT warranting discontinuation, followed by prompt improvement in blood pressure. Some of this drop in blood pressure could be secondary to removal of vasopressors by CRRT. The degree of blood pressure drop is likely related to the proximity of vasopressor delivery to the arterial end hole of the hemodialysis catheter and the prescribed clearance. We report a patient who tolerated CRRT when the vasopressors were infused through a distal port of a Trialysis (Power-Trialysis, short-term triple lumen dialysis) catheter instead of PICC (peripherally inserted central catheter) line which was delivering the pressors close to arterial end hole of the Trialysis catheter.

Case Description: A 64-year-old female who was being treated with antibiotics through a right arm PICC for leg stump infection was transferred to ICU due to acute kidney injury and septic shock. Norepinephrine and vasopressin were infused as vasopressors through the PICC. A right internal jugular Trialysis catheter was inserted to initiate dialysis. CRRT was attempted twice with precipitous drop in blood pressure within 3-5 mins needing significant increase in vasopressor dose, warranting discontinuation of CRRT. A prompt rise in blood pressure and decrease in vasopressor dose to that pre CRRT was noted following discontinuation of CRRT. The possibility of vasopressors being removed by CRRT was suspected due to the proximity of the tip of the PICC to the Trialysis catheter arterial end hole. CRRT was reattempted after switching vasopressors infusion from the PICC to the distal port of the Trialysis catheter. Patients' hemodynamics stayed stable affirming the suspicion of vasopressor removal by CRRT.

Discussion: Inadvertent removal of vasopressors should be considered as a potential cause of hemodynamic instability during CRRT initiation. Risk can be mitigated by infusing the vasopressors away from the arterial end hole of dialysis catheter either distally or proximally, which can be achieved by repositioning the tip of catheter.

SA-PO608

Dialysis Disequilibrium Syndrome in a Patient with a Relatively Low Blood Urea Nitrogen (BUN)

Pedro D. Mogrovejo Pintado, Mariana A. Chang, Anna Krieger, Jai Radhakrishnan. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Dialysis disequilibrium syndrome (DDS) is characterized by a range of neurologic symptoms that can affect patients when they first start hemodialysis (HD) or after multiple missed HD sessions.

Case Description: A 39-year-old patient with a history of lung transplant 5 years ago for idiopathic pulmonary fibrosis, stage 5 chronic kidney disease secondary to CNI toxicity, was admitted with severe nausea/vomiting. On physical examination his BMI was 20, normal vital signs, and no pericardial rub or asterixis were noted. Laboratory results: sodium 135, potassium 4.1, creatinine 8.9, blood urea nitrogen (BUN) 65, bicarbonate 18, blood venous gas 7.26/41. Hemodialysis (HD) was initiated (duration 2 hours, blood flow rate: 200 mL/min, dialysate flow rate: 400 ml/min, dialysate sodium: 138 mEq, dialysate bicarbonate: 25 mEq/L, fluid removal: 0.5L, urea reduction rate: 50%), immediately after his first HD, the patient complained of nausea, vomiting, and moderate to severe headaches. DDS was suspected and 100 ml of 3% hypertonic saline was administered with rapid resolution of the symptomatology, a subsequent head CT scan did not show cerebral edema.

Discussion: DDS is an uncommon but serious complication after HD initiation primarily caused by cerebral edema. The pathogenesis is not clearly defined. The generation of osmotic gradients due to the rapid reduction of extracellular urea and other osmoles could create a transient osmotic gradient between plasma and brain cells. Rapid correction of metabolic acidosis during HD could lead to intracellular cerebral acidosis. Risk factors include first HD, extremes of age, markedly elevated BUN (>175 mg/dl), and conditions associated with increased permeability of the blood-brain barrier (BBB). Hypertonic saline or mannitol to reduce the osmotic gradient is recommended as a treatment. Preventive measures include limiting the BUN clearance to <40%, the use of sodium modeling, or the prophylactic use of hypertonic saline or mannitol. The development of DDS in this patient was unexpected, considering his low BUN and the HD prescription that was used. Potential explanations include the generation of organic osmoles in uremic patients other than urea, that increase the permeability of the BBB and act as osmotically active substances generating an osmotic gradient. The prompt treatment led to full neurologic recovery.

SA-PO609

Dialyzing Brain Dead

Ripudaman S. Munjal,[1] Pranjal Sharma,[2] Harpreet S. Grewal,[3] Gagandeep Dhillon,[4] Rahul Kashyap.[5] *[1]San Joaquin General Hospital, French Camp, CA; [2]Northeast Ohio Medical University, Rootstown, OH; [3]Sacred Heart Hospital, Pensacola, FL; [4]University of Maryland Baltimore, Baltimore, MD; [5]WellSpan Health, York, PA.*

Introduction: Organ transplantation has been increasing worldwide, many of the patients die on wait list. The clinical progression of hemodynamic instability after brain death leads to possible loss of organs that could be harvested. Here we present a case of a twenty-six-year-old male who received kidney replacement therapy after being declared brain dead and was able to successfully donate his organs as per his organ donation status.

Case Description: A twenty-six-year-old male admitted after a motor vehicle accident, was found to have multiple fatal injuries including intracranial hemorrhage. Unfortunately, he succumbed to his injuries and was declared brain dead. He subsequently developed oliguric acute kidney injury (AKI) due to acute tubular necrosis as noted on urine sediment with muddy brown casts, leading to volume overload and hyperkalemia. Nephrology was consulted for stabilization before organs could be procured. Patient was started on Extracorporeal Kidney-Replacement Therapy in the form of Sustained low-efficiency dialysis (SLED). Continuous kidney replacement therapy (CKRT) might have been a preferred option, but due to non-availability of CKRT at our center SLED was initiated. SLED was done to minimize the hemodynamic changes. The heart and

left kidney were evetually procured and successfully transplanted. Family played an important role in deceased organ procurement and helped with every manner.

Discussion: Nearly half of discarded kidneys from 2010-2020 were from donors with AKI. Management of organ donor with AKI is often curtailed due to hemodynamic and electrolyte instability. Dialysis can correct the effects of AKI, but is rarely started after brain-death. Extracorporeal kidney-replacement therapy following brain death has not been extensively explored, CKRT has been studied to some extent. Brain dead patients with AKI treated CKRT have a favorable outcomes in organ donation. At our center, a brain-dead patient received dialysis in the form of SLED which improved hyperkalemia and volume overload, enabling the successful organ procurement. There is a need for further investigation into dialysis after death for organ procurement. Any intervention or treatment provided after death creates an ethical dilemma. There is a need to examine the ethical considerations and guidelines around the use of extra-corporeal kidney replacement therapy in brain dead patients for organ procurement.

SA-PO610

The Role of Duloxetine for Management of Persistent Hypotension in ESKD

Rasha Mohamed Abdul Rahman,[1] Salman Al Jerdi,[2] Awais Nauman,[1] Essa Abuhelaiqa.[1] *[1]Hamad Medical Corporation, Doha, Qatar; [2]Weill Cornell Medicine - Qatar, Doha, Qatar.*

Introduction: Uremic neuropathy is a known complication of end stage kidney disease (ESKD) that has significant morbidity and mortality. It can present as distal sensory, motor neuropathy, or autonomic dysfunction that worsen over several months. ESKD patients can develop intra-dialytic hypotension or persistent hypotension due to sympathetic and parasympathetic dysregulation characterized by preserved cardiac index, absence of reflex tachycardia, anhidrosis and reduction is systemic vascular resistance. Here, we evaluate the use of duloxetine, a serotonin–norepinephrine reuptake inhibitor, for management of persistent hypotension in ESKD on hemodialysis.

Case Description: 33-year-old lady history of ESKD started on hemodialysis for 19 years that over the past 5 years patient has been experiencing progressive and persistent hypotension. 5 years ago, her blood pressure was 90/50mmHg and now it is constantly 40/20 mmHg. Underwent cardiac, and endocrine investigation of hypotension with no specific cause. Therefore, thought to be associated with uremic neuropathy causing autonomic dysfunction. Despite intensifying hemodialysis, use of midodrine, hydrocortisone, and fludrocortisone, patient had no improvement in hypotension. Due to the severe hypotension the patient developed bilateral ischemic retinopathy and vision loss, multiple small bowel ulceration, and peripheral neuropathy. Patient was started on duloxetine 40mg daily trial for peripheral neuropathy. Within one week of therapy, patient noted improvement in neuropathic pain and in addition, blood pressure increase to 50/26. With Blood pressure improvement, patient developed diffuse and constant pulsing headaches required oral analgesic. Upon discontinuing duloxetine, headaches resolved and blood pressure returned to her baseline (41/19).

Discussion: Duloxetine has been commonly used for treatment of depression and anxiety in addition to peripheral neuropathy. One of the known side effects of duloxetine is hypertension, which is thought to be due to increase in norepinephrine levels, therefore, agonizing alpha-receptor, arterial vasoconstriction and increase systemic vascular resistance. Hence, duloxetine has a potential role in management of uremic neuropathy and an alternative treatment of persistent hypotension in ESKD.

SA-PO611

One-Year Effect of Deferoxamine in Sickle Cell Disease with ESRD Patient on Hemodialysis

Jason R. Ledoux, Jafar Alsaid. *Ochsner Medical Center, New Orleans, LA.*

Introduction: Sickle cell disease patient may develop Iron overload due to multiple transfusions. Iron chelation is recommended for treatment. Deferoxamine is eliminated through the kidneys and bowels. In ESRD the elimination is only by bowels. It can be removed by hemodialysis as reported. We are reporting the changes in serum Iron, Ferritin, hospital admission rates and transfusions frequency in an ESRD patient with sickle cell disease after using Deferoxamine for a year.

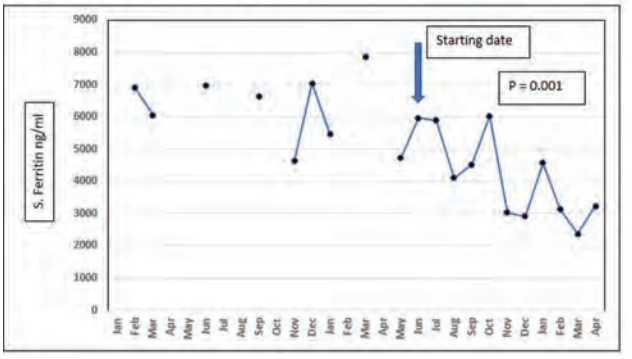
Case Description: 29 years old patient with Sickle cell disease. ESRD for 3 years, started with PD and transitioned to HD 3X weekly for the past year. He had recurrent admission for painful and hemolytic crises with frequent blood transfusions. Iron levels increased up to 235 micgm/dL (45-160) and Ferritin reached 7973 ng/ml (20-300). Hb remains low 3-5 gm/dl (14-18). Deferoxamine was started after review, discussion and assessment, at 1gm IV after each dialysis in June 2022 until May 2023.

Discussion: Deferoxamine is proven to be used with heavy metal intoxication. It is cleared through the kidneys and bowels. In patients with impaired renal function elimination of Deferoxamine will be reduced. Hemodialysis is reported to improve the clearance. Limited data is available on using the drug with Iron overload among dialysis patients. In our patient, we started Deferoxamine at 1gm IV infusion over 1 hour after each dialysis for a year. It was noticed to reduce the Ferritin significantly by 48%. An insignificant reduction trend was observed in S. Iron of 23%. The monthly admission rates for the patient was increased. Other causes needs to be excluded. There was an insignificant decrease in the number of PRBC transfused monthly.

Mean annual monthly admission rate, units of PRBC transfused, S. Iron and Ferritin.

Variables	2021 Mean (SE)	2022 Mean (SE)	2023 Mean (SE)	p value
Monthly admissions	1.2 (0.34)	2.3 (0.7)	3.6 (0.7)	0.001
Monthly transfusions	1.6 (0.5)	1.8 (0.37)	1.2 (0.4)	NS
S. Iron		138 (22)	108 (30)	NS
S. Ferritin	6375 (378)	5050 (476)	3360 (356)	0.001

Graph (1): Ferritin level over the follow up months:



SA-PO612

A Rare Case of Ocular Myasthenia Gravis in a Patient with ESRD

William Giesing, Hector L. Santiago-Gonzalez, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Myasthenia gravis (MG) is a rare autoimmune disorder caused by defective neurotransmitter transmission at the neuromuscular junction. The overall prevalence is about 150 to 200 cases per million. MG typically presents with fluctuating weakness and fatigability of ocular, bulbar, limb, and/or respiratory muscles. Very rarely, patients may present with isolated ocular symptoms, also known as ocular MG.

Case Description: An 82-year-old Hispanic woman with a past medical history of type II diabetes mellitus, hypertension, and end-stage renal disease (ESRD) on hemodialysis (HD) presented with sudden-onset ptosis of the right eyelid. Her vital signs were stable, and the rest of her physical exam was unremarkable. She underwent a computed tomography (CT) scan of the head and magnetic resonance imaging of the brain, both of which were unremarkable. A thyroid function test was normal and a CT of the chest looking for a thymoma was negative. Neurology was consulted and there was a high clinical suspicion for ocular MG. An ice pack test was performed and demonstrated improvement of her ptosis. She was started on pyridostigmine with improvement of her symptoms. Muscle-specific kinase and acetylcholine-binding antibody assays were negative, which is not uncommon in patients with ocular MG.

Discussion: Ocular MG is an extremely rare disease. In patients with ESRD on hemodialysis, it is an even rarer phenomenon. In addition, patients on HD are known to be at increased risk for stroke, a diagnosis often included in a list of differentials considered when assessing patients with physical manifestations of MG. It remains paramount to rule out acute stroke in patients with ESRD on HD presenting with motor deficits. However, it is also important to consider rarer etiologies, such as ocular MG, in the list of differential diagnoses.

SA-PO613

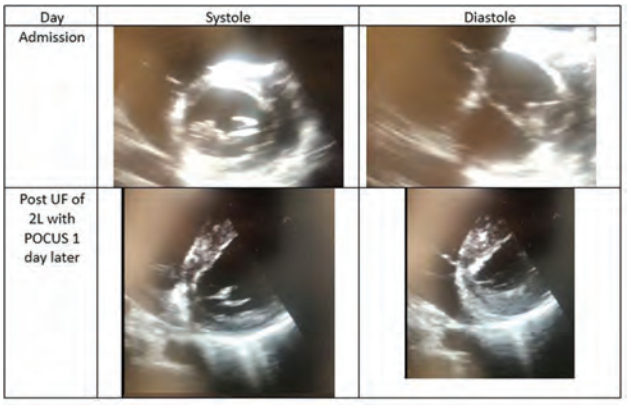
D-Sign Seen on Point-of-Care Ultrasound (POCUS) from Volume Overload and Used to Avoid CT Pulmonary Embolism (CT-PE) in Severe Contrast Allergy Patient

Sylvester Barnes IV.[1,2] *[1]Loyola University Chicago Stritch School of Medicine, Maywood, IL; [2]Edward Hines Junior VA Hospital Cooperative Studies Program, Hines, IL.*

Introduction: A 50y M w/ PMHx of osteosarcoma c/b chemotherapy induced cardiomyopathy now s/p OHT (11/10/17), severe iodine contrast allergy resulting in previous anaphylaxis, ESRD on HD (TTS) with last dialysis one day prior to admission, and RCC with metastases was brought to the ED for low O2 levels at home of 78%. Significant medications include fentanyl patch 25mcg every 72hours, oxycodone 5mg q8 prn, gabapentin 300mg TIW on MWF, tacrolimus, and prednisone. Obtained vitals are BP of 164/82, HR 81, RR 18, 87%O2 sat improved to 96% on 2L NC. The patient is drowsy on exam, lungs clear to auscultation, HR is RRR with no JVD noted, no cyanosis in nail beds or lips. Labs are significant for a negative troponin I, negative viral respiratory panel, BNP 2813pg/nl increased from 1620pg/ml three months prior, and D-Dimer 2655 ng/ml. CXR showed mild interstitial pulmonary edema and a small right pleural effusion. The patient's pain medication was held but there was a concern for possible PE secondary to his underlying malignancy and decreased O2 levels.

Case Description: Bedside POCUS showed cardiac flatting of the interventricular septum with an eccentricity index > 1 ; "D" sign indicating right heart strain. This patient's D sign pattern was observed only in diastole which is more indicative of fluid overload then PE. CT PE protocol was planned for the following day with starting of prophylaxis planned to start the following day as well. The pt underwent HD with removal of 2L of fluid. The next day repeat POCUS was performed showing resolution of the "D" sign along with oxygenation improvement.

Discussion: The patient was discharged the next day without a PE CT scan, EDW adjustment for his dialysis and lower pain medication. The use of POCUS helped to identity a right heart strain pattern with an eccentricity index >1 in diastole only. The POCUS findings before and after HD negated the need for additional studies which in this patient carried significant risk secondary to his severe contrast allergy.



SA-PO614

The Uncertainty of Bleeding Risk Monitoring for ESKD Patient on Continuous Anticoagulation Infusion

Man Kit Michael Siu, Ekamol Tantisattamo, Samir D. Patel. *University of California Irvine, Irvine, CA.*

Introduction: Patients with end-stage kidney disease (ESKD) are at increased risk of bleeding due to: chronic anemia, uremic platelet dysfunction, vascular calcification, and dialysis-related complications. Additionally, the risk of venous thromboembolism is also heightened, making anticoagulation management challenging. This case report presents the unfortunate outcome of an ESKD patient who experienced acute intracranial bleeding after initiation of heparin infusion for ischemic digits, leading to death.

Case Description: Patient is a 38-year-old female with ESKD secondary to diabetes mellitus (DM) on peritoneal dialysis (PD) and a history of scleroderma. She presented with progressive digit pain and discoloration. During hospital stay, she developed worsening respiratory status due to ESBL pneumonia, requiring intubation. She was started on epoprostenol given concern for Raynaud's crisis, as well as heparin infusion for severe atherosclerotic vascular disease with stenosis. Unfortunately, hospital course was further complicated by a non-operable intraparenchymal bleed with cerebral edema and herniation, leading to eventual extubation and transition to comfort care.

Discussion: Bleeding events in ESKD patients, ranging from bruises and bleeding at venipuncture sites to intracranial hemorrhage, significantly contribute to mortality and morbidity. Furthermore, blood transfusions can lead to alloimmunization and limit future transplantation options. In this case, several factors contributed to the adverse events. Team factors, including limited communication between the medical teams involved, may have hindered comprehensive management given patient's ongoing anticoagulation need. Patient factors, such as multiple comorbidities (ESKD, cardiovascular disease on aspirin) and the initiation of epoprostenol (a potent platelet aggregation inhibitor), further increased bleeding risk. Lastly, hospital policies, such as specific protocol tailored to ESKD patient that minimizes bolusing and allow for slower infusion rates could have potentially prevented these adverse events and improve patient outcomes.

SA-PO615

Improving Medication Errors in Hospitalized Hemodialysis Patients

Zain AlShanableh, Muhammad Ebad U. Rehman, Kristen Shimko, Joshua Rosenthal, Vignesh Viswanathan, Ranil N. DeSilva. *UPMC, Pittsburgh, PA.*

Background: The kidney is a key organ for the excretion of several medications and their metabolites. Medical errors relating to dosing and/or timing of medications in patients on hemodialysis (HD) may have serious adverse events. This project was designed to identify and prevent common medications errors in HD patients.

Methods: A quality improvement project was conducted at the University of Pittsburgh Medical Center Presbyterian Hospital from May 2021 to March 2023. Nephrologists identified HD patients and created a single Powerchart list to be electronically reviewed by a dedicated pharmacist who ensured appropriate dosing and timing of renally dosed medications. We included patients admitted to the hospital that were on HD, with acute kidney injury or end stage kidney disease. We excluded patients from units that had on-site dedicated pharmacists or evidence of HD held for more than one week.

Results: A total of 1723 reviews have been completed on 668 patients. Our analysis revealed that 1065 medications were being appropriately dosed and 146 medications required interventions. Of those that required intervention, 125 medications were rescheduled to be given after dialysis and 21 medications required dose adjustment (chart 1). Common medications identified are demonstrated in chart 2.

Conclusions: Approximately, 12% of medications reviewed required an intervention for dose/timing adjustment and 10% were defaulted to be given prior to dialysis. A pharmacist, via electronic review, was able to reduce these potential errors and next steps may include utilizing Electronic Medical Records solutions to automate error reduction.

Medication Reconciliation in Veterans Receiving Dialysis at Edward Hines VA Hospital: A Quality Improvement Initiative

Juan J. Cintrón-García, Roberto Guerrero, Holly J. Kramer, Karen A. Griffin, Kavitha Vellanki. *Loyola University Health System, Maywood, IL.*

Background: Polypharmacy, commonly defined as use of 5 or more medications, is associated with higher morbidity, fall risk, functional decline and disability. We aimed to identify prevalence of medication discrepancy and possible risk factors in veterans receiving dialysis at Hines VA hospital.

Methods: Eligible patients were asked to bring all pill bottles at least once during the study period, October 2022 to March 2023. Medical records were then reviewed to identify discrepancies. Collected data included age, race, sex, cause of end stage renal disease (ESRD), dialysis vintage time, dialysis modality, no: of providers involved, no: of prescribed medications and presence of care giver at home. Cognitive screening was done using Montreal Cognitive Assessment Test (MoCA).

Results: A total 48 patients participated in the study. Baseline characteristics are shown in Table 1. 32 patients had at least one medication discrepancy. Compared to patients that completed MoCA (36/48), those that declined (12/48) had higher percentage of medication discrepancies (75% vs. 63%) despite having a caregiver (71% vs. 61%) (Image 1). 11 of the 12 patients declining MoCA were receiving hemodialysis (HD).

Conclusions: We found high prevalence of medication discrepancy in our veteran ESRD patients. MoCA scores were not associated with medication discrepancies, but those declining MoCA or with poor overall interest tended to have more discrepancies. Our study limitation is small sample size of a single center veteran population.

Funding: Veterans Affairs Support

SA-PO617

Efficiency of a Fully Integrated Hemodialysis (HD) Machine in the Acute Care Setting

Nazli Atefi,[1,2] Nasha Elavia,[1,2] Zain Haq,[1,2] Jagman S. Chahal,[1,2] Abutaleb A. Ejaz,[1,2] Ami M. Patel.[1,2] *[1]VA Medical Center Baltimore, Baltimore, MD; [2]University of Maryland Medical System, Baltimore, MD.*

Background: Tablo™, which is a fully-integrated, adaptive hemodialysis (HD) machine with an internal water purification system without requiring traditional water treatment resources, has a 300 mL/min restriction in the maximum attainable dialysate flow rate (DFR). We investigated the efficiency of Tablo™ in the acute hospital setting.

Methods: We conducted a prospective, single-center analysis. All Veterans with ESKD, who completed ≥ 3hrs of hemodialysis with available blood urea nitrogen pre- and post-treatment, from February 2023 to May 2023 were included. Urea reduction ratio (URR) and calculated Kt/V were compared for selected variables.

Results: 38 Veterans with total of 69 HD sessions met the inclusion criteria for analysis. Participants were 94.2% males, mean age 67.2±10.2 years, dialyzed for 211.3±9.1 mins, blood flow rate (BFR) 354.1±13.1mL/min, with Optiflux F160 (43.5%) and F180 (56.5%) dialyzers, average ultrafiltration 1.9±0.6 L, arteriovenous fistula (26%), arteriovenous graft (5.7%) and central venous catheter (68.3%). Kt/V and URR for full cohort was 1.21±0.2 and 59.5±6.7%, respectively. 43.5% and 27.5% of the sessions achieved adequate Kt/V (≥1.2) and URR (≥65%), respectively. Mutivariable analysis by subclasses are shown in Figure1. Access type, duration of treatment, dialyzer type or BFR were not predictors of adequate Kt/V on multivariate analysis. Despite a favorable trend, significant statistical differences were not observed in Kt/V or URR between the use of Optiflux F160 and F180 dialyzers at same BFR (350 mL/min) and treatment duration (3.5 or 4 hrs).

Conclusions: The restriction of DFR to 300 mL/min with Tablo™ system compromises adequacy of dialysis in acute care setting. This may be mitigated by prolonging session times, albeit at the expense of higher resource utilization. Future studies are necessary to compare adequacy of Tablo™ and conventional dialysis machines using higher typical DFR in a larger cohort.

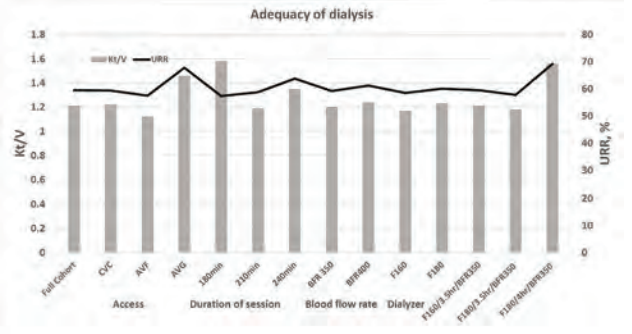

Figure 1 Multivariable analysis of dialysis adequacy with Tablo ™

SA-PO618

Blood Flowrate Accuracy with Dality Hemodialysis System

Clayton Poppe, Nicholas Hyun, Blaine Murakami. *Diality, Irvine, CA.*

Background: As laid out by Williams, Jensen, Gillum and Nabut,[1] blood flow accuracy in hemodialysis machines often does not match the manufacturers' stated accuracy at high blood flowrates. Flowrates might be lower by as much as 80-100 ml/min at a setpoint of 500 ml/min. This compares to the stated accuracy of +/-10% by most hemodialysis machine manufacturers. This difference in blood flowrate can lead to a reduction in Kt/V of 8.4%, depending on the dialysate flowrate. The Diality Hemodialysis System corrects for the factors responsible for reducing the expected flowrate leading to more accurate control of the blood flowrate and thus a higher Kt/V that better matches the theoretical value for dose delivered. [1] Williams HF, Jensen K, Gillum D, Nabut J. Blood pump speed vs. actual or "compensated" blood flow rate. Nephrol Nurs J. 2007 Sep-Oct;34(5):491-9, 525. PMID: 18041451.

Methods: The challenge in controlling blood flow is that parameters that are appropriate for high blood flows may not work a low flowrates. An algorithm that predicts the flowrate from independent variables is used to control the blood flow using a Proportional-Integral-Differential (PID) control methodology. The factors feeding into this algorithm are independently correlated with changes in blood flow. These include: - Pump head speed - Inlet and Outlet Pressures - Tubing Aging - Temperature

Results: The graph on the left-hand side of Figure 1 shows the accuracy of blood flow control at 100 ml/min while the graph on the right-hand side shows the accuracy of blood flow control at 500 ml/min. The green line represents the measured flow from a reference flowmeter while the orange line represents the algorithmically calculated flow from the device. Actual flowrates are well within the stated accuracy of +/-10% for both low and high flowrates.

Conclusions: Understanding the variables that lead to changes in blood flow and using them to control blood flow in real time can leads to better blood flow accuracy. This in turn can lead to higher average Kt/V for higher treatments with high blood flowrates.

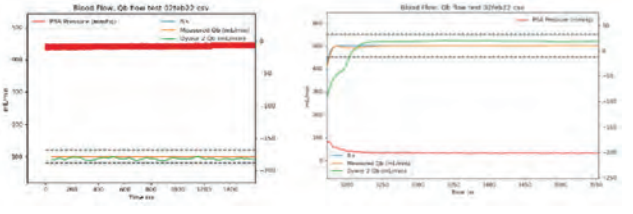

Figure 1: Blood Flowrates of 100 ml/min (right) and 500 ml/min (left)

SA-PO619

Increasing Incidence and Prevalence of Patients on Kidney Replacement Therapy over the Last 40 Years in Uruguay

Leonella Luzardo,[1,2] María Laura Ceretta,[1] Alejandro Ferreiro,[1,2] Valentina Oroza,[1] Maria C. Gonzalez-Bedat.[1] *[1]Uruguayan Dialysis Registry, Montevideo, Uruguay; [2]Nephrology Center, Montevideo, Uruguay.*

Background: From 1980 onwards chronic dialysis (CD) and kidney transplantation (KT) are accessible for the entire population.

Methods: The aim of this study is to describe the trends in the incidence (I), the prevalence (P) and the survival of patients on KRT over the last 40 years.

Results: The P increased from 41 to 1227 pmp (Fig 1). The P on CD increased from 38 on 1981 to 820 pmp in 2020. The P of patients on KT increased from 3 on 1981 to 407 pmp in 2020. The growth of the I and P of CD and KT was higher in the first 2 decades (1981-2000) (278% vs 48%, 533% vs 113%, 1592% vs 23% and 3066% vs 291%) (Fig 2). The growth of the P rate of KT was 10 times higher than the CD P rate. The age on admission to CD increased from 44.3±13.5 in 1981 to 62.2±17.1 years in 2020, while those over 65 years increased from 3.0 to 52.4%. The crude M on CD increased from 14.8 in 1993 to 17.0/100 patient-y, but no changes were observed in the adjusted analysis. The M rate in CD was 17 times higher than that of the general population (Table 1).

Conclusions: The I and P of patients with CKD on KRT in Uruguay have increased between 1981 and 2020 with a higher percentage growth in the P rate of KT. Despite the increasing admission of patients older than 65 years, M has remained stable in recent years.

SA-PO620

Implementing a Protocol for Incremental Hemodialysis in Incident Patients with ESKD: A Quality Improvement Project

Ali Taha,[1] Alexander Messina,[1] Alexander Tom,[1] Reman I. Altar,[1] Nancy Filteau,[1] Daniel Blum,[2] Emilie Trinh,[1] Catherine L. Weber.[1] *[1]McGill University Health Centre, Montreal, QC, Canada; [2]Hopital General Juif, Montreal, QC, Canada.*

Background: Incremental hemodialysis (HD) is the process whereby the frequency of HD is adapted to the patient's residual kidney function, initially starting at twice a week with an increase based on clinical indications. Incremental HD potentially facilitates the transition to HD, reduces patient and caregiver burden, improves quality of life and reduces costs. We sought to increase the number of patients commenced on incremental HD at a tertiary care academic center and to develop a safe process to monitor these patients.

Methods: We performed a prospective cohort quality improvement study. Starting November 1 2022, we aimed to start 75% of eligible incident chronic HD patients on incremental HD within 1 year. Eligible patients were defined as medially stable with no acute, active medical issues, and no indication for more frequent HD. The primary outcome measure was percentage of incident ESKD patients started on incremental HD. The balancing measure was the number of patients requiring transition to three-times per week HD. The incremental HD process was developed with input from all stakeholders.

Results: Between November 1 2022 and March 31 2023, among 35 incident chronic HD patients, 14 were eligible for incremental HD, of which 9 started incremental HD. As of May 2023, 6 patients remain on two-times per week HD and 3 patients required an increase to three-times per week HD. The process developed included a) a patient information sheet about incremental HD b) nursing education, c) a nurse led protocol whereby the patient performs a 24 hour urine collection for volume and the nurse completes a safety checklist every 6 weeks, and d) an alert system for the MD to review the patient's HD prescription if they have uremic symptoms, are volume overloaded or hyperkalemic.

Conclusions: We successfully initiated 64% of eligible incident HD patients on incremental HD, of which two-thirds remained on twice-weekly HD. Our next steps will involve feedback from patients and healthcare staff through quantitative and qualitative surveys with the goal of optimizing our protocol and expanding it to all dialysis units at our center.

SA-PO621

A Vulnerable Population: Case Series Examining Involuntarily Discharged Hemodialysis Patients in an Urban, Predominantly Black US Population

Zikora U. Nnadike,[1] Anjuli Shah,[1] Carol A. Gray,[2] Loren C. Cobb,[3] Christopher M. O'Donnell,[1,2] Jose E. Navarrete,[1,2] Jason Cobb.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory Healthcare, Atlanta, GA; [3]Meharry Medical College, Nashville, TN.*

Background: An overlooked population is the number of insurable involuntarily discharged hemodialysis (HD) patients receiving maintenance HD. Presented is a case series examining involuntarily discharged HD patients receiving maintenance HD in inpatient settings in an urban US population.

Methods: Retrospective chart review of potential involuntarily discharged HD patients from 2020 – 2023 observed at Emory Hospitals and Grady Memorial Hospital. Studied were insurable end stage kidney disease (ESKD) patients who started HD as inpatient and were seen for inpatient dialysis >60 days and patients involuntarily discharged from a HD center.

Results: Among the 25 ESKD patients – all Black race and 68% male. 13 discharged for noncompliance, 8 discharged for disruptive behavior, 3 for insurance reasons, and 1 undetermined. HD vascular access – permcath (n=13), arteriovenous graft (n=4), and arteriovenous fistula (n=8). Observed hospitalizations for HD ranged from 3 to 298. The 3 patients discharged for insurance reasons included 2 patients initiated on HD as an inpatient and declared ESKD and received HD as an inpatient >60 days. Suspected noncompliance prevented them from being accepted despite being insurance eligible. 16 patients received a second chance outpatient HD center, and 1 was discharged from the second chance HD unit.

Conclusions: This case series brings attention to a vulnerable nephrology population. Most of the patients were discharged for subjective reasons like noncompliance and the impact of biases are hard to determine, but the patients being 100% Black is remarkable. The high level of success with second chance HD center placement demonstrates a need for interventions. More data is needed to examine geographic variances, economic impact, and the psychological toll emergency-only inpatient HD is having on these patients.

SA-PO622

Characteristics and Outcomes of High-Acuity Patients Referred for Outpatient Dialysis

Gopa B. Green,[1] Eric D. Weinhandl,[1,2] Graham E. Abra,[1,3] Tejas Gopal,[3,1] Juan D. Ordonez,[1] Wael F. Hussein.[1,3] *[1]Satellite Healthcare, San Jose, CA; [2]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Dialysis-requiring hospitalized patients with co-morbid high-acuity needs are challenging to place in outpatient dialysis centers, leading to extended hospital stays. In 2018, we established a program for physician evaluation of high-acuity referrals for admittance to outpatient dialysis centers. The program provides care coordination with the discharging hospital, necessary dialysis-related medical equipment, and training of center staff to manage need for bed or bariatric bed, left ventricular assist device (LVAD), tracheostomy, behavioral issues requiring supervision, infection with communicable organisms, or other high-acuity co-morbid conditions. Little is known about the safety or efficacy of outpatient dialysis for high acuity patients.

Methods: We describe the characteristics and outcomes of patients referred to the program from January 2018 through April 2023.

Results: The program received 468 referrals, of which 149 (31.8%) initiated dialysis at outpatient dialysis centers of a mid-size non-profit dialysis provider. 304 patients were excluded due to reasons including inadequate staffing or space, clinical instability, and overly complex management needs. The most common indications for admission were the need for a special gurney or bed (99 patients), tracheostomy (22), and LVAD (8). The mean (SD) age was 62.7 (14.0) years, 41% were female, and 59% had diabetes. 21% of patients had a central venous catheter at the time of referral into the program. During 152 patient-years of follow-up, re-hospitalization rate at 1 month was 37%, with an admission rate of 2.7 per patient-year and 21 hospital days per patient-year. Despite this, 94% of the patients' survival time was spent out of the hospital. Survival rates at 3, 6, and 12 months were 76%, 71%, and 59% respectively.

Conclusions: A program that utilizes nephrologist evaluation, care coordination, additional equipment, staffing, and training can facilitate hospital discharges and address the care needs of high-acuity patients undergoing dialysis in the outpatient setting. Despite high comorbidity, these patients can benefit from being out of the hospital the majority of their time post admission to the dialysis center.

SA-PO623

Nephrologist Involvement in the Multi-Organ Failure Patient with Artificial Liver Support Systems: Experience of the Single-Center Extracorporeal Therapy Program in Mexico

Abel Humberto V. Compean,[1,2] Pedro Morales Molina,[1,2] Diana Maldonado Tapia,[1,2] Monica Lopez Mendoza,[1,2] Pamela Prado,[1,2] Claudia B. López,[1,2] Irving G. Ramirez,[1,2] Julio C. Nieto,[1,2] Beatriz R. Cerezo Samperio,[1,2] Juan D. Diaz Garcia.[1,2] *[1]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico; [2]Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.*

Background: The role of the nephrologist in intensive care is critical and includes the implementation of extracorporeal therapies, such as combined artificial hepatic-renal support, which provides time for rapid inclusion in an emergency liver transplantation program or recovery from acute failure. The most used methods are the molecular adsorbent recirculating system (MARS) and single-pass albumin dialysis (SPAD).

Methods: Objective: To expose the experience in the multiorgan support of critically ill patients with extracorporeal liver and kidney support therapies at the Centro Medico Nacional 20 de Noviembre. Retrospective study of patients with acute liver failure from 2016 to 2023 who underwent MARS or SPAD therapy.

Results: Of 21 patients, 43% were women and 57% men, with an average age of 38 years. The etiology of the liver disease was autoimmune in 47%, hepatitis A infection in 19%, cryptogenic in 14%. Ten of these patients had a previous liver transplant, 47% with recurrence of the disease or chronic rejection; the indication for liver support was 66% for acute chronic liver failure and 34% for acute liver failure, with SOFA score 9.8±8, MELD

score 25±15. Five patients received MARS and 16 SPAD, with a total of 63 sessions (average of 3 sessions per patient), with a bilirubin clearance rate of 29.2% (3-47%). Acute kidney injury was present in 62%, of these 54% required CRRT. We found an average survival of 6 months (1 to 56 months) and mortality of 80%.

Conclusions: The use of MARS or SPAD is a therapeutic bridge that allows clinical improvement of the patient or liver (re)transplantation in acute liver failure. Despite the high mortality, there is substantial room for improvement that favors comprehensive care processes in the critically ill patient. Survival of these patients varies according to the severity and availability of donated organs.

SA-PO624

Rural Alaskan Experience Insourcing Innovative Dialysis Technology

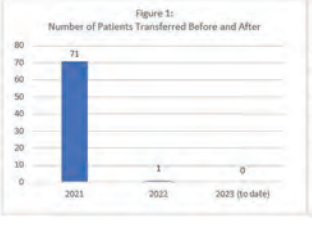
Daniel Russell,[1] Alyssa Krier,[1] Amanda L. Bush,[1] Cynthia J. D'Alessandri-Silva.[2]
[1]Mat Su Regional, Palmer, AK; [2]Outset Medical, San Jose, CA.

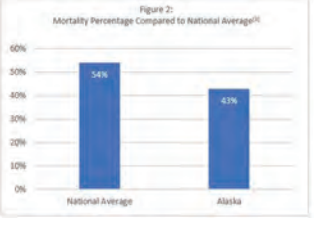
Background: Patients requiring dialysis in rural areas often face obstacles for treatment such as distance to care, financial limitations, and mistrust of the medical community. Studies have revealed moving geographic location of medical services closer, has a positive impact on health, economic and psychosocial states. Alaska has a paucity of acute dialysis services outside of the major cities like Anchorage and Fairbanks, leading to significant cost and complexity to the delivery of care to patients in these areas. Mat Su Regional hospital is a 125-bed hospital located an hour from Anchorage and operationalized a dialysis service line to improve access to care for rural patients in Palmer, AK using an innovative dialysis system, Tablo®. This describes the first year of Intermittent Hemodialysis (IHD) and Sustained-Low Efficiency Dialysis (SLED) treatments.

Methods: A retrospective chart review through the hospitals Electronic Health Records (EHR) was performed on all IHD and SLED treatments since implementation in February 2022.

Results: Since implementation of dialysis services in February 2022, there were 340 combined IHD and SLED treatments in the hospital. Only 1 patient was transferred for care compared to 70 patients the year prior. Training for ICU nursing staff consisted of Tablo hub training modules, 2-hour hands on training and 2- 12-hour treatments with preceptor on the device. In the ICU there were 23 unique patients with 65 total SLED treatments. CLABSI rate was 0% and mortality rate was 43% (Fig 1) with 70% of those patients being male. Most treatments where longer than 10 hrs. (98%) and 49% used automated saline flushes as method for anticoagulation and 9% of treatments ended due to clotting (Fig 2). There was a 4.3% COVID rate.

Conclusions: Implementation of a new dialysis service line using Tablo decreased hospital transfers and displacement of patients in rural Alaska. Mortality rates were slightly better than national averages as were clotting events. Training of staff was relatively easy which allowed hospital wide adoption. More research is needed to increase dialysis services into rural areas for better patient outcomes.





SA-PO625

Building a Framework for Enhancing Dialysis Services in Conflict-Affected Regions: A Multi-Level Action Plan

Sami Alasfar,[1] Hani S. Alashawi,[2] Saleh Kaysi,[4] Gilbert M. Burnham.[3] *[1]Mayo Clinic Arizona, Scottsdale, AZ; [2]Health Cluster, Gaziantep, Turkey; [3]Johns Hopkins University Center for Teaching and Learning, Baltimore, MD; [4]UVC Brugmann, Brussels, Belgium.*

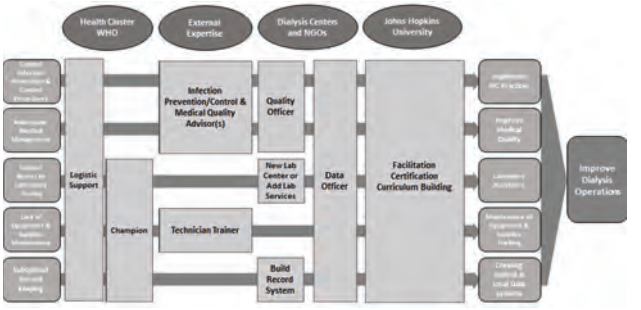
Background: The provision of dialysis to patients with ESKD in areas affected by conflict poses various challenges. Reports have shown a high incidence of hepatitis B&C among patients on hemodialysis (HD) & poor HD operations in Northwest (NW) Syria, an area enduring armed conflict. A framework is necessary to address the hindrances to HD in such environments.

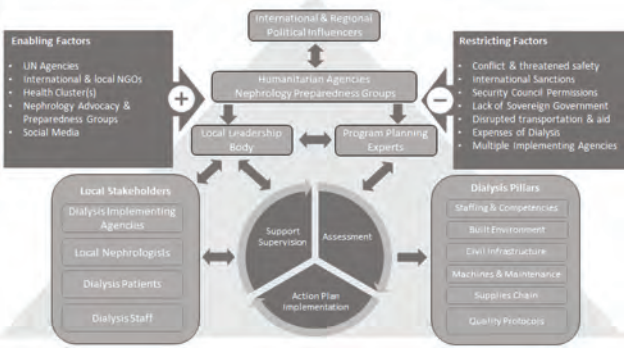
Methods: The Health Cluster Hub in Turkey is collaborating with Johns Hopkins University to spearhead a quality improvement initiative for HD in NW Syria. Objectives are to address difficulties of HD in this region and enhance care delivered by NGOs administering HD. The project comprises 3 phases: baseline asssement, setting up basic standards & action plan, and putting a support supervision system, alongside creating a framework to attain these targets.

Results: The 1st phase involved a survey of HD centers and 2 workshops utilizing the fishbone technique & theory of change models to map the necessary changes. Through this phase, an action plan (Fig 1) was developed and involved various stakeholders with different objectives. The 2nd phase focused on building quality curricula, which were subsequently taught through courses, creating a record system, & establishing minimal standards for HD centers. Furthermore, a framework was created to address dialysis services in NW Syria and other conflict settings (Fig 2).

Conclusions: As it is the responsibility of the nephrology community and humanitarian agencies to ensure quality care for patients with ESKD, we propose a comprehensive framework to enhance HD care in unstable areas. This framework involves engaging all stakeholders in care delivery, establishing minimum standards, and mitigating risks to patients.

Funding: Government Support - Non-U.S.





SA-PO626

Association of Predialysis Education Choice with Optimal Starts in ESRD

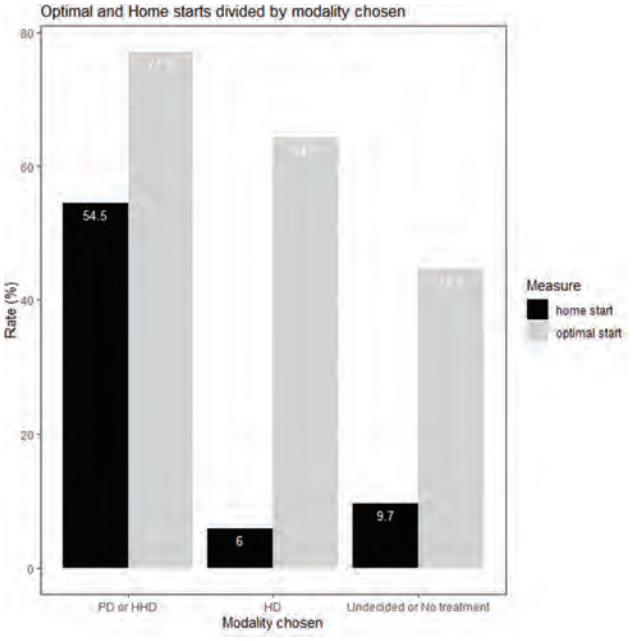
Ken J. Park, Cynthia Tai, Daniel E. Carl. *Kaiser Permanente Northwest, Portland, OR.*

Background: Published studies have shown that choosing home dialysis after modalities education pre-dialysis is associated with higher likelihood of starting on home dialysis (PD or home HD). However, the relationship between patients' dialysis choice after modalities education and optimal starts (receipt of preemptive kidney transplant, initiation of HD with arteriovenous graft or fistula, or initiation of PD) is unknown. We were interested in whether choosing a home modality was associated with higher likelihood of having an optimal start.

Methods: Our retrospective cohort consisted of 525 patients from Kaiser Permanente Northwest who progressed to ESRD (defined as receipt of preemptive kidney transplant, HD, or PD) from January 1, 2019 to December 31, 2022 and had attended modalities education pre-dialysis. Multiple logistic regression was used to examine the association of patients' dialysis choice with having an optimal and home dialysis start.

Results: Hemodialysis was chosen by 26% and home dialysis by 54% of patients. Patients were undecided or chose no treatment in 20% of the cohort. Univariate analysis showed that compared to choosing HD or being undecided / choosing no treatment, patients who chose home dialysis were more likely to start optimally (77% vs. 64% vs. 45%, $p < 0.005$) and to start on home dialysis (55% vs 6% vs. 10%, $p < 0.005$). After adjusting for race, age, diabetes, and gender, patients choosing home dialysis had 3.8-fold ($p < 0.005$) and 1.6-fold ($p = 0.04$) higher odds of starting optimally and a 11.3-fold and 18.3-fold higher odds of starting on home dialysis ($p < 0.005$) compared to the undecided/ no treatment group and hemodialysis group respectively.

Conclusions: Choice of home dialysis after modalities education was associated with a higher likelihood of having an optimal and home dialysis start.



SA-PO627

It Takes Time: Developing a Standardized Strategy to Improve Timely Modality Education and Home Dialysis Choice Rates in Patients with Advanced Kidney Disease in Toronto, Canada

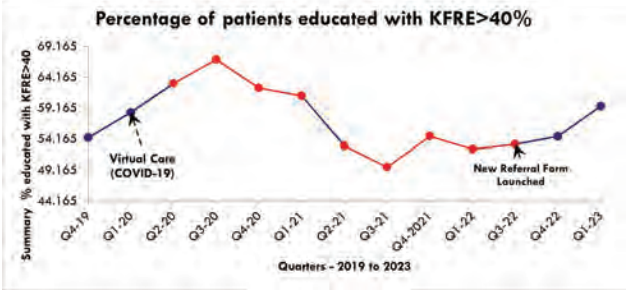
Declan Lu, Sijia Zheng, Bailey Paterson, Lisa Dubrofsky, Bourne L. Auguste. *University of Toronto, Toronto, ON, Canada*.

Background: Patients with progressive chronic kidney disease (CKD) should receive timely education that allows them to choose a treatment path that aligns with their care goals and lifestyle. Home-based dialysis modalities have been associated with increased quality of life and reduced health care costs. Modality education has been shown to increase rates of home dialysis as the initial dialysis strategy. Delays in timely education may reduce home dialysis choice rates. Barriers to timely modality education include lack of a standardized referral process, physician practice variation and patient preparedness to engage in discussion. The aim of this study was to assess whether the implementation of a standardized referral process could increase the rates of timely modality education and home dialysis choice.

Methods: This was a quality improvement study performed at a single center in Toronto, Canada between 2019-2023. Patients with a 2-year Kidney Failure Risk Equation ($KFRE^2$) of >= 40% were recommended for modality education as outlined by the provincial regulatory body. Rates of modality education and home dialysis choice were recorded on a quarterly basis both before and after implementation of a standardized referral process.

Results: 1451 encounters were identified between 2019-2023. Prior to initiation of a standardized referral process, 647/1134 (57.1%) of eligible patients received modality education and 218/647 (33.7%) of educated patients choose home dialysis as their preferred modality. After initiation of a standardized referral process, 177/317 (55.8%) of eligible patients received modality education and 54/177 (30.5%) of patients choose home dialysis as their preferred modality.

Conclusions: There was no significant change in modality education or home dialysis choice rates after initiation of a standardized strategy. Timing of education should not be restricted to arbitrary cut-off values but requires ongoing mentorship and support of patients at an early stage of disease course.



SA-PO628

Shared Decision-Making Intervention Regarding Dialysis Modality in Patients with Stage 5 CKD

Hark Rim,[1,2] Byeonghwa Bak,[1,2] Ye na Kim,[1,2] Ho Sik Shin,[1,2] Yeonsoon Jung.[1,2] *[1]Kosin University Gospel Hospital, Busan, Busan, Republic of Korea; [2]Kosin University College of Medicine, Transplantation Research Center, Busan, Republic of Korea*.

Background: Patients with kidney failure must make complicated decisions about the dialysis modalities used either at home or in-hospital. Different options have varying levels of impact on patients' physical and psychological conditions and their social life. The purpose of this study was to evaluate the implementation of an intervention designed to achieve shared decision making (SDM) in patients' options for dialysis.

Methods: SDM was performed after consent was written for stage 5 chronic kidney disease patients before dialysis, and 435 cases were performed in 408 patients from December 16, 2019 to June 30, 2021. Among these, 101 patients were compared by SDM measurement scale, patient satisfaction, disease recognition scale survey, and dialysis method.

Results: The average age of participants was 56 years, with a gender composition of 55 males (54.5%) and 46 females (45.5%). Following SDM, the final dialysis methods decided upon by patients and clinicians were peritoneal dialysis (67 patients, 66.3%), hemodialysis (22 patients, 21.8%), and kidney transplantation (1 patient, 1.0%).

Conclusions: Among participating patients, SDM was effective when used to decide on dialysis treatment, and patients were satisfied with the dialysis method decision process. On the disease awareness scale, those who participated in this project had relatively high positive and low negative perceptions, so it can be concluded that SDM was relatively effective. The implementation of SDM was helpful in selecting patients' best dialysis methods, and SDM scale results were higher in the peritoneal dialysis group than in the hemodialysis group.

Table 2
Shared decision making measurement scale results.

Questionnaire items	4 Points or higher
1) My attending physician made it clear that a decision was needed.	97.3%
2) My attending physician wanted to know exactly how I was involved in making the decision.	87.4%
3) My attending physician said that there were several options to choose from depending on my health condition.	89.2%
4) My doctor explained in detail the pros and cons of each treatment option.	92.8%
5) My attending physician helped me understand the information.	93.7%
6) My doctor asked what my preferred treatment was.	91.0%
7) My doctor and I thoroughly evaluated the different options for treatment.	84.6%
8) My doctor and I chose treatment together.	88.3%
9) My doctor and I agreed on a course of treatment.	90.1%

Table 8

Choosing the right dialysis method for you.

What is most important to you?
1. Health-related considerations
I want to protect my heart.
I want to protect my bones, joints, and nerves.
I want to live according to my will.
I do not want to be a burden to my family.
I want to keep my quality of life as high as possible.
I want to spend a day without the burden of dialysis.
I do not want to go on dialysis every day.
I want to see a doctor regularly.
I can control my daily routine by myself.
I lead a regular life.
I plan and act in my daily life.
I enjoy exercising.
2. Dialysis environment
I want to go to the hospital as little as possible.
I am more comfortable with expert dialysis.
I like being in a familiar environment.
I hate environmental changes.
I like to experience new things.
I like watching TV.
I find it difficult to lie down for long periods of time.
I am afraid of needles.
I tend to be very conscious of other people's eyes.
I tend to depend a lot on my spouse for my daily life.
I need someone to take care of me.
I do not want a dialysis machine in my house.
3. Daily life
I want to spend as much time as possible with my family.
I live with and take care of my elderly parents.
I am raising a child.
I have to go to school or go to work.
I should be able to eat and drink what I like.
I sweat a lot, so I shower or bathe often.
I tend to care about my appearance.
I take a lot of time to get used to new things.
I have no one to take care of me.
I love to travel and never give up.
I travel abroad a lot.

SA-PO629

Provider Peritoneal Dialysis (PD) Education Can Increase Continuous Ambulatory Peritoneal Dialysis (CAPD) Utilization Without Increased Peritonitis

Michael A. Kraus,[1] Rachel A. Lasky,[1] Linda Ficociello,[1] Edward C. Fisher,[4] Usama T. Hussein,[2] Lisa O. Cabrera,[3] Rajesh Thomas,[1] Patricia Waiblinger.[1]
[1]Fresenius Medical Care Holdings Inc, Waltham, MA; [2]Nephrology Associates of Tidewater LTD, Norfolk, VA; [3]Renal Associates PA, San Antonio, TX; [4]Metrolina Nephrology, Charlotte, NC.

Background: CAPD use is low (<10%) in the US and Automated Peritoneal Dialysis (APD) is the preferred modality of PD (Peritoneal Dialysis). There are many reasons for increased APD utilization, but the perceived bias of healthcare providers toward CAPD may be a driver. CAPD is presumed to have greater burden and higher peritonitis rates, but APD may have greater complexity, more frequent alarms, storage needs, and time attached to a machine. We hypothesized that an education program on the physiology of PD, benefits of CAPD, monitoring KPIs (key performance indicators), and thrice daily exchanges on initiation with ongoing support would increase CAPD utilization without increasing peritonitis rates.

Methods: The program was implemented between 7/22 and 11/22 in 17 Fresenius Kidney Care home units across 3 established PD markets with variable CAPD utilization (7%(I), 13%(II) and 19%(III)). Adults who started PD between 2/22 and 4/23 were included. Outcomes reviewed include new CAPD starts, peritonitis rates, and conversion to hemodialysis (HD) therapy during the five months before and five months after participation in the pilot program.

Results: 215 patients started CAPD during the analysis period. CAPD starts increased from 59% of all new starts (n=111) in the 5 months prior to pilot start to 79% (n=104, p=0.0003) during the initial 5 months of the pilot. Conversion from CAPD to APD declined from 20/111, 18%, to 5/104, 4.8%, from the two periods. 100% of conversions were from a single market (I). Overall CAPD penetration rose in every market (I-61%, II-32%, III-30%) and 36% overall. Peritonitis rates among the new starts improved in the CAPD group, but not in the CCPD group. CAPD group peritonitis rates decreased significantly from 1/32.5 patient months to 1/238 patient months (RR=0.13, p=0.03). CCPD peritonitis rates increased with new starts from 1/55 patient months to 1/40.7 patient months, but the difference was not significant. The rate of conversion to HD remained consistent between the two time periods.

Conclusions: CAPD may offer advantages to many patients in the USA and may be underutilized. Education on PD physiology, potential benefits of CAPD, initiation awareness programs, and ongoing support with review of KPIs can lead to greater utilization of CAPD without an increased peritonitis risk.

SA-PO630

Incidence of Fungal Peritonitis and Exit Site Infections Among Peritoneal Dialysis Patients in a Mid-Sized Dialysis Provider

Eric D. Weinhandl,[1,2] Joanna Neumann,[1] Graham E. Abra.[1,3] *[1]Satellite Healthcare, San Jose, CA; [2]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Fungal infections are a relatively rare complication of peritoneal dialysis (PD). These infections include fungal peritonitis, an especially serious complication, and fungal growth at the catheter exit site. Surprisingly little is known about the epidemiology of fungal infections among PD patients in the United States. We estimated the incidence of fungal peritonitis and exit site infection (ESI) in a multi-center cohort of PD patients.

Methods: We analyzed the electronic health records of Satellite Healthcare, a mid-sized, not-for-profit dialysis provider. We identified patients who initiated PD between January 1, 2011, and March 31, 2023, and retained those that initiated PD during the first year after diagnosis of end stage kidney disease. Patents were followed until the earliest of first fungal infection (either peritonitis or ESI), death, conversion to hemodialysis, kidney transplantation, recovery of function, or April 30, 2023. We estimated the cumulative incidence of each of fungal peritonitis and ESI, and used Cox regression to estimate associations of age, sex, diabetes, and time-varying modality subtype (continuous ambulatory, automated) with the risk of fungal infection.

Results: The cohort included 5743 patients. Overall, 135 patients experienced a fungal infection: 94 patients experienced peritonitis at a mean of 27.9 months after PD initiation, 43 patients experienced an ESI at a mean of 32.0 months after PD initiation, and 2 patients experienced both complications. The cumulative incidence of fungal peritonitis was 0.9% at 2 years after PD initiation and 1.7% at 4 years. No associations with fungal peritonitis were statistically significant, although age of 18-44 years, relative to 45-64 years, and continuous ambulatory PD were associated with lower hazard. At 3 months after fungal peritonitis, the cumulative incidence of conversion to hemodialysis was 80.4%. The cumulative incidence of fungal ESI was 0.4% at 2 years after PD initiation and 0.7% at 4 years. At 3 months after fungal ESI, the cumulative incidence of conversion to hemodialysis was 18.6%.

Conclusions: Fungal infection is a rare event in PD patients, with little overlap between fungal peritonitis and ESI. Fungal infection tends to occur late in the course of PD. Fungal peritonitis is highly likely to be followed by PD discontinuation in the short run.

SA-PO631

Risk Factors for Peritoneal Dialysis Failure: Retrospective Cohort Study

Jennifer Esquivel, Karina Y. Contreras Torres, Mariela Ibarra, Rafael Valdez-Ortiz, L. M. Perez-Navarro. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Patients who start intermittent peritoneal dialysis (IPD) as a bridge therapy to continuous ambulatory peritoneal dialysis (CAPD) may present failure of the IPD technique before starting due to multiple factors. The principal factors identified with loss of technical were peritonitis, tunnelitis, and definitive failure. The aim of this study was to estimate the incidence of technique failure in IPD patients with the IPD program at the General Hospital of Mexico.

Methods: Retrospective cohort study that included 199 patients with IPD, was reviewed the patient records of peritoneal dialysis, during the period between January 2008 and May 2023. The incidence was estimated, as and risk factors for technique failure.

Results: A total of 199 patient records were included; 58% (115) were men, with a mean age of 45.4±14.9 SD years, 65% (127) had diabetes type 2, and 94% had systemic hypertension. In the 62% (123) patients, the initiation of renal function replacement therapy was urgent. It was identified that in 70% (139) of patients, the first catheter was placed percutaneously and 30% (60) was surgical. The catheter type was pig tail in the 93% (185) of the cases. the loss of technique was identified in 24% (48) of patients, including as causes of etiologies events of dysfunction that required catheter replacement and events of peritonitis, the analysis of the first event of peritonitis increased the risk of loss technique (OR 10.1, 95%IC 4.8- 21, p=0.0001). In the follow-up period, 35% (70) of the patients were present with at least one event of peritonitis, 40% (80) presented dysfunction; and 30% turned to hemodialysis.

Conclusions: The principal factor associated with losing the technique was peritonitis, even when the patient did not use dialysis outside of the hospital. Peritonitis is a frequent and serious complication of peritoneal dialysis (PD), representing the most common cause of conversion to hemodialysis in the long term. It is necessary to integrate strategies for the care and management of the ambulatory catheter during IPD.

SA-PO632

Peritoneal Dialysis-Related Mycobacterium abscessus Infections: A Case Series

Ahmed I. Abdelkader, Austin C. Nicholson, Salem Vilayet, Susan Dorman, Michael E. Ullian. *Medical University of South Carolina, Charleston, SC.*

Background: Catheter-associated infections are an important cause of morbidity and catheter loss in people using peritoneal dialysis (PD). *Mycobacterium abscessus* is a rapidly growing non-tuberculous mycobacterium (NTM) that has innate antimicrobial resistance. *M. abscessus* is an uncommon etiology of PD catheter associated infections, with only a handful of cases reported and only 2 cases reported in USA. Thus, there is a lack of evidence-based guidance on management of *M. abscessus* PD catheter infections. During routine clinical care, we encountered several patients with PD related infections due to *M. abscessus*. We sought to determine risk factors for *M. abscessus* PD catheter associated infections and describe treatment outcomes.

Methods: This is a retrospective study in which medical records from one 700-bed tertiary care hospital and one regional dialysis center were reviewed. Information was abstracted to a study-specific case report form. Epidemiological, clinical characteristics, M. *Abscessus* complex subspecies, managements and fate of PD were explored. This study was approved by relevant IRBs.

Results: We identified 7 patients diagnosed with *M. abscesses* PD catheter infection. Among these 7 patients, 4 (57%) presented with symptoms suggestive of peritonitis and 3 (43%) with exit site infections (ESI) / tunnel infections. 7% were males (4/7) with median age of 42 years (range 42-88). Original kidney disease was diabetic nephropathy in 57% (4/7) and mean time on PD before developing NTM infection was 20.5 months. Subspecies were identified in 6 (85%) and revealed 4 (57%) with *abscessus* and 2 (28%) with *massiliense*. 5 patients (72%) were managed with upfront PD catheter removal and antibiotics with good outcomes. PD catheter salvage was attempted in two patients (28%) initially presenting with ESI. One of these patients progressed over a year to peritonitis and tunnel abscess due to *M. abscessus* despite continued antibiotics. The other was shifted to hemodialysis (with PD catheter removal) after persistent *M. abscessus* ESI in the context of antibiotic intolerances.

Conclusions: *M. abscessus* is an important cause of PD catheter-associated infections. Management of peritonitis and tunnel infections requires catheter removal and prolonged antimicrobial therapy. Catheter removal should be considered in people with ESI.

SA-PO633

Peritonitis-Free Survival in Peritoneal Dialysis According to Staphylococcus spp. Nasal Carriage

Naomi A. Alvarez Zapata, Leticia M. Tapia Silva. *Secretaria de Salud de Mexico, Mérida, Mexico.*

Background: Mexico ranks second with the highest prevalence of peritoneal dialysis (PD) in Latin America. Yucatan in Mexico has the highest prevalence of obesity, diabetes, and kidney stones, the main risk factors for progression to kidney failure (KF). The Agustín O'Horan General Hospital receives patients with chronic kidney disease without affiliation to any health service in which PD is the first line treatment for KF. In our center, PD associated peritonitis continues to be a major cause of hospitalization, PD failure, transition to hemodialysis, and even death. Previous reports suggested that nasal carriage of Staphylococcus spp (SS) conferred an increased risk of PD related peritonitis, however this notion has been challenged by new evidence.

Methods: We conducted a prospective study from March 1st 2022 to March 31st 2023. We included all incident PD patients who underwent nasal swabbing prior to PD catheter placement. Patients were followed up for at least 30 days after the PD catheter placement and the time of first peritonitis was recorded. We compared the peritonitis free survival between SS nasal carriers and PD patients with nasal culture negative (CN).

Results: 172 patients started PD during the study period. Fifty one patients were excluded due to contamination or the absence of a nasal swab sample prior to PD catheter placement. 121 patients were included in the study, 54.54% were women, the mean age was 51.6 years, and 61% of the population had type 2 diabetes. Thirty four patients had a positive nasal culture for SS and all of them were treated with intranasal mupirocin. Patients were followed for at least 30 days after PD catheter placement with a mean follow up of 138.9 days. Data were censored for patients who had mechanical complications, did not develop peritonitis or were lost to follow up. 46 cases of peritonitis occurred during the follow up. The etiology of PD related peritonitis included 17 SS, 14 non SS, 8 polymicrobial and 7 CN peritonitis cases. Peritonitis free survival in nasal carriers of SS was 76.2 days compared to 69.3 days in patients with CN. There was no significant difference in peritonitis free survival between the two groups.

Conclusions: Nasal carriage of SS does not appear to have an impact on peritonitis free survival. The benefit of performing a nasal culture prior to PD catheter placement remains to be elucidated.

SA-PO634

Peritonitis Impact on Technique Failure and Time to First Peritonitis Event in Peritoneal Dialysis: A Retrospective Multicenter Cohort Study in the National Health System of the Dominican Republic

Sergio O. Hernandez-Ordonez,[1,5] Erwin I. Campos,[1,2] Elianny S. Polanco,[1] Zulma Lara,[1] Mercedes Aquey,[1] Jose C. Divino-Filho,[3] Janny Guzman Chavez,[1] Miguel A. Cuevas Budhart,[4] Alfonso Ramos.[1] Macrotech. *[1]Macrotech, Santo Domingo, Dominican Republic; [2]Pontificia Universidad Catolica Madre y Maestra - Campus Santo Tomas de Aquino, Santo Domingo, Dominican Republic; [3]Karolinska Institutet Enheten for medicinska njursjukdomar, Huddinge, Sweden; [4]Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico; [5]Universidad Nacional Autonoma de Mexico Departamento de Educacion Medica, Tlalnepantla, Mexico.*

Background: Peritonitis is a concern in peritoneal dialysis (PD) as it is a common complication that impacts outcomes and technical survival. It is a frequent cause of technique failure. The aim of this study is to estimate the impact of peritonitis on technique failure and determine the time to the presentation of the first peritonitis event.

Methods: A retrospective, multicenter, and descriptive cohort study was conducted on patients enrolled in the home PD program of the National Health System of the Dominican Republic. Peritonitis was diagnosed based on the ISPD guidelines. The analysis included incident PD patients enrolled between January 1st, 2016, and December 31st, 2022. Demographic data were collected and presented as mean ± SD for quantitative variables, while qualitative variables were reported as absolute and relative frequencies. A binary logistic regression was performed for the possible association between variables of interest using Odds Ratio, with a confidence interval of 95% and p value < 0.05. To assess survival, only peritonitis events were considered using Kaplan-Meier curves and the Log-Rank test.

Results: We studied 4,476 incident patients with a median follow-up of 693 days, with a range of 30 to 2,465 days. The mean age was 57 ± 15 years, and 58% of the patients were males. Among the patients, 393 (8.7%) experienced a peritonitis event, with 53 (1.1%) having two events, and 10 (0.22%) patients experiencing three or more events. Out of those who had peritonitis, 79% were cured, 12% transitioned to hemodialysis (HD), and 7.9% died. The median time to the first peritonitis events was 474 days (CI 431-517) The factors associated with the development of peritonitis were patients older than 65 years (OR: 1.94; 95%CI: 1.49-2.52: p<.001) and having been on therapy for more than a two-year period (OR: 2.86; 95%CI: 2.10-3.88).

Conclusions: in this analysis, factors such as older age and a longer duration of therapy were associated with an increased risk of developing peritonitis. The time at the first event is higher than reported in other studies. These highlight the importance of implementing preventive strategies and close monitoring in PD.

Funding: Commercial Support - Macrotech

SA-PO635

Prognosis and Treatment of Peritoneal Dialysis-Associated Infection by Nontuberculous Mycobacteria

Nozomi Kadota, Yugo Ito, Kasumi Konishi, Takuya Fujimaru, Fumika Taki, Masahiko Nagahama, Masaaki Nakayama. *St.Luke's International Hospital, Tokyo, Japan.*

Background: Nontuberculous Mycobacterium (NTM) can lead to infections related to peritoneal dialysis (PD) catheters, defined as exit site infection and tunnel infection, and PD related peritonitis. Current guideline lacks clarity regarding the indication for catheter removal and the optimal duration of treatment for these infections. Therefore, the aim of this literature review is to analyze the accurate treatment approaches and prognosis associated with NTM-related PD catheter infections and peritonitis.

Methods: We conducted a literature review of published cases of PD catheter-related infection and peritonitis by NTM in PubMed, Embase, and Ichu-shi databases up to August 2022.

Results: A total of 362 cases were included in the analysis. Among these cases, 226 (62%) were male, with the mean age of 57 years. Diabetic nephropathy accounted for 22% of cases as the most common cause of end-stage kidney disease (ESKD). Mycobacterium abscessus was identified as the most prevalent pathogen, found in 38% of cases. The distribution of cases was as follows: 39% categorized as catheter-related infection alone, 26% as peritonitis alone, and 25% as both catheter-related infection and peritonitis. Only 57% of cases yielded positive NTM cultures on the initial attempt. In 18% of cases, other bacteria, mainly Corynebacterium or diphtheria, were identified in the initial culture, while the first bacterial culture was negative in 24% of cases. Antibiotics alone were used to manage 43% of patients, while 44% eventually required catheter removal. The average duration of antibiotics was 4.8 months. Notably, six cases of peritonitis resulted in death without catheter removal.

Conclusions: This case series represents the largest sample size in NTM-related catheter-related infection and peritonitis. Early submission of acid-fast bacilli smear and culture should be considered, especially when bacterial cultures are either gram positive rods or negative. Catheter removal may be considered as the appropriate management at the early stage of NTM infection.

SA-PO636

Urine Dipstick: A Point-of-Care Tool for the Diagnosis of Peritoneal Dialysis-Associated Peritonitis

Juan P. Gomez Villarreal, Ricardo A. Garza Treviño, Rita B. Aguilar, Mara C. Olivo Gutierrez, Giovanna Y. Arteaga Muller, Lilia M. Rizo Topete, Elisa M. Guerrero Gonzalez. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico*.

Background: PD-associated peritonitis is a complication that impacts the morbidity and mortality of patients. The ISPD recommends diagnosing peritonitis when at least two of the following criteria are met: clinical features such as abdominal pain or cloudy dialysis effluent, dialysis effluent WBC > 100/μL with > 50% PMN, or positive dialysis effluent culture. The Spanish Society of Nephrology suggests using a urine dipstick for early diagnosis based on a new strip designed to test PD fluid.

Methods: A prospective study was conducted at the Hospital Universitario Dr. José Eleuterio González, evaluating consultations for PD-associated peritonitis from the emergency department to the nephrology department during August 2022 through February 2023. After a 2-hour exchange, samples were taken the strip testing (Siemens multistix10 SG) were to the laboratory for cytochemical analysis, culture. The strip results were read after a waiting time of 2 minutes and were interpreted by a nephrologist.

Results: 30 patients were screened, confirming the diagnosis of PD-associated peritonitis based on the strip and cytochemical results. The demographic data shown in Figure1. The strip showed a sensitivity of 73% and specificity of 100% when using a cutoff of 3 crosses. However, these values changed when using a cutoff of 2 crosses, resulting in a sensitivity of 95% and specificity of 100%.

Conclusions: Urine dipsticks are feasible, and cheap tools that can be useful for the diagnosis of PD-associated peritonitis with great sensibility and specificity saving time for the initiation of the antibiotic. It also helps conserve resources and enables patients to continue their treatment outside the clinic using a simple method.

SA-PO637

Does Final Peritoneal Dialysis Catheter Tip Position Predict Early Catheter Dysfunction?

Susan Mcgrath,[1] David Clark,[2] Omar T. Ashour,[2] Arsh Jain.[1] [1]*London Health Sciences Centre, London, ON, Canada;* [2]*Dalhousie University Faculty of Medicine, Halifax, NS, Canada*.

Background: It is believed that, for a functioning peritoneal dialysis (PD) catheter, the inserter needs to place the catheter in an optimal position. Exact tip position within the pelvis in relation to the pubic symphysis can be determined at time of placement for fluoroscopically guided PD catheters.

Methods: A retrospective cohort of adult PD patients in London, Ontario, who underwent percutaneous PD catheter insertion using fluoroscopy from 2013 to 2017 were reviewed. The distance between the top of the pubic symphysis and the bottom of the catheter coil was measured using Citrix software of stored images. Univariate and multivariate backward stepwise logistic regression analyses were conducted for the outcome of early catheter flow dysfunction versus each of final catheter tip position and baseline covariables included age, sex, race, body mass index (BMI), cause of Kidney Failure and number of prior abdominal surgeries with P-value <0.2 for variable inclusion in stepwise regression. Early catheter flow dysfunction was defined as the failure to achieve sufficient inflow/outflow to maintain any modality of PD, refractory to non-procedural interventions, and necessitating a repositioning procedure within 3 months of PD start.

Results: 286 patients who underwent fluoroscopic catheter insertion during the study period had a trial of PD. Of 35 patients who experienced early catheter dysfunction, 31/35 underwent a repositioning procedure. There was no difference between final catheter tip position of catheters that did or did not experience early flow dysfunction [catheter-tip to pubis symphysis median distance (Q1-Q3) 37 (29-53) vs 38 (26-50) mm, p=0.62]. In univariate analyses, no variable was associated with a significant difference in frequency of catheter dysfunction. Backward stepwise multivariate analyses of catheter dysfunction retained BMI, age and cause of Kidney Failure with only BMI significantly associated with frequency of early catheter flow dysfunction (OR 1.07 ± 0.04, p=0.04).

Conclusions: Final pelvic PD catheter tip position, relative to the pubic symphysis at time of fluoroscopic insertion, was not predictive of early catheter flow dysfunction. In light of this, the frequent focus of inserters on “optimal” placement may be unwarranted.

SA-PO638

Peritoneal Dialysis and Technique Survival in Diabetic Patients

Vitória V. Paes de Faria, Joana P. Dias, Catarina Almeida, Rute Carmo, Daniela Lopes, João C. Fernandes, Clara Almeida, Ana Marta Gomes. *Centro Hospitalar de Vila Nova de Gaia Espinho EPE, Vila Nova de Gaia, Portugal*.

Background: Management of end stage renal disease (ESRD) in diabetic patients is an ongoing challenge. Despite potential adverse metabolic effects, peritoneal dialysis (PD) is considered safe and suitable in diabetic ESRD treatment. Previous descriptions of poor technique survival have been contradicted by recent studies, in line with improved dialysis technique and reduced technique-associated complications. We evaluated technique survival in diabetic patients on PD.

Methods: Clinical records of incident PD patients from 2000-2022 were examined. Kaplan-Meier method and log-rank test were used to compare technique survival rate between diabetic and non-diabetic patients. Adjusted HR were calculated using Cox regression.

Results: A total 235 incident PD patients were included, 23% diabetic. Mean age of PD onset 54 ± 15 years. Patients with diabetes mellitus (DM) were older (61 ±14 vs 41 ±15 years), mostly male (74 vs 24%), with higher cardiovascular (CV) burden (p<0.05). Assisted PD modality was more prevalent in this group (29 vs 5%, p<0,05). Median technique survival in DM and non-DM patients was 31 (CI 95% 22-39) and 52 months (CI 95% 42-62), respectively (p=0.002). Main reasons for PD suspension included technical failure (39%) and PD-associated infectious complications (35%). No significant difference in Infectious complications was observed between the two groups (35% vs. 44%, p= 0.513). Modality suspension due to autonomy loss was higher in DM group (12% vs. 3%, p= 0.05). In the univariate model, rate of technique failure was higher in the DM group (HR=1.9, CI 95% 1.2-2.8, *P* = 0.003). This association was not verified in the multivariate model. Due to protocol changes in PD prescription after the availability of biocompatible solutions, separate time period analysis before and after 2008 revealed HR 4.7 (CI 05% 0.75-29.0 P=0.097) and HR of 1.3 (CI 95% 0.3-2.2, p=0.415), respectively.

Conclusions: Decreased technique survival in DM patients was not verified when considering separate time period analysis, with better outcomes in recent years. This reflects technical improvements, biocompatible solutions and prescription tailoring. CV management remains key, and strategies to mitigate the menace of autonomy loss are essential in this subgroup, including helper signaling and increased support for assisted PD.

SA-PO639

Success Rates and Safety of Two Non-Guided Percutaneous Catheter Placement Techniques for Peritoneal Dialysis in Urgent-Start Dialysis: A Single-Center Experience Retrospective Cohort Study

Rafael Moreno-Novales, Froylan David Martinez-Sanchez, Mauricio A. Salinas-Ramirez, Joana B. Juarez, Erika K. Tenorio-Aguirre. *Hospital General Dr. Manuel Gea González, Mexico City, Mexico.*

Background: The optimal technique for catheter placement in uremic patients remains debated. In our center we have been using our non-guided percutaneous modified Seldinger technique. With the availability of the peritoneal dialysis catheter kit in our center, we modified our non-guided Seldinger technique for patients with urgent start dialysis requirement.

Methods: This was a single-center retrospective cohort study of patients hospitalized with urgent-start dialysis requirement of a single center in Mexico City. We aimed to summarize the success rates and safety of our two percutaneous non-guided insertion methods.

Results: A total of 117 patients with urgent-start dialysis requirement were included. Two percutaneous catheter insertion techniques were used, the non-guided percutaneous modified Seldinger technique 62.9% and the non-guided percutaneous modified Seldinger technique with peritoneal dialysis catheter kit technique 48.1%. The mean age of the patients was 54.92 ± 13.49 years, 40.5% were women, the mean body mass index (BMI) was 25.79 ± 4.77 kg/m2, BUN 95 ± 57 and the median in-hospital stay was 19.28 (10-20) days. Overall, 73.3% had diabetes, 76.7% hypertension, and the time from admission to catheter insertion was 7 (3-10) days. The analysis showed that the patients who underwent placement with peritoneal dialysis catheter kit had fewer replacement requirement (p=0.028), and there was no difference in migration, peritonitis, and catheter leak between both groups.

Conclusions: The use of the peritoneal dialysis catheter kit in urgent start dialysis requirement proved less catheter replacement.

Variables	Peritoneal dialysis catheter kit (n= 27)	Non peritoneal dialysis catheter kit (n= 90)	p value
Age (years)	56.26 ± 12.6	54.52 ± 13.79	0.171
Body Mass Index (kg/m2)	25.2 ± 4.95	25.95 ± 4.73	0.066
Type 2 Diabetes (%)	77.5	70.4	0.067
Hypertension (%)	70.4	78.7	0.689
Replacement (%)	0	15.7	0.028
Catheter migration (%)	7.4	14.6	0.329
Leak (%)	1.9	3.1	0.625
Peritonitis (%)	7.4	5.6	0.732

SA-PO640

Evaluation of Impact of Residual Renal Function on Clinical Outcome, Quality of Life, and Prognosis in Patients on Continuous Ambulatory Peritoneal Dialysis (CAPD)

Sweety Kakoti, Mitul Bora, Tonmoy Das, Dhruvajyoti Choudhury. *Apollo Hospitals Guwahati, Guwahati, India.*

Background: Residual renal function (RRF) in patients with ESRD receiving dialysis is defined as the ability of the native kidneys to eliminate water and uremic toxins. It provides small solute clearance, has role in maintaining fluid balance, phosphorus control, and removal of middle molecular uremic toxins, and contributes significantly to the overall health. It is a powerful predictor of mortality.

Methods: A Prospective Observational Study conducted in Apollo Hospitals, Guwahati for 1year. Study Population included all patients who were initiated on CAPD during this study period after excluding those fulfilling exclusion criteria. Their RRF was calculated as the average of urea clearance (Kru) and creatinine clearance (Crcl) in 24 hrs urine sample. All patients were followed up at regular intervals - at the time of initiation of CAPD, 3 and 6 months with clinical, laboratory parameters, prognostic markers.

Results: Following observations were made during the study: Total number of cases was 50 with mean age of 61.6 years with majority (54%) in elderly age group (>60 years) with a male to female ratio of 2.57:1. Most common co-morbidities were hypertension (92%), diabetes (60%), CAD (26%), hypothyroidism (24%). Native kidney diseases observed were diabetic nephropathy (52%), hypertensive nephropathy (50%), chronic glomerulonephritis (14%), chronic tubulointerstitial diseases (4%). Mean renal reserve deteriorated over time from 4.27 ml/min/1.73m2 at baseline to 4.11 ml/min/1.73m2 at 3 months and 3.91 ml/min/1.73m2 at 6 months ($p<0.01$). 36% cases showed a fall of renal reserve >0.5 ml/ min/ 1.73 m2 and 36% showed low renal reserve (0.5 ml/ min/1.73 m2). These cases were observed to be significantly associated with lower urine output, hemoglobin, platelet, sodium, albumin, bicarbonate, vitamin D levels and higher creatinine, potassium, PTH, phosphorus levels, higher degree of malnutrition, depression, co-morbidities, poorer quality of life parameters ($p<0.01$), more incidence of respiratory infections, peritonitis and also higher mortality.

Conclusions: Our study showed low RRF deteriorates over time. A significant correlation between low RRF at baseline and malnutrition, depression symptoms, poor quality of life and solute clearance. Hence preservation of RRF is an essential marker of patient prognosis in CAPD.

SA-PO641

Predictors of Long-Term Patient and Technique Survival in Home Hemodialysis Patients

Koji Tomori, Tsutomu Inoue, Yusuke Watanabe, Hiroaki Amano, Hirokazu Okada. *Saitama Ika Daigaku, Iruma-gun, Japan.*

Background: Home Hemodialysis (HHD) enhances patient quality of life and survival, yet it also increases the risk of access-related complications due to the frequency of treatments. The influence of these complications on long-term treatment survival, particularly in patients with arteriovenous fistulas (AVF), remains unclear. Therefore, our study aims to follow AVF patients over a prolonged period to evaluate long-term treatment survival and identify its predictors in HHD patients.

Methods: We conducted an observational study involving all incident HHD patients at our facility from 2001 to 2020. The cumulative incidence of all-cause mortality and procedure failure (TF) as a composite outcome was calculated at 5- and 10-year intervals. Cox proportional hazards models were used to identify patient characteristics or comorbidities that predicted TF and death.

Results: A total of 77 patients (age of 50.7 years, 15.6% female, and 23.4% with diabetes) were included. All patients self-punctured their AVF, and the median frequency of dialysis was five sessions per week. During a median follow-up of 116 months, we observed 11 deaths and 19 instances of TF. Unadjusted 5- and 10-year adverse event-free survival was 83.5 and 67.2 %, respectively. Both age (aHR 1.09) and diabetes (aHR 4.17) were significantly associated with TF. Cardiovascular disease was the most frequent cause of death, and VA trouble was the primary cause of TF. VA-related TF occurred after 100 months of HHD initiation.

Conclusions: Although the long-term prognosis of HHD patients was favorable, access-related TFs occurred more frequently in patients with long-term HHD. Thus, careful management of VA is important to improve treatment survival.

SA-PO642

Reframing the Role of Buttonhole Cannulation (BHC) in the Home Hemodialysis (HHD) and Self-Care Settings: Outcomes of BHC as a Primary Technique in a Large Single-Center HHD Program

Waleed Zafar, Maria Bermudez. *Geisinger Medical Center, Danville, PA.*

Background: HHD remains underutilized in the U.S. Fear of needle insertion is one of the main patient barriers for widespread adoption of HHD. BHC, once considered the preferred method for self-cannulation given patient- and fistula-friendliness, has fallen out of favor due to concerns about infectious complications. The quality of evidence concerning potential risks of BHC is low. We describe experience from a single center HHD program regarding utilization of BHC technique.

Methods: Patients currently enrolled in the HHD program were surveyed regarding the use of BHC. Since the program predominantly utilizes BHC, we also evaluated the incidence of bacteremia in all patients enrolled in the HHD program between 2008 and 2022.

Results: Between 2008 and 2022 a total of 76 patients were ever enrolled in the HHD program at a single center of whom 18 (23.7%) were currently active, 13 were successfully transplanted, 19 transitioned to in-center hemodialysis and 23 died. No episodes of bacteremia were documented in the HHD program over this period. 14 of the 18 currently active patients who had arteriovenous fistulas were surveyed and 13 of them used BHC technique. All but 2 patients did short daily HHD with remaining two doing nocturnal HHD. Demographics and results from the survey are presented in table 1.

Conclusions: Our 14-year single center experience with BHC has helped develop key elements for the successful implementation of this technique: a single cannulator per fistula, multidisciplinary patient-centered selection, longitudinal education, strict infection control, and reliable nursing support. These have shown to be important in patient and care partner empowerment as well as low incidence of infectious and noninfectious complications.

Table 1: Results of survey about accessing AVF among patients currently enrolled in the HHD program (n=14).

Characteristic		N (%)
Age	Less than 49 years	5 (35.7)
	50 – 69 years	6 (42.9)
	70 or older	3 (21.4)
Sex	Male	8 (57.1)
	Female	6 (42.9)

SA-PO643

A Nephrologist-Driven Percutaneous Peritoneal Dialysis Catheter Insertion Service Increases the Prevalence of Peritoneal Dialysis: A Single-Centre Experience in Singapore

Sreekanth Koduri. *Changi General Hospital, Singapore, Singapore.*

Background: The incidence and prevalence of end stage kidney disease(ESKD) requiring dialysis is increasing all over world, including Singapore. Despite the well documented benefits of peritoneal dialysis(PD) in offering better quailty of life and preservation of residual renal function, only around 15% of prevalent ESKD patients are on PD in Singapore. The aim of the study is to report the success of a percutaneous PD catheter insertion service in increasing the prevalence of PD in a large academic renal centre.

Methods: The number of prevalent PD patients was stagnant in our centre, over last 5years, despite the consistent growth in the number of ESKD patients requiring dialysis during this period. From early 2022, the interventional nephrologists started a percutaneous PD catheter insertion service. Based pre-determined criteria, the patients were selected for appropriate method of PD catheter insertion by the nephrologists, as illustrated in figure 1.

Results: Since 2022, 75.9% of the PD catheters were inserted percutaneously by interventional nephrologists. The complication rates were very low with no episodes of bowel perforation, major bleeding or PD peritonitis within 2weeks of catheter insertion. There was one episode (1.5%) of exit site infection within 2weeks of catheter insertion. Since the introduction of this service, the number of prevalent PD patients increased by 55% by May 2023 when compared to December 2021(104 vs 67prevalent patients), as illustrated in figure 2.

Conclusions: Percutaneous PD catheter insertion by nephrologists, with appropriate selection of patients, is safe and reliable. This service provides timely access creation and increases the penetration of PD.

Longevity of Percutaneously Placed Peritoneal Dialysis (PD) Catheters: Single-Center Study

Alexis Lorio,[1] Mahnoor Liaqat,[1] George L. Parra,[2] Claire Juhas,[1] David I. Nweke,[1] Akwe Nyabera,[3] Manoj Bhattarai,[3] Shweta Bansal.[3] *[1]The University of Texas Health Science Center at San Antonio Joe R and Teresa Lozano Long School of Medicine, San Antonio, TX; [2]The University of Texas Health Science Center at San Antonio Graduate School of Biomedical Sciences, San Antonio, TX; [3]The University of Texas Health Science Center at San Antonio Division of Nephrology, San Antonio, TX.*

Background: Percutaneously placed PD catheters are shown to have similar short-term (1 year) outcomes as compared to surgically placed catheters and have been used increasingly. Data on the longevity of these catheters are sparse.

Methods: We conducted a retrospective chart review study of 114 catheters in 91 patients who initiated PD between 2014 and 2020 at University Health System home dialysis center. The last follow-up was December 2022. PD catheters were placed percutaneously (n=81) either by interventional radiologists or nephrologists, or by laparoscopic surgery (n=33) when there were concerns of hernia or adhesions due to prior extensive abdominal surgery or refractory peritonitis. Demographic and clinical data were analyzed using descriptive statistics.

Results: In the percutaneous group, mean age was 46.4±13 years, 66% were male, mean BMI was 29±6 kg/m^2 and diabetes was the cause of kidney failure in 69% of patients. The surgical cohort had similar demographics except mean BMI was 31.2±7.6 kg/m^2. Median longevity of an individual catheter determined from PD start to cessation was 90.4 (30.6, 158.8) weeks for the percutaneous and 68.7 (29, 123) weeks for the surgical group. Reasons for catheter removal are shown in Figure 1. The percutaneous group had 0.26 episodes of peritonitis per patient-year, while the surgical group had 0.40 episodes per patient-year. The most common mechanical complications were slow drain and leakage, and these were similar between the two groups. Non-randomization precludes comparison analysis between the groups.

Conclusions: This single-center experience demonstrates that percutaneously placed PD catheters are a viable alternative for long-term PD therapy. Further studies from large centers or databases are needed to confirm our findings which have implications for the direction of PD programs to allocate resources appropriately.

SA-PO645

Medical Peritoneal Dialysis Catheter Insertion Can Increase Peritoneal Dialysis (PD) Patient Population: A Single-Centre Study

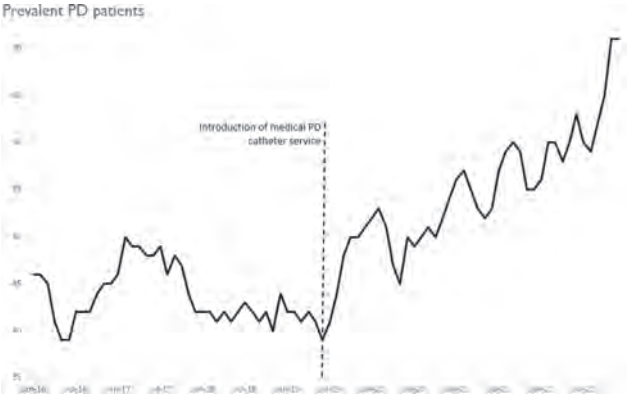
James Talbot-Ponsonby, Yasir Z. Khan, Daniel Jones, Seema Shrivastava, Edward Stern. *St George's University Hospitals NHS Foundation Trust, London, United Kingdom.*

Background: Peritoneal dialysis (PD) can offer improvement in quality of life and treatment costs compared to hemodialysis. Access to PD is often limited by cather insertion facilities. PD catheters can be inserted surgically (laparoscopic or open, both typically under general anaesthesia) or medically (percutaneous, under local anaesthesia). We examined the benefits of introducing a medical PD catheter service in a tertiary renal unit in addition to a surgical service which was already available.

Methods: Safety data (incidence of peritonitis within 90 days and of catheter malpositioning) were reviewed in the electronic health record from July 2017-June 2019 (surgical insertions alone) and July 2019-June 2021 (medical and surgical insertions). PD prevalence was tracked over 6 years.

Results: From June 2017-July 2019 there were 44 surgical catheter insertions compared to 63 (33 medical, 30 surgical) from July 2019-June 2021: a 43% increase in incident PD patients. There was no significant difference in early peritonitis (14% in surgical vs 15% in medical, P=0.77) or malposition (7% in surgical vs 9% in medical, p=0.70). Prevalent PD patients fell by 15% from 2016-2019 but grew by 79% in the 3 years after introduction of medical catheter insertions.

Conclusions: Introducing percutaneous PD catheter insertion by nephrologists was associated with an increase in PD patients with no increase in complications. Contraindications to medical insertion include significant obesity or previous major abdominal surgery. A hybrid medical/surgical service allowed most patients to be offered PD while avoiding general anaesthesia and minimising operating theatre usage. A limitation in this study is the groups arenot matched for complication risk: technically challenging patients will tend to be offered surgical insertion. Nevertheless, we demonstrated that introduction of medical PD catheter insertion can grow the PD population without an increase in complications.



SA-PO646

Surgical Outcomes Associated with Simple vs. Complex Peritoneal Dialysis Catheter Placement

Ankur Shah,[1,2] Susie L. Hu,[1,2] Christina A. Raker.[1,2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: Patients receiving peritoneal dialysis are dependent upon stable, reliable access to their peritoneal cavity via a surgical or percutaneously placed catheter. Advanced laparoscopic catheter placement has been demonstrated to have better catheter related outcomes compared to simple placement. In this study, we report baseline characteristics and 30 day surgical outcomes of simple versus complex laparoscopic PD catheter placement in a national US based cohort.

Methods: We conducted a retrospective analysis using the NSQIP database from January 1, 2013, to December 31, 2018. Patients who underwent peritoneal dialysis catheter placement were identified using relevant Current Procedural Terminology (CPT) codes. Simple catheter insertion was defined as the absence of additional procedures while complex was defined as catheter extension or omentopexy. Data on patient characteristics, surgical approach (simple or complex), and postoperative outcomes were extracted. The primary outcomes of interest included death, length of stay, and surgical site infection.

Results: A total of 9,593 patients who underwent laparoscopic peritoneal dialysis catheter placement were included in the analysis. Of these 89.95% received simple catheter placement, while 10.05% underwent advanced techniques. Patients who underwent complex catheter placement had no difference in mortality (adjusted odds ratio (aOR) 0.54, 95% Confidence Interval (CI) 0.19 – 1.52, p = 0.25), surgical site infection (OR 0.59, 95% CI 0.34 – 1.03, p = 0.06), or prolonged length of stay (>7 days) (OR 0.95, 95% CI 0.51 – 1.78, p = 0.87) compared to patients receiving simple catheter placement.

Conclusions: This study demonstrates that advanced peritoneal dialysis catheter placement techniques are associated with similar surgical outcomes compared to simple techniques. It is already known that patients receiving advanced catheter placement have lower rates of catheter tip migration, flow obstruction, and better long term catheter survival. These findings suggest that the adoption of advanced techniques may lead to improved long-term catheter related outcomes without sacrificing short term surgical outcomes.

Evaluating the Impact of the Advancing American Kidney Health Executive Order on Global Search Interest: An Interrupted Time Series Analysis

Ankur Shah,[1,2] Roger Chou,[1] Susie L. Hu,[1,2] Christina A. Raker.[1,2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: AAKH aimed to improve kidney health outcomes by transforming the kidney care landscape. Understanding the general impact of such policy interventions is crucial for public health surveillance and policy planning.

Methods: We conducted a retrospective analysis using Google Trends data from for two time periods: January 1, 2013 to December 31, 2018, and January 1 2019 to December 31, 2021. Search interest data were extracted using relevant keywords related to kidney health and care. An interrupted time series analysis was performed to assess the impact of the AAKH executive order on global search interest trends. Segmentation was conducted at the time of policy implementation (July 2019) to compare pre- and post-intervention periods.

Results: Overall, interest in home dialysis, home hemodialysis, and peritoneal dialysis were steadily increasing in both the USA and globally. In the USA and globally, relative interest in peritoneal dialysis outweighed home hemodialysis. Home hemodialysis had the greatest variability in RSV with 2014 and 2015 had zero RSVs, leading to the observed dip in the lowess curve.

Conclusions: AAKH has not increased awareness of home dialysis beyond the nephrology community. More steps must be taken to raise awareness and understanding of home dialysis.

Peritoneal Dialysis Offers Similar Outcomes to Hemodialysis in Hospitalized Patients Admitted with COVID-19

Ankur Shah,[1,2] David Painter,[1] Susie L. Hu,[1,2] Christina A. Raker.[2,1] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: The COVID-19 pandemic has resulted in hundreds of millions of infections and more than 6 million deaths worldwide. Maintenance dialysis patients were at uniquely high risk for both acquisition and morbidity and mortality related to COVID-19. Our studies objective is to assess outcomes by dialysis modality using a large, population based database in the United states. Specifically, we sought to quantify the effects of dialysis modality on hospital mortality, length of stay, and hospital charges. This work will be useful in public health planning and resource utilization for a future respiratory pandemic.

Methods: We retrospectively identified patients in the 2020 National Inpatient Sample with primary diagnosis code of COVID-19 and ICD-10-PCS codes for hemodialysis or peritoneal dialysis. Descriptive statistics were performed on demographic, comorbidities, hospital, and outcome variables. Primary outcomes were Mortality and secondary outcomes were Length of Stay and Hospital Charges. Linear and Logistic Regression with survey weights were used to develop models accounting for demographic, clinical, and hospital factors.

Results: A total of 54,580 COVID-19 patients with ESKD were identified in the NIS database, of which 1,730 patients were on PD and 52,850 patients were on HD. After adjusting for demographic and clinical factors, there was no significant difference in in-hospital mortality between PD and HD patients (adjusted odds ratio [aOR] = 1.13, 95% confidence interval [CI]: .85-1.49, p=.389). Similarly, LOS (adjusted mean difference (aMD)= -.344, 95% CI: -1.52-.84, p=.569) and hospital charges (aMD = -4868.31, 95% CI: -27562.54-17825.92, p=.674) did not significantly differ between the two groups.

Conclusions: This study provides evidence that COVID-19 infection requiring hospitalization in PD patients is associated with similar outcomes compared to HD patients. PD patients had similar in-hospital mortality rates, lengths of stay, and hospital charges. These findings suggest that both PD and HD patients with ESKD are equally vulnerable to the morbidity and mortality COVID-19, although PD patients are able to better shield from acquiring the virus. Further research is needed to explore additional factors that may influence outcomes and to guide clinical decision-making for ESKD patients during the COVID-19 pandemic.

SA-PO649

Creatinine Clearance Predicts Longitudinal Phosphate Levels Irrespective of Achieved Urea Kt/V: A Peritoneal Dialysis-MONDO Analysis

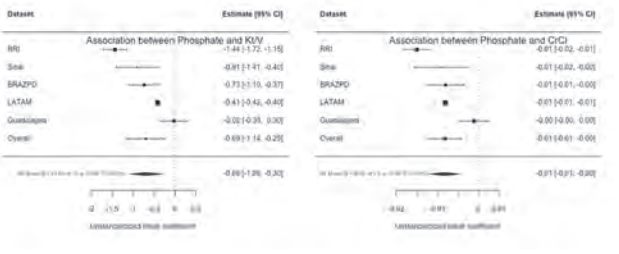
Murilo H. Guedes,[1] Maria Ines Diaz Bessone,[2] Lili Chan,[3] Andres E. De la Torre Quiroga,[4] Ariella E. Mermelstein,[5] Guillermo Garcia-Garcia,[4] Vincent Peters,[6] Constantijn Konings,[7] Adrian M. Guinsburg,[2] Thyago P. Moraes,[1] Peter Kotanko,[5] Jochen G. Raimann,[5] Jaime Uribarri.[3] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Hospital Civil de Guadalajara, Guadalajara, Mexico; [5]Renal Research Institute, New York, NY; [6]Tilburg University, Tilburg, Netherlands; [7]Catharina Ziekenhuis, Eindhoven, Netherlands.*

Background: Serum phosphate (PO4) is associated with worse outcomes among kidney failure patients, and its dialysis clearance is not well predicted by small solute kinetics. Guidelines in peritoneal dialysis (PD) recommend using urea Kt/V over creatinine clearance (CrCl) to monitor dialysis adequacy. We hypothesize that this recommendation may lead to suboptimal PO4 control. We designed this study to evaluate if CrCl predicts longitudinal PO4 irrespective of achieved Kt/V.

Methods: We performed a longitudinal analysis of multiple cohorts of incident PD patients – Fresenius Medical Care Latin America (FMC-LATAM), Renal Research Institute (RRI), Mount Sinai Hospital, Hospital Civil Guadalajara, and the BRAZPD cohort. The exposures were first available Kt/V and CrCl after 90 days of PD initiation. The outcome was longitudinal PO4. Results were pooled using a random-effects metanalysis. The primary estimate was the linear coefficient from linear mixed regression models with random effects. Models were then compared by log-likelihood ratios (LLR) to assess the information added by CrCl on models with Kt/V.

Results: 16.796 patients were included – RRI (n=653), Sinai (n=131), BRAZPD (n=171), LATAM (n=15631), and Guadalajara (n=210). Mean ages ranged from 45 (Guadalajara) to 58 years (Sinai). In most datasets, Kt/V and CrCl were associated with longitudinal PO4 despite adjusting for sex, age, and PO4 binder use. The pooled estimates, despite being heterogeneous, confirmed the results (**Figure**). For all datasets, including CrCl on models adjusted with Kt/V improved information (LLR tests $p < 0.05$ for all datasets).

Conclusions: Among incident PD patients, CrCl predicts longitudinal PO4 irrespective of achieved urea Kt/V. Our results suggest that CrCl may be an important measurement in clinical practice to monitor PO4 clearance in PD patients.



SA-PO650

Effect of Roxadustat vs. Erythropoietin on Nutritional Status in Peritoneal Dialysis Patients: A Retrospective Study

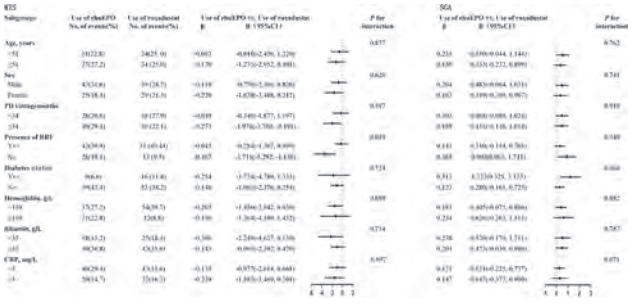
Xiao J. Luo, Qimei Luo, Xianrui Dou. *Shunde Hospital of Southern Medical University, Foshan, China.*

Background: Roxadustat have been used to treat renal anemia in patients undergoing dialysis. The effect of roxadustat on nutritional status in peritoneal dialysis (PD) patients remains uncertain. We aimed to explore the effect of roxadustat on nutritional status, and explore the possible modifiers for the association in PD patients.

Methods: The current study included 136 PD patients with renal anemia. The primary efficacy endpoints included changes from baseline in nutrition-related parameters. Linear regression analysis was performed to analyze the correlation between use of roxadustat with Subjective Global Assessment (SGA) and Malnutrition-Inflammation Score (MIS). Logistics regression analysis was used to evaluate the risk factors for the indicators of MIS.

Results: After a median treatment observation of 20.0 (25^{th}-75th, 16.0–21.0) months, the changes from baseline in serum albumin, prealbumin, total cholesterol, high-density lipoprotein cholesterol, blood urea nitrogen and creatinine levels were not significantly different between two groups. Besides, the use of roxadustat was inversely associated with MIS (β, -0.263; 95% CI: -2.430, -0.096), and was positively associated with SGA (β, 0.440; 95% CI: 0.046, 0.834). Additionally, compared to patients in rHuEPO group, those with the use of roxadustat were associated with more dietary intake (OR, 0.405; 95% CI: 0.190-0.865) and fewer gastrointestinal symptoms (OR, 0.365; 95% CI: 0.164-0.809). The inverse association between the use of roxadustat with MIS was stronger in patients without RRF (*P* for interaction=0.019).

Conclusions: In short, this study found that the use of roxadustat was inversely associated with MIS and positively associated with SGA in PD patients.



SA-PO651

Profiles of Iron and Anemia Indices and Associations in Mental Health Among Incident Peritoneal Dialysis Patients in Brazil and the United States

Vladimir Rigodon,[1,2] Peter G. Pecoits,[1,5] John W. Larkin,[2] Yue Jiao,[2] Len A. Usvyat,[2] Franklin W. Maddux,[2] Peter Kotanko,[3,4] Roberto Pecoits-Filho,[1,5] Thyago P. Moraes,[1,5] Murilo H. Guedes.[1,5] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Fresenius Medical Care, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY; [5]EPICENTER - Center for Epidemiology and Clinical Research, Curitiba, Brazil.*

Background: Management of iron stores and anemia are important to maintaining quality of life in dialysis, yet the associations in mental health are unknown in Peritoneal Dialysis (PD). We aimed to identify and describe the trends in KDQOL mental component summary (MCS) scores and cohort characteristics in patients starting PD in Brazil (BR) and the United States (US), with a focus on iron and anemia indices and related medication use.

Methods: Patients included data on adults who started PD between Dec 2004-Jan 2011, that had ≥1 TSAT, hemoglobin (Hgb), ferritin, and KDQOL result within the first 180 days of PD. We described the BR and US cohort characteristics based on the following MCS categories: ≤35, >35-≤40, >40-≤50, >50. Higher MCS scores show better mental health. This preliminary analysis is descriptive, and it does not include multivariable adjustments.

Results: In both cohorts (BR=2022 vs US=1657), age (mean age BR=57.3 vs US=55.6) and albumin levels were consistent (both 3.7 g/dL). The US cohort had fewer males (BR=45% vs US=54%) and more patients with a white race (BR=62% vs US=72%). TSAT levels and erythropoietin stimulating agent use were higher in the US vs BR (**Figure**). Lower MCS scores were associated with higher ferritin & TSAT levels in BR, though not observed in the US. Higher MCS scores were positively associated with IV iron use in the US, but not observed in BR. Younger patients showed the lowest MCS scores in the US, while the inverse was found in BR.

Conclusions: In this preliminary descriptive analysis, we found some unique profiles in iron and anemia markers associated with mental health outcomes. Although some of these findings may be related to practice patterns, iron and anemia management may potentially influence the mental health of patients at PD initiation. Further investigations are needed to understand this relationship and its implications for patient care and outcomes.

SA-PO652

Higher Iron Deficiency Rates Among Incident Peritoneal Dialysis Patients Without Anemia in Brazil and United States

Vladimir Rigodon,[1,2] Brianna Hartley,[1,3] Peter G. Pecoits,[1,8] Yue Jiao,[2] John W. Larkin,[2] Luca Neri,[6] Len A. Usvyat,[2] Franklin W. Maddux,[2] Jeroen Kooman,[4] Peter Kotanko,[5,7] Roberto Pecoits-Filho,[1,8] Thyago P. Moraes,[1,8] Murilo H. Guedes.[1,8] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Fresenius Medical Care, Waltham, MA; [3]Nova Southeastern University, Clearwater, FL; [4]Maastricht University Medical Center, Maastricht, Netherlands; [5]Renal Research Institute, New York, NY; [6]Fresenius Medical Care, Cremona, Italy; [7]Icahn School of Medicine at Mount Sinai, New York, NY; [8]EPICENTER - Center for Epidemiology and Clinical Research, Curitiba, Brazil.*

Background: The profiles of iron deficiency (ID) are undefined in the peritoneal dialysis (PD) population. This study examines the prevalence of and patient characteristics associated with ID states and the coexistence of anemia in incident PD patients in the United States (US) and Brazil (BR).

Methods: We used data from adults starting PD at 122 clinics in BR and >2500 clinics in the US. We included patients who had at least ≥1 hemoglobin (Hgb), ferritin, and transferrin saturation (TSAT) measurement within 180 days of PD start. ID was defined as TSAT <20%. ID states were categorized as: a. functional ID, no anemia (TSAT <20%, ferritin ≥200 ng/mL, Hgb ≥10 g/dL), b. functional ID with anemia (TSAT <20%, ferritin ≥200 ng/mL, Hgb <10 g/dL), c. absolute ID, no anemia (TSAT <20%, ferritin <200 ng/mL, Hgb ≥10 g/dL), and d. absolute ID with anemia (TSAT <20%, ferritin <200 ng/mL, Hgb <10 g/dL).

Results: Patients starting PD in BR (n=1,365) and the US (n=12,303) had mean age of 59.8 (BR) & 55.2 (US) years, 46.4% (BR) & 55% (US) were male, 61% (BR) & 70% (US) were of a white race. ID was present in >10% of incident PD patients, with a slightly higher prevalence in BR (~4 percentage points). Rates of ID states were relatively consistent in BR and US for functional and absolute ID in patients without anemia, and these represent ≥80% of all ID cases (**Figure 1**). However, functional and absolute ID rates among patients with uncontrolled anemia were ≥3 fold higher in BR vs US.

Conclusions: Prevalence of ID at PD start is >10.6% and ID primarily exists in patients without anemia in both BR and US. Current recommendations suggest ID screening in patients with low Hgb, considerations that may be having implications on patient care. For instance, patients with functional ID had mean ferritin >400 ng/mL, yet levels were >150 ng/mL higher in those with vs without anemia. Ongoing research is underway to understand the trajectories and outcomes associated with ID in PD.

Constipation and Clinical Outcomes in Peritoneal Dialysis: Results from Thailand PDOPPS

Talerngsak Kanjanabuch,[1,2] Guttiga Halue,[3] Huttaporn Tharapanich,[1,4] Jeerath Phannajit,[1] David W. Johnson,[5] Jeffrey Perl,[6] Roberto Pecoits-Filho.[7] *[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]Center of Excellence in Kidney Metabolic Disorders, Faculty of Medicine, Chulalongkorn University, Pathum Wan, Thailand; [3]Phayao Hospital, Phayao, Thailand; [4]Bamrasnaradura Infectious Diseases Institute, Nonthaburi, Thailand; [5]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [6]St Michael's Hospital, Toronto, ON, Canada; [7]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Patient-reported outcome measures (PROM) has gained international recognition as important predictors of clinical outcomes in peritoneal dialysis (PD). We sought to understand the associations between patient-reported constipation and clinical outcomes.

Methods: Constipation was determined in patients across 22 facilities in Thailand Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS) during 2014-2017. Constipation was diagnosed using both objective assessment tools (Bristol Stool Form Scale [BSFS]) and self-reported questionnaire, constipation severity score [CSS]). BSFS is a 7-level scale visual inspection of feces (from 1 to 7, from hard to softer) based on its texture and morphology. Whilst the CSS measures duration (1 item) and severity (7 items: frequency of bowel movement, difficulty, pain, completeness, attempt duration, defecation assistance, frequency of attempt failure) of constipation and is a self-filled questionnaire, with participants being asked to respond on a 5-point Likert scale coded.

Cox proportional hazards model regression was used to estimate associations between constipation and clinical outcomes, including mortality, hemodialysis (HD) transfer and peritonitis.

Results: 634 of 975 randomly selected PD patients from 22 facilities reported their constipation by using BSFS and CSS. In this questionnaire, the patients rated their constipation as well as a change in constipation over time. Constipation was common in the PD population, particularly in patients with older age, marriage, diabetes, lower educational level, and worse nutritional status (including lower time-average serum albumin and phosphate concentrations). Interestingly, self-reported constipation at baseline was significantly associated with shorter time to first and higher rates of peritonitis (hazard ratio [HR] 1.74, 95%CI 1.29-2.34) and death (HR 2.43, 95%CI 1.82-3.24) but not HD transfer (HR 1.25, 95%CI 0.7-2.21) after adjusting for age, gender, PD vintage, comorbidities, shared frailty by study sites, and serum albumin.

Conclusions: Patient-reported constipation was independently associated with higher risks of peritonitis and all-cause mortality, but not HD transfer. This warrants further investigation to identify effective interventions.

SA-PO654

Role of Remote Monitoring in Automated Peritoneal Dialysis: Impact in SONG-PD (Standardized Outcomes in Nephrology-Peritoneal Dialysis) and Results from RPM-APD Multicenter Study

Francisco Javier Centellas Pérez,[1] Juan Perez Martinez,[1] Alonso R. Valente,[2] María Peña Ortega,[3] Paula J. Caro espada,[4] Ramon Devesa Such,[5] Agustín Ortega Cerrto,[1] Manel Vera Rivera,[6] Francisco Barbosa,[7] Laura Espinel,[8] Mercedes Prats,[9] José Pedro M. Macedo,[2] Eduardo Muñoz de Bustillo,[10] Marco Montomoli.[11] *[1]Complejo Hospitalario Universitario de Albacete, Albacete, Spain; [2]Complejo Hospitalario Universitario de Santiago de Compostela, Santiago de Compostela, Spain; [3]Hospital Universitario San Cecilio, Granada, Spain; [4]Hospital Universitario 12 de Octubre, Madrid, Spain; [5]Hospital Universitari i Politecnic La Fe, Valencia, Spain; [6]Hospital Clinic de Barcelona, Barcelona, Spain; [7]Hospital del Mar, Barcelona, Spain; [8]Hospital Universitario de Getafe, Getafe, Spain; [9]Hospital Universitari de Tarragona Joan XXIII, Tarragona, Spain; [10]Hospital General Universitari d'Alacant, Alicante, Spain; [11]Generalitat Valenciana, Valencia, Spain.*

Background: The use of remote monitoring (RPM) in automated peritoneal dialysis (APD) has shown lower hospitalization rates in those patients who used this technique in addition to another series of clinical advantages such as greater technique survival. The present study evaluated the association between RPM use and SONG-PD outcomes.

Methods: A prospective observational multicenter cohort study included 232 patients in 16 Hospitals. A RPM program was used in 176 of the patients and 56 were treated with APD without RPM. The primary outcomes were standardized outcomes in Nephrology (SONG)-PD clinical outcomes and quality of life (EQ-5D-L). Data was recorded al least during 6 months. Propensity score matching (PSM) 1:1 was used to evaluate the association of RPM exposure with outcomes.

Results: There were no differences between baseline and demographic characteristics. Before PSM, APD with RPM (n=176) vs without RPM (n=56) was associated with less mortality (n=1 vs n=4)(HR (95%CI): (0.08 (0.01-0.69) (p=0.020) and with better technique survival (n=10 vs n=11) (HR (95%CI): (0.25 (0.11-0.59) p=0.001). After PSM, APD with RPM continued to associate con with better technique survival (figures 1 and 2)

Conclusions: The use of an RPM program in APD patients may be associated with better technique survival. RPM could be a tool for improvement of APD therapy.

SA-PO655

Association Between Age, Frailty, and Change in Health-Related Quality of Life After Dialysis Initiation?

Maude Pichette,[1] Louis-Philippe Laurin,[1] Remi Goupil,[2] Naoual Elftouh,[1] Annie-Claire Nadeau-Fredette.[1] *[1]Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal Centre de Recherche, Montreal, QC, Canada.*

Background: Despite its key importance, changes in health-related quality of life (HRQOL) after dialysis start are still poorly understood. This study aimed to assess the association between age, frailty and changes in HRQOL during the transition to home dialysis and in-center hemodialysis (ICHD).

Methods: HRQOL was measured using the KDQOL-SF questionnaire. Frailty was evaluated at study baseline using the Clinical Frailty Scale. Changes in physical component summary (PCS), mental component summary (MCS), and kidney-specific domains (burden, symptoms/problems and effects of kidney disease) were assessed in linear regressions comparing scores 6-months before and 6-months after dialysis start, with adjustment for age, frailty, dialysis modality and gender.

Results: Among a cohort of 121 CKD patients, 59 patients initiated dialysis (68 ±13 years, 61% ICHD and 39% home dialysis). HRQOL trajectories, stratified by age and frailty are illustrated in Figure 1. After adjustment, there were no statistically significant predictors associated with score changes at six months. There was however a nearly significant interaction between age and frailty (p=0.052) for MCS whereby frailty was associated with a trend towards decreased MCS for patients <65 years (*B* -18.1, 95% CI -37.4; 1.2, p=0.06), without a significant change in older patients. We also observed a trend towards improved score in the Problems/Symptoms in patients >65 years (vs. <65 years) after dialysis start (*B* 10.7, -0.3; 21.7, p=0.055).

Conclusions: This small prospective study showed that age and frailty may be associated with HRQOL after dialysis start, although we did not identify statistically significant associations. It demonstrates the importance of individualizing the choice of kidney replacement therapy, avoiding generalizing the expected evolution of patients on the basis of isolated characteristics such as age or frailty.

International Comparison of Home Dialysis Uptake: A Multi-Registry Analysis from the INTEGRATED Research Group

Annabel Boyer,[1,2] Isabelle Ethier,[3,4] David W. Johnson,[5,6] Eric D. Weinhandl,[7] Karthik K. Tennankore,[8] Thierry Lobbedez,[1,2] Clémence Béchade,[1,2] Naoual Elftouh,[12] Mark Lambie,[9,10] Annie-Claire Nadeau-Fredette.[11,12] INTEGRATED Research Group. *[1]Centre Hospitalier Universitaire de Caen, Caen, France; [2]Cancers et preventions, Caen, France; [3]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [4]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [5]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [6]The University of Queensland, Saint Lucia, QLD, Australia; [7]University of Minnesota Twin Cities, Minneapolis, MN; [8]Dalhousie University Faculty of Medicine, Halifax, NS, Canada; [9]Keele University Faculty of Medicine & Health Sciences, Keele, United Kingdom; [10]Royal Stoke University Hospital, Stoke-on-Trent, United Kingdom; [11]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [12]Hopital Maisonneuve-Rosemont Centre de Recherche, Montreal, QC, Canada.*

Background: There is a wide variability in home dialysis use from a high of 50% of patients receiving home dialysis in New Zealand to less than 10% in France. We aimed to compare patterns and predictors of home dialysis uptake across different registries.

Methods: This multi-national registry study of home dialysis included data from Australia, New Zealand, Canada, France and USA. Analyses were performed independently in each registry using identical statistical approaches. Multivariable adjusted clustered Cox models were used to evaluate predictors of home dialysis initiation within the first year of kidney replacement therapy (KRT), excluding pre-emptive transplantation.

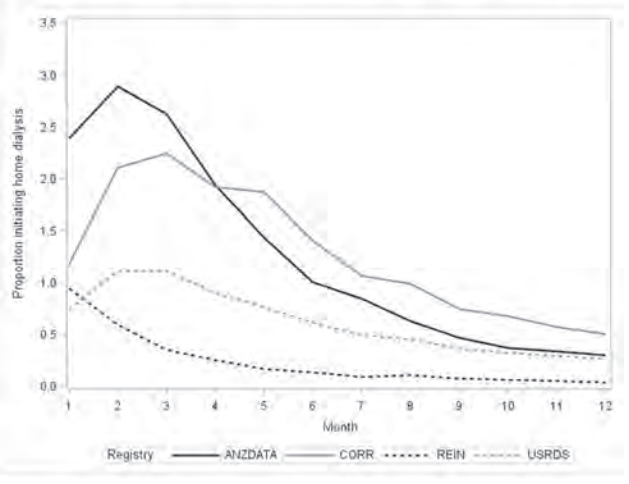
Results: The proportion of patients starting KRT on home dialysis was 29% in ANZDATA, 22% in CORR, 9.2% in REIN and 8.8% in USRDS. Patterns of transfer from in-center hemodialysis to home dialysis varied between countries, with a marked increase in the proportion of transfer to home dialysis 3 months after KRT start in CORR, ANZDATA and USRDS. After adjustment for patient-related characteristics, patients were most likely to initiate home dialysis within the first month of KRT in all registries. There was a diverging association between sex and home dialysis uptake; females had a lower use of home dialysis in Canada and Australia/New Zealand, and higher use in France and USA.

Conclusions: This study showed marked international differences in the pattern of home dialysis uptake within the first year of KRT. Further work should aim to identify how practice patterns, and governance strategies can mitigate these differences to improve access to home dialysis.

Funding: Private Foundation Support

Table 1. Adjusted clustered Cox model of home dialysis initiation within one year after KRT initiation

Figure 1. Percentage of patients transferred from in-center hemodialysis to home dialysis, excluding patients starting on home dialysis, within the first year of hemodialysis initiation, for the three registries



SA-PO657

Is the Cost of the New Home Dialysis Techniques Still Advantageous Compared to In-Centre Hemodialysis?

Dario Roccatello, Roberta Fenoglio, Savino Sciascia. *University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy.*

Background: Three main factors should be considered in the economic evaluation of home dialysis: the progressive reduction in the cost of consumables for in-centre hemodialysis (IC-HD), the widespread use of incremental Peritoneal Dialysis, and the renewed interest in Home Hemodialysis (H-HD). Registries data on incidence and prevalence of dialysis modalities are heterogeneous, showing widespread underemploy of home dialysis. Based on results in clinical and quality of life benefits, underemploy could be no more justified.

Methods: We compared the direct and indirect costs of PD (53 patients), H-HD (21 patients) and IC-HD (180 patients) by measuring the dialysis activity performed from January 1, 2019 to December 31, 2019 at the San Giovanni Bosco Hub Hospital, Turin (Italy). A cost analysis of the different dialysis techniques (DP and HD, home and hospital) was also carried out.

Results: To obtain comparable weekly costs, the following strategy was applied: a) calculating the average weekly frequency of dialysis sessions based on the dialysis modality. b) normalizing the cost of individual sessions per patient per week. c) calculating the monthly and yearly costs. PD proved to be the least expensive (€ 23,314.79 per patient per year), while H-HD has a lower average cost than IC-HD (€ 35,535.00 vs € 40,798.98).

Conclusions: Our data analysis confirms the low cost of Continuous Ambulatory PD and PD. Compared to all other hemodialysis modalities and even Automated Peritoneal Dialysis, Home Bicarbonate Hemodialysis has the lowest costs and the weekly cost of Frequent Home Hemodialysis was found to be comparable to that of In-Centre Bicarbonate Hemodialysis.

SA-PO658

First-Year Impact of the ESRD Treatment Choices (ETC) Model

Brighita M. Negrusa,[1] Darin F. Ullman,[1] Marc Turenne,[2] Purna Mukhopadhyay,[2] Eric W. Young.[2] *[1]Lewin Group Inc, Falls Church, VA; [2]Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: The ETC Model is intended to boost use of home dialysis and kidney transplantation among Medicare fee-for-service beneficiaries with ESRD, while reducing Medicare expenditures and preserving quality of care through performance-based Medicare payment adjustments to ETC participants. We examined impacts in the first year of the ETC Model (2021).

Methods: CMS randomly selected 91 Hospital Referral Regions (HRRs) and four HRRs from Maryland for the ETC Model, with mandatory participation from ESRD facilities and Managing Clinicians. We used difference-in-differences (DiD) regression models to compare changes in outcomes in the 95 ETC HRRs with those in 211 comparison HRRs between 2017-2019 and 2021. We used data from Medicare claims, the ESRD Quality Reporting System, the Scientific Registry of Transplant Recipients, and the In-Center Hemodialysis Consumer Assessment of Healthcare Providers and Systems survey to evaluate impacts on dialysis modality, transplant, utilization, Medicare spending, and patient experience of care.

Results: ETC HRRs constituted 31% of HRRs nationwide and included 2,519 ESRD facilities, 4,749 Managing Clinicians and 99,699 beneficiaries in 2021. Home dialysis increased similarly in ETC (11.8 to 14.7% of patient months) and comparison (12.8 to 15.8%) areas, yielding a non-significant (NS) DiD estimate of -0.11%. Home dialysis training increased 9% more in ETC vs. comparison areas ($p<0.05$). Transplant waitlisting showed a slower decline in ETC (19.5 to 19.0%) vs. comparison (21.1 to 19.8%) areas (DiD=0.83%, ($p<0.1$). Living donor kidney transplant rates fell similarly in ETC and comparison areas (DiD=0.005, NS). Although not directly incentivized by ETC, deceased donor transplants increased more in ETC (3.2 to 4.5 transplants per 1,000 patient months) vs. comparison (3.3 to 4.1) areas (DiD=0.37, $p<0.1$). There was no early impact on hospital utilization, overall Medicare spending and in-center hemodialysis patient experience of care.

Conclusions: Through the first year of the ETC Model, there was evidence of modest gains in home dialysis training, transplant waitlisting and deceased donor transplants, but no impact on home dialysis use or living donor transplants. These are early findings. Future analyses will consider the impact of provider infrastructure development and increased payment adjustments.

SA-PO659

Factors Affecting Survival Rate in Diabetic Patients Who Underwent Immediate-Start Peritoneal Dialysis

Hyunjin Cho, Jee Young Lee, Jung Hwan Park, Young-Il Jo. Division of Nephrology, Dept of Internal Medicine, Konkuk University Medical Center, Seoul, Republic of Korea. *Konkuk University Medical Center, Gwangjin-gu, Seoul, Republic of Korea.*

Background: Peritoneal dialysis (PD) patients with diabetes mellitus (DM) are known to have poorer survival compared to PD patients without DM. However, there are few studies on risk factors associated with patient survival in diabetic end-stage renal

disease (ESRD) patients underwent PD. The aim of this study was to identify factors independently associated with patient survival in diabetic ESRD patients who received immediate-start peritoneal dialysis (ISPD) without a break-in-period.

Methods: In this retrospective cohort study, 178 consecutive patients who started PD at Konkuk University Hospital from August 2005 to March 2023 were enrolled, and 144 patients with ISPD were finally analyzed. These patients were divided into the DM and the non-DM group. The primary outcomes were factors independently associated with patient survival in the DM group, estimated using a Cox proportional hazards regression model. Kaplan-Meier method was used to calculate patient survival rates.

Results: Among 144 patients, 93 (64.5%) had diabetes. The 1-, 5-, and 10-year patient survival rates of the DM and non-DM group were 97.6%, 86.9%, 35.1% and 98.4%, 92.1%, 65.6%, retrospectively. Compared to the non-DM group, the DM group had significantly higher age and body mass index (BMI), and significantly lower hemoglobin and serum albumin levels. However, only CVD was independently associated with patient survival in the DM group in univariate analysis, and this association was confirmed in multivariate analysis (Table 1).

Conclusions: Our study showed that CVD was the only factor independently associated with patient survival in ISPD patients with diabetes. Other factors such as age, BMI, hemoglobin, and serum albumin level did not appear to affect patient survival in diabetic ESRD patients who underwent ISPD without a break-in period.

		Multivariable	
Variables		Hazard ratio(95% CI)	P-value
Age		1.00 (0.96-1.04)	0.983
BMI(kg/m²)	25<BMI<30	1.20 (0.33-4.43)	0.781
	BMI> 30	1.95 (0.46-7.85)	0.364
CVD		3.12 (1.03-9.44)	0.044
Uric acid		1.15 (0.92-1.41)	0.206
Smoking		2.31 (0.58-9.18)	0.233

Healthcare Resource Utilization (HCRU) in Prevalent Dialysis Patients Undergoing Peritoneal Dialysis in the United States

Julie Rouette,[1] James B. Wetmore,[2,3] Sally Wetten,[4] Haifeng Guo,[2] Gema Requena,[4] Suying Li,[2] George Mu,[5] Liyuan Ma,[5] Jolyon Fairburn-Beech,[4] David T. Gilbertson,[2] Anna Richards,[4] Jiannong Liu.[2] *[1]GSK, Montreal, QC, Canada; [2]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN; [3]Division of Nephrology, Hennepin Healthcare, Minneapolis, MN; [4]GSK, Brentford, United Kingdom; [5]GSK, Collegeville, PA.*

Background: CKD is associated with increased HCRU. The US prevalence of patients (pts) undergoing peritoneal dialysis (PD) has more than doubled since 2000. We characterized the HCRU rate in prevalent PD pts in the US.

Methods: This observational cohort study used 2017–2019 United States Renal Data System data. Adults (≥18 years [yrs]) undergoing PD on Jan, 1 2018 (index) and with 6 months of Medicare fee-for-service coverage prior to index (incl.) were included. Follow-up was from index until death, loss of Medicare coverage, kidney transplantation, or Dec 31, 2019. All-cause HCRU was measured as the total number of services provided/total follow-up time (rate per patient-year [PY]).

Results: 20,647 PD pts were included (median age, 62.2 yrs; median dialysis duration, 2.7 yrs; **Table 1**). Diabetes was the most prevalent comorbidity (55.4%) and cause of ESKD (39.9%). Median follow-up was 2 yrs. During follow-up, rate of hospitalization was 1.52 per PY; of intensive care unit use 0.37; of skilled nursing facility (SNF) use 0.29; and of emergency department (ED) encounters 1.09 (**Table 2**). Consultation rates were highest for nephrologists (15.72). Pts treated in units with the largest numbers of pts (>100) had generally lower HCRU; pts outside of large metro areas had a lower hospitalization, but higher outpatient and ED encounters rates.

Conclusions: In the US, PD pts had 1.52 hospitalizations and 1.09 ED encounters per PY. Pts treated in units with >100 pts had generally lower HCRU rates.

SA-PO661

Effect of ESRD Prospective Payment System on Utilization of Peritoneal Dialysis in Patients with Kidney Allograft Failure

Ali I. Gardezi, Zhongyu Yuan, Fahad Aziz, Sandesh Parajuli, Didier A. Mandelbrot, Micah R. Chan, Brad C. Astor. *University of Wisconsin-Madison, Madison, WI.*

Background: The Center for Medicare and Medicaid Services introduced ESRD Prospective Payment System (PPS) in 2011 to increase the utilization of home dialysis modalities, including peritoneal dialysis (PD). Several studies have shown a significant increase in PD utilization after PPS implementation. However, its impact on patients with kidney allograft failure remains unknown.

Methods: We conducted an interrupted time series analysis using data from the United States Renal Data System that include all adult patients with allograft failure who started dialysis between 2005 and 2019. We compared the PD utilization in the pre-PPS period (2005-2010) to the fully implemented post-PPS period (2014-2019) for early (within 90 days of dialysis initiation) and late (91-365 days) PD experience.

Results: 27507 adult recipients with allograft failure started dialysis during the study period. There was no significant difference in early PD utilization between pre-PPS and post-PPS period in either immediate change called "step change" (0.3% increase; 95%CI: -1.95%, 2.54%; p=0.79) or rate of change over time called "slope change" (0.28% increase per year; 95%CI: -0.16%, 0.72%; p=0.18). Subgroup analyses revealed a trend toward higher PD utilization in post-PPS period in for-profit and large-volume dialysis units. There was a significant increase in PD utilization in post-PPS period in those units which had low PD experience in the pre-PPS period (2.2% increase; 95% CI: 1.31, 3.22; p<0.01). Similar findings were seen for the late PD experience.(Table)

Conclusions: PPS did not significantly increase the utilization of PD in patients initiating dialysis after allograft failure.

	Pre-PPS period, % [a]	Post-PPS period, % [b]	Step change, % [c]	P-value	Slope change, % per year [d]	P-value

a. Pre-PPS period: Q2 2005 - Q4 2010
b. Post-PPS period: Q1 2014 - Q4 2019
c. Instant change of the proportion of early PD attempt after PPS.
d. Long-term change in increase rate of the proportion of early PD attempt (% per year) after PPS.

Effect of PPS on late PD experience in patients with allograft failure

SA-PO662

Fewer Communities Left Behind: Peritoneal Dialysis (PD) Initiation Patterns by Health Service Area in an Era of Expansion

Christopher D. Knapp,[1,2] Shuling Li,[3] Chuanyu Kou,[3] Eric D. Weinhandl,[3,2] David T. Gilbertson,[3] James B. Wetmore,[3,2] Allyson Hart,[1,2] Kirsten L. Johansen.[3,2] *[1]Hennepin Healthcare System Inc, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN.*

Background: Use of peritoneal dialysis (PD) has historically varied by community and region, with racially diverse, urban, and northeastern areas having lower utilization of PD than rural, less diverse, and western areas. The trend of PD utilization since 2010 in the communities impacted by these disparities is unclear.

Methods: We used the United States Renal Database System to examine patterns of PD use in Health Service Areas (HSA) in the US. We assigned each of the 754 HSAs with ≥20 prevalent dialysis patients in 2009-2010 into "high" (>11% of dialysis patients using PD), "medium" (5.5-11%) or "low" (<5.5%) PD use categories. We then identified incident dialysis patients from 2011-2020 and described patient characteristics and trends in percentage of patients using PD on day 1 of dialysis according to HSA PD-use category. We used logistic regression with adjustment for demographics to determine whether changes in PD use differed across HSA categories.

Results: 1,195,588 incident dialysis patients were included. In the 2011-2020 period, low-use HSAs had a lower percentage of incident dialysis patients who were White (48.1% vs 63.2%) and a higher percentage of incident dialysis patients living in urban areas (86.3% vs 69.4%) or in the Northeastern US (38.8% vs 8.9%) compared with high-use HSAs. The percentage of patients initiating PD increased in each category of HSA (Figure). The adjusted odds of a patient initiating PD increased more in low-use HSAs (OR per 5 years 1.49, 95% Confidence Interval [CI] 1.45-1.52) than in medium or high-use categories (OR 1.37, 95% CI 1.35-1.39; OR 1.16, 95% CI 1.13-1.19, respectively).

Conclusions: During the 2010s, PD use increased more rapidly in areas where the modality had previously been less-utilized, suggesting that the national increase in PD utilization was geographically robust and did not result in widening differences among HSAs.

Characteristics of Registered Research in Peritoneal Dialysis, Past and Present

Martin L. Li,[1] Ankush Bajaj,[1] Uttam Bhetuwal,[2] Ankur Shah.[1,2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI.*

Background: Recent national policy changes and the continued growth of peritoneal dialysis (PD) as a therapy for end-stage kidney disease has renewed interest in this modality. The objective of this study was to describe the current landscape of PD clinical trials to assess trends and gaps in clinical research.

Methods: An advanced search was completed through ClinicalTrials.gov, yielding 248 studies. Descriptive statistics and Fisher exact tests were used for statistical analysis.

Results: Most studies were completed (197, 79.4%), did not indicate a phase (143, 57.7%), were academically sponsored (156, 62.9%), or conducted in Asia (88, 35.5%). There has been overall growth in PD clinical trials since 1995. Drug studies were more likely to be completed, industry-sponsored, or have surrogate as the primary outcome compared to device, procedure/behavioral, and other studies (17, 77.2%, 16, 72.7%, 71, 72.5%, respectively; p = 0.030; 2, 9.1%, 2, 9.1%, 5, 4.1%, respectively; p < 0.001; 13, 59.1%, 15, 68.2%, 78, 79.5%, respectively; p < 0.001).

Conclusions: Despite growth in PD research worldwide, more studies are being conducted outside the U.S., and static investment in U.S. government sponsored PD research risks not achieving the goal of increasing availability of home dialysis.

SA-PO664

Mobile Technology to Explore Real-Time Symptom Data and Physical Activity in People Receiving Peritoneal Dialysis

Brett Tarca,[1] Shilpa Jesudason,[2] Paul N. Bennett,[1] Thomas Wycherley,[1] Katia Ferrar.[1] *[1]University of South Australia Allied Health & Human Performance Academic Unit, Adelaide, SA, Australia; [2]Central Adelaide Local Health Network, Adelaide, SA, Australia.*

Background: Fatigue is a frequent and debilitating symptom that contributes to poor quality of life for people receiving peritoneal dialysis (PD). The fatigue experience and factors that may influence it (e.g., mood and physical activity) are poorly understood for people receiving PD, in-part, due to the recall instruments typically used to assess fatigue. Mobile ecological momentary assessment (mEMA) is a survey method that captures data in real-time using mobile phone technology, which has not been trialled in this cohort. The aim of this study was to explore the real-time fluctuations and associations between fatigue, mood and physical activity using mEMA.

Methods: A seven-day longitudinal study was conducted with adults receiving PD. Participants completed fatigue (0-130 [No Fatigue - Severe Fatigue]) and mood (0-10 [Happy - Sad]) Likert scales, via a mobile app, five times each day and concurrently wore an accelerometer to capture physical activity. A feasibility questionnaire was completed via the app on the eighth day.

Results: Forty-eight adults (mean age 61.0+13.5 years) completed the study. Relative to mean wake up score, within-day fluctuations were observed with fatigue less severe from mid-morning to early afternoon (10am-1pm: -9%) before increasing later in the afternoon (4pm-7pm: +14%), peaking at bedtime (+27%). Associations between fatigue and mood were observed with a 1-unit change in mood score conferring a 5.2-unit change in fatigue *(p<0.01)*. Acute relationships were observed with every 1-minute of physical activity associated with a -0.53 *(p<0.01)* and -0.01 *(p<0.05)* change in fatigue and mood score, respectively. Overall adherence to the app-based surveys was 73%. Most participants reported mobile phones and the mEMA app being easy to use with some seeing potential in mEMA to assist with the management of their kidney condition, as a self or external monitoring tool.

Conclusions: The results suggest that targeting either fatigue or mood through intervention may be effective for improving both symptoms, with physical activity-based interventions a potential strategy to mitigate fatigue and poor mood. Furthermore, mEMA, and mobile phones, were feasible to capture symptom data with potential to be employed in future research or, as part of improved care.

SA-PO665

A Proof-of-Concept Study: Metoprolol Tartrate Is Readily Cleared by Peritoneal Dialysis

Ozant Helvaci,[1] Dolunay M. Topuz,[2] Emre Yasar,[1] Saliha Yildirim,[1] Galip Guz,[1] Sevgi Akaydin.[2] *[1]Gazi Universitesi Tip Fakultesi, Ankara, Turkey; [2]Gazi Universitesi Eczacilik Fakultesi, Ankara, Turkey.*

Background: The dialyzability of cardioprotective β-blockers such as metoprolol and carvedilol is well-known. Even so, there is no consensus on the choice between metoprolol vs. carvedilol due to studies with conflicting results. The situation is worse for PD patients since the data on PD clearance of β-blockers is far more scarce. Furthermore, some authors have linked β-blockers to UF failure without a clear mechanism. In this proof-of-concept study, we aimed to develop a technique for determining the metoprolol tartrate (MT) level in the effluent and serum samples of PD patients. The completed version of the study will also include metoprolol succinate and carvedilol levels, which we expect to be the first study to investigate that phenomenon.

Methods: We selected nine patients on stable doses of MT aimed at a resting pulse<70/min. All predialysis samples were taken on the dry abdomen. Regardless of APD or CAPD status, an exchange with 1.36% glucose solution was done. After a 2-hour dwell time, post-dialysis blood samples and effluent samples were collected. In addition, pre and post-pulses and ECGs were recorded. The blood samples were analyzed with the HPLC 1220 ® (High-performance liquid chromatography) instrument. The peaks at 262 nm were recorded, and the AUC values were calculated based on the standard analysis. A similar process was followed for the effluent.

Results: The mean age was 58±11 years. Drug doses and baseline pulse rates were similar. The mean pre-PD MT levels were 134±66 ng/mL, and post-PD levels were 51±28 ng/mL. The average effluent drug concentration was 81±51 ng/mL, and the delta change between pre-post dialysis was 60±11%. Patients on APD had numerically higher MT baseline and post-dialysis concentrations, but the difference was insignificant (p=0,190). Residual renal function and transporter types did not affect drug levels. Pre and post-dialysis pulse rates were statistically similar; no tachycardia event was observed.

Conclusions: We have shown that effluent has very high levels of MT. This might be the link to the so-called β-blocker-related UF failure. Furthermore, we have proven that PD readily clears MT. After the completion of the study with the addition of metoprolol succinate and carvedilol levels, we hope to facilitate the "β-blocker" debate in the field of peritoneal dialysis.

Peritoneal Dialysis Patients Exhibit Quantifiable Neurocognitive Impairment but Not Acute Ischemic Brain Injury: A Magnetic Resonance Spectroscopy and Diffusion Tensor Imaging Study

Jessica Vanderlinden,[1] Dickson Y. Wong,[2] Michael Chiu,[3] Christopher W. McIntyre,[2,3] Arsh Jain.[3] *[1]Western University Department of Medical Biophysics, London, ON, Canada; [2]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [3]Lawson Health Research Institute, London, ON, Canada.*

Background: Patients receiving hemodialysis (HD) are known to suffer recurrent ischemic multiorgan injury, which effects the vulnerable vascular beds of the brain. These acute cerebral insults are associated with significant white matter (WM) injury, ultimately leading to neurocognitive impairment. PD patients are not subject to the equivalent circulatory stress as HD patients suggesting PD is relatively neuro-protective. Our objective was to utilize an imaging-based approach previously applied to a HD cohort to examine the acute intradialytic effects of PD.

Methods: Patients completed a neurocognitive battery (The Montreal Cognitive Assessment (MoCA), Trails Making Test (TMT), and Cambridge Brain Science (CBS)), an intradialytic MRI scan encompassing diffusion tensor imaging (DTI, WM integrity), and a proton magnetic resonance spectroscopy (^{1}H-MRS, neurochemistry). Imaging and neurocognitive assessments were performed before PD exchange, with repeat imaging after 90 minutes of dwell time.

Results: 12 patients receiving PD were studied. Patient demographics included (mean±SD): 67±8 years of age, 75% male, 75% diabetic, dialysis vintage 18±10 months, ultrafiltration 0.58±0.36L, and PD exchange 8.3% with 2.5% and 91.7% with 4.25% dextrose. Neurocognitive impairment (%impaired) was evident by the TMTA/B measuring attention (A=92%) and executive function (B=42%). CBS tasks are classified by their contribution to verbal, short-term memory, and reasoning domains. The verbal weighted domain component score demonstrated the most impairment (46%). Finally, 2/12 patients (17%) exhibited global impairment detected by the MoCA. DTI imaging demonstrated no acute effects on WM integrity. However, ^{1}H-MRS detected a 21% increase in brain glucose concentration (p=0.006).

Conclusions: PD patients exhibited quantifiable neurocognitive deficits, but did not suffer acute intradialytic WM injury, supporting that PD may have neuro-protective benefits. PD dwell did result in brain hyperglycemia, indicative of acute metabolic stress. This may translate into an alternative hypothesis for progressive neurocognitive impairment via advanced glycation end-products, but further research is necessary.

Retinopathy Is Associated with Impaired Cognition in Patients Undergoing Peritoneal Dialysis

Jinlan Liao,[1,2] Qijie Wei,[3] Ying Y. He,[1] Yumei Liao,[1] Zibo Xiong,[1] Qing Wang,[1] Dayong Ding,[3] Xiaoyan Huang,[1] Zuying Xiong,[1] Yonggui Wu.[2] *[1]Peking University Shenzhen Hospital, Shenzhen, China; [2]The First Affiliated Hospital of Anhui Medical University, Hefei, China; [3]Vistel AI Lab, Beijing, China.*

Background: This study was aimed at examining the relationship between retinopathy and cognitive impairment in patients undergoing peritoneal dialysis (PD).

Methods: Forty-eight men and 59 women (age range: 21 to 78 years) undergoing PD were included in this **c**ross-sectional study. Retinal microvascular characteristics, such as geometric changes in retinal vascular including tortuosity, fractal dimension (FD), and calibers, were assessed. Retinopathy (such as retinal hemorrhage or microaneurysms) was evaluated using digitized photographs. The Modified Mini-Mental State Examination (3MS) was performed to assess global cognitive function.

Results: The prevalence rates of retinal hemorrhage, microaneurysms, and retinopathy were 25%, 30%, and 43%, respectively. The mean arteriolar and venular calibers were 63.2 and 78.5 mm, respectively, and the corresponding mean tortuosity was 37.7 ± 3.6 and 37.2 ± 3.0 mm^{-1}. The mean FD was 1.49. After adjusting for age, sex, education, mean arterial pressure, and Charlson index, retinopathy was found to be negatively associated with 3MS scores (regression coefficient, -3.71, 95% confidence interval: -7.09 to -0.33, P = 0.03).

Conclusions: Retinopathy, a condition common in patients undergoing PD, was associated with global cognitive impairment.

Funding: Government Support - Non-U.S.

A Novel Mouse Model of Peritoneal Dialysis-Related Encapsulating Peritoneal Sclerosis

Juan Sun, Hui Peng. *Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Encapsulating peritoneal sclerosis (EPS) is a severe complication in patients undergoing peritoneal dialysis (PD), with a high mortality rate. However, the insufficiency of knowledge pertaining to the etiology of EPS hampers the development of effective pharmacotherapeutic treatment, and there is a deficiency in pre-clinical models that can recapitulate the progression of the human disease. Thus, we aimed to develop an efficient and realistic mouse model of PD-associated EPS that could mimic the disease characteristics observed in humans.

Methods: Eight-week-old male C57BL/6J mice received a daily intraperitoneal injection of a combination of 4.25% PD solution and SHS (containing 0.1% chlorhexidine gluconate and 15% ethanol dissolved in saline), along with lipopolysaccharide (LPS) administration once a week. And Saline group was given intraperitoneal injection of the same volume of 0.9% saline (daily) as the control. 3 weeks later, ultrasounic and histochemical examines

were used to detect abdominal changes in mice, and then RNA sequencing (RNA-seq) was performed to uncover the potential molecules and signalings in the pathogenesis of EPS.

Results: In EPS group, 76.67% mice survived and all surviving mice developed significant and diffuse peritoneal adhesion at the end of experiment. Ultrasounic and histopathological analyses demonstrated peritoneal thickening and extensive intra-abdominal adhesion. Combined with the immunohistochemical results of mice sacrificed at weeks 2 and 4, we revealed the dynamic process of adhesion formation in EPS models. Finally, the RNA-seq of peritoneal tissue showed marked fiber deposition and inflammatory cell infiltration dominated by macrophages in EPS group. These results observed in our mouse model were consistent with the characteristics of EPS patients.

Conclusions: Our novel mouse model of PD-associated EPS is efficient to replicate the key features of EPS occured on patients, and provide a promising platform to investigate the molecular pathophysiology and treatment strategy of EPS.

Optical System Shows Promise for Online Detection of Peritonitis in Peritoneal Dialysis

Daniel Kushnir,[1] Tatiana Tanasiychuk,[1] Jeffrey Perl,[3,4] Isaac Teitelbaum,[5] Hezkiah Tsoory,[2] Dimitry Zacharin,[2] Ron Dayan,[2] Victor Frajewicki.[1]
[1]Carmel Medical Center, Haifa, Israel; [2]liberDi Ltd, Or Akiva, Israel; [3]St. Michael's Hospital, Toronto, ON, Canada; [4]University of Toronto, Toronto, ON, Canada; [5]University of Colorado, Denver, CO.

Background: Peritoneal Dialysis (PD) is associated with significant patient morbidity and mortality. Prompt peritonitis diagnosis and treatment is crucial and may be limited by the lack of early patient or care partner recognition of peritonitis signs and symptoms thereby delaying clinical presentation and treatment and adversely impacting peritonitis treatment outcomes.

Methods: The Intelligent Dialysis Assistant (IDA), a new electronic automated ambulatory PD exchange device (part of liberDi's Digital Dialysis Clinic) provides aseptic PD exchanges. The IDA is fitted with an inline WBC sensor that can transmit online detection of white blood cells (WBC) in the PD effluent and aid in the early diagnosis of peritonitis. To check the capabilities of the sensor in- vitro, we created PD solutions with a range of 150- 16,000 cells/μL to mimic PD effluent peritonitis conditions.

Results: The sensor installed in the IDA (part of liberDi's Digital Dialysis Clinic) was able to detect the different concentrations of white blood cells in the solution (from 150 through 16,000 cell/μL), with a high linear correlation (R^2 =0.98).

Conclusions: A point-of-care testing system for detecting peritonitis using a sensor is a promising approach that may improve the prompt diagnosis and treatment of peritonitis in PD patients. The ability of the installed sensor in the IDA to detect low concentrations and volumes of white blood cells suggests that may be a reliable tool to detect peritonitis in the PD effluent and will require validation via further clinical studies.

Funding: Commercial Support - liberDi

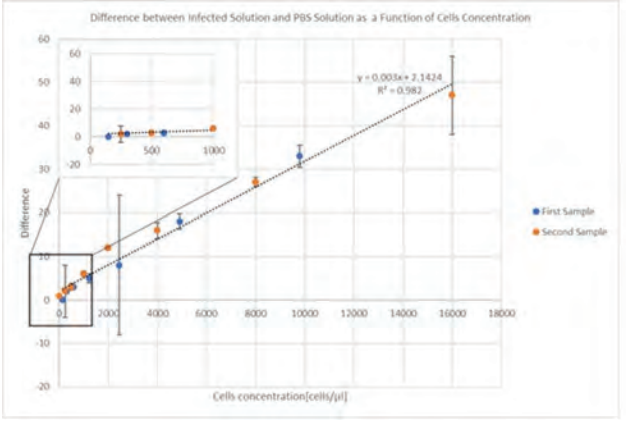

Figure 1 illustrates how the differences in optical system readings between the infected solution and the reference solution varies with different concentrations of white blood cells for two tested blood samples, as well as the average of those samples. Each point denotes 103 readings.

The Effect of Far-Infrared Therapy on the Cardiovascular and Infection Events in Peritoneal Dialysis Patients

Chih-Ching Lin,[1,2] Taipei VGH PD Team. *[1]Taipei Veterans General Hospital Department of Internal Medicine, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.*

Background: Long-term peritoneal dialysis (PD) may be associated with cardiovascular (CV) and infection complications. A previous case reprt has shown that far-infrared (FIR) therapy may improve abdominal discomfort due to encapsulating peritoneal sclerosis in PD patients. Since there is little information concerning this issue, we conducted this study in order to evaluate the possible effects of FIR therapy on the CV and infection events of PD patients.

Methods: A total of 99 PD patients were enrolled and randomly divided into FIR and control groups. WS TY101 FIR emitter (WS Far Infrared Medical Technology Co., Taipei, Taiwan) was used to conduct the FIR therapy. The irradiating power density was set at 20 mW/cm^2 and the top radiator was set at 20 cm above the abdomen. Both groups underwent FIR therapy for 40 minutes twice daily during the first and last exchange of each PD session for 1 year. The outcome measures include (1) CV events such as 3P-MACE (3-point major adverse cardiovascular events [consisting of non-fatal stroke, myocardial infarction, and CV death]), coronary artery disease (CAD), and hospitalized heart failure (HHF) and (2) infection events such as pneumonia and peritonitis.

Results: Peritonitis was found to be statistically significant (hazard ratio (HR)=0.418, P=0.017) while two combinations of events were also found to be significant (CV and infection events [HR=0.338, P=0.007] & CV events and peritonitis [HR=0.336, P=0.012]). The survival curves showed that the FIR group had a slower occurrence of CV and infection events, as well as CV events and peritonitis, than the control group. The log-rank tests for both CV and infection events & CV events and peritonitis showed a significant difference (P=0.005, 0.007, respectively) between the two groups.

Conclusions: FIR therapy may significantly lower the risk of CV and infection events, as well as CV and peritonitis events.

SA-PO671

Impaired Sodium Dipping Is Associated with Poor Blood Pressure Control in Patients on Peritoneal Dialysis

Washington A. Freire Filho, Ana Teresa P. Vieira, Edilene Maria dos Santos, Luiza K. Araujo, Benedito J. Pereira, Hugo Abensur, Zita M. Britto, Rosilene M. Elias. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: Overhydration is often found in patients on peritoneal dialysis (PD). There is no clear association between fluid overload and hypertension in this population. Since short dwells are associated with decreased sodium removal because of peritoneal sodium sieving, we hypothesized that impaired sodium dipping may be associated with worse blood pressure (BP) control.

Methods: This is a cross-sectional analysis of prevalent patients on PD. We evaluated sodium dipping (dialysate sodium dipping after 1 hour with 4.5% glucose bag), fluid overload (excess extracellular volume ≥ 0.39 measured by bioimpedance spectroscopy) and BP control (high BP was defined as office-measured values > 140/90 mmHg).

Results: 47 patients (age 52 ± 18 years, 53% men) were included. Overhydration was found in 62% of patients and high BP in 34% of patients; sodium dipping < 5mmol/L was found in 57% of patients. (Table 1) These patients were characterized by a higher percentage of high BP (81.3% vs 18.8%, p=0.018), despite similar use of antihypertensive drugs, and no difference in overhydration status, membrane transport profile, cycles/volume PD prescription, ultrafiltration volume, and residual renal function. Sodium dipping < 5mmol/L remained significantly associated with high BP in a fully adjusted model (HR 11.8, 95% CI 2.0-68, p=0.006).

Conclusions: The association between lower sodium dipping and poor BP control suggests that dialytic sodium removal should be included as an important parameter of PD adequacy.

Table 1

	Na dipping ≥ 5 mmol/L	Na dipping < 5mmol/L	p

CA-125 Is a Good Biomarker of Overhydration in Peritoneal Dialysis Patients

Ana C. Martins, Gonçalo F. Pimenta, Rita Calça, Patrícia Matias. *Centro Hospitalar de Lisboa Ocidental EPE Hospital de Santa Cruz, Carnaxide, Portugal.*

Background: Volume management in peritoneal dialysis (PD) patients is crucial due to the impact of fluid overload on cardiovascular and non-cardiovascular morbimortality. Clinical examination itself has a poor diagnostic accuracy for minor deviations from normohydration, highlighting the necessity for supplementary tools. The aim of this study was to evaluate the association between serum biomarkers (CA-125 and NT-proBNP) and volume status, assessed through bioimpedance analysis, upon initiation of PD technique and follow-up.

Methods: Single-centre observational cross-sectional study including PD patients that started technique between 2017 and 2023. Demographic and clinical data were collected from electronic records. Parameters evaluated were clinical examination, serum biomarkers, bioimpedance and dialysis adequacy.

Results: A total of 79 patients (51 male) were included with a median age of 59 (IQR 23) years. Baseline (T0) PET showed 77.2% high or high-average transporters. Follow-up (T1) PETs were performed after a median of 18 months (IQR 19). All the patients started with continuous ambulatory peritoneal dialysis (CAPD). Median weekly Kt/V was 2.3 (IQR 0.7). The median residual renal function (RRF) and residual diuresis were 5.9 (IQR 4.9) mL/min/1.73m2 and 1.5 (IQR 1.1) L (5.1% anuric), respectively. Median CA-125 at T0 and T1 were 16.2 U/mL (IQR 17.8) and 13.4 U/mL (IQR 16.1), respectively, which were not statistically different. The median overhydration index at T0 and T1 was 1.55L (IQR 2.5) and 1.1L (IQR 2.3) (p=.001). There was a positive association between D/P of creatinine and CA-125 (r=.25, p=.03) and a negative association between weekly Kt/V and CA-125 (r=-.25, p=.035), both at T0. There was also a positive association between NTproBNP and CA-125 levels at T1 (r=.44, p<.001) and between the NTproBNP variation from T0 to T1 and the CA-125 variation from T0 to T1 (r=.352, p=.004). There was no association between the variation of hydration status and the variation of NT-proBNP and CA-125 levels.

Conclusions: Serum NT-proBNP and CA-125 show a positive correlation, which suggests these biomarkers might be used interchangeably in the evaluation of the patients' hydration. Effective management of hypervolemia improves clinical outcomes. Prospective studies are needed to better understand the use of CA-125 as a surrogate marker of hypervolemia.

CCL18-PITPNM3 Mediates Macrophage-Mesothelial Cross-Talk and Promotes Peritoneal Dialysis-Associated Peritoneal Fibrosis

Yuxiang Sun, Qiang Huang, Hui Peng. *Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China.*

Background: Peritoneal dialysis (PD) is one of the replacement therapies for end-stage renal disease. After long-term PD(LPD) treatment, about 50% of patients will develop peritoneal fibrosis and ultrafiltration failure. Macrophages and metabolic reprogramming have been confirmed to play an important role in PD-related peritoneal fibrosiss.

Methods: We performed scRNA-seq on perfusate cells from patients receiving PD treatment and explored the functions of specific cell types in the development of PD-related peritoneal fibrosis. By cell communication analysis, we interrogated crosstalk among different cell types in PD effluent. Then we used western blot, qPCR and seahorse to investigate the downstream pathway.

