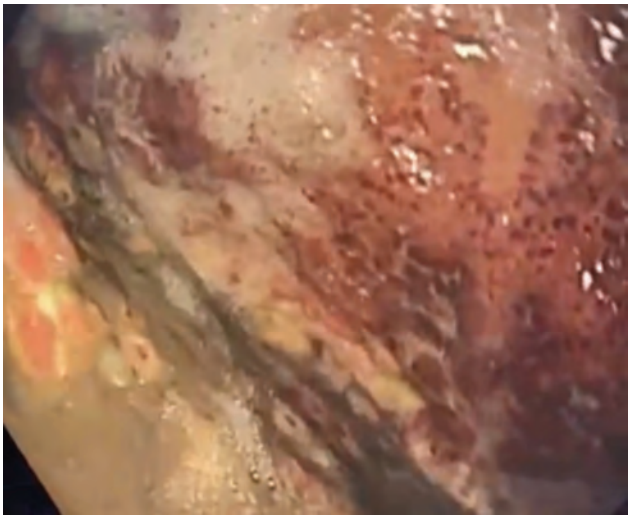
Case Description: This is about a 36-year-old man with a history of type 2 diabetes, systemic arterial hypertension, chronic kidney disease, who underwent a living-related kidney transplant in 2022, with a PRA-SA of 0/0%. He received induction with basiliximab and methylprednisolone, and maintenance immunosuppression with tacrolimus, mycophenolic acid, and prednisone. With baseline creatinine of 1.0 mg/dL. Two months after the transplant, he developed, fever, oral intolerance. He was hospitalized, and a fever of 40 °C was documented, mild epigastric tenderness was noted on abdominal examination. Laboratory tests revealed leukocytosis, elevated C-reactive protein, creatinine (2.5 mg/dL). Abdominal computed tomography confirmed pneumobilia, pneumoperitoneum, gastric wall thickening. Tacrolimus and mycophenolic acid were discontinued, and steroid therapy was continued. Meropenem was initiated. An endoscopy performed within 12 hours of symptom onset revealed multiple areas of diffuse gastric necrosis and purulent material. Linezolid was added to the treatment regimen, and a nasojejunal tube was placed for total enteral nutrition. Pseudomonas aeruginosa putida and Candida glabrata were isolated from the gastric tissue. He was discharged on day 27 with a baseline creatinine level of 0.9 mg/dL, and on cyclosporine and prednisone.

Discussion: PG is a condition with high mortality. It is important to suspect it in immunosuppressed patients with sepsis, as early diagnosis can save the patient's life and prevent serious complications.



FR-PO787

Progressive Dysphagia in Kidney Transplant Recipient: An Unusual Cause

Robert Ryhal, Reem Daloul, Khaled Nashar, Kalathil K. Sureshkumar. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Upper gastrointestinal (GI) symptoms such as dysphagia and odynophagia in immunocompromised hosts are generally caused by viral or fungal infections. We present a kidney transplant recipient who developed progressive dysphagia and odynophagia caused by mycophenolate mofetil (MMF) that improved after discontinuation of MMF and serial endoscopic esophageal dilatation.

Case Description: A 49-year old male (CMV IgG-,EBV IgG+) received kidney transplantation from sister (CMV IgG+, EBV IgG+) with Thymoglobulin induction, tacrolimus/MMF maintenance and infection prophylaxis using valgancyclovir, trimethoprim-sulfamethoxazole and nystain. There was immediate allograft function with discharge serum creatinine of 1.5 mg/dl. One month later, patient presented with progressive dysphagia and odynophagia with reduced appetite and weight loss. MMF was discontinued and replaced with azathioprine. Upper endoscopy showed benign appearing intrinsic severe distal esophageal stenosis (Figure 1A). The stricture was dilated to 7 mm and biopsy showed focal acute inflammation (Figure 1B). PAS staining for fungal elements and immunohistochemistry for CMV and HSV type1/2 were negative. Patient required 9 more stricture dilatations over the next 3 months to a final diameter of 18 mm. His dysphagia gradually resolved with improvement in dietary intake and weight gain over next few months.

Discussion: MMF has several GI side effects and more commonly involve lower GI tract. MMF-related esophageal stricture is extremely rare. The mechanism is not clear but may involve MMF-induced blockade of guanosine nucleotide synthesis thus disrupting GI epithelial barrier. MMF-metabolites may also cause autoimmunity and hypersensitivity-like reactions. Our case highlights MMF as an uncommon cause of esophageal stricture and should be considered as a potential etiology of dysphagia in a transplant recipient.

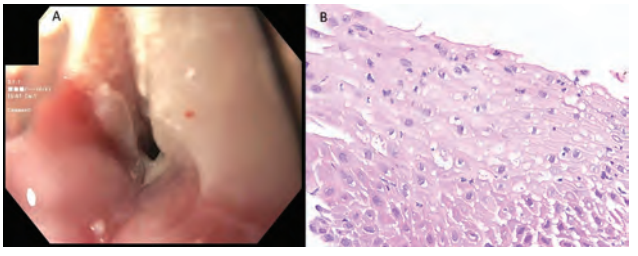


Figure 1: (A) Upper endoscopy showing benign appearing intrinsic severe distal esophageal stenosis that was 5 cm long and 4 mm in diameter. **(B)** H&E staining of stricture area biopsy showing benign squamous mucosa with reactive changes and focal acute inflammation.

FR-PO788

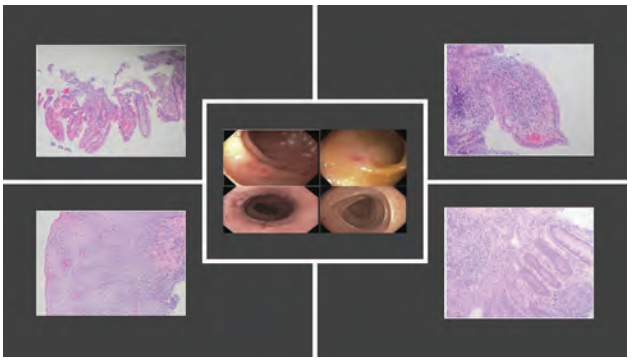
Eosinophilic Gastroenteritis due to Belatacept: Novel Side Effect of a Novel Agent

Aisha Batool, Vineet Veitla, Ehab R. Saad. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Belatacept is a novel fusion protein composed of the Fc fragment of human IgG1 linked to the extracellular domain of cytotoxic T-lymphocyte–associated antigen 4 (CTLA-4), selectively inhibits T-cell activation through costimulation blockade. Eosinophilic Gastrointestinal Disease (EGID) is a rare disorder characterized by focal or diffuse eosinophilic infiltration of the bowel wall with various gastrointestinal manifestations.

Case Description: Our Patient is a 24-year-old Caucasian Male with ESRD s/p LRKT 10 years ago. The patient was induced with Simulect(Basiliximab), thereafter he was started on immunosuppression regimen with Belatacept 750mg intravenous injection, Cellcept 750mg twice daily and tapering doses of Prednisone and has had a smooth post transplant course. About two years after the transplant, he started complaining of epigastric pain, worse on 'bending forward'. Laboratory data revealed peripheral eosinophilia 9% and iron deficiency anemia. Endoscopy revealed mucosal edema with extensive ulcerations and nodularity of esophagus, duodenum, and terminal ileum. Histopathology revealed extensive ulcerations of esophagus, duodenum, and terminal ileum with diffuse eosinophilic infiltration. Belatacept was stopped resulting in complete resolution of clinical symptoms, peripheral eosinophilia, Anemia and also complete resolution of the esophageal and duodenal ulcerations with resolution of eosinophilic infiltration.

Discussion: Drug induced EGIDs are very rare and there are only few case reports of drug induced EGIDs. Diagnosis is usually lead by High index of suspicion paired with exclusion of other causes of peripheral eosinophilia. Final diagnosis is made with biopsy proven eosinophilic infiltration of bowel wall. T cell co-stimulation through CD28 and B7–2 plays an important role in allergic responses and administration of a CTLA-4 immunoglobulin blocks this interaction. Thus, we may surmise that costimulation blockade with Belatacept could trigger allergic conditions such as EGIDs.



FR-PO789

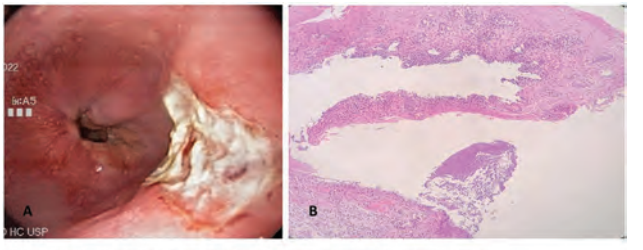
An Uncommon Presentation of Esophageal Actinomycosis in a Patient with Recent Kidney Transplant

Joao P. Ferreira,[1] Liliana M. Kassar,[1] Felipe Carvalho Barros Sousa,[1] Raquel M. Moreira.[2] *[1]Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil.*

Introduction: Actinomycosis is a rare granulomatous disease, caused by a gram positive anaerobic bacterium, which inhabits the gastrointestinal tract and oral cavity in a commensal manner, but can cause an infectious process by invading injured tissue. *Actinomyces israelii* is the main human pathogen. The most common site of involvement is cervicofacial region with formation of abscesses and granulomas, followed by abdominal and thoracic involvement.

Case Description: A 33-years-old male, three months after kidney transplant from deceased donor, zero HLA mismatches, non-sensitized, started with fever and oral ulcers three days prior admission to the hospital. The patient's immunossupression was tacrolimus and mycophenolate. He had been on treatment with Valganciclocir for 20 days due to asymptomatic cytomegaly with positive antigenemia. The patient was hospitalized and started on empirical IV Ganciclovir due to possible cytomegalovirus (CMV) disease. Despite the treatment, he maintained fever episodes and experienced worsening of oral ulcers, and onset of odynophagia, with the presence of esophageal ulcers in the upper digestive endoscopy. Biopsy of esophageal ulcers was performed with the presence of gram-positive colonies and *Actinomyces spp*. The patient was treated with IV ceftriaxone, and then oral amoxicillin for 4 months with clinical improvement.

Discussion: The case reported above is a rare presentation of Actinomycosis, a disease with low prevalence and difficult diagnosis. The occurrence of oral and esophageal ulcers is uncommon with few cases reported. Main clinical forms comprise cervicofacial features with the occurrence of chronic cutaneous nodules and emergence of gastrointestinal tumors, usually in the ileocecal region, presenting with abdominal pain, weight-loss and weakness. In this case, the diagnosis was challenging due to a large number of possible infections such as herpes simplex, CMV, oral moniliasis, among others, especially in the first 6 months after kidney transplant.



A – Patient's esophageal ulcer. B – Esophageal mucosa with *Actinomyces spp* (optical mycroscopy).

FR-PO790

Distinct Mutation Patterns in BK Polyomavirus Genome-Integrated Urothelial Carcinomas and Urothelial Carcinomas with Mutational Signature of Aristolochic Acid

Ya-chung Tian. *Linkou Chang Gung Memorial Hospital, Taoyuan, Taiwan.*

Background: Urothelial carcinoma (UC) is highly prevalent among kidney transplant recipients in certain regions and may be linked to the integration of BK polyomavirus (BKPyV) genome into the human genome. In Taiwan, a high prevalence of aristolochic acid (AA) mutational signatures in UC was exhibited in general population. To better understand these etiologies in UC oncogenesis in kidney transplant patients, whole-genome sequencing (WGS) was employed to determine the integration of BK polyomavirus (BKPyV) genome into the human genome and AA mutational signatures in UC.

Methods: Twenty UC specimens underwent WGS analysis to evaluate BKPyV genome integration and AA mutational signatures, with Sanger sequencing used for confirmation of BKPyV genome integration.

Results: Twenty UC specimens underwent WGS analysis to evaluate BKPyV genome integration and AA mutational signatures, with Sanger sequencing used for confirmation in UC specimens with BKPyV genome integration. Results: BKPyV genome integration was found in 7 out of 20 UC specimens (37%), while 16 out of 20 UC specimens (80%) contained the AA mutation signature. Three specimens (15%) had both characteristics. A total of 106 integration sites in UC specimens with BKPyV genome integration were identified. Most of the integration sites were located in introns and intergenic regions, with only two sites in exons. Notably, a specific integration site with a breakpoint at TAg4289 of the BKPyV genome and at the intron of the human eukaryotic translation initiation factor 2B subunit alpha (EIF2B1) was observed in three distinct UC specimens, and this finding was confirmed via Sanger sequencing. The WGS results also revealed a high prevalence (80%) of the AA mutational signature in these UC specimens. A high percentage of UC cases exhibited mutations in genes related to chromatin modification (KMT2C, 70%), the cell-cycle pathway (TP53, 55%), and the RTK-PI3K pathway (ERBB2, 25%). Interestingly, UC cases with BKPyV genome integration had significantly lower total mutation burden and fewer mutations in these genes compared to those with the AA mutational signature, suggesting distinct mechanisms of carcinogenesis in UC.

Conclusions: In conclusion, our findings provide compelling evidence for different mechanisms underlying the development of UC in Taiwanese kidney transplant recipients.

FR-PO791

Health Equity Gaps in Access to Kidney Transplant

Chiao Wen Lan,[1] Deidra C. Crews,[3] Sumit Mohan,[2] Sherri Morgan-Johnson,[4] Melissa Murphy.[4] *[1]Health Services Advisory Group Inc, Phoenix, AZ; [2]Columbia University, New York, NY; [3]Johns Hopkins Medicine, Baltimore, MD; [4]Centers for Medicare and Medicaid Services (CMS), Baltimore, MD.*

Background: Research has documented cascading barriers to care, while accessing kidney transplant across neighborhood characteristics have not been fully examined.

Methods: ESRD Quality Reporting System (EQRS) data between 1/1/2015-5/20/2023 were analyzed. Access to transplants is examined, including calculating time on dialysis to listing and time on list before transplanted. Data were linked to the Area Deprivation Index (ADI), a neighborhood-level metric that combined 17 specific indicators (e.g., poverty, housing).

Results: 9.5% of patients added to the waitlist were from the most disadvantaged neighborhoods, while 14.6% of ESRD patients residing there. Among patients who received transplants, waitlist time was consistently longer for Black patients compared to White patients ($p<0.001$), and the difference has narrowed over the years, yet the gap remains. Neighborhood characteristics are associated with health disparities, where patients from more disadvantaged neighborhoods waited longer on the list before getting transplanted than those from the least disadvantaged areas (15.3 vs. 13.4 months, $p<0.0001$). Racial disparities exist across neighborhood socioeconomic level. White ESRD patients in the most disadvantaged neighborhoods were added to the waitlist faster than Black patients in the least disadvantaged neighborhoods (38.6 vs. 43.2 months, $p<0.01$). The time on the list before transplantation among White patients in the most disadvantaged neighborhood was shorter than Black patients in the least disadvantaged neighborhoods (14.9 vs. 16.1 months, $p<0.0001$).

Conclusions: The results show significant disparities in access to care among ESRD patients in disadvantaged neighborhoods and that Black patients have reduced access to the transplant waitlist regardless of neighborhood characteristics. These results emphasize the need for policies and strategies that overcome structural racism barriers in addition to improving access for socioeconomically disadvantaged patients.

FR-PO792

Outcome of Organ Procurement and Transplantation Network (OPTN) Policy Allowing for Waiting Time Modification for Candidates Affected by Race-Inclusive eGFR Calculations: Early Impact from a Single Center

Debra Wekesa, Scott G. Westphal, Clifford D. Miles. *University of Nebraska Medical Center, Omaha, NE.*

Background: Black patients have a high burden of kidney disease yet experience lower rates of waitlisting and kidney transplantation. There is a myriad of reasons for these disparities, including the historic race modifier used for GFR estimation, which ascribes a higher GFR at a given serum creatinine level in black individuals. Since eGFR ≤ 20 ml/min is required for waiting time accrual, the eGFR race modifier could delay listing for some black patients. In January 2023, the OPTN implemented a policy whereby registered black transplant candidates could receive waiting time adjustment if a prior race-inclusive eGFR calculation yielded values such that "non-African American" eGFR was ≤ 20 ml/min, but the "African American modified eGFR was >20 ml/min.

Methods: Upon enactment of this policy, our transplant program identified potential candidates, and through internal EMR review, communication with patients, their nephrologists, and PCPs, eligible candidates were identified for waiting time modification. Here, we report the impact of this policy change at a single center one month after submission for waiting time modification for eligible candidates.

Results: 37 adult patients on our waitlist had self-identified as Black or African American. In 19 (51.4%) patients, historic race-inclusive GFR estimates were found that allowed for waiting time modification. In these patients, a mean 753 ± 788 and median 407 (327, 901) additional days of waiting time was added. The maximum time added for a single patient was 3,323 days (9.1 years). 4 of the 19 (21%) candidates received a deceased donor kidney transplant within 1 month of waiting time modification.

Conclusions: At a single center, >50% of patients were eligible for waiting time addition, with an average of >2 years of waiting time added per eligible candidate. Importantly, this modification yielded near immediate impact, with >20% of patients receiving a transplant within the first month of the modification. While the number of black patients on our waiting list is small relative to many centers, this early assessment of the policy impact demonstrates the potential of its intended effects. Centers with large numbers of black patients will require a coordinated effort to ensure timely identification and implementation of appropriate waiting time addition.

FR-PO793

Bridging the Literacy Gap in Living Kidney Donation Information by ChatGPT

Oscar A. Garcia Valencia,[1] Iasmina Craici,[1] Caroline Jadlowiec,[2] Shennen Mao,[3] Michael A. Mao,[3] Napat Leeaphorn,[3] Pooja Budhiraja,[2] Charat Thongprayoon,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN; [2]Mayo Clinic Arizona, Scottsdale, AZ; [3]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Improving diversity and equity in living kidney donation requires ensuring that information on the topic is accessible to people with different levels of literacy. The average American adult reads at an eighth-grade level, highlighting the need to modify complex medical information for easier comprehension. ChatGPT, an AI language model, has the potential to modify medical information to improve readability. This study aimed to assess the effectiveness of ChatGPT in modifying living kidney donation information to an eighth-grade reading level.

Methods: We collected 27 questions and their answers from a widely accessible FAQs website (Donate Life America) related to living kidney donation. ChatGPT (03/23 Version) modified the text of the answers to make them easier to comprehend for those who read at or below an eighth-grade level. Original and modified information were assessed for readability using the well-validated Flesch-Kincaid formula. The grade level of each answer was compared before and after modification, and a paired t-test was used to evaluate the significance of any reduction in grade level.

Results: The average grade level of the original answers was 9.6±1.9, while the average grade level of the modified answers was 7.7±1.8, indicating a significant reduction in grade level ($p<0.001$). ChatGPT was able to modify the information to an eighth-grade reading level or below in 16 out of 27 cases (59%). The grade level of the modified answers ranged from 3.4 to 11.3.

Conclusions: Our study demonstrates that ChatGPT can be a useful tool in improving the grade level readability of information on living kidney donation for individuals with lower literacy levels. Although ChatGPT was not able to modify all the information to below an eighth-grade reading level, it significantly reduced the grade level readability of the modified information compared to the original information. This suggests that ChatGPT may potentially play a role in promoting diversity and equity in living kidney donation by making information more accessible to a wider range of individuals. While our study shows that ChatGPT can significantly reduce the grade level readability of modified information, there is still room for improvement.

FR-PO794

Strategies to Increase Deceased Organ Donation: A Single-Center Experience from an Inner-City Hospital in the Bronx

Oscar Y. Pena,[1] Shiny Teja Kolli,[2] Vishal Reddy Bejugam,[2] Roxanne Todor,[1] Anjali Acharya.[1] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]NYC Health and Hospitals North Central Bronx, New York, NY.*

Background: Kidney transplantation is the treatment of choice for end-stage kidney disease as it improves the quality of life and reduces the mortality risk. However, the average wait time ranges from 4 months to > 6 years, with 1 out of 20 (5%) patients dying each year while waiting. According to a 2022 report by the New York Organ Donor Network, the Bronx has the lowest organ donation rate at 11.3% vs. 18.1% in New York City. The Bronx had the highest number of people on the waiting list, with 1,500 people. Several factors, including SDOH contribute to the Bronx's low organ donation rate. Centers for Medicare & Medicaid Services (CMS) introduced the End Stage Renal Disease Treatment Choices Learning Collaborative (ETCLC) in August 2021 with the goal to accomplish one of the goals of the Advancing American Kidney Health by increasing kidney transplants.

Methods: From June 2020 to March 2022. We excluded patients under 18 years old and those who died upon arrival. Electronic medical records were reviewed, and statistical analysis was performed using StataBE17.

Results: There were a total of 375 patient deaths. Of these, 212 were male (56.53%), and 163 were female (43.47%). The mean age was 68.9 years. Thirty-three patients (8.8%) were diagnosed with brain death. Of these, 14 patients (42%) became organ donors. Acute kidney injury (AKI) was present in 42% of patients with brain death. The breakdown of AKI severity was as follows: KDIGO I: 28% KDIGO II: 50% KDIGO III: 22% Timely referral to the OPO was made in 65% of the cases. Nephrology was contacted for 12% of these patients and all 12% required kidney replacement therapy

Conclusions: Identifying the missed opportunities for deceased organ donations is the first step in improving the process. We have implemented processes such as ongoing education of the stake holders and we are committed to working with our partners at the New York Organ Donor Network to ensure that every eligible patient has the opportunity to receive a life-saving organ transplant.

June 2021 - March 2022 Observations (%)

FR-PO795

Perceived Barriers to Transplantation in the Hispanic Community

Arturo Lopez. *University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS.*

Background: Hispanics have a higher prevalence of kidney disease but a lower rate of kidney transplantation (KT). Multiple barriers have been proposed, but patient reported barriers have not been assessed. We interviewed Hispanic patients with kidney failure to assess first-hand reports of patient perceived barriers to KT.

Methods: We interviewed patients from dialysis units and clinics between June and October 2022. The inclusion criteria were age 18-65, eGFR of ≤ 20 ml/min, and Spanish as the primary language. Interviews were conducted in Spanish, audio recorded, transcribed to English, and uploaded to a qualitative data analysis software DEDOOSE. The interviews were then analyzed and coded into *a priori* twenty-three communication-based categories created by a communications framework.

Results: Most patients felt willing and able to undergo KT. Patients lacked knowledge about the KT process and could not make a well-informed decision. Living donation (LD) was discussed with very few; in general, patients lacked knowledge about LD. Some viewed LD as a significant health risk to the donor. Misconceptions were evident, with a few patients reporting discussions on emigration to their native countries increasing their chances of KT. Lack of insurance or cost of KT were common concerns. Patients reported infrequent counseling, with most interactions with individuals other than a nephrologist. Often, the initial communication regarding KT occurred in the emergency room or when initiating dialysis. Use of translators and Spanish-speaking providers was common. Discussions were limited when a Spanish interpreter was absent. Occasionally, the translation was inadequate or difficult to understand.

Conclusions: Multiple patient perceived barriers to KT were noted during our interviews. These included access to nephrologists, barriers in communication despite interpreters, and infrequent counseling. Additional resources and efforts are needed to improve KT rates in the Hispanic population.

FR-PO796

Promoting Transplant Equity: Characterizing Deceased Organ Donation by Noncitizens in the United States

Katherine M. Rizzolo,[1,2] Jesse D. Schold,[2] Lilia Cervantes.[2] *[1]Boston Medical Center, Boston, MA; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: There are no citizenship restrictions to receiving or donating a kidney transplant per the United Network for Organ Sharing and the Organ Procurement Transplantation Network. However, the major barrier to transplant for most undocumented immigrants are insurance barriers as undocumented immigrants are barred from receiving federal insurance. Non-citizens are aware of the double standard allowing them to donate organs despite the restrictions to receiving them. Restricting access to organ transplant pool while being able to contribute to it is inequitable. However, the degree of contribution to the organ pool by non-citizens has not been recently assessed. The aim of this study is to illustrate the degree to which non-citizens contribute to the organ pool in the US between 2015 and 2020.

Methods: We utilized UNOS data examining decreased organ donors in the US between 2015 and 2020. To summarize recipient and donor characteristics, median and interquartile range (IQR) were used for continuous variables and counts and percents were used for categorical variables. Characteristics were stratified by reported citizenship status. To test for differences across groups, ANOVA (for normally distributed) or Kruskal-Wallis (non-normally distributed) tests were used for continuous variables after testing for normality via the Shapiro-Wilk test and Chi-square tests were used for categorical variables.

Results: Non-US Citizen/US Residents (NCR) accounted for 2.8% and Non-US Citizens/Non-US Residents (NCNR) accounted for 0.4% of the donor population. Compared with US citizens, non-citizen residents were more likely to be older, male, O blood type and have diabetes. Regarding citizenship status of donors and recipients, 91% of NCR and 90% of NCNR organs (n=5581) were received by US citizens. 5.8% of organs (n=9172) donated by US citizens were received by NCR or NCNR recipients.

Conclusions: There are no citizenship restrictions on organ donation from deceased individuals, however, restrictions on federal insurance is a barrier to transplant for non-citizens. We illustrate that non-citizens donate healthy, viable organs to the US organ pool, the majority of which are received by US citizens. Any system that uses these gifts from individuals who would themselves not be considered eligible for an organ transplant is unjust.

FR-PO797

Renal Transplant Outcomes Among Pediatric Non-English Language Preference Patients

Yaritzy M. Astudillo, Ponmali Le, Sonia Solomon. *Westchester Medical Center, Valhalla, NY.*

Background: Non-English language preference (NELP) is associated with disparities in health care access and quality and worse clinical outcomes in children. To our knowledge, no studies characterize the role of NELP in the renal transplant process. The primary aim of this study is to compare pediatric renal transplant outcomes among NELP and English Language Preference (ELP) populations.

Methods: This retrospective single-center study included pediatric patients between the ages of 0 to 21 who received renal transplants between January 2014 and September 2022. The determination of NELP was made based on interpreter use, language spoken at home, or explicit documentation of NELP in the electronic medical record. Proportions were compared using Mann-Whitney, Chi-squared tests, and unpaired t-test. Two-tailed p values of <0.05 were considered significant.

Results: 45 renal transplant recipients were included. 26% (12) of these patients were identified as NELP. The average age at transplant for NELP patients was 12.3 (± 5.3) and ELP was 10.7 (± 5.4). Those identified as NELP were significantly less likely to have a

living donor transplant (p<0.01). Worsened eGFR was seen in the NELP cohort at 7.43 compared to ELP at 5.91 (p=0.12). Rejection and graft failure were more likely in the NELP cohort (50% vs 33%, p=0.30 and 17% vs 3%, p=0.10, respectively). There was no statistical difference in viral activity.

Conclusions: NELP patients were less likely to receive living donor grafts, demonstrating an ongoing disparity. Although not statistically significant, NELP rejection and graft failures appear to be clinically significant for long-term outcomes. Our results suggest NELP is a risk factor for poor transplant outcomes in children. Our single-center study is limited given small sample size. Larger multi-centered studies are needed to identify interventions for bridging the gap among NELP patients.

Table 1. Demographics and Transplant Outcomes

Transplantation, Waitlist Status, and County Indices of Economic Health in West Virginia

Khaled Shawwa, Vishy Chaudhary, Anthony J. Parravani, Mark A. Poling, Jesse M. Thompson, Bethany S. Pellegrino, Rebecca J. Schmidt. *West Virginia University Health Sciences Center, Morgantown, WV.*

Background: Kidney transplantation is the optimal treatment for patients with end stage kidney disease. Many patients are never waitlisted for transplant. West Virginia (WV) has a high poverty rate (PR) (17.1 vs 12.85% for the US) with 33 of its 55 counties recognized as economically distressed or thereby at risk. We searched for a potential association between transplant waitlisting and the receipt of a transplant with indices of economic health.

Methods: Data on initiation of kidney replacement therapy with dialysis or transplant, waitlist for kidney transplant and death between 1965 and 2020 for WV patients were collected from USRDS. Data on county PR and economic distress including composite index (CI) for national economic status were collected from the Appalachian Regional Commission.

Results: Of the 23,055 WV patients identified in USRDS data, 2,999 (13%) were transplanted compared to 514,050 (15.3%) for the rest of the US (p< 0.001). Patients who never received a kidney transplant were from counties with higher PRs (18%) compared to transplanted patients (17.5%); p<0.001. Overall, waitlisted patients (2,375) came from counties with lower PRs than those who were never waitlisted (17.6 vs 18%; p<0.001). Waitlisted patients were less likely to be from distressed or at-risk counties (32 vs 34.3%; p=0.05) or counties with lower CI (141.9 vs 145.2; p<0.001) than patients who were never waitlisted. Among those who were never transplanted, waitlisted patients (792) came from counties with lower PRs (17.1 vs 18%; p<0.001), less distressed or economically at-risk counties (28.9 vs 34.5%; p=0.003) and counties with a lower CI (139 vs 145.5; p<0.001) than those who were never waitlisted (20,479). In multivariable logistic regression, county PR remained an independent predictor of lower odds of being transplanted (OR 0.91, 95% CI: 0.85-0.97; p=0.005) or waitlisted (OR 0.9, 95% CI: 0.84-0.96; p=0.001) per 5% increase in poverty rate after adjusting for age, sex, BMI, tobacco use, functional status, comorbid medical conditions and drug dependence.

Conclusions: Waitlisted patients and transplant recipients from WV were more likely to hail from counties with lower PRs and those in better economic health.

FR-PO799

Assessment of Disparities in Access to Valganciclovir Cytomegalovirus Prophylaxis in High-Risk African American Kidney Transplant Patients

Shipra R. Bethi,[1] Erika Andrade,[1] Zaid M. Mesmar,[3] David J. Taber.[2] *[1]Medical University of South Carolina College of Medicine, Charleston, SC; [2]Medical University of South Carolina Department of Surgery, Charleston, SC; [3]Jordan University of Science and Technology, Irbid, Jordan.*

Background: While access and outcomes disparities in African American (AA) kidney transplant recipients are well-known, there are limited studies assessing medication access disparities in transplant medicine. Cytomegalovirus (CMV) is a common viral infection that can cause serious complications in transplant recipients, with potential excess burden in AA communities. The high out-of-pocket costs associated with valganciclovir prophylactic therapy likely affect its use, so research is needed to fully understand differences in access to antiviral CMV prophylaxis and its impacts on CMV infection in AA transplant recipients.

Methods: This was a single-center, retrospective longitudinal cohort study in high-risk (CMV serostatus D+/R-) adult kidney recipients transplanted between 6/1/2010 and 5/31/2020, representing a 10-year cohort. Data was collected through electronic and manual medical record abstraction. Standard univariate comparative statistics were utilized in conjunction with binary logistic regression for multivariable modeling.

Results: 418 kidney transplant recipients were included, of which 179 (42.8%) were AA and 239 were non-AA. Baseline demographics were significantly different in mean age in years (46.5 ± 12.9 AA vs. 50.9 ± 13.9 non-AA, p=0.001) and private and Medicaid insurance status (p<0.001). AAs experienced higher rates of death-censored graft loss (10.6% AA vs. 5.0% non-AA, p=0.031). There was no difference in CMV infection rate, opportunistic infection rate, leukopenia incidence, or death between AA and non-AA patients. AA patients were 42% less likely to receive valganciclovir assistance in covering out-of-pocket costs (assistance programs and/or fundraising/savings use) compared to non-AA patients (OR 0.58, 95% CI [0.379-0.892], p=0.013). In a multivariable model including age, Medicaid status, and donor marginality variables, the impact of AA race on use of these assistance programs was no longer statistically significant (OR 0.70, 95% CI [0.448-1.094], p=0.118).

Conclusions: In univariate analyses AAs were significantly less likely to utilize assistance programs or fundraising/savings to access valganciclovir, which was somewhat explained by age, insurance status, and donor type. Despite this, CMV infection rates did not differ significantly between the AA and non-AA cohorts.

FR-PO800

Structural Racism and Access to Kidney Transplantation: Examining Residential and Transplant Center Segregation

Yiting Li,[1] Gayathri Menon,[1] Byoungjun Kim,[1] Evelien Quint,[4] Maya N. Clark-Cutaia,[1] Wenbo Wu,[1] Sarah Szanton,[2] Deidra C. Crews,[3] Tanjala S. Purnell,[3] Dorry L. Segev,[1] Mara McAdams-DeMarco.[1] *[1]New York University Grossman School of Medicine, New York, NY; [2]Johns Hopkins University, Baltimore, MD; [3]The Johns Hopkins University School of Medicine, Baltimore, MD; [4]Universitair Medisch Centrum Groningen Centrum voor Congenitale Hartafwijkingen, Groningen, Netherlands.*

Background: Disparities in kidney transplantation (KT) access exist for systematically disadvantaged communities. Racial/ethnic segregation, a marker of structural racism, in a candidate's residential neighborhood and their transplant center's neighborhood may drive KT disparities.

Methods: We identified 158,506 Black and White KT candidates (age≥18) first listed between 1995-2021 using SRTR. Segregation scores were calculated based on Thiel's H method. These scores were subsequently categorized into tertiles. We used proportional hazards models, adjusting for individual- and neighborhood-level factors, to quantify the likelihood of deceased donor KT (DDKT) and live-donor KT (LDKT). We also assessed the differential impact of segregation on KT access for Black candidates, using an interaction term of segregation tertiles and candidate race.

Results: Black candidates were more likely to reside in high-segregation neighborhoods (70.1% vs. 30.9%; P <0.001) and be listed at transplant centers located in these neighborhoods (63.9% vs. 38.2%; P<0.001). Candidates living in a high-segregation neighborhood were less likely to receive LDKT but not DDKT; furthermore, residence in a high-segregated neighborhood was associated with lower access to LDKT for Black candidates (aHR=0.88, 95%CI: 0.82-0.95) but not White candidates ($P_{interaction}$<0.001). Candidates listed in centers in a high-segregation neighborhood had lower access to DDKT, independent of race. However, LDKT access was lower for Black candidates listed at centers in a high-segregation neighborhood (aHR=0.90, 95%CI: 0.84-0.97; $P_{interaction}$=0.042).

Conclusions: Access to LDKT was significantly lower for Black candidates who resided in or were listed in centers in segregated neighborhoods, and access to DDKT was lower for all candidates whose centers were in high-segregation neighborhoods. Targeted efforts should address the impacts of racial/ethnic segregation on equitable access to KT.

FR-PO801

Impact of Race on Estimated Post-Transplant Survival Score in Patients with ADPKD

Sambhavi Krishnamoorthy, Niveditha Girimaji Satishchandra, Arlene B. Chapman, Rita L. McGill. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) affects individuals of every race equally. Access to kidney transplant (Tx) and post-Tx outcomes may vary by race. Estimated Post Transplant Survival (EPTS) scores are used to allocate high-longevity kidneys to patients who are expected to receive the most years of graft function. We examined EPTS scores in ADPKD by race, and compared these results to Tx recipients with other kidney diseases.

Methods: ADPKD and non-ADPKD patients age>30 years who received Tx 1/2000-3/2021 were selected from OPTN/UNOS data when ethnicity was unambiguously identified as White, African American, Hispanic, or Asian with available EPTS scores. Using the current EPTS table, EPTS percentages were categorized as ≤20%, >20-80%, and >80%. The four components of EPTS (age, diabetes, prior Tx, and years of dialysis) were analyzed by race for both groups.

Results: Overall, ADPKD patients were more likely (43.5%) to have EPTS≤20% compared to other kidney disorders (26.1%). Although African American, Hispanic and Asian ADPKD patients were more likely to have EPTS≤20% than other kidney disorders, differences in EPTS≤20% were greater across race in ADPKD individuals than in those with other kidney disorders. In ADPKD patients, White patients had significantly lower duration of dialysis and EPTS was predominantly determined by dialysis duration. In non-ADPKD patients, diabetes and prior transplantation were more often determinants.

Conclusions: Overall, transplanted ADPKD patients had significantly lower EPTS scores than other transplant recipients. However, increased dialysis time among non-white ADPKD patients leads to less favorable EPTS scores reducing allocation of best-quality kidneys to minority patients with ADPKD.

FR-PO802

Impact of Race on Kidney Transplant Outcomes in Patients with ADPKD

Rita L. McGill, Sambhavi Krishnamoorthy, Niveditha Girimaji Satishchandra, Arlene B. Chapman. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is equally present in all ethnicities. Disparities in access to transplant (Tx) exist for African American (AA) and Hispanic (H) ADPKD patients. We examined outcomes among ADPKD patients who received kidney Tx, by self-reported race.

Methods: OPTN/UNOS files were used to identified ADPKD patients age>30 receiving Tx 2000-2021, and ethnicity was White (W), AA, H, or Asian (A). A Cox model provided hazard ratios for death and a subdistribution hazards model for graft failure accounted for death as a competing outcome. Adjustments for age, gender, BMI, HLA/DR mismatch, dialysis years, diabetes, immunosuppression, CMV, cold ischemia, center distance, PRA, private insurance, donor KDPI, delayed graft function, and living/pre-emptive Tx were included with W as the reference.

Results: Among 32,611 ADPKD recipients, W, AA, H, and A were 76.4, 10.7, 9.8, and 3.1% respectively (Table 1). Compared to W, all others had more dialysis years and more mismatches, but less private insurance and fewer living and preemptive Tx. There was more delayed graft function, despite more lymphocyte depleting induction and corticosteroids.

Conclusions: Tx recipient survival did not differ between W and AA ADPKD patients, but was superior in H and A patients. Decreased allograft survival in African American ADPKD patients persisted after adjustment, suggesting that additional biological or social/economic factors remain to be identified.

FR-PO803

The Association of Altered Sense of Smell with Nutritional Status in Patients with Advanced CKD

Ragibe Gulsah Dilaver,[1] Zeynep Bal,[2] Andrew Guide,[3] Robert Greevy,[3] Talat Alp Ikizler.[1] *[1]Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN; [2]Ankara Egitim Ve Arastirma Hastanesi, Ankara, Turkey; [3]Vanderbilt University Medical Center Department of Biostatistics, Nashville, TN.*

Background: Anorexia is common in patients with advanced CKD and could lead to protein energy wasting (PEW). Altered sense of smell, a reflection of olfactory dysfunction, is a potential mechanism that exacerbates the impact of anorexia on PEW. In this study, we examined the extent of altered sense of smell and its association with PEW in patients with moderate to advanced CKD.

Methods: We studied 139 participants (34 healthy subjects, 50 patients with stage 3-4 CKD, 55 patients on maintenance hemodialysis (MHD)) using the odor identification test (Sniffin' Sticks odor screening test containing 12 different smells). Odor identification test were scored as correct or incorrect, and a total odor score was calculated for each participant. Malnutrition Inflammation Score was used to assess PEW.

Results: CKD patients had elevated levels of C-reactive protein and reduced eGFR and serum albumin concentrations compared to controls (Table1). There was a gradual decrease in the total odor score between groups, controls with highest and MHD patients with lowest scores. A similar gradual worsening was observed in MIS scores with MHD patients displaying worst nutritional score ($p \leq 0.001$) (Table 1). The number of participants with severe olfactory dysfunction (≤ 6 correct answers) was statistically significantly higher in the CKD and MHD groups compared to the control group ($p \leq 0.01$) There was a statistically significant inverse correlation between total odor score of the participants and MIS score for the entire population ($r = -0.3$, $p \leq 0.001$) (Figure 1), more prominently observed in the CKD and MHD groups.

Conclusions: This cross-sectional study suggests that olfactory dysfunction, as assessed by an odor identification test, is altered in patients with advanced CKD, most notably in ones on MHD. In CKD patients, the severity of the loss of sense of smell is directly associated with worse protein-energy wasting. Further studies are needed to examine the casual relationship between odor sensation and development of PEW in patients with CKD.

Variable Median (IQR)	Control	CKD	MHD	Compare: All Groups
eGFR	106.6 (96.9–112.4)	40.2 (30.3–47.8)	6.4 (5.3–9.1)	p ≤ 0.001
C-Reactive Protein	1.5 (1.0–2.3)	2.6 (1.9–4.4)	6.6 (3.5–13.4)	p ≤ 0.001
Albumin	4.30 (4.00–4.30)	4.50 (4.30–4.77)	4.05 (3.84–4.39)	p ≤ 0.001
Total Odor Score	9 (7–10)	8 (6–9)	7 (6–9)	p = 0.001
MIS Score	0 (0–0)	2 (1–3)	7 (5–10)	p ≤ 0.001

FR-PO804

Effect of Kidney Transplant (KT) on the Sense of Taste and Its Association with Nutritional Status in Patients with ESRD Who Receive Kidney Transplantation

Enrique Rojas-Campos, Andrea Torres Jiménez, Araceli A. Mendoza, Fabiola Martin del Campo, Alfonso M. Cueto-Manzano. *Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: Taste alteration of bitter, sour, sweet, salty and umami test are common, identification of patients with altered taste perception could reach to implement strategies and to prevent or improve malnutrition. There is not information regarding the change of taste perception after renal transplantation, and the association of taste change with nutritional status.

Methods: Prospective cohort in receptors of 1st transplant (Jan-Oct 2022). Subjects with dental prostheses, oral alterations, and active infection were excluded. The sample was 47 patients, and only 21 have completed the evaluation after the transplant. Subjective global assessment, pica questionnaire, current medications, and taste perception test. Anthropometric measurements were taken.

Results: Forty seven patients were inlcuded, 38.8 years old (mean); 70% were male, 51% had unknown cause of ESRD, 51% had hemodialysis, 43% peritoneal dialysis and 6% early trasplant.

Conclusions: There is a beneficial effect of kidney transplant on the sense of taste and nutritional status. Patients with indicators of adiposity have an alteration of taste before the KT. The umami taste significantly increases the perception of intensity, and the sour taste presents a not significant trend, this after renal transplantation, despite that almost all taste intensities increases. Patients who present BMI 25-30 kg/m2 before the transplant decrease significantly after the transplant and muscle mass indicators (AMA) present a trend.

Funding: Government Support - Non-U.S.

Comparison of nutritional status according to taste alteration

Association Between Physical Activity and Cardiovascular Events, Tumors, and All-Cause Mortality in Patients with Maintenance Hemodialysis with Different Nutritional Status

Hongyan Liu,[1] Yuyang Chen,[2] Tao Feng,[3] Pei Yu.[1] *[1]NHC Key Laboratory of Hormones and Development, Tianjin Key Laboratory of Metabolic Disease, Chu Hsien-I Memorial Hospital & Tianjin Institute of Endocrinology, Tianjin Medicical University, Tianjin, China; [2]Tianjin Dongli Hospital, Tianjin, China; [3]The Second Affiliated Hospital of Baotou Medical College, Inner Mongolia University of Science and Technology, Baotou, China.*

Background: The current research focuses on the effects of nutritional supplementation and exercise on dialysis patients, but Whether exercise can improve outcomes in patients with different nutritional status is not clear.

Methods: The MHD patients were recruited from April 2021 to April 2022. The information of PA was obtained from the IPAQ and followed up once in 3 months. The outcomes were cardiovascular death, myocardial infarction, stroke, heart failure, atrial fibrillation, tumor, and all-cause death. We used COX proportional risk model to estimate the association between PA and the outcomes of MHD patients. Patients are classified into two groups based on Geriatric Nutritional Risk Index (GNRI) and classified by age, and we used COX proportional risk model to estimatehe association of PA and outcomes in subgroups. ISM was used to estimate the effects of replacing LPA with MPA or VPA on risk of cardiovascular events, tumors, and all-cause death in different subgroups. The association between PA and outcomes was estimated with COX proportional risk model in different subgroups stratified according to baseline characteristics. The effects of PA on ankle-brachial index and body fat content were analyzed in different IPAQ groups.

Results: A total of 241 maintenance hemodialysis patients were included, 105 peoples developed cardiovascular death, myocardial infarction, stroke, heart failure, atrial fibrillation, tumor or all-cause death(43.6%). The median follow-up time was 12 months. MPA reduced the risk of outocme in MHD patients or high GNRI patients (40%vs39%). In MHD patients who was under 65 years with high GNRI, MPA reduced cardiovascular death, myocardial infarction, stroke, heart failure, atrial fibrillation, tumoror all-cause death by 55%. PA reduced the risk of cardiovascular event by 65%, but did not reduce the risk of tumor and all-cause death. Replacing LPA with VPA did not improve clinical outcomes. It actually increases the risk of heart failure 0.4%.

Conclusions: MPA reduced the risk of cardiovascular death, myocardial infarction, stroke, heart failure, atrial fibrillation, tumor, or all-cause death in MHD patients under 65 years, while VPA had no health benefit.

FR-PO806

Prevalence and Risk Factors of Sarcopenia in ESRD Patients

Alan F. Almeida, Kiran Bijapur, Rasika Sirsat, Ayan K. Dey, Khairwar Mahesh Prasad. *PD Hinduja National Hospital and Medical Research Centre, Mumbai, India.*

Background: Sarcopenia is a progressive skeletal muscle disorder involving the accelerated loss of muscle mass and strength, associated with increased adverse outcomes like falls, poor quality of life, frailty, and mortality. Prevalence of sarcopenia in the dialysis population varies from 4% to 63%. However, the prevalence and risk factors in the Indian dialysis population remains uncertain.

Methods: The aim was to study the prevalence of sarcopenia, to identify associated risk factors and to assess the effect of dietary counselling on sarcopenia. It was a prospective observational study, in which, 70 adult patients on maintenance hemodialysis were enrolled and monitored for 6 months. All patients were given dietary counselling at baseline, 1, 3 and 6 months. Bio-impedance spectroscopy, a hand grip dynamometer, and a 4-meter walk test were employed to evaluate muscle mass, strength, and function, respectively. Asian Working Group for Sarcopenia criteria were used for defining sarcopenia. Univariate and multivariate analysis was done for the factors affecting sarcopenia.

Results: Seventy dialysis patients were evaluated. Age of the cohort was 55.3 ± 13.74 years old. The prevalence of probable sarcopenia, sarcopenia, and severe sarcopenia was

11.43%, 25.71%, and 7.1% respectively. Increasing age and diabetes were potential risk factors for sarcopenia ($p < 0.0001$ and $P< 0.0093$ respectively). Sarcopenia was associated with lower BMI (p=0.0006), and lower normalised protein catabolic rate nPCR (p=0.026). Hemoglobin, albumin, calcium, phosphorus, and high sensitivity C reactive protein (hsCRP) did not show any association with sarcopenia. Prevalence of sarcopenia at the end of 6 months was reduced to 17.46% from 25.71%. There was a significant improvement in hand grip strength. nPCR at 6 months was significantly increased in all patients as compared to baseline ($p<0.05$) which implies improvement in protein consumption.

Conclusions: High prevalence of sarcopenia in dialysis patients in this study emphasizes the importance of increasing clinical awareness about sarcopenia and nutritional status assessment in this group of patients. Several variables like age, BMI, diabetes mellitus and nPCR were significantly associated with sarcopenia. Detailed dietary recall and nutritional intervention can improve sarcopenia and must be actively pursued.

FR-PO807

Associations Between Submaximal Indices of Physical Function and VO2 Peak in Patients on Hemodialysis

Eliott Arroyo, Heather Burney, Drake Dillman, Syed J. Sher, Sharon L. Karp, Sharon M. Moe, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Cardiopulmonary exercise testing (CPET) is well-recognized as the gold standard tool for quantifying cardiovascular functional capacity (as assessed by peak oxygen uptake, VO_2Peak during exercise). VO_2Peak is a strong predictor of survival in patients with chronic kidney disease (CKD). It is currently unknown whether basic submaximal tests can reliably predict VO_2Peak in patients with advanced CKD. Herein, we sought to compare the association between various submaximal assessments of physical function with VO_2Peak in patients on hemodialysis.

Methods: We analyzed data from the ongoing, "Effects of long interdialytic intervals on Cardiovascular Functional Capacity (ECON)" study, a randomized crossover trial of patients on hemodialysis. All participants underwent CPET and a battery of submaximal tests of physical function and mobility on a non-dialysis day. Multivariable step regression analysis was used to assess the association between the submaximal tests and VO_2Peak.

Results: A total of 30 patients were stratified based on the median VO_2Peak value of 11.2 mL/kg/min into a High group (n=15, 11 [73%] men, age=54 [11]; VO_2Peak=14.4 [2.5] mL/kg/min) and a Low group (n=15, 8 [53%] men, age=56 [12]]; VO_2Peak=9.8 [1.3] mL/kg/min). The High group had a lower BMI (26.7 [5.9] kg/m^2) compared to the Low group (33.6 [7.4] kg/m^2; p=0.008). No group differences were observed in age, sex, race/ethnicity, dialysis vintage, hypertension, or diabetes (all p's>0.05). The High group had a higher balance score (p=0.003), faster usual gait speed (p<0.001), faster time to complete 5 sit-to-stands (STS-5; p=0.013), longer distance walked during the 6-min walk test (p=0.003), and higher scores in the SF36-PFS (p=0.012) and PROMIS Mobility (p=0.004) questionnaires. After adjusting for age, sex, BMI, and diabetes, only STS-5 (ß [SE]=-0.51 [0.20]; p=0.022) remained significantly associated with VO_2Peak.

Conclusions: Our results indicate that the STS-5, a simple submaximal test that can be completed in less than 1 minute, is superior to the 6-min walk test, usual gait speed, and SF36-PFS and PROMIS Mobility questionnaires for predicting VO_2Peak in dialysis patients.

FR-PO808

Aerobic Exercise Capacity and Kidney Function Decline in Heart Failure with Preserved Ejection Fraction Patients

Jae Young Kim,[1,2] Minjae Yoon,[3] Seung Hyeok Han,[2] Tae-Hyun Yoo,[2] Shin-Wook Kang,[2] Jung Tak Park.[2] *[1]National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: Chronic kidney disease (CKD) is a complication frequently found in HFpEF patients and results in poor prognosis. However, factors related with increased risk of kidney function decline in HFpEF are not well known.

Methods: Among a total of 424 HFpEF patients with estimated glomerular filtration rate (eGFR) >60 mL/min/1.73 m^2, aerobic exercise function was assessed by the peak O2 consumption (VO_{2peak}) values obtained through cardiopulmonary exercise test. Primary outcome was development of incident CKD, defined as two consecutive eGFR of <60 ml/min/1.73 m^2 separated by ≥90 days.

Results: The mean age of patients was 64.2 ± 10.6 years and 33.5% were male. Cardiac ejection fraction and eGFR at baseline were 67.0 ± 6.8 % and 87.5 ± 12.2 mL/min/1.73 m^2, respectively. During 1082.8 person-years of follow-up, CKD incidence rate gradually increased in patients with lower VO_{2peak} levels. Multivariable Cox analyses revealed that 1-standard deviation increase in the VO_{2peak} level was associated with a 33% lower risk of CKD development. The adjusted HR (95% CI) of the lowest VO_{2peak} tertile group was 3.07 (1.51-6.24) when compared to the highest tertile group.

Conclusions: Poor aerobic exercise capacity, represented by reduced VO_{2peak} levels, is closely related with a higher risk of CKD development among HFpEF patients.

Table 1. Baseline characteristics among tertile groups stratified by the level of VO_{2peak}.

	Total (N=424)	Tertile groups stratified by the level of VO_{2peak}			P

Measurement Properties of the Most Common Performance-Based Measures of Physical Function in CKD: A Systematic Review

Jennifer M. MacRae,[1] Oksana Harasemiw,[2] Courtney J. Lightfoot,[3] Stephanie E. Thompson,[4] Clara Bohm,[2] Kathryn A. Wytsma-Fisher,[1] Pelagia Koufaki,[5] Thomas J. Wilkinson.[3] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [3]University of Leicester, Leicester, United Kingdom; [4]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [5]Queen Margaret University, Musselburgh, United Kingdom.*

Background: There is wide heterogeneity in physical function tests for clinical and research use in chronic kidney disease (CKD). The aim of this review was to identify and evaluate the most frequent physical function measures in terms of clinimetric properties.

Methods: MEDLINE, EMBASE, Cochrane Central Register of Controlled Trials, Cochrane Database of Systematic Reviews, CINAHL, Scopus, and Web of Science were searched from inception to March 2022, identifying studies which evaluated a clinimetric property (validity, reliability, measurement error, responsiveness) of an objectively

measured performance-based physical function outcome. All ages and any stage of CKD were included. The most common tests (defined as having 4 or more studies) are described in terms of reliability and validity.

Results: 50 studies with 21,315 participants were included, the majority were HD. Clinimetric properties were reported for 22 physical function tests; the following were most common: Hand grip strength (HGS), six minute walk test (6MWT), V02 peak, short physical performance battery (SPPB), gait speed, Sit to stand test-60 (STS-60), timed up and go (TUG), STS-5 and incremental shuttle walk test (ISWT). Very few studies reported properties of criterion (ISWT) and responsiveness (V02 peak and 6MWT).

Conclusions: The SPPB demonstrates high GRADE evidence for construct validity, reliability and measurement error. The next best tests include: 6MWT and TUG with high GRADE for reliability and measurement error. This review is an important step towards standardizing a core outcome set of tools to measure physical function in research and clinical settings for CKD.

Physical function tests GRADE evidence

Physical function test (number of studies)	Construct Validity	Reliability	Measurement Error
HGS (13)	Low	Low	Moderate
6MWT (11)	Low	High	High
SPPB (10)	High	High	High
Gait speed (8)	Moderate	Moderate	Very Low
STS-5 (8)	High	Moderate	Low
V02 peak (8)	Low	Low	Low
TUG (7)	Moderate	High	High
STS-60 (6)	Moderate	High	Moderate
STS-30(4)	Low	High	Moderate
ISWT (4)	Moderate	Low	Low

Association of Myosteatosis with Poor Physical Function and Mortality in Hemodialysis Patients

Dongsheng Cheng, Niansong Wang. *Department of Nephrology, Shanghai Sixth People's Hospital Affilated to Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: Skeletal muscle area, which is measured by computed tomography (CT), can be divided into normal attenuation muscle area with little fat infiltration and low-attenuation muscle area with high fat infiltration. Herein, we aimed to investigate the differential effects of normal and low-attenuation muscles at the L3 vertebra and myosteatosis on physical function and mortality in patients undergoing hemodialysis.

Methods: All patients underwent non-enhanced abdominal CT. The skeletal muscle index (SMI), normal attenuation SMI (NSMI), low attenuation SMI (LSMI), and fatty muscle fraction (FMF) at the L3 vertebra were determined (as shown in figure 1). Physical function was measured using handgrip strength, gait speed, sit-to-stand in 60 s (STS-60) test, and instrumental activities of the daily living scale.

Results: There were 101 patients on maintenance hemodialysis (mean age 52.73, 39.6% women), and 19 patients died during a median follow-up time of 26.2 months. The NSMI was moderately positively correlated with handgrip strength, gait speed, and STS-60 score (rho:0.363 to 0.542;$P < 0.001$); In contrast, the LSMI was negatively correlated with all physical function measures (rho: – 0.439 to -0.317;$P < 0.001$). In multivariate regression analyses, larger NSMI, lower LSMI, and lower FMF than SMI were significant predictors of better physical performance. Moreover, according to the Kaplan–Meier curve and Cox regression analysis, high FMF (aHR 4.09, 95% CI [1.36, 12.32]) and LSMI (aHR 4.28 [1.42,12.89]) were significantly associated with high mortality.

Conclusions: This study demonstrated distinct effects of normal and low-attenuation muscles on physical function. Moreover, it highlights the importance of myosteatosis in determining poor physical performance and predicting mortality in patients undergoing hemodialysis.

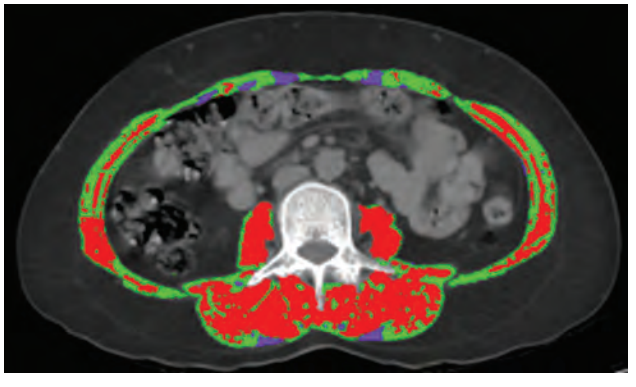

Figure 1. Muscle quality map at L3 derived from abdominal CT using region growing mode. The axial CT images at L3 were segmented into NAMA (red), LAMA (green), and IMAT (purple).

Dialysis Malnutrition Score and Handgrip Strength with Quality of Life Among Patients on Maintenance Hemodialysis in Cebu City, Philippines

Jan Roslyn T. Empinado, Alexander U. Tan. *Cebu Doctors' University Hospital, Cebu City, Philippines.*

Background: Malnutrition is common in hemodialysis patients and is a powerful predictor of morbidity and mortality. End stage renal disease (ESRD) has been shown to negatively affect the Quality of Life (QoL) of patients. Among Chronic Kidney Disease (CKD) patients on maintenance hemodialysis, there is a considerable effect on the functional state and QoL. Malnutrition in CKD patients is one of the factors that afflicts QoL.

Methods: One hundred eight (108) patients on maintenance hemodialysis in a tertiary hospital were assessed nutritionally by DMS and HGS while the overall perception QoL and health was assessed using World Health Organization Quality of Life - BREF (WHOQoL-BREF) questionnaire. Kendall's tau was used to determine whether there is a correlation between DMS and HGS with quality of life scores. A p-value of <0.05 will be considered as statistically significant.

Results: Based on DMS, 87% of patients had mild to moderate malnutrition and 64.8% had renal cachexia based on HGS. Those with poor nutritional status in DMS showed significant decrease in overall perception of their quality of life p = 0.003, quality of health p = 0.026, physical p = 0.013 and environmental domains p = 0.044 of WHOQoL. Handgrip score however did not have any correlation with the overall QoL, perception of general health and on the four domains.

Conclusions: DMS and HGS are simple and accessible nutritional assessment tools to detect malnutrition among hemodialysis patients. DMS correlates with QoL with higher DMS reflecting malnutrition and the overall quality of life decreases. Early detection of malnutrition can prevent further health deterioration with nutritional interventions and therefore improve QoL in the aspects they are most affected.

Table 1. DMS and HGS on Quality of Life ($n = 108$)

Variables		DMS	p-value	HGS	p-value
Overall Quality of Life		-0.265	0.003	-0.001	0.994
General perception of health		-0.219	0.026	0.098	0.311

FR-PO812

Effect of Leucine Supplementation and Resistance Exercise for Prevention of Sarcopenia in Patients on Maintenance Hemodialysis

Eu Jin Lee,[1] Kyungho Park,[1] Heewon Park,[1] Yunkyeong Hwang,[1] Suyeon Han,[1] Hae Ri Kim,[2] Youngrok Ham,[1] Dae Eun Choi,[1] Kiryang Na,[1] Kang Wook Lee.[1] *[1]Chungnam National University Hospital, Daejeon, Republic of Korea; [2]Chungnam National University Sejong Hospital, Sejong, Republic of Korea.*

Background: Sarcopenia frequently occurs in hemodialysis patients up to 40%. We examined the effects of supplementation of leucine amino acid combined with resistance exercise on preventing sarcopenia in patients on maintenance hemodialysis (MHD).

Methods: This was a single center, prospective, single-arm pilot study. 22 non-sarcopenic patients on MHD at our hospital were enrolled. During the intervention period (first 12 weeks), participants were provided with daily 6g of leucine (3g in capsule and 3g via beverage) and a protocol for daily resistance exercise. Both interventions were stopped during following 12 weeks. Bioimpedance analysis (BIA), handgrip strength (HGS), short physical performance battery (SPPB), serum chemistry, immunophenotype of peripheral blood mononuclear cells were examined at baseline, 12 week and 24 week. Participants who expressed 5% or more improvement in each parameter were defined as responders.

Results: Among 22 patients, mean age was 55±11.8 years and hemodialysis vintage was 4.7±3.5 years. 7 patients (31.8%) were female. 21 patients (95.4%) showed improvement in at least one or more parameters. At 12 week, the number of responders were 14(63.5%) for skeletal muscle index and 7(31.8%) for grip strength. Baseline low grip strength (<35.0kg) was the strongest predictor of improvement in grip strength (AUC 0.933). Increase in grip strength was significant in females (7.6±8.2 vs -1.6±7.2%, p=0.03), in age over 60 (5.3±6.2 vs. -1.4±9.1%, p=0.04), and with higher exercise adherence (6.8±7.7 vs -3.2±6.4%, p=0.004). The number of responders were 13 patients (59.1%) for gait speed and 14(63.5%) for sit-to-stand time. Baseline low hemoglobin(<10.5 g/dL) and low hematocrit lower(<30.8%) were predictors of improvement in sit-to-stand time (AUC

0.862 and 0.848, respectively). Immunophenotypic analysis found that the intervention tended to increase naïve/memory $CD8^+$ T cell ratio (from 1.2±0.8 to 1.4±1.1, p=0.07).

Conclusions: Supplementation of leucine amino acid combined with resistance exercise contributed to improvement of muscle mass, muscle strength, and physical performance in certain group of non-sarcopenic hemodialysis patients. This intervention may have effect on prevention of sarcopenia in old-age, anemic, female patients on MHD with lower HGS.

FR-PO813

Electric Acupuncture Mimics Exercise to Ameliorate Muscle Wasting by Promoting Angiogenesis and Neurogenesis in CKD

Zhen Su,[1,2] Xiaomao Luo,[2,3] Shuyang Bian,[2] Hui Cai,[2,4] Xiaonan H. Wang.[2]
[1]The First Affiliated Hospital of Wenzhou Medical University, Wenzhou, China; [2]Emory University, Atlanta, GA; [3]Shanxi Agricultural University, Taigu, China; [4]Joseph Maxwell Cleland Atlanta VA Medical Center, Decatur, GA.

Background: Our previous study demonstrated that acupuncture with low frequency electrical stimulation (Acu/LFES) attenuates skeletal muscle atrophy by improving muscle progenitor cells regeneration. The present study examines whether Acu/LFES improves revascularization, innervation, and protein anabolism in muscle of chronic kidney disease (CKD) mice.

Methods: CKD was induced by the 5/6 nephrectomy. Acu/LFES was applied in hindlimbs of CKD mice. Acu/LFES points were selected by WHO Standard Acupuncture classification. Proteins from hindlimb (gastrocnemius), forelimb (triceps brachii) and back (longissimus) muscles were isolated at 0.5, 6, 24, 48 and 72 hours after Acu-LFES therapy. Protein synthesis was measured by the surface-sensing of translation (SUnSET) assay. Exosomes were isolated using serial centrifugation and subjected to microRNA deep sequencing. NanoSight was used to measure exocomes concentration. The microRNA library was validated using a High Sensitivity DNA chip.

Results: Protein synthesis was enhanced in the Acu/LFES-treated gastrocnemius; however, in non-Acu/LFES treated muscles, triceps brachii and longissimus, protein synthesis was also significantly increased after treatment. These increases were accompanied with increased phosphorylation of mTORC1 and 4EBP-1. Myogenesis markers, Pax7, myoD and myogenin were significantly upregulated. The mRNA expression of PDGF and ENO2 were enhanced by Acu/LFES. The protein amount of Igf-1, Igf-1 receptor, VEGF (a protein that stimulates the formation of blood vessels), and peripherin (expressed mainly in the nervous system) were also increased by Acu/LFES. Deep sequencing revealed that miR-5107-5p and miR-30-5p were sharply decreased in serum exosomes of Acu/LFES mice. Using a luciferase reporter assay, we demonstrated that miR-5107-5p directly inhibits VEGF, and miR-30-5p inhibits ENO2, which suggests a mechanism in which downregulation of these two miRNAs results in expanding VEGF and ENO2 leading to accelerate revascularization and innervation.

Conclusions: Acu/LFES treatment increases myogenesis, angiogenesis and neurogenesis, as well as protein synthesis. Acu/LFES inhibits miR-5107 and miR-30, resulting in increased VEGF and ENO2 contributing to these processes. Our study provides strong mechanistic insights for Acu/LFES treatment of muscle atrophy in CKD.

The Practices and Views of US and Canadian Nephrologists, Nurses, and Allied Health Professionals Regarding Exercise and Physical Activity for People Receiving Peritoneal Dialysis

Paul N. Bennett,[1,2] Clara Bohm,[3] Deborah Lynn Zimmerman,[4] Jennifer M. MacRae,[6] Oksana Harasemiw,[3] Emilie Ford,[3] Nancy Verdin,[6] Iwona Gabrys,[5] Krista D. Stewart,[3] Stephanie E. Thompson.[5]
[1]Griffith University, Nathan, QLD, Australia; [2]Satellite Healthcare, San Jose, CA; [3]University of Manitoba, Winnipeg, MB, Canada; [4]Ottawa Hospital, Ottawa, ON, Canada; [5]University of Alberta, Edmonton, AB, Canada; [6]Global Renal Exercise Network, Winnipeg, MB, Canada.

Background: In the US and Canada people receiving peritoneal dialysis (PD) are frequently sedentary and experience poor physical function. This creates clinical challenges because basic physical function is required to maintain independence for this home-based therapy. The aim of this study was to explore exercise-related practices and perceptions of nephrologists, PD nurses and allied health clinicians across the US and Canada.

Methods: Secondary analysis of an international cross-sectional 13-item web-based survey of PD health professionals, exploring perspectives and practices regarding exercise for people receiving PD. Recruitment in the US and Canada was done through professional nephrology networks including the American Society of Nephrology, the Canadian Society of Nephrology, the American Nephrology Nurses' Association and the Canadian Association of Nephrology Nurses and Technicians.

Results: 211 clinicians (88 nephrologists, 87 nurses and 36 allied health professionals) responded from the US (49%) and Canada (51%) with most (72%) reporting greater than 2 years PD experience. Most respondents (89%) believed PD patients could perform more exercise than they currently do. Most respondents (86%) agreed that structured exercise programs would be beneficial for people receiving PD. Eighty-six percent stated that PD patients would benefit from exercise professionals, however, only 27% of Canadian and 4% of US clinics had exercise professionals involved in programs. Sixty-one percent agreed and 34% were unsure whether people receiving PD could perform abdominal strengthening exercises safely. Seventy-three percent of PD programs had formal guidelines for swimming, 78% for lifting, 63% for falls, and 78% for physical activity resumption following PD catheter insertion.

Conclusions: US and Canadian PD health professionals recognize the importance of exercise in people receiving PD and most programs have exercise-related policies. Even though there are few dedicated PD exercise programs in the US and Canada, most clinicians believed that exercise professionals and structured exercise programs would benefit people receiving PD.

Exercise Has Mode-Specific Effects on Musculoskeletal Health in a Rat Model of CKD-MBD

Keith G. Avin,[1,2] Ashley D. Troutman,[1] Corinne E. Metzger,[2] Neal X. Chen,[2] Kalisha O'Neill,[2] Landon Tak,[2] Matthew R. Allen,[2] Sharon M. Moe.[2]
[1]Indiana University Purdue University Indianapolis, Indianapolis, IN; [2]Indiana University School of Medicine, Indianapolis, IN.

Background: Chronic kidney disease (CKD) progression is associated with deterioration of musculoskeletal health. We hypothesized that voluntary wheel running as compared to forced treadmill would preferentially impact musculoskeletal health in CKD.

Methods: We used a progressive, naturally occurring, CKD rat model (Cy/+ rat) (n=10-12/gr): 1) normal littermates (NL), 2) Cy/+ (CKD) rats, 3) CKD-treadmill (CKD-TM) 4) CKD-wheel (CKD-W). For 10 weeks treadmill rats ran 40 minutes/day, 4 days/week, for 0° grade, wheel rats had 24/7 free access; training volumes similar between the modes. Termination, and blood and tissue collection occurred at 33 weeks. Outcome measures were maximal muscle torque and fatigue, maximal running endurance, and tibia cortical bone morphology. Data analysis included one-way ANOVA with Tukey's multiple comparisons test.

Results: Overall CKD versus NL impaired cortical bone with increased porosity (mean 0.18±0.12 NL, 2.03±1.8 CKD; $p<0.05$), and reduced area (mean 6.64±0.43 NL, 5.77±0.58 CKD; $p<0.01$) and thickness (mean 0.48±0.30 NL, 0.34±0.11 CKD; $p<0.001$). Skeletal muscle function worsened in CKD (vs NL) with reduced maximal torque (mean 57.3±7.7 NL, 47.6±9.3 CKD; $p<0.05$) and increased fatigue (mean 42.8±9.9 NL, 56.5±8.7 CKD; $p<0.01$). Running endurance was significantly reduced in CKD (mean 24.2±3.3 NL, 20.8±4.5 CKD; $p<0.05$). Treadmill running increased maximal torque (mean 47.6±9.3 CKD, 57.1±8.8 CKD-TM; $p<0.05$) and running endurance (mean 20.8±4.5 CKD, 25.9±3.9 CKD-TM; $p<0.05$) when compared to CKD. Wheel running significantly improved maximal running endurance (mean 20.8±4.5 CKD, 24.7.03±2.9 CKD-W; $p<0.05$), but did not impact maximal muscle torque, muscle fatigue or cortical bone parameters.

Conclusions: CKD deteriorates the musculoskeletal system through cortical bone loss, and reduced muscle strength and greater muscle fatigue. To determine optimal delivery of exercise we compared treadmill to wheel running. Both methods improved maximal running endurance after 10 weeks; however, only treadmill running improved maximal muscle strength. These marginal improvements mimic what is seen in clinical meta-analyses and emphasizes the need for novel approaches to exercise prescription and/or the need for pharmaceutical or nutraceutical treatments to improve musculoskeletal health in advanced CKD.

FR-PO816

Progressive Individualized Exercise Intervention Impacted the Cecal Microbiota Composition in a Rat Model of CKD

Annabel Biruete,[1,2] Ashley D. Troutman,[3] Shruthi Srinivasan,[2] Kalisha O'Neill,[2] Kelly Swanson,[4] Neal X. Chen,[2] Sharon M. Moe,[2] Keith G. Avin.[3,2]
[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University Purdue University Indianapolis, Indianapolis, IN; [4]University of Illinois Urbana-Champaign, Urbana, IL.

Background: Exercise interventions are recommended to improve the musculoskeletal and cardiopulmonary health in chronic kidney disease (CKD). Exercise has been shown to impact the gut microbiome, but data in CKD is limited. We have previously shown that bone health and serum biochemistry was improved following 10 weeks of wheel running and this study hypothesized that treadmill running will improve gut microbiome in the Cy/+ rat model of CKD.

Methods: We examined the following groups (n=6-8/group): 1) Normal littermates (NL); 2) CKD rats; 3) CKD + treadmill exercise (CKD+EX). The exercise intervention was performed for at a 5° grade, 50 minutes/day, 4 days/week for 10 weeks. The running speed was progressively increased if the rat was in the upper 1/3 of the belt in the final 10 minutes; maintained if in middle; and reduced if in lower 1/3. Treatments began at 22 weeks until 32 weeks of age (moderate to severe CKD, respectively). Cecal digesta was collected at euthanasia at 32 weeks of age and the V4 region of the 16S rRNA gene was sequenced and analyzed via QIIME2.

Results: Richness of the microbiota (alpha-diversity) was not impacted by CKD phenotype or exercise. The overall microbial community (beta-diversity) was not different between NL and CKD; however, CKD+EX was different from NL and CKD (PERMANOVA corrected $p<0.04$). There was a higher relative abundance of *Bacteroides, Ruminococcus,* unclassified Desulfovibrionaceae, unclassified Peptostreptococcaceae, and *Prevotella* (corrected $p<0.05$) with exercise. Taxa whose relative abundance was lowered by the exercise intervention included *Lactobacillus, Akkermansia,* and *Blautia.*

Conclusions: A personalized progressive treadmill intervention impacted the cecal microbiota. Future studies should aim at examining the impact of exercise on microbially-derived uremic toxins and outcomes in CKD.

Differences in Subjective Global Assessment Score and Mortality Risk Across Race and Ethnicity in a Prospective Hemodialysis Cohort

Ji Hoon Yoon,[1] Yoko Narasaki,[1] Seungsook You,[1] Masaki Okazaki,[1] Adnan M. Ismail,[1] Diana Tran,[1] Man Kit Michael Siu,[1] Sara S. Kalantar,[1] Parth Kumar,[1] Silvina Torres Rivera,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[2] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Protein-energy wasting is a major predictor of mortality in advanced CKD patients, and clinical guidelines endorse use of the Subjective Global Assessment (SGA) survey as a validated measure of nutritional status in HD patients. We examined the relationship between SGA score and survival in a diverse HD cohort and how associations differ across race/ethnicity.

Methods: We evaluated 1018 HD patients from the prospective NIH MADRAD Study recruited across 18 dialysis clinics who underwent protocolized SGA surveys over 10/2011-12/2021. Using Cox models adjusted for expanded case-mix+laboratory covariates, we examined associations of time-dependent and baseline SGA score categorized as tertiles with all-cause mortality risk. We then examined differential SGA score—mortality associations across race/ethnicity using interaction tests.

Results: The mean±SD age of the cohort was 55±14 years, among whom 44% were female; and 53%, 27%, 10%, and 9% were Hispanic, Non-Hispanic (NH) Black, Asian, and NH White. In analyses of time-dependent SGA score, incrementally higher (worse) tertiles were associated with higher mortality (ref: Tertile 1): HRs (95%CIs) 1.41 (1.07, 1.87) and 2.68 (2.06, 3.48), respectively, for Tertiles 2 and 3, respectively (Fig). Similar findings were observed in baseline SGA analyses. Subgroup analyses showed that Tertile 3 of time-dependent SGA scores were associated with higher mortality in all racial/ethnic groups, with the strongest point estimates observed in Hispanic and NH White patients: HRs (95%CIs) 1.91 (1.59, 2.30), 1.47 (1.19, 1.82), 1.50 (1.01, 2.24), and 2.07 (1.29, 3.32) for Hispanic, NH Black, Asian, and NH White patients, respectively (p-interaction <0.001).

Conclusions: In a multicenter prospective HD cohort, higher (worse) SGA scores were associated with worse survival in all racial/ethnic groups. Further studies are needed to determine personalized approaches to optimizing nutritional status in diverse HD populations.

Goal Attainment Scale as an Outcome Measure in a Randomized Controlled Trial of Lifestyle Interventions

Dev K. Jegatheesan,[1,2] William F. Pinzon Perez,[3] Riley Brown,[2] Nicola W. Burton,[4] Lindsey Webb,[1] Amandine Barnett,[2] Marguerite M. Conley,[1] Hannah L. Mayr,[2,1] Shelley Keating,[2] Jaimon T. Kelly,[2] Graeme A. Macdonald,[2,1] Jeff S. Coombes,[2] Ingrid J. Hickman,[2,1] Nicole Isbel.[1,2] *[1]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [2]The University of Queensland, Saint Lucia, QLD, Australia; [3]Queensland Cyber Infrastructure Foundation, Saint Lucia, QLD, Australia; [4]Griffith University, Nathan, QLD, Australia.*

Background: Goal attainment scale (GAS) is a validated patient-reported outcome measure (PROM) that can be used to quantitate achievement of individualised patient goals. GAS has not been assessed as a PROM in lifestyle intervention trials. We report the GAS findings of a predefined sub-analysis of the U-DECIDE study, which assessed the feasibility of digital health-assisted lifestyle interventions (DHALI) in people with kidney and liver disease.

Methods: Adults with kidney or liver disease and metabolic syndrome were randomized to either usual care (UC) or DHALI+UC. All participants received goal setting support, a wearable activity monitor, and individualized dietitian counselling. The DHALI+UC group could opt-in to receive exercise and/or dietetic video consultations; had access to nutrition and exercise applications; and text-message education. Pre-randomization, participants were assisted by a clinician to generate up to 2 SMART (specific, measurable, attainable, realistic and timely) lifestyle goals. Possible outcomes ('much better than expected', 'better than expected', 'as expected', 'worse than expected', 'much worse than expected') for each goal were predetermined and quantified by the participants. The ΔGAS score was calculated for each participant at the end of the trial by using a validated formula which incorporated the importance, difficulty and outcome scores of each goal.

Results: 67 participants were randomized, 46 (70%) with kidney disease. Mean age was 51 ± 13 years, 56% were men. Participants set weight loss (46%), followed by fitness (29%), dietary (15%) and body composition (5%) goals. 66 (99%) participants completed both goal setting (at baseline) and outcome review (at 26 weeks) sessions, each taking <10 minutes per patient. Though underpowered for this outcome, there was no significant difference in ΔGAS between UC and DHALI+UC groups (7 vs 6, p = 0.578) over time.

Conclusions: Participants commonly selected weight loss and fitness goals. GAS is a feasible, convenient and inexpensive PROM that can be used to quantitate change in patient determined lifestyle goals.

FR-PO819

Performance and Self-Perceived Restless Leg Syndrome Associated with Use of High-Flux Dialyzers: Results from the eMPORA III Trial

John W. Larkin,[1] Bettina Griesshaber,[2] Ansgar Erlenkoetter,[3] Petra Ronova,[4] Maria Krizsan,[5] Jennifer Braun,[2] Manuela Stauss-Grabo.[2] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Fresenius Medical Care Deutschland GmbH Werk Sankt Wendel, Sankt Wendel, Germany; [4]Fresenius Nephrocare Praha 9 - Vysocany, Prague, Czechia; [5]FMC, Péterfy II. Dialízis Központ, Budapest, Hungary.*

Background: The eMPORA III study was a prospective, multicenter, crossover trial with 4-week randomized treatment sequences comparing the performance and hemocompatibility of dialyzers (FX CorAL 600 vs two comparators) in post-dilution online hemodiafiltration (HDF). Primary outcome was beta-2 microglobulin (B2M) removal and self-perceived restless leg syndrome (RLS) was also assessed using the International RLS Study Group Rating Scale survey.

Methods: Medically stable adult HDF patients with a functioning fistula/graft were recruited from 8 centers in Germany, Czechia, Hungary (NCT04714281). B2M removal rate (B2M RR) pre-HDF vs 240 min was measured in week 3 of each 4-week treatment period. RLS survey was administered at baseline and the end of periods. Survey captures the severity and impact of symptoms in the prior week on a 0 (no RLS) to 40 (very severe RLS) point scale, and has 2 subscales. Global RLS scores >10 points imply moderate-to-very severe RLS symptoms. Effect of dialyzers were estimated using a linear mixed model adjusted for center and patient in the intention-to-treat (ITT) group.

Results: Study enrolled 82 subjects (76 ITT group, mean age=67.0±15.6 years, 26.3% female, 34.2% diabetes). FX CorAL 600 showed a +0.60±0.39% and +1.82±0.38% higher B2M RR vs FX CorDiax 600 (non-inferiority p<0.0001; superiority p=0.0606) and xevonta Hi 15 (non-inferiority p<0.0001; superiority p<0.0001). Mean global RLS score was 3.2±6.24 (**Figure 1**). FX CorAL 600 showed a +0.24±0.54 and +0.33±0.54 point change in global RLS scores vs FX CorDiax 600 (p=0.65) and xevonta Hi 15 (p=0.54); consistent findings were found for subscale scores.

Conclusions: FX CorAL 600 provided a higher B2M RR than comparator dialyzers. RLS symptoms were consistent between dialyzer types. Average scores indicate mild-to-no RLS among trial participants, yet some patients reported severe symptoms. Higher middle molecule clearance may not affect RLS symptoms, but more investigations are needed with longer follow-up and should consider patients with moderate-to-severe symptoms.

Exploring Health-Related Decision-Making in Advancing CKD

Shena Gazaway,[1] Tamara M. Nix Parker,[1] Orlando M. Gutierrez,[2] Clare N. Lyas,[2] James N. Dionne-Odom.[1] *[1]University of Alabama at Birmingham, School of Nursing, Birmingham, AL; [2]The University of Alabama at Birmingham, Birmingham, AL.*

Background: Patients with chronic kidney disease (CKD) often rely on family caregivers to help cope with illness and make health-related decisions. While many patients desire detailed information about their disease and prognosis, clinicians often report not sharing prognostic information to maintain hope. These decision-making trends leave patients and caregivers under-informed, potentially resulting in missed opportunities for them to take greater ownership of their disease management. Given the scarcity of literature describing health-related decision-making before initiating renal replacement therapy, we undertook a study to describe the needs, challenges, and experiences of patients with CKD and their family caregivers when making health-related decisions.

Methods: A qualitative descriptive study was conducted with individuals with Stage 3 or higher CKD, including end-stage and their family caregivers. Recruitment occurred from April 2022 to December 2022 at two outpatient nephrology clinics within an urban academic medical center. Data was collected via one-on-one, semi-structured interviews. A community advisory group of CKD patients and clinicians developed the guide. Data were analyzed using thematic analysis.

Results: Patient and caregiver participants (*N*=30) were older (over 60; *n*=20), and the majority were female (*n*=21). Black (*n*=14) and White (*n*=16) individuals were represented almost evenly. Three themes describing the decision-making experience were identified: 1) decisions triggered by declining health and broad in scope, 2) challenges to decision-making, and 3) factors influencing decision-making. Participants' experiences demonstrated that decisions were triggered when health declined. Yet, decisions that

impact disease progression were being made as early as stage 3. Decision-making was made difficult due to poor resource utilization and lack of information. Yet, the structure and nature of the medical appointment and resources served to remove challenges by assisting with enhanced communication and greater self-advocacy.

Conclusions: This study's findings demonstrate the need for decision-support interventions upstream of advanced illness that train patients and caregivers to be empowered participants in answer-seeking behaviors that enhance their ability to make informed patient-centered decisions.

Association Between the Fibrosis-4 (FIB-4) Score and ≥20% Decline in the Estimated Glomerular Filtration Rate in the General Population with Abdominal Adiposity

Akihiro Kuma,[1] Masayoshi Nanami,[1] Takahiro Kuragano,[1] Akihiko Kato.[2]
[1]Hyogo Medical University, Nishinomiya, Japan; [2]Hamamatsu University Hospital, Hamamatsu, Japan.

Background: The prevalence of chronic kidney disease is increasing in patients with non-alcoholic fatty liver disease (NAFLD), and obesity is a known risk factor for both conditions. The fibrosis index based on four factors (FIB-4) score, a non-invasive indicator, is strongly associated with liver injury and fibrosis in patients with NAFLD. The association between the FIB-4 score and the estimated glomerular filtration rate (eGFR) slope remains unclear. In this study, we investigated whether the FIB-4 score is associated with eGFR decline in the general population.

Methods: This retrospective observational cohort study included individuals who underwent health check-ups across Japanese companies between 2009 and 2014. Participants who consumed ≥30 g of alcohol/day were excluded. An FIB-4 score of ≥1.30, which indicates moderate-to-severe liver fibrosis, was set as the cut-off value. Propensity score matching based on FIB-4 scores (<1.30, ≥1.30) was performed to eliminate biases associated with covariances across participants' backgrounds.

Results: We recruited 11,296 participants at baseline; however, 5943 participants were excluded, and data of 464 participants were analyzed after propensity score matching. Participants' mean age was 50 years, mean eGFR was 74.7 mL/min/1.73 m^2, and the mean waist circumference (WC) was 81.8 cm. FIB-4 scores ≥1.30 were significantly associated with ≥20% decline in the eGFR over 5-year follow-up (odds ratio [OR] 3.94, 95% confidence interval [CI] 1.29–12.06). Subgroup analysis showed that an FIB-4 score ≥1.30 was significantly associated with ≥20% decline in eGFR 5 years later in participants with WC ≥85 cm (OR 8.78, 95% CI 1.05–73.53) but not in those with WC <85 cm (OR 2.70, 95% CI 0.70–10.38).

Conclusions: Our findings show that an FIB-4 score ≥1.30 was associated with ≥20% decline in the eGFR 5 years later. Abdominal adiposity accompanied by an FIB-4 score ≥1.30 was a particularly important risk factor for eGFR decline.

FR-PO822

Subcutaneous Fat Area Can Predict Two-Year Survival in ESRD Patients Initiating Dialysis

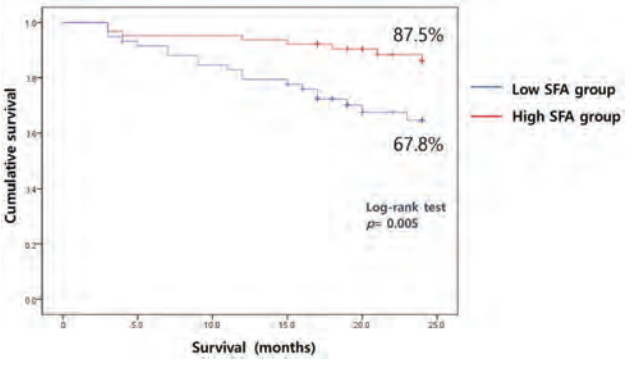
Wonjung Choi. *The Catholic University of Korea, Daejeon, Republic of Korea.*

Background: Obesity is a risk factor for increased cardiovascular disease and diabetes in general population. However, the "obesity paradox" is observed in chronic disease such as ESRD patients. BMI does not discriminate between subcutaneous fat, visceral fat or muscle. Either overhydration or PEW state in the initial dialysis patient makes it difficult to properly assess BMI and muscle mass, the initial measurement of this modality difficult to assess the patient's prognosis. Fat tissue can be assessed relatively accurate than muscle even in patients starting dialysis. However, the association of fat tissue or the distribution of fat and mortality in ESRD patient not established yet. The aim of this study was to investigate the association subcutaneous fat and all-cause mortality in initial dialysis patient.

Methods: total 123 patient newly initiated maintenance hemodialysis who underwent abdominal CT were enrolled between January 2018 and June 2021. Patient with age ≥18year were include. Subcutaneous fat area (SFA) were determined using abdominal CT. The analysis was conducted using open-source software to identify SFA in CT images for body composition analysis.

Results: During the 2-year follow-up period, the Kaplan–Meier survival rates were 67.8%, 87.5% in low SFA group (group 1) and high SFA group (group 2) (log rank p=0.005), respectively (Figure1). In Cox proportional hazards analysis, adjusting for (Model 1)+ CONUT, PNI as nutritional risk evaluation, low SFA group showed high risk for all-cause mortality (HR 2.979, 95% CI 1.137-7.808, p= 0.026) (Table 1).

Conclusions: In conclusion, low SFA increases the risk of 2-year all-cause mortality, suggesting that early SFA analysis may be predictive of mortality in patient risk analysis in initial dialysis populations.



K-M survival curve between SFA groups

	Hazard ratio (95% CI)	p value
Crude	3.105 (1.356-7.113)	0.005
Model 1	3.596 (1.391-9.292)	0.008
Model 2	2.979 (1.137-7.808)	0.026

- **Model 1**: age, sex, SFA grade, visceral fat, DM, HTN, Hb, BUN, Cr, eGFR, total protein, albumin, glucose, Tchol, TG, CRP, BMI
- **Model 2**: Model 1 + CONUT, PNI (nutrition score)

Cox regression for SFA groups

FR-PO823

Association of Weight-Adjusted Waist Index with Abdominal Aorta Calcification and Mortality in Hemodialysis Patients

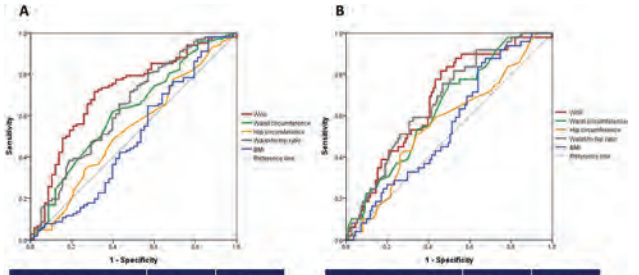
Jiun-Chi Huang,[1,2] Pei-Yu Wu,[2] Szu-Chia Chen,[2] Jer-Ming Chang.[3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Kaohsiung Municipal Siaogang Hospital, Kaohsiung, Taiwan; [3]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan.*

Background: Weight-adjusted-waist index (WWI) is a novel indicator of central obesity, and is associated with abdominal aortic calcification (AAC) and mortality in the general population. However, obesity paradox has been described in patients with kidney disease. The association of WWI with AAC and mortality remains uncertain in hemodialysis (HD) patients.

Methods: This study included 161 patients on maintenance HD >3 months. WWI was determined as waist circumference divided by the square root of weight. Severity of AAC was quantified by the AAC score measured from lateral lumber radiography. The association between WWI and moderate or severe AAC was examined using logistic regression analysis. Cox regression analysis was performed to investigate the association of WWI with all-cause mortality. The area under the receiver operating characteristic curve (AUC) was used to compare the ability of WWI and other obesity indices to predict AAC and mortality.

Results: We found 103 HD patients had moderate or severe AAC. During a median follow-up of 5.0 years, 50 deaths occurred. In multiple logistic regression, the highest WWI category (3rd tertile >11.40 cm/√kg) (OR=4.38, 95% CI: 1.39–13.78, *p*=0.012) was associated with moderate or severe AAC. Compared to the lowest WWI category, 2nd tertile WWI (10.76–11.39 cm/√kg) (HR=3.25, 95% CI: 1.18–8.93, *p*=0.022) was significantly associated with increased risk of all-cause mortality in multivariate-adjusted Cox analysis. Furthermore, WWI had the greatest AUC for predicting moderate or severe AAC (AUC=0.713) and all-cause mortality (AUC=0.667) when compared with body mass index, waist circumference, hip circumference, and waist-to-hip ratio.

Conclusions: These findings indicated that WWI may serve a valuable indicator for identifying moderate or severe AAC and predicting mortality among maintenance HD patients.



Anthropometric indices	AUC	95% CI
WWI	0.713	0.629–0.798
Waist circumference	0.617	0.526–0.709
Hip circumference	0.532	0.437–0.626
Waist-to-hip ratio	0.641	0.550–0.732
BMI	0.489	0.390–0.587

Anthropometric indices	AUC	95% CI
WWI	0.677	0.590–0.763
Waist circumference	0.639	0.550–0.727
Hip circumference	0.561	0.465–0.657
Waist-to-hip ratio	0.673	0.588–0.759
BMI	0.552	0.461–0.644

Area under ROC curves of different obesity indices for predicting (A) moderate or severe AAC and (B) all-cause mortality

FR-PO824

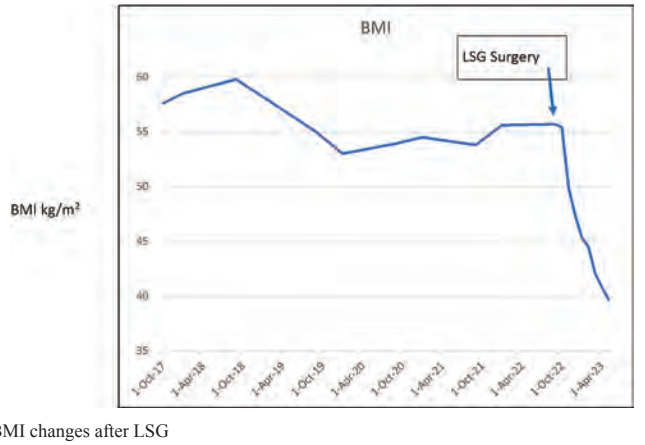
Successful Bariatric Laparoscopic Sleeve Gastrectomy in a Home Hemodialysis Patient Led to Reduced Hemodialysis Frequency

Desiree de Waal, Macaulay A. Onuigbo. *University of Vermont Larner College of Medicine, Burlington, VT.*

Introduction: Bariatric surgery (BS) is an established treatment for achieving weight loss. Patients with kidney disease and not on dialysis had a reduction in mortality compared to matched controls with vertical laparoscopic sleeve gastrectomy (LSG) being the safer option compared to Roux-en-Y gastric bypass. Use of BS in dialysis patients is not common due to fears of complications including high post-operative mortality and myocardial infarction. Furthermore, observational studies suggest a protective association of elevated BMI versus death in HD patients, although this has not been consistently observed in peritoneal dialysis patients. Our patient demonstrated that BS while on HHD is a desirable option to achieve target weight loss.

Case Description: A 36-year-old female started HHD for anuric hypertensive end stage renal disease 5.5 years before LSG. Before LSG, she did HHD 5 times a week to maintain adequacy. The renal and bariatric teams worked closely to provide a unified approach to her diet pre- and post-surgery, which included fluid diets and progression to solids. Medications and supplements were also adjusted to meet both dialysis and bariatric guidelines. Since LSG, she has exhibited progressive weight loss of 26% over 6 months (Figure), while maintaining her nutritional status. We reduced HHD frequency from five to four times weekly to mitigate intradialytic hypotension, and still maintained HD adequacy. She is more active, more energetic, takes longer walks, twice daily, and now works in her garden.

Discussion: Our HHD patient had successful bariatric surgery with 26% weight loss in 6 months and can now be listed for kidney transplant. Despite a paucity of literature on intentional approaches to weight loss in ESRD, LSG is increasingly used for patients with kidney failure and severe obesity. More research is needed to assess long-term cardiovascular and kidney transplant outcomes following BS.



BMI changes after LSG

FR-PO825

Poor Vitamin K Status and Inflammation in Patients with CKD

Denise Mafra,[1,2] Ligia S. Lima,[2] Marcia M. Ribeiro,[2] Ludmila F. Cardozo,[1] Cecile Maassen,[4] Marcelo Ribeiro-Alves,[3] Petra Lux,[4] Leon J. Schurgers.[4] Renal Nutrition - UFF. *[1]Universidade Federal Fluminense, Niteroi, Brazil; [2]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [3]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil; [4]Universiteit Maastricht, Maastricht, Netherlands.*

Background: Vitamin K is vital to cardiovascular and bone health and can mitigate inflammation. Vitamin K inhibits the activation of NF-κB, which seems related to vitamin K-dependent proteins, inhibiting the production of IL-6 by macrophages. Patients with CKD frequently present a deficiency of vitamin K. Considering the high mortality rate linked to cardiovascular disease (CVD), reduced quality of life and poor outcomes related to inflammation, it is essential to understand the relationship between vitamin K deficiency and inflammation, raising the possibility of new therapeutic targets in treating CKD-induced CVD. This study aimed to evaluate the correlation between vitamin K status and inflammation in patients with CKD (non-dialysis and hemodialysis - HD).

Methods: 108 patients undergoing HD (51 male, 52 yrs) and 23 non-dialysis patients (7 male, 58 yrs) were evaluated. Plasma desphospho-uncarboxylated matrix Gla-protein (dp-ucMGP), a functional vitamin K deficiency biomarker, was analysed using the IVD CE-marked chemiluminescent InaKtif MGP assay on the IDS-iSYS system. IL-6 plasma levels were evaluated by ELISA. The results were adjusted for age, sex and BMI.

Results: HD patients had significantly higher values of dp-ucMGP [728 (IQR=724) pmol/L] than non-dialysis patients [563 (IQR=296) pmol/L] (p=0.05), indicating vitamin K deficiency. Furthermore, a significant positive correlation was observed between dp-ucMGP and IL-6 levels in HD patients, which reflects elevated levels of IL-6 in patients with vitamin K deficiency (**Fig. 1**).

Conclusions: The results reveal a positive correlation between vitamin K deficiency and the pro-inflammatory biomarker IL-6 in patients with CKD. Vitamin K supplementation may be a strategy to mitigate inflammation in these patients.

Funding: Government Support - Non-U.S.

Depressive Symptoms Are Associated with Increased Hospitalization Rate in CKD Patients: A Systematic Review and Meta-Analysis of Cohort Studies

Thiratest Leesutipornchai,[1,2] Chinnawat Arayangkool,[1,2] Manasawee Tanariyakul,[1,2] Noppawit Aiumtrakul.[1,2] *[1]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [2]Hawaii Residency Programs Inc, Honolulu, HI.*

Background: Depressive symptoms are relatively common in patients with chronic kidney disease (CKD). Recent studies showed that depressive disorders are associated with increased mortality risk in patients with CKD. However, evidence regarding the impact of depression on the risk of hospitalization in the CKD population is still limited. Therefore, we performed a systematic review and meta-analysis to explore the association between depressive symptoms and the risk of hospitalization in CKD patients.

Methods: We comprehensively searched MEDLINE, EMBASE and Cochrane Library from inception to October 2022. Included studies were cohort studies assessing the association of depressive symptoms on hospitalization rate among CKD patients, using the random-effects to calculate risk ratios (RR) and 95% confidence intervals (CIs).

Results: Six cohort studies were included in the analysis with a total of 11,258 CKD patients (7,404 patients with depressive symptoms and 4,122 patients without depressive symptoms). Subjects with depressive symptoms had an increased risk of hospitalization (pooled RR 1.139, 95% CI: 1.055–1.229, p = 0.001, I2 = 51.1%) compared to those without depressive symptoms. In subgroup analysis, depressive symptoms were associated with an increased risk of hospitalization in both CKD patients who were not receiving dialysis (pooled RR 1.432, 95% CI: 1.204-1.704, P = <0.001, I2 = 0.0%) and CKD patients who were receiving dialysis (pooled RR 1.088, 95% CI: 1.057-1.119, P = <0.001, I2 = 0.0%).

Conclusions: Our meta-analysis demonstrated that depressive symptoms were associated with an increased risk of hospitalization. This possible association is essential given the implication of depression screening to improve the quality of life in CKD patients.

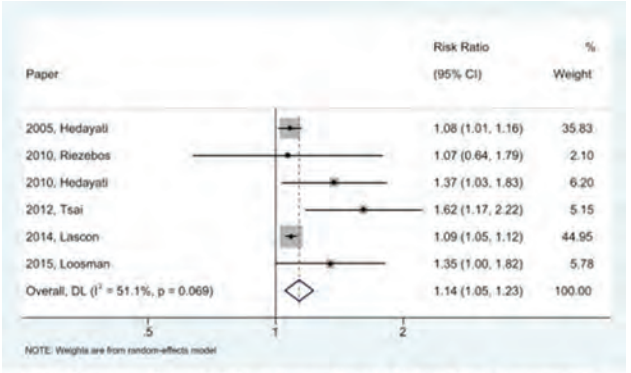

Figure 1: Forest plot of the included studies comparing risk of hospitalization between patients with depressive symptoms vs patients without depressive symptoms (p = 0.001)

FR-PO827

Hypothyroidism (HT) Rate and Testing Among Incident CKD Patients Who Transitioned to Dialysis Within Kaiser Permanente Southern California (KPSC)

Smita Maity,[1] Katherine J. Pak,[1] Hui Zhou,[1,2] Sally F. Shaw,[1] Jiaxiao Shi,[1] Connie Rhee,[3] Benjamin Broder,[1] John J. Sim.[1,2] *[1]Kaiser Permanente Southern California, Pasadena, CA; [2]Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; [3]University of California Irvine, Irvine, CA.*

Background: HT and CKD are highly prevalent conditions with a bidirectional relationship. Among a large diverse real world CKD cohort who transitioned to dialysis, we sought to determine the rate of HT, factors associated with HT, and the overall screening rates for HT

Methods: We conducted a cross-sectional study within KPSC during 2007-2017. Patients aged ≥ 18 years with incident CKD (defined by at least 2 consecutive eGFR less than or equal to 45 at least 90 days apart) who initiated outpatient dialysis (hemodialysis or peritoneal dialysis) were identified. HT was defined as TSH > 4 mIU/L and or use of thyroid replacement medication. The rate of HT and HT screening with TSH measurements were determined. HT rate ratio (RR) and its 95% confidence interval were estimated using multivariable Poisson regressions with Robust error

Results: Among 6,812 CKD patients who transitioned to dialysis 927 (14%) had HT. 50% of incident CKD who initiated outpatient dialysis were screened with a TSH measurement in the 1 year prior to ESKD. Adjusted HT RR (95% CI) were 1.66 (1.19,2.33), 1.73 (1.53,1.95), 1.20 (1.03,1.39), and 1.54 (1.27,1.87) for age ≥ 70 years, females, atrial fibrillation, and weighted Charlson comorbidity index ≥5, respectively. Adjusted HT RR (95% CI) were 1.22(1.05,1.42), 0.62 (0.51,0.75) and 0.75 (0.61,0.93) for non-Hispanic whites, non-Hispanic blacks and Asians, respectively. Heart failure was not associated with HT (Table 2)

Conclusions: Our study observed that 14% of CKD patients who transitioned to dialysis had HT which is higher than the ~5% described among the general population. We observed that only half of CKD patients were screened for HT prior to initiation of dialysis suggesting a potential care gap. Further studies may provide insights into understanding whether greater screening and identification of HT among CKD patients initiating dialysis will lead to improved CKD dialysis related outcomes.

Table 1. Characteristics of Incident CKD Patients who initiated outpatient dialysis by hypothyroidism status

	No Hypothyroidism	Hypothyroidism	Total
N	5,885	927	6,812
Age at index date, n (%)			
18 - 39	441 (12.1)	38 (7.9)	479 (11.6)

Poor Life Prognosis of Patients with Rapid Progression of Peripheral Artery Disease

Satoko Notomi,[1] Mineaki Kitamura,[2] Emiko Otsuka,[1] Satoshi Funakoshi.[1] *[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Habor Medical Center, Nagasaki, Japan.*

Background: Peripheral artery disease (PAD) is one of the major complications in patients undergoing hemodialysis (HD), leading to a higher mortality risk. As skin reperfusion pressure (SRPP) measurement is a useful screening tool for PAD, early detection and prevention of progression using this tool would be important. However, only a few studies have focused on the speed of PAD progression, and its effects on life prognosis and associated factors have not been fully examined yet. We aimed to evaluate the impact of rapid progression of PAD on life prognosis and identify the factors associated with PAD prognosis.

Methods: We included patients undergoing HD with more than two SRPP measurements at our facility between January, 2013 and August, 2022. Patients were followed up until August, 2022. Medical data were collected at the time of the first SRPP measurement, and the associations between survival and patient backgrounds were analyzed.

Results: The study included 142 patients (71.0±9.1 years old; 59.2% men; median dialysis vintage, 58.5 months). The median observation period was 1,142.5 days (interquartile range: 680.8–1,709.8 days), and 76 patients died during the observation time. Among the participants, 17 patients underwent lower limb amputation. The patients were divided into four groups, according to the SRPP reduction rate (Q1–4). Log-rank test analysis showed that patients with SRPP reduction rate Q4 had a poor prognosis ($p<0.001$). Multivariable Cox proportional hazards analysis demonstrated that SRPP reduction rate Q4 (hazard ratio, 2.51; 95% confidence interval [CI]: 1.46–4.30; $p<0.001$) was significantly associated with survival. Multivariable logistic regression analysis revealed that body mass index (BMI) (odds ratio [OR]: 1.13, 95% CI: 1.00–1.28, p=0.048) and serum creatinine level (OR: 0.77, 95% CI: 0.61–0.96, p=0.02) were associated with SRPP reduction rate Q4.

Conclusions: Patients with a large SRPP reduction rate had a poor life prognosis. BMI and serum creatinine levels were associated with a large SRPP reduction rate. As serum creatinine levels in patients undergoing HD can reflect their skeletal muscle mass, sarcopenic obesity, indicated by excessive BMI and low creatinine levels, may be a risk factor for the rapid progression of PAD in our participants. Maintaining adequate body weight and muscle mass is critical in preventing PAD progression.

FR-PO829

Readmission After Gastrointestinal Bleeding Hospitalization Type in Dialysis Patients

Yue Jiao,[1] Belen Alejos,[2] Melanie Wolf,[2] John W. Larkin,[1] Anke Winter,[2] Sheetal Chaudhuri,[1] Manuela Stauss-Grabo,[2] Len A. Usvyat,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux,[6] David C. Wheeler,[3] Peter Stenvinkel,[4] Jürgen Floege.[5] On Behalf of the INSPIRE Core Group. *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]University College London, London, United Kingdom; [4]Dept of Renal Medicine Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden; [5]University Hospital RWTH Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany; [6]Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany.*

Background: The incidence of gastrointestinal bleeding (GIB) is high in the dialysis population. GIB episodes frequently lead to hospitalization, yet associated outcomes have not been defined and may differ by GIB type. The INSPIRE group aimed to define the all-cause hospital readmission rates after an index GIB hospitalization considering the type of GIB (upper or lower).

Methods: We used data on adult chronic dialysis patients who were hospitalized for a GIB in the United States during Jan-2018 to Mar-2021. GIB hospitalizations were identified from ICD discharge diagnosis codes (Zhao et al., AHRQ 2006). All-cause readmission rate considered events within 30 days from an index GIB hospitalization by GIB type. Index GIB hospitalizations with an unspecified location for the GIB were not included in the analysis of GIB types.

Results: In a population of 405,530 patients, 19,663 GIB hospitalizations occurred. Overall, there was a 26.4% all-cause 30-day readmission rate after an index GIB hospitalization. Readmission rate was consistent by GIB types at 26.4% for upper and 26.0% for lower GIB hospitalizations. Readmission rates after a GIB hospitalization were highest among patients 18-44 years old for all GI bleed types (**Figure 1**). Readmission rates after an upper GIB were higher for females, patients ≥75 years old, and those with a black and other race. Readmission after a lower GIB was most common among patients with an Asian and unknown race.

Conclusions: All-cause readmission rate after a GIB hospitalization was about 26% for all GIB types. Readmission rates were higher (>30%) among younger patients for upper and lower GIBs. Sex-dependent differences in readmission rates were observed after an upper-GIB hospitalization, as well as differences by age and race in readmission rates after an upper- and lower-GIB hospitalization. Further adjusted analyses are needed to confirm these findings and understand the disparities in outcomes.

Gastrointestinal Bleeding Types and Associated Mortality Rates in Dialysis Patients

Belen Alejos,[1] Yue Jiao,[2] Melanie Wolf,[1] John W. Larkin,[2] Anke Winter,[1] Sheetal Chaudhuri,[1] Manuela Stauss-Grabo,[1] Len A. Usvyat,[2] Jeffrey L. Hymes,[2] Franklin W. Maddux,[3] David C. Wheeler,[4] Peter Stenvinkel,[5] Jürgen Floege.[6] On Behalf of the INSPIRE Core Group. *[1]Fresenius Medical Care, Bad Homburg, Germany; [2]Fresenius Medical Care, Waltham, MA; [3]Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; [4]University College London, London, United Kingdom; [5]Dept of Renal Medicine Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden; [6]University Hospital RWTH Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany.*

Background: The incidence of gastrointestinal bleeding (GIB) is ~7-fold higher in the dialysis vs general population. The INSPIRE collaborative group has aimed to describe mortality after a GIB episode by the type of bleed among chronic dialysis patients treated at a national provider in the United States (US).

Methods: We used data from adult dialysis patients who had ≥1 GIB episode between Jan-2018 to Mar-2021. GIB episodes were defined from ICD codes for comorbidities, or hospital discharge. We calculated crude mortality rates any time after the first GIB by type (upper or lower; Zhao et al., AHRQ 2006). GIB episodes with an unspecified location were not included in the analysis of GIB types.

Results: The incidence of a patient having ≥1 GIB episode was 7.7% (31,084/405,530). Overall, GIB was most common in patients between ages of 45-64 years (38.9%) & 65-75 years (28.7%), males (56.0%), and those of a white race (54.5%). GIB location was specified for 39.1% of the first GIB episodes. Demographics for patients with and without a specified GIB location did not differ. Crude mortality rate after the first GIB was 41.9% (n=3,392) for upper GIB and 42.3% (n=1,722) for lower GIB. Mortality rate for both GIB types was positively associated with age, and was the highest for patients with missing data on race (10.4% of cohort), followed by white race (**Figure 1**).

Conclusions: Mortality rate after the first GIB episode in a dialysis patient was >40%, regardless of the location of bleeding. Age and race specific differences were consistent for upper and lower GIBs. Most GIB episodes were classified as an unspecified type, suggesting the need for improvements in evaluation/coding. Further adjusted analyses are needed to confirm these results and understand the differences by dialysis modalities, risk factors, and causes of mortality.

FR-PO831

Cigarette Smoking and Prevalent Kidney Stone: The National Health and Nutrition Examination Survey 2011-2018

Jie Tang,[1] Michel Chonchol,[3] Christina A. Raker,[1] Cara Sammartino.[2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Johnson & Wales University, Providence, RI; [3]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Cigarette smoking (CS) may affect the risk of kidney stone (KS) disease because it has been linked to an increased bone loss. In addition, major trace elements found in cigarette can also promote KS formation. Here, we aimed to examine the independent association between CS and prevalent KS disease defined as self-reports of any previous episode of kidney stone.

Methods: We examined The Third National Health and Nutrition Examination Survey (NHANES) 2011-2018, a large US population-based cross-sectional study, and used logistic regression analyses to determine the independent association between CS and prevalent KS disease.

Results: 19,405 participants were included for analysis, 1,895 had KS disease. 19% of stone formers (SF) versus 18% of non-stone formers (NSF) were active smokers (p<0.001), and average daily cigarettes smoked were 14 among SF vs. 12 among NSF (p= 0.02). Mean serum cotinine (a major metabolite of nicotine) concentration (SCC) was 64 ng/ml among SF vs. 54 ng/ml among NSF (p=0.01). Active CS associated strongly with an increased odds of KS disease in regression analysis after adjustment for demographics, BMI, histories of hypertension, diabetes, dyslipidemia and cardiovascular disease, alcohol intake, and dietary sodium, potassium and water intakes, odds ratio (OR)=1.30, 95% confidence interval (CI)=1.05-1.50, p=0.02 (Table 1). Higher SCC also associated significantly with an increased odds of KS disease when SCC was modeled as a continuous variable (OR=1.0007, 95% CI: 1.00-1.01, p=0.003), or when comparing highest tertile of SCC to lowest tertile (OR =1.30, 95% CI: 1.10–1.50, p=0.001)(Table 1). No major interactions were found in the final regression analyses.

Conclusions: Our study showed CS had a strong independent association with an increased risk of KS disease. Future prospective studies are needed to clarify the causal relationship between CS and KS formation.

Dietary Magnesium Intake and Kidney Stones: The National Health and Nutrition Examination Survey 2011-2018

Sandipan Shringi,[1,2] Christina A. Raker,[3] Jie Tang.[1,2] *[1]Rhode Island Hospital, Providence, RI; [2]Brown University Warren Alpert Medical School, Providence, RI; [3]Lifespan Biostatistics, Epidemiology, Research Design, and Informatics Core, Providence, RI.*

Background: The association between dietary magnesium intake (DMI) and kidney stone disease (KSD) is not clear.

Methods: We examined The National Health and Nutrition Examination Survey (NHANES) 2011-2018 and used logistic regression analyses adjusting for age, sex, race, BMI, histories of hypertension, diabetes, thiazide use, cigarette smoking, alcohol drinking, dietary intake of calories, protein, sodium, calcium, and, supplemental calcium and vitamin D to determine the independent associations between DMI and prevalent KSD.

Results: A total of 19271 participants were eligible for the final analysis which included 1878 people who self-reported a history of the stone. The mean DMI was 295.4mg in stone formers and 309.6 mg in non-stone formers, p=0.02 (Table 1). Stone formers tended to be older, more likely to be male and Caucasian, and had a higher BMI. In univariate analysis, lower DMI was strongly associated with increased odds of prevalent KSD when DMI was modeled as a continuous variable (OR 0.94, 95% CI: 0.89-0.99, p=0.02) or when comparing the highest quartile of DMI to the lowest quartile (OR=0.74, 95% CI: 0.60-0.92, p=0.007). As shown in Table 2, after regression analysis, when DMI was modeled as a continuous variable odds of prevalent KSD were 0.92, with 95% CI: 0.84-1.01, p=0.07 but was strongly associated when comparing the highest quartile of DMI to the lowest quartile (OR=0.70, 95% CI: 0.52-0.93, p=0.01).

Conclusions: Our study suggests that higher DMI is associated with a reduced risk of kidney stone disease. Future prospective studies are needed to clarify the causal relationship.

Diet-Induced Oxalate Nephropathy: Eating Too Much "Healthy" Food

Alexander P. Landry, Jefferson L. Triozzi, Agnes B. Fogo, Natalie N. McCall. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Oxalate nephropathy is an intrinsic kidney disease characterized by kidney tubular injury via the deposition of calcium oxalate crystals with initial acute tubular injury that can progress to scarring and eventually to end-stage kidney disease. This condition may be caused by primary hyperoxaluria (genetic), enteric hyperoxaluria (in the setting of fat malabsorption), and ingestions (foods high in oxalate, ethylene glycol toxicity). We present a case of "healthy" diet-induced oxalate nephropathy.

Case Description: A 57-year-old man with type II diabetes mellitus, hypertension, urinary retention requiring indwelling urinary catheterization, and psychiatric comorbidities including obsessive compulsive disorder presented to nephrology clinic with acute kidney injury. He reported a diet consisting of obsessive compulsive eating behavior. He reported heavy ingestion of foods presumed to be healthy, including oranges, assorted nuts, turkey, and up to 5 protein bars at a time. Vital signs and physical exam were unremarkable. Serum creatinine was 2.1 mg/dL (baseline 1.2 mg/dL) with a bland urinalysis without hematuria or proteinuria. Serologic work-up was unremarkable. A kidney biopsy revealed numerous calcium oxalate crystals associated with diffuse acute tubular injury, diagnostic of oxalate nephropathy.

Discussion: Oxalate nephropathy is an intrinsic kidney disease characterized by deposition of calcium oxalate crystals in the kidney tubules. Excessive consumption of foods high in oxalate or its precursors can cause acute or chronic kidney disease. In this case, the ingestion of oranges, nuts, turkey slices, and protein bars may have led to oxalate nephropathy. Vitamin C (ascorbic acid) found in citrus fruits is a precursor to oxalate. However, vitamin C supplementation is more commonly reported as a cause because it is more bioavailable. Nuts are also a high oxalate food, with almonds, Brazil nuts, and pine nuts holding the highest oxalate content. Finally, high protein intake may increase oxalate excretion in the urine. Patients with acute oxalate nephropathy typically recover kidney function and have a better prognosis than those with chronic disease. In this case, the patient reduced his intake of high oxalate foods and increased fluid intake to 2 liters of water daily. Thereafter he had progressive improvement of kidney function back to baseline.

FR-PO834

Coexposure of Melamine and Di-2-Ethylhexylphthalate Changes Mitochondrial Dynamics and Accelerates Kidney Injury in Adenine Diet-Induced CKD Mice

I-Hsuan Tsai,[1] Miao-Yi Wu,[1] Ming-Tsang Wu,[1,2] Yi-chun Tsai,[1,2] Chia-Chu Liu,[1,2] Tusty-Jiuan Hsieh.[1,2] *[1]Kaohsiung Medical University College of Medicine, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Research Center for Environmental Medicine, Kaohsiung, Taiwan.*

Background: Environmental chemical exposures have shown to be risk factors for chronic kidney disease (CKD). Even though the 2008 event of melamine-added formula milk was over, environmental melamine exposure still occurs due to the contamination in daily food products and widely uses of melamine-made tableware. Our previous study found that environmental melamine increased oxidative stress and early kidney injury in adults. Bis-2-ethylhexylphthalate (DEHP) is presented widely in plastic products and has been suggested that it could cause kidney fibrosis. Melamine and DEHP are common environmental pollutants and their interactive toxicity remains unclear. The aims of this study are to clarify the nephrotoxicity of melamine and DEHP coexposure and to investigate the role of mitochondrial oxidative stress in the pathological mechanisms using a mouse model based on the US-FDA suggested human tolerable daily intake (TDI) levels of melamine and DEHP.

Methods: An adenine-rich-diet induced CKD model was conducted in male and female ICR mice with the coexposure of TDI levels of melamine and DEHP for 4 weeks. Urine albumin-creatinine ratio (uACR) was used to monitor kidney function. Kidney injury molecule (KIM-1) immunohistochemistry, Sirius-Red staining and TUNEL assay were applied to observe kidney injury, fibrosis, and apoptosis. We used Western blotting to detect target proteins, real-time PCR to measure mitochondrial DNA (mtDNA) and MitoSOX staining to detect mitochondrial ROS.

Results: Our results showed that melamine and/or DEHP exposure increased uACR, indicating a decline of kidney function. Fibrosis, apoptotic cells and KIM-1 were increased in the kidney sections of CKD mice exposed to melamine and/or DEHP. Biomarkers of oxidative stress (MDA, 4-HNE), inflammation (NF-kB) and fibrosis (TGF-b, collagen IV) were also elevated. Melamine and DEHP increased mitochondrial ROS and changed mtDNA and mitochondrial dynamic proteins (Pink1, Parkin, Mfn2, Drp1, Fis1) in the kidney of CKD mice.

Conclusions: Our findings suggest that melamine and/or DEHP exposure accelerates a progression of kidney injury in CKD, which may be mediated by changes in mitochondrial dynamics. Avoiding exposure of environmental melamine and DEHP should be advised in patients with CKD.

The Vitamin D Metabolite Ratio and Incident Cardiovascular Disease: The Multi-Ethnic Study of Atherosclerosis

Jonathan Cheng,[1,2] Andrew N. Hoofnagle,[3] Ronit Katz,[3] Simon Hsu,[3] Deborah M. Kado,[4,5] Matthew J. Budoff,[6,8] Bryan R. Kestenbaum,[3] Erin D. Michos,[7] Lindsay M. Miller,[1] Joachim H. Ix,[1,2] Ian H. de Boer,[3] Charles Ginsberg.[1] *[1]University of California San Diego, La Jolla, CA; [2]VA San Diego Healthcare System, San Diego, CA; [3]University of Washington, Seattle, WA; [4]Stanford Medicine, Stanford, CA; [5]VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA; [6]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [7]Johns Hopkins Medicine, Baltimore, MD; [8]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Vitamin D deficiency has been linked to cardiovascular disease (CVD) with mixed results. The vitamin D metabolite ratio (VMR), the ratio of $24,25(OH)_2D$ to 25(OH)D, has shown stronger associations with bone health and mortality than 25(OH)D alone. Our study assessed the association between the VMR and CVD outcomes.

Methods: We evaluated 6,313 Multi-Ethnic Study of Atherosclerosis (MESA) participants without CVD using Cox regression to test the associations of both VMR and 25(OH)D with incident CVD (including myocardial infarction, resuscitated cardiac arrest, stroke, coronary heart disease death, and stroke death), heart failure (HF), and cardiovascular mortality. We adjusted models for age, gender, race, physical activity, BMI, smoking, diabetes, blood pressure condition and medication use, C-reactive protein, cholesterol levels and medication use, triglycerides, kidney function, parathyroid hormone, fibroblast growth factor 23, calcium, and phosphate.

Results: The study participants had a mean age of 62, with 53% of them being female. The cohort was 38% White, 28% Black, 22% Hispanic, and 12% Chinese. The mean (SD) 25(OH)D level was 22.7 (11.0) ng/mL, and the mean VMR was 15.2 (5.0). In fully adjusted models, a two-fold increase in VMR was associated with a 24% reduction in incident CVD (HR: 0.76, 95% CI: 0.65-0.88). However, there was no association between the VMR and HF (0.98, 0.78-1.24), or cardiovascular mortality (0.96, 0.77-1.21). 25(OH)D was not significantly associated with any CVD outcome.

Conclusions: In a multi-ethnic cohort, VMR was significantly associated with reduced incident CVD, but not HF or cardiovascular mortality over 15 years of follow-up. The results suggest that VMR may provide greater insight into vitamin D metabolism compared with 25(OH)D levels alone.

Paradoxical Association of Vitamin D Supplementation with Elevated Blood Pressure in Individuals Without Vitamin D Deficiency

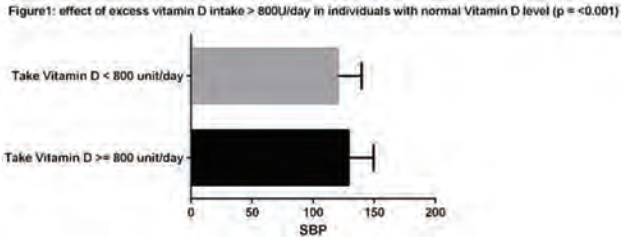
Manasawee Tanariyakul,[1,3] Chinnawat Arayangkool,[1,3] Thiratest Leesutipornchai,[1,3] Noppawit Aiumtrakul,[1,3] Mohammad I. Khan,[1,3] Ekamol Tantisattamo.[2] *[1]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [2]Division of Nephrology, Hypertension and Kidney Transplantation, Department of Medicine, University of California Irvine School of Medicine, Orange, CA; [3]Hawaii Residency Programs Inc, Honolulu, HI.*

Background: While vitamin D(Vit D) deficiency(def) is associated with high blood pressure(BP), potential effects of supplemental Vit D intake on BP in individuals without Vit D def is unknown. This study aims to examine the association of the amount of Vit D intake with BP in individuals with and without Vit D def.

Methods: This cross-sectional study utilized data from the 2017-2018 Continuous NHANES. Participants' average daily Vit D intake over a 30-day period and their BP were collected through questionnaires and examinations. The study included individuals with more or less Vit D intake(>800 or <800IU/day). Difference in systolic and diastolic BP (SBP and DBP) between two groups stratified by presence and absence of Vit D def defined by Vit D level <30 and ≥30nmol/L, respectively was evaluated by an independent sample t-test.

Results: Among participants without Vit D def, 1068 had more and 837 had less Vit D intake. SBP in the former group were greater than those of the latter group ($SBP_{more\ vs\ less}$ 128.95±20.46 vs. 120.37±19.22mmHg; $mean_{difference}$ 8.59mmHg, P <0.001). Similarly, DBP was higher in the more Vit D intake group ($DBP_{more\ vs\ less}$ 70.02±15.09 vs. 67.66±16.35mmHg; $mean_{difference}$ 2.36mmHg, P <0.001). Of 90 participants with Vit D def (34 and 56 with more and less Vit D intake), both SBP and DBP remained higher in the more Vit D intake group but there was no statistical significance ($SBP_{more\ vs\ less}$ 125.71±21.47 vs. 122.82±19.38mmHg; $mean_{difference}$ 2.88mmHg, P 0.513 and $DBP_{more\ vs\ less}$ 70.71±10.17 vs. 69.68±10.79mmHg; $mean_{difference}$ 1.027mmHg, P 0.651)

Conclusions: Although Vit D supplementation is associated with lowering BP in individuals with Vit D def, supplemental Vit D intake greater than 800IU/day is paradoxically associated with higher BP in individuals without Vit D def compared to lesser Vit D takers. In the absence of Vit D def, whether Vit D supplementation causes an imbalance of mineral and bone metabolism related to vascular calcification leading to elevated BP requires further studies.



FR-PO837

A Randomized Controlled Trial Comparing Between Fixed Dose and Serum Level-Based Titration Regimen of Vitamin D Supplementation on Sarcopenia Outcomes Among Dialysis Patients

Saranchana Jiampochaman,[1] Piyatida Chuengsaman,[2] Yingyos Avihingsanon,[1] Somchai Eiam-Ong,[1] Piyawan Kittiskulnam.[1] *[1]King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]Banphaeo-Charoenkrung Peritoneal Dialysis Center, Banphaeo Dialysis Group, Banphaeo Hospital, Bangkok, Thailand.*

Background: Low vitamin D status is associated with either low muscle mass or impaired muscle function in dialysis patients. However, there is no consensus on how best to correct vitamin D deficiency in patients with end-stage kidney disease (ESKD). We investigated the effect of different vitamin D supplementation regimens on sarcopenia outcomes in ESKD patients.

Methods: This was a randomized controlled trial (ClinicalTrial.gov NCT05434377). ESKD patients treated with maintenance hemodialysis or peritoneal dialysis with low vitamin D status, defined as serum 25-hydroxyvitamin D (25-OH D) level <30 ng/mL were 1:1 randomized to either receive oral ergocalciferol using a fixed dose regimen of 20,000 IU/week or utilizing serum 25-OH D level-based titration of dosage adjustment as a control group. The change of muscle mass measured by bioimpedance spectroscopy (BIS), muscle strength using a hand grip dynamometer, and physical performance measured by gait speed were determined. Baseline data after 6 months of supplementation were compared between groups.

Results: A total of 76 dialysis patients were enrolled (HD=43%). Baseline characteristics including age, diabetes mellitus, muscle parameters, and dialysis vintage were similar. After supplementation, the average serum 25-OH D levels in the fixed dose and titration groups were significantly elevated from 14.9±6.4 to 28.8±11.5 ng/mL, p<0.001 and from 15.0±7.2 to 26.9±13.2 ng/mL, p<0.001, respectively, but did not differ between groups at 6 months (p=0.52). Despite comparable energy and protein intake, the mean BIS-derived total-body muscle mass normalized to height squared was significantly increased at 6 months in the fixed dose group (14.4±3.4 to 15.3±3.0 kg/m^2, p<0.03) compared with the titration group (13.6±2.7 to 13.7±3.0 kg/m^2, p=0.58). However, muscle strength and gait speed were not different between two groups (p>0.05). Neither hypercalcemia nor hyperphosphatemia was found throughout the study.

Conclusions: A fixed dose supplementation of ergocalciferol demonstrates better improvement in muscle mass among patients receiving maintenance dialysis. Vitamin D supplementation appears to be a promising treatment of sarcopenia among dialysis population.

Effects of Two-Month Low-Sodium (Na+) Diet on Muscle Na+, Fat, and Function in Hemodialysis (HD) Patients

Hsin-Yu Fang, Kwan-Jin Jung, Samuel Ramos-Acevedo, Kaitlyn Pawelczyk, Kenneth R. Wilund. *University of Illinois Urbana-Champaign, Urbana, IL.*

Background: Higher muscle sodium concentration ([Na^+]) in HD patients is linked with muscle metabolic disturbances. We aimed to test if a 2-month low-Na^+ diet would reduce muscle [Na^+], thereby improving muscle structure or function in HD patients.

Methods: Eleven HD patients (56±11 y) received 2 and 1 low-Na^+ meal(s)/day during the first and second months of intervention, respectively, along with dietary counseling. The [Na^+] and fat fraction (FF) in muscles were measured by 3T ^{23}Na- and ^{1}H-MRI at pre- and post-intervention in 6 muscles: tibialis anterior (TA), extensor digitorum longus (EDL), peronei (PER), soleus (SOL), and lateral (LG) and medial (MG) gastrocnemius. Lower-limb muscle function was assessed using the 30s sit-to-stand (STS) test after MRI. Data were analyzed using the paired t test and Pearson's or Spearman's correlation.

Results: At baseline, muscle [Na^+] was inversely correlated with STS score in all muscles except SOL (**Fig.1**) and tended to positively correlate with FF in MG (r=0.60, P=0.05). There were no significant changes in muscle [Na^+] or FF post-intervention in each muscle studied (all P>0.05), with no improvement seen in STS score (P=0.34). An increase in muscle [Na^+] from pre- to post-intervention was associated with a decrease in STS score in all muscles except SOL (**Fig. 2**). There was no correlation between pre- to post-intervention changes in muscle FF and changes in STS score for each muscle (all P>0.05).

Conclusions: Two-months of a low-Na^+ diet did not reduce muscle [Na^+] in HD patients. However, the inverse correlations between baseline muscle [Na^+] and STS score and the changes in muscle [Na^+] and STS score, may serve as a rationale for developing new interventions to mitigate muscle dysfunction in HD patients by controlling muscle [Na^+].

Funding: Private Foundation Support

The Effect of Controlled Ovarian Stimulation (COS) on Kidney Health Outcomes: A Protocol

Sakshi Kharbanda, Sofia B. Ahmed, Shu Foong, Victoria J. Riehl-Tonn, Sandi M. Dumanski. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: The prevalence of chronic kidney disease (CKD) in females is >12% and prevention of CKD is a patient-identified research priority. Females face unique risks to their kidney health, and exogenous hormone use (hormone replacement therapy and contraceptives) has been implicated in kidney risk. However, there is a paucity of data on how exogenous hormone use in controlled ovarian stimulation (COS), commonly utilized in fertility treatment and preservation, affects kidney health. This prospective study will examine the effect of COS on kidney health outcomes, including 1) filtration fraction (FF), 2) glomerular filtration rate (GFR), and 3) kidney plasma flow (KPF).

Methods: Healthy females treated with COS will be recruited from the fertility clinic in Calgary, Canada to participate in 2 study days in the research laboratory. Study Day #1 will be a baseline visit immediately prior to initiation of COS treatment and Study Day #2 will be completed at the peak of the hormone administration phase of COS. On each study day, serum hormone levels will be measured. Using standardized protocols, participants will receive intravenously-administrated iohexol and para-aminohippurate and subsequent plasma monitoring to determine GFR and KPF, respectively. FF will be calculated as follows: GFR/KPF.

Results: Using a paired non-paramtric student t-test such as the Wilcoxon signed rank test, changes in GFR, KPF and FF will be compared between between Study Day #1 and Study Day #2.

Conclusions: The prevalence of CKD in females is increasing rapidly, highlighting the urgency of preventative interventions. COS treatment is common, and this research will elucidate the relationship between COS and kidney health, inform future studies, and empower females and their care providers in their reproductive choices.

Involvement of Type I Interferon-Responsive Myeloid Cells in Renal Inflammation in a Lupus Mouse Model

Lindsey Han. *Cleveland Clinic Lerner Research Institute, Cleveland, OH.*

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disease that damages multiple organs, including the kidneys in Lupus Nephritis (LN). Current treatments for SLE/LN are limited to conventional disease-modifying anti-rheumatic drugs and corticosteroid therapy. A more targeted therapy is necessary to address the underlying disease pathogenesis. Type I interferon (IFN-I) and its receptor (IFNAR) are known to play a significant role in the progression of SLE/LN, making them a major focus of research and therapy.

Methods: 3 female mice strains were used to investigate whether deficiency of IFNAR on myeloid cells will drive or reduce disease progression of SLE/LN. The study mice were LysM cre/cre, IFNAR flx/flx B6.Nba2 (n=16) with knockout of IFNAR on myeloid cells (cKO). We also used B6.Nba2 (WT) mice that develop lupus-like disease (n=18) and B6 (C57Bl/6) healthy mice (n=4). The tests performed include flow cytometry on 9 month (9mo) kidney cells, spleen multi-cytokine array of pro-inflammatory cytokines and chemokines, and ELISA of urine biomarkers S100a8, VCAM-1, and PF4.

Results: Kidney 9mo flow data revealed elevated neutrophil and decreased monocytic infiltration in the WT, but normalized levels in cKO, as well as specifically reduced levels of B cells in cKO. CD4+ T cells were specifically reduced, CD8+ T cells were specifically elevated, and Double positive (DP) T cells were normalized in 9mo cKO kidneys. Furthermore, we found that urinary biomarkers S100a8 and PF4 were decreased in 9mo cKO compared to the WT. 9mo spleen IL-21, IL-10, IL-6, IL-4, IFN-γ, and TNF-α were reduced in cKO, and cKO mice developed accelerated Splenomegaly at 2 months, followed by Nephromegaly at 9mo.

Conclusions: In essence, we observed reduced levels of neutrophilic cells, B cells, CD4+ T cells and DP T cells associated with reduced levels of urine biomarkers and that lack of type I interferon expression on myeloid cells affects the trafficking pattern of both monocytic and neutrophilic cells. Thus, our hypothesis for LN development follows: IFNAR facilitates the infiltration of neutrophilic cells, leading to the release of chemokines and the recruitment of inflammatory lymphocytes, and ultimately resulting in renal cell damage and the development of LN. Future directions include further analyses of renal infiltrates and additional urinary biomarkers.

Healthy Women Have Higher Systemic Uromodulin Levels: Identification of Uromodulin as an Estrogen Responsive Gene

Azuma Nanamatsu, Radmila Micanovic, Shehnaz Khan, Tarek M. El-Achkar, Kaice A. LaFavers. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Urinary and serum uromodulin (gene: UMOD), secreted by the kidney, gained attention as potential biomarkers for kidney function in the context of acute and chronic kidney diseases and as an overall marker of health. However, there are few analyses focusing on a large number of healthy subjects, and the ranges and physiological regulation of serum uromodulin have not been well established.

Methods: Using ELISA, we measured serum uromodulin levels of healthy human subjects (n = 380) available from the Indiana University Biobank. To identify predictors of levels, we performed automated linear modeling in SPSS using relevant predictor variables extracted from deidentified patient charts (age, sex, body mass index, race, serum creatinine, eGFR, prescription drug usage). We also measured serum uromodulin in mice using ELISA. To identify a potential mechanism for increased serum uromodulin levels in females, mouse kidney thick ascending limb (MKTAL) cells were treated with 17β-estradiol, and uromodulin mRNA and protein expression were evaluated by RT-qPCR and Western blotting, respectively.

Results: Healthy subjects showed a wide range of serum uromodulin levels. Automated linear modeling in SPSS identified sex and body mass index (BMI) as significant ($p < 0.05$) predictors of serum uromodulin level. Serum uromodulin levels are higher in healthy females than healthy males. To identify a potential mechanism for increased serum uromodulin levels in females, we analyzed the UMOD locus in *H. sapiens* and *M. musculus*. We found two non-canonical estrogen response elements (ERE) and 29 canonical half-EREs in the *H. sapiens* sequence and 45 canonical half-EREs in the *M. musculus* sequence. Consistent with this, serum uromodulin levels normalized to weight are higher in female mice. Additionally, treatment with 10 pM – 1 nM of 17β-estradiol increases uromodulin expression at the mRNA and protein levels in MKTAL cells.

Conclusions: Healthy females have higher serum uromodulin levels, likely due to the estrogen responsiveness of the UMOD gene. Since uromodulin has an immunomodulatory role and is protective against acute kidney injury, estrogen-responsive increases in serum uromodulin might partially explain sex-specific susceptibility to infection and kidney injury.

FR-PO842

Sex-Based Differences in Proximal Tubule Recovery of Filtered Proteins

Katherine E. Shipman,[1] Catherine J. Baty,[1] Elynna B. Youm,[1] Aurelie Edwards,[2] Ora A. Weisz.[1] *[1]University of Pittsburgh School of Medicine, Pittsburgh, PA; [2]Boston University, Boston, MA.*

Background: The proximal tubule (PT) efficiently reclaims albumin and other proteins that escape the glomerular filtration barrier to maintain protein free urine. The recovery of filtered proteins occurs via receptor-mediated endocytosis facilitated by the multiligand receptors megalin and cubilin. PT health is impacted by excess albumin uptake that occurs when the glomerular barrier is breached and by nephrotoxic drugs that enter cells in a megalin/cubilin dependent manner. Transcriptomic and proteomic studies in male rodents have demonstrated differences in the expression of megalin and cubilin across the S1, S2, and S3 sub-segments that comprise the PT. Based on this, we previously developed an axial model of protein uptake in mice which predicts that most uptake under normal conditions occurs in S1, with S2 providing excess uptake capacity under nephrotic conditions. Multiple studies have shown that females are more protected from renal injury than males, however, the mechanisms underlying this difference in protection from renal injury are unknown.

Methods: To determine if there are sex-based differences in baseline PT recovery of filtered proteins, urine and kidneys were collected from five male and five female 13-week-old C57BL/6 mice. Urinary albumin was quantified by ELISA. Kidneys were processed for Western blotting and immunofluorescence staining. We used imaging-based approaches to quantify the expression and distribution of megalin and cubilin in SGLT2-positive S1 and SGLT2-negative S2 segments.

Results: Compared to males, female mice had lower levels of urinary albumin excretion when normalized to creatinine at baseline. Female mice had greater expression of total megalin and cubilin and decreased expression of NHE3 in the kidney cortex. Male and female mice had similar levels of megalin expression and surface localization in S1, however, female mice had greater expression and surface localization of megalin in S2. A greater fraction of total cubilin localized to the apical surface compared to megalin along the length of PT.

Conclusions: Our data suggest differences in the capacity of the PT to recover filtered proteins between male and female mice which could be especially relevant under nephrotic conditions. Current studies are focused on incorporating these sex-based differences into a mathematical model of protein uptake along the length of the PT.

Sex Differences in Regional Distribution of Key Steroidogenic Enzymes in the Rat Kidney

Leah B. Shelton,[1] Victoria L. Nasci,[2] Ravneet Singh,[2] Eman Y. Gohar.[2] *[1]Eastern Virginia Medical School, Norfolk, VA; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Extragonadal estrogen (E_2) synthesis has been demonstrated in tissues such as brain, bone, and adipose tissue. We recently demonstrated preliminary evidence for an intrarenal E_2 synthesis machinery in the outer medulla (OM) of Sprague Dawley rats. Measurement of renal E_2 showed higher E_2 levels in female inner medulla (IM) compared to male rats. Thus, we aimed to investigate regional sex differences in renal E_2-synthesizing enzymes that impact sex differences in E_2 abundance.

Methods: Kidneys from male and female Sprague Dawley rats (n=8/group) were flushed, dissected into cortex (CTX), OM, and IM regions, and assessed for mRNA expression or protein abundance of enzymes in the E_2 biosynthesis pathway.

Results: mRNA expression of 3-hydroxy-3methylglutaryl CoA reductase (HMGCR), the key enzyme in cholesterol synthesis (the first substrate in steroidogenesis), was higher in female OM compared to males (100.0 ± 14.4 *vs* 254.4 ± 50.5 relative expression, p=0.0148), while no sex difference in HMGCR mRNA was observed in CTX or IM. Cytochrome P450 (CYP) 17a1, which synthesizes weak androgens, showed greater mRNA expression in female CTX and OM, while males expressed higher levels in IM (CTX: 100.0 ± 34.7 *vs* 204.0 ± 71.1, p=0.0120; OM: 100.0 ± 41.0 *vs* 228.9 ± 78.0, p=0.0017; IM: 100.0 ± 37.5 *vs* 36.3 ± 15.2, p=0.0010). We also assessed mRNA expression of 17b-hydroxysteroid dehydrogenase (HSD17b) 1, 2, and 3 which interconvert androgens and estrogens. HSD17b1 was higher in male CTX and OM (CTX: 100.0 ± 46.5 *vs* 7.6 ± 1.3, p=0.0003; OM: 100.0 ± 52.6 vs 10.1 ± 2.4, p=0.0005), while HSD17b2 and 3 were higher in female CTX and OM (CTX: 100.0 ± 43.8 *vs* : 454.8 ± 271.1, p=0.0042, 100.0 ± 49.9 *vs* 199.5 ± 119.8, p=0.0790, respectively; OM: 100.0 ± 40.5 *vs* 619.6 ± 311.8, p=0.0006, 100.0 ± 25.8 *vs* 164.8 ± 33.2, p=0.0011, respectively). Protein expression of aromatase (estrogen synthase) was detected in CTX, OM, and IM without sex differences.

Conclusions: Our data indicate sex- and region-specific differential expression of the intrarenal E_2 biosynthesis pathway within the rat kidney. HMGCR, CYP17A1, and HSD17b2 and 3 were upregulated within the female rat renal CTX and/or OM, but not IM, compared to males. Region-specific upregulation of these enzymes in females may contribute to renoprotective effects.

Multiple Pregnancy Can Induce Preeclampsia-Like Changes in Complement Factor H Point Mutation Mice

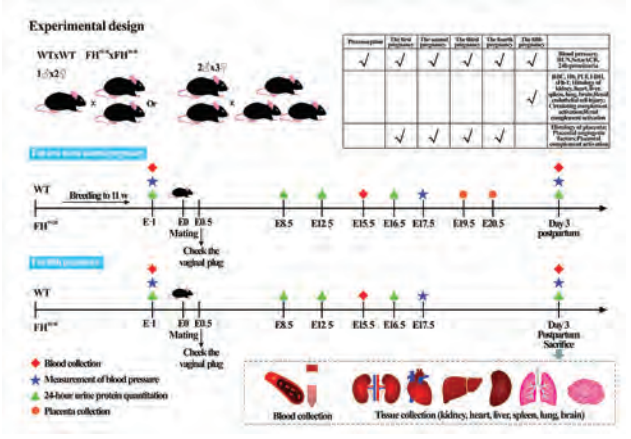
Feifei Chen, Ying Tan. *Peking University First Hospital, Beijing, China.*

Background: Preeclampsia is a severe placenta-related pregnancy disorder, its pathogenesis has still not been fully elucidated. Studies suggested a link between complement activation and preeclampsia. In view of that normal pregnancy can induce appropriate activation of the complement system, we assumed that patients with preeclampsia may have increasing genetic susceptibility to overactivation of complement system, and under the burden of pregnancy, overactivation of the complement system occurs, in turn leading to the occurrence of preeclampsia.

Methods: We mated the female and male mice with heterozygous mutations in complement factor H through five times and assessed clinicopathological indicators of preeclampsia.

Results: Along with complement activation, multiple pregnant heterozygous complement H mutation mice recapitulated the key features of human preeclampsia: hypertension, proteinuria, elevated blood urea nitrogen, lactic dehydrogenase, reduced placental weight, restricted fetal growth, typical histology change in placenta and kidney of preeclampsia, placental imbalance of angiogenesis and renal endothelial cell injury.

Conclusions: This study provided direct evidence that pregnant status can induce overactivation of complement system in mice with mutation in complement regulator gene, which could lead to the development of preeclampsia. This model provided a new option for the investigation of the pathogenesis of preeclampsia.



FR-PO845

Screening Fabry Disease in Women Combining Enzyme Activity with Lyso-GL3: Results of a Brazilian Study

Cassiano Augusto Silva,[1] Fellype Barreto,[2] Osvaldo M. Vieira Neto,[3] Leandro J. Lucca,[3] Fernando A. Vieira,[4] Ana Paula Gueiros,[5] Marta V. Boger,[6] Artur Q. Silva,[7] Felipe Leite Guedes,[7] Karla Cristina P. Israel,[8] Gina Moreno Gordon,[9] Eduarda M. Souza,[10] Valeria Veloso,[11] Gabriela Sevignani,[12] Carolina Barretto,[13] Roberta C. Pascotto,[14] Gelzie S. Ennes,[15] Márcia G. Ribeiro,[16] Luis Gustavo Modelli de Andrade.[1] *[1]Universidade Estadual Paulista Julio de Mesquita Filho, Botucatu, Brazil; [2]Universidade Federal do Parana, Curitiba, Brazil; [3]Universidade de Sao Paulo, Ribeirão Preto, Brazil; [4]Clirenal, Caratinga, Brazil; [5]Instituto de Medicina Integral Professor Fernando Figueira, Recife, Brazil; [6]Metta Saúde Clínica do Rim, Foz do Iguaçu, Brazil; [7]Universidade Federal do Rio Grande do Norte, Natal, Brazil; [8]Universidade Federal do Amazonas, Manaus, Brazil; [9]Grupo Instituto do Rim do Paraná, Curitiba, Brazil; [10]Sanofi-Genzyme, São Paulo, Brazil; [11]Universidade Federal de Goias, Goiania, Brazil; [12]Fundacao Pro-Rim, Joinville, Brazil; [13]Santa Casa de Misericordia de Itabuna, Itabuna, Brazil; [14]Santa Casa de Maringa, Maringa, Brazil; [15]Centro de nefrologia de Nova Friburgo, Nova Friburgo, Brazil; [16]DLE, Rio de Janeiro, Brazil.*

Background: Fabry disease (FD) is a rare X-linked lysosomal storage disease that can affect multiple organs, including the kidneys. The main objective of this study was to evaluate the effectiveness of a combination of α-GAL enzyme activity and plasma levels of lyso-GL3 for screening FD in women with chronic kidney disease (CKD).

Methods: Women with CKD, stages 3 to 5, in regular nephrological follow-up were selected from renal centers in all regions of Brazil. Exclusion criteria: under 18 years old and known diagnosis of FD. Patients underwent biochemical analysis of α-GAL enzyme activity and plasma levels of lyso-GL3. GLA gene sequencing was performed if α-GAL enzyme activity was below and/or lyso-GL3 levels were above the reference range. Sensitivity and specificity analyzes were performed to evaluate the performance of the combined biochemical approach for the diagnosis of FD.

Results: From October 2020 to December 2022 1,647 collections were carried out. Low α-GAL activity was found in 44 (2.6%) of the cases and increased lyso-GL3 was found in 101 (6.1%) of the cases. The mean age was 53 [42 – 64] years. All cases of low α-GAL and/or increased lyso-GL3 were submitted to genetic analysis, and 6 positive cases were found. As for genetic variants, four patients have R118C, one A143T and other with T430G, all considered variants of uncertain significance (VUS). The sensitivity and specificity of α-GAL reduction for the detection of FD was 83.3% and 97.6%, respectively. As for the increase in lyso-GL3, the values were 16.6% and 93.9%, respectively. There were no cases that presented a concomitant increase in lyso-GL3 and a reduction in enzymatic activity.

Conclusions: Preliminary results suggest that the combination of α-GAL enzymatic activity with lyso-GL3 measurement may be a good alternative for screening FD in women with CKD. A thorough medical evaluation is required to determine the pathogenicity of variants in these patients.

FR-PO846

Sexual Function, Activity, and Satisfaction Among Young Females with CKD

Kathryn Corbett,[1,2] Victoria J. Riehl-Tonn,[1,2] Danica H. Chang,[3] Sofia B. Ahmed,[1,2] Sandi M. Dumanski.[1,2] *[1]University of Calgary, Calgary, AB, Canada; [2]Libin Cardiovascular Institute of Alberta, Calgary, AB, Canada; [3]University of Alberta, Edmonton, AB, Canada.*

Background: Up to 80% of women with chronic kidney disease (CKD) experience sexual dysfunction, though its link with sexual activity and sexual satisfaction is not known. Recent literature demonstrates that among older women with kidney failure treated with dialysis, the majority report sexual inactivity, few describe sexual dysfunction and most report high sexual satisfaction. Whether this applies to young females with CKD has not been described. Our objectives were to determine the incidence of sexual activity, sexual dysfunction and sexual satisfaction among young females with CKD.

Methods: Females < 51 years old with CKD were recruited from nephrology clinics in Calgary, Alberta, Canada. Participants completed a modified version of the Female Sexual Function Index, a validated tool to assess sexual function.

Results: Thirty-six females with CKD (61% hemodialysis, 14% peritoneal dialysis, 14% stage G3-5 CKD, 11% transplant) participated. The median age was 37 years old (IQR 32, 43) and all participants identified as cis-gender. Eighteen participants (51%) reported sexual activity, and 82% of these individuals met criteria for sexual dysfunction. Among all participants, only 23% reported satisfaction with their sex life, while 57% reported moderate to severe dissatisfaction. Sexual dissatisfaction was more common among women experiencing sexual dysfunction ($p = 0.003$).

Conclusions: Young females with CKD are sexually active and experience a high incidence of both sexual dysfunction and dissatisfaction. These findings emphasize the importance of screening for sexual dysfunction and providing effective treatment options.

FR-PO847

Albuminuria and Vascular Health in Females with CKD

Badal S. Pattar,[1,2] Nicole Larsen,[1,2] Sofia B. Ahmed,[1,2] Jessalyn K. Holodinsky,[1,3] Sakshi Kharbanda,[1,2] Sarah M. Rabi,[1,3] Darlene Y. Sola,[1,2] Sandi M. Dumanski.[1,2] *[1]University of Calgary, Calgary, AB, Canada; [2]Libin Cardiovascular Institute of Alberta, Calgary, AB, Canada; [3]University of Calgary O'Brien Institute for Public Health, Calgary, AB, Canada.*

Background: Cardiovascular (CV) disease is the leading cause of death in chronic kidney disease (CKD), and elevated CV risk occurs earlier in the CKD disease course in females compared to males. Albuminuria, a marker of CKD severity, has been independently associated with CV disease in females, however the mechanism of this association is not yet understood. This study aimed to determine the association between albuminuria and markers of vascular health, including mean arterial pressure (MAP) and arterial stiffness, as measured by aortic augmentation index (AIx) and pulse-wave velocity (PWV), in females with CKD.

Methods: An exploratory cross-sectional study recruited 54 females with CKD from nephrology clinics in Calgary, Alberta. Albuminuria was quantified by collection of a midstream urine and measurement of urine albumin-to-creatine ratio (ACR). Using standardized protocols, blood pressure and arterial stiffness were measured. Multiple linear regression analysis was used to estimate the association between urine ACR and each marker of vascular health.

Results: Albuminuria was significantly associated with MAP ($R^2 = 0.20$; $p = 0.001$) and AIx ($R^2 = 0.21$; $p = 0.006$), but was not associated with PWV ($R^2 = 0.11$; $p = 0.127$).

Conclusions: Disruptions in vascular health, specifically related to elevated blood pressure and increased peripheral wave reflection, may represent the pathophysiologic mechanism by which albuminuria is associated with increased CV risk in females with CKD. These risk factors may represent modifiable risk factors that serve as treatment targets for CV risk reduction in this important population.

FR-PO848

To Assess Serum Prolactin Levels in Female Patients of CKD on Maintenance Haemodialysis

Anuja P. Makan, Tushar A. Dighe, Charan B. Bale, Pavan Wakhare, Nilesh Shinde, Akshay R. Kulkarni, Abhijit S. Chavan, Debapriya Saha, Chetan U. Phadke, Shreeharsh Godbole, Atul Sajgure. *DY Patil University Deemed to be University School of Medicine, Pune, India.*

Background: Kidneys play an important role in endocrine regulation, not only producing hormones such as erythropoietin and renin but also acting on the metabolism of others such as insulin, cortisol and prolactin. Therefore, CKD patients have numerous endocrine dysfunctions, with changes in feedback loops, reduced transport of protein-bound hormones, and reduced metabolism and hormone elimination. Hyperprolactinemia occurs by several mechanisms of which reduction in metabolism is one of the main mechanism. The other is increased prolactin secretion by lactotrophs in the uremic state – reduced availability of dopamine in the brain directly stimulates prolactin secretion as also increased autonomic production state. As a result of hyperprolactinemia, normal cyclic GnRH secretion decreases, resulting in the loss of pulsatile LH and FSH release. The high elevated level of circulating prolactin in ESRD represents biologically active hormone and is thought to contribute to the high prevalence of hypogonadism, anovulation and sexual dysfunction in patients on dialysis (due to prolactin inhibition of gonadotropin secretion). It is unknown whether higher serum prolactin concentration observed in patients with ESRD are associated with symptoms other than those directly related to relative gonadal deficiency. Thus, hyperprolactinemia in these patients becomes very prevalent, ranging from 30% in CKD early stages to 65% in those on haemodialysis.

Methods: Observational prospective study with a sample size of 30 patients in the age group of 15 to 45 years

Results: In our study of 30 patients, prolactin was high in 16 patients (53%) of end stage renal disease on dialysis.

Conclusions: To summarise, serum prolactin concentrations were high in a large majority of patients with ESRD. Even with a greatly increased prevalence in CKD, the clinical diagnosis of hyperprolactinemia in this population is difficult. Signs and symptoms of hyperprolactinemia are confused with some manifestations of CKD itself such as oligomenorrhoea, amenorrhoea, decreased libido, erectile dysfunction, infertility and osteoporosis.

FR-PO849

Bilateral Ureteral Obstruction: Cause of AKI in Pregnancy

Roland Ngum Kum, Kundana R. Thimmanagai, Heather R. Lefkowitz. *Newark Beth Israel Medical Center, Newark, NJ.*

Introduction: Pregnancy-related acute kidney injury (PR-AKI) has an incidence of about 2% (1). The incidence has decreased significantly over the past years in developed countries and this is attributed to improved antenatal care (2). A rare cause of PR-AKI is bilateral ureteral obstruction, which has been reported in only a few studies. We report the case of obstructive AKI in a pregnant woman at term who had complete reversal of AKI post delivery.

Case Description: A 27-year-old G1P1 female with no known medical history was admitted for induction of labour at 39 weeks. On the night of her admission, she experienced decreased urine output and a foley catheter was inserted. On the second day, she was anuric and repeat labs showed elevated creatinine. She received one litre bolus of IV fluids and one dose of IV Lasix (20 mg). However, her creatinine levels continued to rise and she developed metabolic acidosis. Her creatinine level on admission was 0.61 mg/dL, but it increased to as high as 3.11 mg/dL with a BUN of 29 mg/dL and an HCO3 of 19 mmol/L. Her electrolyte levels were normal, but her uric acid level showed 5.8 mg/dL. Her UA on admission was benign, and she was asymptomatic. Nephrology was consulted for acute kidney injury, and renal ultrasonography showed bilateral mild hydronephrosis of the kidneys. Vitals: blood pressure of 125/77 mmHg, heart rate of 80 BPM, respiratory rate of 18, oxygen saturation of 100% on room air, and temperature of 98.4°F. Nephrology recommended immediate delivery. Immediately after surgery, the patient had good renal recovery with normal creatinine levels of 0.8 mg/dL and very good urine output.

Discussion: AKI is one of the complications that has high feto-maternal mortality and morbidity. Post renal cause of AKI secondary to ureteral obstruction is rare only 18 cases have been reported. Risk factors for AKI in pregnancy are polyhydramnios, twin pregnancy and obstruction of solitary kidney. (3) In normal pregnancy there is progesterone induced smooth muscle relaxation causing ureteral dilation and hydronephrosis. In our case ureteral dilation and hydronephrosis resulted from gravid uterus causing obstruction and possibly high levels of progesterone. The risk is usually greater in primigravida due to higher levels of progesterone.(4) AKI is rapidly reversible when the obstruction is relieved, with return of renal function to baseline.

FR-PO850

Rare Case of Recurrent Hypokalemia in Pregnancy: Broaden Your Differentials

Moazam M. Cheema, Laith Alzyood, Roy Lee, Wei Chen, Maureen Brogan, Sonali Gupta. *Montefiore Medical Center, Bronx, NY.*

Introduction: Geller's syndrome is in the differential diagnosis when a pregnant woman presents with hypertension and severe hypokalemia. Here, we present a case of a patient with severe hypokalemia and hypertension in recurrent pregnancies. Careful history taking, in this case however, revealed a unique cause of her symptoms.

Case Description: A 30 year old, G5P3013 presented at 39 weeks 5 days gestation in labor and found to have severe hypokalemia and HTN. Labs notable for K <2.0 mg/dl, Mg 1.6 mg/dl, calcium 9.1 mg/dl (corrected), phosphorus 4.2 mg/dl and Cr 0.67 mg/dl. EKG noted U-waves. She required aggressive replacement of potassium (IV and PO for 2 days). She had history of severe hypokalemia requiring aggressive potassium repletion in last two pregnancies except first and prior history of preeclampsia. Further workup revealed normal TSH and cortisol levels, with a renin level of 0.39 ng/mL/hr (0.167-5.380 ng/mL/hr) and suppressed aldosterone level (below 1 ng/dL). Urine K < 5 mEq/L at the same time when serum K was 2.6 mg/dl, which was negative for renal potassium wasting. The remaining labs and imaging studies were unremarkable. Within 72 hours following delivery, potassium levels improved and remained normal postpartum. Hypertension was again in setting of pre-eclampsia (had proteinuria with Urine protein/creatinine ratio of 625), with improvement in BP post-delivery. Genetic testing was negative for mutation in mineralocorticoid receptor which ruled out Geller syndrome. On further inquiry, she mentioned that she had been taking calabash, a type of chalk/clay multiple times a day, to ameliorate third trimester symptoms during pregnancy. Clay ingestion was identified as the cause of recurrent hypokalemia. Hypertension was due to recurrent pre-eclampsia and not related to the development of hypokalemia in this case.

Discussion: Clay ingestion is a culturally imbedded common practice based on indigenous knowledge among certain cultures. It is important to be aware of its association with potential pregnancy complications. As in our patient who had normal potassium levels in her first pregnancy, when she did not eat clay, but her three subsequent pregnancies were complicated by severe hypokalemia when she consumed significant amounts of clay. Clay binds to potassium in the gut and leads to increased intestinal excretion of potassium, resulting in hypokalemia.

FR-PO851

Successful Treatment of Nephrotic Syndrome due to Preeclampsia Diagnosed by Renal Biopsy

Yuki Kajio,[1] Hitoshi Suzuki,[1,2] Takeo Koshida,[1] Kenichiro Abe,[1] Arisa Kato,[1] Hiromitsu Fukuda,[1] Hisatsugu Takahara,[1] Yusuke Suzuki.[2] *[1]Juntendo Daigaku Igakubu Fuzoku Urayasu Byoin, Urayasu, Japan; [2]Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan.*

Introduction: Preeclampsia (PE) is the most frequent renal complication of pregnancy and is characterized by hypertension and proteinuria after 20 weeks of gestation. However, some patients with PE do not show hypertension. If the patients left untreated, PE could lead to serious complications for both the mother and baby, such as kidney function impairment, or fetal growth restriction. Thus, PE is no longer considered to be a transitory kidney disease that is cured when the baby is delivered. Moreover, the rate of pre-existing renal disease in preeclamptic women is about 70%. Focal segmental glomerulosclerosis (FSGS) is the common cause of nephrotic range proteinuria in pregnancy. It is difficult to distinguish between PE and glomerulonephritis during late pregnancy.

Case Description: A 32-year-old woman was referred for hypertension (180/108 mmHg) and massive proteinuria (13.7 g/gCr) at 34 weeks gestation. Even after delivery, massive proteinuria (7.3 g/gCr) was detected, despite well controlled blood pressure. Then, renal biopsy was performed for definitive diagnosis. Histological findings showed focal endotheliosis of the glomeruli and double contour. Immunofluorescent study showed no remarkable glomerular deposition. Reticulation of endothelial cell and duplication of GBM were detected by electron microscopy. Histological interpretation lead to definitive diagnosis as PE and to appropriate treatment, resulted in diminish of proteinuria.

Discussion: High levels of proteinuria after delivery is important index for intervention of treatment. Patients after PE has 4 times risk of hypertension, and twice risk of type 2 diabetes and dyslipidemia. Management of lifestyle-related disease after delivery is also important. In present case, histological implication lead to appropriate treatment. Therefore, histological diagnosis is important in PE patient for postpartum management.

FR-PO852

Hey Baby, the Kidney Allograft Is Not a Pillow: A Complex Case of Pregnancy in a Kidney Transplant Recipient

Joseph D. Nguyen,[1] Swati Rao.[2] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]UVA Health, Charlottesville, VA.*

Introduction: Pregnancy in kidney transplant recipients (KTR) have favorable patient, allograft, and fetal outcomes. However, these pregnancies are high-risk for pre-eclampsia (25%), preterm (50%), and C-section (50%). While rates of rejections are low (1-2%), there are high rates of urinary tract infection (UTI) and multifactorial acute kidney injury (40%). We report a case of pregnancy in KTR with a successful outcome despite multiple complications.

Case Description: A 35-year-old with ESKD due to sickle cell disease with kidney transplant 3 years ago had her first planned pregnancy. The first two trimesters were complicated by recurrent UTIs (rUTIs) managed with suppressive antibiotics. At 24 weeks, mild hydronephrosis of the allograft was seen on ultrasound, which progressed to moderate hydronephrosis by week 36 due to the fetal head compressing the renal hilum (Fig 1A/B). Pre-eclampsia developed at 28 weeks; initial hypertension was followed by proteinuria at 34 weeks. Delivery was performed by C-section due to fetal distress at 37 weeks. Meticulous surgical technique ensured the safety of the transplanted ureter. Two days after delivery, hydronephrosis was improved (Fig 1C). She did not have a sickle cell crisis during pregnancy, with the use of erythropoietin stimulating agents and 1 unit of blood transfusion during C-section.

Discussion: Fertility and sexual health are important quality-of-life metrics in KTR, and our patient was determined to pursue pregnancy. Her case is an example of multidisciplinary care by transplant nephrology, maternal-fetal medicine, hematology, and transplant surgery supporting a complex case of pregnancy in KTR. Prior to conception, her allograft function, immunosuppressive regimen, and comorbidities were optimized. Despite multiple insults to the allograft (rUTIs, pre-eclampsia, and hydronephrosis), creatinine remained stable (0.8mg/dL). Postpartum, blood pressure and hydronephrosis are rapidly improving. Proteinuria persists but we expect improvement in the next few weeks as VEGF signaling normalizes and endothelial-podocyte homeostasis recovers.

Ultrasound of transplanted kidney at 24 weeks (A), 36 weeks (B) with fetal head compressing renal hilum (white arrow), and 2 days postpartum (C).

FR-PO853

Renal Artery Stenosis in Early High-Risk Pregnancy

Marielle Llamas, Tyler Andrea. *Samaritan Health Services, Corvallis, OR.*

Introduction: Renovascular hypertension is an uncommon cause of hypertension in pregnancy.[1] Renovascular hypertension management is complicated by contraindication in pregnancy to established first line treatment of ACE-I and ARBs due to teratogenicity. The potential teratogenic risks of radiological intervention using fluoroscopy limits diagnostic options.[2] Previous cases of pregnant patients presenting with new onset or superimposed preeclampsia secondary to renovascular hypertension have been rarely reported.[2] We present a case report of renovascular hypertension in a pregnant patient who was at 17 weeks gestation at the time of diagnosis.

Case Description: 38-year-old pregnant female presenting for routine prenatal care. Preexisting diagnoses of insulin-dependent T2DM complicated by diabetic neuropathy, combined systolic/diastolic heart failure, history of methamphetamine use in remission, prior stroke x2 with residual left-sided deficits (2020), and poorly controlled hypertension. Confirmatory 24 -hour urine protein: 7,410 mg/24H 24h BP monitor: average reading of 185/87 Aldosterone/renin activity ratio: normal Regularly scheduled visits with her obstetrician soon revealed difficulties with hypertension control, resulting in an increase of her labetalol dose to 300 mg twice daily. At 17 weeks gestation, duplex ultrasound of the renal arteries confirmed high-grade stenosis at the origin of high renal artery, greater than 70%. Patient was promptly admitted for renal revascularization with renal artery stenting.

Discussion: Diagnosis of RAS can be done through duplex ultrasound imaging, CTA scan, or MRA. A catheter angiogram, which requires contrast to be injected via a catheter threaded through the renal artery is considered the gold standard diagnostic tool. However, it is not widely used during pregnancy due to radiation effects.[7] While extra-abdominal radiologic examinations render insignificant exposures to the pregnant uterus, high quality tools such as, fluoroscopically- or CT-guided interventional procedures (such as renal artery angioplasty) should be carefully considered during pregnancy.[8] The management of hypertension in early pregnancy should involve screening for RAS, especially in the setting of resistance to antihypertensive medications. [7] The benefits of early diagnosis of renal artery stenosis in pregnancy must be balanced with the risks of diagnostic imaging, interventional procedures, and its teratogenic risks.

FR-PO854

Neither Infantile nor Idiopathic: A Challenging Case of Hypercalcemia During Pregnancy

Eric Magliulo, Saher Aslam, Jay L. Hawkins. *University of Nebraska Medical Center, Omaha, NE.*

Introduction: Idiopathic Infantile Hypercalcemia (IIH) Type 1 is a rare cause of hypercalcemia presents both in infancy and in adulthood. Autosomal recessive mutations in the *CYP24A1* gene, which encodes for the 24-hydroxylase enzyme, were recently identified in patients diagnosed with IIH Type 1. A deficiency or loss of function in this enzyme leads to reduced metabolism of activated vitamin D. Here we present a case of a patient presenting with hypercalcemia, hypertension, and nephrocalcinosis during pregnancy.

Case Description: A 34 year old woman G3P0303 with a history of three pregnancies complicated by hypercalcemia and pre-eclampsia with severe features was referred to Nephrology for evaluation of persistent post-partum hypercalcemia. During her most recent pregnancy, she was hypertensive with a total serum calcium ranged from 9.9 - 12.7 mg/dL. Post-partum, she was initiated on nifedipine, hydralazine, and enalapril. Initial labs were consistent with PTH-independent hypercalcemia with an inappropriately normal serum 1,25 dihydroxy vitamin D. Work up for a granulomatous disease process was negative. Imaging revealed bilateral medullary calcinosis. 24 hour stone analysis showed an increased risk for formation of calcium phosphate stones. A 25 Hydroxyvitamin D:24,25 Dihydroxy-vitamin D ratio could not be calculated as 24,25-Dihydroxy-vitamin D was below the limit of quantification. Genetic testing confirmed the presence of compound heterozygous mutations in the *CYP24A1* gene.

Discussion: A deficiency in the 24-hydroxylase enzyme can manifest in adulthood as hypercalcemia, hypertension, and nephrocalcinosis, often in the setting of pregnancy. Given the rarity of this genetic disease, diagnosis is often delayed. Initial laboratory work up often reveals hypercalcemia, suppressed parathyroid hormone, and normal to mildly elevated 1,25 dihydroxy-vitamin D. Diagnosis requires either genetic testing or an elevated 25 Hydroxyvitamin D:24,25 Dihydroxy-vitamin D ratio, often greater than 80. In our case, the patient developed recurrent gestational hypercalcemia and hypertension. As a result of a delayed diagnosis, measures had not been taken to avoid excess vitamin D and calcium supplementation. This case highlights the importance of pursuing the diagnosis of 24 hydroxylase deficiency in patients that present with hypercalcemia and hypertension in the setting of pregnancy.

Observational Cohort with Embedded Randomised Controlled Trials to Study Pregnancy-Associated Progression of Renal Disease (ORCHARD)

Priscilla Smith,[1] Kathryn Dalrymple,[1] Katherine R. Clark,[1] Yanzhong Wang,[1] Tess M. Harris,[2] Andrew J. Webb,[1] Lucy C. Chappell,[1] Kate Bramham.[1] *[1]King's College London, London, United Kingdom; [2]The PKD Charity, London, United Kingdom.*

Background: 46% of women with moderate-severe chronic kidney disease (CKD) will require dialysis or lose at least 25% of kidney function within six months of delivery with no development of preventative treatments.

Methods: Biological samples, longitudinal and outcome data will be collected in a prospective cohort and eligible women identified to participate in ORCHARD-BEET randomised controlled feasibility trial. Inclusion criteria: singleton pregnancies; 24^{+6} weeks or less; CKD (pre-pregnancy eGFR<90mls/min/m^2 or pregnancy Cr>70µmol/l). Randomisation: 1 to 1. Standard care or daily beetroot juice supplement (nitrate 400mg). Primary outcome: recruitment rate; secondary outcomes: tolerability, acceptability, eGFR change at 6 months postpartum.

Results: 118 women consented to participate in the cohort and 104 were randomised to ORCHARD-BEET trial. 65% of eligible participants approached consented to be enrolled in the trial. Cohort maternal baseline characteristics are presented in Table 1. Trial results will be reported in 2024 once follow up complete.

Conclusions: To our knowledge this is the largest prospective cohort study with embedded pragmatic feasibility trial with concurrent biobanking of pregnant participants which is representative of women with moderate and severe CKD. Findings will be used to inform future intervention trials to prevent pregnancy associated progression of kidney disease. ISRCTN 91211980

Maternal Outcomes Following Nephrology Review in Pregnancy

Sinead Stoneman,[1,3] Hadas Miremberg,[2] Blathnaid O'Connell,[1] Cliona Cowhig,[1] Fionn P. Daly,[1] Michael Clarkson,[1,3] Nóirín Russell,[2,3] Louise Kenny,[4] Liam Plant,[1,3] Sarah M. Moran.[1,3] *[1]Cork University Hospital, Cork, Ireland; [2]Cork University Maternity Hospital, Cork, Ireland; [3]University College Cork, Cork, Ireland; [4]University of Liverpool, Liverpool, United Kingdom.*

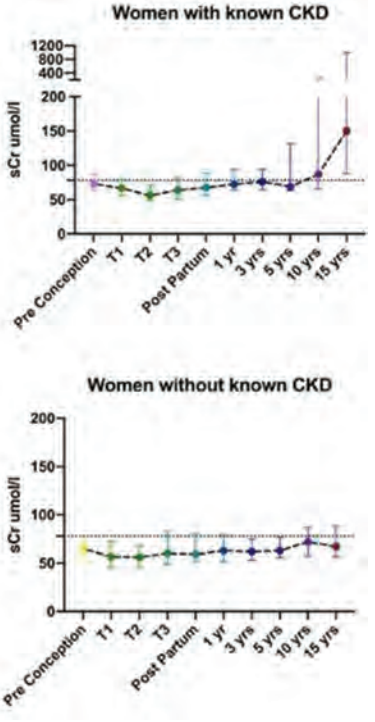
Background: Chronic kidney disease [CKD] is estimated to affect 3% of pregnant women. Dialysis-requiring pregnancy-associated acute kidney injury [PRAKI] is increasing in incidence, however accurate definitions for non-dialysis requiring PRAKI are lacking.

Methods: We conducted a retrospective cohort study of women who were reviewed by our Obstetric Nephrology Service from January 1st 2007 to March 31st 2023. Maternal and fetal outcomes were collected. Ethical approval was provided by the institution's ethics committee. Statistical analysis was performed with GraphPad version 7 and R.

Results: 459 women met inclusion criteria. We report the interim analysis of 154 pregnancies in 128 women. Mean maternal age at conception was 32.9 ± 5.3 years. 30% of mothers were nulliparous and 25% had hypertension pre-pregnancy. Indication

for review was pre-existing CKD (57%), acute kidney injury and/or new proteinuria/ hematuria (20%) and newly diagnosed CKD in the index pregnancy (9%). CKD was attributed to urological causes in 44%, glomerulonephritis in 29% and polycystic kidney disease in 15% of the cohort. In women with newly detected CKD in pregnancy, 26% underwent subsequent kidney biopsy. In women with CKD, serum creatinine [sCr] preconception was 73 µmol/L (63-138) and in trimester 2 during pregnancy was 56umol/L. Follow-up sCr at 1 yr was 73 µmol/L (65-94), 3 yrs was 76 µmol/L (65-94), 10 yrs was 87 µmol/L(66-250) and at 15 years was 150 µmol/L (88-850umol/). 3% of all women developed ESKD during follow up.

Conclusions: Results from this single-center study provide longitudinal kidney and maternal outcomes from a large cohort of women who received obstetric nephrology care.



Serial serum creatinine measurements (µmol/L) from pre-conception to 15 years of follow up.

FR-PO857

Adverse Maternal-Fetal Outcomes in Pregnant Women with CKD on Hemodialysis: A Single-Center Experience

Jorge Andrade-Sierra,[1,2] Berenice Bautista Melo,[2] Mauricio Carvallo Venegas,[2] Adriana Banda Lopez,[2] Salvador Mendoza Cabrera,[2] Ricardo Parra Guerra,[2] María del Rosario Moreno De los Rios,[2] Jose Ignacio Cerrillos,[2] Luis Alberto Evangelista-Carrillo,[2] Miguel Medina Perez.[2] *[1]Universidad de Guadalajara Centro Universitario de Ciencias de la Salud, Guadalajara, Mexico; [2]Instituto Mexicano del Seguro Social Delegacion Jalisco, Guadalajara, Mexico.*

Background: Chronic kidney disease (CKD) pregnant women are at high risk of adverse maternal and fetal outcomes (AMAFO). 4% of women of childbearing age suffer from CKD, an independent risk factor for prematurity, low birth weight, neonatal death, and preeclampsia. **Objective:** To determine the incidence of AMAFO in pregnant women with CKD in hemodialysis (HD).

Methods: Observational retrospective study of 30 patients with CKD in HD and pregnancy from Aug 2017 to Dec 2021. Sociodemographic data, comorbidities, and AMAFO were recorded and analyzed.

Results: The incidence of adverse maternal events was 33%, the most frequent was preeclampsia with severe features (17%), followed by preeclampsia (7 %), HELLP syndrome (3%), gestational diabetes (3%), and placental abruption (3%). Neither patient died during the follow-up. 90% of the newborns present with adverse fetal outcomes, 90% with low birth weight, 40% with prematurity, 13 % with transient tachypnea of the newborn, 7% with premature rupture of the membranes, 7% with fetal distress, and 17% died.

Conclusions: There was a 33% incidence of adverse maternal events and 90% of adverse fetal outcomes in pregnant women with CKD in HD, with only 10% of pregnancies without AMAFO.

	N= 30

Characteristics and Outcomes of Patients with Pregnancy-Related ESKD

Lauren M. Kucirka,[1] Ana M. Angarita,[3] Tracy Manuck,[1] Kim Boggess,[1] Vimal K. Derebail,[1] Mollie E. Wood,[1] Dorry L. Segev,[2] Monica L. Reynolds.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]New York University, New York, NY; [3]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.*

Background: The incidence of pregnancy-related AKI is increasing and associated with morbidity including progression to ESKD. We aimed to examine characteristics and clinical outcomes of patients with a pregnancy-related primary cause of ESKD(PR-ESKD).

Methods: We studied 183,640 reproductive-aged females with incident ESKD, 341 with PR-ESKD, from Jan 2000-Nov 2020 in USRDS. We compared baseline characteristics of those with PR-ESKD to the US birthing population using CDC natality data. We built multivariable Cox/competing risk models to examine 1) mortality, 2) access to kidney transplant(KT), and 3) time to KT after joining the waitlist between those with PR-ESKD and reproductive-age women with other causes of ESKD.

Results: Versus the general US birthing population, Black patients were overrepresented in PR-ESKD(31.9% vs. 16.7%). PR-ESKD had similar/lower hazards of mortality but significantly less acess to KT vs other causes of ESKD(Figure); this persisted in adjusted analyses(Table). Those with PR-ESKD were less likely to have nephrology care prior to ESKD-onset (aRR=0.47,95% CI:0.40-0.56).

Conclusions: Black patients are disproportionately affected by pregnancy-related ESKD. Our finding of reduced access to KT and pre-ESKD care highlight the need for improved postpartum and long-term support.

Figure: Mortality Among Those with Pregnancy-Related ESKD Compared to Those with Other Causes, (a) All Ages, (b) Pregnancy-Related ESKD Compared to an Age-Matched Cohort, and Time from (c) ESKD Onset to Access to Kidney Transplant (Joining the Deceased Donor Waitlist or Receiving a Kidney from a Live Donor), and (d) Among Those Who Were Waitlisted, Joining the Waitlist To Kidney Transplant

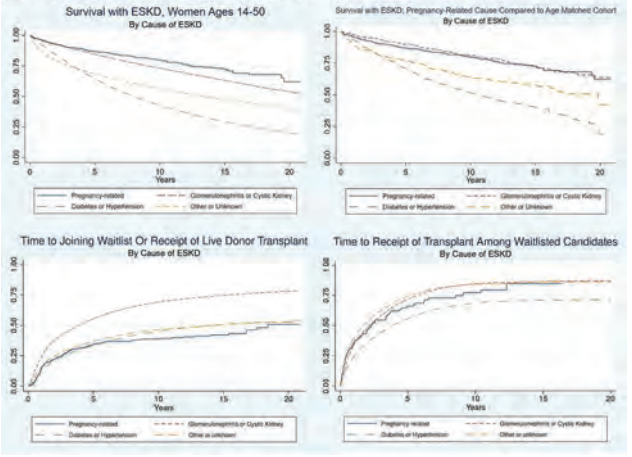

Table: (a) Multivariable Cox Proportional Hazards Model: Time to Death, and Multivariable Competing Risk Models** for (b) Time to Access to Transplant (Joining Kidney Transplant Waitlistor Receipt of Live Donor Transplant), (c) Time to Transplant After Joining Waitlist, Among Reproductive Age Females with End-Stage Kidney Disease, by Primary Cause of Kidney Failure**

(a) Death	HR (95% CI)*	p-value
Pregnancy-related vs	1.00	
Glomerulonephritis/cystic kidney	0.97 (0.78-1.29)	0.8

HR = hazard ratio, SHR = subhazard ratio
**Inverse hazard ratios shown for cause of renal failure, so should be interpreted as the hazard for patients with pregnancy-related ESKD compared to each of the other causes **Model adjusted for potential confounders including race, Hispanic Ethnicity, insurance type,current employment, and comorbidities including congestive heart failure, COPD, cerebrovascular disease, alcohol dependence, hypertension, inability to ambulate, current smoker*

FR-PO859

Acute Starvation Ketoacidosis in Pregnancy: Too Fast, Too Furious

Neev Patel, Yashvi Pethani, Maheen Khan, Oluwadamilola Adisa, Adrian P. Sequeira. *LSU Health Shreveport, Shreveport, LA.*

Introduction: Starvation ketoacidosis in pregnancy is rare and potentially lethal. Maternal mortality rates up to 35% and fetal mortality rates up to 85% have been reported. Moreover, maternal acidosis is associated with detrimental fetal neural development. Majority of previously reported cases were in setting of pre-existing diabetes mellitus and required emergent caesarean section. This case demonstrates a distinctive presentation characterized by severe ketoacidosis in the context of acute starvation, absence of diabetes, and positive fetomaternal outcomes.

Case Description: 26-year-old female G4P2103 at 35 weeks of gestation with history of anemia presented to labor unit with intractable vomiting for around 24 hours. Further history was significant for acetaminophen use for a month. Vitals were significant for pulse 115/min, respiratory rate 20/min, BP 106/63 mm Hg. Blood chemistry showed CO2 9 mmol/L, glucose 61 mg/dL, and anion gap 19. Urinalysis showed specific gravity > 1.030, protein > 300 mg/dL, ketones > 160 mg/dL. On arterial blood gas, pH was 7.184, PCO2 31 mm Hg, and a base deficit –16 mmol/L. Blood lactate, ethanol, methanol, and acetaminophen levels were normal. Beta hydroxy butyrate was 52.29 mg/dL. Diabetic ketoacidosis was ruled out based on glucose 61 mg/dL and hemoglobin A1c 4.8%. Diagnosis of starvation ketoacidosis was made. She was treated with intravenous sodium bicarbonate and dextrose infusion for around 24 hours, with improvement in metabolic acidosis. No fetomaternal complications occurred.

Discussion: In healthy individuals, it takes a minimum of 14 days for starvation to reach its peak severity, characterized by a pH value typically above 7.3 while in pregnancy, starvation ketosis can develop within a few days. In pregnancy, heightened levels of estrogen, progesterone, and human placental lactogen cause insulin resistance, hindering cellular glucose uptake. Consequently, increased lipolysis and free fatty acids lead to ketosis. Management primarily includes bicarbonate and dextrose infusion along with fetal monitoring. Insulin does not play a role in starvation ketoacidosis as opposed to diabetic ketoacidosis.

FR-PO860

Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL) as a Marker of Disease Activity and Pregnancy-Related Adverse Outcomes in Pregnant Women with Inflammatory Bowel Disease

Nour T. Elayan, Linda Shavit. *Shaare Zedek Medical Center, Jerusalem, Israel.*

Background: Control of disease activity in pregnant women with inflammatory bowel disease (IBD) is crucial as an uncontrolled disease is associated with higher risks of adverse pregnancy outcomes for both the mother and newborn. Human neutrophil gelatinase-associated lipocalin (NGAL) is an acceptable biomarker in some pathological conditions such as acute and chronic kidney injuries and high levels of NGAL were observed in the colon, serum, and stool of patients with IBD. In pregnancy, first-trimester NGAL was found to be an early marker of late-onset preeclampsia. However, no data exists on urinary NGAL in pregnant women with IBD.

Methods: The study recruited women with (IBD) who attended the IBDMOM clinic for antenatal and postnatal follow-up. The correlation of urinary NGAL levels with baseline clinical characteristics and its predictive capacity for pregnancy-related adverse outcomes such as preterm birth, preeclampsia, stillbirth, low-birth weight, and IBD flares were assessed by univariate and multivariate stepwise regression analyses.

Results: The median age of patients was 28 years and the median duration of IBD at the time of conception was 6 years. A total of 252 urine samples (172 samples from patients with Crohn's disease, 77 with ulcerative colitis, and 3 with unclassified IBD) were examined. Urinary NGAL measurements were obtained from 192 pregnancies, throughout the different gestational periods (1st trimester n = 90; 2nd trimester n = 111; 3rd trimester n = 92). Urinary NGAL levels were not significantly higher in patients with active IBD compared with inactive IBD (median 47.7 ± 4.7 ng/mL vs. 52.8 ± 3.98 ng/mL, p = 0.242). Forty-nine patients reached secondary outcomes (27, 8 and 14 had preterm deliveries, abortions, and either preeclampsia, IUGR, and stillbirth, respectively). There was no statically significant correlation between urinary NGAL levels and obstetric adverse outcomes. However, the incidence of cesarean sections, treatment regimen changes and hospital admissions during pregnancy were significantly higher in patients with active IBD (p = 0.001).

Conclusions: Our data suggest limited predictive capacity of urinary NGAL levels for predicting disease flares or obstetric adverse outcomes in pregnant women with IBD. However, the role of serum NGAL in this patients population remains to be elucidated.

FR-PO861

Maternal and Foetal Outcomes in ANCA Vasculitis: A Review of the Literature

Tilly Williamson,[1] Lauren Floyd,[2] Wing Yin Leung,[2] Louise R. Moore,[2] Ajay P. Dhaygude,[2] Adam Morris.[2] *[1]The University of Manchester, Manchester, United Kingdom; [2]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom.*

Background: Limited data exists on the effects of ANCA-associated vasculitis (AAV) on maternal and foetal outcomes. Although historically rare in pregnancy and primarily affecting individuals >65 yrs, the incidence of AAV in younger women is increasing. This highlights the significant impact of AAV on fertility and the need for increased healthcare provision and interdisciplinary approach to management. There is however a lack of literature guiding healthcare professionals in managing AAV patients throughout the pre-conception, prenatal and postnatal periods. This review examines maternal and foetal outcomes associated with AAV, compares outcomes with the general population and explores the effectiveness of AAV treatments during pregnancy.

Methods: A literature search using PubMed, Cochrane and WoS was conducted, to identify all published studies that included pregnant women with a diagnosis of AAV. Two reviewers screened the papers and studies were assessed for quality.

Results: Five papers were included with a total of 60 women and 84 pregnancies. Results showed an increased risk of pre-eclampsia, pre-term delivery, low birth weight and high rates of caesarean delivery compared to the general population (Fig.1). Risks varied according to organ involvement with patients who had multi-system involvement at highest risk of adverse outcomes. The majority of patients received prednisolone and or azathioprine treatment during their pregnancy and >30% received no treatment at all. Pregnancies in women with disease remission had favourable outcomes.

Conclusions: Data on pregnancy outcomes in AAV is limited and there is a lack of guidance regarding patient management in the pre-conception, prenatal and postnatal periods. The literature suggests adverse outcomes in pregnant patients with AAV, emphasizing the need for additional support and further research looking at maternal health risks, the impact of disease relapse and the role of data registries.

Study outcomes and patients included (n)	AAV patients (n,%)	Incidence in the general population (developed countries)
Pre-eclampsia (n= 83)	8 (9.6%)	0.4%
Pre-term births (n= 84)	12 (14.3%)	4.3 - 8.7%
Foetal loss (n = 45)	6 (13.3%)	10.0 - 25.0%
Premature rupture of membrane (n = 32)	2 (6.3%)	8.0 - 10.0%
Low birth weight (n = 80)	16 (20.0%)	7.0%
Caesareans (n = 67)	16 (23.9%)	6.0%
Emergency	9 (13.4%)	2.7%
Elective	7 (10.4%)	2.3 %
Deterioration of maternal renal function during pregnancy (n = 35)	5 (14.3%)	-
Disease flare (n= 84)		-
During pregnancy	21 (25.0%)	
Postpartum	15 (17.9%)	
Increase in serum creatinine (n = 25)	10 (40%)	-

Maternal and foetal outcomes in AAV compared to the health population averages

FR-PO862

The Effect of Pregnancy and Delivery on Renal Prognosis in Patients with Autosomal Dominant Polycystic Kidney Disease

Yuki Oba.[1,2] *[1]Toranomon Byoin Bunin, Kawasaki, Japan; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a frequent inherited renal disease, which is caused by PKD1 and PKD2 gene abnormalities and results in the progressive development and enlargement of numerous cysts in the bilateral kidneys, leading to progressive deterioration of renal function and end-stage renal failure. It has been reported that the pregnancy and delivery rates of women with ADPKD are similar to those without it in terms of fertility, miscarriage, stillbirth, and fetal complications. On the other hand, it has also been reported that the hypertensive disorders of pregnancy (HDP) are higher and the risk of renal failure is higher in women with ADPKD. This result may lead ADPKD women who wish to have a baby to hesitate in pregnancy and delivery. This study aims to determine whether the development of HDP affects renal function after delivery in women with ADPKD.

Methods: We performed a questionnaire on pregnancy and delivery to obtain clinical data and circumstances around women with ADPKD. The primary outcome was renal failure, with or without induction of dialysis. Survival analysis was performed to evaluate whether the primary endpoint is HDP with Cox proportional hazards analysis. Factors associated with the risk of the primary outcome will be evaluated using univariate and multivariate logistic analysis.

Results: One hundred eighty-three ADPKD women (including 100 patients on hemodialysis) were enrolled in this study. The median age was 58.6 years. The mean age at first delivery was 26.9 years. The average number of births was 2.5. the mean duration from the first delivery to dialysis is 31.7 years. The age of induction of dialysis was 54.4 years. Eighteen percent of the patients developed HDP at the time of first delivery, and 71.4% of the women with a history of HDP developed HDP at the time of second delivery. Although the incidence of HDP was higher than that of the general population in Japan, there was no difference in cumulative renal survival between patients with HDP (n=28) and those without (n=148). (p=0.27, Log-rank test). Multivariate analysis also showed that the presence or absence of HDP was not a risk for poor renal prognosis.

Conclusions: In female patients with ADPKD, the presence of HDP does not affect renal prognosis and accelerate renal failure.

FR-PO863

Native Renal Biopsy D4 Postpartum

Alexa E. Golbus, Natalie T. Freidin. *Medical University of South Carolina, Charleston, SC.*

Introduction: aHUS is a thrombotic microangiopathy caused by overactivation of the alternative pathway of complement activation. aHUS can be diagnosed on renal biopsy, and treatment with eculizumab should begin as soon as possible in order to prevent progression to ESRD. However, evidence regarding appropriate timing of renal biopsy in pregnancy and the immediate period postpartum is not clear.

Case Description: Following vaginal delivery complicated by postpartum hemorrhage and subsequent dilation and curettage with an estimated blood loss of 1.5 L, a 33-year-old female developed atypical hemolytic uremic syndrome and AKI with serum creatinine to 9.4 mg/dl (baseline 0.6). PLEX was initiated and CT-guided renal biopsy 4 days postpartum demonstrated aHUS with cortical necrosis, which was subsequently treated with eculizumab. In the days following renal biopsy, our patient had abdominal and flank pain and a renal subcapsular hematoma was found on CT, measuring 5.9 x 4.4 cm, but self-resolved without further complication. 18 months later Cr recovered to 1.1 mg/dl.

Discussion: In patients with p-aHUS not treated with eculizumab, 62% reach ESRD within a month, and over 75% ultimately reach ESRD. Eculizumab, a complement C5 inhibitor, significantly reduces the risk of progression to ESRD and need for kidney transplantation. Therefore, early identification in cases of aHUS is important. While pregnancy and the postpartum period are thought to increase risk of complications in renal biopsy including bleeding and hematoma, due to increased blood flow through the kidneys, there is not a consensus regarding appropriate timing of biopsy. A systematic review of renal biopsy in pregnancy and postpartum demonstrated a 7% incidence of complications in pregnant patients, with the majority of serious adverse events occurring in weeks 23-26. Notably, postpartum patients had no severe adverse events, and complications, which occurred in 1% of cases, were mild and included microhematuria and hematoma. While there remain no clear guidelines on timing and specific indication for biopsy in this patient population, timely biopsy in our patient allowed for early initiation of treatment with eculizumab. Renal biopsy in pregnant and postpartum patients is an area lacking research and clear guidance and is likely underperformed due to the perceived risk, whether real or overstated.

FR-PO864

The Positive Association of Black Race with Kidney Diseases Among a Cohort of Pregnant Women May Be Related to a Higher Rate of Prior Nonsteroidal Anti-Inflammatory (NSAID) Use

Sonali Gupta,[1,2] Clara Wilson,[1,2] Dinushika Mohottige,[3] Aastha Vasa,[1] Belinda Jim,[1] Ladan Golestaneh.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Health System, Bronx, NY; [3]Mount Sinai Health System, New York, NY.*

Background: Chronic kidney disease (CKD) portends adverse outcomes for women of reproductive age. Black women have greater CKD prevalence and worse pregnancy outcomes compared to their counterparts. However, key contributors to these racial disparities in CKD and pregnancy outcomes are poorly described.

Methods: We conducted a retrospective cohort study of 21,603 pregnant women who were hospitalized in a large New York City health system in Bronx, NY, between January 1, 2016 and December 31, 2020 and identified 1,289 (5.9%) pregnant patients with preexisting CKD (as defined by eGFR<60 or proteinuria/albuminuria>200mg within 5 years prior to hospitalization). Data was extracted on socio-demographic variables, comorbidities, prior prescriptions for NSAIDS and smoking. We describe socio-demographic and behavioral characteristics (e.g., SES, marital status, smoking status), prior comorbid conditions (e.g. SLE, sickle cell, HTN), and prior NSAID prescription use among those with and without CKD. We quantified the association between preexisting CKD and race/ethnicity using logistic regression, adjusting for age, comorbidities, SES, prior NSAID use and smoking.

Results: Pregnant women with kidney disease (versus without) had higher prevalence of chronic HTN, prior preeclampsia, diabetes, antiphospholipid syndrome, sickle cell disease, systemic lupus and heart failure (p<0.001) and higher prior NSAIDs prescriptions (65.32% vs 41.74%, p<0.001). The majority of prescriptions were written for high dose ibuprofen (600-800mg), naproxen (500 mg) and indomethacin (500mg). After adjusting for age, BMI comorbidity, insurance type and SES, Black women had a 1.46 greater odds of CKD prevalence (p=0.03). After further adjustment for prior NSAID prescriptions, the association between Black race and CKD prevalence was no longer statistically significant (OR 1.37; p=0.08).

Conclusions: Black pregnant women have a higher rate of pre-existing CKD than their counterparts. Further investigation of racial disparities in NSAID use and their contribution to disparities in CKD prevalence among pregnant women is needed.

FR-PO865

Women with Preexisting CKD and a History of Preeclampsia Have a High Rate of Subsequent Pregnancy Complications but Are Seldom Linked to Adequate Care

Sonali Gupta,[1,2] Belinda Jim,[1] Ladan Golestaneh.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY.*

Background: Pregnancy provides a unique opportunity to identify patients with undiagnosed CKD, which includes ongoing proteinuria from previous pre-eclampsia episode, and integrate them with healthcare resources. Pregnant women with pre-existing CKD and a history of pre-eclampsia have a high incidence of adverse outcomes but whether these outcomes occur despite adequate linkage to care is not known.

Methods: We evaluated a retrospective cohort of pregnant women with preexisting CKD (as defined by eGFR<60 or proteinuria >200mg within 6 months and 5 years prior to admission) and a previous history of preeclampsia who were hospitalized in a large New York City health system in Bronx, NY, between January 1, 2016 and December 31, 2019. Data on socio-demographic variables, comorbidities, pregnancy complications, and follow up within 2 years post-discharge was extracted from Looking Glass©, a combined clinical and claims database. Descriptive analyses showed proportion with at least one visit to primary care or nephrology and an instance of proteinuria checked within 2 years in those with preeclampsia and CKD.

Results: We identified 296 hospitalized pregnant women with a history of pre-eclampsia and CKD of which 2.9% were White, 40.5% were Black, and 46.9% were Hispanic. Median eGFR among those with CKD defined by eGFR only was 42.5 (IQR 38-50), while mean proteinuria for all was 469 mg (IQR 325-862). Median age was 30 yrs (IQR 26-34), and mean BMI 34.0 (SD 7.1). Coexisting comorbidities included hypertension in 49.3 %, diabetes in 5.1%, heart failure in 1.0%, and lupus in 1.7% of patients. Overall, 87.5% of patients had at least one pregnancy complication. The most common complications were preeclampsia during current pregnancy (86.4%), followed by oligohydramnios (5.8%) and preterm labor (3.8%). Of this group, 65 (22.0%) had a clinic visit with primary care/nephrology post discharge, and 149 (50.3%) had proteinuria checked within 2 years. Mean time to first clinic visit was 29.2 days (SD 15.9).

Conclusions: Pregnant patients with prior CKD and pre-eclampsia are at high risk of pregnancy complications, yet only a small proportion are linked to care. There is a dire need for patient centered medical care among pregnant women with CKD, to improve clinical outcomes.

FR-PO866

Temporal Trends in Pregnant CKD Patients

Priscilla Koirala, Vesna D. Garovic, Andrea G. Kattah. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Chronic kidney disease (CKD) during pregnancy significantly increases both maternal and perinatal morbidity and mortality and the incidence of CKD is increasing in persons of childbearing age. In this study, we aimed to identify changes in demographics and comorbidities over time in people with CKD and pregnancy in our tertiary care practice.

Methods: We identified pregnancies delivered at Mayo Clinic in Rochester, MN from 2010 to 2022 and screened the population for ICD-9/10 codes for CKD present prior to the date of delivery. If more than 1 pregnancy occurred in the study period, we evaluated the first pregnancy with pre-existing CKD. We abstracted data on demographics, comorbidities, body-mass index, etiology and stage of CKD. Maternal and perinatal outcomes were evaluated. We compared characteristics by era –2010 to 2016 vs. 2016 to 2022 – using Fischer's exact test for categorical variables and Kruskal-Wallis test for continuous variables. Correlations were evaluated by Spearman's correlations.

Results: We identified 67 deliveries in patients with pre-existing CKD. Median (interquartile range (IQR)) pre-pregnancy BMI was lower prior to 2016 than after (24 (22-31) vs. 30.5 (24-34.5), p=0.048). There was also a significant trend toward increasing BMI by year of delivery ($\rho = 0.27$, $p = 0.04$). Consistent with this trend was the increasing incidence of CKD due to diabetes (14.8% to to 27.3%, before vs. after 2016), though this was not statistically significant. Six patients had biopsies during pregnancy, between 11 and 24 weeks gestation, that established the cause of CKD and had no complications. There was no increase in the incidence of preeclampsia, preterm delivery or maternal ICU stays by era. The eGFR at baseline was significantly associated with gestational age at delivery ($\rho = 0.32$, $p= 0.01$) and birth weight ($\rho = 0.30$, $p = 0.02$).

Conclusions: We found that pre-pregnancy BMI has been increasing over time in patients with CKD. Additionally, worse baseline kidney function was associated with earlier gestational age at delivery and lower birth weight in infants. Given that obesity impacts both pregnancy and CKD health and that there are more obesity treatments available, more investigations should be done to understand whether treatment of obesity prior to conception could impact outcomes of pregnancy in patients with CKD.

FR-PO867

Uric Acid and Risk of Preeclampsia: A Mendelian Randomization Study

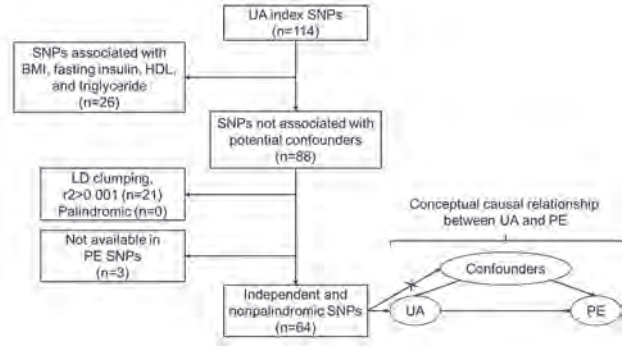
Yitao Lin, Yixin Ma, Lubin Xu, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Maternal serum uric acid (UA) is observationally associated with preeclampsia. However, whether elevated uric acid is a marker of the disease or a causal factor remains unknown. We conducted a two-sample Mendelian randomization (MR) analysis to explore the potential causal effect of UA on preeclampsia.

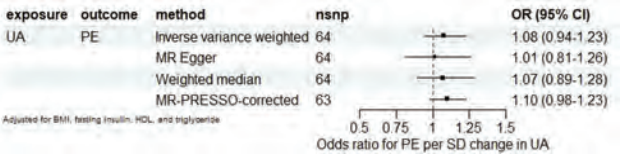
Methods: Summary statistics for UA were from a meta-analysis of genome-wide association studies involving 288,649 individuals of European ancestry, while summary statistics for preeclampsia or eclampsia (PE) were from the FinnGen consortium with 6,436 cases and 176,113 controls. Independent SNPs strongly associated with UA were selected as instrumental variables in causal inference, removing the confounders influencing PE, such as BMI, fasting insulin, HDL, and triglyceride. We applied the inverse variance weighted (IVW) method as the primary analysis and applied MR Egger, weighted median, and MR-PRESSO to evaluate the results. We calculated F statistics to detect weak instrument bias and calculated the power of the MR analysis.

Results: The four MR methods did not reveal the significant causal effect of UA on PE (IVW: OR, 1.08; 95% CI, 0.94-1.23; MR Egger: OR, 1.01; 95% CI, 0.81-1.26; weighted median: OR, 1.07; 95% CI, 0.90-1.27; MR-PRESSO: OR, 1.10; 95% CI, 0.98-1.26). F statistics for individual SNP and overall SNPs were all greater than 10, indicating that weak instrument bias was low. The MR analysis had 48.7% power to detect an OR of 1.1.

Conclusions: This MR study did not support the causal effect of UA on PE.



Selection of instrumental variables.



MR analyses of the causal effect of UA on PE.

FR-PO868

Kidney Hyperfiltration Is Associated with Pregnancy Outcome in Patients with CKD

Shinji Kitajima, Yasunori Iwata, Tadashi Toyama, Akinori Hara, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa Daigaku Fuzoku Byoin, Kanazawa, Japan.*

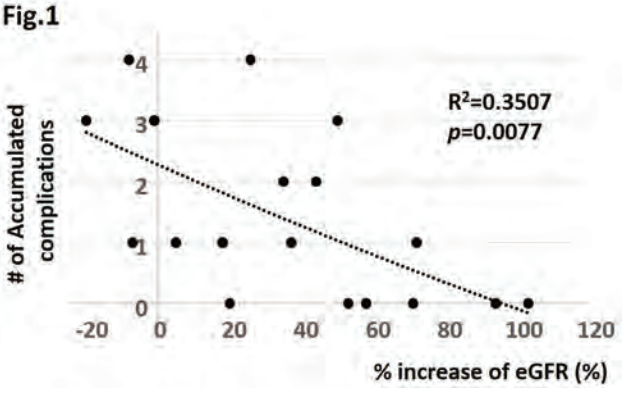
Background: While major population of chronic kidney disease (CKD) is older patients, some population of younger patients are also suffered from CKD. The increased risks of adverse pregnant outcomes were reported in CKD patients. In fact, the frequency of adverse pregnancy outcome is increased in accordance with the severity of kidney dysfunction. In healthy kidney, hemodynamics shifts to hyper-dynamic state during pregnancy. However, details of hemodynamics during pregnancy and its effects for pregnancy outcome are not clear in CKD patients. Therefore, we explored the association between kidney function and pregnancy outcome in CKD patients in this study.

Methods: We retrospectively enrolled 21 CKD patients with pregnancy. The patients visited or were admitted to the Department of Nephrology and Laboratory Medicine and/or Department of Obstetrics in Kanazawa University between 2004 and 2018. The association between kidney function, especially hyperfiltration during pregnancy and adverse pregnancy outcome was evaluated.

Results: The patients without adverse pregnancy complication showed higher eGFR than those with complication during pregnancy period. The increase of estimated glomerular filtration rate (eGFR) during pregnancy is associated with good pregnancy outcome in CKD patients(Fig.1). Even in patients with high eGFR in pre-pregnancy, the absence of increase of eGFR during pregnancy is associated with adverse pregnancy events.

Conclusions: The increase of eGFR during pregnancy was associated with good outcome in CKD patients. Further studies may raise the possibility that assessment of kidney function during pregnancy may be useful marker for the prediction of the pregnancy outcome in CKD patients.

Fig.1



The % increase of eGFR inversely correlated with the numbers of accumulated complications.

FR-PO869

Measurement of Kidney Function and Adverse Pregnancy Outcomes

Anika Lucas, Yixuan Feng, Christina M. Wyatt, Benjamin A. Goldstein. *Duke University School of Medicine, Durham, NC.*

Background: Although it is estimated that 3% of women of childbearing age have kidney disease, there are no guidelines for routinely testing patients for kidney disease in the United States. Our objectives included identifying patients who received 1st and 2nd trimester serum creatinine measurements and evaluating rates of adverse pregnancy outcomes by level of kidney function.

Methods: Pregnant patients with serum creatinine measurements in the 1st and 2nd trimesters of pregnancy were identified in the electronic health record from 2014 to 2019. The 2021 Chronic Kidney Disease Epidemiology Collaboration Equation was used to calculate estimated glomerular filtration rate. Patients were divided into eGFR strata based on previously established eGFR cutoffs. Adverse pregnancy outcomes of interest included low birth weight, preterm birth, gestational hypertension, preeclampsia and a composite outcome.

Results: We identified 6460 patients who had creatinine measurements in the 1st trimester, representing 27% of patients receiving care during the 1st trimester. We further

identified 5268 patients with a 2nd trimester creatinine, only 22% of patients receiving care in the 2nd trimester. Patients who received 1st trimester creatinine measurements were more likely to be <35 years old, Black and from disadvantaged areas. Patients with eGFR <90 ml/min/1.73 m² in the 1st and 2nd trimesters of pregnancy had the highest rates of preterm birth. Patients with eGFR>150 ml/min/1.73 m² had the highest rates of adverse outcomes, though a very small portion of the population.

Conclusions: Less than 1 in 3 patients had serum creatinine measurements available during the 1st and 2nd trimesters of pregnancy. More data is needed to evaluate the utility of creatinine measurements in pregnancy.

Maternal Exposure to Tetrahydrocannabinol (THC) During Pregnancy Increases Kidney Damage in Mouse Offspring

Sahar Emami Naeini, Evila Salles, Bidhan Bhandari, Karim M. Saad, Sholeh Rezaee, Ahmed A. Elmarakby, Jack C. Yu, Lei Wang, Babak Baban. *Augusta University, Augusta, GA.*

Background: Maternal use of cannabis during pregnancy has been associated with adverse effects on fetal development. However, little is known about the impact of maternal cannabis use on kidney development in offspring. In this study, we investigated the effects of maternal exposure to placebo, CBD, and THC inhalers on kidney damage in mouse offspring.

Methods: Pregnant mice were randomly assigned to receive either a placebo, CBD, or THC inhaler throughout pregnancy. Offspring kidneys were collected at birth and evaluated for kidney damage using the Kim-1 antibody. The percentage of Kim-1 was measured using flow cytometry.

Results: Kim-1 expression higher in THC treated group compared to the placebo and CBD groups, suggesting more kidney injuries in THC treated animals.

Conclusions: Our findings suggest that maternal exposure to THC during pregnancy may increase the risk of kidney damage in offspring. These results highlight the need for further research on the potential long-term effects of cannabis use during pregnancy.

FR-PO871

Practice Patterns of Nephrologists Who Care for Pregnant Patients with CKD

Nada Alamri, Mohammad Almomen, Amber O. Molnar, Catherine M. Clase, Anna T. Mathew. *Division of Nephrology, McMaster University, Hamilton, ON, Canada.*

Background: Chronic kidney disease (CKD) increases adverse pregnancy events such as pre-eclampsia, preterm delivery, and progression of maternal CKD. While live birth rates among pregnant people with kidney disease have increased, these pregnancies remain a high risk, emphasizing the critical need for advanced understanding and management strategies. Data on Canadian nephrologist practice patterns and center-specific strategies to improve outcomes for pregnant people with CKD are limited. This study used survey methodology to assess practice patterns and policies in this area.

Methods: We conducted a national, cross-sectional survey to assess the practice patterns of Canadian nephrologists caring for pregnant people with CKD. Following literature review, we developed a list of items covering key aspects of CKD management in people who are pregnant, including pre-conception counseling, multispecialty team collaboration and post-transplant care. Items were refined and deduplicated through iterative review by team members. The survey was distributed through professional networks. The responses were analyzed descriptively and key findings were presented as percentages. Additionally, the results for each aspect of the questionnaire were evaluated in light of existing recommendations.

Results: The survey response rate was 71% (25/35). Of the responding nephrologists, 76% identified as women, and 52% had been in practice between 10 and 19 years. Regarding multispecialty care, 36% reported having a full team, 40% had some team elements, and 24% had no team. Individualization of patient care was the most common practice, as opposed to a conventional or standardized approach. This preference for individualization extended to offering pre-natal genetic counselling, antenatal kidney biopsy and antibiotic prophylaxis, and post-partum ACE inhibitor re-initiation.

Conclusions: Our study is the first to assess the practice patterns and policies of Canadian nephrologists caring for pregnant people with CKD. We found important variations in obstetric nephrology care, and that the majority of programs did not have a full multispecialty team. These results emphasize an opportunity to improve care through the creation of formal multidisciplinary teams and the consistent adoption of evidence-based policies.

FR-PO872

Can ChatGPT Keep up with Obstetric and Gynecologic Nephrology? Assessing Its Proficiency in Key Concepts

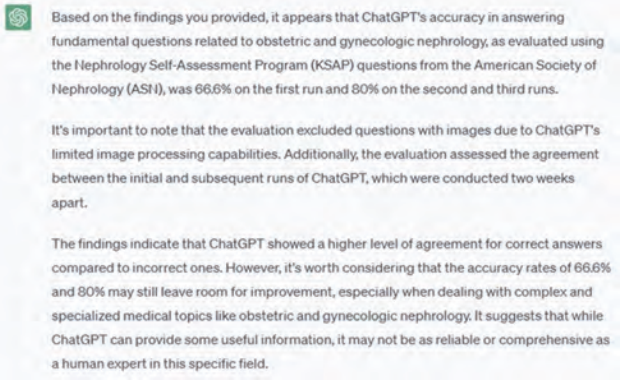
Maria Lourdes Gonzalez Suarez, Vesna D. Garovic, Andrea G. Kattah, Iasmina Craici, Charat Thongprayoon, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ChatGPT is a language model known for its ability to generate responses similar to those of humans across a variety of tasks. Despite ongoing discussions about the potential of ChatGPT to replace clinicians in clinical contexts, its ability to address essential concepts in a multidisciplinary field, such as obstetric and gynecologic nephrology, has not been thoroughly evaluated. The purpose of this study is to evaluate ChatGPT's proficiency in addressing fundamental questions related to the diagnosis, treatment, and management of hypertension in pregnancy.

Methods: Using the Nephrology Self-Assessment Program (NephSAP) issues V15N2 and V21N4 (questions 25-30), we conducted a study of ChatGPT's accuracy in answering fundamental questions related to obstetric and gynecologic nephrology. Questions with images were excluded. Analysis included 30 questions. Each question set was run 3 times using ChatGPT (version Mar 14, OpenAI), and we evaluated the agreement between the initial and subsequent runs, which were conducted 2 weeks apart.

Results: ChatGPT had accuracies of 66.6% on the 1st, 80% on the 2nd and 3rd runs for the NephSAP questions. We found that ChatGPT demonstrated a higher level of agreement for correct answers than for incorrect ones. However, it is important to note that the accuracy rates of 66.6% and 80% may still have room for improvement, particularly when dealing with complex and specialized medical topics like obstetric and gynecologic nephrology. ChatGPT itself acknowledged these results (**Figure 1**).

Conclusions: ChatGPT's proficiency in addressing fundamental queries related to obstetric and gynecologic nephrology management is below the minimum passing threshold of 75% set by the ASN for nephrologists in its 1st attempt, with an accuracy rate of 66.6%. While ChatGPT can provide some useful information, it may not be as reliable or comprehensive as a human expert in this specific field.



Based on the findings you provided, it appears that ChatGPT's accuracy in answering fundamental questions related to obstetric and gynecologic nephrology, as evaluated using the Nephrology Self-Assessment Program (KSAP) questions from the American Society of Nephrology (ASN), was 66.6% on the first run and 80% on the second and third runs.

It's important to note that the evaluation excluded questions with images due to ChatGPT's limited image processing capabilities. Additionally, the evaluation assessed the agreement between the initial and subsequent runs of ChatGPT, which were conducted two weeks apart.

The findings indicate that ChatGPT showed a higher level of agreement for correct answers compared to incorrect ones. However, it's worth considering that the accuracy rates of 66.6% and 80% may still leave room for improvement, especially when dealing with complex and specialized medical topics like obstetric and gynecologic nephrology. It suggests that while ChatGPT can provide some useful information, it may not be as reliable or comprehensive as a human expert in this specific field.

ChatGPT response on its performance

Terminal Complement Activation and Regulation in Placentas of Women with Kidney Transplantation and CKD

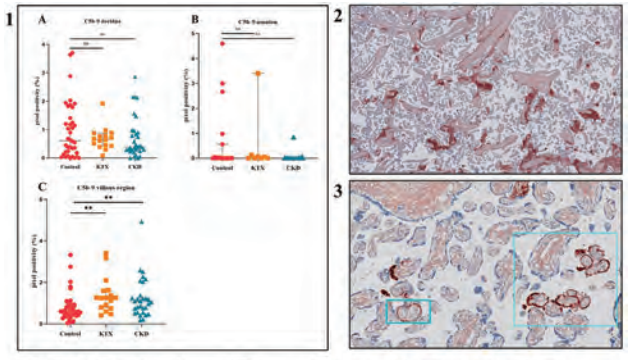
Gesa Tiller,[1] Firas F. Alkaff,[1,2] G. G. Talen,[1] Hanna M. Komdeur,[1] Jelmer Prins,[1] Margriet de Jong,[1] Mirthe H. Schoots,[1] Jacob Van Den Born,[1] Stefan P. Berger.[1] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]Universitas Airlangga Fakultas Kedokteran, Surabaya, Indonesia.*

Background: Women with chronic kidney disease (CKD) or kidney transplant (KTX) are at increased risk of adverse pregnancy outcomes, including pre-eclampsia, intrauterine growth restriction and premature birth. The role of the complement and its relation to placental histopathology has not been studied in this group. We evaluated terminal complement activation and regulation in KTX, CKD and control placentas.

Methods: We retrospectively included 92 placentas, with 33 placentas from CKD, 18 from KTX women, and 42 placentas from healthy pregnancies. Histopathological reports were systematically re-evaluated for lesions scores. Immunohistochemical analysis for terminal complement C5b-9 and its corresponding regulator CD59 were performed in consecutive tissue slides.

Results: C5b-9 expression was pronounced in the villi area of CKD and KTX placentas ($p<0.01$) (1C), with localization of C5b-9 in areas of villous fibrinoids (2). In eight placentas, we noted a unique expression of C5b-9 along the syncytiotrophoblastic layer (3). All of these eight placentas were derived from KTX/CKD women, who were more often treated with tacrolimus during pregnancy ($p<0.05$), and had higher overall expression of C5b-9 in the villous region ($p<0.05$). CD59 expression was higher in the CKD group in the decidual ($p<0.01$), and linked to low birth weight ($p=0.03$) and prematurity ($p=0.049$). Local C5b-9, CD59, and CD59/C5b9 ratio were not linked to lesion scores.

Conclusions: Terminal complement activation in the placental villi of women with KTX or CKD is increased, without corresponding alternations in complement regulation. Altered decidual complement regulation might potentially interfere with placentation, possibly accounting for low birth weight and intrauterine growth restriction. Syncytiotrophoblastic C5b-9 in a subgroup of KTX and CKD women might be of clinical relevance and needs further investigation in a larger cohort.



(1) C5b-9 in KTX, CKD and control placentas in decidua, annuco and villi region, quantified as percentage of pixels. (2) Fibrinoid deposition of C5b-9 as dark red staining (3)Villi with syntiotrophpiblastic positivity are indicated by blue squares. All of these 8 placentas with a syncyitiotrophoblastic staining pattern were amongst the KTX/CKD group.*, significant with p<0.05; ** significant with p<0.01; ns, not significant.

Terminal Complement in KTX, CKD and control placentas

FR-PO874

Multi-Omics of Sex-Based Differences in Nephrotoxic Serum Nephritis

Valerie Garcia,[1] Matthew Wright,[1] Esther Liu,[1] Andra Campbell,[1] Andrew O. Kearney,[1] Jennie Lin.[1,2] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Jesse Brown VA Chicago Healthcare System, Chicago, IL.*

Background: Sex-based differences have been observed in the incidence and clinical course of acute kidney injury as well as chronic kidney disease. Compared to males, female patients are more protected from kidney injury and disease progression. Prior studies have identified sexual dimorphism in kidney development and ischemic response, but the mechanisms by which inflammatory stimuli contribute to kidney sex-based differences have not been fully elucidated.

Methods: To examine these differences, we induced nephrotoxic serum (NTS) nephritis in female and male C57BL/6 mice of either 8-12 weeks or 18 months of age. Changes in urine and serum markers were measured, and differences in fibrosis were quantified by Sirius Red staining in kidneys harvested on Day 10. Multi-omics data from matched single nucleus RNA-seq (snRNA-seq) and single nucleus ATAC-seq (snATAC-seq) were generated from those kidneys, with 66,430 nuclei examined.

Results: On Days 4, 7, and 10 after NTS injection, young male mice had significantly higher urinary albumin to creatinine ratio than young females ($p<0.01$), while no differences in albuminuria were seen in aged males vs. females. Although no significant sex-based differences in serum creatinine or renal fibrosis were observed, on a molecular level snRNA-seq revealed major NTS-induced differences in metabolic programs in young male vs. female proximal tubule segments and endothelial cells, and surprisingly few transcriptomic changes in immune cells. Most differentially accessible chromatin regions (DARs) were found in the S3 segment of the proximal tubule with notable motif enrichment for Hnf4a, while DARs in endothelial cells were enriched for Stat3/5 binding motifs. Overall correlation between DARs and differential gene expression across cell populations was 0.54. Despite loss of female renoprotection in aged females, differentially accessible chromatin regions in young females were not enriched in motifs containing estrogen responsive elements, suggesting that cis-regulation by ESR1 is not the direct driver of sex-based differences in NTS nephritis.

Conclusions: Sexual dimorphism in NTS nephritis is characterized by more severe albuminuria in young male mice, likely due to sex-based differences in metabolic pathways in different cell populations rather than direct cis-regulatory function of estrogen receptor binding activity.

Targeting Interleukin-6/Glycoprotein130 Signaling Ameliorates Renal Injury in Polycystic Ovary Syndrome

Samar Rezq,[1,2] Jelina Basnet,[1] Alexandra M. Huffman,[1] Joseph R. Flaherty,[1] Ahmed Abdelhameed,[1] Amira E. Alsemeh,[3] Tolulope E. Asala,[1] Licy Yanes Cardozo,[1] Damian G. Romero.[1] *[1]The University of Mississippi Medical Center, Jackson, MS; [2]Zagazig University Faculty of Pharmacy, Zagazig, Egypt; [3]Zagazig University Faculty of Human Medicine, Zagazig, Egypt.*

Background: Polycystic ovary syndrome (PCOS) usually presents with hyperandrogenism, chronic low-grade systemic inflammation, and renal injury. The inflammatory cytokine Interleukin-6 (IL-6) is involved in the pathogenesis of several renal injury models by activating its soluble receptor (sIL-6R) and a membrane-bound glycoprotein130 (gp130); however, its role in PCOS-mediated renal damage is unknown. We aimed to test the hypothesis that the increases in systemic and renal IL-6 levels, mediate renal injury in PCOS via IL-6/gp130 signaling activation.

Methods: PCOS was induced in three-week-old female mice using dihydrotestosterone (DHT)-filled Silastic tubes (8 mg, SC) or vehicle for 12 weeks. Eight weeks post-induction, the animals were treated with the IL-6/gp130 signaling inhibitor SC144 (10 mg/kg, SC, 3x/week) or its vehicle for 4 weeks. Body weight, fat mass (EchoMRI), kidney weight, the glomerular filtration rate (GFR, transcutaneous fluorescence), as well as the renal injury markers urinary albumin to creatinine ratio (UACR, clinical chemistry analyzer) and NGAL (ELISA) were assessed. Renal gp130 protein and IL-6 mRNA expression were quantified by Western blot and RT-qPCR, respectively. H&E stained renal sections were used for histopathological analysis, whereas Masson trichrome staining was used to assess renal fibrosis.

Results: DHT significantly ($p<0.05$) increased body weight (26.2±0.9 vs. 22.23±0.4 g), fat mass (3.2±0.4 vs. 1.9±0.4 g), kidney weight (1.4-fold), UACR (1,227±420 vs. 404±169 µg albumin/mg creatinine), urinary NGAL (2-fold), and serum IL-6 levels (2.2-fold). DHT also increased the expression of renal gp130 and IL-6 (1.5-fold). The disturbance in the aforementioned parameters was associated with decreased GFR and a worsen renal histological structure with congested glomeruli, exfoliation of luminal epithelial lining, interstitial hemorrhage, and fibrotic changes. SC144 therapy had no significant effects on kidney weight, GFR, or NGAL, but it attenuated DHT-induced increases in fat mass and UACR while decreasing both glomerular and tubular injury and renal fibrosis.

Conclusions: IL-6/gp130 activation plays a significant role in renal outcomes in PCOS and could be targeted as a novel therapeutic approach to ameliorate renal injury in PCOS.

Recovered Parental AKI Results in Dysfunctional Pregnancy and Offspring Programming

Jessica F. Hebert,[1] Jacqueline M. Emathinger,[1] Nicole K. Andeen,[1] Susan B. Gurley,[1] Michael Hutchens.[2,1] *[1]Oregon Health & Science University, Portland, OR; [2]Portland VA Medical Center, Portland, OR.*

Background: Rhabdomolysis-induced acute kidney injury (RIAKI) follows muscular trauma and is observed in people of childbearing age. Although apparent recovery is common, prior AKI increases the risk of renal and reproductive disease. We hypothesized that recovered AKI induces pregnancy complications and developmentally programs offspring disease.

Methods: Procedures were approved by institutional IACUC. Rhabdomyolysis in 8-12 week old C57BL/6J mice was induced via intramuscular injection of 50% glycerol (8 mL/kg); shams were untreated. AKI was assessed 24 hours later via glomerular filtration rate (GFR; uL/min/100g body weight) and repeated 2 weeks post-recovery to establish functional recovery, followed by 1) timed sham/sham and RIAKI/RIAKI matings for pregnancy (gestational day (GD) 16.5) and 2) adult offspring (12 weeks, 6 months) effects. Urine was collected 24 hours before GFR and tissue harvest for later analysis. Statistics were assessed by t-test for 2 group analyses, and 2-way ANOVA with posthoc tests for analyses by sex.

Results: 1) Despite normal GFR pre-pregnancy, recovered RIAKI dams had lower GFR than shams at GD 16.5 ($p<0.01$). Fetoplacental ratio was lower in RIAKI offspring ($p<0.01$) with no difference in litter size but 3x more perinatal death. Albuminuria ($p<0.01$) was observed in RIAKI dams. RIAKI dams had less megalin ($p<0.05$) and more angiotensin II (AngII) in the proximal tubule brush border than shams, with evidence of subcapsular fibrosis. 2) Offspring of recovered RIAKI parents have sexually dimorphic responses related to renal function. GFR was reduced in offspring of both sexes by 6 months (males: $p<0.05$, females: $p<0.01$). Circulating AngII levels were decreased in

plasma from only female RIAKI offspring compared to shams ($p<0.05$); however, adult males from RIAKI pairings gained more weight than sham males between young and middle adulthood ($p<0.05$).

Conclusions: RIAKI poses reproductive risk long after initial apparent recovery, likely due to new proximal tubule dysfunction in the setting of pregnancy after RIAKI. Renal function in pregnancy, particularly essential function of the proximal tubule via megalin and AngII, is altered by prior RIAKI and developmentally programs offspring with adult-onset reduced GFR, and older male offspring with increased weight gain.

FR-PO877

Prevalence of CKD in Older Adults by Different Filtration Markers in eGFR Equations

Carina M. Flaherty,[1] Aditya L. Surapaneni,[1] Morgan Grams,[1] Jesse C. Seegmiller,[2] Josef Coresh,[3] Shoshana Ballew.[3] *[1]NYU Langone Health, New York, NY; [2]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN; [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: The prevalence of chronic kidney disease (CKD) is known to increase with age, but few studies investigate age specific prevalence and progression of CKD in populations over 65. Glomerular filtration rate (GFR) can be estimated using different filtration markers that have not been thoroughly studied in older populations, opening the door for research on how these markers may differentially characterize the prevalence and progression of CKD in older age.

Methods: The study population included a community-based sample of 6,393 White and Black participants aged 65-100 stratified into 5-year age categories from Visit 5 of the Atherosclerosis Risk in Communities Study (ARIC). GFR was estimated using CKD-EPI (2021) and Inker et al (2021) equations, and by the following combinations of filtration markers: creatinine (eGFRcr), cystatin C (eGFRcys), both (eGFRcr-cys), and combined with beta-2-microglobulin (eGFRcr-cys-b2m). We calculated the proportion of participants with eGFR <60 ml/min/1.73 m^2 by each marker equation across age strata at Visit 5 (2011-2013), 6 (2016-2017), and 7 (2018-2019), and calculated the proportion of participants with a 30% decline in eGFR at ARIC Visit 6 or 7, across age strata.

Results: Average age at Visit 5 was 75.8 years (SD, 5.3). Mean eGFRcr, eGFRcys, eGFRcr-cys, and eGFRcr-cys-b2m were 71, 61, 68, and 65 ml/min/1.73 m^2, respectively. The proportion with eGFR <60 was lowest with eGFRcr and highest with eGFRcys for all age groups at all visits, and prevalence increased with age for all markers (Figure 1). More people with eGFRcr ≥60 were reclassified to <60 when using eGFRcys (33%) compared with eGFRcr-cys (12%) or eGFRcr-cys-b2m (18%). The proportion with 30% eGFR decline was lowest with eGFRcr and highest with eGFRcys, with greater incidence in older age groups for all markers.

Conclusions: The prevalence and progression of CKD increases with age but varies depending on filtration marker used. Creatinine underestimates CKD compared to other filtration markers.

FR-PO878

Estimated Glomerular Filtration Rate Thresholds Associated with Poor Long-Term Outcomes in the Elderly with Diabetes

Kyungho Lee, Subin Hwang, Junseok Jeon, Hye Ryoun Jang, Wooseong Huh, Yoon-Goo Kim, Jung eun Lee. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Age-adapted estimated glomerular filtration rate (eGFR)-based chronic kidney disease (CKD) criteria was recently proposed, which has been supported by the fact that mortality risks start to increase at GFR <45 mL/min/1.73m^2 in the elderly. However, the eGFR threshold for mortality and kidney outcomes in elderly with diabetes was less understood. We aimed to evaluate eGFR categories that raise the risk of mortality and end-stage kidney disease (ESKD) by age group, using an 8-year follow-up cohort of elderly diabetic patients.

Methods: Elderly patients (≥65 years) with type 2 diabetes who visited our outpatient diabetes center during 2009 were identified and followed up until 2017. Patients were categorized into four groups per their CKD-EPI equation-based eGFR: ≥60, 45 to 59, 30 to 44, and 15 to 29 mL/min/1.73m^2. Cox proportional hazard model for all-cause mortality and competing-risk analysis for ESKD (with a competing event of pre-ESKD death) were performed.