Results: We discovered that LPD promoted interactions between macrophages and mesothelial cells. We also found that LPD induced the M2 polarization of macrophages. CCL18 was identified to be the most significantly M2-type macrophage-secreted factor upregulated in LPD patients. Moreover, the increased concentration of CCL18 in the PD effluent of LPD patients was related to the high peritoneal transport. It was found that PITPNM3 was the most abundant and significantly elevated receptor for CCL18 in the mesothelial cells of LPD patients. Knocking down PITPNM3 receptor ameliorated EMT of mesothelial cells induced by CCL18. Finally, we discovered that CCL18-PITPNM3 could promote the expression of glycolysis enzyme HK2 by activating the PI3K-Akt-cMyc signaling pathway.

Conclusions: PD promoted macrophage M2 polarization and increase CCL18 secretion. CCL18 binds to PITPNM3 in mesothelial cells activating the PI3K/Akt/cMyc. HK2 signaling pathway, so as to enhance the glycolysis and EMT of mesothelial cells and lead to PD-related peritoneal fibrosis.

Mesothelial Extracellular Vesicles Promote Fibroblast Activation via Delivering of Integrin-Linked Kinase in Peritoneal Fibrosis

Qiang Huang, Yuxiang Sun, Hui Peng. *The Third Affiliated Hospital of Sun Yet-sun University Department of Nephrology, Guangzhou, China.*

Background: Varieties of cell-cell communications among peritoneal cells play a significant role in peritoneal fibrogenesis induced by peritoneal dialysis (PD). Extracellular vesicles (EVs) have been confirmed to involve in intercellular communication by transmitting various molecules. However, their roles and functional mechanisms in peritoneal fibrosis remain to be determined.

Methods: We performed combined analysis of PD effluent-derived EV proteomics and peritoneal single-cell RNA sequencing to determine the cell source of PD effluent-derived EVs. We blocked mesothelial EVs secretion via GW4869 or shRab27a, and injected mesothelial EVs into mice treated with PD fluid. We detected the percentage of ILK^+ EVs in PD effluent by flow cytometry.

Results: Using integrative analysis of EV proteomics and single-cell RNA sequencing, we characterized the EVs isolated from PD patient's effluent and revealed that mesothelial cells are the main source of EVs in PD effluent. We demonstrated that transforming growth factor-β1 (TGF-β1) can substitute for PD fluid to stimulate mesothelial cells releasing EVs, which in turn promoted fibroblast activation and peritoneal fibrogenesis. Blockade of EVs secretion by GW4869 or Rab27a knockdown markedly suppressed PD-induced fibroblast activation and peritoneal fibrosis. Mechanistically, injured mesothelial cells produced EVs containing high level of ILK, which was delivered to fibroblast and activated them. Clinically, the percentage of ILK positive EVs in PD effluent correlated with peritoneal dysfunction.

Conclusions: Our study highlights that peritoneal EVs mediate communications between mesothelial cells and fibroblasts to initiate peritoneal fibrogenesis. Targeting EVs or ILK could provide a novel therapeutic strategy to combat peritoneal fibrosis.

Intraperitoneal Pressure Induces Peritoneal Dialysis-Related Peritoneal Fibrosis and Stampede Phenomenon Through CD44 Signaling

Yu-Wei Chen,[1,2] Cheng-hsien Chen,[1,3] Mai-Szu Wu,[2,3] Yung-Ho Hsu.[1,3]
[1]Graduate Institute of Clinical Medicine, College of Medicine, Taipei Medical University, Taipei, Taiwan; [2]Taipei Medical University Shuang Ho Hospital Ministry of Health and Welfare, New Taipei City, Taiwan; [3]TMU Research Center of Urology and Kidney, Taipei Medical University, Taipei, Taiwan.

Background: Peritoneal dialysis (PD) is a widely used sustainable kidney replacement therapy. Prolonged use of peritoneal dialysis fluids is associated with mesothelial-mesenchymal transition, peritoneal fibrosis, and eventual ultrafiltration (UF) failure. However, the impact of intraperitoneal pressure (IPP) on the peritoneum remains unclear.

Methods: In this study, we employed a mouse PD model and human Met-5A cells to investigate the influence of pressure on the peritoneum and mesothelial cells. We utilized repeated, chronic infusion of glucose-free phosphate-buffered saline (PBS) to increase IPP and examined its effects.

Results: We observed that increased IPP induced peritoneal fibrosis and upregulated the expression of cluster of differentiation 44 (CD44) in mesothelial cells (Figure 1). Pressurization led to a mesenchymal phenotype, the expression of fibrotic markers and inflammatory factors, increased cell proliferation, and cell migration in Met-5A cells. The mouse PD model and human peritoneum equilibrium tests showed a positive association between higher IPP and both increased small solute transport and decreased net UF. The treatment of CD44 neutralizing antibodies prevented pressure-induced phenotypic changes in mesothelial cells, while a CD44 inhibitor oligo-fucoidan ameliorated pressure-induced peritoneal thickening, fibrosis, and inflammation in PD mice.

Conclusions: Our findings suggest that IPP plays a crucial role in peritoneal fibrosis in PD. CD44-mediated mesothelial changes and inflammation are involved in these processes. The experiments of CD44 blockade showed its potential as a therapeutic approach for PD-related peritoneal fibrosis and UF failure.

FG4592 Ameliorates Peritoneal Dialysis-Associated Peritoneal Fibrosis

Qimei Luo, Xianrui Dou. *Shunde Hospital of Southern Medical University, Foshan, China.*

Background: Inflammatory responses in the peritoneum contribute to peritoneal dialysis (PD)-associated peritoneal fibrosis. Previous studies showed that FG4592 (Roxadustat) suppressed inflammation in renal ischemia-reperfusion injury, alcohol-induced alcoholic liver disease. To date, FG4592 has become widely used for the treatment of anemia in patients undergoing dialysis. However, the role of FG4592 in the progression of peritoneal fibrosis has not been clarified. In this study, we used a PD rat model to investigate the effects of FG4592 on PD-associated peritoneal fibrosis.

Methods: A rat model of peritoneal fibrosis was induced via intraperitoneal injection of 4.25% PD fluid at a dose of 100mL/kg daily for 4 weeks. To investigate the effect of FG4592 on peritoneal fibrosis, rat were intraperitoneally injected with FG4592 at 1mg/kg per day. Rats were randomly divided into three groups: rats injected intraperitoneally with saline equivalent to the amount of PD fluid were defined as the control group (n=6), rats injected with 100mL/kg PD fluid were defined as the PD group (n=6) and rats injected with 100mL/kg PD fluid plus FG4592 were defined as PDF+FG4592 group (n=6). After 28 days of PD treatment, PET was performed on each rat before the rats were kills. The parietal and visceral peritoneal tissues were collected for Masson's thichrome staining, western blotting and real-time PCR.

Results: Compared with the PD group, those of the PDF+FG4592 group showed increased net ultrafiltration volume. Masson's trichrome staining showed that those of the PD group showed thickness of the submesothelial compact zone, and the histological change was accompanied by decreased peritoneal transport of glucose and sodium, and increased peritoneal transport of creatinine and albumin. In contrast, administration of FG4592 prevented the thickening of the peritoneum and improved the peritoneal transport function presenting as increased transport of glucose and sodium, and decreased transport of creatinine and albumin. Injection of 4.25% PD fluid significantly increased the mRNA levels of IL-1b, TNF-a and MCP-1 in the visceral peritoneum, and treatment with FG4592 effectively decreased their expression. Results of western blotting demonstrated that FG4592 inhibited the formation of fibronectin, collagen I and vimentin at protein levels.

Conclusions: FG4592 alleviates the development of peritoneal fibrosis in a rat model of PD.

SA-PO677

Matrix Metalloproteinase-10 Deficiency Has Protective Effects Against Peritoneal Inflammation and Fibrosis via NFκB Pathway Inhibition

Hideki Yokoi,[1] Takuya Ishimura,[1] Akira Ishii,[1,2] Hiroyuki Yamada,[1,3] Naohiro Toda,[1,2] Keita P. Mori,[1,4] Shoko Ohno,[1] Yukiko Kato,[1] Takaya Handa,[1,4] Akie Ikushima,[1] Sayaka Sugioka,[1] Haruomi Nishio,[1] Motoko Yanagita.[1,5]
[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Nephrology, Kansai Electric Power Hospital, Osaka, Japan; [3]Department of Primary Care Emergency Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [4]Department of Nephrology and Dialysis, Tazuke Kofukai Medical Research Institute, Kitano Hospital, Osaka, Japan; [5]Institute for the Advanced Study of Human Biology (ASHBi), Kyoto University, Kyoto, Japan.

Background: One of the most common causes of discontinuation of peritoneal dialysis is impaired peritoneal function. However, its molecular mechanisms remain unclear. We have previously demonstrated that MMP (matrix metalloproteinase)-10 gene expression is significantly increased by microarray analysis of peritoneal fibrosis mice, but its function has not been elucidated yet.

Methods: Chlorhexidine gluconate (CG) was intraperitoneally injected to wild-type and MMP-10 knockout mice to elucidate the role of MMP-10 on peritoneal injury. We also examined function of peritoneal macrophages and mesothelial cells obtained from wild-type and MMP-10 knockout mice, and human MMP-10-overexpressing RAW 264.7 cells and MeT-5A cells. In addition, we investigated MMP-10 expression on human peritoneal biopsy specimen, and association between serum proMMP-10 and peritoneal permeability determined by peritoneal equilibration test (PET).

Results: MMP-10 was expressed in positive cells for WT1, a mesothelial marker, and also for MAC-2, a macrophage marker, in the thickened peritoneum of both mice and humans. Serum proMMP-10 levels were well correlated with peritoneal permeability indicated by D/P Cr. Peritoneal fibrosis, inflammation, and high peritoneal permeability induced by CG were all ameliorated by MMP-10 deletion, with reduction of CD31-positive vessels and VEGF-A-positive cells. Expression of *Ccl2*, *Tnfa*, and *Il6* and phosphorylation of NFκB subunit p65 at S536 were suppressed in both MMP-10 knockout macrophages and mesothelial cells in response to lipopolysaccharide (LPS) stimulation. Overexpression of MMP-10 in RAW 264.7 and MeT-5A cells upregulated mRNA expression of pro-inflammatory cytokines with phosphorylation of NFκB subunit p65.

Conclusions: Inflammatory responses induced by MMP-10 are mediated through NFκB pathway, and that systemic deletion of MMP-10 ameliorates peritoneal inflammation and fibrosis caused by MMP-10-induced NFκB activation of peritoneal macrophages and mesothelial cells.

Peritoneal Endothelial Hyaluronan in Glycocalyx Is Decreased in Peritoneal Dialysis Patients Treated with Conventional Solutions

Keisuke Kamiya,[1] Mitsuhiro Tawada,[2] Akimasa Asai,[1] Hiroshi Kinashi,[1] Makoto Yamaguchi,[1] Masashi Mizuno,[2] Masataka Banshodani,[3] Takuji Ishimoto,[1] Hideki Kawanishi,[3] Yasuhiko Ito.[1] *[1]Aichi Ika Daigaku, Nagakute, Japan; [2]Nagoya Daigaku, Nagoya, Japan; [3]Tsuchiya Sogo Byoin, Hiroshima, Japan.*

Background: Peritoneal membrane dysfunction in peritoneal dialysis (PD) is primarily attributed to angiogenesis; however, the integrity of vascular endothelial cells can affect peritoneal permeability. Glycocalyx is a bioactive gel-like layer and is known to play roles in maintaining a negative charge, regulating coagulation, and controlling microvascular permeability. Degradation of glomerular hyaluronan, a component of the endothelial glycocalyx, leads to proteinuria and structural damage. One hypothesis suggests that development of encapsulating peritoneal sclerosis (EPS) is triggered by protein leakage due to vascular endothelial injury. We therefore investigated the expression of hyaluronan of glycocalyx in peritoneal membrane of normal and diseased conditions.

Methods: We studied the expression of hyaluronan in a total of 254 peritoneal membrane tissues of PD patients and chlorhexidine-induced peritonitis model. Five healthy donors of kidney transplants were used as control. Peritoneal hyaluronan expression was visualized using biotin-labeled human hyaluronan-binding protein (HABP). CD31, CD68 and ratio of luminal diameter to vessel diameter (L/V ratio) were also evaluated.

Results: Hyaluronan expression was much lower in the PD patients undergoing long-term PD treatment with conventional solution than those treated with low-GDP, pH-neutral solutions ($p<0.001$). There were no significant differences in the number of vessels or macrophages between the groups. In EPS cases, L/V ratio and hyaluronan expression significantly decreased in those treated with conventional solutions. The extent of hyaluronan loss correlated with the severity of vasculopathy ($r^2=0.524$, $p<0.0001$). Hyaluronan expression in EPS patients treated with conventional solutions declined even though the L/V ratio was relatively high. In peritonitis of human and animal model, hyaluronan expression were preserved in spite of the inflammatory conditions.

Conclusions: Peritoneal hyaluronan in endothelial glycocalyx was more preserved in patients treated with low-GDP, pH-neutral solution. Loss of hyaluronan in the glycocalyx may induce proteins leakages, leading to the development of EPS in the patients treated with conventional solution.

SA-PO679

The Response of Mesothelial Cells to Fibrotic Stress Is Influenced by Carnitine Acetyltransferase (CrAT)

Valentina Masola,[1] Luciano D'Apolito,[2,3] Angelo D'Alessandro,[4] Mario Bonomini,[5] Giovambattista Capasso,[2,3] Francesco Trepiccione,[2,3] Maurizio Onisto,[1] Tommaso Prosdocimi,[6] Jose C. Divino-Filho,[7] Arduino Arduini.[6] *[1]Department of Biomedical Science, University of Padova, Padova, Italy; [2]Biogem, Institute of Molecular Biology and Genetics, Ariano Irpino, Italy; [3]Department of Translational Medical Sciences, University of Campania "Luigi Vanvitelli", Naples, Italy; [4]Department of Biochemistry and Molecular Genetics, University of Colorado, Denver – Anschutz Medical Campus, Aurora, CO; [5]Department of Medicine, University "G. d'Annunzio" of Chieti-Pescara, Chieti, Italy; [6]Iperboreal Pharma Srl, Pescara, Italy; [7]Division of Renal Medicine, CLINTEC, Karolinska Institutet, Stockholm, Sweden.*

Background: Long exposure to high glucose in peritoneal dialysis (PD) can lead to peritonel fibrosis (PF), resulting in a decline in ultrafiltration capacity. Transforming growth factor-beta (TGF-beta) plays a crucial role in PF, and it is influenced by the hyperglycolytic state induced by glucose-based PD solutions. Now, new biocompatible PD solutions is being developed, incorporating two complementary approaches: reducing glucose and use osmotic-metabolic agents that offer metabolic benefits to counteract excessive local and systemic glucose exposure. One such agent is L-carnitine. This study aims to investigate the impact of L-carnitine and carnitine acetyltransferase (CrAT), a key enzyme in L-carnitine metabolism, on the modulation of TGF-beta's pro-fibrotic effects.

Methods: CrAT overexpression in mesothelial cells (Met5A) was obtained by a transfection of a plasmid encoding CrAT ORF. The expression of CrAT was assessed at both the gene and protein level using real-time PCR and Western blot. Metabolomic analyses were conducted on WT and CrAT-overexpressing cells. Wild-type (WT) and CrAT-overexpressing cells were also exposed to different concentrations of L-carnitine (50 μM and 2 mM) in the presence and absence of TGF-beta. The expression of markers associated with PF and inflammation was examined.

Results: CrAT overexpression was confirmed and unsupervised hierarchical clustering analysis revealed distinct metabolic profiles between WT and CrAT-overexpressing cells. Notably, their response to TGF-beta differed: treatment with TGF-beta at a physiological L-carnitine concentration (50 μM) significantly increased the expression of fibrotic and pro-inflammatory markers, alpha-SMA, vimentin, IL-6 and IL-1β in WT cells. The exposure to supra-physiological L-carnitine levels reduced the increase of these markers in WT cells. In CrAT-overexpressing cells, TGF-beta failed to modulate alpha-SMA, VIM, IL-6, and IL-1β.

Conclusions: CrAT overexpression could provide valuable insights into the mechanisms by which L-carnitine metabolism effectively regulates the progression of fibrosis and inflammation in PD. Utilizing L-carnitine as an osmo-metabolic agent in PD solutions has the potential to significantly decelerate the advancement of PF.

SA-PO680

Role of Plasminogen Activator Inhibitor-1 (PAI-1) on Phenotype Transition and an Induction of Oxidative Stress in Human Peritoneal Mesothelial Cells (MCs)

Duk-Hee Kang,[1] Chor ho Jo,[2] Dal-Ah Kim,[1] Minsung Lee.[1] *[1]Division of Nephrology, Ewha Womans University College of Medicine, Seoul, Republic of Korea; [2]Hanyang Biomedical Research Institute, Hanyang University College of Medicine, Seoul, Republic of Korea.*

Background: The epithelial-to-mesenchymal transition (EMT) of MCs is an early mechanism of peritoneal dysfunction in peritoneal dialysis (PD). Plasminogen activator inhibitor-1 (PAI-1) was initially known as an inhibitor of fibrinolysis by hindering the proteolytic activity of tissue type plasminogen activator and urokinase-type plasminogen activator, and recently reported to regulate EMT of cancer cells. However, there are no studies on the role of PAI-1 in peritoneal EMT and fibrosis.

Methods: For in-vitro experiment, EMT was evaluated by morphological changes of MCs and the expression of E-cadherin and α-SMA by real-time PCR, WB and ICC. E-cadherin promoter activity, activation of Smad2/3, Erk1/2, AKT, nuclear translocation of snail and MMP expression were assessed. ROS generation was assessed by DCF-DA, MitoSox staining, and NOX mRNA expression. For in-vivo, PD mouse model (C57BL/6) was established by daily infusion of 4.25% glucose-based dialysate (100mL/kg/day) for 4 weeks via intraperitoneal catheter with or without oral administration of PAI-1 inhibitor (Tiplaxtinin, 5mg/kg/day). In 4 weeks of PD, dialysate/plasma ratio of creatinine (D/P_{Cr}) and the 2-hour-dialysate/initial dialysate ratio of glucose (D/D_0 glu) were measured. Effects of Tiplaxtinin on EMT, peritoneal thickening and an expression of markers of oxidative stress were investigated.

Results: TGFβ (1 ng/ml) stimulation resulted in an increased expression of PAI-1 mRNA and protein in MCs. TGFβ-induced EMT was ameliorated by siPAI-1 or Tiplaxtinin (20 μM). TGFβ-induced nuclear translocation of snail and decrease of E-cadherin promoter activity were also alleviated by siPAI-1. siPAI-1 inhibited TGFβ-induced activation of Smad2/3, Erk1/2, AKT and MMP2 expression. Tiplaxtinin alleviated NOX- and mitochondria-mediated ROS production. In mouse PD model, Tiplaxtinin ameliorated the changes in D/D_0 glu and D/P_{Cr}. Also, Tiplaxtinin administration also resulted in a decrease in peritoneal thickness and fibrosis and an increase in ratio of reduced to oxidized glutathione and SOD2.

Conclusions: PAI-1 plays a role in peritoneal EMT and fibrosis, and modulation of PAI-1 expression/activity in MCs could be a novel strategy to prevent peritoneal fibrosis in PD patients.

Unveiling the Role of Mesothelial Cells in Methylglyoxal-Induced Peritoneal Fibrosis

Yu-Syuan Wei, Pei-Shiue J. Tsai. *National Taiwan University, Taipei, Taiwan.*

Background: Being one of the renal replacement therapies for end-stage kidney disease patients, peritoneal dialysis (PD) maintains the lives of about 11% of dialysis patients. However, morphological and functional changes in the peritoneum, which is called peritoneal fibrosis (PF), are inevitable during long-term PD. PF can gradually progress into ultrafiltration failure and has a high correlation with encapsulating peritoneal sclerosis, a complication with high mortality. Despite the presence of glucose degradation products (GDPs) produced by heating high glucose-containing dialysate is considered to be the key component to initiating PF, and methylglyoxal (MGO) is one of the most important GDPs; however, the mechanisms of how MGO induces PF, especially the involvement of mesothelial cells, is still unclear.

Methods: Human mesothelial cells (MeT5A), were cultured and treated with different concentrations of MGO. Cell viability and production of free radicals were evaluated first. Next-generation sequencing was then performed to assess the transcriptomic changes after MeT5A was treated with MGO for 6 hours and 24 hours. Differential expression genes (DEGs) and pathway enrichment analysis based on databases of KEGG and gene ontology (GO) were further analyzed.

Results: When compared with control MeT5A, 2009 and 2516 DEGs were detected, respectively, after 6 or 24 hours of MGO stimulation. GO enrichment analysis showed that most DEGs that appeared at 6 hours were related to extracellular matrix organization (p=0.01); while DEGs that appeared at 24 hours were related to extracellular matrix organization (p=0.00002), type I interferon signaling pathway (p=0.002), wound healing (p=0.006), cell adhesion (p=0.01) and angiogenesis (p=0.01). Although epithelial-to-mesenchymal (EMT) was considered an important phenomenon in peritoneal fibrosis, genes that related to EMT, such as *SNAI1*, *SNAI2*, *CDH1*, and *VIM*, were not significantly changed under our experimental setup. Moreover, proteins that are known to activate fibroblasts trans-differentiation into myofibroblasts, except for *TGFB1*, genes such as *IL1B*, *PDGFA*, *PDGFB*, and *PDGFD* were upregulated significantly.

Conclusions: Our study showed that when mesothelial cells were treated with MGO *in vitro*, they tended not to develop EMT but promoted pro-inflammation response and the activation of fibroblasts.

PPARα Modulator Ameliorates Methylglyoxal-Induced Peritoneal Fibrosis

Yutaka Shinkai, Ryo Tamura, Naoki Ishiuchi, Yosuke Osaki, Yujiro Maeoka, Kensuke Sasaki, Takao Masaki. *Hiroshima Daigaku Daigakuin Ikei Kagaku Kenkyuka, Hiroshima, Japan.*

Background: Peritoneal inflammation and fibrosis remain major obstacles to the long-term maintenance of peritoneal dialysis. In this study, we investigated whether PPARα agonism ameliorates peritoneal inflammation and fibrosis in methylglyoxal (MGO) induced peritoneal injury in mice, as well as in cultured human peritoneal mesothelial cells (HPMCs) and THP-1 cells.

Methods: Peritoneal fibrosis was induced by intraperitoneal injection of MGO in male C57/B6 mice for 3 weeks. The mice were fed normal chow diet with a specific PPARα modulator, pemafibtare (0.3 mg/kg), 3 weeks before MGO injection, and then peritoneal tissues were examined. *In vitro* study, HPMC and THP-1 cells stimulated with IFN-γ were examined with or without pemafibrate treatment.

Results: Pemafibrate increased PPARα expression in the peritoneum. Pemafibrate significantly decreased MGO-induced cell density and peritoneal thickening. In immunohistochemical staining, pemafibrate reduced the number of fibrosis markers α-SMA, TGF-β1, and FSP-1 positive cells and deposition of collagen I and III, the expression of the inflammatory cytokine TNF-α, and macrophage infiltration. In addition, pemafibrate improved the deterioration of the dialysate-to-plasma (D/P) ratio of BUN and glucose and reduced TGF-β1 expression in the dialysate. *In vitro* studies, pemafibrate inhibited IFN-γ-induced activation of fibrosis markers (TGF-β1, fibronectin) in HPMC. In THP-1 cells, pemafibrate promoted anti-inflammatory M2 macrophage polarity and inhibited inflammatory M1 macrophage cytokine production, including IL-1β. Moreover, Pemafibrate suppressed not only AP-1 signaling pathway but also NLRP3 inflammasome and caspase-1 activation in HPMC.

Conclusions: The specific PPARα modulator, Pemafibrate ameliorates peritoneal fibrosis by inhibiting peritoneal inflammation.

SA-PO683

The Role of Myocardin-Related Transcription Factor-Serum Response Factor Signaling in Peritoneal Mesothelial Cells

Daichi Kaikoi, Norihiko Sakai, Yuta Yamamura, Keisuke Sako, Keisuke Horikoshi, Takahiro Yuasa, Taichiro Minami, Shiori Nakagawa, Megumi Oshima, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Miho Shimizu, Yasunori Iwata, Takashi Wada. *Kanazawa Daigaku, Kanazawa, Japan.*

Background: Peritoneal membrane failure is a critical complication of long-term peritoneal dialysis treatment. Peritoneal fibrosis has been known to be involved in the development of peritoneal membrane failure. Therefore, clarifying the mechanisms of peritoneal fibrosis is important. Thus far, myocardin-related transcription factor (MRTF) - serum response factor (SRF) signaling is known to drive the development of various fibrosis. Focal adhesion (FA) and lysyl oxidase (LOX) family mediating collagen cross-linking are also known to contribute to the development of organ fibrosis. However, the involvement of MRTF-SRF signaling in the expression of FA components and LOX family in peritoneal fibrosis is unclear. In this study, we investigated the contribution of MRTF-SRF signaling to the expression of FA components and LOX family using peritoneal mesothelial cells (PMC).

Methods: Mouse primary PMCs were stimulated with transforming growth factor (TGF)-β_1. Then, the expressions of α_1 chain of type I procollagen (Col$I\alpha_1$), FA components and LOX family were evaluated. In addition, the effects of MRTF-SRF signal on their expressions were evaluated in TGF-β_1-stimulated PMCs treated with siRNA targeting MRTF-A/-B or MRTF-SRF inhibitor (CCG-1423).

Results: TGF-β_1 induced the expression of Col$I\alpha_1$, LOX family and FA components (integrins and integrin linked kinase) in PMCs. Their expressions were reduced with siRNAs targeting MRTF-A/-B. In addition, the expressions of FA components were also reduced with CCG-1423. Taken together, TGF-β_1 induced the expression of Col1α_1, LOX family and FA components dependent on MRTF-SRF signaling in PMCs.

Conclusions: MRTF-SRF signaling may contribute to the development of peritoneal fibrosis through TGF-β_1-induced FA components and LOX family in PMCs.

Histone Lactylation Facilitates Peritoneal Mesothelial Cell Senescence and Promotes Peritoneal Dialysis-Associated Fibrosis

Fang Yu, Xiaoyue Wang, Qingli Cai, Yani He, Kehong Chen. *Daping hospital, Army Medical Center, Army Medical University, Chongqing, China.*

Background: Peritoneal fibrosis (PF) is a serious clinical complication in patients undergoing long-term peritoneal dialysis (PD). Recently, histone lactylation has been found to increase with glycolysis and intracellular lactate levels, leading to chronic organ damage. Here, we investigated the role and mechanism of histone lactylation in PD-associated fibrosis induced by high-glucose dialysate.

Methods: Mouse models of PF were constructed by 4.25% glucose peritoneal dialysate combined with methylglyoxal. We used a lactylation enhancer (rotenone) and a lactylation inhibitor (oxamate) to validate the effects of histone lactylation in vivo and in vitro. The parietal peritoneum samples and cultured peritoneal mesothelial cells (PMCs) were analyzed for the senescence, fibrosis, glycolysis, and histone lactylation levels. We generated DcR2 (a senescent marker) knockout mice to verify the effects of histone lactylation by clearing senescent cells. Single-cell RNA sequencing (scRNA-seq) was used to characterize the heterogeneity of PMCs clusters under different lactylation intervention conditions.

Results: We found that lactate and glycolysis levels were significantly higher in the PF group compared to the control group, and immunoprecipitation results also showed enhanced levels of histone lactylation modifications in the PF group. In vitro, we also verified that PMCs exhibited enhanced levels of lactate and lactylation in response to stimulation by high glucose, while we found an increasing expression of cell senescent marker (P16, P21, and DcR2) and senescence-associated secretory phenotype. Then we found that PMCs senescence was significantly enhanced in the lactylation-enhanced group, while the lactylation-inhibited group alleviated PMCs senescence. In the PF model of DcR2 knockout mice, compared with the wild group, the peritoneal thickness and the expression of fibrotic markers were significantly reduced. The transcriptomic analysis using scRNA-seq revealed the activation of senescence-related pathway in PMCs clusters of PF group, whereas the senescence-related pathway was down-regulated in the lactylation-inhibited group. The results indicated that histone lactylation may promote PF through PMCs senescence.

Conclusions: Histone lactylation may play a vital role in the progression of PD-associated fibrosis by promoting PMCs senescence.

MMP-12 Inhibitor Ameliorates the Peritoneal Fibrosis in a Peritoneal Dialysis (PD) Mouse Model

Emi Hasegawa,[1] Ryoko Baba,[2] Keiji Kokubu,[2] Tomohiro Shirouzu,[1] Yoichiro Nagai,[1] Hiroshi Ishida,[1] Ikutaro Furuno,[1] Kazutoshi Nakazono,[1] Tetsu Miyamoto,[1] Masaharu Kataoka,[2] Hiroyuki Morimoto.[2] *[1]Kidney Center, University of Occupational and Environmental Health School of Medicine, Kitakyushu, Japan; [2]Sangyo Ika Daigaku, Kitakyushu, Japan.*

Background: Continuous exposure to non-physiological fluids during peritoneal dialysis (PD) is associated with pathological responses, such as sustained microinflammation, leading to tissue fibrosis and angiogenesis. We reported that submesothelial expression of matrix metalloproteinase-12 (MMP-12), an elastin proteinase secreted by macrophages, was enhanced by continuous exposure to peritoneal dialysis fluid(PDF). In this study, we investigated the effects of MMP-12 inhibitor on peritoneal fibrosis.

Methods: Morphological changes of the peritoneum in a PD mouse model were histologically analyzed in a peritoneal dialysis fluid (PDF) group (intraperitoneal PDF instillation once a day for 6 weeks), a control group (saline), and a MMP-12 inhibition group (PDF + MMP-12 inhibitor).

Results: Elastica van Gieson staining showed that the elastin just below the mesothelial cell layer was disorganized and fragmented in the PDF group, compared with the control group. Elastin fragments were observed also in collagenous thickened submesothelial tissue in the PDF group, not in the control group. In the MMP-12 inhibition

group, no degradation of the elastin or no elastin fragments in submesothelial tissue was observed. Mesothelial cell swelling, peritoneal thickening, and increased collagen fiber expression observed in the PDF group were significantly suppressed in PDF+MMP-12 inhibition group.

Conclusions: The results suggest that MMP-12 induced by PDF instillation could be associated with local microinflammation in the peritoneal tissue, suggesting that MMP-12 may be an therapeutic target to relieve peritoneal damage.

SA-PO686

An Unusual Dietary Cause of Hyperphosphatemia and Hypocalcemia Mimicking Tumor Lysis Syndrome

Alvin G. Kwon, Melissa Baker, Hanny Sawaf. *Cleveland Clinic, Cleveland, OH.*

Introduction: In healthy individuals, high dietary phosphate intake is rarely emphasized since there is no correlation proven between phosphate intake and serum inorganic phosphate concentration. Hyperphosphatemia has a variety of etiologies other than traditionally focused cellular shifts. High phosphorus could cause more acute kidney injury (AKI) events and acute phosphate nephropathy can cause AKI in rare cases. Additionally, COVID-19 infection can alter the physiology of phosphate regulation and the severity of AKI. Here we present a patient with COVID-19 infection and sudden onset severe hyperphosphatemia and hypocalcemia in the setting of AKI who was revealed to have a substantial dietary intake of phosphate that improved with the improvement of AKI.

Case Description: The patient is a 52-year-old male who presented with shock in the setting of COVID-19 pneumonia. Further laboratory tests found that he had severe hyperphosphatemia (10.0 mg/dL), hypocalcemia (6.5 mg/dL), and AKI with a serum creatinine that peaked at 8.53 mg/dL. Ionized calcium was also low at 0.96 mmol/L and his uric acid level was elevated at 11.1 mg/dL. These electrolyte derangements initially raised concern for tumor lysis syndrome (TLS). However, there was no evidence of malignancy on physical examination or imaging. It was noted after further history taking that the patient drank 2 liters of soft drinks daily. This unusual diet in the setting of severe AKI likely led to hypocalcemia. The patient's renal function improved with the improvement of his shock. The resolution of the patient's AKI also normalized his hyperphosphatemia and hypocalcemia.

Discussion: In the setting of AKI, dysregulation of the phosphate transporter may interfere with phosphate balance. Although hyperphosphatemia is commonly seen in patients with severe AKI, a dietary cause of severe hyperphosphatemia leading to hypocalcemia is not well recognized. This patient's phosphate intake through soda alone was 300-400 mg a day and phosphorous from food additives is absorbed at a much higher rate than natural sources. This intake likely precipitated a sudden hyperphosphatemia in the setting of the patient's AKI which resulted in hypocalcemia, mimicking TLS. Further studies investigating hyperphosphatemia being the cause of hypocalcemia in instances other than TLS should be followed.

SA-PO687

Intravenous Ferric Carboxymaltose-Induced Severe Hypophosphatemia

Mohammad Gul Yousaf Khan, Shatha A. Herz Allah, Gurwant Kaur. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Introduction: Hypophosphatemia (HP) is a rare and severe adverse effect of some intravenous (IV) iron formulations. Here, we present a case of a patient with severe HP after receiving IV ferric carboxymaltose (FCM) due to renal phosphate wasting with high Urine fractional excretion of PO4 (FEP).

Case Description: A 19-year-old female was initially evaluated in the clinic for Iron deficiency due to heavy menstrual bleeding. She received one dose IV FCM because of inability to tolerate oral medications due to gastroparesis. A few days later she had severe generalized bone pains along with weakness, fatigue, nausea, chills, and headache. Labs showed isolated low serum phosphorous (S. PO4) of 1.9 mg/dl (normal 2.5-4.5 mg/dl). She was started on oral potassium-phosphate (K-PO4). Due to persistent HP and symptoms, she was admitted for further management. At the time of admission, labs revealed persistent HP. Remaining serum electrolytes were within normal range. Urine FEP was >55% with high 24-hour PO4 in the urine of 2.305g/24 hours (0.400-1.300). This favored renal PO4 wasting. Fibroblast growth factor (FGF-23) was 58 pg/ml (normal range was <59 pg/ml as per Mayo Clinic lab). She was managed with IV as well as oral PO4 supplements. She was discharged on oral PO4 supplements along with calcitriol. Follow up clinic visit within 1 month showed that her S.PO4 levels normalized to 4 mg/dl. She was able to come off oral PO4 supplementation. This further supports that it was a short-term effect from IV FCM use.

Discussion: HP has been reported with the use of IV iron preparations, more commonly with IV FCM as compared to other IV formulations. IV FCM induced HP is typically associated with increase in FGF-23 which causes increase in urinary phosphate excretion and suppression of 1,25(OH)2D concentration. Common symptoms include generalized weakness, fatigue, bone, and muscular pain. It is recommended to measure S. PO4 in patients who present with the above-mentioned symptoms. Measuring FEP or TMP/GFR (maximum rate of tubular phosphate reabsorption to the glomerular filtration rate) to confirm intravenous iron-induced renal phosphate wasting has been suggested. Treatment options include activated vitamin D along with phosphate supplements and therapeutic anti-FGF23 antibody.

SA-PO688

The Association Between Urine Oxalate and Citrate May Not Be Diet Driven

Megan Prochaska, Fredric L. Coe, Elaine M. Worcester. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Higher urine oxalate excretion has been associated with higher urine citrate excretion and the magnitude of the association is larger in non-kidney stone patients compared with kidney stone patients. The mechanism for this association may be due to simultaneous dietary intake oxalate and citrate in fruits and vegetables or transporter linkage of SLC26A6 and NaDC1 in the kidney.

Methods: Eleven participants, including 3 kidney stone patients, were admitted to the clinical research center and given sodium oxalate. Timed pre-sodium oxalate (1) and post-sodium oxalate (6) urine samples were collected every hour. Urine composition was measured and excretion rates of oxalate and citrate calculated at each period. Mean and standard error were graphed per period and mixed methods longitudinal models were generated to compare change over time versus pre-oxalate value (Period 1) of oxalate and citrate excretion.

Results: Eight of the 11 participants were women with mean age 54 years. Urine oxalate and citrate excretions were higher than pre-oxalate (Period 1) at Periods 4 to 6, and Periods 4 and 5, respectively (Figure 1).

Conclusions: After consumption of sodium oxalate participants had an increase in urine oxalate excretion, as expected, but they also had an increase in urine citrate excretion. The association between oxalate and citrate excretion may not be completely driven by dietary intake.

Funding: NIDDK Support

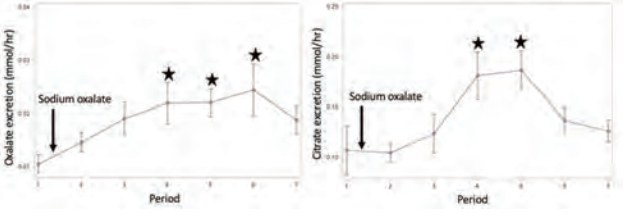

Figure 1. Excretion of oxalate and citrate per study period. Period 1 represents pre-sodium oxalate baseline value. Periods 2-7 are post-sodium oxalate and timed every 1 hour. Starred periods denote where an indiviudal period was statistically higher than Period 1 in the mixed methods longitudinal model.

Quantitative Assessment of Overall Acid-Base Balance in Humans

Yasin R. Badawy, Priya M. Rawal, Fredric L. Coe, Elaine M. Worcester, Megan Prochaska. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Kidney stones are common and understanding mechanisms contributing to stone formation is important in developing effective prevention and treatment strategies. This study aimed to investigate the impact of various predictors on urine pH and acid-base homeostasis, which play a significant role in kidney stone formation.

Methods: Kidney stone patients and non-kidney stone patients provided 24-hour urine collections while at home and eating a free choice diet. A pH titration analysis was performed and acid-base parameters were measured in the urine to assess acid-base balance. Basic statistics and linear models were developed to characterize change in urine acid-base chemistry as a function of demographic and urine factors.

Results: There were 246 participants with mean age 54 years, 133 female, and 190 kidney stone patients. In multivariate analysis, higher age was associated with lower urine pH (-0.005 per year, $p<0.001$) but there was no association by sex. In separate multivariate models, male sex was associated with lower acid excretion (-0.6 meq/mM creatinine, $p<0.001$) and lower urine anions (-0.5meq/mM creatinine, $p<0.01$) compared with female. In separate multivariate models, higher age was associated with higher urine anion (0.02 meq/mM creatinine per year, $p<0.001$) and higher titratable acidity (0.01 meq/mM creatinine per year $p<0.001$).

Conclusions: This study provides valuable insights into the relationships between demographic factors and urine acid-base chemistry. The association between age and sex with urine pH, urine anions, acid excretion, and titratable acidity underscores the importance of age and sex as factors in acid-base balance. This may also suggest different mechanisms for kidney stone formation in older adults and between men and women and is consistent with known data that stone types may change with aging and there are differences between men and women.

Nephrolithiasis as a Manifestation of Primary Hyperaldosteronism Secondary to Adrenal Adenoma

Frida Margarita de la Vega Méndez,[1] Giovanna Y. Arteaga Muller.[2] *[1]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; [2]Christus Muguerza Sistemas Hospitalarios SA de CV, Monterrey, Mexico.*

Introduction: The primary hyperaldosteronism has been considered a rare cause of secondary hypertension with a prevalence up to 12% The variability of presentation of this syndrome is too wide and sometimes it is not the usual one The following is a case of a patient who started with hypertension and recurrent kidney calculi due to primary hyperaldosteronism caused by an adrenal adenoma.

Case Description: 33 years-old male with no significant medical history who presented to hospital due to hypertensive episodes Outpatient laboratory tests were performed and hypokalemia plasma renin activity was requested and reported 0.39 and aldosterone at 20 Primary hyperaldosteronism was suspected After that the patient begins with intermittent episodes of lower abdominal pain, irradiated to right groin and hematuria. Laboratory tests creatinine 0.77 urea 21 Na 145 k 2.5 A renal Doppler ultrasound was performed and reported bilaterally renal calculi the intrarenal circulation was in normal parameters in both kidneys Abdominal tomography was practiced where bilateral renal lithiasis is observed and a stone in the upper third of the right ureter of 3.2 mm diameter A ureterolithotomy was performed the analysis of the calculus reported 60% calcium oxalate 40% calcium phosphate During the following 4 years the patient continued with episodes of urolithiasis without other alterations In the last episode the patient presented again in the emergency room due to abdominal pain and a well-defined hypodense nodular image towards the left adrenal gland was found in the abdominal tomography related to adenoma and multiple intrarenal stones microcysts and simple cysts were observed with presence of free intravesical stones The patient received medical management and lithotripsy was performed after 1 month a laparoscopic radical left adrenalectomy was performed without complications.

Discussion: There are few cases reported in the literature of patients with primary hyperaldosteronism and recurrent nephrolithiasis It has been reported that chronic mineralocorticoid administration and primary hyperaldosteronism facilitate renal calcium excretion This case alerts us of the importance to remember the renal physiology of calcium in hyperaldosteronism and it is one of the most variable presentations and for which the patient will seek medical attention quickly.

SA-PO691

Characterization of a Cohort with Kidney Stones and Enteric Hyperoxaluria

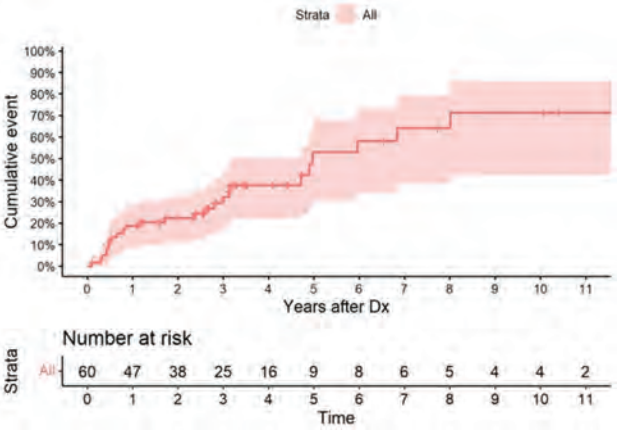
Han Ro,[1] Ryan Tatton,[2] Stephen R. O'Neill,[2] Ramila A. Mehta,[1] John C. Lieske,[1] Mira T. Keddis.[2] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Mayo Clinic, Scottsdale, AZ.*

Background: Enteric hyperoxaluria (EH) is a risk factor for kidney stones. The relationship between risk factors and the natural history remains poorly defined. To address this knowledge gap, we created an EH patient registry.

Methods: The electronic medical record at all 3 Mayo Clinic sites was searched to identify patients with a known cause of EH, 24-hour urine oxalate (Uox) ≥40mg, and history of kidney stones. Symptomatic stone events were defined by the presence of renal colic, stone passage associated with urinary tract infection or hematuria, or procedure for stone removal.

Results: We report on data from the first 74 abstracted patients. The largest group of 34 (46%) had bariatric surgery (29 (85%) of these were Roux En-Y Gastric Bypass (RYGB)), 20 (28%) inflammatory bowel disease (IBD), 11 (15%) pancreatic insufficiency, 5 (7%) short bowel syndrome, 1 (1%) celiac, and 1 (1%) other fat malabsorptive conditions. Mean age at first stone diagnosis was 48.6 ±14.1 years and BMI 31.6±8.71 kg/m^2. EH diagnosis was on average 8 years after first stone event and mean UOx was 65.3±30.9 mg/24 hr. Follow-up after EH diagnosis was available for 60/74 patients, 78% of whom had a prior stone event (average n=4, 45%>2 events). Those with bariatric surgery were more likely to be female (p=0.002), have a higher BMI (p<0.001), and experience asymptomatic kidney stones before surgery (p=0.02). After a median follow-up of 3 years, the 5-year cumulative stone event rate after EH diagnosis was 52.9% (Figure) and did not differ by EH cause.

Conclusions: EH patients experience a high rate of stone recurrence of up to 53% at 5 years regardless of underlying etiology. RYGB is the single most common cause, however other conditions associated with fat malabsorption are also common. These preliminary data strongly support continued efforts to develop a robust EH patient registry to identify specific phenotypic features that are associated with stone disease risk to inform study design for novel therapeutics.



SA-PO692

Injection of Silicone for Cosmetic Gluteal Augmentation Leading to Hypercalcemia

Anita Kamarzarian, Masoud Haghi, Phuong-Chi T. Pham, Golriz Jafari. *UCLA Medical Center Olive View, Sylmar, CA.*

Introduction: Hypercalcemia can be seen in many common Granulomatous disease such as Sarcoidosis, Tuberculosis, and Granulomatosis with Polyangiitis (PTH-indipendent). Silicon injection for cosmetic procedures have also been associated with granuloma formations and subsequent hypercalcemia.

Case Description: 58 yo Hispanic female presents for evaluation of chronic non-healing bilateral gluteal wounds. She has a history of CKD stage 3, nephrolilithiasis, and chronic hypercalcemia not previously worked up. She also has a history of Silicon injections into bilateral Gluteal regions in Mexico for cosmetic purspose 25 years ago. LABS: Sodium-136 mmol/L, Potassium-5.0 mmol/L, Chloride-104 mmol/L, CO2-22 mmol/L, BUN-62 mg/dL, Creatinine-2.21 mg/dL, Calcium-11.0 mg/dL, Corrected Calcium-12.92mg/dL, Albumin-1.6 g/dL, Phosphorus-3.6 mg/dL, Magnesium-2.1 mg/dL, SPEP/UPEP Normal, TSH-1.665 uIU/mL, PTH<2 pg/ml, PTH-RP-16 pg/ml (WNL), Vitamin D 25-OH 12ng/ml, Vitamin D2 1,25-OH 8 pg/ml, Vitamin D3 1,25-OH 60pg/ml, Urine 24H Calcium 283.8 mg/24 HR, Alk Phos 246 U/L.

Discussion: Investigation revealed **depressed** PTH, **Low** vitamin D25 level and **elevated** Vitamin D2-1,25 level. Imaging including CT and PET showed evidence of significant long standing calcified granulomas. Patient also had biopsy of the gluteal wounds which showed foci of foreign body-type multinucleated giant cell reaction and extensive calcifications. Normally conversion of Vitamin D 25-OH to Vitamin D2 1,25 OH occurs in the kidney via a 1-hydroxylase enzyme that is under the physiologic control of PTH, FGF-23, and the serum phosphourus level. In granulomatous diseases, this conversion is occurring independent of these controls inside giant cells. The high levels of converted Vitamin D2 1,25-OH causes increased intestinal calcium absorption and increased bone resorption leading to hypercalcemia.

CT of Abdomen showing extensive soft issue calcified granulomas in gluteal tisssue

SA-PO693

An Unusual Case of Hypercalcemia

James Flatow, Mariana A. Chang, Farid Arman, Pedro D. Mogrovejo Pintado, Qais Al-Awqati. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Antibiotic-eluting calcium sulfate beads are a method of local antibiotic delivery in infections of prosthetic material. Advantages include fewer off-target effects and greater antibiotic concentration at the site of infection than with systemic antibiotics. Hypercalcemia is a rare complication of this that has received little study to date.

Case Description: A 67-year-old man who had undergone endovascular repair of an abdominal aortic aneurysm years prior, presented with septic shock. CT demonstrated a collection in the residual aneurysm sac suggestive of an infected graft. The patient underwent graft removal with gentamicin-eluting beads placed retroperitoneally. He received 6g of calcium chloride intraoperatively and 4g of calcium gluconate over post-operative day (POD) 1; with no additional supplementation afterwards. On POD4, a basic metabolic panel showed worsening acute kidney injury (baseline sCr 0.9 mg/dL) and hypercalcemia (Table 1). Multiple etiologies for hypercalcemia were considered, including immobilization and malignancy, but none was thought to explain the acuity of the rise. The intravenous calcium administered perioperatively was expected to have been excreted by this time, and he was not on any medications associated with hypercalcemia. Workup revealed appropriately low PTH, PTHrP and low-normal Vitamin D 25-OH and 1-25 OH, pointing to the antibiotic-eluting calcium beads as main etiology. The patient was treated with aggressive fluid resuscitation and 4 doses of calcitonin, with improvement in serum calcium and creatinine as seen in Table 1.

Discussion: We present a case of hypercalcemia resulting from intraoperative placement of gentamicin-eluting calcium beads, which can occur 72-hours after insertion, and illustrates the importance of recognizing potential toxicity of local antibiotic vehicles.

Chemistries during post-operative period

Calcitriol-Mediated Hypercalcemia in Mesothelioma

Fnu Parveen. *Baylor College of Medicine, Houston, TX.*

Introduction: Hypercalcemia (hyperca) is common in several hematological and solid organ malignancies however hyperca has rarely been reported in mesothelioma. We report an unusual case of calcitriol mediated hyperca in mesothelioma.

Case Description: An 80-year-old gentleman with stage IV chronic kidney disease was admitted for severe hyperca. Serum calcium (Ca) corrected for hypoalbuminemia 15 mg/dL. He was diagnosed with right lung mesothelioma two months prior followed by first cycle of nivolumab/ipilimumab(Nivo/Ipli) a month prior. He had mild hyperca 6 months prior to mesothelioma diagnosis which progressed despite stopping vitamin D and Ca supplementation. Workup shown in Table 1. Initial imaging revealed concern for lytic lesions of pelvis however subsequent workup including serum free light chains, serum and urine protein electrophoresis, bone and PET scan were negative for plasma cell dyscrasias. Further Imaging revealed 2.3cm left renal mass suspicious of renal cell carcinoma (RCC) however PET scan did not show any uptake into the kidneys. After acute treatment of hyperca the patient continued treatment with immunotherapy(IT) to which he responded.

Discussion: Hyperca from malignancy occurs from either tumor secretion of parathyroid hormone-related protein or tumor production of calcitriol etc. Calcitriol induced hyperca from Nivo/Ipli has also been reported. In our case calcitriol mediated hyperca from mesothelioma is the most plausible etiology. Even though calcitriol levels prior to IT are not available hyperca developed prior to starting IT. Workup of hematologic malignancy was negative and PET scan did not show FDG uptake by the renal mass. Finally his Ca levels improved with further IT and improvement in mesothelioma. Although FDG uptake in RCC has a lower sensitivity and Nivo/Ipli can also treat RCC we believe the time-course of events makes mesothelioma the more plausible etiology.

Table 1

Test	Value

SA-PO695

Hypercalcemia Associated with Severe Tophaceous Gout

Sirisha Gudlawar. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Refractory gout remains a persistent challenge leading to significant functional impairment. Hyperuricemia is strongly associated with chronic kidney disease. Severe hypercalcemia from gout is a rare phenomenon and we, herein present a case with chronic tophaceous gout presented with severe hypercalcemia leading to acute kidney injury (AKI).

Case Description: 40-year-old male with history significant for chronic tophaceous Gout presented to the emergency department from clinic for further evaluation of hypercalcemia and AKI noted on the laboratory results. His symptoms were arthralgias and muscle weakness. Vital signs notable for blood pressure of 150/70 mmHg, Heart rate 92 beats per minute. Laboratory results significant for serum creatinine 3.80 mg/dL (baseline of 1.3 mg/dL), calcium 12.9 mg/dL, albumin 2.9 g/dL, corrected calcium is 13.4 mg/dL, ionized calcium 1.76 mmol/L, phosphorus 4.7 mg/dL, parathyroid hormone 11.1 pg/mL, Thyroid stimulating hormone is 3.58 ulU/mL, 25-hydroxy vitamin D 48.6 ng/mL,1-25, dihydroxy vitamin D was 85.9 ng/mL, uric acid is 11 mg/dL, PTHrP 3.3 pmol/L, work-up for myeloma was negative. X-Ray of the extremities showed multifocal partially calcified tophaceous gout. CT scan of the chest, abdomen and pelvis with no evidence of lymphadenopathy or granulomatous process. Biopsy of the skin lesions was consistent with Gout with calcifications. Given the above findings, it was thought to be secondary to increased production of 1,25 dihydroxy vitamin D (calcitriol) due to granulomatous inflammation caused by severe gout and he was treated with calcitonin x 3 doses, intravenous hydration and prednisone 40 mg daily. His calcium improved to 10 mg/dL, and was discharged home.

Discussion: The most common cause of hypercalcemia is primary hyperparathyroidism, however in the hospital setting it is malignancy. Chronic tophaceous gout results in granulomatous inflammation leading to increased production of calcitriol resulting in hypercalcemia. This is extremely rare and our case illustrates the importance of understanding the pathophysiology for hypercalcemia in chronic gout. Treatment includes primarily corticosteroids.

SA-PO696

Refractory Hypercalcemia: Unmasking Pneumocystis jirovecii Pneumonia in a Renal Transplant Recipient

Wern Lynn Ng,[1] Lillian Sangha,[1] Benjamin Ravichander,[1] Evelyn J. Calderon Martinez,[1] Lay She Ng,[2] Gabriela M. Calderon Barahona,[1] Jia Yi Tan,[3] Seema Sharma Gautam,[1] Irina Mishagina.[1] *[1]UPMC Harrisburg, Harrisburg, PA; [2]Mayo Clinic Minnesota, Rochester, MN; [3]New York Medical College, Newark, NJ.*

Introduction: Refractory hypercalcemia in renal transplant recipients is a challenging consequence of Pneumocystis jirovecii pneumonia (PJP). Accurate diagnosis is crucial, as PJP can present subtly, leading to increased mortality rates. In renal transplant patients, hypercalcemia frequently accompanies PJP and serves as a vital diagnostic clue. In this report, we present a case of refractory hypercalcemia resulting from PJP in a renal transplant recipient, highlighting the need for effective recognition and management.

Case Description: A 57-year-old male with a history of renal transplant, currently on immunosuppressive therapy, who was admitted to the hospital with fevers and general malaise. Laboratory findings revealed marked hypercalcemia (15.6 mg/dL) with suppressed parathyroid hormone (PTH) levels. Extensive Infectious investigations, including urinalysis, chest x-ray, commuted tomography (CT) of the chest, abdomen, and pelvis, blood cultures, viral panel tests yielded no significant findings. Despite administration of isotonic saline, calcitonin, and bisphosphonates, the patient's hypercalcemia remained unresponsive. Further laboratory studies revealed normal PTH-Related Protein (14 pg/mL), elevated 1,25 dihydroxy vitamin D (133 pg/dL), and normal 25-dihydroxy vitamin D (52 ng/dL). Due to persistent fever in an immunosuppressed individual, an extensive infectious investigation was conducted, including tests for various viruses and pathogens. A breakthrough was achieved when the qualitative PCR test for PJ returned positive. The patient was promptly initiated on systemic steroids and atovaquone therapy targeting PJP. Serum calcium returned to normal after completion of therapy.

Discussion: Hypercalcemia in renal transplant patients with PJP results from a granulomatous-like mechanism. Macrophages and monocytes in granulomas play a vital role by producing 1-alpha hydroxylase, converting calcidiol to calcitriol, the active form of Vitamin D. Calcitriol stimulates increased calcium absorption in the intestines and kidneys and calcium mobilization from bone tissue, leading to hypercalcemia. Therefore, when evaluating a renal transplant patient presenting with hypercalcemia, it is crucial to consider PJP as a potential differential diagnosis.

Neonatal Hypocalcemia and Maternal Hypercalcemia: Exploring the Potential Connection to Parathyroid Adenoma and CaSR Mutations

Jhao-Jhuang Ding,[1] Shih-Hua P. Lin,[1] Min-hua Tseng.[2] *[1]Tri-Service General Hospital, Taipei, Taiwan; [2]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan.*

Background: This study aims to investigate the relationship between neonatal hypocalcemia and maternal hypercalcemia, and to explore potential genetic predispositions related to parathyroid adenoma and CaSR mutations in mothers.

Methods: Neonates presenting with late-onset (≥3 days) hypocalcemic tetany or seizures, low serum total calcium, high serum phosphorus, and inappropriately low or normal iPTH levels suggestive of hypoparathyroidism were prospectively enrolled. Hypomagnesemia, high phosphate intake, and kidney function impairment were excluded. Following enrollment, all mothers were evaluated for potential causes of neonatal hypocalcemia.

Results: Seven full-term newborns (six males, one female) and their mothers were enrolled. All newborns were diagnosed with transient hypoparathyroidism secondary to maternal hypercalcemia. To investigate the cause of maternal hypercalcemia, maternal serum calcium, phosphorus, iPTH levels, and parathyroid scans were assessed. Five mothers were found to have parathyroid adenoma, and one was confirmed to have a CaSR loss-of-function genetic mutation. All newborns were treated with oral calcium gluconate combined with cholecalciferol or calcitriol. After approximately one month of treatment, serum calcium and phosphate levels normalized, and the iPTH-Ca correlation was restored. Following parathyroidectomy in mothers with parathyroid adenoma, serum calcium levels normalized, but elevated iPTH levels persisted for months. The mother with the CaSR loss-of-function mutation exhibited a similar trend in serum calcium and iPTH levels.

Conclusions: This study underscores the importance of evaluating maternal calcium homeostasis in cases of neonatal hypocalcemia and highlights a potential genetic association between neonatal symptoms and maternal parathyroid adenoma and CaSR mutations. Further research is warranted to understand the genetic basis and optimize management strategies for both conditions.

SA-PO698

Trends in Serum Parameters Levels According to Renal Function Following Denosumab

Jin Hyeog Lee. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Osteoporosis and chronic kidney disease (CKD) are major risk factors for fracture. Denosumab is widely used to treat osteopenia in patients with CKD; however, its effect on phosphate, calcium, and parathyroid hormone (PTH) levels has not been fully elucidated.

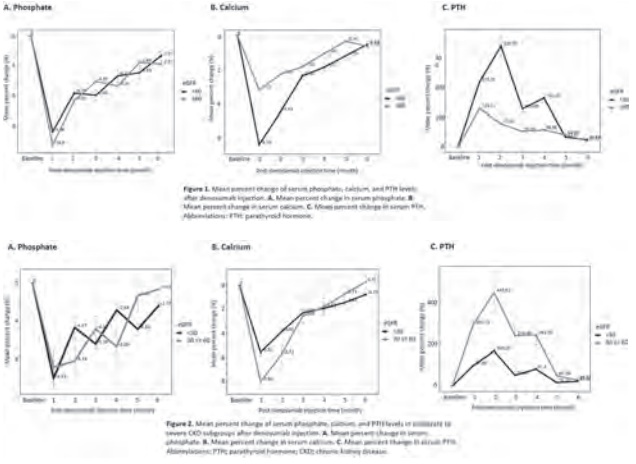
Methods: A retrospective observational study was performed on patients from three hospitals in Korea who were treated with denosumab between November 2016 and December 2021. We compared the mean percentage change in serum phosphate, calcium, and PTH levels from baseline to six months post-denosumab treatment. Among the 11 586 patients (median age, 70.0 years; 89.2% female) included in this study, 10 069 (87.9%) had an estimated glomerular filtration rate (eGFR) over 60 mL/min/1.73 m^2 and comprised the preserved kidney function group. Patients with an eGFR under 60 mL/min/1.73 m^2 (n = 1 517) comprised the reduced kidney function group.

Results: One month after denosumab administration, serum calcium (preserved kidney function group: -3.18%; reduced kidney function group: -6.35%) and phosphate levels (preserved group: -10.9%; reduced group: -9.56%) decreased and serum PTH levels increased (preserved group: +123.54%; reduced group: +216.93%). However, all parameters returned to baseline six months after treatment. Six months after denosumab treatment, a higher rate of hypocalcaemia was observed in the reduced kidney function group relative to that of the preserved kidney function group (4.5 and 8.3%, respectively, $p < 0.001$).

Conclusions: One month post-denosumab treatment, serum phosphate and calcium levels significantly decreased and PTH levels increased; however, these changes were transient. When using denosumab in reduced kidney function patients, close monitoring and replacement of calcium and vitamin D are required.

Hypocalcemia at baseline and 6 months after denosumab treatment

	Overall	Reduced kidney function group (%)	Preserved kidney function group (%)	P-value
	N=11,586 (100.0)	N=1,517 (13.1)	N=10,069 (86.9)	
At baseline	883 (9.1)	137 (10.4)	746 (8.9)	0.091
At 6 months after denosumab treatment	287 (5.0)	67 (8.3)	220 (4.5)	<0.001



SA-PO699

Licorice-Induced Hypocalcemia: A Rare Outcome of Chronic Licorice Consumption

Nabiha Mustafa,[1] Mohammad R. Khan,[1] Areebah Qadir,[1] Aemen S. Khakwani,[5] Sana Ali,[3] Aamna F. Hameed,[2] Sohaib Rasool,[1] Usman A. Khan.[4] *[1]Bakhtawar Amin Medical and Dental College, Multan, Pakistan; [2]Shifa College of Medicine, Islamabad, Pakistan; [3]Allama Iqbal Medical College, Lahore, Pakistan; [4]Oklahoma University Medical Center, Oklahoma City, OK; [5]Suburban Community Hospital, Norristown, PA.*

Introduction: A syndrome mimicking mineralocorticoid excess resulting in hypokalemia, hypertension, and hypernatremia is a common occurrence after chronic licorice consumption, according to various published case reports. However, licorice induced hypocalcemia with eunatremia is rarely reported. The authors present a case of a patient diagnosed with hypocalcemia due to excessive licorice consumption.

Case Description: 69 year old male presented to our department with primary complaints of oral numbness, muscle cramping, and paresthesia. On admission, he was hypertensive (160/90mmHg) with a heart rate of 84 bpm. An initial lab analysis showed hypocalcemia [Ca, 2.7 mg/dL], hypokalemia [2.7 mEq/dL], and hypomagnesemia [1.1 mg/dL]. The patient was immediately started on IV potassium and calcium replacement, and spironolactone. Dietary history revealed that the patient had been consuming licorice excessively since 2 and half months due to its presumed anti-inflammatory action. The replacement therapy was continued to day 3 and then stopped. The laboratory results were monitored till day 7. Follow-up on day 28 showed normal values as summarized in Table 1.

Discussion: Glycyrrhetic acid and Glycyrrhizic acid are two components of Licroice root extract that have been shown to mimic mineralocorticoid excess by inhibiting enzyme 11ßhydroxysteroid which converts cortisol to cortisone. This results in an increased plasma half-life of cortisol, which binds to aldosterone receptors in renal tubules and activates them. Eventually, the volume overload increases sodium, calcium, and magnesium delivery to the distal tubules. Sodium is absorbed in exchange for calcium and magnesium which induces hypocalcemia and hypomagnesemia. Low magnesium

also impairs the function of the Parathyroid hormone. Licorice is quite popular among the geriatric American population because of its assumed anti-oxidant properties and this case report highlights the significance of physician's knowledge regarding its chronic use and but life-threatening complication of hypocalcemia.

Table 1: Laboratory analysis

Day	Potassium [mEq/dL]	Calcium [mg/dL]
1	2.7	5.7
3	3.3	7.1
7	3.9	8.2
28	3.8	8.1

SA-PO700

Years of Hypomagnesemia due to an HNF1B Mutation

Isaac I. Kim, Prakash S. Gudsoorkar. *University of Cincinnati, Cincinnati, OH.*

Introduction: Mutations in the hepatocyte nuclear factor 1B (HNF1B) are an inherited cause of renal malformation that is accompanied by magnesium wasting and a distal tubular dysfunction like Gitelman syndrome. We describe a patient in late adulthood who has hypomagnesemia and an HNF1B mutation.

Case Description: A 39-year-old female presented with intractable nausea and loose stools. She denied any family history of kidney disease. Her laboratory findings revealed a magnesium of 1.0 mg/dL and a potassium of 3.3 mg/dL. Her FeCa was < 0.1% and FeMg was 5.6%. She reported multiple visits to her PCP for IV magnesium infusions twice per week in addition to oral supplementation. She otherwise denied any symptoms of paresthesia or numbness. Genetic testing was performed and revealed a deficiency in HFNB1. She was started on amiloride in an effort to decrease magnesium supplementation. Her subsequent visit revealed a magnesium of 1.4 mg/dL. Renal ultrasound also revealed an innumerable amount of bilateral renal cysts, one of which measured 2.5 cm on the upper pole of the right kidney. No solid renal mass was identified.

Discussion: HNF1B is a transcription factor that is highly expressed in multiple organs that include the kidney, pancreas, and liver. It plays a role in morphological renal development in the form of cystic kidney disease, but also can increase the risk of renal tubular dysfunction and progressive CKD. An HNF1B-related hypomagnesemia may be associated with alteration of the Na/K ATPase in the distal convoluted tubule (DCT). Hypocalciuria occurs when sodium reabsorption in the DCT is impaired, as in Gitelman syndrome and in mutation of the *FXYD2* gene. Our patient likely had longstanding subclinical HNF1B-related hypomagnesemia but was exaggerated in late adulthood by gastrointestinal losses. She has been asymptomatic but still requires frequent magnesium infusions despite amiloride use.

Pertinent lab findings of the patient

Parameter	Initial Presentation	Follow-up 5 months later	Normal Range
Creatinine (mg/dL)	0.68	0.88	0.6-1.3
Magnesium (mg/dL)	1.0	1.4	1.5-2.5
Calcium (mg/dL)	9.5	9.9	8.6-10.3
Phosphorus (mg/dL)	3.4	3.9	2.1-4.7
Albumin (g/dL)	Not obtained	4.6	3.5-5.7
FeCa (%)	< 0.1	< 0.1	> 1
FeMg (%)	5.6	Not obtained	< 4
PTH (pg/mL)	29.5	50.0	12.0-88.0

SA-PO701

Diagnostic Dilemma of a Case of Complex Refractory Hypomagnesemia

Osama Elhilali, Irtiza Hasan, Charles W. Heilig. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: Magnesium (Mg^+) diisorders are usually less common & not well investigated. Renal Mg^+ wasting can be associated with Barter syndrome, Gitelman syndrome, Familial renal magnesium wasting, Hepatocyte nuclear factor-1-beta gene mutations, Epidermal growth factor gene mutation, or Cyclin M2 mutations.

Case Description: A 69-year-old white female with PMH of CKD Stage 2, HTN, DM, Sarcoidosis, presented with severe chronic hypomagnesemia. Her daughter also has chronic hypomagnesemia. She was on pantoprazole & HCTZ for >7 years, HCTZ was discontinued 1 year prior to the presentation. Now on oral & Mg^+ IV infusion (4 gm/month). Other medications included Spironolactone, Gabapentin, Glyburide, Lantus, Aspirin, and Mepolizumab. Pantoprazole was discontinued, continued on oral Mg^+, but increased Mg^+ IV infusions (4 gm/week). Despite these changes her Mg^+ level was still ranging between 0.9 to 1.3 mg/dL. Later stopping spironolactone was also unsuccessful to improve the Mg^+ level, but her K^+ dropped to low normal. Workup as follows: Na^+ 140 mmol/L, K^+ 3.4 mmol/L, Cl^- 102 mmol/L, CO_2 27 mmol/L, BUN 8 mg/dL, Creatinine 0.7 mg/dL, Glucose 205 mg/dL, Ca^+ 9.7 mg/dL, Phosp 4.2 mg/dL & Mg^+ ranging between 1.0 to 1.3. UA- normal. 24-hour urine lytes: Mg^+ 59.4 mg, Ca^+ 68 mg/dL, K^+ 50 mmol, Na^+ 90 mmol. 24-hour Creatinine 0.8 g. Urine Mg^+ 4.4 mg/dL. Fractional excretion (FE) of Mg^+ 6.87%.

Discussion: A daily excretion of >10 to 30 mg or a FE of Mg^+ above 3 to 4% in a person with hypomagnesemia & normal kidney function, indicates renal Mg^+ wasting. In contrast, a 24-hour urinary Mg^+ excretion of <10 mg or a FE of Mg^+ <2% usually indicates an extrarenal Mg^+ losses (typically GI). Our patient's FE of Mg^+ is 6.87%, & 24-hour urine Mg^+ was 59.4 mg. Gitelman syndrome (GS) is the most common form of familial renal Mg^+ wasting. Bartter syndrome (type 3) that resemble GS, may also present with hypomagnesemia. The 24-hour urine calcium/creatinine ratio is 85 mg/g. The upper range for the urine calcium/creatinine ratio in adults is about 200 mg/g. The lower limit of normal for calcium excretion is unknown. A spot urine calcium/creatinine ratio of <70 mg/g has been proposed to define hypocalciuria in adults when Gitelman syndrome is suspected. Our patient has a spot ratio of 19 mg/g. The patient is undergoing genetic testing to identify the etiology of hypomagnesemia.

SA-PO702

Gitelman-Like Syndrome Associated with Seizure Secondary to Chronic Proton Pump Inhibitor Use and Alcohol Consumption: Case Report of Undetectable Magnesium

Sergio P. de Souza, Isadora G. Dultra, Ludmila B. Santos, Maiara V. Requião, Marcel M. Gomes, Marcelo Lopes, Luis M. Conceição, Fernanda O. Coelho, Paulo benigno P. Batista, Rogerio Passos, Marcelo D. Silveira. *Hospital Sao Rafael, Salvador, Brazil.*

Introduction: Magnesium (Mg2+) is the second most common intracellular cation, acting as a cofactor in over 300 metabolic reactions. Magnesium metabolism depends on integrated actions between the kidney and intestine. There are descriptions of reductions in intestinal and renal absorptive capacities by use of a proton pump inhibitor (PPI) as well as by alcohol consumption, but undetectable serum magnesium is not common. We describe a case of severe hypomagnesemia in a patient who has been a chronic user (for 8 years) of PPIs and consumes alcohol daily.

Case Description: Male, 73 years old, hypertensive, diabetic, sarcopenic admitted due to generalized tonic-clonic seizure. He was using antihypertensive drugs (Atenolol 50 mg / day; Lisonopril 20mg / day and Amlodipine 5 mg / day), in addition to the chronic use of Omeprazole (40 mg / day). He had a habit of daily drinking (01 bottle of wine a day) and eating meat, with low intake of vegetables and legumes. In admission exams, the following were identified in the blood: Hb: 12.3 g/dl, creatinine (Cr): 1.0 mg/dl, Mg less than 0.1 mmol/L (RV 0.7 – 1.2 mmol/L) potassium 3.6 mEq/L (RV 3.5 – 5.0 mEq/L), sodium 139 mEq/L, chloride 106 mmol/L, HCO3-: 27.2 mEq/L, PTH: 82.9 pg/L ml. Urinary tests showed: Volume 1.5 L/day; uMg: 2.16 mmol/day; Mg excretion fraction (FeMg) 6%; uCa 13.5 mg/day; uNa 100mEq/day; uCr 46.6mg/dl; uK 11.8 mEq/L; FeK 7%. Omeprazole was suspended and intravenous Mg replacement was started, followed by maintenance with oral Mg replacement. Levels normalized after 2 weeks. The patient was discharged from the hospital using oral Mg at a dose of 260 mg/day of elemental Mg for outpatient follow-up.

Discussion: We describe a case of severe hypomagnesemia in an elderly patient with a history of chronic use of PPIs associated with daily alcohol consumption and low intake of legumes. He also had metabolic alkalosis and hypocalciuria, findings compatible with Gitelman-like syndrome. There was normalization and maintenance of adequate levels of magnesium after discontinuation of PPI and alcohol consumption, demonstrating the role of these factors in this disorder.

SA-PO703

Correction of Refractory Hypomagnesemia by SGLT2 Inhibitor

Jinhua Zhao.[1,2] *[1]VA Northeast Ohio Healthcare System, Cleveland, OH; [2]Case Western Reserve University School of Medicine, Cleveland, OH.*

Introduction: Correcting hypomagnesemia can be difficult due to limited gastrointestinal (GI) absorption of oral Magnesium (Mg) supplements, diarrhea with high dose supplement, and lack of effective agents to decrease renal losses. The reported prevalence of hypomagnesemia is 14%-48% in type 2 diabetic patients. With the growing use of Sodium-Glucose Cotransport 2 Inhibitors (SGLT2i) for cardiac protection, renal protection and proteinuria, etc., post hoc analyses have shown the association of SGLT2i use with increased blood magnesium. A few clinical case reports also demonstrated improvement of hypomagnesemia with SGLT2i. The mechanism by which SGLT2i correct hypomagnesemia is unclear.

Case Description: 74 year old male passed out at a restaurant 4 years ago, he was found to have serum magnesium (Mg) of 0.8mg/dL. Mg supplement was started. He again had severe hypomagnesemia when evaluated for photophobia. Since then he also got intermittent iv Mg. Mg was maintained at 1.4-1.6 mg/dL. Other medical issues include type 2 diabetes, hypertension. No chronic nausea, vomiting; no PPI or diuretic use. He is well nourished, not alcoholic. HbA1c was 6's - 8's. eGFR was >60 cc/min, no microalbuminuria. Work-up showed renal Mg wasting as fractional excretion of Magnesium (FEMg) was 6% when plasma Mg was 1.6 mg/dL in 2/2022. SGLT2i (empagliflozin 12.5mg daily) was added in March 2022, plasma Mg increased to 1.8 mg/dL 1 month later, then to 2.0 mg/dL 3 months later. Plasma Mg has been remain at 2.0 mg/dL over the following 10 months. The increase of plasma Mg from 1.6 to 2.0 mg/dL was associated with decrease of FEMg from 6% to 3%. After plasma Mg stablized at 2.0 mg/dL, FEMg was 13% and 10% on 2 occasions. See Table.

Discussion: GI loss or renal losses are the two major etiologies of hypomagnesemia. This patient had refractory hypomagnesemia despite oral and intermittent iv supplements. His elevated FEMg in presence of hypomagnesemia was consistent with renal wasting. The initiation of SGLT2i rapidly normalized plasma Mg. While plasma Mg remains at 2.0 mg/dL in the following months, the FEMg increased again. This increased most likely represents appropriate renal handling in responding to GI Mg intake.

	2/22/22	4/5/22	7/19/22	2/28/23	4/3/23
Mg (mg/dL)	1.6	1.8	2.0	2.0	2.0
FEMg (%)	6	6	3	13	10

The Drug that Keeps Giving: Hypomagnesemia Fixed by SGLT2 Inhibitor

Ahmed Abdallah,[1] Fatima Ayub,[1] Ahmed Elkalashy,[1] Md R. Hasan,[2] Praveen K. Errabelli,[3] Maulik Lathiya,[3] Manisha Singh,[1] Nithin Karakala,[1] Joseph H. Holthoff.[1] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Arkansas College of Osteopathic Medicine, Fort Smith, AR; [3]Mayo Clinic Health System Albert Lea, Albert Lea, MN.*

Introduction: Sodium-glucose cotransporter 2 (SGLT2) inhibitors are widely used in patients with kidney disease to improve clinical outcomes. They are known to increase serum magnesium levels. There are rare case reports of these helping treat hypomagnesemia with or without urinary losses of magnesium. We present a case report to add to this data in treating refractory hypomagnesemia with a significant improvement in serum magnesium levels.

Case Description: A 72-year-old frail woman with a past medical history of type 2 diabetes mellitus and gastric bypass surgery presented to the emergency department with complaints of worsening fatigue and refractory chronic hypomagnesemia. The patient had experienced generalized weakness, tremors, and reduced appetite for many months. The patient had known chronic hypomagnesemia, hypokalemia, hypocalcemia, and alkalosis, thus a concern for Gitelman syndrome. She was prescribed oral supplementations without significantly improving serum magnesium levels. Her home medications included metformin and pantoprazole. At the time of presentation, the patient had normal vitals, though she was very frail, demented, and resting tremors in her hands. serum magnesium was 0.9 mg/dl. The pantoprazole was discontinued, and oral and intravenous magnesium supplementation was started with a slight improvement in the serum magnesium levels to 1.2 mg/dl. Next, amiloride was added. However, she developed diarrhea likely secondary to the magnesium salts, which added to her gastric losses and inability to tolerate oral repletion. The fractional excretion of magnesium (FeMg) was 69% consistent with renal magnesium wasting, but the genetic tests for Gitleman came back negative. Subsequently, we added an SGLT2 inhibitor with marked improvement in serum magnesium levels to 2.3 mg/dl and complete resolution of tremors.

Discussion: In patients with significant urinary magnesium wasting, supplementation often fails to improve serum magnesium levels. Clinical trials have shown that SGLT 2 inhibitors can improve hypomagnesemia in diabetic patients with urinary magnesium wasting. However, data on their efficacy in nondiabetic patients with hypomagnesemia is scarce. SGLT2 inhibitors may be considered in patients with intractable hypomagnesemia, representing a possible new tool in this challenging clinical disorder.

Urinary Phenotyping in Mesoamerican Nephropathy

Amin Oomatia,[1] Faisal M. Badri,[1] Ali M. Al-Rashed,[1] Marvin A. Gonzalez,[2] Dorothea Nitsch,[3] Neil Pearce,[3] Ben Caplin.[1] The Colt/UK MRC CKDu Study Group. *[1]University College London, London, United Kingdom; [2]Research Centre on Health, Work and Environment at National Autonomous University of Nicaragua, Leon, Nicaragua; [3]London School of Hygiene & Tropical Medicine, London, United Kingdom.*

Background: Mesoamerican nephropathy (MN) is a leading cause of CKD in Central America. Studies suggest an underlying tubulointerstitial nephritis with coexisting electrolyte wasting in affected individuals. The Colt-MRC cohort is a community-based study in Nicaragua, which recruited individuals at risk of MN, measuring serum creatinine (Cr) and collecting questionnaire data and biosamples at annual study visits for 7 years. In this sub-study, we aimed to compare the urinary phenotype of individuals from the cohort who develop early kidney injury (EKI) – defined by a significant decline in eGFR from a healthy baseline, with healthy controls (HC) and those with established MN (eMN).

Methods: We compared concurrent serum and urine samples from EKI cases pre and post decline in eGFR to two samples from HC matched for age, sex, community and study visit, and samples from two consecutive study visits from un-matched eMN participants (Table 1). All serum and urine samples were tested for: Cr, Na, K, PO_4 & Mg, and fractional excretions (FE) of electrolytes were calculated. Urine was also tested for MCP-1 (ELISA) and corrected for urine Cr. Data were analysed using mixed-effects modelling.

Results: FE of all electrolytes were raised in the eMN group, but serum Na and Mg were lower. MCP1 was significantly raised in cases in the visit post EKI compared to pre-EKI, HC and eMN. See Table 1.

Conclusions: Urinary MCP1 levels are higher in cases after incident EKI versus HC and eMN, suggesting acute inflammation at the onset of MN that subsequently subsides. Participants with eMN had raised FE of all measured electrolytes, a common feature of CKD due to decreased nephron mass. However, they also had lower serum Na and Mg, with 50% exhibiting clinical hypomagnesemia, which is not a feature of CKD and suggests ongoing impairment of tubular function in established MN.

A Mystery Solved: Getting a "Grip" on Unexplained Hypermagnesemia in a Patient on Continuous Cyclic Peritoneal Dialysis (CCPD)

Saba Munir, Stephen M. Korbet, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Hypermagnesemia should not occur in a patient on RRT without an exogenous source. We present a pt in whom a [Mg] level of 6.0 mg/dL was found in which there was no history of intake of any Mg containing mediations or supplements despite multiple inquiries.

Case Description: A 27 year old black woman with anuric ESKD secondary to Alport's disease on CCPD presented with a 1-wk history of weakness and syncopal episodes. She reported "blackout" and "spacing out" spells, each lasting a few seconds. She also noted new upper extremity weakness, spontaneously dropping items from her hands. She reported compliance with home PD (1.5 mEq/L [Mg] dialysate). She denied use of laxatives or supplements. She works as a chef and denied any recent increase in Mg containing foods. In the ED her VS were unremarkable except for a BP of 170/90. Her laboratory values were typical for ESKD except for a serum [Mg] of 6.0 mg/dL (nl 1.7-2.7). Her EKG demonstrated a prolonged QTc. She received IV calcium, and her QTc normalized. She was admitted to the hospital and started on rapid exchange PD with a dialysate [Mg] of 0.5 mEq/L. Her neurologic episodes and muscular weakness resolved. Upon further investigation (by the dietician), the patient noted that she recently started rock climbing 4 times per week using climber's chalk to improve her grip (the chalk helps keep hands dry to provide a stronger grip) which upon research was found to be made of magnesium carbonate (Figure 1). Her [Mg] improved in the hospital and decreased further at home with change to a lower [Mg] dialysate and stopping her rock climbing (Fig. 1).

Discussion: Magnesium is easily excreted by the kidneys when renal function is normal, so hypermagnesemia requires a large exogenous source in the setting of renal insufficiency. The exact mechanism by which she absorbed Mg from the climbing chalk remains uknown. Although a dialysate [Mg] of 1.5 mEq/L (0.75 mmol/L) is slightly high relative to a normal serum [Mg], her markedly elevated [Mg] of 6.0 mg/dL (2.5 mmol/L) had to be from an exogenous source that required "Dr. House" like investigation to solve.

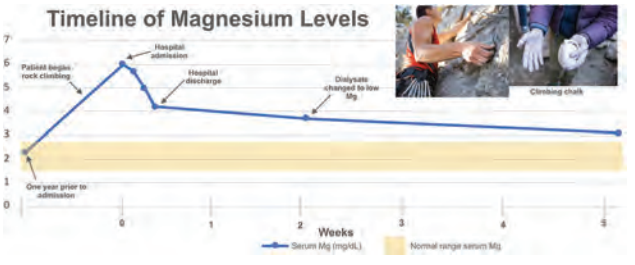

Figure 1. Clinical course of magnesium

SA-PO707

Clinic-Level Fluid Quality Score Associates with Fluid Overload Hospitalizations

Tory Scoggins, Patricia Mccarley, Amanda S. Rivenbark, Amanda Stennett, Brian S. Ash, Kathleen Yatsuhashi, Kellie Y. Becker, Caitlin Monaghan, Sheetal Chaudhuri, John W. Larkin, Jeffrey L. Hymes. *Fresenius Medical Care, Waltham, MA.*

Background: Fluid overload (FO) is a primary cause of hospitalization in the dialysis population. A national dialysis network established a Fluid Action Group (AG) system to help identify patients on hemodialysis (HD) with clinical presentations associated with

hypervolemia to prompt timely evaluations/interventions. Fluid AG assignments for patients are used to calculate a Fluid Clinical Quality Score (CQS) for each HD clinic. This analysis investigated if Fluid CQS was meaningfully associated with FO hospitalizations.

Methods: Fluid AG scoring assigns patients into groups representing a low-to-high FO risk based on the presence of post-HD hypertension coupled with excess interdialytic fluid gains, missed/shortened treatments, unchanged/increased estimated dry weights, and/or multiple blood pressure medications. Fluid CQS Score was calculated based on percent of patients in AGs with the median scoring 5, top decile scoring 10, and bottom decile scoring 1. Data on the Fluid CQS and the average rolling 12-month hospitalization rate considering exposure time were collected from 9/2022- 2/2023. FO hospitalization rate was averaged for each level of the Fluid CQS.

Results: Among patients treated at 2,705 clinics, we observed an inverse relationship between higher Fluid CQS scores and lower FO hospitalization rates ($R^2 = 0.93$). Average FO hospitalization rate was 25% lower at clinics with a Fluid CQS score of 10 vs 1 (0.16 vs 0.12 FO admissions/patient year at clinics with a Fluid CQS score of 10 vs 1, respectively). Consistent trends were observed during each month individually.

Conclusions: Fluid CQS appears to be meaningfully correlated with FO outcomes observed at a clinic and can be viewed as a surrogate marker of the management of fluid control. Further investigations are needed to understand the effectiveness of interventions being performed based on Fluid AG for individual patients.

Funding: Commercial Support - Fresenius Medical Care

Hypertension, Hypokalemia, and Psychosis: A Case Report of Ectopic ACTH Production from Pulmonary Carcinoid Tumor

Amara Sarwal, Siddhartha Kakani, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Pulmonary carcinoid tumours are a rare cause of ectopic ACTH [1]. Herein, we present a case of ectopic ACTH production presenting as acute psychosis due to a pulmonary carcinoid tumor.

Case Description: 63 year old male with rheumatoid arthritis and hypertension presented to the Emergency Department with erratic behavior and altered mental status. Initial workup revealed profound hypokalemia to 1.8 mmol/L, sodium of 152 mmol/L, bicarbonate at 34 mmol/L and serum creatinine at 1.02 mg/dL. Urine toxicology was positive for marijuana. He was also found to be hypertensive at 152/101. Patient noted excessive sweating for 1.5 years along with weight loss of 20 pounds in the last month. Contrasted imaging of the abdomen did not reveal any masses in the adrenals, although did note bilateral adrenal hyperplasia. Hyperaldosteronism was ruled out. 24 hour cortisol was 9948 ug/d with elevated ACTH of 229 pg/mL. Patient's behaviour was thought to be due to acute psychosis from the hypercortisolism, and he was started on ketoconazole with improvement in symptoms. Contrasted imaging of the chest revealed a 1.9cm right upper lung nodule that had been stable since 2020. Unfortunately, patient developed PJP pneumonia, causing a delay in surgical resection. Patient underwent wedge resection a month later, with pathology revealing 1.4cm well differentiated carcinoid tumor with positive ACTH immunostaining.

Discussion: Metastases in pulmonary neuroendocrine tumors have been reported at <15% of cases[1]. >80% of cases of pulmonary carcinoids are curative with surgery [1]. Our patient had a nodule that had been unchanged for years prior to presentation. After ruling out any other causes for ectopic ACTH, we decided to pursue further evaluation of the lung nodule.

Comparison Between Longitudinal Kidney Function and Volume Changes in Association with Heart Failure Outcomes Among Discharged Patients in EVEREST

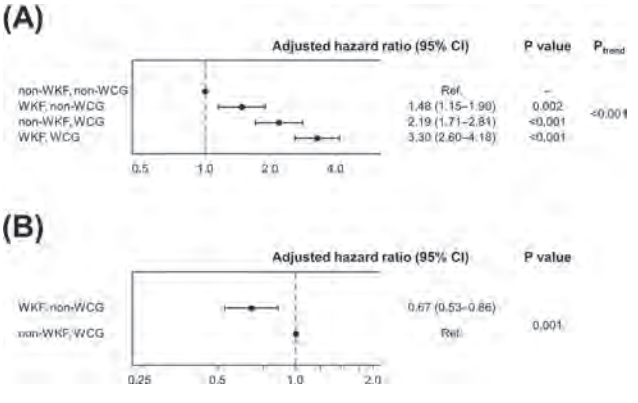
Tatsufumi Oka, Hocine Tighiouart, Wendy I. McCallum, Marcelle Tuttle, Marvin Konstam, James Udelson, Mark J. Sarnak. *Tufts Medical Center, Boston, MA.*

Background: Decongestion can result in kidney function decline. The relative clinical importance of changes in kidney function and changes in volume status remains uncertain in outpatient HF settings.

Methods: This post-hoc analysis of the Efficacy of Vasopressin Antagonism in Heart Failure Outcome Study with Tolvaptan (EVEREST) trial analyzed patients who survived HF hospitalization. As time-varying exposures, worsened kidney function (WKF) and worsened congestion (WCG) were defined as any decrease in eGFR and any increase in B-type natriuretic peptide (BNP) in comparison with values at discharge, respectively. We examined the association of 4 groups (non-WKF, non-WCG group; WKF, non-WCG group; non-WKF, WCG group; and WKF, WCG group) with the composite of cardiovascular death or HF re-hospitalization, particularly focusing on the comparison between WKF, non-WCG and non-WKF, WCG groups. Marginal structural models, which can create a balanced pseudo-population throughout follow-up, were applied to account for time-dependent confounding.

Results: Among 3666 patients, median age, eGFR, and BNP at discharge were 67 years, 57.9 mL/min/1.73 m^2, and 441.9 pg/mL, respectively. During follow-up (median, 44 weeks), 631 patients died due to cardiovascular disease and 1160 experienced HF re-hospitalization. After adjustment for time-dependent confounders, a significant trend was observed in the association between the 4 groups and study outcome with the highest risk in WKF, WCG group (Figure A). Patients in WKF, non-WCG group had a 33%-lower risk of the composite outcome than those in non-WKF, WCG group (Figure B).

Conclusions: WKF-WCG categories discriminated the risk of HF outcomes in discharged patients with HF. Patients in WKF, non-WCG group had fewer adverse HF outcomes than those in non-WKF, WCG group, suggesting the importance of sustaining decongestion over preserving kidney function.



SA-PO710

Dare to Diurese: Lymphedema in a Patient with Spina Bifida

Maheen Khan, Neev Patel, Yashvi Pethani, Martin Brigham, Adrian P. Sequeira. *LSU Health Shreveport, Shreveport, LA.*

Introduction: Evaluation of edema is a common part of medical practice. While there are myltiple etiologies that can cause edema, diuretics are cornerstone of management and have the potential to be overused. We present one such case in a patient with lymphedema from spina bifida. Patients with spina bifida carry 100 times higher risk of developing primary lymphedema compared to healthy individuals[2]. Lymphedema praecox, the most common form of primary lymphedema, has its onset between age 2 and 35 and has a female to male ratio of 10:1[3].

Case Description: A 28-year-old female with past medical history of spina bifida presented to the ED with worsening lower extremity swelling and light-headedness. Prior evaluation by PCP endocrinologist, and cardiologist were unremarkable. She was on lasix 80 mg twice a day, metolazone 2.5 mg twice a day, spironolactone 50 mg daily and 80 mEq of oral potassium. On arrival, BP was 72/40 mm Hg, pulse 70 per minute, and respiratory rate 40/min. physical exam showed non-pitting edema ib bilateral lower extremities. Labs showed Na 132, K 2.3, Cl 89, Cr 0.8. EKG revealed inverted T waves in anterior leads and prolonged QT interval. Echocardiogram was unremarkable with ejection fraction 55%. Diuretic withdrawal, fluid resuscitation, and potassium replacement corrected her electrolyte and hemodynamic abnormalities. Further evaluation for hypokalemia revealed aldosterone 261 ng/L, renin 100 ng/L, ACTH < 5.0, AM cortisol 3.9, TSH 2.067. Upon evaluation by Nephrology, primary lymphedema was deemed to be the cause of nonpitting edema. Pt was discharged on Lasix 80 mg daily and KCl 40 mEq daily.

Discussion: The case reports highlights a few key points including: 1. recognizition of lymphedema in patients with spina bifida 2. importance of evaluation of peripheral edema and it's causes in all patients 3. cautious use of diuretics and mineralocorticoid receptor agonists especially when used in conjunction 4. frequent monitoring of electrolytes when patients are on diuretics and 5. de-escalation of therapies when edema is refractory to therapy or side effects are frequent.

SA-PO711

Therapeutic Plasma Exchange-Related Hypotension: A Comparison of Replacement Fluids

Andrew Yanik,[1] Amara Sarwal,[1] Jamie P. Dwyer,[1] Srinivasan Beddhu,[1] Robert E. Boucher,[1] Josephine Abraham.[1] *[1]University of Utah Health, Salt Lake City, UT.*

Background: Therapeutic plasma exchange (TPE) is used to remove specific pathogenic entities or replace substances that are physiologically lacking. TPE requires replacement fluid administration due to plasma losses, and the most common replacement fluids are albumin and saline. There is limited literature regarding the effect of different replacement fluids on TPE-related hypotension. This study aimed to compare TPE-related hypotension between groups receiving partial-saline and 100% albumin.

Methods: This is a retrospective, single-center study from the University of Utah. Patients who were 18 years old or older and had diagnoses necessitating TPE were considered eligible participants. 2272 TPE sessions were performed in 333 patients from 1/1/2020 and 3/3/2023. All patients before 3/1/22 received partial saline, and all patients after this received 100% albumin. Episodes of TPE-related hypotension were investigated and compared between these two groups using logistic regression models to relate TPE group to the incidence of each type of hypotensive event, with adjustment for SBP, DBP and indication for TPE.

Results: The mean age of the patients was 50.5 years and 48.6% were male. The partial-saline group accounted for 1432 sessions and the 100% albumin group accounted for 840. Hypotension occurred in 32.4% of TPE sessions in the partial saline group, and 31.7% in the albumin group (OR=1.01, 95% CI 0.83-1.23, p=0.865). When analyzing individual criteria of hypotension between the partial saline and albumin groups respectively, the results show: 4.82% vs 2.86% (SBP <90 mmHg OR=1.70, 95% CI 1.03-2.78, p=0.035), 16.13% vs 11.31% (MAP <65 OR=1.39, 95% CI 1.05-1.83, p=0.02), 21.37% vs 22.26% (SBP drop >20 mmHg OR=0.98, 95% CI 0.7-1.23, p=0.84), and 3.84% vs 2.50% (SBP drop >40 mmHg OR=1.74, 95% CI 1.00-3.03, p=0.05). When analyzing the composite of an SBP drop below 90 mmHg, MAP <65, and SBP drop by >40 mmHg, events occurred in 19.41% and 14.05 % of the partial saline and albumin groups, respectively (OR=1.41, 95% CI 1.09-1.80, p=0.007).

Conclusions: Partial saline recipients are significantly more likely to have a hypotensive event. This may reflect support for using 100% albumin as replacement fluid during TPE, reinforcing the physiologic rationale for colloid replacement.

SA-PO712

Differentiating Vasopressin Withdrawal Syndrome from Gestational and Central Diabetes Insipidus: A Learning Case Study

Panupong Hansrivijit,[1,2] Annie Liu,[1,2] Pui Susan W. Cheung.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Introduction: Differentiating vasopressin withdrawal syndrome (VWS) from gestational diabetes insipidus (GDI) and central diabetes insipidus (CDI) in a pregnant woman is challenging. Prolonged administration of exogenous vasopressin can lead to negative feedback on endogenous anti-diuretic hormone (ADH) production from the posterior pituitary gland. CDI can occur following a shock leading to pituitary infarction and usually co-exists with anterior pituitary axis deficits given their enriched blood supply. Finally, GDI is mediated by placenta-derived vasopressinase which degrades endogenous ADH and exogenous vasopressin. GDI typically presents in the 2nd and 3rd trimester and can persist up to 4-6 weeks postpartum. A baseline urine analysis and serum copeptin level is a useful tool in the diagnosis of polyuria in pregnancy.

Case Description: A 32-year-old, 24^{+2}-week pregnant female was admitted to the Intensive Care Unit for peripartum cardiomyopathy requiring Impella device placement. She was started on phenylephrine and vasopressin for hypotension on hospital day (HOD) 1. On HOD13, vasopressin was stopped, and she became polyuric with nine liters of urine output leading to some issues with the Impella device. Urine osmolality was 100 mosm/kg. Vasopressin was then restarted with resolution of polyuria. Nephrology was then consulted. Fortunately, urine analysis was collected on the day of admission and showed urine specific gravity of >1.030. While on vasopressin, the serum sodium was 129 mmol/L, urine osmolality was 678 mosm/kg, copeptin level was <2.8 pmol/L. Anterior pituitary axis work-up was unremarkable. She delivered on HOD21 while on vasopressin. Vasopressin was successfully discontinued on HOD22 with a bridge using desmopressin. Eventually, desmopressin was completely stopped on HOD37 (16 days after delivery).

Discussion: This patient's presentation favors VWS over GDI. First, the urine specific gravity on admission suggested presence of ADH effect which argues against GDI. Second, low copeptin level was auggestive of VWS. The copeptin level is expected to be within reference range in GDI or elevated in the setting of cardiogenic shock. Finally, absence of anterior pituitary axis dysfunction would make CDI very less likely. In conclusion, urine chemistry and copeptin level are essential in the diagnosis of polyuria in pregnancy.

SA-PO713

Running Dry: The Thirsty Journey of Postpartum Diabetes Insipidus

Jeaneishka M. Rivera Rios, Ileana E. Ocasio Melendez, Krystahl Z. Andujar-Rivera, Caleb S. Pacheco-Molina, Carlos G. Rivera-Bermudez, Jesus D. Vega-Colon, Maria E. Rivera. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Diabetes insipidus (DI) is a rare complication of pregnancy, occurring in 1 in 30,000 pregnancies. During pregnancy or the postpartum period, DI can be associated with excessive vasopressinase activity secreted by the placental trophoblasts, which increases the degradation rate of vasopressin.

Case Description: A 28-year-old female G2P1A0 with a trichorionic triamniotic pregnancy at 27 3/7 weeks gestation, was admitted to the hospital due to preterm premature rupture of membranes (PPROM) and later developed preeclampsia. After an emergent cesarean section, she developed acute respiratory distress syndrome requiring endotracheal intubation, was treated for hyperthyroidism and transfused with one packed red blood cells. On day 6 following delivery, the patient developed polyuria, no polydipsia reported while sedated on mechanical ventilation. Laboratory investigations showed normoglycemia, normocalcemia, hypokalemia, hypomagnesemia, hypernatremia (serum sodium level of 151 mEq/L), a urine output of 6.5 L/day, and a urine specific gravity of 1.005. Total placenta weight was found to be 770 g (normal 500-600 g in a full-term pregnancy). Treatment with synthetic analogue 1-deamino-8-D-arginine vasopressin resulted in decreased urine output, increased urinary osmolality, and normalization of sodium levels. The patient was discharged from the hospital with no signs of DI or additional complications. Endocrinological follow-up confirmed that there were no underlying metabolic disorders.

Discussion: This case highlights the diagnostic complexity of transient diabetes insipidus in the postpartum period. It is a rare complication that can occur following pregnancy and delivery, especially in patients with pre-existing medical conditions. Diagnosing DI during pregnancy can be challenging due to physiological changes, which can make interpreting results difficult. A high index of suspicion for vasopressinase-induced DI should be considered in the presence of risk factors such as preeclampsia, hepatic dysfunction, and multiple gestation.

SA-PO714

Arginine Vasopressin Deficiency in the Hypoxic Brain

Leanna V. Ritchie, Abdul Basit, Lyle W. Baker. *Mayo Foundation for Medical Education and Research, Jacksonville, FL.*

Introduction: Hypernatremia is an electrolyte disorder most commonly related to limited access to water or suppression of the thirst compensatory mechanism. Uncommonly hypernatremia may be associated with interruption in the anti-diuretic hormone (ADH) cascade either from a central (pituitary) or nephrogenic etiology. ADH is released in response to elevated serum sodium from the posterior pituitary gland to bind with V2 receptors in the distal tubules and collecting ducts in the kidney to facilitate water reabsorption. If this phenomenon is interrupted, termed arginine vasopressin deficiency (AVD), a patient may present with hypernatremia and polyuria. The most common etiologies of AVD are secondary to infiltrative disease, primary or secondary tumors and traumatic brain injury.

Case Description: Here presented is a case of a 58 year old female with a past medical history remarkable for hypertension, diabetes, seizure disorder and obesity who presented to the hospital after cardiac arrest. The patient had asystole and achieved return of spontaneous circulation after 1 hour of advanced cardiac life support. Following cardiac arrest she developed hypernatremia with polyuria. CT head indicated global hypoxemic brain injury. The patient had absent brainstem reflexes. The patient developed acute kidney injury secondary to renal ischemia and was started on continuous veno-venous hemofiltration (CVVH). Despite renal replacement therapy the patient developed hypernatremia with polyuria. Initially free water flushes were initiated, however the patient developed refractory hypernatremia. Renal replacement therapy was discontinued. Urine osmolality was 259 mOsm/kg, consistent with AVD. The patient's urine volume

reduced in response to desmopressin administration with correction of hypernatremia. She was diagnosed with central AVD secondary to anoxic brain injury. Unfortunately neurological evaluation identified brain death and the patient was terminally extubated.

Discussion: This case has a unique etiology secondary to hypoxic injury versus a trauma, infiltrative disease or brain mass. The pathophysiology of AVD post hypoxic brain injury is poorly understood. It is hypothesized that damage to the hypothalamus or posterior pituitary gland may hinder ADH secretion. This is an uncommon presentation of cerebral injury post cardiac arrest and may be a negative prognostic indicator for recovery.

SA-PO715

Spontaneous Development of Diabetes Insipidus in a Healthy Female: A Rare Case of Central Diabetes Insipidus in the Nephrology Clinic

Allison Mitchell, Hania Kassem. *The University of Texas Medical Branch at Galveston Development Office, Galveston, TX.*

Introduction: Diabetes Insipidus (DI) is a rare complication resulting from vasopressin (AVP) deficiency [central (CDI)] or AVP resistance [nephrogenic (NDI)] leading to polydipsia, polyuria, and hypernatremia. We present a case of CDI in the nephrology clinic setting including diagnosis, imaging, and treatment.

Case Description: A 46-year-old female presented to nephrology clinic with polydipsia and polyuria that began 3 months prior. Her primary complaints were extreme thirst requiring consumption of approximately 20L of water over 2 to 3 days with large volume urination every hour. Initial laboratory findings were consistent with diabetes insipidus: high-normal sodium (Na) of 145, creatinine of 0.55mg/dL, low urine osmolality of 140 mOsm/kg, and low serum AVP (which resulted 2 weeks later). Due to high suspicion for CDI, patient was started on a trial of oral desmopressin 0.1mg daily which was increased over two weeks to desmopressin 0.2mg BID. Patient subsequently improved with resolution of symptoms and labs showing: normal serum Na (140 mmol/L) with improved urine osmolality (494 mOsm/kg). MRI brain showed diffuse thickening of the pituitary infundibulum in the absence of posterior pituitary bright spot and a small meningioma over the left anterior temporal lobe supporting a diagnosis of Langerhans cell histiocytosis (LCH). Patient was referred to neurology and oncology for further evaluation.

Discussion: LCH is a rare disorder characterized by abnormal proliferation of Langerhans cells, histiocyte-like cells, of unknown cause. This disorder is rarely seen in adults (1-2 per million) and is twice as likely to be diagnosed in males. LCH affects the central nervous system by affecting the pituitary infundibulum leading to the initial presentation of DI. An elevated serum Na along with dilute urine in a patient with polyuria and polydipsia was strongly suggestive of DI, which led to the decision of work up and treatment without requiring a confirmatory water deprivation test. Desmopressin dosing titration required close monitoring with patient counseling about decreasing fluid intake once urine output decreases and being aware of the signs of hyponatremia. This was a unique case in the outpatient nephrology setting of a rare disease in an unlikely patient demographic.

SA-PO716

A Deep Dive into Diabetes Insipidus

Billy Zeng, Sijie Zheng. *Kaiser Permanente, Oakland, CA.*

Introduction: Central diabetes insipidus (DI) is a disease caused by absent antidiuretic hormones production, leading to symptoms of polyuria and polydipsia. Head trauma is a typical cause of central DI. We present a case of new onset partial central diabetes insipidus where recurrent scuba diving was considered a likely trigger.

Case Description: A 58-year-old female presented with polyuria, nocturia, and thirst for one month that started after an annual scuba diving trip. Past medical history was notable for anxiety. She was recently prescribed buproprion prior to these symptoms. Physical exam was unremarkable, serum sodium 145 mmol/L, serum osmolality 305 mOsm/Kg, 24-hour urine volume >2.8 L, and urine osmolality 180 mOsm/Kg. She was empirically started on DDAVP to relieve nocturia symptoms and scheduled for a water deprivation test. Nocturia symptoms improved immediately after started DDAVP. Water deprivation test (Figure 1) showed mild elevations of urine osmolality with water deprivation and substantial increase of urine osmolality with DDAVP administration indicative of partial central DI. An MRI was performed, showing an absent neurohypophysis on T1 sequence. According to the patient, a previous head MRI was normal. On further review of the patient's social history, she went on annual scuba diving vacations for many years.

Discussion: To our knowledge this is the first report of central DI associated with scuba diving. Previous studies have shown that recreational diving can cause a reduction of 20% cerebral blood flow, decompression while ascending can also cause brain injury. We hypothesize that repeated exposure to such hypoxic conditions may have caused injury to the posterior pituitary, with potentially some injury associated with each dive until eventually enough posterior pituitary function was affected, resulting in dysfunction of antidiuretic hormone production or release.

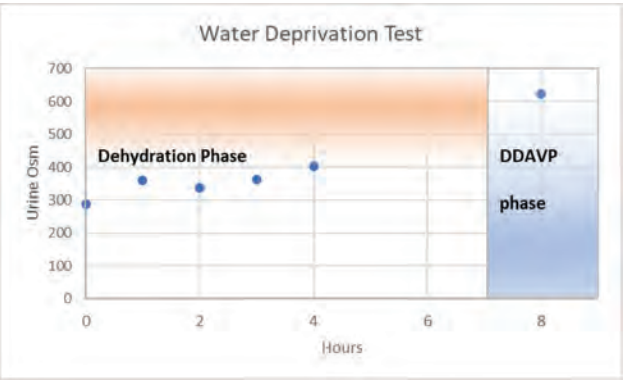


Figure 1. Water deprivation test. Urine osmalality was measured each hour. DDAVP administered at hour 7.

SA-PO717

A Case of Iatrogenic Hyponatremia from Adrenal Insufficiency

Guangchen Zou. *Johns Hopkins University, Baltimore, MD.*

Introduction: Adrenal insufficiency can cause hypersecretion of ADH and lead to hyponatremia. A patient with panhypopituitarism developed severe hyponatremia when hydrocortisone were inadvertently held.

Case Description: A 47-year-old male was admitted for aspiration pneumonia. He had medulloblastoma in his teens and had resection and radiation therapy complicated by panhypopituitarism, and recurrent ischemic strokes with residual right-sided hemiparesis. He was on levothyroxine, hydrocortisone, aspirin, clopidogrel and pravastatin at home. Pneumonia improved and he had a percutaneous gastrostomy tube placed. He was then NPO for a gastric emptying study and his hydrocortisone was inadvertently held and not restarted afterwards. He was restarted on continuous tube feeding (Osmolite 1.2 at 55 ml/h) along with enteral water flushes (150 ml q4h). His sodium was normal since admission for 14 days but dropped from 142 to 117 over 3 days. Systolic blood pressure were 100s-140s. Creatinine was 0.4 mg/dL and potassium was 4.6 mmol/L. Urine sodium was 193 mmol/L, potassium was 37.7 mmol/L and osmolality of 577 mOsm/Kg. Tube feeding were held and he was restarted on hydrocortisone. He was edematous and was given IV furosemide 20 daily. His sodium improved and repeat urine studies 3 days later showed urine sodium of 24 mmol/L. He was later restarted on tube feeding with TwoCal HN. Sodium level remained within normal range 2 weeks later. He was discharged to a skilled nursing facility.

Discussion: Serum sodium dropped when his hydrocortisone was held while being started on tube feeding. Very high urine sodium level which decreased after restarting hydrocortisone were consistent with SIADH from adrenal insufficiency. Clinicians should be careful not to withhold hydrocortisone inadvertently for patients with adrenal insufficiency. For patients with SIADH, serum sodium level should be carefully monitored when they are being started on tube-feeding.

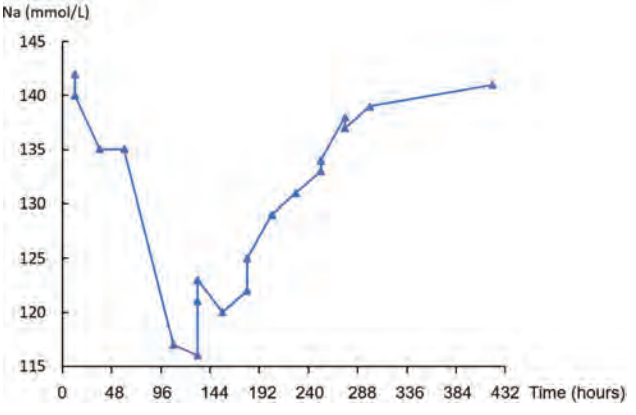

Figure 1. Serum sodium trend. Last dose of hydrocortisone was 14 h before time 0. Hydrocrotisone restarted at 106 h.

SA-PO718

Diagnosing Acute Intermittent Porphyria with SIADH

Mandy Hsu,[1] Abdul-Jawad Majeed,[1] Kevin C. Roe.[2] *[1]Penn State College of Medicine, University Park Program, State College, PA; [2]Mount Nittany Medical Center, State College, PA.*

Introduction: We present a case of acute intermittent porphyria (AIP) presenting with SIADH. AIP is a rare and often overlooked diagnosis. The case highlights the importance of considering AIP when a patient presents with SIADH. Delay in diagnosis led to delayed treatment, multiple emergency department visits and hospitalizations, and unnecessary testing.

Case Description: A 20-year-old female with a history of anemia and anxiety presented with nausea, vomiting, and abdominal pain. She experienced symptoms for two months and underwent extensive evaluation and prior hospitalization. She described the pain as diffuse, inconsistent, and varying in severity. Prior evaluation included upper endoscopy, colonoscopy, CT scans, X-rays, gynecologic evaluation with pelvic ultrasound, and psychiatric consultation. Laboratory evaluation was consistently notable for hyponatremia with serum sodium ranging from 120-130 mEq/L. Hyponatremia was first attributed to dehydration and anorexia treated with IV fluids, free water restriction and salt tablets. However, when euvolemia was achieved a low serum sodium (129 mmol/L) with inappropriately elevated urine osmolality (331 mOsm/kg) persisted. Once the diagnosis of SIADH was determined, a nephrology consultant recognized the association with AIP. Testing for urine porphobilinogens confirmed the diagnosis. The patient was transferred to a tertiary care center to receive appropriate treatment with hemin infusion. Symptoms improved but evidence of SIADH persisted.

Discussion: Early recognition of AIP is often difficult given the rarity of the disease and because the presentation is variable and nonspecific. Our case demonstrates how the presence of low urine sodium levels may help lead to a diagnosis of AIP. This diagnosis may have been missed had the potential cause of SIADH not been taken into consideration. Prompt diagnosis of AIP is important so hemin therapy can be started early to manage future acute attacks and prevent long-term consequences, such as chronic neuropathic pain. Given that the patient had numerous differential diagnoses, it is important to consider the relationship between SIADH and AIP when presented with repeated unexplained abdominal pain, nausea, and vomiting. Teaching points: -Identify the underlying cause when managing SIADH. -AIP and SIADH have an established relationship. SIADH may result from damage to hypothalamus and hypothalamic-hypophyseal tracts in AIP.

SA-PO719

Pressor Dose Vasopressin-Induced Acute Hyponatremia

Raed Nassar, Maureen Brogan, Sonali Gupta, Laith Alzyood, Roy Lee. *Montefiore Health System, Bronx, NY.*

Introduction: Vasopressin infusion is commonly used in intensive care unit for circulatory shock but has rarely been associated with hyponatremia. We describe a case of severe hyponatremia in a patient receiving vasopressin infusion that improved upon discontinuation.

Case Description: A 54-year-old, 74-kilogram male, with a history of interstitial lung disease, was admitted to the intensive care unit for acute hypoxic respiratory failure and shock due to COVID-19 pneumonia. A vasopressin infusion, at 0.03 units/minute, was initiated as an adjunctive medication to Norepinephrine. The patient's sodium level decreased from 136 mEq/L to 122 mEq/L over the first 15 hours. Urine output over this time was 1.2 Liters. Once vasopressin was discontinued, the urine output increased to 300 mL/hour with an osmolarity of less than 100 mOsm/kg. The serum sodium rapidly normalized to 135 mEq/L in 9 hours. The patient required desmopressin and a five percent dextrose infusion for treatment of overcorrection of hyponatremia.

Discussion: Vasopressin, at doses of 0.03 units/minute, is a common medication given in the intensive care unit to support circulatory collapse. Vasopressin can exert antidiuretic effects through interaction with V2 receptors in the renal collecting duct cells by incorporation of aquaporin 2 channels allowing passive free water reabsorption across an osmotic gradient. This results in water intoxication with subsequent hyponatremia. In our patient, discontinuation of Vasopressin resulted in a prompt diuresis and correction of hyponatremia.

SA-PO720

Polyuric Hyponatremia: A Case of Salt Wasting

Manuel Urra, Ryan P. Flood. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Introduction: Renal salt wasting has been described in association with several chemotherapeutic agents, yet the diagnosis may prove elusive as the initial work up may reveal findings consistent with the much more common diagnosis of syndrome of inappropriate anti-diuretic hormone (SIADH). Here we described a case of renal salt wasting (RSW) associated with two chemotherapeutic agents and identify the key diagnostic features to differentiate RSW from SIADH.

Case Description: A 29 male with Stage IV testicular rhabdomyosarcoma undergoing inpatient chemotherapy with Etoposide, Ifosfomide and Cisplatin developed acute hyponatremia with a serum sodium drop from 134mEq/L to 123mEq/L in under 48 hours. Urine studies revealed a urine sodium of 168mmol/L, urine potassium 18.8mmol/L, with a negative electrolyte free water clearance and a urine osmolality of 536mOsm/kg. Initial concern was raised for SIADH given inability to excrete free water, further supported by a diagnosis of active malignancy. Additional evaluation revealed that the patient was polyuric with a daily urinary volume of six liters. Additionally, he was hypotensive with evidence of volume depletion on exam. Urinary evaluation revealed normoglycemic glucosuria and aminoaciduria consistent with proximal tubular injury. The patient required 11 liters of hypertonic saline (HTS) to maintain his serum sodium at near normal levels over a two week course. With on-going supportive management, he was weaned off HTS and transitioned to salt tablets which eventually were discontinued as an outpatient upon completion of his chemotherapy.

Discussion: RSW shares several features with SIADH but this case highlights key differentiators. SIADH is regarded as a state of impaired free water excretion and low urine volumes with maintained volume status resulting from augmented release of arginine vasopressin despite there being no appropriate physiologic stimulus. RSW also exhibits impaired free water excretion but is accompanied by high urine volumes as a defect in tubular sodium reabsorption drives solute diuresis, an accompanying drop in serum sodium and hypovolemia. Cisplatin and Ifosfamide have been noted to cause proximal tubule injury which can manifest as isolated renal salt wasting or in association with Fanconi's syndrome, as was seen in this patient. Urinary volume, concurrent medication use and assessment of volume status serve as important features in differentiating RSW from SIADH.

SA-PO721

An Under-Recognized Complication of Chylous Leak: A Case Report of Rapidly Developed Hyponatremia

Omid Vadpey, Reed Salasnek, Man Kit Michael Siu. *University of California Irvine, Irvine, CA.*

Introduction: Chylous leak is a documented complication of thoracic duct perforation, with co-morbidities including high output volume depletion, hypoalbuminemia, immuno-compromised states, and electrolyte imbalances. Our goal is to demonstrate the importance of adequate and frequent electrolyte monitoring, including serum sodium, as hyponatremia is an overlooked complication that leads to sudden critical clinical statues for the patient. Our case portrays a moderate hyponatremia within 4 days of clinical presentation of chylous thoracic leak.

Case Description: Our case is of a 32 year old male with a past medical history of asthma, presenting after a motor vehicle accident. His course was found to be complicated by recurrent pleural effusions, with bilateral chest tube placement, and high outputs of 5 liters total per day. Chemistry studies demonstrated elevated triglycerides, cholesterol, in concordance with chylous leak, with low fat diet, TPN, midodrine, and octreotide initiation for treatment of the chylous leak. In addition, patient had an intractable headache and nausea, with subsequent development of a hyponatremia as low as 125, with urine sodium <10, urine osmolality of 1100, mOsm/kg, serum osmolality of 267, bicarb of 15, and a Cr of 0.7, at baseline. The clinical picture involved addressing nutrition demands with multi-disciplinary nutrition discussion for enteral feeding regimen, augmented with TPN, increasing salt intake to 3g three times daily, and a bicarb saline infusion to increase solute repletion at rates of 200cc/hr until repeat IR embolization was completed for the thoracic duct laceration. Patient's sodium was improved within 6 meq each day, with a final sodium of 135, with no residual neurologic symptomatology.

Discussion: Different etiologies lead to chylous leaks, including iatrogenic surgery, malignancy, and trauma. The morbidities associated with chylous leak in our case involved dangerous circulatory complications, with 4-5L of fluid per day needing supplementation, in addition to electrolyte repletion including bicarbonate and sodium. This case report is aimed to raise awareness for early monitoring of electrolyte levels in patients with high output effusions, to carefully monitor sodium, and to consider early consultation for nutrition, and diagnostic studies, to guide punctual clinical management.

SA-PO722

Etiology of Severe Hyponatremia in COVID-19 Patients Compared with Hyponatremia with Non-COVID-19 Patients by Urine Osmolarity and Sodium

Isaac Pak, Miniolla Durosier Louis, Shruti Kore, James Beck, George N. Coritsidis. *Westchester Medical Center, Valhalla, NY.*

Background: Lung diseases are known to be associated with hyponatremia and the Syndrome of Inappropriate Antidiuretic Hormone (SIADH). As COVID-19 cases surged during the pandemic, hyponatremia among COVID-19 cases were reported, suggesting an increase in the incidence of SIADH. This study attempts to evaluate for potential causes of severe hyponatremia (HN) prior and during the COVID-19 pandemic.

Methods: Single center, observational retrospective study comparing severe HN (serum sodium 125 mEq/L or less) presenting to Westchester Medical Center Emergency room between 2019- 2022. Demographic variables, urine osmolarity (Uosm), urine sodium (UNa) were collected from EMR. COVID-19 infections were diagnosed by PCR. A total of 477 charts were reviewed. Patients were divided in two groups, severe HN without COVID-19 in the year of 2019 and those with COVID-19 between 2020 and 2022.

Results: 38 patients presented with severe HN and COVID-19 compared to 105 Non- COVID-19 patients in 2019. Complete urinary measurements were found in 26 COVID-19 patients & 66 Non-COVID-19 patients. 16 out of 26 COVID-19 patients preented with concentrated urine, Uosm >300. In patient with Uosm >300 Osm/kgH20 and UNa >20 Meq/L, 31% were COVID-19 positive and 24% Non-COVID -19, In patient with Uosm >300 and UNa < 20, 31% were COVID-19 positive compared to 33% Non COVID-19. Of those presenting with dilute urine Uosm <300, 38% were COVID-19 patients & 42% were Non-COVID-19 patients.

Conclusions: Severe Hyponatremia among COVID-19 and Non COVID-19 patients did not show a significant difference in etiology when comparing predictors Uosm and UNa. Despite other reports suggesting a higher incidence of SIADH, this was not evident in our severe HN COVID-19 patients.

SA-PO723

Prevalence of Hyponatremia in Dengue-Infected Patients: Relationship with Systemic Inflammation

Juan Carlos Ayus,[1] Kyung Min Lee,[2] Daniel Caputo,[2] Armando Negri,[3] Carlos Eghi.[2] *[1]University of California Irvine, Irvine, CA; [2]Hospital Nacional Profesor Alejandro Posadas, El Palomar, Argentina; [3]Universidad del Salvador Facultad de Medicina, Buenos Aires, Argentina.*

Background: Dengue infection is becoming more prevalent worldwide and is associated with systemic inflammation. Systemic Inflammation is associated with non-osmotic release of ADH. Purpose: To evaluate the prevalence of hyponatremia in newly infected patients and its relationship with systemic inflammation.

Methods: Cross-sectional study in 375 patients with newly diagnosed dengue infection at Hospital Posadas in Argentina. Diagnosis was confirmed by IgM serology or PCR. Hyponatremia was defined as serum sodium concentration <135 mEq/L.

Results: Hyponatremia was present in 30.13% of the patients at admission. In multivariate logistic regression model, the OR for hyponatremia adjusting for age and sex was significant in the patients over 65 years, OR 6.034 (IC95 2.652-13.728) p= 0.001. We also analyzed the relationship of hyponatremia with C-reactive Protein (CRP). In multivariate logistic regression model adjusted for age, sex and CRP, OR for hyponatremia was significant in the group of patients with elevated CRP, OR 3.37 (IC95 1.439-7.895) p= 0.005. We found a negative correlation between serum sodium and CRP (Spearman correlation coefficient rho= - 0.283; p=0.002).

Conclusions: 1: The prevalence of hyponatremia is high in newly infected patients with dengue; 2: Degree of hyponatremia correlated with severity of inflammation.

SA-PO724

A Case of Asymptomatic Isotonic Hyponatremia Following Transurethral Bladder Resection

Morgan Hedden, Samir Hirpara, Alison Nguyen, Renu Regunathan-Shenk. Inova Internal Medicine Residency. *Inova Fairfax Hospital, Falls Church, VA.*

Introduction: Hyponatremia is a known, uncommon sequelae of transurethral resection (TUR) of the prostate or bladder. This is usually attributed to perioperative fluid absorption of glycine used during bladder irrigation. However, a less observed occurrence of hyponatremia related to this procedure is due to fluid absorption after a bladder perforation.

Case Description: We present an 85-year-old male who experienced gross hematuria and was found to have a bladder mass requiring TUR of the bladder. During this procedure, the patient underwent bladder irrigation with glycine 1.5% solution. Post operatively, the patient was initiated on continuous bladder irrigation (CBI) with normal saline solution. The morning of the surgery, his serum sodium level was 140 mEq/L. The post-procedure metabolic panel (drawn 12 hours after his TUR) was 130 mEq/L. This sodium was repeated 5 hours later, and was found to be 128mEq/L (Figure 1). Serum osmolality, urine osmolarity and urine sodium were 288 mosm/kg, 297 mosm/kg, and 132 mEq/L respectively. On physical exam, the patient was euvolemic, and had a tender but soft abdomen. These findings were consistent with isotonic, euvolemic hyponatremia. CT urethrogram was performed, which identified an anterior bladder perforation. CBI was discontinued, and he was started on a moderate fluid restriction. His serum sodium improved to 132mEq/L in about 20 hours (Figure 1).

Discussion: Bladder perforation is an uncommon cause of acute isotonic hyponatremia, due to the retention and reabsorption of urine. Transurethral resection of prostate tissue has historically been associated with isotonic hyponatremia due to intraoperative glycine administration and absorption. Our patient likely had a mixed picture, with both causes contributing to the sodium level. This case highlights the importance of ruling out bladder perforation when hyponatremia is found after a TUR procedure.

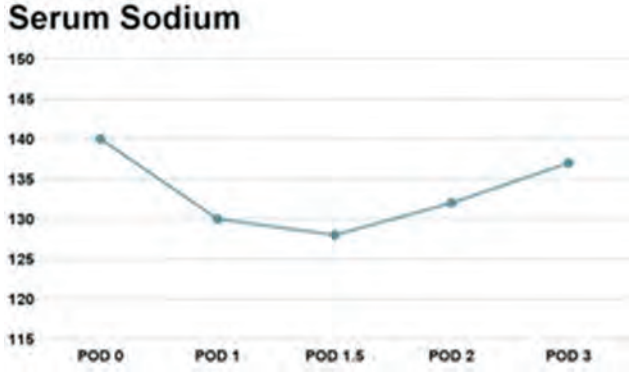

Figure 1: Serum Sodium (mEq/L) vs Postoperative Day (POD)

SA-PO725

Severe Hyponatremia Following Melphalan Use: An Important Recognition

Allaa Almoushref, Jad Tabbara, Laura Ferreira Provenzano. *Cleveland Clinic, Cleveland, OH.*

Introduction: Hyponatremia has been associated with adverse outcomes in various underlying diseases. In cancer patients, syndrome of inappropriate antidiuretic hormone (SIADH) has been a recognized complication of many chemotherapy agents. Melphalan has been reported to cause SIADH in the pediatric population. Still, no previous cases were reported in adults. Here we present a rare case of severe hyponatremia as a complication of melphalan chemotherapy.

Case Description: A 67-year-old female with a history of multiple myeloma achieving partial response on classical bortezomib regimen presented for an autologous stem cell transplant. The patient underwent a high dose of melphalan preconditioning regimen (200 mg/m2) 48 hours prior to the transplant. Serum sodium was 140 mmol/L before melphalan induction. The next day, the patient reported mild nausea. On the third day, serum sodium was 119 mmol/L repeatedly. Further workup showed serum osmolality of 253 mOsm/kg and normal renal function. Urine studies revealed a urine osmolality of 352 mOsm/kg and urine sodium of 41 mmol/L. No other associated symptoms were reported. The patient remained hemodynamically stable, and appeared euvolemic on the exam suggesting that SIADH as the etiology of hyponatremia. The decision was made to proceed with the transplant using only 1 L 0.9% Normal Saline for stem cell infusion. The repeat serum sodium level at 6 hours interval was 134 mmol/L, an increase of 15 mmol/l from the last measured level. Given this rapid correction was noted just after 48 hours of the development of hyponatremia, a re-lowering rescue strategy was applied with desmopressin and an infusion of dextrose 5% in water to avoid osmotic demyelination syndrome. The re-lowering strategy was stopped when serum sodium reached a level of 126 mmol/L, and the patient was then treated with fluid restriction (< 1 Liter/day) until serum sodium gradually increased to a normal level.

Discussion: Melphalan-induced SIADH is a rarely reported complication, particularly in adults. It has been hypothesized that alkylating agents, including melphalan, increase the release of anti-diuretic hormone, leading to hyponatremia. This case underlies the importance of monitoring sodium levels closely after melphalan infusion in adult cancer patients and avoiding high water and hypotonic fluids intake in patients receiving drugs that can trigger SIADH.

SA-PO726

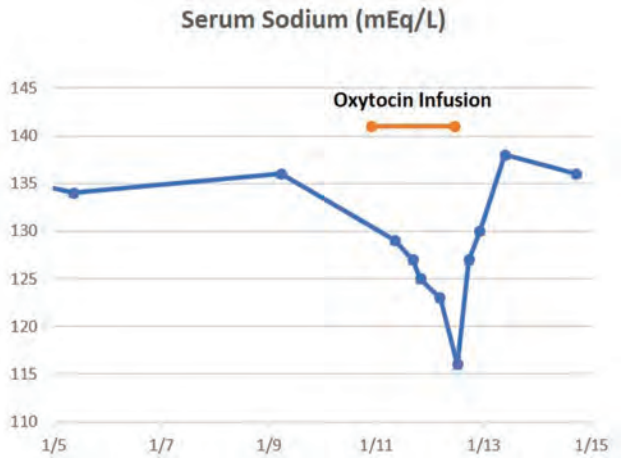
Acute Peripartum Hyponatremia due to Oxytocin

Olakunle A. Jayeola, Chaitanya A. Pal, Darren W. Schmidt, J. Pedro Teixeira. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: Medication-induced hyponatremia is common in hospitalized patients. In addition, the physiology of pregnancy predisposes to hyponatremia. We present a case of oxytocin-induced peripartum hyponatremia.

Case Description: A 40-year-old woman with diabetes and hypertension is admitted for induction of labor at 34 weeks of pregnancy for preterm rupture of membranes. Admission serum sodium (Na) was 136 mEq/L. Oxytocin was given as an infusion over 36 h at a maximum rate of 0.034 units/min and followed by a bolus of 30 units IV for postpartum bleeding. The first Na level after oxytocin started was 129 [Figure]. At hour 30 of the infusion, Na dropped to 123 and then reached a nadir of 116 an hour after the oxytocin was discontinued. Urine studies revealed osmolality 227 mOsm/L and Na 68 mEq/L. Fluid intake was restricted, urine output increased to ≥700 mL/h for 6 h, and Na levels rapidly normalized over the next 20 h.

Discussion: Along with systemic vasodilation and arterial underfilling, pregnancy is characterized by a reset of the osmotic set point for antidiuretic hormone (ADH) release, predisposing to hyponatremia. Pregnancy-specific causes of hyponatremia include syndrome of inappropriate ADH from hyperemesis gravidarum, Sheehan syndrome, and oxytocin-induced hyponatremia. Oxytocin and ADH are cyclic nonapeptides that differ by only 2 amino acids and are synthesized by overlapping groups of neurons in the hypothalamic supraoptic and paraventricular nuclei. Both bind G protein-coupled receptors with significant overlap in affinity. This cross-reactivity gives oxytocin an ADH-like effect. While well described in the literature, oxytocin-induced hyponatremia is likely underrecognized. Nephrologists and obstetricians alike must be aware of this form of medication-induced hyponatremia, allowing for appropriate monitoring and prompt recognition to prevent the maternal and fetal morbidity associated with hyponatremia in pregnancy.



SA-PO727

A Rare Cause of Worsening Hyponatremia in Pulmonary SIADH

Shorya Bector,[1] Yachit Bector.[2] [1]*Icahn School of Medicine at Mount Sinai, New York, NY;* [2]*Baba Farid University of Health Sciences, Faridkot, India.*

Introduction: Primary adrenal insufficiency is a relatively rare entity with most cases in the United States secondary to auto-immune or genetic processes. Here we present a rare case of tuberculous adrenalitis presenting as worsening hyponatremia in a patient with SIADH.

Case Description: 50-year-old male from Mexico, with medical history of pulmonary tuberculosis and chronic hyponatremia (SIADH secondary to tuberculosis), presented with complaints of generalized weakness, nausea and vomiting for 4 days. Initial lab evaluation was significant for hyponatremia of 119. This was a significant change from patient's previous mild hyponatremia readings in 130s which had responded to salt tablets and fluid restriction in the past. This led to further investigation into the cause of this worsening hyponatremia not responsive now to salt tablets or fluid restriction. Labs were significant for low cortisol with no increase seen with ACTH stimulation test, suggestive of primary adrenal insufficiency, subsequently confirmed by high ACTH. Imaging revealed interval worsening of pulmonary tuberculosis with left upper lobe opacity, scattered patchy opacities and tree-in-bud nodularity in lingula, left lower lobe and right upper lobes. Bilateral adrenal hyperplasia and retroperitoneal adenopathy were noted on abdominal CT scan. Patient was re-started on RIPE therapy and hydrocortisone and fludrocortisone supplementation requiring higher doses due to RIPE. Patient's symptoms improved and sodium stabilized in 130s after therapy initiation.

Discussion: Adrenal insufficiency generally appears in tuberculosis cases after 90% glandular destruction. Most patients with active disease have bilateral adrenal enlargement seen on imaging and biopsy is generally not required in cases with evidence of extra-adrenal tuberculosis. This case was unique as there was clear evolution in the cause of hyponatremia with worsening infection. It also highlighted the importance of investigating worsening of chronic hyponatremia in patients with pulmonary tuberculosis. Lastly, it should be highlighted that even with treatment of the infection, adrenal function rarely seems to return to normal likely due to anatomical destruction of the gland, emphazing the importance of early detection and medication compliance in this disease.

SA-PO728

The Prevalence of Hyponatremia in the United States

David A. Woolley,[1] Bhupinder Singh.[2] [1]*University of Oregon, Eugene, OR;* [2]*Nephcentric LLC, Phoenix, AZ.*

Background: Hyponatremia (serum sodium [corrected for hyperglycemia] < 135 mmol/L) is the most common electrolyte abnormality. Hyponatremia prevalence has been estimated in higher risk settings (e.g. 15% - 30% in hospitalized patients) using more recent data, while data regarding overall prevalence date back to surveys conducted prior to 2005. Using data from a nationally representative sample, we estimate the overall prevalence of hyponatremia in the US adult population using pooled data from population-based cross-section samples from 1999 – 2020, providing an analytic sample nearly 4-fold larger than used in previous estimates.

Methods: NHANES (National Health and Nutrition Examination Survey) produces national estimates that are representative of the total noninstitutionalized civilian US population. Typically conducted every 2 years, each cycle provides a nationally representative cross-sectional survey of approximately 10,000 persons, more than half of whom are adults providing serum samples. Multiple cycles can be combined to provide estimates with even greater precision. This study used pooled NHANES data from 1999 – 2020 (n = 55,731) to estimate the overall prevalence of hyponatremia across the general US adult population, as well as by gender and age subgroups. Observed data were used in the primary analyses, with missing data imputed in secondary analyses.

Results: Overall prevalence of hyponatremia in US adults is estimated to be 2.05%. As shown in the table, prevalence is higher in women ($p < 0.001$) and increases with age ($p < 0.001$). Based on US census data, it is estimated that in 2022, 5,944,024 US adults had hyponatremia. Secondary analyses based on imputed data showed very similar results.

Conclusions: Approximately 6 million US adults had hyponatremia in 2022, a prevalence of about 2%. Prevalence was higher in women and increased with age. As the population ages, the prevalence of hyponatremia in the US will likely increase.

Comparison of Local, Regional, and National Annual Trends of Hyponatremia Prevalence Rates in Hospitalized Patients

Iqra Nawaz, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

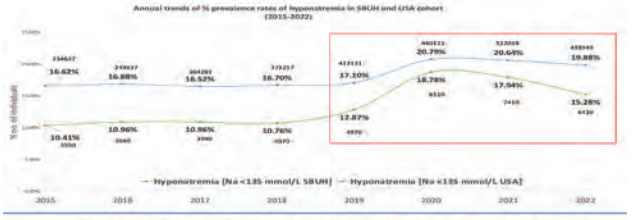
Background: Hyponatremia is the most common electrolyte abnormality among hospitalized patients. A high prevalence of hyponatremia among patients with COVID-19 has been reported in the literature. However, there is a paucity of data assessing hyponatremia's prevalence rates in the pre-and post-COVID-19 pandemic period.

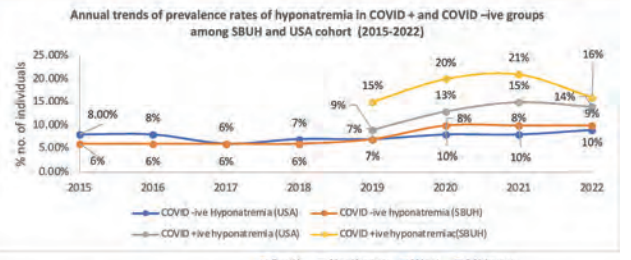
Methods: We used the TriNetX database (Stony Brook healthcare and the US-network (52 organizations)) to identify adults with hyponatremia (Na <135mmol/L) and normal-natremia (Na 135-145mmol/L) within the first 24hrs of inpatient or ED visit from Jan 1, 2015, to Dec 31, 2022.

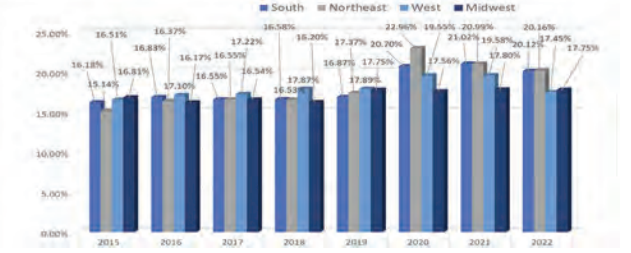
Results: Hyponatremia prevalence was 14% (40,570) in the SBUH cohort (298,130) and 19% (3,066,241) in the US cohort (16,395,015), respectively. Hyponatremia rates increased from 10% (4070) to 18% (6510) in the SBUH cohort, as compared to 16% (371,257) to 20% (460121) in the US cohort from 2019 to 2022. The rise of hyponatremia rates was 15% to 21% in SBUH in COVID +ive group compared to 7% to 10% in COVID -ive group from 2019 to 2021. Hyponatremia rates increased regionally from 2019 to 2022, with the highest rates of 22% and 20% noted among the Northeast and South regions in 2020. Hyponatremia among COVID-19 patients was associated with a significantly higher risk of ICU admissions, mechanical ventilation, and death.

Conclusions: Hyponatremia rates have been increasing locally, regionally, and nationally since 2019. Relatively higher prevalence rates were seen during the 2019-2021 period but were higher in both COVID-19 +ive and COVID-19 -ive groups, with a notably higher rise in hyponatremia rates among patients with COVID-19.

	COVID +ive Hyponatremia (Na <135) n(5030)	COVID+Normonatremia(Na 135-145 mmol/L) n(15,830)	Hazard ratio(CI)
Death	1030(20%)	1900(12%)	1.76(1.593 1.828) p < 0.001
Mechanical Ventilation	710(14%)	1340(8.4%)	1.6(1.531 1.1816) p < 0.003
ICU admissions	1570(31%)	2870(18%)	1.7(1.6,33 1.815) p <0.001







SA-PO730

Risk Factors of Under-Correction in Severe Hyponatremia: A Post Hoc Analysis of the SALSA Trial

Junmo Ahn,[1] Jang Won Seo,[1] Yun Kyu Oh,[2] Sejoong Kim,[3] Seon Ha Baek.[1]
[1]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: The under-correction of hyponatremia, non-optimal correction, is insufficient to improve cerebral edema, associated with increased mortality. Few prospective studies have identified the individuals at high risk of under-correction under controlled hypertonic saline treatment.

Methods: We conducted a post hoc analysis of a prospective randomized controlled study – the SALSA (Efficacy and Safety of Rapid Intermittent Correction Compared With Slow Continuous Correction With Hypertonic Saline) trial in 178 patients with glucose-corrected serum sodium (sNa) ≤125 mmol/L. Six subjects without sNa values during the entire follow-up period were excluded from the study. Under-correction was defined as sNa of less than 5 mmol/L within 24 hours or sNa of less than 10 mmol/L or 130 mmol/L within 24-48 hours.

Results: Mean age was 72.8 years old and mean sNa concentrations were 118.2 mmol/L. Over 48-hour intervention period, mean changes in sNa at 24 hours and 48 hours were 8.6 and 11.5 mmol/L, respectively. Twenty-six of 172 patients (15.1%) experienced under-correction (10 patients within 24 hours and 21 patients within 48 hours). The under-correction group received more amount of hypertonic saline (486 ml vs 932 ml, P <0.001) and had less urine output for 48 hours (4117 mL vs 2647 mL, P = 0.004). High levels of urine osmolality, serum calcium and creatinine and lower levels of body mass index, systolic blood pressure, uric acid, and albumin were associated with greater risk for under-correction. The etiologies of hyponatremia and infusion methods of hypertonic saline were not associated with under-correction.

Conclusions: Among patients with symptomatic severe hyponatremia under controlled hypertonic saline treatment, under-correction occurred in 15% and were associated with baseline patient's information.

SA-PO731

Response of Relowering Treatment and Clinical Significance in Severe Hyponatremia: A Post Hoc Analysis of the SALSA Trial

Junmo Ahn,[1] Jang Won Seo,[1] Yun Kyu Oh,[2] Sejoong Kim,[3] Seon Ha Baek.[1]
[1]Hallym University Dongtan Sacred Heart Hospital, Hwaseong, Gyeonggi, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.

Background: Relowering treatment has been performed in overly rapid correction of hyponatremia and its response may be numerous. However, few studies evaluated response of relowering therapy and its relationship to prognosis in patients with treating hyponatremia.

Methods: One hundred seventy-eight patients with glucose-corrected serum Na (sNa) ≤125 mmol/L were included. Eighty-seven out of 178 patients (in total 207 cases) underwent relowering treatment. Relowering regimen was 5% dextrose infusion of 10 ml/kg over 1hour if sNa level increase is ≥10 mmol/L or ≥18 mmol/L within 24 or 48 hours, respectively. Patients with concurrent desmopressin use or without sNa level after relowering were excluded. Eighty-seven patients (age 73.1 years, male 43.7%, and mean initial sNa 117.0 mmol/L) were classified into responder group (RG) (≥ 2 mmol/L) (34/87) and non-responder (NRG) (< 2mmol/L) (53/87) group according to decrease of sNa after relowering treatment. Overcorrection was defined as increase in the sNa level by >12/18 mmol/L within 24/48 hours.

Results: Mean of sNa at time of relowering treatment and delta sNa from initial sNa were 128.6 mmol/L and 11.7 mmol/L, respectively. Among 87 patients with relowering treatment, overcorrection occurred in 9/34 (26.5%) of RG and 27/53 (50.9%) of NRG (P = 0.024). Median value of sNa decreases by 1 mmol/L (interquartile -1 to 3 mmol/L) in total, 4 mmol/L (interquartile 3 to 6 mmol/L) in RG, 0 (interquartile -2 to 1 mmol/L) in NRG after treatment. Lower initial sNa level (adjusted odd ratio [OR] 0.86, P=0.008), lower initial potassium level (adjusted OR 0.28, P=0.003), NRG (adjusted OR 3.41, P=0.032) were associated with overcorrection.

Conclusions: Our findings indicate that a decrease in sNa levels less than 2 mmol/L following relowering therapy may predict overcorrection in hyponatremic patients treated with hypertonic saline.

SA-PO732

Use of Serum Osmolality to Guide Management of Severe Hyponatremia Outside of Detectable Range

William J. Assante, Sanjeev Gupta, Amol Mittal, Savneek S. Chugh.
Westchester Medical Center, Valhalla, NY.

Introduction: Hyponatremia is common, and it is heterogeneous in its clinical presentation (ranging from mild and asymptomatic to critically low with severe symptoms, such as seizures). Competent management entails identifying the etiology and monitoring sodium closely to avoid overcorrection. Consequently, a challenge arises when the serum sodium is below measurable range for the lab. In such cases, it is more difficult to discern the starting sodium and therefore prevent overcorrection. This case demonstrates use of serum osmolality to estimate sodium in these cases.

Case Description: A 44-year-old male with a history of alcohol abuse was admitted to the hospital due to decompensated cirrhosis. He presented with jaundice, shortness of breath, and swelling in his lower extremities. Sodium on admission was < 106mg/dL, which is lower than the lower limit of calculation for the laboratory. Serum osmolality 219 mOsm/kg, urine Na <20 mmol/L, urine Cl <20 mmol/L, urine osmolality 413, BUN/Cr 7/0.66, serum alcohol level 113.7mg/dL. Despite receiving 3% hypertonic saline for 24 hours, his sodium continued to be below 106mg/dL, even on blood gas analysis. In order to determine the initial sodium level upon admission and the rate of correction, we used the following formula: serum osmolality = 2(Na) + BUN/2.8 + Glucose/18 + EtOH/3.7 (where 219 = 2x Na + other values). According to this formula, the estimated initial sodium level was 94 mg/dL, and subsequent measurements using this formula showed appropriate correction. The patient remained on 3% hypertonic saline for 48 hours, and two days later, his sodium level reached 107. At this point, the administration of 3% saline was discontinued, and the patient was given intravenous Lasix on a daily basis due to suspected hypervolemic hyponatremia in the context of liver cirrhosis. The sodium levels continued to improve slowly, reaching 140 on the eighth day of hospitalization.

Discussion: The patient in this case presented with critically low sodium below detectable range and severe symptoms, necessitating a precise plan of care for improving sodium promptly but also without overcorrecting. Using simple algebraic calculations involving the serum osmolality formula, the patient's sodium was reliably estimated. This guided sodium correction without any episodes of overcorrection in this already critically ill patient.

SA-PO733

Modified Formula to Predict a Change in Serum Sodium in Patient with Hyponatremia Requiring RRT

Shruti Shettigar, Scott D. Cohen, Shane A. Bobart, Surafel K. Gebreselassie.
Cleveland Clinic Florida, Weston, FL.

Introduction: Hyponatremia is a common and feared electrolyte imbalance encountered, but rapid correction of sodium is what most physicians dread. In patients with hyponatremia requiring RRT, controlling the rate of sodium correction can be challenging & often requires the use of a hypotonic solution to dilute the dialysate. Here we present a case of a patient with hyponatremia pending liver transplant, who was started on CVVHD & rather than using a hypotonic solution we used a slower dialysate flow rate to prevent rapid correction of sodium.

Case Description: 39 year old male with decompensated cirrhosis presented with acute, asymptomatic hypervolemic hyponatremia. Initial labs showed S.Na 120, S.Osm 273, U.Osm 328, U. Na 49, BUN 74, Creatinine 2.36, CO2 17, normal TSH & cortisol. Despite fluid restriction, hypertonic saline, furosemide & tolvaptan, his sodium did not improve and fluctuated between 120-124. He also developed worsening renal failure needing initiation of CVVHD. To avoid overcorrection of sodium, the following modified formula was used to predict the rate of correction: [{**Dialysate Na** (140) - **Patient's Na** (120)} /**TBW** {0.6 X patient's weight(141)}] X **Dialysate flow Rate**(1L/hr) **= Rate of sodium correction** (~0.23mEq/L/hr) In our patient we used Qd (Dialysate flow Rate) as 1.5L/hr to get 0.35mEqL/hr as the rate of sodium correction His sodium corrected to 127 on day 1,131 on day 2 and plateaued at 134 on day 3.

Discussion: Rapid correction of hyponatremia in cirrhosis runs a higher risk of patients developing osmotic demyelination syndrome. On CVVHD there is a risk for rapid correction if adjustments like diluting the dialysate with a hypotonic solution to reduce the dialysate sodium, are not made. The above formula helps us adjust the dialysate flow rate so that we can predict the rate of sodium correction to be <8mEq/24hrs, thus preventing an overcorrection of hyponatremia. Various factors can affect the serum sodium in patients on CVVHD like IV infusions, insensible losses, etc. which explains why there wasn't an exact correction of sodium as predicted in this patient. However by setting an upper limit of sodium correction using a slower dialysate flow on CVVHD we could prevent overcorrection of hyponatremia. If predicted change in hourly serum sodium is higher, consider adding hypotonic solution to avoid overcorrection.

SA-PO734

Urea for the Treatment of Hyponatremia: A Two-Center Experience

Anissa Pelouto,[1] Sophie Monnerat,[2] Adrienne A. Zandbergen,[1] Julie Refardt,[2] Mirjam Christ-Crain,[2] Ewout J. Hoorn.[1] *[1]Erasmus MC, Rotterdam, Netherlands; [2]Universitatsspital Basel, Basel, Switzerland.*

Background: Oral urea is an effective treatment for hyponatremia, especially in patients with the syndrome of inappropriate antidiuresis (SIAD). However, data are limited and no predictors for treatment response have been identified. Here, we report our two center experience on efficacy, safety and tolerability of oral urea to correct hyponatremia.

Methods: Retrospective study including hospitalized patients at the Erasmus Medical Center, The Netherlands and University Hospital Basel, Switzerland who received oral urea for hyponatremia (plasma sodium (pNa) <135 mmol/l) between August 2018 and September 2022. The primary outcome was the rise in pNa until discontinuation of urea and/or discharge. The secondary outcomes included the risk of overcorrection (rise in pNa >10 mmol/l in 24h) and urea discontinuation due to side effects. Linear regression analyses were performed to identify predictors for pNa rise.

Results: In 138 patients (median age 69, 53% males, 92% SIAD) 159 urea treatment episodes (median dose 30 g/d) were identified. Concomitant fluid restriction (median 1L/24h) was prescribed in 88%. Under urea, pNa rose from 127 mmol/L (IQR 123–129) to 134 mmol/L (IQR 131–136) in 4 days (IQR 2–7) and pNa normalization was achieved in 47% of the cases. Higher baseline pNa and more liberal fluid intake were associated with a lower pNa rise (-0.7 mmol/L, 95%CI -0.8 to -0.6 and -0.4 mmol/L, 95%CI -0.6

to -0.2, respectively). In contrast, longer treatment duration and higher estimated glomerular filtration rate (eGFR) were associated with a greater pNa rise (0.3 mmol/L, 95%CI 0.1 to 0.4 and 0.2 mmol/L, 95%CI 0.1 to 0.4, respectively). Patients who reached normalization were treated significantly longer than those who did not (median 6 vs 3 days). Overcorrection occurred in 6 patients (4%, rise 13 ± 2 mmol/L in 24h). Urea was discontinued in 12 patients (9%) due to poor palatability and/or gastro-intestinal symptoms. No treatment-related serious adverse events, including osmotic demyelination syndrome occurred.

Conclusions: In this largest cohort reported to date, oral urea effectively corrected hyponatremia with a relatively low rate of overcorrection and side-effects. Higher baseline pNa and more liberal fluid intake were associated with a lower pNa rise, whereas longer treatment and higher eGFR were associated with a greater pNa rise.

SA-PO735

Serum Osmolality Testing and Preserved GFR Are Associated with Improved 30-Day Mortality in Severely Hyponatremic Patients

Oliver J. Fox, Cai Davis, Thomas Ash, Kristin Veighey. *University Hospital Southampton NHS Foundation Trust, Southampton, United Kingdom.*

Background: Despite UK guidelines advocating paired osmolalities and urinary sodium, inadequate investigation of hyponatremia is common. Although many hospitals suggest serum osmolality as an initial test, it is unclear whether this approach improves outcomes. We have built a logistic regression model to explore the association between serum osmolality (sOsm) testing status and mortality in severely hyponatremic patients. We also examined renal function to identify if this conferred greater risk.

Methods: We analyzed sodium values on admission from 87,174 patients in a large UK tertiary hospital. We extracted U/E, measured osmolalities, age, and blood glucose. Since we wanted to isolate the effect of a sOsm test, it was important to control for its value. In the absence of a measured osmolality, we therefore derived a calculated osmolality using the first glucose and urea available within 24h. We validated this by regressing 753 measured and estimated osmolalities ($R2 = 0.6958$, $p < 0.001$). 30-day-mortality was modeled with covariates 'Sodium Result', 'sOsm value (calculated if measured not available)', 'age', 'GFR' and an interaction term identifying if testing was associated with improved mortality when sodium was <126meq/L.

Results: Testing for serum osmolality in patients with sodium values <126meq/L was associated with lower 30 day mortality (coefficient -1.527, $p<0.001$), as was preserved eGFR ($p<0.01$) and younger age ($p<0.001$). Of 1187 patients with Na+<126meq/L, just 39.4% received a sOsm test within 7 days of admission.

Conclusions: In this large hospital cohort, a low proportion of patients received a serum osmolality when severely hyponatremic. Performing serum osmolality testing is associated with lower 30 day mortality. Patients with impaired renal function were at increased risk. Not being able to identify patients who were admitted for palliation or identifying further clinical predictors of mortality were important limitations. This is the first large study where sOsm has been calculated in place of a measured value to model the impact of the test itself on outcomes, a technique which could be used on other datasets. The results of this analysis have led to the adoption of an electronic alert to prompt sOsm testing, the impact of which will be measured in 3 monthly intervals.

SA-PO736

Chronic Hyponatremia Is Independently Associated with Mortality at Each Stage of CKD

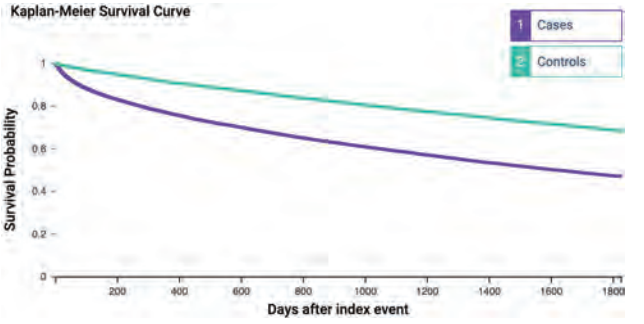
Steven Achinger,[1,2] Ambuj Kumar,[1] Athanasios Tsalatsanis.[1] *[1]University of South Florida Morsani College of Medicine, Tampa, FL; [2]Watson Clinic LLP, Lakeland, FL.*

Background: Prior studies have shown hyponatremia is associated with mortality among patients with CKD. What is not clear is whether or not hyponatremia is a marker of underlying disease severity or if hyponatremia is associated with mortality independent of the severity of the underlying CKD and other comorbid conditions. The objective of this study is to determine if chronic hyponatremia (> 90 days duration) is independently associated with mortality and secondary outcomes at all stages of CKD.

Methods: All adult patients with CKD with chronic hyponatremia (cases) and without chronic hyponatremia (controls) between 2012 and 2018 were eligible for inclusion. The groups were matched for demographics and CKD stage using propensity scores. TriNetX research network was used to identify cohorts. The follow-up time was 5 years after CKD diagnosis. Primary outcome was mortality. Secondary outcomes were cerebrovascular, cardiovascular, infectious, thrombotic and neurodegenerative outcomes. All outcomes were analyzed as time to event using Kaplan-Meier analysis and summarized as hazard ratios. Subgroup analysis was performed for each CKD stage.

Results: The analysis included 25,944 cases and 25,944 matched controls. The mean age for cases was 66.3 (SD 15.8) and 65.9 (SD 16) years in controls. Patients in the cases group had higher chances of death (HR: 2.11, 95% CI: 2.05-2.18, $p<0.001$), stroke (HR: 1.92, 95% CI: 1.82-2.02, $p<0.001$), sepsis (HR: 4.17, 95% CI: 3.99-4.36, $p<0.001$), ischemic heart disease (HR: 1.7, 95% CI: 1.65-1.74, $p<0.001$), myocardial infarction (HR: 2.42, 95% CI: 2.31-2.54, $p<0.001$), CHF (HR: 2.32, 95% CI: 2.24-2.41, $p<0.001$), pneumonia (HR: 2.29, 95% CI: 2.20-2.37, $p<0.001$), cellulitis (HR: 2.06, 95% CI: 1.92-2.14, $p<0.001$), PE (HR: 2.09, 95% CI: 1.92-2.27, $p<0.001$) and dementia (HR: 1.66, 95% CI: 1.56-1.76, $p=0.005$). Subgroup analyses indicated consistent trends in each CKD stage.

Conclusions: At each of stages of CKD, 1 and 2 collectively, 3, 4 and 5, chronic hyponatremia is independently associated with morbidity and mortality.



SA-PO737

Overcorrection in the Management of Hyponatremic Patients [Na+] ≤125 mmol/L Following Emergency Department Admission

Shruti Kore, George N. Coritsidis, Sanjeev Gupta, James Beck. *Westchester Medical Center, Valhalla, NY.*

Background: Hyponatremia (HN) is the most common electrolyte abnormality. Treatment of a low serum sodium [Na^+] level needs to be gradual to avoid overcorrection (OCx). We studied patients who were overcorrected and why.

Methods: Patients admitted to Westchester Medical Center via the Emergency Department from 2019 - 2022 with [Na^+] ≤125 mmol/L were included. An OCx is defined as a [Na^+] correction > 8 mmol/L in 24 hours. Slowing or reversing the OCx is considered a reversal. The use of hypertonic saline (HTS), serum and urine osmolarity (UOs), urine sodium, and the duration were recorded.

Results: 477 patients were studied per the inclusion-exclusion criteria. 43% were on HN-associated medications averaging 1.83 (+/- 0.89) per patient with loop diuretics the most common. Cirrhosis was the most common HN-associated chronic disease, and renal consultation was requested in 58% (275/477). OCx occurred in 89 (19%) of patients, with a higher odds ratio (OR) in patients with UOs<300 (OR 3.9) and in whom HTS was administered (OR 4.5). Psychoactive medications were more common in OCx versus diuretics (27 vs 8%) and chronic diseases less likely in OCx (31.5 vs 60%). The rate of OCx was 9.2 +/- 6.1mmol/L in 24 hours. Reversal of treatment was seen in 50% of OCx and risk was increased in patients with UOs <300 (OR 4.3) and HTS (OR 9.4).

Conclusions: OCx is associated with predictors UOs and HTS. Patients presenting with Na<125, on psychoactive medications, and lacking HN-associated chronic diseases should prompt an immediate renal consult to adequately assess HN physiology, underscore the need for UOs, and assess the selection of empiric fluids. While many of these findings are in general associated with HN, this study also highlights their association with OCx.