Results: Among 3,065 subjects, 19%, 8%, and 2% patients had eGFR 45 to 59, 30 to 44, and 15 to 29 mL/min/1.73m^2 at baseline, respectively. After adjusting multiple clinical covariates, including blood pressure, diabetes duration, urine albumin/creatinine ratio, HbA1c, serum cholesterol levels, and comorbidity index, patients with eGFR 30 to 44 and 15 to 29 mL/min/1.73m^2 had 1.51-fold (95% CI 1.17–1.95, P <.001) and 2.66-fold (1.87–3.79, P <.001) greater risks of death, respectively, whereas patients with eGFR 45 to 59 mL/min/1.73m^2 had a comparable risk (1.18, 0.96–1.45, P = 0.127) to those with eGFR ≥60 mL/min/1.73m^2. Substitution hazard ratios for ESKD were 2.29 (1.41–3.71, P = 0.001), 5.25 (3.27–8.41, P <.001), and 16.74 (9.73–28.80, P <.001) in patients with eGFR 45 to 59, 30 to 44, 15 to 29 mL/min/1.73m^2, respectively. In a subgroup of patients 75 or older (n=800), patients with eGFR 45 to 59 mL/min/1.73m^2 showed comparable risks for both ESKD and mortality, and ESKD risk started to increase from eGFR <45 mL/min/1.73m^2.

Conclusions: Reduced eGFR <60 mL/min/1.73m^2 predicted an increased risk of ESKD in elderly diabetic patients, suggesting that the current traditional eGFR threshold appears feasible. However, in patients ≥75 years, eGFR ranging from 45 to 59 mL/min/1.73m^2 had little effect on long-term outcomes for both mortality and ESKD.

FR-PO879

Large Discordances Between Creatinine (Cr) and Cystatin C-Based Estimated Glomerular Filtration Rates (eGFR) Are Associated with Adverse Outcomes in a Nationally Representative Cohort of Older Adults

Nurit S. Katz, Meghan L. Rieu-Werden, Sachin J. Shah, Meghan E. Sise. *Mass General Brigham Inc, Boston, MA.*

Background: Creatinine based eGFR may be overestimated in adults with sarcopenia. While the combined equation CKD-EPI eGFR-CRE-CYS may be more accurate on a population level, patients whose eGFR-CYS is significantly lower than eGFR-CRE (eGFR discordance) may be at high risk for adverse outcomes.

Methods: In a longitudinal cohort study of adults 65+ yrs, from the Health and Retirement Study 2016 Venous Blood Study, we calculated eGFR-CRE and eGFR-CYS with current CKD-EPI. Outcomes included fall, hip fracture, hospitalization, and death 2 years from baseline assessment. We plotted the relationship between eGFR discordance and likelihood of outcomes in each ventile using a loess plot with span 75%. We fit separate multivariable logistic regression to determine the association between large eGFR discordances (i.e. >30%) and each outcome, adjusted for confounders.

Results: There were 5574 participants with a mean age of 75 ±7.2 yrs, 58% women, 80% white, and 10% Hispanic. 35% had chronic kidney disease (CKD) (eGFR-CRE-CYS <60 ml/min/1.73m^2). 30% had eGFR-CYS >30% lower than eGFR-CRE. We found increasing rates of falls, hospitalizations, and death at higher eGFR discordances **[Figure 1]**. In adjusted analyses, large eGFR discordance was associated with a significantly greater odd of fall, hospitalization, and death **[Figure 2]**.

Conclusions: Older adults with a large eGFR discordances have a greater risk of adverse outcomes, possibly due to misdosing of renally cleared medications, occult CKD or sarcopenia.

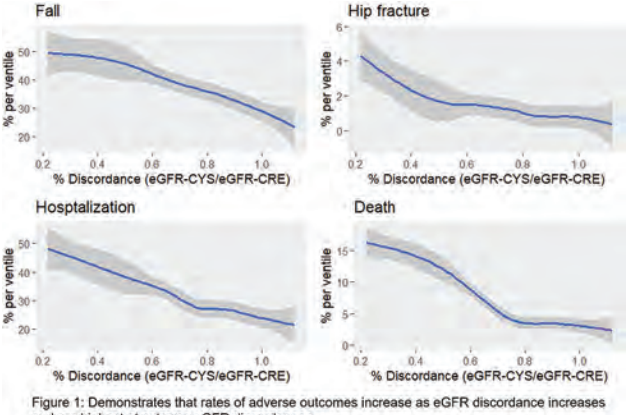

Figure 1: Demonstrates that rates of adverse outcomes increase as eGFR discordance increases and are highest at extreme eGFR discordances.

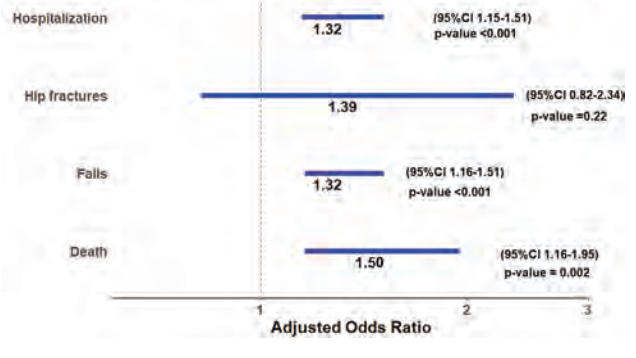
Figure 2: Adjusted odds ratio for adverse outcomes in participants with eGFR discordance > 30%



FR-PO880

Serum and Urine Metabolites and Kidney Function in an Older Community-Based Population

Wan-Jin Yeo,[1] Aditya L. Surapaneni,[1] Jingsha Chen,[2] Peggy Sekula,[3] Anna Kottgen,[2,3] Bing Yu,[4] Casey Rebholz,[2,5] Josef Coresh,[2] Morgan Grams,[1] Sushrut S. Waikar,[6] Eugene P. Rhee,[7] Insa M. Schmidt,[6] Pascal Schlosser.[2,3]
[1]NYU Langone Health, New York, NY; [2]Johns Hopkins University Department of Epidemiology, Baltimore, MD; [3]Institute of Genetic Epidemiology, University of Freiburg, Freiburg, Germany; [4]Department of Epidemiology, Human Genetics, and Environmental Sciences, School of Public Health, University of Texas Health Science Center at Houston, Houston, TX; [5]Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD; [6]Boston University School of Medicine, Boston, MA; [7]Massachusetts General Hospital Division of Nephrology, Boston, MA.

Background: Metabolites represent a cellular read-out of ongoing processes underlying states of health and disease.

Methods: We evaluated cross-sectional and longitudinal associations between 1254 serum and 1398 urine metabolites (untargeted, Metabolon HD4, 713 present in both biofluids) and kidney function in 1613 participants of the Atherosclerosis Risk in Communities (ARIC) Study (visit 5; mean age 76 years, 56.1% women, mean eGFR and urine albumin-to-creatinine levels (ACR) of 62 mL/min/1.73m^2 and 4 mg/g, respectively). All analyses were comprehensively adjusted including for baseline eGFR and ACR.

Results: In cross-sectional analysis, 674 serum and 542 urine metabolites were associated with eGFR (p<4E-5), including 245 in both biofluids. Fewer metabolites (75 serum and 92 urine metabolites, including 7 shared across both biofluids) were associated with ACR. Five metabolites, including 2 unnamed metabolites, were significantly associated with both eGFR and albuminuria (Table 1). In longitudinal analysis, higher levels of N2,N2-dimethylguanosine and X-25422 were associated with greater risk of eGFR decline (defined as 40% decrease over a mean follow-up of 6.6 years) and increase in albuminuria (defined as doubling of UACR levels) in both serum and urine (p<0.05). Next, we estimated the relative fractional excretion (rFE) of metabolites shared in both biofluids (713). The rFE of 482 metabolites had negative associations with eGFR, whereas 5 metabolites had positive associations (p<7E-5). The most negative associations with eGFR were for 5-methylthioribose and 5-oxoproline and the most positive was for gamma-glutamylglutamine. Thirty-eight rFE of metabolites were associated with eGFR decline (p<0.05), including guanine, S-methylcysteine sulfoxide, and hypoxanthine which were protective for eGFR decline, but none met Bonferroni significance (p<5E-5).

Conclusions: In summary, untargeted metabolomic profiling can identify metabolites of interest in kidney disease. Notably, the metabolomic coverage was markedly increased by the inclusion of both matrices.

FR-PO881

Perceptions of Shared Decision-Making and Preferences for Engagement Among Older Adults with CKD: A Mixed-Methods Study

Kristen Kennefick,[1] Daniel E. Weiner,[2] Keren Ladin.[1] DART Team. *[1]Tufts University, Medford, MA; [2]Tufts Medical Center, Boston, MA.*

Background: Older adults with advanced chronic kidney disease (CKD) face preference-sensitive decisions regarding dialysis initiation. Although shared decision-making (SDM) is recommended, clinicians are unsure how to best facilitate SDM and few CKD patients report experiencing SDM. This study characterizes clinician perspectives on SDM and patient preferences for engagement.

Methods: A mixed-method, longitudinal analysis of surveys and semi-structured interviews was conducted with English-speaking adults 70 years or older with CKD stages 4-5 in Boston, Chicago, San Diego, or Portland (ME) as part of the Decision Aid for Renal Therapy (DART) Trial. Patients' preferences for engagement were measured using the validated Control Preferences Scale (CPS), which categorizes patients as preferring active, collaborative, or passive engagement. Semi-structured interviews were conducted with a subset of purposively sampled patients and clinicians at these four sites. We used descriptive statistical analysis to examine quantitative data, and thematic and narrative analyses to examine qualitative data.

Results: Among 363 patient-participants at baseline, 42% were female, 13% identified as Black, and 21% had high school education or less. Overall, 92% preferred to play an active or collaborative role in decision-making. CPS preferences were stable throughout; at the individual level, only 4.6% demonstrated a major change (active to passive or passive to active) between baseline and first follow-up. A subset of 75 participants (44 patients and 31 clinicians) completed qualitative interviews, contributing to four qualitative themes: 1) active and collaborative control preferences tied to patient engagement; 2) clinicians constrain information flow; 3) patients with collaborative and active preferences want free-flowing information; and 4) clinician responsiveness to control preference tied to patient satisfaction.

Conclusions: Older adults with advanced CKD overwhelmingly preferred collaborative or active roles, with more prognostic information earlier in the process. Utilizing the single-item CPS may be a simple and effective way for clinicians to assess patients' preferred level of engagement and determine the flow of information.

FR-PO882

Patient and Clinician Perspectives on an Advance Care Planning Decision Aid for Older Patients with CKD: Decision Aid for Renal Therapy (DART)-Advance Care Planning (ACP)

Kristen Kennefick,[1] Daniel E. Weiner,[2] Keren Ladin.[1] DART Team. *[1]Tufts University, Medford, MA; [2]Tufts Medical Center, Boston, MA.*

Background: Among Medicare beneficiaries 65 and older with chronic kidney disease (CKD), adjusted mortality is over twice as high compared to age-matched non-CKD counterparts. However, few older adults with CKD complete advance care plans (ACP), which can align care with patient preferences. We assessed the accessibility and feasibility of a decision aid tailored to ACP for other populations have been shown to increase knowledge of ACP and readiness for end-of-life conversations.

Methods: Qualitative study using semi-structured interviews (March 2022-March 2023) with purposively sampled patients (CKD stage 4-5 patients, age ≥50) and clinicians (nephrologists). Participants viewed DART-ACP modules prior to interviews. Patient participants were approached in participating nephrology clinics in Greater Boston. Audio recordings were transcribed verbatim, and content and thematic analysis were conducted.

Results: 61 participants (29 clinicians; 33 patients) completed interviewed. Among clinicians, 38% were women and 41% were from the Northeast. Among patients, 36% were women, 39% identified as Black, and mean age was 70 ± 9 years. Four themes emerged during thematic analysis: 1) acceptability of DART-ACP among patients and clinicians; 2) difficulty in understanding granularity and impact of end-of-life decisions; 3) demand for information on palliative care; and 4) empowering patients to document wishes. DART-ACP was described as clear, approachable, and informative for patients across demographic categories and among most clinicians. DART-ACP was acceptable even among patients who reported being hesitant about ACP. Suggestions for improvement included incorporating lived experiences, integrating ACP documents into the modules, and including information for carepartners.

Conclusions: Patients and clinicians found DART-ACP accessible and useful in the context of dialysis decision-making, especially information about palliative care. Participant feedback will inform tailoring DART-ACP for clinical use.

FR-PO883

Understanding Patient Engagement in Advance Care Planning

Kathryn Ducharlet,[1,2] Dov Degen,[2] Dao A. Nguyen,[2] Lisa Colquhoun,[2] Samantha J. Brean,[2] Kelly Habjan,[2] Leeroy William,[2,1] Lawrence P. McMahon.[1,2] *[1]Monash University Eastern Health Clinical School, Box Hill, VIC, Australia; [2]Eastern Health, Box Hill, VIC, Australia.*

Background: Approaches enabling shared decision-making for serious illness and end-of-life care with kidney patients are variable with significant challenges. There is no systematic approach to introduce these conversations and data understanding patient engagement is limited.

Methods: An interventional mixed methods study aimed to understand patient perspectives of advance care planning (ACP) at a single kidney care centre in Australia (Figure 1). A 1-hour conversation between kidney clinicians (nurse or doctor) and patients provided information regarding kidney health, and ACP concepts were introduced. Descriptive statistics and paired t-tests estimated the effect of the intervention and qualitative data were analysed thematically.

Results: Between December 2022 and April 2023, 47 kidney patients were consented: 40 in Part A and 7 in Part B. The average age was 80 years, 57% male, 57% Australian-born, 81% English speaking, 37% CKD, 47% satellite dialysis, 14% home dialysis. Participants' perceived kidney disease related self-efficacy was high, with few symptoms of depression or anxiety. Median time between interview and follow up feedback was 6 weeks [IQR 4,9]. During this period 64% of people reported having an ACP conversation with family or caregivers. The intervention showed an improvement in mean "readiness to formally ask someone to be a medical decision maker" (3.2[1.9] to 3.8[1.6], p=0.04). No improvement on other dimensions of ACP engagement was found. Preliminary analysis of qualitative data highlighted disabling patient factors that hindered ACP engagement, including: 1. Perceived cultural and physical barriers to communication. 2. Coping strategies focused on living in the present. 3. Differing perceptions of the utility of end-of-life discussions. 4. Distress and fear at the prospect of serious illness or death.

Conclusions: These findings suggest that the intervention facilitated conversations between patients and their of medical decision makers. This study also highlights the social and psychological factors which impact patient engagement in future treatment planning.

The Current Status of Advance Care Plan and Dialysis Withdrawal in Elderly Hemodialysis Patients in South Korea

Jangwook Lee,[1] Woo Yeong Park,[2,3] Jang-Hee Cho,[4,5] Byung chul Yu,[6] Miyeun Han,[7] Sang Heon Song,[8] Jae Won Yang,[9,10] Sungjin Chung,[11,12] Yu Ah Hong,[13,14] Young Youl Hyun,[15,16] Eunjin Bae,[17] In O Sun,[18] Hyunsuk Kim,[19,20] Won Min Hwang,[21] Soon hyo Kwon,[22] Kyung Don Yoo,[23,24] Jiyun Jung,[1] Jae Yoon Park,[1] Sung Joon Shin.[1] Korean Society of Geriatric Nephrology (KSGN). *[1]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [2]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [3]Keimyung University School of Medicine, Daegu, Republic of Korea; [4]Kyungpook National University Hospital, Daegu, Republic of Korea; [5]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [6]Soonchunhyang University Hospital Bucheon, Bucheon, Gyeonggi-do, Republic of Korea; [7]National Medical Center, Seoul, Republic of Korea; [8]Pusan National University School of Medicine, Yangsan, Republic of Korea; [9]Wonju Severance Christian Hospital, Wonju, Gangwon-do, Republic of Korea; [10]Yonsei University Wonju College of Medicine, Wonju, Republic of Korea; [11]Catholic University of Korea Yeouido Saint Mary's Hospital, Seoul, Republic of Korea; [12]The Catholic University of Korea School of Medicine, Seoul, Republic of Korea; [13]Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Daejeon, Republic of Korea; [14]The Catholic University of Korea School of Medicine, Seoul, Seoul, Republic of Korea; [15]Kangbuk Samsung Hospital, Jongno-gu, Seoul, Republic of Korea; [16]Sungkyunkwan University School of Medicine, Suwon, Republic of Korea; [17]Gyeongsang National University Changwon Hospital, Changwon, Gyeongsangnam-do, Republic of Korea; [18]Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea; [19]Chuncheon Sacred Heart Hospital, Chuncheon, Gangwon-do, Republic of Korea; [20]Hallym University College of Medicine, Chuncheon, Gangwon, Republic of Korea; [21]Konyang University Hospital, Daejeon, Republic of Korea; [22]Soonchunhyang University Hospital, Seoul, Republic of Korea; [23]Ulsan University Hospital, Ulsan, Republic of Korea; [24]University of Ulsan College of Medicine, Ulsan, Republic of Korea.*

Background: Only a few studies have investigated end of life care or experiences of elderly hemodialysis patients. We aimed to explore advance care plan and dialysis withdrawal in elderly hemodialysis patients at the end of life in South Korea.

Methods: We analyzed medical data of elderly dialysis patients (≥70 years old) who died between January 1, 2010 and December 31, 2017, at 10 university hospitals in the Korean Society of Geriatric Nephrology (KSGN). We examined causes of death, the presence of advance care plan, and clinical variables related to dialysis and life-sustaining treatments.

Results: Of 404 deaths, 57.7% were male and the mean age was 77 years. Dialysis was maintained for an average of 792 days. The most common causes of death in elderly dialysis patients were infection, cardiovascular disease and malignancy accounting for 48.8%, 20% and 8.7% of cases, respectively. The overall rate of advance care planning including Do-Not-Resuscitate orders in these patients reached to 70%. Despite of the explicit expressions against life-sustaining treatment, ventilator care was provided in 45.3% and cardiopulmonary resuscitation was performed in 33.4% of the patients. Moreover, more than half (63.9%) continued to receive hemodialysis until three days before death (91.2% until two weeks prior to death).

Conclusions: Our findings imply the importance to respect patients' preferences and advance care plan when it comes to end of life care in elderly dialysis patients. Shared decision making could play a key role in that regard to resolve the discrepancy between advance care plan and actual provision of life-sustaining treatments at the end of life.

Acceptability of a Palliative Care Intervention for Older Adults Facing Dialysis Decisions: A Qualitative Study of Patients, Caregivers, and Their Nephrologists

Fahad Saeed,[1] Rebecca J. Allen.[2] *[1]University of Rochester Medical Center Department of Medicine, Rochester, NY; [2]Mount St. Joseph University, Cincinnati, OH.*

Background: Older adults in the US often receive kidney therapy (KT) that doesn't align with their goals. Palliative care specialists are experts in decision-making, but few palliative care decision-support interventions exist for older adults with advanced chronic kidney disease.

Methods: A trained research coordinator interviewed patients and nephrologists participating in the CKD-EDU study. Three coders analyzed the data using a thematic analysis approach to identify salient themes around the acceptability of the intervention and nephrologists' views on palliative care.

Results: The study included 20 patients with a mean age of 80.5 ± 4.9 years, of whom 10 (52%) were women, 16 (76%) were White, and 17 (81%) had an education level of ≥12th grade or higher. The study also included 24 nephrologists with a mean age of 43 ± 9.5 years, of whom 15 (63%) were men, 14 (58%) were White, and 12 (50%) had 0-5 years of experience in nephrology. Patients and caregivers found the intervention valuable due to personalized care, assistance with making decisions, and help with understanding prognostic information. Nephrologists appreciated support for their patients in making therapy decisions, assistance with symptom management, and help with a conservative kidney management pathway.

Conclusions: Both patients/caregivers and nephrologists found the intervention for kidney therapy decision-making to be acceptable and useful. Future studies assessing the effectiveness and implementation of palliative care services in routine clinical care are needed.

FR-PO886

Concurrent Hospice in a Veterans Affairs Dialysis Unit: A Single-Center Experience

Eric Magliulo,[1] Kaeli Samson,[1] Saber M. Khan,[2] Nathan C. Birch,[1,2] Ketki K. Tendulkar.[1] *[1]University of Nebraska Medical Center, Omaha, NE; [2]Creighton University School of Medicine, Omaha, NE.*

Background: Patients with end stage kidney disease experience significant underutilization of hospice services. The Centers of Medicare and Medicare Services allows for enrollment in concurrent hospice and dialysis. We sought to share our experience with this program.

Methods: We analyzed all deaths among dialysis patients at our institution (n=49) between 2019 and 2022. Of these, 27 (55%) were enrolled in concurrent hospice. Data collected included: demographics, comorbidities, health care utilization, code status, and location of passing. Descriptive statistics were used for continuous data. Associations between variables of interest and concurrent hospice were assessed using $\chi 2$, Fisher's exact, or Wilcoxon Rank Sum tests. All analyses were performed using SAS 9.4.

Results: Among patients receiving concurrent hospice services and hemodialysis, the median time on hospice was 26 days (IQR: 9.0, 62.0). There were no differences between the two cohorts for year of passing, age and common comorbid conditions. During the last 12 months of life, there were no differences in emergency department visits, hospitalizations, invasive procedures, or blood cultures drawn. A higher proportion of patients on concurrent hospice, had "do not resuscitate" orders at the time of passing (96.3% vs. 22.7%; $p < 0.0001$). Patients on hospice were less likely to pass in the hospital setting (22.2% vs. 63.6%, $p = 0.004$), but more likely to pass at home or in a skilled nursing facility (77.8% vs. 31.8%, $p = 0.002$).

Conclusions: Our data suggests that among the hemodialysis population, enrollment in concurrent hospice services was not associated with increased healthcare resource utilization. This information may help increase enrollment in hospice among dialysis patients and promote optimal end of life care.

Hospice Enrollment Status	Enrolled	Not Enrolled	p-value
N	27	22

Passed at home or SNF	21 (77.8%)	7 (31.8%)	0.0022

FR-PO887

Nephrology Providers' Experiences with Discussing the Option of Forgoing Kidney Replacement Therapy with Patients

Deborah Lee,[1] Julie Chotivatanapong,[2] David K. Prince,[2] Susan P. Wong.[2]
[1]Virginia Mason Franciscan Health, Seattle, WA; [2]University of Washington, Seattle, WA.

Background: Understanding how nephrology providers discuss therapeutic alternatives to kidney replacement therapy (KRT) for advanced kidney disease is paramount to supporting efforts to improve shared decision-making with patients.

Methods: We conducted a cross-sectional survey study of national sample of nephrology providers recruited through US professional societies between March-July 2022 about their experiences caring for patients who forgo KRT. We invited a random sample of survey respondents to complete follow-up qualitative interviews between August-October 2022 about their experiences discussing this option with patients.

Results: Overall, 203 nephrology providers (age 47±12 years, 66.0% female, 53.2% white), of which 49.8% were nephrologists and 50.2% were advanced practice providers completed the survey. The terms "active medical management without dialysis" (44.4%) and "conservative kidney management" (12.0%) were rated "overall best" in conveying the approach to care for patients who forgo KRT. From interviews with 21 (age 54±13 years, 81.0% female, 57.1% white) survey respondents, 3 dominant themes reflecting experiences with discussing this option with patients emerged: 1) Terminology used: there was inconsistency in the terms used to describe this option across different providers, the terms used by the same provider with different audiences, and the meaning of the same term to different providers; 2) Interpreting patients' expressed preferences: when patients communicated a desire not to receive KRT, providers were unsure whether patients truly meant to never pursue KRT and whether patients were likely to change their minds; and, 3) Sharing decision-making: providers spoke to challenges with negotiating respect for patients' autonomy, perceived best interests for the patient, and influences from family members when counseling patients about decisions to forgo KRT.

Conclusions: There is substantial inconsistency and ambiguity in providers' discussions with patients about care for patients who forgo KRT. Our findings highlight a need to build professional consensus on language used to discuss this option and for additional tools to assist providers with navigating these discussions.

FR-PO888

Promoting Goals of Care Conversations in Older Veterans Referred for Dialysis Education: A Quality Improvement Study

Aseel Zghayer,[1,2] Julia Schneider,[1,2] Alexi Vahlkamp,[1] Seema S. Limaye.[1]
[1]Edward Hines Junior VA Hospital, Hines, IL; [2]Loyola University Health System, Maywood, IL.

Background: Elderly patients that progress to end stage kidney disease (ESKD) have multi-morbidity and higher mortality rates than others of similar age. The Veterans Affairs Life Sustaining Treatment Initiative (LSTI) promotes goals of care conversations in high-risk veterans to identify preferences for life sustaining treatments (LSTs). Life-sustaining treatment preferences are then documented in a LST note.

Methods: This quality improvement project created a palliative care (PC) consult trigger process for all ESKD Veterans 70 and older who were referred for dialysis modality education between 9/2022 –4/2023. The goal was to increase rates of LST note completion prior to dialysis initiation.

Results: Twenty Veterans were referred for dialysis education in the six-month period. Sixteen of the 20 Veterans met age criteria for a PC trigger consult, characteristics are shown in table 1. Thirteen veterans attended the PC consult, one did not attend, and two declined. Only three veterans had LST notes completed prior to their referral for dialysis education. All Veterans who met with PC completed LST notes. One of 16 veterans opted for conservative treatment, and three initiated dialysis. Outcomes are shown in Table 2.

Conclusions: Trigger PC consultation at time of dialysis education in older patients led to 100 percent LST note completion rate. Including PC prior to dialysis initiation clarifies and documents preferences for LSTs. Future studies should examine the impact of PC consultation on the clinical course and quality of life in older ESKD Veterans.

Commitment to Practice Change Through Case-Based Learning to Improve Palliative Care for Older Patients with Kidney Failure

Alvin H. Moss,[1] Dale Lupu,[2] Christine M. Corbett,[4] Jeffrey I. Silberzweig.[3]
[1]West Virginia University Health Sciences Center, Morgantown, WV; [2]The George Washington University School of Nursing, Ashburn, VA; [3]Rogosin Institute, New York, NY; [4]University Health Truman Medical Center, Kansas City, MO.

Background: Patients with advanced chronic kidney disease (CKD) and kidney failure have many unmet palliative care needs. Nephrologist buy-in to implement primary palliative care has been cited as a major barrier. Interventions are needed to increase nephrologist awareness of and commitment to palliative care for their patients.

Methods: In a New York City-based CKD and dialysis program, we held a year-long series of monthly Project ECHO-style webinars. CKD and dialysis center staff screened patients for appropriateness for palliative care referral, agreed on pertinent patient issues, and presented their cases to an interdisciplinary expert faculty with backgrounds in nephrology, palliative medicine, and psychology. Participants evaluated webinars for practice relevance, whether they motivated them for practice change, and if so, in what way. Faculty categorized the major issue raised by each case. The online registration tool recorded the number and disciplines of participants.

Results: By discipline, 65 clinicians participated one or more times including nephrologists. nurses, social workers, a psychologist, and palliative medicine physicians. On a scale from 1-5 (low to high relevance), participants rated information from webinars that could be applied to practice a mean of 4.9. Based on webinar content, 95% reported they were planning to make one or more changes to their practice, most commonly involving other team members in decision process (53%) and changing how often they raise palliative care topics (48%). Major issues raised by cases included whether to start frail nonagenarians with comorbidities on dialysis and how to manage the following issues in in-center hemodialysis patients: failing to thrive, dementia-related aberrant behavior, and substance use disorder. Knowledge exchange between nephrology and palliative medicine clinicians was reciprocal and fostered referral relationships.

Conclusions: Project ECHO format with case- and evidence-based experiential learning addressing practical, relevant patient care issues engaged nephrology clinicians and motivated them to implement primary palliative care skills into their practices. These preliminary findings suggest a potentially fruitful approach to gain nephrology clinician buy-in to primary palliative care and warrant further study and collaboration.

Optimizing Veteran Video Connect: Engaging Veterans with Advanced Kidney Disease in Goals of Care Conversations

Seema S. Limaye,[1,2] Talar Markossian,[3,1] Alexi Vahlkamp,[1] Cara E. Ray,[1] Salva Balbale,[4,1] Kevin Stroupe,[1] Julia Schneider.[2,1] *[1]Edward Hines Junior VA Hospital, Hines, IL; [2]Loyola University Health System, Maywood, IL; [3]Loyola University Chicago, Chicago, IL; [4]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Chronic kidney disease (CKD) prevalence and its associated morbidity and mortality is higher among Veterans than in the general population. As such, goals of care conversations (GOCC) are indicated. Little is known regarding the use of tele-palliative consultation for GOCC in older adult Veterans with CKD. This pilot study examined the acceptability, facilitators, and barriers of engaging this population in GOCCs via telehealth.

Methods: This study used prospective observational design and semi-structured interviews. Eligibility criteria included geriatric patients ≥70 with CKD 4 or 5 without documented life-sustaining treatment (LST) preferences in the past 90 days. Patients were referred to palliative care (PC) clinic for GOCCs.

Results: 62 patients were identified and 40 were enrolled. Most patients preferred in-person and telephone PC visits (70%). Only 30% preferred telehealth. There were no clinical or demographic differences among patients based on visit modality preference, including in LST preferences. In patients who preferred an in-person visit, 42% cited discomfort with technology and 25% cited functional deficits.

Conclusions: Life sustaining treatment preferences and note completion rates among older Veterans with advanced CKD did not vary based on GOCC visit modality. Discomfort with technology was the most common barrier to telehealth. Future studies should focus on how to reduce technology barriers for older Veterans.

Funding: Veterans Affairs Support

LST completion rate and preferences by modality of GOCC (n=38)[a]				
		In-person or telephone PC visit (n=28)	VVC or CVT PC visit (n=10)	P-value[b]
		n (%)		
LST completed during PC visit		22 (78.6)	8 (80.0)	1.000
LST preferences selected during completed PC visit				
	DNR	0 (0)	1 (12.5)	0.434
	DNR without limits to LSTs	12 (54.5)	4 (50.0)	
	Full code	6 (27.3)	1 (12.5)	
	Full code without limits to LSTs	4 (18.2)	2 (25.0)	

[a]Two patients died before scheduled visit date and two patients who initially preferred VVC completed their visit by telephone.

[b]Fisher exact test was conducted when expected cell value was less than 5; Wilcoxon rank-sum (Mann-Whitney) test for non-normally distributed variables and t-test for age.

FR-PO891

Using Population Health Management Program to Promote Patient Choice for Medical Management Without Dialysis

Isabel Neckermann, Alexandra E. Bursic, Natalie C. Ernecoff, Amar D. Bansal, Manisha Jhamb, Jane O. Schell. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Patients with advanced chronic kidney disease (CKD) often start on dialysis as the default treatment option, without a shared decision making discussion (SDM) in which they and their care partners actively choose a renal replacement therapy option that best aligns with their values and wishes. We describe a program to promote SDM and characteristics of patients who chose medical management without dialysis (MMWD).

Methods: As part of the ongoing CKD population health management program at UPMC, high-risk CKD patients not seeing a nephrologist are identified through electronic health record and co-managed with their primary care provider. Patients age>85 years with eGFR <30 ml/min, or those with surprise question ("will you be surprised if this patient dies in next 12 months") "no" are automatically referred to discuss treatment options with a kidney palliative care advanced practice provider (APP) via telemedicine. Among people who received care in an APP-led decision-making session, we (1) assessed the frequency of selecting MMWD, and (2) compared demographic and clinical characteristics of those who chose MMWD to those who did not.

Results: Of 150 patients who met with an APP, 74 elected MMWD (49%), while 76 (51%) chose to pursue dialysis as a future treatment option. Patients who chose MMWD did not differ by age (mean 88y vs 86y, p = 0.072), gender (59.5% vs. 61.8% female, p=0.77), or eGFR (mean 29.5 vs 32.2, p=0.085) compared to patients who chose dialysis. Additionally, patients who chose MMWD did not have a significantly higher burden of comorbidities compared to those who chose dialysis, including coronary artery disease (59.5% vs. 56.6%, p=0.72), cancer (40.5% vs 38.2%, p=0.77), chronic heart failure (50% vs 46.1%, p=0.63), chronic obstructive pulmonary disease (28.4% vs 21.1%, p=0.30), depression (28.4% vs 35.5%, p=0.35), and diabetes (50.0% vs 50.0%, p=1.00).

Conclusions: CKD population health management program with automated referrals to palliative care-led decision making session is an innovative method to identify and provide patients with CKD increased access to opportunities to discuss treatment options. Our results demonstrate the need for SDM process to promote patient choice in older patients with CKD.

FR-PO892

Impact of Conservative Management vs. Dialysis on Hospitalization Outcomes in US Veterans with Advanced CKD

Connie Rhee,[1] Yoko Narasaki,[1] Susan T. Crowley,[2] Csaba P. Kovesdy,[3] Dana B. Mukamel,[1] Seungsook You,[1] Ji Hoon Yoon,[1] Alejandra Novoa-Vargas,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[4] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Yale University, New Haven, CT; [3]The University of Tennessee Health Science Center, Memphis, TN; [4]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Given high early mortality rates, healthcare utilization, and withdrawal in incident dialysis subgroups, particularly those of older age or multi-morbidity, there is interest in conservative management (CM) as an alternative treatment strategy for advanced CKD. We examined the impact of CM vs. dialysis transition on hospitalization outcomes in Veterans with advanced CKD.

Methods: We examined Veterans with advanced CKD (≥2 eGFRs <25 separated by ≥90 days) treated with CM vs. dialysis (non-receipt vs. receipt of dialysis within 2-years of the 1st eGFR <25). Patients in the dialysis group were categorized according to timing of dialysis transition, defined as earlier dialysis (ED) vs. intermediate dialysis (ID) vs. very-late dialysis (VLD) (eGFRs ≥15, 10-<15, vs. <10 at dialysis transition). We compared rates of hospitalization (primary outcome) and days hospitalized (secondary outcome) in CM vs. dialysis patients matched by propensity score (PS) in a 1:1 ratio to address confounding using Poisson regression.

Results: In PS-matched models, compared with CM, each dialysis group was associated with higher rates of hospitalization, with incrementally higher rates observed with earlier dialysis transitions: IRRs (95%CIs) 1.53 (1.50-1.56), 1.56 (1.53-1.60), and 1.75 (1.70-1.80) for VLD, ID, and ED, respectively (Fig A). Similarly, each dialysis group was associated with higher rates of days hospitalized, with incrementally higher rates observed with earlier dialysis transitions (ref: CM): IRRs (95%CIs) 1.42 (1.41-1.44), 1.55 (1.54-1.56), and 2.08 (2.06-2.10) for VLD, ID, and ED, respectively (Fig B). Similar findings were observed in sensitivity analyses doubly-adjusted for PS covariates.

Conclusions: Compared with CM, increasingly earlier dialysis transitions were associated with higher rates of hospitalization and days hospitalized. Further studies are needed to examine the comparative effectiveness of CM vs. dialysis transition on other hard endpoints and patient-centered outcomes in US Veterans.

FR-PO893

Dialysis as Destination Therapy vs. Medical Management in a National Cohort of Older Adults with Kidney Failure: A Target Trial Emulation Study

Maria E. Montez-Rath,[1] I-Chun Thomas,[2] Vivek Charu,[1] Michelle Odden,[3] Carolyn D. Seib,[1,2] Manjula Tamura.[1,2] *[1]Stanford University School of Medicine, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA; [3]Stanford University, Stanford, CA.*

Background: For older adults who are not candidates for kidney transplantation, medical management is an alternative to lifelong dialysis, but little evidence is available to inform treatment decisions.

Methods: We emulated a target trial in which patients were randomized to dialysis versus medical management using electronic health record data between 2010 and 2018 from the U.S. Department of Veterans Affairs. We included adults aged 65 years or older with chronic kidney failure and an estimated glomerular filtration rate <12 ml/min/1.73m^2 who were not candidates for kidney transplantation. We used causal inference methods to estimate restricted mean survival time difference using a weighted flexible parametric model and difference in home-time using weighted fractional regression at one and three years.

Results: We emulated a series of 99 trials using data from 16,363 adults with a mean age of 77 ± 9 and mean eGFR of 10 ± 2 who were predominantly male (2%) and white (64%). In intention to treat analyses, compared to medical management, dialysis was associated with an increase in one-year survival of 4 days (95% CI 2.0, 6.1), offset by 8 fewer days at home (95% CI -10, -7). At 3-years, compared to medical management, dialysis was associated with an increase in survival of 35 days (95% CI 23, 47), offset by 11 fewer days at home (95% CI -16, -4). Subgroup analyses showed that the survival benefit of dialysis was larger at older ages and at lower eGFR, and largely explained by an increase in survival in institutional settings (**Figure**).

Conclusions: Among older adults ineligible for transplantation, we found evidence of a modest survival benefit of dialysis compared to medical management, at the expense of fewer days at home. The findings suggest that medical management should be more widely considered as a patient-centered alternative to dialysis treatment and underscore the importance of engaging patients in shared decision-making.

FR-PO894

Results from GUIDAGE-CKD: Guideline-Compliant Care of Patients Aged 70+ with CKD

Natalie Ebert,[1] Elke Schaeffner,[1] Anne-Katrin Fietz,[1] Julia Freitag,[2] Anna Pöhlmann,[1] Nina Mielke,[1] Tim Bothe.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]AOK Nordost - Die Gesundheitskasse, Berlin, Germany*.

Background: Currently, few data exist on guideline-based care for older patients with CKD. The GUIDAGE-CKD project develops quality indicators (QI) for outpatient care of pts 70+ years with CKD and tests them in Berlin Initiative Study (BIS) and claims data. We investigate trends over time after introduction of KDIGO guidelines in 2012.

Methods: Using a Delphi process, a set of 7 QIs was consented for use in claims data (Module 1). QIs were validated in BIS data with comprehensive claims data (Module 2). Prevalences of QIs were described in age- and sex-stratified random samples in claims data (n=62,200 indiv. 70+) for the years 2012, 2014, 2016, and 2018 and standardized to the German 70+ population. Trends over time were examined with Cochran-Armitage trend test (Module 3). Initial results using claims data were reported for 5 QIs.

Results: Prevalence of CKD increased from 17.9% (95% confidence interval [CI] 15.0–21.4) in 2012 to 25.9% (CI 22.3–30.0) in 2018 (Table). Incidence of CKD increased from 6.3% (CI 4.5–8.8) in 2012 to 7.5% (CI 5.5–10.5) in 2018. The proportion of incident CKD cases with urinary albumin creatinine ratio (ACR) measurement (QI 8) increased from 10.9% (CI 10.0–12.0) in 2012 to 12.6% (CI 11.5–13.7) in 2018. The proportion of confirmed CKD G4-5 caseswith perscribed NSAIDs (QI 12, contraindicated) decreased from 3.8% (CI 2.9–4.9) in 2012 to 2.3% (CI 1.8–3.0) in 2018. The proportion of cases with CKD receiving combined prescriptions of ACE inhibitors (ACEi) and ARBs (angiotensin II receptor blockers) (QI 23, contraindicated) decreased from 3.0% (CI 2.6–3.3) in 2012 to 0.6% (CI 0.5–0.7) in 2018.

Conclusions: From 2012-2018, the prevalence and incidence of CKD increased constantly, while the proportion of contraindicated NSAID medications in stage 4-5 CKD and combined prescriptions of ACEi and ARBs decreased. These trends suggest improvements in CKD diagnosis, guideline adherence, and quality of care.

SD = standard deviation. CI = 95% confidence interval calculated using the Wilson method (1927). * statistically significant for p < 0.0083 (after Bonferroni-correction).
[1] Sampling strategy: after an a priori defined case number estimation, an equally distributed random sampling was performed for each year according to following age and sex strata: 50% women and 20% each in the age group 70-74, 75-79, 80-84, 85-89, and ≥90 years.
[2] For CKD, the following diagnoses were used: ICD-10-GM N18.3, N18.4, N18.5, N18.8, N18.9, N19, within 1 year at least 1 outpatient diagnosis with diagnostic certainty "confirmed" or 1 "must" or "secondary" inpatient diagnosis.
[3] For CKD with eGFR <30 ml/min/1.73m², the following diagnoses were used: ICD-10-GM N18.4, N18.5, within 1 year at least 1 outpatient diagnosis with diagnostic certainty "confirmed" or 1 "must" or "secondary" inpatient diagnosis.
[4] The number of eligible persons indicates how many persons were eligible for testing of the respective QI (denominator). E.g., for incidence: only persons who did not have a CKD diagnosis in the respective previous year.
[5] The prevalences of the QIs were standardized using nationwide demographic age and sex distributions (Destatis).
[6] Time trends were tested using the Cochran-Armitage test with Bonferroni correction.

FR-PO895

Baseline Characteristics of the First Geriatric Nephrology Clinic in Mexico City

Jorge I. Fonseca-Correa, Gretell Henriquez Santos, Andrea Perez de Acha Chavez, Ricardo Correa-Rotter. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico*.

Background: Older adults with advanced CKD have a high burden of geriatric syndromes (GS). A Geriatric Assessment is fundamental to optimize care and help with shared decisions. In 2022 an integrated Geriatric Nephrology Clinic was opened at our Institution. Patients ≥70 years with eGFR ≤20 mL/min are referred for evaluation, interventions, and planning by a Geriatric Nephrology team. We present baseline characteristics of this population.

Methods: We included patients (pts) referred to the GNC between Jan. 2022 and Mar. 2023. Charts were reviewed and data regarding GS captured and analyzed.

Results: During this time, 71 pts were referred to clinic; 59 had non-dialysis dependent (NDD) CKD and 12 were on dialysis. Average age was 80 ±7.6 years, 50% were female, and the main cause for CKD was diabetes (49%). Dialysis pts were younger (75.8±8.8 vs. 81.6±7.1, p<0.05), more likely to have healthcare coverage (66.7% vs. 32.2%, p=0.03) and had lower comorbidity (CCI 6.5±1.3 vs. 8.14±3.2, p<0.05). Dialysis vintage was 2 years (IQR 1,4). NDD pts had an average eGFR of 14.2 mL/min, 79% had ≥A2 albuminuria. Risk of progression to CKD was high (2-year KFRE >20%) in 61%. Dialysis pts had better physical performance (SPPB 9.5±1.8 vs. 6.8±2.4 points, p<0.001). No other differences were found. Burden of GS was high, with an average of 6.7±2.2 out of 14 possible. Prevalence of individual GS was: 1) frailty 62%, 2) ADL disability 46%, 3) IADL disability 61%, 4) impaired mobility 56%, 5) falls 51%, 6) low physical performance 78% 7) slow gait 46%, 8) visual deficit 42%, 9) auditory deficit 40%, 10) malnutrition 11%, 11) positive depression screening 16%, 12) altered sleep 21%, 13) abnormal cognitive screening 49%, 14) polypharmacy 91%. After the first visit, 13% of NDD pts opted for dialysis, 24% were undecided, 49% opted for conservative or palliative care and 14% did not answer. One dialysis pt asked for assistance with dialysis discontinuation.

Conclusions: The Geriatric Nephrology Clinic has been fundamental to identify and intervene in geriatric syndromes for our older patients with CKD. Patients referred to our clinic have high comorbidity, high geriatric syndrome burden and are mostly managed conservatively.

FR-PO896

Clinical Characteristics and Outcomes of Hemodialysis Therapy Focusing on Older Patients in Korea from the 2023 Korean Renal Data System

Hyunglae Kim,[1] Yong Kyun Kim,[1] Yu Ah Hong,[2] Tae Hyun Ban,[3] Hajeong Lee,[3] Hee-Yeon Jung.[4] *[1]The Catholic University of Korea St Vincent's Hospital, Suwon, Gyeonggi-do, Republic of Korea; [2]The Catholic University of Korea School of Medicine, Seoul, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [4]Kyungpook National University, Daegu, Republic of Korea*.

Background: As the aging population increases worldwide, the prevalence of older patients with end-stage kidney disease (ESKD) is rapidly increasing. Understanding the characteristics of elderly ESKD patients is essential for establishing suitable dialysis policies and plans, but information on this population is currently unclear in Korea.

Methods: This study investigated the characteristics and outcomes of elderly hemodialysis patients using Korean Renal Data System. Of a total of 173,216 patients, 40,972 hemodialysis patients were included in the final analysis after excluding patients with missing values, who started dialysis before 2001, or who were younger than 18 years old.

Results: Of the enrolled patients, 39.3% were under the age of ≥ 65 years, 26.6% were 65-74 years, and 34.1% were ≥ 75 years (p<0.001). The incidence of ESKD is increasing but the prevalence is decreasing in patients aged ≥ 75 years from 2017 to 2022. The proportion of patients with cardiac disease increased with age: 16% (<65 years), 19.6% (65-74 years), and 21.8% (≥75 years) (p<0.001). The levels of body mass index, hemoglobin, albumin, calcium, phosphorus, and intact parathyroid hormone significantly decreased with increasing age (p<0.001 for each parameter). The proportions of arteriovenous fistula creation and left forearm placement reduced with increasing age (p<0.001, and p<0.001, respectively). Although low surface area (1.0-1.5 m2) dialyzers utilization was increased with age at 41.4% (<65 years), 49.5% (65-74 years), and 58.5% (≥75 years), the urea reduction ratio and Kt/V increased with age, achieving the dialysis adequacy target in all elderly population. Mortality rates had increased in patients aged ≥ 75 years compared to other age groups over the past 20 years and the proportion of deaths due to cardiovascular disease decreased and deaths due to infectious diseases increased with age in older hemodialysis patients (p=0.002, and p=0.025, respectively).

Conclusions: The incidence of elderly hemodialysis patients has increased over time, and especially very older adults aged ≥ 75 years has a higher risk of mortality compared to other age groups in Korea. To improve outcomes for older ESKD patients, appropriate guidelines for ESKD management should be developed based on age-appropriate, individualized strategies.

FR-PO897

A Pragmatic Randomized Clinical Trial: Twice-Weekly vs. Thrice-Weekly Incident Hemodialysis in Elderly Patients (PRIDE): Study Protocol

Miyeun Han,[1] Sang Heon Song,[2] Soon hyo Kwon.[3] *[1]National Medical Center, Seoul, Republic of Korea; [2]Pusan National University, Kumjeong-ku, Republic of Korea; [3]Soonchunhyang University Hospital, Seoul, Republic of Korea*.

Background: The optimal frequency for hemodialysis in older adults with end-stage kidney disease (ESKD) has not been established. This study aims to investigate whether a twice-weekly dialysis schedule using an incremental approach can reduce hospitalization rates in older adults with incident dialysis, compared with conventional thrice-weekly dialysis in South Korea.

Methods: We have designed a pragmatic randomized controlled trial to compare the effects of twice-weekly versus thrice-weekly hemodialysis in 428 ESKD (drop-out rate 20%) individuals aged 60 years or older with residual kidney function (urine output > 500 mL/day). The trial will be conducted across 18 referral hospital-based dialysis centers in Korea. Individual participants will be randomized to either the twice-weekly (with incremental approach) or thrice-weekly dialysis group and will be followed up for 24

months. The primary outcome of the study is the difference in all-cause hospitalization rates, while secondary outcomes include dialysis-specific hospitalization rates, mortality, quality of life, frailty, and cost-effectiveness. Participants have the flexibility to transfer to other dialysis centers as needed. The decision to increase dialysis frequency will be made by the treating physicians.

Results: The study is ongoing and will be completed in May 2026.

Conclusions: This study will provide valuable insights into the benefits and risks of twice-weekly dialysis with an incremental approach in older adults with residual kidney function compared to conventional dialysis treatment.

FR-PO898

Association of Polypharmacy and Incident Frailty Differs Between Older Adults with and Without CKD

Nina Mielke,[1] Muhammad Barghouth,[1] Anne-Katrin Fietz,[1] Cédric Villain,[2,1] Tim Bothe,[1] Natalie Ebert,[1] Elke Schaeffner.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Caen University Hospital, Caen, France.*

Background: Older adults with chronic kidney disease (CKD) have a high prevalence of comorbidities and are prone to polypharmacy. We aim to analyze if CKD modifies the association of polypharmacy and incident frailty.

Methods: Data from the Berlin Initiative (cohort) study were used, in which older adults (≥70 yrs.) were interviewed biennially using a standardized face-to-face questionnaire. Non-frail individuals were followed-up for 2 years and incident frailty according to Fried phenotype was assessed. Polypharmacy was defined as the intake of five or more regularly prescribed drugs and CKD as $eGFR_{BIS2}$ <60 mL/min/1.73m^2 or ACR ≥30 mg/g. Logistic regressions were used to analyze the association of polypharmacy and incident frailty to estimate crude and adjusted odds ratios (OR) and corresponding 95% confidence intervals (CI) in individuals with and without CKD.

Results: Individuals with CKD were older (84 vs. 81 years) and had more often hypertension (85 vs. 68%) or diabetes (25 vs. 13%) compared to individuals without CKD. After 2 years, fewer individuals without CKD became frail (7.5%) compared to individuals with CKD (19.7%), independent of their polypharmacy status. Individuals with CKD and polypharmacy became frail more frequently (26.7%) compared to individuals with CKD without polypharmacy (14.2%) (Table). In individuals without CKD, there was no difference in frailty incidence between those with (8.3%) and without (7.1%) polypharmacy. In individuals with CKD, those with polypharmacy had 2.1 times the odds (95% CI 1.23–3.59) of becoming frail compared to those without. In old adults without CKD, we found no association between polypharmacy and incident frailty.

Conclusions: CKD modifies the effect of polypharmacy on frailty. In older adults with CKD, care providers should be aware of this interaction with polypharmacy and should consider initiating frailty prevention interventions early.

Funding: Private Foundation Support, Government Support - Non-U.S.

Table: CKD modifies the association of polypharmacy and incident frailty

	Total	Number of Events (%)	Crude model OR (95% CI)	Adjusted Model* OR (95% CI)
CKD				
No Polypharmacy	261	37 (14.2%)	Reference	Reference
Polypharmacy	206	55 (26.7%)	2.21 (1.39 – 3.51)	2.10 (1.23 – 3.59)
No CKD				
No Polypharmacy	126	9 (7.1%)	Reference	Reference
Polypharmacy	48	4 (8.3%)	1.18 (0.35 – 4.03)	0.97 (0.23 – 4.11)

FR-PO899

Physical Function Before and After a Health Stressor in Older Veterans with Advanced CKD

Brett Burrows,[1] Maren Olsen,[1,2] Theodore S. Berkowitz,[2] Battista L. Smith,[2] C. Barrett Bowling.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]Durham VA Health Care System, Durham, NC.*

Background: Health stressors (HS), defined as acute health events that require an ED visit or hospitalization, are common among older adults with chronic kidney disease (CKD) and associated with functional decline. Describing the trajectory of function before and after a HS may be vital to predicting future functional status and developing strategies to improve functional recovery after health events.

Methods: The Physical Resilience Prediction in Advanced Renal Disease (PREPARED) is a national, prospective cohort study of Veterans ≥ 70 years old (*n*=412) with advanced CKD (eGFR <30 ml/min/1.73m^2 (excluding dialysis or transplant)) who were tracked longitudinally to detect the occurrence of a HS in near real-time. Participants completed scheduled phone surveys of physical function every 8 weeks. For enrolled participants, if a HS was detected in the VA electronic health record during follow-up, additional phone surveys were conducted immediately following the HS, at 8-, and 16-weeks post-HS. This approach provided data on function approximately 16- and 8-weeks before and 8- and 16-weeks after a HS. Physical function was assessed at each timepoint using the Life-Space Assessment (LSA) score (0-120, higher scores reflect greater community mobility). Linear mixed models were used to assess the trajectory of function in relationship to the HS.

Results: A total of 272 PREPARED participants (77.9 ± 6.4 years old, 98% male, 25% Black) had a HS. On average, LSA score was highest (54.0 ±26.2) at baseline (16-weeks prior to a HS). LSA scores declined 8-weeks prior to a HS (52.2 ±28.6). The lowest LSA score was immediately following the HS (45.3 ±28.6). LSA scores rebounded at 8-weeks (51.0 ±27.7) and 16-weeks post-HS (50.0 ±26.4) but did not return to pre-HS levels. Compared to baseline, statistically significant differences in LSA scores were seen immediately following the HS, and at 8- and 16-weeks post-HS (all p<0.01).

Conclusions: Among older Veterans with advanced CKD declines in physical function occurred leading up to and following a HS. Though physical function improved in the weeks following the HS, participants did not fully regain baseline physical function status even after 4 months. These data demonstrate the importance of developing strategies to bolster older adults' ability to recover following an acute health event.

FR-PO900

Kidney Transplantation in Older People (KTOP): The Frail Experience

Amarpreet K. Thind,[1,2] Michelle Willicombe,[1,2] Edwina A. Brown.[2,1] KTOP Investigator Group. *[1]Imperial College London Faculty of Medicine, London, United Kingdom; [2]Hammersmith Hospital, London, United Kingdom.*

Background: Older people with kidney failure are vulnerable to frailty. Understanding their experiences is integral to kidney transplantation(KT) decision making.

Methods: The KTOP:impact of frailty on outcomes study assessed frailty, quality of life(QoL), and clinical outcomes in people >60, on the waitlist(WL) and after KT. Mixed-effect analysis identified trends and frailty variations.

Results: 210 patients were recruited;118 were transplanted. At recruitment 63.4%(118) were not frail, 19.4%(36) vulnerable, and 17.2%(32) frail. The study was powered only for QOL changes, but on the WL vulnerable/frail candidates were more likely to have major infections and spend longer suspended. After KT vulnerable/frail recipients were more likely to be hospitalised, have longer admissions, and possibly higher graft loss and mortality(table). On the WL, QoL trends showed stable physical component scores(PCS) in not frail candidates and declining scores in vulnerable/frail. Post-KT not frail candidates PCS declined before slowly recovering, whilst PCS stabilised in vulnerable/frail. WL mental component scores (MCS) improved in both groups. MCS after KT declined then improved in not frail candidates, and worsened in vulnerable/frail(figure 1).

Conclusions: Frail/vulnerable older people had worse WL and KT clinical outcomes. KT did not change QoL hugely for either group, but trends varied by frailty. Achieving a holistic understanding will enable better assessment, counselling, and support for older people considering KT.

Clinical outcomes by frailty

Outcome	Not Frail	Vulnerable/Frail	p Value
WL mortality	10 (22.2%)	14 (31.1%)	0.340
WL major infection episode	11 (24.4%)	27 (60%)	0.001
WL total time suspended (days) (mean, ±SD)	307 (244)	434 (295)	0.0246
KT mortality	5 (7%)	8 (18.2%)	0.0774
All cause graft loss	7 (9.9%)	10 (29.4%)	0.0588
KT major infection episode	39 (54.9%)	29 (69%)	0.138
Hospitalised in 1sy year after KT	37 (52%)	32 (73%)	0.028
Total Length of stay in 1st year after KT (days) (mean, ±SD)	20.5 (24.8)	36.6 (32.7)	0.0238

FR-PO901

The Association Between Oral Frailty and Physical Performance in Patients with CKD

Kyu Won Jang, Bon Jin Koo, Do Kyun Kim, Seo Rin Kim, Byung Min Ye, Il Young Kim, Soo Bong Lee, Dong Won Lee. *Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.*

Background: Chronic kidney disease (CKD) is one of the major causes and exacerbating factors for sarcopenia. Patients with CKD frequently experience dry mouth due to water restriction and decreased appetite due to uremic toxins, which leads to malnutrition, protein-energy wasting, and increased mortality. The association between

oral function and the sarcopenia index in CKD remains unclear. The purpose of this study was to evaluate the oral function and its correlation with the sarcopenia index in patients with CKD.

Methods: The participants were non-dialysis CKD patients (stage 3~5) who visited an outpatient clinic in a single center. Oral frailty was evaluated by the Oral Frailty Index-8 and physical examinations assessing the number of teeth, tongue-lip motor function, and tongue coating index. The sarcopenia index and the Frail Questionnaire were assessed.

Results: Among the 72 patients (49 males, 23 females; mean age 67.0±11.8 years; mean serum creatinine level 3.83±2.65 mg/dl), 55.6% of participants had oral frailty, defined as an Oral Frailty Index-8 score of 4 points or more. Male participants had higher serum creatinine levels than the female group (4.24±2.94 mg/dl vs. 2.96±1.67 mg/dl, respectively). Muscle strength measured by handgrip strength in the male group with oral frailty was lower than that without oral frailty (26.9±6.11 vs. 32.6±7.10kg, respectively, P=0.003), whereas there was a decreasing trend in the female group (15.1±4.72 vs. 19.5±5.77kg, respectively, P=0.06). Patients who have oral frailty showed decreased physical performance (with oral frailty 12.9±5.45s, vs. without oral frailty 8.89±3.05s, P<0.001). Oral frailty was linked with lower physical performance, according to the logistic regression analysis (OR 1.30, CI 1.097-1.546, P=0.003). In simple linear regression, the level of serum creatinine and the oral frailty score were associated (r=0.26, P=0.03).

Conclusions: Oral frailty is present in more than half of outpatients with non-dialysis CKD. This suggests the significance of managing physical performance early for CKD patients to avoid oral frailty. Additionally, muscle-strengthening exercises should be more crucial to prevent oral frailty as CKD progresses.

FR-PO902

Gait Speed and Mortality in Older Adults with CKD: The Chronic Renal Insufficiency Cohort

Christine Liu,[1,5] Gomathy Parvathinathan,[1] Margaret R. Stedman,[1] Stephen L. Seliger,[3,4] Daniel E. Weiner,[2] Manjula Tamura.[1,5] CRIC Study Investigators.
[1]Stanford University, Stanford, CA; [2]Tufts Medical Center, Boston, MA; [3]University of Maryland School of Medicine, Baltimore, MD; [4]VA Medical Center Baltimore, Baltimore, MD; [5]VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA.

Background: Current models to predict mortality in older persons with CKD use only demographic, kidney, and medical history data. Yet prior work shows impaired physical function independently and strongly predicts death in older adults. We assessed if a measure of physical function, gait (walking) speed, improves mortality prediction for older adults with CKD.

Methods: We included Chronic Renal Insufficiency Cohort participants who were ≥65 years with eGFR <60 mL/min/1.73m², not receiving kidney replacement therapy, non-missing UACR, and with at least 1 gait speed assessment. Gait speed at usual pace on a 4.57 meter course was timed and then categorized (≥ 0.84 meters/second, 0.83 to 0.65, 0.64 to 0.47, ≤ 0.46, or unable to do). We designated the visit with gait speed measurement as baseline. Our primary outcome was time to all-cause death. We used a flexible parametric modeling approach with kidney replacement therapy as a competing risk, adjusting for age, sex, race, eGFR, UACR, smoking, diabetes, heart failure and stroke. C statistics were used to compare models with and without gait speed as a predictor.

Results: Among 2,345 persons, mean age was 70.0±4.4 years; 43% were female and 41% Black. Mean eGFR was 43.3±12.5 mL/min/1.73m² and median UACR was 33.8 (IQR 9.3-283.4). At baseline, 80% had a gait speed ≤ 0.83 m/s. Over 5 years, 393 persons died, and 164 had kidney failure. For those that died, median survival time was 2.6 years. In time-to-event analyses, slower gait speeds correlated with greater mortality (Figure). After adjustment, the inclusion of gait speed as a predictor improved model performance with the c statistic improving from 0.625 (95% CI 0.624-0.627) to 0.736 (95% CI 0.735-0.737).

Conclusions: In older adults with CKD, we found that gait speed improves mortality prediction. Clinicians should consider assessing gait speed when discussing life expectancy and goals of care with older adults with CKD.

FR-PO903

Ultrasound Evaluation of Rectus Femoris Muscle Thickness as a Diagnostic Tool for Sarcopenia in Peritoneal Dialysis Patients

Gonçalo F. Pimenta, Ana C. Martins, Rita Calça, Patrícia Matias. *Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal.*

Background: Sarcopenia is a frequent cause of morbidity and mortality among patients with chronic kidney disease (CKD), combining loss of both muscle strength and mass. Handgrip strength is a reliable surrogate for measures of arm and leg strength. Several tools have been developed for muscle mass evaluation, such as bioelectrical impedance analysis (BIA). Ultrasound evaluation has been increasing recently, taking advantage of its feasibility in daily clinical setting. The aim of this study was to evaluate the rectus femoris muscle thickness (RFMT) by ultrasound in peritoneal dialysis (PD) patients and its association with muscle strength and BIA parameters.

Methods: Single-centre cross-sectional study including patients on PD for > 3 months and aged > 18 years. Patients with acute infection, amputated limbs and implantable cardiac devices were excluded. Demographic and clinical data were collected from the electronic records. Parameters evaluated included serum biomarkers, BIA and dialysis adequacy. Muscle strength was measured by handgrip strength using a dynamometer. RFMT was evaluated using ultrasound at bedside.

Results: A total of 32 patients (19 male) were included with a mean age of 59±15 years. PD vintage was 17 months (10,5-29,8) with a weekly Kt/V of 1,98 (1,68-2,55). Most were on continuous ambulatory peritoneal dialysis (CAPD; 68,8%), either as high or medium-high transporters (65,6%). Hypertension was reported in 28 patients (87,5%), accompanied by diabetes mellitus (DM; 31,3%), peripheral artery disease (31,3%) and obesity (28,1%). Age (r=-0,442; p=0,013), Clinical Frailty Score (r=-0,481; p=0,006) and NT-proBNP (r=-0,54; p=0,003) were negatively associated with RFMT. Lean tissue index (r=0,357; p=0,049), phase angle (r=0,567; p=0,001) and handgrip strength (r=0,49; p=0,006) were positively associated with RFMT. In a multivariate analysis, phase angle (adjusted R^2=0,261; p=0,026) was positively associated with RFMT, adjusting to age, time on PD, DM and serum albumin.

Conclusions: Ultrasound evaluation of RFMT is feasible in daily practice in the outpatient setting. It may be useful as an additional tool to BIA for diagnosis of sarcopenia, particularly in elderly, fragile and malnourished patients. Further prospective studies are warranted in order to validate this tool for PD patients.

FR-PO904

Relationship Between Frailty, Sodium, and Blood Pressure in Elderly People

Luca D'Urbano,[1] Lorena Citterio,[1] Laura Zagato,[1] Maria Pina Concas,[2] Marco Simonini,[1] Chiara Lanzani,[1] Paolo Manunta.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]IRCCS Materno Infantile Burlo Garofolo, Trieste, Italy.*

Background: The objective of the FRASNET project is to investigate the correlation between frailty, natriuresis, and blood pressure (BP) in the elderly population to identify subgroups useful for diagnostic and therapeutic algorithms.

Methods: The FRASNET geriatric population (1204 subjects) is an Italian observational cohort that includes frail (35%), pre-frail (37.3%) and robust (27.7%) subjects. They have been characterized for BP, renal function, sodium intake (Kawasaki formula), cognitive status, quality of life (QoL), anamnestic factors, health and socio-economic status. ANOVA and conditional inference tree analysis have been carried out.

Results: 745 participants out of 1203 (60%) were under anti-hypertensive treatment but 71.4% had a suboptimal control of BP. The significant elements are the male gender (p=0.002), waist circumference (p=0.01), visceral fat index (p<0.01), and fewer medications taken (p<0.01). An inferential analysis (Fig 1) evidenced a first dissection between males and females, a second one age-related (75 y) and a third with natriuresis (217 mEq Na). Non-frail subjects had the highest values for both systolic and diastolic BP; the frail group had the lowest values, below the 140 mmHg threshold. BPs negatively correlate with frailty status (systolic p=0.048, diastolic p <0.001, Fig 2).

Conclusions: The more severe the frailty, the lower the BP is supposed to be. The evidence of this inverse tendency is supported by physiological explanations and by therapeutic implications. Frail patients are usually more prone to injury; therefore, they are more likely to be prescribed more drugs and the most aggressive therapies to decrease risks. Ultimately, this correlation suggests that both conditions grant a relative decrease in risk with respect to the other one, at least when considering elder individuals.

White Matter Alternation at Corpus Callosum and Stria Terminalis Contributes to the Cognitive Impairment in ESRD via Dysregulating Homeostasis of Calcium

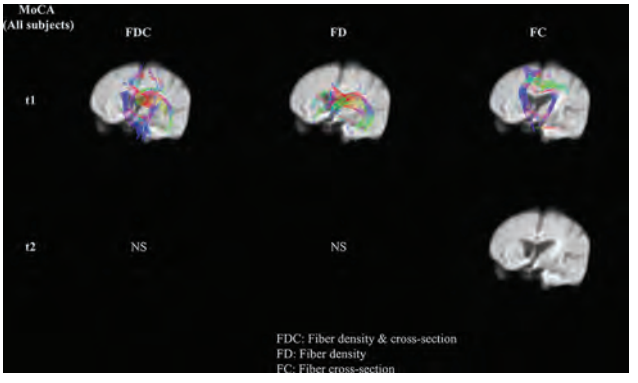
Yi-Chou Hou. *Cardinal Tien Hospital, New Taipei City, Taiwan.*

Background: Cognitive impairment is common in patients with end stage kidney disease (ESRD). White matter alternation is important pathologic change in cognitive impairment, and fixel-based analysis quantifies the fiber loss. The study is to elucidate the white matter alternation in uremic cognitive impairment patients.

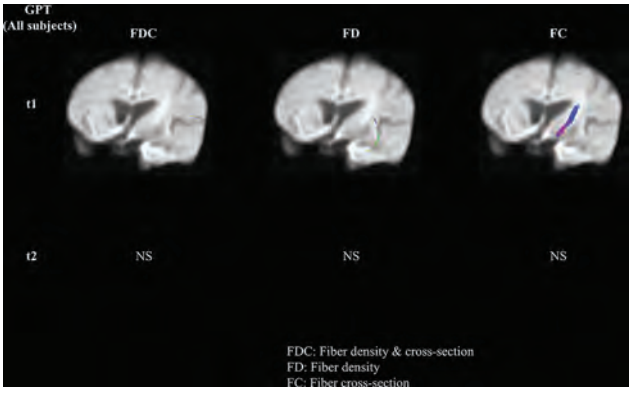
Methods: The study period was from August 2019 to December2020. The participants were divided into three groups according to the MMSE score and the status with end stage renal disease or not: (1) control (n=16): MMSE>24 without end stage renal disease; (2) group 2 (n=17): end stage renal disease with MMSE 25~30; (3) group 3 (n=14): end stage renal disease with MMSE10~24. All participants received magnetic resonance imaging and hematologic and biochemical parameters. Fixel-based analysis was performed to assess the fiber density.

Results: The fiber density, the fiber cross section and the summation of the fiber density and cross section were lower in the ESRD patients. The decrease in corpus callosum and fornix/stria terminalis was associated with the decrease in Montreal Cognitive Assessment($p<0.05$). The concentration of calcium(8.80± 0.79mg, vs 9.27± 0.29mg for control group, $p<0.05$) was lower in ESRD patients. The serum concentration of calcium was positive associated with the fiber density in the corpus callosum and fornix/stria terminalis($p<0.05$).

Conclusions: The white mater density decreased in the ESRD patients, and the decrease was associated with cognitive impairment. Serum calcium positively correlated with the fiber density in corpus callosum and fornix terminalis.



The association between imparied fibers and MoCA.



The fibers influenced by calcium concentration.

Association of Dementia Diagnosis at Dialysis Initiation with Mortality in the Elderly ESKD Population in South Korea

Seongmin Kang,[1] Byung Min Ye,[2] Woo Yeong Park,[3] Jang-Hee Cho,[4] Yu Ah Hong,[5] In O Sun,[6] Won Min Hwang,[7] Soon hyo Kwon,[8] Kyung Don Yoo,[1] Seo Rin Kim.[2] The Korean Society of Geriatric Nephrology.
[1]Ulsan University Hospital, Ulsan, Republic of Korea; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea; [3]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [4]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [5]Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea; [6]Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea; [7]Konyang University Hospital, Daejeon, Republic of Korea; [8]Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea.

Background: Dementia is highly prevalent among patients with end-stage kidney disease (ESKD), with a 2–7 fold increase compared to the general population. However, the clinical implications of dementia have not been sufficiently studied in elderly ESKD patients. Therefore, the aim of this study was to identify elderly ESKD patients with newly started hemodialysis and determine whether the comorbidity with dementia increases mortality.

Methods: The Korean Society of Geriatric Nephrology retrospective cohort includes 2,736 elderly ESKD patients (≥70 years old) who started hemodialysis between 2010 and 2017. Kaplan-Meier survival and Cox regression analyses examined all-cause mortality between patients with and without dementia.

Results: Of the 2406 patients, patients with dementia at the initiation of dialysis were 8.3% (n = 200, Fig. 1), older (79.6±6.0 years old) than patients without dementia (77.7±5.5 years old), and included more women (male:female = 89:111). Pre-ESKD diagnosis of dementia was associated with an increased risk of post-ESKD mortality (HR 1.503; 95% CI, 1.263–1.788; P<0.0001, Fig. 2), and this association remained consistent after multivariate adjustment (HR 1.270; 95% CI, 1.062–1.519; P = 0.009). In the subgroup analysis, prevalent dementia was more closely related to mortality following dialysis initiation in female participants, patients aged 75 to 85, patients with no history of CVA or severe behavior disorder, no nursing home residence, no hospitalization, or short-term hospitalization.

Conclusions: A pre-ESKD diagnosis of dementia was associated with mortality following dialysis initiation in the Korean elderly population. Cognitive assessment at the initiation of dialysis is necessary in the elderly with ESKD, and further studies are needed to compare the prognosis of different treatment options for ESKD in the elderly with dementia.

The Effect of Dementia Screening Tests on Subsequent Kidney Function in the Elderly

So Young Lee,[1] Eun Sil Koh,[1] Eunjin Bae,[2] Hyunsuk Kim,[3] Young Youl Hyun,[4] Soon hyo Kwon,[5] Sung Joon Shin,[6] Yu Ah Hong,[7] Sungjin Chung.[1] *[1]Catholic University of Korea Yeouido Saint Mary's Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea; [2]Gyeongsang National University Changwon Hospital, Changwon, Gyeongsangnam-do, Republic of Korea; [3]Hallym University, Chuncheon, Gangwon-do, Republic of Korea; [4]Sungkyunkwan University, Jongno-gu, Seoul, Republic of Korea; [5]Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea; [6]Dongguk University Medical Center, Goyang, Gyeonggi, Republic of Korea; [7]Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea.*

Background: Previous cross-sectional and longitudinal studies have demonstrated that chronic kidney disease is associated with an increased risk for cognitive impairment at baseline and cognitive decline over time in older adults. However, it is unknown whether older people with subjective cognitive decline would be more likely to subsequently develop kidney dysfunction.

Methods: From the Korean National Health Insurance Service-National Elderly cohort database, this study included 111,846 subjects older than 60 years who completed the Korean Dementia Screening Questionnaire-Prescreening (KDSQ-P) or –Cognition (KDSQ-C) between 2007 and 2015. The association between subject cognitive decline and the incidence of kidney dysfunction was investigated during the follow-up.

Results: After adjusting for potential confounding factors, the risk of kidney dysfunction, defined as a decline of more than 30% in estimated glomerular filtration

rate, was significantly lower in elderly without subjective cognitive decline based on both KDSQ-P results (HR=0.892, 95% CI 0.852-0.935, p <0.001) and KDSQ-C (HR=0.934, 95% CI 0.877-0.996, p=0.048) compared to those with subjective cognitive decline. The number of outpatient visits and admission as well as newly diagnosed cardio-metabolic disorders significantly increased in subjects with subjective cognitive decline after taking the dementia screening tests, indicating that a positive answer on the responses to KDSQ-P or KDSQ-C would have led to an increase in healthcare service utilization.

Conclusions: Subjects aged 60 years and older diagnosed as having suspicious cognitive dysfunction from dementia screening programs tend to have more preserved renal function probably through improvements in appropriate medical care with increased health concerns.

FR-PO908

Association Between Family Longevity and Kidney Function in Ashkenazi Jewish Older Adults

Laith Alzyood,[1] Garry A. Graham,[1,3] Sandra Aleksic,[1,2] Tina Gao,[1,2] Sofiya Milman,[1,2] Wei Chen.[1,2] LonGenity. *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Health System, Bronx, NY; [3]Columbia University, New York, NY.*

Background: Familial longevity is associated with protection against age-related diseases; thus, studying familial longevity may provide insights into the mechanisms that protect against age-related decline in kidney function, which are not fully understood. LonGenity is a longitudinal cohort study of community dwelling Ashkenazi Jewish adults aged 65-94 years that aims to identify genetic determinants of familial longevity. Using this cohort, we hypothesized that offspring of parents with exceptional longevity (OPEL) had better kidney function than offspring of parents with usual survival (OPUS).

Methods: In this cross-sectional study, we used multiple linear regression to compare eGFR between OPEL (n=442, defined as having at least 1 parent living past the age of 95 years) and OPUS (n=455, defined as having neither parent who survived to 95 years). eGFR was calculated based on serum creatinine, age and sex using the CKD-EPI equation.

Results: Compared to OPUS, OPEL were younger (74 vs. 77 years), more likely to be female (59% vs. 51%), and less likely to have diabetes mellitus (7% vs. 11%), hypertension (37% vs. 50%) and cardiovascular disease (11% vs. 19%). OPEL had higher mean eGFR than OPUS (73±16 vs. 70±18 ml/min/1.73m^2, p=0.001; Table). This association remained significant after adjusting for body mass index, socioeconomic status, diabetes and cardiovascular disease (p=0.03), but became non-significant after further adjusting for hypertension.

Conclusions: Using this unique cohort, we found familial propensity for longevity was associated with better kidney function independent of diabetes and cardiovascular disease, but this became nonsignificant after adjusting for hypertension. Whether hypertension mediates the relationship between familial longevity and kidney function needs further investigation.

Funding: NIDDK Support, Other NIH Support - NIA

Multiple linear regression of eGFR with familial longevity (OPEL vs. OPUS)

	β (95% confidence interval)	p
Unadjusted	3.85 (1.62, 6.08)	0.001
Model 1: body mass index, socioeconomic status	3.17 (0.90, 5.44)	0.006
Model 2: 1 plus diabetes mellitus, cardiovascular disease	2.51 (0.26, 4.77)	0.03
Model 3: 2 plus hypertension	1.76 (-0.55, 4.07)	0.14

Familial Longevity Modifies the Association Between Hypertension and Kidney Function in Ashkenazi Jewish Older Adults

Wei Chen,[1,2] Laith Alzyood,[1,2] Sanish Sathyan,[1] Sandra Aleksic,[1,2] Tina Gao,[1] Sofiya Milman.[1,2] LonGenity. *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY.*

Background: Familial longevity is associated with protection against age-related diseases. Prior studies suggest that hypertension worsens age-related decline in kidney function. We hypothesized that familial longevity modified the association between hypertension and kidney function in older adults, and sought to identify its associated proteomic profile.

Methods: LonGenity is a cohort study of community dwelling Ashkenazi Jewish adults aged 65-94 years that aims to identify genetic determinants of familial longevity by comparing offspring of parents with exceptional longevity (OPEL) with offspring of parents with usual survival (OPUS). Exceptional longevity was defined as living past the age of 95 years. GFR was estimated using serum creatinine and CKD-EPI equation. In multiple linear regression, stratified by OPEL (n=422) vs. OPUS (n=455), we examined the cross-sectional association between hypertension and eGFR. Plasma proteins (n=4,265) were measured using SomaScan. Top differentially expressed proteins in OPEL vs. OPUS were identified after adjusting for age and sex using a p-value cut-off of 0.001, and then tested for effect modification with hypertension using first-order interaction terms.

Results: Mean age was 76±7 years; 55% were female; 44% had hypertension; mean eGFR was 71±17 ml/min/1.73m^2. After adjusting for demographics, marital status, waist circumference, diabetes, and cardiovascular disease, the presence of hypertension was associated with 3.3 ml/min/1.73m^2 lower eGFR in OPEL (95% CI: -6.4, -0.1; p=0.04) and 4.7 ml/min/1.73m^2 lower eGFR in OPUS (95% CI: -8.0, -1.5; p=0.004). Among the top 14 differentially expressed proteins identified, protein-tyrosine sulfotransferase 2 (TPST2) and hepatoma-derived growth factor related protein-2 (HDGR2) significantly modified the association between hypertension and eGFR with a p-value for interaction of 0.04 and 0.003, respectively.

Conclusions: In this unique cohort, we found that the status of familial longevity and proteins associated with familial longevity modified the association between hypertension and eGFR. While further studies are needed to validate these findings, our study could have clinical implications on personalized medicine for the management of hypertension in older adults.

FR-PO910

Correlation Between Neutrophil-to-Lymphocyte and Platelet-to-Lymphocyte Ratios and Progression of CKD in Elderly Patients

Juliana M. Cardoso,[1] Ana Teresa P. Vieira,[2] Julia Lauar,[2] Luiza K. Araujo,[2] Washington A. Freire Filho,[2] Mariana L. Innecchi,[2] Rosa M. Moyses,[2] Rosilene M. Elias.[2] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]Universidade de Sao Paulo, Sao Paulo, Brazil.*

Background: The systemic inflammation associated with chronic kidney disease (CKD) increases acute-phase protein and inflammatory mediators, which has been associated with higher mortality. Neutrophil-to-lymphocyte (NLR) ratio and platelet-to-lymphocyte ratios (PLR) have been widely studied as inflammatory markers in malignancies, hypertension, heart diseases, and vascular diseases. NLR predicts CKD progression and PLR predicts mortality among hemodialysis patients. The role of NLR and PLR in predicting CKD progression, death or dialysis initiation in elderly is unknown.

Methods: We assessed the composite outcome of death/dialysis initiation and CKD progression in 139 patients with stages 4 or 5 CKD, aged 70 years or more, participants of an ongoing trial (Aging Nephropathy Study -AGNES). NLR and PLR ratios were measured at the study entry. Fast progression was defined as > 5 mL/minute/year loss of estimated glomerular filtration rate (eGFR).

Results: Average age was 83±7 years, eGFR 19.8±7.0ml/min/1.73m2, 56% men, 53% with diabetes. NLR was 2.9±1.4 and PLR was 131.6. Over time, the decline in eGFR was 2.4 (1.1, 6.2) ml/min/yr. NLR but not PLR was higher in fast progressors (p=0.021 and 0.238, respectively). NLR (p-0.028) but not PLR (p=0.077) was higher in patients who died/started dialysis (N=55, 39.6%). Logistic regression/Cox regression revealed NLR as an independent risk factor for CKD progression and death/dialysis initiation, respectively, in fully adjusted models. ROC curve defined 3.77 as the best cut-off value of NLR to predict death/dialysis initiation (specificity 88.1%).

Conclusions: NLR seems to be a good marker for mortality/dialysis initiation and also CKD progression in older patients with advanced CKD, in a higher value than that described for the general population. NLR, a non-expensive tool, should be widely used in this population to identify patients at risk.

FR-PO911

Relationship Between High-Density Lipoprotein Cholesterol and Mortality in Elderly Hemodialysis Patients: Data from the Korean Society of Geriatric Nephrology Retrospective Cohort

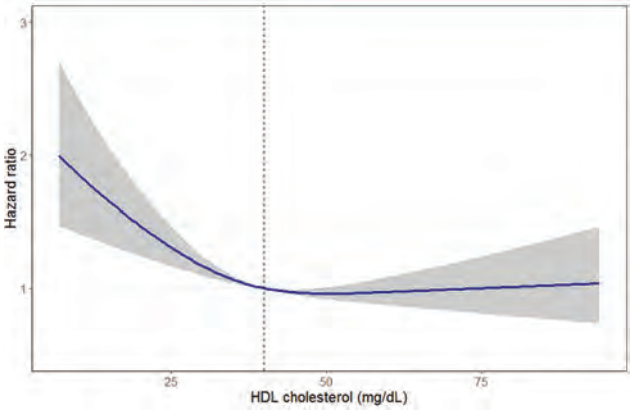
Seung Hye Chu,[1,2] Soyeon Kim,[1,2] Kootae Park,[1,2] Haekyung Lee,[1,2] Soon hyo Kwon,[1,2] Hyunjin Noh,[1,2] Hyoungnae Kim.[1,2] *[1]Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea; [2]Soonchunhyang University Hospital Kidney Center, Yongsan-gu, Seoul, Republic of Korea.*

Background: The association between high-density lipoprotein (HDL) cholesterol and mortality in elderly hemodialysis patients has not been well-established. This study aimed to investigate this association in a Korean elderly hemodialysis patients.

Methods: We recruited 1860 incident hemodialysis patients over the age of 70 from the retrospective cohort of Korean Society of Geriatric Nephrology. The primary outcome was all-cause mortality.

Results: The mean age was 77.8 years and 1049 (56.4%) patients were men. When we grouped patients into HDL cholesterol tertiles, T1 group (HDL level <30 mg/dL in men, <33 mg/dL in women) had a higher proportion of patients with end-stage kidney disease due to diabetic nephropathy. During the median follow-up period of 3.1 years, 1109 (59.7%) deaths occurred. In a multivariable Cox regression model, the T1 group had significantly higher risk of mortality (hazard ratio [HR], 1.29; 95% confidence interval [CI], 1.10-1.50; p=0.002) compared to the T3 group. A non-linear analysis using restrictive spline curve showed that low HDL cholesterol levels were associated with increased HR when HDL cholesterol levels were below 40 mg/dL, but there was no association between HDL cholesterol and mortality when levels above 40 mg/dL. Triglyceride/HDL ratio was not significantly associated with risk of mortality (HR per 1 log increase, 1.08; 95% CI, 0.99-1.18; p=0.075).

Conclusions: Low HDL cholesterol was associated with increased risk of mortality in elderly patients with hemodialysis. However, there was no significant relationship between HDL cholesterol levels and mortality when levels were within the normal range. Therefore, HDL cholesterol lower than normal may be a useful risk factor for predicting mortality in elderly hemodialysis patients.



FR-PO912

Clinical Characteristics of Anti-Nephrin Autoantibody-Positive Minimal Change Disease in Adults: A Case Series in Elderly Japanese

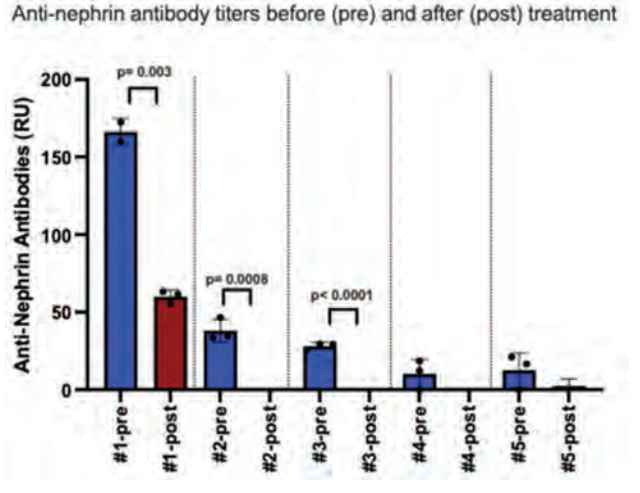
Yoko Fujita,[1,5] Andrew J. Watts,[2,3] Daisuke Ichikawa,[1] Yugo Shibagaki,[1] Tomo Suzuki,[4] Keith H. Keller,[2] Astrid Weins,[2,3] Naoka Murakami.[2,3]
[1]St. Marianna University School of Medicine, Kawasaki, Japan; [2]Brigham and Women's Hospital, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Kameda Medical Center, Kamogawa, Japan; [5]Yokohama General Hospital, Yokohama City, Japan.

Background: Minimal change disease (MCD) is a leading cause of nephrotic syndrome in adults and is more common in the Japanese population. Recently, nephrin autoantibodies were reported in a North American Cohort of adults and children with MCD supporting an autoantibody mediated etiology. However, the clinical characteristics of nephrin autoantibody positive MCD in elderly Japanese patients have scarcely been studied.

Methods: In this single-center case series in Japan, we included 8 consecutive adult cases of biopsy-proven MCD presented to our center in 2021. We evaluated serum, obtained at presentation and following treatment, for circulating nephrin autoantibodies by indirect ELISA. The renal biopsies were evaluated for punctate IgG deposition and co-localization with nephrin by immunofluorescence confocal microscopy imaging.

Results: The median age was 75 years (range 56-84), 43% male, median creatinine and median urine protein/creatinine ratio at diagnosis were 0.92 mg/dL (range 0.47-4.5) and 10.9 g/g (range 7.7-14.0 g/gCr) respectively. Five out of eight cases (63%) had circulating anti-nephrin autoantibodies at presentation and this correlated completely with "punctate IgG" that colocalized with nephrin in the renal biopsies of all positive patients. All 8 patients achieved complete remission after therapy and those with serum anti-nephrin antibodies had reduction in antibody titer with clinical response (Figure). Anti-nephrin antibody positive group had shorter relapse-free time (median 16.5 months), compared to negative group (no relapse).

Conclusions: In our cohort of anti-nephrin antibody-positive adult Japanese MCD cases in elderly Japanese patients, we observed the correlation of anti-nephrin antibody titer with disease activity and shorter relapse-free time. Larger studies are needed to further characterize anti-nephrin antibody positive MCD cases in adults.



FR-PO913

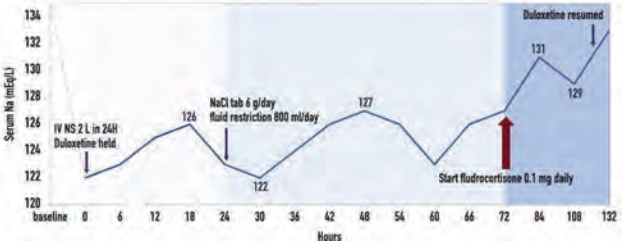
Fludrocortisone-Responsive Hyponatremia in the Elderly

Noppawit Aiumtrakul,[1,3] Chinnawat Arayangkool,[1,3] Manasawee Tanariyakul,[1,3] Thiratest Leesutipornchai,[1,3] Roland C. Ng.[1,2] *[1]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [2]Kuakini Medical Center, Honolulu, HI; [3]Hawaii Residency Programs Inc, Honolulu, HI.*

Introduction: Case studies report a rare manifestation of hyponatremia responsive to fludrocortisone, presenting as SIADH or salt-wasting syndrome (SWS), which fails to correct with both fluid restriction and Na replacement.

Case Description: A 79-year-old Japanese woman with T2DM and depression on duloxetine was found to have asymptomatic hyponatremia with Na level of 122 mEq/L. She reported eating 3 meals and drinking water 2 L/day. Vital signs were hemodynamically stable without presence of dehydration. Initial work-up showed serum osmolality at 256 mOsm/kg, urine Na at 94 mEq/L, urine osmolality at 292 mOsm/kg, serum creatinine at 0.4 mg/dL and BUN at 10 mg/dL, with normal serum glucose, AM cortisol and TSH. CT brain without contrast was unremarkable. Duloxetine was initially held. The patient received 2 L of IV normal saline, followed by NaCl tabs 6 g/day. Fluid intake was restricted to <800 ml/day. The serum Na remained low between 122-126 mEq/L for the next 48 hrs. After initiating fludrocortisone acetate 0.1 mg daily, the serum Na increased to 133 mEq/L within 60 hours, without falling after resuming duloxetine. Her urine output was 1-2 L/day. Her pre- and post-admission weights were 35 and 32.9 kg. Her hematocrit was stable at 34%.

Discussion: Reports in the literature list 10 non-neurosurgical patients with hyponatremia responsive to fludrocortisone, 5 with cerebral salt-wasting, 3 with SIADH, and 2 did not have a clear diagnosis. All of them were Japanese elderly patients. 3 of 10 cases had a prior history of traumatic brain injury. The clinical response of SIADH or SWS to fludrocortisone is rarely discussed as a treatment of hyponatremia in medical patients. This is another case of fludrocortisone-responsive hyponatremia. Common characteristics include Japanese race, female, elderly, hypo osmolality, hypertonic urine and high urine Na. Volume status can be either hypo or euvolemic. In 1987, Ishikawa et al. proposed the concept of mineralocorticoid-responsive hyponatremia of the elderly (MRHE). MRHE is thought to be caused by a decline in the response to the RAAS and in the kidneys' ability to retain sodium.



FR-PO914

Kappa Light Chain Myeloma Presenting as Acute Renal Failure

Lakshmi Menon, Kotresha H. Neelakantappa. *NewYork Presbyterian - Brooklyn Methodist Hospital, Brooklyn, NY.*

Introduction: Multiple Myeloma is a plasma cell dyscrasia commonly affecting the elderly. Acute renal failure carries a particularly poor prognosis. Here we present a 95-year-old woman who came with fatigue, polyuria and new onset renal failure. Work up showed multiple myeloma with kidney biopsy showing diffuse tubular necrosis and bone marrow biopsy showing kappa light chain myeloma. She was started on chemotherapy within 13 days of admission. Despite prompt initiation of chemotherapy, kidney function did not improve, and she deteriorated in a month's time.

Case Description: The patient was a 95-year-old woman with a history of HTN/HLD and a remote history of PE on warfarin. She was fully functional and independent at baseline; she was compliant with medication and labs 6 months prior were normal. She was referred to the ED for bradycardia, had been having polyuria and fatigue one week prior. In the ED, vitals were normal, physical exam showed chronic bilateral hearing loss, labs were notable for a Hgb of 6.5, MCV of 104, a BUN of 150 and a Cr of 12 with a potassium of >7.5, her corrected calcium was 9.5; a stool occult test was positive, and her INR was 7.9. She was admitted to the ICU for CVVHD, concern for acute GI bleed with severe pre-renal AKI, however her hemoglobin normalized and was unable to wean off HD. Workup for RPGN, vasculitis and multiple myeloma was done which showed significantly elevated kappa/lambda ratio, kidney biopsy showed diffuse acute tubular necrosis without glomerulonephritis and bone marrow biopsy and serum studies showed kappa light chain myeloma. Chemotherapy was started 13 days after diagnosis; however, her kidney function did not improve, and she deteriorated within a month from episodes of fluid overload while on dialysis and vascular access site infections.

Discussion: Renal impairment in multiple myeloma has a life expenctancy of less than a year, and is an independent negative prognostic factor when noted in the first 6 months of diagnosis. The biggest indicator of overall prognosis is renal response to treatment including dialysis and chemotherapy. Our patient's case showed a rare case of kappa light chain myeloma presenting with acute renal failure from ATN which unfortunately did not improve with treatment. More research into modalities such as high output dialysis or plasmapheresis in this population would be useful to reduce light chain burden and resulting ATN.

FR-PO915

Association of Serum Magnesium Concentration with Renal Prognosis in Patients with CKD

Seiji Kishi,[1] Nakashima Takaya,[3] Tadahiro Goto,[2] Hajime Nagasu,[1] Naoki Kashihara.[1] *[1]Kawasaki Ika Daigaku, Kurashiki, Japan; [2]TXP Medical, Tokyo, Japan; [3]Nagasaki Daigaku, Nagasaki, Japan.*

Background: Magnesium plays a crucial role in various physiological processes, and disruptions in its balance have been linked to adverse health effects. By investigating the impact of magnesium levels on renal outcomes, this study aims to contribute to our understanding of managing magnesium levels in CKD patients. The findings may provide valuable insights for clinical practice and future intervention studies in this population.

Methods: This study utilized the J-CKD-DB-Ex database, comprising CKD patients enrolled between 2014 and 2020. Only patients with at least two measurements of magnesium and eGFR were included. The index date was established as the time of the initial magnesium measurement, and individuals with an eGFR greater than 15 and less than 60 ml/min/1.73 m^2 at the index date were selected. The study categorized participants into three groups based on their magnesium levels: low, normal, and high magnesium. Patients who had a single clinic visit or a history of hospitalization were excluded from the analysis. The primary outcome was defined as the progression to ESKD, determined by an eGFR below 15 mL/min/1.73m^2 or a decline of 30% or more in eGFR from baseline.

Results: A cohort of 9,996 patients without prior hospitalization was analyzed. Hypomagnesemia was present in 6% of patients, while hypermagnesemia was observed in 4% of patients. Initial Kaplan-Meier survival curve analysis, without adjustment, showed a significantly worse renal prognosis in the hypomagnesemia group. However, to address potential confounding factors, multiple imputation and Cox regression analysis were conducted, with the normal magnesium group as the reference. After adjusting for covariates, the hypomagnesemia group had a hazard ratio of 1.26 (95% confidence interval: 1.08-1.46), indicating an increased risk of adverse renal outcomes compared to the normal magnesium group. Adjusted restricted cubic spline analysis also supported this trend, demonstrating that lower magnesium levels were associated with poorer renal prognosis.

Conclusions: The study findings suggest that the renal prognosis of patients is influenced by their serum magnesium concentration, with poorer outcomes observed in individuals with hypomagnesemia.

FR-PO916

Ionized and Total Magnesium Levels and Cardiovascular Risk in Patients with CKD

Solene M. Laville,[1,2] Maxime Pluquet,[2] Nicolas Mansencal,[3,4] Denis Fouque,[5,6] Maurice Laville,[6] Luc Frimat,[7] Ziad Massy,[8,4] Said Kamel,[2] Natalia Alencar de Pinho,[4] Sophie Liabeuf.[1,2] *[1]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [2]Universite de Picardie Jules Verne, Amiens, France; [3]Ambroise Paré University Hospital, Cardiology department, Boulogne-Billancourt, France; [4]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [5]Hospices Civils de Lyon, Lyon, France; [6]Universite Claude Bernard Lyon 1, Villeurbanne, France; [7]Centre Hospitalier Regional Universitaire de Nancy, Nancy, France; [8]Hopital Ambroise-Pare Service de Nephrologie Dialyse, Boulogne-Billancourt, France.*

Background: We sought to determine whether serum ionized (iMg) and total (tMg) Mg levels are associated with major adverse cardiovascular events (MACE) in patients with CKD.

Methods: CKD-REIN is a prospective cohort of CKD outpatients (not on dialysis). Baseline iMg and tMg serum concentrations were respectively centrally measured using the NOVA BIOMEDICAL Stat Profile PRIME ES and with Atellica® CH SIEMENS analyzers. Adjusted cause-specific Cox proportional hazard models were used to estimate hazard ratios (HRs) for first MACE (CV death, myocardial infarction, stroke or hospitalization for heart failure).

Results: Of the 2419 included patients (median [IQR] age: 68[60-76]; mean (SD) eGFR 33.5(13.5) mL/min/1.73 m^2), 52% had a history of CV disease. Correlation between iMg and tMg was very high (r=0.88; p<0.001). Over a median follow-up of 4.4 years [IQR,2.3-5.0], 351 experienced a first MACE event, leading to an incidence rate [95%CI] of 3.9[3.5;4.3] per 100 person-years (**figure**). After multiple adjustments, patients in Tertile 3 (T3) of iMg had a higher risk of MACE compared to patients in Tertile 1 (T1), HR [95% CI], 1.39[1.05;1.83]. No difference was noted for patients in Tertile 2 (T2) compared to patients in T1. Regarding tMg, patients in T3 of total Mg had a higher risk of MACE compared to patients in T1 (HR=1.40[1.07;1.83]). A nonsignificant lower risk of MACE was noted for patients in T2 compared to patients in T1, revealing a potential U shape relation between MACE risk and tMg level.

Conclusions: This study suggests that high serum iMg and tMg levels are associated to cardiovascular outcomes in patients with moderate to advanced CKD. Further research is needed to explore the shape of the relationships and the mechanisms.

Epidemiology and Outcomes of Hyperphosphatemia in Non-Dialysis CKD Patients in China

Sheng Nie,[1] Shiyu Zhou,[1] Mengchun Gong,[2] Fan Fan Hou.[1] *[1]Southern Medical University Nanfang Hospital, Guangzhou, China; [2]Digital Health China Technology Co., Ltd., Beijing, China.*

Background: Information on epidemiology and outcomes of hyperphosphatemia (HP) in non-dialysis CKD (ND-CKD) patients is still lacking.

Methods: Hospitalized patients aged ≥18 years with a diagnosis of CKD between 2013 and 2020 in the China Renal Data System (CRDS) were included. The prevalence of HP (defined as a serum phosphate concentration > 1.45 mmol/L when first detected during hospitalization) was analyzed. Secondary endpoints were use of phosphorus-lowering medications, all-cause mortality, cardiovascular mortality and progression of kidney disease. This is the interim report of the study.

Results: A total of 210,806 ND-CKD patients from 19 hospitals were screened, of whom 157,987 (74.94%) had serum phosphate testing during the first hospitalization. The overall prevalence of HP was 14.83% in these patients (CKD G1 8.26%, G2 6.17%, G3a 7.32%, G3b 12.43%, G4 26.74%, G5 65.85%). The utilization rates of phosphorus-lowering medications (including calcium acetate, calcium carbonate, lanthanum carbonate, and sevelamer carbonate) in ND-CKD G3-5 were 9.62% (G3a), 11.29% (G3b), 14.84% (G4), and 23.92% (G5), respectively. Among 64,662 patients with a median follow-up of 3.3 year on death, patients with HP (n=8856) had a 13% increased risk of all-cause mortality (HR 1.13, 95% CI 1.06-1.22) and a 28% increased risk of cardiovascular mortality (HR 1.28, 95% CI 1.04-1.56), compared with those with normal serum phosphate concentration at baseline with confounders adjusted for age, sex, region, CKD stage, co-morbidity. Among the patients with HP the risk of all-cause mortality and cardiovascular mortality were reduced by 12% and 16%, respectively, in patients with phosphorus-lowering medications compared to those without phosphorus-lowering medications. Among 47,581 patients with a median follow-up of 1.8 years on kidney function, patients with HP (n=3622) had a 9% increased risk of kidney disease progression than those with normal serum phosphate concentration at baseline (HR 1.08, 95% CI 1.00-1.17).

Conclusions: HP is common in ND-CKD in China and is an independent risk factor for mortality and kidney disease progression. The use of phosphorus-lowering medications was associated with the decreased risk of all-cause mortality and cardiovascular mortality in patients with CKD G3-5.

Intensity of Serum Phosphate Lowering Is Related to the Risk of RRT in Non-Dialysis Dependent (NDD)-CKD Patients with Hyperphosphatemia

Sheng Nie,[1] Qi Gao,[1] Shiyu Zhou,[1] Lichen Hao,[2] Yan Zhang,[3] Muhan Yuan.[3] *[1]Southern Medical University Nanfang Hospital, Guangzhou, China; [2]Sanofi, Bridgewater, NJ; [3]Sanofi, Beijing, China.*

Background: Few studies have explored the association between intensity of serum phosphate lowering and risk of renal replacement therapy (RRT) in patients with non-dialysis dependent chronic kidney disease (NDD-CKD).

Methods: Data was extracted from the Optum Humedica EHR database. The study period started from July 1, 2007, to June 30, 2021. We enrolled NDD-CKD adult patients with two consecutive results of elevated serum phosphorus (defined as non-same day but ≤180 days apart, >4.5 mg/dL on both occasions). The study exposure was defined as the

change in serum phosphorus concentration at 360 days after the enrollment. 360 days after the enrollment was defined as the index date. Study outcome was the initiation of RRT.

Results: A total of 28,165 patients were analyzed, of whom 45% were male, the mean age was 60 years, and 43% were in CKD stage 5. Based on the changes in serum phosphorus concentration at 360 days, 11,599 (41.2%), 10,135 (36.0%), 3,165 (11.2%), 2,293 (8.1%) and 975 (3.5%) were categorized into the high decrease group (decrease of ≥25%), decrease group (decrease of 5% to 25%), stable group (decrease of <5% to increase of <5%), increase group (increase of 5% to <25%), and high increase group (increase ≥25%), respectively. The high decrease group and decrease group were associated with lower risk of RRT compared with the stable (high decrease: adjusted hazard ratio (aHR)=0.51, 95% confidence interval (CI): 0.47-0.56; decrease: aHR=0.75, 95% CI: 0.69-0.81). Meanwhile, the high increase group and increase group were associated with higher risk of RRT compared with the stable (high increase: aHR=1.34, 95% CI: 1.19-1.51; increase: aHR=1.24, 95% CI: 1.13-1.36).

Conclusions: The level of serum phosphate change was associated with the risk of RRT in patients with NDD-CKD and hyperphosphatemia. Our findings suggest that intensive lowering of serum phosphate might help to delay the time to RRT in patients with NDD-CKD.

Metabolic Acidosis and CKD Progression

Carmine Zoccali,[1,2] Graziella D'Arrigo,[3] Mercedes Gori,[3] Giovanni Tripepi,[3] Francesca Mallamaci.[3,4] On Behalf of MAURO Study Group. *[1]Renal Research Institute, New York, NY; [2]BIOGEN, Ariano Irpino, Italy; [3]IFC-CNR, Reggio Calabria, Italy; [4]Nephrology, Dialysis, and Transplantation, Reggio Calabria, Italy.*

Background: An inverse relationship between venous bicarbonate and CKD progression has been reported in several observational studies, but only sparse longitudinal observations testing this relationship exist. Bicarbonate supplementation trials have been conflictual, with limited power and a high risk of bias. Longitudinal studies may provide circumstantial new evidence for implicating metabolic acidosis in the risk of adverse kidney outcomes.

Methods: We performed a longitudinal study in 528 patients with at least 3 longitudinal measurements of bicarbonate over 32 months (IQR: 30-36). The association between bicarbonate trajectories over time and the incidence of renal events (>30% eGFR reduction, dialysis or transplantation) were investigated by a two stages analysis: 1) in the first stage, we identified distinctive group-based bicarbonate trajectories analysis (GBTM); 2) in the second stage we assessed the association between bicarbonate trajectories groups and the risk of renal events by Cox model.

Results: Overall, 126 patients had renal events. Four trajectories of bicarbonate were identified and labelled as low trajectory [bicarbonate: 19.07± 2.5 mEq/L], moderate [21.2± 2.3 mEq/L], moderate-high [25.1± 2.2 mEq/L] and high [27.9± 2.8 mEq/L]. In crude and adjusted analyses (age, gender, systolic BP, haemoglobin, albumin, phosphate, PTH, 24h proteinuria, and eGFR), the hazard rate (HR) of renal events decreased in a dose-dependent fashion from the lowest bicarbonate trajectory (reference category, HR 1) [moderate (HR:0.82, 95%CI 0.50-1.35, p=0.443), high moderate (HR:0.59, 95%CI 0.34-1.00, p=0.050), and high bicarbonate category (HR: 0.37, 95%CI 0.15-0.95, p=0.039), p for trend p=0.010]. (P for trend=0.005). Thus, for patients in the high bicarbonate category (27.9± 2.8 mEq/L), there is an 63% risk reduction for a renal composite endpoint.

Conclusions: In a longitudinal analysis of a cohort of CKD patients, high bicarbonate levels are associated with a substantially reduced risk of renal events. These findings represent a strong call for well-designed, adequately powered randomised trials testing the effect of bicarbonate supplements or pharmacologic interventions that increase serum bicarbonate on renal outcomes. Given the substantial risk reduction in patients in the highest bicarbonate trajectory, these trials are an absolute clinical research priority.

FR-PO920

Serum Uric Acid Trajectories and CKD Progression in the African American Study of Kidney Disease in Hypertension (AASK)

Sungkweon Cho,[1] Jeffrey B. Kopp.[2] *[1]Ajou University School of Medicine and Graduate School of Medicine, Suwon, Gyeonggi-do, Republic of Korea; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Serum uric acid levels increase with progressive kidney disease, due to retention of uric acid resulting from a reduced glomerular filtration rate (eGFR). Chronic elevations in circulating and tissue levels of uric acid may contribute to progression of chronic kidney disease, although this remains controversial.

Methods: We used data from the African American Study of Kidney Disease in Hypertension (AASK) to examine the hypothesis that subjects whose serum urate levels declined during the study period would manifest less composite end-stage kidney disease (ESKD) event. The composite ESKD outcome was defined as 50% decline from baseline eGFR, eGFR ≤15 mL/min/1.73 m2, self-reported initiation of chronic dialysis, or kidney transplantation. To estimate the trajectory, the group-based trajectory modeling of the uric acid level change was done. We classified into 5 groups ; high-stable group, the high-increasing group, the extreme high-stable group, normo-increasing group, and high-decreasing group. Cox proportional hazards model was used to estimate whether the different group membership would predict the composite ESKD outcomes.

Results: We found that compared with subjects in the normal-increasing uric acid group (*i.e.,* those who had the lowest overall serum uric acid levels), three groups had higher incidence of the composite ESKD event: the high-stable uric acid group, HR = 2.28, $p = 0.012$, the high-increasing uric acid group, HR = 1.95, $p = 0.042$, and the extremely high-stable uric acid group, HR = 3.21, $p < 0.001$. Further, the extremely high-stable group had a higher composite ESKD incidence, compared with the high-decreasing group, HR = 1.98, $p = 0.046$.

Conclusions: Uric acid trajectories are associated with ESKD incidence. In particular, subjects whose uric acid levels decreased over time had a better composite ESKD event than other groups.

FR-PO921

Projected Benefits of Gout Control on the Health and Economic Burden of CKD Patients with Uncontrolled Gout

Brad A. Marder,[1] Joshua Card-Gowers,[2] Lise Retat,[2] Marek Piotrowski,[2] Laura Webber,[2] Brian LaMoreaux,[1] Ada Kumar.[1] *[1]Horizon Therapeutics plc, Deerfield, IL; [2]HealthLumen Ltd, London, United Kingdom.*

Background: Gout affects 1 in 4 patients with stage 3-5 CKD and is an independent risk factor for CKD progression. Since oral urate lowering therapies (ULTs) cannot adequately manage gout in some CKD patients, this study examines potential benefits of pegloticase treatment in CKD patients with refractory gout.

Methods: A validated microsimulation model was used to project gout burden in a virtual US CKD population. In the baseline scenario, individuals were assigned an eGFR, albuminuria status, and serum urate (SU) level. Those with gout were assigned complication risks for stroke, diabetes, and hypertension, direct and indirect costs, oral ULT use/efficacy probability (use: 29.9-41.9% [based on eGFR], efficacy: 48.3%) and utility weight. In the intervention scenario, patients with uncontrolled gout (SU>6 mg/dL despite oral ULT, and ≥2 gout flares/year or ≥1 tophi) were "treated" with pegloticase, assuming a 71% SU-lowering efficacy rate (SU<6mg/dL) through simulation end. Health/economic benefits were projected through 2035.

Results: Prevalence of comorbid gout and CKD was projected to rise from 8.2M in 2023 to 10.5M in 2035, with 28% having uncontrolled gout. Annual costs of gout in CKD patients were projected to rise from $39.1B in 2023 to $50.4B in 2035. Pegloticase use in all CKD patients with uncontrolled gout resulted in 301,000 fewer uncontrolled gout cases, 208,000 quality-adjusted life years gained, and 53,000 complications avoided by 2035 (**Figure**). Compared to the baseline (non-treatment) scenario, intervention scenario costs were $23.4B lower in 2035.

Conclusions: Gout prevalence in CKD patients is projected to markedly increase over the next 12 years. This microsimulation suggests that intervention could result in health and quality of life improvements in CKD patients with uncontrolled gout, with associated cost reductions.

FR-PO922

Factors of Poor Prognosis Associated with CKD by Stage in Ambulatory Patients: A Cross-Sectional Study

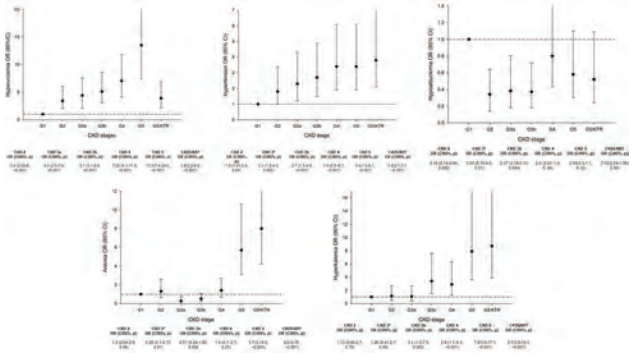
L. M. Perez-Navarro, Rafael Valdez-Ortiz. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Mexico has a high prevalence of chronic kidney disease (CKD) but limited information about the early stages of CKD and their clusters of poor prognosis factors (PPF) such as hyperuricemia, electrolyte abnormalities or comorbidities. Objective. To assess the prevalence of PPF by CKD stages in ambulatory patients.

Methods: A cross-sectional study with 1772 adult patients with CKD that attended the Nephrology Outpatient Clinic. PPF data is reported as adjusted OR (95% confidence interval) (CI).

Results: Mean age was 56.2 ± 15.8 years. Kidney Replacement Therapy (KRT) was reported in 12% of the patients. Type 2 diabetes mellitus (T2DM), age >50 years and male gender were the PPF associated with all CKD stages. The PPF in CKD 2 and 3a hyperuricemia OR 3.4 (2.02,6.0) and 4.4 (2.5,7.6), and hypertension OR 1.8 (1.01,3.4) and 2.3 (1.2,4.3) respectively. In CKD 3b were hyperuricemia OR 5.1 (3.1,8.6), hypertension OR 2.7 (1.5,4.9) and hyperkalemia OR 3.4 (1.5,7.6). For CKD 4, 5 without KRT and 5 were hyperuricemia OR 7.02 (4.1,11.8), 13.5 (7.4,24.6), 3.9 (2.2–6.9), hypertension OR 3.4 (1.9,6.1), 3.4 (1.9,6.1), 3.8 (2.1,7.1), and hyperkalemia 2.9 (1.3,6.3), 7.9 (3.6,17.3), 8.7 (3.9,19.3), respectively. Anemia was important for CKD 5 without KRT and 5 with OR of 5.7 (3.09,10.6) and 8 (4.2,15), respectively.

Conclusions: This is the largest study of Mexican patients with CKD; most of them without KRT. Patients had multiple modifiable PPF. Early and comprehensive management of PPF could prevent or delay progression to KRT. Treatment of associated PPF should be a priority, as it could make a significant difference both for CKD progression and its subsequent cardiovascular risk.



FR-PO923

Hyperuricemia and Polygenic Risk Score for CKD: Evaluating Its Impact Beyond Genetic Predisposition for CKD

Yaerim Kim,[1] Jin hyuk Paek,[1] Kyubok Jin,[1] Seungyeup Han,[1] Jung Pyo Lee,[2] Dong Ki Kim,[3] Chun Soo Lim,[2] Jeonghwan Lee.[2] *[1]Keimyung University School of Medicine, Daegu, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: The bidirectional effect of hyperuricemia on chronic kidney disease (CKD) underscores the importance of hyperuricemia as a risk factor for CKD. We evaluated the effect of hyperuricemia on the presence and development of CKD after considering genetic background by calculating polygenic risk scores (PRSs).

Methods: We employed genome-wide association study summary statistics—excluding the United Kingdom Biobank (UKB) datasets among published CKD Gen Consortium papers—to calculate the PRSs for CKD in white background subjects. To validate PRS performance, we divided the UKB into two datasets to validate and test the data. We used logistic regression analysis to evaluate the association between hyperuricemia and CKD, and performed Cox proportional hazard analysis exclusively for subjects with available follow-up data.

Results: In total, 438,253 clinical data points and 4,307,940 single nucleotide polymorphisms from 459,155 samples were included. We observed a significant positive association between PRS and CKD and the presence and development of CKD. Hyperuricemia significantly increased CKD risk (adjusted odds ratio 1.54, 95% confidence interval 1.49–1.58). The impact of hyperuricemia on CKD was maintained irrespective of PRS range but was more pronounced in subjects with low PRS (1st tertile range). Survival analysis indicates that the presence of hyperuricemia significantly increased the risk of CKD development.

Conclusions: The PRS for CKD thoroughly reflects the risk of CKD development. Hyperuricemia is a significant indicator of CKD risk, even after incorporating the genetic risk score for CKD. Irrespective of genetic risk, patients with a prospective risk of developing CKD require uric acid monitoring and management.

FR-PO924

Polygenic Risk Affects the Penetrance of Monogenic Kidney Disease

Atlas Khan,[1] Ning Shang,[1] Jordan G. Nestor,[1] Chunhua Weng,[1] George Hripcsak,[1] Peter C. Harris,[2] Ali G. Gharavi,[1] Krzysztof Kiryluk.[1] Kiryluk Group. *[1]Columbia University, New York, NY; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Chronic kidney disease (CKD) is a genetically complex disease determined by an interplay of monogenic, polygenic, and environmental risks. Most forms of monogenic kidney diseases have incomplete penetrance and variable expressivity. It is presently unknown if some of the variability in penetrance can be attributed to polygenic factors.

Methods: Using the UK Biobank (N=469,835) and the All of Us (N=98,622) datasets, we examined the two most common forms of monogenic kidney disorders, autosomal dominant polycystic kidney disease (ADPKD) caused by deleterious variants in the *PKD1* or *PKD2*, and COL4A-associated nephropathy (COL4A-AN caused by deleterious variants in *COL4A3*, *COL4A4*, or *COL4A5*). We used the eMERGE-III electronic CKD phenotype to define cases (estimated glomerular filtration rate (eGFR) <60 or kidney failure) and controls (eGFR >90). The effects of the genome-wide polygenic score for CKD were tested in monogenic variant carriers and non-carriers using logistic regression controlling covariates.

Results: As expected, the carriers of known pathogenic and rare predicted loss-of-function variants in *PKD1* or *PKD2* had a high risk of CKD (OR_{meta}=17.1, 95% CI: 11.1-26.4, P=1.8E-37). The GPS was comparably predictive of CKD in both ADPKD variant carriers (OR_{meta}=2.28 per SD, 95%CI: 1.55-3.37, P=2.6E-05) and non-carriers (OR_{meta}=1.72 per SD, 95% CI=1.69-1.76, P< E-300) independent of age, sex, diabetes, and genetic ancestry. Compared to the middle tertile of the GPS distribution for non-carriers, ADPKD variant carriers in the top tertile had a 54-fold increased risk of CKD. In contrast, ADPKD variant carriers in the bottom tertile had only a 3-fold increased risk of CKD. Similarly, the GPS was predictive of CKD in both COL4-AN variant carriers (OR_{meta}=1.78, 95% CI=1.22-2.58, P=2.38E-03) and non-carriers (OR_{meta}=1.70, 95%CI: 1.68-1.73 P<E-300). The carriers in the top tertile of the GPS had a 2.5-fold higher risk of CKD, while the risk for carriers in the bottom tertile was similar to the middle tertile of non-carriers.

Conclusions: Variable penetrance of kidney disease in ADPKD and COL4-AN is partially explained by differences in polygenic risk profiles. Accounting for polygenic factors has the potential to improve risk stratification in monogenic kidney disease and may have implications for genetic counseling.

FR-PO925

Association Between Dyslipidemia and the Risk of Incident CKD Affected by Genetic Susceptibility: Polygenic Risk Score Analysis

Boram Weon,[1,2] Wencheng Jin,[1,3] Ara Ko,[2] Jeonghwan Lee,[1,3] Jung Pyo Lee.[1,3] *[1]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Seoul, Republic of Korea; [2]Seoul National University Hospital Department of Internal Medicine, Seoul, Republic of Korea; [3]Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.*

Background: Polygenic risk of dyslipidemia on kidney disease outcomes has been inconclusive, and it requires further clarification. Therefore, we aimed to investigate the effects of genetic factors on the association between dyslipidemia and the risk of chronic kidney disease (CKD) using polygenic risk score (PRS). score (PRS) provides information of the overall contribution of numerous genetic variants on disease outcomes. The effect

Methods: We analyzed data from 373,523 participants of UK biobank aged 40 to 69 and without history of chronic kidney disease. The PRS for incident CKD was constructed using GWAS summary statistics of CKDGen overall European ancestry (n=480,697). The impacts of lipids and PRS on incident CKD were assessed using Cox proportional hazard model. To investigate the interaction between lipids and genetic factor on incident CKD,

we introduced multiplicative interaction terms between them to multivariable analysis model and performed subgroup analysis stratified by PRS tertiles.

Results: A total of 4,424 participants developed CKD. In multivariate analysis, the PRS was significantly predictive of the risk of incident CKD (continuous variable; HR, 1.075; 95% CI, 1.043-1.109). 1-SD lower levels of total cholesterol (HR, 0.898; 95% CI, 0.867-0.931), LDL-C (HR 0.899, 95% CI; 0.931), HDL-C (HR, 0.877; 95% CI, 0.841-0.914), and higher triglyceride (HR, 1.078; 95% CI, 1.048-1.109) were significantly associated with the risk of incident CKD. The interactions between triglyceride and intermediate (HR, 1.122; 95% CI, 1.026-1.228) and high PRS (HR, 0.932; 95% CI 0.872-0.995) were significant, and the interactions were inversely associated with the risk of incident CKD. Similar relationship between triglyceride and PRS were observed in subgroup analysis stratified by PRS tertiles.

Conclusions: The PRS for incident CKD presented significant predictive power for incident CKD. Higher triglyceride, lower total cholesterol, lower LDL-C, and lower HDL-C increased the risk of incident CKD. There were interactions between triglyceride and genetic factor, and the individuals in the low-PRS group had a higher risk of triglyceride-related incident CKD.

FR-PO926

Discovery and Prioritization of Genetic Determinants of Kidney Function in Approximately 310,000 Individuals from ESKD-Prevalent Taiwan and Japan

Chin-Chi Kuo,[1,2] Hung-Lin Chen,[1] David R. Chang.[2] *[1]Big Data Center, China Medical University Hospital, Taichung, Taiwan; [2]Division of Nephrology, Department of Internal Medicine, China Medical University Hospital, Taichung, Taiwan.*

Background: Limited ancestral diversity in genome-wide association studies (GWASs) on kidney function confines their generalizability to regions with a high incidence of end-stage kidney disease (ESKD).

Methods: We conducted a meta-analysis of GWASs (n=244952) of estimated glomerular filtration rate (eGFR) and a replication dataset (n=27058) from Taiwan and Japan. Additionally, polygenic risk scores (PRSs) for chronic kidney disease (CKD) substantially differentiated the CKD risk in independent cohorts from Taiwan (n=30433) and the United Kingdom (n=260245). (**Fig. 1**)

Results: Our analysis identified 238 independent signals in 97 loci that were associated with eGFR. Functional analyses revealed that variants associated with *F12* expression and *ABCG2* missense mutation link inflammation, coagulation, and urate metabolism to a high risk of decreased kidney function. The median time to 10% CKD incidence in PRS_{CKD} risk groups (above, in-between, and below two standard deviations of mean) was 64, 66, and 71 years after birth, respectively. (**Fig. 2**) The 7-year difference between high– and low–genetic risk groups can be observed from the age of 50.

Conclusions: Our findings suggest that PRS_{CKD} has the potential to be used for early kidney disease prevention, particularly in countries with a high incidence of ESKD.

Abstract Withdrawn

FR-PO928

Common Genetically Predicted Skipping of COL4A4 Exon 27 Is Associated with Hematuria and Albuminuria

Moumita Barua,[1] Frida Lona Durazo,[2] Kohei Omachi,[3] Damian Fermin,[4] Felix H. Eichinger,[4] Jonathan P. Troost,[5] Jeffrey H. Miner,[3] Andrew Paterson,[6] Sarah A. Gagliano Taliun.[2] *[1]Toronto General Hospital, Toronto, ON, Canada; [2]Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; [3]Washington University in St Louis School of Medicine, St Louis, MO; [4]University of Michigan Division of Nephrology, Ann Arbor, MI; [5]Michigan Institute for Clinical and Health Research, Ann Arbor, MI; [6]SickKids Research Institute, Toronto, ON, Canada.*

Background: Hematuria is an established sign of glomerular disease and can be associated with kidney failure, but there has been limited scientific study of this trait.

Methods: Here, we combined genetic data from the UK Biobank with predicted gene expression and splicing from GTEx kidney cortex samples (n = 65) in a transcriptome-wide association study (TWAS) to identify additional biological mechanisms influencing hematuria.

Results: Our TWAS using kidney cortex identified significant associations for 5 genes in terms of expression and 3 significant splicing events. Notably, we identified an association between hematuria and the skipping of *COL4A4* exon 27, which is genetically predicted by intronic rs11898094 (minor allele frequency 13%). The association was also found with urinary albumin excretion. We found independent evidence supporting the existence of this skipping event in glomeruli-derived mRNA transcriptomics data (n = 245) from the NEPTUNE dataset. The functional significance of loss of exon 27 was demonstrated using the split NanoLuc-based type IV collagen α3α4α5(IV) heterotrimer assay, in which heterotrimer formation was quantified by luminescence.

Conclusions: Altogether, our results highlight the value of investigating the role of non-coding sequence, an underexplored region, by integrating multiple data types to shed light on kidney traits and their underlying disease mechanisms.

Circulating Proteins Associated with Mortality in Patients with CKD

Nityasree Srialluri,[1,3] Aditya L. Surapaneni,[2,3] Pascal Schlosser,[3] Teresa K. Chen,[4] Insa M. Schmidt,[5] Eugene P. Rhee,[6] Josef Coresh,[3] Morgan Grams.[2,3] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]New York University Grossman School of Medicine, New York, NY; [3]Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD; [4]University of California San Francisco School of Medicine, San Francisco, CA; [5]Boston Medical Center, Boston, MA; [6]Massachusetts General Hospital, Boston, MA.*

Background: Proteomics could provide pathophysiologic insight into the increased risk of mortality in patients with chronic kidney disease (CKD). This study aimed to investigate associations between the circulating proteome and all-cause mortality among patients with CKD.

Methods: In this observational cohort study, we quantified the associations of 6790 circulating proteins with the outcome of all-cause mortality among 703 participants in the African American Study of Kidney Disease (AASK) Study. Proteins with significant associations were further evaluated among Atherosclerosis Risk in Communities (ARIC) Study participants with chronic kidney disease (Visit 5; N = 1628).

Results: In the AASK cohort, mean age was 54.5 years, 271 (38.5%) were women and mean measured GFR was 46 ml/min per 1.73m^2. Median follow up was 9.6 years and 7 distinct proteins (Lamin-B2, Spondin-1, Somatostatin receptor type 1, N-terminal pro-BNP, DDRGK domain-containing protein 1, Beta-2-microglobulin, and N6-adenosine-methyltransferase 70kDa subunit) were associated with all-cause mortality at Bonferroni-level threshold (p<0.05/6790) after adjustment for demographics and clinical factors, including baseline measured eGFR and proteinuria. In ARIC visit 5 cohort, mean age was 77.2 years, 903 (55.5%) were women, mean estimated GFR was 54 ml/min per 1.73m^2 and median follow up was 6.9 years. Of the seven proteins found in AASK, three (Beta-2-microglobulin, Spondin-1, and N-terminal pro-BNP) were available in the ARIC data, with all three significantly associated with death in ARIC.

Conclusions: Using large-scale proteomic analysis, known and novel proteins were reproducibly associated with mortality in two cohorts of participants with CKD.

Characterization of the Urine Proteome in 769 Patients with Early-Stage CKD

Marisa D. Meier,[1] Yong Li,[1] Oleg Borisov,[1] Burulça Uluvar,[1,2] Anna Kottgen,[1] Stefan Haug.[1] *[1]Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; [2]Computational Medicine, Berlin Institute of Health at Charité–Universitätsmedizin Berlin, Berlin, Germany.*

Background: Analyses of urinary proteins aim to identify new biomarkers for early disease detection, prognosis and therapeutic response in patients with chronic kidney disease (CKD). Hence, we used the antibody-based Olink Explore 3072 platform to quantify 2925 proteins in urine samples from 769 participants of the German Chronic Kidney Disease (GCKD) study and present a comprehensive characterization of the urine proteome at unprecedented scale.

Methods: Proteins were quantified in urine samples from persons with eGFR >45 and ≤60 mL/min/1.73 m^2 and UACR <300 mg/g. Protein detectability was computed as percentage of samples with Normalized Protein Expression above protein-specific limits of detection. Urine dilution was corrected before association and correlation analyses. Plasma detectability of 1463 corresponding proteins (Olink 1536 panel) and comparisons to urine were based on >52,000 participants of the UK Biobank.

Results: In total, 1926 of 2925 (65.8%) proteins had detectability >10% in urine. Of these, 593 (20.3%) were highly detectable (>80%), showing a strong overrepresentation for proteins from extracellular exosomes and extracellular regions. Highly detectable urine proteins were enriched for specific expression in liver, placenta, lung, and kidney, and for molecular functions as proteolytic enzymes or cell adhesion proteins. We found significant associations with participant characteristics for 342 urine proteins, including sex (268 proteins, e.g., prostate-specific MSMB and KLK3 were higher in men), age (20 proteins, e.g. RGMA, CILP) and BMI (54 proteins, e.g. IL1RN, IL1A). Correlation analyses revealed multiple clusters of co-regulated proteins (e.g. AZU1, PRTN3, MPO, all components of azurophilic granules in neutrophils). Compared to plasma, 16 of 1463 proteins (1.1%) had significantly higher detectability in urine, 105 (7.2%) were equally detectable, and 1342 (91.7%) had lower detectability.

Conclusions: The Olink Explore 3072 technology is suitable for urine proteomics with large sample sizes, and yields biologically plausible correlations and associations. The obtained information about detectability, composition and phenotypic associations of the urine proteome represents a basis for biomarker discovery, and facilitates future, more targeted studies in CKD and other diseases.

The Transcriptomic Landscape of microRNAs Encapsulated in Circulating Extracellular Vesicles and CKD Progression in Japanese Adults

Shunsuke Inaba, Shintaro Mandai, Yuta Nakano, Hisazumi Matsuki, Tamami Fujiki, Yutaro Mori, Fumiaki Ando, Takayasu Mori, Koichiro Susa, Soichiro Iimori, Shotaro Naito, Eisei Sohara, Shinichi Uchida. *Department of Nephrology, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University, Bunkyo-ku, Japan.*

Background: The global economic burden of chronic kidney disease (CKD) and end-stage-kidney disease (ESKD) is still increasing. However, non-invasive techniques to predict CKD progression have yet to be established. This study aimed to determine circulating small extracellular vesicle (cEV)-encapsulated miRNAs predictive of kidney outcome in patients with CKD.

Methods: We enrolled 36 Japanese adults with non-dialysis-dependent CKD patients from the previously published cohort studies. We performed miRNA transcriptomic analyses using cEVs extracted from the serum of the participants. The patients were followed up until death, transfer, or ESKD requiring dialysis. The correlation between miRNA expressions and baseline eGFR was examined with the linear regression model. A stratified Cox regression model was used to assess the risk of a kidney composite outcome including ESKD or 30% eGFR reduction. We also performed the logistic regression analysis to examine the risk of rapid eGFR decline, which was defined as eGFR reduction <-5 mL/min/1.73 m^2/year or dialysis initiation within a follow-up of six months. All analyses were adjusted for potential confounders including age, sex, diabetes mellitus, and cardiovascular disease.

Results: The median age of the participants was 71 years (interquartile range, 61-79), 25% was female, and the median baseline eGFR was 31 (21-53) mL/min/1.73 m^2. After a median follow-up period of 636 days, the kidney composite outcome and rapid eGFR decline occurred in 16 and 16 patients, respectively. Among 2578 miRNAs identified, all three criteria including the negative association between miRNA expression levels and baseline eGFR ($P < 0.1$), increased hazards ratios for a risk of the kidney composite outcome (HR ≥ 1.5; $P < 0.05$), and increased odds ratios (ORs) for a risk of rapid eGFR decline (OR ≥ 1.5; $P < 0.1$) were met for three miRNAs. The KEGG molecular pathways associated with miRNA target molecules found ubiquitin-mediated proteolysis, Hippo signaling pathway, protein processing in endoplasmic reticulum, and MAPK signaling pathway.

Conclusions: This study uncovered miRNA signature encapsulated in cEVs that is strongly associated with a risk of CKD progression in adults.

Evaluation of Novel Candidate Filtration Markers from a Global Metabolomics Discovery for Glomerular Filtration Rate Estimation

Nora F. Fino,[1] Ogechi M. Adingwupu,[2] Josef Coresh,[3] Tom Greene,[1] Benjamin Haaland,[1] Michael Shlipak,[4] Veronica T. Costa e Silva,[5] Roberto S. Kalil,[6] Ayse L. Mindikoglu,[7] Susan L. Furth,[8,9] Jesse C. Seegmiller,[10] Andrew S. Levey,[2] Lesley A. Inker.[2] CKD-EPI. *[1]University of Utah Health, Salt Lake City, UT; [2]Tufts Medical Center, Boston, MA; [3]Johns Hopkins University Department of Epidemiology, Baltimore, MD; [4]San Francisco VA Health Care System, San Francisco, CA; [5]Serviço de Nefrologia, Instituto do Câncer do Estado de São Paulo, Faculdade de Medicina, Universidade de São Paulo, Sao Paulo, Brazil; [6]University of Maryland School of Medicine, Baltimore, MD; [7]Baylor College of Medicine, Houston, TX; [8]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [9]The Children's Hospital of Philadelphia, Philadelphia, PA; [10]University of Minnesota Twin Cities, Minneapolis, MN.*

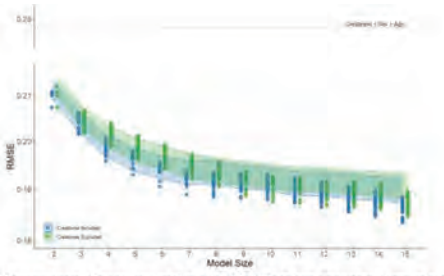
Background: Creatinine and cystatin-C are recommended for estimating glomerular filtration rate (eGFR) but accuracy is suboptimal. Using untargeted metabolomics data, we sought to identify candidate filtration markers using a novel approach based on their maximal joint association with measured GFR (mGFR) and with flexibility to consider their biological and chemical properties.

Methods: We analyzed metabolites measured in seven diverse studies of 2,851 participants on the Metabolon H4 platform that had Pearson correlations with log mGFR. We used a stepwise approach to develop models to estimate mGFR including two to 15 metabolites with and without inclusion of creatinine and demographics. We then selected candidate filtration markers from those metabolites found >20% in models that did not demonstrate substantial overfitting in cross-validation and with small (<0.1 in absolute value) coefficients for demographics.

Results: In total, 456 named metabolites were present in all studies, and 36 had correlations < -0.5 with mGFR. We developed 2,225 models including these metabolites; all had lower root mean square errors (RMSE) and smaller coefficients for demographic variables compared to estimates using untargeted creatinine. Cross-validated RMSEs (0.187-0.213) were similar to original RMSEs for models with ≤ 10 metabolites (Figure). Our criteria identified 17 metabolites, including 12 new candidate filtration markers.

Conclusions: We identified candidate metabolites with maximal joint association with mGFR and minimal association with demographic variables across varied clinical settings. Next, we will assess the selected metabolite biological and chemical characteristics to develop a panel eGFR that is more accurate and less reliant on demographic variables than current eGFR.

Funding: NIDDK Support



Comparison of near-optimal model RMSEs when untargeted creatinine is included as a candidate versus when untargeted creatinine is excluded.
The colored bands show the range of cross-validated (CV) RMSEs. Points are non-CV model errors. Models are fit with study terms but not demographic variables.

FR-PO933

Association Between Serum Kynurenine Levels and Cardiovascular Outcomes and Overall Mortality in CKD

Carolla El Chamieh,[1,2] Natalia Alencar de Pinho,[1] Oriane Lambert,[1] Denis Fouque,[3,4] Luc Frimat,[5,6] Maurice Laville,[4] Solene M. Laville,[7,8] Celine Lange,[1] Ziad Massy,[1,9] Sophie Liabeuf.[7,8] *[1]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [2]Universite de Versailles Saint-Quentin-en-Yvelines, Versailles, France; [3]Centre Hospitalier Lyon-Sud, Pierre-Benite, France; [4]Cardiovasculaire Metabolisme Diabetologie et Nutrition, Pierre Benite, France; [5]Centre Hospitalier Regional Universitaire de Nancy, Nancy, France; [6]Universite de Lorraine, Nancy, France; [7]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [8]Universite de Picardie Jules Verne, Amiens, France; [9]Hopital Ambroise-Pare, Boulogne-Billancourt, France.*

Background: Kynurenine is a protein-bound uremic toxin. Its circulating levels are increased in chronic kidney disease (CKD). Experimental studies showed that it exerted deleterious cardiovascular effects. We sought to evaluate the association between serum kynurenine levels and adverse fatal or nonfatal cardiovascular events and all-cause mortality before kidney replacement therapy (KRT) in patients with CKD.

Methods: The CKD-REIN study is a prospective cohort of CKD patients before KRT (estimated glomerular filtration rate (eGFR) < 60ml/min/1.73m^2) followed-up over five years. Baseline frozen samples of total and free fractions of kynurenine and tryptophan were measured using a validated liquid chromatography tandem mass spectrometry technique. Cause-specific Cox models were used to estimate hazard ratios (HRs) for each outcome.

Results: Of the 2,406 included patients (median age: 68 years; median eGFR: 24.7 ml/min/1.73 m^2), 52% had a history of cardiovascular disease. A 1.5-fold increase in serum free kynurenine levels was associated with a 12%-increased hazard of cardiovascular events (466 events, HR[95% CI]: 1.12 [1.02,1.23]), independently of eGFR, serum free tryptophan level, and traditional cardiovascular risk factors. The association of serum free kynurenine with cardiovascular mortality was also independently significant (87 events; adjusted HR [95%CI]: 1.39[1.07, 1.70]). However, the association of serum free kynurenine with all-cause mortality vanished after adjustment on serum free tryptophan (311 events, HR[95%CI]: 1.06[0.94, 1.21]).

Conclusions: Our findings imply that serum free kynurenine, independently of other cardiovascular risk factors (including eGFR), is associated with fatal or nonfatal cardiovascular outcomes, particularly non-atheromatous cardiovascular events, in patients with CKD. Strategies to reduce serum kynurenine levels should be evaluated in further studies.

Associations of Plasma Trimethylamine N-Oxide-Related Metabolites with the Development and Progression of Albuminuria

Meng Wang,[1] W.H. Wilson Tang,[2] Xinmin S. Li,[2] Marcia C. De Oliveira Otto,[3] Rozenn Lemaitre,[4] Amanda M. Fretts,[4] Ina Nemet,[2] Nona Sotoodehnia,[4] Matthew J. Budoff,[5] Joseph A. Didonato,[2] Zeneng Wang,[2] Mark J. Sarnak,[6] Dariush Mozaffarian,[1] Stanley L. Hazen.[2] *[1]Tufts University, Boston, MA; [2]Cleveland Clinic, Cleveland, OH; [3]The University of Texas Health Science Center at Houston School of Public Health, Houston, TX; [4]University of Washington, Seattle, WA; [5]The Lundquist Institute, Torrance, CA; [6]Tufts Medical Center, Boston, MA.*

Background: Trimethylamine N-oxide (TMAO) is a gut-microbiota generated metabolite of dietary choline and carnitine. In animal models, TMAO increases albuminuria, an early, sensitive marker of kidney damage. Yet, little is known about TMAO and albuminuria in humans. We investigated prospective associations of plasma TMAO and its two microbiome-derived intermediates, crotonobetaine and γ-butyrobetaine, with the development and progression of albuminuria.

Methods: We included 6,101 US adults with normal (<30mg/g) baseline urine albumin to creatinine ratio (ACR) from the Multi-ethnic Study of Atherosclerosis, a community-based cohort. TMAO-related metabolites were measured using mass spectrometry at baseline and year 5. ACR levels were measured up to 4 times during follow-up. Time-varying Cox models related serial TMAO measures to elevated albuminuria, defined as the first occurrence of ACR ≥ 30 mg/g, adjusting for sociodemographic, lifestyle, diet, and CVD risk factors. Linear mixed models related serial TMAO measures to annualized ACR changes in 6,319 participants with at least one follow-up ACR measure (no exclusions for baseline ACR levels), adjusting for baseline ACR and other covariates.

Results: During a median follow-up of 16 years, 995 participants developed elevated albuminuria. Higher levels of TMAO and crotonobetaine, but not γ-butyrobetaine, associated with higher risk of elevated albuminuria (Figure). All three metabolites positively associated with annualized ACR increase (5th vs. 1st quintile [95%CI] =3.54 [1.10, 5.98], 4.28 [1.89, 6.67], and 4.49 [1.36, 7.61] mg/g per year, respectively).

Conclusions: In a multi-ethnic, community-based cohort of US adults, higher levels of gut microbiota-generated TMAO-related metabolites were associated with elevated albuminuria and its progression.

Funding: Private Foundation Support

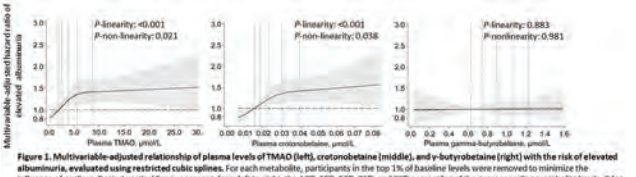

Figure 1. Multivariable-adjusted relationship of plasma levels of TMAO (left), crotonobetaine (middle), and γ-butyrobetaine (right) with the risk of elevated albuminuria, evaluated using restricted cubic splines. For each metabolite, participants in the top 1% of baseline levels were removed to minimize the influence of outliers. Dotted vertical lines represent, from left to right, the 10th, 25th, 50th, 75th, and 90th percentiles of the corresponding metabolite levels. P for linearity was the P value for a given metabolite in a model with the metabolite analyzed as a linear term. P for non-linearity was obtained by a likelihood ratio test comparing the model with linear metabolite vs. the model with all spline terms of the metabolite. Multivariable adjustments included baseline age, sex, race/ethnicity (White, Black, Chinese American, and Hispanic), study site (6 sites), education (<high school, high school, some college, bachelor's degree, graduate school), household income (<$20,000, $20,000 – < $50,000, $50,000 – < $100,000, ≥ $100 000), alternate healthy eating index, total energy intake (kcal/day), and time-varying health status (poor, fair, good, very good, excellent), smoking status (never, former, and current), alcohol intake (drinks/week), physical activity (MET-MIN per week), antibiotic use in the past two weeks, BMI, waist circumference, systolic blood pressure, diastolic blood pressure, LDL-C, HDL-C, triglycerides, CRP, diabetes, anti-hypertensive medication, and lipid-lowering mediation, each updated at the same time as the serial TMAO measures using the most recent measures.

Multivariable-adjusted relationship of plasma levels of TMAO (left), crotonobetaine (middle), and γ-butyrobetaine (right) with the risk of elevated albuminuria

FR-PO935

On the Accuracy of the Kidney Failure Risk Equation

Oskar Ålund,[1] Robert J. Unwin,[2] Philip A. Kalra,[3,4] Maarten W. Taal,[5] Magnus Soderberg.[1] On Behalf of the NURTuRE Investigators. *[1]AstraZeneca PLC, Gothenburg, Sweden; [2]AstraZeneca PLC, Cambridge, United Kingdom; [3]Salford Royal Hospital, Salford, United Kingdom; [4]The University of Manchester, Manchester, United Kingdom; [5]University of Nottingham, Nottingham, United Kingdom.*

Background: The accuracy of Kidney Failure Risk Equation (KFRE) is based on the Receiver Operating Characteristic (ROC) curve, Area Under the ROC Curve (AUC), and Harrell's C-statistic. We examined the predictive power of the 4-variable KFRE described in [1] and considered the limitations of ROC curves and C-statistics.

Methods: We used data from the UK's NURTuRE CKD cohort with outcomes for 2426 CKD patients. 149 patients had reached ESKD at follow up. Model performance was assessed by: * Harrell's C-statistic * AUC * Average precision * Average negative predictive value

Results: The C-statistic was 0.89 and AUC for 2-year discrimination 0.91, both corroborating [1]. The C-statistic on the subset of patients with known time to ESKD was 0.64. Average negative predictive value was 0.99. Average precision was 0.32. Excluding patients above age 40, average precision was 0.42.

Conclusions: The C-statistic is computed by counting patient pairs that the model orders correctly for time to ESKD. Most pairs include a patient who reached ESKD before follow-up and one who did not. Therefore, the C-statistic overestimates the KFREs ability to order patients for time to ESKD. For the subset of patients whose time to ESKD was known, the C-statistic was only 0.64. In other words, the KFRE cannot be used reliably to sort NURTuRE patients by time to ESKD. The AUC is the probability that a randomly chosen positive patient would be assigned a larger risk score than a randomly chosen negative patient. Since most such pairs can be easily sorted for time to ESKD, this metric turns out well. In contrast, precision measures the probability that a patient will reach ESKD given that (s)he is predicted to by the KFRE. A precision of 0.32 in this case means that only 32% of patients predicted to reach ESKD within 2 years will do so. Interestingly we see an increase in precision in younger patients, which we believe is due to a higher correlation between eGFR and time to kidney failure in lower age brackets. In summary: With a negative predictive value of 0.99, the KFRE can rule out near term kidney failure with high probability but cannot confirm it. Therefore, while its application for referrals is appropriate, the KFRE should not be used as a basis for costly or risky medical intervention. **References:** 1. Tangri, Navdeep, et al. *JAMA* 305.15 (2011): 1553-1559.

Kidney Failure Risk Equation Prediction in a Real-World Population with CKD

Leonid Shpaner,[1] Panayiotis Petousis,[1] Obidiugwu Duru,[1] Kenn B. Daratha,[2] Keith C. Norris,[1] Katherine R. Tuttle,[2] Susanne B. Nicholas,[1] Alex Bui.[1]
Center for Kidney Disease Research, Education, and Hope (CURE-CKD).
[1]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [2]Providence Medical Research Center, Spokane, WA.

Background: Risk prediction helps to identify patients with chronic kidney disease (CKD) who may benefit from awareness, detection, and intervention to preserve kidney function. The purpose of this study was to externally validate the Kidney Failure Risk Equation (KFRE) using the 4-variable (4-KFRE) and 6-variable (6-KFRE) equations to predict end stage renal disease (ESRD; eGFR <15 mL/min/1.73 m^2) over 2- and 5-year periods in a real-world population with moderate-to-severe CKD.

Methods: Patients with CKD stages 3 and 4 (N=20,947) were selected from electronic health records data in the CURE-CKD Registry from the UCLA (N=3,599) and Providence (N=17,348) Health systems. Patient demographics (age and sex), estimated glomerular filtration rate (eGFR), and log-normalized urine albumin/creatinine ratio were used for the 4-KFRE. The 6-KFRE was applied to patients who also had diabetes and hypertension.

Results: The prevalence of ESRD was 7% for the 2-year period and 11% for the 5-year period. The performance of the 6-KFRE and the 4-KFRE models was similar (4-KFRE is shown in **Table 1**). Specificity (0.994) reflects the model's ability to predict non-ESRD patients, while sensitivity (0.135) signifies the ability to predict ESRD patients. The area under the precision-recall curve (PR-AUC) was 0.466, and the area under the receiver operating curve (AUC ROC) was 0.853, suggesting accurate KFRE predictions. The model performance improved with lower eGFR.

Conclusions: The KFRE equations depicted high performance when applied to a real-world population with moderate-to-severe CKD. While highly specific for ESRD, it lacked sensitivity, but improved for more advanced CKD stages.

Results from the Four Variable KFRE (UCLA + Providence)

	2-Year Risk of ESRD	5-Year Risk of ESRD
Precision/PPV	0.770	0.696
PR AUC	0.447	0.486
Average Precision	0.447	0.486
Sensitivity	0.070	0.200
Specificity	0.999	0.990
AUC ROC	0.864	0.842
Brier Score	0.052	0.076

KFRE: Kidney Failure Risk Equation; ESRD: end stage renal disease; PPV: positive predictive value; PR AUC: precision recall area under the receiver operating curve

FR-PO937

Colombian Validation of the Kidney Failure Risk Equation with Four Variables

Mauricio Sanabria, Carolina Larrarte, Jasmin Vesga, Freddy Ardila, Fabiola A. Aldana Miranda, Delia Perea. *Baxter Renal Care Services, Bogota, Colombia.*

Background: Chronic Kidney Disease (CKD) programs need to identify patients at risk of progression. Our objective is to evaluate the performance of this 4 variables model in the Colombian population where this risk model has not yet been validated.

Methods: Historical cohort of patients with stage 3, 4 and 5 CKD, adults, with no history of dialysis or kidney transplantation and with a two-year follow-up, belonging to the Renal Care Services Baxter Colombia clinic network. The performance model was evaluated using concordance index and the area under the time-dependent ROC curve, with the nearest neighbor method, as well as the sensitivity and specificity. The degree of agreement between the observed outcome and the probabilities predicted by the model using the Hosmer-Lemeshow statistic.

Results: A total of 5477 patients were included, the mean age was 72 years, and the mean baseline eGFR was 36 ml/min/1.73 m2. The rate of admission to dialysis therapy was 3 events per-100 patient years. See **Figure 1.** Sensitivity 0.938 and specificity 0.757, with the area under the ROC curve 0.92. Harrell C statistic was 0.88 per total population and >65 year was 0.93. The validation of the model showed a good calibration, see **Figure 2.**

Conclusions: In this Colombian cohort, the kidney failure risk equation with 4 variables has excellent calibration and discrimination, therefore its use is recommended in the routine follow-up of these CKD prevention programs.

Validation of a Multimarker eGFR Equation in Preserved and Reduced eGFR Using the GENOA Cohort

Maria Clarissa Tio,[1] Xiaoqian Zhu,[1] Andrew D. Rule,[2] Seth Lirette,[1] Yoshitsugu Obi,[1] Timothy E. Yen,[1] Michael Hall,[1] Neville R. Dossabhoy,[1] Tariq Shafi.[3] *[1]University of Mississippi Medical Center, Jackson, MS; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Houston Methodist, Houston, TX.*

Background: Performance of the race-free CKD-EPI 2021 equation varies with severity of kidney disease. We sought to examine the performance of a novel multimarker eGFR panel (panel-eGFR) among Black and White persons stratified by eGFR categories using the biracial Genetic Epidemiology Network of Arteriopathy (GENOA) cohort.

Methods: We included 224 sex, race/ethnicity, and measured GFR (mGFR)-category-matched persons. GFR was measured using urinary clearance of iothalamate. Panel-eGFR was calculated using serum creatinine, valine, myo-inositol, cystatin C, age, and sex. All GFR's are presented as mL/min/1.73 m^2. We compared panel-eGFR's reliability to the 2021 CKD-EPI creatinine and cystatin C (eGFR-Cr-CysC) equation using bias, precision, and accuracy metrics between race (Black vs. White participants) and eGFR (eGFR-Cr-CysC≥60 or preserved eGFR vs. <60 or reduced eGFR) subgroups.

Results: In the overall cohort, 49% were Black individuals and 79% had eGFR-Cr-CysC≥60. Among those with preserved eGFR, eGFR-Cr-CysC was lower than mGFR by 5.6 and 6.6 among Black and White participants, respectively. In contrast, panel eGFR was unbiased among Black (bias: -0.5; 95% CI: -2.8, 2.9) and White participants (bias: -0.4; 95% CI: -5.6, 4.5) with preserved eGFR. Among those with reduced eGFR, eGFR-Cr-CysC was unbiased among Black and White participants. Conversely, panel-eGFR was higher than mGFR in both Black (bias: -9.8; 95% CI: -11.8, -3.1) and White (bias: -6.3; 95% CI: -9.0, -3.7) participants with reduced eGFR. P30 for panel-eGFR among Black participants with reduced eGFR was 70%. Otherwise, P30 metric was acceptable (>80%) for both equations across race and eGFR subgroups.

Conclusions: A novel panel-eGFR performs better than the current eGFR-Cr-CysC equation among persons with preserved eGFR, and this is consistent between Black and White persons.

Funding: Other U.S. Government Support

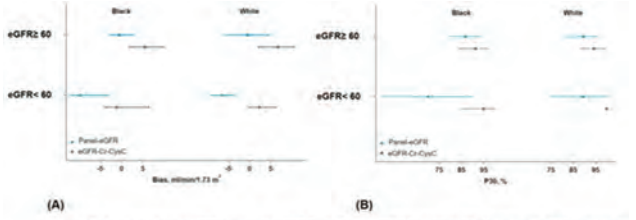

Figure 1: Performance of panel-eGFR compared to eGFR-Cr-CysC in the GENOA cohort stratified by race and eGFR (calculated using the CKD EPI 2021 creatinine and cystatin C equation). (A) Median bias is defined as the median of the differences between mGFR and eGFR, in units of ml/min/1.73m². (B) P30 is defined as the proportion of eGFR within 30% of mGFR.

FR-PO939

Predicting All-Cause Mortality in Patients with Advanced CKD

Ranveer S. Brar,[1,2] Thomas W. Ferguson,[1,2] Manish M. Sood,[3,4] Navdeep Tangri.[1,2] Chronic Disease Innovation Centre. *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]Chronic Disease Innovation Centre, Winnipeg, MB, Canada; [3]Department of Medicine in Ottawa, Ottawa, ON, Canada; [4]Division of Nephrology, Ottawa Hospital, Ottawa, ON, Canada.*

Background: Patients with advanced CKD are at high risk of mortality, kidney failure and cardiovascular events. Accurately identifying patients that are at a higher risk for mortality may aid in clinical decision making and preventing unnecessary dialysis therapies that may cause more harm. We developed and externally validated a risk prediction tool using commonly collected clinical measurements to predict all-cause mortality among patients with advanced CKD.

Methods: We developed a prediction model using demographic, clinical and laboratory data in adult patients (≥ 18 years) with advanced CKD (eGFR <30 mL/min/1.73m²) from Manitoba, Canada, between January 2012, and September 2020, with external validation from Ontario, Canada. Our primary outcome was time to all-cause mortality. If dialysis was initiated in follow-up, we ascertained all-cause mortality within 1 year of dialysis initiation. We assessed model discrimination using the area under the receiver operating characteristic curve (AUC) and calibration using plots of observed and predicted risks.

Results: The development cohort included 397 patients (mean age 65.4 ± 13.9) with 121 events. The final model included age, sex, estimated GFR, hemoglobin, serum albumin and congestive heart failure and achieved a 2-year and 5-year AUC of 74.3 (CI: 68.4 – 80.1) and 80.2 (CI: 75.3 – 85.1), respectfully. Discrimination and calibration were adequate in the external validation data set with 2-year and 5-year AUC scores of 71.4 (CI: 70.8 – 72.0) and 73.0 (CI: 72.5 – 73.5).

Conclusions: We developed a simple prediction model that included commonly measured variables that can accurately predict all-cause mortality in patients with advanced CKD. This equation may aid as a support tool for nephrologists in dialysis decision making, especially in patients who are at high risk of mortality.

FR-PO940

CKD Progression Model (CKD-PM): Development and Validation

Anastasia Uster,[1] Mafalda Ramos,[2] Laetitia Gerlier,[2] Louise E. Muttram,[5] Dominik Steubl,[1,3] Andrew H. Frankel,[4] Mark Lamotte.[2] *[1]Boehringer Ingelheim International GmbH, Ingelheim, Germany; [2]IQVIA Ltd, Brussels, Belgium; [3]Klinikum rechts der Isar der Technischen Universitat Munchen, Munchen, Germany; [4]Imperial College Healthcare NHS Trust, London, United Kingdom; [5]Boehringer Ingelheim Ltd, Bracknell, United Kingdom.*

Background: Patients with CKD are at risk of disease progression and related complications. Existing CKD models are limited to the risk of end stage kidney disease (ESKD) and selected cardiovascular disease (CVD) outcomes. Our aim was to develop a CKD-PM, that uses evolving risk factors to project risk of a broad range of CKD related complications.

Methods: Development of the CKD-PM was informed by systematic and targeted literature reviews of relevant models and risk factors for CKD progression and risk of complications. The result was a patient-level state transition model with KDIGO categories as health states. Evolving risk factors project CKD progression and occurrence of complications, with submodules for: CVD, infections, anemia, diabetes, hypertension, acidosis, hyperkalemia, mineral and bone disorders, hospitalisations, acute kidney injury, cancer and ESKD. Internal and external model validation was performed by comparing predicted outcomes with those observed in cohort studies, utilizing source study patient characteristics and follow up time. An ordinary least squares (OLS) linear regression line (LRL) was fitted to the data, and the slope was used to categorize the quality of the prediction. Deviation <25% from the perfect prediction (LRL slope =1) was considered accurate (mild deviation), 25-50% deviation was considered moderate, and severe beyond 50%.

Results: Core inputs (mortality, CVD and evolution of risk factors including eGFR and uACR) were sourced primarily from two research groups: Chronic Renal Insufficiency Cohort [CRIC] and Chronic Kidney Disease Prognosis Consortium [CKD-PC]). Seven large CKD cohorts studies were used to validate the CKD-PM predictions. Both internal and external validation results demonstrated robust modeling properties. All-cause mortality (ACM) was accurately projected, with mild under-prediction, either through direct prediction (hazard ratio by eGFR and uACR levels) or as a composite of CVD mortality, renal and other deaths. CVD mortality was mildly under-predicted in internal validation, and mildly over-predicted in external validation. Projected mean change of eGFR or uACR values and ESKD rates were within an acceptable range compared to external values.

Conclusions: CKD-PM is a comprehensive tool with robust modeling properties demonstrated through internal and external validation.

IMPACT CKD: Projecting the Growing Environmental Burden of CKD in the United States

Stacey Priest,[1] Hannah A. Guiang,[1] Charlotte M. Johnston-Webber,[2] Naveen Rao,[4] Jieling Chen,[4] Durgesh Bhandary,[3] Rachele Berria,[3] Stephen Brown,[1] Daniel Grima,[1] Neil Skolnik.[5] *[1]Eversana Life Science Services LLC, Milwaukee, WI; [2]The London School of Economics and Political Science, London, United Kingdom; [3]AstraZeneca Pharmaceuticals LP, Wilmington, DE; [4]AstraZeneca PLC, Cambridge, United Kingdom; [5]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) is a significant source of morbidity and mortality with substantial costs associated with renal replacement therapy (RRT) (including dialysis and transplantation). However, it is imperative to understand the wider impact of CKD, including its societal and environmental consequences, to inform healthcare planning and policy development. This study aims to comprehensively quantify the burden of CKD in the United States (US).

Methods: A patient-level simulation model, IMPACT CKD, was developed to simulate the natural history of CKD progression while incorporating the impact of acute kidney injury, cardiovascular events and comorbidities. CKD status was assigned using estimated glomerular filtration rate (eGFR) and albuminuria levels, and clinical progression was predicted by annual eGFR decline rate. The model was used to forecast the 10-year impact of CKD on environment in the US in addition to clinical, economic, and societal outcomes. The model was validated and calibrated for the US setting.

Results: While CKD prevalence is predicted to remain steady from 2022 to 2032 (17%), the number of patients increases from 57 to 60 million. The projected distribution of CKD stages includes 38% in stage 1, 19% in stage 2, 34% in stage 3, 5% in stage 4, and 4% in stage 5 (including RRT) in 2032. Substantial increases are observed in stage 3 to pre-RRT stage 5 (14.5%) and the number of patients receiving RRT is expected to rise by 48% (882,026 to 1,303,141). Alongside the escalating clinical burden, CKD and RRT are poised to exert detrimental environmental impacts. Freshwater consumption, fossil fuel depletion, and CO_2 emissions associated with CKD and RRT are estimated to rise by 26%, 26%, and 37% respectively, from 2022 to 2032. RRT accounts for the most substantial environmental burden, with projected contributions of 1.9 billion m^3 of freshwater consumption, 26.9 billion kg of fossil fuel depletion, and 64.9 billion kg of CO_2 emissions over the next decade.

Conclusions: The IMPACT CKD model highlights the enduring burden of CKD in the US. With projected high prevalence and environmental burdens, improved management strategies mitigating the substantial environmental impact of CKD and RRT are vital for a healthier future.

FR-PO942

Modest Reductions in Kidney Function and Adverse Outcomes in Young Adults

Junayd Hussain,[1,2] Mark Canney,[1] Meghan J. Elliott,[3] Gregory L. Hundemer,[1] Navdeep Tangri,[4] Manish M. Sood.[2,1] *[1]University of Ottawa School of Epidemiology and Public Health, Ottawa, ON, Canada; [2]Institute of Clinical and Evaluative Sciences (ICES), University of Ottawa, Ottawa, ON, Canada; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [4]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.*

Background: Whether modest declines in estimated glomerular filtration rate (eGFR below age-expected values) in younger adults are associated with adverse outcomes is unknown. We aim to estimate the association of an early eGFR decline with adverse outcomes by age group (18-39, 40-49, 50-65 years).

Methods: We included 8.7 million adults (aged 18-65) with ≥1 eGFR value using linked healthcare datasets in Ontario from January 2008-March 2020. The association of eGFR categories from <60 to >120 mL/min/1.73m² and adverse outcomes (death, cardiovascular outcomes, end-stage kidney disease) was examined using adjusted Cox models. Comparisons were relative to age normalized measured GFR categories (100-110 mL/min for 18-39, 90-100 mL/min for 40-49, 80-90 mL/min for 50-65).

Results: The mean age, eGFR and median follow up were 41 years, 104 mL/min and 9.2 years, respectively. 17.3%, 18.9%, and 17.7% had an eGFR below normal for ages 18-39, 40-49, and 50-65, respectively. The risk of an adverse event increased in a stepwise manner with eGFR values below the referent and occurred at higher eGFR values in those 18 to 39 [eGFR 70-80, age 18-39: incidence 4.37 events per 1000 person-years [p-y], HR 1.54(1.46-1.61); age 40-49: incidence 9.78 per 1000p-y, HR 1.18(1.15-1.21); age 50-65: incidence 24.0 per 1000p-y, HR 1.11(1.10-1.12)] (see **Figure**). Results persisted for each outcome individually, and after using repeated eGFR, using a common referent, and adjusting for multiple covariates.

Conclusions: Young adults (18-39) with an early eGFR decline were at a higher risk of adverse events and this occurred at higher eGFR levels relative to middle-aged and older adults.

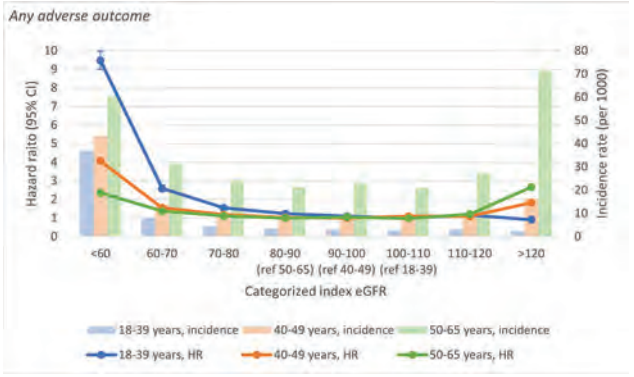

Figure: Incidence rates (events per 1000 person-years) and adjusted hazard ratios (HRs, 95% CI) for any adverse outcome (first of all-cause mortality, cardiovascular outcomes, end-stage kidney disease) relative to age-specific eGFR reference ranges, by age-group.

FR-PO943

Risk Analysis of Healthy Life Expectancy Based on Kidney Function Using the Long-Term Care and Medical Database

Hisayuki Ogura, Tadashi Toyama, Shinji Kitajima, Akinori Hara, Yasunori Iwata, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa Daigaku, Kanazawa, Japan.*

Background: The world's population is rapidly aging, with the aging rate expected to reach 17.8% by 2060. Healthy life expectancy is known to be shortened by unhealthy diet, hypertension, smoking, obesity and diabetes. Kidney dysfunction is also expected to shorten healthy life expectancy due to its effects on physical inactivity, malnutrition, and atherosclerosis. This study aims to clarify the relationship between kidney function and healthy life expectancy.

Methods: This was a community-based historical cohort study of adults living from 2012 to 2022 in Hakui City, Ishikawa Prefecture, Japan. Participants were divided into five groups (<45, ≥45 to <60, ≥60 to <75, ≥75 to <89, and ≥90 mL/min/1.73 m2). The primary composite outcome was the event of unhealthy status (care level ≥2 or death). Care level 2 was a level of social support for those who have difficulty performing basic activities of daily living independently and require some form of nursing care in Japan's long-term care system. Baseline risk factors included age, sex, body mass index, current smoking status, diabetes mellitus, systolic blood pressure, and social support level. Multivariable Cox proportional hazards model adjusted for baseline risk factors was used to estimate the risk of the primary outcome by eGFR group. Total annual healthcare cost, the sum of annual medical and long-term care cost, were examined as a secondary outcome.

Results: The number of participants was 5,592, the mean age was 67 years, the mean eGFR was 70.9 mL/min/1.73 m^2, and the mean follow-up was 6.5 years. During the observation period, 8.2% of the participants reached the primary outcome. For the primary outcome, using eGFR ≥60 to <75 as the reference, the hazard ratios (HRs) for eGFR ≥45 to <60 and eGFR <45 were 1.35 (95% CI 1.05, 1.75) and 1.93 (95% CI 1.41, 2.66), respectively. The HRs for the eGFR ≥75 to <90 and eGFR ≥90 groups were 1.48 (95% CI 1.14, 1.93) and 1.61 (95% CI 1.14, 2.28), respectively. The mean total healthcare cost for those who achieved the primary outcome was approximately 1,760,000 yen per year. The lower eGFR group had higher annual costs.

Conclusions: Both lower and higher eGFR were risk factors for becoming unhealthy, need for long-term care or death. Annual total healthcare costs were higher in people who became unhealthy.

FR-PO944

Long-Term Outcomes in Persons with Stage 3 CKD Recruited from Primary Care

Maarten W. Taal,[1,2] Natasha J. McIntyre,[3] Christopher W. McIntyre,[3] Richard J. Fluck.[2] *[1]University of Nottingham, Nottingham, United Kingdom; [2]University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom; [3]Western University, London, ON, Canada.*

Background: The majority of persons with chronic kidney disease (CKD) are elderly, have moderately reduced glomerular filtration rate (GFR) and are cared for in primary care in the UK. There are few long term studies to describe the risks of adverse outcomes in this under-studied population.

Methods: Participants with CKD stage 3 were recruited from primary care in 2008-10. Clinical assessment and investigations were performed at baseline, 1 and 5 years. In 2019-20, electronic records were reviewed to obtain data on deaths and latest available outpatient estimated GFR (eGFR) and urine albumin to creatinine ratio (UACR). CKD progression was defined as a decline in eGFR of ≥25% and progression to a more advanced stage.

Results: Participants: 1741 with median (IQR) age 74 (67-79) years, eGFR 53.8 (45.3-61.7) ml/min/1.73m^2, UACR 0.3 (0.001-1.5) mg/mmol; 16.9% diabetes at baseline. Outcomes: 680 deaths (39.1%); CKD progression in 430 of 1402 (30.7%) participants after a median 9.8 (9.2-10.0) years; only 24 of 1741 (1.4%) reached CKD stage 5. UACR increased from 0.3 (0.001-1.26) to 1.4 (0.3-5.90) mg/mmol (p<0.001) in 1188 participants with repeat measurements. Changes in KDIGO GFR category are presented in the table. CKD category improved in 161 (11.5%), progressed in 695 (49.6%) and did not change in 546 (38.9%). Logistic regression analysis identified male sex, diabetes status and lower baseline eGFR, higher baseline UACR and systolic blood pressure (SBP) as independent predictors of CKD progression. Cox Proportional Hazards models identified age, male sex, diabetes status, past or current smoking, lower baseline eGFR and higher baseline UACR as independent risk factors for all-cause mortality.

Conclusions: CKD progression was observed in a minority of participants and < 2% reached CKD stage 5. The risk of CKD progression was exceeded by the competing risk of death. Our observations confirm that in primary care, persons with CKD require monitoring and interventions to minimise risk of adverse outcomes but few progress to kidney failure.

FR-PO945

A Distribution-Based Approach to Age Associations Between Continuous Kidney Function and Adverse Events in the General Population

Manish M. Sood,[1] Junayd Hussain,[1] Mark Canney,[1] Meghan J. Elliott,[2] Gregory L. Hundemer,[1] Navdeep Tangri.[3] *[1]University of Ottawa School of Epidemiology and Public Health, Ottawa, ON, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [3]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada.*

Background: Whether having a low eGFR value relative to age-based medians is associated with a higher risk of an adverse event is yet to be explored. We aim to derive continuous age-specific associations between percentiles (1st, 2.5th, 5th, 10th) of eGFR and any adverse outcome (first of death, cardiovascular events, end-stage kidney disease), and obtain corresponding eGFR values.

Methods: We included 8.7 million adults (aged 18-65) with ≥1 eGFR value during January 2008-March 2020 in Ontario. Adjusted Cox models were used to estimate the association of a lower eGFR percentile (1st, 2.5th, 5th, 10th) and an adverse event by age from 18 to 65 relative to the age based median.

Results: Overall eGFR values declined with age and the risk of an adverse event was higher with an eGFR in the 10th percentile of lower across all age groups (see **Figure**). In younger individuals, lower percentiles of eGFR occurred at higher eGFR cutoffs relative to older individuals and were associated with an elevated risk of an adverse event. For example, an eGFR in the lowest 5th percentile would occur < 93 ml/min at age 20, < 80 ml/min at age 40, and below 65 ml/min at age 60 with corresponding adjusted HRs for an adverse event of 1.42, 1.28 and 1.32, respectively.

Conclusions: An age distribution-based approach to identifying lower eGFR values and their associated risk of an adverse event may improve care.

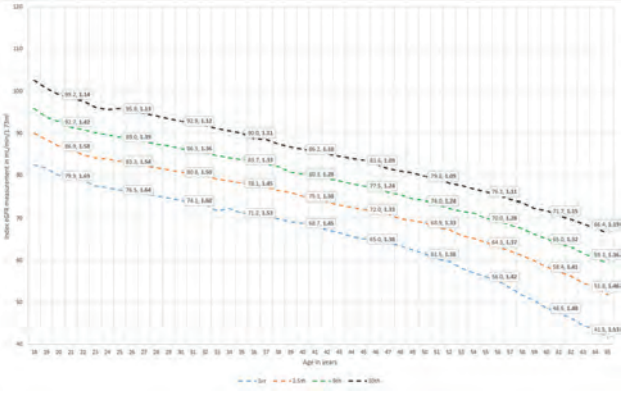

Figure: Trends in index estimated glomerular filtration rate (eGFR, in mL/min/1.73m^2) and associated adjusted HRs of any adverse outcome (first of death, cardiovascular events, end-stage kidney disease) by continuous age

FR-PO946

Kidney Function and Mortality in the Mexico City Prospective Study

Diego J. Aguilar-Ramirez. On Behalf of the Mexico City Prospective Study. *University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom.*

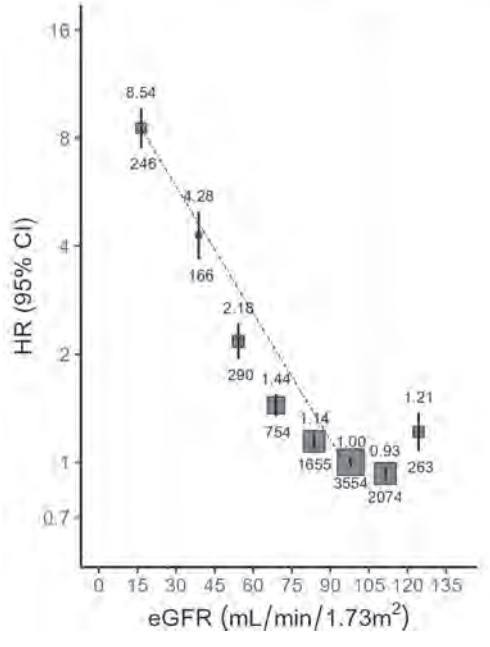
Background: Prospective studies in the US, Europe, Asia, and Australia have shown decreased kidney function is a strong predictor of mortality. There is limited data from Latin America where chronic kidney disease (CKD) is a major cause of morbidity and mortality.

Methods: In 1998-2004, 150,000 adults (aged ≥35 years) were recruited into the Mexico City Prospective Study, and followed for median 19 years. About 120,000 participants currently have nuclear magnetic resonance (NMR) spectroscopy-measured biomarkers in plasma, including creatinine. Cox regression was used to relate a single measurement of baseline eGFR (CKD-EPI equation) to mortality. Analyses were adjusted for age at risk, sex, district, education, smoking, alcohol, physical activity, height, weight, waist and hip circumference, and diabetes. They excluded those who at recruitment had incomplete data or prior chronic disease (except diabetes or CKD).

Results: Among the 33,423 men and 68,133 women aged 35-74 years with complete data, median (IQR) eGFR was 101 (90-109) mL/min/1.73 m^2, mean (SD) BMI was 29.1 (4.9) kg/m^2, 1% had self-reported CKD, 12% had previously-diagnosed diabetes, and 9,002 died at ages 35-74 years. Despite the inaccuracy of a single eGFR baseline measurement, eGFR <30 mL/min/1.73m^2 was associated with eight-fold higher all-cause mortality than eGFR 90-105 (HR 8.5 [95% CI, 9.8-7.5]). Below 90-105, every 15 mL/min/1.73m^2 lower eGFR was associated with 40% higher all-cause mortality (HR 1.40 [1.36–1.42] overall, and 1.37 [1.34-1.40] in those without self-reported CKD). eGFR was most strongly associated with renal deaths (HR 29.9 [24.4-36.9] for eGFR <30 vs 90-105) and vascular occlusive deaths (HR 6.2 [4.4-8.7]). Baseline assessments of blood pressure, lipids, and inflammation explained about a third of the association of eGFR with premature mortality.

Conclusions: In this study in Mexico, lower kidney function was strongly associated with increased premature mortality, with the association about twice as strong as previously reported in high-income countries.

Figure. Relevance of eGFR to ALL-CAUSE mortality at ages 35 to <75 years in the Mexico City Prospective Study.



FR-PO947

Prevalence and Significance of Family History of Kidney Disorders in the EHR in Three Large US Health Care Systems

Alexander R. Chang,[1] Krutika Pandit,[2] Thomas H. Jones,[1] Guilherme Del Fiol,[3] Kensaku Kawamoto.[3] *[1]Geisinger Health, Danville, PA; [2]New York University Grossman School of Medicine, New York, NY; [3]University of Utah Health, Salt Lake City, UT.*

Background: Chronic kidney disease (CKD) affects 1 in 7 adults and has a strong genetic component with prior studies reporting ~15% of White patients and nearly 25% of Black patients with end-stage kidney disease (ESKD) having family history of ESKD. Little is known about the prevalence of family history of CKD and ESKD in electronic health records (EHRs).

Methods: We examined the prevalence of family history of CKD and ESKD among patients 18+ years of age receiving primary care in 3 large health systems (Geisinger [n=454,740], Utah [n=215,432], New York University [NYU; n=284,890]). In additional analyses using Geisinger data, we used logistic regression, adjusted for age, sex, race, and ethnicity, to examine the association of family history of CKD and ESKD with having a diagnosis of CKD and ESKD.

Results: In a sample of 955,062 adults receiving primary care in 3 health systems, prevalence of family history of CKD was fairly similar across health systems (Geisinger 4.6%, Utah 4.0%, NYU 5.1%), as was family history of ESKD (Geisinger 0.8%, Utah 0.6%, NYU 0.9%). By comparison, 36.8% of patients at Geisinger had family history of diabetes. Individuals with a family history of CKD were at increased risks of having CKD (OR 1.86, 95% CI: 1.78, 1.94) and ESKD (OR 5.63, 95% CI: 5.12, 6.20). Similar risks were observed for family history of ESKD with having CKD (OR 2.27, 95% CI: 2.07, 2.48) and ESKD (7.68, 95% CI: 6.55, 9.00). Among individuals with ESKD at Geisinger, Black patients were more likely than non-Black patients to have family history of kidney problems (27.1% vs. 19.5%; p=0.008) though not specifically family history of ESKD (6.9% vs. 6.4%; p=0.9).

Conclusions: EHR-reported family history of CKD is strongly associated with risks of CKD and ESKD and infrequently reported across 3 large health systems. Future research is needed on how to improve capture of this important CKD risk factor.

FR-PO948

Greater Variability in eGFR Is Associated with CKD Progression: A Retrospective Japanese Nationwide Database Study

Yasuhiro Onishi,[1] Hajime Nagasu,[2] Kenji Tsuji,[1] Katsuyuki Tanabe,[1] Hiroshi Morinaga,[1] Haruhito A. Uchida,[1] Yuichiro Yano,[3] Naoki Kashihara,[2] Jun Wada.[1] *[1]Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Faculty of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan; [2]Department of Nephrology and Hypertension, Kawasaki Medical School, Kurashiki, Japan; [3]NCD Epidemiology Research Center, Shiga University of Medical Science, Otsu, Japan.*

Background: Variability in renal function is a phenomenon frequently observed in routine clinical practice. This variability may be indicative of pathophysiological factors, including the impaired autoregulation of renal blood flow and the effective circulating volume. With this study, our aim was to assess the relationship between the variability in eGFR and the risk of CKD progression.

Methods: We utilized the Japanese Chronic Kidney Disease Database (J-CKD-DB-Ex), a comprehensive, nationwide, multicenter longitudinal CKD registry, and included individuals with stage 3 and 4 CKD from 2014 to 2020 for the current analysis. We defined the variability of eGFR over a year using the coefficient of variation (eGFR-CV), standard deviation adjusted for the number of measurements (eGFR-adjSD), and average real variability (eGFR-ARV). The primary endpoint included the progression of CKD, defined as either a 40% decline in eGFR or the development of end-stage renal disease (ESRD).

Results: Of 24,986 participants, with an average age of 71.1 ± 11.8 years and 56.5% were male, the mean eGFR was calculated as 49.6 ± 7.8 ml/min/1.73m^2, and the median coefficient of variation for eGFR (eGFR-CV) was 7.6% [IQR 5.2 – 11.7]. Over a follow-up period of 3.3 years, 1,324 (5.3%) participants experienced a 40% decline in eGFR and 647 (2.6%) developed ESRD. Higher eGFR variability was associated with an increased risk of CKD progression in all patients after adjusting for eGFR slope over a year, and eGFR and other covariates at baseline (Table). These results were similar when other variability indices (eGFR-SD, eGFR-adjSD, and eGFR-ARV) were used instead of eGFR-CV. Furthermore, incorporating eGFR-CV into a predictive model that already included proteinuria and eGFR slope improved the prediction of outcomes, as evidenced by an increase in Harrell's c-index by 0.040 (95%CI 0.030 - 0.049, P<0.001).

Conclusions: eGFR variability is an independent predictor for CKD progression.

Funding: Government Support - Non-U.S.

Association Between Changes in Urinary Albumin and Protein Excretion and Risk of Kidney Failure in Patients with CKD: The CKD-JAC Study

Tadashi Toyama,[1] Takahiro Imaizumi,[2] Naohiko Fujii,[3] Takeshi Hasegawa,[4] Hirotaka Komaba,[5] Takayuki Hamano,[6] Masafumi Fukagawa.[5] *[1]Kanazawa Daigaku, Kanazawa, Japan; [2]Nagoya Daigaku, Nagoya, Japan; [3]Hyogo Kenritsu Nishinomiya Byoin, Nishinomiya, Japan; [4]Showa Daigaku, Shinagawa-ku, Japan; [5]Tokai Daigaku, Hiratsuka, Japan; [6]Nagoya Shiritsu Daigaku, Nagoya, Japan.*

Background: There has been progress in studying albuminuria as a surrogate endpoint for kidney failure with replacement therapy (KFRT) in patients with chronic kidney disease (CKD). However, the relationship between changes in proteinuria and KFRT has not been well studied.

Methods: The Chronic Kidney Disease - Japan Cohort (CKD-JAC) is a prospective observational study of patients with CKD in Japan. This study used the CKD-JAC cohort to examine the associations between a twofold increase in albuminuria (urine albumin-creatinine ratio) within the first two years of follow-up and the subsequent development of KFRT. In addition, in the subgroup with available proteinuria during follow-up, the relationship between the doubling of proteinuria (urine protein-creatinine ratio) in the first and second year and KFRT was examined in a similar way. A multivariable Cox proportional hazards model was used for analyses.

Results: The study analyzed 1,753 patients with an average age of 60 years, a mean eGFR of 30 mL/min/1.73 m^2, and a mean albuminuria of 419 mg/gCr. During the observation period, 618 patients (35.2%) initiated kidney replacement therapy. The hazard ratio (HR) and 95% confidence interval of KFRT for a doubling of albuminuria within 2 years was 1.57 (1.46, 1.70). Further analysis of the subgroup with proteinuria demonstrated that a doubling of proteinuria was associated with KFRT at the 2-year change (HR 1.41 [1.25, 1.59]). A similar association was found for the 1-year change of proteinuria as well (HR 1.30 [1.15, 1.47]).

Conclusions: In subjects with CKD, a doubling of albuminuria within the first two years of follow-up could potentially serve as a surrogate endpoint for KFRT. Similarly, proteinuria could also be a surrogate endpoint for KFRT.

Risk Factors for Progression to Kidney Failure in Patients with CKD Stages 3B and 4 in a Singaporean Cohort

Wanting Weng, See Cheng Yeo, Xi Yan Ooi. *Tan Tock Seng Hospital, Singapore, Singapore.*

Background: The prevalence of chronic kidney disease (CKD) is increasing globally and the burden of kidney failure is also increasing. We aim to examine the risk factors for progression to kidney failure in patients with CKD stages 3B and 4 and develop a risk prediction model for predicting kidney failure in our local multi-ethnic population.

Methods: Demographics, clinical and laboratory data of patients with CKD stages 3B and 4 referred from polyclinics to Tan Tock Seng Hospital(TTSH) Renal Medicine between April 2017 to February 2022 were collected. The primary outcome was kidney failure defined as an estimated glomerular filtration rate (eGFR)<15ml/min/1.73m^2. The secondary outcome was that of a composite of kidney failure, death, doubling of serum creatinine and eGFR decline by 40%. Multivariate cox proportional hazard regression analyses were used to evaluate risk factors for the primary outcome. A risk prediction model for predicting kidney failure was developed and performance was evaluated by C-statistic.

Results: There were 2033 patients with CKD 3B and 4 referred from polyclinics to TTSH between 2017 to February 2022. 848 patients with less than 1 year of follow up was excluded(except if they developed kidney failure in less than 1 year, n=8). There were 1193 patients included in the analysis of which 66.3% had CKD 3B and 33.7% had CKD 4. The median age of these patients was 70.8(31.3-83.6) years old. 56.9% were males and the median eGFR was 33(IQR:15-44)ml/min/1.73m^2. 73.1% of the cohort had diabetes mellitus and 93.8% had hypertension. 80.6% of patients were on an ACE inhibitor or ARB. Mean duration of follow up was 36.8 months. 6.2% of patients died and 12% developed the primary outcome. 19.6% of patients developed the secondary outcome. Higher proteinuria (HR 1.15,95%C.I 1.02-1.30) higher serum creatinine (HR 1.04, 95%C.I 1.03-1.05), higher annual rate of decline of eGFR, Malay ethnicity (HR2.13 95% C.I 1.05-4.33), higher diastolic blood pressure(HR 1.05 95%CI 1.01-1.08) and female gender were risk factors for kidney failure. The Harrell C-statistic for the final model was 0.93.

Conclusions: Our model for predicting kidney failure in patients with CKD stage 3B and 4 including the variables ethnicity, annual eGFR decline, baseline proteinuria and serum creatinine had a C-statistic of 0.93 and should be validated in a larger population of patients.

FR-PO951

Early-Stage Characteristics and Potential Predictors of CKD Among US Veterans

Levente Dojcsak,[1] Cheng Chen,[1] Stephen Grady,[1] Yamini Mallisetty,[2] Haoran Niu,[1] Prabin Shrestha,[2] Keiichi Sumida,[2] Fridtjof Thomas,[2] Michael A. Langston,[1] Csaba P. Kovesdy.[2,3] *[1]University of Tennessee, Knoxville, TN; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]VA Memphis Medical Center, Memphis, TN.*

Background: Chronic Kidney Disease (CKD) is prevalent but under-diagnosed across the world. Its prediction remains a formidable challenge, even when complete clinical and demographic information is available. We studied a large patient cohort from the US Department of Veterans Affairs (VA) in an effort to identify predictive characteristics common to those afflicted with CKD before the disease becomes clinically evident.

Methods: From a cohort of 692,942 veterans with stable eGFR >60 ml/min/1.73m^2, we identified 174,627 patients who developed CKD within up to eight years following enrollment and compared them to patients who remained CKD free. Over these two patient subgroups, we calculated Pearson correlation coefficients for all baseline variable pairs and, for each such pair, we examined those that were differentially correlated as defined by an absolute difference of at least 0.15 between the CKD and non-CKD cohorts. Using a graph theoretic approach, we created finite, simple, undirected graphs, with variables of interest represented by vertices and edges weighted by correlation then thresholded. From these graphs we extracted dense subgraphs indicative of latent variable relationships to account for complex correlations.

Results: Age and a variety of specific comorbidities were correlated higher within the non-CKD subgroup than within the CKD subgroup. From graph theoretical analysis, we found that the Charlson index, congestive heart failure (CHF), myocardial infarctions (MI), and peripheral vascular disease (PVD) formed a dense subgraph indicative of highly interconnected disease relationships (Figure). Age and cardiovascular disease (CVD) only entered this putative network among non-CKD patients.

Conclusions: These results suggest that kidney disease belongs to a constellation of comorbidities that may help to act as predictors of incipient CKD. Chronological age may not play a prominent role in the development of comorbidities in patients with CKD, which may be explained by premature ageing seen in CKD.

FR-PO952

Physical Activity Is an Independent Predictor of CKD Development Among Healthy Individuals

Pazit Beckerman, Orit Erman, Shmuel Tiosano, Husam Qasim. *Sheba Medical Center, Tel Hashomer, Israel.*

Background: The cardiovascular and metabolic benefits of physical activity has been discussed in length, however, the association between physical fitness and progression to kidney disease is lacking. We aimed to identify the association between cardiorespiratory fitness and development of chronic kidney disease (CKD) among healthy population.

Methods: We investigated 11,579 healthy self-referred subjects who underwent annual medical screening. All subjects had an eGFR above 60 ml/min/1.73m2, no known kidney disease, hematuria or proteinuria, and were free of diabetes or cardiovascular disease at baseline. All participants completed a maximal exercise test, and were categorized into low and high cardiorespiratory fitness groups based on age- and gender-specific quintiles. The primary end point was the development of CKD defined as eGFR below 45 ml/min/1.73m2 during follow-up.

Results: Median follow-up was 7.6 years, and the median participants' age was 50±8years. Baseline creatinine and eGFR were 1.02 mg/dl and 81 ml/min/1.73m2, respectively. During follow-up, 81 (0.6%) participants developed CKD, the cumulative probability significantly higher among the low fitness group (HR=2.41, p=0.001). The effect of physical fitness on the risk to develop CKD remained significant after adjusting for age, gender, baseline creatinine and other cardiovascular risk factors.

Conclusions: Cardiorespiratory fitness is an independently risk factor inversely associated with development of significant CKD.

FR-PO953

Association Between Physical Activity and Renal Outcomes in Patients with CKD G3b-5: A Result from a Japanese Cohort Study, the REACH-J

Junichi Hoshino,[1] Ryoya Tsunoda,[2] Hirayasu Kai,[2] Chie Saito,[2] Hirokazu Okada,[3] Ichiei Narita,[4] Takashi Wada,[5] Shoichi Maruyama,[6] Kunihiro Yamagata.[2] The REACH-J. *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Tsukuba Daigaku, Tsukuba, Japan; [3]Saitama Ika Daigaku, Iruma-gun, Japan; [4]Niigata Daigaku, Niigata, Japan; [5]Kanazawa Daigaku, Kanazawa, Japan; [6]Nagoya Daigaku, Nagoya, Japan.*

Background: Association between physical activity and renal outcome in patients with chronic kidney disease (CKD) has remained largely unexamined.

Methods: We recruited 2,249 advanced CKD patients (eGFR<45 ml/min/1.73m²) receiving nephrologist care from a national sample of 31 facilities throughout Japan, randomly selected with stratification by region and facility size, aligned with the international CKD Outcomes and Practice Patterns Study (CKDopps). Association between baseline physical activity levels (active or inactive, from Rapid Assessment of Physical Activity (RAPA) surveys) and 5-year renal outcomes (40% eGFR decline, end-stage kidney disease, or death) were analyzed.

Results: Of 1808 eligible CKD patients with RAPA assessment, 407 patients with diabetic kidney disease (DKD) and 1401 patients without diabetes (non-DKD) were enrolled. Of them, 1237 patient (68% of total, 66% of DKD and 69% of non-DKD) were categorized "active" (often active or very active by RAPA score), and others were categorized "inactive". The mean ages and eGFRs in "active" and "inactive" patients were 68.5±12.5 and 70.8±11.7 years, and 24.1±10.4 and 22.1±10.4 mL/min/1.73m², respectively. Crude rates for CKD progression per 100 person-years in "active" and "inactive" patients were 19.4 and 22.1 events in DKD, and 12.1 and 13.7 events in non-DKD, respectively. In addition, crude rates for mortality in those patients were 3.9 and 4.8 events in DKD, and 1.8 and 3.8 events in non-DKD, respectively. Composite CKD progression and mortality were considerably lower at higher physical activity in both DKD and non-DKD patients, with hazard ratios of 0.84 (0.66, 1.08) and 0.80 (0.69, 0.93), respectively.

Conclusions: This multicenter study suggested the association between higher physical activity and lower CKD progression and better survival in both DKD and non-DKD patients. These findings may support future studies understanding impact of physical activity for better renal outcomes in patients with CKD stage G3b-5.

FR-PO954

Longitudinal Impacts of Bariatric Surgery on Renal Function in CKD

Siddharth S. Madapoosi, Laura H. Mariani. *University of Michigan, Ann Arbor, MI.*

Background: Prior studies of obesity show improved renal function after bariatric surgery. This study examines renal function over 10 years pre- and post-bariatric surgery among patients with a reduced baseline eGFR, including patients with CKD.

Methods: Retrospective cohorts of patients with CKD and/or who underwent bariatric surgery prior to 11/30/22 were identified from the Michigan Medicine EHR using ICD-10 and CPT codes. Multivariable piecewise linear mixed models were fit on eGFR (2021 CKD-EPI), adjusting for age, gender, race, ethnicity, BMI, hypertension, diabetes, and surgery type or CKD stage. Pre- and post-surgery eGFR trajectories were compared in patients with a baseline eGFR<90. eGFR trajectories were then compared between CKD patients post-surgery and either propensity score-matched non-CKD patients post-surgery or CKD patients who did not undergo surgery.

Results: Patients with baseline eGFR<90 (n=688) had a slower annual rate of eGFR decline [95% CI] post vs. pre-surgery (-1.85 [-1.97,-1.72] vs. -3.22 [-3.41,-3.02] mL/min/1.73m²; p<0.001). Following surgery, CKD patients (n=139) had a slower annual rate of eGFR decline compared to 278 matched non-CKD patients (-1.28 [-1.87,-0.69] vs. -2.62 [-2.83,-2.41] mL/min/1.73m²; p<0.001). Annual eGFR decline was also slower among CKD patients who underwent surgery compared to 278 matched CKD patients who did not (-0.20 [-0.83,0.43] vs. -1.11 [-1.37,-0.85] mL/min/1.73m²; p<0.001).

Conclusions: Bariatric surgery is associated with a slower rate of eGFR decline in patients with a reduced baseline eGFR, including CKD patients. Future modeling of proteinuria may support these findings and identify if the faster eGFR decline in healthy patients correlates to a decrease in glomerular hyperfiltration after surgery.

FR-PO955

Association Between Weight Change from 20 Years of Age and the Risk of All-Cause and Cardiovascular Mortality in Patients with CKD

Kazuhiro Okamura,[1] Shigeru Tanaka,[1] Hiromasa Kitamura,[1] Hiroto Hiyamuta,[3] Kazuhiko Tsuruya,[2] Takanari Kitazono,[1] Toshiaki Nakano.[1] *[1]Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu Daigakuin Igaku Kenkyuin, Fukuoka, Japan; [2]Nara Kenritsu Ika Daigaku Igakubu Igakuka Daigakuin Igaku Kenkyuka, Kashihara, Japan; [3]Fukuoka Daigaku Igakubu Daigakuin Igaku Kenkyuka, Fukuoka, Japan.*

Background: Weight changes from a young age have been reported as being linked to poor life outcomes in the general population. However, little is known concerning the association between weight changes from a young age and life expectancy in patients with chronic kidney disease (CKD).

Methods: The data of 2,806 non-dialysis CKD patients who participated in the Fukuoka Kidney disease Registry (FKR) Study, a multi-center observational study, were analyzed. All-cause mortality was the primary outcome, while cardiovascular mortality was a secondary outcome. The covariate of interest was weight change, defined as the difference between body weight at study enrolment and that at 20 years of age. We estimated the risks of mortality for participants with weight changes of ≥5 or <5 kg using Cox proportional hazards models, as compared to those with stable weights.

Results: In total, 243 participants (8.7% of the total) died from all-cause, and 62 participants died from cardiovascular disease within the 5-year observation period. The risk of all-cause mortality was significantly higher in the weight loss group than in the stable weight group (multivariable-adjusted hazard ratio [95% confidence interval], 2.11 [1.52–2.93]). In addition, the risk of cardiovascular mortality was significantly higher in the weight loss group than in the stable weight group (multivariable-adjusted hazard ratio [95% confidence interval], 2.48 [1.32–4.64]). No significant associations were found between weight gain and the risks of all-cause and cardiovascular mortality.

Conclusions: Weight loss since 20 years of age is associated with increased risks of all-cause and cardiovascular mortality in non-dialysis CKD patients.

FR-PO956

Appraisal of a Simplified Protein Energy Wasting Score in CKD Patients at a Single University-Based Hospital: A Five-Year Retrospective Cohort Study

Manoch Rattanasompattikul,[1,2] Jadenapa Phicheansoonthorn,[1,2] Nuttawut Rongkiettechakorn,[1,2] Malinporn Jampong,[1,2] Moltira Promkan.[3] *[1]Golden Jubilee Medical Center, Nakorn Pathom, Thailand; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]Mahidol University Faculty of Medical Technology Bangkok Noi Campus, Bangkok, Thailand.*

Background: Undernutrition poses a significant complication of chronic kidney disease (CKD), leading to devastating effects on quality of life, morbidity, hospitalization, and mortality. We developed a novel Protein Energy Wasting (PEW) score, utilizing the nomenclature proposed by the International Society of Renal Nutrition and Metabolism in 2008.

Methods: We enrolled participants aged 18 years or older, with CKD stages G3 to G5ND between January 2016 and December 2020. These were utilized for diagnosing PEW using the simplified PEW score (sPEW). The sPEW was defined by the following criteria (**Figure 1**), and the Lean Body Mass Index (LBMI = LBM/height2) was subsequently determined.

Results: In total, 224 patients were identified (64% male, 36% female; mean age 77 years), with the majority classified as stages 3a, 3b, and 4 CKD (41%, 38%, and 18%, respectively). The prevalence, according to the sPEW score, showed 85 (38%) with mild PEW, 26 (12%) with moderate PEW, and four (2%) with severe PEW. LBMI was 17.3 ± 22.4, 15.7 ± 1.9, 15.5 ± 2.1, and 13.5 ± 0.5 kg/m2 in the none, mild, moderate, and severe sPEW groups, respectively (P<0.001). The multiple linear regression analysis indicated that changes in lean body mass index negatively correlated with changes in the sPEW score and gender (P<0.001) (**Figure 2**).

Conclusions: These studies suggest that the sPEW, when used in CKD patients, appears to reflect the LBMI in these populations. Further research is required to determine the validity of the sPEW as a nutritional marker and to explore its predictive value for other clinical outcomes in CKD patients.

Simplified Protein Energy Wasting Score (sPEW)

Definition of the Simplified Protein–Energy Wasting Score		Score Point
Serum albumin (g/dL)	≤3.8	1
Body mass index (kg/m2)	≤23	1
nPNA (g/kg/day)	≤0.8	1

No PEW = 0; Mild PEW = 1; Moderate PEW = 2; Severe PEW = 3

Figure1

Prevalence and association of simplified PEW score and risk factors with lean body mass index in chronic kidney disease population

	Prevalence	Lean body mass index (kg/m²) regression coefficient (95% CI)	
		Univariate analysis	Multivariate analysis *
sPEW:			
- mild	38%	-1.60 (-2.36; -0.85)	-1.53 (-2.27; -0.79)
- moderate	12%	-1.86 (-2.97; -0.74)	-1.50 (-2.64; -0.36)
- severe	2%	-3.834 (-6.92; -0.75)	-2.70 (-5.71; 0.31)
Gender (female)	36%	-2.75 (-3.42; -2.14)	-2.77 (-3.39; -2.15)
Low serum albumin (<3.8 g/dl)	14%	-0.73 (-1.79; 0.33)	-1.12 (-1.20; 0.96)
Low body mass index (<23 kg/m²)	37%	-2.02 (-2.72; -1.32)	-1.198 (-2.88; -1.29)
Low dietary protein intake (<0.80 g/kg/d)	16%	-0.37 (-1.42; 0.68)	-0.22 (-1.24; 0.79)
Low dietary energy intake (<25 kcal/kg/d)	25%	1.11 (0.23; 1.98)	1.28 (0.43; 2.13)

FR-PO957

Food Insecurity and High Blood Pressure Among Individuals with CKD in West Africa

Raghavee Neupane,[1] Titilayo O. Ilori,[2] Runqi Zhao,[2] Sushrut S. Waikar,[2] Edward P. Kwakyi,[3] Jessica Chern,[2] Ifeoma I. Ulasi,[4] Adaobi Solarin,[5] Dwomoa Adu,[6] Manmak Mamven,[7] Rasheed A. Gbadegesin.[8] *[1]Boston University School of Public Health, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]University of Ghana School of Medicine and Dentistry, Accra, Ghana; [4]University of Nigeria, Nsukka, Nigeria; [5]Lagos State University Teaching Hospital, Lagos, Nigeria; [6]University of Ghana School of Medicine and Dentistry, Accra, Ghana; [7]University of Abuja, Abuja, Nigeria; [8]Duke Medicine, Durham, NC.*

Background: Based on the Diet, CKD, and ApolipoproteinL1 (DCA) study data, this cross-sectional study examines the relationship of food insecurity with estimated glomerular filtration rate (eGFR) and systolic and diastolic blood pressure (SBP and DBP). Very few studies have yet studied these associations in sub-Saharan African populations. Understanding the impact of food insecurity is crucial to guide care for patients with CKD.

Methods: We recruited 570 participants with CKD (eGFR < 60mL/min/1.73m², or albuminuria > 30 mg/g) from 7 centers in the H3Africa Kidney Disease study. We measured food insecurity using a standardized question, "Did you cut meals size/skip meals because there was insufficient money during the past year?" We used mixed-effect linear regression models with clinical centers as random intercepts. Outcomes were eGFR (CKD-EPI 2009 equation), SBP, and DBP. We analyzed factors associated with food insecurity using logistic regression with a random intercept for the clinical center.

Results: The mean age for our population was 48.7 (SD = 17.5), and 47% were female. The prevalence of food insecurity in the DCA cohort was 28%, with the highest in Southeast Nigeria (69%, p<0.0001). Individuals with CKD stages 3-5 had the lowest prevalence of food insecurity (25%). The overall study population had no significant association of food insecurity with eGFR, SBP, or DBP (Table 1). Higher BMI (OR: 0.90–0.98, p<0.01), higher education (OR: 0.25–1, p=0.05), and higher income (OR: 0.003–0.38, p=0.01) were all associated with lower odds of food insecurity.

Conclusions: Our study shows a higher prevalence of food insecurity in Southeast Nigeria and a lower prevalence of food insecurity in patients with more advanced CKD. Investigating the true effect of food security on kidney function or cardiovascular disease in sub-Saharan Africa merits further study.

Funding: NIDDK Support

Associations between Food Insecurity, eGFR and Blood Pressure

	Unadjusted Model		Fully Adjusted Model*	
Outcome	Beta Coefficient (95% CI)	p-value	Beta Coefficient (95% CI)	p-value
eGFR	8.26 (0.37 to 16.23)	0.04	5.51 (-1.09 to 12.00)	0.11
Systolic BP	0.45 (-4.07 to 4.82)	0.84	1.88 (-2.53 to 6.13)	0.40
Diastolic BP	1.76 (-1.26 to 4.82)	0.26	2.31 (-0.79 to 5.45)	0.15

Economic Burden of CKD in the United States: A Systematic Literature Review

Satabdi Chatterjee,[1] Hannah Rochon,[2] Katherine M. Osenenko,[2] Bonnie M. Donato.[1] *[1]Boehringer Ingelheim Pharmaceuticals Inc, Ridgefield, CT; [2]Broadstreet HEOR, Vancouver, BC, Canada.*

Background: With nearly 37 million cases of CKD in the US, the economic impact is substantial. To fully understand the economic burden of CKD to payers and health systems, as well as drivers of burden, a comprehensive assessment of the recent evidence base is needed. This review aimed to characterize direct medical costs of those diagnosed with CKD in the US, overall and by CKD stage, insurance type, and presence of diabetes mellitus (DM), cardiovascular disease (CVD), and obesity.

Methods: A systematic literature review was conducted using MEDLINE and Embase, supplemented by a grey literature search, to identify studies reporting direct medical costs for CKD in the US, published between 01/01/2017 and 07/27/2022. Conference proceedings from 2020 to 2022 that were identified in the search were also considered for inclusion. Two reviewers independently performed study selection and data extraction according to PRISMA guidelines. Patient characteristics and cost estimates were summarized; mean annual cost estimates were converted to 2022 USD and reported.

Results: From 3,424 abstracts, 52 citations representing 39 distinct studies were included. Sample sizes ranged from 52 to 7,091,324; mean age ranged from 45 to 79 years and the percentage of males from 33% to 98%. Direct medical costs ranged from $6,592 to $280,727 per patient. In studies of CKD-only patients reporting costs by stage (n=3), costs ranged from $6,592 (stage 3) to $143,745 (end stage kidney disease [ESKD]). Of studies evaluating comorbidities (n=14), patients with DM had costs as high as $280,727 (new onset ESKD & DM), while those with CVD had costs as high as $70,742 (CKD & heart failure). No studies investigated costs among those with comorbid obesity. In studies reporting components of medical costs for CKD-only (n=7), inpatient costs tended to be the largest component ranging from $2,331 to $116,309. No trend was observed in costs by payer type.

Conclusions: The review found that direct medical costs among patients with CKD continues to be high, primarily driven by inpatient costs. Other contributory factors included advanced CKD stages and presence of cardiometabolic comorbidities.

Funding: Commercial Support - This study was funded by Boehringer Ingelheim.

FR-PO959

Improving Compliance with CKD Screening and Monitoring in a Resident Continuity Clinic

McKenna Eisenbeisz, Adam Blaine, Kimiya Nourian, Alexander A. Garza, Colten C. Stewart, Erin L. Sternhagen, Lisa M. Antes, Diana I. Jalal, Melissa L. Swee. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Chronic kidney disease (CKD) is a significant burden on the adult population, affecting up to 1 in 10 individuals. Early identification and intervention in early-stage CKD are crucial for preventing cardiovascular morbidity and mortality, specially with the availability of advanced treatment options. Guidelines recommend annual measurement of estimated glomerular filtration rate (eGFR) and proteinuria quantification in individuals at risk of CKD or with early-stage CKD. As only one third of primary care providers (PCPs) are completely confident in how to screen, diagnose, and manage CKD, we hypothesized that compliance with CKD monitoring and screening would be suboptimal in our Resident Continuity Clinic (RCC).

Methods: We conducted a quality improvement project in our RCC, comprising 34 internal medicine resident physicians serving as PCPs. We focused on patients seen in the RCC between July 1, 2020 and February 28, 2023. We assessed CKD monitoring by determining the percentage of patients with CKD, diabetes, or hypertension who underwent at least one measurement of eGFR and urine protein/creatinine or urine albumin/creatinine ratio (ACR) during the study timeframe. Patients were considered to have diabetes, hypertension, or CKD if the disease specific ICD-10 code was present on their chart.

Results: 59% of the 1,811 patients seen in the RCC during the evaluation period had CKD, diabetes, or hypertension. While eGFR was measured in 90% of these patients, only 24% had eGFR and proteinuria measured. To address this gap, we implemented Plan-Do-Study-Act cycles to include resident education, introduction of an order set in the electronic medical record (EMR) to facilitate appropriate laboratory testing, and an

EMR update to prompt PCPs to order yearly urine ACR for patients with diabetes. Post-intervention data will be collected quarterly, with initial results available July 2023.

Conclusions: Despite satisfactory adherence to eGFR measurements, proteinuria evaluation was underutilized. Proteinuria is an independent predictor of cardiovascular morbidity and mortality and CKD progression and has therapeutic implications. Our findings highlight the need for healthcare system interventions to ensure proper proteinuria evaluation in patients at risk for CKD.

FR-PO960

Investigating Barriers to Implementation of Functional Status Assessments in CKD Care: A Mixed Methods Study Among Stakeholders

Sarah J. Schrauben, Caroline S. O'Brien, Andrea Bilger. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) clinical practice guidelines (CPG) recommend regular functional status assessments at all stages of CKD to identify those at high risk for poor functional decline. However, functional status tests are not routinely incorporated into CKD care, and the reasons for this gap have not been explored.

Methods: We used the Consolidated Framework for Implementation Research (CFIR) to guide survey and interview questions to identify barriers to implementing CPG recommended functional status assessments in CKD care. Online survey invitations were sent to stakeholders in CKD care, including staff providing direct care and administrators with decision-making roles in a large health system in southeastern Pennsylvania. Volunteers among survey respondents participated in phone interviews with a qualitative researcher. Interviews were transcribed verbatim and de-identified. Transcripts were analyzed with inductive coding as well as deductive coding using CFIR domains, and codes were grouped into themes.

Results: Thirty-nine stakeholders in CKD care responded to surveys: 28 were nephrologists, 9 were other care staff, and 2 were administrators; 62% were women, 59% White, 31% Asian, and 5% Black. Only 36% were aware of CPG recommendations for functional testing in CKD care and 22% reported that testing was currently performed. Two-thirds of respondents agreed that functional testing should be performed in CKD care (66%) and that these tests could be conducted effectively in their clinics (69%). In the survey, the three most commonly selected barriers to performing functional testing were: clinical burden, lack of familiarity with tools, and lack of space and/or equipment. Seven respondents volunteered to be interviewed (3 nephrologists, 4 advanced practitioners). Themes identified as barriers to CPG implementation included: limited awareness/knowledge, limited resources (time, space), lack of competence/confidence in conducting tests and interpreting results, and lack of a standard operating procedure for testing.

Conclusions: Identified barriers, including limited awareness/knowledge, resources (time, space, equipment), and a standard procedure will inform strategies to improve the implementation of CPG recommended functional testing in CKD care.

Implementation of the Kidney Failure Risk Equation in a US Nephrology Clinic

Dipal Patel,[1] Bryce M. Churilla,[1] Heather Thiessen Philbrook,[1] Yingying Sang,[2] Morgan Grams,[3] Chirag R. Parikh,[1] Deidra C. Crews.[1,2] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]New York University Grossman School of Medicine, New York, NY.*

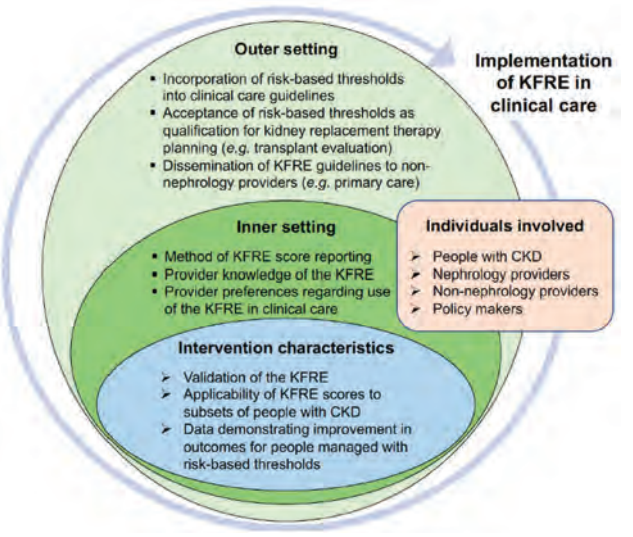
Background: The kidney failure risk equation (KFRE) estimates a person's risk of kidney failure. We explored implementation of the KFRE in a U.S. nephrology clinic.

Methods: We integrated KFRE scores into the electronic health record (EHR) for patients with CKD being seen in Johns Hopkins nephrology clinics. We quantified documentation of KFRE scores in clinic notes and conducted surveys and focus groups of nephrology providers to assess provider perspectives on its use. Focus groups were audio-recorded and transcripts were coded using thematic analysis.

Results: Documentation of KFRE scores increased over time, reaching 25% of all eligible outpatient nephrology clinic notes after 11 months. Of 44 nephrology providers, 3 documented KFRE scores in > 75% of notes, whereas 25 documented scores in < 10% of notes. Survey respondents (n=25) reported variability in use of KFRE scores for decisions such as maintaining nephrology care, referring for transplant evaluation, or providing dialysis modality education. Provider perspectivess, assessed by qualitative analysis of focus groups transcripts, included three common themes: 1) KFRE scores may be most impactful in care of specific subsets of people with CKD; 2) there is uncertainty surrounding KFRE risk-based thresholds to guide clinical care, and 3) education of patients, nephrology providers, and non-nephrology providers on appropriate interpretations of KFRE scores may help maximize their utility. Based upon these findings, we propose key components of KFRE implementation as a roadmap for future efforts to increase its use in clinical care (Figure).

Conclusions: KFRE score documentation increased over time, with variability in adoption by providers. Further knowledge surrounding utilization of the KFRE in clinical decisions may enhance its implementation.

Funding: NIDDK Support



Roadmap for KFRE implementation.

A Quality Improvement Initiative to Bridge Gaps in Treatment and Interprofessional Care of CKD

David Cappel,[1] Michelle Zhao,[1] Jeffrey D. Carter,[1] Cherilyn L. Heggen,[1] Katherine R. Tuttle.[2,3] *[1]PRIME Education LLC, Fort Lauderdale, FL; [2]Providence Washington, Seattle, WA; [3]University of Washington School of Medicine, Seattle, WA.*

Background: Diagnosing, treating, and coordinating care for patients with chronic kidney disease (CKD) can be challenging, contributing to gaps in the quality of care in CKD. Uncovering the needs of nephrology care teams treating patients with CKD can help to close these gaps and improve patient outcomes.

Methods: A quality improvement (QI) initiative within 5 nephrology clinics was conducted to assess current practice patterns through surveys administered to nephrology care team members (n=83). Each center then participated in an interactive audit-feedback educational session with a national CKD expert and developed action plans to address system-specific barriers to treatment.

Results: Provider surveys identified gaps in patients meeting clinical targets and receiving guideline-directed care. Notably, 37% of providers reported less than half of their CKD patients were meeting blood pressure targets and 67% of providers reported that less than half of their CKD patients were meeting HbA1C targets. When CKD care team members were asked how many of their patients with CKD were prescribed an SGLT2 inhibitor, 53% of respondents reported that less than 25% of their patients were receiving an SGLT2 inhibitor as part of their treatment plan (Fig. 1). Following the intervention, CKD care team members prioritized the following areas for improvement to support patients and align clinical practice with current guideline recommendations: 1) patient education to improve lifestyle modification (41%), 2) developing individualized treatment plans based on patient specific factors (22%), and 3) improving co-management of patients with primary care physicians and other specialists (22%).

Conclusions: The surveys identified real-world challenges inhibiting patients from achieving clinical targets and contributing to discordances with guideline-directed treatment recommendations. Overall, QI programs for interprofessional CKD care teams are critical tools for understanding and addressing system-specific barriers to effective treatment of CKD.

The Role of Patients' Education in Improving Quality Outcomes in CKD

Rula A. Abdulrahman, Sandeep K. Mallipattu. *Stony Brook University, Stony Brook, NY.*

Background: CKD prevalence in US is ~ 14%. The measures to delay CKD progression are well known to providers but not to most patients with CKD, specifically minorities and patients in the lower socioeconomic class. Providing intense CKD education can improve quality outcome in this population and delays dialysis requirement. Home dialysis (HoD) therapies have been associated with improved quality of life and reduced costs, in US HoD percentage is ~13%. Currently most patients start dialysis with central venous catheter (CVC) ~ 83%in US, our goal is to increase HoD, efficiency of arteriovenous fistula (AVF) or arteriovenous graft (AVG) placement, and to increase referrals and listing for kidney transplantations (KT), as suggested in ESRD treatment choice model.

Methods: We initiated a CKD education clinic (CKDEC) with 3 aims: delay the progression of CKD and onset of dialysis, increase the number of HoD, improve access and timely referral to KT. Individuals who attend the clinic will be educated to avoid the factors and behaviors that can expedite CKD progression and dialysis initiation. Patients will be provided with guidance about controlling underlying medical diseases and introduced to ESRD treatment modalities. We also facilitate their access to obtain permanent access in a timely manner. We are educating the patients about KT and facilitate the appointments & encourage follow up.

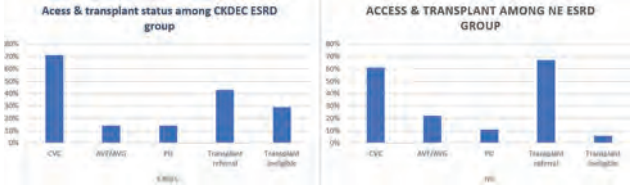
Results: 209 patients that are CKD IV and V at our outpatient facility & 25 dialysis. Of those, who chose HoD after CKDEC are 14.3%. This is higher than the national rate of 13%. CKDEC improved referral rate to KT and vascular access (Table 1). Many of our patients who started dialysis in 2021-2022 used CVC (71%) after CKDEC, this is lower than the national CVC rate (83%) image 1

Conclusions: CKD education improves HoD rate, referrals to KT and dialysis access among CKD but not ESRD group. we need to continue earlier access to CKD education clinic to continue to improve our outcome measures.

Table 1

	CKDEC transplant referral	CKDEC access referral	NE transplant referral	NE access referral
CKD IV	42.8%	23.8%	2.8%	2.2%
CKD V	71.4%	92.8%	61.3%	67.7%

CKDEC: chronic kidney disease education clinic. NE: did not attend CKDEC



FR-PO964

Optimizing Palliative Care Referrals for Veterans with Kidney Disease in the Iowa City VA Health Care System

Melissa L. Swee,[1,2] Qianyi Shi,[1] Mary V. Sarrazin,[1,2] Benjamin R. Griffin,[1] Masaaki Yamada,[1,2] Meenakshi Sambharia,[1] Diana I. Jalal.[1,2] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA.*

Background: The kidney clinic at Iowa City VA (ICVA) sees 20-40 patients weekly, with an estimated 5-15% benefiting from palliative care referrals. Hospice aims to enhance end-of-life quality and enable death at home. However, the lack of quality metrics in the industry hinders care assessment. National median length of stay (LOS) in hospice was 18 days in 2018. In ICVA, only 1.8% of palliative care referrals were for kidney disease patients, with a median LOS of 14 days, highlighting the need for improvement.

Methods: We aimed to evaluate delays in kidney disease referrals to palliative care and enhance appropriate referral percentage. Mixed methods were used, reviewing referral data and examining qualitative barriers. Three iterative Plan-Do-Study-Act (PDSA) cycles were implemented. The first focused on educating the kidney team to consider the patient holistically. The question, "Would death within six months not be unexpected?" was introduced. The second involved a multidisciplinary conference, broadening education. The third proactively reviewed charts of returning patients to identify referral candidates.

Results: Analysis using a Statistical Process Control (SPC) p-chart showed consistent low referrals (<10% of eligible Veterans), indicating the need for improvement. Barriers identified included concerns about time required for discussions and referrals.

Conclusions: Our project has not entered the sustainability phase, as there has been no significant improvement in referrals for eligible patients. Further iterative PDSA cycles are necessary to integrate palliative care effectively. Future efforts will focus on reducing rural disparities in accessing palliative care through virtual visits. We aim to align resources in the kidney clinic, increase efficiency, and consider implementing an opt-out process for Veterans on dialysis or with significant kidney disease. By addressing these challenges, we aim to improve appropriate palliative care referrals, enhance end-of-life care for kidney disease patients at ICVA, and provide early access to specialized person-centered care, ultimately improving their quality of life.

FR-PO965

Impact of Conservative Management vs. Dialysis Transition on Survival in a National Advanced CKD Cohort

Connie Rhee,[1] Ji Hoon Yoon,[1] Seungsook You,[1] Yoko Narasaki,[1] Csaba P. Kovesdy,[2] Dana B. Mukamel,[1] Susan T. Crowley,[3] Silvina Torres Rivera,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[4] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]Yale University, New Haven, CT; [4]Harbor-UCLA Medical Center, Torrance, CA.*

Background: While dialysis has been the dominant treatment paradigm in advanced CKD patients progressing to ESKD, this approach may lead to impaired physical function, independence, and quality of life among certain subpopulations. We compared the impact of non-dialytic conservative management (CM) vs. dialysis on survival in a national advanced CKD cohort.

Methods: We compared survival in advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days) treated with CM vs. dialysis (non-receipt vs. receipt of dialysis within 2-years of the 1st eGFR <25) over 1/1/07-6/30/20 from the Optum Labs Data Warehouse, which contains de-identified administrative claims, including medical/pharmacy claims and enrollment records for commercial/Medicare Advantage enrollees, and EHR data. In secondary analyses, we examined finer gradations of dialysis timing, defined as earlier dialysis (ED) vs. later dialysis (LD) (eGFRs ≥15 vs. <15 at dialysis transition), and in tertiary analyses we compared ED, intermediate dialysis (ID), vs. very-late dialysis (VLD) (eGFRs ≥15, 10-<15, vs. <10 at dialysis). We compared survival in CM vs. dialysis patients matched by propensity score (PS) in a 1:1 ratio to address confounding by indication using Cox models.

Results: In 28,829 CM patients PS-matched to 28,829 dialysis patients, dialysis transition was associated with higher mortality vs. CM: HR (95%CIs) 1.18 (1.16, 1.21). In secondary analyses, both ED and LD were each associated with higher mortality vs. CM: HRs (95%CIs) 1.21 (1.17, 1.25) and 1.17 (1.14, 1.20), respectively. In tertiary analyses, increasingly earlier dialysis transition was associated with worse survival vs. CM. Similar findings were observed in sensitivity analyses doubly-adjusted for PS covariates.

Conclusions: Patients treated with CM as an alternative patient-centered treatment strategy had lower mortality risk compared to dialysis, irrespective of dialysis transition timing. Further studies are needed to examine the comparative effectiveness of CM vs. dialysis on CKD outcomes.

FR-PO966

Ambulatory Palliative Care (PC) in Advanced CKD

Prasanti S. Ravipati, Mary K. Buss, Scott J. Gilbert. *Tufts Medical Center, Boston, MA.*

Background: Under 10% of patients on dialysis discuss goals, values, and preferences with their nephrologist; nearly 90% want to. PC can enhance patient quality of life, improve illness understanding and alter decisions at end of life. Global ambulatory renal PC clinics have been successful but are rare in the US. We tested the feasibility of integrating ambulatory PC for patients with CKD via manual EMR screening.

Methods: Renal and PC developed screening criteria: 1. Age >70 w/ stage 5 CKD 2. Age >70 w/ stage 4 CKD and cardiovascular disease or diabetes 3. Age >80 w/ stage 4 CKD For 11 weeks, study staff used the EMR to screen patients scheduled in renal clinic. A list of patients who met criteria were emailed to renal providers. If deemed appropriate, renal introduced PC to the patient. If the patient agreed, a PC referral was placed. PC saw referred patients before or after their renal clinic visit in the same room.

Results: See Fig 1. Renal agreed 33% of patients who met criteria were PC appropriate. Of patients who met criteria, 19% were seen by PC (Fig 2). PC saw significantly more patients in the 3 months after the intervention (n= 22), compared to before the intervention (n = 3), [$X^2 = 14.3$; $p < 0.001$].

Conclusions: Our study showed the feasibility of using screening criteria to integrate PC into renal clinic for advanced CKD patients. The higher volume seen by PC suggests the process helped renal providers identify patients appropriate for PC. Manual screening was resource intensive. An automated EMR screen would be more sustainable. The continued increase in PC visits after the study suggests a change in practice and improved access to PC. Our model for an integrated renal PC clinic promotes patient centered quality care for patients with advanced CKD.

FR-PO967

Effect of Social Support on Response to Treatment of Depression in Patients with CKD

Blake N. Lackey, Tianyi Wang, Thomas Carmody, Meredith C. McAdams, Susan Hedayati. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: The Chronic Kidney Disease Antidepressant Sertraline Trial (CAST) was a randomized, double-blind, placebo-controlled trial of sertraline vs. placebo in patients with nondialysis CKD, which did not reveal a statistically significant improvement in depressive symptoms. Using the validated Kidney Disease Quality of Life Questionnaire (KDQOL) and Quick Inventory of Depressive Symptomatology-Clinician Rated scale (QIDS-C), we investigated whether higher baseline social support would affect adherence to study drug by pill count and improve response to antidepressant treatment.

Methods: Two-hundred-and-one patients with stages 3b-5 non–dialysis CKD were enrolled. The primary outcome was improvement in depressive symptoms from baseline to 12 weeks by QIDS-C (higher score, more depression), stratified by baseline social function tertiles (higher tertile, higher social function). The interaction of treatment group (sertraline vs. placebo) by social function was also tested.

Results: Mean age was 58.2±13.2 years. Those in the highest tertile of social function were more likely to be older (p=0.0002), male (p=0.01), live alone (p=0.04), and be less educated (p=0.009) than the lowest tertile. Baseline CKD stage or eGFR did not differ between tertiles. Participants with the highest level of social function at baseline had the largest decrease in QIDS-C score if treated with placebo (-6.13), but participants with the lowest level of social functionhad the largest decrease in QIDS-C if treated with sertraline (-5.87), interaction p=0.03. There was a stepwise increase in percent of drug taken (88%, 95%, and 97%) for lowest, middle and highest tertiles of social function in the sertraline group (p=0.008) which was not observed in the placebo group. In addition, there was a significant interaction such that participants assigned to sertraline took a higher percent of their study drug if their social function was better at baseline, but this was not true of placebo, interaction p=0.01.

Conclusions: Sertraline may be more effective than placebo for improving depression in those with non-dialysis CKD with worse social functioning at baseline, even though participants with lower social function may be less adherent to antidepressant medications.

FR-PO968

Unexpected Improvement of CKD After Removal of Over-the-Counter Agent

Gabriel D. Perez Cordero, Juan C. Santiago-Gonzalez, Enrique Leal, Jorge B. Barletta Farias. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Prescription and over-the-counter (OTC) nonsteroidal anti-inflammatory drugs (NSAIDs) represent an important component in the treatment of acute and chronic pain. Products containing salicylates are one of the most widely used medications. They can be found in topical ointments, lotions, solutions used in hot steam, and oral and topical analgesia. Approximately 10-30% of salicylates are excreted via the kidneys as free salicylic acid but it is unknown whether the efficacy may be due to direct local absorption or the result of systemic absorption and distribution throughout the vasculature. Here we present a worsening of chronic kidney disease with OTC topical analgesic.

Case Description: Case of a 65-year-old male with a past medical history of CHF, DM2 and CKD who presented with shortness of breath. Patient with bilateral lung crackles and peripheral edema, who was admitted due to decompensated CHF. Medication regimen included apixaban, atorvastatin, metoprolol succinate, lisinopril, spironolactone and empagliflozin, and NSAIDs use was denied. Laboratory remarkable for worsening renal function. Patient's nephrotoxic medications were placed on hold and his creatinine level started to improve after careful IV diuresis. Upon achieving euvolemia, the diuretic was transitioned to oral. All of a sudden his renal function started to decline. Renal ultrasound resulted with no obstructive uropathy but with cortical thinning and increased echotexture. Urinalysis was remarkable for few epithelial cells. FEUrea resulted in 41.7% suggestive of intrinsic damage. Upon further questioning, the patient had been using a topical methyl-salicylate every 4 hours for articular and muscle pain without disclosing it for 48-72 hours. Once topical NSAIDs were removed, and IV hydration was implemented the serum creatinine gradually returned to baseline in the following days.

Discussion: Topical NSAIDs has been less associated with renal impairment than the oral route. Around 9.3% of patients with salicylate poisoning develop AKI and increased risk of organ failure, in-hospital mortality, longer length of hospital stay, and higher cost of hospitalization. This case highlights the importance of a careful review of patients' medication history including OTC medication and raises concern of potential role and impact on renal function not well known by topical NSAIDs.

FR-PO969

Association Between Laxative Use and Serum Phosphate Levels in Patients with CKD: A Large Nationwide Observational Study of US Veterans

Keiichi Sumida,[1] Yamini Mallisetty,[1] Prabin Shrestha,[1] Satya Surbhi,[1] Fridtjof Thomas,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3]
[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]VA Memphis Medical Center, Memphis, TN.

Background: Reducing intestinal phosphate (P) absorption is key to maintain normal P balance in patients with CKD. Laxative use may enhance fecal P excretion and help reduce serum P levels; however, little is known about the association of laxative use with serum P levels.

Methods: In a nationwide cohort of 513,653 US veterans receiving care from the VA healthcare system from 2004-2006 and with ≥1 outpatient serum P measurements during the follow-up through 2019, we examined the association of time-varying non-P containing laxative use with serum P levels across CKD stages, using generalized estimating equations with adjustment for demographics, smoking status, BMI, comorbidities, and time-varying use of relevant drugs, number of different types of laxatives, serum calcium, and eGFR. Serum P levels at each P measurement were treated as a repeated multinomial outcome (i.e., <2.5 [low-P], 2.5-≤3.5 [normal-P: reference], and >3.5 mEq/L [high-P]).

Results: Patients were 66.5±11.9 years old; 94.3% were male; 20.9% were African American; and 39.4% were diabetic. Their baseline eGFR was 76.8±23.3 mL/min/1.73m^2. There was no significant interaction between laxative use and eGFR (p=0.85). After multivariable adjustment, the use (vs. non-use) of laxatives was significantly associated with greater risk of low-P (adjusted OR [95% CI], 1.10 [1.04-1.16]) and high-P (1.07 [1.03-1.11]) in patients with CKD stages G1-2 (Table). The greater risk of low-P associated with laxative use was more pronounced in patients with more advanced CKD stages; while the laxative use-related risk of high-P was not evident in those with CKD stages G3-5 (Table).

Conclusions: The use of non-P containing laxatives was independently associated with greater likelihood of lower serum P levels in patients with CKD, particularly in those with more advanced CKD stages. Our findings suggest potentially distinct pharmacological contribution of laxatives to P homeostasis across CKD stages.

Funding: Veterans Affairs Support

Adjusted odds ratios (95% CI) for low and high serum phosphate levels associated with the use (vs. non-use) of time-varying non-P containing laxatives (n=513,653)

	Time-varying serum phosphate concentration (mEq/L)		
	<2.5 (low-P)	2.5 to =3.5 (normal-P)	>3.5 (high-P)
% of all repeated values	6.9 %	53.7 %	39.4 %
CKD stages† (n)			
G1-2 (394,280)	1.10 (1.04-1.16)	1 [reference]	1.07 (1.03-1.11)
G3a (68,475)	1.20 (1.04-1.38)	1 [reference]	0.98 (0.90-1.07)
G3b (34,017)	1.23 (1.01-1.50)	1 [reference]	1.04 (0.92-1.16)
G4-5 (16,881)	1.27 (0.96-1.70)	1 [reference]	0.94 (0.80-1.11)

†Model was adjusted for demographics, smoking status, BMI, comorbidities, and time-varying use of relevant medications, number of different types of laxatives, serum calcium, and eGFR

FR-PO970

Effects of Lactobacillus rhamnosus GG on Gut-Derived Uremic Toxins and Gut Microbiome in Non-Dialysis CKD Patients

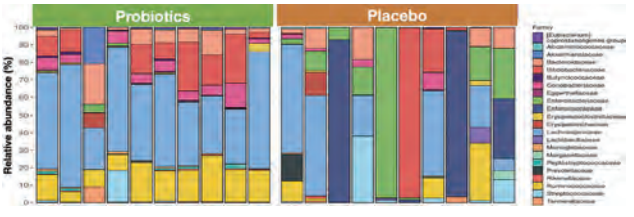
Somkanya Tungsanga,[1,2] Sedthasith Treewatchareekorn,[1] Win Kulvichit,[1] Pisut Katavetin,[1] Asada Leelahavanichkul.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.*

Background: Accumulation of uremic toxins in chronic kidney disease (CKD) is linked to progression to kidney failure via multiple mechanisms, including gut dysbiosis and gut-derived uremic toxins (GDUT) production. We explored the effects of *Lactobacillus rhamnosus* GG (GG), a probiotic, on GDUT and gut microbiome in CKD patients.

Methods: We conducted a randomized, double-blinded, controlled trial. After 2-week run-in, non-dialysis CKD stage 3-5 patients were assigned to receive LGG or placebo for 8 weeks and additional 12-week follow-up. Primary outcomes were changes in serum GDUTs (Indoxyl sulfate;IS, P-cresol sulfate;PCS) at end of treatment. Secondary outcomes included fecal microbiome analysis, serum inflammatory markers, eGFR, proteinuria, and adverse effects. In parallel, *in vitro* effects of *E.coli* lysate (ECL) with/without LGG-conditioned media (LCM) were explored in Caco-2 enterocytes and THP-1 macrophages.

Results: Among 60 participants (aged 70.15±12 years; 57% male; eGFR 38.17 ml/min/1.73m^2), 30 each group, baseline characteristics were comparable. At the end of treatment, median changes in serum IS and PCS from baseline were lower in probiotic group (-0.89 vs +0.15 μmol/L, P<0.01) and (+0.1vs +1.0 μmol/L, P=0.01), respectively. Serum inflammatory markers were lower in probiotic group (endotoxin 0.29 vs 1.19 U/mL; P=0.02, IL-6 1.25 vs 2.52 pg/mL; P<0.01, and TNF-a 0.04 vs 0.36 pg/mL; P=0.02). The eGFR, proteinuria, and adverse effects were comparable. Fecal microbiome analysis in probiotic group showed decreased diversity and reduction in pathogenic *Proteobacteria* (Fig 1). *In vitro*, there were higher pro-inflammatory gene expression in Caco-2 and THP-1 cells with ECL, and lower enterocyte integrity. These effects were attenuated with LCM, indicating protective effects on enterocyte inflammation and integrity.

Conclusions: LGG improved gut dysbiosis, attenuated GDUT production, and reduced inflammatory responses linked to CKD progression. Probiotics may have a role in retarding CKD progression. Larger RCT is warranted.



Fecal microbiome analysis at end of treatment

FR-PO971

Lubiprostone Inhibits Progression of Renal Failure via Intestinal Microbiome

Shun Watanabe,[1] Masaaki Nakayama,[2] Takashi Yokoo,[3] Satoru Sanada,[4] Katsuhiko Asanuma,[5] Yusuke Suzuki,[6] Tsuneo Konta,[7] Takaaki Abe.[1] *[1]Tohoku Daigaku, Sendai, Japan; [2]St. Luke's International Hospital, Chuo-ku, Japan; [3]Tokyo Jikeikai Ika Daigaku Igakubu Igakuka Jinzo Koketsuatsu Naikagaku, Minato-ku, Japan; [4]Japan Community Health Care Organization Sendai Hospital, Sendai, Japan; [5]Chiba Daigaku, Chiba, Japan; [6]Juntendo Daigaku, Bunkyo-ku, Japan; [7]Yamagata Daigaku, Yamagata, Japan.*

Background: The gut microbiota and chronic kidney disease (CKD) are believed to be closely interrelated. We previously reported that the administration of the chronic constipation treatment drug lubiprostone (Lubi) in a mouse model of renal failure suppressed the accumulation of uremic toxins in the body during renal failure and demonstrated a renal protective effect. Based on these findings, we hypothesized that Lubi could be a potential novel treatment for kidney diseases.

Methods: The objective of this study was to investigate the effects of Lubi on the suppression of uremic toxin accumulation and disease progression in patients with renal failure. The trial design was randomized, double-blind, placebo-controlled, multicenter collaborative, and exploratory physician-initiated. A total of 118 patients with CKD Stage 3b were assigned to the placebo group (33 patients), 8 μg group (35 patients), or 16 μg group (50 patients), and the trial was conducted at eight domestic facilities from 2017 to 2020. The primary outcome was the change in plasma indoxyl sulfate (IS) levels from baseline to 24 weeks after the start of the trial. The secondary outcomes included changes in uremic toxins (phenyl sulfate, p-cresyl sulfate, trimethylamine N-oxide) and eGFR. Statistical analysis involved conducting ANCOVA analysis with the eGFR value at allocation and the baseline values of each evaluation item as covariates, followed by post hoc testing using Dunnett's method.

Results: The change in IS levels was as follows: placebo group: 0.13±0.15 μg/ml, 8 μg group: 0.091±0.15 μg/ml, 16 μg group: 0.13±0.13 μg/ml (least squares mean ± standard error), and no significant differences were observed. However, the change in eGFR was as follows: placebo group: -1.55±0.65 ml/min/1.73m^2, 8 μg group: -0.34±0.66 ml/min/1.73m^2, 16 μg group: 0.37±0.54 ml/min/1.73m^2, with a significant difference observed between the placebo and 16 μg groups (p-value = 0.0457).

Conclusions: While Lubi 16 μg did not improve uremic toxin levels, it improved eGFR, thereby generating new evidence for the treatment of CKD. In the future, we plan to analyze metabolites and the gut microbiota from the samples obtained in this trial to explore the mechanism of the inhibitory effect of Lubi on the progression of renal failure and search for new targets for renal failure treatment.

FR-PO972

Extended-Release Calcifediol: A Data Journey from Phase 3 Studies to Real-World Evidence Highlights the Importance of Early Treatment of Secondary Hyperparathyroidism (SHPT)

Akhtar Ashfaq,[1] Domenico Merante,[2] Henrik Schou,[2] Isabelle Morin,[2] Marius C. Manu,[2] Charles W. Bishop,[1] Stephen A. Strugnell.[1] *[1]OPKO Health Inc, Miami, FL; [2]CSL Vifor, Zurich, Switzerland.*

Background: Early secondary hyperparathyroidism (SHPT) diagnosis and treatment are crucial to delay the progression of SHPT and related complications, in particular, cardiovascular events and bone fractures. Extended-release calcifediol (ERC) has been developed for the treatment of SHPT in patients with stage 3 or 4 chronic kidney disease (CKD) and vitamin D insufficiency (VDI).

Methods: In this descriptive analysis, laboratory parameters of SHPT-CKD stage 3–4 subjects randomised to ERC in two phase 3 clinical studies (NCT01651000 [N=141] and NCT01704079 [N=144]) were compared with those treated with ERC in a RWE study (MBD-AWARE study; N=174]).

Results: The main baseline laboratory parameters showed consistency between the phase 3 studies and the RWE study, except for baseline parathyroid hormone (PTH). Mean±standard deviation baseline PTH levels were 147±56 pg/mL and 148±64 pg/mL in the intent-to-treat populations on ERC in NCT01651000 and NCT01704079, respectively, and 181±98 pg/mL in the RWE study. Moreover, in the RWE study, 53% of subjects receiving ERC had CKD stage 4 with an even higher baseline PTH level versus stage 3 CKD subjects. ERC treatment significantly reduced PTH levels and increased 25-hydroxyvitamin D [25(OH)D], regardless of CKD stage, in all 3 studies. In the phase 3 per-protocol populations, 74% of subjects treated with ERC were up-titrated to 60 μg daily after 12 weeks at 30 μg daily, 97% attained 25(OH)D levels ≥30 ng/mL, and 40% achieved ≥30% reductions in PTH. In contrast, based on an apparent 'wait longer approach' to test key markers of SHPT, only 2% of subjects in the RWE study were up-titrated. Nevertheless, 70% of subjects achieved 25(OH)D levels ≥30 ng/mL, and 40% had a ≥30% reduction in PTH, consistent with the phase 3 results.

Conclusions: These data suggest a 'continuum' of clinical evidence of ERC effectiveness for treating SHPT, irrespective of CKD stage. A clinically relevant response was observed with ERC in the RWE study, consistent with the phase 3 studies, despite higher baseline PTH levels and lower ERC dose. In summary, these data support early treatment initiation with ERC, following diagnosis of SHPT, VDI and stage 3 CKD, to delay the progression of SHPT.

FR-PO973

Effects of Three Months of Ergocalciferol Supplementation in Patients with Stages 3 and 4 CKD: Results from a Randomized Clinical Trial

Paola Gudino,[1] Belinda Jim,[1] Seth I. Sokol,[1] Maria Coco,[2] Amanda C. Raff,[2] Zaher Hamadeh,[2] Yungtai Lo,[2] Tanya S. Johns,[2] Matthew K. Abramowitz,[2] Thomas H. Hostetter,[2] Michal L. Melamed.[2] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Montefiore Medical Center, New York, NY.*

Background: Patients with chronic kidney disease (CKD) have higher prevalence of vitamin D deficiency. This is associated with albuminuria but clinical studies have shown mixed results. This randomized, placebo-controlled, double-blind clinical trial hypothesized that supplementation with ergocalciferol would decrease albuminuria in participants with CKD stages 3 and 4.

Methods: 74 participants were assigned to either oral ergocalciferol 50,000 IU or placebo weekly for 8 to 12 weeks depending on baseline 25 hydroxyvitamin D (25OHD) levels. The primary outcome was change in albuminuria. Secondary outcomes included change in laboratory values serum 25 hydroxy vitamin D (25-OH-D), 1,25-dihydroxy vitamin D (1,25OH2D), calcium, phosphate, intact PTH (iPTH), fibroblast growth factor 23 (FGF-23), estimated GFR levels, emergency department (ED) visits and hospitalizations.

Results: Mean age of participants was 58 years (standard deviation (SD): 13 years). The participants were 43% female, 48% Hispanic, 38% non-Hispanic Black.

68% had CKD stage 3 at enrollment. There was no significant difference in the change in albuminuria between the groups (Placebo group: 437 mg/gm [IQR 158-1256] at baseline, 580 mg/gm [IQR 175-1160] at 12 weeks; Ergocalciferol group: 829 mg/gm [IQR 244-1942] at baseline, 850 mg/gm [IQR 137-1405] at 12 weeks; p value= 0.13). Analysis of secondary outcomes showed significant differences in 25(OH)D levels at 12 weeks placebo 16.6 ng/mL (SD 7.8) versus ergocalciferol group 29.4 ng/mL (SD 13.4) (p<0.001) and mean eGFR (Placebo: 36.7 (SD 13.4) at baseline and 37.6 (SD 16.2) at 12 weeks; Ergocalciferol group: 37.7 (SD 14.3) at baseline and 30.5 (SD 12.3) at 12 weeks; p=0.001). There was no difference in 1,25OH2D, calcium, phosphate, intact PTH or FGF-23 between the groups. Participants in the ergocalciferol group had fewer hospitalizations and ED visits (seventeen) versus the participants treated with placebo (twenty-seven).

Conclusions: Among non-Hispanic Black and Hispanic adults with CKD stage 3 or 4, supplementation with ergocalciferol resulted in no significant difference in albuminuria levels and mineral metabolism markers. However, eGFR significantly decreased at 12 weeks after treatment with ergocalciferol.

Effect of Cholecalciferol Supplementation on Immune Modulation, Inflammation, and Vascular Function in CKD

Kajal Kamboj,[1] Sachin M. Naik,[1] Ankur Chaudhary,[1] Manphool Singhal,[1] Vivek Kumar,[1] Ashok K. Yadav,[1] Vivekanand Jha.[2] *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]The George Institute for Global Health India, New Delhi, India.*

Background: Vitamin D deficiency is common in chronic kidney disease (CKD) and short term studies have shown beneficial effect of vitamin D supplementation on vascular function in CKD. In this study we investigated the effect of cholecalciferol supplementation on vascular and immune functions in non-diabetic patients with early stage CKD.

Methods: In this pre-post study, non-diabetic CKD with eGFR 15-60 ml/min/1.73m^2 and 25(OH)D levels <20 ng/ml were enrolled. Participants receive 300000 IU of cholecalciferol at enrolment and 8 weeks. Change in circulating T cell subsets, flow mediated dilatation (FMD), serum levels of pro and anti-inflammatory cytokines and mRNA expression of Cathelicidin, VDR, Cyp27b1, IL-10 were analysed at 16 weeks.

Results: Out of these 69 participants enrolled, 62 participants completed follow up. 25(OH)D levels increased at 16 weeks (14.4 ± 8.6 ng/ml vs 39.8 ± 19.1 ng/ml, P<0.001). A significant increase in Th2 cell and Th17 population was noted whereas no change was observed in Th1 and Treg cell populations (Table 1). FMD showed a significant increase at 16 weeks (10.54± 6.30 % vs 13.82±8.62 %, P=0.02). Increased mRNA expression of Cathelicidin, IL-10, VDR and Cyp27b1 by 2 to12 fold (Fig.1A) and significant changes in levels of various pro-inflammatory and anti-inflammatory cytokines (Fig.1B) were observed at follow-up.

Conclusions: Cholecalciferol supplementation in vitamin D deficient patients with non-diabetic CKD significantly improved the immune and vascular function, inflammatory responses and enhanced the expression of vitamin D responsive.

Comparison of the Effect of Benidipine and Amlodipine on Clinical and Biochemical Parameters in CKD with Hypertension and Proteinuria

Rasika Sirsat, Sneha M. Lute, Alan F. Almeida, Ayan K. Dey, Khairwar Mahesh Prasad. *PD Hinduja National Hospital and Medical Research Centre, Mumbai, India.*

Background: Amlodipine targets L-type calcium channels on glomerular afferent arterioles resulting in their dilation, and leading to an increase in intraglomerular pressure and proteinuria. Benidipine blocks L-, N-, and T- type calcium channels which lower efferent arteriolar resistance and intraglomerular pressure, thereby reducing glomerular hypertension and proteinuria. We compared the effect of benidipine and amlodipine on proteinuria, blood pressure and estimated glomerular filtration rate (eGFR).

Methods: Sixty CKD patients with hypertension on maximum tolerated renin-angiotensin blockage whose UPCR (Urine protein creatinine ratio) >150 mg/gm were included in this study. Out of sixty patients, thirty patients were randomly assigned to either amlodipine (n=30) or benidipine (n=30). Blood pressure, serum creatinine, eGFR, UPCR, and serum albumin were monitored at baseline, 3rd month and 6th month. Continuous variables between the study drugs were compared by independent t-test (normal distribution) or Mann–Whitney U test (skewed distribution). Within-group comparisons at each follow-up for both drugs were done by Paired t-test (normal distribution) or Wilcoxon sign rank test (skewed distribution).

Results: Blood pressure decreased in both groups in the 3rd and 6th months. Systolic blood pressure (SBP) has decreased significantly in the benidipine group as compared to the amlodipine group (p-0.0014). UPCR values in benidipine and amlodipine groups changed from 2.89±2.17 to 1.42±1.34 and 2.27±1.46 to 2.47±1.55 after 6 months respectively (p-0.07). Despite not attaining the target systolic blood pressure (SBP<120 mm of Hg), it was observed that there was a significant decrease in UPCR at follow-up visits in the benidipine group. There was no significant change in eGFR in both groups at the end of the study. There was a significant improvement in serum albumin in benidipine-treated patients (p-0.001).

Conclusions: Benidipine is more effective than amlodipine in reducing proteinuria and blood pressure in chronic kidney patients with hypertension

FR-PO976

Impact of Oral Spherical Carbon Adsorbent in Predialysis CKD on Cardiovascular Outcomes and Mineral-Bone Disorder After Dialysis Therapy

Hee Jung Jeon,[1,2] Takhyeon Kweon,[1,2] Younkyung Kee,[1,2] Dong Ho Shin,[1,2] Jieun Oh.[1,2] *[1]Kangdong Sacred Heart Hospital, Gangdong-gu, Seoul, Republic of Korea; [2]Hallym University College of Medicine, Chuncheon, Gangwon, Republic of Korea.*

Background: Oral spherical carbon adsorbents (OSCA) are known to slow the progression of chronic kidney disease (CKD) by inhibiting the absorption of uremic toxins produced in the intestine. In this study, we evaluated the impact of using OSCA in pre-dialysis CKD patients on cardiovascular outcomes and mineral-bone disorder after dialysis therapy.

Methods: This study was a retrospective cohort study that enrolled patients who started dialysis therapy including hemodialysis and peritoneal dialysis at Kangdong Sacred Heart Hospital. A total of 294 patients were included in this study, including 98 CKD patients who were administered OSCA before dialysis therapy (OSCA group) and 196 patients who were not administered OSCA with 1:2 matching by age and sex (control group).

Results: The mean age was 62.2 ± 12.7 years, with 60.2% male, and the most common cause of CKD was diabetes (67.0%). The ejection fraction in the echocardiogram was significantly higher in the OSCA group (58.1 ± 9.1 % vs. 55.5 ± 9.9 %, P = 0.033). The cardiovascular events in the control group were higher than those in the OSCA group, however, there were statistically not significant (26.0% vs. 19.4%, P = 0.266). However, the patients who were administered OSCA for more than 113 days showed significantly fewer cardiovascular events after dialysis therapy than those less than 113 days (P = 0.032 by log-rank test), which remained significant in multivariate cox regression analysis (HR 1.48, 95% CI 1.05-2.08, P = 0.025). There was no difference in bone mineral density, pulse wave velocity, bone-specific alkaline phosphatase, parathyroid hormone, and 25(OH) vitamin D levels. In the subgroup analysis of diabetes, all-cause mortality was significantly lower in the OSCA group (27.1% vs. 12.7%, P = 0.029).

Conclusions: The administration of OSCA in CKD patients before dialysis tended to reduce the incidence of cardiovascular events after the start of dialysis therapy, and the longer the period of administration of OSCA, the more significant difference was shown.

FR-PO977

Effect of Sodium Bicarbonate Treatment on Cognitive Function in CKD

Jessica B. Kendrick, Petter Bjornstad, Zhiying You, Allison Shapiro, Seth B. Furgeson. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Cognitive impairment, prevalent in adults with chronic kidney disease (CKD), contributes to mortality, functional decline, depression, frailty, and diminished quality of life. Lower serum bicarbonate levels, even within normal parameters, associate with cognitive impairment in CKD. However, the effect of sodium bicarbonate ($NaHCO_3$) supplementation on cognitive function in CKD is not known. We examined the effect of $NaHCO_3$ therapy on cognitive function in patients with CKD stage 3B-4.

Methods: We performed an ancillary study using participants in the Bicarbonate Administration in CKD Trial, which was a randomized prospective, double-blind, placebo-controlled trial of 109 participants with CKD stage 3B-4 (eGFR 15-44 ml/min/1.73m^2) with serum bicarbonate levels 22-27 mEq/L. Participants were randomly assigned to receive either $NaHCO_3$ or placebo at a dose of 0.5 mEq/LBW-kg/day for 12 months. Cognitive function was measured at baseline and 12 months using the National Institutes of Health Toolbox® (NIH-TB) cognitive battery, which assesses fluid cognition (e.g., executive and memory function) and crystallized cognition (e.g., language skills).

Results: 90 patients (50.4% female) with a mean (SD) age of 61.7 ± 11.6 years and eGFR of 35.9 ± 9.8 ml/min/1.73m^2 completed the study. The mean (SD) serum bicarbonate level at baseline was 23.4 ± 2.2 mEq/L. After 12 months, serum bicarbonate levels increased, on average, 1.35 mEq/L (95% CI: 0.34-2.36, p=0.003) in the $NaHCO_3$ group compared to placebo. Both the $NaHCO_3$ and placebo groups had a significant increase in fluid cognition scores after 12 months, but there was no significant difference between the groups (Figure). $NaHCO_3$ therapy did not result in a significant improvement in crystallized or total cognition. $NaHCO_3$ therapy was safe and well-tolerated with no significant changes in blood pressure, anti-hypertensive medication, weight, calcium or potassium levels.

Conclusions: Twelve months of $NaHCO_3$ therapy in patients with moderate to advanced CKD and normal serum bicarbonate levels did not improve cognitive function.

Observations from the LiFT Study: Lokelma for Maximization of RAASi in Patients with CKD and Heart Failure, Ongoing Trial

Mahrukh A. Ali,[1,2] Daniel Murphy,[1] Ella H. Tumelty,[2] Isaac W. Chung,[1] Tony W. Lopez,[2] Simran Parmar,[2] Riny Paul,[2] Sharirose Abat,[2] Lisa J. Anderson,[3,2] Debasish Banerjee.[3,2] *[1]St George's University of London, London, United Kingdom; [2]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [3]St George's University of London Cardiology Clinical Academic Group, London, United Kingdom.*

Background: The management of patients with chronic kidney disease (CKD) and heart failure (HF) - CKD-HF poses a clinical challenge. The use of renin-angiotensin-aldosterone inhibitors (RAASi) reduces hospital admissions due to fluid overload and has mortality benefit; however, this is limited by hyperkalaemia, and concerns of worsening renal function. The purpose of this trial is to evaluate the role of sodium zirconium cyclosilicate (SZC) in maximizing of RAASi in CKD-HF. We present preliminary data regarding uptitration of RAASi achieved as part of the study

Methods: This is a double blind, placebo-controlled, phase III randomised control trial. The primary outcome is to compare SZC and Placebo with respect to enabling patients to achieve the maximum tolerated RAASi dose while keeping [K+] < 5.6mmol/L. Secondary outcomes include the number and maximum doses of ACEi/ARBs (angiotensin converting enzyme inhibitors/angiotensin receptor blockers) and MRA (mineralocorticoid receptor blockers) achieved during the study period

Results: We present preliminary data regarding up-titration of RAASi achieved for 35 patients who have completed the trial so far, having started with none or sub-optimal RAASi. The mean age of participants is 74 years. Of the 35 participants, 34 achieved uptitration to maximum tolerated doses in the treatment duration of 2 to 12 weeks. There was no significant change in the eGFR at end of treatment compared to start

Conclusions: While the study is ongoing preliminary data suggests that rapid maximization of RAASi in this frail, comorbid group can be achieved without detriment to renal function

Funding: Commercial Support - AstraZeneca, Government Support - Non-U.S.

A Phase IIb Randomized, Double-Blind, Placebo-Controlled, Multi-Centre, Dose Ranging Study of Atuliflapon in Participants with Proteinuric CKD

Hiddo J. Heerspink,[1] Marcin Ufnal,[2] C Gordon Law,[3] Carl A. Whatling,[4] Hans I. Ericsson,[4] Jane Knöchel,[4] Kathleen Connolly,[5] Russell J. Kinch,[5] Iain MacPhee.[5] FLAIR Study Investigators. *[1]University Medical Center Groningen, Groningen, Netherlands; [2]AstraZeneca R and D, Warsaw, Poland; [3]Early Biometrics & Statistical Innovation, R&D, AstraZeneca, Gaithersburg, MD; [4]AstraZeneca R and D, Gothenburg, Sweden; [5]AstraZeneca R&D Cambridge, Cambridge, United Kingdom.*

Background: 5-lipoxygenase activating protein (FLAP) is a key component in the synthetic pathway for leukotrienes and thought to contribute to inflammation and CKD progression. We assessed the albuminuria lowering effect of Atuliflapon (AZD5718), a reversible FLAP inhibitor.

Methods: Participants with proteinuric CKD: eGFR 20 -75 mL/min/1.73m^2; uACR 200-500 mg/g were randomised to three doses of Atuliflapon or placebo. Treatment period 1 of 12 weeks on existing standard of care (SOC), which included SGLT2i in 25% of the DKD patients, was followed by treatment period 2 where all participants initiated 8 weeks treatment with 10 mg dapagliflozin on top of existing SOC.

Results: A total of 613 participants were randomised. Following the results of an interim analysis the Sponsor decided to terminate the study early based on no significant reduction in uACR compared to placebo after 20 weeks of treatment (Table), at which point 438 had completed treatment period 1 and 318 had completed treatment period 2. Median age was 66 years (range 27-87); 65.8% male; Type 2 DM 76.5%; Median eGFR 40 mL/min/1.73m^2. The target of 80% suppression of urinary and plasma leukotriene B4 was achieved. The expected reductions in uACR and eGFR on commencing SGLT2i treatment were seen after the addition of dapagliflozin in the second treatment period. There were no significant safety issues.

Conclusions: Atuliflapon did not significantly reduce uACR in any of the treatment groups compared to placebo.

Funding: Commercial Support - AstraZeneca

Table

Dose Atuliflapon	uACR baseline (mg/g; Geometric mean)	Difference vs placebo after 20 weeks of treatment (% change; 95% CI)	p-value
Placebo	735		
Low	615	-5.49% (-21.37, 13.60)	0.55
Medium	744	-3.58% (-19.74, 15.82)	0.70
High	708	-8.07% (-23.24, 10.10)	0.36

Design and Baseline Characteristics of the FIND-CKD Trial: Efficacy of Finerenone on Kidney Disease Progression in People with Non-Diabetic CKD

Hiddo J. Heerspink,[1] Rajiv Agarwal,[2] George L. Bakris,[3] David Cherney,[4] Carolyn S.P. Lam,[5] Brendon L. Neuen,[6] Katherine R. Tuttle,[7] Christoph Wanner,[8] Meike Daniela Brinker,[9] Sara Dizayee,[10] Peter Kolkhof,[11] Patrick Schloemer,[12] Paula H. Vesterinen,[13] Vlado Perkovic.[6] On Behalf of the FIND-CKD Steering Committee and Investigators. *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Indiana University School of Medicine, Indianapolis, IN; [3]The University of Chicago Medicine, Chicago, IL; [4]University Health Network, Toronto, ON, Canada; [5]National Heart Centre Singapore and Duke-National University of Singapore, Singapore, Singapore; [6]The George Institute for Global Health, Sydney, NSW, Australia; [7]Providence Washington, Seattle, WA; [8]Universitatsklinikum Wurzburg, Wurzburg, Germany; [9]Cardiology and Nephrology Clinical Development, Bayer AG, Wuppertal, Germany; [10]Regulatory Strategy Cardiology and Nephrology, Bayer AG, Wuppertal, Germany; [11]Preclinical Research Cardiovascular, Research and Development, Bayer AG, Wuppertal, Germany; [12]Statistics & Data Insights, Bayer AG, Berlin, Germany; [13]Cardiology and Nephrology Clinical Development, Bayer AG, Espoo, Finland.*

Background: Finerenone, a selective, nonsteroidal mineralocorticoid receptor antagonist, improved kidney and cardiovascular (CV) outcomes in people with CKD and type 2 diabetes (T2D) in two phase 3 outcome trials. However, CKD is due to non-diabetic etiologies in most people across many parts of the world. The effects of finerenone on kidney outcomes in people with CKD without diabetes are being investigated in the FIND-CKD trial (NCT05047263 and EudraCT: 2021-000421-27).

Methods: FIND-CKD is a randomized, double-blind, and placebo-controlled phase 3 trial for people with CKD of non-diabetic etiology. People with a urine albumin-to-creatinine ratio of ≥200–≤3500 mg/g and estimated glomerular filtration rate (eGFR) ≥25–<90 ml/min/1.73 m^2 at screening are randomized 1:1 to once daily 10 or 20 mg finerenone or placebo on top of optimized renin-angiotensin system blockade. The primary efficacy outcome is total eGFR slope, defined as the mean annual rate of change in eGFR from baseline to month 32. Secondary efficacy outcomes include a combined cardiorenal composite outcome comprising time to kidney failure, sustained ≥57% decrease in eGFR, hospitalization for heart failure or CV death, as well as separate kidney and CV composite outcomes. Adverse events are recorded to assess tolerability and safety.

Results: The FIND-CKD trial will study the efficacy and safety of finerenone in people with non-diabetic causes of CKD at high risk of disease progression. The first patient was enrolled in September 2021 and patient enrolment completed in May 2023. Baseline clinical characteristics and demographics will be presented.

Conclusions: FIND-CKD is the first phase 3 trial of finerenone in people with CKD of non-diabetic etiology. This trial will determine the potential expanded role for finerenone for the treatment of CKD beyond T2D.

FR-PO981

Effects of Empagliflozin on Weight and Blood Pressure in CKD: Analyses from the EMPA-KIDNEY Trial

Kaitlin J. Mayne.[1,2] The EMPA-KIDNEY Collaborative Group. *[1]University of Oxford Nuffield Department of Population Health, Oxford, United Kingdom; [2]University of Glasgow College of Medical Veterinary and Life Sciences, Glasgow, United Kingdom.*

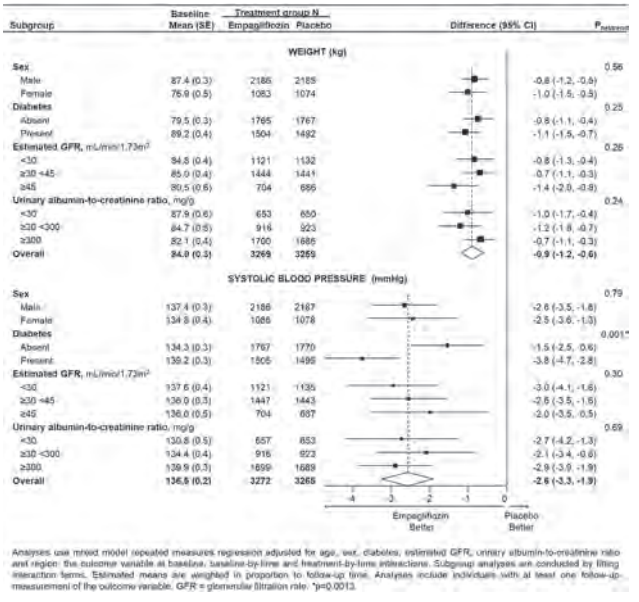
Background: Sodium-glucose co-transporter-2 (SGLT2) inhibitors slow kidney disease progression and reduce cardiovascular risk in patients with CKD. SGLT2 inhibitors have additionally been shown to reduce weight and blood pressure (BP). We aimed to assess whether diabetes status or kidney function modify the effects of empagliflozin on weight and BP.

Methods: EMPA-KIDNEY compared empagliflozin 10 mg once daily with placebo among 6609 patients with CKD (Clinicaltrials.gov: NCT03594110). Eligible patients had an eGFR of 20 to <45; or 45 to <90 ml/min/1.73m^2 with a urinary albumin-to-creatinine ratio (uACR) ≥200 mg/g. Changes in weight and blood pressure from baseline were pre-specified analyses using mixed model repeated measures regression. Results were assessed overall and in important subgroups and put in the context of a bioimpedance substudy of 660 participants which is reported separately.

Results: At baseline, mean±SD eGFR was 37.3±14.5 mL/min/1.73m^2 with mean weight of 84.1±21.4 kg, and mean systolic and diastolic BP were 136.5±18.3 and 78.1±11.8 mmHg, respectively. The study-average between-group difference in weight was -0.9 (95% CI -1.2, -0.6) kg with similar-sized effects in all subgroups (Figure). Effects on weight persisted over time and bioimpedance analyses in a 660-participant substudy demonstrated that it reflected reductions in intracellular and extracellular water with no significant effect on adiposity. The study-average between-group differences (95% CI) in systolic and diastolic BP were -2.6 (-3.3, -1.9) and -0.5 (-0.9, -0.1) mmHg, respectively, with similar difference by baseline eGFR and uACR, but somewhat larger effects in patients with diabetes.

Conclusions: In a broad range of patients with CKD, empagliflozin reduces weight and BP, even at low eGFR, low uACR and in the absence of diabetes.

Funding: Commercial Support - Boehringer Ingelheim & Eli Lilly



Analyses use mixed model repeated measures regression adjusted for age, sex, diabetes, (estimated) GFR, urinary albumin-to-creatinine ratio and region; the outcome variable at baseline, baseline-by-time and treatment-by-time interactions. Subgroup analyses are conducted by fitting interaction terms. Estimated means are weighted in proportion to follow-up time. Analyses include individuals with at least one follow-up measurement of the outcome variable. GFR = glomerular filtration rate. *p=0.0013.

FR-PO982

Albuminuria-Lowering Effect of Sodium-Glucose Cotransporter 2 Inhibitors, Finerenone, and Their Combination in Patients with CKD

Mohamad A. Hanouneh,[1,2] Carmen E. Cervantes,[1] Jonathan G. Lim,[1,2] Veena K. Acharya,[1,2] Tareq Hanouneh,[3] Hyung M. Lim.[1,2] *[1]Johns Hopkins University, Baltimore, MD; [2]Nephrology Center of Maryland, Baltimore, MD; [3]Mayo Clinic in Florida, Jacksonville, FL.*

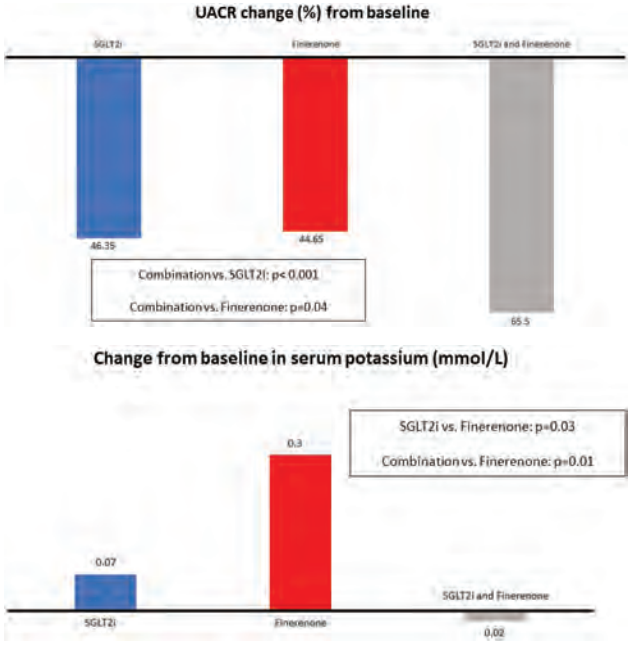
Background: Sodium-Glucose Cotransporter 2 Inhibitors (SGLT2is) and Finerenone reduce urine albumin-to-creatinine ratio (UACR) and confer kidney and cardiovascular protection in patients with Chronic Kidney Disease (CKD).

Methods: We conducted a retrospective study in patients seen in a community nephrology practice with eGFR 25-90 ml/min per 1.73 m2 and UACR ≥30 mg/g Cr. Patients were stratified into 3 groups: 8 months treatment period with SGLT2is, 4 months treatment period with Finerenone, and 8 months with combination therapy (SGLT2i for 4 months followed by SGLT2i and Finerenone for additional 4 months). The outcome was the percent change in UACR from baseline.

Results: Of 402 patients screened between 1/2022 and 9/2023, 85 were included with mean eGFR, 51.5 ml/min per 1.73 m2, and median UACR 594 mg/g. 47 patients received SGLT2i (dapagliflozin 10 mg/day or empagliflozin 10 mg/day), 19 received Finerenone

(20 mg/d for eGFR > 60 or 10 mg/d for eGFR 25-60, and 19 were on combination therapy. The mean percentage change from baseline in UACR in the SGLT2is group and Finereone group was -46.35% (95% CI, -53.39 to -39.31) and -44.65% (95% CI, -68.67, -20.64), respectively. SGLT2i-Finerenone combination therapy decreased UACR by -65.5% (95% CI, -71.82, -59.17; P<0.001 vs SGLT2i; P=0.04 vs Finerenone) (Fig 1). Compared with the Finerenone group, the mean change in serum potassium level (mmol/L) was significantly lower in the combination group (+ 0.3 vs -0.02, P=0.01). (Fig 2)

Conclusions: Combining dapagliflozin or empagliflozin with Finerenone resulted in a significantly additive UACR-lowering effect with a significant decrease in the risk of hyperkalemia.



FR-PO983

Dapagliflozin Suppresses Urinary Biomarkers of Kidney Damage Regardless of Proteinuric Levels in CKD

Soyeon Kim, Seung Hye Chu, Hyunjin Noh, Soon hyo Kwon.
Soonchunhyang University Hospital, Seoul, Republic of Korea.

Background: Sodium glucose cotransporter 2 inhibitor (SGLT2i) reduce the risk of chronic kidney disease (CKD) progression in individuals with or without diabetes mellitus (DM). However, the beneficial effect of SGL2i on CKD patients with low levels of proteinuria has not been established. The objective of this study was to compare the effect of dapagliflozin on biomarkers of kidney injury in CKD patients stratified by albuminuria level.

Methods: We prospectively enrolled healthy volunteers (HVs) (n=20) and CKD patients (n=43) with or without DM. The CKD group received dapagliflozin (10mg). Urine and serum samples were collected before treatment and 3 and 6 months after administration of dapagliflozin. We measured kidney injury molecule-1 (KIM-1), interleukin-1β (IL-1β) and mitochondrial DNA nicotinamide adenine dinucleotide dehydrogenase subunit-1 (mtND1) copy number in the urine.

Results: Age did not differ between HV and CKD patients (52.05 ± 8.13 vs 53.90 ± 14.96 years, p=0.774). The estimated glomerular filtration rate (eGFR) level of CKD patients was lower than that of HV (62.55 ± 24.22 vs 94.95 ± 11.21 mL/min, p < 0.001). Among the CKD patients, 11 % (n=5) had diabetes. The median urinary albumin/creatinine ratio (uACR) in CKD patients was 339.80 mg/g (IQR 80.0-647.0 mg/g). Kidney injury markers were significantly elevated in the CKD patients compared to the HVs. Dapagliflozin reduced urinary KIM-1, IL-1 β and mtND-1 in CKD at 6 months after treatment (p < 0.001, p < 0.001 and p = 0.021, respectively). Futhermore, when CKD patients were divided into two groups according to uACR level (< 300 mg/g, ≥ 300 mg/g), dapagliflozin decreased urinary KIM-1 and IL-1β at 3 months after treatment in the high albuminuria group (n=22) (p=0.034 and p=0.047, respectively). In the low albuminuria group (n=20), uKIM-1 and IL-1β decreased after 6 months of dapagliflozin treatment (p=0.004 and p=0.0021). However, dapagliflozin did not change uACR and eGFR during the study period.

Conclusions: CKD patients with high albuminuria showed an earlier response to dapagliflozin compared to those with low albuminuria. Nevertheless, dapagliflozin demonstrated a reduction in urinary kidney injury biomarkers in CKD patients regardless of proteinuria levels. These findings suggest that SGLT2i may attenuate the progression of low proteinuric CKD.

A Novel Titratable Pig Model of Mild, Moderate, and Severe CKD

Unimunkh Uriyanghai,[1] Christine Wai,[1] Jasleen Sidhu,[1] Vinay A. Sudarsanam,[1] Diego Celdran-Bonafonte,[1] Eyla C. Arteaga,[1] Taylor G. Lewis,[1] Nicole D. Massoud,[1] Steven Shipley,[1] Thomas H. Hostetter,[1] Gang Xi,[1] Prabir Roy-Chaudhury.[1,2] *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]VA Salisbury Healthcare System, Salisbury, NC.*

Background: Patients with CKD stages 3-5/ESKD have a very significant cardiovascular (CV) and peripheral vascular morbidity and mortality characterized by a "reverse epidemiology". Despite the magnitude of the clinical problem there has been minimal investigation into the impact of different levels of uremia on vascular complications (cardiovascular *and* vascular access) in CKD/ESKD patients. In order to address this unmet translational science need we aimed to surgically induce differing levels of uremia corresponding to CKD stages 3-5 in a pig model.

Methods: Yorkshire Cross pigs underwent a unilateral nephrectomy followed by selective ligation of the arterial tree of the contralateral kidney in order to leave 30% (mild CKD), 15% (moderate CKD) or 7.5% (severe CKD) only of the contralateral kidney with viable perfusion.

Results: Fig 1 describes the initial rise in creatinine followed by a stable creatinine (days 20-30) in the three groups above. Initial data also documents increased levels of known uremic vascular toxins such as indoxyl sulphate and para cresol in the uremic pigs. Importantly, the pigs remained responsive at high creatinine levels (upto 20mg/dL) and did not have significant hyperkalemia.

Conclusions: The described titratable uremic pig model will allow us to (a) describe the concentrations of known uremic vascular toxins such as indoxyl sulphate at different levels of CKD severity (b) perform "omic" analyses on vascular tissue at different levels of CKD severity both prior to and following vascular injury and (c) identify uremia specific pathways of vascular injury that could result in the identification of novel biomarkers and druggable targets for CV risk stratification and future CV therapeutic intervention respectively in CKD patients.

A Novel Mouse Model: Authentic Reproduction of Human CKD

Qiwen Deng, Gerlinde Wernig. *Stanford University School of Medicine, Stanford, CA.*

Background: Animal models are vital for understanding chronic kidney disease (CKD) pathogenesis and developing effective treatments. However, existing models fail to accurately replicate typical changes in human CKD. We present a novel mouse model faithfully recapitulating key aspects of human chronic kidney diseases.

Methods: We employed the *Pax8*-rtTA transgenic mouse model with high expression of the reverse tetracycline-dependent transactivator (rtTA) in kidney tubules under the control of the *Pax8* promoter. Through crossing *Pax8*-rtTA mice with tetracycline-responsive Jun mice, an inducible CKD-JUN model was established, resulting in *Jun* overexpression specifically in kidney tubules upon doxycycline administration. Control mice were generated without doxycycline or *Jun* expression. Ten-week-old mice received continuous doxycycline (0.5 mg/ml) in their drinking water for 2 or 12 weeks. Body weight and kidney size were measured. Blood urea nitrogen (BUN) and serum creatinine were determined. Kidney tissue was subjected to H&E, PAS, and Trichrome staining to evaluate histological changes. Renal inflammation was evaluated through Luminex analysis of cytokine secretion in serum and kidney tissue supernatants, along with assessment of immune cell infiltration.

Results: Following a 2-week induction, histological analysis confirmed acute tubular necrosis in CKD-JUN mice, validating early tubular injury due to Jun induction. After a 12-week induction, both male and female CKD-JUN mice exhibited stable kidney impairment, with males showing a higher propensity for chronic kidney injury and faster CKD progression. CKD-JUN mice displayed decreased body weight, reduced kidney size, elevated BUN and creatinine levels indicative of renal function failure, increased pro-fibrotic inflammatory cytokines in serum and kidney tissue supernatants, and histological signs of glomerular hypertrophy, tubular dilation, interstitial fibrosis, and inflammatory cell infiltration. Other organs in CKD-JUN and Control mice showed no significant

differences, confirming the kidney-specific nature of this model. These findings closely resemble characteristic renal abnormalities observed in human CKD.

Conclusions: Our CKD-JUN mouse model faithfully recapitulates essential clinical and histological characteristics of human CKD, making it a reliable and invaluable tool for studying CKD mechanisms and evaluating therapeutic interventions.

FR-PO986

Transcriptome-Wide Association Study Identified USP24 as a Kidney Disease Risk Gene

Keita Hattori,[1] Shoma Tsubota,[1] Junichiro Hagita,[1] Tomohito Doke,[1] Shoichi Maruyama.[2] *[1]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [2]Nagoya Daigaku, Nagoya, Japan.*

Background: Established transcriptome- wide association study (TWAS) have shown lower USP24 expression in kidneys associated with higher eGFR. USP24 has been shown to deubiquitinates proteins associated with apoptosis, DNA repair, and inflammation in tumor cells. However, the role of USP24 on kidney diseases is not well described. We believe the elucidation of the function of USP24 on kidneys help to achieve the future precision medicine.

Methods: LocusZoom was used to visualize single nucleotide polymorphisms (SNPs). Correlated gene expression and pathway analysis was examined using the database of around 400 human kidneys. An established single-cell database was used to annotate cell types expressing USP24. Immunostaining of USP24 with renal tubule markers was examined in kidneys from humans and various mice models CRISPR-CAS9 system was used to generate tubule-specific USP24 deletion mice. Immunoprecipitation analysis was attempted for exploring protein-protein interaction.

Results: The SNPs highly associated with eGFR and USP24 expression in kidneys were located near the promotor regions, and these SNPs had strong linkage disequilibrium ($r>0.8$). The alternative allele of top SNP (rs17413465) showed a positive Z-score for eGFR GWAS, and negative beta value with USP24 expression in kidney eQTL, indicating higher USP24 expression associated with lower eGFR. Kidney single-cell data showed higher USP24 expression in renal tubule cells compared to non-tubule cells. Double immunofluorescent staining of USP24 with tubule marker, KSP validated the expression of USP24 in renal tubules. Gene correlation analysis in a large scale of human kidney samples showed enrichment of genes correlated with USP24 expression in biological pathways related to chromatin modification, and DNA repair, consistent with the previous reports. Successful insertion of the floxed allele next to USP24 with the CRISPR-CAS9 system was confirmed by genotyping PCR. The cloning of USP24 from cultured mice renal tubules and insertion of HaloTag to the C-terminal of USP24 was confirmed by subsequent DNA sequence.

Conclusions: Multi-omics analysis and experimental analysis suggested lower expression of USP24 in renal tubules might protect from kidney dysfunction by modulating chromatin status and DNA repair.

FR-PO987

Mitochondrial Aldehyde Dehydrogenase rs671 Single Nucleotide Polymorphism Increases the Susceptibility of Kidney Injury in Adenine-Induced CKD Mice

Tusty-Jiuan Hsieh,[1,2] Miao-Yi Wu,[1] I-Hsuan Tsai,[1] Chia-Chu Liu,[1,2] Yi-chun Tsai,[1,2] Ming-Tsang Wu.[1,2] *[1]Kaohsiung Medical University College of Medicine, Kaohsiung, Taiwan; [2]Kaohsiung Medical University Research Center for Environmental Medicine, Kaohsiung, Taiwan.*

Background: In Taiwan, chronic kidney disease (CKD) and end stage kidney disease are major public health issues. Genetic factors increase the susceptibility and severity of kidney diseases. Genome-wide association studies have discovered hundreds of genomic loci associated with CKD. However, which genes are critical contributors to CKD remain unclear. ALDH2 is a mitochondrial enzyme and plays a central role in the liver to metabolize acetaldehyde produced from ethanol into acetate. In addition to liver, ALDH2 is also highly expressed in the kidney, especially in kidney tubular cells. ALDH2 gene has a variant ALDH2*2 allele (rs671) that appears to be the most prevalent in Han Chinese and Taiwanese as higher than 40% in population. Individuals who carry ALDH2*2 allele have lower ALDH2 enzyme activity. Thus far, limited studies investigate genetic polymorphisms of ALDH2 on chronic kidney disease. In this study, we investigated whether ALDH2*2 variants could increase susceptibility to kidney injury.

Methods: We conducted an animal model that male C57BL/6 mice and ALDH2*2 knock-in mice were treated with 100 mg/kg body weight/day of adenine in drinking water to induce early stage CKD. Transdermal GFR measuring system and urine albumin-creatinine ratio (uACR) were used to monitor kidney function. We applied Periodic Acid-Schiff (PAS) staining, Masson trichrome staining, TUNEL assay, MitoSOX staining, real-time PCR and Western blotting to observe kidney injury, fibrosis, apoptosis, mitochondrial ROS, mitochondrial DNA (mtDNA) copy number and related protein expression, respectively.

Results: We found that declined kidney function, tubular damage, tubulointerstitial fibrosis and apoptosis were enhanced in the ALDH2*2 knock-in mice, compared to the wild-type mice. The biomarkers of oxidative stress (MDA, 4-HNE), inflammasome (NLRP3) and fibrosis (Collagen I) were significantly elevated in the kidney of ALDH2*2 knock-in mice. We also observed increased mitochondrial ROS, decreased mtDNA copy number and differential expressed mitochondrial dynamic proteins (Pink1, Parkin, Mfn2, Opa1, Drp1, Fis1) in the kidney of ALDH2*2 knock-in mice.

Conclusions: Our findings suggest that the carrier of ALDH2*2 variant may be more susceptible to kidney injury due to mitochondrial dysfunction.

Shared and Distinct Renal Transcriptome Signatures in Three Standard Mouse Models of CKD

Adam B. Marstrand-Jørgensen,[1] Frederikke E. Sembach,[1] Stine T. Bak,[1] Maria K. Ougaard,[1] Mikkel Christensen-Dalsgaard,[1] Ditte M. Jensen,[1] Thomas Secher,[1] Sebastian Møller Nguyen Heimbürger,[1] Lisbeth N. Fink,[1] Ditte Hansen,[2] Henrik H. Hansen,[1] Mette V. Østergaard,[1] Michael Christensen,[1] Louise Dalbøge.[1] *[1]Gubra, Hørsholm, Denmark; [2]Kobenhavns Universitet Det Natur- og Biovidenskabelige Fakultet, Frederiksberg, Denmark.*

Background: Various mouse models with differing disease etiologies are available in preclinical chronic kidney disease (CKD) research. Characterizing these models according to their renal transcriptomics enables better selection of the optimal model for preclinical drug discovery studies. We therefore characterized the kidney transcriptome signature of three well-established models of CKD, i.e. unilateral ureter obstruction (UUO), unilateral ischemic reperfusion injury (uIRI) and adenine-supplemented diet feeding (ADI).

Methods: Male C57BL/6J mice were used in all studies. Mice underwent UUO or uIRI surgery and were terminated two- and six-weeks post-surgery, respectively. Sham-operated mice served as controls. For ADI, mice received an adenine-supplemented diet or control diet for six weeks. Endpoints included plasma biochemistry, kidney histology and RNA sequencing.

Results: All three models displayed increased macrophage infiltration (F4/80) and fibrosis (Col1a1). An excessive number of renal differentially expressed genes (≥11,000) was observed in all three models, with a notable overlap in their transcriptome signatures. Gene expression markers of inflammation, fibrogenesis and kidney injury supported histological findings in the models. A subset of genes showed model-specific changes, including genes representing current drug targets for CKD (e.g., Ednrb, Nr3c2, Glp1r, Flt1 and Ptch1), emphasizing the applicability of the three CKD models in preclinical target and drug discovery.

Conclusions: While the UUO, uIRI and ADI mouse models of CKD demonstrate notable commonalities in renal transcriptome signatures, model-specific transcriptional changes in genes encoding current drug targets emphasize that the three models have different utility in preclinical drug discovery.

FR-PO989

Characterising Human Kidney Disease Using Single-Cell Resolution Spatial Transcriptomics

David A. Ferenbach,[1] Maximilian Reck,[2] David P. Baird,[1] Marie Docherty,[1] Laura Denby,[2] Bryan Conway.[2] *[1]The University of Edinburgh Centre for Inflammation Research, Edinburgh, United Kingdom; [2]The University of Edinburgh Centre for Cardiovascular Science, Edinburgh, United Kingdom.*

Background: There is accumulating evidence of the role played by subsets of transcriptionally altered epithelia in the progression of experimental chronic kidney disease (CKD) (Muto et al 2021, Mylonas et al 2021). Whilst bulk and single cell RNA-seq analysis has increased our understanding of kidney biology – the lack of spatial context has limited efforts to identify pathways by which inflammatory Vcam1+ epithelia, leukocytes and fibroblasts interact within the human kidney. Advances in spatial sequencing now provide single cell resolution analysis in formalin fixed, paraffin embedded renal biopsies. We hypothesized that spatial analysis of cell-cell signalling in human kidneys would uncover signalling pathways relevant to progressive chronic kidney disease

Methods: We used the NanoString CosMx spatial molecular imager to analyse ~1000 RNA transcripts in 13 human renal biopsies spanning benign (minimal change disease, MCD) non progressive IgAN and progressive IgAN CKD (defined as >30% eGFR loss over study period).

Results: Interrogating our spatial dataset, we identified 19 transcriptionally distinct cell types – including previously published and novel Vcam1+ epithelia from proximal tubules and loop of Henle. Analysis was undertaken on Vcam1+ epithelia in patient biopsies of MCD and IgAN. Assessment of ligand receptor signalling pathways between Vcam1+ epithelia, leukocytes and fibroblasts within 50microns revealed multiple spatially linked ligand/receptor pathways (see Figure below). One example was the spatial link between reduced Vcam1+ epithelia<>fibroblast distance and increased fibroblast Col1a1 and Col3a1 production (n=10,935 total fibroblasts, all $p<0.0001$ vs spatially distant SC/fibroblast pairings, with reduced mean distance in progressive IgAN vs MCD).

Conclusions: Our data demonstrates the ability of spatial transcriptomic analysis to identify and map multiple transcipts and ligand/receptor pairings. The addition of spatial information adds additional information about putative signalling pathways in disease progression

FR-PO990

A Novel Method to Identify and Visualize Senescent Cells In Vivo with High Sensitivity

Ryo Yamada,[1] Takuya Morinishi,[1] Yohei Iwashige,[1] Koji Muro,[1] Shigenori Yamamoto,[1] Toshio Kitamura,[2] Motoko Yanagita.[1] Cell Cycle Group. *[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan; [2]Koeki Zaidan Hojin Kobe Iryo Sangyo Toshi Suishin Kiko, Kobe, Japan.*

Background: Cellular senescence occurs in response to repeated passages, persistent DNA damage, and oxidative stress and is characterized by permanent growth arrest. Recently, it has been noticed that senescent cells accumulate *in vivo* and correlate with organ dysfunction, but a highly sensitive method to identify senescent cells *in vivo* has not yet been established.

Methods: The cell cycle of proximal tubular cells was evaluated in mice expressing the proximal tubule-specific G0 marker (*Ndrg1CreER^{T2}:R26-mVenus-p27K^{-}*). The G0 marker is mVenus-p27K^{-}, a fusion protein that combines the fluorescent protein mVenus with CDK inhibitor p27^{Kip1} mutant p27K^{-} (p27 protein without CDK inhibitory function), and is usually used to identify cells in quiescent phase (G0 phase). Using this mouse line, we analyzed cell cycle of proximal tubular cells after DNA damage caused by aristolochic acid and cisplatin nephropathy models. We also performed spatial transcriptomics of G0 marker-positive cells using photo-isolation chemistry (PIC)-based system.

Results: In G0 marker mice, almost all proximal tubular cells remained in the G0 phase under physiological conditions. In the chronic phase of kidney injury, most proximal tubular cells were G0 marker-positive, but some G0 marker-positive cells exhibited nuclear abnormalities, such as nuclear enlargement. Surprisingly, immunohistochemical analysis revealed the G0 marker-positive cells with nuclear abnormalities expressed high levels of cyclin D1 along with the G0 marker (G0^{+}CycD1^{high}), which was inconsistent with normal cell cycle. The PIC-based RNAseq study showed that G0^{+}CycD1^{high} cells exhibited the characteristic features of “Injured PTC” and “Senescence” compared with G0^{+} cells in the vehicle group. We also isolated primary proximal tubular cells from G0 marker mice and induced senescence. Time-lapse imaging assays revealed that these senescent cells continuously expressed G0 marker. Furthermore, most of the senescent cells with G0 marker expressed Cyclin D1 and had enlarged nuclei.

Conclusions: Our data suggest that G0 marker mice can be a useful tool for identifying senescent proximal tubular cells both *in vivo* and *in vitro*, in combination with cyclin D1 expression. This system can be used to identify new markers of cellular senescence *in vivo* and evaluate the efficacy of senolytic treatments.

FR-PO991

Multiplexed Imaging of Senescent Chromatin States in Single Cells in Kidney

Hannah S. Perry, Madeline K. Wong, Benjamin C. Mustonen, Joshua C. Vaughan. *University of Washington, Seattle, WA.*

Background: The gradual loss of kidney function with age and disease can be linked to changes in physiology and single cell epigenetics. As cells become stressed or damaged from these conditions, they undergo the process of becoming senescent, a state of permanent cell cycle arrest associated with massive chromatin rearrangement, as a way to mitigate further damage. The order of events and extent of epigenetic changes within single cells and their correlation to physiological alterations as the kidney ages or becomes diseased and senescence forms are not fully understood.

Methods: Super-resolution optical microscopy techniques were used with advanced chemical labeling methods to concurrently study epigenetic states and nanoscale physiology in mouse kidney slices. We used multiplexed imaging to simultaneously study histone marks, gene loci, and tissue morphology at the single cell level.

Results: The use of optical super-resolution techniques allows for ~70 nm spatial resolution. Multiple histone modifications have been detected and quantified at locations of repetitive DNA sequences (telomeres, major and minor satellites) and genes of interest (e.g. *Nphs2*, *CDKN1a/2a, PAI-1*) in single cells with a high degree of accuracy. In the same sample, these single cell epigenetic signatures were correlated with nanoscale features within glomeruli. The quantification of these nanoscale features includes the glomerular basement membrane thickness, width of individual podocyte foot processes, and the size of endothelial fenestrations. Multiplexed imaging has allowed for the use of 6-8 unique stains in one sample, with the potential for more.

Conclusions: The combination of these advanced labeling methods and super-resolution optical microscopy techniques allow for an unprecedented view and correlation of single cell epigenetic states and nanoscale physiology in kidney tissue at many age points. Our approach has implications for identifying specific epigenetic changes in the kidney that precede the development of senescence and related diseases and their physiological markers. Understanding the sequence of events may assist in predicting disease formation along with studying the effectiveness of various treatments.

FR-PO992

Aging Alters Microenvironmental Cues for Gli1+ Myofibroblast Progenitors to Promote Tissue Remodeling in the Kidneys

Yoshiharu Muto, Eoghainín Ó hAinmhire, Flavia G. Machado, Benjamin D. Humphreys. *Washington University in St Louis, St Louis, MO.*

Background: Aging is associated with decreased renal function as well as tissue alteration including interstitial fibrosis. We previously identified Gli1+ myofibroblast progenitors that contribute to tissue fibrosis in the kidney and other organs. However, the role of this cell type in aging-induced alteration in the kidney remains elucidated.

Methods: We genetically labeled Gli1+ cells in Gli1-CreERt2; R26-tdTomato mice by pulsing with tamoxifen at 8 weeks of age and chasing them until 12 weeks (young) or 2 years of age (old). We sorted tdTomato+ cells and performed bulk RNA-seq. We also performed single nucleus transcriptomic analysis (snRNA-seq) on these mouse kidneys (n=3 pairs: 12 weeks vs 2 years of age) using 10x Genomics platform.

Results: We identified tdTomato+ cells in 2-year-old mouse kidneys labeled at 8 weeks of age. Bulk RNA-seq on sorted tdTomato+ cells from aged kidneys showed a tissue-remodeling gene expression signature with increased *Ccn2*, *Serpina1b*, *Mmp3* expressions. We performed snRNA-seq on these mouse kidneys and identified all major cell types (35,592 nuclei from n=3 young and old kidneys; 19 cell types). We observed a large cluster of immune cells as well as emergence of *Vcam1*+ failed-repair proximal tubular cells (FR-PTC) with pro-inflammatory and pro-fibrotic gene expression signature in aged kidneys. Immunofluorescence analysis validated Vcam1+ atrophic tubules in 2-year-old mouse kidneys. Intercellular communication inference based on snRNA-seq data indicated interactions between FR-PTC and fibroblast/pericyte cluster through molecules modifying tissue fibrosis (*Tgfb2, Spp, Pdgfd, Bmp6*). Endothelin expressed in FR-PTC was also predicted to target fibroblast/pericytes in 2-year-old mice. In situ hybridization validated high level of *Edn1* expression in *Vcam1*+ tubular cells, suggesting a potential role of endothelin to mediate interaction between FR-PTC and Gli1+ myofibroblast progenitors to promote interstitial fibrosis in elderly population.

Conclusions: By combining long-term lineage tracing and snRNA-seq we elucidated a molecular interaction between Gli1+ myofibroblast progenitor and FR-PTC. Targeting this interaction may mitigate age-related renal fibrosis.

FR-PO993

Lineage-Tracing Experiments of Senescent Cell Marker p16INK4a-Positive Cells Show that Kidney Aging Proceeds on a Nephron-by-Nephron Basis

Koji Muro,[1] Ryo Yamada,[1] Takuya Morinishi,[1] Yohei Iwashige,[1] Shigenori Yamamoto,[1] Tomonori Kimura,[2] Makoto Nakanishi,[3] Motoko Yanagita.[1] *[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu Jinzo Naikagaku, Kyoto, Japan; [2]Kokuritsu Kenkyu Kaihatsu Hojin Iyaku Kiban Kenko Eiyo Kenkyujo, Ibaragi, Japan; [3]Tokyo Daigaku Ikagaku Kenkyujo, Minato-ku, Japan.*

Background: Senescent cells in *in vitro* experiments are the cells that have permanently arrested the cell cycle and acquired senescence-associated secretory phenotypes. p16^{INK4a} is a known marker for senescent cells. However, the lack of good antibodies has made it difficult to identify p16^{INK4a}-positive cells *in vivo* and to elucidate their distribution and dynamics in tissues.

Methods: We lineage-traced senescent cells using p16Cre^{ERT2}:R26-tdTomato mice, where tdTomato (tdT) was induced by tamoxifen in the cells with p16^{INK4a} activity. We analyzed the localization of tdT+ cells in aged mice and young mice with kidney injury models, specifically focusing on the proximal tubules (PTs). Using the novel photo-isolation chemistry (PIC) technology, which allows us to obtain RNA from a single cell in tissue sections, we compared PIC-RNAseq in three groups: tdT+ proximal tubular cells (PTCs), tdT- PTCs located in PTs with or without tdT+ PTCs.

Results: Among the other segments, the PTs had the highest number of tdT+ cells. Interestingly, the number of tdT+ PTCs was significantly higher in old female mice than that in young female mice, whereas there was no difference between young and old male mice. Furthermore, tdT+ PTCs were significantly increased in female mice with ovariectomy as well as in male mice that received irradiation. Tissue clearing and three-dimensional imaging of the kidneys of aged female mice revealed a unique localization of tdT+ PTC, which clustered and contiguous within the same nephron. PIC-RNAseq showed shared gene expression patterns between tdT+ PTCs and tdT- PTCs located in the same PTs, and genes involved in ER stress, stress response and post-translational modifications were heterogeneously enhanced in these cell groups compared with tdT- PTCs in PTs without tdT+ PTCs. These results were further confirmed by immunostaining.

Conclusions: We found that senescent cells clustered in the same proximal tubules in aged kidneys and that senescent cells and non-senescent cells that reside in the same tubule shared common characteristics. These results indicated that kidney aging occurs at the nephron level, which is important for future therapeutic strategies.

FR-PO994

Skeletal Muscle Mitochondrial Dysfunction in Patients with CKD and Heart Failure (HF)

Mert Demirci,[1] Javier Jaramillo Morales,[1] Baback Roshanravan,[4] Sandip K. Zalawadiya,[3] Talat Alp Ikizler,[1] Jorge Gamboa.[2] *[1]Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN; [2]Vanderbilt University Medical Center, Division of Clinical Pharmacology, Nashville, TN; [3]Vanderbilt University Division of Cardiovascular Medicine, Nashville, TN; [4]University of California Davis, Division of Nephrology, Sacramento, CA.*

Background: Skeletal muscle dysfunction is a well-known cause of decreased physical performance and quality of life in patients with CKD and HF. While muscle mitochondrial dysfunction has been proposed as a possible mechanism in patients with either CKD or HF. The incremental effect of co-existing HF and CKD is not studied in detail. We hypothesized that the presence of HF and CKD is associated with worse mitochondrial function and physical performance compared to CKD alone.

Methods: In this cross-sectional study, we examined 24 patients, 6 with CKD Stage 3-5 with a clinical diagnosis of HF, and 18 with CKD Stage 3-5 without HF. Patients on dialysis were excluded. ^{31}Phosphorus magnetic resonance spectroscopy (^{31}P-MRS) was

used to measure PCr recovery time after exercise. A longer PCr recovery results in a greater time constant tau (τ), which indicates worsening mitochondrial function. Physical performance was measured with the six-minute walk test (6MWT) and repeated chair stand test.

Results: Groups were similar in terms of age, gender, race, and eGFR. Patients with co-existing CKD and HF presented a prolonged time constant compared to patients with CKD alone [CKD/HF: 77.825 (71.2, 82.515) *vs.* CKD alone: 48.41 (41.13, 49.175), p<0.001, **Figure 1A**] Patients with co-existing CKD and HF walked a shorter distance than patients with CKD alone [CKD/HF: 372 (294, 395) *vs.* CKD alone: 491 (417, 519.5) meters, median (IQR), p=0.003, **Figure 1B**].

Conclusions: Our results suggest that presence of HF worsens mitochondrial dysfunction in patients with moderate to advanced CKD. Similar adverse impact of HF is observed in physical performance measures. Future studies should evaluate the mechanisms leading to muscle dysfunction in these two chronic diseases to provide new insights into novel therapeutic targets.

Interplay Between Skeletal Muscle Catabolism and Remodeling of Arteriovenous Fistulae via YAP1 Signaling

Yongdong Wu,[1] Ming Liang,[1] Tae Hoon Lee,[1] Fengzhang Huang,[1] Luan D. Truong,[2] Jizhong Cheng.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Houston Methodist Hospital, Houston, TX.*

Background: Arteriovenous fistulae (AVFs) are the preferred dialysis access choice, but they are prone to complications and have a high incidence of failure. The aim of this study is to understand the crosstalk of skeletal muscle catabolism and AVF maturation failure, and the role of myostatin and YAP1 signaling pathway in regulating AVF maturation.

Methods: AVFs were created in mice with chronic kidney disease (CKD). The skeletal muscle metabolism and AVF maturation were evaluated in mice that were treated with myostatin or its antagonist antibody. The role of YAP1 in transdifferentiation of adventitial mesenchymal stem cells (MSC) into neointima cells was investigated. Finally, "red light"-controlled verteporfin nanoparticles were used to block YAP1 activation in AVFs.

Results: PDGFRA reporter mice showed that positive MSCs were found both in muscle interstitial and vascular adventitial. These MSCs were activated in response to myostatin, that was increased in atrophied muscle fibers in CKD mice and was associated with vascular stiffness. Increased trichrome signals and stenosis were observed in AVFs from mice that were treated with myostatin. In contrast, blocking myostatin function by anti-myostatin peptibody not only improved body weight and muscle size in CKD mice, but also decreased neointima formation in AVFs. These responses were paralleled with decreased accumulation of PDGFRA$^+$ cells in AVFs. In cultured MSCs, YAP1 signaling mediated activation and differentiation of MSCs when MSCs were treated with myostatin or seeded on hard surface. "Red light"-controlled release of verteporfin nanoparticles, YAP1 inhibitor, alleviated MSC activation. Local application of verteporfin nanoparticles significantly suppressed accumulation of neointima cells in AVFs in irradiation group vs non-irradiated groups.

Conclusions: There were increased muscle atrophy and myostatin production in CKD mice, the latter stimulates MSCs activation and vascular fibrosis that are linked to AVF stenosis. YAP1 signaling was activated in this process. Blocking myostatin or inhibiting YAP1 activation suppressed neointimal formation with improved AVF function.

Therapeutic Targeting of Vascular Calcification by KL1 in a CKD-MBD Rat Model

Arvin Halim, Gayatri Narayanan, Shruthi Srinivasan, Kalisha O'Neill, Neal X. Chen, Sharon M. Moe, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Vascular calcification is a common complication in patients with CKD that causes arterial stiffening, which can lead to hypertension and adverse cardiac remodeling. Klotho-deficient animal models exhibit a similar vascular calcification phenotype seen in patients with CKD, which can be ameliorated with exogenous administration of full-length Klotho. The KL1 domain of Klotho can be cleaved from full-length Klotho removing its FGF23-binding domain. Studies have shown that KL1 is biologically active, however it is unknown whether KL1 can directly exert anti-calcific effects similar to full-length Klotho.

Methods: Cy/+ male rats were fed a casein-based diet starting at 22 weeks old, and then treated daily with intraperitoneal injections of 50 μg/kg human recombinant KL1 (Cat. No. 100-53, PeproTech; *n*=6) or vehicle (0.1% bovine serum albumin in 0.9% saline; CKD, *n*=12) for 5-7 weeks starting at 27 weeks old. Rats were euthanized for tissue collection at 32-34 weeks old. Normal littermates (NL, *n*=8) were used as a control. Tissue calcification assessment, histology and protein analysis of the aorta were performed.

Results: CKD rats, compared to NL rats, developed elevated BUN (mean±SD: 46.13±9.41 mg/dL vs. 19.44±3.57 mg/dL; *P*<0.001), creatinine (1.53±0.61 mg/dL vs. 0.44±0.053 mg/dL; *P*<0.001), plasma phosphate (12.67±4.71 mg/dL vs. 6.17±1.12 mg/dL; *P*<0.001), decreased eGFR (671.61±463.83 μL/min vs. 2912.01±213.51 μL/min; *P*<0.001) and increased total kidney weight normalized to body weight (TKW/BW, 13.46±3.36 mg/g vs. 6.69±0.23 mg/g; *P*<0.001). CKD rats developed significant aortic calcification (62.88±31.22 mg/dL) compared to NL rats (27.69±14.27 mg/dL; *P*<0.005). Moreover, CKD rats treated with KL1 exhibited significantly reduced aortic calcification (32.5±15.53 mg/dL; *P*<0.018) and BUN (37.76±1.95 mg/dL; *P*<0.02) compared to vehicle treated CKD rats. Phosphate (10.99±1.38 mg/dL, *P*>0.27), creatinine (1.57±0.35mg/dL; *P*>0.86), eGFR (599.84±190.48 μL/min; *P*>0.65), and TKW/BW (13.31±2.44 mg/g; *P*>0.91) in KL1 treated rats did not significantly differ from vehicle treated CKD rats.

Conclusions: KL1 reduces aorta vascular calcification in a rat CKD-MBD model. This suggests that the KL1 domain of Klotho can directly exert cardiovascular protective effects. Further studies are warranted to elucidate the underlying molecular mechanisms.

Homocysteine Is Associated with Kidney Injury and Increased Arterial Stiffness

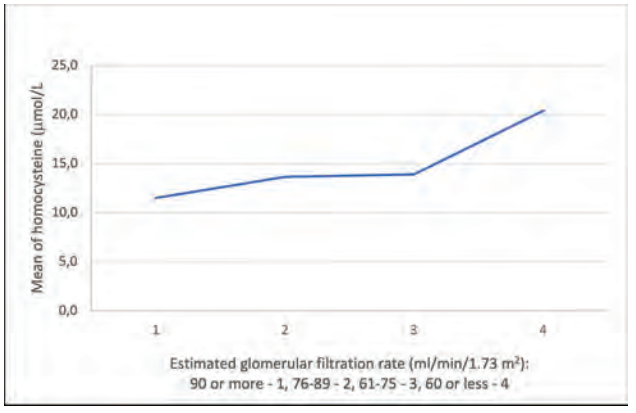
Nejc Piko, Sebastjan Bevc, Radovan Hojs, Tadej Petreski, Luka Varda, Robert Ekart. *Univerzitetni Klinicni Center Maribor, Maribor, Slovenia.*

Background: Homocysteine (Hcy) promotes atherogenesis and is elevated in chronic kidney disease (CKD). Few studies addressed the association between Hcy, different markers of kidney injury and arterial stiffness (AS).

Methods: 127 patients (70.9% male, mean age 65.0±9.2 years, 78.7% hypertensive, and 20.5% diabetics) were admitted due to elective coronarography. The immunoassay method was used to measure serum Hcy (mmol/L) and cystatin C (CysC, mg/L). Hyperhomocysteinemia was defined by Hcy≥15 (Group 1, n=37), and patients with Hcy<15 were included in Group 2 (n=90). Albuminuria was expressed as UACR (mg/g). The glomerular filtration rate was estimated (eGFR) by the CKD-EPI 2009 equation (ml/min/1.73 m^2). Carotid-femoral pulse wave velocity (cfPWV, m/s) was used as a marker of AS (SphygmoCor®, Atcor, Australia). SPSS® (version 22) was used for statistical analysis.

Results: Mean Hcy was 14.1±5.7, eGFR 75.5±17.2, CysC 1.1±0.7, UACR 25.9±35.7 and cfPWV 10.3±2.7. Spearman's test showed a significant correlation between Hcy and CysC (r_s=0.608, p<0.001), UACR (r_s=0.264, p=0.004), eGFR (r_s=-0.485, p<0.001) and between Hcy and cfPWV (r_s=0.328, p<0.001). Group 1 had lower eGFR (62.4±21.5 vs 80.3±12.2, p<0.001), higher cysC (1.5±1.2 vs 0.9±0.2, p<0.001), higher UACR (49.6±57.5 vs 16.5±13.7, p<0.001), and higher cfPWV (11.5±3.3 vs 9.6±2.1, p<0.001). No difference was observed in comorbidities or medications. Multiple regression analysis (independent variables gender, age, diabetes, hypertension) confirmed a correlation between Hcy and eGFR (β=-0.535, p<0.001), UACR (β=0.331, p<0.001) and cysC (β=0.561, p<0.001). Hcy was higher in patients with lower eGFR (Figure 1). An independent correlation was also found between Hcy and cfPWV (β=0.238, p=0.005) and age and cfPWV (β=0.407, p<0.001). No association was found between cfPWV/Hcy and coronary artery disease (CAD).

Conclusions: Serum Hcy is associated with decreased eGFR, increased UACR, increased cysC and increased AS, but not CAD.



FR-PO998

The Nonsteroidal Mineralocorticoid Receptor Antagonist Finerenone Improves Left Ventricular Function in Preclinical CKD

Frederic Jaisser,[1] Ixchel Q. Lima Posada,[1] Yohan Stephan,[2] Matthieu Soulié,[1] Roberto Palacios Ramirez,[1] Benjamin Bonnard,[1] Lionel Nicol,[2] Peter Kolkhof,[3] Paul Mulder.[2] Diabetes, metabolic diseases and comorbidities
[1]INSERM, UMRS 1138, Centre de Recherche des Cordeliers, Sorbonne Université, Université Paris Cité, Paris, France; [2]Univ Rouen Normandie, INSERM EnVI UMR 1096, Rouen, France; [3]Cardiovascular Precision Medicines, Research and Early Development, Pharmaceuticals, Bayer AG, Wuppertal, Germany.

Background: The mineralocorticoid receptor (MR) plays an important role in the development of CKD and associated cardiovascular complications. Antagonizing the overactivation of the MR with MR antagonists (MRA) is a therapeutic option. Finerenone is a novel non-steroidal MRA that has been recently studied in two large clinical trials showing the beneficial effects in stage 1 to 4 CKD patients with type 2 diabetes (T2D) in the FIDELIO-DKD and FIGARO-DKD trials. **Aim:** To test whether finerenone improves renal/cardiac functions in preclinical non-diabetic CKD.

Methods: CKD was induced by 5/6 nephrectomy in 6 weeks old Sprague Dawley rats. Finerenone (10 mg/kg/day) was administered as curative treatment (1 month after 5/6 nephrectomy). Left Ventricle (LV) function/hemodynamics, LV tissue perfusion and GFR were assessed in vivo at the age of 24 weeks. Cardiac fibrosis was estimated by Sirius red staining and activation of eNOS (peNOS ser 1177) in the heart was estimated by western-blot analysis.

Results: 12 weeks after 5/6 nephrectomy, the rats showed classical signs of CKD: reduced GFR and increased kidney weight; associated with LV diastolic dysfunction: increased in LV end-diastolic pressure (LVEDP), LV relaxation constant (Tau) and LV end-diastolic pressure volume-relation (LVEDPVR), while LV perfusion was reduced. Changes associated with increased cardiac fibrosis and reduced peNOS ser 1177. Curative treatment with finerenone reduced significantly both LVEDPVR and Tau; and increased LV tissue perfusion, associated with a reduction in cardiac fibrosis and increased eNOS phosphorylation. Finerenone treatment did not impact GFR but reduced renal hypertrophy.

Conclusions: Curative treatment with finerenone improves non-diabetic CKD related LV diastolic function, associated with a reduction of cardiac fibrosis, and increased cardiac eNOS activating phosphorylation (ser 1177) independently from changes in kidney function.

CKD, Heart Failure, Cytokines, and NF-κB: Is There a Connection?

Alejandro R. Chade,[1] Tamer Mohamed,[2] Alfonso Eirin.[3] *[1]University of Missouri, Columbia, MO; [2]University of Louisville, Louisville, KY; [3]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Nuclear factor kappa (NF-κB) is a master transcription factor of inflammatory signaling and its prolonged activation is cytotoxic and may promote heart failure (HF). We developed a translational swine model of chronic kidney disease (CKD) that displays early-stage HF and cardiac activation of NF-κB. However, the mechanisms underpinning cardiac NF-kB activation in CKD remain unclear. We hypothesize that inflammatory cytokines released from the kidney and retained in the heart contribute to cardiac NF-κB activation and cardiac injury in CKD.

Methods: Normal and CKD pigs (n=6 each) were studied after 14 weeks; their systemic inflammatory cytokine profile was characterized (pig Luminex multi-panel assay) and their renal (renal vein - systemic) and cardiac (coronary sinus - systemic) gradients calculated. *In vitro* NF-kB expression (qPCR) and activation (immunofluorescence) was studied in pig heart slices and cardiomyocytes exposed to normal plasma, and CKD plasma with or without cytokine neutralizing antibodies (NA).

Results: Out of 13 cytokines, we found that tumor necrosis factor (TNF)-α and interleukin (IL)-6 showed the most significant increase in CKD, paired with positive renal and negative cardiac gradients, suggesting TNF-α/IL-6 renal release and cardiac retention. *In vitro* NF-kB expression and activation were higher in heart slices and cardiomyocytes exposed to CKD plasma but decreased in those treated with TNF-α and IL-6 NA (Figure).

Conclusions: These observations shed light into targeted mechanisms of cardiac NF-kB activation and may support future development of novel modulatory strategies to offset cardiac injury in CKD.

Funding: NIDDK Support, Other NIH Support - NHLBI

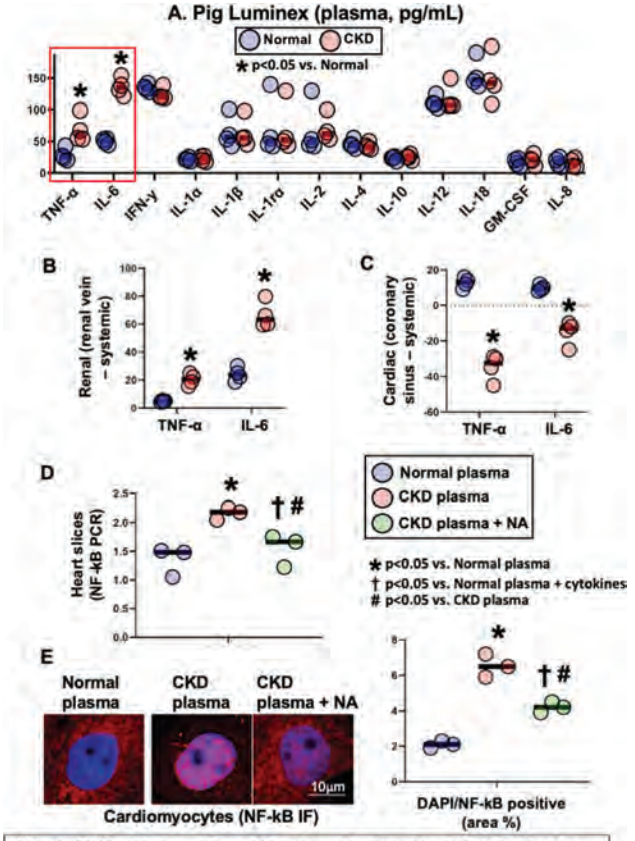

Figure: Unbiased pig multi-panel Luminex showing elevated systemic plasma levels of TNF-α and IL-6 in CKD **(A)**, paired with positive renal **(B)** and negative cardiac **(C)** gradients, suggesting renal release and cardiac retention. NF-kB cardiomyocyte expression (PCR, heart slices, **D)** and activation (IF, nuclear expression, **E)** increases after exposure to CKD plasma and decreases after treatment with NA.

FR-PO1000

Novel Role of ST2+ Tubular Cells in Shaping Immune Microenvironment

Vikram Sabapathy,[1] Gabrielle Costlow,[1,2] Franklin J. Herbert,[1] Bushra Mehkri,[1] Saleh Mohammad,[1] Rahul Sharma.[1] *[1]University of Virginia, Charlottesville, VA; [2]Virginia Commonwealth University, Richmond, VA.*

Background: IL-33 is an 'alarmin' cytokine that regulates the immune response during injury. After release, IL-33 acts in an autocrine/paracrine manner on its membrane receptor (ST2 aka interleukin 1 receptor-like 1, IL1RL1), triggering innate and adaptive immune responses. ST2 expression is induced in tubular cells during chronic inflammation in various kidney diseases. However, the role of ST2^{+} tubular cells and their implication in chronic kidney injury (CKI) is poorly understood.

Methods: *ST2*$^{fl/fl}$ mice were crossed with *PEPCK*^{Cre} mice for proximal tubular cell (PTC)-specific ST2 deletion. Bilateral ischemia-reperfusion (IR) induced acute injury (AKI) and mice were euthanized 24hrs later. Unilateral ischemia-reperfusion injury simulated chronic injury, with contralateral nephrectomy performed on day 13 post-IRI. Kidney structure and function were analyzed using flow cytometry, histology, immunohistochemistry, gene expression, and biochemical analysis. In vitro, ST2-deficient and ST2-sufficient primary mouse PTC were subjected to ischemic conditions and assessed for metabolic fitness using Seahorse metabolic flux analyzer and cytokine production.

Results: ST2's potential involvement in immune cell activation and mobilization to injury sites was investigated. Selective ST2 deletion in PTC, in acute and chronic injury models, resulted in reduced renal injury. In the chronic injury model, the absence of IL33/ST2 signaling in tubular cells led to decreased immune cell infiltration, reduced inflammatory cytokine production, and lower fibrosis. Interestingly, *in vitro* treatment of TKPTS, PTC cell-line with recombinant IL-33 increased metabolic fitness, indicated by higher oxygen consumption rate (OCR) and extracellular acidification rate (ECAR) in a dose-dependent manner. Additionally, IL-33 treatment paradoxically enhanced the expression of autophagy and mitochondria-related genes LC3, Beclin, and Rubicon in TKPTS cells. These findings underscore the intricate role of IL-33/ST2 biology in PTC.

Conclusions: $ST2^+$ tubular cells play a crucial role in leukocyte trafficking to the injured kidneys. Our data provide novel information to suggest epithelial-immune cell crosstalk mediated through the IL-33/ST2 axis and identification of novel therapeutic targets.

Magnesium Protects Against CKD Progression by Reducing DNA Damage

Makoto Matsubara, Kensuke Sasaki, Naoki Ishiuchi, Akira Takahashi, Yosuke Osaki, Yujiro Maeoka, Takao Masaki. *Hiroshima Daigaku Daigakuin Ikei Kagaku Kenkyuka, Hiroshima, Japan.*

Background: DNA damage accelerates the the progression of chronic kidney disease (CKD) and kidney aging. Emerging evidence suggests that magnesium (Mg) has the ability to suppress DNA damage by promoting chromatin aggregation. In this study, we aimed to investigate the potential of Mg administration in reducing DNA damage and mitigating the progression of CKD.

Methods: Male C57BL/6 mice (8 weeks old) were treated with a dosage of 600 mg/kg of Mg or deionized distilled water (DDW) and were subjected to renal irradiation with 8 Gy of radiation. As another model, male C57BL/6 mice (8 weeks old) underwent unilateral ischemia/reperfusion (I/R) injury with renal pedicle clamping for 35 minutes. These mice received Mg or DDW every 12 hours after I/R. Then, mice were sacrificed one- or three-week after I/R. *In vitro* experiments were also conducted using rat renal tubular (NRK52E) and rat kidney fibroblast (NRK49F) cells, which were irradiated with 1 Gy of radiation at different Mg concentrations (0.8mM, 3.2mM, 6.4mM) in the medium.

Results: Western blotting analysis revealed that the effects of radiation injury were confirmed by an increase of γH2AX, a marker of DNA double-strand breaks. Mice were treated with 600 mg/kg of Mg and subjected to renal irradiation with 8 Gy of radiation. Remarkably, the Mg-treated group exhibited reduced levels of γH2AX in the kidneys compared to the non-treated group. Furthermore, NRK52E and NRK49F cells irradiated with 1 Gy of radiation showed a reduction in γH2AX levels as the Mg concentration in the medium increased (0.8 mM, 3.2 mM, 6.4 mM). In the one-week I/R model, Western blotting analysis revealed that Mg administration resulted in a reduction of DNA damage markers (γH2AX and rad51), markers of aging (p16 and p21) and the inflammation marker (cGAS-Sting). Immunostaining demonstrated that Mg administration resulted in a reduction of markers of aging (p16 and p21) and the inflammation marker (F4/80). Furthermore, real-time PCR analysis indicated that Mg administration led to a decrease in markers of inflammation (IL-6 and IL-1β). In the three-week I/R model, Western blotting and immunostaining revealed that fibrotic markers (αSMA and collagen I) were also reduced in the Mg-treated group.

Conclusions: Administration of Magnesium reduces DNA damage and mitigates renal I/R injury, including aging, inflammation and fibrosis.

FR-PO1002

A Novel, Small Molecule Inhibitor of Gut Microbial Choline Trimethylamine Lyase (CutC) Slows the Loss of Kidney Function in a Rat Model of CKD

Jerry Buysse, Robert Matunas, Camilla V. Simpson. *Zehna Therapeutics Inc., Cleveland, OH.*

Background: Trimethylamine *N*-oxide (TMAO), a gut microbiota-dependent uremic toxin, is both a cause and driver of chronic kidney disease (CKD). Choline trimethylamine (TMA) lyase (CutC) is a microbial enzyme that plays a key role in the formation of TMA, a precursor of TMAO, in the gut. Here we describe the pharmacological effects of a novel, small molecule CutC inhibitor on serum TMAO level and kidney function in an adenine-induced rat model of CKD.

Methods: CKD was induced in rats by adding 0.75% adenine to a standard chow diet for 2 weeks (induction phase) and maintained by adding 0.25% adenine to the diet supplemented with 1% choline in the drinking water for 4 weeks (maintenance phase). The small molecule CutC inhibitor, ZTx101, was administered via ileal-cecal catheter directly into the colon at doses of 15, 50, and 150 mg/kg of body weight, twice a day, during the maintenance phase. Serum TMAO was quantified using LC-MS/MS. Kidney function was assessed by serum levels of creatinine and blood urea nitrogen (BUN). Renal fibrosis was assessed by biomarker analysis and histology.

Results: Serum levels of TMAO, creatinine, and BUN were elevated in rats with adenine-induced CKD supplemented with choline. Administration of ZTx101 at all three doses resulted in rapid and sustained reduction of serum TMAO to the normal range (<5 μM) during the maintenance phase of the study. At the end of study, ZTx101 significantly reduced serum levels of creatinine (1.5 mg/dL in 150 mg/kg ZTx101 vs. 3.1 mg/dL in untreated; $P<0.0001$) and BUN (102.6 mg/dL in 150 mg/kg ZTx101 vs. 140.0 mg/dL in untreated; $P<0.05$). ZTx101 also significantly reduced TGF-β level in the kidney (36.6 pg/mg tissue in 150 mg/kg ZTx101 vs. 70.2 pg/mg tissue in untreated; $P<0.0001$), a biomarker of renal fibrosis. In addition, neutrophilic tubulitis and tubulointerstitial nephritis were reduced in animals treated with ZTx101, compared to untreated controls.

Conclusions: The small molecule CutC inhibitor ZTx101 is effective in reducing and normalizing elevated levels of uremic toxin TMAO and slowing the loss of kidney function in a rat model of CKD. Reduction of serum TMAO level by the CutC inhibitor ZTx101 may provide a potential new approach to slow disease progression in persons with CKD.

Protective Effects of Lrp2 Knockout Are Independent of Sex-Specific Renal Injury in Mice on Western Diet

Elynna B. Youm, Wafaa N. Albalawy, Allison L. Marciszyn, Jared Lashway, Corry D. Bondi, Cary R. Boyd-Shiwarski, Roderick J. Tan, Michael J. Jurczak, Ora A. Weisz. *University of Pittsburgh, Pittsburgh, PA.*

Background: Megalin (*Lrp2*) is a multiligand receptor that plays a crucial role in maintaining endocytic flux in the kidney proximal tubule (PT). Knockout (KO) or disabled function of megalin is protective against nephrotoxicity, though the mechanism(s) are unknown. We previously found that KO of *Lrp2* in opossum kidney cells and mice reduces transcription of sodium-glucose cotransporter-2 (*Sglt2*). Because *Sglt2* inhibition attenuates hyperglycemia in diabetic patients and protects against kidney disease in non-diabetic patients, we compared metabolic and renal function in male and female wild type (WT) and *Lrp2* KO mice fed regular chow (RC) or Western diets (WD).

Methods: Sixteen-week-old WT or *Lrp2* KO mice on RC were administered glucose tolerance tests (GTT) and then placed in metabolic cages for 48 h. The mice were tested again after 6 weeks on WD. Spot urine samples were also collected. Urine, tissue, and blood samples were collected at sacrifice for analysis.

Results: Male and female *Lrp2* KO mice on RC and WD had increased glucose tolerance compared to WT mice. *Lrp2* KO mice also consumed more water and had increased activity. Respiratory exchange ratio (RER) data suggests a difference in fatty acid oxidation between genotypes. These features persist in male and female *Lrp2* KO mice fed WD, and both gained far less fat mass than their WT counterparts. Strikingly, whereas female *Lrp2* KO mice had normal blood electrolyte, BUN, and creatinine levels, these values suggested kidney injury in male *Lrp2* KO mice on WD. Histology and qPCR analyses confirmed that *Lrp2* KO male mice exhibited significant kidney injury.

Conclusions: *Lrp2* KO mice had increased glucose tolerance, water consumption, and RER compared to WT mice. This phenotype is similar to those of *Sglt2* KO mice or WT mice treated with Sglt2 inhibitors. Remarkably, these features persist following WD in both female and male *Lrp2* KO mice, despite male mice exhibiting significant kidney disease. These results suggest that the protective effects of *Lrp2* KO are independent of kidney injury. Further studies are underway to understand how megalin regulates PT function in a high-fat environment.

Farnesoid X Receptor Agonism Prevents Neutrophil Extracellular Traps via Reduced Sphingosine-1-Phosphate in CKD

Bryce A. Jones,[1] Komuraiah Myakala,[1] Mahilan Guha,[1] Shania R. Davidson,[3,1] Sharmila Adapa,[1] Isabel Lopez Santiago,[1,2] Isabel Schaffer,[1] Xiaoxin Wang,[1] Avi Z. Rosenberg,[2] Moshe Levi.[1] *[1]Georgetown University Medical Center, Washington, DC; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Howard University College of Arts and Sciences, Washington, DC.*

Background: Activation of the farnesoid X receptor (FXR) reduces renal inflammation, but the underlying mechanisms remain elusive. Neutrophil extracellular traps (NETs) are webs of DNA formed when neutrophils undergo specialized programmed cell death (NETosis). Sphingosine-1-phosphate (S1P) is a signaling lipid that stimulates NETosis via its receptor on neutrophils. Here, we identify FXR as a negative regulator of kidney NETosis via repressing S1P signaling in male but not female mice.

Methods: We determined the effects of the FXR agonist obeticholic acid (OCA) in mouse models of adenosine phosphoribosyltransferase deficiency and Alport syndrome. We assessed renal NETosis by immunofluorescence in these models and in biopsies from patients with Alport syndrome (6 male, 9 female). We also inhibited de novo sphingosine production in Alport mice to show a causal relationship between S1P signaling and renal NETosis.

Results: Renal FXR activity is greatly reduced in both models, and OCA prevents kidney fibrosis, inflammation, and lipotoxicity. OCA reduces renal neutrophilic inflammation and NETosis in male adenine and Alport mice, but not in female adenine mice. Extensive NETosis was also identified in human Alport kidney biopsies. Kidney sphingosine kinase 1 (Sphk1) expression is increased in mice with kidney disease and reduced by OCA in male but not female mice. Also, Sphk1 expression correlates with NETosis in male but not female mice. Short-term inhibition of sphingosine synthesis reduces neutrophilic inflammation and NETosis.

Conclusions: FXR agonism represses kidney Sphk1 expression in male but not female mice. This inhibits renal S1P signaling, thereby reducing neutrophilic inflammation and NETosis in a sex-dependent manner.

Lactobacillus acidophilus KBL409 Protects Against Kidney Injury via Improving Mitochondrial Function with CKD

Jaejin Ryu,[1,2] Ki heon Nam,[3] Boyoung Nam,[1,2] Gyu R. Kim,[1,2] Ye Eun Ko,[1,2] Hyung Woo Kim,[1,2] Jung Tak Park,[1,2] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Seung Hyeok Han.[1,2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Institute of Kidney Disease Research, College of Medicine, Yonsei University, Seoul, Republic of Korea; [3]Division of Integrated Medicine, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea.*

Background: Recent advances have led to greater recognition of the role of mitochondrial dysfunction in the pathogenesis of chronic kidney disease (CKD). There has been evidence that CKD is also associated with dysbiosis. Animal studies have shown that dysregulated gut microbiota can alter mitochondria metabolism of intestinal mucosa cells, leading to mitochondrial dysfunction. Here, we aimed to evaluate whether probiotic supplements can have protective effects against kidney injury via improving mitochondrial function.

Methods: KBL409 was selected because this strain was proved to maintain intestinal integrity and reduce p-cresyl sulfate level *in vitro* in prior experiments. An animal model of CKD was induced by feeding C57BL/6 mice a diet containing 0.2% adenine. KBL409, a strain of *Lactobacillus acidophilus*, was administered via oral gavage at a dose of 1×10^9 CFU daily. We isolated primary mouse TECs and treated them with TGF-β (10 ng/ml) or p-cresyl sulfate (0.5mM) and sodium butyrate (10μM), a short-chain fatty acid that is considered the end products of commensal bacteria.

Results: There were prominent structural alterations in CKD mice and KBL409 administration significantly attenuated renal fibrosis. Transcript and protein expression levels of PGC-1α, a key regulator of mitochondrial biogenesis, were significantly decreased in CKD mice, which were restored by KBL409. There were concomitant changes in mitochondrial content and mitochondrial dynamic-related proteins in response to KBL409. In addition, mice with KBL administration showed improvement in fatty acid oxidation defect and mitochondrial structure compared with CKD mice. *In vitro*, TGF-β or p-cresyl sulfate treatment in TECs recapitulated the findings of *in vivo* study and these alterations were reversed by butyrate administration. Mitochondrial function assay showed that butyrate significantly improved mitochondrial respiration, fatty acid oxidation defect, oxidative phosphorylation, and ATP production in TGF-β- or p-cresyl sulfate-treated TECs.

Conclusions: This study demonstrates that administration of the probiotic *Lactobacillus acidophilus* KBL409 protects against kidney injury via improving mitochondrial function.

N-Acetylcysteine Ameliorates Hematuria-Associated Tubulointerstitial Injury in 5/6 Nephrectomy Mice

Sergey V. Brodsky,[1] Ajay Kumar Medipally,[1] Min Xiao,[1] Laura Biederman,[1,2] Alana Dasgupta,[1] Galina Mikhalina,[3] Anjali A. Satoskar.[1] *[1]The Ohio State University, Columbus, OH; [2]Nationwide Children's Hospital, Columbus, OH; [3]Rochester Regional Health, Rochester, NY.*

Background: Chronic kidney disease (CKD) is characterized by increased interstitial fibrosis and tubular atrophy (IFTA) in the kidney. Chronic hematuria is a hallmark of several human kidney diseases and often is seen in patients on anticoagulation therapy. We had previously demonstrated that chronic hematuria associated with warfarin increases IFTA in 5/6 nephrectomy (5/6NE) rats, and such treatment increases reactive oxygen species (ROS) in the kidney. The goal of this study was to evaluate the effects of the antioxidant N-acetylcysteine (NAC) on the progression of IFTA in 5/6NE mice.

Methods: 5/6NE C57BL/6 and 5/6NE 129S1/SvImJ mice were treated with warfarin alone or with warfarin and NAC for 23 weeks. Serum creatinine SCr), hematuria, blood pressure (BP), and ROSs in the kidney were measured; kidney morphology was also evaluated. Warfarin doses were titrated to achieve prothrombin time (PT) increase to the levels seen with therapeutic human doses.

Results: Warfarin treatment resulted in an increased SCr, systolic BP, hematuria (Figure 1), and ROS in the kidney in both mouse strains. IFTA was increased as compared with control 5/6NE mice, and this increase in IFTA was more prominent in 129S1/SvImJ than in C57BL/6 mice. NAC ameliorated the warfarin-associated increase in SCr and BP but not hematuria. IFTA and ROS in the kidney were reduced in mice treated with NAC and warfarin as compared to mice treated with warfarin alone.

Conclusions: NAC mitigates the increase in SCr and IFTA in mice with chronic hematuria by reducing oxidative stress in the kidney. This data open novel possibilities for treatments in CKD patients.

Funding: NIDDK Support

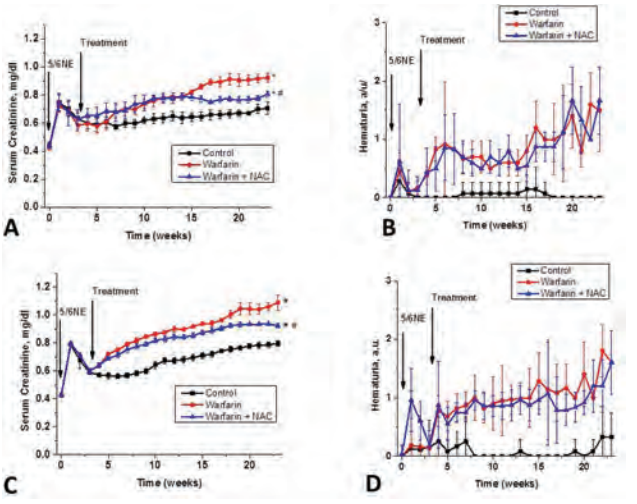

Figure 1. Changes in serum creatinine and hematuria in mice treated with NAC and warfarin.

Glucagon Agonism Protects the Kidney from Obesity by Restoring Peroxisomal Catalase and Fatty Acid Oxidation Capacity

Ross T. Lindsay,[1] Rhianna C. Laker,[4] Benji M. Gill,[4] Zhen Yan,[2] Martin R. Larsen,[3] Christopher J. Rhodes.[4] *[1]AstraZeneca R&D Cambridge, Cambridge, United Kingdom; [2]Virginia Polytechnic Institute and State University, Roanoke, VA; [3]Syddansk Universitet, Odense, Denmark; [4]AstraZeneca R&D Gaithersburg, Gaithersburg, MD.*

Background: Obesity challenges the nephron through fatty acid overload, leading to impaired energy metabolism and impaired renal filtration. Glucagon agonism elicits well described enhancement of fatty acid oxidation and mitochondrial rejuvenation in the liver and other organs, and was hypothesised here to protect the kidney from obesity-related pathology.

Methods: Sprague Dawley rats fed HFHS (DIO) or chow diet for 10 weeks were administered 10nmol/kg lipidated glucagon receptor agonist g1437 daily for seven days. IF was used to visualise the distribution and morphology of peroxisomes and mitochondria across the kidney, alongside the organelle content of key metabolic and ROS handling enzymes. Primary human PTECs transfected with either MitoTimer or with a novel peroxisomal ROS sensor were cultured with and without linoleic/oleic acid for 72 hours alongside 100 nM g1437 or vehicle. To interrogate the underlying signalling mechanism of glucagon, cortex and medulla from mice acutely administered 10nmol/kg g1437 were analysed by phosphoproteomics.

Results: Kidneys of DIO rats demonstrated peroxisomal proliferation and altered mitochondrial morphology. Glucagon agonism also induced mitochondrial and peroxisomal morphological changes. Peroxisomal catalase and FAO enzyme content was perturbed in kidneys of DIO relative to chow fed rats. Concomitantly with weight loss, renal peroxisomal and mitochondrial FAO enzyme content was partially restored in g1437 administered rats. Primary human PTECs cultured with 150 μM linoleic/oleic acid mixture for 72 hours demonstrated greater mitochondrial and peroxisomal reactive oxygen species generation than controls. Phosphoproteomics determined that catalase was 1.48-fold more phosphorylated in kidney cortex of mice acutely administered g1437, a phosphorylation shown to enhance catalase activity. Peroxisomal fatty acid oxidation biogenesis were pathways significantly phosphorylated as part of the glucagon signalling cascade.

Conclusions: Obesity and fatty acid overload led to fission of renal mitochondria and peroxisomes, alongside increased capacity for ROS production and FAO. Glucagon agonism did not reverse changes in organelle morphology, yet enhanced FAO capacity and lowered ROS production capacity, possibly through catalase phosphorylation.

Proximal Tubular FHL2 Mediates Obesity-Induced Renal Tubulointerstitial Inflammation via Regulating FoxO1 Activity

Yan Wang, Weichun He. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Lipid accumulation caused by fatty acid β-oxidation deficiency in renal proximal tubular cells (PTCs) is a major factor triggering obesity-related chronic kidney disease (OR-CKD), and the low activity of forkhead box class O1 (FoxO1) is a key mediator between metabolic abnormalities and cellular damage. It was reported that four and a half LIM domain-only protein 2 (FHL2) could inhibit FoxO1 activity in prostate cancer cells. However, the potential effect of FHL2 on FoxO1 activity and lipid toxicity injury in PTCs during OR-CKD remains to be elucidated.

Methods: Mice with PTCs-specific deletion of FHL2 were generated by mating FHL2-floxed mice with Ggt1-Cre transgenic mice. The expression and function of FHL2 were examined in palmitate acid (PA)-stimulated NRK-52E cells (rat PTCs) and in the kidneys from mice with obesity induced by high-fat diet, respectively.

Results: PA induced FHL2 expression in a time- or dose-dependent manner in cultured NRK-52E cells. Knockdown of FHL2 via small interfering RNA largely suppressed PA-induced mRNA expression of several inflammatory factors including interleukin-6, monocyte chemoattractant protein-1, and tumor necrosis factor α (TNFα). *In vivo*, FHL2 was induced in renal PTCs in the obesity mice at 16 weeks after feeding on high-fat diet. Compared with wild-type littermates, the kidneys from mice with PTCs-specific ablation of FHL2 exhibited less interstitial inflammation, lower levels of urinary neutropil gelatinase-associated lipocalin, and lower urinary albumin-creatinine ratio. *In vitro*, PA induced FHL2 physically interact with FoxO1 in the nuclei. Treatment with PA resulted in a decrease in FoxO1 activity, which was evidenced by an increase in the phosphorylation (Ser256) of FoxO1 and a decrease in the abundance of FoxO1 in the nuclei. Knockdown of FHL2 inhibited the phosphorylation (Ser256) of FoxO1 in cells treated with PA, whereas ectopic expression of FHL2 promoted the phosphorylation (Ser256) of FoxO1. In addition, ChIP assay revealed that TNFα-induced protein 1 (TNFAIP1), an inhibitor of NF-κB signaling, was a putative downstream target gene of FoxO1.

Conclusions: Our results suggest that FHL2, via regulating FoxO1 activity, plays a crucial role in mediating PA-induced inflammatory reaction in PTCs and contributes to tubulointerstitial inflammation and kidney damage resulted from obesity.

Renal Microvascular Inflammation in Human Obesity Detected by Urinary Extracellular Vesicles

Mina H. Al Saeedi, Kyra L. Jordan, Xiang yang Zhu, Alfonso Eirin, Lilach O. Lerman. *Mayo Clinic Research Rochester, Rochester, MN*.

Background: Obesity is characterized by systemic inflammation and activation of the inflammatory marker monocyte chemoattractant protein (MCP)-1, but the involvement of inflammation in early renal injury is unclear. Plasmalemmal vesicle-associated protein (PLVAP), a marker of renal peritubular capillaries, is upregulated in diabetes. We hypothesized that human obesity induces renal microvascular inflammation detectable by elevated levels of PLVAP+/MCP-1+ urinary extracellular vesicles (uEVs).

Methods: Obese patients (OB, n=6) and healthy volunteers (HV, n=7) were prospectively enrolled. Blood and urine were collected, and uEVs were isolated (Total Exosome). uEVs were quantified (Nanoparticle Tracking Analysis) and characterized (Flow cytometry) for CD31, PLVAP, CD144 (expressed on glomerular endothelium), and MCP-1, and their relationship with body mass index (BMI) and serum glucose levels was evaluated.

Results: OB had significantly higher BMI than HV, but both groups showed preserved renal function and glucose levels (Table-1), and a similar number and size of uEV. However, the fraction of CD31-/PLVAP+/CD144-/MCP-1+ was higher in OB and directly correlated with both glucose levels and BMI in OB but not in HV (Figure-1).

Conclusions: Non-diabetic obese patients show elevated numbers of PLVAP+/MCP-1+ uEVs that correlate with BMI and glucose levels. These early markers of renal microvascular inflammation that herald the development of pre-diabetes might be useful in the management of patients with obesity.

Insulin Resistance and Intermuscular Adipose Tissue (IMAT) in Patients with CKD

Ragibe Gulsah Dilaver,[1] Baback Roshanravan,[2] Talat Alp Ikizler,[1] Jorge Gamboa.[3] *[1]Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN; [2]University of California Davis, Division of Nephrology, Sacramento, CA; [3]Vanderbilt University Medical Center, Division of Clinical Pharmacology, Nashville, TN*.

Background: Insulin resistance (IR) is commonly observed in CKD and plays a critical role in protein energy wasting (PEW). We have found that patients with moderate to advanced CKD have increased IMAT accumulation. In this study, we hypothesized that the extent of IMAT is associated with homeostatic model assessment of insulin resistance (HOMA-IR), a measure of insulin resistance and systemic inflammation

Methods: In this cross-sectional study, we included 46 patients (21 control, 25 with CKD stage 3-5). Anthropometry, inflammatory biomarkers, and HOMA-IR) were measured in all participants. Quadriceps IMAT was analyzed with magnetic resonance imaging (MRI) of the thigh.

Results: The control and CKD groups were matched by gender and body mass index. There was no difference in HOMA-IR, glucose, or insulin levels between the groups. Quadriceps IMAT accumulation was higher in patients with Stage 3-5 CKD compared to the control group (**Figure 1A**). Higher insulin resistance was associated with greater IMAT accumulation (rho=0.55, p<0.001, **Figure 1B**). Greater IMAT accumulation was associated with increased levels of tumor necrosis factor-alpha (TNFα) (rho=0.16, p=0.005, **Figure 1C**).

Conclusions: In patients with stage 3-5 CKD, there is greater accumulation of IMAT that associates with insulin resistance and increased TNFα levels compared to controls. IMAT accumulation may contribute to skeletal muscle insulin resistance by promoting a local inflammatory milieu. Further studies should evaluate if IMAT reduction may improve insulin sensitivity in CKD.

High-Fat Diet Changes Lipid Profiles and Induces Podocyte Injury in Unilateral Kidney Model: Targeted Lipidomic and Kidney Podocyte-Specific Analysis

You-Jin Kim,[1] Sehyun Oh,[1] Eun-Joo Oh,[2] Ju-Min Yook,[2] Ji-Sun Ahn,[2] Jeong-Hoon Lim,[1,2] Jang-Hee Cho,[1,2] Chan-Duck Kim,[1,2] Sun-Hee Park,[1,2] Yong-Lim Kim.[1,2] *[1]Kyungpook National University, Daegu, Republic of Korea; [2]Kyungpook National University Hospital, Daegu, Republic of Korea*.

Background: We investigated that high fat diet changes lipidomic profiles and dysregulated lipid metabolism induces podocyte injury in unilateral nephrectomized mouse model using targeted lipidomics analysis and podocyte specific analysis.

Methods: Mice were randomized to undergo unilateral nephrectomy and fed standard or high-fat diets for 13 weeks. There were four groups; normal diet (ND), high-fat diet (HD), normal diet and received uninephrectomy (NDU), and high-fat diet and received uninephrectomy (HDU). After 13 weeks, lipidomics analysis was performed in podocytes isolated from the kidney. In vitro, CIHP-1 cells were treated with cholesterol ester for 24 hours.

Results: A high-fat diet accompanied by unilateral kidneys accelerated the increase in podocyte lipid droplets, glomerular size and tubular cell vacuole formation, resulting in deterioration of renal function. HDU showed different lipidomics profiles compared to other groups. Specifically cholesterol ester (CE), the CE20:4, increased significantly in HDU. Expressions of nuclear receptors, ABCA1, and CPT1A related to lipid metabolism decreased in the HDU and CIHP-1 cells treated with CE 20:4. Transmission electron microscopy confirmed loss of mitochondrial cristae, morphological changes and increased autophagosome formation in the HDU. In addition, reduction of NRF1/2 and increase of DRP1 were confirmed in HDU. In CIHP-1 cells stimulated with CE20:4, proteins related to mitochondrial, such as NRF1/2, PGC1-α, and PDK4 decreased, and mitochondrial fission was increased. Expressions of Beclin-1 and P62 were significantly increased in the HDU and CIHP-1 cells treated with CE 20:4. Kidney injury by such abnormal lipid metabolism induced renal fibrosis in the HDU.

Conclusions: High-fat diet increases lipid accumulation and lipid toxicity in podocytes induced renal structural and functional damage in the unilateral kidney model. In addition, lipotoxicity reduces mitochondria biogenesis, increases fission of mitochondria and increases incomplete action of autophagy.

Bariatric Surgery: Benefits that May Harm, a Cause of Rapid Deterioration of Kidney Function

Enrique F. Morales Lopez, Juan D. Diaz Garcia, Ydris Z. Rosillo-Salgado, Martin B. Yama Estrella, Francisco J. Hernandez Copca, Francisco Velasco Garcia Lascurain, Jose L. Ortega, Victor M. Ulloa Galvan, Mario Alamilla-Sanchez, Guillermo E. Ramírez Garcia, Irving G. Ramirez. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico*.

Introduction: Secondary hyperoxaluria in post-bariatric surgery patients is well documented. The en y de roux and gastric band bypass techniques are the most closely related. A frequent complication is renal lithiasis with progressive loss of renal function.

Case Description: 63-year-old female, history of gastric bypass due to morbid obesity (150 to 90 kg), DM 2 difficult to control. He was admitted to nephrology due to rapidly progressive deterioration of function, basal creatinine 1.12 mg/dl, on admission with 4.5 mg/dl, C3 49 mg/dl, C4 17 mg/dl (low) ANA 1:80. Renal biopsy: with 2 silver + acellular nodules, interstitium with patches of fibrosis and tubular atrophy, infiltrate of lymphocytes, polymorphonuclear cells, and eosinophils. Birefringent intratubular calcifications, loss of brush border. negative IFI

Discussion: Lithogenicity from bariatric surgery is multifactorial with mechanisms: (1) calcium saponification as a result of fat malabsorption reduces calcium-oxalate binding. (2) Increased bile salts in the colon (as a result of their decreased absorption in proximal portions of the intestine) increased mucosal permeability to oxalate (3) reduced colonization by oxalobacter formigenes, especially with the use of beta-lactams. **Conclusions:** serum and urinary metabolic screening of patients after bariatric surgery would allow an increase in the early detection of patients at high risk of enteric hyperoxaluria. once the lithiasic disease is detected, dietary adjustments and avoiding the indiscriminate use of antibiotics are essential to prevent the progressive deterioration of renal function.

FR-PO1013

Endoplasmic Reticulum (ER) and Mitochondrial Stress Markers of Heavy Metals Exposure in the CRIC Study

Justin T. Baca,[1] Robert M. Taylor,[1] V. Shane Pankratz,[1] Wei Yang,[2] Xue Wang,[2] Mark L. Unruh,[1] Vallabh O. Shah.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) is a progressive disease that affects ~13% of the population. Heavy metal (HM) exposure contributes to the rapid progression of kidney disease due to persistent stress stimuli that lead to dysregulation of inflammatory and oxidative stress pathways. Our hypothesis is that cumulative exposure to metals increases progression of CKD via inflammation and oxidative stress.

Methods: We obtained matching nail samples (n=40) from 20 participants of the Chronic Renal Insufficiency Cohort (CRIC) at baseline (n=20) and 24-month follow-up (n=20). An equal number of subjects had fast progressing disease (n=10) and stable disease (n=10). Samples were a random pick of all available samples and were sent anonymized prior to analysis. We quantified twenty-five metalloids in the nail samples using Inductively Coupled Plasma Mass Spectrometry (ICP/MS). Mercury was measured on a Flow Injector Mercury System (FIMS), and boron with ICP/Optical Emission Spectroscopy (ICP/OES). Biochemical markers were measured at the CRIC Scientific and Data Coordinating Center (SDCC) using commercial kits.

Results: Marker concentrations at baseline and follow-up are shown for the fast progressing and stable progression cohorts.

Conclusions: Although not significant, in the fast-progressing disease cohort, ATF, VAR6, and PERK were all increased while GRP78, Caspase 12, and mitofilin were all decreased at follow-up. In the stable cohort, all markers were increased at follow-up with the exceptions of mitofilin (decreased) and PERK (unchanged). Increased ER and mitochondrial stress markers showed a trend towards higher metal burden.

Funding: NIDDK Support

Marker	Pathway	Fast Progression		Stable Progression	
		Baseline	Follow-up	Baseline	Follow-up
GRP78	ER Stress	0.245 ± 0.133 ng/mL	0.159 ± 0.140 ng/mL	0.174 ± 0.108 ng/mL	0.411 ± 0.581 ng/mL
ATF6	ER Stress	0.089 ± 0.148 ng/mL	0.330 ± 0.676 ng/mL	0.130 ± 0.187 ng/mL	0.250 ± 0.252 ng/mL
caspase 12	ER Stress	607 ± 244 pg/mL	453 ± 271 pg/mL	453 ± 201 pg/mL	523 ± 426 pg/mL
VAR6	ER Stress	3.34 ± 2.14	4.90 ± 4.97	4.88 ± 6.00	5.43 ± 5.36
PERK	ER Stress	648 ± 261 pg/mL	711 ± 507 pg/mL	646 ± 341 pg/mL	645 ± 303 pg/mL
mitofilin	Mitochondrial Stress	1.354 ± 0.595 ng/mL	4.731 ± 7.992 ng/mL	3.302 ± 4.514 ng/mL	2.611 ±3.725 ng/mL

FR-PO1014

Heavy Metals Quantification in Nail Samples from the CRIC Study

Robert M. Taylor,[1] Justin T. Baca,[1] V. Shane Pankratz,[1] Wei Yang,[2] Xue Wang,[2] Mark L. Unruh,[1] Vallabh O. Shah.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Chronic kidney disease (CKD) affects >37 million American adults who experience high rates of cardiovascular events, kidney failure, and premature mortality. Recent reports suggest that environmental heavy metal (HM) exposure contributes to the rapid progression of kidney disease. Our overall hypothesis is that cumulative exposure to trace metals increases progression of CKD and higher metal burden will correlate with CKD risk.

Methods: We obtained matching nail samples (n=40) from 20 participants of the Chronic Renal Insufficiency Cohort (CRIC) at baseline (n=20) and 24-month follow-up (n=20). An equal number of subjects had fast progressing disease (EGRF CRIC difference between baseline and follow-up of -1 to 1) (n=10) and stable disease (EGFR CRIC difference between baseline and follow-up <= -10) (n=10). Metal concentrations were analyzed using Inductively Coupled Plasma Mass Spectrometry (ICP/MS). Mercury was measured on a Flow Injector Mercury System (FIMS), and boron was measured using ICP/Optical Emission Spectroscopy (ICP/OES).

Results: We successfully quantified 25 metalloids in all nail samples. Most metalloids had concentrations < 5 μg metalloid / g sample. Aluminum, boron, copper, iron, and zinc had concentrations between 5-80 μg/g. A trend was seen of lower concentrations in the 24-month, compared with the baseline samples. Chromium concentrations in the fast-progressing group were significantly lower at follow up (0.59 ± 0.45 μg/g) versus baseline (2.01 ± 1.64 μg/g) (p=0.036). Average total metal burden (sum of all metal concentrations) across all participants was 520 ± 72 μg/g and 327 ± 40 μg/g for the baseline and 24-month visits, respectively. At baseline, metal burden was 659 ±1006 μg/g and 382 ± 345 μg/g for subjects with fast and slow progressing CKD, respectively. At 2-year follow-up, metal burdens were 313 ± 327 μg/g and 340 ± 415 μg/g, respectively.

Conclusions: All metals we examined were above the limit of detection. Although not significant with a Wilcoxon Rank Sum Test, a trend of higher total metal burden was observed in the rapid progressing cohort, compared with stable progressing cohort.

FR-PO1015

Cosmic Kidney Disease: A Pan-Omic Investigation of the Health Consequence of a Trip to Mars and Back

Keith Siew, Stephen B. Walsh. London Tubular Centre. *University College London, London, United Kingdom*.

Background: Missions into Deep Space are planned this decade. Yet the health consequences of exposure to microgravity and galactic cosmic radiation (GCR) over years-long missions on indispensable visceral organs such as the kidney are largely unexplored.

Methods: We performed biomolecular (epigenomic, transcriptomic, proteomic, epiproteomic, metabolomic, metagenomic), clinical chemistry (electrolytes, endocrinology, biochemistry) and morphometry (histology, 3D imaging, miRNA-ISH, tissue weights) analyses using samples and datasets available from 11 spaceflight-exposed mouse and 5 human, 1 simulated microgravity rat and 4 simulated GCR-exposed mouse missions.

Results: We found that spaceflight induces: 1) renal transporter dephosphorylation which may indicate astronauts' increased risk of nephrolithiasis is in part a primary renal phenomenon rather than solely a secondary consequence of bone loss; 2) remodelling of the nephron that results in expansion of distal convoluted tubule size but loss of overall tubule density; 3) renal damage and dysfunction when exposed to a Mars roundtrip dose-equivalent of simulated GCR.

Conclusions: This study is the largest to ever look at the effect of spaceflight on kidney function. We have demonstrated that there is renal structural and functional remodelling likely caused by microgravity, probably synergistically with GCR. We have shown that this remodelling is a potential driver of kidney stone formation and many of the changes in the urinary biochemistry of humans and animals experienced by those exposed to spaceflight. We have also shown that acute exposure to simulated GCR causes both acute and chronic tubular epithelial and vascular damage that appears both progressive and irreversible

FR-PO1016

Therapeutic Potential of Oxalobacter formigenes in CKD Development and Progression

Xiaozhong Xiong, Nadim Zaidan, Lila Cardozo, Amalya M. Charytan, Melody Ho, Arnav Mishra, Lama Nazzal, Safirya Ambersley. New York Institute of Technology College of Osteopathic Medicine. *NYU Langone Health, New York, NY*.

Background: Cardiovascular events are the leading cause of death in chronic kidney disease (CKD) patients, but the mechanisms are poorly understood. Oxalate retention has been shown to induce systemic fibrosis and inflammation, contributing to CKD progression and cardiovascular complications in renal failure. Hydroxyproline is a common component of meats and a precursor of oxalate. Oxalobacter Formigenes (OxF) is a specialist oxalate degrader in the human intestines. We hypothesize that OxF colonization in CKD mice reduces oxalate levels and attenuates CKD progression and cardiovascular damage.

Methods: Twenty 5/6 nephrectomy (CKD) mice and 20 Sham-operated mice received a 1% hydroxyproline-supplemented diet for five months. 10 CKD and 10 Sham mice received one dose of OxF (1x109 CFU), and the other mice received culture medium as control. Mouse urine and blood were collected at different time points for measuring oxalate and creatine. All mice were sacrificed after five months, and their kidneys and hearts were harvested.

Results: Hydroxyproline supplementation induced kidney damage. Plasma oxalate and creatine level were increased in all mice. OxF treatment reduced plasma oxalate and creatine in both Sham and CKD groups. CKD mice had more severe inflammation and

fibrosis in the kidney than Sham mice. OxF treatment ameliorated inflammation and fibrosis in both Sham and CKD mice. Perivascular fibrosis was found in the heart of CKD mice, but OxF-treated CKD mice displayed less perivascular fibrosis. RNA-seq of heart tissue revealed that the top altered genes and pathways in CKD compared to control mice were related to increased inflammation and fibrosis, decreased lipid metabolism, and increased lipid accumulation. However, OxF treatment reversed those pathways and genes altered in CKD control mice.

Conclusions: Hydroxyproline promoted CKD development and progression, likely through increased oxalate levels. OxF treatment attenuated CKD progression and ameliorated cardiovascular damage.

FR-PO1017

Spatiotemporal Landscape of Kidney Tubular Responses to Glomerular Proteinuria

Anna Faivre,[1] Milica Bugarski,[2] Anna Rinaldi,[3] Thomas Verissimo,[1] David Legouis,[1] Sara Barreiro Correia,[2] Pietro E. Cippa,[3] Sophie M. De Seigneux,[1] Andrew Hall.[2] *[1]Universite de Geneve, Geneve, Switzerland; [2]Universitat Zurich, Zurich, Switzerland; [3]Ospedale Regionale di Lugano, Lugano, Switzerland.*

Background: Large increases in glomerular protein filtration induce major changes in kidney function and body homeostasis, and increase the risk of cardiovascular disease. We investigated how elevated protein exposure modifies the landscape of tubular function along the entire nephron, to better understand the cellular changes that mediate these important clinical phenomena.

Methods: We conducted single nuclei RNA sequencing, functional intravital imaging, and antibody staining to spatially map transport processes along the mouse kidney tubule. We then delineated how these are altered in a transgenic mouse model of inducible glomerular proteinuria (POD-ATTAC) at 7 and 28 days. Results were compared to an ischemic model of tubular injury.

Results: Glomerular proteinuria activates large-scale and pleotropic changes in tubular cell gene expression in all major nephron sections, the majority of which are functional in nature. Extension of protein uptake from the early to late part of the proximal tubule results in a substantial shift in the balance of reabsorptive and secretory processes, and associated metabolic pathways, including lipid metabolism. Meanwhile, overflow of luminal proteins to the distal tubule causes transcriptional convergence between specialized regions and generalized dedifferentiation.

Conclusions: Proteinuria is a potent modulator of cell signaling in tubular epithelia and triggers extensive remodeling, in a segment specific manner. Thus, luminal protein concentration is a critical micro-environmental factor that links glomerular and tubular function in vivo. These findings could explain some of the well-recognized clinical complications that arise in proteinuric kidney disease, and may also be important for understanding nephron patterning in organ development.

FR-PO1018

Urinary Phosphate Contributes to Kidney Injury, Cyst Formation, and Inflammation

Kyle Jansson, Timothy A. Fields, Jason R. Stubbs. *The University of Kansas Medical Center, Kansas City, KS.*

Background: High dietary phosphate intake increases urinary phosphate excretion and has been associated with an increased risk for chronic kidney disease (CKD) progression. We hypothesize that high dietary phosphate hastens CKD progression by stimulating tubular nanocrystal formation, epithelial cell injury, microcyst formation, and inflammation when concentrations of phosphate exceed supersaturation in tubular fluid; however, the mechanisms driving this relationship remain poorly defined.

Methods: First, a mouse model of cystic kidney disease, the *Pkd1*$^{RC/RC}$ mouse, was fed a high versus low phosphate diet and analyzed for changes in kidney cyst growth, mineral deposition, tubular injury, inflammation, and fibrosis. Second, NaPi2a$^{-/-}$ mice, a model of primary urinary phosphate wasting, was evaluated to determine the direct effect of urinary phosphate excretion on mechanisms of kidney injury and inflammation.

Results: *Pkd1*$^{RC/RC}$ mice fed a high phosphate diet exhibited more rapid cyst growth and increased deposition of phosphate-based crystals in their kidneys compared to mice fed a low phosphate diet. Mineral deposits in these kidneys were spatially colocalized with macrophages and osteopontin, a matricellular protein that is critical for maintaining urinary phosphate solubility. Moreover, gene expression for markers of kidney injury, inflammation, and fibrosis were increased in *Pkd1*$^{RC/RC}$ mice on a high phosphate diet. In separate studies utilizing NaPi2a$^{-/-}$ mice, phosphaturic mutants exhibited extensive kidney crystal deposition, reduced kidney function, as well as increased gene expression for markers of kidney injury, inflammation, and fibrosis compared to wild-type controls. Separate analysis of electron microscopy in wild type mice on a high phosphate diet showed interaction of phagocytic cells with kidney mineral deposits.

Conclusions: Increased urinary phosphate excretion directly contributes to tubular injury, kidney cyst growth, inflammation, and fibrosis in CKD. Current evidence suggests a direct interaction between phosphate-based nanocrystals and local inflammatory cells may be a primary contributor to this relationship.

Gut-Derived Uremic Toxins Correlate with Anxiety and Decreased Locomotor Activity in CKD Mice

Yitong Zhao, Han Liu, Joshua J. Jung, Nikitha M. Vancheeswaran, Lily Tran-Phung, Wei Ling Lau. *University of California Irvine, Irvine, CA.*

Background: The altered gut microbiome in chronic kidney disease (CKD) is a source of circulating uremic toxins including p-cresyl sulfate (pCS), indoxyl sulfate (IS), and trimethylamine N-oxide (TMAO). Microbe-derived uremic toxins have been correlated with depression and cognitive impairment in CKD patients. In the current study, continuous subcutaneous infusion of gut-derived toxins was done to evaluate the impact of gut-derived uremic toxins on behavior outcomes in CKD mice.

Methods: Male and female C57Bl/6J mice were randomly assigned to control or CKD groups. Tubulointerstitial nephritis CKD was induced by 0.2% adenine diet. Alzet pumps containing placebo (PBS) or uremic toxins (a mix of pCS, IS and TMAO) were implanted which delivered continuous subcutaneous dosing for 4 weeks. Prior to termination, spontaneous locomotion and anxiety (open field test) and recognition memory (novel object recognition test) were assessed. Serum levels of creatinine and gut-derived uremic toxins were measured. Group means were compared using ANOVA, and correlation analyses were done using Spearman's coefficient (r).

Results: Serum creatinine, pCS, IS, and TMAO were significantly elevated in CKD vs control mice (Table). Toxin infusion in CKD animals (CKD/Toxins) further increased serum pCS and IS compared to CKD/PBS mice in both sexes. Male and female CKD animals demonstrated decreased exploratory behavior (increased anxiety). Higher levels of creatinine, IS and TMAO were significantly associated with anxiety behavior. Infusion of gut-derived toxins did not further increase anxiety behavior compared to PBS (Figure). Recognition memory was not altered in CKD mice.

Conclusions: Gut-derived uremic toxins were significantly correlated with anxiety behavior in CKD mice. However, infusion of toxins did not further worsen behavior scores beyond control vs CKD status.

CKD Induces Endotoxin-Related Activation of the Innate Immune System and Is Associated with Overall Mortality

Björn K. Meijers,[1,2] Sander Dejongh,[1] Mara Lauriola,[1] Pieter Evenepoel,[1,2] Ricard Farre.[1] *[1]Katholieke Universiteit Leuven Groep Biomedische Wetenschappen, Leuven, Belgium; [2]UZ Leuven, Campus Gasthuisberg, Nephrology Unit, Leuven, Belgium.*

Background: Chronic inflammation is associated with poor outcome. The gut-kidney axis is considered an important contributor via the leaky gut. Lipopolysaccharide (LPS) is a pyrogen found in the exterior cell membrane of most gram-negative bacteria. When absorbed through the intestinal epithelium, LPS induces inflammation by activating macrophages and monocytes. Due to short half-life direct quantification of LPS is a poor marker of innate immune system activation. Lipoprotein binding protein (LBP) is an essential component of the innate immune response to LPS. Circulating LBP significantly enhances the sensitivity of CD14+ cells (mostly monocytes and macrophages) to stimulation by LPS. Levels of LBP peak in serum shortly after endotoxemia, and remain increased up to 72 hours later. We hypothesized that CKD increases levels of LBP and is associated with an increased risk of mortality.

Methods: We analyzed plasma LBP (species-specific ELISA, HycultBiotech, The Netherlands) in the Leuven mild-to-moderate CKD cohort (NCT00441623). To study causality, we used animal models of experimentally induced CKD. To exclude model-related bias, two different rat models of CKD, i.e. 5/6th nephrectomy and 0.25% w/w adenine supplementation, were used. We analysed the association between LBP and overall mortality using Cox proportional hazards analysis.

Results: In a cohort of 460 patients with CKD, LBP is significantly inversely correlated with eGFR (p <0,0001; Spearman r: -0,2209). In two different rat models, induction of CKD resulted in a significant increase of LBP. In these animals, we observed a significant inverse association between eGFR (and measured creatinine clearance) and LBP concentrations (P<0.0001). In univariate Cox proportional hazard analysis, plasma LBP was significantly associated with mortality (p <0.01). This association remained significant in multivariate models adjusted for the systematic coronary risk evaluation (score) model.

Conclusions: Patients with CKD have higher levels of LBP. Experimental CKD leads to elevation of LBP, indicative of a causal relationship. Higher LBP associates with increased risk of overall mortality. Combined with functional data on increased gut permeability our data strengthen the hypothesis of the gut-kidney axis as a source of chronic inflammation.

Omega-3 Fatty Acid Modifies the Mitochondrial Membrane Fatty Acid and the Erythrocyte Membrane Fatty Acid in Uremic Rats

Su mi Lee, Won Suk An. *Dong-A University, Busan, Republic of Korea.*

Background: The kidney has the second highest mitochondrial content in the human body. Fatty acids (FAs) are one of the important energy sources and main constituents of cell membranes. Higher erythrocyte membrane oleic acid contents are related to acute coronary syndrome and omega-3 FA can reduce oleic acid contents. We investigated whether omega-3 FA modifies not only erythrocyte membrane FA but also mitochondrial membrane FA of kidney in adenine-induced uremic rats.

Methods: Male Sprague-Dawley rats were fed diets containing 0.75% adenine and 2.5% protein for three weeks. Rats were randomly divided into six groups that were fed diets containing 2.5% protein and saline with cholecalciferol (3000 IU/kg/week) or omega-3 FAs (300 mg/kg/day) with cholecalciferol, and supplemented by gastric gavage for four weeks: normal control, adenine control sacrified at 3 weeks, adenine control sacrified at 5 weeks, adenine control sacrified at 7 weeks, omega-3 FAs group sacrified at 5 weeks, and omega-3 FAs group sacrified at 7 weeks. The mitochondrial isolation membrane was used for renal mitochondrial extraction. The mitochondrial and erythrocyte membrane FA contents were measured by gas chromatography.

Results: Compared to the normal controls, serum creatinine levels in adenine controls were significantly increased and improved in omega-3 FA group. Compared to the adenine controls, erythrocyte and mitochondrial membrane monounsaturated FA contents including oleic acid and arachidonic acid (AA) levels were significantly decreased in omega-3 FA group. FA compositions were similar between erythrocytes and mitochondrial membranes in each group. Monounsaturated FA contents including oleic acid, and eicosapentaenoic acid (EPA) were higher and saturated FA was lower in the mitochondrial membrane than erythrocyte membrane in adenine controls.

Conclusions: Omega-3 FA affects not only erythrocyte membrane FA but also mitochondrial membrane FA in uremic rats. Erythrocyte membrane FA contents can reflect mitochondrial membrane FA contents of the kidney.

Mendelian Randomization of Hypothyroidism and Kidney Function in Veterans

Sebastian Hinojosa, Jefferson L. Triozzi, Guanchao Wang, Otis D. Wilson, Adriana Hung. Million Veteran Program. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Hypothyroidism and chronic kidney disease (CKD) are highly prevalent conditions with a potential mechanistic link. A previous study in women from the WGHS (N 3336) demonstrated an association of hypothyroidism and CKD. We studied the association of genetically predicted hypothyroidism in MVP, a large cohort composed of 93% men (exposure), and kidney function (outcome). The outcomes were creatinine-based GFR and cystatin-based GFR (both log-transformed) from CKDGen. We replicated our findings using two additional genetic datasets for the exposure.

Methods: Two-sample MR was conducted to study the associations between hypothyroidism and kidney function. The primary genetic instrument of the exposure for MR was derived from GWAS of hypothyroidism using data from MVP in 289,307 European American individuals (18,740 cases, 270,567 controls). We repeated the analysis in the FinnGen study (26,064 cases, 59,912 controls) and in UKBB (16,376 cases, 320,783 controls). In MVP and UKBB, the definition of hypothyroidism was based on diagnosis codes, and in FinnGen, on levothyroxine prescription purchases. The outcome was evaluated using summary statistics from GWAS for eGFR from CKDGen for eGFR creatinine (N 133,413) and eGFR-cystatin (N 32,834).

Results: Genetically predicted hypothyroidism demonstrated a causal relation with the risk of lower kidney function. In our primary analysis Cohorts: MVP/CKDGen (beta (SE): -0.009 (0.002), p 0.001). Results were consistent in sensitivity and replication analyses, as shown in **Table 1.** There was no evidence of horizontal pleiotropy.

Conclusions: Our study findings support that hypothyroidism is causally associated with lower kidney function. The mendelian randomization methodology supports a causal relationship and is less susceptible to confounding and reverse causation biases.

Action of 3-Hydroxymethylglutaryl CoA Reductase Inhibitors on ABCA-1 Protein (ATP-Binding Cassette Transporter-1) in Endothelial Cells Stimulated with Uremic Serum

Marcelo C. Batista,[1,2] Beata M. Quinto.[1] [1]*Universidade Federal de Sao Paulo, São Paulo, Brazil;* [2]*Sociedade Beneficente Israelita Brasileira Albert Einstein, Sao Paulo, Brazil.*

Background: High incidence of cardiovascular events in chronic kidney disease (CKD) presents an epidemic character, including patients on predialysis, hemodialysis and post-transplant patients covering about 50% of deaths, with a mortality rate around 9% per year. The statins have been used primarily in the treatment of dyslipidemia and have pleiotropic effects not fully elucidated, as well as, there is no evidence to support its use for attenuation of the cardiovascular outcome and its potential action on ABCA-1 transporter modulation in DRC. Thus, our aim was to verify the effect of statins on ABCA-1 modulation in cells culture of human umbilical vein (HUVEC) incubated with uremic serum from CKD patients.

Methods: Human umbilical cord vein endothelial cells (HUVEC) were pretreated with simvastatin and incubated with uremic serum. All groups were incubated for 24 hours at 37ºC, under ideal conditions of humidity and CO_2 concentration. Expression of LxR α, LxRβ, RxR-α, and ABCA-1 was performed by real-time PCR, the levels of Interleukin 10 and TNF-α in the cell supernatant were measured by enzyme immunoassay, using the ELISA kit. Transfection of HUVEC cells was performed for analysis of promoter activation mediated by LxR and RxR-reporter gene and the expression of LxRβ, RxRα and ABCA1 evaluated by Western Blott.

Results: We demonstrate that statins act on the inflammatory response of HUVEC cells exposed to the uremic environment by decreasing TNF-α secretion when compared to basal secretion. Our results suggest that the uremic environment reduces the expression of LxR-β and RxR-α leading to a consequent decrease in ABCA-1 expression in HUVEC. Pretreatement of endothlial cellwith simvastatin showed increased expression of ABCA-1, LxR-β and RxR-α, as well as the transcription of ABCA-1, LXR-β and RxR-α was significantly increased.

Conclusions: Our results suggests that statins may exert positive modulation on the LxR-β and RxR-α receptors for ABCA-1 transcription activation.

AQP7 as a Novel Marker of p-Cresol-Induced Renal Cell Damage: Beneficial Effects of Hydroxytyrosol and a Polyphenolic Enriched Complex Derived from Olive Oil Mill Wastewater

Ines Angelini, Mariangela Centrone, Mariagrazia D'Agostino, Daniela Semeraro, Maria Mastrodonato, Giusy Rita Caponio, Annarita Di Mise, Marianna Ranieri, Giovanna Valenti, Grazia Tamma. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: *p*-cresol, a gut microbiota-derived uremic toxin, is related to renal injury and Chronic Kidney Disease (CKD). Nevertheless, the molecular mechanisms causing renal damage are still far from being clarified. Here, the actions of *p*-cresol and the beneficial effects of a polyphenolic enriched complex (Momast®) and hydroxytyrosol were evaluated.

Methods: Human proximal tubular kidney cells (HK-2) were used as an experimental cell model. Several cell stress biomarkers were assayed, including Reactive Oxygen Species (ROS) generation and Oil Red O lipid droplets formation. Gene and protein expression was tested by Real Time PCR and Western Blotting.

Results: Exposure of HK-2 cells to *p*-cresol (100 μM for 24 hours) caused a significant increase in ROS content and polymerization of the actin cytoskeleton. Moreover, a significant accumulation in lipid droplets was found as well. Interestingly, Real Time PCR and Western Blotting analysis revealed that *p*-cresol significantly upregulates the expression of the aquaglyceroporin AQP7. Notably, selective inhibition of AQP7 using Z433927330 prevented the *p*-cresol-induced lipid droplets storage. Of interest, the harmful actions induced by *p*-cresol were reversed by treating cells with Momast®, a natural complex derived from olive oil mill wastewater enriched with hydroxytyrosol (HT), which is filtered by the kidney and recovered in the urine. Preliminary data revealed that HT itself also prevents the *p*-cresol-induced AQP7 increase.

Conclusions: Altogether these findings propose for the first time AQP7 as a novel target related to *p*-cresol exposure. Selective inhibition of AQP7 significantly decreased lipid droplets accumulation, which is known to be correlated with renal cell injury. Additionally, treatment with Momast® prevented the effects induced by *p*-cresol. Moreover, obtained data indicate HT as a possible natural coadjuvant to counteract renal cellular injuries induced by *p*-cresol.

Exaggerated Angiotensin II-Induced NF-kB p65 Signaling and Oxidative Stress in GSTM1-Deficient Kidney Primary Tubular Epithelial Cells Is Ameliorated by Hydrogen Sulfide

Luojing Chen, Timothy J. Beane, Yves T. Wang, Ahmed Q. Alnuaimi, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Glutathione S-transferase μ-1 (GSTM1) belongs to the superfamily of GSTs that are phase II antioxidant enzymes regulated by nuclear factor erythroid 2-related factor 2 (Nrf2). In humans, homozygous carriers of the common *GSTM1(0)* null allele are deficient of the enzyme and have increased risks of chronic kidney disease (CKD) progression. Global *Gstm1* knockout (KO) mice have increased renal levels of reactive oxygen species (ROS), inflammation, and kidney injury in angiotensin II (Ang II)-induced hypertension. We previously reported that deletion of *Gstm1* augments Ang II activation of proinflammatory NF-kB p65 signaling pathway in primary tubular epithelial cells (PTECs). Recently, we discovered that GSTM1 modulates the transsulfuration (TSP)-hydrogen sulfide (H_2S) pathway; loss of GSTM1 downregulates H_2S production. GYY4137, an H_2S donor, has been shown to prevent multi-organ damage in disease models. We hypothesize that GYY4137 would ameliorate AngII-induced NF-kB activation and ROS production in *Gstm1* KO PTECs.

Methods: PTECs were isolated from *Gstm1* KO and wild-type (WT) kidneys. Cells were starved for 4 hr, then treated with Ang II (100 nM) and with or without GYY4137 (100 mM) for 24 hr. Cells were stained with anti-NF-kB p65 antibody and assayed for ROS production using ab113851 kit (Abcam). NF-kB p65 nuclear staining was quantified as % of p65 nuclei-positively stained cells to the total cells, with 5 random fields counted (n = 6 mice in each group).

Results: After Ang II treatment, compared to WT, KO PTECs had significantly increased nuclear p65 staining (% p65+ cells: WT 9.8 ± 1, KO 23.8. ± 2.5; p = 0.001), and ROS (1.48 x higher than WT; p = 0.002). Compared to Ang II only, Ang II + GYY4137 significantly decreased p65 nuclear translocation by 4.2% in WT (p = 0.02) and 11.4 % in KO (p=0.003), and ROS generation in both WT(55%, p = 0.002) and KO PTEC (68%, p = 0.001).

Conclusions: Deletion of *Gstm1* augments Ang II induced ROS production and activation of NF-kB in PTECs in an H_2S dependent manner. Targeting the TSP-H2S pathway may be a novel therapeutic approach for CKD in those genetically susceptible.

Antisense Oligonucleotide-Mediated Terminal Intron Retention of Endoglin to Reduce Extracellular Matrix Production in Chronic Allograft Dysfunction

Tessa Gerrits,[1] Roel Bijkerk,[2] Jan A. Bruijn,[1] Marion Scharpfenecker,[1] Hans J. Baelde.[1] *[1]Leiden University Medical Center, Department of Pathology, Leiden, Netherlands; [2]Leiden University Medical Center, Department of Nephrology, Leiden, Netherlands.*

Background: Chronic allograft dysfunction (CAD) is a chronic, progressive, and irreversible process associated with progressive interstitial fibrosis and tubular atrophy. Transforming growth factor-beta (TGF-β) is considered an important cytokine in the development of interstitial fibrosis. The TGF-β co-receptor endoglin *(ENG)* tends to be upregulated in several human organs when chronic damage and fibrosis is present, including the kidney. *ENG* has two membrane bound isoforms occurring by alternative splicing. The long endoglin isoform (l-*ENG)* was previously shown to enhance the extent of renal fibrosis in an UUO mouse model, while the short endoglin isoform (s-*ENG*) inhibited renal fibrosis in this model.

Methods: We isolated mRNA from kidney biopsy material of patients with CAD (n=12) to investigate expression of *ENG* and short endoglin (s-*ENG*). As a control, kidneys that were excluded for transplantation were used (n=6). Furthermore, we designed antisense oligonucleotides (ASOs) to achieve higher levels of s-*ENG* by terminal intron retention of the *ENG* pre-mRNA and transfected these in the human kidney fibroblast cell line TK173.

Results: *ENG* mRNA is 2.3 fold ($p<0.05$) upregulated in the interstitium of patients with CAD compared to mRNA from controls. Interestingly, mRNA levels of s-*ENG* were not upregulated. Therefore, the fraction of s-*ENG* from the total *ENG* mRNA was significantly lower in CAD patients compared to controls (2.4% vs 4.3%; $p<0.05$). We showed that ASOs enhanced the splicing to the short endoglin isoform (2 fold; $p<0.05$). Combining multiple ASOs did not amplify this enhancement. After transfection with various ASOs, the ASO covering the exonic splicing enhancer decreased *CCN2*, *COL1A1* and *FN1* mRNA expression after TGF-β1 stimulation (respectively 20%, 30%, 20%; $p<0.05$).

Conclusions: *ENG* mRNA levels are upregulated in CAD, but s-*ENG* which is suggested to inhibit renal fibrosis, does not increase accordingly. With ASOs targeting *ENG* splicing we were able to alter the *ENG* isoform ratio towards s-*ENG* and reduce TGF-β1 downstream signaling. These results open the way to explore the potential of *ENG* ASOs as a therapy to reduce interstitial fibrosis and thereby slowing down the progression to end stage kidney disease.

FR-PO1027

p300/CBP-Associated Factor (PCAF) Modulates HIF-1 Activity at Multiple Steps

Yu Kurata,[1] Mai Sugahara,[1] Tetsuhiro Tanaka,[2] Masaomi Nangaku.[1] *[1]Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan; [2]Tohoku Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Sendai, Japan.*

Background: Hypoxia-inducible factor (HIF) is a transcription factor that mediates the cellular response to hypoxia. The activity of HIF may be inadequate relative to the degree of hypoxia in patients with chronic kidney disease (CKD), resulting in impaired cellular adaptation to hypoxia. p300/CBP-associated factor (PCAF) is a transcriptional coactivator and has acetyltransferase activity. Recent studies have suggested that PCAF expression is downregulated in patients with end-stage kidney disease (ESKD). We aimed to elucidate the relationship between PCAF and HIF-1 in the kidney.

Methods: We subjected human kidney-2 (HK-2) cells, a human proximal tubular cell line, to hypoxia and examined the association between PCAF and HIF-1 by qPCR, western blotting, microarray analysis, hypoxia-responsive element-luciferase (HRE-luc) reporter assay, and Gal4 responsive element-luciferase (GRE-luc) reporter assay. GRE-luc assay employed a vector encoding Gal4 DNA binding domain (DBD)-HIF-1α transactivation domain (TAD) fusion protein and a GRE-driven luciferase reporter vector.

Results: Knockdown (KD) of PCAF resulted in decreased expression levels of HIF-1α protein and *VEGF* mRNA, one of the major HIF-1 target genes. The HRE-luc assay revealed that PCAF KD reduced HIF-1 transcriptional activity. The GRE-luc assay showed the inhibition of HIF-1α TAD activity by PCAF KD. Overexpression of full-length PCAF upregulated GRE-luc activity, whereas a mutant PCAF lacking the histone acetyltransferase (HAT) domain failed to increase GRE-luc activity, indicating that the HAT domain was necessary for the regulation of HIF-1α TAD activity. Additionally, PCAF KD led to decreased mRNA and protein levels of ARNT, a binding partner of HIF-1α, and inhibited the interaction between HIF-1α and ARNT. Transcriptome analysis using microarray revealed that PCAF KD globally downregulated the expression of hypoxia-inducible genes.

Conclusions: Our findings demonstrate that PCAF modulates HIF-1 activity at multiple steps and serves as a global positive regulator for HIF-1.

Pathophysiology of Hyperoxaluria in SAMP1/YitFc Mice

Nadim Zaidan,[1,2] Melody Ho,[1] Lila Cardozo,[1] Xiaozhong Xiong,[1] Vibha Mital,[1] Ambika Nair,[1] David S. Goldfarb,[1] Lama Nazzal.[1] *[1]NYU Langone Health, New York, NY; [2]Staten Island University Hospital, Staten Island, NY.*

Background: Enteric hyperoxaluria (EH) is postulated to arise from increased oxalate (Ox) bioavailability in the gastrointestinal (GI) tract secondary to fat malabsorption. This could lead to chronic kidney disease progression or recurrent kidney stones. Crohn's disease (CD) is one of the most prevalent conditions causing EH. The SAMP1/YitFc (SAMP1) mouse model develops spontaneous ileal inflammation mimicking human CD pathology. In this ileitis mouse model, we aim to confirm the development of the EH phenotype and explore the different factors underlying EH pathophysiology.

Methods: We compared adult SAMP1 mice and their closest genetic control (AKR mice) on three different fat-containing diets (10%, 45%, and 60%), all supplemented with 1% Ox. Urine (U), plasma (P), and fecal samples were collected during the study and GI segments were harvested at sacrifice at week 5. We measured Ox and creatinine (Cr) levels in the blood and urine. We performed lipidomics assessments of fecal fats to assess malabsorption. Tight junction proteins are important determinants of gut permeability. Occludin and ZO1 were assessed in the ileum using qPCR and Western Blots (WB), respectively.

Results: UOx increased with the percentage of dietary fat, an increase marked in the SAMP1 mice compared with AKR. At sacrifice comparing SAMP1 to AKR, UOx/UCr was 0.40±0.01 vs 0.28±0.01 μmol/mg on 45% fat and 0.45±0.04 vs 0.28±0.02 μmol/mg on 60% fat (both $p<0.0001$). At sacrifice, POx and PCr were higher in SAMP1 mice compared to AKR. The SAMP1 mice had a higher abundance of lipid species in the feces. Specifically, increased amounts of diacylglycerols and free fatty acids in SAMP1 stool samples suggest fat malabsorption. ZO1 and Occludin levels were lower in SAMP1 as compared to AKR mice.

Conclusions: After confirming the EH phenotype, we were able to characterize important factors underlying EH in this model. Decreased TJ in SAMP1's ileum, suggesting increased gut permeability, and a higher bioavailability of Ox arising from fat malabsorption contribute to increased passive Ox reabsorption. Next steps will include exploring the microbiome of these mouse models and characterizing the determinants of kidney injury in these models.

Glutathione Synthesis Contributes to the Formation of Tertiary Lymphoid Tissues in the Kidney

Hiroyuki Arai,[1] Shinya Yamamoto,[1] Takahisa Yoshikawa,[1] Yuki Sugiura,[2] Motoko Yanagita.[1] *[1]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu Jinzo Naikagaku, Kyoto, Japan; [2]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan.*

Background: Tertiary lymphoid tissue (TLT) is an ectopic lymphoid tissue that is induced in non-lymphoid organs by several stimuli such as autoimmunity, aging, and chronic inflammation. TLTs serve as local sites for adaptive immune responses, in which vigorous lymphocyte proliferation and inflammatory cytokine production occur. Unlike the systemic activation of secondary lymphoid tissues, de novo formation of TLTs in local organs may require significant metabolic remodeling to meet the increased demand for metabolic resources both in parenchymal cells and immune cells. However, how renal parenchymal cells and locally recruited immune cells undergo metabolic alterations that support TLT formation remains to be elucidated.

Methods: We employed imaging mass spectrometry and metabolome analysis to investigate the key metabolic pathways that characterize renal TLTs. We also performed in situ hybridization combined with immunofluorescence to investigate the key molecules that govern the metabolic microenvironment of TLTs. Furthermore, we analyzed urine samples from both humans and mice to explore the metabolites that predict the presence of renal TLTs.

Results: Compared to other organs, the kidney contained more cysteine/cystine, a glutathione substrate. Kidneys with TLTs exhibited a significantly higher concentration of glutathione than normal kidneys, and high-level enrichment of glutathione was observed specifically in renal TLTs, highlighting the altered redox homeostasis within TLTs. DCs and fibroblasts within TLTs co-expressed xCT and MRP1, which are essential for external cystine intake and intercellular glutathione transport, respectively. Pharmacological inhibition of xCT prevented renal TLT formation, highlighting the importance of glutathione synthesis in renal TLT formation. Furthermore, enhanced glutathione synthesis in TLTs was reflected in the urinary glutathione concentrations in both mice and humans, indicating that urinary glutathione levels could effectively predict the presence or absence of renal TLTs.

Conclusions: We demonstrated that enhanced glutathione synthesis facilitates TLT formation in the kidney and that urinary glutathione can serve as a biomarker to detect renal TLTs. Immunometabolic interventions may provide new therapeutic strategies for kidney diseases.

DNA Double-Strand Breaks in Proximal Tubular Epithelial Cells Induce a Systemic Lipodystrophy-Like Phenotype

Erina S. Nishimura, Akihito Hishikawa, Ran Nakamichi, Eriko Y. Hama, Kaori Hayashi. Division of Endocrinology, Metabolism and Nephrology, Dept of Internal Medicine. *Keio Gijuku Daigaku Igakubu Daigakuin Igaku Kenkyuka, Shinjuku-ku, Japan.*

Background: We have recently reported that podocyte DNA double strand breaks (DSBs) induce alteration in DNA methylation of CD8 memory T cells which exacerbates severe podocyte injuries (Cell Rep 2023). We next investigated the pathophysical significance of DNA DSBs in PTECs.

Methods: To investigate the significance of DNA double-strand breaks (DSBs) in PTECs, we generated PTEC-specific I-PpoI-expressing mice (I-PpoI mice) which express homing endonuclease I-PpoI inducing non-mutagenic DNA DSBs.

Results: I-PpoI mice showed only mild elevation of tubular markers, but presented weight loss, increased liver free fatty acid content, decreased epidermal fat mass and impaired glucose tolerance at 16 weeks of age, which was consistent with the phenotype of systemic lipodystrophy. Metabolomic analysis showed mitochondrial dysfunction with impaired fatty acid metabolism in kidney cortex and liver. Single-cell RNA seq analysis revealed a marked expansion of inflammatory $Ly6C^{hi}$ monocytes and $Ccr2^{hi}$ $CD11c^{+}$ macrophages in renal cortex of I-PpoI mice, which is reported to play an important role on metabolic derangement in adipocytes and insulin resistance. In vitro analysis of cultured PTECs overexpressing I-PpoI showed mitochondrial dysfunction as observed in I-PpoI mice measured by Seahorse Extracellular Flux Analyzer. In addition, culture medium of PTECs overexpressing I-PpoI caused an activation of macrophages. Next, methylated DNA Immunoprecipitation (MeDIP)-Sequencing of peripheral blood cells in wild type and I-PpoI mice was performed. Interestingly, the motif analysis showed hypomethylated regions in binding sites of KLF9, which is reported to be associated with diabetic complications in humans (Nat Metab 2020). It was also confirmed that downstream genes of KLF9 was hypomethylated, including PFKFB3, which is reported to promote the proliferation and infiltration of inflammatory $Ly6C^{hi}$ monocytes into tissues and its differentiation into macrophages.

Conclusions: DNA damage in PTECs activated a different population of immune cells and caused quite different phenotypes from that in podocytes. PTEC DNA damage causes systemic metabolic alterations, associated with altered DNA methylation in peripheral blood cells.

FR-PO1031

Detection of Cellular Respiration Pattern of Platelets and Peripheral Blood Mononuclear Cells in CKD

Ayesan Rewane. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: Reduced cellular respiration of platelets and increased respiration of peripheral blood mononuclear cells (PBMCs) were reported to be associated with more severe chronic heart diseases. This cellular phenotype remains to be established for patients with chronic kidney disease (CKD).

Methods: The analysis included stage 4 or 5 CKD patients and healthy controls with normal kidney function. The investigation was performed using Oroboros O2K-respirometer on intact and digitonin permeabilized cells. Cellular respiration was measured with a high resolution respirometry. Demographic and medical characteristics of participants including the cellular respiration of platelets and PBMCs were compared using Wilcoxon Rank Sum or Chi-square test.

Results: There were 27 CKD participants and 15 controls; median age (y) was 61 and 56, respectively. Two-third CKD subjects were African Americans and half of them were diabetic. The median GFR was 18 in the CKD group and 90 in the control group. There were no differences in white blood cell count or platelet count between the two groups. There was reduced respiration in the intact CKD platelets and in the permeabilized CKD platelets via Complex I & II of the electron transport chain (ETC). There was increased respiration in the intact CKD PBMCs as well as in the permeabilized CKD PBMCs via complex I & II of ETC.

Conclusions: Cellular respiration is reduced in CKD platelets and is increased in CKD PBMCs. Future studies should explore whether these cellular phenotypes result in a pro-inflammatory CKD state that is associated with worse cardiorenal outcomes.

Alterations in Frequency and Function Exhausted Memory B Cells in Lupus Nephritis and Systemic Lupus Erythematosus

Litong Zhu, Yat Hin Desmond Yap. *Queen Mary Hospital, Hong Kong, Hong Kong.*

Background: Various B cell abnormalities have been implicated in the pathogenesis of LN, and our previous studies have demonstrated that memory B cells assume pathogenic relevance in disease relapse. Exhausted B cell is a B lymphocyte aberration initially reported in HIV infection, and was also observed in autoimmune disorders. The pathogenic roles of exhausted B cells in LN and disease relapse remains unclear.

Methods: Classical memory (CD19+CD21+CD27+) and exhausted B cells (CD19+CD21–CD27–) were measured in LN patients with multiple relapses (MR) (n=12) or no relapse (NR) (n=12) during disease remission. B cell-related cytokines, homing and inhibitory receptors, proliferation and calcium mobilization in classical and exhausted memory B cells were also assessed. Using single-cell RNA sequencing data from NIH and GEO, we also performed bioinformatics analysis to identify genes and pathways relevant to memory and exhausted B cells in SLE, LN and healthy controls.

Results: The MR group exhibited higher proportion of circulating exhausted B cells compared to NR (16.7 ± 9.5% vs 10.5 ± 5.7%, $p < 0.05$). Blood levels of IL-6, BAFF and IL-21 in MR patients were higher than the NR group (75.1 ± 37.2 vs 33.6 ± 14.2 pg/ml; 1491.1 ± 680.9 vs 1120.1 ± 384.1 pg/ml and 23.5 ± 23.0 vs 5.1 ± 3.1 pg/ml respectively; $p<0.05$, for all). The MR had higher blood levels of Siglec-6, CXCR3 and CD62L than the NR group (2.6 ± 0.8 vs 1.3 ± 0.6 ng/ml; 2.3 ± 1.4 vs 1.6 ± 0.8 ng/ml; 3240.9 ± 1002.0 vs 2497.0 ± 671.8 ng/ml respectively, $p<0.05$ for all). Expression of inhibitory receptors CD22, CD85j, CD183 and FCRL4 in exhausted B cells were increased in the MR group compared to the NR group. Exhausted B cells from MR patients also showed decreased proliferation compared to NR patients (1.9 ± 1.1% vs 3.8 ± 1.3%, $p<0.05$) and impaired calcium mobilization in response to B-cell receptor triggering. STAT1, XAF1, MX1, IFI44L, EPSTI1, LCP1, OAS1, NEAT1, IFI16, IFI44 in exhausted B cells and XAF1, MX1, IFI44L in memory B cells play a pathogenic role in LN patients. SLE patient also show increased proportion of exhausted B cells compared to healthy control and the expression of STAT1, XAF1, MX1, IFI44L correlate positively with the proportion of exhausted B cells.

Conclusions: Our results suggested that altered numbers and function of exhausted B cells may have pathogenic significance in SLE and LN.

FR-PO1033

Leukocyte Chemotactic Factor 2 Amyloidosis in an Egyptian Immigrant

Madeline Kirby,[1] Keiko I. Greenberg,[1] Donghyang Kwon.[2] *[1]MedStar Georgetown University Hospital Nephrology Services, Washington, DC; [2]Medstar Georgetown University Hospital Department of Pathology, Washington, DC.*

Introduction: Amyloidosis results from the accumulation of misfolded protein in one or more organs. Over 30 amyloid proteins have been discovered[1]. Identification of the pathogenic amyloid protein is crucial for the management of amyloidosis. Here we present a case of an unexpected cause of amyloidosis.

Case Description: A 69-year-old Egyptian man was referred for evaluation for chronic kidney disease. His history included well-controlled diabetes and hypertension. His creatinine was 1.7 mg/dL, having increased steadily from 0.96 mg/dL five years prior. Urinalysis was bland and urine protein to creatinine ratio was 0.1 g/g. Serologic evaluation was unremarkable except for a monoclonal spike seen on urine protein

electrophoresis. He underwent a kidney biopsy to evaluate for monoclonal gammopathy of renal significance. It showed abundant amyloid deposition in the interstitium; amyloid was also seen in the mesangium and glomerular capillary walls. Mass spectrometry analysis at the Mayo Clinic Laboratories identified the amyloid protein not as an immunoglobulin but as leukocyte chemotactic factor 2 (LECT-2). He does not appear to have LECT-2 amyloidosis (ALECT-2) involvement of other organs. He continues to be managed supportively with an ACE-inhibitor and a SGLT-2 inhibitor. Despite these measures, his creatinine continues to increase by 0.2-0.3mg/dL per year.

Discussion: ALECT-2 was first described in 2008 in an individual with nephrotic syndrome[2]. Nephrotic syndrome has only been found in a minority of cases of ALECT-2 in subsequent series – individuals typically have a bland urine sediment and minimal proteinuria. ALECT-2 commonly affects the kidneys and liver; cardiac involvement appears rare. Its prevalence appears to vary significantly among ethnic groups. In the United States, it has been found most commonly in Hispanic populations, particularly in those of Mexican descent[2]. ALECT-2 is also common in Egypt; in an Egyptian case series, it was the second most common type of renal amyloidosis, accounting for 31% of cases[3]. It is unclear why it is more common in certain populations, although a single nucleotide polymorphism of the LECT2 gene has been found in individuals of Mexican ancestry. Currently, there is no specific treatment for ALECT-2. ALECT-2 is likely underdiagnosed due to the frequent lack of proteinuria. An individual's ancestry may provide a clue toward the diagnosis.

Unveiling the Masquerade: Misdiagnosis of CKD in the Shadow of HIV Treatment

Yariana E. Rodriguez Ortiz, Tariq Shafi, Angelina Edwards. *Houston Methodist Hospital, Houston, TX*.

Introduction: HIV is associated with acute and chronic kidney disease (CKD). The co-existence of CKD with HIV is associated with poor outcomes and limits therapeutic interventions, particularly those that require renal-dose adjustment. Specific antiretroviral therapies (ART) are directly nephrotoxic, leading to low GFR (Glomerular Filtration Rate) and elevated serum creatinine. However, some ART can increase serum creatinine by inhibiting the tubular secretion of creatinine, leading to elevated serum creatinine, erroneous estimation of GFR by eGFR, and a misdiagnosis of CKD. These drugs include non-nucleoside reverse transcriptase inhibitors (NNRTI) such as rilpivirine, HIV integrase inhibitors such as dolutegravir, and pharmacokinetic boosters such as cobicistat. We present a case of mislabeled CKD in the setting of cobicistat use.

Case Description: A 44-year-old man with a history of hypertension, non-insulin-dependent type 2 diabetes, and HIV was referred for evaluation of "CKD," diagnosed due to persistent elevation of serum creatinine. The patient's HIV was well controlled on Genvoya®, ART containing elvitegravir, cobicistat, emtricitabine, and tenofovir. Previous creatinine levels were 1.2, 1.4, and 1.6 mg/dL, in the last 12 months. Recent pre-clinic labs showed a creatinine of 1.48 mg/dL with an eGFR of 59 mL/min/1.73 m2 without albuminuria or hematuria. Renal ultrasound showed preserved renal size and normal anatomy. To obtain an accurate assessment of GFR, we directly measured GFR (mGFR) using plasma clearance of iohexol, a non-radiolabeled contrast agent. The mGFR of 72 mL/min/1.73 m2. Thus, the eGFR calculation was incorrect and mislabeled him as CKD. Cobicistat reduces serum creatinine secretion by reducing proximal tubular creatinine efflux by the SLC47A1 cation transporter.

Discussion: Evolving combination HIV therapies have improved compliance, tolerance, and sustained viral suppression. However, clinicians must be mindful of the impact of ART on the kidney. Our case highlights the false elevation of serum creatinine induced by ART like Genvoya® and the importance of directly measured GFR. Modern methods to measure GFR are simple and easy to implement in outpatient practice. It is essential that nephrologists learn these techniques and use them in clinical practice to prevent misdiagnosis of CKD and avoid further invasive tests, including kidney biopsy.

Finerenone Added to Renin-Angiotensin System (RAS)/SGLT2 Blockade for Non-Diabetic CKD: Results of a Preclinical Randomized Controlled Trial

Zhihui Zhu,[1,2] Yoshihiro Kusunoki,[1] Chenyu Li,[1] Martin Klaus,[1] Peter Boor,[3] Paola Romagnani,[4] Hans J. Anders.[1] *[1]Medizinische Klinik und Poliklinik IV, LMU Klinikum, Munich, Germany; [2]Beijing Anzhen Hospital, Capital Medical University, Beijing, China; [3]RWTH University Hospital Aachen, Aachen, Germany; [4]Department of Biomedical Experimental and Clinical Sciences "Mario Serio", University of Florence, Florence, Italy*.

Background: Dual inhibition of RAS plus SGLT2 or plus MR demonstrated additive renoprotective effects in large clinical trials. We hypothesized that triple therapy with a combination of RAS/SGLT2/MR inhibitors would be superior to dual RAS/SGLT2 blockade in prolonging kidney lifespan.

Methods: We performed a preclinical randomized controlled trial (PCTE0000266) in *Col4a3*-/- Alport mice. Treatment was initiated late (6 weeks of age) in mice with elevated serum creatinine and albuminuria and in presence of glomerulosclerosis, interstitial fibrosis and tubular atrophy. We randomized male and female mice to either nil (vehicle) or late onset food admixes of either monotherapy, ramipril (10 mg/kg) plus empagliflozin (30 mg/kg) or ramipril plus empagliflozin plus finerenone (10 mg/kg). Other control mice received empagliflozin or finerenone monotherapy.

Results: Mean lifespan was 63.7 ± 10.0 days (vehicle), 77.3 ± 5.3 days (ramipril), 70.4 ± 9.2 days (empagliflozin), 71.1 ± 7.1 days (finerenone), 80.3 ± 11.0 days (dual), and 103.1 ± 20.3 days (triple), respectively. Sex did not affect outcome. Histopathology, pathomics, and RNA sequencing revealed significant add-on anti-inflammatory and anti-fibrotic effects on the tubulointerstitial compartment when adding finerenone to dual RAS/SGLT2 inhibition.

Conclusions: This pRCT suggests that triple RAS/SGLT2/MR blockade may significantly prolong uremia-free lifespan significantly in patients with Alport syndrome and possibly other progressive chronic kidney disorders for its synergistic protective effects on the glomerular and tubulointerstitial compartment, respectively.

Protective Effect of Resveratrol on Glycocalyx Loss due to Endothelial Cell Dysfunction in Renal Aging

Injoon Hwang, Donghyuk Kang, Eun Nim Kim, Ji Hee Lim, Hyung Duk Kim, Cheol Whee Park, Bumsoon Choi, Tae Hyun Ban. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Aging had an effect on diminished endothelial glycocalyx caused by various mechanisms, and sirtuin1 (SIRT1) pathway was one of the crucial components of them. As aging process, there was decline in SIRT1 activity with consequent increase in oxidative stress and inflammation, which were known causes of aging. Resveratrol, an SIRT1 activator, may prevent these undesired events by activating SIRT1 pathway. We examined whether resveratrol could improve renal function and prevent from diminishing endothelial glycocalyx caused by aging, and consequently with changes of oxidative stress.

Methods: Male 2-month-old and 18-month-old C57BL/6 mice were divided into three groups: 2-month-old young group, 18-month-old aged control group and 18-month-old aged treatment group. Resveratrol (40 mg/kg) was administered to aged treatment group for 6 months. Renal function, histologic changes and aging-related protein expression, especially with oxidative stress and SIRT1 pathway, were measured. Endothelial glycocalyx was also examined by immunofluorescence staining with WGA.

Results: Compared to young group, aged group showed decreased renal function, increased oxidative stress, progressed renal fibrosis, decreased expression of SIRT1, eNOS and increased expression of iNOS, NF-κB, heparanase which is consistent with

aging process. On the contrary, aged treatment group showed improvement of creatinine clearance and albuminuria which represent renal function. Histologic changes of mesangial proliferation and tubulointerstitial fibrosis were also improved. Expression of SIRT1 protein and eNOS was also increased and expression of iNOS, NF-κB, and heparanase was decreased, which could explain that activation of SIRT1 pathway ameliorate oxidative stress. Endothelial glycocalyx of treatment group was also markedly observed, whereas which of aged group sparsely observed.

Conclusions: These results suggest that the activation of SIRT1 had protective effect against aging-related oxidative stress in mice via SIRT1 pathway and consequently gave a stability in endothelial glycocalyx.

FR-PO1037

The Effect of Ischemia-Reperfusion Injury on Mitochondrial Reduced Glutathione Levels in Kidney Cortex and Medulla from Aging Female Lewis Rats

Marianna J. Zamlauski-Tucker, Bingwei Ye. *Ball State University, Muncie, IN.*

Background: The purpose of the study was to determine the effect of ischemia-reperfusion injury (IRI) on changes in the mitochondrial reduced glutathione (GSH) levels in kidney cortex and medulla from old rats. GSH is the major antioxidant inside cells, and a decrease in GSH levels would result in oxidative stress and damage due to increased generation of free radicals in IRI.

Methods: Anesthetized female Lewis rats (22 months of age) were used. Both renal pedicles were clamped for 60 min, followed by 60 min of reperfusion in the Experimantal Group (n =5). The kidneys were then harvested, separated into cortex and medulla, and homogenized. Kidneys in the Control Sham Group (n=5) were not subjected to IRI before being harvested. The mitochondrial fractions were isolated by differential centrifugation, and GSH levels were measured using a spectrophometric assay. The water contents of the cortex and medulla were determined to allow GSH levels to be expressed as nmol/g kidney dry weight. A Student's T Test was used to compare groups, and statistical significance was determined at $p< 0.05$. All data reported as X ± SEM.

Results: There was a significant 58% decrease in mitochondrial GSH levels in the kidney cortex, from 388 ± 19 nmol/g kidney dry wt in the Control Group to 163 ± 6 nmol/g kidney dry wt in the Experimental Group. There was also a significant 40 % decrease in mitochondrial GSH levels in the kidney medulla, from 531 ± 32 nmol/kidney dry wt in the Control Group to 318 ± 22 nmol/ g kidney dry wt in the Experimental Group.

Conclusions: Mitochondrial GSH levels in rat kidney cortex and medulla did not return to normal levels after one hour of reperfusion following 60 minutes of ischemia. This finding suggests that mitochondria in both the kidney cortex and medulla are experiencing major oxidative stress, and this may be contributing to the renal dysfunction seen in IRI.

FR-PO1038

Age-Related CKD: Roles of Advanced Glycation End Products and Insulin-Like Growth Factor Binding Protein-3

Shing-Hwa Liu, Chih-Kang Chiang, Ting-Yu Chang. *National Taiwan University, Taipei, Taiwan.*

Background: CKD is more prevalent in US adults aged 65 years or older. Advanced glycation end products (AGEs) are highly associated with diabetic nephropathy, and its levels are elevated in individuals with advancing age. A pro-apoptotic effect of insulin-like growth factor binding protein-3 (IGFBP-3) was found in diabetic nephropathy. Blood IGFBP-3 levels increase in CKD patients that is negatively correlated with eGFR. Roles of AGEs and IGFBP-3 in renal senescence and dysfunction during aging process remains unclear that's what we want to investigate.

Methods: A commercial tissue microarray for human normal kidneys from subjects with various ages was used to test the expression of Nε-(1-Carboxymethyl)-L-lysine (CML; an AGEs) and IGFBP-3. Male C57BL/6 mice with the age of 6, 19, 70 and 107 weeks were used. To determine the roles of AGEs and IGFBP-3 in aging kidney, aged mice (70-week-old) were orally administered with aminoguanidine, an inhibitor of AGEs, or injectedly administered with a neutralizing IGFBP-3 antibody.

Results: Both CML and IGFBP-3 protein expression levels in the human kidneys were significantly higher in the elderly (≥ 50 years) than in the young ($p<0.05$, n=24). In naturally aged mice (70- and 107-week-old), the blood renal function markers examination, Periodic acid-Schiff stain, and Masson's trichrome stain showed that there were renal dysfunction, histological changes, and collagen deposition, respectively ($p<0.05$, n=8). The depositions of CML/AGEs and IGFBP-3 were obviously increased in the kidneys of aged mice compared to the young controls ($p<0.05$, n=8). Moreover, the protein expression levels of markers for senescence and fibrosis increased in the kidneys of aged mice ($p<0.05$, n=8). The pathological features, increased CML and IGFBP-3 protein expression, and increased senescence and fibrosis-related markers protein expression in the kidneys of aged mice could be effectively antagonized by AGE inhibitor aminoguanidine treatment ($p<0.05$, n=8). The neutralizing IGFBP-3 antibody treatment could also alleviate the pathological features and fibrosis in the kidneys of aged mice ($p<0.05$, n=8).

Conclusions: These findings demonstrated that both AGEs and IGFBP-3 played the roles in age-related CKD. An AGEs-regulated IGFBP-3 signaling pathway may contribute to the renal dysfunction and injury during natural aging process.

FR-PO1039

Aldehyde Dehydrogenase 2 Interacts with PHB2 to Alleviate Renal Fibrosis and Ferroptosis in a Mitochondria-Dependent Manner

Jiaying Li, Jiatong Xu, Xiaoxiao Shi, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: We recently proved the protective role of acetaldehyde dehydrogenase 2 (ALDH2) in acute kidney injury (AKI). In this study, we aimed to investigate the impact of ALDH2 on renal fibrosis in regulating ferroptosis in a mitochondria-dependent manner.

Methods: Renal fibrosis model was established by unilateral ureteral obstruction (UUO) in C57BLmice, followed by injection of Alda-1 (an ALDH2 agonist) on the first postoperative day and continued for 14 days until mice were sacrificed. We assessed renal fibrosis, ferroptosis, and mitochondrial function in vivo and in vitro using RSL-3 (a ferroptosis-inducing agent) in human renal proximal tubular epithelial (HK-2) cells, with or without Alda-1 (20μm). Furthermore, we identified the potential targets of ALDH2 in regulating ferroptosis and mitochondrial dysfunction by mass spectrometry screening and co-immunoprecipitation assays, then explored the role of ALDH2 on different cell types by single-cell RNA sequencing.

Results: ALDH2 protein was reduced by 64% in UUO mice accompanied by renal interstitial fibrosis. ALDH2 agonist Alda-1 alleviated renal interstitial fibrosis, as confirmed by Masson staining and the decreased expression of α-SMA and collagen 1. Ferroptosis was initiated during UUO-induced renal fibrosis, while Alda-1 inhibited ferroptosis, indicated by reduced malonaldehyde (MDA) (1.60±0.10 versus 0.66±0.08 nmol/mg, $P<0.001$) and elevated GSH/GSSH ratio (1.42±0.32 versus 6.80±0.84, $P<0.05$). In addition, decreased mitochondrial-related proteins (PGC-1α and ATP5a1) were observed in UUO mice but reversed by Alda-1 treatment. In HK-2 cells, ALDH2 improved RSL-3-induced ferroptosis, fibrosis, and mitochondrial dysfunction. Mechanistically, mass spectrometry screening and co-immunoprecipitation assays revealed the interaction of ALDH2 with prohibitin 2 (PHB2), a crucial mitophagy receptor and ferroptosis inhibition target. Immunofluorescence staining revealed the co-localization of ALDH2 and PHB2, and Alda-1 facilitated PHB2 recruitment into mitochondria from the cytoplasm.

Conclusions: ALDH2 might be a promising therapeutic target in alleviating renal fibrosis and ferroptosis by interacting with PHB2 to facilitate their mitochondrial translocation.

FR-PO1040

Acyloxyacyl Hydrolase Protects Against Kidney Injury via Inhibition of Tubular CD74-Macrophage Cross-Talk

Zhenkai Wu, Yu Pan, Feng Ding. *Shanghai Jiao Tong University School of Medicine Affiliated Ninth People's Hospital, Shanghai, China.*

Background: Renal tubulointerstitial fibrosis is the final common pathway in the progression of chronic kidney disease (CKD) to end-stage renal disease (ESRD). Acyloxyacyl hydrolase (AOAH) is expressed in renal tubular epithelial cells and other immune cells. Research shows that AOAH plays a critical role in infections and chronic inflammatory diseases. However, its role in kidney injury and fibrosis is unknown.

Methods: AOAH expression was examined in human and mouse kidneys. Single cell RNA sequencing (scRNA-seq) was performed for kidneys from FA-treated wild type (WT) and *Aoah*$^{-/-}$ mice. *Aoah*$^{-/-}$ mice and *Aoah*$^{-/-}$ mice with overexpression of *Aoah* in kidney were used to determine its role in kidney injury induced by folic acid (FA), unilateral ureteral obstruction (UUO), and lipopolysaccharide (LPS).

Results: AOAH expression was positively correlated with estimated glomerular filtration rate (eGFR) while negatively correlated with the degree of renal fibrosis in human kidney biopsy tissue. AOAH deletion led to exacerbated kidney injury and fibrosis after FA administration, which was reversed by overexpression of *Aoah* in kidney. scRNA-seq analysis revealed that *Aoah*$^{-/-}$ mice exhibited increased subpopulation of proximal tubular epithelial cells (PTECs) expressing CD74, even though total PTECs were decreased compared to WT mice after FA treatment. Finally, exacerbated renal inflammation and fibrosis seen in *Aoah*$^{-/-}$ mice after kidney injury was attenuated via administration of ISO-1, an inhibitor of macrophage inhibition factor (MIF) and CD74 binding.

Conclusions: AOAH plays a protective role in renal inflammation and fibrosis by inhibiting renal tubular epithelial cells CD74 signaling pathways, which involves tubule-macrophage crosstalk. Targeting kidney AOAH represents a promising strategy to prevent renal fibrosis progression.

FR-PO1041

Protective Role of Tubular Interferon Regulatory Factor 5 (IRF5) Against Renal Tubulointerstitial Fibrosis

Mengqiu Wu, Zhanjun Jia, Aihua Zhang. *Children's Hospital of Nanjing Medical University, Nanjing, China*.

Background: Tubulointerstitial fibrosis (TIF) is the inevitable outcome of chronic kidney diseases, regardless of etiology. Interferon regulatory factor 5 (IRF5) is a key transcription factor involved in regulating the expression of proinflammatory cytokine and responses to infection in immune cells, but its role in renal epithelial cells and renal TIF remain unknown.

Methods: Renal biopsies of CKD patients and kidney of unilateral ureteral obstruction (UUO) and unilateral ischemia reperfusion (UIR) mice were used to evaluate the expression pattern of IRF5 in fibrotic kidneys. Then, the function of IRF5 was explored in UUO mice via high-throughput tail vein delivery of IRF5 over-expression plasmids or IRF5 targeting CRISPR/Cas9 plasmids. The TIF was histologically detected by Masson staining; pro-fibrosis gene expressions were evaluated via Western blotting and qRT-PCR techniques. *In vitro*, mouse proximal tubular epithelial cells (mPTCs) were transfected with IRF5 over-expression plasmids and then stimulated with TGF-β1 for phenotype evaluation. IRF5 over-expression mPTCs were also co-cultured with renal interstitial fibroblasts (NRK-49Fs) and macrophage cells (RAW 264.7). Finally, IRF5 overexpressing mPTCs were treated with Smad3 selective inhibitor SIS3 to explore whether the anti-fibrotic effect of IRF5 is Smad3 dependent.

Results: IRF5 was consistently up-regulated in fibrotic kidneys of CKD patients and mice models, dominantly in the tubules. Overexpression of IRF5 markedly alleviated renal TIF, and knocking down of IRF5 significantly aggravated the degree of fibrosis in UUO mice. *In vitro*, overexpression of IRF5 inhibited TGF-β1 induced partial epithelial-mesenchymal transition (p-EMT) of mPTCs. IRF5 over-expression in TGF-β1 induced mPTCs also suppressed the activation of co-cultured NRK-49Fs and RAW 264.7 cells. Mechanic research revealed that IRF5 suppressed fibrotic response possibly by antagonizing TGF-β1/Smad3 signaling.

Conclusions: These findings demonstrated that up-regulation of IRF5 may inhibit p-EMT of tubular epithelial cells via antagonizing TGF-β1/Smad3 signaling. In turn, protected tubular epithelial cells attenuated the activation of interstitial fibroblasts and macrophages and thus attenuate kidney fibrosis. Targeted activation of IRF5 may serve as a potential intervention strategy in retarding CKD progression.

TP53RK in Fibroblasts Drives the Progression of CKD by Phosphorylating Birc5

Mengqiu Wu, Zhanjun Jia, Aihua Zhang. *Children's Hospital of Nanjing Medical University, Nanjing, China*.

Background: Renal fibrosis is a common characteristic of various chronic kidney diseases (CKDs) driving the loss of renal function. During this pathological process, proliferation and activation of interstitial fibroblasts chiefly determine the extent of renal fibrosis. TP53RK is an atypical protein kinase and an important component of the EKC/KEOPS complex. Recently, TP53RK was identified as novel monogenetic cause of Galloway–Mowat syndrome. However, no experimental evidence confirmed the role of TP53RK in CKDs.

Methods: Expression and localization of TP53RK was evaluated in kidneys of CKD patients and mice with unilateral ureteral obstruction (UUO) and unilateral ischemia reperfusion (UIR). Then, the specific function of fibroblast TP53RK in CKD was determined with fibroblast specific TP53RK knockout mice with UUO or UIR and TGF-β1-treated renal interstitial fibroblasts (NRK-49F). Furthermore, co-immunoprecipitation and immunofluorescent staining were applied to determine the co-localization and interaction between TP53RK and Birc5. UUO mice with global Birc5 knockdown were employed to specify the role and downstream mechanism of Birc5 in renal fibrosis. Finally, TP53RK inhibitor fusidic acid and Birc5 specific inhibitor YM-155 were tested in UUO mice to evaluate the translational potential of pharmacological blockade in treating CKD.

Results: P53RK was upregulated in fibrotic human and animal kidneys with a positive correlation to kidney dysfunction and fibrotic markers. Specifically, TP53RK was up-regulated in interstitial fibroblasts of fibrotic kidneys. Fibroblasts specific deletion of TP53RK could mitigate renal fibrosis in UUO and UIR mice models. *In vitro*, knocking down of TP53RK attenuated activation and proliferation of NRK-49F. Mechanistic investigations revealed that TP53RK phosphorylated Birc5 and facilitated its nuclear translocation, which displayed a pro-fibrotic effect possibly via activating PI3K/Akt and MAPK pathways. Moreover, pharmacologically inhibiting TP53RK and Birc5 using fusidic acid and YM-155 respectively both ameliorated kidney fibrosis in UUO mice.

Conclusions: These findings demonstrate that activated TP53RK/Birc5 signaling promotes the proliferation and activation of renal interstitial fibroblasts, thus driving CKD progression. A genetic or pharmacological blockade of this axis serves as a potential strategy for retarding fibrosis in CKD.

Activation of GPER1 in macrophage ameliorates Unilateral Ureteral Obstruction (UUO)-Induced Renal Fibrosis

Xiangchen Gu,[1,2] Lin Xie,[1,2] Ye Cheng,[1,3] Yi Wang,[1] Min Chen.[1] *[1]Shanghai University of Traditional Chinese Medicine Yueyang Hospital of Integrated Traditional Chinese Medicine and Western Medicine, Shanghai, China; [2]Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China; [3]Huashan Hospital Fudan University, Shanghai, China*.

Background: Numerous studies have established the fundamental role of macrophages in the process of renal fibrosis. Interestingly, emerging data suggested that G protein-coupled estrogen receptor 1 (GPER1), a novel estrogen receptor, plays a ubiquitous role in regulating macrophage activities and proinflammatory pathways. However, the precise role of GPER1 in macrophage-mediated renal fibrosis remains unknown.

Methods: First, we pretreated ovariectomized (OVX) female and male mice with G-1 (GPER1 agonist) and subjected them to UUO (Ureteral Unilateral Obstruction) surgeries. And renal fibrosis and M1 and M2 macrophage infiltration were analyzed. Next, using CRISPR/Cas9 gene editing technique, we also generated global knockout Gper1 mice. We performed UUO modeling on the male Gper1-/- mice and measured the degree of renal fibrosis and inflammation. In in vitro study, bone marrow-derived macrophages were treated with G-1 in response to LPS/Interferon γ or Interleukin 4 and cocultured with PTECs (primary tubular epithelial cells) or fibroblasts.

Results: Compared to vehicle-treated OVX female and male mice subjected to UUO, both G-1-treated OVX female and male UUO mice exhibited fewer renal fibrotic lesions and less M1 and M2 macrophage infiltration in the kidney tissues, respectively. On the other hand, Gper1 deletion accelerated renal fibrosis and enhanced chemokines and proinflammatory cytokines expression. In vitro study demonstrated that GPER1 activation prevented M0 macrophages from polarizing towards the M1 and M2 phenotypes. The Gene Ontology analysis of differentially expressed genes in macrophages treated with or without G-1 indicated that GPER1 activation was primarily involved in the inactivation of MAPK pathways, which was further validated by immunoblotting. In addition, PTECs cocultured with G1-pretreated M1 macrophages exhibited fewer injuries and immune activation, and fibroblasts cocultured with G1-pretreated M2 macrophages showed downregulated extracellular matrix expression.

Conclusions: Overall, our study is the first study to demonstrate the effect of GPER1 on macrophage-mediated renal fibrosis via inhibition of M1 and M2 macrophage polarization. These results indicate that GPER1 may serve as a promising therapeutic target for the treatment of renal fibrosis.

GPER1 Plays a Protective Role Against AKI to CKD Transition

Xiangchen Gu,[1,2] Lin Xie,[1,2] Min Chen,[2] Yi Wang,[2] Jingyuan Xie.[1] *[1]Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China; [2]Shanghai University of Traditional Chinese Medicine Yueyang Hospital of Integrated Traditional Chinese Medicine and Western Medicine, Shanghai, China*.

Background: Male patients have a higher prevalence of CKD and increased rates of ESRD than those observed in female patients. Many factors are believed to be involved in this phenomenon. GPER1, a de novo estrogen receptor, has been shown to play an important role in the renal fibrosis process. Whether GPER1 is protective against AKI to CKD transition and its main mechanism remains unclear.

Methods: Using CRISPR/Cas9 gene-editing technique, we generated Gper1 global knockout mice. We subjected the mice to Aristolochic acid(AA) and Folic acid(FA) injections to mimic AKI to CKD transition. We treated AA-injected and FA-injected mice with a GPER1 agonist(G-1). We also cultured primary tubular epithelial cells(TECs) from wild-type and *Gper1*$^{-/-}$ mice and treated the primary cells and NRK-49F cell lines with TGFβ1 and oleic acid with or without G-1 administration.

Results: In both AA and FA injection models, Gper1 knockout mice exhibited more severe renal fibrosis, increased inflammation infiltration, decreased fatty acid oxidation, and activated PI3K/AKT pathway compared to wild-type mice. GPER1 agonist attenuated renal fibrosis and improved fatty acid oxidation in AA-injected and FA-injected mice models, respectively. In vitro study, TGFβ1-treated Gper1-/- TECs showed a reduction in fatty acid oxidation and ATP synthesis. GPER1 activation restored fatty acid oxidation and ATP synthesis, which were suppressed by TGFβ1 and oleic acid in primary PTECs and NRK-49F.

Conclusions: These results suggest that GPER1 may play a protective role against AKI to CKD transition through the fatty acid oxidation pathway. Activation of GPER1 expression may provide a new therapeutic target for AKI to CKD transition.

Funding: Government Support - Non-U.S.

Inhibition of ATP-Citrate Lyase Improves CKD Through Multiple Mechanisms

Kian S. O'Neil, Zeel Patel, Asfia Soomro, Russta Fayyazi, Jackie Trink, Bo Gao, Melissa Macdonald, Joan C. Krepinsky. *McMaster University, Hamilton, ON, Canada.*

Background: ATP-citrate lyase (ACLY), upregulated in chronic kidney disease (CKD), catalyzes the synthesis of acetyl-coA from citrate. Acetyl-CoA is a vital precursor for lipid synthesis and histone acetylation that regulates gene expression. In kidney cells, ACLY regulates fibrogenic, lipogenic and inflammatory gene expression; its inhibition reduced fibrosis in the unilateral ureteral obstruction (UUO) model. The ACLY metabolic by-product malonyl-coA, however, is also an important inhibitor of fatty acid oxidation (FAO), and defective FAO in proximal tubular epithelial cells (PTEC) is now established as a major contributor to fibrosis. Here we tested the efficacy of a novel ACLY inhibitor (ACLYi) on reducing fibrosis and its potential role in improving FAO in UUO.

Methods: 8-week-old male C57BL/6J mice underwent UUO surgery and were treated orally with an ACLY inhibitor (Espervita Therapeutics) for 10 days. Kidneys were assessed by immunohistochemistry, immunoblotting and RNAseq. Effects of ACLYi were tested on the HK2 PTEC cell line and primary renal fibroblast responses to TGFβ1 (5ng/ml, 48h), a cytokine known to promote fibrosis and reduce FAO. Lipid accumulation was assessed by Oil Red O staining and LC/MS analysis.

Results: ACLYi significantly and dose-dependently decreased fibrosis in the UUO model determined by trichrome, PSR, fibronectin and α-smooth muscle actin (SMA) expression. ACLYi decreased macrophage (F4/80) infiltration including that of the profibrotic M2 phenoype marked by CD206. RNAseq analysis showed upregulation of FAO-related hallmark pathways and reduction in inflammation pathways with ACLYi. Defective FAO is known to result in PTEC apoptosis and lipid accumulation. ACLYi reduced both apoptosis, as assessed by the presence of cleaved caspase 3, as well as lipid accumulation, with a particular decrease in cholesteryl esters. In HK2 cells and renal fibroblasts, TGFβ1-induced fibrotic protein expression was inhibited by ACLYi, and lipid accumulation was reduced in PTEC.

Conclusions: ACLYi reduced renal fibrosis, apoptosis and lipid accumulation in UUO mice. ACLYi also prevented profibrotic responses to TGFβ1 in PTEC and fibroblasts. Current studies are ongoing to confirm beneficial effects on restoring FAO.

Immunomodulatory and Metabolic Adaptation in Transcriptional Signature After Knockdown of Proliferating Lymphatic Vessels in Mice with Renal Fibrosis

Zheng Wang, Danni Hu, Guangchang Pei, Ying Yao, Gang Xu, Rui Zeng. *Division of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Our previous study has reported that renal lymphangiogenesis accelerates the progression of chronic kidney disease (CKD). However, it is not clear which immune cell types drive renal outcome.

Methods: We established the selective proliferating lymphatic vessel knockout mice for unilateral ureteral obstruction (UUO)-induced fibrosis. Bulk RNA sequencing and single-cell RNA sequencing were used to characterize changes in the transcriptional profiles of renal parenchymal and immune cell following the knocking down of lymphatic vessels (LVs).

Results: The fibrosis were alleviated following knockdown of LVs. Bulk RNA sequencing showed that the impaired secretion of cytokines and chemokines, and impaired energy metabolism were improved. Single-cell RNA sequencing confirmed that the decreased proportion of epithelial cells was restored, and the immune cells aggregation (especially NK cells and T lymphocytes) was dissipated. Three subpopulations of NK cells were identified: NK1, characterized as $CD27^{+}CD11b^{+}$ NK cells that primarily facilitate the migration of myeloid immune cells, was enhanced; NK2, characterized as $CD27^{+}CD11b^{-}$ NK cells that mainly stimulate the differentiation of lymphoid immune cells, was increased; and NK3, characterized as $CD27^{-}CD11b+$ NK cells that function as pro-inflammatory cells, was significantly decreased. Ten subpopulations of T lymphocytes were identified: the proportion of CD8+T, CD4+ T, γδT, NKT, IFN-related T, effector memory T, and Tregs were increased, serving mainly to promote immunity cell activation, while the proportion of proliferative T, Th17, and naïve CD8+T, that mainly promoting the migration of immune cells, were significantly decreased. Subsequently, stromal cells and their extra-cellular matrix (ECM) production capacity decreased following LV knockdown. Additionally, the LVs knockdown caused an attenuation of G2/M arrest and programmed death in injured tubular epithelial cells (TECs) while restoring fatty acid oxidation and gluconeogenesis.

Conclusions: Knocking down of proliferating LVs improve the inflammatory immune microenvironment via the regulation of NK and T cells, and then inhibit stromal cells to produce ECM and restore the energy metabolism of TECs, which suggest proliferating LVs is a potential therapeutic target for renal fibrosis.

1,3-Butanediol Decreases Unilateral Ureteral Obstruction (UUO)-Induced Tubulointerstitial Inflammation and Fibrosis by Regulating the mTORC1 Signaling Pathway

Wenjia Li,[1] Tian Wang,[1] Soo jin Lee,[1,2] Yujin Shin,[1,2] Kyung Pyo Kang.[1,2] *[1]Jeonbuk National University Medical School, Jeonju, Jeollabuk-do, Republic of Korea; [2]Jeonbuk National University Hospital Biomedical Research Institute, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: Chronic kidney disease (CKD) has long been considered a prominent contributor to global mortality due to its extensive prevalence and profound negative consequences. Given the widespread prevalence and severe adverse impact of CKD, it is imperative to develop new strategies for the prevention and treatment. Acetoacetate, β-hydroxybutyrate (BHB), and acetone can be called "endogenous ketone bodies." It has been suggested that renal ketogenesis, specifically BHB contributes to cell metabolism under conditions of energy deprivation, including fasting and exercise. This study evaluated the effect of exogenous BHB in UUO-injured renal inflammation and fibrosis mice.

Methods: Seven to eight-week-old male C57BL/6 mice were divided into four groups randomly and assessed whether unilateral ureteral obstruction operated or sham-operated in this experiment. The mice were administered with whether 20% 1,3-butanediol (1,3-BD) solution or vehicle served as a daily drink seven days before UUO surgery and continued for 14 days after surgery. We evaluated renal histology, immunohistochemistry, and immunofluorescent staining for renal tubulointerstitial inflammation and fibrosis. We also assessed proinflammatory cytokines and chemokines by qRT-PCR and western blotting.

Results: 1,3-BD is an exogenous ketone body chemical that can be administered orally. 1,3-BD treatment mitigates UUO-induced renal tubular injury, inflammatory cell infiltration, and fibrosis. The inflammatory response was induced with the recruitment of inflammatory cells and tissue regeneration, and treatment of BHB in UUO-injured mice decreased proinflammatory cytokines and cell adhesion molecules expression. There was an increased phosphorylation/activation of mTORC1 signaling in the veh-treated UUO group, and it was attenuated after the administration of 1,3-BD.

Conclusions: Administration of 1,3-BD decreases the UUO-induced renal tubulointerstitial injury, inflammation, and fibrosis by suppressing the activation of the mTORC1 signaling pathway. Suppression of mTORC1 signaling might have a protective effect on UUO-induced tubular injury, fibrosis, and inflammation.

Dicarboxylic Acids Protect Against CKD

Rebecca M. Uhlean,[1,2] Debora Malta C.S Santos,[2] Anne C. Silva Barbosa,[1,2] Katherine Pfister,[1] Jacqueline Ho,[1,2] Sunder Sims-Lucas,[1,2] Eric S. Goetzman,[2] Bob B. Zhang,[1] Birgit Schilling.[3] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [3]Buck Institute for Research on Aging, Novato, CA.*

Background: Chronic kidney disease (CKD) affects 30 million people in the US and over 800 million people worldwide. Treatment for end-stage renal failure is largely limited to renal transplant or lifelong dialysis, creating an urgent need for new therapies. We have shown that dicarboxylic acids are protective against acute kidney injury (AKI) in the proximal tubule via hypersuccinylation of mitochondrial and peroxisomal proteins, thereby bolstering peroxisomal fatty acid oxidation over mitochondrial FAO. In this study we aimed to determine whether this mechanism could be leveraged to protect against fibrotic damage due to chronic kidney injury, which we model using Unilateral Ureteral Obstruction (UUO) surgery.

Methods: Wild-type male B6/129 mice were procured from Jackson Laboratories and the experimental group fed with an 10% 8-chain dicarboxylic acid (DC_8, suberic acid) diet. Both the experimental and the control groups underwent UUO surgery, whereby the ureter of one kidney was obstructed for three days before both kidneys were harvested. Each kidney was split into four pieces as follows – 1. histological and immunohistochemical staining; 2. fatty acid oxidation analysis; 3. succinylome analysis using targeted mass spec; 4. snap-frozen for validation and downstream analysis of fibrosis, as well as peroxisomal and mitochondrial signaling.

Results: As previously shown, there was hypersuccinylation in the DC_8 treated animals compared to control fed animals. This was accompanied with corresponding upregulation of peroxisomal FAO specifically in the collecting ducts, which was confirmed by targeted mass spec. Supplementation of DC_8 showed marked protection in the collecting ducts, with decreased dilation and tubular epithelial shedding compared to controls. There was also a decrease in the dilation of the renal pelvis in DC_8 treated animals. Further to this immunohistochemical staining showed a decrease in fibrotic markers in the kidneys of DC_8-fed animals.

Conclusions: Taken together this suggests that DC_8 is protective against collecting duct damage and fibrotic changes that occur in CKD. This expands the utilization of DC8 therapy beyond the acute setting and into fibrosis and chronic kidney disease.

FR-PO1049

Dose-Dependent Nephroprotective Effects of an ALK5 Inhibitor in the Unilateral Ureteral Obstruction (UUO) Mouse Model of Kidney Fibrosis

Stine T. Bak, Jacob Nøhr-Meldgaard, Ditte M. Jensen, Ida Rune, Frederikke E. Sembach, Alex Frias Hernandez, Thomas Secher, Maria K. Ougaard, Michael Christensen. *Gubra, Hoersholm, Denmark.*

Background: Development of renal fibrosis is a hallmark of chronic kidney disease (CKD) and an essential factor for progressive loss of kidney function and development of end-stage kidney disease. The unilateral ureteral obstruction (UUO) mouse is a widely used surgery-induced model of CKD with rapid induction of renal inflammation and fibrosis. Here, we characterized the effect of an anti-fibrotic TGF-β type 1 receptor kinase inhibitor (ALK5 inhibitor, ALK5i) on renal outcomes in the UUO mouse.

Methods: Male C57BL/6J mice (9 weeks old) were randomised into study groups based on body weight and were either sham-operated or underwent UUO surgery. UUO mice received vehicle or ALK5i (3, 10 or 30 mg/kg, PO, BID) for 8 days. Vehicle-dosed sham-operated mice served as controls. At termination, both kidneys were weighed, and the obstructed left kidney was processed for quantitative histological assessment of macrophage infiltration (F4/80), fibrosis (Col1a1, Col3a1), myofibroblast activation (α-SMA) and tubular injury (KIM-1). Plasma was sampled for measurement of KIM-1 levels.

Results: UUO mice displayed marked kidney tubular injury, macrophage infiltration, myofibroblast activation, and fibrosis as compared to sham-operated animals. ALK5i dose-dependently improved kidney histology and plasma KIM-1 levels.

Conclusions: ALK5i exerted dose-dependent nephroprotective effects in the UUO mouse. Given the rapid induction of fibrosis and inflammation, the UUO mouse is optimal for screening of compounds with potential anti-inflammatory and anti-fibrotic effects.

Cellular Prion Protein Attenuates Renal Fibrosis by Interaction with Epithelial Growth Factor Receptor

Nana Song.[1,2] *[1]Zhongshan Hospital Fudan University Department of Nephrology, Shanghai, China; [2]Fudan Zhangjiang Institute, Shanghai, China.*

Background: Cellular prion protein (Prp^c) coded by the *Prnp* gene, is a kind of cell-surface copper-binding protein, anchoring on cell membrane lipid rafts through glycosyl phosphatidyl inositol anchor (GPI), and plays an important role in cell information transmission. Prp^c is expressed in the kidney. However, the role of Prp^c in regulating fibrotic maladaptive repair of the injured kidney remains largely unknown.

Methods: Wild-type FVB mice, $Prnp^{-/-}$ mice were used for in vivo studies. Renal I/R injury model was induced by bilateral renal pedicle clamping for 35 minutes. Renal fibrosis models were induced by unilateral renal pedicle clamping for 30 minutes (UIR) and by unilateral ureteral obstruction (UUO). HK-2 cells were used for in vitro studies. HK-2 cells were treated with TGF-β induce EMT.

Results: Prp^c is overexpressed in the kidney biopsies from patients with CKD. This is supported by our experimental data showing that Prp^c is gradually upregulated in the kidney following I/R, UIR and UUO insult and Prp^c deletion by knocking out *Prnp* promoted AKI and facilitated fibrosis at later stages. Proteomics analysis indicated that the expression of key protein in DDR, including replication protein A (RPA), minichromosome maintenance protein 2/4/6 (MCM2/4/6) and cyclin-dependent kinases 1/2 (CDK1/2), as well as epidermal growth factor receptor (EGFR) drastically upregulate in the I/R kidney, while in $Prnp^{-/-}$ mice, EGFR rises even further with DDR-associated protein slumping. Furthermore, we uncover a critical role of Prp^c in the control of EGFR signaling by promoting internalization of EGFR in renal tubular epithelia cells, which in turn influences DNA replication followed injury and renal fibrosis.

Conclusions: In summary, our study provides experimental evidence showing that Prp^c plays an adaptive nephroprotective role by modulating activation of EGFR pathway and promoting cell cycle progression.

Piperazine Ferulate Regulates Renal Fibrosis by Alleviating Oxidative Stress in Renal Tubular Epithelial Cells

Min Yu, Xiang Zhong, Yi Li, Kaixiang Liu, Li Wang, Guisen Li. *Sichuan Provincial People's Hospital, Yibin, China.*

Background: Chronic kidney disease (CKD) is one of the greatest public health hazards worldwide with a high mortality rate, poor quality of survival. Oxidative stress in CKD could aggravate tubular injury to renal fibrosis. The treatment of oxidative damage to renal tubular epithelial cells still needs extensive research and development of drugs. This study was conducted to explore the effect of piperazine ferulate on renal fibrosis and the antioxidant mechanism of renal tubular epithelium and to provide a theoretical basis for the application of piperazine ferulate in CKD.

Methods: 36 male C57 mice at 6-8 weeks were randomly divided into six groups (n=6): sham group (saline 0.2 mL), UUO group (saline 0.2 mL), piperazine ferulate low-dose intervention in UUO group (piperazine ferulate 50 mg/kg, 0.2 mL), piperazine ferulate medium-dose in UUO group (piperazine ferulate 100mg/kg, 0.2 mL), piperazine ferulate high dose in UUO group (piperazine ferulate 200mg/kg, 0.2 mL), and piperazine ferulate alone (piperazine ferulate 200mg/kg, 0.2 mL). The mice were then anesthetized and executed on the 7th day after surgery, and the relevant samples were collected and stained with HE, PAS and Masson to observe the tubular shape, atrophy, necrosis and the degree of interstitial fibrosis, and the fibrosis-related indexes FN, collagen-1, αSMA and p-Smd3 were observed by immunohistochemistry or protein blotting. The safe concentration range of piperazine ferulate in HK2 cells was screened by CCK8 in vitro and IC50 was calculated to select a safe concentration for intervention in TGF β-treated HK2 cells, subsequently protein blotting was used to detect FN, collagen-1, p-Smad3, KIM-1, HO-1 and dichlorofluorescein (DCF) was revealed in HK2 cells after intervention. of renal tubular epithelial cells were detected by protein blotting.

Results: Pathological staining showed that the fibrosis, renal tubular epithelial injury and oxidative stress significantly ameliorated in UUO mice after piperazine ferulate treatment at a dosage dependent manner, compared to that of sham-operated group. We also observed the same phenomenon in the HK2 cells with piperazine ferulate treatments upon TGF β stimulation.

Conclusions: Piperazine ferulate could significantly alleviate oxidative stress injury in renal tubular epithelial cells against renal fibrosis.

FR-PO1052

Apabetalone Reduces Fibrotic Inflammatory and Calcific Factors in Renal Cells and Patient Plasma

Dean Gilham,[1] Sylwia Wasiak,[1] Brooke D. Rakai,[1] Li Fu,[1] Laura Tsujikawa,[1] Chris Sarsons,[1] Agostina Carestia,[1] Kenneth E. Lebioda,[1] Jan O. Johansson,[2] Michael Sweeney,[2] Kamyar Kalantar-Zadeh,[3] Ewelina Kulikowski.[1] *[1]Resverlogix Corp, Calgary, AB, Canada; [2]Resverlogix Inc, San Francisco, CA; [3]Harbor-UCLA Medical Center, Torrance, CA.*

Background: The BET protein inhibitor apabetalone downregulates the expression of genes involved in fibrosis, inflammation and calcification, processes that drive cardiovascular disease and kidney dysfunction. In the phase 3 BETonMACE trial, apabetalone reduced the risk of major acute cardiac event (MACE) by 50% in the subpopulation with CKD (eGFR<60) implying favorable effects on the kidney-heart axis. Here we examine effects of apabetalone on processes of nephropathy in human renal mesangial cells (MCs) and assess plasma proteomics in CKD subjects or controls.

Methods: MCs were stimulated with TGF-β1, a pro-fibrotic cytokine, ± 1 to 25μM apabetalone. Gene expression was measured by real-time PCR, protein secretion by ELISA, smooth muscle actin (α-SMA) by immunofluorescence, collagen with picrosirius red, cell contraction in collagen gels and tissue non-specific alkaline phosphatase (TNAP) activity in biochemical assays. Plasma proteomics (Somascan 1.3) were evaluated in 8 CKD subjects (eGFR <30) and 8 controls after a 100mg dose of apabetalone. Ingenuity Pathway Analysis (IPA) analyzed upstream regulators.

Results: In MCs, apabetalone downregulated TGF-β1 stimulated α-SMA gene expression up to 89% and abolished α-SMA stress fiber formation and cell contraction. Collagen deposition was reduced to unstimulated levels. mRNA and enzyme activity levels for TNAP, involved in calcification, were reduced up to 96%. Apabetalone countered TGF-β1 induced gene expression and protein secretion of key drivers of fibrosis and inflammation including thrombospondin, fibronectin, periostin, osteonectin and IL-6 ($p<0.001$ for all MC results). Plasma levels of these factors were reduced 12h after taking apabetalone specifically in CKD subjects. IPA predicted TGF-β1 pathway activation in CKD vs controls, and its inhibition after the dose of apabetalone.

Conclusions: Through epigenetic regulation of transcription in MCs, apabetalone suppresses fibrotic, inflammatory and calcific factors associated with CKD. Plasma levels of fibrotic and inflammatory proteins were reduced specifically in CKD subjects. This may, in part, explain reduced MACE risk in the CKD subpopulation receiving apabetalone in BETonMACE, which will be further evaluated in future phase 3 trials.

FR-PO1053

Deletion of EZH2 from Renal Tubular Cells and Stroma-Derived Interstitial Cells Protects Mice from Kidney Fibrosis by Inhibition of Notch Signaling and Preservation of Klotho and BMP7 Expression

Chao Yu,[1] Shougang Zhuang.[2] *[1]Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China; [2]Brown University Warren Alpert Medical School, Providence, RI.*

Background: Although histone methyltransferase enhancer of zeste homolog 2 (EZH2) was denovo expressed in multiple cell types in the injured kidney, the contribution of EZH2 in specific cell type to renal fibrosis and the underlying mechanism remains poorly defined.

Methods: Mice with deletion of EZH2 from renal interstitial fibroblasts or renal tubular cells were generated and subjected to unilateral ureteral obstruction (UUO) to investigate renal fibrotic changes and signaling mechanisms and in comparison with the effect of EZH2 inhibitors. Chromatin immunoprecipitation was performed to analyze the association of EZH2 and H3K37 with Notch1 and Notch 3 as well as klotho and BMP7 promoters, respectively.

Results: Compared with wild type, mice with conditional deletion of EZH2 in renal interstitial cells or in renal tubular cells developed less renal fibrosis following UUO injury. Tubule-specific deletion of EZH2 was associated reduced expression of vimentin and Snail and preserved expression of E-cadherin. Genetic depletion of EZH2 in either cell type or pharmacological inhibition of EZH2 reduced injury –induced expression of Notch1 and Notch3, active form of Notch1 and their signaling components Jagged-1, Hes1 and Hes2. In wild-type mice, pharmacological inhibition of EZH2 with GA or GSK126 also improved tubulo-interstitial damage and antagonized activation of Notch

signaling. In cultured renal epithelial cells, TGFb1 exposure promoted the interaction of EZH2 with Notch1 or Notch3, and expression of Jagged-1, Hes1 and Hes2, and EZH inhibition abrogated these responses. Finally, chromatin immunoprecipitation indicates that kidney injury enhanced EZH2 and H3K27me3 at the promoter regions of the Notch1 and Notch3 promoter, and treatment with EZH2 inhibitor abolished this response.

Conclusions: Our data indicate that overexpression of EZH2 in renal tubular cells and fibroblasts contributes to renal fibrosis by a mechanism associated with the activation of Notch signaling and suppression of Klotho and BMP7.

FR-PO1054

Protective Effect of Heparan Sulphate Derivative Against Glycocalyx Damage-Induced Renal Fibrosis in Aging Mice

Injoon Hwang, Donghyuk Kang, Eun Nim Kim, Ji Hee Lim, Hyung Duk Kim, Cheol Whee Park, Bumsoon Choi, Tae Hyun Ban. *Division of Nephrology, Department of Internal Medicine, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea.*

Background: Aging-related glycocalyx loss causes renal fibrosis in aging kidneys. Heparan sulphate (HS) derivative was anticipated overcoming diabetic nephropathy model. Sulodexide is a well-known HS derivative. We investigated the effects of SDX on the PI3K/Akt pathway as a renoprotective pathway in a mouse model of aging.

Methods: C57BL/6 mice were divided into four groups according to age and SDX administration for six months: the eight-month-old mice with vehicle (YM group, n= 10), the eight-month-old mice with SDX (YM+SDX group, n=8), the twenty four-month-old mice with vehicle (AM group, n= 10), the twenty four-month-old mice with SDX (AM+SDX group, n=8). SDX was administered to 10 mg/kg per oral daily for six months. We compared the following parameters between the groups: renal function, blood pressure, renal pathology, activities of the PI3K-Akt-MMP2 and MMP9-Syndecan4 in renal tissue.

Results: Renal function was improved based on serum creatinine and 24 hours albuminuria in AM+SDX group compared with the AM group ($p<0.05$ for all), but it was not different between the YM group and the YM+SDX group. Areas of renal fibrosis and expressions of protein related to fibrosis significantly reduced in the AM+SDX group compared with the AM group ($p<0.05$), but the YM+SDX group was similar with the YM group. In protein related with PI3k-Akt pathway, the AM+SDX group showed significantly lower expression of PI3K, phosphorylated Akt, MMP2, MMP9 and syndecan4 than the AM group ($P<0.05$ for both), but the YM+SDX group was not different compared with the YM group.

Conclusions: SDX, which is a HS derivative, alleviated the protein expression associated with PI3k-Akt pathway in kidneys of aging mice, but those changes were not observed in that of young mice. SDX may provide renoprotective effects via PI3k-Akt pathway in aging kidneys.

Rubus coreanus Extract Attenuates Kidney Fibrosis Through TGF-β/Smad Pathway Inhibition

Wencheng Jin,[1,2] Boram Weon,[2,1] Ara Ko,[1] Nayeon Shin,[2] Jung Pyo Lee,[1,2] Jeonghwan Lee.[1,2] *[1]Seoul National University, Gwanak-gu, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: Rubus coreanus, a wild berry belonging to the Rosaceae genus, has been found to have various health benefits, including anti-oxidative effects.

Methods: Male C57BL/6 mice (7 weeks old, n = 30) were randomly assigned to the sham/vehicle (distilled water), sham/MN705 (600 mg/kg/day), UUO/vehicle, UUO/MN705-low dose (300 mg/kg/day), and UUO/MN705-high dose (600 mg/kg/day) groups in the same numbers (n = 6 in each group). MN705 and distilled water were administered orally using a stainless feeding needle. After 7 days of pre-treatment, sham or UUO operation was performed, and treatment drugs were administered at the same dose for 7 days. In addition, HK-2 cells were cultured and challenged with TGF-β (2 ng/ml) with or without an extract of Rubus coreanus (0.05-0.2 mg/ml).

Results: In the histopathologic specimen of Masson's trichrome stain, areas of kidney interstitial fibrosis were attenuated in the treatment group (3.6 ± 0.9 % area vs. 8.7 ± 3.0 % area, $P < 0.01$).). In the Western blot analysis, protein abundance of collagen-1 (50.6% of control, $P = 0.04$) significantly decreased in the treatment group. In the *in vitro* experiment, HK-2 cells treated with TGF-β and MN705 showed a dose-dependent significant decrease in the protein expression of fibronectin (64.7% of control in 0.1 mg/ml dose, 22.3% of control in 0.2 mg/ml dose, $P = 0.01$). and phospho-smad2/3 (87% ± 22% of control in 0.2 mg/ml dose, $P < 0.01$)

Conclusions: The extract of Rubus coreanus attenuates kidney fibrosis in the UUO mouse model and TGF-β-treated human kidney proximal tubular cells. TGF-β-related Smad and Smurf signaling pathways involved in the development of fibrosis in both *in vivo* and *in vitro* models are effectively inhibited through extract of Rubus coreanus and can be a potential target for treatment of kidney fibrosis**.**

FR-PO1056

HSP90 Inhibitor 17-DMAG Downregulated METTL3 and Attenuates Renal Fibrosis in AKI to CKD Model

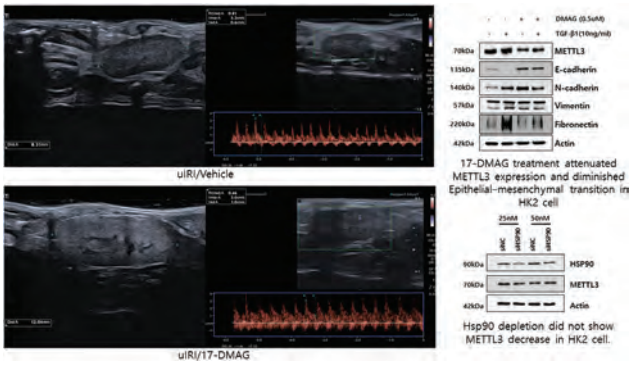
Wencheng Jin,[1,2] Nayeon Shin,[2] Boram Weon,[1,2] Myoung Seok Lee,[2] Jeonghwan Lee.[1,2] *[1]Seoul National University, Gwanak-gu, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: N6-methyladenosine (m6A) RNA methylation has been reported to participate in post-transcriptional gene expression regulation and development of kidney fibrosis.

Methods: AKI to CKD transition was induced by unilateral ischemic-reperfusion (uIRI) method (transient clamping followed by de-clamping of renal artery) in C57BL/6 mice. HSP90 Inhibitor 17-DMAG was injected intraperitoneally with 20 mg/kg dose. Renal fibrosis is evaluated using both imaging and molecular parameters. As imaging parameters, size, resistive index (RI), vascular index (VI; colored pixels / all pixels on microvascular imaging), and shear wave parameters were compared. Histology-based fibrosis score was also evaluated. And we evaluated the expression of fibrosis and inflammatory marker proteins such as TGF-β, α-SMA, Collagen 1 and E-Cadherin in uIRI model. Furthermore, we incubated human proximal tubular epithelial (HK2) cells under TGF-β (10 ng/ml) treatment as an in vitro model of kidney fibrosis.

Results: Imaging biomarkers of uIRI/17-DMAG showed better results than that of uIRI/vehicle (Size, 7.3±3.3mm vs. 10.7±0.86mm; RI, 0.79±0.09 vs. 0.68±0.05; VI, 9.4±6.0% vs. 18.0±4.1%, all $p<0.05$). Shear wave elastography did not show significant difference between uIRI/17-DMAG and uIRI/vehicle mice. 17-DMAG treatment attenuated the degrees of kidney fibrosis in vivo mice uIRI model (Histology-based fibrosis score 7.5±1.2 in uIRI/vehicle vs. 4.6±1.7 in uIRI/17-DMAG, $P = 0.016$). Expression of α-SMA and Collagen 1 proteins were lesser in uIRI/17-DMAG compared to uIRI/vehicle. In HK2 cell, 17-DMAG attenuated METTL3 expression regardless of TGFβ treatment. 17-DMAG treatment also downregulated epithelial marker (E-cadherin), and upregulated interstitial markers (N-cadherin, Vimentin, NET1). However, Hsp90 depletion using siHsp90RNA did not show METTL3 decrease in HK2 cell.

Conclusions: 17-DMAG treatment attenuated renal fibrosis both in vitro TGFβ-challenged HK2 cell model and in vivo AKI to CKD mice model. METTL3 expression was diminished by 17-DMAG treatment.



FR-PO1057

Omega 3 Fatty Acids Attenuated AKI to CKD Transition and Renal Fibrosis: Identification of Anti-Fibrotic Metabolites

Kai Tokumaru, Hiroshi Watanabe, Toru Maruyama. *Kumamoto Daigaku Yakugakubu Daigakuin Yakugaku Kyoikubu, Kumamoto, Japan.*

Background: Renal fibrosis, recognized as a histological hallmark of CKD, has become an object of interest as a prospective therapeutic target. Recent meta-analyses showed that the patients with AKI are at high risk of developing CKD, and the concept of AKI to CKD was established. ω3 fatty acids (ω3PUFA) were reported to exhibit renal protective effects. However, their renal protective mechanism has remained unclear. In this study, we aimed to investigate the effect of ω3PUFA on AKI to CKD and to identify the active fatty acid metabolites against renal fibrosis.

Methods: Mice were fed a normal diet or an ω3PUFA diet. After 4 weeks of feeding, bilateral renal ischemia-reperfusion (IR) was performed. The activity of fatty acid metabolites was assessed by using human monocyte-derived cell lines (THP-1 cells) and human tubular epithelial cell lines (HK-2 cells) and rat renal fibroblasts cell lines (NRK49F cells).

Results: The normal or ω3PUFA diet was fed for 4 weeks, and IR (35 min) was performed to induce severe AKI. ω3PUFA diet improved the survival after AKI as compared to the normal diet. Next, AKI to CKD model (IR: 30 min) was subjected to evaluate the effect of ω3PUFA. ω3PUFA group exhibited the suppression of tubular damage and fibrosis at day 14 after renal IR. Renal fatty acid metabolites were measured, and multivariate analysis showed a significant increase in eicosapentaenoic acid (EPA) and its metabolites (18-HEPE, 17,18-EpETE, 17,18-diHETE) in the ω3PUFA group. When THP-1 cells were stimulated with LPS and the supernatant was added to HK-2 cells, an increase in IL-6 expression was observed, whereas when THP-1 cells were co-treated with EPA's metabolites, IL-6 expression was suppressed. In NRK-49F cells, TGF-β1-stimulated upregulation of α-SMA expression was suppressed by the presence of EPA and its metabolites.

Conclusions: Feeding ω3PUFA improved the survival after severe AKI and reduced tubular damage and renal fibrosis in AKI to CKD. The anti-inflammatory and anti-fibrotic effects of EPA and its metabolites were shown.

FR-PO1058

Inhibition of HDAC11 Attenuates Renal Fibrosis Through Blocking Partial Epithelial-Mesenchymal Transition

Yingjie A. Guan. *RI Hospital, Providence, RI.*

Background: HDAC11 is the only member of the class IV histone deacetylases (HDACs) and is highly expressed in brain, heart, kidney et al and participates in diverse pathophysiological processes, such as tumor growth, immune regulation, oxidant stress injury et.al. However, it remains unclear whether HDAC11 involves in renal fibrosis.

Methods: In this study, we assess the role of HDAC11 in the development of renal fibrosis in Unilateral Ureteral Obstruction (UUO) mouse model. To examine the efficacy of HDAC11 in renal fibrosis after UUO injury, FT895 at 5mg/kg in 50 uL DMSO was given intraperitoneally after ureteral ligation and then administered daily for 7 days. The mice were euthanized kidney was collected on day 7.

Results: Masson trichrome staining results showed collagen fibrils were extensively deposited within the interstitial space in the kidney after UUO injury. Immunoblot analysis of kidney tissue lysate demonstrated increased expression of αSMA, collagen I, and fibronectin in the kidney after UUO injury. However, administration of FT895 significantly reduced ECM deposition and significantly decreased the expression levels of αSMA, collagen I, and fibronectin. To determine the effect of HDAC11 inhibition on the arrest of epithelial cells at G2/M and partial epithelial-mesenchymal transition (EMT), we examined the expression of pH3Ser10, a hallmark of cells arrested at G2/M and Snail and Twist, key transcription factors that drive EMT development in the obstructed kidney. Immunoblot analysis results showed that administration of FT895 significantly reduced the expression of pH3Ser10, Snail and Twist. In addition, we further visualize the immune cell infiltration by immunohistochemistry analysis of F4/80, a macrophage marker. FT895 treatment decreased infiltration of F4/80 macrophages in the interstitial areas of the obstructed kidneys.

Conclusions: These data provide strong evidence that inhibition of HDAC11 attenuates development of renal fibrosis in vivo through suppression of several events associated with partial EMT development. Therefore, inhibition of HDAC11 would be a promising therapeutic strategy for the treatment of renal fibrosis.

FR-PO1059

Neuropilin-1, the Co-Receptor of TGF-β and TNF-α, Is a Novel Therapeutic Target for Renal Injury and Renal Fibrosis

Yinzheng Li, Ying Yao, Rui Zeng. *Division of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Renal fibrosis is the ultimate common pathway of a variety of progressive kidney diseases, in which TGF-β plays an important role. However, current strategies targeting TGF-β showed poor clinical efficacy. One of the reasons for its futility is the co-receptor surrogacy. Neuropilin-1 (NRP1) is a transmembrane glycoprotein acting as a co-receptor of TGF-β and TNF-α, which is recently identified as a potential therapeutic target for pulmonary fibrosis. However, its role in kidney injury and renal fibrosis is unclear.

Methods: Kidney samples from patients with transplanted renal insufficiency and ischemia-reperfusion mice was analyzed. NRP1-KSP mice were generated to deplete NRP1 in renal tubular epithelial cells (TECs). The molecular mechanisms of NRP1 in kidney injury and renal fibrosis were explored via multi-omics analysis of single cell sequencing, transcriptomics and proteomics.

Results: NRP1 expression is upregulated in TECs in transplanted renal insufficiency patients and mice with IR induced AKI, which is co-expressed with receptors of TGF-β or TNF-α. Knockdown of NRP1 in TECs reduced IR-induced kidney injury and fibrosis in mice. NRP1+ distal tubular cells secreted collagen and cytokines, and communicated with myofibroblasts, exacerbating renal fibrosis by activating the SMAD pathway in TECs in a TGF-β receptor dependent manner. Meanwhile, in TGF-β receptor negative distal TECs, NRP1 upregulated TNF-α and its target gene NFKB1 via TNR1A (TNF-α receptor), thereby inhibiting ETV6-related crotonylase expression, which led to downregulation of lysine crotonylation on key glucose metabolic enzymes, exacerbating renal injury, inflammation and fibrosis.

Conclusions: NRP1 is a key molecule promoting kidney injury and fibrosis via activation of SMAD3, TECs-myofibroblasts crosstalk and inhibiting crotonylation of key glucose metabolic enzymes, which promotes the pro-fibrotic and pro-inflammatory effects in both TGF-β receptor negative and positive TECs. Therefore, NRP1 is a novel therapeutic target for kidney disease.

Therapeutic Strategies Targeting RAGE Prevent Kidney Injury and Renal Fibrosis in Systemic Lupus Erythematosus

Kensei Taguchi, Tomofumi Moriyama, Goh Kodama, Kei Fukami. *Division of Nephrology, Kurume University School of Medicine, Kurume, Japan.*

Background: Lupus nephritis (LN) occurs in up to 60% of patients with systemic lupus erythematosus (SLE). Despite of current development of immunosuppressant agents, LN still impairs the survival and quality of life in SLE patients. Receptor for advanced glycation endproducts (RAGE) is a multi-ligand receptor is associated with innate immune system. In the present study, we examined whether RAGE is involved in the development of LN. Further, we explored the therapeutic impact of DNA-aptamer directed against RAGE (RAGE-apt) on lupus-related kidney injury.