Table 1: Baseline Characteristics

	Total population (n=477)	OCx (n=89)
Males	254 (53%)	39 (44%)
Average age (years)	62.74 (+/- 16.04)	61.52(+/-16.83)
Patients on any HN-inducing Medication*	203 (43%)	40(45%)
Loop Diuretic	158 (33%)	7(8%)
Thiazide Diuretic	50 (10%)	13(15%)
Psychoactive Medication	86 (18%)	24 (27%)
Kidney Disease	86 (18%)	14(16%)
Liver Cirrhosis	137 (29%)	10(11%)
Congestive Heart Failure	64 (13%)	4(4%)

Table 2: Total Adequate Correction vs Overcorrection

	Adequate Correction (n=388)	Overcorrection (n=89)	p-value
Average Initial Sodium (mmol/L)	121.68 (+/- 3.82)	118.94 (+/- 4.33)	**<.001**
Empiric IV Fluids	209 (54%)	68 (76%)	**<.001**
Hypertonic Saline	16 (4%)	18 (20%)	**<.001**
Renal Consult	215 (55%)	60 (67%)	**0.038**
Average Time to Renal Consult (hours)	25.12 (+/- 45.36)	13.51 (+/- 17.25)	0.065
Full Lab Workup	121 (31%)	40 (45%)	**0.013**
Average Time to Workup (hours)	24.28 (+/- 54.28)	14.09 (+/- 37.92)	**0.019**

Use of Copeptin to Diagnose Nephrogenic Diabetes Insipidus Secondary to Hypercalcemia

Olivia R. Drummond, Adrian J. Baudy. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Diabetes insipidus (DI) is a condition characterized by polyuria caused by inadequate antidiuretic diuretic hormone (ADH) activity. Differentiating between central and nephrogenic DI is usually accomplished by an indirect water deprivation test, which is effective, however inconsistencies in sample collecting can confound results. An emerging method of determining the etiology of DI is through the measurement of Copeptin, a moiety which is cleaved off the pro-ADH molecule and is a surrogate marker for ADH levels. Here, we discuss a case of a nephrogenic DI, in which a Copeptin level was used to assist in diagnosis.

Case Description: A 23-year-old woman presented to the hospital with abdominal pain and vomiting. She was found to have necrotizing pancreatitis and a calcium of 16 mg/dL. She was treated with IV fluids, calcitonin and zoledronic acid. An ultrasound and sestamibi scan revealed a parathyroid adenoma. The patient then developed hypernatremia up to 167 mmol/L with urine osmolality of 130 mosmol/kg, despite daily fluid resuscitation. Workup for differentiating central from nephrogenic DI included TSH, cortisol, MRI brain which were unrevealing. The patient had no response to DDAVP 0.1 mcg or 2 mcg subcutaneously. However, with a higher dose of 4 mcg, the urine osmolality increased to 307mosmol/kg and sodium decreased by 2 mmol/L. Given the incomplete response to DDAVP, nephrogenic DI was diagnosed and treated with a thiazide diuretic and D5W until her sodium normalized. Copeptin levels returned at more than double the upper limit of normal, confirming the diagnosis of nephrogenic DI. This further confirmed hypercalcemia as the culprit and parathyroidectomy was planned after discharge.

Discussion: Copeptin can be a useful tool in differentiating nephrogenic DI from central DI. Response to DDAVP or water deprivation tests are widely used, however in our patient, as in many cases, the results were difficult to interpret as the lab collection times and urine output measurements were inconsistent. An elevated copeptin level provided a simplified way to assess the patient's level of ADH and confirm the diagnosis of nephrogenic DI. ADH is an unstable molecule and degrades quickly, thus cannot easily be measured directly. However, copeptin is a stable, surrogate marker for ADH levels and can be measured alone or in combination with water deprivation.

SA-PO739

From Shock to Sprinklers: A Rare Case of Polyuria in the ICU

Juan P. Moreno-Ortiz, Hiba Hamdan, Dana Sheely, Shubha Ananthakrishnan. *UC Davis Health, Sacramento, CA.*

Introduction: Arginine vasopressin deficiency (AVD), previously known as central diabetes insipidus, is most commonly idiopathic, a result of a tumor, neurosurgery, or trauma. Here, we present a case of massive polyuria caused by transient vasopressin deficiency in an ICU patient after discontinuation of therapeutic vasopressin used for septic shock.

Case Description: A 56-year-old man with a history of COPD, AIDS, R ear Squamous Cell Carcinoma, was admitted for COPD exacerbation. His course was complicated by respiratory failure requiring mechanical ventilation and septic shock due to R ear infection, managed with vasopressin. When stopped after two days, urine output went from an average of 1.5 to a peak of 8.2 L/day, associated with serum sodium rise from 130 to a peak of 148 mmol/L. Urine osmolality reached a nadir of 57 mOsm/kg and serum copeptin level was 3 pmol/L. Concerned for AVD, IV vasopressin was restarted and desmopressin was trialed, both resulting in resolution of polyuria, urine osmolality peaking at 547 mOsm/kg, and normalization of serum sodium. Oral desmopressin was initiated. ACTH, AM Cortisol, LH, TSH and prolactin levels were normal. Brain MRI did not reveal structural abnormalities. After eight days of serum sodium 135-145 mmol/L and urine output 2-3L/day, desmopressin was tapered off and patient was discharged. Sodium levels off desmopressin 12 days later were stable. Further review of his chart revealed a similar presentation following cessation of vasopressin during a hospitalization for septic shock five years prior, resolving without intervention.

Discussion: Vasopressin is released by the posterior pituitary gland in response to thirst, hyperosmolality, and hypotension. Analogs are used to treat catecholamine-resistant shock, and abrupt cessation has been reported to lead to transient AVD. Neurosurgical and cardiothoracic surgical patients have been reported to be at risk. We present a case of AVD in sepsis. Prior case series have proposed downregulation of V2 receptors as a mechanism for the polyuria and hypernatremia, however, a low normal copeptin level in the face of hypernatremia suggests that suppression of endogenous arginine vasopressin is a more likely process. Given the recurrent nature of AVD in this patient, future research is needed to identify predisposing factors.

Unintended Consequences: Severe Hypernatremia and Metabolic Alkalosis Following Baking Soda Ingestion for Urine Drug Screen Evasion

Manasawee Tanariyakul,[1,2] Thiratest Leesutipornchai,[1,2] Witina Techasatian,[1,2] Chinnawat Arayangkool,[1,2] Noppawit Aiumtrakul,[1,2] Mohammad I. Khan,[1,2] Christie H. Izutsu.[1,3] *[1]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [2]Hawaii Residency Programs Inc, Honolulu, HI; [3]Queen's Medical Center, Honolulu, HI.*

Introduction: Baking soda, also known as sodium bicarbonate, has various uses such as cleaning and treating conditions like metabolic acidosis and acid reflux. However, baking soda overdose can lead to fatal adverse events. We report a case of severe hypernatremia caused by intentional abuse of sodium bicarbonate to alter a urine drug screening (UDS) test result.

Case Description: We report a case of an individual found unconscious in a courthouse restroom. Initial findings revealed hypoglycemia to 55mg/dL and seizure activity upon EMS arrival. The patient was encephalopathic, prompting intubation. Formal laboratory tests showed critical hypernatremia, hypokalemia and metabolic alkalosis with Na>180, K=2.4, Cl=111, CO2>50, pH in blood gas=7.56. Further information was obtained from the patient's mother, revealing that the patient likely ingested baking soda with water before the UDS in an attempt to manipulate the test results. Interestingly, the initial UDS on admission returned negative for methamphetamine, but a repeat test done two days later resulted positive. The nursing staff also found white powder in the patient's bag. After mixing the powder with vinegar, bubbles were observed, raising suspicion of a baking soda ingestion. Sodium correction using D5W and LR, was initiated along with antiepileptic drugs in conjunction with serial lab monitoring to ensure that sodium levels were appropriately lowered. Unfortunately, the patient deteriorated further with development cerebral edema and brain herniation.

Discussion: Metabolic alkalosis occurs from an accumulation of $HCO3^-$ or an inability to eliminate excess $HCO3^-$. This case involved a patient with severe hypernatremia and metabolic alkalosis due to exogenous alkali intake from baking soda, presenting with seizures and encephalopathy. The initial blood gas indicated an acute metabolic alkalosis with respiratory compensation. Cytotoxicity resulting from seizure and fluid shifts from rapid changes in sodium levels can explain the cerebral edema. Notably, a simple test demonstrating the reaction between vinegar and baking soda can be done to confirm the substance and may change the clinical course.

SA-PO741

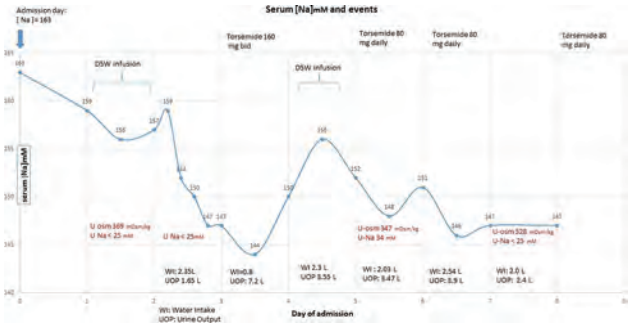
A Man with Serum [Na] 163 mM Who Is Not Thirsty

Eithan Orlev-Shitrit, Alan Segal. MMP Nephrology. *Maine Medical Center, Portland, ME.*

Introduction: Lack of thirst sensation is a rare cause of hypertonicity, as thirst is the main defense to maintain isotonicity and normal intracellular volume. Hypertonicity is sensed by osmoreceptor cells, which control thirst and ADH release. The ability to sense/act on thirst is both necessary and sufficient to prevent dehydration, with ADH playing a supportive role by increasing the kidney water absorbtion. We present a case of a patient who developed hypertonicity due to an acquired injury resulting in defects in both thirst (resulting in hypodipsia) and ADH release (resulting in reduced water retention).

Case Description: A 60-year-old man with a history of CHF, DM, HTN and CKD ([Cr] 1.5 mg/dL) was admitted for cardiogenic shock. He was managed with diuresis and discharged with Torsemide and water/salt restrictions. During the admission, [Na] increased from 132 to 154 mM. Four days after discharge, he was re-admitted when follow-up laboratory tests showing serum [Na] of 163 mM and urine osmolality of only 369 mOsm/L. Surprisingly, he did not complain of thirst. He was treated with D5W, reduced Torsemide dose, and daily water consumption of ~ 2.5 L. Within two days, serum [Na] corrected to 144 mM. CT head did not show a brain lesion (cardiac defibrillator precluded MRI). A transient resumption of Torsemide and liberation of water consumption led to an immediate worsening of hypernatremia. He was discharged with serum [Na] of 147 mM and instructions to keep strict water intake of ~3 L per day. To date, the patient is isotonic.

Discussion: Our patient developed severe hypernatremia, which—although initially promoted by water restriction and Torsemide—was maintained by a remarkable lack of thirst sensation and urine concentration defect. Most of the patients with this rare condition, are young and have an identified CNS etiology (e.g. tumor), whereas our patient was 60 years old without a brain lesion. We conclude that our patient developed hypertonicity due to a rare combination of lack of thirst (hypodipsia) and partial arginine vasopressin deficiency and was treated successfully with an increased water intake.



SA-PO742

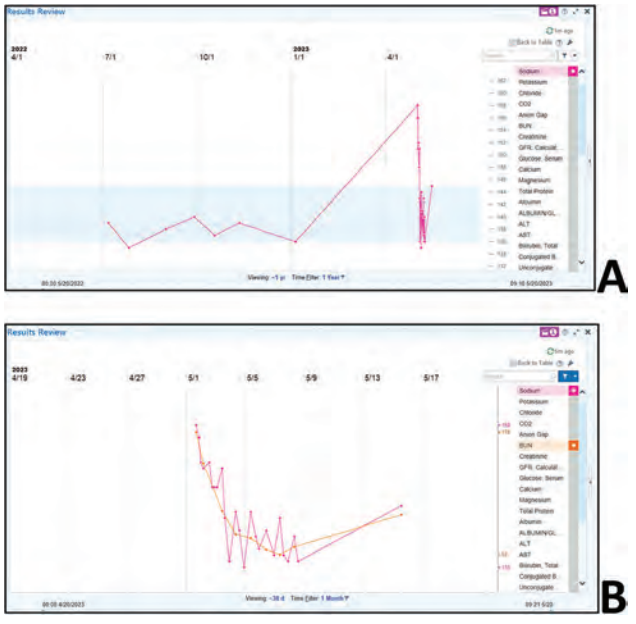
Unusual Polydipsia-Polyuria Syndrome, Hypernatremia, and Hypercopeptinemia: What Is the Diagnosis?

Aaron Henry,[1] Travis Mann-Gow,[1] Nneoma Agbasi,[3] Chidiebube Jeremiah,[2] Macaulay A. Onuigbo.[1,3] *[1]University of Vermont Larner College of Medicine, Burlington, VT; [2]East Tennessee State University, Johnson City, TN; [3]University of Vermont Medical Center, Burlington, VT.*

Introduction: Polydipsia-Polyuria Syndrome (PPS) can represent central diabetes insipidus (DI), nephrogenic DI or primary polydipsia (PP). Correct differentiation is crucial; Copeptin assay is useful. We describe PPS, hypernatremia, and hypercopeptinemia: Is this a new syndrome?

Case Description: A 76-yo female with Alzheimers disease was evaluated for dizziness, fatigue, incessant thirst, and chest pain. She was drinking excessively even from public faucets and had increased very wet diapers. The daughter restricted water intake at home. Vitals signs were stable. Physical examination was unremarkable. Sodium was 158 mmol/L, BUN 178 mg/dL, creatinine higher at 1.46 mg/dL, BNP 2000 pg/mL. Chest radiograph and non-contrast head CT were non-diagnostic. She received IV D5W and drank to thirst. Sodium normalized (Figure A). BUN trajectory was a near mirror image of Na trajectory (B). Incessant thirst persisted. Copeptin was 79.7 (<13.1) pmol/L. She was discharged with a diagnosis of PP and a Psychiatry referral.

Discussion: Does our patient have partial nephrogenic DI from AKI, drug-induced SIADH (?Sertraline), and/or PP, or a combination thereof? Hypernatremia on admission probably reflected true water deficit following forced restriction of water intake at home by the daughter in the few days preceding the admission. Follow up would require a delicate balance of controlled water intake. Psychiatry management of suspected PP could include behavioral therapy, health education, relaxation techniques and positive reinforcement. Her dementia could be a barrier. Recent evidence supports a role for GLP-1 agonists in PP. Several unanswered diagnostic and therapeutic questions around PPS remain and call for further research.



Na and BUN trajectories

Identification and Characterization of a Novel CASR Mutation Causing Familial Hypocalciuric Hypercalcemia

Shih-Hua P. Lin, Chien-Ming Lin, Chih-Chien Sung. *Tri-Service General Hospital Department of Internal Medicine, Taipei, Taiwan.*

Background: Although familial hypocalciuric hypercalcemia type 1 (FHH1) is primarily caused by monoallelic mutation in calcium-sensing receptor (*CASR*) gene, the characterization of the newly-identified CaSR mutation linked to clinical response to calcimimetics remains limited.

Methods: A 45-year-old male presenting with hypercalcemia, hypocalciuria, and inappropriately high parathyroid hormone (PTH) had a good response to cinacalcet (total serum calcium from 12.5 to 10.1 mg/dl). Sanger sequencing of *CASR*, *GNA11*, and *AP2S1* genes was performed in this family. The simulation model was used to predict the function of the identified mutant. The *in vitro* studies including immunoblotting, immunofluorescence, cycloheximide chase study, Calbryte™ 520 calcium (Ca^{2+}) detection, and half-maximal effective concentration (EC50) were examined.

Results: The patient was identified to carry a *de novo* heterozygous *CASR I554N* mutation, located in the cysteine-rich domain (residues 542–612) crucial to affect the ligands (Ca^{2+}) binding. This missense mutation was pathogenic based on the different software prediction models and ACGME criteria. The simulation model showed *CASR I554N* mutation decreased its binding energy with Ca^{2+}. Human *CASR I554N* mutation attenuated the stability of CASR protein, reduced the expression of p-ERK 1/2, and blunted the intracellular Ca^{2+} response to gradient extracellular Ca^{2+} (eCa^{2+}) concentration. EC50 study also showed calcimimetics rescued the function of *CASR I554N* mutation.

Conclusions: This novel *CASR I554N* mutation decreases CASR stability and its binding affinity with Ca^{2+}. Its correction of blunt response to eCa^{2+} by calcimimetics may support the therapeutic effect of cinacalcet for this patient.

Combined Consideration of Sex, Genotype, and Total Liver Volume Progression Determines the Risk of Hospitalization in an International Multicenter Cohort of Autosomal Dominant Polycystic Liver Disease

Dana Sierks,[1] Ria A. Schönauer,[2,1] Melissa M. Boerrigter,[3] Tabinda Jawaid,[4] Marie-Pierre Audrezet,[5] Léa Caroff,[5] Jan C. Degenhardt,[6] Jonathan de Fallois,[1] Bernhard Schlevogt,[7,8] Thomas Berg,[9] Frederik Nevens,[10] Terry J. Watnick,[11] John A. Sayer,[12] Whitney Besse,[13] Emilie Cornec-Le Gall,[5] Peter C. Harris,[4] Joost P. Drenth,[3] Jan Halbritter.[2,1] *[1]Division of Nephrology, Department of Internal Medicine, University of Leipzig Medical Center, Leipzig, Germany; [2]Division of Nephrology and Internal Intensive Care Medicine, Charité – Universitätsmedizin Berlin, corporate member of Freie Universität Berlin and Humboldt-Universität zu Berlin, Berlin, Germany; [3]Division of Hepatology, Department of Internal Medicine, Radboud University Medical Center, Nijmegen, Netherlands; [4]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [5]University of Brest, Inserm, CHU Brest, Brest, France; [6]Department of Nephrology, University Hospital Cologne, Cologne, Germany; [7]Department of Medicine B, University Hospital Muenster, Muenster, Germany; [8]Department of Gastroenterology, Medical Center Osnabrueck, Osnabrueck, Germany; [9]Division of Hepatology, Department of Internal Medicine, University of Leipzig Medical Center, Leipzig, Germany; [10]University Hospitals KU, Leuven, Belgium; [11]University of Maryland Medical System, Baltimore, MD; [12]Translational and Clinical Medicine Institute, Faculty of Medical Sciences, Newcastle University, Newcastle upon Tyne, UK; NHS Foundation Trust, Newcastle upon Tyne Hospitals, Renal Services, Newcastle upon Tyne, UK; National Institute for Health Research Newcastle Biomedical Research Centre, Newcastle University, Newcastle upon Tyne, United Kingdom; [13]Departments of Internal Medicine (Nephrology), Yale University School of Medicine, New Haven, CT.*

Background: Autosomal dominant polycystic liver disease (ADPLD) is a rare disease with female preponderance, majorly based on pathogenic variants in PRKCSH or SEC63. Clinically, ADPLD is characterized by vast heterogeneity ranging from asymptomatic courses to highly symptomatic hepatomegaly. Little is known to predict disease progression at early stages hindering clinical management and genetic counselling. By establishing genotype-phenotype correlations, this study aims to improve disease prognostication in ADPLD.

Methods: We analyzed an international cohort from ten tertiary centers with 265 ADPLD patients harboring pathogenic variants in PRKCSH or SEC63. Genotypes were correlated with in-depth phenotypic data including normalized age-adjusted liver volume (nTLV) and PLD-related hospitalization (liver event).

Results: 185 (70%) patients with ADPLD-PRKCSH and 80 (30%) patients with ADPLD-SEC63 were included (76% females). Classifying individual nTLV into predefined, age-adjusted progression groups yielded predictive risk discrimination for future liver events independent of sex and genetic defect **(Fig. 1A)**. Additionally, severe disease in terms of onset of liver events was more likely in patients with PRKCSH variants as compared to those with SEC63 variants **(Fig. 1B-C)**. A newly developed clinical score consisting of basic genotype and patient sex was able to discern mild courses from moderate and severe disease.

Conclusions: Both imaging and clinical genetic scoring have the potential to inform ADPLD-patients on their risk of developing symptomatic disease. Hereby, the combination of female sex, PRKCSH-disease, and rapid progression of hepatomegaly is associated with the greatest odds of PLD-related hospitalization.

Funding: Government Support - Non-U.S.

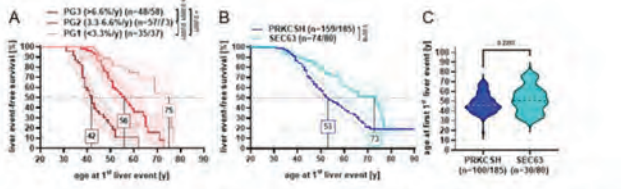

Fig. 1 (A) Risk classification for liver events stratified into age-adjusted progression groups (PG) defined by differential yearly change in normalized total liver volume (nTLV) (<3.3%/year – mild PG1 in pink; > 3.3 – 6.6%/year – moderate PG2 in red; >6.6%/year –severe PG3 brown). Liver event-free survival showed significant discrimination for all groups (median age 42 yrs (PG3) versus 56 yrs (PG2) versus 75 yrs (PG1). **(B)** Survival analysis stratified by basic genotype shows an increased likelihood of experiencing symptomatic liver events in *PRKCSH* individuals compared to *SEC63* individuals (median age 53yrs vs. 73yrs,, p<0.0018). **(C)** Comparison of symptomatic disease cases only did not yield significant differences in age at event (46yrs for *PRKCSH*- versus 50 yrs for *SEC63*-alteration, p=0.22).

SA-PO745

Outcomes of Foam Sclerotherapy for Large Kidney/Liver Cysts using Multi-Stage (Same/Next Day) and Multiple Sequential Procedures

Cassie Howe, Ryan Helland, Adriana Gregory, Timothy L. Kline, Lisa E. Vaughan, Vicente E. Torres, Marie C. Hogan. *Mayo Clinic Minnesota, Rochester, MN.*

Background: We have been performing sotradecol foam sclerotherapy (SFS) outpatient procedures to ablate liver/kidney cysts. SFS has led to substantial reductions in Targeted Kidney & Liver Cyst (TKCV/TLCVs), total kidney/liver volumes (TKV/TLV), improved QOL, & augments cyst volume reduction in addition to tolvaptan (kidney cysts) & octreotide (liver cysts). We examined efficacy in individuals with multiple large cysts who opt to undergo multiple or multi-stage SFS (same day or 2 consecutive days).

Methods: Kidneys & liver were segmented using a deep-learning algorithm & cysts segmented using semi-automated segmentation software, pre & 4+ mo post SFS. Wilcoxon tests assessed %Δ pre/post SFS. Median % Δ TKCV/TLCVs were calculated (per-patient) by taking median %Δ of targeted cysts within patient & compared to outcomes from single stage cyst procedures.

Results: For **multiple liver procedures**,(n=15) median Δ% TKCV/TLCVs was -76.5% [IQR, -90.3%, -42.8%, P<0.001] & ΔTLV % -1.9% [IQR, -7.4%, 0.42%, P=0.11] (**Fig 1**). For patients undergoing **multiple kidney procedures** (n=16), median % ΔTKCV was -88.8% [IQR, -95.1%, -82.0%, P<0.001] & Δ% TKV -13% [IQR, -23.8%, -4.9%, P<0.001]. Only 5 had **multi-stage liver procedures;** median Δ% TLCV post SFS -73% [IQR, -93%, -71%, P=0.06], & only 2 underwent **multi-stage kidney procedures**; median Δ% TKCV -52%[IQR, -73.5%, -31%, P=0.5].

Conclusions: Multiple SFS procedures led to substantial reductions in TKCV/TLCV/TKV/TLV; data on patients who underwent multi-stage procedures were sparse, but still demonstrated positive results. SFS is feasible & convenient for patients seeking ablation of multiple cysts in a single 1 or 2 day session. Multiple & multi-stage SFS appear to be effective for patients with high cyst burden mainly due to a limited number of large cysts, with good patient satisfaction.

The Clinicopathologic and Genetic Characteristics of Autosomal Recessive Polycystic Kidney Disease Presenting in Adulthood

Elhussein A. Elhassan,[1,2] Sahin Sarihan,[2] Susan M. McAnallen,[1] Orla Marie Dunne,[3,4] Katherine A. Benson,[2] Gianpiero Cavalleri,[2] Peter J. Conlon.[1,2] *[1]Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland; [3]Letterkenny University Hospital, Letterkenny, Ireland; [4]University of Galway, Galway, Ireland.*

Background: Autosomal recessive polycystic kidney disease (ARPKD) is a rare ciliopathy that causes massively enlarged kidneys and pulmonary hypoplasia in perinatal children, frequently leading to fetal demise. In the survivors, ductal plate malformation often causes congenital hepatic fibrosis and Caroli disease. However, the spectrum of presentation and disease varies considerably.

Methods: We examined the clinicopathologic characteristics of *PKHD1*-defined ARPKD. Genetic testing was performed using whole exome sequencing.

Results: Three unrelated families (4 adult individuals) were identified to harbor disease-causing *PKHD1* variants sequenced by the Irish Kidney Gene Project. The average age of initial presentation was 16.5 ± 18.6 years. In family (1), we identified biallelic *PKHD1* variants (NM_138694.4: c.2702A>C;p.N901T & c.107C>T;p.T36M) in a female patient with congenital hepatic fibrosis and non-enlarged cystic kidneys, during the evaluation of elevated creatinine. She had gradually progressed into ESKF at 53 years of age. In family (2), the renal-limited phenotype of PKD was identified in two siblings. No liver involvement was identified. The two siblings detected a homozygous missense variant in the *PKHD1* gene, NM_138694.4: c.5221G>A;p.V1741M. Patients progressed to ESKF at ages 36 and 40 years, respectively. In family (3), the index patient presented with predominant hepatic phenotype - recurrent cholangitis, portal hypertension, and Caroli disease at clinical disease-onset aged 48 years. A liver biopsy was performed and demonstrated marked liver fibrosis with numerous multifocal cystic dilatation of intrahepatic ducts. She was found to have multiple small bilateral kidney cortical cysts with impaired function. At the last assessment, aged 61 years, she developed slowly progressive kidney insufficiency, with a serum creatinine of 201 μmol/L and creatinine clearance of 23 ml/min about 15 years after her presentation. Exome-sequencing revealed pathogenic biallelic *PKHD1* variants (NM_138694.4; c.8068T>C; p.W2690R and c.338delG; p.G113Dfs*4).

Conclusions: While ARPKD is remarked with early-onset and high disease mortality, these cases illustrate disease heterogeneity, and *PKHD1*-defined ARPKD is not merely a pediatric disease.

SA-PO747

An Updated Analysis of the Irish Kidney Gene Project Registry

Elhussein A. Elhassan,[1,2] Sahin Sarihan,[2] Susan M. McAnallen,[1] Dervla M. Connaughton,[3] Kendrah O. Kidd,[4] Anthony J. Bleyer,[4] Gianpiero Cavalleri,[2] Katherine A. Benson,[2] Peter J. Conlon.[1,2] *[1]Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland; [3]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [4]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Over 700 genes have been implicated in monogenic nephropathies (MN), a significant cause of chronic kidney disease (CKD), but their prevalence is often underestimated. Diagnosing MN can personalize clinical management with better-informed choices of therapies and targeted disease surveillance and influence prognosis and genetic counseling for patients and their families. Herein, we provide an update on the diagnostic yield of various technologies (exome sequencing, targeted gene panel, and *MUC-1* sequencing) and immunostaining utilized by the Irish Kidney Gene Project (IKGP).

Methods: All results from the multidisciplinary genetic kidney clinic between January 2014 and March 2023 were analyzed in this prospective cohort study. All clinic visit records were analyzed for clinical and genetic factors associated with solved cases. Using the guidelines of the American College of Medical Genetics and Genomics, pathogenic or likely pathogenic variants were evaluated as disease-causing.

Results: Through the IKGP, 593 families (976 individuals) had been sequenced, of which 49.4% (482/976) were female. At the last follow-up, 58.5% of patients, with an average age of 42.3 ± 16.5 years, had reached end-stage kidney disease. We were able to demonstrate a likely-pathogenic/pathogenic variant in 47.4% (281/593) of families, encompassing 52 distinct monogenic entities. Three phenotypes accounted for up to 82% of positive results in genes related to autosomal dominant polycystic kidney disease (*PKD1* (number for families (*n*)=155), *PKD2* (*n*=23), *IFT140* (*n*=4)), autosomal dominant tubulointerstitial kidney disease (*UMOD* (*n*=8), *MUC1* (*n*=10), *HNF1B* (n=2), and *DNAJB11* (n=1)), and COL4A-related phenotypes (*COL4A5* (*n*=20), monoallelic *COL4A4* (*n*=1), *COL4A3* (monoallelic *n*=5; biallelic n=3)). Disease-causing variants identified in the remaining 42 genes comprised 17.4% of the solved families. In 31.1% (*n*=24) of the 77 families referred with *a priori* diagnosis of CKD of undetermined cause were found to have a known monogenic cause.

Conclusions: The use of broad genomic strategies had a high success rate, especially in the presence of family history.

SA-PO748

Incompletely Penetrant Variants Underlie the Familial Variability in Disease Progression in Adults with ADPKD

Elhussein A. Elhassan,[1,2] Katherine A. Benson,[2] Stephen Madden,[2] Francesca Ciurli,[3] Valeria Aiello,[3,4] Anna Vella,[3,4] Francesca Montanari,[3] Carlotta P. Cristalli,[3] Gaetano La Manna,[3,4] Irene Capelli,[3,4] Gianpiero Cavalleri,[2] Peter J. Conlon.[1,2] *[1]Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland; [3]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [4]Universita degli Studi di Bologna, Bologna, Italy.*

Background: Although familial variability is one of the most prominent characteristics of autosomal dominant polycystic kidney disease (ADPKD), its molecular causes remain unknown. We hypothesize that co-inheritance of additional *PKD1* or *PKD2* variants with a pathogenic inactivating variant may contribute to familial disease progression.

Methods: Family members with clinically diagnosed polycystic kidney disease were recruited. Primary disease-causing variants were identified using ADPKD targeted next-generation sequencing panel. Additional variants (AV) were investigated using the criteria listed below: 1) rare (allele frequency <0.01), 2) missense variants in exonic or splicing regions, and 3) SIFT and PolyPhen predicted to be detrimental to protein formation variants were included. All AVs were deemed as variants of uncertain significance. We compared the progression to end-stage kidney failure (ESKF) between families with AV (at least one member with an additional ADPKD variant per family) and families with only primary variants.

Results: A total of 115 families with ADPKD (338 individuals, 55.9% female, 53.8% progressed to ESKF) were included; 60 different truncating *PKD1* variants, 37 non-truncating *PKD1* changes, and 7 *PKD2* variants. 31 (26.9%) families (52 individuals) had at least one patient with AV. Among these families, those with non-truncating *PKD1* variants and AV had a lower mean age of ESKF than in families without additional variants (46 ± 10.1 vs. 52.35 ± 11.6, $p = 0.041$). The mean age of ESKF was not different between families with truncating *PKD1* and *PKD2* variants based on AV, 47.8 ± 8.4 vs. 47.3 ± 9.2 and 61.5 ± 3.5 vs. 67.3 ± 11.6, respectively. In a multivariate Cox mixed-effects model (adjusted for sex, early-onset of hypertension, early-onset urological events, and primary ADPKD variants), we identified an independent effect of the additional variants on familial disease progression [multivariate shared frailty model $p = 0.0015$].

Conclusions: Our findings suggest that familial variability in ADPKD may be explained by co-inheritance of additional damaging variants, particularly in families with *PKD1* non-truncating variants.

SA-PO749

ADPKD Comorbid Conditions at a PKD-Focused Center

Allen Chao, Ying Gao, Diana Etwaru, Meyeon Park. *University of California San Francisco, San Francisco, CA.*

Background: We are a center providing multidisciplinary care to patients with autosomal dominant polycystic kidney disease (ADPKD). We sought to evaluate the prevalence of common co-morbid conditions in our patient population.

Methods: We used the Epic Systems electronic medical record (EMR) at our institution to perform a search for clinical data on patients with ADPKD seen in our health system. We used the following ICD-10 codes: hypertension (I10, I15.1, N28.89), flank pain (R10.9, G89,29), hematuria (R31.0, R31.1, R31.9, R31.2), pancreatic cysts (D49.0, K86.2, Q45.2), hernia (K45.0, K42.9), brain aneurysm (Q28.3, I72.9, I67.1, I71.21, I71.9, I71.4, Z86.79), nephrolithiasis (N20.0), liver cysts (Q44.6, K76.89), urinary tract infection (UTI, N39.0), liver transplant (Z94.4), and family history of PKD (Z84.1). We performed chart review to validate data on a subset of patients.

Results: 556 unique patients were identified out of a total of 3561 Nephrology clinic visits at our center since 2011. The median age was 48 years old [IQR 35-62]. 301 patients (54.1%) were women. A majority of patients identified as White (302, 54.3%), 42 (7.6%) Black, 95 (17.1%) Asian, 62 (11.2%) LatinX, and remainder Other race categories. The mean (SD) systolic blood pressure (SBP) obtained from office visit measures was 133.3±17.8 mmHg and mean (SD) diastolic blood pressure (DBP) was 77.0±11.4 mmHg. The median [IQR] estimated glomerular filtration rate (eGFR) was 60.0 [38.5, 93.0] ml/min/1.73m^2. Median [IQR] urine albumin to creatinine ratio was 19.5 [8.6, 99.7] mg/g. 63 (11%) patients had received a kidney transplant. Co-morbidities are shown in the Figure. We found that brain aneurysm was inaccurately coded due to automatic generation of a diagnosis of cerebral aneurysm when ordering magnetic resonance angiography (MRA) at our center; only 22 out of 74 patients with screening had a true positive brain aneurysm after chart review.

Conclusions: EMR data can identify ADPKD patients for both coordinated care and research purposes. Further efforts to quality control true positive cerebral aneurysm coding at our center are needed.

Autosomal Dominant Polycystic Kidney Disease: Prevalence of Pericardial Effusion

Vera C. Wulfmeyer, Johanna S. Jost, Till F. Kaireit, Bernd Auber, Johannes Beller, Kai M. Schmidt-Ott, Roland Schmitt. Roland Schmitt Lab. *Medizinische Hochschule Hannover, Hannover, Germany.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is associated with a variety of extrarenal manifestations. Previous studies reported a prevalence of pericardial effusion (PE) in ADPKD of up to 35% in U.S. cohorts. Our study is the first to evaluate systematically the prevalence and determinants of PE in a non-U.S. ADPKD cohort.

Methods: Clinically stable ADPKD patients from a specialized outpatient clinic were reviewed retrospectively. Magnetic resonance imaging and computed tomography scans were investigated regarding the presence of PE (≥4mm). Imaging findings were linked to clinical characteristics.

Results: 208 out of 286 ADPKD patients had imaging suitable for evaluation of PE. We detected PE with a mean size of 6.8±3.3mm in 17 patients (8.2%). The prevalence of autoimmune diseases was higher in patients with PE (11.8% versus 2.1%, p=0.022). Overall, we observed a clear female preponderance with a prevalence of PE of 7.8% in females (3.8% in male patients). PE dimension was generally larger in patients with known PE etiology other than ADPKD. Presence and size of PE were not associated with signs of rapidly progressive disease, ADPKD genotype, patient age, body mass index, medications, and other parameters. Exploratory investigation of individual characteristics of patients with PE by regression tree analysis suggested renal functional impairment, sex, and proteinuria as candidate variables.

Conclusions: The prevalence of PE in our cohort was up to four times lower than previously reported and showed a clear female preponderance. The low prevalence of PE compared to recent U.S. data may point to an unknown environmental factor as a cause of PE in ADPKD. Furthermore, our data suggest that patients with a PE size >10mm deserve further attention, as they may have additional non-ADPKD related pathologies.

SA-PO751

Polygenic Effects on the Risks of Intracranial Aneurysms Among Patients with ADPKD

Shohdan H. Osman,[1] Elhussein A. Elhassan,[1,2] Kane E. Collins,[3,4] Katherine A. Benson,[2,3] Gianpiero Cavalleri,[2] Peter J. Conlon.[1,2] *[1]Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland; [3]Centre for Research Training in Genomics Data science, Dublin, Ireland; [4]Future Neuro Research Centre, Dublin, Ireland.*

Background: Patients with autosomal dominant polycystic kidney disease ADPKD are at an increased risk of intracranial aneurysms (IA). Although there is an ongoing debate on who to screen, current strategies do not provide a personalised evaluation on risk of development and progression of IA. In this study, we aimed to identify the association of risk of IA in patients with ADPKD and genome-wide polygenic scores (PGS).

Methods: All adult ADPKD patients enrolled in the Irish Kidney Gene Project who underwent cerebral image screening for IA were included. Using previously published array SNP genotype data, we created PGS for six traits (hypertension (HTN) albuminuria, total kidney volume (KV), intracranial aneurysm (IA), and stroke, and glomerular filtration rate(GFR). Using PRSice2 software, PGS were calculated, and each trait was quantified categorically into three groups (high PGS >70%, average PGS 31%–70%, and low PGS <30%). To identify potential IA-specific risk factors, the polygenic effects of each GPS trait were compared between patients with and without IA using logistic regression.

Results: A total 226 participants (mean age 57.1 ± 14.4 years, 59.7% female) were assessed for IA-specific genomic risk stratification. 213 (88%) patients had hypertension, and 140 patients progressed to kidney failure at mean age 49.4 ± 10.4 years. Family history of IA was confirmed in 75 (33.1%) patients. Forty-seven (20.8%) patients had intracranial aneurysms, with 31.9% having multiple IA. Compared to the average (31%–70%) PGS distribution for each trait, the distribution of high or low PGS did not have a differential impact on the risk of IA development in patients with ADPKD.

Conclusions: Our current method did not identify a significant polygenic effect for the risk of IA in ADPKD patients, possibly due to the small sample size. To test this hypothesis, a larger study would be needed.

SA-PO752

Prevalence and Characteristics of Intracranial Aneurysms and Cerebral Hemorrhage in Patients with Autosomal Dominant Polycystic Kidney Disease in the Japanese Nationwide Database

Yusuke Ushio,[1] Hiroshi Kataoka,[1] Yosuke Shimada,[2] Saori Nishio,[3] Toshio Mochizuki,[1] Shun Manabe,[1] Ken Tsuchiya,[1] Kosaku Nitta,[1] Junichi Hoshino,[1] Tomonori Kimura,[4] Ichiei Narita,[5] Satoru Muto.[2] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Juntendo Daigaku, Bunkyo-ku, Japan; [3]Hokkaido Daigaku, Sapporo, Japan; [4]Reverse Translational Research Project, National Institutes of Biomedical Innovation, Health and Nutrition (NIBIOHN), Ibaraki, Osaka, Japan; [5]Niigata Daigaku, Niigata, Japan.*

Background: Selective screening for cerebral aneurysms in patients with autosomal dominant polycystic kidney disease (ADPKD) is recommended worldwide. In this study, we analyzed data from a cohort of Japanese patients with ADPKD, for which universal screening is recommended. We describe the prevalence and characteristics of intracranial aneurysms and cerebral hemorrhage in patients with ADPKD.

Methods: We examined the nationwide registry data of 4447 patients with ADPKD who held a new certificate of medical subsidy from the Japanese Ministry of Health, Labor, and Welfare from 2015 to 2017. We investigated the screening rates and risk factors for intracranial aneurysms, and prevalence of intracranial aneurysms and intracranial hemorrhage in patients with ADPKD. To analyze the diagnostic rate of intracranial aneurysms, we also compared the prevalence of intracranial aneurysms between patients who received MRI and those who did not.

Results: Overall, 693 patients (15.6%) had intracranial aneurysms, and 256 (5.8%) had intracranial hemorrhage. The MRI screening rate for intracranial aneurysms in patients with intractable diseases was 78.2%. The prevalence of intracranial aneurysms in patients who underwent MRI increased to 19.2% (odds ratio [OR] =9.33) compared with that in patients who did not (2.5%). The prevalence of intracranial aneurysms in MRI-screened patients was 22.6% in patients aged ≥ 50 years, 19.4% in patients with hypertension, and 21.5% in female patients. Hypertension (OR=1.46; P=0.002), age ≥ 50 years (OR=1.39; $P < 0.001$), female sex (OR=1.52; $P < 0.001$), and CKD stages 4–5 (OR=1.29; P=0.005) were risk factors associated with intracranial aneurysms. Female sex was found to interact with age and was not a risk factor for intracranial aneurysms in patients under 50 years of age but was a risk factor for intracranial aneurysms in those over 50 years of age ($P < 0.05$ for the interaction).

Conclusions: Screening with MRI improved the diagnostic rate of intracranial aneurysms in patients with ADPKD, which is particularly important for attributes at risk for intracranial aneurysms such as patients aged ≥50 years, with hypertension, female sex, and CKD stages 4–5.

SA-PO753

Targeted Genetic Testing with Broad Panel Informs Secondary Genetic Factors in Polycystic Kidney Disease

Yasar Caliskan, Bahar Bastani, Fadee Abu Al Rub, Kana N. Miyata, Amy Mosman, Thanh-Mai N. Vo, Marie D. Philipneri, Krista L. Lentine, John C. Edwards. *Saint Louis University Department of Internal Medicine, Saint Louis, MO.*

Background: Currently, a major obstacle in autosomal dominant polycystic kidney disease (ADPKD) research is the low number of African American (AA) patients in clinical studies and lack of studies evaluating a potential interaction of *APOL1*-related nephropathy with ADPKD. In this pilot study, we aimed to identify the causal and secondary variants in a cohort including AA patients.

Methods: Genetic testing was performed using a commercially available next-generation sequencing-based 382 gene kidney disease panel. Pathogenic (P), likely pathogenic (LP) variants and variant of uncertain significance (VUS) were reported. Demographic data and urine protein creatinine ratio (UPCR) were obtained from electronic medical reports.

Results: Genetic testing was performed for 13 ADPKD patients (9 men and 4 women, mean age 56±10 yrs, Table 1). Five individuals were found to have heterozygous *PKD1* mutations (2 with P variants, 1 with LP variant, 2 VUSs). Two individuals were found to be heterozygous for a *PKD2* P variant. Six individuals had no identified P, LP variants or VUS in *PKD1* or *PKD2*. There were 5 AA patients and all have *APOL1* renal risk variants. Mean UPCR of AA patients were significantly higher than European American patients (2.15±1.27 vs 0.57±0.95 g/g, p=0.035). Of these AA patients, one had two *APOL1* risk alleles (G1/G2), one with homozygous G1/G1 and 3 had heterozygous *APOL1* G0/G1 risk allele.

Conclusions: Use of broad panel genetic testing in patients with PKD identifies factors underlying disease variability and progression. This preliminary data suggests the importance of genetic testing for *APOL1* risk variants in AA ADPKD patients. Proteinuria may be an important sign of APOL1 associated kidney disease in AA ADPKD patients.

Funding: Private Foundation Support

"Genotype-First" Approach to Analyzing the Diversity and Prevalence of Genes in a Cohort of Cystic Disease Patients

Dinah Clark, Zhiji Zhang, Robert T. Burns, Nour Baddar, Michelle Bloom, Hossein Tabriziani, Sumit Punj. *Natera, Inc., Austin, TX.*

Background: Cystic kidney diseases are one of the most prevalent forms of monogenic kidney diseases. Variants in *PKD1* and *PKD2* reportedly comprise 93% of genetic causes of cystic kidney diseases with variants in other genes (i.e. *IFT140, GANAB,* etc) accounting for a small proportion. As variants in these less common genes lead to milder or atypical presentations, a "phenotype-first" approach to identifying cases with cystic disease may lead to an underestimation of their contribution. Using comprehensive genetic testing, we present a "genotype-first" approach that identifies contributions of cystic kidney and/or liver disease, providing real-world insights.

Methods: A retrospective analysis of results from patients tested with a 385 renal gene panel (the Renasight™ test) was performed. Cases were selected based on having one pathogenic (P) or likely pathogenic (LP) variant in a gene associated with autosomal dominant cystic disease (*PKD1/2, IFT140, HNF1B, UMOD, ALG9, GANAB, SEC63, PRKCSH).*

Results: Among 41,182 total cases reviewed, 3698 (9.0%) had positive results in a cystic gene, 23 of which (0.6%) had findings in more than one cystic gene. P/LP variants in *PKD1/2* comprised the majority (74.0%, n=2,739) of the positive findings. A total of 1113

variants were identified in *PKD1/2*, of which 67% were private to a single case. Behind *PKD1/2*, variants in *IFT140* (9.6%; n=357), *HNF1B* (8.2%, n=304) and *UMOD* (4.6%, n=171) comprised small but significant proportions of the positive cases. Findings in each of the remaining cystic genes (*ALG9, GANAB, SEC63, PRKCSH*) had prevalence < 1.0%.

Conclusions: This study, representing the largest real-world experience, provides new insight into estimates of the prevalence of cystic disease causing genes in a "genotype-first" approach. While our observation of private mutations in *PKD1/2* is consistent with prior reports, we showed that *PKD1/2 were* etiologically implicated in a smaller proportion of cases than has previously been reported. These new insights into the genetic landscape of cystic disease will have important implications for clinical practice given the prognosis and implications for management differ greatly between *PKD1/2* and the other genetic causes.

SA-PO755

Population Analyses to Determine Genetic Causes of Kidney Cysts

Hana Yang,[1] Josh T. Bublitz,[2] Nicholas B. Larson,[2] Doaa E. Elbarougy,[1] Rachel S. Schauer,[1] Vicente E. Torres,[1] Peter C. Harris.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic, Division of Clinical Trials and Biostatistics, Department of Quantitative Health Sciences, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a genetically heterogeneous disease with two major and at least seven minor genes. Information on the phenotypic penetrance of variants in these genes is biased as their analysis is usually limited to known ADPKD populations. In addition, the full genetic causes of kidney cysts may not be fully identified because kidney clinic patients are usually screened. Large populations with detailed clinical/imaging data and whole exome sequencing (WES) allow genotype- and phenotype-first approaches to clarify kidney cyst genetics. The Mayo Clinic Biobank (MCBB; n=52,865) is a population-based cohort with clinical records and WES that can allow these approaches to be employed.

Methods: In a phenotype-first approach, ICD9/10 codes and other diagnoses of kidney cysts have been employed to identify ADPKD and kidney cyst populations in the MCBB. WES data associated with these groups are being screened for likely causative variants. In the genotype-first approach, we are screening for loss-of-function (LoF) and known pathogenic variants in the ADPKD genes in MCBB participants. Examination of clinical records and imaging will determine the cystic disease penetrance of these variants.

Results: Using 15 renal/hepatic cyst related ICD codes, we identified a total of 1,093 individuals in the MCBB (2.08%). Of these, 184 were coded as ADPKD (0.35% in the MCBB), 579 with other cystic kidney phenotypes (1.10%), 294 with a single cyst (0.56%), and 36 with just liver cysts (0.07%). Analysis of the MCBB for patients previously diagnosed with ADPKD identified 108 patients; reassuringly, 101 (93.5%) were also found with the ADPKD ICD codes. MCBB also contains 50 patients previously diagnosed with kidney cysts; 26 had cystic ICD codes. Utilizing CPT codes, we have found that 1,013 (92.7%) of these patients have available imaging data (MRI, CT, or ultrasound). Manual inspection is underway to verify the phenotypes, and genetic variants from 341 PKD/ciliopathy genes are being retrieved for these patients. LoF and known pathogenic variants in all ADPKD genes are also being identified in the whole MCBB for the genotype-first analysis.

Conclusions: Population-based analyses can better explain the genetics of kidney cysts and penetrance of ADPKD genes, and the MCBB is ideally suited for this analysis.

Genome-Wide Copy Number Analysis in 11,754 Trios Identifies Human Gene Knockout Patients Including 12 Patients with NPHP1 Whole Gene Deletions

John A. Sayer, Ian J. Wilson, Eric G. Olinger. *Newcastle University, Newcastle upon Tyne, United Kingdom.*

Background: Whole genome sequencing (WGS) to detect rare genetic diseases is becoming increasingly common. However, pipelines to analyse copy number variants (CNV) are underutilised.

Methods: Using a bespoke CNV analysis of Genomics England 100,000 Genomes Project (100kGP) WGS data from 11754 parent-child trios, we searched for homozygous deletions overlapping with a gene, or "whole gene", or contiguous gene deletions across the 22 autosomes. We filtering for frequency (<0.5% in a control cohort of 15440 cancer patients within 100kGP population) and for autosomal recessive inheritance mode. Identified regions of deletions were also analysed in 18877 additional rare disease singletons within the 100kGP.

Results: A homozygous ~150kb whole gene deletion of *NPHP1-MALL* on chromosome 1, which aligned with a known region containing segmental duplications (SD), was the most frequent observation among all autosomal recessive (AR) OMIM-morbid genes, identified in 3 parent-child trios. Clinical phenotypes were consistent with this genotype including nephronophthisis and retinal dystrophy. We extended our analysis to look for *NPHP1* whole gene deletions in 18877 additional singletons within the 100kGP. This reverse genetics approach identified an additional 9 patients with whole gene deletions and matching phenotypes. The frequency of heterozygous *NPHP1* whole gene deletion was assessed in a control cohort of 15440 cancer patients within 100kGP and was found to be 0.35%.

Conclusions: In conclusion, NPHP1 was the most frequently observed AR OMIM-morbid gene knockout in our trio analysis. Homozygous whole gene deletions in *NPHP1* may be easily missed using standard WGS pipelines which don't assess fully for CNVs and a targeted read-depth approach to identify CNVs in parent-patient trios and singletons is valuable in identifying these deletions.

SA-PO757

Recessive Variants in NEK1 and NEK8 Are Associated with Cystic Kidney and Kidney Stone Disease

Victoria C. Gauntner,[1] Ghaleb H. Daouk,[1] Melanie P. Napier,[2] Martine T. Besouw,[3] Christopher J. LaRosa,[4] Alanna Strong,[5] Shrikant M. Mane,[6] Shirlee Shril,[1] Arlene B. Chapman,[7] Friedhelm Hildebrandt,[1] John A. Sayer,[8] Amar J. Majmundar.[1] *[1]Division of Nephrology, Department of Medicine, Boston Children's Hospital, Harvard Medical School, Boston, MA; [2]GeneDx Inc, Gaithersburg, MD; [3]Department of Pediatric Nephrology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [4]Division of Nephrology, Department of Pediatrics, Perelman School of Medicine at the University of PA, Philadelphia, PA; [5]Division of Human Genetics, Children's Hospital of Philadelphia, Philadelphia, PA; [6]Yale Center for Mendelian Genomics, Yale University School of Medicine, New Haven, CT; [7]Section of Nephrology, Department of Medicine, University of Chicago, Chicago, IL; [8]Tranlsational and Clinical Research Institute, Newcastle University, Newcastle upon Tyne, United Kingdom.*

Background: ~9-20% of chronic kidney disease patients have a Mendelian genetic cause. Mice with biallelic deleterious variants in *Nek1* and *Nek8*, encoding NimA-related serine/threonine kinases, develop adult-onset cystic kidney disease. In humans, biallelic *NEK1* and *NEK8* pathogenic variants are associated primarily with severe fetal/neonatal disease with multiple congenital anomalies including kidney malformations (14/16 congenital renal onset). It remains unclear if variants in these genes cause later onset kidney disease.

Methods: Variants in *NEK1* (NM_001199397.3) and *NEK8* (NM_178170.1) were detected by panel, exome or genome sequencing in >5457 families with cystic kidney or kidney stone disease (Boston Children's Hospital), with renal/urologic disease patients (Genomics England), with suspected hereditary kidney disease (University of Chicago), or with clinical genetic testing identifying bi-allelic *NEK1/8* variants (GeneDx, University of Iowa, University Medical Center Groningen).

Results: Six families (seven individuals) with cystic kidney disease and/or kidney stone disease were identified with rare recessive variants in *NEK1* (two) or *NEK8* (four). Deleterious variants exhibited rare population frequency (gnomAD genome database), ≥2 deleterious *in silico* prediction scores (PolyPhen2.0, MutationTaster, SIFT, CADD) and strong amino acid conservation in vertebrate orthologues. All *NEK1* variants (p.Ala313Thr; p.Met564ValfsTer35; p.Ser909Cys) and four of five *NEK8* variants (p.Thr41Ile, p.Ile170Phe, p.Ser224Cys, p.Arg294His) were novel, while one *NEK8* variant (p.Arg599*) was previously reported. Clinical phenotyping revealed cystic kidney disease (5/7), nephrolithiasis and/or nephrocalcinosis (3/7), nephromegaly (3/7), and chronic kidney disease (3/7). Age of kidney disease diagnosis ranged from age 5-18 years. In contrast, no deleterious bi-allelic variants were observed in exome data from 1285 non-disease control subjects.

Conclusions: Recessive *NEK1* and *NEK8* variants were identified in individuals with non-congenital cystic kidney and kidney stone disease, suggesting a novel association between *NEK1/8* variants and later-onset kidney disease.

SA-PO758

TMEM67 Allelic and Other Effects Drive Vast Phenotypic Heterogeneity Across a Broad Spectrum of Ciliopathies

Cynthia J. Sieben,[1] Peter G. Czarnecki,[2] Christina M. Heyer,[1] Ines Sturmlechner,[1] Peter C. Harris.[1] *[1]Mayo Clinic Research Rochester, Rochester, MN; [2]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Ciliopathies are genetically and phenotypically heterogeneous inherited diseases, impacting multiple organs systems, including kidneys. Kidney phenotypes include polycystic kidney disease (PKD) and renal cystic dysplasia, and genes associated with integrity/function of primary cilia. *TMEM67* variants are found in several ciliopathies, with varying severity, including Meckel (MKS), Joubert syndromes (JBTS), and nephronophthisis (NPHP). MKS is the most severe, including perinatal lethality, PKD, CNS defects, CHF, and polydactyly. Whereas NPHP, tubulointerstitial nephritis and cysts, is the mildest. It is currently unclear how *TMEM67* variants cause such an array of phenotypes and disease severity.

Methods: To investigate the pathogenicity, penetrance, and pathomechanisms of *TMEM67* missense variants (19) across these diseases, we employed *in vitro* exogenous expression systems and patient derived cell lines to assess TMEM67 maturation/trafficking to the apical plasma membrane (glycosylation status/western blotting, surface immunolabelling/flow cytometry, and immunofluorescence [IF] imaging) and primary cilia transition zone [TZ; IF], and primary cilia protein composition (IF).

Results: All the MKS-associated *TMEM67* missense variants that we assessed, are fully penetrant (7/7), and abolish trafficking of TMEM67 to the cell surface and TZ (1/1, patient cells). Whereas only a subset in the milder JBTS (7/13) and NPHP (2/5) diseases, are fully penetrant, and incompletely penetrant/mild and apparent neutral alleles are present (~31 and 60%, respectively). Interestingly, many of these variants (11/19) are misfolded and can be partially or completely rescued by enhancing folding conditions, even for the fully penetrant variants found in MKS (~57%). In addition, absence of TMEM67 from the TZ, perturbs trafficking of other ciliary proteins, inversin and ARL13B.

Conclusions: Our preliminary studies assessing 19 *TMEM67* variants (MKS, JBTS, and NPHP) have revealed that: 1) allele penetrance correlates with disease severity to some degree (TMEM67 maturation/trafficking), 2) perturbed TMEM67 maturation/trafficking

represents a common pathomechanism, resulting from defective TMEM67 folding in many cases; and 3) fully penetrant membrane trafficking variants also perturb primary cilia protein composition and TMEM67 TZ localization.

Multiple Unilateral Subcapsular Cortical Hemorrhagic (MUCH) Cystic Disease of the Kidney: First Case in Brazil of a Possible New Clinical Entity of Unknown Etiology

Pedro G. Pascoal,[1,2] Gustavo G. Thomé,[1,2] Renata Asnis Schuchmann,[1,2] Gabriel Sartori Pacini,[1,2] Ana Wolffenbüttel,[1] Francisco V. Veronese,[1,2] Elvino Barros,[1,2] Cristina Karohl,[1,2] Luciano Wolffenbuttel.[1,2] *[1]Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.*

Introduction: The occurrence of MUCH Cystic Disease of the Kidney was described in 14 patients from the USA, France, Canada and Japan by Yoshida et al. in 2019. We describe the first similar case in Brazil.

Case Description: A 36-year-old hypertensive Brazilian man was referred to our Nephrology Clinic due to nephrotic syndrome (NS) along with acute kidney injury requiring dialysis. An extensive investigation of systemic diseases associated with NS (viral serologies, syphilis, autoimmune diseases and neoplasms) was negative. Abdominal MRI showed multiple subcapsular cortical hemorrhagic cysts in the left kidney with normal right kidney. The cysts measured <1cm on average, the biggest one 2.5cm. The signal was hyperintense on T1 and hypointense on T2-weighted MRI, suggesting hemorrhagic content. Biopsy of the right kidney revealed focal segmental glomerulosclerosis (FSGS), tip lesion variation, added to acute tubular necrosis in recovery phase. Complete remission of NS and recovery of renal function were achieved after 8 weeks of immunosuppressive treatment.

Discussion: Yoshida et al described 14 cases with distinctive renal image findings, similar to the presented. No patients had positive family history of kidney disease. 6 of them underwent genetic evaluation and results were negative for renal cystic disease. The characteristics of the cysts (unilateral, subcapsular with hemorrhagic content) suggest a different etiology from that of the classic APKD1/2, ARKD or medullary cystic kidney disease. Whole genome sequencing is currently being processed. None of the patients previously described had NS nor FSGS, suggesting a non-causal association. These clinical and radiological findings might be features of a new non-inherited renal cystic disease.

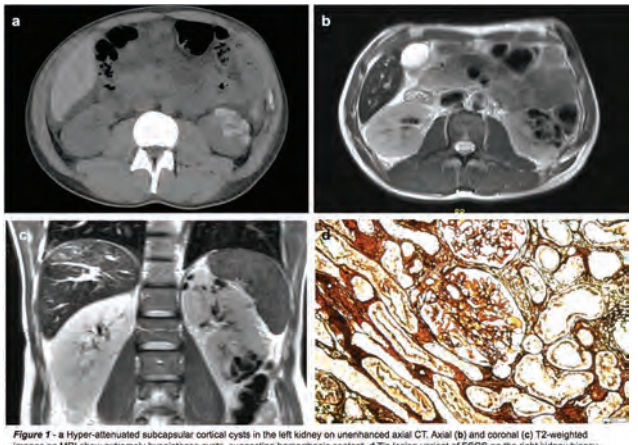

Figure 1 - a Hyper-attenuated subcapsular cortical cysts in the left kidney on unenhanced axial CT. Axial (b) and coronal (c) T2-weighted images on MRI show extremely hypointense cysts, suggesting hemorrhagic content. d Tip lesion variant of FSGS on the right kidney biopsy (PASM,original magnification× 200).

SA-PO760

A Rare Case of Polycystic Kidney Disease due to Pathogenic Variants in the ALG9 and TTC21B Genes

Garry A. Graham,[1,2] Khyra Cunningham,[1] Wei Chen,[1,3] Molly Fisher.[1,3] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Columbia University, New York, NY; [3]Montefiore Medical Center, New York, NY.*

Introduction: *ALG9* is a novel disease gene that accounts for <1% of cases on the polycystic kidney disease (PKD) spectrum. Pathogenic mutations of the *TTC21B* gene are associated with nephronophthisis, characterized by tubulointerstitial disease and kidney cysts. Animal studies suggest that *TTC21B* modifies the phenotype of PKD due to the *PKD* gene mutation. Whether *ALG9* interacts with *TTC21B* is unknown. We present a rare case of PKD due to heterozygosity for pathogenic variants in *ALG9* and *TTC21B*.

Case Description: A 65-year-old Hispanic woman with well-controlled human immunodeficiency virus, osteoporosis and nephrolithiasis presented for evaluation of chronic kidney disease, proteinuria, and bilateral kidney cysts. Serum creatinine fluctuated between 1.1-1.3 mg/dL (eGFR 44-54 ml/min/1.73m^2) with no hematuria. Urine protein-creatinine ratio was 442 mg/g. Replacing tenofovir in her antiretroviral regimen did not improve kidney function. Kidney ultrasound revealed slightly enlarged kidneys of 12.4 cm on the left and 11.5 cm on the right, increased parenchymal echogenicity as well as numerous bilateral cysts, some of which were complex. A CT abdomen showed 4 cysts in the left kidney and 3 cysts in the right kidney that were >8 mm in diameter, as well as innumerable bilateral cysts that were too small to count. There were no liver cysts. She reported had no known family history of cystic kidney disease. Genetic test revealed a heterozygous *ALG9* nonsense, loss of function mutation (c.1219C>T, p.Arg407*) and a heterozygous *TTC21B* variant that resulted in a frame-shift (c.2913dup, p.Val972Serf*11). Using UCSC Genome Browser, we found evidence that *ALG9* and *TTC21B* both interact with ubiquitin C.

Discussion: *ALG9* encodes a-1,2-mannosyltrasnsferase, which adds specific mannose molecules to a *N*-glycan precursor in the endoplasmic reticulum lumen. *ALG9* mutation is associated with a milder phenotype than *PKD* mutations. *TTC21B* encodes a retrograde intraflagellar transport protein. A previous case reported that *TTC21B* heterozygous variants exacerbated the phenotype of PKD due to *PKD1* mutation. The interactions between *PKD* genes and *TTC21B* were validated in animal studies. However, whether *ALG9* interacts with *TTC21B* is unknown. Addressing this knowledge gap will help define the prognosis and guide treatment therapy in patients like ours.

SA-PO761

HNF1B Nephropathy Mimicking Autosomal Dominant Polycystic Kidney Disease: A Case Report

Nada Alamri,[1,2] Matthew B. Lanktree.[1,2] *[1]Departments of Medicine and Health Research Methodology, McMaster University, Hamilton, ON, Canada; [2]Division of Nephrology, St Joseph's Healthcare, Hamilton, ON, Canada.*

Introduction: Hepatocyte nuclear factor1beta (HNF1B) nephropathy is characterized by hypomagnesemia, hyperuricemia, congenital anomalies of the kidneys and urinary tract (CAKUT), and multiple small cortical cysts without kidney enlargement. It also involves multi-organ manifestations including insulin-deficient diabetes (or maturity-onset diabetes of the young [MODY]), pancreatic exocrine dysfunction, liver dysfunction and neurodevelopmental abnormalities including autism spectrum disorder (ASD). We present a rare case of HNF1B nephropathy with atypical large kidney cysts mimicking autosomal dominant polycystic kidney disease (ADPKD).

Case Description: A 37-year-old male with ASD initially presented with hypertensive emergency. The patient reported occasional flank pain and distension but no other symptoms. The patient was estranged from his father, and his mother had normal kidney function without cysts. There was no known history of kidney failure, aneurysms, or sudden death in his extended family. Physical examination revealed distended abdomen with palpable organomegaly. Laboratory results showed elevated creatinine levels (2.41 mg/dl) and reduced eGFR (33 ml/min/1.73 m2) with an eGFR decline of 5 ml/min/1.73 m^2 in the last year. Fasting blood glucose levels and liver function tests were normal. CT showed innumerable bilateral kidney cysts, the largest of which measured 19 cm on the right and 12 cm on the left, and an enlarged spleen. An initial diagnosis of *de novo* ADPKD was suspected. Genetic testing of *PKD1* and *PKD2* found no responsible variant, leading to a broader cystic gene panel sequencing. A heterozygous 1.26 Mb deletion (chr17:g.34842466_36104935del), encompassing whole *HNF1B* gene was detected. Cascade screening showed that the patient's mother was unaffected.

Discussion: HNF1B nephropathy displays substantial phenotypic heterogeneity. We present a case of HNF1B nephropathy clinically mimicking ADPKD with extreme kidney enlargement and loss of kidney function, without hypomagnesemia, hyperuricemia, or MODY. Phenocopies are not uncommon, and this case further exemplifies the role of genetic testing to obtain a concrete diagnosis. This case report contributes to the understanding of phenotypic variability in HNF1B nephropathy and emphasizes the importance of considering this diagnosis in patients with large kidney cysts.

SA-PO762

Glomerulocystic Kidney Disease with Concurrent Thin Basement Membrane Disease in an Adult Male

Thomas T. Yoo,[1] Marvi Hussain,[2] Richard M. Treger.[2] *[1]Loma Linda University Medical Center, Loma Linda, CA; [2]Kaiser Permanente Southern California, Pasadena, CA.*

Introduction: Glomerulocystic kidney (GCK) is a rare condition that presents as progressive renal insufficiency and is typically found in pediatric patients with only a few cases described in adults. GCK is defined by the dilation of Bowman space to 2-3 times that of normal size and more than 5% of glomeruli are involved. Patients with GCK have rapid development of renal insufficiency in less than 1 year and most progress to ESRD. Multiple cases of GCK have been reported; however, GCK with concurrent TBMD has an even rarer occurrence.

Case Description: A 30-year-old Asian male patient with history of bilateral glaucoma and gout with no family history of renal disease was admitted for evaluation of urinary retention and renal insufficiency. Foley catheter was placed with 900 ml of yellow urine suggesting urinary obstruction. Physical exam reveals no flank tenderness. Renal ultrasound showed increased echogenicity of the kidneys, without hydronephrosis. No renal stones, perinephric stranding, hydronephrosis, or cysts in organs were noted on CT. The patient underwent a renal biopsy with preliminary findings consistent with obstructive nephropathy. Patient's renal function did not improve with foley insertion. GN serology was unrevealing. UA with 4-10/HPF RBC, 2+ Hb and 1+ protein. Biopsy was reviewed again with renal pathologist, and the findings were consistent with GCKD with concurrent thin basement membrane and chronic tubulointerstitial disease. The patient was started on hemodialysis and referred to genetics clinic. A pathogenic variant was detected in the COL4A1 gene and heterozygous pathogenic variants in the ECHS1 & ITPA genes.

Discussion: To our knowledge, this is the first case of GCK with concurrent TBMD with pathogenic variants of the COL4A1, ECHS1, and ITPA genes. Previous literature has identified 5 main types of GCK: GCK in PCKD, hereditary, syndromic, obstructive,

and sporadic. Our case is most consistent with hereditary variant of GCKD. This has been reported in one case study by Hashimoto et al. in which no pathogenic mutations in genes had been identified. A pathogenic COL4A1 gene can lead to hereditary angiopathy with nephropathy, aneurysms, and associated with renal cystic lesions and basement membrane involvement as seen in our patient. GCKD with concurrent TBMD can present in adulthood. This case report highlights this rare presentation of GCKD.

SA-PO763

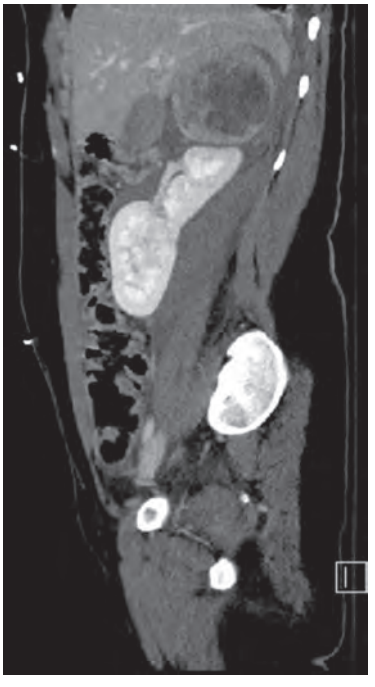
PAGE Phenomenon in a Crossed Fused Renal Ectopia: A Rare Phenomenon in a Rare Anomaly

Farah Heis,[1] Jayasree Ravilla,[1] Mohamed Heis.[2] *[1]Monmouth Medical Center, Long Branch, NJ; [2]Yarmouk University, Irbid, Jordan.*

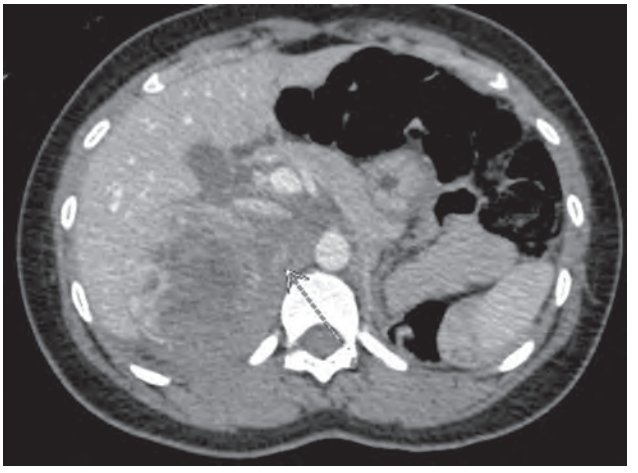
Introduction: PAGE phenomenon is rare. It occurs due to an external compression of the renal parenchyma, usually by subcapsular hematoma. Crossed fused renal ectopia (CFRE) is another rare finding. We present an unusual case of a young female with CFRE complicated by PAGE kideny due to pheochromocytoma.

Case Description: A 28 yo F with CFRE presented with Rt flank pain for 3 days. Pain was severe, radiating to the back, associated with nausea. She denied vomiting and headache. In the ED, she was found to have hypertensive urgency, BP 202/117, HR 103 bpm. PE was significant for RLQ tenderness with no rebound or rigidity. Blood work showed Hgb of 11.3 g/dL. CMP, including BUN and Cr were wnl. US of the abdomen showed diffuse echogenic appearance of the Rt kidney with scattered cysts. CT Urogram showed large Rt retroperitoneal and subcapsular hematoma and a heterogenous right suprarenal mass. She was admitted to the ICU and was treated with Nicardipine drip. Urine catecholamines were significantly elevated. Patient was stabilized and was transferred to urologic oncology surgeon for intervention.

Discussion: PAGE kidney is rare and is commonly traumatic or iatrogenic. However, it can be caused by an adrenal mass. It carries high morbidity especially in patients with solitary kidney and CFRE. Urgent intervention is warranted to salvage the kidney.



CT Abdomen showing CFRE



CT Abdomen showing Rt adrenal mass with active bleeding.

SA-PO764

Case Report: Mosaic TSC2/PKD1 Contiguous Gene Deletion Syndrome

Elise Fryml,[1] Matthew B. Lanktree.[2,3] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]McMaster University, Hamilton, ON, Canada; [3]Population Health Research Institute, Hamilton, ON, Canada.*

Introduction: A rare overlap of tuberous sclerosis complex (TSC) and autosomal dominant polycystic kidney disease (ADPKD) can occur when large deletions impact the adjacent *TSC2* and *PKD1* genes, leading to *TSC2/PKD1* contiguous gene deletion syndrome. We present a case of *TSC2-PKD1* contiguous gene deletion syndrome with somatic mosaicism where initial genetic testing did not identify a pathogenic variant.

Case Description: A 21-year-old female patient was referred to the McMaster Kidney Genetics Clinic with clinical features consistent with TSC, including childhood epilepsy, multiple bilateral brain tubers, angiofibromas, ash leaf lesions, and bilateral kidney cysts. There was no family history of TSC or PKD. In childhood, she was diagnosed with bilateral renal angiomyolipomas (AMLs) on ultrasound. Her most recent creatinine was 0.75 mg/dL with eGFR of 117 ml/ min/1.73m^2. Magnetic resonance imaging of the kidneys at age 18 revealed numerous bilateral kidney cysts including complex heterogenous cysts in an atypical lopsided distribution (Mayo class 2) but no evidence of fat containing AML. Clinical genetic testing with capillary sequencing and multiplex ligation-dependent probe amplification (MLPA) for *PKD1, PKD2, TSC1,* and *TSC2* did not identify a responsible pathogenic variant. A follow up cystic kidney disease gene panel was arranged which identified a deletion spanning exons 15-46 of *PKD1* and exons 32-42 of *TSC2* predicted to be in 35% of the patient's circulating white blood cells, suggesting somatic mosaicism and a diagnosis of *TSC2-PKD1* contiguous gene deletion syndrome.

Discussion: Through unexpectedly low read depths, next generation sequencing gene panels can identify deletions. However, detection of somatic mosaicism can be challenging as the variant allele frequency can be above the expected 50% for a heterozygous deletion. Patients with somatic variants may present atypically with more subtle phenotypic features than patients with classical pathogenetic variants. Patients with TSC can have small kidney cysts, though their phenotype should be quite clinically distinct from ADPKD. Our case demonstrates an example of mosaic *TSC2-PKD1* contiguous gene deletion syndrome and the improved sensitivity for somatic genetic variants with gene panel sequencing over traditional capillary sequencing and MLPA.

SA-PO765

Tolvaptan Use in Patients with Autosomal Dominant Polycystic Kidney Disease and Gilbert Syndrome

Andreja Marn Pernat.[1,2] *[1]University Medical Center Ljubljana, Ljubljana, Slovenia; [2]Univerza v Ljubljani Medicinska fakulteta, Ljubljana, Slovenia.*

Introduction: Jinarc therapy is contraindicated in patients with elevated liver enzymes. Gilbert's syndrome, one of the most common genetic disorder, is characterised by mild fluctuating unconjugated hyperbilirubinemia. A search of the available medical literature did not identify any studies or information that evaluated the use of tolvaptan in patients with ADPKD and Gilbert's syndrome. We present two cases with ADPKD and Gilbert's syndrome, in whom treatment with tolvaptan was initiated.

Case Description: Case 1 was a 31- year-old male patient and Case 2 was a 34-year-old female sibling. They have rapidly progressive ADPKD and a family history of Gilbert's syndrome. Blood testing for systemic markers of liver function were performed prior to and two weeks after initiation of Jinarc, continuing monthly thereafter. Their renal function was normal. Both patients received Jinarc 45 mg in the morning and 15 mg in the afternoon, and the dose was not increased during first 4 months of follow-up. A sustained urine osmolality (Uosm) of 280 mOsm/kg was achived in both patients. Case 1 had Uosm between 65 nad 138 mOsm/kg and Case 2 between 43 and 287 mOsm/kg. Case 1 had mild hyperbilirubinemia prior to tolvaptan initiation but no significant additional elevation of bilirubin was observed during treatment. Case 2 had an increase in bilirubin immediately after starting treatment but it remained < 2 ULN thereafter. The table presents the bilirubin values in both patients before and during tolvaptan therapy. All other parameters of potential hepatocellular injury, including hepatic transaminases, were within the normal range in the first 4 months.

Discussion: In two young adult siblings with rapidly progressive ADPKD and a benign Gilbert's syndrome we cautiously started treatment with tolvaptan. We observed an isolated elevated serum bilirubin in the absence of the other criteria for hepatic injury. We feel that patients with Gilbert's syndrome can also be considered for tolvaptan therapy. Still, safety studies in patients with impaired bilirubin glucuronidation are warranted.

Total and direct bilirubin presented for cases 1 and 2.

	Prior tolvaptan	After 2 weeks	1 month	2 months	3 months	4 months
Total bilirubin, mcgmol/L Case 1	37	35	24	25	28	30
Case 2	19	28	30	22	31	31
Direct bilirubin,mcgmol/L Case 1	10	13	10	10	11	11
Case 2	5	10	11	8	11	12

SA-PO766

Phenotypic Variabilities of Neonatal Autosomal Recessive Polycystic Kidney Disease

Ei E. Khin,[1,2] Divya Ramdas,[1,2] Javier E. Rodriguez.[1,2] *[1]Texas Tech University Health Sciences Center El Paso Paul L Foster School of Medicine, El Paso, TX; [2]El Paso Children's Hospital, El Paso, TX.*

Introduction: Autosomal Recessive Polycystic Kidney Disease (ARPKD) is caused by a mutation in the PKHD1 gene and is an inherited cause of chronic kidney disease in children. The most typical presentations in neonates are a history of oligohydramnios, massively enlarged kidneys, and the Potter sequence with pulmonary hypoplasia that can lead to respiratory insufficiency and perinatal death. Extra-renal manifestations include congenital hepatic fibrosis, cholangitis, and portal hypertension. A subset of ARPKD patients can have a predominant liver phenotype.

Case Description: We report the variable clinical manifestations of three cases of neonatal ARPKD. Case 1 is the male neonate with enlarged ventricles in the brain, atypical extra-renal manifestation, and confirmed the diagnosis by genetic testing. Although he did not require renal replacement therapy in the neonatal period, he developed severe hypertension at 3 months. Case 2 was born with a history of oligohydramnios and required ventilator support for 3 days. His neonatal course was unremarkable and developed hypertension at 8 weeks of life. He received a renal transplant at 4 years of age. Case 3 is a full-term neonate who developed pulmonary hypoplasia, was on a high-frequency ventilator at birth, and required initiation of dialysis and nephrectomies in the neonatal period. Clinical and laboratory findings of cases are shown in Table 1.

Discussion: It should be aware of variable presentations of ARPKD cases and some may require aggressive management of nephrectomies and dialysis in the neonatal period. Due to its multi-system effects, a multidisciplinary team of nephrologists, gastroenterologists, surgeons, and neonatologists help families of patients make informed treatment decisions.

Fig. 1: Clinical and laboratory findings of 3 neonatal cases with ARPKD

	CASE 1	CASE 2	CASE 3
Gestational age (weeks)	33	31	36
Birth weight(Grams)	2053	1500	2600
Oligohydramnios	Yes	No	Yes
Pulmonary hypoplasia	None	None	Yes
Renal Ultrasound findings	Normal sized kidneys, bilateral pelviectasis and cysts	Enlarged kidneys with the pelviectasis and cysts.	Very enlarged kidneys >9 cm bilaterally with multiple tiny cysts
Extra-renal manifestations	Ventriculomegaly, colpocephaly.	Hepatic cysts	Pulmonary hypoplasia, hepatic fibrosis
eGFR at 28 days of life (mL/min/1.73m^2)	37.7	27	8
Serum Creatinine at 14 and 28 days of life (mg/dL)	0.5	0.6	2.3
Initiation of dialysis before 28 days (Yes/No)	No	No	Yes

Discovery of a Novel Candidate Gene Implicated in X-Linked Polycystic Kidney Disease

Takayasu Mori,[1] Takuya Fujimaru,[1] Chunyu Liu,[2,3] Karynne Patterson,[4] Kohei Yamamoto,[7] Takefumi Suzuki,[1] Motoko Chiga,[1] Shintaro Mandai,[1] Fumiaki Ando,[1] Yutaro Mori,[1] Koichiro Susa,[1] Yue-Qiu Tan,[5,6] Feng Zhang,[2,3] Shinichi Uchida,[1] Eisei Sohara.[1] University of Washington Center for Rare Disease Research. *[1]Department of Nephrology, Tokyo Medical and Dental Sciences, Tokyo, Japan, Bunkyo-ku, Japan; [2]Obstetrics and Gynecology Hospital of Fudan University, Shanghai, China; [3]Shanghai Key Laboratory of Female Reproductive Endocrine Related Diseases, Fudan University, Shanghai, China; [4]University of Washington, Seattle, WA; [5]Institute of Reproductive and Stem Cell Engineering, NHC Key Laboratory of Human Stem Cell and Reproductive Engineering, School of Basic Medical Science, Central South University, Changsha, China; [6]Clinical Research Center for Reproduction and Genetics in Hunan Province, Reproductive and Genetic Hospital of CITIC-Xiangya, Changsha, China; [7]Department of Comprehensive Pathology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Bunkyo-ku, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by typical imaging findings and a family history and ~90% of cases have a genetic explanation. In contrast, the underlying genetic basis of adult-onset sporadic cystic kidney disease remains incompletely elucidated, with ~30% of patients in our cohort remaining unexplained by variants in established cyst-related genes, leading to inconclusive diagnoses. These individuals were presumed to harbor potentially unreported mutations in novel candidate genes associated with PKD.

Methods: An NGS panel screening was conducted to analyze 69 known genes associated with renal cysts in adult patients with no familial history of the condition. Whole genome sequencing was performed on 47 unrelated individuals who did not exhibit any pathogenic candidate variants, aiming to identify novel genes implicated in renal cyst formation.

Results: Candidate gene A, located on the X chromosome, exhibited missense variants found in three male patients aged 74 (PT570), 80 (PT698), and 58 (PT1216) years, respectively. These patients demonstrated renal function impairment with estimated glomerular filtration rates (eGFR) of 53.5, 21.8, and 20.2 ml/min/1.73m^2, respectively. Hypertension was a shared characteristic among all patients, while no complications associated with hepatic cysts were observed. The protein product of gene A was found to be expressed in the primary cilia of human renal tubules. Kidneys from 12-month-old male knockout mice lacking gene A exhibited vacuolation of tubular cells and tubular dilation, providing evidence that gene A is a novel causative gene involved in cyst formation.

Conclusions: Gene A is a newly discovered gene associated with PKD, demonstrating X-linked inheritance, which is uncommon in inherited cases of PKD. Further accumulation of cases is warranted for a more comprehensive understanding.

Determine the Pathogenic Mechanism Underlying Infantile ADPKD Caused by a Novel Monoallelic NEK8 Mutation

Chuan Chen, Peter C. Harris, Kun Ling. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ADPKD is mainly caused by mutations in *PKD1* and *PKD2* that encode polycystins, PC1 and PC2, respectively. Current evidence suggests that the dosage of PCs in primary cilia controls the severity and progression of ADPKD. But the molecular mechanisms mediating the trafficking of PCs into primary cilia remain unclear. NEK8 is the only known protein kinase residing in primary cilia, in the Inversin compartment, and is associated with a syndromic ciliopathy when both alleles are mutated. Interestingly, a novel monoallelic *NEK8* mutation (p.Arg45Trp) was recently identified in 3 Mayo families with early onset PKD without extrarenal manifestations. This finding suggests that the mutation selectively causes PKD, and thus represents a unique tool for investigating the molecular mechanisms specifically regulating renal cystogenesis.

Methods: Mutagenesis Transfection CRISPR/Cas9 Immunostaining Kinase assay Fluorescence

Results: To understand how p.Arg45Trp (R45W) affects NEK8, we inactivated *Nek8* in IMCD3 cells, and then re-expressed wild type (WT) or R45W variant NEK8. Primary cilia in *Nek8*$^{-/-}$ cells were truncated but were rescued equally well by NEK8-WT and NEK8-R45W, which show comparable expression and stability. The level of GPR161 in cilia remained the same with or without *Nek8*. Yet, ANKS6 as a binding partner of NEK8, lost its localization in *Nek8*$^{-/-}$ cilia, which was fully recovered by reexpressing NEK8-WT or R45W. These data suggest that the overall structure of primary cilia is not affected by the R45W mutation. However, we observed that PC2 levels significantly decreased in *Nek8*-null cilia; a defect rescued by NEK8-WT but not R45W, although the total protein level of PC2 appeared comparable. Our results indicate that the R45W mutation specifically impairs PC2 in cilia. Moreover, we showed that the autophosphorylation of NEK8-R45W was significantly decreased compared to NEK8-WT, implying a partial loss of kinase activity. This suggests that adequate NEK8 kinase activity is necessary for supporting the normal level of PC2 in cilia.

Conclusions: We found that a novel ADPKD variant of NEK8 (R45W) selectively repressed the ciliary level of PC2. In future, we will seek NEK8 partners in cilia that are specifically affected by this single-point mutation in NEK8. Our work will provide critical information to the understanding of PC trafficking in cilia and ADPKD etiology.

Molecular Testing in a Clinical Laboratory Cohort Reveals Significantly Increased Incidence of PKD1 Truncating Variants in ADPKD Patients with Pediatric-Onset vs. Adult Presentation

Laura A. Sulmonte, Vincent D. Ustach, Patricia Celestino Soper. *GeneDx, LLC, Stamford, CT.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a multisystem disorder characterized by multiple kidney cysts and extrarenal features. *PKD1* and *PKD2* (likely) pathogenic (L/PATH) variants cause 95% of ADPKD. Although the majority of ADPKD cases present in adulthood, approximately 1-2% have onset before age 15. While severe presentation is usually associated with truncating *PKD1* variants in adults, the variant spectrum in pediatric ADPKD cases is not well-established.

Methods: We examined the age distribution and variant spectrum in pediatric and adult cases in a retrospective study of 1582 cases referred for next generation sequencing multi-gene panel clinical testing for Cystic Kidney Disease (CKD). Testing included sequence and copy number analysis of *PKD1, PKD2, PKHD1* and other genes associated with renal cysts.

Results: The pediatric sub-cohort accounted for nearly one-third of cases tested. Our analysis revealed a diagnostic rate of 42% for the entire cohort and involved 13 genes (40% within adult and 46% within pediatric sub-cohorts – including ADPKD patients with prenatal onset). Diagnostic cases primarily had L/PATH variants in *PKD1* (69%) or *PKD2* (16%), but also included *HNF1B* (2% adult, 16% pediatric), bi-allelic *PKHD1* (1% adult, 7% pediatric) and *GANAB* (2% adult, 2% pediatric). Truncating *PKD1* L/PATH variants were significantly enriched in both our pediatric (p-value<0.001) and adult (p-value<0.001) sub-cohorts. A statistically significant association was found between the age groups and variant types (p-value<0.05), with 68.9% of L/PATH variants in pediatric patients being *PKD1* truncating compared to 59.8% in adults.

Conclusions: Consistent with published data, our results indicated that *PKD1* L/PATH variants, particularly truncating, were the cause of the majority of ADPKD, regardless of age of onset or presentation. Additionally, we found that *PKD1* truncating variants were more significantly enriched in the pediatric cohort compared to adults. Lastly, findings from clinical genetic testing for patients with CKD may inform clinical management, guide decision-making for reproductive and familial cascade testing, and generate research questions to better characterize genotype-phenotype correlations that may impact future patient care.

SA-PO770

Benefits of Genetic Testing in Patients with Polycystic Kidney Disease (PKD)

Marissa R. Samuels, Wing H. Zeng, JingJing Zhang. *Thomas Jefferson University, Philadelphia, PA.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common inherited kidney disease, responsible for ~10% of end stage renal disease. The most common mutated genes are PKD1 or PKD2 and ~90% of patients have an identifiable genetic variant within the two. While genetic testing has identified these mutations and their predictive values, the specific clinical significance is still not well defined. Additionally, comprehensive screenings have successfully identified PKD1 and PKD2s roles in ADPKD, but there are still patients who have no mutation detected in either gene.

Methods: Data recorded by electronic medical record of patients with image diagnosed PKD at a single nephrology clinic was collected and analyzed. Natera Genetic testing results identified genetic variants. Family history (FH) was used to determine genetic predisposition.

Results: Forty patients with PKD were identified between December 2020 and December 2022. Twenty Seven were positive for a PKD1/PKD2 mutation, 7 of which had a variant of uncertain significance (VUS) of PKD1/PKD2. Seventeen of these 27 had a positive FH of PKD, while 8 were negative and 1 unknown. Three patients did not have a PKD1/PKD2 mutation, but tested positive for mutations COL4A1, COL4A4 and TTC21B. Lastly, there were 3 patients with negative results, one of which has a FH.

Conclusions: Eighty Five percent of the patients in our cohort have a PKD1/PKD2 mutation or PKD1/PKD2 VUS, with some VUSs becoming pathogenic at a later time. However, 30% of those patients do not have a FH. The genetic study thus confirmed the diagnosis and helped predict their prognosis. The existence of heterozygous PKHD1 together with Col4A4 mutation may be the culprit of the kidney cysts in patients with Alport syndrome. The patients with true negative results remain unclear, but the sequence data will contribute to the nationwide database and help identify the true variants. Our experience advocates that the benefit of genetic testing is imperative to detecting and identifying true causative variants and that this can provide prognostic information for patients with ADPKD.

Table 1 Genetic Profiles of patients without PKD1/PKD2 mutation

Case #	PKD1/PKD2 VUS	VUS	Carrier Variant/Carrier of VUS	Family history
1	PKD1	Duplication of Exons 22-34	ATP7B; MOCOS; LRP2; ANK26; LRP4	Yes
2	PKD1	c.11695C>G (p.Leu3899Val) c.10290G>A (p.Val3430=)	HBB, BBS7, APOL1 (heterozygous),SLC3A1; AGPAT2; IFT122; WFS1; CYP27B1	Yes
3	PKD1	c.1529G>C (p.Arg510Pro)	GLI2; MNX1; CREBBP; LMX1B; CFI; LRP2; PLCE1; MEFV; COX10; SLC26A1	Yes
4	PKD1	c.9454C>T (p.Arg3152Trp)	PRKCSH; ITGB4; SLC26A1; AGPAT2; NPHP4; MEFV	No
5	PKD1	c.8809G>A (p.Glu2937Lys)	BBS1,HNF1A,NEK8	Yes
6	PKD2	c.1748T>A (p.Met583Lys)	FLCN; ALMS1; IQCB1; CYP11A1; MEFV; BBS2	Yes
7	PKD1 PKD2	c.266A>C (p.Asn89Thr),c.266A>C (p.Asn89Thr) c.709+4A>G (p.?)	TSC2; C3; FREM1; MYO1E; CUBN; G6PC; PLCE1; HPS1; SLC4A4; ELP1	Yes
	Non-PKD/PKD2 VUS	**Mutation**		
8	COL4A1	c.2095+1G>T (p.?)	BBS9; CEP164; FANCI	Yes
9	TTC21B.	c.2500C>T (p.Gln834*)	LPIN1	No
10	COL4A4	c.4599T>G (p.Tyr1533*)	HBB;PKHD1	No
11	None	N/A	Negative	No
12	None	N/A	Negative	No
13	None	N/A	SLC7A9; CLCN2; XDH; BBS12; BBS10; LRP2; NEDD4L	Yes

SA-PO771

Elucidating the Genetics of Unresolved PKD in a Large Unselected Cohort

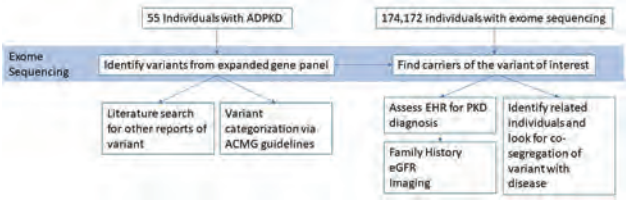
Bryn S. Moore, Alexander R. Chang, Tooraj Mirshahi. *Geisinger Health, Danville, PA.*

Background: We reported on 235 individuals with typical, mild or atypical PKD from an unselected cohort of 174,172 individuals with exome sequencing. Variants in 11 known cystic genes *(PKD1, PKD2, ALG8, ALG9, DNAJB11, GANAB, HNF1B, IFT140, PKHD1, PRKCSH,* and *SEC63*) were identified in 76.5% of these individuals, leaving 55 with no candidate causal variant.

Methods: The 55 individuals with unresolved genetics consisted of 37 with typical, 6 mild and 12 atypical PKD. We expanded the analysis to include 121 cystic genes identified by the Kidney Cystic and Ciliopathy Disorders Gene Curation Expert Panel in an attempt to identify candidate causal variants. Exome sequencing combined with EHR was leveraged to identify rare variants from these genes in these individuals. Variants were evaluated in the general population for cosegregation with disease and evidence of PKD in carriers.

Results: 47/55 individuals had at least one rare variant (MAF<0.001) including 13 with protein truncating variants in the 121 genes. Two unrelated individuals, one with mild and one with atypical PKD have the same *BICC1* frameshift variant: *His141ThrfsTer16* (10:58786953:T:TC). Another with typical PKD is a carrier of two missense variants in *BBS2*. This individual has several unaffected 1st degree relatives who are carriers of one the variants of *BBS2*. Additional efforts are underway to determine other candidate variants as well as their penetrance.

Conclusions: Genetic variants in genes other than *PKD1* and *PKD2* may play a significant role especially in atypical or mild PKD. Exome sequencing in an unselected cohort is a powerful approach to demonstrate the phenotypic and genetic variability of PKD and in determining penetrance.



SA-PO772

Complex Genetic in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Taher Dehkharghanian,[1] Mauricio A. Miranda Cam,[1] Amirreza Haghighi,[2,1] Sol M. Carriazo Julio,[1] Saima Khowaja,[1] Xuewen Song,[1] Matthew B. Lanktree,[3] Andrew Paterson,[4] York P. Pei.[1] *[1]University Health Network, Toronto, ON, Canada; [2]Brigham and Women's Hospital, Boston, MA; [3]Saint Joseph's Healthcare Hamilton - Charlton Campus, Hamilton, ON, Canada; [4]SickKids Research Institute, Toronto, ON, Canada.*

Background: ADPKD is genetically heterogeneous and primarily due to mutations in *PKD1* or *PKD2*. Complex inheritance with biallelic *PKD1* or digenic *PKD1* and *PKD2* mutations (a.k.a. complex genetic) has been reported in a small number of families. Here, we report the prevalence and genotype-phenotype correlation of patients with complex genetic from the extended Toronto Genetic Epidemiology Study of PKD.

Methods: All study patients underwent *PKD1* and *PKD2* mutation screening by targeted Next-Generation sequencing (NGS) and multiplex ligation-dependent probe amplification in mutation-negative cases. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF≤1%) deleterious variants of high and moderate impact as predicted by multiple predictive algorithms. Patients with complex genetic were defined as those with two pathogenic mutations in *PKD1*, or in *PKD1* and *PKD2*. Phase was determined in all patients with *PKD1* biallelic mutations.

Results: We found genetic complexity in 47/993 (4.7%) of families with an identifiable *PKD1* or *PKD2* mutations. Preliminary results from 44 of 53 patients in these families suggest that patients with a *protein-truncating (PT)* and a *non-truncating (NT) PKD1* mutation have more severe disease (by eGFR and TKV; see figure) than patients with two *PT-PKD1* mutations *in-cis*, two *NT-PKD1* mutations *in-trans*, or *PKD1* and *PKD2* digenic mutations.

Conclusions: In this large cohort study from a single geographic region, we found that patients with genetic complexity in ~5% of families with a known *PKD1* or *PKD2* mutation. Delineating complex genetic by NGS has important implications for genetic counselling and may improve clinical prognostication in ADPKD.

SA-PO773

ADPKD and Collagen Genes (COL4A3, COL4A4, COL4A5)

Carlotta Caprara, Valentina Corradi, Matteo Rigato, Barbara Mancini, Nenzi Marzano, Omar Perbellini, Fiorella Gastaldon, Claudio Ronco, Monica Zanella. *Ospedale San Bortolo di Vicenza, Vicenza, Italy.*

Background: The familial hematuria diseases are a heterogeneous group of monogenic conditions caused by mutations in one of the collagen IV genes: COL4A3/A4/A5 that are expressed in the glomerular basement membranes (GBM) and are responsible for the most frequent forms of microscopic hematuria (MH), Alport syndrome, and thin basement membrane nephropathy (TBMN). Data suggest that about 1% of the world population may have MH and TBM, a frequency leads to occasional superimposition of TBMN with other glomerulopathies. Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a major genetic disorder affecting up to 12.5 million individuals worldwide and it is the fourth most common global cause for renal replacement therapy. Two are the principle causative genes: PKD1 and PKD2. The aim of the study was to describe a cohort of clinically ADPKD patients (pts) studying collagen IV genes COL4A3/A4/A5.

Methods: We performed NGS with Sophia Genetic "Nephropathies Solution" Panel on clinically ADPKD pts. This panel includes 44 genes (target region 105.8kb) involved in different types of nephropathies. We considered variants that are categorized as Vous, likely pathogenic or pathogenic (Class 3, 4 or 5 of ACMG) in COL4A3, COL4A4 and COL4A5 genes.

Results: We found 13 (6.3%) clinically potentially interesting (Class 3, 4 or 5 of ACMG) variants in collagen genes in 250 consecutive clinically ADPKD pts. We found 2 pts PKD1, PKD2, PKHD1 negative: 1pt variations carrier COL4A4 NM_000092.5: c.2908C>T (p.Gln970Ter) and c.2756A>G (p.Glu919Gly); 1 pt carrier COL4A3 NM_000091.5: c.609+3_609+6del and COL4A5 NM_000495:c.169G>A p.(Gly57Arg). We also found 4 pts with 4 Vous variants in collagen genes combine with at least 1 pathogenic or likely pathogenic variant in PKD1 or PKD2 genes. We found 3 pts with likely pathogenic variants in COL4A4 or COL4A3 genes combined with Vous or likely benign variants in PKD1 or PKD2 genes and 1 pt with 1 variant likely pathogenic in COL4A3 and 1 likely pathogenic variant in PKD1.

Conclusions: The study outlines the importance to consider also collagen genes even if we have a clear clinical manifestation of ADPKD. Analysis of genes involved in these 2 pathologies could lead to better understand the phenotype-genotype correlation at least in patients with both conditions.

SA-PO774

Intraflagellar Transport 140 Mutations in Taiwan Polycystic Kidney Disease

Daw-yang Hwang,[1,2] Siao Muk Cheng,[1] Chih-Chuan Yu,[2] Yi-Wen Chiu.[2] *[1]National Health Research Institutes, Tainan, Taiwan; [2]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is primarily caused by *PKD1* and *PKD2*, followed by a small portion of cases caused by GANAB and DNAJB11. Other genes, including *ALG8, ALG9, PKHD1,* and *COL4A* can cause similar cystic ab-normality and mimic ADPKD. We previously performed the genetic analysis in a total of 920 ADPKD families and identified nearly 70% of the genetic causes. However, many families remained undiagnosed or had only a variant of uncertain significance identified. We performed exome sequencing in a total of 286 families aiming to identify their disease-causing genes.

Methods: A total of 286 probands from 286 families were included in this study. The study was approved by the institutional review boards of the Kaohsiung Medical University Hospital. Nextera Flex for Enrichment and Exome panel (CEX V2, Illumina) was used for exome library creation. The resulting fastq data were aligned to the reference human genome sequence and performed nucleotide variant calling using the DRAGEN Bio-IT platform (Illumina). The VCF file was analyzed in CLC Genomics Workbench (Qiagen). FastreeR was used to calculate distances, build phylogenetic trees, and perform hierarchical clustering between the samples.

Results: A total of 11 families were identified to have 6 different heterozygous *IFT140* truncation or obligatory splicing variants, including p.Glu51*, p.Leu540*, p.Gln667*, p.Asp738fs, p.Tyr923fs, and p.Gln1162* in the Taiwan ADPKD cohort. Two recurrent mutations, p.Glu51* and p.Leu540* were identified. Phylogenetic analysis showed that the two families with the p.Leu540* variant should be close relatives, while the 5 families with p.Glu51* have various degrees of kinship. Most affected individuals have relatively fewer and larger kidney cysts than classical ADPKD individuals. Their kidney function deterioration rate differs significantly in these 11 affected individuals.

Conclusions: Our data showed that heterozygous *IFT140* pathogenic mutations represented a small but significant 1.2 percent of ADPKD in Taiwan. All our *IFT140* pathogenic mutations are different from the report by Senum *et. al.* in 2022, although 4 of them existed in the GnomAD database. Missense variants of *IFT140*, as well as variants in the other intraflagellar proteins, were also identified. However, their role in the pathogenicity of ADPKD needs further evidence and functional analysis.

Funding: Government Support - Non-U.S.

SA-PO775

Monoallelic IFT140 Pathogenic Variants in Adult Polycystic Kidney Disease Patients Without Family History

Takuya Fujimaru,[1,2] Takayasu Mori,[1] Motoko Chiga,[1] Shintaro Mandai,[1] Yu Hara,[1] Tamami Fujiki,[1] Hiroaki Kikuchi,[1] Yutaro Mori,[1] Fumiaki Ando,[1] Koichiro Susa,[1] Soichiro Iimori,[1] Shotaro Naito,[1] Shinichi Uchida,[1] Eisei Sohara.[1] *[1]Tokyo Medical and Dental University, Tokyo, Japan; [2]St. Luke's International Hospital, Tokyo, Japan.*

Background: *IFT140* encodes a subunit of intraflagellar transport complex A, which is involved in retrograde ciliary transport. *IFT140* is known as a causative gene of Meinzer-Sardino syndrome, an autosomal recessive ciliopathy that presents with short-costothoracic dysplasia. Recently, heterozygous variants in *IFT140* were reported to cause autosomal dominant polycystic kidney disease (ADPKD). We investigated the presence of *IFT140* pathogenic variants in patients with polycystic kidney disease without family history.

Methods: We performed a comprehensive genetic analysis in 151 adult polycystic kidney patients without family history. Targeted genes were 69-92 genes including *IFT140* responsible for 6 hereditary cystic kidney diseases (ADPKD, autosomal recessive polycystic kidney disease, nephronophthisis, nephronophthisis-related ciliopathies, autosomal dominant tubular interstitial kidney disease, and autosomal dominant polycystic liver disease).

Results: Through this analysis, 50 patients (33%) had pathogenic variants in *PKD1* or *PKD2* genes. Additionally, 4 patients had pathogenic variants in other genes (*HNF1B*, n = 2; *OFD1*, n = 1, *PKHD1*, n = 1). In 6 of 97 patients (6%) who did not have any apparent pathogenic variant in known causative genes, heterozygous pathogenic variants were detected in *IFT140* gene (frameshift variant, n = 3; nonsense variant, n = 2; splicing variant, n = 1). None of the patients with heterozygous pathogenic variants in *IFT140* had liver cysts. Additionally, although total kidney volume were large (median, 1357 ml), renal cysts were asymmetric and atypical. Furthermore, the patients with *IFT140* pathogenic variants were older (median, 59.5 years old) and had better renal function (median eGFR, 57.2 ml/min/1.73m^2) at the time of genetic analysis.

Conclusions: *IFT140* should be considered as the responsible gene for polycystic kidney disease, even in the patients had no family history.

Identification of Transcripts Critical to Tuberous Sclerosis Complex (TSC)-mTOR Axis Dysregulation in Tuberous Sclerosis Complex Renal Cystic Disease

Kamyar A. Zahedi,[1,2] Sharon L. Barone,[1,2] Nathan Zaidman,[2] Manoocher Soleimani.[1,2] *[1]New Mexico VA Health Care System, Albuquerque, NM; [2]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Tuberous sclerosis complex (TSC) is an autosomal dominant disorder caused by mutations in TSC1 or TSC2 genes, and affects over two million individuals worldwide. In the kidney, TSC is associated with the development of cysts and angiomyolipomata, leading to renal failure. The cyst epithelia in various models of *Tsc* knockout mice (e.g., principal cell specific KO of *Tsc1* or *Tsc2*, pericyte specific KO of *Tsc1*, and heterozygote *Tsc2*$^{+/-}$), as well humans with TSC is overwhelmingly comprised of hyper-proliferating A-intercalated cells (ICs). Deletion of Foxi1, the transcription factor critical to the acid secretion and IC viability, completely abrogated the cystogenesis in *Tsc1* KO mice.

Methods: RNA-seq analyses comparing the renal transcriptome of Wildtype (WT), *Tsc1 KO*, *Tsc1*/*Foxi1* dKO, and *Foxi1* KO mice were used to identify the differentially expressed transcripts (DET) that were activated in *Tsc1* KO (exhibiting many cysts) and downregulated in *Tsc1/Foxi1* dKO (that had no cysts) mice. The expression levels of mRNAs and proteins of interest were confirmed by northern and western blot analysis, and their localization was ascertained by immunofluorescence microscopy.

Results: RNA-seq analyses identified arginine vasopressin receptor 1a (*Avpr1a*) and the oncogene c-*Kit* (a receptor tyrosine kinase) as DET with robust activation in the kidneys of *Tsc1 KO* mice and complete abrogation in *Tsc1/Foxi1* dKO mice. Northern and Western blot analyses confirmed the increased expression of *Avpr1a* and c-*Kit*, and immunofluorescence displayed abundant labeling of both proteins on the basolateral membrane of ICs lining the cysts in *Tsc1* KO mice. KEGG enrichment analysis and expression studies showed the activation of MAPK and PI3K/AKT pathways, which are critical in AVPR1 and c-KIT signal transduction. Further, Tsc2 in ICs lining the cysts was shown to be phospho-inactivated on multiple ERK, AKT and RSK1 target sites.

Conclusions: The activation of AVPR1a and c-KIT oncogene, in association with enhanced ERK1/2 signaling and TSC2 inactivation, point to a novel pathway that disrupts the TSC/mTORC1 axis in ICs and leads to unregulated cell growth in TSC cystogenesis

Tuberous Sclerosis Complex (TSC) Renal Cyst Extracellular Vesicles (EVs) Have Unique miRNA and Protein Profile

John J. Bissler.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]St. Jude Children's Research Hospital, Memphis, TN.*

Background: Over one million people worldwide have tuberous sclerosis complex (TSC), and half exhibit renal cystic disease. There is an unmet clinical need as there are no approved therapies. We identified that TSC renal cystogenesis is a cell non-autonomous disease process. To address this, we investigated the role of extracellular vesicles (EVs) as a novel mechanism of renal cystic disease to find new therapeutic options. Understanding the mechanism(s) for TSC-associated renal cystogenesis has significant ramifications. Similar to the renal cystic disease-associated renal cell carcinoma seen in von Hippel Lindau disease, TSC-associated renal cystic disease also is associated with renal cell carcinoma in 4-5% of the patient. An in-depth understanding of renal cystogenesis and the abnormal proliferation that leads to renal cell carcinoma will lead to better prevention strategies and therapies.

Methods: After Institutional Review Board approval, we isolated TSC patient derived EVs and performed tunable resistive pulse sensing, electron microscopy, dynamic light scatteringm and western blot analysis to characterize the EVs. We also performed mass spectroscopy for protein analysis, and RNASeq to better understand the miRNA and lncRNA associated with this diease state. For comparison, we used TSC serum derived EVs. For the analysis we used unsupervised clustering with hierarchical clustering and Pearson's correlation coefficients as well as a principal component analysis.

Results: The EVs from the human cyst fluid showed the expected cup shape morphology. Western blot analyses revealed a signature for small EVs, which also contained aquaporin 2, supporting their origin from principal cells. Sizing by TRPS and DLS revealed the EVs were approximately 140 nm in diameter at a concentration of 10^9 EVs per ml. There was strong agreement among DLS, TRPS, and TEM sizing methods. The protein analysis revealed three major groups of proteins that clearly distinguish the EVs isolated from the renal cyst from the EVs isolated from plasma. These experiments clearly reveal the the cyst EVs are unique when compared to EVs derived from patients with TSC. Furthermore, there were unique miRNA and lncRNA signatures for the EVs isolated from the cysts.

Conclusions: EVs in TSC patient cyst fluid continue unique protein and RNA signatures that may offer new avenues into the biology of the diease, and more importantly, into possible therapeutic approaches.

Characterization of Exosomes Isolated from the Kidneys of Wild-Type (WT) and Tsc1 Knockout (Tsc1 KO) Mice

Morgan E. Mackenzie,[1] Kamyar A. Zahedi,[2,1] Sharon L. Barone,[2,1] Christos Argyropoulos,[1] Manoocher Soleimani.[2,1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]New Mexico VA Health Care System, Albuquerque, NM.*

Background: TSC is caused by mutations in TSC1 or TSC2 genes. Cysts are a major renal manifestation of TSC and can lead to end stage kidney disease. In human and mouse models of TSC the cystic epithelium is overwhelmingly comprised of genotypically normal A-intercalated cells (AIC). This suggests the presence of signals that alter the proliferation of AIC. EXO are membrane-bound particles generated by cells and mediate cellular communication, function, and growth. We posit that EXO are important mediators of dysregulated proliferation of AIC lining the cysts in TSC. To this end, we isolated, characterized, and identified the differences in the RNA content of EXO from WT and *Tsc1* KO mice.

Methods: EXO from kidney explants were isolated by size exclusion chromatography. The isolated EXO were characterized by western blot analysis, transmission electron microscopy (TEM), and fluorescent nanoparticle tracking analysis (fNTA). EXO RNA was isolated and run through cDNA library preparation methodology for Nanopore sequencing and mapped to the mouse transcriptome.

Results: TEM studies showed that EXO sizes range from 50 to 300nm. The fNTA studies revealed that greater than 70-77% of isolated particles were EXO with a size range of 50 to 300nm. The EXO were of similar size and distribution; however, the number of EXO was significantly higher in the preparations from the kidneys of *Tsc1* KO mice. Isolated EXO were highly enriched for CD63 and RAB27A markers. RNAseq analysis revealed that 145 transcripts were differentially represented ($p<0.05$) in the EXO isolated from the kidneys of *Tsc1*KO vs. WT mice. These included 24 lncRNAs (4 previously identified), 1 vtRNA, 107 mRNAs, and 8 pseudogenes. Enrichment analysis revealed numerous pathways that differed between *Tsc1* KO and WT exosomes, with significant fold enrichment found in the mTOR and phospholipase D signaling pathway and those of glycerophospholipid metabolism. The mRNA for *SLC25A26*, a mitochondrial protein that functions in S-adenosylmethionine (SAM) S-adenosylhomocysteine (SAH) exchange, and *Lpin2* were substantially enriched in *Tsc1* KO, mice.

Conclusions: LPIN2 and SLC25A26 may affect mTOR activation via SAH levels and DAG signaling, respectively, pointing to a potentially novel mechanism in TSC cystogenesis.

CFTR Absence Affects Kidney Structure and Function

Mateusz Miszczuk,[1] Jennifer R. Charlton,[2] Agnieszka Swiatecka-Urban.[2]
[1]University of Virginia School of Medicine, Charlottesville, VA; [2]University of Virginia, Charlottesville, VA.

Background: Cystic fibrosis (CF) is an autosomal recessive disorder arising from mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene and leads to impaired ion transport across epithelial cells. CFTR plays a critical role in renal progenitor self-renewal during nephrogenesis suggesting that altered CFTR expression could impair nephron endowment and predispose to renal hypodysplasia. During aging, chronic kidney disease (CKD) is morecommon in people with cystic fibrosis (PwCF) than in non-CF individuals. Here, we evaluated the effect of the absence of CFTR on the kidney structure in young mice.

Methods: Kidneys from 7–9 week old C57BL/6J mice expressing wild-type (WT) CFTR or G542X CFTR (CFTR KO; N=2/group/sex) were formalin-fixed and paraffin-embedded. We performed morphometric analysis of glomerular and tubular structures using PAS staining. Glomerular density was assessed by counting the number of glomeruli using light microscopy (n=3/kidney). Cortical area of the kidney was measured using Amira software. Glomerular density was expressed as the number of glomeruli per unit area (glomeruli/mm^2). Lotus tetragonolobus lectin staining of proximal tubules was performed to evaluate presence of the functional glomerulo-tubular junctions (GTJ). Absence of Lotus positive cells in Bowman's capsule defined the loss of GTJ.

Results: The mean renal cortical area was 31% smaller in KO male, compared to WT male. Thecorresponding kidney weight was 25% lower in KO male. The mean cortical area was 8% biggerdespite 20% lower kidney weight in KO female, compared to WT female. Glomerular densitywas 40% and 33% higher in KO male and female, compared to WT male and female, respectively. The loss of GTJ connections was higher in the KO groups (49% and 65% in KO males and females, compared to 27% and 40% in the WT counterparts).

Conclusions: Decreased kidney weight, smaller mean cortical area, higher glomerular density, and loss of GTJ connections in KO groups support the critical role of CFTR in the kidney and suggest that CFTR dysfunction may predispose PwCF to CKD. Increased mean cortical volume despite a lower kidney weight and loss of GTJ connections in KO females emphasize that the impact of CFTR absence is modulated by sex-specific factors.

Novel Regulatory Networks of CFTR in the Kidneys

Mateusz Miszczuk,[1] Agnieszka Swiatecka-Urban.[2] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]University of Virginia, Charlottesville, VA.*

Background: Cystic fibrosis (CF) is an autosomal recessive genetic disorder arising from mutations in the cystic fibrosis transmembrane conductance regulator (CFTR) gene and leads to impaired ion transport across epithelial cell membranes. While the most affected organs in people with CF (PwCF) are the lungs and digestive system, advancements in clinical care and novel high efficiency CFTR modulator therapy have increased life expectancy for most PwCF, unveiling impacts on other organs, including the kidneys. Adult PwCF have up to 20-fold higher risk of end stage kidney disease. In vitro studies suggest that CFTR may regulate renal metabolic pathways and protect from fibrosis, but nothing is known about such role in vivo. We performed single-nuclei (sn) multiomic analysis to elucidate the molecular mechanisms underlying CFTR role in the kidney.

Methods: Kidneys from 7–9-week-old male and female C57BL/6J mice expressing wild-type (WT) CFTR or CFTR G542X (CFTR KO [1]; N=1/group/sex) were subjected to nuclei isolation, Chromium Single Cell Multiome Assay, and snRNA-seq and ATAC-seq profiling. We annotated clusters and assigned cell types based on the expression pattern of knowledge-based cell type marker genes. We assessed the linkage between differentially expressed genes and accessible chromatin regions. This enabled the identification of potential regulatory elements and molecular changes in CFTR KO kidneys.

Results: We detected 27K of high-quality cells in both snRNA-seq and snATAC-seq. In WT and KO groups we identified reads corresponding to Cftr region, predominantly in the proximal tubuleepithelial (PTE) cells. Feature linkage plots corresponding with ATAC accessibility peaks (1Mbrange) and expression of CFTR gene across different cell types showed a robust positive and negative correlation network in the proximity of CFTR gene along with higher overall peak strength in KO groups.

Conclusions: The novel transcriptional and epigenetic CFTR regulatory networks suggest a novel role of CFTR in the kidney and emphasize that CFTR dysfunction may predispose PwCF to CKD.

SA-PO781

CFTR Modulators Mitigate Autosomal Recessive Polycystic Kidney Disease

Cristian Ciobanu, Liudmila Cebotaru. *Johns Hopkins University, Baltimore, MD.*

Background: ARPKD caused by mutations in PKHD1 results in systemic and portal hypertension, fibrosis of the liver, hepatosplenomegaly, and fusiform dilation of the collecting ducts that progresses to end-stage renal disease.

Methods: We injected in pkhd1del3-4/del3-4 (del3-4) deletion model mice with 30 mg/kg of VX-809 every other day for 30 days beginning at 5 days of age or 4 months old and necropsied the mice after 30 days of treatment.

Results: Untreated 5-month-old del3-4 mice had serious liver disease with numerous cysts. Fig.1A illustrates this wide range of cyst sizes, with cysts that are very large in some parts of the liver, and in other parts, numerous but smaller. VX-809 had a profound effect in reducing cysts of all sizes, including the largest ones, as illustrated in Fig.1A&B. The summary data in Fig.1C show that VX-809 had profoundly reduced the larger cysts and was remarkedly effective in reducing even the smaller cysts. We stained liver sections in 5-week-old mice with Ki67, a marker of proliferation, and with CK19, a cholangiocyte marker. There was a substantially (~50-fold) higher percentage of del3-4 cells that were positively stained for both Ki67 and CK19, demonstrating that increased proliferation occurred within the bile duct. VX-809 reduced the staining by one-half. Further experimentation found using confocal microscopy that CFTR is located at the apical membrane in cholangiocytes from the del3-4 mice. VX-809 reduced the CFTR at the apical membrane but increased it at the basolateral membrane.

Conclusions: These data indicate that VX-809 reduces proliferation and the presence of CFTR at the apical membrane while increasing CFTR at the basolateral membrane. Demonstration of liver cyst reduction increases the therapeutic potential of VX-809 as a treatment of ARPKD.

SA-PO782

The Pkhd1del3-67 Deletion Disrupts Local Genomic Architecture Resulting in Reduced Expression of Tfap-2b in the Developing Eye and Peters Anomaly

Yu Ishimoto, Naoki Nakaya, Karla Y. Barbosa Sabanero, Fang Zhou, Laura Kerosuo, Stanislav I. Tomarev, Luis F. Menezes, Gregory G. Germino. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Mutations in *PKHD1*, a gene that spans ~500kb, cause Autosomal Recessive Polycystic Kidney Disease (ARPKD). Mice with genomic deletion from intron 2 through the 3'UTR of *Pkhd1* develop eye and teeth abnormalities. While neither phenotype has been associated with ARPKD, a transgenic mouse strain with a genomic rearrangement mapping close to the *Pkhd1* locus and a strain with *Tfap2b* deletion in Neural Crest Cells (NCC) develop similar eye pathology.

Methods: We recorded eye weights and intraocular pressures (IOP) of *Pkhd1*$^{del3\text{-}67/del3\text{-}67}$ mice and litter mate controls from P7 through P28 and performed histological evaluation of their eyes from E15.5 through P28. We generated *Pkhd1*$^{del3\text{-}67/+}$;*Tfap2b* $^{ko/+}$ transheterozygotes and evaluated their eye, kidney and liver phenotypes.

Results: All *Pkhd1*$^{del3\text{-}67/del3\text{-}67}$ mice developed Peters anomaly, a form of anterior segment dysgenesis, with elevated IOP, corneal opacities and most having enlarged globes. Retinal ganglion cell (RGC) number was normal at P7 but decreased by P28. Adult eyes had disruption of the iridocorneal angle with the iris adherent to the cornea, a finding associated with angle closure glaucoma. E15.5 mouse eyes had less compact cornea with large gaps within stroma and cornea and lens adhesion. *Pkhd1* expression was low in all cell types of normal E15.5 eyes. *Tfap2b* expression was normal in pre-migratory and migrating NCC of *Pkhd1*$^{del3\text{-}67/del3\text{-}67}$ but decreased in corneal endothelium and angle tissue at E15.5, suggesting a defect in NCC-derived cells after they have already populated the eye cup. *Pkhd1*$^{del3\text{-}67/+}$; *Tfap2b* $^{ko/+}$ developed eye and incisor abnormalities like those of *Pkhd1*$^{del3\text{-}67/del3\text{-}67}$ but had phenotypically normal livers and kidneys.

Conclusions: Our results suggest that the eye and incisor abnormalities observed in *Pkhd1*$^{del3\text{-}67/del3\text{-}67}$ mice likely result from disruption of local genomic architecture compromising *Tfap-2b* expression in NCC-derived cells, rather than from loss of expression of *Pkhd1*. This model will be useful for studying the complexities of *Tfap-2b* gene regulation and interventions that prevent RGC loss in glaucoma. GWAS studies have identified SNPs in *PKHD1* associated with elevated IOP. Our data may suggest a possible explanation for this relationship.

Differential Regulation of MYC Expression by PKHD1/Pkhd1 in Human and Mouse Kidneys: Phenotypic Implications for Recessive Polycystic Kidney Disease

Naoe Harafuji,[1] Chaozhe Yang,[1] Ljubica Caldovic,[1,2] Girija Thiruvengadam,[1] Heather Gordish-Dressman,[1] Robert G. Thompson,[4] Phillip D. Bell,[4] Avi Z. Rosenberg,[3] Zsuzsanna M. Bebok,[4] Lisa M. Guay-Woodford.[1,5]
[1]Children's National Hospital, Washington, DC; [2]The George Washington University, Washington, DC; [3]Johns Hopkins University, Baltimore, MD; [4]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [5]Children's Hospital of Philadelphia, Philadelphia, PA.

Background: ARPKD (MIM 263200) is caused by mutations in *PKHD1*, which encodes FPC. We previously showed that: 1) MYC/Myc is overexpressed in human ARPKD and mouse *Cys1*$^{cpk/cpk}$ (*cpk*) kidneys, but not in several *Pkhd1* mutants; 2) the FPC C-terminal domain (FPC-CTD) upregulates, while cystin downregulates, the *MYC/Myc* P1 promoter; 3) mouse and human FPC-CTD differ in subcellular localization (Yang, 2021). Here we present new data from informatic analyses and FPC-CTD overexpression in mouse and human renal epithelia.

Methods: Evo-devo mammalian organ database was queried for developmental expression patterns of cystogenes. ClustalOmega and WebLOGO3 were used to analyze the vertebrate FPC conservation. Immunoblotting and qRT-PCR were used to quantify proteins and mRNA.

Results: *PKHD1* mRNA expression peaked before *CYS1* mRNA in fetal human kidney; in contrast, *Cys1* mRNA expression peaked before *Pkhd1* mRNA in the developing mouse kidney. Developmental expression patterns of *MYC/Myc* mRNA were similar in human and mouse kidneys, peaking in early fetal development and gradually decreased thereafter. Sequence alignment of 102 vertebrate FPCs revealed higher conservation score of the extracellular (1.9) than the intracellular cytoplasmic (1.5) domain. *Cys1* mRNA and cystin protein were downregulated by 80% and 70%, respectively, in mIMCD-3 cells stably overexpressing mFPC-CTD. Stable hFPC-CTD overexpression in TERT immortalized human renal epithelial (hTERT-HRE) cells was unsuccessful, suggesting cytotoxicity. Transient hFPC-CTD overexpression in hTERT-HRE cells did not alter cystin expression.

Conclusions: Higher expression of *Cys1* vs. *Pkhd1* in the developing mouse kidney and the suppression of *Myc* expression by cystin could contribute to the low renal MYC expression in *Pkhd1* mutant mice. In contrast, the relatively lower levels of *CYS1* vs. *PKHD1* in developing human kidney may preclude a cystin-driven protective effect for renal cystogenesis. In addition, the low cross-species conservation of the FPC-CTD suggests functional differences that may contribute to differing susceptibilities to *PKHD1/Pkhd1* mutations and the disparate renal phenotypes.

SA-PO784

Spontaneously Occurring Pkhd1 Mutation (Pkhd1cyli/cyli) with Altered Renal mRNA Processing and Hormonally Sensitive Hepato-Biliary Disease

Naoe Harafuji,[1] Chaozhe Yang,[1] Ljubica Caldovic,[1,2] Weiying Yu,[1] Heather Gordish-Dressman,[1] Zsuzsanna M. Bebok,[3] Lisa M. Guay-Woodford.[1,4]
[1]Children's National Hospital, Washington, DC; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC; [3]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [4]Children's Hospital of Philadelphia, Philadelphia, PA.

Background: ARPKD (MIM 263200) is a hereditary hepato-renal fibrocystic disorder that causes early childhood morbidity and mortality. Mutations in the *PKHD1* gene, which encodes fibrocystin/polyductin complex (FPC), causes all typical forms of ARPKD. Several mouse strains carrying diverse, genetically-engineered disruptions in the orthologous *Pkhd1* gene do not exhibit the classic ARPKD renal phenotype. Here we present the phenotypic and molecular characterization of new mouse model with a spontaneous recessive *Pkhd1* mutation which causes isolated cystic liver (*cyli*) disease.

Methods: A backcross mating scheme and MIT microsatellite makers were used map the *cyli* mutation. DNA sequencing was used to identify the *cyli* mutation. Kidneys and livers were harvested for HE histology. *Pkhd1* mRNA and FPC protein expression were analyzed by RT-PCR, qRT-PCR, Oxford Nanopore sequencing, and immunoblotting.

Results: We mapped the *cyli* mutation to Chromosome 1 and identified an insertion/deletion mutation within *Pkhd1* exon 48, which was predicted to result in a premature termination codon (UGA). *Pkhd1*$^{cyli/cyli}$ (*cyli*) mice exhibited progressive hepato-biliary pathology and longitudinal analysis revealed that pregnancy exacerbated liver disease severity in female mutants. Renal cystic disease was not observed in mutants aged to 6-months. Abundance of *Pkhd1* mRNA was lower in *cyli* than in wild-type kidneys. Several alternatively spliced *Pkhd1* transcripts, all containing exon 48, were detected in *cyli* kidneys. We identified an AAAAAT motif in exon 48 immediately upstream of the *cyli* mutation that could enable ribosomal frameshifting and nonsense mediated decay (NMD) escape.

Conclusions: The *cyli* mutation caused cystic liver similar to the hepato-biliary disease in human ARPKD. The low abundance of *Pkhd1* transcripts in *cyli* kidneys suggests an escape from NMD. Ribosomal frameshifting could allow production of sufficient amounts of FPC for renoprotection in the *cyli* mouse. Further analysis will be required to assess differences in ribosomal frameshifting activity in renal epithelia from the *cyli* mouse and humans with truncating *PKHD1* exon 48 mutations.

Functional TRPV4 Status Sets the Rate of Cytogenesis in Autosomal Recessive Polycystic Kidney Disease (ARPKD) During Variations in Dietary Potassium

Kyrylo Pyrshev, Anna Stavniichuk, Mariya Kordysh, Oleg L. Zaika, Oleh Pochynyuk. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Background: Autosomal Recessive Polycystic Kidney Disease (ARPKD) manifests as a progressive growth of the fluid-filled cysts in the collecting duct. Cystic cells are characterized by the impaired intracellular Ca^{2+} signaling ($[Ca^{2+}]_i$), elevated cAMP levels to drive augmented proliferation. Mechanosensitive TRPV4 channel plays a dominant role in maintaining $[Ca^{2+}]_i$ homeostasis and flow-sensitive $[Ca^{2+}]_i$ signaling in the collecting duct. Systemic TRPV4 stimulation with GSK1016790A impedes cystogenesis in ARPKD models. Previously, we demonstrated that high dietary K^+ regimen elevates both activity and expression of renal TRPV4.

Methods: Here, using fluorescence microscopy and systemic measurements, we tested how regulation of renal TRPV4 function by dietary K^+ intake modulates the rate of cystogenesis and mechanosensitive $[Ca^{2+}]_i$ signaling in cystic cells of PCK453 ARPKD rats.

Results: One month treatment with both high KCl (5% K^+) and KB/C (5% K^+ with bicarbonate/citrate) diets significantly augmented renal TRPV4 expression in PCK453 rats in comparison to that on the regular diet (0.9% K^+). We next explored $[Ca^{2+}]_i$ levels in freshly isolated renal cysts upon application of TRPV4 agonist GSK1016790A and high flow. Treatment with KCl diet significantly augmented TRPV4-dependent Ca^{2+} influx in cystic cells. Unexpectedly, rats on KB/C intake exhibited diminished elevation of $[Ca^{2+}]_i$ concentration in cystic cells in response to both high flow and the agonist comparing to the control. High KCl diet reduced cAMP levels in cystic cells. In contrast, KB/C diet led to the increased cAMP-dependent signaling in cystic cells of ARPKD rats. At the systemic level, high KCl diet significantly decreased kidney-to-bodyweight ratio and reduced the cystic area in kidneys of PCK453 rats. High KB/C diet accelerated ARPKD progression and renal injury leading to a marked increase in the cystic area and particularly the number of cystic dilations in the renal cortex. Of note, application of TRPV4 antagonist GSK2193874 reversed beneficial effects of high KCl diet.

Conclusions: Overall, we demonstrate that TRPV4 channel activity negatively regulates cAMP levels in cystic cells thus attenuating (high activity) or accelerating (low activity) ARPKD progression. Augmenting TRPV4 activity by increased dietary K^+ intake may have therapeutic potential in PKD.

Ultrasound and 3D Imaging Characterisation of a Rat Model of Polycystic Kidney Disease

Maria K. Ougaard, Trine Porsgaard, Frederikke E. Sembach, Louise Thisted, Jacob L. Skytte, Johanna Perens, Michael Christensen. *Gubra, Hoersholm, Denmark.*

Background: Polycystic kidney disease (PKD) is a congenital fibrocystic disorder for which there is no curative treatment. Consequently, PKD is classified as a medical condition with high unmet therapeutic need. Animal models with improved clinical translatability can optimally inform about potential efficacy of novel drug candidates for PKD. The polycystic kidney (PCK) rat is an established genetic model of PKD with natural history and renal histologic abnormalities that resemble the human disease. Gubra has established a PCK rat breeding program to enable fast turnaround time of preclinical drug discovery within PKD. In this study, we have characterised disease progression in the PCK rat to aid in designing future pharmacological intervention studies.

Methods: Male PCK (PCK/CrljCrl-Pkhd1pck/Crl) and control (CRL:CD(SD)) rats were randomised into study groups based on body weight (10 weeks). At the age of 17 and 25 weeks, rats underwent ultrasound assessment of kidney volume, urine collection for quantification of albuminuria, and plasma sampling for urea and creatinine analysis. At termination, kidneys were collected and total kidney volume, cyst number and volume were analysed using quantitative 3D imaging.

Results: Compared to age-matched control rats, PCK rats displayed marked albuminuria at 25 weeks of age. Plasma urea was progressively increased at both 17 and 25 weeks, while plasma creatinine was only increased at week 25. *In vivo* ultrasound measurements revealed that total kidney volume progressively increased (25 wks.: 4909 mm^3) compared to control rats (2174 mm^3). 3D light sheet imaging enabled whole-kidney counting of cysts and quantification of cyst volume (control: 10.9 mm^3 vs 25 wks.: 413.5 mm^3) as well as the total kidney volume that correlated to kidney ultrasound results.

Conclusions: The PCK rat displays hallmarks of PKD, characterized by age-dependent progressive increase in biomarkers of kidney injury, kidney hypertrophy and cyst formation. *In vivo* ultrasound and *ex vivo* quantitative whole-kidney 3D light sheet imaging is highly instrumental for detailed assessment of progressive kidney disease in the PCK rat. Accordingly, these imaging modalities are instrumental as key endpoints for assessment of potential therapeutic effects of preclinical drug candidates in the PCK rat model.

Background: *APOL1* variants (*G1* or *G2*) are the genetic cause of progressive, proteinuric nephropathies referred to as APOL1-mediated kidney disease (AMKD). The prevalence of *APOL1* variants, which are common in persons of recent African ancestry, is not well known as *APOL1* genotyping is not routine in kidney disease care. We report data from a new interim analysis on the prevalence of *APOL1* genotypes in proteinuric chronic kidney disease (CKD).

Methods: This ongoing global study is enrolling up to 2500 participants of recent African ancestry with FSGS or proteinuric (UPCR >0.5 g/g) nondiabetic kidney disease (NDKD) to determine the percent of participants with 2 *APOL1* variants, including by genotype category, and identify potential participants for trials evaluating APOL1 therapies. During a single visit, a blood sample is collected to determine the *APOL1* genotype (validated PCR assay); genetic counseling is available.

Results: Interim analysis included 1463 participants. Among 392 participants with FSGS and 1071 with NDKD, 184 (46.9%) and 248 (23.2%) have 2 *APOL1* variants, respectively (**Table**). Most participants with 2 *APOL1* variants and proteinuric CKD are >30 to ≤60 years old (n=321/432; 74.3%).

Conclusions: The high prevalence of 2 *APOL1* variants in participants with recent African ancestry and proteinuric CKD emphasizes the importance of *APOL1* genotyping in kidney disease care to inform disease management and enable referral for clinical trials of APOL1-targeted therapies.

Small Molecule Inhibition of APOL1 Reverses Albuminuria in a Chronic Mouse Model of APOL1-Mediated Kidney Disease

Victoria Assimon, Sarah Bronner, Cecile Yu, Helen Chan, Sheela Crasta, Patrick S. Lee, Baiwei Lin, Yunqi Luo, Angela Octaviani, Adam Reid, Laura Sanman, Licheng Shi, Eva Situ, Sam Tep, Birong Zhang, David T. Beattie, Christopher Sinz, Maarten Hoek, Harold S. Bernstein, David J. Morgans, Eric Green. *Maze Therapeutics Inc, South San Francisco, CA.*

Background: Two coding variants in the *APOL1* gene (G1 and G2) confer a greater risk for progressive, proteinuric kidney disease in individuals of African ancestry. Available therapies do not address the causal genetic driver of disease, highlighting the need for novel efficacious APOL1-targeted treatments. We have previously shown that pharmacologic inhibition of APOL1 pore function ameliorates albuminuria in an acute mouse model of APOL1-mediated kidney disease (AMKD). Here we describe the development of a chronic mouse model of AMKD with robust albuminuria and glomerulosclerosis and demonstrate that inhibition of APOL1 with a small molecule attenuates these features of AMKD.

Methods: A novel model, heterozygous for the APOL1 G1/G2 variants, was developed for these studies in addition to the homozygous APOL1 G2 mouse model previously described. Continuous increased APOL1 expression was achieved by infecting mice with an adeno-associated virus (AAV) engineered to express interferon-γ (IFN-γ). These mouse models were used to assess the effect of APOL1 small molecule inhibition on glomerular injury and urinary albumin-to-creatinine ratios (UACR).

Results: Administration of AAV-IFN-γ in APOL1 transgenic mice increased interferon levels and signaling after virus injection and led to sustained APOL1 induction, elevated UACR, and glomerulosclerosis on both genetic backgrounds. Oral administration of an APOL1 inhibitor robustly attenuated chronic IFN-γ–induced albuminuria in APOL1 transgenic mice.

Conclusions: Small molecule inhibition of APOL1 attenuates albuminuria in a chronic mouse model of AMKD. These findings support continued development of precision medicines for patients with AMKD.

APOL1 Risk Variants Induce Mitochondrial Dysfunction in Patient-Derived Kidney Organoids

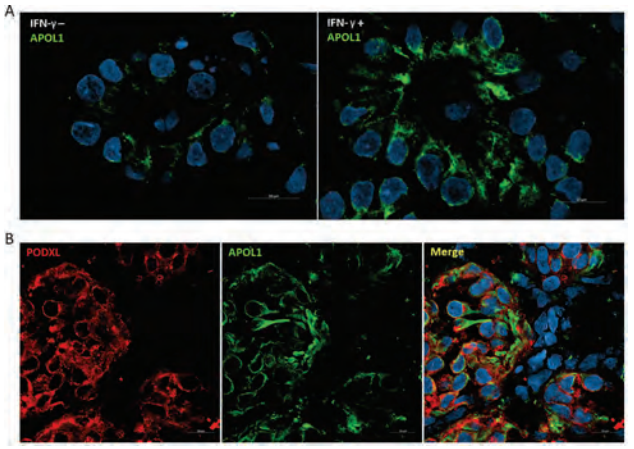
Heein Song,[1] Sébastien J. Dumas,[1] Lijun Ma,[2] Gangqi Wang,[1] Franca Witjas,[1] Cathelijne W. Van den Berg,[1] Michael V. Rocco,[2] Barry I. Freedman,[2] Ton J. Rabelink,[1] Siebe Spijker.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Apolipoprotein L1 (*APOL1*) high-risk genotypes cause CKD in the presence of interferon gamma (IFN-γ). To elucidate mechanisms, patient-derived induced pluripotent stem cells (iPSCs) were used to generate a kidney organoid model of *APOL1* nephropathy.

Methods: iPSCs were generated from fibroblasts of two patients with APOL1 nephropathy homozygous for G1G1 and G2G2 risk variants (RV). Isogenic control of the G2G2 patient iPSCs was created with CRISPR-Cas9 gene editing. Kidney organoids were generated using G1G1, G2G2 and isogenic control iPSCs. Organoids were treated with IFN-γ and analyzed by single cell transcriptomics, immunofluorescence imaging and mitochondrial respiration assay.

Results: APOL1 gene expression was upregulated in all genotypes following IFN-γ. Single cell transcriptomics of organoids 3 days post IFN-γ treatment showed APOL1 induction was mainly in podocytes, confirmed with colocalized immunolabeling of APOL1 and podocalyxin. RV podocytes showed significantly decreased expression of nuclear DNA-encoded OXPHOS related genes, while mitochondrial DNA-encoded gene expressions were increased. Further, a novel subpopulation in RV podocytes was identified, characterized by a metabolic switch to glycolysis. Next, glomeruli were isolated from RV and isogenic control organoids to assess oxygen consumption rate and reactive oxygen species (ROS). In RV glomeruli, maximal respiration rate upon IFN-γ treatment did not increase, unlike in the isogenic control, and ROS levels were 30% higher.

Conclusions: We generated a kidney organoid model of *APOL1* nephropathy using patient-derived RV and isogenic control iPSCs. Exposure of *APOL1* RV organoids to IFN-γ induced podocyte mitochondrial dysfunction and may provide a mechanism for development of CKD. This model supports further research in mechanisms and potential therapeutics for *APOL1* nephropathy.



APOL1 expression increased upon IFN-γ treatment (A), specifically in the podocyte population (B).

SA-PO790

APOL1-Inflammation and Hypoxia Axis in Ischemic Donor Kidneys

Yasar Caliskan, Kento Kurashima, Meghan M. Unes, Edward L. Portz, Fadee Abu Al Rub, David S. Brink, Mustafa Nazzal, Ajay Jain, Krista L. Lentine, John C. Edwards. *Saint Louis University, Saint Louis, MO.*

Background: The presence of two *APOL1* renal risk variants (RRVs) in donor kidneys negatively impacts kidney allograft survival. We examined the effects of *APOL1* RRVs on APOL1 expression and compared the differences in cytokine and APOL1 expression patterns between preservation methods cold storage (CS) and normothermic machine perfusion (NMP).

Methods: Discarded deceased donor kidney pairs underwent 6-hour NMP (n=6) and CS (n=6). Perfusion, biochemical, and histologic parameters were recorded. Paired donor kidneys with different *APOL1* genotypes were compared with regard to the aforementioned parameters and gene expression under NMP and CS. DNA is extracted and genotyping for *APOL1* RRVs G1 (rs73885319) (rs60910145) and G2 (rs71785313) were performed by Sanger sequencing.

Results: Donor genotyping showed 5 kidney pairs with G0/G0 and a kidney pair with heterozygous G0/G1 RRV. Kidneys were successfully perfused, with improved renal blood flows and resistance over the course of perfusion, and evidence of urine output (Table 1). Transcriptomic analyses showed different expression patterns between *APOL1* G0/G0 kidneys and G0/G1 kidney, particularly under NMP (Fig. 1). The kidney with *APOL1* G0/G1 showed higher fold increase in expression of APOL1, TGF-β and IFN-γ compared to kidneys with G0/G0 under 6 hrs of NMP. Overall, APOL1 expression was significantly correlated with KIM1 (r=0.87, p<0.001), TGF-β (r=0.83, p=0.001), IFN-γ (r=0.77, p=0.004) and HIF-1α (r=0.81, p<0.001) in all kidney pairs.

Conclusions: Donor kidney with *APOL1* G0/G1 RRV demonstrated different transcriptomic response to alternative preservation methods. Further studies needed to clarify the interplay between APOL1, inflammation and kidney injury in the setting of allograft ischemia and reperfusion.

Funding: Private Foundation Support

SA-PO791

Single-Nucleus RNA Sequencing Analysis of Interferon-Exposed APOL1 High-Risk Transgenic Mouse Reveals Distinct Injury Patterns in Podocytes and Endothelial Cells

Khun Zaw Latt,[1] Teruhiko Yoshida,[1] Shashi Shrivastav,[1] Jurgen Heymann,[1] Yongmei Zhao,[1] Avi Z. Rosenberg,[2] Jeffrey B. Kopp.[1] *[1]National Institutes of Health, Bethesda, MD; [2]Johns Hopkins University, Baltimore, MD.*

Background: *APOL1* high-risk genetic variants, termed G1 and G2, compared to the common variant G0, cause focal segmental glomerulosclerosis (FSGS), collapsing glomerulopathy, and arterionephrosclerosis in individuals with sub-Saharan African ancestry. Gene expression profiles of glomerular cells in APOL1-mediated cell injury have not been studied at the single cell level. We performed single-nucleus RNA sequencing (snRNA-seq) of glomeruli from wild-type (WT) and bacterial artificial chromosome (BAC)/APOL1-G0 and -G1 transgenic mice following interferon-g administration.

Methods: BAC/*APOL1* transgenic mice received a single dose of interferon-g, administered retro-orbitally, and were euthanized 24 hours later. Glomeruli were isolated and nuclei were captured for snRNA-seq. The snRNA-seq data from BAC/APOL1-G0, BAC/APOL1-G1 and wild-type mice were integrated and analyzed using Seurat4. Podocytes and glomerular endothelial cell clusters were identified by expression of known marker genes. Subclustering and pseudotime analysis were performed to identify cell subpopulations and their characteristic gene signatures.

Results: The combined analysis of snRNA-seq datasets identified podocyte clusters expressing *Nphs1* and glomerular endothelial cell (GEC) cluster expressing *Ehd3* and *Hecw2*. *APOL1* was expressed by podocytes and endothelial cells. Expression levels were similar between *APOL1*-G0 and *APOL1*-G1 expressing cells within each cluster. Podocytes and GECs showed similar gene expression patterns of early injury but distinct patterns with more severe injury. Genes specific to the podocyte severe injury cluster in BAC/*APOL1* mice showed higher expression in human FSGS *APOL1* high-risk urinary podocytes, compared to APOL1-low-risk podocytes.

Conclusions: Following interferon administration to BAC/APOL1 mice, we observed a unique gene expression profile in a *APOL1*-G1 risk allele mouse compared to a *APOL1*-G0 mouse. *APOL1* was expressed in podocytes and GECs. However, the gene expression patterns of injury in these two cell types were different and may reflect different roles by which these cells contribute to glomerular pathology in APOL1 glomerular disease.

SA-PO792

HIV-1 Protein Nef Acts in Synergy with APOL1-G1 to Impair Nephrocyte Function by Inhibiting Autophagy and Endocytosis Pathway

Junyi Zhu. *University of Maryland Baltimore, Baltimore, MD.*

Background: Individuals carrying APOL1 risk alleles G1 and G2 have higher chances of developing HIV-associated nephropathy (HIVAN). The role of APOL1 in HIVAN is mostly derived from studies done in cultured renal cells or clinical genetic

studies. However, very little is known about how APOL1 risk alleles and HIV-1 genes interact *in vivo* to induce HIVAN. The basic mechanisms responsible for the synergistic renal pathological effects of APOL1 risk alleles and HIV-1 are still unclear.

Methods: Because *Drosophila* nephrocyte, is remarkably similar, both structurally and functionally, to the mammalian podocyte, here we generated transgenic flies selectively expressing APOL1 nephropathy risk Alleles G1 and HIV-1 protein Nef in *Drosophila* nephrocytes. We then investigated the structural and functional effects on the fly nephrocytes.

Results: As transgenic flies with APOL1-G1 aged, we found nephrocyte function declined, cell size increased, the structure of the slit diaphragms defected, and nephrocytes died prematurely. Furthermore, we showed that the expression of APOL1-G1 impaired the nephrocyte function by affecting the acidification of organelles by inhibiting the endocytosis pathway. Next, we noticed that the expression of HIV-1 protein Nef facilitated these nephrocyte impairments. We further found that expressing of HIV-1 protein Nef in nephrocytes induced the accumulation of autophagosomes and inhibited the autophagy pathway, which facilitated the impairments of the acidification of organelles, and functional structure of nephrocytes.

Conclusions: These results suggested that Nef and APOL1-G1 lead to the increased risk of renal failure through their synergistic regulation of the autophagy and endocytosis pathway, which will provide new therapeutic targets to prevent HIV-associated nephropathy.

SA-PO793

Atypical Hemolytic Uremic Syndrome (aHUS) Clinical Characteristics and Outcomes During Index Hospitalization Diagnosis in the Era of C5 Inhibitor Therapy (C5i)

Stephen W. Olson,[1] Briana C. Ndife,[1] Jennifer Nguyen,[1] Elizabeth Nagelhout,[2] Andrea Gabriela B. Barthel,[2] Yingjie Ding.[2] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Genesis Research LLC, Hoboken, NJ.*

Background: C5i therapy has significantly improved clinical outcomes for aHUS. Due to its rarity, there are few previous large aHUS retrospective cohort studies and these are limited to patients from outside the US, children, and/or prevalent patients from before the era of C5i. This study sought to describe the clinical characteristics and outcomes in one of the largest and most diverse incident adult US aHUS cohorts treated with C5i to date.

Methods: This was a retrospective cohort study of adult aHUS patients in the US diagnosed during hospitalization, derived from the US Premier Healthcare Database, which contains ~25% of all US hospitalizations (1/2011–6/2021). aHUS was defined as the presence of a diagnostic code for thrombotic microangiopathy (TMA) or HUS and a treatment code for C5i in the absence of a diagnostic code for secondary causes of TMA or HUS. Prespecified clinical and outcome data were collected and analyzed using descriptive statistics.

Results: The cohort comprised 634 patients with a median age of 51 years (interquartile range [IQR] 32–64). The majority were female (67.2%), White (61.5%), and non-Hispanic (76.3%). Baseline co-morbidities included hypertension (70.3%), chronic kidney disease (30.4%), and diabetes (18%). Median intensive care unit (ICU) and hospital stays (IQR) were 6 (3–11) and 20 days (14–32), respectively. The median time from admission to C5i was 9 days (5–15). For patients receiving corticosteroids (CS) (78.5%) and therapeutic plasmapheresis (TPE) (69.1%), the median time from admission to treatment was 2 days (1–5) and 3 days (2–5), respectively. Median treatment durations for CS and TPE were 17 days (8–28) and 5 days (3–12). Renal replacement therapy (RRT) was initiated in 77.3% of patients and discontinued prior to discharge in 51% of these patients. In-hospital mortality was 12.3%, and 22.7% of patients required follow-up in skilled care facilities.

Conclusions: Despite the substantial clinical benefits from C5i, aHUS remains a morbid disease, as shown by hospital and ICU stay duration, RRT incidence, discharge care requirements, and mortality described in this US cohort. Future efforts should focus on improved time to treatment and developing novel therapies.

SA-PO794

Atypical Hemolytic Uremic Syndrome (aHUS) Clinical Characteristics and Treatment Patterns Associated with Mortality During Index Hospitalization

Stephen W. Olson,[1] Briana C. Ndife,[1] Jennifer Nguyen,[1] Elizabeth Nagelhout,[2] Andrea Gabriela B. Barthel,[2] Deval Gor.[2] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Genesis Research LLC, Hoboken, NJ.*

Background: aHUS is caused by dysregulation of the alternative complement pathway and is associated with significant morbidity and mortality. C5 inhibitors (C5i) improve thrombotic microangiopathy (TMA) response and renal recovery. This study described clinical characteristics and treatment patterns associated with mortality using real-world evidence from one of the largest, most diverse incident aHUS cohorts in the US during the C5i era.

Methods: This was a retrospective cohort study of 634 incident hospitalized adult aHUS patients, derived from the US Premier Healthcare Database, which contains ~25% of all US hospitalizations (1/2011–6/2021). aHUS was defined as the presence of a diagnostic code for TMA/HUS *and* a treatment code for a C5i in the absence of a diagnostic code for secondary causes of TMA/ HUS. Demographic and clinical characteristics were analyzed using t-test, Wilcoxon rank test, Fisher's exact test or Chi-squared test as appropriate.

Results: Overall, 78 patients (12.3%) died during hospitalization. Of 285 patients with mortality data post-discharge, 30- and 365-day mortality rates were 4% and 9%, respectively. In-hospital aHUS mortality was associated with older median age (63 vs 49 years, p<0.001), diabetes (30% vs 16%, p=0.003), longer median intensive care unit stay (14 vs 5 days, p<0.001) and hospital stay (31 vs 20 days, p<0.001), but not race, ethnicity, gender, history of hypertension, or CKD. In-hospital mortality was associated with a longer median delay between admission and therapeutic plasmapheresis (TPE) (5 vs 2 days, p<0.001) and C5i (15 vs 8 days, p<0.001). Although not associated with exposure or time until corticosteroids (CS), mortality was associated with duration of CS use (27 vs 16 days, p<0.001) and time from C5i initiation to CS discontinuation (14 vs 6 days, p=0.02). Mortality was associated with increased median time to renal replacement therapy (RRT) (5 vs 3, p<0.001) but not RRT requirement.

Conclusions: Delayed TPE, RRT, and C5i treatment and prolonged CS exposure are associated with increased mortality in aHUS. Future efforts should be made to reduce any treatment delays and develop more targeted, steroid-sparing treatments.

SA-PO795

Atypical Hemolytic Uremic Syndrome (aHUS) Clinical Characteristics Associated with Renal Replacement Therapy (RRT) Initiation During Index Hospitalization and RRT Requirement After Discharge

Stephen W. Olson,[1] Briana C. Ndife,[1] Jennifer Nguyen,[1] Elizabeth Nagelhout,[2] Colette Ndiba-Markey,[2] Swastina Shrestha.[2] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Genesis Research LLC, Hoboken, NJ.*

Background: aHUS is caused by dysregulation of the alternative complement pathway and is associated with significant renal morbidity. This study described the clinical characteristics and treatment patterns associated with RRT, using real-world evidence from one of the largest and most diverse incident aHUS cohorts in the US during the C5 inhibitor (C5i) era.

Methods: This was a retrospective cohort study of 634 incident hospitalized adult aHUS patients derived from the Premier Healthcare Database, which contains ~25% of all US hospitalizations (1/2011–6/2021). aHUS was defined as presence of a diagnostic code for thrombotic microangiopathy (TMA) or HUS *and* a treatment code for a C5i in the absence of a diagnostic code for secondary causes of TMA or HUS. Demographic and clinical characteristics were analyzed using t-test, Wilcoxon rank test, Fisher's exact test or Chi-squared test as appropriate.

Results: The in-hospital RRT initiation rate was 77%. Compared with patients not requiring RRT, those who initiated RRT were significantly more likely to be White (64% vs 53%, p=0.04), have a history of heart failure (22% vs 9%, p<0.001), and have a longer median duration of intensive care unit (6 vs 4 days, p<0.001) and hospital (22 vs 16 days, p<0.001) stay. Age, sex, ethnicity, hypertension (HTN), CKD, and diabetes were not associated with RRT requirement. Patients receiving in-hospital RRT had a longer delay between admission and therapeutic plasmapheresis (TPE) (3 vs 2 days, p=0.007) or C5i (10 vs 7 days, p=0.006), but not corticosteroids (CS). RRT was discontinued by discharge in 51% of survivors. RRT requirement at discharge was associated with a history of HTN (79% vs 66%, p=0.004) and CKD (37% vs 26%, p=0.02) but not with age, race, ethnicity, sex, or diabetes. In-hospital RRT discontinuation was associated with TPE (84% vs 65%, p<0.001) and CS (81% vs 73%, p=0.04) but not with time between admission and C5i, TPE, or CS.

Conclusions: In patients with aHUS, preservation of renal function remains a challenge. Treatment and time to treatment are associated with renal outcomes. Future efforts should be made to measure the effect of aHUS treatment delay.

Funding: Commercial Support - Novartis Pharmaceuticals Corporation

Rapid Nephrogenomics in Intensive Care for Early Intervention in Adult Thrombotic Microangiopathies

Nadhir Yousfi,[1,2] Marie Mille,[3] Abderaouf Hamza,[4] Sophie Vandermeersch,[1] Sacha Beaumeunier,[3] Denis Bertrand,[3] Michael Blum,[3] Julien Doudement,[3] Carine El Sissy,[5] Paula Vieira-Martins,[5] Nicolas Philippe,[3] Veronique Fremeaux Bacchi,[5] Laurent Mesnard.[1,2] *[1]INSERM-Sorbonne Université UMRS 1155, Paris, France; [2]CNR-MAT APHP, Paris, France; [3]SeqOne Genomics, Montpellier, France; [4]Institut Curie, Paris, France; [5]Hopital Europeen Georges Pompidou, Paris, France.*

Background: Nephrogenomics, represents the study of genetic factors influencing kidney function and diseases. The field has rapidly advanced in recent years due to the development of high-throughput sequencing technologies such as next-generation sequencing (NGS). Thrombotic microangiopathy (TMA) encompasses various genetically driven diseases with some of them could benefit from early intervention (C5 blocking, VitB12 therapy). Structural variants (SV) in the CFH/CFHR gene region leading to the formation of gene fusions constitute a specific molecular diagnostic bottleneck associated with 5% of complement dependent TMA (c-TMA) cases. However, the highly repetitive character of sequences in this region, makes it difficult to detect these SVs when using standard short-read sequencing. Our current turn-around time for the diagnosis of TMA (3 weeks) is too long in some clinical context. Ultra-fast sequencing techniques using long reads Nanopores technologies can provide efficient and versatile cost-effective analysis in a matter of hours.

Methods: Here we report diagnostic results of Nanopore sequencing with adaptive sampling in TMA, which is a method to enrich sequences or genes of interest. We lower our TAT to 5 days with long reads sequencing and adaptive sampling. We established a rapid molecular diagnosis that allows time-decision making on the use of anti-C5 treatment for complement-mediated TMA (c-TMA), as averting unnecessary costly and potentially harmful therapy in patients who will in any case not respond to the anti-C5 treatment.

Results: With rapid and long reads sequencing, we were able to diagnosis a case of independent complement-TMA with a variant in *MMACHC*. We also retrospectively validated the detection of known SVs in four samples on which MLPA (Gold standard method to identify SV) analysis was performed. We were able to detect all the SVs in these samples such as CFH-CFHR1 hybrid, CFHR1-CFH hybrids of different sizes and a deletion of CFHR1-CFHR3.

Conclusions: Thus, rapid genomics using nanopore technologies can provide valuable insights into disease detection and treatment efficacy improving patient diagnosis and prognostic, enabling optimal and early therapeutic intervention.

Unusual Case of Thrombotic Microangiopathy (TMA) in the Setting of Severe Hypertension

Melinda K. Solomon,[1] Aaron M. Dommu,[2] Sandeep Ghai,[1] Jean M. Francis.[1]
[1]Boston Medical Center, Boston, MA; [2]Nephrology Associates, PC, Trumbull, CT.

Introduction: 22-year-old female with a past medical history of hypertension since age 3, left ventricular hypertrophy since childhood, and hypokalemia and metabolic alkalosis who was referred for severe active on chronic thrombotic microangiopathy in the setting of difficult to control blood pressure. Her blood pressure had been previously well controlled but developed refractory hypertension starting in 12/2020. She had been on Nifedipine and Losartan but developed bilateral lower extremity edema in 2021 and was switched to Verapamil and Enalapril. She was continued on Amiloride and due to uncontrolled blood pressure, was switched from Hydralazine to Labetalol with better blood pressure control. Despite the combination of enalapril and amiloride, she remained with low levels of potassium.

Case Description: Previous work-up for secondary hypertension had been negative and patient had no family history of HTN. Renal biopsy in 2021 showed chronic-active thrombotic microangiopathy, largely affecting blood vessels, focal segmental and diffuse global sclerosing glomerulopathy, severe tubular atrophy and interstitial fibrosis, severe and diffuse chronic changes, and advanced IFTA and global glomerulosclerosis. TMA secondary to TTP, anti-cardiolipin syndrome, scleroderma, drugs, and infection were ruled out. Patient had a positive ANA but negative ENA and no clinical or laboratory signs of lupus. Genetic testing for complement regulatory proteins that are associated aHUS were unrevealing.