Methods: [Protocol 1] RAGE expression in kidneys and urinary RAGE excretion (uRAGE) were determined at several time points by real-time PCR and ELISA, respectively in MRL/lpr, SLE-prone mice. [Protocol 2] LN was induced by peritoneally injecting pristane in wild type and RAGE globally knockout mice. [Protocol 3] MRL/lpr mice were subcutaneously administrated with RAGE-apt or Control-aptamer (Ctrl-apt) for 10weeks. [Protocol 4] Isolated proximal tubules from wild type and RAGE knockouts were treated with CpG-ODN for 7 days in the presence or absence of chroloquine.

Results: [Protocol 1] uRAGE was increased since 8-week-old MRL/lpr mice, and was positively correlated with urinary NAG, a tubular injury marker. RAGE was upregulated in distal tubules in early stage, meanwhile RAGE started to be extensively expressed in nephron at later time point. In proximal tubules (PTC), RAGE was co-localized with cathepsine D, a lysosomal aspartyl protease, and Rab7, a marker of late endocytosis, suggesting that PTC RAGE is involved in endosome pathway. [Protocol 2] Pristane-induced kidney injury and renal fibrosis were attenuated in RAGE knockouts with reduction in systolic blood pressure. [Protocol 3] Administration of RAGE-apt reduced systolic blood pressure and attenuated renal dysfunction. Expression levels of IL-6, TNF-a, and MCP-1 were inhibited by RAGE-apt, but not Ctrl-apt, in MRL/lpr mice. [Protocol 4] α-SMA was upregulated in wild type primary PTC, but not RAGE KO primary PTC, which was prevented by chroloquine, suggesting that the protective effect of RAGE inhibition is possibly through endosome-lysosome pathway.

Conclusions: RAGE could be involved in the pathogenesis of LN, and RAGE-apt can be potential to become a promising therapeutic option for preventing the development of LN.

Daphnepedunin A, a Natural Small Molecule, Targets Cdc42-Mediated GSK-3β/β-Catenin Signaling to Combat Renal Fibrosis

Xinrong Hu,[1,2] Yi Zhou.[1,2] *[1]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]NHC Key Laboratory of Clinical Nephrology (SunYat-Sen University) and Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, China.*

Background: Renal fibrosis is a common fate in various chronic kidney diseases (CKD), eventually leading to renal dysfunction. So far there is no effective treatment for this pathological process. *Wikstroemia chamaedaphne*, a shrub endemic in China, is a medicinal plant that have been used in folk medicines to treat edema, but its application and mechanism in kidney-related diseases are unknown.

Methods: The inhibitory effects of ethanolic extracts of *Wikstroemia chamaedaphne* on the activation of renal fibroblasts were detected in the *in vitro* model of rat renal fibroblast cell line stimulated by transforming growth factor-β1. A phenotypic screening was conducted to identify the most potent diterpenoid isolated from *Wikstroemia chamaedaphne* on the *in vitro* model of renal fibroblast activation. Unilateral uretera obstruction mouse model of renal fibrosis was utilized to confirm the anti-renal fibrotic activity of the diterpenoid. The drug efficacy of the diterpenoid was compared with pirfenidone, the anti-renal fibrotic drug undergoing clinical phase 2 trial. RNA-sequencing was employed to explore the underlying pharmacological mechanism. By incorporating cellular thermal shift assay with quantitative mass spectrometry (MS-CETSA), the direct target of the diterpenoid was identified. Surface plasmon resonance and active GTP-binding cdc42 pull-down experiments was performed to verify the target protein. Small interfering RNA was used to knock down the target protein in NRK-49F cells and the drug efficacy of the diterpenoid was testified.

Results: In our bioassay-guided chemical investigation on the medicinal plant *Wikstroemia chamaedaphne*, the daphne diterpenoid daphnepedunin A (**15**) was identified as a promising anti-renal fibrotic lead. **15** showed significant anti-renal fibrosis effects both *in vitro* and *in vivo*, much more potent than the clinical trial drug pirfenidone. Leveraging MS-CETSA, we identified cell division cycle 42 (cdc42), a GTPase, as the direct target of **15**. Mechanistically, **15** inhibited the activity of cdc42, disrupting cdc42-dependent glycogen synthase kinase-3β (GSK-3β) serine 9 phosphorylation, which in turn activates GSK-3β and downregulates downstream β-catenin profibrotic signaling.

Conclusions: Our findings suggest that cdc42 is a potential therapeutic target for renal fibrosis, and **15** has great potential as a cdc42 inhibitor for the treatment of CKD.

The Renal Damage Induced by an Experimental Model of Early CKD Is Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL) Dependent

Stefanny M. Figueroa,[1] Javier I. Reyes Osorio,[2] Patricio A. Araos,[1] Maria J. Fuenzalida,[3] Rodrigo Pacheco,[3] Cristián A. Amador.[2] *[1]Institute of Biomedical Sciences, Universidad Autónoma de Chile, Santiago, Chile; [2]Laboratory of Renal Physiopathology, Faculty of Medicine and Sciences Health, Universidad San Sebastián, Santiago, Chile; [3]Laboratory of Neuroimmunology, Fundación Ciencia & Vida, Santiago, Chile.*

Background: In chronic kidney disease (CKD), the progressive decline in renal function is accompanied by inflammatory and fibrotic processes. These processes can contribute to the increasing levels of proteinuria, which is recognized as a risk factor in patients and associated to the CKD progression. Neutrophil gelatinase-associated lipocalin (NGAL) is an accepted biomarker for assessing renal damage in CKD patients and experimental animals. However, it is still uncertain whether NGAL actively promotes proteinuria in the context of early CKD, and whether this phenomenon is related to the renal pro-inflammatory/fibrotic status. **Objective:** To determine whether the 5/6 nephrectomy ($Nx_{5/6}$) at 5 days in mice is associated to renal dysfunction and to the pro-inflammatory/fibrotic damage, and whether this is NGAL-dependent.

Methods: Male C57BL/6 Wild type (WT) and knock-out for NGAL (NGAL-KO) mice (8-12 weeks), underwent a model of $Nx_{5/6}$ for 5-days (n=4-6), to evaluate function and kidney damage.

Results: The $Nx_{5/6}$ model at 5 days in WT and NGAL-KO mice resulted in a significant reduction in glomerular filtration rate, with 56.1% and 58.2%, respectively. Notably, the increase in blood urea levels was significantly higher in WT mice compared to NGAL-KO (43.07±2.15 *vs.* 29.58±13.08mg/dl). Also, the ratio protein/creatinine in urine exhibited NGAL-dependency (10.29±3.90 vs. 2.09±0.62 arbitrary units in NGAL-KO). Concerning the renal damage, the early CKD model induced tubular lumen dilation in WT mice (13.6±0.9 *vs.* 8.0±0.3mm in Sham), which was prevented by the NGAL absence ($P<0.01$). Additionally, the normalized fibrosis area in remanent kidney was significantly 2.3 times lower in the NGAL-KO mice with respect to WT animals, which correlated with the mRNA abundance of interleukin-6 ($P<0.01$). Finally, we found an increased protein production of macrophage (Mf) monocyte chemoattractant (CCL2) in kidneys of WT mice due to $Nx_{5/6}$ model, which was not observed NGAL-KO mice ($P<0.05$).

Conclusions: Our results show that renal overexpression of IL-6 and CCL2 after 5-days of $Nx_{5/6}$ are NGAL-dependent. This pro-inflammatory phenotype correlates with the tubular remodeling, fibrosis, and the proteinuria, suggesting a possible role of NGAL for the CKD progression from the early stages.

Identification of Surrogate Biomarkers Reflecting Tubular Failed Repair in CKD

Tobias Bohnenpoll,[1] I-Ju Lo,[1] Seamus Ragan,[2] Shawn S. Badal,[2] Olivier Radresa,[1] Jay Kuo,[2] Jennifer H. Cox,[2] Uwe Andag,[1] Andrew J. King,[2] N. Eric Olson.[2] *[1]Evotec International GmbH, Göttingen, Germany; [2]Chinook Therapeutics Inc, Seattle, WA.*

Background: Interstitial fibrosis, tubular atrophy and inflammation (IFTA) are common final pathways to end-stage kidney disease (ESKD), contributing to progressive nephron loss and functional decline in most chronic kidney diseases (CKD), including those typically glomerular in origin. Disease-associated failed repair proximal tubule cells (FR-PTs) have been described in rodent models and are characterized by a proinflammatory and profibrotic phenotype that contributes to IFTA severity. We have recently demonstrated that accumulation of FR-PTs in humans predicts reduced event-free survival in multiple CKD etiologies. Here we used multi-omics analysis of patient-matched kidney biopsies and biofluids from the NURTuRE CKD cohort to discover biomarkers associated with an accumulation of FR-PTs to non-invasively identify patients at risk for progression.

Methods: Serum (n = 99) and urine samples (n = 22) from multiple etiologies from the NURTuRE biobank were assayed using Olink and SomaScan proteomics platforms, respectively. Patient-matched kidney biopsies for each of the samples were analyzed via RNA-Seq and scored for a gene signature reflecting FR-PTs. Correlation analysis of biofluid protein abundance with kidney mRNA expression and FR-PTs signature scores suggested candidate non-invasive biomarkers for further validation ($r \geq 0.4$ and $p \leq 0.05$).

Results: Proteomic analysis identified 78 serum and 79 urine proteins significantly correlated with the kidney biopsy FR-PT score in CKD patients. Strong positive correlation of 14/78 serum and 9/79 urine proteins with kidney mRNA expression suggests these proteins originate from the kidney or share a common regulatory mechanism. Importantly, expression of the respective genes was negatively correlated with eGFR and enriched in FR-PTs and immune cells, likely reflecting the kidney inflammatory and fibrotic microenvironment.

Conclusions: This study identified potential surrogate biomarkers associated with the accumulation of FR-PTs in subjects with different CKD etiologies from the NURTuRE cohort. These may aid in identifying patients with a disease-relevant phenotype and at risk for progression and will complement our target identification and validation focused on maladaptive tubular repair.

Single-Cell Sequencing Identifies Novel Activated Fibroblast Marker, Distal Spatial Tubular Injury Pattern, and Functionally Significant Nephrogenic Program Reactivation in Adult AKI-to-CKD Transition

Valeria Rudman-Melnick, Prasad Devarajan. *Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Examining kidney fibrosis is crucial for mechanistic understanding and developing targeted strategies against chronic kidney disease (CKD). Enduring fibroblast activation and tubular epithelial cell (TEC) injury and dedifferenriation are key CKD contributors. However, specific activated kidney fibroblast markers and mechanistic targets of renal parenchymal remodeling remain elusive.

Methods: scRNA-seq, thorough molecular analysis and TEC specific transgenic model were used to mechanistically dissect AKI-to-CKD progression in two clinically relevant UIR and UUO murine models.

Results: Advanced kidney injuries elicited three separate "secretory", "contractile" and "vascular" fibroblast clusters. Gucy1a1 was validated as a novel marker selectively labelling three fibroblast populations. Also, we found robust and previously unrecognized distal nephron tubular segment (DNTS) injury in both models, while the surviving proximal tubules (PTs) showed restored transcriptional signature. Both models elicited failed repair TECs (frTECs) exhibiting decline of mature epithelial markers and elevation of stromal and injury genes, which shared transcriptional identity with DNTSs of the embryonic kidney. We also found a persistent nephrogenic signature, including *Sox4* elevation previously reported by us in AKI, in the UIR and UUO DNTSs. *Sox4* targeting using *KspCre^{ERT2}* transgenic model revealed renoprotective effects of *Sox4* DNTS specific ablation in the kidney fibrosis.

Conclusions: We identified Gucy1a1 as a novel kidney fibroblast specific marker and targeting *Sox4* in DNTSs as a promising strategy to halt AKI-to-CKD progression. Our findings might advance understanding of and targeted intervention in fibrotic kidney disease.

BRCA1 Potentiates Maladaptive Repair and Fibrosis Through Induction of Proximal Tubule G2/M Arrest and Senescence

Amrendra K. Ajay,[1,2] Cody C. Gifford,[1,2] Akinwande A. Akinfolarin,[1,2] Venkata Sabbisetti,[1,2] Joseph V. Bonventre.[1,2] Bonventre Lab. *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: DNA damage is a major contributing factor in the progression of fibrotic renal disease. Proximal tubular (PT) epithelial cells are particularly vulnerable to toxic, ischemic, and obstructive injury in the kidney, leading to replication fork arrest and DNA double-strand breaks (DSBs), triggering the DNA damage response. Subsequent to DSBs, ATM-mediated phosphorylation of BRCA1^{Ser1524} initiates the DDR, a protective adaptation in many pathologies, notably in the prevention of carcinogenesis. Until recently, the role of BRCA1 in renal fibrosis has been largely unexplored. We hypothesized that the effect of BRCA1 on arresting the cell cycle would exacerbate maladaptive repair through the initiation of G2/M cell cycle arrest.

Methods: *Slc34a1-Cre* mice were crossed with *Brca1*$^{flox/flox}$ mice yielding mice with PT *Brca1 exon 11* gene deletion. Mice were subjected to bilateral ischemia/reperfusion (BIRI) or aristolochic acid (AA)-induced injury. Markers of DNA damage, cell cycle arrest, senescence and fibrosis were evaluated by immunofluorescence staining and western blot analysis of tissue sections and patient-derived PTCs subjected to AA or cisplatin. HKC8 cells were transfected with shRNA and treated with either cisplatin or AA to investigate the role of BRCA1 in injury-associated apoptosis, growth arrest and senescence.

Results: BRCA1 protein expression was increased in human CKD kidneys. The expression of *Brca1 exon 11* was increased following BIRI or AA. PT *Brca1* deletion protected mice from fibrosis, as shown by Sirius red staining, fibronectin, collagen 1, and a-smooth muscle actin (a-SMA) following BIRI or AA. PT-*Brca1* depleted mice had fewer pH3+ cells, a G2/M cell cycle phase marker and reduced S-β-Gal, a senescence marker. Primary PTCs displayed increased p-BRCA1^{Ser1524} after 48h AA or cisplatin treatment, with increased activation of growth arrest genes p53 and p21. shRNA-induced reduction of BRCA1 in HKC8s decreased the percentage of cells in the G2/M cell cycle phase and significantly reduced cell viability.

Conclusions: BRCA1 induces fibrosis after tubular injury. Loss of BRCA1 from PTs reduces G2/M cell cycle arrest, cellular senescence, and secretion of profibrotic mediators *in vivo* and *in vitro*. Thus, transient inhibition of BRCA1 can be beneficial for preventing AKI-CKD transition.

FR-PO1066

Elucidating the Function of a Novel Arg-1+/Clec4d+ Scar-Associated Monocyte-Derived Macrophage Population in Driving Fibrosis in Kidney Disease Models

Rachel Bell,[1,2] Laura Denby,[1] Bryan Conway,[1] Cécile Bénézech.[1] *[1]University of Edinburgh, Edinburgh, United Kingdom; [2]British Heart Foundation, Edinburgh, United Kingdom.*

Background: Fibrosis is the final common pathway in all progressive kidney disease. Macrophages are a major myeloid cell component of the renal mononuclear phagocyte system, with roles in defence against infection, renal injury, and repair. Using single-cell RNA sequencing, we identified a novel myeloid cell subset exclusively present in acute injury of the unilateral ureteric obstruction (UUO) model of kidney fibrosis. This population transcriptomically aligns to monocytes but is enriched for both *Arginase-1* (*Arg1*) and the *C-type lectin 4d* (*Clec4d)* and a large number of pro-inflammatory and pro-fibrotic genes. We hypothesise that this novel *Arg1*$^{+}$*/Clec4d*$^{+}$ population contributes to fibrosis deposition in progressive kidney disease.

Methods: The presence of the *Arg1*$^{+}$*/Clec4d*$^{+}$ cells was validated in the UUO, unilateral ischaemic reperfusion injury (uIRI) and subtotal nephrectomy models of kidney injury.

Results: Analysis of intra-renal inflammation revealed CD45^{+}CD11b^{+}Arg1^{+} cells persisted and increased in number across 7 days in our injury models. Post-injury, Arg1^{+} cells were confirmed to be Clec4d^{hi}. As time progressed post-injury, consistent with a monocyte to macrophage transition, there was a decrease in Ly6C but increase in F4/80, MHCII and CD206 expression in this subset. To confirm that Arg1^{+}/Clec4d^{+} cells were derived from monocytes (Ccr2^{+}), we administered tamoxifen to Ccr2Cre^{ERT2}-TdTomato mice under a single or multiple-dose regimen following UUO surgery. At day 7 post-injury, ~50% and ~90% of the Arg1^{+} cells were TdTomato^{+} following a single or multiple doses of tamoxifen, respectively, suggesting that these cells are primarily monocyte derived. Moreover, the Arg1^{+}/Clec4d^{+} cells were found to localise to areas of scarring. To investigate the therapeutic potential of targeting Clec4d^{+} expressed on the Arg1^{+}/Clec4d^{+} macrophages, mice underwent UUO surgery and were given multiple doses of a Clec4d-neutralising antibody. A decrease in *Arg1* and fibrosis-related gene expression was evident by day 7 post-injury.

Conclusions: Further investigation into targeting this population in kidney disease has the potential to aid the development of novel therapeutics to limit fibrosis and halt progression of disease.

The Adenine-Induced Mouse Model of CKD Shows Rapid Development of Impaired Kidney Function, Renal Fibrosis, Muscle Wasting, and Anemia

Maria K. Ougaard, Frederikke E. Sembach, Jacob Nøhr-Meldgaard, Adam B. Marstrand-Jørgensen, Henrik H. Hansen, Michael Christensen. *Gubra, Hoersholm, Denmark.*

Background: Translational rodent models are essential to identify more efficacious treatment options for patients with chronic kidney disease (CKD). However, most preclinical CKD models do not demonstrate impaired kidney function as determined by decreased glomerular filtration rate (GFR). Here, we characterize an adenine diet-induced (ADI) mouse model of CKD that enables clinical translational studies of CKD.

Methods: Male C57BL/6j mice (11 weeks old) were randomized into study groups (n=8-10 per group) based on body weight. ADI mice received a control diet from study day -2 and a CKD-inducing diet containing 0.2% adenine from study day 1, while control mice received a control diet from day -2 and continued with it throughout the study period. All groups received oral vehicle dosing once daily starting from day 1 until termination. Transdermal GFR (tGFR), urine creatinine-to-albumin ratio, and plasma cystatin C(pCyC) were evaluated at week 3 and 5. Blood was collected for glycated haemoglobin analysis, and gastrocnemius muscle and kidney tissue were sampled and weighed. Kidneys were collected for RNA sequencing or processed for histological evaluation of markers of macrophage infiltration (F4/80) and fibrosis (Col1a1).

Results: Compared to controls, ADI mice showed a significant tGFR decline correlating with an increased pCyC and marked albuminuria at 3 and 5 weeks after diet-induction. At termination, ADI mice showed significantly decreased glycated haemoglobin (14.7 vs 17.6 g/dL) and gastrocnemius muscle weight compared to mice receiving the control diet (0.12 vs 0.15 g). Furthermore, Quantitative kidney histomorphometric analysis demonstrated an increase in kidney fibrosis (Col1a1) and macrophage infiltration (F4/80) in ADI mice. Consistent with tGFR decline and kidney histology, the renal transcriptome signature in ADI mice indicated upregulation of gene expression markers of fibrosis (e.g. *Col1a1, Grem1)*, inflammation (e.g. *Il6, Il1b)*, and angiogenesis (e.g. *Ednra, Agt)*.

Conclusions: ADI mice rapidly develop functional, biochemical and histological hallmarks of CKD complicated by anaemia and muscle wasting. Consequently, ADI mice are highly relevant in preclinical target and drug discovery for CKD.

FR-PO1068

Annexin A2 Promotes Tubular Epithelial Trans-Differentiation and Kidney Fibrosis

Ling Lin, Kebin Hu. *Penn State College of Medicine, Hershey, PA.*

Background: Annexin A2 is a Ca^{2+}- and phospholipid-binding protein widely expressed in various cells and tissues. It acts as a cell surface receptor for tissue plasminogen activator (tPA) and plasminogen, regulating the homeostasis of blood coagulation, fibrinolysis and matrix degradation. However, its role in kidney fibrosis remains largely unknown. Our previous *in vitro* work has shown that annexin A2 mediates NF-κB activation and promotes macrophage M2 to M1 phenotypic change, suggesting a critical role of annexin A2 in kidney fibrogenesis.

Methods: Unilateral ureteral obstruction (UUO) was induced in a novel annexin A2 knockout mice and their wildtype counterparts. Renal histology was evaluated. Kidney fibrosis, renal annexin A2 level, and epithelial transdifferentiation were examined in these mice.

Results: Annexin A2 was dramatically induced in the obstruction-induced fibrotic kidneys in a time-dependent manner, and its induction correlated with the extent of fibrotic injury as indicated by fibronectin deposition. Intriguingly, double immune staining analysis found that annexin A2 was dramatically induced in the interstitial F4/80-positive macrophages. It was further found that, after obstructive injury, annexin A2 knockout mice displayed significantly reduced tubular epithelial damage and dramatically decreased deposition of matrix components such as collagen and fibronectin than that of their control littermates. Additionally, obstruction-induced epithelial transdifferentiation was significantly reduced in annexin A2 knockout mice as indicated by increase of Ecadherin and decrease of de novo induction of αSMA.

Conclusions: Thus, it is clear that annexin A2 promotes epithelial transdifferentiation and kidney fibrosis after obstructive injury. Additionally, our results indicate a role of macrophages in annexin A2-mediated epithelial damage and transdifferentiation.

Alveolar Type II Cell-Specific Mitofusins Modulate Kidney Fibrosis and Associated Lung Injury

Divya Bhatia, Eleni Kallinos, Edwin Patino, Maria Plataki, Augustine M. Choi, Mary E. Choi. *Weill Cornell Medicine, New York, NY.*

Background: Chronic kidney disease (CKD)-associated lung injury and implications of deleterious lung-kidney crosstalk on the progression of kidney fibrosis are under-recognized. Mitochondrial fusion proteins, mitofusin (MFN)1 and MFN2, play critical roles in regulating mitochondrial physiological function, which is essential for kidney homeostasis. We studied the effects of type II alveolar epithelial cell (AEC II)-specific loss of *Mfn1* or *Mfn2* on kidney fibrosis and associated lung injury during CKD.

Methods: AEC II (*Spc-Cre*$^{+/-}$)-specific *Mfn1* (*Mfn1*$^{fl/fl}$) or *Mfn2* (*Mfn2*$^{fl/fl}$) knockout (KO) and control (*Spc-Cre*$^{+/-}$) mice were subjected to unilateral ureteral obstruction (UUO) or sham surgery (7-days) or fed with adenine (AD) or control diet (28-days). Kidneys, lungs, blood, and bronchoalveolar lavage (BAL) fluid were analyzed by western blot, Masson's trichrome staining, and flow cytometry. Serum creatinine (Scr) and blood urea nitrogen (BUN) were measured.

Results: MFN1 and MFN2 in AEC II (EpCAM+ CD45-), lungs, and kidneys decreased while pro-inflammatory monocytes (CCR2+ Ly6C+ CD11b+) in blood, kidneys, lungs, and BAL fluid increased after UUO or AD. AEC II-specific *Mfn1* or *Mfn2* KO mice displayed higher expression of fibronectin, arginase-I, galectin-3, IL-1β, and TGF-β1, and collagen deposition in the kidneys and lungs after UUO than control mice. *Mfn1* or *Mfn2* loss in AEC II resulted in increased kidney macrophages (KM, CD11b+ F4/80+ CD45+) in obstructed kidneys and increased alveolar macrophages (AM, siglecf F+ CD11C+ CD45+) in the lungs and BAL fluid after UUO. KM and AM from AEC II-specific *Mfn1* or *Mfn2* KO mice exhibited higher mitochondrial-specific reactive oxygen species and galectin-3 after UUO than control mice. Moreover, AEC II-specific *Mfn2* KO mice displayed a lower number of proximal tubular cells (megalin+ CD45-) in obstructed kidneys, and higher BUN and Scr levels than control mice after UUO.

Conclusions: In 2 models of kidney fibrosis, we show downregulation of MFN1/2 in both the lungs and kidneys. AEC II-specific loss of *Mfn(s)* augmented inflammatory and fibrotic responses in KM and AM during CKD, suggesting the role of macrophages in inter-organ crosstalk. Mitochondrial-derived damage-associated molecular patterns from AM and injured AEC II may be involved in deleterious lung-kidney crosstalk and aggravate kidney fibrosis.

The Uremic Toxin Indoxyl Sulfate Contributes to Renal Fibrosis via mTORC1 Signaling Pathway

Takehiro Nakano, Hiroshi Watanabe, Toru Maruyama. *Department of Biopharmaceutics, Graduate School of Pharmaceutical Sciences, Kumamoto University, Kumamoto, Japan.*

Background: Activation of mTORC1 in renal tissue has been reported in chronic kidney disease (CKD)-induced renal fibrosis. This suggests that the regulation of renal mTORC1 activity represents a potential therapeutic target for the treatment of renal fibrosis. However, the molecular mechanisms responsible for activating mTORC1 in CKD pathology are not well understood. The purpose of this study was to identify the uremic toxin involved in mTORC1-induced renal fibrosis.

Methods: Human renal proximal tubule epithelial cells (HK-2 cells), rat renal interstitial fibroblast (NRK-49F cells), and human monocytes (THP-1 cells) were used in *in vitro* studies. Adenine-induced CKD mice were used in *in vivo* studies.

Results: Among the seven protein-bound uremic toxins, only indoxyl sulfate (IS), an indole-containing compound, caused significant activation of mTORC1 in HK-2 cells. This IS-induced mTORC1 activation was inhibited in the presence of an organic anion transporter inhibitor, a NADPH oxidase inhibitor, and an antioxidant. IS also induced epithelial-mesenchymal transition of tubular epithelial cells, differentiation of fibroblasts into myofibroblasts, and inflammatory response of macrophages, which are associated with renal fibrosis, and these effects were inhibited in the presence of rapamycin (mTORC1 inhibitor). In *in vivo* experiments, IS-overload was found to activate mTORC1 in the mouse kidney. The administration of AST-120 or rapamycin targeted to IS or mTORC1 ameliorated renal fibrosis in CKD mice.

Conclusions: The findings reported herein indicate that IS activates mTORC1, which then contributes to renal fibrosis. Therapeutic interventions targeting IS and mTORC1 could be effective against renal fibrosis in CKD.

FR-PO1071

The Role of SRY-box Transcription Factor 4 in Renal Fibrosis

Hao Du,[1] Baihai Jiao,[1] Melanie Tran,[1] Bo Song,[1] Yanlin Wang.[1,2] *[1]UConn Health, Farmington, CT; [2]VA Connecticut Healthcare System, West Haven, CT.*

Background: Chronic kidney disease (CKD) is a widely prevalent disorder around the world, which affects over 10% adults. The pathological feature of CKD is renal fibrosis, characterized by the excessive production and deposition of extracellular matrix (ECM). The production and accumulation of ECM is partly due to tubular epithelial cell (TEC) dedifferentiation. However, the molecular mechanisms underlying TEC dedifferentiation are not fully understood. In this study, we investigated the role of SRY-box transcription factor 4 (SOX4) in regulating TEC dedifferentiation during the development of CKD.

Methods: We generated SOX4 conditional knockout mice by crossing SOX4 floxed mice with tamoxifen-inducible CAG-CreER mice. CAG-Cre$^{+/-}$SOX4$^{f/f}$ mice were given tamoxifen to induce SOX4 deletion (SOX4^{GKO}). CAG-Cre$^{-/-}$SOX4$^{f/f}$ mice received the same dose of tamoxifen and used as controls (SOX4^{CON}). Both SOX4^{CON} and SOX4^{GKO} mice were subjected to unilateral ureteral obstruction (UUO). Kidneys were harvested at 10 days after UUO injury. Kidney sections were prepared and stained for histological and immunological analysis. Western blot analysis and immunostaining were performed to detect the levels of signaling molecules, fibronectin, collagen type I, and alpha-SMA in the kidneys. Sirius red staining was performed to detect total collagen deposition in the kidney. Cultured TECs were employed to examine the role and molecular mechanisms of SOX4 in the regulation of TEC dedifferentiation *in vitro*.

Results: The expression of SOX4 was increased in TEC after UUO injury. In response to obstructive injury, SOX4^{CON} mice exhibited TEC dedifferentiation with senescence and G2/M arrest, fibroblast activation and developed substantial total collagen deposition and ECM protein production in the kidney. Global SOX4 deficiency significantly alleviated TEC dedifferentiation, suppressed fibroblast activation, and reduced total collagen deposition and ECM protein production in the kidney with UUO injury. Furthermore, knockdown SOX4 by shRNA inhibited TEC dedifferentiation in cultured TEC in response to TGF-β1. Mechanically, SOX4 facilitated TGF-β1-Smad3 signaling to promote TEC dedifferentiation.

Conclusions: Our results demonstrate that SOX4 plays an essential role in the development of renal fibrosis by regulating TEC dedifferentiation and fibroblast activation. Therefore, SOX4 may serve as a novel therapeutic target for CKD.

Cell-Specific Iron Metabolism in Kidney Fibrosis

Chantalle A. Campbell, Jade Matthews balcombe, Edwin Patino, Kanza Baqai, Divya Bhatia, Mary E. Choi, Oleh M. Akchurin. *Weill Cornell Medicine, New York, NY.*

Background: Chronic kidney disease (CKD) affects 10-15% of the adult U.S. population. Our recent data indicate that in CKD, most kidney macrophages (KMφ) have pathologically depleted cellular labile iron pool, which induces their pro-fibrotic responses. However, the mechanism of intracellular iron deficiency of KMφ and iron metabolism in other cell types that participate in fibrosis, particularly in tubular epithelial cells (TEC) have not been elucidated in CKD.

Methods: We used two models of kidney fibrosis, adenine diet and unilateral ureteral obstruction (UUO). We analyzed expression of iron-related genes (*Tfrc*: iron importer, transferrin receptor 1 [TfR1], a marker of cellular iron deficiency or overload; *Fth1* and *Ftl*: ferritin heavy and light chains; *Slc40a1*: iron exporter, ferroportin [FPT]; and *Ncoa4*, a marker of ferritinophagy) and respective proteins in whole kidney tissue, as well as in sorted KMφ and TEC (isolated using CD11b and CD133 magnetic microbeads). We also analyzed expression of these genes in publicly available single cell/nucleus transcriptomic mouse and human kidney fibrosis datasets.

Results: In contrast to KMφ, *Tfrc* gene was suppressed in whole kidney tissue and in the proximal TEC of UUO kidneys, suggesting iron excess in some (e.g., proximal tubules) and labile iron deficiency in other (e.g., KMφ) cell types during kidney fibrosis. Interestingly, LIP depletion in KMφ was observed despite suppression of FPT in CD11b-positive KMφ, while both *Slc40a1* gene and FPT protein were induced in whole kidney tissue during fibrosis. This suggests that regulation of FPT is independent of systemic

hepcidin in most kidney cells (but not in KMφ) during fibrosis. *Fth1* and *Ftl* genes were suppressed while FtH and FtL proteins were induced in whole kidney tissue, KMφ, and in TEC during fibrosis. Taken together with TfR1/*Tfrc* data, this suggests excessive expression of FtH in KMφ and insufficient in TEC during fibrosis. Cell-specific ferritin dysregulation in kidney fibrosis may owe to disrupted ferritinophagy. Indeed, NCOA4 expression was drastically reduced in KMφ and had only a trend toward reduction in TEC during fibrosis.

Conclusions: Cellular iron status varies among different cell types participating in kidney fibrosis, which likely differentially modulates fibrotic responses of these cells and may inform novel cell-specific therapeutic targets.

IRhom2 Promotes Kidney Fibrosis Through Activation of EGFR in Fibroblasts

Shirong Cao,[1] Yu Pan,[2,1] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Shanghai Jiao Tong University, Shanghai, China.*

Background: In the kidney, tubulointerstitial fibrosis can result from incomplete recovery from acute kidney injury (AKI). Activation of the epidermal growth factor receptor (EGFR) has been implicated as a potential mediator of interstitial fibrosis. **iRhom2**, an inactive member of the Rhomboid intramembrane proteinase family, can regulate EGFR signaling pathway via activation of ADAM17 (TACE) and secretion of EGFR ligands, including amphiregulin and HB-EGF as well as secretion of TNF-α. The current studies were designed to investigate the potential role of iRhom2 in the development of kidney fibrosis.

Methods: iRhom2 knockout (iRhom2-/-) and WT mice (C56/Bl6, male, 8-12 weeks old) were used for all experiments. Models of kidney injury included ischemia/reperfusion (IRI) and unilateral ureteral obstruction (UUO). Kidney myeloid cells and fibroblasts/myofibroblasts were isolated with corresponding microbeads.

Results: In the UUO model, iRhom2 mRNA expression increased in total kidney, isolated myeloid cells, and isolated kidney fibroblasts/myofibroblasts. Immunofluorescent staining confirmed iRhom2 expression in renal macrophages (F4/80+ iRhom2+ cells) and myofibroblasts (α-SMA+ iRhom2+ cells). Although the numbers of α-SMA+ cells and p-EGFR+ α-SMA+ cells were minimal under normal condition, they markedly increased after UUO for 8 days. In iRhom2-/- mice, both the numbers of α-SMA+ myofibroblasts and p-EGFR+ (indication of EGFR activation) α-SMA+ myofibroblasts decreased, with the percentage of p-EGFR expressing myofibroblasts decreasing from 43% to 17%. Quantitative Picrosirius red staining clearly showed less kidney interstitial fibrosis in iRhom2-/- mice. Four weeks after ischemic injury, iRhom2-/- mice also developed less fibrosis, as indicated by reduction in kidney profibrotic and fibrotic gene and protein expression as well as quantitative Picrosirius red staining. In addition, iRhom2-/- mice had preserved kidney function, as indicated by higher glomerular filtration rate 4 weeks after ischemic injury.

Conclusions: These studies provided evidence for a potential role of iRhom2 in development of kidney fibrosis in response to kidney injury, due at least in part by stimulating EGFR activation in fibroblasts/myofibroblasts. Targeting iRhom2 may provide a new strategy for prevention of kidney interstitial fibrosis.

IGFBP-5/TGF-β1-Induced Cell Cross-Talk Between Endothelia and Tubular Epithelia Promotes Renal Fibrosis

Shuqiang Wang,[1,2] Chengcheng Song,[3] Kun Chi,[1] Xueguang Zhang,[3] Zhangning Fu,[1] Xiaodong Geng,[1] Chao Liu,[1] Guangyan Cai,[1] Xiangmei Chen,[1] Quan Hong,[1] Di Wu.[3] *[1]First Medical Center of Chinese PLA General Hospital Nephrology Institute of the Chinese People's Liberation Army, Beijing, China; [2]Peking University Shenzhen Hospital, Shenzhen, China; [3]Beijing Electric Power Hospital, Beijing, China.*

Background: Renal fibrosis is a common pathophysiological characteristic of chronic kidney disease (CKD) for which there is no effective treatment. The mechanism of renal fibrosis is complicated and remains unclear. Our previous study revealed that Insulin-like growth factor binding protein 5 (IGFBP-5) induces glycolytic activation in ECs and ultimately aggravates renal inflammation in diabetic kidney disease (DKD).

Methods: HK-2 and HUVEC cells were included in this study. UUO and ANN model were obstructed by Wild-type, *IGFBP-5*$^{-/-}$ and IGFBP-5$^{flox/flox}$, cre mice. IGFBP-5, TGF-β and fibrosis makers were detected to explore the mechanism of IGFBP-5 in fibrosis.

Results: We found that the serum IGFBP-5 levels were significantly increased in CKD, that IGFBP-5 was dominantly localized in vascular endothelial cells (ECs) of kidney tissue, and that IGFBP-5 deficiency relieved renal fibrosis in CKD model mice. In vitro experiments indicated that IGFBP-5 exacerbated the fibrosis phenotypic alteration of tubular epithelial cells (TECs) by the TGF-β1/p-Smad3 signaling pathway. In turn, TGF-β1 could facilitate the synthesis of IGFBP-5 in ECs. The crosstalk between TECs and ECs mediated by IGFBP-5 and TGF-β1 was confirmed in a coculture system and endothelial-specific IGFBP-5-deficient mice.

Conclusions: Renal fibrosis is exacerbated by TEC-EC cellular crosstalk through the feedback loop consisting of IGFBP-5 and TGF-β1. These findings suggest that IGFBP-5 may be a new pathogenic factor in renal fibrosis and a potential new therapeutic target in CKD.

Mechanism of the involvement of IGFBP-5 in renal fibrosis

FR-PO1075

Lcn2 Plays a Key Role in Dot1l-HDAC2-ET1-Mediated Kidney Fibrosis

Akaki Tsilosani, Chao Gao, Chenchun Guo, Enuo Chen, Wenzheng Zhang. *Albany Medical Center, Albany, NY.*

Background: Kidney fibrosis is a hallmark of chronic kidney disease. The genetic and epigenetic factors regulating kidney fibrosis are largely unknown. Kidney injury marker Lipocalin 2 (Lcn2) is involved in kidney fibrosis. We reported that *Aqp2Cre* mice express Cre specifically in Aqp2^{+} progenitor cells, which generates at least 5 types of cells forming distal convoluted tubule 2 (DCT2), connecting tubule (CNT) and collecting duct (CD). Our recent studies also indicated that disruption of histone H3 K79 methyltransferase *Dot1l* in Aqp2^{+} progenitor cells led to upregulation of endothelin 1 (ET1) and kidney fibrosis through histone deacetylase 2 (HDAC2) during normal aging. Here, we hypothesize that Lcn2 is a new component of this process and upregulates HDAC2, which in turn increases ET1 and facilitates kidney fibrosis.

Methods: Using the *Aqp2Cre* driver, we developed three conditional knockout mice: 1) DCT2/CNT/CD-specific *Dot1l* conditional knockout mice (*Dot1l*$^{f/f}$ *Aqp2Cre* or *Dot1l*^{AC}); 2) DCT2/CNT/CD-specific *Dot1l* and *Edn1* double conditional knockout mice (*Dot1l*$^{f/f}$ *Edn1*$^{f/f}$ *Aqp2Cre* or *DE*^{AC}*);* 3) DCT2/CNT/CD-specific *Dot1l* conditional knockout plus Lcn2 global knockout mice (*Dot1l*$^{f/f}$ *Aqp2Cre Lcn2*$^{-/-}$ or *DL*$^{-/-}$). WT and the three knockout mice were analyzed at the age of 14 months. A variety of approaches including immunofluorescence staining coupled by high-resolution confocal microscopy, metabolic assays, real-time RT-qPCR, and Western blotting were used to assess kidney fibrosis, kidney function, and/or expression of HDAC2, Lcn2, and ET1 in mice, in IMCD3 cells overexpressing Lcn2, or in IMCD3 cells treated with various doses of recombinant Lcn2.

Results: Like *DE*^{AC} vs. *Dot1*^{AC} mice, *DL*$^{-/-}$ vs. *Dot1*^{AC} mice displayed less pronounced kidney fibrosis and improved kidney function. While high Lcn2 expression remained in *DE*^{AC} vs. *Dot1*^{AC} mice, significantly reduced HDAC2 and ET1 levels were observed in *DL*$^{-/-}$ vs. *Dot1*^{AC}. In IMCD3 cells, silencing *Dot1l* in IMCD3 cells led to upregulation of Lcn2, and addition of recombinant Lcn2 or overexpression of Lcn2 increased expression of HDAC2 and ET1.

Conclusions: Dot1l-Lcn2-HDAC2-ET1-kidney fibrosis may be considered as a new fibrogenesis pathway. That is, disruption of *Dot1l* in Aqp2^{+} progenitor cells not only directly upregulates ET1, but also indirectly through Lcn2, which positively regulates HDAC2, further facilitating ET1-mediated kidney fibrosis.

Stimulator of Interferon Genes (STING) Mediates Endoplasmic Reticulum Stress Activation Causing Renal Fibroinflammation

Magaiver A. Silva,[1,2] Poonam Dhillon,[1] Andrea Sanchez Navarro,[1] Hailong Hu,[1] Andrea M. Bergeson,[1] Jonathan J. Miner,[1] Katalin Susztak.[1] Susztak Lab. *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Universidade de Sao Paulo, São Paulo, Brazil.*

Background: Endoplasmic reticulum (ER) stress plays a pivotal role in kidney disease pathogenesis, yet the mechanisms leading to ER stress are largely unexplored. Viruses are known to manipulate ER-related processes, potentially aiding their replication or pathogenesis. The adaptor molecule STING, known for detecting double-strand DNA in pathogenic infections. In light of these insights, we investigated the relationship between STING, ER stress, and the development of kidney disease.

Methods: We utilized STING N153S mice, exhibiting constitutive STING activation, and mice with a conditional deletion of STING from kidney tubules. We performed in vitro experiments, including the silencing of STING or ER stress pathways, and analyzed molecular events through immunofluorescence, qPCR, western blot, and immunoprecipitation techniques. Gene expression data was scrutinized through RNA sequencing from human control and diseased samples, as well as mouse kidney disease models.

Results: In both the cisplatin and UUO models, we identified a consistent activation of STING and the ER stress–activated eIF2α kinase (PERK) pathway. Interestingly, STING was found to physically interact with and activate PERK, leading to ER stress and, subsequently, renal fibroinflammation. On the contrary, deletion of STING or PERK inhibition showed a protective effect against disease development. Further, transcriptomic

analysis of human CKD patients and mouse kidney injury models bolstered the association between renal dysfunction and ER stress pathway activation.

Conclusions: Our findings unveil a novel mechanism wherein STING activation triggers ER stress via the PERK pathway, leading to kidney tubule injury and fibrosis. This breakthrough research offers promising avenues for devising strategies to modulate ER stress and develop potent therapies for treating fibroinflammatory kidney diseases.

Hyaluronan Synthase Contributes to Tubulointerstitial Fibrosis in a Murine Model of CKD

Susan Yung, Yuesong Xu, Cristina A. Garcia Cordoba, Tak Mao D. Chan. *Department of Medicine, School of Clinical Medicine, the University of Hong Kong, Hong Kong, Hong Kong.*

Background: Chronic kidney disease (CKD) is characterized by progressive tubulointerstitial fibrosis and tubular atrophy, leading to kidney failure. There is currently no effective treatment for CKD. Understanding the mechanisms that mediate tubulointerstitial fibrosis is prerequisite for the development of novel treatment options. Hyaluronan (HA) is a ubiquitous component of the extracellular matrix and has pleiotropic functions depending on its molecular weight. High molecular weight HA is generated by HA synthase (HAS) I and II and possesses anti-inflammatory and anti-fibrotic properties, whereas low molecular weight HA is synthesized by HAS III and contributes to inflammatory and fibrotic processes. We investigated the role of HAS I, II and III in tubulointerstitial inflammation and fibrosis in CKD.

Methods: CKD was induced in wild-type (WT) and HAS I, III or I/III-knockout (KO) mice by feeding with 0.2% adenine in casein-based chow for 8 weeks after which time, mice were sacrificed and kidneys harvested and assessed for histopathological changes. Twenty-four hour urine was collected to determine proteinuria. WT and KO mice fed with casein-based chow served as non-CKD controls.

Results: Tubulointerstitial HA expression was increased in WT CKD mice compared with non-CKD WT controls and this was accompanied by development of proteinuria, tubular atrophy, infiltration of immune cells, and increased collagen and α-smooth muscle actin expression. HAS I, III and I/III KO mice with CKD showed less severe histopathological abnormalities with decreased expression of mediators of fibrosis and reduced immune cell infiltration, the latter being more pronounced in HAS I KO mice, compared to WT CKD mice. Moreover, HAS I and HAS III KO, but not HAS I/III KO mice with CKD showed a significant reduction in proteinuria compared to WT CKD mice ($P<0.05$, for both).

Conclusions: Our data suggest that HAS I, II and III have distinct contribution to kidney function deterioration and tubulointerstitial inflammation and fibrosis in murine adenine-induced CKD.

Excessive Mitochondrial Copper Load Driven by Upregulated Copper Transporter 1 Contributes to Mitochondrial Dysfunction and Renal Fibrosis

Saiya Zhu. *Tongji University, Shanghai, China.*

Background: Copper is an essential trace element in living organisms and serves as a crucial cofactor for various enzymes. Our previous research has revealed that intracellular copper overload promotes renal fibrosis. However, the underlying mechanisms remain largely unknown. In this study, we found that copper ions mainly accumulate in mitochondria, leading to oligomerization of the DLAT protein involved in the tricarboxylic acid cycle, mitochondrial dysfunction, cellular apoptosis and renal fibrosis. Additionally, copper transporter 1 (CTR1), responsible for transporting copper ions into cells, was significantly upregulated in the renal fibrosis models. Therefore, we propose that CTR1 may drive mitochondrial copper overload, resulting in mitochondrial dysfunction and renal fibrosis.

Methods: We assessed the expression levels of CTR1 in fibrotic renal biopsy samples, 28-day fibrosis model of ischemia-reperfusion injury, and NRK-52E cell treated with TGF-β1. We used lentiviral vectors to overexpress and downregulate of CTR1 in NRK-52E and used CTR1 knockdown transgenic mice. Molecular dynamics simulations were conducted to explore the effect of copper ions on the lipoylated DLAT protein. ICP-MS was used to study the regulatory role of CTR1 on mitochondrial copper content. Non-reducing gel electrophoresis was performed to detect DLAT oligomer level. DLAT enzyme activity was evaluated. We used mitoSOX staining and electron microscopy to investigate mitochondrial function. We also use WB, QPCR and Masson to explore the role of CTR1 in renal fibrosis.

Results: Compared to the sham-operated group, mitochondrial copper was overload in IRI 28d fibrotic model and led to mitochondrial swelling and mitochondrial dysfunction. Furthermore, mitochondrial copper overload targeted lipoylated modification sites of DLAT, leading to DLAT oligomerization, enzyme activity inhibition and increased mitochondrial reactive oxygen species. Additionally, CTR1 was increased in fibrotic renal biopsy samples, IRI 28d fibrosis model and TGF-β1 treated cells. Downregulation of CTR1 decreased mitochondrial copper level and improved mitochondrial function.

Conclusions: In renal fibrosis, high expression of CTR1 drives mitochondrial copper overload, leading to abnormal aggregation of lipoylated DLAT protein, enzyme activity inhibition, mitochondrial dysfunction and renal fibrosis.

FR-PO1079

TSPO Mediates Tubulointerstitial Fibrosis and Kidney Inflammation After Unilateral Ureteral Obstruction

Yuchen Feng, Wai Han Yiu, Sarah W.Y. Lok, Yixin Zou, Jingyuan Ma, Kar Neng Lai, Sydney C. Tang. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

Background: Tubulointerstitial fibrosis is a hallmark of chronic kidney disease (CKD) and predicts progression to kidney failure. A better understanding of its pathogenetic mechanisms is required for designing novel and effective treatments for this irreversible pathological process. Translocator protein (TSPO), located on the outer mitochondrial membrane, is associated with renal tubular cell death and regeneration in acute kidney injury. However, the role of TSPO in progressive CKD remains unknown.

Methods: Unilateral ureteral obstruction (UUO) or sham operation were performed on C57BL/6J mice to establish progressive tubulointerstitial fibrosis. TSPO antagonist PK11195 or vehicle was administrated daily to UUO mice for 7 days starting on the day of surgery. Kidneys were harvested for histology, inflammation and fibrosis.

Results: Histopathologically, tubular damage induced by UUO was reversed by PK11195 treatment. Induction of TNF-α, CCL-2 and IL-1β mRNA in the UUO kidney was reduced in PK11195 group compared to vehicle control. UUO-induced collagen deposition, as demonstrated by Masson's Trichrome and Picrosirius Red staining, was decreased after PK11195 treatment, and immunohistochemical analysis further confirmed significant reduction of Col-1 and Col-3 expression. Furthermore, PK11195 treatment downregulated UUO-induced fibronectin, α-SMA, vimentin and TGF-β levels by Western blotting.

Conclusions: We provided novel data to show that blockade of TSPO activity could alleviate kidney fibrosis and inflammation in murine UUO, suggesting that TSPO could play an important role in regulating progressive kidney disease. **Funding:** Health and Medical Research Fund (HMRF) of Hong Kong (grant no. 09202356); Hong Kong Society of Nephrology Research Grant 2022

Tryptophan Metabolite Accumulation in CKD: Unraveling the Link Between Kidney Dysfunction and Brain Injury

Afaf Saliba, Shane Matta, Leila Hejazi, Subrata Debnath, Kumar Sharma. Center for Precision Medicine - Laboratory of Kumar Sharma. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: The prevalence of cognitive impairment increases dramatically with the progression of Chronic Kidney Disease (CKD). The underlying pathophysiology of cognitive decline with advanced CKD remains to be established. We performed targeted metabolomics in plasma from patients with CKD stages 3 to 5 and kidney and brain samples from a mouse model of rapid kidney failure.

Methods: Clinical plasma samples were analyzed via mass spectrometry for essential amino acid tryptophan and its metabolites. A mouse kidney failure model was established by MDM2 deletion in proximal tubules in a doxycycline-inducible mouse model. Six days post-doxycycline administration, control and MDM2-conditional knock-out (cKO) mice were sacrificed, and kidneys and brains were harvested for cryosectioning, protein, and RNA extractions. Metabolomics analysis was performed via a Thermo-Orbitrap QExactive HFX) and microfluidic platform (ZipChip, 908 Devices). Data and pathway analysis were performed using MetaboAnalyst 5.0.

Results: Neurotoxic tryptophan metabolite 3-hydroxykynurenine (3-HK) was significantly ($p<0.01$) elevated in patients with CKD stage 5 (n=8) not-on-dialysis compared to CKD stages 3B and 4 (n=18). Mice lacking MDM2 in the renal tubules (n=4) exhibited aggressive renal tubular loss with increased systemic inflammation based on a significant increase in neutrophils to lymphocytes ratio ($p<0.05$) and plasma IL-6 levels ($p<0.01$), compared to control mice (n=4). Metabolomics analysis in plasma samples of MDM2cKO vs. control mice highlighted an accelerated tryptophan degradation via the kynurenine pathway with resultant accumulation of 3-HK levels ($p<0.01$). 3-HK plasma concentration correlated with plasma creatinine ($r=0.82$; $p<0.01$). Interestingly, brain tissue analysis showed increased 3-HK levels ($p<0.01$). Assessment of the brain cortex of the MDM2cKO mice via TUNEL assay identified a significant increase in apoptotic cells.

Conclusions: Our study indicates that advanced CKD is associated with accelerated tryptophan degradation and increased levels of circulating 3-HK, which can readily cross the blood-brain barrier. Accumulation of 3-HK potentially causes brain cell toxicity and cognitive dysfunction in CKD.

Uremic Toxin Indoxyl Sulfate Impairs Hydrogen Sulfide Formation in Nephrectomy Rats

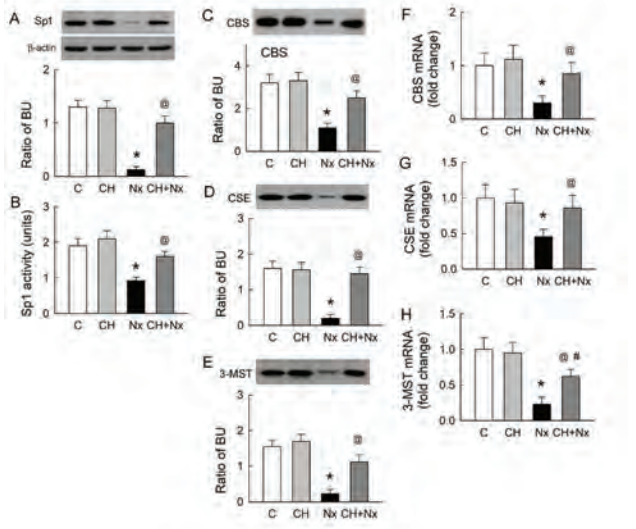
Chien-Lin Lu.[1,2] *[1]Fu Jen Catholic University, New Taipei, Taiwan; [2]Fu Jen Catholic University Hospital, New Taipei, Taiwan.*

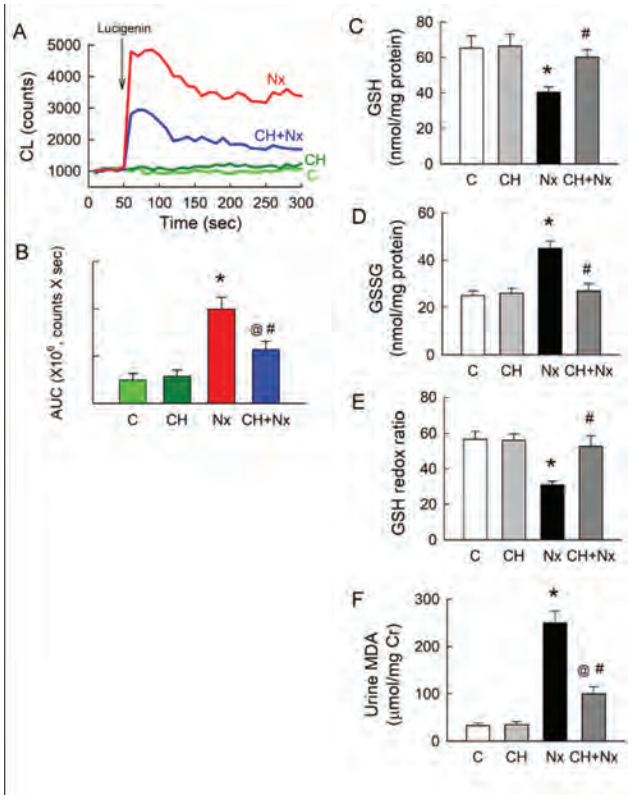
Background: Hydrogen sulfide (H2S) has antioxidant properties but is reduced in CKD, making the cells more vulnerable to oxidative damage. The interaction between Indoxyl Sulfate (IS) and H2S in CKD needs further exploration.

Methods: Male Wistar rats had nephrectomy and received CH-223191, an AhR antagonist. Blood and urine samples were collected post-treatment for H2S level measurement. Kidney tissue was evaluated for H2S-producing enzyme and Sp1 protein activity, and reduced GSH and oxidized GSSG levels.

Results: Administering CH-223191 to rats after nephrectomy prevented the harmful effects of IS on the kidneys. CH-223191 restored H2S levels, reduced IS accumulation, and reversed the changes in H2S-producing enzymes and the transcription factor Sp1 (Fig1). It also decreased oxidative stress and lipid peroxidation in the nephrectomy rats (Fig2). These findings indicate that CH-223191 protects against kidney damage by mitigating IS-induced effects, preserving H2S generation, and reducing oxidative stress.

Conclusions: Impaired H_2S generation caused by IS renders the kidney susceptible to oxidative stress damage, representing one of the mechanisms underlying IS-mediated kidney function loss.





FR-PO1082

The Pathogenic Role of C5a/C5aR Axis in AKI-to-CKD Transition

Jingyuan Ma, Wai Han Yiu, Sarah W.Y. Lok, Yixin Zou, Yuchen Feng, Kar Neng Lai, Sydney C. Tang. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

Background: Activation of complement C5a/C5aR axis contributes to the pathogenesis of acute kidney injury (AKI). However, whether it plays a role in the transition to chronic kidney disease (CKD) after AKI remains unclear. In this study, we investigated the chronic effects of bilateral ischemia-reperfusion injury on C5aR deficient mice and dissected C5aR-dependent mechanisms during AKI-to-CKD transition.

Methods: Wild type $C5aR^{+/+}$ and knockout $C5aR^{-/-}$ mice were subjected to bilateral ischemia and sacrificed at day 3 and 7 after reperfusion. Kidney damage was assessed by evaluating kidney function, histopathological changes and expression levels of pro-inflammatory, fibrotic, oxidative and injury markers.

Results: Compared to the $C5aR^{+/+}$ controls, $C5aR^{-/-}$ mice showed significant decrease in serum creatinine and reduced expressions of Kim1 and Ngal in both the 3-day and 7-day BIRI models. The improvement in kidney injury in BIRI $C5aR^{-/-}$ mice was further confirmed by PAS staining. The expression levels of MCP-1, TNF-α, IL-6 and IL-1b were significantly decreased in $C5aR^{-/-}$ mice after BIRI. In particular, there was decreased infiltration of M1 macrophages with an increase in M2 macrophage number in $C5aR^{-/-}$ mice on day 7 after reperfusion. Sirius red and Masson Trichrome staining demonstrated a progressive development of interstitial fibrosis in $C5aR^{+/+}$ mice after BIRI, which were suppressed in $C5aR^{-/-}$ mice with less deposition of collagen 1 and collagen 3 in the post-ischemic kidneys. Moreover, the oxidative stress markers NOX2 and 8-OHdG were significantly reduced in $C5aR^{-/-}$ mice after BIRI.

Conclusions: C5aR deficiency protected mice from kidney inflammation and fibrosis by reducing oxidative stress during AKI-to-CKD transition. **Funding:** Research Grants Council of Hong Kong (General Research Fund, grant no. 17108222), Hong Kong Society of Nephrology Research Grant (2021)

FR-PO1083

Establishment and Application a Novel Reversible Unilateral Ureteral Obstruction (RUUO) Mouse Model and in Mechanism Study of AKI to CKD

Xinyue Mao,[1] Xiaogang Li,[2,3] Bing Li.[1] *[1]Hainan Medical University, Haikou, China; [2]Mayo Clinic Department of Internal Medicine, Rochester, MN; [3]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN.*

Background: Acute kidney injury (AKI) is a worldwide health problem. About 35-71% of AKI progress to chronic kidney disease (CKD) due to renal repair failure. Studies on the progression of AKI to CKD are focused on animal models of prerenal and renal AKI. It is necessary to establish an animal model to investigate the progression of postrenal AKI to CKD.

Methods: We established a RUUO mouse model. In brief, we ligated the left ureter to create a ureteric obstruction in mice. After 5 or 10 days, ureteral obstruction was removed by the coincidation of the ureter and bladder. Three days later, we performed the right nephrectomy and then monitor renal function and molecular mechanisms on the left kidney with IF and IHC staining, scanning electron microscopy and flow cytometry analysis.

Results: We observed adaptive and maladaptive repairs in 5 and 10 days RUUO kidneys. During the complete recovery of AKI in 5 days RUUO kidneys, 1) the infiltration of M2 macrophages marked by F4/80 + CD206 and CD11b + $ly6C^{int}$ was increased; 2) the expression of inflammatory factors (TNF-α, IL-1β, IL-6 and IL-4, IL-10), autophagy components (Beclin-1, Bcl-2, BNIP3, LAMP2, LC3BII/I and P62), and HIF-1α and HIF-2α, and the population of peritubular capillaries (PTC) (VEGF and CD31) were normalized to baseline; and 3) the activation of pericytes into myofibroblasts was blocked and alleviated as examined by PDGFRβ+α-SMA staining. In the process of AKI to CKD in 10 days RUUO kidneys, 1) M1 macrophages marked by F4/80+iNOS and CD11b+$Ly6C^{high}$ were dominant at the beginning, and then gradually transformed into pro-fibrotic CD11b+$Ly6C^{low}$ cells; 2) the expression of pro-inflammatory factors was high, but the expression of antiinflammatory factors was low; 3) the expression of the components of autophagy was decreased and would not be recovered; 4) the population of PTC maintained at low level; 5) pericytes were constantly be activated into myofibroblasts to form fibrosis, and 6) the expression of HIF-1α and HIF-2α was initially increased, then decreased to baseline (normal) level but increased again in the late stage.

Conclusions: With our new RUUO mouse model, we confirm that renal adaptive repair occurs in 5-days-RUUO kidneys to simulate the complete recovery of AKI, whereas renal maladaptive repair occurs in 10-days-RUUO kidneys to simulate the progression from AKI to CKD.

FR-PO1084

Clinical Characteristics and Renal Outcome of Patients with Thrombotic Thrombocytopenic Purpura from a Large Multicenter Cohort (USTMA Registry)

Nattawat Klomjit,[1] Michael D. Evans,[2] Marshall Mazepa.[3] *[1]Division of Nephrology and Hypertension, University of Minnesota, Minneapolis, MN; [2]University of Minnesota Twin Cities Clinical and Translational Science Institute, Minneapolis, MN; [3]Division of Hematology, Oncology and Transplantation, University of Minnesota, Minneapolis, MN.*

Background: Thrombotic thrombocytopenic purpura (TTP) is a rare hematological disease caused by autoimmune deficiency of ADAMTS13 and responds to urgent plasma exchange. Renal dysfunction is typically mild and several clinical scores have incorporated creatinine (Cr) level < 2.0 mg/dL to differentiate TTP from other thrombotic microangiopathies. However, renal dysfunction and outcomes are not well studied in TTP. Therefore, we used the United States Thrombotic Microangiopathies (USTMA) TTP registry, the largest US TTP registry, to evaluate clinical characteristics of patients with severe renal dysfunction at presentation and estimate loss of kidney function over time.

Methods: The USTMA TTP registry contains data on TTP episodes between 1985 to 2019 from 14 centers across the US. We compared the clinical characteristics

upon presentation between patients presenting with mild (Cr ≤ 2 mg/dl) versus severe (Cr >2 mg/dl) renal dysfunction. To model eGFR loss over time with TTP episodes, we used longitudinal linear mixed-effects models.

Results: Between 1985-2019, there were 1257 TTP episodes (771 patients) and the majority of episodes had mild renal dysfunction (n=1115, 88.7%). Compared to mild renal dysfunction, patients with severe renal dysfunction had more severe symptoms, lower platelets and higher lactate dehydrogenase (LDH). There were 285 unique patients with multiple TTP episodes to evaluate for eGFR loss over time. Overall, we found a mean slope of eGFR per year of -0.70 (95% CI –0.84, –0.56). There were no differences in eGFR slopes according to the number of TTP episodes a patient experienced. LDH level was associated with eGFR loss between episodes, with a modestly sized effect (change in eGFR per year slope 0.020 (95% CI 0.008-0.032) per 2-fold increase in LDH).

Conclusions: Severe renal dysfunction is uncommon in TTP but it is more likely to be present in patients with multi-organ dysfunction. Hence, existing clinical prediction scores are likely less accurate in more severe TTP episodes. Loss of eGFR over time is consistent with previous estimates of age-related eGFR, hence we conclude that subsequent TTP episodes do not significantly affect eGFR loss and likely confirms previous findings that most patients with TTP recover normal renal function with modern treatment.

FR-PO1085

Chromatin Remodeling Factor, INO80, Inhibits PMAIP1 in Renal Tubular Cells Through Exchange of Histone Variant H2A.Z for H2A

Imari Mimura, Rika Miura, Masaomi Nangaku. *Tokyo Daigaku, Bunkyo-ku, Japan.*

Background: Epigenetic modifications such as histone modifications and chromatin structures in the kidney contribute towards the progression of chronic kidney disease (CKD). In this study, the role of chromatin remodeling factor, inositol requiring 80 (INO80) was investigated because INO80 has been reported to be associated with renal function in a genome-wide analysis. Although INO80 regulates transcription by altering the chromatin structure at the nucleosome level, its role in the kidney remains unknown. Our aim of this study is to clarify the pathophysiological role of INO80 in the kidney.

Methods: We evaluated the expression level of *INO80* using UUO (unilateral urethral obstruction) model rats. We also investigated INO80 mRNA expression in a proximal tubular cell line (HK2) under hypoxia. To identify the downstream target genes of INO80, we performed RNA-seq using siRNA of INO80. We examined the effects of INO80 on apoptosis of tubular cells.

Results: The mRNA level of INO80 extracted from UUO group (n = 6) was significantly reduced compared to the contralateral kidney group. INO80 knockdown promoted apoptosis, suggesting that INO80 plays a role in inhibiting tubular cell apoptosis. The expression levels of INO80 in HK2 cells under 1% hypoxic condition significantly decreased than those under normoxia. We identified 32 down-regulated genes and three up-regulated genes. These genes were suspected to be INO80 downstream target candidates. As a result of gene ontology (GO) apoptosis-related genes such as *TP53* (tumor protein p53), *E2F1* (E2F transcription factor 1), and *PMAIP1* (phobol-12-myristate-13-acetate-induced protein 1 were significantly associated with INO80 functions. *PMAIP1* is a member of pro-apoptotic subfamily of the BCL-2 protein family and is a known target of p53. Chromatin immunoprecipitation was performed on HK-2 cells with *INO80* knockdown using the H2A.Z. antibody, because INO80 has been reported to remove the H2A.Z. variant and exchange it for the H2A variant. INO80 knockdown significantly increased H2A.Z. in the promoter region of *PMAIP1*, while H2A expression significantly decreased in the promoter region of *PMAIP1*.

Conclusions: INO80 plays an important role in exchanging H2A.Z. for H2A in the promoter region of *PMAIP1* in tubular cells to inhibit apoptosis during CKD progression.

Subclinical Acidosis Assessed by a New Urine Acid-Base Score Is an Independent Risk Factor for CKD Progression

Samuel L. Svendsen,[1,2] Rasmus Carlsen,[2] Niels H. Buus,[2] Henrik Birn,[2] Jens G. Leipziger,[1] Peder Berg,[1] Mads V. Sorensen.[1] *[1]Aarhus Universitet Faculty of Health, Aarhus, Denmark; [2]Aarhus Universitetshospital, Aarhus, Denmark.*

Background: Acidosis is reported to exacerbate the gradual loss of kidney function in patients with chronic kidney disease (CKD). Current guidelines advise assessing acid-base (AB) status of CKD patients by plasma bicarbonate, although covert acidosis may be present before it is reflected in this. Indeed, others have found a correlation between subclinical acidosis (SA), evidenced by low urinary NH_4^+ excretion, and progression of kidney disease. However, low NH_4^+ excretion may also be present in physiological states with low demand for acid elimination. To identify a sensitive and specific marker of SA, we analyzed several AB markers in urine samples from CKD patients. We hypothesized that a measure incorporating both pH_u and $[NH_4^+]_u$ would reflect the demand and capacity for sufficient renal acid excretion in CKD patients, and that this would be associated with CKD progression.

Methods: We included biobanked urine samples from CKD patients from two clinical studies (RENVAS, development cohort, 81 CKD patients and 25 healthy controls and PUMA, validation cohort, 65 CKD patients). Outcomes included mGFR at 18 months and composite outcome of 50% eGFR reduction or kidney failure defined by initiation of dialysis or kidney transplantation. AB-score was calculated from $[NH_4^+]_u$ and pH_u. Patients were stratified as SA if their AB score was below the 2.5th percentile of the control group or non-SA if their score was above.

Results: In the development cohort (mean eGFR 34.1mL/min, age 61.7y) 62% had SA. A higher baseline AB score was associated with a slower decrease in mGFR (p=0.002) and patients with SA had a greater mGFR decline after 18 months (p=0.039). Renal events were more frequent in patients with SA (p<0.001, mean follow-up 5.1y). When adjusted for covariates, including tCO2 and eGFR, the hazard ratio (HR) of reaching the composite outcome was 0.41(95%CI 0.21-0.79, p=0.009) per SD higher AB score and in patients with SA 5.3 (95%CI 1.2-24.2, p=0.039). In the validation cohort (mean eGFR 36.8mL/min, age 68.0y, mean follow-up 3.4y) 65% had SA. Adjusted HR was 0.27 (95%CI 0.1-0.76, p=0.013) per SD higher AB score and in patients with SA 15.5 (95%CI 1.9-129.4, p=0.011).

Conclusions: SA associates with greater mGFR decrease after 18 months and an increased risk of kidney failure or a >50% reduction of eGFR.

Kidney Medullary Oxygen Availability Is Higher in CKD: Truth or Fallacy?

Pottumarthi V. Prasad, Luping Li, Bradley K. Hack, Nondas Leloudas, Stuart M. Sprague. *NorthShore University HealthSystem, Evanston, IL.*

Background: Chronic hypoxia hypothesis (CHH) suggests kidneys with progressive CKD are hypoxic. Currently Blood Oxygenation Level Dependent (BOLD) MRI is the only known technique to afford evaluation of kidney oxygen status in humans. Results to-date show higher R2* (i.e. lower O2 availability) in cortex but lower R2* in medulla (suggesting higher O2 availability) in CKD compared to controls. Whether the lower R2* in medulla in CKD an anomaly remains untested. Hypothesizing that reduced fractional blood volume (fBV) within tissue is the cause for this anomaly [PMID: 29571450], we measured fBV in CKD using ferumoxytol, an intravascular MRI contrast agent.

Methods: Data was available in 9 each in controls and individuals with CKD. After baseline R2* maps were acquired, ferumoxytol (5mg/kg) was administered and R2* measurement repeated. fBV, and oxygen saturation of hemoglobin (StO2) were calculated using equations described previously for brain MRI [31482602].

Results: Table 1 summarizes the R2*, fBV, StO2 and bloodPO2 for cortex and medulla. Consistent with prior reports, R2* in medulla is significantly lower in CKD implying higher O2 availability in CKD. However, when including the fact that fBV is lower in CKD, estimated StO2 and bloodPO2 are significantly lower in medulla.

Conclusions: Our data for the first time demonstrate that fBV is significantly lower in CKD in both cortex and medulla. When including this lower fBV, cortex and medulla are both moderately hypoxemic in CKD while in controls, cortex was normoxemic and medulla mildly hypoxemic. The blood pO2 estimates are consistent with the only report to-date in rat kidneys [16357065].

Eicosanoids and Related Metabolites Associated with ESKD in a Community-Based Cohort

Aditya L. Surapaneni,[1] Pascal Schlosser,[5] Eugene P. Rhee,[2] Susan Cheng,[3,4] Josef Coresh,[5] Morgan Grams.[1] *[1]New York University Department of Medicine, New York, NY; [2]Mass General Brigham Inc, Boston, MA; [3]Brigham and Women's Hospital, Boston, MA; [4]Cedars-Sinai Medical Center Smidt Heart Institute, Los Angeles, CA; [5]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Eicosanoids are derivatives of polyunsaturated fatty acids and participate in the inflammatory response and endothelial function maintenance. Specific eicosanoids have been linked to various diseases, including hypertension and asthma, and may reduce renal blood flow. A systematic investigation of eicosanoid-related metabolites and adverse kidney outcomes could identify key mediators of kidney disease and inform work in drug development.

Methods: Profiling of eicosanoid-related metabolites was performed in 9,650 participants in the Atherosclerosis Risk in Communities Study (visit 2; mean age, 57 years). The associations between metabolite levels and the development of ESKD was investigated using Cox proportional hazards regression (N= 256 events; median follow-up, 25.5 years). Metabolites with statistically significant associations with ESKD were evaluated for a potential causal role using Mendelian randomization techniques, linking genetic instruments for eicosanoid levels to genome-wide association study summary statistics of estimated GFR.

Results: The 223 eicosanoid-related metabolites that passed QC were generally uncorrelated with eGFR in cross-sectional analyses (median Spearman correlation, -0.03; IQR -0.05 to 0.002). In models adjusted for multiple covariates, including baseline eGFR, three metabolites had statistically significant associations with ESKD (p-value <0.05/223). These included a hydroxyoctadecenoic acid, a dihydroxydocosapentaenoic acid which were protective and an arachidonic acid, detrimental. Mendelian randomization suggested a causal role for the hydroxyoctadecenoic acid in determining eGFR.

Conclusions: High throughput eicosanoid profiling can identify metabolites that may play a protective role in the development of kidney disease.

Glomerular Hyperfiltration and Th17 Responses Precede Glomerulosclerosis Following Nephron Loss

Jing Liu, Luojing Chen, Thu H. Le, Jing (Jason) Wu. *University of Rochester Medical Center Department of Medicine, Rochester, NY.*

Background: Chronic kidney disease (CKD) affects 37 million Americans resulting in $87 billion healthcare cost annually. Impaired renal autoregulation in obesity, diabetes and hypertension causes elevated glomerular capillary pressure and glomerular hyperfiltration (GHF), ultimately leading to glomerulosclerosis (GS) and CKD. Increased renal perfusion pressure directly drives T cell infiltration and T helper (Th) 17 cells promote renal fibrosis in hypertension and kidney ischemia-reperfusion injury, but their roles in GS are poorly understood.

Methods: We investigated the roles of GHF and Th17 responses in GS in a mouse CKD model induced by reduced kidney mass (RKM), which involved uninephrectomy and partial renal artery ligation in the remaining kidney such that the functional renal mass is reduced by ~ 3/4. Male 129/S6 mice received sham or RKM surgery at 8 weeks of age, and blood pressure (BP, by radiotelemetry), glomerular filtration rate (GFR, by transcutaneous FITC-sinistrin) and serum/urine CKD markers were assessed at baseline (BL), and day (D) 0, 3, 7, 14, 21, 28, 56, and 84 post-surgery.

Results: BP and GFR of RKM mice were identical to sham controls at BL (n=4-6). Immediately after RKM, GFR dropped to 22% of BL, consistent with the extent of renal mass ablation. BP increased by 29 mmHg by D5 post RKM (144 ± 8 vs 112 ± 2 mmHg, p<0.05, 2-way ANOVA), and serum creatinine, blood urea nitrogen and urinary albumin were significantly elevated by D14. BP and CKD markers were significantly elevated through D84 in RKM mice, but remained at BL levels in sham controls. The GFR of RKM mice gradually increased to 38% of BL at D3, 57% at D7 and 68% at D14, and plateaued at ~70% at D21-28, suggesting that the early rise in BP and impaired autoregulation may have caused GHF following initial nephron loss. The adaptive increase in GFR post-RKM was associated with marked renal Th17 cell infiltration at D14, preceding glomerular hypertrophy and mesangial expansion at D28 and subsequent recruitment of myeloid cells, monocyte/macrophages and T regulatory cells. Importantly, GFR declined to 42% of BL at D56 post-RKM, with concomitant GS and interstitial fibrosis as evidenced by Periodic Acid Schiff and Picro Sirius Red staining.

Conclusions: Together, our data suggest that both GHF and Th17 responses promote CKD progression and further loss of nephrons through glomerular fibrosis.

Regenerative Capacity Decline and Progressive Tubular Cell Polyploidization as Adaptive Kidney Tubule Response to Aging

Elena Lazzeri,[1] Giulia Antonelli,[1] Letizia De Chiara,[1] Paola Romagnani.[1,2] *[1]Universita degli Studi di Firenze, Firenze, Italy; [2]Children's Meyer Hospital, Florence, Italy.*

Background: Kidney function declines progressively with age, leading to chronic kidney disease (CKD) in the elderly. CKD is a major global health problem, explaining why there is the need to understand the age-related mechanisms in CKD development. Most adult organs contain a pool of stem cells, whose function decline leads to tissue ageing. To what extent do resident stem cells or differentiated cells contribute to organ ageing remain to be clarified. Recently, we revealed two response programs in the kidney tubule to recover kidney function and a structural integrity upon AKI. On the one hand, a population of resident renal progenitors (RPC) self-renew and differentiate to replace lost tubular cells. On the other, tubular cells (TC) undergo endoreplication to become polyploid. We aimed to study how these two mechanisms affected the kidney ageing.

Methods: To study RPC, we used the inducible Pax2/Confetti mice, in which RPC (Pax2+cells) are randomly labelled by one of the four fluorescent reporter genes. To identify polyploid TC, we used two inducible mouse models: the heterozygous Pax8/Confetti mice and Pax8/FUCCI2aR mice. In the former model, all TC are labelled randomly by one of the four fluorescent reporter genes. Polyploid TC appear as bi-coloured due to recombination of two fluorochromes in the same cell. In the second model, polyploid TC are identified by expression of cell cycle fluorescent proteins (FUCCI2aR technology) in combination with DNA content analysis. Mice were analyzed at 2, 6, 12 and 18 months of age.

Results: Pax2/Confetti mice revealed that Pax2+RPC of proximal tubule declined during ageing and their clonogenic capacity is impaired. By contrast, Pax8/Confetti mice showed an increase of polyploid TC during ageing. Analysis of aged Pax8/FUCCI2aR mice revealed that polyploid TC increased furtherly their DNA content by going through additional cell cycles and that this was associated with fibrosis, senescence and kidney function decline. Thus, while the pool of RPC is progressively lost during ageing, impairing the kidney tubule regenerative capacity, TC enter the cell cycle to become polyploid. These accumulate in aged kidneys and trigger fibrosis and senescence, leading to CKD.

Conclusions: These results suggest a previously unknown role for RPC and polyploid TC in kidney tubule response to ageing.

FR-PO1091

In Vivo Single Cell Analysis of Senescence in Aging Kidney Disease and CKD

Sae Aratani,[1,2] Teh-Wei Wang,[1] Makoto Nakanishi.[1] *[1]Tokyo Daigaku Ikagaku Kenkyujo, Minato-ku, Japan; [2]Nihon Ika Daigaku, Bunkyo-ku, Japan.*

Background: It remains largely unknown how senescent cells affect kidney aging and chronic kidney diseases (CKD) in vivo. Previously, we generated a p16-CreERT2-tdTomato mouse model (p16-tdTomato mice hereafter) in which cells with high p16 expression, a prototypical senescent marker, were labeled with tdTomato through the administration of tamoxifen. In this study, we aimed to reveal the pathophysiological role of senescent cells in the kidney using p16-tdTomato mice.

Methods: We investigated three different kidney conditions; normal aging kidneys, adenine-induced kidney diseases, and rhabdomyolysis-induced kidney diseases model. Male 6-24-month-old p16-tdTomato mice and 2-3-month-old p16-tdTomato mice were used for the normal aging process and disease models, respectively. The adenine diet was administered for three weeks, while 50% glycerol was injected into each leg to induce rhabdomyolysis thrice weekly. All the mice were sacrificed after the five times of tamoxifen injections. For further analysis of single senescent cells, the kidneys were directly digested, and flow cytometry (FACS) separately sorted tdTomato-positive senescent or tdTomato-negative cells.

Results: In the normal aging process, 20-24-month-old mice showed an accumulation in tdTomato-positive senescent cells compared to young mice. In both CKD models, the serum analysis demonstrated kidney dysfunction with increased BUN and Cr. Histopathological examinations showed tubular damage, interstitial fibrosis, and infiltration of immune cells, resembling CKD progression. Notably, the tdTomato-positive senescent cells increased following CKD; mainly, tdTomato-positive senescent PTECs were significantly detected. RNA-sequence analysis revealed that tdTomato-positive senescent PTECs collected from the CKD model by FACS showed high inflammatory signaling pathways, including hallmark TNFα signaling through NFkB, IL6 JAK-STAT, and TGFβ signaling. These inflammatory cascades are all related to senescence-associated secretory phenotype (SASP).

Conclusions: These data suggest that CKD progression might cause premature kidney aging. In particular, tdTomato-positive PTECs might contribute to an inflammatory environment in CKD by producing SASP. These tdTomato-positive PTECs might be a therapeutic target to prevent CKD progression and rejuvenate premature kidney aging.

FR-PO1092

Possible Involvement of Renal Tubular NFAT5 in Aging-Associated Renal Phenotypes and Dysfunction

Kosuke Maruyama, Yuichiro Izumi, Makoto Ono, Yutaka Kakizoe, Takashige Kuwabara, Masashi Mukoyama. *Department of Nephrology, Kumamoto University Graduate School of Medical Sciences, Kumamoto, Japan*.

Background: The number of patients with chronic kidney disease (CKD) and hypertension is increased with age; however, it is not clearly defined why and how aging causes renal dysfunction and hypertension. Nuclear factor of activated T-cells 5 (NFAT5) is a transcription factor that is activated upon hypertonic conditions as observed in the renal medulla. We have already shown that the renal tubular cell-specific NFAT5 conditional knockout (KO) mice exhibit salt-sensitive hypertension, while the mice exhibit impaired urine concentrating ability and are susceptible to renal fibrosis. These phenotypes resemble aging-associated renal dysfunction, i.e., urine concentrating disorder, salt-sensitive hypertension, and renal fibrosis. We therefore investigated the possible involvement of NFAT5 in aging-related changes of the kidney.

Methods: The mRNA expressions of NFAT5 and its downstream genes including AQP2, urea transporter A-1 (UTA-1), and aldose reductase (AR) were examined by real-time PCR in the whole kidney tissue of wild type (WT) mice at 3, 6, 12, and 18 months old. To investigate the involvement of NFAT5 in aging-related phenotypes of the kidney, kidneys collected from NFAT5 KO mice (3 and 18 months old) were characterized and compared with WT mice. Senescence-associated beta-galactosidase (SA-β-Gal) activity was examined by fluorescence study in the whole kidney slices. Gene expressions of senescence-associated secretory phenotype (SASP)-related factors (TGF-β1, COL1A1, ICAM1, PAI-1, and MMP3) were examined by real-time PCR. Renal fibrosis was evaluated by AZAN staining.

Results: While the expression of NFAT5 was increased with age, the mRNA expressions of AQP2, UTA-1 and AR were decreased significantly at 6 and 12 months old compared to 3 months old. SA-β-Gal activity was increased in the corticomedullary region in KO mice at 3 months. Gene expressions of SASP-related factors were significantly increased in KO mice. At 18 months old, KO mice exhibited renal atrophy and fibrosis in the medulla, which phenotypes were significantly accelerated than WT mice.

Conclusions: These results indicate that the expression of genes downstream of NFAT5 could be decreased with aging kidney, suggesting that the decreased activity of NFAT5 may be involved in aging-related renal dysfunction.

Single-Nucleus RNA Sequencing Reveals Cellular Heterogeneity and Cell-Cell Interactions Contributing to Tertiary Lymphoid Tissue Development in the Aged Injured Kidney

Takahisa Yoshikawa,[1] Akiko Oguchi,[1,3] Naoya Toriu,[1,2] Yuki Sato,[1] Takuya Yamamoto,[4,2] Yasuhiro Murakawa,[2,3] Motoko Yanagita.[1,2] Yanagita Group. *[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Institute for the Advanced Study of Human Biology (WPI-ASHBi), Kyoto University, Kyoto, Japan; [3]RIKEN Center for Integrative Medical Sciences, Yokohama, Japan; [4]Department of Life Science Frontiers, Center for iPS Cell Research and Application (CiRA), Kyoto University, Kyoto, Japan*.

Background: Tertiary lymphoid tissues (TLTs) are ectopic lymphoid structures that develop in non-lymphoid organs with chronic inflammation. TLTs can develop in kidney diseases such as IgA nephropathy and transplanted kidneys and are associated with poor renal prognosis. However, how TLTs affect renal tissues and expand remains unclear.

Methods: Single-nucleus RNA-sequencing (snRNA-seq) was performed on three aged mouse kidneys with TLTs after ischemia–reperfusion injury or an aged kidney after sham surgery. The results were validated using immunostaining, *in situ* hybridization (ISH) of murine and human kidneys, and *in vitro* experiments.

Results: snRNA-seq identified 15,986 and 7,485 nuclei in the injured kidneys and the sham-treated kidney, respectively. In the injured kidneys, proinflammatory and profibrotic *Vcam1*$^+$ injured proximal tubules (PTs) with activation of NFκB and interferon (IFN)-inducible transcription factors were detected. Importantly, VCAM1$^+$ PTs were preferentially localized around TLTs and suggested to drive inflammation and fibrosis via the expression of multiple chemokines or cytokines. snRNA-seq analysis and ISH revealed that *Tnf* and *Ifng* were highly expressed by lymphocytes within TLTs, and these inflammatory cytokines synergistically upregulated *VCAM1* and chemokine expression in cultured PT cells. In addition, snRNA-seq and immunostaining identified proinflammatory and profibrotic fibroblasts, which resided within and outside TLTs, respectively. Proinflammatory fibroblasts with STAT1 activation expressed various chemokines or cytokines, including *Cxcl9/Cxcl10* and *Tnfsf13b* (encoding B cell-activating factor), suggesting their contribution to lymphocyte recruitment and survival. IFNγ upregulated the expression of these molecules in cultured fibroblasts in a STAT1-dependent manner, indicating potential bidirectional interactions between proinflammatory fibroblasts and IFNγ-producing CXCR3$^+$ T cells within TLTs. These cellular and molecular components were confirmed in human transplanted kidneys with TLTs.

Conclusions: TLTs develop via intense interactions between proinflammatory renal parenchymal and immune cells. These interactions may serve as novel therapeutic targets in kidney diseases with TLT formation.

FR-PO1094

Single-Nucleus Transcriptome Revealed Differential Cell Fate of Human Proximal Tubular Cells with Aging

Su Woong Jung,[1] Jihoon Park,[2] Yang Gyun Kim,[1] Tae Hoon Lee,[2] Ju young Moon.[1] *[1]Kyung Hee University, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea*.

Background: Proximal tubular cell (PTC) is a high energy-requiring cell-type in the kidneys. But how this cell type ages remains incompletely understood throughout life course.

Methods: We explored transcriptional profiles through life time using the public dataset, Kidney Precision Medicine Project. We extracted the nuclei annotated as PTC from normal kidneys and discarded potential doublets that expressed other cell-type markers, which retained 18,765 nuclei.

Results: We found transcriptionally distinct 7 subclusters reannotated as healthy PT-1, healthy PT-2, stressed PT, scattered PT, injured PT-1, injured PT-2, and proliferating PT. Healthy PT-2 distinctively expressed PLIN2, a lipid dropet marker, and stressed PT showed enhanced expressions of ALDOB, PCK1, and GPX3. Scattered PT and injured PT-2 commonly expressed VIM, CD24, and S100A6, and injury PT population only expressed VCAM1. We found that healthy PT-2 showed the highest gene expression implicated in lipid metabolism, such as HMGCS2, ACSL1, and CPT1, and its PPAR-α signaling is upregulated than Healthy PT-1. In addition, scatter cells were enriched with lysosomal genes and has upregulation in glycolysis, oxidative phosphorylation, and actin cytoskeleon regulation compared to Healthy PT-1. In the trajectory analysis, healthy PT has two disintact pathes, one of which flow toward scattered PT through stressed PT and the other of which direct to injured PT. Each path had differential metabolic fate represented by enhanced and impaired fatty acid oxidation along the former and latter pathes.

Conclusions: PTC undergoes differential cell fate with aging on the view of gene expression and metabolism.

FR-PO1095

Higher Serum IL-6 and IFN-γ Are Associated with Increased Seroconversion Rate Against SARS-CoV-2 Spike Protein Either After Vaccination or SARS-CoV-2 Infection

Narayan Prasad, Brijesh Yadav, Sonam Gautam, Deependra K. Yadav. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*.

Background: Maintenance immunosuppressives lead to a decreased immunogenic response to SARS-CoV-2 infection and vaccination in renal transplant recipients (RTRs) than in healthy populations. However, healthy people with SARS-CoV-2 infection often develop neutralizing antibodies and secrete high quantities of cytokines leading to virus clearance and sometimes more severe COVID-19. Associations of cytokines with seroconversion rate in immunocompromised RTRs are not well studied, particularly in living donor scenarios.

Methods: In this study, we included 210 living-related RTRs, who acquired SARS-CoV-2 infection or were vaccinated with two doses of either COVISHIELD or COVAXIN; and 35 healthy controls who were neither vaccinated nor had anti-SARS-CoV-2 spike IgG as controls. Cytokines IL-6, IFN-γ, TGF-β, and IL-10 were measured using the ELISA, and SARS-CoV-2 spike protein-specific IgG titre by chemiluminescent microparticle immunoassay methods.

Results: We found a seroconversion rate of 115/132 (87.12%), with a median antibody titer of 706.40 au/ml (IQR, 215.45-1844.42) in the infection group and 63/78 (80.76%) with a median titer 1454.20 (IQR, 80.52-3838.75) au/ml in vaccination group. The IL-6, IFN-γ, TGF-β, and IL-10 levels were significantly higher in both the infection and vaccination groups than in the healthy control. In the infection group, IL-6 (55.41±24.30 vs 31.64±16.98 pg/ml; p<0.001); IFN-γ (91.21±33.09 vs 61.69±33.28 pg/ml; p=0.001), were significantly higher in the seroconverter group as compared to non-seroconverter. TGF-β (730.48±400.47 vs 765.47±366.39 pg/ml; p=0.92) and IL-10 (91.31±48.54 vs 96.73±59.53 pg/ml; p=0.88) were similar between seroconverter and non-seroconverter. Similarly, in the vaccination group, IL-6 (50.31±25.67 vs 30.00±11.19 pg/ml; p=0.002) and IFN-γ (65.70±39.78 vs 32.14±17.48 pg/ml; p=0.001) were significantly higher in seroconverter post-vaccination compared to non-seroconverter. In contrast, TGF-β (820.96±415.78 vs 1045.57±204.66; p=0.046) was elevated in non-seroconverter, and although IL-10 (93.18±35.45 vs 112.90±59.61 pg/ml; p=0.11) was similar between seroconverter and non-converter.

Conclusions: Inflammatory cytokines IL-6 and IFN-γ are significantly associated with higher seroconversion rates in RTRs after SARS-CoV-2 infection and vaccination.

FR-PO1096

Usefulness of Multiplex Immunodot Method for COVID-19 Vaccination Monitoring in Dialysis Patients: Results of the COVIDIAL Study

Frederic Debelle,[1,2] Fabrice Gankam Kengne,[3] Miguel-Ange Guillen-Anaya,[4] Anne-Emilie Decleves.[2] CoviDial Study Group. *[1]Centre Hospitalier EpiCURA Baudour, Baudour, Belgium; [2]Universite de Mons, Mons, Belgium; [3]Centre Hospitalier EpiCURA Ath, Ath, Belgium; [4]Centre Hospitalier EpiCURA Hornu, Hornu, Belgium.*

Background: COVID-19 vaccine was demonstrated to be effective in dialysis patients, but boosters are mandatory due to a rapid waning of anti-spike antibodies. A vaccination strategy based on efficient immunologic response monitoring might be useful to maintain a favourable risk-benefit balance in this vulnerable population.

Methods: CoviDial is an observational prospective study enrolling 121 dialysis patients to receive a 3-dose mRNA-1273 vaccine according to a uniform schedule. At baseline, months 1, 3, 6, 9, and 12, anti-spike antibodies against four epitopes (S1, S2, ECD-S1+S2, RBD) were monitored with a multiplex immunodot enzymatic assay. Potential correlation between initial serologic response and subsequent COVID-19 infection was then assessed.

Results: Overall, 96.2% and 96.8% of patients developed anti-RBD antibodies at 3 and 12 months, respectively. All antibodies titres significantly decreased at month 6 compared to month 3. Booster vaccine induced a robust serologic response at month 9, but with a waning three months later, particularly for anti-S2 (37.2 ± 3.3 vs. 61.3 ± 3.0, p<0.0001) and anti-S1+S2 antibodies (68.4 ± 3.3 vs. 88.4 ± 2.3, p<0.01). Fifteen patients were later tested positive for SARS-CoV-2. At month 3, mean titres of anti-RBD, anti-S1+S2 and anti-S2 antibodies were lower in the subsequent SARS-CoV-2 infected cohort (71.57±9.01 *vs.* 85.79±2.61, $p<0.05$; 41.07±7.96 *vs.* 61.68±3.56, $p<0.05$; 13.79±5.03 *vs.* 39.70±3.86, $p<0.01$; respectively).

Conclusions: Three doses of mRNA-1273 vaccine induce a robust but time-limited immunologic response in dialysis patients. Lower anti-spike antibodies titres after initial vaccination are associated with a higher risk to subsequently contract SARS-CoV-2, even beyond six months.

Barriers to COVID-19 Vaccination in Dialysis Populations: A Patient Perspective

Arksarapuk Jittirat,[1,2] Kenneth A. Andreoni,[3] Mahboob Rahman.[1,2] *[1]UH Cleveland Medical Center, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH; [3]Thomas Jefferson University, Philadelphia, PA.*

Background: ESKD patients are at risk for serious illnesses and death related to COVID-19. It is challenging for ESKD patients to stay updated with recommended COVID vaccination. We aim to study the perceived barriers to complete COVID vaccination in our dialysis population.

Methods: 205 ESKD patients consented to complete our questionnaires. Descriptive statistics including proportions, median, and interquartile range were calculated for categorical and continuous variables to describe the study population, and to report the patient perceived barriers to vaccination. Comparisons by age, race/ethnicity, sex, level of education and income were conducted to evaluate differences between those vaccinated vs unvaccinated.

Results: 205 patients participated in the study. 88.3%(n=181) received at least one COVID vaccine. 80.5%(n=165) completed primary series. 54.6%(n=112) received the bivalent booster. 7%(n=8) of males and 17.5% of females (n=16) were unvaccinated. Majority of unvaccinated patients were unemployed/retired/disabled, have income ≤ $30,000, and with at least a high school education. Among vaccinated group, 96.6% reported it was easy to get vaccines, while 56.2% were concerned to be vaccinated. 25.3% of patients received the vaccine because it was required by transplant program, and 28% felt pressure to be vaccinated. Of 24 unvaccinated patients, 62.5% were concerned with potential long term complications. 66.7% were unsure of the efficacy. 52.4% of patients felt that the vaccine was safe, and 78.3% were aware it was free. 12.5% thought they had medical reason not to be vaccinated. Only 22.7% of patients believed that vaccination decreased death or ICU admissions. 20.8% of patients felt social media influenced on their decision.

Conclusions: Most ESKD patients reported having received vaccines and did not feel that physical limitation, transportation, or accessibility were barriers to vaccination. Uncertainty of long term complications and efficacy of vaccinnation appeared to be the major barriers.

Selective Responses From 24 Unvaccinated ESKD Patients					
N = 24	Yes (%)	No (%)			
Reasons for not getting COVID-19 vaccine:					
- Do not think the vaccine is safe	62.5%	37.5%			
- Unsure about long term complications	37.5%	62.5%			
- Unsure about the efficacy	66.7%	33.3%			
Aware vaccine is free	78.3%	21.7%			
No difficulties to get COVID-19 vaccine	50%	50%			
Feel that social media sites have influenced their decision	79.2%	20.8%			
	Not at all	Little	Mod	Very	
Concerned getting COVID disease	25%	45.8%	12.5%	16.7%	
Is COVID vaccine safe for you	47.6%	28.6%	14.3%	9.5%	
	Strongly Disagree	Disagree	Neither	Agree	Strongly Agree
Believe vaccine decreases chances of dying or ICU admission	4.5%	13.6%	59.1%	18.2%	4.5%
Felt pressured to get vaccine	62.5%	12.5%	8.3%	0%	16.7%

FR-PO1098

Malnutrition Is a Risk Factor for Lower Humoral Immune Response After Anti-SARS-CoV-2 Vaccination in Patients on Hemodialysis: A Multi-Center Clinical Study

Luis Toro,[1] Rene Clavero.[2] *[1]Hospital Clinico Universidad de Chile, Santiago, Chile; [2]Hospital Gustavo Fricke, Valparaiso, Chile.*

Background: Malnutrition is frequent in patients with end-stage renal disease (ESRD). This condition is an independent risk factor for developing adverse events, including severe infections and infection-related deaths. Previous studies have shown that patients with malnutrition, both in the general population and ESRD patients, have an impaired immune response. Currently, there is little data on malnutrition's effects on the induction of the immune response to anti-SARS-CoV-2 vaccination. Therefore, our objective was to evaluate the impact of malnutrition on the humoral immune response after anti-SARS-CoV-2 vaccination in ESRD patients on hemodialysis.

Methods: Prospective cohort of ESRD patients on chronic hemodialysis who received a three-dose anti-SARS-CoV-2 immunization schedule between 2021 and 2022. We measured the plasma levels of anti-SARS-CoV-2 IgG antibodies before vaccination, four months after doses 2, 3 and 4. Based on anthropometric parameters and subjective global assessment (SGA), we stratified patients according to their baseline nutritional status. In addition, we evaluated potential predictors of humoral response using multivariate analysis.

Results: 214 patients were evaluated in four hemodialysis centers. Age: 63.7 ± 16.3 years, men: 116 (54.2%). 41 patients (19.1%) were diagnosed with malnutrition. Malnourished patients had a lower humoral response after anti-SARS-CoV-2 vaccination compared to those without malnutrition (4 months after the second dose: 61.3% vs. 79.4%, p<0.01; 4 months after the third dose: 78.3% vs 93.1%, p<0.01. Figures 1 and 2). Multivariate analysis indicated that malnutrition is an independent risk factor for a decreased humoral immune response after vaccination (OR: 3.1, [1.5-9.9], p=0.01).

Conclusions: Our results suggest malnutrition is a risk factor for a lower humoral response after anti-SARS-CoV-2 vaccination in ESRD patients on hemodialysis. These data suggest that improving nutritional status can improve the post-vaccination immune response, which should be evaluated in future studies. Study supported by FONDECYT Regular 1221571.

High Fibroblast Growth Factor 23 Levels Increase Risk of SARS-CoV-2 Infection and Mortality in End-Stage CKD on Hemodialysis: A Three-Year Follow-Up Prospective Cohort

Luis Toro, Luis Michea, Maria E. Sanhueza, Ruben Torres, Leticia Elgueta, Miriam Alvo. *Hospital Clinico Universidad de Chile, Santiago, Chile.*

Background: End-stage renal disease (ESRD) patients are a population with high rates of COVID-19 and mortality. Fibroblast Growth Factor 23 (FGF23) is a protein hormone associated with impaired immune response in experimental murine models.

ESRD patients have high plasma levels of FGF23, and recent studies suggest that patients with high FGF23 levels have increased rates of severe infections and infection-related mortality. Therefore, our objective was to evaluate the association between FGF23 levels and the development of SARS-CoV-2 infection in ESRD patients on hemodialysis.

Methods: A prospective cohort of ESRD patients on hemodialysis who had plasma intact FGF23 (iFGF23) measurements in 2019. We evaluated rates of SARS-CoV-2 infection and severe COVID-19 (COVID-related hospitalization or death) between January 2020 and December 2022 (3-year follow-up). In addition, we evaluated potential predictors of outcomes using multivariate analyses.

Results: 243 patients were evaluated. Age: 60.4±10.8 years. Women: 120 (49.3%), diabetes: 110 (45.2%). 57 patients developed COVID-19 (23.4%), 41 were hospitalized, and 46 died (mortality rate: 18.9%). Patients with high iFGF23 (equal to or greater than 350 pg/mL) had a higher rate of SARS-CoV-2 infection (30.8% vs. 18.1%; Hazard ratio: 1.81 [1.08–3.04], p=0.024) and severe COVID-19 (23.1% vs. 11.9%; Hazard ratio: 2.02 [1.09–3.73], p=0.031) compared to those with lower levels (Figures 1 and 2). Multivariate analysis showed that elevated iFGF23 plasma levels were an independent risk factor for SARS-CoV-2 infection and severe COVID-19.

Conclusions: Our data suggest that increased iFGF23 levels are a risk factor for developing COVID-19 in ESRD patients on hemodialysis. In addition, these data support the potential immunosuppressive effect of FGF23, which may contribute to the increased risk of adverse clinical outcomes in renal patients. Study supported by FONDECYT Regular 1221571.

FR-PO1100

The Comparison of Humoral Response Between Third and Fourth Doses of COVID-19 Vaccines in ESRD on Hemodialysis (HD)

Dae Kyu Kim,[1] Yoosun Joo,[2] Su Woong Jung,[2] Jin sug Kim,[1] Ju young Moon,[2] Kyunghwan Jeong,[1] Hyeon Seok Hwang,[1] Yang Gyun Kim.[2] *[1]Kyung Hee University Medical Center, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Seoul, Republic of Korea.*

Background: The humoral response of coronavirus disease 2019 (COVID-19) vaccine in hemodialysis (HD) patients decrease substantillay overtime compare to the general population. Currently, experts recommend to recieve additional boosting vaccines against these high risk patients. However, the effects between additional third and fourth boosting vaccine in HD patients are not yet clear.

Methods: Total 86 HD patients from two hospitals (Gangdong Kyung Hee University Hospital and Kyung Hee Medical Center) were enrolled in this study. Patients were classifed into 4 groups according to the total dose of vaccines and whether they were infected with COVID-19. Serum IgG to receptor-binding domain (RBD) of the S1 subunit of the spike protein of SARS-CoV-2 was measured at 1 month after the first dose (T1), 2 months (T2) and 4 months after the second dose (T3), 4 months after third dose and (T4), 4-7 month after fourth dose of vaccine or 11 month after third dose (T5) for all groups. Neutralizing antibody also measured at T3 and T4 by plaque reduction neutralization test.

Results: Anti-RBD IgG after the second dose (T3) of vaccine was rapidly decreased (median [interquartile range] 1255.7[642.0, 2337.1] AU/ml), but it was significantly elevated after third dose (T4) in COVID19 naïve HD patients 3979.1[1966.1, 17098.1] AU/ml. The level of anti-RBD IgG was markedly higher in the COVID19 naïve patients with 4th doses than in them with 3rd doses (14075.3[4527.1, 30460.0], 2492.5[851.2, 17086.3] AU/ml, P < 0.001). However, the difference of anti-RBD IgG levels between 3rd and 4th vaccine was not observed in the COVID19 infected HD patients. Anti-RBD antibody titers were well correlated with neutralizing antibodies against omicron and delta at T3 and T4 (P < 0.001). Of the total 34 COVID-19 infected patients, 6 patients had high severity(4 hospital admission, 2 death), and their anti-RBD IgG showed a lower trend than those with COVID-19 naïve 1255.7[642.0, 2337.1] AU/ml and low severity COVID-19 infected patients 1486.4[677.6, 3044.1]. In particular, two death HD patientsed showed significantly lower anti-RBD IgG(342, 317 AU/ml).

Conclusions: Humoral response was better after 4th dose compared with 3rd doses in COVID-19 naïve HD patients.

FR-PO1101

Vaccination, Prior Infection, and the Risk of COVID-19 Reinfection Across the Spectrum of CKD

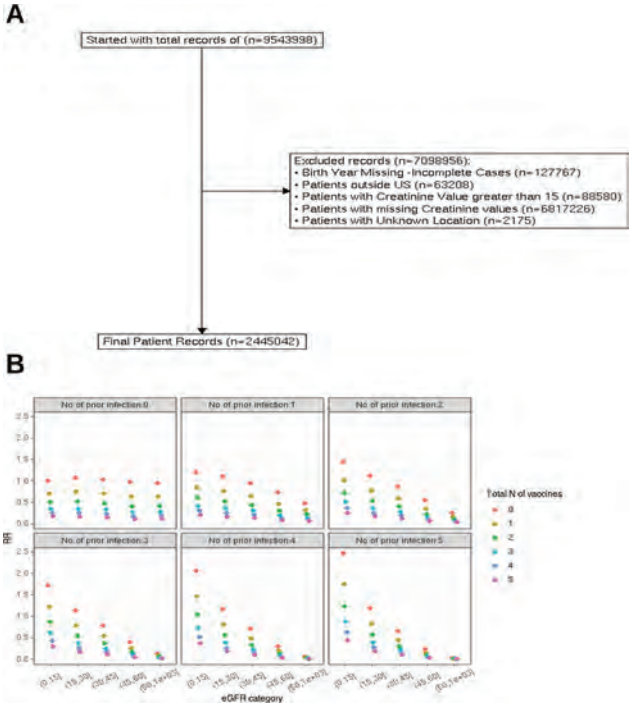
Hamza Mir, Pablo Garcia, Christos Argyropoulos, Maria-Eleni Roumelioti. *The University of New Mexico, Albuquerque, NM.*

Background: Patients with CKD have a higher burden of sequelae due to COVID19 (C19), but little is known about the impact of prior vaccination (vax) & infection (inf) on the risk of reinfection (reinf) across the spectrum of CKD.

Methods: We analyzed C19 inf (ICD10 B97.29, U07.1, U07.2, J12.82, B34.2) & vax data from the TRINETX Health Research Network of electronic medical records from 59 healthcare organizations from inception until June, 1st 2022. eGFR was assessed with the CKDEpi 2021 formula using the most recent creatinine to the first inf or C19 vax. Repeated C19 episodes were analyzed with proportional hazards models using cluster variance methods. Interactions between eGFR & time updated prior number of infections(NI) or vaccinations (NV) were used to answer the primary question. Patients who tested negative for C19 served as controls.

Results: 9.5M pts were identified, but 2.4M were eligible for analyses (most pts were excluded due to missing eGFR [Fig]A. Mean age was 56, 42.4% were male, 9.7% were Hispanic & African Americans were 19.2%. 90.7% of pts were unvaxxed, 2.1%, 4.13% & 2.4% had received 1,2,3 vax. 10.3% of pts had a single C19 inf, 3.2% 2 & <0.1% more than 3 inf. In models adjusting for demographics, region, age, eGFR, and secular trends, there was a statistical significant interaction between CKD stage and NI and NV [Fig]B. While a prior C19 inf reduced the risk of a subsequent reinf for eGFR>30, it increased the risk for those with eGFR≤30. Cumulative NV was protective across all eGFR levels.

Conclusions: Prior C19 inf increases subsequent risk for inf for pts with eGFR <30, even after adjusting for number of vax. Pts with CKD stages 4-5 should strongly consider adhering to nonpharmaceutical interventions & stay up to date with C19 vax to reduce their risk of C19 disease.



FR-PO1102

Immune Response After the Fourth COVID-19 Vaccine Dose in Hemodialysis Patients

Belen Alejos,[1] Jennifer Braun,[1] Abraham Rincón,[2] Kaitlyn Croft,[1] Manuela Stauss-Grabo,[1] Anke Winter,[1] Stefano Stuard,[1] Maria E. Baro,[2] Otto Arkossy.[1] *[1]Fresenius Medical Care, Bad Homburg, Germany; [2]Fresenius Medical Care, Madrid, Spain.*

Background: Hemodialysis (HD) patients have shown a suboptimal immune response to COVID-19 vaccines, and it remains unclear whether current vaccination schemes are suitable for these patients. We assessed humoral and cellular responses after the administration of the 4th dose of mRNA-based COVID-19 vaccine in HD patients.

Methods: We included HD patients from a NephroCare clinic in Spain who were vaccinated with three doses of an mRNA-based COVID-19 vaccine and scheduled to receive the 4th dose. Humoral response was assessed at T0 (max. 4 weeks before 4th dose) and T1 (1 month post 4th dose) using a Bioplex IgG antibody panel. IFN-g released by S1 protein stimulated T-cells was used to assess cellular response in a subsample of 5 patients.

Results: Twenty patients (80% males and median age 76.3 (IQR: 65.2; 84.2) years) were analyzed. Immune response was measured at T0 in a median period of 158 days after the 3rd dose and 100% patients maintained Anti-RBD and Anti-Spike 1 IgGs above the protective level. At T1, all humoral response markers significantly increased and cellular response was positive in 80% (4/5) patients. Anti-Nucleocapsid IgG, detecting contact with the virus, were positive in 3 (15%) patients at T0 and 4 (20%) at T1 but no COVID-19 infection was reported in the study period (figure 1).

Conclusions: Our study suggests that HD patients maintain a reasonable immune protection after three doses of an mRNA COVID-19 vaccine that further increases after the 4th dose. The first and second authors contributed equally to this work.

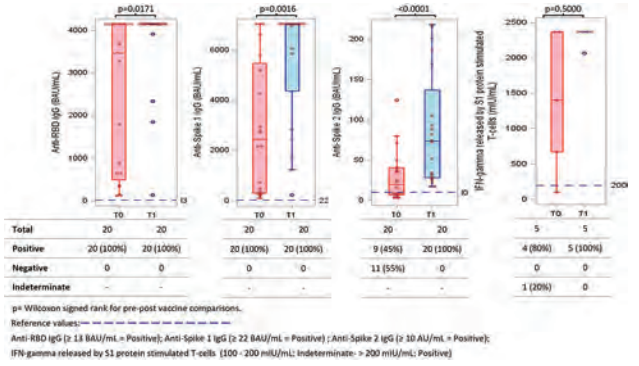

Figure 1: Humoral and cellular immune levels before and after the fourth COVID-19 vaccine dose in HD patients.

FR-PO1103

Longitudinal SARS-CoV-2 Antibody and T-Cell Immune Responses in Patients on Hemodialysis During the Omicron Era

Andrew H. Karaba, Jiashu Xue, Trevor S. Johnston, Caroline Traut, Joel Blankson, Chirag R. Parikh, Stuart C. Ray. *Johns Hopkins University, Baltimore, MD.*

Background: Individuals receiving renal replacement therapy via hemodialysis (HD) are at high risk for severe outcomes from COVID-19, have attenuated responses to the original COVID-19 vaccine series, and are at increased risk for contracting SARS-CoV-2 due to frequent healthcare exposures. How immunity to SARS-CoV-2, and risk for severe disease, evolve with episodes of infection and additional booster vaccinations in this vulnerable population has not been described.

Methods: An observational multicenter cohort of 55 HD patients (>90% received at least two doses of mRNA COVID-19 vaccine, 56% female, 47% with diabetic kidney disease, age [med, IQR] 67, 58-74 years) were followed for 24 weeks between Dec 2021 and Nov 2022 and provided blood samples at enrollment (week 0), 8 weeks, and 24 weeks. Plasma was tested for anti-SARS-CoV-2 IgG and ACE2 inhibition (surrogate neutralization; 0-100% with >25% consistent with neutralizing antibody) against ancestral, Beta, Delta, and Omicron subvariants using the MSD platform. T cell responses to SARS-CoV-2 spike and nucleocapsid were assessed via ELISpot. Changes in antibody and T cell responses were assessed by paired Wilcoxon rank-sum testing. Additionally, responses were compared to boosted healthy controls (HC) (n=11).

Results: Antibody responses against ancestral virus remained relatively constant in the HD cohort (p = 0.9). Neutralization of BA.5 remained low throughout with 48% of participants below the 25% threshold associated with live-virus neutralization. While ACE2 inhibition was similar to HCs (Figure), the proportion of HD participants above the 25% threshold for BA.5 was significantly lower than HCs (p = 0.004). Neutralizing capacity of BA.5 among HD patients with a history of COVID-19 was not greater than those with no history of COVID-19. Spike specific T cell responses increased in HD patients over time.

Conclusions: Original vaccine formulations are insufficient to induce reliable Omicron subvariant neutralization in HD patients.

FR-PO1104

Symptoms After COVID-19 Vaccination Are Associated with Anti-SARS-CoV-2 Antibody Response in Kidney Transplant Recipients

Rikako Oki,[1,2] Kohei Unagami,[1,2] Kazuya Omoto,[1,2] Hideki Ishida.[1,2] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Yochomachi clinic, Tokyo, Japan.*

Background: SARS-CoV-2 messenger RNA (mRNA) vaccines, BNT162b2 (Pfizer-BioNTech) and mRNA-1273 (Moderna), have been associated with local and systemic symptoms. We investigated the association of self-reported post-vaccination symptoms with anti-SARS-CoV-2 antibody response among kidney transplant recipients.

Methods: This study included data collected from 251 kidney transplant recipients at Yochomachi Clinic from 2021 to 2022. All participants were administered an mRNA vaccine (BNT162b2 or mRNA-1273), as indicated. Serum samples from each patient were subsequently collected before the first and second vaccination and at 1, 3, and 6 months after the second vaccination. For the assessment of antibody titers, S-IgG and N-IgG levels were measured (Elecsys®, Roche). As post-vaccination symptoms, local (injection site pain, rash, heat sensation, swelling, itchiness) and systemic (headache, fever, moderate to severe fatigue) symptoms were recorded from the 1st day of vaccination to the 10th day, for both the first and second vaccination.

Results: Major symptoms after the second vaccination included injection site pain (80%), itchiness (43%), moderate to severe fatigue (27%), and headache (19%). Itchiness and headache were significantly less common in the group of patients <1 year post-transplant (p=0.049, 0.03). Based on vaccine type, itchiness and fatigue were significantly more common with the mRNA1273 vaccine (p<0.01). S-IgG titers at 3 and 6 months after the second shot were significantly higher in patients who reported fatigue or headache (p<0.05). Logistic regression analysis revealed that headaches were associated with acquisition of anti-SARS-CoV-2 antibodies 3 months after the second shot, independent of age and sex. (Table1)

Conclusions: Systemic symptoms after vaccination for COVID-19 might be related to acquisition of anti-SARS-CoV-2 antibodies.

Funding: Government Support - Non-U.S.

COVID-19 Vaccine Immune Response in Hemodialysis Patients

Kashif Gulzar, Fakhriya J. Alalawi, Hind H. Alnour, Amna K. Al Hadari. *Dubai Health Authority, Dubai, United Arab Emirates.*

Background: COVID-19 infection is associated with increased morbidity and mortality in chronic kidney disease patients, especially those on maintenance hemodialysis. The comparison of immunogenicity of different COVID vaccines in the dialysis populations is lacking especially in the middle east region.

Methods: We conducted a retrospective observational study, that includes 164 hemodialysis patients (HD) and 54 health workers (HW), who received 2 doses of either Pfizer-BioNTech or Sinopharm vaccine. The primary endpoint was to report the rate of seroconversion and the factors affecting it.

Results: HD patients have a significantly low seroconversion rate than HW (HD vs HW: 76.54% and 100%, p=<0.05), also S1 IgG antibody level was significantly low in HD patients (HD vs HW: 183.5 and 400 BAU/ml, p=<0.05). The type of vaccine and hypo-response to the HBV vaccine were two statistically significant factors affecting the seropositivity rate in HD patients. As compared to Sinopharm, Pfizer-BioNTech vaccinated HD patients exhibit not only higher seroconversion rate (Pfizer-BioNTech vs Sinopharm: 90.80% and 60%, p=<0.05) but also express high S1 antibody titer (Pfizer-BioNTech vs Sinopharm: 425 and 162 BAU/ml (p=<0.05), however, there is no significant difference in post-vaccine COVID infection rate among the two vaccines (Pfizer-BioNTech vs Sinopharm: 39.24% and 42.22% (p= 0.176).

Conclusions: Lower Immune response to the COVID vaccine is observed in HD patients as compared to HW participants, also Pfizer-BioNTech vaccinated HD patients exhibit better seroconversion rates and higher antibody titer than Sinopharm vaccine in HD patients, so alternative vaccine strategies should be designed in dialysis patients

Omicron BA.1, BA.5, BQ.1.1, and XBB.1.5 Neutralizing Antibodies Following BNT162b2 BA.4/5 vs. mRNA-1273 BA.1 Bivalent Vaccination in Hemodialysis Patients and Kidney Transplant Recipients

Kevin Yau,[1,2] Darren A. Yuen,[1,3] Jeffrey Perl,[1,3] Christopher T. Chan,[1,4] Adeera Levin,[5] Matthew J. Oliver,[1,2] Michelle A. Hladunewich.[1,2] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [3]St Michael's Hospital, Toronto, ON, Canada; [4]Toronto General Hospital, Toronto, ON, Canada; [5]BC Provincial Renal Agency, Vancouver, BC, Canada.*

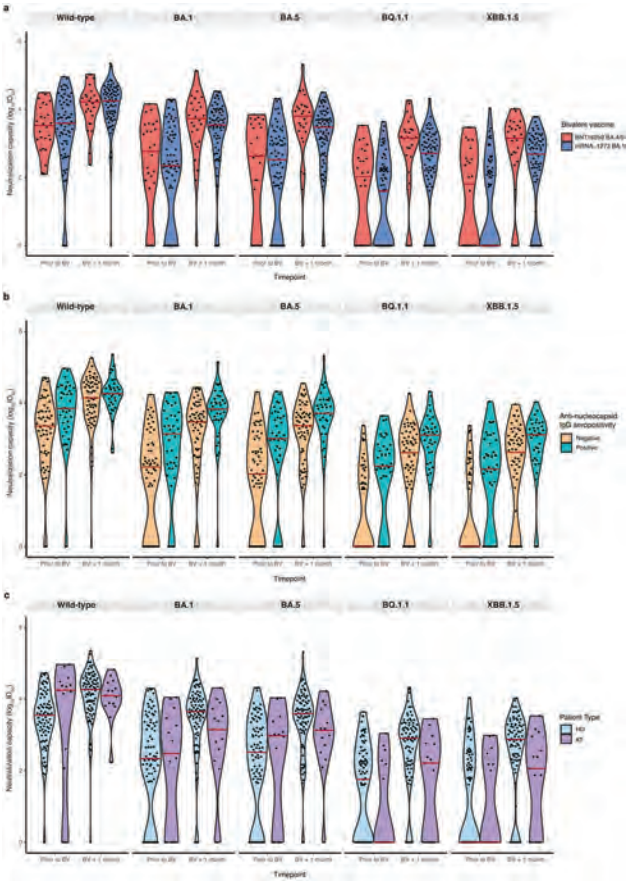
Background: Bivalent COVID-19 vaccines are recommended, however differences in neutralization of emerging Omicron subvariants by vaccine type have not been evaluated in patients with kidney disease.

Methods: This was a prospective observational cohort study at three centres in Toronto, Canada from July 25, 2022 to November 30, 2022 in 98 patients receiving hemodialysis or with a kidney transplant. Participants received either the BNT162b2 (original and Omicron BA.4/BA.5) or mRNA-1273 (original and Omicron BA.1) COVID-19 vaccine. Neutralizing antibodies against wild-type, Omicron BA.1, BA.5, BQ.1.1, XBB.1.5 subvariants were measured prior to and one month following the receipt of a bivalent vaccine.

Results: Neutralizing antibodies against BA.1, BA.5, BQ.1.1, and XBB.1.5 increased 8-fold one month following bivalent vaccination. In comparison to wild-type, neutralizing antibodies against Omicron-specific variants were 7.3-fold lower against BA.1, 8.3-fold lower against BA.5, 45.8-fold lower against BQ.1.1, and 48.2-fold lower against XBB.1.5. Viral neutralization did not differ by bivalent vaccine type: wild-type (p=0.48), BA.1 (p=0.21), BA.5 (p=0.07), BQ.1.1 (p=0.10), XBB.1.5 (p=0.10).

Conclusions: The BNT162b2 and mRNA-1273 bivalent vaccines induced similar neutralization against all Omicron subvariants in hemodialysis and kidney transplant recipients, suggesting that bivalent vaccines confer protection against emerging Omicron subvariants even if they are antigenically different from the circulating variant.

Funding: Government Support - Non-U.S.



Neutralizing antibody levels stratified by a) bivalent vaccine type b) anti-nucleocapsid IgG seropositivity c) and hemodialysis versus kidney transplant recipients.

Safety and Efficacy of One and Two Booster Doses of SARS-CoV-2 mRNA Vaccines in Kidney Transplant Recipients: A Randomized Clinical Trial

Petr Drenko,[1] Martin Kacer,[1] Lukas Kielberger,[1] Tomas Vlas,[2] Radek Kucera,[3] Tomas Reischig.[1] *[1]Department of Internal Medicine I, Faculty of Medicine in Pilsen, Charles University, and University Hospital, Pilsen, Czechia; [2]Department of Immunology and Allergology, Faculty of Medicine in Pilsen, Charles University, and University Hospital, Pilsen, Czechia; [3]Department of Immunochemistry Diagnostics, Faculty of Medicine in Pilsen, Charles University, and University Hospital, Pilsen, Czechia.*

Background: Kidney transplant recipients are at risk for a severe course of COVID-19 with a high mortality rate. Although an adequate humoral response to COVID-19 vaccination is therefore essential, a considerable number of patients remains without a satisfactory serological response after the baseline and adjuvant SARS-CoV-2 vaccination schedule.

Methods: In this prospective, randomized study, we evaluated the efficacy and safety of one and two booster doses of mRNA vaccines (either mRNA-1273 or BNT162b2) in 125 COVID-19 naive, adult kidney transplant recipients who showed an insufficient humoral response (SARS-CoV-2 IgG <10 AU/ml) to the previous 2-dose vaccination schedule. The primary outcome was the occurrence of a positive antibody response between one and two booster doses at one month after the final booster dose.

Results: A positive humoral response was observed in 36 (62%) patients who received two booster doses and in 28 (44%) patients who received one booster dose (p=.043). Moreover, median SARS-CoV-2 IgG levels were higher with two booster doses (p=.009). The number of patients with positive virus neutralizing antibody levels was numerically higher in the two booster doses compared to the single booster dose, but without statistical significant (66% vs. 50%, p=.084). There was no significant difference in the rate of positive seroconversion and antibody levels between mRNA-1273 and BNT162b2 vaccines.

Conclusions: A higher number of kidney transplant recipients achieved a positive antibody response after two booster doses compared to one booster dose.

SARS-CoV-2 Vaccination Reduces the Frequency of Acute Kidney Disease in COVID-19 Patients: A Prospective Multicenter Multinational Study

Raul Lombardi,[1] Alejandro Ferreiro,[1] Joanna Y. Venegas justiniano,[2] Mariana B. Pereira,[3] Maria C. Carlino,[4] Rolando Claure-Del Granado,[5] Daniela Ponce,[6] Maria A. Zinoveev.[1] *[1]Universidad de la Republica Facultad de Medicina, Montevideo, Uruguay; [2]Corporacion Arzobispo Loayza SAC, Lima, Peru; [3]Universidade de Sao Paulo, Sao Paulo, Brazil; [4]Circulo Medico de Rosario, Santa Fe, Argentina; [5]Universidad Mayor de San Simon, Cochabamba, Bolivia, Plurinational State of; [6]Universidade Estadual Paulista Julio de Mesquita Filho, Sao Paulo, Brazil.*

Background: The development of renal alterations in SARS-CoV-2 infection is frequent and is associated with poor outcome. Objectives. To evaluate AKD (proteinuria, hematuria, AKI) and the impact of immunization with vaccine for the acquisition of kidney complications of the disease.

Methods: Observational, prospective, multicenter, multinational, longitudinal study. Inclusion criteria: patients ≥ 18 years with COVID-19 by RT-PCR who required hospital admission between march 2021 and may 2022. Patients receiving KRT, or CKD stage 4 - 5 were excluded. Data collected in electronic web form. Approved by the Ethics Committee. H_0 was rejected with a p value <0.05.

Results: 360 patients from 5 countries: Peru (45%), Brazil (22.5%), Bolivia (14.7%), Argentina (11.1%), Uruguay (6.7%). 57.7% male. Age 62 (48-75) years. Comorbidities: hypertension (49.7%), diabetes (31.8%) obesity (26.3%). 73.8% were hospitalized in a conventional ward, 15.6% in the ICU and 10.6% in the emergency room. At admission: Scr 0.86 (0.68-1.07) mg/dl, proteinuria 225 patients (62.5%); (27,4% developed at evolution). 36,4% developed AKI, most of them KDIGO stage 3 (47.9%) KRT (37.4%). Diuresis preserved in 71.4%. Complete recovery 40.2%, partial 12.4% and 47.4% had no recovery. 50.9% were admitted to the ICU and 163 (45.3%) received mechanical ventilation. 56.2% developed sepsis. In-hospital mortality was 30.2%. Mortality was analyzed according 4 groups: 1) without proteinuria or AKD (5,8%); 2) proteinuria without AKI (24,1%) ; 3) AKI withot proteinuria or hematuria (36,4%) ; 4) proteinuria and AKI (55,5%) (p< 0.0001). Patients who received at least one dose of SARS CoV-2 vaccine had lower frequency of proteinuria (52 vs 71.8% p<0.001), hematuria (24.4 vs 44.4%, p<0.01), AKI (42 vs 47.1%, p<0.05) and mortality adjusted for comorbid factors (25 vs 44.5%, p<0.001).

Conclusions: The epidemiological profile of COVID associated AKD in Latin America was similar to previous reports. Isolated proteinuria was the most frequent manifestation of AKD. Mortality of AKD was maximal in AKI associated with proteinuria. Vaccination against SARS CoV-2 decreased the frequency of AKD, and was associated with a decrease in mortality.

FR-PO1109

Despite Vaccination, Risk of COVID-19 Outcomes Is Elevated in Patients with ESRD: Initial Results from INFORM Retrospective Study in England using National Health Service Datasets

Sabada Dube,[1] Yi Lu,[2] Richard J. McNulty,[3] Sophie Graham,[2] Sofie Arnetorp,[4] Nahila Justo,[5,6] Renata Yokota,[7] Kathryn Evans,[8] Lucy Carty,[9] Mark Yates,[2] Sylvia Taylor,[10] Jennifer K. Quint.[11] *[1]Epidemiology, Vaccines and Immune Therapies Unit, AstraZeneca, Cambridge, United Kingdom; [2]Real-World Evidence, Data Analytics, Evidera, London, United Kingdom; [3]Medical Affairs, Vaccines and Immune Therapies Unit, AstraZeneca, Cambridge, United Kingdom; [4]Health Economics and Payer Evidence, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [5]Real-World Evidence, Data Analytics, Evidera, Stockholm, Sweden; [6]Department of Neurobiology, Care Science and Society, Karolinska Institute, Stockholm, Sweden; [7]P95, Leuven, Belgium; [8]Real-World Evidence, Data Analytics, Evidera, Waltham, MA; [9]Medical and Payer Evidence Statistics, BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom; [10]Medical Evidence, Vaccines and Immune Therapies Unit, AstraZeneca, Cambridge, United Kingdom; [11]National Heart and Lung Institute, Imperial College London, London, United Kingdom.*

Background: Patients (pts) with end-stage renal disease (ESRD) are considered immunocompromised. However, pre-exposure prophylaxis (PrEP) is not always recommended in this population. We report initial results from the INFORM retrospective study on severe COVID-19 outcomes in fully vaccinated (≥3 doses) pts with ESRD or dialysis (ESRD or D) and ESRD with dialysis (ESRD+D).

Methods: COVID-19–related hospitalizations and deaths in pts aged ≥12 years in England were identified from a random sample of 25% of pts in National Health Services datasets (Jan 1, 2022–Dec 31, 2022). Incidence rates (IRs) per 100 person years (PY) were determined in pts with ESRD or D and with ESRD+D. Incidence rate ratios (IRRs) per 100 PY (crude and adjusted for age and sex) were calculated for pts with ESRD or D and ESRD+D versus those without.

Results: Pts with ESRD or D or with ESRD+D had higher IRs for COVID-19–related hospitalizations or deaths than those without. Adjusted IRRs for hospitalization and mortality were higher in pts with ESRD or D and ESRD+D than those without. Hospitalization adjusted IRRs for pts with ESRD or D and ESRD+D were 5.59 (95% CI 5.07–6.16) and 9.91 (95% CI 8.69–11.30), respectively (Table). Mortality adjusted IRRs for pts with ESRD or D and ESRD+D were 5.04 (95% CI 4.11–6.16) and 8.68 (95% CI 6.41–11.77), respectively (Table).

Conclusions: Despite full COVID-19 vaccination, including boosters, pts with ESRD or D and ESRD+D are at greater risk of severe COVID-19 outcomes than those without. Therefore, vaccinated pts with ESRD may benefit from PrEP to reduce the risk of severe COVID-19.

Funding: Commercial Support - AstraZeneca

Table. COVID-19 hospitalizations and deaths in 2022 in patients with ESRD or dialysis and patients with ESRD and dialysis who are fully vaccinated (≥3 doses)

	N* (%)	COVID-19-related hospitalizations: Total number of hospitalizations,*#	Pts with (1 hospitalization, n (%))	Incidence rate per 100 person-years	Crude IRR (95% CI)	Age and sex adjusted IRR (95% CI)	COVID-19-related mortality: Deaths, n (%)	Death rate per 100 person-years	Crude IRR (95% CI)	Age and sex adjusted IRR (95% CI)
Fully vaccinated (≥3 doses) pts with ESRD or dialysis^	99 450 (0.3)	680	470 (3.4)	2.47 (2.26–2.69)	10.17 (9.02–11.21)	5.59 (5.07–6.16)	105 (0.5)	0.38 (0.32–0.76)	10.15 (8.79–13.19)	5.04 (4.11–6.16)

Risk Factors for COVID-19-Related Hospitalization After Reinfection in Maintenance Dialysis Patients

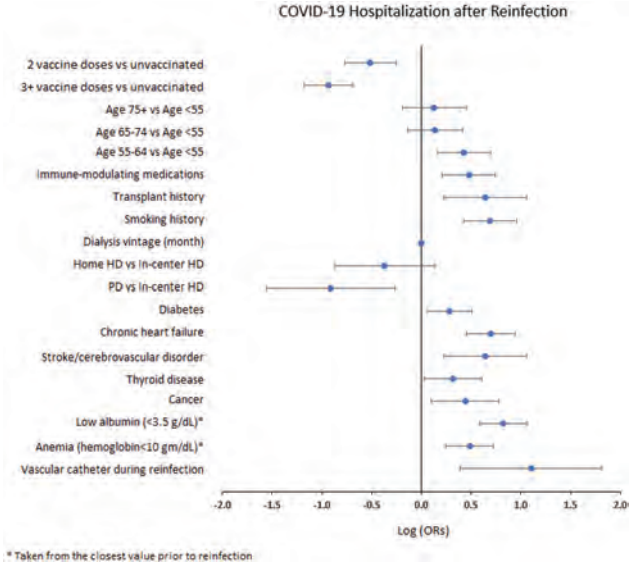
Monica Shieu,[1] Harold Manley,[1] Nien Chen Li,[1] Antonia Harford,[1] Caroline M. Hsu,[2] Dana Miskulin,[2] Daniel E. Weiner,[2] Doug Johnson,[1] Eduardo K. Lacson.[1] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

Background: SARS-CoV-2 reinfection is a common occurrence. However, risk factors for COVID-19-related hospitalization with COVID-19 recurrences among maintenance dialysis patients are uncertain.

Methods: All adult maintenance dialysis patients at Dialysis Clinic, Inc. with 1) at least two COVID-19 diagnoses between 2/1/2020 and 1/31/2023 and 2) the second diagnosis was after 2/1/2021 (when vaccine became available) were included. SARS-CoV-2 reinfection was defined by a positive test >90 days after the first positive test. SARS-CoV-2-related hospitalization (within 30 days) of a recurrent infection were defined by a documented primary diagnosis for the episode of care of COVID-19. Stepwise logistic regression models were used to identify risk factors for COVID-19 hospitalization after reinfection. Exposure time accounting for time since last vaccination and prior COVID-19 infection was weighted for all models.

Results: Of 610 patients with ≥2 COVID-19 infections included in the analysis, 99 (16.2%) patients were hospitalized after COVID-19 reinfection. 410 were not hospitalized, 165 were hospitalized once, and 35 were hospitalized twice. Unvaccinated status, older age, usage of immune-modulating medications, transplant history, smoking history, comorbidities, low serum albumin, anemia, and vascular catheter usage were associated with increased risk for COVID-19 hospitalization after reinfection. There was a dose-response relation between higher vaccine number and lower risk of hospitalization (p for trend=0.02).

Conclusions: Hospitalization risk for COVID-19 reinfection remained high (16.2%). Despite prior infection, unvaccinated patients had higher risk. Traditional risk factors such as age, diabetes, low serum albumin, and catheter usage remained significant.



COVID-19 Hospitalization after Reinfection

Outcomes of Patients with CKD and ESRD Hospitalized with COVID-19: A Retrospective Cohort Study in Michigan

Justin Khine,[1,2] Ghadeer N. Hannoudi,[2] Anupam Sule,[2] Barry M. Wall.[1]
[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]Trinity Health, Livonia, MI.

Background: A large patient cohort, multivariate regression models, and inverse probability of treatment weights (IPTWs) to determine the effect of kidney disease on mortality in hospitalized CoVID-19 patients.

Methods: 6,737 hospitalized, SARS-CoV-2 positive patients from the South East Michigan CoVID Consortium dataset were analyzed for common dimensions of risk factors for increased mortality. Univariate, multivariate logistic regression, and IPTW propensity scoring models were used to reflect the effect of each variable on outcomes. IPTW models required patient population trimming to include patients only within the region of common support, thus less patients were analyzed in the fully adjusted (N=6,117) and IPTW (N=4131) models.

Results: Unadjusted models show significant increases in all outcomes in any level of renal disease. No association with increased mortality as a result of renal disease after adjusting for covariates. IPTW model finds that renal dysfunction infers longer duration of hospitalization, and average higher SOFA scores. In CKD patients, SOFA scores were 1.34 times higher (p<0.001) versus control patients. ESRD patients were hospitalized longer (IRR=1.19;p<0.001), and had higher SOFA scores (IRR=1.98;p<0.001) than control patients.

Conclusions: Here, we show that renal disease in of itself does not directly lead to increased mortality in CoVID-19 patients. Initial findings of increased mortality in CKD and ESRD patients may more likely be a result of chronic disease burden as shown by sequela comorbidities seen in CKD and ESRD patients.

Association between CKD/ESRD and Binary CoVID-19 Outcomes

COVID-19 Omicron Infections in a Chinese Peritoneal Dialysis Center

Jin Chen, Guisen Li. *Sichuan Academy of Medical Sciences and Sichuan Provincial People's Hospital, Sichuan Clinic Research Center for Kidney Diseases, School of Medicine, University of Electronic Science and Technology of China, Chengdu, China.*

Background: In December 2022, an outbreak of the COVID-19 Omicron variant occurred in China, resulting in widespread population transmission. Peritoneal dialysis (PD) patients, as a predisposed group, faced significant risks. The aim of this study was to investigate the outcomes and risk factors in peritoneal dialysis (PD) patients infected with COVID-19.

Methods: Demographic and clinical characteristics of 341 PD patients were recorded at admission. Both binary logistic regression analysis and Cox proportional hazard regression analysis were used to evaluate potential risk factors for infection and mortality.

Results: COVID-19 was confirmed in 260 (76.2%) patients. Among infected patients, 57 (16.7%) were hospitalized and 11 (4.2%) patients died. Old age (odds ratio [OR] 1.042, 95% confidence interval [95% CI] 1.010-1.075, p=.01), dyspnea (OR 6.113, 95% CI 2.268-16.475, p<.001), use of systemic glucocorticoids (OR 5.830, 95% CI 1.164-29.201, p= .03), baseline hyponatremia (OR 3.096, 95% CI 1.125-8.517, p=.03), and baseline high-sensitivity C-reactive protein (hsCRP) (OR 1.089, 95% CI 1.011-1.173, p=.02) were associated with hospitalization. Patients with a higher Charlson comorbidity index score (OR 2.143, 95% CI 1.094-4.198, p=.03), weight loss (OR 9.168, 95% CI 1.604-52.399, p= .01), and baseline hyponatremia (OR 19.345, 95% CI 2.229-167.862, p=.007) were more likely to die compared to survivors.

Conclusions: Older PD patients with dyspnea, in receipt of glucocorticoid therapy, and baseline hyponatremia had a higher risk of hospitalization. Charlson comorbidity index score, weight loss, and baseline hyponatremia were associated with mortality.

FR-PO1113

Encapsulating Peritoneal Sclerosis Related to SARS-CoV-2 Infection

Enrique I. Rodríguez García, Daniel F. Ovando-Morga, Mercedes A. de la Cruz Jasso, Ruth Ixel Rivas Bucio, Juan J. Salazar. *Instituto de Seguridad y Servicios Sociales de los Trabajadores del Estado, Mexico City, Mexico.*

Introduction: Encapsulating peritoneal sclerosis (EPS) is an extremely rare complication of long-term PD, associated with high morbidity and mortality (50%). The reported incidence is 0.7 and 13.6 per 1,000 pts-year. PD duration is the key risk factor, higher dialysate glucose exposure, peritonitis rate, younger age, abdominal surgery, icodextrin (ICO), UF failure, and higher peritoneal solute transport rate as well. Diagnosis is based upon a combination CT findings and intermittent subacute bowel obstruction. Only a fibrous cocoon wrapped around the bowel is diagnostic.

Case Description: 41-year-old female, history of diabetes and hypertension. CKD of unknown etiology since 2020, she began APD since 1 yr, 2.5% PD solution + ICO. 3 episodes of peritonitis in 2021. History of umbilical hernia repair and 2 cesareans. 9 days before admission with a + Covid-19 test, 3 days before she had abdominal pain and clinical data of intestinal oclussion (IO). She was admited with BP 60/40 mmHg, IV resuscitated and treated w/MTZ and CRO. PD count (PDC) showed 1,842 leu, concluding IO and peritonitis. An exploratory laparotomy (EL) was performed with removal and replacement of catheter. After 5 days a PDC showed refractory peritonitis, transferred to HD and antibiotics were escalated (VCM and CTZ). 7 days after EL, PD catheter was removed. She persisted with IO, a CT scan corroborate it; A new EL was done with finding of fibrous cocoon wrapped around the bowel and peritoneal biopsy with fibrosis and chronic inflammation.

Discussion: The patient has risk factors for EPS: PD with ICO, and 2.5% PD solutions, however the main reported risk factor is time in PD, in her case it was considered low. Covid-19 infection has been associated with a possible effect of the virus on the peritoneal mesothelial cells (MCs). Although there is no in vivo direct evidence so far of MCs infection by the virus, despite this, MCs have been found to express SARS-CoV-2 specific receptors/co-receptors ACE2. In this case we consider a strong association between Covid-19 and EPS. To our knowledge there are not previous reported cases and this represents and area for future research.

FR-PO1114

Comparing Infectious Diagnoses in ESKD Before and After the COVID Era

Jay Manadan, Neil Manadan, Nilam Patel, William L. Whittier. *Rush Nephrology, Chicago, IL.*

Background: Undoubtedly, the 2020 worldwide COVID-19 pandemic had a major impact on healthcare. This study aims to compare infections among inpatients with end stage kidney disease (ESKD) before and after the onset of the pandemic in the USA.

Methods: All adult hospitalizations from the 2016-2020 National Inpatient Sample (NIS) database with a principal diagnosis of infection and a secondary diagnosis of ESKD were analyzed. We compared data between the pre-COVID era (2016-2019) with those from the COVID era (2020).

Results: 990,550 hospitalizations between 2016-2020 had both an infection and ESKD. Of those, 752,640 were from the pre-COVID era and 237,910 were from the COVID era (figure 1). Those from the COVID era had less females, higher inpatient charges, and higher adjusted in-hospital mortality (14.4% vs 10.2%; p<0.001) (figure 1). In 2020, COVID-19 became the second most frequent infection seen in ESKD inpatients (figure 2). Various types of sepsis remained frequent in both groups, along with pneumonia, line infection, peritoneal dialysis catheter infection, and urinary tract infection.

Conclusions: ESKD patients with an infection experienced a higher adjusted in-hospital mortality in 2020. COVID became the second most common infection in ESKD patients in 2020. Nine of the top ten infections remained identical between the groups. Sepsis remained the predominant infection in the post-COVID era. This information should alert nephrologists to the frequency of COVID in ESKD inpatients.

Figure 1: Descriptive Characteristics of Endstage Kidney Disease Patients Hospitalized Primarily for an Infection Before and After 2019 (n=990,550)

Descriptive Characteristics	Infections in ESKD 2016-2019 (n=752,640)	Infections in ESKD in 2020 (n=237,910)	P-value
Age, median (IQR)	65 (54-74)	65 (54-74)	0.819
Female (%)	46.2%	44.4%	<0.001

The Effect of ESKD on COVID-19 In-Hospital Mortality

Neil Manadan, Jay Manadan, Nilam Patel, William L. Whittier. *Rush Nephrology, Chicago, IL.*

Background: Significant morbidity resulted when the COVID-19 infection became a pandemic in the United States. This study aimed to study the effect of end stage kidney disease (ESKD) on mortality on those with COVID.

Methods: We performed a retrospective analysis of all adult hospitalizations with a principal diagnosis of COVID from the 2020 National Inpatient Sample (NIS) database. They were subdivided in those with and without ESKD. Variables with a p value ≤0.2 in the univariable screen were included in a multivariable analysis for in-hospital death.

Results: There were 27,668,666 adult hospitalizations in the 2020 NIS database. Of those, 1,011,340 had COVID without ESKD and 38,705 had COVID with ESKD (figure 1). Among COVID inpatients, univariable analysis showed an association for death for the following variables: age, CCI, male gender, White, African American, Hispanic, Native Americans, ESKD, Income Q1, and Income Q3. Multivariable analysis showed higher odds for death for the following variables: Age (OR 1.04; p<0.001), CCI (OR 1.18; p<0.001), Male (OR 1.39; p<0.001), Hispanics (OR 1.09; p= 0.019), Native American (OR 1.57; p<0.001), ESKD (OR 1.25; p<0.001), and Income Q1 (OR 1.12; p<0.001) (figure 2).

Conclusions: Age, CCI, male gender, Hispanic race, Native American ethnicity, ESKD, and a lower income were associated with higher odds of death among those hospitalized with COVID. This information can alert clinicians of the negative effects of ESKD on COVID mortality. Further studies on COVID mortality must account for ESKD.

Variable	COVID without ESKD (n=1,011,340)	COVID with ESKD(n=38,705)	P-value
Age, median (IQR)	66 (54-77)	65 (55-74)	< 0.001
Male, n (%)	532,710 (52.6%)	21,740 (56.2%)	<0.001

COVID-19's Impact on Dialysis Waste: A Greek Dialysis Group's Experience

Kyriaki Stamatelou,[1,2] Ioannis Agrogiannis,[1] Vasileios Giannikos,[1] Aikaterini Vlachonikolou,[1] Eirini Mpountou,[1] Konstantinos Vithoulkas.[1] *[1]Mesogeios Nephrology Center, Haidari, Greece; [2]Nephros.EU Private Clinic, Athens, Greece.*

Background: The COVID-19 pandemic has increased the generation of biomedical waste and put enormous strain on waste collection thus damaging the environment. Our dialysis group operates 9 dialysis clinics in Greece treating approximately 1000 patients. We are continuously implementing national regulations-protocols and extra measures protecting patients from COVID-19. We investigated the effect of COVID-19 pandemic on the generation of hazardous and infectious waste amounts and waste production rate in our dialysis clinics.

Methods: We performed routine weighing of all dialysis clinics' infectious and hazardous waste including: 1.Personal protective equipment(PPE): gloves, gowns, tapes, coveralls, goggles, masks, caps, shoe covers. 2.The SARS-CoV-2 rapid antigen test (RAT) components 3.dialyzer filters, circuits, connections. 4.Contaminated single-use material, drapes, gauzes, compresses, bandages, and single-use care kits. We compared all amounts of waste produced before the pandemic, year 2019, and during the pandemic, years 2020, 2021 and 2022: per waste category, as total categories' aggregates, per dialysis session, per dialysis clinic and for all dialysis clinics.

Results: Aggregated hazardous and infectious waste increased during the pandemic in all our dialysis clinics. Indicatively: Total kilograms of waste discarded were 142361.04, 152978.25, 149448.92 and 166640.5 in the years 2019, 2020, 2021 and 2022 respectively. 2022 presented a 4% increase compared to 2019. Per dialysis session Kilograms of waste increased from 0.997191409 in 2019 to 1.018591946 in 2020 and 1.034520114 in 2022. PPE and RATs were the main attributes of increase. In one dialysis clinic RATs weighted 0, 4.860, 34.956 and 98.217 kilograms in 2019, 2020, 2021 and 2022 respectively.

Conclusions: Dialysis waste management is of paramount importance. In the years following the pandemic, our dialysis clinics' waste generation increased, making efficient waste management even more critical. Our group's dialysis clinics are currently implementing new, more efficient and environment friendly practices and we trust that their beneficial effects will be soon documented.

Nationwide In-Hospital Morbidity and Mortality Analysis of COVID-19 Infection in Advanced CKD (aCKD), Dialysis Patients, and Kidney Transplant (KT) Recipients

Mingyue He, Avrum Gillespie. *Temple University Hospital, Philadelphia, PA.*

Background: Individuals with kidney disease, including aCKD, end-stage kidney disease (ESKD), and KT have an increased risk for COVID-19 infection, hospitalization, and mortality compared to those without CKD (CKD-free). The comparative morbidity and mortality among hospitalized COVID-19 patients with aCKD, ESKD, KT, and CKD-free remain uncertain.

Methods: We queried the 2020 Nationwide Inpatient Sample (NIS) database for non-elective adult COVID-19 hospitalizations. Patients were classified into four kidney disease categories: aCKD (stage 3-5, non-dialysis), ESKD (dialysis), KT, and CKD-free. The primary outcome was in-hospital mortality; secondary outcomes included morbidity (septic shock, acute respiratory failure, acute respiratory distress syndrome (ARDS), mechanical ventilation, pressor requirement) and resource utilization (length of hospital stay (LOS), total charges). Outcomes were analyzed with either multivariable logistic or linear regression and adjusted for demographic and comorbidity confounders.

Results: A total of 1,018,915 adults hospitalized for COVID-19 in 2020 were included. Of these, 5.9% had aCKD, 3.9% had ESKD, 0.4% were KT recipients, and 85.0% had no pre-existing CKD. The all-cause in-hospital mortality was 9.7% for CKD-free, 20.5% for aCKD, 19.7% for ESKD, and 12.4% for KT. Results were shown in Figures.

Conclusions: Our study found hospitalized COVID-19 patients with aCKD and ESKD exhibited more comorbidities and higher mortality than those without renal disease. Notably, mortality in KT patients was comparable to the CKD-free group. Thus, managing comorbidities and promoting vaccination is critical in aCKD and ESRD patients.

Figure 1. Outcomes of adult patients hospitalized for COVID-19

		Total	CKD-free	aCKD	ESKD	KT	P-value

FR-PO1118

Circulating FGF23 Is Associated with AKI and Predicts Survival in COVID-19

Gayatri Narayanan, Heather Burney, Eliott Arroyo, Arvin Halim, Yang Li, Xiaochun Li, Syed J. Sher, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: 20-40% of severely ill COVID-19 patients develop acute kidney injury (AKI). AKI is now considered to be a negative prognostic factor for survival in COVID-19 patients. FGF23 is a bone-derived phosphatonin that is elevated in AKI. To-date, no study has investigated the associations between FGF23 and AKI in the COVID-19 population. Herein, we performed a study evaluating FGF23 levels in a cohort of COVID-19 patients and its association with AKI status and survival.

Methods: We conducted a prospective cohort study in 111 patients hospitalized with COVID-19. Total FGF23 levels were measured using an ELISA assay (Quidel). AKI status and FGF23 levels were determined concurrently. The primary outcome was death and secondary endpoint was AKI status. The median follow-up to death was 22.6 months. Associations between FGF23 levels and AKI status and survival were assessed by logistic regression and cox proportional hazards models, respectively.

Results: Of the 111 patients, 77 had no AKI (eGFR=91.0 [69.2,101.3] ml/min/1.73m^2), 17 had AKI (eGFR=39.7 [28.7,57.8] ml/min/1.73m^2), and 17 had end-stage kidney disease (ESKD, p<0.001). Patients did not significantly differ in sex (p=0.6) or age (p=0.9) but differed in BMI (p=0.023). Median FGF23 levels were higher in patients with AKI (305.6 [134.6, 350.8] RU/mL) and ESKD (3,607.7 [440.5, 7,452.7] RU/mL) compared to those with no AKI (120.7 [64.3, 249.7] RU/mL]; p<0.001). After adjusting for patient age, patients with high FGF23 showed increased odds of having AKI (p=0.004). Survival at 24 months was higher among non-AKI patients (71%) compared to AKI (65%) and ESKD (35%) patients (p=0.02). Finally, controlling for patient age and group-specific death hazards among non-AKI, AKI and ESKD groups, FGF23 was significantly associated with an increased risk of death (p<0.001).

Conclusions: Elevated FGF23 levels are associated with AKI and were predictive of survival in a cohort of COVID-19 patients. These findings indicate that FGF-23 levels may help with risk stratification and management of AKI in patients with COVID-19.

Kidney Injury Molecule-1 Is an Independent Receptor from ACE2 for SARS-CoV-2 in Lung and Kidney

Makiko Mori,[1,2] Yutaro Mori,[1,2] Corby Fink,[3] Takaharu Ichimura,[2] Keisuke Sako,[2] Yuki Nakao,[1] Astrid Weins,[4] Shinichi Uchida,[1] Joseph V. Bonventre.[2]
[1]Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan; [2]Division of Renal Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, MA; [3]Department of Microbiology & Immunology, Schulich School of Medicine & Dentistry, Western University, London, ON, Canada; [4]Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA.

Background: Coronavirus disease 2019 (COVID-19) caused by SARS-CoV-2 continues to contribute to a world-wide pandemic. SARS-CoV-2-associated respiratory failure and acute kidney injury are major complications of infection. KIM-1 is a scavenger receptor expressed by renal epithelial cells and has been reported to be a receptor for several viruses. We hypothesized that KIM-1 is a receptor for SARS-CoV-2 and may play an essential role in COVID-19 lung and kidney injury.

Methods: Human lung and kidney autopsy samples were immunostained and analyzed. Uptake of "virosomes", liposomal nanoparticles displaying the SARS-CoV-2 spike protein, by A549 lung epithelial cells, mouse primary lung epithelial cells, and human kidney tubular organoids was evaluated in the presence or absence of anti-KIM-1 antibody or TW-37, a KIM-1-mediated endocytosis inhibitor. Protein-protein interaction characteristics between purified SARS-CoV-2 spike protein and purified KIM-1 were determined using flow cytometry-based immunoprecipitation. HEK293 cells expressing human KIM-1 but not functional angiotensin-converting enzyme 2 (ACE2), a known receptor, were infected with live SARS-CoV-2. ACE2 complete knockout HEK293 cells were produced and exposed to the SARS-CoV-2 spike protein.

Results: KIM-1 was expressed in lung and kidney epithelial cells in COVID-19 patient samples. Human and mouse lung and kidney epithelial cells expressed KIM-1 and endocytosed spike-virosomes. Both anti-KIM-1 antibodies and TW-37 inhibited uptake. Enhanced KIM-1 expression in human kidney tubular organoids increased virosome uptake. Purified SARS-CoV-2 spike protein and KIM-1 bound to each other and TW-37 inhibited the binding. KIM-1-expressing HEK293 cells without functional ACE2 expression had increased susceptibility to infection by live SARS-CoV-2 when compared with control cells. KIM-1-expressing ACE2 knockout HEK293 cells internalized SARS-CoV-2 spike protein.

Conclusions: KIM-1 is an independent receptor from ACE2 for SARS-CoV-2 in the lung and kidney based on ACE2 knockout cell condition. TW-37 can be potential therapeutic agent and/or prophylactic agent for COVID-19.

JAK Inhibitor Exaggerates Kidney Injury in the Early Phase of SARS-CoV-2 Infection in a Murine COVID-19 Model

Hibiki Sakai,[1] Masanori Obana,[1] Hiroyasu Kamuro,[1] Nagisa Tokunoh,[2] Ayaha Yamamoto,[1] Yoshiaki Okada,[1] Yasuo Yoshioka,[2] Yasushi Fujio.[1]
[1]Osaka Daigaku, Suita, Japan; [2]Osaka Daigaku Biseibutsubyo Kenkyujo, Suita, Japan.

Background: COVID-19 is a respiratory illness caused by SARS-CoV-2 infection, and its clinical manifestations range from mild respiratory illness to severe progressive pneumonia and multiple organ failure. The serious cases of COVID-19 are treated with blockade of IL-6/JAK signaling, such as anti-IL-6 receptor antibody (anti-IL-6R mAb) and JAK inhibitor Baricitinib. Kidney injury is one of the complications of COVID-19; however, the mechanisms by which SARS-CoV-2 infection results in kidney injury and the effects of current therapies against COVID-19 on kidneys are not fully understood.

Methods: Male Balb/c mice (6-10-week old) were nasally infected with mouse-adapted SARS-CoV-2 (MA10). PCR was performed with specific primers for the detection of MA10 to examine for viral entry into the lungs and kidneys. MA10 infection-induced lung injury was evaluated with H&E staining and the expression of inflammatory cytokines. Measurements of serum creatinine (sCr) level, urinary albumin/creatinine ratio

(ACR), and urinary Ngal/Cr ratio, and histological analyses were performed to evaluate kidney injury day 4 after MA10 infection. MA10-infected mice were treated with anti-IL-6R mAb (1.4 mg/head, i.p.) or Baricitinib (10 mg/kg, p.o.) at day 1 or day1-3, respectively.

Results: MA10 infection caused about 20% body weight loss in mice day 4 after infection. H&E staining and quantitative PCR revealed that inflammation was induced in the lungs of MA10-infected mice. sCr level, ACR, and Ngal/Cr ratio was increased, and tubular damage was observed in the kidneys day 4 after MA10 infection, suggesting that kidney injury was evoked in the murine COVID-19 model. However, PCR analysis revealed that MA10 was not detected in the kidneys, whereas in the lungs. As we hypothesized that cytokine storm induced kidney injury in COVID-19, MA10-infected mice were treated with anti-IL-6R mAb or Baricitinib. Unexpectedly, ACR and Ngal/Cr ratio tended to be increased in anti-IL-6R mAb group. Upon Baricitinib treatment, ACR and Ngal/Cr ratio was significantly increased.

Conclusions: Blockade of IL-6/JAK signaling in the early phase of SARS-CoV-2 infection exaggerates kidney injury, providing a novel insight into the pathogenesis of COVID-19-related kidney injury.

FR-PO1121

Ferroptosis of Kidney After SARS-CoV-2 Infection

Woong Park,[1] Yujin Jung,[1] Hyeongwan Kim,[1,2] Jihyun Yeom,[2] Soo jin Lee,[2] Yujin Shin,[2] Won Kim.[1,2] *[1]Jeonbuk National University Medical School, Jeonju, Jeollabuk-do, Republic of Korea; [2]Jeonbuk National University Hospital, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: Although kidney involvement have been evaluated for human Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV-2) infection, none have fully evaluated the ferroptosis in the kidney after SARS-CoV-2 infection. Here, we evaluate the ferroptotic renal injury in the transgenic mice expressing the human ACE2 receptor driven by the cytokeratin-18 gene promoter (K18-hACE2) after SARS-CoV-2 infection.

Methods: To investigate the effect of SARS-CoV-2 on renal ferroptosis, we administered 2.5 x 10^4 p.f.u. SARS-CoV-2 via intranasal to K18-hACE2 mice. After 7 days SARS-CoV-2 infection, kidney tissues were harvested. SARS-CoV-2 infection and ferroptosis were evaluated by immunohistochemistry. Next, ferroptosis-related markers, glutathione peroxidase 4(*Gpx4*), prostaglandin-endoperoxide synthase 2(*Ptgs2*), Acyl-CoA synthetase long chain family member 4(*Acsl4*), nuclear factor erythroid-2-related factor 2(*Nrf2*), heme oxygenase-1(*Ho-1*), transferrin receptor 1(*Tfr1*), ferritin heavy chain 1(*Fth1*) and nuclear receptor coactivator 4(*Ncoa4*) were evaluated by quantitative PCR.

Results: SARS-CoV-2 infection significantly increase the expression of SARS-CoV-2 spike protein in the tubular epithelial cells of the renal cortex and medulla. Protein expression of GPX4 was significantly decreased in the renal medulla. In the kidney of SARS-CoV-2-infected mice, the ferritin-related markers ferritin heavy chain 1(FTH1) and transferrin receptor 1(TFR1) and lipid peroxidation marker, dihydroethidium (DHE) were also increased in histological experiments. Next, the mRNA levels of *Ptgs2*, *Acsl4*, *Nrf2*, *Ho-1*, *Fth1* and *Ncoa4* were increased in the kidneys of SARS-CoV-2 infected mice compared to non-infected mice.

Conclusions: All of our data suggest that SARS-CoV-2 infection shares many features of ferroptosis in the kidney and can be used to define the ferroptosis of kidney injury and antiviral-based countermeasures in COVID-19 infection.

University of California (UC) Kidney COVID-19 Study AKI Cohort

Hiba Hamdan, Brian M. Paciotti, Blythe Durbin-Johnson, Juan P. Moreno-Ortiz, Brian Y. Young, Baback Roshanravan. *UC Davis Health, Sacramento, CA.*

Background: A wide range of rates of AKI associated with COVID-19 have been reported, often specific to select timeframes and associated SARS-CoV-2 variants of the pandemic. The aim of our study is to comprehensively describe the rates of AKI in people hospitalized with COVID-19 over the course of the first two years of the pandemic and identify risk factor for AKI in that population.

Methods: We conducted a retrospective cohort study of adults receiving care within the 5 major University of California (UC) Health Systems. The cohort included people who underwent PCR testing and were positive for SARS-CoV-2 between March 1, 2020, and December 31, 2021, and required hospitalization within 10 days of testing. The cohort was further restricted to those without ESKD, without documented pregnancy, and length of stay ≥1 day. To examine risk factors associated with AKI, we used a logistic model including age, gender, race, Area Deprivation Index (ADI), UC site of care, DM, HTN, heart failure, CKD, smoking status, BMI, use of NSAIDS at time of admission, use of ACEIs/ARBS at time of admission, ARDS, sepsis, mechanical ventilation, and month of COVID-19 diagnosis.

Results: The cohort included 5451 people with COVID-19. Patients had an average age of 59 years, 59% were male and 45% were Hispanic. From March 2020 to December 2021 the rates of AKI ranged from 20-38% and varied over the course of the pandemic (Figure 1). The factors associated with the highest odds (OR,95% CI) of AKI were: Black race (2.2,1.0-1.5), mechanical ventilation (5.1,4.2-6.2), sepsis (2.9,2.4-3.6), HTN (1.7,1.4-2.1) and CKD (1.5,1.1-2.0).

Conclusions: In a large cohort of people hospitalized with COVID-19, in one of the largest healthcare systems in California, AKI rates generally exceeded 25%. Black race, HTN, CKD, and in hospital sepsis and mechanical ventilation were associated with higher odds of AKI.

University of California (UC) Kidney COVID-19 Study Outpatient Cohort

Hiba Hamdan, Brian M. Paciotti, Blythe Durbin-Johnson, Brian Y. Young, Juan P. Moreno-Ortiz, Baback Roshanravan. *UC Davis Health, Sacramento, CA.*

Background: The long-term kidney effects of COVID-19 infection are unknown, especially among non-hospitalized patients where changes may be less noticeable. Among five major University of California (UC) Health Systems, we compared changes in kidney function between non-hospitalized COVID-19 patients to those without COVID-19.

Methods: We conducted a retrospective cohort study that included all adults who had SARS-CoV-2 PCR testing between 3/1/20-12/31/21 and were not hospitalized within 10 days of testing. Individuals were classified with or without COVID-19 based on index SARS-CoV-2 PCR. Inclusion required kidney function measurement within 12 months prior and at least one outpatient creatinine 30 days after index SARS-CoV-2 PCR. Follow up was until December 31, 2022. The cohort excluded patients with ESKD or pregnancy. We also excluded from controls any patients with a subsequent positive SARS-CoV-2 PCR test during the study period. Thus, none of the controls were ever COVID-19 positive. The primary outcome was the difference in the rate of change in eGFR at least 30-days after index SARS-CoV-2 PCR. Three linear mixed models were fitted, as detailed in the figure below.

Results: The cohort included 10915 and 152620 people with and without COVID-19. COVID 19. Patients were more likely to be Hispanic, have higher BMI and DM, and reside in areas with higher ADI (Area deprivation index). Results of the three liner mixed effects models are shown in figure below.

Conclusions: In a cohort from the largest academic health system in California, in adjusted models we didn't observe a statistically significant difference in the rate of eGFR loss in non-hospitalized COVID-19 patients compared to controls over an average follow up period of two years. This study has one of the longest follow up times of kidney function post SARS-CoV-2 infection.

Association Between Urine Sediment Examination and Adverse Outcomes in Hospitalized Patients with AKI and Severe COVID-19

Julio A. Vasquez Vasquez, Froylan David Martinez-Sanchez, Luis A. Bastida Castro, Alejandra Diaz-Jarquin, Laura Viviana Vargas-Sánchez, Fidel Ivan Flores Perez, Omhariany Medina Garza, Javier Andrés Meza Hernández, Victor Manuel P. Zarza, Rafael Moreno-Novales, Juan Carlos G. García, Mauricio A. Salinas-Ramirez, Joana B. Juarez, Erika K. Tenorio-Aguirre. *Hospital General Dr. Manuel Gea Gonzalez, Mexico City, Mexico.*

Background: COVID-19 and Acute kidney injury (AKI) are associated with increased mortality and worse kidney outcomes. Although several factors including age, sex, and comorbidities are associated with increased morbimortality, to our

knowledge, no study has dwelled into the evaluation of urine sediment and prognosis in patients who developed AKI during Covid-19.

Methods: Retrospective cohort study that included clinical and biochemical data of 288 hospitalized patients with COVID-19 who developed AKI at any stage. Univariate and Cox regression analyses were used to evaluate the role of urine sediment and progression in AKI with Covid-9. Mayor Adverse Kidney Events (MAKE) was a composite of AKI stage 3, mortality, and need for renal replacement therapy. The Perazella score was used to evaluate the number of cellular renal tubular epithelial cells (CRTEC) and granular casts.

Results: The mean age of the patients was 57 ± 14 years, 69% were women, the mean body mass index (BMI) was 27.9±5.6 kg/m2, and median time in hospital was 11 (6-19) days. Overall, 47.3% had diabetes and 33.8% hypertension. The rate of AKI 3, MAKE, and mortality was 32.3%, 46.3% and 32.6%, respectively. After adjusting for demographics and comorbidities the Cox model regression, a Perazella score 2 and 3 was associated with increased risk for AKI 3 (HR= 2.664 [1.174-6.645] and HR= 3.273 [1.172-9.139]; respectively), MAKE (HR= 3.162 [1.486-6.727] and HR= 4.644 [1.815-11.886]; respectively), and mortality (HR= 3.322 [1.375-8.251] and HR= 4.743 [1.594-14.112]; respectively).

Conclusions: The examination of the urine sediment could predict worse outcomes in patients with AKI and severe Covid-19.

FR-PO1125

The Association Between COVID-19 Medications and AKI: Analysis of the United States Food and Drug Administration (FDA) Adverse Event Reporting System (FAERS) and Bulk Kidney RNA-seq Data

Feng Cheng,[1] Robert Morris,[1] Rahinatu Ali,[1] Jie Zhang,[2] Jin Wei.[2] *[1]University of South Florida College of Pharmacy, Tampa, FL; [2]Boston University, Boston, MA.*

Background: The FDA has approved three medications: Tocilizumab, Remdesivir, and Baricitinib, and issued several existing emergency use authorizations (EUAs) medications such as Paxlovid, REGEN_COV antibody et al., for the treatment of COVID-19. However, it has been observed that these medications may pose a risk factor for acute kidney injury (AKI). This study aims to investigate the potential association between the usage of these medications and the occurrence of AKI, as well as to elucidate the molecular mechanism underlying AKI induced by COVID-19 medications.

Methods: The risk of AKI was compared among the COVID-19 patients receiving different medications. Pharmacovigilance data obtained from the FAERS was analyzed. Furthermore, we investigated whether the risk of AKI was influenced by factors such as sex, dosage, and potential drug-drug interactions among the medications used in COVID-19 patients. Additionally, we sought to identify genes and pathways associated with AKI that are regulated by COVID-19 medications, by comparing gene expression of kidneys from mice treated with COVID-19 medications to those from control mice. Whole kidney RNA-seq data was generated and analyzed.

Results: We found that COVID-19 patients treated with remdesivir demonstrated a significantly higher risk of AKI compared to patients treated with other medications. Specifically, patients aged 50-70 or over 70 years were twice as likely to report AKI, compared to the <50 age demographic. Male patients prescribed remdesivir had a two-fold higher likelihood of reporting AKI compared to females. Additionally, patients who took vancomycin alongside remdesivir exhibited a 3.87-fold increased likelihood of reporting AKI as an adverse event (P<0.0001) when compared to patients prescribed vancomycin or remdesivir alone. Furthermore, RNA-seq revealed that genes up-regulated by remdesivir included Edar, Per1, Gadd45g, Wnt7b, Wnt16, Agt, and Dusp15. The corresponding regulated pathways include Stress-activated MAPK cascade and JNK cascade.

Conclusions: COVID-19 patients treated with remdesivir exhibited a higher risk of reporting AKI as an adverse event than patients prescribed other approved treatments for COVID-19 infection. This increased occurrence of AKI may be attributed to the activation of MAPK/JNK signaling pathway.

FR-PO1126

Impact of AKI in Critical Patients Hospitalized with COVID-19: A Cohort Study in the Western Amazon

Cinthya O. Nascimento,[1] Isadora A. Praxedes,[1] Emanuelli M. Patricio,[1] Júlia M. Barros,[1] Iara D. Scharff,[1] Natalia F. Gomes,[1] André Oliveira,[1] Débora G. Morello,[1] Lucas V. Alves Pereira,[1] Vitor P. de Albuquerque,[1] Flavio D. De Santana,[1] Iane D. Scharff,[1] Thaís X. de Paula,[1] Isadora A. Negri,[1] Poliane Pierra M. Patricio,[1] Isabela D. Negri,[1] Vitor H. Reis,[2] Luan S. Luan.[1] *[1]Centro Universitario Mauricio de Nassau, Cacoal, Brazil; [2]Universidade Federal do Tocantins, Palmas, Brazil.*

Background: The coronavirus pandemic had a significant impact on areas of the Western Amazon. Intensive care units (COVID ICU) were developed specifically for infected patients in response to this demand. Considering the renal impairment caused by COVID-19, the objective of this study was to analyze the development of acute kidney injury (AKI) and its association with the outcome of critically ill patients.

Methods: A retrospective, multicentric cohort, carried out in two hospitals in a region of the Western Amazon from March 2020 to March 2022. Patients (aged ≥18 years) hospitalized with COVID-19, with a length of stay longer than 48 hours in a COVID ICU, and who did not have previous kidney disease. The exposure was the development of LRA (using the KDIGO classification to define it). The outcome analyzed was in-hospital death.

Results: Of the 385 patients evaluated, 75.1% had previous comorbidities, with a predominance of males (60%), a mean age of 59.3 (18–96) years, and a mean length of stay of 13.5 (2–75) days. Based on the total number of patients in the study, 54.5% of patients developed some degree of AKI (Stage 1: 39.5%, Stage 2: 14.2%, Stage 3: 7.6%, and Stage 3D: 38.7%). Compared with patients who did not have AKI, the number of deaths was higher in patients with AKI (61% vs. 17%; absolute risk difference was 44% [95% CI, 41–46]). The degree of acute kidney injury was directly proportional to the death rate (39.7% AKI 1, 60% AKI 2, 68.7% AKI 3, and 81.4% AKI 3D). Finally, taking those without AKI as the reference group, we observed higher risks of in-hospital death for patients with AKI 1-3D (HR 3.5 [95% CI, 2.6–4.1]).

Conclusions: The occurrence of AKI and the need for renal replacement therapy (AKI 3D) were common in critically ill patients with COVID-19. Advanced stages of AKI are associated with extremely high mortality in these patients. However, it was observed that the development of some degree of kidney injury is already associated with a significant risk of death.

FR-PO1127

Long-Term Outcomes After AKI in Hospitalized Patients with COVID-19

Joana Gameiro, Bernardo Marques da Silva, Claudia Costa, Carolina Branco, Filipe Marques, José Agapito Fonseca, Jose A. Lopes. *Centro Hospitalar Universitario Lisboa Norte EPE, Lisboa, Portugal.*

Background: Acute kidney injury (AKI) is frequent in hospitalized patients with COVID-19 and contributes to adverse short and long-term outcomes. We aimed to evaluate the association of AKI and long-term outcomes in a cohort of survivors of a hospitalization for COVID-19.

Methods: Single-centre and retrospective study of hospitalized patients admitted to a Dedicated Unit for COVID-19 at Centro Hospitalar Universitário Lisboa Norte, Portugal, between March 2020 and October 2020. AKI was defined and classified according to the Kidney Disease: Improving Global Outcomes (KDIGO) classification, using SCr criteria. The analysed outcomes were development of major adverse kidney events (MAKE), major adverse renal cardiovascular events (MARCE), and mortality over a two-year follow-up period. MAKE was defined as a composite of death from any cause, renal replacement therapy dependence or worsened kidney function (decrease in eGFR to <25% of baseline and/or eGFR<60 mL/min/1.73m2). MARCE was defined as major adverse kidney event (death, RRT dependence or worsened renal function) and/or major adverse cardiovascular event (myocardial infarction, stroke, and heart failure).

Results: From the included 409 patients, AKI occurred in 60.4% (n=247). Within two years after discharge, 31.8% (n=130) of patients had an eGFR<60mL/min/1.73m2 and/or a 25% decrease on eGFR and 1.7% (n=7) of patients required RRT, 5.6% (n=23) of patients had CV events and 27.9% (n=114) of patients died. The incidence of MAKE was 60.9% (n=249), and MARCE was 36.6% (n=155). On a multivariate analysis, older age (adjusted HR 1.02 (95% CI: 1.01-1.04), p=0.008), cardiovascular disease (adjusted HR 2.22 (95% CI: 1.24-3.95), p=0.007), chronic kidney disease (adjusted HR 5.15 (95% CI: 2.22-11.93), p<0.001), and AKI (adjusted HR 1.76 (95% CI: 1.12-2.78), p=0.015) were independent predictors of MAKE. Older age (adjusted HR 1.06 (95% CI: 1.04-1.08), p<0.001) and neoplasia (adjusted HR 4.88 (95% CI: 2.37-10.04), p<0.001) were independent predictors of mortality.

Conclusions: AKI was independently associated with the risk of long-term need for dialysis and/or renal function decline and/or mortality after hospital discharge for COVID-19. Given the long-term impact of AKI, early detection of high-risk patients is essential to improve the outcomes of COVID-19 patients.

FR-PO1128

Association of Body Mass Index with Multiple Organ Failure in Hospitalized Adults with COVID-19

Timothy H. Phillips,[1] Abdallah Mughrabi,[1] Levindo Jose Garcia Quarto,[1] Christopher El Mouhayyar,[1] Laith Hattar,[3] Hocine Tighiouart,[2] Andrew H. Moraco,[1] Claudia Nader,[1] Bertrand L. Jaber.[1] *[1]St. Elizabeth's Medical Center, Boston, MA; [2]Tufts University School of Medicine, Boston, MA; [3]University of Massachusetts Chan Medical School, Worcester, MA.*

Background: Patients with severe coronavirus disease 2019 (COVID-19) experience an excessive cytokine release syndrome, which promotes an increased risk of acute organ dysfunction and death. The aim of our study was to examine whether excessive adipose tissue, as measured by body mass index (BMI), is associated with higher systemic markers of inflammation and higher risk of severe acute organ failure or in-hospital death among hospitalized patients with COVID-19.

Methods: 1370 hospitalized adults (18 years or older) with COVID-19 during the first wave of the pandemic in Massachusetts (March 1, 2020, to July 31, 2020) met inclusion criteria. Our primary outcome was the composite of severe acute kidney injury (AKI), as defined by acute dialysis requirement, severe acute lung injury (ALI), as defined by use of high-flow nasal canula, non-invasive ventilation, or mechanical ventilation, or in-hospital death. Secondary endpoints of interest included the association of BMI with serum peak CRP level, a systemic marker of inflammation.

Results: After adjustment for age, gender, race, Charlson Comorbidity Index (CCI), baseline eGFR, and the NIH clinical spectrum of SARS-CoV-2 infection, the highest BMI stratum of > 40 kg/m^2 (compared to the BMI <25 kg/m^2 reference group) was associated with higher odds for the composite of severe AKI, severe ALI, or in-hospital death (adjusted odds ratio [OR_{adj}] 1.69; 95% CI 1.03, 2.78), and the composite of severe ALI or in-hospital death (OR_{adj} 1.69; 95% CI 1.03, 2.77). As a continuous variable, BMI (per 5-kg/m^2 increase) remained independently associated with these outcomes. Interestingly, this association was no longer significant after adjustment for peak CRP level.

Conclusions: Among hospitalized adult with COVID-19, higher BMI associates with higher risk of severe organ failure or death, which dissipates after adjustment for CRP level. This supports the hypothesis that inflammation is a downstream mediator of the adipose tissue on acute organ dysfunction, possibly through dysregulated immune responses. More research is needed to understand this association in COVID-19.

FR-PO1129

Prolonged Myoglobinuric AKI in Young Female in the Era of the COVID-19 Pandemic

Nora Hajnoczky,[1] Prashamsa Shenoy,[2] Rakesh Gulati.[2] *[1]Albert Einstein Healthcare Network, Philadelphia, PA; [2]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA.*

Introduction: We present a 26-year-old female with no pertinent medical history who presented to the nephrologist with persistently elevated creatinine (Cr) and urinalysis significant for microscopic hematuria without red blood cells.

Case Description: The patient reported being ill 2 months prior to presentation with symptoms of fatigue, myalgias, pharyngitis and general malaise. During her illness, she ran a marathon, treated her myalgias with NSAIDs and discontinued spironolactone for acne vulgaris. On assessment, she described ongoing symptoms of fatigue, myalgias and decreased appetite. Lab work indicated Cr of 2.15mg/dL (baseline <1 mg/dL), mild metabolic acidosis, urinalysis and urine chemistry indicated +1 myoglobulin (88.26 ng/mL, normal <21 ng/mL), and creatine phosphokinase 44 IU/L. Further studies revealed normal ANA, complements, ANCA, myositis panel and other autoimmune workup. She was diagnosed with myoglobinuric acute kidney injury (AKI) in the setting of recent viral illness, remote NSAID and spironolactone use, however the extent and persistence of her AKI was not completely understood. COVID antibody screen was positive for antinucleocapsid antibody and antispike glycoprotein antibody titer >250 units/mL. She was closely monitored with biweekly labs, encouraged to drink electrolyte rich fluids, and treated with oral sodium bicarbonate. Her Cr peaked at 2.3 mg/dL and urine myoglobin at 278.9 ng/mL, however both normalized by the fourth month. We concluded the patient likely had COVID-19 infection in November and was experiencing "long COVID" renal disease.

Discussion: COVID-19 infection can directly injure kidneys through endothelial destruction, complement activation, coagulopathy and indirectly through multiorgan damage. Large-scale studies exploring COVID-19 and AKI focus on severely ill, unvaccinated, older patients, with multiple comorbidities. There are also a handful of small case reports that have examined COVID-19 induced rhabdomyolysis requiring hemodialysis. However, there remains limited understanding of why healthy, vaccinated, young patients may develop persistent AKI and what this means for their future kidney function, even in cases where creatinine levels return to normal. This case demonstrates the importance of considering COVID-19 induced AKI, even in patients who are not at high risk of developing severe infection related illness.

FR-PO1130

Predictors of Mortality in COVID-19 Patients Diagnosed with AKI: A Case-Control Study

Gustavo Aroca Martinez,[1] Daniela Russi Pulgar,[2] Maria D. Velez,[1] Carlos G. Musso,[1] Alex Dominguez-Vargas,[2] Edgar Navarro-Lechuga.[2] *[1]Universidad Simon Bolivar Facultad de Ciencias de la Salud, Barranquilla, Colombia; [2]Universidad del Norte Division Ciencias de la Salud, Barranquilla, Colombia.*

Background: COVID-19 caused by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), is a multi-systemic infection with various manifestations, including acute kidney injury (AKI). This study aimed to identify factors associated with mortality in COVID-19 patients diagnosed with AKI during hospitalization at Clínica de la Costa in Barranquilla, Colombia from 2020 to 2022.

Methods: A case-control study. COVID-19 patients with acute kidney injury (AKI) were enrolled. Cases included fatal outcomes, while controls survived. AKI was defined using The Kidney Disease: Improving Global Outcomes criteria. A range of independent variables, including sociodemographic characteristics, comorbidities, initial laboratory parameters, and clinical features, were examined. Inferential analysis was performed using Chi-square, t-test, and Mann-Whitney U tests ($p < 0.05$). Associations were further evaluated using logistic regression, and odds ratios (ORs) with 95% confidence intervals were calculated.

Results: The study sample included 159 cases (deceased) and 74 controls (survivors). The average age in the deceased group was 66 ± 14 years, significantly higher than the average age of 59 ± 17 years in the survivor group (p-value = 0.005). No statistically significant differences were observed in terms of gender (p-value = 0.278) and municipality of residence (p-value = 0.078) between the study groups. The final adjusted model revealed several significant risk factors for mortality, including admission to the intensive care unit (OR = 4.8; 95% CI 1.5-15.6), invasive mechanical ventilation (OR = 51.1; 95% CI 10.9-240.7), renal replacement therapy (OR = 11.7; 95% CI 1.1-123.0), and Acute Kidney Injury Network (AKIN) II classification (OR = 8.8; 95% CI 2.5-30.5).

Conclusions: It is crucial for healthcare providers to maintain heightened surveillance in Covid-19 patients with AKI who require ICU admission, IMV, and RRT, as these factors are associated with higher mortality rates.

Proteinuria and Clinical Outcomes in Hospitalized COVID-19 Patients: Bolivia Experience

Rolando Claure-Del Granado,[1,2] Alem J. Garcia-Aguayo,[1,2] Jason W. Yang,[3] Jingyao Zhang,[3] Pei Lun Lee,[3] Rakesh Malhotra.[3] *[1]Division of Nephrology Hospital Obrero No 2 - CNS, Cochabamba, Bolivia, Plurinational State of; [2]Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of; [3]University of California San Diego School of Medicine, La Jolla, CA.*

Background: Kidney involvement is frequent among patients with coronavirus disease 2019 (COVID-19), and occurrence of AKI is associated with higher mortality in this population. The objective of this study was to describe incidence of proteinuria and its influence on AKI in COVID-19 patients.

Methods: We conducted a single-center prospective study among patients who were admitted with COVID-19 in a tertiary care center in Bolivia. Urine dipstick was performed, and spot urine protein/creatinine ratio was quantified within 24 hours of admission. AKI at hospital admission was excluded from analysis. Subsequent development of AKI was diagnosed using KDIGO criteria over 7 days follow-up. Secondary outcome was initiation of renal replacement therapy and death.

Results: Among 57 patients, de novo proteinuria at admission was present in 44 patients (77.1%). Mean urine protein/creatinine ratio was 896±1420 mg/g; with 4 patients (9%) presenting nephrotic range proteinuria. Patients with de novo proteinuria had higher leukocyte count (6395±1580/mm3 vs. 5212±870/mm3; p = 0.0127). De novo proteinuria was not different in patients with diabetes, hypertension or CKD. Of patients with de novo proteinuria, 34% (15/44) patients developed subsequent AKI. Majority of AKI cases (80%) were mild (stage 1 KDIGO). Urine protein-creatinine ratio ≥150 mg/g was associated with AKI (odds ratio (OR), 17.4; 95% CI, 0.97 to 31; p = 0.05). None of patients required kidney replacement therapy. Total proteinuria was associated with mortality in unadjusted and adjusted models.

Conclusions: We observed higher prevalence of proteinuria among patients admitted for COVID-19. Patient will proteinuria also had a higher risk of developing AKI and a poor prognosis for survival. Future studies should focus on proteinuria for risk stratification and prognosis.

FR-PO1132

Liver and Kidney Cross-Talk in Korean COVID-19 Patients

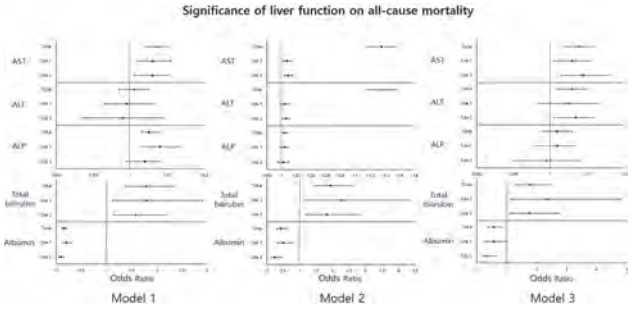
Yae-hyun Kim,[1] Yaerim Kim,[2] Soie Kwon,[3] Jeonghwan Lee,[4] Jung Pyo Lee.[5,4] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Keimyung University School of Medicine, Daegu, Republic of Korea; [3]Chung Ang University Hospital, Seoul, Republic of Korea; [4]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Previous studies suggested that liver function tests (LFTs) could serve as a prognostic tool in assessing the severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) infections. However there have been no published large-scale studies conducted for Koreans with similar topics.

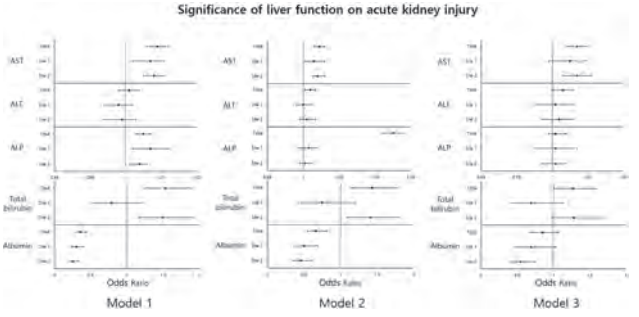
Methods: This research was conducted using the data from two hospitals in Korea. Data from 4,367 adults out of 4,423 patients without missing values, end-stage renal disease, a history of kidney transplant, or use of immunosuppressants were analyzed. We used LFTs measured on the day of hospitalization for SARS-CoV-2 infection. The main outcomes of interest were two things: all-cause mortality and the incidence of acute kidney injury (AKI). Statistical analysis was performed with logistic regression.

Results: Analysis of data for 4,367 people (mean age 54.5±18.3 years, 54.3% female) suggests that high bilirubin is associated with high mortality (adjusted hazard ratio [aHR], 1.794; 95% confidence interval [CI], 1.292 to 2.492; P<0.001) and risk of AKI (aHR, 1.263; 95% CI, 1.005 to 1.588; P=0.045). Also low albumin level is associated with high mortality (aHR, 0.574; 95% CI, 0.378 to 0.873; P<0.001). However no significant impact of alanine transferase and alkaline phosphatase on mortality and the incidence of AKI is identified.

Conclusions: Abnormal LFTs, especially in aspartate transaminase, total bilirubin and albumin level, is relevant to higher mortality and risk of AKI in Koreans with COVID-19. Therefore LFTs should be performed early in hospitalization as a screening tool for risk stratification in Korean COVID-19 patients.



Significance of liver function on all-cause mortality



Significance of liver function on the incidence of AKI

FR-PO1133

Long-Term Renal Outcome and Mortality in Hospitalized Patients with COVID-19 Infection and AKI at UCLA

Niloofar Nobakht, Charley Q. Jang, Mohammad Kamgar. *University of California Los Angeles, Los Angeles, CA.*

Background: Acute kidney injury (AKI) is a common complication in patients with COVID-19 infection and has been associated with poor outcomes. At the ASN 2022 Kidney Week, we presented data from RECOVID study evaluating the need for renal replacement therapy (RRT) and early mortality among patients with COVID-19 infection and AKI in both vaccinated and unvaccinated populations. Here we present updated long term mortality follow-up data from RECOVID cohort.

Methods: In this retrospective, observational cohort study, we explored long term mortality data for the RECOVID cohort, which evaluated patients admitted for COVID-19 infection who developed an AKI at UCLA from March 2020. These patients were followed until February 2023.

Results: Among the 3527 hospitalized patients with COVID-19, 878 patients met criteria for inclusion in the study. Of the 878 patients with AKI 46.8% did not receive the COVID-19 vaccine and 53.2% were vaccinated. When evaluating long term follow-up among AKI patients, vaccinated patients continued to have significantly less mortality with a mean survival of 715 days (95% CI, 667-762) as compared to unvaccinated patients with a mean survival of 316 days (95% CI, 262-369). Association of unvaccinated status with shorter overall survival remained significant after multivariate analysis (HR, 5.11 [3.87- 6.76]; $P < .001$).

Conclusions: Vaccinated patients with COVID-19 infection and AKI had improved long-term survival and were less likely to be dialysis-dependent.

Characteristic/Outcome	Vaccinated (n=467)	Unvaccinated (n=411)	*p*-value

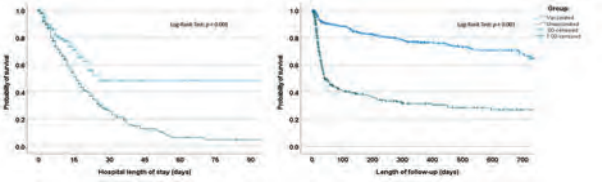
Table 1. Patient Characteristics and Outcomes



FR-PO1134

Patient Outcomes in De Novo Kidney Replacement Therapy Requiring AKI Following COVID-19 Infection

Sanjay Chaudhary,[1] Manoj Ghimire,[2] Gunjan Mundhra,[2] Pramod K. Guru,[1] LaTonya J. Hickson,[2] Kianoush Kashani.[1] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Mayo Clinic Florida, Jacksonville, FL.*

Background: Among patients infected with COVID-19, AKI affects >20% of hospitalized patients and >50% of patients admitted to the ICU. While kidney function recovery in COVID-19 patients at discharge and for a short duration of follow up after discharge has been studied, little is known about longer-term outcomes and kidney function recovery in patients who go on to require dialysis during the acute hospitalization for COVID. The aim of the study was to look at the factors associated with dialysis requiring AKI, the impact on survival, the factors associated with continued need for dialysis in patients who start KRT during hospitalization for COVID-19 pneumonia and rate of kidney function recovery following the initiation of KRT.

Methods: A retrospective observational cohort study was conducted at the Mayo Clinic Hospital system in the United States. The study included hospitalized patients aged 18 years or older who were admitted between January 1, 2020, and December 31, 2022, and had a diagnosis of both SARS-CoV-2 infection and new onset Acute Kidney Injury (AKI) requiring Kidney Replacement Therapy (KRT). The primary outcome was mortality and the secondary outcomes included incidence of the composite outcome of death, requirement for KRT and kidney function decline of ≥25% from baseline at 60 days and 365 days (MAKE60 and MAKE365).

Results: A total of 145 patients required Kidney Replacement Therapy (KRT). Among them, 64 patients (44.1%) survived to discharge and 21 patients (14.5%) remained dependent on dialysis at discharge. At 60 days, major adverse kidney event (MAKE60) was 17.2%. Among the patients discharged on dialysis, the MAKE 365 incidence was 52.4%.

Conclusions: COVID-19-associated AKI was associated with high mortality, was associated with worse long-term post-AKI kidney function recovery and MAKE outcomes.

Association of Renal Function with Mortality Among Hospitalized Patients Treated with Remdesivir for COVID-19

Maria Lourdes Gonzalez Suarez, Kristin C. Mara, Christina Rivera, Supavit Chesdachai, Evan Draper, Raymund Razonable. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Renal dysfunction is associated with poor outcomes in patients with coronavirus disease 2019 (COVID-19). In an effort to improve outcomes, intravenous remdesivir has been broadly used off label for the treatment of COVID-19 in patients with low estimated glomerular filtration rate (eGFR). Our study assessed the outcomes of patients with low eGFR after treatment with remdesivir for COVID-19.

Methods: We conducted an observational, retrospective, cohort study of adults hospitalized with COVID-19 treated with at least one dose of remdesivir between 11/6/2020, and 11/5/2021. Electronic medical records were reviewed to obtain patient characteristics, laboratory data, and outcomes. Primary endpoint was all-cause mortality by day 28. Multivariable logistic regression was used to evaluate association among groups.

Results: We studied 3024 patients hospitalized with COVID-19 and treated with remdesivir. Median age was 67 [IQR 55, 77] years; 42.7% were women, 88.6% were white. Median eGFR was 76.6 mL/min/1.73 m^2 [IQR 52.5, 95.2]; 67.2% of patients had eGFR ≥ 60, while 9% had eGFR <30. All-cause mortality by day 28 was 8.7%. All-cause mortality rates were significantly higher among patients with impaired renal function (Odds Ratio [OR] 1.94 for patients with eGFR 30-59; OR 1.94 for eGFR 15-29; OR 3.62 for eGFR <15 and OR 9.08 for patients on dialysis) compared to patients with eGFR ≥60 (all p<0.01) (Figure 1).

Conclusions: Lower eGFR is an independent risk factor for mortality in COVID-19 despite treatment with remdesivir. These observations suggest that, even with the availability of effective antiviral treatment, prevention of COVID-19 remains a major goal especially among those with impaired renal function.

Decision Tree Analysis to Study the Short- and Long-Term Renal Outcomes in Patients Hospitalized During the First Year of the COVID-19 Pandemic

Weihao Wang, Janos G. Hajagos, Laura J. Fochtmann, Wei Zhu, Farrukh M. Koraishy. *Stony Brook University, Stony Brook, NY.*

Background: COVID-19 has been associated with AKI in hospitalized patients and GFR decline after discharge. However, analysis of risk factors associated with renal outcomes has been limited to traditional machine learning models. Additionally, length of hospitalization (LOH) or days on the ventilator (DOV) have not been typically used for risk prediction.

Methods: In this retrospective single center study, we applied a Classification and Regression Trees algorithm (CART decision trees) to study renal outcomes in patients hospitalized in the United States during the COVID-19 pandemic in 2020 (pre-vaccination era). Outcomes: Moderate/severe AKI (Stage 2 & 3) in the hospital and eGFR decline during a 24-month follow-up (until February 2023. To address the effect of confounding demographics in ICU vs. non-ICU and COVID-19 positive vs. negative patients, propensity score matching (PSM) was applied. Influential variables were selected based on feature importance in Random Forest plots.

Results: In our initial cohort of adult 6.933 patients (without baseline end-stage kidney disease), 10.4 % (719) were diagnosed with AKI-2/3. CART decision tree analysis on the primary cohort and the ICU and COVID-19 status PSM cohorts showed DOV, sepsis, age and vasopressor use as key factors for AKI-2/3 risk categorization. In the follow-up study hospital survivors (n = 1,747), those originally admitted to the ICU and those with COVID-19 had a greater mean GFR decline compared to control groups. CART analysis (Figure 1) showed LOH, age, AKI-2/3, body mass index, vasopressor use, and baseline CKD as the main features that risk categorized patients for rate of GFR decline.

Conclusions: To our knowledge, this is one of the first studies to report renal outcomes in patients with and without COVID-19 using CART decision tree analysis. Besides traditional risk factors, days in the hospital and on the ventilator were noted as key features that stratified patients' risk for renal outcomes.

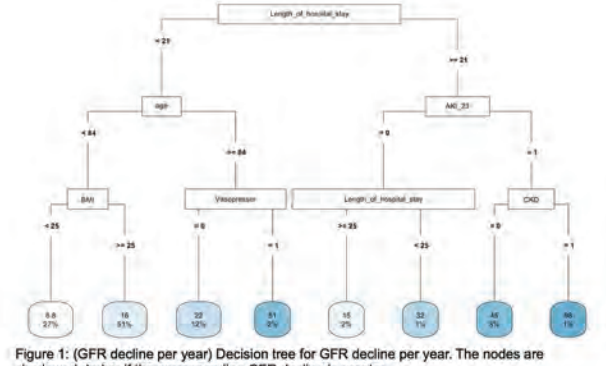

Figure 1: (GFR decline per year) Decision tree for GFR decline per year. The nodes are shadowed darker if the corresponding GFR decline is greater.

FR-PO1137

Long-Term Kidney Function of Hospitalized COVID-19 Survivors Who Did or Did Not Develop AKI

Nancy Romero, César A. Becerra-Gutiérrez, Mariana C. Villasana B, Fabiola Martin del Campo, Enrique Rojas-Campos, Alfonso M. Cueto-Manzano. UIMER. *Hospital de Especialidades del Centro Medico Nacional de Occidente IMSS, Guadalajara, Mexico.*

Background: COVID-19 increases acute kidney injury (AKI) risk; however, it is unclear its long-term effect in high CKD prevalence settings. Aim: To assess evolution, at least 6 months after discharge, of kidney function in hospitalized COVID-19 survivors who did or did not develop AKI.

Methods: Prospective cohort of confirmed COVID-19 patients (03/20-10/21) From inpatient registry, survivors were contacted; those who agreed to participate had a clinical interview and eGFR and albumin/creatinine ratio evaluation.

Results: Of 585 COVID-19 patients discharged alive, 121 (21%) developed AKI; 166 without AKI and 34 with AKI were included and evaluations performed at 20.0±0.3 months. Comparisons between groups are shown in Table 1 and Table 2. Overall mean time survival was 26.1±0.5 months; comparison according to AKI development is shown in Figure.

Conclusions: A fifth of surviving patients hospitalized for COVID-19 developed AKI, 73% of them recovered kidney function upon discharge. Patients with AKI had lower kidney function throughout the study and higher ACR at end of follow-up compared to those without AKI; however, the latter displayed slight eGFR decrease at the end of the study compared to baseline. Survival was significantly lower in patients with AKI and seemed to be worse in those with higher stages.

Identification of COVID-19 Disease and Impact on Kidney Function Using Urine Raman Spectroscopy and Chemometrics

Ryan S. Senger,[1] Mariana Gomez de la Espriella,[2] Jasmine Y. Jackson-Akers,[2] Amr Sayed Issa,[1] John L. Robertson,[1] Tasaduq Fazili.[2] *[1]Virginia Polytechnic Institute and State University College of Engineering, Blacksburg, VA; [2]Carilion Clinic, Roanoke, VA.*

Background: COVID19 can have a deleterious effect on renal function. Timely prediction of renal dysfunction is not achievable with available laboratory armamentarium, and scores currently used for severity of illness are highly provider dependent and subjective in nature.

Methods: We developed a Raman spectroscopic technology (Rametrix® molecular urinalysis) to detect COVID19 systemic/renal effects by analysis of patient urine. It is based on chemometric analysis of the Raman spectrum of urine and detects metabolomic differences. The technology is not designed to detect virus/viral components. We hypothesized that COVID19 disease would alter urine composition and that Rametrix® analysis could detect renal dysfunction via urine molecular 'fingerprinting'. We applied Rametrix® analysis on 85 urine specimens from 64 patients hospitalized for COVID19 disease (Omicron variant prevalent). Patients were 30-92 years of age (median age 67), and ca. 50%/50% M/F. Collections were done at admission (n=66), discharge (n=7), and follow-up (n=12). Medical record and laboratory data were correlated with Rametrix® results; 66 patients had GFR values at both admission and discharge. Disease severity scores were collected repeatedly during hospitalization. Using chemometric analysis, we compared hospitalized patient COVID19 urine spectra with urine spectra from healthy controls (pre-COVID19), patients with CKD (pre-COVID), asymptomatic-mildly symptomatic outpatients (2020/mid-2021 variants), bladder cancer patients (pre-COVID19) and Lyme disease patients (pre-COVID19).

Results: Rametrix® molecular urinalysis distinguished COVID19-associated changes in urine composition with predictive metrics (accuracy, sensitivity, specificity, PPV, and NPV) ranging between 93-96.5%. A correlation between changes in urine Raman spectra and physician assessment of disease severity was also found through computational analysis. Spectra from patient urine collected at admission and stratified based on eGFR, demonstrated molecular 'fingerprints' predictive of future renal dysfunction in 91.7% of high-risk patients.

Conclusions: Raman molecular urinalysis can be a useful tool in detecting and predicting future renal dysfunction in patients hospitalized with COVID19 disease.

Postdischarge All-Cause Mortality in COVID-19-Recovered Patients: The Impact of CKD

Guilherme Schittine Bezerra Lomba, Pedro Henrique A. da Silva, Natalia F. Rosário, Thalia Medeiros, Lilian S. Alves, Jorge Reis Almeida, Jocemir R. Lugon. *Universidade Federal Fluminense, Niteroi, Brazil.*

Background: In Brazil, the COVID-19 burden was substantial, and risk factors associated with higher in-hospital mortality rates have been extensively studied. However, information on short-term all-cause mortality and factors associated with death in patients who survived the hospitalization period of acute SARS-CoV-2 infection is less abundant. We analyzed the 6-mo post-hospitalization mortality rate and possible risk factors of COVID-19 patients admitted from Mar/20 to Dec/20 in a single center in Brazil.

Methods: Retrospective cohort study focused on a 6-mo follow-up. Exclusion criteria were: death during hospitalization, transference to another hospital, and age under 18. We collected data from the charts of all hospitalized patients from Mar/20 to Dec/20 with positive RT-PCR test for SARS-CoV-2, a time when vaccination against the infection was not available and no variant other than the wild one had been identified in Brazil. The main outcome was death after hospitalization. Comorbidities and demographics were evaluated as risk factors.

Results: We studied 106 patients. The crude post-hospitalization death rate was 16.0%. The first 30 days of follow-up had the highest mortality rate. In a Cox regression model for post-hospitalization mortality, previous CKD (HR, 4.06, 95%CI 1.46 – 11.30) and longer hospital length of stay (HR 1.01, 95%CI 1.00 - 1.02) were the only factors statistically associated with death.

Conclusions: Substantial 6-mo all-cause mortality was observed. Within the 6-mo follow-up, a higher risk of death was observed for patients who had prior CKD and longer hospital length of stay. These findings highlight the importance of more intensive medical surveillance during this period.

Microphysiological Model of Human Kidney Collecting Duct

Soongweon Hong,[1,3] Minsun Song,[1,3] Kyle McCracken,[2] Joseph V. Bonventre.[1,3] *[1]Brigham and Women's Hospital, Boston, MA; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]Harvard Medical School, Boston, MA.*

Background: Understanding kidney physiology is indispensable for maintaining human health, developing effective treatment strategies, implementing therapeutic interventions, and advancing personalized medicine approaches. However, much of our current knowledge of kidney physiology relies on non-human models, which do not accurately reflect human cell and system responses. To overcome this challenge, human stem cell-derived cells can be employed within a physiological microenvironment to achieve advanced physiological functions.

Methods: We developed a physiologically relevant human kidney collecting (CD) duct model using human stem cell-derived CD cells on the Epithelial Microphysiological Analysis Platform (Epi-MAP). scRNA-Seq analysis identifies the ureteric bud organoids as highly enriched in inner medullary CD principal epithelial cells We designed physiological media with compositions resembling intraluminal and basolateral conditions *in vivo* and used physiologically relevant tubular flow rates. Moreover, our Epi-MAP is integrated with proximal surface electrodes for in-situ real-time monitoring of physiological dynamics, enabling simultaneous tracking of optical microscopy and electrophysiological records.

Results: Compared to stationary cultures without flow, our Epi-MAP culture conditions significantly enhanced various aspects of the CD physiology. This includes improved epithelial morphology and enhanced mRNA expression of genes related to ion transport, tight junctions, water and urea transport, and receptor signaling. Our electrophysiological monitoring shows that CD-specific functions of vectorial transport and epithelial tight junction are further advanced in the physiological Epi-MAP culture. We also observed the conversion of CD principal cells to intercalated cells, resulting in a more physiological model. With our high-precision, continuous electrophysiological characterization, we also comprehensively studied the CD responses to vasopressin and aldosterone signaling, particularly on ion and water flux and tight junction integrity.

Conclusions: This human cell-derived, physiologically relevant model represents a powerful model *in vitro* for understanding human kidney biology, increasing drug modeling precision, understanding disease processes, and potentially serving to help create an important functional component of a biohybrid artificial kidney.

A High-Throughput Kidney-on-a-Chip Platform for CKD Therapy Discovery

Morgan Chandler,[1] Alaa Alsebahi,[1] Qi Zhang,[2] Stefano Da Sacco,[2] Laura Perin,[2] Kristin Bircsak.[1] *[1]MIMETAS US, Gaithersburg, MD; [2]Children's Hospital Los Angeles, Los Angeles, CA.*

Background: Glomerular and/or proximal tubule (PT) dysfunction often culminates in the onset of chronic kidney disease (CKD). Existing therapies address symptoms rather than the underlying causes, resulting in significant side effects. More targeted therapies with increased specificity to the glomerulus or PT are needed, but their development is greatly hindered by the lack of relevant human model systems. To address this, we developed a three-dimensional *in vitro* kidney-on-a-chip mimicking glomerular and PT function in a high-throughput platform: the NephroPlate.

Methods: The NephroPlate was established in MIMETAS' OrganoPlate, a 40-assay format allowing culture with inner tissue flow in a standard microtiter plate. The glomerular unit was prepared using primary human podocytes and glomerular endothelial cells. The PT unit was prepared using renal PT epithelial cells (RPTEC) and human umbilical vein endothelial cells (HUVEC). Barriers were assessed using transepithelial electric resistance via Organo(TEER). To assess glomerular filtration (GF), FITC-albumin was added to cultures mimicking either healthy or Membranous Nephropathy (MN) conditions. Expression was confirmed by immunostaining and media were collected for evaluation of secreted factors.

Results: Cultures within the NephroPlate maintained cell phenotypes in a three-dimensional format, facilitating the de novo production of glomerular basement membrane (GBM) components and mimicking GF. While all donor-derived cultures recapitulated healthy functions, treatment with serum from patients with MN resulted in a donor-dependent loss of GF and TEER. In CKD models, treatment with α-melanocyte-stimulating hormone rescued the MN serum-mediated loss of GF as demonstrated by albumin retention, while TEER did not recover within the experimental timeframe. Upon transfer of CKD glomerular filtrate to the PT, elevated KIM-1, a marker of PT injury, was observed.

Conclusions: The NephroPlate captures many aspects of the kidney microenvironment, including complex composition as well as GF function and its dynamic response to mimic CKD. The high-throughput capabilities of our system allow for up to 40 conditions to be assessed simultaneously, enhancing our ability to screen existing and novel drugs as well as identifying better, more targeted therapies for CKD.

Tubuloids on Primary Human Renal Tubular Epithelial Cells (hRTECs) Recapitulates Cisplatin-Induced Kidney Injury

Yuki Nakao, Yutaro Mori, Makiko Mori, Shintaro Mandai, Tamami Fujiki, Fumiaki Ando, Koichiro Susa, Takayasu Mori, Eisei Sohara, Shinichi Uchida. *Department of Nephrology, Tokyo Medical and Dental University, Tokyo, Japan.*

Background: Kidney organoids derived from human pluripotent stem cells has been an attracting pathophysiological model recapitulating a response of human kidney to drugs in recent years. Here, we have developed an alternative way to make more homogeneous epithelial-like structures called tubuloids based on primary human renal tubular epithelial cells (hRTECs) and tested their efficacy by administering cisplatin.

Methods: hRTECs were obtained from the non-tumor kidney tissue removed from patients with renal or ureteric malignancies. Renal cortex was diced and digested with collagenase. Tubules were seeded on plates with serum-free media containing epidermal growth factor. After passage, cells were cultured on ultra-low attachment plates for several days and transferred into media containing matrigel, epithelial growth factor, hepatocyte growth factor, fibroblast growth factor-2 and 5% fetal bovine serum. After tubuloids were completed, cisplatin was administered at a concentration of 0.2 – 20.0 μg/ml.

Results: Tubuloids expressed LTL and Megalin, indicating that they were highly differentiated structures composed of proximal tubular epithelial cells. Treatment of tubuloids with cisplatin increased γH2AX, a marker for DNA damage, in a dose-dependent manner. KIM-1, a marker of kidney injury, and cleaved caspase-3, a marker for apoptotic signals were expressed as well. Vimentin, an intermediate filament, was also upregulated by cisplatin treatment, suggesting that tubular epithelial cells were in the process of epithelial-mesenchymal transition. Enhancement of the NF-κB and IL-1β was also observed. These findings may recapitulate the events of post-acute kidney injury, which, after an acute phase response, acquires senescence-associated secretory phenotype (SASP) and induces inflammation and fibrosis.

Conclusions: We succeeded in establishing a model of cisplatin-induced kidney injury based on tubuloids using hRTECs. Tubuloids can be utilized to simulate the response of epithelial cells to toxins and therapeutic agents. This alternative way is potentially an excellent tool not only as cisplatin-induced kidney injury, but also as a pathological model for various renal diseases including chronic kidney disease.

In the Same Vein: Developing a Novel In Vitro Flow Model for Endothelium Using 3D-Printed, Patient-Specific Arteriovenous Fistulas

Nasir A. Shah,[1,4] Zoltan Endre,[1,4] Tracie Barber,[2] Blake Cochran,[3] Jonathan H. Erlich.[1,4] *[1]University of New South Wales School of Clinical Medicine, Sydney, NSW, Australia; [2]University of New South Wales School of Mechanical and Manufacturing Engineering, Sydney, NSW, Australia; [3]University of New South Wales School of Biomedical Sciences, Sydney, NSW, Australia; [4]Prince of Wales Hospital and Community Health Services, Randwick, NSW, Australia.*

Background: Endothelial cell dysfunction is a feature of several medical conditions including chronic kidney disease (CKD). The global prevalence of advanced CKD (Stage 3-5) is approximately 8%, affecting an estimated 850 million people worldwide. For patients with end stage kidney disease treated with hemodialysis, easy vascular access is best achieved using a surgically-created arteriovenous fistula (AVF). Why some AVFs fail to mature while others develop high blood flow is unclear. Standard cell culture provides valuable insight into the role of endothelial cells in this process, but the flat surface neglects the complex physiology of disturbed blood flow through intricate vessel geometries. The use of animal models is limited by the ethical implications of the required interventions, the necessary surgical skill, an inability to simulate relevant comorbidities, differences in vessel size, breed genetic diversity, and limited commercially available reagents. The aim of this study was to use 3D-printing to create patient-specific models of arteriovenous fistulas for use in vascular research.

Methods: Patient AVFs were imaged using a modified ultrasound device. Specialised segmentation software generated AVF geometries which were 3D-printed using a water-soluble filament. Prints were cast in silicone and dissolved away leaving an AVF-shaped cavity. Human dermal microvascular endothelial cells (HMEC-1) were cultured on the internal surface of these models. Closed circuit hemodialysis tubing was then used to expose the endothelial cells to varying magnitudes of continuous flow.

Results: Fabrication of patient-specific models was accurate and reproducible. Immunofluorescence with DAPI and Phalloidin confirmed an HMEC-1 monolayer on the luminal surface. The endothelial cell monolayer was maintained after exposure to continuous flow over a 24-hour period. HMEC-1 cells exposed to flow polarized in the direction of flow as judged by alignment of the actin cytoskeleton.

Conclusions: Our 3D in vitro model overcomes limitations of current cell culture techniques whilst maintaining the 3D geometry only seen in humans and animal models. This will allow rapid investigation of endothelial cell signalling in true AVF geometries.

Using Organ-on-a-Chip Co-Culture Technology to Explore the Pathophysiology of Tubulopathies: A Paradigm Shift in Kidney Disease Research

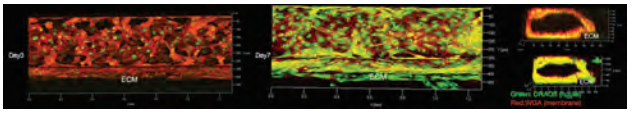
Chutong Zhong, Alessandra Grillo, Keith Siew, Stephen B. Walsh. London Tubular Centre. *University College London, London, United Kingdom.*

Background: Tubulopathies are a group of renal disorders that significantly impact patient morbidity and mortality, with limited current treatment options. The complex pathophysiology of these diseases hampers our understanding, resulting in a pressing need for advanced, physiologically relevant models. This research harnesses Organ-On-a-Chip (OOaC) technology to simulate human tubular physiology, thus elucidating the pathogenesis of tubulopathies and potentially facilitating development of novel therapeutic strategies.

Methods: Urine-derived renal tubular epithelial cells (uRTEC) and blood outgrowth endothelial cells (BOEC) were isolated from urine and blood samples collected from healthy volunteers and patients from tubular clinic by methods previously described (Ormiston et al., 2015; Ikeda et al., 2020). uRTEC and BOEC cells were applied adjacently in a three-lane microfluidic chip platform OrganoPlate following manufacture's protocol with modifications on the constitution of the extracellular matrix gel.

Results: Patient-derived renal tubules and blood vessel endothelium formed in the OrganoPlate channel on an average of 7-10 days of culture. Barrier integrity assay in the OrganoPlate using fluorescent probes confirmed tight junctions between cells. qPCR of the cell lysate showed these tubules expressed the distal convoluted tubule specific marker NCC (*SLC12A3*).

Conclusions: These preliminary data demonstrate that patient-derived uRTEC and BOEC were able to form tubule/blood vessel-like structures in the OrganoPlate. Given these samples are primary cells from patients, we propose this OOaC model will dynamically reflect *in vivo* human renal physiology with tubule-capillary interaction. We highlight the potential of OOaC culture systems combined with patient-derived cells to uncover tubulopathy. Furthermore, this innovative methodology can be employed to screen a panel of drugs, revealing varying drug efficacies and toxicity profiles individually with continuous monitoring of disease progression, ultimately bringing personalised medicine to tubular diseases.



The 3D confocal imaging of the immortalised uRTEC cells in the OOaC on Day 3 and Day 7, showing a gradual completion of the tubule in the plate.

SA-PO006

Proteomic Profiling of a Novel Immortalised Human Distal Convoluted Tubule Cell Line

Chutong Zhong, Keith Siew, Stephen B. Walsh. London Tubular Centre. *University College London, London, United Kingdom.*

Background: Tubulopathies are renal disorders with complex and inadequately understood pathophysiology, creating an urgent need for improved *in vitro* models to facilitate research. The development of a novel immortalised human distal convoluted tubule cell (hDCT) line represents a breakthrough in this field, offering a promising model for investigating the pathogenesis of tubular diseases. This research focuses on the proteomic characterisation of this cell line, a critical step towards understanding its utility for research into distal tubulopathies.

Methods: Four immortalised hDCT cell lines, primarily isolated from healthy volunteer's urine, were gifted from Dr Kusaba and were cultured as previously described (Ikeda et al., 2020). Cells were treated in 8M urea and 0.1% SDS in the presence of phosphatase and protease inhibitors for protein extraction and cell lysates were analysed through Liquid Chromatography and tandem Mass Spectrometry (LCMS). Western blot analysis was performed for DCT-specific marker NCC (*SLC12A3*).

Results: WNK1, SPAK, CAB39, CUL3, OxSR1 and PMCA1 (*AT2B1*) have been identified by LCMS from four hDCT cell lines at a high level, of which hDCT3 has an additionally abundant detection for WNK4 and KCC4 (*SLC12A7*). NCC was detected from all four hDCT cell lysates in the western blot.

Conclusions: The proteomic analysis of the novel immortalised hDCT cell line has unveiled the presence of key proteins of the DCT region. Notably, the identification of regulator proteins such as WNK1 and SPAK and ion channel corroborates the promising potential of this cell line as a representative model for studying DCT physiology. These findings serve as a preliminary validation of the hDCT cell line's suitability for tubular modeling, enriching our toolset for investigating renal disorders. In future research, we aim to focus on functional experiments for a more comprehensive characterisation of the cell line, solidifying its utility in unraveling the physiology of tubulopathies and potentially guiding targeted therapeutic developments.

SA-PO007

Quantifying Composition Changes in Serum Biomarkers of Vascular Calcification in CKD

Isaac Pence, James A. Reneau, Orson W. Moe. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Vascular calcification (VC) is a strong predictor of cardiovascular morbidity and mortality for chronic kidney disease (CKD). Cardiovascular disease (CVD) is the leading cause of death for patients with CKD worldwide. Despite its importance in CVD/CKD, there are no tools to noninvasively diagnose VC, monitor progression, or prognosticate outcomes. Calciprotein particles (CPPs) are circulating biological nanoparticles composed of minerals, lipids, and proteins, and represent a novel biomarker of CVD. When CKD disrupts serum mineral and protein balance, CPPs mature into pathogenic secondary CPPs, which initiate tissue calcification. Here, we present the development of a new technology to assess VC risk: Raman Trapping Analysis (RTA), a quantitative label-free optical technique, is used to quantify composition of healthy and uremic patient derived serum.

Methods: Serum collected from healthy and uremic patients was processed to isolate CPPs and initiator components. Size exclusion was used to separate soluble CPP constituents and incubation in FBS supplemented with Ca and PO_4 was used to generate mature CPPs. The gel-filtration method using OsteoSence reporter was used to quantify CPP levels, and dynamic light scattering (DLS) and transmission electron microscopy (TEM) to assess particle size and morphology. RTA of CPPs was acquired during maturation (24 hr) and after incubation (72 hr). Particle spectra were analyzed to investigate compositional differences between disease groups and time points.

Results: Analysis validated the formation of secondary CPPs. DLS/TEM confirmed particle maturation, and the OsteoSense assay indicated increased CPP levels between uremic vs healthy samples. RTA obtained particle spectra from CPPs comprising Ca-PO_4 mineral, lipid, and protein signatures. A spectral model of chemical constituents was developed, and signatures were extracted for further statistical analysis.

Conclusions: RTA is capable of noninvasive label-free chemical characterization of CPPs derived from patient serum and provides novel information regarding dynamic changes in the composition and heterogeneity of these biomarkers. Precise evaluation of these signatures may provide new insights into serum biomarkers that can differentiate innate mineralization propensity and prognosticate patient risk for VC.

New Translational Screening Assay with Phenotypic and Transcriptomic Readouts Using Induced Pluripotent Stem Cell (iPSC)-Derived Cells and Organoids from a Nephrotic Syndrome Patient

Wenying Xian,[1] Rena Gratz,[1] Jana Drössler,[1] Evrim Ercetin,[1] Ryuichi Nishinakamura,[2] Anna Guhl,[1] Uwe Andag,[1] Olivier Radresa,[1] Nele Schwarz,[1] Maximilian Naujock.[1] iPSC META. *[1]Evotec SE, Hamburg, Germany; [2]Kumamoto Daigaku, Kumamoto, Japan.*

Background: Professor Nishinakamura's group previously generated pluripotent stem cell (iPSC)-derived kidney organoids from a patient suffering from a congenital nephrotic syndrome caused by the mutations in the nephrin gene (c.G1379A, c.2515delC in NPHS1). We further developed this system into a robust, reproducible, and high-throughput organoid assay useful for the progression of drug discovery programs.

Methods: To enable readouts in 384w, we scaled up the production of iPSC-podocytes and iPSC-kidney organoids. We also developed and applied a 3D whole mount immunostaining readout to quantify the phenotypic signature of iPSC-derived podocytes and kidney organoids. Bulk ScreenSeq™ and single-nucleus sequencing was applied to characterize the transcriptomic profiles of both systems.

Results: A specific lack of nephrin phosphorylation was confirmed via automated western blotting. Besides, our kidney organoids completely lacked nephrin signals in synaptopodin-positive regions of glomerular structures. We further quantified the general nephrin deficit with a new script-based whole mount imaging analysis. Finally, by comparing transcriptomic disease signatures, we showed the translational relevance of these organoids for drug discovery in the field of podocytopathies.

Conclusions: We successfully developed and characterized a patient-derived kidney organoid assay and made it available in a high-throughput format. This translational system will prove useful in the identification and validation of candidate targets and for the progression of new kidney therapeutics.

Design of Kidney-Targeted Nanoparticles for Delivery of Gene Therapies

Arantxa Roach,[1] Anastasiia Vasylaki,[1] Pratyusha Ghosh,[1] Edgar A. Jaimes,[2] Ryan Williams.[1] *[1]The City College of New York, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

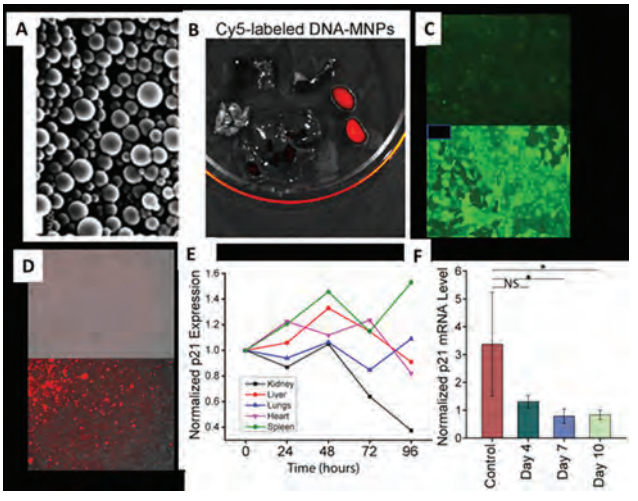
Background: Therapeutic gene and drug delivery to organ sites outside of the liver remains elusive with few strategies to do so for renal diseases. In prior studies, we found that polymeric mesoscale nanoparticles (MNPs) localize to the kidneys up to 26-fold greater than any other organ, specifically to the renal proximal tubular epithelium.

Methods: Here, we investigated the potential to adapt this MNP platform to specifically deliver various RNA-based gene therapies to the renal proximal tubules. We formulated MNPs loaded with either reporter or gene-specific siRNA, mRNA, or CRISPR gRNA/Cas9 that conformed to the 300-400 nm diameter size range which demonstrates tubular localization. We then conducted in vitro studies using renal proximal tubular epithelial cells, as well as in vivo studies with healthy mice, to confirm their function and renal-specific delivery.

Results: Our results demonstrated successful modification of polymeric MNPs such that they maintained kidney targeting while encapsulating RNA therapeutics. mCherry mRNA-loaded MNPs exhibit rapid and bright protein translation in vitro with no cytotoxicity. GFP-targeted CRISPR gRNA/Cas9 MNPs turned off expression of GFP in a stably-transfected cell line. In vivo, we found that kidney-targeted MNPs specifically target the kidneys and achieve gene-specific knockdown.

Conclusions: In ongoing studies, we are using this modified MNP design to deliver gene therapies that modulate inflammation and oxidative stress in salt-sensitive hypertension models of chronic kidney disease.

Funding: Other NIH Support - CA132378



a) Images of mesoscale nanoparticles. b) Kidney-specific delivery of fluorescently-labeled nucleic acids. c) GFP expression in vitro (bottom) is deleted by delivery of GFP CRISPR gRNA-Cas9 d) Renal cell lines (top) express mCherry fluorescent protein upon addition of mRNA-loaded MNPs. e) MNPs reduce gene expression specifically in the kidneys. f) Knockdown persists for up to 10 days.

Integrative Systems Analysis of Calcineurin Inhibitor Action on Podocytes and Proximal Tubular Epithelial Cells

Anthony Mendoza,[1] Maria Paola Santini,[1] Jenny Wong,[1] Linda M. Rehaume,[2] John Viel,[2] Kirk N. Campbell,[1] Evren U. Azeloglu.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.*

Background: Calcineurin inhibitors (CNI), including Cyclosporin A (CSA), Tacrolimus (TAC) and Voclosporin (VCS) are used to treat proteinuric kidney disease. The mechanisms driving differential podocyte and tubular cell responses upon clinical exposure are poorly understood. Here, we tested the in vitro cellular response of these three most commonly used CNIs using a combination of integrated systems biology methods.

Methods: We used high content image analysis to assess the changes in cytoskeletal and focal adhesion architecture; isobaric-tagged LC-MS/MS to assess altered proteomic response; image-based and colorimetric assays to assess viability and metabolic response. For all above assays, immortalized human podocytes and proximal tubular epithelial cells were treated with increasing doses of CSA, TAC and VCS. Respective drug dose responses were mapped back to the translational plasma concentrations as measured in the associated clinical trial.

Results: All CNIs were well tolerated by immortalized human podocytes with minimal change in viability. Immortalized human tubular epithelial cells also showed little change in cell viability with high levels of cell death only in the highest doses of TAC. Morphometric changes were similar in CNIs, with increased focal adhesion area and aspect ratio. Levels of remodeling for all CNIs mirrored their respective calcineurin IC50 values with VCS showing a more robust dose response for both altered focal complex signaling and cell spreading. Quantitative proteomics at the physiologically relevant drug doses recapitulated the altered focal adhesion complex signatures for all CNIs. While network analyses of the differentially abundant podocyte adhesome showed a core CNI proteomic signature, this was supplemented by differing peripheral drug-specific networks that showed different neighborhoods for each CNI.

Conclusions: While integrated viability, proteomic and high-content morphometric analyses show a common CNI-induced signature within human proximal tubular epithelial cells and podocytes, differences were observed among CSA, TAC and VCS for both differentially abundant proteins and drug dose responses. Consistent adhesome and cytoskeletal changes may point to a conserved biophysical role of calcineurin in podocytes with differences in off-target effects.

Funding: Commercial Support - Aurinia

Development of a Glomerulus-on-a-Chip Model: An Innovative Model to Study Paracrine Pathways to Unravel Glomerular Disorders

Dilemin Yildiz,[1] Daan C. 't Hart,[1] Gianluca V. Di Giovanni,[1] Burcu Gumuscu,[2] Johan Van der vlag,[1] Tom Nijenhuis.[1] *[1]Radboudumc, Nijmegen, Netherlands; [2]Technische Universiteit Eindhoven, Eindhoven, Netherlands.*

Background: Crosstalk between glomerular endothelial cells (GEnC) and glomerular epithelial cells (podocytes) is increasingly becoming apparent as a crucial mechanism to maintain the glomerular filtration barrier (GFB) integrity. However, *in vitro* studies directly investigating the effect of this crosstalk are scarce because of the lack of suitable models. Therefore, we developed a custom-made glomerulus-on-a-chip model recapitulating the GFB, in which we investigated the effects of co-culture of GEnC and podocytes on barrier function and cellular phenotype.

Methods: The custom-made glomerulus-on-a-chip model was designed using soft lithography. The chip consisted of two parallel microfluidic channels separated by a semi-permeable polycarbonate membrane. iPSC derived podocytes and conditionally immortalized GEnC and podocytes were differentiated in the chip. Shear stress induced by laminar flow was applied on endothelial cells. Cellular morphology and glycocalyx was visualized by fluorescent staining. The barrier integrity of the model was determined by measuring the transport rate of labelled dextran from top to bottom channel. The effect of crosstalk on the transcriptome of GEnC and podocytes was investigated via RNA-sequencing.

Results: GEnC and podocytes were successfully cultured on opposite sides of the membrane in our glomerulus-on-a-chip. Barrier integrity of the chip was significantly improved when GEnC were co-cultured with podocytes compared to monocultures. Co-culture enlarged podocyte foot process surface area and increased glycocalyx thickness. RNA-sequencing analysis revealed the regulation of cellular pathways involved in cellular differentiation and cellular adhesion as a result of the interaction between GEnC and podocytes.

Conclusions: We present a novel custom-made glomerulus-on-a-chip and demonstrated that co-culture in the device affects the morphology and transcriptional phenotype of GEnC and podocytes. Moreover, we showed that co-culture improves barrier function as a relevant functional readout for clinical translation. This model can be used in future studies to investigate specific glomerular paracrine pathways and unravel the role of glomerular crosstalk in glomerular (patho) physiology.

SA-PO012

Isolation and Purification of Mesangial Cells for Bioengineered Kidneys

MacKenna A. Stachel, Tori Nelson, Emily C. Beck. *Miromatric Medical Inc., Eden Prarie, MN.*

Background: With over 85,000 patients waiting for a kidney transplant, bioengineered kidneys (BEKs) offer a way to address this large clinical need. BEKs are created from isolated native cell types from donor kidneys not accepted for transplant. Of these isolated cell types, mesangials help maintain the glomerular filtration barrier of the kidney. Here, an isolation and purification process are presented to isolate mesangial populations that can be used for glomerular recapitulation of the BEK.

Methods: Using enzymatic digestion, whole glomeruli were isolated from human kidneys and then plated on tissue culture flasks for 14 days. Mesangials were purified from the outgrowths using CD140b/PDGFRβ positive magnetic bead sorting. Purification of the bound mesangial cell population was confirmed using flow cytometry. Post sort, mesangials were expanded, then cryo-banked at passage 2. Cryopreserved cells were thawed and expanded to passage 5, where the mesangials were seeded into a BEK along with other native glomerular cell types.