Discussion: At time of referral, we performed genetic testing and patient was found to have compound heterozygous mutations in HSD11B2 gene, which results in apparent mineralocorticoid excess (AME) an autosomal recessive disorder. Patient progressed to end stage renal disease. She received a deceased donor kidney transplant after a short course of peritoneal dialysis. Post-transplant course was complicated with prolonged hypotension secondary to chronic adrenal suppression, and responded well to Florinef. This case highlights the heterogeneity of TMA presentation and inform providers on management of hypotension after kidney transplantation in patients with AME.

Primary Atypical Hemolytic Uremic Syndrome Presenting with Raynaud Phenomenon Triggered by COVID-19

Husam El Sharu,[1] Akil S. Kavcar,[1] Tiffany Lee,[2] Richard K. Grey,[2]
Anthony Provenzano.[2] *[1]East Carolina University Brody School of Medicine, Greenville, NC; [2]Eastern Nephrology Associates PLLC, Greenville, NC.*

Introduction: COVID-19 has been linked to atypical hemolytic uremic syndrome (aHUS), although skin manifestations are rarely reported.

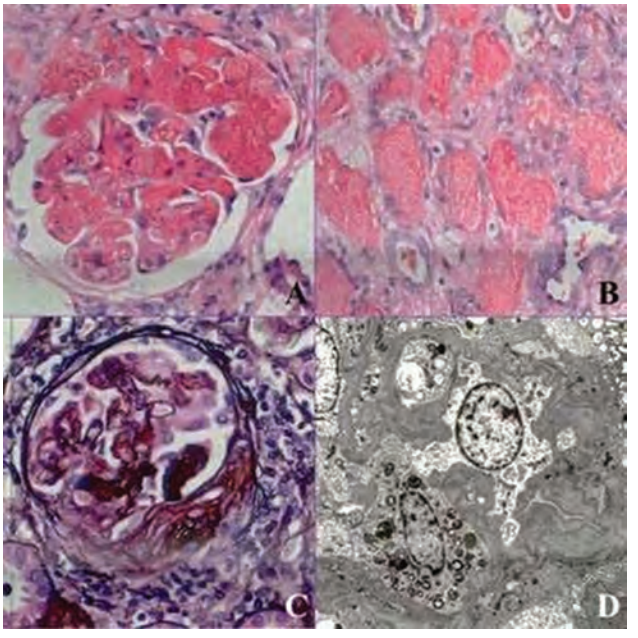
Case Description: A 48-year-old female with Mixed connective tissue disease (MCTD) presented after COVID-19 with Raynaud's phenomenon. Blood film showed schistocytes, ADAMTS13 level was 45%, before PLEX therapy. Labs (Coombs, antiphospholipid, CH50, hepatitis, HIV) were unremarkable but she had a positive RNP antibody and ANA with a titer of 1:320. Renal biopsy showed thrombotic microangiopathy and 20% interstitial fibrosis. Genetic testing revealed a heterozygous MCP/CD46 gene mutation. She needed 2 months of hemodialysis, but symptoms, platelets, and creatinine improved with ravulizumab initiation.

Discussion: Our case highlights skin involvement in primary genetic aHUS and the potential association between MCP/CD46 gene mutation and MCTD, which is rarely reported.

Results

Hemoglobin (mg/dL)	11
Platelets (mcL)	20
Creatinine (mg/dL)	8.44
Blood Urea Nitrogen (mg/dL)	84
Haptoglobin (mg/dL)	22
Lactate dehydrogenase (U/L)	5000

Raynaud's Phenomenon



A Global fibrin thrombus
B Acute tubular necrosis
C Segmental sclerosis, adhesions, and GBM corrugation
D Mesangiolysis and increased lamina rara interna.

SA-PO799

Complement-Mediated Hemolytic Uremic Syndrome due to CD46 Pathogenic Variant Unmasked by COVID-19

Jessica M. Rosario-Falero, Ihor V. Yosypiv. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Complement-mediated hemolytic uremic syndrome (HUS) is rare, with an estimated incidence of 10 cases per 1,000,000 children in the U.S. Only 5 to 10 percent of these cases are from *CD46* gene variants. We report the case of a pediatric patient with a history of COVID-19 infection, presenting with severe thrombocytopenia, anemia and renal dysfunction who was found to have an extremely rare mutation in *CD46*.

Case Description: A previously healthy 3 y/o male presented with fever, abdominal pain, anorexia, and dark colored urine for 5 days. He had recent history of COVID-19. Mother denied him having had diarrhea. He had no prior history of kidney diseases and family history was non-contributory. Physical exam was remarkable for scleral icterus, and diffuse abdominal tenderness. Laboratory workup showed anemia (hemoglobin: 6.4 g/dL), thrombocytopenia (21 x 10^3µL), acute kidney injury (BUN 102 mg/dL, plasma creatinine 2.45 mg/dL), and schistocytes in peripheral blood smear. He also had hyperbilirubinemia (total bilirubin 2.4 mg/dL, direct bilirubin 1.7 mg/dL), elevated lactate dehydrogenase (2,991 U/L), gross hematuria and nephrotic range proteinuria (urine protein to creatinine ratio 4.6 mg/mg). Clinical picture was consistent with thrombotic microangiopathy. Further workup revealed a negative direct antiglobulin test, normal complement C3 and C4 levels, and normal ADAMTS13 activity level. Stool was negative

for Shiga toxin. We suspected this was a case of atypical HUS (aHUS) in the setting of recent viral infection (COVID-19). Genetic panel for aHUS was ordered, and patient was started on Eculizumab (human anti-C5 monoclonal antibody).

Discussion: Patient's clinical status significantly improved after the first dose of Eculizumab. Platelet count and BUN normalized. Hemoglobin and plasma creatinine improved significantly (8.5 g/dL and 0.8 mg/dL respectively). LDH was down trending by the time of discharge (1238 U/L). Genetic panel revealed an extremely rare heterozygous nonsense variant in exon 5 of the *CD46* (c.486T>A, p.Cys162Stop) confirming our working diagnosis. This case demonstrates the importance of prompt recognition of aHUS, early genetic/functional testing for complement-mediated aHUS and early initiation of Eculizumab to reduce the risk of permanent kidney damage. It also shows that COVID-19 infection may act as trigger for complement-mediated aHUS.

SA-PO800

Partial Rescue of Complement-Induced Organ Injuries in a Factor H Mutant Mouse by MASP3 Deficiency

Hangsoo Kim,[1,3] Damodara Gullipalli,[1] Takashi Miwa,[1] Sayaka Sato,[1] Madhu Golla,[1] Matthew Palmer,[2] Wen-Chao Song.[1] *[1]Department of Systems Pharmacology and Translational Therapeutics, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [2]Department of Pathology and Laboratory Medicine, Perelman School of Medicine, University of Pennsylvania, Philadelphia, PA; [3]Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan.*

Background: Complement is activated through three canonical pathways: classical pathway (CP), lectin pathway (LP) and alternative pathway (AP). MASPs was known as a component of LP, but according to recent reports, MASPs was also participate AP. *MASP1* gene knock-out mice (MASP-1/3 lacked) showed no AP activity and furthermore, MASP3 was clarified that it was responsible for the AP activation through maturation of pro factor D. These findings open the door to developing MASP3 targeting therapy for AP mediated disease, but we need to confirm blocking MASP3 is truly effective in vivo. In this study, we tested whether MASP3 deficiency abrogate phenotypes of a murine atypical HUS(aHUS) model with complement factor H point mutation.

Methods: We generated MASP3 knockout mice ($MASP3^{-/-}$) and crossed with complement factor H mutant mice($FH^{R/R}$) which showed thrombotic microangiopathy and systemic thrombophilia as we previously reported. We then compared $FH^{R/R}$ $MASP3^{-/-}$ with littermates, $FH^{R/R}$ MASP3 wild type($FH^{R/R}$) in survival, hemoglobin or platelet level, and histologic change in major organs including kidney.

Results: We found that MASP3 deficiency rescued $FH^{R/R}$ from thrombocytopenia, anemia and renal failure. They were also prevented from large vein thrombi in liver and kidney. However, about 30% of $FH^{R/R}$ $MASP3^{-/-}$ died of extra-renal organ injuries such as intestinal injury, pulmonary hemorrhage and cerebral ischemia. We measured LPS based AP activity with 20% serum from mice and found that a complement AP activity in $FH^{R/R}$ $MASP3^{-/-}$ was significantly lower than that in $FH^{R/R}$, but higher compared with that in $FH^{R/R}$ $FD^{-/-}$.

Conclusions: These findings demonstrated that MASP3 could be therapeutic target for complement AP mediated diseases, but it is important to assess whetheher residual AP activity by pro-FD cause tissue injury in each setting.

An Unusual Case of Lupus-Associated Atypical Hemolytic Uremic Syndrome Presenting with Diffuse Alveolar Hemorrhage and Acute Renal Failure

Andrea Theodoru. *Northside Hospital Inc, Atlanta, GA.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) is a rare genetic disease characterized by acute renal injury (AKI), thrombotic microangiopathy (TMA), and other end-organ damage. It occurs when genetic mutations alter complement regulatory proteins, most commonly complement factor H. As a diagnosis of exclusion, it presents a unique diagnostic challenge. Eculizumab, a monoclonal antibody against complement C5, is the treatment of choice for primary aHUS.

Case Description: A 43 year old male with past medical history of systemic lupus erythematosus, Grave's disease, and hypertension presented to our institution with respiratory distress, hemoptysis, and subjective fevers. He had recently been treated with intravenous antibiotics after sustaining a cat bite. On presentation, he was profoundly hypoxic with elevated D-dimers, thrombocytopenia, and diffuse bilateral alveolar infiltrates. Patient was subsequently intubated, and serial bronchiolar lavage was consistent with diffuse alveolar hemorrhage (DAH). Renal function rapidly declined and lupus pneumonitis and nephritis were suspected; renal biopsy showed class III lupus nephritis. Pulse dose steroids and rituximab were initiated. Despite this, patient developed recurrent hemoptysis, worsening renal failure, and purpuric rash, which did not improve with plasmapheresis. In setting of markedly elevated D-dimers and LDH, thrombocytopenia, low haptoglobin, and peripheral smear revealing schistocytes, thombotic microangiopathy was suspected. Furthermore, markedly depressed complement levels pointed towards complement activation, likely triggered by his previous infection, resulting in adult onset atypical hemolytic uremic syndrome. Eculizumab was initiated and patient was eventually discharged to rehabilitation unit. Genetic testing revealed he was positive for aHUS with thrombomodulin gene mutation.

Discussion: This is an unusual case of lupus associated aHUS, likely triggered by infection caused by cat bite which triggered alternate complement pathway causing DAH. Atypical HUS presenting as DAH is extremely rare, and this case pointed towards lung restricted TMA. It is imperative that aHUS remains on the differential for patients with AKI and suspected TMA, as recognition of this diagnosis drastically alters management. Timely management lowers morbidity and mortality in aHUS.

SA-PO802

Diagnostic Utility of Whole Exome Sequencing in Adults with CKD and Biological Markers of Thrombotic Microangiopathy

Yannis Lombardi,[1] Cedric Rafat,[1] Alice Doreille,[1] Hugo Garcia,[1] Cyril Mousseaux,[1] Yosu Luque,[1] Laurent Mesnard.[1,2] *[1]Assistance Publique - Hopitaux de Paris, Paris, France; [2]Centre National de Référence des Microangiopathies Thrombotiques, Paris, France.*

Background: Chronic kidney disease (CKD) in adults may be associated with biological markers of thrombotic microangiopathy (TMA), defined as a mechanical hemolytic anemia with a decreased platelet count. In a number of cases, even after an extensive investigation including the search for variants in genes regulating the complement pathway, a definitive diagnosis cannot not be achieved. Whole Exome Sequencing (WES), which examines the entire coding regions of the genome, could be of interest in these clinical forms.

Methods: We included all consecutive adult patients who underwent WES for CKD of unknown origin between 10/10/17 and 31/12/22 in the Nephrology Department of Sorbonne University (Tenon and Pitié-Salpêtrière hospitals). The collection of clinical characteristics, including the presence of biological markers of TMA, is prospectively done by the prescribing physician. We retrospectively assessed whether patients had been accurately classified (Figure 1). All diagnoses were made according to the guidelines of the American College of Medical Genetics and Genomics.

Results: During the study period, 1410 patients underwent WES, and 193/1410 (14%) exhibited biological markers of TMA. Among them, WES identified a variant consistent with the renal phenotype in 31/193 (16%) cases. 22/31 (71%) did not involve genes regulating the alternative complement pathway: type 4 collagens (*COL4A3*, *COL4A4*, *COL4A5*) (n=7); nephronophthisis-associated genes (*TTC21B*, *NPHP3*, *NPHP4*) (n=5); *IFT140* (n=2); *TRPC6*, *PAX2*, *SOX18*, *HNF1A*, *MMACHC*, *SPTB*, and *MT-TL1* (n=1 each). Complement-related disorders involved *CFH* (n=4), *CFI* (n=3), *CD46* and *C2* (n=1 each).

Conclusions: Whole Exome Sequencing of 193 patients with CKD associated with TMA resulted in a diagnosis in 31/193 (16%) of the cases, and 22/31 (71%) diagnoses did not involve the alternative complement pathway.

Characteristic	N	No TMA, N = 1,217[1]	TMA, N = 193[1]	p-value[2]

SA-PO803

The Value of Advanced Cardiac Magnetic Resonance Imaging Technologies in Detecting the Characteristics of Cardiac Involvement in Anderson-Fabry Disease

Junlan Yang, Bin Wang. *Southeast University, Nanjing, China.*

Background: Anderson-Fabry disease (AFD) is a genetic disorder associated with cardiac involvement. Advanced cardiac magnetic resonance (CMR) technologies, including T1 mapping and gadolinium-enhanced CMR, have been used to detect and evaluate cardiac involvement in AFD patients. However, there is limited information on the characteristic CMR manifestations in Chinese AFD patients.

Methods: In this cross-sectional study, data were collected from patients with AFD diagnosed at this center from January 2022 to March 2023. Compared with echocardiography, CMR was used to evaluate cardiac function, the degree of cardiac structural lesions, and to analyze characteristic CMR findings in AFD.

Results: 20 patients with AFD from nine families were included. This study showed that left ventricular hypertrophy (LVH) was detected in 85% of patients (18.41 ± 4.56 mm) by CMR, whereas echocardiography identified LVH in only 65% of patients (16.86 ± 2.74 mm), suggesting that echocardiography may underestimate the severity of LVH in AFD patients (P=0.001). Moreover, all patients exhibited characteristic CMR findings of cardiac involvement in AFD (Fig.1, Fig.2), including decreased T1 values (95% of patients) and late gadolinium enhancement (LGE) associated with myocardial fibrosis (55% of patients).

Conclusions: This study demonstrated that CMR is a valuable tool for detecting and assessing cardiac involvement in AFD patients, providing characteristic CMR findings, including LVH, decreased T1 values, and LGE associated with myocardial fibrosis. Moreover, this study highlighted the diagnostic superiority of CMR over echocardiography in assessing LVH in AFD patients.

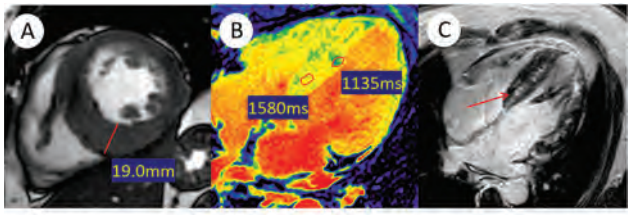

Fig.1. A: End-diastolic frames from cine in AFD patient (F1f): The myocardium is extensively thickened, the ventricular septal myocardium is significantly thickened, and the thickest myocardium is 19mm; B: T1Mapping(3.0T) in AFD patient (F1f): T1 values was uneven, the T1 value in the corresponding area of LGE was increased, the T1 value of non LGE zone is about 1100-1200ms; C: Gadolinium-enhanced cardiac magnetic resonance (10-15min) in AFD patient (F1f): Decreased subendocardial perfusion and LGE (indicated by the red arrow) were observed in the apical segment.

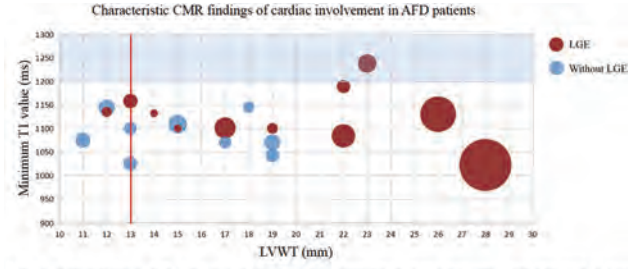

Fig.2 Characteristic CMR findings of cardiac involvement in AFD patients. The abscissa is the LVWT (mm) of each patient; The ordinate is the minimum T1 value (ms) of each patient; The bubble width is the LVMI of each patient. The red bubble represents that the patient has LGE, the blue bubble represents that the patient has no LGE. The red line is the critical line for the diagnosis of left ventricular hypertrophy (LVWT≥13mm), and the blue rectangle is the normal T1 value (1200--1300ms) in this center. LVWT: left ventricular wall thickness, LVMI: left ventricular mass index.

FollowME Fabry Pathfinders Registry: Renal Effectiveness in a Cohort of Patients on Migalastat Treatment for at Least Three Years

Michael L. West,[1] Derralynn Hughes,[2] Gere Sunder-Plassmann,[3] Ana Jovanovic,[4] Eva Brand,[5] Daniel G. Bichet,[6] Antonio Pisani,[7] Albina Nowak,[8] Roser Torra,[9] Aneal Khan,[10] Olga Azevedo,[11] Anna Lehman,[12] Ales Linhart,[13] Jasmine L. Rutecki,[14] Joseph D. Giuliano,[14] Eva Krusinska.[14] *[1]Dalhousie University Faculty of Medicine, Halifax, NS, Canada; [2]Royal Free London NHS Foundation Trust and University College London, London, United Kingdom; [3]Medizinische Universitat Wien Universitatsklinik fur Innere Medizin III, Wien, Austria; [4]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom; [5]Interdisciplinary Fabry Center Münster, University Hospital Münster, Münster, Germany; [6]Hôpital du Sacré-Coeur, University of Montréal, Montréal, QC, Canada; [7]Azienda Ospedaliera Universitaria Federico II, Napoli, Italy; [8]University Hospital Zurich and University of Zurich, Zurich, Switzerland; [9]Fundació Puigvert, Universitat Autònoma de Barcelona, Barcelona, Spain; [10]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [11]Hospital Senhora da Oliveira, Guimarães, Portugal; [12]The University of British Columbia, Vancouver, BC, Canada; [13]Univerzita Karlova, Praha, Czechia; [14]Amicus Therapeutics Inc, Philadelphia, PA.*

Background: The followME Fabry Pathfinders registry (EUPAS20599) is evaluating real-world safety, effectiveness and patient-reported outcomes for patients with Fabry disease who were enrolled into one of three groups: migalastat-amenable *GLA* variants receiving migalastat, any *GLA* variant receiving enzyme replacement therapy and migalastat-amenable *GLA* variants not receiving Fabry disease-specific therapy (untreated).

Methods: We present effectiveness data across categories of kidney function at enrollment in a cohort of patients who had received ≥3 years of migalastat treatment. Enrolled patients were ≥12 years old with an estimated glomerular filtration rate (eGFR) >30 mL/min/1.73 m2.

Results: As of August 2022, 125 patients (60.0% males; median age, 58.0 years) with amenable *GLA* variants had a mean migalastat exposure of 3.9 years. At enrollment, mean±SD eGFR was 83.7 ± 22.5 mL/min/1.73 m^2, and overall, 17 (14.7%) patients had an eGFR <60 mL/min/1.73 m^2. Median urine albumin: creatinine ratio was 19.0 mg/g (range 0–1124, n=40). Mean (SD) eGFR annualized rate of change (mL/min/1.73 m^2/year) in the overall cohort was –0.9 (4.9). When analyzed by eGFR category at enrollment annualized change was –1.0 (3.9) in patients with eGFR ≥90 (33.6%), –1.0 (5.9) in patients with eGFR ≥60–90 (43.2%), and –0.4 (3.5) in patients with eGFR ≥30–60 (12.8%). Overall, 94.4% of patients did not experience a renal Fabry-associated clinical event (FACE: doubling of serum creatinine level from the start of analysis [two consecutive values]; end-stage renal disease requiring long term dialysis or transplantation). Seven patients each experienced one renal FACE for an incidence of 14.2/1000 patient-years. When excluding patients with the mostly cardiac variant p.N215S (69.6%, n=87) mean eGFR rate of change was –1.4 (4.6) mL/min/1.73 m^2/year, n=81) and renal FACEs incidence was 20.9/1000 patient-years.

Conclusions: These data support sustained effectiveness with migalastat, regardless of kidney function at enrollment, in an amenable real-world cohort of patients with Fabry disease.

Evaluation of Long-Term Renal Outcomes in Fabry Disease: A Single-Centre Prospective Cohort Study in North-West England

Fahmida Mannan, Ryan Wiltshire, Rajkumar Chinnadurai, Philip A. Kalra, Ana Jovanovic. Salford Fabry Observational Study. *Northern Care Alliance NHS Foundation Trust Salford Care Organisation, Salford, United Kingdom.*

Background: Fabry disease (FD) is a rare X-linked lysosomal storage disorder whereby deficiency of α-galactosidase-A results in progressive renal impairment and end-stage renal failure (ESRF). International recommendations suggest enzyme replacement therapy (ERT) in those with early signs of renal dysfunction, yet limited data exist on long-term outcomes.

Methods: 395 patients were included from a national FD database from conception to 1 February 2022. Baseline data include FD mutation, diagnosis and ERT initiation dates, renal biochemical values, co-morbidities and medications. Those on renal replacement therapy (RRT) were excluded. Rapidly progressive renal dysfunction was defined as eGFR decline of > 1 ml/min/year. Primary outcomes include ESRF requiring RRT, all-cause mortality, and non-fatal cardiovascular events (NFCVE).

Results: 395 patients (M=172;F=223) with median follow-up of 6.4 years were analysed. Males received more treatment (147 v 92, p<0.001), had RRT (12 v 1, p<0.001), experienced NFCVE (75 v 42, p<0.001) and all-cause mortality (21 v 8, p<0.001). Sub-cohort analysis (n=260) showed faster eGFR decline was not predictive of RRT, but associated with higher rates of NFCVE (52 v 50, p=0.01) and all-cause mortality (17 v 8, p=0.004;fig.1). Multivariate regression demonstrated only advancing age associated with faster renal disease progression (OR:1.05; 95% CI: 1.02-1.07; p<0.001). 33 developed CKD during median follow-up of 10.9 years. Genetic analysis showed highest prevalence of the commonest late-onset variant *c.644A>G/p.N215S.* 18(55%) started ERT, and 6 discontinued due to gastrointestinal intolerance or tiredness. 15(45%) experienced NFCVE, with stroke/TIA being commonest (n=6).

Conclusions: Our study supports early initiation of ERT, prior to onset of any renal decline, and advanced age a predictor of adverse outcomes.

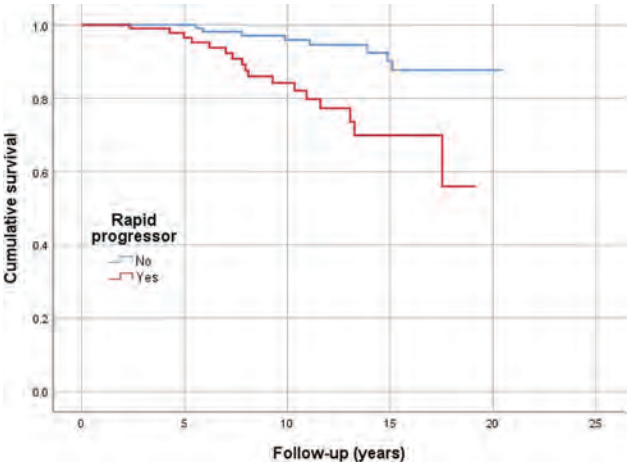

Figure 1: Rate of survival (all-cause mortality) of faster/slower eGFR progressors. Log-rank p<0.001

SA-PO806

Multidisciplinary Approach to Assessment and Management of Children with Fabry Disease: A Multicentre Study

Liu Jialu, Hong Xu, Qian Shen. Internet Plus Nephrology Alliance of the National Center for Children's Care. *Children's Hospital of Fudan University, Shanghai, China.*

Background: Considering the diversity manifestations of Fabry disease (FD) in chlidren, methods to improve screening and management of the suspects are needed. In April 2020, our hospital established China's first multidisciplinary diagnosis and treatment team (MDT) for children with FD, from July 2021 to January 2022, the MDT promoted to 15 centers in China.

Methods: This study summarizes characteristics and treatment of 45 children diagnosed with FD before January 1, 2023 by pediatric MDT teams of 21 centers in China. Data were derived from a multicenter network (Chinese Children Genetic Kidney Disease Database). A questionnaire specifically designed.

Results: Diagnostic median age was 10.9 year in males and 9.8 year in females, 26.4% in males and 81.8% in females were diagnosed by family screening, 11.8% in males were diagnosed by genetic test for other genetic disorders. At enrollment (median age 12.0 year), 29 (85.3%) of males and 5 (45.0%) of females reported symptoms (Fig1, 2). The median age of symptom onset was 6.7 year in males and 8.0 year in females. The most frequent symptom, neuropathic pain, was reported by 79.4% of males (median age 8 year) and 45.0% of females (median age 9 year). Anhidrosis or hypohidrosis were reported by 48.9%. 50% of males underwent lung function evaluation indicated obstructive respiratory diseases. 4 Of the 6 males developed Low bone mineral density. A few patients had serious manifestations, stage 5 chronic kidney disease (n=1), arrhythmia (n=4), and left ventricular hypertrophy (n=3). 22 had received agalsidase (start at median age 13.7 year in males and 13.5 year in females).

Conclusions: We provide an overview of the multicenter network of MDT for children with FD in China.

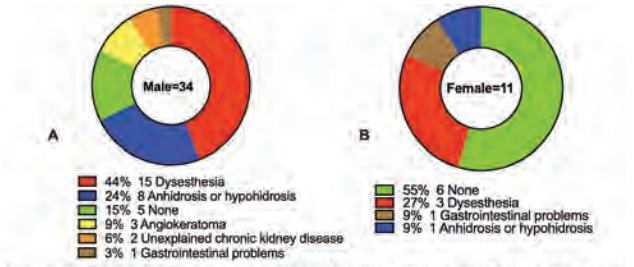

Figure 1. The first symptoms in male (A) and female (B) patinets diagnosed with Fabry disease

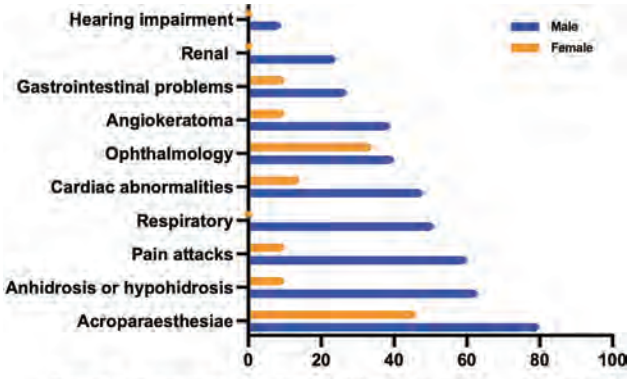

Figure 2. Proportion of male (n = 34) and female (n = 11) patients with Fabry disease showing different clinical manifestations.

New Biomarkers to Quantify Fabry Disease Activity

Seyda G. Ozcan,[1] Necmi Eren,[2] Mevlut T. Dincer,[1] Metin Ergul,[2] Hakan Özer,[3] Kultigin Turkmen,[3] Sinan Trabulus,[1] Nurhan Seyahi.[1] *[1]Istanbul Universitesi-Cerrahpasa, Istanbul, Turkey; [2]Kocaeli Universitesi Tip Fakultesi, Izmit, Turkey; [3]Necmettin Erbakan Universitesi Meram Tip Fakultesi Hastanesi, Konya, Turkey*.

Background: Fabry disease (FD) is a rare, genetic lysosomal storage disease. Kidney and cardiac involvement are the leading causes of morbidity and mortality. Slow progression, genotypic and phenotypic heterogeneity prevents accurate prediction of the disease progression. We aimed to investigate the association of different biomarkers with FD activity for this unmet need.

Methods: In this case-control study, we examined 87 Fabry patients (FP), 46 CKD patients and 41 healthy controls (HC). Study subjects were recruited according to inclusion and exclusion criteria. We studied KIM-1, MCP-1, YKL-40, TNFR-1, TNFR-2, CysC with ELISA and eGFR was calculated based on cr and cr-Cys-C in all subjects. Statistical analysis was carried out using log transformed values of biomarker levels adjusted for age, sex and BMI.

Results: Box plots of biomarker levels are shown in Figure 1. While there was no difference between FP and HC regarding eGFR(cr); eGFR(cr-CysC) was significantly lower in FP. KIM-1 was significantly higher in FP compared to HC. MCP-1 was significantly lower in FP compared to CKD patients, and it was significantly higher in FP with cardiac involvement than in those without cardiac involvement as in renal involvement. YKL-40 was significantly lower in FP without kidney involvement compared to both control groups, probably reflecting the effect of enzyme replacement therapy (ERT). KIM-1 and YKL-40 were correlated with Lyso Gb3 while MCP-1 was not.

Conclusions: MCP-1, KIM-1, YKL-40 and CysC seem to be useful markers for the management of FP, each associated with a different aspect of the disease. While KIM-1 appears to be independent of organ involvement, MCP-1 seems to be associated with kidney and cardiac involvement independent of Lyso Gb3. YKL-40 might be associated with response to ERT. Identification of new pathogenic pathways associated with those biomarkers, might contribute to new treatment approaches.

Funding: Government Support - Non-U.S.

SA-PO808

The Utility of Obtaining Kidney Biopsy in Female Patients with Fabry Disease

Victor Bedros,[1] Brenden Amiotte,[1] Hana Hamdan,[2] Ahmad M. Tuffaha.[1] *[1]University of Kansas School of Medicine, Kansas City, KS; [2]Kansas City University, Kansas City, MO*.

Background: Fabry Disease (FD) is an X-linked inherited disorder caused by alpha-galactosidase-A enzyme deficiency resulting in the accumulation of the large fatty substrate Globotriaosylceramide (GL-3) in different cell types and organs. FD affects both males and females, but males usually develop symptoms at an earlier age and have more severe manifestations. Male patients with FD should be started on treatment at time of diagnosis. The decision to treat female patients with FD has been mostly determined by the severity of manifestations. Obtaining kidney biopsies in female patients with FD to support the decision to start treatment with enzyme replacement therapy or chaperone-based therapy remains controversial.

Methods: 14 female patients with FD underwent kidney biopsy at the University of Kansas Hospital shortly after being diagnosed with FD between 2011 and 2023. The age range was from 10 to 55 years. Serum creatinine, urine protein quantification, genetic mutation and clinical manifestations were recorded at the time of biopsy.

Results: Only one kidney biopsy revealed normal findings. 11 kidney biopsies revealed Fabry nephropathy as the sole pathology with light microscopy showing vacuolation in podocytes, glomeruli and tubular epithelial cells and electron microscopy showing lamellated inclusions. 6 of the 11 patients with Fabry nephropathy had microalbuminuria, 2 of which had abnormal kidney function. One kidney biopsy revealed crescentic glomerulonephritis coexisting with Fabry nephropathy in a patient with abnormal kidney function and non-nephrotic range proteinuria. Another kidney biopsy revealed IgA glomerulonephritis coexisting with Fabry nephropathy in a patient with abnormal kidney function and nephrotic range proteinuria.

Conclusions: This case series shows that Fabry nephropathy in female patients with FD is common despite most patients presenting with normal kidney function and no or minimal microalbuminuria. These findings suggest a beneficial role for kidney biopsy in female patients with FD to help guide treatment plan and to rule out coexisting conditions.

SA-PO809

Advanced Disease Modeling of the Fabry Disease Cardiorenal Phenotype with Organoids from Patient-Derived Human-Induced Pluripotent Stem Cells

Anna Reinelt,[1] Sandra D. Laufer,[1] Milagros N. Wong,[1] Fabian Haas,[1] Luise Foerster,[1] Linda Blomberg,[2] Christine E. Kurschat,[2] Nicola Wanner,[1] Victor G. Puelles,[1] Arne Hansen,[1] Tobias B. Huber,[1] Fabian Braun.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Universitatsklinikum Koln, Koln, Germany*.

Background: Fabry disease is a multi-systemic lysosomal storage disorder resulting from mutations in the *GLA* gene. This complex lysosomal storage disorder can currently not be modelled accurately in animal models. Our project, therefore, aims at establishing advanced human in vitro systems to further our molecular understanding of the disease's pathology. To establish these informative systems, we employ human induced pluripotent stem cells (hiPSC) of Fabry patients and differentiate them into disease-relevant organoid systems.

Methods: We reprogrammed hiPSC from primary urinary cells (PUCs) collected from Fabry patients with different mutations (classical, classical and chaperone amenable, late onset, unclear significance). Isogenic control lines were created by CRISPR Cas9 gene editing. Using published protocols, we differentiated these cell lines into kidney and heart organoids as well as engineered heart tissue (EHTs) using published protocols.

Results: We confirmed the loss of alpha-galactosiade A protein, enzyme activity and the accumulation of globotriaosylceramide in patient-derived hiPSC lines and organoids

This phenotype did not impair the differentiation into organoids and EHTs. We established the treatment with enzyme replacement and, where applicable, chaperone therapy. Kidney organoids contained different nephron segments and confirmed the recently published pathologic accumulation of synuclein alpha in Fabry nephropathy. Heart organoids contracted and depicted several cardiac cell types including cardiomyocytes with sarcomeres and Z-Disc formation. Fabry EHTs contracted with reduced force and were prone to arrhythmias mirroring the clinical phenotype seen in Fabry patients.

Conclusions: We have established a novel unique discovery platform for human *in vitro* disease modelling to study Fabry disease. Ongoing experiments focus on single cell analyses of the established systems in combination with deep proteomic and spatial phenotyping combined with the application of available therapies.

SA-PO810

Exome Sequencing in Individuals with CAKUT Identifies De Novo Variants in Novel Candidate Genes in 15.5%

Caroline M. Kolvenbach,[1] Lea M. Merz,[1] Chunyan Wang,[1] Nils D. Mertens,[1] Steve Seltzsam,[1] Bshara Mansour,[1] Selina Hölzel,[1] Nina Mann,[1] Katharina Lemberg,[1] Ken Saida,[1] Florian Buerger,[1] Camille H. Nicolas Frank,[1] Kirollos Yousef,[1] Daanya Salmanullah,[1] Seyoung Yu,[1] Alina Hilger,[3] Velibor Tasic,[2] Shirlee Shril,[1] Friedhelm Hildebrandt.[1] *[1]Boston Children's Hospital, Boston, MA; [2]Medical Faculty of Skopje, Skopje, Macedonia (the former Yugoslav Republic of); [3]University of Erlangen, Erlangen, Germany*.

Background: Congenital anomalies of the kidney and urinary tract (CAKUT) represents the most frequent birth defect and encompasses a large variety of malformations arising from defective nephrogenesis. To date, mutations in 50 monogenic genes are known to cause CAKUT. However, in only 15-20% of CAKUT cases a causative mutation in a known monogenic CAKUT gene can be identified. Recent studies show the impact of *de novo* variants in *FOXP1* and *ZMYM2* in individuals with CAKUT, suggesting that *de novo* variants contribute to the genetic disease etiology.

Methods: In this study, we performed exome sequencing (ES) in 731 families out of which 264 were trio families in order to detect novel CAKUT candidate genes.

Results: i) Through proband-parent based evaluation, a variant in a single candidate gene was detected in 79 of 264 families (29.9%). **ii)** In 41 of 264 trio families (15.5%), we identified strong *de novo* variants in 43 potential novel CAKUT candidate genes. **a)** Of these 43 *de novo* variants, truncating or splice site *de novo* variants were found in nine genes (*ASPHD1, COPS7A, DUSP23, FBXW7, GRHL1, MTHFD1, PLA2G4A, SLTM, SOX13*). **b)** Four *de novo* variants were detected in murine CAKUT genes (*AGRN, COPS7A, PDE1A, PDS5A*). **c)** Interestingly, a relatively high percentage of *de novo* variants (25.6%, 11 out of 43) occurred in genes that are involved in transcription (*BRPF1, BSX, COPS7A, DLX3, FBXW7, GRHL1, IRX6, PROX1, SLTM, SOX13, TLK2*). **d)** Four *de novo* variants were found in genes that are paralogs of known disease causing CAKUT genes (*AGRN, HSP90AB1, PTPRZ1, SOX13*). Scoring variants in identified genes based on these categories (**a-d**), identified *COPS7A* and *SOX13* as the most promising new candidate genes for CAKUT.

Conclusions: Our findings suggest that *de novo* variants in novel candidate genes may contribute to the CAKUT pathogenesis. Here, we propose two novel candidate genes for CAKUT.

SA-PO811

GEN1 Is a Likely Candidate Gene for Human Congenital Anomalies of the Kidney and Urinary Tract

Qian Shen, Hong Xu, Xuanjin Du. *Children's Hospital of Fudan University, Shanghai, China*.

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) are among the most prevalent birth defects. Although many pathogenic genes of CAKUT have been discovered, they are far from enough to reveal the causes of all CAKUT patients. Previous studies suggest that *Gen1* is a mouse CAKUT gene.

Methods: There are three main parts, population data collection, in vitro function verification, and point mutation mouse construction and phenotypic observation (Fig1).

Results: DNA from 910 individuals with CAKUT were collected, among which 26 *GEN1* variants were identified, and two *GEN1* (missense) variants in a non-CAKUT group were found. In vitro, 10 variants (eight in the CAKUT group and two in the non-CAKUT group) were selected to verify mutant protein stability and protein stability changed in six variants in the CAKUT group. Using an electrophoretic mobility shift assay on eight variants (six in the CAKUT group and two in the non-CAKUT group) the enzymatic hydrolysis and DNA-binding abilities of mutant proteins were found to be impaired to varying degrees in CAKUT group, among which the most serious functional damage was observed in the *Gen1* variant that produced a truncated protein. Moreover, a mini-gene splicing assay showed that the c.1071+3 A>G variant in CAKUT group significantly affected splicing function. Three point mutant mouse strains were constructed and CAKUT phenotypes were replicated (Fig2).

Conclusions: Our findings promoted that *GEN1* is likely a human CAKUT candidate gene.

A Case Report of Functional Renal Impairment in Adult Patient with Townes-Brocks Syndrome

Ali A. Rawabdeh, Irtiza Hasan, Charles W. Heilig. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: A late presentation of functional renal impairment without structural changes in a patients with Townes-Brocks Syndrome (TBS).

Case Description: A 48-year-old male patient with no significant past medical history presented to Nephrology clinic with incidental diagnosis of abnormal renal function on routine blood work. He does not endorse any other concomitant clinical symptoms including genito-urinary symptoms, denies regular use of NSAIDs, history of drug abuse or any history of hepatitis or HIV. Lab works showed elevated serum creatinine at 1.81 mg/dL and GFR of 46, urine albumin 1+, protein/creatinine ratio of 192 mg/g (in 24 hours), positive ANA (homogenous; 1:160) with normal C3, C4, C-ANCA and P-ANCA. Other CKD labs were reviewed and found to be within normal range. Serum protein electrophoresis and immunofixation did not reveal any monoclonal paraproteinemia. Renal ultrasound showed normal sized kidneys with increased echogenicity bilaterally, but no structural changes or hydronephrosis. No specific aetiology for CKD was identified. Coincidently, his son was born with one kidney as a part of congenital Townes-Brocks syndrome with chromosome analysis showing abnormality in chromosome 19, which is autosomal dominant and paternally inherited. Paternal chromosome analysis revealed similar diagnosis with heterozygous genotype.

Discussion: Towne-Brock's syndrome (TBS) is a rare autosomal dominant condition resulting from heterozygous variant in SALL1 gene and characterized by triad of imperforate anus, dysplastic ears and hand malformation. Renal impairment occurs in 42% of cases including ESRD with or without structural abnormalities and malformations. However, data on long term prognosis of renal involvement, slope of declining renal function and risk of developing renal failure is lacking. Thus, yearly renal function assessment throughout the life is indicated for patients with TBS as well as those with first degree relatives with TBS. Also, there is a need to determine the evidence of SALL1 mutation in patients with late-onset functional kidney disease without structural changes as well as in those with nephropathies of unknown origin in adulthood.

Large-Scale Exome Sequencing Analysis Implicates FOXQ1, FOXI2, EXOSC2, and MMP15 as Candidate Genes for Human Congenital Obstructive Uropathy

Juntao Ke,[1] Tze Yin Lim,[1] Yask Gupta,[1] Gundula Povysil,[1] Gina Jin,[1] Jeremiah Martino,[1] Francesco Scolari,[2] Velibor Tasic,[3] Cathy L. Mendelsohn,[4] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York City, NY; [2]Universita degli Studi di Brescia, Brescia, Italy; [3]Medical Faculty of Skopje, University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [4]Columbia University Irving Medical Center, New York, NY.*

Background: Congenital obstructive uropathy (COU) is the most frequent urinary tract anomaly occurring in up to 2% of pregnancies, constituting a leading cause of pediatric chronic kidney disease. The genetic causes of COU are not well understood and remain to be deciphered.

Methods: We conducted an exome sequencing (ES) study on 880 COU cases, encompassing three main classes of congenital urinary obstructions: a) Ureteropelvic Junction Obstruction (UPJO; N=331), b) Ureterovesical Junction Obstruction / megaloureter (UVJO; N=188), and c) COU not otherwise specified (COU-NOS; N=361). To investigate the excess burden of rare coding variants on COU, we performed exome-wide collapsing analysis comparing the above 880 cases and 16,135 population controls with ES data using 4 main genetic models (3 dominant and one recessive). Analyses were conducted on the entire dataset and then again after removal of cases harboring diagnostic/pathogenic Mendelian mutations and structural variants. Study-wise exome-wide significant threshold was set at 1.25×10^{-6}.

Results: In the analysis on the entire cohort of 880 COU cases, the top signal was for *FOXQ1* in the dominant ultrarare model from European population ($P = 8.49 \times 10^{-6}$; OR= infinite). The signal improved after removal of solved cases, exceeding exome-wide significance ($P = 7.64 \times 10^{-7}$; OR= infinite), and supporting candidacy for this gene. Moreover, *Foxq1* is specially expressed in the mouse developing ureteric buds, ureteric epithelium cells of fetal mouse and human urinary tracts. From the subtype analysis, we found the following suggestive signals: *EXOSC2* ($P = 2.96 \times 10^{-5}$; OR= infinite) and *FOXI2* ($P = 5.52 \times 10^{-5}$; OR= 82.63) for UPJO; *MMP15* ($P = 2.56 \times 10^{-5}$; OR= 21.93) for UVJO.

Conclusions: These findings expand and deepen our understanding of the genetic underpinning of COU, identify novel candidate genes, and highlight the high genetic heterogeneity of disease. We are currently pursuing these findings using human and mouse derived urinary tract enriched organoid systems.

Unraveling the Role of TET2 Gene Variants in Kidney Disease Development: A Multi-Omics Approach

Xiujie Liang, Hongbo Liu, Jianfu Zhou, Amin Abedini, Hailong Hu, Andrea Sanchez Navarro, Konstantin A. Kloetzer, Katalin Susztak. Susztak Lab. *University of Pennsylvania, Philadelphia, PA.*

Background: In the quest to understand the genetic causes of kidney disease, Genome-wide association studies (GWAS) have recognized hundreds of sites, yet the precise genes, variants, and pathways remain ambiguous.

Methods: To pinpoint the genes linked to kidney disease, we combined kidney function GWAS, human kidney expression quantitative trait analysis (eQTL), and methylation quantitative trait analysis (meQTL). To discover the variants that modify gene expression in kidney cells, we utilized single-cell chromatin accessibility (snATACseq) and (Crispr-based) genome editing. We created kidney-specific Tet2 knockout mice and manipulated gene expression in human kidney cells using CRISPR to study its role in kidney disease progression. We performed single-nucleus multiomics studies in knock-out mice to delve into the role of Tet2.

Results: We identified the ten–eleven translocation (Tet) DNA demethylase TET2, and the variants that change its expression in kidney tubule cells as a novel kidney disease risk gene, risk loci and target cell type. Experiments with kidney-specific Tet2 knockout mouse models confirmed its protective roles in cisplatin-induced acute kidney disease and UUO/adenine-induced chronic kidney disease and kidney fibrosis development. Single-nucleus profiling of Tet2 knock-out mice indicated changed expression in genes related to cellular differentiation in the absence of Tet2. Further cellular studies suggested that Tet2 might be vital for tubule cell differentiation and could instigate kidney disease development by altering the cytosine hydroxymethylation level of associated differentiation genes.

Conclusions: Our findings underscore the crucial role of Tet2-mediated active cytosine hydroxymethylation on genes associated with differentiation in tubule cells in the onset of kidney disease.

Genetic Contributions to Lower Urinary Tract Dysfunction

Nina Mann, Lily Hiltebeitel, Steve Seltzsam, Chunyan Wang, Shirlee Shril, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Proper bladder function requires coordinated interactions between the urothelium, detrusor smooth muscle, urethral sphincter, and neuronal circuitry. Historically, severe voiding dysfunction, or the so-called non-neurogenic neurogenic bladder, was attributed to urinary withholding and behavioral maladaptation. However, several monogenic causes of lower urinary tract dysfunction have been identified, leading to a paradigm shift in our understanding of this disease. The aim of this study is to better understand the genetic landscape of voiding dysfunction in children.

Methods: We performed exome sequencing (ES) in 16 individuals with non-neurogenic neurogenic bladder or voiding dysfunction. Individuals with obstructive uropathy, spinal cord lesions, or a known neurological cause for their disease were excluded. In addition, we reviewed ES results from 24 individuals with non-neurogenic neurogenic bladder who have been described in our prior studies (van der Ven *JASN* 2018; Seltzsam *Genet Med* 2022) and analyzed data for variants in 76 candidate genes purported to play a role in urothelial signaling, detrusor function, or neuronal innervation of the bladder.

Results: We identified a pathogenic variant in 3/16 (18%) individuals with lower urinary tract dysfunction. Two individuals had homozygous variants in *HPSE2* (c.1099-2A>G, essential splice; exon9 deletion) and one individual had a homozygous variant in a phenocopy gene *ARL6* (c. 500_502delGAG, p.Gly67del), which causes a renal-retinal ciliopathy. Of the 24 individuals described in our prior publications, four had known pathogenic variants, of which three were homozygous pathogenic variants in *HPSE2* (c.457C>T, p.Arg153*; c.1099-2A>G, essential splice; exon 9 deletion). In total, 7/40 (17%) of our cohort were found to have a monogenic cause for their disease. Notably, two individuals in this cohort had homozygous deletions in exon 9 in *HPSE2*, which were identified only through manual inspection of ES data.

Conclusions: Variants in *HPSE2* are a common cause of non-neurogenic neurogenic bladder in our consanguineous cohort. Structural variants in *HPSE2* were identified in our cohort and have been described previously (Beaman *Front Genet* 13:896125, 2022), underscoring the importance of incorporating CNV analyses into genetic testing for individuals with lower urinary tract or voiding dysfunction.

SA-PO816

Phenotypic Quantification of an Hnf1b Knockout Mouse Model

Selina Hölzel, Caroline M. Kolvenbach, Florian Buerger, Katharina Lemberg, Ken Saida, Seyoung Yu, Daanya Salmanullah, Bshara Mansour, Izzeldin Elmubarak, Nils D. Mertens, Shirlee Shril, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Congenital Anomalies of the Kidney and Urinary Tract (CAKUT) constitute the most frequent birth defect and are the leading cause of chronic kidney disease in the first three decades of life. Approximately 50 monogenic genes, if mutated, are known to cause CAKUT, explaining 5–20% of disease origin. Mutations in the transcription factor HNF1B represent the most common monogenic cause of CAKUT in 5% up to 30% of affected patients. To date, prevention and treatment options for patients with CAKUT are limited. To enable gene replacement therapy (GRT) for CAKUT, we re-phenotyped a published conditional *Hnf1b* knockout mouse model (Gresh *EMBO* J 7:1657-68, 2004) and developed an additional quantifiable phenotyping method to generate reproducible reference for evaluation of future GRT effects.

Methods: Kidney specific *Hnf1b* inactivation is achieved by usage of the Cre-LoxP technology under a kidney specific promoter (KspCre). We utilized a colony of heterozygous breeder pairs ($Hnf1b^{flox/+}$, KspCre+, C57BL/6J) and phenotypically evaluated mutant animals ($Hnf1b^{flox/flox}$, KspCre+) compared to heterozygous littermate controls starting at P0. For quantitative analyses we focused on the following independent parameters, adapted to Gresh et al.: Kaplan-Meier survival, weight gain over time, macroscopic and light microscopic examination of kidney and urinary tract.

Results: 83.3% (n=6) of mutant mice died before weaning with survival rates ranging from 1-12 days (median 9 days). Mutant mice living past P5 (n=2) showed growth retardation and an average weight reduction of 41% compared to controls. Macroscopically, we observed ureteral dilatation in 100% and hydronephrosis in 33.3% of mutant animals (n=3). Upon light microscopy we detected and quantified renal tubular cysts in equatorial kidney sections with an average of 129 cysts in mutant animals (n=3) and 0 cysts in controls (n=3).

Conclusions: We performed quantitative phenotype evaluation of a kidney specific *Hnf1b* knockout mouse model (Gresh et al.) providing reference for future *in vivo* mouse studies aiming for treatment of CAKUT.

A Causal Relationship Between Body Mass Index and AKI Is Mediated by the Metabolome

Jefferson L. Triozzi,[1] Claire Lo,[1] Cassianne Robinson-Cohen,[1] Edward D. Siew,[1,2] Adriana Hung.[2,1] Million Veteran Program. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Obesity is a known risk factor for chronic kidney disease, but its association with acute kidney injury is unclear. We investigated the causal relationship between body mass index (BMI), the metabolome, and acute kidney injury (AKI) using a Mendelian randomization (MR) experiment.

Methods: We performed MR using genome-wide association summary statistics of BMI as the exposure (GIANT Consortium, n = 681,275), the metabolome as a mediator (MuTHER Consortium, n = 7,822), and AKI as the outcome (FinnGen Consortium, n = 2,383 cases, n = 212,841 controls). First, a two-sample MR tested the association of AKI on BMI using the inverse variance weighted (IVW) primary analysis, and the weighted median, weighted mode, and MR-Egger regression sensitivity analyses. We then applied

multi-step and multivariable MR to integrate the role of the metabolome. In the first step, metabolome-wide MR identified causal relationships between BMI and metabolites. In the second step, univariable MR identified causal relationships between metabolites and acute kidney injury. Finally, multivariable MR assessed the indirect effect of BMI on AKI as mediated by metabolites.

Results: BMI demonstrated a causal relationship with AKI in the IVW (β= 0.56, SE = 0.097, p < 5.85E-09), weighted median (β= 0.55, SE = 0.17, p < 1.17E-03), weighted mode (β= 0.58, SE = 0.28, p = 0.03), and MR-Egger regression analyses (β= 0.617, SE=0.26, p=0.01). There were 14 significant BMI-metabolite relationships (p < 1.11E-04), of which there was 1 suggestive metabolite-AKI relationship (p < 0.05). This yielded a putative pathway between BMI, metabolonic lactone sulfate, and AKI. In the multivariable MR analysis, the indirect effect of BMI on AKI via the metabolome was 0.52925.

Conclusions: The causal relationship between BMI and AKI may be partially mediated by the metabolome, particularly metabolonic lactone sulfate. This metabolite has known associations with cardiometabolic health, with possible influence on blood pressure, lipid metabolism, and insulin resistance. This is the first report connecting this metabolite with AKI. The MR methodology supports a causal relationship and is less susceptible to confounding and reverse causation biases. Mechanisms linking obesity, the metabolome, and kidney outcomes deserve further investigation.

Decreased Kidney Volume Is Associated with AKI

Piera A. Sosa,[1] Jefferson L. Triozzi,[1] Cassianne Robinson-Cohen,[1] Edward D. Siew,[1,2] Adriana Hung.[2,1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Decreased kidney volume may increase glomerular filtration and nephron workload, potentially increasing the risk of acute kidney injury (AKI). However, the mechanisms of this relationship are unclear. In this study, we investigated the relationship between kidney volume, as measured by MRI, and AKI using Mendelian randomization (MR).

Methods: We performed a two-sample MR experiment using genome-wide summary statistics for kidney volume as the exposure from the UK Biobank (n = 32,860) and AKI as the outcome from the FinnGen Consortium (n = 2,383 cases, n = 212,841 controls). The inverse variance weighted (IVW) analysis was the primary outcome, and the weighted median, weighted mode, and MR-Egger regression were sensitivity analyses. Heterogeneity and pleiotropy were tested.

Results: An association between kidney volume and acute kidney injury was observed in the IVW analysis (β = -0.89, SE = 0.28, p = 0.0012) and supported in the weighted median (β = -1.054, SE = 0.30, p = 0.00055), weighted mode (β = -1.36, SE = 0.53, p = 0.031), and MR Egger regression analyses (β = -4.18, SE = 1.44, p = 0.020). There was no heterogeneity (IVW Q-statistic p = 0.16, MR Egger Q-statistic p = 0.47) but possible horizontal pleiotropy (MR Egger regression intercept p = 0.049). Ten SNPs were analyzed, of which six are related with anthropomorphic features, including body height and waist-hip ratio.

Conclusions: Kidney volume may have a causal effect on acute kidney injury. Larger kidney volume may protect against acute kidney injury. Some of the involved genes relate to anthropomorphic features, such as *PTCH1*. Further investigation is warranted to understand the mechanisms of this relationship and the role of the genes involved.

Mendelian Randomization of Kidney Volume and Acute Kidney Injury

SA-PO819

Identifying Somatic Mosaicism for Tuberous Sclerosis Complex by Targeted Next-Generation Sequencing

Sol M. Carriazo Julio,[1] Ryan R. Ting,[1] Amirreza Haghighi,[1] Xuewen Song,[1] Andrew Paterson,[2] York P. Pei.[1] *[1]University Health Network, Toronto, ON, Canada; [2]SickKids Research Institute, Toronto, ON, Canada.*

Background: Tuberous sclerosis complex (TSC) is a rare disease typically manifested with hamartomas affecting the skin, heart, brain, liver, and kidney. However, 15-20% of patients display mild clinical features suggestive but not diagnostic of TSC, and often they have no pathogenic *TSC1* and *TSC2* mutation detected (NMD). Here, we report our study of a cohort of patients with mild clinical features suspicious of TSC somatic mosaicism (SM) using Next Generation Sequencing (NGS).

Methods: We performed targeted gene panel screen by NGS using DNA samples from blood, buccal mucosa, and urinary epithelial cells (when available) and a minor allele frequency of 1% cut-off to detect mosaicism. Standard algorithms for sequence alignment, base calling, and QC filtering were applied to identify rare (MAF ≤1%) deleterious variants of high and moderate impact as predicted by multiple predictive algorithms. All potential pathogenic mosaic *TSC1* and *TSC2* variants were validated by a novel in-house assay (Mosaic Detection by Enrichment of Mutant Allele; MODEMA) or droplet digital PCR.

Results: From a clinical review of 80 pts with confirmed or possible TSC, 18 patients with mild disease suspicious of TSC SM were sequenced. We found germline missense *TSC1/TSC2* mutations in 5 patients, mosaic *TSC1/TSC2* mutations in 9 patients in whom 7 were validated by MODEMA and/or digital PCR, and 4 with NMD. Patients with confirmed TSC SM were predominantly young female; all had multiple renal angiomyolipomas and few extra-renal clinical features.

Conclusions: Patients with mild clinical features suggestive but not diagnostic of TSC can be caused by missense or mosaic *TSC1/TSC2* mutations. The diagnosis of TSC SM has important implications for genetic counselling and clinical prognostication, and can be improved by NGS.

SA-PO820

Renal Transplantation in a Recipient with Birt-Hogg-Dube Syndrome

Rojin Esmail,[1,3] Adriana Medina,[1,3] Timothy E. Trestrail,[2] Armando Salim Munoz Abraham,[2] Franco H. Cabeza Rivera,[1,2] Gaetano Ciancio.[2] *[1]Miami Transplant Institute, Miami, FL; [2]University of Miami School of Medicine, Miami, FL; [3]Ross University School of Medicine, Miramar, FL.*

Introduction: Birt-Hogg-Dube Syndrome (BHDS) is a rare autosomal dominant disorder caused by folliculin (FLCN) germline mutations. Renal cell carcinoma (RCC) is the most serious manifestation of this condition occurring at a rate of 30%. Unlike other inherited renal cancers, BHDS is associated with a wide range of histologies. Although preserving renal function remains the central goal of management, the risk of end stage renal disease remains high. Patients with other inherited renal carcinomas (e.g. Von Hippel Lindau) have been successfully transplanted in the past. Herein, we have demonstrated how renal transplant can also be a viable treatment course for some patients with BHDS related RCC.

Case Description: A 48-year-old male presented to our facility for evaluation of recurrent pneumothorax. CT chest revealed bilateral pulmonary cysts and multiple bilateral renal masses. Given the coexisting pulmonary cysts and renal masses, he was evaluated and diagnosed with BHDS. After discussion with the patient, bilateral radical nephrectomy was performed due to the presence of multifocal tumors measuring up to 5 cm. Tumor pathology was consistent with oncocytoma and chromophobe RCC, pT1bN0M0. After two years of hemodialysis and surveillance, the patient was deemed a candidate for kidney transplant. Induction therapy consisted of thymoglobulin and solumedrol and the patient was discharged with mycophenolate mofetil, prednisone, and tacrolimus as maintenance.

Discussion: Tumor aggressiveness, metastasis risk, and time in remission are important factors when evaluating a patient with history of BHDS associated RCC for renal transplant. BHDS associated chromophobe and hybrid chromophobe/oncocytic tumors are less aggressive and it has been observed that the metastasis associated with these cancers tends to be more indolent in nature. Therefore, these patients are suitable candidates for transplant after a minimum waiting period. Post-transplant, immunosuppression with mTOR inhibitors can be considered since mutation of tumor suppressor FLCN in the mTOR pathway is central to BHDS pathogenesis.

The Progressive Decline of Kidney Function: Can We Have an Answer?

Feruza Abraamyan,[1] Erdal Sarac,[1,2] Hilmer O. Negrete.[1,2] *[1]Mercy Health St Elizabeth Youngstown Hospital, Youngstown, OH; [2]Northeast Ohio Medical University, Rootstown, OH.*

Introduction: With the field of nephrology moving towards personalized medicine, genetics is taking its lead in providing patient care. Tuberous sclerosis complex (TSC) is an inherited disorder with lesions involving multiple organs, including the kidneys. While TSC is often diagnosed during childhood, some cases might not be recognized until adulthood.

Case Description: Here we present a 58 y.o. female with a history of breast cancer, seizures, parathyroid adenoma, strictures of the esophagus, dental pitting, oral fibromas, and hyperpigmented macules in the mouth, who was referred due to abnormal results: Creatinine 1.6 mg/dL, eGFR 33 mL/min/1.73. Her family history was positive for cancer in her father of unknown origin. Her kidney ultrasound showed multiple fat-density tumors within both kidneys and a left renal cortical cyst. CT abdomen demonstrated bilaterally enlarged kidneys with innumerable fat-containing lesions consistent with angiomyolipomas. CT head revealed intracranial calcifications with MRI positive for cortical and subcortical glioneuronal tumors and giant cell gliocytoma. On CT lungs, there were numerous scattered thin-walled cysts throughout both lungs with numerous scattered nodules. Recently, the patient underwent surgery to remove a 4.4 cm invasive adenocarcinoma of the rectum with negative margins and lymph nodes for malignancy on biopsy. Genetic testing was performed that showed heterozygous pathogenic missense mutation in the TSC2 gene with AD inheritance mode: c.1832G>A (p. Arg611Gln), NM_000548.5 supporting the diagnosis of TSC. Multiple laboratories in the Clinvar Database predict this variant as pathogenic and absent in the gnomAD dataset, which tells about the rarity of this mutation. Silico's analysis supports the idea that this missense variant disrupts protein structure/function. Inactivation of the tuberin-hamartin complex leads to cell proliferation and size discoordination, which explains the pathophysiologic mechanism of our patient's phenotype.

Discussion: Currently, the patient continues to have progressive worsening of kidney function with a creatinine of 3.5-3.7 mg/dL. However, knowing the exact diagnosis helped with the appropriate management, prognosis and offered potential screening and diagnosing opportunities for family members.

SA-PO822

Investigation of T Cells Contributing to the Production of IgA-Type Autoantibodies Against Mesangial Cells in IgA Nephropathy

Hiroyuki Iwasaki, Ryousuke Aoki, Yoshihito Nihei, Hitoshi Suzuki, Yusuke Suzuki. *Juntendo University, Tokyo, Japan.*

Background: In IgA nephropathy (IgAN), the mechanism by which IgA antibodies (Abs) are selectively deposited in the glomerular mesangial region has not been elucidated. However, we have recently uncovered its mechanism by identifying IgA type auto-Ab against mesangial antigens, βII-spectrin, in gddY mice, a spontaneous IgAN animal model and IgAN patients (*Y. Nihei, H. Iwasaki and Y. Suzuki et al, Sci. Adv 2023*). We also found that a significant number of IgA+ plasmablasts (PBs) accumulated in the kidneys of gddY mice and these PBs produced IgA auto-Abs that bind to βII-spectrin and the surface of mesangial cells. We cloned cDNAs encoding IgA heavy and light chains from single IgA+ PB isolated from the kidney of gddY mice and found that most of the heavy- and light-chain V region genes of these PBs contained significant numbers of somatic mutations, indicating that they were generated in a T-cell-dependent manner through the germinal center. However, the detailed mechanisms of IgA auto-Abs production, such as which types of T cells are responsible for the induction of auto-Abs, are not clear. In the present study, we analyzed CD4+T cells in the kidney of gddY.

Methods: GddY mice were generated through selectively mating individuals within an early-disease onset group of ddY mice for more than 20 generations. All individual gddY mice exhibit proteinuria and glomerular IgA deposition by 8 weeks of age, followed by obvious renal failure and the pathology being similar to human IgAN. Isolated leukocytes from kidney of gddY or BALB/c mice at age of 8 weeks were analyzed by flow cytometry.

Results: We found that a significant number of CD4+ T cells accumulated in the kidneys of gddY mice compared to BALB/c. In details, Th1(CD4+ IFN-γ+), Th17(CD4+ IL-17+) and Treg(CD4+ Foxp3+) cells were significantly accumulated in the kidney of gddY compared to BALB/c. No significant differences were seen in the number of Th2(CD4+ IL-4+) accumulated in the kidney of gddY and BALB/c.

Conclusions: Present findings revealed that a significant number of CD4+ T cells, especially Th1, Th17 and Treg, but not Th2 cells accumulated in kidney of gddY. We will clarify the role of these CD4+ T cells in the induction of IgA auto-Abs in IgAN.

SA-PO823

Molecular Classification of Lupus Nephritis Based on Immune Pathway Profiling: Correlations with Histological Class and Clinical Manifestations

Danting Zhang. Dr. Yap, Yat Hin Desmond Team. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

Background: LN (lupus nephritis) ISN/RPS histopathological classification is the gold standard for assessment, however, does not inform the underlying immunological aberrations. A classification based on molecular typing of immune-related pathways may better stratify LN patients.

Methods: The expression matrix and clinical data were extracted from GEO and Nephroseq databases. ssGSEA method was used to derive immune phenotype with gene expression data. Hierarchical clustering with ssGSEA scores of selected gene sets classified LN tissues. Functional characterization and PPI of the DEGs were analyzed with Metascape. Kruskal-Walli test and chi-square test were performed to compare the clinical parameters.

Results: We calculated ssGESA scores of 96 immune-related gene sets in the glomerular and tubulointerstitial regions of LN kidney biopsy samples. Samples were then categorized into three clusters (Immune-Mild, Immune-Moderate, and Immune-Severe). Interferon-stimulated genes are a hallmark of LN. When compared to other groups, the Immune-Mild cluster from the glomerular region showed no T-cell activation pathway. The Immune-Mild (tubulointerstitial) showed minimal lymphocyte activation. PPI networks with MOCDE components further suggested that STAT1 and ISG15 are the core DEGs in different subgroups. The immune-Mild (Glomerular) showed a high prevalence of Class II and V LN, and Immune-Mild (Tubulointerstitial) showed more Class V LN. Immune-Severe group showed a higher degree of proteinuria and blood pressure but lower eGFR compared to the Immune Mild/Moderate groups.

Conclusions: A new molecular classification of LN based on the degree of immune pathway activation shows correlation with clinical manifestations, and may potentially guide personalized therapy in LN patients.

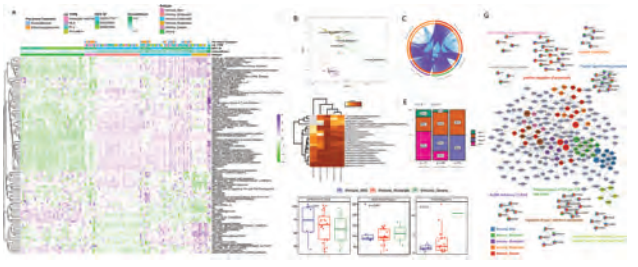

Figure 1. Features of Glomerular clusters.

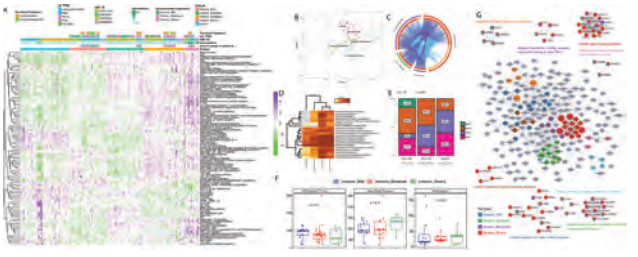

Figure 2. Features of Tubulointerstitium clusters.

Proximal Tubular Sirt6 Has a Protective Role in the Murine Lupus Nephritis Model by Regulating Tubulointerstitial Inflammation

Tian Wang,[1] Wenjia Li,[1] Soo jin Lee,[1,2] Yujin Shin,[1,2] Kyung Pyo Kang.[1,2] *[1]Jeonbuk National University Medical School, Jeonju, Jeollabuk-do, Republic of Korea; [2]Jeonbuk National University Hospital Biomedical Research Institute, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: Systemic lupus erythematosus (SLE), an autoimmune disease, involves tissue inflammation of multiple organs, including the kidney. *Lupus nephritis* is an autoimmune complex glomerulonephritis that develops as a complication of SLE. Dysregulation of intrarenal immune tolerance to nuclear autoantigens produces autoantibody and immune disorders. Sirt6 is the NAD+-dependent deacetylase and mono-ADP ribosyltransferase and is involved in genome maintenance and metabolism. This study investigates the effect of proximal tubule-specific Sirt6 knockdown on murine lupus nephritis.

Methods: To investigate the role of Sirt6 specifically in proximal renal tubules, we crossed *gGt1*-cre mice and *Sirt6*flox/flox mice to generate Sirt6 conditional knock-out mice. The back area's skin was shaved and treated topically three times per week, with 100 μg of resiquimod in 100 μl of acetone for eight weeks. After murine kidney sample collection, we evaluated renal histology and immunofluorescent study for inflammatory cells and lymphatic vessels. We also assessed inflammatory cytokines and chemokines, lymphangiogenic factors by qRT-PCR.

Results: The loss of Sirt6 in proximal tubules aggravates glomerular mesangial cell proliferation and tubulointerstitial inflammation, and there also increases glomerular deposition of IgG, IgM, and C3 in immunofluorescence staining. LYVE-1(+) lymphatic vessels have increased expression and infiltration of F4/80, CD11c, and B220 (+) inflammatory cells in proximal tubule-specific Sirt6 knock-out mice. The pro-inflammatory cytokines and chemokines such as ICAM-1, VCAM-1, MCP-1, BAFF, LTβ, and CXCL13 mRNA levels were increased compared with wild-type mice.

Conclusions: Our data suggest that proximal tubule Sirt6 is important in resiquimod-induced lupus nephritis, especially in regulating tubulointerstitial inflammation.

Analysis of Galnt14-Null Mice Links O-Glycosylation Defects to Elevated Circulating IgA Levels and Altered IgA+ B Cell Tissue Distribution

Nicholas J. Steers,[1] Sindhuri Prakash-Polet,[1] Isabel Robbins,[1] Jenna Simpson,[1] Sharvari Pathak,[1] Kelsey O. Stevens,[1] Jan Novak,[2] Ali G. Gharavi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]University of Alabama at Birmingham, Birmingham, AL.*

Background: Defects in *O*-glycosylation of IgA1 are a characteristic finding in IgA nephropathy. It is not known if aberrant *O*-glycosylation can impact IgA homeostasis, such as B-cell residence, homing, and migration. At least 17 distinct *N*-acetylgalactosami nyltransferases (GalNAc-T1-17*)* can initiate *O*-glycosylation of proteins.

Methods: We studied the circulating IgA, and the mucosal and non-mucosal tissue resident IgA+ B-cells in *Galnt14-/-* and WT mice using ELISA and flow cytometry.

Results: *GALNT14* is expressed in human and murine lymphoid tissue, specifically within germinal centers which is the major site for B-cell maturation, antibody class switching and proliferation. Serum IgA levels were significantly elevated in the *Galnt14-/-* mice compared to the WT mice (1.31±0.4 mg/ml and 0.75±0.1 mg/ml, respectively, $P < 0.01$). IgA+ B-cells in mucosal and non-mucosal tissues were examined to determine if there was an abnormal distribution of IgA+ B-cells. An increase in the percentage of IgA+ B-cells was observed in non-mucosal tissues of *Galnt14-/-* mice compared to WT mice (PMBC: 3.9±0.7% and 2.6±0.4%, respectively, $P < 0.01$; spleen: 4.2±0.9% and 3.0±0.7%, respectively, $P < 0.01$; and peritoneal cavity: 6.1±2.3% and 3.8±0.9%, respectively, $P < 0.01$). In addition, a significant decrease in the percentage of IgA+ B-cells was observed in the Peyer's patches of *Galnt14-/-* mice compared to WT mice (20.2±3.7% and 24.4±3.8%, respectively, $P < 0.01$). No differences in the percentage of IgA+ B-cells was observed in non-mucosal lymph nodes. The increased IgA in the circulation in *Galnt14-/-* mice correlated with the increased IgA+ B-cells in the circulation ($P < 0.01$) and the reduced IgA+ B-cells in the Peyer's patches ($P < 0.01$). Finally, reciprocal adoptive transfer experiments demonstrated that splenic derived B-cells isolated from *Galnt14-/-* mice have a reduced ability to home to the spleen, regardless of the recipient genotype.

Conclusions: *Galnt14-/-* mice have an altered distribution of IgA+ B-cells in mucosal and non-mucosal tissues, partially explaining the elevated levels of circulating IgA. We are currently exploring the mechanisms of the alterations observed in IgA+ B-cell recruitment and residence in mucosal and lymphoid tissues of *Galnt14-/-* mice.

Spatial Transcriptomic Profiling to Understand Organ Cross-Talk: Insight into Environment-Linked Pulmonary-Renal Disease

Mary H. Foster,[1,2] Vaibhav Jain,[1] Lanette Fee,[1] Robert M. Tighe.[1] *[1]Duke University, Durham, NC; [2]Durham VA Health Care System, Durham, NC.*

Background: Environmental inhalational exposures are implicated in etiopathogenesis of autoimmune pulmonary-renal diseases and CKDu. Underlying mechanisms of disrupted immune control and cross-organ injury are poorly understood. To gain insight into this under-studied field, we leveraged a tractable preclinical model dependent on mouse lung exposure to crystalline silica (cSi) dust. Inhalation of cSi is linked to SLE and ANCA vasculitis in humans and exposure to cSi generated from burned crops is suspected in pathogenesis of CKDu. In mice cSi exposure induces lung inflammation and lymphoid aggregates and promotes autoimmunity. To gain insight into molecular pathways dysregulated by inhaled cSi, we used spatial gene expression (GE) profiling.

Methods: Transcriptome analysis was performed using a 10X Genomics Visium platform with CytAssist at the Molecular Genomics Core of the Duke Molecular Physiology Institute. An FFPE section of lung harvested 3 months after cSi exposure was H&E stained, imaged, hybridized using a mouse transcriptome barcoded probe set, transferred, probes extended, and libraries constructed and paired-end sequenced on a NextSeq 1000 (Illumina). Raw data were preprocessed using Space Ranger, mapped to the mm10 genome, and aligned to the tissue image. Data filtering, normalization, and analysis were performed with the Seurat R package.

Results: Spatial sequencing yielded mean ~57K reads/spot, with median 2,041 genes/spot and total >19K genes detected. After dimensionality reduction, unsupervised spot clustering based on differential GE yielded 8 clusters. Overlay of molecular and image data showed spatial localization of clusters to lymphoid aggregates, granulomas, peribronchiolar loci, and minimal injury areas, supported by marker gene identification, as well as unexpected regional heterogeneity. Two clusters had strong Ig signals, consistent with distinct local adaptive immune niches. Upregulated genes with spatial restriction include a subset linked to immune control and two genes encoding soluble proteins implicated as circulating mediators of cardiopulmonary crosstalk in acute kidney injury.

Conclusions: Spatial transcriptome analysis in cSi-injured lung provides novel insight into the molecular framework of dysregulated tissue niches as well as potential biological pathways engaged in pulmonary-renal crosstalk.

A Role for Lung Foxp3+ T-Regulatory (Treg) Cells in Modulating Lupus Autoantibody Production Exacerbated by Silica Dust Exposure

Mary H. Foster,[1,2] Advika Kumar,[1] Koki Abe,[1] Tomokazu Souma,[1] Robert M. Tighe,[1] Lanette Fee.[1] *[1]Duke University, Durham, NC; [2]Durham VA Health Care System, Durham, NC.*

Background: Gene-environment (GxE) interactions promote systemic autoimmunity and induction of autoantibodies (autoAb) that destroy kidneys in SLE and ANCA vasculitis. In mice, inhalation of crystalline silica (cSi) dust, an exposure compellingly linked to human autoimmune diseases, induces local tertiary lymphoid structures (TLS) enriched in T and B cells. In lupus and other autoimmune-prone strains, cSi inhalation increases local and systemic autoAb and accelerates nephritis. To test the hypothesis that immune control is defective in GxE-influenced tissue microenvironments in lupus, we measured cells expressing transcription factor forkhead box protein 3 (Foxp3), a key marker of regulatory T cells (Treg), in cSi-exposed lupus BXSB and non-autoimmune C57BL/6J (B6) mice.

Methods: Lungs harvested from female mice 7-9 weeks after cSi exposure were sectioned and stained with anti-Foxp3 and anti-B220 (B cell) antibodies and visualized using a Zeiss Axio Imager. TLS-associated Foxp3+ nuclei were enumerated in n=16 TLS per mouse using Zeiss Zen software, with TLS identified as loci of densely packed nuclei overlapping B220+ clusters. In situ hybridization was performed using RNAScope on FFPE tissue sections from cSi and vehicle (V) exposed autoAb transgenic (Tg) B6 mice, using Foxp3 and control probes.

Results: Foxp3+ nuclei were identified within TLS in lung tissue of all cSi-exposed mice. In one of three BXSB mice, a single TLS had an exceptionally high Foxp3+ cell count, highlighting the potential for microniche heterogeneity. Exclusion of this outlier revealed significantly fewer Foxp3+ cells/TLS in BXSB vs B6 mice: 4.6±0.2 in BXSB vs 8.1±4.6 in B6 (mean±SD), $p<0.05$. Immunofluorescence and RNAScope imaging showed that Foxp3+ cells also localized to TLS regions in cSi-exposed autoAb Tg mice, whereas only a few scattered Foxp3+ cells were identified in V-exposed lung.

Conclusions: Foxp3+ Treg are recruited to lungs after cSi inhalation and localize to lymphocyte-rich TLS, suggesting a role in regulation of local autoimmune responses. The relative paucity of Foxp3+ cells in BXSB TLS may contribute to autoimmunity in this lupus-prone strain. Understanding the composition and contribution of local tissue immune niches in GxE-influenced pulmonary-renal diseases such as lupus may identify novel approaches to therapy.

Targeting Sphingosine-1-Phosphate Receptor 4 in a Mouse Model of Alport Syndrome

Matthew Tolerico, Judith T. Molina David, Sandra M. Merscher, Alessia Fornoni. *University of Miami School of Medicine, Miami, FL.*

Background: Alport syndome is a genetic condition in which the ability to produce the heterotrimer collagen 4a345 is disrupted. Alport syndrome results in glomerular disease and eventually renal failure. Sphingosine-1-phosphate (S1P) is a bioactive sphingolipid that exerts its effects by interacting with one of its five receptors (S1PR1-5). S1P signaling has a wide range of effects depending on the receptor and the cell type. S1P siganling plays a large role in the immune system as lymphocyte migration is dependent on it. However the role of S1P siganling in podocytes and the kidney is largely unknown.

Methods: S1P was measured through liquid-chromatography mass spectrometry. Col4a3 -/- mice were treated with either vehicle or 25mg/kg CYM50358 (S1PR4 antagonist) every other day starting at 4 weeks of age until sacrifice at 8 weeks of age. Albumin to creatinine ratio was determined through ELISA. Mesangial expansion was determined by PAS staining. Lipid accumulation was determined by oil red o staining. Fibrosis was determined by picro-sirius red staining.

Results: Col4a3 -/- mice have elevated S1P in the kidneys compared to control mice. We see higher kidney cortex expression of S1PR4 in Col4a3 -/- mice compared to control mice. We see that treatment with a S1PR4 antagonist is sufficent to lower proteinuria, lipid accumulation in the kidney, mesangial expansion and fibrosis.

Conclusions: Our results suggest that S1P may drive progression of renal failure in alport syndrome. We see that reducing S1PR4 signaling through pharmacological treatment is beneficial to renal outcomes in col4a3 -/- mice. Targeting other S1PR may be beneficial as well for slowing the progression of renal failure.

The High-Throughput Approach Identifies Compounds that Block PLA2R and Anti-PLA2R Antibody Interaction

Zixin Feng,[1] Fusheng Guo,[2,3] Zhao Cui.[1] *[1]Peking University First Hospital Department of Nephrology Renal Division, Beijing, China; [2]Peking University College of Chemistry and Molecular Engineering, Beijing, China; [3]Peking University Synthetic and Functional Biomolecules Center, Beijing, China.*

Background: The pathogenicity of anti-phospholipase A2 receptor (PLA2R) antibodies has been elucidated in primary membranous nephropathy (MN).

Methods: Small-molecule compounds were screened for their inhibition effects to the binding between PLA2R and its antibodies by ELISA. The affinity of anti-PLA2R

antibodies from MN patients to the full-length extracellular PLA2R was determined by surface plasmon resonance (SPR). The blocking ability of each compound was tested by SPR competition study. The affinity of each compound was determined by SPR.

Results: 15 candidate compounds were selected from a library of over 4,000 small-molecule compounds for their inhibition rates > 20% to the binding between PLA2R and its antibodies. The affinity of anti-PLA2R antibodies and PLA2R antigens was similar among patients as approximately 1.0nM. The inhibitory potential of the 15 candidates was assessed by SPR and three compounds, Macrocarpal B, Doramectin, and Hypocrellin exhibit reproducible inhibitory ability, with Macrocarpal B being the most significant one. Macrocarpal B could eliminate nearly 30% of the antigen-antibody interaction in a dose-dependent manner, which was similar to the performance of the 31-mer peptide in SPR competitive inhibition assay. The competing Macrocarpal B bound to the immobilized PLA2R with an affinity of approximately 1.1Mm, whereas no interaction was detected between it and anti-PLA2R antibody/IgG.

Conclusions: We found a small molecular compound, Macrocarpal B, which could efficiently abrogate the binding between PLA2R and anti-PLA2R antibodies. These findings may have potential clinical value.

SA-PO830

Potency Assessment of a Recombinant IgA Protease: Toward the Treatment of IgA Nephropathy

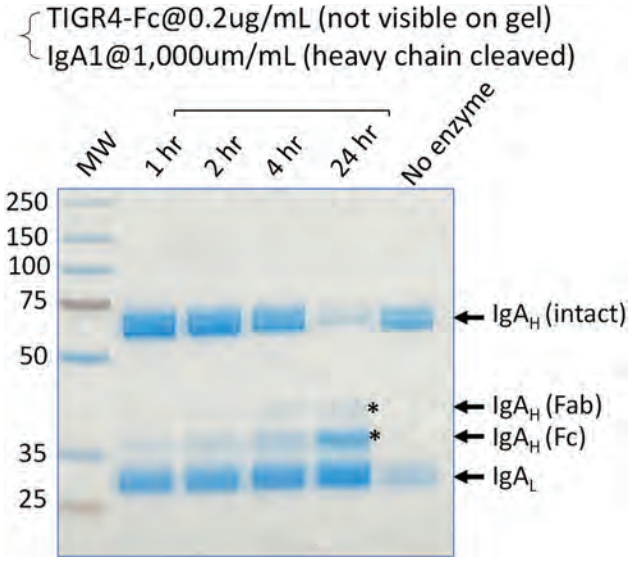
Chutian Shu,[1] Jing Jin,[2] Yuan Zhu,[1] Chencai Liang,[1] Andrew Mareczko.[1]
[1]Alebund Biotech, Inc., Shanghai, China; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.

Background: Microbial IgA proteases represent a structurally heterogenous group of proteins. Despite their structural diversity, IgA proteases are highly specific to cleave the hinge region of human IgA1 heavy chain. Here we explore the potential use of an IgA protease derived from *Streptococcus* strain TIGR4 for the treatment of IgA nephropathy by the clearance of IgA deposits in the glomerular mesangial area.

Methods: We designed a TIGR4 with a truncation at its N-terminus in a fusion configuration with Fc for extending its plasma half-life. We then expressed this TIGR4-Fc fusion in *E. coli* strain BL21 under a Tac promoter, purified through MabSelect PrismA™ columns, and assessed its purity, stability, and potency.

Results: Recombinant TIGR4-Fc was expressed as a ~350 kDa dimer attributable to dimeric Fc in its native fold. The purity is estimated to be >90% on an SDS PAGE. At 10 mg/mL, it remains stable in pbs at 20°C for over a week without visible precipitation. When subjecting TIGR4-Fc to pbs of human IgA1, enzymatic cleavage of the heavy chain occurs. With TIGR4-Fc at 2 and 20 μg/mL, and the substrate at 1,000 μg/mL, all IgA was cleaved by the enzyme. When TIGR4-Fc is at 0.2 μg/mL, a partial cleavage of IgA was observed with an incremental of cleavage over a period of 24 hours.

Conclusions: These results demonstrated the feasibility of constructing a recombinant IgA protease in fusion with Fc. The resulting biologic exhibited stability in solution and showed an exceptional enzymatic potency for human IgA1. Based on the calculated EC90 of 0.2 μg/mL, a therapeutic dose of TIGR4-Fc of as little as 1 mg is sufficient to clear 90% of IgA contents in an adult patient. The Fc fusion may further extend the *in vivo* efficacy to 10-15 days in clearing IgA in both circulation and existing kidney deposits.



Fab and Fc of IgA$_H$ are cleavage fragments.

SA-PO831

Type 2 Innate Lymphoid Cells Are Activated in Steroid-Resistant Nephrotic Syndrome

Liangjian Lu,[1] Chang-Yien Chan,[2,1] Yaochun Zhang,[2,1] Sharon Teo,[1] Yi Yang Lim,[1] Mya Than,[2,1] Kar Hui Ng,[2,1] Hui Kim Yap.[2,1] *[1]Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore; [2]National University of Singapore Yong Loo Lin School of Medicine, Singapore, Singapore.*

Background: 15% of children with nephrotic syndrome (INS) have steroid-resistant disease, which portends a poor renal prognosis. Approximately half of these patients are able to achieve remission, but only with intensive immunosuppression including calcineurin inhibitors and/or Rituximab. Given the demonstrated role of Type 2 innate lymphoid cells (ILC2) in steroid-resistant allergic asthma, and the association between INS and atopic disease, this study aimed to examine ILC2 populations in steroid-resistant (SRNS) compared to steroid-dependent INS (SDNS).

Methods: We recruited 18 patients (age: 15.7±1.9 years) with SDNS or SRNS, 9 of whom were in partial/complete relapse (urine protein:creatinine ratio>0.1g/mmol). ILCs were identified as CD45+Lin-CD127+ cells. Of these, ILC2 were CRTH2+, and inflammatory ILC2 were CRTH2+ CD45RO+.

Results: Patients with SRNS had a higher proportion of ILC2 compared to SDNS patients (28.6±4.4% vs 11.7±2.4%, p=0.003), including inflammatory ILC2 (19.7±3.5% vs 7.9±2.1%, p=0.01). Similar findings were observed even if ILC2 was defined with greater stringency as CRTH2+CD127^{hi} (p=0.02), while no concomitant changes were noted in ILC1 (p=0.61), ILC3 NCR+ (p=0.88) or ILC3 NCR- (p=0.45) populations. This elevation of ILC2 in SRNS compared to SDNS patients was more marked in relapse (35.4±2.4% vs 10.6±3.5%, p=0.002) compared to in remission (18.3±0.7% vs 12.7±3.6%, p=0.46). Correspondingly, ILC2 increased in relapse for SRNS patients (p=0.01) but not SDNS patients (p=0.99) (Figure).

Conclusions: ILC2s are activated in SRNS during relapse, but not in SDNS. If validated, ILC2s can be a potential target for therapy in SRNS.

Funding: Government Support - Non-U.S.

Neutrophil Reactive Oxygen Species Generation and Association with Clinical Disease Markers in Lupus Nephritis

Rebecca Lightman, Makayla Brady, Nicholas A. Short, Shweta Tandon, Michelle T. Barati, Madhavi J. Rane, David W. Powell, Dawn J. Caster.
University of Louisville School of Medicine, Louisville, KY.

Background: There is growing evidence for neutrophil involvement in lupus nephritis (LN). Neutrophils infiltrate the glomerulus and mediate cellular injury via granular release of toxic and immunologic molecules including reactive oxygen species (ROS). We aim to determine if LN neutrophils are more primed to produce ROS than controls and if ROS generation is associated with clinical disease features.

Methods: Neutrophils were isolated from whole blood of 16 LN patients and 6 healthy controls for use in superoxide assay. Cells were untreated, treated with fMLF, or treated with fMLF plus TNF-α. fMLF is a positive activator and TNF-α primes the response. Clinical data were obtained from Epic: UPCR, C3, C4, anti-dsDNA, and creatinine. eGFR was calculated using the 2021 CKD-EPI creatinine equation. Control data were not available.

Results: ROS generation was compared by treatment group and patient status using mixed-effects analysis with Šídák multiple comparisons test. For fMLF alone, LN neutrophils produced more ROS than controls (p=0.0028). Fold change in ROS was calculated for untreated to fMLF as well as untreated to fMLF plus TNF-α priming, and the difference was compared using unpaired T-tests. For LN, fold change from untreated did not differ between fMLF and fMLF plus TNF-α (p=0.6221). However, fold change

from untreated to fMLF plus TNF-α was greater in controls (p=0.0041). Multiple linear regression was used to determine if clinical data is associated with ROS generation in LN. For untreated, anti-dsDNA (p=0.0439) and eGFR (p=0.0318) were associated. For fMLF, C4 (p=0.0286) was associated. For fMLF plus TNF-α, UPCR (p=0.0210), C3 (p=0.0199), C4 (p=0.0025), creatinine (p=0.0325), and eGFR (p=0.0130) were associated. Finally, anti-dsDNA was associated with fold change in ROS for untreated to fMLF (p=0.0136) and untreated to fMLF plus TNF-α (p=0.0152).

Conclusions: LN neutrophils had a greater response to fMLF than controls. This suggests the possibility of endogenous primers in LN serum, which may play a role in LN pathogenesis and affect neutrophils beyond ROS generation. Discussion and investigation are ongoing regarding the utility of clinical markers in LN as well as potential new markers. Using clinical data to predict underlying disease may improve future treatments.

SA-PO833

Dapagliflozin vs. Ramipril Therapy in Mice with Alport Syndrome

Kana N. Miyata,[1] Jian Ping Li,[1] Faith A. Yeargin,[1] Michifumi Yamashita,[2] Shao-Ling Zhang,[3] John S. Chan,[3] Jeffrey H. Miner.[4] [1]*Saint Louis University School of Medicine, Saint Louis, MO;* [2]*Cedars-Sinai Medical Center Department of Pathology & Laboratory Medicine, Los Angeles, CA;* [3]*Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada;* [4]*Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Angiotensin-converting enzyme inhibitors (ACEi) have been the best studied treatment for Alport syndrome with established benefits for renal function and survival in animals and humans. Recent clinical trials have shown that sodium glucose cotransporter 2 inhibitors (SGLT2i) are a key disease-modifying therapy to prevent the progression of chronic kidney disease when used on a background of renin-angiotensin-aldosterone system (RAAS) blockade. The objective of this study is to investigate whether SGLT2i exerts renoprotection as much as ACEi in Alport syndrome.

Methods: We studied male Col4α3 knockout mice, an Alport syndrome model, on a 129S1/SvImJ background. Dapagliflozin (1.5 mg/kg/day) or Ramipril (10 mg/kg/day) were orally administered via drinking water, starting at 4 weeks of age to 10 weeks of age (N=6-8/group). Wild-type (WT) and Alport littermates received vehicle for the same duration and served as controls. Glomerular filtration rate (GFR) was measured by inulin-FITC clearance in conscious mice, and kidneys were processed for histology (PAS, Sirius Red staining).

Results: Alport mice treated with Dapagliflozin had enhanced glucose excretion in urine, but blood glucose level was not changed. At 10 weeks of age, Alport mice developed a significant weight loss, decreased GFR/body weight, and elevated BUN. These were attenuated by Ramipril, but not by Dapagliflozin. Histological analysis of Alport mouse kidneys showed global and segmental glomerulosclerosis, tubular casts and tubulointerstitial fibrosis, which were more consistently improved by Ramipril than by Dapagliflozin.

Conclusions: Ramipril had more favorable effects on preservation of renal function and renal architecture in Col43 knockout Alport mice than Dapagliflozin. Our head-to-head comparison indicates that SGLT2i may not be an alternative option for ACEi in glomerular diseases. Further studies are currently ongoing to investigate the effects of a higher dose of Dapagliflozin and of combined treatment of SGLT2i with RAASi.

SA-PO834

Plasma TET2 as Potential Noninvasive Biomarker for Type IV Lupus Nephritis

Hua Zhou,[1] Jeffrey B. Kopp,[2] Jiayue Liu,[1] Hongyu Yang,[1] Congcong Jiao,[1] Junjun Luan.[1] [1]*Shengjing Hospital of China Medical University, Shenyang, China;* [2]*National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Therapeutic regimen of lupus nephritis (LN) should be based on the pathological classification by renal biopsy. The class IV is the most common type and has the worst prognosis in LN patients. However, some patients are contraindicated to renal biopsy. A non-invasive biomarker that can mirror to renal classification will help clinical decision-making. Ten-eleven translocation methylcytosine dioxygenase 2 (TET2) has been reported to involve in the pathogenesis of systemic lupus erythematosus and kidney diseases. We aim to verify whether plasma TET2 can reflect renal classification in LN patients.

Methods: Plasma samples were collected from 49 patients diagnosed as LN approved by renal biopsy in our department from January 2019 to January 2023 and 27 age-and -sex matched healthy volunteers (NC). Class IV (n=14) and class III + V/IV +V/ V (n=31) were included in LN patients. Plasma levels of TET2 were analyzed by enzyme-linked immunosorbent assay. Student's t test or one-way ANOVA test and receiver operating characteristic curve (ROC) were used for the data analysis.

Results: Plasma TET2 levels were increased in LN patients compared to NC. Plasma TET2 differentiated LN from NC with a high diagnostic accuracy with area under the curve (AUC=0.77, p<0.001, n=76). The sensitivity for diagnosing LN was 65.30%, and the specificity was 85.20%. Further more, plasma TET2 levels in class IV were decreased compared to that in class III+V/IV+V/V inside LN patients. Plasma TET2 also differentiated class IV from class III+V/IV+V/V (AUC=0.73, p<0.001, n=45) with the sensitivity 78.6%, and the specificity 71%. Serum albumin (sAlb) differentiated class IV from the other classes with 0.684 of AUC (p=0.047). With combination of blood TET2 and sAlb, AUC was increased to 0.83 (p<0.001) to differentiate class IV from class III+V/IV+V/V. The sensitivity was 85.7%, and the specificity was 80.6% with TET2 cutoff as 350 pg/ml.

Conclusions: Plasma TET2 level differentiated LN class IV from class III+V/IV+V/V. Combination with sAlb increased the differentiation efficiency. A panel of blood TET2 and sAlb might help on diagnosing LN class IV for those patients with contraindication of renal biopsy and benefiting to therapeutic decision. This study needs to be validated in large cohort of LN patients.

Funding: Government Support - Non-U.S.

Identification of Anti-Peroxidasin Antibodies in Human and Experimental Glomerulonephritis

Lyndon H. Costa, Amrita Dhutia, Charles D. Pusey, Stephen P. McAdoo, Maria Prendecki. *Imperial College London, London, United Kingdom.*

Background: Peroxidasin (Pxdn) is an extracellular matrix (ECM) haem peroxidase critical for forming sulfilimine bonds which crosslink type 4 collagen. Sulfilimine bonds contribute to structural integrity and stability of the ECM and act to sequester the Goodpasture antigen giving it immune privilege. Autoantibodies to peroxidasin have previously been identified in patients with anti-glomerular basement (GBM) disease and MPO-ANCA associated vasculitis (MPO-AAV).

Methods: Circulating anti-Pxdn IgG was measured by ELISA in serum from patients (anti-GBM disease, AAV, and healthy volunteers) and rats with experimental autoimmune glomerulonephritis (EAG), an autoimmune model of anti-GBM disease. For coating, recombinant rat peroxidasin was expressed in HEK293 cells and purified; human peroxidasin was from a commercial source (Origene). Antibody specificity was confirmed using immunoblotting. Expression of Pxdn, deposited IgG, and smooth muscle actin (SMA) in kidney tissue was assessed by indirect immunofluorescence (IF).

Results: Circulating anti-Pxdn IgG antibodies were detected in 29.4% of (15/51) patients with anti-GBM disease, 14.2% (2/14) of patients with active MPO-AAV, and 0% (0/6) patients with active PR3-AAV (Fig 1A). Circulating anti-Pxdn IgG antibodies were detectable at day 28 after induction of EAG (peak glomerular injury) in 86.7% (13/15) of rats (Fig 1B). Anti-PXDN antibodies were detectable at low titre from day 18 suggesting they may arise later than anti-α3(IV)NC1 antibodies which are detected from day 7. IF staining of kidney tissue in EAG identified Pxdn at areas of glomerular injury and crescent formation. Pxdn co-localised with SMA but not with deposited rat IgG (Fig 1C).

Conclusions: We confirm the presence of anti-Pxdn antibodies in patients with glomerular disease. In EAG, anti-Pxdn antibodies were evident after the development of antibodies against α3(IV)NC1 and glomerular Pxdn expression was only detected after disease onset: thus we suggest anti-Pxdn antibodies may arise by a process of inter-molecular epitope spreading in the diseased glomerulus.

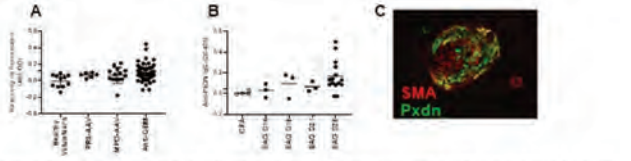

Figure 1(A). Circulating anti-PXDN antibodies in patients with anti-GBM disease and AAV. (B) Circulating anti-PXDN antibodies in rats at 28 days after induction of EAG. (C) Glomerular expression of PXDN co-localises with SMA 28 days after induction of EAG. (A+B) Dotted lines represent mean+2sd for HV and CFA respectively.

Glomerular Parietal Epithelial Cell Expression of Cathepsin C Increases in Tg26 Mouse Model of HIV-Associated Nephropathy (HIVAN)

Michelle T. Barati, Jon B. Klein, Michael Merchant. *University of Louisville, Louisville, KY.*

Background: Collapsing glomerulopathy (CG) is a feature of human immunodeficiency virus-associated nephropathy (HIVAN). Previous studies in kidney biopsies of patients with primary, collapsing variant of focal segmental glomerulosclerosis (cFSGS) demonstrated activated glomerular parietal epithelial cells (PEC) expressing cathepsin C protease, migrating into glomerular tufts. Similar results were found with preliminary lab studies in biopsies of HIVAN patients. Cathepsin C is normally absent in the glomerular tuft, suggesting that PEC introduction of this protease may contribute to extracellular matrix (ECM) remodeling in cFSGS. For this study, we addressed the hypothesis that cathepsin C expression increases in PECs lining Bowman's capsule and PECs migrating onto glomerular tufts in Tg26 mouse model of HIVAN.

Methods: Kidneys from 8 week old male and female Tg26 transgenic and FVB wt mice used for this study were provided by Klotman lab, baylor college of medicine. Formalin-fixed paraffin-embedded kidney sections were subject to co-immunofluorescence staining for claudin-1, a marker of PECs, and cathepsin C. Images were acquired by confocal microscopy.

Results: claudin-1 and cathepsin C were localized to glomerular parietal epithelial cells lining Bowman's capsule in wt mice. In glomeruli of Tg26 mice, PECs lining Bowman's capsule showed increased expression of cathepsin C and had hypertrophied morphology, suggesting PEC activation. Glomeruli of Tg26 mice also showed migration of Claudin-1-positive PECs onto the glomerular tuft and these cells also expressed cathepsin C.

Conclusions: Glomerular PECs exhibit increased expression of cathepsin C in Tg26 mouse model of HIVAN CG. These findings are similar to our findings from human primary cFSGS and HIVAN, demonstrating utility of this mouse model to define the role of PEC induction of cathepsin C in the pathogenesis of CG. Defining the cellular and molecular basis for abnormal ECM remodeling in cFSGS offers the potential of interrupting disease progression.

SA-PO837

Interstitial Fibrosis in ANCA-Associated Vasculitis: Myeloperoxidase (MPO) vs. PR3

Helena Marco,[1,2] Jordi Vilardell,[1,2] Irene Silva,[1] Beatriz Bardaji de Quixano,[1] Montserrat M. Diaz Encarnacion.[1,2] Group of Renal Inflammatory Diseases (GERI). *[1]Fundacio Puigvert, Barcelona, Spain; [2]Universitat Autonoma de Barcelona, Barcelona, Spain.*

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a necrotizing vasculitis characterized by inflammation of small blood vessels, being the kidney one of the most frequently affected organs. AAV has a high morbidity and mortality rate, leading to rapidly progressive renal failure that may lead to end-stage kidney disease. Its pathogenesis is a complex and multifactorial process involving inflammation and fibrosis. PR3-AAV and MPO-AAV have clinical-demographic differences and different renal phenotypes observed in kidney biopsy. The histopathological subgrouping into four classes (focal, crescentic, mixed, and sclerotic) is useful for predicting long-term renal survival, the worst being sclerotic class. Our aim is to determine whether interstitial fibrosis in AAV is at least as important as glomerular sclerosis in prognosis.

Methods: Retrospective single-center study of 95 AAV patients (78 MPO-AAV and 17 PR3-AAV) diagnosed by renal biopsy, with at least 1-year follow-up. Type of ANCA, immunosuppressant therapy and renal/patient survival were evaluated. Histomorphometric quantification using MetaMorph® software on trichrome-stained biopsies slides to measure the degree of fibrosis. Data analysis performed under standard conditions.

Results: PR3-AAV population was predominantly male (70%, mean age=62, mean follow-up=54 months), while MPO-AAV population was mainly female (65.8%, mean age=66, follow-up=65 months). There were no statistically significant differences in renal function between MPO and PR3-AAV at diagnosis. Albeit renal function improved throughout follow-up in MPO ($p<0.01$) and PR3-AAV ($p=0.05$), MPO-AAV showed worse renal function than PR3-AAV ($p=0.01$) at the end of follow-up. MPO-AAV showed more interstitial fibrosis at diagnosis than PR3-AAV ($p=0.01$). However, there were no significant differences in the incidence of glomerulosclerosis ($p=0.26$). PR3-AAV showed more crescentic proliferation ($p=0.03$) but less fibrotic crescents than MPO-AAV at diagnosis.

Conclusions: The method we used allows a quantitative assessment of renal fibrosis. Our data confirm that renal prognosis is better in PR3-AAV than in MPO-AAV. This could be explained by a greater interstitial fibrosis, as well as more fibrotic crescentic in MPO-AAV at diagnosis.

SA-PO838

The Protein/Creatinine Ratio Is a Reliable Indicator of 24-Hour Urine Protein, Regardless of the Level of Renal Function in Patients with Glomerulopathies

Gabriel Brayan Gutierrez Peredo,[1,2] Iris Montaño-Castellon,[1,2] Andrea Jimena Gutierrez-Peredo,[1,2] Antonio A. Lopes.[1,2] TUNARI Study. *[1]Professor Edgard Santos University Hospital, Federal University of Bahia, Salvador, Brazil; [2]Postgraduate Program in Medicine and Health, Federal University of Bahia, Salvador, Brazil.*

Background: We aimed to determine the accuracy of the urine isolated protein/creatinine ratio (PCR) test, against the gold standard 24-hour urine protein (24hUP) measurement in patients with glomerulopathies, and according to the levels of renal function.

Methods: This prospective study of patients with glomerulopathies was developed at Professor Edgard Santos University Hospital in Salvador, Bahia-Brazil. The PCR and 24hUP measurements were performed using conventional methods within a maximum interval of 24 hours between the measurements. The patients were classified into three groups according to their renal function, group 1= <30 ml/min/1.73m^2, group 2= 30-60 ml/min/1.73m^2 and group 3= >60 ml/min/1.73m^2. Spearman correlation coefficient (r_s) and ROC curves were employed to compare PCR with 24hUP.

Results: The total was 167 urinary samples from 134 patients. The mean age was 42 ± 16 yrs, 68% were female and 91% non-white. A good correlation was observed between PCR and 24hUP total sample (r_s= 0.7, p= <0.000), as well as in comparison with the different levels of renal function (r_s= 0.8 for group 1, r_s= 0.9 for group 2 and r_s= 0.8 for group 3). The ROC between PCR and 24hUP total sample yield an AUC of 0.94 (CI= 0.89, 0.97), high sensitivity of 91% and specificity of 83%, at the optimal cut-off point was 0.7. The groups representing three levels of renal function showed high sensitivity and specificity in comparisons of both methods (group 1= 82%, 100%, group 2= 97%, 89% and group 3= 88%, 92%) with an AUC of 0.92, 0.96 and 0.96, respectively.

Conclusions: PCR shows high sensitivity and specificity for monitoring patients with glomerulopathies compared to 24hUP. Our findings suggest that PCR is a useful parameter to evaluate and monitor patients with different glomerulopathies regardless of the level of renal function.

Results in the total sample and by degree of renal function comparing protein/creatinine ratio with 24-hour urine protein

Variables	Total N=167	Spearman Correlation	Cut-off by Youden Index	Sensitivity (%)	Specificity (%)	Area under ROC curve (95%CI)
PCR vs 24hUP total sample	167	0.8	0.7	91	83	0.94 (0.8;0.9)
Degree of kidney function						
<30 ml/min/1,73 m2	35	0.7	0.8	82	100	0.92 (0.8;0.9)
30-60 ml/min/1,73 m2	42	0.8	0.9	97	89	0.96 (0.9;1.0)
>60 ml/min/1,73 m2	90	0.8	0.8	88	92	0.96 (0.9;1.0)

Association of Neuroblastoma Suppressor of Tumorigenicity 1 (NBL1) with Interstitial Fibrosis Severity and Kidney Function Decline in IgA Nephropathy

Hiroki Kobayashi,[1,2] Eiichiro Satake,[2] Masanori Abe.[1] *[1]Nihon University School of Medicine, Tokyo, Japan; [2]Joslin Diabetes Center, Boston, MA.*

Background: We recently showed that the presence of neuroblastoma suppressor of tumorigenicity 1 (NBL1) in circulation is closely linked to the progression of kidney disease and histological abnormalities in individuals with diabetic kidney disease. This research aimed to investigate the potential association between serum NBL1 levels and kidney function, as well as renal histological leisons, in patients with IgA nephropathy (IgAN).

Methods: In this study, we assessed the NBL1 levels in 109 individuals with IgAN by using serum samples collected immediately before renal biopsy. We also evaluated the significance of serum NBL1 in relation to kidney function and renal histological findings based on the Oxford Classification (MEST score). Moreover, we examined the correlation between serum NBL1 and the long-term decline in kidney function among IgAN patients who had follow-up data on their estimated glomerular filtration rate (eGFR) (n=76).

Results: In early-stage IgAN patients, serum NBL1 levels were found to be higher compared to healthy individuals (n=93). Logistic regression analysis revealed a significant and independent association between serum NBL1 levels and tubular atrophy/interstitial fibrosis. Through immunohistochemical staining, NBL1 was highly expressed in the tubulointerstitium during the early stages of IgAN. Additionally, a significant correlation between serum NBL1 levels and the eGFR slope was identified on Spearman's rank correlation.

Conclusions: The serum NBL1 level was significantly associated with the severity of renal interstitial fibrosis and future kidney disease progression in patients with IgAN. Thus, circulating NBL1 may serve as a good biomarker for evaluating renal interstitial fibrosis and the risk of kidney disease progression.

Longitudinal Changes in IgA1 O- and N-Glycoforms in IgA Nephropathy

Masaya Hirayama, Yukako Ohyama, Yudai Tsuji, Naotake Tsuboi, Kazuo Takahashi. *Fujita Health University School of Medicine, Toyoake, Japan.*

Background: An increased level of circulating aberrantly glycosylated IgA1 has been considered a significant initial step in the pathogenesis of IgAN. Recently, the molecular features of IgA1 *O*- and *N*-glycoforms in patients with IgAN have been reported using high-resolution mass spectrometry (HRMS). While specific glycopeptides have been reported to be a possible predictor of IgAN and glomerular function, it is still largely unclear how the glycosylation of IgA1 changes according to treatment. In this study, we aimed to determine the difference in IgA1 *O*- and *N*-glycoform changes between different treatment groups at two time points: at diagnosis and post-treatment, using a prospective cohort enrolled at Fujita Health University Hospital.

Methods: We registered patients diagnosed with primary IgAN by renal biopsy during 2017–2019. Ten patients who received tonsillectomy and corticosteroid therapy (T-CST group), eight patients who received conservative therapy (CO group), and five patients with other renal diseases who were treated with corticosteroid therapy (ORD group) were enrolled. IgA was purified from the serum of patients at two time points (at diagnosis and post-treatment). After neuraminidase treatment, *O*-glycoforms of the hinge region (HR) and *N*-glycoforms of the Fc region were analyzed using online liquid chromatography-HRMS.

Results: The mass spectrometry analysis of *O*-glycoforms of IgA1 HR showed that the number of *N*-acetylgalactosamine in the IgA1 HR was significantly increased only in the T-CST group from diagnosis to post-treatment (P = 0.0325), while the number of galactose in the IgA1 HR remained unchanged in all groups. The mass spectrometry analysis of *N*-glycoforms also showed several changes only in the T-CST group. In asparagine $(Asn)^{340}$, at post-treatment, there was a significant increase in the relative abundance of the oligomannose-type (P = 0.0020) and a significant decrease in the galactosylation of the tri-antennary-type (P = 0.0098); whereas in Asn^{144}, there was a significant decrease in the relative abundance of fucosylated glycan (P = 0.0195).

Conclusions: This study found that some glycoforms previously reported to be characteristics of IgAN were altered only in the T-CST group of IgAN but not in the CO group of IgAN or the ORD group. The detection of *O*- and *N*-glycoform alterations may be IgAN-specific biomarkers of disease activity.

Integrin β1 Mediates Interactions of IgA1-Containing Circulating Immune Complexes from IgA Nephropathy Patients with Cultured Primary Human Mesangial Cells

Zhi qiang Huang,[1] Stacy D. Hall,[1] Dana V. Rizk,[2] Bruce A. Julian,[2] Jan Novak.[1] *[1]University of Alabama at Birmingham, Department of Microbiology, Birmingham, AL; [2]University of Alabama at Birmingham, School of Medicine, Birmingham, AL.*

Background: Biopsy features of IgA nephropathy include proliferation of mesangial cells and glomerular IgA1 that probably originates from deposition of circulating immune complexes (CIC) with variable amounts of IgA1, IgG, complement C3, and other proteins, e.g., fibronectin (FN). C-terminal segment of FN may bind IgA, and serum levels of IgA-FN complexes may have diagnostic value for IgA nephropathy. The mechanism by which CIC induce proliferation of the mesangial cells is not well understood. We explored interactions between CIC, mesangial cells, FN, and FN's receptors (integrin α1β1 and α5β1).

Methods: Cultured quiescent human mesangial cells were incubated for 15 min at 37°C with CIC from sera of patients with IgA nephropathy, without or with integrin α1β1 inhibitor obtustatin or integrin α5β1 inhibitor RGD. The integrins were immunoprecipitated (IP) from cell lysates using specific antibodies. Cell lysates and IP products were analyzed by SDS-PAGE/immunoblotting with antibodies specific for IgA, IgG, IgM, FN, and selected phosphoproteins. To assess effects of FN on CIC association with mesangial cells, CIC were incubated 15 min at 37°C with the cells and purified FN, with or without obtustatin.

Results: Variable amounts of IgA and IgG were detected in the lysates of cells incubated with CIC. CIC induced phosphorylation of several proteins, including PDGFR-β, Axl, ERK, and integrin β1. Obtustatin reduced the amounts of IgA and IgG in the lysates and decreased CIC-induced phosphorylation of ERK, Axl, integrin β1, and PDGFR-β. IgA, IgG, and FN were detected in the IP with antibodies specific for integrin α1β1 and α5β1. Obtustatin reduced amounts of IgA and IgG in the IP. Addition of FN to the cells with CIC enhanced the amounts of IgA, IgG, and IgM in lysates about 1.2-4.7-fold. Obtustatin decreased the FN-enhanced amounts of IgA, IgG, and IgM in lysates by about 10-25%.

Conclusions: CIC from patients with IgA nephropathy added to cultured mesangial cells induced cellular signaling and variable association of IgA/IgG/IgM in the cell lysates. Addition of FN enhanced the association of IgA/IgG/IgM with the cells. Future studies are needed to define mechanisms of integrin β1 and CIC interactions and a possible role of FN in these processes.

Characterization of IgA1-Containing Circulating Immune Complexes in Patients with IgA Nephropathy with Progressive vs. Nonprogressive Disease

Graham Gurganus,[1] Stacy D. Hall,[1] Zhi qiang Huang,[1] Nicolas Maillard,[2] Zina Moldoveanu,[1] Dana V. Rizk,[1] Bruce A. Julian,[1] Matthew B. Renfrow,[1] Jan Novak.[1] *[1]University of Alabama at Birmingham, Birmingham, AL; [2]Hospital and University Jean Monnet of Saint-Etienne, Saint-Etienne, France.*

Background: IgA nephropathy (IgAN) is an autoimmune disease wherein circulating immune complexes (CIC) deposit in the glomeruli and induce mesangioproliferative injury. These CIC contain IgA1 with some *O*-glycans deficient in galactose (Gd-IgA1) bound by IgG autoantibodies (AuAb) specific for Gd-IgA1. Serum levels of Gd-IgA1 and IgG AuAb predict disease progression, but little is known about characteristics of the CIC. Here, we analyzed the mesangioproliferative capacity and composition of CIC from patients with progressive vs. non-progressive IgAN.

Methods: CIC from sera of IgAN patients with progressive (IgAN-P; n=3) or non-progressive (IgAN-Np; n=2) disease were isolated by size-exclusion chromatography (SEC). IgAN-P were defined as having eGFR loss (2021 CKD Epi formula) >2 ml/min/1.73 m^2 per year. Median follow up was 13 years. Mesangioproliferative activity of CIC was assessed by using cultured primary human mesangial cells (MC). Jacalin affinity chromatography was used to deplete total serum IgA1 before SEC. Serum levels of IgA, Gd-IgA1, and IgG AuAb were determined by ELISA and CIC composition was assessed by SDS-PAGE/immunoblotting with antibodies specific for IgA, IgG, or complement C3.

Results: CIC of molecular mass (Mr) >700 kDa stimulated proliferation of MC. These CIC contained IgA, IgG, and C3. Most of C3 in these CIC was covalently associated with IgG and IgA, presumably through a thioester bond. Immunoblotting of CIC electrophoretically separated under reducing conditions revealed C3, C3b, and iC3b. CIC from IgAN-P exhibited greater mesangioproliferative activity compared to CIC from IgAN-Np. Jacalin removed these stimulatory CIC from serum, and the corresponding SEC fractions were devoid of IgA, IgG, and C3.

Conclusions: IgAN CIC with Mr >700 kDa that stimulated cellular proliferation of MC contained IgA1 with IgG and covalently attached C3. Jacalin affinity chromatography confirmed association of IgA1 with C3 and IgG. Moreover, IgAN-P had more active CIC compared to IgAN-Np CIC. Future studies will determine similarities and differences in the composition and amounts of these CIC associated with disease severity and/or progression.

Therapeutic Effect of Nanoparticle-Mediated shRNA Delivery in Lupus Nephritis Mice

Wenhai Shao, Yuxuan Zhen, David E. Adams. *University of Cincinnati College of Medicine, Cincinnati, OH.*

Background: Lupus nephritis (LN) is the most common and severe manifestation of systemic lupus erythematosus (SLE). LN pathogenesis is complex and incomplete understood. Therapy approach are predominantly nonspecific immunosuppressive medications. More effective drugs with favorable safety profiles are urgently needed. MRL/lpr mice develop lupus nephritis that mostly assemble disease manifestation in lupus patients. WD repeats and FYVEdomain-containing protein 1 (WDFY1) is an adaptor protein involving in inflammatory pathways in LN.

Methods: Protein levels of WDFY1 were analyzed by Western blot and immunofluorescent staining in the kidney of nephritic MRL/lpr mice and lupus nephritis patients. Lupus-like disease was first induced in C57BL/6 mice by ip administration with 1 X 10^8 splenocytes from bm12 mice. Serum autoantibody levels were measured by ELISA. Germinal center reaction and cell subtypes were analyzed. Twelve-week old MRL/lpr mice were treated with nanoparticle encapsuled WDFY1-shRNA for 5 weeks. Renal pathology, immune complex deposition, and complement activation were examined.

Results: Significantly enhanced WDFY1 expression was detected in the kidney of MRL/lpr mice compared to the age/sex-matched MRL/MpJ mice. The expression levels also correlated with the nephritis disease activity. Kidney sections from LN patients also showed increased WDFY1 expression compared to kidney samples from healthy controls. B6.WT mice developed increased levels of anti-dsDNA and anti-chromatin autoAbs after receiving bm12 splenocytes. AutoAb production was significantly diminished in B6.WDFY1-KO mice receiving the same dose of bm12 splenocytes. Most importantly, MRL/lpr mice treated with nanoparticle encapsuled WDFY1-shRNA showed improved kidney function with significantly decreased BUN and proteinuria.

Conclusions: Observations made here support the usefulness of WDFY1 for the treatment of lupus and lupus nephritis. Results may lead to more effective and safer molecule-specific approaches.

Humoral Immune Responses Primed by the Alteration of Gut Microbiota Were Associated with Galactose-Deficient IgA1 Production in IgA Nephropathy

Xinfang Xie,[1] Li Gao,[1] Huixian Li,[1] Wanhong Lu,[1] Jicheng Lv,[2] Jing Jin.[3] *[1]Department of Nephrology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [2]Renal Division, Peking University First Hospital; Peking University Institute of Nephrology, Beijing, China; [3]Department of Medicine-Nephrology and Hypertension, Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Galactose-deficient IgA1 (GdIgA1) is critical in the formation of immunodeposits in IgA nephropathy (IgAN), whereas the origin of GdIgA1 is unknown. We focused on the immune response to fecal microbiota in IgAN patients.

Methods: By running 16S rRNA gene sequencing, we compared IgAN samples to the control samples from household-matched or nonrelated individuals. Levels of plasma GdIgA1 and poly-IgA complexes were measured, and candidate microbes that can either incite IgA-directed antibody response or degrade IgA through specific IgA protease activities were identified.

Results: The IgAN group showed distinct composition of fecal microbiota as compared to healthy controls. Particularly, high abundance of Escherichia-Shigella was associated with the disease group based on analyses using Receiver-operating Characteristic (AUC 0.837, 95% CI 0.738-0.914), Principe Coordinates, and the LEfSe algorithm (LDA score: 4.56, $p<0.001$). Accordingly, the bacterial levels directly correlated with high titers of plasma GdIgA1($r=0.36$, $p<0.001$), and patients had higher IgA1 against stx2(2.88±0.46 IU/ml *vs*. 1.34±0.35 IU/ml, $p=0.03$), the main antigen of Escherichia-Shigella. Conversely, the healthy controls showed relatively higher abundance of the commensal bacteria that produce IgA-degrading proteases. Particularly, the abundance of some intestinal bacteria expressing IgA proteases showed an inverse correlation with the levels of plasma GdIgA1 in IgAN.

Conclusions: Our data suggest that mucosal IgA production, including those of GdIgA1, is potentially linked to the immune reactivities against gut Escherichia-Shigella, and conversely, the IgA protease-producing microbiota in the gut are suppressed in IgAN patients.

Neutrophil Degranulation in Lupus Nephritis

David W. Powell, Makayla Brady, Shweta Tandon, Rebecca Lightman, Nicholas A. Short, Madhavi J. Rane, Michelle T. Barati, Dawn J. Caster. *University of Louisville School of Medicine, Louisville, KY.*

Background: There is accumulating evidence for neutrophil involvement in lupus nephritis (LN). Neutrophils are recruited into glomeruli following immune complex deposition, where they release toxic antimicrobial agents and immune regulatory molecules from preformed granules. Our previous reports with mice and cultured

cells show that neutrophil granule proteins contribute to immune complex-mediated glomerular injury and directly injure podocytes and glomerular endothelial cells. The aim of this study is to investigate the contribution of neutrophil degranulation in human LN.

Methods: Levels of twelve neutrophil granule proteins were measured in urine and serum from 10 LN patients with active disease and 8 healthy controls (HC) using an antibody-based array and ELISA validations. Flow cytometry was used to measure markers of secretory, specific, and azurophilic granule release in untreated neutrophils from LN patients and HC and in HC neutrophils in response to LN patient or HC serum.

Results: Six of the targeted granule proteins (neutrophil elastase, olfactomedin-4, lactoferrin, a-1AG, MMP-9, and cathelicidin) were significantly elevated in urine from LN patients, and neutrophil elastase was the only protein higher in LN serum. Degranulation of all granule subsets were significantly enhanced in untreated neutrophils from LN patients compared to HC. Serum from active LN patients, but not HC serum, significantly activated granule release in HC neutrophils.

Conclusions: Our findings suggest that enhanced neutrophil degranulation could play a role in LN pathology and that urine measurement of neutrophil granule proteins could serve as markers of kidney inflammation.

SA-PO846

The C-Terminal Region of HTRA1 Is the Predominant Target for Autoimmunity in HTRA1-Associated Membranous Nephropathy (MN)

Laith Al-Rabadi,[1] Linda Reinhard,[2] Michael Ehrmann,[4] Elion Hoxha,[2] Laurence H. Beck.[3] *[1]University of Utah Health, Salt Lake City, UT; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]Boston Medical Center, Boston, MA; [4]Universitat Duisburg-Essen, Duisburg, Germany*.

Background: We previously identified HTRA1 as a novel antigen in 4.2% of uncharacterized MN patients. This secreted serine protease is expressed in various tissues with high homology across human and rodent species (~92%). The trypsin-like serine protease domain in HTRA1 is responsible for its proteolytic activity whereas its PDZ domain facilitates protein-protein interactions by tethering HTRA1 to specific sites in the extracellular matrix.

Methods: Immunoblotting/cyclic constrained epitope mapping of patient serum from two independent cohorts with various truncated recombinant HTRA1 proteins. WT and HTRA1 KO mice were immunized with full-length human HTRA1.

Results: Sera from patients with HTRA1-associated MN is known to recognize native and recombinant human HTRA1 even under reducing conditions, which are expected to disrupt the conformation of the highly disulfide bonded N-terminal region of HTRA1. Accordingly, both circulating and glomerulus-eluted antibodies from patients with HTRA1-associated MN recognize the HTRA1 C-terminus, which encompasses its PDZ and protease domains. Immunization of WT or HTRA1 KO mice with human HTRA1 generates mouse Ab against HTRA1. Importantly, these mouse autoantibodies recognized the HTRA1 C-terminus (similar to what is seen with patient-derived autoantibodies). To further approximate the location of the targeted epitopes of HTRA1 autoantibodies, immunoblotting of reactive sera with various truncated recombinant HTRA1 proteins showed that HTRA1 autoantibody-containing human sera recognized full length HTRA1 and HTRA lacking AA 1-158 (referred to as DeltaMac25)**.** To identify any outliers or conformation-specific epitopes, the commercially available PEPperMAP Cyclic assay was performed. This analysis revealed the top three antibody responses were against non-conformational peptides with the consensus motifs AIINYGNS**GGPL** (AA 312-332, which encompasses the AA 328 site known to be required for HTRA1 protease function), and **GGPL**VNLDGEV (AA 329-339) in the protease domain, and IEVIPD (AA 415-420, required for HTRA binding activity) in the PDZ domain.

Conclusions: Together, these findings suggest that the targeted epitope in HTRA1 is non-conformational and located within the C-terminus which raises the possibility that anti-HTRA1 antibodies may interfere with biological function and/or binding.

Oxford Kidney Pathology Atlas: Single Cellular Profiling of Renal Biopsy Tissue

Jessica Kepple,[1,2] Simon Davis,[1] Roman Fischer,[1] Katherine R. Bull.[1] Oxford Renal Pathology Research Group-Bull. *[1]University of Oxford, Oxford, United Kingdom; [2]Novo Nordisk A/S Global Research, Malov, Denmark*.

Background: Glomerular damage is central to many kidney diseases, thus a better understanding of glomerular cell pathology is essential for developing more targeted therapeutics. Transcriptomic and proteomic profiling of human renal tissue may address this challenge. Many studies utilize nephrectomy sections, with limited samples, technical glomerular dissociation bias, and non-standardized methodology restricting the research application of biopsies. As part of the Oxford Kidney Pathology Atlas study, we developed experimental protocols for processing standard human renal biopsy samples for single-nuclei RNA sequencing (snRNA-Seq) and glomerular proteomics and generated pilot data from healthy donors and an early primary idiopathic nephrotic syndrome (iNS) case.

Methods: Biopsy cores from diseased patients and pre-transplantation controls were processed for clinical histology, snRNA-Seq and targeted glomerular proteomics. SnRNA-Seq libraries were analyzed using the R package Seurat. Glomerular regions from formalin-fixed paraffin-embedded (FFPE) renal biopsy sections were isolated via targeted laser capture microdissection coupled with mass spectrometry (MS). MS results were analyzed using DI-ANN and Perseus software to assess relative protein abundance.

Results: We conducted a targeted proteomics titration experiment with varying numbers of isolated glomeruli from healthy donors to establish the minimum material required for proteomics. We isolated glomerular proteins from FFPE-embedded renal section, quantifying over 4.5k unique proteins from a single glomerulus and over 5k proteins from 6-10 human glomeruli. By snRNA-Seq, libraries were generated per single biopsy core, with glomerular and tubular populations represented. Despite normal histology, iNS patient-derived nuclei enriched in select proximal tubule and glomerular cell clusters, with altered gene signatures including increased cellular transport function and extracellular matrix accumulation, and reduced podocyte function.

Conclusions: We demonstrate that glomerular proteomic markers can be captured from 6 glomeruli from a human FFPE biopsy section. Key renal cell types are detectable by snRNA-Seq from standard clinical biopsy core, sufficient to detect differential cell composition and gene expression in disease tissue. This platform will be applied to identify novel therapeutic targets in kidney disease.

SA-PO848

C5b-9 Deposition on Cultured Endothelial Cells in Patients with Thrombotic Microangiopathy of Different Etiology

Elena Guillen,[1] Víctor J. Escudero-Saiz,[1] Marta Martínez-Chillarón,[1] Luis F. Quintana,[1] Julia Martinez-Sanchez,[2] Alex R. López,[2] Patricia M. Moreno,[2] Maribel Diaz-Ricart,[2] Marta Palomo,[3] Josep Miquel Blasco Pelicano.[1] *[1]Department of Nephrology and Renal Transplantation, Hospital Clinic de Barcelona, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Universitat de Barcelona, Barcelona, Spain; [2]Hemostasis and Erythropathology Laboratory, Hematopathology, Pathology Department, Biomedical Diagnostic Center (CDB), Hospital Clínic de Barcelona, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Universitat de Barcelona, Barcelona, Spain; [3]Hematology External Quality Assessment Laboratory, Biomedical Diagnostic Center (CDB), Hospital Clinic de Barcelona, Institut d'Investigacions Biomediques August Pi i Sunyer (IDIBAPS), Universitat de Barcelona, Barcelona, Spain*.

Background: Thrombotic microangiopathies (TMAs) are a group of diseases linked by endothelial injury for different mechanisms, one of which is deregulation of the complement system. The differential diagnosis of TMAs is challenging due to the etiological overlap and the absence of specific biomarkers, hence complement assessment may be a useful tool to improve the management of these patients.

Methods: Complement terminal pathway was assessed by analyzing deposition of C5b-9 (C5b-9d) on cultured endothelial cells (CEC), by immunofluorescence, after exposing them to the plasma of patients with TMA from different etiology, obtained between June-2021 and April-2023. C5b-9 deposits were calculated as percentage of labeled area over the total area analyzed. An increase ≥ 2x was considered significant.

Results: 120 samples were included (95 patients, 51(53.7%) men, 49±15 years), of which 58(48.3%) had a positive result (C5b-9d ≥ 2x;Figure 1). Of these, 40(69.0%) presented renal function impairment at diagnosis: 6(10.3%) AKI-1, 7(12.1%) AKI-2, 17(29.3%) AKI-3 and 10(10.7%) required dialysis. Regarding the evolution of renal function, 33(56.9%) patients presented complete remission, 9(15.5%) partial remission, 2(3.4%) started long-term dialysis program and 6(10.3%) died.

Conclusions: Our series shows that TMA is a frequent condition, with high morbi-mortality. The analysis of C5b-9d on CEC could be a useful biomarker to differentiate those cases in which there is a complement overactivation, which may allow to individualize the treatment and follow-up of these patients. In addition to aHUS, C5b-9d was mainly observed in TMA associated with hematological diseases, drugs, and infections.

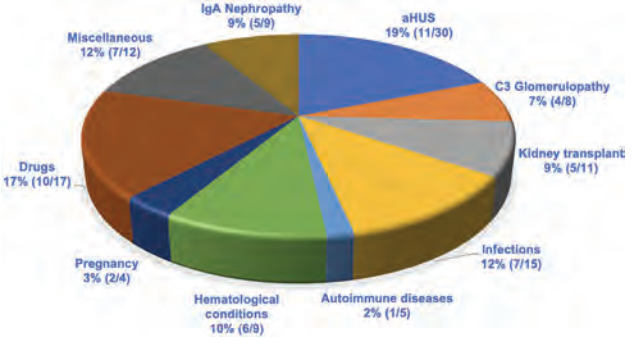

Figure 1. Etiology of TMA in patients with positive dC5b-9. The percentage expresses the positive cases of each etiology over the total number of positive cases. In parentheses, positive cases are shown over the total number of cases analyzed for each etiology.

SA-PO849

Late Renal Recovery in a Patient with Solitary Kidney and ANCA-Positive Glomerulonephritis (GN) Treated with Rituximab

Soo Hyun Kae,[1] Alina Cheema,[2] Matthew Min,[2] Ari B. Geller,[3] Sankar N. Niranjan.[3] *[1]Trinity Health of New England, Hartford, CT; [2]UConn Health, Farmington, CT; [3]Greater Hartford Nephrology, Bloomfield, CT.*

Introduction: ANCA vasculitis is the most common form of new-onset GN in adults >50. It is often associated with high rate of morbidity and mortality, especially when it causes significant renal injury requiring RRT. These patients often do not come off RRT, primarily when they have known CKD.

Case Description: 82yoF with CKD stage IIIa baseline SCr 0.9-1.1 with solitary right kidney due to renal cell cancer s/p left nephrectomy was found to have rapidly progressive AKI with SCr rising from 2.2 to 3.7 in a span of 2 weeks with associated dyspnea, leg edema, and fatigue. She was found to have focal necrotizing and crescentic pauci-immune GN with vascular findings consistent with vasculitis on her kidney biopsy. The crescents were limited to 4 of 46 glomeruli but had 13 globally sclerosed glomeruli with moderate interstitial fibrosis and 40-50% tubular atrophy. Along with positive c-ANCA and anti-MPO antibodies, she was confirmed to have ANCA vasculitis. Although she remained non-oliguric, her SCr continued to rise at 4.6 requiring hemodialysis (HD), which was continued even after hospital discharge. She was pulsed with steroids and was started on rituximab infusion after discharge. She was continued on rituximab and was able to come off HD after 8 months due to improvement in her SCr to 2.0-2.2 range. She remains off HD with last SCr of 2.1 from earlier this month.

Discussion: ANCA vasculitis remains a rare yet lethal disease that is yet to be fully understood as it is still unknown how ANCA antibodies develop. One study has shown that only 43% of patients who required RRT at the time of diagnosis were able to come off at 1 year. The prognosis is even poorer when they have known CKD with much lower rates of meaningful kidney recovery after initiating RRT at around 5%. Xu et al. emphasize how pathologic severity may determine renal recovery for ANCA vasculitis requiring RRT at disease onset with high proportion of fibrous crescent and global glomerulosclerosis being a predictor of dialysis dependence. Our patient's renal recovery indicates that even with advanced age, baseline CKD, and moderate tubulointerstitial involvement, it is worth treating the active vasculitis in the form of crescentic glomerular lesions with rituximab. We also make a case for biopsy of a solitary kidney when absolutely indicated despite the risks involved.

SA-PO850

Paraneoplastic IgA Nephropathy Associated with Renal Cell Carcinoma

Michael A. Libre,[1] Natalie N. McCall,[2] Jefferson L. Triozzi.[2] *[1]Vanderbilt University School of Medicine, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Malignancy is a rare and underrecognized cause of secondary IgA nephropathy, particularly in elderly patients. We present a case of IgA nephropathy likely paraneoplastic to renal cell carcinoma (RCC) that resolved after tumor resection.

Case Description: A 71-year-old previously healthy woman presented to the nephrology clinic with an elevated serum creatinine. Although asymptomatic, the patient noted her son had IgA nephropathy requiring kidney transplant. On examination, she was hypertensive to 158/88 mm Hg but had a normal cardiopulmonary examination with no peripheral edema. Laboratory studies showed a serum creatinine elevated to 2.7 mg/dL from normal baseline. Urinalysis showed 100 mg/dL protein, large blood, 68 WBC/HPF, and 83 RBC/HPF. Serologic workup was unremarkable. A kidney ultrasound and subsequent MRI showed a mixed solid cystic mass measuring 4.6 x 4.1 x 3.8 cm involving the lower pole of the right kidney. A biopsy of the left kidney demonstrated IgA dominant immune complex glomerulonephritis with necrosis and crescents, for which she was treated with high dose prednisone. A biopsy of the right kidney mass identified clear-cell renal cell carcinoma, for which she underwent uncomplicated partial nephrectomy. Her kidney function subsequently stabilized allowing for discontinuation of steroids.

Discussion: IgA nephropathy can be associated with infection, autoimmune conditions, liver disease, and malignancies—such as lung cancers, lymphomas, IgA myeloma, and RCC. This case represents a paraneoplastic IgA nephropathy associated with clear cell RCC that resolved post-nephrectomy. Although fewer than ten cases related to RCC are reported in the literature, multiple studies have identified pathologic evidence of IgA nephropathy in RCC nephrectomy specimens. This suggests that IgA nephropathy may result from tumor-induced antigen-antibody response. The primary goal of treatment is to address the underlying malignancy to minimize the risk of further kidney damage and allow for recovery. The role of steroids or other immunosuppressive therapies is unclear. In this case, removing the tumor led to significant improvement possibly due to elimination of tumor-induced immune interactions.

SA-PO851

Peripheral Neuropathy Leading to Diagnosis of ANCA-Associated Glomerulonephritis

Matthew F. Baker, Laura Malone, Maura A. Watson, Amy J. Frankston. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: ANCA-associated glomerulonephritis (GN) rarely presents with concomitant neurologic symptoms.

Case Description: A man in his seventies with type 2 diabetes mellitus and hypertension was admitted with 6-months of worsening extremity weakness and gait instability leading to a fall. Electromyelogram demonstrated diffuse demyelinating polyneuropathy. On admission, he had acute kidney injury (AKI) with serum creatinine 1.86 mg/dL (0.9 mg/dL at baseline). Urine microscopy showed acanthocytes, red blood cell casts, and dense granular casts. Renal biopsy demonstrated crescentic GN, acute interstitial nephritis with tubular necrosis, and a medium-sized artery occluded by thrombus. Direct immunofluorescence was positive for C3 and negative for IgG, IgM, IgA, C1q, fibrinogen, albumin, or kappa/lambda light chains. Perinuclear ANCA titer was elevated at 1:320. Anti-MPO antibodies were >8 units; anti-PR3 antibodies were elevated at 2.7 units. Diagnoses of ANCA-associated GN and microscopic polyangiitis (MPA) were made. He was treated with induction methylprednisolone and rituximab followed by prednisone taper. After treatment, renal function and extremity neuropathy symptoms improved. Serum creatinine improved from 2.42 mg/dL pre-treatment to 2.0 mg/dL at hospital discharge.

Discussion: The initial presentation of weakness and polyneuropathy is an unusual dominant symptom for MPA, which may have delayed recognition of renal involvement. He lacked other symptoms, including rash or sinusitis, that are often associated with systemic small-vessel vasculitis. C3 positivity on direct immunofluorescence does not rule out ANCA-associated GN despite its classic "pauci-immune" appearance. Plasmapheresis was considered due to concurrent AKI and autoimmune-mediated demyelinating polyneuropathy but was deferred due to lack of rapid renal failure or pulmonary hemorrhage. Immunosuppressive therapy directed at preserving kidney function also improved the neuropathy suggesting that these were both due to MPA. Recognition of unusual features of MPA-associated GN as demonstrated in this case aided diagnosis and should be considered in AKI cases with neurologic derangements. *The views expressed in this abstract are those of the author(s) and do not necessarily reflect the official policy of the Department of Defense or the U.S. Government.*

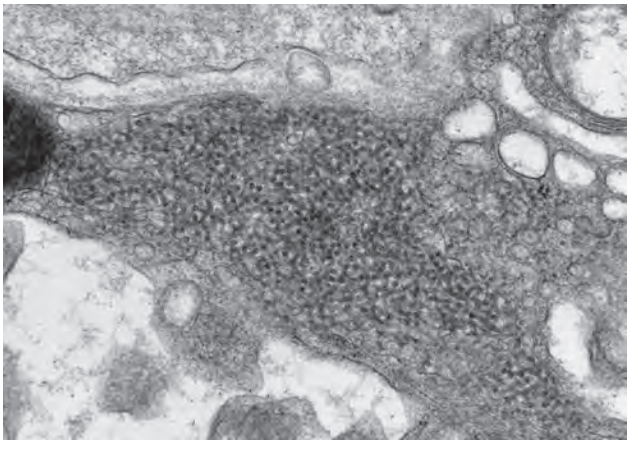
SLEeping in the Cold

Ryan Bonner, Koyal Jain. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Glomerular diseases in patients with systemic lupus erythematosus (SLE) can take many forms, however the classification of lupus nephritis by ISN/RPS does not include cryoglobulinemic vasculitis. We describe a patient evaluated for lupus nephritis who was found to have SLE-induced mixed cryoglobulinemic vasculitis.

Case Description: A 68-year-old woman with SLE and no prior kidney involvement was referred to the nephrology clinic for suspected lupus nephritis. Two months prior to evaluation, she developed edema and exercise intolerance, with workup notable for new proteinuria with urine protein-to-creatinine ratio (UPCR) of 3.8 g/g, mildly elevated serum creatinine (0.75 mg/dL) from baseline (0.60 mg/dL), low C4, and normal C3. There was no evidence of SLE or vasculitis on history or physical exam. Urine sediment microscopy was notable for many acanthocytes. Kidney biopsy was consistent with membranoproliferative glomerulonephritis and noted cryoglobulin deposits on electron microscopy. Further workup was notable for the presence of type II cryoglobulins (2%), elevated rheumatoid factor (140 IU/mL), negative hepatitis C virus antibodies, and normal serum free light chains. She was diagnosed with cryoglobulinemic vasculitis. Treatment with oral prednisone and mycophenolate mofetil resulted in improved proteinuria (UPCR 0.375 g/g) and decline in rheumatoid factor titers (59 IU/mL), however during her steroid taper the patient developed a purpuric leukocytoclastic rash, prompting the addition of rituximab. Her symptoms have markedly improved since receiving rituximab.

Discussion: While the most common glomerular disease affecting patients with lupus is lupus nephritis, many glomerular diseases are associated with SLE, including lupus podocytopathy, thrombotic microangiopathy, antiphospholipid antibody syndrome, and cryoglobulinemic vasculitis. Treatment of cryoglobulinemic vasculitis due to SLE is initially focused on treating the SLE itself, however with progressive or persistent disease, rituximab may be added.



SA-PO853

First Reported Association of Subcutaneous Panniculitis-Like T-Cell Lymphoma (SPTCL) and C3 Glomerulopathy with Renal-Limited Thrombotic Microangiopathy (TMA)

Muhammad U. Jahngir, Alaaeldin Mustafa, Ziauddin Ahmed, Iris J. Lee. *Temple University, Philadelphia, PA.*

Introduction: SPTCL constitutes <1% of peripheral T-cell lymphomas, with a 5-year survival of >80%. We report the first case of C3 glomerulopathy (C3G) with renal-limited TMA associated with SPTCL.

Case Description: A 71-year-old African American woman with history of hypertension, presented for a gradually spreading, hyperpigmented indurated plaque on the right thigh for 2 months, punch biopsy demonstrated SPTCL. In three weeks she developed similar lesions on both calves and right forearm. She was admitted for an elevated creatinine (2.74mg/dl; 0.82mg/dl baseline), lactate dehydrogenase (1471U/L), and uric acid (8.3mg/dl). Hemoglobin was stable, platelets and renal imaging were normal and urine protein-to-creatinine ratio showed new proteinuria (1410mg/g). She developed progressive renal injury requiring hemodialysis. Infectious and autoimmune work up remained negative except ANA of 1:320. Hemophagocytic lymphohistiocytosis and lupus were ruled out. Pulse dose steroids (250mg for 3 days) was given due to concerns for rapidly progressive glomerulonephritis. Kidney biopsy showed TMA with global glomerulosclerosis, 65% IFTA, without endocapillary hypercellularity, sclerosis or crescent formation. Immunofluorescence showed glomerular capillary wall and mesangium staining for C3 (4+). She completed 1.8g/m2 of fractionated cyclophosphamide (CYC) and 1.5mg/kg orally for 6 months. She received eculizumab, with a plan to continue pending complement work up. Despite therapy and improvement in urine output, she continued to be dialysis dependent.

Discussion: Direct association of complement activation with SPTCL is not reported, but there is growing evidence on complement dysregulation with tumorigenesis. As complement plays a role in immune surveillance against malignant cells, modified expression of complement proteins and regulators by tumor microenvironment can lead to over activation of complement pathways (1). We propose that SPTCL may contribute to complement dysregulation and resulted in renal-limited TMA in our patient. CYC was used to treat SPTCL and eculizumab for C3G and renal-limited TMA findings with success (2). Further understanding of mechanisms driving complement dysregulation with specific tumors are needed to explore potential treatment options.

SA-PO854

"Tag - You're It!" Use of Tagged Red Blood Cell (RBC) Scan to Localize Gross Hematuria

Fatima Ayub,[1] Wadhah M. Bin Homam,[1] Md R. Hasan,[2] Joseph H. Holthoff,[1] Nithin Karakala.[1] *[1]University of Arkansas System, Little Rock, AR; [2]Arkansas College of Osteopathic Medicine, Fort Smith, AR.*

Introduction: Tagged red blood cell (RBC) scan performed with technetium-99m-labeled autologous erythrocytes has proven to be a clinically useful tool for localizing bleeding in the gastrointestinal (GI) tract. However, it has never been used to identify a bleed in the kidneys or genitourinary tract (GU). We hereby present the first known case in which a tagged RBC scan was utilized to detect an occult GU source of bleeding.

Case Description: A 58-year-old African American female with an extensive history of gross hematuria and chronic severe anemia requiring monthly blood transfusions presented to the emergency department with complains of extreme fatigue. She has been having hematuria with the passage of blood clots for at least 25 years. She has had extensive hematological work up including bone marrow biopsy, angiograms and cystoscopies with no clear source of bleeding identified. She even underwent radical left nephrectomy with pathology revealing papillary necrosis and thin basement membrane disease. She was hypotensive and appeared extremely pale on presentation. Initial labs revealed a hemoglobin of 1.1 g/dl with surprisingly normal renal chemistry. After initial stabilization with multiple blood transfusions, the patient underwent CT angio abdomen and pelvis which did not show any evidence of active bleeding followed by an unremarkable cystoscopy. Patient was recommended to have the right nephrectomy as well which would have guaranteed lifelong dialysis dependency. In an attempt to identify the source of bleeding before any surgical intervention, she subsequently underwent a tagged RBC scan with technetium that did not show any evidence of renal bleeding, but instead showed increased radio tracer uptake in the urinary bladder wall representing the likely source of bleeding. This was followed by the placement of a percutaneous nephrostomy tube which drained clear urine versus the persistently bloody urine draining in the urinary bag further ruling out a renal source of bleeding and in turn salvaging her kidney.

Discussion: Tagged RBC scans are recommended to confirm gastrointestinal (GI) bleeding. We suggest this modality could be an alternative tool to localize bleeding in the kidneys and the GU tract, especially in difficult cases like ours, where there was no identifiable source of chronic hematuria. It proved to be an organ saver in her case.

SA-PO855

AA Amyloid Masquerading as C3 Glomerulonephritis

Arunava Paul, Varun Malhotra, Sandeep Magoon, Harlan C. Rust. *Eastern Virginia Medical School, Norfolk, VA.*

Introduction: C3 glomerulopathies are a group of rare kidney disorders characterized by complement dysregulation. We present a case of AA amyloidosis presenting as C3 glomerulonephritis.

Case Description: 55-year-old woman with a history of metastatic vulvar squamous cell carcinoma, presented with right lower extremity pain, right groin abscess and acute kidney injury (AKI). Baseline creatinine was 0.46 mg/dL and peaked at 6.9. No nephrotoxins were reported on history or review of medical records. Urinalysis was significant for WBC 21-50/hpf, RBC 0-2/hpf, protein 300 mg/dL, small blood and Urine protein to creatinine ratio was 9g/g. Hep C was positive with HCV RNA PCR-657,000. Complements were normal. Serological and paraproteinemia workup was negative. Kidney biopsy showed MPGN pattern with lesions suggestive of thrombotic microangiopathy (TMA) in 80% of capillary loops on light microscopy (LM) and immunofluorescence (IF) was positive for diffuse 3 + mesangial and capillary loop reaction for C3. No reaction to IgG, IgA, IgM, C1q, kappa, lambda or fibrin. Based on LM and IF findings, diagnosis of C3GN and TMA was made, although TMA itself is very uncommon. It was presumed that activation of alternate complement pathway was due to infection. There was minimal endocapillary proliferation which did not fit with typical C3GN with such high serum creatinine level. Electron microscopy (EM) eventually cleared the final diagnosis. EM revealed thin delicate randomly arrayed fibrils within the mesangial matrix and Congo Red and Thioflavin-T staining was positive in the mesangium and capillary loops. What was read as TMA were actually amyloid deposits. Mass spectrography revealed AA Amyloid.

Discussion: This patient presented with multiple challenges in terms of diagnosis. Hepatitis C related MPGN, Infection related glomerulonephritis and paraneoplastic related GN were all considerations. Light microscopy and IF were suggestive of C3GN with TMA which fit clinical picture (and all can present in a similar fashion). Eventually EM clinched the diagnosis. It proved to be a case of mistaken identity. EM is invaluable in making management decisions especially when LM and IF are not corroborating with clinical and pathological findings. Patient deterioration was rapid and did not pursue active treatment and chose hospice care.

SA-PO856

Collapsing Focal Segmental Glomerulosclerosis (FSGS) with APOL1 Gene Mutation in Adult-Onset Still Disease (AOSD)

Zain AlShanableh, Syeda B. Ahmad. *UPMC, Pittsburgh, PA.*

Introduction: Collapsing FSGS is a distinct variant characterized by hypertrophy and hyperplasia of podocytes with glomerular tuft collapse. Collapsing FSGS is mostly seen with HIV or COVID-19 and cases not attributed to HIV are often idiopathic. Amongst the other secondary causes are autoimmune diseases such as AOSD. We present a case of collapsing FSGS attributed to AOSD in a high risk patient with APOL1 gene mutation.

Case Description: Our patient is a 24-year-old incarcerated African-American male with history of left nephrectomy who presented with orbital and facial swelling. He reported subjective fevers for 4 to 5 months, 40 pound weight loss; pain, stiffness, and swelling in bilateral hands. On exam, patient was febrile to 101 Fahrenheit, tachycardic to 110 beats/minute with periorbital edema, swelling and tenderness of bilateral second-fourth proximal interphalangeal joints. Skin examination revealed a rash over his right eyelid and bilateral knuckles. Lab investigations revealed WBCs 13.1 with 82% neutrophils, creatinine 4.3 mg/dL, albumin 2.1 g/dL, AST 206 IU/L, ALT 292 IU/L, ALP 130 IU/L, total bilirubin 0.5, ferritin 1737 ng/mL, ESR 104, CRP 7.3, urine protein/creatinine ratio (UPCR) 14,450. Other than ANA positivity 1:80, his additional work up, including hepatitis profile, TB, COVID, HIV, syphilis, CMV, EBV, C3/C4, and Anti-CCP, was negative. Renal biopsy was consistent with collapsing FSGS with mild-moderate interstitial fibrosis. Malignancy screening was negative. Genetic testing for APOL1(G1 & G2) was positive.

Discussion: AOSD displays renal manifestations in 25% of cases including mesoangioproliferative glomerulonephritis. Collapsing FSGS secondary to AOSD is extremely rare. To the best of our knowledge, there have been four previously reported cases. In our reported case, the renal biopsy provided a histological diagnosis of collapsing FSGS. Serologic and infectious workup were negative and a diagnosis of AOSD was established after fulfilling the Yamaguchi criteria. Our case is the first reported case to describe collapsing FSGS attributed to AOSD in a high risk patient with APOL1 gene mutation. Further studies are needed to determine treatment options. Our patient was treated with losartan and prednisone 60mg daily with symptom improvement and UPCR downtrended to 8,153 within 2 months.

SA-PO857

Carfilzomib-Associated Thrombotic Microangiopathy with Kidney Infarction Treated with Eculizumab

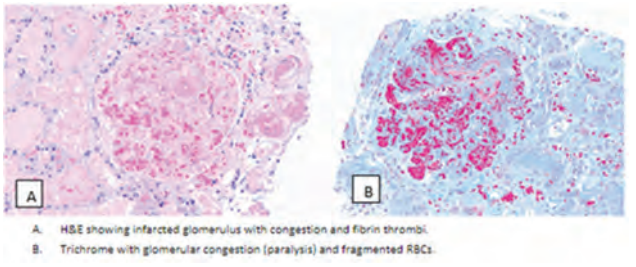
Kristen L. Pietrzyk, John Mowrey, Natalie M. Beck, Kuang-Yu Jen, Nasim Wiegley. *University of California Davis, Davis, CA.*

Introduction: Thrombotic microangiopathy (TMA) results from endothelial cell injury that can lead to kidney injury. Drug-induced TMA (DITMA) is a rare but serious adverse effect of certain medications, including carfilzomib, a proteasome inhibitor used for multiple myeloma (MM). Parenchymal kidney infarction is a rare and severe complication of TMA, which can lead to significant acute kidney injury (AKI). We report a case of kidney infarction with anuric AKI associated with carfilzomib use.

Case Description: A 66 yo White woman with refractory IgG lambda MM began carfilzomib-based therapy. Kidney function was stable until 6 months after starting carfilzomib, when she experienced rapid decline in urine output and AKI with a creatinine of 7.4 mg/dL (baseline 0.6 two weeks prior), with thrombocytopenia and anemia. Within 2 days she was anuric and required hemodialysis (HD). Labs showed low haptoglobin and high lactate dehydrogenase, suggesting microangiopathic hemolytic anemia. ADAMTS-13, C3, C4, E. coli Shiga-like toxins were normal. A kidney biopsy confirmed TMA with fibrin thrombi affecting glomeruli and arterioles, plus parenchymal kidney

infarction. (Fig 1) Carfilzomib was discontinued. Despite a negative complement genetic panel, eculizumab was started for severe TMA. Kidney function slowly improved, and HD was discontinued after 3 months.

Discussion: DITMA can be a rare but life-threatening complication of anti-cancer therapies. Carfilzomib has been associated with TMA. Although the exact mechanism is not fully understood, it is thought that Carfilzomib causes endothelial injury leading to TMA. Management of carfilzomib- associated TMA with kidney infarction involves prompt discontinuation of the drug. In severe cases, anti-complement therapy can be considered. A high index of suspicion is needed when caring for patients on this agent, as prompt recognition and management are essential for optimal patient outcomes.



A. H&E showing infarcted glomerulus with congestion and fibrin thrombi.
B. Trichrome with glomerular congestion (paralysis) and fragmented RBCs.

SA-PO858

Monoclonal Gammopathy of Renal Significance Presenting as Cryoglobulinemic Glomerulonephritis

Shirley Botros, Emmanuel A. Aydin-Ghormoz, Swati Mehta, Krishnakumar D. Hongalgi. *Albany Medical College, Albany, NY.*

Introduction: Monoclonal gammopathy of undetermined significance (MGUS) is a premalignant plasma cell disorder characterized by serum monoclonal protein <3g/dL, clonal plasma cells <10% on bone marrow biopsy, and absence of end-organ damage. Treatment is not recommended. When monoclonal immunoglobulin causes kidney damage, monoclonal gammopathy of renal significance (MGRS) is diagnosed and treatment involves chemotherapy. We describe a patient with known MGUS presenting with AKI and cryoglobulinemic glomerulonephritis (CG) secondary to development of MGRS.

Case Description: A 73 year-old-man with CKD stage 3, type 2 DM, chronic microscopic hematuria, and MGUS presented with AKI. Previous CKD workup showed 0.5g/day proteinuria, positive ANA, low C4, positive rheumatoid factor, and negative dsDNA and ANCAs. He had elevated free kappa light chains on SPEP and bone marrow biopsy confirmed IgM MGUS. CKD and proteinuria were attributed to diabetic kidney disease. Work-up of chronic hematuria was unrevealing. He presented 8 month later with fatigue, dyspnea, epistaxis, lower extremity rash, and hematuria with Cr 2.2 mg/dL (baseline 1.7) and 24 hour urine protein 3.5g. Serology was positive for cryoglobulin and negative for Hepatitis B, C, and HIV. Kidney biopsy showed diffuse, focally crescentic mixed cryoglobulinemic glomerulonephritis, likely type II, with focal leukocytoclastic vasculitis, focal severe arteriosclerosis, and moderate to severe interstitial fibrosis and tubular atrophy. He underwent 5 sessions of plasmapheresis, IV rituximab, and induction with oral steroids. Symptoms resolved and Cr improved to 1.9 mg/dL at discharge. He continued steroid taper, rituximab, and started IVIG. At last follow-up, he had full resolution of symptoms with stable Cr of 1.8 mg/dL.

Discussion: This case describes a patient with known MGUS presenting with AKI and CG secondary to MGRS. Treatment was rapidly initiated with improvement in kidney function. CG can be caused by a variety of infections, autoimmune diseases, and hematologic malignancies. Identification of the underlying cause is important and guides treatment. Prompt nephrology referral and biopsy in MGUS patients with elevated creatinine, proteinuria, and hematuria allows for diagnosis of MGRS and initiation of therapy to preserve kidney function, avoid long term dialysis, and reduce mortality.

SA-PO859

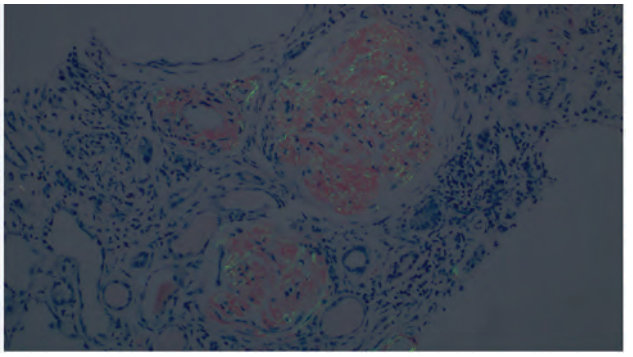
A Unique Presentation of AA Amyloidosis

Totini S. Chatterjee,[1] Amanda Tchakarov,[2] Peyman Dinarvand,[1] Carl P. Walther.[1] *[1]Baylor College of Medicine, Houston, TX; [2]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: While the overall prevalence of kidney amyloidosis in native kidney biopsies performed globally is 1.6%, in the United States, only 7% of these cases are due to AA amyloidosis. We describe a unique multisystem presentation of AA amyloidosis.

Case Description: A 64 year-old Pakistani woman with hypertension and goiter presented to the hospital for five days of abdominal pain and watery diarrhea, in addition to several weeks of worsening fatigue. She had goiter and tachycardia on exam, and laboratory studies demonstrated hyperthyroidism and non-oliguric kidney failure with 8.8 g protein in a 24 hour urine collection. Thyroid ultrasound showed diffuse fatty infiltration; kidney and urinary tract ultrasound was unremarkable. Kidney histology showed glomerular mesangial expansion with eosinophilic matrix and substantial fibrosis. Congo red stain revealed amyloid deposition in glomeruli, vessels, and the tubulointerstitium, identified as amyloid A with immunohistochemistry. Thyroid histology showed adipocytes with entrapped benign thyroid follicles (diffuse lipomatosis) and amyloid deposits in vessel walls by Congo red stain.

Discussion: AA amyloidosis is caused by extracellular deposition of serum amyloid A protein—a hepatic acute phase reactant—in tissues, and can occur in many chronic inflammatory conditions. Proteinuric kidney disease is a common presentation of AA amyloidosis; amyloid goiter is an uncommon presentation and associated hyperthyroidism is rare. Our patient's presentation with amyloid goiter, hyperthyroidism, and kidney failure has not previously been reported to our knowledge. Treatment of AA amyloidosis largely depends on identification of an inciting chronic inflammatory disease; however, extensive workup did not reveal a cause in our patient. She was initiated on hemodialysis for kidney failure and treated with beta blockade and methimazole for hyperthyroidism.



SA-PO860

Membranoproliferative Glomerulonephritis: A Rare Presentation in Systemic Sclerosis

Batoul Dekmak, Emmanuel A. Aydin-Ghormoz, Krishnakumar D. Hongalgi, Swati Mehta. *Albany Medical College, Albany, NY.*

Introduction: Systemic sclerosis (SSc) is a chronic autoimmune condition that can affect multiple organ systems. Renal involvement in SSc can range from asymptomatic reduction of GFR to life-threatening scleroderma renal crisis (SRC). Membranoproliferative glomerulonephritis (MPGN) is a rare and under-investigated renal manifestation of SSc. MPGN is a histological pattern of glomerular injury consisting of mesangial hypercellularity and proliferation of glomerular capillary walls with subsequent formation of new basement membrane. Although MPGN can be caused by a variety of primary and secondary conditions, descriptions of its association with SSc are limited. We present a unique case of MPGN as a manifestation of systemic sclerosis in an adult patient, highlighting the challenges of diagnosis and management of MPGN in the context of SSc.

Case Description: A 64-year-old woman with a history of SSc, controlled hypertension, Raynaud's syndrome, and chronic kidney disease presented to our hospital with acute kidney injury and elevated blood pressure. Laboratory tests showed AKI, proteinuria, microscopic hematuria, and low complement levels. He did not meet the Scleroderma Clinical Trials Consortium Scleroderma Renal Crisis Working Group diagnostic criteria for SRC. Serologies were unrevealing for SLE and hepatitis B and C. No paraprotein was detected. A renal biopsy revealed immune complex-mediated glomerulonephritis (ICGN) with an MPGN pattern. The patient was started on mycophenolate mofetil (MMF) and showed improvement in renal function and complement levels.

Discussion: This case represents, to our knowledge, the second reported case of MPGN associated with SSc. It emphasizes the importance of understanding the various renal manifestations of SSc in patients with this condition and AKI, and the importance of considering diagnoses other than SRC. MPGN can be immune complex-mediated or complement-mediated, with specific complement levels indicating the pathway involved. Treatment depends on the underlying cause and may involve immunosuppressive agents for underlying autoimmune disease, chemotherapy for hematologic malignancies, or antimicrobials for systemic infection. In this case, the patient showed improvement with MMF therapy. Prompt evaluation and intervention are crucial to prevent permanent kidney damage in SSc patients with renal involvement.

SA-PO861

A Rare Case of ANCA-Negative Pauci-Immune Necrotizing Glomerulonephritis

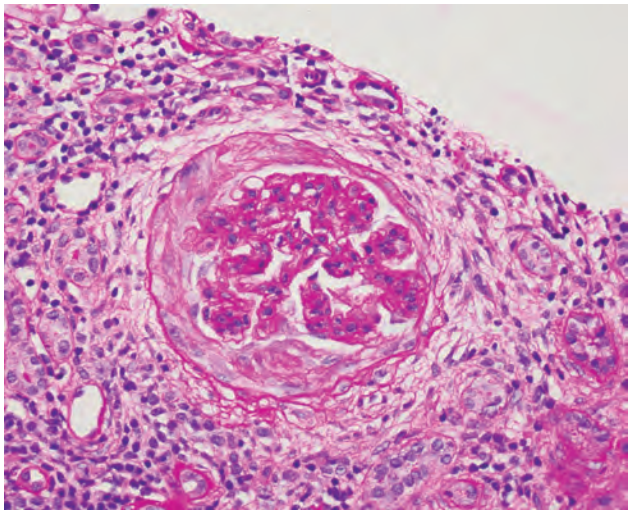
Abdullah Jalal, Ignacio A. Portales Castillo. *Washington University in St Louis, St Louis, MO.*

Introduction: Pauci-immune necrotizing glomerulonephritis (PING) is the most common subtype of crescentic glomerulonephritis accounting for 80% of cases. Among these, 90% have an association with ANCA antibodies. However, 2-3% of patients can have PING in the absence of ANCA Antibodies. Thus far, data on this clinical entity has been limited to few case reports and series. Herein we present a rare case of ANCA-negative Pauci-Immune Glomerulonephritis (AN-PING).

Case Description: 47 year old undomiciled male with past medical history of CKD3B, polysubstance use disorder, untreated hepatitis C, presented with lower back pain. Recently had MRSA bacteremia complicated by diskitis/vertebral osteomyelitis and epidural abscess treated non-operatively with daptomycin. Unfortunately patient later left AMA without antibiotics or outpatient follow-up. On this admission patient's imaging showed stable vertebral osteomyelitis/diskitis with interval decrease in epidural abscess size. Treated non-operatively with ceftaroline and pain management. During

hospitalization patient developed an AKI with Cr 1.65 mg/dL on presentation (recent baseline Cr 1.3-1.5 mg/dL) which rapidly peaked to Cr 3.6 mg/dL over the next 7 days. Initial concern was for acute interstitial nephritis from antibiotics vs infection-related GN. Notable labs include 24 hour UPCR 282 mg; UA: >50 RBCs, 0-5 WBCs. On urine microscopy, numerous isomorphic RBCs seen with few acanthocytes, no RBC/WBC or granular casts. Immunologic workup revealed normal complement levels (C3 94 mg/dL, C4 26 mg/dL), negative ANA, ANCA, Anti-GBM, cryoglobulin levels. Renal biopsy performed revealed pauci-immune focal crescentic glomerulonephritis. There was consideration to starting immunosuppression with corticosteroids; however, patient's Cr spontaneously down trended on supportive management with IV antibiotics (ceftaroline). On discharge patient's creatinine was 1.6 and 1.2 on follow-up 3 months later.

Discussion: AN-PING is rare, poorly recognized clinical entity among crescentic glomerulonephritis. Primarily related to its negative serology, AN-PING is often diagnosed late on renal biopsy. This delayed diagnosis has resulted in AN-PING patients having a worse prognosis and higher mortality relative to ANCA-positive GN. Treatment of AN-PING is challenging due to its association with Infection and malignancy (20%), and must be approached on a case-by-case basis.



SA-PO862

Secondary IgA Nephropathy as Red Herring in a Case of AKI

Emmanuel A. Aydin-Ghormoz, Andrea R. Lightle, Mauricio Monrroy. *Albany Medical College, Albany, NY.*

Introduction: Liver disease, and particularly alcoholic cirrhosis, is the most common cause of secondary IgA Nephropathy (IgAN), with 50-90% of cirrhotic patients exhibiting glomerular IgA deposition. Despite this, <10% of adult patients show clinical evidence of glomerular kidney disease. We report a case of ATN with underlying diabetic kidney disease and microscopic hematuria due to cirrhotic IgAN.

Case Description: A 65-year-old man with history of type-2 diabetes mellitus and hypertension presented to our hospital after outpatient lab work showed elevated creatinine. His diabetes was managed with insulin. He had been prescribed metformin 6 months earlier but discontinued it 3 weeks before presentation due to severe diarrhea, which had partially resolved after cessation. He denied any known history of kidney disease and did not use NSAIDs. He did report heavy alcohol use for many years. Serum creatinine level was 3.7mg/dL with unknown baseline. UA was active with 3+ protein, 50-100 RBCs/HPF, and 0-5 coarse granular casts/HPF. He had ascites with nodular contour of the liver and an atrophic left kidney on imaging. Paracentesis revealed SAAG >1.1 and ascites total protein 1.6g/dL. Creatinine remained stable. ANA, dsDNA, C3, C4, cryoglobulins, ANCAs, and hepatitis panel were all negative. Serum immunofixation revealed no paraprotein. Right kidney biopsy was performed and showed ATN, significant mesangioproliferative IgA deposition, diabetic and hypertensive nephropathy with severe arteriosclerosis and arteriolar hyalinosis, and secondary FSGS. His acute rise in creatinine was attributed to ATN, hematuria and proteinuria were explained by glomerular accumulation of IgA, while FSGS was attributed to diabetic Kimmelstein-Wilson nodule formation and segmental scarring due to immune complex deposition. Kidney function slowly worsened with development of uremic symptoms, requiring initiation of hemodialysis.

Discussion: Decreased hepatic clearance of IgA complexes is the suspected etiology of secondary IgAN in patient with liver cirrhosis. Despite its infrequent presentation, this diagnosis should be suspected in cirrhotic patients presenting with AKI and active UA, with the decision to perform kidney biopsy based on the clinical presentation. Regretfully, our patient's biopsy showed advanced chronic changes due to DM, HTN, and secondary FSGS, and progression to ESRD was inevitable.

SA-PO863

Complex Clinical Interplay: A Case of Systemic Lupus Erythematosus Coexisting with Type II Cryoglobulinemia

Madison M. Ladines, Salem Vilayet, Waleed A. ElSheikhMohammed, Tibor Fulop. *Medical University of South Carolina, Charleston, SC.*

Introduction: The coexistence of Systemic Lupus Erythematosus (SLE) and cryoglobulinemia, characterized by the presence of cryoglobulins in the serum, represents a rare and challenging clinical scenario. This report highlights a case of a 32-year-old female with both conditions, presenting with acute kidney injury.

Case Description: A 32-year-old African American female with SLE and Type II cryoglobulinemia presented with severe shortness of breath, kidney failure, and pericardial effusion. Initial lab work revealed acute kidney injury (creatinine: 0.6 mg/dL to 2 mg/dL in 3 weeks). Treatment included azathioprine, prednisone, and hydroxychloroquine (methotrexate discontinued due to transaminitis). Her condition deteriorated with increased shortness of breath and hemoptysis. Lab findings: positive antinuclear antibodies, kappa-restricted IgM monoclonal protein (Type II cryoglobulin with monoclonal IgM kappa and polyclonal IgG), negative hepatitis panel, and red blood cells in urine. Kidney biopsy showed hyaline pseudo-thrombi and subendothelial/mesangial deposits on electron microscopy. Subsequently treated with therapeutic plasma exchange and cyclophosphamide infusions. Discharged with a stable creatinine level (0.9 mg/dL) on rituximab, hydroxychloroquine, and prednisone.

Discussion: The intersection of SLE and Type II Cryoglobulinemia presents a complex clinical picture with multiple implications. While studies suggest that cryoglobulinemia in SLE patients does not necessarily correlate with severe complications unless coupled with cryoglobulinemic vasculitis, our patient developed biopsy-proven lupus cryoglobulinemic glomerulonephritis, indicating systemic involvement. This case underscores the critical need for kidney biopsy in lupus management to target therapy for optimal outcomes.

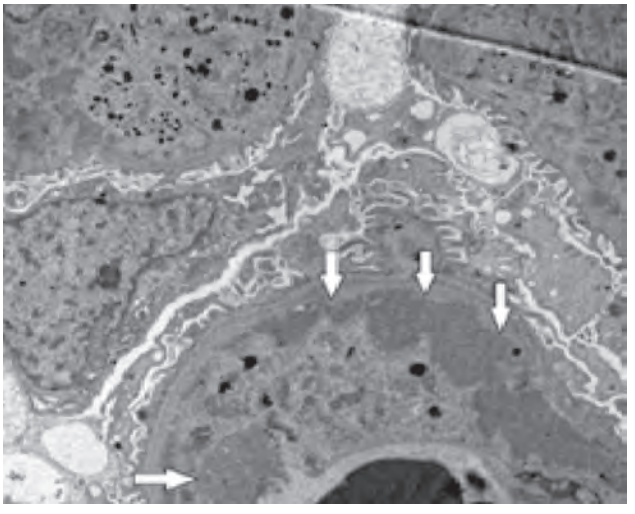


Figure 1: Electron Microscopy of glomeruli notable for subendothelial and mesangial deposits.

SA-PO864

Renal Riddles: Acute Interstitial Nephritis in Newly Diagnosed HIV

Amulya Rajagopal, Ruchi J. Sahota, James Hanna, Vivek Soi, Mark D. Faber, Lalathaksha Murthy Kumbar. *Henry Ford Hospital, Detroit, MI.*

Introduction: Acute interstitial nephritis (AIN) is an inflammatory process often triggered by medications, infections, autoimmune diseases, or idiopathic factors. Interstitial nephritis can occur as a direct consequence of HIV infection, but cases demonstrating this through exclusion of other etiologies are rare. We present a case of acute interstitial nephritis overlying non-collapsing focal segmental glomerulosclerosis (FSGS) in a patient with newly diagnosed HIV.

Case Description: A 51 year old African American male presented with hypertensive emergency along with 3 days of lower extremity edema, cough, dyspnea, and fatigue. Significant labs included: Cr 4.80 mg/dl (unclear baseline), UA with blood and > 500 protein, UPCR 9.9 g/g. Serology workup of nephrotic syndrome revealed ANA 1:640, ds-DNA 1:20, C3 low. Hepatitis panel was negative. HIV-1 positive, with viral load < 30 copies/mL, CD4 547, and Treponemal IgG with nonreactive RPR. Renal ultrasound showed bilateral increased renal echogenicity. Renal biopsy revealed primary FSGS non-collapsing variant and AIN with plasma cell rich infiltrate. Treatment with highly active antiretroviral therapy (HAART) was initiated. One month later, patient was readmitted with right cranial nerve (CN) III and VI palsy. MRI brain revealed possible new meningioma or inflammatory process. Repeat serology showed C3 improved, elevated IgG4, normal SSA/Ro and SSB/La, elevated rheumatoid factor, cerebrospinal fluid pleocytosis of mononuclear cells, and elevated IgG index and oligoclonal bands. Restaining of prior renal biopsy was negative for IgG4-related disease. Patient was started on corticosteroids for possible inflammatory neurologic process. Follow-up visits noted improvement in Cr < 1.0 mg/dl with continued nephrotic range proteinuria despite treatment.

Discussion: This case underscores the complexity of diagnosis in the presence of, autoimmune markers, HIV infection, and overlapping clinical features. The diagnosis of AIN occurred prior to initiation of HAART or any other medications. The patient's renal function showed initial improvement with HAART, but a more significant improvement was observed upon the initiation of corticosteroid treatment. The recommended treatment for HIV-associated interstitial nephritis involves initiating HAART, while the efficacy of corticosteroids in this condition remains uncertain.

SA-PO865

Human Immunodeficiency Virus-Associated Lupus-Like Nephritis: An Undetectable Viral Load and Negative Lupus Serology

Muhammad Z. Khan, Jason M. Kidd, Kennerly C. Patrick. Katz Family Division of Nephrology and Hypertension. *Virginia Commonwealth University Health System, Richmond, VA.*

Introduction: HIV is a common cause of a wide array of kidney abnormalities including both glomerular and tubular disorders. HIV associated immune complex kidney disease (HIVICK) is a unique entity which includes lupus like nephritis which presents without classic serologic findings of lupus. We describe the case of a 29year old man with HIV who was diagnosed with lupus like nephritis without a diagnosis of lupus.

Case Description: A 29year old man with a history of HIV on anti-retroviral therapy (ART) and chronic kidney disease stage 4 presented with dyspnea and acute kidney injury. Pertinent labs included serum creatinine of 3.7 mg/dl up from 2.7 mg/dl and urine dipstick positive for hematuria and proteinuria. Urine microscopy had acanthocytes. Spot urine protein creatinine ratio was 0.7 g/g. A broad serologic workup was performed which was unremarkable (Table). HIV viral load was undetectable. A kidney biopsy was performed. Mesangial expansion and hypercellularity was noted without crescents. There was patchy tubular atrophy and interstitial fibrosis. Immunofluorescence staining pattern was positive for Ig (Immunoglobulin) A, IgG, IgM, C (complement)1q, and C3. Electron microscopy showed multiple subepithelial and mesangial electron dense deposits. A diagnosis of lupus like glomerulonephritis was made. Given the undetectable viral load kidney function was monitored closely without any active pharmacologic intervention.

Discussion: We present the case of HIV related immune complex glomerulonephritis. This case is unique because lupus like nephritis developed despite an undetectable HIV viral load and negative lupus serologies. The pharmacologic therapy in such cases is a subject for research. The optimal treatment remains unknown as of yet.

Pertinent serologic markers

Anti nuclear antibody (ANA)	-	cryoglobulin	-
C3	136 mg/dl (80-200)	rheumatoid factor	-
C4	30 mg/dl (10-50)	kappa/lamba	1.2 (0.2-1.6)

Efficacy of ANCA Autoantibody Clearance by High-Dose Immunoglobulins Prior to Plasma Exchange in Severe Pulmonary Renal Syndrome

Bjoern Tampe. *Universitatsmedizin Gottingen, Gottingen, Germany.*

Introduction: Plasma exchange rapidly depletes pathogenic anti-neutrophil cytoplasmic autoantibodies (ANCAs) and is considered for induction therapy in severe ANCA-associated vasculitis. The aim of plasma exchange is to remove putative disease mediators from the circulation, such as toxic macromolecules and pathogenic ANCAs.

Case Description: To our knowledge, we here provide the first report of applying high-dose IVIGs prior to plasma exchange and assessment of ANCA autoantibody elimination in a patient with severe pulmonary renal syndrome due to ANCA associated vasculitis. After high-dose application of intravenous immunoglobulins (IVIGs) prior to plasma exchange treatment, efficacy of myeloperoxidase (MPO)-ANCA autoantibody elimination was substantially increased, associated with rapid clearance of MPO-ANCA autoantibodies. High-dose IVIGs resulted in marked reduction of MPO-ANCA autoantibody levels and did not directly affect autoantibody clearance by plasma exchange itself, as also confirmed by comparable MPO-ANCAs in the exchange fluid relative to serum levels. Moreover, measurements of serum creatinine and albuminuria confirmed that high-dose IVIGs were well tolerated and did not exacerbate kidney injury.

Discussion: We are aware that our observations require validation in larger study populations, that kinetics may have also been affected by previous induction therapy, pretreatment time of IVIGs or ANCA autoantibody subtypes, and that the exact mechanisms contributing to our observations require further investigation. Furthermore, the immunoassay is not fully accurate due to values higher than the manufacturer's reference range. Nevertheless, this ANCA level-driven approach might contribute to novel therapeutical strategies to increase efficacy of pathogenic ANCA autoantibody clearance in severe AAV.

SA-PO867

Extreme Fatigue as the Only Complaint in Double-Positive Anti-Glomerular Basement Membrane (GBM) and ANCA Disease: An Unusual Presentation

Juan J. Cintrón-García, Kavitha Vellanki, Maria M. Picken, Aseel Zghayer. *Loyola University Health System, Maywood, IL.*

Introduction: Acute glomerulonephritis (GN) due to anti-glomerular basement membrane (GBM) disease is extremely rare with reported incidence of one per million. Double positive disease with anti-GBM phenotype on kidney biopsy and ANCA positive titers on serology is reported to present in older population with high relapse rates compared to anti-GBM disease alone. Extreme fatigue as the only presenting complaint is uncommon, here we present one such case.

Case Description: 76 year old female who leads an active life-style presents to her PCP's office with extreme fatigue of 3 weeks duration. Initial work-up revealed AKI with serum creatinine of 4.19 mg/dL. She was admitted for further evaluation. Urinalysis was +ve for large blood, >10 RBC/HPF, and protein. She received IV fluids, serology for GN work up was sent and discharged home. She was re-admitted later as myeloperoxidase (MPO)-ANCA titers were reported positive. Kidney biopsy revealed cresenteric GN with 85% glomerular involvement. Treatment was initiated with pulse steroids, rituximab and plasma exchange for ANCA vasculitis till kidney biopsy findings confirmed anti GBM disease (Figure 1), anti-GBM titer results following a few days after kidney biopsy. Response to treatment is shown in Figure 2.

Discussion: Double-positive vasculitis with anti-GBM and ANCA is rare. Our patient did not have any lung involvement. While Rituximab alone for induction is not commonly reported in double positive disease, our patient was extremely frail and hence did not receive cyclophosphamide. A high degree of clinical suspicion for acute GN is needed when elderly patients present with AKI and an abnormal UA, extreme fatigue could be the only complaint.

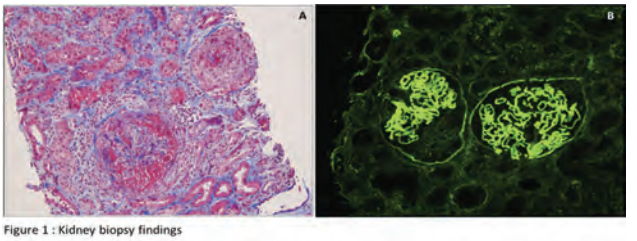

Figure 1 : Kidney biopsy findings

A - Trichome stain showing glomeruli with crescents and fibrinoid necrosis (85% cellular crescents noted).

B - Diffuse linear IgG GBM deposition by immunofluorescence.

The Effects of the Intensified B Cell Depletion Therapy in ANCA Vasculitis with Extremely Severe Renal Impairment Compared with Conventional Immunosuppression

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy.*

Background: Rituximab (RTX) has shown to be an effective induction treatment for ANCA associated vasculitides (AAV) in both newly diagnosed and relapsing patients. However, the role of RTX in the management of the most severe cases of AAV remains to be fully elucidated. The aim of this study was to assess both safety and efficacy of an intensified B-cell depletion therapy (IBCDT) protocol, including RTX, cyclophosphamide (CYC), and methylprednisolone pulses without additional maintenance immunosuppressive therapy in a cohort of 15 AAV patients with the most

severe features of AVV renal involvement (as <15 ml/min GFR and histological findings of paucimmune necrotizing glomerulonephritis with more than 50% crescents of non-sclerotic glomeruli at the renal biopsy)

Methods: Results of the IBCDT regimen have been compared to those obtained in a control cohort of 10 patients with AAV treated with a conventional therapy regimen based on oral CYC and steroids followed by a prolonged maintenance therapy with azathioprine (AZA). Plasma exchange was equally employed in the study and the control group.

Results: Complete clinical remission (BVAS 0) was observed at 6 months in 14 of 15 patients treated with IBCDT (93%). All cases who achieved a complete clinical remission experienced a depletion of peripheral blood B cells at the end of therapy. Of the 10 dialysis dependent patients at onset, 6 subjects (60%) experienced a functional recovery allowing the suspension of dialysis treatment. When compared to the control group, no statistically significant difference was observed in patients treated with IBCDT in terms of overall survival, 6-month therapeutic response rate, and 6-, and 12-month functional renal recovery. The cumulative total dose of CYC in the case group was on average 1 g/patient while in the control group on average 8.5 g/patient ($p = 0.00008$).

Conclusions: Despite the retrospective design and relative limited sample size, IBCDT appeared to be safe and had the same efficacy profile when compared to the conventional therapy with CYC plus AZA in the management of the most severe patients with AAV. Additionally, this avoided the need of prolonged maintenance therapy for long, and limited the exposure to CYC with consequent reduced toxicity and drug-related side effect rates.

SA-PO869

Non-Hepatitis C Virus (HCV)-Related Mixed Cryoglobulinemic Vasculitis with Biopsy-Proven Renal Involvement: The Effects of Rituximab

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy*.

Background: Remarkable results in severe HCV-related cryoglobulinemic vasculitis have been obtained with Rituximab. Details of the clinical characteristics and effective treatment of non HCV-related cryogloulinemic syndromes are presently lacking.

Methods: This paper reports on a prospective single-Center open study aimed at evaluating the clinical presentation and effects of Rituximab administered alone in patients with severe non HCV-related cryoglobulinemic syndrome.

Results: The study group included 11 patients followed for at least 6 months. Three patients had type I cryoglobulinemia, 6 had type II and the remaining 2 patients had type III. Mean cryocrit was 2.5%. Four out of 11 patients had symptomatic sicca complex with anti-SSA (Ro)/anti SSB (La) antibodies. All 11 patients presented with biopsy-proven renal involvement, 4 out of 11 with leukocytoclastic vasculitis, and 8 with involvement of the peripheral nervous system. Renal biopsy revealed diffuse membranoproliferative glomerulonephritis (MPGN) in 9 out of 11 patients. Extracapillary proliferation and necrosis of the glomerular tuft was observed in 1 of these 9 cases. Interstitial nephritis together with mesangial expansion and capillary immune deposits were observed in 1 patient. Prevalent interstitial fibrosis and glomerular sclerosis were detected in the remaining case. Patients underwent treatment with rituximab alone. After 6 months we observed a remarkable improvement in the necrotizing skin ulcers and a substantial amelioration of the electrophysiological parameters of motor and sensory peripheral neuropathy. Improvement in both renal function (from 2.8 to 1.4 mg/dl, $p < 0.001$) and proteinuria (from 4.2 g/24 to 0.4 g/24 h, $p < 0.001$) was found in 10 out of 11 patients, while 1 could not be fully treated because of a severe infusion reaction and sudden development of anti-Rituximab antibodies. Good renal response was confirmed at the end of follow-up (38.4 months). Three patients had a relapse at 6, 12, and 48 months, respectively.

Conclusions: In our cohort the administration of 4 once-weekly infusions of Rituximab followed by 2 more infusions after 1 and 2 months proved to be effective in the management of these rare patients.

SA-PO870

Safety and Efficacy of Avacopan in Patients 65 Years and Older with ANCA-Associated Vasculitis

Duvuru Geetha,[1] Christian Pagnoux,[2] Sebastian E. Sattui,[3] Peter A. Merkel,[4] David R. Jayne.[5] ADVOCATE Study Group. *[1]Johns Hopkins University, Baltimore, MD; [2]University of Toronto, Toronto, ON, Canada; [3]University of Pittsburgh, Pittsburgh, PA; [4]University of Pennsylvania, Philadelphia, PA; [5]University of Cambridge, Cambridge, United Kingdom.*

Background: Older adults are at increased risk of glucocorticoid (GC)-related toxicity; minimization of GCs is a major focus for treatment of patients with ANCA-associated vasculitis (AAV). Although AAV especially affects older adults, many studies have excluded patients >75 years (y). In the Phase 3 ADVOCATE trial of avacopan, there was no exclusion criterion for maximum participant age.

Methods: This post hoc analysis reports safety and efficacy of avacopan compared to a prednisone taper in the subgroups of patients 65-74y (N=109) and ≥75y (N=51).

Results: In both studied age and treatment groups, a similar proportion of patients (69.4-73.1%) achieved remission at week 26 (**Table 1**). In the 65-74y age group, sustained remission rates at week 52 were 55.1% in the prednisone arm and 65.0% in the avacopan arm. Relapse rates were 18.8% in the prednisone arm and 12.3% in the avacopan arm. The total all-source median GC dose was 5.3x higher in the prednisone vs avacopan arm. Serious adverse events (SAEs) occurred in 22/49 patients (45%) in the prednisone arm (2 deaths) and 25/60 patients (42%) in the avacopan arm (2 deaths). In the ≥75y age group, sustained remission rates at week 52 were 56.0% in the prednisone arm and 65.4% in the avacopan arm. Relapse rates were 20.8% in the prednisone arm and 3.8% in the avacopan arm. Median GC dose was 4.8x higher in the prednisone vs avacopan arm. SAEs occurred in 14/25 patients (56%) in the prednisone arm and 17/26 patients (65%) in the avacopan arm. Other results including renal and quality of life outcomes are in **Table 1**.

Conclusions: A subgroup analysis of patients ≥65y demonstrated similar trends of efficacy and safety of avacopan as in the overall ADVOCATE trial, including reductions in GC-related toxicities, supporting a role for avacopan in the treatment of older patients with AAV.

Efficacy and Safety Experience with Avacopan Beyond 52 Weeks in the Early Access Program (EAP)

Federico Alberici,[1] Carlo Salvarani,[2] Christine Chan,[3] Achim Obergfell,[4] Tamara Popov.[4] *[1]Universita degli Studi di Brescia, Brescia, Italy; [2]Azienda Unita Sanitaria Locale - IRCCS Tecnologie Avanzate e Modelli Assistenziali in Oncologia di Reggio Emilia, Reggio Emilia, Italy; [3]CSL Vifor, Redwood, CA; [4]Vifor Pharma Management Ltd, Glattbrugg, Switzerland*.

Background: Avacopan, a selective C5aR1 inhibitor, has demonstrated efficacy and safety over 52 weeks in patients with anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis. However, efficacy and safety data on avacopan beyond 52 weeks are limited. Here, we describe the experience with avacopan beyond 52 weeks from the EAP.

Methods: Safety data in patients with severe, active granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) within the EAP were recorded in a global safety database from Feb 2019 – Apr 2023. Adverse events (AE) included a lack of effect and other events (i.e., relapse or worsening of disease).

Results: A total of 19 patients were treated with avacopan beyond 52 weeks within the EAP. Average age was 47 years, with 13 patients (68%) diagnosed with GPA and 6 (32%) with MPA. The median duration of therapy was 17 months (range 12–45). A total of 9 AEs were recorded in 2 patients (10.6%) (Table 1). One vasculitis flare was recorded 6 months after avacopan initiation and coincided with an unintended dose reduction to 20 mg BID, due to a product supply issue during COVID. The event was well-managed with rituximab, with no additional use of glucocorticoids, and avacopan 30 mg BID was reinstated. No further cases of a lack of effect, worsening of disease, or disease relapse were reported. Data regarding concomitant medications did not indicate a decline in the patients' status during treatment. No treatment discontinuations due to AEs were recorded.

Conclusions: These results suggest that continuation of avacopan beyond 52 weeks is generally well-tolerated in patients with GPA and MPA and may be effective in terms of disease control. Limitations of this program include low patient number, potential underreporting, and incomplete data.

SA-PO872

Avacopan in Combination with Rituximab and Low-Dose Cyclophosphamide for Treatment of Severe ANCA-Associated Glomerulonephritis

Amrita Dhutia,[1,2] Maria Prendecki,[2] Fathima R. Shuaib,[1] Marie B. Condon,[1] Megan Griffith,[2,1] Jeremy B. Levy,[2,1] Nicholas R. Medjeral-Thomas,[2,1] Lina Nikolopoulou,[1] Tom Cairns,[1] Stephen P. McAdoo.[2,1] *[1]Imperial College Healthcare NHS Trust, London, United Kingdom; [2]Imperial College London, London, United Kingdom.*

Background: Avacopan is approved in the USA and Europe as a novel treatment for ANCA-associated vasculitis. There are limited data regarding avacopan use in those with severe renal disease, and of 'real-world' experience using avacopan in combination remission-induction regimens.

Methods: Prospective cohort study of patients with ANCA-associated glomerulonephritis (ANCA-GN) treated at a single centre in London, UK from December 2022. Data presented as median (+/- IQR) unless otherwise stated.

Results: To date, 27 patients with ANCA-GN have received avacopan (median age 58 years [range 24-90]; 22 *de novo* disease, 5 relapsing). *Baseline parameters*: BVAS 16 (IQR 12-19), CRP 61mg/dL (21-174), creatinine 258µmol/L (149-391), eGFR 19ml/min/1.73m^2 (12-39), uPCR 164mg/mmol (6-216). 21 patients had confirmatory kidney biopsy, with no predominant Berden class. *Immunosuppressive treatment*: 23 patients received combination induction treatment with rituximab (2g) and low-dose IV cyclophosphamide (median dose 2.2g [1.0-2.5]); 4 were treated with rituximab alone; 8 received adjunctive plasma exchange. *Glucocorticoid (GC) use*: The median dose of IV methylprednisolone was 0mg (0-500). 25/27 patients received oral prednisolone with median dose and duration of 270mg (210-420) and 8 days (7-16), respectively. *Outcomes*: The median duration of follow up is currently 2 months: 26/27 have achieved disease remission (BVAS =0; 1 patient had progressive eGFR decline). Improvements in renal parameters were as follows: creatinine 152µmol/L (125-257), eGFR 37ml/min/1.73m^2 (23-48), uPCR 42mg/mmol (15-281). In those who presented with eGFR ≤20ml/min/1.73m^2 (n=15), median eGFR improved from 13 (9-18) to 27 (12-39). *Adverse Events*: 2 infections occurred (uncomplicated UTI treated with oral antibiotics; LRTI requiring IV antibiotics). 1 patient developed transaminitis requiring drug cessation.

Conclusions: This early series suggests that avacopan is well-tolerated and facilitates GC minimisation in patients with active ANCA-GN, in a non-trial setting, and in combination with rituximab and low-dose cyclophosphamide. Renal recovery was favourable in those presenting with eGFR ≤20ml/min/1.73m^2. Ongoing analysis will examine long-term renal recovery in this subgroup.

SA-PO873

Avacopan in ANCA Vasculitis: A Real-World Experience

Faten Aqeel,[1] Reza Zonozi,[2] Abdallah Sassine Geara,[3] Sebastian E. Sattui,[4] Dustin Le,[1] Gabriel Sauvage,[2] Isabelle Ayoub,[5] Frank B. Cortazar,[6] Aisha Shaikh,[7] Andrew S. Bomback,[8] Colin Diffie,[7] Karina P. Guaman,[8] Ora Singer,[9] David H. Bulbin,[10] Jason C. George,[10] John Niles,[2] Duvuru Geetha.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Harvard University, Cambridge, MA; [3]University of Pennsylvania, Philadelphia, PA; [4]University of Pittsburgh, Pittsburgh, PA; [5]The Ohio State University, Columbus, OH; [6]St. Peter's Health Partners, Albany, NY; [7]Washington University in St Louis, St Louis, MO; [8]Columbia University, New York, NY; [9]University of Michigan, Ann Arbor, MI; [10]Geisinger Medical Center, Danville, PA.*

Background: Avacopan (AVP) is a recently approved adjunct therapy for remission induction of ANCA-associated vasculitis (AAV). Data on real-world use of AVP in AAV are lacking.

Methods: We performed a multi-center retrospective observational study of adult patients with AAV treated with AVP and collected clinical, treatment and outcome data. Data are presented as mean (±SD), median (IQR), or number (percent).

Results: Eighty patients were included. Mean age was 59 (17) years, 65% were female, 74% had MPO ANCA, and 95% had kidney involvement. AVP was used with rituximab ± cyclophosphamide in 95% of patients. AVP was started 8.8 (19.6) weeks after glucocorticoid initiation with 58 (73%) patients discontinuing prednisone 7.5 (18) weeks after starting AVP. At diagnosis, 19 (24%) patients had eGFR <15 with 8 dialysis dependent. Outcomes are summarized in Table 1. Among the 60 (75%) patients with hematuria at diagnosis, 70% had resolution of hematuria 14 (14) weeks after AVP initiation. Nadir proteinuria of 0.3 (0.1 – 0.7) g/g was achieved 10 (21) weeks after AVP initiation. The cumulative dose of IV methylprednisolone was 2.4 (1.4) g, and 12-week oral prednisone was 1.8 (1.1) g. At week 26, 5 of 39 (13%) patients remained on prednisone. AVP was stopped in 25 patients: 11 after 52 weeks, and 14 before 52 weeks due to adverse events. At a mean follow-up time of 8 (6) months, 5 had disease relapse, 7 had infections requiring hospitalization, 3 remained dialysis-dependent, and 3 died.

Conclusions: AAV patients treated with AVP have high clinical remission rates at weeks 26 and 52 and sustained improvement in eGFR.

Table 1. Outcomes of AAV patients treated with Avacopan

	Diagnosis	AVP initiation	Follow-up	
	T = 0 | N = 80	T = 8.8 (20) | N = 80	T = 26 | N = 59	T = 52 | N = 32
BVAS	13 (10 – 19)	6 (3 – 12)	0 (0 – 0)	0 (0 – 0)
uPCR, g/g	1.5 (0.3 – 2.7)	1.3 (0.3 – 2.3)	0.4 (0.2 – 1.1)	0.3 (0.1 – 0.7)
Hematuria	60 (75%)	37 (46%)	11 of 30 (37%)	3 of 10 (30%)
eGFR, mL/min/1.73m^2	47 (34)	42 (32)	59 (34)	62 (38)
ΔeGFR from baseline	-	-4.4 (19)	+8.3 (28)	+14 (29)
Clinical remission	-	-	54 (92%)	29 (91%)

Data are presented as mean (SD), median (IQR), or number (percent)Abbreviations: T = time in weeks; N = Number; BVAS, Birmingham Vasculitis Activity Score; eGFR, estimated glomerular filtration rate; uPCR, urine protein-to-creatinine ratio.

Pneumocystis jirovecii Pneumonia Prophylaxis in Patients with ANCA Vasculitis on Rituximab Maintenance Therapy

Faten Aqeel, Dustin Le, Duvuru Geetha. *Johns Hopkins University, Baltimore, MD.*

Background: Although an increased risk of Pneumocystis jirovecii pneumonia (PJP) has been reported in adults receiving rituximab, current evidence is lacking on the utility of PJP prophylaxis in AAV patients on maintenance rituximab therapy.

Methods: We performed an observational, single-center, retrospective study examining outcomes of patients with AAV on rituximab maintenance therapy with and without PJP prophylaxis. We included patients that were followed in our center from 6/1/2009-4/1/2023. Outcomes included PJP prophylaxis use, PJP infections, infections requiring hospitalizations, death, and end-stage kidney disease (ESKD). Outcomes were analyzed using T test, Fisher exact test, univariate, and multivariate logistic regression as appropriate.

Results: A total of 129 patients were included. The mean (SD) age was 62.5 (±16) years old and the mean (SD) follow-up was 7.2 (±5.4) years. 44% of patients received PJP prophylaxis, whereas 56% of patients did not. Trimethoprim-Sulfamethoxazole was used in 31% of patients, followed by Dapsone (7%), and Atovaquone (6%). In the PJP prophylaxis group, the mean (SD) duration of rituximab therapy was 3.6 (±2.5) years, and the mean (SD) prednisone dose was 0.66 mg (±1.87). In patients who did not receive PJP prophylaxis, the mean (SD) duration of rituximab therapy was 3.1 (±2.1) years, and the mean (SD) prednisone dose was 1.13 mg (±2.47). There were no PJP infections in the entire cohort. Lung involvement was associated with increased odds of PJP prophylaxis prescription (OR 4.09 [95% CI 1.8-9.82]). CD4 count <200 cells/mm^3 (n=5) and serum IgG level <500 mg/dL (n=32) were not associated with higher odds of PJP prophylaxis prescription (p=0.99 and p=0.08, respectively). PJP prophylaxis did not decrease infection rates requiring hospitalizations, ESKD, or death. Corticosteroid use was associated with increased rates of infections requiring hospitalizations (OR 5.75 [95% CI 2.00-16.92]) and death (OR 4.49 [95% CI 1.26-15.82]) even after adjustment for age, gender, and PJP prophylaxis use.

Conclusions: Regardless of use of PJP prophylaxis, PJP pneumonia was not observed in AAV patients receiving maintenance rituximab therapy. AAV patients with lung involvement were more likely to be on PJP prophylaxis. Additional studies are needed to confirm these findings to guide PJP prophylaxis use in AAV patients.

SA-PO875

EQUALISE Type B: Clinical Results of Itolizumab, a Novel Anti-CD6 Therapy, in Subjects with Lupus Nephritis

Kenneth Kalunian,[1] Sreejith Parameswaran,[2] Robert W. Levin,[3] Nelson P. Kopyt,[4] Stephen Connelly,[5] Eugene Sun,[5] Catherine Kim,[5] Maple M. Fung,[5] Manish Rathi.[6] *[1]University of California San Diego, La Jolla, CA; [2]Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India; [3]University of South Florida, Tampa, FL; [4]Lehigh University, Bethlehem, PA; [5]Equillium Inc, La Jolla, CA; [6]Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: Itolizumab is a first-in-class, non-depleting, monoclonal antibody against the co-stimulatory receptor CD6 that blocks its interaction with ALCAM, to inhibit T_{eff} cell activity and trafficking. It is being evaluated to treat immuno-inflammatory diseases where T cells play a central role, including active proliferative lupus nephritis (apLN). We present results from EQUALISE (Type B; NCT04128579), a Phase 1b study of itolizumab in subjects with apLN.

Methods: 17 adult subjects with apLN (ISN/RPS class III or IV with or without class V) were enrolled. All were treated with open-label itolizumab 1.6 mg/kg SC Q2W for up to 13 doses in combination with MMF (2-3g/d) and systemic corticosteroids (rapid taper to <prednisone 10mg/day by W10). Subjects had 12 weeks follow-up post dosing. Safety and efficacy were assessed.

Results: The median subject age was 34 years; 94% were female with 82% Asian; most subjects had class IV+V disease (47%). Mean duration of LN was 5.4 years with Baseline mean 24 hour urine protein of 4.9 g and eGFR of 104 ml/min/1.73m2. Treatment was completed in 11 subjects with 4 discontinuing early (3 due to adverse event (AE) and 1 due to physician decision) and 2 are still dosing. 88% of subjects experienced at least 1 AE, most common were peripheral edema and lymphopenia. At least 1 low lymphocyte count was reported by 7 subjects (41%). Serious AEs occurred in 2 subjects (12%), including dehydration and COVID-19, with none deemed related to study treatment. Based on the 14 subjects that completed/terminated the study and had a post-baseline measure, there was a median 72% reduction in spot urine protein creatinine ratio (UPCR), resulting in high partial and complete response (PR and CR) rates (FIGURE). These responses occurred as early as prior to Week 4 on study.

Conclusions: EQUALISE Type B demonstrates that subjects with proteinuric apLN had high CR and PR rates with rapid and deep reduction in UPCR when itolizumab was added to MMF and steroids. Further controlled studies are warranted in this population at high risk of disease progression and end stage kidney disease.

SA-PO876

Long-Term Safety and Efficacy of Voclosporin in Black Patients with Lupus Nephritis

Gabriel Contreras,[1] Matthew G. Baker,[2] Lucy S. Hodge,[2] Ernie Yap.[2] *[1]University of Miami Health System, Miami, FL; [2]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada.*

Background: Black patients with lupus nephritis (LN) are reported to have more severe disease, are often refractory to treatment, and have worse long-term outcomes. Voclosporin in conjunction with low-dose glucocorticoids and mycophenolate mofetil (MMF) has shown significant benefit across ancestries and classes of LN. Here we report outcomes on up to three years of follow-up in patients identifying as Black and treated with voclosporin during the global Phase 3 AURORA studies.

Methods: Key inclusion criteria for the parent AURORA 1 study included biopsy-proven LN, urine protein creatinine ratio (UPCR) ≥1.5 g/g (≥2 g/g for Class V) and estimated glomerular filtration rate (eGFR) >45 mL/min/1.73 m^2. Patients completing AURORA 1 were eligible to enter the AURORA 2 continuation study on the same blinded therapy of voclosporin or placebo in combination with MMF and glucocorticoids for an additional two years. Programmed complete renal response (CRR; UPCR ≤0.5 g/g, stable eGFR, low-dose steroids, and no rescue medication), partial renal response (PRR; reduction in UPCR of ≥50% from baseline) and safety were assessed in patients self-identifying as Black or mixed Black.

Results: Twenty-six of 179 (14.5%) and 19 of 178 (10.6%) patients identified as Black or mixed Black in the voclosporin and control arms of AURORA 1. Baseline characteristics were similar between arms. CRR rates at one year numerically favored voclosporin (46.2% vs 15.8%, OR 3.92 [CI 0.95, >9.99] p=0.0597) as did PRR rates (69.2% vs 47.4%, OR 2.62 [CI 0.72, 9.45] p=0.1422). Eighteen voclosporin-treated patients and seven control-treated patients in the Black subgroup continued into AURORA 2. Response rates at three years continued to numerically favor voclosporin (CRR, 44.4% vs. 14.3%, OR 4.17 [CI 0.41, >9.99] p=0.2276; PRR, 66.7% vs. 42.9%; OR 1.67 [CI 0.23, >9.99] p=0.6094). Greater reductions in mean UPCR were observed over the three-year period in the voclosporin arm (change from baseline -3.4 vs -1.5 g/g, p=0.0349). Mean eGFR levels remained stable and in the normal range over three years of treatment.

Conclusions: Black patients treated with a voclosporin-based regimen achieved higher rates of renal response than patients treated with MMF and glucocorticoids alone. For patients entering the continuation study, the response was largely durable for up to 3 years.

Comparison of Dual-Immunosuppressive Therapy and a Voclosporin-Based, Triple-Immunosuppressive Regimen for Lupus Nephritis: A Propensity Analysis of ALMS and AURORA 1

Ernie Yap,[1] Maria Dall'Era,[2] Matt Truman,[1] Lucy S. Hodge,[1] Neil Solomons.[3] *[1]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada; [2]University of California San Francisco School of Medicine, San Francisco, CA; [3]Neil Solomons Consulting Inc., Victoria, BC, Canada.*

Background: To understand the safety and efficacy of a voclosporin-based, MMF and glucocorticoid-sparing, triple immunosuppressive regimen as an initial approach to therapy in active lupus nephritis (LN) compared to conventional high-dose MMF and glucocorticoid regimens, we compared and analyzed clinical data in propensity-matched patients from ALMS and AURORA 1. We hypothesized that a voclosporin-based, triple immunotherapy approach would reduce exposure to toxicities associated with glucocorticoids and MMF, resulting in an improved safety profile without compromising efficacy.

Methods: Both studies enrolled participants with active LN. In ALMS, MMF was dosed to a target of 3 g/day with oral glucocorticoids initiated at a maximum dose of 60 mg/day and tapered every 2 weeks to 10 mg/day. In AURORA 1, participants received voclosporin 23.7 mg BID in combination with MMF at a target dose 2 g/day and oral glucocorticoids started at 25 mg/day and tapered to 2.5 mg/day by Week 16. Propensity matching generated 2 groups of matched patients based on demographic and disease characteristics. Safety and efficacy outcomes were assessed at 3 and 6 months.

Results: Propensity matching identified 96 pairs of participants with similar demographics and baseline disease characteristics. At 3 and 6 months, MMF and glucocorticoid exposure was more than 2-fold higher in ALMS than AURORA 1. Overall, fewer adverse events (AE) were observed in AURORA 1 across the majority of organ systems, including gastrointestinal, skin and subcutaneous tissues, endocrine, and psychiatric disorders, although more patients in AURORA 1 were reported to experience eGFR decrease; most reductions in eGFR were manageable by dose modification. The incidence of serious AEs was similar in both groups at 3 and 6 months. In the first 3 months, significantly more patients in AURORA 1 achieved >25% UPCR reduction from baseline (81.3% AURORA 1, 65.6% ALMS; p=0.011); the proportions of patients achieving UPCR ≤0.5 mg/mg and >50% UPCR reduction from baseline were numerically greater in the voclosporin arm; the differences were not statistically significant.

Conclusions: The above findings affirm the KDIGO 2023 recommendation that a voclosporin-based, triple-immunotherapy regimen should be considered as initial therapy in active LN.

SA-PO878

Results of Single-Arm, Phase 1b Study of Anti-C1q Treatment (ANX009) Show that the Classical Pathway Is a Key Driver of Complement Activation and Consumption in Patients with Active Lupus Nephritis

Min Bao,[1] Juan Lichauco,[2] Hsiang Chen,[3] Harold Gomez,[4] Michael L. Tee,[5] Caroline Arroyo,[6] Joung-Liang Lan,[7] Yao-Fan Fang,[8] Edmund Chang,[1] Noosha Yousefpour,[1] Julian Low,[1] Qing Chang,[1] Jeannette Osterloh,[1] Paul Manser,[1] Ann Mongan,[1] Ted Yednock,[1] Dean R. Artis,[1] Henk-Andre Kroon,[1] Yaisa Andrews-Zwilling,[1] Maria Dall'Era.[9] *[1]Annexon Biosciences, Brisbane, CA; [2]Saint Luke's Medical Center, Quezon City, Philippines; [3]Tri-Service General Hospital, Taipei, Taiwan; [4]Angeles University Foundation Medical Center, Angeles City, Philippines; [5]Medical Center Manila Inc, Manila, Philippines; [6]Iloilo Doctors Hospital, Iloilo City, Philippines; [7]China Medical University Hospital, Taichung, Taiwan; [8]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan; [9]University of California San Francisco, San Francisco, CA.*

Background: Lupus nephritis (LN) is an autoantibody-mediated disease involving glomerular deposition of immune complexes containing pathogenic anti-C1q antibodies, leading to C1q binding and activation of the classical complement pathway. ANX009 is a subcutaneously administered antigen-binding fragment of a humanized antibody that inhibits C1q interaction with immune complexes. Plasma measures of classical complement activation (C4d/C4 ratio) strongly correlate with disease activity in LN patients, suggesting that these patients may benefit from anti-C1q therapy.

Methods: LN-01 is an ongoing, single-arm, phase 1b study evaluating safety and tolerability of ANX009 in patients (N≤8) with class III or IV LN, high plasma C4d/C4 ratio, and urine protein/creatinine ratio >0.5 g/g at study enrollment. Patients undergo an 8-week screening period, a 3-week treatment period, and an 11-week off-treatment follow-up period. Primary and secondary endpoints are the percentage of patients with treatment-emergent adverse events (TEAEs) and change in complement biomarkers, respectively.

Results: To date, 4 patients completed treatment, one patient discontinued treatment, and screening is ongoing. Among 3/5 patients, 29 TEAEs occurred. All AEs were non-serious, except fever of unknown diagnosis in one patient. Injection site reactions arose in 3/5 patients—mild, mostly erythema. C4d/C4 ratio decreased with treatment in all 5 patients and returned to baseline after treatment cessation. Inhibition of C1q also resulted in normalization of downstream complement markers of activation and consumption for the entire pathway.

Conclusions: In this interim analysis, ANX009 administered subcutaneously was well tolerated and demonstrated C1q target engagement and complement inhibition in 5/5 patients. Normalization of all downstream activation markers and primary components, notably C3 and C5b-9, suggests the classical pathway, not the alternative pathway, is a key driver of complement activation in these LN patients. These interim results support further study of anti-C1q therapy in LN patients.

SA-PO879

Long-Term Efficacy and Relapse in Lupus Nephritis Treated with Mycophenolate Mofetil and Tacrolimus Combination Therapy

Yoichi Imai, Hidekazu Ikeuchi, Masato Kinoshita, Junya Suwa, Yuko Ohishi, Mitsuharu Watanabe, Masao Nakasatomi, Hiroko Hamatani, Toru Sakairi, Yoriaki Kaneko, Keiju Hiromura. *Gunma University Graduate School of Medicine Depatment of Nephrology and Rheumatology, Maebashi, Japan.*

Background: Although recent research has shown the effectiveness of combination therapy with mycophenolate mofetil (MMF) and a calcineurin inhibitor for the initial treatment of active lupus nephritis (LN), its long-term outcomes still need to be explored.

Methods: We reviewed the medical records of 27 LN patients (4 males, 23 females) who underwent combination therapy with MMF and tacrolimus as an induction treatment from October 2009 to November 2018 in our department. Complete remission (CR) was defined by two criteria: 1) a urine protein to creatinine ratio (UPCR) of less than 0.5 g/gCr, and 2) a serum creatinine level (S-Cr) either normal or no more than 15% higher than the baseline. Both these criteria had to be met on two consecutive visits. A relapse was defined as a doubling of UPCR and ≥1.0 g/gCr on two consecutive visits or an intensification of immunosuppressive therapy after CR. Data are presented as median (IQR) or number (%).

Results: The median age was 38 (30-45) years, with 17 patients having new LN onset. Pre-treatment UPCR and eGFR were 4.21 (2.19-5.99) g/gCr and 62.6 (45.1-89.0) mL/min/1.73m^2, respectively. Renal histology (ISN/RPS 2003) showed: Class III in 1, III+V in 4, IV in 13, IV+V in 8, and V in 1. CR rates at 6 and 12 months were 59% and 74%, respectively. The combination regimen was administered for 25 (5.5-37.0) months, and the total observation period was 94.0 (63.0-111.5) months. During this period, one patient died from heart failure. No patient reached end-stage kidney disease or experienced a doubling of S-Cr. Although 26 (96.3%) patients achieved CR in total, 16 (59.3%) patients experienced a relapse. Kaplan-Meier analysis revealed that chronic lesions (A/C) in renal biopsy and the absence of a low C4 level were associated with relapse (P=0.006 and P=0.0007, respectively, by Log-rank test).

Conclusions: Combination therapy for LN was effective in inducing CR and preserving renal function over a long-term period. However, patients with chronic histological lesions or the absence of a low C4 level were more likely to relapse.

SA-PO880

Efficacy of Rituximab in Long-Term Maintenance of Remission in Lupus Nephritis

Qiyu Wang, Reza Zonozi, Karen A. Laliberte, John Niles, Anushya Jeyabalan. *Massachusetts General Hospital, Boston, MA.*

Background: Rituximab(RTX) is known to be effective in inducing remission in patients (pts) with refractory lupus nephritis (LN). However, utility of RTX as maintenance therapy remains unclear.

Methods: We analyzed clinical data of 19 pts with LN treated at MGH who received RTX as maintenance therapy for >=12 months(mos) after achieving complete/partial remission. Pts were followed from the date of first RTX infusion after remission(baseline) to 6 mos after their last dose of RTX or development of ESKD. Renal relapse, renal survival and effect of oral immunosuppression reduction were described.

Results: Among the 19 pts, the main indication for RTX maintenance therapy was prior treatment failure with mycophenolate(n=13). Mean age was 36 (IQR 25-43),18/19 pts were female, 13/19 were white. Median creatinine(Cr) was 0.8mg/dL (IQR 0.7-1.4) and median proteinuria was 0.5g/g (IQR 0.3-1.0) at baseline.17 pts had class III/IV±V LN, 2 had pure class V LN. 6 renal relapses occurred in 5 pts during a median follow-up of 36 mos (IQR 24-71). All but 1 had B cell repopulation during relapse (Figure 1). 3 pts developed ESKD: all had advanced CKD at baseline(Cr >2mg/dL). 9/19(47%) pts were on RTX monotherapy at baseline, 11/19(58%) at 12 mos, 8/12(67%) at 24 mos. Median prednisone dose was 5mg/day (IQR 0-7.5) at baseline and 0 at 12 and 24 mos (Figure 2). 2 pts discontinued RTX due to infection.

Conclusions: RTX may be an effective alternative for long-term maintenance of remission in LN.

Post Hoc Analyses of Biomarkers Predictive of a Renal Response to Intravenous (IV) Belimumab (BEL) Plus Standard Therapy (ST) in Patients with Lupus Nephritis (LN)

Brad H. Rovin,[1] Richard Furie,[2] Ana Malvar,[3] Cynthia Aranow,[4] José M. Pego-Reigosa,[5,6] Elena Zakharova,[7] Andreas Schwarting,[8] Angela R. Jones-Leone,[9] Jennifer A. Gilbride,[10] Beulah Ji,[11] David A. Roth,[9] Paula S. Curtis,[12] André van Maurik.[10] *[1]Ohio State University Wexner Medical Center, Columbus, OH; [2]Zucker School of Medicine at Hofstra/Northwell, Great Neck, NY; [3]Hospital Fernandez, Buenos Aires, Argentina; [4]Feinstein Institutes for Medical Research, Manhasset, NY; [5]Complexo Hospitalario Universitario de Vigo, Hospital Meixoeiro, Vigo, Spain; [6]Galicia Sur Health Research Institute and IRIDIS (Investigation in Rheumatology and Immune-Mediated Diseases) Group, Vigo, Spain; [7]Moscow City Clinical Hospital n.a. S.P. Botkin, Moscow, Russian Federation; [8]University Center of Autoimmunity, Mainz, Germany; [9]GSK, Collegeville, PA; [10]GSK, Stevenage, United Kingdom; [11]GSK, Shanghai, China; [12]GSK, Brentford, United Kingdom.*

Background: In BLISS-LN (GSK BEL114054), a Phase 3 trial of adults with LN treated with BEL 10 mg/kg/month IV or placebo (PBO), + ST, BEL resulted in significantly more kidney responses (Primary Efficacy Renal Response [PERR] and Complete Renal Response [CRR]), and greater improvements in anti-dsDNA and anti-C1q autoantibodies and complement C3 and C4 levels than PBO over 104 weeks (wks). This post hoc analysis of BLISS-LN assessed the characteristics of patients with LN most likely to benefit from the addition of BEL to ST.

Methods: Post hoc logistic regression models tested the ability of potential baseline (BL) biomarker levels and biomarker level changes in the first 12 months of treatment to predict PERR and/or CRR at Wk 104.

Results: Overall, 446 patients were evaluated. High BL anti-C1q predicted a PERR with BEL and a CRR with PBO (**Table**). High BL levels of immunoglobulin (Ig)A and a decrease in IgA at Wk 8 with BEL were predictive of PERR, and high BL levels of naïve B cells were predictive of PERR and CRR to BEL. Low BL plasmablasts, and a decrease in IgA or IgM at Wk 24 predicted a PERR in both groups and a decrease in IgA at Wk 24 predicted CRR to BEL. A reduction in anti-C1q at Wk 52 and of uPCR at Wk 12 also predicted PERR and CRR in both groups. Changes in B-cell subsets were not predictive of a response in the BEL group.

Conclusions: High levels of IgA and naïve B cells at BEL initiation, as well as early reductions in IgA, predicted attainment of PERR and/or CRR for BEL but not PBO. Early reductions in uPCR predicted responses regardless of whether patients received BEL or PBO.

Funding: Commercial Support - GSK (GSK BEL114054; NCT01639339)

Outcome of Lupus Nephritis Patients Treated with a New Anti-CD40 Monoclonal Antibody According to Kidney Biopsy Features

Martina Uzzo,[1,2] Helmut Schumacher,[3] Juergen Steffgen,[4] Simone Deutschel,[4] David R. Jayne,[5] Ingeborg M. Bajema.[2] *[1]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [2]Department of Pathology and Medical Biology, University of Groningen, University Medical Center, Groningen, Netherlands; [3]Statistical Consultant, Ingelheim, Germany; [4]Boehringer Ingelheim International GmbH, Biberach, Germany; [5]University of Cambridge Department of Medicine, Cambridge, United Kingdom.*

Background: Lupus Nephritis (LN) is responsible for SLE-related mortality and morbidity. A phase II trial tested different doses of the anti-CD40 monoclonal antibody BI655064 as add-on therapy to the standard of care in class III or IV LN patients with active renal disease. A post-hoc analysis showed a potential benefit of the higher tested dosages (180mg/240mg) versus low dosage (120mg) and placebo. Monocytes constitutively express CD40. We investigated whether the efficacy of BI655064 was predicted by the presence of monocytes in the kidney biopsy.

Methods: 101 renal biopsies of LN patients enrolled in the BI 655064 trial were scored centrally. eGFR and spot urine protein/urine creatinine ratio (UP/UC) were evaluated at every visit. Through a linear regression model (last available value vs. baseline), patients were divided according to their ″Better'' or ″Worse'' performance compared to the average. Biopsy parameters which differed between the two groups in the univariate analyses ($p<0.1$) were entered into a multivariate logistic regression model, and a routine model selection procedure ($p<0.2$) used to identify parameters predictive for proteinuria reduction or increase in eGFR (LN class IV vs III, Mesangial sclerosis, Lymphocytes, Microthrombi, Modified Chronicity index for UP/UC; Adhesions, Modified Activity index, Modified Chronicity index for eGFR). A logistic regression model adjusted for the same parameters was used to investigate whether the efficacy of BI655064 associated with the presence of renal monocytes.

Results: A lower modified chronicity index was predictive of UP/UC improvement (P=0.032); eGFR tended to be higher with a lower modified chronicity and a higher modified activity index. A higher treatment dose (BI655064 180/240mg vs Placebo/ BI655064 120mg) was associated with a greater proteinuria reduction when kidney biopsies contained glomerular monocytes (OR 3.72 (1.07–12.9), P=0.039). No substantial association between monocytes and eGFR change was detected.

Conclusions: In this post-hoc analysis, we showed that BI 655064 treatment in LN may improve the rate of proteinuria over time when monocytes are present in the biopsy, suggesting that specific renal biopsy characteristics could direct the choice of treatment for individual LN patients.

Atacicept in IgA Nephropathy (IgAN): Continued Protective Titers to Diphtheria and Tetanus and Balanced Infections vs. Placebo with a Focus on COVID-19

Jonathan Barratt,[1] Bart D. Maes,[2] Rubeen K. Israni,[3] Xuelian Wei,[3] Vladimir Tesar,[4] Gerald B. Appel,[5] Yusuke Suzuki,[6] Celia J. Lin,[3] Richard A. Lafayette.[7] *[1]University of Leicester, Leicester, United Kingdom; [2]AZ Delta vzw, Roeselare, Belgium; [3]Vera Therapeutics, Inc., Brisbane, CA; [4]Univerzita Karlova, Praha, Czechia; [5]Columbia University, New York, NY; [6]Juntendo Daigaku, Bunkyo-ku, Japan; [7]Stanford University, Stanford, CA.*

Background: Atacicept is a dual anti-BLyS/APRIL fusion protein currently in clinical development for IgA nephropathy (IgAN) treatment. Better understanding vaccine response and immunity with atacicept, especially to COVID-19, may help assess atacicept's benefit risk profile. Atacicept has been studied in IgAN in the Ph2a JANUS study which measured tetanus and diphtheria vaccine titers up to 72w, and the Ph2b ORIGIN study where impact of atacicept on COVID-19 infection rates and severity could be assessed.

Methods: JANUS and ORIGIN were double-blind placebo (PBO) controlled studies that enrolled adults with biopsy-proven IgAN and UPCR >0.75g/g who were on stable doses of renin-angiotensin system inhibitors. Patients (pts) were randomized 1:1:1 to PBO, atacicept 25, or 75mg SC qw for 72w in JANUS (n=16) and 2:1:2:2 to PBO, atacicept 25, 75, or 150mg SC qw for 36w in ORIGIN (n=116). In JANUS, tetanus and diphtheria titers were measured at 1, 48 and 72w in addition to safety assessments. In ORIGIN, safety data on infections were analyzed by treatment arm up to 36w.

Results: The JANUS population was 50% male with baseline (BL) median age 44; the ORIGIN population was 59% male, median age 37. No JANUS pts changed from protective to nonprotective status for diphtheria or tetanus toxin; overall infections were balanced between atacicept and PBO. ORIGIN pts across atacicept and PBO arms had similar rates of overall and COVID-19 infections (Table). All pts with COVID-19 had ≥1 COVID-19 vaccine dose prior to infection. No COVID-19 infection was serious; most were mild. Median duration of COVID-19 infection was 7.5 (IQR 7, 9) days. There were no permanent discontinuations although some COVID-19 infections led to temporary study drug interruption. No COVID-19 infection was reported as study drug related.

Conclusions: Atacicept treatment was associated with continued protective immunity to tetanus and diphtheria in the Ph2a JANUS study. In JANUS and ORIGIN, infections were balanced between atacicept and PBO with no increase in incidence or severity of COVID-19 infections in the Ph2b ORIGIN study.

Table. Summary of COVID-19 Infections in the Ph2b ORIGIN Study (36 Week Double Blind Period)

n (%) or Median (IQR)		Atacicept 25 mg, n=12	Atacicept 75 mg, n=33	Atacicept 150 mg, n=33	Placebo, n=34
Infections overall		6 (38)	16 (48)	12 (36)	11 (32)
COVID-19 infections		4 (25)	9 (27)	8 (24)	6 (18)
COVID-19 vaccine prior to infection		4 (100)	9 (100)	8 (100)	6 (100)
Severity	Mild	3 (75)	8 (88.9)	7 (87.5)	6 (100)
	Moderate	1 (25)	1 (11.1)	1 (12.5)	0
	Severe	0	0	0	0
Outcome	Recovered	4 (100)	9 (100)	7 (87.5)	6 (100)
	Recovering	0	0	1 (12.5)	0
Action taken	No dose change	2 (50)	4 (44.4)	5 (62.5)	3 (50)
	Drug interrupted	2 (50)	5 (55.6)	3 (37.5)	3 (50)
Duration of COVID-19 infection, days*		11.5 (8.5, 14)	8 (7, 9)	8 (6, 8)	6.5 (6, 7)

*Duration of AE reported as median and interquartile range in days for 25 out of 27 participants who had outcome of AE as recovered/resolved.

SA-PO885

IMAGINATION: A Global Phase 3 Trial of RO7434656, an Antisense Oligonucleotide Inhibitor of Complement Factor B, in IgA Nephropathy

Jonathan Barratt,[1] Jürgen Floege,[2] Vishal Duggal,[3] Nadine Schmit,[4] Ji (Emmy) Cheng,[5] Jeannette Lo,[3] Brad H. Rovin.[6] *[1]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom; [2]Division of Nephrology, University Hospital, Rheinisch-Westfälische Technische Hochschule (RWTH) Aachen, Aachen, Germany; [3]Genentech Inc, South San Francisco, CA; [4]F Hoffmann-La Roche AG, Basel, Switzerland; [5]Hoffmann-La Roche Limited, Mississauga, ON, Canada; [6]Department of Internal Medicine, The Ohio State University College of Medicine, Columbus, OH.*

Background: RO7434656 (IONIS-FB-L_{Rx}, ISIS 696844), a ligand-conjugated antisense oligonucleotide targeting complement factor B mRNA, was engineered for enhanced delivery to the liver as the primary site of factor B production. In a Phase 2 trial (NCT04014335), RO7434656 inhibited alternative complement pathway activation and demonstrated a clinically meaningful reduction in UPCR resulting in a stable eGFR in patients with IgA nephropathy (IgAN; **Fig 1**).

Methods: IMAGINATION (NCT05797610), a Phase 3, randomized, double-blind, placebo-controlled trial will evaluate the efficacy and safety of RO7434656 in adults with biopsy-confirmed primary IgAN (**Fig 2**). 428 patients will be divided into 2 cohorts: a primary cohort with eGFR ≥30 mL/min/1.73m^2 and an exploratory cohort with eGFR 20-29 mL/min/1.73m^2. Patients on maximally tolerated doses of ACEi/ARB will be randomized 1:1 to receive RO7434656 or placebo subcutaneously (SC) on Days 1, 15 and 29 and every 4 weeks (Q4W) thereafter for 105 weeks, with the option to continue double-blind or open-label treatment. The primary endpoint is change from baseline in 24h UPCR at Week 37. Key secondary endpoints include eGFR slope from baseline at Week 105, time to the composite kidney failure endpoint and patient-reported outcomes. Blood, urine and optional kidney biopsies will be collected throughout the study to assess biomarkers.

Results: Expected upon study completion.

Conclusions: The unique antisense modality and long tissue half-life of RO7434656 enables Q4W SC administration to inhibit the alternative complement pathway. IMAGINATION aims to evaluate the efficacy and safety of RO7434656 in adults with IgAN using a broad range of assessments over 105 weeks.

Modeling Based on NefIgArd Two-Year eGFR Total Slope Predicts Long-Term Clinical Benefit of Nefecon in a Real-World IgA Nephropathy (IgAN) Population

Jonathan Barratt,[1] Andrew M. Stone,[2] Heather N. Reich,[3] Richard A. Lafayette.[4] *[1]College of Medicine Biological Sciences and Psychology, University of Leicester, Leicester, United Kingdom; [2]Stone Biostatistics Ltd., Crewe, United Kingdom; [3]Division of Nephrology, University Health Network, Department of Medicine, University of Toronto, Toronto, ON, Canada; [4]Division of Nephrology, Department of Medicine, Stanford University, Stanford, CA.*

Background: Nefecon, a targeted-release budesonide formulation, is approved for the treatment of patients (pts) with immunoglobulin A nephropathy (IgAN). Data from the full Phase 3 NefIgArd trial showed that 9 months of Nefecon 16 mg/d preserved estimated glomerular filtration rate (eGFR) and reduced urine protein–creatinine ratio (UPCR) vs placebo. These effects were maintained during the 15-month off-drug follow-up period, indicating that Nefecon is disease-modifying. We conducted a modeling analysis to predict the potential long-term benefit of Nefecon on clinical outcome (i.e., a composite endpoint of end stage renal disease, eGFR <15 mL/min/1.73m^2, or sustained doubling of serum creatinine) in a real-world IgAN population.

Methods: In the final analysis of the NefIgArd trial, there was a treatment benefit in 2-year eGFR total slope of 2.78 mL/min/1.73m^2 per year (95% confidence interval [CI] 1.39–4.17) with Nefecon vs placebo (linear spline mixed-effect model). This difference was applied to a published linear regression between treatment effects for the change in 2-year eGFR total slope and the log hazard ratio (HR) of clinical outcome, based on a meta-analysis involving >60K CKD pts (Inker et al. *JASN* 2019;30:1735-45). Median time to clinical outcome for a reference group receiving supportive standard of care (SoC) only was estimated by modeling long-term registry data from pts at Leicester General Hospital (LGH), UK, matching NefIgArd-recruited pts to individual LGH pt records based on their baseline UPCR and eGFR. Time to clinical outcome for SoC pts was estimated using a Weibull model.

Results: 352/364 NefIgArd pts were matched with 886 unique records from 192 LGH pts, which contained 287 clinical outcome event-times from 68 LGH pts. The NefIgArd 2-year eGFR total slope translated to a log HR for clinical outcome of 0.38 (95% CI 0.21–0.63), a 62% risk reduction vs placebo. Median time to clinical outcome was estimated at 9.6 years in SoC pts and 22.4 years in Nefecon-treated pts (median delay 12.8 [95% CI 4.8–27.9] years). 52% of SoC pts were predicted to have a clinical outcome within 10 years vs 24% of Nefecon-treated pts.

Conclusions: Modeling analyses indicate that the clinical benefit seen with Nefecon predicts a substantial delay in progression to kidney failure.

SA-PO887

Atacicept 150 mg Reduces Serum Gd-IgA1, a Biomarker Associated with Long-Term Outcomes in IgA Nephropathy (IgAN): 36W Results from the Ph2b ORIGIN Study

Jonathan Barratt,[1] Bart D. Maes,[2] Celia J. Lin,[3] Xuelian Wei,[3] Sean Barbour,[4] Richard K. Phoon,[5] Sung Gyun Kim,[6] Vladimir Tesar,[7] Jürgen Floege,[8] Vivekanand Jha,[9] Richard A. Lafayette.[10] *[1]University of Leicester, Leicester, United Kingdom; [2]AZ Delta vzw, Roeselare, Belgium; [3]Vera Therapeutics, Inc., Brisbane, CA; [4]The University of British Columbia, Vancouver, BC, Canada; [5]The University of Sydney, Sydney, NSW, Australia; [6]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [7]Univerzita Karlova, Praha, Czechia; [8]Rheinisch-Westfalische Technische Hochschule Aachen, Aachen, Germany; [9]The George Institute for Global Health India, New Delhi, India; [10]Stanford University, Stanford, CA.*

Background: IgA nephropathy (IgAN), the most common primary glomerulonephritis and a significant contributor to ESRD worldwide, is characterized by elevated serum levels of galactose-deficient immunoglobulin A1 (Gd-IgA1). High Gd-IgA1 levels are associated with greater risk of renal function deterioration. Gd-IgA1 production is driven by the B Lymphocyte Stimulator (BLyS)–A PRoliferation-Inducing Ligand (APRIL) signaling

pathway's effect on B cells and plasma cells. Atacicept is a dual anti-BLyS/APRIL fusion protein in clinical development for IgAN treatment. The Ph2b ORIGIN study of atacicept in IgAN met its primary endpoint. The objective of this analysis is to evaluate change in serum Gd-IgA1 quartiles over 36 weeks (w) with atacicept 150mg, the dose being evaluated in a pivotal Ph3 study, vs placebo (PBO).

Methods: The randomized, double-blind, PBO controlled Ph2b ORIGIN study included 116 patients (pts) with biopsy-proven IgAN, eGFR ≥30mL/min/1.73m², and urine protein >0.75g/24h or UPCR >0.75g/g despite optimized renin–angiotensin system blockade. Pts were randomized 2:2:1:2 to atacicept 150, 75, or 25 mg vs PBO SC qw for 36w. At baseline (BL), 4, 12, 24, and 36w, Gd-IgA1 values were assessed and classified into quartiles using cutoffs derived from BL Gd-IgA1 values.

Results: Atacicept 150mg (n=30) achieved 64% mean Gd-IgA1 reduction vs 7% for PBO (n=29) at 36w (p<0.001) in pts with BL and 36w data. Atacicept 150mg led to steady Gd-IgA1 reduction to the lowest quartile 1 at 36w in 27/33 pts while most PBO pts transiently increased or decreased by 1 quartile (Figure). In the atacicept 150mg arm, 5/8 pts with BL quartile 4 had reductions to quartile 1 at 36w, while in the PBO arm 8/9 with BL quartile 4 remained in quartile 3 or 4 at 36w.

Conclusions: Atacicept 150mg achieved a durable and significant Gd-IgA1 reduction over 36w. Regardless of BL quartile, the vast majority of pts receiving atacicept 150mg for 36w had Gd-IgA1 reductions to the lowest quartiles, which has been associated with greater renal survival. These results provide further evidence supporting atacicept as a potential disease-modifying treatment for IgAN.

Utilization of Corticosteroid Therapy in Patients with IgA Nephropathy and C1 Lesion

Jose Cabrales, Vivek Charu, Blake Shaw, Richard A. Lafayette. *Stanford Medicine, Stanford, CA.*

Background: IgA nephropathy (IgAN) frequently leads to chronic kidney disease and progressive kidney failure. Among the prognostic factors is the presence of crescents on kidney biopsy, as a component of the MEST-C score, leading many to consider steroid treatment when crescents are found, even when seen in mild to moderate numbers (1-25%, C1 lesion). We wanted to assess if steroid treatment does indeed impact the outcome of IgAN patients with crescents.

Methods: Retrospective review of patient records from 2017-2022 who had biopsy proven IgAN with C1 lesions and adequate follow up was undertaken to assess patient characteristics, treatment and longitudinal follow up of outcomes of changes in eGFR and proteinuria. A multivariate model was created to relate steroid therapy to short to moderate term changes in kidney function (by eGFR slope).

Results: 68 of 176 consecutive patients met the study criteria, they had an average age of 41 years, 57% were women, mostly Asian, variable activity and chronicity in MEST score. Median (IQR) of crescent percent was 8.5(4.8-14.2%), UPCR median was 1.78g/g, eGFR mean (SD) was 63±36 ml/min/1.73m². Average follow up was 2 years. Most patients (75%) had been treated with renin-angiotensin system inhibitors. 37 of the patients underwent steroid therapy shortly after biopsy. There were differences in age, gender and MESTC score between treated and untreated patients. There were variable impacts on proteinuria. Utilizing linear mixed effects modeling, there was no significant difference between treated and untreated patients in their annual decline in eGFR, which averaged 2.13 ml/min/year (difference in slopes [treated v. untreated] of 0.70 ml/min/year, p=0.35).

Conclusions: Patients with IgAN and C1 lesions are frequently treated with corticosteroid therapy after kidney biopsy. In this predefined cohort, steroid therapy provided a non-significant trend for less disease progression over this follow up. Larger cohorts should be followed for longer periods of time, but presently, it does not appear prudent to choose steroid therapy based on C1 lesions seen on the biopsy.

SA-PO889

Kidney Outcomes with Corticosteroid Treatment in IgA Nephropathy According to the Oxford-MEST-C Classification

Bancha Satirapoj, Thapana Chueaboonchai, Narongrit Siriwattanasit, Narittaya Varothai, Naowanit Nata, Theerasak Tangwonglert, Amnart Chaiprasert, Ouppatham Supasyndh. *Phramongkutklao College of Medicine, Bangkok, Thailand.*

Background: Despite optimization of renin-angiotensin-aldosterone system (RAAS) inhibition, patients with IgA nephropathy remain at risk for kidney failure. The effect of steroids on kidney outcomes in IgA nephropathy with different renal pathologic lesions has been uncertain.

Methods: We retrospectively studied 67 patients with biopsy-proven IgA nephropathy who were receiving optimized RAAS inhibitor therapy and persistent proteinuria > 1 g/day between January 2016 and December 2020. Clinical parameters including estimated glomerular filtration rate (GFR) decline were compared between corticosteroids and supportive treatment.

Results: Overall, 68.7% of patients received treatment with corticosteroids. Median estimated GFR decline was significantly lower in the steroids than in the controls (-0.65 (IQR 7 to -3.45) vs - 5.75 (IQR -0.7 to -10.65) mL/min/1.73 m2/year, P=0.025, respectively). Slope of estimated GFR were also significantly different between the steroids and the controls in subgroup of patients with baseline GFR >50 mL/min/1.73 m2 (3.90±11.42 vs -9.31±5.08 mL/min/1.73 m2/year, P=0.011, respectively), mesangial hypercellularity M0 score (4.69±11.37 vs -2.63±6.42 mL/min/1.73 m2/year, P=0.049, respectively), and C0 score (2.48±12.63 vs -5.58±8.4 mL/min/1.73 m2/year, P=0.026, respectively). In additionally, the rapid GFR decline >5 mL/min/1.73 m2/year occurred in 9 (19.6%) in the steroids compared with 11 participants (52.4%) in the controls (P=0.006).

Conclusions: Corticosteroids therapy in addition to optimized RAAS inhibition has lower the risks of kidney disease progression in patients with IgA nephropathy especially baseline GFR >50 mL/min/1.73 m², Oxford classification M0 and C0 score.

SA-PO890

Targeted Release Formulation (TRF) Budesonide (Nefecon) Reduces Serum Biomarkers of Lymphocyte Activation in IgA Nephropathy, Which Correlates with Changes in Serum B Cell-Activating Factor (BAFF) Levels

Nadia Nawaz,[1] Karen Molyneux,[1,2] Jonathan Barratt.[1,2] IgA Nephropathy Group. *[1]University of Leicester, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

Background: The targeted-release formulation of budesonide, Nefecon, is designed to deliver budesonide to the gut-associated lymphoid tissue of the terminal ileum, a major site of immunoglobulin A (IgA) production. In the phase 2b NEFIGAN trial, treatment with Nefecon significantly reduced serum levels of galactose-deficient IgA1IgA/IgG immune complexes and cytokines involved in B-cell activation. This study investigates the effect of Nefecon on biomarkers of lymphocyte activation in the Part A population of the phase 3 double-blind, randomized controlled NefIgArd trial in which 9 months' treatment with Nefecon led to a reduction in proteinuria at 9 months (p=0.0005), and a reduction in loss of estimated glomerular filtration rate at 24 months (p<0.0001) compared with placebo.

Methods: Levels of the soluble cluster of differentiation (CD)23, CD27, and CD30 were measured using Luminex technology in 160 NefIgArd Part A participants using serum samples collected at baseline and 3, 6, and 9 months post randomization. Comparisons between placebo and Nefecon treated groups were made at each time point using unpaired t-tests, with a significance level of p<0.05.

Results: Treatment with Nefecon 16 mg/day resulted in a significant reduction in the levels of sCD23, sCD27, and sCD30 at 3 months (all p values <0.0001), 6 months (all p values <0.0001), and 9 months (all p values <0.0001), confirming the findings from the NEFIGAN trial. The extent of sCD23, sCD27, and sCD30 suppression correlated with the magnitude of B-cell activating factor (BAFF) reductions at each timepoint. sCD30 reductions at 6 months and 9 months correlated with the magnitude of reductions in IgA/IgG immune complexes.

Conclusions: These data validate the findings from the phase 2b study and further support a disease-modifying action of Nefecon, specifically an action on the BAFF-lymphocyte interactome and immune complex formation in immunoglobulin A nephropathy.

Funding: Commercial Support - Calliditas Therapeutics

SA-PO891

An Open-Label Trial Evaluating the Safety and Efficacy of Budesonide in Patients with IgA Nephropathy at High Risk of Progression

Bogdan Obrisca, Roxana A. Jurubita, Bogdan Sorohan, Andreea Andronesi, Alexandra Vornicu, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania.*

Background: We sought to evaluate the efficacy and safety of budesonide (Budenofalk®) in the treatment of patients with IgA Nephropathy (IgAN).

Methods: The BUDIGAN trial (ISRCTN47722295) is a prospective, interventional, open-label, non-randomized study that enrolled 32 patients with IgAN, at high risk of progression defined as persistent proteinuria over 1 g/day despite adequate RAAS blockade for at least 3 months or patients with proteinuria between 0.5 and 1 g/day after RAAS blockade if they had additional risk factors for progression (eGFR<60 ml/min/1.73m2, presence of proliferative lesions). Patients were treated with Budenofalk® at a dose of 9 mg/day for the first 12 months, subsequently tapered to 3 mg/day for another 12 months. The primary endpoints were change of eGFR, proteinuria and hematuria at 36 months.

Results: The study cohort had a mean age of 41.7 ± 9.4 years (72% were males), while the mean eGFR and median 24-h proteinuria were 59 ± 24 ml/min/1.73m2 and 1.5 g/d (IQR:1.05-2.4), respectively. 25% and 12.5% of patients had a proteinuria level of 2-3.5 g/d and over 3.5 g/d, respectively. Treatment with budesonide determined a reduction in proteinuria at 12, 24 and 36 months by -42.3% (95%CI, -52.2 to -1.24), -61.5% (95%CI, -72.2 to -35.9) and -74.3% (95%CI, -80.6 to -55.7). The proteinuria at last follow-up was 0.34 g/d (IQR:0.12-0.86), significantly lower than the study baseline (p<0.001). The improvement in hematuria was similar to proteinuria with a reduction at 36 months by -92.6% (95%CI, -95 to -58.6). Budesonide treatment determined an eGFR preservation corresponding to a 12, 24 and 36 month change of +6.1% (95%CI, -9.5 to 21.7), +7.1% (95%CI, -10.2 to 24.3) and +4.7% (95%CI, -13.5 to 23), respectively.

The overall eGFR change/year was +0.61 ml/min/y (95%CI, -1.37 to 2.59). Budesonide (Budenofalk®) was well-tolerated, and treatment emergent adverse events were mostly mild in severity and reversible.

Conclusions: Budesonide (Budenofalk) was effective in the treatment of patients with IgAN at high-risk of progression in terms of reducing proteinuria, hematuria and preserving renal function over 36 months of therapy.

SA-PO892

Analysis of the NefIgArd Part A Study Population Confirms Nefecon Reduces Levels of Dietary Antigen-Specific IgA in Patients with IgA Nephropathy

Vicky Cotton,[1] Irem Karaer,[1] Roisin C. Thomas,[1] Karen Molyneux,[1,2] Jonathan Barratt.[1,2] IgA Nephropathy Group. *[1]University of Leicester, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

Background: Nefecon, the targeted-release formulation of budesonide, is delivered to the gut-associated lymphoid tissue (GALT) of the terminal ileum, a major site of immunoglobulin A (IgA) production. The Phase 3, double-blind, randomized controlled clinical trial NefIgArd tested the efficacy of Nefecon in patients with IgA nephropathy (IgAN) at high risk of progressive kidney disease despite optimized supportive care. The trial comprised 9 months of treatment with either placebo or Nefecon 16 mg/day, and a 3-month (Part A) or 15-month (Part B) off-drug observational follow-up period. Treatment with Nefecon 16 mg/day significantly reduced proteinuria after 9 months of treatment compared with placebo (p=0.0003) and this effect was maintained, along with preservation of estimated glomerular filtration rate (p<0.0001), over the 15-month off-drug observational follow-up period. The aim of this study was to determine the effect of Nefecon treatment on circulating levels of dietary antigen-specific IgA, secretory IgA, and a marker of gut permeability, fatty acid-binding protein 2 (FABP2).

Methods: Circulating levels of anti-gliadin IgA, anti-casein IgA, secretory IgA and FABP2 were measured in baseline serum samples and 3, 6, and 9 months after randomization during Part A of the NefIgArd trial using enzyme-based immunosorbent assays. Comparisons between placebo and Nefecon-treated groups were made at each study time point using unpaired t-tests, with a significance level of p<0.05.

Results: Treatment with Nefecon 16 mg/day significantly reduced levels of anti-gliadin IgA at 3 months (p=0.044), 6 months (p=0.029), and 9 months (p=0.027), and levels of anti-casein IgA at 9 months (p=0.023), compared with antibody levels at baseline. These data are consistent with Nefecon 16 mg/day results obtained in the Phase 2b NEFIGAN clinical trial. No significant changes were seen in levels of secretory IgA or FABP2.

Conclusions: Reductions in IgA antibodies against mucosally encountered antibodies confirm a local mucosal effect of Nefecon in IgAN. This effect is likely mediated by a direct action on GALT B cell IgA production rather than an effect on gut permeability and increased antigen exclusion.

SA-PO893

Analysis of the NefIgArd Part A Study Confirms Nefecon Modulates Proteins Involved in the Intestinal Immune Network for IgA Production

Roisin C. Thomas, Nadia Nawaz, Karen Molyneux, Jonathan Barratt. *University of Leicester, Leicester, United Kingdom.*

Background: Nefecon, the targeted release formulation of budesonide, is delivered to the gut-associated lymphoid tissue (GALT) of the terminal ileum, a major site of immunoglobulin A (IgA) production. Results from the Phase 2b NEFIGAN and Phase 3 NefIgArd trials demonstrated that treatment with 16 mg/day Nefecon significantly reduces proteinuria and loss of estimated glomerular filtration rate compared with placebo. A number of serum biomarkers have been measured in the 2 trials and many of those identified to be modulated by Nefecon in the Phase 2b study have now been validated in Part A of the NefIgArd study. The aim of this study was to determine biological pathways modulated by Nefecon treatment using the data currently available from the Part A biomarker analysis program.

Methods: NefIgArd is a Phase 3 double-blind, randomized, controlled clinical trial designed to determine the efficacy of Nefecon in patients with immunoglobulin A nephropathy (IgAN) at high risk of progressive kidney disease despite optimized supportive care. The trial comprised 9 months of treatment with placebo or Nefecon 16 mg/day, and a 3-month (Part A) or 15-month (Part B) off-drug observational follow-up period. An interactome analysis was performed incorporating all serum proteins significantly modulated by treatment with Nefecon 16 mg/day in Part A of the NefIgArd study using the STRING protein-protein interactions database, which contains known and predicted protein interactions, to determine which biological processes and pathways are modulated by Nefecon treatment.

Results: Consistent with the Phase 2b findings, functional analysis demonstrated that serum biomarkers significantly modulated by Nefecon treatment in Part A of the NefIgArd trial are enriched for proteins involved in the KEGG (Kyoto Encyclopedia of Genes and Genomes) pathway database for intestinal immune network for IgA production, and biological processes involved in B cell activation control, indicating the mechanism of action of Nefecon is, at least in part, driven by an effect within the GALT.

Conclusions: These findings support a disease modifying effect of Nefecon at the ileal mucosal surface and a direct effect on the ileal GALT, further strengthening the link between the gut and the kidneys in IgAN.

Funding: Commercial Support - Calliditas

SA-PO894

Mycophenolate Mofetil and Steroid for Treatment of Patients with IgA Nephropathy

Jing Miao, Parikshit Duriseti, Yeshwanter Radhakrishnan, Lisa E. Vaughan, Fernando C. Fervenza, Ladan Zand. *Mayo Clinic Minnesota, Rochester, MN.*

Background: The efficacy of steroids and mycophenolate mofetil (MMF) treatment in patients with IgA nephropathy (IgAN) is the subject of ongoing debate. We retrospectively evaluated the effects of MMF+steroid treatment compared to steroid alone or conservative therapy on incident kidney failure in adults with biopsy proven IgAN.

Methods: The study population was derived from biopsy proven adult IgAN patients seen at Mayo Clinic Rochester from 1/1/2008 to 12/31/2018. Patients were categorized into treatment groups based on which therapy they received within the first 3 months following kidney biopsy. The association between treatment group and risk of incident kidney failure was evaluated using Cox proportional hazards regression models using inverse probability of treatment weighted (IPTW) estimation with propensity scores to control for pre-treatment imbalances on observed variables.

Results: A total of 166 patients were included in the final analysis, with 30 (18%) patients developing incident kidney failure during a mean follow-up of 6.2 years. The conservative group exhibited lower levels of serum creatinine, degree of hematuria, and histopathological M, E, and C scores when compared to the treated groups. Conversely, the conservative group demonstrated higher eGFR compared to the treated patients (**Table 1**). The incidence of kidney failure was significantly reduced by 88% in patients who received MMF+steroid therapy compared to those who underwent conservative therapy (HR 0.12, 95% CI 0.02, 0.95, p=0.04). Although patients who received steroids alone were also less likely to experience kidney failure compared to conservative therapy, the results did not reach statistical significance (HR 0.50, 95% CI 0.19, 1.36, p=0.17).

Conclusions: Our data suggests that combined therapy of MMF+steroid could be a promising treatment strategy for white IgAN patients, particularly those with active inflammatory lesions on kidney biopsy.

Table 1. Baseline characteristics of patients with IgA nephropathy, overall and by treatment group

Baseline	Total (N=166)	Conservative (N=105)	Steroid alone (N=39)	MMF+steroid (N=22)	P

Efficacy of Therapeutic Apheresis for Cryoglobulinemic Vasculitis Patients with Renal Involvement

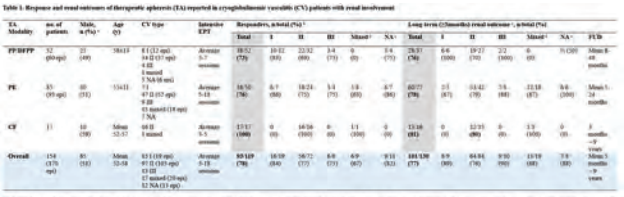
Jing Miao, Pajaree Krisanapan, Supawit Tangpanithandee, Charat Thongprayoon, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: The administration of therapeutic apheresis (TA) to eliminate excessive abnormal immunoglobulins in patients with cryoglobulinemic vasculitis (CV) is a frequently employed approach; however, its efficacy has not been firmly established. This systematic review aimed to evaluate the efficacy of various TA modalities such as plasma exchange (PE), plasmapheresis (PP), and cryofiltration (CF) in patients with renal involvement suffering from CV.

Methods: A literature search was conducted using MEDLINE, EMBASE and Cochrane Databases through December 2022. Studies that reported outcomes of TA in adult CV with renal involvement were assessed.

Results: A total of 154 patients from 76 studies (comprising 13 case series and 63 case reports) were evaluated, with 51% males and a mean age of 49 to 58 years. There were 15 type I, 97 type II, and 13 type III; the remaining patients were either mixed (n=17) or their CV type was undetermined (n=12). Hematologic malignancy and HCV were the common causes of type I (53%) and type II (27%), respectively. PE, PP and CF were performed in 85 (56%), 52 (34%), and 17 (11%) patients, respectively. The overall response rate for TA was 78%, with type I, II, and III patients experiencing response rates of 84%, 77%, and 75%, respectively. The overall response rates of PE and PP were similar (76% vs 73%), but lower than CF (100%). Most patients received steroids, immunosuppressants, and treatment targeting the causative disease during TA and follow-up period. The overall long-term renal outcome rate was 77%, with type I, II and III patients experiencing response rate of 89%, 76% and 90%, respectively. The renal outcome in patients receiving PE, PP and CF were similar (78%, 76% and 81%, respectively).

Conclusions: This systematic review demonstrates that incorporating TA in conjunction with other treatments, such as immunosuppressive therapy, is a successful strategy for managing severe renal involvement in CV patients. While PE, PP, and CF were all effective TA modalities, PE was the most commonly used approach.



SA-PO896

Mycophenolate Mofetil in Steroid Nonresponsive IgA Nephropathy

Soumita Bagchi, Arunkumar Subbiah, Raj K. Yadav, Sandeep Mahajan, Dipankar M. Bhowmik, Sanjay K. Agarwal. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Immunosuppression use is suggested in patients of primary IgA nephropathy (IgAN) with persistent proteinuria≥1 g/day. We examined the role of mycophenolate mofetil (MMF) in steroid non-responsive IgAN.

Methods: In a retrospective study (2012-21) we included patients with primary IgAN who had received MMF for persistent proteinuria(≥1g/day) despite treatment with oral steroids(1mg/kg/day) for at-least 8 weeks. All patients had received MMF 1-2g/day for at-least 3 months. Patients with C2 lesions were excluded. Primary outcome was deterioration of renal function defined as sustained decline in estimated glomerular filtration rate(eGFR) by > 50% documented during at-least 2 consecutive clinic visits with no recovery or progression to end stage kidney disease. Complete remission (CR) was defined as proteinuria <500 mg/d with stable eGFR and partial remission (PR) as proteinuria<1g/day, at-least 50% reduction in proteinuria and decline of proteinuria to <3.5g/day with stable eGFR.

Results: 81 patients were included. Median age at presentation was 32(IQR 25-42) years and 67.9% were males. 67.9% had hypertension. 68(84%) had M1, 12(14.8%) had E1, 58(71.6%) had S1, 37(45.7%) had T1, 5(6.2%) had T2 and 16(19.8%) had C1 lesions. Median eGFR was 46.3(IQR 37.6-67.0) ml/min/173m2, median serum albumin was 3.9(IQR 3.4-4.3) g/dl and median proteinuria was 3.5(IQR 2.1-4.4) g/day at time of initiating MMF treatment. 70(90.1%) cases received renin angiotensin system (RAS) blockade therapy. 44(54.3%) patients achieved remission with MMF therapy (CR:24, PR:20) of whom 12/44(27.3%) relapsed. During a median follow up of 52.2 (IQR 30.8 to 69.1) months after diagnosis, 35(43.2%) patients had progressed to primary outcome. 35(43.2%) patients had adverse effects, 4 had diarrhea and 31 had infections.7 patients developed tuberculosis.

Conclusions: MMF has limited efficacy in steroid non-responsive IgAN but with significant adverse effects.

SA-PO897

Mycophenolate Mofetil (MMF) and Corticosteroids in Crescentic IgA Nephropathy (IgAN)

Maria Jose Vargas-Brochero,[1] Miriam Machado,[1] Nancy Daniela Valencia-Morales,[2] Ladan Zand,[1] Yeshwanter Radhakrishnan,[1] Maria Jose Soler,[3] Fernando C. Fervenza.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Hospital Clinico San Carlos, Madrid, Spain; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: There is no gold standard for the treatment of crescentic IgAN.

Methods: Biopsy-proven crescentic IgAN patients treated with MMF plus corticosteroids 2000-2022(Figure1). Renal outcomes analyzed: hematuria, proteinuria, estimated glomerular filtration rate(eGFR), and end-stage kidney disease(ESKD) after one year.

Results: A total of 22 patients, 72.7% male, 86.4% white, age 38.9±15.3 years. Follow-up 3.9±2 years. Baseline serum creatinine(sCr)2.0±0.78mg/dl, and 100% had hematuria. Kidney biopsy showed(MEST, M1 [90.9%], E1 [59.1%], S1[86.4%], T0[59.1%], T1[27.3%], T2[13.6%], C1[72.7%], C2[27.3%]).95.4% no previous immunosuppression, 77.3% Intravenous methylprednisolone, and 100% received oral corticosteroids, time biopsy to MFF 19 [IQR3.5-69.5] days. At one-year, kidney survival 100%, hematuria disappeared in 68.4%, eGFR(CKD-EPI) increased from 35.6[IQR24.7-71.5] to 51.3[IQR36.4-87]ml/min/1.73m^2(p=0.003), proteinuria g/24h decreased from 1.8[IQR 1.2-4.0] to 0.55 [IQR0.2-1.3](p=0.003). The renal survival with IFTA≥40% was 40% vs. 88.2%with IFTA<40%. Persistent hematuria(PH) had a renal survival of 50% vs. 92.3% with no PH. Most common adverse event was infection(n=6), with temporary treatment discontinuation.22.7% developed ESKD.

Conclusions: MMF plus corticosteroids is associated with 100% kidney survival at one year and 77.3% at the end of follow-up. Advanced interstitial fibrosis and PH seem to be associated with worse prognosis in crescentic IgAN.

Figure 1 Flowchart for the selection of the patients with IgA Nephropathy (IgAN)

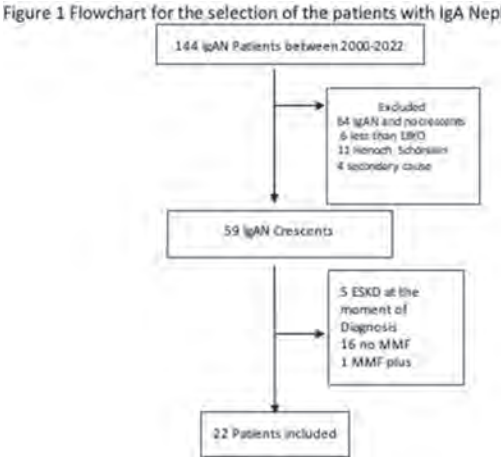


Figure2 Cumulative probability of survival without ESKD in patients with crescentic IgAN during the follow-up.

Mycophenolate Mofetil in Immunoglobulin A Nephropathy: A Systematic Review and Meta-Analysis of Randomized Controlled Trials

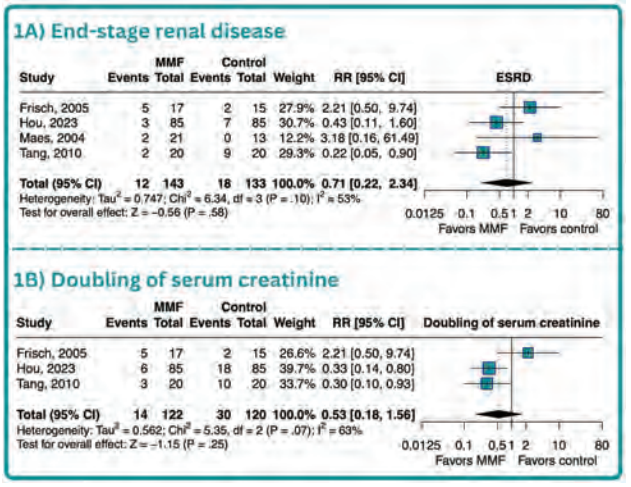
Marcelo A. Braga,[1] Nicole Felix,[2] Alleh Nogueira,[3] Jhonny W. Limachi Choque,[4] Sofia de Assis Oliveira,[5] Luis Claudio Santos Pinto.[6] *[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Universidade Federal de Campina Grande, Campina Grande, Brazil; [3]Escola Bahiana de Medicina e Saude Publica, Salvador, Brazil; [4]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; [5]Centro Universitario Tocantinense Presidente Antonio Carlos, Araguaina, Brazil; [6]Centro Universitário Metropolitano da Amazônia, Belém, Brazil.*

Background: Immunoglobulin A nephropathy (IgAN) is a prevalent primary glomerular disease worldwide. The efficacy of mycophenolate mofetil (MMF) for treating IgAN has yielded inconsistent findings in randomized controlled trials (RCTs).

Methods: In accordance with PRISMA guidelines, we systematically searched PubMed, Embase, Cochrane, and Web of Science in May 2023 for RCTs with long-term follow-up comparing MMF versus placebo or standard of care for IgAN with persistent proteinuria. Statistical analyses were performed using R software version 4.2.2.

Results: We included four RCTs comprising 276 patients with IgAN, of whom 51.81% were randomized to MMF. Average follow-up ranged from 24 to 72 months. MMF did not significantly reduce the incidences of end-stage renal disease (ESRD; RR 0.71; 95% CI 0.22-2.34; p=0.58; I2=53%; Fig. 1A) or doubling of serum creatinine (RR 0.53; 95% CI 0.18-1.56; p=0.25; I2=63%; Fig. 1B) as compared with placebo or standard of care in patients with IgAN.

Conclusions: In this meta-analysis of RCTs, there was no significant difference between MMF and placebo or standard of care in terms of ESRD and doubling of serum creatinine in patients with IgAN.



There was no significant difference between groups in terms of ESRD and doubling of serum creatinine.

SA-PO899

Long-Term Follow-Up of Methylprednisolone (MP) Pulse and Mesenchymal Stem Cell (MSC) Therapy in Severe IgA Nephropathy

Byoung-Soo Cho,[1] Won-Hee Cho.[2] *[1]Dr. Cho's Kidney Clinic, Seoul, Republic of Korea; [2]Sahmyook General Hospital, Seoul, Republic of Korea.*

Background: Up to date there is no specific treatment method for severe IgA nephropathy, but giving ARB, MRA, omega-3, antiplatelet therapy, complement inhibitors, Nefecon, endothelin inhibitors, SGLT2 inhibitor etc. and eventually fall into ESRD and need dialysis or KTP. Cell based therapy especially autologous adipose derived stromal vascular fraction (SVF)/mesenchymal stem cells (MSC) is an emerging field in intractable immune-mediated disorders such as GVHD, multiple sclerosis, Crohn's disease, osteoarthritis and even immune dysregulating infectious diseases, however reports in nephrology field are very rare. We firstly reported 2 years follow up results of MP pulse and MSC in severe IgAN in 2015 (ASN) with promising results. We tried MP pulse therapy followed by autologous MSC and follow up for 7 to 9 years in severe IgA nephropathy.

Methods: We selected severe IgA nephropathy as two groups, first group by clinical CKD stage 3b or more (A) and second group by pathologically severe group as Lee's classification grade IV or V (B), and tried methylprednisolone pulse therapy followed by SVF/MSC. One cycle of methyl PD pulse is (20-30mg/kg/day, max 1g/day) for 3 consecutive days. We tried 3 to 17 cycles depends on the renal pathology, followed by autologous adipose derived SVF/MSC intravenously. Mean cell count was 3x10(7)/injection. Depends on the amount of harvested fat we tried 2-4 times.

Results: Seven patients were group A. Mean age 60 years old. Mean initial eGFR before therapy was 28 ml/min and after therapy 39 ml/min. Mean follow up period was 6.8 years. Control patient (eGFR 33 ml/min) without treatment started hemodialysis in 2 years. Three patients were group B. Mean age 25 years old. Mean initial eGFR before therapy was 85 ml/min and after therapy 106 ml/min. Mean follow up period was 9.3 years. No significan side-effects were noted. Follow up renal biopsy showed disapperance of mesangisl deposits, reduced mesangial proliferation, improved epthelial foot process fusion and disappearance of IgA depositon by immunofluorecent microscopy.

Conclusions: Follow up renal biopsy after MP pulse and SVF/MSC showed disappearance of immune deposits and improved subepthelial foot process fusion. Longterm follow up of MP-pulse and MSC/SVF therapy in severe IgA nephropathy showed a promising results and could be a lifesaving therapeutic strategies, although further studies are mandatory

SA-PO900

Treatment of IgA Nephropathy in Chinese Patients: Evidence from Real-World Data

Weiming Wang,[1] Runqin Li,[2] Ping Li,[2] Fei Gao,[2] Serge Smeets,[3] Aneesh T. George,[4] Jonathan de Courcy.[5] *[1]Shanghai Ruijin Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Beijing Novartis Pharma. Co. Ltd., Shanghai, China; [3]Novartis Pharma AG, Basel, Switzerland; [4]Novartis Healthcare Private Limited, Hyderabad, India; [5]Adelphi Real World, Bollington, United Kingdom.*

Background: Immunoglobulin A nephropathy (IgAN) accounts for more than 50% of primary glomerulonephritis in China[1]. The aim of this real-world study was to describe and compare the treatment strategy of Chinese nephrologist with nephrologists across the world for patients with IgAN.

Methods: A point-in-time, cross-sectional survey utilizing data from Adelphi Real-world IgAN Disease-Specific Programme was conducted in China, Japan, United States (US) and Europe (EU5: France, Germany, Italy, Spain, United Kingdom), from June to October 2021. 60 nephrologists from China completed a structured online record for successive 587 IgAN patients, including treatment regimens and patient clinical characteristics.

Results: The proportion of different lines of treatments with ACEi/ARB, SGLT2i, corticosteroids and other therapy was analyzed and shown (Figure 1). Compared with EU5 and US, the proportion of ACEi/ARB use at first line was lower in Asia (EU5 84%, US 86%, China 74%, Japan 59%), while the use of corticosteroids in Asia as first line was higher (EU5 36%, US 44%, China 47%, Japan 63%). Main reasons to stop corticosteroids was when patient's condition improved, treatment course completed, or side effects, of which weight gain (51%), acne (43%) and insomnia (30%) were most reported by Chinese nephrologists. Despite different lines of treatment, the proteinuria and eGFR levels were not well controlled (Table 1).

Conclusions: Despite attempts to alter various therapeutic regimens, IgAN remained poorly controlled. These data highlight an unmet need for the development of more effective drugs to treat and mitigate disease progression.

Sparsentan as First-Line Treatment of Incident Patients with IgA Nephropathy: Preliminary Findings from the SPARTAN Trial

Chee Kay Cheung,[1] Colleen Burns,[2] Neeraj Dhaun,[3] Sian V. Griffin,[4] Alexandra L. Howson,[1] Radko Komers,[2] Alex Mercer,[5] Matthew Sayer,[3] Smeeta Sinha,[6] Lisa C. Willcocks,[7] Jonathan Barratt.[1] *[1]University of Leicester & Leicester General Hospital, Leicester, United Kingdom; [2]Travere Therapeutics Inc, San Diego, CA; [3]Royal Infirmary of Edinburgh, Edinburgh, United Kingdom; [4]University Hospital of Wales, Cardiff, United Kingdom; [5]JAMCO Pharma Consulting, Stockholm, Sweden; [6]Salford Royal Hospital Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom; [7]Addenbrooke's Hospital, Cambridge University Hospitals, Cambridge, United Kingdom.*

Background: Sparsentan (SPAR) is a novel, non-immunosuppressive, single molecule Dual Endothelin Angiotensin Receptor Antagonist (DEARA) approved by the US FDA for treatment of adults with IgA nephropathy (IgAN). SPARTAN is an open-label, single-arm, multi-center, exploratory trial, investigating the safety and efficacy of SPAR as first-line therapy in newly diagnosed IgAN patients. We report preliminary findings.

Methods: Patients were aged ≥18 yrs with biopsy-proven IgAN diagnosed within 6 months before enrollment, proteinuria ≥0.5 g/d, and eGFR ≥30 ml/min/1.73m² at screening. No previous treatment with ACEis/ARBs within the past 12 months was permitted. Patients receive SPAR for 110 wks with 4-wk safety follow-up. In addition to safety monitoring, assessments include proteinuria, estimated and measured GFR, 24h ambulatory blood pressure (BP), and total body water assessment (TBW, bioimpedance). Renal and cardiac MRIs are performed at pre-defined time-points and repeat kidney biopsy at Wk 24.

Results: At data cutoff (4May2023) 6 patients had received ≥1 dose of SPAR with 12 wks follow-up. Mean (SD) age at enrolment was 42 (14) yrs (n=4 female). At baseline, median (IQR) proteinuria was 1.4 (0.6-2.0) g/d, mean (SD) eGFR 67 (27) ml/min/1.73m² and systolic/diastolic BP 122/80 (7/6) mmHg. **Table 1** and **Figure 1** summarize data over the first 12 wks. One patient discontinued due to hypotension.

Conclusions: As first-line treatment in newly diagnosed IgAN patients, preliminary findings show SPAR was safe and generally well-tolerated and reduced proteinuria >70% over 12 wks, with reduced total body water over time.

Funding: Commercial Support - Travere Therapeutics, Inc.

Table 1: Summary data over the first 12 wks (n=6)

	Baseline	Wk 2	Wk 4	Wk 6	Wk 12
Body weight, kg, mean (SD)	83 (29)	83 (29)	83 (29)	83 (29)	83 (29)
Total body water, l, mean (SD)	47 (4)	-	-	44 (10)	44 (9)

Sparsentan and Sodium-Glucose Cotransporter 2 Inhibitors (SGLT2i) in the PROTECT Open-Label Extension (OLE) Substudy and SPARTACUS: Trials in Progress

Isabelle Ayoub,[1] Radko Komers,[2] Alex Mercer,[3] Priscila Preciado,[2] Sydney C. Tang,[4] Brad H. Rovin.[1] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Travere Therapeutics Inc, San Diego, CA; [3]JAMCO Pharma Consulting, Stockholm, Sweden; [4]The University of Hong Kong, Queen Mary Hospital, Pok Fu Lam, Hong Kong.*

Background: Sparsentan (SPAR) is a nonimmunosuppressive, single-molecule, dual endothelin and angiotensin II receptor antagonist (DEARA). In the phase 3 PROTECT study, SPAR is compared to active control irbesartan in patients with immunoglobulin A nephropathy (IgAN). Subgroup analyses from the DAPA-CKD and EMPA-KIDNEY studies indicate SGLT2i reduce the risk of progression to kidney failure in patients with IgAN. The combination of SGLT2i and DEARA may provide therapeutic benefit due to potentially additive kidney protection. The double-blind period of PROTECT did not permit SGLT2i; however, an OLE substudy has been initiated which randomizes patients on stable SPAR to SGLT2i or no SGLT2i. The ongoing SPARTACUS study allows patients on stable SGLT2i to receive SPAR. These studies will evaluate the safety and effect of concomitant SPAR and SGLT2i in patients with IgAN.

Methods: The PROTECT OLE substudy is investigating the safety and effect of SGLT2i add-on with SPAR as compared to SPAR alone in patients with IgAN. SPARTACUS is a phase 2 study of SPAR safety and effect in IgAN patients on a stable dose of an SGLT2i. The **Figure** reports study designs and relevant inclusion criteria.

Results: The PROTECT OLE substudy and SPARTACUS safety and effect endpoints are reported in the **Table**, and results from these studies may be expected by late 2024 and early 2025, respectively.

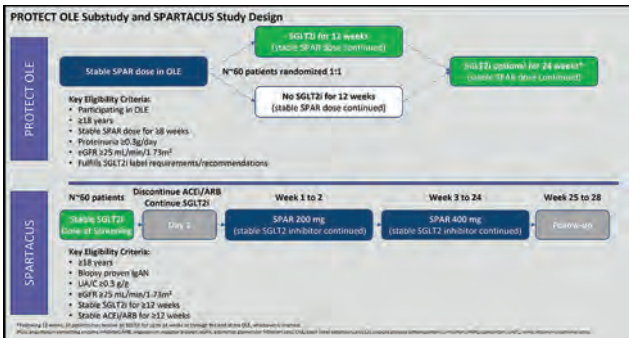
Conclusions: The PROTECT OLE substudy and SPARTACUS study will evaluate the safety and effect of concomitant SPAR and SGLT2i in patients with IgAN.

Funding: Commercial Support - Travere Therapeutics, Inc.

Table. PROTECT OLE Substudy and SPARTACUS Endpoints

Endpoints	PROTECT OLE Substudy	SPARTACUS
Safety endpoints	TEAEs	TEAEs SAEs AEs leading to treatment discontinuation AEs of interest
Primary effect endpoints	Mean change from baseline in UP/C and UA/C at Week 12 Achievement of urinary protein excretion <0.3 g/day at Week 12 Change in absolute and percent change from baseline in eGFR at Week 12	Change from baseline in UA/C at Week 24
Secondary effect endpoint	-	Achievement of UA/C <0.2 g/g at Week 24

AE, adverse event; BP, blood pressure; eGFR, estimated glomerular filtration rate; SAE, serious adverse event; TEAE, treatment-emergent adverse event; UA/C, urine albumin to creatinine ratio; UP/C, urine protein to creatinine ratio.



SA-PO903

Concomitant Sparsentan and Sodium-Glucose Cotransporter-2 Inhibitors (SGLT2i) in Patients with IgA Nephropathy (IgAN) in the PROTECT Open-Label Extension (OLE)

Laura Kooienga,[1] Robert Malecki,[2] Priscila Preciado,[3] Ping He,[3] Alex Mercer.[4] On Behalf of the DUPRO Steering Committee. *[1]Colorado Kidney Care, Denver, CO; [2]Nephrology Department of MSS, Warsaw, Poland; [3]Travere Therapeutics Inc, San Diego, CA; [4]JAMCO Pharma Consulting, Stockholm, Sweden.*

Background: Sparsentan (SPAR) is a non-immunosuppressive, single-molecule dual endothelin and angiotensin II receptor antagonist (DEARA). In the ongoing PROTECT trial SPAR is compared to irbesartan in patients with IgAN. SGLT2i may slow disease progression in IgAN as suggested in subgroup analyses from DAPA-CKD and EMPA-KIDNEY. Combined DEARA and SGLT2i therapy may provide additional kidney-protective effects with unknown adverse events. Concomitant treatment with SGLT2i was prohibited during the PROTECT double-blind period (DB); however, SGLT2i are allowed in the OLE. We report the early clinical experience of SGLT2i added to ongoing SPAR treatment in patients with IgAN enrolled in the PROTECT OLE.

Methods: Patients who completed the PROTECT DB and met eligibility criteria were enrolled in the PROTECT OLE. All patients received SPAR with a target dose of 400 mg/day. Investigators, at their discretion, could initiate concomitant SGLT2i treatment at any time during the OLE. Body weight, systolic and diastolic blood pressure, and urine protein/creatinine ratio (UP/C; based on 24-hour urine sample) were evaluated at baseline and at weeks 12, 24, and 36 after baseline. Baseline was defined as the OLE visit closest to SGLT2i start (ie, before or <14 days after). Treatment-emergent adverse events (TEAEs) were examined.

Results: At data cutoff, 21 patients (7 female) had received SPAR and add-on SGLT2i in the OLE. Mean (SD) age was 42 (11) years. Median (IQR) time from OLE start to SGLT2i start was 25 (11, 48) weeks. Summary data for selected variables are shown in **Table.** Eleven (52%) patients had TEAEs; most common were COVID-19, headache, hyperkalemia and hypotension in 2 patients (10%) each. Two patients discontinued SGLT2i and no patients discontinued SPAR.

Conclusions: Early clinical experience during the PROTECT OLE shows that SGLT2i added to a stable dose of SPAR appears to be generally well-tolerated. Data are consistent with an additive benefit on proteinuria. A randomized sub-study within the OLE is further investigating SPAR+SGLT2i combined treatment.

Funding: Commercial Support - Travere Therapeutics, Inc.

Table. Summary data for clinical variables at each timepoint during the PROTECT OLE

	Pre-SGLT2i Treatment Baseline[b] n=19	Week 12 n=18	Week 24 n=16	Week 36 n=12
Body weight, kg, mean (SD)	81.8 (19.47)	81.2 (18.68)	80.6 (20.03)	77.8 (18.95)

Treatment Patterns and Outcomes in Crescentic IgA Nephropathy and Vasculitis

Manish K. Saha, Lauren N. Blazek, Duy Vu, Ronald Falk, George Terinte-Balcan, Susan L. Hogan, Vanessa Moreno, Vimal K. Derebail, Yichun Hu, Amy K. Mottl. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Treatment patterns and consequent outcomes in crescentic IgA Nephropathy (IgAN-C) and IgA vasculitis (IgAV-C) are unknown.

Methods: We conducted a retrospective chart review of adults with biopsy proven IgAN-C/IgAV-C registered in the Glomerular Disease Collaborative Network from 1996 to 2018. Treatments were categorized as: IV cyclophosphamide (CYC) + steroids OR mycophenolate (MMF) + steroids, steroids alone or conservative therapy (CT). Minimal treatment included 2 months of CYC and 4 months of MMF or steroids. Azathioprine or MMF were used in all cases for maintenance treatment following CYC and MMF

induction therapy. MEST-C scoring was performed by a single nephropathologist. The composite kidney endpoint was a 40% decline in eGFR, ESKD or eGFR < 15ml/min/1.73m^2.

Results: The baseline demographics, clinical characteristics and endpoints are shown in Table 1. Median duration of follow-up was 46 months (95% CI 20-84) in the full cohort and was statistically similar across treatment groups (p=0.8). The only baseline difference between groups was in the severity of mesangial hypercellularity (MH) and crescentic involvement. MH was numerically lowest in the CT group and ≥25% crescents was numerically greatest in CYC group. The composite kidney endpoint was common, occurring in 60 (65%) of the total sample. Outcomes were similar across treatment groups, though there was a numerically lower risk for the composite kidney endpoint in the CYC group.

Conclusions: CYC may be superior for treatment of IgAN-C/IgAV-C. A randomized clinical trial is indicated to inform optimal therapy for this high-risk population.

Demographics and Clinical Characteristics	Cyclophosphamide (N=31) Median (95% CI)	Mycophenolate (N=15) Median (95% CI)	Steroids Alone (N=30) Median (95% CI)	Conservative Treatment (N=17) Median (95% CI)	p-value

From Famine to Feast in IgA Nephropathy: New Treatments Present New Opportunities for Patients

Chris Dudzenski, Meghan Weiss, Stephen Regan. *Spherix Global Insights, Exton, PA.*

Background: As of only a few years ago, IgA nephropathy (IgAN), a common form of glomerulonephritis worldwide, had few treatment options beyond RAAS inhibitors and corticosteroids. The approval of SGLT2 inhibitors to treat non-diabetic CKD patients, along with accelerated approvals for targeted budesonide and sparsentan over the past three years have created new options. This analysis explores the evolution of IgAN treatment in the US.

Methods: Data from 1,359 patient charts were collected in partnership with 496 US nephrologists via HIPAA compliant online surveys annually from 2021 to 2023. Additionally, launch metrics have been collected on a monthly basis via an online survey of ~75 nephrologists each wave, beginning with the launch of targeted budesonide in February 2022.

Results: Audited chart data reveals US nephrologists are embracing new options, with exponential growth in the use of SGLT2is in IgAN patients (6% in 2021, 21% in 2022, and 43% in 2023) and steady growth in the adoption of newly approved agents. Correspondingly, as use of targeted budesonide grew from 2022 to 2023, corticosteroid use in IgAN patients dropped (14% in 2021 and 2022 to 7% in 2023). As of May 2023, 53% of US nephrologists reported they had prescribed targeted budesonide, having grown from 18% six months post-launch and 39% after 12 months on the market. In May 2023, after only a few months on the market, 87% of US nephrologists were aware of sparsentan's approval and 43% considered it an advance over other treatment options; a minority of physicians had written a prescription for the agent (21%). Sparsentan's REMs monitoring requirements may impact overall use as the product continues its launch. Despite newer options, 66% of nephrologists still perceive there to be a high unmet need for new IgAN treatments. The pipeline of potential disease-targeting mechanisms is robust, including complement inhibitors, anti-APRIL agents, and anti-BLyS agents. Notably, 68% of nephrologists believe the complement system plays an active role in the pathogenesis of IgAN as they seek non-immunosuppressive options that target the cause of the disease.

Conclusions: Within a short timeframe, nephrologists have gone from few treatment options for IgAN patients to having a more substantial arsenal. As more disease-targeting agents potentially come to market, care for IgAN patients is likely to continue to evolve.

SA-PO906

Low-Density Lipoprotein (LDL) Apheresis Removes Atherogenic Mediators in Focal Segmental Glomerulosclerosis

Jacob A. Humphrey,[1] James Rose,[1] Kelli A. Krallman,[1] Joshua Zaritsky,[3] Michael L. Moritz,[2] Stuart Goldstein,[1] Elif Erkan.[1] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [3]Phoenix Children's Hospital, Phoenix, AZ.*

Background: Focal Segmental Glomerulosclerosis (FSGS) is the most common cause of end stage kidney disease in adolescents. Lipid dysregulation causes cardiovascular morbidity and disease progression in FSGS. Unregulated lipoprotein associated phospholipase A2 (Lp-PLA2) activity causes increased oxidation of low-density lipoprotein (oxLDL) and production of inflammatory cytokines, leading to atherosclerosis and poor cardiovascular outcomes. However, this has not been explored in children with FSGS. We hypothesize that LDL apheresis can improve cardiovascular outcomes by removal of atherogenic mediators in patients with FSGS.

Methods: We enrolled 10 patients with FSGS from 4 centers (mean age 15.3 years, M/F: 6/4). Five patients had post-transplant FSGS recurrence. Patients received 12 LDL apheresis treatments via the Liposorber in addition to standard immune therapies. Atherogenic lipid metabolites (Lp-PLA2, oxLDL) and cytokines (TNFα, IL-6, IL-1β) were collected pre and post-treatment at set intervals and measured via ELISA. Proteinuria was measured by urine protein to creatinine ratio (UPC) and cystatin C GFR was monitored pre and at the completion of LDL apheresis treatment. Results expressed as mean±SEM.

Results: OxLDL was reduced from 94.7 ± 15.3 to 78.6 ± 11.4 u/L (p=0.019) at the completion of LDL apheresis. Lp-PLA2 showed a trend of reduction from 173.6 ± 36.8 to 117.9 ± 15.7 ng/mL (p=0.07). Interestingly, the mean baseline ox-LDL levels were significantly elevated, comparable to patients with extreme obesity. UPC was reduced from 10.3 ± 2.5 to 5.7 ± 1.8 mg/mg (p=0.005). Mean cystatin C GFR was 57mL/min at baseline and was unchanged over the study period.

Conclusions: We demonstrated that children and adolescents with FSGS have elevated levels OxLDL and Lp-PLA2, increasing the risk for long term atherogenesis and cardiovascular morbidity. We propose that monitoring and normalizing these lipid metabolites will promote cardiovascular health in patients with FSGS. LDL apheresis remains a safe and effective method of reducing oxLDL and Lp-PLA2 in patients with FSGS. This was accompanied by a significant reduction in proteinuria inducing disease remission. Larger studies are needed to further assess the effects of LDL apheresis and antilipidemic treatments on cardiovascular outcomes in this patient population.

Obinutuzumab in Treatment-Resistant Primary Focal Segmental Glomerulosclerosis (FSGS): A Report of Four Cases

Yeshwanter Radhakrishnan,[1] Amit Sethi,[2] Ladan Zand,[1] Fernando C. Fervenza.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: There is no definite approach in treating patients with primary FSGS who fail to respond to immunosuppressive (IS) therapy including corticosteroids and calcineurin inhibitors. Other IS therapy such as rituximab (RTX), Acthar gel and mycophenolate have been use with sub-optimal response. Obinutuzumab is type II anti-CD20 monoclonal antibody that has been shown to be effective in treating patients who have been resistant to RTX in diseases such as ANCA associated vasculitis or membranous nephropathy.

Methods: We report 4 patients with treatment-resistant primary FSGS with negative genetic testing who were treated successfully with obinutuzumab. They were treated with an average of 4 other IS with sub-optimal response as shown in Table 1.

Results: The mean age was 48 years and 50% were males. The mean serum creatinine and mean serum albumin at the time of presentation was 2.2 mg/dL and 2.0 g/dL respectively. The mean proteinuria at the time of diagnosis and before initiation of obinutuzumab was 10.7 g/24 hours and 7.6 g/24 hours respectively. The mean proteinuria at 6 and 12 months after the infusion was 1.6 g/24 hours and 1.7 g/24 hours respectively. Mean serum albumin improved to a mean of 4.0 g/dL and 4.3 g/dL at 6 months and 12 months respectively. None of the patients experienced any adverse effects or infusion reactions. CD20+ B cells remained depleted over an average of 10.5 months.

Conclusions: We report 4 cases of treatment-resistant primary FSGS that were treated successfully with obinutuzumab infusions with 1 complete remission and 3 partial remissions. The efficacy of Obinutuzumab on treatment-resistant FSGS should be evaluated through a randomized clinical trial to determine short- and long-term outcomes and adverse effects.

Intravenous Rituximab vs. Oral Mycophenolate Mofetil in Sustaining Remission in Calcineurin Inhibitor-Dependent Steroid-Resistant Nephrotic Syndrome: An Open-Label Randomized Controlled Trial

Aditi Sinha, Arvind Bagga. Division of Nephrology, Dept of Pediatrics; Nephrotic Syndrome Study Group. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Retrospective unicenter studies in patients with steroid-resistant nephrotic syndrome (NS) show that switching of calcineurin inhibitors (CNI) to oral mycophenolate mofetil (MMF) or IV rituximab enables remission and is corticosteroid- and CNI-sparing, while avoiding therapy-associated adverse effects (AE). However, prospective controlled studies are lacking.

Methods: This open-label multicenter RCT will examine the superiority of IV rituximab *versus* oral MMF in maintaining satisfactory remission in patients with steroid-resistant NS who were in complete or partial remission while on therapy with tacrolimus or cyclosporine for over 2-yrs, but continued to show steroid-sensitive relapses. Eligible consenting patients with steroid-resistant NS, 1-18 yr-old, with complete or partial remission and steroid sensitive relapses while on ≥2-yr therapy with CNI, will be randomized to switch therapy to either oral MMF for 1-yr or IV rituximab (2 doses a week apart; 1 dose 6-months later). The primary outcome, on intention-to-treat analysis, will be the proportion of patients with satisfactory remission (sustained remission or infrequent relapses) at 1-yr (Fig. 1). Secondary outcomes are the proportions of patients with frequent relapses, steroid resistance & serious AE, incidence of relapses, prednisolone exposure, and changes in anthropometry & biochemistry (CTRI/2022/10/046890).

Results: The study began enrolment in October 2022 and will close enrolment in February 2025.

Conclusions: Findings from the study shall have important implications for guiding the choice of non-nephrotoxic therapies following induction and maintenance of remission with CNI for childhood idiopathic steroid-resistant NS.

Monthly Mini-Dose Rituximab for Primary Membranous Nephropathy: A Different Approach

Song Wang, Zhenling Deng, Danxia Zheng, Sijia Zhou, Wen-Han Bao, Yue Wang. *Peking University Third Hospital, Beijing, China.*

Background: The currently recommended dose of rituximab for primary membranous nephropathy is as high as that for lymphoma. This study assessed the efficacy of monthly 100 mg rituximab monotherapy in patients with primary membranous nephropathy.

Methods: This retrospective study included 32 patients with primary membranous nephropathy treated at Peking University Third Hospital between March 2019 and January 2023. All patients were anti-phospholipase A2 receptor (PLA2R) antibody-positive and received rituximab 100 mg intravenously monthly for at least 3 months without other immunosuppressive therapy.

Results: The baseline parameters included: proteinuria, 8.5±3.6 g/day; serum albumin, 24.8±3.4 g/L; and anti-PLA2R antibody, 160 (20-2659) RU/mL. B-cell depletion was achieved in 87.5% patients after the first dose of rituximab 100 mg and in 100% after the second equivalent dose. The median follow-up was 24 months (range 18-38). Twenty-seven (84%) patients achieved remission, with 11 (34%) patients achieving complete remission by last follow-up. The relapse-free survival from the last infusion was 13.5 months (range 3-27). Patients were stratified into the low-titer (<150 RU/mL, n=17) and high-titer groups (≥150 RU/mL, n=15) based on the anti-PLA2R titer. Sex, age, urinary proteins, serum albumin, and estimated glomerular filtration rate at baseline did not differ significantly between the two groups. At 18 months, compared to the low-titer group, the rituximab dose (960±387 vs 694±270 mg, p=0.030) was higher, while serum albumin (37.0±5.4 vs 41.3±5.4 g/L, p=0.033) and the complete remission rate (13% vs 53%, p=0.000) were lower in the high-titer group.

Conclusions: Monthly rituximab 100 mg appeared as a potential effective regimen for treating anti-PLA2R-associated primary membranous nephropathy with a low anti-PLA2R titer.

Funding: Government Support - Non-U.S.

Felzartamab Reduces aPLA2R Ab by Selectively Depleting CD38+ Plasma Cells and Plasmablasts, the Main Pathogenic Cellular Drivers of Disease in Primary Membranous Nephropathy (PMN)

Donna Flesher,[1] Rainer Boxhammer,[2] Tabea Kräft,[2] Lisa Kivman,[1] Stefan Haertle,[2] Jaideep Dudani,[1] Houston N. Gilbert,[1] Uptal D. Patel,[1] Brad H. Rovin.[3] *[1]Human Immunology Biosciences Inc, South San Francisco, CA; [2]MorphoSys AG, Planegg, Germany; [3]The Ohio State University, Columbus, OH.*

Background: Felzartamab (felza) is a fully human monoclonal antibody that binds to CD38 with high affinity and depletes CD38+ antibody-producing cells such as plasma cells/plasmablasts primarily via antibody-dependent cellular cytotoxicity & phagocytosis. In studies of high-risk PMN patients, felza substantially reduced aPLA2R with associated improvements in UPCR and serum albumin. To further characterize felza with respect to efficacy biomarkers and preservation of protective immunity, we analyzed samples collected prospectively during the M-PLACE (NCT04145440) and NewPLACE (NCT04733040) trials.

Methods: Serum and whole blood were collected pre/post- felza treatment in patients with aPLA2R+ PMN. Biomarker analyses were performed for aPLA2R (ELISA), total IgG (turbidimetry), anti-Tetanus Toxoid (TT) (ELISA), and B cell populations (flow cytometry).

Results: Felza reduced aPLA2R comparably in patients with baseline levels <150 and ≥150 RU/mL (Table 1). A dose-dependent effect on aPLA2R reduction at 6 months was observed across both M-PLACE (9 infusions) and NewPLACE (5 or 2 infusions). Depletion of detectable CD38+ plasmablasts was observed 1 wk after felza treatment. Treatment did not impact other B cell populations, as absolute counts of total, naïve, and memory B cells were unchanged. Total IgG decreased on treatment then recovered above baseline by end of study. Anti-TT titers decreased on treatment, however levels were maintained above the protective threshold (0.1 IU/mL).

Conclusions: Felza selectively depleted CD38+ plasmablasts and plasma cells, reducing pathogenic aPLA2R to a greater extent than protective anti-TT titers and total IgG, which was dose-dependent and durable. Treatment of PMN with Felza suggests an efficient and selective treatment concept with preservation of vaccine response compared to conventional immunosuppressive therapies.

Combined Rituximab and Cyclophosphamide Therapy in PLA2Rab-Associated Membranous Nephropathy (MN)

Anne-Els van de Logt, Coralien Vink-van Setten, Jack F. Wetzels. *Radboudumc, Nijmegen, Netherlands.*

Background: Optimal treatment of MN is debated: oral high-dose cyclophosphamide (CP) is effective (>90% immunological remission (IR)), but associated with toxicity. Rituximab (RTX) is less toxic, but also less effective (IR 65%). We evaluated the "McAdoo" treatment regimen (RTX 2*1000mg; CP 1.5mg/kg/day * 8weeks and prednisone (iv 2* 1gr + 3 weeks oral starting at 1mg/kg) in high risk MN. In this preliminary analysis, we evaluated PLA2Rab kinetics and immunological remission, a surrogate biomarker for later onset clinical remission.

Methods: We analysed data of incident patients with MN, at high risk for progression, treated according the prescribed protocol. aPLA2Rab levels were measured by ELISA in available samples collected at baseline (n=26), and 2 (n=18), 4 (n=20), 8 (n=20) and 12 (n=23) weeks after start of therapy.

Results: We included 26 patients (M/F 15/11, age 60 [47-68] years, Screatinine 128 µmol/l [102-136], Salbumin 18 g/l [14-21] and UPCR 7.1 gram/10 mmol [5.7-10.0]). Baseline PLA2Rab levels were 176 RU/ml [115-460]. Overall, there was a very fast decrease of PLA2Rab levels, with a decrease > 50% within 2 weeks in all but two patients. Within 8 weeks complete IR (ELISA < 2RU/ml) was 83 %. IR was associated with baseline PLA2Rab tertile (Table). The lower IR rate at 8weeks in patients in the highest tertile was not merely explained by the high baseline PLA2Rab levels, but more likely the consequence of a prolonged PLA2Rab half-life (Table). Most patients with high baseline PLA2Rab levels have received additional therapy (mostly RTX 2 gr).

Conclusions: Our study showed early and high immunological response rate in patients with PLA2Rab associated MN. The longer T1/2 in patients with very high PLA2Rab levels suggest immunological differences (increased B cell proliferation, presence of long-lived plasmacells). Assessment of PLA2Rab levels within 2-4 weeks after start of therapy may enable to identify patients who need more intensive therapy.

Tertiles of baseline PLA2Rab and outcome

PLA2Rab tertile	Low	Middle	High
PLA2Rab (RU/ml)	16-131	151-273	280-1500
IR after 8 weeks	100 %	100 %	43 %
PLA2Rab T1/2 > 7 days	0 %	0 %	71 %
Additional therapy	0 %	11 %	75 %

SA-PO912

Analysis of the Efficacy and Influencing Factors of Rituximab in the Treatment of Primary Membranous Nephropathy

Jiawei Cheng, Zhangzhe Peng. *Xiangya Hospital Central South University, Changsha, China.*

Background: Membrane nephropathy (MN) is the most common primary glomerular disease that causes adult nephrotic syndrome in the world. Primary membranous nephropathy (pMN) can progress to end-stage renal disease. Rituximab (RTX) has been listed as the first-line treatment for patients with medium and high risk pMN.

Methods: This study retrospectively analyzed 83 patients with pMN in XX Hospital who were confirmed by renal biopsy and received RTX treatment. According to the clinical outcome, the patients were divided into complete remission (CR), partial remission (PR) and no response (NR). CR, PR were considered effective in treatment while NR was considered ineffective in treatment. The baseline values of patients with different clinical outcomes were compared to explore the influencing factors that affect the efficacy of RTX in the treatment of pMN patients.

Results: After a follow-up of 10.66 (7.25, 16.46) months, 65.1% of those pMN patients achieved clinical remission, of which 27.7% had complete remission and 37.3% had partial remission. Patients with effective treatment (CR, PR) showed a significant decrease in urinary protein creatinine ratio after RTX treatment, while creatinine and eGFR remained stable. Patients with ineffective treatment (NR) showed no decrease in urinary protein creatinine ratio after RTX treatment, while creatinine significantly increased and eGFR significantly decreased. During follow-up, 9 patients (10.8%) experienced infection related adverse reactions. Multivariate Cox regression analysis showed that the combined use of glucocorticoids (p=0.027, HR=2.05), serum albumin (p=0.006, HR=1.10), and urinary light chain LAMBDA/KAPPA ratio (>0.622)(p=0.011, HR=0.33) were independent influencing factors on the effectiveness of RTX in treating pMN. Patients with lower serum albumin and higher urinary LAMBDA/KAPPA ratio may be more likely to have ineffective treatment, and the combined use of glucocorticoids may promote RTX induced disease remission.

Conclusions: RTX has a good therapeutic effect on pMN, which can reduce urinary protein and increase albumin in patients, maintain the stability of blood creatinine and eGFR, and have a low incidence of adverse reactions. The combined use of glucocorticoids, serum albumin and urinary LAMBDA/KAPPA ratio are independent factors affecting the effectiveness of RTX in the treatment of pMN.

Background: Guidelines recommend standard rituximab therapy (1000mg*2 or 375mg/m²*3-4) for patients with idiopathic membranous nephropathy (IMN) at high risk of progression to ESRD. This study assessed the safety and efficacy of B cell and anti-PLA2R antibody targeted low-dose rituximab therapy in patients with IMN.

Methods: In this prospective study, we compared the partial and complete remission, serious and non-serious events between the personalized treatment group and standardized protocols group. Patients were followed once every 2 months for 12 months. The primary outcome was a composite of complete or partial remission of proteinuria. In addition, laboratory indexes and safety were assessed.

Results: A total of 101 were available for statistical analysis out of 140 participants at inclusion. At 12 months, 34 out of 55 patients (61.8%) in the personalized group and 29 of 46 (63.04%) in the standardized group had complete or partial remission. Kaplan–Meier curves indicated no difference for the cumulative incidence of participants with IMN who progressed to the end point according to the two arms (Figure 2). The median (quartile) of total RTX dose at one year was 700 (600,1100) mg per patient with a total cost of RMB (yuan) 18786 (17388, 24378) per unit utility in the personalized group, which was markedly lower than that in the standardized group. Anti-PLA2R autoantibody depletion 6 months post-treatment could predict a higher probability of remission. There were statistically significant differences in the frequency of adverse events between groups (P=0.02).

Conclusions: B cell and anti-PLA2R antibody targeted rituximab therapy was as effective as standard protocols. It was a more economical and safer strategy for IMN patients.

Funding: Government Support - Non-U.S.

Impact of Time to Treatment on Outcomes in Primary Membranous Nephropathy

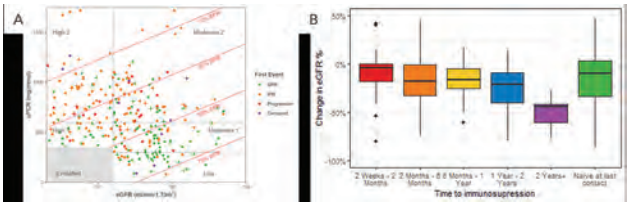
Patrick Hamilton,[1] Sebastian G. Bate,[1] Omar S. Ragy,[1] Mrityunjay Hiremath,[2] Anirudh Rao,[2] Arif Khwaja,[3] Durga Anil K Kanigicherla.[1] *[1]Manchester University NHS Foundation Trust, Manchester, United Kingdom; [2]Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom; [3]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom.*

Background: Despite treatment, progression of renal dysfunction remains a significant burden globally in patients with primary MN (pMN). Clinicians use individualized risk assessment to choose immunosuppression therapy after '*watchful wait*' to help avoid side-effects in those who could otherwise have achieved remission spontaneously. Here we describe features of renal disease during the *'watchful wait'* period and its association with longer term outcomes.

Methods: Retrospective longitudinal cohort study of patients with pMN (biopsy-proven or positive serology in the absence of secondary causes). Data collected from three specialist centres in the North of England, with patients presenting as proteinuric kidney disease from Jan 2003 to July 2019, with follow-up data to Sept 2021. Risk markers included uPCR, eGFR and baseline demographic factors. Primary outcomes were CKD5 and Partial Remission (PR). Secondary outcomes were Progression (composite of doubling of creatinine, CKD5, and death). Analysis investigated the change in eGFR based on risk categorisation. Cox proportional hazard models were used to assess the association of outcomes with risk markers.

Results: 312 patients were included. Using eGFR and uPCR, patients in the low and moderate risk groups were more likely to achieve spontaneous PR (Fig 1A). The strongest predictor of renal outcome was eGFR at the start of immunosuppression (IS), irrespective of baseline function, and the longer patients waited to start treatment, the worse the renal decline (Fig 1B).

Conclusions: Combined eGFR and uPCR can be used to predict patients who are more likely to attain SR and that in patients who require IS, the longer it takes to initiate treatment, the worse their renal outcomes. This has significant implications for future guidelines in the management of pMN.



A) eGFR & uPCR at baseline and first key outcome B) Percent change in eGFR between baseline and start of IS **Low:***uPCR<350 & eGFR>60*; **Mod 1:***350≤uPCR<600 & eGFR>60*; **Mod 2:***uPCR≥600 & eGFR≥60*; **High 1:***300≤uPCR<600 & eGFR<60*; **High 2:**uPCR≥600 & eGFR<60; **SPR:** *Spontaneous PR;* **IPR:** *PR with IS; uPCR - mg/mmol; eGFR - ml/min*

SA-PO915

Anticoagulation Thromboprophylaxis Is More Effective than Antiplatelet Thromboprophylaxis for Individuals with High-Risk Membranous Nephropathy

Ayman Al Jurdi,[1] Christopher El Mouhayyar,[1] Karim Yatim,[1] Orhan Efe,[1] Saif A. Muhsin,[2] Leonardo V. Riella,[1] Reza Zonozi,[1] Karen A. Laliberte,[1] John Niles,[1] Anushya Jeyabalan.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Background: Data on the use of apixaban and antiplatelet therapies for thromboprophylaxis in MN are limited.

Methods: We conducted a multicenter retrospective cohort study of all individuals with high-risk MN, defined as having a serum albumin nadir < 2.5 g/dL in the setting of nephrotic-range proteinuria. The primary outcome was the incidence of thrombotic events within 12 months, stratified by thromboprophylaxis strategy.

Results: 66 individuals met the study's inclusion criteria. Median serum creatinine was 1.2 mg/dL (IQR 0.9-1.5), median UPCR was 12.2 g/g (IQR 8.5-16.6), and mean nadir serum albumin level was 1.9 ± 0.4 g/dL. 23 (35%) received no thromboprophylaxis, 20 (30%) received antiplatelet [AP] prophylaxis, and 23 (35%) received anticoagulant [AC] prophylaxis. Thrombotic events occurred in 11 subjects (17%): 1 in the AC group, 4 in the AP group, and 6 in the no prophylaxis group. No thrombotic events occurred in individuals who received apixaban (n = 11), while one individual in the warfarin group (n = 7) developed a recurrent ischemic stroke. The incidence of thrombotic events was lower in the AC group compared to both AP and no prophylaxis groups (log-rank P = 0.041, Fig 1A). In individuals with anti-PLA2R antibody-associated MN, higher anti-PLA2R antibody levels were associated with a higher risk of thrombotic events (Fig 1B) at various levels of serum albumin (Fig 1C). Three subjects had significant bleeding events, 1 in the AP group and 2 in the AC group.

Conclusions: AC prophylaxis, including apixaban, is associated with a lower risk of thrombotic events compared to AP or no prophylaxis in individuals with high-risk MN.

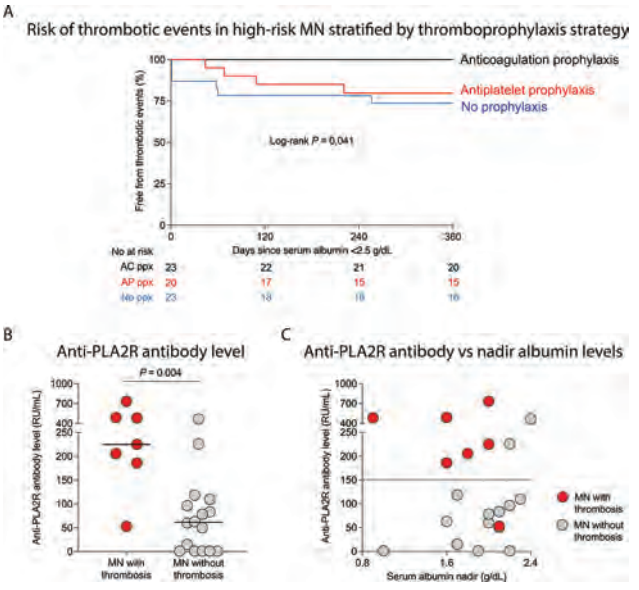


Figure 1. Thrombotic risk in individuals with high-risk Membranous nephropathy (MN).

C3 Glomerulopathy Current Treatment Options and Real-World Management: Results from a Multi-Country Study

Richard A. Lafayette,[1] Katharina Pannagl,[2] Briana C. Ndife,[3] Serge Smeets,[4] Kathleen Murphy,[3] Jonathan de Courcy,[5] Susanna Libby,[5] Clare Proudfoot.[4]
[1]Stanford University School of Medicine, Stanford, CA; [2]Novartis Pharmaceuticals UK Ltd, London, United Kingdom; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [4]Novartis Pharma AG, Basel, Switzerland; [5]Adelphi Real World, Bollington, United Kingdom.

Background: Complement 3 glomerulopathy (C3G) is a rare kidney disease, with an estimated incidence of 1-2/million/year. C3G is associated with a high risk of disease progression, approximately 50% of patients reach kidney failure within 10 years of diagnosis. KDIGO guidelines recommend treating with renin-angiotensin-aldosterone system inhibitors (RAASi) and in some patients, corticosteroids (CS) or mycophenolate mofetil (MMF), or eculizumab. This analysis aimed to better understand the treatment of C3G in the US, Europe, and Asia.

Methods: Data were drawn from the Adelphi C3G Disease Specific Programme, a real-world cross-sectional survey of C3G-treating nephrologists in US, France, Germany, Italy, Spain, UK (EU5), China and Japan from August 2022 to April 2023. Nephrologists completed forms via online links for consecutive patients presenting with C3G. Forms included patients' demographics, clinical characteristics and C3G treatments.

Results: 111 nephrologists completed records for 385 C3G patients (US 100, EU5 189, China 60, Japan 36). 321 (83%) patients were receiving treatment at time of survey. Of these, median patient age was 41 years, and 60% were male. Median proteinuria was 1.3 g/day. 63% of patients had proteinuria ≥1 g/day (Table 1). 70% were receiving RAASi, 49% CS, 27% MMF, and 30% biologics.

Conclusions: C3G is a rapidly progressing disease with no approved therapy. Most patients in this study were treated with both conventional immunosuppressants and biologics frequently added to RAASi. Despite this, proteinuria remained high, in most patients ≥1 g/day. This highlights the need for targeted therapies to treat the root cause of C3G.

Change in GFR and UPC (Urinary Protein:Creatinine Ratio) Before and After Eculizumab in C3 Glomerulopathy

Tina Liu,[1] Lauren O. Fergus,[1] Monica D. Hall,[1] Patrick D. Walker,[2] Richard J. Smith,[1,4] Carla M. Nester.[1,3] *[1]University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA; [2]Arkana Laboratories, Little Rock, AR; [3]The University of Iowa Stead Family Department of Pediatrics, Iowa City, IA; [4]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: C3 Glomerulopathy (C3G) is an ultra-rare kidney disease characterized by alternative complement pathway dysregulation. Most patients reach end-stage renal disease (ESRD) within 10 years of diagnosis. The complement inhibitor, eculizumab, has been used to treat C3G with mixed results. In this study, we compared differences in GFR and UPC trends in a cohort of C3G patients before and after eculizumab treatment.

Methods: 14 patients from the University of Iowa's C3G Natural History Study were included in the cohort. Inclusion criteria: baseline native biopsy diagnosis of C3G and ≥1 year of clinical data (C3, GFR, UPC) prior to and after starting eculizumab. Exclusion criteria: teatment with other complement inhibitors, dialysis, and kidney transplant. Simple linear regression of the change in GFR and UPC before and after eculizumab initiation was measured. Paired t-test with p values were used to evaluate the significance of GFR and UPC change pre/post treatment; $p < 0.05$.

Results: GFR changes per year pre/post eculizumab were insignificant ($p = 0.201$). Trends showed a pattern of GFR decline with a median difference from pre- to post-eculizumab of -6.47. UPC change per year was also not significant ($p = 0.981$). General patterns showed improvement with a median difference in UPC change per year pre/post eculizumab of -0.26.

Conclusions: Most patients showed no significant change in disease trajectory with eculizumab therapy. There was a general trend towards worsening kidney function following eculizumab, though with a slight decrease in UPC. Limitations include sample size and gross slope estimation with only simple linear regression. Future directions include examining the baseline C3G histology, complement biomarkers, and other clinical markers to determine if outcome may be predicted.

CPV-104, a Recombinant Variant of Human Complement Factor H Produced in Moss, to Be Studied in a Phase 1/2 Clinical Trial in Patients with C3 Glomerulopathy (C3G)

Karin Heidenreich,[1] Björn Cochlovius,[1] Martin Bauer,[1] Andreas Busch,[1] Paulina Dabrowska-Schlepp,[1] Andreas Schaaf,[1] Fabienne C. Zeitter,[1] Karsten Häffner,[2] Joerg Koehl,[3] Tilman Schmidt,[6] Thorsten Wiech,[4] Peter F. Zipfel.[5] Eleva Clinical Trial Group. *[1]eleva GmbH, Freiburg, Germany; [2]Albert-Ludwigs-Universitat Freiburg Medizinische Fakultat, Freiburg, Germany; [3]Universitat zu Lubeck Sektion Medizin, Lubeck, Germany; [4]University Hospital Hamburg, Hamburg, Germany; [5]Leibniz-Institute for Natural Product Research and Infection Biology, Jena, Germany; [6]Universitat Greifswald, Greifswald, Germany*.

Background: Human complement factor H (CFH) is the main regulator of the alternative pathway (AP). CFH deficiency is associated with several complement-mediated diseases, such as C3 Glomerulopathy (C3G) or atypical hemolytic uremic syndrome (aHUS). C3G is caused by an uncontrolled overactivation of AP in fluid phase and on cell surfaces with overlapping clinical and pathophysiological features. AP dysregulation leads to predominant C3 fragment deposition within the glomeruli. C3G appears with proteinuria, microhematuria, acute kidney injury, and chronic kidney failure. About 50% of patients develop end-stage renal disease within 10 years. Recurrence of C3G after kidney transplantation is common. Currently there is no established disease-modifying treatment available. CPV-104 is produced in the suspension culture of moss *Physcomitrium patens* in 500L single-use bioreactors.

Methods: The current clinical program aims to develop CPV-104 for treatment of C3G.

Results: Preclinical in vivo (FH (-/-) knockout mice) and in vitro studies with CPV-104 demonstrated comparable or superior efficacy to that achieved with serum-derived CFH.

Conclusions: CPV-104 is a promising candidate for the 1st disease modifying treatment option in C3G. In preclinical studies CPV-104 demonstrated a strong potential to rebalance the dysregulated complement pathway, simultaneously maintaining its natural defense potential against infectious agents and pathogens. Following successful phase 1 and a proof-of-concept clinical trial in C3G, CPV-104 may also become a new treatment option for a broader spectrum of complement mediated diseases.

Outcome of Kidney Transplantation in Atypical Hemolytic Uremic Syndrome (aHUS): Eculizumab Prophylaxis vs. Rescue Therapy

Caroline Duineveld,[1] Emily Glover,[2] Romy N. Bouwmeester,[1] Nicole Van De Kar,[1] David Kavanagh,[2] Jack F. Wetzels,[1] Neil S. Sheerin.[2] *[1]Radboudumc, Nijmegen, Netherlands; [2]Newcastle Upon Tyne Hospitals NHS Foundation Trust, Newcastle Upon Tyne, United Kingdom*.

Background: Prophylactic eculizumab therapy is advised in aHUS kidney transplant recipients in view of high risk of recurrence. However, historical recurrence rates may be overrated and early start of eculizumab therapy at relapse ("rescue") may prevent graft loss. The efficacy, safety, and costs of different treatment strategies have not been compared in RCT's. We performed a comparative cohort study, including patients from a previously described Dutch cohort (NL) treated with eculizumab rescue therapy [PMID 37069997] and a UK aHUS cohort using eculizumab prophylaxis [PMID 36413152].

Methods: NL: we selected all adult aHUS patients who received a kidney transplantation between 2010-2021 in the Radboudumc (n=30) and enriched this cohort with 8 patients who received rescue therapy in other centers. UK: all adult aHUS patients transplanted between 2013 and 2017 were included.

Results: We included 38 NL patients (29 F, median age 45y, range 22-68) and 35 UK patients (24 F, median age 42y, range 17-64). Overall characteristics were comparable, although the UK cohort included more patients with a mutation in CFH SCR 20 / hybrid gene (31% versus 5%; $p<0.01$), whereas NL patients more often received a living donor kidney (66% versus 20%; $p<0.001$). The majority of the NL patients (74%) was transplanted using low dose tacrolimus (TAC). Eighteen (47%) NL patients were treated with eculizumab rescue therapy. Follow-up was comparable, NL 70.8m (range 10-134), and UK 55.4m (range 2-95). There were no significant differences in death-censored graft survival between the two cohorts (Figure).

Conclusions: Eculizumab rescue therapy was not inferior to eculizumab prophylaxis with respect to death-censored graft survival. **Limitation**: this conclusion holds for use of rescue therapy in a population characterized by low prevalence of "very high risk" genes, low TAC levels, and predominant use of living donor kidneys.

SA-PO920

Ravulizumab Is Associated with Positive Clinical and Quality-of-Life Outcomes in Patients with Atypical Hemolytic Uremic Syndrome in a Real-World Setting

Yan Wang,[1] Francesca Gatta,[2] Moh-Lim Ong,[1] Gregor Gibson,[3] Kieran S. Wynne-Cattanach,[3] Joe Conyers,[3] Karl-Johan Myren.[4] *[1]Alexion, AstraZeneca Rare Disease, Boston, MA; [2]Alexion Pharma GmbH, AstraZeneca Rare Disease, Zurich, Switzerland; [3]Adelphi Real World, Bollington, United Kingdom; [4]Alexion, AstraZeneca Rare Disease, Stockholm, Sweden.*

Background: Ravulizumab (RAV) is a complement C5 inhibitor first approved in 2019 for the treatment of atypical hemolytic uremic syndrome (aHUS), a rare disease characterized by hemolytic anemia, thrombocytopenia and organ damage. This study assessed real-world clinical and quality of life (QoL) outcomes in patients with aHUS treated with RAV.

Methods: Data were drawn from the Adelphi aHUS Disease Specific Programme™, a cross-sectional survey of physicians reporting on their consulting patients with aHUS (data collected August–December 2022). This analysis included physician-reported, patient data from Germany, Italy, Spain, the UK, and the USA. Patients included had physician-diagnosed aHUS and were treated with RAV at time of survey.

Results: Overall, 65 patients were included: 31 had switched from eculizumab (ECU; switch cohort) and 34 had not received ECU before RAV initiation (naive cohort). Median (range) age at time of survey was 34 (15–75) and 39 (14–66) years in the switch and naive cohorts, respectively; 10% (n = 29) and 16% (n = 32) had family history of kidney disease. For switch and naive cohorts, respectively, median (interquartile range) time from aHUS diagnosis was 531 (233–1043) and 257 (152–456) days and RAV treatment duration was 163 (93–293) and 201 (106–476) days; prior ECU treatment duration was 150 (62–440) days (switch cohort only; n = 24). Two patients (6%) in the switch cohort had had a kidney transplantation before switching. Clinical outcomes are shown in the **Table**. Physician-reported overall QoL was rated 'good' to 'excellent' in 97% (overall physical/mental health: 97%/93%) and 82% (overall physical/mental health: 82%/85%) of patients in the switch and naive cohorts, respectively.

Conclusions: After initiation of RAV, the majority of patients had better clinical outcomes (compared with before RAV initiation) and a favorable QoL.