Results: The bound mesangial population isolated from 6 kidney donors had 89.2% ± 13.4% CD140b positive cells. To assess the potential of isolated mesangials for cryo-banking and expansion, mesangials were cryopreserved, and expanded in 2D up through passage 5. The mesangials remained viable through 2D culture (95.3% ± 2.9% at passage 5, n=7), and were seeded and cultured in 3D in a BEK (n=1) along with other glomerular cell types (podocytes). This BEK demonstrated improved protein and RBC filtration in comparison to BEKs seeded only with podocytes and parietal epithelial cells, after 60 minutes of whole porcine blood perfusion.

Conclusions: Mesangial cells are a necessary cell type known for their structural support as well as their contractile properties to aid in ultrafiltration. This study demonstrates a process in which the mesangial population can be isolated from human donor kidneys, purified, cryo-banked, and expanded for making BEKs. Furthermore, when seeded into a BEK, the mesangials demonstrated improved BEK filtration function. Cryo-banked populations of mesangial cells, as well as other cell types, will allow for BEK creation on demand, thus helping to reduce the number of patients waiting for a kidney transplant.

Case Series of Novel PTEC Isolations from Human Kidney Biopsy: Optimized Protocols and Systematic Characterisation

Sebastjan Bevc,[1,2] Tadej Petreski,[1] Luka Varda,[3] Lidija Gradisnik,[2] Uros Maver,[2] Nejc Piko,[3] Robert Ekart,[3,2] Radovan Hojs.[1,2] *[1]Department of Nephrology, University Medical Centre Maribor, Maribor, Slovenia; [2]Faculty of Medicine, University of Maribor, Maribor, Slovenia; [3]Department of Dialysis, University Medical Centre Maribor, Maribor, Slovenia.*

Background: Human kidneys provide water, electrolyte, and acid-base homeostasis while enabling endo- and exogenous compound metabolism and excretion. Various causes, such as medications (especially in polypharmacy), can quickly disrupt this delicate balance, and currently used methods for nephrotoxicity assays limit the prediction of human response. Our work aimed to develop novel and optimised protocols for isolating proximal tubular epithelial cells (PTEC) from human kidney biopsy.

Methods: We performed nine diagnostic kidney biopsies (informed consent was obtained from the patients) with parts of tissue used to isolate and characterise PTEC. We used two protocols, using five and four biopsy specimens, respectively. The first employed enzymatic dissociation with 0.25% trypsin/EDTA and culture with Advanced DMEM supplemented with 5% fetal bovine serum. In comparison, the second used 0.2% collagenase type 1 and was cultured in selective serum-free culture media (Advanced DMEM/F12 with added insulin, transferrin, selenite, epidermal growth factor, and hydrocortisone). Light microscopy was used for morphologic characterisation, while several markers characteristic of PTEC were chosen for phenotypic characterisation.

Results: Following the protocols resulted in isolating cells that formed first colonies after seven days (range 1-13 days) and three days (range 1-5 days), respectively. Based on light microscopy, the cells exhibited a cobblestone appearance and reached confluence after approximately three weeks following the first protocol and ten days following the second protocol. Population doubling time (PDT) for the best isolate in the first and the second protocol was 29.7 hours and 23.6 hours, respectively. The isolated cells were positive among others for sodium-glucose cotransporter 2 (SGLT2), multidrug-resistant protein 4 (MRP4), organic anionic transporter 1 and 3 (OAT1 and OAT3), organic cationic transporter 2 (OCT2), p-glycoprotein (p-gp), multidrug and toxin extrusion protein 1 (MATE1), and N-cadherin.

Conclusions: In this study, we developed two protocols for isolating and cultivating primary human PTEC from biopsy samples. To the best of our knowledge, we have performed the most extensive systematic characterisation following the isolation of PTEC from the diagnostic kidney biopsy reported.

SA-PO014

Investigating Use of the Biodesix Microsampling Device for Longitudinal Biomarker Studies in Glomerulonephritis (GN) and Renal Transplantation

Kashif J. Anwari, Alan D. Salama. *University College London, London, United Kingdom.*

Background: There has been an increase in the availability of devices allowing home testing of urine, blood and most recently NP aspirates. Biodesix is a lateral flow microsampling device that has been validated in the performance of proteomics, and potentially could be used by patients at home to collect blood and urine, then sent by post for subsequent analysis. We studied whether this device could be used to identify changes in patients with a) GN flares using urine (normalized CD-163) and blood (PR3 antibody and serum-PR3 antigen levels) and b) renal transplant dysfunction (DSA), by comparing with conventional methods of isolating serum and urine.

Methods: Following ethical approval and informed consent, blood/urine samples were obtained from patients with GN (during disease flare and remission) and from renal transplant patients with positive anti-HLA antibodies and CRF >90%. 250uL of sample was placed on a biodesix paper and incubated at room temperature for 5-10 days. The plasma component of the biodesix paper was treated in a standardized manner, reconstituted with 500uL PBS, vortexed for 5 minutes and then centrifuged in 0.45um spin filters for 3 minutes. Samples were analyzed using commercially available ELISA kits and via Luminex (DSA). Biodesix samples were compared with centrifuged blood/urine.

Results: All patients with active GN (n=7) demonstrated raised normalized-CD163 levels with the biodesix device that were comparable with standard urine isolation (p=0.17). Serum and biodesix samples showed concordance with PR3-antibody levels (n=3, p=0.40) and serum-PR3 antigen levels (n=4, p=0.49), and similar results were noted between biodesix samples processed at various time points after blood collection (3, 10 or 90 days). Luminex revealed near identical HLA profiles for biodesix samples vs whole blood in transplant patients (n=4), but MFI values were significantly lower for former.

Conclusions: We have demonstrated that the biodesix device can provide comparable data to standard urine/blood analysis, and potentially be used to identify GN flares and development of de novo DSAs. These devices provide potential benefits including patient convenience, ability to perform more frequent monitoring with earlier detection, and access to a wider patient cohort for biobanking. Further work to validate the biodesix device in these cohorts is required.

SA-PO015

Rapid Loss of Proximal-Tubule-Specific Gene Expression in Primary Culture Associates with HNF4a Downregulation

Asha C. Telang, Madison C. McElliott, Jenna T. Ference-Salo, Jeffrey A. Beamish. *University of Michigan, Ann Arbor, MI.*

Background: Cell culture models are used widely to study the functions of proximal tubule epithelial cells on the implicit assumption that in vitro cell behavior represents in vivo cell function. The advent of tools for transcriptome-wide analysis in culture models has revealed that immortalized cell lines poorly mimic the native proximal tubule. While the dedifferentiation of proximal tubules induced by cell culture has long been appreciated, the dynamics of genome-wide transcription changes accompanying this process have not been described in detail yet are critical to interpret findings in bioengineered and standard cell culture models.

Methods: We isolated proximal tubules from 6-week-old female C57B6 mice by enzymatic and mechanical dissociation followed by gradient centrifugation yielding > 90% proximal tubules. We cultured cells on standard non-porous tissue culture plastic in a standard incubator (37 °C, 5% CO2) in DMEM/F-12 with standard glucose (3.8 g/L) supplemented with low serum (0.5%) and epidermal growth factor (EGF) as representative conditions among the myriad of reported techniques. At various timepoints, RNA was harvested and subjected to bulk RNA sequencing. Cells also were characterized by immunofluorescence staining.

Results: Proximal-tubule-specific genes with more than 15 transcripts per million detected decreased from 77% to 18% after only 4 d. This fraction did not increase with culture duration despite the formation of morphologically mature epithelial structures including typical cuboidal morphology, apical Zo-1 staining, and basolateral sodium potassium ATPase identified by confocal microscopy. Gene set enrichment against the Molecular Signatures Database Hallmark gene sets indicated cultured cells permanently downregulate genes associated with oxidative and fatty acid metabolism within the first 24 h of culture. The transcriptional networks inferred by these changes using ChEA3 point to a central role of decreased HNF4a activity, which itself is silenced by 1 week of culture.

Conclusions: Our results indicate that cultured proximal tubules irreversibly silence most proximal tubule specific genes within just a few days of culture. These findings highlight the need for optimized culture conditions from the moment of isolation.

AMP-Activated Protein Kinase (AMPK) and TGF-β Alter Cell Size and Morphology in Renal Tubule Epithelial Cells

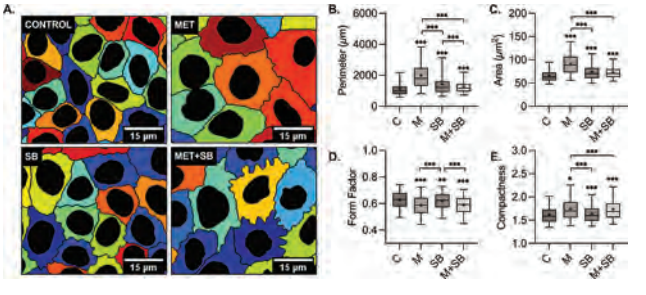
Kuniko Hunter,[1] William H. Fissell,[2] Shuvo Roy.[3] The Kidney Project. *[1]Vanderbilt University, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of California San Francisco, San Francisco, CA.*

Background: Epithelial barrier function is regulated by tight junction protein complexes (TJ) between adjacent cell membranes. TJ may develop non-linear ruffled or spiked architectures which in turn alter cell morphology. Here we observe that AMP-activated protein kinase (AMPK) and Transforming Growth Factor-β (TGF-β) alter renal tubule epithelial cell (RTEC) morphology and induce a ruffled appearance when administered together.

Methods: Primary human RTEC were obtained from Innovative Biotherapies (Ann Arbor, MI). Cells were maintained in DMEM/F12 and seeded onto polycarbonate cell culture inserts at 100,000 cells/cm^2. After two weeks, cells were apically supplemented with AMPK activator Metformin (200μM, MET), TGF-β receptor I inhibitor SB431542 (10μM, SB), or both. After four weeks, cells were stained for DAPI and ZO-1, and imaged using conventional methods. CellProfiler (Broad Institute) was used to threshold and segment nuclei and cell perimeters. Form factor (FF) was calculated as 4*pi*area/perimeter^2. Compactness index (CI) was calculated as the mean^2 distance between the objects pixels from the centroid divided by area. Statistical significance was assessed by performing 2-way ANOVA using Prism 9 (GraphPad).

Results: In comparison to controls, all treatments increased cell perimeter and cell area. MET increased cell perimeter and cell area, in comparison to SB and combination treatments. All treatments significantly reduced FF and increased CI, respectively.

Conclusions: All treatments increase cell perimeter and area, suggesting cell swelling. All treatments reduce FF, suggesting reduced circularity. All treatments increase CI, which suggests increased irregularity of shape, such as increased cell interdigitation or plasma membrane ruffling.



SA-PO017

Smad4 Knockout Increases NHE3 Expression in Renal Tubule Epithelial Cells In Vitro

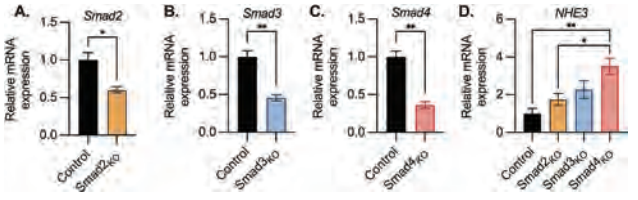
Kuniko Hunter,[1] Harold D. Love,[1] Shuvo Roy,[2] William H. Fissell.[1] The Kidney Project. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California San Francisco, San Francisco, CA.*

Background: Sodium-hydrogen antiporter 3 (NHE3) is a critical indicator of terminal renal proximal tubule epithelial cell (RPTEC) differentiation and accounts for 80% of tubular water reabsorption in vivo. In vitro, RPTEC have reduced NHE3 expression, which limits their functional fidelity. Transforming Growth Factor-β (TGF-β) is a pleiotropic cell signaling pathway, involved in the regulation of epithelial cell fate and plasticity. Canonical TGF-β signaling is mediated by the Smad proteins, Smad2/3/4. Here we observe that knockout of Smad4 increases NHE3 transcription in vitro.

Methods: HEK293 (ATCC, Manassas, VA) were plated at a density of $5x10^5$ in 35mm plates to achieve 60% confluence the following day. Cells were co-transfected with CRISPR sgRNA with PiggyBac (Pb) hygromycin resistance and eGFP vectors and the m7pB hyperactive Pb transposase at a 3:1 ratio using Lipofectamine LTX Plus (Thermo Fisher). For control transfection, cells were transfected with a scramble sequence. 48 hours post-transfection, cells were supplemented with 200μg/mL hygromycin for one week. Cells were passaged once then harvested for RT-PCR analysis.

Results: Smad2, Smad3, and Smad4 knockouts significantly reduced expression of Smad2, Smad3, and Smad4, respectively. NHE3 expression significantly increased with only Smad4 knockout.

Conclusions: Smad4 modulates NHE3 expression in renal tubule epithelial cells.



SA-PO018

Advancing Urine-Based Cell Studies: Introducing the Cell Catcher Device

Katia Nazmutdinova, David A. Long, Stephen B. Walsh. *University College London, London, United Kingdom.*

Background: Urine-derived cells have gained prominence as a valuable tool for biomedical research and clinical applications due to their non-invasive and repeatable acquisition from patients, in contrast to invasive biopsies. However, the full potential of urine-derived cells remains untapped, due to lack of standardised protocols and reliance on lab-based centrifugation within 4 hours. This study aims to address these limitations by evaluating a novel filtration-based Cell Catcher device, and comparing its efficiency to centrifugation.

Methods: We obtained urine from 18 adults attending a tubulopathy clinic and directly compared the effectiveness of viable cell isolation using either Cell Catcher or centrifugation by using paired analysis.

Results: The results demonstrate that the Cell Catcher device significantly improves the chances of obtaining viable cells, with a 28% increase compared to centrifugation. Furthermore, the device enhances the yield of primary renal cells capable of attachment and proliferation, with a twofold increase compared to conventional methods. The cultured cells showed heterogeneity in terms of cell morphology and expression of renal markers. In all samples, we detected expression of *WT1* and *ENPEP* suggestive of podocyte and proximal tubule cells. Some samples were also positive for *NPHS2*, but not *NPHS1*, *AQP3*, *UMOD* or *UPK3A.*

Conclusions: This innovation in urine processing methods has the potential to revolutionize urine-based cell studies and unlock the vast potential of urine as a non-invasive source of patient-specific cells. Further refinements and investigations are warranted to explore the device's compatibility with different cell types and its potential applications in nephrology, regenerative medicine, and urological cancers.

A Microfluidic Approach for Cardiovascular Risk Stratification in CKD and ESKD Patients

Mitesh Rathod, Wen Yih Aw, Elizabeth L. Doherty, Gang Xi, Prabir Roy-Chaudhury, William J. Polacheck. *UNC Chapel Hill, Chapel Hill, NC.*

Background: Cardiovascular (CV) complications are responsible for over 50% of the overall morbidity and mortality in CKD and ESKD patients. Surprisingly, conventional cardiovascular risk factors such as hyperlipidemia and obesity are not as predictive of CV complications in the CKD/ESKD population as compared to the general population and statins in particular do not reduce CV events in hemodialysis patients. This so called "reverse epidemiology" is thought to reflect a primacy of uremia induced vascular dysfunction in the pathogenesis of CV complications in this unique patient population. In order to develop novel, real world and holistic markers of uremia induced inflammation, oxidative stress and endothelial dysfunction, we herein report a 3D microfluidic device to quantify the negative effects of uremic serum on endothelial cells.

Methods: HUVECs were seeded in cylindrical channels in collagen I hydrogels to form microvessels (Fig. 1). After 48 h, perfusion media was exchanged from cell culture media to 100% human serum for 24 hours. To mimic the uremic environment, we added pathophysiological levels of indoxyl sulfate (IS) to serum from healthy donors (Fig 1A-B).

Results: Microvessels perfused with serum from healthy donors exhibited distinct, pericellular VE-cadherin staining, while microvessels perfused with serum containing IS displayed diffuse VE-cadherin indicating immature or dysfunctional adherens junction integrity (**Fig. 1A**). Consistent with these observations, microvessels perfused with serum containing IS exhibited marked increase in solute permeability compared to microvessels perfused with healthy serum (**Fig. 1B**).

Conclusions: These results demonstrate a humanized microfluidic device that can be used to assess endothelial dysfunction in response to uremic toxins. We demonstrate high sensitivity of the assay, as IS at concentrations similar to those for CKD-3 patients resulted in significant cytoskeletal and permeability defects, suggesting that this platform could be used to screen for CV risk in CKD/ESKD patients.

Pulsed Ultrasound of the Splenic Nerve Increases the Splenic Resistive Index in Humans

Faeq Husain-Syed,[1,2] William Nash,[1] Igor Shumilin,[1] Jennie Z. Ma,[1,3] John Hossack,[4] Mark D. Okusa.[1] *[1]University of Virginia Division of Nephrology, Center for Immunity, Inflammation and Regenerative Medicine, Charlottesville, VA; [2]Justus Liebig Universität Giessen Department of Internal Medicine II, Giessen, Germany; [3]University of Virginia Department of Public Health Sciences, Charlottesville, VA; [4]University of Virginia Department of Biomedical Engineering, Charlottesville, VA.*

Background: Splenic pulsed ultrasound (pUS) attenuates ischemia-reperfusion injury-induced systemic inflammation and AKI in mice by activating the cholinergic anti-inflammatory reflex pathway (CAP). We aimed to translate the preclinical discoveries to human inflammation and identify clinical parameters for evaluating the efficacy of pUS. Given the dense splenic innervation by sympathetic neurons (SNs) and norepinephrine (NE) release by sympathetic nerve terminals following CAP activation, we hypothesized that NE release post-pUS increases vascular resistance and, hence, the resistive index (RI).

Methods: We analyzed data from an ongoing human pilot study that tests whether pUS within FDA-approved limits of diagnostic medical sonography attenuates inflammation and alters immune cell composition (clinicaltrials.gov; NCT05685108). Healthy adults were exposed to pUS targeting the splenic nerve with varying ultrasound intensities as defined by burst mechanical index (MI). Spectral Doppler ultrasonography was performed before, immediately after, and 24 h after pUS to determine any functional effects.

Results: 23 pUS procedures were performed in 12 subjects (median age, 28 [IQR, 26 to 36] years; median BMI 24 [22 to 27] kg/m^2; 50% male). We observed a significant increase in splenic RI (+0.05 [0.01 to 0.08]; $P<0.001$) and decrease in splenic volume (-8.4 [-23.1 to -1.1] cm^3; $P=0.008$) immediately after pUS, but not in renal RI nor renal volume. The splenic RI increase was accompanied by an increase in the ratio of systolic-to-diastolic flow velocity, and seemed to depend on the magnitude of applied MI (Figure). 24 h post-pUS, the observed splenic changes were no longer detectable (data not shown).

Conclusions: Our preliminary results in humans demonstrate that pUS transiently increases the splenic RI. This novel physiological effect of pUS provides proof of concept that pUS activates SNs. The increase in vascular resistance may serve as a functional clinical measure of pUS and may contribute to the anti-inflammatory effect of CAP activation.

Fluid Shifts in Septic Shock During Early Hospitalization: A Bioelectrical Impedance Analysis (BIA) Study

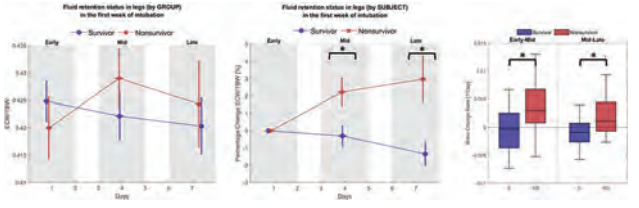
Susie Cha,[1] Jesse E. Diaz Correa,[2] Harold M. Szerlip.[3,4] *[1]InBody, Cerritos, CA; [2]Grupo Renal del Este, Caguas, Puerto Rico; [3]Medical University of South Carolina, Charleston, SC; [4]Baylor College of Medicine, Dallas, TX.*

Background: In the early management of septic shock, aggressive fluid resuscitation is crucial but carries the risk of fluid overload, potentially increasing mortality rates. However, our understanding of fluid distribution and dynamics in the body during this phase is limited. To address this, bioelectrical impedance analysis (BIA) has emerged as an effective tool for monitoring fluid status and guiding treatment decisions in the ICU.

Methods: An observational study was conducted in a university hospital ICU from Feb 2020 to Jul 2021 to assess fluid status in adult septic shock patients. Enrolled patients required mechanical ventilation for respiratory failure. Assessments using the InBody S10, a multifrequency BIA device, were performed at three time points: within 24 hrs of admission, and on days 3 and 7 of ICU stay. Parameters evaluated included extracellular water (ECW) ratio, ECW, intracellular water, and total body water. Fluid status changes were calculated by comparing subsequent measurements to the baseline (day 1). Survival data at 60 days were collected, with 11 survivors and 8 non-survivors.

Results: The study found that most ICU patients had persistent overhydration. Survivors showed a progressive decrease in fluid status, while non-survivors had a temporary increase on day 3, followed by a decrease on day 7, but still elevated compared to the baseline. These fluid fluctuations were mainly driven by changes in ECW, particularly in the legs and trunks. The relative change in fluid status highlighted divergent trends between the groups. Survivors had a sustained decrease of -0.3% and -1.4% on days 3 and 7, respectively, while non-survivors had a sustained increase of 2.2% and 3.0% on days 3 and 7, respectively, with significant differences observed between the groups at those time points. No significant weight change was observed.

Conclusions: Assessing individual changes was crucial due to patient variability. The findings offer insights into fluid shifts and the prognostic implications of BIA parameters in sepsis management, demonstrating its practicality for personalized measurements and informed treatment decisions.



Daily Fluid Change Comparing Survivors and Non-survivors

SA-PO022

A 3D Organ-on-Chip Model of the Collecting Duct for the Study of Electrolyte Disorders

Alessandra Grillo, Chutong Zhong, Keith Siew, Stephen B. Walsh. London Tubular Centre. *University College London Research Department of Renal Medicine, London, United Kingdom.*

Background: Kidney basement membrane components play a crucial role in the function of different segments of the nephron. For example hensin is an ECM protein that promote transition between α and β intercalated cells, stimulating different mechanisms of action in the collecting duct (CD). Current models using organ-on-chip systems mainly use collagen I, without considering segment-specific compositions. Additionally, most kidney models reproduce proximal tubule systems, with no current 3D model of the collecting duct to study physiological mechanisms *in vitro*. Therefore, the aim of the study is to develop a 3D model of the collecting duct using organ-on-chip system by integrating more biomimetic ECM components and physiological cues.

Methods: M1-CCD cells from collecting duct were cultured on the top channel of a three-lane organ-on-chip systems (OrganoPlate, Mimetas) to produce tubular structures, where the middle channel was filled with a permeable ECM formed by collagen I. Different combinations of collagen I, collagen IV and laminin I were used as ECM scaffold. Human umbilical vein endothelial cells (HUVEC) were seeded on the bottom channel to mimic the renal vascular system in contact with the CD.

Results: M1-CCD showed intrinsic ability to form 3D structures when seeded on low-attachment plates. M1-CCD were then cultured on the OrganoPlate system including different combinations of basement membrane proteins, such as collagen IV and laminin, in addition to collagen I, to create a biomimetic environment for collecting duct epithelial cells. M1-CCD cells successfully formed a tubular structure as shown in Figure. The bottom channel was cultured with endothelial cells and transport of small ions was evaluated between the two channels.

Conclusions: We successfully developed and characterised a 3D *in vitro* model of the collecting duct using the organ-on-chip technology. Further steps include the incorporation of patient urine-derived epithelial and blood-derived endothelial cells to create a more accurate and personalised platform for disease modelling and drug testing.

An Immunoprotective Multi-Channel Kidney Bioreactor for Implantable Renal Replacement

Alonso Torres,[1] Edward Porock,[1] Charles Blaha,[1,2] Nathan Wright,[1] Thomas Sorrentino,[1] Eun jung Kim,[1] Caressa Chen,[1] Tariq M. Haniff,[1] Benjamin W. Chui,[1] Jarrett Moyer,[1] Paul R. Brakeman,[1] H. David Humes,[3] William H. Fissell,[4] Shuvo Roy.[1,2] *[1]University of California San Francisco, San Francisco, CA; [2]Silicon Kidney, San Francisco, CA; [3]University of Michigan, Ann Arbor, MI; [4]Vanderbilt University Medical Center, Nashville, TN.*

Background: Clinical renal replacement therapy for end-stage renal disease should replace the kidney's filtration function and vital endocrine role. Our group engineered single-channel macroencapsulation devices housing silicon nanopore membranes (SNM) to act as renal proximal tubule epithelial cell (RPTEC) bioreactors and implanted these subclinical-scale devices in swine. To approach clinical efficacy, we are developing a scalable multi-channel design of blood-interfacing SNM bioreactors to house increased renal cell mass.

Methods: SNM with an average pore size of 7 nm and total surface area of 21 cm^2 covered with thin Al_2O_3 coatings were plasma bonded in alternating four-channel stack pattern. The stacks were incorporated into polycarbonate housings. Cell inserts were machined from acrylic, epoxied to porous transwell membranes, seeded with 500,000 human RPTEC/cm^2, and inserted into ultrafiltrate chambers of the SNM stack on the opposite side of the blood flow path. Bioreactors (n=3) were anastomosed to iliac vessels and implanted into the retroperitoneum of Yucatan minipigs. No immunosuppression or therapeutic anticoagulation was administered. Vascular angiograms using contrast were performed after a week prior to explant. Live/dead imaging of RPTEC as well as ammonia and calcitriol concentrations were measured from the ultrafiltrate chambers and pig plasma via enzyme-linked immunosorbent assays.

Results: There were no technical complications from the implants and devices were patent at explant. Angiograms showed rapid transit of contrast through the multi-channel bioreactors 7 days after implant. Live/dead imaging showed comparable cell viability in the bioreactor compared to *in-vitro* controls (61.0±5.70% vs 56.0±9.10%). Ammonia concentrations were similar in the pig plasma and bioreactor ultrafiltrate (0.35±0.01E-2 vs 0.36±1.00E-3 mM). Levels of calcitriol were decreased compared to pig plasma (48.0E2±93.0 vs 172.0±21.0 pg/mL).

Conclusions: We demonstrated successful implantation of multi-channel bioreactors with RPTEC for 7 days despite no immunosuppression or anticoagulation. Future directions include improving RPTEC viability and function, conducting a longer temporal study, and scaling up to larger multi-channel devices.

Exposure of Mesenchymal Stromal Cells (MSCs) to INF-γ Boosts the Therapeutic Potency of Their Exosomes (Exos) in the Rescue Therapy of Severe AKI in Rats

Christof Westenfelder,[1] Anna Gooch,[1] Mikhail Skliar.[2] *[1]SymbioCellTech, Salt Lake City, UT; [2]University of Utah Dept of Chemical Engineering, Salt Lake City, UT.*

Background: Preclinical and clinical studies have shown MSCs and their Exos to be effective for prevention of AKI. Yet when MSCs are given 48 hrs post-insult, a time when most patients with severe AKI are diagnosed, show them to be ineffective or even detrimental due to the compromised microvasculature. MSCs' are renoprotective by their paracrine release of anti-inflammatory, trophic cytokines and their Exos. Exos signal, post uptake, through the lateral transfer of mRNAs, miRNAs, DNA, proteins, and lipids. We tested here whether priming of human MSCs with INFγ would result in the release of a more potent Exos-based biotherapy in rats with severe IRI AKI.

Methods: (1) 12 sets of hMSCs were culture expanded, then changed to SFM. 6 were exposed ON to 10ng/ml INFγ (*Expt*), and the other 6 to vehicle (*Control*). All Exos sizes and numbers (NanoSite), mRNAs and miRNAs were determined (rtPCR, Rosalind). **(2)** 3 groups of anesthetized adult female Fisher rats (n=6) were subjected to I/R AKI (55 min bilateral renal pedicle clamp) and infused via left carotid artery at 48 hrs post reflow with **(a)** vehicle (1 ml PBS, *Control*), **(b)** Exos harvested from ~2x10e6 hMSCs (Exos), **(c)** Exos harvested from ~2x10e6 INF-g exposed MSCs (*ExptExos*). Each Exos treatment was the equivalent of ~400 mg protein or ~ 2x10e9 particles. Post injury, SCreatinine, and Uprotein/creatinine were assessed at baseline, days 1-10, then monthly x 3.

Results: (1) Exos numbers were comparable in *Expt* and *Control* groups. *ExptExos* were slightly larger than *Controls. ExptExos*' cargo contained both significantly increased immune modulatory mRNAs (IDO-1, CCL8, CXCL9, CXCL10, PD-L1) and 4 anti-inflammatory, angiogenic and anti-apoptotic miRNAs (MiR-548-3P; MiR-548N; MiR-148-3P; MiR-877-5P). **(2)** *In vivo*, Exos therapy with both unexposed and INFg-treated MSCs reduced SCr short and long term vs. control. Only Exos from the INFg group significantly reduced both SCr and UProtein/Creatinine at 3 mos.

Conclusions: Programming of MSCs with INFγ results in the release of Exos that deliver significantly greater renoprotective activities in the compromised microvasculature of severe AKI. We posit, these data have significant clinical promise as rescue therapy in AKI.

Application Myo-Inositol Oxygenase Fluorescent Renal Proximal Tubular-Specific Mitochondrial AKT1 Transgenic Mice in Kidney Disease Research

Hugo Y. Lin,[1,6] I-Ya Chen,[2] Tzu M. Wang,[5] Yen-Hua Chen,[3] Si-Tse Jiang.[4]
[1]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; [2]Chang Gung University, Taoyuan, Taiwan; [3]National Sun Yat-sen University, Kaohsiung, Taiwan; [4]National Applied Research Laboratories National Laboratory Animal Center, Tainan, Taiwan; [5]China Medical University Hospital, Taichung, Taiwan; [6]Kaohsiung Medical University, Kaohsiung, Taiwan.

Background: Renal tubular AKT1 is activated and translocated into mitochondria upon renal injuries. To determine whether tubular mitochondrial AKT1 (mito-AKT) plays a protective role, we generated a novel transgenic mouse strain harboring inducible mitochondria-targeting constitutively active AKT1 (mcaAKT) driven by the renal proximal tubule-specific promoter.

Methods: The manufacturing process used a bacterial artificial chromosome clone containing mouse *Miox* as the transgene backbone and inserted the IRES-CreERT2-polyA and promoter CAGGS-loxP-GFP-polyA-loxP-MTS-AKT1(308T>D; 437S>D)-3XFLAG-polyA cassettes into the exon 5 and 3' downstream of *Miox,* respectively, using Red/ET DNA recombination technology. The CreERT2 is tamoxifen-inducible Cre recombinase, the GFP is a green fluorescent protein, and the MTS is the mitochondria-targeting sequence. The modified transgenic construct was injected into mouse pronuclei and transferred into a surrogate mother to generate the transgenic mice.

Results: The GFP was expressed ubiquitously and observed by epifluorescence in transgenic mice carrying the transgene. The expression of mcaAKT protein was only detected in the kidneys of tamoxifen (TAM)-injected KMioCAKT but not in corn oil-KMioCAKT mice or TAM-wildtype (WT) mice. The mcaAKT was exclusively expressed in kidneys but not in other organs in TAM-KMioCAKT. Moreover, we confirmed mcaAKT co-localized with mitochondria in the renal tubules with tissue staining. To measure the mitochondrial respiratory capacity, we used the Seahorse XF Analyzer and found significant differences in basal respiration, spare respiration, and ATP-dependent respiration ($p<0.05$) between TAM-KMioCAKT and corn oil-KmioCAKT.

Conclusions: These findings suggest that mitochondrial AKT1 is a renal tube bioenergy regulator. We will continue to explore whether it plays a protective role in renal tubules. These findings shed new light on the application in nephrology research. They may be used to screen for new drugs and develop new strategies for preventing and treating kidney diseases.

Optimizing Free Radical Scavenger-Loaded Kidney-Targeted Polymeric Nanoparticles for Increased Therapeutic Efficacy in CKD

Anastasiia Vasylaki,[1] Arantxa Roach,[1] Pratyusha Ghosh,[1] Edgar A. Jaimes,[2] Ryan Williams.[1] *[1]The City College of New York, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

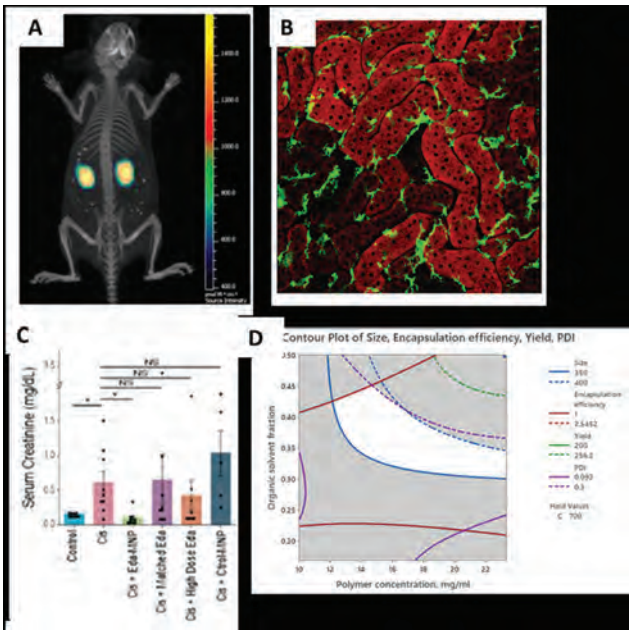
Background: Therapeutic development for renal diseases has been hampered by a lack of poor pharmacological properties by many investigational drugs. To alleviate this bottleneck, our prior studies discovered a polymeric mesoscale nanoparticle (MNP) system capable of targeting the kidneys, specifically the renal proximal tubules. Here, we sought to define MNP formulation characteristics such that the system is robust to delivery of a small molecule cargo while maintaining the appropriate surface chemistry and size necessary for renal targeting.

Methods: We used a quantitative statistical modelling approach based on the Design of Experiments (DoE) to define which drug and particle formulation characteristics allow for MNP renal targeting. We formulated MNPs with the FDA-approved ROS scavenger edaravone and a biocompatible, FDA-approved polymer made of poly(lactic-co-glycolic acid) coated with polyethylene glycol (PLGA-PEG).

Results: We found that MNP formulation parameters control the ability to target the renal proximal tubules and modifications allow for robust production of MNPs with varying therapeutic cargoes. Specifically, polymer concentration and solvent ratios allow mesoscale formulation and optimization of drug cargo loading for therapeutic drug delivery to the kidney.

Conclusions: Ongoing studies are aimed at using these formulation parameters to incorporate increased therapeutic cargo and their ability to ameliorate hypertensive chronic kidney disease.

Funding: Other NIH Support - CA132378



a) MNP localization to the kidneys in mice. b) MNPs (red) in mouse kidneys. C) Edaravone-loaded MNPs successfully ameliorate cisplatin-induced acute kidney injury. d) Contour plot from DoE indicating the appropriate formulation parameters to obtain kidney-targeted MNPS (in white).

Racial and Ethnic Differences in Incident CKD in US Veterans

Guofen Yan,[1] Julia J. Scialla,[1] Robert Nee,[2] Wei Yu,[1] Fei Heng,[3] Tom Greene,[4] Alfred K. Cheung,[4] Keith C. Norris.[5] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]University of North Florida, Jacksonville, FL; [4]University of Utah, Salt Lake City, UT; [5]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Despite a well-documented higher incidence of end-stage kidney disease among racial and ethnic minorities compared to White adults, less is known about the incidence of earlier-stage chronic kidney disease (CKD) by race and ethnicity. We examined risks of incident CKD among veterans of various racial and ethnic groups in the US Veterans Health Administration (VHA).

Methods: The cohort included 1,883,779 veterans with the first occurrence (index date) of the estimated glomerular filtration rate (eGFR) between 60 and 100 mL/min/1.73m^2 (based on the 2021 CKD-EPI equation) during 2003-2015, followed through May 2018. Veterans who had a prior eGFR <60 mL/min/1.73m^2 or were in VHA for <2 years prior to the index date were excluded. The outcome was incident CKD (CKD stage G3 or higher) defined as the first time when follow-up eGFRs decreased to <60 mL/min/1.73m^2 for >3 months. We examined hazard ratios (HR) of incident CKD, censoring for death, by racial and ethnic groups compared to the non-Hispanic White group.

Results: At the index date, the average age was 56 years overall, with Black veterans being the youngest (51 years) and White veterans the oldest (58 years). Average eGFR was 85 mL/min/1.73m^2 for Black veterans and 87-89 mL/min/1.73m^2 for other groups. Overall, after adjusting for age, sex, index year, and baseline eGFR, compared to Whites, the adjusted risk of incident CKD was 53% greater for Blacks and 3-9% greater for other race groups (Table). For subgroups of baseline eGFR 90-100 and 60-89 mL/min/1.73m^2 and those with available data on urine albumin-to-creatinine ratio (UACR) ≥30 mg/g, Black veterans exhibited consistently greater risks of CKD (29% to 81% greater) while other groups varied depending on the subgroup.

Conclusions: Racial and ethnic minority veterans had a greater risk of CKD, as defined by eGFR, compared to their White peers. Enhanced screening programs for racial and ethnic minority adults to detect early stages of CKD is warranted.

Facility-Level Variation in Care of Veterans with Urinary Stone Disease

Sheikh Raza Shahzad,[1] Calyani Ganesan,[1] I-Chun Thomas,[1,2] Maria E. Montez-Rath,[1,2] Simon John Christoph Soerensen,[1] Glenn Chertow,[1] Alan C. Pao,[1,2] John Leppert.[1,2] *[1]Stanford University School of Medicine, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA.*

Background: Urologic care after kidney stone procedure presents an opportunity to implement stone prevention measures, but the frequency of urologic follow up and stone prevention measures are not known. We studied variation in urology visits and stone prevention measures within 6 months after a urinary stone procedure.

Methods: We used data from the Veterans Health Administration (VHA) to identify patients from 97 facilities who had a stone procedure between 2016 and 2018. We constructed multilevel regression models to estimate Median Odds Ratio (MOR) for facility-level variation for urology follow up visits and stone prevention measures. The base model was a random intercept for facility. The 2nd model was adjusted for patient covariates (age, sex, race, driving distance to nearest VA, comorbidities). The 3rd model was adjusted for patient and facility characteristics (geographic region, complexity). We used MOR to quantify facility-level variation and variance partition coefficient (VPC) to quantify the sources of unexplained variation.

Results: Our cohort included 24,057 Veterans who were predominantly white (78.7%) and male (93.8%), with a mean age of 63.8 years. Within 6 months of stone procedure, 93.8% had urology follow-up, 7.4% completed 24-hour urine testing, 7.8% had serum PTH measurement, and 26.2% received stone-related medications. The fully adjusted MOR for urology follow-up, 24-hour urine testing, PTH measurement, and medication prescriptions was 1.59, 1.98, 1.40 and 1.20 respectively. The fully adjusted VPC was 0.19, 0.33, 0.11 and 0.03 respectively.

Conclusions: Sizable variation exists in stone disease care across VHA facilities. Variation due to between-facility differences was higher for 24-hour urine testing (33%) and urology follow-up (18.6%) and lower for PTH measurement (10.8%) and prescription of stone-related medications (3%). Variation across facilities was 1.6-fold in rates of urology follow-up, 2-fold in rates of 24-hour urine testing, 1.4-fold in obtaining PTH levels, and 1.2-fold in stone-related medication prescriptions. There is a need for standardization of urinary stone disease care across facilities. More work is needed to establish clear guidelines for stone prevention and the factors underlying variation in stone prevention care in the VHA and civilian healthcare systems.

Risk of ESKD and Death Among Homeless Veterans with Incident CKD

Alain K. Koyama,[1] Robert Nee,[2] Wei Yu,[3] Devasmita Choudhury,[3,4] Fei Heng,[5] Alfred K. Cheung,[6,7] Keith C. Norris,[8] Monique E. Cho,[6,7] Guofen Yan.[3] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]University of Virginia, Charlottesville, VA; [4]Salem VA Medical Center, Salem, VA; [5]University of North Florida, Jacksonville, FL; [6]VA Salt Lake City Health Care System, Salt Lake City, UT; [7]University of Utah Health, Salt Lake City, UT; [8]University of California Los Angeles, Los Angeles, CA.*

Background: Chronic kidney disease (CKD) requires comprehensive management to limit disease progression, a particular challenge among the homeless. We evaluated the risk of end-stage kidney disease (ESKD), defined by transplant or dialysis requirement, and death among homeless veterans with incident CKD in the US Veterans Health Administration (VHA).

Methods: Incident CKD was defined as the first time estimated glomerular filtration rate (eGFR) decreased to <60 mL/min/1.73 m^2 for >3 months. We excluded veterans with <2 years of VHA care prior to diagnosis of incident CKD or those with pre-existing ESKD. Homelessness was defined using VHA specific codes and/or ICD diagnosis codes for homelessness recorded ≥1 time during the 2 years prior to incident CKD. Cox proportional hazards models examined the association between homeless status and risk for ESKD and death.

Results: An incident CKD cohort of 836,361 veterans were identified from 2005-2017, with follow-up through 2018. A total of 46,561 veterans (6%) were identified as homeless. In a model adjusted for age, sex, race, incident CKD year and eGFR, homelessness was significantly associated with a 6% increased risk of ESKD and a 46% increased risk of death. Further adjustment for variables that may be both a cause and consequence of homelessness (body mass index, comorbidities, use of renin-angiotensin-aldosterone system antagonists and statins, behavioral factors) attenuated findings for both outcomes. Therefore, the abovementioned factors may in part explain the observed associations between homelessness and ESKD and death.

Conclusions: The hazard for ESKD or death is significantly higher among homeless veterans compared to thosenot experiencing homelessness, and the increased risk is partly driven by modifiable factors. These findings emphasize the importance of housing and comprehensive health care in addressing the difficulties in CKD management among homeless veterans.

Implementing a Successful Tele-Nephrology Program for Rural Veterans

Ramon Bonegio,[1,2] Katharine Tuozzo,[1] Ian R. Rifkin,[1,2] Aimee Kroll-Desrosiers,[1,3] Susan T. Crowley,[1,4] Kristin Mattocks,[1,3] David T. Moore.[1,4] On Behalf of the Telenephrology Enterprise Wide Initiative. *[1]Veterans Health Administration, Boston, MA; [2]Boston University, Boston, MA; [3]University of Massachusetts Chan Medical School, Worcester, MA; [4]Yale School of Medicine, New Haven, CT.*

Background: Rural Veterans experience increased morbidity and mortality as a result of chronic kidney disease (CKD) and refractory hypertension. Nephrologists usually practice in urban, acute-care facilities and decreased access to specialist care likely contributes to poorer outcomes in rural Vaterans.

Methods: We established a Tele-Nephrology Hub & Spoke Network (TNN) to provide care to rural facilities. Hub nephrologists reviewed the medical record and provided video-based visits to spoke sites in Maine, New Hampshire, Indianapolis, Oklahoma, Montana, and Colorado. Where possible, hub staff trained a local advanced practice provider (APP) to triage consults and manage emergencies. To understand barriers and facilitators to TNN implementation, we conducted semi-structured interviews with clinicians at five spoke sites. We used the Reach, Effectiveness, Adoption, Implementation and Maintenance (RE-AIM) framework to develop our interview guide. Interviews were conducted using Microsoft Teams and qualitative data was analyzed using open thematic analysis. Results are presented according to each major RE-AIM dimension.

Results: Reach: Rural and highly rural Veterans were seen at all spoke sites. Veterans were given the option of seeing a local and/or tele-provider. Adoption: Adoption was more successful when facilities had a local APP. Local APPs were quickly able to triage consults and address emergencies independently. Where APP were not available, more reliance was placed on hub providers. Implementation: The TNN was successfully implemented at each facility, with >50% of consults being addressed through telenephrology. Maintenance: A telenephrology champion organized the program. Across nearly every interview, the telenephrology champion was mentioned as a critical reason for program success. We anticipated finding that sites had challenges with technology or that Veterans were uncomfortable with remote care but neither of these issues emerged during interviews. We found that the Covid-19 pandemic served as an excellent introduction to telehealth and so there was little anxiety about receiving care from remote nephrologists.

Conclusions: In conclusion, establishing a TNN improved access to specialist care for rural veterans. A telenephrology champion and local APPs with renal training facilitate program adoption and expansion.

SA-PO031

Interaction of Race and Treatment with GLP1-RA, SGLT2i, and Insulin on Mortality in Veterans with Type 2 Diabetes Mellitus (T2DM) and CKD

Stephen R. Sammons,[1,2] Augustine Takyi,[2] David Kim,[2] George Bissada,[2] Guo Wei,[1,2] Ravinder Singh,[2] Robert E. Boucher,[1,2] Amara Sarwal,[1,2] Sydney E. Hartsell,[1,2] Srinivasan Beddhu.[1,2] *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT.*

Background: Racial disparities in the use of anti-glycemic medications have been reported but it is unclear whether there is an interaction between diabetic medications and race on mortality.

Methods: In an active comparator, new user design study of veterans (N = 30165) with T2D with CKD (eGFR < 60) on metformin who then initiated on IG or SGLT2i or GLP1-RA for the first time between 01/01/2018 to 12/31/2021, we 1. examined racial disparities in initiation of these agents and 2. the mortality associations of each of these agents with Black, White and Other races.

Results: Mean age was 71 years, mean baseline eGFR 49.5 ml/min/1.73m2. Compared to White veterans, Black veterans were less likely to be prescribed GLP1-RA's (OR 0.69, CI 0.63-0.77), were more likely to be prescribed insulin glargine (OR 1.11, CI 1.04-1.19), and were similarly prescribed SGLT2i's (OR 1.05, CI 0.99-1.12). There were 4,660 deaths over 80,043 patient-years in the entire cohort. Compared to GLP1RA, insulin glargine was associated with increased mortality in both Blacks and Whites (Figure)

Conclusions: Even though there are racial disparities in prescription of insulin glargine, race does not appear to modify the increased mortality associated with insulin glargine compared to GLP1RA.

SA-PO032

Factors Influencing SGLT2i Utilization in an Inner-City Public Hospital

Luis C. Despradel,[1,2] Nang San Hti Lar Seng,[1,2] Belinda Jim.[1,2] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i's) remained underutilized in chronic kidney disease (CKD) patients despite their renoprotective benefits. We present the factors associated with SGLT2i prescription in a public hospital in New York City.

Methods: Cross-sectional analysis of adult primary care patients at Jacobi Medical Center, Bronx, NY was done from Jan 2022 to Dec 2022. The sample included patients with CKD and Type 2 Diabetes Mellitus (T2DM). Exclusion criteria were no medication list and eGFR<20 mL/min/1.73 m^2. Descriptive statistics and logistic regression analysis were performed using STATA 18 (StataCorp).

Results: Among 2307 eligible patients, SGLT2i prescription rate was 14%. After controlling for gender, age, and subspecialty follow-up, no significant association was found between the prescription of SGLT2i and the patient's race, language, or coexisting comorbidities/complications. Please see Table 1 for the odds ratios of different significant variables.

Conclusions: Women were found to be prescribed less SGLT2i than men, perhaps due to side effects that affect women not identified in this study. Patients without insurance or with public insurance were more likely to be prescribed. As the drug can be dispensed in our hospital pharmacy for the uninsured as opposed to the need for an onerous prior authorization process for those with insurance; public insurances usually do not require prior authorization. Subspecialized services and hospital physicians increased the likelihood of SGLT2i prescription, perhaps reflecting the higher level of evidence-based application in a teaching hospital. By understanding these factors, we can strategize to enhance the utilization of this class of medications.

SA-PO033

High Prevalence of Diabetes and Kidney Disease in Areas of Chicago Historically Subjected to Housing Discrimination Laws (Redlining)

Jennifer L. Bragg-Gresham,[1] Linda Fraunhofer,[2] Ana Laura Licon,[1] Tiffany C. Veinot,[3] Michael Heung,[1] Jennifer L. Ennis,[2] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]Laboratory Corporation of America Holdings, Burlington, NC; [3]University of Michigan School of Information, Ann Arbor, MI.*

Background: In 1940, Home Owners' Loan Corporation (HOLC) produced a map of Chicago, IL as a safety investment guide for mortgage lenders. The areas labeled "hazardous" reinforced racial residential segregation with lasting patterns of inequality continuing today. We hypothesize that individuals residing in these "less desirable" neighborhoods continue to face numerous challenges contributing to the development and progression of kidney disease, including a higher prevalence of diabetes.

Methods: Using 2022 Labcorp data from ~400K laboratory tests from individuals residing in previously mapped HOLC districts, we spatially joined results to each category (A: Best, B: Desirable, C: Declining, and D: Hazardous). We examined results for both kidney disease indicators (eGFR <60 ml/min/1.73m^2 and urine albumin to creating ratio >30 mg/g), as well as HbA1c to examine potential diabetes (HbA1c ≥6.5%) and prediabetes (HbA1c of 5.7%-6.4%). The odds of kidney disease, diabetes, and prediabetes by HOLC grade were assessed by logistic regression, adjusting for age and sex.

Results: Individuals who live in HOLC-A neighborhoods (<1%) were older with a higher proportion of males than the other HOLC categories, which were more similar in demographic characteristics (53 years vs. 48 years and 42.3% vs. 40.8% male). Mean HbA1c was higher in HOLC grades B-D vs A, with correspondingly higher rates of potential diabetes and prediabetes. After adjusting for differences in age and sex, the odds of all three outcomes were significantly higher in HOLC grades B-D, compared to HOLC-A (p<0.0001).

Conclusions: Significant associations were seen between historically redlined areas and the odds of diabetes, prediabetes, and kidney disease. It is imperative to both understand the mechanisms underlying these observations and to develop place/person-centered intervention programs to mitigate the effects of these disparities.

Funding: Other U.S. Government Support

SA-PO034

Individual vs. Neighborhood-Level Social Determinants of Health and ESKD Mortality

Dasol Kang,[1,2] Will Simmons,[1,2] Arindam Roychoudhury,[1,2] Kwan Kim,[1,2] Jeffrey I. Silberzweig,[1,2] Deirdre L. Sawinski,[1,2] Sri Lekha Tummalapalli.[1,2] *[1]Weill Cornell Medicine, New York, NY; [2]Rogosin Institute, New York, NY.*

Background: Social determinants of health (SDOH) have a substantial impact on disease morbidity and mortality. Neighborhood-level SDOH indices are increasingly being used for clinical risk prediction and resource allocation to improve health equity. However, whether neighborhood-level SDOH are independently associated with mortality among incident end-stage kidney disease (ESKD) patients is unknown.

Methods: We identified patients with incident ESKD admitted to the Rogosin Institute, a New York City-based non-profit dialysis organization, and excluded patients with missing Social Vulnerability Index (SVI) and acute kidney injury requiring dialysis. We used Cox regression to generate four nested prediction models for mortality. Model 1 adjusted for age, sex, and race and ethnicity. Model 2 additionally adjusted for primary cause of ESKD and 31 Elixhauser comorbidities. Model 3 additionally adjusted for individual SDOH (marital status and employment). Model 4 additionally adjusted for census tract-level SVI, which incorporates Census variables of socioeconomic status, household composition and disability, minority status and language, and housing type and transportation.

Results: Of 3,585 patients with incident ESKD, the median age was 62 (IQR 50 – 73). A total of 56% were male, 37% non-Hispanic Black, 24% non-Hispanic White, 15% Hispanic, and 14% were Asian. The mortality prediction model containing age, sex, and race and ethnicity had a Harrell's C-statistic of 0.7028. Adding cause of ESKD and comorbidities improved prediction performance (Harrell's C 0.7585, likelihood ratio

[LR] test p<0.001). Individual SDOH also improved prediction performance (Harrell's C 0.7652, LR test p<0.001). Census tract-level SVI and SVI themes did not improve mortality prediction (Harrell's C 0.7653, LR test p = 0.645).

Conclusions: Neighborhood-level SVI did not improve mortality prediction in a diverse cohort of incident ESKD patients in New York City, independent of demographics, comorbidities, and individual-level SDOH. Neighborhood-level SDOH indices may have limited utility to predict clinical outcomes in the ESKD population.

SA-PO035

Health Inequalities in Kidney Disease: Meeting the Urgent Need to Identify Early Disease in High-Risk Communities (HIDDEN-CKD): A Feasibility Study

Roseline E. Agyekum,[1] Kathryn Griffiths,[1] Rachel Z. Musomba,[2] Neerja K. Jain,[3] Denis O. Onyango,[2] Kate Bramham.[1] HIDDEN Working Group. *[1]King's College London, London, United Kingdom; [2]Africa Advocacy Foundation, London, United Kingdom; [3]Kidney Research UK, Peterborough, United Kingdom.*

Background: There is a global epidemic of chronic kidney disease (CKD) and people of ethnic minority groups and those living with socioeconomic deprivation are disproportionately affected. Peer educators (PEs) are members of target demographic groups and provide culturally congruous education and support. HIDDEN-CKD explored the feasibility of using PE led kidney health screening events in South East London to increase the reach, equity and acceptability of routine healthcare interventions to identify early disease in African and Caribbean communities.

Methods: Stage 1: Public engagement to co-develop culturally appropriate CKD materials **Stage 2:** PE recruitment and accredited training; engagement with local faith and non-faith community leaders **Stage 3:** Events were held in African and Caribbean faith and non-faith based community settings; following an educational session people were invited to consent to the study and demographic and medical details, blood pressure, body mass index and urinary albumin creatinine ratio (uACR), (measured by smart-phone analysis) were collected. Culturally tailored information and peer support were available throughout and after testing. **Stage 4**: All participants individually followed up by phone and supported to seek medical attention where appropriate. **Stage 5:** Quantitative analysis of uACR results.

Results: We have trained 30 PEs, who have performed 305 uACR semi quantitive tests in community settings to date. The majority of participants were black African or black Caribbean (n= 228, 75%; n = 29, 10% respectively), female (n = 163, 53%) and had no known medical history (n=128, 49%). 164 (54%) tests were ACR >3mg/mmol and 24 (8%) >30mg/mmol.

Conclusions: People from African and Caribbean communities appear to be willing to participate in PE led community CKD screening, and high rates of albuminuria are detected. Further qualitative and longitudinal work is underway to assess acceptability and to confirm CKD diagnosis. This approach may provide a new opportunity to reduce health inequalities.

SA-PO036

Social Deprivation Index and Kidney Failure Replacement Therapy (KFRT) Risk Among 2.5 Million Patients

Deidra C. Crews,[1,5] Yingying Sang,[2,4] Morgan Grams,[3] Shoshana Ballew,[2,4] Chiadi E. Ndumele,[1,5] Kunihiro Matsushita,[2,4] Josef Coresh.[2,4] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]New York University, New York, NY; [4]Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD; [5]Johns Hopkins Center for Health Equity, Baltimore, MD.*

Background: Neighborhood-level social determinants of health (SDOH) are known to influence kidney disease risk. However, limited SDOH data are available from large, multi-ethnic, national samples with measured risk factors. We aimed to determine the extent to which place-based measures of SDOH relate to KFRT risk, and whether the associations vary by race/ethnicity.

Methods: We studied 2,536,627 patients in the Optum Labs Data Warehouse. Social deprivation index (SDI, deciles 1 to 10 as a composite measure of poverty, education, employment, home rental & crowding, single-parent households and no car ownership, with 10 representing the most deprived status) was geocoded at the zip code level. Cox models quantified the adjusted relative hazard of incident KFRT defined using hospitalization billing codes overall, and stratified by race/ethnicity (as coded in the electronic health record).

Results: Patients were a mean age of 52 years, 57% were female, 9.8% were Black and 4.3% were Hispanic persons; most were insured (76% commercial, 16% Medicare, 2.6% Medicaid, 2.4% uninsured and 0.8% other type). Median SDI differed by race/ethnicity, with Black and Hispanic patients having markedly higher social deprivation. SDI was associated with risk of KFRT in all models overall and across race/ethnicity groups.

Conclusions: Social deprivation is consistently associated with KFRT risk even after adjustment for established risk factors. The unequal distribution of SDI by race/ethnicity likely reflects both present and past influences, including structural racism.

Funding: NIDDK Support, Private Foundation Support

SA-PO037

Population Impact of Social Determinants of Health on Premature Death Among US Adults with CKD

Joshua D. Bundy,[1] Ling Tian,[1] Alexander D. Kimbrough,[1] Katherine T. Mills,[1] Amanda H. Anderson,[1] Hua He,[1] Katherine Theall,[1] Jing Chen,[2,1] Jiang He.[1,2] *[1]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [2]Tulane University School of Medicine, New Orleans, LA.*

Background: Social determinants of health (SDOH) are important underlying components of population health and are associated with adverse outcomes among patients with chronic kidney disease (CKD). However, the US population-level impact of SDOH on premature death among adults with CKD is unknown.

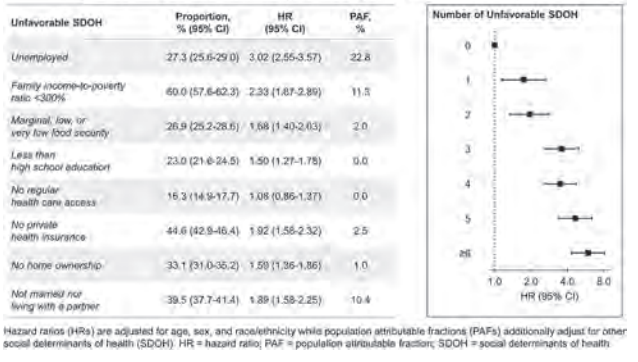
Methods: A nationally representative sample of individuals aged 20-74 from the US National Health and Nutrition Examination Survey (NHANES) 1999-2018 were included. We selected those with CKD defined as estimated glomerular filtrate rate <60 ml/min/1.73 m^2 and/or urinary albumin-creatine ratio ≥30 mg/g. Self-reported SDOH were collected in each survey cycle (Figure). Deaths were ascertained from linkage to the National Death Index through 2019. Multivariable Cox proportional hazards regression and average population attributable fractions were used to investigate the contributions of SDOH to population-level premature all-cause mortality. All analyses accounted for the complex survey design.

Results: A total of 8422 individuals aged 20-74 years with CKD were included (11.0% weighted population prevalence). Mean survey-weighted age was 52.6 years and 55.3% were women. During a mean 8.6-year follow-up, 1252 deaths were recorded. After adjustment for age, sex, and race/ethnicity, all SDOH were significantly and independently associated with higher all-cause mortality and accounted for substantial portions of the US population mortality burden (Figure). Furthermore, dose-response associations were observed between the cumulative number of unfavorable SDOH and premature death, with having six or more unfavorable SDOH increasing mortality 6-fold.

Conclusions: SDOH were strongly and independently associated with premature death among US adults with CKD, and accounted for 50% of premature deaths in this population. Innovative structural policy interventions are urgently needed to prevent adverse events associated with SDOH among patients with CKD.

Funding: Other NIH Support - National Institute of General Medical Sciences (P20GM109036)

Figure. SDOH and premature all-cause mortality in US adults aged 20-74 years with chronic kidney disease.



Hazard ratios (HRs) are adjusted for age, sex, and race/ethnicity while population attributable fractions (PAFs) additionally adjust for other social determinants of health (SDOH). HR = hazard ratio; PAF = population attributable fraction; SDOH = social determinants of health

SA-PO038

Impact of Race-Free Estimated Glomerular Filtration Rate (eGFR) on Racial Disparity in Receiving Timely Outpatient Nephrology Care

Gabrielle E. Fricker,[1] David J. Gunderman,[1] Kasyap K. Kondury,[1] Sharon M. Moe,[2] Akram Almakki.[1,3] *[1]Indiana University School of Medicine - West Lafayette, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Indiana University Health Arnett Inc, Lafayette, IN.*

Background: In 2021, an international taskforce of kidney experts recommended implementation of a revised formula for estimated glomerular filtration rate (eGFR) that removes the race variable. Differences in eGFR and chronic kidney disease (CKD) stage

have been reported for Black patients following implementation of the new CKD-EPI 2021 formula. However, the impact of the new equation on care and referral disparities is not well understood.

Methods: We conducted a retrospective cohort study of all adult patients referred to Indiana University Health outpatient nephrology clinics during a two-year period surrounding the change in eGFR formula. To analyze the impact of the new formula, we performed a multivariate linear regression with eGFR as the dependent variable, and sex, self-reported race, age, timeframe, BMI, and an interaction term between race and timeframe as covariates.

Results: 812 patients met our criteria for analysis. Multivariate linear regression revealed that mean eGFR was statistically influenced by sex, race, age, and implementation of the new formula. Mean eGFR increased by 5.9 mL/min/1.73m2 (95% CI: 0.3, 11.4) for all patients after implementation of the new formula. However, the analysis revealed no evidence that the racial disparity in mean eGFR at the time of the first visit with nephrology was significantly influenced by the formula change (-3.7, 95% CI: -10.1, 2.7). Mean eGFR at the first visit was 6.7 mL/min/1.73m2 (95% CI: 2.4, 10.9) lower for Black patients compared to non-Black patients across the entire study period.

Conclusions: A general trend of increased mean eGFR across all patients after the equation change indicates earlier overall referrals to nephrology. Despite this improvement, our analysis did not reveal a significant change in the existing disparity in timely referral to nephrology observed between Black and non-Black patients. Black patients still had a lower mean eGFR at the initial visit to nephrology when compared to non-Black patients after implementation of the new eGFR formula, suggesting a persistent delay in referral to nephrology for Black patients.

SA-PO039

Combatting CKD: Kidney Health Screenings Through the Kidney Disease Screening and Awareness Program at the University of Virginia

Marissa Yee, Tushar Chopra. *University of Virginia, Charlottesville, VA.*

Background: The Kidney Disease Screening and Awareness Program (KDSAP) was initially founded with the goal to increase awareness about chronic kidney disease (CKD) in the community through education and free kidney health screenings. The KDSAP chapter at the University of Virginia (UVA) was founded in 2021 to bring these initiatives to members of the Charlottesville area.

Methods: The Diversity, Equity, Inclusion, and Community Health Grant funds KDSAP at UVA through the UVA Department of Medicine. In the spring of 2023, KDSAP at UVA hosted its first kidney health screening at Mt Zion First African Baptist Church. The screening is run by volunteers, organized by undergraduate students, and supported by medical students, residents, fellows, and physicians. Participants proceeded through 8 stations within 30 minutes: registration, form filling, urinalysis, BMI, blood glucose, blood pressure, physician consultation, and exit survey. We performed a descriptive analysis amongst screened membersself-reproted racial representation. Descriptive data is reported as numbers (n). The reported race/ethnicity was: White/Non-Hispanic White, Black, Asian, Hispanic or Latin(o), and not reported.

Results: 34 community members were screened during the inaugural KDSAP at UVA kidney health screening. 15 participants were referred to follow-up with nephrology due to abnormal results from: urinalysis, blood pressure, or blood glucose. With regards to racial representation amongst folks screened are outlined in the table.

Conclusions: KDSAP at UVA is the first organization to be led by undergraduate students in collaboration with the UVA Department of Medicine for kidney health-related community outreach to underserved populations. We screened 58.8% African americans, 26% Asians, 2% hispanic or latin(o), 8% white population. Continued efforts to host more kidney health screenings in different locations in Charlottesville, targeting at-risk communities, will forge a future of increased kidney disease awareness and early detection.

Race	Male	Female
African American	11	9
Asian	6	3

SA-PO040

A Trauma-Informed Approach to Address Systemic Racism in Outpatient Clinics

Valerie O. Nwanji,[1] Kimberly M. Brown,[2] Yuvaram N. Reddy.[1,2] *[1]University of Pennsylvania, Philadelphia, PA; [2]Corporal Michael J Crescenz VA Medical Center, Philadelphia, PA.*

Background: The primary objective of this project is to mitigate perceptions of racism noted among Black Veterans with kidney disease at the Crescenz VA Medical Center (Philadelphia). Understanding that racism can be traumatic, we hypothesized that a trauma-informed care intervention to address systemic racism would reduce perceptions of racism, improve trust in our healthcare system, and lead to improvements in overall health (*e.g.*, reduction in no-show visits).

Methods: Informed by the Center for Health Care Strategies, we developed a multi-level intervention: provider training, environmental scan (health equity walkthrough), developing a patient advisory board, and creating a referral pathway for racial trauma. We provided two 60-minute workshops to clinicians. We provided a framework to define interpersonal discrimination from structural racism and tools to help center Black Veterans and their experience with systemic racism. The training provided guidance to create an inclusive environment during clinical encounters. Clinicians were surveyed to evaluate the acceptability and feasibility of the surveys. We conducted a "walkthrough" of the Renal clinic to assess how the clinic infrastructure could be redesigned to be more inclusive for all Veterans. A health equity researcher, led the walkthrough and invited Veterans and clinicians to conduct their own walkthroughs of the clinic. Findings were compiled to generate action items to improve the clinic infrastructure.

Results: Eight clinicians (42%) attended the 2 workshops conducted in November 2022. The clinicians included 5 advanced practice providers and staff, 2 MDs, and 1 social worker. Five participants completed the surveys, all of whom ranked the workshop quality as "high" (on a scale from "very low" to "very high") and noted they would recommend the training to others. Participants "completely agreed" that the workshop was appropriate to education, experience, and skill level. All "agreed" or "completely agreed" to use the information and skills provided by the workshop during clinical encounters with their patients.

Conclusions: Our pilot demonstrates that 1) it is feasible and acceptable to deliver trauma-informed care training to clinicians to help address perceptions of systemic racism in clinics and 2) health equity walkthroughs can generate action items to expand inclusivity in healthcare settings.

Advancing Excellence in Diversity, Equity, and Inclusion: A Concept Map for Development of a DEI Chief Fellowship in Nephrology

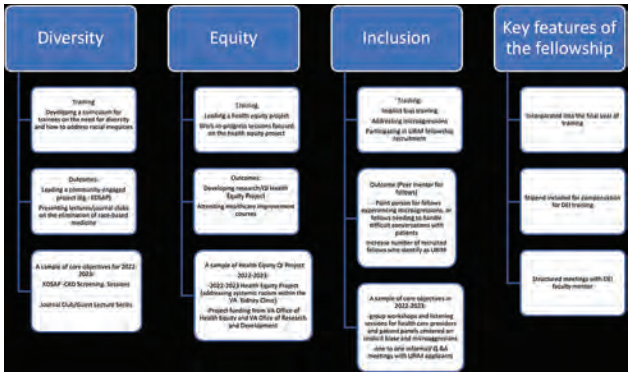
Valerie O. Nwanji, Yuvaram N. Reddy, Amanda K. Leonberg-Yoo. *University of Pennsylvania, Philadelphia, PA.*

Background: Despite decades of attempts to recruit and retain a diverse physician workforce that better represents the patients we serve, inequities in medicine persist. In keeping with the 2021 Executive Order to advance racial equity, the University of Pennsylvania's Renal-Electrolyte & Hypertension Division developed the DEI Chief Fellowship program to provide training and a leadership role to fellows interested in advancing excellence in DEI. This abstract describes a concept map of the core components of the DEI chief fellowship.

Methods: Through stakeholder feedback and a review of the AAMC DEI competencies, we developed a concept map outlining the core trainings and objectives of the DEI fellowship.

Results: See attached image

Conclusions: The DEI Chief Fellowship is a structured year-long position designed to help trainees become leaders in responsibly advancing excellence in DEI through 1) furthering the inclusion of those underrepresented in medicine, 2) identifying and reducing healthcare disparities, 3) expanding equity into quality improvement and research, and ultimately 4) to improve patient outcomes. It encompasses work-in-progress sessions, leadership experience (*e.g.*, leading community engagement projects, facilitating fellowship recruitment), and core lectures (*e.g.*, addressing implicit biases and microaggressions, incorporating health equity into learning health system). The Renal DEI Chief Fellowship position helped establish similar DEI tracks in Endocrinology and Pulmonary/Critical Care Division within the University of Pennsylvania. We hope Nephrology Divisions across the country will use this concept map to build a pipeline of leaders who graduate fellowship with a strong foundation of excellence in DEI.



SA-PO042

Beck Depression Index-II Scores and Survival in a Multi-Center Prospective Hemodialysis Cohort

Ji Hoon Yoon,[1] Yoko Narasaki,[1] Man Kit Michael Siu,[1] Seungsook You,[1] Matthew D. Nguyen,[1] Diana S. Kalantar,[1] Lisa Le,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh,[2] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Population-based studies have uncovered a high burden of depression among advanced CKD patients, including those receiving dialysis. We examined the relationship between self-reported depression and mortality among a diverse multi-center prospective cohort of HD patients.

Methods: We evaluated 956 HD patients from the prospective NIH MADRAD Study recruited across 18 dialysis clinics across Southern California who underwent protocolized Beck Depression Index-II (BDI-II) surveys over 2011-2021. Using multivariable Cox models adjusted for expanded case-mix covariates, we examined associations of time-dependent BDI-II score categorized as tertiles with all-cause mortality risk. We then examined differential BDI-II score—mortality associations across race/ethnicity using interaction tests.

Results: The mean±SD age of the cohort was 55±14 years, among whom 45% were female; 29% were Black; and 55% were Hispanic. In analyses of time-dependent BDI-II score, the highest (worse) Tertile 3 was associated with higher death risk (ref: Tertile 1): HR (95%CI) 1.40 (1.08, 1.81) (Fig A). Subgroup analyses showed that point estimates for the highest Tertile 3 of BDI-II scores was associated with higher mortality in Black vs. Non-Black patients (HRs [95%CIs] 1.30 [0.81, 2.08] and 1.18 [0.87, 1.61]) and in Hispanic vs. Non-Hispanic patients (HRs [95%CIs] 1.18 [0.83, 1.68] and 1.25 [0.86, 1.82]), with non-significant p-interaction values suggesting equivalent risk across race/ethnicity (Fig B).

Conclusions: In a multicenter prospective HD cohort, higher (worse) BDI-II scores were associated with worse survival in all racial/ethnic groups. Further studies are needed to identify multi-modal strategies that effectively treat depression in diverse HD populations.

SA-PO043

Association of Food Insecurity and Treatment Nonadherence or Hospitalization Among Adults on Hemodialysis

Kathryn Taylor,[1] Marlena Fisher,[1] Sydney Santos,[2] Yuling Chen,[1] Owen W. Smith,[1] Nancy A. Perrin,[1] Deidra C. Crews.[3] *[1]Johns Hopkins University School of Nursing, Baltimore, MD; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: Food insecurity is associated with hospitalization among children on hemodialysis, but existing research has not tested associations among adults.

Methods: We conducted a prospective cohort study to test associations between food insecurity and missed treatments or hospitalizations. We enrolled a convenience sample of adults (>=18 years) on hemodialysis (>=3 months) from 17 facilities in Maryland, Washington, D.C., or Virginia from February through November 2021. Participants completed demographics and the US Adult Food Security Survey Module at baseline and remained in the study for 6 months. We collected missed treatment counts and hospital admission and discharge dates (all-cause and fluid or electrolyte-related) from facility records. We created negative binomial regression and Cox models to test associations between food insecurity and missed treatments or hospitalizations, respectively. We repeated hospitalization analyses stratifying by age (<55 or >=55 years) to account for confounding.

Results: We analyzed data from 288 out of 322 participants (89%) who completed surveys. Mean age was 60 years (range 27 – 86 years), 58% of the sample were male, 73% self-identified race as Black. At baseline, 61 participants (21%) reported food insecurity. During follow-up, 138 participants (48%) missed at least one hemodialysis treatment (range 0 – 29 treatments) and 91 participants (32%) were hospitalized (range 0 – 5 hospitalizations). Twenty participants (7%) were hospitalized due to fluid overload or hyperkalemia. Participants reporting food insecurity missed more dialysis treatments (**Table 1**). Food insecurity was not associated with all-cause hospitalization, but the association differed by age group (*food insecurity x age group* interaction term p = 0.14). In bivariate analyses, food insecurity increased relative hazard of fluid or electrolyte-related hospitalization.

Conclusions: This is the first report of associations between food insecurity and outcomes among adults on hemodialysis. Food insecurity was associated with missed treatments and fluid or electrolyte-related hospitalizations.

Funding: Other NIH Support - National Institute of Nursing Research

Multilevel Challenges Faced in Renal Replacement Therapy of Morbid Obesity

Lina Frauenfeld, Sheena Pramod. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: We discuss the challenges faced in treatment options in a morbidly obese patient with advanced CKD Methods: Dialysis modalities have significantly improved over the years with several options. Home dialysis increases patient autonomy, portability and compliance, but remains low due to multiple challenges.

Case Description: 57 year old male is referred to with advanced CKD. PMHx includes morbid obesity, gastric bypass in 2003, anemia and proteinuria. Previously, patient weighed 700 lbs, before gastric bypass, and went down to 300 lbs. He is 598 lbs at the time of evaluation. Since 2018, he has been bedridden due to back issues and has not been able to leave his home until his visit in a modified stretcher. Labs reveal: Serum Creatinine of 4.1 mg/dl, EGFR (CKD-EPI) of 16 mL/min/1.73m2, microalbumin/Creatinine ratio 938 mg/g creatinine and urine protein creatinine ration 2,272 mg/g creatinine suggestive of secondary FSGS. On follow up visit, he reports mild uremic symptoms, resulting in a discussion regarding his RRT options. In-center HD was not an option given his physical condition and inability to sit in HD chair or weight bear. Home HD was considered, but 6 week home training was not feasible because of wife's work needs, bariatric stretcher unable to fit through doorways, and out of pocket costs of transportation for training. We considered PD as a last option. He would need a pre-sternal PD catheter placed given his large pannus. Surgeon though agreeable to place pre-sternal PD catheter, if cleared by anesthesia, sadly, his bariatric stretcher was too large to fit the local dialysis home units, prohibiting his training and an option to perform PD training at home was limited. The only future alternative is him presenting to emergency room for inpatient hemodialysis knowing that he may not receive OP placement. He was referred for home palliative care simultaneously.

Discussion: This case highlights the challenges faced by our morbidly obese population which are growing in numbers despite the advancements that have been made in home hemodialysis. Dialysis and insurance companies should incentivize and support units to provide training at patient's homes, alleviating some of the hurdles faced in improving the shift to home therapy. The ability to train younger patients such as ours in their own homes may alter their clinical trajectory.

SA-PO045

Sex, Gender, and Quality of Life in Hemodialysis

Victoria J. Riehl-Tonn,[1] Jennifer M. MacRae,[1] Sandi M. Dumanski,[1] Meghan J. Elliott,[1] Neesh I. Pannu,[3] Kara Schick-Makaroff,[4] Kelsea Drall,[3] Colleen M. Norris,[4] Hassan Behlouli,[2] Sofia B. Ahmed.[1] *[1]University of Calgary, Calgary, AB, Canada; [2]McGill University, Montreal, QC, Canada; [3]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [4]University of Alberta Faculty of Nursing, Edmonton, AB, Canada.*

Background: Women with kidney failure treated with hemodialysis (HD) report lower quality of life (QoL) compared to men. Decreasing HD frequency is a potential strategy to improve QoL but may result in undertreatment of females compared to males due to biological differences in body water distribution.

Methods: Individuals initiating HD in Alberta, Canada were recruited. Sex assigned at birth (SAAB) and gender identity were self-reported and gender score, a measure of social expectations and norms typically associated to a given gender, was calculated using the GENESIS-PRAXY scale. The primary outcomes were the change in Kidney Disease Quality of Life 36 physical (PCS) and mental component scores (MCS) at 3 months, validated markers of mortality, stratified by HD dose (3 vs 2 sessions/week). The associations between SAAB, gender score and change in PCS and MCS by HD dose were measured using non-parametric test and multiple linear regression, respectively.

Results: There were 33 participants on 3x/wk HD (14 female, 19 male) and 27 on 2x/wk (12 female, 15 male). PCS increased with 3x/wk (p=0.010) but not 2x/wk (p=0.521) in females, but no differences were observed in MCS. No changes were observed in PCS or MCS in males, irrespective of HD dose. Gender score was positively associated with change MCS on 2x/wk HD (p=0.049) but not 3x/wk HD (p=0.102). While gender score was not associated with change in PCS, HD dose modified the relationship (p=0.035).

Conclusions: Higher HD dose was associated with improved physical health in females, but lower HD dose was associated with improved mental health in participants with roles traditionally ascribed to women.

SA-PO046

Race and Ethnicity Do Not Influence the Performance of Fistula Failure Machine Learning Model

Suman K. Lama,[1] Joanna Willetts,[1] Caitlin Monaghan,[1] Sheetal Chaudhuri,[1] John W. Larkin,[1] Franklin W. Maddux,[1] Nwamaka D. Eneanya,[1] Michael A. Kraus,[1] Murat Sor,[2] Len A. Usvyat.[1] *[1]Fresenius Medical Care Holdings Inc, Waltham, MA; [2]Azura Vascular Care, Malvern, PA.*

Background: Risk stratification models are important decision support aids in medicine yet can inadvertently introduce bias if social factors, such as race and ethnicity, are included in models that predict biological outcomes. (Obermeyer et al., Science 2019). The inclusion of social factors in model development may not have a significant impact on model performance. In the development of a model to predict an arteriovenous fistula (AVF) failure event in a hemodialysis (HD) patient, we investigated the effect of inclusion/exclusion of race and ethnicity as predictor variables on model performance.

Methods: AVF failure was defined by the change from active to unusable status within 30 days. We built two machine learning (ML) algorithms (XGBoost) using HD patient data from Jan to Dec 2018 at large integrated kidney disease healthcare provider. Models were trained using demographics, treatment, laboratory, comorbidity, clinical notes, hospitalization data. Model A included race and ethnicity and Model B did not. Both models considered approximately 2,400 predictor variables. Dataset was randomly split into 60% training, 20% validation 20% testing data. Unseen testing data was used to evaluate the model's performance.

Results: Models were developed using data on approximately 67000 patients (approximately 14000 patients had events). Model A & B showed an area under the curve (AUC) of 0.76 vs 0.75, sensitivity of 0.53 vs 0.53, and specificity of 0.84 vs 0.84 respectively (**Figure 1**).

Conclusions: ML model performance was not affected by race or ethnicity data, suggesting they should be excluded from models of biological outcomes to minimize biases that could disproportionally classify risk and lead to disparities in care. Patient factors that may affect biology are critical to consider and validate during model development, and should span beyond race and ethnicity.

Funding: Commercial Support - Fresenius Medical Care

SA-PO047

Racial and Ethnic Differences in Arteriovenous Access (AVA) Use One Year After Hemodialysis (HD) Initiation with a Central Venous Catheter (CVC)

Melandrea L. Worsley, Jingbo Niu, Kevin F. Erickson, Wolfgang C. Winkelmayer, L Parker Gregg. *Baylor College of Medicine, Houston, TX.*

Background: Racial and ethnic differences exist in AVA use, which includes AV fistulas and grafts, at HD initiation. We evaluated temporal trends in racial/ethnic differences in AVA use and anatomic location 1 year after HD initiation among those who had initiated HD with a CVC.

Methods: Using data from a large dialysis organization (LDO), we identified patients who initiated HD with a CVC between 2006 and 2016 and who remained on HD with same LDO for 1 year. Race/ethnicity (hereafter referred to as race) was categorized as Black, Hispanic, White, & Other. The use of an AVA within 1 year after HD initiation was plotted by calendar year, Annual racial differences in proportions with AVA were assessed using logistic regression, adjusted for demographics and comorbidities, and changes over time were assessed using a race x calendar year interaction term. Anatomic locations of AVA were defined as lower arm, upper arm, or other/missing/multiple locations.

Results: Of 198,186 participants, 67,315 (34%) were Black, 31,711 (16%) Hispanic, 86,117 (43%) White, and 13,043 (7%) were of other races/ethnicities. Compared to White patients, Black, Hispanic, and Other patients were younger and less likely to have heart failure or peripheral arterial disease, whereas the Hispanic and Other groups were more likely to have diabetes than Black and White patients. From 2006 to 2016, use of an AVA within 1 year increased in all racial/ethnic groups (P<0.001), with race x calendar year interaction at P=0.01 (**Figure 1A**). Compared to White patients, Black patients had similar odds of using an AVA within 1 year, while those of Other race were consistently more likely and the Hispanic group was at times more likely than Whites. However, Black patients were less likely to use an AVA placed in the preferred location in the lower arm than the other groups (**Figure 1B**).

Conclusions: Although there has been an improvement in AVA use at 1 year after initiation of HD with a CVC in all racial groups, differences in AVA use and location remain and warrant further investigation.

SA-PO048

Sociodemographic Characteristics of Hemodialysis Patients Prescribed Sucroferric Oxyhydroxide and Other Phosphate Binders

Meijiao Zhou, Joanna Willetts, Linda Ficociello, Nwamaka D. Eneanya, Len A. Usvyat. *Fresenius Medical Care Global Medical Office, Waltham, MA.*

Background: Promoting health equity in the treatment of hemodialysis (HD) patients (pts) includes ensuring ready access to effective medications, regardless of an individual's sociodemographic characteristics (SDC). One such medication is sucroferric oxyhydroxide (SO), a brand-name phosphate binder (PB) that has demonstrated effectiveness in managing serum phosphorus with a lower pill burden. However, the cost of brand-name medication may limit its availability to certain pt populations. To address this issue, Velphoro Access Solution (VAS) was created as a program to explore available resources that make SO more accessible and affordable through the benefit investigation (BI) process. In 2022, > 56,000 BIs were submitted to VAS for Fresenius Kidney Care (FKC) pts. This study examines the SDC of HD pts prescribed SO and other PBs, to identify any disparities in SO access that may exist.

Methods: Adult HD pts from FKC with active prescription (Rx) of PBs (SO, ferric citrate, lanthanum carbonate, sevelamer, and calcium acetate) during 7/1/2022-12/31/2022 were included. Pts were divided into 2 groups: SO Rx (n=30,513) and other PB Rx (n=121,357). We described SDC such as age, gender, race, ethnicity, and insurance status.

Results: 20% of pts were prescribed SO. The average age of pts with SO Rx was 60, 4 years younger than those with other PB Rx. There was a 4% higher proportion of male (61% vs 57%) and African American (40% vs 36%) and 4% lower White (54% vs 58%) pts among those prescribed SO. The ethnic composition was similar in SO group and other PB group (Hispanic 18% vs 19%). A higher % of pts with commercial insurance (17% vs 14%) and Medicaid (47% vs 44%) but with lower % Medicare (34% vs 38%) were observed in those with SO compared to pts with other PB Rx.

Conclusions: In our analysis of FKC HD pts, we found a higher % of pts prescribed SO who were younger, male, African American, and insured by Medicaid or commercial coverage. Programs such as VAS may improve access and affordability of medications that are crucial for dialysis care.

Funding: Commercial Support - Fresenius Medical Care

Applying Sequence Analysis Techniques to Describe ESKD Patients' Treatment Histories

Jonathan Daw,[1] Léa Pessin,[1] Avrum Gillespie,[2] Catherine Butler.[3]
[1]Pennsylvania State University Department of Sociology & Criminology, University Park, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [3]University of Washington School of Medicine, Seattle, WA.

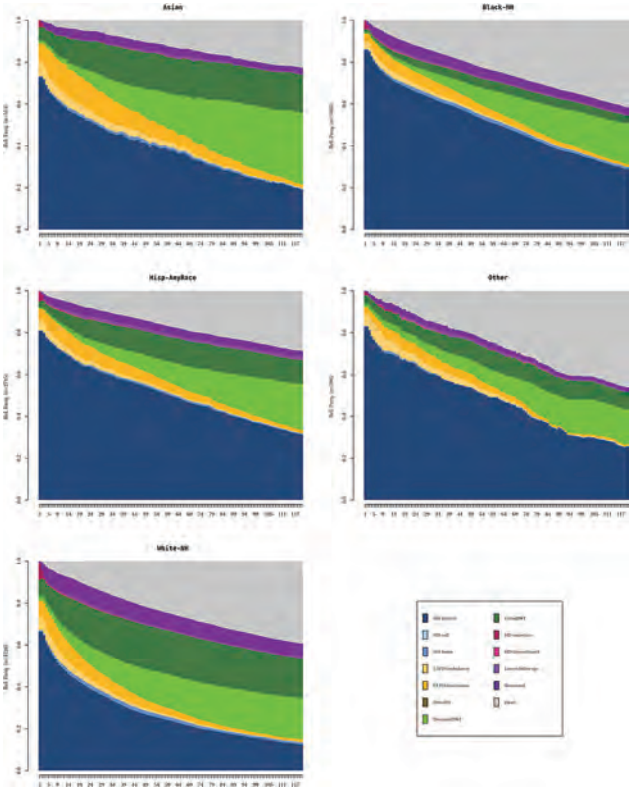
Background: Although outcomes for particular treatments for ESKD have been studied, characterizing full treatment sequences (including timing, order, and duration) for different racial/ethnic groups may offer deeper insights into patient experiences and outcomes.

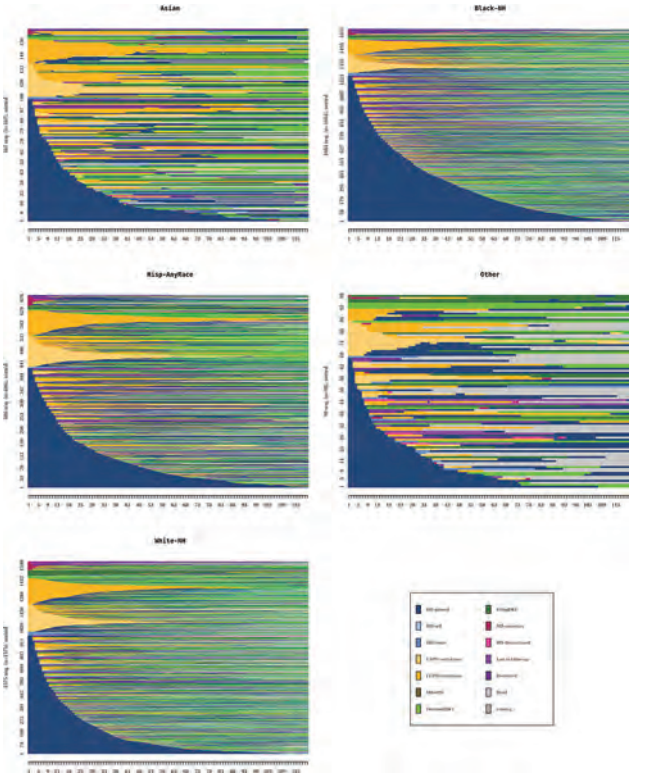
Methods: We study 10-year treatment sequences of the 2009 incident ESKD cohort age 18-44 in the USRDS. The state plot characterizes the distribution of treatments over time; the index plot traces individual patients' treatment sequences with one line per unique sequence.

Results: *State plot*: White and Asian groups exhibit higher rates of hemodialysis (especially CAPD and CCPD for Asians) and transplant. *Index plot*: More sequences for non-White patients involve uninterrupted hemodialysis than for White patients. More sequences for Black patients involve early loss to follow-up. White patients have more preemptive LDKTs than other groups. Significant shares of sequences for White, Hispanic, and Asian patients begin with CCPD/CCAD before transitioning to other treatments, but this is a smaller share of sequences for Black patients.

Conclusions: Sequence analysis techniques hold potential to more fully describe ESKD patient treatment histories and offer a new insight into racial/ethnic disparities.

Funding: NIDDK Support





SA-PO050

Switchers from Medicare Fee-for-Service Program to Medicare Advantage Early 2021 Among ESKD Patients

Jiannong Liu,[1] James B. Wetmore,[1,2] David T. Gilbertson,[1] Eric D. Weinhandl,[3] Kirsten L. Johansen.[1,2] *[1]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Satellite Healthcare, San Jose, CA.*

Background: Before 2021, Medicare beneficiaries with end-stage kidney disease (ESKD) were not permitted to switch from traditional Medicare (Medicare fee-for-service, MFFS) to Medicare Advantage (MA). However, starting in January 2021, beneficiaries were eligible to switch to MA, thanks to the 21st Century Cures Act. Using the United States Renal Data System, we examined differences between beneficiaries who continued with MFFS and those who switched to MA.

Methods: Adults (aged≥18 years) on dialysis or with a kidney transplant (ktx), with MFFS as primary payor, as of December 2020 were assessed for their Medicare coverage in January 2021.

Results: In total, 412,769 patients (pts) were included; 315,015 receiving dialysis and 97,754 with a ktx. Among dialysis pts, 11.5% switched from MFFS to MA (9.6% among home dialysis pts, 11.8% among in-center dialysis pts); 5.4% among Ktx pts. Those who switched were younger (median age for dialysis pts, switcher vs non-switcher: 61.3 vs 65.6 years; for those with a ktx, 62.4 vs 63.6). Pts who switched were also more likely to be non-Hispanic (NP)-Black or Hispanic (dialysis pts, NP-Black: 47.9% vs 32.7%; Hispanic, 17.8% vs 15.3%; ktx recipients, NP-Black, 37.3% vs 21.6%, Hispanic, 15.8% vs14.1%); and more likely to have dual Medicare and Medicaid coverage (dialysis, 51.7% vs 43.8%; ktx, 35.7% vs 29.1%). Those who switched were also more likely to have diabetes or hypertension as their cause of ESKD (Table).

Conclusions: In 2021, more than one tenth of pts with ESKD switched from MFFS to MA; switching was associated with age, race/ethnicity, and Medicaid enrollment. This shift alters the generalizability of the MFFS population with ESKD, and heightens the need for monitoring of outcomes among patients enrolled in MA.

Funding: NIDDK Support

Characteristics of Migrant and Non-Migrant ESRD Patients in Nepal

Shailendra Sharma,[1] Yoko Inagaki,[2] Rishi K. Kafle,[3] Sweta Koirala,[4] Nasatya Khadka,[4] Pooja K.c.,[4] Kristina M. Jakobsson,[5] Jason R. Glaser,[6] Catharina Wesseling,[6] Dinesh Neupane.[2] *[1]Sparrow Health System, Lansing, MI; [2]Johns Hopkins University, Baltimore, MD; [3]National Kidney Center, Kathmandu, Nepal; [4]Nepal Development Society, Pokhara, Nepal; [5]Goteborgs universitet Sahlgrenska Akademin, Goteborg, Sweden; [6]La Isla Foundation, Ada, MI.*

Background: Thousands of young Nepali migrant workers have died and many developed ESRD while working abroad. Although the etiology of kidney disease is yet to be established, exposure to recurrent heat stress is identified as a potential risk factor.

Methods: Cross-sectional study was conducted in 2 dialysis centers. Patients 18-80 yrs of age getting incenter hemodialysis were sampled. Questionnaire with migration and occupational history was administered.

Results: A total of 354 patients were included (mean age 46.5 ±13.9 yrs; 36% female). 31% were returnee migrant workers (88% male; 83% worked in the Gulf States, Malaysia, & India). The median duration of work abroad was 14 yrs (IQR 9-18) & >50% returned due to health problems. 50% of returnee migrant workers were <40 yrs old, compared to 30% of non-returnee migrant workers (P<0.001). A lower prevalence of diabetes (12% vs 24%; P=0.009) & immunologic diseases (5% vs 14%; P=0.022) were observed among returning migrants. Returnee migrants experienced extreme workloads (36%), no breaks (37%), & exhaustion (68%). Among those who reported heat exposure at work, 70% were exposed daily.

Conclusions: The findings provide meaningful information on potential risk factors for CKDnT. These results underscore the importance of conducting further studies to better understand & address the specific risks & challenges they face.

Funding: Private Foundation Support

Table 1: Participants characteristics

	All	Returnee Migrant Workers	Non-Returnee Migrant Workers	P-value
Age, mean (SD)	46.5(13.9)	43.1 (11.2)	47.9 (14.6)	0.003
Age < 40, n (%)	128 (36.2%)	54 (49.5%)	74 (30.2%)	<0.001

Assessment of Dialysis Operations in Conflict-Affected Areas: Insights from Survey Results from Northwest Syria

Sami Alasfar,[1] Hani S. Alashawi,[4] Lina Murad,[3] Gilbert M. Burnham.[2] *[1]Mayo Clinic Arizona, Scottsdale, AZ; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]Metropolitan Access Center, Bretnwood, MD; [4]The Health Cluster, Gaziantep, Turkey.*

Background: In areas affected by armed conflict, the opertions of hemodilayis (HD) are hindered by the lack of required infrastructure. Despite the growing prevalence of kidney disease, humanitarian agencies have given little attention to HD in such situations. Northwest (NW) Syria is an example of such a conflict-affected region where approximately 800 patients rely on HD provided by non-governmental agencies (NGOs).

Methods: We conducted a survey conisting of 346 questions to assess HD operations in NW Syria. Onsite visits were made to interview HD facilities managers and technicians, and the data was collected during these visits. The survey covered various areas related to HD operations, including current infection and prevention and control practices, medical protocols, built environment, health care worker competencies, equipment maintenance, dialysis unit management and leadership, and record keeping.

Results: Answers to selected questions of the survey are in tables 1&2.

Conclusions: In regions affected by conflict, there are significant deviations from the standards of HD operations, highlighting the need for an action plan that involves NGOs responsible for administering HD, in order to implement and maintain minimal standards for HD.

Table 1: Answers to selected survey questions about Infection Prevention and Control (IPC) practices

Item		Result
Presence of IPC Protocol		
IPC Protocol present		7/14 (50%)
Presence of IPC Advisor		5/14 (36%)
Key Components of IPC		
Hepatitis B and C testing		6/7 (85%)
Effective cleaning & disinfection of equipment		6/7 (85%)
IPC Training		
IPC Training in the last 12 months		8/14 (43%)
Training on accessing dialysis access		6/8 (75%)
IPC Surveillance		
Process to review surveillance results		4/7 (57%)
Frequency of screening for Hepatitis B and C	Every 3 months Every 6 months	2/14 (14%) 11/14 (79%)
IPC Implementation		
Hepatitis B patients undergo hemodialysis in isolation		8/14 (57%)
Staff who are not vaccinated for Hepatitis B are allowed to administer dialysis to patients with Hepatitis B		2/14 (14%)
Staff caring for hepatitis B positive patients are allowed to care for hepatitis B negative patients at the same time		12/14 (86%)
IPC Monitoring		
Regular assessment of prevalence of infections		8/14 (57%)
Written procedures to examine infection control practice once a patient is found to have hepatitis B or C or if there in an infection outbreak		2/14 (14%)
Built Environment and Supplies		
The design of the unit follows a national or international guideline for dialysis units		3/14 (21%)
IPC records		
IPC Training Records	Yes No No training received	4/14 (29%) 4/14 (29%) 6/14 (43%)
Records of patients' hepatitis B vaccination		3/14 (21%)

Primary Caregiver Burden in a Mexican Hemodialysis Facility: Prevalence and Risk Factors

Edgar Solis, Sergio Hernández-Estrada. Medica Santa Carmen. *Médica Santa Carmen, Guanajuato, Mexico.*

Background: Caregiver burden is a subjective interpretation of resources, abilities and impact of caregiving process. A validated Zarit survey has been recommended among caregivers in patients with HD.

Methods: Primary HD caregivers from a single facilitie in Mexico responded a validated Zarit survey. Incident patient and caregivers (< 3 months) were excluded. Social and demographic caregiver data also included. Descriptive, linear regression and coef. correlation analysis was done.

Results: 86 primary caregivers answered: Most females with a mean age of 47. Housewives 43% was the main occupation. Couples take care of patients in 42%. Median monthly income 220 dlls. We identified burden in 54%: slight 32% and severe 68%. Female sex and unemployees predicts higher scores. A non-significative negative correlation was found between income and score.

Conclusions: Caregiver burden is prevalent. Economic difficulties exacerbate complexity and caregiver burden. Results should be added to public health burden of ESRD in Mexico.

Caregiver factors and Zarit Score - Linear regression analysis

Variable	Coef	IC (95%)	p value
Female sex	11.01	(1.51 - 20.52)	0.02
Unemployee	27.64	(10.44 - 44.84)	0.002
Caregiver age	-0.33	(-0.61, -0.04)	0.02
Monthly income	-0.001	(-0.003 - 0-000)	0.01

Adjusted by caregiver age, illness, sleeping hours, life spent caring, patient-caregiver relation, meals a day, social security.

General Characteristics	n = 86
Age, mean (SD)	47 ± 15
Female, n (%)	66 (77)
Sleep hours	6.5 ± 1.6
Monthly Income, median (dlls)	220 (132 - 453)
Marital Status	
Married	66 (77)
Single	11 (13)

Increasing Home Dialysis Among Spanish-Speaking Mexican American Patients: Challenges and Opportunities

Karen-Marie Eaton,[1] Steven M. Brunelli,[1] Danelle Radney,[2] Unini Odama,[2] Francesca Tentori.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Home dialysis offers patients another treatment option for kidney failure. Since home dialysis use is lower in Mexican American patients, in this study we sought to understand experiences and uncover influencing factors and barriers that patients and care partners face.

Methods: A total of 28 participants (Mexican American patients at a dialysis provider, both in-center and home, and their care partners) were recruited to join in-person focus groups held in December 2022. Focus groups were audio and video recorded and transcribed verbatim. Groups were held in Spanish language, translated in real time by a certified interpreter, and transcribed in English. Responses were analyzed using inductive thematic analysis.

Results: Patients reported that physicians did not make a clear connection between poor management of underlying health conditions and kidney failure; this led to difficulty accepting a kidney failure diagnosis and need for dialysis. Patients and caregivers want improved education in English and Spanish to help make the initial modality decision. Physician guidance was cited as the most important factor in the initial modality decision for Mexican American patients and care partners. Trust in physician recommendation is largely unquestioned, influenced by factors such as respect for physician authority, limited literacy, and language barriers. While most patients and care partners acknowledge the benefits of home dialysis, significant barriers included the fear of being solely responsible for a complex procedure and loss of social interaction and/or support from other dialysis patients and center staff. Unsurprisingly, care partners are a critical part of the decision to choose home dialysis. Faith plays a significant role for many respondents; many speak about their experience of disease in faith-based terms, such as trusting God.

Conclusions: Opportunities exist to build on the strong patient preference for physician led health information, and to focus on decreasing literacy and language barriers in the Mexican American population.

SA-PO055

Disparities in Home Dialysis for Latinx People with Kidney Disease: A National Qualitative Study of Dialysis Social Workers

Katherine M. Rizzolo,[1,2] Lilia Cervantes.[2] *[1]Boston Medical Center, Boston, MA; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Latinx people have a 2.1 fold higher incidence rate of kidney failure compared to non-Latinx White individuals, yet are less likely to use home dialysis. This discrepancy has not been completely explained by medical, socioeconomic, or demographic variables. Improving access to home dialysis is a priority of the Advancing American Kidney Health Initiative, a 2019 executive order to transform kidney disease care for individuals in the US. Dialysis social workers play a crucial role in home dialysis assessment and education. In this study, we utilized qualitative interviews with dialysis social workers across the US to better understand the facilitators and barriers to home dialysis for Latinx patients with kidney failure.

Methods: We conducted a qualitative study with adult (age >18) dialysis social workers in the US with experience working with Latinx populations. The semi structured interview guide included open ended questions exploring dialysis modality education, dialysis decision making, and home dialysis uptake and maintenance. Interviews were audio-recorded, transcribed verbatim, de-identified and transcripts were analyzed independently by two members utilizing thematic analysis.

Results: We interviewed 20 dialysis social workers from ten different states, with a median age range of 30-40 (35%), 100% female, 14 (70%) identified as White and 5 (25%) of participants spoke Spanish. Participants described five themes affecting home modality access for Latinx people: 1) Variation in modality education 2) Evaluating candidacy for home dialysis 3) Role of language and communication 4) Facilitators to home dialysis and 5) Barriers to home dialysis (Table).

Conclusions: Our study illustrates early language and culture concordant education is critical for home modality uptake amongst Latinx people with kidney disease. Involving the social worker early in the home dialysis is critical for evaluating for important issues that may affect home dialysis treatment.

Funding: NIDDK Support

Theme	Sub themes	Illustrative quote
Variation in home modality education	-Standardized modality classes -Forms of educational materials -Role of the social worker -Early and frequent education	- As a social worker get very frustrating when you try to advocate for change and try to get things that are systemic fixed and it's just barrier after barrier, after barrier. - I think it's being able to see it like the pictures help more and not just talking about it.
Evaluating candidacy for home dialysis	-Assessment of barriers to home -Overcoming structural barriers -Housing and space -Insurance and financial barriers	- When I talk to them in Spanish, I tend to find out that they are here undocumented, that they are working under the table, that they're getting paid in cash, that, you know, they share a room with ten other people or whatever it is to be here. - I wish it was more equitable, accessible to everyone despite where they come from.
Language and communication	-Experience with interpreters -Clinician-patient communication barriers -Language concordant staff -Working with illiterate patients -Gender differences in communication	- I am bilingual. So, I think that helps, because even though I am Caucasian speaking Spanish, I think it just gives you that added layer of rapport and trust. - I think the men are definitely more guarded. That's normally who has the trust issues with providers and the medical system as a whole. But if they are younger and they lose their job and their wife is the primary breadwinner at that point, you can definitely see depression and just feeling the loss of worth.
Facilitators to home dialysis	-Family support -Culture concordant care -Importance of trusting relationships - Supportive clinic environment -Patient activation - Motivation for autonomy	- I think it speaks about a lot of our families, right there. Is there a grandparent in the home, they come living with their children and grandchildren, like a lot of our Hispanic families are multi-generational. - The community outreach is really important, in certain areas, certain neighborhoods rather, there's more of population of Latinx, and the community being able to reach out to their neighbors if they know someone who also has kidney disease requiring them to have dialysis, then there's some camaraderie there, I have found that to be the case.
Barriers to home dialysis	-Responsibility is overwhelming -Health literacy and language incongruency -Fear and isolation -Burden on family -Misinformation amongst Latinx community -Transition from in-center	- Fear around being responsible for this treatment has been one really big one. Not wanting people in their house. You know, wanting to be more private about their living situation has been another really big one. - One of the experiences I've had is that a lot of times they talk to each other, it's a small community tight-knit, so if one person has a bad experience, it gets spread to everybody else that it has been poor for that patient.

SA-PO056

Racial and Socioeconomic Differences in Success on Home Dialysis

Catherine A. Moore,[1] Catherine W. Liu,[1] Justin C. Weissberg,[1] Tramanh Phan,[1] David Skrill,[1] Sai Subhodhini Reddy,[1] Veronica G. Yu,[2] Eliot Sachsenmeier,[3] Hongmei Yang,[1] Scott E. Liebman.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]Swedish Cherry Hill, Seattle, WA; [3]New York University, New York, NY.*

Background: Home dialysis offers several advantages to patients and health care systems including improved patient-centered outcomes, lower cost, and equal if not better clinical outcomes. Despite this, utilization of home dialysis remains low. Although home dialysis is not always the ideal modality for patients with End Stage Renal Disease (ESRD), most dialysis patients are viable candidates for this modality. Variance in home dialysis underutilization falls along both racial and socioeconomic lines, with lower home dialysis utilization by racial and ethnic minorities and higher rates among black individuals of transfer to in-center dialysis. Provider fear of adverse outcomes and home dialysis failure remains a barrier to home therapy referral. We investigated whether markers for sociodemographic stress would predict success on home therapy.

Methods: We performed a retrospective cohort study of adult incident ESRD patients from January 1 2015 through December 31 2021 admitted to providers within the University of Rochester division of nephrology (N= 898, including 794 in-center hemodialysis, 39 home-hemodialysis and 65 Peritoneal dialysis) with observation period ending December 31, 2021. Using cox proportional hazards model, we compared race to social deprivation index (derived through Census Tract) as predictors for home dialysis failure (defined by conversion to in-center dialysis or death).

Results: Black and African American patients were more heavily represented amongst subjects starting in-center HD (31% vs 16.3%). There was no significant difference between mean social deprivation index (SDI) or Charlson co-morbidity index (CCI) scores in subjects starting in-center compared to at home. Over the observation period, 128 subjects performed home dialysis for a mean of 45 months. None of the variables evaluated were predictors of success on home therapy (age, sex, race, SDI or CCI).

Conclusions: Despite similar markers of medical co-morbidity and sociodemographic stress, fewer non-white patients started dialysis on a home modality compared to in-center. Neither social deprivation nor race predicted success on home therapy. This highlights a disparity in the initial referral process to home therapy which is not supported by commonly cited predictors of adverse outcome.

SA-PO057

Disparities in Home Dialysis Utilization Among Dual Eligible Medicare Fee-for-Service (FFS) Beneficiaries

Emily Belowich, Jack Fagan, Shalini Parekh, Mark J. Gooding. *Avalere Health, Washington, DC.*

Background: Since the 2019 Advancing American Kidney Health (AAKH) initiative, the federal government has focused on enhancing prevention and treatment of kidney disease, including introducing new incentives for home dialysis use for patients who require renal replacement therapy. Access to optimal kidney care services influences greater mortality and morbidity rates. We hypothesized that patients with lower socioeconomic status may have lower use of home dialysis due to the nature of what is required to access this dialysis modality (e.g., health literacy, caregiver support, proper home infrastructure).

Methods: We used 100% Medicare Fee-For-Service (FFS) claims data to identify patients with End Stage Renal Disease (ESRD) who received renal replacement therapy (peritoneal dialysis and hemodialysis) excluding beneficiaries who have received a kidney transplant between January 2019 to June 2022. We stratified beneficiaries by Medicaid dual eligibility status.

Results: Between Q1 2019 – Q2 2022, the rate of home dialysis utilization grew from 12.3% to 15.9% across all Medicare FFS beneficiaries. In Q2 2022, 12.0% of 113,226 dual-eligible beneficiaries utilized home dialysis compared to 19.7% of 115,497 non-dual eligible beneficiaries utilizing home dialysis ($p<0.01$). This difference in utilization

was consistent across the period of analysis; the rate of non-dual eligibles utilizing home dialysis was 7.7 percentage points higher than dual eligible beneficiaries in Q1 2019 and 7.4 percentage points higher in Q1 2022.

Conclusions: The AAKH initiative – compounded by the COVID-19 pandemic – served as a catalyst to advancing home dialysis. However, these findings indicate that access to care is still greatly influenced by socioeconomic status, even with policy changes that intentionally aim to close disparity gaps. Future research and policy should seek to identify how disparities in socioeconomic status and associated challenges can be addressed to allow for equitable access to all treatment modalities for ESRD.

Rates of Unique Medicare FFS Patients with a Home Dialysis Service in the Given Quarter

Social Determinants of Health and AKI During Hospitalization

Tomonori Takeuchi,[1] Lama Ghazi,[1] Elizabeth H. Baker,[1] Gabriela R. Oates,[1] Lucia D. Juarez,[1] Ariann F. Nassel,[1] Akm F. Rahman,[1] Edward D. Siew,[2] Orlando M. Gutierrez,[1] Javier A. Neyra.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Vanderbilt University, Nashville, TN.*

Background: AKI is highly prevalent in hospitalized patients. Social determinants of health (SDOH) have been understudied as AKI risk factors. Our goal was to determine whether SDOH impacts AKI risk and AKI recovery during hospitalization.

Methods: Retrospective cohort study of patients aged ≥18 years without end-stage kidney disease admitted to the hospital from 10/2014 to 9/2017. Outcome measures were (1) Incident AKI defined by the KDIGO SCr-criteria and (2) AKI recovery defined as last SCr before discharge <25% or <0.3 mg/dL from baseline and not receiving dialysis within 72 h of discharge in patients who survived the hospitalization. We linked geocoded patient addresses at the index hospitalization to the corresponding U.S. Census tracts and block groups and the following SDOH measures: (1) neighborhood socioeconomic status measured with Area Deprivation Index (ADI) scores, (2) food access measured with Low Income Low access (LILA) scores, (3) rurality measured with Rural Urban Commuting Area (RUCA) scores, and (4) residential segregation measured with dissimilarity and isolation scores. Multivariable logistic regression was used to quantify the association between SDOH measures, each independently, and AKI development and recovery.

Results: Out of 26,769 patients, 6,976 (26%) developed AKI during hospitalization. Compared to those who did not develop AKI, patients who developed AKI were older (60 [47,71] vs 57 [47,68] years), more likely to be men (55 vs 50%), and more likely to be Black (38 vs 33%). Patients who lived in the highest tertile for ADI (most disadvantaged) were more likely to develop AKI during hospitalization even after adjustment (Table). In the fully adjusted model, Patients who lived in the highest tertile of ADI and in a LILA tract were less likely to have AKI recovery at the time of discharge (OR 0.85 [0.72,0.99] and OR 0.86 [0.74,0.99]). Rurality and residential segregation were not associated with incident AKI or AKI recovery.

Conclusions: Patients in the highest tertile of neighborhood disadvantage were more likely to develop AKI and less likely to recover.

Funding: NIDDK Support

Table: Association of SDOH measures with incident AKI in hospitalized patients

Health-Related Social Needs During the COVID-19 Pandemic in the Chronic Renal Insufficiency Cohort (CRIC) Study

Tessa K. Novick,[1] Michelle M. Osuna-Diaz,[1] Jeanne Charleston,[2] James P. Lash,[3] Lawrence J. Appel,[2] Debbie L. Cohen,[4] Natalie Meza,[3] Angela Allen,[4] Deidra C. Crews.[2] *[1]The University of Texas at Austin, Austin, TX; [2]The Johns Hopkins University School of Medicine, Baltimore, MD; [3]University of Illinois Chicago, Chicago, IL; [4]University of Pennsylvania, Philadelphia, PA.*

Background: Health-related social needs, such as housing and food insecurity, are associated with risk factor control and care engagement among people with CKD. Social needs were exacerbated for many during the COVID-19 pandemic.

Methods: Questionnaires on social needs (housing insecurity, food insecurity, and transportation and utility issues) were administered to participants from three sites of the CRIC study from 2020 to 2023. We examined the prevalence of social needs, and used multivariable logistic regression to identify correlates of social needs.

Results: Among 600 participants, 122 (20%) experienced ≥1 social need, and 29 (5%), 61 (10%), 67 (11%), and 22 (4%) reported housing insecurity, food insecurity, transportation and utility issues, respectively. Compared to participants without social needs, those reporting ≥1 social need were more likely to be female (63% vs 43%) and Hispanic/Latino/a/x (27% versus 23%), and less likely to have a college education (21% versus 42%) (Table).

Conclusions: Among CRIC study participants, Black and Hispanic/Latino/a/x individuals and females were more likely to experience health-related social needs during the COVID-19 pandemic. Associated long-term outcomes are worthy of investigation.

Funding: NIDDK Support

Food Security in Jamaicans with CKD Following the COVID-19 Pandemic: A Pilot Observational Study

Lori- Ann M. Fisher, Marshall K. Tulloch-Reid. *The University of the West Indies, Kingston, Jamaica.*

Background: Limited data exists on food security amongst persons with chronic kidney disease (CKD) in the Caribbean, especially since the onset of the COVID-19 pandemic. We describe the prevalence of food-insecurity in persons living with CKD from a single centre in Jamaica.

Methods: A cross-sectional survey was conducted between December 1,2022 and March 31, 2023 among 18 and 74 year old patients attending the University Hospital of the West Indies renal clinic prior to the onset of the pandemic (March 2020) and who were not on dialysis. Informed consent was obtained from patients who agreed to share their contact information with the study team prior to enrolment. A telephone administered questionnaire that included details on demographics, food security and health care utilization was administered by trained interviewers. Data on cause of CKD, creatinine values at each clinic visit, and hospital and emergency room visits were abstracted from hospital records. Self-reported food insecurity was based on responses to a standard Centers for Disease Control questionnaire. Means and standard deviations were used to describe continuous variables, whilst proportions were used to describe categorical data.

Results: 43 participants [51.4±14.8 (mean ±SD) years, 72% female] were included. The majority (32%) had CKD Stage 3 disease, with 11% with CKD Stage 4 and 2% with CKD Stage 5. CKD was attributed to diabetes/hypertension in 30% of persons, lupus in 25%, and sickle cell disease in 28%. The majority (84%) had at least high school education and 35% were either retired or unemployed. Food insecurity was reported by 42 (95% CI=28-59)% of participants before the pandemic and 52(36-68)% during the pandemic. Less than half (46%) of patients had one or more hospitalizations or emergency room visit during the covid pandemic. There was no difference in mean age between food secure and insecure(52.1 versus 48.2 years, p=0.238) but a higher proportion of women reported food insecurity (61 versus 27%, p=0.05) during the pandemic. There was no statistically significant association between hospitalization or emergency room visits and food insecurity (p=0.169).

Conclusions: There was a high prevalence of food insecurity in the patients with CKD evaluated. Larger studies are needed to examine how this impacts health care outcomes and utilization in the region.

Area Deprivation Index and Spanish Language Are Barriers to Equitable Nephrology Care in a Hispanic Pediatric Subspecialty Cohort

Carlos C. Becerril Romero, Alexander J. Kula, Priya S. Verghese, Debora Matossian. *Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Hispanics are the largest population of Chicago youth and they have an increased risk and rate of chronic kidney disease progression. Addressing healthcare disparities in Hispanic patients is important to improve health outcomes. This study aims to understand the impact of language and socioeconomic disadvantage on access to care in Hispanic patients seen in pediatric nephrology clinics.

Methods: All patients that identified as Hispanic seen in Lurie Children's Hospital nephrology clinic between January and June 2021 received the validated tool "Barriers

to Care Questionnaire" to assess healthcare access. Parents or patients older than 18 completed the survey in their preferred language. A score of 100 equates no barriers to care, and a score < 75 equates a failed score due to high barriers. We also collected sociodemographic data and the Area Deprivation Index (ADI), a metric of socioeconomic disadvantage that incorporates 17 socioeconomic measures. The national ADI score ranges from 1 (most advantaged) to 100 (most disadvantaged). We created linear regression models to describe the association between barriers and ADI scores and tested for interactions based on language.

Results: In 109 surveys (49% Spanish, 51% English), we identified high skills and pragmatic barriers to care, with mean (+/-standard deviation) scores of 74 (+/-26) and 75 (+/-21), respectively. The mean ADI score was 55 (+/-20). Spanish-speaking families had higher skills barriers (p<0.001); no difference in pragmatic barriers (p=0.40*)* and mean ADI score (p=0.38). A higher ADI score correlated with higher total barriers (p=0.006*)* and significant interaction effect by language (p=0.04).

Conclusions: Hispanic youth in Chicago face significant barriers to accessing nephrology care. Spanish-speaking patients with higher socioeconomic disadvantages struggle to navigate the healthcare system. Findings indicate the need for a diverse and multicultural team to support Spanish-speaking families. Prospective studies are necessary to advocate for programs and policy changes to address these barriers and reduce racial and ethnic disparities in pediatric nephrology care.

SA-PO062

Impact of Social Determinants of Health on the Prevalence of CKD in Jalisco, Mexico

Alexia Romero, Andres E. De la Torre Quiroga, Guillermo Garcia-Garcia, Jonathan Chavez, Juan Gómez Fregoso, Clementina Elizabeth Calderon Garcia, Manuel Arizaga Napoles. *Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: Social determinants of health have been linked with disparities on the incidence and prevalence of CKD. In Mexico, CKD has become an important public health problem; current guidelines recommend routine CKD testing in patients at increased risk. We report the impact of social determinants of health on the prevalence of chronic kidney disease in Jalisco.

Methods: Between 2006-2019 we screened people at risk for the presence of CKD using mobile units that traveled to rural and urban communities of Jalisco. Trained personnel collected demographic and clinical data and obtained blood and urine for serum chemistry and dipstick urinalysis. Individuals who were aware they had kidney disease were not assessed; all others were eligible to participate. GFR was estimated with the EPI-CKD formula. CKD was defined as an eGFR < 60 ml/min/1.73 m2.

Results: Between 2016-2019, 63,918 individuals were evaluated. Findings in individuals with CKD and without it were compared. CKD was more prevalent among individuals without schooling (p=< 0.001), homelessness (p=0.003), unemployed (p< 0.001) and lacking health care insurance (p<0.001) (Table 1). By multivariate analysis, illiteracy (OR 1.10, 95% CI 1.01-1.21, p=0.04) and lack of health care insurance (OR 1.12, 95% CI 1.04-1.19, p 0.001) independently increased the risk of CKD.

Conclusions: Social determinants of health were associated with a greater prevalence of CKD in our population. Our findings suggest that interventions addressing the social determinant factors are needed in individuals with CKD.

Table 1.- Demographics characteristics of the participants.

	CKD n = 5,868 n (%)	no-CKD n = 58,050 n (%)	p
Age (years)	65.9 ±13.4	48.6 ±14.4	<0.001
Female gender	4,340 (74.0%)	36,914 (63.6%)	<0.001
DM	1,868 (31.8%)	10,232 (17.6%)	<0.001
HTA	3,146 (53.6%)	14,645 (25.2%)	<0.001
eGFR (ml/min/1.73m2)	48.9 (11.2)	88.0 (16.0)	<0.001
Illiterate	792 (13.5%)	2,689(4.6%)	<0.001
Homeless	105 (1.8%)	763 (1.3%)	0.003
Unemployed	3,075 (52.4%)	19,695 (33.9%)	<0.001

SA-PO063

Mesoamerican Nephropathy: Opening New Horizons

Carmen L. Cajina Aguirre,[1] Carlos A. Marín,[2] Anna Strasma.[3] *[1]The University of Kansas Medical Center, Kansas City, KS; [2]Hospital Monte España, Managua, Nicaragua; [3]Duke University, Durham, NC.*

Introduction: Mesoamerican nephropathy is a chronic kidney disease of significant importance in Central America. It mainly affects young men in the agricultural field from the Pacific Coast of Nicaragua, and a prevalence of up to 42% has been described in this population. The precise etiology of Mesoamerican Nephropathy (MeN) still remains a mystery.

Case Description: A 37-year-old male from an urban area, who works in construction, with no personal history of hypertension, diabetes, or autoimmune diseases, presents with edema and fatigue. Creatinine levels of 16.5 mg/dL and BUN of 78 mg/dL were observed. Physical examination revealed normal blood pressure and hyporeflexia. Significant laboratory findings included uric acid: 10.6, potassium:3.1 mmol/l, sodium: 134 mmol/l, urinalysis showing proteinuria lower than 0.7 g/dL, and urate crystals. Imaging findings were consistent with CKD. Considering his place of origin and occupation, which expose him to thermal stress and repetitive episodes of dehydration, and in the absence of other causes that could explain the CKD, the first differential to be considered is MeN. Histopathological studies are not feasible for diagnostic confirmation. According to case definitions, this patient can be classified as a probable case of MeN. The patient initiated renal replacement therapy with hemodialysis in a 3-session-per-week schedule, resulting in significant improvement of the clinical condition.

Discussion: The high risk of CKD in agricultural workers in warm areas of Central America has been previously described. However, a high prevalence (12.1%) has also been reported in other occupation with high temperature expose. MeN diagnosis still remains a challenge due to the lack of access to histopathological diagnosis confirmation in the healthcare system. This clinical case allows us to consider other occupation and geographical locations as possible risk factors for the occurrence of MeN. Priority and urgent actions to contain the advancement of this disease should be focused on early diagnosis and prevention in high-risk areas and occupations. It is important to expand the study of MeN to other occupations that share exposure to high temperatures. The economic and health impact of MeN should be mitigated with diagnostic and treatment strategies, as well as expanded research funding for other occupations.

SA-PO064

Geographic Disparities in the Rate of Major Adverse Kidney Events Among Patients with CKD in Alberta

Joseph Lunyera, Feng Ye, Stephanie E. Thompson, Kailash K. Jindal, Scott Klarenbach, Aminu K. Bello. *University of Alberta, Edmonton, AB, Canada*.

Background: Individuals in rural communities in Alberta disproportionately experience adverse health outcomes. Characterizing temporal trends in the incidence of major adverse kidney events (MAKE) by geographic characteristics could identify inequities in the management of CKD that can guide policy action.

Methods: We quantified the annual incidence of MAKE in Alberta from 2003-2019, overall and by geographic characteristics of patients' residential zip codes, using routine healthcare data available in the Alberta Kidney Disease Network (AKDN) database. CKD status for cohort eligibility was ascertained based on outpatient eGFR and defined as 2 eGFR values <60 ml/min/1.73m^2 at least 60 days apart; patients entered the cohort on the date of the second qualifying eGFR measurement. MAKE was defined as all-cause death or kidney failure (i.e., chronic dialysis, transplant or sustained eGFR <15 ml/min/1.73m^2) and assessed as the annual proportion of patients with the event from April 1 to March 31. Temporal trends in the rate of change of MAKE were estimated using linear regression.

Results: Among 262,392 patients (median age 75 years; 56% female), the overall incidence rate of MAKE decreased from 7.3% between 2003 and 2004 to 6.5% between 2018 and 2019; and the corresponding rate of change in the annual incidence of MAKE was -0.08 (95% confidence interval -0.10 to -0.06). There was an excess incidence rate of MAKE in rural vs urban locations between 2003 and 2004 (8.7% vs 7.4%); however, this excess rate was attenuated between 2018 and 2019 (6.7% vs 6.5%). Likewise, the excess incidence rate of MAKE in residential locations >100 km vs ≤50 km from the nearest nephrology center between 2003 and 2004 (9.3% vs 6.8%) was substantially reduced between 2018 and 2019 (6.5% vs 6.4%).

Conclusions: Disparities in incident MAKE by geographic characteristics of patients in Alberta have improved over the last 2 decades. Future studies exploring factors (e.g., CKD care indicators, population mix) that might have contributed to these noticeable improvements are needed for development of policy interventions to optimize CKD outcomes equitably for all patients.

Searching for Significance in Oceania: A Voyage of Recurrent FSGS in a Patient from the Marshall Islands with Variants of Uncertain Significance

Salvatore E. Mignano,[1] Rhiana L. Lau,[2,3] Christie H. Izutsu,[4,3] Lisa Kim.[4,3] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Kapiolani Medical Center for Women and Children, Honolulu, HI; [3]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [4]Queen's Medical Center, Honolulu, HI.*

Introduction: The success of next generation exome sequence analysis has dependency on clinical and pathologic phenotypic correlation. There is a gap in knowledge of genetic variants in glomerulopathy unique to those referred to the Pacific Basin's single adult organ transplantation program. The effects of the U.S. Nuclear Weapons Testing Program (USNWTP) in the Bikini Atoll between 1946-1958 with aggregate detonation of "7,200 Hiroshima atomic bombs" are unknown for the relocated inhabitants. We present a case of recurrent FSGS with unusual mesangial IgM predominant deposits and associated variants of uncertain significance.

Case Description: The patient is a 21 year old female from the Marshall Islands with history of deceased donor renal transplant 3 years prior who presents with increased proteinuria. Renal biopsy showed no evidence of rejection but segmental sclerosis with IgM positivity in a membranoproliferative pattern along with diffuse mesangial C4d positivity with electron dense deposits (Figure 1). Review of history showed she was diagnosed with FSGS on biopsy in the Philippines at age 16 then relocated to Honolulu, Hawaii where she was evaluated by pediatric nephrology. Results from KidneySeq^{tm}v3.0 (Figure 2) revealed heterozygous variants of uncertain significance. Two were in XPO5 (exportin-5), variants of which have been associated with autosomal recessive FSGS, one in NPHS2 (podocin), and a variant in CUBN, a receptor on intestinal mucosa with high affinity binding to APOA1/HDL and intrinsic factor-vitamin B12.

Discussion: We demonstrate the possibility of a recurrent glomerulopathy due to circulating factor rather than donor related disease. VUS analysis must be made alongside biopsy phenotype correlation for greatest benefit. Patients most in need of equity in health and technology must also be included in gene variant databases.

Climate Change and Sustainability in Kidney Care in Canada: A Knowledge, Attitudes, and Practices (KAP) Survey by the Canadian Society of Nephrology's Sustainable Nephrology Action Planning Committee

Isabelle Ethier,[1,2] Ahmad R. Tarakji,[4,5] Caroline E. Stigant.[3,6] Canadian Society of Nephrology - Sustainable Nephrology Action Planning Committee. *[1]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [3]Royal Jubilee Hospital, Victoria, BC, Canada; [4]St. George Medical Center, Kitchener, ON, Canada; [5]McMaster University, Hamilton, ON, Canada; [6]The University of British Columbia, Vancouver, BC, Canada.*

Background: Climate change impacts kidney health while threatening the stability of kidney care delivery systems, while health care itself has a significant environmental impact. Knowledge and attitude of Canadian kidney care providers toward climate change is unknown, and there are limited published data on environmental sustainability measures in kidney care in Canada. This study aimed to (1) assess knowledge and attitude about climate change among Canadian kidney care providers; (2) establish the current state of kidney care sustainability activities in Canada.

Methods: An electronic KAP survey, created by the Canadian Society of Nephrology – Sustainable Nephrology Action Planning (CSN-SNAP) committee, was distributed to kidney care providers across Canada.

Results: A total of 386 individuals completed the survey, while an additional 130 incomplete answers were provided. Most respondents (79%) identified as women and 26%, 31% and 26% were aged 30-39, 40-49 and 50-59 years, respectively. Consultant nephrologists and kidney nurses comprised 23% and 44% of respondents, respectively. Most respondents were either extremely (25%), very (46%) or moderately (23%) concerned about climate change; and similarly extremely (23%), very (39%) or moderately (28%) concerned about the amount of waste generated in their kidney care program. Respondents deemed reducing the carbon footprint important in both their personal lives (very 39%; important 35%; fairly 17%), and in the kidney care services they provide (very 34%; important 37%; fairly 18%). The sustainable strategies most frequently incorporated into kidney care were reduced use of office consumables and equipment, water saving taps, waste management (mostly bins, including recycling), clinical care consumables' use prioritized by expiry dates, virtual care options to minimize unnecessary transportation, and medication stewardship strategies.

Conclusions: Most Canadian kidney care providers are highly concerned about climate change and think it is important to reduce the environmental impact in both their personal lives, as well as in the kidney care services they provide. Few sustainable strategies are incorporated into kidney care services across the country.

SA-PO067

Assessment of Equity, Inclusiveness, and Quality of Life for French-Speaking Male and Female Nephrologists: A Survey by the FEMKY Group

Bénédicte Sautenet,[1,2] Sabine Karam,[3] Laurence Vrigneaud,[5] Cecile M. Vigneau,[6] Valerie Chatelet Pouliquen.[4] Group FEMKY from SFNDT. *[1]Universite de Tours, Tours, France; [2]Centre Hospitalier Regional Universitaire de Tours, Tours, France; [3]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN; [4]Normandie Universite, Caen, France; [5]Hopital Prive La Louviere, Lille, France; [6]Universite de Rennes, Rennes, France.*

Background: Recent surveys report a high rate of burnout for nephrologists. The quality of life at work and in personal life as well as the perception of gender discrimination at work are insufficiently defined.

Methods: The FEMKY group (FEMmes KYdney) conducted a cross-sectional 'descriptive observational study by sending an online survey to French-speaking nephrologists members of the Francophone Society of Nephrology, Dialysis and Transplantation (SFNDT) and of the young nephrologists club in France (CJN), from November 2022 to January 2023. We assessed 6 domains: demographic characteristics, working conditions, quality of life at work and in personal life, gender discrimination and history of workplace harassment.

Results: 257 female and 128 male nephrologists responded. 76% of women and 66% of men were under 45 years old and 53% and 51% respectively worked in a university hospital. Quality of life at work was similar for both genders but significantly lower for women at the personal level ($p=0.03$). Feeling of fatigue ($p=0.01$) and dissatisfaction with leisure time were significantly higher in women ($p<0.001$). The opinions of the two genders were significantly different regarding whether the fact of being a woman closes doors at work ($p=0.02$), that women are less trusted ($p<0.001$), and that pregnancies and children education are an obstacle for a woman career ($p=0.001$). Harassment and humiliation at work were described by 37% and 46% of women and 26% and 36% of men ($p=0.03$ and $p=0.06$ respectively).

Conclusions: The quality of life at work was similar between the two genders despite a more important and concerning rate of feeling of discrimination, harassment, and humiliation at work for women and a lower quality of personal life.

SA-PO068

Fellow Attitudes and Perceptions of Health Equity Care and Training in Nephrology

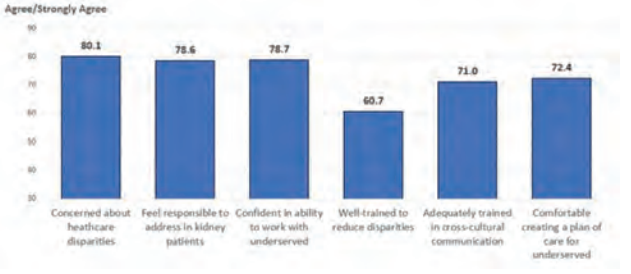
Areeba Jawed, Jennifer L. Bragg-Gresham, Michael Heung, Laura H. Mariani, Panduranga S. Rao, Julie A. Wright Nunes. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Little is known about the current state of Health Equity care and training within Nephrology Fellowship. We developed a survey to assess fellow attitudes about caring for diverse and underserved patient populations and perceptions on fellow training to prepare them to do so.

Methods: Via a survey administered to all U.S nephrology trainees through the ASN inservice training exam (ITE) Spring 2022 we assessed fellow attitudes and perceptions. The survey included 13 questions: 5 demographics and 8 assessing attitude in caring for underserved patients and perceptions of how well training prepared them to do so.

Results: Of the 816 trainees taking the ITE survey, 706 provided informed consent to use their responses, and 689 responses were analyzed due to missing data, for a response rate of 84.4%. The survey reliability factor was 0.7-0.8. Respondents were on average 34 years old, 57% Male, and 11% Hispanic. Predominant races were White (34.2%) and South Asian (27.7%) and most were international (26.3%) or US (24.3%) medical graduates, with 72.3% reporting working with underserved populations often/always. In multivariate analysis Hispanic and African American fellows and graduates of US medical schools were more likely to have worked with underserved patients and show concern for disparities within nephrology. Women and fellows who were further out in training scored lower when it came to confidence and perceptions regarding adequate training to reduce health care disparities.

Conclusions: Although fellows stressed the importance of caring for underserved patients a high proportion did not feel fellowship prepared them adequately for this. Effort needs to be made to better equip trainees with the skills they need to care for all patients, with opportunity to address needs in women.



SA-PO069

Trends in Race/Ethnicity of ASN Kidney Week Faculty (Speakers, Moderators, and Program Chairs): 2018-2022

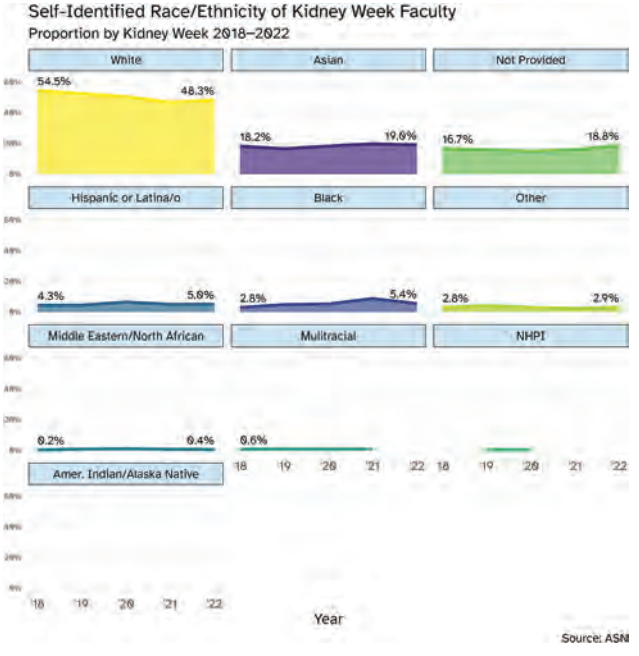
Tushar Chopra,[1] Kurtis A. Pivert,[2] Rasheed A. Balogun,[1] Suzanne Boyle,[3] Jason Cobb,[4] Sana Waheed,[4] Hassan Gorji,[5] Rakesh Malhotra.[5] *[1]University of Virginia, Charlottesville, VA; [2]American Society of Nephrology, Washington, DC; [3]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [4]Emory University School of Medicine, Atlanta, GA; [5]University of San Diego, San Diego, CA.*

Background: ASN Kidney Week (KW) is the world's premier nephrology meeting. As one of ASN's key goals is to promote diversity, equity, and inclusion (DEI) to advance kidney health, we analyzed self-reported racial/ethnicity amongst KW faculty.

Methods: We conducted a retrospective analysis of trends in race/ethnicity of U.S. KW faculty 2018–2022. Self-reported race/ethnicity for KW faculty (speakers, moderators, and program chairs) was obtained from ASN's database. We performed a descriptive analysis amongst KW faculty cohort racial proportions over time. Descriptive data is reported as relative percentage frequency. The reported race/ethnicity was: White/Non-Hispanic White, Black, Asian, Hispanic or Latin(o), American Indian or Alaska Native, Native Hawaiian or Pacific Islander, and Mixed. We also added a category of others/unknowns who did not report race.

Results: 23% (mean n=12,132) of ASN members and 16% (mean n=508) of faculty did not self-report race/ethnicity during KW 2018–2022. White (33-35%) was the most common self-reported race among ASN members, followed by Asian (24%). Blacks were 4.3-4.6%, and Hispanics or Latin(o) were 5.4-6% among ASN members. Over the five years, white faculty declined from 54.5% to 48.3%. At the same time, we found improving trends of Blacks in KW faculty representation from 2.7 to 5.4%. Hispanic or Latin(o) representation remains stable at 5.4-6% among KW faculty.

Conclusions: We found that Asian, Black and Hispanics KW faculty were underrepresented as KW faculty. However, these findings may also be reflection of their lower representation as ASN members. Prioritizing DEI to close this gap is key to fostering the innovation and creativity needed to advance kidney health.



Trends in Race/Ethnicity of KW Faculty

SA-PO070

Validation of ISN 0by25 Acute Kidney Injury Risk Score for Low- and Low Middle-Income Countries

Rolando Claure-Del Granado,[1,2] Fabiana M. Calatayud Rosso,[2] Jason W. Yang,[3] Pei Lun Lee,[3] Jingyao Zhang,[3] Rakesh Malhotra.[3] *[1]Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of; [2]Clinica Los Olivos, Cochabamba, Bolivia, Plurinational State of; [3]University of California San Diego School of Medicine, La Jolla, CA.*

Background: Incidence of Acute Kidney Injury (AKI) is increasing in low-resource countries and is associated with morbidity and mortality. Early identification of patients at increased risk for AKI is the first step to implement preventive and treatment strategies. Multiple risk scores to predict AKI have been developed in higher-income countries and are specific for particular risk settings. Here, we validated new symptoms-based ISN 0by25 AKI risk score that can be easily implementable in resource-constrained environments.

Methods: Forty-seven hospitalized patients from Clinica "Los Olivos" in Cochabamba, Bolivia were enrolled in this ongoing study. Data for predictor variables was extracted from patient's medical charts at the time of admission. The ISN 0by25 risk score was calculated at admission and patients with a risk score of ≥ 3 points were included. Patient information was recorded from the time of diagnosis and renal function (serum creatinine[sCr]) was followed up daily up to 7 days. AKI was defined using KDIGO sCr criteria.

Results: A total of 29 patients (61.7%) developed AKI and 77% were female. The main risk factors for AKI were age ≥65 years (64%), DM (60%) and congestive heart failure (40%). The 3 main causes of AKI were nephrotoxins exposure (93.6%), dehydration (87.2%), and hypotension (38.2%). Positive and negative predictive values for the optimal cutoff value of ≥ 6 points in the cohort were 87.5% and 65.2% respectively with an odds ratio (OR) of 13.1 (95% CI 3.0-57.8; p=0.0007). The risk score has a good performance in predicting AKI with a ROC-AUC of 0.85 (95% CI 0.75 - 0.96; p = 0.0001). None of the patients who developed AKI required dialysis.

Conclusions: We validated the performance of the ISN 0by25 risk score in predicting hospital-acquired AKI, which showed good performance. This risk assessment tool could help clinicians stratify patients for primary prevention, surveillance and early therapeutic interventions to improve the care and outcomes of high-risk patients in low-resource settings.

SA-PO071

Assessing Ambient Heat Exposure and AKI Using Alternate Case Definitions

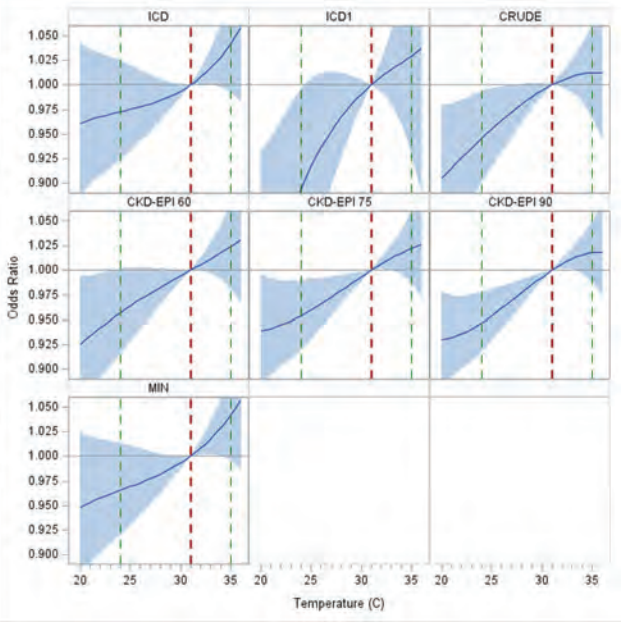
Benjamin Rabin,[1,2] Rohan Dsouza,[2] Ethel J. Weil,[1] Howard Chang,[2] Stefanie Ebelt,[2] Noah Scovronick.[2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory University School of Public Health, Atlanta, GA.*

Background: Ambient heat exposure is an established risk factor for the development of acute kidney injury (AKI). However, prior work using International Classification of Disease (ICD)-coded data has important limitations in evaluating heat-AKI. We hypothesized that Kidney Disease: Improving Global Outcomes (KDIGO)-based AKI definitions would improve the accuracy of heat-AKI effect estimates compared to ICD-coded data by improving AKI case sensitivity.

Methods: We conducted a case-crossover study comparing AKI-related emergency department (ED) visits with same-day maximum temperatures in Atlanta, Georgia during 6 consecutive warm seasons. We created 7 case definitions for AKI using ICD-coded data and KDIGO-derived equations. KDIGO definitions compared an individual's serum creatinine measurements to surrogate values for baseline renal function.

Results: We analyzed 368,682 total ED visits between 2014 and 2019. Cases of AKI ranged from 5,868 to 64,269 across the 7 definitions. Higher temperatures were associated with AKI-related ED visits in all 7 definitions (Figure 1). When we stratified individuals by the presence of an ICD-coded AKI diagosis, we detected a persistent heat-AKI effect among individuals *without* a coded AKI diagnosis under the "CKD-EPI 75" (OR 1.06, 95% CI 1.02-1.12) and "CKD-EPI 90" (OR 1.07, 95% CI 1.03–1.11) definitions.

Conclusions: Our results support KDIGO-based definitions as an improved tool to evaluate the heat-AKI relationship. This method may enable reseachers to capture additional AKI cases otherwise missed by code-classified data, for whom a significant heat-AKI effect exists.



Exposure response functions by case definition for the risk of AKI across daily maximum temperature (Odds ratios provided with 95% CI).

SA-PO072

Worldwide Incidence and Associated Mortality of AKI in Neonates: A Systematic Review and Meta-Analysis

Jahnavi Phanidhar Kocharlakota,[1] Jitendra Meena,[1] Joginder Kumar Yadav,[2] Amit Kumar,[1] Aditi Sinha,[1] Pankaj Hari,[1] Arvind Bagga.[1] *[1]All India Institute of Medical Sciences, New Delhi, India; [2]Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: There is limited literature on the global incidence of acute kidney injury (AKI) and associated mortality in neonates. We aim to systematically assess the worldwide incidence of AKI in neonates to increase awareness and inform policymakers.

Methods: We searched three databases (PubMed, Embase, Web of Sciences) from 2004 to December 2022 without language or geographical restrictions. Cohort and Cross-sectional studies reporting the incidence of AKI in neonates were included in this systematic review. Eligible studies had at least 10 participants and used AKIN, RIFLE, and KDIGO or their equivalent criteria to define AKI. Two authors independently extracted data about the study and patients' characteristics and outcomes (incidence and AKI-associated mortality) and assessed the risk of bias. We used a random-effects meta-analysis to generate pooled estimates.

Results: From the initial 6990 records, we included 201 studies (98470 neonates) from 51 countries. The pooled incidence of any stage AKI was 34% (95% confidence interval: 31-37), and that of severe AKI was 15% (14-17). The incidence of AKI was lower in high-income 31% (27-35), low-middle-income 40% (32-48), and low-income 47% (6-97) countries. Pooled mortality was higher (OR 3.2; 95% CI 2.9-3.5) in neonates with AKI (29%; 95% CI 25-34) compared to those without AKI (8%; 95% CI 8-10). Mortality was lower in high-income 25% (20-30), low-middle-income 30% (20-42), and low-income 37% (20-56) countries.

Conclusions: AKI was observed in almost one-third of hospitalized neonates and is associated with increased mortality risk. Incidence and mortality associated with AKI were higher in low-middle-income countries than in high-income countries.

Epidemiology of Perioperative AKI in Neonates Undergoing Noncardiac Surgeries

Morgan E. Beebe,[1] Brett Klamer,[2,1] Jonathan L. Slaughter,[1] Tahagod Mohamed.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: The epidemiology of AKI in neonates requiring cardiac surgeries exists; however, the incidence of AKI in neonates undergoing noncardiac surgeries is not fully characterized. Our study aims to evaluate the epidemiology and outcomes of perioperative AKI (POAKI) in neonates undergoing noncardiac surgeries in the first 28 days of life at our institution. We hypothesized that noncardiac surgeries can be a risk factor for AKI, and infants who develop POAKI have worse short-term outcomes.

Methods: This is a retrospective review of neonates admitted to a single, level IV neonatal intensive care unit from Nov '14-Jan '22. Neonates aged 0-28 days who required a noncardiac surgery in the first 28 days of life were included for analysis. Neonates requiring a cardiac surgery, ECMO, had a lethal chromosomal abnormality, or with significant underlying kidney disease were excluded. Data were evaluated for the development of AKI in the 72 hours following surgery according to the neonatal modification of Kidney Disease: Improving Global Outcomes (KDIGO) criteria. We evaluated the distribution of fluid balance in the postoperative period. Descriptive statistics were used to summarize patient characteristics. Fisher's exact test, Pearson's Chi-squared test, and the Wilcoxon rank sum test were used to analyze the relationship between AKI status with other variables. Statistical significance was assessed at an alpha level of 0.05.

Results: A total of 873 neonates were included. Of those, 705 neonates had creatinine measurements available and 42% were females. The median gestational age, birthweight and age at surgery were 37 weeks, 2760 g and 4 days respectively. Abdominal, ENT, and Neuro- surgeries were most common. The rate of POAKI was 5%. With POAKI, the 1 min Apgar scores were significantly lower, postoperative day 1 fluid balance was significantly higher (11 vs 4%) and hospital mortality rates significantly higher (25 vs 4%).

Conclusions: In this single-center retrospective analysis, POAKI occurred in 5% of neonates requiring non-cardiac surgeries in the first 28 days of life. Low Apgar scores, fluid overload, and hospital mortality were more frequent in neonates who developed POAKI. Future work should focus on monitoring kidney health in neonates undergoing non-cardiac procedures to prevent AKI and implement effective therapies for management of fluid overload.

SA-PO074

A Case of Fulminant Leptospirosis

Sakshi Yadav, Hanni Menn-Josephy. *Boston Medical Center, Boston, MA.*

Introduction: Leptospirosis, the most prevalent zoonosis worldwide, is a disease that has historically had low reported cases in the United States. However, recent discussions have focused on the re-emergence of Leptospirosis in this region.

Case Description: We present the case of a 69-year-old Hispanic male who presented with acute onset abdominal pain, fever, and muscle cramps persisting for three days. The patient was found to have acute kidney injury(with a creatinine of 3.3 mg/dL) and promptly initiated on intravenous fluids and empiric antibiotics. Urinalysis revealed mild proteinuria and hematuria, with microscopic examination of the urine sediment showing a few red and white blood cells, few granular casts, and rare white blood cell casts cellular casts. A 24-hour urine protein collection yielded a result of 452 mg. Despite antibiotic therapy, the patient continued to experience daily fevers, excessive night sweats, and severe myalgias and continued to deteriorate with worsening nonoliguric kidney injury (creatinine level peaked at 5mg/dL). He developed thrombocytopenia (platelet count nadir of 45) and hyperbilirubinemia (total bilirubin 6mg/dL with direct bilirubin 4mg/dL), despite otherwise normal liver function. The patient had markedly elevated inflammatory markers with an erythrocyte sedimentation rate (ESR) of 104 mm/hour, C-reactive protein (CRP) of 226 mg/dL, and a fibrinogen level of >800 mg/dL. Complement (C3 and C4) levels, creatine kinase, were within the reference range, and serological/autoimmune workup was negative. Subsequent renal biopsy revealed predominant acute interstitial nephritis and some focal acute tubular injury. An infectious workup confirmed the presence of Leptospira DNA. The patient was initiated on doxycycline therapy, leading to symptom resolution and improvement of multiorgan failure.

Discussion: Leptospirosis, previously regarded as a rural disease primarily affecting tropical regions, is now increasingly reported in urban areas and temperate climates. Factors such as weather changes, population growth, and habitat encroachment have heightened the risk of human exposure to Leptospirosis and its carriers. Therefore, in cases of fulminant multiorgan failure with presumed infectious etiology, clinicians should consider Leptospirosis as a potential cause. Timely initiation of treatment can prevent the progression of chronic kidney disease and, ultimately, end-stage kidney disease.

SA-PO075

Persistent AKI Following Orthotopic Liver Transplant: Prevalence, Risk Factors, and Long-Term Renal Outcomes

Noemi Del Toro-Cisneros, Luis Á. Rivas Sánchez, Karina C. Felix Bauer, Adela U. Pérez, Olynka Vega. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: This study investigated the pre- and postoperative factors associated with the development of persistent AKI (AKI >72 hours of duration) post-transplant and its impact on renal function during a 5-year follow-up.

Methods: Retrospective study that included all patients who underwent OLT from January 2008 to December 2018. Demographic data, data inherent to the surgical procedure and post-operative factors associated with AKI. Subsequently, we performed logistic analysis with variables to predict persistent AKI. Finally, we analyzed the renal trajectory between the two groups: those with persistent AKI and those without it.

Results: 305 patients were included, 23% developed persistent AKI post-OLH. Demographic characteristics, comorbidities, and perioperative variables are shown in **Table 1**. In the multivariate analysis, the significant variables are shown in **Table 2**. Mortality at hospital discharge was not different between the groups. In the analysis of the renal trajectories, the patients who presented persistent AKI had a lower eGFR with a median difference at 5 years of follow-up of 10ml/min/1.73m2.

Conclusions: In the present study, the factors associated with AKI development were: male gender, ascites drainage during surgery, diuresis <500ml in the first 24 hours post-OLT, use of antifungals, and anhepatic time >50 minutes. Long-term renal function in patients who developed persistent AKI deteriorated more compared to those who did not.

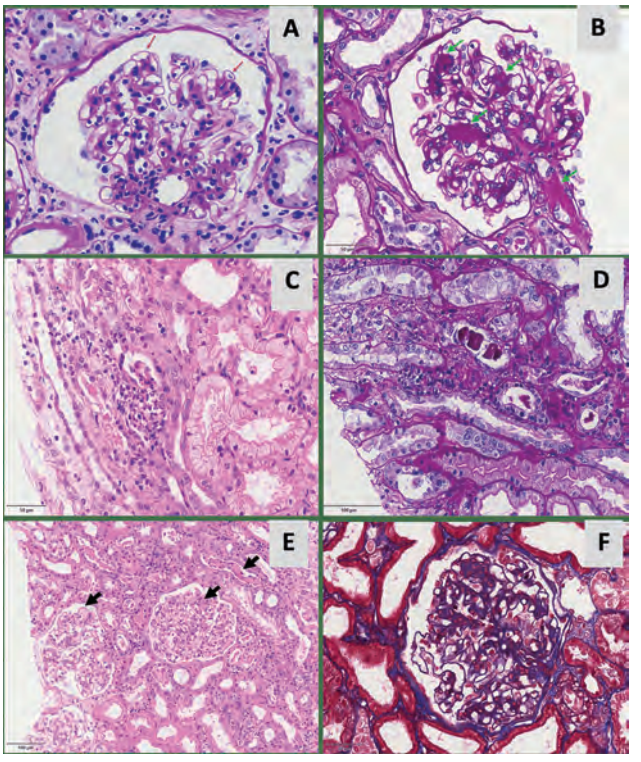
SA-PO076

AKI due to Acute Tubulo-Interstitial Nephritis and Diabetic Nephropathy in a Patient with Pulmonary Aspergillosis

Clementina Elizabeth Calderon Garcia, Guillermo Navarro Blackaller, Eric J. Zavala López, Jonathan Chavez. *Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico.*

Case Description: A 45-year-old woman with diabetes mellitus, 8 years of evolution in poor control, asthma, and chronic smoking. Admited with hyperglycemic crisis due to pneumonia: procalcitonin 0.3, Hb 16g/dl, WBC 16, albumin 3.74g/dl, SCr 0.79mg/dl, urea 25mg/dl, glucose 933mg/dl, HbA1c 14%. Patient presents cough, fever, hemoptysis, a chest tomography with pulmonary infiltrates and cavitated nodules. Bronchoscopy reported Aspergillus. Management with liposomal amphotericin, presented acute kidney injury, SCr 4 mg/dl, proteinuria 1g/24hrs, urinary sediment: leukocytosis, erythrocytes without acanthocytes. Renal biopsy reports: Acute tubulointerstitial nephritis (aTIN), presence of a mixed lymphoplasmacytic infiltrate of lymphocytes and eosinophils suggestive of aTIN due to drugs and a concomitant diabetic nephropathy (Thickening of glomerular capillaries, diffuse glomerulosclerosis, with mesangial expansion and Kimmelstiel-Wilson nodules). Management with pulsed methylprednisolone 250mg and prednisone 0.5mg/kg per day for 6 weeks.

Discussion: aTIN is a form of glomerular-sparing non-oliguric renal disease that results from an allergic or immunologic reaction to intrarenal antigens and leads to tubular damage. The drugs normally associated are NSAIDs, antibiotics, and proton pump. Our patient was exposed to liposomal amphotericin. In the case series of renal biopsies in patients with DM2 (4876 patients), the prevalence of glomerulopathy not associated with DN was up to 35% and mixed forms 45%. Conclusion In the case that we present a patient living with chronic and poorly controlled diabetes who presented AKI, DN, the AKI approach must be considered regardless of comorbidities where the use of drugs is not innocuous.



SA-PO077

Parenchymal and Nontraditional Etiologies of AKI in Patients with End-Stage Liver Disease

Vipin Varghese, Akanksh Ramanand, Lauren Cohen, Dustin R. Chalmers, Juan Carlos Q. Velez. *Ochsner Health, New Orleans, LA.*

Background: In the context of acute kidney injury (AKI) and end-stage liver disease (ESLD), AKI is frequently attributed to either hepatorenal syndrome type 1 (HRS-1), ischemic acute tubular injury (ATI), or pre-renal azotemia (PRA). We hypothesized that other parenchymal causes of AKI including toxic ATI, acute glomerulonephritis (AGN) and acute interstitial nephritis (AIN) may account for a small but not negligible proportion of cases of AKI in patients with ESLD.

Methods: We established prospective data collection in patients with ESLD with AKI stage ≥ 2 (AKIN) over 5-years who were seen by the nephrology consultation service. Demographic and clinical data were collected. Etiology of AKI was adjudicated based on history, clinical assessment, laboratory results, urine microscopy findings, and kidney biopsy data.

Results: We included 234 patients with AKI and ESLD. The median age was 57 (20-88), 37% were female, 76% were white, and 15% were black. CKD was a pre-existing comorbidity in 26%. PRA was the cause of AKI in 12 (5%) (low rate likely explained by resolution without consultation to nephrology), HRS-1 in 76 (32%), cardiorenal syndrome type 1 (CRS-1) in 6 (3%) abdominal compartment syndrome (ACS) in 2 (1%) and obstructive uropathy (OU) in 3 (1%). Parenchymal etiologies of AKI were noted in 137 (59%) of patients. Among parenchymal etiologies of AKI, ischemic ATI was the primary diagnosis in 78 (58%), toxic ATI in 26 (19%), ischemic/toxic ATI in 22 (16%), AIN in 2 (1%), and AGN in 7 (5%). Among those with toxic ATI, 3 were due to vancomycin, 2 to ciprofloxacin, 1 to uric acid, 1 to contrast, 15 to cholemic tubulopathy, and 4 due to other drugs. Both cases of AIN were associated with ciprofloxacin use. Among those with AGN, 4 were biopsy-proven (3 IgA nephropathy, 1 immune complex-GN) and 3 were clinical diagnoses (2 IgA nephropathy, 1 SLE-GN).

Conclusions: Combining toxic ATI (drug-induced, endogenous toxins), AIN, and AGN, non-traditional parenchymal causes of AKI accounted for 15% of the cases in these cohort of patients with ESLD and AKI. When added to CRS-1, ACS and OU, a total of 19% of the cases were not within the traditional 3-way split (PRA, HRS-1, ischemic ATI). Comprehensive diagnostic assessment is recommended in this clinical setting.

SA-PO078

Rare Case of Mycobacterium avium Complex (MAC)-Associated Immune Reconstitution Inflammatory Syndrome (IRIS) Presenting as Acute Interstitial Nephritis

Puja Mehta, Jeffrey M. Turner, Grace L. Malvar. *Yale School of Medicine, New Haven, CT.*

Introduction: With the advent of antiretroviral therapy (ART), HIV associated comorbidities have declined significantly. However, new conditions related to HIV treatment, rather than progression of the disease itself, have emerged. One such condition

is immune reconstitution inflammatory syndrome (IRIS). ART can lead to a rapid decline in circulating HIV RNA within 1-2 weeks after initiating therapy, which then results in the reemergence of both memory and naïve CD4 T cells, which can sometimes lead to unmasking of opportunistic infections (OIs) by an exaggerated immune response. One of the earliest OIs unmasked after ART therapy is Mycobacterium avium Complex (MAC). MAC- related IRIS occurs in 3.5% of the patients, and usually occurs when the CD4+ count is below 100 cells/mL prior to ART initiation. Common manifestations include lymphadenitis, pulmonary-thoracic disease, and intra-abdominal disease, with less commonly affected organs like skin, bone. We present here a rare case of MAC-associated IRIS presenting as acute interstitial nephritis (AIN).

Case Description: The patient is a 54-year-old male who had been started on Biktarvy after being diagnosed with advanced HIV (initial CD4 count 8, VL 119k). At the time of HIV diagnosis, he had signs and symptoms that included the following: left cervical lymphadenopathy with a predominant node measuring 5cm, fevers, night sweats, fatigue, and significant weight loss. A biopsy of the enlarged left cervical lymph node 1 month after ART initiation revealed the presence of MAC infection. He was subsequently initiated on MAC therapy with azithromycin+ethambutol. Prior to the initiation of these antimicrobials, he was noted to have AKI with Cr 2.7 (baseline 0.8-1). His urine microscopy showed numerous RTE casts without notable WBCs or WBC cast. Kidney biopsy was performed showing AIN with an infiltrate consisting of predominantly CD8+ T cells and histiocytes. He was then started on slow prednisone taper over months while continuing ART with eventually improving kidney function.

Discussion: MAC-associated IRIS is a rare cause of AKI in patients with HIV/AIDs. It presents after initiation of ART, making it sometimes difficult to differentiate from medication associated kidney injury. The injury pattern on kidney biopsy is AIN, which may not be apparent based on urine microscopy as in the case we described here.

SA-PO079

Late-Onset Shiga Toxin-Related Hemolytic Uremic Syndrome

Norman Wall. Section of Nephrology, Dept of Medicine; LSU Health New Orleans. *Louisiana State University, New Orleans, LA.*

Introduction: HUS may occur after improvement of gastrointestinal tract symptoms, andl we should carefully monitor for the onset of HUS, even if the patient has few symptoms.

Case Description: A 34-year-old male transferred to the University Medical Center New Orleans for evaluation of nephrotic range proteinuria and edema. He presented to his local hospital ED with edema and bloody diarrhea that started in November and resolved in April after a course of antibiotics for acute pancreatitis. He reported weakness and fatigue, an 11-pound weight loss, nose bleeds, and shortness of breath for about 5 days prior to admission. His initial treatment consisted of 5 UPRBC, and diuresis. He developed an AKI, and a renal biopsy was performed that was consistent with Post-Infectious Glomerulonephritis. WBC 17.0 10’3/uL, Hgb 7.5 gm/dl, Hct 23.4 %, Plt 667 10’3/uL, Schistocytes 3+, Retic Count 7.5%, C3 Compliment 172 mg/dL, C4 Compliment 35 mg/dL, LDH 433, ADAMTS 13 Activity 73.9%, Urine PH 5.0, SG >1.030 Glucose >500 mg/dL, Bld 0.03 mg/dL, RBC 3-5, Protein 100 mg/dL, Prt/Cr ratio 1,100, Hep B, Hep C, HIV all negative, Na 139 mmol/L, K 3.9 mmol/L, Cl 106 mmol/L, CO2 mmol/L, BUN mg/dL, Cr 1.24 mg/dL, ANA neg, haptoglobin <30 mg/dL.

Discussion: Shiga toxin-related hemolytic uremic syndrome (HUS) is a thrombotic microangiopathy that typically begins days after clinical gastroenteritis caused by Shiga toxin–producing Escherichia coli and is characterized by a triad of thrombocytopenia, microangiopathic hemolytic anemia, and acute kidney injury. The patient in this case report presented with few subjective symptoms, and the onset of HUS may not have been noticed if the patient was not hospitalized. In conclusion, this abstract describes a patient with late onset HUS that was preceded by the appearance of minimal gastrointestinal and HUS symptoms, who was successfully treated with IV fluid therapy and corticosteroids alone. In adults with an EHEC infection, HUS may occur after improvement of gastrointestinal symptoms. Careful monitoring of HUS symptoms and changes in chemistry, hematology and urinalysis findings is recommended, regardless of the severity of gastrointestinal symptoms.

SA-PO080

Associations Between Blood Pressure Variability and Renal Recovery and Mortality During Continuous Renal Replacement Therapy

Ji Eun Kim, Kipyo Kim. *Inha University Hospital, Incheon, Republic of Korea*.

Background: Acute kidney injury (AKI) requiring dialysis is frequently occurred in critically ill patients, leading to chronic kidney disease progression and dialysis dependency. Blood pressure variability (BPV) has been known to contribute the development of AKI by impairing kidney perfusion. However, the association between short-term and long-term BPV and AKI recovery and mortality remains uncertain.

Methods: We enrolled the patients aged ≥18 years who underwent continuous renal replacement therapy (CRRT) due to AKI for ≥24 hours at Inha University Hospital from January 1, 2018 to December 31, 2020. Patients with end-stage kidney disease were excluded. We extracted 1-hour-interval blood pressure records during CRRT and calculated several BPV parameters including standard deviation (SD), coefficient of variation (CV), average real variability (ARV), and variation independent of mean (VIM). Outcomes are in-hospital mortality and dialysis dependence at the time of discharge. Multivariable logistic regression and Cox proportional hazard analysis were poerformed.

Results: A total of 243 patients were included in the main analysis. Mean age was 69.7 years and male was 56.8%, and 52.2% were sepsis-associated AKI. Median duration of CRRT was 4 days. Multivariable logistic regression showed a significant association between four BPV parameters and dialysis dependence at discharge (SD, OR 1.94 (95% CI 1.07-3.59); CV, OR 2.69 (95% CI 1.47-5.06); VIM, OR 1.92 (95% CI 1.06-3.54), ARV, OR 1.90 (95% CI 1.03-3.54)). These parameters also showed close associations with in-hospital mortality in cox-proportional hazard analysis (SD, HR 1.74 (95% CI 1.25-2.43); CV, HR 2.17 (95% CI 1.55-3.03); VIM, HR 1.77 (95% CI 1.27-2.47), ARV, HR 1.65 (95% CI 1.17-2.32)).

Conclusions: BPV during CRRT was found to be an independent predictor of dialysis dependence at discharge and in-hospital mortality in AKI patients who underwent CRRT. Minimizing BPV during CRRT might be an important factor for recovery to dialysis independence and patient survival.

Figure 1. Kaplan-Meier curves of coefficient of variation for (A) dialysis independence at discharge (B) in-hospital mortality.

Hope in Hardship: AKI in Haiti

Fritz V. Vernet,[1] Aditya S. Pawar,[2,3] Philip C. Cleophat,[1] Brian D. Remillard,[4] Robert S. Brown.[2,3] *[1]Hôpital Universitaire de Mirebalais, Mirebalais, Haiti; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Background: AKI is a significant global issue, especially in low-resource areas with limited healthcare. Worldwide estimates suggest 13 million AKI occurrences/year with 1.7 million deaths, 85% in developing nations. In this study, we describe the presentation of AKI to a single healthcare center in Haiti and how collaboration can improve health care delivery for AKI.

Methods: The Hôpital Universitaire de Mirebalais (HUM), a 300 bed Partners in Health facility in rural Mirebalais has six residency programs. A partnership was formed between Beth Israel Deaconess Medical Center (BIDMC), Dartmouth Health and HUM focusing on educating internal medicine residents and staff through online presentations and short visits to Boston or Hanover for training in nephrology, urinalysis, HD, kidney biopsy, and bedside renal ultrasound. We planned that trainees would advance the ISN goal of eliminating preventable or treatable deaths from AKI by 2025.

Results: This program has enhanced the knowledge of medical residents and students in AKI diagnosis, management, electrolyte physiology, and HD, improving patient care and clinical outcomes at HUM. Between July 2021 to October 2022, 194 patients presented with AKI (11 cases/wk). Their mean age was 48 and main causes were heart failure (43%), glomerulopathy (26%), sepsis (12%) eclampsia (5%), other infectious diseases (e.g., leptospirosis, COVID, 2%), and volume depletion (2%). Due to lack of dialysis nurses, all HUM medical residents receive training in hemodialysis, and if the patient meets criteria for HD, a resident will initiate the procedure, performed without cost, as the majority of Haitians cannot afford dialysis. Of these 194 AKI patients, 19% had received HD of which 83% survived. The overall survival was 78%. Despite shortages of HD supplies and other medical equipment and inability to bring visiting professors to teach in Haiti due to multiple lockdowns and unrest, we have found alternative ways to receive shipments and to train our residents online. These residents become our future teachers, as with only 10 nephrologists for 11 million Haitians, the internists and general practitioners provide care for a large proportion of patients with AKI.

Conclusions: HUM, through education and training, in cooperation with BIDMC and Dartmouth, has provided care for patients with AKI, small victories that offer hope in managing hardship in Haiti.

SA-PO082

AKI in Hospitalizations with Sickle Cell Disease in Jamaica

Lori- Ann M. Fisher, Monika Asnani. *The University of the West Indies, Kingston, Jamaica*.

Background: Renal disease is amongst the leading causes of mortality in persons living with sickle cell disease (SCD). We describe the epidemiology and associations of acute kidney injury (AKI) in Jamaicans hospitalized with SCD.

Methods: A retrospective cohort study of admissions with coded diagnoses of SCD between January 1, 2016 to December 31, 2019 at the University Hospital of the West Indies was performed. Exclusion criteria were age < 1 month or if less than two creatinines were available. AKI was defined using Kidney Disease improving global outcomes (KDIGO) as either an increase of at least 1.5 times baseline creatinine if known. If baseline creatinine was unavailable this was defined as an increase of 1.5 times the maximum creatinine to the lowest creatinine in the admission. The index admission for each case was analysed. Data were described using summary statistics. Differences between AKI and non-AKI groups were performed using chi-square or t-tests were appropriate. Multivariable logistic regression was used to determine associated factors with AKI.

Results: Of 144 participants, mean age 27.0 ±15.4 years, 62.2% were female and 84.5% Hemoglobin-SS genotype. One third (n=48) of participants were children (age<18 years). AKI occurred in 19.4% (n=28). The main admitting diagnoses were vaso-occulsive crises in 61.1%, Acute chest syndrome 27.8%, Lower Respiratory Tract Infection 17.4%, hepatic sequestration 13.2%. Baseline CKD was reported in 6.3%, hydroxyurea use in 4.9% and NSAID use 20.1%. Three participants were admitted to the intensive care unit. There were no in-hospital deaths. Mean duration of hospitalization was 8.8±8.3 days(range:1-59 days). A quarter of patients (26.4%) had red blood cell (RBC) transfusion, exchange transfusion was performed in 2 children. Compared to no AKI, AKI participants were older (mean age 32.1 ±14.9 versus 25.8 ±15.4 years, p=0.05), with a higher proportion receiving RBC transfusion (46% versus 21.6%, p=0.007). Based on a logistic regression model adjusting for age and sex, RBC transfusion was associated with AKI in adults (OR 3.1 95% CI: 1.1-8.6, p=0.003), but not children (OR: 0.5 95%CI 0.04-6.5, p=0.612). There was no difference in length of hospital stay in AKI and non AKI groups.

Conclusions: AKI frequently complicates admissions with sickle cell disease. Further studies determining long-term outcomes following AKI events are needed.

SA-PO083

Black Patients at Higher Risk of Hospital-Acquired AKI but Lower Risk of Community-Acquired AKI

Clara Wilson,[1] Ayana K. April-Sanders,[2] Joel Neugarten,[1] Ladan Golestaneh.[1]
[1]Montefiore Medical Center, New York, NY; [2]Rutgers School of Public Health, Piscataway, NJ.

Background: Previous studies showed higher incidence of acute kidney injury (AKI) among Black patients compared to Whites but failed to adequately characterize this difference. Further detail on racial/ethnic risk of defined types of AKI could inform preventive interventions.

Methods: We describe a cohort of hospitalizations of pediatric and adult patients without prior kidney failure in Montefiore Health System, Bronx, NY, between October 1, 2015 and December 31, 2018. We defined community-acquired AKI(CAAKI) as criteria met by KDIGO in first 48 hours of admission and hospital-acquired AKI(HAAKI) as a 48-hour window rise in creatinine defined by KDIGO occurring after 48 hours of admission and before discharge. We examined unadjusted logistic regression with HAAKI and CAAKI as outcomes, race as exposure, and sequentially adjusted variables accounting for comorbidities and in-hospital risk of mortality. We stratified multivariable adjusted models by in-hospital events according to: 1-severe illness: exacerbation of heart or liver failure, sepsis/shock, cardiac arrest and mechanical ventilation, 2-exposure to nephrotoxic agents: contrast, NSAIDS, diuretics and nephrotoxic chemotherapy, and 3-surgery: occurrence of cardiopulmonary, vascular, orthopedic or neurosurgery; to understand association of race with risk of HAAKI in each scenario.

Results: Of a total 286,383 hospitalizations, 42% were male, 11% were White, 29% were Black, and mean age was 48 years(SD:27). White patients [mean age 63 years(SD: 23)] were older than Black [51 years(SD:25)]. AKI occurred in 56,731 (20%) instances, of which 23,524 (41%) were CAAKI and 33,207 (59%) were HAAKI. In adjusting for age and sex, Black patients were at higher risk for HAAKI [OR 1.21, (CI 1.17-1.27)] and lower risk for CAAKI [0.92, (CI 0.88-0.96)]. Risk for HAAKI attenuated with addition of prior comorbidities, BMI and APR score, but remained significant [OR 1.13, CI (1.08-1.17)]. Black patients had higher odds of HAAKI than White patients when hospitalized with severe illness and underwent major surgery. There was no difference in HAAKI by race with nephrotoxic agent exposure.

Conclusions: Black patients are at higher risk of HAAKI when hospitalizations involve severe illness or major surgery, and at lower risk of CAAKI. Drivers of higher HAAKI risk among severely ill Black patients should be identified.

SA-PO084

Association of Black Race, Diabetes, and Obesity with AKI During Hospitalization in a Large Multicenter US Cohort

Tomonori Takeuchi,[1] Javier A. Neyra,[1] Lama Ghazi,[1] Orson W. Moe,[2] Robert D. Toto,[2] Akm F. Rahman,[1] Edward D. Siew,[3] Orlando M. Gutierrez.[1]
[1]The University of Alabama at Birmingham, Birmingham, AL; [2]The University of Texas Southwestern Medical Center, Dallas, TX; [3]Vanderbilt University Medical Center, Nashville, TN.

Background: AKI is a common complication during hospitalization that is associated with morbidity and mortality. Whereas multiple studies have identified risk factors for the development of AKI in hospitalized patients, few have examined risk factors for the severity of AKI, including non-recovery of AKI.

Methods: Multicenter retrospective cohort study of patients ≥18 years old without ESKD or kidney transplant who were admitted to the hospital from 10/2014 to 9/2017. Data were extracted from electronic health records of 3 large academic medical centers. Study outcomes included (1) incidence and severity of AKI and (2) non-recovery from AKI in those who survived the hospitalization. AKI was defined by KDIGO SCr-criteria, using all inpatient SCr data available and the lowest value of the first three inpatient measurements as the baseline. Non-AKI recovery was defined in hospital survivors as persistent AKI stage ≥1 using the last SCr during the hospitalization or if the patient received dialysis within 72h of hospital discharge. We used multivariable logistic regression models to evaluate the association of black race, diabetes and obesity (BMI ≥30 vs. <30 kg/m^2) with the outcomes, and each of the models was adjusted for 2 other of these main factors, and covariates such as study site, age, sex, baseline eGFR, and Elixhauser comorbidity score.

Results: Among 56,056 patients included in the study, 12,954 (23%) developed AKI during hospitalization. In adjusted models, black race (OR 1.26, 95%CI 1.20-1.32), diabetes (OR 1.14, 95%CI 1.08-1.19) and obesity (OR 1.14, 95%CI 1.10-1.20) were all associated with incident AKI, though only obesity was associated with AKI stage 2 or 3. Only obesity was associated with non-recovery from AKI at hospital discharge (OR 1.27, 95%CI 1.17-1.39).

Conclusions: Black race, diabetes and obesity were associated with incident hospitalized AKI, but only obesity was associated with moderate to severe AKI and non-recovery from AKI at hospital discharge. Obesity may help identify individuals at highest risk for severe AKI and those survivors requiring close follow-up after discharge.

Table: Association of race, diabetes, and obesity with incident AKI and non-recovery from AKI in a multicenter cohort of adult hospitalized patients

	Black vs. non-Black race OR (95%CI)	Diabetes vs. no-Diabetes OR (95%CI)	BMI ≥ vs. < 30 kg/m2 OR (95%CI)
Incident AKI (n = 56,056)	**1.26 (1.20, 1.32)**	**1.14 (1.08, 1.19)**	**1.14 (1.10, 1.20)**
AKI Stage 1	**1.27 (1.21, 1.34)**	**1.16 (1.11, 1.22)**	**1.10 (1.06, 1.16)**
AKI Stage 2	1.09 (0.88, 1.35)	0.79 (0.63, 1.00)	**1.58 (1.31, 1.90)**
AKI Stage 3	1.00 (0.82, 1.21)	1.00 (0.81, 1.23)	**1.92 (1.61, 2.28)**
Non-recovery from AKI in survivors (n = 11,672)	0.85 (0.77, 0.93)	1.02 (0.93, 1.12)	**1.27 (1.17, 1.39)**

SA-PO085

Nephrology Follow-Up After Community-Acquired AKI Among US Veterans

Clarissa J. Diamantidis,[1,2] Lindsay Zepel,[1] Matthew L. Maciejewski,[1,2] M. Alan Brookhart,[1] C. Barrett Bowling,[1,2] Virginia Wang.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]Durham VA Health Care System, Durham, NC.*

Background: Community-acquired acute kidney injury (CA-AKI) is a common condition developed outside of the hospital that increases the risk of future hospitalization and death. Little is known about care patterns following CA-AKI, so we evaluated post-AKI nephrology care after an episode of advanced CA-AKI.

Methods: We constructed a retrospective cohort using national VA administrative and lab data to assess the cumulative CA-AKI incidence among active VA primary care users in 2013-2017 with a recorded outpatient serum creatinine (SCr). Veterans with a history of severe kidney disease (≥ Stage 5 or kidney transplant) were excluded. Stage 2 and 3 CA-AKI were defined as ≥ 2.0-2.9-fold or ≥ 3 fold relative increase, respectively, in outpatient SCr or inpatient SCr (≤ 24 hours from admission), from a reference value defined as the preceding outpatient SCr ≤ 12 months prior. A Cox model was used to estimate the association between baseline socio-demographics, comorbidities, care patterns, and CA-AKI event characteristics (stage, setting).

Results: Of the 43,473 veterans with Stage 2 (73%) or Stage 3 (27%) CA-AKI between 2013-2017, mean age was 66.7 years; 5.6% were female, 21.3% Black race, and 6.6% Hispanic ethnicity. Mean eGFR was 70.9 ml/min/1.73m^2 and 16.1% had documented CKD. The majority (62.6%) had a history of primary care visit ≤ 90 days prior to the CA-AKI event but few (1%) had a nephrology visit before CA-AKI. Overall, 3.5% of veterans were seen by nephrology ≤ 90 days after their CA-AKI event (3.3% Stage 2, 4.0% Stage 3, 3.8% outpatient CA-AKI, 3.0% inpatient CA-AKI); half (47.7%) of these visits included a diagnosis code for AKI. Veterans with inpatient CA-AKI (HR 0.64 [95% CI 0.57, 0.72]), advancing age (HR 0.88 [0.86, 0.91] per 5 years), and female gender (0.73 [0.56, 0.95]), were less likely to see nephrology within ≤ 90 days after CA-AKI. Those with a CKD (1.58 [1.38, 1.80]), Stage 3 CA-AKI (1.60 [1.43, 1.80]), lower eGFR (1.13 [1.12, 1.15] per 5 unit decrease) or prior nephrology visit ≤ 90 days (3.40 [2.74, 4.22]) had higher likelihood of a follow-up nephrology visit.

Conclusions: Few veterans with Stage 2 or 3 CA-AKI were seen by nephrology in the 90 days after a CA-AKI event. Post-AKI care models prioritizing recognition and nephrology care may improve the adverse outcomes associated with CA-AKI.

SA-PO086

Contrast-Related Risk of Progressing to ESRD in Patients Undergoing Percutaneous Coronary Intervention: Iohexol vs. Iodixanol

David R. Chang, Sz Ying Lu, Zi-Han Lin, Chin-Chi Kuo, Hsiu-Yin Chiang.
China Medical University Hospital, Taichung, Taiwan.

Background: Our study aims to determine the differential risk of accelerated progression to end-stage renal disease (ESRD) associated with the contrast agents Iohexol and Iodixanol in patients undergoing percutaneous coronary intervention (PCI). This research is particularly important for addressing concerns about the use of PCI in individuals with chronic kidney disease (CKD).

Methods: This matched cohort study identified patients undergoing PCI of China Medical University Hospital between 2003 and 2017. For each patient administered with Iohexol, we identified a corresponding patient who was administered Iodixanol, ensuring that they were matched in terms of age, sex, baseline serum creatinine, and the year of the procedure. We employed multivariable Cox proportional hazard models to evaluate the risk of ESRD in the Iohexol group in comparison to the Iodixanol group. Subgroup analyses were further conducted specifically for patients with and without CKD.

Results: Among a total of 5,335 patients who used Iohexol and an equal number of control patients who used Iodixanol, we noted ESRD incidence rates of 3.47% and 3.26%, respectively. In the subcategory of patients with CKD, the incidence rates were 17.4% and 17.3% respectively for the Iohexol and Iodixanol groups. After adjusting for factors such as hypertension, diabetes, heart failure, medication use, electrolyte levels, and hemoglobin, we found that Iodixanol significantly associated with lower risk of

ESRD with an adjusted hazard ratio (aHR) of 0.65 (95% CI, 0.47–0.90; p-value: 0.01), compared with the Iohexol group. In the subgroup analysis, the protective effect was only observed among patients with CKD with an adjusted hazard ratio (aHR) of 0.70 (95% CI, 0.49–0.99; p-value: 0.04).

Conclusions: Our study suggests that Iodixanol is significantly associated with a reduced risk of progression to ESRD following PCI compared to Iohexol in real-world practice. Therefore, when considering contrast agents for these procedures, particularly in CKD patients, Iodixanol emerges as a preferable choice to mitigate the risk of ESRD.

Imaging Evidence of Contrast-Induced Nephropathy: A Case Report

Jie Ouyang,[1,2] Isha Puri,[1,2] Arye Kremer,[1] Moro O. Salifu,[1] Mary C. Mallappallil.[1,2] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Introduction: AKI after IV contrast media (CM) exposure has been reported since 1950. CKD and DM are two major risk factors associated with contrast-induced nephropathy (CIN). One of the mechanisms is that the hyperosmotic property of CM increases tubular fluid viscosity which leads to renal CM retention and eventually tubular and medullary injuries. We report a case of CIN with a CT scan visualizing the prolonged CM renal retention.

Case Description: An 85-year-old man with HTN, DM II, CAD, and BPH was admitted for syncope with poor oral intake while taking furosemide. His initial serum BUN and serum creatinine (sCr) were 32mg/dL and 1.6mg/dL (baseline 1.3mg/dL). He received IV fluids (IVF) and furosemide was continued. sCr was 2.3mg/dL on day 2 when furosemide was stopped. sCr improved to 1.9mg/dL and he had CTA of chest to rule out pulmonary embolism with Omnipaque 95 ml. His sCr rose to 3.5md/dL within 48 hours. After addition of Valsartan he became oliguric. Renal service recommended IVF, post void bladder scan and discontinuation of Valsartan, with differential diagnoses including CIN, pre-, and post-renal etiology. Urinary obstruction was ruled out. However his sCr continue to rise 3 days after IV contrast. A non-contrast CT of abdomen to evaluate lymphadenopathy revealed renal parenchyma significantly enhanced by contrast administered 5 days ago. His sCr worsened to 6.7mg/dL on day 10, with improved urine output and normal electrolytes. He had a cardiac arrest and passed away before planned RRT.

Discussion: We hypothesized that this patient developed CIN with risk factors of DM, AKI on CKD, dehydration, use of ARB and urinary retention, with CT scan 5 days after IV contrast still showing contrast in the renal parenchyma. This prolonged exposure to CM proved by imaging may have contributed to his severe renal injury. This case report provides imaging evidence and highlights the risk factors that are strongly associated with CIN.

SA-PO088

Atorvastatin and Renoprotective Effects for Contrast-Induced NephropAthy Prevention (ARENA): A Pilot Feasibility Randomized Controlled Trial

Jeerath Phannajit,[1,2] Nuttha Lumlertgul,[2,3] Nattachai Srisawat,[2,3] Paweena Susantitaphong,[2] Pisut Katavetin.[2] *[1]Division of Clinical Epidemiology, Department of Medicine, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand; [2]Division of Nephrology, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [3]Excellent Center for Critical Care Nephrology, King Chulalongkorn Memorial Hospital, Thai Red Cross Society, Bangkok, Thailand.*

Background: Contrast-induced acute kidney injury (CI-AKI) can complicate coronary angiography (CAG) that can lead to increased morbidity and mortality. Previous studies have shown the protective effects of high-dose statin pretreatment in various scenarios. However, the role of statins in preventing subclinical AKI is still under investigation.

Methods: We conducted a randomized controlled trial including 50 patients at stage G3-4, who were randomly assigned to receive either 80 mg of atorvastatin or placebo once daily for 2 days prior to undergoing CAG. The primary outcome was the change in urine NGAL concentration 6 hours after CAG compared to baseline. Secondary outcomes included the incidence of AKI based on serum creatinine criteria, changes in estimated glomerular filtration rate (eGFR) from baseline to 7 days after the procedure, and the occurrence of adverse events such as hepatitis and myositis. Additionally, an in-vitro study was conducted to explore the effect of radiocontrast on NGAL assay.

Results: The mean baseline eGFR was 53.4 ± 17.8 ml/min/1.73m^2, and 22 patients (44%) had not previously used statins. Percutaneous coronary intervention was performed in 19.1% of patients, and all participants received iso-osmolar contrast with a median volume of 37.5 [30-80] ml. There were no significant differences observed in urine NGAL concentrations 6 hours after CAG between the atorvastatin and placebo groups (median [IQR] 4.4 [2.8-18.1] vs 6.6 [2.4-13.0], p = 0.9). The analysis also revealed no significant interaction with prior statin use, and no cases of CI-AKI were identified based on serum creatinine criteria. No adverse events were reported, and there were no significant increases in transaminase and creatine phosphokinase enzymes. The additional in-vitro study demonstrated no assay interference of radiocontrast in measuring urine NGAL.

Conclusions: The administration of high-dose atorvastatin as pretreatment of CAG was well tolerated in this study involving patients with early CKD and low-volume iso-osmolar contrast. However, the study did not demonstrate a renoprotective effect in this population, indicating a limited benefit for atorvastatin in this low-risk setting.

SA-PO089

Spilling the Tea ON AKI

Gabrielle V. Carroll,[1] Gabriella Primera,[2] Connie Chen,[2] Parth Patel,[2] Kathryn Jobbins,[2] Daniel L. Landry.[2] *[1]University of Massachusetts Chan Medical School, Worcester, MA; [2]Baystate Medical Center, Springfield, MA.*

Introduction: Oxalate nephropathy (ON) is characterized by oxalate crystal deposition in the tubulointerstitium leading to acute kidney injury (AKI) and possible chronic kidney disease (CKD).[1] We present two cases of ON from excessive black tea consumption with full recovery.

Case Description: Case 1: A 52-year-old diabetic male was admitted after two weeks of poor solid food intake complicated by three days of acute left-sided vision loss and creatinine 8.5 mg/dl (baseline 1.6 mg/dl). Urinalysis showed benign sediment without proteinuria. Renal ultrasound revealed no hydronephrosis. MRI orbit showed bilateral increased optic nerve enhancement. Renal biopsy demonstrated acute tubular injury with calcium oxalate deposits and underlying diabetic nephropathy (DN). He later reported consumption of 5.5 liters of black tea a day for several weeks. He had full recovery of his renal function 2 months later after complete cessation of black tea intake. He never regained left eye vision, which was likely due to acute oxalate vasculopathy. Case 2: A 70-year-old diabetic male was admitted for abnormal creatinine of 5.9 mg/dL (baseline 1.2 mg/dl) in the setting of one week of diarrhea. He denied toxic ingestion but had consumed large volumes of black tea for months to lose weight. He had a benign urinary sediment and enlarged kidneys on ultrasound (13 cm). Renal biopsy revealed DN changes with acute ON.[2] Avoidance of black tea led to full renal recovery within 4 months.

Discussion: Hyperoxaluria is defined as a urine oxalate level greater than 40-45 mg/day.[2] US diets contain approximately 150 mg/day of oxalate with intake over 1000 mg/day associated with toxicity.[3] A recent 2020 study described 4.1% of biopsies in the New York City metro area containing oxalate deposits, contributing to CKD progression in 3.6% of cases.[4] Causes of hyperoxaluria include primary hyperoxaluria type1 and 2, and secondary hyperoxaluria from nutritional deficiencies, increased intestinal absorption, impaired excretion, or excessive intake of oxalate-rich foods or precursors.[2] Black tea contains 50-100 mg of oxalates per 100ml.[5] Treatment of ON includes supportive care and calcium supplementation to bind intestinal oxalate. Over-ingestion of black tea is an underrecognized cause of acute ON. While acute ON can lead to residual CKD, our cases are notable for full renal recovery after timely cessation of the offending agent.

SA-PO090

Outcomes of Intravenous Contrast Media on Patients with CKD: Systematic Review and Meta-Analysis

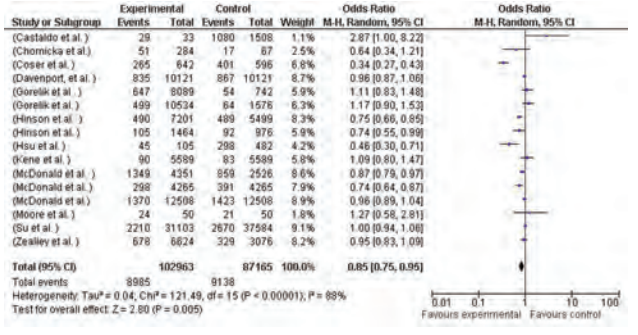
Ibrahim Tawhari. King Khalid University College of Medicine. *King Khalid University, Abha, Saudi Arabia.*

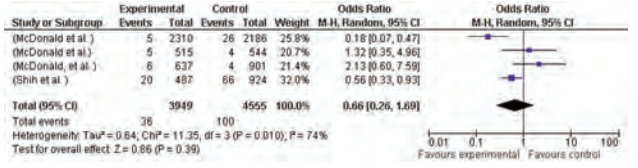
Background: Intravenous contrast media is frequently used in diagnostic and interventional procedures. Contrast-associated acute kidney injury (AKI) had been described as a complication associated with intravenous contrast media, which can lead to acute kidney injury and adverse clinical outcomes, especially in patients with underlying chronic kidney disease (CKD). However, this complication has been a subject of debate. The goal of this analysis is to evaluate the outcomes of intravenous contrast media use in patients with CKD.

Methods: A systematic search was conducted in PubMed, Scopus, ScienceDirect and Google Scholar for articles published from 2013 to March 2023. The reference lists of the included studies were also searched to retrieve possible additional studies.

Results: The meta-analysis included a total of 24 studies with a combined sample size of 278,908 participants. The pooled incidence of acute kidney injury in the OR was 0.85 (95% confidence interval [CI]: 0.75-0.95, P=0.005). In the association of dialysis and contrast media, had OR of 0.66(95%CI: 0.26-1.69), p=0.39.

Conclusions: These findings suggest that contrast media use is not associated with a higher risk of acute kidney injury and dialysis needs in patients with chronic kidney diseases. More research is needed to fully understand the potential risks of contrast media used in this patient population.





SA-PO091

Return of the MAC: Granulomatous Interstitial Nephritis Secondary to Disseminated Mycobacterium Avium Complex (MAC) Infection

Muhammad A. Monk,[1] Catherine Soodi,[1] Jordan Torres,[1] Srinidhi Shyamkumar,[1] Majd Al Shaarani,[2] Sowmya Puthalapattu.[1] *[1]HCA Houston Healthcare Kingwood, Kingwood, TX; [2]The University of Texas Health Science Center at Houston, Houston, TX.*

Introduction: Mycobacterium Avium Complex (MAC) is a group of non-tuberculous mycobacteria with the potential to cause severe infection in the immunocompromised, notably with HIV and AIDS. MAC is mostly known as a respiratory pathogen, however can disseminate in the bloodstream and has been seen in nearly all organ systems.

Case Description: A 27-year-old male with a history of HIV on antiretroviral therapy (ART) presented with 2 weeks of painful swelling of his left jaw. He was diagnosed with HIV 5 months prior and discharged on ART. After discharge, the patient's blood cultures became positive for MAC but he was never informed or treated. Vital signs were stable, and physical exam showed a tender subcutaneous mandibular mass. CT of the face showed a 3.8 cm abscess adjacent to the mandible. A chest radiograph showed no acute findings. Labs showed BUN of 78 mg/dL, serum Creatinine of 12.2 mg/dL, and an estimated 24-hour proteinuria of 1g/day. Kidney function was previously normal. Ultrasound showed enlarged kidneys without hydronephrosis. HIV PCR was undetectable, and CD4 testing could not be calculated due to severe lymphopenia The abscess was drained, and cultures were positive for MRSA and MAC. The patient was started on cefazolin, ethambutol, and azithromycin, and symptoms improved rapidly. Testing for other opportunistic infections was negative. ART was held until definitive diagnosis for AKI was made on biopsy, which showed granulomatous tubulointerstitial nephritis and crystalline nephropathy. Renal function stabilized, ART was resumed, and outpatient follow-up was arranged.

Discussion: Given the positive MAC culture found in subcutaneous abscess drainage and severe granulomatous inflammation seen on kidney biopsy disseminated MAC infection was the likely underlying etiology of the patient's AKI. MAC is less commonly known to affect the skin, though several case descriptions can be found in the literature. Granulomatous interstitial nephritis is a rare finding, occurring in less than 1% of all biopsies. Other considered etiologies of AKI included HIV associated nephropathy, sarcoidosis, and granulomatosis with polyangiitis. Clinicians should be aware of extrapulmonary manifestations of MAC and ensure prompt outpatient follow-up at the time of HIV diagnosis in order to prevent adverse outcomes.

SA-PO092

Preadmission Veterans Aging Cohort Study Index Is Associated with AKI in Hospitalized People with HIV

Molly Fisher,[1] David B. Hanna,[1] Melissa Fazzari,[1] Uriel R. Felsen,[1] Christina M. Wyatt,[2] Matthew K. Abramowitz,[1] Michael J. Ross.[1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Duke Medicine, Durham, NC.*

Background: People with HIV (PWH) are at increased risk for acute kidney injury (AKI) and its sequelae. Numerous biomarkers have been shown to predict AKI but most are not routinely measured in practice. The Veterans Aging Cohort Study (VACS) index is a score based on age, CD4 count, HIV viral load, hemoglobin, eGFR, hepatitis C virus (HCV) antibody, platelets, AST and ALT. The VACS index predicts a number of outcomes and is highly correlated with markers of inflammation, including TNF alpha and IL-6 which have been shown to be predictive of AKI. We therefore hypothesized that preadmission VACS index would be associated with AKI.

Methods: We performed a cohort study of 1,186 PWH hospitalized in a New York City health system between 2010-2019. Outpatient laboratory values prior and closest to admission (7-365 days) were used to create the VACS index. The VACS index was divided into quartiles (≤22, >22 to 34, >34 to 55, >55). AKI was defined by KDIGO criteria. Multivariable Cox regression adjusting for sociodemographics, diabetes and intensive care unit admission was used to determine the association between VACS quartile and risk of AKI, treating the competing risks of death and discharge as censoring events.

Results: Median age was 53 years (IQR 43, 60), 516 (43.5%) were women, 500 (42.2%) were Hispanic, 522 (44%) were non-Hispanic Black and 195 (23.1%) were coinfected with HCV. Median CD4 count was 465 cells/mm^3 (IQR 201, 714) and 65% were virally suppressed (<200 copies/mL). The unadjusted AKI incidence was higher with increasing VACS quartile: 39 (10.7%) in Q1, 41 (18.6%) in Q2, 61 (28.1%) in Q3 and 107 (60.7%) in Q4. Compared to those in the lowest VACS quartile, the adjusted relative hazard (aHR) of AKI was 1.50 times higher (95% CI 0.96, 2.33; p=0.07) in Q2, 1.93 times higher (95% CI 1.28, 2.91) p=0.002) in Q3 and 3.23 times higher (95% CI 2.21, 4.74; p<0.0001) in Q4.

Conclusions: Preadmission VACS index is independently associated with AKI. The VACS index may allow for timely identification of PWH at risk for AKI and initiation of preventative strategies including intravenous fluids, avoidance of nephrotoxic medications and careful drug dosing. Our findings should be replicated in a larger cohort and future studies should evaluate its ability to predict severe AKI and nonrecovery from AKI.

SA-PO093

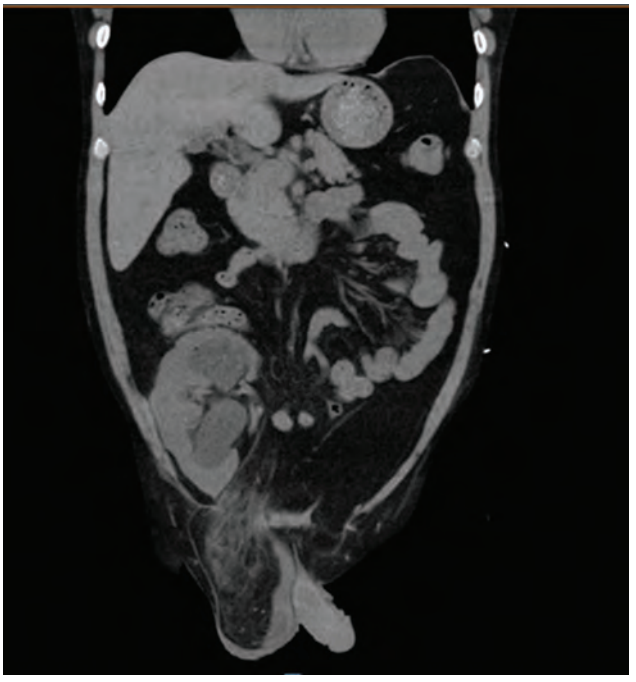
Unique Presentation of Hydronephrosis of a Transplanted Kidney from an Inguinal Hernia

Alexander N. Fleischhacker,[1] Shane W. Quo,[1] Elissa Klein,[2] Mary Parianos,[1] Aakash Padodara,[1] Ahmed A. Waheed.[1] *[1]University of Miami Health System, Miami, FL; [2]University of Miami, Coral Gables, FL.*

Introduction: End stage renal disease (ESRD) increases morbidity and worsens quality of life. Kidney transplants improve clinical outcomes in ESRD. This is a unique case of a post-renal acute kidney injury in a transplanted kidney secondary to a complicated right inguinal hernia.

Case Description: A 56-year-old male with history of right inguinal hernia and right kidney transplant on immunosuppression presented to the ED with a tender inguinal hernia for two days and inability to completely void. Prior attempts to reduce the hernia had been successful and notably improved his urinary symptoms. However, he could not longer reduce the hernia. On arrival, the patient was found to have a creatinine of 1.81 (baseline 1.1) and BUN of 32. A CT abdomen and pelvis showed a right inguinal hernia containing the distal ureter of the transplanted kidney and portions of the bladder. (Figure 1). General surgery was able to reduce the hernia. Once reduced, the patient began producing normal range urine output, and creatinine improved. He was transferred to a transplant facility for surgical evaluation. He underwent open inguinal hernia and incisional repair with mesh, which revealed bladder sidewall protruding through the hernia. Post-operatively, the patient continued to clinically improve, and his creatinine was near baseline.

Discussion: Kidney transplants provide an avenue without dialysis dependency and can increase life expectancy. We present a unique case of an AKI of a transplanted kidney due to complications from an inguinal hernia. Renal transplant recipients have unique changes to their anatomy, which can generate uncommon presentations of ordinary medical cases. We hope to raise awareness among physicians to diversify their differentials when encountering a transplant patient.



SA-PO094

Kidney Failure Requiring Dialysis due to Renal Metastatic Spread from a Laryngeal Squamous Cell Carcinoma

Niklas Ayasse, Julian Marinez, Clara Daschner, Zoran Popovic, Anne Lammert, Bernhard K. Krämer. *Universitatsklinikum Mannheim, Mannheim, Germany.*

Introduction: Renal metastatic spread from laryngeal squamous cell carcinoma (SCC) is particularly rare. We here report the unique case of a patient with acute dialysis requiring renal failure due to diffuse metastatic spread of a laryngeal SCC.

Case Description: A 59-year-old man presented with progressive dyspnea, and anuria. His past medical history was remarkable for right sided supraglottic laryngeal cancer cT3cN2bcM0 diagnosed two and a half years earlier. The histopathological work-up had revealed a squamous cell carcinoma (SCC). A radiochemotherapy had been effectuated and the patient had since then been in remission. The initial diagnostic workup revealed acute kidney failure AKIN-3. Initially, a prerenal cause was assumed. Bedside sonography did not show urinary retention. Due to uremia symptoms intermittent hemodialysis was initiated. Since renal function did not improve, a percutaneous kidney biopsy was obtained. The histopathological work-up revealed squamous cell carcinoma infiltrates consistent with renal metastasis from the supraglottic laryngeal carcinoma (Figure 1). The neighboring healthy renal parenchyma showed only few vital glomeruli, without any signs of glomerular damage. We hence concluded that the origin of the kidney failure was a diffuse renal metastatic spread from the primary cancer. Due to persistent anuria, a tunneled dialysis catheter was placed and the patient was started on intermittent hemodialysis thrice a week.

Discussion: To the best of our knowledge, only 3 previous cases of renal metastasis from laryngeal SCC have been described in the literature (Paul, Harden et al. 1999, Lecoeuvre, Degardin et al. 2003, Erbag et al. 2013). In contrast to these previous reports dealing with unilateral renal metastasis, our patient case is unique in the way that both kidneys were diffusely infiltrated by metastasis, that led to end-stage kidney disease. This case report highlights that one should always consider renal metastasis as a cause of acute kidney failure in tumor patients.

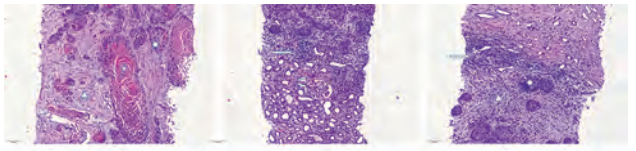


Figure 1: Squamous cell carcinoma infiltrating kidney tissue
Left – typical 'nested' morphology of moderately differentiated squamous cell carcinoma (○) with keratinization (☆) and prominent desmoplastic stroma reaction (△).
Center and right – kidney tissue with tumor-associated acute inflammation (▭) next to vital glomeruli (◎).
Image acquisition was done using a PreciPoint scanning microscope (using objective ×40/0.65 NA) and MicroPoint software (v.2016-02-05; PreciPoint, Freising, Germany).

SA-PO095

Recurrent AKI for a Patient with Mutation in the MCP/CD46 Gene and Plasminogen Deficiency

Tariku T. Gudura, Melissa Baker, Laura Ferreira Provenzano, Leal C. Herlitz, Robert J. Heyka, Xiangling Wang, Jonathan J. Taliercio. *Cleveland Clinic, Cleveland, OH.*

Introduction: Complement-mediated thrombotic microangiopathy (CM-TMA) is a systemic disease characterized by hemolytic anemia, thrombocytopenia, and organ damage including acute kidney injury (AKI). Some causes of CM-TMA occur from dysregulation of complement proteins leading to loss of function in regulators and gain of function in effectors. Pathogenic gene variants of plasminogen, a component of the coagulation cascade, are thought to play role for CM-TMA. We present a case report of a patient with plasminogen deficiency and mutation in MCP/CD46 gene presenting with recurrent AKI.

Case Description: 64 years old female patient with history of asthma, alopecia universalis and gout presented for evaluation of recurrent episodes of AKI. She reports around five episodes of AKI over 5 years. She required dialysis and steroids in two occasions with complete kidney recovery. Her symptoms start with nausea, vomiting and flank pain followed by gross hematuria. Past work up was notable for thrombocytopenia, elevated D-dimer and AKI. Kidney biopsies obtained in 2016 and 2019 revealed acute tubular injury without signs of thrombotic microangiopathy (TMA). During her most recent episode, she presented with similar symptoms. Labs showed Hgb 10.9 g/dl, platelet 78.1 K/uL (150 - 400), D dimer >35,200 ng/ml (< 500), creatinine of 4.9 mg/dl (0.6 - 1), LDH of 3417 U/L (135 - 214), haptoglobin < 10mg/dl (31 - 238), plasminogen Assay 52% (69 - 137), plasminogen antigen 6.2 mg/dl (7.5 -15.5), schistocytes on peripheral smear, norma ADAMT-13 and unrevealing bone marrow. Genetic testing showed a variant in MCP/CD46 gene and a variant in plasminogen. She was treated with steroids, fresh frozen plasma and IVIG for 3 days, and discharged on tapered dose steroids for a month. On subsequent follow up, her kidney recovered within a month.

Discussion: The exact interplay between individual coagulation factors and complement system is not well understood. Plasmin has been shown to have some inhibitory role on complement mediated hemolysis. Pathogenic variants of the coagulation proteins such as plasminogen is found to play a role in CM-TMA such as atypical hemolytic uremic syndrome. In this case, plasminogen deficiency is likely contributing to TMA from MCP/CD46 mutation warranting further studies for better understating.

SA-PO096

Renal Function Recovery After Urinary Stone Removal Is Diverse for Patients with Urinary Stones in Different Locations

Wen Wen. *Beijing Tsinghua Changgung Hospital, Beijing, China.*

Background: The impact on renal function might be diverse in urolithiasis in different locations. We conducted a retrospective cohort study to analyze the trend of estimated glomerular filtration rate (eGFR) variation for urolithiasis in different locations after stone removal.

Methods: Clinical and laboratory characteristics of urolithiasis patients hospitalized in Beijing Tsinghua Changgung Hospital from March 2015 to September 2017 were screened according to our eligibility criteria. Creatinine values on 4 different time points (before surgery, 1 day after surgery, 7 days after surgery, and 1 month after surgery) were collected. Multi-level random effect models were constructed and the variations of eGFR were compared among patients with different stone locations. Subgroup analyses were done in patients with impaired renal function at baseline (eGFR < 60ml/min*1.73m^2).

Results: Among the 760 urolithiasis patients included (mean age: 50.8 ± 21.6 years, males: 62.8%), 483 had kidney stones, 168 were with ureter stones, and 109 had stones in both kidney and ureter. Coronary artery disease, urinary tract infection, hemoglobin, and serum albumin were unevenly distributed factors (P<0.001). The greatest improvement in eGFR and the most significant proportion of eGFR improvement was seen in patients with ureter stones. In contrast, the worst eGFR recovery was noted in patients with kidney stones (P<0.001). In multi-level models adjusted for related factors or not, a decrease of eGFR was noted at day 7 and an increase of it was observed at day 30 compared to baseline (P<0.05). Similar trends were noted in patients with ureter stones and those with kidney&ureter stones. However, the eGFRs kidney stone patients were not improved at day 30 (P>0.05).

Conclusions: Patients with stones only located in kidney may have the worst outcome in renal recovery after surgery. Large prospective studies are warranted to further establish the relationship between stone location and renal recovery.

Clinical Characteristics and Outcomes of Urolithiasis

Sungyeon Kim,[1] Young Eun Choi,[1] Yookyung Jang,[1] Suk Min Chung,[1] Ko Yoon Sook,[1] Lee Hee Young,[1] Jihyun Yang,[2] Tai yeon Koo,[1] Sewon Oh,[1] Myung-Gyu Kim,[1] Sang-Kyung Jo.[1] *[1]Korea University, Seongbuk-gu, Republic of Korea; [2]Kangbuk Samsung Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Recent studies have showed the incidence of urolithiasis is increasing and known to be associated with chronic kidney disease (CKD)/end stage kidney disease (ESKD). Although kidney and ureter stones are heterogenous in composition, it is usually considered as single entity. The aim of this study was to compare the different clinical characteristics and outcomes of kidney/ureter stone diseases according to compositions.

Methods: We performed a single center retrospective study of symptomatic stone formers with known stone compositions (n=758). Baseline characteristics, blood and urinary excretory profiles, prevalence of diverse comorbid conditions as well as acute kidney injury (AKI) and long-term outcomes including ESKD and death were compared.

Results: Mean age was 58.6 yrs with male predominance (64.5%). Calcium oxalate stone was the most common type (68%) followed by struvite stone (15.5%), uric acid stone (13%) and mixed stones. Uric acid stone formers were significantly older (68yrs) with male predominance (76.5%) and showed higher prevalence of diabetes mellitus, hypertension, ischemic heart disease/heart failure, dementia and cancer. Calcium oxalate stone formers excrete significantly higher levels of glucose and calcium while uric acid stone formers showed low urinary pH. Incidence of AKI was 36.3% and older age, hypertension, low total CO2, and uric acid stone were found to be independent risk factors of AKI. During the mean follow-up of 456 days, 33 (4.3%) progressed to ESKD and 35 (4.6%) died. AKI was found to be an independent risk factor for both ESKD and mortality regardless of stone composition.

Conclusions: Kidney stone disease is thought to be a heterogenous condition with different clinical characteristics and longterm outcomes. Occurrence of AKI regardless of stone composition is an important predictor for adverse longterm outcomes. Better understanding of epidemiology, risk factors and pathogenesis of this heterogenous conditions are needed.

SA-PO098

The Clinical and Pathologic Characteristics of Patients with Oxalate Nephropathy

Maria Llanos,[1] Alvin G. Kwon,[1] Leal C. Herlitz,[1] Surafel K. Gebreselassie,[2] Hanny Sawaf,[1] Shane A. Bobart.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Florida, Weston, FL.*

Background: Oxalate nephropathy (ON) is characterized by deposition of calcium oxalate crystals in the kidney and is commonly underrecognized. Causes of ON include primary hyperoxaluria, enteric hyperoxaluria and ingestion of excess oxalate or its precursors.

Methods: We report the clinical and pathological characteristics of the largest series of native kidney oxalate nephropathy to date, from January 2015 to March 2023 at the Cleveland Clinic.

Results: Of 11900 kidney biopsies, we identified 60 native biopsies with oxalate deposits and excluded patients with clinically insignificant biopsies (n=12) or lack of data (n=17). 31 patients with native oxalate nephropathy were described. The mean age at diagnosis was 66.2 years (±12.1) and 58.1% were female. 87.1% had hypertension, 58.1% had diabetes, 42% had nephrolithiasis, and 77.4% had underlying CKD with a mean baseline creatinine of 1.8 mg/dL ±1.3. The mean creatinine at biopsy was 5.2 mg/dL ±1.7. Kidney biopsies showed abundant calcium oxalate crystal deposits, and 27 of 31 biopsies had additional diagnoses, the most common of which were acute tubular injury n=17 (54.8%) and diabetic glomerulosclerosis n=7 (22.6%). Severe and moderate interstitial fibrosis was present in 38.7% (n=12) and 51.6% (n=16) of biopsies respectively. 10 had a single etiology of ON, 10 had a multifactorial etiology (both enteric hyperoxaluria and high precursor intake) and 11 had an unclear etiology. Notably, only 7 patients had a history of gastric bypass. The mean duration of follow-up was 26.8 months and 26 patients had follow up data >1 year. Of these, 21 required dialysis and 5 were dialysis free at presentation. 5 of the 26 were deceased at 1 year, with 12 patients (38.7%) deceased at last follow up. 14 patients received targeted management while 12 patients did not receive targeted treatment and all 12 required hemodialysis. More patients (31.6%) had vitamin C intake post COVID pandemic (2020-2023) vs 16.7% prior to 2020.

Conclusions: Oxalate nephropathy presents as AKI or acute on CKD. The prognosis is poor with most patients requiring dialysis at presentation with high morbidity and mortality. Clinicians need to be aware of the risk factors associated with oxalate nephropathy to aid prompt diagnosis and management.

SA-PO099

Multifactorial Rhabdomyolysis in an HIV Patient: Management of AKI

Uma D. Gupta, Thi My Nguyet Nguyen, Saphal N. Subedi. *Interfaith Medical Center, Brooklyn, NY.*

Introduction: Rhabdomyolysis is common in HIV patients with drug abuse history, however literature is scarce regarding management. In our multifactorial rhabdomyolysis case, CK level is more than 100,000 with proteinuria, which is a rare presentation. The findings in our case highlight the importance of individualized management approach based on the underlying etiologies and the patient's clinical status.

Case Description: In our case, a 32-year-old male with unknown past medical history presented to the emergency department with altered mental status. He was diagnosed with Strep Pneumonia, subsequently with HIV, HCV, polysubstance abuse (amphetamine, cocaine, and opiates) and later developed rhabdomyolysis with nephrotic range proteinuria. The patient received conservative treatment with 10-20 ml/kg of isotonic saline with 1 Liter of glucose 5% with 100 mmol of bicarbonate bolus. The goal was to maintain Urine output of 1 to 2 ml/kg/hour. Notably, there was a progressive improvement in the proteinuria, (from 4.5 grams per day to 1.45 grams per day). Considering the decline in proteinuria and the restoration of renal function, a renal biopsy was not planned at this stage. To support the patient's nutritional needs, a high protein diet was administered via a nasogastric tube, targeting a dosage of 1.6-1.8 grams per kilogram of body weight.

Discussion: This HIV patient with rhabdomyolysis and nephrotic range proteinuria who developed AKI due to multifactorial causes was treated with various management strategies- including pharmacological interventions targeting the specific etiologies, fluid therapy for volume resuscitation and electrolyte balance, and nutritional support. The efficacy of the conservative interventions was evaluated by improvement in renal function and reduction in proteinuria.

Trend of CK level

The Rise of Rhabdomyolysis in Philadelphia's Fentanyl Crisis

Rami Bzeih, David Jimenez, Jean Lee, Avrum Gillespie. *Temple University Hospital, Philadelphia, PA.*

Background: Philadelphia has experienced a recent surge of fentanyl use and unintentional overdose, particularly the area served by the Temple University Hospital System (TUHS). Patients admitted to the hospital for overdose are often found to have rhabdomyolysis and acute kidney injury (AKI). While opioids like heroin have been previously associated with causing rhabdomyolysis, it is our belief that fentanyl has exacerbated this problem. In this study, we determine whether there has been a rise in patients developing AKI from drug-associated rhabdomyolysis that correlates with the 50% increase of fatal fentanyl overdoses in Philadelphia over the past 6 years.

Methods: We conducted a retrospective cross-sectional study to examine trends in fentanyl-associated rhabdomyolysis and AKI. Our sample comprised 1060 patients aged 18-60 admitted to TUHS for drug-associated rhabdomyolysis. Data were collected from electronic medical records and screened for inclusion criteria. Patients with end-stage kidney disease or a hospital stay of less than 24 hours were excluded.

Results: From 2016 to 2022, the incidence of drug-associated rhabdomyolysis at TUHS has increased from 8.8 cases per month to 16.4 cases per month. Among those cases, the incidence of AKI rose from 5.8 cases per month to 13.8 cases per month. The greatest increase was noted between 2019 and 2020 (6.5 to 10 cases per month). Fentanyl was first tested in late 2018, and 60% of included patients since then were tested for fentanyl. Of those who were tested for fentanyl, positivity rate steadily increased from 52% in 2019 to 75% in 2023. Since 2016, AKI cases associated with other opioids declined from 67% to 16%. AKI cases positive for cocaine has remained around 43%.

Conclusions: Our findings suggest a strong correlation between the increased incidence of drug-associated rhabdomyolysis and AKI at TUHS and rising fentanyl abuse. This correlation was not observed with other drugs included in toxicology screens. Further research is required to ascertain the potential contribution of adulterants such as xylazine and phenylbutazone, and to develop effective harm reduction strategies to mitigate fentanyl-associated rhabdomyolysis and AKI.

SA-PO101

Hantavirus: A Rare Cause of Rhabdomyolysis

Pratiksha Singh,[1] Katherine Toma.[2] *[1]Rutgers Health Community Medical Center, Toms River, NJ; [2]Jersey Coast Nephrology and Hypertension Associated LLC, Brick, NJ.*

Introduction: Rhabdomyolysis has physical and nonphysical causes including toxins, trauma, and viral infections. Hantavirus presents flu-like symptoms and multisystem involvement including gastrointestinal, renal, and nervous systems.

Case Description: The patient is a 70-year-old male with a history of non-insulin-dependent diabetes, obesity, hyperlipidemia, arthritis, and chronic NSAID use who presented with altered mental status and inability to stand up after a fall eight hours prior. An initial examination found him disoriented, afebrile, and normotensive. Labs revealed a creatinine of 3.37 mg/dl and CK of 59100 U/L. CNS and renal imaging were all unremarkable. The patient became anuric on hospital day three and required continuous renal replacement therapy. On hospital day four he became febrile (101F). He was treated with aztreonam, vancomycin, cefepime, and empiric coverage with doxycycline. All blood cultures were negative. Collateral information was obtained from the family, who found his home in great disarray and infested with rats. This prompted testing for Hantavirus, which returned positive. The patient's renal function eventually recovered, with a creatinine of 3.26 mg/dl.

Discussion: Hoarders are at increased risk of exposure to Hantavirus due to contact with rodent droppings, saliva, urine in poorly ventilated areas. This is easily missed unless emphasis to social history including hobbies are explored. It is imperative to focus on The Social determinants of health for timely diagnosis and management.

Assessing Discharge Communication and Follow-Up of AKI: An Opportunity for Quality Improvement

Bader Al-Zeer,[1] Peter C. Birks,[1] Daniel T. Holmes,[1] Rami Elzayat,[1] Mark Canney,[3] Ognjenka Djurdjev,[4] Yuyan Zheng,[4] Samuel A. Silver,[2] Adeera Levin.[1] *[1]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [2]Queen's University, Kingston, ON, Canada; [3]University of Ottawa, Ottawa, ON, Canada; [4]Provincial Health Services Authority, Vancouver, BC, Canada.*

Background: Acute kidney injury (AKI) affects up to 20% of hospitalizations and is associated with increased chronic kidney disease, mortality, and healthcare costs. Proper documentation of AKI in discharge summaries is critical for optimal monitoring and treatment of these patients once discharged. This study aimed to evaluate the accuracy and quality of documentation of episodes of AKI at a tertiary care centre, in British Columbia, Canada.

Methods: This was a retrospective chart review study of adult patients who experienced AKI during hospital admission between January 1, 2018, and December 31, 2018. Laboratory data was used to identify all admissions complicated by AKI defined by KDIGO criteria. A random sample of 300 AKI admissions stratified by AKI severity (e.g., stage, 1, 2, and 3) were identified for chart review. Discharge summaries were reviewed for documentation of the following: presence of AKI, severity of AKI, AKI status at discharge, practitioner and laboratory follow up plans, and medication changes.

Results: Of the 300 discharge summaries reviewed, 38 were excluded. AKI was documented in 140 (53%) of discharge summaries and was more likely to be documented in more severe AKI: stage-1 38%; stage-2 51%; stage-3 75%. Of those with their AKI documented, 94 (67%) documented AKI severity and 116 (83%) mentioned the AKI status at discharge. 239 (91%) of discharge summaries mentioned a follow up plan with a practitioner, but only 23 (10%) had documented nephrology follow up. For laboratory investigations, 92 (35%) of summaries had documented recommendations. In summaries that included medications typically held during AKI, only about half made specific reference to those medications. For those with NSAIDS listed, 64% mentioned holding, and 9% mentioned a discharge plan. For those with ACEi/ARB, 38% mentioned holding these medications, and 46% mentioned a discharge plan. In ones with diuretics listed, 35% mentioned holding, and 51% included a discharge plan.

Conclusions: We found suboptimal quality and completeness of discharge reporting in patients hospitalized with AKI. This may contribute to inadequate follow up and post hospitalization care for this patient population. Strategies are required for increasing the presence and quality of AKI reporting in discharge summaries.

SA-PO103

Renal Malakoplakia in a Young Patient

Sanjivani Shrestha, Dustin Le, Mohamed G. Atta, John Sperati. *The Johns Hopkins University School of Medicine, Baltimore, MD.*

Introduction: Malakoplakia is a rare inflammatory disorder which commonly affects the genitourinary tract, but may also involve the gastrointestinal tract, lungs and skin. It is usually described in patients above age 40 years and is associated with infections and immunosuppressed conditions. We present a case of renal malakoplakia in a young female in the setting of *E. coli* urinary tract infection (UTI).

Case Description: A 32-year-old female with history of recurrent UTI, Raynaud's phenomenon, COVID-19, presented with 2 days of shortness of breath and lower extremity weakness. On examination, she was afebrile, tachycardic, hypotensive with diffuse petechial skin rash and hepatosplenomegaly. Labs showed leukocytosis, anemia, thrombocytopenia and acute kidney injury with creatinine 6.4 mg/dL (baseline 0.64mg/dL). Blood culture grew *E. coli*. CT abdomen pelvis showed marked bilateral kidney enlargement and continuous renal replacement therapy was started in the setting of worsening septic shock. The differential diagnosis of enlarged kidneys includes diabetes mellitus, cystic disease and infiltrative disease like amyloidosis, lymphoma, IgG4 related disease, hemophagocytic lymphohistiocytosis and malakoplakia. HIV and TB testing were negative. Kidney biopsy demonstrated pyelonephritis with focal micro-abscesses and diffuse CD163 positive inflammatory infiltrate consistent with macrophage/histiocytic cells. Von Kossa stain was positive with round inclusions in histiocytes, typical of Michaelis-Gutman bodies. Biopsy findings consistent with Malakoplakia. She was treated with antibiotics, bethanechol and ascorbic acid with recovery of kidney function sufficient to stop dialysis. Given intermittent fevers, persistent leukocytosis and enlarging left renal abscesses on CT, she underwent left nephrectomy 2 months into hospitalization. She was discharged home on oral minocycline.

Discussion: This case highlights the importance of considering malakoplakia in the differential diagnosis of nephromegaly, even in young patients. It is due to defective destruction of phagocytosed microorganisms by macrophages, although the underlying mechanisms remain unclear. Optimal therapy is uncertain, and this case emphasizes the importance of aggressive care.

SA-PO104

Kidney Epithelium Origin Cell-Free DNA: A Promising Biomarker in Prediction Sepsis-Induced AKI

Ruilian You,[1] Xiangming Quan,[2] Peng Xia,[1] Huadong Zhu,[1] Ling Yang,[2] Limeng Chen.[1] *[1]Peking Union Medical College Hospital, Dongcheng-qu, China; [2]GenePlus-Beijing, Beijing, China.*

Background: Sepsis-induced acute kidney injury (SI-AKI) is a common complication of sepsis with high morbidity and mortality, with the diagnosis based on serum creatinine (Scr) and urine volume. Tracing the origin of the kidney epithelium origin cell-free DNA (Kidney-ep cfDNA) using the methylome atlas is a promising diagnostic biomarker for SI-AKI and has not been reported yet.

Methods: We extracted plasma cfDNA from 7 sepsis non-acute kidney injury (SN-AKI) and 9 SI-AKI patients for TET-assisted pyridine borane sequencing, used a reference methylation atlas of 40 cell types to analyze sequence reads to quantitate the relative contribution of cfDNA from different cell types by using the UXM fragment-level deconvolution algorithm. We multiplied the contribution by the total concentration of cfDNA, to obtain the concentration of Kidney-ep derived molecules. We determined the correlation of Kidney-ep cfDNA measures to SI-AKI, and then evaluated the diagnostic value of the Kidney-ep cfDNA. Differential methylation regions (DMR) were analyzed, and then we performed GO/KEGG pathway enrichment analysis using these DMR-related genes.

Results: Compared to healthy controls, all sepsis patients showed significantly elevated concentrations of cfDNA (P < 0.01). Compared to SN-AKI patients, SI-AKI patients had approximately 8.57-fold higher levels of cfDNA, consistent with the disorders of coagulation cfDNA (P = 0.022). The relative contribution and concentration of Kidney-ep cfDNA in SI-AKI patients was higher than in non-AKI patients (P = 0.003). The Area Under Curve (AUC) in differentiating SI-AKI from spesis patients reached 0.9206, which was higher than that of the cfDNA concentration (0.9206 vs. 0.8889). Also, there was a significant negative correlation between the concentration of kidney-ep cfDNA and the number of days after being diagnosed with SI-AKI (R=0.81, *P* = 0.028). Except for coagulation dysfunction, the concentration of Kidney-ep cfDNA was not affected by age, hypertension or septic shock (*P*<0.05). The pathways enriched the DMR genes, including complement and coagulation pathway, lymphocyte differentiation, etc.

Conclusions: Our study first showed the kidney-ep cfDNA is a novel biomarker of the SI-AKI diagnosis with real-time functional response.

SA-PO105

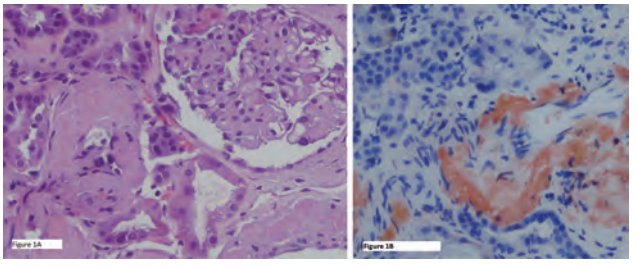
Chest Pain, Diarrhea, AKI, and Anemia: Uniting Them

Jaspreet Sian, Swee-Ling Levea, Allen Hendricks. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Introduction: Amyloidosis is a systemic disease with multiorgan involvement affecting 4000 Americans a year. Diagnosis is often delayed and overlooked. In this case a patient presents with many symptoms and a renal biopsy unites them.

Case Description: 69 year old male with pancreas and kidney transplant presents for chronic diarrhea for several weeks, chest pain, acute kidney injury (AKI) and anemia. GI panel positive for sapovirus. Cr improves with IV fluids but with ongoing diarrhea colonoscopy is done showing edematous colon. Chest pain persists and catheterization showed 60% proximal stenosis of the LAD and 40% left circumflex and RCA stenosis. He is discharged on aspirin. One week later, he has a rash and AKI with a Cr of 13.3. UA has eosinophils and cholesterol emboli is diagnosed. Dialysis is initiated and patient transferred for renal biopsy which is performed. The glomeruli had diffuse mesangial expansion by eosinophilic, amorphous, acellular material, walls of arteries and arterioles were expanded by the same material (Figure 1A). A Congo red stain was positive in glomeruli, arteries, and arterioles (Figure 1B). This is consistent with AL amyloidosis, lambda light chain type. Bone marrow biopsy shows plasma cell neoplasm involving 40 to 50% of bone marrow. Cardiac MRI is consistent with amyloid. Colon biopsy positive for amyloid. Patient was started on chemotherapy but expired.

Discussion: Amyloidosis is deposition of insoluble amyloid proteins that form B-pleated sheets. AL amyloid is composed of monoclonal gamma or kappa light chains. Light chains deposit in many organs and can present as anasarca, GI bleeding, dysphagia, weight loss, portal hypertension, diarrhea, chest pain, arrythmia and macroglossia. Diagnosis requires a biopsy of a fat pad or bone marrow and undergo evaluation for extent of organ involvement with cardiac MRI, coloscopy and skin biopsy. In this patient, due to his history of transplants, his work up was focused on infectious etiology for diarrhea. With the rarity of this disease, many are diagnosed late or not at all, which is why it is important to consider a unifying diagnosis for what may appear to be independent disease processes.



SA-PO106

Preoperative Serum Creatinine-to-Cystatin C Ratio and Risk of AKI After Cardiac Surgery

Hee Byung Koh,[1,4] Hyo Jeong Kim,[2,4] Hyung Woo Kim,[3,4] Sung Jin Moon,[1] Seung Hyeok Han,[3,4] Tae-Hyun Yoo,[3,4] Shin-Wook Kang,[3,4] Jung Tak Park.[3,4]
[1]Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea; [2]Gangnam Severance Hospital, Seoul, Republic of Korea; [3]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [4]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea.

Background: Postoperative acute kidney injury (AKI) is a serious complication after cardiac surgery, but risk stratification measures are limited. Decreased muscle mass is linked to negative outcomes, including kidney disease, in various clinical settings. More recently, the creatinine to cystatin C (Cr/Cys) ratio has shown correlation with muscle mass in several patients populations. This study aims to explore the association between preoperative serum Cr/Cys ratio and postoperative AKI in cardiac surgery patients.