Funding: Commercial Support - Alexion, AstraZeneca Rare Disease. The DSP is an Adelphi Real World product. Alexion were a subscriber to the DSP and did not influence the original survey through either contribution to the design of questionnaires or data collection.

Treatment Satisfaction with Ravulizumab in Patients with Atypical Hemolytic Uremic Syndrome in a Real-World Setting

Yan Wang,[1] Francesca Gatta,[2] Karl-Johan Myren,[3] Gregor Gibson,[4] Kieran S. Wynne-Cattanach,[4] Joe Conyers,[4] Moh-Lim Ong.[1] *[1]Alexion, AstraZeneca Rare Disease, Boston, MA; [2]Alexion Pharma GmbH, AstraZeneca Rare Disease, Zurich, Switzerland; [3]Alexion, AstraZeneca Rare Disease, Stockholm, Sweden; [4]Adelphi Real World, Bollington, United Kingdom.*

Background: Atypical hemolytic uremic syndrome (aHUS) is a rare disease characterized by hemolytic anemia, thrombocytopenia, and organ damage. Ravulizumab (RAV) is a complement C5 inhibitor approved for the treatment of aHUS in 2019. Our study assessed real-world RAV treatment satisfaction.

Methods: Data were drawn from the Adelphi aHUS Disease Specific Programme™, a cross-sectional survey of physicians and their patients with aHUS (Aug–Dec 2022) in Europe and the USA. Physicians reported broad attitudinal data and demographics, treatment history, and treatment satisfaction for their patients with aHUS. Patients could report their treatment satisfaction in a separate survey.

Results: Overall, 53 physicians who completed the survey had experience with RAV (EU5 [58%], USA [42%]), most were nephrologists (53%) practicing in urban areas/major city centers (66%) with a median of 11 (range: 1–22) years of experience treating patients with aHUS. Of the surveyed physicians, 87% were 'completely satisfied' or 'satisfied' with RAV; no physicians were 'dissatisfied' or 'completely dissatisfied'. In total, 65 patients currently treated with RAV were included: 31 switched from eculizumab (ECU; switch cohort) and 34 did not receive ECU prior to RAV initiation (naive cohort). In the switch and naive cohorts, respectively, median RAV treatment duration was 163 (interquartile range: 93–293) and 201 (106–476) days; and time since aHUS diagnosis was 531 (233–1043) and 257 (152–456) days. Data from patient records showed high physician satisfaction with RAV (**Table**). In 84% of patients in the switch cohort, physicians reported higher satisfaction with RAV vs ECU (n=26; top reasons were fewer infusions required [92%] and less burdensome to patient/caregiver [54%]); no physicians reported higher satisfaction with ECU. From the patient survey, RAV satisfaction was 100% (switch cohort; n=8) and 83% (naive cohort; n=11).

Conclusions: There was concordance in high satisfaction with RAV between physicians and patients, regardless of prior ECU treatment. No dissatisfaction with RAV was reported.

Funding: Commercial Support - Alexion, AstraZeneca Rare Disease. The Disease Specific ProgrammeTM is an Adelphi Real World product. Alexion was a subscriber to the Disease Specific ProgrammeTM and did not influence the original survey through either contribution to the design of questionnaires or data collection.

	Switch cohort (n=30) [a]	Naive cohort (n=34)
Physician satisfaction with RAV from patient records [b], n (%)		
'Completely satisfied'	10 (33)	13 (38)
'Satisfied'	19 (63)	19 (56)
'Neither satisfied or dissatisfied'	1 (3)	2 (6)
'Dissatisfied'	0	0
'Completely dissatisfied'	0	0

[a] n=1 patient excluded as RAV initiation was on the same day as the survey; [b] Physycians were asked to rate their satisfaction with RAV regarding the treatment of specific patients with aHUS based on patient records.

Characteristics and Outcomes of Patients with Atypical Hemolytic Uremic Syndrome Switching to Ravulizumab from Eculizumab: A Global Registry Analysis

Franz S. Schaefer,[1] Imad Al-Dakkak,[2] Ekaterina Anokhina,[2] David J. Cohen,[3] Larry A. Greenbaum,[4] María Ariceta.[5] *[1]Heidelberg University Hospital, Heidelberg, Germany; [2]Alexion, AstraZeneca Rare Disease, Boston, MA; [3]Columbia University Medical Center, New York, NY; [4]Emory University School of Medicine and Children's Healthcare of Atlanta, Atlanta, GA; [5]Vall d'Hebron Hospital, Barcelona, Spain.*

Background: There are currently no real-world cohort data on clinical characteristics and outcomes in patients with atypical hemolytic uremic syndrome (aHUS) who switched to ravulizumab (RAV) from eculizumab (ECU). This study aimed to address this need.

Methods: This was a post-marketing, observational, non-interventional, multinational registry study of patients diagnosed with aHUS who switched to RAV from ECU up to 27-Mar-23 (NCT01522183).

Results: Overall, 60 patients (24 pediatric) were included from Germany (45%), UK (18%), USA (18%), Denmark (10%), Spain (5%), and Israel (3%). Median (range) age at RAV initiation was 34 (2–72) years and 70% of patients were female. Overall, 58% of patients had a pathogenic variant or anti-complement factor H antibodies. Median (range) time on treatment was 21 (2–40) months for RAV and 62 (11–155) months for ECU. No new events of dialysis, kidney transplant, or thrombotic microangiopathy (TMA) relapse were reported during RAV treatment. Estimated glomerular filtration rates (eGFR) remained stable during the evaluation period (**Figure**).

Conclusions: Switching to RAV from ECU resulted in sustained maintenance of kidney function without evidence of new events of dialysis, kidney transplant, or TMA relapse over the median treatment period of 21 months. These results support the real-world effectiveness of RAV in patients with aHUS who switched from ECU.

SA-PO923

Efficacy of 12-Week Pegcetacoplan in Kidney Transplant Recipients with Recurrent C3 Glomerulopathy (C3G) or Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN)

Andrew S. Bomback,[1] Erica Daina,[2] John Kanellis,[3] David Kavanagh,[4] Matthew C. Pickering,[5] Gere Sunder-Plassmann,[6] Patrick D. Walker,[7] Zhongshen Wang,[8] Zurish Ahmad,[8] Fadi Fakhouri.[9] *[1]Columbia University Irving Medical Center, New York, NY; [2]Istituto di Ricerche Farmacologiche Mario Negri, Bergamo, Italy; [3]Monash Medical Centre Clayton, Clayton, VIC, Australia; [4]National Renal Complement Therapeutics Centre, Newcastle University, Newcastle upon Tyne, United Kingdom; [5]Imperial College London, London, United Kingdom; [6]Medizinische Universitat Wien, Wien, Austria; [7]Arkana Laboratories, Little Rock, AR; [8]Apellis Pharmaceuticals Inc, Waltham, MA; [9]Centre Hospitalier Universitaire Vaudois, Lausanne, Switzerland.*

Background: Pegcetacoplan (PEG; C3 inhibitor) may prevent C3G or IC-MPGN progression. NOBLE (NCT04572854) is the first prospective randomized controlled trial of PEG vs standard of care (SOC) in kidney transplant recipients (KTRs) with primary C3G or IC-MPGN recurrence.

Methods: Adult patients (pts) were randomized 3:1 to subcutaneous PEG 1080 mg twice weekly plus SOC (n=10) or SOC only (n=3). Primary endpoint: reduction in renal biopsy C3c staining (≥2 orders of magnitude [OOM]) from baseline to Week 12 (W12). Additional W12 endpoints: changes in eGFR, uPCR, C3G activity score, serum C3, and serum sC5b-9.

Results: 9 (69.2%) pts had C3G and 4 (30.8%) had IC-MPGN. At W12, 5 (50%) PEG pts had ≥2 OOM reduction in C3c staining (4 had 0 intensity); 8 (80%) had ≥1 OOM reduction (**Figure**). 9 (90%) PEG pts had reduced C3G activity score at W12. In subgroup (≥1000 mg/g), uPCR decreased with PEG (–39.2%) at W12. eGFR remained stable, serum C3 increased, and sC5b-9 decreased with PEG (**Table**). There were no discontinuations/deaths due to treatment-emergent adverse events.

Conclusions: As early as W12, pegcetacoplan reduced C3c staining and proteinuria with stable eGFR, targeted the pathophysiology of C3 dysregulation, and was well tolerated in KTRs with recurrent C3G or IC-MPGN.

Table. Clinical and biomarker changes in C3G and IC-MPGN

		uPCR (mg/g)		uPCR (mg/g) [a] (Patients with ≥1000 mg/g at Baseline)		Serum C3 (mg/dL)		Serum sC5b-9 (ng/mL)		eGFR (mL/min/1.73m²)

C3G, C3 glomerulopathy; eGFR, estimated glomerular filtration rate; IC-MPGN, immune complex membranoproliferative glomerulonephritis; PEG, pegcetacoplan; SD, standard deviation; SOC, standard of care; uPCR, urinary protein-to-creatinine ratio.
[a] Measured by triplicate first-morning spot urine.
[b] Patients received subcutaneous pegcetacoplan 1080 mg twice weekly plus standard of care. Of 10 patients, 8 (80%) had C3G, and 2 (20%) had IC-MPGN. The mean (SD) age of the patients was 39.8 (12.59) years.
[c] Patients received standard of care only (SOC). Of 3 patients, 1 (33%) had C3G and 2 (67%) had IC-MPGN. The mean (SD) age of the patients was 44.3 (24.03) years.
[d] Means were calculated only using non-missing values.

SA-PO924

Efficacy of Combined Rituximab (Anti-CD20) and Daratumumab (Anti-CD38) in Steroid-Resistant Nephrotic Syndrome and in Post-Transplant Recurrent FSGS

Andrea Angeletti,[1] Maurizio Bruschi,[1] Francesca Lugani,[1] Enrico E. Verrina,[1] Gianluca Caridi,[1] Edoardo La Porta,[1] Xhuliana Kajana,[1] Sonia Spinelli,[1] Paola Romagnani,[2] Alberto Magnasco,[1] Paolo Cravedi,[3] Gian Marco Ghiggeri.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]University of Florence, Florence, Italy; [3]Mount Sinai Health System, New York, NY.*

Background: Multidrug-resistant nephrotic syndrome (MRNS) accounts for 15% of overall cases of nephrotic syndrome (NS) in childhood. MRNS is associated with high risk of kidney failure and recurrence after kidney transplant (KT). Common treatments, including rituximab and plasma exchange (PEX), are poorly effective.

Methods: We ran a phase II proof-of concept clinical study (NCT05704400) including patients with MRNS (lack of antiproteinuric effect of therapy based on steroid plus CNI and MMF for at least 12 months before enrolment) and post-transplant FSGS recurrence (FSGSr) resistant to rituximab and PEX. We administered rituximab (single infusion 350mg/m², i.v.) + daratumumab (single 16mg/kg infusion). Primary outcome was complete (CR) or partial remission (PR defined as >50% proteinuria reduction).

Results: We enrolled 8 patients: 5 with MRNS and 3 FSGSr (**Fig.1a**). MRNS resulted resistant to previous infusion of rituximab alone (last infusion at least 9 months before enrollment). Combined rituximab + daratumumab therapy induced CR or PR in 3 and 2 subjects with MRNS, respectively (**Fig.1b**). In one patient with older history of MRNS (5yrs), proteinuria remission was transient, but she refused a second treatment. All 3 FSGSr achieved CR/PR and PEX was stopped. Relapse occurred after 4 months in all pts. We repeated the combined treatment in 2 pts that after initial reduction, had a second relapse after 4 months. Thereafter, administration of daratumumab alone obtained remission as well (**Fig.1c**). Treatment was well tolerated and all patients are in active follow-up.

Conclusions: Combined treatment with rituximab and daratumumab is effective in inducing proteinuria remission in MRNS and FSGS recurrence. In KT, relapse-free time was 4 months and repeated infusions were needed. Therefore, targeting CD20 and CD38 may represent a valid therapeutic strategy in MRNS and FSGS recurrence.

The Type II Glycoengineered Anti-CD20 Antibody MIL62 or Cyclosporine in Chinese Primary Membranous Nephropathy: Updated Results of an Ongoing, Multicenter, Randomized, Open-Label Phase 1b/2 Trial

Ming-Hui Zhao,[1] Zhao Cui,[1] Zhang Yimiao,[1] Heng Li,[2] Hua Zhou,[3] Hong L. Lin,[4] Guangqun Xing,[5] Wei Chen,[6] Wei Liang,[7] Ping Luo,[8] Chen X. Lan,[9] Hui Xu,[10] Yan Zha,[11] Yue Wang,[12] Xing Chen,[13] Zhaohui Ni,[14] Junjun Zhang,[15] Wanhong Lu,[16] Li Hua Zhang,[17] Dong Sun,[18] Feng Li,[19] Min Wei,[19] Liang Jinjin,[19] Song Meng.[19] *[1]Peking University First Hospital, Beijing, China; [2]Zhejiang University School of Medicine First Affiliated Hospital, Hangzhou, China; [3]Shengjing Hospital of China Medical University, Shenyang, China; [4]The First Affiliated Hospital of Dalian Medical University, Dalian, China; [5]The Affiliated Hospital of Qingdao University, Qingdao, China; [6]Sun Yat-sen University First Affiliated Hospital, Guangzhou, China; [7]Wuhan University Renmin Hospital, Wuhan, China; [8]The Second Hospital of Jilin University, Changchun, China; [9]Affiliated Hospital of Nantong University, Nantong, China; [10]Xiangya Hospital Central South University, Changsha, China; [11]Guizhou Provincial People's Hospital, Guiyang, China; [12]Peking University Third Hospital, Beijing, China; [13]The First Affiliated Hospital of Xiamen University, Xiamen, China; [14]Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China; [15]The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China; [16]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [17]Nanjing General Hospital of Nanjing Military Region, Nanjing, China; [18]The Affiliated Hospital of Xuzhou Medical University, Xuzhou, China; [19]Beijing Mabworks Biotech Co Ltd, Beijing, China.*

Background: A novel glycoengineered type II anti-CD20 antibody, MIL62 with a nearly completely afucosylated N-glycans in Fc region, has demonstrated superior activity compared with rituximab and obinutuzumab in vitro and in vivo, respectively. We have many clinical data of MIL62 in lymphoma, so we chose two doses to evaluate the safety, tolerability, and efficacy of MIL62 in pMN.

Methods: Eligible pts with pMN diagnosed by kidney biopsy, proteinuria of at least 3.5 g per 24 hours received intravenous MIL62 (two infusions, 600 or 1000 mg each, administered 14 days apart; repeated at 6 months) or Cyclosporine (CsA, starting at a dose of 3.5 mg per kilogram of body weight per day for 12 months). Patients were followed up for up to 104 weeks. The primary outcome were immunological remission (iR) at 12 weeks and a composite of complete or partial remission of proteinuria with stable eGFR at 24 weeks.

Results: From Feb. 23th, 2022 to Dec. 21th, 2022, 86 patients (pts) were randomly enrolled. As of Mar. 23th, 2023, median follow up time was 24 weeks. 22/35 (62.9%) pts in the MIL62 group and 6/18 (33.3%) pts in the CsA group achieved remission at 24 weeks (P< 0.05). In the 69 pts positive for anti-PLA2R Abs (≥14RU/mL) at baseline, 41/47 (87.2%) pts in the MIL62 group achieved iR, which was superior to the CsA group [12/22 (54.5%), P< 0.05] at 12 weeks. The remission to MIL62 in our study was faster than Rituximab because 62.9% (22/35) of patients achieved complete or partial remission at 24 weeks compared with the 35% (23/65) 6-month response rate reported in the Mentor study. Treatment-related adverse events occurred in 73.3%, 77.1% and 88.5% pts in the MIL62 600mg, MIL62 1000mg and CsA group respectively; No treatment-related deaths occurred.

Conclusions: The 12-week iR and 24-week overall remmision of MIL62 was significantly higher than CsA, and had a manageable safety profile. A phase III clinical trial of MIL62 in pMN is ongoing (NCT05862233).

	Immunological Remission at 12 weeks		Overall Remission at 24 weeks	
	MIL62 (N=47)	Cyclosporine (N=22)	MIL62 (N=35)	Cyclosporine (N=18)
Remission rate n (%), 95%CI	42 (87.2) (74.3, 95.2)	12 (54.5) (32.2, 75.6)	22 (62.9) (44.9, 78.5)	6 (33.3) (13.3, 59)

An Exploratory Trial of an Investigational RNA Therapeutic, IONIS-FB-LRx, for Treatment of IgA Nephropathy: New Interim Results

Sean Barbour,[1] Angela Makris,[2] Michelle A. Hladunewich,[3] Sven-Jean Tan,[4] Muh Geot Wong,[5] Jason Choo Chon Jun,[8] Ashley Frazer-Abel,[6] Lixuan Yin,[7] Qingqing Yang,[7] Jon L. Ruckle,[7] Richard Geary,[7] Eugene Schneider,[7] Michael Mccaleb,[7] Gary T. Brice.[7] *[1]University of British Columbia, Vancouver, BC, Canada; [2]Liverpool Hospital, Liverpool, NSW, Australia; [3]Sunnybrook Research Institute, Toronto, ON, Canada; [4]The Royal Melbourne Hospital, Melbourne, VIC, Australia; [5]University of Sydney, Sydney, NSW, Australia; [6]Exsera Labs, Denver, CO; [7]Ionis Pharmaceuticals Inc, Carlsbad, CA; [8]Singapore General Hospital, Singapore, Singapore.*

Background: Overactivity of the complement Alternative Pathway (AP) has been proposed to contribute to pathogenesis of IgA nephropathy (IgAN). An antisense oligonucleotide to complement factor B (FB), IONIS-FB-L_{Rx} (ISIS696844, RO7434656) targets FB mRNA in the liver. IONIS-FB-L_{Rx} treatment led to inhibition of AP and reduction in proteinuria in IgAN patients (2022 ASN Abstract#SA-PO714).

Methods: An exploratory, single-arm, multi-national open-label Ph2 study (NCT04014335) recruited patients with biopsy-confirmed IgAN, proteinuria>1.5 g/d, eGFR>40mL/min/1.73m^2, and hematuria despite maximum tolerated RAAS blockade. Patients received monthly SC administration of IONIS-FB-L_{Rx} for 24 weeks. Primary outcome was change in 24-hr proteinuria at Wk29 (4 weeks after last dose) compared to baseline (BL).

Results: 13 subjects have completed study to date, 25-62 yr, 40% Female, 7 Asian, and 6 White. There was a selective reduction of plasma complement FB levels, serum AP activity, urinary Ba and urinary sC5b-9 (mean % change of -69%, -36%, -92%, and -26% respectively). Median 24-hr proteinuria at BL was 1.80 g/g (IQR 1.23, 2.33 g/g). At Wk29, a 47% geometric mean ratio reduction was observed. There was no change in eGFR at Wk29 compared to BL (mean±SD; BL 70±25; Wk29 72±22 mL/min/1.73m2). One subject opted to extend treatment and continued to receive treatment through Wk61, demonstrating a sustained reduction in proteinuria. One subject discontinued study drug after 4 months of treatment (last dose Wk17) to initiate SGLT-2 inhibitors. 24-hr urine samples collected 3 weeks after the last dose of IONIS-FB-L_{Rx}, but prior to use of SGLT-2 inhibitors (Wk27), demonstrated a 41% reduction in proteinuria. IONIS-FB-L_{Rx} demonstrated an acceptable safety profile with no Treatment Emergent SAE. The only clinically meaningful safety signal (moderate TEAE) was a reversible ALT elevation without a change in bilirubin in 1 subject.

Conclusions: This Ph2 open-label study provides continuing clinical evidence that IONIS-FB-L_{Rx} reduces complement levels and proteinuria in patients with IgAN, supporting Ph3 development (NCT05797610) to determine the potential of IONIS-FB-L_{Rx} to reduce the progression of IgAN.

Plasma Osteopontin Differentiates Active and Inactive Lupus Nephritis and Is Associated with Response to Therapy

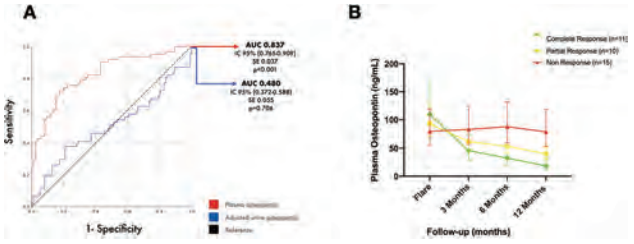
Fernanda Zavala Miranda,[1,2] Abril A. Pérez Arias,[1] Sofia E. M. Macedo,[1] Oscar Pena,[1] Bernardo Juarez Cuevas,[1] Luis E. Morales-Buenrostro,[1] Juan M. Mejia-Vilet.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico.*

Background: New biomarkers are needed to differentiate activity from chronic damage in Lupus nephritis (LN) & to monitor response to treatment. Osteopontin (OPN) is an N-linked glycoprotein with integrin-binding ligands that has been identified as a potential biomarker of activity in systemic lupus erythematosus (SLE).

Methods: This is a diagnostic study with a cross-sectional and a longitudinal phase to describe the course of plasma (pOPN) & urinary OPN (uOPN) in a LN cohort. We recruited 62 patients with biopsy-proven active LN. As disease controls, we included 88 patients with non-renal activity, chronic LN on kidney biopsy, & inactive SLE. To evaluate the diagnostic yield of OPN we built ROC curves from the cross-sectional data. In the longitudinal phase, we included 36 active LN patients with prospective follow-up and plasma/urine samples collected at 3, 6, & 12 months. Response to therapy was evaluated at 6 & 12 months. Linear mixed models were fitted to evaluate the association between pOPN, uOPN, and response to therapy.

Results: Active LN patients had the highest levels of pOPN (81.18 ng/mL, IQR 53.75-169.46). Elevated pOPN levels correlated with SLEDAI-2K activity score (r= 0.51, p<0.001), SLICC/ACR damage index (r=0.24, p=0.003), ISN/RPS class IV LN (r=0.24, p=0.03), histologic activity index (r=0.46, p<0.001) and eGFR <60 mL/min/1.73m2 (r=0.35, p<0.001). There were no differences in uOPN between the groups. pOPN >58 ng/mL had 72% (95%CI 0.60-0.82) sensitivity and 81% (95%CI 0.71-0.88) specificity to differentiate active LN from inactive patients. The course of pOPN in response to therapy was associated with the type of response, with continuous reduction in complete responders and persistent elevation in non-responders. There was no association between uOPN and response to therapy.

Conclusions: Plasma OPN correlates with LN activity, it has a fast reduction within the first 3 months of therapy and is associated with response to therapy.



OPN ROC curves (A) & course of pOPN in response to therapy (B)

Identification of New Therapeutic Targets of Arsenic Trioxide for Lupus Nephritis: Machine Learning Bioinformatics and In Vitro Studies

Ruiyan Xie, Danting Zhang, Ka Ho Jason Sher, Yat Hin Desmond Yap.
Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China.

Background: Lupus nephritis (LN) is a serious complication of systemic lupus nephritis (SLE). Preliminary study suggested that low-dose ATO treatment in active SLE patients was associated with reduced flare rates, but the underlying mechanisms have not well characterized.

Methods: The potential targets of differentially expressed genes (DEGs) from human SLE and LN PBMCs datasets were identified by bioinformatic analysis and network pharmacology. Characteristic hub genes were further selected using machine learning method. The relationship between the potential targets and immune cells was also examined.

Results: Twelve predicting immune related intersection DEGs in SLE were identified. KEGG pathway analysis indicated that ATO could attenuate IL-17 signaling pathway (p=1.67E-18), and TNF signaling pathway (p=5.77E-11) in SLE. Five genes of features importance were selected by three machine learning models, in which MMP9 showed the highest performance in predicting SLE development (ROC AUC: 0.942). MMP9 also showed positive correlations with macrophages and neutrophils in ssGSEA analysis (r=0.88 and 0.66 respectively). Our in vitro studies further demonstrated that ATO treatment downregulated MMP9 expression in PBMCs obtained from LN patients during disease remission (n=5).

Conclusions: ATO can attenuate LN via reduction of MMP9 expression in PBMCs and different inflammatory pathways.

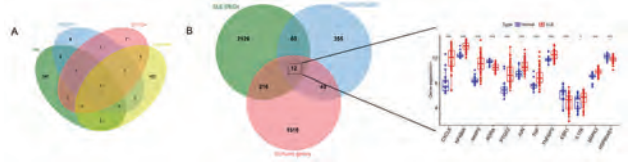

Figure 1. Intersection immune associated genes of arsenic trioxide in systemic lupus erythematosus (SLE).

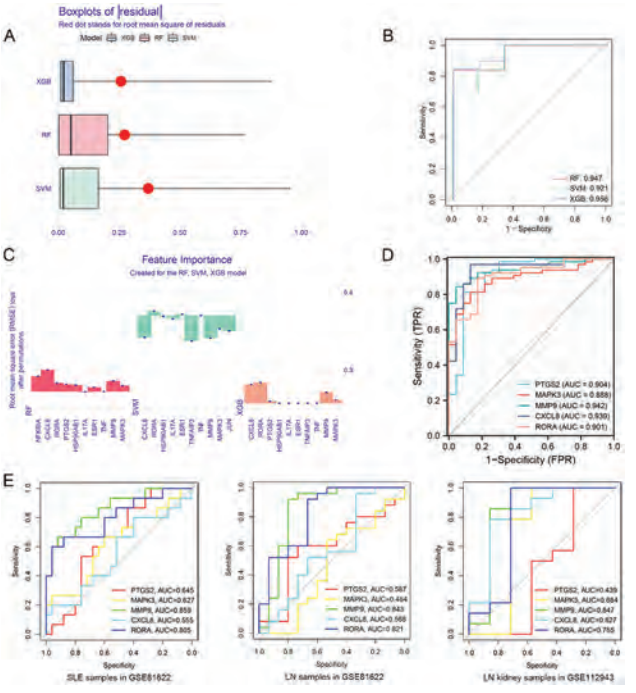

Figure 2. MMP9 was selected as the hub target in systemic lupus erythematosus (SLE).

Genetic Determinants of Lupus Nephritis and Kidney Function in Systemic Lupus Erythematosus

Magdalena Riedl Khursigara,[1] Nicholas Gold,[1] Daniela Dominguez,[1] Deborah Levy,[1,9] Damien G. Noone,[1,9] Jingjing Cao,[1] Murray B. Urowitz,[3] Karen S. Onel,[4] Elizabeth A. Harvey,[1,9] Chia-Chi J. Lee,[5] Caroline Jefferies,[5] Joan Wither,[6] Diane L. Kamen,[7] Janet Pope,[8] Christine A. Peschken,[2] Michelle Petri,[10] Daniel W. Goldman,[10] Thai-Son Tang,[1] Mariko Ishimori,[5] Andrea Knight,[1,9] Earl Silverman,[6] Linda T. Hiraki.[1,9] Systemic Lupus Erythematosus Collaborative Clinics (SLICC). *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Krembil Research Institute, Toronto, ON, Canada; [4]Hospital for Special Surgery, New York, NY; [5]Cedars-Sinai Medical Center, Los Angeles, CA; [6]University Health Network, Toronto, ON, Canada; [7]Medical University of South Carolina, Charleston, SC; [8]London Health Sciences Centre, London, ON, Canada; [9]University of Toronto, Toronto, ON, Canada; [10]Johns Hopkins University, Baltimore, MD.*

Background: Lupus nephritis (LN) is one of the most common and severe manifestations of SLE. We completed an LN genome wide association study (GWAS) in a multi-ethnic cohort of children and adults with SLE.

Methods: We included SLE patients from dedicated Lupus clinics and the SLICC cohort. All patients met ACR and/or SLICC SLE classification criteria and were genotyped on a multi-ethnic Illumina array. LN was defined by SLE criteria. Kidney function (eGFR) was estimated using the Schwartz Bedside formula for measures <18 years and CKD-EPI (without ancestry) for >18 years of age, collected longitudinally over time. Wilcoxon rank sum or Chi-square test were used for significance between LN and Non-LN patients. We completed GWAS of LN in marginal and multivariable adjusted regression models with principal components for ancestry, sex and cohort site.

Results: We included 2981 patients with SLE, 88% female, 46% of European ancestry, 27% childhood-onset SLE. LN was present in 45%. People at time of LN diagnosis were younger and more likely of African American or East Asian ancestry. People with LN had significantly lower within-person mean eGFR, greater eGFR variability and slope over time compared to those without LN (Table). GWAS of LN demonstrated a peak on chromosome 8, yet did not reach a genome-wide significance ($p < 5x10^{-8}$).

Conclusions: Our GWAS did not identify a significant locus for LN. We plan to repeat GWAS of repeated eGFR measures, as it is a more informative outcome that may improve power for detecting genetic loci for LN.

Funding: Government Support - Non-U.S.

Discovery and Validation of Novel Circulating Auto-Antibodies in Lupus Nephritis Using Peptide Array Technology

Marco Prunotto,[1] Maurizio Bruschi,[2] Enrico E. Verrina,[2] Andrea Angeletti,[2] Gian Marco Ghiggeri.[2] *[1]Roche Diagnostics International AG, Rotkreuz, Switzerland; [2]Istituto Giannina Gaslini, Genova, Italy*.

Background: Systemic Lupus Erythematosus (SLE) and Lupus Nephritis (LN) are prototypes of autoimmunity. Autoantibodies determining the first hit in LN have been identified; autoantibodies involved in renal progression remain an open issue.

Methods: We investigated sera of SLE, LN, rheumatologic and normal controls (20/20/60/40) using a high-density peptide array (17,402 peptides) covering the coding sequences of 464 proteins involved in rheumatologic/immunologic processes. The immune-fluorescence intensity was calculated by repeating incubation of sera with peptides 20 times to reduce variability for an overall of 348,040 peptide spots. The noise cutoff was set at IF>50. Validation of results was done by either specific assays (ELISAs) in many more patients (130 SLE, 91 LN) and by renal immuno-histochemistry (12 LN).

Results: Overall, 133 proteins reactive with SLE and LN sera were identified by the peptide array. Annexin A1 (ANXA1) and Formin-like 1 Protein (FMNL1) had the highest probability to be true antigens. Anti-ANXA1 antibodies have been already associated with LN and SLE, FMNL1 is a new identified antigen. Anti-ANXA1 and anti-FMNL1 IgG2 (ELISAs) were high in serum of LN and SLE patients (LN >SLE); FMNL1 co-stained with macrophage markers (CD68) in glomeruli, high expression being associated with proliferative LN (stage IV). FMNL1 was recognized in macrophage cell lysates 'in vitro' by sera of LN patients with high anti-FMNL1 IgG2.

Conclusions: Overall, these findings show many potential antigens in SLE and LN based on an innovative peptide array technology. Circulating anti-ANXA1 and anti-FMNL1 IgG2 were high in both conditions. Anti-FMNL1 antibodies target a protein of macrophages associated with proliferative LN, suggesting that targeting cells potentially involved in tissue damage and/or repair might have a definite role in determining the disease outcome.

Classical Complement Activation in Lupus Nephritis Correlates with Disease Biomarkers: Results from Two Observational Studies

Edmund Chang,[1] Julian Low,[1] Noosha Yousefpour,[1] Min Bao,[1] Jeannette Osterloh,[1] Qing Chang,[1] Dean R. Artis,[1] Henk-Andre Kroon,[1] Yaisa Andrews-Zwilling,[1] Maria Dall'Era,[2] Ted Yednock,[1] Ann Mongan.[1] *[1]Annexon Biosciences, Brisbane, CA; [2]University of California San Francisco Department of Medicine, San Francisco, CA.*

Background: Lupus nephritis (LN) is an autoantibody-mediated disease that can activate C1q and the classical complement pathway. Pathogenic anti-C1q antibodies (PACAs) are often present, amplifying classical pathway inflammation and contributing to progressive kidney damage. Elevated C4d and reduced C4 are markers of classical complement activation and consumption, respectively. For LN patients in the CLUES/UCSF Study, C4d/C4 ratio positively correlated with PACAs and urine protein-creatinine ratio (UPCR). To validate this correlation, the Sanguine Bio study was conducted.

Methods: Samples were collected from 40 LN patients (plus 20 healthy controls) from the CLUES/UCSF Study and 24 LN patients (plus 10 healthy controls) from Sanguine Bio. Complement activation and consumption (C4d, C4), exploratory biomarkers in plasma and urine, and UPCR were evaluated.

Results: Sanguine Bio samples from a subset of LN patients demonstrated elevated C4d/C4 compared to healthy controls indicating classical complement pathway activation (**Figure**). Urinary biomarkers of LN correlated with C4d/C4 ratio in these patients.

Conclusions: In these LN patients, C4d/C4 ratios were elevated and correlated with LN biomarkers in blood and urine, supporting classical complement activity. These data support an ongoing, phase 1b study of ANX009 with the goal of assessing safety, tolerability, and pharmacodynamics of repeat-doses of subcutaneous ANX009 with standard of care in adults with LN. ANX009 is an anti-C1q antigen binding fragment targeting LN patients with evidence of classical complement activity (elevated C4d/C4).

EXT-1/EXT-2 and NCAM-1 Expression in Taiwan Patients with Lupus Membranous Nephropathy

Kun-Hua Tu,[1,2] Tsai-yi Wu,[2] Yi-Ran Tu.[1] *[1]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan*.

Background: Lupus nephropathy could be divided into 6 categories according to WHO classification. Class V lupus nephropathy have similar histologic features with primary membranous nephropathy. There are several autoantibodies and autoantigens demonstrated in primary membranous nephropathy, since the discovery of anti-PLA2R. Similarly, there are also some novel autoantigens found in lupus membranous nephropathy. EXT-1/EXT-2 and NCAM-1 were postulated recently in lupus membranous nephropathy. Therefore, we conducted a prospective study to evaluate the prevalence of EXT-1/EXT-2 and NCAM-1 expression in patients with lupus membranous nephropathy.

Methods: This prospective invesitgation is conducted at a tertiary medical center in Taiwan. During the study period, there are totally 55 patients with pathologic diagnosis of lupus membranous nephropathy. In addition to routine histologic examination by experienced renal pathologist, the investigators completed the immunohistochesmistry (IHC) stain of PLA2R, EXT-1 and NCAM-1. Demographic datas and clinical informations were also collected and evaluated.

Results: Among the 55 subjects, there are 52 subjects with successful IHC stain for EXT-1 and 49 subjects with successful IHC stain for NCAM-1. All the subjects are negative of IHC stain for PLA2R. EXT-1 and NCAM-1 expression could be found with ratio of 26.9% (14/52) and 2.0% (1/49), respectively. Comparing with other group, the prevalence of EXT-1 and NCAM-1 in this investigation is relatively lower.

Conclusions: In this prospective investigation, we first demonstrate the prevalance of EXT-1 and NCAM-1 expression in Taiwan patients of lupus membranous nephropathy. The prevalence of these 2 autoantigen is lower than former studies. The role of these autoantigen is not clarified yet. Further studies are needed.

SA-PO933

Urine sCD163/Creatinine Ratio Is a Potential Biomarker of Disease Severity in Patients with IgA Nephropathy

Kun-Hua Tu,[1,2] Yi-Ran Tu,[1] Tsai-yi Wu.[2] *[1]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan.*

Background: IgA nephropathy is the most common glomerular disease in adults. There are several prediction model postulated for IgAN but no one could be validated successfully. In addition, no any one biomarker was proved to predict severity and survival for patients with IgA nephropathy. Recently, one urinary metabolite from macrophage, soluble CD163 (usCD163) was found remarkably elevated in patients with IgA nephropathy. Gong et al demonstrate urine sCD163/creatine ratio seems correlated to disease severity of IgA nephropathy. Thus, the investigator conducted a prospective study to elucidate the role of urine sCD163/creatinine in IgA nephropathy.

Methods: The investigators initiated a prospective cohort of glomerular disease at a tertiary medical center in Taiwan. Mid-stream spot urine sample was prospectively obtained before renal biopsy. During the study period, there are 150 subjects with pathologic diagnosis of IgA nephropathy. After exclusion as criteria, there are totally 70 subjects believed as primary IgA nephropathy was studied. Pre-stored urine sample were used to check the level of soluble CD163 and creatinine.

Results: The level of urine soluble CD163/creatinine could be devided into 3 tertiles. Between these tertiles, there are no remarkable difference in serum creatinine and GFR. Greater tertiles of usCD163/Cr have greater severitiy of hypoalbuminemia, proteinuria, hypercholesterolemia and hypertension. Greater tertiles of usCD163/Cr have also more obsoleted glomeruli, greater severity of tubulointerstitial fibrosis, and more crescents formation. ≥ 50% decline of estmitaed glomerular filtration rate (eGFR) and entering dialysis during study period didn't achieve stastistical difference between 3 tertiles of usCD163/Cr. Survival analysis toward ≥ 50% eGFR deline and entering dialysis, however, revealed lower survival probability in tertile 3 compared to tertile 1+2.

Conclusions: Urine sCD163/creatinine ratio seems correlated to proteinuria and the symptoms associated with nephrosis. It also correlated to histologic injury of glomerular sclerosis and tubulointerstitial fibrosis. Although there are no stastistical significance of ≥ 50% eGFR decline and entering dialysis between these tertiles, survival analysis proved that lower survival probability in tertile 3 compared to tertile 1+2.

SA-PO934

Urinary Proteomics Identifying Novel Biomarkers for Predicting the Activity of ANCA-Associated Nephritis

Shuo Zhang, Xin Chen, Xiaoyue Tang, Jiatong Xu, Yuting Hu, Yan Qin, Peng Liu, Limeng Chen. *Peking Union Medical College Hospital, Beijing, China.*

Background: Despite the pathogenic role of ANCA in ANCA-associated glomerular nephritis (AAGN), it's still challenging to determine the active stage. Urinary proteomics, specifically data-independent acquisition (DIA) proteomics, might be the non-invasive and efficient method to find potential biomarkers to identify the active AAGN.

Methods: The urine samples used for proteomic analysis were from patients diagnosed as AAV at Peking Union Medical College Hospital from May 2022 to April 2023. We performed LC-MS/MS analysis with quality control and identified differentially expressed genes (DEGs). Weighted gene co-expression network analysis (WCGNA), Least Absolute Shrinkage and Selection Operator (LASSO), and Random Forest analysis were used to figure out the target molecule and validated in the validation cohort by ELISA.

Results: In this study, 40 patients performed the urine DIA analysis, and the other 50 patients were in the validation group, with 56.7% female, with an average age of 58±15 years old. In the 358 DEGs identified between AAV with and without renal involvement, the top pathways were the complement, coagulation cascade, and cholesteryl mechanism. After WGCNA, Lasso, and Random forest analysis, four urine proteins, marked complement factor D (CFD), coagulation factor II (F2), fibrinogen Alpha Chain (FGA), and plasminogen (PLG) were highly associated with AAGN in the active stage and confirmed by ELISA (Figure 1). The receiver operating characteristic curve (ROC) values of F2 combined CFD in AAV patients with active renal involvement was 0.922 (P<0.001) with a sensitivity of 75% and a specificity of 97.1%.

Conclusions: Several biomarkers from the complement and coagulation cascade might be potential urine biomarkers for AAGN in the active stage.

Funding: NIDDK Support

SA-PO935

Citrullinated Histone H3-Positive Neutrophils May Be Associated with Disease Activity in ANCA-Associated Vasculitis

Natsumi Kamijo, Akiko Mii, Rei Nakazato, Akira Shimizu, Yukinao Sakai. *Nihon Ika Daigaku, Bunkyo-ku, Japan.*

Background: Neutrophil extracellular traps (NETs) formation is reportedly involved in the onset of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Citrullinated histone H3 (H3Cit) is an important component of NETs. Previously, we reported that the presence of H3Cit (+) neutrophils is more specific in AAV than in other glomerular diseases and H3Cit staining is useful for identifying activated neutrophils. However, there were no detailed analysis of association between H3Cit neutrophils and AAV disease activity.

Methods: We selected kidney biopsy cases with AAV at Nippon Medical School Hospital during 2011 to 2022. Clinical findings included age, gender, serum creatinine (sCr) level, CRP, MPO/PR3-ANCA titer, and urinary findings (urinary protein (U-P) level, urinary β2-microglobulin (uβ2-MG)). Histological findings were assessed as follows: rates of global sclerotic glomeruli, crescent formation, interstitial fibrosis, and atherosclerosis score). MPO (neutrophil marker) and H3Cit (NETs marker) staining were performed.

Results: A total of 49 cases with AAV were selected and were divided into two groups : H3Cit (+) group (n=44) and H3Cit (-) group (n=5) according to the presence or absence of H3Cit+ neutrophils in renal tissues. Clinically, sCr level and uβ2-MG level were significantly higher in the H3Cit (+) group although there were no significant differences in age, CRP, ANCA titer and U-P level. Histologically, H3Cit (+) neutrophils were observed in tubulointerstitial lesions in 43 cases, and in both tubulointerstitial lesions and glomeruli in 13 cases. Only one case showed glomerular involvement. H3Cit (+) neutrophils were observed mainly in peritubular capillaries, and around necrotic lesions of arteries and glomeruli. The rates of crescent formation and interstitial fibrosis were significantly higher in the H3Cit (+) group while there was no differences in rates of global sclerotic glomeruli and atherosclerosis score.

Conclusions: The H3Cit (+) group exhibited significantly worse renal function and urinary findings, as well as higher tissue activity. The presence of H3Cit+ neutrophils serves not only a disease-specific marker but also a potential indicator of disease activity in AAV.

SA-PO936

Clinical Implication of Platelets and Complement C3 as Link Between Innate Immunity and the Coagulation System in ANCA-Associated Renal Vasculitis with Myeloperoxidase (MPO) ANCA Seropositivity

Eva Baier, Bjoern Tampe. *Universitatsmedizin Gottingen Klinik fur Nephrologie und Rheumatologie, Gottingen, Germany.*

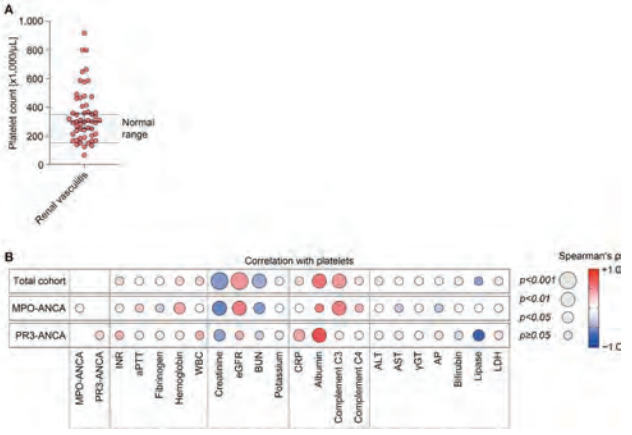
Background: Antineutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) is a potentially life-threatening systemic small vessel vasculitis (SVV). It is well established that AAV patients feature an increased risk of developing thrombotic events, and platelets are activated in AAV patients being triggered by the alternative complement pathway. We here aimed to systematically assess the relevance of platelet counts and systemic complement system activation regarding distinct histopathological lesions in ANCA associated renal vasculitis (AARV).

Methods: A total of 53 patients with biopsy proven AARV were retrospectively enrolled in a single center observational study. Multivariate regression analysis was performed to identify parameters associated with platelet counts in AARV compared to disease controls. Finally, the relevance of platelets for disease course and recovery was assessed by survival analysis.

Results: Lower platelet counts correlated with markers of kidney injury including eGFR loss (*p=0.0004*) and lower complement C3 levels (*p=0.0037*). Multivariate and subgroup analysis revealed that this association was only present in the MPO ANCA subgroup (eGFR loss: *p=0.0009*, lower C3: *p=0.0032*). Lower platelet counts correlated with interstitial fibrosis (*p=0.0313*), and tubulitis in areas of interstitial fibrosis and

tubular atrophy (*p=0.0033*). Finally, we observed significant differences with increased requirement of kidney replacement therapy or death in the subgroup below median platelet counts (HR: 4.1, 95% CI: 1.6-10, *p=0.0047*), associated with a prolonged hospitalization in this subgroup (HR: 0.5, 95% CI: 0.3-0.9, *p=0.0113*).

Conclusions: Based on our observed association between platelets and complement system activation in the MPO ANCA subgroup, we here show an impact on disease course and histopathological lesions implying distinct damage modes in different subtypes of AARV.



SA-PO937

Clinical Application of IgA-Type Autoantibodies Against Mesangial Autoantigen, βII-Spectrin, in IgA Nephropathy

Yoshihito Nihei,[1] Hiroyuki Iwasaki,[1] Ryousuke Aoki,[1] Mingfeng Lee,[1] Hitoshi Suzuki,[1,2] Yusuke Suzuki.[1] *[1]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Department of Nephrology, Juntendo University Urayasu Hospital, Chiba, Japan.*

Background: Half a century has passed since the first report of patients with IgA nephropathy (IgAN), however, the whole pathogenesis of IgAN remains elusive. In particular, the important question why IgA antibodies (Abs) are selectively deposited in the mesangial region, a hallmark of IgAN, remains unanswered. Recently, we have uncovered the answer to this critical question by identifying IgA type autoantibodies directed against mesangial autoantigen, βII-spectrin, in sera of patients with IgAN (Y. nihei et al. *Science Advances* 9, eadd6734, 2023). We confirmed that serum anti-βII-spectrin IgA was positive in 60% of patients with IgAN by Western blot. In present study, we aim to elucidate the specificity of serum levels of anti βII-spectrin in patients with IgAN and to clarify clinical aspects of serum anti βII-spectrin IgA.

Methods: To evaluate the specificity of anti-βII-spectrin IgA, serum anti-βII-spectrin IgA were measured by enzyme-linked immuno sorbent assay (ELISA) in patients with biopsy-proven IgAN (N=70) or other kidney diseases (N=32). The clinical parameters were compared between patients with IgAN who were positive for anti-βII-spectrin IgA and those who were negative. To test whether serum anti-βII-spectrin IgA titers correlate with disease activity, we compared the titers before and after steroid treatment in IgAN patients with positive for anti-βII-spectrin IgA.

Results: We found that 24 of 70 patients with IgAN have serum anti-βII-spectrin IgA while only two of 32 were positive for anti-βII-spectrin IgA in patients with other kidney diseases. No differences in eGFR, proteinuria, or histopathological findings were found between IgAN patients with positive and negative for serum anti-βII-spectrin IgA at the time of renal biopsy. The titer of anti-βII-spectrin IgA in patients with IgAN decreased after treatment with improvement in hematuria and proteinuria.

Conclusions: We found that anti-βII-spectrin IgA were detected in patients with IgAN with high specificity (specificity, 93.8%), suggesting that serum anti-βII-spectrin IgA may be useful for the diagnosis of IgAN. The decrease in serum anti-βII-spectrin IgA titers with improvement in hematuria and proteinuria after treatment indicated that serum anti-βII-spectrin IgA can be also used as a biomarker for monitoring disease activity.

SA-PO938

GalD: An Available and High-Performing Lectin-Based Test for Serum Galactose-Deficient IgA1

Tomasz Szul,[1] Janusz Tucholski,[1] Tatum Street,[1] Bruce A. Julian,[1,2] Will Placzek.[1,2] *[1]Reliant Glycosciences, LLC, Birmingham, AL; [2]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Quantitative lectin-based assay for serum galactose-deficient immunoglobin A1 (Gd-IgA1) has been established as leading biomarker for kidney outcomes of patients with IgA nephropathy (IgAN) since 2007. This Gd-IgA1 analysis has been included in multiple landmark papers and been used as the quantitative phenotypic basis for genome-wide association studies of IgAN and serum Gd-IgA1. Initially, the lectin-based Gd-IgA1 analysis was not amenable for broad use due to lack of scalability, long sample-analysis timeframe, and user-to-user variation. Here, we report our development of the GalD biomarker test, a highly reproducible, fast, and newly available lectin-based assay for Gd-IgA1.

Methods: We used a 24-serum-sample quality-control set that spans the Gd-IgA1 concentrations reported in the literature in a 5-hour detection protocol to perform standard validation analysis. This approach included intra- and inter-assay performance and serial measurements to assess serum freeze-thaw stability. Additionally, multiple batches of key reagents were evaluated over time to ensure assay consistency.

Results: Our validation analysis demonstrated high-quality assay performance, with less than 10% plate-to-plate error. Furthermore, the assay demonstrated six-month stability of the components. The entire range of the calibrated assay was 29-2000 ng/mL. The lower limit of detection was determined to be 0.425 ng/mL. The lower limit of quantitation was 29 ng/mL. The GalD test is fully scalable to enable testing across multiple sample plates, dates, or users, and with same-day readout.

Conclusions: Our GalD test now brings the ability to measure serum Gd-IgA1 concentration to any laboratory while assessing the full spectrum of galactose-deficient IgA1 present in serum samples.

Single-Cell RNA Sequencing Reveals Immune Cell-Specific Genes and Pathways Associated with IgA Nephropathy

Le Wang, Honghui Zeng, Yi Xiao, Siweier Luo, Xiaoqiang Yang, Yiming Zhou. *Sun Yat-Sen Memorial Hospital, Guangzhou, China.*

Background: IgA nephropathy (IgAN) is one of the most common primary glomerulonephritis globally. Increasing evidence suggests the importance of host immunity in the development of IgAN, but its dynamics during the early stage of IgAN pathogenesis are still largely unclear. Single-cell RNA-sequencing is a high-throughput sequencing technology with cells as minimal units, which could be applied to explore the pathogenesis of IgAN.

Methods: Peripheral venous blood samples were collected from 6 healthy controls and 10 newly diagnosed IgAN patients. Peripheral blood mononuclear cells (PBMCs) were isolated by FACS sorting with above 80% cell viability. Then single cell RNA-sequencing was performed using the BD Rhapsody platform. Downstream analysis was performed with the Seurat V3.0. Meanwhile, the clinical data of the IgAN patients were co-analyzed with single-cell RNA-sequencing results. Experimental and research procedures were approved by and in accordance with the internal review board and human subject guidelines of the Sun Yat-sen Memorial Hospital and Sun Yat-sen University.

Results: First, we generated an single immune cell landscape of early IgAN. The differentially expressed genes (DEGs) between the control and IgAN groups were mainly related to the NK cell-mediated cytotoxicity and NK cell killing pathways. We found that significant decreases in the NK cell numbers and cytotoxicity genes. Interestingly, we discovered that NK cell numbers and marker genes were negatively correlated with many clinical parameters, including urinary protein creatinine ratio (UPCR) and serum galactose-deficient IgA1 and IgA. In contrast, DEGs of B cells were enriched in different viral infection pathways, and one specific B cell subgroup exhibiting the inhibition of NFκB signaling, was positively correlated with IgAN clinical parameters. In addition, a subpopulation of monocytes expressing interferon-inducing genes was positively associated with clinical severity of IgAN. Finally, we identified vast dynamics in intercellular communications of NK cells and monocytes in IgAN.

Conclusions: We constructed a landscape of peripheral blood mononuclear cells from early IgAN patients by using scRNA-seq and found significant alterations in the number and gene expression pattern of immune cells, some of which are closely related to clinical manifestations.

SA-PO940

Low eGFRcys/eGFRcreat Ratio Indicates Glomerular Filtration Impairment in the Patients with IgA Nephropathy

Hiroki Nobayashi, Go Kanzaki, Kentaro Koike, Nobuo Tsuboi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku Igakubu Igakuka Jinzo Koketsuatsu Naikagaku, Minato-ku, Japan.*

Background: Most glomerular diseases are characterised by disruption of the glomerular filtration barrier (GFB). The reduced pore size of GFBs as a result of endothelial damage is thought to result in lower clearance of medium-sized molecules (5000-3000 Da) such as cystatin C (cys) compared to small molecules (<900Da) such as creatinine (creat). Recently, the Shrunken pore syndrome (SPS) has been highlighted as a new phenotype of renal dysfunction characterised by an eGFRcys/eGFRcreat ratio < 60-70%. However, no reports examined the pathological association between the eGFRcys/eGFRcreat ratio and glomerular capillary wall. In the present study, we analyzed the clinical and pathological features associated with eGFRcys/eGFRcreat ratio in the patients with IgA nephropathy (IgAN).

Methods: 62 patients diagnosed with IgAN by kidney biopsy were analyzed. Thickness of capillary wall was determined by measuring the distance from endothelial to podocyte plasma membrane according to the past study. To evaluate the effect of muscle mass to creatinine, we measured surface of iliopsoas using CT images.

Results: Subjects with low eGFRcys/eGFRcreat ratio had more iliopsoas muscle mass, higher creatinine, thinner capillary wall, more severe microscopic hematuria (Table 1). The eGFRcys/eGFRcreat ratio was correlated with iliopsoas muscle mass (r=0.36, p=0.012), thickness of capillary wall (r=0.44, p<0.001) and severity of microscopic hematuria (r=-0.47, p<0.001). On multiple regression analysis, only capillary wall and microscopic hematuria contributed to eGFRcys/eGFRcreat ratio.

Conclusions: Present study showed for the first time the IgAN patients with low eGFRcys/eGFRcreat ratio had thinner glomerular capillary wall and more severe microscopic hematuria. Although their renal function was preserved, they might have

filtration impairment according to the concept of SPS. Therefore, it was suggested that it could also be a useful biomarker for impaired GFB in IgAN.

Table 1. Clinicopathological characteristics in 62 subjects.

	eGFRcys/eGFRcreat tertile			
	Low N=21	Intermediate N=21	High N=20	p for trend

Exploring Differentially Expressed Proteins in Plasma Extracellular Vesicles for Early Detection of IgA Nephropathy

Chih-chin Kao. *Taipei Medical University College of Medicine, Taipei, Taiwan.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis and may develop end stage renal disease. The overproduction of galactose-deficient IgA1 (Gd-IgA1) leads to the production of autoantibodies, resulting in the formation of nephritogenic immune complexes. Extracellular vesicles (EVs) are cell-derived membranous vesicles encapsulating various proteins, lipids, and mRNAs. We aimed to develop EV-biomarkers for the early diagnosis of IgAN.

Methods: Size exclusion chromatography was used for isolating plasma EVs. A total of 60 plasma samples from individuals with IgAN, chronic kidney injury (CKD), and control group were utilized in this study. Each plasma had been reduced by dithiothreitol (DTT), alkylated by Iodoacetamide (IAA), and digested by trypsin. Tryptic peptides were analyzed using nano-liquid chromatography-mass spectrometry. PEAKS Proteomics, Reactome Pathway Database, FunRich, and Kyoto Encyclopedia of Genes and Genomes (KEGG) analyses were performed to identify differentially expressed proteins in IgAN patients.

Results: There were 86 differentially expressed proteins between the three groups. Of these, 92.9% of the cellular component was associated with the extracellular protein. After analyzing by Reactome Pathway Database, our results showed that the main functional pathways of the EVs from clinical plasma samples were the immune system pathway and the vesicle-mediated transport. We also compared the protein components of plasma-EVs from clinical samples. 12 out of 19 proteins showed significant differences, which may be served as EV markers for IgAN.

Conclusions: We have developed and validated a workflow to isolate plasma-EVs for proteomics analysis, and proteins that showed statistical differences among the three groups were identified. Potential EV biomarkers were discovered in this study and are under validation as well.

SA-PO942

Gut Microbiota Profiles Representing Pathogenic Severity in IgA Nephropathy Patients

Yaerim Kim,[1] Jin hyuk Paek,[1] Woo Yeong Park,[1] Kyubok Jin,[1] Seungyeup Han,[1] Jung Pyo Lee,[2] Dong Ki Kim.[3] *[1]Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Although immunoglobulin A nephropathy (IgAN) is not a definite genetic disease, it has an autoimmune trait of complex architecture with a solid genetic predisposition. Herein, we aimed to evaluate the difference in microbiota profile among patients with IgAN and healthy controls. In addition, we tried to evaluate the microbiome representing the disease severity.

Methods: We prospectively recruited subjects with IgAN and healthy control between July 2019 and December 2021. Gut microbiota was analyzed using the Illumina MiSeq system based on the 16S rRNA gene. We compared the abundance of the microbiome in each level of phylum, class, order, family, and genus between the groups using Mann–Whitney U test. Also, we tried to find a specific genus representing the disease severity based on the Oxford classification.

Results: A total of 87 subjects (IgAN 59, healthy control 24) were finally included in the study. The mean age was 40.3 and 38.1 years old in IgAN and healthy controls, respectively. The mean eGFR was 89.2 and 107.6 mL/min/1.73 m^2, respectively. At the genus level, there were 32 microbiomes that indicated a detection rate of more than 70% in all of the individuals. In comparing between two groups, the abundance of *Blautia*, *Anaerobutyricum*, *Dorea*, *Romboutsia*, and *Clostridium* was higher in IgAN patients. In contrast, *Prevotella* and *Lachnospira* were significantly lower in IgAN patients. According to the Oxford classification, the microbiome responsible for the difference in the T score was discovered the most, while the microbiome responsible for the difference in the E and S score was discovered the least. The abundance of *Blautia* was higher in T1, but *Prevotella*, *Lachnospiraceae*, *Escherichia*, *Kineothrix*, *Lachnospira*, and *Veillonella* were lower in T1 compared to T0. In contrast, only Coprococcus was detected at a higher level in E1, while Parabacteroides was detected at a lower level in S1.

Conclusions: The gut microbiota was well discriminated in subjects with IgAN from healthy controls. In addition, it was also differently observed according to the status of the pathologic findings of IgAN. These results may provide a basis for further metagenomics analysis of IgAN.

SA-PO943

Urinary Exosomal miRNA Signature of IgA Nephropathy: A Case-Control Study

Mythri Shankar. *Institute of Nephro Urology, Bangalore, India.*

Background: IgAN is a progressive disease. The current gold standard for diagnoses is kidney biopsy-invasive procedure with life-threatening complications. The hour needs a non-invasive, reliable, stable & accurate biomarker.miRNAs are small, non-coding endogenous RNA. Urinary exosomes are rich in miRNA and can be used as novel non-invasive biomarkers. We aim to study the urinary exosomal miRNA signature of pts with IgAN.

Methods: 50 biopsy-proven IgAN pts & 50 healthy controls were recruited in India. Urinary exosomes were isolated & miRNA extracted. Analysis was done with digital multiplexed nCounter® human miRNA Expression Assay which contains 799 unique miRNA barcodes. Lasso regression & consensus clustering were performed to discover significant miRNA.

Results: Mean age:36.8yrs. Male:Female=3:1. Mean creatinine & proteinuria : 2.2 mg/dl and 2.9 gms/day respectively. Majority miRNAs were significantly downregulated. A group of 5 candidate miRNAs hsa.miR.146b.3p+hsa.miR.599+hsa.miR.4532+hsa.miR.664b.5p+hsa.miR.221.5p which could successfully differentiate between IgAN cases and healthy controls with very high sensitivity and specificity.

Conclusions: The group of five candidate urinary exosomal miRNAshsa.miR.146b.3p+hsa.miR.599+hsa.miR.4532+hsa.miR.664b.5p+hsa.miR.221.5p has the potential to serve as novel non-invasive biomarkers for IgA nephropathy.

Relevance of Serum A Proliferation-Inducing Ligand (APRIL) as a Biomarker in South Asian Prospective Longitudinal Observational IgA Nephropathy Cohort (GRACE-IgANI)

Suceena Alexander,[1] Selvin Sundar Raj Mani,[1] Santosh Varughese,[1] Jonathan Barratt,[2] George John.[1] GRACE-IgANI. *[1]Christian Medical College Vellore, Vellore, India; [2]University of Leicester, Leicester, United Kingdom.*

Background: The role of serum APRIL as a biomarker in a prospective longitudinal South Asian IgAN cohort (GRACE-IgANI) and the impact of immunosuppression (IS) is not known.

Methods: Serum APRIL levels were measured in baseline and longitudinal sera (1year, 2year & 3year) in IgAN patients, and at baseline in disease controls and healthy controls by ELISA (R&D Systems; Catalog No: DY884B). Short course IS was

given to patients with proteinuria ≥1g/day and/or renal impairment (73%). Composite outcome (CO) was defined as ≥50% fall in eGFR (CKD EPI) from baseline and/or eGFR <15ml/min/1.73m^2 or RRT/death.

Results: Lower baseline serum APRIL levels were diagnostic of IgAN in our cohort compared to disease controls and healthy controls (398 vs. 550 vs. 516 pg/mL, p=0.002). Serum APRIL levels had significant but weak positive correlation with baseline eGFR. MEST-C T1/T2 scores were significantly associated with lower baseline serum APRIL levels (T0: 490 vs. T1/T2: 372 pg/mL, p=0.007). In the treatment group I (low-risk group without IS), there was no significant association with CO at 3year. In the treatment group II (high-risk group with IS), there was significant association between lower serum APRIL levels at 1year, 2year, 3year and CO at 3year (1Y: 590 vs. 356 pg/mL, p<0.001; 2Y: 508 vs. 314 pg/mL, p=0.003; 3Y; 519 vs. 271, p<0.001) and the ROC curve of serum APRIL level at 1year showed good discrimination (AUC 0.75) for CO. There was a significant longitudinal increase in serum APRIL levels from baseline to 1year and which was sustained at 3year (Baseline: 414 vs. 1Y: 590 vs. 2Y: 508 vs. 3Y: 519 pg/mL, p<0.0001) in patients with favorable renal outcome.

Conclusions: Serum APRIL levels were an indepenpendent risk factor for progressive kidney disese in this cohort.

SA-PO945

The Level of Poly-IgA Immune Complexes in the Short-Term Efficacy Evaluation and Disease Activity Monitoring of IgA Nephropathy (IgAN)

Yulei Chen, Xiao Zhang, Yuxin Luo, Junzhe Chen, Ying Tang. Nephrology Dept. *The Third Affiliated Hospital of Southern Medical University, Guangzhou, China.*

Background: The formation of Poly-IgA immune complexes play a key role in IgAN. The levels of poly-IgA in IgAN were higher than those in healthy controls or in controls with non-IgAN disease. The changes of Poly-IgA in patients with IgAN are related to the severity of the disease. Whether Poly-IgA changes after treatment can evaluate the therapeutic effect, whether Poly-IgA level is an independent risk factor for non-remission, and whether it can be combined with other indicators to achieve a more accurate individual evaluation of IgAN patients still needs research.

Methods: 74 IgAN patients in Department of Nephrology, The Third Affiliated Hospital of Southern Medical University from March 17, 2022 to March 28, 2023 were recorded. 54 individuals had been treated with corticosteroids or immunosuppressants. Paired-samples T test was used to compare the levels of Poly-IgA before and after treatment. 39 of them with proteinuria > 0.5g/ day at the beginning or after treatment were selected for short-term efficacy Evaluations. They were divided into two groups based on changes in urinary protein(UP) levels before and after treatment. Patients with UP level less than 0.5g/ d after treatment were classified as remission group, otherwise as non-remission group. Risk factors for its short-term efficacy were analyzed using logistic regression.

Results: 54 IgAN patients were enrolled to compare the levels of Poly-IgA before and after treatment. We found out that the levels of Poly-IgA before treatment (Mean=18.91, SD=3.73) was significantly higher than that after treatment (Mean=14.24, SD=10.49), (P=0.01). The multivariate logistic regression identified that for every 0.306 increase in levels of Poly-IgA after treatment, the risk of disease progression in IgAN patients increased by 35.8%(P=0.022).

Conclusions: The findings suggest that elevated Poly-IgA levels after treatment are associated with an increased risk of non-remission in IgAN patients. Therefore, monitoring Poly-IgA level can be used as a valuable biomarker to evaluate the efficacy of IgAN. Further studies are needed in the future to validate these findings and to explore the potential of combining Poly-IgA with other measures to construct and optimize models for evaluating short - and long-term outcomes in IgAN patients to more accurately personalize the assessment of IgAN patients.

SA-PO946

Correlation of Immunoglobulin A/Complement Factor 3 (IgA/C3) Ratio with the Clinico-Histological Characteristics and Outcome in IgA Nephropathy

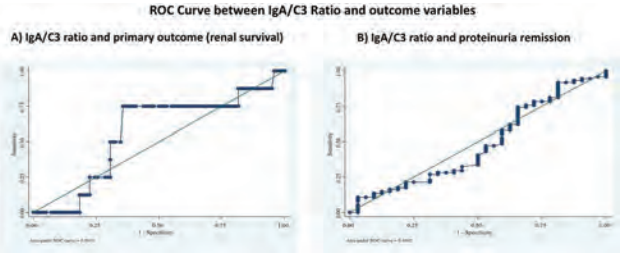
Anitha Swamy,[1,2] Adarsh Barwad,[1] Geetika Singh,[1] Arunkumar Subbiah,[1] Raj K. Yadav,[1] Sandeep Mahajan,[1] Dipankar M. Bhowmik,[1] Sanjay K. Agarwal,[1] Soumita Bagchi.[1] *[1]All India Institute of Medical Sciences, New Delhi, India; [2]All India Institute of Medical Sciences, Bibinagar, Hyderabad, India.*

Background: IgAN is a heterogenous disease and has an aggressive clinical course in Asians. The serum IgA/C3 ratio at biopsy has been shown to correlate well with the prognosis of IgAN in few studies. We conducted this study to evaluate this non-invasive biomarker in our patients.

Methods: In an ambispective study we evaluated the baseline serum IgA and C3 levels, and IgA/C3 ratio in patients with biopsy proven primary IgAN and eGFR ≥ 30 ml/min/1.73m^2. For the patients recruited retrospectively, the same was determined from serum samples stored in a biorepository at the time of kidney biopsy. The ratio was evaluated in relation to the clinical severity at the time of presentation in terms of eGFR and proteinuria and histological severity assessed using the Oxford classification. We also assessed the role of the baseline IgA/C3 ratio as a prognostic biomarker in this cohort. The primary outcome assessed was renal survival which was defined as absence of > 40% decline in eGFR and/or progression to end stge renal disease. Remission of proteinuria was defined as urinary protein creatinine ratio(UPCR) <1g/g with stable renal function (≤ 25% decline in eGFR).

Results: 106 patients with a median follow-up period of 17.3 months with a median serum creatinine of 1.3 (0.4-2.6) mg/dl at presentation were analyzed. 46 patients (43.4%) had a baseline eGFR < 60 ml/min/1.73m^2. The mean UPCR at baseline was 2.1 ±1.6 g/g with 18 patients (17.0%) having nephrotic range proteinuria. The median IgA/C3 ratio in the population was 2.5 (0.79-4.75). The serum IgA/C3 ratio at baseline did not corelate with the baseline eGFR, proteinuria and the MEST-C characteristics. The ratio did not predict the primary outcome or the remission of proteinuria.

Conclusions: Future studies with larger sample size, milder cases, longer follow up period and a serial measurement of IgA/C3 are warranted for better clarification of any possible role of this biomarker in IgAN in our population.



SA-PO947

Association of Anti-EPOR Antibodies with Clinicopathological Findings in Patients with IgA Nephropathy

Sho Kajikawa, Megumi Oshima, Keisuke Horikoshi, Keisuke Sako, Takahiro Yuasa, Taichiro Minami, Shiori Nakagawa, Tadashi Toyama, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa Daigaku Fuzoku Byoin Jinzo Naika, Kanazawa, Japan.*

Background: Disease severity in immunoglobulin A nephropathy (IgAN) is mainly determined by pathological findings. Noninvasive and more convenient biomarkers are thus required for evaluating its activity. In previous studies, the presence of autoantibodies to the erythropoietin receptor (anti-EPOR antibodies) has been shown to be associated with high disease activity and kidney function decline in patients with various kidney diseases including lupus nephritis, type 2 diabetes, and anti-neutrophil cytoplasmic antibody-associated vasculitis. In this study, we therefore investigated the association of anti-EPOR antibodies with clinical and pathological findings in patients with IgAN.

Methods: This retrospective cohort study included 56 patients with biopsy-proven IgAN between 2006 and 2016 at Kanazawa University Hospital. Serum anti-EPOR antibodies at kidney biopsy were measured by using enzyme-linked immunosorbent assays. We then evaluated the associations of anti-EPOR antibodies with clinical and pathological characteristics.

Results: The presence of anti-EPOR antibodies was detected in 12 (21%) patients. Mean age, eGFR, and hemoglobin were comparable at baseline between the patients with and without anti-EPOR antibodies. Serum IgA/C3 ratio was higher in patients with anti-EPOR antibodies than those without (4.33 versus 3.19, p = 0.001). For pathological findings, patients with anti-EPOR antibodies were more likely to have active glomerular lesions, such as crescents or adhesions, compared to those without (91.7% versus 66.7%). During mean follow-up of 7.6 years, no statistical differences were found in annual eGFR declines between the patients with and without anti-EPOR antibodies (Mean±SD: 1.4±3.8 vs. 3.0±3.8 ml/min/1.73 m^2/year).

Conclusions: The presence of anti-EPOR antibodies may reflect disease activity in patients with IgAN.

Funding: Government Support - Non-U.S.

SA-PO948

Rate of Loss of eGFR and Time-Averaged Proteinuria in IgA Nephropathy (IgAN) Patients Progressing from Early-Stage Disease to Kidney Failure

David Pitcher,[1] Fiona E. Braddon,[1] Bruce M. Hendry,[2] Alex Mercer,[3] Kate Osmaston,[1] Moin Saleem,[4] Retha D. Steenkamp,[1] Wu Gong,[2] A. Neil Turner,[7] Jonathan Barratt,[5] Daniel P. Gale.[6] *[1]UK Renal Registry, Bristol, United Kingdom; [2]Travere Therapeutics Inc, San Diego, CA; [3]JAMCO Pharma Consulting, Stockholm, Sweden; [4]University of Bristol & Bristol Royal Hospital for Children, Bristol, United Kingdom; [5]University of Leicester & Leicester General Hospital, Leicester, United Kingdom; [6]Royal Free Hospital & University College London, London, United Kingdom; [7]University of Edinburgh, Edinburgh, United Kingdom.*

Background: Cohort studies in IgAN have analyzed time-averaged proteinuria (TA-PU) and eGFR decline over long-term follow-up (f/u), and randomized controlled trials typically measure proteinuria and eGFR over 1-2 years, but none compare disease progression in early vs later stages of disease. In this study of patients enrolled into the UK National Registry of Rare Kidney Diseases (RaDaR) with biopsy-proven IgAN and f/u data spanning early-to-late CKD stages, we present preliminary findings comparing the extent of proteinuria (PU) and eGFR decline prior to and after entering CKD stage 3B.

Methods: Linear regression of eGFR values from baseline (first PU value ≥6mo after diagnosis) until kidney replacement therapy initiation or end of f/u was used to define patient's Time0 as the estimated date their eGFR passed 45. Longitudinal PU was assessed as TA-PU. Differences in eGFR slope and TA-PU before and after Time0 were analyzed using multilevel models and paired t-test; patients were required to have ≥3 eGFR and ≥2 PU values before and after Time0.

Results: eGFR decline was rapid and comparable in the 2 periods, either unadjusted or adjusted for age and sex (Table 1A; Figure). TA-PU was 41.4% greater in patients after progressing through the 45 ml/min/1.73m^2 threshold than before reaching this mark (Table 1B).

Conclusions: Given the comparability of eGFR decline prior to and after passing an eGFR of 45ml/min/1.73m^2, slope measurements in early disease stages may be useful in estimating future eGFR loss. Comparability of eGFR slopes but differences in TA-PU suggest patients with stable rates of eGFR loss suffer increasing damage to the glomerular filtration barrier.

Funding: Commercial Support - Travere Therapeutics, Inc.

Comparative Analysis of Clinical and Pathological Traits in IgA Nephropathy with Nephrotic Range Proteinuria Based on Serum Albumin Level

Sang Hun Eum,[1,9] Ji Won Min,[2,9] Eun Sil Koh,[3,9] Tae Hyun Ban,[4,9] Suyeon Hong,[5,9] Yu Ah Hong,[6,9] Byung ha Chung,[7,9] Yong Kyun Kim,[8,9] Seok Joon Shin,[1,9] Hye Eun Yoon.[1,9] *[1]Incheon St. Mary's Hospital, Incheon, Republic of Korea; [2]Bucheon St. Mary's Hospital, Bucheon, Republic of Korea; [3]Yeouido St. Mary's Hospital, Seoul, Republic of Korea; [4]Eunpyeong St. Mary's Hospital, Seoul, Republic of Korea; [5]Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea; [6]Daejeon St. Mary's Hospital, Daejeon, Republic of Korea; [7]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [8]St. Vincent's Hospital, Suwon, Republic of Korea; [9]The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea.*

Background: Presently, the clinical outcomes associated with IgA nephropathy exhibiting heavy proteinuria and the potential correlation between decreasing serum albumin levels and adverse prognosis have not been conclusively established. The present study was designed to elucidate the clinical and pathological characteristics of IgA nephropathy patients who present with nephrotic-range proteinuria, particularly in relation to serum albumin levels.

Methods: This retrospective study was conducted using data from biopsy-confirmed IgA nephropathy patients presenting with nephrotic-range proteinuria between 2017 and 2022 from eight university-affiliated hospitals in South Korea. Patients were stratified into two groups based on a serum albumin level of 2.5g/dl. The study involved a comparative assessment of clinical and pathological characteristics across these two groups, as well as an evaluation of clinical prognosis with respect to the end-stage kidney disease (ESKD).

Results: The analysis included a total of 105 patients. Of these, 86 patients had a serum albumin level above 2.5g/dl (designated as the preserved albumin group, or PA group), while 19 patients had levels below 2.5g/dl (designated as the decreased albumin group, or DA group). The baseline characteristics of the two groups were found to be statistically similar. The mean age of the patients was 46.25 years, and 45.71% were male. Serum erythrocyte sedimentation rate, total cholesterol and low-density lipoprotein-cholesterol levels were significantly higher in the DA group. Pathological findings revealed more pronounced global sclerosis, interstitial fibrosis, and tubular atrophy in the PA group. Diffuse foot process effacement was more prominent in the DA group. During a median follow-up period of 23.64 months (range 0.03-69.53 months), 22 patients (25.58%) in the PA group progressed to ESKD, compared with 1 patient (5.26%) in the DA group. There was no statistically significant difference between the two groups in terms of progression to ESKD (P = 0.055).

Conclusions: In patients with IgA nephropathy presenting with nephrotic-range proteinuria, a decline in serum albumin levels was associated with less chronic lesions, and it was not found to be associated with adverse prognosis.

SA-PO950

Application of Prediction Tools in Patients with IgA Nephropathy: A Single-Center Cohort

José Agapito Fonseca,[1] João Riesenberger,[2] Iolanda Godinho,[1] Marta Pereira,[1] Jose A. Lopes,[1] Joana Gameiro.[1] *[1]Serviço de Nefrologia e Tranplantação e Renal, Hospital de Santa Maria, Centro Hospitalar e Universitário Lisboa Norte, Lisboa, Portugal; [2]Faculdade de Medicina da Universidade de Lisboa, Lisboa, Portugal.*

Background: IgA nephropathy (IgAN) is the most common glomerular disease. Despite the development of prognostic scores, such as then IgAN Prediction Tool (IgAN-PT), long-term clinical course is difficult to predict. The Kidney Risk Failure Equation (KFRE) is a four-variable equacionar which allows to predict the two and five-year probability of requiring kidney replacement therapy (KRT), but its accuracy on IgAN has not been established. The aim of this study was to assess the discriminative ability of the KFRE compared to the IgAN-PT to predict KRT in patients with IgAN.

Methods: We conducted a retrospective analysis of patients with IgAN followed by the Nephrology and Kidney Transplantation Department in Centro Hospitalar Universitário Lisboa Norte for five years. The primary outcome was the need for KRT within five years after kidney biopsy. The IgAN-PT and the four-variable KFRE were calculated for multiple follow-up points.

Results: Twenty-nine patients were included and 58.6% were male. At presentation, mean age was 41.3 ± 13.6 years, serum creatinine was 1.60 ± 1.17 mg/dL, and proteinuria was 1360 ± 1120 mg/g. At biopsy, the five-year KFRE score was 13.9 ± 25.6% and the five-year IgAN-PT score was 14.7 ± 15.9%. Three patients started KRT (10.3%) during follow-up. Proteinuria at presentation (3032 mg/g vs. 1159 mg/g, p=0.004) and serum creatinine on kidney biopsy (2.81 mg/dL vs. 1.35 mg/dL, p=0.003) were associated with need for KRT. Both the IgAN-PT and the KFRE correctly identified patients with higher risk for KRT, with the KFRE equation at clinical presentation exhibiting a slight superiority over the IgAN-PT (AUC 0.885 vs. 0.846).

Conclusions: The KFRE score at five-years after clinical presentation in patients with IgAN has shown excellent discriminative ability for identifying patients at risk of KRT. Moreover, it has demonstrated equivalent accuracy compared to the more specific IgAN-PT, being easier to apply and allowing for longer-term prognosis.

SA-PO951

Cnm-Positive Streptococcus mutans, a Major Pathogen of Dental Caries, May Cause IgA Nephropathy via Tonsils

Taro Misaki,[1,2] Shuhei Naka,[3] Yasuyuki Nagasawa,[4] Daiki Matsuoka,[3] Seigo Ito,[5] Saaya Matayoshi,[6] Ryota Nomura,[7] Michiyo Matsumoto-Nakano,[3] Kazuhiko Nakano.[6] *[1]Division of Nephrology, Seirei Hamamatsu General Hospital, Hamamatsu, Japan; [2]Department of Nursing, Faculty of Nursing, Seirei Christopher University, Hamamatsu, Japan; [3]Okayama Daigaku, Okayama, Japan; [4]Hyogo Ika Daigaku, Nishinomiya, Japan; [5]Japan Self-Defense Iruma Hospital, Iruma, Japan; [6]Osaka Daigaku, Suita, Japan; [7]Hiroshima Daigaku, Higashihiroshima, Japan.*

Background: The presence of *Streptococcus mutans*, a major pathogen of dental caries, expressing Cnm protein encoded by *cnm* in the oral cavity has been associated with the pathogenesis of IgA nephropathy (IgAN). Although tonsillectomy is applied for the treatment of IgAN, its effectiveness in the patients harboring *cnm*-positive *S. mutans* in the oral cavity is not clear. This study aimed to investigate the effects of tonsillectomy on patients with IgAN who harbor *cnm*-positive *S. mutans* in the oral cavity.

Methods: The presence of *cnm*-positive *S. mutans* was analysed by polymerase chain reaction in saliva specimens from 117 patients with IgAN. The patient's history of tonsillectomy was examined, and they were divided into four groups based on the results of *cnm*-positive *S. mutans* detection and tonsillectomy history: group A (n=52) (tonsillectomy (-), *cnm*-positive *S. mutans* (-)); group B (n=35) (tonsillectomy (+), *cnm*-positive *S. mutans* (-)); group C (n=16) (tonsillectomy (-), *cnm*-positive *S. mutans* (+)), and group D (n=14) (tonsillectomy (+), *cnm*-positive *S. mutans* (+)). The subjects' clinical parameters were analysed.

Results: The proportion of patients with an estimated glomerular filtration rate <60 mL/min was significantly higher in group C than the other groups ($p < 0.0083$). The proportion of proteinuria 2+ or higher was significantly higher in group C than the other groups ($p < 0.0083$). In the *cnm*-positive *S. mutans* (+) groups, serum IgA was significantly lower in tonsillectomy group than in non-tonsillectomy group (266.9mg/dl vs 358.9mg/dl, $p < 0.05$).

Conclusions: These results suggest that the exacerbation of IgAN by *cnm*-positive *S. mutans* may be mediated by the tonsils and tonsillectomy may be effective in patients with IgAN who harbor *cnm*-positive *S. mutans* in the oral cavity.

SA-PO952

Porphyromonas gingivalis Infection in Oral Cavity Is Associated with Elevated Galactose-Deficient IgA1 in IgA Nephropathy

Taro Misaki,[1,2] Seigo Ito,[3] Shuhei Naka,[4] Yasuyuki Nagasawa,[5] Daiki Matsuoka,[4] Saaya Matayoshi,[6] Ryota Nomura,[7] Michiyo Matsumoto-Nakano,[4] Kazuhiko Nakano.[6] *[1]Seirei Hamamatsu Byoin, Hamamatsu, Japan; [2]Seirei Kurisutofa Daigaku, Hamamatsu, Japan; [3]Japan Self-Defense Iruma Hospital, Iruma, Japan; [4]Okayama Daigaku, Okayama, Japan; [5]Hyogo Ika Daigaku, Nishinomiya, Japan; [6]Osaka Daigaku, Suita, Japan; [7]Hiroshima Daigaku, Higashihiroshima, Japan.*

Background: The association between Porphyromonas gingivalis, a major periodontal bacteria, and the pathogenesis of IgA nephropathy (IgAN), with a focus on galactose-deficient IgA1 (Gd-IgA1), has not been fully understood.

Methods: Saliva samples were obtained from 30 IgAN patients and 44 patients with chronic kidney disease (CKD) to analyze the presence of P. gingivalis using PCR with a specific set of primers. The association between P. gingivalis detection and clinical parameters, including plasma Gd-IgA1, was analyzed for each group.

Results: IgAN group showed a significantly higher serum Gd-IgA1 level than CKD group ($p < 0.05$). *P. gingivalis*-positive group had a significantly higher serum Gd-IgA1 level than *P. gingivalis*-negative group in IgAN and CKD patients ($p < 0.05$). *P. gingivalis*-positive group in IgAN patients also showed a significantly higher serum Gd-IgA1 level than *P. gingivalis*-negative group in IgAN patients ($p < 0.05$). As for kidney biopsy findings, *P. gingivalis*-positive group exhibited a significantly higher frequency of the existence of segmental glomerulosclerosis than *P. gingivalis*-negative group when evaluating by the Oxford classification of IgAN ($p < 0.05$).

Conclusions: Our results suggest that *P. gingivalis* presence in oral cavity may be associated with IgAN pathogenesis due to induction of elevated level of Gd-IgA1.

SA-PO953

Validation of the International Immunoglobulin A (IgA) Risk Prediction Tool in American Indians and Hispanics

Saeed K. Shaffi,[1,2] Edgar G. Fischer,[2] Brent Wagner.[1,2] *[1]Raymond G. Murphy VA Medical Center, Albuquerque, NM; [2]University of New Mexico School of Medicine, Albuquerque, NM.*

Background: The International IgA risk prediction equation performance has not been studied in the Hispanic and American Indian population. Studies have reported a higher frequency of IgAN in American Indians. Therefore, we conducted this single-center study based in New Mexico to assess the performance of the International IgA risk prediction tool without race/ethnicity.

Methods: We searched the University of New Mexico kidney biopsy registry - a repository of kidney biopsies from 2002 -2016 - for instances of IgA nephropathy. We calculated the 5-year risk of developing kidney failure and assessed the equation performance using the metrics of calibration, discrimination, and overall prediction error in patients with primary IgA nephropathy on whom the predictions variables were available.

Results: Thirty-four patients were included, most of whom identified as of Hispanic race/ethnicity (44.1%), or as American Indians (26.5%). At biopsy, the median (IQR) age, serum creatinine, and spot urine protein to creatinine ratio were 38 years (27-45), 2.15 mg/dl (1.51-3.04), and 2.7 g/g (1.5-5.8), respectively. The equation identified patients at high risk of developing kidney failure early with a concordance statistic of 0.79 (95% CI 0.68 – 0.89). The agreement between observed and predicted outcomes at 5 years was marginal, with over-estimation of risk for patients with low observed risk and vice versa. Overall prediction error was suboptimal in this cohort [index of prediction accuracy 0.34 (0.03 -0.51)].

Conclusions: The International IgAN risk prediction equation without race accurately identified patients at elevated risk of developing kidney failure. At 5 years, the agreement between the observed and predicted outcomes was sub-optimal, possibly due to advanced kidney disease in this cohort. A diverse development population may improve the risk prediction.

Performance measures of the International IgAN Risk Prediction Tool without race in the study cohort

Metric	Value
Discrimination	
C-Statistics at 5 years	0.79 (0.64 – 0.79)
Area Under the Curve at 5 years	0.79 (0.68 – 0.89)
Calibration	
Observed/Estimated Risk at 5 years (O/E)	0.88 (0.51 – 1.25)
Calibration Intercept	0.10 (-0.37 – 0.58)
Calibration Slope	3.03 (0.43 – 5.64)
Overall Prediction Error	
Index of Prediction Accuracy (IPA)	0.33 (0.02 – 0.50)

SA-PO954

Challenges and Lessons Learnt Learned from Industry-Driven Multi-Centre Global Clinical Trials in IgA Nephropathy (IgAN): Site Investigators' Perspective

Selvin Sundar Raj Mani, Suceena Alexander. *Christian Medical College Vellore, Vellore, India.*

Background: IgA nephropathy (IgAN) is the most common glomerulonephritis worldwide. Recently, many promising bio-molecules are being studied in clinical trials which are industry sponsored, multi-centre and global. Does the uniform protocol across the centers really reflect the regional practices or standard of care in a geographically varied disease like IgAN?

Methods: This was the site investigators' perspective after being involved in 5 ongoing industry driven phase 2/3/OLE multi-centre clinical trials in IgAN. More than 20 eligible patients were enrolled from one of the largest not-for profit quaternary medical centre in South India over a span of 3 years. We are highlighting some of the best practices and some of the regional challenges for participants.

Results: Consent process- The entire process of providing trial related information, informal consultations with relatives and family doctors before providing an informed written consent could take 3-4 months. The strength of this long-drawn pre-consenting phase is improved overall retention and minimal drop-outs. **Screening phase-** In India, it is common to test positive for latent tuberculosis using IGRA tests due to community exposure. This is one of the major impediments for recruitment as otherwise they would have received immunosuppression in the absence of active disease. Another major road block was the anti-hepatitis B core antigen testing in the absence of hepatitis B surface antigen or hepatitis B viral DNA positivity. **Recruitment and Retention phase-** Flexible appointment times, frequent reminders and good rapport with the clinical trial team gained the participants' trust and helped in retention. Reimbursement of actual expenses is vital to ensure proper visits and compliance to treatment. Investigators meetings and regular newsletters helped us to track recruitment and SAEs at a global scale. **Post trial access-** Indian regulatory approval for open label extension is long drawn which has directly affected the post-trial access to potentially valuable bio-molecules for participants in phase 2/3 clinical trials.

Conclusions: Industry driven global clinical trials are indispensable but sponsors could consider some regional modifications in the entry criteria and post-trial access. This also highlights the need for academic trials that repurpose the already available molecules.

SA-PO955

A Multi-Targeted Serologic Approach for Antigen-Specific Diagnosis of Membranous Nephropathy (MN) in the Clinical Routine

Linda Reinhard,[1] Céline Marie Brauer,[1] Thorsten Wiech,[2] Elion Hoxha.[1] *[1]III. Deparment of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Institute for Pathology, Section Nephropathology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: MN is caused by circulating antibodies (ab) targeting PLA2R1 or THSD7A in 70-80% of cases. Over the last years a diverse repertoire of other potential antigens has been identified, however, it remains unclear how an autoantibody-specific diagnostic workflow in patients with MN can be implemented in clinical routine.

Methods: We implemented a multi-targeted serologic screening procedure, which allows detection of ab directed against sensitive, conformational epitopes of multiple antigens within one experiment. Results were validated using ELISA, Western blot and immunohistochemistry of kidney biopsies. The clinical applicability of this system was tested in 410 patients with biopsy-proven MN.

Results: A PLA2R1-induced MN was diagnosed in 307 (74.9%) of 410 patients. Using our multi-targeted serology screening approach, we identified 17 (4.2%) NELL1-ab positive patients, 10 (2.4%) THSD7A-ab positive patients and 12 (2.9%) patients with circulating ab against one of the other antigens (PCDH7, HTRA1, NTNG1, CNTN1, or SEMA3B). Interestingly, 5 of these 12 patients showed ab against two different antigens simultaneously. Every ab result was validated using Western Blot showing concordance of results in 95% of cases. 20 (31.2%) of the remaining 64 sera showed reactivity to different preparations of human glomerular extract (HGE), indicating that for each antigen, ab detectability is strongly dependent on the experimental protocols used to extract the HGE antigens. 83% of patients with no reactivity to any antigen or the HGE in any experimental condition, had a remission of proteinuria, in 66% of them it was a spontaneous remission without use of immunosuppression.

Conclusions: We report a multi-targeted serologic approach, which allows an antigen-specific diagnosis of MN within days and is therefore applicable in clinical routine. To fully accomplish an antigen-specific MN diagnosis in every patient, sera with reactivity to HGE are used for antigen identification via immunoprecipitation. The 10% of cases with no serologic activity show a good prognosis, while antigen identification is performed by tissue-based mass spectrometry. For the implementation of the later two steps into clinical routine further adjustments are required, especially concerning the turn-around time for antigen identification.

Funding: Government Support - Non-U.S.

SA-PO956

Monoclonal Characterization of Autoreactive PLA2R1 Antibody Responses in Membranous Nephropathy (MN)

Linda Reinhard,[1] Sara Montagner,[2] Martine Marchant,[2] Mariavittoria Iazeolla,[2] Alexandra Lavoisier,[2] Elisabetta Traggiai,[2] Elion Hoxha.[1] *[1]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Novartis AG, Basel, Switzerland.*

Background: Membranous nephropathy (MN) is caused by circulating antibodies, which in 70-80% of cases are directed against PLA_2R1. The CysR domain of the PLA_2R1 is the immune dominant domain and all patients with PLA_2R1-induced MN exhibit antibodies against this domain of the protein. Today, all treatment options for MN are unspecific concerning the molecular disease pathogenesis.

Methods: We isolated PBMCs from patients with PLA_2R1-induced MN. Using tagged PLA_2R1, PLA_2R1-specific B cells were isolated and the corresponding B cell receptors were cloned, in order to produce monoclonal human PLA_2R1-antibodies (PLA_2R1-mAb) corresponding to autoantibodies from patients with MN. The inhibitory potential of these PLA_2R1-mAb for human PLA_2R1-antibody binding to PLA_2R1 was tested *in vitro* by competition ELISA using 60 sera from patients with PLA_2R1-induced MN and *in vivo* in a rat model, which expresses the human PLA_2R1 ($hPLA_2R1$) specifically on podocytes.

Results: In total, four PLA_2R1-mAb were cloned from PLA_2R1-specific B cells from patients with MN and bound epitopes on the CysR domain. Every PLA_2R1-mAb was tested for its inhibitory capability using 60 PLA_2R1-antibody positive sera from patients with PLA_2R1-induced MN. The PLA_2R1-mAb inhibited the PLA_2R1-antibody binding capacity of the patient sera by 45% - 96%. The inhibitory effect of each PLA_2R1-mAb was independent of the PLA_2R1-antibody level of the sera; i.e. the PLA_2R1-mAb with the highest inhibition of 96% exhibited a PLA_2R1-antibody inhibition of 95%, 96% and 96%, when sera with PLA_2R1-anitbody level of 40-79 U/ml, 80-250 U/ml and > 250 U/ml were used, respectively. PLA_2R1-mAb were injected into a rat with podocyte-specific $hPLA_2R1$-expression prior to passive transfer of human PLA_2R1-antibodies from patients with MN. This PLA_2R1-mAb led to an inhibition of PLA_2R1-antibody binding by 80% *in vivo*.

Conclusions: We report for the first time the characterization of human monoclonal antibodies specific for PLA_2R1 derived from memory B cells of MN patients. Cloned autoantibodies showed strong inhibition of PLA_2R1 autoantibody binding both *in vitro* and *in vivo*, opening the possibility of a potential PLA_2R1 epitope specific treatment.

SA-PO957

Utility of Anti-PLA2R and Anti-THSD7A Antibodies in Predicting Membranous Nephropathy Recurrence: A Multi-Center Retrospective Cohort Study

Frank E. Hullekes,[1,2] Ruchâma Verhoeff,[1,2] Paolo Cravedi,[3] Leonardo V. Riella.[1,2] *[1]Massachusetts General Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

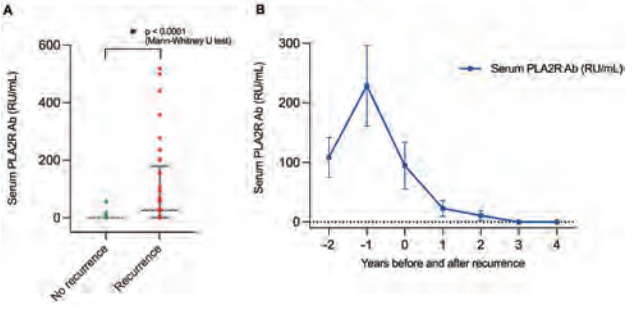
Background: Membranous nephropathy (MN) is a leading cause of nephrotic syndrome, frequently leading to kidney failure. The discovery of autoantibodies against podocyte antigens, including PLA2R and THSD7A, is a major advancement in our understanding of disease pathophysiology. The predictive value of PLA2R and THSD7A serum Abs in detecting recurrent MN remains undefined.

Methods: Through the Post-Transplant Glomerular Disease (TANGO) Consortium, we initiated a multi-center retrospective cohort study, investigating MN post-Tx, using clinical data and serum samples. Adults with biopsy-proven MN, transplanted between 2005-2021, were identified to study the predictive value of PLA2R and THSD7A in detecting recurrence.

Results: 22,921 patients were screened by 16 Tx centers across 3 continents. 86 kidney Tx recipients with biopsy-proven MN were included for anti-PLA2R Abs assessment. 46 patients were also screened for anti-THSD7A Abs. 37 patients (43%) developed recurrence at a median of 3.5 years (IQR: 1.5-6.1). Of these, 22 (59%) tested positive for anti-PLA2R Abs prior to recurrence. All 46 patients tested negative for anti-THSD7A Abs. The mean anti-PLA2R Abs for samples collected prior to recurrence was 136.9 RU/mL (95 CI: 55.7-218.2). These were taken with a median of 2.7 months (IQR: 12.9 – 0.1) before recurrence. Patients with recurrence had higher anti-PLA2R Ab than patients without (Figure 1A). Therapy consisted of RAAS inhibition for 30 patients (81%) and/or rituximab in 21 (56%) of the cases. After treatment, anti-PLA2R Abs notably decreased, with a mean of 13.9 RU/mL (95 CI: 3.7-24.1). These were taken with a median of 25.1 months (IQR: 4.0 – 54.6) after recurrence (Figure 1B).

Conclusions: The presence of anti-PLA2R antibodies may have predictive value in detecting recurrent MN post-transplant. Monitoring anti-PLA2R antibody levels and implementing appropriate therapies, in particular rituximab, could potentially aid in the management of recurrent MN.

Figure 1 | Comparison of anti-PLA2R Ab levels between patients with and without MN recurrence (A) and (B) serial anti-PLA2R Ab levels before and after MN recurrence.



SA-PO958

Effects of Rituximab on T Lymphocyte Subsets in the Treatment of Idiopathic Membranous Nephropathy and Its Significance

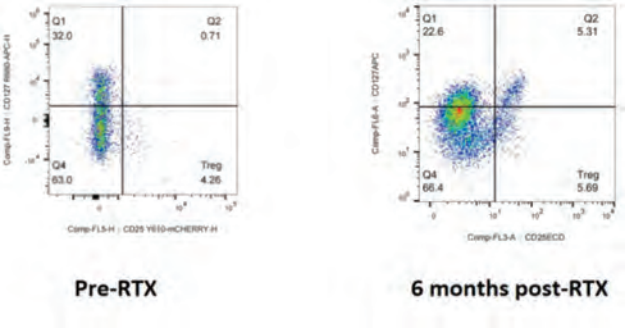
Lei Shen,[1] Yuanyuan Zhang,[2] Jingjing Yang,[1] Jiani Sun,[1] Jianzhong Li.[1] *[1]The First Affiliated Hospital of Soochow University, Suzhou, China; [2]Suzhou Hospital, Affiliated Hospital of Medical school, Nanjing Universtiy, Suzhou, China.*

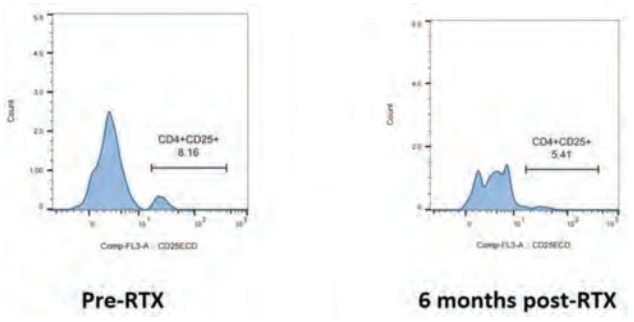
Background: We studied T lymphocyte subsets in patients with idiopathic membranous nephropathy (IMN) and examined the impact and significance of rituximab (RTX) on these subsets.

Methods: We examined peripheral blood lymphocyte subsets in 58 patients with IMN and 25 normal controls by flow cytometry. We followed up the above indicators in 33 patients for 6 months after RTX administration. We also evaluated the changes of anti-PLA2R antibody titers and 24-hour urinary protein before and after treatment.

Results: 1. Compared to the control group, peripheral blood CD3-CD19+B cells, CD3+ T cells, CD3+CD4+T cells, CD4+/CD8+, CD4+CD25+ T cells were significantly higher in IMN group before treatment($P<0.05$). The levels of peripheral blood Treg cells ($CD4+CD25+CD127^{lo}$), CD3+CD8+ T cells in IMN group were lower($P<0.05$). 2. After 6 months of RTX treatment, all the above abnormal indicators were reversed,especially Treg and CD4+CD25+ T cells($P<0.05$) 3. Before and after RTX treatment, the changes of peripheral blood CD4+ T lymphocyte subsets of IMN patients were not correlated with B lymphocyte counts and anti-PLA2R antibody titers.

Conclusions: IMN patients exhibit an abnormality in T lymphocyte subsets, particularly in CD4+ T cell subsets. RTX could restore the balance of CD4+ T lymphocyte subsets and enhance the levels of Treg cells. Importantly, this effect is not solely dependent on B lymphocyte depletion or changes in anti-PLA2R antibody titers. These findings suggest that RTX may have a beneficial impact on cellular immunity in IMN patients.





SA-PO959

Anti-PLA2R Antibody Levels and Treatment Response in Primary Membranous Nephropathy (MN)

Anne-Els van de Logt, Coralien Vink-van Setten, Jack F. Wetzels. *Radboudumc, Nijmegen, Netherlands*.

Background: We introduced individualized therapy in patients with MN and positive anti-PLA2R antibodies (PLA2Rab) by IIFT test (*Vink et al. Kidney International Reports 2023*). Treatment (cyclophosphamide combined with steroids) was stopped when the IIFT test (measured at 8, 16, or 24 weeks) became negative. After 8 weeks, 71% of patients were in immunological remission. Unfortunately, 30% of these latter patients needed renewed therapy within 12 months because of immunological and/or clinical relapse. We questioned if quantitative PLA2Rab measurement would predict treatment response.

Methods: Available, stored serum samples were retrieved, and PLA2Rab levels were measured by ELISA in available samples collected at baseline, and 8, 16, and 24 weeks after start of therapy. (EUROIMMUN Lübeck, Germany).

Results: The analysis included 46 incident patients (M/F 35/11, age 59 ± 12 years, serum creatinine 127 µmol/l [98-164], serum albumin 20 g/l [16-25] and urine protein-creatinine ratio 8.2 gram/10 mmol [6.0-11.7]). Baseline PLA2Rab levels were 145 RU/ml [IQR 97-381]. Thirty patients (65%) developed IIFT remission after 8 weeks, and of these 18 developed persistent clinical remission (group A1), while 12 patients received renewed therapy during follow-up (group A2; no clinical remission). Sixteen patients received initial treatment ≥ 16 weeks (group B), with 7 patients needing continued therapy beyond 6 months. PLA2Rab titer was numerically lower in group A compared to Group B (median 120 RU/mL [IQR 91-261] vs 267 RU/mL [142-436], p = 0.059). Patients with baseline ELISA <80 RU/mL (n =7) developed persistent immunological and clinical remission after only 8 weeks of cyclophosphamide. In patients with baseline PLA2Rab > 80 RU/ml neither baseline PLA2Rab levels, nor absolute or percentage change of PLA2Rab levels from baseline to 8 weeks predicted response or duration of therapy. All patients with at 8 weeks PLA2Rab levels > 20 RU/ml required treatment beyond 6 months (n=4).

Conclusions: Changes in PLA2Rab levels after start of therapy are not helpful in guiding treatment decisions. Still, for a limited number of patients quantitative analysis of PLA2Rab levels at baseline and at 8 weeks after start of therapy provides information that can be used in counseling and treatment planning.

SA-PO960

The Genetics of Idiopathic Nephrotic Syndrome at the Population Level

Benjamin Wooden,[1] Gina Jin,[1] Adele Mitrotti,[1,2] Yask Gupta,[1] Mark Elliott,[1] Tze Yin Lim,[1] Pietro A. Canetta,[1] Maddalena Marasa,[1] Atlas Khan,[1] Giovanni Montini,[10] Velibor Tasic,[3] Mario Giordano,[4] Francesco Scolari,[5] Giovanni Conti,[6] Riccardo Magistroni,[7] Andrew S. Bomback,[1] Krzysztof Kiryluk,[1] Enrico Fiaccadori,[9] Loreto Gesualdo,[2] Yasar Caliskan,[8] Vivette D. D'Agati,[1] Gian Marco Ghiggeri,[9] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [3]University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [4]Pediatric Hospital "Giovanni XXIII", Bari, Italy; [5]Universita degli Studi di Brescia, Brescia, Italy; [6]Azienda Ospedaliera Universitaria "G. Martino", Messina, Italy; [7]Universita degli Studi di Modena e Reggio Emilia, Modena, Italy; [8]Saint Louis University, Saint Louis, MO; [9]Istituto Giannina Gaslini, Genova, Italy; [10]IRCCS Policlinico di Milano, Milano, Italy*.

Background: Genetics play an important role in idiopathic nephrotic syndrome (NS), but our current understanding of clinical-genetic correlations is drawn from small or highly selected studies, with limited representation of different ancestries, ages of onset, and responses to therapy. Here, we present results from a large and broadly-representative cohort of patients with INS who underwent whole exome sequencing.

Methods: 2,009 patients were enrolled and sequenced. The cohort included patients with proteinuric kidney disease with a biopsy showing FSGS or minimal change disease, or NS without biopsy. Patients with a known secondary cause were excluded. The cohort included children and adults of different genetic ancestries, irrespective of family history of NS or prior response to immunosuppression.

Results: Overall, 10.6% of patients were found to have a monogenic variant known to be associated with inherited NS. Across genetic ancestries, the rates of monogenic variant discovery were largely similar, with the notable exception being patients of African ancestry, in whom non-APOL1 Mendelian variants were much less common. Overall, the highest rate of discovery was in steroid-resistant pediatric patients. In adult-onset disease, there was also a significant rate of monogenic variant discovery, including in steroid-sensitive patients -- most of this group featured heterozygous COL4A variants. Pathway analysis showed that GBM-related variants were most common in adult-onset cases, while podocyte genes predominated in pediatric disease. APOL1 high-risk genotypes were associated with risk of ESKD within individuals of African ancestry, as well as faster eGFR decline even in steroid sensitive cases.

Conclusions: In this large cohort of patients with idiopathic NS, exome sequencing analyses provide a diagnostic roadmap for clinical-genetic correlations across the lifespan, ancestry, phenotype, and response to immunosuppression.

SA-PO961

B-Cell Lymphocyte Profiling Identifies Steroid-Dependent Forms of Idiopathic Nephrotic Syndrome Since Disease Onset

Marina Vivarelli, Martina Riganati, Annalisa Candino, Federica Zotta, Francesco Emma, Manuela Colucci. *Ospedale Pediatrico Bambino Gesu, Roma, Italy*.

Background: The clinical evolution of steroid-sensitive forms of idiopathic nephrotic syndrome (SSNS) is highly heterogeneous, ranging from non-relapsing or infrequently relapsing patients (NRNS/IRNS), treated only with standard courses of glucocorticoids (GC), to patients who present frequent relapses (FRNS) and lastly to severe patients showing a steroid-dependent course of disease (SDNS). This last group invariably require second-line steroid-sparing agents. Recently, the therapeutic benefit of anti-CD20 monoclonal antibodies in treating SSNS and the discovery of anti-nephrin antibodies in patients with minimal change disease have pointed to a role of B cells in disease pathogenesis. In particular, we and others have shown that memory B cells predict relapse following and before receiving anti-CD20 (rituximab) infusion in patients with mainly SDNS forms of disease. However, a prospective characterization of B cell subsets from disease onset, before GC and other immunosuppressive treatment, is lacking.

Methods: In this study, we characterized by flow cytometry the profile of circulating B-cell subsets in 19 SSNS children (11 males) at disease onset, before starting GC treatment. All patients were then followed for 12 months in order to define the clinical subtype of their form of SSNS based on the frequency of relapses in relation to GC treatment in the subsequent months.

Results: During follow-up, 6 patients never relapsed (NRNS), 3 were classified as FRNS and 10 as SDNS. Mean (SD) age was higher in NRNS patients (8.5±4.1 years) compared to FRNS patients (4.7±2.3 years, p=0.07) or SDNS patients (4.1±1.8 years, p<0.01). When compared with NRNS patients, FRNS patients showed similar amount of total CD19+ (p=0.66), transitional (p=0.43), mature-naive (p=0.25), and memory (p=0.62) B cells. In contrast, SDNS patients had significantly higher levels of all these B-cell subsets compared to NRNS patients (p<0.05). Moreover, they had similar levels of total CD19+ (p=0.16), transitional (p=0.31) and mature-naive B cells (p=0.77), but a significantly higher amount of memory B cells (p=0.04), when compared to FRNS patients.

Conclusions: Increased levels of circulating memory B cells may allow to discriminate SDNS from FRNS starting from disease onset.

Kidney Transcriptomics of Blood Pressure (BP) in Minimal Change Disease (MCD) and Focal Segmental Glomerulosclerosis (FSGS)

Christine B. Sethna,[1] Sean Eddy,[2] Fadhl Alakwaa,[2] Markus Bitzer,[2] Patrick H. Nachman,[3] Katherine R. Tuttle,[4] Gentzon Hall,[5] Tarak Srivastava,[6] Daniel C. Cattran,[7] Dorey A. Glenn,[8] Agustin Gonzalez-Vicente,[9] John R. Hartman.[2] NEPTUNE. *[1]Cohen Children's Medical Center, Queens, NY; [2]University of Michigan, Ann Arbor, MI; [3]University of Minnesota Twin Cities, Minneapolis, MN; [4]University of Washington, Seattle, WA; [5]Duke University, Durham, NC; [6]Children's Mercy Kansas City, Kansas City, MO; [7]University of Toronto, Toronto, ON, Canada; [8]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [9]Cleveland Clinic, Cleveland, OH*.

Background: Individuals with MCD and FSGS are at high risk for hypertension and cardiovascular disease, however molecular markers of BP in this population are unknown. The objective was to investigate kidney tissue differential gene expression associated with BP in MCD/FSGS.

Methods: Participants with biopsy-proven MCD or FSGS from the Nephrotic Syndrome Study Network (NEPTUNE) with previously sequenced genome-wide mRNA expression profiling of kidney tissue were included. Glomerular and tubulointerstitial transcriptomics were assessed for differentially expressed (DE) genes in adjusted linear models for enrollment BP. Systolic and diastolic BP were indexed (SBPi/DBPi) to the 95th%ile for children <13 years and to 130 mmHg for those ≥13 years.

Results: Participants included 192 children (age 11 IQR 5-14 yr, 57.3% male) and 370 adults (age 45 IQR 32.8-58.3 yr, 60.8% male), with 28.7% FSGS. Median SBPi was 0.8 IQR 0.70-0.9 and DBPi was 0.87 IQR 0.78-1, with 47.3% on RAAS blockade. Adjusting for sex only, there were 865 genes at 5% and 1622 at 10% FDR associated with SBPi, but none for DBPi. Adjusting for sex, age, and glomerular filtration rate (eGFR) revealed no significant genes for either SBPi or DBPi at 10% FDR (Figure 1). By p-value, the top genes in the SBPi and DBPI models were PNMA8C (p=3.2e-5) and PHTF1 (p=5.6e-5), respectively. There were no DE genes from tubulointerstitial tissue associated with BP.

Conclusions: Though hypertension is an important risk factor for progression of kidney disease, BP was not associated with differential gene expression in kidney tissue after adjusting for common confounders in patients with MCD/FSGS enrolled in NEPTUNE.

Proteinuria Trajectories Among Patients with Minimal Change Disease (MCD) and FSGS in NEPTUNE

Abigail R. Smith,[1] Margaret Helmuth,[1] Laura H. Mariani.[2] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

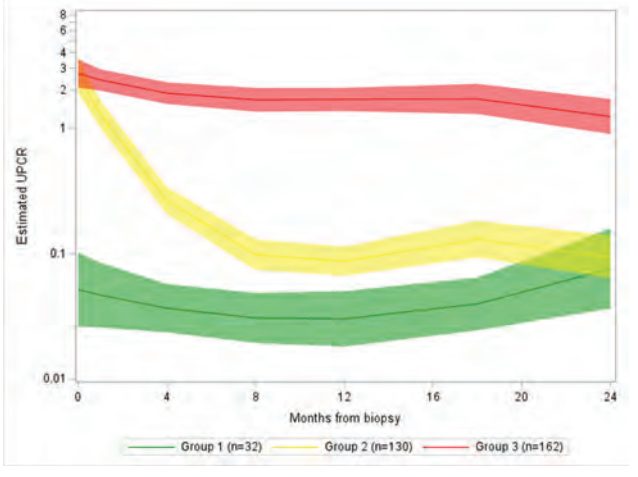
Background: Proteinuria is a primary symptom of nephrotic syndrome and known risk factor for disease progression. Our objective was to identify patient-groups based on longitudinal proteinuria trajectories.

Methods: Patients with minimal change disease (MCD, n=151) and focal segmental glomerular sclerosis (FSGS, n=173) enrolled at the time of biopsy in the Nephrotic Syndrome Study Network (NEPTUNE) were included. Group based trajectory modeling was applied to UPCR measurements from the first 2 years post-biopsy; groups were compared on demographics, clinical presentation, histopathologic features, and eGFR trajectories.

Results: Three groups were identified; Group 1 (n=32) had low proteinuria on average over the first 2 years post-biopsy; Group 2 (n=130) had nephrotic range proteinuria at biopsy that resolved within the first year; Group 3 (n=162) had nephrotic range proteinuria across the 2 years post-biopsy (Figure). Groups 1 and 2 were majority MCD (90% and 58%, respectively); Group 3 was 72% FSGS. Group 3 had more of glomeruli with global sclerosis/obsolescence, segmental obliteration, podocyte abnormalities, interstitial fibrosis/tubular atrophy, interstitial inflammation, and endothelial cell abnormalities. Group 1 was more likely to be treated with immunosuppression (IST, mostly glucocorticoids) prior to biopsy (63%) compared to Groups 2 and 3 (38% and 24%, respectively). By 2 years post-biopsy 92%, 85%, and 66% of Groups 1, 2, and 3, respectively had been exposed to IST. After 2 years post-biopsy eGFR increased by 3.8 ml/min/1.73m^2 per year on average in Group 1, and decreased by 2.2 and 4.6 ml/min/1.73m^2 per year on average in Groups 2 and 3, respectively ($p<0.001$).

Conclusions: Proteinuria trajectories identified patient phenotypes that did not completely align with traditional histopathologic diagnosis. These groups also differ on baseline clinical and histopathologic features that may help predict response to treatment.

Funding: NIDDK Support



Average proteinuria trajectories by group.

SA-PO964

Patients with Primary Focal Segmental Glomerulosclerosis with Detectable Urinary CD80 Are More Similar to Patients with Minimal Change Disease in Clinicopathological Features

Xiaojie Gong, Jing Huang, Zhao Cui. *Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: Focal segmental glomerulosclerosis (FSGS) is an important cause of refractory nephrotic syndrome (NS) in children and adults. Urinary CD80 is elevated in some patients with primary FSGS, however, its clinical value is not fully clarified. This study aims to evaluate the clinical and pathological significance of urinary CD80 in patients with primary FSGS.

Methods: Sixty-one adult patients with biopsy-proven primary FSGS, with standard treatment and long-term follow up, were enrolled retrospectively. Urinary CD80, at the day of kidney biopsy, was measured using commercial ELISA kits and adjusted for urinary creatinine excretion. Their associations with clinical and pathological parameters were investigated.

Results: Urinary CD80 was detectable in 30/61 (49.2%) patients, who presented with a higher level of proteinuria (10.7 vs. 5.8 g/d; P=0.01), a lower level of serum albumin (19.3±3.9 vs. 24.2±8.2 g/L; P=0.005), a higher prevalence of hematuria (70.0 vs. 38.7 %; P=0.01), and showed lower percentage of segmental glomerulosclerosis lesion [4.8 (3.7-14.0) vs. 9.1 (5.6-21.1) %; P=0.06]. The cumulative relapse rate was remarkably high in these patients (log-rank, P=0.001). Multivariate analysis identified that the elevated urinary CD80 was an independent risk factor for steroid-dependent NS (OR 8.81, 95% CI 1.41-54.89; P=0.02) and relapse (HR, 2.87; 95% CI 1.29-6.38; P=0.01).

Conclusions: The elevated urinary CD80 is associated with mild pathological change and steroid-dependent cases of primary FSGS adults, which indicates these patients are more similar to minimal change disease (MCD).

SA-PO965

Clinical Significance of IgM and C3 Immunofluorescence Deposition Patterns in Patients with Focal Segmental Glomerulosclerosis

Gabriel Figueiredo,[1] Betina F. Cecchini,[2] Lectícia Jorge,[1] Luis Yu,[1] Viktoria Woronik,[1] Cristiane B. Dias.[1] *[1]Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; [2]Universidade Nove de Julho, Sao Paulo, Brazil.*

Background: The presence of IgM and C3 deposits on immunofluorescence in some patients with Focal Segmental Glomerulosclerosis (FSGS) are considered to be a trapping of these molecules by mesangial sclerosis. However, there are studies that associate these deposits with a worse renal prognosis when compared to patients with negative immunofluorescence or only IgM deposit. We conducted this study aiming to evaluate the association of worse renal outcome with the presence of IgM and C3 deposits in glomeruli of patients from a Brazilian cohort with FSGS.

Methods: This is a retrospective study of clinical, laboratory, light microscopy histopathological and immunofluorescence (IF) data of patients diagnosed with FSGS, in the Nephrology Service of the Hospital das Clínicas of the School of Medicine of USP, from 2009-2017. Through immunofluorescence the patients were divided into four groups: with concomitant IgM + C3 deposition, IgM only, C3 only and without any deposition. These groups were compared to each other regarding data at diagnosis and at the end of follow-up.

Results: In the stipulated period, 114 patients were eligible for the study. The most commonly found IF patterns were concomitant IgM + C3 deposits in 46 patients (40.4%) and no deposits in 43 (37.7%). The other two patterns found were, exclusive IgM or C3 deposition, which occurred in seven (6.1%) and 18 patients (15.8%), respectively. When comparing these four groups, baseline creatinine, final creatinine and final proteinuria were significantly higher in the immunofluorescence groups with IgM + C3 and exclusive C3 deposition. The pattern of Collapsing Glomerulopathy was statistically significantly more frequent in the groups with IgM + C3 and exclusive C3 immunofluorescence (28.2 and 22.2% respectively) compared to those with negative immunofluorescence and exclusive IgM deposition (11.6 and 0% respectively) with $p<0.0001$. These first two groups also had the highest percentages of end-stage renal disease compared to the last two groups.

Conclusions: Our study showed that the presence of IgM and C3 on immunofluorescence is related to a worse renal prognosis. There is a need to return to the theme of a probable participation of the complement system in this disease.

SA-PO966

Identification of Biomarkers for Minimal Change Disease Based on LMD-DIA Technology Quantitative Proteomics

Fanna Liu, Sining Chen. *Nephrology, Guangzhou, China.*

Background: Minimal change disease (MCD) accounts for 80%-90% of idiopathic nephrotic syndrome in children and 10%-15% in adults. There is no apparent pathological change in the kidney tissue under the light microscope, but the podocyte foot process is diffusely disappeared under the electron microscope.

Methods: The kidney tissues of 5 MCD patients and 5 normal patients were selected as the experimental and control group. The three regions of kidney: the glomerulus, renal tubule, and renal interstitium were sequentially cut by using a laser microdissection device. The fold change ≥1.5 was used as the criterion of significant difference to screen different proteins. GO enrichment analysis, KEGG pathway analysis, Gene Set Enrichment Analysis and PPI analysis were performed on the identified differential proteins to determine the target protein.

Results: We found that 552 differentially expressed proteins (DEPs) in the glomerulus group, 61 DEPs in renal interstitium group, 108 DEPs in renal tubular group. After bioinformatics analysis of the DEPs in the glomerular group, we found that the oxidative phosphorylation pathway and regulation of actin cytoskeleton pathway were play a significant role in MCD. In the renal interstitium group, Heterogeneous nuclear ribonucleoprotein K (hnRNP-K) were the most up-regulated DEPs and 4-hydroxyphenylpyruvate dioxygenase (HPD) were most down-regulated DEPs. In renal tubules group. Down-regulated HSP90AB1 have great influence in Akt to increase the apoptosis of renal tubule cell by PI3K–Akt signaling pathway.

Conclusions: ACTN4, ZYX, CSK and CAN1 are potential biomarkers for early diagnosis of MCD. COPD, HPRT, FIBG, HEMO, GTR1 and WBP2 may be the key proteins interacting with the immune compartment of the MCD kidney.

SA-PO967

Differential Contributions of C5b-9 and C5a/C5aR1 Pathways to Thrombosis in Thrombotic Microangiopathy (TMA) Patients

Xiaotian Liu, Ying Tan. *Peking University First Hospital, Beijing, China.*

Background: This study aimed to clarify the critical role of C5a/C5aR and C5b-9 pathways in macrovascular thrombosis (MAT) and renal microthrombosis (MIT) formations based on a complement-mediated thrombotic microangiopathy (C-TMA) cohort.

Methods: Seventy-three renal biopsy-proven C-TMA patients from 2012 to 2019 in Peking University First Hospital were collected. Amongst 73 C-TMA patients, 9 patients with pure MAT and 13 patients with pure MIT were selected. Their plasma and urinary C5a and soluble C5b-9 (sC5b-9) levels were evaluated, respectively. C5a receptors and C5b-9 depositions in renal biopsied specimens were assessed.

Results: Compared to patients with pure MAT, patients with pure MIT had lower levels of hemoglobin (P=0.008) and eGFR (P=0.049), and higher renal acute arterial scores (P=0.011). Plasma C5a and sC5b-9 levels were significantly higher in C-TMA patients with MAT than those with MIT (P=0.008, P=0.041, respectively). The mean optical density (MOD) of C5aR1 in the kidney was significantly higher in MAT patients than in those with MIT ($P < 0.001$). No significant difference was found in MOD of C5b-9 or C5L2 in the kidney or urinary C5a and C5b-9 levels between the two groups. However, urinary sC5b-9 level and renal depositions of C5b-9 were both associated with renal MIT formations (P=0.009; P=0.031, respectively).

Conclusions: MAT was not rare in C-TMA patients. The local C5b-9 and C5a/C5aR1 pathways might have differential contributions to MIT and MAT formations in the disease.

SA-PO968

Ex Vivo Test of Complement Dysregulation in Atypical Hemolytic Uremic Syndrome Kidney Transplant Patients: A Pilot Study

Caroline Duineveld, Romy N. Bouwmeester, Nicole Van De Kar, Jack F. Wetzels. *Radboudumc, Nijmegen, Netherlands.*

Background: In 2014 the ex-vivo complement assay, which evaluated C5b-9 deposition on cultured endothelial cells, was proposed a possible biomarker for patients with aHUS. In our center eculizumab prophylaxis is not used in aHUS patients after kidney transplantation (Tx). A sensitive biomarker could improve management. The endothelial assay has not been studied in kidney transplant patients.

Methods: Pilot study. Serum samples of transplanted patients with aHUS who were in remission without eculizumab treatment, and transplanted patients with other primary kidney diseases (controls) were blindly evaluated in the complement assay (Noris lab).

Results: We included 13 patients (M 4; F 9) with aHUS, age 54 yrs (range 35-69), time after Tx 5.9 yrs (range 0.25-14.1), and 13 controls (M 7; F 6; age 42 yrs (27-60), time after Tx 5.8 yrs (1.6-11.7). All but 1 patient were treated with a calcineurin inhibitor. There were no significant differences in C5b9 deposits on resting (R) or activated (A) endothelial cells between aHUS patients (R 136%, range 93-382%, A 196%, range 99-388%) and controls (R 121%, range 75-200%; A 170%, range 113-260%, Figure 1). Three aHUS patients and 4 controls showed elevated C5b-9 deposits on resting cells, which should correspond to active aHUS or TMA. None of these patients has laboratory signs of TMA, and during follow-up of 15.8 m (range 6-21), eGFR has remained stable in all. Notably, in 5 aHUS patients with a genetic variant no increase in deposits were found on activated endothelial cells, which contrasts with literature suggesting that a positive test should identify carriers of a genetic variant.

Conclusions: Our data questions the accuracy of the ex-vivo complement assay in kidney transplant patients. We hypothesize that endothelial injury due to transplantation related factors may result in a positive test result. Further study is necessary before the test can be used in routine care for aHUS transplant patients.

Funding: Commercial Support - This work was supported by a research grant from the Dutch Board of Health Insurance Companies (Zorgverzekeraars Nederland)., Government Support - Non-U.S.

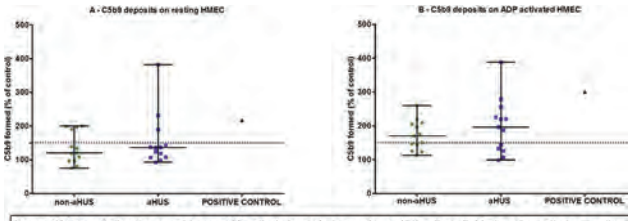

Figure: C5b9 deposits (median, range) in non-aHUS patients (controls, in green) and aHUS patients (in blue) and in a patient with active aHUS in native kidneys, in panel A deposits on resting cells, in panel B deposits on activated cells. C5b9 deposits of >150% is considered abnormal.

Urinary Acanthocytes and Red Blood Cell Casts for the Diagnosis of Glomerulonephritis and Its Crescentic Forms

Ana I. Stark, Swetha Rani Kanduri, Akanksh Ramanand, Vipin Varghese, Dustin R. Chalmers, Mu'ath N. Abdeen, Muner Mohamed, Ivo Lukitsch, Juan Carlos Q. Velez. *Ochsner Health, New Orleans, LA.*

Background: Identification of urinary acanthocytes (uAc) is fairly specific for the diagnosis of glomerulonephritis (GN), but it is perceived as having suboptimal sensitivity. We hypothesized that combining the finding of urinary red blood cell casts (uRBCC) with uAc for the diagnosis of GN, the sensitivity of urine microscopy (uMICRO) as a whole can be optimized. Furthermore, whether uAc provides diagnostic value for identification of more severe (ie, crescentic) forms of GN is unknown.

Methods: Records of patients seen in nephrology consultation who had a uMICRO over a 5-year period were reviewed. We identified cases in which a kidney biopsy was performed within 2 weeks of the uMICRO. We assessed the performance of uAc alone and that of uAc in combination with uRBCC for the diagnosis of biopsy-proven GN or for any glomerular disease (GD). In addition, we evaluated the performance of uAc for the identification of crescentic forms of GN.

Results: Of 747 patients who underwent uMICRO, 217 underwent kidney biopsy. Mean age was 56, 51% women, 47% White, 7% Hispanic, 41% Black. Mean serum creatinine was 3.5 mg/dL. Biopsy diagnosis was GD in 77%, GN in 54%, and others in 23%. The sensitivity (SENS), specificity (SPEC), positive predictive value (PPV) and negative predictive value (NPV) of uAc for diagnosing GN were 62%, 85%, 75% and 76%, respectively. Combining the presence of either uAc or uRBCC, the SENS, SPEC, PPV and NPV changed to 69%, 100%, 100% and 64%, respectively. When examining uAc to predict any form of GD, the SENS, SPEC, PPV and NPV were 45%, 100%, 100% and 35%, respectively. As for crescentic GN, either uAc or uRBCC were found in 29 out of 33 (88%). The SENS, SPEC, PPV and NPV of uAc for crescentic GN were 88%, 42%, 47% and 86%, respectively. Notably, uAc were comnon in IgA nephropathy (71%), pauci immune ANCA (81%), and infection-related GN (IRGN) (83%), but uncommon in lupus GN (29%).

Conclusions: With proficient examiners and well-equipped laboratory, identification of uAc and uRBCC by uMICRO aid in the diagnosis of GN. uAc are pathognomonic of GD. Crescentic forms of GN and certain pathologies (IgA nephropathy, pauci immune ANCA, IRGN) most commonly present with uAc and/or uRBCC.

Background: This is a retrospective study exploring the clinical picture and outcome of sars-cov2 infection in patients with glomerular diseases (GD) and its impact in the probability of GD relapse.

Methods: Patients with biopsy-proven GD, who had been infected by sars-cov2 were studied. Patients who ended up in ESKD prior to infection or received the diagnosis of GD after the sars-cov2 infection were excluded. We recorded demographics, histopathological diagnosis, past medical history, immunosuppressive regimens, status of GD at the time of infection, clinical picture and outcome of the infection and the GD at end of follow up.

Results: 312 patients have been included in the study, of whom 214(68,5%) were diagnosed with sa, while the remaining 98 did not. Infected patients were younger compared with those not infected [44(28-59.75) versus 53(38-64) years, p<0.001]. The mean time from the diagnostic biopsy to Covid-19 was 67,6(±59,3) months. 82,5% of the infected patients were vaccinated against sars-cov2 and 49,1% were on immunosuppressive therapy at vaccination. 28(13%) of the infected patients required admission to hospital, which lasted 8,3(±5,1days. 84,2% of the infected patients experienced complete recovery of the infection, 4(1,9%) died due to Covid-19 and 24(11%) had symptoms for more than 3 months. Among patients who were in remission for the GD, the frequency of relapse of the primary disease was higher in patients with Covid-19 versus not infected patients (11.9% vs. 2.1 %, p=0.007).

Conclusions: According to the findings from this cohort, sars-cov2 infection appears to have a significant impact in patients with GD due to the related morbidity but also by increasing the probability of relapse of the primary disease when compared with patients who not infected with sars-cov2.

SA-PO971

Anti-Nephrin Autoantibodies Broadly Detected in the General Population and in Non-Kidney Disease Patients

Pan Liu, Lorenzo G. Gallon, Jing Jin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

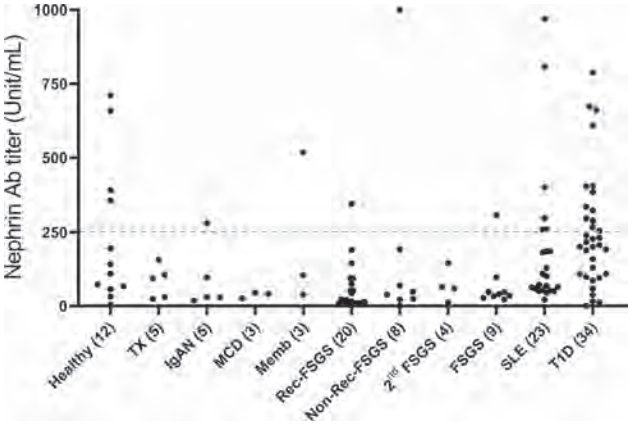
Background: Nephrin is the key structural component of the interpodocyte-spanning slit diaphragm, and mutations of *NPHS1* are associated with congenital nephrotic syndrome. Recently, Watts and colleagues discovered anti-nephrin autoantibodies in patients with MCD (*J Am Soc Nephrol*. 2022 Jan;33:238-252.), suggesting these autoantibodies may be directly attributable to the etiology of podocytopathy and also might play a role in primary FSGS. With our own focus on FSGS, we collected plasma samples from kidney and non-kidney diseases and had them examined for anti-nephrin antibodies.

Methods: We tested a total of 126 plasma samples of recurrent vs nonrecurrent FSGS, primary and 2nd FSGS, MCD, MN, LN, IgAN, TX, T1D with no kidney involvement, and health controls (Fig). Anti-nephrin antibody titers were measured using ELISA coated with recombinant Nephrin extracellular domain (R&D Systems, Cat:9399-NN-050). In addition, we performed Western blotting (WB) analyses of the antisera against nephrin (C-FLAG tagged full-length nephrin from CHO cell transfection with plasmid).

Results: Based on an arbitrary cutoff, a majority of samples were negative for anti-nephrin antibodies, whereas between 5% and 38% of the patients were tested positive for the antibody with varying titers. However, positive antibodies were broadly detected across the spectrum of the disease types, with the highest titer from a nonrecurrent FSGS

patient (post-renal transplant), and the highest percentage of antibody-positive cases in T1D. Consistently, high antibody titers detected by ELISA correlated well with high antibody signals in WB, confirming the robustness of our assays.

Conclusions: Admitting caveats, we were unable to find direct correlations between nephrin autoantibody titer and specific kidney or non-kidney disease types. Further studies are warranted to have a larger sample size, more balanced disease categories, and better methodologies for anti-nephrin autoantibody detection.



SA-PO972

Impact of Kidney Biopsy Findings Including Oxford MEST-C Scores on Kidney Outcomes in IgA Vasculitis Nephritis (IgAVN): A Study of the International IgA Nephropathy Network

Sean Barbour,[1,2] Rosanna Coppo,[3] Lee Er,[2] Evangeline Pillebout,[4] Mark Haas.[5] *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]BC Provincial Renal Agency, Vancouver, BC, Canada; [3]Fondazione Ricerca Molinette, Torino, Italy; [4]Hopital Saint-Louis, Paris, France; [5]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Nephritis is a common manifestation of IgAV and is morphologically indistinguishable from IgA nephropathy (IgAN). However, while MEST-C scores are predictive of outcomes in IgAN, their value in IgAVN has not been widely studied.

Methods: Biopsies from 361 patients with IgAVN (262 children, 99 adults) from 17 centers in N. America, Europe and Asia were independently scored by 3 pathologists. Median time from clinical onset to biopsy was 2.0 mo, median post-biopsy follow-up was 2.7 y, 309 (85.6%) patients received immunosuppression (IS) during follow-up. As few patients developed ESKD or ≥30% eGFR decline, Latent Class Mixed Models (LCMM) were used to analyze eGFR trajectory post-biopsy in patients treated with IS. Association of clinical and histologic parameters with the different classes of eGFR trajectory was examined by logistic regression.

Results: Two classes were identified by LCMM (Figure), one with initial improvement in eGFR followed by a more notable decline (Class 1, n = 91) and one with stable disease (Class 2, n = 218). Among MEST-C scores, only E1 was predictive of Class 1 by multivariable analysis (OR 2.3; 95% CI 1.1,4.5); other scores were not although only 4.5% of patients had T>0. Other predictors of Class 1 were age ≤18 y, male sex, lower eGFR at biopsy, and extrarenal, non-cutaneous disease. Fibrous crescents were predictive of Class 2.

Conclusions: The clinical course of biopsied and treated patients with IgAVN is determined by active lesions, notably endocapillary hypercellularity (E1) which is not part of the ISKDC classification for IgAVN. The results support including MEST-C scores in biopsy reports of IgAVN. Patients with IgAVN, even those with initial therapeutic response, require long-term follow-up due to risk of late renal function decline.

Background: Reliable prediction tools are needed to improve prognostication and personalisation of treatment in anti-neutrophil cytoplasmic antibody (ANCA) glomerulonephritides (GN). We aimed to update the ANCA Renal Risk Score (ARRS) prediction model.

Methods: We collated a retrospective multicentre international longitudinal cohort from referral centres and registries across the globe to revise the ARRS in a validation and recalibration study. The primary endpoint was end stage kidney disease (ESKD) and patients were censored at last follow-up. Cox proportional hazards models were used to reweight risk factors and develop a modified scoring system. Kaplan-Meier estimates, Harrell's C statistics and calibration plots were used to assess model performance.

Results: Of a total of 1591 patients, 1439 were included in the final analyses (959 in the development cohort, 52% male, median age 64 years). The ARRS demonstrated a discrimination of C=0.800, comparable to the original cohort. Updating the model found an additional useful cut-off for kidney function (K), and serum creatinine replaced glomerular filtration rate which provided higher reliability (K0: <250 μmol/l = 0 points, K1: 250-450 μmol/l = 4 points, K2: >450 μmol/l = 11 points). The risk points for the percentage of normal glomeruli (N) and interstitial fibrosis and tubular atrophy (T) were reweighted (N0: >25% = 0 points, N1: 10-25% = 4, N2: < 10% = 7, T0: none, mild or < 25% = 0 points, T1: ≥ mild-moderate or ≥ 25% = 3 points). We created four risk groups based on the sum of points: low (0 – 4 points), moderate (5 – 11), high (12 – 18) and an additional very high-risk (21). The model discrimination was C=0.831 and a supplemental continuous model was developed to supply a patient-specific annual risk. Three-year kidney survival was 96%, 79%, 54%, and 19%. The ARRS23 performed similarly well in the validation cohort with excellent calibration.

Conclusions: We demonstrated the out-of-sample validity of the ARRS and present the modified and improved score to optimise prognostication and risk stratification for clinical practice and trials.

SA-PO974

The Use of Antimalarials in Lupus Nephritis Is Associated with Better Response to Therapy and Long-Term Kidney Survival

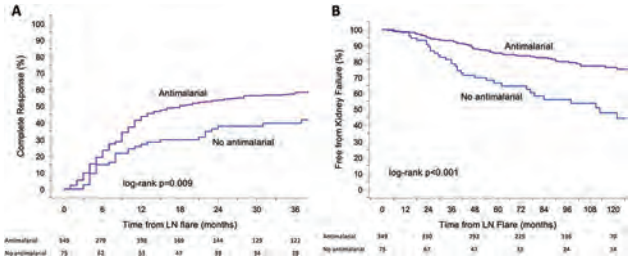
Juan M. Mejia-Vilet, Oscar Pena, Sofia E. M. Macedo, Bernardo Juarez Cuevas, Abril A. Pérez Arias, Fernanda Zavala Miranda, Luis E. Morales-Buenrostro. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Mexico City, Mexico.*

Background: The use of antimalarials (AM) in systemic lupus erythematosus (SLE) has been associated with lower disease flares and long-term damage accrual. Few studies have evaluated the effect of AM in lupus nephritis (LN) cohorts. We evaluated the association between AM use and response to therapy, LN flares, and long-term kidney survival in a large LN cohort.

Methods: The records of 424 patients with biopsy-proven LN were evaluated. We registered the dates of start and end of AM use, the type of AM (hydroxychloroquine [HCQ], chloroquine [CQ], or both), and the temporality of the AM initiation regarding the LN flare (previous and continued use, started at LN flare, or no use). The outcomes of complete response (CR), LN flare, kidney and patient survival were evaluated by uni and multivariable survival analyses.

Results: Out of 424 patients, 349 (82%) used an AM: 53 (13%) chloroquine, 282 (67%) hydroxychloroquine, and 36 (8%) used both AM at different times of follow-up. Of those taking AM, 195 (56%) had previous and continued use and in 154 (44%) the AM was started at flare. The time to CR was shorter in AM users than in non-users (log-rank p=0.009, Figure 1A). The incidence of LN relapses (p=0.017) and kidney failure (p<0.001) was lower in AM users (Figure 1B). The observations of better CR and lower incidence of LN flares and kidney failure with AM use were maintained when the data was analyzed according to the type of AM (HCQ or CQ) as well as the timing of use regarding the LN flare (previous and continued use or started at LN flare). The incidence of maculopathy was 1.2%, 5.9%, and 13.8% by 2-, 5-, and 10-years of AM use. There was no difference in the incidence of maculopathy between users of HCQ or CQ.

Conclusions: The use of AM in lupus nephritis is associated with better response to therapy, lower LN flares, and higher kidney survival. The rates of maculopathy are higher in LN cohorts than in general SLE cohorts.



Time to complete response (A) and kidney survival (B) according to the use of antimalarials.

SA-PO975

Voclosporin Ameliorates Both Proteinuria and Dyslipidemia in a Model of Noninflammatory Glomerular Disease

Yu Kamigaki,[1] Julie Dougherty,[1] Amanda P. Waller,[1] Linda M. Rehaume,[2] Katelyn Wolfgang,[1] Eman Abdelghani,[1] Bryce A. Kerlin,[1,3] William E. Smoyer.[1,4] *[1]Center for Clinical and Translational Research, Nationwide Children's Hospital, Columbus, OH; [2]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada; [3]Division of Pediatric Hematology/Oncology/Blood & Marrow Transplantation, Department of Pediatrics, The Ohio State University College of Medicine, Columbus, OH; [4]Division of Nephrology, Department of Pediatrics, The Ohio State University College of Medicine, Columbus, OH.*

Background: Idiopathic nephrotic syndrome (INS) is one of the most frequent glomerular diseases in children. There is a critical need for the development of more effective and less toxic INS treatments. Voclosporin (VCS) is a novel calcineurin inhibitor (CNI) approved in the USA, EU, Great Britain and Switzerland on a background of immunosuppressive therapy for the treatment of adults with active lupus nephritis. VCS does not require therapeutic drug monitoring due to an improved pharmacokinetic profile. We thus investigated whether VCS could reduce proteinuria in *non*-inflammatory glomerular disease using an animal model of nephrotic syndrome (NS).

Methods: Male Wistar rats received 50 mg/kg puromycin aminonucleoside (PAN) or saline via tail vein injection on day 0. Rats were gavaged twice daily with vehicle (VEH), VCS (4 mg/kg/dose), or cyclosporine (CsA, 10mg/kg/dose) at clinically relevant doses. Rats were euthanized on Day 11 and proteinuria, lipid profile, glomerular cell injury (TUNEL), and hypercoagulability (TGA) were measured.

Results: PAN induced proteinuria in all disease groups. VCS ameliorated proteinuria more effectively vs. CsA (mean reduction vs. disease control was 81% vs. 17%, respectively). Mean triglyceride (TG) levels increased by 74% vs. controls in the PAN + VEH group vs. 22% in the PAN + CsA group vs. -26% in the PAN + VCS group. Similarly, PAN induced increases in all other lipid levels vs. controls, while VCS reduced these lipid levels. Flow cytometry TUNEL positivity of isolated glomeruli revealed injury of 2.1% in control podocytes vs. 5.3% in PAN + VEH cells (152% increase) vs. 8.5% in PAN + CsA cells (305% increase) vs. 4.1% in PAN + VCS cells (95% increase). TGA assays revealed that VCS effectively improved PAN-induced hypercoagulopathy.

Conclusions: A clinically relevant dose of VCS ameliorated PAN-induced proteinuria, hypercoagulopathy, and *in situ* glomerular injury in a model of non-inflammatory glomerular disease, without apparent exacerbation of NS-associated dyslipidemia. Compared to CsA, VCS more effectively ameliorated proteinuria, hypercoagulopathy, and glomerular injury and led to a better lipid profile.

Altered Bone Marrow Myelopoiesis Contributes to Glomerular Dysfunction

Ryan Spear,[1] Alexis P. Jimenez Uribe,[1] Yanxia Cao,[1] Steve Mangos,[1] Flavio Vincenti,[2] Jochen Reiser,[1] Eunsil Hahm.[1] *[1]Rush University Medical Center, Chicago, IL; [2]University of California San Francisco, San Francisco, CA.*

Background: Myeloid-biased hematopoiesis is observed in disease conditions associated with CKD, including infection, chronic inflammation, diabetes, CVD, and aging. Despite identifying immature myeloid cells (MCs) in the bone marrow (BM) as a significant contributor to renal injury in mice, the link between BM and kidney function in humans is not yet determined. Here, we tested if inflammatory signals alter BM myelopoiesis leading to glomerular dysfunction.

Methods: Flow cytometry (FC) was performed to evaluate the immunophenotyping of BM cells from CKD patients and healthy individuals, as well as human MCs differentiated in vitro. Bioenergetic and epigenetic changes in monocytes were assessed by Seahorse and ATAC-seq. Secretome analyses were performed using ELISA multiplex cytokine assay and FC staining. We assessed the impact of functionally altered MCs and their soluble factors to podocyte structure and filtration function by conducting an immunofluorescence assay on cultured podocyte and two different animal models.

Results: CKD patients exhibited increased levels of TNFα and suPAR in their BM and a myeloid-biased hematopoiesis, with an increase in inflammatory monocytes expressing uPAR. In vitro assays revealed that TNFα can alter myelopoiesis by skewing hematopoietic stem cell (HSC) differentiation towards monocytic lineage cells, leading to functional changes in the resultant monocytes. These TNFα-driven monocyte subsets exhibited increased uPAR expression and suPAR secretion, metabolic activity, and production of proinflammatory cytokines. Also, TNFα increased chromatin accessibility to genes for proinflammatory cytokines, metabolic activity, and those involved in inflammation signaling pathways, as evidenced by ATACseq. The soluble factors secreted by TNFα-driven MCs caused cytoskeletal rearrangement in cultured podocytes and filtration dysfunction in a transgenic zebrafish model. Mice injected with TNFα and IFNγ exhibited suPAR-associated glomerular dysfunction, demonstrated by albuminuria, and an increase in BUN levels, suPAR levels, and uPAR-expressing BM MCs.

Conclusions: This study reveals, for the first time, that TNFα contributes to renal injury by altering BM myelopoiesis and promoting the development of metabolically and epigenetically reprogrammed monocyte subsets that secrete soluble permeability factors and cytokines.

SA-PO977

Identification of a Podocyte-Derived Cytokine as a Potential Mediator of Injury in FSGS via Single-Cell RNA Sequencing of Human Kidney Tissue

Vidhi Dalal,[1,2] Yalu Zhou,[2] Tomoko Hayashida,[3] Susan E. Quaggin.[2] *[1]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Horizon Pharma Inc United States Operations, Lake Forest, IL.*

Background: Focal segmental glomerulosclerosis (FSGS) is a major cause of end stage kidney disease (ESKD) worldwide, and patients with primary and genetic forms of FSGS are frequently resistant to existing treatments. As such, there is a strong need for the development of new treatments for FSGS. There is evidence that cytokines may play a role in the pathogenesis of FSGS. Most of this evidence is based on immune cell-derived cytokines, and little is known about podocyte-derived cytokines in FSGS. The podocyte has been shown to produce cytokines and even act as an antigen presenting cell in other forms of kidney disease, but its role as an immune cell in FSGS has not yet been explored. That is the aim of our study.

Methods: Single cell RNA sequencing performed on kidney tissue from a patient with a genetic form of FSGS revealed increased expression of two different interleukins in the patient's podocytes versus podocytes from healthy kidneys. Because one of these interleukins, hereby referred to as interleukin (IL)-X, has also been shown to promote injury in other forms of kidney disease, we evaluated the expression of IL-X and NPHS2 in kidney tissue from patients with primary and genetic forms of FSGS via RNA scope.

Results: Baseline glomerular expression of IL-X was low to virtually undetectable in control kidneys. When IL-X was detected in control kidneys, it was seen in intercalated cells and immune cells that were negative for NPHS2 with only faint staining seen in the rare NPHS2+ podocyte. In kidneys with FSGS, both primary and genetic forms, IL-X was seen in NPHS2+ podocytes more frequently, and the IL-X signal in podocytes was consistently stronger in diseased kidneys than in control kidneys. Notably, single cell RNA sequencing data from the patient with genetic FSGS indicated that the receptor for IL-X was expressed primarily on lymphocytes.

Conclusions: Our findings indicate that IL-X expression is increased in podocytes in both primary and genetic forms of FSGS. Given that the receptor for IL-X is

expressed primarily on lymphocytes, we hypothesize that podocyte-derived IL-X recruits inflammatory cells to the glomerulus to propagate injury. We will use *in vivo* and *in vitro* models to define the role of IL-X in the pathogenesis of FSGS and to determine its utility as a therapeutic target in FSGS.

SA-PO978

Podocytopathy with a Novel Variant in ARHGAP24 and an APOL1 Risk Allele

Vidhi Dalal,[1,2] Jerome C. Lane,[1,2] Susan E. Quaggin.[2] *[1]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Introduction: Genetic mutations cause up to 30% of steroid resistant nephrotic syndrome (SRNS) cases. A missense mutation responsible for hereditary podocytopathy was first described in ARHGAP24, a gene that encodes a GTPase activating protein (GAP) required for regulating podocyte motility, in 2011. We report a case of SRNS with an ARHGAP24 variant that has not been previously reported to our knowledge and a concurrent APOL1 risk allele.

Case Description: A 16-month-old male presented with anasarca, nephrotic range proteinuria, hypoalbuminemia, hypertension, microscopic hematuria, and severe anemia. Infectious work-up (hepatitis, HIV, COVID) was negative, and serum complement levels were within normal limits. Renal biopsy showed severe podocytopathy. Genetic testing showed a G1 APOL1 risk allele and a heterozygous missense mutation (c.584 A>C; p.K195T) in ARHGAP24. After a lack of response on 8 weeks of high dose steroids, the patient was transitioned to tacrolimus.

Discussion: Our patient's ARHGAP24 mutation is in the critical GAP domain that regulates podocyte motility. The ARHGAP24 mutation described in 2011 was also in the GAP domain, causing reduced GAP activity and increased podocyte motility with a dominant effect attributed to heterodimerization of the mutated and wildtype (WT) proteins. Our patient's mutation replaces lysine (positively charged) with threonine (neutral). This lysine residue, per Alphafold, is predicted to form a cation-pi interaction with a tyrosine residue in the GAP domain of the WT protein. Lysine is also highly conserved at this position across species. Therefore, we hypothesize that the positively charged lysine residue is required for preserving the GAP domain's integrity, and changing the residue to a neutral amino acid (threonine in our patient's case) disrupts the GAP domain. Despite the genetic findings, we opted to treat with tacrolimus, as the pathogenicity of this variant has not been confirmed. The patient also has a G1 APOL1 risk allele – while 1 allele is not expected to confer the risk associated with having 2 APOL1 risk alleles, the combination of 1 risk allele with a possibly pathogenic mutation in another gene has not been well-described. Thus, our patient presents multiple genetic findings that require further investigation to define their contribution to his podocytopathy and to determine if and how the two gene variants interact with each other.

SA-PO979

Circulating Hypo-Sialylated IgM by FSGS Subjects Induce Proteinuria and Podocyte Injury

Andrea Angeletti, Maurizio Bruschi, Giovanni Candiano, Xhuliana Kajana, Francesca Lugani, Enrico E. Verrina, Gianluca Caridi, Sonia Spinelli, Gian Marco Ghiggeri. *Istituto Giannina Gaslini, Genova, Italy.*

Background: Sialylation is an important regulator of protein function. Previous data showed that sialylation of total circulating IgM in Idiopathic Nephrotic Syndrome is significantly reduced compared to healthy subjects. The role of hiposialylated-IgM (hIgM) on podocytes in FSGS pathogenesis is unknown.

Methods: We characterized IgM derived by patients affected by multi-drug resistant FSGS (defined as lack of antiproteinuric effect of a double therapy based on steroid plus CNI and MMF for at least 12 months before enrolment). IgM were first analysed through two-dimensional electrophoresis. Sialylation levels were measured in total circulating IgM through incubation with biotinylated *Sambucus nigra* agglutinin (SNA). Then, sialylated and hyposialylated-IgM were put in culture with human podocytes. Incubation of podocytes with medium was used as control. IgM purified from serum of a patient were injected in rats.

Results: We enrolled 10 patients with resistant FSGS and 5 healthy controls, matched for age and sex (**Fig1a**). IgM derived from FSGS subjects induced significantly higher proteinuria than IgM from HC when injected in rats (**Fig1b**). IgM purified from serum of FSGS patients resulted significantly more cationic than IgM of HC (**Fig1c**), and as previously demonstrated, IgM cationic charge derived by hyposialylation (**Fig1d**). Co-incubation with hIgM, significantly induced human podocytes damage as opposed to sialylated IgM, which had no injurious effect (**Fig1e**).

Conclusions: Pathophysiology of FSGS is still largely unknown and common treatments often result poorly effective. We here reported that sialylation of IgM may be of relevance in this context, showing that hIgM induce *in vivo* proteinuria and *in vitro* podocytes structural damage. Therefore, hIgM may represent a promising therapeutic target for FSGS.

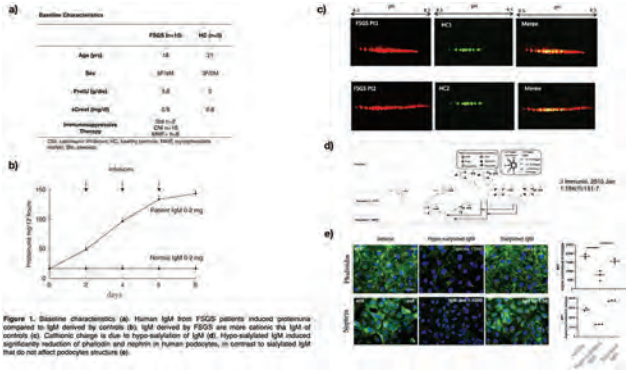

Figure 1. Baseline characteristics (a). Human IgM from FSGS patients induced proteinuria compared to IgM derived by controls (b). IgM derived by FSGS are more cationic than IgM of controls (c). Cationic charge is due to hypo-sialylation of IgM (d). Hypo-sialylated IgM induced significantly reduction of phalloidin and nephrin in human podocytes, in contrast to sialylated IgM that do not affect podocytes structure (e).

Potential Roles of Autoantibodies Targeting the Podocyte in the Idiopathic Nephrotic Syndrome

Simon Leclerc, Lamine Aoudjit, Tomoko Takano. *Research Institute of the McGill University Health Centre, Montreal, QC, Canada.*

Background: The idiopathic nephrotic syndrome (INS) is characterized by heavy proteinuria, hypoalbuminemia, and edema. In both forms of INS, minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS), podocytes are injured by mechanisms that are still mostly unknown. This injury causes changes in their actin cytoskeleton, leading to the effacement of their foot processes. Recent evidence suggests that autoantibodies targeting the podocyte might play a role in this process. Our objective is to establish if such autoantibodies are implicated in the pathogenesis of INS and to understand how they contribute to podocyte injury and foot process effacement.

Methods: As previously published (Hada and al., *J Am Soc Nephrol*. 2022;33(11):2008-2025.), INS was induced in C3H/HeN mice by immunization with recombinant Crb2, a transmembrane protein expressed both at the murine and human podocyte's slit diaphragm. Immortalized podocytes expressing mouse Crb2 were incubated with serum from Crb2-immunized and control mice, then stained for phospho-ezrin, the phosphorylated form of ezrin, a protein that links Crb2 to the actin cytoskeleton. Sera from human INS patients in active disease and healthy controls were tested with quantitative ELISA specific for anti-Crb2 and anti-nephrin antibodies.

Results: C3H/HeN mice developed significant anti-Crb2 antibody titer and proteinuria 4 weeks after immunization. Podocytes incubated with Crb2-immunized mouse serum showed a significant increase in ezrin phosphorylation compared to podocytes incubated with control mouse serum (average staining intensity per cell of 1370 vs 68, $p<0.0001$). Among 67 INS patients in active disease, 22 (32%) had a positive anti-Crb2 antibody titer and 6 (9%) had a positive anti-nephrin antibody titer, while no healthy controls had a positive titer of either antibodies.

Conclusions: Mice immunized with the podocyte protein Crb2 develop an INS-like disease, and their anti-Crb2 antibodies induce phosphorylation of ezrin, which links Crb2 to the cytoskeleton. Such anti-Crb2 antibodies are also present in human INS patients in active disease, along with anti-nephrin antibodies, indicating that autoantibodies targeting podocyte proteins may contribute to the cytoskeletal changes and podocyte injury seen in INS.

Prospective Study of B-Cell Subsets in New-Onset Primary Podocytopathy in Adults

Joyita Bharati,[1,2] Kenar D. Jhaveri.[2] *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Data on children suggests the involvement of an altered B-cell immunophenotype in the pathogenesis of nephrotic syndrome (NS) due to primary podocytopathy. Characterization of the immune signature in NS patients will likely improve therapeutic strategies. We examined B-cell subsets in a cohort of adults with new-onset NS.

Methods: This was a prospective study at a tertiary care center in India. Adults with new-onset NS due to biopsy-proven primary minimal change disease or focal segmental glomerulosclerosis were included. Three sequential visits for blood sampling were: 1(on the day of starting prednisolone), 2 (2 weeks after visit 1), and 3 (6 months after visit 1 and 2 weeks after stopping prednisolone). B-cell subsets studied were: naïve B cells (CD19+27-), memory B-cells (CD19+27+), and transitional B-cells (CD19+27-38+24+). Patients were categorized based on steroid responsiveness as steroid resistant (SR), infrequently relapsing NS, and steroid-dependent NS; the latter two were grouped as steroid sensitive (SS).

Results: Of 67 patients, 87% were steroid-sensitive (SS) within four weeks of therapy. The transitional B-cell proportion was lower, and the total B-cell proportion was higher in patients at baseline than 35 healthy controls. The baseline naive B-cell proportion was lower, and the memory B-cell proportion was higher in steroid-resistant (SR) patients than in steroid-sensitive (SS) patients (Table). The naive B-cell proportion decreased at the second visit and was followed by a plateau at the third visit (p=0.003). Memory B-cell proportion increased at the second visit, followed by a plateau at the third visit (p=0.005). Transitional B-cell proportion remained similar across all three visits (p=0.18).

Conclusions: Memory B-cell proportion was higher, and naïve B-cell proportion was lower in SR patients than in SS patients. While naive B-cells decreased, memory B-cells increased initially during prednisone treatment in the whole cohort.