Methods: Patients aged ≥18 years who underwent cardiac surgery at two tertiary hospitals between 2006 and 2020 were retrospectively evaluated. Their preoperative serum Cr/Cys ratios were categorized into quartiles. Primary outcomes were postoperative mild AKI (KDIGO stage 1) and moderate-severe AKI (KDIGO stage 2-3). Secondary outcome was length of hospital stay.

Results: Of the 2,354 enrolled patients (median age, 67.0 years; male, 65.2%), mild AKI and moderate-severe AKI were noted in 803 (34.1%) and 150 (6.4%) patients, respectively. Patients with higher Cr/Cys ratio had lower frequency of postoperative AKI and shorter lengths of hospital stay. Logistic regression analysis revealed that the odds ratios (ORs) [95% CI] for postoperative mild AKI and moderate-severe AKI decreased in a stepwise manner towards higher Cr/Cys ratio quartiles (mild AKI: Q2, 0.77 [0.61-0.97]; Q3, 0.75 [0.59-0.95]; Q4, 0.62 [0.49-0.79]; moderate-severe AKI: Q2, 0.67 [0.43-1.02]; Q3, 0.45 [0.28-0.73]; Q4, 0.54 [0.34-0.85] relative to the Q1, both *P* for trend <0.001). These associations were maintained after adjusting for confounding factors. Multivariable linear regression analyses revealed that patients in the 4th quartile of the Cr/Cys ratio had shorter hospital (-3.32 days, 95% CI, -5.34 to -1.30) stay than those in the 1st quartile.

Conclusions: Higher preoperative Cr/Cys ratios were associated with a lower risk of AKI development after cardiac surgery.

Table. Logistic regression for AKI and linear regression for hospital stay according to Cr/Cys ratio

Determination of Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL) Reference Intervals for Healthy Adult and Pediatric Individuals

Ronnie O. Pedersen,[1] Dennis Broyles,[2] Christopher Bird,[1] Ursula Klause.[1]
[1]Bioporto A/S, Hellerup, Denmark; [2]L3 Healthcare Solutions LLC, San Diego, CA.

Background: Neutrophil gelatinase-associated lipocalin (NGAL) is a 25kDa protein implicated in multiple biological processes, including attenuation of apoptosis and differentiation of renal tubule epithelial cells and nephrons. NGAL is also produced and secreted by injured kidney tubule epithelial cells. As such, NGAL can serve as an early urinary biomarker for acute kidney injury (AKI). This multi-site, cross-sectional study aimed to establish reference intervals for urinary NGAL (uNGAL) in healthy pediatric and adult populations using a particle-enhanced turbidimetric assay.

Methods: Apparently healthy individuals, aged ≥3 months, were eligible for this study. Subjects with urinary tract infections, acute kidney injury (AKI) or a history of AKI, stage 4 or 5 chronic kidney disease (CKD), known congenital anomalies of the kidney and urinary tract, known urothelial, urological, or kidney malignancies were excluded from the study. Subjects with uncorrected congenital heart disease, having undergone solid organ or bone marrow transplantation, receiving renal replacement therapy, and having undergone surgery (urologic, nephrectomy, or correction of congenital heart disease) were also excluded. Six hundred eighty-eight (688) subjects were screened, 677 were eligible, and 629 (91.4%) were considered evaluable. Urine samples were collected and tested for NGAL and UTI.

Results: The following table describes the NGAL summary statistics and upper 95th reference intervals by age and gender.

Conclusions: These data demonstrate the normal urine NGAL reference intervals in apparently healthy pediatric and adult populations.

Funding: Commercial Support - BioPorto A/S

Table: NGAL Summary Statistics and Upper 95th Reference Intervals (by Age and Gender)

Age Categories	Male			Female		
	N	NGAL Mean ± SD	Upper 95th (90% CI)	N	NGAL Mean ± SD	Upper 95th (90% CI)
≥3 month to <2 years of age	42	50.48 ± 3.08	50 (50 to 70)	31	53.58 ± 13.07	94 (59 to 119)
≥2 years to <12 years of age	75	50.67 ± 0.58	50 (50 to 51)	64	57.59 ± 56.53	93 (58 to 193)
≥12 years to <22 years of age	72	50.15 ± 1.30	50 (50 to 54)	64	54.83 ± 16.77	89 (68 to 146)
≥22 years to <65 years of age	77	54.34 ± 24.57	74 (50 to 143)	81	59.3 ± 26.34	132 (82 to 176)
≥65 years of age	62	52.92 ± 15.38	80 (50 to 148)	81	57.52 ± 23.23	117 (68 to 240)

SA-PO108

Improved Outcomes with Early Nephrology Consultation After Biomarker Measurement

Ashley La, Varsha Swamy, Samantha Gunning, Jay L. Koyner. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Novel urinary biomarkers, including Tissue Inhibitor Metallo-protease-2 and Insulin-like Growth Factor Binding Protein 7 ([TIMP-2]*[IGFBP7], T2*I7), have been developed to predict which patients are at risk for stage 2/3 AKI. While T2*I7 is approved as a risk stratification tool, data on its "real-world" use in conjunction with Nephrology consult and impact on AKI care is lacking.

Methods: We conducted a single-center prospective quality improvement study of ICU patients at risk for AKI or with KDIGO serum creatinine (SCr) stage 1 AKI. T2*I7 measurements and Nephrology consults were at the discretion of the primary ICU team. ICU providers were given KDIGO AKI-guideline-based practice recommendations based on T2*I7 results.

Results: Of 116 patients, 86(74%) had elevated T2*I7 ≥0.3. Of those, 30(26%) patients received nephrology consultation, 20 of whom had consultation within 1 day of T2*I7 measurement (early consult), and 10 had consults on days 2 or later (delayed consult). Patients with early and delayed consults had similar T2*I7 values (mean(SD) 3.0(3.1) vs 3.0(2.9), p=0.89), SCr at T2*I7 measurement (2.0(0.7) vs 2.0(0.5), p=0.75), and incidence of stage 1 AKI at time of T2*I7 measurement (15(75%) vs 9(90%), p=0.63). Despite more exposure to nephrotoxins, patients with early consults had significantly lower incidence of severe AKI, less dialysis, and improved mortality (p<0.05 for all) (Table). With renal consultation, T2*I7 was a poor predictor of severe AKI in 7 days (AUC 0.56(0.32-0.79), p=0.61).

Conclusions: Despite similar baseline characteristics and biomarker values, early nephrology consults were associated with improved outcomes and diminished the ability of T2*I7 to predict severe AKI. Future studies should continue to investigate if early kidney care, prompted by T2*I7, is beneficial in high-risk AKI patients.

Outcomes of Early vs Delayed Nephrology Consult

	Early Consult (n=20)	Delayed Consult (n=10)	p-value
Peak Change in SCr in 7 days (mg/dL)	2.7 (1.4)	4.7 (1.6)	0.003
Incidence of Stage 2 or 3 AKI in 7 days	9 (45%)	10 (100%)	0.004
Net I/O (mL) in 7 days	-1787.4 (6716)	+4973.7 (15540)	0.47
Diuretic Exposure	19 (95%)	8 (80%)	0.25
Exposure to Nephrotoxins (exposure x days exposed)	1.7 (2.4)	0.6 (1.0)	0.27
Length of Stay in ICU (days)	15.5 (11)	31.3 (23)	0.062
Total Length of Stay (days)	27.6 (16.5)	43.3 (21.0)	0.024
Inpatient Receipt of Dialysis	2 (10%)	7 (70%)	0.002
Inpatient Mortality	1 (5%)	4 (40%)	0.031

SA-PO109

Mortality Associated with the Neutrophil-Lymphocyte Ratio in Septic AKI Requiring Continuous Renal Replacement Therapy

Jeongin Song,[1] Jinwoo Lee,[1] Donghwan Yun,[1] Seong Geun Kim,[2] Dong Ki Kim,[1] Kook-Hwan Oh,[1] Seung Seok Han,[1] Yong Chul Kim.[1] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Inje University Sanggye Paik Hospital, Nowon-gu, Seoul, Republic of Korea.*

Background: Sepsis is an important cause of acute kidney injury in intensive care unit patients, accounting for 15–20% of renal replacement therapy prescriptions. The neutrophil-lymphocyte ratio, a marker of systemic inflammation and immune response, was previously associated with the mortality rate in multiple conditions. Herein, we aimed to examine how the neutrophil-lymphocyte ratio relates to the mortality rate in septic acute kidney injury patients requiring continuous renal replacement therapy.

Methods: Neutrophil-lymphocyte ratios of 6 and 18 were used for dividing neutrophil-lymphocyte ratios into three groups and, thus, were set higher than those in previous studies accounting for steroid use in sepsis. Cox proportional hazard models were used to calculate hazard ratios of mortality outcomes before and after matching their propensity scores.

Results: A total of 798 septic acute kidney injury patients requiring continuous renal replacement therapy were classified into three neutrophil-lymphocyte ratio groups: low (< 6), medium (6 ≤ x < 18), and high (≥ 18) (277, 115, and 406, respectively). The in-hospital mortality rates per group were 83.4%, 74.8%, and 70.4%, respectively (Table 1, $P < 0.001$). Per the univariable Cox survival analysis after propensity score matching, a high neutrophil-lymphocyte ratio was related to approximately 24% reduced mortality. The survival benefit of the high neutrophil-lymphocyte ratio group compared with the other two groups remained consistent across all subgroups, showing any P for interactions > 0.05.

Conclusions: A high neutrophil-lymphocyte ratio is associated with better clinical outcomes, such as low mortality, in septic acute kidney injury patients undergoing continuous renal replacement therapy.

Mortality outcomes according to the NLR results

	Total (n = 798)	NLR < 6 (n = 277)	6 ≤ NLR < 18 (n = 115)	18 ≤ NLR (n = 406)	P
On CRRT mortality (%)	61.4	70.4	60.9	55.4	<0.001
ICU mortality (%)	66.8	74.7	65.2	61.8	0.002
In hospital mortality (%)	75.6	83.4	74.8	70.4	0.001

NLR, neutrophil/lymphocyte ratio; ICU, intensive care unit; CRRT, continuous renal replacement therapy

SA-PO110

Higher IL-17A Levels Associate with AKI and Correlate with Biomarkers of Kidney Damage

Jason A. Collett,[1] Lucas J. Liu,[2] Alexander H. Flannery,[2] Tomonori Takeuchi,[3] David P. Basile,[1] Javier A. Neyra.[3] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Kentucky Medical Center, Lexington, KY; [3]The University of Alabama at Birmingham, Birmingham, AL.*

Background: AKI is associated with increased morbidity, mortality, and risk of CKD. IL-17A plays an important role in acute injury. We showed that IL-17A levels were elevated in critically ill patients with AKI and associated with hospital mortality and major adverse kidney events. IL-17A may be involved in AKI-to-CKD transition in AKI survivors. We hypothesize that IL-17A levels are elevated in hospitalized patients with AKI at diagnosis, and sustained elevation after discharge is associated with CKD incidence or progression.

Methods: Observational convenience sampling study of hospital survivors of Stage 2 or 3 AKI and controls without AKI from ASSESS-AKI study. Patients were classified as either "progression" or "non-progression" based on a composite of CKD incidence (≥25% decline in eGFR from baseline and achieving CKD stage ≥3), progression (≥25% decline in eGFR from baseline or <15 ml/min) or ESRD. IL-17A levels were evaluated at 0, 3 and 12 months post-AKI, and analyzed along with clinical and biomarker data over a period of up to 84 months.

Results: Among 171 AKI and 175 non-AKI participants, IL-17A levels were significantly elevated in AKI vs. non-AKI patients at 0M, 3M and 12M (p<0.05, Figure). IL-17A levels were significantly elevated in the progression vs. non-progression group, at the 3- and 12-month timepoints for outcomes occurring at 3-6 months and 12-84 months, respectively (p<0.05). In multivariable models that adjusted for demographics, comorbidity, eGFR and albuminuria, there was no independent association between IL-17A levels and the CKD outcome. IL-17A levels were positively correlated with kidney health biomarkers, including UNGAL, UIL-18, TNFa, and TNFRII at all three timepoints (p<0.001).

Conclusions: IL-17A levels were higher in hospital survivors that suffered from AKI when compared to those without AKI from diagnosis to post-discharge follow-up at 3 and 12 months, and according to AKI severity and post-hospitalization status of incident/progressive CKD. IL-17A levels were not independently associated with the CKD outcome but significantly correlated with several biomarkers of kidney health.

Risk Prediction Score for AKI in Critically Ill Septic Filipino Patients Admitted in Perpetual Succour Hospital: An Analytical Prospective Cohort Single-Center Study

Joel John C. Mejos, Grecia Darunday, Eratosthenes S. Polito. *Perpetual Succour Hospital, Cebu City, Philippines.*

Background: Acute kidney injury (AKI) is a lethal complication of critical illness characterized by the rapid loss of the kidney's excretory function encountered in 50% of intensive care unit (ICU) admissions. Its impact on the outcome of critically ill patients makes AKI a significant cause of morbidity and mortality.

Methods: This is a prospective cohort study conducted in a tertiary hospital in Cebu from February to September 2020. The data of 2545 patients were identified by chart review but only 607 patients with a quick Sepsis Organ Failure Assessment Score (qSOFA) score of ≥2 were included in the pre-screening. A total of 198 septic ICU patients were enrolled. Demographic profile, laboratory results and outcome data were collated. Variables were screened then stepwise forward elimination was done to identify the significant predictors. An AKI risk score model was developed with binomial regression analysis by identifying independent prognostic factors. The diagnostic ability of the model was determined by the Area under the Receiver Operating Characteristics (AuROC).

Results: AKI developed in 155 (78%) patients. The significant predictors for Acute Kidney Injury were age, hypertension, atherosclerotic cardiovascular disease, weight, white blood count, creatinine, and BUN. An AKI prediction model with a cut off score of 161.9 was made with a fair diagnostic ability for predicting AKI at 0.79 based on AuROC.

Conclusions: The developed risk prediction tool using routinely available variables is found to be fairly accurate to predict the development of AKI among critically ill septic patients. This can aid clinicians to identify high risk population and will provide strategies for prevention, early diagnosis and treatment.

Table 14. The AKI Risk Predictors Based on the Binomial Logistic Regression for the Development of the AKI Predictive Model: Step 4

Predictors	OR	Conditions for the Model
Age	1.055	If ≥54 = score 1.055, else 0
Hypertension	1.907	If yes, = score 1.907, else 0
Atherosclerotic Coronary Vessel Disease	1.889	If yes = score 1.889, else 0
Admitting creatinine	1.944	If ≥1.07 = score 1.944, else 0
BUN	1.028	If ≥19.5 = score 1.028, else 0
Estimated weight	1.064	If ≥59 = score 1.064, else 0
WBC	1.030	If ≥7.56 = score 1.030, else 0
Total Score	**L321**	**If ≥161.9 = score as AKI**

*Cutoff Scores were based on the ROC Coordinates of the Curve with ≈ 0.80

The cut-off total score of 161.9 was used in the formulation of AKI detection as dictated by the receiving operating characteristic (ROC) based on the coordinates at ≈ 0.80 (*sensitivity/specificity*).

Metabolomics Analysis and Classic Biomarkers to Predict Mortality in Patients with AKI and Kidney Replacement Therapy

Noemi Del Toro-Cisneros, Miguel A. Martinez-Rojas, Isaac González Soria, Juan Antonio Ortega-Trejo, Norma Bobadilla, Olynka Vega. *Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico*.

Background: Acute kidney injury (AKI) requiring kidney replacement therapy (KRT) is associated with mortality in critically ill patients. Serum metabolic biomarkers and markers of tubular damage might differentiate patients with a high risk of mortality.

Methods: Prospective cohort study of patients with critical COVID-19 in intensive care unit (ICU) with invasive mechanical ventilation (IMV) and who required KRT, admitted to Mar 2020 - Feb 2022. Patients with CKD stages 4 or 5 and kidney transplant were excluded. Urine SerpinA3, KIM-1, nGAL, HSP-72, and metabolomics analysis were measured on day 0 (start of KRT). Serum IL-6, IL-10, and TNF-alpha were also measured on day 0.

Results: Sixty patients were included, 52% died before discharge. The parameters measured at the beginning of the KRT were not different between living and dead patients (**Fig 1**). Of the urinary biomarkers studied, KIM-1 was the best mortality predictor (**Fig.2a**). The rest of the biomarkers had AUC minors (0.5-0.6) to predict this outcome. In the discriminant analysis of differential metabolites between the living (HD-A) and the dead (HD-D), p-cresol glucuronide was present in higher amounts in HD-D (**Fig.2b**).

Conclusions: In this study it was observed that KIM-1 was the best predictor of mortality. In the metabolomics analysis, p-cresol glucuronide was the metabolite present in highest amounts among the deceased patients.

Figure 1. Clinical characteristics of patients at the beginning of KRT, divided according to the outcome of hospitalization live vs deceased.

	Live (n=29)	Deceased (n=31)	p-Value
Demographics			
Age, years	51 ± 12.2	56 ± 12.2	0.085
Male, n (%)	20 (69)	26 (84)	0.173
Body mass index, kg/m^2	31 (29-35)	29 (27-38)	0.240

Mortality Prediction of Plasma Presepsin in Septic Patients Requiring Continuous Renal Replacement Therapy

Ji won Lee, Gibeop Lee, Se-Hee Yoon, Sung-Ro Yun, Won Min Hwang, Yohan Park. *Konyang University Hospital, Daejeon, Republic of Korea*.

Background: Presepsin is a more specific biomarker of sepsis, and many research results have been reported recently. However, since presepsin is highly affected by kidney function, acute kidney injury (AKI), especially the situation requiring continuous renal replacement therapy (CRRT), has a significant impact on presepsin dynamics and has not been elucidated. This study analyzed the relationship between plasma presepsin and mortality in patients requiring CRRT due to AKI.

Methods: From April 2022 to March 2023, patients who underwent a presepsin test just before CRRT were included. A total of 57 patients were enrolled, of which 35 were sepsis and 22 were non-sepsis. The predictive values of APACHE-II score, SOFA score, and plasma presepsin for 28-day mortality were analyzed using receiver operating characteristics (ROC) curve analysis.

Results: In predicting 28-day mortality in the overall cohort, area under the ROC (AuROC) values of APACHE-II score, SOFA score, and serum presepsin were 0.663, 0.731, and 0.636, respectively, which the presepsin showed the lowest predictive value. However, in the analysis of only sepsis patients, the AuROC values of APACHE-II score, SOFA score, and serum presepsin were 0.645, 0.681, and 0.802, respectively, which the presepsin was the best predictive marker for 28-day mortality. Moreover, in Cox regression analysis, high presepsin level was observed as an independent risk factor for 28-day mortality in sepsis patients (HR 3.823, P = 0.011).

Conclusions: Presepsin was not a useful marker of 28-day mortality in overall CRRT patients, including non-sepsis. However, in patients with sepsis, it was observed as the good predictive marker of mortality, which is thought to be because presepsin is a very specific marker for infection. Presepsin may be helpful in clinical practice for predicting mortality in CRRT patients with clinically suspected sepsis.

SA-PO114

Collagen Type III Biomarkers Are Prognostic for Adverse Outcomes After AKI

Nadja Sparding,[1] Federica Genovese,[1] Morten A. Karsdal,[1] Nicholas M. Selby.[2] [1]*Nordic Bioscience, Herlev, Denmark;* [2]*Centre for Kidney Research and Innovation University of Nottingham, Nottingham, United Kingdom*.

Background: Acute kidney injury (AKI) is defined as a fast decrease in kidney function and may be associated with structural damage. Even though early markers predicting AKI are emerging, tools to monitor the long-term health risk of patients after AKI are still needed. The novel biomarkers PRO-C3 and C3M are reflecting collagen type III (COL3) formation and degradation, respectively. In this study, we evaluated the potential of these biomarkers of COL3 as prognostic biomarkers of adverse outcomes in patients after AKI.

Methods: We measured PRO-C3 and C3M in plasma samples collected 1 year after the episode of AKI, using novel ELISAs in 800 patients from the AKI Risk in Derby (ARID) study, who were then followed prospectively until year 3. 392 of the patients had been hospitalized for an episode of AKI, and 408 patients who did not sustain AKI were included as controls (non-AKI). Kidney disease progression (KDP) was defined as ≥25% decline in eGFR and a decline in eGFR stage.

Results: By year 3, a total of 42 (AKI=25/control=17) patients had KDP, 70 (43/27) died, 103 (62/41) had heart failure (HF), 193 (104/89) had cardiovascular events (CVEs), and 531 (267/264) were readmitted. We performed multivariate logistic regression analysis with KDP as outcome and Cox regression analysis with mortality, HF, CVE or readmission as outcome with backwards elimination including age, sex, ACR, baseline CKD and diabetes status, eGFR, PRO-C3 and C3M. For KDP, PRO-C3 was retained in the final model in the AKI (OR=1.02, P<0.05) but not the control group, whereas C3M was not retained in the final model in any of the groups. In the AKI group, PRO-C3 retained in the final models for mortality (HR=1.02, P<0.0001), HF (HR=1.01, P<0.05) and readmission (HR=1.00, P<0.05), whereas C3M was retained in the final model for CVEs (1.06, P<0.01). In the control group, PRO-C3 was only retained in the final model for HF (HR=1.01, P<0.01), and C3M was not retained in any of the models.

Conclusions: In this study we showed that biomarkers of COL3 are prognostic for adverse outcomes in patients after AKI. Our findings may indicate that these biomarkers identify patients with active fibrogenesis after AKI, suggesting that long-term renal injury after AKI is important for patient outcome.

SA-PO115

Plasma Humanin Level in AKI and CKD Patients

Wenjing Cai, Min Wu, Qingying Shi, Xinyi Fu, Chenyu Lei, Yuanhan Chen, Zhiming Ye, Xinling Liang, Zhilian Li. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Humanin is a mitochondrial-derived cytoprotective peptide that reflects mitochondrial damage. Its level in the plasma of patients with AKI and CKD has not been reported yet. We aimed to determine the diagnostic value of humanin for kidney injury.

Methods: A total of 188 patients with kidney disease and 32 healthy controls were collected, patients with kidney disease were divided into AKI group (n=54) and CKD group (n=134) according to KDIGO definition. The plasma humanin level of each group was detected by enzyme-linked immunosorbent assay. ROC curves were used to analyze the diagnostic performance of humanin for AKI and CKD.

Results: A total of 188 patients (54 AKI, 134 CKD) and 32 healthy people were studied. The plasma humanin level in the AKI group and the CKD group was significantly higher than that in the healthy control group [576.5 (430.0-796.2) pg/mL vs 298.6 (188.8-366.4) pg/mL, p=0.0006 and 325.9 (207.3-631.4) pg/mL vs 298.6 (188.8-366.4) pg/mL, p=0.0164, respectively]. On the basis of receiver-operating characteristic analysis humanin could predict AKI and CKD [area under the curve (95% confidence interval) 0.869 (0.794-0.944) and 0.620 (0.529-0.711), respectively]. A cut-off point >413.2 pg/mL for humanin had a sensitivity of 0.78 and specificity of 0.91 in predicting AKI and a cut-off point >481.4 pg/mL for humanin had a sensitivity of 0.38 and specificity of 0.89 in predicting CKD.

Conclusions: Humanin is expressed in patients with AKI and CKD and may be a novel biomarker in response to kidney damage.

SA-PO116

Dickkopf-3, a Key Driver of Renal Fibrosis, Is Increased in the Urine of Patients with AKI

Momoko Sekiguchi, Takayuki Hamada, Izumi Nagayama, Kaori Takayanagi, Hajime Hasegawa, Akito Maeshima. *Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: The WNT–β-catenin system, an evolutionary conserved signaling pathway involved in morphogenesis and cell organization during embryogenesis, is usually suppressed in adulthood but can be re-activated in organ injury and regeneration. Dickkopf (DKK) proteins serve as inhibitors of WNT–β-catenin signaling. Animal models showed that DKK-3 is released by 'stressed' tubular epithelial cells and drives kidney fibrosis. However, the role of DKK-3 in human acute kidney injury (AKI) remains unknown. In the present study, we measured urinary DKK-3 in patients with AKI to test if urinary DKK-3 is useful to monitor the degree of tubular damage and/or recovery in human AKI.

Methods: AKI patients (n=66) who were treated in our department (December 2020 to December 2022) and healthy adults (n=16) were enrolled in this study. Written informed consent was obtained from all patients. Serum and urinary DKK-3 were measured by ELISA. The correlation of urinary DKK-3 with renal function, urinary protein level, clinical parameters and various AKI biomarkers were analyzed. This study was approved by the Ethics Committee on Human Research of our institutions (Approval number 2487).

Results: Compared to healthy subjects, urinary DKK-3 was significantly increased in AKI (1.02 ± 0.06 vs. 10.5 ± 1.26 ng/mL, p<0.001). There was no significant difference in urinary DKK-3 level between prerenal and renal AKI, but there was a significant increase according to the stage of AKI. There is a significant correlation of urinary DKK-3 with serum creatinine level, eGFR, urinary NGAL, and urinary beta2-microglobulin, but not with urinary protein level, urinary KIM1, or urinary NAG. Among the causes of AKI, urinary DKK-3 was markedly increased in patients with microscopic polyangiitis, in which urinary DKK-3 was significantly decreased after therapeutic intervention. In cases of kidney transplantation recipients, urinary DKK-3 was markedly increased at 1 day after transplantation but was decreased and became undetectable thereafter.

Conclusions: Urinary DKK-3 might be useful as a marker reflecting tubular damage as well as interstitial fibrosis in patients with AKI.

SA-PO117

Urinary DcR2/Cr Level Predicts Renal Outcome in Patients and Mouse Models with AKI

Xiangling Yi, Jia Chen, Yani He, Kehong Chen. *Daping Hospital, Army Medical University, Chongqing, China.*

Background: Acute kidney injury(AKI) is a well-recognized complication of critical illness with poor prognosis. Decoy receptor 2(DcR2), a senescent marker, is expressed specifically in senescent tubular epithelia. The aim of study is to investigate the association of urine DcR2 with renal outcome of AKI.

Methods: 153 biopsy-proven AKI patients were included from Daping Hospital, Army Medical University from January 2018 to October 2022. A composite renal endpoint included creatinine more than 50% higher than the baseline or ESRD after 90 days. All patients were divided into positive endpoints(n=75) and negative endpoints(n=78). The clinical characteristics were collected, and the uDcR2 levels were measured and normalized to urinary cre(uDcR2/Cr). By using correlation analysis, logistic regression and Kaplan-Meier curves, we explored the relationship between uDcR2/Cr and kidney outcome. We used experimental animals to further verify,and mice were randomly divided into 3 groups as follows: control, cisplatin, and aristolochic acid.

Results: The level of uDcR2/Cr was positively correlated with cystatin C and renal pathological acute scores, and negatively correlated with eGFR. Univariate logistic regression results increase the risk factors for poor kidney prognosis are age, female, with hypertension or(and) CKD, eGFR, Cystine C and uDcR2/Cr. Multivariate logistic regression analysis showed that the effect of uDcR2/Cr on renal outcome was statistically significant. After a median follow-up of 16 months, 75 participants achieve endpoint. The ROC curve was used to analyze the value of uDcR2/Cr for predicting kidney prognosis in AKI with an area under the curve of 0.72 and the cut-off value of 365ng/g Cr. The median time from at the time of AKI to endpoint in the uDcR2/Cr≥365ng/g Cr group(7.6 months) was significantly shorter compared to the uDcR2/Cr<365ng/g Cr group(36.6 months). To explore the trend of uDcR2 levels after AKI, uDcR2/Cr levels increased at 3d in cisplain-induced and aristolochic acid-induced AKI models compared with the control group, and the levels at 7d and 21d were still higher in the two models.

Conclusions: Urinary DcR2/Cr is closely associated to kidney injury and renal prognosis of AKI, suggesting that uDcR2/Cr could sever as a novel biomarker for predicting adverse outcomes in patients and mouse models with AKI.

Effects of Lanosterol Synthase Gene on the Development of AKI After Cardiac Surgery

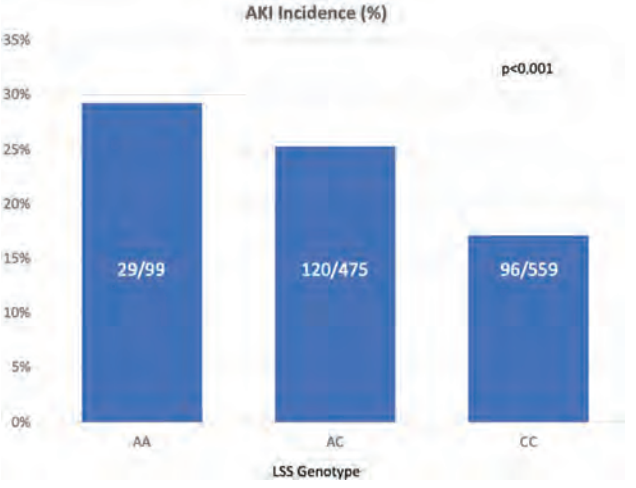
Lorenzo Cocchini, Luca D'Urbano, Davide Raimondo, Marta De Filippo, Chiara Lanzani, Laura Zagato, Lorena Citterio, Paolo Manunta, Marco Simonini. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Acute kidney injury (AKI) is a common post-surgery complication, significantly affecting morbidity and mortality. Recent studies reported that high plasma levels of endogenous ouabain (EO) are associated with worse kidney outcomes after cardiac surgery. Our group demonstrated that EO activity is affected by a missense variant (rs2254524 C → A, Val642Leu) in Lanosterol Synthase (LSS) gene. This work aims to analyze the relationship between this LSS polymorphism and the development of AKI after cardiac surgery.

Methods: 1237 patients undergoing elective cardiac surgery were enrolled in the study. For each patient, preoperative biological samples and LSS genotypes were collected. Primary outcome was AKI development according to KDIGO guidelines.

Results: 21.4% of patients developed AKI. Different preoperative clinical variables were analyzed, identifying five independent elements significantly correlated to AKI in multivariate logistic regression analysis: age (p<0.001), FE (p=0.005), NYHA class (p<0.001), reoperation (p=0.002) and complex surgical intervention (p< 0.001). No significant differences were observed between preoperative EO plasma levels and allelic variants of the LSS gene; moreover, patients with the less common A allele were not associated with a more severe preoperative clinical presentation, expressed as EuroScore. LSS minor variants (A) turned out to be significantly associated with the incidence of AKI (AA=29.3%; AC=25.3%; CC=17.2%; X^2 p=0.001). This evidence remains significant after correction for covariates associated with AKI previously reported (Log regression p=0.002; RR for AA variant: 2.09 IC95% 1.15-3.78).

Conclusions: Patients with at least one mutated allele of the LSS variant have a higher probability of developing AKI after cardiac surgery. We think these results could be of interest to further understand cellular mechanisms underlying AKI development.



SA-PO119

Low Cardiac Output During Cardiac Surgery Is Associated with Renal Tubular Injury Measured by Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL)

Lee A. Goeddel, Natalie Waldron, Emily Rodriguez, James Buchanan, Wassim Obeid, Chirag R. Parikh. *Johns Hopkins University, Baltimore, MD.*

Background: Low cardiac output (CO) during cardiac surgery may contribute to renal hypoperfusion and AKI. It is challenging to associate intraoperative low CO to renal injury using serum creatinine as it is non-sensitive to injury and it its increases are delayed by 24-48 hours after surgery. We assessed the relationship between low CO and urinary neutrophil gelatinase-associated lipocalin (NGAL), which is a sensitive marker of renal tubular injury.

Methods: We enrolled 30 patients with preserved left-ventricular ejection fraction undergoing coronary-artery bypass surgery to collect urine samples at baseline, after cardiopulmonary bypass, and at intensive care unit (ICU) arrival. Cardiac index (CI) was calculated from continuous arterial waveform analysis that generates CI every five seconds and value of <= 2 L/min/m² was used as the threshold for low CI. We used the Meso Scale discovery platform to assess NGAL.

Results: Mean age was 62.7+/- 8 and 28% were female. On average, 210 ± 58 minutes of CI readings were available on each patient. Mean Low CI was 100.1± 73 minutes per patient. **Figure 1a** shows log2 NGAL at the three timepoints. Mean (SD) change from baseline to ICU arrival was (3.27 +/-3.89) pg/ml. On multivariable regression analysis adjusted for age, sex, and minutes MAP<65mmHg, each 10 minutes of CI <2 L/min/m² was associated with increased NGAL (beta 0.2; p=.078, **fig. 1b**). There was minimal association between changes in serum creatinine and low CI

Conclusions: Low CO during cardiac surgery appears to be associated with renal tubular injury and can be detected by urinary NGAL. This finding was independent of exposure to hypotension (minutes<MAP of 65 mmHg). Additional investigation of low CO and NGAL are warranted.

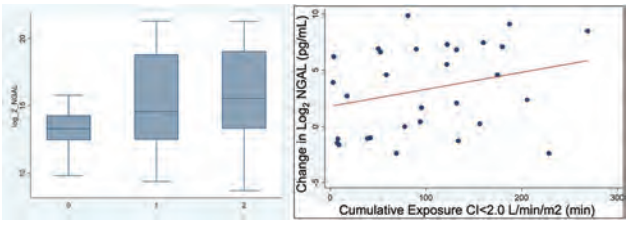


Figure 1: (a) Log2 NGAL increases from baseline (0), after cardiopulmonary bypass (1) to ICU arrival (2). (b) Low CI is associated with change in NGAL from baseline to ICU arrival.

SA-PO120

Association Between AKI and Biomarkers KIM-1, Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL), and Cystatin C in Patients Undergoing Cardiac Surgery

Bhupinder Singh, Jeannette Rodriguez, Ali C. Johnson, Richard A. Zager, Stacey Ruiz. *Renibus Therapeutics, Southlake, TX.*

Background: Patients undergoing cardiac surgery are at risk of developing acute kidney injury (AKI), which negatively impacts short and long-term clinical outcomes. Biomarkers that provide earlier detection of AKI may allow for timely intervention. Urinary excretion of kidney injury molecule-1 (KIM-1), neutrophil gelatinase-associated lipocalin (NGAL), and cystatin C (CysC) is increased during experimental AKI. We investigated the association between these biomarkers and AKI in patients undergoing elective coronary artery bypass graft (CABG) and/or valve surgery on CPB.

Methods: Urine and plasma samples were collected from 121 adult patients who participated in a Phase 2 study designed to test the ability of an investigational drug (RBT-1) to induce an organ preconditioning response and prevent post-operative complications. AKI was defined as a ≥1.5X increase in serum creatinine (sCr) or oligoanuria through post-op Day 5 or need for dialysis. The study was neither powered nor enriched to test for potential RBT-1-induced AKI protection. Urine and plasma KIM-1, NGAL, and CysC were measured through post-op Day 3.

Results: Of the 121 patients, 22 (18.2%) developed AKI. Urinary levels of KIM-1 (uKIM-1) and CysC (uCysC) were higher in patients who did not develop AKI post-operatively (uKIM-1: 6.27 ng/mL vs 14.41 ng/mL [p=0.013]; uCysC: 2.92 ng/mL vs 6.45 ng/mL [p=0.011] for AKI vs No AKI). While uNGAL was higher in those who developed AKI (10.30 ng/mL vs 6.41 ng/mL), this result was not statistically significant (p=0.472). Correlation analyses indicated no relationship between max post-op sCr and uKIM-1 (r=0.0572), uCysC (r=0.2953), or uNGAL (r=0.3176). In contrast, plasma levels for these biomarkers were higher in patients who developed AKI post-op (KIM-1: 158 pg/mL vs 101 pg/mL; CysC: 2.39 mg/L vs. 1.61 mg/L; NGAL: 185 ng/mL vs. 126 ng/mL). Correlation analysis also showed a stronger relationship between max post-op sCr and plasma levels of CysC (r=0.7771, p<0.0001) and NGAL (r=0.7585, p<0.0001) at Day 3; no correlation was observed with KIM-1 (r=0.2941, p=0.001).

Conclusions: Urinary KIM-1, NGAL, and CysC did not correlate with AKI in this cohort of adults undergoing cardiac surgery. Plasma KIM-1, NGAL, CysC levels may hold greater promise and should be studied further.

Exploring Lipid Biomarkers of Cardiac Surgery-Associated AKI Based on Lipidomics

Youjun Xu, Fangfang Zhou, Lailiang Wang, Shuzhen Zhang, Xingyue Zheng, Qun Luo. *Ningbo No. 2 Hospital, Ningbo, China.*

Background: Cardiac surgery-associated acute kidney injury (CSA-AKI) is a frequently occurring complication. Lipids played important roles in many biological pathways and could work as biomarkers of disease. The purpose of this study was to explore lipid biomarkers of CSA-AKI.

Methods: Plasma samples were collected when patients admitted to the ICU after cardiac surgery from 24 CSA-AKI patients and 31 controls. Lipidomic approach based on liquid chromatography mass spectrometer (LC-MS) was used to analyze plasma lipidomic alterations and potential biomarkers for CSA-AKI patients. Univariate and multivariate statistical analyses were utilized to screen the differential lipids between two groups.

Results: Lipidomics analysis detected 4053 lipid species totally. Differentially expressed lipids were screened based on the criteria variable importance at projection (VIP) value > 1, p value < 0.05, and fold change (FC) > 1.5 or < 0.67. Lipidomics identified that 65 lipids satisfied the criteria. The volcano plot showed the results of differential expression of lipids (figure 1). Heat map presented the relative levels of lipids (figure 2).

Conclusions: Lipidomics profiles could change significantly in CSA-AKI patients, and some lipid species were notably upregulated in the early stage of CSA-AKI, which could serve as potential biomarkers for CSA-AKI.

Intra-Operative Shedding of Endothelial Glycocalyx in Cardiac Surgery-Associated AKI: A Prospective Longitudinal Cohort

Jennifer R. Joslin,[1,2] Ranjit Deshpande,[3] Kathryn Griffiths,[1] Simon C. Satchell,[4] Claire C. Sharpe,[2] Kate Bramham.[1,2] *[1]King's College London, London, United Kingdom; [2]King's Kidney Care, King's College Hospital, London, United Kingdom; [3]Cardiothoracic Surgery, King's College Hospital, London, United Kingdom; [4]University of Bristol, Bristol, United Kingdom.*

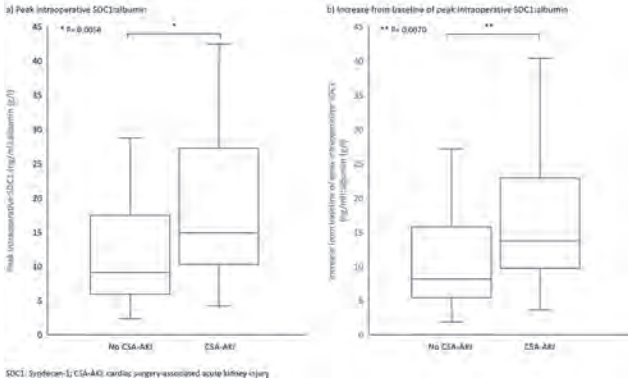
Background: This novel study aimed to consider the temporal association between microvascular disruption and cardiac surgery-associated acute kidney injury (CSA-AKI) by investigating dynamic endothelial glycocalyx changes.

Methods: We conducted a prospective observational cohort study of 61 patients undergoing non-emergency coronary artery bypass graft (CABG) surgery with serial sampling at set time-points in the pre, intra and post-operative period. We measured plasma syndecan-1 (SDC1), a major endothelial glycocalyx structural component, and calculated a ratio against plasma albumin (SDC1:alb) to take account of intraoperative haemodilution fluctuations. CSA-AKI within 48 hours was assessed using Kidney Disease Improving Global Outcomes (KDIGO) criteria. Demographic, clinical and surgical variables were considered in analysis.

Results: 14/61 (23.0%) participants developed CSA-AKI. Peak intraoperative SDC1:alb and increase from baseline of peak SDC1:alb were significantly higher in participants who subsequently developed CSA-AKI compared to those who did not (P=0.0063; P=0.008). (Figure 1) The best predictor variables of CSA-AKI were peak SDC1:alb (AUC 0.777) and urine protein:creatinine ratio (uPCR, AUC 0.840). After adjusting for uPCR and other key variables, odds of CSA-AKI in patients with peak SDC1:alb greater than the derived optimal cut-off of 23 were 11 times those with a lower peak SDC1:alb (OR 11.0 (95% CI 1.57- 106.91, P=0.021)).

Conclusions: This is the first demonstration of increased intraoperative shedding of SDC1, a core endothelial glycocalyx constituent, in CABG patients who subsequently developed CSA-AKI. These findings suggest endothelial glycocalyx disruption and microvascular dysfunction in CSA-AKI may provide a target for early therapeutic intervention and / or facilitate earlier identification of patients at greatest risk.

Figure 1: Comparison of SDC1:alb between patients who did and did not develop CSA-AKI



SDC1: Syndecan-1; CSA-AKI: cardiac surgery-associated acute kidney injury

Growth Differentiation Factor (GDF)-15, a Stress-Induced Cytokine, Is Increased in Patients with AKI

Takayuki Hamada, Momoko Sekiguchi, Izumi Nagayama, Kaori Takayanagi, Hajime Hasegawa, Akito Maeshima. *Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.*

Background: Growth Differentiation Factor (GDF)-15, a member of the TGF-beta superfamily, is one of the stress response cytokines that promotes cell death. Under physiological conditions, GDF-15 is expressed in high levels in the placenta, prostate, and bladder. High circulating levels of GDF-15 have been associated with chronic inflammatory conditions including lung, liver and cardiovascular diseases, rheumatoid arthritis, and cancers. In the kidney, GDF-15 is expressed in renal tubules but its role in acute kidney injury (AKI) remains unknown. To address this issue, we measured urinary GDF-15 in patients with AKI to test if GDF-15 is involved in pathophysiology of human AKI.

Methods: AKI patients (n=86) who were treated in our department (December 2020 to December 2022) and healthy adults (n=19) were enrolled in this study. Written informed consent was obtained from all patients. Serum and urinary GDF-15 were measured by ELISA. Correlations of urinary GDF-15 with renal function, urinary protein level, clinical parameters and various AKI biomarkers were analyzed. This study was approved by the Ethics Committee on Human Research of our institutions (Approval number 2487).

Results: Urinary GDF-15 was detectable in healthy adults but was significantly increased in patients with AKI (5.1 ± 1.0 vs. 18.4 ± 1.5 ng/mL, p<0.001). Especially, urinary GDF-15 was markedly elevated in patients with ischemic AKI, drug-induced AKI, lupus nephritis, and ANCA-associated vasculitis. In most cases of AKI, urinary GDF-15 was decreased after therapeutic intervention. In cases of deceased donor kidney transplant recipients, urinary GDF-15 was significantly elevated at 1 day after transplantation but was decreased with improvement of kidney function thereafter. There was a significant correlation of urinary GDF-15 with urinary neutrophil gelatinase-associated lipocalin (NGAL), urinary kidney injury molecule-1 (KIM-1), urinary NAG, urinary β2-microglobulin, and urinary protein level, but not with serum creatinine level or L-FABP.

Conclusions: Collectively, urinary GDF-15 might be useful as a marker reflecting tubular stress and/or damage in patients with AKI.

SA-PO124

Urinary Follistatin Is a Marker Reflecting the Severity of Tubular Damage in Patients with AKI

Izumi Nagayama,[1] Kaori Takayanagi,[1] Daisuke Nagata,[2] Hajime Hasegawa,[1] Akito Maeshima.[1] *[1]Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan; [2]Division of Nephrology, Department of Internal Medicine, Jichi Medical University, Shimotsuke, Japan.*

Background: Follistatin is an activin-binding protein that antagonizes the function of activin A, a member of TGF-beta superfamily. In animal models of acute kidney injury (AKI), the blockade of activin A by exogenous follistatin has been shown to attenuate kidney damage and improve renal function, suggesting that endogenous activin A negatively regulates tubular repair after AKI. Follistatin acts as a local modulator of activin A in many tissues. However, the role of follistatin in the kidney remains unknown.

Methods: To address this issue, we examined the localization of follistatin in normal human kidney and measured urinary follistatin in patients with AKI to test if urinary follistatin is useful as a marker for AKI. Patients with AKI (n=131) and healthy adults (n=13) were enrolled in this study. Serum and urinary follistatin was measured by ELISA. Correlations of urinary follistatin with other clinical parameters were analyzed.

Results: Follistatin was localized in renal tubules of normal kidney. Follistatin-producing cells were positive for Na-Cl co-transporter and uromodulin but were negative for aquaporin 1 or aquaporin 2. Urinary follistatin, undetectable in healthy adults, was significantly increased in patients with AKI (0.00 ± 0.00 vs. 458.1 ± 150.4 pg/mL, p<0.05) and was positively correlated with the severity of AKI. Urinary follistatin was significantly increased in patients requiring renal replacement therapy compared to those who did not. There was a significant correlation of urinary follistatin with urinary protein, alpha1-microglobulin, urinary NGAL, but not with urinary KIM-1, urinary L-FABP, urinary NAG, urinary beta2-microglobulin, serum creatinine. No correlation between urinary and serum follistatin was observed, suggesting that urinary follistatin is originated from the kidney but not from blood.

Conclusions: Collectively, follistatin produced by distal tubules of the kidney become detectable in the urine of AKI patients. Urinary follistatin might be useful to monitor the severity of acute tubular damage.

SA-PO125

Comparative Analyses of Classical Urinary Discriminators in Pre- vs. Biopsy-Proven Intrarenal AKI

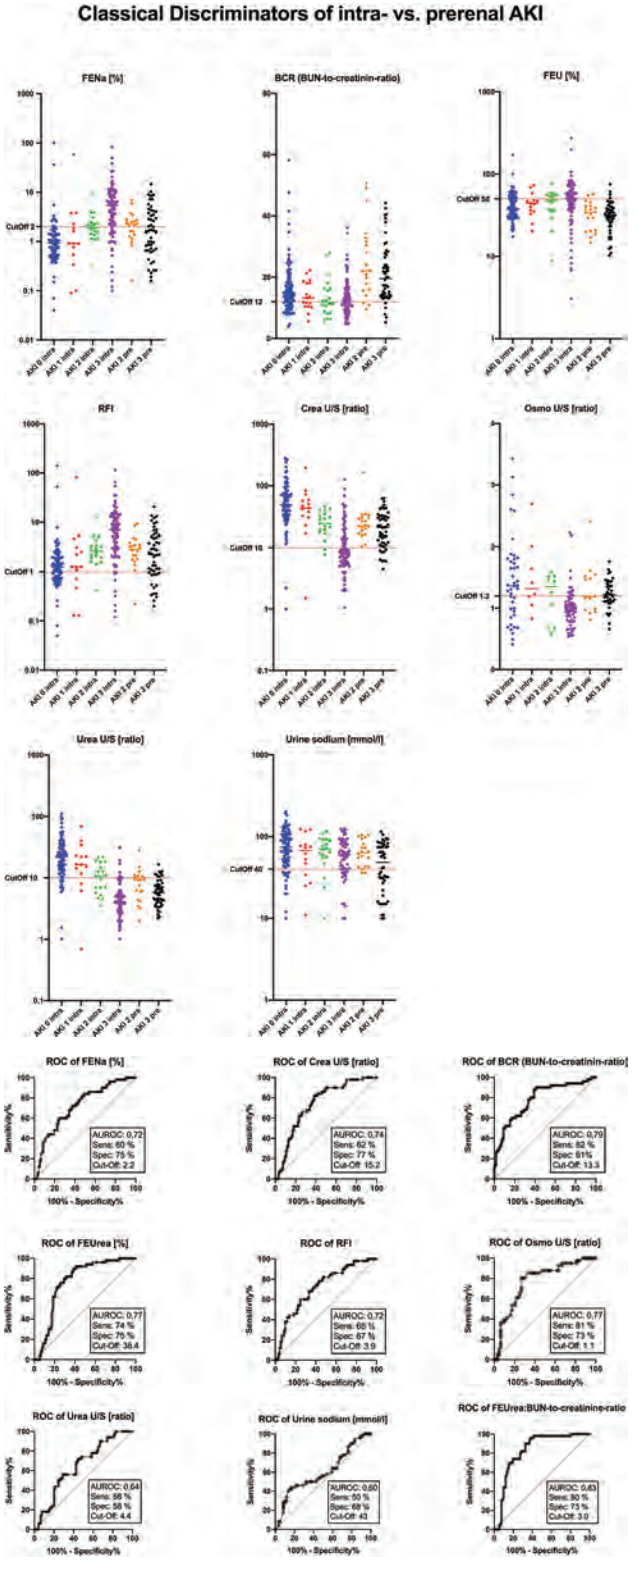
Martin Russwurm. AG Translational Nephrology. *Philipps-University Marburg, University Hospital, Center for Internal Medicine, Renal Division, Marburg, Germany.*

Background: The clinical distinction between prerenal and intrarenal acute kidney injury (AKI) remains challenging. Many biomarkers have been proposed, yet no comprehensive analyses of their performance has been conducted.

Methods: Classcial Urine AKI-Biomarkers of patients with biopsy-proven intrarenal AKI and prerenal AKI have been compared.

Results: Kindey urine composition handling showed alterations according to severity (Figure 1) of AKI in most discriminators. ROC analyses (of AKI 3 prerenal vs. intrarenal) showed some discriminatory power of the investigated classical biomarkers (Figure 2). Best performance was observed with BUN-to-creatinine-ratio (area-under-the-roc / AUROC = 0.79; sensitivity 60%, specificity 83%), worst with urine sodium concentration (AUROC 0.6; sensitivity 50%, specificity 68%). The ratio of FEUrea devided by BUN-to-creatinine-ratio yielded the best discriminatory power (AUROC 0.83; sensitivity 80%, specificity 73%).

Conclusions: This analysis is the first to comprehensively compare the discriminatory power of classic urine biomarkers to distinguish between prerenal and intrarenal AKI. To foster reliabilty the intrarenal group was based on kidney biopsy diagnosis. Overall, most parameters showed medium performance. We identified a new ratio (FEUra devided by BUN-to-creatinine-ratio), which performed best according to AUROC analysis.



SA-PO126

Fractional Excretion of Urea for the Differential Diagnosis of AKI: A Systematic Review and Meta-Analysis with Comparison to Fractional Excretion of Sodium

Mohammad O. Abdelhafez,[1] Abdurrahman M. Hamadah,[2] Kamel A. Gharaibeh.[3,1] AQU Collaborators. *[1]Al-Quds University, Jerusalem, Palestine, State of; [2]St. Luke's Hospital, Duluth, MN; [3]University of Maryland School of Medicine, Baltimore, MD.*

Background: Differentiating between intrinsic and prerenal acute kidney injury (AKI) presents a challenge. This study aims to assess the performance of fractional excretion of urea (FEUrea) and compare it to fractional excretion of sodium (FENa) in distinguishing intrinsic from prerenal AKI.

Methods: We searched MEDLINE, Embase, CENTRAL, the Cochrane Library, and Scopus until July 2022. Studies evaluating FEUrea, with or without FENa, for differentiating AKI etiologies in adults were included. We assessed the methodological quality using the QUADAS-2/-C tools. We conducted a meta-analysis using the bivariate random effects model, with subgroup analyses to explore the impact of diuretic therapy on FEUrea performance. We performed direct statistical comparisons between FEUrea and FENa in the overall AKI patients and subgroups with and without diuretic therapy. Study protocol: PROSPERO, CRD42022341290.

Results: We included 11 studies with 1108 hospitalized patients. Among 8 studies (915 patients) evaluating FEUrea at 35% threshold, the pooled sensitivity and specificity for distinguishing intrinsic from prerenal AKI were 66% (95% CI, 49-79%) and 75% (95% CI, 60-85%), respectively. In a subset of 6 studies (573 patients) comparing FEUrea at 35% to FENa at 1%, there was no significant difference in sensitivity (69% vs. 86%, *P*=0.089) but a significant difference in specificity (81% vs. 64%, *P*=0.038). Additionally, In 302 patients not on diuretics, there were no significant differences in sensitivity (77% vs. 89%, *P*=0.410) or specificity (80% vs. 79%, *P*=0.956). In 4 studies with 244 patients on diuretics, FEUrea demonstrated lower sensitivity (52% vs. 92%, *P*<0.001) but higher specificity (82% vs. 44%, *P*<0.001) compared to FENa.

Conclusions: Both FEUrea and FENa have limited utility in differentiating intrinsic from prerenal AKI. FEUrea does not provide a superior alternative to FENa, even in patients receiving diuretic therapy.

Figure. Forest plot for the studies included in the meta-analysis of FEUrea at 35% for intrinsic versus prerenal AKI

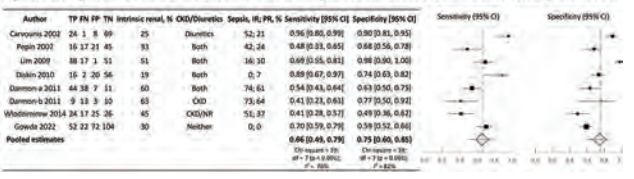


Table. Direct comparison between FEUrea at 35% and FENa at 1%

Test	Group/ subgroup	No. of studies; patients	Intrinsic AKI, %	Pooled sensitivity [95% CI]; I^2	Pooled specificity [95% CI]; I^2	Abs difference in sensitivity [95% CI, p]; Abs difference in specificity [95% CI, p]
FEUrea	All patients	6; 573	41	69% [48%, 84%]; 76%	81% [68%, 90%]; 77%	-20% [-44%, 3%, 0.089]; 16% [1%, 31%, 0.038]
FENa				90% [65%, 98%]; 86%	65% [56%, 74%]; 72%	
FEUrea	Not on diuretics	6; 302	44	77% [52%, 91%]; 86%	80% [64%, 90%]; 76%	-12% [-40, 16%, 0.410] 0.4% [-14%, 15%, 0.956]
FENa				89% [53%, 98%]; 85%	79% [72%, 85%]; 0%	
FEUrea	On diuretics	4; 244	42	52% [40%, 64%]; 78%	82% [54%, 95%]; 73%	-39% [-55%, -23%, <0.001] 38% [14%, 63%, <0.001]
FENa				92% [72%, 98%]; 50%	44% [31%, 58%]; 68%

Fractional Excretion of Urinary Sodium and Urinary Sediment Microscopy for Prediction of Response to Vasoconstrictors in Hepatorenal Syndrome Type 1

Walter Lam, Terrance J. Wickman, Muner Mohamed, Juan Carlos Q. Velez. *Ochsner Health, New Orleans, LA.*

Background: Because of diagnostic challenges around differentiating hepatorenal syndrome type 1 (HRS-1) from acute tubular injury (ATI), proper selection of patients who can benefit from vasoconstrictor therapy (VCT) remains suboptimal. We hypothesized that markers of tubular function or injury may correlate with therapeutic response to VCT.

Methods: Records from hospitalized patients with HRS-1 treated with VCT without shock were reviewed. We selected those who achieved ≥5 mmHg rise in mean arterial pressure (MAP) within 48 hours and had available fractional excretion of urinary sodium (FENa) (marker of tubular function) and microscopic examination of the urinary sediment (MicrExUrSed) (marker of tubular injury). Lower limit for urinary Na was <10 mEq/L. HRS-1 was diagnosed by ICA criteria + FENa <1% + no overt ATI by MicrExUrSed (abundant dark granular casts). Absence of ATI by MicrExUrSed was defined as bland sediment or only hyaline casts. The primary endpoint was percentage of change in serum creatinine (sCr) at the end therapy (day 7-14).

Results: A total of 44 patients with HRS-1 treated for 2-7 days with either norepinephrine (n=40) or midodrine/octreotide (n=4) were included. Median age was 52 (IQR 46-62), 41% female and 57% had alcoholic cirrhosis. At the start of VCT, median MAP was 71 mmHg (IQR 68-74) and median sCr was 3.8 mg/dL (IQR 2.8-4.9). Median FENa was 0.4% (IQR 0.29-0.49). FENa significantly correlated with change in serum Cr (r=0.395, p=0.007). Thus, lower FENa was associated with reduction in sCr. All patients with >30% reduction in sCr had FENa between 0.05 and 0.42%. Among those with MAP rise >10 mmHg (n=30), the correlation between FENa and change in sCr turned stronger (r=0.599, p=0.0004). Furthermore, the correlation between MAP rise and improvement

in sCr was stronger among those with absence of ATI by MicrExUrSed (n=24) (r=-0.579, p=0.003) compared to those with scattered elements of ATI (n=20) (r=-0.23, p=0.32). Among those with MAP rise >10 mmHg, 10 of 16 (63%) of those with no ATI by MicrExUrSed achieved >30% reduction in sCr compared to 4 of 14 (27%) of those with ATI elements (p=0.06).

Conclusions: Functional and injury urinary markers may offer predictive information respect to response to VCT in HRS-1.

SA-PO128

Kinetics of Mature Platelet Fraction as a Tool for Predicting the Time Course of Shiga Toxin-Producing Escherichia coli-Associated Hemolytic Uremic Syndrome (STEC-HUS)

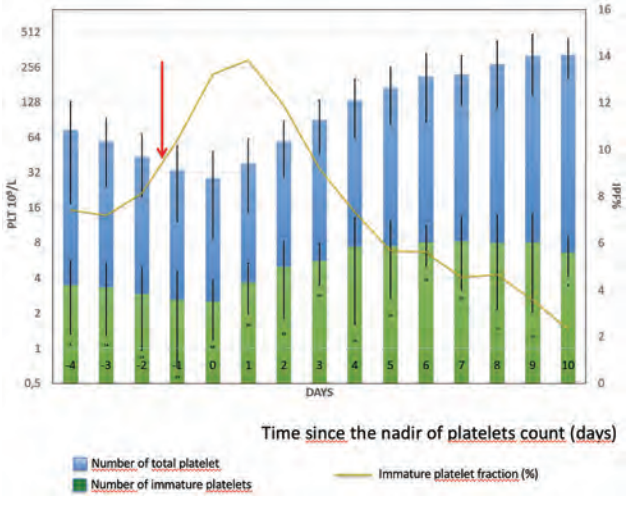
Gianluigi Ardissino, Thomas Ria, Maria Cristina Mancuso, Valentina Capone, Laura Daprai, Valeria Amico, Francesco Spanu. *Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Background: Shigatoxin-related Hemolytic Uremic Syndrome (STEC-HUS) is a common thrombotic microangiopathy in children characterized by platelet consumption, hemolysis and kidney dysfunction. Being the time course of the disease relatively regular, the description of platelets kinetics, including reticulated platelets, may provide some useful insights for predicting the short-term course of the disease.

Methods: We considered all patients with STEC-HUS referred to our center during the last 5 years. Blood count for both total and reticulated platelets was performed daily with a XN-9000 hematology analyzer since admission until recovery. Results are expressed as absolute number and percentage of total.

Results: Fourty patients with documented STEC-HUS were studied. Results are displayed in the figure showing the time course of total and reticulated platelets in the coohort of patients (time 0 identifies the nadir of total platelets). When immature platelet fraction reaches the threshold of 10% the resolution of thrombocytopenia, thus the beginning of recovery, is approaching and is expected in 24-48 hours.

Conclusions: During the course of STEC-HUS the rise of immature platelet fraction above 10% anticipates (by 24-48 hours) the increase of total platelets count thus predicting the beginning of disease recovery.



SA-PO129

Through the Haze: Sailing the Turbid Waters of Uremic Ophthalmopathy

Caleb S. Pacheco-Molina, Jesus D. Vega-Colon, Maria E. Rivera, Jeaneishka M. Rivera Rios, Ileana E. Ocasio Melendez, Krystahl Z. Andujar-Rivera, Carlos G. Rivera-Bermudez, Lydwan Pérez Westerband. *Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Ophthalmic disease can be a consequence of many metabolic conditions, rarely is caused by uremia. This is an uncommon etiology of ophthalmic disease and there are only a few cases reported.

Case Description: A 45-year-old man with arterial hypertension, horseshoe kidney and a previous episode of acute kidney injury (AKI) presented complaining of a three-month history of bilateral blurry vision, eye pain and fatigue. Denied changes in urinary habits, recent infections, travel, toxic habits, NSAIDs use, or family history of kidney disease. Evaluation was remarkable for elevated blood pressure, 168/85 mmHg, and bilateral lower extremity edema. Ophthalmologic evaluation was notable for bilateral optic nerve inflammation. Laboratory results were remarkable for anemia, azotemia with BUN of 182.9 mg/dL, creatinine level of 29.5 mg/dL, severe hyperkalemia, and metabolic acidosis with HCO_3 level of 7.5 mEq/L. Urinalysis with findings of proteinuria, and hematuria with positive RBCs and WBCs without casts. Urine protein-creatinine ratio of 3.5 g/g. Workup for glomerular disease, vasculitides, HIV, HBV and HCV yielded negative results. Renal US showed small kidneys with increased cortical echogenicity compatible with intrinsic parenchymal disease, without hydronephrosis or nephrolithiasis. CT scan confirmed the presence of horseshoe kidney. Patient was started on hemodialysis with immediate improvement in visual symptoms. Follow up ocular evaluation was notable for improved optic nerve inflammation bilaterally. Head CT scan was negative for intracranial pathologies, as well as orbital CT scan. Patient was discharged home on hemodialysis and ophthalmologic symptoms continued improving.

Discussion: Uremic ophthalmopathy is a rare finding worth sharing. In the case of our patient that a clear etiology of renal injury was not found, it is more likely that the subject had progressive renal function decline for which he was not receiving appropriate care, and this finding might be secondary to chronic uremia. For this reason, it is fair to consider uremia as the cause of ophthalmopathy in patient in which other metabolic causes are not a clear culprit.

SA-PO130

Severe AKI due to Cortical Necrosis in Postpartum Patient

Mushfique Choudhury, Pamela S. Trio, Clay A. Block. *Dartmouth College Geisel School of Medicine, Hanover, NH.*

Introduction: Severe post-partum AKI is rare in the United States, but has a challenging differential diagnosis that often includes atypical hemolytic uremic syndrome (aHUS), ATN and acute cortical necrosis (ACN). Establishing the diagnosis is critical to provide specific therapy. We present a case of aHUS in a post-partum patient in whom the diagnosis of aHUS was confounded by simultaneous influenza, peri-partum hemorrhage, and microangiopathic hemolysis, elevated liver enzymes, and HELLP syndrome, proteinuria, cardiomyopathy, and endometritis.

Case Description: A 33-year-old woman was hospitalized for hypovolemic shock and coagulopathy following term, vaginal delivery complicated by severe hemorrhage. She received RBC transfusion besides vasopressor support for several hours. Oligo-anuric kidney failure ensued requiring dialysis support. Echo showed severe global left ventricular dysfunction. CT with contrast was consistent with cortical necrosis of kidney. Platelet count of 63,000/uL, high LDH, low haptoglobin, and presence of schistocytes were consistent with microangiopathy. C3 and C4 and ADAMTS13 activity were normal. Liver chemistries normalized soon. UPR was elevated at 2.1. Empirical therapy for aHUS with Eculizumab was initiated with rapid improvement in platelet count and urine output but dialysis dependence persisted. Kidney biopsy performed that demonstrated cortical necrosis and could not confirm or reject a diagnosis of aHUS. Functional complement assays were nondiagnostic. Genetic profile was negative for mutations. Because of her clinical response, Eculizumab was maintained for 6-months. Unfortunately, patient remained dialysis dependent.

Discussion: Post-partum AKI can occur by a variety of mechanisms with variable prognosis and management. Eculizumab is specific treatment for aHUS but confers risk for infection and is expensive. Treatment of ATN or ACN is supportive, Alternative complement pathway functional and genetic profiles can facilitate diagnosis but results are delayed and may be non-informative as in this case. Kidney biopsy demonstrated cortical necrosis but patchy injury. ACN might have been demonstrable by CT or MRI by showing meduallary enhancement in the absence of cortical enhancement ("reverse rim sign") but were not obtained. Although aHUS was suspected based on hematologic and biochemical data, ACN appears to have been the dominant process.

SA-PO131

A Case of Atypical Manifestation of Uremic Encephalopathy: Acute Psychosis

Kristi Dodbiba, Alexander M. Pennekamp, Huiwen Chen. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Uremic encephalopathy UE is a cerebral dysfunction caused by the accumulation of toxins resulting from acute or chronic renal failure. The clinical presentation is broad, and the clinical course is always progressive when untreated. Patients generally exhibit the signs of UE when glomerular filtration rate is less than 15 ml/min/1.73 m2 and the symptoms usually include fatigue, nausea, restlessness, drowsiness and diminished ability to concentrate. Paranoia is sometimes described as a uremic presentation, but rarely do patients exhibit acute psychosis. Here we present a patient with acute psychosis as her first sign of uremic encephalopathy.

Case Description: The patient is a 66-year-old female with past medical history of CKD stage III with baseline 2.4 mg/dl, coronary artery disease status post percutaneous coronary intervention, HFpEF, DM2 who presented to the hospital after failing outpatient management of mastitis. Her hospital course was complicated by acute kidney injury stage II, mild hyperkalemia and acute pychosis. Her manifestations include vocalization of her displeasure of the hosptal, aggressive language, noncompliance to the treatment plan and severe paranoia. Patient did not have any psychiatric history. Her peak BUN was 59 and peak creatinine was 5.68 mg/dl. She was deemed to be competent by the psychiatry team. Antipsychotics were given for paranoia, but her conditions did not improve. However, her mental status improved drastically after two sessions of dialysis treatment.

Discussion: Timing of dialysis initiation is an important topic in nephrology. The current practice is to delay dialysis unless there is an absolute indication. Uremic encephalopathy is a clinical diagnosis and can have various presentations, most notably catatonia or hypoactive symptoms. Acute psychosis is a very atypical presention of uremia and can be missed as an indication for dialysis initiation. In our patient, delayed dialysis would significantly impacted the delivery of her overall care due to her psychosis.

SA-PO132

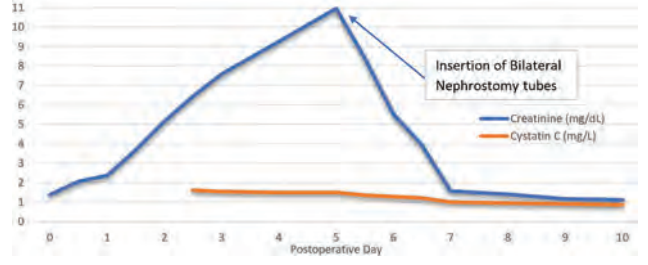
Cystatin C as a Diagnostic Marker for a Postoperative Urine Leak

Rahul Maheshwari, Jeffrey Kott, Holly M. Koncicki. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Evaluating kidney function after urologic procedures can be challenging in the presence of complications such as urine leaks. This case report illustrates a scenario where serum creatinine provided misleading Glomerular Filtration Rate (GFR) estimations, prompting the use of cystatin C for diagnostic accuracy.

Case Description: A 67-year-old male with a history of prostate cancer underwent uneventful robotic assisted laparoscopic prostatectomy. Postoperatively, serum creatinine rapidly increased from a baseline of 0.9 mg/dL. On postoperative day (POD) 1, significant output from a Jackson-Pratt (JP) drain indicated possible urine leak. However, a CT scan on POD 2 did not show obstruction or leak. Due to ongoing suspicion, nephrology consultation recommended obtainng daily cystatin C, hypothesizing that elevated serum creatinine mirrored urine resorption rather than a GFR decline. On POD 5, discrepant serum creatinine and cystatin C values (10.95 mg/dL, 1.5 mg/L respectively) along with a JP drain fluid creatinine of >40 mg/dL led to the placement of nephrostomy tubes. Post-procedure, serum creatinine and cystatin C levels normalized and JP output decreased.

Discussion: This case highlights the use of cystatin C in diagnosing postoperative urine leaks and the limitations of using serum creatinine as the sole kidney function marker after urologic procedures. Despite a non-diagnostic CT scan, the divergent serum creatinine and cystatin C pointed towards a urine leak. The mild cystatin C elevation, which improved post nephrostomy tube placement, suggests some obstructive uropathy or intrinsic kidney injury. Our case aligns with a case by Saro-Nunez et al 2018, where cystatin C was similarly used for eGFR measurements in a urinoma. Cystatin C, correlates with residual kidney function in peritoneal dialysis patients, suggesting minimal transport across the peritoneal membrane. Considering creatinine's absorption in peritoneal and retroperitoneal spaces, cystatin C may offer a more reliable marker. This case highlights cystatin C's potential utility in urologic surgery complications like urine leaks, despite its rare use in acute kidney injury.



SA-PO133

Comparison of cROCK, KDIGO, and Their Combined Criteria for Detecting AKI in Hospitalized Adults with CKD

Ling Sun,[1] Luxi Zou.[2] [1]*Xuzhou Central Hospital, Xuzhou, China;* [2]*Xuzhou Medical University, Xuzhou, China.*

Background: Acute kidney injury (AKI) in chronic kidney disease (CKD), also known as acute-on-chronic kidney disease (ACKD) increases the risk of CKD progression, major adverse cardiovascular events (MACEs), and all-cause mortality. Hou et al. set up a reference change value (**R**CV) of the serum creatinine (SCr) **O**ptimized **C**riterion for A**KI** in **C**KD (cROCK), which is defined as a >25% increase of SCr over 7 days. This study aimed to evaluate the ability of the novel criterion of **cROCK** to detect ACKD patients and then compared the effects of the criteria of cROCK and KDIGO in predicting long-term outcomes in ACKD patients.

Methods: This was a retrospective observational study with a 3-year follow-up period. The electronic medical records data of inpatients admitted to Xuzhou Central Hospital between January 2016 and June 2018 were screened. All included patients with CKD stage 3 were evaluated using cROCK, KDIGO, and their combined criteria. The renal composite endpoints, MACEs, and all-cause mortality were recorded as the clinical outcomes.

Results: A total of 812 patients was enrolled and assigned to 4 groups depending on the KDIGO and cROCK criteria (Fig 1). The baseline and follow-up data were described in Table 1. The cROCK detected 8.5% more ACKD events than KDIGO criterion (67.98% vs. 59.48%, $P < 0.001$). During the 3-year follow-up, 683 patients experienced renal composite endpoint events, with groups ranked from high to low percentage of free events as KDIGO(−)&cROCK(−), KDIGO(+)&cROCK(−), KDIGO(−)&cROCK(+), and KDIGO(+)&cROCK(+) (Fig 2A). 650 patients developed MACEs, with groups ranked as KDIGO(−)&cROCK(−), KDIGO(−)&cROCK(+), KDIGO(+)&cROCK(−), and KDIGO(+)&cROCK(+) (Fig 2B). 405 patients died with trends similar to MACEs (Fig 2C).

Conclusions: Compared to the KDIGO criterion, the cROCK detected more ACKD events. Combining the cROCK and KDIGO criteria might improve the predictive ability for long-term outcomes in ACKD patients.

Smaller Kidney Volume Is Associated with AKI Following Cardiovascular Surgery, Especially Among Patients Treated with Renin-Angiotensin System Inhibitors

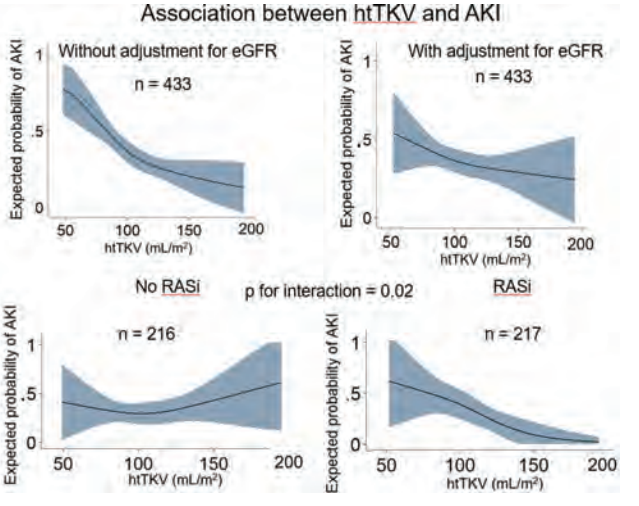
Takahisa Kasugai, Miho Murashima, Tatsuya Tomonari, Minamo Ono, Masashi Mizuno, Takayuki Hamano. *Nagoya Shiritsu Daigaku, Nagoya, Japan.*

Background: Kidney volume might reflect atherosclerotic changes in the vascular bed in the kidney independent of eGFR and thus might be independently associated with postoperative AKI.

Methods: In this retrospective cohort study, we enrolled adults who underwent cardiovascular (CV) surgery from 2014 to 2021 at our facility and computed tomography (CT) scans within 6 months before surgery. We excluded those with multiple or large cysts, single kidney, serum creatinine >4 mg/dL, or undergoing kidney replacement therapy. Exposure of interest was height-adjusted total kidney volume (htTKV) measured by software using the three-dimensional CT reconstruction. The outcome was postoperative AKI defined by the KDIGO creatinine criteria. We employed logistic regression models and the results were shown as cubic spline curves. Effect modifications by renin-angiotensin system inhibitors (RASi, defined as angiotensin-converting enzyme inhibitors and/or angiotensin receptor blockers), loop diuretics, and non-steroidal anti-inflammatory drugs (NSAIDs) were assessed.

Results: Among 433 patients, 147 (33.9%) developed AKI. Those with smaller htTKV were older, less likely to be diabetic, had lower eGFR, and higher prevalence of CV comorbidities. Smaller htTKV tended to be associated with AKI even after adjustment for eGFR. Smaller htTKV was associated with AKI especially among the users of RASi (p for interaction 0.02). Loop diuretics and NSAIDs did not significantly modify the association between htTKV and AKI(p for interaction 0.44 and 0.42, respectively).

Conclusions: Smaller htTKV was associated with postoperative AKI independent of eGFR, especially among patients using RASi. Among patients with smaller htTKV, withdrawing RASi before CV surgery might be protective against post-operarive AKI.



SA-PO135

Combining Arterial and Venous Intrarenal Doppler Assessment for the Prediction of AKI After Cardiac Surgery

Cameron Giles,[1] André Denault,[2] William Beaubien-Souligny.[2] [1]*McMaster University, Hamilton, ON, Canada;* [2]*Universite de Montreal, Montreal, QC, Canada.*

Background: Acute kidney injury (AKI) is common after cardiac surgery and often hemodynamically mediated. The roles of ultrasound measures of intrarenal perfusion to predict AKI are yet to be determined. The objective of this study was to determine if point-of-care ultrasound Doppler measures of intrarenal arterial and venous flow predict AKI after cardiac surgery.

Methods: We conducted a secondary analysis of a prospective cohort study of adult patients undergoing cardiac surgery in whom ultrasound assessments were performed at ICU admission after surgery. AKI was defined by the KDIGO creatinine criteria. Intrarenal arterial markers included renal resistive index (RRI) and velocity-time integral normalized to peak systolic velocity (VTI/PSV), while venous markers included intrarenal venous flow (IRVF) categories and renal venous stasis index (RVSI). The area under the receiving operating characteristic (AUROC) curves were used to determine the predictive characteristics for post-operative AKI. The performance of individual markers were compared to a combined RRI and RVSI logistic regression model using the net classification index (NRI) and AUROC were compared with the DeLong test.

Results: We included 131 patients in total, with 47 patients (35.9%) developing post-operative AKI. All studied ultrasound markers showed moderate discrimination for the subsequent development of AKI (Table 1). More complex measurements (VTI/PSV and RVSI) were not superior to simpler indices (RRI and IRVF). In a multivariable model, both RRI (aOR:1.70, CI:1.09-2.66, p=0.02) and RVSI (aOR:0.85, CI:0.04-0.98, p=0.048) remained associated with AKI. The predicted probabilities from the model were slightly better than each index taken individually according to the NRI. However, the AUROC were not significantly different (Table 1).

Conclusions: Intrarenal arterial and venous Doppler indices moderately predict the development of post-operative AKI in cardiac surgery patients. However, combining arterial and venous Doppler indices only marginally improves prediction.

Echographic Parameters and AKI After Cardiac Surgery

Echographic Parameter	Postoperative Day 0			DeLong Test/Net Reclassification Index
	AUROC	95% CI	P Value	
RRI	0.64	0.55-0.74	0.006	p=0.38 / NRI: 0.32 (CI: -0.06; 0.69)
VTI/PSV	0.67	0.57-0.77	0.001	
IRVF Category	0.64	0.53-0.74	0.009	p=0.19 / NRI: -0.52 (CI: -0.82; 0.20)
RVSI	0.60	0.50-0.71	0.045	
Predicted probability of model: RRI + RVSI	0.69	0.59-0.78	<0.001	Vs RRI: p=0.50 / NRI: 0.50 (CI: 0.17; 0.84) Vs RVSI : p=0.38 / NRI: 0.38 (CI: 0.04; 0.70)

Association of Aortic Pulsatility Index with Clinical Outcomes and In-Hospital eGFR Slope Among Patients Admitted for Acute Decompensated Heart Failure Requiring Hemodynamic Monitoring

Run Banlengchit,[1,2] Hocine Tighiouart,[1,3] Marcelle Tuttle,[1] Amanda I. Moises,[5] Hannah L. Sarnak,[1] Jeffrey M. Testani,[4] Tatsufumi Oka,[1] Michael S. Kiernan,[1] Mark J. Sarnak,[1] Wendy I. McCallum.[1] [1]*Tufts Medical Center, Boston, MA;* [2]*UCSF Medical Center, San Francisco, CA;* [3]*Tufts Medical Center Institute for Clinical Research and Health Policy Studies, Boston, MA;* [4]*Yale School of Medicine, New Haven, CT;* [5]*Tufts University School of Medicine, Boston, MA.*

Background: Aortic pulsatility index (API), (systolic–diastolic blood pressure)/pulmonary capillary wedge pressure, is a hemodynamic parameter reflecting cardiac contractility and forward perfusion. We examined whether API is associated with mortality, cardiovascular (CV) outcomes and kidney outcomes among patients admitted for acute decompensated heart failure (ADHF).

Methods: For patients admitted for ADHF requiring invasive hemodynamic monitoring from 2015 to 2021, API was calculated at the time of pulmonary artery catheter placement. Mortality and end stage renal disease (ESRD) events were linked to the state death registry and the United States Renal Data System. Heart transplant (HT) and left ventricular assist device (LVAD) implantation events were obtained from the medical record. Cox proportional hazards regression models were used to evaluate the association between API quartiles and a composite endpoint of death, HT, or LVAD. Associations between API and baseline eGFR and in-hospital eGFR slope were evaluated using linear regression and linear mixed models, respectively. Cox proportional hazards regression models were used to evaluate quartiles of API and ESRD.

Results: Among 743 patients, mean (SD) age and baseline eGFR were 62 (14) years, 58 (27) ml/min/1.73m^2 respectively. Initial median (IQR) API was 1.8 (1.2, 2.7). Over median follow-up of 23 months, 259 (35%) died, 107 (14%) had HT, and 15 (2%) had LVAD implantation; 62 (8%) developed ESRD. In reference to the quartile with highest API, Quartile 1 (lowest API) was associated with increased risk of the composite outcome of mortality, OHT or LVAD. There was no association between API and baseline eGFR or in-hospital eGFR slope per week (0.42 [-1.69, 2.53]; 0.17 [-0.37, 0.71] per doubling API, respectively), nor any association between quartiles of API with ESRD.

Conclusions: Low API is associated with a higher risk of a composite of death and cardiovascular outcomes but not with baseline or in-hospital eGFR slope or development of ESRD.

Funding: NIDDK Support

Table. Hazard ratios ((95% CI) for composite outcome of death, heart transplant, or LVAD by API quartiles

	Quartile 1 (n=186)	Quartile 2 (n=184)	Quartile 3 (n=186)	Quartile 4 (n=187)

The Impacts of Skeletal Muscle Mass and Quality on Kidney Recovery of Patients with AKI Receiving Continuous Renal Replacement Therapy

Jae Yoon Park,[1] Jin hyuk Paek,[2] Jiyun Jung,[1] Jeong-Hoon Lim,[3] Yong Chul Kim,[4] Tae Hyun Ban,[5] Kipyo Kim,[6] Hyosang Kim,[7] Woo Yeong Park.[2] [1]*Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea;* [2]*Keimyung University Dongsan Medical Center, Daegu, Republic of Korea;* [3]*Kyungpook National University Hospital, Daegu, Republic of Korea;* [4]*Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea;* [5]*The Catholic University of Korea School of Medicine, Seoul, Republic of Korea;* [6]*Inha University School of Medicine, Incheon, Republic of Korea;* [7]*Asan Medical Center, Songpa-gu, Seoul, Republic of Korea.*

Background: Although there are increasing interests in kidney recovery after acute kidney injury (AKI), little is known about patients with severe AKI requiring continuous renal replacement therapy (CRRT). It is known that sarcopenia is associated with poor prognosis not only in chronic inflammatory conditions but also in acute disease. Recent study revealed that muscle mass and quality were significant determinants of mortality in patients with CRRT. However, few studies evaluated the effect of sarcopenia on kidney recovery in patients receiving CRRT.

Methods: We collected 2051 AKI patients who underwent CRRT from eight medical centers between 2006 and 2021. The skeletal muscle area (SMA) was measured from the automated software from CT images at 3rd lumbar vertebra within 15 days of CRRT initiation, and classified as normal attenuation muscle area (NAMA) and low attenuation muscle area (LAMA) according to muscle density. We used Fine and Gray model to investigate the effects of muscle index adjusted by body mass index (BMI) on kidney recovery.

Results: Of the 813 CRRT survivors, 682 (83.9%) patients were discharged without RRT. Increased SMA/BMI was independently associated with decreased risk of RRT dependence. Also, the 4th quartile of NAMA/BMI was significantly associated with decreased RRT dependence risk. However, non-significant effects of LAMA/BMI were observed.

Conclusions: In patients with severe AKI receiving CRRT, not only the quantity but also the quality of muscle affects RRT dependence.

Contract Induced Nephropathy in Kidney Transplant Recipients: A Systematic Review and Meta-Analysis

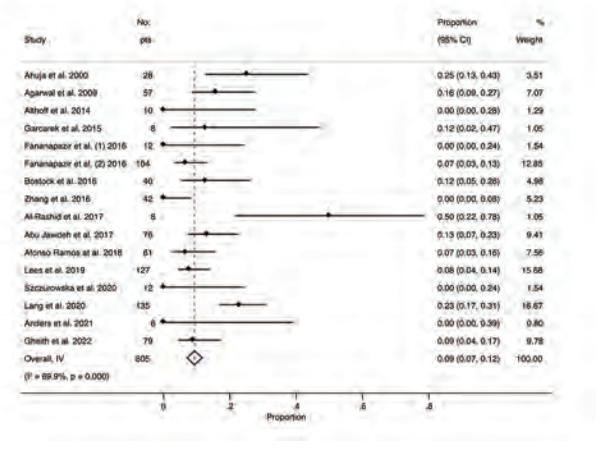
Umar Zahid, Amir Hayat, Puneet Bedi, Samuel Spitalewitz. *Brookdale University Hospital and Medical Center, Brooklyn, NY.*

Background: Kidney transplant recipients (KTR) may be at higher risk of contrast induced Nephropathy (CIN) because of associated risk factors. The incidence proportion of CIN in native kidneys has been reported to be 9% in a recent meta-analysis with 0.5% requiring renal replacement therapy (RRT). We aimed to determine the incidence proportion of CIN in KTR.

Methods: Medline, Embase, and Cochrane databases were used to search the studies assessing the incidence of CIN in KTR from inception until January 2023. We applied Random effect model to estimate the incidence of CIN in KTR.

Results: Sixteen studies, including 805 contrast studies in KTR, were included in the analysis. The estimated incidence of CIN in KTR and CIN requiring RRT was 9.3% (95% confidence interval (CI) 7.1 % to 11.7%) and 1.1% (95% CI: 0.0% to 1.4%), respectively. None of the CIN patients required permanent RRT. In subgroup analysis, the incidence of CIN in KTR who received Iso-osmolar (300 mOsm/kgH20) vs hypo-osmolar CM (550 mOsm/kgH20) was 5.0% (95%CI: 0.8% to 11.2%) and 8.7% (95% CI: 5.6% to 12.2%), respectively. An estimated incidence of CIN in KTR who underwent coronary angiography was 14% (95% CI: 8% to 22%). Angiograms, including allograft renal artery angiograms (without angioplasty/stenting) and CT scans resulted in CIN in 12% (95% CI: 4% to 18%), in 8.6% (95% CI: 5% to 12% CI), respectively. CIN in KTR who underwent angioplasty/stenting to relieve renal artery stenosis (RAS) was 3%. There was complete reversal of CIN with successful therapeutic intervention for RAS, renal function improved above baseline. No graft loss was reported within 30 days post CM administration regardless of the type of CM administered.

Conclusions: The estimated incidence of CIN in KTR is 9.3%, equal to the incidence of CIN in native kidneys (9%). Therefore, it appears that the risk of CIN in KTR patients is not different than the general population.



Forest plot of incidence of CIN in KTR.

Effect on Kidney Function Recovery Guiding Decongestion with Venus Evaluation by Ultrasound System (VExUS) in Patients with Cardiorenal Syndrome 1, A Randomized Control Trial

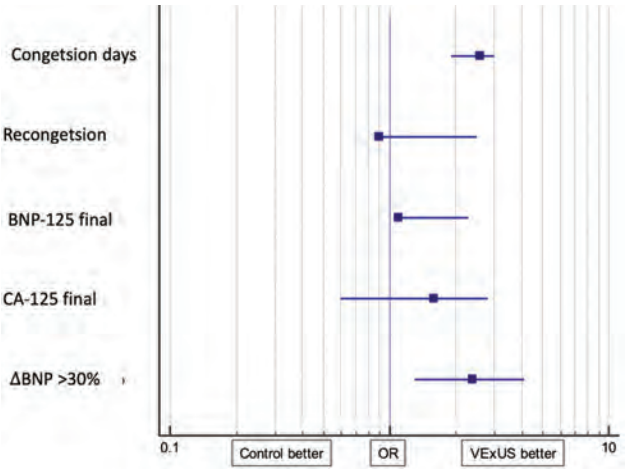
Jonathan Chavez,[1,2] Jahir R. Camacho,[1,2] Ramon Medina,[1] Karina Renoirte,[1,2] Maria de la Luz Alcantar Vallin,[1,2] Guillermo Navarro Blackaller,[1,2] Guillermo Garcia-Garcia,[2] Alejandro Martínez Gallardo González,[1] Juan Gómez Fregoso,[1] Francisco Gonzalo Rodríguez García.[1] *[1]Hospital Civil de Guadalajara, Guadalajara, Mexico; [2]Universidad de Guadalajara, Guadalajara, Mexico.*

Background: In cardiorenal syndrome type 1 (CRS1) vascular congestion is a common complication, the Venus Evaluation by Ultrasound System (VExUS) could guide decongestion with diuretics effectively and thereby improve renal function and outcomes.

Methods: In this double-blind randomized clinical trial, patients with CRS1 were randomized to guide decongestion with VExUS compared to usual clinical evaluation. The primary and secondary endpoint was to assess kidney function recovery (KFR), days of hospitalization, mortality, changes in brain natriuretic peptide (BNP) and CA-125. Protocol register number is HCG/CEI-0836/22.

Results: During the period from March 2022 to February 2023, a total of 140 patients were randomized, 70 in the VExUS group and 70 in the Control group. KFR in the VExUS group, compared to Control, no significant difference was found. VExUS improve in more than twice the speed (in days) with which decongestion is achieved (OR 2.6, CI 1.9-3.0, p=0.01). With VExUS is two-fold more likely to reach a decrease of BNP >30% (OR = 2.4; CI 1.3-4.1, p = 0.01). Survival at 90 days was similar between groups. Recongestion, CA125 and mortality were similar between groups.

Conclusions: In patients with CRS1, we observed that VExUS guided decongestion, compared to clinical evaluation, did not improve the probability of KFR, but decongestion could be achieved more efficiently in fewer days.



SA-PO140

Discordance Between the Initial Etiological Diagnosis of AKI and that of the Nephrologist Based on a VExUS Study of Patients with AKI in an Acute Care Setting

Edva Noel,[1] Hema Balina,[1] Hannah Calvelli,[3] Abhilash Koratala,[2] Avrum Gillespie.[1] *[1]Temple University Hospital, Philadelphia, PA; [2]Medical College of Wisconsin, Milwaukee, WI; [3]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Background: Acute kidney injury (AKI) is associated with high morbidity and mortality. The correct diagnosis is essential for appropriate management because the treatments are very different between volume depletion, cardiorenal syndrome, hepatorenal syndrome, and acute tubular necrosis (ATN). We compare the initial diagnosis on presentation of AKI and the likely diagnosis based on the evaluation of a nephrologist based on a later chart review of the clinical course and diagnostic results.

Methods: In this single center, prospective, cohort study of ICU and ward patients who developed AKI during the admission we sought to determine the application of venous excess ultrasounds of intra-abdominal organs in discriminating the cause of AKI. We performed bedside US using a Logiq e BT12 machine, chart review and collection of baseline characteristics of all enrollees for 3 consecutive days. Baseline characteristics included: vital signs, 2D-echocardiogram, central venous pressure, right heart catheterization, urine electrolytes, urine protein-to-creatinine ratio, urine sediment. Ultra sonographers were blinded to the clinical diagnosis.

Results: We enrolled 80 patients with the initial diagnosis of AKI established by the primary care. Primary teams suspected ATN (23.5%), volume depletion (39.5%), hepatorenal (8.6%), cardiorenal (26%), and other causes (2.5%). The diagnoses posed by the primary care team were correct in 75% of the cases. ATN was mistakenly categorized as volume depletion 24% of the time and volume depletion as hepatorenal 29% of the time. Granular casts were present in 45% of ATN cases and 8% of non-ATN cases (p=0.0001), sensitivity 45%, specificity 92%. This includes 41% of misdiagnosed cases. As for VExUS, 70% of ATN cases were Grade 0, 64% of volume depletion, 50% of hepatorenal, and 33% of cardiorenal.

Conclusions: In a single-center prospective study of 80 patients with an initial diagnosis of AKI, the cause of AKI determined by the primary care team was discordant to that of the nephrology specialist in only 25% of the case. Urine sediment remains a useful tool in the diagnosis of AKI than VExUS. Future research is needed to examine the role of VExUS as a diagnostic tool.

Hepatic Duplex: Can the Liver Be of Service to the Kidney in Diagnosing AKI?

Hema Balina,[1] Edva Noel,[1] Hannah Calvelli,[1] Ryan C. Gibbons,[1] Thomas Costantino,[1] Abhilash Koratala,[2] Avrum Gillespie.[1] *[1]Temple University, Philadelphia, PA; [2]University of Wisconsin System, Madison, WI.*

Background: Acute kidney injury (AKI) has a significant morbidity and mortality and better tools to diagnose the cause and inform the correct treatment are a research priority. We examined whether bedside venous duplex ultrasound of intra-abdominal organs differs in different causes of AKI.

Methods: A prospective single-center study of patients with cardiorenal, hepatorenal, acute tubular necrosis(ATN), and volume depletion acute kidney injury (AKI). Arrhythmias and body mass index (BMI)>30 were exclusions. Clinical data were obtained via chart review. Inferior vena cava diameter(IVC); hepatic vein and renal vein patterns; and Renal Resistive Indices(RRI) were obtained via Logic e BT-12 ultrasound. Sonographers were blinded from diagnoses. We used analysis of variance (ANOVA) for continuous variables and chi-square tests for categorical variables.

Results: We enrolled 81 AKI subjects, 34% with volume depletion, 19% cardiorenal, 35% ATN, 6% hepatorenal, and 3% other. Participants' mean creatinine 2.74 (±1.47) mg/dL. The IVC diameters in ATN, volume depletion, hepatorenal, and cardiorenal were 2,

1.87, 1.95, and 2.34 cm respectively (p=0.17). Diminished or reversed systolic hepatic duplex was seen in only 2 patients with volume depletion(p=0.0001), and both these patients had moderate tricuspid regurgitation and elevated pulmonary arterial pressures on echocardiogram. Similar hepatic duplex findings were noted on day 2 and day 3. Portal vein was continuous in 62.1% ATN, 60.7% volume depletion, and 31.3% cardiorenal patients(p=0.74). Renal venous flow was continuous in 18.8% of the cardiorenal patients(p=0.67). RRI was not different in ATN(0.65±0.05), volume depletion(0.67±0.07), hepatorenal(0.69±0.09), and cardiorenal(0.67±0.08, p=0.25).

Conclusions: Hepatic vein, but not IVC, renal and portal venous flow, nor RRI can differentiate types of AKI. This non-invasive bedside tool can help diagnose AKI and future trials will examine management.

SA-PO142

Association of Kidney Biopsy Needle Gauge with Post-Procedure Complications and Biopsy Adequacy

Kanika K. Garg,[1,2] Mary Kate Staunton,[1,2] Candice Kent,[1,2] Melissa M. Shaw,[1,2] Francis P. Wilson,[1,2] Dennis G. Moledina.[1,2] *[1]Clinical and Translational Research Accelerator, New Haven, CT; [2]Yale University Department of Internal Medicine, New Haven, CT.*

Background: Narrower kidney biopsy gauge needles are thought to lead to fewer post-biopsy complications but could risk inadequate sampling for diagnosis. We examine the association of needle gauge with post-biopsy complications and sampling adequacy.

Methods: Using data from participants enrolled in the Yale biopsy cohort between 7/2020 and 4/2023, we tested the association of needle gauge (16G vs. 18 or 20G) with biopsy-related complications and number of glomeruli sampled using a chi-squared test for proportions for categorical outcomes or a Wilcoxon rank sum test for continuous outcomes.

Results: Of the 511 adult participants, median age was 60 (43,70), 49% were female, 60% were White, 33% were hospitalized and 52% underwent a biopsy for acute kidney injury. Those with 18G were more likely to have AKI (60% vs. 48%, P=0.01) and be hospitalized (40% vs. 29%, P=0.007). Needle gauge was not associated with seeking adverse post-biopsy complications, but participants who underwent a biopsy with narrower needle gauge required more imaging studies after biopsy (21% vs. 11%, p=0.004) primarily driven by concerns of hemoglobin drop. Narrower needle gauge was associated with fewer glomeruli available for diagnosis (11.5 [7.0-17.0] vs 14.0 [9.0-20.0], p<0.001).

Conclusions: Our data show that the narrower gauge biopsy needle was associated with fewer glomeruli available for diagnosis and greater need for postoperative imaging. However, we cannot rule out confounding by indication such that those at higher risk of complications underwent biopsy with narrower needle gauge. Further investigation into the complications associated with biopsy needle size controlling for detailed risk factors for post-biopsy complications is needed to confirm these findings.

Funding: NIDDK Support

Table of Kidney Biopsy Patients Complications

Post-biopsy complication	All patients (N=511)	18 G (n=326)	18 G or 20 G (n=185)	P-value*
Sought medical attention, n (%)	18 (4%)	10 (3%)	8 (5%)	0.43

Erroneous Diagnosis of Acute Interstitial Nephritis on Gallium-67 Scintigraphy

Arslan Mahmood, Jordan L. Rosenstock. *Lenox Hill Hospital, New York, NY.*

Introduction: Acute interstitial nephritis (AIN) and acute tubular necrosis (ATN) are common etiologies for acute kidney injury (AKI) in a patient with infection being treated with antibiotics. Kidney biopsy is the gold standard to distinguish between these diagnoses, but gallium-67 scintigraphy is sometimes used if a biopsy is considered high risk. We report a case where the gallium scan gave an erroneous result.

Case Description: We present a case of a 32-year-old male admitted for right elbow swelling, associated with fever to 100.4 for one day. Physical exam was significant for chronic venous malformations on the right arm, one of which was now tender to touch and palpation. Thrombophlebitis was suspected. Creatinine was 1.62 mg/dl which improved to 1.19 after 2 Liters of normal saline. Piperacillin/Tazobactam and Vancomycin were started. Blood cultures grew Pasteurella Multocida. Antibiotics were tailored towards this infectious agent. However, the patient remained febrile for three days after the bacteremia had cleared. Meanwhile, his creatinine rose from 1.19 to 2.81 in 72 hours. Urinalysis showed 100mg/dl protein, sterile pyuria and few granular casts. Renal ultrasound showed normal size and echogenicity. A gallium scan was done to identify the source of ongoing fever and revealed intense activity in the kidneys suggestive of interstitial nephritis. Kidney biopsy was done to confirm the diagnosis. Empiric Prednisone 1mg/kg/day was started while waiting for biopsy results. The biopsy showed ATN. Prednisone was then discontinued. Creatinine improved to 1.0 one week after discharge.

Discussion: Kidney biopsy is the gold standard for diagnosing acute interstitial nephritis but is not always attainable. Gallium-67 scintigraphy has emerged as an alternative modality to diagnose AIN. Graham et al showed 100% specificity but poor sensitivity when using an uptake cutoff of grade 5, which means the intensity of radioisotope uptake in the kidney is higher than in the liver. Few older studies have shown varying degrees of sensitivity and specificity. Our patient had a grade 5 uptake, yet the biopsy did not show AIN. Thus, our case highlights the limitations of the gallium scan in diagnosing AIN and confirms that when the clinical picture is unclear, biopsy may be preferred.

Catheter-Directed Thrombectomy in Acute Renal Vein Thrombosis

Amanda K. Ames, Tyler D. Yan, Gerald A. Da Roza, Zameer Hirji, Brian P. Yang. *The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.*

Introduction: Renal vein thrombosis (RVT) is a rare condition that can lead to severe complications including acute kidney injury or renal failure. Malignancy and nephrotic syndrome are the most common etiologies accounting for up to 66% and 20% of cases, respectively. The standard treatment for RVT is anticoagulation, but in the presence of declining renal function or contraindications, catheter-directed thrombectomy (CDT) can be considered.

Case Description: A 64-year-old female with CKD stage IIIa, hypertension and nephrolithiasis presented with acute left flank pain, AKI (creatinine 1.35mg/dL) and a 7cm left renal subcapsular hematoma with large RVT. Urinalysis revealed trace blood and protein with urine ACR of 8.2mg/mmol. On day three, kidney function declined to creatinine of 2.1mg/dL. Due to the rapid decline in kidney function and renal hematoma, precluding anticoagulation, CDT was performed. The clot was successfully retrieved and renal flow was restored. The creatinine approached baseline within a few days. Interestingly, the pathology demonstrated fragments of renal cell carcinoma within the thrombus despite no clear evidence of malignancy on CT or MRI imaging.

Discussion: We present the successful use of CDT for acute RVT secondary to renal cell carcinoma for diagnostic and therapeutic purposes. CDT permits rapid re-cannulization of the renal vein and facilitates faster renal recovery. Direct access permits interventions including venoplasty or stent placement for persistent stenosis or elastic recoil. To our knowledge, there are no previously reported cases of thrombectomy for acute RVT secondary to tumor thrombus. CDT is a potentially safe and effective treatment option for acute RVT, especially in the setting of declining renal function or contraindications to anticoagulation.

Urinoma Treated with Transcatheter Arterial Embolization for Renal Artery: A Case Report

Fumika Iemura, Takahito Moriyama, Masahiro Arai, Rie Suzuki, Yoshitaka Miyaoka, Yoshihiko Kanno. *Tokyo Ika Daigaku, Shinjuku-ku, Japan.*

Introduction: Transcatheter arterial embolization (TAE) for renal artery was generally performed for renal cancer, aneurysm, polycystic kidney disease and bleeding. Here, we report a case of urinoma with the renal abscess successfully treated with TAE.

Case Description: A-79-year-old man with a past medical history of bladder cancer with total cystectomy and ileal conduit and ureterolithiasis with left ureteral stent was admitted to our hospital. He showed septic shock and disseminated intravascular coagulation (DIC) with the left renal abscess due to the dislodged left ureteral stent. He also showed acute kidney injury (AKI) and his serum creatinine was elevated to 7.37 mg/dL from baseline of 3.43 mg/dL a month before admission. He was given antibiotic for septic shock and underwent hemodialysis for AKI. He was also found to have hemorrhage from dorsal branch of the left renal artery due to DIC and performed the emergent TAE for that branch. After the TAE, we performed percutaneous drainage from the left renal abscess. However, fluid was continued to drain away from a tube inserted into the abscess. Laboratory findings showed the creatinine in the fluid was 17.09 mg/dL, and then we diagnosed as a urinoma. To treat the urinoma with infection, we performed TAE against the left renal artery to completely disrupt the renal function (Figure). After that, the fluid was dramatically decreased, the urinoma size was reduced, the abscess was fully improved, and the drainage tube was removed, though the maintenance dialysis was required.

Discussion: In this case, TAE was performed for disruption of renal function to treat the urinoma. Radical nephrectomy was also considered, but it was suspected difficult due to adhesions after infection. TAE may be the one of the treatment options for the urinoma.

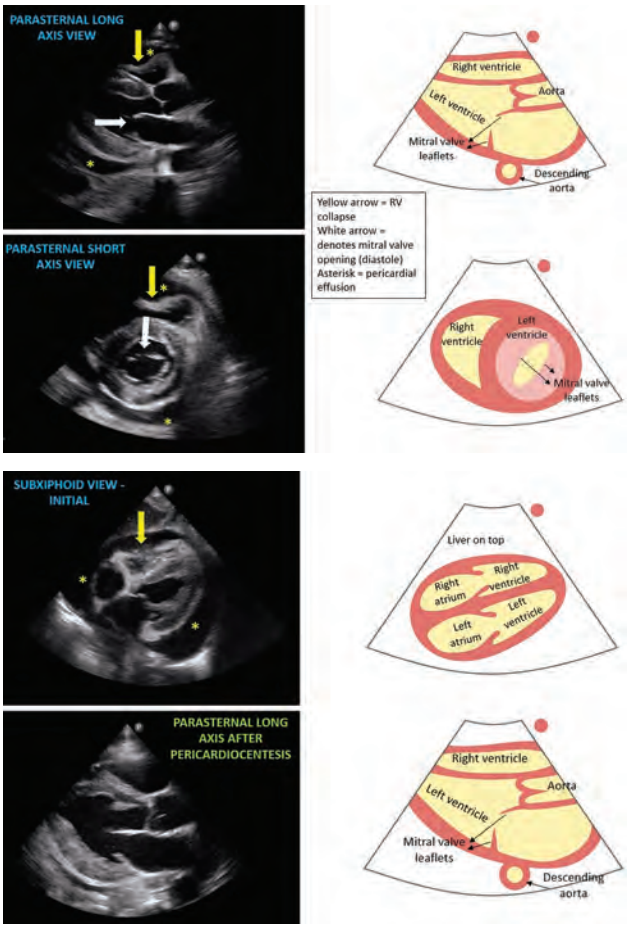
Cardiac Tamponade on Nephrologist-Performed Focused Cardiac Ultrasound

Aisha Batool, Abhilash Koratala. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Point of care ultrasonograhy (POCUS) has evolved as a component of physical examination in various specialties and nephrology is catching up quickly. Herein, we describe a case where focused cardiac ultrasound helped us appropriately manage AKI.

Case Description: A 59-year-old man with a history of untreated hypothyroidism presented with lower extremity swelling and shortness of Breath. Laboratory testing revealed a significantly elevated level of thyroid stimulating hormone of 43 mIU/mL (ref: 0.5-5). Chest X-ray showed an enlarged cardiac silhouette; transthoracic echocardiography demonstrated moderate to large circumferential pericardial effusion without tamponade and severely reduced LV systolic function. The patient was started on intravenous levothyroxine. The hospital course was complicated by hypotension requiring vasopressor therapy (presumed to be mixed septic and cardiogenic shock) and worsening renal function with oliguria. As assessing hemodynamics is a vital component of AKI evaluation, we performed POCUS, which revealed a plethoric inferior vena cava and a large circumferential pericardial effusion. Right ventricular diastolic collapse was clearly demonstrated (Figures 1 and 2) suggestive of tamponade physiology. The patient underwent emergent pericardiocentesis with removal of 450 mL of fluid resulting in cessation of the need for vasopressors as well as improvement in urine output.

Discussion: 1. POCUS (not limited to kidney) aids in the management of AKI. 2. Hemodynamics are dynamic. Having a recent formal echocardiogram should not preclude POCUS.



SA-PO147

Recovery of Chronic Thromboembolic Pulmonary Hypertension (CTEPH)-Associated Renal Failure After Pulmonary Endarterectomy (PEA)

Robert L. Jameson, George M. Nassar, Steffi Sathiyaraj, Nayda Bidikian, Nelson A. Villasmil Hernandez, Sandeep Sahay. *Houston Methodist Hospital, Houston, TX.*

Introduction: Chronic thromboembolic pulmonary hypertension (CTEPH) is a recognized cause of severe pulmonary hypertension (PH). Acute Kidney Injury (AKI) is a common occurrence in advanced cases of CTEPH and often progresses to require permanent renal replacement therapy (RRT). We present two patients with CTEPH and AKI who had persistent need for RRT; however, after successful pulmonary endarterectomy (PEA) both patients experienced renal recovery and no longer required RRT.

Case Description: **Case 1:** A 43-year-old male with antiphospholipid syndrome was hospitalized with congestive heart failure (CHF) and AKI. He was diagnosed with CTEPH by ventilation-perfusion scan and pulmonary angiogram. He underwent a right heart catheterization (RHC) which confirmed the presence of severe PH, and his echocardiogram revealed RV dysfunction. Despite intense pharmacological treatment for PH, he continued to require RRT and was discharged home on peritoneal dialysis. Five months later, he underwent a successful PEA and within 48 hours, he recovered from needing RRT. Two years later, he continues to be dialysis-free and maintains a serum creatinine of 1.7 mg/dl. **Case 2:** A 57-year-old woman with known CTEPH was admitted due to worsening right-sided CHF and AKI. Her echocardiogram showed RV systolic dysfunction and severe tricuspid regurgitation. She initially required intensive critical care (ICU) management with vasopressors and continuous RRT (CRRT). After she stabilized, she underwent PEA and tricuspid valve repair. She was discharged on PH medications and dialysis. Renal recovery occurred over the next six months, following which she got off dialysis. Four years later, she was still dialysis free and had a creatinine of 1.96.

Discussion: This report demonstrates the reversal of dialysis-requiring AKI in CTEPH patients following PEA. PEA is a promising therapy for CTEPH with significant renal benefits and should be considered as the optimal treatment for patients with CTEPH and concomitant AKI.

SA-PO148

Meprin β Regulates Protein Kinase A-Mediated TGF-β Signaling in Ischemia/Reperfusion-Induced Kidney Injury

Shaymaa Abousaad,[1] Faihaa Ahmed,[2] Ayman Abouzeid,[1] Elimelda M. Ongeri.[1] *[1]North Carolina Agricultural and Technical State University, Greensboro, NC; [2]NC State University, Raleigh, NC.*

Background: Ischemia/reperfusion (IR) is a leading cause of acute kidney injury (AKI) and is associated with high morbidity and mortality rates. Meprins, zinc metalloproteases have been implicated in the pathology of IR. Meprins are capable to proteolytically processing the catalytic subunit of protein kinase A (PKA-C) and several mediators of inflammation. The protein kinase A (PKA) signaling pathway plays an important role in renal fibrosis, promoting the production of transforming growth factor-β (TGF-β) and/or TGF-β-dependent molecules. The TGF-β signaling is involved in wound healing and tissue repair of injured kidneys. Activation of Smad2 and Smad3 is the major downstream event of the TGF-β signaling pathway. The objective of the current study was to determine how meprin β expression impacts PKA C-mediated TGF-β signaling in IR-induced kidney injury.

Methods: We used surgical procedures to achieve unilateral IR with contralateral nephrectomy in wild-type (WT) and meprin β knockout (βKO) mice. The mice were sacrificed at 96 h post-IR and kidney tissues obtained for analysis. Real-time PCR, and immunohistochemical staining, were used to evaluate the expression levels of PKA C and TGF-β. Statistical analysis utilized two way ANOVA.

Results: Real-time PCR data showed significant increases in mRNA levels of PKA C only in βKO kidneys after IR. In contrast, the mRNA levels for TGF-β were higher in both WT and βKO at 96 h post-IR Interestingly, the baseline mRNA levels for TGF-β were higher in meprin βKO mice. Immunohistochemical data showed significant increases in the levels of PKA C proteins in select kidney tubules of both genotypes after IR. Similarly, staining intensity for TGF-β were higher in select kidney tubules of both WT and meprin β deficient mice at 96 h IR. Immunofluorescence of kidney tissues with anti-meprin β, anti-PKA C and anti-TGF-β antibodies showed a positive correlation between meprin β expression and tubular PKA C and TGF-β levels in kidneys subjected to IR.

Conclusions: These findings suggest that meprin β regulates PKA C-mediated TGF-β signaling pathway in IR-induced kidney injury and provides new insights on the mechanisms underlying meprin β modulation of the pathophysiology of IR-induced renal injury.

SA-PO149

Role of LTBP4 in Kidney Injury: A Study on the Effect of LTBP4 on Angiogenesis and Inflammation in Renal Fibrosis

Chi-Ting Su,[1,2] Daniel H. See,[1] Yue-Jhu Huang,[1] Jenq-wen Huang,[1] Kuan-Yu Hung.[1] *[1]National Taiwan University Hospital, Taipei, Taiwan; [2]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA.*

Background: Transforming growth factor beta (TGFβ), a key player in renal fibrosis, is regulated by latent transforming growth factor beta binding protein 4 (LTBP4). However, we hypothesized that LTBP4 also plays a role in angiogenesis and inflammation, both TGFβ related and TGFβ independent. This is significant because the role of angiogenesis and inflammation in kidney injury is widely recognized.

Methods: We employed wild-type (WT) and *Ltbp4*^{PTKO}-/- [*Ltbp4* proximal tubule knockout (PTKO)] mice for our animal experiments. Additionally, we used human proximal tubule cells (HK-2 cells) transfected with LTBP4 lentiviral knockdown for *in vitro* cellular studies. To induce kidney injury, the mice underwent 30 min of bilateral renal ischemia-reperfusion injury (IRI) surgery. HK-2 cells were subjected to 24 h of hypoxia at 1% O_2, 5% CO_2, and 94% N_2 to simulate pathological kidney injury. Subsequently, molecular studies were conducted on mice kidney samples and HK-2 cells to assess the extent of injury and the expression of proangiogenic molecules and inflammatory cytokines.

Results: Our study demonstrated increased expression of LTBP4 in mice after kidney injury. Fourteen days post-IRI, *Ltbp4*^{PTKO}-/- mice showed more pronounced fibrosis than WT mice. Immunohistochemistry analysis revealed stronger positive staining for CD31, an endothelial marker, in WT mice than in *Ltbp4*^{PTKO}-/- mice. Moreover, WT mice exhibited higher expression of vascular endothelial growth factor (VEGF) than *Ltbp4*^{PTKO}-/- mice after undergoing IRI surgery. Transcriptomic analysis revealed upregulation of genes linked to angiogenesis in LTBP4-overexpressed HK-2 cells. Cellular studies reflected similar results in HK-2 cells, where VEGF expression was lower in LTBP4 knockdown cells. Additionally, inflammatory cytokines were upregulated in *Ltbp4*^{PTKO}-/- mice compared with those in WT mice after injury.

Conclusions: Our study findings show that LTBP4 plays a key role in regulating angiogenesis and inflammation during kidney injury. We demonstrated that LTBP4 partly has a protective effect in the progression of kidney disease. The increased angiogenesis and reduction in inflammation aid in the recovery of kidney injury and potentially mitigates long-term complications. These findings highlight the potential therapeutic avenues for utilizing LTBP4 in managing kidney injury.

Role of SMPDL3b in Radiation-Induced Nephropathy

Anis Ahmad,[1] Shamroop Kumar Mallela,[2] Jumana Afaghani,[1] Saba Ansari,[1] Misha Ali,[1] Sandra M. Merscher,[2] Youssef Zeidan,[3,1] Alessia Fornoni,[2] Brian Marples.[1,4] Dept of Radiation Oncology, University of Miami, Miller School of Medicine. *[1]Department of Radiation Oncology, Miller School of Medicine/Sylvester Cancer Center, University of Miami, Miami, FL; [2]Peggy and Harold Katz Family Drug Discovery Center and Division of Nephrology, Department of Medicine, University of Miami, Miami, FL; [3]American University of Beirut (AUB) School of Medicine, Beirut, Lebanon; [4]Department of Radiation Oncology, University of Rochester, Rochester, NY.*

Background: The kidneys are radiosensitive and dose-limiting organs for radiotherapy (RT) targeting abdominal and paraspinal tumors. Excessive radiation doses to the kidneys lead to radiation nephropathy (RN). In this study, we investigated a novel role for the lipid-modifying enzyme, sphingomyelin phosphodiesterase acid-like 3b (SMPDL3b), in regulating the response of renal podocytes to radiation injury.

Methods: Podocytes were irradiated with either 4Gy or 8Gy and Ezrin, and apoptosis, DNA damage, and survival were quantified at different time points post-RT. For *in vivo* studies, 10–14 weeks old C57BL/6 received bilateral kidney irradiation of 14Gy or 6x5Gy with or without rituximab (50 mg/kg; IP, 1h before RT). 20 weeks post RT, glomerular filtration rate (GFR) was measured by transdermal monitors. Urine and serum samples were analyzed to quantify urinary albumin-to-creatinine ratio (ACR), serum BUN, and creatinine levels. Kidney cortex sections were stained with H & E, Periodic Acid-Schiff, Picrosirius red, and Masson's trichrome staining. Ultrastructural Changes in the glomerular filtration barrier were quantified by transmission electron microscopy.

Results: Podocyte survival decreased in a dose-dependent manner post-RT. SMPDL3b overexpression prevented RT-induced DNA damage and apoptosis in cultured podocytes. 24 h post-RT, Podocyte DNA damage and apoptosis increased significantly more in podocyte-specific knockout (pSMPDL3b-KO) mouse kidney cortex than in SMPDL3b wild-type mice (p 0.0166 and p = 0.0302, respectively). Fibrosis, glomerular basement membrane (GBM), and foot process width, mesangial expansion score, BUN, creatinine ACR increased significantly more in pSMPDL3B-KO mice than in SMPDL3b wild-type mice ($p < 0.05$). GFR decreased significantly in SMPDL3B wild type and pSMPDL3B-KO mice 20 weeks post-RT ($p < 0.05$). Rituximab treatment to SMPDL3b wild-type mice prevented SMPDL3b downregulation, podocyte loss, reduced fibrosis, mesangial expansion score, GBM thickness, and foot process width and significantly improved renal function (BUN, Creatinine, and ACR) post-RT ($p < 0.05$).

Conclusions: Rituximab treatment restored SMPDL3b basal expression levels and decreased radiation-induced podocyte injury and albuminuria. Our findings suggest SMPDL3b as a potential therapeutic target in radiation-induced renal damage.

Renal IsoLG-Containing Antigen-Presenting Cells Modulate Endothelial Cells of Lymphatic Vessels via ET-3/ERB During Kidney Injury

Ashley L. Pitzer, Jianyong Zhong, Haichun Yang, Annet Kirabo, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Previously, we showed that sodium (Na^+) promotes the formation of the lipid oxidation product, isolevuglandins (IsoLGs) in antigen-presenting cells (APCs) which, in turn, have been linked to lymphangiogenesis and systemic hypertension. Lymphangiogenesis accompanies multiple experimental and human kidney diseases. Our recent studies show that albuminuric kidney injury leads to a high Na^+ environment within the kidneys and promotes renal accumulation of IsoLGs.

Methods: To induce nephrotoxic injury in mice, we used a sheep anti-glomerular antibody and harvested kidneys 3 weeks later.

Results: We observed a 370% increase in albumin: creatinine ratio, a 30% decrease in GFR, and increased systolic blood pressure (+20.1 mmHg) in nephrotoxin injured vs uninjured controls. Immunostaining of renal F4/80 expression, a macrophage marker, revealed a striking increase in the interstitium of nephrotoxic mice vs controls. Using flow cytometric analysis, nephrotoxin-injured kidneys were found to have elevated IsoLGs in monocytes and dendritic cells when compared to controls. Lymphatic endothelial cells (LECs) co-cultured together with APCs in a high Na^+ environment have increased IsoLGs as well as expression of endothelin receptor B (ETB), which are blocked with 2-hydroxybenylamine (2-HOBA) treatment. Additionally, when co-cultured with LECs, dendritic cells have increased IsoLG and expression of vasoactive peptide Endothelin-3 (ET-3) in response to a high Na^+ environment. Similarly, these observed increases are blocked with 2-HOBA treatment. Using RNA sequencing data and informatics in LECs co-cultured with APCs, we found high Na^+ significantly increased ET-3 in immune cells and ETB receptor in LECs.

Conclusions: These findings were validated using RT-PCR. Taken together, this data suggests LEC uptake of IsoLGs is potentiated by high Na^+ environment and interaction with inflammatory immune cells, and IsoLGs may play a role in the ET-3/ETB ligand: receptor intersection and crosstalk with LECs. The work was supported by NIH T32HL144446, 1P01HL116263, K01HL13049, R03HL155041, and R01HL144941.

SA-PO152

Exposure to Systemic Hypoxia After Renal Ischemia Reperfusion Injury (IRI) Promotes Kidney Repair

James O'Sullivan, Ratnakar Tiwari, Gabriella Borkowski, Pinelopi P. Kapitsinou. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: We and others have shown that activation of hypoxic signaling prior to renal ischemia reperfusion injury (IRI) exerts renoprotective effects. However, it is unclear whether induction of hypoxia (Hx) after injury regulates kidney recovery. Here, we investigated how exposure to systemic hypoxia regulates post-IRI kidney repair.

Methods: Male C57/BL6 mice were subjected to uIRI via clamping for 25 minutes. 6-hrs post-injury, groups were placed in hypoxia chamber at 8% O2 for 24 or 72 hrs, while control groups remained in normoxia (Nx). Mice were then sacrificed and kidneys collected for bulk RNA-Seq, metabolomic analysis and histology, while serum was collected for metabolomic analysis.

Results: After exposure to 72 hrs of Hx or Nx following IRI, the Hx group was found to have significantly lower injury via kidney injury scoring on H&E stained tissue sections (3.3±0.5 Nx vs 2.2±0.4 Hx, P=0.02, n=4 Nx, n=4 Hx) and Kim1 gene expression (2.5 fold suppression compared to Nx, P=0.0002, n=4 Nx, n=4 Hx). Hypoxia exposure for 24 hours did not significantly reduce kidney injury scores, but did reduce Kim1 expression (P=0.03). KEGG/GO pathway analysis of RNA-Seq data at 72 hours revealed a prominent inflammatory signature in the downregulated genes, such as cytokine-cytokine receptor interaction, TNF and NF-κB pathways (KEGG), as well as immune response, inflammation response and cytokine production (GO), indicating hypoxia exposure attenuated post-ischemic renal inflammation. On the other hand, pathway analysis of upregulated genes showed significant enrichment for metabolic pathways such as tryptophan metabolism, PPAR signaling, glutathione metabolism, fatty acid degradation and retinol metabolism. Furthermore, quantitative assessment of kidney and serum metabolite profile using a comprehensive LC-MS metabolite panel, as well as a targeted LC-MS assay for tryptophan related metabolites were carried out. Here, we found significant increases in tryptophan pathway metabolites in kidney tissue and serum, such as kynurenine, xanthurenic acid, 3-hydroxy-anthranilic acid and NAD+.

Conclusions: In summary, exposure to hypoxia in the context of established ischemic injury promotes early reparative processes. Among the altered metabolic pathways, changes in tryptophan metabolism may contribute to the mechanisms by which hypoxia promotes adaptive repair.

Modulation of Stimulator of Interferon Genes (STING) Signaling Differentially Affects Outcomes of AKI

Wulf Tonnus,[1,2] Andreas Linkermann.[1,2] Linkermann Lab. *[1]Technische Universitat Dresden, Dresden, Germany; [2]Universitatsklinikum Carl Gustav Carus, Dresden, Germany.*

Background: Activation of cGAS/STING signaling leads to both type I interferon production and NFkB-dependent transcription in a Tbk1-dependent manner. During acute kidney injury (AKI), we recently described a population of innate immune cells expressing gasdermin D to be recruited to the surroundings of acute tubular necroses. Interestingly, these GSDMD+ cells seemed to signal back on the ongoing cell death, a concept termed necroinflammation. As recent work demonstrated a crucial role for free DNA and RNA fragments in the pathogenesis of AKI, we hypothesized that these might contribute to innate immune activation via the cGAS/STING pathway.

Methods: We tested STING-deficient mice in two established models of AKI, which reflect toxic tubular injury (cisplatin-induced AKI, CP-AKI) and redox stress (ischemia/reperfusion injury, IRI). Furthermore, pharmacological activation of STING by diABZI or inhibition by C-176 was investigated. Next to blood values, organ injury was determined by histological workup. Mechanistic insights were derived from immunohistochemistry and Western Blot analyzes in addition to cell culture experiments.

Results: STING-deficient mice were less susceptible to IRI as exemplified by less strongly elevated values of serum creatinine and urea as well as lower tissue injury scores, whereas STING activation by diABZI did not ameliorate AKI. In contrast, STING-deficiency did not influence CP-AKI, but co-treatment with diABZI led to massively accelerated lethality. We found this to be dependent on regulated cell death, which was neither apoptosis, necroptosis, nor ferroptosis. Interestingly, GSDMD-deficient mice (the effector protein of pyroptosis, already identified as a protective factor against cisplatin-induced AKI) could not be further sensitized by STING-activation. Western Blot analyzes from primary tissue confirmed a correlation between pSTING and both GSDMD expression and proteolytic activation.

Conclusions: We found STING to be critically involved in different models of AKI. Unexpectedly, the results of STING activation seem to be context-dependent, as STING-deficiency was protective in IRI, whereas concomitant STING activation accelerated lethality in CP-AKI. Further workup is ongoing to identify underlying mechanisms.

Endonuclease G (EndoG) Inhibits DNase I-Mediated Apoptosis and DNA Repair in Kidney Tubular Epithelial Cells During Cisplatin Injury

Alexei G. Basnakian,[1,2] Shenyang Li,[2] Randal S. Shelton,[1] Todd Fite.[2] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Central Arkansas Veterans Healthcare System John L McClellan Memorial Veterans Hospital, Little Rock, AR.*

Background: We have previously shown that kidney tubular epithelial (KTE) endonuclease G (EndoG, EG) is induced by cisplatin and translocated from mitochondria to the nucleus during apoptosis. However, it is unknown whether EG causes apoptotic DNA fragmentation and how it leads to cell death. EG is the only apoptotic endonuclease found in the nucleus during apoptosis, has RNase activity, and induces inactive truncated isoform of another endonuclease, DNase I (DI).

Methods: We hypothesized that the role of EG in apoptosis depends on the presence of DI in the cell, and used cisplatin kidney injury *in vitro* and *in vivo* models to test this.

Results: To our surprise, although EG was often present in TUNEL-positive nuclei of KTE cells in mice treated with cisplatin (20 mg/kg), it did not colocalize with DNA fragmentation measured by TUNEL or with endonuclease activity measured by a fluorescent probe in apoptotic nuclei in cultured KTE NRK-52E cells. EG overexpression in DI-positive NRK-52E cells showed EG was not cytotoxic but instead protective against cisplatin injury (60 μM) as determined by flow cytometry. EG overexpression induced alternative splicing and inactivation of DI. When the same experiment was repeated using DI-negative HCC1954 cells, EG was cytotoxic and promoted cisplatin-induced cell death. Further study showed that EG was induced but was not cytotoxic in cisplatin kidney injury *in vivo*. After injection of cisplatin, no protection in EG null mice versus wild-type (WT) mice was observed by BUN, SCr, or histology. EG induction by cisplatin in WT mice was associated with the decrease of native DI expression and the appearance of inactive truncated DI. In addition to DNase I inactivation, an overexpression of EG in mouse KTE TKPTS cells induced mRNA alternative splicing (inactivation) of several DNA repair genes.

Conclusions: This study showed that EG acts as a proapoptotic enzyme in the absence of DI and it is anti-apoptotic in the presence of DI in KTE cells and the kidney during cisplatin injury. In addition, the overexpression of EG causes inactivation of several DNA repair genes thus likely causing an aggravation of the cisplatin injury.

14-3-3ζ Targets β-Catenin Nuclear Translocation to Maintain Mitochondrial Homeostasis, Promoting Balance of Proliferation and Apoptosis in Cisplatin-Induced AKI

Zhaoxing Sun, Xiaoqiang Ding, Xiaofang Yu. *Zhongshan Hospital Fudan University, Shanghai, China.*

Background: Cisplatin, an extensively used chemotherapeutic agent for solid tumors, is limited in clinical use due to its side effects, especially nephrotoxicity. Cisplatin-induced acute kidney injury (AKI) is characterized by DNA damage, cell cycle arrest and mitochondrial oxidative stress. Recent work demonstrated that 14-3-3ζ plays important role in cancers, nerve disease and kidney disease, but the role and regulatory mechanism in cisplatin AKI remain to be further clarified.

Methods: Here, we found that 14-3-3ζ mRNA was upregulated in human kidney organoids (GSE145085) when treated with cisplatin, which was confirmed in experimental mice. Then, we used inhibitor for 14-3-3 (BV02) in animal experiment, knocking down and overexpressing 14-3-3ζ respectively in vitro experiments to test the role of 14-3-3ζ in cisplatin-induced AKI.

Results: The use of protein interaction inhibitor for 14-3-3 (BV02) aggregated drop of renal function, apoptosis, mitochondrial dysfunction and oxidative stress in cisplatin-induced AKI. Accordingly, increased apoptosis, cell cycle arrest, ROS production and lipid dysbolism in cisplatin-treated NRK-52E cells were exacerbated in cells knocking down 14-3-3ζ. Besides, blocking 14-3-3ζ both in vivo and in vitro suppressed β-catenin and its nuclear translocation, downregulating the expression of downstream gene cyclin D1 in cisplatin-induced damage. In contrast, overexpression of 14-3-3ζ relieved injury caused by cisplatin and promoted nuclear transportation of β-catenin. Further, a non-specific agonist of β-catenin BIO reversed the effects of knocking down 14-3-3ζ in cisplatin-induced damage in NRK-52E by activating β-catenin. The direct interaction between 14-3-3ζ and β-catenin was then verified.

Conclusions: Taken together, these findings indicate that 14-3-3ζ protects against cisplatin-induced AKI by improving mitochondrial function and balance of proliferation and apoptosis through facilitating β-catenin nuclear translocation.

Reno-Protective Effect of Ginsenoside Rg3 in Ischemia Reperfusion Injury Mice by Inducing Autophagy Flux

Suyeon Han,[1] Kyungho Park,[1] Heewon Park,[1] Yunkyeong Hwang,[1] Hye Rim Park,[2] Eu Jin Lee,[1] Hae Ri Kim,[3] Youngrok Ham,[1] Kiryang Na,[1] Kang Wook Lee,[1] Dae Eun Choi.[1,2] *[1]Chungnam National University Hospital, Daejeon, Republic of Korea; [2]Department of Medical Science, Chungnam National University, Daejeon, Republic of Korea; [3]Chungnam National University Sejong Hospital, Sejong, Republic of Korea.*

Background: The protective effects of Ginsenoside Rg3 (Rg3) have been demonstrated through different mechanisms. Nevertheless, the specific evaluation of its renal-protective effect and the involvement of autophagy remain unclear. This study aims to examine how Rg3 induces autophagy flux and diminishes renal cell death in renal ischemia reperfusion injury (IRI).

Methods: C57Bl/6 mice were categorized into the subsequent groups: sham; sham treated with Rg3; IRI mice treated with saline; IRI mice treated with Rg3. Kidneys and blood samples were obtained 24 hours after the surgical procedure (sham and IR operation). Renal function, kidney histology, and the protein expression of autophagy markers were assessed.

Results: In the IRI mice group, there was an elevation of BUN and s-Cr levels compared to the sham group. However, the administration of Rg3 resulted in a reduction of BUN and s-Cr levels in the IRI mice. Furthermore, Rg3 treatment led to a decrease in renal injury, as evidenced by a lower renal tubular cell detachment and necrosis score in the IRI mice. The Rg3-treated IRI mice exhibited reduced oxidative stress and improved autophagy, characterized by increased levels of LC3 and Beclin-1, decreased levels of p62, and higher levels of renal ATP6E compared to the IRI mice treated with saline. Additionally, Rg3 treatment promoted the phosphorylation of AMPK in the kidneys of IRI mice.

Conclusions: Rg3 exhibits renal protection against renal IRI by enhancing autophagy flux.

SA-PO157

OTUD5 Mediates GPX4 Stability and Ferroptosis in Renal Tubular Cells During Ischemia-Reperfusion Injury

Jun Liu,[1] Ssu-Wei Hsu,[1] Fujia Guo,[2] Lindsay Oshiro,[1] Xiang-Ming Yan,[3] Ching-Hsien Chen.[1] *[1]University of California Davis, Davis, CA; [2]University of California Los Angeles, Los Angeles, CA; [3]Children's Hospital of Soochow University, Suzhou, China.*

Background: Acute kidney injury (AKI) is a severe kidney disease often linked with renal tubular cell ferroptosis, an iron-dependent, non-apoptotic cell death characterized by lipid peroxide accumulation. This can be triggered by ischemia-reperfusion (I/R) and typically results from decreased glutathione peroxidase 4 (GPX4) expression. However, the specific molecular events underlying GPX4 reduction following I/R remain poorly understood.

Methods: Our research involved identifying and characterizing the role of GPX4-interacting proteins in renal tubular cells. We also studied the susceptibility of renal regions to I/R injury using spatial transcriptomics. Both in vitro assays and in vivo experiments using mice with conditionally deleted Otud5 were employed to evaluate the function of OTU deubiquitinase 5 (OTUD5) in ferroptosis and AKI.

Results: OTUD5 was found to interact with and stabilize GPX4, conferring resistance to ferroptosis in renal tubular cells. During I/R, the inability of OTUD5 to deubiquitinate, triggered by mTORC1-mediated macroautophagy, led to GPX4 degradation and ferroptosis. Spatial transcriptomics revealed hyperactivity of cell ferroptosis and autophagy in the region between the kidney's inner cortex and medulla outstrip, susceptible to I/R injury. Functionally, OTUD5 deletion resulted in heightened renal tubular cell ferroptosis in vitro, and mice with tubular epithelial cell-specific Otud5 deletion demonstrated exacerbated AKI in response to I/R. Conversely, adeno-associated virus-mediated Otud5 delivery reduced ferroptosis and promoted renal function recovery.

Conclusions: Our findings unveil a novel autophagy-dependent ferroptosis module: I/R-induced OTUD5 macroautophagy leads to GPX4 degradation and tubular cell ferroptosis. Targeting this pathway may offer a potential therapeutic strategy for I/R-related kidney diseases.

Kidney HMGCS2 Protects Against Ischemic Kidney Injury

Sarah C. Huen,[1] Andrea H. Venable,[1] Kyle C. Feola,[1] Lauren Elizabeth Lee.[1,2] *[1]The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Evidence for abnormal renal fatty acid oxidation (FAO) in kidney disease suggests that dysregulated metabolism is a key component of kidney disease pathogenesis. Ketogenesis is a central metabolic pathway in which ketone bodies are produced from FAO. While the liver is the main ketogenic organ, the rate-limiting enzyme for ketogenesis, mitochondrial Hydroxymethylglutaryl-CoA synthase 2 (HMGCS2), is induced in the proximal tubule of the kidney during fasting. We previously demonstrated that HMGCS2 induced in the kidney does not contribute to the circulating pool of ketones during fasting and cannot compensate for hepatic ketogenic deficiency. We hypothesized that kidney HMGCS2 may be acting locally within the kidney to maintain normal function during metabolic stress or injury.

Methods: *Six2-Cre;Hmgcs2$^{fl/fl}$* (Six2^{Hmgcs2KO}) mice with kidney-specific *Hmgcs2* deletion and *Hmgcs2$^{fl/fl}$* littermate controls were subjected to ischemia/reperfusion injury (IRI). An acute kidney injury models with right nephrectomy and left IRI was used. Plasma creatinine and/or kidney mRNA/protein expression were assessed 24 hours after IRI. Using novel mouse models with proximal tubular hemagglutinin (HA)-tagged mitochondria with (*Ggt1-Cre;Hmgcs2$^{fl/fl}$;MITO-Tag*, Ggt^{Hmgcs2KO}-MT) or without (*Ggt1-Cre; MITO-Tag*, Ggt-MT) *Hmgcs2* deletion, proximal tubular-specific mitochondria were isolated using anti-HA magnetic beads after unilateral IRI. Fatty acid oxidation (FAO) capacity was measured using palmitoylcarnitine as a substrate and oxygen consumption rate was determined by Seahorse.

Results: Six2^{Hmgcs2KO} mice had significantly higher plasma creatinine levels and expression of kidney injury markers (*Kim1*) 24 hours after IRI compared to *Hmgcs2$^{fl/fl}$* littermate controls. Kidneys lacking HMGCS2 also had an increase in lipid droplet accumulation accompanied by a decrease in *Ppargc1a* expression, however there was no significant difference in renal *de novo* lipogenesis gene expression. Proximal tubular-specific mitochondria isolated 24-hour post IRI from Ggt-MT and Ggt^{Hmgcs2KO}-MT kidneys demonstrated that mitochondria lacking HMGCS2 had significantly lower basal and ADP-stimulated FAO capacity.

Conclusions: Our data provide evidence that proximal tubular HMGCS2 may play an important role in maintaining mitochondrial function and FAO capacity, resulting in protection against ischemic kidney injury.

Peroxisomal Inhibition Abolishes Dicarboxylic Acid-Mediated AKI Protection

Anne C. Silva Barbosa,[1,2] Katherine Pfister,[1,2] Takuto Chiba,[1,2] Rebecca M. Uhlean,[1,2] Birgit Schilling,[3] Eric S. Goetzman,[1,2] Sunder Sims-Lucas.[1,2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC Children's Hospital of Pittsburgh Child Development Unit, Pittsburgh, PA; [3]Buck Institute for Research on Aging, Novato, CA.*

Background: Peroxisomes play important roles in metabolism, including in fatty acid oxidation (FAO). Interestingly, post-translational modification of lysine residues by succinylation promotes FAO and has also been linked to acute kidney injury (AKI). In addition, octanedioic acid (DC_8) is a dicarboxylic acid that, upon FAO, promotes hypersuccinylation. Finally, studies suggest that 10,12-tricosadiynoyl-CoA (TDYA) inhibits peroxisomal activity. Therefore, we hypothesized that DC_8 protects from AKI via hypersuccinylation of renal peroxisomes and that TDYA blocks this response.

Methods: To test the role of DC_8 in AKI, mice were fed with control or 10% w/w DC_8 diet, then, subjected to unilateral renal ischemia-reperfusion (IRI). Six days after IRI, mice underwent contralateral nephrectomy and were euthanized the following day. Supplementation was provided until sacrifice. To test if TDYA would promote an opposite response, we treated another cohort of animals with or without daily doses of 2mg/kg TDYA for 18 days. On the third day, animals began being fed on 10% DC_8 and underwent IRI as previously. Biochemical, histologic, and proteomic analyses were performed together with mitochondrial and peroxisomal activities.

Results: DC_8 prevented the rise of renal injury markers in IRI mice and improved morphology compared with controls, demonstrating efficient protection against AKI. Proteomics evidenced a substantial increase in peroxisomal succinylation in DC_8-fed animals, which was confirmed by immunofluorescence and peroxisomal FAO activity, while mitochondrial activity was shown to be preserved. Furthermore, TDYA completely abolished all the protective responses of DC_8 as it inhibited peroxisomal activity.

Conclusions: DC_8 supplementation drives renal hypersuccinylation, promoting a shift from mitochondrial to peroxisomal FAO, and protecting against AKI. Meanwhile, peroxisomal inhibition with TDYA completely inhibits this protection and confirms the important role of peroxisomal succinylation in AKI protection following DC_8 administration.

SA-PO160

Mitochondrial Morphology Regulates Proximal Tubule Cell Differentiation Status

Sho Sugahara, Bertha C. Elias, Craig R. Brooks. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Acute Kidney Injury (AKI) frequently occurs in hospitalized patients and predisposes them to developing chronic kidney disease (CKD). Our lab and others have shown prolonged proximal tubule cell (PTC) dedifferentiation in the form of maladaptive repair contributes to this AKI-to-CKD transition. One of the most striking histological features of dedifferentiated PTCs is fragmentation of the mitochondria, which occurs through the mitochondrial fission pathway involving dynamin related protein 1 (Drp1). While it is known mitochondrial fragmentation reduces mitochondrial function, it is unclear if fragmentation contributes to PTC dedifferentiation.

Methods: Mitochondrial morphology in kidney tissue was monitored using super-resolution microscopy. Using primary PTCs and LLC-PK1 cells treated with aristolochic acid (AA), we developed an in vitro model of PTC dedifferentiation. Mitochondrial fragmentation was suppressed with specific inhibitors. In vivo, inducible Drp1 KO mice ($Drp1^{\Delta PT}$) were used to regulated mitochondrial fragmentation and compared to wild-type (WT) littermates age 8-12. Kidney injury was induced by aristolochic acid nephropathy, repeat low-dose cisplatin, and bilateral ischemic reperfusion injury models. Dedifferentiation markers were measured by immunofluorescence, protein expression and mRNA levels.

Results: Using super-resolution imaging of kidney tissue, we found that dedifferentiated PTCs had greatly reduced mitochondrial volume and network length, indicating mitochondrial fragmentation. In vitro, AA treatment reproduced this phenotype by inducing mitochondrial fragmentation early after injury, which was followed by dedifferentiation at later time points. Pharmacological inhibition of mitochondrial fragmentation prevented PTC dedifferentiation. Similarly, knocking out Drp1 in vivo after kidney injury improved mitochondrial morphology and reduced markers of dedifferentiation in all three injury models tested. Improved mitochondrial morphology was associated with reduced kidney fibrosis in all three models.

Conclusions: Inhibition of mitochondrial fragmentation prevents proximal tubular cell dedifferentiation and reduces renal fibrosis. Interventions targeting mitochondrial health may lead to novel therapeutics to improve chronic kidney injury.

SA-PO161

A Novel RIPK3/BRD4 Small Molecule Inhibits Arsenical-Induced AKI

Arin Melkonian, Kyle H. Moore, Amie Traylor, Laurence M. Black, Anna A. Zmijewska, Stephanie Esman, Ritesh Srivastava, Mohammad Athar, James F. George, Anupam Agarwal. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Arsenicals such as lewisite, cause blistering of the skin as well as lung, kidney, and multi-organ damage. The development of antidotes to warfare chemicals is a priority of the NIH CounterACT Program. To this end, we used single nucleus RNA sequencing (snRNAseq) to explore the nephrotoxic effects of phenylarsine oxide (PAO, a lewisite mimic) in an unbiased manner and synthesized a novel dual inhibitor (duali) that targets two necroptotic markers that are upregulated after lewisite exposure: receptor interacting serine/threonine kinase 3 (RIPK3) and bromodomain-containing protein 4 (BRD4). BRD4 plays a critical role in inflammation and redox metabolism. Here we identify transcriptional alterations in the kidney following arsenical-induced damage and test the hypothesis that the duali protects against injury using *in vivo* and *in vitro* models.

Methods: snRNAseq was performed on kidneys from mice treated topically with PAO (4mg/kg) or vehicle for 6 and 24 hours. Protective effects of duali were evaluated *in vitro* utilizing proximal tubule cells (PTCs). Cells were pretreated with duali 1 h before PAO and examined via immunostaining, western blots, and qPCR at 4, 20, or 24 hours. *In vivo* efficacy was assessed 24 h post PAO (4-6mg/kg). Duali was applied topically 30 min post PAO exposure.

Results: Duali treatment inhibits phospho- mixed lineage kinase domain-like pseudokinase (MLKL) and total RIPK3 and MLKL transcripts ($p < 0.05$) *in vitro*. We also observed a recovery of glomerular filtration rate in PAO exposed mice following duali treatment, which was associated with decreased expression of pRIPK3. snRNAseq in PAO treated mice revealed that fatty acid (FA) β-oxidation, FA biosynthesis, and PPAR-alpha pathways were upregulated in PTC and endothelial cells.

Conclusions: While the treatment with duali ameliorated PAO induced kidney injury, the mechanism of action remains to be elucidated. We have shown that cutaneous PAO exposure alters gene transcription and upregulates FA metabolism suggesting a compensatory response following metabolic perturbation. We conclude that our duali may be used as a potential therapeutic in arsenical-induced AKI. Future studies aim to confirm the precise mechanisms behind BRD4- and duali-mediated improvements of renal function.

Continuous Antithrombin III Infusion in a Clinically Relevant Sepsis Model

Naoki Hayase, Rohit R. Chari, Alef Aragao Carneiro dos Santos, Yoshitaka Naito, Xuzhen Hu, Peter S. Yuen, Robert A. Star. *National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Despite unacceptably high mortality and economic burden, effective therapeutic strategies for sepsis remain elusive. Discrepancies between septic patients and animal models may be caused by drug pharmacokinetics, route, and timing of drug administration. Antithrombin III (AT) is an anticoagulant that might ameliorate sepsis-induced multiorgan dysfunction, though clinical trial results are conflicting due to variation in patient selection and drug regimens. AT has not been tested in clinically relevant sepsis models. AT has a short half-life, so we devised a method to continuously infuse drugs starting 6-12 h after cecal ligation and puncture (CLP). We asked, "Is AT effective in a clinically translatable sepsis model, and does the route of administration matter?"

Methods: We catheterized the mouse jugular vein, then connected the catheter to an osmotic minipump containing saline. After 1 wk stabilization, we performed CLP and replaced the minipump with one containing AT or saline. We set a 6-12-h time delay between sepsis induction and treatment by incorporating a 4 cm saline-filled catheter in the circuit. We measured the actual time lag with FITC-sinistrin and measured its systemic appearance with a transdermal fluorescence detector. Survival studies were conducted. In separate experiments, we collected blood, kidney, liver, and lung at 48 h for biochemical and histological tests. To examine the effect of administration route, we compared continuous AT infusion with saline infusion, and a conventional bolus AT injection.

Results: First, we detected a sustained fluorescence signal in the systemic circulation 5–6 hours after adding FITC-sinistrin to our drug administration system. Second, delayed, continuous AT infusion significantly improved 7-day survival compared to saline-infusion (65% vs. 29%, n = 21 /group, p = 0.018). Continuous AT infusion markedly improved survival vs. a single injection of AT (65% vs. 19%, n = 21 /group, p = 0.003). Continuous AT attenuated liver injury but not renal or lung injury in the histology and biochemistry analyses.

Conclusions: We created a clinically relevant murine sepsis model with both a continuous infusion and time lag. Survival was higher in continuous AT infusion than either single bolus injection or vehicle. Future studies will elucidate the mechanism of the survival benefit.

Quantitative Proteomics Analysis of Differentially Expressed Proteins in Septic Mice Kidney With Humanin Treatment

Zhilian Li, Zhenmeng Xiao, Qingying Shi, Wenjing Cai, Yuanhan Chen, Zhiming Ye, Xinling Liang. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Sepsis-associated acute kidney injury (SA-AKI), which carries a high morbidity and mortality in patients, has no effective therapeutic strategies and its mechanisms are not fully understood. Increasing evidence have already showed that renal mitochondrial dysfunction plays a pivotal role in sepsis. We aimed to determine the effects of humanin, a mitochondrial-derived cytoprotective peptide on kidney injury in septic mice, and look for differentially expressed proteins after humanin treatment.

Methods: A murine model (C57BL/6 mice, 8-10 weeks, male, n=6 for each group) was constructed by one single dose of intraperitoneally lipopolysaccharide (LPS) injection (10mg/kg, LPS group) or PBS (Control group). HNG (a potent analog of humanin) was intraperitoneally injected 15 minutes later with a dose of 1mg/kg (HN group). Blood urea nitrogen (BUN), serum creatinine (Scr) and Kim-1 was determined, kidney histology staining, renal inflammatory cytokines, mitochondrial function were evaluated. To analyze the global proteome of the kidney tissue, the 4D-Label-free quantification analysis was applied to screen differentially expressed proteins in 3 groups (n=3 for each group). The parallel reaction monitoring (PRM) was used to verify the selected target proteins.

Results: HNG significantly reduced serum levels of Scr and BUN in a dose-dependent manner (0.2mg/kg, 0.4mg/kg and 1mg/kg), inhibited renal expression of IL-6, IL-1β and HMGB1 and reduce the damage of mitochondria in renal tubular epithelial cells in LPS-induced AKI. Collectively, 5900 proteins were identified in the label free quantification mass spectrometry, 5111 of which were quantifiable. NF-kappa B, Toll-like receptor, NOD-like receptor or IL-17 signaling pathways were significantly enriched,among which 7 proteins were selected for verification by PRM, and they were CD14, Casp3, Rela, Gbp2, Gbp3, Gbp5 and S100a9.

Conclusions: Humanin improves mitochondrial function and alleviates renal tubular injury in LPS-induced AKI. The map of the global proteomics enables further understanding of SA-AKI and will provide great help for seeking more potential therapeutic targets for SA-AKI.

Funding: Government Support - Non-U.S.

Differential Renal Responses to Dexamethasone in Rats and Mice Following AKI

Henriette Frikke-Schmidt,[1] Stephen Beck,[1] Meghan M. Pryor,[2] Rong Meng,[1] Joseph Strizziere,[2] Matthew M. Rankin,[1] Lili Guo,[1] Fuyong Du,[1] Shefali Patel,[2] Andrea R. Nawrocki,[1] Jan M. Dieleman,[3] Mark P. de Caestecker,[4] Alessandro Pocai.[1] *[1]Cardiovascular Metabolism Janssen, Spring House, PA; [2]Janssen Research and Development LLC, Spring House, PA; [3]Westmead Hospital, Westmead, NSW, Australia; [4]Vanderbilt University Medical Center, Nashville, TN*.

Background: Acute kidney injury (AKI) is a common cause of kidney failure and mortality. No treatments are approved, but the availability of novel diagnostic tools and biomarkers and better understand of human pathogenesis have increased the likelihood of developing an effective therapy. A major missing link to support successful clinical trials in this area is the lack of evidence that efficacy in preclinical models of AKI is translatable into humans. Because there is existing evidence of dexamethasone (dexa) beneficial effect in human (DECS trial) and rodent AKI, dexa was evaluated in ischemia-reperfusion (IR) induced AKI in rats and mice.

Methods: Dexamethasone was administered via IP injection to mice (12 mg/kg) and rats (3 mg/kg) 30 min before kidney ischemia reperfusion (IR). Plasma creatinine (pCre), transcutaneous GFR (tGFR) and kidney gene expression were evaluated 24h after the procedure.

Results: Dexa reduced plasma creatinine, kidney proinflammatory genes (IL-6, CCL2, IL-1β) and increased tGFR on day 1 after IR in rats but not in mice. Consistently, dexa treatment reduced plasma corticosterone levels (translational target engagement (TE) biomarker) only in rats. Kidney mRNA level of glucocorticoid receptor NR3C1 was downregulated in mouse IR but remained unchanged in rat IR. Similar plasma dexa concentrations were detected in rat and mice.

Conclusions: While the interpretation of these data is limited by the lack of availability of TE and plasma exposures in the DECS clinical trial, the differential responses observed in rat and mice may be attributed to downregulation of steroid receptor expression in mouse kidneys. Appropriate omics characterization together with translational biomarkers and compound exposures in humans and animals may provide significant insights and increase preclinical model translatability in AKI.

Acute Exposure to Particulate Matter Affects Renin-Angiotensin System in the Kidneys

Jin Joo Cha, Bum Sik Tae. *Korea University Ansan Hospital, Ansan, Republic of Korea*.

Background: Recent studies have shown that exposure to fine particulate matter (PM) leads to systemic inflammation and furthermore increases the risk of cardiovascular disease. Epidemiologic studies have shown a significant association between exposure to PM and chronic kidney disease and progression to end-stage renal disease. In order to understand the underlying mechanism of PM to systemic effects, we examined the effects of acute exposure to high-concentration fine PM on kidney injury in an experimental mice model.

Methods: Unilateral Ureteral Obstruction (UUO) was induced in 10-week-old Sprague Dawley rats. For fine PM, we used Carbon black CP(CAS No 1333-86-4) dispersed in a specialized inhalation chamber. SD rats were exposed to high-concentration CP particles for 3 hours for 3 days in a nose-only inhalation chamber. Groups were divided into 1) Control, 2) UUO, 3) PM, 4) UUO + PM, 5) UUO+ PM+ ARB L158809 (Merck & Co, Inc, NJ, USA) by drinking water (1.5mg/kg/d).

Results: Weight loss was apparent in rats exposed to carbon black and PM exposure groups. Blood pressure was significantly elevated after the study in the PM and UUO groups. In the lung of PM exposure, renin, angiotensinogen, AT2R gene expression significantly increased and ACE2 decreased. In the kidney, the expressions of renin, and angiotensinogen were not changed after PM exposure, but ACE2 expression significantly decreased in the kidney and UUO further diminished the expression. ARB treatment restored the expression.

Conclusions: Altogether, these findings suggest that exposure to PM can affect the renin-angiotensin system in the kidney, in a different manner from other organs.

SA-PO166

Functioning and Molecular Mechanism of Histone Lactylation in AKI

Zhenzhen Liu. Xinwei Research Group. *Shandong First Medical University, Jinan, China*.

Background: Acute kidney injury (AKI) is a common clinical problem, which is defined as the abrupt deterioration of kidney function that results in a decreased glomerular filtration rate. Studies have demonstrated that AKI is associated with a reduced survival rate of patients, increased incidence of chronic kidney disease (CKD), and other complications.

Methods: Although lactylation has been widely studied in the context of cancer, inflammation, and regeneration, its role in AKI remains poorly understood. To address this gap, we conducted a comprehensive investigation into the effects and mechanisms of lactylation in ischemic AKI, utilizing flow cytometry, Western blot, PCR, immunofluorescence, Seahorse in vivo and in vitro.

Results: Our findings demonstrated that pan-lactylation and H3K18 lactylation were significantly reduced in tubular epithelial cells (HK-2 cells) and renal tissue under ischemia in vitro and in vivo. Interestingly, we found that ING2 expression were significantly reduced under ischemia and overexpression of ING2 could inhibit apoptosis of HK-2 cells. In mechanism, ING2 knockout or overexpression could regulate lactylation. Finally, ING2 could regulate lactylation through p300 and promoting histone lactylation could reverse ischemia-induced HK-2 cells injury and ischemia-reperfusion induced AKI in mice.

Conclusions: These results suggested that a unrecognized role of lactylation in kidney injury and a promising target for therapeutic intervention of AKI.

SA-PO167

Assessment of Extracellular Vesicles Isolated from the Culture Medium of Ischemic Renal Proximal Tubular Epithelial Cells

Raquel Silva Neres dos Santos,[1,2] Marcela S. Carneiro-Ramos,[1] Dylan Burger.[2] *[1]Universidade Federal do ABC, Santo Andre, Brazil; [2]University of Ottawa, Ottawa, ON, Canada*.

Background: Extracellular vesicles (EVs) are membranous particles released by a cell into the extracellular environment. They play an emerging and important role in cell communication and have been implicated in a variety of pathological conditions including acute kidney injury and chronic kidney diseases. Our objective was to characterize the dynamics of extracellular vesicle release by proximal tubular epithelial cells exposed to hypoxia and reoxygenation (H/R).

Methods: Primary human renal proximal tubule epithelial cells (hPTECs, n=3) were exposed to 24 hours of 1% hypoxia followed by 3 hours of reoxygenation. Proximal tubule phenotype was verified by megalin immunofluorescence and EVs were isolated from the conditioned culture medium by ultracentrifugation (100.000g for 1h30min). Extracellular vesicle size and quantity were assessed by nanoparticle tracking analysis (NTA) and EV protein quantification.

Results: The immunofluorescence analysis indicated hPTECs were megalin-positive and this was not altered by H/R. NTA indicated that the H/R exposed cells released ~2-fold more EVs than normoxia ($p<0.05$). This was further supported by an increase in EV protein in conditioned media of H/R vs normoxia (1.08±0.17 vs 0.75±0.12 μg/μl, $p<0.05$). The mean particle sizes were not significantly different between H/R (153.5nm) and normoxia (145.8nm) groups.

Conclusions: Our initial data suggest that under hypoxia induces a shift in EV release from proximal tubule cells with greater EV release. These findings suggest that proximal tubule EV release may be altered in the context of ischemic kidney disease. Such changes may contribute to disease pathogenesis.

The Blood Transcriptome Is Reflective of Renal Tissue Injury in Endotoxin-Associated Acute Kidney Failure

Danielle Janosevic,[1] Maria Fernanda Martinez Lopez,[2] Thomas De Luca.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Universidad Iberoamericana, Santo Domingo, Dominican Republic*.

Background: MicroRNA (miR) regulate the translation of RNA involved in renal injury and recovery processes in endotoxin-associated acute kidney injury (sAKI). We previously identified the renal tissue response in sAKI as a series of temporally unique stages consisting of inflammation progressing to translation shutdown and organ failure. We hypothesize the blood miR and RNA (transcriptome) exhibits a response reflective of underlying renal tissue sAKI stage.

Methods: Kidney bulk RNAseq and miRNAseq were performed in an established murine model of sAKI at 0 (baseline) and 1,16 hr (injury) after endotoxin tail vein injection (LPS, n= 5 per timepoint). Total RNA (consisting of RNA and miRNA) extracted from bulk kidney tissue and whole blood (blood), DNAse treated, and globin depletion (blood only) performed. For each miR and RNA, libraries prepared and sequenced (miR: 10-15 million read depth/sample, RNA: 25-30 million read depth/sample) aligned to mm10 transcriptome (STAR). Counts were TMM normalized, log-transformed (counts-per-million, EdgeR), generating expression data. Pearson correlation between blood and kidney performed and common genes with $r>0.8$ and FDR <0.05 considered significantly correlated and pathway analysis performed (Pathfindr).

Results: Transcriptome analyses performed in the blood and the kidney revealed positively correlated miR (n=133 $r > 0.8$) and RNA (n= 388, $r >0.99$) shared between the blood and kidney at each timepoint. Pathway analysis revealed significant upregulation ($p <0.05$) of inflammatory, extracellular matrix/migratory pathways at 1 hr after LPS (NFKB pathway, cell-matrix adhesion, endothelial cell migration). At 16 hr after LPS there were shared alterations in transcription processing, miR regulation, viral responses, and catabolic processes. Analysis of the transcriptome shared between the blood and the kidney revealed parallel activation of RNA involved in the innate immune response and metabolic processes, regulated by miR (miR-144/Cxcl10, miR-298/Cd14, miR-345/Saa2).

Conclusions: Our data suggest that miR regulate RNA in several important sAKI-related pathways. These data demonstrate that the blood transcriptome may be reflective of underlying sAKI tissue stage indicating the utility of these transcriptomic biomarkers.

An IL10Ra-Mediated Regulation of T Regulatory Cells by Myeloid Cells in AKI

Franklin J. Herbert, Vikram Sabapathy, Jitendra K. Gautam, Molly Sander, Bushra Mehkri, Saleh Mohammad, Rahul Sharma. *University of Virginia, Charlottesville, VA.*

Background: IL-10 is a cytokine with multiple effects in immunoregulation and inflammation. IL-10 can protect the kidney from ischemia-reperfusion injury (IRI) - a condition that causes tubular injury and dysfunction due to hypoxia and inflammation. IL-10 binds to its receptor (IL-10R) on the cell surface and activates intracellular signaling pathways that suppress the production of pro-inflammatory cytokines and pro-apoptosis factors. However, the mechanistic role of IL10Ra has not been investigated in AKI, especially during the resolving phase.

Methods: We generated IL10Ra$^{fl/fl}$ LysM-Cre mice for specific deletion of IL10Ra in myeloid cells and subjected them to bilateral or unilateral IRI (uIRI) followed by reperfusion for 13 days. The mice were analyzed for immunophenotypic, histopathological, biochemical, and molecular analysis to evaluate immune profile and pathophysiology. Bioenergetics with parameters of oxidative phosphorylation and glycolysis, along with Differentiation assays were performed to gain a mechanistic view of immunomodulation.

Results: Myeloid-cell-specific deletion of IL-10Ra led to a significant increase of CD4 effector memory cells and a marked reduction of regulatory T cells in the spleen as compared to IL-10Ra-sufficient controls. The expression of pro-inflammatory cytokines, co-stimulatory markers as well as activated CD8 T cells and CD8 effector memory T cells were also elevated in the KO mice as compared to the control. There were no differences observed in kidney function in KO mice subjected to bilateral IRI for 24 hours (Acute phase). However, when subjected to uIRI, the IL10Ra deletion led to reduced kidney function as shown by increased plasma Creatinine and BUN, increased tubular Injury score, and marked elevation of injury biomarkers KIM1 and NGAL. Interestingly, KO macrophages subjected to bioenergetics analysis revealed a reduction in mitochondrial respiration and altered potential in generating Foxp3^{+} T-regulatory cells (Tregs).

Conclusions: Our findings reveal a previously unrecognized link between mitochondrial dysfunction, Treg-differentiation, and IL10Ra signaling in resolving of AKI, and could also serve as a potential target for therapeutic modulation.

SA-PO170

Angiotensin II Type 2 Receptor (AT2R) Modulates CD4+ T Cells into Regulatory T Cells (Tregs) in Kidney Ischemia-Reperfusion Injury in Rats: Role of PP2A

Tahmid Faisal, Riyasat Ali, Tahir Hussain. *University of Houston System, Houston, TX.*

Background: Kidney ischemia reperfusion injury (IR) is the common pathophysiology of acute kidney injury (AKI) associated with immune cell infiltration including T cells. Male kidney is more susceptible to AKI than females. Recently, we have shown that IR causes infiltration of CD45+T cells in male rats and AT2R activation reduced renal CD45+ T cells infiltration and modulated CD4+T cells into anti-inflammatory Tregs ameliorating AKI. Infiltration of these cells in females and the mechanism of AT2R-mediated modulation of CD4T cells into Tregs are unknown.

Methods: Bilateral IR was performed on female SD rats for 30 mins. The rats were divided into 3 groups: sham, IR, and IR+C21 (AT2R agonist, i.p. 0.3 mg/kg b.wt). After 3 days kidney cells were isolated and analyzed with flow cytometry for investigating CD45+, CD3+, CD4+, and FoxP3+ Treg cells. Also B6 mouse splenic CD4+T cells were isolated using magnetically labelled anti-CD4, which were activated with anti-CD3/anti-CD28/ IL2/ TGFβ and treated with C21 alone or in the presence of AT2R antagonist PD123319, NO synthase inhibitor LNAME, PP2A inhibitor okadaic acid.

Results: The female rats showed CD45+, CD3+ and CD4+ T cells infiltration 3days after IR. However, the renal accumulation of CD45 and Tregs is lower in female (<1% of total kidney cells) compared to 3 days IR data in male (7%) rats- suggesting a sex difference. C21 administration reduced the CD45+ T cells infiltration, and increased CD4+FoxP3+ regulatory T cells population and reduced kidney injury as evident by reduced plasma creatinine. However, BUN and proteinuria analysis did not suggest any significant changes with AT2R activation at 3 day post-IR. The ex-vivo splenic CD4+T cells revealed that C21 treatment modulated the CD4+T cells into CD4+Treg cells as determined by 2- fold increase in transcription factor FoxP3 expression. AT2R antagonist PD123319 reduced 2- fold, suggesting the involvement of AT2R. The PP2A inhibitor okadaic acid remarkably attenuated C21-induced FoxP3 increase indicating while the NO synthase inhibitor L-NAME caused only a moderate reduction in C21-induced FoxP3 expression.

Conclusions: IR causes a lower immune cell infiltration in females than males and the AT2R-mediated protection and Treg modulation occurs via PP2A pathway.

Macrophage Subtypes Affect the Damage and Repair of Sepsis-Associated AKI by Regulating the Phagocytic Function of Kidney Epithelial Cells

Lili Huang,[1] Yuanyuan Wu,[2] Bin Yang.[1,3] *[1]Affiliated Hospital of Nantong University, Nantong, China; [2]Nantong University, Nantong, China; [3]University of Leicester, Leicester, United Kingdom.*

Background: Different subtype macrophages play different roles in acute kidney injury, but how they work is still not fully defined. This research highlighted the mechanism underpinning the clearance of dying cells and its impact on the surrounding environment including the phagocytotic function of kidney epithelial cells.

Methods: Mouse RAW264.7 cells (peritoneal macrophage cell line) were cultured, in which LPS or IL-4 was used to induce the M1 or M2 phenotype macrophages. The changes of phenotype were verified by Western Blot and flow cytometry. M1 and M2 macrophages were then co-cultured with TCMK-1 cells (kidney epithelial cell line) with or without LPS treatment for 24 h in a trans-well system. Inflammation cytokines were detected by quantitative real-time PCR (qPCR). Apoptotic cell death was accessed by Annexin V/Proidium iodid staining, while the phagocytotic capacity of TCMK-1 cells was evaluated by the uptake of FITC-labelled pHrodo E.coli Bioparticles® Conjugate, and then detected by a flow cytometer.

Results: RAW264.7 cells were successfully induced into M1 and M2, which were verified by increased iNOS expression, F4/80^{+}CD86^{+} cells and F4/80^{+}iNOS^{+} cells in M1 macrophages, and increased Arg-1 expression, F4/80^{+}CD206^{+} cells and F4/80^{+}Arg-1^{+} cells in M2 macrophages. In trans-well culture, M1 macrophages increased pro-inflammatory mediators including IL-1β, IL-6 and TNF-α in TCMK-1 cells, especially with LPS stimulation, but M2 macrophages raised anti-inflammation mediators. A similar change trend was revealed in the percentage of apoptotic TCMK-1 cells, together with Bax and EPOR protein expression. Most importantly, regardless of LPS, the phagocytotic function of TCMK-1 cells was decreased by co-cultured M1 macrophages, but it was enhanced by co-cultured M2 macrophages.

Conclusions: M1 macrophages affect adjacent kidney epithelial cells by releasing inflammatory mediators, inducing apoptotic cell death, compromising phagocytotic function and further repair, whereas M2 macrophages have opposite impacts.

AKI Results in Sustained, Long-Term Alterations of Kidney Lymphatics

Gelare Ghajar-Rahimi,[1] Daria Barwinska,[2] Grace Whipple,[1] Malgorzata Kamocka,[2] Shehnaz Khan,[2] Seth Winfree,[3] James F. George,[4] Tarek M. El-Achkar,[2] Anupam Agarwal.[1] *[1]The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of Nebraska Medical Center, Omaha, NE; [4]The University of Alabama at Birmingham Department of Surgery, Birmingham, AL.*

Background: Acute kidney injury (AKI) is a serious clinical problem associated with significant morbidity and mortality that are inadequately addressed by current treatment options. The kidney endothelial system, comprised of blood and lymphatic vascular systems, responds dynamically to injury. In several models of AKI, kidney lymphatics undergo a process of expansion or lymphangiogenesis (LA). While this process is thought to be acutely protective, long-term alterations in kidney lymphatics following initial injury have never been assessed.

Methods: C57BL/6J mice subjected to bilateral ischemia-reperfusion injury (BIRI) or sham operation were followed for 1, 3, 6, and 9 months. Kidney function was monitored with serial measurements of serum creatinine (SCr) and transcutaneous glomerular filtration rate (GFR). Lymphangiogenic response was assessed by western blot and quantitative real-time PCR at end points. Large-volume confocal imaging followed by a three-dimensional tissue cytometry (3DTC) analytical approach was used to assess lymphatic architecture in relation to serial changes in kidney function.

Results: AKI was confirmed by reduced GFR and increased SCr 24 hours following BIRI. Kidney function improved over time, but BIRI mice had consistently reduced GFR relative to sham mice out to 9 months post-surgery. Histologic evaluation of glomerular and tubular damage showed a similar pattern. Expression of lymphangiogenic factors VEGF-C and VEGF-D, and lymphatic marker VEGFR-3 differed between sham and BIRI mice over time. 3DTC and volumetric tissue exploration and analysis of lymphatic architecture revealed BIRI mice consistently exhibited greater Lyve-1 than sham controls.

Conclusions: In the first long-term (9 month) study to evaluate kidney lymphatics following AKI, we show sustained alterations in the spatiotemporal dynamics of kidney lymphatic vasculature. Future studies will aim to elucidate the functional significance of injury-associated LA that persists beyond initial injury.

SA-PO173

Impact of HIF Stabilizer ICA on Nrf2/Keap1 Pathway in Macrophages

Johanna T. Kurzhagen,[1] Max Schauer,[1] Sanjeev Noel,[2] Hamid Rabb,[2] Carsten Willam.[1] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Johns Hopkins University, Baltimore, MD.*

Background: Mice treated with HIF-stabilizer 2-(1-chloro-4-hydroxyisoquinoline-3-carboxamido) acetate (ICA) were protected from ischemia-reperfusion induced AKI, as were mice after treatment with Nrf2-inducer 1-[2-cyano-3-,12-dioxooleana-1,9(11)-dien-28-oyl] imidazole (CDDO-Im). However, the potential interactions of HIF and Nrf2/Keap1 pathways have not been studied in this context.

Methods: Bone marrow was isolated from wildtype (WT) and HIF1α-KO mice and differentiated into bone marrow-derived macrophages (BMDM). Cells were cultured for 5 days before treatment with vehicle, CDDO-Im (50nM), ICA (250μM) or CDDO-Im+ICA (50nM+250μM) for 24 hours. Cells were harvested and mRNA expression of Nrf2- (*Nqo1*) and HIF1α-target genes (*Hmox1, Glut1, Ldha*) using quantitative real time PCR was analyzed. Protein expression of Keap1, Nqo1 and HIF1α was studied by Western blotting. Statistical analyses were performed using one-way ANOVA and Dunnett post hoc test.

Results: In BMDM from WT mice, treatment with CDDO-Im, ICA or the combination of both (CDDO-Im+ICA) resulted in an upregulation of *Nqo1* mRNA expression (Vehicle: 1.3±0.2 vs. CDDO-Im: 4.4±1.3 ($p<0.05$); vs. ICA: 4.1±1.4 ($p>0.05$); vs. CDDO-Im+ICA: 4.4±1.5 ($p<0.05$)) and *Hmox1* (Vehicle: 1.3±0.2 vs. CDDO-Im: 1.7±0.4 ($p>0.05$); vs. ICA: 5.0±1.3 ($p>0.001$); vs. CDDO-Im+ICA: 4.1±0.6 ($p<0.001$)). This effect was not reversed in HIF1α-KO cells for *Nqo1* (Vehicle: 1.4±0.3 vs. CDDO-Im: 5.4±1.5 ($p<0.001$); vs. ICA: 3.9±0.1 ($p<0.05$); vs. CDDO-Im+ICA: 4.8±0.6 ($p<0.01$)). However, HIF1α-target genes *Hmox1, Glut1* and *Ldha* were significantly upregulated by ICA treatment in WT mice, but not by CDDO-Im or vehicle treatment. Western blotting confirmed these results at the protein level with a decrease of Keap1 expression (Vehicle: 1 vs. ICA: 0.7±0.5) and an increase of Nqo1 expression (Vehicle: 1 vs. ICA: 1.3±0.4) in WT and HIF1α-KO mice.

Conclusions: These *in vitro* studies demonstrate an upregulation of the Nrf2-target gene *Nqo1* following HIF-stabilizer, ICA, treatment. However, this effect was Hif1α independent. These results indicate a potential overlap of the two pathways HIF and Nrf2/Keap1 playing important roles in ischemic AKI. I*n vivo* studies in AKI-models are warranted to assess the impact on these dual effects.

Neutrophil Extracellular Traps (NETs) in the Peritoneal Cavity Contribute to Septic AKI (SAKI) via IL-17A Production in a Mouse Cecal Ligation and Puncture (CLP) Sepsis Model

Yoshitaka Naito, Naoki Hayase, Rohit R. Chari, Alef Aragao Carneiro dos Santos, Xuzhen Hu, Peter S. Yuen, Robert A. Star. *National Institutes of Health, Bethesda, MD.*

Background: There are no specific treatments for SAKI. We previously showed that the Toll-like receptor 9 (TLR9) pathway contributes to SAKI: (1) TLR9 is stimulated by mitochondrial DNA endogenously released during sepsis, (2) TLR9 activates interleukin (IL)-17A, and (3) knockout of TLR9 or IL-17A improves sepsis. Mitochondrial DNA was reported to stimulate NET formation via TLR9 in pulmonary graft dysfunction. Knockout of Peptidyl Arginine Deiminase 4 (PAD4), an enzyme essential for NET formation, completely abolished IL-17A accumulation during atherosclerosis in aorta. Treatment with Cl-amidine, a PAD inhibitor, improved survival after CLP. We hypothesized that NET formation in an infectious site could contribute to SAKI via IL-17A production in sepsis.

Methods: PAD4 KO, IL-17A KO and wild type (WT) controls were subjected to CLP. We assessed kidney function and IL-17A levels in peritoneal lavage fluid (PLF) and blood. Leukocyte infiltration in PLF, blood, and kidney were assessed by flow cytometry. NET formation in the cells in PLF was assessed by immunocytochemistry. To further investigate the effect of NETs on SAKI, we collected neutrophils from WT PLF at 18h after CLP and administered them intraperitoneally into PAD4 KO mice immediately after CLP.

Results: PAD4 KO and IL-17A KO attenuated SAKI and PAD4 KO decreased IL-17A levels in PLF and blood at 18h after CLP. CLP upregulated neutrophil infiltration into PLF, blood, and kidney at 18h. IL-17AKO attenuated neutrophil increase in blood and infiltration into kidney, but not in PLF. The cells in PLF at 18h after CLP contained >70% of neutrophils and formed NETs without any stimulation *ex vivo*. Adoptive transfer of WT neutrophils partially counteracted the protective effect of PAD4 KO against SAKI.

Conclusions: We found that PAD4 KO and 17A KO protected against SAKI, and PAD4 KO decreased IL-17A production in plasma and peritoneal cavity. IL-17A promoted neutrophil infiltration into blood and kidney after CLP. Adoptive transfer of WT neutrophils into the peritoneal cavity reversed the beneficial effect of PAD4 KO on CLP-induced SAKI. These findings suggest that NETs in the peritoneal cavity might contribute to a distant organ effect of SAKI via IL-17A production.

Distant Organ Consequences of Renal Ischemia and the Effect of Renal Extracellular Vesicles (Exosomes)

Katherine J. Kelly,[1,2] Jesus H. Dominguez.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Richard L Roudebush VA Medical Center, Indianapolis, IN.*

Background: Acute kidney injury is common, expensive and deadly. Morbidity and mortality remain very high; there is no specific treatment, yet the cause of death is frequently due to failure of extra-renal organs. We and others have demonstrated remote organ dysfunction and systemic inflammation following renal ischemia. We have also shown beneficial effects of extracellular vesicles (EV, exosomes) in models of renal injury. We hypothesized that EV would also decrease remote organ inflammation following renal ischemia. However, the effect of EV in the presence of renal failure could be limited.

Methods: The studies employed a well-characterized model of renal ischemia. Multiple time periods of ischemia were used in order to assess the effect of EV treatment independent of renal function. Both tissue and systemic inflammation as well as cell death were quantified.

Results: As in previous studies, markedly improved renal function and structure were found postischemia in groups treated with renal EV, given 24 hours after renal ischemia when renal failure had been established. Systemic inflammation, quantified as serum interleukin-1, -6 and tumor necrosis factor alpha, was significantly decreased in the treated group, even in the presence of prolonged ischemia. Tissue inflammation varied with the organ examined. The number of neutrophils in the heart decreased in the renal ischemia/EV group (figure 1). Anti-inflammatory interleukin-10 was significantly increased in all organs evaluated in the EV treated group, from 110-138% of sham levels. Evidence of apoptotic cell death was decreased in the heart in the EV treated groups.

Conclusions: Systemic and remote organ manifestations of inflammation after renal ischemia are amenable to treatment. Exosomes derived from renal tubule cells improve multiple abnormalities following renal ischemia.

Analysis of TCRαβ+CD4+CD8+ (Double Positive) T Cells in Normal and Diseased Kidneys in Both Mice and Humans

Sanjeev Noel, Andrea M. Newman-Rivera, Shishir K. Patel, Kyungho Lee, Sepideh Gharaie, Nirmish Singla, Hamid Rabb. *Johns Hopkins University, Baltimore, MD.*

Background: The roles of CD4, CD8 and double negative (DN) T cells are being increasingly recognized in normal and diseased kidneys. However, there is little information about kidney TCRαβ+CD4+CD8+ (double positive, DP) T cells. We therefore studied DPT cells in normal and diseased mouse and human kidneys.

Methods: Flow cytometry and single cell RNA-seq (scRNA-seq) were used to analyze kidney DPT cells in C57BL/6J mice at baseline, after ischemia reperfusion (IR) and cisplatin-induced AKI in comparison to CD4, CD8 and DN T cells. Effects of LCMV (virus) infection as well as gut microbiome were studied. Human kidneys from patients with renal cell carcinoma, with and without underlying ESRD were studied.

Results: DPT cells constituted a minor (0.16±0.03%) population of the total TCRαβ+ cells in normal mouse kidneys. AMNIS imaging flow cytometry confirmed the presence of both CD4 and CD8 co-receptors on individual DPT cells. DPT cells had significant Ki67 (87.4±3.3%) and PD1 (22.7±3.6%) expression. DPT cells had effector (69.6±7.5%) and central (18.3±3.5%) memory phenotype with significant IFNγ, TNFα and IL-17 expression. DPT cells expressed the metabolism-related proteins namely HKII, CPT1a and pS6. Percentage of DPT cells increased after ischemic AKI (0.47±0.11%, P=0.048) and cisplatin-induced AKI (0.40±0.14%, P=0.17) at 24 hrs compared to baseline. LCMV infection elevated kidney DPT cell percentage (0.40±0.08% vs 0.16±0.03%, P£0.01) and induced distinct functional and metabolic changes. Germ-free mice kidney DPT cell proportions and functional properties were comparable to WT mice. scRNA-seq analysis showed increased expression of *Klf2* and *Ccr7* and enrichment of TNFα and oxidative phosphorylation signaling related genes in DPT cells. Human kidneys contained high

DPT cell populations in both adjacent normal (median (IQR) = 0.97(.44-1.49)%) and cancer portion of (median (IQR) = 9.69(0.29-10.40)%) renal cell carcinoma tissue.

Conclusions: TCRαβ+CD4+CD8+ double positive T cells constitute a minor population of both mouse and human kidney T cells, with distinct features in normal and diseased kidney compared to other T cells. Future studies of this T cell population are needed to evaluate their roles in normal and diseased kidney.

Coronin 1α Remodels Inflammatory Microenvironment to Dictate AKI Prognosis

Yuan Gui, Yuanyuan Wang, Jack L. Wang, Dong Zhou. *University of Connecticut School of Medicine, Farmington, CT.*

Background: T-cell-mediated immune response is a key mechanism in AKI onset. Our proteomics data indicate that coronin-1α is markedly induced in the kidneys after AKI, and it is highly expressed in T cells and macrophages to regulate immune cell activation, migration, and phagocytosis. As a protein first noted for its role in modulating actin dynamics and pathogen-host interactions, coronin-1α is spread throughout the cytoplasm and the cell cortex when the cell is resting. Once a pathogen enters the cell, coronin-1α binds to the phagosomal membrane, ensuring the binding and activation of calcineurin, ultimately stopping the fusion of lysosomes with phagosomes. Whether coronin-1α plays a role in AKI is unknown.

Methods: Male and female coronin-1α knockout (Coro1A-/-) mice were used to induce AKI by renal ischemia-reperfusion injury (IRI) at 1, 2, and 3 days (d) or cisplatin at 3d, respectively. A 3-month IRI model was constructed to evaluate AKI long-term outcomes in Coro1A-/- mice. AKI patients samples were employed. Global-/phospho-proteomics and single-nucleus RNA-Seq were utilized.

Results: After AKI, serum creatinine and blood urea nitrogen levels were largely preserved in Coro1A-/- mice compared with wild-type mice. Kidney morphological damages and the expression of the tubular injury markers and chemocytokines were consistently decreased in Coro1A-/- mice. Knockout coronin 1α effectively increased the clearance of apoptotic cells by macrophages. As a consequence, tubular cell proliferation was enhanced in Coro1A-/- mice. In the 3-month IRI model, Coro1A-/- mice exhibited significantly improved kidney function, histology and less fibrotic lesions. Mechanistically, global and phospho-proteomics revealed that inflammation-related signaling pathways were repressed after deleting coronin 1α, and T-lymphokine-activated killer-cell-originated protein kinase (TOPK) was the topmost differentially expressed protein in Coro1A-/- mice diseased kidneys. Single-nucleus RNA-Seq showed higher expression of TOPK in the isolated Coro1A-/- immune cells. *In vivo and ex vivo*, TOPK regulated an inflammatory microenvironment formation, enhancing apoptotic neutrophil clearance and providing favorable conditions to prime tubule repair and regeneration.

Conclusions: Coronin 1α is vital in determining AKI prognosis, and TOPK is a potential immune checkpoint in mitigating AKI.

Glutamine Blockade After Severe AKI Reduces Kidney Fibrosis by T-Cell Metabolic Reprogramming

Kyungho Lee,[1,2] Shishir K. Patel,[1] Sepideh Gharaie,[1] Andrea M. Newman-Rivera,[1] Lois J. Arend,[1] Sanjeev Noel,[1] Barbara S. Slusher,[1] Hamid Rabb.[1] *[1]Johns Hopkins University School of Medicine, Baltimore, MD; [2]Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Metabolism regulates T cell function, and metabolic reprogramming by glutamine antagonism was previously demonstrated to reduce early injury in AKI. Given that T cells also mediate organ repair, we studied the effects of glutamine blockade on AKI repair and fibrosis.

Methods: Severe AKI was induced with 45 min unilateral ischemia in C57B6 mice. The glutamine antagonist, JHU083, was administered starting 24h after reperfusion. Kidneys were collected at 4 weeks and stained with Masson's trichrome. Kidney T cells were studied using spectral flow cytometry and machine learning-based analyses.

Results: Glutamine blockade by JHU083 reduced kidney fibrosis in both cortex (21.2±4.2 vs 4.0±0.6%, *P*=0.001) and medulla (17.3±3.2 vs 9.2±1.4%, *P*=0.038) compared to vehicle treatment (*n*=8 /each group). Unbiased high-dimensional analyses segregated T cells from JHU083-treated and vehicle groups. JHU083 increased double-negative (DN) T cells (CD4- CD8-), which have anti-inflammatory properties (6.3±0.7 vs 23.4±1.6% of αβT cells, *P*<.001, 2.2±0.3 vs 3.0±0.2 ×10^5 cells/g kidney, *P*=0.035) and naïve CD4 T cells (1.1±0.1 vs 12.8±2.2%, *P*<.001, 2.2±0.2 vs 6.3±0.7 ×10^4 cells/g kidney, *P*<.001), whereas effector-memory CD4 T cells decreased (92.8±0.8 vs 75.9±3.5%, *P*<.001, 1.8±0.1 vs 0.4±0.1 ×10^6 cells/g kidney, *P*<.001). JHU083 reduced CD4 T cell activation and proliferation (Ki67 94.2±0.5 vs 76.0±3.3%, *P*<.001; CD69 87.9±0.9 vs 77.2±1.8%, *P*<.001) as well as CD8 T cells (Ki67 93.5±0.5 vs 80.8±2.6%, *P*<.001; CD69 97.5±0.2 vs 94.2±0.6%, *P*<.001). JHU083 downregulated hexokinase II (normalized MFI, CD4 0.49±0.04 vs 0.18±0.04, *P*<.001; CD8 0.42±0.03 vs 0.27±0.04, *P*=.021), CPT1a (CD4 0.74±0.07 vs 0.13±0.03, *P*<.001; CD8 0.72±0.08 vs 0.27±0.04, *P*<.001), VDAC1 (CD4 0.73±0.08 vs 0.13±0.05, *P*<.001; CD8 0.77±0.07 vs 0.23±0.05, *P*<.001), and mTOR expression (CD4 0.58±0.04 vs 0.30±0.02 *P*<.001; CD8 0.29±0.03 vs 0.09±0.02, *P*<.001), but upregulated Tomm20 (CD4 0.16±0.04 vs 0.47±0.03, *P*<.001; CD8 0.28±0.05 vs 0.83±0.04, *P*<.001).

Conclusions: Reconstitution of T cell metabolism by glutamine blockade *after* severe AKI reduced kidney fibrosis, increased kidney DN T cells and decreased effector CD4 T cell activation. This is a novel approach to potentially mitigating AKI to CKD, as well as other causes of CKD progression.

β2-Integrins Are Indispensable for HIF1α Activation in Neutrophils by Controlling Translational Initiation Factor Phosphorylation

Lovis Kling,[1,2] Claudia Eulenberg-Gustavus,[2] Uwe Jerke,[2] Anthony Rousselle,[2] Andranik Ivanov,[3] Kai-Uwe Eckardt,[1] Adrian Schreiber,[1,2] Ralph Kettritz.[1,2] *[1]Department of Nephrology and Medical Intensive Care, Charité – Universitätsmedizin Berlin, Berlin, Germany; [2]Experimental and Clinical Research Center, Charité – Universitätsmedizin Berlin and Max Delbrück Center for Molecular Medicine in the Helmholtz Association, Berlin, Germany; [3]Berlin Institute of Health at Charité – Universitätsmedizin Berlin, Core Unit Bioinformatics, Berlin, Germany.*

Background: In several inflammatory kidney diseases, circulating blood neutrophils migrate to sites with high cytokine but low oxygen concentrations. Migrating neutrophils interact with extracellular matrix proteins via β_2-integrins. We hypothesized that β_2-integrins control hypoxia-inducible factor 1α (HIF1α) activation under basal and inflammatory conditions.

Methods: HIF1α in human neutrophils was studied by immunoblotting, qPCR, bulk mRNA sequencing. Neutrophil suspension was achieved on polyhema, and adhesion on fibronectin (FN). Prolyl hydroxylases (PH) were inhibited with Roxadustat (ROX) and normobaric hypoxia (1% O_2). β_2-integrin signaling was analyzed by blocking and activating antibodies.

Results: We observed HIF1α protein in ROX-, but not GMCSF-treated neutrophils after 4h with a 3-fold synergistic effect by combined GMCSF/ROX treatment. Increased HIF1α protein was observed in neutrophils cultured on FN but not under stringent suspension conditions on polyhema. Importantly, HIF1α protein in combined ROX/GMCSF-treated neutrophils on FN was strongly reduced by blocking β_2-integrins and, conversely, induced by activating β_2-integrin antibodies on polyhema. The synergistic ROX/GMCSF effect as well as the blocking β_2-integrin effect for HIF1α protein were recapitulated under hypoxic conditions. Mechanistically, the HIF1α mRNA increase by GMCSF was necessary but not sufficient to explain the adhesion-dependent HIF1α protein induction. Importantly, GMCSF increased serine phosphorylation of eIF4E and 4EBP1 HIF1α translation initiation factors in neutrophils on FN in an β_2-integrin dependent manner. Synergistic HIF1α protein induction was demonstrated in neutrophils that transmigrated through FN towards GMCSF and ROX in vitro. Neutrophil bulk mRNA sequencing revealed HIF1α-dependent enrichment of cytoskeletal gene sets under inflammatory conditions. Finally, PH inhibition by ROX or hypoxia enhanced cytoskeleton-dependent neutrophil adhesion.

Conclusions: β_2-integrin engagement restricts HIF1α activation to neutrophils that emigrate from the blood to inflammatory sites under pharmacological or hypoxic conditions.

Clonal Hematopoiesis of Indeterminate Potential Associates with Severe AKI

Jianchun Chen,[1] Caitlyn Vlasschaert,[2] Cassianne Robinson-Cohen,[1] Bryan R. Kestenbaum,[3] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Queen University, Kingston, ON, Canada; [3]University of Washington, Seattle, WA.*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is the clonal expansion of hematopoietic stem cells due to somatic mutations like TET2 gene mutation, without evidence of hematologic malignancy or cytopenia. CHIP is associated with a pro-inflammatory state. The role of inflammation in acute kidney injury (AKI) among individuals with CHIP remains unclear.

Methods: Bone marrow cells (BMC) were collected from recipient mice (CD45.1 isotype), Tet2-deficient and control mice (CD45.2 isotype). Lethally irradiated male recipient mice underwent retroorbital injection of 5×10^6 BMC, consisting of 80% recipient cells and 20% *Tet2*-deficient (*Tet2*$^{-/-}$) or control (*Tet2*$^{+/+}$) cells. Flow cytometry confirmed successful engraftment and clonal expansion of *Tet2*-deficient cells, and then the chimeric mice underwent unilateral kidney vascular clamping with contralateral nephrectomy (Unx-IRI). Renal function was assessed by BUN and creatinine levels, and kidney macrophages were isolated for analysis.

Results: The chimeric mice with *Tet2*$^{-/-}$ BMC developed CHIP, indicated by flow cytometry of peripheral blood cells. *Tet2*$^{-/-}$ mice exhibited increased CD45.2 cells in the intrinsic myeloid kidney cell population. Following Unx-IRI, *Tet2*$^{-/-}$ mice had more severe kidney injury compared to control mice. Higher levels of tubule injury markers (KIM-1, NGAL) and more severe tubule injury were observed in *Tet2*$^{-/-}$ mice at 8 days after Unx-IRI. The kidneys of *Tet2*$^{-/-}$ mice displayed elevated expression of proinflammatory cytokines (Tnf, Il6, Il1b), chemokines (Ccl2, Ccl3), profibrotic genes (Tgfb, Ctgf, Acta2), and extracellular matrix-associated genes (Col1a1, Col3a1, Fn, Vim) compared to *Tet2*$^{+/+}$ mice. Macrophages isolated from the kidneys of *Tet2*$^{-/-}$ mice exhibited increased expression of proinflammatory cytokines both before and after injury. Additionally, increased co-expression of NLRP3 inflammasome and IL-1β with CD68-positive macrophages was observed in kidneys only in the CD45.2 macrophages and not in the CD45.1 macrophages.

Conclusions: This study demonstrates that CHIP is associated with an increased risk of severe AKI in this mouse model, potentially caused by enhanced infiltration of inflammatory cells into the kidneys and subsequent excessive production of proinflammatory cytokines and chemokines.

AKI-Activated CCR2+ Classical Monocytes Drive Remote Lung Neutrophilic Capillaritis with Hypoxemia due to Ventilation-Perfusion Deficits and Endothelial Leakage

Yohei Komaru, Liang Ning, Anusha Suresh, Carine Lama, Eirini Kefalogianni, Andreas Herrlich. *Washington University in St Louis, St Louis, MO.*

Background: Acute respiratory distress syndrome and acute kidney injury frequently occur together in multiorgan failure patients and portend high mortality due to a lack of mechanistic understanding and therapeutic options. Pre-clinical animal models of this clinical kidney-lung interaction reveal that AKI induces remote lung inflammation with accumulation of neutrophils and interstitial macrophages in the lung, interstitial edema, and hypoxemia. How this remote lung inflammation is established and causes hypoxemia lacks understanding.

Methods: Flow-cytometry was used to determine the amount of classical/non-classical monocytes and of lung intravascular, marginated or extravasated neutrophils in the lung 24 hours after bilateral renal ischemia-reperfusion injury (IRI). Single-cell RNA sequencing (scRNAseq) analysis was used to study the remotely injured lung after AKI. In-vivo two-photon imaging was used to image lung neutrophils and monocytes after AKI. In vitro, permeability assays using primary lung endothelial cell monolayers were employed.

Results: After AKI, classical monocytes and neutrophils increased in the lung. Lung neutrophils accumulated in lung capillaries, impeded blood flow, and did not extravasate, unlike in LPS-induced direct lung injury, suggesting ventilation-perfusion deficits as important cause of the observed hypoxemia. scRNAseq analysis revealed that monocytes enter the lung and transition into interstitial macrophages. Depletion of $CCR2^{+}$ classical monocytes, but not of non-classical monocytes, blocked lung interstitial macrophage and neutrophil accumulation after AKI. In vitro, primary lung endothelial cell permeability in the presence of AKI serum was strongly enhanced when neutrophils from AKI mice, but not sham mice, were added.

Conclusions: $CCR2^{+}$ classical monocytes are required for neutrophil recruitment in remote lung inflammation after AKI and give rise to lung interstitial macrophages. In contrast to direct lung injury, AKI-induced remote lung inflammation after AKI shows massive neutrophilic capillaritis with neutrophil plugging of vessels that impedes capillary perfusion and thus oxygen uptake. This oxygenation deficit is further negatively affected by increased endothelial permeability.

SA-PO182

Plasma Sialic Acid as a Marker for Kidney Function Decline in Preclinical Models of AKI

Manjula Darshi,[1] Rong Meng,[2] Eugene Myshkin,[1] Raul Camacho,[2] Fuyong Du,[2] Li-Jun Ma,[2] George Ho,[2] Jianying Liu,[2] Qiu Li,[2] Kamal A. Albarazanji,[2] Jeramie Watrous,[3] Tao Long,[3] Mo Jain,[3] Andrea R. Nawrocki,[2] Dermot F. Reilly.[1] *[1]Janssen Research and Development LLC, Boston, MA; [2]Janssen Research and Development LLC, Spring House, PA; [3]Sapient Bioanalytics, San Diego, CA.*

Background: Acute kidney injury (AKI) occurs in approximately 10–15% of hospitalized patients leading to high degree of mortality in clinic and is a major risk factor for CKD development and progression. Novel biomarkers could improve diagnosis and help define molecular pathways associated with AKI.

Methods: Untargeted metabolomics was performed on plasma samples from rat and mouse AKI models induced by ischemia reperfusion injury (IRI) using Rapidfire high throughput LC-MS technology. Samples from lean Sprague Dawley (SD) rats, and lean C57Bl/6J mice were collected 24 hours after IRI surgery using bilateral clamping. We also developed an obese and diabetic model of IRI, uninephrectomized (Unx) obese ZSF1 rats which are more susceptible to AKI compared to lean ZSF1 rats. AKI was confirmed by increased plasma Creatinine (pCr), increased kidney injury markers (KIM-1 and NGAL) and a decline in Glomerular Filtration Rate. Plasma sialic acids and creatinine levels were validated by targeted LC-MS/MS methods. Sialic acids were also measured in a Cecal slurry (CS)-induced Sepsis model of AKI in mice.

Results: A total of 20,472 spectral features were extracted from untargeted metabolomics and 123 of them were assigned putative annotations based on m/z and RT with the library of standards. Principal component analysis of the annotated metabolites showed distinct separation between AKI and control groups in all 3 models of IRI. Several gut-microbiome derived metabolites, uremic toxins and sialic acids were significantly increased across all models of AKI and correlated highly with plasma creatinine. Validation of free sialic acid using targeted LC-MS confirmed that plasma sialic acids are significantly increased in AKI and strongly correlated positively with plasma creatinine (Pearson r^2: 0.95 in CS, 0.91 in SD rat IRI, 0.77 in mouse IRI, and 0.60 in ZSF IRI, $p<0.0001$) in both IRI and sepsis models of AKI.

Conclusions: Increases in circulating free sialic acid, consistently observed in preclinical models for IRI or sepsis induced AKI, may be due to impaired filtration and could serve as a surrogate marker for AKI diagnosis

SA-PO183

Myeloid Cell Deletion of the Cationic Channel TRPM2, a Target of Uromodulin Inhibition, Is Protective in Murine Sepsis

Kaice A. LaFavers, Angela R. Sabo, George Rhodes, Tarek M. El-Achkar. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Kidney-derived uromodulin is protective in a mouse model of sepsis, where it promotes proper myeloid cell function in the response to infection. One of the ion channel targets of uromodulin inhibition, cationic channel TRPM2, is expressed on myeloid cells and plays a role in their function. We therefore hypothesized that uromodulin modulates myeloid cell function in sepsis via TRPM2 and that its loss on myeloid cells would be protective in this setting.

Methods: A myeloid specific knockout of TRPM2 was generated by crossing a $TRPM2^{fl/fl}$ mouse with a myeloid cell specific Cre recombinase mouse ($LysM^{Cre}$). The resulting mice ($TRPM2^{fl/fl}$ $LysM^{Cre/+}$) and their littermate controls ($TRPM2^{fl/fl}$ $LysM^{+/+}$) were utilized in the cecal ligation and puncture model of sepsis. Animals were euthanized at various time points post-surgery to assess survival or to collect tissue and serum for imaging and biochemical studies. Immune cell distribution within the kidney will be measured using the Akoya Phenocycler system and immune cell signaling within the kidney is being analyzed by single-cell RNA-sequencing on the 10X Genomics platform.

Results: $TRPM2^{fl/fl}$ $LysM^{Cre/+}$ mice have increased survival and decreased sepsis severity at 48 hours post-surgery compared to $TRPM2^{fl/fl}$ $LysM^{+/+}$ controls. This is despite similar bacterial burden within the peritoneal organs of both genotypes at 24 hours post-surgery. To determine the potential mechanism for increased survival in $TRPM2^{fl/fl}$ $LysM^{Cre/+}$ animals, we harvested kidneys at 10 hours post-surgery and isolated immune cells for single cell RNA-sequencing. We found a reduction in transcriptional markers of immune defense in many cell types of $TRPM2^{fl/fl}$ $LysM^{Cre/+}$ mice. Markers of lymphocyte and natural kill cell mediated immunity were decreased despite the lack of expression of LysM in adaptive and innate lymphoid cells. This suggests that loss of TRPM2 on myeloid cell cells is blocking crosstalk between cells within the immune system to promote immune tolerance.

Conclusions: Myeloid cell knockout of TRPM2 is protective in a mouse model of sepsis. This is consistent with the previously described protective role for uromodulin in sepsis, as uromodulin is an inhibitor of TRPM2. This protection could be due to an increase in immune tolerance and prevention of death from septic shock.

Integrin β1-Rich Extracellular Vesicles of Kidney Tissue Recruit Fn1+ Macrophages to Aggravate Ischaemia-Reperfusion-Induced Inflammation

Wenjuan Wang,[1,2] Quan Hong,[2] Guangyan Cai.[2,1] *[1]Nankai University School of Medicine, Tianjin, China; [2]First Medical Center of Chinese PLA General Hospital Nephrology Institute of the Chinese People's Liberation Army, Beijing, China.*

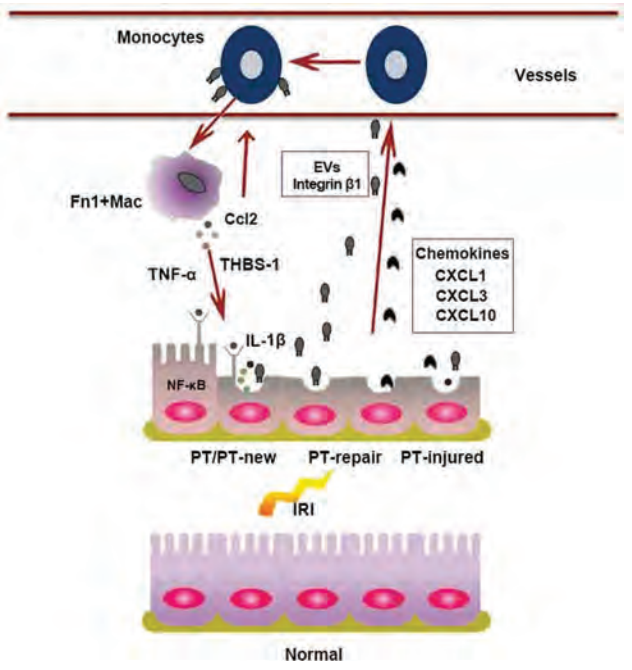
Background: Ischaemia-reperfusion injury (IRI)-induced acute kidney injury is accompanied by mononuclear phagocyte/macrophagocyte (MP) invasion and inflammation. However, the exact kidney-derived extracellular vesicle (EV)-carried proteins that mediate intercellular crosstalk remain elusive.

Methods: Multiomics analysis combining scRNA-seq data and kidney EV protein profiling was used to explore the transcriptomic diversity of proximal tubular cells (PTs) and MPs and differential protein expression of kidney EVs to elucidate how the PT-MP interaction amplifies local inflammation. Transmission electron microscopy, nanoparticle tracking analysis, co-immunoprecipitation, molecular docking, co-culture experiments, siRNA transfection technology, flow cytometry, RT-qPCR, western blotting, and immunohistochemistry were used for verification of functional experiments.

Results: Targeted adhesion and migration of various MPs were caused by secretion of multiple chemokines as well as the integrin β1-rich EVs by ischemic damaged PTs after IRI. These recruited MPs, especially Fn1+ Macs, amplified the surviving PTs' inflammatory response by secreting inflammatory factor TNF-α, Ccl2, and thrombospondin 1 (THBS-1), which could interact with integrin β1 to promote more MP adhesion as well as interact with CD36 to further promote the secretion of IL-1β from surviving PTs. However, blocking EVs with GW4869 maintained a moderate inflammatory response by reducing MP infiltration, promoting repair.

Conclusions: Our findings establish the molecular bases by which chemokines and kidney EVs mediate PT-MP crosstalk in early IRI and provide new insights into systematic intercellular communication.

Funding: Government Support - Non-U.S.



Summary of renal inflammation especially mediated by the intercellular crosstalk among PTs and MPs following IRI-AKI.

Uromodulin Alleviates Interstitial Fibrosis in AKI to CKD Transition in a Cisplatin-Treated Rat Model via the Inhibition of EGFR Pathway

Zheyu Xing, Yuqing Chen. *Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: Severe or recurrent acute kidney injury (AKI) episode is liable to cause the occurrence and acceleration of chronic kidney disease (CKD). Uromodulin has been reported as a protective factor for AKI and CKD. Here, we explored its role in the AKI-CKD transition.

Methods: Wild-type SD rats and *UMOD*$^{-/-}$ rats were given cisplatin at 3.2mg/kg for 4 times every 2 weeks to induce the transition of AKI-CKD. Serum, urine and kidneys were collected to assay the protect effect of uromodulin. Western blots, IHC and qPCR were used to investigate mechanisms. HK-2 cell culture in cisplatin was treated with or without uromodulin for further validation.

Results: *UMOD*$^{-/-}$ rats didn't develop spontaneous kidney injury or fibrosis. However, uromodulin deficiency accelerated the progression of AKI to CKD in our rat model, as evidenced by more serious kidney insufficiency and fibrosis. The levels of SCR, BUN, urinary KIM1 and NGAL were significantly increased in cisplatin-treated *UMOD*$^{-/-}$ rats compared with *UMOD*$^{+/+}$ rats. PAS and Sirius staining showed heavier renal lesion and fibrosis in *UMOD*$^{-/-}$ rats. During the transition of AKI-CKD, *UMOD*$^{-/-}$ rats showed elevated levels of fibrosis markers and over-activation of EGFR/ERK, according to Western blot and IHC. The native uromodulin supplement to cisplatin-stimulated HK-2 cells decreased the expressions of fibroblast markers and down-regulated the EGFR/EKR.

Conclusions: Uromodulin deficiency may exacerbate the progression of AKI-CKD transition induced by cisplatin via the overactivation of EGFR.

Kidney Damage Associated with Liver Fibrosis Is Differentially Orchestrated by YB-1 Depending on Its Cellular Origin

Xiyang Liu,[1] Daniela Hermert,[1] Anna Leitz,[1] Yingying Gao,[1] Jialin Wang,[2] Jürgen Floege,[1] Tammo Ostendorf,[1] Ute Raffetseder.[1] [1]*Department of Nephrology and Clinical Immunology, University Hospital RWTH-Aachen, Aachen, Germany;* [2]*Department of Nephrology, Zhongshan Hospital, Fudan University, Shanghai, China.*

Background: Acute kidney injury is a common and life-threatening complication of liver disease. In a previous study, we showed that the Y-box-binding protein (YB)-1 modulates the liver-kidney crosstalk. In a model of liver fibrosis (biliary duct ligation; BDL), mice with half-maximal *Ybx1* expression (*Ybx1*$^{+/-}$) exhibited significantly reduced liver damage, but the resulting kidney damage was increased. The purpose of the present study was to clarify the influence of organ/cell specific YB-1 expression on liver and kidney damage after induction of liver fibrosis.

Methods: For this purpose, BDL was performed as a liver fibrosis model in conditional *Ybx1* knockout animals with specific depletion in hepatocytes (*Ybx1*^{fl}*xAlfp*^{cre}), in myeloid immune cells (*Ybx1*^{fl}*xLysM*^{cre}) and in renal tubular cells (*Ybx1*^{fl}*xPax8*^{cre}).

Results: We found that targeting *Ybx1* in hepatocytes reduced liver fibrosis and kidney damage (e.g. tubular damage, *Ngal* mRNA expression)/fibrosis (e.g. collagen1A staining). Compared to WT animals, BDL mice with *Ybx1*-specific knockout in myeloid immune cells showed significantly reduced serum levels of liver enzymes but increased evidence of kidney damage and fibrosis. Finally, decreased expression of YB-1 in kidney tubular cells resulted in increased expression of fibrosis markers in the liver.

Conclusions: In summary, cell-specific YB-1 expression has a major influence on the respective organ damage in the context of the liver-kidney crosstalk. In addition, we document that renal YB-1 expression also has implications for liver fibrosis. Furthermore, the previously observed reduced liver damage with increased kidney damage occurring in the *Ybx1*$^{+/-}$ animals is best mimicked by a specific YB-1 reduction in immune cells.

Effects of Sodium-Glucose Cotransporter-2 Inhibitor (SGLT2i) on Renal Vascular Reactivity in Cirrhotic Rats

Chiao-Lin Chuang,[1,2] Hui-Chun Huang.[1,2] [1]*Taipei Veterans General Hospital, Taipei, Taiwan;* [2]*National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.*

Background: Variceal bleeding-associated hypotension may activate endogenous vasoconstrictors, leading to renal vasoconstriction and subsequent acute kidney injury (AKI) in cirrhotic patients. Sodium-glucose cotransporters-2 inhibitors (SGLT2i) are a new class of oral anti-hyperglycemic drugs with pleiotropic effects. In addition to the reductions in blood pressure and body weight, SGLT2i showed improvements in renal outcomes. The possible mechanisms included inhibition of inflammation and oxidative stress and a reduction in glomerular hyperfiltration via afferent arteriolar vasoconstriction. Cirrhotic kidney has the same picture of renal hyperfiltration with diabetic kidney. Therefore, the renoprotective role of SGLT2i in cirrhotic kidneys is worth evaluating.

Methods: Liver cirrhosis was induced in S-D rats with common bile duct ligation (CBDL). Rats received oral distill water or SGLT2i (Empagliflozin, 30 mg/kg/day) for 28 days. On the 28th day, AKI was induced by ischemic-reperfusion injury (IRI). On the 29th day, the following was investigated: (a) hemodynamic parameters, (b) serum glucose, BUN, Cr, ALT, AST, IL-1, IL-6, TNF-α, (d) in-situ kidney perfusion, (e) oxidative stress and western analysis of kidneys.

Results: SGLT2i treatment showed no significant change in serum parameters, but lower TNF-α ($p < 0.05$) in CBDL rats. Renal IRI enhanced renal vascular reactivity to endothelin-1 (ET-1) and led to significant increases in serum BUN and Cr (all $p < 0.05$), suggesting AKI. Compared with DW-treated rats, SGLT2i treatment abrogated IRI-related renal vascular hyper-reactivity to ET-1 (Fig) and showed lower BUN and Cr following IRI (all $p < 0.05$). The exact mechanisms of renal protection remained under analysis.

Conclusions: In conclusion, our results demonstrated beneficial effects of SGLT2i in kidneys of CBDL rats, including reduced inflammation, abrogated IRI-related renal vascular hyper-reactivity to vasoconstrictor, and protection from AKI. Therefore, SGLT2i might be recommended for cirrhotic patients.

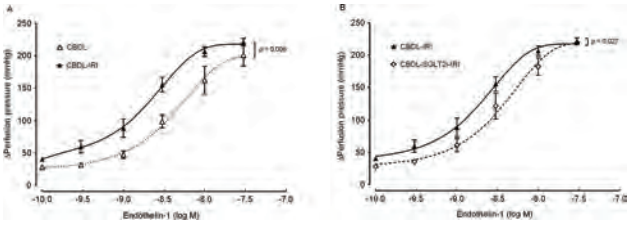

Fig. IRI increased renal vascular response to ET-1 in CBDL rats (A). SGLT2i treatment abrogated renal vascular hyper-reactivity to ET-1 following IRI (B).

SA-PO188

Transient Inhibition of the Sodium-Glucose Cotransporter 2 After Ischemia/Reperfusion Injury Ameliorates CKD in Rats

Miguel A. Martinez-Rojas,[1,2] Hiram Balcázar,[2] Isaac González Soria,[3,2] Jesus M. Gonzalez Rivera,[2] Mauricio E. Rodríguez Vergara,[2] Laura A. Velázquez Villegas,[2] Rosalba Pérez-Villalva,[1] Norma Bobadilla.[1,2]
[1]Universidad Nacional Autonoma de Mexico Instituto de Investigaciones Biomedicas, Ciudad de Mexico, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [3]Universidad Nacional Autonoma de Mexico Facultad de Medicina, Ciudad de Mexico, Mexico.

Background: A severe episode of Acute Kidney Injury (AKI) can lead to Chronic Kidney Disease (CKD). The sodium-glucose cotransporter 2 (SGLT2) inhibitor, dapagliflozin, has exhibited nephroprotective actions in CKD, but the specific mechanisms remain elusive. We evaluated if a transient administration of Dapa after ischemia/reperfusion injury (IRI) prevents CKD.

Methods: Forty-one male Wistar rats (300-350 g) were randomized in: Sham surgery, IRI for 30 min (IR), and IRI + dapagliflozin (IR+Dapa). Daily treatment with Dapa was initiated 24 h after IRI and maintained only 10 days. After this period, one half of rats was euthanized for kidney functional, histological, and molecular analyses. The other half was followed for 5 months. Proteinuria was determined monthly; kidney function and fibrosis were evaluated at the 5th month. Differences between groups were analyzed through ANOVA with a significance level of $p<0.05$.

Results: Ten days after IRI, rats receiving Dapa exhibited an early restoration of renal blood flow (RBF) with a notorious reduction in RVR and a recovered Creatinine Clearance (CrCl) compared to the IR group alone. Importantly, IR rats persisted with detrimental changes in mitochondrial homeostasis indicated by a significant decrease in Sirtuin-3, a low Mitofusin/Drp1 ratio, and an abnormal mitophagy process with PINK1 up-regulation and reduced Parkin. There was a reduction in OXPHOS Complex I and less total NAD/NADH levels in this group. Interestingly, all these changes were prevented with SGLT2 inhibition. We also demonstrated that this short treatment prevented CKD after five months as indicated by proteinuria, CrCl, and fibrosis.

Conclusions: A short treatment with dapagliflozin after IRI is enough to prevent maladaptive repair and CKD in rats. This renoprotective effect seems to be mediated by an improved renal circulation and restoration of mitochondrial homeostasis. These findings highlight the relevance of the initial days of reperfusion, indicating that maladaptive repair can be modulated after severe AKI to prevent the development of long-term consequences.

Empagliflozin Protects Kidney by Preventing Autophagic Stagnation via Reducing Megalin-Mediated Reabsorption of Lipotoxic Albumin

Sho Matsui,[1] Takeshi Yamamoto,[1] Yoshitsugu Takabatake,[1] Atsushi Takahashi,[1] Tomoko Namba,[1] Jun Matsuda,[1] Satoshi Minami,[1] Shinsuke Sakai,[1] Hiroaki Yonishi,[1] Jun Nakamura,[1] Shihomi Maeda,[1] Hideaki Kawai,[1] Motoko Yanagita,[2] Yoshitaka Isaka.[1] *[1]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan; [2]Kyoto Daigaku Daigakuin Igaku Kenkyuka Igakubu, Kyoto, Japan.*

Background: Evidence from clinical studies such as DAPA-CKD and EMPA-KIDNEY trials suggests that sodium glucose cotransporter 2 (SGLT2) inhibitors confer renal protection regardless of the presence of diabetes, although the underlying mechanisms remain unclear.

Methods: We investigated the following aspects: 1) the impact of empagliflozin (EMPA) on lipotoxicity in kidney proximal tubular epithelial cells (PTECs) in both wildtype and inducible megalin knockout mice, 2) the effect of EMPA on albumin reabsorption in PTECs, 3) the influence of EMPA on autophagic activity, and 4) the effect of EMPA on ischemia-reperfusion injury (IRI) when autophagy and/or megalin are blocked.

Results: High-fat diet (HFD) induced the formation of cytosolic vacuoles (enlarged lysosomes containing phospholipids) in PTECs, which was alleviated by EMPA. Since vacuolar formation was rarely observed in HFD-fed inducible megalin knockout mice, we assessed megalin-mediated fluorescent albumin reabsorption in PTECs. HFD led to hyperreabsorption of albumin in both S1-2 and S3 segments, which was restored by EMPA. Subsequently, we measured plasma levels of 24 fractions of free fatty acids bound to albumin. EMPA improved the imbalanced lipoquality induced by HFD. Furthermore, employing inducible Atg5 knockout mice and GFP-MAP1LC3 transgenic mice, we found that EMPA mitigated the HFD-induced increase in autophagic demand and alleviated the stagnation of autophagy. Finally, we aimed to determine whether the reduced reabsorption of lipotoxic albumin and restoration of autophagic flux by EMPA improve the HFD-induced susceptibility to ischemic stress. The renoprotective effect of empagliflozin against IRI-induced acute kidney injury was attenuated when megalin and/or autophagy were blocked.

Conclusions: The reduction of toxic albumin reabsorption and prevention of autophagic stagnation in PTECs may be crucial for SGLT2 inhibition-mediated renoprotection.

Gut Dysbiosis and Altered Gut-Derived Metabolites in Patients with Active Lupus Nephritis

Tak Mao D. Chan,[1] Sheng Xu,[2] Jing Yu,[1] Joshua W. Ho,[2] Susan Yung.[1]
[1]Department of Medicine, School of Clinical Medicine, The University of Hong Kong, Hong Kong, Hong Kong; [2]School of Biomedical Sciences, The University of Hong Kong, Hong Kong, Hong Kong.

Background: Lupus nephritis (LN) is an important cause of acute kidney injury and chronic kidney disease. Emerging evidence suggests that gut dysbiosis may contribute to LN pathogenesis. We investigated gut dysbiosis and changes in gut-derived metabolites in LN patients.

Methods: Fecal samples were collected from 69 patients with kidney biopsy-proven Class III/IV±V LN (16 patients with active LN and 53 patients in remission). Age- and sex-matched samples from healthy subjects (n=15), patients with non-renal lupus (n=27), and patients with non-lupus chronic kidney disease (n=37) served as controls. Bacterial DNA was isolated from fecal samples and submitted to Novogene for shotgun metagenomic sequencing at an average depth of 41 million paired end reads with a read length of 150bp. Sequenced reads were processed to remove adapter regions and low-quality bases, and Phix and human contamination were filtered. High-quality reads were taxonomically profiled at different taxonomic levels using MetaPhlAn4. Microbial pathways and predicted metabolite abundance was assessed using HUMAnN3.6 pipeline and MelonnPan respectively.

Results: Three samples (1 LN and 2 non-renal lupus) failed quality control and were removed from analysis. Alpha and beta diversity were comparable between LN patients and controls. Active LN was accompanied by an increase in the abundance of *Megamonas funiformis* and *Ruminococcus torques* and a decrease in *Candidatus Avimicrobium caecorum* and *Alistipes shahii* compared to LN patients in remission and control groups ($P<0.05$, for all). Microbial pathways were similar in patients with active LN and remission, whereas fatty acid β-oxidation, hexitol degradation, ornithine degradation, and NAD salvage pathways were enriched in LN patients compared to healthy subjects. Analysis of microbiota-derived metabolites showed increased abundance of ADMA and chenodeoxycholate, and downregulation of pyridoxamine and nicotinic acid in patients with active LN compared to remission ($P<0.05$, for all).

Conclusions: LN is associated with gut dysbiosis and altered metabolite abundance. Whether these changes are of pathogenic significance remains to be established.

ACE2 Overexpression Mediates Spatial Distribution of Pathologic Features in AKI

Jacqueline M. Emathinger,[1] Joshua A. Robertson,[1] Jonathan W. Nelson,[1] Vanderlene L. Kung,[1] Michael Hutchens,[2] Susan B. Gurley.[1] *[1]Oregon Health & Science University School of Medicine, Portland, OR; [2]Portland VA Medical Center, Portland, OR.*

Background: Acute kidney injury (AKI) is a widespread health problem often caused by ischemia. Angiotensin II (AngII) drives pathologic changes in AKI. Angiotensin converting enzyme 2 (ACE2) metabolizes AngII and extinguishes its effects. While several studies have examined the role ACE2 plays in chronic kidney disease and hypertension, less is known about ACE2 in AKI. We hypothesize that ACE2 overexpression promotes recovery after AKI via AngII metabolism.

Methods: We use K18-hACE2 mice which overexpress human ACE2 in epithelial cells. Unilateral renal ischemia reperfusion (IRI, 25-min ischemia) with contralateral nephrectomy was performed on age-matched K18-hACE2 and wildtype (WT) littermates. Blood urea nitrogen (BUN), plasma creatinine (Cr), and histology was performed.

Results: Human hACE2 mRNA expression is increased in K18-hACE2 kidneys (53.5 ± 1.3-fold over WT mice; $p<0.05$, **1A**). At baseline, there was no significant difference in kidney AngII content in K18-hACE2 mice (428.4 ± 307.0 fmol/g vs 246.6 ± 122.8 fmol/g; **1B**). 24 hours after IRI, renal function (BUN and plasma Cr) was similarly decreased in WT and K18-hACE2 mice. Quantification of tubular injury revealed less brush border loss in the corticomedullary junction (CMJ) of K18-hACE2 kidneys (13.4 ± 11.6 in WT vs 4.3 ± 4.7, $p<0.01$, **2A, B**). In the cortex, overexpression of hACE2 caused lower levels of necrosis (23.2 ± 14.0 vs 10.9 ± 11.1 in WT, $p<0.01$, **2C**).

Conclusions: We show that K18-hACE2 mice are a valuable tool for understanding ACE2 in the context of kidney injury. Reduced brush border injury scores in CMJ, and lower cortical necrosis in K18-hACE2 mice following IRI suggests that ACE2 mediates regional differences in pathologic injury. Unchanged AngII at baseline may suggest that renal ACE2 mediates acute changes in AngII in association with control of spatial injury pattern. Examination of the injury and repair processes will elucidate the impact of ACE2 overexpression on injury mechanisms.

Loss of Tubular Angiotensin-Converting Enzyme 2 (ACE2) into the Urine with ACE2 Casts: A Key Pathophysiologic and Diagnostic Alteration in AKI?

Cosimo L. Cianfarini, Mina Shirazi, Jan Wysocki, Jiao-Jing Wang, Minghao Ye, Zheng J. Zhang, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: In acute kidney injury (AKI) the renin angiotensin system (RAS) is overactive. ACE2 is a tissue RAS enzyme that is highly expressed in the apical tubular border in kidney cortex and corticomedullary region where it controls Angiotensin II degradation to form Angiotensin 1-7. We hypothesize that in AKI there is a loss of apical tubular ACE2 that amplifies RAS overactivity and results in worsening of proximal tubular injury.

Methods: We used the mouse model of AKI by ischemia-reperfusion-injury (IRI) in male C57BL/6 mice by clamping of the left renal pedicle for 30min followed by removal of the right kidney (unilateral IRI). Kidneys were harvested 48hrs after the surgery and stained for ACE2 by immunohistochemistry (IHC) and immunofluorescence (IF). Kidney ACE2 protein was assessed in membrane protein lysates and enzymatic activity measured using a fluorogenic substrate. ACE2 protein by western blot and enzymatic activity were assessed in mouse urine collected 48hrs post IRI.

Results: IHC and IF revealed a striking maldistribution of tubular ACE2 (Fig. A, B) compared to healthy control kidneys including spillage into the tubular lumen and presence of ACE2 positive luminal casts in the medulla (C) where ACE2 is usually absent. ACE2 protein in membrane lysates and enzymatic activity were reduced (37±3.5 vs. 100±5.6 ACE2/ß-Actin, p=0.0004 and 96±14 vs. 152±5.6 RFU/µg total protein/h, p=0.006). In the urine the full-length membrane bound ACE2 protein was increased (2606±1764 vs. 100±47 ACE2/µl urine, p=0.04) and activity in the urine sediment was increased as well (7.7±1.9 vs. 2±0.2 RFU/µg Cr, p=0.01). Moreover, ACE2 containing casts were recovered in the urine sediment.

Conclusions: In a mouse model of AKI caused by IRI there is a marked loss of ACE2 from the apical tubular border with deposition of ACE2 positive material in the medulla and increased urinary excretion of the full length membrane-bound ACE2. The deficiency of apical ACE2 not only results in the loss of its kidney protective effects but may also serve as a diagnostic marker of AKI.

Urinary mRNA Profile in Recipients of Allogeneic Hematopoietic Cell Transplant with AKI

Victoria Gutgarts,[1,2] Insara Jaffer Sathick,[1,2] Carol Y. Li,[2] Belen A. Nunez,[1] Justine Jorgensen,[1] Jessica M. Abukoush Szczerba,[1] Arianna Mohan,[1] Michael Scordo,[1] Manikkam Suthanthiran,[2] Thangamani Muthukumar,[2,1] Edgar A. Jaimes.[1,2] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Background: Allogeneic hematopoietic cell transplantation (HCT) is curative for hematologic malignancies but carries risk of acute kidney injury (AKI) in up to 80% within the first 100 days. The etiology of AKI is multifactorial and includes non-immune (ischemic, drug toxicity) and immune-mediated mechanisms. Herein we investigated whether AKI in HCT recipients is associated with a urinary cell three-gene signature validated for kidney graft recipients to detect intragraft inflammation (Suthanthiran et al. NEJM 2013).

Methods: We prospectively collected urine specimens at baseline, weekly while inpatient, and monthly outpatient until day 100, from individuals who had their first allogeneic HCT at MSKCC. AKI was defined as ≥ 7-day elevation of ≥ 1.5x baseline serum creatinine. Urine samples closest to the time of AKI and time from transplant-matched samples from patients without AKI were analyzed. Using RT-qPCR assay, we measured the absolute quantity of panel of mRNAs (T cell marker CD3e, proinflammatory chemokine CXCL10/IP10, and cytokine TGFB1), and 18SrRNA in urinary cells and calculated the CTOT04 molecular signature.

Results: A total of 32 urine samples from 32 HCT recipients were analyzed; 16 with AKI and 16 without AKI. There was no statistically significant difference in the urinary cell molecular signature score between the group with AKI and without AKI (Table).

Conclusions: Our findings suggest that AKI in HCT recipients is not associated with increased trafficking of activated T cells through the kidney. Ongoing studies in our laboratory to profile the transcriptome of urinary cells in an unbiased way using RNA-sequencing would likely yield molecular clues to differentiate causes of AKI in this patient population that is difficult to biopsy.

Urinary Cell Levels of mRNAs in HCT Recipients With and Without AKI

Type of urinary cell transcript	AKI (N=16) copies/µg total RNA	No AKI (N=16) copies/µg total RNA	P value
18S rRNA	1.55E+09	2.73E+09	0.82
TGFB1 mRNA	1.25E+04	1.17E+04	0.60
CD3e mRNA	3.53E+02	2.88E+02	0.80
CXCL10/IP10 mRNA	3.94E+02	7.97E+02	0.52
CTOT04 Signature*	-1.658	-1.793	0.82

*Validated molecular signature which correlates with kidney allograft-rejection (NEJM 2013 Jul 4;369(1):20-31).

SA-PO194

Dimensions of Urinary Muddy Brown Granular Casts and Waxy Casts and Clinical Correlations

Lauren Cohen,[1] Mckinley H. Antley,[3] Dustin R. Chalmers,[2] Akanksh Ramanand,[1] Juan Carlos Q. Velez.[1] *[1]Ochsner Health, New Orleans, LA; [2]Louisiana State University, Baton Rouge, LA; [3]College of Charleston, Charleston, SC.*

Background: Muddy brown granular casts (MBGC) have distinctive microscopic characteristics and are pathognomonic of acute tubular injury (ATI). Waxy casts (WxC) are found in a wider range of tubular and glomerular diseases. There is significant variability in MBGC and WxC size. We aimed to determine whether cast dimensions may correlate with clinical parameters.

Methods: Urine specimens from patients seen in inpatient nephrology consultation were collected. Cases with specimens containing MBGCs or WxC were sampled. At least 12 casts per case were imaged using SeBaCam® and SeBaView at 40x to 400x magnification. Using ImageJ, each cast was measured lengthwise 3 times and widthwise 6 times for MBGC, and 10 times for WxC. Clinical data was extracted from medical records. Data was analyzed by Spearman correlation and t-test.

Results: Twenty-one patients with MBGC and 18 patients with WxC were included. The primary etiology of acute kidney injury (AKI) was ischemic ATI in 61%, toxic ATI in 11% and acute glomerulonephritis in 28%. Mean (range) length for MBGC was 102 (33-317) µm and 223 (28-1714) µm for WxC. Mean (range) width for MBGC was 35 (9-110) µm and 43 (5-253) µm for WxC. For MBGC, width significantly correlated with height (r=0.535, p=0.012), whereas length significantly correlated with age (r=-0.436, p=0.048), FENa (r=0.698, p=0.008), urine chloride (r=0.896, p=0.001) and urine phosphate (r=-0.717, p=0.03). Further, mean MBGC length was found to be significantly longer in patients that received dialysis (p=0.057). WxC length did not correlate with age, need for dialysis or any other parameter, whereas WxC width significantly correlated with serum creatinine (sCr) value at the time of urine microscopy (r=0.855, p<0.001).

Conclusions: MBGC and WxC dimensions significantly correlated with various antropometric, chemical and clinical parameters. Correlation of MBGC length with need for dialysis as well as WxC with sCr suggest that cast dimensions may be related to severity of AKI. With implementation of automated image scanners and computational model training, these observations suggest that urinary cast dimensions may provide valuable diagnostic and prognostic information. Further larger studies are needed to verify and expand these observations.

The Spectrum of Thrombotic Microangiopathy Related to Monoclonal Gammopathy

Daan P. van Doorn,[1,2] Sjoerd Timmermans,[1,2] Myrurgia Abdul-Hamid,[3] Pieter van Paassen.[1,2] Limburg Renal Registry, Maastricht UMC+ Center of Expertise for Vasculitis and Immune-Mediated Kidney Disease. *[1]Maastricht University Medical Centre+, Department of Nephrology and Clinical Immunology, Maastricht, Netherlands; [2]Cardiovascular Research Institute Maastricht (CARIM), Maastricht, Netherlands; [3]Maastricht Universitair Medisch Centrum+, Maastricht, Netherlands.*

Background: Patients with thrombotic microangiopathy (TMA) should be classified according to etiology to indicate targets for treatment, having impact on treatment and prognosis. Recent studies showed a high prevalence of monoclonal gammopathy (MG) in patients with TMA aged over 50 years. TMA was provisionally added as a MG of renal significance (MGRS) lesion by the International Kidney and MG Research Group. Recent studies suggested that complement dysregulation is common in this group. Here, we studied this premise in 7 patients with TMA and coexisting MG using complement measures, functional *ex vivo* endothelial cell tests, and genotyping.

Methods: Patients with TMA on kidney biopsy and/or peripheral blood were recruited from the Limburg Renal Registry and prospective COMPETE cohort. Patients with ADAMTS13-activity <10% or Shiga-toxin mediated disease were excluded. Patients were screened for rare variants and rearrangements in complement genes. Massive *ex vivo* C5b9 formation on endothelial cells, factor H autoantibodies (FHAA) or pathogenic variants in complement genes defined complement dysregulation. IgG was purified from serum to study monoclonal mediated complement activation. As a control, kidney biopsies of 27 patients with MGRS lesions were studied for morphologic features of TMA.

Results: Eighty-four out of 113 patients with TMA were screened for MG. Seven out of 84 patients presented with MG, classified as MGRS (*n*=6) and multiple myeloma (*n*=1). MG clustered in patients aged over 50 years (*n*/*N*=6/32, 19%). Severe acute kidney injury was noted in all patients. Four out of 7 patients presented with normal complement levels. Serum of one patient induced massive *ex vivo* C5b9 formation on the endothelium; IgG induced massive *ex vivo* C3c and C5b9 formation on the perturbed endothelium. Neither IgG nor C4d were found. No pathogenic variants were found. FHAA were present in 2 patients, without homozygous deletion of CFHR3-1. None of the MGRS patients presented with coexisting TMA on kidney biopsy or massive *ex vivo* C5b9 formation on the endothelium.

Conclusions: MG clustered in patients with TMA aged over 50 years. One patient with MG related TMA presented with alternative pathway activation. We found no evidence of TMA in a MGRS control group. With little evidence for complement dysregulation, the mechanism of MG induced TMA should be studied further.

SA-PO196

Monoclonal Gammopathy of Renal Significance (MGRS) Without Detectable Clones: Clinical Treatment Dilemma

Maho Terashita,[1] Umut Selamet,[2] Shonali Midha,[2] Omar Nadeem,[2] Jacob Laubach,[2] Helmut G. Rennke,[1] Naoka Murakami.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Dana-Farber Cancer Institute, Boston, MA.*

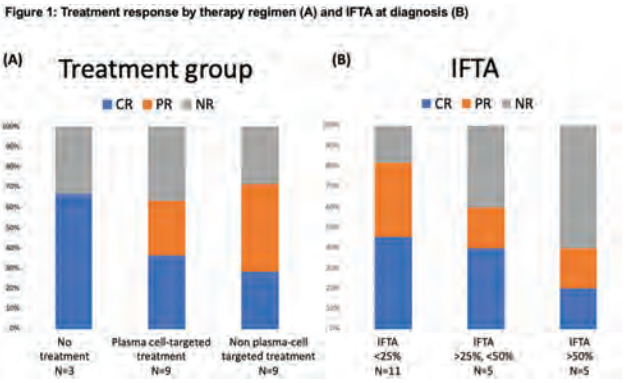
Background: Monoclonal gammopathy of renal significance (MGRS) is characterized by monoclonal immunoglobulin deposition in kidneys. However, monoclonal immunoglobulin is not always detectable in blood, urine, or bone marrow (BM). Treatment response and kidney outcome of MGRS without a detectable clone remains unclear.

Methods: In this single-center, retrospective cohort study, we identified 192 cases of monoclonal immunoglobulin deposition disease (MIDD) from our biopsy repository between 2010 to 2022, of which 86 had follow-up at our center. Inclusion criteria were: (1) negative serum protein electrophoresis and immunofixation, (2) normal serum free light chain ratio adjusted for kidney function, (3) no clone identified in BM, and (4) no specific hematologic diagnosis. We analyzed the best kidney response by therapies (no therapy, plasma cell (PC)-targeted vs. non PC-targeted targeted therapy). Those with at least one PC-targeted treatment were classified as the PC-targeted group.

Results: We included 26 native kidney and 2 transplanted kidney biopsies in this analysis. The median age was 58 (IQR 47-66) and 54% were male. The most frequent subtype of monoclonal immunoglobulin deposited in the kidneys was IgG3 kappa. 67% of patients who had proteinuria >1.0 g/gCr at diagnosis achieved complete response (CR)/ partial response (PR) regardless of the treatment regimen (Figure). Lower proportion of patients achieved CR if they had >50% interstitial fibrosis tubular atrophy (IFTA) at diagnosis. Two cases of MGRS in transplanted kidneys did not respond to treatment. Six out of 7 re-biopsies showed IFTA progression.

Conclusions: Treatments and outcomes of MGRS without a detectable clone were extremely variable. Re-biopsy provided limited information to assess disease activity or the need for additional treatment. More sensitive tools are needed to detect clones and to assess treatment response.

Figure 1: Treatment response by therapy regimen (A) and IFTA at diagnosis (B)



SA-PO197

Beyond Plasma Cell Disorders: Monoclonal Gammopathy of Renal Significance with Marginal Zone Lymphoma

Yara Bilen, Ali Mehdi, Korey Bartolomeo, Leal C. Herlitz, Mohammad A. Sohail. *Cleveland Clinic, Cleveland, OH.*

Introduction: Monoclonal Gammopathy of Renal Significance (MGRS) is well recognized with pre-malignant plasma cell disorders. We report a case of MGRS with nephrotic range proteinuria and rapid loss of kidney function in the context of Marginal Zone Lymphoma (MZL).

Case Description: A 65-year-old man with diabetes mellitus and heart failure is admitted for progressive kidney dysfunction. He has chronic kidney disease, baseline creatinine (Cr) 1.5mg/dL, presumably due to diabetes. On presentation, Cr was 2.1mg/dL. Urinalysis with 2+ proteins and 11-25 RBCs/HPF. 24h urine collection revealed proteinuria at 3.5g. 12.5cm kidneys of normal parenchymal thickness and echogenicity were noted on US with no hydronephrosis. Further workup showed C3 56mg/dL (nl: 86-166) and C4<2mg/dL (nl: 13-46). Serum monoclonal testing revealed a low-grade IgM kappa M protein at 0.09g/dL and a free light chain kappa to lambda ratio of 4.04 (nl: 0.26-1.65). A kidney biopsy showed membranoproliferative glomerulonephritis and IgM kappa restricted deposits. Serum cryoglobulins resulted as positive, type II with a monoclonal IgM Kappa and polyclonal IgG. IgM Cryoglobulin resulted at 17mg/dL with IgA and IgG cryoglobulin at 3 and 19mg/dl respectively. A clinico-pathologic diagnosis of cryoglobulinemia related MPGN was thus made. A bone marrow biopsy unmasked an underlying lymphoproliferative disorder consistent with MZL. CT imaging showed borderline diffuse adenopathy. As such, patient was started on Rituximab, Cytoxan, Vincristine and Prednisone. His kidney function worsened requiring dialysis. Despite cryoglobulins clearance, he remains dialysis dependent while on therapy for his MZL at four months post-diagnosis.

Discussion: Despite an improvement in recognition, MGRS remains a foreign entity both in the nephrology and hematology spheres. It is frequently thought of in the context of plasma cell neoplasms. This case illustrates an MGRS case occurring with an underlying B-cell clone and manifesting as MPGN with progressive kidney dysfunction and nephrotic range proteinuria. A high index of suspicion and a low threshold for kidney biopsy are key to making the diagnosis. As in this case, the kidney biopsy might be the only clue to the underlying lymphoma and a crucial diagnostic step with paramount therapeutic implications, both for kidney and overall patient survival.

SA-PO198

Renal IgG Heavy Chain (AH) Amyloidosis as Monoclonal Gammopathy of Renal Significance: From Accurate Diagnosis to Adequate Treatment

Felipe Pascoal, Enéias S. Machado, Ana Teresa P. Vieira, Livia B. Cavalcante, Lectícia Jorge, Irene L. Noronha, Luis Yu. Division of Nephrology, University of São Paulo. *Universidade de Sao Paulo, Sao Paulo, Brazil.*

Introduction: Monoclonal Gammopathy of Renal Significance (MGRS) is a B or plasma-cell clonal disorder that does not meet the criteria for cancer but produces a monoclonal immunoglobulin that leads to kidney injury. It can rarely manifest as AH amyloidosis, in which highly ordered heavy-chain fibrils deposit in the kidneys. We report a case in which a patient with MGRS was diagnosed and treated for renal AH Amyloidosis.

Case Description: A 77-year-old patient was referred to our Nephrology Clinic due to chronic kidney disease (1.4mg/dL baseline creatinine), proteinuria (2.2g/24h), monoclonal gamma spike (0.75g/dL), hypertension and feet paresthesia. Bone marrow biopsy showed 6% plasmocyte clonal proliferation. Eletrocardiogram, echocardiogram, myocardial scintigraphy and bedside kidney ultrasound were unremarkable. Further workup showed 8.7g/dL hemoglobin, 1.28mmol/L ionized calcium, rare eritrocytes and 2+ protein on urinalysis, 6.3 Kappa-to-Lambda ratio and 1058 mg/dL IgG. Renal biopsy was performed for suspected MGRS with glomerular involvement (images attached). AH Amyloidosis was diagnosed and CyBorD chemotherapy started. After 4 sessions, creatinine and blood urea nitrogen levels improved from 2.2mg/dL and 60.2mg/dL to 1.58mg/dL and 30mg/dL respectively. Proteinuria reached 0.86g/24h.

Discussion: This is a case of rare renal AH Amyloidosis diagnosed in a patient with hypertension, subnephrotic proteinuria and isolated kidney injury, which differs from the typical hypotension, nephrotic-range pronteinuria and multi-organ involvement seen in AL Amyloidosis. Since elevated serum free light-chain levels might be seen on both conditions, renal biopsy is vital for precise diagnosis and fibril deposit distinction. As new therapies are surging for MGRS and Amyloidosis, there is a need for prompt suspicion and accurate diagnosis, which can improve renal outcomes, mitigate disease burden and prevent overt malignancy such as multiple myeloma.

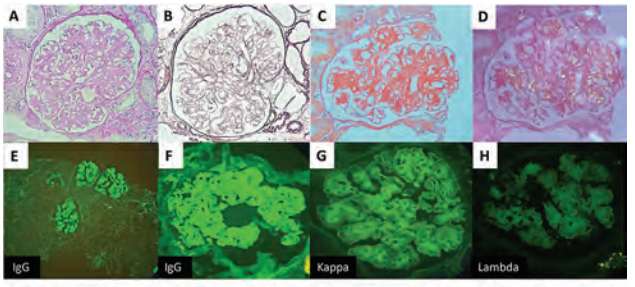


Figure 1 – Glomerulus showing global mesangial and segmental capillary loop deposition of PAS-pale, silver-negative substance (A. PAS, 400x; B. PAMS, 400x). The glomerular deposits are Congo Red-positive and show apple-green refringence under polarized light (C and D. Congo red, 400x), typical of amyloidosis. Diffuse global glomerular IgG positivity (E and F), with negative kappa and lambda (G and H).

Kidney Biopsy

SA-PO199

The Clinico-Pathologic Characteristics of Patients with Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits

Tariku T. Gudura,[1] Hanny Sawaf,[1] Leal C. Herlitz,[1] Ali Mehdi,[1] Surafel K. Gebreselassie,[2] Shane A. Bobart.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Florida, Weston, FL.*

Background: Proliferative glomerulonephritis with monoclonal immunoglobin (Ig) deposits (PGNMID) is a rare form of monoclonal gammopathy of renal significance (MGRS). However, the Monoclonal (M) protein and hematologic clone is found in less than half of the cases.

Methods: We identified all patients with PGNMID from the Cleveland Clinic Kidney Biopsy Epidemiology Project from January 2015 to March 2023. Retrospective chart review was performed to obtain demographic and clinical characteristics.

Results: From 34 patients with PGNMID, 16 patients were excluded due to insufficient data. Of the 18 remaining patients, 67% were male and 78% of patients self-reported as white. The median age was 60 years, with 22% of patients < 50 years. Clinically, features at kidney biopsy were: hypertension (78%), acute kidney injury (72%), hematuria (78%), nephrotic syndrome (22%), and hypocomplementemia (23%). M protein was identified in 33% with an underlying clone identified in only 17% (3/18) of cases (MM, CLL and B cell lymphoma). Mean serum creatinine and proteinuria at biopsy were 3.2mg/dl (0.64 - 9.0) and 4.3 gm/dl (0 - 14.0gm) respectively. Regarding pathology, endocapillary hypercellularity (55%), pure mesangial (28%) and MPGN (16%) patterns were most common. The majority of patients (>65%) had mild chronicity and 1 case had crescents. IgG/Kappa was the predominant finding (83%), one patient had IgM/Kappa. Of 13 patients with IgG subclass staining, 77% had IgG3 and one case each of IgG1, IgG2 and IgG4. CyBorD and CyBord-Daratumumab were the most common chemotherapy regimens used, each accounting 35% followed by Rituximab in 12% of cases. Regarding outcomes, 18 patients had follow up data, with 8 (44%) progressing to ESKD post biopsy with mean duration of 7.8 months (0 - 13) and 44% had either complete (< 0.5 g) or partial remission (proteinuria reduction > 50% with stable eGFR) during follow up. No clinico-pathologic variables were predictive of response on univariate and multivariable analysis.

Conclusions: Our study adds to growing evidence of low clonal detection rate among patients with PGNMID and high rate of disease progression despite treatment. More studies are needed to better understand the true nature of this disease to hopefully guide therapeutic interventions.

SA-PO200

Triple Monoclonal Protein-Related Kidney Lesions in a Patient with Plasma Cell Dyscrasia

Arsalan A. Alvi,[1] Alexander J. Gallan,[2] Nattawat Klomjit.[1] *[1]University of Minnesota Twin Cities Division of Nephrology and Hypertension, Minneapolis, MN; [2]Department of Pathology, Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Toxic monoclonal protein typically results in a single type of kidney pathology due to biophysical properties of monoclonal protein. Multiple type of lesions is rarely reported. We report a patient with monoclonal gammopathy who has light chain cast nephropathy (LCCN), light chain proximal tubulopathy (LCPT) and thrombotic microangiopathy (TMA).

Case Description: A 57-year-old male with history of dermatomyositis and sarcoidosis on mycophenolate mofetil and prednisone who presented with fever, nausea, and loose stool for 3 days. He was diagnosed with concealed ruptured diverticulitis. He had a baseline creatinine (Cr) of 0.8-1.0 mg/dl but it was 1.47 mg/dl 3 months ago. Upon presentation, Cr was 2.81 mg/dl which continued to rise and peaked at 9.29 mg/dl requiring hemodialysis. Platelet (Plt) and Hemoglobin (Hb) were normal upon admission but continued to decrease along with the presence of hemolysis marker. ADAMTS13 activity was 28%. Kappa light chain (LC) of 16 mg/dl and kappa lambda (K/L) ratio of 7.17. Serum electrophoresis showed IgG kappa with M- spike of 0.2 g/dl. His urine analysis showed blood and granular cast, and his protein to creatinine ratio of 1.33 mg/mg. He underwent a kidney biopsy which showed kappa LCCN, TMA and non-crystalline LCPT with minimal interstitial fibrosis. Bone marrow biopsy showed less than 3% of kappa-restricted plasma cell. Complement study showed elevated sC5b-9. Given the finding of progressive TMA, he underwent plasma pheresis for 3 sessions as a bridging therapy before initiating anti-plasma cell therapy with daratumumab, bortezomib and dexamethasone. Due to recent infection, eculizumab was on hold. After the 1st cycle, he is still dialysis dependent but kappa free light chain came down to 3.83 mg/dl with K/L ratio 1.32. Hb and Plt improved but still has positive hemolysis marker so the plan is to start Eculizumab and continue chemotherapy.

Discussion: This case highlights the importance of toxic properties of monoclonal protein in causing kidney diseases. Triple monoclonal protein related kidney lesions can occur but rare. LCCN is a myeloma defining event but his LC (<50 mg/dl) and plasma cell burden is low (<10%) which makes this case very unusual. Sepsis-induced low flow stage may induce LCCN in this patient. Aggressive therapy is likely needed to eradicate the clone in order to achieve organ response.

SA-PO201

A Case of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits Presenting as Hypertensive Emergency

Keith L. Saum, Evan A. Farkash, Markus Bitzer. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Introduction: Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID) is a subtype of monoclonal gammopathy of renal significance (MGRS), resulting from deposition of intact monoclonal IgG in glomeruli. Herein, we present the case of a 65-year-old who presented for new headaches and hypertensive emergency and was subsequently found to have PGNMID.

Case Description: A 65-year-old female with no significant past medical history developed new headaches and was treated with ibuprofen 800 mg TID for 5-months. Subsequently, she was found to have new hypertension with BP of 190/90 mmHg, serum creatinine of 1.0 mg/dl and nephrotic-range proteinuria of 5.4 g/g creatinine. Urinalysis was positive for protein and blood with no dysmorphic RBCs or casts on urine sediment. Labs also revealed new anemia and thrombocytopenia with elevated LDH, undetectable haptoglobin, and normal peripheral blood smear. Further serologic evaluation for C3, C4, ANA, cryoglobulin, ANCA, HIV, HBV, HCV, Anti-PLA2R, DAT, and ADAMSTS13 activity were normal/negative. Paraproteinemia evaluation with SPEP and UPEP were without evidence of M-protein, aside from a marginal free Kappa/lambda light chain ratio (1.8). Despite cessation of NSAIDS and adequate blood pressure control with amlodipine and losartan, proteinuria persisted with rising creatinine. Therefore, kidney biopsy was pursued which showed neutrophilic glomerulitis with a membranoproliferative pattern and rare fibrocellular crescents. Immunofluorescence showed only mesangial and capillary C3 and C1q deposits; however, pronase treated paraffin tissue unmasked IgG-kappa restricted subendothelial and mesangial deposits, diagnostic of PGNMID. She was treated with six cycles of cyclophosphamide, bortezomib, and dexamethasone (CyBorD) resulting in initial improvement in proteinuria and serum creatinine. Repeat bone marrow was without residual plasma cells on flow cytometry.

Discussion: PGNMID is a MGRS that does not meet criteria for multiple myeloma or lymphoma, and a monoclonal immunoglobulin or abnormal bone marrow B cell clone is detected in only 30% of cases. Pronase treatment of paraffin tissue to reveal masked immunoglobulin deposits can provide insightful guidance in glomerular deposition diseases when routine immunofluorescence is not diagnostic.

SA-PO202

Proliferative Glomerulonephritis with Monoclonal IgG Deposits: A Mysterious Renal Disorder

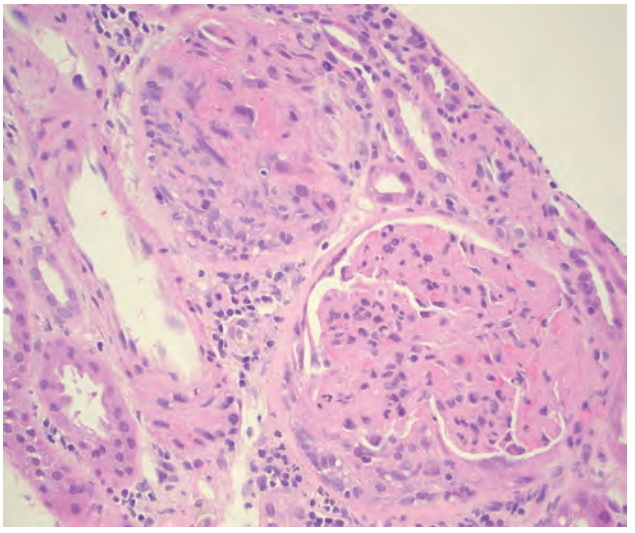
Umair Khan, Zehra N. Kocas, Kostas Papamarkakis. *University of Massachusetts Chan Medical School - Baystate Regional Campus, Springfield, MA.*

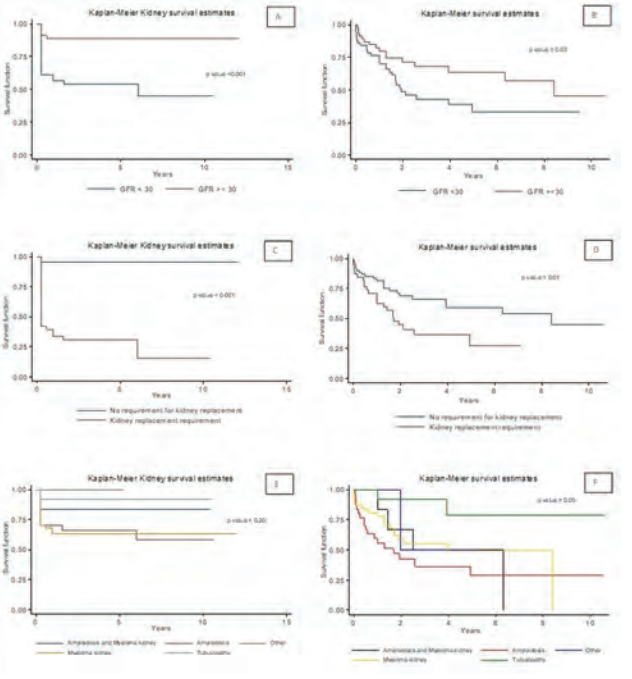
Introduction: Proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) is a rare form of glomerulonephritis characterized by glomerular monoclonal deposits. It predominantly presents with nephrotic range proteinuria and renal dysfunction. A third of patients with PGMID progress to ESRD. It is a renal-limited disorder, however, rare cases of PGNMID in association with CLL have been reported. Herein, we present a case of severe renal failure due to PGNMID in the setting of underlying CLL.

Case Description: An 88-year-old female with CLL presented with oliguric renal failure. Labs revealed an elevated serum creatinine level of 7.9 mg/dL (baseline 1.1 mg/dL), and nephrotic range proteinuria. Renal biopsy showed kappa-restricted immune complex-mediated proliferative and crescentic glomerulonephritis (Fig 1) with linear staining of glomerular capillary loops for IgG (3+), and kappa (3+) suggestive of PGNMID. It was presumed that her PGNMID was due to CLL and hence decision was made to continue with ibrutinib and assess hematological response.

Discussion: PGNMID, a rare form of GN, appears as one of the most mysterious renal disorders associated with monoclonal gammopathy. When present, it should raise the possibility of an underlying secondary etiology as hematological malignancies, especially CLL, have been recognized as a rare cause of PGNMID. Early recognition of PGNMID is a key factor for long term renal survival. Treatment therapy is aimed at monoclonal proliferation and hematological response. Identification of pathogenic clone is vital to guide treatment. The usual absence of any detectable clonal proliferation

makes its management challenging. Further studies in understanding the mechanisms of monoclonal deposition would help refine treatment strategies. This case highlights the importance of close monitoring and individualized treatment plans in the management of PGNMID.





SA-PO203

Prognostic Factors Associated with Renal Survival and Mortality of Renal Involvement Proven by Biopsy Associated with Monoclonal Gammopathy

Sebastian Gomez Jiménez,[1] Simón Cano Rodas,[1] Luis F. Arias,[1] Jose N. Carvajal,[1,3] Joaquin Rodelo Ceballos.[1,2] *[1]Universidad de Antioquia, Medellin, Colombia; [2]Hospital Universitario San Vicente de Paul, Medellin, Colombia; [3]Hospital Alma Mater de Antioquia, Medellín, Colombia.*

Background: Monoclonal gammopathies can generate a wide and diverse renal compromise that can condition the patient's prognosis. This study seeks to determine those factors associated with renal survival and mortality.

Methods: A retrospective cohort study of 98 patients older than 18 years with biopsy-proven renal involvement due to monoclonal gammopathy was conducted. For the analysis of renal and patient survival, the Kaplan Meier method was obtained, renal survival curves were compared with the histological diagnosis and the Log Rank Test was obtained. To determine the predictive factors at the time of biopsy that correlate with death and ESKD, univariate and multivariate cox analyzes were performed.

Results: The need for RRT was related to the combined outcome of ESKD and death (HR 4.86 CI 2.01-11.79). A GFR at the time of biopsy less than 30ml/min/1.73 was correlated with an increased risk of ESKD (HR 4.02 CI 1.38-11.71). Amyloidosis and age over 60 years are factors associated with higher mortality (HR 2.38, IC 1.22-4.86 and 1.96 IC 1.06-3.61 respectively). The presence of tubulopathy (myeloma Kidney) in renal biopsy was associated with better survival compared with other histological compromises (p 0.05).

Conclusions: The requirement of RRT and GFR less than 30 ml/min/1.73 were associated with adverse outcomes in patients with MGRS. Amyloidosis and age are factors negatively related to patient survival.

Combined death and end stage chronic kidney disease

	Univariate (HR)	Multivariate (HR)
Age <60 years	1.58 (CI 0.88-2.85, p 0.12)	1.36 (CI 0.73-2.56, p 0.32)
GFR at biopsy ≤ 30 ml/min/1.73	3.53 (CI 1.90-6.54, p 0.000)	1.21 (CI 0.48-3.04, p 0.68)
Amyloidosis	1.08 (CI 0.61-1.92, p 0.76)	1.28 (CI 0.70-2.34, p 0.41)
Need for RRT	5.63 (CI 3.10-10.24, p 0.000)	4.86 (CI 2.01-11.79, p 0.000)

SA-PO204

A Rare Case of Proliferative Glomerulonephritis with Monoclonal IgA Lambda Deposits with Crescents

Neeharik Mareedu,[1] Ravi T. Pilla.[2] *[1]UPMC Western Maryland, Cumberland, MD; [2]Virginia Commonwealth University Health System, Richmond, VA.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is an uncommon condition under the spectrum of renal disorders grouped under monoclonal gammopathies with renal significance (MGRS). Even more uncommon is the type of immunoglobulin (Ig) deposition other than IgG subclasses (IgG3 heavy chain being most common type of deposition) in PGNMID, which may be IgA or IgM as well as light chain only deposition.

Case Description: We report a 65 y/o Caucasian female patient (pt) with history of hypertension, recurrent urinary tract infections and non-obstructive nephrolithiasis with recent worsening of creatinine (Cr) to 1.3-1.6 mg/dL, with albuminuria 1.8 g/g, proteinuria 2.2 g/g and hematuria and negative nephritic workup. Pt was also noted to have low kappa/lambda light chain ratio (0.14) with significantly elevated free lambda light chains (206.23). No significant abnormalities were noted on serum protein electrophoresis, serum immunofixation electrophoresis or urine protein electrophoresis. While awaiting hematology consultation and renal biopsy the pt was admitted with low back pain and was noted to have new retroperitoneal mass/adenopathy concerning lymphoma. Pt developed progressive renal failure necessitating initiation of hemodialysis (HD). Retroperitoneal mass biopsy positive for diffuse large B-cell lymphoma (DLBCL) with renal biopsy notable for proliferative glomerulonephritis with monoclonal IgA lambda deposition with crescents in the setting of lymphoma and MGRS w/ monoclonal IgA lambda. The pt was started on R-CHOP chemotherapy (CT) for management of her DLBCL while continuing her on HD. Pt eventually achieved DLBCL remission as well as renal recovery with discontinuation of HD with 2 R-CHOP and 4 R-COEP cycles.

Discussion: PGNMID is a rare cause of renal disorder. Though it is usually recognized with deposition of IgG3 subclass heavy chains in glomeruli, it can rarely be recognized with deposition of other immunoglobulins like IgA and IgM as well as light chains. Treatment of this disease is based on clone directed therapy, which could lead to complete or partial remission in these patients. Our case is a one of the rarer cases as it involved uncommon monoclonal IgA lambda chain deposition and it is also associated with diffuse large B-Cell lymphoma.

Cryoglobulinemic Thrombotic Microangiopathy: A Subtype of Monoclonal Gammopathy of Renal Significance

Andrew Ling, Kavita Mistry, Shanmugha Vigneshwar Padmanabhan, Stewart H. Lecker, Cristian Riella, Jeffrey H. William. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) encompasses a set of disorders in which a cell clone secretes immunoglobulin that causes kidney damage without meeting criteria for a malignant plasma cell dyscrasia. These conditions often involve damage mediated by direct monoclonal Ig deposition, though less commonly include processes like thrombotic microangiopathy (TMA) without direct

antibody deposition in the kidney. Here, we present a case of kidney injury secondary to a cryoglobulin-mediated TMA responsive to steroids and clone-directed therapy.

Case Description: A 45-year-old African American woman with recent COVID-19 infection presented with weakness. Vital signs and exam were unremarkable. Labs were notable for creatinine of 8.3 mg/dL, hemoglobin 7.6 g/dL, platelet count 121 K/μL, and LDH 439 IU/L. Urinalysis revealed 4+ blood and 4+ protein with >182 RBC/hpf and muddy brown casts. PLASMIC score was 4. ADAMTS13 activity and functional TMA panel were normal. SPEP/UPEP showed monoclonal IgG lambda. Renal biopsy revealed chronic thrombotic microangiopathy. With a cryocrit of 2.5%, biopsy findings were most consistent with a cryoglobulinemic TMA with absence of paraprotein or immune deposits. She was discharged with a prolonged course of corticosteroids with clinical improvement. Six months later, she re-presented with recurrent AKI (creatinine 3.1 mg/dL), anemia, and thrombocytopenia. Renal function continued to worsen with repeat pulse-dose corticosteroids. Plasmapheresis and clone-directed therapy with bortezomib resulted in dramatic improvement in renal function (creatinine 1.1 mg/dL).

Discussion: Thrombotic microangiopathy is a less common manifestation of monoclonal gammopathy of renal significance and even more rarely associated with Type I cryoglobulinemia. This case demonstrates a paraprotein-mediated process causing disordered complement regulation leading to a TMA. To our knowledge, this is only the second reported case of severe acute kidney injury caused by a cryoglobulinemic thrombotic microangiopathy that was successfully treated with plasma exchange and clone-directed therapy. The role of these therapies in cryoglobulinemic TMA as well as consideration of eculizumab as a subsequent line of therapy in refractory cases merits ongoing discussion.

SA-PO206

Nephrotic Syndrome with Monoclonal Gammopathy of Undetermined Significance (MGUS): A Case Report

Chae Won Kim. *Gangnam Severance Hospital, Seoul, Republic of Korea.*

Introduction: Nephrotic syndrome is characterized by proteinuria, edema, hypoalbuminemia, and hyperlipidemia. A diverse range of disorders has been associated with nephrotic syndrome. Causes of the nephrotic syndrome vary and it can show a vigorous expression of medical conditions. Therefore, it is necessary to establish and treat the etiology of nephrotic syndrome. Differential diagnosis for nephrotic syndrome is challenging due to possibility of nephrotic-range proteinuria by monoclonal gammopathy of undetermined significance (MGUS). Following is a case of a 60-year-old male diagnosed with MGUS concomitant with nephrotic syndrome.

Case Description: A 60-old-male was hospitalized in the nephrology division due to proteinuria, microscopic hematuria, edema in his both ankles and decreased renal function. To rule out glomerulonephritis, blood tests, urinanalysis, kidney biopsy, serum protein electrophoresis (EP), random urine protein EP and immune fixation EP were performed. Blood test results revealed hypoalbuminemia and dyslipidemia. Initial urinary protein-to-creatinine ratio (UPCR) level was 12.5 g/gCr. In the serum protein EP, the M protein was 0.2g/dL, and in the urine protein EP, Bence-Jones proteinuria was detected. The kidney biopsy revealed positive staining for ihC-CD68 in intraglomerular histiocytes; a high possibility of histiocytic glomerulopathy. As this condition has been reported to be associated with underlying hematologic diseases, we requested a consultation with the hematology department for further evaluation. The hematologist performed a bone marrow examination to differentiate between MGUS and myeloma, and to determine the percentage of plasma cells. On bone marrow examination, plasma cells constitute 4.7% of the nucleated cells on aspirate smears. Additionally, a PET scan did not reveal any evidence of primary malignancy or distant metastasis. The patient was diagnosed with MGUS as M protein level was less than 3g/dL, plasma cell ratio was less than 10%, and there were no accompanying myeloma symptoms. Furthermore, it was confirmed that there were no treatable diseases associated with histiocyte-related malignancy or plasma cell disorders.

Discussion: This case showed that MGUS might be a rare cause of nephrotic syndrome and thorough differential diagnosis for myeloma could be necessary to ensure not to miss the optimal treatment timing.

SA-PO207

Membranous Nephropathy Masquerading as Amyloid Nephropathy in a Multiple Myeloma Patient

Lachlan P. Shiver, Jessica K. Cobb, Charles Russell, Claude Bassil. *University of South Florida, Tampa, FL.*

Introduction: Renal dysfunction is a common presentation in many plasma cell dyscrasias, including multiple myeloma. In these disorders, malignant plasma cells proliferate and produce monoclonal immunoglobulins (Ig). These Igs can result in myeloma cast nephropathy, light chain deposition disease, and most commonly, amyloid light chain (AL) amyloidosis. In AL amyloidosis, Ig light chains deposit into renal parenchymal tissue and cause proteinuria and progressive chronic renal failure. Therefore, dysproteinemia-associated kidney disease should be suspected in any patient with plasma cell dyscrasia and renal dysfunction.

Case Description: The patient was a 73-year-old Caucasian female first diagnosed with multiple myeloma, Durie-Salmon Stage IIIA, in 2014. She underwent chemotherapy and autologous stem cell transplant (SCT) in 2015, with complete remission. After SCT, she continued on maintenance immunomodulatory agents with a good hematological response. In 2022 she developed progressive lower extremity edema, worsening pain, and increased fatigue. Workup revealed proteinuria of 7g/24hr and increased urinary M-spikes. Given clinical suspicion for dysproteinemia- associated kidney disease, the patient underwent a repeat bone marrow and kidney biopsy. The bone marrow biopsy revealed myeloma plasma cells occupying only 5% of marrow. Kidney biopsy revealed immune complex deposits involving capillary loops in a subepithelial distribution, a finding consistent with membranous nephropathy (MN). Notably, Congo red staining was negative and ruled out amyloid deposits. Anti-phospholipase A2 Receptor (PLA-2R) immunostaining was negative, and nerve epidermal growth factor-like 1 (NELL-1) immunostaining was positive. Age-based cancer screening was initiated, and NSAIDS were discontinued.

Discussion: Herein, we present a case of NELL-1 positive MN in a patient with multiple myeloma. Membranous nephropathy is the second leading cause of nephrotic syndrome. MN can be idiopathic, related to infection, medication use (NSAIDs), or autoimmune diseases. Notably, NELL-1-positive MN has been linked to solid organ malignancies. Management of these patients should emphasize discontinuing possible causative agents and a thorough cancer screening. This case represents the importance of a thorough workup of nephrotic syndrome, even in patients with a high pretest probability of AL amyloidosis.

SA-PO208

The Meaningful Medulla: Apolipoprotein A-IV Amyloidosis

Sydney E. Hartsell, Monica P. Revelo Penafiel, Sarah Gilligan, Laith Al-Rabadi, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Apolipoprotein A-IV (ApoAIV) amyloidosis is a rare disease affecting the kidney. The few existing case reports cite limited proteinuria with renal decline. We report a case of ApoAIV amyloidosis presenting with acute renal failure and nephrotic range proteinuria.

Case Description: A 67-year-old man with a history of gout presented with 3 months of fatigue and leg swelling after mildly symptomatic COVID-19. Labs revealed a serum creatinine of 11.5 mg/dl, increased from 1.3 mg/dl at baseline. He had no diabetes or significant nonsteroidal use and no family history of renal disease. Urine protein-creatinine ratio was 4.7 g/g. Ultrasound showed increased renal echogenicity without obstruction. Renal biopsy sampled only medulla and revealed interstitial Congo red positive amyloid deposits without light chain clonality (Fig. a-c). He received a short steroid taper and started hemodialysis. Subsequent workup was notable for normal serum kappa:lambda light chain ratio, serum and urine electrophoresis, bone marrow biopsy, and PET/CT. A second renal biopsy sampled only cortex and showed focal and segmental glomerulosclerosis (FSGS) with incomplete podocyte effacement, 70% interstitial fibrosis and tubular atrophy (IFTA), moderate arterio- and arteriolosclerosis, and no amyloid deposits (Fig. d-f). Mass spectrometry of the medullary deposits showed ApoAIV amyloid. He remains on dialysis and has been listed for transplant.

Discussion: ApoAIV amyloid is a rare cause of renal amyloidosis, often presenting as progressive kidney failure with minimal proteinuria. Renal pathology is notable for amyloid deposits restricted to the medulla with cortical sparing. This patient additionally showed chronic pathological changes and proteinuria here is presumed to be due secondary FSGS. This case highlights an unusual presentation with nephrotic syndrome and the importance of mass spectrometry for amyloid subtyping.

SA-PO209

Abnormal Kidney Function in a Patient with Peri-Vascular AL Amyloidosis

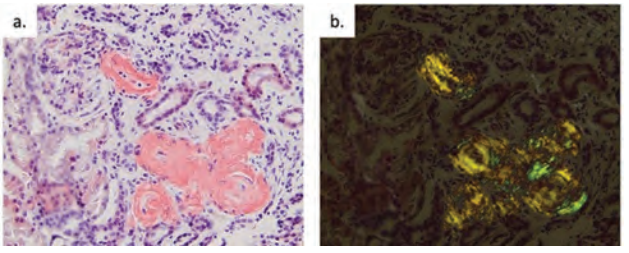
Abdalla Ismail, Sergey V. Brodsky, Amy Yau. *The Ohio State University Wexner Medical Center, Columbus, OH.*

Introduction: Classic presentation of renal involvement of amyloidosis includes nephrotic syndrome due to amyloid fibril deposition in the glomerulus giving a "cauliflower" nodular appearance on light microscopy. Rarely amyloid deposits can be seen in a peri-vascular pattern and present with elevated creatinine and non-nephrotic range proteinuria. Patients with vascular limited amyloidosis are well described in AA amyloidosis but information about this pattern in AL amyloidosis is limited.

Case Description: We present a 71 year old white male with hypertension and IgG Kappa monoclonal gammopathy of undetermined significance present for screening colonoscopy. During the colonoscopy, a tubular adenoma was biopsied with findings consistent with AL kappa amyloidosis. On follow up evaluation, his creatinine rose from

a baseline of 0.9 mg/dL to 3.5 mg/dL. Upon chart review, 6 months prior his creatinine was already increased at 1.6 mg/dL. His work up was significant for a random urine microalbumin to creatinine ratio of 59 mg/g and urine protein to creatinine ratio of 742 mg/g. Serum kappa was 237 mg/l, serum Lambda 11.5 mg/l and Kappa/Lambda ration 20.6. Serum immunofixation Showed IgG Kappa monoclonal protein 673 mg/dl. Urine immunofixation showed monoclonal free Kappa light chains 73 mg/24hrs. Because of the degree of renal failure in the setting of non-nephrotic proteinuria and AL amyloidosis, he underwent renal biopsy. Renal biopsy confirmed AL kappa amyloid deposition in the vascular wall with little to no deposition in the glomeruli with 60% of cortex showing interstitial fibrosis and tubular atrophy.

Discussion: Immunoglobulin light chain amyloidosis can be deposited in diffuse pattern or vascular limited pattern. Our patient demonstrates a rare case of AL amyloidosis in a vascular limited pattern. He also had evidence of vascular involvement outside of the kidney as well. Further studies are needed to recognize this pattern of amyloid deposition.



Renal biopsy under Light microscopy shows amorphous hypoeosinophilic deposits in the vascular walls(a), which is positive by Congo red stain and shows bright apple-green birefringence under the polarized light (b).

SA-PO210

Membranous-Like Glomerulopathy with Masked IgG Kappa Deposits (MGMID) in a Patient with Sezary Syndrome

Chandra Kumar Mallick Kodavanti,[1] Darren W. Schmidt,[1] Michael B. Kuperman,[2] Pablo Garcia.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Arkana Laboratories, Little Rock, AR.*

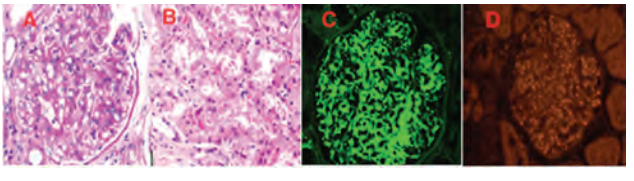
Introduction: MGMID is a rare pattern of glomerulonephritis (GN) that has recently been described in the literature and is characterized by sub-epithelial and/or mesangial immune deposits (Figure 1) that are masked to routine immunofluorescence but strongly stain for IgG and Kappa light chain after protease digestion. Commonly seen in young females < 40 years of age with a mean 24-hour proteinuria of 3.5 g (range 0.5-12.8) and have weakly positive antinuclear antibody titers. We present a patient with Sezary syndrome and nephrotic range proteinuria, and was found to have MGMID. To our knowledge, MGMID in Sezary Syndrome has not been reported yet.

Case Description: 65 year-old female with Sezary Syndrome on Mogamulizumab and type 2 Diabetes Mellitus (DM) presented for evaluation of albuminuria and was found to have nephrotic range proteinuria. She denied symptoms of volume overload. Her DM was well controlled. Her serological work up (Table 1) was negative. Kidney biopsy showed MGMID. She was treated with losartan and empagliflozin. Proteinuria decreased from 5.2 gm/day to 2.5 gm/day. Renal function continues to be stable, and she is currently continuing treatment with biweekly mogamulizumab for Sezary syndrome.

Discussion: This case emphasizes the need for research into this unique pattern of GN to figure out etiology and treatment. At this time, anti-proteinuric medications seem to be a reasonable option. Frequent presence of C3-only staining by routine immunofluorescence (IF) microscopy could lead to misdiagnosis as C3 GN in the absence of protease digested paraffin IF evaluation thereby underscoring the need to use paraffin IF. Serum Amyloid P (SAP) is also key to the diagnosis.

Laboratory values

Serum creatinine- 0.65 mg/dL (0.50-1.04); urine protein-creatinine ratio- 5.25 gm/gm; urine albumin-creatinine ratio- 3.7 gm/gm; urine analysis- 7 RBCs, 1 WBC; Hepatitis panel- Negative; Kappa-lambda ratio – 1.50; C3 and C4 are normal; ANA- negative; ANCA- negative; Hemoglobin A1c-6.3



A. PAS: Mild mesangial expansion within an enlarged glomerulus
B. H&E: Acute tubular injury with epithelial cell sloughing and epithelial simplification
C. Kappa (paraffin): Granular capillary and mesangial staining on protease digested paraffin-embedded tissue "unmasking" the immune deposits
D. Serum Amyloid P: Granular capillary and mesangial staining with SAP confirming the diagnosis of MGMID

SA-PO211

A Case of Membranous Nephropathy Secondary to Chronic Lymphocytic Leukemia in Association with a Novel Antigen

Yeshwanter Radhakrishnan, Sanjeev Sethi, Fernando C. Fervenza, Ladan Zand. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Membranous nephropathy (MN) is an uncommon presentation in patients with chronic lymphocytic leukemia (CLL). A novel target antigen has not been detected in MN associated with CLL. We describe a case of MN in association with CLL successfully treated with acalabrutinib and propose a novel antigen EGF-containing fibulin-like extracellular matrix protein (EFEMP2) as a possible target antigen in this disease.

Case Description: A 72-year-old male presented with bilateral lower extremity edema. His serum creatinine (Scr) was 1.7 mg/dL, serum albumin (SA) was 2.2 g/dL with 24-hour urine protein (24hUP) of 9g. Kidney biopsy revealed a PLA2R antibody negative and thrombospondin7A domain antibody negative MN with 1% of lymphocytic interstitial infiltrate consistent with CLL. He received rituximab (RTX) 1 g 2 doses 2 weeks apart. He went into partial remission with a 24hUP 1000 mg. He relapsed with reconstitution of B-cells due to which 2 additional RTX 1 g doses were given. However, he remained nephrotic despite RTX and a CD20+ B cell of 0. Subsequently, tacrolimus (TAC) 2 mg twice a day was initiated. He went into complete remission 1 year after TAC initiation but relapsed despite therapeutic levels of TAC. His 24hUP at the time of relapse was 13g with SA of 2.1 and Scr of 3.0. He received 2 doses of obinutuzumab 1 g 2 weeks apart for refractory MN. Despite that, he remained nephrotic over the next 4 months. He underwent a repeat kidney biopsy which demonstrated MN with 20% interstitial infiltrate that was PAX5, CD23, CD20 and CD5 stain positive consistent with clonal B-cell lymphoproliferation with features of CLL. Bone marrow (BM) biopsy showed CLL with 5-10% of the BM cellularity. CT chest and abdomen demonstrated widespread lymphadenopathy. Mass spectrometry of the first kidney biopsy showed moderate spectral count for EFEMP2 as the potential antigen in this case. He was initiated on Acalabrutinib 100 mg twice a day monotherapy. At last FU (12-month) he was in complete remission with Scr 2.4, 24hUP 370 mg and SA 4.5 without other therapies.

Discussion: Acalabrutinib monotherapy led to complete remission of MN with CLL. EFEMP2 is a possible target antigen in MN associated with CLL. Further studies are needed to confirm the presence of this antigen, disease association and outcomes in this patient cohort with MN and CLL.

SA-PO212

Clinical and Pathological Analysis of Five Cases of Immune Checkpoint Inhibitor (ICI)-Associated Membranous Nephropathy

Minami Matsumoto, Shinya Yamamoto, Ryota Akagi, Takeshi Matsubara, Motoko Yanagita. *Kyoto Daigaku, Kyoto, Japan.*

Introduction: Since ICIs have become a promising approach and have shaped a paradigm shift in tumor therapies, clinicians are increasingly confronted with immune-related adverse events (irAEs). Acute interstitial nephritis (AIN) is the most common renal irAE, and the treatment of ICI-AIN is based on ICI discontinuation and corticosteroids, which, in most cases, leads to recovery. On the other hand, ICI-associated membranous nephropathy (MN) is relatively rare, and its clinical and histological features and treatment remain unclear.

Case Description: We conducted a multicenter study on renal irAEs by the nationwide Onconephrology Consortium in Japan and analyzed five patients with ICI-associated MN. Patients received Nivolumab for NET, lung adenocarcinoma (two patients), ovarian cancer, and renal cell carcinoma. All patients presented with proteinuria after ICI initiation. Three patients responded to ICI discontinuation and immunosuppressive treatment, including corticosteroids and cyclosporine, and finally achieved remission, whereas two patients did not. The time from ICI administration to disease onset was longer (17.6 months) in treatment responders, whereas it was shorter (6 weeks) in patients with persistent proteinuria. Histologically, in all patients, immunofluorescence microscopy showed granular staining in the capillary walls for IgG (IgG1>4) and C3, and negative PLA2R staining, suggesting secondary MN. Two of the three remission cases showed granular staining for nerve epidermal growth factor-like 1 (NELL-1), which is frequently reported in malignancy-associated MN. The remaining remission case showed a lupus-like deposition pattern with high electron dense deposits in the subepithelial, intramembranous, and subendothelial areas. Two patients with persistent massive proteinuria showed negative NELL-1 staining and no dense deposit in subendothelial area.

Discussion: We revealed that the ICI-MN population is clinically and pathologically heterogeneous, and some patients showed proteinuria remission with treatment. The characteristics of slow-onset and NELL-1-positivity might be predictors of proteinuria remission. Our results speculated that ICI may induce underlying antibodies against tumor antigens such as NELL-1, leading to malignancy-associated MN, or may trigger immune responses, causing lupus-like MN.

SA-PO213

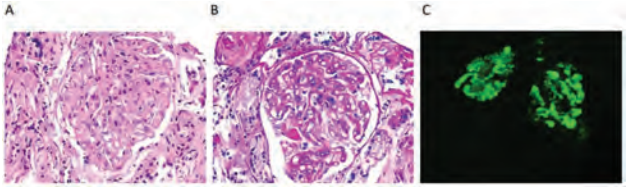
Bevacizumab-Associated Glomerular Microangiopathy: It's Not Always Thrombotic

Dasol Kang,[1,2] Steven Salvatore,[1,2] Alexander Drilon,[2,1] Victoria Gutgarts.[2,1]
[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.

Introduction: Bevacizumab is a monoclonal antibody targeting vascular endothelial growth factor (VEGF). It has been associated with thrombotic microangiopathy (TMA) classically with fibrin thrombi on histology. Recent cases suggest a separate glomerular microangiopathy (GMA) with distinct histopathologic findings, including pseudothrombi, subendothelial dense materials, and full house pattern on immunofluorescence (IF). Herein, we describe a case of anti-VEGF therapy-induced GMA.

Case Description: A 52-year-old female with metastatic lung cancer for six years was referred for proteinuria. She was initially started on carboplatin, pemetrexed, and bevacizumab, then transitioned to bevacizumab monotherapy the past year. Other medical history includes undifferentiated mixed connective tissue disease. Urinary findings showed new-onset proteinuria with urine protein/Cr 5.1g/g with last urinalysis with no proteinuria four years ago. She had stable renal function creatinine 1.3-1.4mg/dl for the past two years, no thrombocytopenia, with normal haptoglobin and lactate dehydrogenase. Proteinuria workup was negative for complement abnormalities and monoclonal gammopathy. She had a positive ANA titer 1:320, with normal cryoglobulin and anti-double stranded DNA. Kidney biopsy showed (Figure) PAS-positive circulating materials and duplication of glomerular basement membrane on light microscopy. IF showed IgM and C3 staining. Electron microscopy showed subendothelial electron dense materials. These findings were most consistent with bevacizumab-associated GMA and bevacizumab was held. Proteinuria improved to 1.3g/g on follow up.

Discussion: As anti-VEGF therapy is commonly used, it is essential to recognize the glomerular findings of PAS-positive pseudothrombi that occur outside of previously reported fibrin thrombi. Pseudothrombi are thought to form as a result of VEGF inhibition, endothelial cell permeability and protein accumulation in the subendothelium. Differentiating this diagnosis from other causes of proteinuria is especially important in patients with history of autoimmune disease to avoid unnecessary use of immunosuppressants.



A. H&E. B. PAS. Pseudothrombi are seen in the capillaries. C. IF for IgM

SA-PO214

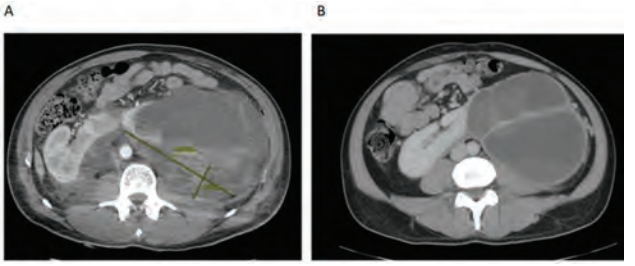
Calyceal Rupture of Horseshoe Kidney Following Chemotherapy

Dasol Kang,[1,2] Jonathan Landa,[2,1] James K. Park,[2,1] Ellin Berman,[2,1]
Victoria Gutgarts.[2,1] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: Horseshoe kidney (HSK) is the most common congenital renal fusion anomaly. During embryogenesis, fusion of the kidneys prevents independent rotation and ascent. Vascular supply to HSK involves small arteries branching from aorta or renal arteries. Complications of HSK are pelviureteric junction obstruction, renal stones, infections, and tumors. Rupture of HSK has been reported in few case series and mainly due to trauma. Herein we describe a case of calyceal rupture of HSK in the setting of thrombocytopenia following chemotherapy.

Case Description: 40-year-old male with HSK was diagnosed with acute myeloid leukemia. Baseline imaging showed left renal atrophy with hydronephrosis. Labs showed normal renal function, creatinine 0.8mg/dl. He was started on induction chemotherapy with cytarabine and daunorubicin. Ten days later, he developed abdominal pain, distension, and hematuria. He was hypotensive, platelet count 25 K/mcL, hemoglobin 6.9 g/dL. CT scan showed increased severe left hydronephrosis, large volume hemorrhagic fluid with dilated calyces and large perinephric/retroperitoneal hemorrhagic fluid consistent with calyceal rupture. (Figure. A) He received 2 units of blood and platelets and underwent emergent interventional radiology (IR) embolization to multiple arterial branches of the kidney. Future cycles of cytarabine were carefully planned with heme, renal, urology, and blood bank.

Discussion: Bleeding and calyceal rupture was an unexpected potentially life threatening complication in this patient with known HSK. In patients planned for chemotherapy that can be complicated by thrombocytopenia, we recommend a) obtaining baseline renal imaging of HSK b) involving nephrology or urology early in the patient care and c) close monitoring and considering platelet transfusion with a higher platelet count threshold of 50K rather than 20K in collaboration with the blood bank given complicated arterial blood supply. In the event of hematuria and thrombocytopenia, we recommend early IR involvement for consideration of embolization.



(A) Calyceal rupture as described above (B) Repeat CT scan with decreased size of perirenal collection.

SA-PO215

Frequency and Characteristics of Chemotherapy-Associated Thrombotic Microangiopathy: Analysis from a Large Pharmacovigilance Database

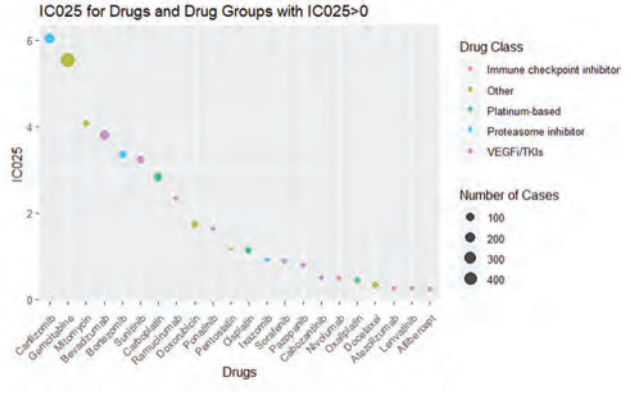
Nattawat Klomjit,[1] Rich Evans,[3] Shruti Gupta.[2] *[1]Division of Nephrology and Hypertension, university of Minnesota, Minneapolis, MN; [2]Dana Farber Cancer Institute, Boston, MA; [3]University of Minnesota Masonic Cancer Center, Minneapolis, MN.*

Background: Thrombotic microangiopathy (TMA) is a rare but detrimental complication of chemotherapy. We examined the frequency and characteristics of chemotherapy-associated TMA using a large pharmacovigilance database.

Methods: We utilized Vigibase, a global drug monitoring database containing over 30 million adverse reports, to examine the frequency of TMA after each of these drug classes: immune checkpoint inhibitors (ICPi), proteasome inhibitors (PI), platinums, tyrosine kinase inhibitors (TKI)/vascular endothelial growth factors inhibitors (VEGFi), conventional chemotherapy (gemcitabine and mitomycin) and other conventional chemotherapy (bleomycin, docetaxel, pentostatin and doxorubicin). The strength of association was determined using information component (IC), a measure of disproportionality between the observed and expected number of reports for a drug-event combination. A positive IC indicates that the number of observed reports exceeds the number of expected reports. We also analyzed characteristics of individual cases who had TMA.

Results: Between 2010 and 2023, there were 4703 reports of chemotherapy-associated TMA in 1099 individuals. The drugs with the highest IC were carfilzomib (5.92), gemcitabine (5.52), mitomycin (4.22), bevacizumab (3.87) and bortezomib (3.69) (**Figure 1**). Among cases where only a single agent was used, TMA was most common with conventional chemotherapy (n=379, 41.2%) followed by PI (n=228, 24.8%), TKI/VEGFi (n=185, 20.1%), and platinums. Time to TMA onset was shortest in patients receiving other chemotherapy (31 days, IQR 30-34) and PI (35 days, IQR 8-178) and longest for conventional chemotherapy (156 days, IQR 91-245). Though uncommon, ICPI-associated TMA was associated with the highest mortality rate (41%).

Conclusions: The drugs most commonly associated with TMA were PI, TKI/VEGFi and conventional chemotherapy. Time to onset was shortest for patients receiving other conventional chemotherapy, while ICPi-TMA was associated with the highest mortality.



SA-PO216

Rechallenging Gemcitabine with Eculizumab in a Patient with Gemcitabine-Induced Thrombotic Microangiopathy

Purva D. Sharma, Nerihan Hadji, Abhishek Nimkar. *Northwell Health, New Hyde Park, NY.*

Introduction: Thrombotic microangiopathy (TMA) secondary to gemcitabine therapy (GiTMA) is a rare pathology that carries a poor prognosis, with nearly half of the cases progressing to end stage kidney disease. The mainstay of management is withdrawal of the offending drug and supportive care. Furthermore, a C5 inhibitor, eculizumab, has been successfully used in the treatment of GiTMA.

Case Description: A 78-year-old lady with a history of ovarian adenocarcinoma stage 4 on gemcitabine was referred for abnormal kidney function. She had CKD with a baseline serum creatinine (Scr) of 1.6-1.8 mg/dl. On this presentation, she had new onset hypertension and Scr was elevated to 2.8mg/dl. Hemoglobin was 8.7 mg/dl with elevated serum lactate dehydrogenase (539 U/L) and low haptoglobin (<20mg/dl). Urine analysis showed moderate proteinuria and hematuria with 30RBCs/HPF. Her spot urine protein-creatinine ratio (UPCR) was elevated at 1.5. A kidney biopsy was pursued which showed chronic thrombotic microangiopathy with severe glomerular capillary wall remodeling, 20% global glomerulosclerosis. Work up for causes of TMA was done including ADAMTS-13 level, antinuclear antibody level, HIV, direct antiglobulin levels, serum complement 3, serum complement 4, anti-neutrophilic cytoplasmic antibody levels and atypical HUS panel which came back unremarkable. Gemcitabine was thought to be the culprit medication and was withheld. Scr did not improve and the patient was initiated on eculizumab with an improvement in Scr to 2mg/dl. After a multidisciplinary discussion with oncology and the family, and based on the premise that gemcitabine was the only drug working for adenocarcinoma, it was decided to re-challenge Gemcitabine concurrently with eculizumab therapy. 3 months follow up showed Scr stable at 1.8mg/dl, normal LDH, Haptoglobin and a UPCR at 0.1.

Discussion: TMA secondary to Gemcitabine therapy is a rare condition. Physicians should have a high index of suspicion to diagnose GiTMA early in the course of the disease. Mainstay of management is discontinuation of gemcitabine and supportive care. Eculizumab has been tried in GiTMA with great success in improving hematologic and kidney parameters. However, continuation of Gemcitabine along with Eculizumab therapy is a novel strategy that has limited data. Further research is needed to validate this strategy.

SA-PO217

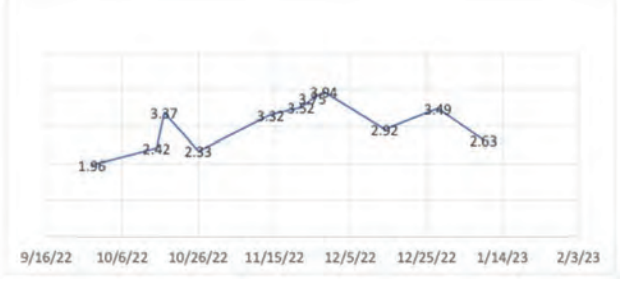
Gemcitabine-Induced Thrombotic Microangiopathy Treated with Eculizumab in a Patient with Pancreatic Cancer: A Case Report

Mohit Madken,[1,2] Shruti Gupta,[1,2] David B. Mount.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Introduction: Thrombotic microangiopathies (TMA) are characterized clinically by the presence of microangiopathic hemolytic anemia (MAHA), thrombocytopenia, and ischemic organ injury. Drug-induced thrombotic microangiopathy (DITMA) is often under-recognized and under-reported. The incidence of gemcitabine-induced TMA (GITMA) has been reported to be between 0.02% and 2.2%.

Case Description: 67-year-old female with history of DM, Hypertension, CKD (B/L creat 1.8-2.0), Ca Pancreas s/p Whipple's on neoadjuvant chemotherapy (FOLFIRINOX followed by Gemcitabine/Abraxane) was admitted with history of frequent falls and worsening left upper and lower limb weakness for 3 days. She had received gemcitabine with cumulative dose of 15,000 mg/m2 for the preceding 1 year, with last dose 2 months prior to her presentation. On admission, her BP was 170/90 mm Hg, serum creatinine 3.5 mg/dl, serum albumin 3.1 g/dl, worsening anemia (hemoglobin 7.1 g/dl), thrombocytopenia (platelet count 89,000/mm^3), LDH 447 IU/L, with schistocytes on blood film. Urinalysis revealed RBC casts with urine microalbumin-creatinine 2400 mg/gm. ANA, ANCA, hepatitis B and C serologies were negative and complements normal. A diagnosis of GITMA was onsidered and she was stabilized with conservative measures. She was started on treatment with Eculizumab with which her renal functions improved with stable Hb.

Discussion: TMA occurring in a patient with a malignancy can be either malignancy or drug-induced. Mechanism of drug-induced TMA can be direct endothelial damage (type 1, dose dependent) or immune-mediated through the development of drug-dependent autoantibodies (type 2, none-dose dependent). Treatment of drug-induced TMA includes supportive therapy and withdrawal of the drug. Eculizumab has shown promise as an effective therapy for GITMA.



SA-PO218

Renal-Limited Thrombotic Microangiopathy from Bleomycin-Etoposide-Cisplatin Chemotherapy in a Young Male with Testicular Cancer

Ali W. Rizvi,[1] Sergey V. Brodsky,[2] Tyler Gutkoski,[1] Amy Yau.[1] *[1]The Ohio State University Wexner Medical Center Department of Internal Medicine, Columbus, OH; [2]Ohio State University Wexner Medical Center, Department of Pathology, Columbus, OH.*

Introduction: Thrombotic microangiopathy (TMA) is a systemic illness stemming from endothelial dysfunction. However some patients present with only renal-limited. In the context of chemotherapy, TMA is typically drug induced, classically associated with therapies such as gemcitabine and mitomycin with a delayed onset or with newer therapies such as tyrosine kinase inhibitors and anti-vascular endothelial growth factor (anti-VEGF) therapies any time during therapy. TMA can also be related to malignancy alone. However TMA has rarely been described in the context of testicular cancer and its therapies.

Case Description: We present a 33 year old caucasian male with past medical history of type 1 diabetes mellitus, CKD stage 3a/A3 due to genetic focal segmental glomerulosclerosis (FSGS) mitochondrial disorder with maternal inherited diabetes and deafness (MIDD) syndrome. His baseline Cr was 1.7 mg/dL with proteinuria of 4-5 grams over 24 hours despite maximal antiproteinuric therapy. He presented to the hospital with worsening edema, 20 pound weight gain, and rise in creatinine to 3.5 mg/dL. Proteinuria had dramatically increased to 11 g in 24 hours with microscopic hematuria. He was recently diagnosed with testicular cancer just two months prior and was now status post radical orchiectomy and is on cycle 2 of bleomycin, cisplatin, and etoposide. Just two weeks prior he was admitted for shiga toxin negative diarrhea and neutropenic fever in the setting of significant pancytopenia. Renal biopsy revealed active TMA with endothelial cell swelling seen on electron microscopy with stable moderate foot process effacement with mild to moderate chronic kidney disease. Unfortunately, due to his hypervolemia, he was initiated on renal replacement therapy followed by eculizumab with hopes his renal function would recover.

Discussion: Drug-induced TMA (DITMA) accounts for 10-13% of all TMA cases however its pathophysiology is unclear. Drugs which do not cause TMA when administered alone may do so when combined with other nephrotoxic agents. This is the second reported case of bleomycin-etoposide-cisplatin therapy related TMA. Understanding which chemotherapeutic combinations increase risk for TMA and how they affect the complement cascade can help prognosticate the degree of renal recovery and after treatment using complement inhibition therapy.

SA-PO219

Renal-Limited Thrombotic Microangiopathy due to Anti-VEGF/Tyrosine Kinase Inhibitor (TKI) Immunotherapy for Metastatic Renal Cell Carcinoma Presenting as Nephrotic Syndrome

Sundus Sardar, Omar K. Salameh, Abdel-Rauof M. Akkari, Mohammad Gul Yousaf Khan, Naman Trivedi, Nasrollah Ghahramani. *Penn State College of Medicine, Hershey, PA.*

Introduction: Vascular endothelial growth factor (VEGF) inhibition may result in proteinuria, worsening hypertension, chronic kidney injury or glomerular disease. Recently, systemic VEGF inhibition has been reported to cause nephrotic disorders and thrombotic microangiopathy (TMA). We present a unique case of renal-limited TMA presenting as nephrotic syndrome in a patient on anti-VEGF/TKI immunotherapy for metastatic renal cell carcinoma.

Case Description: A 73-year-old male with history of metastatic renal cell carcinoma, managed with combination immunotherapy with axitinib and pembrolizumab, who presented with generalized swelling, increasing weight gain up to 30 lbs, heavy proteinuria, hypoalbuminemia concerning for nephrotic syndrome. Workup showed urine protein creatinine ratio of 14. Renal biopsy revealed renal-limited thrombotic microangiopathy, most likely attributed to anti-VEGF/TKI therapy. He had no evidence of immune complex deposition on electron microscopy; however, noted to have extensive foot process effacement which accounted for heavy proteinuria. His anti-VEGF/TKI therapy was discontinued and he is maintained on losartan and dapaglifozin with improvement in urine protein creatinine ratio to 7g upon followup.

Discussion: Our case suggests that renal involvement in patients on anti-VEGF/TKI immunotherapy may manifest as nephrotic-range proteinuria and clinically nephrotic syndrome with renal-limited histological TMA and cessation of anti-VEGF/TKI therapy results in significant improvement in proteinuria with possibility of re-challenge with immunotherapy. In such cases, other differentials may include minimal change disease or collapsing focal segmental glomerulosclerosis (FSGS). Cessation of anti-VEGF/TKI therapy results in significant improvement in proteinuria with possibility of immunotherapy re-challenge in the future. In case of concerns for renal sequelae with anti-VEGF/TKI involvement, prompt referral to nephrology for further evaluation is necessitated for appropriate and timely management.

SA-PO220

Renal Limited Thrombotic Microangiopathy (TMA) Secondary to Chronic Lymphocytic Leukemia (CLL): A Case Report

Sabine Karam, Nattawat Klomjit. *University of Minnesota Twin Cities School of Medicine, Minneapolis, MN.*

Introduction: Chronic lymphocytic leukemia (CLL) is a monoclonal B cell lymphocytosis that produces a nephrotoxic monoclonal immunoglobulin (MIg). Complement-TMA and C3 Glomerulonephritis with systemic manifestations have been rarely reported associated to CLL. We report the first case of renal limited TMA secondary to CLL.

Case Description: 70-year-old female with a history of type 2 diabetes exceeding10 years, hypertension (HTN), and CLL diagnosed nine years prior presented with massive proteinuria with a UPCR a 10g/g, increased from 1.9 g/g six months prior along with lower extremity edema. The creatinine level was 0.84 mg/dL (eGFR around 74 mL/min/m^2) and at baseline. Her CLL had never been treated as she had been considered asymptomatic despite having a WBC count above 200000. Her UA showed pyuria and microscopic hematuria. The serological work-up was unrevealing except for trace cryoglobulin IgG lambda with a kappa lambda ratio at 0.34. A total body CT scan done 5 months prior to presentation had shown stable mild retroperitoneal lymphadenopathy and unchanged mild splenomegaly. A kidney biopsy showed early nodular sclerosis likely from diabetes along

with endothelial injury with glomerular basement membrane duplication and endothelial swelling suggestive of TMA on electron microscopy. Pronase immunofluorescence studies were negative for immune deposits. There was no evidence of peripheral TMA with stable hemoglobin and platelet counts and normal LDH and reticulocyte count. Complement studies revealed unregulated activity at the C3 and C5 convertase level with depleted CH50 levels. The patient's HTN and proteinuria were initially managed with losartan 50 mg daily, empagliflozin 10 mg daily and furosemide 40 mg daily, however as her UPCR increased to 17g/g, her nephrotic syndrome was deemed to be secondary to her CLL and she was initiated on ibrutinib. The proteinuria improved and is now 4.82 g/g three months later. In addition, her WBC count went down to 92.8k.

Discussion: The significant improvement in proteinuria after initiation of ibrutinib and the unregulated activity at the C3 and C5 convertase level suggests renal endothelial injury secondary to activation of the complement pathway by the MIg. Clinicians need to be aware of this potential complication of CLL to initiate treatment promptly.

SA-PO221

Renal TMA Presenting After Eight Years of Sunitinib Therapy

Anukul Ghimire, Rebecca J. Brassington, Kim Solez, Aminu K. Bello.
University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada.

Introduction: Thrombotic microangiopathy (TMA) is a rare side effect of Tyrosine Kinase Inhibitor (TKI) therapy that has almost always been reported as occurring within the first year of TKI initiation, with very few cases reported between two-three years. We report a case of renal-TMA occurring after eight years of TKI therapy.

Case Description: A 70-year-old male was seen for worsening renal function and edema in early 2022. He had a history of metastatic renal clear cell carcinoma treated with left renal resection in 2013 and was started on Sunitinib (TKI) in 2014. His baseline serum creatinine was 151 umol/L and peaked to 260 umol/L with urine protein: creatinine ratio (UPCR) of 857 mg/mmol at the time of referral. Physical exam revealed hypertension and bilateral lower extremity pitting edema. Rheumatologic work up, complement levels, and paraproteinemia panel were unremarkable. Renal biopsy revealed hyaline occlusive glomerular microangiopathy. Sunitinib was discontinued and within one week, his serum creatinine decreased from 260 umol/L to 182 umol/L. He was switched to Nivolumab in late 2022. After a year of discontinuation of Sunitinib, his serum creatinine and UPCR decreased from 260 umol/l and 857 mg/mmol respectively at referral, to 135 umol/l and 50 mg/mmol. The only other treatment that was leveraged was the optimization of his renin-angiotensin blockade using Irbesartan. No recurrence of renal dysfunction was noted after a year of follow-up and his hypertension and edema had resolved.

Discussion: To the best of our knowledge, our case is the first to highlight renal TMA occurring after three years TKI therapy. In previous case reports, renal recovery was seen with simply discontinuing the medication and supportive care such as renin-angiotensin inhibition, as was seen with our case. Some reports have used steroid therapy however these cases have almost always included stopping the offending agent as well. Mixed results have been reported with re-introducing TKI therapy. Take-away points from this case include: (1) Renal TMA can occur even after many years of TKI therapy, and should be monitored for as a possible long term side effect (2) Management involves obtaining renal biopsy, stopping the TKI, and supportive care to optimize hypertension and proteinuria (3) Further work is needed to understand if steroid treatment is effective and if re-introducing TKI therapy is safe

SA-PO222

Nirmatrelvir Plus Ritonavir-Induced Acute Interstitial Nephritis

Belen A. Nunez,[1] Insara Jaffer Sathick,[1] Surya V. Seshan.[2] *[1]Department of Medicine, Division of Nephrology, Memorial Sloan Kettering Cancer Center, New York, NY; [2]Department of Pathology and Laboratory Medicine, Weill Cornell University Medical Center, New York, NY.*

Introduction: Drug induced acute interstitial nephritis is an idiosyncratic delayed type IV hypersensitivity reaction that manifests 7-10 days after exposure to the culprit drug. We present a case of biopsy-proven drug-induced acute interstitial nephritis in a patient who received oral antiviral therapy for the treatment of COVID-19

Case Description: 73y woman with CKD stage II and resected HER 2+ Stage IIA Lung Adenocarcinoma actively treated with fam-trastuzumab and deruxtecan since December 2021, referred to our nephrology clinic for AKI noted on routine testing. One-year prior referral, baseline renal function was at 1.0-1.2 mg/dl. During initial encounter, patient reported traveling outside the US where she contracted COVID-19 and was given Paxlovid for treatment. Initial referral labs revealed WBC 8500cells/mm^3 and 1.9% eosinophils, SCr 1.8mg/dl, BUN 38mg/dl and renal ultrasound with normal echogenicity of both kidneys. Follow up labs after initial encounter showed SCr of 2.3mg/dl, BUN 36 and UA with moderate leukocyte esterase, negative nitrite, 4-6 RBC per hpf, >50 WBC cells/hpf and negative urine culture. Treatment with prednisone 60mg daily was started with plan to taper based on initial response. Over the next 3 months her SCr returned to 1.4 mg/dl while receiving tapering doses of prednisone

Discussion: Nirmatrelvir plus Ritonavir (Paxlovid™) was developed for the treatment and post exposure prophylaxis of COVID-19. While the exact mechanism for its association with acute interstitial nephritis is unknown, there is a distinctly dysregulating immunological response primarily a T cell–driven process. The withdrawal of the causative drug is fundamental as an initial step in management however in some cases corticosteroid therapy is initiated due to moderate to severe renal injury based on their potent anti-inflammatory effects and prevention of irreversible structural changes resulting in renal fibrosis

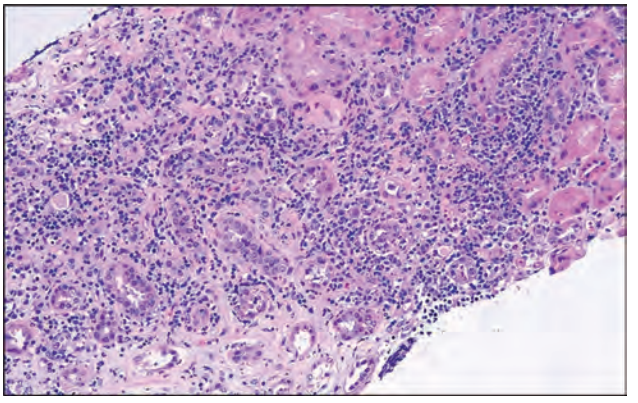


Fig1. Renal cortical tissue shows fairly diffuse active and chronic tubulo-interstitial inflammation. HEx200

SA-PO223

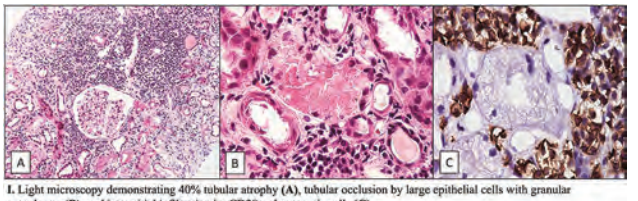
An Unusual Case of Kidney Infiltration by Heavy Chain Disease with Lamellar Inclusion Bodies

Gabriel Cojuc,[1,2] Denisse N. Tinajero Sánchez,[1] Juan Carlos Ramirez-Sandoval.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Red de Universidades Anahuac, Naucalpan de Juarez, Mexico.*

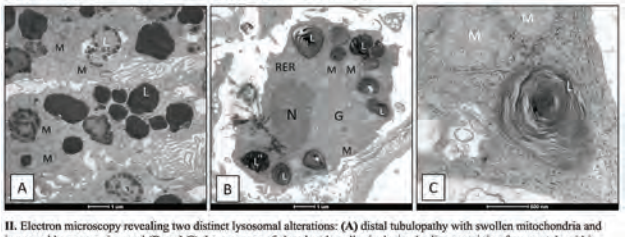
Introduction: Heavy chain diseases (HCDs) are rare B-cell proliferative disorders characterized by the production of a monoclonal protein composed of incomplete immunoglobulin heavy chains. To the best of our knowledge, we report the first case of renal HCD infiltrated by plasmacytic cells exhibiting distinctive lamellar inclusion bodies.

Case Description: A 65-year-old woman with systemic lupus erythematosus in remission with hydroxychloroquine and low-dose prednisone presented with fatigue, weakness, weight loss, and shortness of breath. Examination revealed pallor, hepatosplenomegaly, and inguinal lymphadenopathy. Laboratory tests showed anemia (Hb 5.2 g/dL), elevated creatinine (3.9 mg/dL, baseline 0.6), nephrotic-range proteinuria (6.2 g/day), and increased IgG levels (12,267 mg/dL). Imaging demonstrated bilateral kidney enlargement. Extensive workup for multiple potential etiologies was negative. Further analysis revealed a spike in the beta-1 region in serum protein electrophoresis and gamma-heavy chain presence in serum and urine immunofixation, with a normal free k/l light chain ratio. Bone marrow aspirate showed 6% plasmatic cells and a B-cell lymphoproliferative process with plasma cell differentiation and gamma heavy chain expression without light chain restriction. A kidney biopsy was performed (Fig 1). The patient underwent treatment with cyclophosphamide, bortezomib, and dexamethasone, resulting in kidney function improvement.

Discussion: The observed lamellar bodies are residual lysosomes often seen in lysosomal storage diseases, in subjects receiving lysosomotropic drugs, and rarely in plasma cell dyscrasias. In this case, they were located in the cytoplasm of plasma cells rather than in the tubules or podocytes, corresponding to heavy chain deposits. Kidney involvement is uncommon in HCDs, and its coexistence with lamellar inclusion bodies is even rarer, providing additional insights into this disease.



I. Light microscopy demonstrating 40% tubular atrophy **(A)**, tubular occlusion by large epithelial cells with granular cytoplasms **(B)**, and interstitial infiltration by CD38+ plasmacytic cells **(C)**.



II. Electron microscopy revealing two distinct lysosomal alterations: **(A)** distal tubulopathy with swollen mitochondria and increased lysosome size, and **(B and C)** the presence of abundant lamellar inclusion bodies containing few crystals within plasma cells.

Kidney Biopsy

SA-PO224

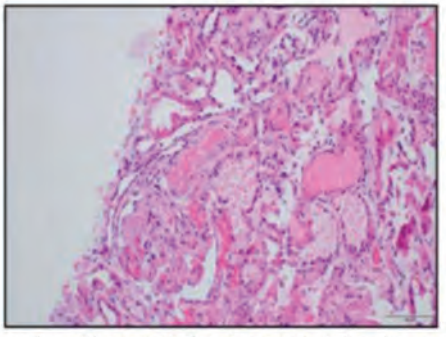
Atypical Hemolytic Uremic Syndrome (aHUS)/TMA in Genetically Predisposed Patients Treated with a Novel Agent for Relapsed/ Refractory Multiple Myeloma

Jiten Gosai,[1] Demah Alobaidi,[2] Majd Al Shaarani,[1] Amanda Tchakarov,[1] Sreedhar A. Mandayam.[3] *[1]The University of Texas Health Science Center at Houston, Houston, TX; [2]Baylor College of Medicine, Houston, TX; [3]UT MD Anderson Cancer Center, Houston, TX.*

Introduction: A number of therapies are being studied to treat relapsed/refractory multiple myeloma (RRMM). Modakafusp alfa (TAK-573) is a novel candidate for treating RRMM. It is a first-in-class immunocytokine that delivers interferon alpha-2b (IFNα2b) to CD38+ cells, showing promising anti-myeloma activity.

Case Description: Here we present two adult males, ages 46 (Patient 1) & 56 (Patient 2) seen at MD Anderson Cancer Center, both with history of RRMM & enrolled in clinical study 2022-0497 G2A4 carfilzomib and modakafusp alfa. Both presented with oliguric AKI requiring RRT, new-onset thrombocytopenia, schistocytosis & transaminitis with elevated LDH. Both had genetic testing & kidney biopsy while admitted. Patient 1 is heterozygous for the extended CFH-H3 risk haplotype, consistent with increased risk for development/progression of atypical hemolytic uremic syndrome (aHUS). The kidney biopsy showed acute/active thrombotic microangiopathy (TMA)-like changes. Patient 2 is heterozygous for a CFHR1-3 deletion (strongly suggesting a large contiguous deletion of both CFHR1 and 3 genes). Patient 2's kidney biopsy also showed findings consistent with TMA features. Both patients had hemodialysis & eculizumab while inpatient & are continuing on hemodialysis on an outpatient basis.

Discussion: Both patients were recently started on carfilzomib & modakafusp alfa, a relatively new phase I/II clinical trial. Preliminary results from 2021 show modakafusp alfa caused side effects such as neutropenia, thrombocytopenia & mild reactions post-infusion. aHUS/TMA with AKI from modakafusp alfa has not previously been reported to our knowledge. Case reports of aHUS/TMA from carfilzomib do exist, however. We conclude that it is reasonable to perform genetic testing prior to initiating treatment with modakafusp alfa +/- carfilzomib, to mitigate the risk of aHUS/TMA as seen in our two patients.



H&E: glomerulus with congested and somewhat shrunken appearance, arteriole with fibrinoid necrosis, tubular epithelial injury.

SA-PO225

Digital Necrosis: Presenting Feature of Type 1 Cryocrystalglobulinemia

Chaudhry Hamood A. Dhillon, Roger A. Rodby. *Rush University Medical Center, Chicago, IL.*

Introduction: Type I cryoglobulinemia involves cryoprecipitable monoclonal Igs associated with multiple myeloma, Waldenstrom macroglobulinemia, or chronic lymphocytic leukemia (CLL). Some cryoglobulins can "crystalize", causing vaso-occlusive gangrene in addition to a glomerulopathy with a specific pattern of injury.

Case Description: A 64-y/o man presented with a purpuric ankle rash, and bluish discoloration of his fingers and toes (Fig. 1). Labs revealed AKI with pancytopenia, microscopic hematuria, and a urine Alb/Creat ratio of 500 mg/g. He had negative or normal testing for hepatitis B and C, HIV, Protein C and S activity, ANA, AntiDS-DNA, anti-scleroderma and anti-centromere antibodies, C3 and C4 levels, RF, antiphospholipid Abs, and ANCA. Serum immunofixation showed a monoclonal IgG kappa paraprotein. Cryoglobulin (CG) testing was negative X2. A renal bx demonstrated an MPGN pattern of injury with vascular thrombi, both with IgG kappa restricted staining on immunofluorescence. Electron micrographs revealed subendothelial and intraluminal electron-dense deposits with crystalline lattice-like substructures c/w cryocrystalglobulinemia (Fig. 1). Repeat CG testing showed a cryocrit of 5% that was also IgG kappa restricted on immunofixation. He received plasmapheresis and steroids. He developed AKI and required HD for a week after which his AKI resolved. He was eventually diagnosed with CLL and received clone-directed therapy with acalabrutinib. His digits required amputation, but his kidney tests normalized.

Discussion: The majority of CGs are "mixed" Type 2 & 3 associated with infections and autoimmune dz. Type 1 cryoglobulinemia is from a paraprotein produced by a plasma cell dyscrasia or a lymphoproliferative disorder. When the CGs form a crystalline substructure, they can cause vascular occlusion (his digits). Fortunately, his renal disease remitted. His presentation of digital ischemia suggested vasculitis, catastrophic anti-phospholipid syndrome, and cryoglobulinemia. The dx in this case ultimately depended on a renal biopsy and demonstrating the CG, a test that requires proper delivery and measurement.

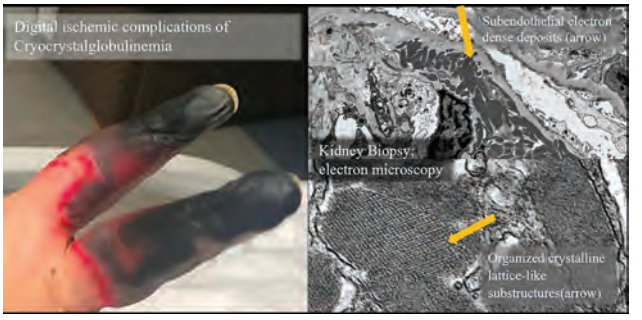


Fig. 1.

SA-PO226

Unmasking the Invisible: A Puzzling Case of Type 1 Cryoglobulinemic Glomerulonephritis with Hidden Immunoglobulin Deposits

Tinn Hongboontry,[1] Darlene Ariyaskul,[1] Jerasit Surintrspanont,[2] Wonngarm Kittanamongkolchai.[1] *[1]King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [2]King Chulalongkorn Memorial Hospital Department of Pathology, Bangkok, Thailand.*

Introduction: Monoclonal immunoglobulins (Ig) occasionally yield false negative results on standard immunofluorescence (IF). Identifying these Ig is vital for determining the patient's disease pathogenesis and therapeutic intervention.

Case Description: A 60-year-old female presented with fever, dysuria, and flank pain. She was diagnosed with *E. coli* pyelonephritis and received ceftriaxone. Her symptoms resolved after a week, but she developed oliguria without urinary tract obstruction seen on ultrasound. Her urine examination revealed dysmorphic red blood cells and urine protein creatinine index of 5.5 g/g. Lab tests showed low C3, C4 levels, detectable cryoglobulins, elevated ASO titer and anti-DNase B. Serum protein electrophoresis (SPEP) showed IgG lambda monoclonal protein. Considering the patient's history of HCV infection, mixed cryoglobulinemia was suspected. A renal biopsy demonstrated diffuse endocapillary proliferation and focal membranoproliferative glomerulonephritis (MPGN) pattern with focal wire loops and hyaline thrombi. IF stains revealed isolated granular staining for C3 in the mesangium and capillary loops. Electron microscopy showed electron dense deposits in the mesangium and subendothelium with vague microtubular structures (20–25 nm). To differentiate GN with predominant C3 (post-infectious GN) from type I cryoglobulinemic GN with masked monotypic Ig deposits, paraffin IF with pronase digestion was performed. This method revealed the presence of IgG, lambda, C3, while kappa remained negative, leading to the final diagnosis of type I cryoglobulinemic GN. Bone marrow biopsy showed a normocellular trilineage marrow. The reatment was switched to a bortezomib-based regimen. Later her urine output improved, and serum creatinine declined to 2.25 mg/dL. Subsequent SPEP detected no monoclonal protein.

Discussion: High suspicion is necessary to avoid misdiagnosis in this case. Positive ASO and anti-DNase B, coupled with C3 dominant GN on renal biopsy, could have been erroneously diagnosed as post-infectious GN. Our case highlights the importance of performing paraffin IF with pronase digestion to detect masked Ig. This is crucial for patients whose kidney biopsy shows C3 dominant GN or MPGN pattern with concurrent monoclonal gammopathy or microscopic characteristics of cryoglobulinemic GN.

SA-PO227

Cryoglobulinemic Glomerulonephritis in the Setting of Chronic Lymphocytic Leukemia

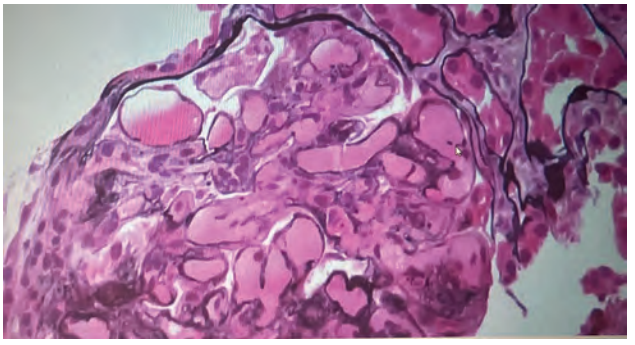
Alejandro Valdesuso,[1] Ankur Shah,[2] Anthony Chang,[3] Susie L. Hu.[2] *[1]Landmark Medical Center, Woonsocket, RI; [2]Rhode Island Hospital, Providence, RI; [3]The University of Chicago Medicine, Chicago, IL.*

Introduction: Cryoglobulinemia is characterized by the presence of immunoglobulins that precipitate in vitro at temperatures below body temperature. End organ damage can occur due to hyperviscosity syndrome, more specifically in the kidney due to the formation of intracapillary (known as cryo-plugs), capillary wall and mesangial cryoglobulin deposits. This is referred to as cryoglobulinemic glomerulonephritis.

Case Description: A 76-year-old female with a history of biopsy proven chronic lymphocytic leukemia presented with dyspnea, edema, and weight gain. Evaluation was notable for hematuria and proteinuria, quantified at 5.8g/g. Serologies revealed an elevated C3 and undetectable C4. Serum cryocrit was 50 UL cryo/ml serum and serum viscosity was 1.4. Cryoglobulin isotyping showed monoclonal IgM-kappa (gamma), faint monoclonal IgM-kappa (beta) and faint monoclonal IgA-lambda (gamma) most consistent with type I cryoglobulinemia in view of her chronic lymphocytic leukemia. Kidney biopsy was obtained demonstrating prominent immune complex deposition in the form of numerous hyaline pseudothrombi with frequent duplication of the glomerular basement membrane most consistent with membranoproliferative glomerular injury. Patient met criteria for plasmapheresis due to the significantly elevated cryocrit and underwent one session. Afterwards, additional plasmapheresis was held and she was started on cyclophosphamide and rituximab. Patient continued to deteriorate and died due to respiratory failure.

Discussion: Type I cryoglobulinemia typically causes end organ damage through hyperviscosity with type II and III cryoglobulinemia doing so through vasculitis.

Atypical to our case was a serum viscosity at the lower limit of normal. We hypothesize that the degree of cryo-plugging was so high it resulted in hyperviscosity at the level of the glomerular capillary that was not detectable in the blood. The possibility of this constellation is important for clinicians to be aware of.



Cryo-plugging on light microscopy H&E stain

SA-PO228

Type I Cryoglobulinemic Glomerulonephritis in Solitary Kidney

Austin M. Morris, Matthew Jacobs, Jamal Abu-Khaled. *Corewell Health, Royal Oak, MI.*

Introduction: Cryoglobulinemia (CG) is a disease in which immunoglobulins precipitate in serum at lower temperatures and then redissolve once warmed again. Glomerulonephritis (GN) is a common complication with type II and III CG but rarely documented with type I. We describe a patient with type I CG (IgM) induced GN without identified source.

Case Description: 66-year-old male with past medical history of a. fib, OSA, and solitary right kidney s/p nephrectomy at age 8 presenting with lower extremity edema and dyspnea on exertion found to be in hypertensive crisis. He denied hematuria or dysuria. Initial blood pressure of 212/104, started on nitroglycerin. Urinalysis with 2+ blood, >20 RBC, >500 protein, and granular casts. BMP electrolytes normal, BUN 37 mg/dL, creatinine 1.63 mg/dL (baseline 1.02). Normal TSH, metanephrines, and cortisol levels. Hepatitis panel negative. Negative renal arterial doppler. Nephritic workup with low C3, normal C4, and nephrotic range proteinuria (5.41 grams). SPEP with IgM monoclonal protein. Bone marrow biopsy negative, peripheral cytology with monoclonal B-cell population (CD5+, CD23-), cytogenetics negative. Renal biopsy IF studies IgM 3+, IgG 1-2+, C3 1-2+, and lambda 1+. EM with membranoproliferative pattern, focal hyalin thrombus, segmental fusion of foot processes, paired tubular structures identified in subendothelial spaces and pseudo-thrombus consistent with cryoglobulinemic GN. No subepithelial deposits. R-CHOP started for suspected lymphoma. Developed vasculitic lesions in mid-2021, C3 and C4 low, cryocrit positive for the first time. Transitioned to bendamustine with plasmapheresis. Second opinion felt lymphoma unlikely and started Velcade. Third opinion recommended ibrutinib with plasmapheresis for 4 weeks, renal function remains stable, blood pressure controlled but IgM band on serum immunofixation and urine sediment remain active.

Discussion: GN is common in mixed CG but extremely rare in type I, with our literature review showing 11 cases. Of those, 9 were due to hematolymphoid disease and the remaining 2 are IgG monoclonal bands. Our case shows that type I IgM CG can present with renal involvement and should be evaluated for in patients with unexplained AKI and positive IgM monoclonal protein with kidney biopsy. Furthermore, this case is unique in showing that renal biopsy can be done safely in a solitary kidney in order to have an accurate diagnosis.

SA-PO229

Monoclonal Gammopathy of Renal Significance (MGRS): An Alternative Pathway to C3 Glomerulonephritis (C3GN)

Eric Magliulo, Saher Aslam, Kirk W. Foster, Prasanth Ravipati, Felipe S. Naranjo. *University of Nebraska Medical Center, Omaha, NE.*

Introduction: C3 glomerulonephritis (C3GN) is characterized by dysregulation of the alternative complement pathway and is commonly accompanied by a monoclonal gammopathy in older patients. These associated paraproteins are now increasingly recognized as the underlying drivers of complement dysregulation in many cases, which has important implications regarding treatment.

Case Description: An 86 year old male with a past medical history of atrial fibrillation and congestive heart failure presented with a ground level fall, sustaining a small subdural hematoma. On arrival, he was hypotensive secondary to atrial fibrillation with a slow ventricular response requiring an implantable pacemaker. He was hypoxic due to pulmonary edema seen on imaging. Labs showed a rise in serum creatinine to 3.89 mg/dl from a baseline of 1.0 mg/dl. Urine dipstick showed 3+ hematuria and a urine protein to creatinine ratio was measured at 2 g/g. He was presumed to have acute tubular injury and received intravenous diuretics with improvement in hypoxia. Nephrology was consulted to assist with diuretic management. Manual urine microscopy was performed which revealed numerous dysmorphic red blood cells (RBCs). Serologic testing was unremarkable except for a monoclonal IgG kappa paraprotein identified on immunofixation. We ultimately decided to pursue a kidney biopsy which revealed a C3 dominant crescentic glomerulonephritis with mesangial proliferation and rare mesangial electron dense deposits. The bone marrow biopsy showed hypercellularity with a polyclonal plasmacytosis. He was diagnosed with C3GN with monoclonal gammopathy and was started on treatment with bortezomib and steroids.

Discussion: We present a challenging case of acute kidney injury in an elderly male. Ultimately, the finding of dysmorphic RBCs on urine microscopy informed our decision to pursue a kidney biopsy, leading to a diagnosis of C3GN with monoclonal gammopathy. Recent evidence suggests that in many cases, dysregulation of the alternative pathway is driven by a monoclonal paraprotein. Furthermore, treatment directed towards the underlying hematologic disease has shown promise in achieving a renal response. For this reason, we elected to pursue treatment targeting the underlying hematologic disorder.

Successful Obinutuzumab-Based Treatment of Chronic Lymphocytic Leukemia (CLL)-Associated Membranoproliferative Glomerulonephritis (MPGN) Lesion with Kidney Infiltration

Andrea Broka, Kuang-Yu Jen, Nasim Wiegley. *UC Davis Health, Sacramento, CA.*

Introduction: Chronic lymphocytic leukemia (CLL) is a mature B-cell neoplasm characterized by the accumulation of monoclonal cells in the blood and bone marrow with an indolent course. Extramedullary CLL with kidney involvement is rare, and treatments are based on retrospective studies and expert opinion. We present a patient with CLL-associated kidney involvement and successful complete remission after treatment with an Obinutuzumab-based regimen.

Case Description: A 68-year-old White man with CLL, chronic kidney disease and heart failure who presented with worsening edema and kidney function on outpatient labs. Workup showed creatinine (Cr) of 4.4 mg/dL (baseline 1.4) with urine protein/creatinine ratio >5g/g, white blood cell count of 83 x10^9/L (baseline) (Fig 1). Complement C3 was low, and Hepatitis panel, HIV, Rheumatoid factor, cryoglobulin, and C4 were negative. Kidney biopsy showed a membranoproliferative glomerulonephritis pattern of injury with cellular crescents, possible cryoglobulins, and focal involvement by CLL cells (Fig 2). Obinutuzumab-based therapy in combination with steroids, cyclophosphamide, and vincristine resulted in an improvement of kidney function and complete remission of nephrotic syndrome and CLL.

Discussion: CLL-associated MPGN pattern of injury with cryoglobulinemia and leukemic cell infiltration of the kidneys is a rare complication of CLL, more common in White elderly men compared to others. Previously, chemotherapy with rituximab plus other agents was the standard of care. However, Obinutuzumab has shown better efficacy compared to rituximab in patients with untreated CLL. Obinutuzumab is a second-generation anti-CD20 monoclonal Ab with enhanced antibody-dependent cellular cytotoxicity and superior progression-free survival. Detection of proteinuria or declining kidney function in patients with CLL should trigger evaluation and consideration of kidney biopsy. Prompt treatment with Obinutuzumab regimen can result in kidney recovery and improved patient outcomes.

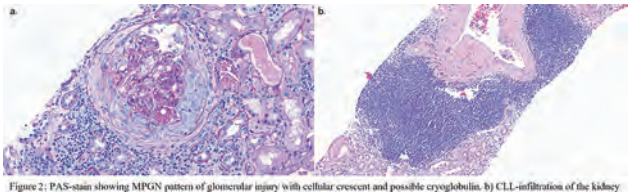

Figure 2: PAS-stain showing MPGN pattern of glomerular injury with cellular crescent and possible cryoglobulin. b) CLL-infiltration of the kidney

SA-PO231

Water, Water Everywhere: Not a Drop to Diurese

Shelden S. Rodrigues, Anitha Vijayan. *Washington University in St Louis, St Louis, MO.*

Introduction: Anasarca is a common yet challenging symptom to manage, with common causes being cardiac, hepatic or renal failure. It is important to consider rarer etiologies when conventional therapies fail to respond.

Case Description: A 56-year-old woman with metastatic breast cancer, on Trastuzumab-deruxtecan presented with worsening anasarca and weight gain of 40kg. Workup ruled out heart, liver and renal failure(creatinine 0.6mg/dL) and nephrotic syndrome. Attempts at diuresis using various combinations (loop, thiazide, and carbonic anhydrase inhibitors) were unsuccessful and resulted in contraction alkalosis and worsening renal function. Due to lack of alternate diagnoses, we considered a diagnosis of capillary leak syndrome (CLS) possibly induced by trastuzumab-deruxtecan and filgrastim. We started amiloride 20mg and administered one dose of tocilizumab 800mg. Over the next

few days, daily urine output increased to 4L on furosemide 40mg with no contraction alkalosis or worsening renal function. She had steady improvement in volume status and decrease in weight (Figure 1). Patient was discharged on day 14 post tocilizumab with marked improvement in her functional status and edema, with weight back to baseline. She has not required re-hospitalization and her weight has remained stable on amiloride 20mg.

Discussion: Capillary leak syndrome refers to the collection of manifestations due to increased capillary permeability to proteins. Several drugs have been implicated such as gemcitabine, interleukins and monoclonal antibodies. Management of volume status is crucial in treating CLS but there is no well-established treatment protocol due to rarity of the condition. Cytokine release syndrome is a subset of CLS occurring in the setting of malignancy treatment or administration of monoclonal antibodies resulting in cytokine surge, endothelial cell injury and capillary leakage. Therapeutic options aim to block this cytokine storm with IVIG or steroids. This case highlights the success of tocilizumab, an interleukin-6 inhibitor for CLS induced by trastuzumab and filgrastim.

Preliminary Results from a Genome-Wide Association Study (GWAS) in Bladder Cancer: Toward a Multi-Omics Approach

Tze Yin Lim,[1,2] Alessandra Allione,[1] Carla Debernardi,[1] Cecilia Di Primio,[1] Carlotta Sacerdote,[3] Simone Sanna-Cherchi,[2] Giuseppe Matullo.[1,4]
[1]Universita degli Studi di Torino, Torino, Italy; [2]Columbia University, New York, NY; [3]CPO-Piemonte, Torino, Italy; [4]Azienda Ospedaliero Universitaria Citta della Salute e della Scienza di Torino, Torino, Italy.

Background: Bladder cancer is one of the most prevalent cancers, and its heterogeneity in clinical outcomes necessitates further investigation into the molecular mechanisms contributing to the disease to improve risk stratification, treatment, and prognosis. Here, we present the preliminary results of a GWAS in bladder cancer in an Italian cohort (N = 581) with paired genotyping and multi-omics data.

Methods: 594 individuals were genotyped with the Infinium OmniExpressExome-8 kit. PLINK2 was used for standard GWAS QC. The resulting dataset of 581 unrelated individuals consisting of 148 cases and 433 controls were imputed with the ToPMed panel (R2, GRC38). Logistic regression was performed on dosages under the additive model adjusting for age, sex, and principal components. Polygenic Risk Score (PRS) was calculated with PRSice-2 v2.3.5.

Results: 581 individuals (148 cases and 433 controls) and 594,108 SNPs remained after QC. Post-imputation QCs requiring SNP call rate (>95%), MAF (>1%) and Hardy-Weinberg ($P < 1 \times 10^{-6}$) within the cohort yielded a final set of 7,660,056 SNPs for GWAS. We identified three loci with suggestive association: chr10p15.3 (rs2605905, OR=3.06, $P = 1.53 \times 10^{-6}$; *DIP2C*), chr5p13.3 (rs5026245; OR = 2.14; $P = 3.83 \times 10^{-6}$; *ADAMTS12)*, and chr15q21.3 (rs17543144; OR = 2.03; $P = 4.46 \times 10^{-6}$; nearest gene *FAM214A*). The quantile-quantile plot showed no evidence of inflation ($\lambda = 0.969$) suggesting no residual population stratification. An interim assessment of the portability of existing PRS(PGS000782) on this cohort showed significant differences in means between cases and controls ($P = 2.17 \times 10^{-4}$).

Conclusions: An initial comparison of summary statistics between our cohort and larger bladder cancer cohorts deposited in the GWAS catalog showed consistent directionality in effect sizes at previously reported significant loci. Our GWAS may be underpowered for new discoveries but, leveraging on paired epigenomic and transcriptomic data available in our cohorts, we are well positioned for constructing multi-omics genetic correlations to dissect known and novel bladder cancer loci and provide insights into the pathobiology of disease. Finally, an interim assessment of PGS000782 showed portability in distinguishing cases from controls in this cohort.

SA-PO233

Glomerular Pathology of Vascular Endothelial Growth Factor Inhibition: 12-Year Single-Center Experience

Mariam Charkviani, Raad B. Chowdhury, Salvatore E. Mignano, Alessia Buglioni, Mariam P. Alexander, Sandra Herrmann. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Vascular endothelial growth factor inhibitors (VEGF-I) are frequently used for cancer treatment. VEGF-I can cause proteinuria and acute kidney injury. Thrombotic microangiopathy (TMA) is common, but other glomerular pathologies are not well characterized. We aim to describe clinical characteristics and glomerular lesions associated with VEFG-I in a single center cohort.

Methods: We performed a retrospective chart review of patients treated with VGEF-I and underwent kidney biopsies from 2010 to 2022. Biopsy findings were reviewed by our pathologists.

Results: Nineteen biopsies were performed during 2010-2022 for kidney dysfunction in patients treated with VEGF-I. Eleven/19 had complete data. The median age was 62 (IQR 58-66) years, and the most common malignancy was renal cell carcinoma. TMA was found on 8/11 biopsies. Proteinuria was the most common reason for biopsy in patients with TMA. Three patients presented with other lesions besides TMA. One had anti-phospholipase A2 receptor-negative membranous nephropathy and both VEGF-I and pembrolizumab were stopped. She received prednisone with improvement in proteinuria. Another patient had known cryoglobulinemia with nephrotic range proteinuria exacerbated by VEGF-I peaking at 11g/day. Despite stopping VEGF-I and treating with prednisone+rituximab, he progressed to ESKD. Third patient had IgA nephropathy with diabetic changes, proteinuria progressed even after stopping VGEF-I (Table).

Conclusions: In this review of patients treated with VEGF-I undergoing kidney biopsy, we described the histological characteristics, clinical course, and outcomes. Our review adds information to the sparse literature on patients with renal dysfunction after receiving VEGF-I.

Patient	Gender	Age	Kidney Biopsy Findings	Primary Malignancy	Cancer Treatment	Outcome
1	F	55	PLA2R Negative Membranous Nephropathy, Minimal IgA Nephropathy	Renal Cell Carcinoma	Axitinib + pembroluzimab	N/A
2	M	59	Cryoglobulinemia Type II	Renal Cell Carcinoma	Pazopanib	Progression of Cancer
3	M	72	IgA Nephropathy Diffuse DM glomerulosclerosis	Hepatocellular Carcinoma	Atezolizumab + Bevacizumab	Progression of Cancer
4	F	51	Acute to subacute TMA	Ovarian Cancer	Bemcitabine + bevacizumab	Deceased
5	F	63	Subacute TMA	Colon Cancer	Bevacizumab	Disease progression, deceased
6	F	65	TMA	Glioblastoma Multiforme	Bevacizumab	Progression of Cancer
7	F	67	TMA	Endometrial cancer	Bevacizumab	Progression of Cancer, Decreased
8	M	62	Subacute TMA	Gastrointestinal stromal tumor	Imatinib, Noilotinib, Regorafenib, Sunitinib, Pazopanib, Imatinib + Dasatinib	Progression of Cancer
9	F	58	TMA	Ovarian Cancer	Bevacizumab	Progression of Cancer
10	M	60	TMA	Renal Cell Carcinoma	Nivolumab + Ipilimumab, + Cabozantinib	N/A
11	M	68	TMA	Renal Cell Carcinoma	Axitinb + Pembrolizumab	Progression of Cancer

SA-PO234

Bilateral Resection of Renal Cell Carcinoma with Postoperative Urinary Ascites

Matthew F. Baker, Maura A. Watson. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Urinary ascites is a rare complication of nephrectomy in the absence of bladder or ureteral injury.

Case Description: A man in his fifties with bilateral renal cell carcinomas underwent left total nephrectomy and right partial nephrectomy. He was treated with neo-adjuvant and adjuvant nivolumab. His pre-operative creatinine was 1.0 mg/dL. Two weeks post nephrectomies, he was hospitalized for anuric acute kidney injury. Urine microscopy revealed acute tubular necrosis (ATN). He had large-volume ascites, despite normal hepatic function, which was consistent with urine based on drained ascitic fluid creatinine level of 78.9 mg/dL. Serum creatinine peaked at 12.65 mg/dL and improved to 2.2 mg/dL after paracentesis and right ureteral stenting. Creatinine decreased to 1.9 mg/dL at discharge. He was readmitted two months later for Enterococcus faecalis bacteremia. CT IV pyelogram demonstrated active extravasation of contrast from the right renal pelvis and formation of a right perinephric urinoma which was 5.1 cm wide. Serum creatinine increased from 2.2 mg/dL on admission to 3.25 mg/dL by the time of hospital discharge. Follow-up imaging one month later demonstrated decrease in size of the right perinephric urinoma but with persistent extravasation of contrast from the right renal collecting system. Four months after right ureteral stent placement, the stent was removed and intraoperative retrograde pyeloureterogram showed no renal collecting system extravasation. His serum creatinine eventually settled at 1.9 mg/dL with a stable estimated glomerular filtration rate of 49 mL/min.

Discussion: Urinary ascites directly from the renal collecting system, as shown on imaging in this case demonstrates an unusual complication of bilateral nephrectomies. Loss of nephron mass, bacteremia, and post-operative ATN contributed to chronic kidney disease development, but estimation of renal function was likely clouded by reabsorption of creatinine from extravasated urine. The urinoma eventually became walled off and collecting system defects in the remaining kidney healed. Urinary leak leading to large volume ascites may occur post nephrectomy and should be considered in patients without hepatic injury. *The views expressed in this abstract are those of the author(s) and do not necessarily reflect the official policy of the Department of Defense or the U.S. Government.*

SA-PO235

A Case of Possible Malignancy-Related Polyangiitis Overlap Syndrome with Henoch-Schönlein Purpura and ANCA-Negative Pauci-Immune Glomerulonephritis as a Manifestation of Neuroendocrine Cancer

Muhammad Ali,[1] Natasha Ghalib,[2] Fadila Noor,[1] Susan E. Collins.[1] *[1]Nuvance Health, Poughkeepsie, NY; [2]Montefiore Medical Center Jack D Weiler Hospital, New York, NY.*

Introduction: Henoch Schönlein purpura (HSP) is an immunoglobulin A (IgA) mediated small vessel vasculitis involving the skin, gastrointestinal tract, kidneys, and joints. It is often precipitated by infections but has also been reported with malignancies. Pauci immune crescentic glomerulonephritis (PICGN) is a cause of rapidly progressive glomerulonephritis (RPGN) and is usually ANCA positive with a paucity of immune complexes on renal biopsy. It is associated with microscopic polyangiitis (MPA), granulomatosis with polyangiitis (GPA), eosinophilic granulomatosis with polyangiitis (EGPA), or renal limited vasculitis. Polyangiitis overlap syndrome with features of more than one vasculitis has also been reported. We report a unique case of HSP and ANCA-negative PICGN in association with metastatic neuroendocrine cancer.

Case Description: A 54-year-old male with no medical history presented with fatigue, colicky abdominal pain, and dark urine for 2 weeks. He denied recent respiratory or gastrointestinal infection. He had new-onset hypertension (BP 163/96 mmHg), a purpuric rash on the buttocks and lower extremities, and acute kidney injury (AKI). Urinalysis showed hematuria, pyuria, and proteinuria. Skin biopsy showed IgA vasculitis consistent with HSP. Prednisone was started but he required hospitalization due to worsening AKI (BUN 36 mg/dL & creatinine 3.11 mg/dL). Workup showed anemia (Hb 12.8 g/dL), normal platelet count and coagulation profile, proteinuria of 1g/day, positive ANA (titer 1:80), negative anti-MPO & PR3 ANCA, anti-GBM, and anti smith antibodies. CT abdomen showed multiple liver masses and biopsy showed metastatic neuroendocrine cancer. Renal biopsy showed acute pauci immune necrotizing crescentic glomerulonephritis. Chemotherapy (carboplatin & etoposide) was initiated with steroids leading to the resolution of AKI.

Discussion: We report a unique case of HSP and ANCA-negative PICGN in association with metastatic neuroendocrine cancer. The difference in skin and renal biopsies indicates possible malignancy-related polyangiitis overlap syndrome. HSP and PICGN can be manifestations of occult malignancy, especially in adult males. Diagnosis of malignancy is crucial as remission of vasculitis may require both treatment of cancer and immunosuppressants.

SA-PO236

BK Virus Nephropathy (BKVN) in a Native Kidney of an Immunosuppressed Patient

Omar A. Ayah,[1] Gabriela Dande,[1] Akwe Nyabera,[1] Evan A. Farkash,[2] Tareq I. Nassar.[1] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]University of Michigan Medical School, Ann Arbor, MI.*

Introduction: BK virus nephropathy (BKVN) is common in kidney allografts but in native kidneys, BK reactivation is typically transient. However, there are a growing number of reports of native kidney fulminant BKVN in immunocompromised patients. We present a case of a patient with native BKVN mimicking an ifosfamide-related karyomegalic-like nephritis.

Case Description: A 53-year-old male with a past medical history of marginal zone lymphoma with transformation to diffuse B-cell lymphoma presented with worsening serum creatinine. He was in remission after chemotherapy including R-CHOP (2018-2019), R-ICE (2019), CD 19 CAR-T cell therapy (2019 –2020), fludarabine and cyclophosphamide lymphodepletion, and Obinutzumab with Brentuxumab vedotin (2020- 03/2021). 1 year after his last treatment, serum creatinine rose from a baseline of 0.99mg/dL to 2.13mg/dL. Urine protein-creatinine ratio was 223mg/g. Kidney biopsy showed interstitial nephritis with marked epithelial atypia, initially diagnosed as karyomegalic-like interstitial nephritis, likely related to treatment with ifosfamide. High-dose steroids were initiated without further improvement. Serum creatinine and UPCR increased when steroids were tapered. Cellcept was added to his regimen, as reported in other case reports, but his kidney function further declined. Cellcept was discontinued due to gastrointestinal side effects. An external review of pathology slides was obtained, and immunohistochemistry for Large T Antigen showed diffuse positivity, diagnostic of BKVN. Despite immunosuppression cessation the patient progressed to home hemodialysis.

Discussion: Non-kidney solid organ transplantation (32%) and hematologic malignancy (15%) are the most common associations with native kidney BKVN, which frequently progresses to end stage kidney disease. Pathologic hallmarks of BKVN in allografts such as plasma cell-rich infiltrates and nuclear inclusions are often subtle or absent in native BKVN. Interestingly, most cases of native BKVN associated with hematologic malignancy occur in the setting of ongoing treatment or active neoplasia, while this patient presented in remission. This case highlights the challenging nature of native BKVN diagnosis, and the importance of having a high index of suspicion for BKVN and other viral infections in patients with active or recent immunocompromise or immunosuppression.

SA-PO237

Diversity Outbred Mouse Model for Investigating Genetic Determinants of Cisplatin Nephrotoxicity

Yves T. Wang, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Cisplatin is a commonly used chemotherapy agent that is highly effective against several cancers. However, it has significant toxicity to several organs including the kidney. This has a significant impact on patient outcomes, as 50% of patients have to reduce dosages or discontinue use of cisplatin and up to 30% suffer from acute kidney injury (AKI). The causes of inter-individual variability in cisplatin nephrotoxicity are unknown, but evidence points to the involvement of genetic factors. We propose to use a mouse model with high genetic variability to identify potential gene candidates involved with modifying cisplatin nephrotoxicity. Here, we demonstrate the feasibility of using the Diversity Outbred mouse model, which was designed to mimic genetic heterogeneity in humans, in a small pilot study that demonstrates highly variable nephrotoxic response to chronic cisplatin administration.

Methods: Male and female Diversity Outbred mice (The Jackson Laboratory) were exposed to 9 mg/kg cisplatin subcutaneously weekly over 4 weeks (n = 8/sex) or to vehicle control (n = 4/sex). Three days after the last dose, plasma was collected and creatinine was measured by mass spectrometry and BUN was measured by a colorimetric assay at the UAB/SD O'Brien Center for Acute Kidney Injury Research.

Results: Control mice had plasma creatinine levels of 0.06±0.02 mg/dL [range: 0.04-0.08] in males and 0.07±0.02 mg/dL [0.06-0.11] in females. Compared to controls, cisplatin treated mice had significantly elevated plasma creatinine levels of 0.21±0.10 mg/dL [0.08-0.37] in males (p=0.0051) and 0.28±0.19 mg/dL [0.11-0.70] in females (p=0.016). Similarly, BUN was elevated in treated males (77.3±26.4 mg/dL [21.3-104.1] vs 26.5±8.4 mg/dL [18.1-36.5], p=0.00073) and females (65.7±27.5 mg/dL [21.9-92.0] vs 23.5±7.6 mg/dL [12.4-29.6], p=0.0030).

Conclusions: The Diversity Outbred mice display highly variable degrees of AKI after cisplatin exposure. While the majority of treated mice exhibited significantly elevated markers of AKI, some had markers similar to control mice. This model is suitable for quantitative trait loci (QTL) mapping to identify genes that modify susceptibility to cisplatin nephrotoxicity. Identification of these genes may enable pharmacogenetic application to tailor chemotherapy and enable development of adjunct therapies to limit cisplatin-induced AKI.

SA-PO238

Albuminuria Changes and Risk of Incident Cancer: The Stockholm CREAtinine Measurements (SCREAM) Project

Li Luo,[1] Lyanne M. Kieneker,[1] Roemer J. Janse,[2,3] Alessandro Bosi,[2] Rudolf A. de Boer,[4] Priya Vart,[5] Ron T. Gansevoort,[1] Juan J. Carrero.[2,6] *[1]Department of Nephrology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [2]Department of Medical Epidemiology and Biostatistics, Karolinska Institutet, Stockholm, Sweden; [3]Department of Clinical Epidemiology, Leiden University Medical Center, Leiden, Netherlands; [4]Department of Cardiology, Erasmus University Medical Center, Rotterdam, Netherlands; [5]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, University of Groningen, Groningen, Netherlands; [6]Division of Nephrology, Department of Clinical Sciences, Karolinska Institutet, Danderyd Hospital, Stockholm, Sweden.*

Background: A single albuminuria measurement is reported to be an independent predictor of future cancer risk. Whether progressive albuminuria (i.e. albuminuria changes) adds further prognostication is not known.

Methods: We included 64,303 subjects of the Stockholm Creatinine Measurements (SCREAM) project without a history of cancer and with at least 2 urine albumin-creatinine ratio (ACR) tests up to 2 years apart. Albuminuria changes were quantified by the fold change in ACR over 2 years, and stratified into the absence of clinically elevated albuminuria; albuminuria that remained constant; and albuminuria that increased; or decreased. The primary outcome was overall cancer incidence. Secondary outcomes were site-specific cancer incidences.

Results: During a median follow-up of 3.7 (IQR, 3.6-3.7) years, 5,126 subjects developed de novo cancer. After multivariable adjustment including baseline estimated glomerular filtration rate and baseline ACR, subjects with increasing ACR over 2 years had a 19% (HR, 1.19; 95% CI, 1.08-1.31) higher risk of overall cancer compared to those with absent albuminuria. No association with cancer risk was seen in the groups with decreasing or constant ACR. Regarding site-specific cancer risks, subjects with increasing ACR or constant ACR had a higher risk of developing urinary tract and lung cancer. No other associations between 2-year ACR changes and site-specific cancers were found.

Conclusions: Increases in albuminuria over a 2-year period are associated with a higher risk of developing overall, urinary tract, and lung cancer, independent of baseline kidney function and albuminuria.

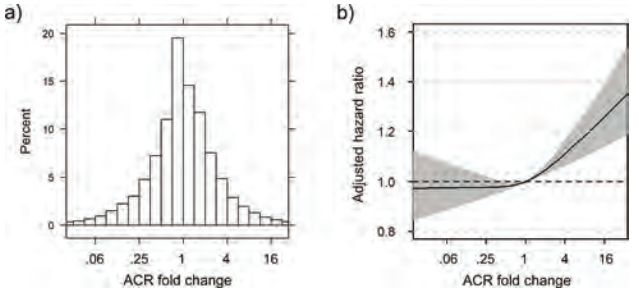

Figure 1. Distribution of 2-year ACR changes (panel A) and adjusted hazard ratio of overall cancer incidence associated with 2-year ACR changes (panel B). Restricted cubic splines of 2-year ACR changes with 3 knots at 0.1, 0.5, 0.9 quantiles of 2-year ACR fold change.

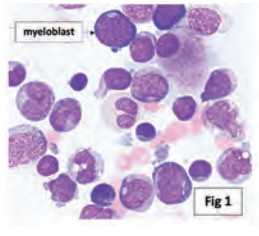
Dripping Clues: Unveiling Diabetes Insipidus (DI), a Sneaky Presentation of Acute Myeloid Leukemia (AML)

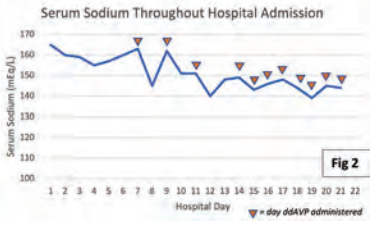
Naveen Rathi, Isaac I. Kim, Prakash S. Gudsoorkar. *University of Cincinnati College of Medicine, Cincinnati, OH.*

Introduction: DI is a rare complication of AML seen with cytogenetic defects especially monosomy 7 & inversion 3. It can occur before or after diagnosis of AML, with or without brain imaging abnormalities. Here, we report a case of hypernatremia from DI in a patient with AML.

Case Description: A 68-year-old male with no medical history presented to ICU with altered mental status & polyuria (urine output > 5L/day), noted to have hemoglobin 6.8 g/dL. Led to AML diagnosis based on blood and bone marrow tests (Fig1). Karyotyping revealed inversion 3 [inv(3)(q21q26)] & monosomy 7. His serum sodium (SNa) was high on admission at 168 mEq/L. Over the past 3-4 weeks, he had increased urination. Further evaluations, including an MRI of the brain, showed no abnormalities. Urine osmolality was 168 mOSm/L (other metabolic tests were normal). Treatment with diamino D-arginine vasopressin (ddAVP) (2- 4 mcg/day) & free water boluses improved SNa (Fig2) and urine osmolality. Diagnosis of probable central DI based on the response to ddAVP, was made. With his mental status improving, he was switched to oral desmopressin (0.05 mg BID) and maintained stable SNa (140-145 mEq/L) upon discharge. Unfortunately, due to the non-response to his therapy for AML (decitabine), he was transitioned to hospice.

Discussion: The pathogenesis of DI associated with AML (DI-AML) is not well understood. A possible mechanism is due to hypothalamic-pituitary infiltration of the leukemic cells or dysregulation of ADH due to dysthrombopoesis. Since approximately 90% of circulating ADH is associated with platelets, dysthrombopoesis in AML could lead to decreased levels and function of ADH. The 2 most common cytogenetic defects associated with DI-AML are monosomy 7 (80%) and inv-3 (46%). Patients with inv-3 and 50% involving monosomy 7 demonstrate activation of the MECOM [(MDS1 and EVI1 (ectopic virus integration site 1 protein homolog) complex] gene, leading to an increase in EVI-1 (a protein product). This disrupts the hypothalamic ADH secretion. We need more studies to prove an association between DI & AML. Our patient had features of CDI based on the evaluation & treatment response.





SA-PO240

Paraneoplastic Membranoproliferative Glomerulonephritis Associated with Neoplasm Transformation

Pardeep Ratnani,[1] Omar Mamlouk,[2] Amit Lahoti,[2] Majd Al Shaarani.[3] *[1]Baylor College of Medicine, Houston, TX; [2]The University of Texas MD Anderson Cancer Center Children's Cancer Hospital, Houston, TX; [3]The University of Texas System, Houston, TX.*

Introduction: Paraneoplastic glomerulonephritis is a rare complication of malignancy and early recognition could prevent ineffective and potentially harmful therapy. The mechanism is unclear and doesn't appear to be correlated with the tumor burden, invasion, or metastasis but possibly with the by-products of tumor cells. We present an interesting and rarely reported case of paraneoplastic proliferative glomerulonephritis with monoclonal IgG deposits (PGNMID) associated with Diffuse large B-cell Lymphoma (DLBCL) that responded to Cyclophosphamide/doxorubicin/prednisone/rituximab/Vincristine (R-CHOP).

Case Description: A 63-year-old woman with a history of hypertension, and chronic lymphocytic leukemia(CLL) failed two lines of therapy admitted to the hospital for a second opinion. She was recently admitted for severe acute kidney injury (AKI) attributed to chemotoxicity with partial recovery upon therapy cessation. On exam, the patient appeared hypervolemia, with labs notable for acute kidney injury. Urinalysis with hematuria and 3+ proteinuria; urine protein: creatinine ratio of 1.9gm/24hr. A secondary workup showed Low C3, M protein < 0.1 g/dL, and SPEP/IFE showed a small protein peak in the gamma region (IgG2 kappa). The renal biopsy showed Membranoproliferative glomerulonephritis with a monoclonal IgG deposit (IgG2 Kappa). PET scan significant for hypermetabolic soft tissue lesion in the oropharynx with tonsil biopsy confirming the transformation of CLL to DLBCL. The patient received R-CHOP with subsequent improvement in renal function and proteinuria.

Discussion: PGNMID has previously been reported to be associated with hematological malignancies, including CLL and lymphomas, solid malignancies, and infections, in addition to Monoclonal gammopathy of renal significance(MGRS). Effective treatment requires differentiating between these associated conditions as treatment is directed toward that disease. Our patient had confirmed hematologic malignancy at the time of PGNMID, the diagnosis for which paraneoplastic PGNMID is more reasonable than MGRS. The observed paraproteinemia is likely evolved as a part of an underlying immunoproliferative disorder. Increased free light chain level has been considered an adverse prognostic factor and early chemotherapy is emphasized for patients with PGNMID-associated hematological malignancies.

SA-PO241

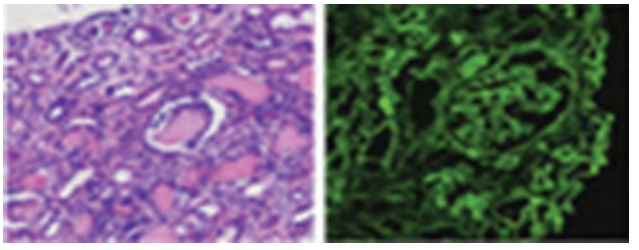
A Case of Combined Light Chain Deposition Disease and Light Chain Cast Nephropathy

Durga Pemmaraju, Iskra Myers. *ECU Health, Greenville, NC.*

Introduction: Light chain cast nephropathy (LCCN) is the most common renal disease caused by multiple myeloma (MM). Light chain deposition disease (LCDD) is characterized by the tissue deposition of non-amyloid immunoglobulin (Ig) light chains. Cases of LCCN with coexistent LCDD remain sporadically documented in literature with reported incidence of 10-50%. Diligent histopathologic analysis is required for correct diagnosis. We report a case of acute renal failure in a patient with MM caused by combined LCCN and LCDD.

Case Description: 57-year-old male presented with several weeks duration of bilateral ribs pain requiring multiple doses of ibuprofen. Physical exam was rather unremarkable. Initial blood work indicated creatinine 13.95 mg/dL, potassium 7.5 mg/dL, calcium 14.8 mg/dL, and hemoglobin 9.1 g/dL. The skeletal survey revealed diffuse lytic lesions. Retroperitoneal ultrasound showed bilateral kidneys ~15 cm in size. Serum protein electrophoresis revealed restricted peak in the gamma region, κ- to lambda (λ)-FLC ratio 7501.38. The patient required urgent dialysis followed by 5 treatments with plasmapheresis. Once bone marrow biopsy confirmed myeloma, chemotherapy with Cytoxan-Bortezimib-Dexamethasone regimen was initiated. Renal biopsy showed tubules with hard casts, diffuse linear glomerular and tubular basement membranes all staining for k-LC on IF. Electron dense deposits were not observed on EM. Patient remained dialysis dependent however, passed away 18 months later.

Discussion: Diagnosis of combined LCCN-LCDD is challenging and can be easily missed without meticulous analysis of LM, IF, and EM. Zand's group at Mayo Clinic, in largest study to date, reported that < 50% of the patients with LCCN-LCDD had evidence of electron dense deposits on EM but had evidence of LCDD by IF. Worse renal and overall survival outcomes are observed in LCCN-LCDD patients compared to those with LCCN or LCDD alone with mortality rate of >50% within the first year of diagnosis. Therefore, early detection and treatment is crucial for renal function stabilization and further studies are needed to establish an optimal mode of therapy.



SA-PO242

Single-Cell Sequencing Analysis of Paired Peripheral Blood Mononuclear Cell (PBMC) and Bone Marrow Mononuclear Cell (BMMC) Samples from Amyloidosis (AL) Patients

Weiting He. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Systemic light chain amyloidosis (AL) is the most common type of systemic amyloidosis. It has a variety of clinical manifestations and can involve multiple organs, kidney and heart are the most commonly affected organs. The diagnosis of AL depends on the presence of amyloid deposition of immunoglobulin light chain or heavy light chain as a precursor protein confirmed by biopsy, the existence of monoclonal immunoglobulin or free light chain in blood or urine, or the monoclonal plasma cells /B cells found in bone marrow examination. Previous studies have confirmed that single-cell sequencing is helpful to explore the pathogenesis of AL. Here, we performed single cell sequencing in AL patients with renal damage, and explored the specific clones and molecular characterization.

Methods: In this study, paired peripheral blood mononuclear cell (PBMC) and bone marrow mononuclear cell (BMMC) of 5 newly diagnosed AL patients and 3 healthy controls from Guangdong Provincial People's Hospital from March 2022 to June 2022 were collected. Single-cell sequencing and single cell repertoire sequencing were used to performed. Differentially expressed genes were obtained, and the related biological pathways were explored by GO and KEGG enrichment analysis.

Results: κ light chain (n=4) and λ light chain (n=1) were included in the 5 AL patients. UMAP map showed that AL patients had different expression patterns and contained more plasma B cells. GO and KEGG analysis showed that most of the marker genes were enriched in infection and binding related pathways. 274 differentially expressed genes were found between IGK and IGL cells. Using immune repertoire as comparison, specific clones were found such as the variable region of antibody V1-33 in subject AL2 was significantly expanded clones. Furthermore, the top five up-regulated genes were RHOB, CTSW, HSPA5, KRTCAP2 and MZB1, while the top five down-regulated genes were BTG1, CD79A, CD37, HLA-DRB1 and JUND.

Conclusions: Single-cell sequencing and single-cell immune repertoire sequencing revealed that AL patients contained more plasma B cells than healthy controls, most of the marker genes were enriched in infection and binding related pathways, and specific clonal amplification was found in some AL patients. The sequencing results can provide theoretical basis for the discovery of diagnostic biomarkers in AL patients with kidney damage in the future.

SA-PO243

A Novel In Vivo Model of Renal Cell Carcinoma (RCC) Angiogenesis

Rena Levin-Klein,[1] Grace Rabinowitz,[1] Shoshana Greenberger,[1,2] Pazit Beckerman,[1,2] Oren Pleniceanu.[1,2] *[1]Sheba Medical Center, Tel Hashomer, Israel; [2]Tel Aviv University, Tel Aviv, Israel.*

Background: Renal cell carcinoma (RCC) is the most common tumor in the kidney and currently lacks effective treatments. Remarkably, although RCC is an extremely angiogenic tumor, existing drugs aimed at inhibiting angiogenesis have shown disappointing results in patients. One potential reason for this discrepancy is the fact that most models used to dissect the molecular mechanisms of RCC angiogenesis involve transplantation of human tumor cells into mice, which results in development of host-derived vasculature, putting into question their clinical relevance. We have previously shown that combined transplantation of human kidney cells alongside human vessel forming cells into immunodeficient mice allows the generation of vascularized reno-vascular units. Herein, we aimed to develop a novel in-vivo model that will include RCC cells and vessels that are both human-derived.

Methods: We inoculated immunodefficient NOD-SCID mice with a combination of 10^6 fresh RCC cells and two types of human cells: (1) $5X10^5$ Endothelial Colony Forming Cells (ECFC); (2) $5X10^5$ Multipotent Stromal Cells (MSC), and analyzed the grafts following 3 weeks using immunostaining.

Results: Remarkably, the grafts developed into vascularized tumor units consisting of both RCC-like tissue, expressing classical markers of the tumor (e.g., PAX2 and PAX8), as well as human, HLA-positive blood vessels, contatining CD31+ endothelium, which were seen to feed the tumor tissue.

Conclusions: Taken together, this model represents a new purely-human inv-vivo model that allows studying the process of RCC angiogenesis, which could facilitate the uncovering of new mechanisms governing this critical process.

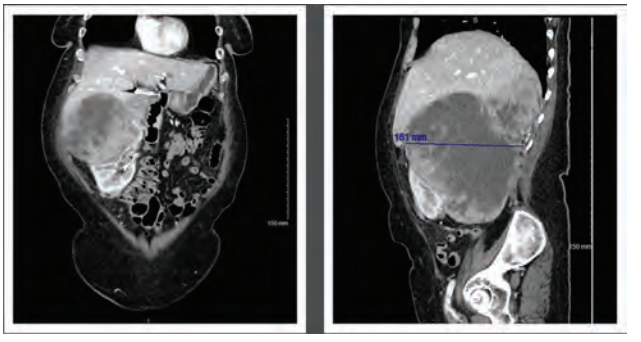
Elevated 1,25-Dihydroxy-Vitamin D Level: A Perplexing Case of Renal Sarcoma with Osteoclast-Like Giant Cells

Gregory Poulton,[1] Aisha Batool,[1] Veitla Rao,[2] Alexander J. Gallan,[1] Vineet Veitla.[1] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]Advocate Aurora Health Inc, Milwaukee, WI.*

Introduction: Elevated 1,25 Dihydroxy vitamin D(DHVD) level is commonly attributed to increased macrophage activity in chronic granulomatous conditions such as sarcoidosis. There are no reports yet of DHVD elevation in renal tumors. Renal sarcoma is very rare accounting for 0.8–2.7% of malignant kidney tumors and coexistence with Extra-skeletal Osteoclast-like giant cell tumors (OGCT) is not yet reported.

Case Description: Our patient is 74 years old Caucasian female with history of HTN. She came to ER with complaints of right sided abdominal pain, also reported 18 lb weight loss and poor appetite. CT abdomen with contrast revealed Interval enlargement of the very large, heterogeneous right renal mass compatible with renal cell carcinoma now measuring up to 15.2 x 16.1 x 17.9 cm which directly invades the right hepatic lobe (hepatic invasion has increased) and possibly the posterior abdominal/chest wall. Laboratory data significant for total serum calcium level 15.0 mg/dl, 25 Hydroxy vitamin D level 33.6ng/ml, 1, 25 hydroxyvitamin D level 133 pg/ml, iPTH level 6.4 pg/ml and PTH related peptide level 1.7 pmol/L. She underwent radical nephrectomy with histopathology showing High grade dedifferentiated sarcoma, with multinucleated giant cells involving kidney and extending into liver segment 6 and 7 (19.2 cm), with lympho-vascular and perinephric adipose tissue involvement. Cytogenetics significant for CD 10 positive, RCC markers negative, MDM2 focally positive, High positive for PD-L1. One week postoperative, laboratory data significant for normalization of 1,25 DHVD level 9.6pg/ml, and serum calcium 8.7 mg/dl.

Discussion: Resolution of hypercalcemia and normalization of DHVD levels after Sarcoma resection in our patient is very unique. The most effective therapy for renal and retroperitoneal sarcomas is the gross total resection of the tumor. Increased rates of necrosis, poor differentiation, mitotic activity and increased histological grade are associated with a poor prognosis.



SA-PO245

A Case of Paraneoplastic ANCA-Associated Glomerulonephritis in a Patient with Non-Small-Cell Lung Carcinoma

Nader Ismail, Kammi J. Henriksen, Marco A. Bonilla Arevalo. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Introduction: Paraneoplastic glomerular diseases are rare immune-mediated disorders temporally correlated with the detection of an underlying malignancy. The association between malignancies and glomerular diseases has been most commonly described with solid tumors and membranous nephropathy. In contrast, Anti-Neutrophil Cytoplasmic Antibody (ANCA) vasculitis in patients with solid carcinomas is a rare occurrence.

Case Description: A 76-year-old female former smoker with a medical history of Sjogren's syndrome presented to our nephrology clinic to evaluate worsening kidney function. Two months prior, she was diagnosed with metastatic squamous cell carcinoma of the lung and received 1 dose of pembrolizumab 1 week prior to nephrology evaluation. She reported decreased appetite, weight loss, and fatigue. Physical examination was remarkable only for blood pressure of 152/68 mmHg. Laboratory findings showed worsening serum creatinine from a baseline of 1.6 mg/dL (two months prior) to a peak of 4.1mg/dL. Urinalysis showed positive blood with >20 RBCs per HPF and a urine protein and creatinine ratio of 5g/g. Serological workup showed positive anti-SSA, positive anti-MPO, and negative anti-PR-3 titers. She underwent a kidney biopsy which revealed a focal pauci-immune crescentic and sclerosis glomerulonephritis. The decision was to temporarily hold the immunotherapy and to start treatment with corticosteroids and Rituximab. A 2-month clinical follow-up showed a serum creatinine stable to 2.4mg/dL.

Discussion: In the last decade, there has been increased awareness of the association between malignancies, cancer treatment, and glomerular diseases. A paraneoplastic glomerular disease can be challenging to distinguish from a drug-induced or a primary glomerular disease in the setting of illness and treatment of underlying malignancy. Moreover, it poses an essential dilemma regarding management decisions concerning treatment for underlying cancer versus treating the glomerular disorder if the therapies cannot be given concurrently. In our case, we attributed the AAV to a paraneoplastic glomerular disease; the subacute rise in the creatinine coincided with the newly diagnosed lung cancer. One dose of immune checkpoint inhibitor was less likely the culprit. This case adds to the literature on this rare manifestation of AAV presenting as a paraneoplastic disease.

SA-PO246

IgG4-Related Disease with an Unusual Presentation

William M. Paredes, Marjorie Mailing Flores Chang, Bessy Suyin Flores Chang.
SBH Health System, Bronx, NY.

Introduction: Immunoglobulin G4-related disease (IgG4-RD) is a chronic immune-mediated disease that can present with tumefactive lesions, fibrosis, and polyclonal IgG4-positive plasma cell infiltrate in nearly any anatomic site. It can manifest as lymphadenopathy, eosinophilia, and polyclonal hypergammaglobulinemia, and often mimics other hematologic conditions. However, the lack of a relationship between IgG4-related kidney disease and monoclonal gammopathy of renal significance (MGRS) warrants further investigation.

Case Description: 56-year-old male with spastic paraparesis secondary to cervical myelopathy due to severe cervical stenosis (C4-C5) with a history of chronic longstanding nasal congestion and obstruction. Started to have hyporexia, anosmia, weight loss, fatigue, rash and xerostomia for approximately 4 months. Accompanied by renal failure which was first detected 2 months prior to the onset of his symptoms. Urinalysis was negative and on microscopy had a bland appearance, ultrasound of the kidneys showed a mild bilateral increase in size. Further workup was relevant for Serum Free Kappa light Chains ratio of 9.7. Serum immunofixation was positive for IgG monoclonal protein with kappa light chain. Due to concern for myelodysplastic disorder, the patient underwent bone marrow biopsy which showed plasma cells that comprised 8-10 % of the nucleated hematopoietic bone marrow well-differentiated cells. There was no detectable clonal plasma cell population on flow cytometry prompting a diagnosis of MGUS for which he underwent kidney biopsy that revealed acute on chronic interstitial nephritis with many IgG4-positive plasma cells, suspicious for IgG4-RD. Currently receiving treatment with Rituximab and renal function has remained stable.

Discussion: This patient presented with xerostomia, constitutional symptoms, and development of renal failure, workup was diagnostic of MGUS. However, a kidney biopsy was performed and showed acute on chronic interstitial nephritis with IgG4-positive plasma cells, which leads to a diagnosis of IgG4-RD. An increased free light chain concentration has been reported in a variety of inflammatory and autoimmune diseases and reflects the polyclonal B lymphocyte activation in these pathologies. This presentation is fairly uncommon and the intention of this abstract is to make physicians aware of this for the future and warrant further investigation.

SA-PO247

Proximal Tubulopathy Secondary to Chronic Lymphocytic Leukemia After COVID-19 Infection

William M. Paredes, Marjorie Mailing Flores Chang, Bessy Suyin Flores Chang.
SBH Health System, Bronx, NY.

Introduction: Light chain proximal tubulopathy is a rare kidney disorder that occurs when free light chains are filtered by the kidneys and then accumulate in the tubules, leading to kidney damage and dysfunction. This condition is often associated with multiple myeloma. While chronic lymphocytic leukemia (CLL) is not typically associated with light chain proximal tubulopathy, there have been rare cases reported in the medical literature. However, to our knowledge, no reports have been found of developing both conditions after a COVID-19 infection.

Case Description: A 60-year-old male with pre-DM presented were decreased appetite, fatigue, and dizziness his physical examination was unremarkable. Initial workup was significant for COVID-19 infection, serum creatinine of 3.2 mg/dL, GFR: 20 cc/min, however, was discharged for outpatient follow-up. Urinalysis showed proteinuria and hematuria (33 RBC per hpf), serum creatinine stable to 3.3 mg/dL, GFR: 20 cc/min, spot protein to creatinine ratio of 1.8 g, ANCA profile, hepatitis B and C serologies were non-reactive. Complement C3 slightly decreased 73 mg/dL (82-167mg/dL), serum-free light chains ratio of 14.6. Prior serum creatinine was 0.9 mg/ dl ~4 years prior. Kidney biopsy demonstrated focal endocapillary and extra capillary proliferative glomerulonephritis with apparent lgG1 kappa deposits (light chain proximal tubulopathy), supporting the diagnosis of monoclonal gammopathy of renal significance (MGRS). Hemato-oncology evaluation noted worsening weight loss since the COVID-19 infection and left supraclavicular and bilateral inguinal lymphadenopathy with palpable hepatosplenomegaly. He underwent a bone marrow biopsy showing atypical lymphocytosis, trisomy 12 in 45.5% of cells, and flow cytometry findings of the clonal B-cell population (60-65% of total), immunophenotypically represents (CLL). Treatment was started with Venetoclax, febuxostat, and obinutuzumab. His serum creatinine stabilized at 2.4 mg/dL with a GFR of 28 cc/min.

Discussion: Chronic lymphocytic leukemia rarely can present with deposition of free light chains in the kidneys leading to Light chain proximal tubulopathy. We present a case of a patient who had this presentation after having a COVID-19 infection. To our knowledge, there have been no reported cases of MGRS or chronic lymphocytic leukemia after a COVID-19 infection.

SA-PO248

A Case of Multicentric Castleman Disease Mimicking IgG4-Related Kidney Disease

Erika Sawada, Yuya Shioda, Yuko Ono, Hajime Hasegawa, Akito Maeshima.
Department of Nephrology and Hypertension, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan.

Introduction: Multicentric Castleman disease (MCD) is a benign lymphoproliferative disorder with heterogenous clinical symptoms and involves systemic organs in addition to lymph nodes. Case reports have documented mesangial proliferative glomerulonephritis, membranoproliferative glomerulonephritis, and amyloidosis in patients with MCD. Here, we report a case of MCD showing numerous IgG4+plasma cell infiltration in the kidneys.

Case Description: A 55-year-old man was referred to our hospital for high fever and diarrhea. His laboratory data revealed anemia, renal dysfunction (eGFR 30 mL/min/1.73m^2), polyclonal gammopathy (IgG 7130 mg/dL), an elevated serum IgG4 level (2130 mg/dL) and an elevated C-reactive protein level (8.0 mg/dL). Abdominal CT showed multiple lymph nodes swelling (axillary, hilar, para-aortic, and inguinal). Biopsy of the axillary lymph node showed expansion of the interfollicular areas by heavily infiltrating plasma cells. Renal biopsy showed a significant plasma cell infiltration into the tubulointerstitium. Immunohistochemical analysis revealed a 45% IgG4-positive:IgG-positive plasma cell ratio, which meets the diagnostic criteria for IgG4-related disease. Amyloid A deposition was found along the vessel walls. No abnormality was found in most glomeruli. IF showed no deposition of immunoglobulins and complements. Serological cytokine analysis revealed elevated levels of interleukin-6 (9.3 pg/ml) and vascular endothelial growth factor (VEGF) (1210 pg/ml). Human herpesvirus-8 was negative. Taken together with histological finding of lymph node biopsy, idiopathic MCD was diagnosed.

Discussion: Corticosteroid monotherapy resolved the serological and imaging abnormalities, but was partially effective. Additional therapy with tocilizumab is planned. Given that response to steroid therapy and prognosis are different between MCD and IgG4-related disease, diagnosis of MCD should be carefully made based on a combination of findings including organ distribution of disease, response to steroid therapy, and other pathological findings. Highly specific diagnostic biomarkers that can distinguish between these diseases are needed.

SA-PO249

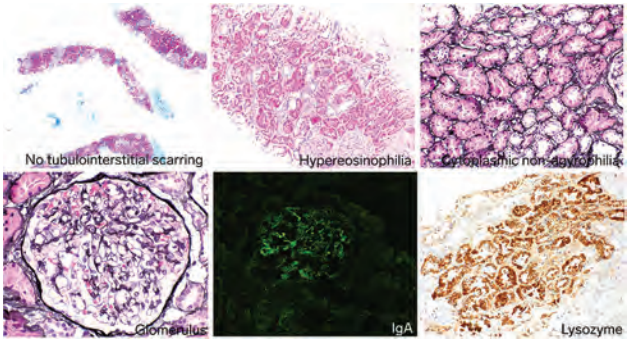
Lysozyme-Associated Nephropathy Successfully Treated with Dasatinib in Chronic Myeloid Leukemia

Chaitanya A. Pal,[1] Raja Ravender,[1] Saeed K. Shaffi,[1] J. Pedro Teixeira,[1] Darren W. Schmidt,[1] Tiffany Caza,[2] Pablo Garcia.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Arkansas Department of Education, Little Rock, AR.*

Introduction: Lysozyme-associated nephropathy (LyN) is a rare and underrecognized entity causing acute tubular injury. Serum lysozyme levels are elevated in chronic myelomonocytic leukemia and other forms of leukemia with myelomonocytic differentiation. We present a case of acute kidney injury (AKI) treated with dasatinib in the setting of chronic myeloid leukemia (CML) secondary to LyN.

Case Description: A 45-year-old man with a recent diagnosis of BCR-ABL-positive CML was referred to our clinic for abnormal renal function. At the time of CML diagnosis, his serum creatinine was 1.94 mg/dl and white blood cell count (WBC) was 203,000/microliter. He was treated with the tyrosine kinase inhibitor dasatinib and after six months his WBC normalized and creatinine improved to 1.6. His exam in renal clinic was notable for no hypertension or edema. Labs were significant for urine protein-creatinine ratio (UPCR) 0.2 g/g, kappa-lambda ratio mildly elevated to 1.85, and no evidence of Fanconi syndrome. Kidney biopsy revealed tubular injury with positive lysozyme staining in the proximal tubules and 2+ mesangial IgA staining with minimal interstitial fibrosis with a MEST-C score of 0. Since his CML was adequately treated, we concluded his lysozyme levels were likely improving. He continued dasatinib, and three months later creatinine improved further to 1.43 and UPCR was undetectable.

Discussion: Lysozyme is a cationic protein mainly produced by monocytes and macrophages. It is freely filtered at the glomerulus and reabsorbed in the proximal tubule via endocytosis. Excessive lysozyme production causes proximal tubulopathy and can result in AKI, Fanconi syndrome, and proteinuria. LyN is an underdiagnosed entity that often resolves with cytoreductive therapy. Interestingly, our patient had minimal proteinuria and no evidence of Fanconi syndrome, and we concluded his LyN had already responded to dasatinib by the time he was seen in renal clinic.



SA-PO250

Identification of Pathological Micro-Domains in Renal Carcinoma Biopsies Using High-Resolution Spatial Transcriptomics Signatures

Lavanya Muthukrishnan Iyer, Carolin Wiechers, Menglin Zheng, Silke Strassenburg, Leonie Neumann, Ramon Oliveira Vidal, Britta Seip, Timur Samatov, Rüdiger Fritsch, Uwe Andag. Spatial Team. *Evotec SE, Hamburg, Germany*.

Background: Kidney cancer globally ranks 14th in men, 9th in women, with most prevalence in North America and Europe. Clear cell renal cell carcinoma (ccRCC) arises in the proximal tubular epithelial cells (PTECs) and is currently treated with anti-angiogenic molecules and immune checkpoint inhibitors, leading to increased survival rates in responders. However, not all patients respond to these treatments. Here, we applied high-resolution spatial transcriptomics to biopsies of ccRCC patients, identified known markers of progression and gained novel insights into the micro-environments (ME) of affected kidney tissues.

Methods: FFPE tumor and healthy adjacent tissue biopsies from 2 ccRCC patients (ICD-10: C64) (51yr male-"A", 54yr female-"B") from Indivumed were assayed using 10x Genomics Visium CytAssist (FFPE human panel) and NanoString CosMx (1000-plex universal human panel, IF staining with CD298/B2M, PanCK, CD45, CD3) platforms.

Results: Initial analysis of Visium data revealed distinct differences between the two ccRCC patient tumors- while both patients showed a clear T cell response, we noted an extensive B cell response exclusively in patient A, whereas patient B showed a high number of proliferating tumor cells with angiogenesis. Within tumor A, we observed a striking correlation of the tissue ME to tumor PTECs function. While immune ME preserved normal PTEC metabolism, stromal ME comprised of fully transformed PTECs, highlighting that spatial ME plays a crucial role in tumor progression in ccRCC. Integrated analysis with a scRNAseq reference and CosMx further revealed rare populations of immune cells along the tumor edge within healthy adjacent tissue.

Conclusions: Overall, our high-resolution spatial transcriptomics data revealed patient-specific disease micro-domains and characterized molecular pathways in kidney cancer progression, paving the way for further analysis on distinct disease progression and unraveling potential therapeutic targets at the individual level.

SA-PO251

Characterization of Extracellular Matrix Composition in Wilms Tumor and Its Impact on Cellular Behavior

Laura Perin,[1,2] David S. Koos,[2] Matthew E. Thornton,[1] Brendan Grubbs,[1] Stefano Da Sacco,[1,2] Astgik Petrosyan.[1,2] *[1]University of Southern California Keck School of Medicine, Los Angeles, CA; [2]Children's Hospital Los Angeles, Los Angeles, CA.*

Background: Wilms Tumor (WT) is a pediatric renal cancer that arises from abnormal kidney development. The extracellular matrix (ECM) in the tumor microenvironment plays a critical role in supporting normal and cancerous cells and is essential for tumor growth and development. This study aims to understand the differences in ECM composition between normal kidneys and WT samples and how these variations affect cellular behavior.

Methods: We decellularized normal kidneys and WT patient samples using an optimized decellularization technique. Second-harmonic generation (SHG) microscopy and two-photon excited fluorescence (TPEF), combined with immunohistochemistry, were used to characterize the decellularized matrices (dECM). Expression of various cancer-related proteins in WT dECM samples was compared to normal kidney dECM samples using Proteome Profiler Human XL Oncology Array. Changes in gene expression of seeded SIX2+CITED1+ WT and human fetal kidney (hFK) progenitor cells on different dECM scaffolds were examined by immunofluorescence and bulk RNA-seq.

Results: Our study found differences in ECM fiber expression in WT dECM, with the outer layer comprising dense and elongated fibers, followed by pocketed and mesh-like structures. WT dECM exhibited elevated levels of oncoproteins ERBB2/3, SERPINE1, and MMP2 compared to normal kidney dECM. The dECM supported the long-term survival, migration, and proliferation of WT and hFK cells. When seeded on different dECM scaffolds, WT and hFK cells showed altered transcriptomic profiles and changes in cellular behavior. WT and hFK cells on WT dECM exhibited variations in ECM binding proteins (integrins) and increased expression of EMT and cancer stem cell markers like vimentin and SOX9 compared to normal kidney dECM.

Conclusions: This study provides valuable insights into the role of the ECM in regulating cancer cell behavior. The findings have significant implications for developing physiologically relevant in vitro tumor models and identifying novel therapeutic targets and mechanisms.

SA-PO252

Spontaneous Tumor Lysis Syndrome

Saeed Suleiman,[1] Charles Russell,[2] Naveen Punchayil Narayanankutty,[2] Kartikeya Srivastava,[4] Punith C. Chirumamilla.[3] *[1]Al Balqa Applied University, Al-Salt, Jordan; [2]University of South Florida, Tampa, FL; [3]Guntur Medical College, Guntur, India; [4]Srivastava Orthopaedic and Fracture Care Centre, Agra, India*.

Introduction: Tumor lysis syndrome is a life-threatening oncological emergency characterized by metabolic abnormalities including hyperuricemia, hyperphosphatasemia, hyperkaliemia and hypocalcemia. These metabolic complications predispose the cancer patient to clinical toxicities including renal insufficiency, cardiac arrhythmias, neurological complications and potentially sudden death. TLS is typically associated with the start of chemotherapy; however, in some instances, spontaneous TLS may occur without prior exposure to chemotherapy. STLS is typically seen in high-grade hematological malignancies such as B-cell non-Hodgkin lymphoma.

Case Description: A 68-year-old male with a history of hypertension presented with fatigue, poor appetite, and generalized weakness. He had been previously admitted to another hospital for hematemesis and was diagnosed with high-grade B-cell lymphoma found in a gastric ulcer biopsy. He developed acute kidney injury and urinary obstruction during that hospitalization. On presentation to our hospital, he denied other symptoms and had no further episodes of hematemesis. Initial lab results showed extremely high uric acid (>33.1 mg/dl), abnormal values for phosphorus, calcium, and creatinine. The patient was diagnosed with AKI secondary to acute spontaneous TLS. Standard treatment was initiated with Rasburicase, the patient needed hemodialysis. Chemotherapy was initiated for the lymphoma. After five days, the patient's lab values improved, and he remained stable, transitioning to continuous renal replacement therapy.

Discussion: In conclusion, this case report underscores the importance of recognizing and promptly treating STLS in patients with high-grade hematological malignancies. Even in the absence of chemotherapy, STLS can occur and lead to severe metabolic abnormalities and renal dysfunction. Early intervention with appropriate pharmacological and supportive measures is crucial to prevent complications and improve patient outcomes. Further research and awareness are needed to better understand the pathophysiology and optimal management of STLS.

	Day 0	Day 1	Day 2	Day 3	Day 4	Day 5

BUN (mg/dl)	119	89	61	48	26	33

SA-PO253

Chronic Myelomonocytic Leukemia (CMML)-Related Glomerulopathy Without Lysozyme Nephropathy

Priscilla Koirala, Raad B. Chowdhury, Nelson Leung. *Mayo Clinic Minnesota, Rochester, MN*.

Introduction: Myeloproliferative neoplasms (MPN) are clonal hematopoietic cell disorders characterized by expansion of the myeloid lineages. We are increasingly recognizing myeloid disorders causing glomerular disease. Chronic Myelomonocytic Leukemia (CMML) is a unique MPN overlap which has a few glomerular presentations. We present a rare case of myeloproliferative glomerulopathy secondary to CMML and review the renal course as the neoplasm progressed.

Case Description: A 85-year-old male with past medical history of heart failure and CMML was admitted for acute kidney injury and proteinuria. Initial labs were significant for creatinine of 2.18 (baseline function of 1.1-1.3) mg/dl, 2.6g/day of total proteinuria and 1.8g/day albuminuria. Urinary sediment showed less than 3 red cells, 1-3 white cells, with occasional granular casts and free fat. Serological evaluation and infectious workup were unrevealing. Kidney biopsy was consistent with MPN associated with glomerulopathy. There was no evidence of lysozyme nephropathy even though serum lysozyme levels were elevated >10.8 mcg/ml. Post hospital, he was seen in clinic and was started on a course prednisone with improvement of pr/cr to 0.30 mg/mg and creatinine improved to 1.4 mg/dl. After completing steroids, his renal function and proteinuria began to worsen to >3 mg/dl and 1.48 mg/g, respectively. Additionally, he continued to have worsening leukocytosis (126x103/µl) and monocytosis. There were increasing peripheral blasts and serum lysozyme levels worsened to >19.3 mcg/ml. It was apparent that the patient's CMML progressed to AML with coinciding worsening renal parameters.

Discussion: Renal manifestations secondary to MPNs are rare. When it is present, those with elevated lysozyme are presumed to have lysozyme nephropathy, a sign of advanced hematological disease. In this case, the patient's proteinuria and renal function improved with steroids. Once stopped, his hematological parameters worsened, with laboratory evidence of peripheral blasts, indicative of progression to AML. This coincided with worsening lysozyme levels and precipitous decline in renal function. In conclusion, renal disorders in the context of myeloid neoplasms warrant thorough investigation as it may be a sign of worsening hematological disease and the potential role of steroids for nephroprotection should be explored.

SA-PO254

Piperacillin/Tazobactam Dosing Recommendation in Critically Ill Patients Receiving Tablo Kidney Replacement Therapy

Susan J. Lewis,[1,2] Bruce A. Mueller.[3] *[1]University of Findlay, Findlay, OH; [2]Mercy Health St. Anne hospital, Toledo, OH; [3]University of Michigan, Ann Arbor, MI*.

Background: Tablo kidney replacement therapy (KRT) machines provide flexibility in treatment duration, frequency, and effluent rates to treat ICU patients with AKI. These KRT options may clear piperacillin/tazobactam (PIP/TAZ) differently than conventional KRTs. This study's purpose was to predict PIP/TAZ doses likely to attain the efficacy targets in critically ill patients receiving Tablo KRT, using Monte Carlo simulation (MCS).

Methods: Pharmacokinetic models were developed using pertinent demographic & pharmacokinetic parameters to predict PIP/TAZ exposure in 5,000 virtual, anuric patients receiving 5 different KRT regimens (Table 1). PIP/TAZ doses with 0.5 or 4 hour infusions were simulated to assess the probability of target attainment (PTA). The 3 PIP efficacy targets used were 1) free plasma concentrations above the MIC for ≥50% of the dosing

interval (≥50% *f*T>MIC), 2) free concentrations for ≥50% of the dosing interval ≥4 times above the MIC (≥50% *f*T >4xMIC), or 3) 100% *f*T >MIC. Breakpoint MIC used was 16 mg/L for *P. aeruginosa.* TAZ target was ≥50% fT> threshold concentration of 4 mg/L. The toxicity risk of each PIP dose was predicted with using a safety threshold (157 mg/L). The smallest doses attaining PTA≥90% during 1-week of therapy were considered optimal.

Results: PIP/TAZ doses attaining the different efficacy targets in the 5 KRT settings are shown in Table.

Conclusions: MCS predicted the same PIP/TAZ doses for 3x/wk HD, daily HD, sequential HD/UF, and PIKRT while higher doses are necessitated for extended therapy. Higher doses were required for aggressive efficacy targets, but these were likely to increase the toxicity risk. These findings need clinical validation.

Funding: Commercial Support - Outset Medical

Table. PIP/TAZ Dosing Recommendations in 5 Tablo KRT regimens

Setting #	Tablo KRT Settings				PIP/TAZ Doses Attaining Different Targets		
	Type	Effluent Rate (mL/min)	Duration (hours)	Frequency	50% fT>MIC	50% fT>4xMIC	100% fT>MIC
1	HD	Qd 300	4	Mon-Wed-Fri	4.5g q12h*	4.5g q8h or 3.375g q6h*	3.375g q6h*
2	HD	Qd 300	4	Daily			
3	Sequential HD/UF	Qd 300 Quf 5	HD 4, then UF 20	Daily			
4	PIKRT	Qd 100	9	Daily			
5	Extended Therapy	Qd 50	24	Daily	3g q8h	4g q6h	3g q6h

HD: Hemodialysis; UF: Ultrafiltration; PIKRT: Prolonged Intermittent Kidney Replacement Therapy;
Qd: dialysate rate; Quf: ultrafiltrate rate
Doses may be administered over 0.5 or 4 hours.
*Doses should be given after HD in settings 1-3 but can be given before or after in setting 4.

Drug-Drug Interaction Between Phosphate Binders and Daprodustat in ASCEND-D

Nicole S. Stankus,[1] Amy M. Meadowcroft,[2] Nisha Bhatt,[2] Angela R. Jones-Leone,[2] Purav R. Bhatt,[2] Jennifer Shannon,[2] Ajay K. Singh.[3]
[1]University of Chicago, Chicago, IL; [2]GSK, Collegeville, PA; [3]Brigham and Women's Hospital and Harvard Medical School, Boston, MA.

Background: Daprodustat (Dapro), a hypoxia-inducible factor–prolyl hydroxylase inhibitor (HIF-PHI), is an oral alternative to erythropoiesis-stimulating agent (ESA) therapy and is indicated in the USA for the treatment of anemia of chronic kidney disease (CKD) in adults receiving dialysis for at least four months. Phosphate binders (PB) are widely prescribed for hemodialysis (HD) or peritoneal dialysis (PD) patients (pts) in the USA (66.1% and 57.8%, respectively). Previous studies indicate the absorption of some HIF-PHIs may be affected by co-administration with PBs.[1,2] However, results from a phase II study of Dapro indicate PB use does not have a major impact on hemoglobin (Hb) values. Here we examined the effect of PB use at baseline on Dapro treatment dose and Hb using data from the phase III ASCEND-D study (NCT02879305) (Singh AK, et al. *N Engl J Med.* 2021;385:2325–2335).

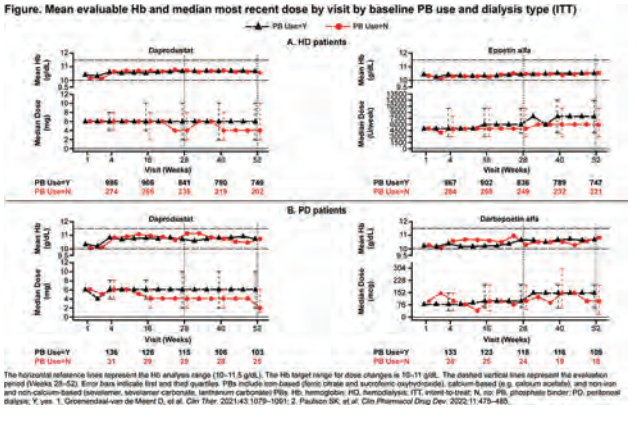
Methods: In ASCEND-D, 2964 pts with CKD undergoing dialysis and receiving ESAs were randomized in a 1:1 ratio to receive Dapro or injectable ESAs (epoetin alfa in HD pts or darbepoetin alfa in PD pts). Change in Hb and median doses from Weeks 1 to 52 was reported by baseline PB use and dialysis modality.

Results: 656 (22%) pts reported no PB use at baseline. In HD pts, the Hb profile in baseline PB users was generally indistinguishable from that in non-users, and the median Dapro/ESA dose was approximately one dose step higher than for pts with no PB use (**Fig. A**). While similar results were observed in PD pts, the number of pts reporting no PB use at baseline was too small to draw definitive conclusions (**Fig. B**). At Week 52, the majority of PB users and non-users had Hb within 10–11.5 g/dL, irrespective of treatment randomization.

Conclusions: This analysis demonstrated that baseline PB use had no major impact on the effect of Dapro on Hb levels in HD and PD pts.

Funding: Commercial Support - The study and this analysis were funded by GSK.

Figure. Mean evaluable Hb and median most recent dose by visit by baseline PB use and dialysis type (ITT)



The horizontal reference lines represent the Hb analyses range (10–11.5 g/dL). The Hb target range for dose changes is 10–11 g/dL. The dashed vertical lines represent the evaluation period (Weeks 28–52). Error bars indicate first and third quartiles. PBs include non-based (ferric citrate and sucroferric oxyhydroxide), calcium-based (e.g. calcium acetate), and non-iron and non-calcium-based (sevelamer, sevelamer carbonate, lanthanum carbonate) PBs. Hb: hemoglobin; HD, hemodialysis; ITT, intent-to-treat; N, no; PB, phosphate binder; PD, peritoneal dialysis; Y, yes. 1. Groenendaal-van de Meent D, et al. *Clin Ther.* 2021;43:1079–1091; 2. Exploring the Potential of Renal Dopaminergic System-Mediated Enhancement in Sodium Excretion by Canagliflozin

Guy Watanabe,[1,2] Shoichiro Horita,[2] Mamoru Satoh,[3] Shuichi Shigetomi,[4] Kenju Shimomura,[2] Junichiro J. Kazama.[1] *[1]Department of Nephrology and Hypertension, Fukushima Medical University School of Medicine, Fukushima, Japan; [2]Department of Bioregulation and Pharmacological Medicine, Fukushima Medical University School of Medicine, Fukushima, Japan; [3]Ota Nishinouchi Byoin, Koriyama, Japan; [4]Futaba Kosei Hospital, Futaba, Japan.*

Background: We have found that the renal dopaminergic system starts to activate along with the onset of diabetes/diabetic nephropathy, leading to sodium excretion before the occurrence of polyurea using spontaneously diabetic SDT rats. We raised the question of whether the SGLT2 inhibitors exert the natriuretic effects via the renal dopaminergic system in non-diabetic SD rats.

Methods: Sprague-Dawley (SD) rats (9-11 weeks old, male, N = 8 for non-treated rats, N=7 for canagliflozin-treated rats) were fed a commercial rodent diet. Canagliflozin (1.5-2mg/kg/day) dissolved with 200-250 mL of drinking water were orally administered every morning, from 14 to 25 weeks of ages. Blood samples were collected from the tail vein every week from the ages of 13 to 25 weeks, after which the body weight and the glucose levels. Each rat was individually housed in a metabolic cage for 24 h every week from the ages of 13 to 25 weeks and collected urine samples. At 26 weeks of age, rats were euthanized, perfused intracardially with saline containing heparin (20 IU/mL) and paraformaldehyde (PFA) for histological analyses.

Results: The plasma sodium concentration and blood glucose levels were similar across groups. But significant differences were observed in urinary sodium excretion, urinary glucose excretion, demonstrating the efficacy of canagliflozin. In mass spectrometry imaging analyses, mean values of cortical ionized L-DOPA intensity in canagliflozin-treated SD rats were significantly higher than the L-DOPA in non-treated SD rats. Also, we have observed that canagliflozin-treated SD rats exhibit significantly higher levels of reduced glutathione compared to control SD rats, suggesting a potential contribution to the reduction of renal oxidative stress.

Conclusions: Although further study needs to be conducted, we speculate that each mechanism, the activation of renal dopaminergic system and the suppression of oxidative stress, is another possible mechanism for kidney protection brought about by SGLT2 inhibitors. Possibly, the increased cortical reduction of oxidative stress may contribute to the detoxification caused by excess amounts of L-DOPA and DA.

One Drug, Different Mechanisms of Side Effects: Linezolid-Induced Thrombocytopenia and Type B Lactic Acidosis

Brock Manley, Ayman M. Alghamdi, Tushar Chopra. *University of Virginia, Charlottesville, VA.*

Introduction: As the burden of antibiotic-resistant bacteria grows, we must understand the pathophysiology and management of rare side effects of Linezolid.

Case Description: 73 yo male with a history of HTN, CKD 3 [baseline serum creatinine(Scr) of 1 mg/dl], and lumbar radiculopathy status post lumbar fusion complicated by infections from Enterobacter cloacae, vancomycin-resistant Enterococci, and methicillin-resistant Staphylococcus aureus (MRSA) treated with- ciprofloxacin 500 mg twice daily for 60 days before admission, 30 days of tedizolid 200 mg daily, and Linezolid 600 mg twice daily for 9 days, leading to this admission. On admission, the patient had a Scr of 1.6 mg/dl, platelets of 93 K/UL, and lactate of 3.35 mmol/L. Lactate increased to 3.9 mmol/L on hospital day (HD) 1 and returned to normal limits by HD 2 mmol/L. He had a platelet nadir of 43 K/UL on HD 5, along with improvement in Scr to 1.1 mg/dl. Platelet count recovered to 570 K/UL 12 days after admission.

Discussion: Linezolid induced lactic acidosis and thrombocytopenia is diagnosed after excluding other conditions such as hypoxemia, anemia or low cardiac output. Approximately 30% of linezolid is eliminated via the renal route, with an elimination half-life of 5 to 7 hours with the therapeutic trough concentration being 2–8 μg/ml. In patients with impaired renal function, elimination half-life increases from 6.1 to 8.4 hours. Mitochondrial toxicity of linezolid causes severe lactic acidosis usually related to its toxic trough serum levels. Two mechanisms of LIT have been proposed; decreased platelet production via bone marrow suppression, and immune-mediated platelet destruction. Pharmacokinetic modeling of the two mechanisms found that suppression of platelet formation was the significantly more prominent mechanism of LIT. Immune-mediated platelet destruction typically develops within 7-14 days and recovers rapidly, whilst bone marrow suppression-associated thrombocytopenia develops gradually over multiple weeks and recovers gradually. The latter was observed in this case; a gradual decline and recovery of platelet counts. One has to consider reducing linezolid dose in patients with renal insufficiency on prolonged treatment to reduce toxicity amongst patients at low risk for treatment failure while being guided by therapeutic drug monitoring.

SA-PO258

Linezolid Adsorption During In Vitro Model of Hemoperfusion with Mini-Module of HA380 Cartridge

Anna Lorenzin, Massimo de Cal, Claudio Ronco, Monica Zanella. *San Bortolo Hospital and IRRIV, Vicenza, Italy.*

Background: AKI due to sepsis is the result of a dysregulated host immune response to infection, with the production of inflammatory mediators and cytokines. Jafron HA380 cartridge has been specifically designed for cytokine storm in sepsis. Given the growing application of these hemoperfusion device, an unsolved problem is whether these polymers adsorb drugs, including antibiotics. *In vitro* experiments were conducted to determine its adsorption capacity towards Linezolid (LZD) antibiotic.

Methods: *In vitro* circulation was performed using a dedicated testing platform Galileo. A customized cartridge was built assembling mini-module components scaled in dimension towards HA380 and filled with 75g of HA380 beads (25% of the regular size). Blood pump was set at 250ml/min. Saline and human blood solutions enriched with 600mg of LZD have been tested for 2hrs. Samples were collected after the first passage (FP) through the cartridge and every 5 or 10min. LZD concentrations were measured. Adsorption was assessed considering the Removal Ratio:$RR(\%)=100x(C_0- C_t)/ C_0$.

Results: Experiment with saline solution was performed in duplicate. *In vitro* circulation confirms the affinity of beads material in binding LZD. The kinetics shows a rapid adsorption in the very first part of the experiments, after that the adsorption rate decreased due to the decrease of antibiotic available in the solution. After FP of the solution through the cartridge, a RR higher than 80% has been achieved. At the end of the experiments the adsorption reached about the 100% of RR. Blood circulation reinforced these results: the RR of FP was higher than 80%, and at the end the mass injected in the solution was almost entirely adsorbed (see table).

Conclusions: HA380 adsorbs significant amounts of LZD. Further investigation using a higher quantity of LZD is necessary to reach the saturation of the cartridge and understand the sorbent material capacity. These preliminary results highlight that there is an interaction that could affect the clinical outcome.

SA-PO259

Use of Antiplatelet Drugs Targeting Platelet P2Y12 Receptor Is Associated with Reduced Risk for Infectious Death in Veterans with CKD

Nishank Jain,[1] Prabin Shrestha,[2] Keiichi Sumida,[2] Fridtjof Thomas,[2] Jun Ling Lu,[2] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[2,4] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA; [4]VA Memphis Medical Center, Memphis, TN.*

Background: Platelets modulate thrombosis and inflammation, a hallmark of CKD pathophysiology. As a result, antiplatelet drugs are commonly used to reduce the risk of thrombosis in patients with CKD. Recent studies also demonstrated that platelet P2Y12 receptor inhibitors (P2Y12i) reduce inflammatory burden in patients with CKD, but their clinical impact on inflammation-related outcomes in CKD is not established. We investigated whether treatment with P2Y12i is associated with reduction in infection related deaths among patients with CKD.

Methods: We examined a national cohort of 90,701 US Veterans with incident CKD who were new P2Y12i users and 431,188 who never received P2Y12i. We used clinical trial emulation methods to examine the association of P2Y12i therapy with infectious deaths in competing risk regressions and cause-specific Cox models using propensity score (PS) overlap weighting to balance for baseline differences in demographics, comorbidities, laboratory values, and relevant medications use.

Results: Overall mean (SD) age was 69 (11) years, and eGFR was 69 (17) ml/min/1.73m^2; 95% were men; 16% were African Americans; 46% were diabetics. During a median follow-up of 6.8 years, there were 4,823 infectious deaths with 986 deaths in P2Y12i users (event rate and 95%CI: 0.87/1000PY, 0.82-0.92) and 3,837 deaths in non-users (1.45/1000PY, 1.4-1.5). P2Y12i therapy was associated with a reduced risk of infectious deaths in competing risk regressions and in cause-specific Cox models (Table).

Conclusions: In a large national cohort of Veterans with incident CKD, use of P2Y12i was associated with reduced risk of infectious deaths. The role of P2Y12i in the management of inflammation in CKD requires additional testing in prospective trials.

Torasemide Decreases Kynurenic Acid Production in Rat Kidney In Vitro

Izabela Zakrocka, Wojciech T. Zaluska. *Uniwersytet Medyczny w Lublinie, Lublin, Poland.*

Background: Loop diuretics are one of the most widely used agents in the treatment of congestive heart failure or arterial hypertension and related edemas. Torasemide is known to have longer time of action compared to other class representatives and thus more often chosen to stimulate diuresis. It was speculated that torasemide by volume depletion can be responsible for impaired kidney function, however direct nephrotoxic effect cannot be excluded. Tryptophan metabolites are well described uremic toxins. Among them kynurenic acid (KYNA) presents ambiguous effects. KYNA is a broad spectrum glutamatergic receptors antagonist, an agonist of cholinergic alpha-7-nicotinic receptors and a ligand of aryl hydrocarbon receptors. Direct precursor of KYNA, kynurenine (KYN) is metabolized through kynurenine aminotransferases (KATs). In animal models of hypertension KYNA was reported to cause natriuresis and lower the heart rate. On the other hand, it was observed that KYNA accumulated in the body proportionally to kidney function decline in animal and human studies. The aim of our study was to examine the influence of torasemide on KYNA synthesis and KATs isoenzymes activity, KAT I and KAT II, in rat kidney *in vitro*.

Methods: KYNA production and enzymes activity was analyzed in kidney homogenates and on purified enzymes after 2 hours incubation in the presence of L-KYN and torasemide in 6 different concentrations (1 μM, 10 μM, 50 μM, 100 μM, 500 μM, 1 mM). Due to limited drug's solubility torasemide was tested in kidney homogenates up to 500 μM concentration, whereas enzymes activity was analyzed up to 1 mM concentration. The amount of formed KYNA was quantified by high-performance liquid chromatography.

Results: Torasemide at 500 μM concentration decreased KYNA production to 68 % ($p < 0.05$) of control value. At 500 μM and 1 mM concentration torasemide inhibited KAT I activity to 78 % ($p < 0.05$) and 43 % ($p < 0.05$) of control value, respectively. Only at 1 mM concentration torasemide lowered KAT II activity to 17 % ($p < 0.01$) of control value.

Conclusions: We show for the first time that torasemide inhibits KYNA production and KATs activity in rat kidney *in vitro*. Further studies are warranted to investigate the impact of presented results on kidney function.

SA-PO261

Lack of Consistency in Loop Diuretic Strategies of Acute Heart Failure

Amer A. Belal, Alejandro J. Ruiz Toledo, Amir Kazory. *University of Florida College of Medicine, Gainesville, FL.*

Background: Symptoms and signs of fluid overload are the primary reason for hospitalization of patients with acute heart failure (AHF). Intravenous loop diuretics (LD) remain the mainstay of therapy in this setting, with a significant subset of patients showing suboptimal response. The efficacy of combination diuretic therapy (CDT), a widely applied strategy to counter renal sodium avidity, is compared against LD-based regimens that are considered the standard of care. We sought to explore the consistency of LD use in contemporary trials of CDT in AHF.

Methods: Articles cited in the PubMed database using keywords "acute heart failure", "diuretic", and "congestion" were searched. Available data from clinical trials performed between January 2005 and December May 2023 were included. The studies were selected if 1) they were randomized controlled trials that explored the role of CDT in management of AHF, and 2) included loop diuretics as their control arm. Pertinent data on clinical and laboratory parameters (e.g. diuresis, weight change, and renal function) were extracted and reviewed.

Results: A total of 13 studies with 7,826 participants were included with a mean age of 72 years. They consisted of a variety of HF populations with a mean ejection fraction of 38% and an estimated GFR of 49 ml/min. The add-on agents were SGLT-2 inhibitors, acetazolamide, hydrochlorothiazide, spironolactone, and tolvaptan. There was substantial variation across studies both in the loop regimen and the reporting of decongestion markers (e.g. diuresis and weight change). The urine output on day-1 ranged from 1183 to 2400 ml (mean 1620.8 ±413 ml), while weight loss on day-1 was more consistent (0.94 to 1.2 kg; mean 1.04±0.1 kg).

Conclusions: While the current guidelines of AHF recommend intensifying LD therapy prior to CDT to enhance the decongestion process, there is no consensus on an optimal diuretic strategy. This study shows that 1) the LD regimens used in contemporary trials of CDT are highly variable, 2) the inconsistency in these regimens results in a highly variable diuresis as a marker of decongestion, and 3) a reliable comparison of the efficacy of add-on agents is challenging due to lack of consistency in the control arm. These results call for the development of an optimal LD strategy for AHF to help improve the decongestion process.

Accelerating Drug Discovery for CKD Through Mendelian Randomization Analyses of Druggable Proteins

Jefferson L. Triozzi,[1] Guanchao Wang,[1] Adriana Hung.[1,2] Million Veteran Program. *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: Drug repurposing can accelerate the discovery of treatments for chronic kidney disease. To identify potential therapeutic targets, we conducted Mendelian randomization analyses using genetic instruments for proteins targeted by approved drugs or drugs in clinical development.

Methods: Genetic instruments for 879 druggable proteins were derived from the Genotype-Tissue Expression (GTEx) project. Kidney outcomes included estimated glomerular filtration rate (eGFR), chronic kidney disease (CKD), and end-stage kidney disease (ESKD) derived from genome-wide association study summary statistics of European ancestry individuals in the Million Veteran Program (MVP). A drug target was considered significant if it met study-wide Bonferroni significance in the inverse variance weighted analysis for all three kidney outcomes stratified by diabetes status. Significant findings in MVP were replicated in the Chronic Kidney Disease Genetics Consortium (CKDGen). Analysis was performed using the TwoSampeMR package in R version 3.3.3 using the Vanderbilt Advanced Computing Center for Research and Education.

Results: Our study identified 69 independent drug targets within MVP ($p < 9.48E-06$). Shared targets in non-diabetic patients were Myosin Heavy Chain 7B (p_{eGFR} = 8.70E-08, p_{CKD} = 5.95E-17, p_{ESKD} = 5.80E-12) and Gonadotropin Releasing Hormone Receptor (p_{eGFR} = 3.61E-14, p_{CKD} = 1.94E-15, p_{ESKD} = 2.07E-09, 3.24E-17). Shared targets in diabetic patients were HLA-DRB1 (p_{eGFR} = 3.31E-54, p_{CKD} = 1.05E-53, p_{ESKD} = 1.72E-14), Glycoprotein Nmb (p_{eGFR} = 1.52E-14, p_{CKD} = 5.37E-16, p_{ESKD} = 2.31E-10), and Gonadotropin Releasing Hormone Receptor (p_{eGFR} = 2.56E-15, p_{CKD} = 5.45E-08, p_{ESKD} = 1.42E-08). All findings in MVP were replicated in CKDGen. The direction of effect was consistent across all findings, except for Gonadotropin Releasing Hormone Receptor which exhibited a positive effect in diabetic patients and a negative effect in non-diabetic patients.

Conclusions: Our findings highlight potential targets for therapeutic intervention in CKD. Pathway enrichment analyses are underway to explore underlying mechanisms. Further studies should confirm the causal relationship between druggable proteins and kidney outcomes.

Health Effects (Renal) Of Extra Strength Avmacol (HEROES) Study: Results from the Pharmacokinetic Phase of a Randomized Double-Blind Placebo-Controlled Trial

Yves T. Wang, Allison J. Stewart, Sharvari A. Sonawane, Rita Ghimirey, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Increased oxidative stress is a major molecular underpinning of chronic kidney disease (CKD) progression. Decreases in the antioxidant enzyme glutathione-S-transferase μ-1 (GSTM1) due to a very common null gene variant have been shown to elevate oxidative stress and increase disease progression in animal and clinical studies. GSTM1 and many other antioxidant enzymes are regulated by the nuclear factor erythroid 2-related factor 2 (Nrf2) pathway. This pathway can be upregulated by sulforaphane (SFN), which can be obtained naturally from cruciferous vegetables such as broccoli. Commercially available SFN supplements provide much greater consistency in dosage compared to dietary intake, and mouse studies have shown oral supplementation to be protective in CKD. We hypothesize that daily intake of SFN – in the form of Avmacol Extra Strength (ES) – will decrease CKD progression rate and decrease markers of oxidative stress and inflammation. We will test the safety, tolerability, and efficacy of Avmacol ES taken daily for 6 months in CKD Stages 3-4 in a randomized, double-blind, placebo controlled clinical trial.

Methods: A pharmacokinetic (PK) study was first performed to establish an optimal dose of Avmacol ES for CKD patients with eGFR of 25 – 45 mL/min/1.73m² to achieve similar peak concentrations and area under the curve (AUC) of plasma SFN observed in non-CKD patients. Subjects were given 2, 4, or 6 tablets once daily for 7 days. Plasma was collected at 0-8 h after the last dose. SFN levels were measured by LC/MS/MS.

Results: Peak plasma concentration (C_{max}) was reached between 2-4 h (t_{max}) in subjects taking 4 tablets (average C_{max}: 120 nM, AUC8h: 824 nmol h/L, n = 4) and in those taking 2 tablets (average C_{max}: 85.1 nM, AUC8h: 581.4 nmol h/L, n=4). No C_{max} was observed in those taking 6 tablets during 8h, and gastrointestinal (GI) side effects (SE) were significant. Both 2 and 4 tablets daily were well tolerated with minimal GI SE.

Conclusions: In CKD 3-4, SFN t_{max} is delayed compared to the 1-2 h t_{max} reported in non-CKD subjects. Avmacol ES 4 tablets daily is well-tolerated with greater and more consistent C_{max} and AUC than 2 tablets daily and is being used in the on-going randomized phase.

Magnetic Resonance Imaging Contrast Agent Safety: Prodigious Phosphorus in Renal Gadolinium-Rich Nanoparticles

Brent Wagner,[1,2] Karol Dokladny,[1,3] G. P. Escobar,[1,3] Joshua Deaguero,[1,3] Ian Henderson,[5,1] Tamara A. Howard,[3,1] Adrian Brearley.[4,1] *[1]Kidney Institute of New Mexico, Albuquerque, NM; [2]New Mexico VA Health Care System, Albuquerque, NM; [3]University of New Mexico Health Sciences Center, Albuquerque, NM; [4]University of New Mexico, Albuquerque, NM; [5]Omphalos Bioscience, Albuquerque, NM.*

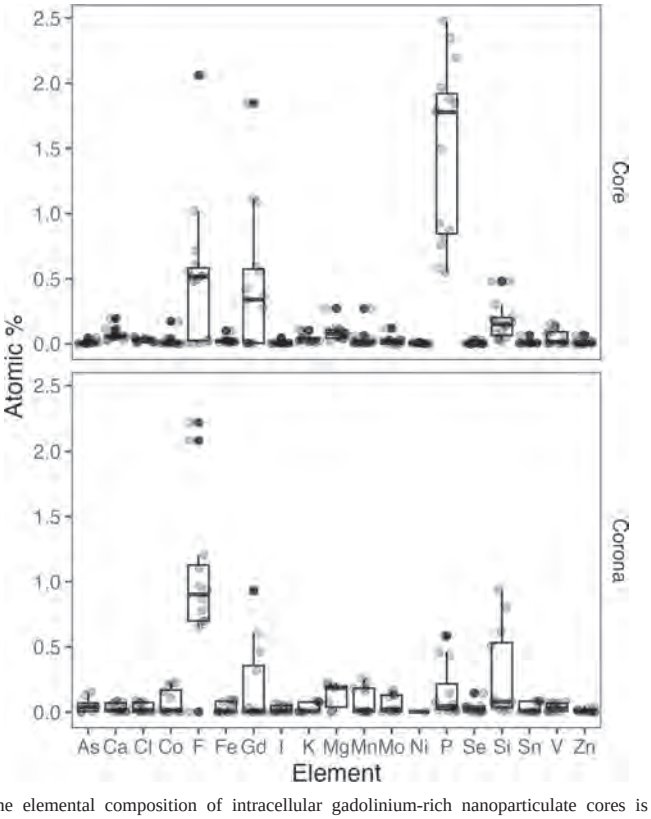
Background: Magnetic resonance imaging (MRI) contrast agent complications include fibrosis, kidney injury, and fatal gadolinium encephalopathy. Routine diagnostic imaging leads to the formation of gadolinium-rich nanoparticles in human kidneys. The mechanism is unclear.

Methods: Mice were treated with a MRI contrast agent. After four weeks of treatment and a washout period of 0.5 weeks, the kidneys were harvested. Flash-frozen kidney samples were homogenized in radioimmunoprecipitation assay buffer. Gadolinium-rich nanoparticles were purified from homogenate ultracentrifuged through sucrose gradients of different concentrations. We localized the nanoparticles using transmission electron microscopy (TEM). The elemental characterization of the nanoparticles was obtained using X-ray energy-dispersive spectroscopy (aberration-corrected scanning TEM, JEOL NEOARM). We compared quantities between core and coronal areas using a two-tailed t-test. We adjusted the p-values using the Benjamini-Hochberg (B-H) method to account for false discoveries.

Results: Electron-dense intracellular debris peppered the proximal tubular epithelium. The dendritic cores and coronas contained high levels of gadolinium. Among the elements, phosphorus was 9.5-fold higher in the cores ($p = 1.2 \times 10^6$).

Conclusions: There is more than one side to the argument concerning the safety of MRI contrast agents. Our findings suggest that nanoparticulate dendritic cores exhibit high phosphorus levels, which does not support the formation of $GdPO_4$ precipitate. These results contribute to understanding the mechanism of gadolinium-induced complications.

Funding: NIDDK Support, Other NIH Support - UL1TR001449, Veterans Affairs Support, Private Foundation Support



The elemental composition of intracellular gadolinium-rich nanoparticulate cores is glutted in phosphorus than the peripheral coronas.

Hydralazine Adduct Formation on Myeloperoxidase Contributes to Development of Drug-Associated ANCA Vasculitis

Gang Xi,[1] Elizabeth A. McInnis,[1] Olivier Lardinois,[2,1] John S. Poulton,[1] Dhruti P. Chen,[1] Evan Zeitler,[1] Vimal K. Derebail,[1] Ronald Falk.[1] [1]*The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC;* [2]*National Institute of Environmental Health Sciences, Research Triangle Park, NC.*

Background: Hydralazine exposure, an anti-hypertensive agent and a carbonyl scavenger, is associated with the development of ANCA vasculitis. We propose a pathogenic mechanism for hydralazine associated ANCA vasculitis hinging on formation of hydralazine adducts on myeloperoxidase (MPO), the primary immunogen for MPO ANCA.

Methods: *In vitro* hydralazine studies were performed using horse metmyoglobin (Mb) and human MPO. Hydralazine labeled Mb was digested by trypsin and peptides were analyzed with reverse phase HPLC and electrospray mass spectrometry. In addition, hydralazine labeled MPO was separated using PAGE gels and the hydralazine adduct was detected using an anti-hydralazine antibody. Commercially anti-MPO antibodies recognizing different portions of MPO were used to investigate the conformational change of the MPO heavy chain after hydralazine adducts formation. In addition, an immunoprecipitation assay was performed to detect hydralazine adducts on circulating MPO from patients. Furthermore, anti-MPO IgM and IgG antibodies were measured using ELISAs. Purified IgM and IgG from patients and healthy controls' plasma were investigated their ability to recognize control MPO or hydralazine labeled MPO.

Results: *In vitro* studies showed that carbonyl groups formation on primary amines of a protein in the presence of aldehydic products, such as acrolein, is required for hydralazine to bind a protein. Mass spectrometry data showed that hydralazine bound to a carbonyl group of Mb. Under similar conditions, hydralazine adducts were formed on MPO. Importantly, the hydralazine adducts on MPO could be detected in plasma from hydralazine associated ANCA patients but not from patients with non-hydralazine associated ANCA or healthy subjects. Using commercially anti-MPO antibodies, we demonstrated that hydralazine adducts formation on MPO resulted in conformation changes. In addition, purified IgG and IgM autoantibodies from hydralazine associated ANCA patients were reactive against hydralazine labeled MPO.

Conclusions: Under appropriate reactive conditions, hydralazine adducts were able to be formed on MPO in some subjects who were exposed to hydralazine. Hydralazine adducts induced MPO conformational changes which may facilitate autoantibody development, leading to hydralazine associated ANCA vasculitis.

Dapagliflozin Ameliorates Cisplatin-Induced Nephrotoxicity by Upregulating Nuclear Factor Erythroid 2-Related Factor 2/Heme Oxygenase-1 Signaling Pathway: A Pre-Clinical Molecular Approach

Anuradha A. Nair, Mohamed Farook, Nirmal N. Binu, Sofiya Khan, Mohamed Yehya Mohamed Mustafa, Mohammed M. Khan, Shakta Mani Satyam, Laxminarayana K. Bairy, Abdul Rehman. Dr. Satyam's Lab - DAPA CKD Team. *Ras Al Khaimah Medical and Health Sciences University College of Medical Sciences, Ras Al Khaimah, United Arab Emirates.*

Background: A dose-limiting side effect of cisplatin administration is nephrotoxicity which impairs a patient's quality of life. No potent nephroprotective agent is available to combat cisplatin-induced nephrotoxicity. This study aimed to explore the nephroprotective potential of dapagliflozin and silymarin alone and in combination against cisplatin-induced nephrotoxicity in Wistar rats.

Methods: 30 adult Wistar rats were randomly divided into five groups (n=6/group): Group I- Normal control, Group II- Negative control, Group- III- Silymarin, Group IV- Dapagliflozin and Group V- Dapagliflozin + Silymarin. Nephrotoxicity was induced in Group II to Group V by administering cisplatin weekly for seven weeks. Biomarkers for kidney injury, inflammation, and oxidative stress were estimated following a histopathological examination of the kidney.

Results: Chronic kidney disease was significantly ($p<0.05$) demonstrated in cisplatin-intoxicated (negative) control compared to normal control rats. Dapagliflozin alone and in combination with silymarin significantly ($p<0.05$) reduced serum urea, creatinine, inflammatory cytokines, and oxidative stress markers compared to negative control.

Conclusions: The present study revealed that dapagliflozin alone and in combination with silymarin ameliorates cisplatin-induced nephrotoxicity in Wistar rats via stimulating Nrf2/HO-1 signaling pathway.

Pharmacological Inhibition of Lysine-Specific Histone Demethylase 1 Protects Against AKI

Baihai Jiao,[1] Hao Du,[1] Melanie Tran,[1] Bo Song,[1] Yanlin Wang.[1,2] [1]*UConn Health, Farmington, CT;* [2]*VA Connecticut Healthcare System, West Haven, CT.*

Background: Acute kidney injury (AKI) is a common clinical condition associated with increased mortality and morbidity. Current therapeutic options for this serious disorder are often limited and ineffective. Therefore, new therapeutic strategies are urgently needed to prevent or treat AKI. Macrophages play a critical role in the pathogenesis of cisplatin-induced AKI. However, the molecular mechanisms underlying macrophage activation in AKI are not fully elucidated. In this study, we investigated the role of lysine-specific histone demethylase 1 (LSD1) in the regulation of macrophage activation in the development of cisplatin-induced AKI.

Methods: To examine the role of LSD1 in cisplatin-induced AKI in vivo, wild-type C57BL6/J mice were administered intraperitoneally with a single dose of 20 mg/kg cisplatin to induce AKI and treated with GSK-LSD1, a selective LSD1 inhibitor, at 1 mg/kg or vehicle daily by intraperitoneal injection for 3 days. Cultured bone marrow-derived macrophages were used to examine the role and mechanisms of LSD1 in the regulation of macrophage activation in vitro.

Results: The expression of LSD1 was increased in macrophages in the kidney following cisplatin-induced AKI. Pharmacological inhibition of LSD1 with GSK-LSD1 protected the kidney from cisplatin-induced AKI and preserved kidney function in vivo. Furthermore, pharmacological inhibition of LSD1 with GSK-LSD1 suppressed macrophage activation, attenuated the NLRP3 expression, and inhibited inflammasome activation, resulting in reduced cleaved caspase 1 and IL-1β levels in the kidneys of cisplatin-induced AKI. In bone marrow-derived macrophages, pharmacological inhibition of LSD1 with GSK-LSD1 abolished macrophage activation and suppressed proinflammatory cytokine production. Moreover, GSK-LSD1 blocks NLRP3 expression and inflammasome activation in bone marrow-derived macrophages.

Conclusions: Our study identifies LSD1 as a critical regulator of NLRP3 expression and inflammasome activation in macrophages, leading to proinflammatory molecule production and development of cisplatin-induced AKI. Therefore, targeting LSD1 may represent a novel therapeutic strategy for AKI.

Human Primary Renal Proximal Tubule 3D Spheroid Model for Kidney Injury and Drug Discovery

Yougang Zhai, Shanker Kalyana-Sundaram, Alessandro Pocai, Lifeng Wang. CVMR-PH Discovery, Janssen Research & Development LLC. *Janssen Research and Development LLC, Raritan, NJ.*

Background: Renal proximal tubular epithelial cells (RPTECs) have a prominent role in maintaining kidney function by reabsorbing filtered nutritional substances, while allowing other substances to be excreted in the urine. RPTEC injury, cell death, and de-differentiation are mechanisms involved in kidney diseases including acute kidney injury (AKI). Human primary RPTECs isolated from normal human kidney tissue maintain the original phenotype *in vitro* for several passages and provide a translational advantage for studying nephron function and pathophysiology. Conventional two-dimensional culture methods frequently result in loss of tissue-specific RPTEC phenotypes partially due to changes of cell-cell communications and microenvironment. Hence, 3D models of RPTECs are being developed and used for drug discovery.

Methods: Primary hRPTECs were cultured in ULA spheroid plates for 4 days to form spheroids. Cellular injury was then induced by treatment with cisplatin or incubation in hypoxic chambers. Cytokine concentration, cell viability and apoptosis were measured by using commercial kits. RNA-seq were carried out, and pathway enrichment were analyzed by using Ingenuity Pathway Analysis software.

Results: Here we found that compared to 2D cultured cells, the hRPTEC 3D spheroid increased cisplatin induced injury responses and sensitivity with higher apoptosis and lower cell viability. Hypoxic condition induced significant increase of cell apoptosis and decrease of cell viability in hRPTEC spheroid. Transcriptomic analysis on the 3D hRPTEC hypoxia injury model identified similar pathway changes that found in *in vivo* in ischemic AKI models. Pathway analysis in this model supports a role of IL-17A in promoting hRPTEC inflammation and injury. In contrast, SIRT3 activator treatment protected hRPTEC from hypoxia injury likely by improving energy metabolism and mitochondria function.

Conclusions: 3D injury models in primary hRPTEC spheroid are more sensitive to cisplatin injury than 2D cultures and pathway analysis revealed pathway changes consistent with a role of IL-17. The models provide a physiological and pathophysiological tool, to evaluate the function and pathophysiology of the kidney with higher translational relevance and can be leverage for fast screening and evaluation of potential therapeutic targets for kidney diseases.

Distinct Pharmacokinetics of AAV9 and AAVKP1 Enable Context-Dependent Efficient Renal Transduction

Taisuke Furusho, Mia S. Galbraith-Liss, Anusha Sairavi, Ranjan Das, Hiroyuki Nakai. *Oregon Health & Science University, Portland, OR.*

Background: Recent progress in capsid engineering led to generation of numerous adeno-associated virus (AAV) vectors with novel phenotypes. However, they have not been evaluated in the context of renal gene transfer. Increased permeability of glomerular and peritubular capillary (PTC) is a common feature of CKD, but renal transduction in CKD kidney is yet to be characterized.

Methods: Renal transduction of 47 different AAV vectors following IV and renal vein (RV) administration was evaluated in C57BL/6J mice using NGS-based high-throughput method called AAV Barcode-Seq. Effect of CKD on renal transduction was assessed in X-linked Alport syndrome model mice. Select AAV vectors were individually vectorized and relationship between renal transduction and pharmacokinetics was evaluated.

Results: AAV Barcode-Seq followed by individual characterization revealed that proximal tubule (PT) and podocyte transduction is not attainable by IV administration of AAV vectors. On the other hand, AAVKP1 but not AAV9 transduced PT following RV administration. Assessment of injection path using fluorescent microspheres showed accumulation in the cortical interstitial space following RV administration. Interestingly, >10 times more AAVKP1 vectors were detected in the injected kidney ten minutes post RV administration compared to AAV9. These observations suggest that RV administration bypasses PTC and efficient interstitial retention of AAVKP1 enables PT transduction from basolateral side. In contrast to minimal urinary excretion of AAV vectors in healthy mice, excretion of AAV9 but not AAVKP1 was significantly increased in CKD mice by about 10^4 times following IV administration. Difference between AAV9 and AAVKP1 is explained by rapid blood clearance of AAVKP1 that shows >1000 times less blood concentration than AAV9 over eight hours post injection. Consistent with this observation, IV administration of AAV9 but not AAVKP1 achieved efficient podocyte and PT transduction in CKD kidney, suggesting that higher blood concentration of AAV9 facilitates access to podocytes and PT across leaky glomerular filtration barrier and PTC in CKD.

Conclusions: Our study underscores the important role of AAV pharmacokinetics in renal gene transfer. Appropriate selection of AAV vector depending on administration route and host condition is vital for successful gene therapy.

SA-PO270

RXFP1, the Relaxin Receptor, Is a Therapeutic Target Expressed in the Human Kidney, Not Rodent

Mark Lal,[1] Sean Eddy,[2] Jeffrey B. Hodgin,[2] Magnus Althage,[1] Pernille B. Laerkegaard Hansen,[1] Jaakko Patrakka,[3] Matthias Kretzler.[2] *[1]AstraZeneca PLC, Gothenburg, Sweden; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Karolinska Institutet, Stockholm, Sweden.*

Background: RXFP1 is a G-protein coupled receptor (GPCR) potently agonized by its cognate ligand, relaxin. Historically named the pregnancy hormone following its identification and physiological description in rodents, relaxin is broadly recognized as a circulating hormone possessing several potentially clinically relevant cardiovascular-modulating and anti-fibrotic properties. It has long been recognized that there is remarkable diversity among species with regard to tissue source, regulation of synthesis and secretion, and physiological effects of relaxin. On the other hand, there is limited and inadequate understanding of RXFP1's tissue and cell expression across species, especially human.

Methods: Here, we describe the human target validation of RXFP1 in human kidney and highlight striking differences with rodent.

Results: As opposed to mouse and rat kidney, where RXFP1 is poorly expressed, RXFP1 is identified as one of the most highly expressed GPCRs in human glomeruli. Specifically, by single cell RNAseq, in situ hybridization and immunohistochemistry, we identify glomerular endothelial cells as the principal cell type expressing RXFP1. Through extensive analysis of human kidney expression data sets from patient biopsies, we find that RXFP1 expression correlates with kidney function and disease progression. We identified a 428 gene RXFP1 co-expression network (R>0.6, FDR<0.05) that was enriched for an endothelial cell gene signature.

Conclusions: These observations provide a vital foundation to building our pharmacologic understanding of relaxin/RXFP1 function in human and suggest that kidney-intrinsic target engagement may mechanistically explain the renal hemodynamic actions noted in clinical trials with relaxin. Great care needs to be taken to avoid conflation of relaxin's diverse physiological effects observed in species where RXFP1 cellular expression is not congruent with human.

A Novel and Unique Fc-Fusion Protein i-Body AD-214 Ameliorates Kidney Fibrosis Through Inhibition of Leukocyte Migration

Qinghua Cao,[1,2] Xinming Chen,[1,2] Carol A. Pollock.[1,2] Renal Medicine, Kolling Institute. *[1]Kolling Institute of Medical Research, St Leonards, NSW, Australia; [2]The Univeristy of Sydney, Sydney, NSW, Australia.*

Background: Tissue fibrosis is the common pathological pathway in progressive chronic kidney disease (CKD). Current clinical practices are ineffective in limiting renal fibrosis. CXCR4 has been demonstrated to be central to the development of fibrosis. The usage of neural cell adhesion molecules as scaffolds by incorporating binding loops, mimicking the shape of shark antibody, allows construction of fully humanized single-domain antibody-like scaffold, designated as i-bodies. The i-body AD-214, which bind CXCR4 with high affinity, has been shown to be effective in limiting lung fibrosis. However, the role of AD-214 in renal fibrosis has not been investigated.

Methods: Renal proximal tubular cells (PTC) were incubated with TGFβ1 with/without AD-214 for 48 hours. Supernatant was collected and collagen-3 (Col-3) and collagen-4 (Col-4) were measured by Western blot. Mice with unilateral ureteral obstruction (UUO) were administrated AD-214 every two days from one day after UUO for 14 days. Changes in renal morphology were examined by H&E and PSR staining. Renal histology, mRNA, analysed by qRT-PCR, extracellular matrix (ECM) and leukocyte markers detected by immunohistochemistry (IHC) and kidney function, assessed by the blood urea nitrogen (BUN) and kidney injury molecule-1 (KIM-1) were examined. The *in vitro* scratch assay was conducted to investigate the impact of AD-214 on macrophage migration.

Results: AD-214 suppressed TGFβ1-induced overexpression of Col-3 and Col-4 by RPTEC cells compared to negative control. In UUO model, mice treated with AD-214 markedly ameliorated collagen deposition (30.4% reduction) relative to UUO+negative i-body treated group. IHC staining revealed that administration of AD-214 significantly attenuated the Col-4 and fibronectin (FN) deposition by 74.4% and 34.6% respectively relative to negative i-body treatment group. Consistently, physiological parameters BUN and KIM-1 were markedly reduced in mice treated with AD-214. Mechanism studies revealed AD-214 inhibited the infiltration of leukocytes including macrophages and neutrophils into UUO kidneys. In the *in vitro* scratch assay, AD-214 effectively inhibited the migration of macrophages induced by LPS.

Conclusions: Blocking CXCR4 using the i-body AD-214 is a promising therapeutic strategy to prevent the development of CKD.

Optimized Normothermic Machine Perfusion of Kidney, Liver, and Combined Liver-Kidney to Predict Human Pharmacokinetics

Arianne Van Koppen, Reinout Stoop. *TNO, Leiden, Netherlands.*

Background: Robust translational models are key to predict the intestinal absorption, hepatic clearance (metabolic and biliary) and renal clearance of compounds. Ex vivo normothermic machine perfusion (NMP) of whole organs is a promising tool, especially

when combined with physiologically-based pharmacokinetic (PBPK) modeling to reliably predict human exposure levels. We aimed to optimize organ functioning during NMP and to demonstrate prediction of ADME data of model drugs (rosuvastatin, digoxin, metformin and furosemide) of liver and kidney combined with ex vivo intestinal absorption studies and PBPK modeling to predict the drug PK profile in humans.

Methods: Three ex vivo models were applied using porcine organs 1) the inTESTine system (n=3) to study apical to basolateral intestinal transport, 2) normothermic machine perfusion of ex vivo liver (n=3) to determine hepatic uptake, clearance and biliary excretion and 3) normothermic machine perfusion of ex vivo kidney (n=3) to determine renal clearance and urinary excretion.

Results: Intestinal absorption of digoxin and rosuvastatin were limited. Perfused porcine livers rapidly cleared rosuvastatin and digoxin from perfusate (hepatic extraction ratio of 0.82 and 0.31). Compounds were traced in bile after 10 min (rosuvastatin; 23%, digoxin; 51%, metformin and furosemide; ~0.2%). Renal excretion of rosuvastatin and digoxin was low, but high for furosemide and metformin (>90%).

Conclusions: NMP can be optimized to sustain organ functionality during perfusion. The combination of ex vivo gut, liver and kidney models with a generic PBPK model is a unique and powerful combination to predict ADME profile of (new) drugs, including the possibility to calculate the fraction that undergoes enterohepatic circulation. Future research is aimed at studying drug-drug interactions and the effects of disease processes.

Figure 1. Graphical representation of combined ex vivo liver and kidney perfusion; generating perfusate, bile and urine fractions.

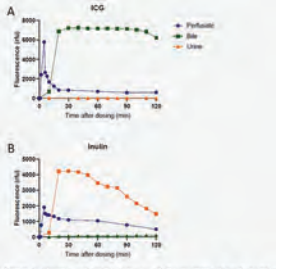

Figure 2. Hepatic and renal clearance of fluorescently labelled model compounds ICG (hepatic and biliary clearance) and inulin (renal and urinary clearance). (A) ICG is excreted into bile and not into urine (B) inulin excretion into urine and not into bile.

Metabolomics of Drug-Induced Mitochondrial Biogenesis in Aged Mice Kidneys

Austin D. Thompson,[1,2] Jaroslav Janda,[1] Rick G. Schnellmann.[1,2]
[1]The University of Arizona College of Pharmacy, Tucson, AZ; [2]Southern Arizona VA Health Care System, Tucson, AZ.

Background: Mitochondrial dysfunction is important in the aging process of many organs. We have shown that MC16, a drug candidate, induces mitochondrial biogenesis (MB) in mouse renal cortices and improves renal function in response to acute kidney injury. Thus, we hypothesized that stimulation of MB in aged mouse kidneys would improve global metabolomics in the kidney cortex.

Methods: Aged 22-month-old male C57B/6J mice were administered 1.0mg/kg MC16 or normal saline every other day over 21 days (n=8-9/group). Seven-month-old controls were administered normal saline every other day over 21 days (n=7). Kidneys were harvested and snap frozen in liquid nitrogen. Cortical biopsies were analyzed by Metabolon via multi-mass spectrometry. After mass normalization, log-transformation, and imputation, Welch's two-sample t-test was used to identify metabolites that differed significantly between treatment groups. A p-value of $p \leq 0.05$ and a false discovery rate of $q<0.10$ were used to identify global metabolite changes and correct for multiple comparisons.

Results: In total, the dataset of detected metabolites consisted of 1,010 biochemicals (BCs). Of these, 441 were statistically different in saline-treated old mice compared to young control mice, with 276 BCs increased and 165 BCs decreased. 140 BCs were statistically different in the MC16-treated old mice group compared to the saline-treated old mice group, with 72 BCs increased and 68 BCs decreased. Saline-treated old mice had reduced 1,5-anhydroglucitol and elevated glucose-6-phosphate, fructose-6-phosphate, and dihydroxyacetone phosphate compared to young control mice, indicative of enhanced glycolysis. Conversely, MC16-treated old mice had no statistical changes in glycolysis metabolites compared to young control mice. While both groups had elevated carnitine levels, MC16-treated old mice derived most of their carnitines from fatty acid metabolism, indicative of impaired fatty acid metabolism in the saline-treated old mice group.

Conclusions: These data reveal that global metabolomics can be utilized to identify various age-related kidney metabolic alterations within the renal cortices of mice. This approach will allow us to identify and monitor age-/disease- related metabolic changes in the renal cortex of mice to evaluate potential pharmacological agents that may alter/blunt the progression of renal dysfunction in future studies.

Development of Drug Efficacy Testing Platform for Glomerulonephritis

Eun-Jeong Kwon, Sejoong Kim. *Seoul National University Bundang Hospital Department of Internal Medicine, Seongnam, Gyeonggi-do, Republic of Korea.*

Background: There was little evidence for the treatment of glomerulonephritis (GN), although the guideline of GN was published. Therefore, we developed drug efficacy testing platform for GN using a 3D glomeruli tissue chip.

Methods: A gravity-driven glomerular-filtration-barrier (GFB) chip was designed with human podocytes and endothelial cells, allowing bi-directional flow in the bottom channel. Puromycin was used to induce glomerulonephritis (GN) models, and serum from membranous nephropathy (MN) patients was used to establish personalized models on the chip. The reproducibility of MN and the effects of tacrolimus were compared with clinical data. RFP-Gendo, WT1, and nephrin, representing the glomerular filtration barrier's molecular structure, were examined. Functional aspects of the GFB, such as cell viability and albumin permeability, were also evaluated.

Results: In the PAN-induced GN model, podocytes exhibited reduced levels of WT1 and nephrin, resulting in decreased albumin permeability and cell viability compared to the standard GFB. However, after the administration of tacrolimus, WT1 expression increased while nephrin expression decreased in the PAN-induced GN model. Tacrolimus also led to a reduction in albumin permeability and restoration of cell viability in this model. MN patients (MN1, MN2, and MN5) who received tacrolimus showed significant improvement. MN1 and MN2 had the most severe pathological injury among the enrolled patients. In the serum-induced MN1 and MN2 models on the chip, there was a significant decrease in cell viability compared to other groups, which was restored after tacrolimus treatment. Additionally, albumin permeability decreased in the MN1, and MN5 models following tacrolimus treatment on the chip. WT1 and nephrin expression increased in after tacrolimus treatment in the case of MN1 model, which had the most favorable response clinically.

Conclusions: The efficacy of tacrolimus was successfully evaluated using PAN-induced and serum-induced GN models on a chip that mimics the structure and function of the GFB. The GFB-mimicking chip holds promise as a personalized platform for assessing drug efficacy using patients' serum samples.

Endothelin Receptor Antagonists (ERAs) May Protect Against Rapid Kidney Function Decline: A Drug-Target Mendelian Randomization Study

Yixin Ma, Lubin Xu, Ruohuan Zhao, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

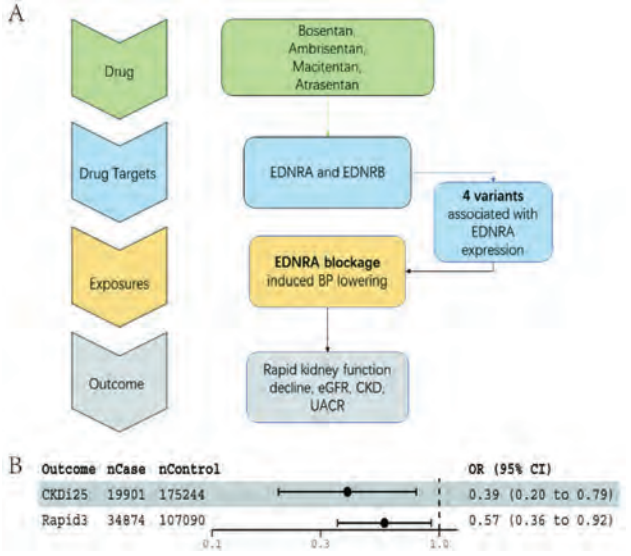
Background: Currently, the efficacy of ERAs to treat kidney disease is being tested in randomized controlled trials, positive effect in reducing albuminuria, preserving eGFR, and lower blood pressure has been reported. However, evidence from large randomized controlled trials comprehensively comparing the long-term renal effects of ERAs is lacking.

Methods: We applied a two-sample Mendelian Randomization approach to evaluate the causal effect of genetically mimicked ERA-induced blood pressure lowering on a series of kidney outcomes. Endothelin receptor (EDNR) SNPs associated with blood pressure and EDNR expression level were selected using GWAS summary data from the International Consortium of Blood Pressure (ICBP) and GTEx. GWAS summary statistics on kidney outcomes, including eGFR, proteinuria, and rapid kidney function decline, were drawn from CKDGen. We use fixed effects inverse variance weighted (IVW) meta-analysis of SNP-specific Wald estimates for primary analysis,the weighted median and MR-Egger methods for sensitivity analysis.

Results: Four EDNRA SNPs and no EDNRB SNPs met the inclusion criteria. Genetic mimicry of EDNRA blockage was associated with a lower risk of rapid kidney function decline (OR = 0.39, 95% CI = 0.20-0.79 for eGFR decline>25%, OR = 0.57, 95% CI = 0.36-0.92 for eGFR decline>3 unit per year) and a higher eGFR based on creatinine (β = 0.02, 95% CI = 0.01-0.04). Despite the significant proteinuria-lowering effect reported in clinical trials, we do not observe a causal effect for EDNRA inhibition on UACR, in the general population or the population with diabetes at baseline.

Conclusions: Mendelian randomization study suggests ERAs may protect against rapid kidney function decline through the blood pressure-lowering effect induced by EDNRA blockage.

Funding: Government Support - Non-U.S.



A: Study Design. **B:** The OR and 95% CI indicate the effect estimates of decrease in disease risk per 10 mmHg lowering of SBP via EDNRA inhibition.

SA-PO276

Sparsentan Receptor Occupancy Modeling, Clinical Actions, and Safety

Bruce M. Hendry,[1] Donald E. Kohan,[2] Rob Geletka,[1] Celia P. Jenkinson,[1] Charles Chen,[1] Patricia W. Bedard.[1] *[1]Travere Therapeutics Inc, San Diego, CA; [2]University of Utah Health, Salt Lake City, UT.*

Background: In the PROTECT study, sparsentan, which targets both the endothelin type A (ET_AR) and angiotensin type 1 (AT_1R) receptors, reduced proteinuria vs active comparator in IgA nephropathy with minimal changes in fluid status. This contrasts with greater fluid retention, including heart failure hospitalization, in studies using agents targeting ET_AR alone (ERA). This may relate to differences in comorbidities; however, aspects of dual receptor binding by sparsentan may also be a factor. Since ET_AR blockers favor fluid retention while AT_1R blockers may promote fluid excretion, continual high blockade of AT_1R during ET_AR blockade may help maintain normal fluid balance. The pharmacokinetic (PK) properties of sparsentan were used to estimate diurnal changes in receptor occupancy (RO) at steady state in the PROTECT study.

Methods: Receptor affinities (Ki) were determined for sparsentan at ET_AR, ET_BR, and AT_1R using radioligand binding assays. PopPK modeling of sparsentan was used to derive 24-hour PK and RO profile of patients in PROTECT.

Results: Sparsentan receptor affinities and PK data of a typical IgAN patient in the PROTECT study are shown in Fig. 1A. The 24-hour plot of sparsentan RO for ET_AR, ET_BR, and AT_1R using PK data estimated for 400 mg daily shows RO is ~60%-90% for ET_AR, >95% for AT_1R, and <1% for ET_BR (Fig. 1B).

Conclusions: Sparsentan has a stable 24-hour relationship in relative RO of ET_AR to AT_1R in which AT_1R RO always exceeds ET_AR RO. In contrast, when a drug solely targets ET_AR, on top of AT_1R blockade, periods of relatively unaccompanied ET_AR antagonism may occur, representing a risk for fluid retention. This could partly explain the fluid retention seen with ERA and the minimal changes in fluid status seen with sparsentan.

Funding: Commercial Support - Travere Therapeutics, Inc.

SA-PO277

Targeted Mass Spectrometry to Detect and Quantify Circulating α-Klotho Isoforms

Arvin Halim, Gayatri Narayanan, Sharon M. Moe, Emma H. Doud, Amber Mosley, Kenneth Lim. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Progress in α-Klotho research has been stunted by the lack of reliable assays that can discriminate between various α-Klotho isoforms which potentially exert differential physiological roles. We designed a novel targeted liquid chromatography-tandem mass spectrometry (LC-MS/MS) assay to detect and quantify the known circulating α-Klotho isoforms: soluble full-length Klotho (sFL-K), secreted KL1 (secKL1), soluble KL1 (sKL1) and soluble KL2 (sKL2).

Methods: We developed a parallel reaction monitoring-based (PRM) LC-MS/MS method that exploits unique peptide sequences present at the α2/β-cut site and the C-terminus of secKL1. During assay design, we tested enzymatic digestions of recombinant human sFL-K and secKL1 with commercially available proteases: trypsin, Lys-C, Asp-N, or chymotrypsin. After determining that chymotrypsin successfully created unique peptides covering the various α-Klotho isoforms, 11 synthetic peptides were used to optimize LC-MS/MS parameters and to determine limit of detection and quantification (LOD/LOQ) in solvent matrix. These peptides included chymotrypsin missed cleavages and deamidated Asn residues which were observed in our preliminary studies. We then utilized recombinant sFL-K and secKL1 proteins spiked into Top14 depleted plasma for further optimization and assessment of the assay.

Results: Only chymotrypsin digestion produced peptide signatures that cover the α2/β-cut site to differentiate between sKL1, sKL2 and sFL-K and the unique secKL1 C-terminus to identify secKL1 from sFL-K and sKL1. The LOD/LOQ for synthetic peptide signatures in solvent matrix ranged from 0.02/0.06 to 1.3/3.8 fmol. Synthetic peptides with an intact α2/β-cut site resulted in multiple peaks, most likely due to the high number of prolines in the peptide which can create distinct conformers that were resolved with application of a 60°C column heater. Deamidated peptides were detectable in depleted plasma matrix spiked-in with recombinant sFL-K and secKL1 proteins. sFL-K and sKL1 were detectable in human serum samples.

Conclusions: This is the first α-Klotho assay that can specifically detect and quantify different isoforms of circulating α-Klotho and overcome limitations of antibody-based methods. Further optimization for robustness, reproducibility as well as validation studies are required to assess α-Klotho isoforms in other sample types.

Identification of RNAs in Urinary Extracellular Vesicles for Detecting Renal Nrf2 Activation

Haruka Takayama,[1] Hiroko Sonoda,[1] Yoshiki Higashijima,[2] Ayae Tanaka,[1] Masahiro Ikeda.[1] *[1]Labolatory of Veterinary Pharmacology, Faculty of Agriculture, University of Miyazaki, Miyazaki, Japan; [2]Institute for Promotion of Tenure Track, University of Miyazaki, Miyazaki, Japan.*

Background: NF-E2-related factor 2 (Nrf2), a master transcription factor, is known to be activated in response to oxidative stress, leading to producing antioxidant molecules. Renal oxidative stress condition can be estimated by measuring oxidative by-products and reactive oxygen species in urine. On the other hand, since activation of antioxidant molecules may mask renal oxidative stress condition, detecting renal Nrf2 activation is likely helpful for early detection of renal oxidative stress. However, little is known about the non-invasive detection method. Urinary extracellular vesicles (uEVs) released from renal epithelial cells contain RNAs that may serve as biomarkers for renal diseases. Here, we examined RNAs in uEVs after administration of bardoxolone methyl (BARD), an Nrf2 activator, in rats.

Methods: Male SD rats were randomly divided into two groups: the BARD (10 mg/kg intraperitoneally) and vehicle (75% corn oil/25% DMSO) groups. The urine was collected for 6 hrs after the administration, and uEVs were isolated. Kidneys were also obtained at 6 hrs post-treatment. RNAs were extracted from uEVs and kidneys and analyzed by next-generation sequencing and microarray techniques.

Results: Based on the blood and urine tests, BARD administration did not impair renal function. Microarray analyses revealed that 19 genes in the kidney and 211 genes in uEVs were significantly altered after BARD administration. Next-generation sequencing identified 958 genes that were significantly changed by BARD treatment in the uEVs. Of these genes, only two genes, Pir and Ephx1 were commonly increased in the kidneys and uEVs (Pir: > 3-fold, Ephx1: approximately 2-fold). Since the increase in Pir was higher than in Ephx1, we further investigated Pir as a potential biomarker for detecting Nrf2 activation. *In situ* hybridization revealed that BARD-treatment increased Pir expression in the proximal and distal tubules of the renal cortex. Moreover, we established the pre-amplification method of RNAs in uEVs and successfully detected Pir in uEVs by PCR.

Conclusions: Theoretically, Nrf2 is activated before the early onset of kidney diseases or under pre-oxidative stress condition. Thus, detecting Nrf2 activation in the kidney by measuring Pir in uEVs could be a potential tool to detect early kidney diseases.

SA-PO279

Prospective Evaluation of an Improved Eculizumab Initial Phase Dosing Regimen in Adult Patients with Atypical Hemolytic Uremic Syndrome

Mendy ter Avest, Romy N. Bouwmeester, Caroline Duineveld, Lambertus P. Van den heuvel, Jack F. Wetzels, Nicole Van De Kar, Rob Ter heine. The CUREiHUS Study Group. *Radboudumc, Nijmegen, Netherlands.*

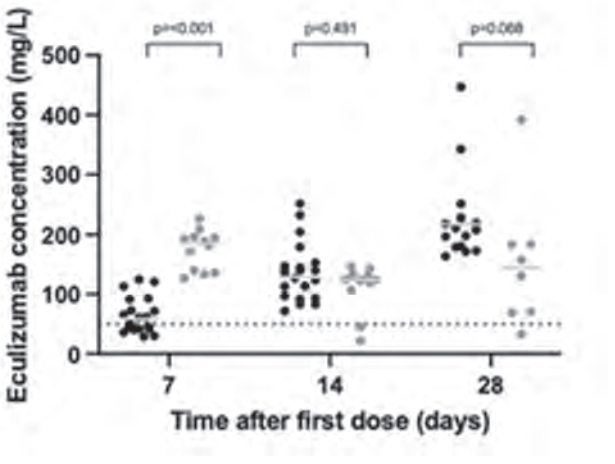
Background: Complete complement inhibition is often not achieved after the first dose of eculizumab due to subtherapeutic eculizumab concentrations (<50mg/L), while adequate complement inhibition is critical to prevent irreversible organ damage in aHUS. In this study we prospectively evaluated an improved initial phase dosing regimen.

Methods: The new regimen consisted of a weight-based loading dose on day 1 (>120kg: 2400mg; 90-120kg: 2100mg; 60-90kg: 1800mg; 40-60kg: 1500mg), followed by the standard biweekly 1200mg from day 15 onward. Eculizumab concentrations were measured to monitor therapy and compared with a historical cohort that received the standard dose. At each timepoint (day 7, 14, 28), we calculated the geometric mean eculizumab trough concentration and the fraction of patients with a subtherapeutic eculizumab concentration (<50mg/L) for both groups.

Results: 15 patients receiving the new dosing regimen and 22 patients receiving standard dose were evaluated. Baseline characteristics were similar across the groups. The eculizumab concentrations and the geometric mean concentrations on day 7, 14 and 28 are shown in Figure 1. Eculizumab concentrations were subtherapeutic in 42% (8/19), 0% (0/21) and 0% (0/16) of the patients on day 7, 14 and 28 respectively (standard dose) and in 0 (0/12), 20% (2/10) and 12.5% (1/8) of the patients on day 7, 14, and 28 respectively (new dose).

Conclusions: We prospectively confirmed improved early target attainment of a weight-based loading dose of eculizumab on day 1 followed by the maintenance phase dose from day 15 onward.

Funding: Government Support - Non-U.S.



Eculizumab concentrations for standard (black) and new initial phase (grey). Horizontal lines represents the geometric mean concentration. The dotted line represents an eculizumab concentration of 50 mg/L (threshold for complete C5 inhibition).

Phase 3 COMMODORE Trials of Crovalimab in Paroxysmal Nocturnal Hemoglobinuria (PNH): Impact on Kidney Function

Sasha Sreckovic,[1] Cristian Brocchieri,[2] Patty G. Leon,[1] Nadiesh Balachandran,[2] Marianne Uguen,[2] Simon Buatois.[2] *[1]Genentech, Inc., San Fransisco, CA; [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland.*

Background: Complement inhibition is the standard of care in PNH and atypical hemolytic uremic syndrome (aHUS). Crovalimab (crova), a C5 inhibitor, enables rapid, complete and sustained C5 inhibition with subcutaneous self-administration in patients (pts) with PNH who are complement inhibitor-naive or switching to crova. Crova has non-inferior efficacy vs eculizumab (ecu) and a safety profile is consistent with that of other C5 inhibitors. Here we evaluate kidney function in the Phase 3 pts.

Methods: Pts with PNH received crova or ecu in one of the Phase 3 studies: global, randomized COMMODORE 1 (treatment-switch pts) and COMMODORE 2 (naive pts), or China-based, single-arm COMMODORE 3 (naive pts). In COMMODORE 1 and 2, pts receiving ecu could switch to crova after the primary treatment period. Data were pooled for safety and kidney function evaluation.

Results: 111 pts received ecu and 377 crova (192 naive, 185 switched to crova at study initiation or after primary period). Shifts in serum creatinine of ≥2 grade (gr) from BL occurred in 4.5% (5/111) of ecu pts vs 6.9% (26/377) of crova pts (8.3% [16/192] of C5 naive vs 5.4% [10/185] of switch pts; Table). Post-BL gr 3/4 shifts occurred in 1 ecu pt (BL: gr 2), 1 naive pt (BL: gr 0) and 4 switch pts (BL: gr 0). Shifts occurred much later than the onset of ecu-C5-crova immune complexes, suggesting the shifts were unrelated to switching. Urine protein, albumin and creatinine levels were not concerning. Type 3 hypersensitivity reactions, associated with complexes, occurred in 18% (33/185; 21 gr 1-2, 12 gr 3) of switch pts.