Cooperative Elicitation of Complement-Dependent Cytotoxicity by Anti-PLA2R Autoantibodies in Primary Membranous Nephropathy

Tsai-yi Wu,[1] Kun-Hua Tu,[1,2] Cheng-Lung Ku.[1] Laboratory of Human Immunology and Infectious Diseases. *[1]Chang Gung University, Taoyuan, Taiwan; [2]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan.*

Background: Primary membranous nephropathy (pMN) is an autoimmune disease causing abnormalities in the glomerular basement membrane and podocytes, leading to proteinuria. These changes relate to autoantibodies and accumulated activated complement proteins on the glomerulus. Autoantibodies, primarily against phospholipase A2 receptor 1 (PLA2R) found in 80% of pMN patients, are thought to activate the complement system and contribute to pMN. Surprisingly, the predominant PLA2R autoantibodies in pMN patients are IgG4, which doesn't activate the complement, while the complement-activating IgG1 and IgG3 are less common, questioning the role of PLA2R autoantibodies in pMN pathogenesis.

Methods: We isolated monoclonal anti-PLA2R antibodies (mAbs) from pMN patients' PBMC using single B cell sorting, then amplified the IgG gene for cloning into F293 cell vectors. We confirmed the mAbs' characteristics via Western blot, ELISA, and a BLI system. These mAbs were found binding to the membrane-bound PLA2R on human podocyte cells through immunocytochemistry. By using a Lentivirus system, we created a PLA2R-overexpressing podocyte line for a disease model. We assessed the mAbs' ability to trigger complement-dependent cytotoxicity (CDC) using a CellTiter-Glo assay to measure cell viability and complement-induced lysis.

Results: We studied PLA2R-reactive IgGs' role in complement activation in pMN, using a single-cell method to generate 16 anti-PLA2R mAbs from five patients. Our analysis revealed variable binding affinity across mAb groups, independent of binding sites. Using a CDC assay on PLA2R-overexpressing podocytes, we discovered that the combination of CTLD1 with another mAb significantly boosted CDC activation. After modifying the mAbs to IgG4, we found that a single IgG1 mAb was critical for CDC activation, but IgG4 could enhance it. Intriguingly, polyclonal IgGs from pMN patients, not from healthy volunteers, induced CDC. Furthermore, some patients with only CysR-IgG3 showed increased CDC activation with added CTLD1-IgG1 mAb.

Conclusions: These results identify an essential role of complement-reactive IgGs, presumably IgG1 and IgG3 synergies between single-domain epitopes CysR and CTLD1, which underlies pMN.

SA-PO983

ApoL1 in Podocyte-Derived Urinary Microparticles

John C. Edwards, Rebecca L. Winkler. *Saint Louis University, Saint Louis, MO.*

Background: ApoL1 variants contribute the the high risk of progressive kidney disease in people of African ancestry. Overexpression of ApoL1 in podocytes may drive disease in people with high risk genotypes; ability to assess podocyte ApoL1 expression in vivo could be useful. Microparticles are 100-1000 nm vesicles that represent a sample of plasma membrane of their cells of origin, and hence may reflect the level of expression of specific proteins. Cells lining the nephron shed microparticles into the urine, and may provide a non-invasive way to assess protein expression in vivo.

Methods: The study was approved by the St. Louis University IRB. Urine was collected from 10 people with proteinuric kidney disease (3 membranous GN, 4 with immune complex GN (2 SLE nephritis, 2 infection-related), 2 diabetic nephropathy, and 1 AL amyloidosis) and one control. Microparticle-enriched urine sediment from 1.4 ml of urine was prepared by differential centrifugation, resuspended in buffered saline and incubated with fluorescently labelled probes to define microparticles (Annexin V), to identify podocyte origin (antibody to podocalyxin) and with antibody to ApoL1. Microparticles were analyzed by flow cytometry. Matched negative controls for each probe were used to define signal thresholds. Size gate was determined using polystyrene reference beads. Total particle number was normalized to urine creatinine concentration.

Results: A size gate of 250 to 1000 nm was applied. Annexin V positive population identifies the urinary microparticles (UMPs). Podocalyxin positive UMPs define the podocyte-derived urinary microparticles (PDUMP), and PDUMPs which also stain for ApoL1 are the ApoL1-positive PDUMPs (A^+PDUMPs). Urine from the patients had much higher total UMPs, PDUMPs and A^+PDUMPs than did control urine. Number of PDUMPS and A^+PDUMPs seemed to correlate with cause and activity of kidney disease: number of both PDUMPs and A^+PDUMPS were greatest in two patients with active membranous GN. The number of A^+PDUMPS, the ratio of PDUMPs to total UMPs, and the ratio of A^+PDUMPS to total PDUMPs all correlated weakly with proteinuria.

Conclusions: We have demonstrated the presence of ApoL1 in podocyte derived urinary microparticles. In this small sample, the A^+PDUMPs seem to correlate with the type of glomerular disease, with the highest level in patients who would be expected to have direct podocyte injury driving the disease.

SA-PO984

Topology of Membrane-Inserted ApoL1

John C. Edwards, Jonathan M. Bruno. *Saint Louis University, Saint Louis, MO.*

Background: ApoL1 inserts into membranes at low pH where it functions as an anion permease. Titration of the cis compartment to neutral suppresses the anion permeablity and activates a cation channel activity. pH 6.0 is optimal for membrane association that leads to cation channel after titration; pH 5 is optimal for the anion permease activity. As pH is lowered from 6 to 5, the total amount of protein associated with membranes increases along with the anion pemease, but the potential for cation permease after titration is suppressed. We hypothesize that the structure of the membrane inserted ApoL1 is altered by the pH at which it encounters the membrane.

Methods: Single cysteine substitution mutant were generated at position 40, 80, 89, 149, 168, 178, 204, 226, 236, 247, 263, 300, 314, 330, and 365, expressed in bacteria and purified. Each protein was mixed with preformed lipid vesicles. Accessibility of the engineered cysteine was probed with AF488-maleimide (AF-Mal) from the cis or trans compartment. Lipid-protein vesicles were separated by chaotropic wash followed by sepharose 4B chromatography. Membrane associated protein was separated by SDS PAGE. AF-Mal modification was detected by in-gel fluorescence, total protein by western blot.

Results: Protein associated at pH 6 was accessible to trans-modification at positions 300, 314, and 330 only, and this was unchanged by subsequent titration to pH 7.5. Protein associated at pH 5 was accessible to trans-modification at the same sites, plus at 365.

Conclusions: ApoL1 associated with vesicles at pH 6 has only one trans-accessible segment detected by these methods, minimally including positions 300 through 330 and we detect no change in topology with transition to conditions that activate the cation channel, consistent with a previously published model (Schaub et al., JBC (2021) 297: 101009). However, association at pH 5 leads to a larger portion of the molecule accessible from the trans comparment, consistent with the entire C-terminal region from 330 to the end translocated across the membrane. This additional translocation would eliminate the transmembrane segment that has been proposed to form the cation selective pore and would explain the decrease in cation channel activity after association at lower pH, additionally predicting different ion permeability activities depending on where along the endocytic pathway ApoL1 inserts into membranes.

APOL1 G1-Mediated Cation Transport Inhibits Amino Acid Transport and Increases Endoplasmic Reticulum Calcium Release, Causing Podocytopathy

Opeyemi A. Olabisi,[1] Somenath Datta,[1] Brett M. Antonio,[2] Nathan Zahler,[2] Douglas Krafte,[2] Hans-Ewald Hohmeier,[1] Alec Chaves,[1] Sarah Nystrom,[1] Guofang Zhang,[1] Olga Ilkayeva,[1] Daniel P. Silas,[1] Jonathan W. Theile,[2] Michael Muehlbauer,[1] Thomas C. Becker,[1] Guojie Li,[1] James R. Bain,[1] Karen Soldano,[1] Christopher B. Newgard.[1] *[1]Duke University, Durham, NC; [2]Ligand Pharmaceuticals Incorporated Icagen Ion Channel Technology Center, Durham, NC.*

Background: How two coding variants of *APOL1* gene (G1 and G2) cause kidney disease is poorly understood. While experimental models have shown that these *APOL1* renal risk variants induce cytotoxicity, the causal mechanism underlying these effects is unknown. Previously, we reported that RRVs form cation pores that transport Na^+ and K^+ across the plasma membrane of mammalian cells.

Methods: We blocked APOL1 G1-cation channel function with a new small molecule inhibitor, VX-147 in inducible HEK293 cells and human-derived podocytes and measured cytotoxic phenotypes. We used Real-time cation sensors including genetically-encoded Ca^{2+} sensor to measure levels of cations in the cytoplasm and the endoplasmic reticulum (ER). We used inhibitor of IP3R and CRISPR-Cas9-mediated IP3R knockout to determine the impact of IP3R on APOL1-G1-induced increases in cytoplasmic Ca^{2+} and cell viability. Finally, using metabolomics and related methods, we measured APOL1-GI-mediated changes in amino acid transport, protein synthesis and ATP production, in the presence and absence of VX-147 treatment.

Results: We demonstrate for the first time that APOL1 G1-mediated transport of Na^+ and K^+ induces Ca^{2+} release from the ER via IP3R and ryanodine receptor (RyR), and that the liberated Ca^{2+} triggers a sequence of downstream cytotoxic events including mitochondrial dysfunction and inhibition of protein synthesis via AMPK-TSC2-mTORC1 and eIF2a signaling. We also discovered for the first time that APOL1 G1 cation function impedes amino acid uptake in kidney cells. All observed cytotoxic phenotypes are reversed by VX-147.

Conclusions: These findings established APOL1-mediated Na^+/K^+ transport as the proximal driver of podocyte injury, and that Ca^{2+} signaling and protein synthesis are potential therapeutic targets for APOL1 nephropathy.

SA-PO986

Characterizing Roles of Reference and Haplotype FAT10 in APOL1-Related Kidney Diseases in Human Podocyte

Nang San Hti Lar Seng,[1,2] Heidi Karttunen,[2] Sahir K. Chaudhry,[2] Michael J. Ross.[3,2] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Medical Center, New York, NY.*

Background: FAT10 is a ubiquitin-like modifier, which can covalently link to target proteins or non-covalently interact with proteins, thereby altering protein function and/or stability. FAT10 is highly expressed in HIV-associated nephropathy (HIVAN) and is upregulated in glomeruli of nephrotic patients with APOL1 high-risk genotypes. FAT10 was also reported to interact with APOL1 and to accelerate degradation of APOL1 risk variants in vitro. A FAT10 haplotype with 4 missense mutations, referred to here as *FAT10b*, has a high allele frequency in persons of African ancestry. However, it is not known whether the *FAT10b* variant has altered effects on APOL1 compared to the *FAT10a* (reference) allele. Since expression of APOL1 risk alleles in podocytes promotes glomerular injury, we compared the effects of FAT10 variants upon APOL1 G0 and G1 proteins in human podocytes.

Methods: *APOL1G0/G0* (G0) and *APOL1G1/G1* (G1) podocytes were transfected with GFP-FAT10 variants using a Neon Transfection System. Immunoprecipitation (IP) was performed using anti-GFP antibody to pull down GFP-FAT10 and western blotting was performed to detect FAT10 and APOL1. Proteasome inhibitor MG132 (5 μM) was added 4 hours before IP.

Results: FAT10a increased endogenous APOL1-G0 and -G1 protein abundance, whereas FAT10b suppressed them. Both APOL1-G0 and G1 co-immunoprecipitated with FAT10a and FAT10b. 70kD and 110kD bands were observed only in *APOL1G1/G1* podocytes transfected with *FAT10b*, likely representing novel covalent FAT10 conjugates but western blotting revealed these FAT10 conjugates did not contain APOL1.

Conclusions: FAT10a and FAT10b interacted with APOL1-G0 and -G1, but FAT10a increased APOL1 G0 and G1 abundance whereas FAT10b increased APOL1 degradation. The emergence of high molecular weight FAT10 covalent conjugates only in podocytes co-expressing APOL1 G1 and FAT10b may indicate important new targets that contribute to podocyte injury in persons with high risk APOL1 and FAT10b genotypes. These data support the importance of further studies to elucidate mechanisms by which FAT10 variants modify APOL1-mediated kidney injury.

RNAomics of APOL1 Risk and Non-Risk Allele Expressing Podocytes in HIV Milieu

Prabhjot K. Johal,[1] Vinod Kumar,[1] Karl Skorecki,[2] Raja Ramachandran,[1] Ashwani Malhotra,[3] Pravin C. Singhal.[3] *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]Bar-Ilan University, Ramat Gan, Israel; [3]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.*

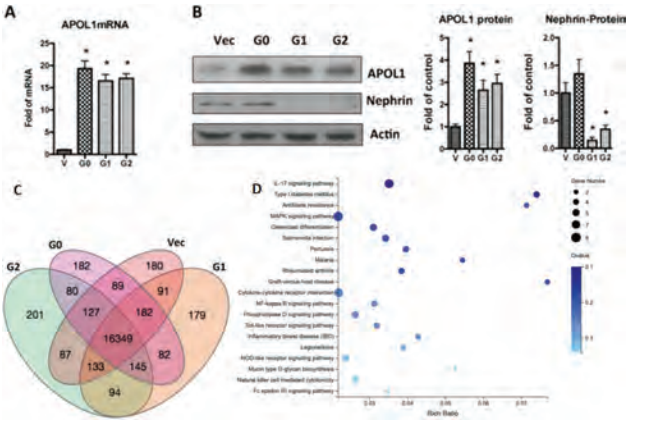
Background: African Americans (AAs) develop chronic kidney diseases (CKD) at 4-5 folds higher rates than European Americans (EAs), and this disparity is over 10 folds in the case of HIV-associated nephropathy (HIVAN), which is predominantly related to two risk alleles (G1 and G2) in APOL1 gene in AAs. To explore the underlying molecular mechanisms, we evaluated the gene expression profiles in podocytes expressing APOL1-G0 (wild-type), G1, and G2 in the HIV milieu.

Methods: Stably expressing APOL1-G0, G1, or G2 cell lines were transduced with HIV, followed by the extraction of RNAs and RNA-seq analysis.

Results: All cells expressed comparable RNA and protein expression of APOL1, but G1- and G2-podocytes displayed attenuated nephrin expression (a marker of podocyte health) in the HIV milieu. RNA-seq analysis showed similar gene expression alterations in G1- and G2-podocytes, their expression profiles differed from that in G0-podocytes. KEGG pathway enrichment analysis revealed predominant alterations in inflammation-regulating signaling pathways such as MAPK, NF-kappa B, phospholipase D, NOD-like receptor, and Fc epsilon RI in G-1 and G2- podocytes when compared with G0-podocytes.

Conclusions: These findings suggest that AAs may suffer from a higher occurrence of CKD due to enhanced inflammatory milieu in podocytes caused by APOL1 risk alleles. Our study provides insight into the underlying molecular mechanisms in developing APOL1-associated nephropathy.

Funding: NIDDK Support



All cells expressed comparable RNA (Figure A) and protein expression of APOL1 (Figure B), but G1- and G2-podocytes displayed downing of podocyte nephrin expression in HIV milieu. RNA-seq analysis showed that G1- and G2-podocyte expression profiles were disparate from that in G0-podocytes (Figure C). KEGG pathway enrichment analysis revealed that compared with APOL1-G0, the risk alleles G1 and G2 mainly altered inflammation regulating signaling pathways (Figure D).

SA-PO988

Microvesicular Passage of APOL1

Prabhjot K. Johal,[1] Vinod Kumar,[1,2] Ashwani Malhotra,[2] Karl Skorecki,[3] Pravin C. Singhal.[2] *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; [3]Bar-Ilan University, Ramat Gan, Israel.*

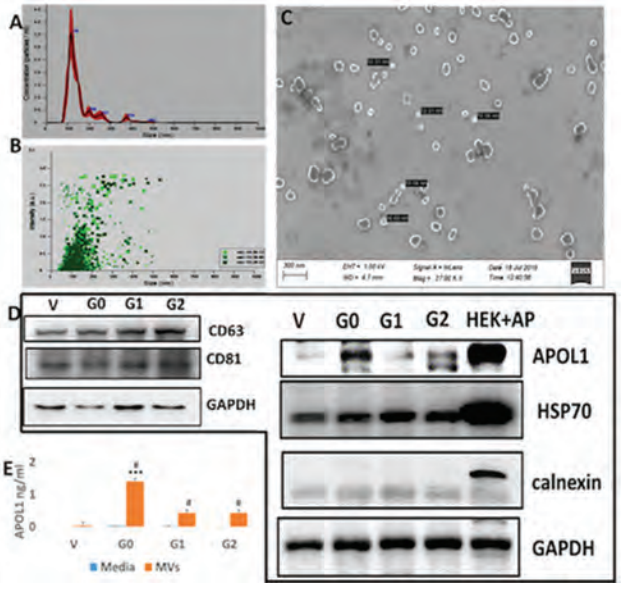
Background: Podocyte-APOL1 (pAPOL1) carry a signal peptide, but its secretion and paracrine/endocrine role are controversial. We propose that APOL1 secretion in podocytes use microvesicles (MVs) to get out of cells rather than direct secretion to the medium.

Methods: APOL1 (wild-type, G0) and its risk variants (G1 or G2) were over-expressed in human podocytes. After 48hr of incubation, the culture medium was collected and processed for MVs isolation by ultracentrifugation and MVs isolation kit. Isolated MVs were characterized by HSP70, CD81, and CD63 and the absence of Calnexin by Western Blot (WB) and FACS. The size was measured using the Nanosite system and Scanning Electron Microscopy (SEM). APOL1 was detected in the culture medium and lysed MVs using ELISA & WB. The isolated MVs were further incubated with non-APOL1 expressing Human Embryonic Kidney (HEK) cells, and after 48hr, HEK cell lysate was analyzed for APOL1 presence by WB.

Results: Nanosite & SEM measured the size of isolated MVs between 90-125nm. These MVs stained positive for the expression of CD63, CD81, and HSP70 but were negative for the expression of calnexin. Thereby confirming that there was no cytosolic contamination. We observed the presence of APOL1 protein only in the lysed MVs. However, the level of APOL1-G0 (intensity: 1.92±0.01) is much higher compared to Vector (0.11±0.01) G1 (0.12±0.01) and G2 (0.17±0.02) as shown in the figure.

Conclusions: This preliminary study shows that podocyte and HEK cells secrete APOL1 through the MVs pathway.

Funding: NIDDK Support



MVs size was measured using Nanosite system (A&B), and SEM (C). The expression of MVs protein marker and APOL1 are displayed (D). ELISA of APOL1 media was performed to detect MVs (E). ***p<0.001, #p<0.001 (*G0 Vs. V, G1 or G2; #media vs. MVs)

SA-PO989

HIV-Associated Nephropathy (HIVAN) Phenotype Is a Consequence of Compromised Parietal Epithelial Trans-Differentiation in the APOL1 Renal Risk Milieu

Vinod Kumar,[1,2] Ashwani Malhotra,[2] Karl Skorecki,[3] Pravin C. Singhal.[2]
[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY; [3]Bar-Ilan University, Ramat Gan, Israel.

Background: HIV-infected patients with African ancestry carrying APOL1 variants (ARRVs G1 and G2) have a several-fold higher risk of developing HIVAN than patients with APOL1 wild-type (G0). HIV enhances APOL1 expression in parietal epithelial cells (PECs). We hypothesized that HIV-mediated PECs' proliferation and transition are compromised in the ARRV milieu & result in PECs' accumulation in Bowman's space, manifesting HIVAN phenotype (a collapsing variant).

Methods: The cultured human parietal epithelial cells (PECs) were transduced with vector, G0, G1 & G2 & analyzed for their proliferative, fibrotic, & podocyte (PD)-specific differentiation phenotype (transition markers) using western blotting (WB). For phenotype-specific proliferative, profibrotic, and transition markers under the HIV milieu, V/G0/G1/G2-PECs were transduced with HIV(NL4-3) for 48hr(n=4) & analyzed by WB. The expression of mTOR signaling and PECs' transition markers was measured using Western blotting and miR193a expression by RT-PCR to evaluate the involved mechanisms. Renal tissues from control & Tg26 (a HIVAN model) mice were analyzed for miR193a & mTOR expression by FISH & IHC in PECs.

Results: In vitro studies, G1/G2-PECs displayed an increased expression of profibrotic (CD44, PERK, α-SMA, Fibronectin, Vimentin, MMP9, SNAIL) but an attenuated expression of transition markers in control and HIV milieus when compared to G0-PECs; in contrast, G0-PECs showed attenuated expression of profibrotic but an enhanced expression of transition markers in HIV milieu. These findings indicate that PEC to PD transition is compromised in G1/G2-PECs in the control and HIV milieu. G1/G2-PECs also displayed increased expression of p-mTOR, p-70S6K, p-4EBP, & p-eEF, indicating the activation of mTOR signaling. Renal cortical sections of Tg26 mice showed an increased accumulation of PECs in their Bowman's space and increased miR193a & mTOR expression by PECs compared to control mice.

Conclusions: HIVAN phenotype (collapsing variant) results from the compromised transition in profibrotic PECs to podocytes in APOL1 renal risk (G/G2) milieu in HIV-infected patients.

Transcriptional Profiling of Induced Pluripotent Stem Cell (iPSC)-Derived Podocytes Comparing APOL1 Risk Variants

Lauren Haines, Uyen Tran, John R. Sedor, John F. O'Toole, Oliver Wessely.
Cleveland Clinic, Cleveland, OH.

Background: African Americans of sub-Saharan ancestry have a 3.5-fold increased risk for end-stage kidney disease compared to populations of European descent due to, in part, two high-risk variants G1 and G2 in the apolipoprotein L1 (*APOL1*) gene. Individuals with two high-risk alleles are predisposed to kidney disease through an undetermined mechanism. We sought to determine if *APOL1* expression in high-risk human induced pluripotent stem cell (iPSC)-derived podocytes causes transcriptional differences compared to reference APOL1 iPSC-derived podocytes.

Methods: We utilized iPSC-derived podocytes engineered with *APOL1* reference (G0) and high-risk (G1, G2) variant genotypes. Our lab has also developed a protocol to directly differentiate these iPSCs into podocyte populations that express *APOL1* with IFN-γ stimulation. To characterize the transcriptional impact of APOL1 variants, we performed mRNA-sequencing on G0/G0, G1/G1, and G2/G2 podocytes either untreated or treated with IFN-γ. EdgeR was used for differential gene expression and further analyzed by principal component analysis, gene ontology enrichment, and Gene Set Enrichment Analysis.

Results: Variant APOL1 iPSC lines differentiate into podocyte populations using our protocol, express *APOL1* with IFN-γ stimulation, and do not demonstrate differential cell death. Transcriptome principal component analysis shows both untreated (lacking *APOL1* expression) and, unexpectedly, IFN-γ treated (with *APOL1* expression) podocytes are not statistically different between reference and high-risk genotypes. The majority of variance (68%) results from IFN-γ treatment and the upregulation of more than 400 genes (2-fold change, FDR 0.05). Furthermore, the few differentially expressed genes between reference and high-risk podocytes could not be assigned a functional role using pathway analysis methods.

Conclusions: We were not able to identify an APOL1-specific transcriptome response between reference and high-risk APOL1 iPSC-derived podocytes. Variant-dependent differences may be overshadowed by the robust transcriptional response to INF-γ used for *APOL1* induction. This supports the need to induce *APOL1* expression without inflammatory stimulation in order to assess the effect of APOL1 variants on podocyte biology.

FSGS Recurrence Modeling Using Induced Pluripotent Stem Cell (iPSC)-Derived Podocytes in Patients with Idiopathic Nephrotic Syndrome

Bartholomeus T. van den Berge,[1,2] Jitske Jansen,[3,2] Jack F. Wetzels,[1] Bart Smeets,[2] Rutger J. Maas.[1] *[1]RadboudUMC department of Nephrology, Nijmegen, Netherlands; [2]RadboudUMC department of Pathology, Nijmegen, Netherlands; [3]RWTH Aachen Institute of Experimental Medicine and Systems Biology, Aachen, Germany.*

Background: Clinical outcome is highly variable, often resulting in renal failure, in patients with idiopathic Nephrotic syndrome and disease returns after transplantation (Tx) in about 50% of patients. Proposed circulating permeability factors (CPFs) are as of yet few and unvalidated in larger cohorts. *In vitro* assays to detect podocyte damage result in heterogeneous outcomes. Taken together, there are potential patient- and donor-specific characteristics that influence disease outcome after Tx. Here, we modelled FSGS recurrence using iPSC-derived podocytes.

Methods: We included 5 patient-donor couples with known outcomes of FSGS recurrence after Tx (3x recurrence, 2x non-recurrence) and generated iPSCs out of PBMCs. We subsequently exposed iPSC-derived podocytes to suspected CPF-containing plasmas and measured podocyte damage using various previously published *in vitro* damage assays.

Results: Using an optimized hybrid directed differentiation protocol, we successfully created iPSC-derived podocytes showing podocytes-specific markers. We were able to model primary FSGS using patients' iPSC-derived podocytes exposed to pre-Tx plasma (patient-specifically) mimicking the *in vivo* situation. We also modelled FSGS recurrence using donor iPSC-derived podocytes exposed to post-Tx plasma (patient-specifically) (Figure 1) again according to the *in vivo* situation. Differences in damage response between iPSC-derived podocyte cellines suggest we found proof for donor-specific characteristics that may influence disease recurrence after Tx using a crossmatching experiment.

Conclusions: iPSC-derived podocytes can be used to model primary FSGS and FSGS recurrence. Data suggests that currently unknown donor-specific characteristics may influence disease outcome after Tx in patients with idiopathic Nephrotic syndrome. We aim to further study these potential donor-specific characteristics.

Modeling Podocytopathies in Human Kidney Organoids

Jamal El Saghir,[1] Celine C. Berthier,[1] Moritz Lassé,[2] Matthew Fischer,[1] Akihiro Minakawa,[1] V. Vega-Warner,[1] Rajasree Menon,[1] Markus M. Rinschen,[2] Matthias Kretzler,[1] Jennifer L. Harder.[1] MiKTMC. *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Podocytopathies include multiple kidney diseases such as Focal Segmental Glomerulosclerosis (FSGS) and Minimal Change Disease (MCD) in which podocyte injury results in albuminuria. Kidney organoids (KOrgs) derived from human pluripotent stem cells generate 3D architecture with multiple cell types seen in native kidneys more reflective of the human in vivo podocyte environment. The aim of this study was to assess KOrg podocyte (KOrg-podos) response to inflammatory stressors and hypoxia and to evaluate their ability to capture pathways relevant to human podocytopathies.

Methods: KOrgs were treated with recombinant TNFα or interferon-γ (IFNG) or subjected to 1% O_2 environment for 24 and 48h. Assessment of gene/protein expression in KOrgs included qRT-PCR, bulk and single cell (Sc) RNAseq, ELISA, IF and untargeted proteomics. Probability of ligand-target cell engagement was assessed by NicheNet based on differential protein expression. Organoid stressor-specific gene signatures were generated from bulk RNA-seq and/or proteomics data and used to assess summary gene expression in proteinuric human kidney tissue (NEPTUNE cohort).

Results: Proteomics analysis showed that baseline KOrgs expressed >90% proteins detected in human glomeruli; IF imaging confirmed anticipated localization of slit diaphragm proteins SYNPO and CD2AP in KOrg-podos. Further, NicheNet analysis confirmed that KOrg-podos responded to a host of ligands expressed by other cell types. Following treatment with TNFα, IFNG or hypoxia, Sc transcriptional profiling revealed that KOrg-podos lose expression of key podocyte markers (NPHS1, PODXL) and increase expression of genes observed in early glomerular epithelial cells (LYPD1, CDH6) as well as pathways associated with inflammatory response (NFkB) and mitochondrial stress. KOrgs stressor-specific gene signature expression segregated subgroups of individuals in a podocytopathic cohort.

Conclusions: Our multi-platform integrative analysis of KOrgs demonstrates that KOrg-podos functionally respond to multiple stimuli thought to contribute to podocytopathies. Further, KOrgs stressor-specific gene activity identified individuals with poor outcome in proteinuric kidney disease. These results confirm the relevance of KOrgs to studies of molecular mechanisms of podocytopathies.

Studying Organoid Phenotypes in CoQ10-Deficient Glomerulopathy

Seyoung Yu,[1,2] Friedhelm Hildebrandt,[2] Heon Yung Gee.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Boston Children's Hospital, Boston, MA.*

Background: Monogenic causes of steroid resistant nephrotic syndrome (SRNS) account for 11-30% of childhood. Genes involved in coenzyme Q10 (CoQ_{10}) biosynthesis, such as *PDSS2, COQ2, COQ6 and ADCK4*, are well established causes of SRNS and focal segmental glomerulosclerosis (FSGS). CoQ_{10} is a component of the mitochondrial inner membrane which plays an important role in supporting electron transport of oxidative phosphorylation and protection from oxidative stress. ADCK4-deficient glomerulopathy can be partially treated by CoQ_{10} supplementation, but the therapeutic efficacy of this treatment is variable and has limitations. We here established a robust *in vitro* model system of CoQ_{10}-deficient glomerulopathies to study the therapeutic effects of drugs using elaborate manipulations, and to better understand the disease and thereby develop more effective treatment.

Methods: We generated CoQ_{10}-deficient kidney organoids from human induced pluripotent stem cells (iPSCs) using the well-established *in vitro* induction protocol (Taguchi et al). To establish CoQ_{10}-deficient human iPSCs, gRNAs targeting PDSS2, COQ2, COQ6 or ADCK4 were used with Cas9 protein individually. We performed immunostaining and light microscopy analysis to evaluate the extent of their differentiation and further test the mitochondrial dysfunction to observe the phenotypic characteristics due to CoQ_{10} deficiency.

Results: Gene ablation of the four genes in iPSCs was confirmed by sanger sequencing. CoQ_{10}-deficiency did not lead to failure of induction to nephron progenitors in organoids. CoQ_{10}-deficient kidney organoids were positive for NPHS1 (a podocyte marker), LTL (a proximal tubule marker), and ECAD (a distal tubule marker) expression, and no difference was observed when compared with control organoids. Further studies will assess mitochondrial dysfunction and ROS levels to quantify pathogenic characteristics

Conclusions: In conclusion, we have developed a modeling system of CoQ10-deficient glomerulopathy that can be used to further evaluate the efficacy of potential drugs for this disease.

Podocytopathy in Diabetic Nephropathy

Divya Ravi, Mohammad AL Wahadneh, Wajid M. Choudhry. *Rochester Regional Health, Rochester, NY.*

Introduction: Minimal change disease constitutes 15% of adult idiopathic nephrotic syndrome. The exact mechanism is unknown but is postulated to be due to T cell dysfunction and the production of glomerular permeability factor. With an underlying immune mechanism involved, minimal change disease responds to steroids and steroid-sparing agents. We present a case of diabetic kidney disease with overlying podocytopathy.

Case Description: A 47-year-old female with a past medical history of hypertension, and poorly controlled diabetes presented with complaints of worsening swelling of legs along with abdominal distension and reported weight gain of 40 pounds over a few weeks. She reported no improvement with oral furosemide 40 mg daily which she was prescribed for her edema and was not using her insulin for the past 9 months before admission. Her creatinine at presentation was 0.9. 24-hour urine protein revealed 6.4 grams/day. Autoimmune workup was negative. The patient was started on IV diuretics. She underwent a kidney biopsy which revealed moderate chronic kidney disease with podocyte foot effacement suggestive of minimal change disease. CT imaging was done to assess for any lymphoproliferative disease which found mildly enlarged inguinal lymph nodes. Oncology was consulted for the possibility of lymphoproliferative disease and believed that malignancy was unlikely. The patient was offered a steroid course versus immunosuppressive medications like mycophenolate mofetil. The patient chose to start mycophenolate mofetil to avoid steroids and their effect on diabetes. Proteinuria decreased and patient was discharged on mycophenolate mofetil 1000 mg twice daily with outpatient follow-up.

Discussion: Minimal change disease is often an idiopathic disease but has also been known to be associated with the use of certain drugs, infections, and hematological malignancies. The mainstay of diagnosis remains to be a kidney biopsy. In our patient, the most likely diagnosis at presentation was diabetic kidney disease from poorly controlled diabetes, the kidney biopsy proved vital in the assessment of the coexisting minimal change disease. Few case reports have been listed where patients with diabetes presented with sudden onset nephrotic syndrome and were found to have minimal change disease.

SA-PO996

DLBS3233 Reduces Homeostatic Model Assessment for Insulin Resistance (HOMA-IR) and Increases Peroxisome Proliferator-Activated Receptor Gamma and Nephrin in Diabetic Rat Podocytes

Chandra I. Mohani. *Universitas Brawijaya, Malang, Indonesia.*

Background: DLBS3233 is a standardized extract derived from *Cinnamomum burmanii* and *Lagerstroaemia speciosa*, has shown antidiabetic effects. Here, we sought to explore the potential benefits of DLBS3233 to regulate insulin signaling in renal podocytes cell, represented by HOMA-IR, as well as podocytes PPAR gamma and Nephrin in diabetic rats with insulin resistance.

Methods: Thirty adult male Wistar rats were randomly divided into six groups (n=5 per group): nondiabetic rat group as a negative control (group I); untreated diabetic rats (group II), diabetic rats treated with DLBS3233 4,5mg/kgBB (group III); 9mg/kgBB (group IV); 18mg/kgBB (group V), and diabetic rats treated with pioglitazone (group VI). We checked HOMA-IR to confirm the occurrence of insulin resistance before and after administration of DLBS3233 in a group of rats with diabetes. Convocal examination was performed to examine the expression of PPARγ and Nephrin. The data were analyzed using paired t-test and ANOVA for pre and post DLBS3233 for HOMA IR.

Results: Administration of DLBS3233 showed work on improving insulin resistance from a significant decrease in HOMA-IR compared to the control group ($p < 0.05$). Increased expression of PPARg and Nephrin also confirmed the effect of a significant improvement in insulin resistance ($p<0.05$).

Conclusions: DLBS3233 was able to improve insulin sensitivity in diabetic rats with insulin resistance. The insulin sensitizing effect was projected from the reduction of HOMA-IR, increase of PPAR gamma and nephrin expression in renal podocytes cell. So further studies are needed to clinically test the efficacy of DLBS3233.

Extracellular Vesicles of Podocytes Impact Intraglomerular Signaling and Parietal Epithelial Cell (PEC) Activation

Alexander Pausch,[1] Annika Gathmann,[1] Kilian Teicher,[1] Inka C. Homeyer,[1] Milagros N. Wong,[1] Anja Obser,[1] Kian Deheshwar,[1] Kelly A. Dryden,[3] Hetty N. Wong,[2] Nicola Wanner,[1] Maja Lindenmeyer,[1] Lawrence B. Holzman,[2] Catherine Meyer-Schwesinger,[1] Franz L. Ricklefs,[1] Uta Erdbruegger,[3] Victor G. Puelles,[1] Tobias B. Huber,[1] Fabian Braun.[1]
[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]University of Pennsylvania, Philadelphia, PA; [3]University of Virginia, Charlottesville, VA.

Background: Extracellular vesicles (EVs) have the ability to impact basic pathological processes such as malignant, metabolic and autoimmune diseases through intercellular signaling. However, we lack a concise knowledge about their role in kidney health and disease. Our study aims to characterize the intraglomerular signalling propagated by medium sized (mEVs) and small EVs (sEVs) shed by podocytes.

Methods: Using differential (ultra-) centrifugation we separated mEVs and sEVs from cell culture supernatants, kidney tissue and urine samples. Using Western Blot, immunofluorescence microscopy as well as image flow cytometry and cryo electron microscopy we investigated the release dynamics of podocyte-specific EVs in different models of murine podocyte damage *in vitro* and *in vivo*. Life microscopy and cross culture experiments were used to determine the effect of podocyte-specific EVs on parietal epithelial cells (PECs). To determine potential signaling factors we performed proteomic analysis of EV content.

Results: Podocytes shed medium-sized and small EVs detectable in culture supernatant, murine kidney tissue as well as the urine of healthy human volunteers. Upon podocyte damage *in vitro*, we detected an increase in EV release as a unified response with a size-shift in certain conditions revealed in Cryo-EM. Surprisingly, podocyte-specific EVs exerted different effects on the migratory behavior and proliferation of PECs depending on EV size and the initial insult to the podocyte. Proteomics revealed limited differences in the EV proteome in different stress conditions, with first candidate proteins potentially propagating the effect on PECs. *In vivo*, decreased EV release by podocytes resulted in reduced PEC activation and limited recruitment of macrophages in a model of crescentic nephritis.

Conclusions: Our study yields essential insights on podocyte-specific release of different sizes of extracellular vesicles, their protein contents and functional implications in health and upon podocyte damage. Ongoing experiments focus on further elucidating the impact of podocyte-specific release *in vivo* and the impact of knocking-out identified EV candidate proteins.

PIK3CA Activation in Extracapillary Glomerulonephritis

Junna Yamaguchi,[1] Pierre Isnard,[1] Clément Hoguin,[1] Aurelie Hummel,[2] Guillaume Canaud.[1] Team "Mechanisms and Therapeutic Strategies in Overgrowth Syndromes and Vascular Anomalies." *[1]Institut Necker-Enfants Malades, Paris, France; [2]Hopital Universitaire Necker-Enfants Malades, Paris, France.*

Background: Extracapillary glomerulonephritis are severe kidney disorders frequently associated with end stage kidney disease. Therapeutic options for these diseases are limited especially due to insufficient understanding of their pathophysiology.

Methods: Following the identification of a somatic *PIK3CA* gain-of-function mutation in podocytes of a patient, we used multiple genetically engineered mouse models, single cell RNA sequencing and spatial transcriptomics to unveil the role of PI3K-Akt mTOR pathway in podocyte biology of proliferative glomerulonephritis. Alpelisib, a pharmacological PI3Ka inhibitor, was used to inhibit the pathway.

Results: Podocyte-specific *PIK3CA* overactivation in mice developed progressive focal segmental glomerulosclerosis with podocyte proliferation, dedifferentiation and inflammation. Alpelisib treatment improved glomerular lesions and kidney function in different models of collapsing glomerulopathy and lupus nephritis by targeting podocytes. In addition, even more importantly and unexpectedly, we uncover that pharmacological inhibition of PI3Ka affects B and T lymphocyte population in lupus nephritis mouse models with reduction in proinflammatory cytokine and auto antibodies production, immunoglobulin and complement deposition. These findings were further confirmed in Human lymphocytes isolated from patients with lupus nephritis.

Conclusions: We demonstrate the crucial role played by PI3Ka for proliferative glomerular diseases and showed for the first time that alpelisib represents a promising therapeutic acting on both, podocytes and immune compartment.

Podocytic and Endothelial Infolding in Focal Segmental Glomerulosclerosis with INF2 Mutation

Tingting Yang, Jianhua Zhu. *Chengdu First People's Hospital, Chengdu, China.*

Introduction: Podocytic infolding glomerulopathy (PIG) is characterized by podocyte cell invading into the GBM and intra-GBM spherules with around 40 reports only. The invaginations of endothelial cells to the GBM were generally not described. We report the specific ultrastructure of endothelial cells evidently invading into the GBM besides podocytes of a 25-year-old woman with the inverted formin-2 (INF2) mutation.

Case Description: The patient presented as nephrotic syndrome whithout autoimmune disorders. Light microscopy of kidney biopsy showed the basement membrane was irregularly thickened (Figure 1(A-B)). Electron microscopy revealed diffuse irregular thickening of the basement membrane with podocyte foot-process infolding into and with many microspheres, some membrane like structures and a few electron-dense deposits inside (Figure 1(C-F)). Notably, villous cytoplasmic protrusion of endothelial cells were more conspicuous in the GBM. The gene sequencing showed novel heterozygous mutations in the INF2 gene (NM_022489.4). The c.395T>C mutation was classified as significance undetermined. The patient is stable with olmesartan and diuretics.

Discussion: The pathogenesis of PIG remains unclear. In particular, villous protrusions of endothelial cells were more remarkable in the GBM in our case, suggesting that endothelial cells may be related to PIG. When the GBM is injured, the disordered skeletal structure may also easily trap the decomposing podocyte or endothelial cell processes in and dissociate them. Genetic mutations may also be involved in PIG. Whether the c.395T>C mutation had connection with PIG remains unclear. To our knowledge, this is one of the minority reported cases of PIG with gene detection. The specific pathogenesis and genetic explanation of PIG still needs to be further explored.

Laminin α2-Mediated Podocyte Damage Is a Dominant Driver of Glomerular Disease in Alport Mice

Dominic E. Cosgrove, Jacob D. Madison, Daniel T. Meehan. *Boys Town National Research Hospital, Omaha, NE.*

Background: Earlier work showed that the progressive accumulation of laminin α2 in the GBM activates focal adhesion kinase and NF-kappa B, resulting in elevated expression of pro-inflammatory cytokines and metalloproteinases. The receptor(s) for laminin α2 were never identified, nor the functional consequences of activation of the laminin α2 receptors on podocytes.

Methods: Cultured podocytes were overlayed with recombinant laminin 211 (or not) then transfected with either scrambled SiRNA or SiRNA specific for α-dystroglycan (DAG) and RNA analyzed by RNA-seq. Cell signaling characterization was done using the Full Moon Biosystems (Sunnyvale, CA) *"cell signaling phospho Ab array"*. This platform has 312 antibodies representing the most common cell signaling pathways. We performed this analysis on podocytes transfected with scrambled Si RNA +/- and either α-dystroglycan or integrin α7 knockdown in podocytes treated (or not) with laminin 211.

Results: SiRNA studies show the genes that are most abundant and up regulated by laminin 211 that are normalized by DAG knockdown. This list includes profibrotic genes such as Acta2, Scube3, and TGF-Beta3, as well as genes that up-regulate ECM expression (Ccn2, which encodes CTGF) and Col4A1. KEGG analysis of this data implies important roles for laminin α2-mediated α-dystroglycan receptor activation in cell adhesion and cell migration. Full Moon cell signaling array studies demonstrate that laminin 211-mediated α-dystroglycan and α7β1 integrin signal by both shared and unique signaling pathways and are thus both functioning in laminin 211-mediated signaling in cultured podocytes. Both receptors showed significant activation of PI3K/AKT, Apoptosis, Cell cycle, Jak Stat, NFkappaB, p53, Ras and VEGF signaling pathways. mTor signaling was primarily influenced by integrin α7β1, and the TGF-beta signaling cascade was primarily activated by α-dystroglycan. Thus, the two receptors function both independently and more commonly through co-receptor signaling.

Conclusions: Laminin α2-mediated activation of integrin α7β1 and α-dystroglycan receptors is a major contributor to podocyte damage and glomerular disease progression in Alport mice.

EPAC1-Mediated cAMP Signaling Promotes Cellular Energy Adaptations and Glycolytic Metabolic Shift in Podocytes to Protect from Glomerulonephritis

Lilia Abbad,[1] Maximin Detrait,[2] Panagiotis Kavvadas,[1] Lisa Melis,[1] Frank Lezoualc'h,[2] Christos Chatziantoniou.[1] *[1]Inserm U1155, Paris, France; [2]Inserm U1297, Toulouse, France.*

Background: Many efforts are made to identify new therapeutic targets to slow down, prevent Chronic Kidney Disease (CKD) progression. One of the therapeutic approaches is activating the renoprotective cAMP pathway. The exchange factor directly activated by cAMP 1 (EPAC1) has been identified as a novel, PKA-independent, mediator of cAMP signalling. EPAC1 is a guanidine exchange factor that regulates important cellular functions. Here we aim to determine the role of EPAC1 in CKD progression.

Methods: An immunostaining of EPAC1 is performed on biopsies of patients with glomerulonephritis. Nephrotoxic serum glomerulonephritis (NTS-GN) is induced in genetically modified mice with total and conditional EPAC1 deletion in podocytes. Then isolated glomeruli from the conditional mice are analysed by RNA-sequencing. The main metabolic energy pathways are studied in podocytes *in vitro* under oxidative stress exposure in the presence/absence of an EPAC1 agonist.

Results: EPAC1 is expressed in different GN disease and localized in glomeruli. Following the induction of NTS-GN, mice with genetic deletion of EPAC1 show aggravated renal disease, characterized by increased proteinuria, tissue inflammation and fibrosis compared to control mice. Conversely, pharmacological activation of EPAC1, with the agonist 8-pCPT-2-OMe-cAMP, delays NTS-GN progression. Since in human and mouse kidney tissues we observe EPAC1 expression in podocytes, mice with conditional deletion of EPAC1 in podocytes are generated. Similar to the whole-body knockout, conditional mice show worsened disease progression compared to control mice. RNA-sequencing analysis of glomeruli isolated from these mice show that gene expression of proteins linked to the pathway of glycolysis are abolished in early stage of NTS-GN. EPAC1 activation under oxidative stress in podocytes *In vitro*, promotes glycolysis with cellular energy production independently from mitochondrial respiration. The EPAC1-mediated glycolysis protected podocytes by increasing cell viability.

Conclusions: Podocytes-derived EPAC1 plays a protective role against the development of GN through cellular energetic adaptations based on metabolic shift to glycolysis. Activating the cAMP-EPAC1 signalling axis could represent a therapeutic option to delay CKD.

Preliminary Renal Biopsy Registry: Dominican Republic

Anthony J. Gutierrez,[1] Juan M. Cruz,[1] Denazir Atizol Rodriguez,[1] Jordy Batista,[1] Rocio E. Checo,[1] Eliana Dina-Batlle.[2,1] Grupo colaborativo Registro Nacional Biopsia Renal RD. *[1]Pontificia Universidad Catolica Madre y Maestra, Santiago de los Caballeros, Dominican Republic; [2]Hospital Metropolitano de Santiago, Santiago De Los Caballeros, Dominican Republic.*

Background: The rising incidence of renal diseases and the need to enhance their prevention, diagnosis, and treatment have prompted the establishment of national renal biopsy registries. These registries provide essential information about the epidemiology of renal diseases and can inform the design of clinical trials and the development of therapeutic strategies. With this premise, the Preliminary Renal Biopsy Registry was implemented in the Dominican Republic, aiming to compile and analyze renal biopsy data nationwide. This registry provides a valuable data source for studying renal diseases in this specific country, enabling the identification of risk factors and the evaluation of the effectiveness of public health interventions.

Methods: A retrospective database analysis was conducted, collecting national renal biopsy data. A call was made to nephrologists performing renal biopsies through the national society. Biopsies from 2002 to 2022 were included.

Results: A total of 929 biopsy were included of this study. Consisting of 814 (87.62%) non-transplanted and 115 (12.38%) transplanted patients. 455 (55.9%) were female, 604 (74.2%) biopsies were performed in northern part of the country and just 32 patients (3.9%) were re-biopsied. The five more common primary biopsy diagnosis in non-transplanted patient were the following: focal segmental glomerulosclerosis 174 (21.4%), lupus nephritis (14.3%), minimal change disease (10.3%), membranous nephropathy 73 (9%) and Alport syndrome/thin membrane disease 66 (8.1%). In transplanted patients however, the five more common were: acute rejection 45 (39.1%), no rejection 25 (21.7%), chronic rejection 22 (19.1%), acute tubular necrosis 5 (4.3%) and focal segmental glomerulosclerosis 4 (3.5%).

Conclusions: According to our study, FSGS was the most common type of glomerulonephritis in our population. Also, this study showed a high frequency of Lupic nephritis, ranking second among all the glomerulonephritis diagnoses, followed by minimal change disease. This pattern is similar to other studies in Latin America, revealing a higher frequency of lupus nephritis compared to European and American countries. This information is essential to realize and emphasize kidney diseases' importance, especially autoimmune glomerular disorders in Latin America.

SA-PO1003

Mechanisms of TMEM30A/NLRP3 Inflammasome Pathway-Mediated Podocyte Pyroptosis in FSGS

Yanpei Hou, Yi Li, Li Wang, Guisen Li. *Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China.*

Background: Primary Focal and Segmental Glomerulosclerosis (FSGS) is a renal histological disease characterized by podocyte injury. Transmembrane Protein 30A (TMEM30A) is involved in FSGS podocyte injury, but the underlying mechanism remains unclear.

Methods: Bioinformatics techniques were used to screen datasets related to FSGS in GEO database and search for keygenes. 20 FSGS patients and 20 normal control renal tissues were collected, and multispectral fluorescence staining was used to detect the expression levels of TMEM30A, Nephrin and NLRP3 in renal podocytes. In vivo study, adriamycin(ADR)-induced podocyte injury mice were constructed, and the expression levels of TMEM30A, Nephrin and NLRP3 were observed by multispectral fluorescence staining. Meanwhile, Podocyte specific *Tmem30a* knockout mice were constructed, and the expression levels of Nephrin and NLRP3 in renal podocytes were detected by multispectral fluorescence staining. In vitro study, ADR was used to induce mouse podocytes and *Tmem30a* knockdown mouse podocytes were constructed to observe the expression levels of podocyte protective marker and pyroptosis related proteins. After the intervention of NLRP3 inhibitor, the changes of podocyte marker protein and pyroptosis related protein were observed.

Results: In kidney tissues of FSGS patients and ADR-induced mice, We found that the level of TMEM30A and Nephrin significantly reduced and the level of NLRP3 significantly increased with obvious colocalization. In addition, multi-spectral fluorescence staining showed that NLRP3 was significantly increased in the kidney tissue of podocyte-specific *Tmem30a* knockout mice, colocalized with podocyte-related protein Nephrin. In vitro study, we successfully constructed adriamycin induce mouse podocytes and *Tmem30a* knockdown mouse podocytes with decreased podocyte marker WT1 and Nephrin. Then, We further found the expressions of pyroptosis-related proteins NLRP3, Caspase 1 and GSDMD were significantly increased. The NLRP3 inhibitor MCC950 could inhibit podocyte pyroptosis and improve podocyte injury.

Conclusions: TMEM30A could inhibit the activation of NLRP3 inflammasome, prevent the production of active Caspase 1 and the cleavage of GSDMD, reduce the podocytes pyroptosis, weaken the damage of podocytes, and improve FSGS.

SA-PO1004

Deletion of IRE1α Exacerbates Diabetic Nephropathy in Mice

Andrey V. Cybulsky,[1] Joan Papillon,[1] Julie Guillemette,[1] José R. Navarro-Betancourt,[1] Chen-Fang Chung,[1] Takao Iwawaki,[2] Ivan G. Fantus.[1] *[1]McGill University, Montreal, QC, Canada; [2]Kanazawa Medical University, Uchinada, Japan.*

Background: Protein misfolding in the endoplasmic reticulum (ER) of podocytes is an important contributor to the pathogenesis of glomerular diseases. ER protein misfolding activates a compensatory signaling network called the unfolded protein response (UPR). Deletion of the UPR transducer, inositol-requiring enzyme 1α (IRE1α) in mouse podocytes leads to podocyte injury and albuminuria in aging, and exacerbates injury in glomerulonephritis. This study addresses the role of the UPR and IRE1α in diabetic nephropathy.

Methods: We studied mice with podocyte-specific deletion/knockout (KO) of IRE1α. Hyperglycemia was induced in male mice (age 3-4 months) with streptozotocin.

Results: Streptozotocin-treated control and IRE1α KO mice developed comparable hyperglycemia (diabetes). Diabetes caused progressive albuminuria in control mice (3.7 mg/mg creatinine at 6 months) that was exacerbated in IRE1α KO mice (8.5 mg/mg creatinine; $P<0.01$). Albuminuria was ~1 mg/mg creatinine in non-diabetic groups (4-13 mice/group). Compared to diabetic controls, diabetic IRE1α KO mice showed a reduction in podocytes (WT1-positive cells; $P<0.0001$) and synaptopodin ($P<0.05$). Both non-diabetic and diabetic IRE1α KO mice showed increased glomerular matrix expansion compared to their respective controls. Glomerular ultrastructure was altered only in diabetic IRE1α KO mice; changes included widening of foot processes and glomerular basement membrane, microvesiculation of podocyte plasma membranes, and markedly dilated ER and mitochondrial architectural damage in podocytes. Activation of the UPR (increased glomerular ER chaperones) and autophagy (increased LC3-II, decreased p62) was evident in diabetic control, but not diabetic IRE1α KO mice. Analysis of human glomerular gene expression in the JuCKD (Nephroseq) database demonstrated activation of pathways and gene ontology categories, as well as induction of genes associated with the ER, UPR and autophagy in diabetic nephropathy.

Conclusions: Mice with podocyte-specific deletion of IRE1α demonstrate more severe diabetic nephropathy. This was associated with an attenuation of the glomerular UPR and autophagy, implying a protective mechanism mediated via IRE1α. These results are consistent with data in human diabetic nephropathy and highlight the potential for therapeutically targeting these pathways.

The miR-143/145 Cluster Induced by TGF-β1 Suppresses Wilms Tumor 1 Expression in Cultured Human Podocytes

Akifumi Tabei,[1] Toru Sakairi,[1] Yuko Ohishi,[1] Mitsuharu Watanabe,[1] Masao Nakasatomi,[1] Hiroko Hamatani,[1] Hidekazu Ikeuchi,[1] Yoriaki Kaneko,[1] Jeffrey B. Kopp,[2] Keiju Hiromura.[1] *[1]Gunma Daigaku Igakubu Fuzoku Byoin, Meabashi, Japan; [2]National Institutes of Health, Bethesda, MD.*

Background: Transforming growth factor (TGF)-β1 contributes to podocyte injury in various glomerular diseases, including diabetic kidney disease (DKD), probably in part by attenuating expression of Wilms' tumor 1 (WT1). We aimed to identify microRNAs associated with TGF-β1-induced podocyte injury.

Methods: miR-microarray studies were performed using total RNA extracted from differentiated human podocytes exposed to 5 ng/mL TGF-β1 for 24 h and control podocytes. db/db mice were used as animal models of type-2 diabetic nephropathy.

Results: Microarray analysis identified miR-143 as the miR with the greatest increase following exposure to TGF-β1 (2.3 fold increase as 2ΔLMR vs. control, p=0.0000077). We confirmed by reverse transcription-quantitative polymerase chain reaction that the miR-143/145 cluster expression significantly increased in a time-dependent manner for up to 48 hours after exposure to of TGF-β1 in cultured human podocytes (13.3 ± 3.7/ 17.4 ± 0.4 fold at 48 h vs. 0 h). We also observed upregulation of miR-143 in glomeruli of 16-week-old type 2 diabetic db/db obese mice compared to control mice, although miR-145 levels were comparable. Lentiviral ectopic expression of miR-143 and miR-145 in cultured human podocytes suppressed mRNA and protein expression of WT1 compared to ectopic expression of scramble allele as control, both with TGF-β1 exposure and non-exposure (0.37 ±0.057/ 0.49 ±0.084 fold vs. control for mRNA, 0.44 ± 0.093/ 0.38 ± 0.066 fold vs control for protein). Further, inhibition of SMAD signaling by shRNA targeting SMAD4 and inhibition of mammalian target of rapamycin (mTOR) signaling by exposure to rapamycin partially and significantly reversed the TGF-β1-induced increase in miR-143/145 and decrease in mRNA and protein expression of WT1.

Conclusions: In summary, in cultured human podocytes, TGF-β1 induces expression of the miR-143/145 cluster, in part through the classic SMAD and mTOR pathway, and miR-143/145 reduces expression of WT1. Thus, miR-143/145 may contribute to the TGF-β1-induced podocyte injury.

SA-PO1006

Integrin α3β1 as a Potential Target for Diabetic Kidney Disease (DKD)

Nikolay O. Bukanov,[1] Thomas A. Natoli,[1] Vaja Chipashvili,[1] Wen Zhou,[1] Rajashree Rana,[1] Pavlos Pissios,[1] Gang Zheng,[1] Gladys A. Nchaw,[1] Brendon R. Lutnick,[1] Stephen S. Yip,[1] Fu-Yang Lin,[2] Terence Moy,[2] Nadia Leloup,[2] Habtom Habte,[1] James F. Tobin,[1] Maria Chiara Magnone.[1] *[1]Janssen Research and Development LLC, Raritan, NJ; [2]Morphic Therapeutic Inc, Waltham, MA.*

Background: Integrin α3β1 is highly expressed in kidney and is critical for maintaining the glomerular filtration barrier integrity by mediating adhesion of podocytes to laminin on the glomerular basement membrane. In human, loss-of-function mutations of α3 or its ligand laminin cause congenital nephrotic syndrome. We hypothesized that α3β1 activity in DKD is reduced and that activating α3β1 should preserve podocyte adhesion and kidney function. Here, we tested this hypothesis in a *proof of mechanism* (POM) experiment using the integrin β1-agonistic antibody 9EG7 in translational mouse model of severe DKD.

Methods: Integrin α3β1 loss in DKD was measured by α3 expression in kidney tissues from DKD patients with increasing disease severity by immunofluorescence staining. Antibody 9EG7 was characterized *in vitro* using adhesion assay in cells overexpressing α3β1, as well as adhesion, binding and cell morphology in human and mouse podocytes. The *in vivo* POM experiment with 9EG7 was performed in hypertensive diabetic ReninAAV Unix db/db mice. End points were kidney function (albuminuria), biomarkers (podocytes markers in urinary shed cells (uSC) and exosomes-like vesicles (ELV)), AI-based assessment of podocytes counts and the analysis of podocyte foot process effacement (measured by super-resolution microscopy).

Results: We confirmed that in DKD there is a progressive loss and mis-localization of α3 with disease progression, supporting the notion of a potential beneficial effect of an agonistic mAb. *In vivo* efficacy studies with integrin β1-agonistic monoclonal antibody 9EG7 (2 weeks treatment) showed a dose dependent decrease in uACR ratio and reduction of podocyte markers in whole urine and isolated urinary ELV and uSC. AI-enabled quantification of podocyte marker WT1 showed increased podocytes counts per glomerulus. Quantitative analysis of podocyte foot process formation by super-resolution microscopy showed improved podocyte structure.

Conclusions: Integrin β1-activation with the monoclonal antibody 9EG7 ameliorated hypertension-and diabetes-induced albuminuria, increased podocyte counts in glomerulus and decreased urinary podocyte markers in a preclinical model of DKD. These findings suggest that α3β1 could be a potential target for DKD.

Nephrotic Syndrome-Associated TRIM8 Variants Impair the Proteasome-Dependent Turnover and Condensation of TRIM8 Protein

Vineeta Sharma,[1,2] Alexander Rubin,[1] Lorrin Liang,[3] David A. Ball,[1] Victoria C. Gauntner,[1] Friedhelm Hildebrandt,[1,2] Amar J. Majmundar.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Boston University School of Medicine, Boston, MA.*

Background: Nephrotic syndrome (NS) is the second leading cause of chronic kidney disease. *De novo* C-terminal truncating variants in *TRIM8* (tripartite motif containing 8) cause a novel form of NS. As N-terminal truncating *TRIM8* variants present in gnomAD controls precluded haploinsufficiency, we hypothesized that NS-associated *TRIM8* variants cause a podocytopathy through dominant-negative or gain-of-function mechanisms.

Methods: Protein-protein interactions were determined by co-immunoprecipitation (co-IP). The 26S proteasome inhibitor MG132 was used to modulate the levels of tagged wildtype (WT) and patient variant (PV) TRIM8 protein. The half-life of tagged TRIM8 protein was assessed by cycloheximide chase assay. Tagged WT and PV TRIM8 protein ubiquitination was measured by IP upon overexpression of HA-tagged *Ubiquitin*. GFP-tagged WT and PV TRIM8 protein cellular localization was evaluated by confocal microscopy.

Results: Wildtype and patient variant TRIM8 co-immunoprecipitated with WT TRIM8, indicating NS-associated *TRIM8* variants do not impair TRIM8-TRIM8 interactions. MG132 treatment increased WT TRIM8 but not PV TRIM8 protein levels, demonstrating disease-associated variants impair 26S proteasome-dependent TRIM8 degradation. PV TRIM8 exhibited increased stability (half-life > 5 hours) relative to WT TRIM8 protein (half-life 3 hours) by cycloheximide chase assay. Tagged TRIM8 WT protein underwent polyubiquitination, which was impaired by NS-associated *TRIM8* variants. GFP-tagged WT TRIM8 exhibited increased condensation to nuclear bodies upon proteasome inhibition, while PV TRIM8 maintained pan-nuclear localization in the presence or absence of MG132.

Conclusions: NS-associated variants in *TRIM8* cause increased TRIM8 protein stability but reduced protein condensation, suggesting these variants have hyper- or neomorphic effects.

A Novel Frameshift Mutation in CLCN5 in a Family with Podocytopathy Phenotype

Adolya M. Moore,[1] Brandon M. Lane,[2,3] Megan Chryst-Stangl,[2,3] Guanghong Wu,[2,3] Rasheed A. Gbadegesin.[2,3] *[1]Duke University, Durham, NC; [2]Duke University School of Medicine, Durham, NC; [3]Duke Molecular Physiology Institute, Durham, NC.*

Background: Steroid resistant nephrotic syndrome (SRNS) is a common cause of pediatric chronic kidney disease (CKD). However, the cause of approximately 80% of familial SRNS cases remain unknown. We hypothesized that additional genetic causes of disease can be discovered through next generation sequencing analysis of a large cohort of families with NS.

Methods: To identify the genetic cause of podocytopathy we performed whole genome sequencing, followed by direct sequencing and segregation analysis in over 300 patients from ~200 families.

Results: We identified a novel segregating hemizygote truncating mutation (c.1199del, p.Gly400ValfsTer29) in the gene encoding Chloride Voltage Gated Channel 5 (*CLCN5*) in a family with four affected boys with NS phenotypes including nephrotic range proteinuria and biopsy proven focal segmental glomerulosclerosis (FSGS). Segregation analysis revealed that the mother is heterozygous for the same variant, while the variant is absent in the father. Chloride Voltage Gated Channel 5 encodes a member of the chloride ion channels and ion transporters that regulate endosomal acidification and receptor mediated endocytosis in tubules. Mutations in *CLCN5* is a major cause of Dent Disease, a proximal tubulopathy characterized by hypercalciuria, nephrocalcinosis and nephrolithiasis. However, *CLCN5* is enriched in the podocyte at the mRNA and protein level. We also analyzed whole exome sequencing data from additional 200 patients with nephrotic syndrome and identified another family with a hemizygote variant of unknown significance (VUS).

Conclusions: Pathogenic variants in *CLCN5* represent a rare cause of secondary podocytopathy and should be included in the gene panel for SRNS. Analysis of iPSC-derived podocytes from this family will unravel the mechanisms by which *CLCN5* deficiency in podocyte can cause a podocytopathy-like phenotype.

Gene Expression and Regulatory Activity Disruptions in Glomerular Disease Patients

Ksenia Sokolova,[1] Chandra L. Theesfeld,[1] Chen Wang,[2] Krzysztof Kiryluk,[2] Laura H. Mariani,[3] Matthias Kretzler,[3] Olga Troyanskaya.[1,4] CureGN Consortium Genetics Working Group. *[1]Princeton University, Princeton, NJ; [2]Columbia University Vagelos College of Physicians and Surgeons, New York, NY; [3]University of Michigan Michigan Medicine, Ann Arbor, MI; [4]Flatiron Institute, New York, NY.*

Background: The role of noncoding variants in glomerular disease is not well understood. In this work we use deep learning to analyze contributions of these variants to gene expression and regulatory activity disruptions in the CureGN cohort, which includes patients with minimal change disease (MCD), membranous nephropathy (MN), IgA nephropathy (IgAN) and focal segmental glomerulosclerosis (FSGS).

Methods: To systematically assess the functional impact of the variants, we used deep learning models to predict gene expression changes in primary human cell types and the underlying biochemical disruptions to chromatin regulators across millions of patient variants.

Results: Gene expression changes were predicted for over 3 million variants in 25 kidney cell types. Effects of rare variants were accumulated per gene. We found multiple genes and pathways (Reactome) that were significantly dysregulated across all patients. For example, a gene with significant gene expression disruption was RABGGTB (*p-val=1.42e-74*), which is prognostically unfavorable in renal cancer. Others include RREB1 (*p-val=1.178e-88*) and MAPK7 (*p-val=2.738e-220*). Top variants from each diagnosis group impacted distinct sets of partially overlapping genes and pathways. In addition to gene expression, we obtained predictions for regulatory activity disruption for over 25 million gene proximal patient variants. Predicted chromatin biochemical disruption was more severe for strongly conserved variants and variants associated with disease-related pathway genes. A subset of genes and pathways were significantly disrupted between and within patient groups. For example, within variants found in MCD patients, genes involved in PCSK9 reactions had stronger chromatin profiling disruptions (*p-val=6.36e-05*) than the other variants of MCD patients.

Conclusions: Through comprehensive analysis of the non-coding variants in the CureGN cohort, we discovered variants, genes, and biological pathways disproportionately perturbed across the CureGN patients. Gene expression predictions provided functional effects, while chromatin profiling predictions offered additional insight into disruption of molecular mechanisms. This analysis provides hypotheses for disease-contributing biology and a resource for the future experimental follow-up.

SA-PO1010

Podocyte-Specific Deletion of MCP-1 Fails to Protect Against Angiotensin II- or Adriamycin-Induced Nephropathy

Corry D. Bondi,[1] Hannah L. Hartman,[1] Brittney M. Rush,[1] Roderick J. Tan.[1,2] *[1]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [2]Veterans Health Administration, Pittsburgh, PA.*

Background: Investigating the role of podocytes in the pathophysiology of proteinuric disease is important to remedy the increasing global burden of chronic kidney disease (CKD). Monocyte chemoattractant protein-1 (MCP-1 or CCL2) is a chemokine upregulated in proteinuric CKD. Since podocytes can express both MCP-1 and its receptor (CCR2), we hypothesized that an autocrine MCP-1/CCR2 loop contributes to proteinuric CKD. To test this hypothesis, we generated podocyte-specific MCP-1 knockout mice (Podo-*Mcp-1*$^{fl/fl}$) and exposed them to proteinuric injuries.

Methods: Podo-*Mcp-1*$^{fl/fl}$ mice were generated by crossing MCP-1 floxed mice with mice harboring Cre recombinase under the transcriptional control of the podocin promoter. Podo-*Mcp-1*$^{fl/fl}$ mice and control littermates were subjected to either angiotensin II (Ang II; 1.5mg/kg/day x 28 days) or Adriamycin (Adr; 18mg/kg) to induce glomerular injury. Weekly spot urines were assessed for albuminuria. After 28 days, sera were collected to assess renal function while kidney tissues were used for histological, immunofluorescence, immunoblot, and quantitative PCR analyses. Unpaired Student's t-test (two-tailed) was performed for two group comparisons. Log-rank test was used to compare survival distributions. The threshold for significance was $P<0.05$.

Results: At baseline, there were no between-group differences in body weight, histology, albuminuria, and podocyte markers. After 28 days of injury with either Ang II or Adr, there were no between-group differences in survival, albuminuria, renal function, inflammatory mediators, histopathology, podocyte loss, nephrin expression, and fibrosis.

Conclusions: Due to the lack of protection in the knock-out mice, our findings suggest that podocyte-specific MCP-1 production is not a major contributor to either Ang II- or Adr-induced glomerular injury. MCP-1 signaling must originate from a non-podocyte cell type. Future studies will determine the source cell of MCP-1.

SA-PO1011

Effect of Transglutaminase-Induced Stiffening of Glomerular Basement Membrane on Podocyte Function

Dan Wang, Sethu M. Madhavan, Nicholas J. Ferrell. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Glomerular basement membrane (GBM) and podocytes are important components of the glomerular filtration barrier. Podocytes are terminally differentiated cells that develop an intricate 3D architecture in vivo that is difficult to maintain in vitro. New approaches to maintaining podocyte differentiation may improve in vitro studies. Matrix stiffening is closely related to cellular function and GBM stiffness is altered in chronic kidney disease. How GBM mechanical properties affect molecular permeability and podocyte function is not fully understood. This work aims to investigate podocyte differentiation on native and transglutaminase crosslinked GBM and evaluate its effects on molecular transport.

Methods: Glomeruli were isolated from pig kidneys by sieving. The stiffness of native and transglutaminase (TG) crosslinked glomeruli was evaluated by a customized compression system. Decellularized and lyophilized glomerular matrix was rehydrated in PBS and coated on a 12-well plate. Immortalized human podocytes were plated on sterilized native GBM, TG treated GBM, and Matrigel coated plates. Podocytes were proliferated at 33°C, followed by transferring to 37°C for 14 days differentiation. Podocyte specific markers (nephrin, WT-1, and synaptopodin) and tight junction markers (ZO-1) were evaluated by immunofluorescence. Glomerular matrix was pressure compacted to Transwell membranes under pressure in a stirred cell to evaluate barrier function.

Results: Crosslinking GBM with transglutaminase increases its stiffness. Podocytes express nephrin and WT-1 after 14 days differentiation in culture on native and crosslinked GBM, and Matrigel coated coverslips. There is no synaptopodin expression in undifferentiated podocytes, but it has strong expression in differentiated podocytes. Podocytes cultured on native GBM show clear ZO-1 staining but weak staining on the TG treated GBM. Diffusive permeability measured on GBM with cultured podocytes is significantly reduced after 14 days differentiation compared to 7 days differentiation. This suggests podocyte differentiation contributes to barrier permeability.

Conclusions: We provide an easy method to fabricate biomimetic GBM which can support podocyte differentiation during long-term culture. Stiffening of GBM affects podocyte differentiation and junction marker that may contribute to loss of filtration barrier integrity.

A Novel Mutation in Podocyte-Specific Protease HtrA1 Is Associated with Glomerular Disease Progression

Abhijit S. Naik, Damian Fermin, Viji Nair, Felix H. Eichinger, Jennifer L. Harder, Laura H. Mariani, Matthias Kretzler. *University of Michigan, Ann Arbor, MI.*

Background: In kidney allografts, IGF-1 signaling was associated with reduced expression of Integrin A3, a key podocyte adhesion protein, and accelerated podocyte detachment. Insulin-like growth factor binding protein 2 (*IGFBP2*) and the high-temperature requirement factor A1 (*HTRA1*) contributed to the observed IGF-1 signaling. Podocyte specificity of *HTRA1* was affirmed by single-cell RNA sequencing of healthy kidney tissue. The *HTRA1* encodes a protease and makes bound IGF-1 locally bioavailable(doi.org/10.1016/s0014-5793(96)01229-x). Since 99% IGF-1 is bound, functional mutations in the *HTRA1* gene could therefore perturb local IGF-1 signaling with functional consequences.

Methods: We searched for *HTRA1* coding variants in the NEPTUNE cohort (n=620). Six distinct variants passed QC filtering. Each variant was then examined for its association with negative outcome (ESRD or 40% reduction in GFR). Transcriptional consequences on IGF-1 signaling of these mutations were evaluated in glomerular RNA-sequencing data.

Results: One variant was associated with a 2.7-fold increased risk of negative outcome. This relatively rare SNP (rs369149111); allele frequency-0.0248 results in a missense mutation, leading to alanine to valine change within the conserved signaling peptide (Ala20Val) region. Corresponding higher expression of IGF-1R in glomeruli as observed in patients with this variant.

Conclusions: SNP (rs369149111) is associated with glomerular disease progression. This rare allele likely interacts with glomerular IGF-1 signaling that then contributes to podocyte loss observed in glomerular diseases and transplanted kidneys. Further studies are necessary to confirm the prevalence and mechanistic implications of this *HTRA1* variant

SA-PO1013

Novel Allosteric Agonists of Integrin a3b1 as Therapeutics for FSGS

Richard Helmuth,[1] Santiago Balza Pineda,[2] Darlah M. Lopez-Rodriguez,[2] Khulood Alzahrani,[1] Vineet Gupta.[1,2] *[1]Rush University Medical Center, Chicago, IL; [2]149 Bio, LLC, Miami, FL.*

Background: Podocytes form the kidney filter that allows separation of urine and waste from blood. They attach to the extracellular basement membranes via cell surface integrin a3b1. Reduced podocyte adhesion, due to injury or mutations in a3b1, associated membrane proteins (CD151), or the integrin linked cytoskeleton, results in podocyte detachment and loss that weakens the kidney filter, resulting in progressive glomerular disease. Reinforcement of podocyte adhesion, via increased integrin-mediated cell adhesion and strengthened cytoskeleton is protective in various kidney diseases.

Methods: We used a human phage display library to identify a3b1 activating antibodies. K562 cells stably expressing a3b1, differentiated podocytes, and human SKOV cells were used in *in vitro* assays. K562 cells were used in flow-cytometry assays to characterize a3 agonists. Podocytes were used in High-Content Screening (HCS) based assays to quantify puromycin aminonucleoside (PAN) induced cell damage and integrin agonist mediated protection. Cells were also utilized in cell adhesion and cell migration based functional assays.

Results: Measurement of F-actin fibers, focal adhesions and active integrin levels in podocytes showed a quantifiable change due to PAN injury in podocytes, and protection from PAN-injury by b1 integrin agonists 9EG7 and pyrintegrin as well as by the novel antibodies. a3b1 agonists also showed increased cell adhesion and reduced cell migration *in vitro*. Mapping of the antibodies using various integrin chimeras showed that they selectively bound to the a3 head-domain, away from the ligand binding pocket.

Conclusions: We previously reported that activation of podocyte-expressed integrin a3b1 increases podocyte adhesion to matrix proteins and protects cells from damage. Here, we show that novel, integrin a3b1-directed allosteric agonist antibodies can be used to reinforce podocyte adhesion to the basement membrane. Data from our currently ongoing *in vivo* efficacy studies will provide further evidence of the therapeutic efficacy of this approach as a novel therapeutic strategy against a variety of glomerular diseases.

SA-PO1014

Expression and Modulation of SGLT2 in Human Podocytes: Not All in Tubule

Marta Riera,[1] Eric Galdón,[1] David S. García,[1] Ana A. Fajardo,[1] Cristina C. Milan,[1] Claudia M. Rosco,[1] Eva Rodriguez,[2,1] Marta Crespo,[2,1] Clara Barrios.[1,2] GREN. *[1]Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain; [2]Hospital del Mar, Barcelona, Spain.*

Background: Inhibitors of the sodium-glucose cotransporter type 2 (iSGLT2) modify important non-glycemic pathways that lead to the protection of target organs. Its renoprotective pleiotropic effects in CKD, associated or not with diabetes, justifies further studies to elucidate the mechanisms of action (MoA) of these drugs. Although the co-transporter is mostly expressed in the proximal tubule, its location and function in other cells, potential therapeutic targets for inhibitor drugs, has not been well studied. We explored the presence of SGLT2 in human podocyte cells and whether it is modified in different situations of cellular stress.

Methods: Differentiated immortalized human podocytes were cultured under different experimental conditions for 24 or 48 h: Normoxia (Control); Normoxia + High concentration of glucose (HG); Hypoxia+2h Reoxygenation(H) and the combination H+HG. We also incubated with 0.1uM Dihydrotestosterone (DHT). SGLT2 gene expression was determined by quantitative PCR and SGLT2 protein was detected by Western Blot (WB) and immunofluorescence (IF).

Results: Sglt2 gene expression was detected with an increase after 24h of exposure to HG. Protein expression by WB showed a non-significant increase after 48h of exposure to HG and hypoxia, which was significant with co-incubation with DHT. The IF measured by intensity of area did not show an increase in the protein expression of the transporter under HG incubation. However, protein expression increased under all hypoxia conditions: Control 50.05±3, Hypoxia 140±16.3 ($p<0.05$ vs control) and HG+Hypoxia 253±21.29 ($p<0.001$ vs control).

Conclusions: Our data suggest that podocyte may be one of the therapeutic targets on which the iSGLT2 are acting. The experimental conditions described did not show differences in the expression of the transporter before the single stimulus of glucose, but they did under hypoxia and the combination Hypoxia-high glucose. In addition, co-incubation with testosterone seems to enhance the expression. Studying the MoA of iSGLT2 will open better comprehension of the kidney pathophysiology, particularly in the podocytopathies, regardless of diabetes.

SA-PO1015

A Case of Steroid Refractory Lupus Podocytopathy: Is Glucocorticoid Monotherapy Sufficient?

Cameron T. Lawson,[1] Brent J. Portz.[2] *[1]East Carolina University, Greenville, NC; [2]Eastern Nephrology Associates PLLC, Greenville, NC.*

Introduction: Lupus Podocytopathy (LP) is a rare, but clinically impactful, manifestation of Systemic Lupus Erythematous (SLE). Accepted management of LP, Minimal Change (MC) and FSGS - subtypes alike, utilizes glucocorticoid (GC) monotherapy for proteinuria suppression. We present a case of high-grade podocyte effacement LP with MC subtype refractory to conventional GC management requiring the addition of an immunosuppressive agent.

Case Description: 38 yo female with SLE and no chronic kidney disease presented with nephrotic syndrome and acute kidney injury. Creatine on presentation was 5.7mg/dL and urine protein:creatinine ratio 11g. Serologies demontrated +ANA > 1:640 and +dsDNA. Renal biopsy was performed and suggestive of LP - MC subtype. Electron Microscopy: diffuse (90%) visceral epithelial foot process effacement; no endothelial tubuloreticular inclusions or subendothelial immunocomplex deposits were noted (Figure 1). Light Microscopy and immunofluorescence were unremarkable for chronicity or proliferative nephritis. High-dose prednisone was initiated at 1mg/kg. No significant change in nephrotic syndrome was observed despite 4 months of prednisone monotherapy. Mycophenolate Mofetil (MMF) was subsequently incorporated achieving complete remission of proteinuria and return to baseline creatinine.

Discussion: Small retrospective studies evaluating LP have suggested GC monotherapy should be successful in achieving clinical remission, especially in MC subtypes. The case presented suggests the addition of a non-glucocorticoid agent may be required to mitigate the proposed pathogenic cytokine and T-cell dysfunctions. Factors such as high-grade podocyte effacement and heavy proteinuria should prompt consideration for empiric dual-agent immunosuppression. Larger-scale randomized studies are needed to demonstrate the clinical and pathologic criteria determining single vs. dual immunosuppressive therapy for LP.

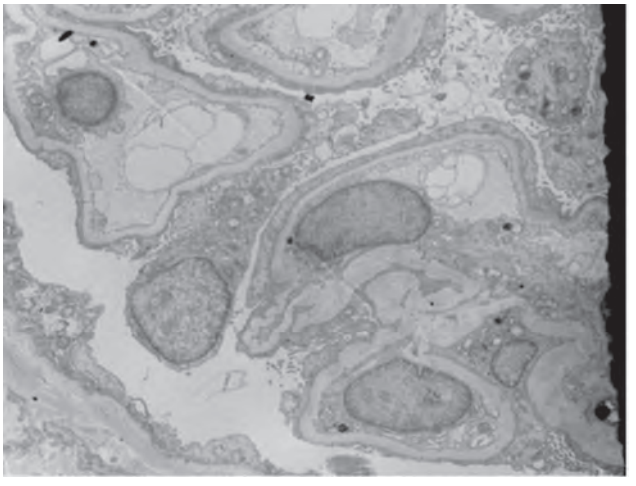

Figure 1 Electron Microscopy

SA-PO1016

A Case of Steroid-Resistant Focal Segmental Glomerulosclerosis in a Patient with a Heterozygous Mutation of COL4A3 Gene Variant of Uncertain Significance

Mark Rudy,[1] Katherine Donaldson,[1] Laura Biederman,[2] Sadiq Ahmed.[1] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]The Ohio State University, Columbus, OH.*

Introduction: Focal segmental glomerulosclerosis (FSGS) is a histopathological lesion that can manifest as severe hypertension, proteinuria, and nephrotic syndrome. FSGS can be a primary disorder or a secondary process related to medications, viruses, or genetic mutations. In this case, a 21-year-old patient presents with nephrotic syndrome secondary to collapsing FSGS with a heterozygous mutation of the COL4A3 gene.

Case Description: A 21-year-old black male presented with nephrotic syndrome. Labs revealed urine protein to creatinine ratio (UPCR) of 6.9 g/g, hematuria with 21-50 RBC/hpf, serum albumin of 1.1 g/dL, and serum creatinine of 1.2 mg/dL. A kidney biopsy showed minimal change disease. He was treated with high dose prednisone and tacrolimus. At 8 weeks, the patient had a UPCR of 14.5 g/g, serum albumin of 0.8 g/dL, and serum creatinine of 7.1 mg/dL. A second kidney biopsy was performed, showing collapsing FSGS with normal thickness of the glomerular basement membrane (Figure 1). Infectious work-up for HIV, hepatitis A, B, and C was negative. A Renasight kidney

genetic panel revealed a heterozygous mutation (p.Leu648Ile) of the COL4A3 gene with autosomal dominant and autosomal recessive inheritance patterns. It is a variant of uncertain significance, absent from the Broad gnomAD dataset. Patient was started on hemodialysis after failing immunosuppressive management.

Discussion: Heterozygous mutations of COL4A3 in patients with treatment-resistant FSGS with a normal glomerular basement membrane have been reported in the literature. Recognizing new genetic variants will help with developing future therapies and avoiding ineffective immunosuppression. More research will be necessary in this field.

SA-PO1017

De Novo Relapsing Podocytopathies Following Novel COVID-19 Infection: A Case Series

Omid Vadpey, Man Kit Michael Siu, Antoinette Abdelmalek. *University of California Irvine, Irvine, CA.*

Introduction: COVID-19 Infection can result in significant multi-system disease, including pneumonia and renal pathologies. Thirty published articles have shown wide yet limited variety of underlying pathologies including collapsing FSGS, minimal change disease, and TMA following infection and vaccination. Our case series reintroduces discussion for unique podocytopathies following COVID-19 infection and vaccination, with relapsing MCD proteinuria, resistant MCD, and TIPS variant FSGS.

Case Description: Our first case is a 22 year old female, with no past medical history, who had an initial presentation of abdominal distension, extremity edema, nausea, and novel COVID-19 positivity, with a 24 urine protein of 5.3g, and secondary serologies negative. Her renal biopsy showed MCD phenotype. Her proteinuria initially responded to prednisone therapy, but relapsed secondary to a taper, requiring rituximab, with remission over 3 months. For this second case, a 36 year old male with a history of mast cell activation syndrome, thin basement membrane nephropathy, anabolic steroid use, presented with lower extremity edema and proteinuria of microalbumin to creatinine ratio of 4.5g, with kidney biopsy demonstrating TIPS variant FSGS, following COVID-19 infection positivity. Patient with poor tolerance to tacrolimus and prednisone due to adverse drug reactions, pending evaluation for sparsentan and rituximab. The third case is a 43 year old female with a history of APLS, presented with swelling, proteinturia, following COVID-19 infection, found to have a 24 hr urine protein of 10.7 grams. Patient initially responded to prednisone, however, had flare of proteinuria following taper, and COVID-19 vaccinations. Course unresponsive to cyclophosphamide treatment, with minimal responsiveness to rituximab, however given anticoagulation for APLS, repeat biopsy deferred.

Discussion: This case series reinforces an association between COVID-19 infection, vaccination and podocytopathy. However, it also provides groundwork for exploration of resistant and relapsing nephrotic syndromes, and the utility in early biopsies for early treatment. This raises the question whether there are long term effects of COVID-19 on renal health, and if COVID-19 induced nephrotic syndrome deserves its own treatment guidelines over traditional therapies.

SA-PO1018

Mapping the Molecular Atlas of Podocyte Response to Glucocorticoids Using Multi-Omics Analyses

Martijn van den Broek,[1,2] Bartholomeus T. van den Berge,[1,3] Michiel F. Schreuder,[2] Bart Smeets,[1] Jitske Jansen.[4] Smeets Lab. *[1]Department of Pathology, Radboud University Medical Center, Nijmegen, Netherlands; [2]Department of Pediatric Nephrology, Radboud University Medical Center, Amalia Children's Hospital, Nijmegen, Netherlands; [3]Department of Nephrology, Radboud University Medical Center, Nijmegen, Netherlands; [4]Institute of Experimental Medicine and Systems Biology. RWTH Aachen University, Aachen, Germany*.

Background: Glucocorticoids are the mainstay of therapy for idiopathic nephrotic syndrome (iNS). Glucocorticoids have been found to directly influence podocyte behaviour and morphology, but the exact mechanism is unknown. Understanding this mechanism may help to identify targets for more effective treatment options with fewer side effects compared to glucocorticoids. We established an animal and kidney organoid model of steroid-sensitive NS to dissect the molecular mechanisms of glucocorticoids on podocytes using single-cell ATAC and RNA sequencing.

Methods: We used the puromycin aminonucleoside (PAN) rat model using one intravenous injection of PAN (10mg/100g) and daily intraperitoneal injections of prednisolone (1.5mg/100g). Human induced pluripotent stem cells were used to make kidney organoids, which were injured to various degrees using Adriamycin (ADR; ranging 0.5-2.5 ug/mL) or PAN (ranging 25-100ug/mL) and rescued with prednisolone (ranging 5-100 ug/mL). Single-cell sequencing was performed using the 10X genomics platform.

Results: Increased proteinuria, foot process effacement and increased podocyte specific desmin-protein expression were observed after PAN injection in rats. The injury was partially rescued by prednisolone treatment, whereas higher doses of prednisolone showed more proteinuria and desmin expression. Prednisolone treatment was not able to rescue more severe injury (by higher PAN injection). At the moment we are analysing single-cell ATAC and RNA sequencing data to identify responses in the podocytes to prednisolone. ADR and PAN can both be used to injure podocytes in kidney organoids, confirmed by western blot for autophagy markers and immunofluorescence for podocyte markers and caspase 3. Currently, rescue with prednisolone is tested before single-cell RNA sequencing is used to map molecular changes in the rescued podocytes.

Conclusions: We established a partially glucocorticoid-responsive *in vivo* model of NS and are currently performing single-cell sequencing to unravel mechanisms involved in prednisolone-induced podocyte recovery. Interestingly, high doses of prednisolone have adverse effects, and when the injury is too severe it cannot be rescued with prednisolone. In human kidney organoids, podocytes can be injured with ADR or PAN and recovery is being tested at the moment.

SA-PO1019

Nephrotic Syndrome from Primary Amyloidosis Can Be Linked with Multiple Myeloma: A Rare Presentation of a Case

Masuma Islam,[1,2] Raquel Hoopes,[3] Monzurul H. Chowdhury.[1] *[1]St Mary's Hospital, Waterbury, CT; [2]Yale Affiliated Hospitals Program, New Haven, CT; [3]Quinnipiac University, Hamden, CT*.

Introduction: Nephrotic syndrome from primary amyloidosis can co-exist with multiple myeloma on rare occasions. Early diagnosis and Appropriate management is crucial for the prognosis of these patients as the combination can reduce life expectancy.

Case Description: A 61-year-old female with PMH of Type 2 DM, HTN was seen for nephrotic range proteinuria detected by PCP screening. Her DM and HTN have been well-controlled for over 10 years. She had no complaints. Physical examination was unremarkable. She has had microalbuminuria since 2017 but developed significant proteinuria and hypoalbuminuria over the last year. A renal ultrasound was done which showed normal kidneys. Laboratory tests showed normal kidney function. Serum electrophoresis revealed monoclonal gammopathy and urine immunofixation showed monoclonal lambda plus IgG lambda fragments. Renal biopsy showed amyloidosis with randomly elevated fibrillary structure. Bone marrow biopsy showed mildly hypercellular marrow with 30% plasmacytosis. Flow cytometry showed lambda light chain. The patient was diagnosed with asymptomatic multiple myeloma and amyloidosis presenting as nephrotic syndrome. She was treated with daratumumab plus CyBorD, which includes cyclophosphamide, bortezomib, and dexamethasone. Over several months, her serum albumin levels have increased and the lambda light chain has decreased.

Discussion: Multiple myeloma (MM) is a malignant plasma cell disorder characterized by uncontrolled proliferation and infiltration of monoclonal plasma cells to the bone marrow. MM is observed concomitantly with amyloidosis in 12-15% of cases 1. Amyloidosis refers to the abnormal deposition of immunoglobulin light chains throughout body tissues. This case highlights a rare but possible scenario of asymptomatic multiple myeloma and amyloidosis that presented as nephrotic syndrome. Diagnosing asymptomatic multiple myeloma and amyloidosis can be challenging, as patients may have no significant symptoms. Further research is needed to investigate which types of patients are at risk. In this case, the patient was diagnosed following routine urine screening for diabetic nephropathy, emphasizing the importance of screening for these conditions. Treatment for asymptomatic multiple myeloma and amyloidosis largely overlaps, focusing on reducing abnormal proteins and managing complications such as renal damage.

SA-PO1020

Novel Anatomic and Macromolecular Models Define Realistic Glomerular Barrier

Robert L. Luke. *Maine Medical Center, Portland, ME*.

Background: The glomerular barrier has been studied extensively using the polysaccharides dextran and Ficol, both modeled as rigid impervious spherical particles. Recent glomerular reconstructions reveal that afferent and efferent glomerular arterioles are joined by non-communicating branches; these parallel tubes are combined into a single uniform cylindrical filter composed of the two most restrictive layers of the glomerular capilary wall, basement membrane and visceral epithelial cells joined by slit diaphragm.

Methods: The classic matrix formulation is modified for flow dependent solute size because water penetrates partial draining polysaccharides such as dextran, but not non-draining proteins; linear regression yields fiber density from slope and transepithelial shunt from intercept. This model is introduced with the permeability of α1acidglycoprotein, albumin, transferrin, IgG, and α2macroglobulin in newly reported patients with primary glomerular disease and completed using appropriate hydrostatic pressures, vascular dimensions, and the permeability of dextran, Ficoll, albumin, and IgG in similar patients obtained from the literature.

Results: Fiber density was similar to fiber density reported for islolated basement membrane and was essentially the same in controls and patients; epithelial shunts

were proportional to total urinary protein excreted, fiber density was not. Effective polysaccharide size decreased when confined by fibers in basement membrane and when confined by streamlines in slit pore. Four-fold higher fiber density encountered by small polysaccharides compared to proteins and large polysaccharides reflect the stratified nature of the glomerular basement membrane and define two pathways through the glomerular capillary wall, a selective route direct through lamina densa and slit diaphragm, a non-selective indirect route through more lamina rara externa and infrequent widely spaced epithelial defects. Filtration area was similar to reported anatomic measurements in controls and was decreased in proportion to histologic abnormality in patients.

Conclusions: Dextran and Ficoll are more permeable than similar size proteins such as albumin and IgG because moving water penetrates, rearranges, and aligns chemically similar polysaccharides. In disease the basement membrane is preserved, but the visceral epithelium is not.

The Expression Profile of Complements in Human Renal Mesangial Cells, Endothelial Cells, Podocytes, and Proximal Tubular Epithelial Cells

Yueming Gao, Jin Ma, Zhenling Deng, Yue Wang. *Department of Nephrology, Peking University Third Hospital, Beijiing, China.*

Background: More and more evidence indicated that the kidney was a notable source of complements. We aimed to explore the expression profile of complements in human renal mesangial cell (HRMC), glomerular endothelial cell (HRGEC), podocyte (HPC), and proximal tubular epithelial cell (PTEC) under physiological conditions.

Methods: Single-cell RNA sequencing (scRNA-seq) by a 10xGenomics Chromium system was used to identify the transcription of 30 complement genes in HRMCs, HRGECs, HPCs, and PTECs. RT-PCR was used to verify the expression of complement genes in cultured primary HRMC and HRGEC, and in HPC and PTEC cell lines. Immunofluorescence was used to confirm the protein expression of several key complements.

Results: By scRNA-seq, the transcription of nearly all complement genes was found in HRMCs, HRGECs, HPCs, and PTECs, and the expression of complement regulatory proteins was highest. RT-PCR confirmed the transcription of C1S, C1R, C4, CFD, MBL2, MASP1, MASP2, C3, C5, CFI, DAF, CD46, CD59, protein S, and C3AR1 in cultured cells. Immunofluorescence verified the expression of C3, DAF, CD46, C4BPB, and CD59.

Conclusions: Under physiological conditions, HRMCs, HRGECs, HPCs, and PTECs express multiple complements involved in three activation pathways.

Membranous-Like Glomerulopathy with Masked Monoclonal Deposits in a Patient with Class 5 Lupus Nephritis: A Case Report

Mohammed N. Alkhulaifawi. *Prolato Clinical Research Center, Houston, TX.*

Introduction: Membranous-like glomerulopathy with masked IgG kappa (k) deposits is a pattern of immune complex deposition characterized by masked deposits that show IgG k restriction and are subepithelial and mesangial by electron microscopy. We present a case of a patient with SLE and biopsy-proven class 5 lupus nephritis whose repeat biopsy showed MMMD.

Case Description: A 26-year-old Hispanic female was admitted for the evaluation of persistent proteinuria. She was diagnosed with systemic lupus erythematosus (SLE) in 2015 and underwent a kidney biopsy in 2019 for proteinuria >1g that return with positive dsDNA, anticardiolipin antibody (IgG and IgM), and low C4. Initial biopsy was reported as "Membranous Glomerulonephritis consistent with class 5 Lupus Nephritis. The IgA was Glomeruli with focal segmental trace peripheral granular staining, IgG was Glomeruli with diffuse and global, peripheral granular staining 3+, IgM was Glomeruli with diffuse, segmental to global, mesangial, and peripheral granular staining 2+, C3 was Glomeruli with focal and segmental weak peripheral staining, arterioles +, C1q was Glomeruli with diffuse and global, peripheral granular staining 1+ to 2+. She volunteered to participate in a clinical trial for lupus nephritis in mid-2023, her labs were positive for dsDNA, low C4, and proteinuria >1g. FLC ratio indicates that Kappa and Lambda Glomeruli with diffuse and global, peripheral granular staining 3+, tubular protein droplets are positive, the second renal biopsy was done at this visit that reported as Membranous Glomerulonephritis, consistent with Lupus Class V Given the new finding of MMMD, a search for monoclonal gammopathy was initiated looking for flow cytometry, the serum protein electrophoresis (SPEP), and serum-free light chains, all of which were reported as negative (see table). Given the negative workup for Monoclonal gammopathy/MGRS, the MMMD was considered secondary to lupus nephritis, a rarely reported renal manifestation of Lupus Nephritis. She is currently on Mycophenolate, Hydroxychloroquine, Lisinopril, and Hydrochlorothiazide, based on recent lab results there is no significant improvement in her proteinuria.

Discussion: In conclusion, patients with SLE can develop Membranous glomerulonephritis with masked monoclonal deposits as a renal manifestation of the SLE in addition to classic class 5 lupus nephritis.

SA-PO1023

The Decrease of the Filtration Slit Density, Not Proteinuria, Is the Early Indication of Filtration Barrier Dysfunction

Nicole Endlich,[1,4] Christos E. Chadjichristos,[2,3] Christos Chatziantoniou,[2,3] Nihal Telli,[1] Vedran Drenic,[1] Tim Endlich.[1] *[1]NIPOKA GmbH, Germany, Germany; [2]INSERM UMR S 1155, Hôpital Tenon, Paris, France; [3]Faculty of Medicine, Sorbonne University, Paris, France; [4]Department of Anatomy and Cell Biology, University Medicine Greifswald, Greifswald, Germany.*

Background: Intact podocyte foot processes (FP) are essential for a proper slize selective filtration. Changes in FP morphology are thought to be the first event leading to proteinuria, but this has yet to be proven. Since FP are below the optical resolution of a light microscope, changes are studied on ultrathin sections by electron microscopy. Here, we show the relationship between morphology and proteinuria using podocyte exact morphology measurement procedure (PEMP), which is a 3D-SIM-based procedure.

Methods: Mice were treated with NTS and sacrificed 24, 48, and 72 h after injection. 3D-SIM was done on podocin and integrin co-stained standard formalin-fixed and paraffin-embedded kidney sections (3 μm). The filtration slit density (FSD) was measured by PEMP (Siegerist, 2017). Electron microscopic analysis were done on glutaraldehyde fixed tissue and processed using standard procedures. Albumin to creatine ratios were also analyzed.

Results: We have found, that mice developed moderate proteinuria 48 h after NTS injection. Using PEMP, we found that the FSD was already significantly reduced in NTS-treated mice at 24 h compared to control-injected mice. Transmission electron microscopy analysis confirmed the presence of these structural alterations, indicating that effacement of the podocytes serves as the initial indication, followed by the onset of proteinuria.

Conclusions: PEMP analysis of standard histological sections from NTS-injected and control mice demonstrated that the first event in the functional loss of the size selectivity of the filtration barrier is the effacement of FP morphology, followed by detectable proteinuria. Therefore, the assessment of the FSD is a promising strategy for early and accurate detection of a loss of filtration barrier integrity, providing opportunities for faster and precise diagnostics.

Expression Evaluation of CD2AP, ITGA3, and ITGB1 in Podocyte Cell Culture After Albumin Overload with and Without Puromycin-Aminoglycoside Damage

Mara S. Guaragna,[1,2] José R. Alves Troleze,[1] Jackeline P. da Silva,[1] Marcela L. Souza,[1] Felipe R. de Oliveira,[1,3] Heber Antonio,[1] Luana dos Santos,[1] Taís N. Mazzola,[1,3] Adriana S. Torsoni,[4] Vera Maria S. Belangero,[2] Maricilda P. de Mello.[1] *[1]State University of Campinas, Center for Molecular Biology and Genetic Engineering (CBMEG), Campinas, Brazil; [2]Universidade Estadual de Campinas Faculdade de Ciencias Medicas, Campinas, Brazil; [3]State of University of Campinas, Growth and Development Laboratory, Center for Investigation in Pediatrics (CIPED), School of Medical Sciences, University of Campinas, Sao Paulo, Brazil, Campinas, Brazil; [4]State University of Campinas, Faculty of Applied Sciences, Limeira, Brazil.*

Background: Proteinuria is considered a prognostic marker for kidney disease and one of the main symptoms of podocytopathies. Several molecules participate in the maintenance of glomerular filtration barrier, including the CD2-associated protein (CD2AP) present in the slit diaphragm and the α3β1 integrin in the basal membrane of podocytes. This study aimed to evaluate the relative expression of *CD2AP, ITGA3* and *ITGB1* genes after overload of albumin in podocytes *in vitro.*

Methods: Conditionally immortalized human podocytes were exposed to progressive concentrations of albumin (0, 3, 20 and 40 mg/ml) for 24 hours under two conditions: with or without 12 hours of 15 ug/uL of puromycin aminoglycoside (PAN) treatment. We evaluated *CD2AP, ITGA3* and *ITGB1* genes relative expression through qPCR (n=3). The Friedman test was used to compare the different albumin exposures with and without PAN ($p<0.05$).

Results: The fold change of *CD2AP, ITGA3* and *ITGB1* genes are presented in Table 1. No significant difference was found among the albumin exposures, neither with nor without PAN ($p>0.05$).

Conclusions: In the condition here studied, albumin overload have not modulated *CD2AP, ITGA3* and *ITGB1* genes.

Funding: Government Support - Non-U.S.

Significance of Single-Point Cystatin C Measurement

Abutaleb A. Ejaz,[1,2] Evan I. Fisher,[1] Nazli Atefi,[1] Zain Haq,[1] Taylor R. Moody,[1] Stephen L. Seliger.[1,2] *[1]University of Maryland Baltimore, Baltimore, MD; [2]VA Maryland Healthcare System, Baltimore, MD.*

Background: Single-point serum Cystatin C in the absence of prior reference points has resulted in difficulties in interpretation of changes in kidney function. We investigated the correlation between Cystatin C and prior year change in creatinine (SCR) based eGFR for which multiple datapoints were available.

Methods: Simultaneously measured SCR and Cystatin C and their respective eGFRs were analyzed.

Results: 33 SCR-Cystatin C pairs were available for analysis. Patient characteristics included: mean age 72.1±8.7 years, 90.9% male gender, 84.8% African American race, prevalence of hypertension 90.9%, diabetes 48.4%, BMI 28.8±6.2, SCR 2.1±0.8mg/dL, eGFR CKD-EPI 41.8±14.9mL/min, Cystatin C 2.1±0.7mg/dL and Cystatin-eGFR 35.6±14.6mL/min. The mean difference in SCR-Cystatin was 0.00±0.41mg/dL. Mean rate of prior year eGFR decline was 2.4±4.1mL/min/year. SCR-Cystatin C demonstrated good correlation, as did eGFR CKD-EPI and Cystatin-eGFR. Although statistically significant, Cystatin C and prior year eGFR CKD-EPI changes demonstrated poor correlation. There were no significant correlation between delta SCR-Cystatin and delta eGFR CKD-EPI – Cystatin eGFR, Cystatin-BMI. Significant inverse correlation was observed between Cystatin C and eGFR CKD-EPI ($R^2=0.69$, $p<0.001$.

Conclusions: In a small sample of CKD patients, serum Cystatin C, while well correlated with simultaneously measured SCR and GFR, was a poor indicator of prior year change in GFR.

Evaluation of Plasma Oxalate Measurements

Lila Cardozo,[1] Kerry A. Pierce,[2] Nadim Zaidan,[1] Xiaozhong Xiong,[1] Clary B. Clish,[2] Lama Nazzal.[1] *[1]NYU Langone Health, New York, NY; [2]Broad Institute, Cambridge, MA.*

Background: Oxalate is a uremic retention solute that accumulates in end-stage kidney disease since it is not efficiently removed by hemodialysis (HD). This increased plasma oxalate (POx) has been associated with higher cardiovascular (CV) mortality in HD patients. Oxalate is usually measured by oxalate oxidase methods, however, multiple large trials are now measuring metabolites using global metabolomics platforms allowing a great opportunity to mine data and identify associations between POx and CV outcomes. Our goal was to evaluate the congruence between targeted and untargeted methods.

Methods: We assessed oxalate in plasma samples previously collected during the pretreatment phase for a study evaluating inulin in HD patients (PMID: 35369018). In this post-hoc analysis, we measured POx in plasma samples for 12 HD patients, both at baseline and after 8 weeks. We first used the Trinity Oxalate Kit, with a protocol adapted for plasma samples. We then sent the same samples to the Broad Institute for HPLC coupled with Mass Spectrometry (MS). This metabolomics assessment was done in duplicate, and on thawed and non-thawed samples. Oxalate measurements were then calculated from a calibration curve using isotopically-labeled oxalic acid.

Results: First, based on the colorimetric output, POx ranged from 115 μM to 23 μM with a mean of 57.38 μM ± 27.94 μM. Based on the MS output, POx ranged from 17 to 31μM with a mean of 22.98 μM ± 3.17 μM, which is within the range described in the literature. POx levels were stable over 2 months for each patient. This low within-subjects variability highlights the stability of POx levels in the HD population. Regarding temperature effect, thawed sample values were 4% higher on average than non-thawed samples. Finally, a comparison of the colorimetric and the MS methods showed consistently higher colorimetric POx levels, on average 2.43-fold higher.

Conclusions: By quantifying oxalate in HD patients using a commercial metabolomics platform and an enzymatic bench assay, we identified a discrepancy between both measurements. Leaving the samples at room temperature did not majorly affect the MS output. Next steps will involve the optimization of the bench colorimetric assay.

SA-PO1027

Purple Haze: An Uncommon Presentation of a Common Condition

Alexandra Schwarz, Ruchika Batwara. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Urine discoloration is a well-known clinical sign that often indicates an underlying pathology. However, purple-colored urine is a visually striking and rarely observed phenomenon that can cause great concern for patients and healthcare workers when encountered.

Case Description: An 80-year-old man with a chronic suprapubic urinary catheter presented with altered mental status following a fall. The patient's catheter was draining purple urine on arrival (as seen in Figure 1). Initial labs showed acute kidney injury (creatinine: 9.55 mg/dL) with previously normal creatinine at baseline, mild rhabdomyolysis (peak creatine phosphokinase: 2,734 U/L), and leukocytosis (white blood cells: 16.3 K/uL). Urinalysis revealed a large amount of leukocyte esterase and >182 white blood cells per high-power field. Renal and bladder imaging did not show any obstruction. The patient was managed as presumed urosepsis and promptly treated with meropenem and vancomycin, fluid resuscitation, and replacement of the suprapubic catheter. Antibiotics were started before sending cultures, so there was no growth observed in urine and blood cultures. The urinary catheter was draining yellow urine the following day and renal function returned to baseline during hospitalization.

Discussion: Purple Urinary Bag Syndrome (PUBS) is a rare phenomenon caused by certain bacteria that produce enzymes that metabolize tryptophan into indigo (blue)

and indirubin (red) pigments, resulting in purple urine color. Risk factors include old age, female gender, alkaline urine, constipation, and the use of plastic urinary bags. The discoloration itself is benign but timely recognition of this uncommon presentation of urinary tract infection is crucial to ensure prompt diagnosis and treatment while avoiding unnecessary investigations.

SA-PO1028

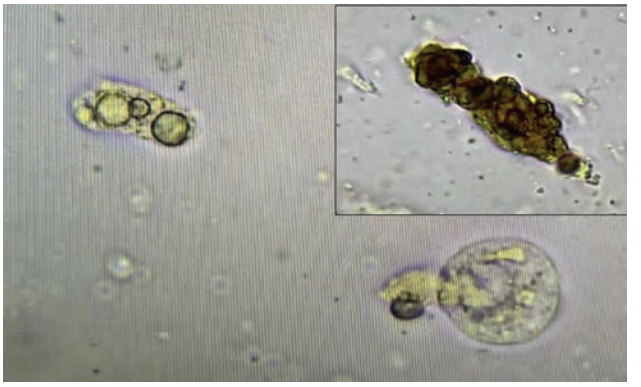
Melanuria: Black Urine as a Presenting Sign of Metastatic Melanoma

Patricia Nogueira De Sa, Asheen Zariat, Rachel Shulman, Amanda K. Leonberg-Yoo. *University of Pennsylvania, Philadelphia, PA.*

Introduction: The worldwide incidence of malignant melanoma has been increasing at an average annual rate of 5%.[1]We describe a case of melanuria as an initial sign of metastatic melanoma in a previously healthy young woman.

Case Description: A 24-year-old female with no medical history presented with two weeks of abdominal pain. On admission, she had mild tachycardia. Physical exam was notable for abdominal tenderness and lower extremity edema. Blood work showed creatinine of 1.5 mg/dL, lactate 19mmol/L, LDH 5000 IU/L. Amber urine that turned black upon exposure to air. Urine studies were negative for hemoglobin and bilirubin and microscopy showed dark brown casts and atypical cells with dense inclusions exhibiting a dark rim. Abdominal CT showed multiple hepatic and splenic lesions, suspicious for neoplasm. Liver biopsy showed BRAF-negative metastatic melanoma. Despite treatment, the patient expired on hospital day 13th.

Discussion: Melanuria is the urinary excretion of melanin precursors leading to black discoloration of the urine. It is present in up to 15% of cases of malignant melanoma and typically occurs with diffuse melanosis.[2,3]Urine sediment may show atypical pigment-laden cells and dark brown casts. Our patient had dark casts with atypical cells suggesting melanin-containing tubular epithelial cells and histiocytes. Although we did not test her urine for melanin precursors, we proposed the melanuria resulted from extensive tumor necrosis causing cytolysis of melanocytes and subsequent excretion in the urine. This case demonstrates that metastatic melanoma should be considered in the differential diagnosis of black urine.



SA-PO1029

No Need for Beef: A New Vegetarian Test to Measure Renal Functional Reserve

Juan P. Huidobro,[1] Rodrigo Sepúlveda,[1] Jorge E. Vega.[2,3] *[1]Pontificia Universidad Catolica de Chile, Santiago, Chile; [2]Universidad de Valparaiso, Valparaiso, Chile; [3]Hospital Naval de Vina del Mar Almirante Nef, Vina del Mar, Chile.*

Background: Renal functional reserve (RFR) corresponds to the physiologic increase in glomerular filtration rate (GFR) after a stimulus. It can be measured to evaluate living kidney donor candidates, risk and recovery of AKI in critical care situations and even risk of pre-eclampsia. The most frequently used test to measure RFR is by ingesting an oral load of protein from animal meat. We aimed to develop an alternative test to measure RFR without the need of meat consumption using L-arginine, a precursor of nitric oxide. Herein, we present the results of a pilot study.

Methods: A 4-hour creatinine clearance (ClCr) was measured in 7 healthy individuals in whom eGFR by CKD-EPI equation was 103.9 mL/min/1.73m^2 (range 92.3-113.4) after a day of plant-based diet and normal ingestion of fluids. The next day, at the same hour, a new 4-hour CrCl was measured, this time after the ingestion of 5 grs of L-Arginine 1 hour before the start of urine collection. RFR was calculated as the difference between indexed post-L-Arginine CrCl and indexed basal CrCl.

Results: Median basal CrCl was 124.6 mL/min/1.73m^2 (range 54.7-162). Post-L-Arginine CrCl was significantly augmented to 145.4 mL/min/1.73m^2 (range 81.1-179.7) ($p<0.05$). Median RFR was 20.8 mL/min/1.73m^2 (range -7.6-48.9). No adverse effects were reported.

Conclusions: Evaluation of RFR can be safely done using L-Arginine stimulation and could be considered as an alternative to meat consumption in vegetarian population. This preliminary data needs to be confirmed in a larger cohort. The optimal dosing of L-Arginine for this purpose should be determined in larger studies.

SA-PO1030

Augmented CD36 Stimulation by Fatty Acids Promotes Macrophage Activation and Endothelial Injury in ANCA-Associated Vasculitis

Xiang Zhang, Xiong Z. Ruan, Alan D. Salama. *UCL Department of Renal Medicine, Royal Free Hospital, London, United Kingdom.*

Background: ANCA-associated vasculitis (AAV) is characterised by monocyte/macrophage activation and small blood vessel inflammation leading to organ damage. In some patients, macrophage activation leads to giant cell and granuloma formation, resulting in further tissue damage. CD36 is a transmembrane glycoprotein expressed on various cells, including macrophages and endothelial cells. CD36 is crucial in the modulation of inflammatory processes. However, the role of CD36 in AAV remains understudied.

Methods: Cellular expression of CD36 and endothelial cell activation markers was assessed by FACS and immunohistochemistry on tissue sections. ELISA was used to measure soluble(s) CD36 in serum and cell supernatants. Multinucleate Giant cell(MNGC) formation was investigated using established protocols following Palmitic acid (PA) stimulation of cells with or without CD36 knockdown. Macrophage activation markers were examined using qPCR.

Results: CD36 expression was found to be increased in AAV kidney biopsies on glomerular and tubular macrophages. Additionally, CD36 expression on classical and intermediate monocytes was significantly increased in AAV patients compared to healthy controls. Serum sCD36 was elevated in AAV patients, specifically in the PR3-ANCA subtype, in both remission and active disease. Stimulation of THP1-derived macrophages with PA resulted in an increase in CD36 expression, increased the expression of c-Myc and ATF-2, and generated M1 polarised macrophages with significant MIF production. In addition, there was an increase in MNGC formation. These findings were all attenuated by CD36 knockdown or MIF antagonism. Similarly, PA stimulation of endothelial cells increased CD36 and VCAM expression and promoted MIF production. Co-culture of endothelial cells and macrophages with PA resulted in increased migration of macrophages towards the activated endothelial cells.

Conclusions: AAV patients demonstrate elevated levels of monocyte and sCD36. Stimulation of CD36 by fatty acids promotes inflammatory responses in both macrophages and endothelial cells, potentially contributing to many of the features found in AAV. Targeting CD36 or its downstream effector MIF is a novel therapeutic strategy to be tested in AAV.

Longitudinal Analysis of Urine Metabolomics of Preterm Infants Based on Ultra-High-Performance Liquid Chromatography-Tandem Mass Spectrometry (UHPLC-MS/MS) Technique

Qian Shen, Hong Xu, Sha Hong. *Children's Hospital of Fudan University, Shanghai, China.*

Background: To explore the regular urinary metabolomic characteristics of preterm infants in the early postnatal period and find the association between early metabolic adaptation and urinary metabolism.

Methods: Between June 1, 2021 and September 31, 2022, 36 preterm infants were recruited from the Children's Hospital of Fudan University, urine samples were collected on postnatal day 1 (PND1), PND7) and PND14 respectively, for a longitudinal cohort self-control analysis. UHPLC-MS/MS was used to characterize urinary metabolomic changes at postnatal week 1 and week 2. Multivariate analyses were used to screen for differential metabolites and metabolic pathway.

Results: Widely targeted metabolomic analysis of urine from the first week of postnatal life in preterm infants identified 57 metabolites whose levels were upregulated and 18 metabolites that were downregulated from birth(Fig1). Widely targeted metabolomic analysis of urine from preterm infants at postnatal week 2 revealed that urine levels of 22 metabolites were upregulated and 7 metabolites were downregulated compared to week 1. Metabolic pathways significantly enriched in 29 urinary differential metabolites in the second postnatal week in preterm infants, the gluconeogenesis/glycolysis pathway was the metabolic pathway significantly associated with all urinary differential metabolites in the first 2 postnatal weeks (Fig2).

Conclusions: Urinary metabolic changes in preterm newborns were more pronounced in the 1st week after birth than in the 2nd week, suggesting metabolic adaptation in preterm newborns occurs mainly in the 1st week after birth. Glycometabolism is the key to the changes in urine metabolism in preterm infants during the first 2 weeks of life, and it is hypothesized that the regulation of glucose homeostasis in preterm infants is the focus of their early metabolism and development.

Preservation of Slides of Fixed Urinary Sediment for Educational Purposes

Lauren Cohen,[1] Juan Carlos Q. Velez,[1] Jay R. Seltzer.[2] *[1]Ochsner Health, New Orleans, LA; [2]Missouri Baptist Medical Center, Saint Louis, MO.*

Background: Urine sediment slides for microscopy are best inspected promptly, as drying artifact, the result of evaporation, will occur and limit the time the slide is viable for viewing. Although teaching urine microscopy using stored images of cells, casts, and crystals is useful, there is no replacement for real-time microscopic examination of a urine sediment slide. Thus, we aimed to develop a reproducible method of preserving urine sediment slides.

Methods: Urine specimens from patients at Ochsner Medical Center (New Orleans) and Missouri Baptist Medical Center (St Louis) seen by the nephrology department were randomly chosen based on the presence of distinct urine sediment findings. Specimens were centrifuged and the supernatant discarded. Ten drops of 10% buffered formalin were added to resuspended pellets. After 30 minutes, samples were centrifuged for 2 minutes and remaining supernatant was discarded. The new pellet was resuspended in a solution of 1 drop of Sternheimer-Malbin stain, 2 drops of glycerol, and 1 drop of clear Elmer's® glue. One drop of this mixture was placed on the slide and a coverglass applied. CoverGrip® was painted around the perimeter of the coverglass as a sealant. Slides were examined at regular intervals (24, 48, 96 hours; 1, 2, 4, 8 weeks) and images were captured using SeBaCam®. Slide quality was evaluated for structure retention, stain intensity, and evaporation artifact.

Results: Various cast types (granular, waxy, cellular, vacuolated), acanthocytes, and crystals were captured in the preserved slides across all specimens (n = 12). The integrity of the structures identified on day 1 was preserved up to 8 weeks in all cases. No significant decay in quality was observed over time. Artifacts observed included evaporation artifact, cloudiness, and stain fading. However, none of those factors altered the overall interpretation of the slide. A library of preserved slides was successfully used by the authors in a recent hands-on educational workshop (KidneyCon).

Conclusions: Our novel method of urine sediment slide preservation was effective in preserving the quality and quantity of the findings revealed upon inspection immediately following urine collection. This technique can be implemented in academic centers for educational and clinical purposes. Further studies are required for optimization.

SA-PO1033

New Method of Immunophenotyping of Urinary Cells by Multicolour Flow Cytometry: A Pilot Study

Ivan Rychlík, Peter Habara, Karolína Krátká, Martin Havrda, Renata Lazanska. Nephrology Unit. *Univerzita Karlova 3 lekarska fakulta, Praha, Czechia.*

Background: Podocyturia, non-invasive option, was used to diagnose glomerulopathies(GN), namely fibrosis and glomerulosclerosis, previously detected only by renal histology(RB). Urinary sediment analysis after labelling with antibodies against podocalyxin and podocyte-specific transcription factor WT-1 was proven as clinically useful. Determination of mRNA was used, too, but hardly usable due to high instability.

Methods: Patients(pts) who underwent RB for nephrotic syndrome, regardless of its etiology, were examined before RB. First morning urine sample was collected. Urinary cell concentrates were prepared by ultrafiltration using strainers. Conventional staining protocol was used with panel of antibodies: anti-podocalyxin-PE, anti-CD86-FITC, anti-CD87-BV510, anti-CD24-Pe-Cy7, anti-CD10-PerCp, anti-CD133-APC, anti CD45-APC-Cy7. Heathy volunteers and isotype controls were used. The Hoechst33342 DNA dye was applied to identify cells. Gating strategy:only population of cells binding the DNA dye Hoechst33342 was selected to exclude non-nuclear elements, then exclusion of white blood cells, and then immunophenotypically specific rare cell populations could be observed in scatter plots.

Results: 13 pts with histology: DKD 5x, obesity-related glomerulopathy 2x, IgA nephropathy 5x, ANCA associated vasculitis 1x and 5 healthy controls were examined. Population of PCX+/CD10+/CD133+/CD24+ cells was detected in varying degrees of abundance, as well as a population of PCX-/CD10+/CD133+/CD24+ cells. The former population predominated mainly in patients where the histological findings were dominated by degenerative changes (interstitial fibrosis and glomerulosclerosis). In contrast, the latter population was more prevalent in active inflammatory changes, most notably in AAV and IgAN with the presence of fibroepithelial crescents. None of the above cell populations were present in healthy controls, both isotype controls.

Conclusions: The method significantly reduces the autofluorescence background of urine samples to remove noise that prevented multi-color analysis of urinary cells on flow cytometer and thus capture different rare populations of urine glomerular cells, which no published approach to urine flow cytometry has yet allowed. The method is inexpensive and offers the potential for non-invasive differential diagnosis and monitoring of therapy. *Supported by COOPERATIO 34.*

SA-PO1034

MUC1 on Urinary Extracellular Vesicles for Detection of Impaired Renal Function

Keiichi Takizawa, Tatsuya Nishimura, Yutaka Harita. *Tokyo Daigaku, Bunkyo-ku, Japan.*

Background: The nephron's various cell types produce urinary extracellular vesicles (uEVs), which have the potential as a promising biomarker resource. Aiming to detect chronic kidney disease (CKD) in its early stage, we performed proteome analysis of uEVs from patients with a congenitally reduced number of functional nephrons and found that pediatric CKD can be detected accurately by the expression levels of molecules such as MUC1 in uEVs (iScience, 2022). In this study, we validated the diagnostic capacity of an ELISA-based test method analyzing uEVs to separate adult individuals with decreased renal function in a Japanese community cohort of the Tohoku Medical Megabank Project.

Methods: Two hundred eleven samples (male 109, female 102) provided were analyzed. The mean age ± SD was 51.2 ± 14.7 years. The expression levels of MUC1 and CD9, a classical exosomal marker, on the surface of uEVs (uEVs_MUC1 and uEVs_CD9) were measured using ELISA plates that enabled the isolation of uEVs and quantitation of expression of molecules. The correlation between the expression levels and clinical parameters was analyzed.

Results: uEVs_MUC1 showed a positive correlation with uEVs_CD9 but not with urinary albumin. As in pediatric patients with kidney diseases, the expression of uEVs_MUC1 was significantly decreased in adult individuals with reduced renal function (eGFR <60 ml/min/1.73m^2) ($P < 0.001$). uEVs_MUC1 had an AUC of 0.88 for separating individuals with eGFR <45 from those with eGFR ≥45 and 0.92 for separating those with eGFR <30 from those with eGFR ≥30. When combined with urinary albumin, the diagnostic accuracy was further enhanced. To further apply this ELISA to clinical testing, we generated a high-titer monoclonal antibody against MUC1, and established a protocol to quantify uEVs_MUC1 in clinical samples.

Conclusions: MUC1 expression in uEVs can be a biomarker of renal dysfunction independent from proteinuria, which was validated in childhood and adult cohorts. Future research will focus on elucidating the mechanism and conducting prospective investigations in order to advance with the development of the uEVs-based noninvasive test technique robustly diagnostic for CKD.

Findings in Urinary Sediment Inspected by Microscopy Several Days After Collection

Serenella A. Velez,[1] Lauren Cohen,[1] Jay R. Seltzer,[2] Juan Carlos Q. Velez.[1]

[1]Ochsner Health, New Orleans, LA; [2]Missouri Baptist Medical Center, Saint Louis, MO.

Background: Textbooks and clinical practice manuals recommend inspection of urinary sediment specimens immediately or within < 2 hours of collection because of presumed loss of specimen quality over time. However, there is no conclusive evidence supporting that recommendation. Based on anecdotal observations, we hypothesized that adequacy of urinary sediments can be maintained way beyond the 2-hour limit.

Methods: An experimental study was conducted utilizing urinary sediment specimens obtained from patients seen by the nephrology inpatient consultation service due to acute kidney injury. Aliquots of the specimens were stored at both room temperature (RT) and at 4^{o}C. Urine microscopy was performed at the time of collection, 24 hours, 48 hours, and 1 week post collection, and assessed for presence of granular casts (GC), waxy casts (WxC), renal tubular epithelial cell casts (RTECC), red blood cell casts (RBCC), acanthocytes, and lipids. Abundance of casts was assessed by an adaptation of the Perazella score (cast number/low power field).

Results: A total of 16 urine specimens were collected and divided into RT (n=16) and 4^{o}C (n=14). Overall, only 4.6% (3/65 data points) revealed a change in density of findings. By 48 hours, GC, WxC, RTECC and RBCC did not change in presence or abundance at either RT or 4^{o}C. By 1 week, 90% (9/10) did not change GC score for both RT and 4^{o}C, 75% (3/4) and 80% (4/5) did not change WxC score at RT and 4^{o}C, respectively, and 83.33% (5/6) and 100% (7/7) did not change RTECC score at RT and 4^{o}C, respectively. For samples with acanthocytes, at RT, 2 did not change in abundance for up to 1 week, whereas 1 changed from 40% to 25% at 48 hours. At 4^{o}C, 1 case did not change in acanthocyte abundance for up to 1 week, whereas 1 changed from 40% to 25% at 48 hours. For samples with lipids, 100% (5/5 at RT, 3/3 at 4^{o}C) maintained lipid presence for up to 1 week.

Conclusions: Our findings challenge the traditional knowledge and demonstrate that immediate inspection of the urinary sediment, although recommended, is not essential in clinical practice. Collected specimens can be kept for later examination in the event that an expert observer is required for corroboration of findings. Further research is necessary to precisely determine at which point urinary sediment quality begins to decay.

SA-PO1036

Urinary Sediment Podocin mRNA Excretion in Healthy Adults

Akihiro Fukuda,[1] Miho Suzuki,[1] Ryo Kurimoto,[1] Jun Okita,[1] Hiroki Uchida,[1] Akiko Kudo,[1] Takeshi Nakata,[1] Yuji Sato,[2] Hirotaka Shibata.[1] *[1]Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan; [2]Takachiho Town Hospital, Takachiho-cho, Japan.*

Background: We have previously reported that the excretion of urinary sediment podocin (U-sed Pod) mRNA is a useful biomarker for the early diagnosis and evaluation of various glomerular diseases. However, no study has been conducted on healthy adults. In this study, we investigated the excretion of U-sed Pod mRNA in healthy adults, including the effects of gender and age.

Methods: We studied 249 healthy individuals (48 in their 20s, 52 in their 30s, 58 in their 40s, 49 in their 50s, and 42 in their 60s or older, including 40 in their 60s and 2 in their 70s; a male-to-female ratio of approximately 1:1) who received health checkups from June 2018 to March 2019 and did not have hypertension (>140/90 mmHg), diabetes (fasting blood sugar >126 mg/dL), albuminuria (U-Alb/Cre >30 mg/gCre), or chronic kidney disease (eGFR > 60 ml/min/1.73m^2) and were not receiving medication. We measured the excretion of U-sed Pod mRNA in spot urine samples.

Results: No significant differences in U-sed Pod mRNA normalized to urinary creatinine (U-sed Pod mRNA/Cre) or U-sed Pod mRNA normalized to urinary sediment aquaporin 2 (U-sed AQP2) mRNA (U-sed Pod mRNA/AQP2 mRNA) were observed among the healthy adults less than 60 years of age. In addition, neither marker was significantly different between the genders. However, U-sed Pod mRNA/Cre excretion was significantly lower in subjects over 60 years of age compared to those less than 60 years (1.9 ± 0.5 M/gCre×10^{-12} vs. 12.4 ± 1.4 M/gCre×10^{-12}, p <0.001). Furthermore, U-sed Pod mRNA excretion was not detected in approximately 30% of subjects over 60 years of age. U-sed AQP2 mRNA excretion was also significantly lower in subjects over 60 years of age, similar to U-sed Pod mRNA excretion.

Conclusions: No age or gender differences were detected in U-sed Pod mRNA/Cre or U-sed Pod mRNA/AQP2 mRNA excretion in healthy adults less than 60 years of age who could be used as normal controls.

Rapid Diagnosis of Urinary Tract Infection by Flow Cytometry-Based Urine Analyser

Ouppatham Supasyndh,[1] Patid Tanaboriboon,[1] Thanapat Punchucherd.[2] Division of Nephrology, Dept of Medicine, Phramongkutklao Hospital, Bangkok, Thailand. *[1]Phramongkutklao College of Medicine, Bangkok, Thailand; [2]Sysmex Thailand Co.,Ltd, Bangkok, Thailand.*

Background: Urinary tract infections (UTIs) are important healthcare problems for hospitalized and community patients. Various bacterial species can cause UTI, the most common of which is the Gram-negative bacilli Escherichia coli. The gold standard for UTI diagnosis remains urine culture, followed by antibiotic sensitivity testing. However, it takes around 48 hours for urine culture to be reported. Therefore, a rapid screening test for UTI is highly desirable to guide clinical decision-making. The Sysmex UF-5000 is a flow cytometry-based automated urine analyzer capable of providing WBC and bacterial counts and the Gram staining of the causative bacteria that positive impact on the rate of antimicrobial resistance. Our prospective cohort study aims to validate the automated flow cytometric analysis using Sysmex UF-5000 for rapid UTI screening and discrimination of gram-positive and gram-negative bacteria, compared to urine culture and conventional Gram staining.

Methods: Midstream urine samples from patients with suspected UTIs were collected in sterile containers. They were then subjected to analysis by Sysmex UF-5000 automated urine analyzer, conventional Gram staining, and urine culture. The correlation and agreement between the different methods were then determined and ROC curve analysis was performed where appropriate.

Results: A total of 285 urine samples were collected from 285 patients for analysis. An almost equal gender distribution was achieved. Out of the 285 patients included, 163 were outpatient, 104 were inpatient, 14 were wards in the ICU, and 4 presented to the emergency department). In total, 140 of 285 samples (49%) yielded ≥ 10^3 CFU/ml bacterial growth (73 with Gram-negative bacteria, 36 with Gram-positive bacteria, 27 with mixed cultures, and 4 with yeast). In comparison, 68 samples (23.9%) yielded ≥ 10^5 CFU/ml bacterial growth on urine cultures. We found that a UF-5000 bacterial count of ≥ 590.3 /uL predicted ≥ 10^5 CFU/ml bacterial growth on urine culture with a sensitivity of 86.8% and specificity of 81.1%. The bacterial discrimination performance of the UF-5000 for GN bacteria was superior to that for GP bacteria.

Conclusions: UF-5000 demonstrated a good potential utility for rapid UTI screening. The instrument's ability to predict Gram-negative bacterial infection is reasonable despite the need for further evaluation.

SA-PO1038

Urinary Immune Complex of V-Set Immunoglobulin Domain-Containing 4 as a Novel Biomarker of Lupus Nephritis

Tianfu Wu,[1] Ramesh Saxena.[2] *[1]University of Houston, Houston, TX; [2]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Lupus nephritis (LN) is a devastating chronic kidney disease (CKD) caused by Systemic lupus erythematosus (SLE). However, to monitor disease activity and predict the risk of LN flare is still challenging, and there is an urgent need to identify novel biomarkers of LN that have high diagnostic or predictive values. In our recent study, by using a quantitative proteome immunoarray, V-set Immunoglobulin-domain-containing 4 (VSIG4) was found siginifcantly elevated in the serum and kidneys of LN patients compared to healthy controls, and could reflect renal pathology of LN. We were interested to ask if VSIG4 was secreted into the urine in LN patients.

Methods: In an intial testing using ELISA, we simultaneously measured the free form, autoantibody, and immune complex levels of VSIG4 in the urine and serum samples from the same LN patients (N = 28), compared to other chronic kidney disease controls (CKD, N = 7) and healthy controls (N = 13).

Results: We found that the free form of VSIG4 was not detectable in the urine of LN or controls by using commercial sandwich ELISA kits. Interestingly, the urinary immune complex of VISG4 (VSIG4 ICx) was detectable in LN and controls. Importantly, the urinary VSIG4 ICx was significantly elevated in the LN patients, compared CKD controls (P-value = 0.031) and healthy controls (P-value = 3.05E-05). Urinary VSIG4 ICx was also significantly increased in the CKD patients compared to healthy controls (P-value = 2.58E-05). In the same patients, the free form of VISIG4 was significantly elevated in LN, compared to CKD contorls (P-value = 2.6E-05) and healthy controls (P-value = 1.14E-10); both serum autoantibody and serum ICx levels of VSIG4 were also significantly elevated in LN compared to healthy controls. By using a Spearman's paired test, the urinary VSIG4 ICx levels were positively correlated with the serum free-form VSIG4 levels ($r = 0.67$, $p < 0.001$). More interestingly, the urinary VSIG4 ICx levels were positively correlated with the following clinical parameters: SLEDAI (Spearman's Rank Correlation Coefficient $r_s = 0.49$, $p = 0.007$), rSLEDAI ($r_s = 0.44$, $p = 0.03$), urine protein/creatinine ($r_s = 0.4$, $p = 0.03$), and white blood cell counts ($r_s = 0.49$, $p = 0.04$).

Conclusions: Urinary VSIG4 immune complex may be a promising novel biomarker of SLE and LN.

SA-PO1039

Profiling of Urinary RNA Biomarkers for CKD with Nanopore Sequencing

Morgan E. Mackenzie,[1] Maria-Eleni Roumelioti,[1] Darren W. Schmidt,[1] Christos Argyropoulos.[1,2] *[1]University of New Mexico School of Medicine, Albuquerque, NM; [2]University of New Mexico Clinical and Translational Science Center, Albuquerque, NM.*

Background: There is a need to develop new biomarkers of kidney dysfunction & damage that are more informative than the estimated glomerular filtration rate (eGFR) & urine albumin to creatinine ratio (UACR). While RNAseq is increasingly being used for biomarker discovery, there are few reports of applications of 3rd generation sequencing platforms (Nanopore) to CKD.

Methods: Urinary RNA from participants in the COMPASS study (PMC5830321) with variable kidney function & UACR was isolated to make cDNA libraries with a novel pipeline for Nanopore sequencing (PALS-NS, https://www.biorxiv.org/content/10.1101/2022.12.16.520507v1). RNA counts were normalized via Analysis of Variance and analyzed via negative binomial mixed effects models (NBMEM, PMC5499834).

Results: 19 cDNA libraries were made from the initial and follow up (12 mo) samples of 7 pts (6F), aged 54 ± 22 yrs with SBP 132 ± 15 mmHg, UACR 48 ± 73 mg/g, eGFR was assessed via the 2021 CKD Epi formulas for Creat (74 ± 35), Beta 2 microglobulin (65.5 ± 30), Creat/Cystatin (86.53 ± 39). Protein coding and long non coding (lncRNA) RNAs were the most frequently encountered RNA species (14-20% and 8-9% respectively). Correlation of the counts between follow up & baseline samples was high (>0.89). NBME estimates of the effects of eGFR on counts were correlated highly with each other, correlated moderately with UACR and not correlated with SBP[fig]. Term analysis mapped the differentially expressed RNAs (>70% lncRNA) to trascriptional factors and the lysine degradation pathway (including several lysine methyltransferases) that has been recently implicated in the pathogenesis of CKD (PMC9283537) and podocyte injury (PMC9086358).

Conclusions: Nanopore sequencing provides a cheap, portable, platform for novel RNA biomarker discovery & quantification in CKD.

Melatonin Increases Survival Through Upregulation of Clock NEAT1 and Enhancer-Associated Histone Modifications in Albumin-Injury Tubular Cells

Chia-Chao Wu,[1] Kuo-Cheng Lu.[2] *[1]Tri-Service General Hospital Department of Internal Medicine, Taipei, Taiwan; [2]Taipei Tzu Chi Hospital, Taipei, Taiwan.*

Background: Melatonin modulates circadian rhythm via the core clock genes, thereby regulating numerous physiological conditions in kidneys. The melatonin-regulated coding RNA is highly identified, it remains unknown whether long noncoding RNAs (lncRNAs) can be modulated by melatonin and exhibit the diurnal rhythm in renal tissue.

Methods: We identify melatonin-regulated clock lncRNAs including *NEAT1*, which are upregulated by melatonin and BMAL1/CLOCK heterodimer in human renal tubular epithelial cells (TECs).

Results: *Neat1* oscillations associated nocturnal change of core clock genes and endogenous melatonin in mouse TECs. Clock *NEAT1* promote TECs proliferation through an increased occupancy of histone 3 lysine 27 acetylation (H3K27ac) and histone 3 lysine 4 mono-methylation (H3K4me1) levels at MKI67 enhancer regions. Molecular studies showed that melatonin enhanced *NEAT1* expression via increasing BMAL1 stability and thereby enrichment on NEAT1 promoter. Treatment of albumin-injured TECs with melatonin alleviated cell death by transactivating clock *NEAT1* and restore the reduction levels of H3K4me1, H3K27ac, core clock genes and MKI67. Using an experimental membranous nephropathy (MN) model, exogenous melatonin treatment ameliorates the proteinuria and hypoalbuminaemia in experimental MN kidneys associated with the increased levels of core clock genes, H3K27ac, Mki67 and Neat1 in TECs.

Conclusions: Collectively, our results suggest that melatonin enhanced cell proliferation in albumin-injured TECs via upregulation of clock *NEAT1* and NEAT1 mediated-changes in histone modifications and MKI67 levels, which has the potential for therapeutic intervention.

SA-PO1041

Single-Cell Transcriptome Atlas in C57BL/6 Mice Encodes Morphological Phenotypes in the Aging Kidneys

Shanzhi Yang. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: C57BL/6 mice are commonly used murine models with the desired genetic background for modification in different research settings. So far, there is still a lack of comprehensive kidney morphology and single-cell transcriptome atlas at various developmental stages of C57BL/6 mice. To provide an interactive set of reference standards for the scientific community, we designed the present study to dissect the kidney from the capillary-loop stage of development till senescence at 30 months of age.

Methods: Eight groups, with five to six mice each, represented embryonic (18.5 days), newborn (1 day), adolescent (1 month), young (3 months), adulthood (6 months), middle-aged (10 months), old (20 months), and senescent (30 months) animals, respectively. Periodic acid-Schiff and silver staining were used to examine the histology of the kidney. The ultrastructure features of the kidney were examined using transmission electron microscopy. Kidney single-cell transcriptome analysis was conducted in three and 30 month-old mice to reveal the gene expression profiles in glomerular cells. Unbiased sampling and quantitation method was used to analyze the glomerular structures.

Results: With age, there was an increase in the glomerular size, the percentage of podocyte foot process effacement, and the extent of mesangial expansion. The number

of Wilm's tumor 1 (WT1) positive podocytes remained stable from the young till 20 months of age. By age 20 months, the number of WT1 positive podocytes was reduced till 30 months of age. Of note, GBM knobs appeared at three months and became frequent with age. The level of urinary albumin to creatinine ratio (UACR) was increased in the senescent mice compared with the maturing and middle-aged mice. Using single-cell transcriptomic data, we assessed cell-type-specific manifestations of different hallmarks of aging, such as changes in the genes of intrinsic renal cells and biological alterations involved with age.

Conclusions: In conclusion, the availability of comprehensive kidney morphology and single-cell transcriptome atlas at various developmental stages of C57BL/6 mice would be a new and significant resource for mechanistic investigations and testing of potential therapeutic interventions.

Funding: Government Support - Non-U.S.

SA-PO1042

Investigation of Temporal Patterns of Biomarker Expression from Different Segments of the Kidneys in Healthy Subjects

Samantha G. Upson,[1] Morgan Greig,[1] Margaret Selesky,[1] Hayrettin Yavuz,[1] Abdulrahman A. Alwagdani,[1] Michael A. Harding,[1] Luca Musante,[2] Uta Erdbruegger.[1] *[1]University of Virginia, Charlottesville, VA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Urinary extracellular vesicles (uEVs) may parallel physiologic and pathologic processes taking place in their kidney cell of origin. Combined with their ease of access, this makes uEVs excellent candidate biomarkers. It is known that kidney physiology and expression of some proteins follow a circadian pattern. Therefore, the normal daily variation in uEV excretion and the content of specific protein cargoes must be understood. The goal of this study is to examine changes over a 24 hour period of uEV markers of glomerula and tubular origin. In addition, we examined TSG101 (Tumor susceptibility gene protein 101) as an EV marker.

Methods: Each void during a 24-hour period for 13 healthy individuals (108 samples total) was collected. uEVs from each void was isolated by differential centrifugation at 20,000g, and washed with a low ionic strength buffer to remove uromodulin. uEV count and sizing was performed on each final pellet using Nanoparticle Tracking Analysis (ZetaView; Particle Metrix). Flow Cytometry using SpectralFlow was performed on uEVs stained with an antibody panel including CD35 (CR1), CD26 (DPP4), CD9 (Tetraspanin) and CD10 (Neprilysin). uEV protein lysates were immunoblotted for SLC12A3 and TSG101.

Results: TSG101 signal normalized to total protein has a positive linear correlation with creatinine ($r=0.62$, $p<0.001$); indicating it may be expressed steadily. Normalizing to creatinine or TSG101 expression of SLC12A3 vary over a day in a temporal pattern. The antibody panel of glomerular and tubular markers detected with single flow cytometry did not express a temporal pattern when normalized to TSG101.

Conclusions: uEV biomarker expression may be normalized to TSG101 signal as it correlates with creatinine. SLC12A3 has a critical role in kidney function with sodium reabsorption and has shown circadian pattern of expression previously in rodent models. Our results demonstrate a similar temporal pattern of a large range of uEVs carrying SLC12A3 in humans. This temporal variation of uEV markers needs to be further analyzed on other kidney markers in healthy individuals and disease. However, characterizing temporal protein expression patterns of uEVs has potential to accelerate uEV biomarker discovery for kidney diseases.

Nicotinamide Adenine Dinucleotide (NAD) Deficiency Contributes to Progressive Kidney Disease in HIV Nephropathy Mice

Teruhiko Yoshida,[1] Komuraiah Myakala,[2] Bryce A. Jones,[2] Xiaoxin Wang,[2] Shashi Shrivastav,[1] Briana A. Santo,[6] Yongmei Zhao,[5] Vincent M. Tutino,[6] Pinaki Sarder,[3] Avi Z. Rosenberg,[4] Moshe Levi,[2] Jeffrey B. Kopp.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]Georgetown University, Washington, DC; [3]University of Florida, Gainesville, FL; [4]Johns Hopkins University, Baltimore, MD; [5]Frederick National Laboratory for Cancer Research, Frederick, MD; [6]University at Buffalo, Buffalo, NY.*

Background: HIV disease remains prevalent in the USA and is even more highly prevalent in sub-Saharan Africa. Recent investigations revealed that renal mitochondrial dysfunction contributes to HIV-associated nephropathy (HIVAN) in Tg26 transgenic mice. We hypothesized that nicotinamide adenine dinucleotide (NAD) deficiency contributes to energetic dysfunction and progressive tubular injury.

Methods: Tg26 and wild-type (WT) mice were treated with nicotinamide riboside (NR), 500 mg/kg body weight/day in drinking water or the farnesoid-X receptor agonist INT-747, 10 mg/kg body weight/day in the diet from 6 to 12 weeks of age. We used multi-omic characterization of kidney tissue transcriptomes and metabolomes to investigate metabolomic mechanisms of HIVAN tubulopathy and the effects of treatment with NR and INT-747.

Results: Treatment with NR and INT-747 ameliorated kidney tubular injury in Tg26 mice, as shown by serum creatinine, urine albumin and the tubular injury marker, urinary neutrophil-associated lipocalin (NGAL). NAD levels were significantly lower (2.86 [2.54-3.28, IQR] nmol/mg) in Tg26 kidney compared with WT mouse kidney (6.94 [5.48-8.72] nmol/mg) and levels were restored by either NR or INT-747 treatment. Integrated analysis of transcriptomic and metabolomic measurements showed that the NAD salvage pathway was downregulated in Tg26 mouse kidney. Sirtuin3 acetylation activity and mitochondrial oxidative phosphorylation activity were lower in *ex vivo* proximal tubules from Tg26 kidneys compared to those of WT mice. These activities were restored by supplementation with NR and with INT-747.

Conclusions: NAD deficiency contributes to HIVAN tubulopathy and mitochondrial dysfunction in Tg26 mice. Restoration of NAD levels in kidney improves these pathologies.

Funding: NIDDK Support

Systemic Immune Dysregulation in a Mouse Model of Oxalate Nephropathy

Hendrik Bartolomaeus, Moritz I. Wimmer, Ariana Rauch, Harithaa Anandakumar, Martin Reichel, Felix Knauf, Nicola Wilck. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Chronic kidney disease (CKD) is a leading cause of mortality and morbidity. Crystalline nephropathy induced by high oxalate is an established cause of CKD. CKD and crystal formation were shown to influence immune cell composition and gut microbiota. To investigate the impact of oxalate nephropathy on the immune system and the microbiome, high oxalate-fed mice were analyzed by flow cytometry and 16S sequencing.

Methods: To investigate the effects of oxalate we fed single housed C57BL6/N mice (n=7) a high oxalate diet for 10 days. Chow diet fed littermates served as healthy controls. Both groups were analyzed for immune cell composition (flow cytometry) of the spleen, kidney and small/large intestine (lamina propria immune cells [si/cLPL]) and bulk RNA sequencing of the kidney. Microbiota composition was analyzed by 16S sequencing.

Results: Mice fed a high oxalate diet demonstrated hyperoxaluria and increased kidney injury as measured by plasma creatinine concentration. Furthermore, we observed a significant reduction in body weight. Bulk RNA sequencing revealed a prominent inflammatory signature of the kidney, including increased classical damage markers (*Lcn2*, *Havcr1*), as well as genes enriched for Th17 differentiation pathway. Flow cytometry analysis identified more than 100 dysregulated immune subpopulations in the kidney. Furthermore, we detected a pronounced inflammatory response in the spleen and the intestine. Interestingly, type 17 T cells (IL-17A+ and RORgt+) within conventional T helper and regulatory T cells were the main and overlapping phenotypic drivers across different organs, namely the kidney, small and large intestine. Compared to the immune system, the microbiome only showed small scale taxonomic shifts (increase of 4 vs. decrease of 9 operational taxonomic units).

Conclusions: Our in-depth immune phenotyping uncovers a pronounced inflammatory signature across several organs (intestine, spleen and the kidney). Our study provides a comprehensive description of immune cell alterations and serves as a valuable resource for the scientific community.

SA-PO1045

Renal Medullary Macrophages Play a Pivotal Role in Cleaning off Intratubular Particles

Xiao Shen, Jian He, Peng Shi. *Zhejiang University, Hangzhou, China.*

Background: During the passage of the glomerulus filtrates through the renal tubular system, various microscopic sediment particles, including mineral crystals resulting from urine concentration, are generated. Dislodging these particles in the intratubular compartment is critical to ensure free flow of filtrate and the final formation of urine. However, the underlying cellular mechanism for the clearance is unclear.

Methods: The interactions of macrophages and segments of renal tubules were analyzed by high-resolution confocal microscopy and scanning electron microscopy. Live movement of renal macrophages was monitored by two-photon microscopy. Bulk RNA-seq was performed to analyze the transcriptomic difference between cortical and medullary macrophages. Hyperoxaluria model was used to induce kidney stone formation.

Results: We uncovered that the juxtatubular macrophages in the renal medulla constitutively formed transepithelial protrusions and were "sampling" urine contents. This transepithelial protrusions were formed in a transcellular route instead of between epithelial cells, so that the overall junctional architecture of tubular epithelium was intact. In particular, juxtatubular macrophages were efficient in sequestering and phagocytosing intraluminal particles, and occasionally making transmigration to the tubule lumen to "escort" the excretion of sediment particles. As such, mice with underrepresentation

of renal macrophages were prone to developing various intratubular sediments. Mechanistically, integrin β1-mediated ligation to the tubular epithelium is crucial to the transepithelial behaviors of medullary macrophages.

Conclusions: This study unveils a previously unappreciated role of renal macrophages in keeping the tubular system unobstructed. In contrast to the traditional view that the renal epithelial barrier is insurmountable to cells, we found that these juxtatubular macrophages in the medulla constitutively formed transepithelial protrusions, and the underlying molecular mechanisms were provided as well. In addition, we demonstrated a divergence between medullary and cortical macrophages in transcriptomes and in behaviors. These findings may pave way for developing novel therapeutics for nephrolithiasis as well as renal infection caused by ascending microbes.

Vascular Injury-Derived Exosomes Trigger Renal Tertiary Lymphoid Structures and Accelerate Lupus Nephritis

Marie-Hélène Normand,[1,3] Sandrine Juillard,[1,3] Natalie Patey,[4] Eric Boilard,[5,6] Mélanie Dieudé.[1,2] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Hema-Quebec, Saint-Laurent, QC, Canada; [3]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [4]Chu Sainte Justine, Montreal, QC, Canada; [5]Universite Laval, Quebec, QC, Canada; [6]Chu de Québec, Montreal, QC, Canada.*

Background: Microvascular damage is an emerging contributing factor to Lupus Nephritis (LN) leading to end stage renal disease. We have demonstrated that apoptotic exosomes derived from vascular injury (ApoExo) trigger the production of SLE-associated antibodies in wild-type mice. ApoExo infusion induces autantibody production and tertiary lymphoid structure (TLS) formation in a murine vascular allograft rejection model. We hypothesize that ApoExo induce an autoimmune response that accelerates the development of lupus nephritis.

Methods: 20 weeks old NZB/WF1 mice were infused with ApoExo or vehicle every second day for 3 weeks. Circulating anti-LG3 and ApoExo levels were measured by ELISA and hs-FCM respectively. Kidneys were collected and renal histology and 3D in vivo micro-computed tomography (MicroCT) analyses were performed.

Results: NZB/WF1 mice infused with ApoExo show higher levels of circulating anti-LG3 compared with the vehicle group ($p=0.0034$). MicroCT data suggest microvascular involution associated with LN development. In addition, ApoExo infused NZB/WF1 mice demonstrate significant renal inflammatory infiltration compared to mice infused with vehicle. ApoExo triggered the recruitment to the renal interstitium of $CD3^+$, $CD20^+$, and AID^+ lymphocytes into nodules reminiscent of TLS ($p=0.0342$) associated with increased Lyve 1+ suggesting lymphoangiogenisis. Finally, heightened renal tubular damage ($p<0.05$), blood urea nitrogen levels ($p<0.05$) and decreased survival ($p=0.0055$) were observed in ApoExo infused NZB/WF1 mice compared to the ones infused with vehicle.

Conclusions: ApoExo infusion increases renal nodular lymphocyte infiltration, autoantibody production increase renal damage in lupus prone mice. This project is, to our knowledge, the first to evaluate the contribution of vascular injury derived extracellular vesicles to LN.

Funding: Private Foundation Support, Government Support - Non-U.S.

Extracellular DNA Traps Are Induced by Medullary Range NaCl, but Not Urea, and Protect Against Bacterial Pyelonephritis In Vivo

Adrian Goldspink,[1] Jessica Schmitz,[2] Olena Babyak,[1] Anne M. Breloh,[2] Susanne V. Fleig,[1] Florian Wagenlehner,[3] Jan H. Braesen,[2] Christian Kurts,[1] Sibylle Von Vietinghoff.[1] *[1]University and University Clinic Bonn, Bonn, Germany; [2]Medizinische Hochschule Hannover, Hannover, Germany; [3]University Giessen Clinic for Urology, Giessen, Germany.*

Background: Excessive NaCl and urea concentrations characterize the kidney medulla. Their effects on innate immune cell death, namely extracellular DNA trap (ET) formation were not known. A role for ET in response to renal bacterial infections had not been defined.

Methods: ET generation and myeloid cell death was studied in varying osmolyte concentrations and pharmacologic modulations of different cell death pathways. ET were studied in murine and human pyelonephritis and functions explored by pharmacologic PAD inhibition and modulation of the renal electrolyte gradient.

Results: Medullary-range NaCl, but not urea, dose-, time- and PAD4-dependently induced ET formation even in the absence of other stimuli. Moderately elevated NaCl promoted myeloid cell apoptosis. NaCl induced myeloid cell calcium influx. Modulation of Na-K ATPase and NCX channel were ineffective. Ca^{2+}-free media or Ca^{2+}-chelation reduced NaCl-induced apoptosis and ET formation. LPS amplified it. ET of granulocytic and monocytic origin were present in human pyelonephritis kidneys, predominantly in the renal medulla. Citrullinated histone levels were systemically elevated in patients suffering from acute pyelonephritis. PAD4 inhibition prevented renal ET formation and promoted pyelonephritis in mice. Depletion of the renal NaCl gradient by loop diuretic therapy diminished renal medullary ET formation and increased pyelonephritis severity.

Conclusions: Our data demonstrate that renal medullary range NaCl concentrations are novel inducers of programmed myeloid cell death, namely ET formation. PAD4-dependent extracellular DNA traps promote antibacterial host response in the kidney.

Gadolinium Retention Is Modulated by Prior Magnetic Resonance Imaging Contrast Agent Exposures

Karol Dokladny, Abdul Mehdi S. Ali, Joshua Deaguero, Tamara A. Howard, G. P. Escobar, Brent Wagner. *The University of New Mexico, Albuquerque, NM.*

Background: Complications of magnetic resonance imaging (MRI) contrast agents include crippling systemic fibrosis, kidney injury, and fatal gadolinium encephalopathy. Gadolinium, a rare earth metal in the periodic table's lanthanide series, has been extensively used in modern diagnostic medicine to enhance MRI procedures. Gadolinium-based contrast agents (GBCAs) are grouped into two categories: linear (Omniscan) or macrocyclic (Dotarem). Patients are often exposed to multiple brands of contrast agents. The impact of this practice on gadolinium retention and pathology has never been examined.

Methods: In our study, 21 male mice were randomized to five experimental groups: (1) saline-treated controls; gadolinium-based contrast agent-treated (2) Omniscan (OMN), (3) Dotarem (DOT), or in combination (4) OMN (1 week) followed by DOT administration for 3 weeks or (5) DOT (1 week) followed by OMN treatment for 3 weeks. Saline or contrast agents were administered via intraperitoneal injections 5 days a week for 4 weeks according to our established protocols. Tissues were excised and snap-frozen in liquid nitrogen. On average, 15 mg of tissue were digested in nitric acid, and gadolinium concentrations were quantified using PerkinElmer NexION 300D inductively coupled plasma mass spectrometry (ICP/MS) with a detection limit of 0.01 ppb.

Results: Regardless of the mode of exposure, 4-week treatment of OMN or DOT only or in combination (OMN-DOT or DOT-OMN) resulted in a significant accumulation of gadolinium in the tested organs. Gadolinium accumulation in the liver was lower in animals treated with DOT alone or in combination with OMN (OMN-DOT) than in animals administered with OMN alone or with DOT (DOT-OMN). In the kidney, the lowest gadolinium accumulation was observed in the OMN-DOT group in comparison with other GBCA-treated groups. GBCA treatments did not influence calcium levels in the kidneys or livers.

Conclusions: Our data indicate that prior GBCA exposures influence gadolinium retention in the kidney or liver. Future studies are needed to determine if this factor is influential in the pathophysiology of NSF in humans.

Semiautomated Pipeline for Quantitative Analysis of Uremic Cardiomyopathy

Patrick Droste,[1,2] Dickson W. Wong,[2] Mathias Hohl,[3] Saskia von Stillfried,[2] Barbara M. Klinkhammer,[2] Peter Boor.[2,1] Laboratory of Nephropathology. *[1]Universitatsklinikum Aachen Klinik fur Nieren- und Hochdruckkrankheiten rheumatologische und immunologische Erkrankungen, Aachen, Germany; [2]Universitatsklinikum Aachen Institut fur Pathologie, Aachen, Germany; [3]Universitatsklinikum des Saarlandes und Medizinische Fakultat der Universitat des Saarlandes, Homburg, Germany.*

Background: Cardiac remodeling in patients with chronic kidney disease, also called uremic cardiomyopathy, is a leading cause of high mortality in these patients. The histological changes include cardiomyocyte hypertrophy and capillary rarefaction, the quantification of which is both technically challenging and highly time-consuming. Here we developed a semiautomated pipeline for quantification of the size of cardiomyocytes and capillary density in cardiac histology.

Methods: We generated macros in ImageJ, a broadly used, open-source, java-based software. We have used modified Gomori silver staining, which is easy to perform and digitize in high throughput, or Fluorescein-labeled lectin staining. The latter can be easily combined with other stainings, allowing additional quantitative analysis, e.g., of nuclei, capillary density, or single-cardiomyocyte protein expression. We validated the pipeline in a mouse model of cardiac hypertrophy induced by transverse aortic constriction, and in autopsy samples of patients with and without aortic stenosis.

Results: In both animals and humans, ImageJ-based histology quantification revealed significant hypertrophy of cardiomyocytes and enabled the analysis of protein expression in individual cardiomyocytes. The analysis also revealed that murine and human cardiomyocytes had similar diameters in health and extent of hypertrophy in disease. The number of capillaries relative to the size of the cardiomyocytes indicates a rarefaction of microvasculature.

Conclusions: The pipeline enables a rapid analysis not feasible by manual methods and facilitates quantitative histology analyses in preclinical and clinical samples. The software requires few hardware requirements and is freely available.

DQB1 Mismatch in Living Donor Kidney Transplantation

Olga Charnaya,[1] Tanveen Ishaque,[2] John Schmitz,[3] Olga A. Timofeeva,[4] Eszter Lazar-Molnar,[5] Gerald P. Morris,[6] Myra Coppage,[7] Scott M. Krummey,[1] Luis G. Hidalgo,[8] Aiwen Zhang,[9] Dorry L. Segev,[2] Anat R. Tambur,[10] Allan Massie.[2] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]NYU Langone Health, New York, NY; [3]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Georgetown University, Washington, DC; [5]University of Utah Health, Salt Lake City, UT; [6]University of California San Diego, La Jolla, CA; [7]University of Rochester, Rochester, NY; [8]University of Wisconsin System, Madison, WI; [9]Cleveland Clinic, Cleveland, OH; [10]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Several studies have reported an association between HLA-DQ mismatch, and formation of dnDSA and ABMR. Given the notable linkage in inheritance of HLA- DR and -DQ, we sought to determine what additional benefit can be gained by adding DQB1 allele matching to predicting allograft outcome.

Methods: We included living donor kidney transplant recipients (N=3886) transplanted between 2010-2022. Clinical, demographic, and outcome data were obtained from SRTR. HLA DQB1 allele typing and DR antigen was provided by each center. Using multivariable Cox-proportional hazards models we evaluated the hazard (aHR) of graft failure with level of DR and DQB1 mismatching. We used AIC to evaluate which model provide the best fit.

Results: In an unadjusted model, DQB1 allele mismatching was not associated with an increased hazard of death-censored graft failure (DCGF). In adjusted models, both DQB1 and DR were independently associated with increased hazard of DCGF aHR per mismatch 1.2 (1.01, 1.44) and 1.21 (1.02, 1.45), respectively. When both DR and DQB1 are in the model, neither is statistically significant. The model with DQ+DR provided best fit, although the difference was not statistically significant (delta-AIC<2).

Conclusions: Despite a strong association between DQB1 mismatching and dnDSA/ABMR, its' addition to matching algorithms in living donor recipients when considering DCGF may not provide added benefit over DR matching, likely due to the strong linkage disequilibrium between these two loci.

Table 1. Association between death-censored graft failure and DQ allele mismatch/DR antigen mismatch.

	Hazard Ratios				
	Unadjusted	Model A	Model B	Model C	Model D
Zero mismatch	Ref	Ref	Ref	Ref	Ref
For each mismatch	1.16	1.20	1.21	1.11	1.12
AIC		4060.66	4060.47	4061.90	4059.91

All models adjusted for donor age per 10 years (splined at 50), sex, race (white, AA, Hispanic, others), recipients age per 10 years (splined at 50), sex, race (white, AA, Hispanic, others), Diagnosis (Glomerular disease, DMN, HTN, PCK, congenital/metabolic abnormalities, others), peak PRA (0,1-19,20-79,80-98,99-100) in addition to:
[i] Model A: DQB1 allele mismatch (per 1 mismatch)
[ii] Model B: DR antigen mismatch (per 1 mismatch)
[iii] Model C: DQB1 allele mismatch (per 1 mismatch) **[reported]** and DR antigen mismatch (per 1 mismatch)
[iv] Model D: Combined DQB1 allele + DR antigen mismatch (per 1 mismatch) [Range 0 – 4]

Noninvasive Monitoring for Rejection: Need of the Hour, an In-Center Experience with Donor-Derived Cell-Free DNA (dd-cf-DNA) and Its Association with Antibody-Mediated Rejection (ABMR)

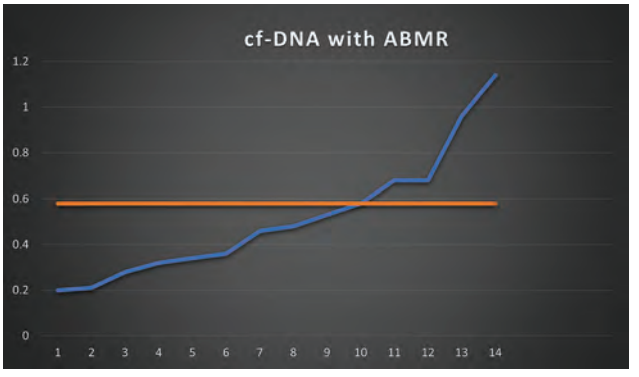
Umair Khan, Fatima Z. Warraich, Barbara A. Greco, Michael J. Germain. *University of Massachusetts Chan Medical School - Baystate Regional Campus, Springfield, MA.*

Background: Conventional modalities for detecting allograft rejection predominantly revolve around serial measurements of serum creatinine, and proteinuria. Serum creatinine, is a poor marker for detection of rejection as it lags considerably, and histologic analysis can be non-specific and operator dependent. Allograf biopsy remains the gold standard for detecting allograft rejection however biopsy is an expensive and invasive procedure by itself with risk of multiple complications. The quest for non-invasive tests for early rejection has been elusive. Recent advancements have shifted this paradigm towards newer diagnostic tests that independently provide an estimate into the injury state of the allograft kidney. Of these newer diagnostic modalities, dd-cf-DNA and gene expression, can be done regularly and can be used to complement traditional histological analysis.

Methods: We undertook a retrospective observational study in our renal transplant recipients to assess an association of dd-cf-DNA, gene expression, molecular tissue markers and histological analysis. We looked at the correlation of these variable with presence of antibody mediated rejection (ABMR) that was validated via protocol biopsy and molecular tissue marker analysis.

Results: We observed that dd-cf-DNA > 0.58% correlated with histological and molecular tissue marker proven antibody mediated rejection (ABMR). Furthermore, cf-DNA did not correlate with TCMR nor gene expression had any association with ABMR. With this study we report that a dd-cf-DNA of more than 0.58% is suggestive of ABMR which in the future can be used as a sole noninvasive test to diagnose ABMR and thereby avoiding the need for protocol biopsy.

Conclusions: Noninvasive monitoring for rejection is a need of the hour. Available literature along with our study supports the notion that cf-DNA is valuable in detecting ABMR.



Correlation of dd-cf-DNA with ABMR.

Blood Gene Expression Profile and dd-cfDNA for Diagnosis of Persistent Rejection

James Fleming,[1] Sookhyeon Park,[2] Christabel Rebello,[2] Steven Kleiboeker,[3] John M. Holman,[1] John J. Friedewald.[2] *[1]Transplant Genomics, Framingham, MA; [2]Northwestern University, Evanston, IL; [3]Eurofins Viracor, Lenexa, KS.*

Background: Persistent rejection (PRx) after treatment of BPAR is increasingly recognized and associated with worse outcomes. Repeat biopsies in the absence of clinical concern are rare.

Methods: This was a post hoc analysis performed on subjects with BPAR from the CTOT-08 study that had repeat biopsies available within 270 days after BPAR, and subanalysis of those within 90 days.

Results: Overall, 64 "index" BPAR with repeat biopsies were identified and 61% had PRx within 270 days. Rejection types are in Figure 2. Biomarker test characteristics for F/U biopsies within 270 days and 90 days are shown in Figure 1. PRx was in clinically stable patients in 67% within 270 and 71% within 90 days. Biomarker results and rejection type are shown in Figure 2. There was 2-year clinical F/U data available for 52 subjects showing 32 subjects (62%) met the composite endpoint of the CTOT-08 trial and subjects with PRx were more likely to meet the CCE (65% vs 34%, p=0.025).

Conclusions: Blood GEP and dd-cfDNA demonstrate excellent capability of identifying PRx, with high PPVs. PRx was associated with worse outcomes. GEP and dd-cfDNA may be tools to identify those in need of a F/U biopsy even when no clinical alterations are present (2/3 of subjects had stable function). The overlap of biomarker results shows that the 2 tests identify different rejections.

Donor-Derived Cell-Free DNA in Biopsy-Proven Antibody-Mediated Rejection (ABMR) vs. Recurrent IgA Nephropathy After Kidney Transplantation

Bilgin Osmanodja, Aylin Akifova, Klemens Budde. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Antibody-mediated rejection (ABMR) and recurrent IgA nephropathy (IgAN) are major causes of graft loss and show comparable clinical features such as decline in renal function, proteinuria or worsening hypertension. Since ABMR and recurrent IgAN are indistinguishable using eGFR and urine albumin-creatinine-ratio (uACR) alone, we evaluated the ability of donor-derived cell-free DNA (dd-cfDNA) to discriminate both entities in consecutive cases from an ongoing prospective, observational trial.

Methods: At the time of clinically indicated biopsies, we collected venous blood samples and measured absolute (cp/mL) and relative (%) dd-cfDNA. We included 57 dd-cfDNA-matched biopsies, and assigned them to 3 groups based on histopathology: (1) active or chronic active ABMR (n=21), (2) recurrent IgAN (n=15), (3) no signs of rejection, infection or glomerulonephritis (n=21).

Results: Absolute and relative dd-cfDNA were lower in recurrent IgAN than in ABMR (median 11 cp/mL [IQR 7 - 13] vs. 76 cp/mL [IQR 57 - 103], p<0.001; median 0.32% [IQR 0.24 - 0.41] vs. 1.68% [IQR 1.1 - 2.7], p<0.001), but did not differ between recurrent IgAN and no rejection (median 11 cp/mL [IQR 7 - 13] vs. 12 cp/mL [IQR 7 - 16], p=0.995; median 0.32 % [IQR 0.24 - 0.41] vs. 0.30 % [IQR 0.26 - 0.54], p=0.983) (Figure 1). Using the prespecified cutoff of 50 cp/mL, no patient with recurrent IgAN, but 17/21 patients (81%) with ABMR had increased absolute dd-cfDNA levels. Four patients (27%) with crescent formation as a sign of severe recurrent IgAN had low absolute (min-max: 6 - 21 cp/mL) and relative dd-cfDNA (min-max 0.26 - 0.35%) as well.

Conclusions: Dd-cfDNA does not increase in recurrent IgAN after kidney transplantation.

Funding: Commercial Support - Oncocyte

SA-PO1054

Use of Donor-Derived Cell-Free DNA and Gene Expression Profiling to Facilitate Belatacept Monotherapy in Kidney Transplant Recipients

Juan D. Salcedo Betancourt,[1] Morgan Marsh,[1] Cyrus Feizpour,[2] Hwarang S. Han,[3] Laila S. Lakhani,[1] Swee-Ling Levea,[1] David Wojciechowski.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]Indiana University School of Medicine, Indianapolis, IN; [3]The University of Texas at Austin UT Health Austin, Austin, TX.*

Background: Studies have demonstrated that a donor-derived cell free DNA (dd-cfDNA; AlloSure) >1.0% can be used as a biomarker of allograft rejection. A gene expression profiling (AlloMap) threshold of 11.5 has shown to discriminate rejection from immune quiescence. We aimed to investigate their utility in weaning to Belatacept monotherapy immunosuppression.

Methods: Between December 2022 and April 2023, we enrolled adult kidney recipients on Belatacept immunosuppression with stable renal function (eGFR > 40 mL/min/1.73 m2) and negative Donor-Specific Antibodies (DSA) into a prospective, single-center, observational pilot study. Patients with acute rejection episodes were excluded. AlloSure, AlloMap, serum creatinine, urine protein, and DSA were measured at monthly Belatacept infusion visits. Patients deemed immune quiescent underwent immunosuppression tapering. Outcomes were: 1) Incidence of biopsy-proven acute rejection and 2) allograft and patient survival, change in eGFR, development of proteinuria or de-novo DSA.

Results: We analyzed the first 11 patients who completed 6 months of follow-up. Subjects were predominantly male (n=7), with a mean age of 57 years, mean eGFR of 65.1 mL/min/1.73m2 ± 14.7 SD on enrollment, and 67 mL/min/1.73m2 ± 15.0 SD at the 6 months follow up. The most common agents used with Belatacept were Prednisone and Mycophenolate (n = 9) followed by Prednisone and Everolimus (n = 2). Mean AlloSure and AlloMap values throughout follow up were 0.20% ± 0.05 and 11.5 ± 1.4 respectively. 5 patients (45%) were weaned off steroids; no subjects were weaned entirely off mycophenolate or everolimus due to an AlloMap over the threshold. There was 100% patient and graft survival, with no cases of biopsy-proven rejection, proteinuria or DSA development.

Conclusions: Despite having AlloSure <1%, the mean AlloMap score was above the reported treshold shown to discriminate rejection from quiescence. We hypothesize that patients on Belatacept-based immunosuppression regimen have a higher baseline AlloMap levels even if immune quiescent, as prior AlloMap studies primarily included patients treated with tacrolimus-based immunosuppression. Higher cutoffs may be necessary for these patients. Investigation is ongoing to assess this hypothesis in our cohort.

SA-PO1055

Early Detection of Microvascular Injury in Renal Allografts Utilizing Donor-Derived Cell-Free DNA (cfDNA)

Naseer Khan,[1,2] Amna Ilahe,[1,2] Irfan Agha.[1,2] Dallas Renal Group. *[1]Medical City Dallas Hospital, Dallas, TX; [2]Methodist Dallas Medical Center, Dallas, TX.*

Background: Early detection of allograft injury is critical in improving long-term allograft outcomes. Standard tests of renal function are insensitive, while renal biopsies are invasive and expensive. cfDNA allows sensitive surveillance of allograft injury. We present a series of patients where we identified microvascular injury (MVI) without evidence of alloantibody (DSA or donor directed non-HLA Ab) or C4d on biopsy based on elevatyed cfDNA.

Methods: We followed universal surveillance with cfDNA at month 1, 2, 3, then quarterly till 24 months. A biopsy was triggered if the surveillance value of cfDNA was >1%. Isolated MVI was diagnosed if their glomerulitis (g)+ peritubular capillaritis (ptc) score of >2 and C4d was negative. There were no other histopathological indicators of AMAR or CMR or infection based on Banff 2017 criteria. DSA and non-HLA antibodies (anti-AT1R, Anti-MICA) were negative.

Results: We followed 120 consequetive patients from 2/2022 till 2/2023. 5 patients with isolated MVI biopsied solely on elevated cfDNA signature. Their renal function was normal. C4d, DSA and non-HLA antibody panels were negative. None of these biopsies satisfied the Banff 2017 criteria for AMAR Patients were treated based on individual physician prerogative. Patients 1 & 2 received steroids only. Patients 3, 4 & 5 received steroids as well as 5 sessions of Plasmapharesis and IVIG. All five patients maintained renal function and showed decreased allograft injury based on reduced cfDNA signature (Table 1).

Conclusions: 1. Surveillance with cfDNA is an important tool to detect allograft injury. 2. Early detection of MVI by cfDNA provides an opportunity to treat it before allograft dysfunction becomes apparent 3. The exact nature of isolated MVI remains unclear. It can be postulated as an alloimmune response or allograft injury due to missing self class I antigens. 4. The exact treatment regimen remains unclear. In our series, there was stabilization in injury based on cfDNA signature by increasing immunosuppression.

Donor Derived Cell-free DNA Results in Patients with Micro-vascular Injury

Patient ID	Baseline Allosure %	Pre-Biopsy Allosure %	Post treatment Allosure %
1	0.31	1.8	0.95
2	0.18	1.7	0.41
3	0.79	7.6	0.5
4	2.9	6.6	3.0
5	3.9	5.4	1.8

Prospective Assessment of the Need, Discrepancies, and Added Value of Molecular Diagnostics of Kidney Allograft Biopsies: An Evaluation in Clinical Practice

Thomas Schachtner, Seraina C. Von Moos, Kai C. López, Lukas Weidmann, Dusan Harmacek, Nicola Bortel, Raphael Korach, Thomas F. Mueller. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: The Molecular Microscope Diagnostic System (MMDx) may resolve inconclusive histology findings, as preserved biopsy material can be examined after histology findings have been obtained. The extent to which this proposed approach can be implemented in clinical practice remains an open question.

Methods: We prospectively analyzed 102 consecutive indication kidney allograft biopsies by histology and MMDx at the University Hospital Zurich from April to September 2022. Pathologists and clinicians with experience in MMDx assessed the need for MMDx by questionnaire when the histology report was available. Clinicians then assessed the discrepancy rate and assumed added value by questionnaire when the MMDx report was available.

Results: The need for MMDx was most frequently assessed for suspected ABMR (12/20) and mixed ABMR/TCMR (9/18) but less frequently for proven ABMR (1/11), TCMR/borderline (1/6), DSA only (1/20), and no ABMR/TCMR (3/28). Discrepancies were observed most frequently in cases with proven/suspected rejection (36/55) but rarely in the absence of histologic rejection (1/47). Clinicians considered an added value of molecular diagnostics mostly in suspected ABMR (3/20), mixed ABMR/TCMR (7/18), and TCMR/borderline (3/6). Classification into molecular ABMR occurred in 9 of 32 cases with suspected ABMR. However, classification into molecular TCMR was not observed in any of the 17 cases with suspected TCMR.

Conclusions: The need for MMDx in clinical practice goes beyond the recommendation for suspected ABMR. While discrepancies appear to be limited to cases with histologic rejection, an added value of MMDx is particularly suspected along the ABMR continuum. Because MMDx aims to overcome the inter-observer variability of histology, the potential added value of MMDx must be determined for each center individually.

The Molecular Microscope Diagnostics System (MMDx) Does Not Identify Early Molecular Antibody-Mediated Rejection (ABMR) in the Presence of Donor-Specific Antibodies (DSA), but Absence of Microvascular Inflammation

Thomas Schachtner, Lukas Weidmann, Dusan Harmacek, Kai C. López, Nicola Bortel, Raphael Korach, Thomas F. Mueller. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: The development of de novo donor-specific antibodies (DSA) or an increase in MFI values of preformed DSA are common indications for kidney allograft biopsies. If changes in transcript patterns analyzed by the Molecular Microscope Diagnostic System (MMDx) may precede histological antibody-mediated changes and identify early antibody-mediated rejection (ABMR), however, remains uncertain.

Methods: In this single-center cohort of 326 indication kidney transplant biopsies assessed by histology and MMDx at the University Hospital Zurich, we analyzed 138 cases with no glomerulitis (g0) and no ABMR (not meeting Banff 2019 ABMR criteria 1 and 2) concerning the presence (n=49) and absence (n=89) of DSA.

Results: Kidney allograft biopsies in the presence of DSA were performed later post-transplantation (median 37 months (IQR 5-170) compared to biopsies in the absence of DSA (median 13 months (IQR 3-93; p=0.03). Molecular ABMR was observed in 0/49 cases (0%) in the presence of DSA and 2/89 cases (2%) in the absence of DSA (2 cases of mixed molecular ABMR/TCMR with histological TCMR). 17/49 cases (35%) in the presence of DSA showed an all ABMR rejection phenotype score (sum of R4, R5, and R6) ≥0.20 compared to 22/89 cases (25%) in the absence of DSA (p=0.116). 13/49 cases (26%) with transplant glomerulopathy (cg) showed an all ABMR rejection phenotype score ≥0.20 compared to 26/89 cases (29%) without cg (p=0.1). Among cases with cg, the all ABMR rejection phenotype score did not differ between cases with DSA compared to cases without DSA (p=0.294). 1/4 cases with isolated C4d positivity ≥2 in the presence of DSA showed an all ABMR rejection phenotype score ≥0.20.

Conclusions: MMDx does not differentiate early molecular ABMR in the presence of DSA and/or transplant glomerulopathy but in the absence of histological antibody-mediated changes. If minor molecular changes are meaningful, at least in a subgroup of cases, needs to be assessed in the context of follow-up biopsies.

Isolated Glomerulitis Is Associated with the Absence of Molecular Antibody-Mediated Rejection (ABMR) in Cases with Histologically Suspected and Confirmed ABMR

Thomas Schachtner, Lukas Weidmann, Dusan Harmacek, Nicola Bortel, Kai C. López, Raphael Korach, Thomas F. Mueller. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: According to the 2018 Banff classification, the Molecular Microscope Diagnostic System (MMDx) is indicated in cases when histology is insufficient to diagnose antibody-mediated rejection (ABMR) due to an absence of diagnostic criteria groups 2 (antibody interaction with tissue) and/or 3 (DSA and equivalents). The impact of isolated glomerulitis (g>0, ptc0) on the likelihood of molecular ABMR appears critical to the implementation of this new biomarker.

Methods: We analyzed 326 kidney allograft biopsies by histology and MMDx at the University Hospital Zurich. Histologic findings were classified into: (1) 30 cases with suspected ABMR: isolated mild glomerulitis (g1), DSA-, (2) 32 cases with suspected ABMR: isolated mild glomerulitis (g1), DSA+, (3) 33 cases with suspected ABMR: MVI (g+ptc>1), DSA-, (4) 60 cases with confirmed ABMR: MVI (g+ptc>1), DSA+.

Results: MMDx diagnosed ABMR in 5/30 cases (17%) with isolated g1 without DSA, 12/32 cases (38%) with isolated g1 with DSA, 18/33 cases (55%) with MVI without DSA, and 30/60 cases (50%) with histologically proven ABMR. While only 17/65 cases (26%) with molecular ABMR showed isolated glomerulitis, 64/90 cases (71%) without molecular ABMR showed isolated glomerulitis (p<0.001). Among cases with isolated glomerulitis, molecular ABMR was detected more frequently in cases with proteinuria (p=0.011), the presence of DSA (p=0.033), and transplant glomerulopathy (cg; p=0.014).

Conclusions: MMDx confirms ABMR in a relevant proportion of cases with isolated mild glomerulitis. However, isolated glomerulitis is associated with the absence of molecular ABMR in cases with suspected and confirmed ABMR. Proteinuria, DSA, and transplant glomerulopathy are associated with molecular ABMR among cases with isolated glomerulitis.

SA-PO1059

Impact of Donor-Specific Antibodies (DSA) with Low Median Fluorescent Intensity (MFI) on Allograft Outcomes in Kidney Transplant

Rungthiwa Kitpermkiat, Punlop Wiwattanathum, Surasak Kantachuvesiri. *Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand.*

Background: Many factors are associated with allograft failure in kidney transplantation patients (KTs). Immune-mediated rejection is one of the most common causes of allograft failure. Many studies demonstrated that high level of donor specific antibody (DSA) correlated with complement binding capability and more severe tissue

injury. However, data on DSA with low MFI are scarce. We compared allograft outcomes in KT patients with low-MFI DSA in this study.

Methods: Post kidney transplant patients who were tested for DSA at Ramathibodi Hospital from January 2007 to December 2021 and had DSA with MFI < 1000, reported as negative, were evaluated. KTs were separated into two groups: those with very low DSA (VLL) (MFI 1-500) and those with low DSA (LL) (MFI 501-1000). The primary outcome was the incidence of acute rejection. One and 5-year serum creatinine, allograft and patient survival in KTs with and without antibody-mediated rejection (ABMR) were also studied. Univariate and multivariate analyses were used to analyze factors associated with rejection.

Results: Thirty-six KTs were identified (VLL n = 27, LL n = 11). Demographic characteristics were similar between the 2 groups except slightly higher use of ATG for induction in LL group. The LL group had significantly higher T-cell mediated rejection (TCMR) than the VLL group (45% vs. 12%, P = 0.04). Ten patients developed ABMR. Rate of ABMR, 5 years allograft survival and patient survival were comparable between groups. There was a trend toward higher MFI in KTs with ABMR than without ABMR (MFI 442 [74-684] vs. 198 [33-475]; P = 0.21). At 5 years, the median serum creatinine level among ABMR was significantly higher than in non-ABMR KTs (2.25 [2.00-2.98] mg/dl vs. 1.41 [1.11-1.87] mg/dl) (P = 0.03). Univariate and multivariate analyses revealed that LL was a risk factor for rejection.

Conclusions: DSA with low MFI is associated with higher incidence of rejection. DSA with low MFI should not be reported as negative and overlooked. All DSA should be reported regardless of MFI. These group of KTs should be monitored closely and have their immunosuppression intensified to reduce the incidence of rejection.

Torque Teno Virus Load to Monitor Changes in Immunosuppression in Kidney Transplant Recipients with Indication Biopsy

Marvin Reineke,[1] Claudius Speer,[1] Julian Klein,[2] Christian Nusshag,[1] Florian Kälble,[1] Christoph F. Mahler,[1] Martin G. Zeier,[1] Ralf Bartenschlager,[2] Paul Schnitzler,[2] Christian Morath,[1] Louise Benning.[1] *[1]Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany, Heidelberg, Germany; [2]Heidelberg University, Medical Faculty Heidelberg, Department of Infectious Diseases, Virology, Heidelberg, Germany, Heidelberg, Germany*.

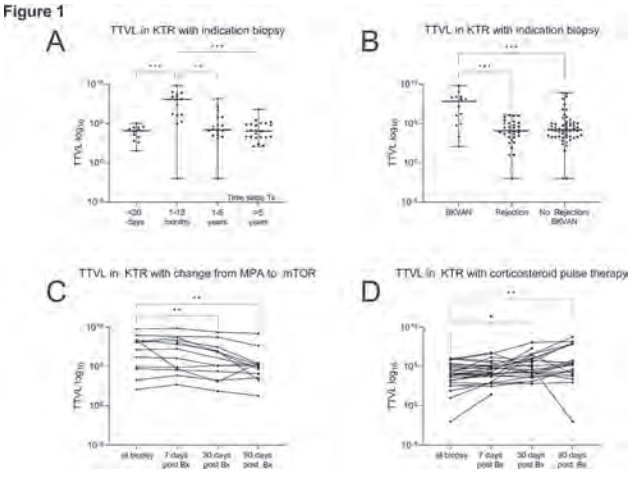
Background: Torque teno virus (TTV) is a potential surrogate parameter to monitor immunocompetence in kidney transplant recipients (KTR) early after transplantation. However, its use in monitoring changes in immunosuppression in KTR late after transplantation with different graft-associated pathologies requires further investigation.

Methods: In this post-hoc analysis we quantified TTV load in sera of 108 KTR with indication biopsy. TTV loads of 34 KTR with biopsy-proven acute rejection (BPAR) and 74 KTR with other pathologies, including 15 KTR with BKV-associated nephropathy (BKVAN), were quantified the day of biopsy, as well as 7, 30 and 90 days post-biopsy to identify changes in viral load related to adjustments in immunosuppressive therapy.

Results: In KTR with no BPAR or BKVAN, TTV load increased in the first month following transplantation and was highest in patients that received a graft biopsy between 1-12 months post-transplantation. Subsequently, with a reduction in immunosuppression, there is a gradual decline in TTV load across patients (Figure 1A). Patients with BKVAN had significantly higher TTV loads than patients with BPAR or other pathology (P<0.001 for both; Figure 1B). When converted from mycophenolic acid (MPA) to mTOR-inhibitors because of BKVAN, TTV loads decreased significantly in these patients (P<0.01, Figure 1C). In KTR with BPAR who received high-dose corticosteroid pulse therapy, a significant increase in TTV loads was observed between biopsy to 30d and 90d post-biopsy (P<0.05 and P<0.01, respectively; Figure 1D).

Conclusions: TTV load reflects changes in immunosuppressive therapy. Individual changes of TTV load appear to be of greater significance than universally defined cut-off values as TTV load varies depending on the time after transplantation.

Figure 1



SA-PO1061

Valacyclovir for Prevention of Cytomegalovirus Infection After Kidney Transplantation

Jin sug Kim,[1] Soo-Young Yoon,[1] Dae Kyu Kim,[1] Hyo Jin Lee,[1] Yang Gyun Kim,[2] Ju young Moon,[2] Hyeon Seok Hwang,[1] Kyunghwan Jeong.[1] *[1]Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea*.

Background: Cytomegalovirus (CMV) infection is a frequent and devastating complication after kidney transplantation (KT). Although guidelines recommend anti-viral prophylaxis with ganciclovir or valganciclovir, there is a demand for alternative regimen for CMV prevention. We investigated the effects of valacyclovir-based prophylaxis for 3 months on CMV infection and clinical outcomes in KT recipients using a nationwide cohort.

Methods: 2,584 KT recipients from 20 transplant centers registered with the Korean Organ Transplantation Registry were analyzed in this study. The recipients were divided into two groups according to valacyclovir prophylaxis (valacyclovir prophylaxis group and non-prophylaxis group). The impact of valacyclovir-based prophylaxis on CMV infection and disease, and clinical outcomes including rejection, graft loss, cardiac events, and all-cause mortality were investigated. Risk factors for the development of CMV infection were also analyzed.

Results: Valaciclovir prophylaxis group showed significantly lower incidence of CMV infection and rejection compared to non-prophylaxis group (3.64 vs. 10.25 events per 100 person-years and 1.85 vs. 7.27 events per 100 person-years, respectively). The risk of CMV infection and rejection was significantly decreased in valaciclovir prophylaxis group compared to non-prophylaxis group. Valacyclovir prophylaxis, donor age, whether deceased donor or not, length of hospitalization after KT, anti-thymocyte globulin usage, and CMV serological mismatch between the donor and the recipient (donor+ and recipient–) were independent risk factors for the development of CMV infection.

Conclusions: Valacyclovir prophylaxis after KT significantly reduced CMV infection and rejection. Valacyclovir could be considered as an alternative strategy for CMV prophylaxis after KT. Well-designed randomized controlled trials with large sample size are needed.

SA-PO1062

Plasma Fibroblast Growth Factor 21 (FGF21) Concentration in Patients After Kidney Transplantation

Marcin Adamczak, Magdalena Bartmanska, Andrzej Wiecek. *Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland*.

Background: Fibroblast growth factor 21 (FGF21) is a protein hormone involved in the regulation of metabolism and energy expenditure. Results of clinical studies suggest that plasma FGF21 concentration increases with the progression of chronic kidney disease (CKD). The aim of the present clinical study was to analyze the effect of successful kidney transplantation (KTx) on plasma FGF21 concentration and to study the factors related to plasma FGF21 concentration in patients long-term after KTx.

Methods: The first part of the study, i.e. the 6 months prospective observation**,** included 40 CKD patients directly before KTx [26 women and 14 men aged 47.0 (39.2 – 54.0) years]. In the second part of the study 184 patients long-term after KTx [72 women and 112 men aged 52.0 (48.0 – 54.0) years] and 50 healthy subjects (HS) [28 women and 22 men aged 52.0 (48.0 – 58.0) years] were enrolled. FGF21 plasma concentration was measured using Human FGF-21 ELISA (BioVendor R&D). Results were presented as median and 95% CI.

Results: In CKD patients directly before KTx plasma FGF21 concentration were significantly higher than in HS [1013.0 (689.6–1635.8) pg/ml *vs* 239.5 (219.0–294.5) pg/ml respectively; p<0.001]. At 14, 30 days and 6 months after KTx, a significant decrease of plasma FGF21 was observed [322.5 (197.3– 579.6) pg/ml; 355.0 (268.5–547.6) pg/ml; 344.0 (264.1–405.6) pg/ml (p<0.001), respectively]. In patients long-term after KTx, a negative correlation was found between plasma FGF21 concentration and estimated glomerular filtration rate and a positive correlations between plasma FGF21 concentration and BMI and serum concentration of triglycerides, insulin, interleukin 6, CRP and cystatin C.

Conclusions: 1. In CKD patients plasma FGF21 concentration measured directly before KTx is significantly higher than in HS. 2. Successful KTx leads to a significant decrease of plasma FGF21 concentration. 2. Plasma FGF21 concentration in patients long-term after KTx is related to the degree of graft function impairment and several metabolic abnormalities of these patients.

SA-PO1063

Is Metabolic Acidosis a Risk Factor for Worse Long-Term Prognosis in Patients After Kidney Transplantation?

Marcin Adamczak, Damian Gojowy, Julia Dolega, Michal Górecki, Katarzyna Skiba, Magdalena Bartmanska, Aureliusz Kolonko, Andrzej Wiecek. *Department of Nephrology, Transplantation and Internal Medicine, Medical University of Silesia, Katowice, Poland*.

Background: Metabolic acidosis (MA) frequently occurs in patients after kidney transplantation (KTx). Results of both experimental and clinical studies suggest that MA may contribute to faster progression of chronic kidney disease. Data on such relationship

in KTx patients is very limited. The aim of this clinical, single center, retrospective, observational study was to examine the relationship between MA and both mortality and renal outcomes in patients after KTx.

Methods: Blood bicarbonate concentration was measured in 486 patients (290 male; 196 female) aged 48.2 ± 12.0 years at least one year after KTx and subsequently all patients were observed during 11 years. MA was defined as the blood bicarbonate concentration lower than 22 mmol/L. The endpoints in Kaplan-Meier survival curves analysis were death, initiation of dialysis therapy or retransplantation as well as cumulative endpoint of the study i.e. death or initiation of dialysis therapy. Differences in survival curves were analyzed with log-rank test and were consider as significant when $p<0.05$. Relative risks (RR) were presented with 95% CI.

Results: Metabolic acidosis was diagnosed in 57 (12%) patients being long-term after KTx. The Kaplan-Meier curves analysis have shown that patients with MA reach endpoints of follow-up earlier (log-rank $p=0.002$ for death and $p<0.001$ for dialysis or retransplantation and for cumulative endpoint $p<0.001$). In patients with MA the risks of starting dialysis therapy or retransplantation was significantly higher than in patients without MA [RR=2.00 (1.42-2.82), $p<0.001$]. In patients with MA the risks of death was significantly higher than in patients without MA [RR=1.61 (1.01-2.55), $p=0.04$]. Risk of cumulative endpoint of the study (death and initiation of dialysis therapy or retransplantation) was also higher in patients with MA [RR=1.83 (1.49-2.23), $p<0.001$].

Conclusions: 1. Metabolic acidosis is an important risk factor for increased mortality and progression of graft failure in kidney transplant patients. 2. The prospective interventional studies with correction of MA in patients prone to allograft nephropathy progression will provide information whether treatment of MA improves the survival of both patients and transplanted kidneys.

Application of Machine Learning for Repertoire Analysis in Antibody-Mediated Rejection (ABMR) of Kidney Transplantation

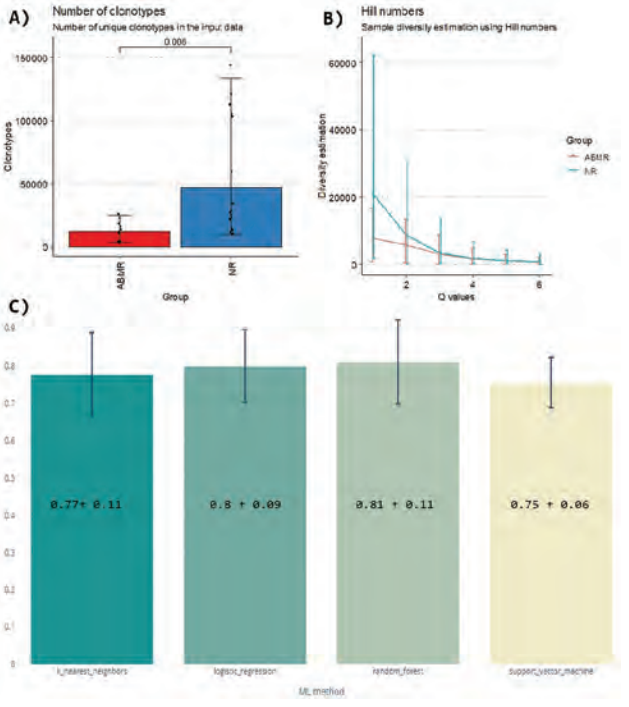
John J. Yang. *Korea University Guro Hospital, Seoul, Republic of Korea.*

Background: The adaptive immune receptor repertoire (AIRR)-sequencing analyzes the individual repertoire at sequence level. Here we compare AIRRs of kidney transplant recipients using repertoire analyses and machine learning, regarding ABMR.

Methods: Total of 30 repertoires (9 ABMR and 21 No rejection) were analyzed. Bulk gDNA (2μg) was sequenced at 500,000 target read-depth (equivalent of 10,000 B lymphocytes). The MiXCR tool (v4.3.2) was used for preprocessing and normalization. Repertoire analysis using the immunarch R package (v1.0.0) included clonality, diversity and V(D)J gene usage analyses. Machine learning by ImmuneML (v2.2.4) used four algorithms of KNN, SVM, RF and logistic regression. Using 3-mer aminoacids encoding and ABMR status as classifiers, the performances of ML algorithms were assessed by AUC.

Results: From repertoire analyes, decreased number of clonotypes (P=0.008) and decreased diversity (P=0.02) were seen in ABMR. There were differences in V gene utilization, from which IGHV1-2 and IGHV1-8 were decreased in ABMR group, while IGHV3-30 usage was higher (P=0.026, 0.014 and 0.018). The AUC of ML algorithms KNN, LR, RF and SVM were 0.77±0.11, 0.8±0.09, 0.81±0.11 and 0.75±0.06. Analysis of 3mer correlated V gene usages, from which NEI, TEC, WAK and WAR were statistically significant 3mers after Bonferroni correction (P<0.00000625).

Conclusions: Reproducible and clinically applicable AIRR-seq workflow was implemented using IVD product. Repertoire analysis was capable of demonstrating differences from kidney transplant recipients. ML models using different algorithms generated overall favorable performances in classifying ABMR status, indicating that direct interpretation of AIRR-seq data is possible.



Differences in number of clonotypes (A), diversity (B) between ABMR and No rejection groups. The performances of ML algorithms (C).

SA-PO1065

Sodium Restriction Is Associated with Decreased Kidney Function Through TonEBP Downregulation in Calcineurin Inhibitor (CNI)-Treated Kidney Transplant Recipients

Satoru Sanada, Saki Katano, Mitsuhiro Sato. *Japan Community Health Care Organization Sendai Hospital, Sendai, Japan.*

Background: Tonicity responsive enhancer binding protein (TonEBP) protects kidney tubular cells against hypertonicity by adapting the osmolar gap across the membrane. Under hypertonic conditions, TonEBP shifts from the cytoplasm to the nucleus for the transactivation of tonicity responsive genes. Calcineurin inhibitors (CNI) are known to suppress TonEBP by hampering its nuclear translocation. We examined whether CNI induced nephrotoxicity in transplant recipients could be due to impaired TonEBP activity.

Methods: A total of 385 kidney transplant recipients at JCHO Sendai Hospital between 2000 to 2022 were enrolled. Data for these patients were extracted from medical records. TonEBP immunohistochemistry was performed by biopsy specimens from 144 patients. The decline of eGFR were described using Kaplan-Meier methods.

Results: By immunohistochemistry, TonEBP was predominantly located in the cytoplasm among CNI nephrotoxicity compared to nuclear-cytoplasmic staining in rejections, suggesting that TonEBP transactivation was restricted in CNI nephrotoxicity. Cytoplasmic TonEBP staining was observed regardless of acute or chronic CNI induced kidney injury. Next, we examined sodium intake, which is the primary TonEBP activator of the kidney. Patients diagnosed as CNI nephrotoxicity revealed significantly lower sodium chloride intake compared to rejections (7.5 vs 10.8g/day, $p<0.05$). A 10% decline of eGFR among transplant recipients without any history of rejection (nor pre/post renal injury events) was significantly faster in the low sodium intake group (<8g/day) compared to the higher intake group (≧8g/day) (Median follow up: 10 years, Log-Rank P=0.03).

Conclusions: 1) TonEBP transactivation of renal tubular cells could be impaired in CNI nephrotoxicity and sodium restriction may exacerbate its activity, which could fail the TonEBP-mediated cell protection from the hypertonicity. 2) Sodium intake of kidney transplant recipients should be reevaluated from the view of preventing CNI nephrotoxicity.

SA-PO1066

Recipient Obesity on Deceased Donor Kidney Transplant (DDKT) Outcomes: Overlooked Threats to Allograft Dysfunction and Delayed Graft Function (DGF)

Suyeon Hong,[1,2] Byung ha Chung,[3,2] Chul Woo Yang,[3,2] Woo Yeong Park.[4]
[1]Uijeongbu Saint Mary's Hospital, Uijeongbu, Gyeonggi-do, Republic of Korea; [2]Catholic Medical University of Korea, Seoul, Republic of Korea; [3]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea; [4]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.

Background: As the prevalence of obesity increases globally, appreciating the effect of recipient obesity on graft outcomes is of increasing importance. However, the impact of recipient body mass index (BMI) on kidney transplant outcomes has been controversial. This study is designed to investigate the effect of recipient BMI on short and long-term outcomes of patients undergoing DDKT.

Methods: A total of 743 patients receiving deceased donor KT between 2005 and 2019 among 3 multi-centers were included in the study. Patients were divided according to their body mass index(BMI) into underweight (BMI<18.5,N=47), normal weight (BMI≧18.5 to BMI<25kg/m2,N=488), and obese (BMI≧25kg/m2,N=208) groups. Their clinicopathological characteristics, graft functions, graft survival rates and delayed graft function (DGF) were analyzed retrospectively.

Results: Obesity was associated with deterioration of allograft function. Kidney function was significantly lower in obese group compared with underweight and normal BMI groups after 3 months to 3 years follow up after DDKT(3 months follow up p= 0.005, 1year p=0.009, 3year p=0.034). Multivariate analysis showed that recipient obesity (BMI≧25) was an important prognostic factor for DGF (OR1.24, 95% CI, 1.011-1.438, P=0.042). Though statistically insignificant, the death-censored graft survival rate tends to be negatively associated with recipients' BMI level.

Conclusions: In conclusion, recipients' obesity increases the risk of allograft dysfunction and it is found to be statistically significant prognostic factor for DGF. Therefore, appropriate risk-adapted information concerning BMI should be provided to patients and efforts to improve recipients' obesity should be taken in advance to DDKT.

Long-Term Evaluation of Coronary Calcifications in Kidney-Transplanted Patients: A Single Center Follow-Up of 15 Years

Carlo Alfieri,[1,2] Alessandro Perna,[3] Laura Forzenigo,[1] Giorgia Schiraldi,[1] Anna Regalia,[1] Paolo Molinari,[1,2] Giuseppe Castellano.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy; [3]Universita degli Studi della Campania Luigi Vanvitelli, Caserta, Italy.*

Background: Few data are available on the long term behavior of coronary artery calcifications (CAC) in kidney transplantation (KTx). In a previous paper (Alfieri C et al. Sci Rep. 2019), we evaluated the factors implicated with CAC progression after 5 years of KTx. Here we present the preliminary data about CAC follow-up of the same population after 15 years of KTx (T15).

Methods: Previously 67 KTxps (2007-2008) were studied. At the present time, 19 of them were lost from the follow up: 8 died, 4 because of major cardiovascular event (MACE), 11 had a graft loss and 20 did not adhere to the control. Then, we evaluated 28 KTxps (M=18; age 60±9 yrs). Clinical, blood and urinary data were recorded for 15 years, considering the mean values in the analyses. At baseline and T15, using coronary TC, Agatson score was evaluated and patients were accordingly categorized in 4 groups: 1)0-10; 2)10-100; 3)100-400; 4)>400. The CAC progression was tested using the modification in CAC category (Cat-Prog+T15) and the formula proposed by Sevrukov (Prog+).

Results: At baseline and at T15, 46% and 18 % of pts were in the 1st grp, 14% and 25 % in the 2nd, 29% and 18% in the 3rd and 11 % and 39% in 4th, respectively. CAC at T15 were significantly higher than baseline (156±50 vs 334±71 p<0.0001). Both at baseline and at T15 CAC correlated directly with age and with each other. In the 79% Cat-Prog+T15 was found, in the 10,7% of more than 1 grp of CAC. 71% of KTxps were Prog+. They had higher systolic blood pressure levels, with no difference in specific therapy, lower mean Hb and Ca levels. Mean Ca Levels resulted the only independent factor inversely related with Prog+ (p=0.04). During the 15 years of KTx 25% of KTx had a MACE. No impact for CACs was found in MACE.

Conclusions: To the best of our knowledge, our study is the first one to evaluate CACs in KTxps for such a long time. According to the preliminary data obtained: 1) the prevalence of CAC in KTxps is high, and is related to age; 2) CAC worsening was observed in a consistent part of the cohort and was related to different parameters, especially to Ca levels. Future researches, possibly involving a higher number of KTxps could explain better these findings and explore more deeply the relation of CACs with MACE in the long term.

SA-PO1068

Association Between Pretransplant Dialysis Modality and Long-Term Graft Outcomes

Young Kyeong Seo, Taehee Kim, Yunmi Kim, Hyuk Huh, Yeong Hoon Kim.
Inje University Busan Paik Hospital, Busan, Republic of Korea.

Background: previous systemic reviews have shown that peritoneal dialysis (PD) is associated with substantial improvements in patient survival and delayed graft function compared with hemodialysis (HD) treatment as a pretransplant modality, the association between pretransplant dialysis modalities and posttransplant outcomes remains controversial.

Methods: We retrospectively collected records from 773 kidney transplant recipients between January 2008 and October 2021 in 2 transplant centers. We excluded recipients under the age of 18, 2nd or 3rd transplant recipients, and preemptive recipients. The final analysis included 558 kidney transplant recipients(fig. 1)We examined graft survival across pretransplant modality.

Results: 558 kidney transplant recipients were 47.5 years old and included 42% females and 28% diabetes. 407 recipients underwent HD, and 151 recipients underwent PD before transplantation. The overall graft survival between pretransplant HD and PD showed no statistical difference (P=0.197)(Fig. 2). pretransplant HD seemed to be favorable for graft survival over a long-term follow-up period of over 10 years.

Conclusions: Pretransplant modalities during the transition to a kidney transplant are not associated with graft survival.

The Effect of Kidney Transplantation on Biventricular Structure and Function Evaluated by Transthoracic Echocardiography

Claudia A. Navarrete,[1] Luis E. Morales-Buenrostro,[1] Jorge A. Joya Harrison,[2] Lluvia A. Marino-Vazquez,[1] Arturo A. Martinez-Ibarra,[2] Luis Baeza Herrera.[1]
[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Tecnologico de Monterrey, Monterrey, Mexico.

Background: Kidney transplant (KT) recipients experience a higher risk of cardiovascular disease outcomes when compared with the general population. Due to the increasing number of patients requiring a transplant, better identification of cardiac risk is required to prevent premature death with a functioning graft.

Methods: We performed a single-center prospective and longitudinal study that included all transplant-eligible patients (living or deceased donors) from January-May 2022. The candidates underwent pre-transplant transthoracic echocardiography (TE) as per institutional protocol and a second one a year later. We excluded patients who were lost to follow-up or suffered a cardiovascular event during the studied period. The most representative cardiovascular structure and function values were evaluated.

Results: Seventeen patients were included a mean age of 50 years and 64.7% were men. The median time spent on dialysis was 2.6 years, 64.7% were on hemodialysis and 29.4% on peritoneal dialysis. Reverse remodeling of the left ventricular was observed following the KT as the LV mass decreased from 101 g to 82 g (p = 0.01). End-diastolic volume decreased from 124 to 100 ml (p=0.022), end-systolic volume from 52 to 30 mL (p= 0.031), and ejection fraction increased from 57% to 61% (p=0.06). E/e' did not significantly change (9 vs 7.65 p= 0.14). Additionally, there were no statistically significant differences in left and right ventricle strain (18.5 vs 19.4 p=0.191 and 24 vs 24 p=0.55).

Conclusions: Reverse cardiac remodeling following the KT was observed as a reduction in left ventricle mass and improvement in ejection fraction, left and right ventricle strain did not change. Further description and understanding of cardiovascular function modification before and after KT is needed to improve graft and overall survival.

Association Between Clinical Atherosclerotic Cardiovascular Disease and Some Kidney Transplant Outcomes: A Retrospective Study

Emmanuel O. Adeyemi,[1] Chikodili N. Nebuwa,[2] Oluwabunmi A. Oke,[3] Shaunak A. Dwivedi.[1] *[1]Saint Peter's University Hospital, New Brunswick, NJ; [2]Nuvance Health, Poughkeepsie, NY; [3]Heatherwood Hospital, Ascot, United Kingdom.*

Background: Atherosclerotic cardiovascular disease (ASCVD) is a common comorbidity in patients with end stage renal disease that eventually get a kidney transplant. This study seeks to explore the association between clinical ASCVD and specific kidney transplant outcomes.

Methods: This study used the 2010-2022 data from the Scientific Registry of Transplant Recipients (SRTR). The SRTR data system includes data on all donors, waitlisted candidates and transplant recipients in the US submitted by the members of the Organ Procurement and Transplantation Network (OPTN). The Health Resources and Services Administration (HRSA), US Department of Health and Human Services provides oversight to the activities of the OPTN and SRTR contractor. Independent variables in our study include history of angina/coronary artery disease, history of peripheral vascular disease, history of cerebrovascular disease. Kidney transplant outcomes in this study include acute graft rejection, delayed graft function (measured in this study as failure of creatinine decline by 25% or more in the first 24hrs) and graft failure. Chi square was used to explore the association between atherosclerotic cardiovascular disease and kidney transplant outcomes.

Results: There were 108,927 kidney transplant recipients. 8,146 (7.5%) patients had clinical atherosclerotic cardiovascular disease. 2.5% of patients with clinical ASCVD vs 2.2% of patients without clinical ASCVD developed acute graft rejection (P-value=0.0401). 61.7% of patients with clinical ASCVD vs 52.5% of patients without clinical ASCVD developed delayed graft function (P-value=<0.0001). 1.7% of patients with clinical ASCVD vs 1.4% of patients without clinical ASCVD developed graft failure (P=0.0091).

Conclusions: Our study has shown that pretransplant atherosclerotic cardiovascular disease is a risk factor for acute graft rejection, delayed graft function and graft failure. This finding highlights the importance of both primary and secondary prevention of atherosclerotic cardiovascular disease in chronic kidney disease patients.

The Impact of Recipient's Pre-Transplant Viral Status on Acute Kidney Transplant Rejection in the United States: A Retrospective Study

Emmanuel O. Adeyemi,[1] Shaunak A. Dwivedi,[1] Oluwabunmi A. Oke,[2] Chikodili N. Nebuwa.[3] *[1]Saint Peter's University Hospital, New Brunswick, NJ; [2]Heatherwood Hospital, Ascot, United Kingdom; [3]Nuvance Health, Poughkeepsie, NY.*

Background: Acute graft rejection is a feared complication of kidney transplant and some studies have suggested that certain viral infections could be a contributor to this feared outcome. This study therefore set out to identify the impact of some viruses on acute kidney transplant rejection in the United States.

Methods: This study used the 2010-2022 data from the Scientific Registry of Transplant Recipients. This data system includes data on all donors, waitlisted candidates and transplant recipients in the US submitted by the members of the Organ Procurement and Transplantation Network. The study included patients aged 18 years or older who had kidney transplants in the United States. Independent variables include age group of recipients, recipient's gender, recipient's race, donor gender, donor race, donor type, previous transplant in recipient, viral detection (HBV, HCV, HIV) in recipient at transplant time, number of HLA mismatches and pre-transplant malignancy. The dependent variable was acute rejection between transplant and discharge. Univariate, bivariate (Chi-square and t-test) and multivariable logistic regression (stepwise selection with P-value for entry and stay of a variable put at <=0.05) analyses were done using SAS 9.4.

Results: There were 207,732 kidney transplants. On multivariable logistic regression that adjusted for significant variables on bivariate analysis (age group of recipients, recipient's race, previous transplant in recipient, number of HLA mismatches prior to transplant), transplant patients who were positive for HBV surface antigen had 57% (AOR: 95% CI 1.21-2.02) higher odds of developing acute rejection compared to those negative for the antigen. Those who had HCV detected at transplant time had 27% (AOR: 95% CI 1.07-1.49) higher odds of acute rejection compared to those who had no HCV detected. HIV positive patients had 107% (AOR: 95% CI 1.61-2.66) higher odds of developing acute rejection compared to those negative for HIV.

Conclusions: Our study has shown that viral infections (HBV, HCV, HIV) increase the risk of acute rejection in kidney transplants. These findings suggest that treating these viruses to non-detectable levels prior to transplant could reduce the risk of acute graft rejection.

SA-PO1072

Successful Kidney Donation After Gastric Bypass Surgery Using Individualized Stone Risk Assessment

Sambhavi Krishnamoorthy, Anna L. Zisman. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: The effects of increased prevalence of morbid obesity in the general population is reflected in the population presenting for living kidney donation as well. Bariatric surgery is the most successful and longest-lasting treatment for morbid obesity. Some centers may exclude donors who have undergone Roux en Y gastric bypass due to the risk of hyperoxaluria and risk of stone events post donor nephrectomy. We describe four living donor candidates who underwent evaluation at our kidney stone prevention program that allowed an individualized risk assessment to assess their candidacy keeping donor safety as a priority.

Methods: Retrospective review of electronic medical records was used to identify four living kidney donor (LKD) candidates with history of Roux en Y gastric bypass between 2012 and 2022. Patients submitted paired 24 hour blood and urine samples for metabolic evaluation. We compared the characteristics of the LKDs who went on to donate and the ones who were declined.

Results: Table 1a and 1b summarize the demographics and urinary metabolic parameters. Patient 1 went on to donate kidney as she did not have any hyperoxaluria. Patient 2 had hyperoxaluria on her initial testing, which normalized on repeat testing after counseling (Table 1c). She went on to successfully donate. Both patients 3 and 4 were declined as candidates for living kidney donation due to significant hyperoxaluria. The patients who were approved for donation were 10 years and 14 years out from gastric bypass surgery versus the ones who were declined who were 1 and 2.5 years out respectively.

Conclusions: Successful living kidney donation after bariatric surgery is possible with careful individualized evaluation of metabolic stone risk paramatersat an experienced stone center prior to approving their candidacy.

	Age	Sex	Race	BMI	Years from gastric bypass surgery	Kidney donation approved
Patient 1	55	F	W	26.4	10	YES
Patient 2	54	F	H	33.8	14	YES
Patient 3	63	F	W	32.5	1	NO
Patient 4	42	F	W	31.0	2.5	NO

	Patient 1	Patient 2	Patient 3	Patient 4
Urine volume (L)	1.0	2.2	3.0	1.0
Urine calcium (mg/day)	143	41	111	100
Urine oxalate (mg/day)	31	77	158	49
Urine citrate (mg/day)	1143	314	411	469

The Efficacy and Safety of SGLT2 Inhibitors and GLP1 Receptor Agonists in Kidney Transplant Recipients

Vikas Sridhar,[1] Maïté Zelderloo,[2] Yanhong Li,[1] David Cherney,[1] Sunita K. Singh.[1] [1]*University Health Network, Toronto, ON, Canada;* [2]*Katholieke Universiteit Leuven, Leuven, Belgium.*

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) and glucagon-like peptide-1 receptor agonists (GLP1RA) decrease adverse cardiorenal outcomes in the general population. We aimed to evaluate the efficacy and safety of SGLT2i and GLP1RA monotherapy and combination therapy in kidney transplant recipients (KTR).

Methods: This was a retrospective cohort study of all adult KTR started on SGLT2i and/or GLP1RA between January 1, 2000 and December 31, 2021. Baseline characteristics, drug safety/tolerability, estimated glomerular filtration rate (eGFR), and cardiorenal outcomes were collected.

Results: Of 227 patients analyzed, 78 were on SGLT2i, 79 on GLP1RA and 70 on combination therapy. 120 patients had pretransplant diabetes (DM) (53.6%) and 103 had post-transplant DM (46.0%). Compared to the period before drug initiation, there were no differences in rates of CV events and graft failure with either monotherapy or combination therapy. After one month, SGLT2 inhibition resulted in a median eGFR decline of 6 ml/min/1.73m^2 (interquartile range -11 to 3.5) (**Figure 1**). Drug discontinuation was high, with 19.2% of SGLT2i users, 28.7% of GLP1RA and 41.4% on combination therapy stopping therapy – 'hospitalization' with SGLT2i and 'intolerance' with GLP1RA and combination therapy were the most frequent causes of discontinuation. However, compared to the period before drug initiation, rates of urinary tract infections, ketoacidosis, acute kidney injury and hepato-pancreato-biliary complications were not significantly different.

Conclusions: SGLT2i, GLP-1RA and combination therapy appear to be safe in KTR, though drug discontinuation is relatively common. The acute eGFR 'dip' observed with SGLT2 inhibition suggests tubular-glomerular mechanisms are intact in this unique population.

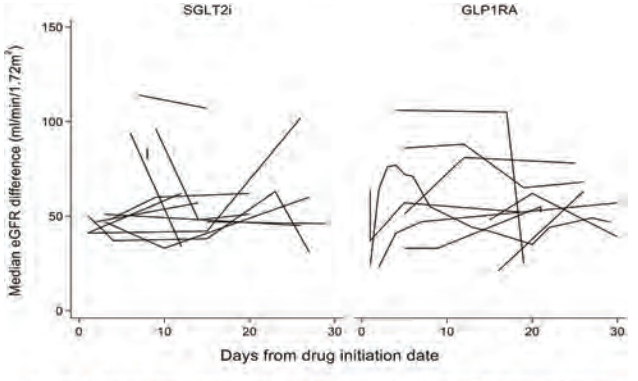

Figure 1: Individual patient trends in eGFR over 1 month after drug initiation

A Systematic Investigation on the Impact of Invasive Kidney Allograft Biopsy on Urinary Cell mRNA Profiles

Thalia Salinas, Carol Y. Li, Sheavonnie Wright, Perola Lamba, Manikkam Suthanthiran. *Weill Cornell Medicine, New York, NY.*

Background: Liquid biopsies offer an unprecedented window into intragraft events. It is preferred that biospecimens are collected prior to biopsy since mechanical injury from this invasive procedure may alter circulating levels of biomarkers of interest, (Kyeso Y et al. Transplantation Direct 2021). In the Clinical Trials in Organ Transplantation (CTOT)-04 study consisting of 485 kidney transplant recipients (KTR), 298 biopsy-matched urine specimens were used to develop and validate a urinary cell 3-gene signature consisting of 18S rRNA normalized CD3ε mRNA and CXCL10 mRNA (CTOT-04 signature) and all but 10 specimens were collected at the time of biopsy or ≤3 days prior (Suthanthiran M et al. N Engl J Med 2013). There were no paired pre and post biopsy specimens to investigate the impact of kidney allograft biopsy on absolute copy numbers of the transcripts or CTOT-04 signature. The current study was designed to fill this gap in knowledge.

Methods: We collected urine from KTR before and after kidney allograft biopsy, both ≤6 hours of biopsy. We used the Weill Cornell Hybrid Protocol consisting of urine filtration to collect eluate with stable RNA and mRNA enrichment during RNA isolation using a silica-membrane-based cartridge (Salinas T et al. J Immunol Methods 2022). We measured absolute copy numbers of CD3ε mRNA, CXCL10 mRNA, and 18S rRNA (CTOT-04 signature), and mRNAs for TGFβ1, FOXP3, and BKV VP1 in urine samples collected pre and post kidney allograft biopsy.

Results: Box and whisker plots show that the various urinary cell mRNA levels and CTOT-04 signature score are not different between urine samples collected before and urine samples collected after kidney allograft biopsy (**Fig. 1 A-G**, All P values >0.05, Wilcoxon matched pairs signed-rank test).

Conclusions: Urinary cell mRNA levels and CTOT-04 signature score are not impacted by the kidney allograft biopsy and yield indistinguishable results irrespective of whether the urine was collected prior to or after the invasive kidney allograft biopsy procedure.

Effect of Different Treatment Regimens on Kidney Graft Function and Mortality in Patients with a Diagnosis of Antibody-Mediated Rejection

Laura E. Díaz González,[1] Ana C. Hernandez Pugh,[1] Jose Ignacio Cerrillos,[1] Jorge Andrade-Sierra,[2,1] Enrique Rojas-Campos,[1] Luis Alberto Evangelista-Carrillo,[1] Basilio Jalomo martínez,[1] Miguel Medina Perez.[1] [1]*Instituto Mexicano del Seguro Social, Guadalajara, Mexico;* [2]*Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico.*

Background: The optimal treatment for Antibody mediated rejection (AMR) remains uncertain, and its presence causes up to 60% of kidney grafts loss.

Methods: A retrospective cohort from May-2016 to June 2022, that included 176 patients ≥18 years old, hospitalized with graft dysfunction and histopathological diagnosis of AMR to receive treatment. Were categorized into 3 groups; 1. Plasmapheresis (PF) + Intravenous immunoglobulin (IVIG), 2. IVIG + Rituximab (RTX) 3. Steroids and immunosuppression treatment optimization.

Results: On average, 63% of patients were men, and a majority were transplanted with a living donor kidney (89%), showing a median of age 32 ± 9; baseline serum creatinine (CrS) was 1.15 and during the rejection, 2.75 mg/dL; timing of biopsy 6 ± 5 years; C4d positive (68%) comparing groups of treatments there were no significant difference by CrS at the end of the follow up, episodes of infections was 27%, 20% and 10% (P=0.61), mortality was 6.8%, 2.5% and 5.8% each group (P=0.47).

Conclusions: There was no significant difference in graft function and mortality between treatment groups, but in a logistic regression analysis, predictive variables of poor graft prognosis were: CrS greater than 2.5 mg/dl at the beginning of treatment, using steroids and immunosuppression optimization treatment; greater chronicity and being younger at the time of diagnosis.

Table 1: Results N:176	Plasmapheresis + IVIG + Rituximab (44)	IVIG + Rituximab (80)	Steroids + immunosuppression treatment optimization (52)	p Value

SA-PO1076

Relationship of Serum Procalcitonin (PCT) Levels with Kidney Graft Function in the Immediate Post-transplantation Period in Kidney Transplant Recipients

Beatriz R. Cerezo Samperio,[1,2] Ana C. Acosta Peña,[1] Abel Humberto V. Compean,[1] Claudia B. López,[1] Pedro Morales Molina,[1] Julio C. Nieto,[1] Juan D. Diaz Garcia,[1] Irving G. Ramirez,[1] Jose H. Cano Cervantes.[1] *[1]Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico; [2]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico*.

Background: Renal function is one of the major determinants of PCT levels, which is why its relationship as a marker of acute kidney injury not associated with sepsis has previously been described. In kidney transplantation (KT) the persistently high levels of PCT seem to show a relationship with the function of the kidney graft because its levels increase after the elevation of other inflammatory cytokines in events of exaggerated inflammatory response and it is poorly cleared in patients with delayed graft function. This study seeks to find the relationship of serum PCT levels as well as their association with kidney graft function in the immediate period.

Methods: We conducted a retrospective cohort study from February 2016 to May 2022 of Nephrology and Transplant patients. A number of 82 KT recipient patients with PCT determination in the immediate postransplant period were obtained. Statistical analysis: Descriptive statistics, interferential statistics were performed by comparing groups and intragroup for categorical variables with x2 and Fisher's exact test; for non-parametric continuous variables Mann-Whitney U.

Results: They were classified as normal graft function (NGF), slow graft function (SGF) and delayed graft function (DGF). Within the baseline characteristics, no statistically significant differences were found for age, type of transplant, leukocytes, and hemoglobin at admission. Finding that a level > 3 ng/dl of procalcitonin conferred a greater risk of DGF, as well as higher levels in this group compared to patients with NGF.

Conclusions: Procalcitonin is an early marker to identify patients who develop delayed kidney graft function.

Characteristics

Variable	NGF n = 23	DGF n = 45	SGF n = 14	P value
Age (years)	37 ± 12	43 ± 15	46 ± 16	0.155
Male (%)	10 (43)	26	13	0.310
Deceased Donor (%)	16	35	12	0.556
Cold ischemia (Hrs)	11.5 (1-14.25)	16 (12-18)	13.25 (10.25-15.25)	0.0145
Leukocytes (miles/mm3)	7.5 (5.5-8.6)	7.9 (5.8-12.3)	8.6 (4.7-13.1)	0.562
Procalcitonin (ng/ml)	1.41 (0.23 – 3.97)	5.6 (0.79 – 29)	2.55 (0.37 – 6.77)	0.0230
PCT > 3 ng/dL	6	26	4	0.0203

SA-PO1077

Characteristics of Renal Allograft Survivors of More than 15 Years: A Single-Center Experience

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain*.

Background: We studied the characteristics and the predictors of graft and patient survival in Bahraini renal transplant recipients with an allograft that functioned for more than 15 years.

Methods: Out of 185, underwent renal transplantation between 1982 and 2007, 52 patients (28.1%) maintained functioning allografts for more than 15 years (range 15-41 years). Characteristics of the surviving patients, data on graft survival, and determinants of outcome were obtained by reviewing all medical records.

Results: The mean age at time of renal transplantation was 43.1 ± 11.3 years and 75% were males. The cause of end-stage renal disease was diabetic nephropathy in 28.5% and 86% received dialysis therapy before transplantation. The source of the graft in 39 (75%) recipients was from living related donors with a mean age of 31.7 ± 6.6 years, and it was the first graft in 50 recipients. The primary immunosuppression regimen was cyclosporine (CsA) based in 29 patients (29.1%), tacrolimus (Tac) based in 21 patients (40.4%) while three patients (5.6%) received steroids and azathioprine only. Induction therapy was administered to 58 patients. Acute rejection episodes occurred in 10 patients (19.2%), of whom two experienced two episodes. During the last follow-up, the mean serum creatinine was 123 ±36 µmol/L. Two patient were successfully treated for Covid-19 viral infection. A history of hypertension was encountered in 66% and posttransplant diabetes mellitus in 21%. We compared the graft functioning group with the graft failure group and found that the independent determinants of long-term graft survival included age of the recipient, time of late acute rejection episodes, use of induction therapy, histopathologic findings of chronic allograft damage, and serum creatinine at one year.

Conclusions: We conclude that renal transplantation in its earliest years and despite the associated numerous complications has provided a fifteen-year or more of near-normal life to patients with end-stage renal disease.

SA-PO1078

Navigating the Crossroads: Cytomegalovirus (CMV), Neutropenia, and Kidney Transplant Survival in High-Risk Patients

Johannes Muench, Ellen von Hoerschelmann, Klemens Budde, Fabian Halleck. *Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: Cytomegalovirus (CMV) infections constitute a significant condition in kidney transplant (KT) recipients with a major impact on morbidity, mortality and graft survival, with CMV negative recipients (R-) transplanted from a CMV positive donor (D+) at highest risk. The prevention of CMV disease in KT recipients mainly relies on antiviral prophylaxis and preemptive therapy with virostatics, e.g., valganciclovir (VGCV). Although these strategies proved to be efficient, their use is limited due to substance related toxicities. This study aims to evaluate the effects of VGCV administration on the development of neutropenia and graft survival in CMV high risk KT.

Methods: A retrospective data analysis was used to analyze KT recipients with CMV high risk constellation, transplanted at Charité Berlin (Germany) between 2003-2019. The incidence of neutropenia (<1/nl), severe neutropenia (<0.5/nl) and KT survival within the first 2 years after KT was assessed for recipients with and without a VGCV prophylaxis during day 0-200.

Results: 556 patients with CMV high risk constellation received a KT, including 437 (78.6%) and 119 (22.4%) with and without prophylactic VGCV administration, respectively. The likelihood of developing (severe) neutropenia was elevated in KT recipients with VGCV administration (log-rank 0.0289, **Fig.A**). The time to onset of neutropenia was 145±96 days for recipients with VGCV prophylaxis and 122±84 days for those without VGCV (p=0.062). The development of neutropenia was associated with an increased risk of graft failure within the first 2 years (p<0.01, **Fig.B**). However, VGCV administration was not linked to reduced graft survival (p=0.482).

Conclusions: Our results show that VGCV prophylaxis in CMV high-risk KT recipients is linked to an increased likelihood of developing neutropenia. However, the timing of the onset of neutropenia is not significantly altered by VGCV. Given the potential negative impact of neutropenia on KT outcomes, it is crucial to closely monitor neutropenic KT recipients. Further research may elucidate if targeting neutropenia could improve KT outcomes.

SA-PO1079

Time-to-Graft Loss Prediction in Kidney Transplant Recipients

Tamas Szili-Torok,[1] Max J. Verbeek,[1] Daan Kremer,[1] Uwe J. Tietge,[2] Stephan J. Bakker,[1] Martin H. De Borst.[1] *[1]University Medical Center Groningen, Department of Internal Medicine, Groningen, Netherlands; [2]Division of Clinical Chemistry, Department of Laboratory Medicine, Karolinska Institutet, Stockholm, Sweden.*

Background: Several predictions models have been proposed which estimate graft failure risk in kidney transplant recipients (KTR). However, the risk resulting from the model is challenging to interpret. Therefore, this study aims to propose a machine learning model which predicts time to kidney graft loss.

Methods: Data were derived from the transplant registry of the University Medical Center Groningen, including KTR transplanted after 1-1-1995. Data for model training was obtained 1 year after transplantation. KTR with missing data <5 years after transplantation were excluded. Graft loss was defined as death or graft failure. To predict the time to graft loss, extreme gradient boosting (XGBoost) with the accelerated failure time objective was utilized. The model was trained using a bootstrap aggregating (bagging) approach. Variables included in the model were selected by feature selection. The performance of the machine learning model was internally evaluated using the C-index on 20% of the dataset which was not used for training.

Results: From the 2195 included patients (age 52 [41-61] years, 42% female), 1225 (56%) developed graft loss during median follow-up of 8.1 [5.1-13.0] years. The final model was trained using 45 commonly determined clinical variables, including eGFR, hemoglobin, age, and several feature-engineered variables. Feature engineered variables are new variables created from existing ones to improve the performance of the model. Hematocrit*eGFR, recipient age and gamma-glutamyltransferase were identified as the most important variables driving time to kidney graft loss. Internal validation showed a C-index of 0.74.

Conclusions: The machine learning model developed predicts time to graft loss with a reasonable accuracy.

SA-PO1080

Association Between Early State of Volume Overload with Delayed Graft Function in Kidney Transplantation

Juan Reyna-Blanco, Maribel Merino, L. M. Perez-Navarro, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Delayed graft function (DGF) following kidney transplantation (KT) is a common problem and has been associated with decreased graft survival and increased risk of acute rejection. One of the factors that has been poorly studied so far is the state of volume overload as a risk factor for DGF. The aim is to associate the state of volume overload estimated by the daily accumulated fluid balance and measured through bioimpedance vectors, ultrasonographic parameters, serum B-type natriuretic peptide (sBNP), and Ca-125 with the development of DGF.

Methods: All patients over 18 years undergoing KT were included. Fluid balance was recorded, sBNP and Ca-125 were measured. Electrical bioimpedance and ultrasound measurements were also performed such as diameter of the inferior vena cava (IVC) and the portal vein pulsatility fraction (PVPF). Measurements were taken before KT and then every 24 hours for 3 days after KT. The primary outcome was the development of DGF, defined as the need for renal replacement therapy within the first 7 days post-transplantation.

Results: A total of 34 patients with KT were included, with an average age of 31 (26-42) years, and the main type of renal transplant was deceased donor (68%). Eight patients (23.5%) developed DGF. Analysis of the volume status revealed that the accumulated balance at 72 h was -79.7 mL (-3648 to -1875 mL) in the non-DGF group and 5596 mL (5126 to 7232 mL) in those who developed DGF (p<0.001). Pretransplant sBNP levels were 100.1 pg/mL (38-248) without DGF vs 525 pg/mL (74-1815) with DGF; p=0.045. Pretransplant Ca-125 levels were 12.1 U/mL (7.9-19) without DGF vs 10.1 U/mL (9-13) with DGF; p=0.92. Pretransplant IVC diameter was 1.6 cm (1.4-1.7) without DGF vs 2.3 cm (range 1.7-2.4) with DGF; p=0.1. Pretransplant PVPF was 23% (17-31) without DGF vs 37% (25-71) with DGF; p=0.09. Pretransplant total body water was 35.8 L (32.1-38.6) without DGF vs 39.5 L (35.9-42.7) with DGF; p=0.31. Univariate analysis revealed that only pretransplant BNP levels were associated with the development of DGF (OR: 1.002, 95% CI:1.001-1.003; p=0.04).

Conclusions: Volume overload, estimated by accumulated fluid balance, was associated with the development of DGF. However, the use of different volume status biomarkers only revealed that sBNP at baseline were associated with the development of DGF.

Drug-Drug Interaction of Potassium Competitive Acid Blocker with Tacrolimus and Mycophenolate in Kidney Transplant Recipients: A Randomized Controlled Trial Using Smart Clinical Trial Platform

Seong-Wook Lee, You Hyun Jeon, Jeong-Hoon Lim, Hee-Yeon Jung, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho. *Kyungpook National University Hospital, Daegu, Republic of Korea.*

Background: Potassium competitive acid blocker (P-CAB) is a newly developed gastric acid inhibitor exhibiting faster action and lower drug toxicity than proton pump inhibitor (PPI). However, the drug-drug interaction of P-CAB with tacrolimus and mycophenolate is not investigated in kidney transplant recipients (KTRs). The study aimed to compare the changes in the blood concentration of immunosuppressants after the administration of P-CAB.

Methods: A total of 62 KTRs were randomized to either P-CAB (Tegoprazan®) or PPI group. A smart clinical trial platform monitored the enrolled patients with remote monitoring and safety management systems. Remote monitoring system transmitted data about adherence to the study drug, blood pressure, body temperature, and electrocardiogram. Questionnaires for general and gastrointestinal (GI) symptoms were surveyed using a self-developed app installed on the patient's phone. One non-face-to-face video visit was scheduled during the study period. Trough levels of tacrolimus and mycophenolate were checked monthly for 3 months.

Results: Baseline characteristics including trough levels did not differ between groups. The adherence to the study medication was 100% in both groups. A total of 13,726 biometric information and 5,031 questionnaire answers were collected. We conducted 5,704 feedback messages and 56 non-face-to-face video visits. Mean trough levels of tacrolimus and mycophenolate did not differ between P-CAB and PPI groups at 3 months (5.5 ± 2.5 vs. 5.8 ± 3.8 ng/dL, P = 0.50 and 2.7 ± 2.0 vs. 2.6 ± 2.0 ng/dL, P = 0.66, respectively). The intragroup difference of the trough levels between baseline and 3 months was not significant in both groups. The average questionnaire scores of GI symptoms were comparable between groups. The vital signs and allograft function maintained stably without significant difference during the study period.

Conclusions: P-CAB does not affect the serum trough levels of tacrolimus and mycophenolate in KTRs. P-CAB showed a similar effect on the patient-reported GI symptoms compared to PPI. Our smart clinical trial system with non-face-to-face video visits demonstrated the efficacy and safety in performing randomized trials.

Use of an LCP Tacrolimus (LCPT) in Kidney Transplantation: A Delphi Consensus Survey of Expert Clinicians

Alexander C. Wiseman,[1] Suphamai Bunnapradist,[2] Tarek Alhamad,[3] Rita R. Alloway,[4] Beatrice P. Concepcion,[5] Matthew Cooper,[6] Richard N. Formica,[7] Christina L. Klein,[8] Vineeta Kumar,[9] Nicolae Leca,[10] Fuad S. Shihab,[11] David J. Taber,[12] Sarah Mulnick,[13] Donald M. Bushnell,[13] Monica Hadi.[13] *[1]Porter Adventist Hospital, Denver, CO; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]Washington University in St Louis, St Louis, MO; [4]University of Cincinnati College of Medicine, Cincinnati, OH; [5]University of Chicago Pritzker School of Medicine, Chicago, IL; [6]Froedtert Hospital, Milwaukee, WI; [7]Yale School of Medicine, New Haven, CT; [8]Piedmont Healthcare Inc, Atlanta, GA; [9]UAB Hospital, Birmingham, AL; [10]University of Washington, Seattle, WA; [11]The University of Utah School of Medicine, Salt Lake City, UT; [12]Medical University of South Carolina, Charleston, SC; [13]Evidera Inc, Bethesda, MD.*

Background: LCPT (Envarsus XR®) is a common once-daily, extended-release oral tacrolimus formulation used in kidney transplantation. Variations in real-world use mean uncertainty remains on how best to use LCPT in kidney transplantation in de novo and conversion populations. The objective of this study was to address the gaps in published data by developing consensus statements on the use of LCPT in kidney transplantation using the Delphi process with a panel of expert clinicians.

Methods: A panel of 12 clinicians with expertise in nephrology and kidney transplantation reviewed available clinical evidence on LCPT. The Delphi panel survey consisted of three rounds of an online survey. Consensus was achieved when ≥75% agreed strongly or with reservation to a statement.

Results: Twenty-three statements were evaluated: 14 on de novo and nine on general or conversion use. After two rounds, consensus was achieved for 20 statements (Figure 1). De novo, LCPT was recognized as a first-line option based on its safety and efficacy compared to immediate-release tacrolimus. In a conversion setting, full consensus was achieved for converting to LCPT to address neurological side effects related to immediate-release tacrolimus and for the time required (~7 days) for steady state LCPT trough levels to be reached.

Conclusions: The consensus statements generated in this study provide a real-world guide to using LCPT in kidney transplantation, especially in a de novo setting, for which guidance is currently lacking.

Funding: Commercial Support - Veloxis, Inc.

Final Recommendation	Consensus
De novo setting	
In the de novo setting, Envarsus XR® can be used as first-line therapy considering its efficacy and safety are equivalent to BID tacrolimus. A. Envarsus XR® has a similar efficacy profile as tacrolimus IR B. Envarsus XR® has a similar safety profile as tacrolimus IR	92%
Compared to twice-daily tacrolimus... When considering safety and efficacy, Envarsus XR® is preferred as first-line therapy for African American patient population in the de novo setting.	83%
Compared to twice-daily tacrolimus... When considering safety and efficacy, Envarsus XR® is preferred as first-line therapy in known rapid metabolizers in the de novo setting.	83%
In the de novo setting, the first assessment of trough levels of Envarsus XR® can be after the third dose although steady state is not expected until after 7 days on a stable dose.	92%
In the de novo setting, the Envarsus XR® dosing should begin with 0.14 mg/kg/day and should be calculated for ideal body weight in the setting of obesity, except in the following scenarios: A. The initial dosing of Envarsus XR® may be reduced in the setting of depleting antibody therapy when using induction therapy B. The dose may be increased in known rapid metabolizers. C. The dose may be adjusted in the presence of known drug interactions that influence tacrolimus metabolism.	92%
In the de novo setting, ideal body weight should be used as the preferred initial dosing weight for Envarsus XR® in obese recipients.	100%
In the de novo setting, Envarsus XR® should be initiated on the morning of POD1 for all kidney transplant recipients, regardless of initial kidney function.	83%
In the de novo setting, initial dosing of Envarsus XR® can be reduced in the setting of depleting antibody therapy when using induction therapy.	83%
In the de novo setting, initial dosing of Envarsus XR® can be adjusted in patients for whom the risk of supratherapeutic levels outweighs the benefit of rapid achievement of therapeutic levels.	100%
During the first week post-transplant the dose of Envarsus XR® should only be adjusted in circumstances of a supratherapeutic level or circumstances of a significantly subtherapeutic trough level suggestive of rapid metabolism (e.g., tacrolimus trough <3 ng/ml after postoperative day 3).	75%
Conversion to Envarsus XR® is recommended to address neurological side-effects related to BID Tacrolimus.	100%
Steady state is achieved after Envarsus XR® dose 7 and therefore, on a stable dose, dose adjustments can be made per clinical practice protocols following the seventh dose.	75%
Further evidence of clinical long-term outcomes (graft survival, renal function) would help support the use of Envarsus XR® in current clinical practice, in both the de novo setting and conversion setting	92%
Conversion setting	
Patients should consistently take Envarsus XR® on an empty stomach, rather than consistently with or without food.	92%
Trough level assessment of Envarsus XR® should take into account the time to achieve steady state (approximately 7 days).	100%
When available, pharmacogenomic screening is recommended for initial dosing considerations for Envarsus XR®.	83%
Additional cost and formulary considerations pose barriers to the use of Envarsus XR® as first line therapy in the de novo setting.	75%
Additional costs and staff time required pose barriers to conversion to Envarsus XR®.	92%
Intrapatient variability has been shown with tacrolimus preparations. There are no specific recommendations for utilization of Envarsus XR® related to intrapatient variability.	83%
Further evidence of clinical long-term outcomes (graft survival, renal function) would help support the use of Envarsus XR® in current clinical practice, in both the de novo setting and conversion setting.	92%

Effect of Prolonged-Release vs. Immediate-Release Tacrolimus on Neurocognition in Kidney Transplant Recipients: A Pilot Randomized Controlled Trial (RCT)

Hadia Lala Gul, Macey Sockolov, Amanpreet Kaur, Michelle Occhipinti, Heejung Bang, Muna Alnimri, Yihung Huang, Ling-Xin Chen, Katherine A. Howes. *UC Davis Health, Sacramento, CA.*

Background: Tacrolimus is known to cause neurological side effects and elderly individuals seem particularly vulnerable. It is unknown if the prolonged-release (PR) tacrolimus (Envarsus XR) formulation minimizes neurocognitive side effects compared to immediate release (IR) tacrolimus due to lower peak serum levels. We aimed to compare the neurocognitive side effects of PR and IR tacrolimus in elderly kidney transplant recipients within the first months post-transplantation.

Methods: In this single center, prospective, open-label, randomized trial, 64 kidney transplant recipients aged 60 or above were randomized to PR tacrolimus or IR tacrolimus between 4 and 8 weeks post-transplantation and followed for 6 weeks. Neurocognitive performance was assessed by the Montreal Cognitive Assessment (MOCA) and Digit Symbol Substitution Test (DSST). Secondary outcomes of tremor and quality of life were assessed through the Quality of Life in Essential Tremor Questionnaire (QUEST) and Organ Transplant Symptom and Wellbeing Instrument (OTSWI).

Results: 32 patients were randomized to the IR tacrolimus arm and 31 into the PR tacrolimus arm. Mean age was 69 in both arms and 37% were women. Table 1 shows the assessment scores for the primary and secondary outcomes. There was no statistically significant difference between groups in the change in MOCA or DSST scores from baseline to 6 weeks or in tremor or quality of life measures.

Conclusions: Although prior studies indicated improvement in neurological side effects in PR tacrolimus compared with IR tacrolimus, the improvement does not appear to extend to neurocognitive side effects as assessed by the MOCA or DSST tests in this cohort.

SA-PO1084

The Association Between 25-Hydroxyvitamin D and Recurrence of Glomerulonephritis in Kidney Transplant Recipients

Zhongyu Yuan,[1,2] Michal L. Melamed,[3] Tripti Singh,[2] Sandesh Parajuli,[2] Sarah E. Panzer,[2] Didier A. Mandelbrot,[2] Brad C. Astor.[1,2] *[1]University of Wisconsin-Madison Department of Population Health Sciences, Madison, WI; [2]University of Wisconsin-Madison Department of Medicine, Madison, WI; [3]Albert Einstein College of Medicine, Bronx, NY.*

Background: Disease recurrence contributes significantly to allograft failure in kidney transplant recipients (KTR) with kidney failure due to glomerulonephritis (GN). Accumulating evidence has revealed a role of vitamin D in innate and adaptive immunity. While vitamin D deficiency is common among KTRs, the association between 25-hydroxyvitamin D [25(OH)D] and GN recurrence in KTRs remains unclear.

Methods: Data from KTRs with GN (focal segmental glomerulosclerosis, IgA nephropathy, membranous nephropathy, membranoproliferative GN, or lupus nephritis) transplanted at our center from 2000-2019 were analyzed. All post-transplant serum 25(OH)D measurements were included as a time-varying covariate. Disease recurrence was identified via allograft biopsy following abnormal clinical signs or laboratory measures. Survival models considered other causes of allograft loss, including death, as competing risk events. Disease recurrence within one year after each 25(OH)D measurement was considered as the event of interest. Models were adjusted for age at transplant, sex, race, donor status, prior transplant, and time of 25(OH)D measurement.

Results: A total of 63 cases of GN recurrence (median: 4.6 years) were identified in 823 KTRs followed for a median of 7.6 years after transplant. Each 1 ng/ml lower serum 25(OH)D was associated with a 5% higher incidence of recurrence (adjusted hazard ratio [aHR] = 1.05; 95% CI, 1.02-1.07). Vitamin D deficiency (≤ 20 ng/ml) was associated with a 3.04-fold (aHR = 3.04; 95% CI, 1.60-5.78) higher incidence of recurrence compared with vitamin D sufficiency (≥ 30 ng/ml). Similar results were found after further adjusting for concurrent urinary protein:creatinine ratio and excluding events within 30 days after 25(OH)D measurement (Table).

Conclusions: Vitamin D deficiency is associated with a higher incidence of GN recurrence in KTRs independently of proteinuria. Additional research is needed to explore the utility of vitamin D surveillance and management in KTRs with GN.

Models	Sample size		Serum 25(OH)D	Adjusted hazard ratio (95% CI)	P-value
Model A [a]	823 KTRs (63 events)	Continuous	Per ng/ml decrease	1.05 (1.02, 1.07)	<0.01
		Categories	Sufficiency (≥ 30 ng/ml)	Reference	
			Insufficiency (20 – 29 ng/ml)	1.26 (0.68, 2.36)	0.46
			Deficiency (≤ 20ng/ml)	3.04 (1.60, 5.78)	<0.01
Model B [b]	679 KTRs (51 events)	Continuous	Per ng/ml decrease	1.05 (1.02, 1.08)	<0.01
		Categories	Sufficiency (≥ 30 ng/ml)	Reference	
			Insufficiency (20 – 29 ng/ml)	1.07 (0.53, 2.14)	0.86
			Deficiency (≤ 20ng/ml)	3.33 (1.54, 6.34)	<0.01
Model C [c]	672 KTRs (39 events)	Continuous	Per ng/ml decrease	1.04 (1.01, 1.07)	0.02
		Categories	Sufficiency (≥ 30 ng/ml)	Reference	
			Insufficiency (20 – 29 ng/ml)	0.60 (0.34, 1.86)	0.60
			Deficiency (≤ 20ng/ml)	2.54 (1.14, 5.66)	0.02

25(OH)D, 25-hydroxyvitamin D; CI, confidence interval; KTR, kidney transplant recipients

Cryptococcosis in Kidney Transplant Recipients

Laurène Tardieu,[1] Gillian Divard,[2] Laurent Mesnard,[3] Jean-philippe Rerolle,[4] Marie Frimat,[5] Cecile M. Vigneau,[6] Gabriel Choukroun,[7] Matthias Buchler,[8] Renaud Snanoudj,[9] Valerie Moal,[10] Moglie Lequintrec-Donnette,[1] Hannah Kaminski,[11] Cedric Rafat.[3] *[1]Centre Hospitalier Regional Universitaire de Montpellier, Montpellier, France; [2]Hopital Universitaire Necker-Enfants Malades, Paris, France; [3]Hopital Tenon, Paris, France; [4]CHU Dupuytren 2, Limoges, France; [5]Centre Hospitalier Universitaire de Lille, Lille, France; [6]Hopital Pontchaillou, Rennes, France; [7]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [8]Hopital Bretonneau, Tours, France; [9]Hopital Bicetre, Le Kremlin-Bicetre, France; [10]Assistance Publique Hopitaux de Marseille, Marseille, France; [11]Universite de Bordeaux, Talence, France.*

Background: Cryptococcosis is the third most common invasive fungal infection in solid organ transplant recipients. Clinical management and disease prognosis have already been previously scrutinized in this setting but had yet to be investigated specifically in kidney transplant recipients(KTr).

Methods: We carried out a cohort study of patients diagnosed with cryptococcosis after KT in France. Cases were matched with controls derived from a multicenter KT database. Our main objective was to describe course of graft function and patient survival. Secondary endpoints consisted in investigating practices pertaining to immunosuppressive treatment adjustments, identifying risk factors. Multivariable analysis was performed using conditional logistic regression to identify risk factors for cryptococcosis.

Results: Eighty-eight patients were included, matched with 79 controls. During induction treatment of cryptococcosis, 37.5% of patients presented with acute kidney injury (AKI) with 13.3% warranting renal replacement therapy. 35.5% of AKI were caused by drug toxicity. 34% of the patients experienced 1 side effect :amphotericin B-related nephrotoxicity predominated (39%) and was characterized by AKI in every case. All surviving patients were exposed to azole treatment. Of these, 41.8% experienced an overdose of tacrolimus, half of which were complicated by AKI. Twelve months after diagnosis of cryptococcosis or equivalent period for controls, 22.4% of KTr experienced loss of graft function compared with 1.4% for control KTr ($p<0.001$). In 61.4% of patients on mycofenolate mofetil, drug was stopped whereas it was continued at unchanged doses in 12.3%. Dose of calcineurin inhibitors was not modified in 42.4% and reduced in 37.9% Upon multivariable analysis, patient's age (OR 1.04 p=0.004) and history of rejection (OR 2.32 p=0.04) were significantly associated with the development of cryptococcosis.

Conclusions: Cryptococcosis is associated with a highly impact on overall and kidney graft survival in KTr. Risk of acute graft dysfunction followed a threefold temporal sequence characterized by amphotericin-related tubular injury, tacrolimus overdose due to fluconazole/tacrolimus interaction through CYP competition and acute graft rejection in the setting of immunosuppression tapering.

SA-PO1086

Chronic Lymphocytic Leukemia in Solid-Organ Transplant Recipients: A Single-Center Experience

Liza Cholin, Todd E. Pesavento, Priyamvada Singh. *The Ohio State University, Columbus, OH.*

Background: To date, only two case series on chronic lymphocytic leukemia (CLL) in solid-organ transplants (SOT) has been published which showed an increased risk for severe infections and mortality. The aim of our study was to add to the limited literature on this topic, by evaluating the overall safety of transplanting such patients.

Methods: A 10 year retrospective chart review was performed to identify patients with a diagnosis of CLL who had undergone SOT at a large transplant center. Post-transplant outcomes including infectious complications, graft loss, and mortality were reviewed.

Results: A total of 10 CLL patients were studied: 5 had a CLL diagnosis pre-SOT, and 5 were diagnosed with CLL post-SOT (table 1). All kidney transplant recipients received anti-thymocyte globulin for induction, while liver transplant recipients received either Basiliximab or steroids. Maintenance immunosuppression (IS) therapy amongst the SOT recipients was similar, with 8 out of 10 patients receiving a calcineurin-inhibitor and mycophenolate derivative. Average follow up for pre-SOT CLL patients was 2.9 years (min 1, max 6) with 1 out of 2 deaths attributed to an infectious complication (COVID). Post-SOT CLL patients had a mean of 9 years between transplantation and CLL diagnosis. On an average follow up of 2.8 (min 0, max 7) years after CLL diagnosis, 3 out of 5 post-SOT CLL patients had death as an outcome.

Conclusions: Short-term outcomes in SOT recipients with a diagnosis of CLL prior to transplantation appear acceptable. However, SOT recipients who developed CLL post-transplantation seem to have an increased mortality risk. Infectious complications are a known cause for increased morbidity and mortality in CLL patients. As such, reduction in maintenance IS therapy in patients who are years out from transplantation may allow for improved outcomes.

Donor-Derived Large B-Cell Lymphoma After SPK

Akshay Athreya, Gaurav Gupta, Ambreen Azhar, Layla Kamal, Selvaraj Muthusamy, Muhammad I. Saeed, Aamir Khan. *Virginia Commonwealth University, Richmond, VA.*

Introduction: Absolute risk of lymphoma transmission with SOT is unknown. In this unique case, DLBCL was detected after SPK with delayed renal allograft dysfunction with functional pancreas & mate kidney.

Case Description: Recipient was nonsensitized 42-year-old EBV IgG+ type 1 diabetic male. Donor was 39-year-old female with paraplegia due to multiple sclerosis on no treatment. No history of cancer at time of death, no leukocytosis & preprocurement CT abd/chest was normal. Cause of death was cerebellar bleeding. Donor was EBV IgG+, KDPI 31% with negative XM. Before implantation, a core needle biopsy was performed. LM showed CD20+ atypical lymphocytic infiltrate. The recipient received rATG induction & maintenance FK, MMF & steroids per protocol. A creatinine rise prompted biopsy 2 weeks post transplant. It showed diffuse mononuclear inflammatory tubulointerstitial infiltrate with clusters of atypical cells in interstitium & peritubular capillaries staining diffusely for CD20, Ki67(~50%) & variably for BCL2 & MUM1 indicating DLBCL. Atypical cells in procurement biopsy showed similar pattern. Simultaneous tissue gene expression testing (MMDx) showed AbMR, possibly indicating host vs tumor response. Immunosuppression was withdrawn except steroids. PET scan & peripheral flow cytometry were negative. Patient underwent allograft pancreatectomy & nephrectomy. Explant pathology showed DLBCL invasion of renal graft & portion of small bowel. Due to risk of microinvasion of tumor, rituximab (weekly *4) was given with serial PET scans & R-CHOP. No other donor derived lymphomas were reported to UNOS from heart, liver, lungs & mate kidney from this donor.

Discussion: Early allograft removal, immunosuppression withdrawal & cancer therapy was offered to the patient to maximize treatment efficacy & confer the best chance of survival in this high risk disease.

Post-Transplant Lymphoproliferative Disorders in Kidney Transplant Recipients: A Retrospective Single-Center Cohort Analysis

Muhammad Y. Jan,[1] Bethany Kelly,[1,2] Ahsan Raza,[1] Oluwafisayo O. Adebiyi,[1] Muhammad S. Yaqub,[1] Asif A. Sharfuddin.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University Health University Hospital, Indianapolis, IN.*

Background: To characterize the posttransplant lymphoproliferative disorders(PTLD) including the Epstein-Barr virus (EBV) status, histological subgroups, site of occurrence and the clinical outcomes of kidney transplant recipients at our institution.

Methods: A retrospective cohort study of all kidney transplant recipients who developed PTLD and were followed up at our transplant centers from 1999 through 2021.

Results: 44 patients developed PTLD, with majority 86.4% being kidney alone transplants, while 13.6% were Kidney-Pancreas recipients. Heme-Oncology were primarily responsible for the treatments which was tailored to their individual type and stage and site of PTLD. Immunosuppression was lowered on an individualized basis.

Conclusions: We describe a large series of PTLD cases, with their outcomes with reasonable outcomes. The time-line to PTLD was not limited to early post-transplant course as seen in other series, and EBV-ve PTLD was more common. Careful adjustment of immunosuppression, early detection, and aggressive treatment can lead to acceptable outcomes.

Demographics	
Mean age at transplant	42.8+/-20.5 ; Median 44 (range 3.1-76.9)
Race	88.6% Whites; 9.1% AA

Kidney MR Elastography on Controls and Patients with Kidney Transplant

Suraj D. Serai,[1,2] Hansel J. Otero,[1,2] Laura S. Finn,[1,2] Tricia Bhatti,[1,2] Bernarda Viteri.[1,2] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: To compare the diagnostic performance of MR elastography in controls and in pediatric patients with transplant kidneys.

Methods: A prospective study of pediatric kidney transplants undergoing clinically indicated biopsy & healthy controls, was performed. MRE was performed on a 3T MRI scanner equipped with MRE hardware consisting of an active-passive driver system. A 2D & 3D spin-echo planar MRE sequence were used to acquire coronal wave images and mean kidney stiffness (in kPa) were measured. For each patient, one to three needle biopsy cores of the lower pole were obtained and fixed in formalin. Three micron sections were stained with hematoxylin & eosin, and Masson trichrome. The severity of interstitial fibrosis and tubular atrophy (IFTA) was graded according to Banff 2017. A comparative analysis was performed using one-way ANOVA.

Results: A prototype hardware, software and acquisition sequence for Kidney MRE was developed and implemented. 10 pediatric controls were enrolled (Median age: 14.5 years). Mean kidney stiffness was 3.8 kPa. We also enrolled 4 healthy adults (Median age: 28 years). Mean stiffness measured by MRE was 4.2 kPa. Significantly higher mean baseline stiffness was observed in adult controls as compared to children. 12 kidney transplant recipients were enrolled (Median age: 15.5 years). Mean stiffness measured was 5.3 kPa. We found the mean stiffness of kidneys in children with allografts was significantly higher than controls. MRE showed significant differences among the allograft groups when evaluating IFTA.

Conclusions: Our study has shown that MRE has the potential to be utilized as non-invasive tools for quantitative measurement of fibrosis in renal allografts with a correlation with histopathology. MRE technology has the potential of detecting IFTA in patients with kidney transplant.

Noninvasive Evaluation of Renal Allograft Fibrosis Using Magnetization Transfer Imaging

Mina H. Al Saeedi, Deep Gandhi, Kai Jiang, Amir Lerman, James Glockner, Mark D. Stegall, Aleksandra Kukla, Lilach O. Lerman. *Mayo Clinic Research Rochester, Rochester, MN.*

Background: Fibrosis negatively affects kidney allograft survival, but the options for early noninvasive diagnosis are limited. Magnetic transfer imaging (MTI) magnetic resonance imaging (MRI) assesses tissue macromolecule accumulation (like collagen), a characteristic of fibrosis. We tested the hypothesis that MTI non-invasively detects allograft fibrosis in patients with KT.

Methods: Multiparametric MRI was performed in 13 (M9/F4) KT recipients with stable kidney function prior to the protocol allograft biopsy (Table 1). Cortical and medullary magnetization transfer ratio (MTR) at 1.5T MRI, oxygenation (blood oxygen level-dependent MRI), perfusion (arterial spin labeling), and microstructure (diffusion-weighted imaging) were compared with interstitial fibrosis (IF) on the kidney biopsy (trichrome staining) and with albumin-to-creatinine ratio (ACR). Glomerular filtration rate (GFR) was measured using iothalamate clearance.

Results: MTR correlated directly with both cortical and medullary histological IF and with ACR (Figure-1) but not with GFR. No other imaging-derived index correlated with any renal parameter.

Conclusions: Both the % of IF on kidney biopsy and ACR correlated significantly with MTR-MRI but not with any other MRI indices. Hence, MTR may provide a noninvasive tool for the detection and assessment of IF in renal allografts, pending confirmation in a larger number of patients.

Prognostic Implications of Chronic Active T-Cell-Mediated Rejection Diagnosed on Renal Allograft Protocol Biopsies

Arjun L. Kalaria, Hussain A. Karimi, Matthew Pittappilly, Massiel P. Cruz Peralta, Sundaram Hariharan, Chethan M. Puttarajappa, Puneet Sood, Akhil Sharma, Rajil B. Mehta. *UPMC, Pittsburgh, PA.*

Background: Banff 2017 introduced Chronic Active TCMR(CA-TCMR) into the classification of rejection. However, the significance of this finding on early protocol biopsies has not been explored.

Methods: We identified a cohort of patients with serial protocol biopsies performed between Oct 2018-Jan 2022. Biopsies were done at 3- and 12- months. We chose the protocol biopsy closest to the 1-year time point. We included both living and deceased donor kidney transplants. De-novo and repeat kidney transplants were included. We excluded biopsies with borderline rejection, antibody mediated rejection or BK virus nephritis. Biopsies that qualified for TCMR were further divided into acute TCMR(n=31) and CA-TCMR(n=36). Biopsies with no major abnormalities (NMA) were used as control. The maximum follow up period was 5.5 y with a median follow up of 3.5 y. All patients received induction therapy with anti-thymocyte globulin and maintenance immunosuppression with tacrolimus and MMF. Patients with cPRA>90% also received maintenance steroids.

Results: See below

Conclusions: CA-TCMR is common in early protocol biopsies and is more common in deceased donor kidney transplants. Allograft survival was lower in biopsies with CA-TCMR. Finding of CA-TCMR on early protocol biopsies prognosticates long term allograft outcome.

Leveraging Machine Learning Methods and Novel Data Sources to Develop Race-Free Algorithms to Predict Deceased Donor Kidney Quality

Jeremy Rubin,[1] Jarcy Zee,[1] Sarah J. Ratcliffe,[4] David S. Goldberg,[3] Michael O. Harhay,[1] Chirag R. Parikh,[2] Emily A. Vail,[1] Peter Abt,[1] Peter P. Reese,[1] Vishnu S. Potluri.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Johns Hopkins Medicine, Baltimore, MD; [3]University of Miami School of Medicine, Miami, FL; [4]University of Virginia, Charlottesville, VA.*

Background: To help transplant professionals choose appropriate kidneys for patients, the national transplant organization uses the Kidney Donor Risk Index (KDRI) that predicts the risk of graft failure. Unfortunately, the KDRI has modest predictive accuracy (C-statistic 0.6). The KDRI has been criticized for penalizing hepatitis C virus (HCV), given recent therapies, and race, given ethics concerns. We aimed to develop machine learning based, race-free models and longitudinal organ donor lab data to predict 3-year all-cause kidney (graft) survival and delayed graft function (DGF, dialysis in the first week post-transplant).

Methods: Using registry data, we assembled a cohort of adult (≥18 years) recipients of deceased donor kidneys between 5/1/07-12/31/21. We developed models with different combinations of donor and recipient characteristics using standard regression (Cox and logistic regressions) and machine learning algorithms (Random Forest, Ridge, Lasso, Elastic Net).

Results: The final cohort included 162,905 recipients of kidneys from 95,811 donors. Median donor age was 39.5 years (IQR 27-51) and 38% were female. For 3-year kidney survival, the C-statistic of KDRI was 0.59. Removal of donor race and HCV covariates, or inclusion of donor longitudinal data, made little difference, but inclusion of recipient covariates improved the C-statistic to 0.63-0.64 across different algorithms (Figure). For DGF, the KDRI had a C-statistic of 0.60. Refitting models with or without donor race had similar C-statistics of 0.68-0.69. The inclusion of recipient covariates improved the C-statistics for DGF to 0.74-0.75.

Conclusions: These models demonstrated the feasibility of eliminating donor HCV and race without a meaningful decrement in predictive accuracy for kidney survival and DGF outcomes. The addition of recipient characteristics substantially improves prediction of both outcomes.

Figure 1. Comparison of C-Statistics for 3-year Deceased Donor Kidney Survival

Model	Model 1	Model 2	Model 3	Model 4
Variables	Variables in KDRI (includes race and HCV)	Model 1 + excluding race and HCV	Model 2 + recipient variables & donor-recipient interactions	Model 3 + restricted to April 2016 and later (new antivirals available)
KDRI (Reference)	0.592	0.592	0.592	0.545
Lasso	0.592	0.589	0.631	0.646
Ridge	0.592	0.589	0.631	0.646

Inflammation Alters Relationship Between High-Density Lipoprotein Cholesterol and Risk of CKD: Results from UK Biobank Study

Hui-Yun Jung, Seung Hyeok Han. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

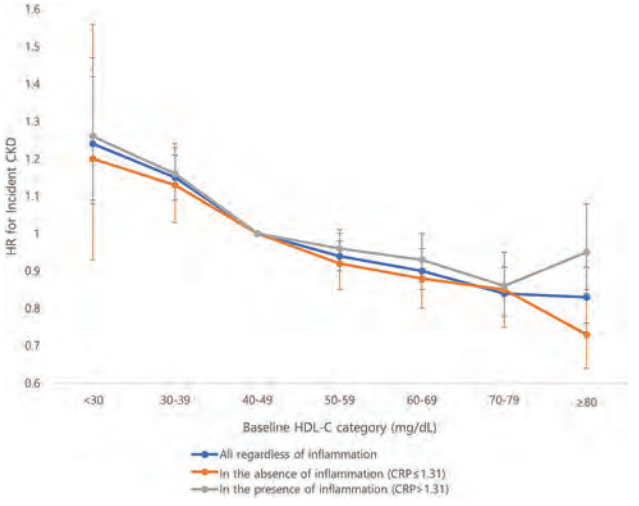
Background: Under inflammatory condition, the functional changes of high-density lipoprotein-cholesterol (HDL-C) can transition from a protective role to a proatherosclerotic direction. We aimed to investigate whether inflammation could modify the relationship between HDL-C and risk of incident chronic kidney disease (CKD).

Methods: We conducted an observational study in 342,204 European adults, aged 38 to 73 years, who were free of CKD at recruitment between Mar 13, 2006, and Oct 1,

2010, from the UK Biobank study. The main exposure was HDL-C level. The presence of inflammation was defined when high sensitivity C-reactive protein (hs-CRP) level was above the median (>1.31 mg/L). The primary outcome was incident CKD.

Results: During a follow-up period of 3,983,553 person-years (median, 11.9 years), the primary outcome occurred in 13,950 (4.1%) participants. Overall, a higher HDL-C level was associated with a decreased risk of incident CKD in multivariable Cox analysis after adjustment of confounders. There was a significant interaction between HDL-C and the presence of inflammation on the risk of incident CKD (*P*-for-interaction=0.019). In patients without inflammation, the protective association of a higher HDL level remained similar. The hazard ratios (HRs) (95% CIs) for HDL-C of <30, 30-39, 50-59, 60-69, 70-79, ≥80 mg/dL were 1.20 (0.93-1.56), 1.13 (1.03-1.24), 0.92 (0.85-1.00), 0.88 (0.80-0.96), 0.85 (0.75-0.95), 0.73 (0.64-0.85), respectively, compared with HDL-C of 40-49 mg/dL. However, this association was attenuated in patients with inflammation, particularly for HDL-C ≥80 mg/dL. Notably, a lower HDL level was associated with a higher risk of CKD in all patients with a stronger increased risk observed in patients with inflammation.

Conclusions: A higher HDL-C level is associated with decreased risk of incident CKD, but this association was weak under inflammatory condition. These findings suggests that inflammation may modify the relationship between HDL-C and the development of CKD.



SA-PO1094

The Association Between Higher Serum Triglyceride Level and Poor Kidney Outcome Among Patients with CKD: The Fukuoka Kidney Disease Registry (FKR) Study

Mai Seki, Toshiaki Nakano, Shigeru Tanaka, Hiromasa Kitamura, Hiroto Hiyamuta, Kazuhiko Tsuruya, Takanari Kitazono. *Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu Daigakuin Igaku Kenkyuin, Fukuoka, Japan.*

Background: Dyslipidemia, especially hypertriglyceridemia, is a very common complication in patients with chronic kidney disease (CKD). Although hypertriglyceridemia is known to be a risk factor for the development of CKD in the general population, it is unclear whether there is a relationship between higher serum triglyceride levels and the progression of kidney failure in patients with CKD. The aim of this study was to investigate the relationship between serum triglyceride levels and the progression of kidney failure.

Methods: A total of 4,101 Japanese outpatients aged ≥16 years were prospectively followed for 5 years. Patients were divided into four groups based on quartiles of serum triglyceride levels at baseline (<87, 87-120, 121-170, >170 mg/dL). The primary outcome was the progression of kidney failure, defined by a 1.5-fold increase in serum creatinine from baseline or the development of end-stage kidney disease. We estimated the relationship between serum triglyceride and the outcome using a multivariable-adjusted Cox proportional hazards model.

Results: During the 5-year observation period, 1410 patients developed the progression of kidney failure. The incidence rate of the progression of kidney failure increased linearly with the increase in serum triglyceride levels (*P* for trend <0.05). In the multivariable-adjusted analysis, the hazard ratio (HR) for the progression of kidney failure in the highest serum triglyceride quartile (Q4) was 1.22 (95% CI, 1.02-1.45; *P* <0.05) compared with the lowest serum triglyceride quartile (Q1). This association was increased in patients with higher baseline BMI (≥ 25 kg/m^2) (*P* for heterogeneity <0.05).

Conclusions: The current study shows that higher serum triglyceride level is associated with the progression of kidney failure in patients with CKD. It also highlighted that this relationship was more pronounced in individuals with a higher BMI.

Incidence of CKD in Prediabetes

Radica Z. Alicic,[1,2] Obidiugwu Duru,[3] Cami R. Jones,[1] Lindsey M. Kornowske,[1] Kenn B. Daratha,[1] Meda E. Pavkov,[4] Alain K. Koyama,[4] Susanne B. Nicholas,[3] Joshua J. Neumiller,[5] Yoshihisa Miyamoto,[4] Keith C. Norris,[3] Katherine R. Tuttle.[1,2] CURE-CKD Registry. *[1]Providence Health and Services, Spokane, WA; [2]University of Washington School of Medicine, Seattle, WA; [3]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [4]Centers for Disease Control and Prevention, Atlanta, GA; [5]Washington State University, Pullman, WA.*

Background: Diabetes complications may occur in persons with prediabetes mellitus (PDM) defined by hyperglycemia below the threshold for diabetes diagnosis. The study aim was to assess the incidence of chronic kidney disease (CKD) in PDM in a real-world population.

Methods: The study population was derived from the Center for Kidney Disease Research, Education, and Hope (CURE-CKD) Registry of electronic health records from Providence and UCLA Health systems. PDM was defined by HbA1c 5.7-6.4%, 2 measures of fasting (100-125 mg/dL) or random (140-199 mg/dL) blood glucose at least 1 day apart, or ICD-9/10 codes. CKD was defined by estimated CKD-EPI 2021 glomerular filtration rate (eGFR) <60 mL/min/1.73 m^2, urine albumin/creatinine ratio ≥30 mg/g, or urine protein/creatinine ratio ≥0.15 g/g ≥90 days apart, or ICD-9/10 codes. Incidence of CKD was estimated in persons ≥18 years old with PDM and without CKD in the previous 6 months. Estimates for 2015-2020 were standardized to the 2020 US population. Incidence rate ratios (IRR) compared CKD incidence within age, race/ethnicity, and sex groups.

Results: Persons with PDM (N=256,829) were 55% women and 56±15 years old. At baseline, mean eGFR was 93±16 mL/min/1.73 m^2; mean HbA1c and systolic blood pressure were 5.8±0.3% and 127±16 mmHg. After a median follow-up of 2.6 years (interquartile range 1.5-3.8), CKD was identified in 7%. Of these, 43% had an eGFR <60 mL/min/1.73 m^2. Standardized incidence rate of CKD was 30.4 cases/1,000 person-years (95% CI 29.8-31.0). IRRs are presented in the Figure.

Conclusions: CKD developed among 1 in 14 persons with PDM in a short period of time. Older age and non-White race groups with PDM, except the Asian patient group, had higher incidence of CKD compared to the White group, whereas women had lower risk than men. These results suggest that certain demographic groups may benefit from targeted awareness, detection, and strategies to prevent CKD progression.

Funding: Other U.S. Government Support

Impact of Hyperglycemia on Renal Prognosis in Lean Individuals

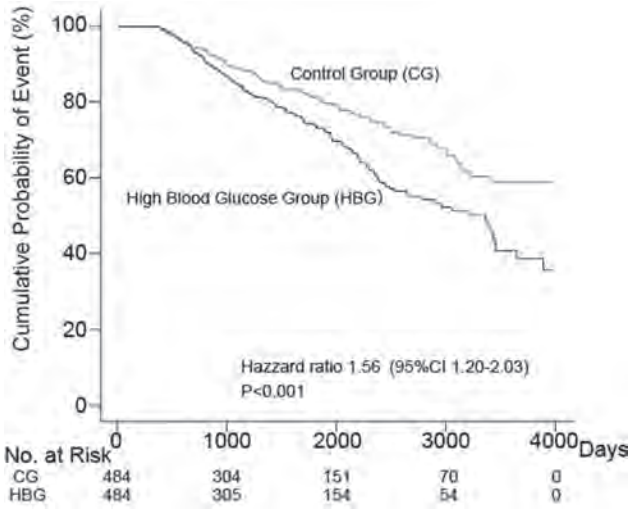
Makoto Araki. *Sapporo Tokushukai Hospital, Sapporo, Japan.*

Background: Obesity not only affects blood glucose but also influences haemodynamics and adipocytokines, making it unclear to what extent hyperglycemia alone contributes to organ damage. Therefore, our aim was to investigate the specific impact of hyperglycemia on renal prognosis in lean individuals with elevated blood glucose levels.

Methods: In this single-center study from 2012 to 2022, we analyzed body mass index (BMI), estimated glomerular filtration rate (eGFR), and hemoglobin A1c (HbA1C) data. Individuals with a BMI <18.5 at any time were selected, excluding those under 18 years old, on dialysis, or with one year of data. Participants with HbA1C >6.5% were assigned to the hyperglycemic group (HBG), while the rest formed the control group (CG). Propensity score matching adjusted for background factors, and both groups underwent time-to-event analysis for a 40% eGFR decline. A 12-month landmark analysis minimized guarantee time bias.

Results: Among individuals with recorded BMI, 14.2% experienced a BMI below 18.5 during the study. Out of the initial 3149 individuals, 516 were classified as HBG, having a significantly higher average age than CG (74.3 vs. 63.7 years). Among those who did not reach a renal function endpoint within one year of enrollment, we selected a final sample of 484 patients in each group after adjusting for background factors including gender, age, first-year eGFR, duration of observation, and minimum BMI. The selected participants had a mean age of 74.9 years, mean duration of observation of 1755.4 days, and mean minimum BMI of 16.5. Survival time analysis showed that HBG reached the endpoint significantly more often than CG (Hazard ratio: 1.56 (95%CI 1.20-2.03), P < 0.001).

Conclusions: Lean individuals with hyperglycemia, who were more likely to be elderly, exhibited a significantly higher prevalence of impaired renal function compared to background-matched controls.



SA-PO1097

Changes in the Thyroid, Pituitary, and Gonadal Hormones in CKD Patients During One-Year Follow-Up

Aleksandra Rymarz, Ksymena Lesniak, Stanislaw Niemczyk. *Wojskowy Instytut Medyczny - Panstwowy Instytut Badawczy, Warszawa, Poland.*

Background: Hormonal disorders are common complications of chronic kidney disease (CKD). Endocrine disturbances interplay with nutritional status and both are associated with kidney function and influence long term outcomes. The aim of the study was to examine changes of serum levels of chosen hormones, changes in kidney function and nutritional parameters in CKD patients during one-year follow-up.

Methods: Male CKD patients with eGFR lower than 45 ml/min/1.73m^2 on conservative treatment formed cCKD group and male patients treated with hemodialysis for more than three months formed HD group. In both groups serum levels of total (TT), free testosterone (FT), dehydroepiandrosterone sulfate (DHEA-S), sex hormone binding globulin (SHBG), luteinizing hormone (LH), prolactin (PL), thyroid-stimulating hormone (TSH), free triiodothyronine (fT3), free thyroxine (fT4), creatinine (Cr), albumin (A) were measured at the moment of inclusion and after one year.

Results: 21 men aged 67±7 were included to cCKD group and 20 aged 63±8 to HD group. Over one-year follow-up in cCKD group serum levels of LH, PL and TSH increased significantly whereas DHEA-S decreased. Serum levels of TT, FT, SHBG, fT3, fT4 as well as Cr, A and levels did not change significantly. In HD group over one year follow-up serum levels of fT3 and fT4 significantly decreased. Whereas the rest of parameters did not change significantly.

Conclusions: In male with CKD on conservative treatment significant changes of DHEA, LH, prolactin and TSH were observed during one-year follow-up whereas at the same time Cr, eGFR and nutritional markers did not change significantly. In HD group only fT3 and fT4 decreased significantly. We can suspect that hormonal changes can precede decline in kidney function and deterioration of nutritional status in CKD patients.

SA-PO1098

Impact of Lifestyle Changes on Quality of Life in Patients with CKD: Results from a Real-World Study

James Jackson, Dean A. Taylor, Muhammad Jamee, Sophie Barlow, Mollie Lowe. *Adelphi Real World, Bollington, United Kingdom.*

Background: Lifestyle changes can slow progression of chronic kidney disease (CKD) but can be difficult for patients to implement. We assessed the impact of lifestyle changes on quality of life in patients with CKD.

Methods: Data were drawn from the Adelphi CKD Disease Specific Programme™, a cross-sectional survey of physicians and patients conducted in the USA from Jan-June 2022. Non-dialysis patients completed the Short Form Health Survey 12-item (SF-12) and provided information on the successes in implementing recommended lifestyle changes. Two groups were formed, 'successfully implemented' and 'unsuccessfully implemented'. T-tests were used to compare groups.

Results: Overall 221 patients provided data, the mean [SD] age was 63.2 [12.58], 55% were male, and 66% were white. Lifestyle changes were recommended to 74%, and 95% of these patients reported difficulty implementing the change(s), of which 20% found it very/extremely difficult. In the SF-12 physical health domain, stopping/reducing alcohol consumption, improving sleep pattern, starting/increasing exercise and reaching/maintaining a healthy weight had the largest difference in composite scores between successful vs unsuccessful (p <0.001) [Table 1]. In the SF-12 mental health domain, stopping/reducing alcohol consumption, stopping/reducing smoking, reaching/maintaining a healthy weight, reducing potassium intake, and consulting a nutritionist had the largest difference in composite scores between successful vs unsuccessful (p <0.05) [Table 1].

Conclusions: High numbers of patients describe difficulty implementing lifestyle changes recommended by their physician. Unsuccessful implementation can lead to a greater impact on physical and mental quality of life. Support is needed to help patients with these changes, provide optimal care and better patient outcomes.

Table 1 - Mean patient reported SF-12 scores, shown per recommended lifestyle change

Recommended lifestyle change	SF-12 Physical Health Composite			SF-12 Mental Health Composite		
	Unsuccessfully implemented mean (n)	Successfully implemented mean (n)	P-value	Unsuccessfully implemented mean (n)	Successfully implemented mean (n)	P-value
Reduce dietary sodium intake	41.84 (106)	44.48 (70)	0.0808	47.21 (106)	50.45 (70)	0.0342
Reduce intake of foods high in sugar	41.28 (101)	45.89 (55)	0.0052	47.43 (101)	51.60 (55)	0.0084
Start/increase exercise	40.84 (107)	51.70 (28)	<0.0001	48.72 (107)	53.27 (28)	0.0264

Factors Influencing Quality of Life in Moderate to Severe CKD

Cholwiwat Polpattaraset, Kraiwiporn Kiattisunthorn. *Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand.*

Background: Improving quality of life is one of the targets of CKD management which are involved in several factors including physical, mental and social factors. In addition to factors in general population, evaluation tools for health related QoL (HRQoL) in CKD patients should include kidney related parameters. KDQOL-SF1.3 is a tool developed and established to demonstrate QoL in ESRD, but data in non-dialysis CKD is scarce. Therefore, this study is to present factors contributing to HRQoL in stage 3-5 CKD.

Methods: There were 94 stage 3-5 CKD patients followed up at Siriraj CKD Clinic, Faculty of Medicine Siriraj Hospital, included into the study from November 2021 and August 2022. The data were collected at the baseline for age, gender, comorbidities, CKD etiology, household incomes and education, current medications and pill numbers, blood pressure, nutritional status, physical activity, muscle mass, handgrip strength, and physical performance. Laboratory data included serum creatinine based estimated CKD-EPI GFR, hemoglobin, serum albumin, calcium, phosphate and intact parathyroid hormone (PTH). HRQoL was assessed by KDQOL-SF1.3.

Results: Demographic data were demonstrated in table 1. There was no difference of overall scores of HRQoL in each stage of CKD (stage 3; 70.0 ± 15.3, stage 4; 69.0 ± 18.3 and stage 5; 73.5 ± 16.2; p = 0.545). However, lower HRQoL scores were associated with poor physical capacity parameters and PTH. Mean 6-minute walk test was 184.9 ± 79.7 m vs. 259.1 ± 89.4 m; p=0.002, median 5-times chair stand test was19.9 (7.9) vs. 13.2 (6.9) seconds; p=0.004 and metabolic equivalent of task (MET) was 100 (420) vs. 480 (2200) MET-min/week; p=0.009, among the patients with HRQoL <60 and ≥60, respectively. PTH was associated with lower physical component summary (PCS) scores [median PTH 149 (106) vs. 90.4 (94.0) pg/ml in PCS <38 vs. PCS >38, respectively; p=0.025].

Conclusions: Lower physical capacity is strongly associated with poor QoL in moderate to severe CKD. Factors associated with physical activity and skeletal health in CKD should be further evaluated to intervene for improving the outcomes.

An Investigation into the Relationship Between Frailty and Health-Related Quality of Life in Patients with CKD and Heart Failure

Ella H. Tumelty,[1] Thomas W. Mcnally,[1] Isaac W. Chung,[2] Souradip Mookerjee,[1] Sabba A. Hussain,[1] Debasish Banerjee,[1,2] Mahrukh A. Ali.[2] *[1]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [2]St George's University of London, London, United Kingdom.*

Background: An increasing number of patients have comorbid Chronic Kidney Disease (CKD) and Heart Failure (HF); CKD-HF. Patients with CKD and HF have high frailty levels. Frailty is a predictor of morbidity; however, its association with health-related quality of life (HRQOL) is poorly understood. The aim of this study was to investigate the relationship between frailty and HR-QOL in patients with CKD-HF.

Methods: This was a single centre, cross-sectional study of adults with CKD stage 3-5 with HF. Frailty was defined as Modified Frailty Phenotype (MFP) score >=3. HRQOL was assessed using the validated Short Form (SF-36) Health Survey. All data was collected at one point in time.

Results: The characteristics of the 103 included participants were: median age 76 years (IQR 13), 62% (64/103) male, mean BMI was 28.7 (SD 6.3) and median eGFR 30 (IQR 17). Fifty-one (50%) of participants were frail, and 52 (51%) were non-frail according to the MFP. Compared to non-frail patients, frail patients had significantly worse physical functioning scores (frail 20.88+/-14.48, non-frail 53.24+/-25.94, p-value <0.001), general health scores (frail 29.51+/- 16.86, non-frail 45.00(+/-20.05, p-value <0.001), bodily pain scores (frail 46.29+/-33.60, non-frail 63.27+/-29.22, p-value 0.008), social functioning scores (frail 52.23+/-29.65, non-frail 72.58+/-28.05, p-value 0.001) and energy levels (frail 26.37+/-18.31, non-frail 49.71+/-19.22, p-value<0.001). Most respondents cited 'better quality of life' as their healthcare priority.

Conclusions: Better quality of life is a priority for patients with CKD-HF. Frailty is negatively associated with quality of life. Early detection and intervention of frailty should be a priority for healthcare professionals.

Funding: Other NIH Support - This study received £1,000 from St George's University Academic Training (GAT) Faculty 'Small Grant Fund'- St George's University, GAT office, Crammer Terrace, London, SW17 0RE.

Sleep Duration and Kidney: Does Weekend Sleep Matter?

Chia-Chao Wu,[1] Kuo-Cheng Lu.[2] *[1]Tri-Service General Hospital Department of Internal Medicine, Taipei, Taiwan; [2]Taipei Tzu Chi Hospital, Taipei, Taiwan.*

Background: Weekend sleep duration is linked to health issues, including mortality. However, how weekend sleep duration can impact chronic kidney disease (CKD) still needs to be understood. Therefore, we aimed to analyze how weekend sleep duration is associated with kidney function.

Methods: Data were obtained from the 2017-2018 National Health and Nutrition Examination Survey. We included 5,362 study participants and categorized them into nine subgroups by sleep duration (≤6 hours, 6–9 hours, and ≥9 hours) on weekdays and weekends and analyzed for the respective association with renal function using multivariable linear regression.

Results: Weekend sleep duration for 9 hours or more was associated with decreasing estimated glomerular filtration rate (eGFR) levels by 2.8 to 6.4 ml/min/1.73 m^2 among people with long to short weekday sleep duration compared with short weekday and weekend sleep durations (control group) after adjusting for demographic characteristics, body measurement, sleep quality, smoking, and comorbidities. The study population with short weekday sleep duration (sWK) and long weekend sleep duration (lWKD) had the most significant decline in eGFR. For the study population with sWK, eGFR level significantly decreased by 1.1 ml/min/1.73 m^2 as sleep duration on weekends increased by one hour. Therefore, weekday and weekend sleep duration should both be considered when investigating the relationship between sleep duration and CKD.

Conclusions: Longer weekend sleep duration was linked to a decrease in eGFR levels. It warrants further study to confirm the causal association and clarify the mediators

Depressive Symptoms Do Not Worsen over Time in Individuals with CKD: The BRINK Study

Christopher D. Knapp,[1,2] Allan Y. Gao,[2] Nicholas S. Roetker,[1] Kayla L. Horak,[1] Ashley Farnum,[1] Allyson Hart,[1,2] Kirsten L. Johansen,[1,2] Anne M. Murray.[1,2] *[1]Hennepin Healthcare System Inc, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: The prevalence of depression is high in the chronic kidney disease (CKD) (20-40%) and dialysis (30-50%) populations. It is unclear how depression symptoms change over time in patients with CKD.

Methods: Participants in the Brain in Kidney Disease (BRINK) cohort completed a Patient Health Questionnaire (PHQ-9) and an eGFR annually. We completed a retrospective longitudinal analysis of this cohort using a mixed linear effects model to examine the mean change in PHQ-9 score by CKD stage compared with the changes among people without CKD. We also compared changes in depression scores among those who initiated dialysis and those with CKD5.

Results: We followed 571 participants for up to five years, of whom 31% reported a diagnosis of depression at baseline. Baseline PHQ-9 scores were 3.5, 4.4, 4.3, 4.7, and 4.8 for participants without CKD (n=147) and those with CKD3a (n=98), 3b (n=190), 4 (n=112), and 5 (n=24), respectively. After adjustment for baseline PHQ-9 score and covariates, mean PHQ-9 scores improved by 0.20 points per year (95% confidence interval [CI] 0.08-0.33) for people who remained without CKD, and improved by 0.30 points (95% CI 0.14-0.47) and 0.19 points (95% CI 0.07-0.32) for people with CKD 3a and 3b (figure), while annual mean PHQ-9 scores among patients with CKD 4 or 5 and dialysis-dependent CKD did not change significantly. Compared with participants who did not develop CKD, no differences in changes in PHQ-9 scores for any CKD subgroup were observed, nor when comparing change in PHQ-9 scores between people with dialysis-dependent CKD and CKD 5. Results were similar in a sensitivity analysis that excluded 141 individuals reporting anti-depressant use.

Conclusions: We found that mean PHQ-9 scores improved slightly over time in people without CKD and those with stage 3 CKD, but not among those with later stage CKD. However, when we directly compared changes in PHQ-9 scores between those with any stage of CKD and those without CKD, we did not observe significant differences. Our study suggests that progression of CKD may not result in worsening depressive symptoms.

CKD-Associated Pruritus (CKD-aP): Associations with Cardiovascular and Infection Events in Non-Dialysis CKD Patients

Jennifer S. Scherer,[1] Charlotte Tu,[2] Ronald L. Pisoni,[2] Elodie Speyer,[3] Antonio A. Lopes,[4] Warren Wen,[5] Frederique Menzaghi,[5] Josh Cirulli,[5] Natalia Alencar de Pinho,[3] Roberto Pecoits-Filho,[2] Angelo Karaboyas.[2] *[1]New York University Grossman School of Medicine, New York, NY; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [4]Universidade Federal da Bahia, Salvador, Brazil; [5]Cara Therapeutics Inc, Stamford, CT.*

Background: Chronic kidney disease associated pruritus (CKD-aP) is a disturbing symptom of CKD. We describe the prevalence of CKD-aP in non-dialysis CKD, treatment patterns, and associations with clinical outcomes.

Methods: We analyzed 4410 patients from 91 clinics in Brazil, France, and US enrolled in the CKDopps (2013-2021), a prospective cohort of adults not on dialysis with an eGFR <60 mL/min/1.73m^2. CKD-aP was self-reported by response to the question*: During the past 4 weeks, to what extent were you bothered by itchy skin?* Associations with time-to-event outcomes were investigated using Cox regression models adjusted for potential confounders.

Results: The proportion of patients not at all, somewhat, moderately, very much, and extremely bothered by itchy skin was 49%, 27%, 13%, 7%, and 3%, respectively. Among patients at least moderately bothered, 23% were prescribed at least one pharmacotherapy – 35% in the US, 19% in France, 4% in Brazil – including antihistamine (10%), gabapentin (6%), topical corticosteroids (4%), pregabalin (3%), or sedating antihistamine (3%). The hazard ratio (95% CI) for patients extremely (vs. not at all) bothered was 1.84 (1.22, 2.75) for cardiovascular events and 1.36 (0.80, 2.31) for infection events.

Conclusions: CKD-aP can cause significant discomfort for individuals, however we found less than a quarter impacted in our cohort received treatment, and medications chosen can have significant side effects. We also found an increased risk of adverse clinical events with worsening CKD-aP. These results highlight the need for further investigation and education about CKD-aP.

The Association of the Influenza Vaccination with CKD Progression to ESKD in a High-Risk Patient Population

Clara Wilson,[1] Jun Li,[1] Crystal K. Jobson,[1,2] Molly Fisher,[1] Tanya S. Johns,[1] Michal L. Melamed.[1] *[1]Montefiore Medical Center, Bronx, NY; [2]Yale School of Medicine, New Haven, CT.*

Background: Individuals with CKD who received influenza vaccination have lower risk of infection-related hospitalizations, cardiovascular events, and mortality compared to unvaccinated. However, the association between influenza vaccination status and risk of progression to ESKD has not been studied.

Methods: We describe a cohort of 4,020 adult patients with CKD stage 3b or 4 (eGFR < 45 mL/min/1.73 m^2) identified through ATLAS and FluSurv-Net database from 9/2008 to 9/2010 (index dates) at risk for progression to ESKD. Primary exposure was receipt of influenza vaccine during the index period. Patient were followed to ESKD (primary outcome) or administratively censored at 12/31/2019. Multivariable Cox proportional hazards models were used to determine the association between influenza vaccination status and progression to ESKD.

Results: In this cohort, 46% were unvaccinated and 54% vaccinated. Vaccinated patients mean age was 71 years (SD 13.2), were predominantly Black (45.7%) and Hispanic (27.5%). Compared to unvaccinated patients, vaccinated patients were significantly older, more likely to be female, White or Hispanic, have higher baseline eGFR and comorbidities like hypertension, diabetes, congestive heart failure, peripheral vascular disease, malignancy, and neurologic disease (Table 1). In the unadjusted Cox model, risk of progression to ESKD in unvaccinated vs. vaccinated patients was 24% higher [HR 0.76 (95% CI: 0.67, 0.86)]. However, this risk attenuated [HR 0.92 (95% CI 0.81, 1.03)] after adjusting for age, sex, race/ethnicity, and comorbidities.

Conclusions: Influenza vaccination was associated with a lower risk of progression from CKD to ESKD; however, significance of risk reduction was attenuated by concomitant comorbidities and sociodemographic factors.

Table 1. Clinical Characteristics of CKD Stage 3b/4 Patients by Flu Vaccination Status

	Unvaccinated (N=1852)	Vaccinated (N=2168)	P value

PCV13 and PPSV23 Effectiveness in Individuals with and Without Reduced Kidney Function

Dustin Le,[1] Alexander R. Chang,[2] Morgan Grams,[3] Josef Coresh,[4] Junichi Ishigami.[4] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Geisinger Health, Danville, PA; [3]New York University Grossman School of Medicine, New York, NY; [4]Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD.*

Background: Individuals with chronic kidney disease have increased risk of infection and decreased serologic response to pneumococcal vaccination. The comparative effectiveness of pneumococcal vaccination in individuals with and without CKD is unknown.

Methods: Test negative design of all hospitalized adults at Geisinger Health System with a pneumococcal urine antigen test from 2016 – 2021. Cases were defined by a composite of positive urine test, body fluid culture, or diagnostic code for pneumococcal disease. Controls were those who tested negative. We used doubly robust estimation by controlling for the probability of receiving a pneumococcal vaccine using inverse probability of treatment weighting as well as multivariable logistic regression to estimate the odds ratios (ORs) of receiving vaccination between cases and controls. VE was calculated as 1-OR*100.

Results: We identified a total of 180 cases and 3,889 controls (mean age 69 years, female 48%, White 97%, mean eGFR 71 mL/min/1.73 m^2). The receipt of PCV13, PPSV23, and both was seen in 42%, 76%, and 39% among cases, and 51%, 78%, and 48% among controls. In the overall population, the adjusted PCV13 VE was 36% (95% CI 2.6 – 58%), and combination PCV13 & PPSV23 was 40% (13 - 59%); but not evident for PPSV23 (VE -16% [95% CI -93 – 31%]). When stratified by eGFR, the adjusted PCV13 VE was consistent in eGFR ≥60 (VE 38% [95% CI -5.2 - 64%]) and 30-59 ml/min/1.73m^2 (VE 57% [95% CI 11 – 79%]) without significant interaction; but not calculable for eGFR <30 due to small sample size.

Conclusions: Receipt of PCV13 was associated with reduced risk of pneumococcal diseases in individuals with reduced kidney function.

Table. Vaccine Effectiveness against Streptococcal Pneumonia by CKD Status in a Test-Negative Design[a]

PCV13	Vaccinated Cases		Vaccinated Controls		Unadjusted VE	Adjusted VE
All cases	75/180	(42%)	1,982/3,887	(51%)	31 (7.2 – 49)*	36 (2.6 – 58)*
eGFR[b] ≥60	44/117	(38%)	1,113/2,495	(45%)	25 (-9.2 – 49)	38 (-5.2 – 64)
eGFR 30 – 59	26/55	(47%)	709/1,127	(63%)	47 (9.0 – 70)*	57 (11 – 79)*
eGFR <30	5/8	(62%)	160/265	(60%)	–	–
PPSV23						
All cases	136/180	(76%)	3,018/3,887	(78%)	11 (-27 – 37)	-16 (-93 – 31)
eGFR ≥60	85/117	(73%)	1,853/2,495	(74%)	8.0 (-41 – 39)	-47 (-144 – 11)
eGFR 30 – 59	43/55	(78%)	947/1,127	(84%)	32 (-37 – 64)	36 (-32 – 69)
eGFR <30	8/8	(100%)	218/265	(82%)	–	–
PCV13 & PPSV23						
All cases	70/180	(39%)	1,858/3,887	(48%)	31 (5.9 – 49)*	40 (13 – 59)**
eGFR ≥60	41/117	(35%)	1,043/2,495	(42%)	25 (-10 – 50)	38 (1.6 – 61)*
eGFR 30 – 59	24/55	(44%)	664/1,127	(59%)	46 (7.1 – 69)*	59 (25 – 78)**
eGFR <30	5/8	(62%)	151/265	(57%)	–	–

[a] Adjusted VE calculated by combining logistic regression for vaccine receipt among Test Negative Cases/Controls with IPTW of vaccine receipt (doubly robust estimation). Covariates for both models included demographics, medical comorbidities, eGFR, immunosuppression use, and relevant vaccination history (PPSV23 in the PCV13 model; PCV13 in the PPSV23 model). VE calculated as 1-OR x 100%.
[b] Race-free 2021 eGFR$_{Cr}$ (mL/min/1.73 m^2); * P-value < 0.05; ** P-value ≤ 0.01

Progress Against Progression? CKD Management in the Age of Telenephrology

Zachary A. Scherzer,[1,2] Dyan M. Lesnik,[2] Laura J. Maursetter.[1,2] [1]*University of Wisconsin Hospital and Clinics, Madison, WI;* [2]*William S. Middleton Memorial Veterans Hospital, Madison, WI.*

Background: Nephrology has seen an uptick in transition to remote care delivery, but there has been limited direction for optimal selection of patients appropriate for this method of care. Furthermore, there is limited literature to show which profile of patients utilize the telenephrology platform. In this study, we report the baseline population differences between telenephrology and in-person care groups that are naturally selected when this option is available.

Methods: Single center retrospective cohort analysis involving 1,305 patients seen across 4,230 visits over a 3-year period at a well-established nephrology clinic within the Veterans Affairs health system. Baseline characteristics and health profile data were assessed based on grouping of individuals to the telenephrology group (>50% virtual visits) or in-person group (≤50% virtual visits).

Results: Baseline characteristics including demographic information and comorbid conditions were similar between the two groups. A higher preponderance of those living in rurally defined areas, as compared to those in urban settings, were found to receive in-person care. Individuals who received in-person care were noted to have twice as many emergency department (ED) visits and hospitalizations throughout the course of the study. Similarly, those seen in-person were significantly more likely to be referred for hospice/palliative services.

Conclusions: Understanding the health profiles of those who receive telenephrology versus in-person care can inform future decision-making for appropriate utilization. It was surprising to see a higher degree of telemedicine visits occurring with individuals residing in urban locations. Discomfort with aspects of technology and/or lack of reliable internet for those living in rural areas are possible factors implicated in this. More surprising was the increase in ED visits, hospital admissions, and palliative care by those seen in-person. It could be that those seen in-person were more ill, this was a use of convenience due to proximity, or that care is being missed with telenephrology. These finding makes future research on the cause of these differences, as well as the impact of telenephrology on CKD progression, imperative.

Exploring the Implementation of Telenephrology in the Iowa City Veterans Affairs Health Care System: A Qualitative Study

Melissa L. Swee,[1,2] Bradley S. Dixon,[2] Mary V. Sarrazin,[2] Qianyi Shi,[1] Benjamin R. Griffin,[1] Masaaki Yamada,[1,2] Meenakshi Sambharia,[1] Diana I. Jalal.[1,2] [1]*University of Iowa Hospitals and Clinics, Iowa City, IA;* [2]*Iowa City VA Medical Center, Iowa City, IA.*

Background: Telenephrology has emerged as a promising approach to improve access to nephrology care, particularly for Veterans residing in rural areas. This qualitative study aimed to explore the implementation process and identify key factors influencing the adoption and utilization of telenephrology in the Iowa City Veterans Affairs Health Care System.

Methods: A multidisciplinary team collaborated to create a scalable and flexible dashboard system in the Iowa City Veterans Affairs healthcare system. Using iterative Plan-Do-Study-Act cycles and employing thematic analysis, nephrologists, primary care physicians, and case managers actively contributed to dashboard design. The Kano Model was utilized to prioritize features based on user needs. The project was initially piloted in four rural clinics, and subsequent cycles focused on refining parameters and enhancing efficiency as telenephrology was implemented in additional rural clinics.

Results: Findings from the semi-structured interviews revealed several important themes. Participants expressed appreciation for the potential of telenephrology to improve access to specialized nephrology care, particularly for Veterans living in remote areas. The convenience and reduced travel burden were highlighted as major advantages. However, concerns were raised regarding the coordination of care and potential increases in workload for primary care practitioners. Autonomy and the need for clear guidelines in integrating telenephrology into existing care processes were also discussed.

Conclusions: This qualitative study sheds light on the experiences and perspectives of key stakeholders involved in the implementation of telenephrology in the Iowa City Veterans Affairs Health Care System. The findings underscore the potential benefits of telenephrology in improving access to nephrology care for Veterans in remote areas. Addressing concerns related to care coordination, workload, and autonomy is crucial for successful adoption and integration of telenephrology. The insights gained from this study can inform future initiatives to optimize the implementation and utilization of telenephrology in similar healthcare settings.

Telenephrology Dashboard for Active Surveillance of Kidney Disease in Primary Care: A Quality Improvement Initiative

Melissa L. Swee,[1,2] Bradley S. Dixon,[2] Mary V. Sarrazin,[1,2] Qianyi Shi,[1] Benjamin R. Griffin,[1] Meenakshi Sambharia,[1] Masaaki Yamada,[1,2] Diana I. Jalal.[1,2] [1]*University of Iowa Hospitals and Clinics, Iowa City, IA;* [2]*Iowa City VA Medical Center, Iowa City, IA.*

Background: Early detection and management of kidney disease are essential for optimal care and cost savings. We implemented a quality improvement project to develop a telenephrology dashboard for active surveillance of kidney disease in primary care clinics.

Methods: A multidisciplinary team collaborated to create a scalable and flexible dashboard system in the Iowa City Veterans Affairs healthcare system. Using iterative Plan-Do-Study-Act cycles and employing thematic analysis, nephrologists, primary care physicians, and case managers actively contributed to dashboard design. The Kano Model was utilized to prioritize features based on user needs. The project was initially piloted in four rural clinics, and subsequent cycles focused on refining parameters and enhancing efficiency as telenephrology was implemented in additional rural clinics.

Results: Findings from the semi-structured interviews revealed several important themes. Participants expressed appreciation for the potential of telenephrology to improve access to specialized nephrology care, particularly for Veterans living in remote areas. The convenience and reduced travel burden were highlighted as major advantages. However, concerns were raised regarding the coordination of care and potential increases in workload for primary care practitioners. Autonomy and the need for clear guidelines in integrating telenephrology into existing care processes were also discussed.

Conclusions: This qualitative study sheds light on the experiences and perspectives of key stakeholders involved in the implementation of telenephrology in the Iowa City Veterans Affairs Health Care System. The findings underscore the potential benefits of telenephrology in improving access to nephrology care for Veterans in remote areas. Addressing concerns related to care coordination, workload, and autonomy is crucial for successful adoption and integration of telenephrology. The insights gained from this study can inform future initiatives to optimize the implementation and utilization of telenephrology in similar healthcare settings.

Initiatives to Enhance the Quality of Referrals from Primary Care to Nephrology: A Systematic Review

Anukul Ghimire,[1,2] Feng Ye,[1] Vinash K. Hariramani,[1] Abdullah Abdulrahman,[1] Somkanya Tungsanga,[1] Ikechi G. Okpechi,[1] Aminu K. Bello.[1] [1]*University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada;* [2]*University of Calgary, Calgary, AB, Canada*.

Background: Excessive referrals to nephrology are major determinants for prolonged wait times to access specialist kidney care. We conducted a systematic review of initiatives aimed at improving the quality of referrals to the nephrology service.

Methods: Studies published from inception to April 1, 2021, that were designed to increase guideline concordant (GC) referrals or to reduce wait times and/or total referrals of adult patients with chronic kidney disease from primary care (PCP) to nephrology services were included. The primary outcomes of interest were changes to wait times, changes in the total number of referrals, and changes in the proportion of guideline-concordant referrals. The review was performed using a pre-specified protocol and reported using the PRISMA model. The results are reported based on taxonomy of interventions (provider education, provider reminder system, audit and feedback, multiple interventions, and other).

Results: 27 studies met eligibility criteria, including 16 pre-post designs, 5 observational studies, 3 interrupted time series studies, and 2 randomized control trials. Among 6 studies that provided information on the relative change in total referrals after an intervention was applied, the proportionate change in total referrals was 15.3% [IQR: -16.7-80.6%]. 8 studies showed an increased trend in absolute number of referrals for the study periods with a median 23.2 [IQR, 22.0-56.2]. Among four pre-post design studies that reported the mean change in wait times, a significant reduction in the overall wait time was noted (median -26.3 [IQR, -104.2-1.6] days). Three studies used multiple interventions per each initiative, and two of these studies showed a relative increase by 11-fold in GC referrals pre and post intervention.

Conclusions: Practice-based initiatives designed to improve the quality of referrals from PCP to nephrology services had different effects on their outcomes of interest. It appears that multifaceted interventions are more appropriate for a greater impact as no single intervention in our study showed a greater effect over another on reducing wait times, absolute number of referrals, or proportion of GC referrals.

Identifying Opportunities to Improve Early Referral for Hematuria with Concomitant Proteinuria in a Large Health System

Alexander R. Chang,[1] Thomas H. Jones,[1] Yirui Hu,[1] Jamie A. Green,[1] Lauren Gummo,[1] Jennifer Nguyen,[2] Briana C. Ndife,[2] Carolina A. Aldworth.[2] *[1]Geisinger Health, Danville, PA; [2]Novartis Pharmaceuticals Corporation, East Hanover, NJ.*

Background: Hematuria is a common problem encountered in primary care though limited data exists on appropriate referral patterns. The purpose of this study was to examine opportunities to improve workup of hematuria for early diagnosis of important associated conditions such as glomerulonephritis and urologic malignancy.

Methods: The study cohort included adults 18+ years of age, with hematuria (defined as 1+ or greater blood on dipstick), who received care at Geisinger, a large regional health system in Central and Northeast PA from 01/01/2022 to 9/30/2022. The proportion of patients with hematuria who were referred to nephrology or urology within 3 months were examined. Characteristics of patients who were referred vs. not referred were compared using descriptive statistics and non-parametric tests as appropriate.

Results: Out of 507,423 patients who had at least 1 outpatient visit during the study period, 63,895 underwent urinalysis; of these, 8,790 patients had 1+ or greater hematuria. After excluding 3,102 who had a prior nephrology or urology appointment, 419 of 5,688 (7.4%) had a nephrology or urology appointment within 3 months and 483 (8.5%) had a nephrology or urology appointment within 6 months. Completion of nephrology or urology appointments at 3 months was higher for patients with greater hematuria (1+: 5.7% vs. 2+: 9.9%; p<0.001) and for patients with concomitant proteinuria (no proteinuria: 5.1%, trace: 8.3%, 1+: 7.7%, 2+: 7.3%, 3+: 9.3%; p=0.01). In a sensitivity analysis excluding patients with positive nitrite and leukocyte esterase (surrogate for possible infection risk), rates of completed nephrology or urology appointments were similarly low (3 months: 234/2,968 [7.9%]; 6 months: 265/2,968 [8.9%]; p<0.001 for chi-square test). Other factors associated with higher completed nephrology or urology appointments included male sex, White race, having a Geisinger primary care provider, and having concomitant proteinuria.

Conclusions: In a regional health system, we identify low referral rates to nephrology and urology after hematuria diagnosis, even among patients with concomitant proteinuria. Future studies are needed to determine optimal strategies to improve follow-up and management of hematuria.

Palliative and Hospice Care Utilization Among a National Cohort of Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Yoko Narasaki,[1] Kamyar Kalantar-Zadeh,[2] Ji Hoon Yoon,[1] Csaba P. Kovesdy,[3] Dana B. Mukamel,[1] Susan T. Crowley,[4] Lisa Le,[1] Seungsook You,[1] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]The University of Tennessee Health Science Center, Memphis, TN; [4]Yale University, New Haven, CT.*

Background: Given the high symptom burden of the aging and ailing advanced CKD population, there is compelling need for palliative or hospice care in routine nephrology management to optimize quality of life. Little is known about the comparative utilization of palliative/hospice care in advanced CKD patients treated with conservative management (CM) vs. dialysis.

Methods: We examined a national cohort of advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days) treated with CM vs. dialysis (defined as non-receipt vs. receipt of dialysis within 2-years of 1st eGFR <25) over 1/1/07-6/30/20 from the Optum Labs Data Warehouse, which contains de-identified administrative claims, including medical/pharmacy claims and enrollment records for commercial/Medicare Advantage enrollees, and EHR data. We compared time to 1st referral to palliative care (primary outcome) or hospice (secondary outcome) among CM vs. dialysis patients who were matched by propensity score (PS) in a 1:1 ratio with a caliper distance of ≤0.2 to address confounding using Cox models.

Results: Among 28,740 CM patients PS-matched to 28,740 patients who transitioned to dialysis, baseline characteristics were well-balanced. In the PS-matched model, compared to CM, dialysis was associated with higher likelihood of palliative care referral: HR (95%CI) 1.29 (1.23-1.35). In contrast, dialysis was associated with lower likelihood of hospice referral vs. CM: HR (95%CI) 0.80 (0.77-0.84). Similar findings were observed in analyses doubly-adjusted for PS covariates.

Conclusions: In a national advanced CKD cohort, compared to patients treated with CM, those who transitioned to dialysis had higher palliative care referral yet lower hospice utilization. Further studies are needed to determine the underlying factors contributing to the differential utilization of palliative care vs. hospice among advanced CKD patients transitioning to CM vs. dialysis.

Hospitalization Outcomes in a National Cohort of Advanced CKD Patients Treated with Conservative Management vs. Dialysis

Connie Rhee,[1] Ji Hoon Yoon,[1] Yoko Narasaki,[1] Seungsook You,[1] Csaba P. Kovesdy,[2] Dana B. Mukamel,[1] Susan T. Crowley,[3] Matthew D. Nguyen,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[4] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Yale University, New Haven, CT; [4]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Dialysis has been the default treatment strategy in advanced CKD patients progressing to ESKD, yet may be associated with higher healthcare utilization in certain subgroups. We compared hospitalization outcomes in a national cohort of advanced CKD patients treated with conservative management (CM) vs. dialysis.

Methods: We examined advanced CKD patients treated with CM vs. dialysis (defined as non-receipt vs. receipt of dialysis within 2-years of the 1st eGFR <25) over 1/1/07-6/30/20 from the Optum Labs Data Warehouse, which contains de-identified administrative claims, including medical/pharmacy claims and enrollment records for commercial/Medicare Advantage enrollees, and EHR data. In secondary analyses, we examined finer gradations of dialysis timing, defined as earlier dialysis (ED) vs. later dialysis (LD) (eGFRs ≥15 vs. <15 at dialysis transition); in tertiary analyses we compared ED, intermediate dialysis (ID), vs. very-late dialysis (VLD) (eGFRs ≥15, 10-<15, vs. <10 at dialysis transition). We compared rates of hospitalization (primary outcome) and days hospitalized (secondary outcome) in CM vs. dialysis patients matched by propensity score (PS) in a 1:1 ratio with a caliper distance of ≤0.2 using Poisson regression.

Results: Among 28,850 CM patients PS-matched to 28,850 dialysis patients, dialysis transition was associated with higher rates of hospitalization and days hospitalized vs. CM: IRRs (95%CIs) 2.21 (2.19, 2.23) (Fig A) and 2.80 (2.75, 2.86) (Fig B), respectively. In secondary and tertiary analyses, compared to CM patients, those who transitioned to dialysis had higher rates of hospitalization and days hospitalized vs. CM, irrespective of timing of dialysis initiation.

Conclusions: Patients treated with CM had lower rates of hospitalization and days hospitalized vs. those who transitioned to dialysis. Further studies are needed to determine the downstream sequelae of the differential hospitalization patterns in CM vs. dialysis patients.

QI Project: Identify Modifiable Risk Factors and Improve the Safety of Performing Kidney Biopsies

Sandeep R. Sasidharan, Tahir A. Jatoi, Mohammad W. Abushawer, Yasmin N. Mahmoud, Angelika C. Gruessner, Subodh J. Saggi. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: Bleeding events are the most feared complication in patients undergoing kidney biopsies (KB). Certain factors have consistently shown to carry an increased risk such as CKD. Not assessed in all prior studies was whether KBs done under real-time CT vs ultrasound (USG) guidance or whether transplanted kidneys (TK)

versus native kidneys (NK), or whether the use of automated trocar-guided biopsy guns (ATGBG) or the use of non-trocar guided biopsy guns (NTGBG) of various sizes carried any differential risk.

Methods: All KBs performed at our hospital between 2015 to 2022 were included. Two independent physicians reviewed the charts to acquire the data. Quantitative variables were presented as means +/- SDs using the Wilcoxon test, while qualitative variables as frequencies or %s and compared using the chi-square or Fisher's exact test. Only factors with p-value <0.3 were included for logistic regression.

Results: Overall, information on 174 biopsies performed was collected, of which native was 83% and 17% in a transplanted kidney. Blacks constituted 90% of cases. The median age was 42 Years [7-78 years]. Detailed descriptive results are in Table 1. Univariate analysis showed bleeding risk statistically higher in >65 years and lower in CT-guided KB. In multivariable analysis, age was the most influential risk factor with every 5 years increased bleeding by 24%. Every 5-unit increase in BMI increased bleeding by 43% but not statistically. Fig 1

Conclusions: Our study found that additional safety measures needed to be considered when performing biopsies in the elderly. Using CT instead of USG guidance might be warranted for additional safety. We did not find any additional differential in risk of bleeding between NK versus TK or by the use of ATGBG versus NTGBG as far as some real time procedures were utilized.

Demographic

Total Biopsy 174	Blacks 156 (90%)	Native kidney 144 (83%)	Transplant 30 (17%)	Automated trocar 132 (76%)	Non trocar guided 42% (24%)	USG guide 144 (83%)	CT guided 30 (17%)	Median age 42 [7-78]	Bleeding 17 (9.7%)

A Comparison of Standard Survival Analysis and Recurrent Event Analysis in the KNOW-CKD Study

Dha Woon Im,[1] Jayoun Kim,[2] Ji Hye Kim,[3] Minsang Kim,[1] Kook-Hwan Oh.[1]
[1]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [3]Chungbuk National University Hospital, Cheongju, Chungcheongbuk-do, Republic of Korea.

Background: Recurrent events are typically defined as events that occur repeatedly. While many clinical studies primarily focus on identifying risk factors for the first occurrence of an event, known as incident events, there is also interest in investigating the risk factors associated with recurrent events and examining whether there are differences compared to a conventional method.

Methods: We conducted a recurrent event analysis on cardiovascular(CV) events using data from the KoreaN Cohort Study for Outcomes in Patients With Chronic Kidney Disease(KNOW-CKD). Statistical models employed in the analysis included Poisson regression, proportional intensity model, Prentice-Williams-and Peterson total time and gap time models, and frailty model. Furthermore, we compared the results of these models with those from Cox proportional hazards model.

Results: During a median follow-up period of 7.205 years, a total of 2,238 participants were included in the analysis. Among these participants, 155 experienced a CV event for the first time, while 35 experienced a second recurrent event, and 4 experienced a third recurrent event. Using Poisson regression model, we further identified associations between recurrent CV events and sex, mean blood pressure, alcohol consumption, hemoglobin levels, and urine protein-creatinine ratio. However, we found that BMI was only associated with incident events and not with recurrent events. Other models did not yield any significant differences compared to the results obtained from Cox proportional hazards model.

Conclusions: Our analysis of recurrent event data provided us with valuable insights that were not attainable through a conventional survival analysis focused solely on the time to the first event.

Kidney Outcomes Associated with Adherence to Recommendation from Evidence-Based Clinical Practice Guidelines for CKD 2018 in Japanese Real-World Clinical Practice

Hirokazu Okada,[1] Zannatun Nyma,[2] Yuichiro Yano,[2] Hiroshi Kanegae,[3] Kaori Kitaoka,[2] Nomin Bayaraa,[2] Seiji Kishi,[4] Hajime Nagasu,[4] Naoki Kashihara.[4] *[1]Saitama Ika Daigaku, Iruma-gun, Japan; [2]Shiga Ika Daigaku, Otsu, Japan; [3]Genki Plaza Medical Center for Healthcare, Tokyo, Japan; [4]Kawasaki Ika Daigaku, Kurashiki, Japan.*

Background: Adherence to recommended treatment is critical in chronic kidney disease (CKD) to prevent complications and progression to kidney failure. The purpose of this study was to explore the adherence to recommendation of patients with CKD, using the Japan Chronic Kidney Disease Database (J-CKD-DB-Ex).

Methods: We developed clinical questions (CQ) recommendation scoring from Clinical Practice Guidelines for CKD 2018 (see Table). We quantified adherence to each of the 8 component metrics, with metric scores ranging from 0 points (poor adherence to recommendation) to 8 points (meeting recommendation). Kidney failure defined estimated glomerular filtration rates (eGFR) <15 mL/min/1.73m^2 or eGFR ≥30% reduction. We evaluated the adherence of CQ recommendations and the decline of eGFR and composite kidney outcomes by the Cox proportional hazards models adjusted for age, sex, and eGFR baseline.

Results: Among 4,455 CKD patients, mean age was 67.2 years, mean eGFR was 54.6 mL/min per 1.73 m^2, and women was 46.5 % at baseline. Scores of CQ recommendation of 0-5 points group was 12.0%, 6 points group was 29.3%, 7 points group was 41.1%, 8 points group was 17.6%. 838 composite kidney outcomes occurred, more than 6 points groups were at significantly lower risk (6 points: HR 0.67, 95% CI 0.54–0.83).

Conclusions: Great adherence of CQ recommendations was associated with prevention of complications and progression to kidney failure.

Funding: Other U.S. Government Support