Conclusions: Serum creatinine shifts were comparable between ecu pts and pts who changed from ecu to crova or stayed on crova. Overall, the crova Phase 3 data show that the risk/benefit profile of crova is favorable in PNH and no new safety signals, including for kidney function, were observed. Crova is being evaluated for aHUS in the ongoing COMMUTE-a (NCT04861259) and COMMUTE-p (NCT04958265) studies.

Funding: Commercial Support - This study was funded by F. Hoffmann-La Roche, Basel, Switzerland

Long-Term Outcomes Comparing Belatacept vs. Tacrolimus in Older and Marginal Kidney Transplant Recipients: A UNOS Database Analysis

Stalin I. Canizares Quisiguina,[1] Adriana Montalvan,[1] Devin Eckhoff,[1] David D. Lee,[1] Kalathil K. Sureshkumar,[2] Bhavna Chopra.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Allegheny Health Network, Pittsburgh, PA.*

Background: Studies have shown that kidney transplantation with even a marginal kidney provides a survival advantage in older patients when compared to dialysis. Older kidney transplant recipients (KTR) of marginal organs where KDPI ≥85% are more likely to be negatively impacted by the nephrotoxic effects of calcineurin inhibitors. Hence, the aim of the study was to compare long term patient and graft outcomes in older and high KDPI KTRs stratified by Tacrolimus (Tac) vs Belatacept (Bela) maintenance immunosuppression.

Methods: We identified adult, first-time kidney only transplant recipients from 2010 to 2022 who received induction therapy and were discharged on Tac or Bela based maintenance immunosuppression from the UNOS database. Multivariate Cox regression models adjusting for several donor, transplant and recipient factors were used to compare long term outcomes Tac vs. Bela maintenance in KTRs with age ≥65 yrs, KDPI ≥85%, and donation after cardiac death (DCD).

Results: The results comparing Tac vs. Bela groups are detailed in Table 1. Bela use was associated with higher DCGF and death in KDPI ≥85% group ($p<0.05$). The rest of the long-term outcomes were similar between the groups.

Conclusions: The use of Bela in older KTRs recipients and DCD kidney recipients is associated with non-inferior outcomes, likely due to GFR advantage with Bela. Inferior outcomes in the Bela group among high KDPI KTRs could reflect selection bias. Other contributory factors could include higher risk for early rejections and opportunistic infections in the Bela group. These identified associations should be regarded as preliminary evidence, taking into account the retrospective nature of the study. They serve as a catalyst for future analysis.

Comparison of long-term outcomes in older and marginal kidney transplant recepients based on maintenance immunosuppression.

Association Between Mycophenolic Acid (MPA) Pharmacokinetics and In Vitro MPA Glucuronide (MPAG) Turnover by Gut Microbiota of Kidney Transplant Recipients

Guillaume C. Onyeaghala,[1,2] Duy Vo,[1] Moataz Mohamed,[2] Abdelrahman Saqr,[2] Bryan P. Brito Sanchez,[1] Sarah Elmer,[1] Ryan C. Hunter,[2] Levi Teigen,[2] Casey R. Dorr,[1,2] Christopher Staley,[2] Baolin Wu,[3] Weihua Guan,[2] Rasha El-Rifai,[2] Arthur J. Matas,[2] William S. Oetting,[2] Pamala A. Jacobson,[2] Ajay K. Israni.[1,2]
[1]Hennepin Healthcare Research Institute, Minneapolis, MN; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]University of California Irvine, Irvine, CA.

Background: Pharmacokinetic (PK) studies show enterohepatic recycling (EHR) of mycophenolic acid (MPA) due to MPA glucuronide (MPAG) hydrolysis by gut b-glucuronidases (BGUS). EHR increases MPA systemic exposure and likely enhances immunosuppression and toxicity in kidney transplant recipients (KTRs). We hypothesized that extensive EHR in-vivo would correlate with higher MPAG to MPA in-vitro.

Methods: 9 KTRs underwent simultaneous PK and stool collection at 30-60 days post-transplant. MPA % EHR was defined as MPA $AUC_{5\text{-}12\ hour}$ / $AUC_{0\text{-}12\ hour}$ x 100. Stool samples were anaerobically exposed to 100 mg/mL of MPAG in 7mL of YCFA (Yeast extract-Casein hydrolysate-fatty acids) broth, with aliquots collected at 0, 30, 60, 90 and 120 minutes. Total MPA and MPAG concentrations were assessed using mass spectrometry. Microbiota were characterized by 16S sequencing. We applied the Louvain Modularity Maximization algorithm to the correlation between in-vitro MPA levels, MPA PK, and BGUS producers present in >10% of samples (Threshold R=0.3).

Results: After exposure to MPAG, we observed an increase in MPA with a concurrent decrease in MPAG concentrations across all in-vitro samples. Further comparison showed a positive correlation between MPA AUC and in-vitro MPA at 0, 30, 60, 90 and 120 mins post incubation (R = 0.85, 0.68, 0.58, 0.48, 0.43 respectively, $p < 0.05$ at 0 and 30 mins). We included 7 out of 31 previously known BGUS producers in our network analyses, which suggested that the relative abundances of *B. uniformis*, *R. gnavus* and *C. aerofaciens* correlated with in-vitro MPA in the first hour and MPA AUC (FIG 1).

Conclusions: These data suggest that MPAG metabolism to MPA by the stool microbiome is correlated to the relative abundance of known BGUS producers. Further studies are needed to associate the extent of MPA PK with BGUS producers.

Take Drug Interactions Seriously: Paxlovid in Transplant Patients Taking Tacrolimus

Batoul Dekmak, Nika Samadzadeh Tabrizi, Emmanuel A. Aydin-Ghormoz, Geovani Faddoul, Krishnakumar D. Hongalgi. *Albany Medical College, Albany, NY.*

Introduction: Kidney transplant recipients are highly susceptible to severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) and are eligible candidates for Paxlovid™ (nirmatrelvir and ritonavir), an antiviral medication that reduces morbidity associated with COVID-19 infection. Ritonavir effectively maintains serum concentrations of nirmatrelvir by inhibiting CYP3A but can also elevate levels of other drugs metabolized by this enzyme, including immunosuppressive medications. We describe a kidney transplant recipient who received Paxlovid and subsequently developed supratherapeutic tacrolimus levels after dose titration upward.

Case Description: A 65-year-old man with history of ESKD due to type 1 diabetes mellitus and renal transplant on tacrolimus (dosed at 0.5mg BID) presented to our ED with symptomatic COVID-19 infection, for which Paxlovid was initiated. Tacrolimus was held. He was hospitalized for two days and discharged with instruction to continue Paxlovid and hold tacrolimus until outpatient follow-up. The next day, he presented again with anuria, leg edema, and AKI. Tacrolimus level was 2.0 ng/mL and creatinine had risen from baseline 1.8 mg/dL to 2.7 mg/dL. Due to a concern for acute rejection, Paxlovid treatment was stopped, and he was given two 2mg doses of tacrolimus 12 hours apart before lab work revealed a sudden rise in serum tacrolimus level to 54 ng/mL on hospital day 2. Tacrolimus was again held. Serum levels trended down to therapeutic range within four days. AKI steadily improved with supportive care.

Discussion: The introduction of tacrolimus has transformed the field of kidney transplantation. Maintaining therapeutic serum levels remains challenging due to its metabolism by CYP3A, resulting in potential drug interactions and high tacrolimus levels that can lead to irreversible nephrotoxicity. Transplant recipients frequently receive Paxlovid, and tacrolimus is often held during treatment. After Paxlovid is dicontinued, 70-90% of CYP3A inhibition is relieved within 2-3 days, but may take longer with advancing age. Our case highlights the crucial need for cautious and conscientious resumption and dose titration of immunosuppression in the days after cessation of Paxlovid to avoid supratherapeutic and nephrotoxic serum levels of tacrolimus.

Genistein Reduces Albuminuria by Inhibition of Caveolae-Mediated Endocytosis into Glomerular Endothelial and Epithelial Cells

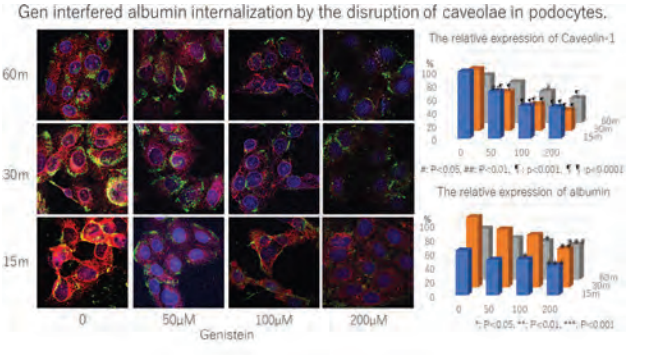
Takahito Moriyama, Rie Suzuki, Yoshitaka Miyaoka, Yoshihiko Kanno. *Tokyo Ika Daigaku, Shinjuku-ku, Japan.*

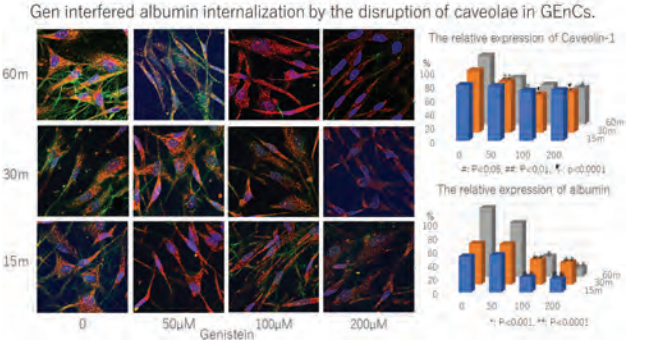
Background: We previously reported the intracellular trafficking pathway of glomerular endothelial cells (GEnCs) and epithelial cells (podocytes) through caveolae as the possibility of new etiology of albuminuria. The non-steroidal phytoestrogen belonged to potent soy isoflavone, genistein (Gen) inhibits Src kinase, which plays an important role of internalization of caveolae coated pits into cytoplasm as caveolae endocytosis. In this study, we analyzed the effect of Gen to reduce albuminuria by inhibiting albumin endocytosis through caveolae into GEnCs and podocytes.

Methods: After 1 hour pre-treating cells with 50, 100, or 200 μM of Gen, cells were incubated with time course treatment of albumin (15, 30, and 60 min), and then the expression of caveolin-1 (Cav-1), albumin, and p-Src were evaluated by immunofluorescence (IF) and western blots (WB) analysis. It was also analyzed whether 14 days treatment of Gen reduced albuminuria in the streptozotocin induced diabetic nephropathy modeled mice (STZ mice).

Results: Albumin and caveolin-1 (Cav-1) expression levels were significantly decreased with dose dependent manner of Gen in IF and WB analysis (Figure). The expression of p-Src was also decreased in WB analysis. In vivo study, though body weight and blood glucoses were not changed, Gen significantly decreased the urinary albumin/creatinine ratio in STZ mice (0.28 to 0.05, p=0.02) in comparison to non-treated STZ mice (0.21 to 0.14, p=0.37).

Conclusions: Gen interfered albumin endocytosis through caveolae by suppressing caveolae expression according to inhibit Src kinase and resulted in reduced albuminuria in STZ mice. These results indicated the possibility of Src kinase inhibitor, Gen as the new therapeutic approach to reduce albuminuria in diabetic nephropathy.





SA-PO285

Dexamethasone and Enalaprilat but Not SB525334 Exhibit Anti-Inflammatory Properties in Precision-Cut Kidney Slices (PCKSs) Obtained from Mice with Adriamycin-Induced Nephropathy

Wioletta Pijacka,[1] Gisele Lincevicius,[1] Jessica Willis,[1] Connor T. Levers,[2] Stephanie Butler,[1] Steven Vickers,[1] Sharon Cheetham.[1] *[1]Sygnature Discovery Ltd, Nottingham, United Kingdom; [2]University of Nottingham, Nottingham, United Kingdom.*

Background: Precision cut kidney slices (PCKS) provide a valuable step between in vitro and in vivo testing. PCKS obtained from rodents exposed to adriamycin exhibit specific pathological features associated with glomerular and tubular injury, inflammation and eventual fibrosis. In this study, we have evaluated the effects of dexamethasone, enalaprilat, and SB525334 on inflammation and fibrosis in PCKS from kidney slices from adriamycin-treated mice.

Methods: Male mice were dosed with adriamycin (11.25 mg/kg, iv) to induce nephropathy. On Day 7 mice were humanely sacrificed and kidneys were cut at 250μm on a vibratome. Slices were cultured in Williams Medium E media. Tissue viability was evaluated at 0h to 96h by LDH assay and qPCR (versus control). Independent slices were treated with SB525334 (1μM), Dexamethasone (1μM) and enalaprilat (10μM) for 24 to 96h. Pro-fibrotic (Fn1, Col1a, Col3a, PAI1), pro-inflammatory genes (*IL-6, TNFα, IL-1*β and *CCL2*) and genes indicative of glomerular and tubular injury (nephrin, KIM-1 and WT1) were determined.

Results: PCKS were viable for 96h. All pro-inflammatory and pro-fibrotic gene expression were significantly increased from 24h onwards, p<0.001. Nephrin, *WT1* expression decreased, and *KIM-1* increased at 24h and remained elevated, p<0.001. SB525334 decreased the expression of all pro-fibrotic genes, p<0.001 but not the pro-inflammatory markers (NS) and increased nephrin and *KIM-1* (p<0.05, p<0.001) but had no effect on *WT1*. Dexamethasone significantly reduced *TNFα, IL-6, IL-1*β, *CCL2* (p<0.001) as well as *Fn1, Col1a, Col3a* and *PAI1* (p<0.001). Dexamethasone increased *WT1* and reduced *KIM-1* (p<0.05, p<0.001) but unchanged nephrin. Enalaprilat effects were limited, it reduced *IL-1*β (p<0.01) and increased *WT1* (p<0.05).

Conclusions: Dexamethasone and enalaprilat produced a reduction in inflammation and fibrosis (dexamethasone only) leading to protection of the functional unit of the kidney. In contrast, SB525334 effects were limited to fibrosis but the effects on kidney health were inconclusive. Taken together, inflammation plays a crucial role in adriamycin-induced nephropathy and PCKS present a reliable platform to test novel anti-inflammatory and anti-fibrotic therapies.

SA-PO286

Antifibrotic Effects of Tadalafil, a Phosphodiesterase 5 Inhibitor, with PAI1 Downregulation via cGMP in Rats and Fibroblasts

Misuzu Noda,[1] Yuji Hotta,[2,3] Aya Naiki-Ito,[4] Natsumi Tomita,[2] Akimasa Sanagawa,[2,3] Tomoya Kataoka,[5] Yoko Hibi,[3] Satoru Takahashi,[4] Kazunori Kimura.[2,3] *[1]Department of Hospital Pharmacy, Faculty of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [2]Department of Hospital Pharmacy, Graduate School of Pharmaceutical Sciences, Nagoya City University, Nagoya, Japan; [3]Department of Clinical Pharmaceutics, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [4]Department of Experimental Pathology and Tumor Biology, Graduate School of Medical Sciences, Nagoya City University, Nagoya, Japan; [5]Department of Pharmacology, Graduate School of Pharmaceutical Sciences, Chiba Institute of Science, Choshi, Japan.*

Background: Renal fibrosis is common in cases of renal dysfunction, and the development of therapeutic agents for renal fibrosis is desired. It was recently reported that phosphodiesterase 5 (PDE5) inhibitors, used for the management of erectile dysfunction and pulmonary hypertension due to increased cGMP, have renoprotective effects. Thus, in this study, we investigated whether tadalafil, a PDE5 inhibitor, has antifibrotic effects via cGMP in rats and renal fibroblasts.

Methods: Dahl salt-sensitive rats were used as a renal dysfunction model and divided into the following groups: normal salt (NS), high salt (HS), and HS plus tadalafil (HS+T). The NS group was fed a normal diet (0.3% NaCl), and the HS group and HS+T group were fed a high-salt diet (8% NaCl). Tadalafil (10 mg/kg/day) was orally given once a day. After 8 weeks, renal fibrosis was evaluated using AZAN staining. The mRNA expression level of the profibrotic factor, plasminogen activator inhibitor1 (PAI1), was also examined. Furthermore, NRK-49F cells, fibroblasts, were treated with the vehicle, transforming growth factor (TGF)β1 (2 ng/ml), or TGFβ1 + 8-Br-cGMP (1 mM). After 6 h, PAI1 mRNA expression levels and active PAI1 protein levels were measured.

Results: Collagen-rich areas visualized by AZAN-staining obviously increased in the HS group compared with that in the NS group and those areas decreased in the HS+T group compared with that in the HS group. Furthermore, while PAI1 mRNA expression in kidney tissue significantly increased in the HS group compared with that in the NS group ($P < 0.01$), it decreased in the HS+T group compared with that in the HS group ($P = 0.06$). The expression levels of PAI1 mRNA in TGFβ1-stimulated NRK-49F cells increased compared with those in the vehicle-treated cells. 8-Br-cGMP addition decreased the expression levels of PAI1 mRNA. Active PAI1 protein levels in the TGFβ1-stimulated cells was significantly upregulated compared with that of the vehicle-treated cells ($P < 0.01$) and that of the 8-Br-cGMP-treated cells was significantly downregulated compared with that of the TGFβ1-stimulated cells ($P < 0.01$).

Conclusions: Tadalafil shows antifibrotic effects, which may be due to the prevention of active PAI1 expression due to increased cGMP in fibroblasts.

SA-PO287

When Hepatic Therapy Backfires: Unraveling the Intricacies of Rifaximin-Induced Rhabdomyolysis Post-Transplantation

Salem Vilayet, Genta Uehara, Karim Soliman. *Medical University of South Carolina, Charleston, SC.*

Introduction: Rhabdomyolysis, a severe condition marked by muscle cell content leakage into circulation, manifests as weakness, pain, swelling, and myoglobinuria. It can result from diverse causes, leading to complications like acute kidney injury (AKI). We report a case of rifaximin-induced rhabdomyolysis.

Case Description: A 56-year-old male with a pancreas-kidney transplant, and cholestatic/drug-induced cirrhosis due to lacosamide (Stage 1 fibrosis on biopsy, now Stage IV). The initial presentation included weakness and altered mental state; labs revealed hyperammonemia (155 umol/L), elevated tacrolimus level (9.7 ng/mL), and creatinine (1.7mg/dL). He was started on intravenous fluids, rifaximin, lactulose, and continuation of his atorvastatin, resolved hepatic encephalopathy, and improved creatinine to 1.4 mg/dL. He returned three weeks later with increased weakness and leg pain. Labs showed elevated creatinine kinase (14614 U/L), creatinine peaking at 4.5 mg/dL, and a tacrolimus level of 8.9 ng/mL. A renal biopsy suggested acute tubular injury, rhabdomyolysis-induced pigment nephropathy, and borderline acute rejection. Management included pulse-dose solumedrol (500mg/3 days), followed by a taper, discontinuation of rifaximin, intravenous fluids, and dose reduction of tacrolimus, leading to resolution of rhabdomyolysis and improved kidney injury.

Discussion: In this case, rifaximin, a medication started during the patient's initial presentation, likely caused the rhabdomyolysis. Despite its limited gut absorption, hepatic impairment may enhance absorption. The mechanism could involve rifampin-induced mitochondrial oxidative stress in muscle, promoting myofibrillar proteolysis, similar to statin-induced rhabdomyolysis. This case underscores rifaximin's potential for inducing rhabdomyolysis, especially in patients with hepatic impairment.

AKI and Erythema Multiforme Associated with Helicobacter pylori Eradication Therapy: Not Invariably Drug Allergy

Moe Kawashima,[1,2] Shun Manabe,[1,2] Harufumi Ogino,[1] Kaori Watanabe,[1,3] Kawachi Keiko,[1,2] Koji Kanai,[1] Junichi Hoshino.[2] *[1]Tokyo Rosai Hospital, Ota-ku, Japan; [2]Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]Toho University Omori Medical Center, Ota-ku, Japan.*

Introduction: Helicobacter pylori (H. pylori) infection might lead to gastric carcinoma; hence, the elimination of H. pylori is pursued in infected individuals. One of the first-line therapeutic regimens consists of amoxicillin (AMPC), clarithromycin (CAM), and proton pump inhibitor (PPI). However, AMPC is an agent recognized for inducing interstitial nephritis and skin eruptions. PPI-associated interstitial nephritis has gained attention in recent years. Here, we present an intriguing case of a hypersensitive reaction following H. pylori eradication.

Case Description: A 70-year-old Asian male received a 7-day course of AMPC, CAM, and PPI for the treatment of H. pylori infection. Two days after completing the medication, his serum creatinine level was 0.89 mg/dL. The following day, he developed a febrile state accompanied by a generalized rash. By the fifth day after completing the treatment, he continued to experience fever along with a deteriorating skin rash. Laboratory investigations revealed the following findings: creatinine 2.82 mg/dL, C-reactive protein 16.7 mg/dL, procalcitonin 5.14 ng/mL, urinary NAG 88.8 IU/L, and urinary β2MG 155,000 μg/L. The patient was diagnosed with acute kidney injury and erythema multiforme. Additionally, rhabdomyolysis became evident. Pulse steroid therapy followed by oral prednisolone (0.8 mg/kg body weight) led to the amelioration of symptoms and full recovery of renal function. Kidney biopsy revealed acute tubular injury but not interstitial nephritis. Prednisolone was discontinued within three weeks. Leukocyte transforming test (LTT) and skin prick test for AMPC, CAM, and PPI yielded negative results, while LTT using H. pylori antigen showed a positive reaction. Consequently, the case was diagnosed as a hypersensitivity reaction against the eradicated H. pylori.

Discussion: Hypersensitivity reactions associated with the treatment of H. pylori infections were predominantly diagnosed as drug allergy. However, hypersensitivity against the eradicated H. pylori itself has recently been reported from Japan as a novel mechanism. To the best of our knowledge, this is the first case in which acute kidney injury manifested as complications. Recognition of this mechanism is crucial not only for dermatologist but also for nephrologist to prevent misdiagnosis.

SA-PO289

A Case of Drug-Induced Thrombotic Microangiopathy During Pulmonary Tuberculosis Treatment

Hyung Duk Kim,[1] Yaeni Kim.[2] *[1]Catholic University of Korea Eunpyeong St Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea; [2]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

Introduction: Drug-induced thrombotic microangiopathy is a rare, but serious complication. Here, we report a case of severe rifampicin-associated TMA with acute kidney injury required renal replacement therapy during pulmonary tuberculosis treatment.

Case Description: A 67-year-old man diagnosed with pulmonary tuberculosis was referred to nephrology department for hematuria. The patient had a history of diabetes and hyperlipidemia. Isoniazid, rifampicin, pyrazinamide and ethambutol were administered after the diagnosis of pulmonary tuberculosis. And on the 7th day of tuberculosis treatment, gross hematuria and purpura were developed. Laboratory tests showed a hemoglobin level of 8.4 g/dL, a leukocyte count of $9.01x10^9$/L, a platelet count of $11x10^9$/L, a urea nitrogen of 132.8 mg/dL and a creatinine level of 13.8 mg/dL. Hemodialysis was initiated to control severe metabolic acidosis and uremic symptoms. Direct Coombs' test was positive and schistocytes were observed on peripheral blood smear. Hemolytic anemia with thrombocytopenia and acute kidney injury were suspected to be related to rifampicin. So, we discontinued the rifampicin and start therapeutic plasma exchange. In vitro test for drug-induced immune complex proved that hemolytic anemia was induced by rifampicin. After 4 sessions of plasma exchange, the patient's renal function was gradually recovered and hemodialysis was stopped.

Discussion: It is known that hemolytic anemia occurs because rifampin binds to circulating antibodies to form immune complex and attaches to the surface of red blood cells, which activates the complement cascade. Thrombocytopenia also occurs by an immunological mechanism induced by rifampin. Hemolytic anemia and thrombocytopenia are usually known to appear on the 3rd day to 3rd week of rifampin administration. Here, we report a case of severe thrombotic microangiopathy with acute kidney injury in which the etiology was identified with an immune complex test and successfully treated with plasma exchange.

Results of the drug-induced immune complex test

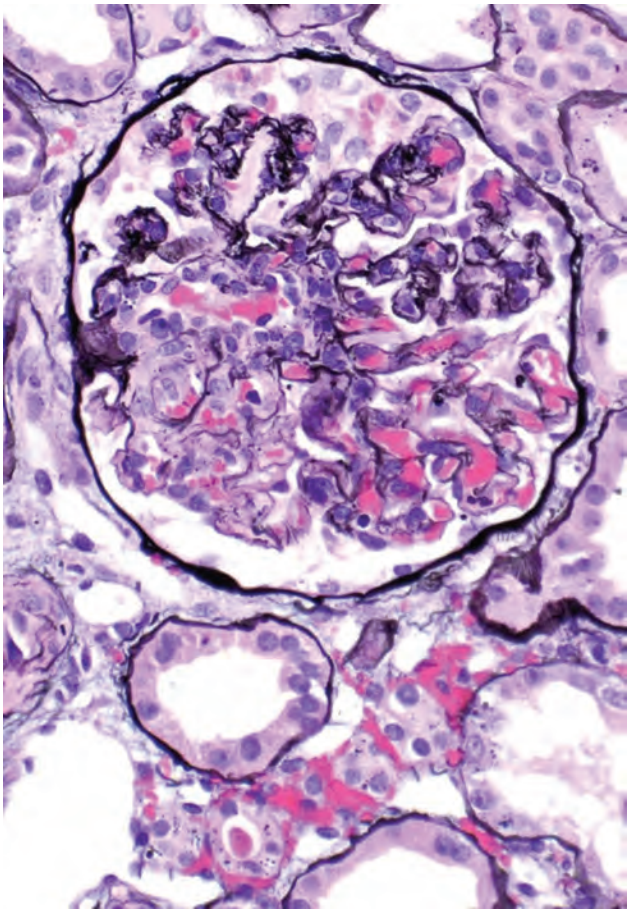
Drug-Mediated Thrombotic Microangiopathy Associated with Eltrombopag

Mohammad Tinawi. *Nephrology Specialists PC, Gary, IN.*

Introduction: Eltrombopag is a thrombopoietin-receptor agonist indicated in resistant chronic immune thrombocytopenia (ITP). This is the first report of full-blown biopsy-proven thrombotic microangiopathy (TMA) with acute kidney injury (AKI) and the nephrotic syndrome (NS) in an ITP patient on eltrombopag.

Case Description: 65-year-old woman with steroids and immunoglobulins resistant ITP presented with confusion, worsening thrombocytopenia, fever, and AKI. Eltrombopag was started 4 days prior to admission. Three weeks earlier, creatinine was 0.84 mg/dl, and platelets 84,000/uL. On admission, Creatinine was 5.22 mg/dl, and platelets 50,000/uL with schistocytes. LDH was 1,193 U/L. Urine protein-to-creatinine ratio was 6510 mg/g with hyperlipidemia and hypoalbuminemia. Blood and urine cultures, and direct Coombs were negative. Anticardiolipin antibodies, hepatitis B and C, and connective tissue disorders serologies were unremarkable. Pre-plasma exchange ADAMTS13 was normal. Eltrombopag was stopped, IV corticosteroids and hemodialysis (HD) were started. Renal biopsy showed focal cortical necrosis, ischemic changes in the glomerular capillary loops, and focal arteriolar fibrin thrombi with red blood cell fragmentation. After 7 daily plasma exchange sessions, platelets normalized and confusion resolved. Two months later she was taken off HD.

Discussion: There are four reports of eltrombopag-associated AKI, one was renal limited TMA, another in a patient with antiphospholipid syndrome, and two presented with AKI and NS. In this case report, Naranjo adverse drug reaction probability scale showed a score of 7 or a probable relationship between eltrombopag and TMA. Eltrombopag drug-mediated TMA is uncommon. Drug cessation, corticosteroids, plasma exchange and renal replacement therapy should be considered in the management of this disorder.



Ischemic glomerulus with fibrin thrombi

SA-PO291

Ophthalmological Safety of Hydroxychloroquine in CKD

Darin Ftouni,[1] Ashutosh M. Shukla,[1,2] Malea Joyce,[1] Kailyn Pearce,[1] Selin Kavak,[1] Wanda Martinez-Navarro,[1] Mark S. Segal,[1,2] Alfred K. Cheung,[3] Sudhir V. Shah.[4] *[1]VA Medical Center Malcom Randall, Gainesville, FL; [2]University of Florida, Gainesville, FL; [3]University of Utah Health, Salt Lake City, UT; [4]University of Arkansas for Medical Sciences College of Medicine, Little Rock, AR.*

Background: Hydroxychloroquine (HCQ) is routinely used in advanced CKD for rheumatological disease, despite known concerns for its ophthalmological safety in older individuals and patients with CKD. Recently, HCQ has been implicated in therapeutically treating cardiovascular (CV) disease in patients with CKD.

Methods: We report the findings of the planned interim analysis examining the short-term ophthalmological safety of HCQ among all enrolled Veteran participants (n=100) in the **Ma**nagement of **C**V disease in c**K**d (MaCK) study, a phase 2b, randomized placebo-controlled trial aimed to examine the impact of HCQ on CV and renal outcomes. Blinded ophthalmological evaluations were done at baseline and at one-year after randomization by measuring visual acuity and evaluating macular health with autofluorescence(AVF), Humphrey's visual field (HVF), and optical coherence tomography (OCT), when clinically needed.

Results: Across the 100 Veterans aged 71.21±5.92, 95%male with eGFR of 40.04±7.72 and albuminuria of 438.0±784.4 mcg/gm of creatinine, randomized in 1:1 proportion between placebo:HCQ, worsening of visual acuity was similar across both groups (16 vs. 18, p >0.87). Ophthalmological symptoms prompted repeat macular health evaluation in 22 participants on follow-up with no significant difference between abnormalities detected on AVF (2 in each group), HVF (2 vs. 1 participant), and OCT (2 in each group).

Conclusions: Use of HCQ is safe from short-term ophthalmological perspectives among elderly, predominantly male participants with significant CKD.

Prevalence of Polypharmacy and Associated Adverse Outcomes in Kidney Transplant Recipients

Tai yeon Koo, Sungyeon Kim, Yookyung Jang, Sang-Kyung Jo. *Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Polypharmacy (PP) continues to increase, and is associated with numerous adverse clinical outcomes and mortality. Although the burden of medication in kidney transplant recipients (KTRs) is well-known, PP has not been characterized in detail in the KTRs. The aim of this study was to assess the prevalence of PP among KTRs and the association between PP and clinical outcomes in the KTRs.

Methods: A total of 972 KTRs from a prospective multicenter observational cohort study in Korea (KNOW-KT; The KoreaN cohort study for Outcome in patients With Kidney Transplantation) between 2012 and 2016 were included in the study. We investigated the association between the number of prescribed medications and adverse outcomes such as graft failure, all-cause mortality and cardiovascular events. PP was defined as the use of more than 10 medications per day at 1 year after kidney transplantation.

Results: The patients with PP were noted in 478 (49.2%) patients. The PP prevalence at 1, 2, 3, 5, and 8 years after transplantation was 49.2%, 36.5%, 35.7%, 36.3% and 24.6%, respectively. The prevalence of diabetes, dyslipidemia and history of cardiovascular disease was significantly higher in the PP group than in the non-PP group (the use of fewer than 10 medications; n= 494). The mean follow-up period was 6.9 years, and there were 69 graft failures, 63 new-onset cardiovascular diseases, and 36 deaths. When the effect of PP prescribed at 1-year post-transplant on clinical outcomes was analyzed, there was no difference in glomerular filtration rate between the non-PP and PP groups, and the hazard ratio of graft failure and death in the PP group was 1.07 (0.718 to 1.59) and 1.37 (0.71 to 2.64), respectively, compared to the non-PP group. However, multivariate analysis adjusted for classical risk factors showed that PP and medication counts independently increased the risk of new cardiovascular disease (adjusted HR 1.76 (1.051-2.950); p=0.032, adjusted HR 1.079 (1.00-1.164, p= 0.049), respectively) after KT.

Conclusions: These results showed that PP is common in KTRs, and considering the adverse effects of PP on KT outcomes, physician's attention and efforts are needed to systematically manage and prevent inappropriate PP after KT. Long-term and large-scale research is needed to establish management guidelines for PP in the future.

SA-PO293

The Relationship of Polypharmacy with Increasing CKD Stage

Rie Suzuki, Takahito Moriyama, Yoshitaka Miyaoka, Yoshihiko Kanno. Tokyo Medical University. *Tokyo Ika Daigaku, Shinjuku-ku, Japan.*

Background: Previously, chronic kidney disease (CKD) and hemodialysis has been reported as the one of the risk factors of polypharmacy. However, it has been unclear the relationship of increasing CKD stage with the higher number of medications.

Methods: In this retrospective cohort analysis, 408 CKD patients (CKDG1 and 2 (n=23), CKDG3-5 (n=81) and CKDG5D (n=304) were conducted. We analyzed the backgrounds, the number and details of prescribed medications in January 2017, the number of patients who met STOPP (Screening Tool of Older Person's Prescriptions) criteria, and the risk factors for polypharmacy (6-9 medications) and hyper-polypharmacy (≧ 10 medications).

Results: The mean number of medications was significantly different among three groups and increased as the higher CKD stage (4.5±2.6 in CKDG1 and 2, 8.0±3.5 in CKDG3-5, and 9.7±3.5 in CKDG5D, p<0.001). The number of patients of polypharmacy and hyper-polypharmacy was increased as the CKD stage (polypharmacy: 26.1% in CKDG1 and 2, 72.8% in CKDG3-5, and 87.2% in CKDG5D, p<0.001, hazard ratio (HR) 3.23/ one stage increase, p<0.001, hyper-polypharmacy: 4.35% in CKDG1 and 2, 32.1% in CKDG3-5, and 51.0% in CKDG5D, p<0.001, HR 2.78/one stage increase, p<0.001). In STOPP criteria, the number of patients who had any duplicate drugs were significantly different among three groups and increased as CKD stage (4.35% in CKDG1 and 2, 14.8% in CKDG3-5, and 27.6% in CKDG5D, p=0.004), and patients who had benzodiazepines for > 4weeks were also significantly different (8.7% in CKDG1 and 2, 7.41% in CKDG3-5, and 24.7% in CKDG5D, p=0.001). Multivariate logistic analysis indicated that CKD stage and diabetes were independent risks for polypharmacy and hyper polypharmacy (polypharmacy: CKD stage; HR 1.62/ one stage increase, p<0.001, and diabetes: HR 2.23 (vs. without DM), p=0.007, hyper polypharmacy: CKD stage; HR 1.54, p<0.001, and diabetes: HR 1.64, p=0.017).

Conclusions: The number of medications, patients with polypharmacy, and the risk for polypharmacy were increased as higher CKD stage.

SA-PO294

Barriers and Facilitators of Pharmacist-Led Programs: Insights from Survey Among Providers

Masaaki Yamada,[1,2] Diana I. Jalal.[2,1] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA.*

Background: Hypertension is a leading cause of cardiovascular death in the United States (US). Despite current guidelines emphasizing strict blood pressure control, over half of the US population fails to reach the recommended goal. Clinical pharmacists can play a crucial role in a team-based approach to overcome these challenges. However, our previous survey found that pharmacists are underutilized despite positive attitudes among providers. To understand the barriers and facilitators of implementing pharmacist-led programs, we conducted a thematic analysis of survey data from providers.

Methods: To gain insights into the utilization of pharmacists, we conducted a survey among providers at a single academic institution and its affiliated Veterans Affairs (VA) hospital where the pharmacist-led medication management is routinely available. We conducted sentiment and thematic analyses of providers' narrative comments to better understand their attitudes and experiences with the utilization of pharmacists.

Results: The survey response rate was 37% (153 of 413 surveyed providers), with 36 providers (24%) providing comments. The majority of the providers (n=27, 75%) were Primary Care (PC) providers, with half of them (n=15, 50%) based in the VA practice. In the sentiment analysis, we observed more positive attitudes among PC APPs (n=5 of 8, 63%) compared to PC clinicians (n=7 of 19, 37%). Among VA PC clinicians (n=4), concerns were expressed. The thematic analysis results, summarized in Fig 1, highlight a lack of awareness among providers potentially leading to underutilization of pharmacists. However, there were other providers who expressed the value of pharmacists and held positive perceptions, likely based on their former experiences.

Conclusions: The lack of awareness among providers is a major barrier to implementing pharmacist-led programs.

Theme	Number of Mentions
Barrier: Lack of Knowledge/Information	10
Barrier: Concerns for Patient's Knowledge and Capability	7
Barrier: Concerns about Pharmacist Involvement	7
Facilitator: Need for Collaboration and Relationship Building	6
Facilitator: Positive Experiences with Pharmacists	5
Facilitator: Potential Benefits of Pharmacist Involvement	4

Barriers:

Lack of Knowledge/Information
- *"Neutral because I do not know."*
- *"I'm unaware of pharmacist availability in managing hypertension."*
- *"Don't know anything about the pharmacy-guided program."*
- *"Hard to judge, I have not seen it done."*
- *"I am not very familiar with pharmacist-guided management of BP meds."*
- *"Have not used pharmacists for blood pressure management."*

Concerns for Patient's Knowledge and Capability
- *"Unsurprisingly, it really depends on the patient as to the success and risk."*
- *"I don't have enough information about pharmacist-guided patient-driven self-titration, but I can tell you my patients are highly uneducated and I do not trust them to self-titrate their meds."*
- *"They are often confused with instructions even when written down. I think that is a very dangerous idea and I won't be referring patients for that service."*
- *"It can lead to confusion for patients."*
- *"Pharmacist involvement can lead to confusion for patients. Sometimes it leads to excessive lab draws. I would advocate nursing staff involvement for BP treatment and monitoring."*

Concerns about Pharmacist Involvement
- *"I never want the pharmacist involved in clinical decision making."*
- *"I do not require any assistance from individuals with no licensing authority to practice medicine."*
- *"I want to be in control of my patient's care."*
- *"I am ultimately responsible for them."*
- *"Hypertensive care is what I was trained to do."*

Facilitators:

Positive Perception of Pharmacist Involvement
- *"I think the pharmacist-guided approach makes a lot of sense."*
- *"I would love to have more pharmacist help in the outpatient clinics."*
- *"Pharmacists are an integral part of my practice and have been extremely helpful."*
- *"Depends on the pharmacist! But in general, after a diagnosis and secondary causes of hypertension ruled out, I'm happy to let my trusted clinical pharmacist assist with management."*
- *"Our pharmacists have guided me on multiple occasions."*
- *"I may be biased as my off-site clinic participated in some of the clinical trials of collaborative care both for hypertension and diabetes and it helped tremendously."*
- *"Having a clinical pharmacist in-house is an excellent resource for us clinicians."*
- *"I feel that involving a pharmacist in the treatment process helps us interact with patients more frequently than once every 2-3 months visits."*

Recognition of Pharmacist's Value in Clinic
- *"I find the pharmacist to be my most valuable asset in clinic."*
- *"Outstanding PACT pharm dx management at the IC VA, and I appreciate their care and excellent communications."*
- *"In my experience as a Heart Failure cardiologist, HF pharmacist take over HF medication titration in Heart Failure patients."*
- *"I am usually very satisfied having the pharmacist involved with HTN management."*
- *"Patients with advanced renal disease could work collaboratively with the pharmacy when needed."*
- *"Our clinical pharmacist at IRL provides a great service for our patients with suspected or confirmed hypertension."*

SA-PO295

Use of Guideline-Recommended Medication Therapy in a High-Risk CKD Population in the Kidney CHAMP Trial

Melanie R. Weltman,[1] Zhuoheng Han,[2] Alaa A. Alghwiri,[2] Jonathan Yabes,[4] Linda-Marie U. Lavenburg,[1,2] Thomas D. Nolin,[3,2] Manisha Jhamb.[1,2] *[1]UPMC, Pittsburgh, PA; [2]University of Pittsburgh Renal-Electrolyte Division, Pittsburgh, PA; [3]University of Pittsburgh School of Pharmacy, Pittsburgh, PA; [4]University of Pittsburgh Department of Medicine, Pittsburgh, PA.*

Background: Use of guideline-recommended medication therapy to improve kidney and cardiovascular outcomes in patients with chronic kidney disease (CKD) is suboptimal. Kidney CHAMP is a pragmatic randomized controlled trial evaluating the effectiveness of a population health management (PHM) approach to improve CKD care. The intervention leveraged electronic health records to identify patients with CKD at high risk of progression and communicate recommendations from a nephrologist-led e-consult and pharmacist-led medication review to primary care providers (PCP) randomized to the intervention group. We compared the use of guideline-recommended medication therapy in patients in the intervention group vs patients receiving usual care per their PCP.

Methods: Eligible patients were 18-85 years with high-risk CKD and not followed by a nephrologist. Guideline-recommended medication therapy included use of ACE inhibitor (ACEi) or angiotensin II receptor blocker (ARB) if baseline urine albumin-to-creatinine ratio (UACR) ≥ 300 mg/g, moderate or high intensity statin if baseline age ≤ 75 years, and SGLT2 inhibitor (SGLT2i) and/or GLP1 receptor agonist (GLP1RA). Changes in medication use between groups were tested using logistic regression via generalized estimating equations.

Results: Among 1596 patients enrolled, 58% were females, the mean age was 74 years, mean eGFR 37 mL/min/1.73m^2, and mean UACR 410 mg/g at baseline. Comorbidities included hypertension (95%), diabetes (64%), and cardiovascular disease (78%).

Over a median 18 month study period, ACEi/ARB use changed from 49% to 43% (p=0.10) vs 51% to 40% (p=0.005), statin use changed from 52% to 55% (p=0.55) vs 54% to 50% (p=0.25), and SGLT2i and/or GLP1RA use changed from 9% to 20% (p<0.001) vs 5% to 13% (p<0.001) in the intervention vs usual care groups, respectively. There was no between group difference in the change in ACEi/ARB (p=0.46), statin (p=0.12), or SGLT2i and/or GLP1RA (p=0.80) use.

Conclusions: A PHM approach did not improve use of guideline-recommended medication therapy in patients with high-risk CKD compared to usual care. This research supports a need to address barriers in the primary care setting, including therapeutic inertia and access to clear practice guidelines, and efforts to improve the delivery of CKD care.

Outcomes of Australian and New Zealand Dialysis and Transplant Patients with Kidney Failure Attributed to Kidney Stones

Hicham I. Cheikh Hassan,[1,2] David J. Tunnicliffe,[3,4] Lyn Lloyd,[5] Adela Yip,[4,3] Brydee Cashmore,[3] Adam W. Mullan,[6,7] Matthew D. Jose,[8,9] Andrew J. Mallett.[10,11] *[1]University of Wollongong Faculty of Science Medicine and Health, Wollongong, NSW, Australia; [2]Illawarra Shoalhaven Local Health District, Wollongong, NSW, Australia; [3]The Children's Hospital at Westmead, Westmead, NSW, Australia; [4]The University of Sydney, Sydney, NSW, Australia; [5]Auckland City Hospital, Auckland, New Zealand; [6]The University of Auckland, Auckland, New Zealand; [7]Te Whatu Ora Health New Zealand Te Tai Tokerau, Whangarei, New Zealand; [8]Royal Hobart Hospital, Hobart, TAS, Australia; [9]University of Tasmania, Hobart, TAS, Australia; [10]Townsville Hospital and Health Service, Townsville, QLD, Australia; [11]James Cook University College of Medicine and Dentistry, Townsville, QLD, Australia.*

Background: Prevalence of kidney stones in the general population can reach 15-20%. Kidney stone formers (KSF), compared to non-KSF, have an increased risk of developing chronic kidney disease and kidney failure (KF). While risk factors, aetiology and outcomes in KSF is well established there remains little data for patients after they develop KF. We therefore set out to examine outcomes of KSF with KF (transplant or recieving dialysis).

Methods: Using the Australian and New Zealand Dialysis and Transpant (ANZDATA) registry we included adult patients with KF who recieved dialysis or transplant (1973-2020). We divided our cohort into KSF and non-KSF groups. For dialysis, we included haemodialysis and peritoneal dialysis to determine risk of mortality. A joinpoint model examined annual rates of KSF diagnosed with KF over time. A seperate analysis was conducted for transplant recipients to examine risk of mortaity and graft failure. Multivariate Cox regression analysis was used to determine hazard ratio (HR) and 95% confidence interval (CI) of outcomes.

Results: In the dialysis cohort 79,670 patients were followed (293,255 patient-years) with 871 (1.1%) having KF from calculi. Compared to non-KSF the KSF group were less likely to have diabetes (26%vs45%) or vascular disease (17%vs45%) and were older (61vs58 years), *P*<0.001. Proportion of KF with calculi as a cause declined annually by 2.7% (95%CI 1.9-7.4, *P*<0.01). There was no difference in mortality between KSF and non-KSF in patients in multivariate analysis (HR 0.93, 95%CI 0.86- 1.01, *P*<0.001). In the transplant cohort 25,052 patients were included, with 219 (0.9%) having KF from calculi. Pre-emptive transplant occurred in 2,221 (2.7%) of the whole group but only in 12 (1.3%) of KSF. Compared to the non-KSF the KSF group were less likely to be diabetic (20%vs12%) and older (48 vs 51 years) (*P*<0.001). There was no difference in mortality risk (HR 1.04, 95%CI 0.86-1.26) or graft failure (HR 1.01, 95%CI 0.77-1.34) between the two groups in multivariate analysis.

Conclusions: In Australia and New Zealand, KSF as a cause of KF is rare and declining over time. There is no difference in mortality risk between KSF and non-KSF in patients who start dialysis, or a difference in graft failure rate in those who received a transplant.

SA-PO297

Characterization of Nephrocalcinosis Phenotypes at Pediatric or Adulthood Ages of Onset

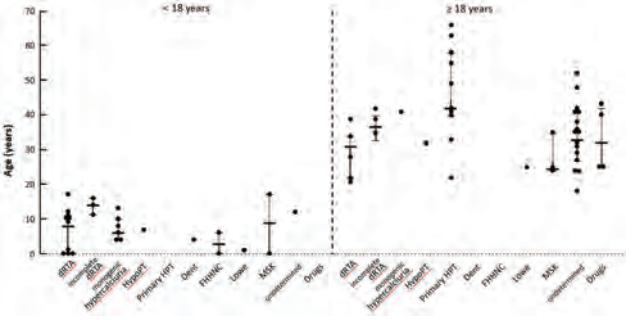
Elenice A. Milhomem, Ana Cristina Matos, Maria H Vaisbich, Ita P. Heilberg. *Universidade Federal de Sao Paulo, Sao Paulo, Brazil.*

Background: This study aimed to compare the clinical and laboratorial presentation and etiology of Nephrocalcinosis (NC) at different ages of onset.

Methods: A retrospective study was conducted based on clinical and laboratorial data from medical records of outpatients aged < or ≥ 18 years old with radiologic evidence of renal parenchymal calcifications by computed tomography or renal ultrasound suggesting NC at presentation.

Results: A total of 81 patients, divided into 2 groups, 56 adults (44 F/12M, ≥18 yrs) and 25 pediatric (14F/11M, <18 yrs), were included**.** Pediatric patients were referred mostly because of hydroelectrolytic/metabolic disorders as the primary presentation of NC (84 vs 30%, p< 0.01), history of failure to thrive (48 vs 3%, p< 0,001) and deafness (28 vs 5%, p< 0,01), against higher association of NC with nephrolithiasis and more urological procedures in adults (70 vs 40%, p < 0.001 & 45 vs 24%, p= 0.056, respectively). Mean estimated glomerular filtration (eGFR) rate was lower in adults (88 ± 31 vs 108 ± 21 mL/min/1.73m2, p< 0.01). Molecular diagnosis could be established in 17/19 genetically tested cases corresponding to 21% of the whole sample. The individual distribution of underlying causes of NC per age are shown in the Figure. Distal renal tubular acidosis (dRTA) and monogenic hypercalciuria were statistically more frequent in the pediatric group (40 vs 13 % and 24 vs 11 %, p= 0.001, respectively) and primary hyperparathyroidism (HPT) and use of drugs were seen only in adults (14 and 7%). Undetermined or still under investigation cases were more common among adults. Cases of familial hypomagnesaemia with hypercalciuria and nephrocalcinosis (FHHNC), medullary sponge kidney (MSK), Lowe, Dent, Hypoparathyroidism (HypoPT) did not differ.

Conclusions: Adults with nephrocalcinosis exhibited reduced renal function at presentation possibly due to delay on diagnosis, worse clinical outcome or previous urological procedures. Molecular analysis could help to further elucidate clinical causes of NC in this group.



SA-PO298

Characteristic Alterations of Bone and Mineral Metabolism in Children and Adults with Nephropathic Cystinosis

Dieter Haffner,[1] Johannes Lahring,[1] Annika Ewert,[1] Christian Köppl,[2] Nadine Herzig,[3] Anja K. Büscher,[4] Julia Thumfart,[5] Katharina Hohenfellner,[6] Maren Leifheit-Nestler.[1] *[1]Hannover Medical School, Hannover, Germany; [2]Clinic Traunstein, Traunstein, Germany; [3]Schoen Clinic Muenchen Harlaching, Munich, Germany; [4]Essen University Medical Centre, Essen, Germany; [5]Charite Universitatsmedizin Berlin, Berlin, Germany; [6]Ro Med Clinics, Rosenheim, Germany.*

Background: The pathophysiology of nephropathic cystinosis (NC) associated bone disease is poorly understood.

Methods: We examined serum/plasma concentrations of 8 bone markers and routine parameters of mineral metabolism in 63 children (mean age 10.8 years) and 40 adults (mean age 28.3 years) with NC by ELISA and autoanalyzer. Data are given as age- and sex-dependent z-scores as a function of estimated glomerular filtration rate (eGFR).

Results: Pediatric and adult NC patients with eGFR > 60 ml/min/1.73 m² showed reduced z-scores for serum phosphate and calcium, and elevated bone-specific alkaline phosphatase (BAP) despite treatment for Fanconi syndrome. Hypocalcemia was more pronounced in children, whereas BAP z-scores were more elevated in adults (each p<0.001). Intact and total fibroblast growth factor 23 (FGF23) and parathyroid hormone levels were suppressed in NC patients with eGFR > 60 ml/min/1.73 m² (each p<0.001). FGF23 z-scores progressively increased in parallel with decreasing eGFR, reaching 6 SD in patients with eGFR < 30 ml/min/1.73 m², while calcitriol levels progressively declined. The Wnt signaling inhibitor sclerostin was increased by 1 SD in pediatric but not in adults NC patients irrespectively of eGFR. The osteoclast marker tartrate-resistant acid phosphatase 5b (TRAP5b) was increased by 1 SD (children) and 2 SD (adults) independent of eGFR despite the absence of hyperparathyroidism in the majority of patients (each p<0.001). Receptor-activator of NF-κB ligand (RANKL), an inhibitor of osteoclast activity, was reduced by SD 1.0 in pediatric but not in adult NC patients. Finally, the RANKL inhibitor osteoprotegerin (OPG) was increased by 2 SD in children with eGFR < 30 ml/min/1.73 m², whereas adult patients consistently showed reduced OPG z-scores.

Conclusions: Pediatric and adult NC patients show hypophosphatemia, hypocalcemia, hypovitaminosis D, and increased osteoblast activity indicating persisting rickets/osteomalacia despite treatment for Fanconi syndrome. Increased osteoclast activity despite counter regulation via OPG/RANKL and suppressed PTH levels suggests a primary osteoclast defect in NC resulting in increased bone resorption, which is more pronounced in children compared to adult patients.

SA-PO299

Low Expression of Renal Claudin-2 Increases Medullary Pro-Inflammatory Macrophages and Calcification in Nephrectomy Patients with a History of Urinary Stone Disease

Muthuvel Jayachandran, Miles Delbusso, Loren P. Herrera Hernandez, Zejfa Haskic, Andrew D. Rule, Kevin Koo, John C. Lieske. *Mayo Clinic College of Medicine and Science, Rochester, MN.*

Background: The transmembrane protein claudin-2 (Clnd2) is highly expressed in the proximal tubule and descending thin limb where it is key for ~70% of filtered Ca^{2+} reabsorption. Men with a rare missense mutation in Clnd2 manifest hypercalciuria and urinary stone disease (USD). However, the relationship of Clnd2 expression to renal calcification and interstitial cellular responses is not known. Thus, we examined Cldn2

expression, interstitial calcification, and pro- and anti-inflammatory macrophages (Mφ's) in nephrectomy samples from patients with and without a USD history.

Methods: Non-cancerous kidney tissue sections from patients with (n=31 stone formers (SFs); 10F/21M) and without (n=50 non-stone formers (NSFs); 16F/34M) a history of USD were used for immunohistochemical analyses. Data are presented as median (25th, 75th percentile) and analyzed by Wilcoxon rank-sum test to identify statistically significant (P<0.05) differences between groups.

Results: Expression of Clnd2 protein in both cortex and medulla of kidneys was significantly (P=0.02) lower in SFs than NSFs. Renal medullary calcification (% calcification) and populations of M1 Mφ's (proinflammatory) were significantly (p<0.001) greater in SFs. There were no differences in the renal tissue population of M2 Mφ's (anti-inflammatory), age, body mass index, hypertension before surgery, serum creatinine, and eGFR between groups.

Conclusions: These results suggest that SFs have decreased expression of Clnd2 protein in the proximal tubule and thin descending limb of Henle's loop. This in turn may increase the formation of interstitial calcifications and populations of pro-inflammatory Mφ's in USD formers. NIDDK (DK135097) and Mayo Foundation.

Controls but Not Patients with Calcium Nephrolithiasis Secrete Less Urinary Uromodulin After Salt Loading

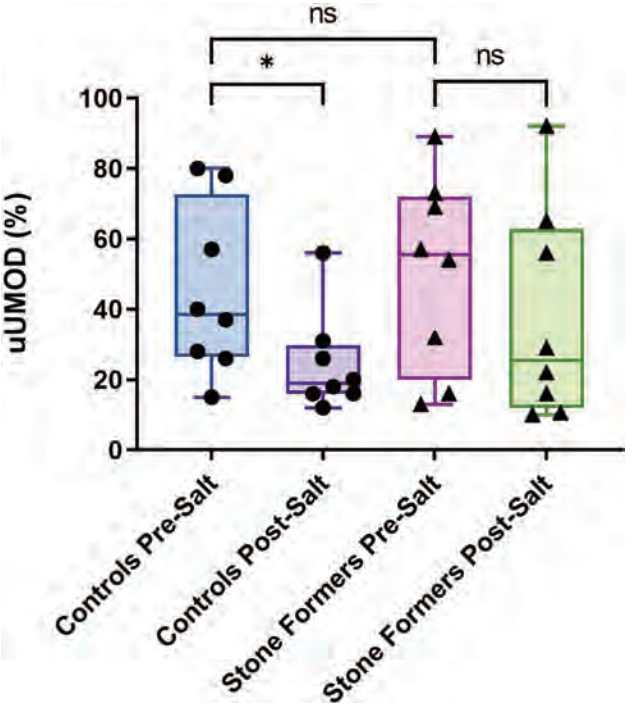
Salar Bani Hani,[1,2] Matthias T. Wolf,[1] Khashayar Sakhaee.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]NewYork-Presbyterian Brooklyn Methodist Hospital, Brooklyn, NY.*

Background: Calcium is the most common constituent of kidney stones. Uromodulin (UMOD) enhances TRPV5 membrane abundance increasing renal Ca^{2+} absorption thus reducing hypercalciuria. UMOD stimulates Na^{+} absorption via NKCC2 causing hypertension. High salt intake is also risk factor for nephrolithiasis. We hypothesize that a higher urinary UMOD secretion with a high salt diet compensates for the higher stone risk by improving hypercalciuria.

Methods: This is a prospective, randomized, cross-over study. Stone-formers and controls were randomized to a control or a high salt diet for 2 days. After washout, the participants received the diet they were not exposed to previously. After each diet, we obtained 24-hour urine and fasting serum studies.

Results: At baseline, there was no significant difference for urinary UMOD secretion between stone-formers and controls. In contrast to our hypothesis, we found that urinary UMOD secretion was significantly reduced after the salt load in controls but not in stone-formers.

Conclusions: There was no lower baseline urine UMOD level in stone-formers. After salt loading, we show lower urinary UMOD secretion in controls but not in stone-formers. As UMOD enhances NKCC2 contributing to hypertension, acute downregulation of UMOD after a salt loading makes physiologically sense.



Salt-loading reduces uUMOD in controls only (P<0.05).

CYP24A1 Activity Associates with Phenotypic Traits in Idiopathic Hypercalciuria

Daniel G. Fuster,[1] Matteo Bargagli,[1] Olivier Bonny.[2,3] *[1]Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]Service of Nephrology, Lausanne University Hospital, Lausanne, Switzerland; [3]Service of Nephrology, Department of Medicine, Fribourg State Hospital, and University of Fribourg, Fribourg, Switzerland.*

Background: Hypercalciuria is the most frequent abnormality in kidney stone formers. The underlying mechanisms remain unknown in most cases, hence the designation "idiopathic hypercalciuria". We hypothesized that the Vitamin D-inactivating enzyme CYP24A1 contributes to the pathogenesis of hypercalciuria in kidney stone formers.

Methods: We conducted association analyses between CYP24A1 activity, estimated by the Vitamin D metabolite diagnostic ratio (25(OH)-/24,25 $(OH)_2$ Vitamin D_3 ratio; VMDR), and the phenotype of participants in two observational cohorts of kidney stone formers, the Swiss Kidney Stone Cohort and the Bern Kidney Stone Registry. Linear and logistic regression models adjusted for multiple confounders, including plasma 25(OH) Vitamin D_3, were applied. Plasma 25(OH)- and 24,25 $(OH)_2$ Vitamin D_3 were quantified using an established, highly sensitive and specific LC-MS/MS assay.

Results: In total, 974 participants were included in the analysis. After multivariable adjustment, a higher VMDR (i.e. lower CYP24A1 activity) was associated with higher

total plasma calcium (β 0.07; 95% CI 0.01, 0.14; p = 0.02), ionized calcium (β 0.11; 95% CI 0.03, 0.18; p < 0.01) and absolute and fractional excretion of urinary calcium (β 0.06; 95% CI 0.00, 0.11; p = 0.04 and β 0.10; 95% CI 0.04, 0.16; p < 0.01, respectively). A higher VMDR was further associated with an increased risk of forming stones composed of calcium oxalate dihydrate (Odds ratio 1.64; 95% CI 1.22, 2.35; p < 0.01) and a reduced bone mineral density at the femoral neck (β -0.07; 95% CI 0.14, -0.01; p = 0.04). VMDR was not associated with plasma or urinary phosphate, 1,25 $(OH)_2$ Vitamin D_3 or parathyroid hormone.

Conclusions: Our study reveals that CYP24A1 activity is associated with traits previously linked to idiopathic hypercalciuria.

SA-PO302

Distinguishing Uric Acid Stone Formers from Type 2 Diabetics with Low Urine pH: The Role of Impaired Buffering

Seyed Alireza Zomorodian, John Poindexter, Khashayar Sakhaee, Naim M. Maalouf, Orson W. Moe. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: The prevalence of uric acid (UA) nephrolithiasis has increased in the past decades, particularly among patients with metabolic syndrome, and this lithogenicity is driven by acidic urine pH. Previous studies in these patients on random diets showed that this lower urine pH results from higher acid excretion and insufficient urinary buffering by ammonia. However, intrinsic vs. extrinsic contributors are hard to discern because diet was not controlled. In addition, patients with type 2 diabetes mellitus (T2DM) often exhibit an acidic urine, but only a minority develop UA stones. Here, we provide a comprehensive report of acid-base and stone risk parameters in UA stone formers (UASF) and non-stone forming controls with and without T2DM who were equilibrated and studied under a fixed metabolic diet.

Methods: A total of 74 UASF, 13 T2DM patients without a history of kidney stones, and 51 normal subjects without stones or diabetes (Ctrl) were studied. All participants were equilibrated on metabolic diet for at least 5 days. Blood and urine samples were collected for analysis of acid-base and stone risk parameters. Statistical analyses were performed to compare the stone risk profiles among the three groups.

Results: Participants were comparable with respect to demographic characteristics, with age range of 48-60 years (aligning with peak incidence of UA stones). UASF had slightly higher and Ctrl exhibited a lower body mass index. Under a fixed diet, UASF and T2DM exhibited lower urinary pH, higher net acid excretion (NAE), and lower levels of citrate and bicarbonate compared to Ctrl. The proportion of NAE excreted as ammonium (ammonium/NAE) was significantly lower in UASF [0.50 (95% confidence intervals: 0.46-0.54)] compared to T2DM [0.64 (0.53-0.76)] and Ctrl [0.74 (0.68-0.81)].

Conclusions: This study has the largest number of subjects evaluated on a controlled metabolic diet to date. We found a similarly high NAE in UASF and T2DM non-stone formers; the parameter that sets aside UASF was the significantly lower ammonium/NAE in UASF. An increased acid load to the kidney is an important contributing factor in the development of UA nephrolithiasis but it is not sufficient, and a defect in urinary buffering is necessary for its full pathogenesis.

SA-PO303

Adherence to Potassium Citrate and Changes in 24-Hour Urine Stone Risk Parameters

Joseph J. Crivelli,[1] Mary K. Oerline,[6] Ryan Hsi,[5] Kevin Smith,[3] Brian Denton,[3] John R. Asplin,[2] Vahakn Shahinian,[6] John M. Hollingsworth.[4] *[1]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [2]Laboratory Corporation of America Holdings, Burlington, NC; [3]University of Michigan College of Engineering, Ann Arbor, MI; [4]NorthShore University HealthSystem, Evanston, IL; [5]Vanderbilt University School of Medicine, Nashville, TN; [6]University of Michigan Medical School, Ann Arbor, MI.*

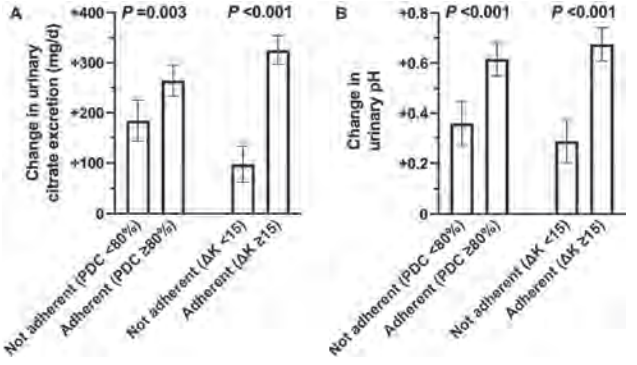
Background: Patient adherence to potassium citrate therapy for urinary stone disease (USD) is low. We assessed associations of potassium citrate adherence with changes in 24-hour urine parameters.

Methods: We identified adults enrolled in Medicare with USD, a baseline 24-hour urine collection (Litholink, 2011-2017), hypocitraturia or low urine pH, a prescription for monotherapy with potassium citrate tablets within 3 months, and a follow-up urine collection 6-12 months after baseline. We defined two measures of adherence: (1) percentage of days covered (PDC) over 0-3 months based on pharmacy claims and (2) change in urinary potassium (ΔK) between baseline and follow-up. We assessed the association between PDC and ΔK using an independent t-test and the association of adherence with changes in urinary citrate and pH using ANCOVA. Finally, we compared the strength of association of PDC and ΔK with these changes using a Wald test.

Results: Among 432 patients, 366 (85%) had hypocitraturia and 266 (62%) had low urine pH. Patients adherent to medication based on pharmacy claims (PDC≥80%) had a significantly higher mean ΔK compared to those not adherent to medication (+26.1 mEq/day vs. +17.9 mEq/day, *P*<0.001). The adjusted mean increase in urinary citrate and pH among patients adherent to medication significantly exceeded that of patients not adherent to medication (Figure). Compared to PDC, ΔK had a stronger association with change in urinary citrate (*P*<0.001) and pH (*P*=0.07), though the latter was not statistically significant.

Conclusions: Compared to pharmacy claims, the increase in urinary potassium was generally more predictive of increased urinary citrate and pH, emphasizing the value of urinary potassium as a measure of adherence.

Funding: NIDDK Support



Mean change in (A) urinary citrate and (B) pH stratified by adherence. Estimates are adjusted for age, sex, race, region of residence, dual eligibility, comorbidity score, and medication dose. Error bars represent 95% CIs.

SA-PO304

Differential Effects of Thiazide, Alkali, or Both on Urine Determinants of Stone Risk in Calcium Oxalate (CaOx) and Calcium Phosphate (CaP) Stone Formers

Audrey Steely, Elaine M. Worcester, Megan Prochaska. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Thiazide type diuretics, potassium citrate (K-Cit), and lifestyle changes are used to prevent calcium kidney stones. Thiazides decrease stone risk by decreasing urine calcium (Ca). Citrate (Cit) is an inhibitor that decreases urine supersaturations (SS); however, it also increases urine pH and therefore Ca phosphate (CaP) SS. Thus, the effect of K-Cit on stone risk is complex.

Methods: To study the effects of common treatments for Ca stone risk we analyzed the 24-hour urinalysis of Calcium Oxalate (CaOx) and CaP stone formers (SF) by 4 different treatment types: lifestyle, K-Cit, thiazide, or both medications.

Results: Thiazides reduced urine Ca in both CaOx SF (-74±95 mg/day) and CaP SF (-102±100 mg/day). K-Cit alone and when combined with thiazide had no effect on urine Ca. K-Cit increased urine Cit in CaOx SF (252±306 mg/day), but not in CaP SF (36±353 mg/day). Thiazide decreased urine Cit among CaP SF (-118± 249 mg/day). K-Cit and thiazide combined increased Cit in CaOx SF (118±264 mg/day), but not CaP SF (94±217 mg/day). Urine pH rose in all groups except CaP SF on only lifestyle treatment. Among CaOx SF, pH increased in patients receiving K-Cit (0.6±0.6) and both (0.7±0.6) compared to patients receiving thiazide (0.1±0.5). There is a similar pattern among CaP SF receiving K-Cit (0.3±0.5), both (0.5±0.5), or thiazide (0.1±0.3). Thiazide decreased CaOx SS in both CaOx SF (-3.3±3.5) and CaP SF (-3.1±2.9). K-Cit did not lower CaOx SS in either CaOx or CaP SF. Thiazide decreased CaP SS in both CaOx SF (-0.5±0.9) and CaP SF (-0.8±0.9).

Conclusions: K-Cit had no significant effect on urine Ca and increased urine Cit levels in CaOx SF; however, increased urine pH lead to increased CaP SS for CaOx SF. The study raises questions about the best preventive treatment for patients with CaP stones and suggests that K-Cit may not confer the same benefits on CaP SF as it does on CaOx SF.

Funding: NIDDK Support

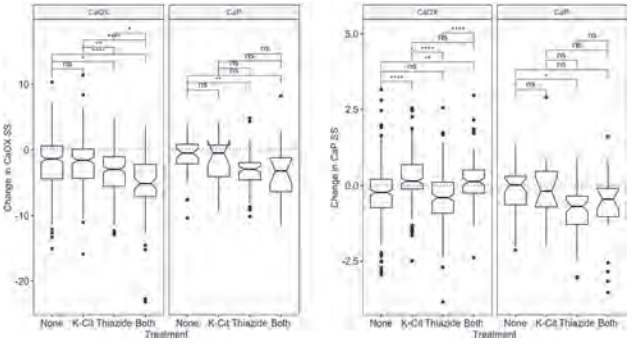


Figure 1. Boxplots of the change in urine CaOx and CaP SS by treatment group and stone type. Each includes t-tests comparing treatment groups.

SA-PO305

Effect of Hydrochlorothiazide on Bone Mineral Density in Patients with Kidney Stones: A Post Hoc Analysis of the NOSTONE Trial

Matteo Bargagli,[1] Dionysios Drakopoulos,[2] Elias Primetis,[2] Grazia M. Cereghetti,[1] Beat Roth,[3] Olivier Bonny,[4] Daniel G. Fuster.[1] *[1]Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [2]Department of Radiology, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland; [3]Department of Urology, Lausanne University Hospital, University of Lausanne, Lausanne, Switzerland; [4]Service of Nephrology, Department of Medicine, Fribourg State Hospital and University of Fribourg, Fribourg, Switzerland.*

Background: Low bone mass and fractures are highly prevalent in patients with kidney stones. Thiazide diuretics lower urine calcium and hence may preserve bone mass. No placebo-controlled randomized trial (RCT) has been conducted to examine the impact of thiazide diuretics on bone mineral density (BMD) in patients with kidney stones.

Methods: We conducted a post-hoc analysis of the NOSTONE trial to assess a range of hydrochlorothiazide (HCT) doses or placebo on bone mineral density in patients with recurrent calcium-containing kidney stones. Computed tomography (CT) attenuation was measured at T12-L3 vertebrae in Hounsfield units (HU) at baseline and the end of the study, using a previously validated approach, with lower values corresponding to lower BMD. BMD measurements were performed by two independent readers blinded to the study intervention. Random-effects linear regression models were used to investigate treatment effects on changes from baseline.

Results: BMD measurements were available in 388 of 416 (93%) randomized patients. Median follow-up time was 2.92 years. At baseline, mean BMD was directly associated with eGFR (β 0.934 HU, 95% confidence interval [CI] 0.680; 1.189, p < 0.001) and inversely with age (β -2.208 HU, 95% CI -2.510; -1.907, p < 0.001). Mean BMD decreased by 6.4±15.7 HU in the placebo group, by 5.1±15.1 in the 12.5mg HCT group (β coefficient vs placebo, 0.368 HU, 95% CI -1.735; 2.472, p = 0.732), by 4.1±16.3 in the 25mg HCT group (β 0.926 HU, 95% CI -1.335; 3.187, p = 0.422), and by 4.8±15.9 in the 50mg HCT group (β 0.699 HU, 95% CI -1.450; 2.848, p = 0.524). No association was observed between HCT dose and change in BMD (p = 0.430). The results were confirmed in sensitivity analyses for eGFR, urinary calcium, body mass index, and in per-protocol analyses.

Conclusions: In patients with recurrent calcium-containing kidney stones, loss of bone mineral density was similar in patients receiving hydrochlorothiazide at a dose of 12.5 mg, 25 mg, or 50 mg or placebo once daily.

SA-PO306

Vascular Calcification in Kidney Stone Formers: The Impact of Age and Stone Composition

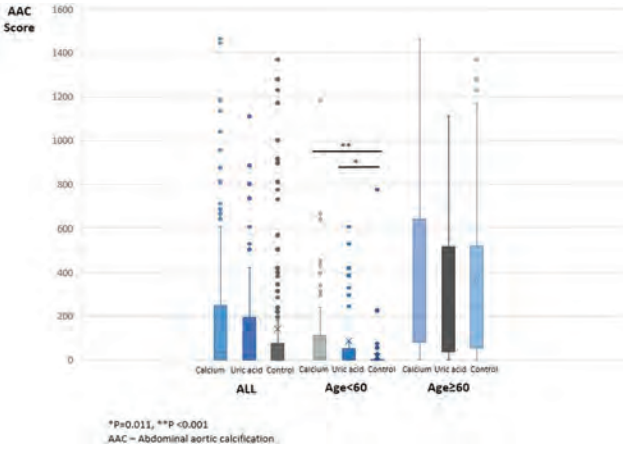
Alon Bnaya, Yehezkel Barhoum, Ilan Z. Kafka, Linda Shavit. *Shaare Zedek Medical Center, Jerusalem, Israel.*

Background: Nephrolithiasis is a common condition, associated with increased cardiovascular morbidity. Previous observational studies have showed that kidney stone formers (KSF) have increased vascular calcifications (VC) and osteoporosis. However, data regarding the effect of age and stone component on VC in these patients is limited.

Methods: This is a retrospective, single center, matched case-control study. KSF with a pure stone analysis (uric acid stone or calcium oxalate) who were treated in the urology clinic of Shaare Zedek Medical Center from 2015 to 2021 were identified. Fully matched controls without history of nephrolithiasis were drawn from patients hospitalized or admitted to the emergency room of the same hospital. Abdominal aortic calcification (AAC) and vertebral bone mineral density (BMD) were assessed using available computed tomography (CT) imaging. KSF and non-KSF were compared for prevalence and severity of AAC and BMD.

Results: A total of 335 patients were investigated, 134 with calcium oxalate stone, 67 with uric acid stone, and 134 fully matched controls. Overall, the severity of VC, measured by the AAC score, did not differ significantly between the groups. However, in patients aged <60 years, both prevalence and severity of aortic calcification were significantly higher in calcium oxalate and uric acid stone groups compared to control (55.1%, 37.8% and 21.8%, p = 0.001, for the prevalence of aortic calcification and 95.4±187.5, 85.8±166.6 and 16.3±86.6, p = 0.001, for ACC score, respectively). The prevalence of osteoporosis was similar between the groups.

Conclusions: In this study, the prevalence and severity of VC was higher in younger KSF. These findings may suggest premature vascular calcification among patients with nephrolithiasis, both in calcium oxalate and uric acid stone formers.



SA-PO307

SYNB8802 Lowers Urinary Oxalate During a Diet-Controlled Study in Patients with Roux-en-Y Gastric Bypass

Caroline B. Kurtz,[1] Alistair Wheeler,[1] Julie B. Blasbalg,[1] William Denney,[2] James Macdougall,[1] Kyle Wood,[3] Aoife M. Brennan.[1] *[1]Synlogic, Cambridge, MA; [2]Human Predictions, LLC, Cambridge, MA; [3]University of Alabama, Birmingham, AL.*

Background: Patients with Roux-en-Y (RnY) gastric bypass surgery are at risk for development of intestinal malabsorption which can increase the absorption of dietary oxalate, resulting in enteric hyperoxaluria (EH). Hyperoxaluria may lead to kidney stone formation, kidney damage, and deposition of oxalate in other tissues and organs. SYNB8802 is an engineered probiotic bacteria designed to consume oxalate in the GI tract and reduce urinary oxalate (UOx) absorption.

Methods: Study SYNB8802-CP-002 was a Phase 1b, randomized, placebo-controlled, single-center inpatient study in subjects with a history of RnY gastric bypass surgery. Subjects were placed on a 12-day diet-controlled study containing 300 mg of oxalate and 400 mg of calcium. A diet and placebo run-in period of 3 days was followed by oral administration of increasing dose levels of SYNB8802 up to $3x10^{11}$ lives cells or placebo for 12 days. 24-hour urine was collected daily from days -3 to 12 and analyzed for urine oxalate content as well as other analytes.

Results: SYNB8802-CP-002 enrolled 11 subjects (median (SD) age 56 (8.6), 1 M/10 F) with a history of RnY gastric bypass, and no prior kidney stones. Seven subjects received SYNB8802 and 4 patients received placebo. Two placebo subjects were excluded from the efficacy analysis because of major protocol violations (antibiotic use and incomplete dosing). The oxalate diet resulted in a baseline mean (SD) UOx of 29.4 (2.3) mg/24h for the placebo and 32.5 (9.0) mg/24h for the SYNB8802. SYNB8802 lowered UOx by -41.0% (p<0.01) compared to -8.8% (p=0.73) for placebo but the change over placebo (-35.3%) did not achieve statistical significance (p=0.16). A post-hoc pharmacometrics model incorporating the effects of dose and frequency showed a significant UOx lowering of -37.3% [95% CI: 45.9, 28.3] relative to placebo (p<0.05). The most common adverse events were mild to moderate and GI related. There were no SAEs.

Conclusions: SYNB8802 was well tolerated in patients with RnY gastric bypass and demonstrated the capacity to lower UOx. SYNB8802 should be further evaluated in subjects afflicted with kidney stone disease and EH.

SA-PO308

Assessment of Health-Related Quality of Life in Primary Hyperoxaluria

Frank Modersitzki,[1] Carly Banks,[2] Kim Hollander,[3] John C. Lieske.[2] *[1]New York University Grossman School of Medicine, New York, NY; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Oxalosis and Hyperoxaluria Foundation, New York, NY.*

Background: Primary hyperoxaluria (PH) is a rare monogenic disorder; all 3 known forms are associated with frequent kidney stone events and a risk for chronic kidney disease. Here we assessed patient quality of life (QoL) metrics.

Methods: PH patients (pt) and caregivers were recruited by the Oxalosis and Hyperoxlauria Foundation. QoL was measured via disease specific questions plus validated instruments.

Results: Both PH pt (n=25) and caregivers (n=21) participated. The majority of PH cases were diagnosed as a child. The cohort included all 3 types (20 PH1, 15 PH2, 12 PH3). The majority (78%) of pt were diagnosed by genetic testing, 9% by liver biopsy, and in 13% pt did not know. Most pt (49%) formed their first stone as an infant or toddler, 23% as a preschool or school-age child, and 11% as teenagers. Only 4% formed their first stone as adults, and 13% never had a kidney stone. The main PH health concerns are shown in graph 1. Other significant health burdens are chronic kidney disease and fatigue. Adult pt see kidney stones as troubling compared to parents and caregivers (p=0.03). Socializing and traveling (34%, 10 adults, 6 children), attending school or work (23%, 4 adults, 7 children), and participating in sports (21%, 6 adults, 4 children) were the most impacted

activities of daily life in our sample. Anxiety regarding recurrent stone events and future kidney failure was high among all 3 PH types. PH 3 pt scored highest (least impacted) in all QoL domains, followed by PH 2 with the lowest scores for PH1.

Conclusions: Depression, anxiety, bodily pain, kidney stones and CKD are important QoL factors regardless of the underlying PH cause. These patient reported outcomes can be used to guide future treatment targets.

Sample characteristics

	Male	Female	Non-binary	Total
Living with PH	10	14	1	25
Parent or caregiver	13	8	0	21

SA-PO309

Suboptimal Identification and Investigations of Renal Stones in a Tertiary Irish Centre: A Retrospective Analysis

Emmett Browne,[1] Denise M. Sadlier.[2] *[1]Ireland East Hospital Group, Dublin, Ireland; [2]University College Dublin, Dublin, Ireland.*

Background: Nephrolithiasis is a common medical problem with 10-20% of men, and 5% of women in Ireland having one kidney stone in their lifetime. Simple investigations and stone analysis can identify metabolic or structural factors that increase risk, allowing prompt treatment. There are clinical characteristics that should prompt these investigations, and this often requires multi-disciplineary approach.

Methods: EAU+ AUA recommend in depth metabolic screening for patients with these features: Young age Multiple or bilateral stones. Recurrent stone formers Structural kidney abnormalities Metabolic Co-morbidities that increase risk, Certain Stone Compositions We performed a retrospective analysis of patients admitted with stone disease between July 2022 and Feb 2023. We collected data on; Patient demographics Treatment choice First stone vs recurrent Testing of basic biochemistry Presence of Risk factors as above.

Results: We analysed 214 unique patient identifiers This consisted of 129 males and 85 female. Average number of stone episodes per month was 30.57. Mean age of patients was 50.25, with 19 patients under the age of 30yrs (9%). Age range 20-95yrs old. Patient presentation to our service was emergency in 158/214 (74%), 21 were elective admissions (10%), and emergency transfers from secondary hospitals consisted of 35/214 patients (16%). Inpatient admission with Medical Expulsive Therapy (MET) consisted of 15 of 214 patients (7%) 7 Patients were discharged home with MET (3%) 15 were admitted for ureteric stent placement alone(7%) 177 of the 214 patients were brought for ureteroscopy (83%) Looking at features as mentioned above that warrant screening, we note this of our population: 25% had recurrent or bilateral stones 9% had stone compositions that were high risk for recurrence 3% had co-morbidities that increase risk of recurrence as detailed above 9% under the age of 30yrs, and 28% under the age of 40. 5.6% had existent structural abnormalities.

Conclusions: There are a large proportion of patients that are at high risk of recurrence and thus a systematic and comprehensive approach is required to identify and investigate these patients. By proactively addressing this gap in patient care, we can enhance patient outcomes, reduce the burden of recurrent renal stones on healthcare systems, and ultimately improve the quality of life for individuals affected by this condition.

SA-PO310

A Case of Primary Pseudohypoparathyroidism Presenting with Normal Serum Phosphorus

Kian Ghodrati,[1,2] Vikyath Prakash,[2] Samir Nangia.[2,3] Dallas Renal Group. *[1]Wilfrid Laurier University Faculty of Science, Waterloo, ON, Canada; [2]Dallas Renal Group, Dallas, TX; [3]Burnett School of Medicine, Fort Worth, TX.*

Introduction: Pseudohypoparathyroidism (PHP) is a very rare genetic disorder characterized by hypocalcemia/hyperphosphatemia secondary to parathyroid hormone (PTH), target organ resistance. PHP is a congenital disorder that is diagnosed in childhood. This is a unique presentation of a rare condition that was initially diagnosed in adulthood.

Case Description: We present a unique case of a 37-year-old woman who was referred for a second opinion before undergoing parathyroidectomy for a positive nuclear scan with an elevated intact parathyroid hormone (iPTH). She had a history of hypocalcemia beginning in her 30s with no family history for the same. Physical exam revealed short stature but no brachydactyly or intellectual disability. Initial findings showed a corrected serum calcium level was 8.3, iPTH 214, vitamin D 44, phosphate 3.6, magnesium 2.1, bicarbonate 25, and creatinine 0.9 and was placed on calcium supplementation and calcitriol. The urinary Fractional excretion of calcium was elevated and her bone density scan was normal. She was treated with a thiazide diuretic and an increase in the calcitriol dose which led to a corrected serum calcium 9.1 and iPTH 93. She did not undergo parathyroidectomy and we can conclude she likely has pseudohypoparathyroidism 1a or 1c.

Discussion: To our knowledge, this is one of the first reported cases of PHP diagnosed with normal serum phosphorus levels. The current literature review does not examine patients that have PHP despite having normal serum phosphorus levels. The goal of this case report was to increase awareness and education that PHP can be diagnosed later in life due to its varying phenotypic penetrance. Future studies can examine a larger cohort of patients that present with similar symptoms to determine the genetic cause. Above all, it is essential to provide knowledge to patients as well as physicians alike.

SA-PO311

Pseudo-Hyperphosphatemia: A Diagnostic Conundrum

Maulik Lathiya, Praveen K. Errabelli, Abdul M. Khan, Jaime R. Jimenez Lopez, Devender Singh. *Mayo Clinic Health System North West Wisconsin, Eau Claire, WI.*

Introduction: Hyperphosphatemia is commonly seen in patient with chronic kidney disease however there are rare clinical situations where it can be seen in patients with normal renal function when interpretation of serum phosphate levels can be challenging due to potential analytical limitations. We present a case report demonstrating the diagnostic challenge of pseudo hyperphosphatemia to highlight the importance of high suspicion of spuriously elevated phosphate level.

Case Description: This is a 54-year-old female with history of multiple myeloma and diagnosed 1 year ago presented with fever and confusionI. In the ER and she was noted to have severe anemia and thrombocytopenia. In addition she was noted to have phosphorus level of 19.2 mg/dL with plasma creatinine was 0.55 mg/dL. Despite aggressive hydration and diuresis repeated measurement of phosphate levels showed persistent elevation and highest phosphate level being 25.7 mg/dL. After excluding common causes of hyperphosphatemia and noted resistance to treatment a diagnosis for spuriously pseudo hyperphosphatemia was made. This was attributed to analytic interference of elevated paraprotein level.

Discussion: True Hyperphosphatemia with normal renal function is a rarely reported condition. Clinicians should have a high suspicion for pseudo hyperphosphatemia/ spurious hyperphopahtemia due to analytical limitations to avoid expensive diagnostic work up, treatment and prologned hospital stay.

SA-PO312

The Dangers of Vitamin D Powder Supplements, Found Over-the-Counter, Causing Vitamin D Toxicity

Hira Tahir, Hubert Wang, Fatima Sheikh. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: Vitamin D toxicity is a rare but serious condition, potentially leading to death if not treated in a timely manner. This case highlights risks of misusing powder vitamin D supplements marketed directly to consumers.

Case Description: A 54-year-old female with no medical history presented with 4 days of headache, fatigue, nausea, vomiting, polydipsia, polyuria and constipation. She took no medications but had self-started vitamin D powder taking “a tablespoon daily in coffee for health and strong bones.” She learned vitamin D could decrease risk of COVID-19 infection as alternative to vaccination. Further investigation revealed this over-the-counter vitamin D powder was sold in 8 ounce bags with a 50 mg serving size equal to 5000 international units (IU) of Vitamin D3. Each bag contained 4,520 servings equaling 21,250,000 IU. “One tablespoon” of powder every morning equated to 1,328,125 IU, exceeding maximum recommended dose. Admission labs showed high Cr 1.76 mg/dL, calcium 14.4 mg/dL and ionized calcium 6.9 mg/dL but normal phosphorus 3.2 mg/dL, albumin 4.6 g/dL, PTH 26.3 pg/mL and TSH 1.21 uIU/mL. Renal US and CT imaging were unremarkable. EKG noted Osborn waves in leads II, III, aVF, V5, and V6, and QTc 412. 25-hydroxy vitamin D level was high at 650 ng/mL, 24-hour urine calcium was high at 410 mg/24 hr, 1,25-dihydroxy vitamin D was high at >600pg/mL. PTHrP, SPEP and UPEP with immunofixation were negative. Vitamin D toxicity was diagnosed with counseling for powder vitamin D supplement cessation. With IV hydration, calcitonin and bowel regimen, symptoms and calcium levels improved and patient was discharged with follow up.

Discussion: Vitamin D toxicity reported in literature recommends discontinuation of exogenous vitamin D. Previous case studies suggest glucocorticoids or bisphosphonates but clear guidelines for therapy are not identified. The most common cause of toxicity is excess exogenous intake greater than 10,000 IU/day causing 25-hydroxy vitamin D concentration >150ng/mL [1]. During COVID-19 pandemic, there was emphasis on supplements including vitamin D thought to protect against respiratory viral infections [5]. Our case elucidates risks of misusing over-the-counter supplements in a generation of changing trends in nutrition. Further studies should be performed to find treatments given risks of unintentional overdose.

SA-PO313

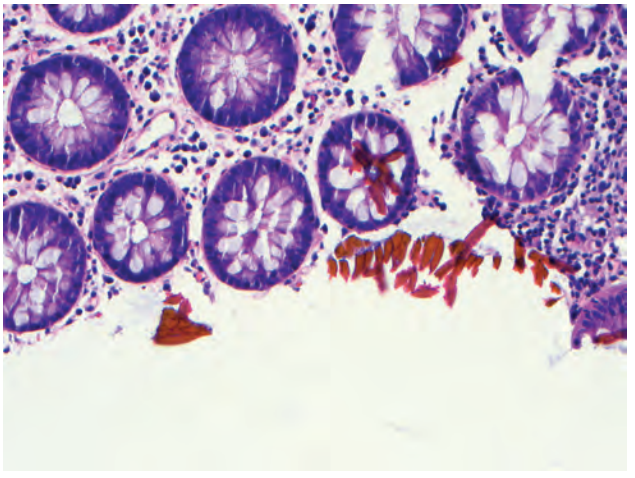
I Am in a Crystal Bind! A Case that Gave Us Ulcers

Ahmed Elkalashy, Ahmed Abdallah, Yazan A. Bashtawi, Wadhah M. Bin Homam, Neriman Gokden, Manisha Singh, Nithin Karakala. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: In patients with ESKD, hyperphosphatemia has been shown to increase mortality. Common complications include vascular and heart calcification, as well as hyperparathyroidism. Managing hyperphosphatemia includes dietary modifications as well as phosphate binders. Sevelamer, a non-calcium phosphate binder, is commonly prescribed and usually well tolerated. Side effects of sevelamer are generally nonspecific and limited to nausea and gastrointestinal discomfort.

Case Description: A 37-year-old man with ESKD on intermittent hemodialysis, hypertension, congestive heart failure, and recent mitral and aortic valve repair presented with hematochezia and fatigue. His hemoglobin level was 5.9mg/dl upon admission. He was transfused and underwent an urgent colonoscopy, which revealed ulcerative mucosal injuries in the colon. Biopsy showed mucosal ulcers with sevelamer crystals. The patient was taken off sevelamer, stabilized, and switched to sucroferric/lanthanum for hyperphosphatemia and is stable at follow-up.

Discussion: Hyperphosphatemia is a common complication of end-stage kidney disease (ESKD) due to decreased renal elimination and continued intestinal absorption of dietary phosphate. Sevelamer, a non-calcium phosphate binder, is commonly used to control hyperphosphatemia. We present a case of a patient with ESKD on sevelamer, with lower gastrointestinal bleeding and endoscopic finding of colonic mucosal injuries with sevelamer crystals. Though reported in gastrology literature, nephrology reports show a paucity of discussion around this increasingly common adverse effect and the need for vigilance in ESKD.



Colon biopsy shows ulcerative mucosal injuries with typical reddish-brown crystals with a characteristic "fish-scale" pattern, described for sevelamer crystals.

SA-PO314

Three Patients with Recurrent Nephrolithiasis and Heterozygous ABCC6 Mutations

Douglas R. Farrell, Jaime Uribarri, Joshua L. Rein. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Pseudoxanthoma elasticum (PXE) is an autosomal recessive disease caused by mutations in the *ABCC6* gene, which encodes an ATP efflux transporter. Loss-of-function results in low extracellular PPi levels, which results in progressive ectopic deposition of CaP leading to skin papules, ocular lesions, and arterial calcification. The association between PXE and nephrolithiasis (stones) is known, though this has not been implicated in those who are heterozygous. We present three cases of recurrent stones without overt risk factors (Fig. 1), but with heterozygosity in *ABCC6*.

Case Description: Patient 1 45 yo F with recurrent CaP stones and nephrocalcinosis. Family history significant for mother with recurrent stones. Genetic testing showed *ABCC6* heterozygous variant of uncertain significance (VUS): c.1685T>C (p.Met562Thr). Skin biopsy and retinal exam did not reveal calcification. **Patient 2** 35 yo M with recurrent CaOx stones (20+) and numerous 2nd & 3rd degree relatives with stones. Genetic testing showed *ABCC6* heterozygous VUS: c.933C>A (p.Phe311Leu). **Patient 3** 24 yo F with recurrent CaOx/CaP stones and HTN. She had yearly stones since age 2 but an unknown family history. Genetic testing showed heterozygous for likely pathogenic variant in *ABCC6*: c3413G>A (P.Arg1138Gln) and heterozygous VUS for *PHEX* and *SLC34A3*, both associated with stones, without either phenotype.

Discussion: We hypothesize that heterozygous *ABCC6* mutations are underrecognized in recurrent stone disease, without extrarenal manifestations of PXE. Threshold for genetic testing of patients with recurrent stones without clear causes should be lowered given increasing testing availability. In vitro functional assays are underway to analyze the VUS mutations.

A Case of Fibroblast Growth Factor 23-Induced Hypophosphatemia in Waldenström Macroglobulinemia

Nozomi Kadota, Takuya Fujimaru, Chiharu Aizawa, Kasumi Konishi, Yugo Ito, Fumika Taki, Masahiko Nagahama, Masaaki Nakayama. *St.Luke's International Hospital, Tokyo, Japan.*

Introduction: Fanconi syndrome and fibroblast growth factor 23 (FGF23)-induced hypophosphatemia are the main causes of hypophosphatemia due to renal phosphorus excretion in cancer patients. FGF23 induced hypophosphatemia is often associated with benign mesenchymal tumors of the mixed connective tissue type. As far as we know, this is the first case of FGF23 induced hypophosphatemia associated with Waldenström macroglobulinemia (WM).

Case Description: The patient was diagnosed with WM at the age of 74 years due to a lumbar compression fracture. Because he had severe neuropathy, he received rituximab as symptomatic WM. After treatment, clinical symptoms disappeared, and serum IgM decreased from 5800 mg/dl to 1800 mg/dl. Four years later, his serum IgM increased (3000 mg/dL) and serum phosphorus decreased (1.5–2.0 mg/dL). Six months later, he was referred to our nephrology department due to hypophosphatemia (serum phosphorus 0.8 mg/dL). He already received alphacalcidol 0.5 μg/day and alendronate 35 mg weekly. His serum IgM was 3263 mg/dL, serum creatinine was 0.98 mg/dl, corrected calcium was 9.6 mg/dl, parathyroid hormone was 39 pg/ml, 1.25-(OH)2 vitamin D was 11 pg/ml (normal range 20-60 pg/ml), and urine glucose was negative. The phosphate excretion rate was 44% and serum FGF23 was 91 pg/ml (normal range <30 pg/ml). The whole-body bone scintigraphy revealed bone destruction in the tenth thoracic vertebra. Contrast-enhanced CT showed multiple enlarged lymph nodes. He was diagnosed as FGF23-related hypophosphatemia due to WM. Sodium phosphate monobasic and tirabrutinib was initiated. Three months after treatment, serum IgM decreased to 423 mg/dl, and serum phosphate increased to 3.7 mg/dl.

Discussion: From the previous report, there are only three types of hematological malignancy that cause FGF23-related hypophosphatemia: diffuse large B-cell lymphoma, natural killer T-cell lymphoma and acute leukemia. We should also consider WM induce FGF23-related hypophosphatemia.

SA-PO316

Calciphylaxis in a Patient with Polymyositis and Absence of Renal Disease

Doree Morison, Sarah J. Lewis, Stella Radosta, Erin E. Boh, Flor Alvarado. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Calciphylaxis is a rare and life-threatening disease in which calcium accumulates in small arteries and can cause tissue necrosis, thrombosis, and painful, non-healing skin ulcers. It is most often seen in patients with advanced choric kidney disease (CKD) but may occur when risk factors such as autoimmune or inflammatory conditions are present. We describe a case of calciphylaxis in a patient with polymyositis and acute kidney injury (AKI) without CKD.

Case Description: A 61-year-old man with polymyositis presented to the hospital with worsening dyspnea, and painful, lower leg wounds. He first noticed the leg wounds following a muscle biopsy for his polymyositis about 6 months prior to presentation; he reported the wounds increased in size since the biopsy. Medical history was significant for polymyositis on prolonged prednisone course, bronchiolitis obliterans organizing pneumonia, atrial fibrillation, hypertension, diabetes, and systolic heart failure. Physical exam revealed sinus tachycardia, coarse breath sounds with bilateral crackles. On his left leg, there were two tender-to-touch ulcers (~2x2 cm, clean-based, with dry yellow fibrinous exudate and surrounding hyperpigmentation). Laboratory data revealed a white blood cell count of 19.6 (81% neutrophils), blood urea nitrogen 52 mg/dl, creatinine 1.8 mg/dl (baseline 1 mg/dl), calcium 10 mg/dl, phosphorus 3.6 mg/dl, and lactic acid 4.1 mmol/L. He was admitted for further work-up of sepsis and AKI. Dermatology was consulted and took a biopsy of the wound which showed calcinosis with thrombotic vessels and fat necrosis consistent with calciphylaxis. Over the course of his hospitalization, the patient improved with antibiotics and fluids, and his AKI resolved. Blood cultures remained negative throughout his hospital stay, and antibiotics were adjusted accordingly by discharge. He was given clinic follow-ups with dermatology and rheumatology.

Discussion: To our knowledge, this is the first case of calciphylaxis reported in a patient with polymyositis and no underlying CKD. Clear treatment guidelines

for calciphylaxis are lacking and many physicians are not familiar with nonuremic presentations of calciphylaxis. We present this case to further advance awareness and knowledge of calciphylaxis occurring in the absence of advanced CKD.

SA-PO317

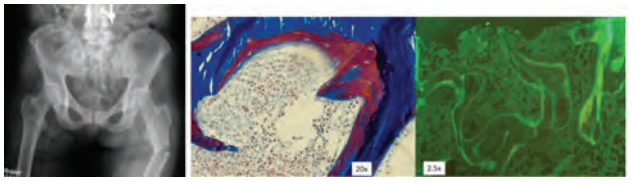
Bone Disease Related to Severe Vitamin D Deficiency in an Adult

Amandeep Singh,[1] Madhumathi Rao,[1] Carter Cassidy,[2] Hartmut H. Malluche.[1] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]University of Kentucky Medical Center, Lexington, KY.*

Introduction: Severe vitamin D deficiency (VDD) as a cause of bone disease is seen very rarely. While VDD can cause osteomalacia, associated secondary hyperparathyroidism (HPT) can also produce significant histopathological changes in the bone.

Case Description: A 60-year-old post-menopausal Caucasian woman, was admitted with a left subtrochanteric femur fracture in 2021, following a ground-level fall and underwent ORIF. She has had prior vertebral fractures, stage 3A CKD, and 30 pack year smoking history. Laboratory data revealed vitamin D (VD) <6.5 ng/ml, iPTH 492 pg/ml, calcium 7.9 mg/dl, ALP 602 U/l and BSAP >120 ug/l. Albumin, phosphorus, creatinine, and eGFR were 4.2 g/l, 2.9 mg/dl, 1.0 mg/dl, and 50ml/min, respectively. Imaging indicated diffuse sclerosis of the spine. Whole-body bone scintigraphy showed diffuse increased uptake throughout the skeleton in a "super scan" pattern. Forearm bone density showed a T-score of -2.6. Undecalcified bone biopsy of the iliac crest with double tetracycline labeling revealed a mixed pattern with high turnover, low mineralization and increased bone volume with areas of woven bone, with diffuse single labels on fluorescent microscopy (image). Malabsorption workup was inconclusive. Aggressive vitamin D replacement over a year, resulted in progressive normalization of VD, iPTH and BSAP levels, and improvement in radiological sclerosis.

Discussion: This patient presented with severe VDD in the setting of multiple fractures, with severe secondary HPT, bony sclerosis and renal osteodystrophy. The severity of HPT was out of proportion to her CKD and caused by VDD. Aggressive treatment with vitamin D resulted in marked reversal of bone abnormalities. With a fourth of the US population estimated to have VDD (<20ng/mL), it is important to consider VDD as a treatable secondary cause of and contributor to bone disease and fracture.



(Left) Femur fracture with varus angulation, increased sclerosis of the spine. (Center) Undecalcified bone biopsy (Masson-Goldner trichrome, 20x) showing mixed osteodystrophy with unmineralized osteoid, osteoblasts and multinucleate osteoclasts. (Right) Fluorescent microscopy (2.5x) showing isolated single labels with diffuse tetracycline deposition.

The Pursuit of the Perfect Body: Need for Myocardial Revascularization and Dialysis After Polymethylmethacrylate Injection

Washington A. Freire Filho, José Guilherme R. Gonçalves, Tassila G. Maia, Liliana M. Kassar, Carolina M. Lima, Maria Julia C. Araujo, Daniela Via Reque Cortes, André P. Guimarães, Renato L. Medeiros, Lizbeth K. Vivanco Balcazar, Vanda Jorgetti, Rosa M. Moyses. *Universidade de Sao Paulo Hospital das Clinicas, São Paulo, Brazil.*

Introduction: Polymethylmethacrylate (PMMA) is a synthetic polymer, initially used to correct HIV-associated lipodystrophy. However, gluteal augmentation for aesthetic purposes are procedures that are increasingly performed all over the world, mainly in Latin America. PMMA can promote foreign body granulomas around its microspheres, leading to increased calcitriol synthesis and, consequently, hypercalcemia.

Case Description: A 58-year-old female patient with a history of arterial hypertension, type-2 diabetes mellitus and sleeve gastrectomy performed a gluteal bioplasty with PMMA 2 years ago. Thirty days after the procedure, the patient had type A anginal pain, acute myocardial infarction with ST-segment elevation and the need for myocardial revascularization. Upon admission, there was evidence of increased serum creatinine, associated with parathyroid-independent hypercalcemia and hyperphosphatemia. In the following 4 months, the patient progressed to end-stage chronic kidney disease and required renal replacement therapy. Renal biopsy showed 60% of tubular atrophy and interstitial fibrosis, with intratubular calcific casts. Positron emission tomography showed irregular densifications in the gluteal muscular plane (fig 1). Despite the previously described findings, no specific treatment was prescribed, as the proper diagnosis of hypercalcemia etiology was not done.

Discussion: PMMA injection promotes granulomatous reaction, with overexpression of 1α-hydroxylase. This leads to extrarenal production of calcitriol by macrophages, and subsequent hypercalcemia, associated with vascular calcification and nephrocalcinosis. This environment favors the onset of acute kidney injury and the progression of vascular damage. If not identified and treated quickly, it may predispose to ischemic events and progression to chronic kidney disease. As some patients have an unfavorable evolution even after treatment, the use of PMMA in large quantities should be prohibited.

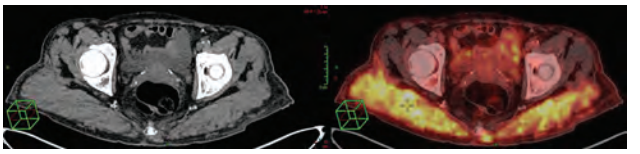

Fig 1

When Woman Turns to Stone: Extraosseous Calcification in a Dialysis Patient

Italo R. Alves, Lucas S. Xavier, Thais O. Santos, Denise M. Costa, Jose E. Gueiros, Ana Paula Gueiros. *Hospital das Clinicas, Recife, Brazil.*

Introduction: Extraosseous calcification (EC) involves vascular and soft tissue calcification, calciphylaxis and is a serious complication of chronic kidney disease (CKD), associated with mortality. EC is an active process arising from the complex interrelationship between electrolyte levels, cell differentiation, and dysregulation of many biochemical pathways. We report the case of a patient with diffuse EC.

Case Description: A female, aged 43, CKD of unknown etiology, on hemodialysis for four years. One year ago, the patient felt pain in the lower limbs, muscle weakness and hard edema in the legs. Seven months ago, she stopped walking, with disabling muscle weakness. On examination, edema in the lower limbs, palpable diffusely hardened nodules, and increased volume and pain in the right clavicle. No calciphylaxis. Admission exams (March 2023): intact parathyroid hormone (iPTH pg/dL) 4296, total alkaline phosphatase 706 U/L, calcium (mg/dL) 13, and phosphorus (mg/dL) 5.4. She was on paricalcitol 15 μg/wk and sevelamer 7.2 g/day. She has never tolerated cinacalcet. Previous exams confirmed a 2-year progressive increase in iPTH from 658 to 4296, monthly calcium average of 14 and phosphorus of 5.9. Paricalcitol was withdrawn. Radiology: extensive calcifications in the subcutaneous tissue of the legs and thighs, bilateral fracture of the femoral neck, brown tumor in the right clavicle, calcifications in the abdominal aorta and iliac arteries and calcifications in the mitral and aortic valves. Ophthalmology: calcifications in lower conjunctiva. Bone densitometry T score: lumbar spine -5.2 and femoral neck -4.2. Scintigraphy: capture in inferior parathyroids. The patient is awaiting parathyroidectomy.

Discussion: This is an unusual case of severe EC in a young, non-diabetic patient on dialysis for a short time. We confirmed the role of bone turnover disorders in the pathogenesis of EC, where the rapid progression of secondary hyperparathyroidism was a determinant of the patient's clinical manifestations. We emphasize the interrelation of bone and vessel, demonstrated by the severe loss of bone mass and the intensity of the EC. Nephrologists must understand the consequences of the mineral and bone disorder of CKD, so that interventions are early, in order to avoid very serious cases such as the one reported herein.

SA-PO320

The Developing Kidney Actively Negotiates Geometric Packing Conflicts to Avoid Defects

Louis S. Prahl, Alex Hughes. *University of Pennsylvania, Philadelphia, PA.*

Background: Ureteric bud (UB) tubules branch at the kidney's surface, where their tips specify sites of nephron induction through interactions with the surrounding cap mesenchyme. The extent of UB branching determines nephron endowment at birth (up to ~1 million in humans) and low nephron count poses a risk of hypertension and adult disease. Here, we examine physical and geometric factors involved in UB tip packing into a limited organ surface area and how UB morphology changes across developmental stages to accommodate branching.

Methods: We use confocal immunofluorescence of embryonic day (E)14-18 mouse kidneys and tissues to investigate the organization of UB and cap mesenchyme. Live kidney explants were treated with dispase to disrupt adhesion between the UB and mesenchyme and tubule retraction was measured by confocal microscopy. We used a computational model to predict branching tubule structures and defects that occur as a function of packing density, repulsion between tips, and node depth. Models were compared to our acquired data and previously published imaging studies of genetic mouse models.

Results: Surface packing density of UB tips increases between E14-18, accompanied by morphological changes in the size and shape of cap mesenchyme clusters and intervening stromal tissue boundaries. Branching tip morphologies change across this interval as well, with branch points progressively moving into deeper tissue layers. Physics-based computational modeling predicts these anatomical changes using geometric parameters. Consistent with model predictions, experimental measurements of tubule retraction following dispase treatment show that actomyosin-based forces are necessary for progressive restructuring of tubules. Our model also predicts conditions where 'packing defects' form, including colliding, or overlapping tubules ('short circuits') or tips being forced into deeper tissue layers ('buried tips'). We successfully reproduce the buried tips defect in microdissected kidney tissues and investigate published literature examples of mouse mutations that exhibit packing defects.

Conclusions: Our work indicates that the UB must actively restructure during development to avoid organizational defects. We suggest new classification criteria for branching morphogenesis-related congenital defects.

Probing Mechanical Regulation of Kidney Morphogenesis Through a Novel 3D Explant Culture Technique

Aria (Zheyuan) Huang,[1] Alex Hughes.[1,2] *[1]University of Pennsylvania School of Engineering and Applied Science, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Achieving proper tissue organization during kidney development plays a vital role in its subsequent functions. For example, congenital anomalies of the kidney and urinary tract can manifest as underdeveloped or disorganized tissue compartments that cause dysfunction or disease. While underlying genetic and molecular factors have been studied, there is little understanding of their interplay with tissue-level cell composition, geometry, and mechanics that together set the final organ structure. Here we address the limited capability to observe developing kidney tissues in a 3D context and seek to uncover the physical principles that set kidney architecture during embryonic development.

Methods: We incorporated a hydrogel droplet into a silicone ring device to encapsulate mouse embryonic day 13 (E13) kidneys for subsequent 3D culture. We tested different organotypic hydrogels (Matrigel, Collagen I) as embedding materials, and characterized their mechanical properties using microindentation. E13 kidneys grown in 3D gels and at in traditional air-liquid interface cultures were imaged every hour and fixed after 4 days.

Results: Our data showed that kidney morphogenesis proceeded in ECM-derived gel droplets, not just in air-liquid interface cultures. Both methods yielded similar numbers of ureteric bud branches and nephrons, as confirmed by immunofluorescence. Notably, our live branch tracking analysis revealed dynamic growth and rearrangement of ureteric tubules in unflattened kidneys for the first time. The mechanical properties of the embedding gel also impacted overall explant morphology. Low concentration Collagen I (0.3-1mg/ml, E<2kPa) best mimicked in vivo development. Matrigel (E<1kPa) failed to maintain the 3D integrity of the explant, resulting in partially flattened tissue. High concentration Collagen I (3mg/ml, E=4.2kPa) impeded development and lead to enlarged ureters in some samples, resembling certain congenital defects.

Conclusions: We present a 3D culture technique that not only supports ex vivo morphogenesis but also enables live imaging of mouse embryonic kidneys. Our data suggest organ ex vivo development is influenced by its mechanical environment. This work aims to transform long-term explant culture techniques and clarify the role of the mechanical environment in kidney development.

Intracellular Acetyl-CoA Levels Are Pivotal for Nephron Progenitor Cell Fate Decisions

Giovane G. Tortelote, Fabiola Diniz, Sylvia Hilliard, Samir S. El-Dahr. Tortelote Lab. *Tulane University School of Medicine, New Orleans, LA.*

Background: Low nephron endowment at birth correlates with the development of hypertension in later life. Nephron endowment at birth is governed by a delicate balance between nephron progenitor cells (NPC) self-renewal and differentiation. Previous studies showed that inhibition of glycolysis pushes NPC to differentiation and causes progenitor pool depletion.

Methods: Organ culture experiments: E12.5 embryonic kidneys cultured for 24h-48h in the presence of a vehicle or several pharmacological agents: the glycolysis inhibitor drug, YN1; the mitochondrial pyruvate carrier 1 blocker, UK5099; sodium acetate or canonical Wnt signaling activator (CHIR99021). Immunofluorescence was performed to characterize the observed phenotypes. Bulk. RNA seq. and Proteomics: NPCs were extracted by MACS (passage 0), cultured for 24h with the vehicle, CHIR, and YN1, and then processed for proteomics and bulk RNA sequencing. Data Analysis. Differential gene expression, pathway analysis, and GO enrichment analysis were performed in R.

Results: Here, we showed a direct relationship between glucose metabolism and NPC fate decisions. First, E12.5 embryonic kidneys cultured in the presence of YN1 showed reduced extracellular acidification rate (ECAR), and increased differentiation rate. Second, E12.5 embryonic kidneys stimulated with UK5099 showed an increased ECAR, reduced ATP production from oxidative phosphorylation, augmented NPC pool, and reduced differentiation. We compared the proteome and transcriptome of E13.5 NPC stimulated with either a CHIR or YN1 to dissect the molecular mechanism underlying these phenomena. Decreased cholesterol biosynthesis emerged as a top pathway targeted by both drugs. Inhibition of cholesterol synthesis stimulated NPC differentiation at the cost of cap mesenchyme depletion, which, in turn, phenocopied YN1 treatment. Acetyl-CoA links cholesterol production and glucose metabolism. Sodium-acetate is an alternative source of acetyl-CoA. Sodium-acetate supplementation increased cytosolic acetyl-CoA levels and cap mesenchyme size, without hindering NPC differentiation. Co-treatment with exogenous sodium-acetate abrogated the adverse effects of glycolysis inhibition.

Conclusions: This study identifies acetyl-CoA as a key metabolite for kidney development and sodium-acetate as a potential exogenous substrate to promote kidney growth and development

Real-Time ATP Imaging Reveals the Metabolic State During Kidney Development

Akiko Mii,[1,2] Shinya Yamamoto,[1] Shigenori Yamamoto,[1] Motoko Yanagita.[1] *[1]Kyoto University Graduate School of Medicine, Kyoto, Japan; [2]Nippon Medical School, Tokyo, Japan.*

Background: Maternal malnutrition is associated with a reduced nephron number and an increased risk of hypertension and chronic kidney disease in later life. However, very little is known about what determines the nephron number, and about the metabolic state during nephrogenesis.

Methods: We focused on the cytosolic adenosine 5-triphosphate (ATP) level and its changes to examine an energy metabolism in embryonic kidneys. To explore the spatiotemporal dynamics of the cytosolic ATP level, we used transgenic mice expressing the cytosolic ATP-FRET biosensor, called GO-ATeam2 mice. We performed visualization and analysis of cytosolic ATP level in real-time *ex-vivo* imaging during branching nephrogenesis and examined the dependence of ATP production on glycolysis and oxidative phosphorylation during nephrogenesis.

Results: We succeeded in visualizing the cytosolic ATP level at a single cell level and investigated the spatiotemporal dynamics of the cytosolic ATP level in both ureteric bud (UB) and cap mesenchyme (CM) cells. The UB forms the collecting ducts through repeated bifurcation of the ureteric tree, while the CM differentiates into nephron epithelial cells. The reciprocal interaction between UB and CM cells is crucial for proper kidney development. During branching nephrogenesis, ATP levels of UB tip cells were significantly lower than those of UB stalk and CM cells. Glycolytic inhibition in the early phase of metanephric kidney (embryonic day E12.5) severely reduced the ATP level in both cells in a dose dependent manner, but ATP reduction was faster and more prominent in UB cells rather than in CM cells. In addition, the expression of specific markers for UB and CM cells were significantly reduced and electron microscopy images showed a loosening of cell-cell adhesion and irregular cell alignment in CM cells after glycolytic inhibition. Furthermore, glycolytic inhibition resulted in suppressed UB branching and reduced number of both branch segments and UB tips. On the other hand, these effects were not observed by an oxidative phosphorylation inhibitor.

Conclusions: The mice allowed us to perform real-time *ex-vivo* ATP imaging of embryonic kidneys. We found that UB branching was heavily dependent on glycolysis and that UB cells in the early branching phase were sensitive to glycolytic inhibition.

SA-PO324

Highly Parallel Production of Designer Kidney Organoids by Mosaic Patterning of Progenitors

Catherine M. Porter,[1] Alex Hughes.[1,2] Hughes Lab. *[1]University of Pennsylvania Department of Bioengineering, Philadelphia, PA; [2]University of Pennsylvania Department of Cell and Developmental Biology, Philadelphia, PA.*

Background: Kidney organoids derived from human induced pluripotent stem cells (iPSCs) are a promising approach for congenital and adult disease modeling, regenerative medicine, and gaining fundamental understanding of organogenesis. However, organoids are limited in their production scale, reproducibility, and physiologic function and structure, posing a considerable barrier to their application. Thus, an important open question is the extent to which engineering control over culture conditions can guide organoids toward specific outcomes in composition and organization. Here, we study this by precisely controlling iPSC-derived kidney progenitor cell numbers and ratios in microwell-format organoid cultures.

Methods: We began by adapting transient 2D cell patterning technology to a microwell format suited for transition to long-term 3D organoid culture. We first applied our validated culture system to study the effect of initial nephron progenitor (NP) number on organoid morphogenesis. Since reciprocal interactions between NPs and ureteric bud (UB) tip cells influence nephron endowment during kidney organogenesis, a major predictor of kidney disease, we next examined how modulating ratios of these cells affects organoid morphogenesis.

Results: In our NP-only organoids, we discovered that throughout culture, organoid sizes directly depend on the number of initial NPs. Moreover, larger nephron organoids display a shift in final composition, with a significant increase in proximal tubule proportion from 40% to 61% from 2D cell pattern size diameters 200 to 500 μm. Preliminarily, we have found that regardless of cell ratio, transition of 2D mosaic cell patterns of NPs and UB tip cells to 3D suspension culture facilitates cell sorting and discrete compartment formation early in organoid development, which resembles physiologic organization. Furthermore, UB tip cells and NPs synergistically upregulate stromal cell populations.

Conclusions: Here, we contribute an integrated cell patterning and long-term culture platform that decouples organoid size from well geometry, enables 3D suspension culture, and maintains discrete organoid cultures. Our approach makes significant advances in organoid homogeneity relevant to drug screens and modeling of development and diseases as well as improved control over tissue interface formation crucial to engineered morphogenesis efforts.

SA-PO325

Generation of Human Kidney Organoids with Three-Dimensional Vascular-Like Systems

Kexin Peng.[1,2] *[1]Hunan Provincial Maternal and Child Health Care Hospital, Changsha, China; [2]Southern University of Science and Technology, Shenzhen, China.*

Background: Kidney organoids are hampered by their inability to imitate mature organ architecture since they are lack of vasculature, which creates essential niches. Here, we demonstrate two novel paradigms for generating three-dimensional vascularized kidney organoids.

Methods: Method 1. We differentiated the HiPSCs into kidney organoids and blood vessel organoids respectively. Then we co-cultured the 3D blood vessel networks with kidney progenitor aggregates to form the assembloids. Method 2. We induced the HiPSCs into the kidney progenitor aggregates. Then we transfected with mCherry-hETV2 plasmids into kidney progenitor cells. 7 days later, the organoid got matured.

Results: Generation of assembloids from blood vessel networks and kidney progenitor aggregates To study organ-to-organ communication circuits within different organoids, we co-cultured the blood vessel organoid and kidney organoid. At later stage, the blood vessel networks penetrated the entire kidney organoid and assembled into multiple lineage organoids, enabling us to study the characteristic of the micro-physiological system within different organoids. **hETV2 promotes the vascularization of kidney organoids** We transfected with mCherry-hETV2 plasmids into the kidney progenitor aggregates. The hETV2 overexpressing kidney organoid positioned podocytes (NPHS1+) and tubular parts (LTL+) packed with numerous endothelial networks (CD31+).

Conclusions: 1) Blood vessel organoids penetrated the kidney progenitor aggregates, and formed entiely blood vessel networks within kidney organoids. 2) hETV2 transcription factor elicited the process of vascularization for kidney organoid.

Deletion of Crkl Splice Isoforms in the Mouse Kidney Disrupts Intercompartmental Signaling Required for Progenitor Renewal and Branched Morphogenesis

Jeremiah Martino,[1] Tze Yin Lim,[1] Qingxue Liu,[1] Juntao Ke,[1] Gregory B. Whittemore,[1] Yask Gupta,[1] Gina Jin,[1] Cathy L. Mendelsohn,[3] Ali G. Gharavi,[1] Vivette D. D'Agati,[1,2] Rosemary V. Sampogna,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]Columbia University Department of Pathology and Cell Biology, New York, NY; [3]Columbia University Department of Urology, New York, NY.*

Background: We previously showed that haploinsufficiency and point mutations in *CRKL* drive kidney and urinary tract malformations in the DiGeorge, or 22q11.2, Syndrome (DGS) and in sporadic CAKUT, respectively. Here, we examined the developmental requirement of the two *Crkl* splice variants (T1 & T2) when conditionally and differentially deleted in the metanephric mesenchyme (MM).

Methods: We characterized phenotypic abnormalities in developing kidneys from mice with conditional deletion of both T1 and T2 ("No Crkl"), or only the T1 isoform ("T2 only"), specifically within the MM. Bulk and scRNAseq data were acquired and analyzed from embryonic kidneys isolated from 13.5 and 15.5dpc wild-type and mutant mice. IHC and ISH analyses were used to validate and identify key signaling pathways.

Results: At P0, both "No *Crkl*," and "T2 only" kidney phenotypes were characterized by severe hypoplasia and near-absence of nephrogenic progenitors (NP). Morphometric analysis of the renal collecting system at 13.5 and 15.5dpc shows a hyperbranched phenotype in "No *Crkl*" mutants, while expression of only T2 led to a hypobranched phenotype. Using our single-cell data to "deconvolve" bulk RNAseq data, we found an overrepresentation of early proximal tubule (ePT) markers in "No *Crkl*" mice, and an underrepresentation in "T2-only" mice, suggesting a cell type-based contribution to the divergent branching phenotypes. Both groups of mutants also showed an underrepresentation of NP markers, where scRNAseq and ISH analyses confirmed decreased expression of *Fgf8* and *Fgf9* in NPs and renal vesicle. Lastly, in-depth time-based analyses of bulk RNAseq datasets revealed 3 differentially regulated gene sets that may explain the divergent branching phenotype between the two mutants.

Conclusions: Genetic manipulation of *Crkl* confirms a crucial role in kidney development, where disrupted *Fgf8* expression suggests a cellular mechanism underlying renal hypodysplasia. Furthermore, disruption of splice isoform balance reveals a dichotomous pattern in early branching, suggesting a differential role for each isoform in regulating STOP and GO signaling associated with growth and branching morphogenesis.

HNF4A Re-Expression Restores a Proximal Tubular Phenotype in Cultured Primary Cells

Michelle Kha,[1] Gülay Altiparmak,[1] Karl Swärd,[2] Martin E. Johansson.[1] *[1]Goteborgs universitet Sahlgrenska Akademin, Goteborg, Sweden; [2]Lunds Universitet, Lund, Sweden.*

Background: The tubular part of the nephron is composed of distinct segments. The transcription factor hepatocyte nuclear factor 4α (*HNF4A*) is a master regulator for the phenotype of the proximal tubules, controlling features such as brush border formation and transport. Culture of primary proximal tubular cells is an essential model system for kidney research, but during culture, the cells display a less differentiated phenotype with expression of markers associated with kidney injury. The aim of this study was to evaluate if HNF4A transduction of cultured primary proximal tubular cells could revert the cells to a more mature phenotype.

Methods: Primary proximal tubular cells obtained from human cortical kidney tissue were cultured and harvested at consecutive passages. The change in protein expression at different passages was evaluated using immunohistochemistry. *HNF4A* adenoviral transduction was performed on primary proximal tubular cells, followed by RNA sequencing and bioinformatic analysis. The effects of *HNF4A* transduction were furthermore analyzed by qPCR, Western blot, and immuno electron microscopy.

Results: Culture of primary proximal tubular cells resulted in major HNF4A loss. In contrast, the mesenchymal and injury marker vimentin was induced. HNF4A was successfully reintroduced by adenoviral transduction and this caused upregulation of known target genes associated with brush border formation, transport, and metabolism. Gene set enrichment analysis revealed pathways linked to absorption, transport, and digestion as well as microvilli and brush border. Using immuno electron microscopy, morphological features of proximal tubular cells could be visualized in HNF4A-positive cells.

Conclusions: In summary, human primary proximal tubular cells rapidly lose HNF4A expression during culture, but by reintroduction of HNF4A using adenoviral transduction, the cells regain expression of genes essential for brush border formation and transport. This suggests that HNF4A expression may improve the reliability of *in vitro* models of proximal tubular cells.

High-Throughput Discovery of Novel Therapeutic Candidates for Human Podocytopathies

Amanda Barreto, Morgan A. Burt, Labannya Samanta, Samira Musah. Musah Lab. *Duke University, Durham, NC.*

Background: Chronic kidney disease (CKD) impacts 12% of the world population. Currently, the best treatment options for patients experiencing advanced stages of CKD include dialysis or kidney transplantation. Therefore, there is an urgent need for novel therapies that address the underlying causes of kidney dysfunction and disease progression. Damage to podocytes is associated with CKD. In addition to comorbidities and predisposition factors, CKD occurrence can be aggravated by the administration of prescription drugs. These compounds include the chemotherapy drug Adriamycin (ADR), which exhibits off-target nephrotoxic effects in podocytes.

Methods: By employing our established protocol for hiPSC-derived podocytes, we developed a high-throughput screening (HTS) strategy to help discover new protective biomolecules and potential therapeutic candidates for podocytes. We screened the hiPSC-podocytes with a library of bioactive molecules and ADR. To eliminate the compounds that did not protect against ADR injury, the threshold for positive hits was considered above ADR control viability. These compounds were selected as potential hits and were subject to low-throughput secondary validation metrics.

Results: The cells co-treated with the bioactive hits and ADR seemed to have been protected from ADR-induced injury by retaining healthy cell spread, and cytoskeletal

structures such as actin fibers. In subsequent 48hrs experiments, podocytes were pre-treated with the compounds in low-throughput environments, and podocyte cell viability and cytoskeleton arrangement were protected against ADR injury.

Conclusions: Our preliminary work led to the identification of three new compounds that protected human stem cell-derived podocytes from severe injury by ADR treatment *in vitro*. Ultimately, a podocyte-directed therapeutic could protect cells against known nephrotoxic drugs, potentially reducing the need for dialysis or kidney replacement in the future.

T Cell-Mediated Immune Rejection of B2M Knockout Induced Pluripotent Stem Cell (iPSC)-Derived Kidney Organoids

Cathelijne W. Van den Berg,[1,2] Lonneke Gaykema,[1,2] Rianne Y. van Nieuwland,[1,2] Ellen Lievers,[1,2] Juliette A. de Klerk,[1] Sébastien J. Dumas,[1,2] Jesper Kers,[1] Arnaud Zaldumbide,[1] Ton J. Rabelink.[1,2] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]The Novo Nordisk Foundation Center for Stem Cell Medicine (reNEW), Leiden, Netherlands.*

Background: "Stealth" induced pluripotent stem cell (iPSC)-derived kidney organoids represent an attractive strategy and could potentially be used in clinical transplantation. Genetic modification of the human leukocyte antigen (HLA) class I molecules in iPSCs prior to transplantation of their derived tissues could prevent immune rejection. Here we evaluated the effect of β2-microglobulin (B2M) knockout on T cell-mediated rejection of iPSC-derived kidney organoids.

Methods: Specific genetic modification achieved by CRISPR-Cas9 was used to knockout *B2M* gene expression and prevent HLA class I surface expression on iPSCs. Kidney organoid immunogenicity was determined in vitro by coculture with alloreactive T cells and in vivo following transplantation in humanized mice.

Results: We found that iPSC-derived $B2M^{-/-}$ kidney organoids were protected from T cell rejection *in vitro*. To evaluate *in vivo* protection, unmodified (control) and $B2M^{-/-}$ kidney organoids were transplanted in humanized mice that were engrafted with human peripheral blood mononuclear cells (PBMCs). Successful engraftment of the human PBMCs was validated and 4 weeks after PBMC injection we observed the infiltration of $CD4^+$ and $CD8^+$ T cells in the kidney organoids. There was no difference in the infiltration rate of $CD4^+$ and $CD8^+$ T cells, proliferation of T cells and T cell cytotoxicity between control and $B2M^{-/-}$ organoids. Control and $B2M^{-/-}$ organoids tissue integrity was similarly affected, showing tubulitis and loss of tubule integrity. Although the $B2M^{-/-}$ organoids were unable to express HLA class I on the cell surface, we found increased expression of HLA class II in control and $B2M^{-/-}$ organoids that were transplanted in mice with human PBMCs. HLA class II expression was expressed not only by endothelial, but also epithelial cells of the kidney organoid, posing an additional immunological barrier to the transplantation.

Conclusions: We conclude that knockout of the *B2M* gene alone is not enough to protect iPSC-derived kidney organoids from T cell mediated immune rejection and highlight the importance of HLA class II signalling in the graft rejection process.

SA-PO330

Therapeutic Potential of Induced Nephron Progenitor Cells and Their Extracellular Vesicles in Aristolochic Acid-Induced CKD: Insights from Organoid and Mouse Models

Justin M. Farry,[1] Julie Bejoy,[2] Lauren E. Woodard.[2,3] *[1]Vanderbilt University Department of Biomedical Engineering, Nashville, TN; [2]Vanderbilt University Division of Nephrology and Hypertension, Nashville, TN; [3]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: CKD affects 15% of US adults, with Aristolochic acid (AA) being a valuable model for CKD. We explored CKD therapies using induced nephron progenitor cells (iNPs) and their extracellular vesicles (iNP-EVs). iNPs are engineered HK-2 reprogrammed to a nephron progenitor phenotype using an inducible *piggyBac* transposon expressing *SNAI2, EYA1*, and *SIX1*. We compared the efficacy of iNP cells to iNP-EVs. EVs have similar benefits to injected stem cells while avoiding many associated pitfalls. This study investigated the potential therapeutic effects of iNPs and iNP-EVs on AA-induced renal injury in both iPSC-derived human kidney organoids and animal models.

Methods: Organoids were grown following established protocols and were treated with 10 μM AA for 48 hrs. AA was followed by 24 hrs of exposure to either iNPs or iNP-EVs. *In vivo* experiments were performed in NSG mice, an immunocompromised mouse strain, to avoid an immune response to iNPs. In brief, mice were injected with 2 mg/kg AA three times per week for two weeks; then, the injury was allowed to develop for an additional two weeks, then mice were treated with iNPs or iNP-EVs.

Results: iNP-treated organoids showed decreased Dickkopf-1 (DKK1) levels compared to EV-treated, untreated, and control organoids. Both iNPs and EVs treatment reduced macrophage colony-stimulating factor (M-CSF) compared to untreated organoids, with EV treatment showing a more pronounced effect. Immunofluorescent staining revealed increased alpha-smooth muscle actin (α-SMA) levels in AA-treated organoids, with lower expression in iNP and EV-treated organoids.

Conclusions: Analysis of tissue sections stained for α-SMA showed that the AA + iNP-EVs treated group had fewer myofibroblasts than the AA-only and AA + iNP-treated groups. All groups receiving AA had more α-SMA staining than the untreated control group. DKK1 is a Wnt signaling inhibitor, suggesting that iNPs may encourage proliferation through a non-exosomal mechanism. The M-CSF reduction suggests an iNP EV-dependent immunomodulatory effect. M-CSF is released from activated fibroblasts, so decreased M-CSF levels could indicate reduced numbers of myofibroblasts, supported by the improvement in α-SMA levels. In conclusion, iNPs and iNP-EVs may mitigate fibrosis in mouse and human models of AA-induced CKD.

SA-PO331

Kidney Organoid Transplantation Promotes Endothelial Cell Proliferation and Transition Toward a Human Fetal Arterial/Afferent Arteriolar-Like Phenotype

Sébastien J. Dumas,[1,5] Marije Koning,[1] Elda Meta,[2,3] Ellen Lievers,[1] Mila Borri,[2,3] Yonglun Luo,[4,6] Bernard van den Berg,[1] Peter Carmeliet,[2,3] Cathelijne W. Van den Berg,[1,5] Ton J. Rabelink.[1,5] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Katholieke Universiteit Leuven, Leuven, Belgium; [3]Vlaams Instituut voor Biotechnologie, Gent, Belgium; [4]Aarhus Universitet, Aarhus, Denmark; [5]The Novo Nordisk Foundation Center for Stem Cell Medicine (reNEW), Leiden, Netherlands; [6]Lars Bolund Institute of Regenerative Medicine, Qingdao-Europe Advanced Institute for Life Sciences, BGI-Qingdao, BGI-Shenzhen, Qingdao, China.*

Background: Kidney organoids (KORs) derived from induced pluripotent stem cells hold promise for regenerative medicine and kidney modeling. However, KORs lack proper vascularization, hindering maturation despite the emergence of endothelial cells (ECs). *In vivo* KOR transplantation prevents EC regression, enabling chimeric vascularization, blood perfusion, and nephron maturation. This study aimed to characterize the molecular effects of KOR transplantation on ECs.

Methods: Day7+12 KORs were transplanted into chicken embryos for 1 or 8 days, or further cultured *in vitro* for the same time period. FACS-sorted CD31+ KOR ECs underwent scRNA-seq (11,966 ECs). A human fetal kidney EC reference (8-17 weeks of gestation, >3,000 ECs) was created from publicly available scRNA-seq data. Immunostainings were performed to validate the findings.

Results: Both time and transplantation altered KOR EC transcriptomes, with the latter having a greater impact. KOR transplantation induced a metabolic transcriptome switch from oxidative phosphorylation to glycolysis, associated with hypoxia response geneset enrichment at day 1. At day 8, KOR transplantation prevented DNA damage response and decreased nuclear division, while upregulating antigen presentation, matrix deposition, angiogenesis, blood coagulation/circulation genesets, indicating response to blood perfusion. Consistent with angiogenesis, EC proliferation was increased in that condition (especially in M phase), as confirmed by Ki67 staining. ECs also underwent a major vein-to-arterial phenotypic transition, with a decreased pool of NR2F2+ ECs and the emergence of arterial ECs, and upregulated EC tissue-specific genes (especially kidney-related). Arterial ECs characterized by laminar shear stress response and Notch signaling, showed a similar transcriptome as human fetal kidney arterial/afferent arteriolar ECs. Transplantation-induced EC reprogramming involved *SOX7* transcription factor upregulation and regulon enrichment.

Conclusions: KOR transplantation led to the development of arterial ECs alike human fetal kidney artery/afferent arteriolar ECs, likely via SOX7 and blood flow exposure. These findings provide insights for the development of KOR vascularization strategies.

SA-PO332

Vessel-Promoting Factors npas4l/cloche and hand2 Act in Parallel to Inhibit Intermediate Mesoderm Specification

Elliot Perens,[1,2] Deborah Yelon.[1] *[1]University of California San Diego, La Jolla, CA; [2]Rady Children's Hospital San Diego, San Diego, CA.*

Background: Proper organ formation depends on precise organ territories containing defined numbers of progenitor cells. Kidney progenitors reside in the intermediate mesoderm (IM), two bilateral stripes of cells in the posterior mesoderm. Previously we showed that the transcription factors Hand2 and Osr1 are essential for defining the dimensions of the IM by balancing the specification of IM and laterally adjacent vessel progenitors. Recently the transcription factor Npas4l/Cloche – well characterized as an early, essential regulator of vessel and blood progenitor formation – was shown to inhibit kidney development. Here we determine how kidney and IM specification is coordinated among *hand2*, *osr1*, and *npas4l*.

Methods: Taking advantage of the robust genetic, optical, and experimental benefits of the zebrafish model organism, we interrogate the IM at the single cell level. Here we employ a combination of loss and gain-of-function genetic analyses and whole mount RNA in situ and antibody staining.

Results: First, *hand2* and *osr1* regulate the development of *npas4l*-expressing lateral vessel progenitors (LVPs). Interestingly, like *hand2* loss-of-function, *npas4l* loss-of-function rescues *osr1* mutant kidney developmental defects. However, unlike in *hand2*; *osr1* double mutants in which LVP specification is restored, vessel progenitor formation is not rescued in *npas4l*; *osr1* mutants, suggesting that *hand2* and *npas4l* may implement different mechanisms to regulate kidney and vessel progenitor fates. Additionally, *npas4l* and *hand2* overexpression can inhibit kidney formation independent of one another's function suggesting the two factors can function in parallel to inhibit kidney specification. Importantly, like *hand2* mutants, *npas4l* mutants have expanded IM, but in *npas4l* mutants the increased IM is found outside *hand2*-expressing cells suggesting alternative sources of increased IM within the two mutants. Finally, consistent with parallel functions for *hand2* and *npas4l* in IM inhibition, *hand2*; *npas4l* double mutants have increased IM beyond that seen in either single mutant.

Conclusions: Together our findings reveal that proper kidney specification depends on parallel genetic pathways that inhibit IM specification while promoting vessel progenitor formation

Profiling the Epigenetic Landscape of the African Spiny Mouse, A Mammalian Model of Kidney Regeneration

Elizabeth D. Nguyen,[1,2] Joshua Gere,[2] Yeji Bae,[2] Daryl M. Okamura,[1,2] Sarah J. Collins,[2] Scott R. Houghtaling,[2] Danny Miller,[1] Kiheon Suh,[2] Alison G. Paquette,[1,2] David R. Beier,[1,2] Mark W. Majesky.[1,2] *[1]University of Washington School of Medicine, Seattle, WA; [2]Seattle Children's Research Institute, Seattle, WA.*

Background: The African spiny mouse is the first mammal to demonstrate full restoration of kidney function without fibrosis after injury (Okamura et al., 2021) and provides an opportunity to elucidate mechanisms promoting kidney regeneration. The transcriptome of the spiny mouse and house mouse kidneys are the same, but its response to injury is remarkably different, indicating that epigenetic control of gene expression may be the key to its regenerative capabilities. We hypothesize that the African spiny mouse kidney is poised to respond differently before injury occurs through accessible chromatin for critical genes that are regulated by histone methylation.

Methods: Single nuclei ATAC-sequencing identified accessible regions of chromatin in normal African spiny mouse kidneys (n=3). Cleavage Under Targets and Release Under Nuclease (CUT&RUN) identified which regulatory elements were targeted by activating (H3K4me3) and repressive (H3K27me3) histone marks in spiny mouse kidney (n=2). Data was aligned to a spiny mouse reference genome we constructed with long-read DNA sequencing. For data analysis, we used Cellranger for ATAC-seq clustering, SEACR for CUT&RUN peak calling and HOMER for peak annotation and motif detection.

Results: Single nuclei ATAC-seq data mapped to the spiny mouse reference genome at >85%. Over 4,300 high quality peaks were generated from 27,000 cells, generating 10 distinct clusters. CUT&RUN sequencing data mapped to the reference genome at >95%. 2608 consensus H3K4me3 peaks and 1560 consensus H3K27me3 peaks were detected. Several key progenitor motifs marked by H3K4me3 were significantly enriched in the spiny mouse kidney ($p<0.01$) and had accessible chromatin based on ATAC-seq data, including *Nkx3.1*, *Osr1*, *Myb* and *Tead2*.

Conclusions: This work demonstrates that chromatin for nephrogenic progenitor genes in spiny mouse is accessible and poised for transcription through histone methylation. These experiments are being extended to injured kidneys of the spiny mouse to identify how gene regulation is controlled by histone marks in the setting of kidney regeneration. These results will have an important positive impact by providing targets and potential mechanisms for the redirection of kidney injury towards regeneration of functional tissue.

SA-PO334

Inflammatory Cytokine Signaling in New Nephron Formation After AKI in Adult Zebrafish

Heiko J. Schenk,[1,2] William Sampson,[2] Caramai N. Kamei,[2] Iain A. Drummond.[2] *[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Mount Desert Island Biological Laboratory, Salsbury Cove, ME.*

Background: Adult progenitor cells in the mesonephric zebrafish kidneys are required during neo-nephrogenesis replacing injured tubules by forming new nephrons. Single-cell RNA transcriptomes of adult kidney progenitor cells point to components of NF-kB and inflammatory cytokine receptors that may initiate stem cell-based nephrogenesis. Here, we present evidence that gentamicin induces inflammation-associated injury, which potentially stimulates stem cell-based nephrogenesis. The stimulatory effect on the progenitor cells to form new nephrons may be recapitulated by LPS injection without prior injury.

Methods: Adult zebrafish were injected *i.p.* with gentamicin or LPS at day 0. NF-kB signaling was determined 4 days post-injection (dpi) by NF-kB:GFP detection of the NF-kB reporter line *Tg(NF-kB:EGFP)* and NF-kB-associated gene expression using qRTPCR. Requirement of NF-kB signaling during regeneration was evaluated by pharmacological NF-kB inhibition. Bulk RNAseq from positive selected GFP^+ and $mcherry^+$ single cells by FACS was performed from kidneys 7 dpi by gentamicin injection using *Tg(lhx1a:EGFP;cdh17:mCherry)* fish.

Results: Gentamicin-induced kidney injury leads to increased tubular NF-kB reporter expression at 4 dpi and is associated with an upregulation of NF-kB target gene expression detected by qRTPCR. Additionally, gentamicin administration upregulated mRNA expression of GH receptors at 7 dpi, along with kidney progenitor markers osr1 and eya4. This was accompanied by an increased formation of new nephron aggregates, as indicated by elevated expression of Tg(lhx1a:GFP). Pharmacological inhibition of NF-kB signaling resulted in reduced expression of kidney progenitor markers, while LPS injection induced an upregulation of these markers. Bulk RNAseq analysis of positive-selected GFP+ Lhx1a+ cells at 7 dpi with gentamicin confirmed the induction of cytokine receptors in kidney progenitor cells.

Conclusions: Multiple pathways may converge on adult kidney stem cells to activate the formation of new nephrons. We propose that gentamicin-induced acute kidney injury (AKI) triggers inflammation, which, in turn, activates stem cells in the distal tubules. However, it remains unclear at this stage whether cytokine stimulation, such as that induced by LPS in the absence of injury, is sufficient to induce neo-nephrogenesis.

The Transcription Factor TCF21 Protects Stromal Cell Precursors During Kidney Development

Gal Finer,[1,2] Yalu Zhou,[1] Deborah R. Winter,[1] Roberto Ariel Gomez,[4,5] Maria Luisa S. Sequeira Lopez,[4,5] Susan E. Quaggin.[1,3] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [3]Northwestern Memorial Hospital, Chicago, IL; [4]UVA Health, Charlottesville, VA; [5]University of Virginia, Charlottesville, VA.*

Background: Normal kidney development requires coordinated interactions between multiple progenitor cells. Foxd1+ cells are critical for normal nephrogenesis and their heterogeneity is increasingly appreciated. However, the molecular mechanisms and trajectories that drive the differentiation of Foxd1+ cells toward the renal stroma, capsule, mesangial cells, renin cells, pericytes, and vascular smooth muscle cells (VSMCs) are poorly understood. Tcf21 is a mesoderm-specific bHLH transcription factor critical for embryogenesis.

Methods: To investigate the developmental origins of Tcf21 effects on stroma, we performed single-cell RNA sequencing (scRNA-seq) on GFP+ cells from E14.5 *mTmG+;Foxd1Cre+;Tcf21$^{f/f}$* kidneys and control kidneys.

Results: Clustering of the entire dataset identified a large stromal population and a smaller representation of non-stromal lineages. Subclustering of stromal cells identified eight populations: proliferating, medullary/perivascular, 'Tcf21 mutant', nephrogenic zone/ureter, nephrogenic zone, collecting duct, ureteric associated stroma, and metanephric mesenchyme. Loss of Tcf21 resulted in a dramatic reduction in the proliferating, medullary/perivascular, nephrogenic zone, and collecting duct associated stromal populations. Immunostaining confirmed that mutants had severe reduction in the medullary and collecting duct stromal space of mutants. A unique cluster, exclusively present in mutant kidneys and named 'Tcf21 mutant', expressed high levels of extracellular matrix (*Spracl1*, *Fras1*), perivascular cells (*Rgs5*, *Akr1b7*), and endothelial cells (*Endomucin*) genes. Mutant cells showed upregulation of pathways involved in extracellular matrix organization, VSMCs and fibroblast proliferation, and negative regulation of angiogenesis.

Conclusions: These data underscore a role for Tcf21 in the emergence of the milieu of Foxd1+ derivatives, whereas loss of Tcf21 leads to stromal cell fate change that results in abnormal kidney development.

Funding: NIDDK Support

SA-PO336

Increased mTOR Signaling Secondary to a Human Integrin-Linked Kinase (ILK) Missense Variant Inhibits Nephrogenesis with Decreased ATP Generation

Xiangyue Hu,[1,2] Norman D. Rosenblum.[1,2] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada.*

Background: Signaling pathways that control nephrogenesis are critical to our understanding of kidney health and disease. Previously, we demonstrated increased mTOR signaling in vitro by overexpression of a CAKUT-associated human missense variant (T173I) of Integrin-Linked Kinase (*ILK*), a key regulator of renal development. Here, we investigate the hypothesis that ILK-T173I disrupts renal development in vivo via dysregulation of mTOR signaling.

Methods: mTOR signaling was analyzed in *Ilk*-T173I knock-in mice with *Ilk*-T173I replacing the WT *Ilk* allele. Morphogenic effects of *Ilk*-T173I on renal development were quantitated. Ureteric and non-ureteric cell populations were isolated by FAC sorting. Gene expression was analyzed by whole genome RNA microarray and qPCR. Cell proliferation and nephron maturation were evaluated by immunostaining and specific markers. Energy metabolism was characterized using the Seahorse assay.

Results: Homozygous *Ilk-T173I* knock-in mice were characterized by a 13.6% decrease in nephron number (n=6, P=0.04), a 35.2% decrease in ureteric branching (n=5, P=0.006) and an 88% increase in mTOR signaling (n=3, P=0.01). Rapamycin treatment of *Ilk-T173I*-knock-in embryonic kidney explants rescued ureteric branching to normal levels. Genome-wide RNA expression analysis in *Ilk-T173I*-knock-in ureteric and non-ureteric cell populations demonstrated elevated mTOR signaling in non-ureteric cells only. *Ilk-T173I*-knock-in non-ureteric populations expressed a 431% increase in *Osr1*

(n=3, P=0.002), a mesenchymal cell progenitor marker, and a 54% decrease in *Lhx1* (n=3, P=0.04), a marker for maturing nephrons. *Ilk-T173I* knock-in embryonic kidneys demonstrated a 2075% increase in phospho-Histone H3-labeled cells (n=3, P=0.0005), an indicator of cell proliferation, in the ureteric, nephrogenic and stromal lineages, and a 16.1% decrease in the percentage of S-shaped bodies (n=4, P=0.01), the mature form of nephrogenic intermediates. Metabolic profile of *Ilk-T173I*-knock-in, non-ureteric cells exhibited a 17% decrease in both oxidative ATP production (n=3, P=0.04) and total ATP production (n=3, P=0.02).

Conclusions: These data show that human Ilk-T173I variant impairs renal development in a mTOR-dependent manner, specifically acting within the non-ureteric cell population by increasing proliferation and disrupting maturation and cell metabolism.

SA-PO337

PRRX1 Is a Master Regulator of Renal Fibroblast Cell Fate and Regulates Myofibroblast Activation in Response to TGF-β via Alteration of the Chromatin Landscape

Ericka J. Bonifacio, Ivan Krupa, Niall B. Carruthers, Caitriona Scaife, Jessie Davis, John Crean. *University College Dublin Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland.*

Background: Emerging evidence suggests that changes in the chromatin landscape in response to TGFβ likely contributes to the pathogenesis of diabetic kidney disease (DKD). Using iPSC derived kidney organoids, we have recently shown that TGF-β signalling to chromatin unleashes a programme of gene expression intiating fibroblast to myofibroblast activation. We hypothesise that SMAD3 and the Polycomb Repressive Complex 2 core component, EZH2, co-occupy regulatory regions within chromatin to deposit histone post-translational modifications (PTMs), thereby facilitating a chromatin landscape which drives fibroblast activation in DKD. Our data suggests that PRRX1 acts as a master transcription factor in regulating fibroblast to myofibroblast differentiation through association with SMAD3/EZH2. To characterise this proposed epigenetic mechanism, proteomic and transcriptomic analysis was performed on iPSC-derived kidney organoids treated with TGFβ1.

Methods: Histone extraction was performed on undifferentiated iPSCs, iPSC-derived nephron progenitor cells, iPSC-derived kidney organoids, and kidney organoids treated with recombinant TGFβ1. Histones were then subjected to LC-MS/MS for analysis of global histone modifications. Single cell RNA-sequencing (scRNA-seq) was performed on iPSC derived kidney organoids treated with EZH2 inhibitor, GSK343, for 1h prior to TGFβ1 treatment for 48 hours.

Results: Mass Spectrometry data revealed differential abundance of trimethylated lysine residues on Histone 3 (H3K27me3) between TGFβ treated and control, indicating dynamic changes in transcriptionally permissive states. scRNA-seq analysis of kidney organoids treated with TGFβ1 revealed cluster specific changes in PRRX1 expression in response to TGFβ1, specifically in stromal cells and activated myofibroblast clusters. These changes in PRRX1 in response to TGFβ1 were consistently observed in other fibroblast cell lines.

Conclusions: TGF-β is a key driver of chromatin dynamics as evidenced by H3K27me3 and likely contributes to gene repression through interaction between SMAD3 and EZH2. We propose that subsequent silencing of PRRX1 expression mediates fibroblast to myofibroblast activation and represent a tractable therapeutic target for the amelioration of fibrosis in DKD.

SA-PO338

Regeneration-Associated Cell-Derived Extracellular Vesicles Preserve Kidney Function After Acute Ischemia Injury

Amankeldi Salybekov,[1,2] Shigeaki Okamura,[1] Sumi Hidaka,[1] Takayasu Ohtake,[1] Takayuki Asahara,[1] Shuzo Kobayashi.[1] *[1]Shonan Kamakura Sogo Byoin, Kamakura, Japan; [2]Qazaq Institute of Innovative Medicine, Astana, Kazakhstan.*

Background: Under vasculogenic conditioning, pro-inflammatory cell subsets of peripheral blood mononuclear cells (PBMCs) shift their phenotype to pro-regenerative cells such as vasculogenic endothelial progenitor cells, M2 macrophages, and regulatory T cells, collectively designated as regeneration-associated cells (RACs). In this study, we evaluated the therapeutic efficacy of RAC-derived extracellular vesicles (RACev) compared with a vehicle-treated group using the rat kidney ischemia-reperfusion injury (K-IRI) model.

Methods: Human PBMCs were cultured with defined growth factors for seven and then two days to harvest RACs and RAC-ev, respectively. EV sizes were characterized by nanoparticle tracking analysis. Transmission electron microscopy revealed a bi-layered membrane structure and flow cytometry confirmed the presence of EV-specific markers (CD9, CD63, and Alix).

Results: Notably, systemic injection of RACev significantly decreased serum creatinine and blood urine nitrogen ($P < 0.01$ and $P < 0.005$) at day three after the onset of K-IRI than the control group. Histologically, the treatment group showed less fibrosis in the cortex and medullary areas ($P < 0.04$ and $P < 0.01$) compared to the control group. CD31 staining confirmed enhanced capillary densities at the cortex and medullary areas in the treatment group compared to the control group ($P < 0.003$). These beneficial effects were coupled with significant expression of angiogenesis (miR-126-3p/5p, miR-195-3p/5p, miR-146-3p/5p), anti-fibrosis (miR-133a-3p, miR-29b-3p), anti-inflammation (miR-10a-3p, miR-21-3p, miR-24-2p), and anti-apoptosis miRs by RACev. In vivo bioluminescence analysis showed preferential accumulation of RACev in the IR-injured kidney.

Conclusions: In conclusion, systemic transplantation of RACev improved kidney function via protecting from tissue fibrosis, anti-inflammation, and angiogenesis miR delivery to the ischemic tissue.

SA-PO339

Partitioning-Defective (Par1) Inhibition Protects Against Kidney Fibrosis in Mice

Kimberly J. Reidy, Zhongfang Du, Vellia Zhou. *Albert Einstein College of Medicine, Bronx, NY.*

Background: Partioning defective (Par) 1a and 1b (*MARK2/3*) expression is required for normal kidney development and increases in damaged tubules following tubular injury by unilateral ureteral obstruction (UUO) and folic acid (FA) injection in mice. *Par1a/MARK3* expression in human kidney tissues correlates with kidney fibrosis and eGFR. Par1a mutant (*Mark3*$^{-/-}$) mice are protected against kidney fibrosis following UUO and FA induced injury. We hypothesized tubular Par1a/b expression is maladaptive following kidney injury and sought to test the effect of tubular Par1a/b deletion and chemical Par1 inhibition on fibrosis following kidney injury.

Methods: We generated tubular conditional Par1a/b knock out mice (*Pax8-rtTA:tet-O-Cre:Mark2flox/flox:Mark3flox/flox*) mice. Tubular deletion was induced using doxycycline treatment 7 days prior to injury by UUO. Sham operated (for UUO) mice was used as control for the injury model. Both injured and uninjured uninduced *Pax8-rtTA:tet-O-Cre:Mark2flox/flox:Mark3flox/flox* mice and doxycyline treated *Mark2flox/flox:Mark3flox/flox* mice were used as controls. A MARK/Par-1 Activity Inhibitor (Sigma, 39621) was injected via IP injection for 3 days after UUO injury. Kidney phenotype was analyzed at 7 days post UUO injury or sham surgery.

Results: Par1a/b (*Mark2/3*) gene expression is highest in injured, dedifferentiated proliferating (Sox9 and Ki67+) tubular cells. Dual Par1a/b cKO mice were protected from injury induced fibrosis following UUO induced injury ($p=0.001$). MARK Inhibition after injury protected against UUO induced fibrosis.

Conclusions: Genetic tubular deletion of Par1a/b before injury and inhibition post UUO induced injury was protective against kidney fibrosis. Ongoing experiments are testing other models of kidney injury and mechanisms of Par1a/b protection.

miR-17/-20a Alleviates Renal Interstitial Fibrosis by Repressing Frmd6 Expression in Renal Epithelia

Debora Malta C.S Santos,[1] Maliha Tayeb,[1] Andrew J. Bodnar,[1] Corynn Appolonia,[1] Roderick J. Tan,[2] Arohan R. Subramanya,[2] Markus Bitzer,[3] Jacqueline Ho.[1,4] *[1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [3]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [4]University of Pittsburgh Department of Pediatrics, Pittsburgh, PA.*

Background: An estimated 37 million Americans have chronic kidney disease (CKD), and its prevalence is increasing with higher rates of diabetes mellitus, hypertension and obesity. Regardless of the underlying etiology, renal fibrosis is the final manifestation of CKD. microRNAs (miRNAs) are endogenous, small non-coding RNAs that bind to target mRNAs and regulate their expression. In this study, we investigated the role of the *miR-17~92* cluster (comprises *miR-17*, *-18a*, *-19a*, *-19b*, *-20a* and *-92a*) in renal fibrosis.

Methods: Genetic mouse models of inducible epithelial-specific *miR-17~92* loss-of-function (*imiR-17~92*^{EpiLOF}) or gain-of-function (*imiR-17~92*^{EpiGOF}) were generated by crossing *Pax8Cre-rtTA; LC1-cre* mice with *miR-17~92* floxed mice or with a mouse line containing a constitutively active CAG promoter ahead of a *loxP*-flanked STOP cassette preventing transcription of the downstream *miR-17~92* sequence, respectively. Unilateral ureteral obstruction (UUO) and acute kidney injury (AKI) to CKD model were performed. Renal fibrosis was assessed by immunostaining with anti-collagen III and anti-α-SMA antibodies, followed by semi-quantitative analyses with ImageJ. The human proximal tubular epithelial cell line HK2 was transfected with either empty vector or a vector containing the *Frmd6 cDNA*. HK2 cells were used for experimental identification of *miR-17~92* target genes using PAR-CLIP.

Results: *miRs-17*, *-18a*, and *-20a* were upregulated in UUO and the AKI to CKD model. Interestingly, *imiR-17~92*^{EpiLOF} mice exhibited increased predisposition to renal fibrosis with aging and after UUO, which was accompanied by increased expression of known *miR-17~92* profibrotic targets, p-Stat3 and p-Smad3. Conversely, UUO-induced fibrosis was ameliorated in *imiR-17~92*^{EpiGOF} kidneys. *Frmd6*, an activator of Hippo signaling, was identified as a novel *miR-17/-20a* target. Frmd6 was increased in the tubular epithelium of obstructed *imiR-17~92*^{EpiLOF} kidneys compared to controls. Finally, overexpression of Frmd6 in HK2 cells resulted in increased expression of the mesenchymal markers *SNAI1* and *FN1*, and elevated secretion of collagen III in conditioned media.

Conclusions: Together, our findings indicate that the *miR-17~92* cluster in renal epithelia functions to limit fibrosis by regulating multiple pro-fibrotic pathways.

miR193a-VDR/RXR Axis and Renin Expression in the Transition of Parietal Epithelial Cells to Podocytes

Vinod Kumar,[1,2] Ashwani Malhotra,[2] Pravin C. Singhal.[2] [1]*Post Graduate Institute of Medical Education and Research, Chandigarh, India;* [2]*Northwell Health Feinstein Institutes for Medical Research, Manhasset, NY.*

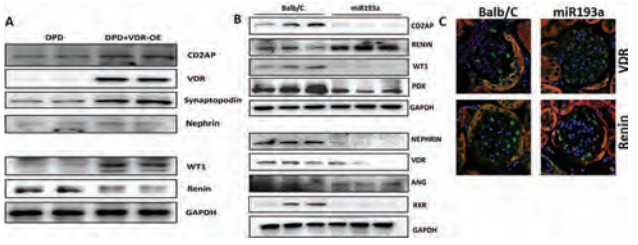
Background: Loss of kidney cells is a predominant cause of impaired kidney function in aging kidneys. Renin-expressing cells make a pool of renal progenitor cells, where the lack of renin expression determines their differentiation potential. Since microRNAs are the regulators of gene expression, we analyzed the role of the mir193a-VDR/RXR axis in regulating the renin expression and the stemness of Parietal Epithelial cells (PECs).

Methods: Human PECs were grown and analyzed for the expression of miR193a, renin, VDR, and RXR using real-time PCR and Western blotting. PECs were transitioned to podocytes by transfecting either miR193a plasmid or an inhibitor of miR193a. The PECs transition potential was also analyzed under the overexpression of VDR and RXR. Immunoprecipitation assays were performed to evaluate the potential interaction of VDR/RXR and Renin. Luciferase experiments were carried out to elucidate the binding of miR193a to VDR 3'UTR. In vivo, studies were carried out in control (Balb/C) and miR193a transgenic mice.

Results: Differentiated podocytes (DPD)-overexpressing (OE) VDR showed enhanced expression of VDR and podocyte markers but a decreased renin expression (Figure A). Renal tissues of miR193a transgenic mice not only showed attenuated podocyte markers (Nephrin, podocalyxin [PDX], WT1) and VDR/RXR but also showed enhanced renin expression when compared to control mice (Figures B and C). The miR193a expression inversely regulated the VDR expression, and the downing of VDR prevented hetero-dimerization with RXR contributing to poor reprogramming of PECs.

Conclusions: miR193a-VDR/RXR regulates renin expression and determines the efficient transition of PECs to podocytes.

Funding: NIDDK Support



A. Protein blots of differentiated podocytes (DPD) -overexpressing (OE) VDR were probed podocyte markers and renin. B. Protein blots of renal tissues of control (Balb/C) and miR193a transgenic mice were probed podocyte markers (Nephrin, PDX, WT1), VDR/RXR, renin and Angiotensinogen (Ang) expression. C. Immunolabeling of renal cortical sections of mice for VDR and renin.

Modeling Kidney Development, Disease, and Plasticity with Clonal Expandable Nephron Progenitor Cells and Nephron Organoids

Biao Huang, Zipeng Zeng, Hui Li, Chennan Zhang, Riana Parvez, Nuria M. Pastor-Soler, Kenneth R. Hallows, Nils Lindström, Andrew P. McMahon, Zhongwei Li. Zhongwei Li Lab. *University of Southern California, Los Angeles, CA.*

Background: During kidney organogenesis, nephron progenitor cells (NPCs) self-renew and differentiate into nephrons, the functional units of the kidney. Dysregulation of NPC fates underlies a number of congenital kidney diseases while uncontrolled proliferation of NPCs in Wilms tumor is the most prevalent pediatric kidney cancer. Thus, a deeper insight into NPC biology is central to improving an understanding of kidney development, congenital disease and cancer, and to applying developmental insight to regenerating kidney functions.

Methods: A synthetic niche is formulated that allows the in vitro long-term clonal expansion of primary mouse and human NPCs, and induced NPCs (iNPCs) from human pluripotent stem cells. Nephron organoids are generated from cultured NPCs following a chemically-defined differentiation protocol. Genome-wide CRISPR screening is performed in the cultured NPCs to identify novel genes associated with kidney development and disease. Multiplexed CRISPR/Cas9 genome editing in the cultured NPCs generate a rapid, efficient, and scalable organoid model for polycystic kidney disease (PKD), allowing drug screening.

Results: Cultured iNPCs resemble closely primary human NPCs, generating nephron organoids with abundant distal convoluted tubule cells, which are not observed in published kidney organoids. The synthetic niche reprograms differentiated nephron cells into NPC state, recapitulating the plasticity of developing nephron *in vivo*. Scalability and ease of genome-editing in the cultured NPCs allow for genome-wide CRISPR screening, identifying novel genes associated with kidney development, congenital kidney diseases, and Wilms tumor. Cystic PKD organoid models are generated directly from genome-edited human NPCs in as short as 8 days. Proof-of-concept drug screening identified a drug candidate targeting epigenetic pathway.

Conclusions: These NPC and nephron organoid-based technological platforms have broad applications to kidney development, disease, plasticity, and regeneration.

TRIM72 Immunomodulatory Functions Protect the Kidney During Inflammation

Pei-Hui Lin, Pu Duann, Haichang Li, Brad H. Rovin. *The Ohio State University, Columbus, OH.*

Background: TRIM72 (MG53) is a muscle-predominant protein and functions as a circulating myokine that appears to confer tissue protection during ischemia-reperfusion (I/R) acute kidney injury and UUO-mediated kidney fibrosis. We discovered the functional duality of TRIM72 in kidney protection serving as a membrane repair protein and also modulating the immune system by suppressing NF-kB signaling during kidney inflammation. Here we explored the biological role and therapeutic potential of engineered MG53-containing extracellular vehicles (EVs) in the treatment of kidney inflammation.

Methods: TRIM72 protein expression was characterized in human kidney, immortalized kidney parenchymal cell lines, and mouse proximal tubular epithelial cells derived from wildtype (*mg53* $^{+/+}$) or *trim*72-null (*mg53* $^{-/-}$) age and gender-matched mice. We investigated whether I/R- injured kidney recruits circulating TRIM72-containing EVs as a means of protection. Furthermore, we engineered TRIM72 expression in several cell systems and further investigated whether TRIM72 affected the cells' inflammatory cytokine profiles.

Results: TRIM72 expression was detected in total human kidney lysates and in immortalized human podocytes and mesangial cells. A serum pro-inflammatory cytokine panel confirmed elevation of pro-inflammatory cytokines in *trim*72-null mice. The relative fold increase in *trim*72-null mice compared to *wildtype* mice were: CXCL1--1.2; IL-2 --1.6; TNFa --1.38; IL-5 -- 2.8; IL-1--1.5. I/R-injured kidneys recruited TRIM72-containing EVs derived from C2C12 myotubes as shown by IVIS imaging of DiR-labeled EVs 2 hours post-injury. The kidneys from *trim*72 null mice that received C2C12 EVs over 4 weeks expressed comparable levels of TRIM72 to that of wildtype mice.

Conclusions: TRIM72 is detected in the kidney may be an endogenous inhibitor of pro-inflammatory cytokine expression. EVs loaded with TRIM72 are recruited to acutely injured kidneys, and can replenish renal TRIM72 levels in trim72 null mice. These results suggest that TRIM72-loaded EVs may be applied therapeutically to control kidney inflammation.

Development of a System for the Replacement of Animal Fetal Kidneys with Human Nephrons: Toward Clinical Application

Kenji Matsui, Shuichiro Yamanaka, Eiji Kobayashi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Background: Our focus is on "xenogeneic regenerative medicine," aiming to regenerate human nephrons using porcine fetal kidneys as a scaffold. Crucial to this approach is the replacement of porcine nephron progenitor cells (NPCs) with human NPCs. Previous studies using mouse models have shown complete replacement of the host nephrogenic niche with exogenous nephrons through Six2 (+) NPC suicide driven by diphtheria toxin (DT) or tamoxifen (TAM). However, there are limitations, such as DT's inability to target human NPCs and concerns about TAM's side effects. To facilitate future clinical applications, we have developed a novel inducible-caspase 9 (iCasp9) system. It activates the intrinsic apoptotic pathway upon the administration of a chemical inducer of dimerization (CID) without harming the surrounding renal tissue. Importantly, our study demonstrates efficient cell clearance using this new system in animal models.

Methods: Six2-iCasp9 mice were generated using TALEN-mediated gene modification. The knock-in site was positioned downstream of the exon to prevent lethality in homozygotes. CID was administered both *in vitro* to fetal kidneys and *in vivo* to neonatal mice with either Six2-iCasp9$^{+/+}$ or Six2-iCasp9$^{+/-}$ genotype. Additionally, exogenous mouse and rat progenitor cells, as well as induced human NPCs, were injected into Six2-iCasp9$^{+/+}$ fetal kidneys with CID administration.

Results: In the culture of Six2-iCasp9$^{+/+}$ fetal kidneys, treatment with CID induced efficient apoptosis of all NPCs within 18 hours, whereas the conventional TAM-driven model showed insufficient apoptosis at the same time point. *In vivo* administration of CID to neonates also led to the complete removal of NPCs. On the other hand, NPC removal was not observed in the Six2-iCasp9$^{+/-}$ mice. Following the injection of exogenous progenitor cells, successful nephron replacement was achieved in Six2-iCasp9$^{+/+}$ fetal kidneys.

Conclusions: We successfully developed an iCasp9 system that enables rapid and complete cell clearance, providing an optimal environment for NPC replacement and subsequent nephron regeneration in an animal model. The phenotypic differences between homozygotes and heterozygotes might be attributed to the varying levels of iCasp9 expression. This achievement marks a clinical advancement in the development of the porcine fetal replacement system.

The Role of Gata3 in Renin Cell Identity

Jesus Neyra, Silvia Medrano, Maria Luisa S. Sequeira Lopez, Roberto Ariel Gomez. *University of Virginia, Charlottesville, VA.*

Background: Renin cells are precursors for other cell types in the kidney and show high plasticity in postnatal life in response to challenges to homeostasis. Our scRNA-seq studies revealed that the dual-zinc finger transcription factor Gata3, important for cell

lineage commitment and differentiation in many tissues, is expressed in mouse renin cells under normal conditions and homeostatic threats. Based on our Chip-seq data, we found an enhancer associated with Gata3 in renin cells. In addition, we identified a potential Gata3 binding site upstream of the renin gene leading us to hypothesize that Gata3 is essential for renin cell identity.

Methods: We studied 60 and 120-day-old mice carrying a conditional deletion of *Gata3* in renin cells: *Gata3$^{fl/fl}$;Ren1$^{dCre/+}$* (*Gata3-cKO*), and control *Gata3$^{fl/fl}$;Ren1$^{d+/+}$* counterparts. BUN and plasma renin levels were measured from blood samples collected by cardiac puncture. Ren1, Acta2, and Gata3 were visualized in kidney sections by immunohistochemistry. Histological analysis was performed on adult kidney sections with hematoxylin and eosin (H&E), periodic acid-Schiff (PAS) solution, or Masson's Trichrome chemical reactions. The juxtaglomerular area (JGA) index was calculated as a ratio of renin-positive JGAs per the total number of glomeruli and expressed as a percentage.

Results: *Gata3-cKO* mice have: 1) a marked reduction in Gata3 staining, demonstrating *Gata3* deletion in renin lineage cells; 2) a marked reduction of *Ren1* and *Akr1b7* mRNA levels in renin cells compared to controls; 3) a significant decrease in circulating plasma renin compared to controls under basal conditions and physiological threat; 4) a significantly reduced JGA index; 5) flattened JG cells compared to the plump and rounded morphology of control mice; 6) glomeruli with abnormal misplaced renin staining in the Bowman's capsule; 7) an absence of cubical epithelial cells in the Bowman's capsule, dilation of distal tubules, dilation of the glomerular capillaries and evidence of glomerular sclerosis and fibrosis. There was prominent glomerular hemorrhage with aneurysms and evidence of perivascular, peritubular, and periglomerular infiltration of inflammatory cells; 8) misplaced Acta2 staining in the intraglomerular mesangium, interstitium, and Bowman's capsule.

Conclusions: Our results suggest a role of *Gata3* in the identity of the cells of the renin lineage.

Repetitive Administration of Cultured Human CD34+ Cells Improve Adenine-Induced Kidney Injury in Mice

Takayasu Ohtake,[1,2] Amankeldi Salybekov,[2] Takayuki Asahara,[2] Shuzo Kobayashi.[2] *[1]Regenerative Medicine, The Center for Cell Therapy & Regenerative Medicine, Shonan Kamakura General Hospital, Kamakura, Japan; [2]Regenerative Medicine, Shonan Research Institute of Innovative Medicine (sRIIM), Kamakura, Japan.*

Background: There is no established treatment to impede the progression of diabetic kidney disease in human.

Methods: We evaluated the efficacy of cultured human CD34$^+$ cells with enhanced proliferating potential in chronic kidney injury model in mice. Human umbilical cord blood (UCB)-derived CD34$^+$ cells were incubated for one week in vasculogenic conditioning medium. This culture method significantly increased the number of CD34$^+$ cells (60-fold) and their ability to form endothelial progenitor cell colony-forming units (40-fold). Adenine-induced tubulointerstitial chronic kidney injury was induced in NOD/SCID mice, and cultured human UCB-CD34$^+$ cells were administered at a dose of 1×10^6/mouse on days 7, 14, and 21 after the start of adenine diet (cell therapy group n=18). In the control group (n=17), vehicle was administered at the same time point. Time-course of kidney function, pathological damage, and CD31-positive peritubular capillary density and macrophage infiltration in the kidney at the time of sacrifice (day 28) were evaluated.

Results: Repetitive administration of cultured UCB-CD34$^+$ cells significantly improved the time-course of serum creatinine levels in the cell therapy group compared with that in the control group (1.09 ± 0.09 mg/dL *vs* 1.41 ± 0.14 mg/dL on day 28, p =0.035). Both interstitial fibrosis area and tubular injury score were significantly reduced in the cell therapy group compared with that in the control group (interstitial fibrosis: 8.1 ± 5.4% *vs* 16.3 ± 7.0%, $p < 0.01$, tubular injury score: 1.48 ± 1.27 *vs* 2.83 ± 1.00, $p < 0.01$). Peritubular capillary density was significantly preserved in the cell therapy group compared with that in the control group (57.3 ± 6.4% *vs* 31.0 ± 6.1%, $p < 0.01$), and macrophage infiltration in the kidney tissue was dramatically decreased in the cell therapy group compared with those in the control group (1.3 ± 0.3% *vs* 14.4 ± 1.1%, $p < 0.001$).

Conclusions: Repetitive administration of cultured human UCB-CD34$^+$ cells significantly improved kidney dysfunction and chronic tubulointerstitial damage in adenine-induced kidney injury in mice *via* the protective effect of microvasculature integrity and anti-inflammatory effects. A clinical trial using cultured human UCB-CD34+ cells for progressive kidney disease might be expected.

SA-PO347

A Clinical Trial of Comprehensive Regenerative Treatment for Acute and Chronic Kidney Injury by Autologous Granulocyte-Colony Stimulating Factor (G-CSF)-Mobilized Peripheral Blood-Derived CD34+ Cell Administration

Takayasu Ohtake, Yasuhiro Mochida, Kunihiro Ishioka, Machiko Oka, Sumi Hidaka, Shuzo Kobayashi. *Kidney Disease and Transplant Center, Shonan Kamakura General Hospital, Kamakura, Japan.*

Background: There has been no established treatment to improve severe acute kidney injury (AKI) and progressive chronic kidney disease (CKD) in human. We are performing a clinical trial of regenerative medicine using autologous G-CSF-mobilized CD34$^+$ cells for AKI and CKD.

Methods: After permission of government permitted ethical committee, a clinical trial of regenerative treatment for severe AKI and progressive CKD is now undergoing. Potential subjects comprised of patients with dialysis-dependent severe AKI or patients who could fortunately be withdrawn from dialysis treatment but did not recover to baseline renal function within 4 weeks after the onset of AKI (AKI arm), and patients with progressive CKD (CKD stage G3b and G4 with decrease of reciprocal serum creatinine more than 0.01mL/mg/month) (CKD arm). Autologous G-CSF-mobilized peripheral blood-derived CD34+ cells at a dose of $1x10^6$/kg body weight were administered into renal arteries, and safety and efficacy were evaluated.

Results: Until now, six patients (2 AKI patients with malignant hypertension and 4 CKD patients with IgA nephropathy) were registered, and 4 patients (2 AKI patients and 2 CKD patients) completed their follow-up after cell therapy. As for safety, no major adverse events were observed. AKI case 1 showed rapid increase of estimated glomerular filtration ratio (eGFR) from 9.2 at transplantation to 20.0 mL/min/1.73m^2 at 4 weeks after cell therapy, and further improved to 24.9mL/min/1.73m^2 at 52 weeks. AKI case 2 could be withdrawn from hemodialysis treatment one month after cell transplantation, and eGFR gradually increased to 12.8 mL/min/1.73m^2 at 52 weeks. eGFR in CKD case 1 decreased from 15.0 at transplantation to 10.2 mL/min/1.73m^2 at 6 months after cell therapy. However, eGFR in CKD case 2 increased from 15.2 at transplantation to 17.5 mL/min/1.73m^2 at 6 months after cell therapy. CKD case 3 and 4 are now under follow-up period.

Conclusions: Regenerative cell therapy using autologous G-CSF-mobilized CD34$^+$ cells might have beneficial effect in patients with severe AKI. In progressive CKD patients with severely decreased renal function, further patients' recruitment and clarification of the efficacy of this cell therapy is necessary.

SA-PO348

Benchmarking Mitochondrial Organization and Abundance in Organoids Against Fetal and Newborn Kidney Tissue

Mohsina A. Khan, Leif Oxburgh. *Rogosin Institute, New York, NY.*

Background: Proximal tubule (PT) epithelia are some of the most energy demanding cells in the body, and rely on mitochondria for a large variety of ATP-dependent functions. Fidelity of stem cell-derived kidney tissue depends on achieving similar mitochondrial function. Our previous investigations revealed a paucity of mitochondria in PT epithelia of human stem cell-derived organoids. In this study we benchmarked synthetic PT epithelia against natural PT epithelia, and used a screening approach to boost mitochondrial mass in organoid epithelia.

Methods: Mitochondria were localized by staining with anti-TOMM20, LTL and anti-HNF4A were used for PT. TMRM was used to identify energetically active mitochondria in kidney tissue.

Results: Human fetal kidney (HFK) and newborn mouse kidneys were stained for mitochondria and PT. Newly formed PT stain weakly for HNF4A and LTL have characteristic apically arranged mitochondria. The mitochondria translocate basolaterally as these cells differentiate and mitochondrial mass increases several-fold, suggesting an abrupt activation of biogenesis. Live tissue staining of newborn mouse kidney with TMRM reveals undetectable mitochondrial polarization in apical mitochondria of nascent epithelial cells, while cells with basolateral mitochondria show strong mitochondrial polarization. Presumptive PT epithelia in stem cell-derived organoids have almost exclusively apically located mitochondria, suggesting that these cells may be functionally immature despite HNF4A and LTL staining. Single cell data from HFK and organoids were mined for mitochondrial biogenesis, mitophagy and mitocytosis pathways. Compounds selected based on this analysis were tested for their capacity to modify mitochondrial mass and function in a flow cytometry-based screening assay using organoids with fluorescent reporters for mitochondria and for PT. As expected, modifiers of the biogenesis regulator AMPK modulate mitochondrial mass, but we also found unanticipated effects of modulating LRRK2, which determines mitochondrial positioning within the cell.

Conclusions: Subcellular localization of mitochondria serves as a hallmark of epithelial cell functional maturity in human stem cell derived kidney organoids, and modulating mitochondrial mass is an important step in developing high-fidelity human kidney organoids.

SA-PO349

Urine-Derived Stem Cell Administration Attenuates Renal Injury in an Adriamycin-Induced Nephropathy

Kyungho Park,[1] Heewon Park,[1] Yunkyeong Hwang,[1] Suyeon Han,[1] Hye Rim Park,[2] Eu Jin Lee,[1] Hae Ri Kim,[3] Youngrok Ham,[1] Kiryang Na,[1] Kang Wook Lee,[1] Dae Eun Choi.[1,2] *[1]Chungnam National University Hospital, Daejeon, Republic of Korea; [2]Department of Medical Science, Chungnam National University, Daejeon, Republic of Korea; [3]Chungnam National University Sejong Hospital, Sejong, Republic of Korea.*

Background: Stem cell-based therapy as a potential alternative to conventional drug therapies for kidney diseases has attracted significant attention. While mesenchymal stem cells have been extensively studied in early clinical trials for various kidney diseases, research on urine-derived stem cells (UDSCs) remains limited. This study aims to evaluate the efficacy of UDSC administration in improving Adriamycin (ADR)-nephropathy using both an in vivo BALB/c mice model and an in vitro podocyte model.

Methods: 10 week-old male BALB/c mice were divided into four groups: sham, ADR, ADR+HS (single dose of UDSC), ADR+HM (three doses of UDSC) to establish the in vivo model. ADR was administered on day 0, followed by UDSC administration one week later. Necropsy and analysis were conducted on the 21st day. The urine albumin/creatinine ratio (ACR) was measured on days 0, 7, 14, and 21, and kidney

tissue was examined using light microscopy, immunofluorescence microscopy, and electron microscopy. In vitro, the protective effect of UDSC co-culture with ADR-treated podocytes was investigated through cell viability assessment and the expression of podocyte-specific markers, such as α-actinin-4 and synaptopodin.

Results: Both single-dose (ADR+HS) and multiple-dose (ADR+HM) UDSC administration significantly reduced the urine ACR levels compared to the ADR group. Histological analysis revealed notable improvements in renal tissue damage, including glomerulosclerosis and fibrosis, in both the ADR+HS and ADR+HM groups compared to the ADR group. Moreover, UDSC administration protected podocytes from damage, as indicated by increased foot process width. UDSC administration also enhanced expression of synaptopodin and α-actinin-4. Notably, ADR+HM showed a more pronounced effect on foot process width increase and improvement in the expression of α-actinin-4 and synaptopodin in podocytes compared ADR+HS. In vitro model, co-culture with UDSC significantly enhanced podocyte cell viability compared to ADR-treated podocytes alone. Furthermore, co-culture with UDSCs led to a significant increase in the expression of α-actinin-4 and synaptopodin in ADR-treated podocytes.

Conclusions: Administration of UDSCs demonstrates significant reduction in kidney damage in both in vivo and in vitro models of ADR-induced nephropathy.

SA-PO350

Depot-Specific Alterations in Visceral Adipose Tissue-Derived Mesenchymal Stem Cells in CKD: Insights from Single-Cell RNA Sequencing

Hyunjin Noh, Hyoungnae Kim, Mi ra Yu, Soon hyo Kwon. *Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea.*

Background: Patients with chronic kidney disease (CKD) experience systemic conditions such as chronic inflammation, oxidative stress, and protein-energy wasting. While previous studies have explored inter-organ communication to understand these conditions, the specific changes occurring in adipose tissue within a uremic environment remain poorly understood. This study aimed to investigate the characteristics of visceral adipose tissue in CKD patients, with a focus on adipose tissue-derived mesenchymal stem cells (ADMSCs).

Methods: We collected retroperitoneal adipose tissue (RP) near the kidneys and omental adipose tissue (OM) from healthy kidney donors as well as CKD patients who underwent kidney transplantation or peritoneal catheter insertion. The characteristics of the stromal vascular fraction were evaluated using single-cell RNA sequencing. Additionally, adipose tissue fibrosis and the expression of thermogenic genes were assessed in the total adipose tissue from these two different depots.

Results: We harvested 66,668 cells. In the ADMSCs cluster of RP, CKD patients showed a significant upregulation of antioxidant genes, such as metallothioneins, SOD2, and GPX3. Gene Ontology and pathway analysis revealed that differentially expressed genes (DEGs) upregulated in CKD were related to ribosomal biogenesis and ferroptosis. We observed an increase in the S phase of the cell cycle in RP of CKD, accompanied by enhanced FOXO signaling pathway and cellular senescence to prevent DNA damage. In OM of CKD, DEGs specifically upregulated were related to ATP synthesis processes, including fatty acid β-oxidation, the TCA cycle, and oxidative phosphorylation in mitochondria. Additionally, the median cell size of adipocytes from CKD patients was significantly smaller than that of healthy controls, specifically in OM. Adipocytes of CKD OM showed a significant increase in the expression of thermogenic genes, such as UCP1, CIDEA, PGC1α, TBX1, and TMEM26.

Conclusions: We identified depot-specific alterations in ADMSCs and adipose tissue characteristics in CKD patients. Further investigations are needed to elucidate the potential role of these adipose tissue changes in the systemic conditions associated with CKD.

The Effects of Regulatory T Cell Induction by Mesenchymal Stem Cells Pretreated with Interferon-Gamma on Renal Inflammation and Fibrosis

So Kurawaki,[1] Ayumu Nakashima,[2] Naoki Ishiuchi,[1] Ryo Kanai,[1] Kensuke Sasaki,[1] Takao Masaki.[1] *[1]Hiroshima Daigaku Byoin, Hiroshima, Japan; [2]Yamanashi Daigaku Igakubu Fuzoku Byoin, Chuo, Japan.*

Background: Mesenchymal stem cells (MSCs) exert the anti-inflammatory effect by secreting various humoral factors, which contribute to the regeneration of damaged tissues. Interferon-gamma (IFN-γ) can enhance the anti-inflammatory effect of MSCs, and the enhancement of regulatory T (Treg) cell induction is thought to be an underlying mechanism. In this study, we investigated the effects of Treg cell induction by IFN-γ MSCs on renal inflammation and fibrosis.

Methods: Rats were subjected to contralateral nephrectomy and unilateral renal ischemia reperfusion injury (IRI) by clamping the renal artery. Subsequently, phosphate-buffered saline, untreated MSCs (control MSCs), or IFN-γ MSCs were administered to the renal artery. At 7 or 21 days after administration, rats were sacrificed and their kidneys were collected to examine renal inflammation and fibrosis. In addition, *in vitro* experiments were performed to examine expression levels of indoleamine 2,3-dioxygenase (IDO), the key regulator of Treg cell induction, in IFN-γ MSCs. Finally, we examined the therapeutic effects of IFN-γ MSCs transfected with IDO1 siRNA in IRI rats.

Results: Administration of IFN-γ MSCs induced Treg cells and inhibited infiltration of inflammatory cells in IRI rats more drastically than control MSCs. In addition, administration of IFN-γ MSCs more significantly attenuated renal fibrosis compared with administration of control MSCs. IDO expression levels in conditioned medium from MSCs were enhanced by pretreatment with IFN-γ. Functional experiments demonstrated that IDO1 knockdown in IFN-γ MSCs reduced their anti-inflammatory and anti-fibrotic effects in IRI rats by reducing Treg cell induction.

Conclusions: Our findings suggest that the increase of Treg cells induced by enhanced secretion of IDO by IFN-γ MSCs played a pivotal role in their anti-fibrotic effects. Administration of IFN-γ MSCs may potentially be a useful therapy to prevent renal fibrosis progression.

SA-PO352

Tonsil-Derived Mesenchymal Stem Cells Alleviate Gentamicin (GM)-Induced AKI by an Amelioration of Oxidative Stress and Apoptosis via an Incorporation into Damaged Renal Tubules

Duk-Hee Kang,[1] Mina Yu,[1] Dal-Ah Kim,[1] Chor ho Jo.[2] *[1]Division of Nephrology, Ewha Womans University School of Medicine, Seoul, Republic of Korea; [2]Hanyang Biomedical Research Institute, Hanyang University College of Medicine, Seoul, Republic of Korea.*

Background: The therapeutic effect of mesenchymal stem cells (MSCs) in repairing damaged renal cells in AKI has been demonstrated. Human palatine tonsil is an attractive alternative high-yield source of adult stem cells since they are readily available from surgically removed waste tissue. The aim of this study is to investigate the therapeutic potential of T-MSCs in GM-induced AKI.

Methods: Twenty male Sprague-Dawley rats were divided into four groups: Control, GM (140 mg/kg/day, intraperitoneal injection for 10 days), GM+T-MSCs ($1x10^7$ cells, intravenous injection at 1 day after the 1st GM injection), and T-MSC group. To examine the intra-renal localization of T-MSCs, T-MSCs were labeled with PKH-26 red fluorescence before infusion. Measurement of BUN, Cr, proteinuria and histologic analysis including TUNEL staining were performed on 16 days of GM injection. Effect of T-MSC on renal tubular cells was also evaluated using a transwell co-culture system of NRK cells and T-MSC. Intracellular ROS was analyzed by measuring NOX activity, H_2O_2 generation, NOX mRNA expressions with DCF-DA staining.

Results: The infusion of T-MSCs in GM-induced AKI rats preserved renal function with a decrease in proteinuria. T-MSCs injection decreased apoptotic cells and the expression of Bax, cytochrome C, and cleaved caspase and increased Bcl-2. T-MSCs suppressed oxidative stress as reflected by a decrease in the level of urinary 8-OHdG with an increase in antioxidant enzymes (glutathione peroxidase and catalase) in the kidneys. Anti-human nuclei and PHK-26 staining demonstrated the localization of T-MSCs in the tubules of renal cortex. In-vitro study revealed that T-MSC or T-MSC-conditioned media ameliorated GM-induced NOX-1 expression, H_2O_2 generation, and apoptosis of NRK cells.

Conclusions: Our study demonstrated that T-MSCs ameliorated GM-induced AKI by directly incorporating into the damaged renal tubules, exerting anti-apoptotic and anti-oxidative effects.

Comparison of Therapeutic Effects of Adipose- and Bone Marrow-Derived Mesenchymal Stem Cells on Renal Fibrosis

Maria Yoshida,[1] Ayumu Nakashima,[2] Naoki Ishiuchi,[1] Kisho Miyasako,[1] Yoshiki Tanaka,[1] Keisuke Morimoto,[1] Kensuke Sasaki,[1] Takao Masaki.[1] *[1]Hiroshima Daigaku Byoin, Hiroshima, Japan; [2]Yamanashi Daigaku Igakubu Fuzoku Byoin, Chuo, Japan.*

Background: Mesenchymal stem cells (MSCs) have garnered strong interest as a therapeutic tool for renal fibrosis. Although both adipose-derived and bone marrow-derived MSCs (ADSCs and BMSCs, respectively) suppress renal fibrosis, which of these two has a stronger therapeutic effect remains unclear. This study aimed to compare the antifibrotic effects of ADSCs and BMSCs from the same rats.

Methods: ADSCs and BMSCs were extracted from adipose tissue and bone marrow from same rats and cultured in serum-containing and serum-free medium, respectively. After renal ischemia-reperfusion injury, ADSCs and BMSCs were injected through the abdominal aorta. At 21 days post-injection, the rats were sacrificed, and their kidneys were analyzed. Next, ADSCs and BMSCs were infused into mice via tail vein, and 24h survival rate and pulmonary emboli were analyzed. In in vitro experiments, we compared the procoagulation factors and humoral factors in ADSCs and BMSCs.

Results: When cultured in serum-containing medium, ADSCs had a more potent inhibitory effect than BMSCs on renal fibrosis induced by ischemia-reperfusion injury in rats. ADSCs and BMSCs cultured in serum-free medium were equally effective in suppressing renal fibrosis. Mice infused with ADSCs (serum-containing or serum-free cultivation) had a higher death rate from pulmonary embolism than those infused with BMSCs. *In vitro*, mRNA levels of tissue factor, tumor necrosis factor-α-induced protein 6 and prostaglandin E synthase were higher in ADSCs than BMSCs, while that of vascular endothelial growth factor was higher in BMSCs than ADSCs. Although ADSCs had a stronger antifibrotic effect, these findings support the consideration of thromboembolism risk in clinical applications.

Conclusions: Our results emphasize the importance of deciding between ADSCs and BMSCs based upon the target disease and culture method.

Selected Renal Cells Improve Renal Function in a Canine Model of CKD

Prakash Narayan, Andrew T. Bruce, Elias A. Rivera, Tim A. Bertram, Deepak Jain. *ProKidney, Winston-Salem, NC.*

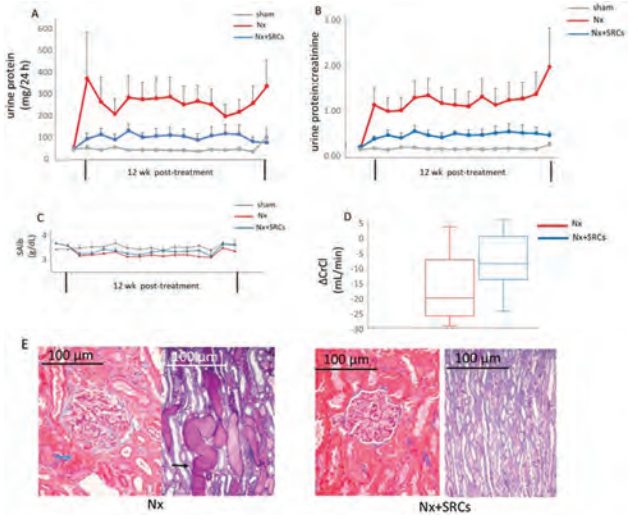
Background: Selected renal cells (SRCs) express podocyte, ureteric bud and cap mesenchyme markers associated with glomerular barrier function, renal filtration and urine concentration. In the present study we tested the hypothesis that cortical administration of autologous SRCs improves renal filtration and preserves renal microarchitecture in the canine subtotal nephrectomy (Nx) model of renal hypertensive chronic kidney disease.

Methods: SRCs were sourced from the excised contralateral kidneys of adult male mongrel dogs subjected to Nx. At weeks 15 and 43 post Nx, dogs were administered SRCs (~300x10^6 cells/dog into the remnant renal cortex, n=4) or placebo (n=4). Renal filtration was monitored over weeks 44 through 57 and renal microarchitecture (Masson's Trichrome) evaluated at sacrifice. A sham cohort served as control.

Results: There was no difference between the two Nx cohorts prior to randomization. SRC treatment was associated with increased body weight ($p<0.01$), reduced urine protein ($p<0.01$) and urine protein to creatinine ratio ($p<0.01$), and improved serum albumin ($p<0.01$) and creatinine clearance profiles ($p<0.05$, A-D). SRCs did not reduce blood pressure, rather their activity appeared to be directly related to preservation of renal microarchitecture evidenced by reduced - glomerular hypertrophy, tubular dilatation, cast deposition, inflammation and fibrosis (E).

Conclusions: These data suggest that SRCs, a standalone cell-based platform, has anti-inflammatory and anti-fibrotic activity and preserves glomerular and tubular microarchitecture and improves multiple indices of renal function in a large animal model of renal disease.

Funding: Commercial Support - ProKidney



SRCs improve renal filtration (A-D) and preserve renal microarchitecture (E) in a canine model of hypertensive chronic kidney disease.

Renal Involvement After Pediatric Liver Transplantation: A Large Single-Center Cohort

Adi Glass,[1] Ori J. Goldberg,[2,3] Yael Mozer Glassberg,[4,3] Orith Waisbourd-Zinman,[4,3] Orly Haskin,[5,3] Shelly S. Levi,[5,3] Daniel Landau,[5,3] Hadas Alfandary.[5,3] *[1]Schneider Children's Medical Center of Israel Department of Internal Pediatrics A, Petah Tikva, Israel; [2]Schneider Children's Medical Center of Israel Institute of Pulmonology, Petah Tikva, Israel; [3]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel; [4]Schneider Children's Medical Center of Israel Institute of Gastroenterology Nutrition and Liver Diseases, Petah Tikva, Israel; [5]Schneider Children's Medical Center of Israel Institute of Nephrology, Petah Tikva, Israel.*

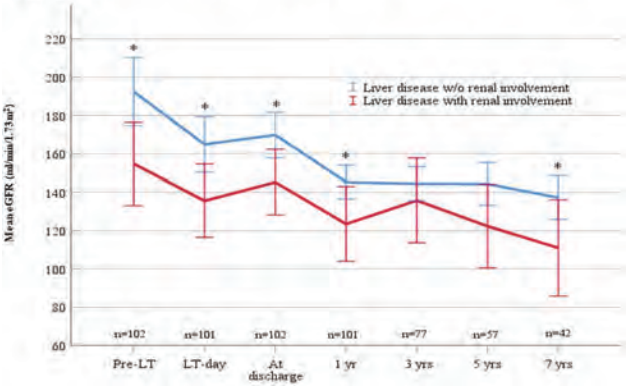
Background: Survival after pediatric liver transplantation has increased dramatically over the years, revealing extra-hepatic complications including impaired renal function. We conducted a large single center retrospective study to evaluate thoroughly renal outcomes after pediatric liver transplantation.

Methods: Pre and post-transplant data was collected from electronic charts of children who underwent liver transplantation at SCMCI from 2007-2020. Incidence of renal injury which included proteinuria, hypertension or decreased eGFR was documented. Additional renal assessment by renal ultrasound and the presence of acute kidney injury (AKI) was performed. Predictors for hypertension or decreased eGFR at last follow-up were identified using univariate and multivariate regression models.

Results: 121 children were followed for a median of 5.12 (IQR 2.94-7.3) years. After excluding 18 patients who died, or underwent renal transplantation, any renal injury was observed in 33.9% of the children, hypertension: 12.6%, proteinuria: 23.3%, and eGFR<90 mL/min per 1.73 m^2: 6.7% at their last follow-up. Reduction in eGFR was observed along the follow-up, and was accentuated in the first year post transplant (figure 1). AKI was seen in 41.7% of the children during follow-up. An abnormal renal ultrasound was seen in 44.7% of the children at last visit, significantly higher rates than before transplant, 10.7% ($p<0.001$). Abnormal renal ultrasound before transplant (OR=4.49, 95% CI 1.1-18.3) and liver disease with risk of renal involvement (OR=4.32, 95% CI 1.4-13.0) were found to be predictors for hypertension or decreased GFR at last follow-up.

Conclusions: Renal injury is very common in children after pediatric liver transplantation. Therefore, thorough renal pretransplant evaluation and follow-up are necessary for preserving and improving renal function.

Figure 1. Trends of estimated glomerular filtration rate (eGFR; mean, 95% CI) over the years in pediatric liver transplant patients.



*P< 0.05 Liver disease with renal involvement versus without. LT, liver transplant.

Increasing Cardiovascular Burden Among Young Adults with Pediatric CKD at Time of Transition to Adult Care

Mark Mitsnefes,[1] Joseph T. Flynn,[2] Ankur K. Patel,[3] Susan L. Furth,[4] Bradley A. Warady,[5] Derek K. Ng.[3] Chronic Kidney Disease in Children Study. *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]Seattle Children's Hospital, Seattle, WA; [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Children's Mercy Kansas City, Kansas City, MO.*

Background: Transition to adult care for young adults with pediatric chronic kidney disease (CKD) is critical phase of clinical care and may present challenges for cardiovascular disease (CVD) management. To investigate CVD burden among young adults, we assessed the prevalence of cardiovascular and metabolic comorbidities among participants > 18 years and compared to the same participants prior to age 18.

Methods: Using data from the Chronic Kidney Disease in Children (CKiD) study, we estimated prevalence of high blood pressure (elevated, Stage 1 or 2), obesity, and hyperglycemia before and after age 18 among those who reached young adulthood free of ESKD. Logistic models with generalized estimating equations for prevalence odds ratios (older vs. younger) for each comorbidity, adjusting for GFR, proteinuria and diagnosis.

Results: Among 313 participants who attained age 18 with an average GFR of 47 ml/min|1.73m2, the prevalence of high blood pressure (BP) was 38% among young adults (864 person-visits) with a median age was 19.8 [IQR: 18.8, 21.1], compared to 26% among the same participants prior to age 18 (1332 person-visits) at a median age 15.2 [12.8, 16.7] with an average GFR of 50. There were no significant differences in obesity (21% vs. 19%) or hyperglycemia (6% vs. 7%). Older age was associated with an unadjusted prevalence odds ratio for high BP of 1.70 (95%CI: 1.40 to 2.09), which remained significant in an adjusted model (OR: 1.63, 1.30 to 2.04).

Conclusions: Among young adults with pediatric CKD who had not reached ESKD, the prevalence of high BP was significantly higher compared to when they were younger. Adult nephrologists receiving patients with pediatric CKD should be vigilant for the potential worsening of BP control during the transition period.

Food Insecurity Is Associated with Short Stature, Slow Growth Velocity, and Lower Cognitive Function in the Chronic Kidney Disease in Children (CKiD) Cohort

Margaret Murphy,[1] Matthew Matheson,[2] Aftab S. Chishti,[1] Stefan Kiessling,[1] Stephen R. Hooper,[5] Bradley A. Warady,[4] Susan L. Furth.[3] *[1]University of Kentucky College of Medicine, Lexington, KY; [2]Johns Hopkins University, Baltimore, MD; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Children's Mercy Kansas City, Kansas City, MO; [5]The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Food insecurity is defined as the state of being without reliable access to an adequate amount of affordable and nutritious food. Food insecurity is associated with disparities in chronic kidney disease in adults; however less is known in children.

Methods: The Chronic Kidney Disease in Children (CKiD) study is a multicenter, observational cohort of children with eGFR 30-90ml/min/1.73m^2. Food insecurity screening was added in 2022 via the Hunger Vital screen. Cross-sectional analyses used Wilcoxon rank-sum test or Fisher's exact test, as appropriate, to determine the association between food insecurity and disease outcomes related to growth and cognition.

Results: Of the 181 participants included, 9% of subjects (n=17) reported food insecurity. Food insecure subjects had a median age of 9.7 (IQR, 8.4-17.9), median GFR of 42 (IQR, 26, 66), 53% were male, and 18% had glomerular disease. Food insecure patients had a higher prevalence of short stature and lower growth velocity. None of these patients were on growth hormone; however, food insecure patients were significantly more likely to be seen by a nutritionist (p=0.003). Food insecure patients performed less well on IQ tests (mean 89 vs 102, p=0.03) and were from households with lower income and maternal education. Follow-up analyses found the effect of food insecurity on IQ to be independent of maternal education.

Conclusions: Children with CKD and food insecurity, which is frequently associated with lower household income, and lower maternal education, are more likely to present with impairments in growth and lower performance on IQ testing. This study highlights the need to screen for food insecurity as early identification and intervention may improve CKD-related health outcomes. Further analyses will investigate the impact of food insecurity on longitudinal outcomes of CKD progression and cardiovascular factors.

Performance of CKD-EPI GFR Estimating Equations in a Cohort of Young Adults with Pediatric CKD

Derek K. Ng,[1] Lesley A. Inker,[2] Susan L. Furth,[3] Bradley A. Warady,[4] George J. Schwartz.[5] Chronic Kidney Disease in Children Study. *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]Tufts Medical Center, Boston, MA; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Children's Mercy Kansas City, Kansas City, MO; [5]University of Rochester Medical Center, Rochester, NY.*

Background: The Chronic Kidney Disease in Children (CKiD) study previously documented an overestimation bias by the 2009 age-sex-race CKD-EPI eGFR among young adults aged 18 to 24 with a history of pediatric CKD. However, the recently updated 2021 race-free CKD-EPI equations have not been evaluated among young adults with a history of pediatric CKD.

Methods: Using CKiD data from young adults 18 to 25 years, we evaluated three CKD-EPI equations: 2021 SCr (with age and sex; AS), 2012 CysC, and the 2021 SCr-CysC (AS) Bias (eGFR - mGFR), accuracy (proportion within 10% and within 30%) and root mean square error (RMSE) were estimated.

Results: Among 313 person-visits, the median age was 19.4 years [IQR: 18.6, 20.6] and the median mGFR was 44.8 ml/min|1.73m^2 [IQR: 31.3, 65.1]. Table 1 summarizes agreement metrics. The average biases were +8.81 (95%CI: +7.09, +10.53), +3.73 (+2.04, +5.41), and +4.31 (+2.84, +5.78) for the SCr, CysC, and combined CKD-EPI equations, respectively. The proportion of eGFR within 30% of mGFR was 69.0%, 78.3% and 81.5%, respectively. The lowest RMSE was observed for the combined equation (11.75) and the creatinine-based and cystatin c-based equations RMSEs were 14.83 and 14.03, respectively.

Conclusions: Application of the new CKD-EPI SCr equation to CKiD data demonstrated overestimation of measured GFR and high root mean square errors. The cystatin-based and combination equations performed better than creatinine alone. As previously published, the race-free CKiD U25 equations had no significant bias (range: -0.89 to +0.70) and p30 between 85-90% among young adult participants, but performance is expected to be better in internal validation because it randomly differed from the data used to develop the U25 eGFR. For pediatric CKD patients transitioning to adulthood, care needs to be exercised when using disparate equations that yield abrupt differences in estimates of GFR. Use of U25 eGFR through 25 years is recommended for this population.

Funding: NIDDK Support, Other NIH Support - NICHD, NHLBI

Agreement between CKD-EPI eGFR and mGFR (bias, p10, p30, and root mean square error (RMSE) among 208 young adults participants in CKiD (≥ 18 years) with 313 assessments of mGFR

CKD-EPI eGFR	eGFR – mGFR (95% CI)	p10: eGFR within 10% of mGFR	p30: eGFR within 30% of mGFR	RMSE ml/min|1.73m2
2021 SCr-only	8.81 (7.09, 10.53)	26.2%	69.0%	14.83
2012 CysC only	3.73 (2.04, 5.41)	30.0%	78.3%	14.05
2021 SCr- and CysC-combined	4.31 (2.84, 5.78)	37.4%	81.5%	11.75

Development of an Adaptive Clinical Web-Based Prediction Tool for Kidney Replacement Therapy in Children with CKD

Derek K. Ng,[1] Matthew Matheson,[1] George J. Schwartz,[2] Susan R. Mendley,[3] Susan L. Furth,[4] Bradley A. Warady.[5] Chronic Kidney Disease in Children Study. *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]University of Rochester Medical Center, Rochester, NY; [3]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Children's Mercy Kansas City, Kansas City, MO.*

Background: Clinicians need improved prediction models to estimate time to kidney replacement therapy (KRT) for children with chronic kidney disease (CKD). We aimed to a) develop and validate a prediction tool using clinical variables for time to KRT from the Chronic Kidney Disease in Children (CKiD) study using statistical learning methods and b) to design an online calculator for clinical use.

Methods: We constructed an elementary model using eGFR, proteinuria and diagnosis as predictors in a parametric generalized gamma (GG) survival model and used penalized likelihood to identify optimal nonlinear combinations of these three. We then used random survival forest (RSF) to identify additional candidate predictors from a large panel of demographics and clinical markers. From the top predictors we used best subset selection, a learning method, to identify the best combination in an enriched GG model.

Results: Among 890 children, 9 candidate predictors were identified from 172 variables in RSF which were added to the elementary model. Best subset selection yielded an enriched model additionally based on blood pressure, 1 year change in eGFR, anemia, albumin, chloride and bicarbonate. Four additional partially enriched models were constructed for clinical situations with incomplete data and integrated as an adaptive tool (Figure). Discrimination was high in cross-validation (c= 0.86) and in an external European cohort (c= 0.85) with strong calibration. We designed an adaptive online tool for clinical use.

Conclusions: This clinical prediction tool for time to KRT in children was developed in a large, representative pediatric CKD cohort with an exhaustive evaluation of potential predictors and statistical learning methods. While models performed well internally and externally, further external validation of enriched models is needed.

Funding: NIDDK Support, Other NIH Support - NICHD, NHLBI, Other U.S. Government Support

Validating CKiD U25 eGFR Equations for Differing Body Habitus

Christopher B. Pierce,[1] Derek K. Ng,[1] Bradley A. Warady.[2] Chronic Kidney Disease in Children Study. *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]Children's Mercy Kansas City, Kansas City, MO.*

Background: The Chronic Kidney Disease in Children (CKiD) U25 eGFR equations provide unbiased estimates of glomerular filtration rate (eGFR) and strong levels of agreement with measured GFR (mGFR) for CKD patients 1-25 years old. However, the performance of these equations by body habitus has not been assessed.

Methods: Data were from the CKiD U25 validation set comprising 832 observations from 302 participants. Median age was 12 [IQR: 8,16] years and iohexol mGFR was 44 [32,61] mL/min/1.73m^2. We evaluated three U25 equations: creatinine, cystatin C and the average of the two. Within BMI categories (underweight, normal weight, overweight, obese), we summarize agreement as mean bias (eGFR-mGFR) and percent of eGFR within 30% of mGFR (P30). Mean bias was calculated from a mixed effects model to account for multiple observations per participant.

Results: All equations overestimated GFR in underweight subjects with the two cystatin C-based equations exhibiting statistically significant biases which persisted after adjusting for sex, age and GFR level. All equations underestimated GFR in overweight subjects but these biases were not significantly different than those in the normal weight subjects after adjustment. There was no bias observed in the obese category, suggesting this bias may not be a direct function of larger body habitus for age and sex. All three equations yielded lower P30 values in underweight compared to non-underweight subjects.

Conclusions: U25 eGFR slightly overestimated mGFR in underweight compared to non-underweight subjects, with U25 eGFR(cr) exhibiting the smallest bias of the three equations in this BMI group. The U25 equations performed well in non-underweight children, adolescents and young adults with CKD.

Funding: NIDDK Support, Other NIH Support - NICHD, NHLBI

	BMI Category			
	Underweight	Normal	Overweight	Obese
N subjects (observations)	44 (65)	204 (485)	87 (138)	63 (144)
Mean Bias (eGFR-mGFR), mL/min/1.73m2, Est. (95%CI)				
U25 eGFR(cr)	1.7 (-0.7, 4)	0.0 (-1.2, 1.2)	-2.0 (-3.8, -0.2)	2.1 (-0.4, 4.6)
U25 eGFR(cysC)	4.6 (1.8, 7.5)	-0.8 (-1.8, 0.2)	-2.0 (-3.8, -0.2)	-1.7 (-3.8, 0.5)

Neonatal Risk Factors for CKD Progression in Children

Joya M. Sims,[1] Matthew Matheson,[2] Derek K. Ng,[2] Bradley A. Warady,[3] Susan L. Furth,[1] Erum A. Hartung,[1] CKiD Study Investigators.
[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [3]Children's Mercy Kansas City, Kansas City, MO.

Background: Neonatal risk factors for childhood CKD include prematurity, acute kidney injury (AKI), and sepsis. It is not known how these factors, assessed in the 1st 90 days of life, are associated with early childhood kidney function in children with congenital kidney diseases.

Methods: Neonatal data including gestational age (GA); AKI or sepsis in first 90 days; and serum creatinine (SCr) at discharge was retrospectively collected on Chronic Kidney Disease in Children (CKiD) cohort study participants with congenital anomalies of the kidneys and urinary tract and other congenital kidney diseases. Participants with ≥1 CKiD study eGFR in follow up were included. SCr at NICU discharge was indexed to published mean SCr for GA and postnatal age (PMID: 34142253). We assessed univariate relationships between each predictor and incidence of eGFR<30 mL/min/1.73m^2 by age 5 years (eGFR<30$_{5y}$) and parametric survival for time to eGFR<30 mL/min/1.73m^2 (eGFR<30).

Results: 123 children (71% male; median [IQR] baseline age 3.0 [1.7, 4.3] y) had available neonatal data. 36% were premature (GA<37 weeks). Median [IQR] birth weight was 3.13 [2.60, 3.46] kg; discharge age was 21 [7, 40] days;median discharge SCr was 1.00 [0.65, 1.55] mg/dL; discharge SCr index was 3.3 [2.0, 4.5]. 40% had history of AKI; 13% had history of sepsis. Prematurity, AKI, and sepsis were not associated with risk of eGFR<30$_{5y}$. SCr index >3.5 at discharge was associated with 52% earlier time to eGFR<30. Cumulative incidence of eGFR<30$_{5y}$ was 21% for participants with discharge SCr index ≤3.5 and 47% for those with discharge SCr index >3.5 **(Figure 1)**.

Conclusions: SCr index >3.5 by 90 days of age was associated with a significantly higher risk of eGFR <30 mL/min/1.73m^2 by age 5 years in children with congenital kidney diseases in the CKiD cohort. Prematurity, AKI, and sepsis were not associated with CKD progression risk in this cohort.

Ultrasound-Based Machine Learning Model and Renal Parenchymal Area as Predictors of Kidney Function Decline in Children with CKD

Bernarda Viteri,[1] Susan L. Furth,[1] Joya M. Sims,[1] Hannah C. Derwick,[1] Katherine M. Fischer,[1] Jennifer Roem,[2] Joseph R. Logan,[1] Gregory E. Tasian.[1] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]Johns Hopkins University, Baltimore, MD.*

Background: Few prediction models of kidney function decline include imaging features. Here, we apply machine learning-derived renal ultrasound features and compare the performance to renal parenchymal area (RPA) in the Chronic Kidney Disease in Children (CKiD) cohort study.

Methods: We determined the predictive performance of a previously developed machine learning algorithm among 119 subjects with non-glomerular chronic kidney disease (CKD) enrolled at 14 sites in the prospective CKiD study. The primary outcome was CKD progression defined as initiation of renal replacement therapy or 50% decline of estimated glomerular filtration rate (eGFR) assessed by the CKiD U25 equation. We assessed the predictive performance of three different models: (1) Clinical model (CM), (2) Deep Learning model (DLM), and (3) Deep Learning +Clinical model (DL+CM). The CM included baseline clinical features: age, eGFR, systolic blood pressure, urine creatinine, urine protein, and serum creatinine. The DLM used features extracted automatically from the first available kidney ultrasound. In a subset of 46 subjects, we compared the performance of ensembled models (3) DL+CM to (4) RPA +Clinical model (RPA +CM). The RPA model included age and the mean RPA values measured by an attending urologist and nephrologist blinded to outcomes. We used a random survival forest model to estimate CKD progression.

Results: Ninety-one subjects with a median age of 11.5 months, IQR [0.2, 78.2] at ultrasound were included in the DL+CM. CKD progression occurred for 20% over a median follow-up of 9 yrs, IQR [3.8,9.7]. For the subset of 46 subjects, median age at ultrasound was 9.7 months, IQR [1.4, 79.3] and CKD progression occurred in 28% over a median follow-up of 6.4 yrs IQR[4.1, 9.2]. Of the models presented, the DL+CM and RPA+CM had the best performance with C-index of 0.74 and 0.77, respectively.

Conclusions: Our ensemble models accurately predicted CKD progression using imaging features in children with CKD. The comparison of the performance of deep learning features and RPA was limited by the small sample size. These results in a prospectively enrolled cohort suggest that *early* ultrasound imaging features could identify children at greatest risk of CKD progression in clinical practice.

Ultrasound Evaluation of Fibrosis in Pediatric Kidney Transplant Recipients

Bernarda Viteri, Laura S. De Leon-Benedetti, Tatiana Morales-Tisnes, Tricia Bhatti, Laith R. Sultan, Sandra Amaral, Hansel J. Otero. *The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: To evaluate doppler resistive indices, ultrasound elastography, and contrast ultrasound as imaging biomarkers of fibrosis in pediatric kidney transplants.

Methods: A prospective study of children with kidney transplant and healthy controls was conducted from February 2020 to May 2023. All subjects underwent ultrasound with spectral Doppler to measure resistive indices (RI) and shear wave elastography to assess renal stiffness. RIs were assessed in the upper, interpolar, and lower poles and median elastography values were averaged from 10 regions of interest. Kidney transplant recipients undergoing clinically indicated biopsies underwent contrast-enhanced ultrasound (CEUS) and Time-Intensity Curves were generated. CEUS time to peak, peak enhancement, perfusion index, area under the curve, and mean transit time were examined. All kidney allografts were classified as with interstitial fibrosis and tubular atrophy (IFTA) or without IFTA based on histopathology. Subjects with rejection were excluded. Kruskall-Wallis was used to compare RI and elastography between the three groups. Dunn test was used for post-hoc analysis. For the CEUS studies, Mann-Whitney analysis was used to compare allografts without vs. with fibrosis.

Results: 16 healthy control kidneys were examined among 8 subjects with median age 14.5 yrs. Among 11 kidney allografts, six (54.6%) were from living donors; median recipient age 16 yrs. Of the 11 allografts, 4 (33.3%) had IFTA (all grade 1). We found no difference in resistive indices (p=0.53) between allografts without vs. with fibrosis, or controls. Elastography measures differed between controls and all allografts (p=0.01); but did not differ between allografts with or without fibrosis. Among subjects with CEUS, mean transit time was the only parameter significantly prolonged in the allografts with fibrosis (vs. those without) (p=0.04).

Conclusions: In this cohort, RIs did not differ between groups. Tissue stiffness, by elastography, differed between controls and allografts but not between those with and those without fibrosis. CEUS detected differences in mean transit time between allografts with vs. without fibrosis, suggesting CEUS may be a sensitive biomarker to detect fibrosis. A larger sample and longitudinal data are needed for validation.

Longitudinal Changes of Left Ventricular Diastolic Function and Fibroblast Growth Factor 23 in Young Hemodialysis Patients

Wacharee Seeherunvong, Chryso P. Katsoufis, Marissa J. Defreitas, Sethuraman Swaminathan, Carolyn L. Abitbol, Michael Freundlich. *University of Miami School of Medicine, Miami, FL.*

Background: Left ventricular diastolic dysfunction (DD) occurs early in patients on hemodialysis. Both traditional factors like hypertension and non-traditional factors including fibroblast growth factor-23 (FGF23) levels, erythropoietin, and treatment with vitamin D receptor activators such as paricalcitol may affect the progression of DD. Our objectives were to investigate the association of longitudinal changes of diastolic function with FGF23 levels and treatment with paricalcitol and erythropoietin in young dialysis patients.

Methods: Conventional and tissue Doppler imaging measurements and their respective age-adjusted Z-scores were used to measure early (E), late (A) diastolic transmitral flow velocities, corresponding mitral annular tissue velocities (e' and a'), and to evaluate DD in 20 young hemodialysis patients age 16.7±3.6 years. DD was defined as an abnormal Z-score of E, A, E/A or E/e' ratios. We analyzed associations of longitudinal DD changes with sequentially measured FGF23 levels, and with doses of erythropoietin and paricalcitol administered while on maintenance hemodialysis throughout a period of 7.1 ± 2.1 months.

Results: Compared with the standardized healthy age-matched controls, echocardiographic markers of diastolic function by Z-score cutoff revealed DD in 93% at baseline and 90% at follow-up. FGF23 levels were markedly elevated at baseline and follow up (25,238 ± 30,244 and 19,153 ± 25,191 RU/ml, respectively). FGF23 levels correlated only with the baseline mitral E/e' ratio, but not with any other measurement of diastolic function. Hypertension correlated with DD. Paricalcitol dose was associated with improved diastolic function while erythropoietin dose showed no correlation with FGF23 levels or diastolic function.

Conclusions: In young hemodialysis patients, DD is highly prevalent. Elevated FGF23 levels and hypertension may contribute to DD. Erythropoietin is neither associated with FGF23 levels nor with DD while paricalcitol may attenuate DD.

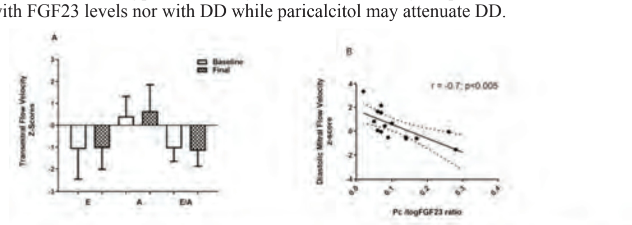

Figure A. Diastolic Function Z scores by Conventional Echocardiography in Hemodialysis Patients. The figure shows baseline and final transmitral early (E) and late (A) filling flow velocities and the E/A ratio obtained by 2-D imaging. Data expressed as Z-scores, average ± standard deviation.

Figure B. Regression of diastolic functional marker of late transmitral flow velocity z-score with the paricalcitol (Pc) dose. The Pc/log FGF23 ratio represents the Pc dose (µg/kg/week) divided by the calculated log FGF23 value.

SA-PO365

Urine Proteomic Profiling and Insights into CKD Progression in Children

Jason H. Greenberg,[1] Arthur Lee,[2] Josef Coresh,[3] Bradley A. Warady,[4] Joachim H. Ix,[5] Susan L. Furth,[2] Michelle Denburg.[2] [1]*Yale University, New Haven, CT;* [2]*The Children's Hospital of Philadelphia, Philadelphia, PA;* [3]*Johns Hopkins University, Baltimore, MD;* [4]*Children's Mercy Kansas City, Kansas City, MO;* [5]*University of California San Diego, La Jolla, CA.*

Background: Chronic kidney disease (CKD) progresses to end stage kidney disease (ESKD) and is associated with mortality rates that are 30-150 times higher than in the general pediatric population. We hypothesized that large scale proteomic measurements may provide insights to the molecular basis of CKD progression in children and may identify therapeutic protein targets.

Methods: In the CKiD Cohort Study, children with CKD were enrolled and eGFR was assessed annually. Among participants with an eGFR of 60-90 ml/min/1.73m^2 at baseline, 22 CKiD participants with CKD progression were matched by subtype of kidney disease to 22 CKiD participants without CKD progression. The primary outcome of CKD progression was defined as a composite of 50% decline in eGFR or ESKD. We measured 2904 urine proteins collected at the 6 month visit after enrollment using the Olink Proteomics Explore Assay.

Results: Of the 44 children included, the median age was 12 years, 66% were male, 68% had a glomerular cause of CKD, and baseline eGFR was 68 [IQR, 63, 81] ml/min/1.73m^2. In the full cohort, 38/2904 proteins were statistically significantly different (p-value cutoff of 0.000017 using the Bonferroni correction) when comparing those with CKD progression to those without CKD progression (Table). B-cell activating factor, Complement 2 (C2), and C5, all druggable targets, were more than 10-fold higher in children with CKD progression relative to those without progression. Pathway analyses demonstrated that TGF-β1, TNF, IL-1β, IL-4, IFN-γ, and angiotensinogen were key pathways activated in children with CKD progression.

Conclusions: Many urine proteins were elevated, and pro-inflammatory and pro-fibrotic pathways were upregulated in children with CKD progression. The application of large-scale proteomics to the study of CKD in children may inform pathomechanisms and identify new therapeutic targets.

Serum FGF23 and Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL) Correlation with Glomerular Filtration Rate, Measured with a Reference Technique in Children with CKD

Atessa Bahadori,[1,2] Carole Salomon,[1] Cyril Jaksic,[1] Christophe Combescure,[1] Alexandra Wilhelm-Bals,[1] Paloma Parvex.[1] [1]*Hopitaux Universitaires Geneve, Geneve, Switzerland;* [2]*The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Prognosis of chronic kidney disease (CKD) is closely related to early diagnosis and initiation of nephroprotective measures. Current kidney injury biomarkers are suboptimal for predicting kidney disease progression. Fibroblast Growth Factor 23 (FGF23) is well described as an early marker that increases proportionally to worsening CKD stages in adults. Neutrophil gelatinase-associated lipocalin (NGAL) is known to increase early after acute kidney injury, as a marker of AKI severity, however, it has not been validated as an early marker in CKD. The aim of this study is to investigate the association between FGF23, NGAL and glomerular filtration rate (GFR) in children and evaluate their role in ascertaining moderate to severe CKD.

Methods: Children aged 5 to 20 years old requiring kidney function assessment following primary nephropathy, solid organ transplantation or secondary nephropathy were recruited prospectively in a tertiary hospital of Switzerland for a reference measure of their GFR, with simultaneous measurement of plasma FGF23 and urinary NGAL.

Results: 123 clearances were analyzed, in children mostly post solid organ transplantation (46%) or with primary nephropathy (37%). 42% had stage I CKD, 40% had stage II CKD and 12% had stage III or IV CKD. FGF23 was significantly higher in stage III or IV CKD (mean: 282.02 UI/ml ± 174.71) compared to stage I (mean: 143.76 UI/ml ± 178.61 ; p<0.001) or stage II (mean: 104.61 UI/ml ± 63.52; p<0.001). The area under the ROC curve for FGF23 to discriminate CKD stages I-II versus III-IV was 0.864 (95% confidence interval (CI): 0.780-0.947). NGAL values were more elevated in stage III or IV CKD (mean: 103.65 UI/ml ± 129.43) compared to stage I (mean: 36.19 UI/ml ± 100.36 ; p=0.016) or stage II (mean: 44.86 UI/ml ± 104.66; p=0.082). The area under the ROC curve for NGAL to discriminate CKD stages I-II versus III-IV was 0.688 (95% CI: 0.512-0.864).

Conclusions: FGF23 is significantly associated with decreasing GFR in children and discriminates for the presence of moderate to severe CKD in children. NGAL was not as strongly associated to decreasing GFR. Further studies are needed to evaluate FGF23 and NGAL as markers of CKD progression.

SA-PO367

Association Between N-Terminal pro-B-Type Natriuretic Peptide with CKD Progression in the CKD in Children Cohort

Alexander J. Kula,[1] David K. Prince,[2] Joseph T. Flynn,[3] Nisha Bansal.[2] [1]*Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL;* [2]*University of Washington, Seattle, WA;* [3]*Seattle Children's Hospital, Seattle, WA.*

Background: Elevations in the serum biomarker N-terminal pro B-type natriuretic peptide (NT-proBNP) are strongly associated with CKD progression in adults. It is unknown whether these associations are also seen in children with CKD, and may help identify a novel risk factor in this population. The objective of this study was to examine the association of NT-proBNP with CKD progression in youth with mild to moderate CKD.

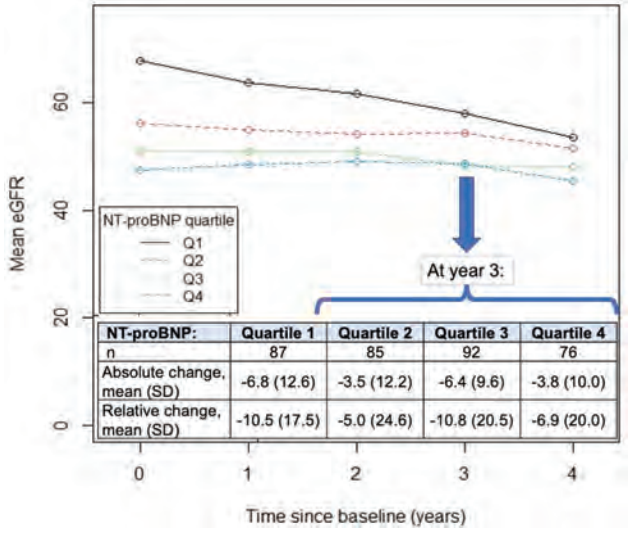
Methods: We measured serum NT-proBNP at the baseline visit of participants with available samples enrolled in the Chronic Kidney Disease in Children (CKiD) study (N=493). Included participants were aged 1-18 years with an eGFR of 30-90mL/min/1.73m^2. Exclusion criteria included history of kidney transplant, dialysis < 3 months, or structural heart disease. CKD progression was defined as a 40% decline in eGFR and/or progression to ESKD. We utilized nested Cox proportional hazards models to test the association between baseline NT-proBNP with CKD progression.

Results: Mean ±SD baseline NT-proBNP and eGFR were 127 ±173pg/mL and. 55 ±21mL/min/1.73m^2, respectively. Median duration of follow-up was 3.9 years and 107 (22%) met criteria for CKD progression. In unadjusted models, NT-proBNP was

associated with CKD progression (HR, [95% CI] per doubling: 1.36, [1.18, 1.56]). NT-proBNP was not associated with CKD progression in adjusted models (HR, [95% CI] per doubling: 1.06 [0.87, 1.29]). There was no interaction for participants with an eGFR above or below 45mL/min/1.73m2 (p= 0.84). Absolute and relative decline in eGFR was not different across baseline quartiles (**Figure 1**).

Conclusions: Unlike adults with CKD, NT-proBNP was not associated with CKD progression in a large, well-characterized cohort of youth with CKD. Potential explanations include physiologic differences across the lifespan and/or relatively short duration of follow-up.

Funding: Private Foundation Support



NT-proBNP:	Quartile 1	Quartile 2	Quartile 3	Quartile 4
n	87	85	92	76
Absolute change, mean (SD)	-6.8 (12.6)	-3.5 (12.2)	-6.4 (9.6)	-3.8 (10.0)
Relative change, mean (SD)	-10.5 (17.5)	-5.0 (24.6)	-10.8 (20.5)	-6.9 (20.0)

SA-PO368

Racial Differences in Outcomes in Children on Maintenance Dialysis Enrolled in the North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS)

Kathleen Altemose,[1] Ankana Daga,[2] Sara A. Boynton,[3] Alicia Neu,[3] Michael J. Somers.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Harvard Medical School, Boston, MA; [3]The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: The NAPRTCS dialysis registry includes 8923 children from the last 30 years. We aim to describe racial differences in this cohort.

Methods: Children on maintenance dialysis at a NAPRTCS center are enrollment eligible. Demographic and clinical data are obtained at dialysis initiation and every 6-months until dialysis terminates. Before 2018 race was categorized as white, black or Hispanic, but race (white, black, other) and ethnicity are now separate. Outcomes include dialysis modality, cardiovascular health, time to transplant and survival.

Results: Table 1 shows clinical characteristics at dialysis initiation. There were more white than black children on both peritoneal dialysis (PD) and hemodialysis (HD), although a higher % of blacks were on HD. Those initiating HD with catheter access were more likely white than black (43% vs 29%); no racial difference with AV fistulas (36% white and 36% black). Mean Kt/V and URR were higher for non-black than black race on HD (1.61 vs 1.55, and 72.6 vs 70.7), with similar findings for PD mean Kt/V (2.45 non-black vs 2.14 black). More blacks than non-blacks had hypertension (48% vs 35%), left ventricular hypertrophy (32% vs 29%), and hypercholesterolemia (60% vs 20%). Over time, whites were transplanted more than blacks when listed for deceased donor transplants (50% vs 30% at 12 months; 87% vs 75% at 36 months). In those remaining on dialysis, survival was slightly higher for blacks than whites (89% vs 86% at 36 months).

Conclusions: White children have higher rates of kidney developmental anomalies, whereas racial differences are absent with FSGS frequency. Whites receive PD more than non-whites, whereas blacks receive HD at higher rates. Whites are more likely to initiate HD with catheter access. Regardless of modality, blacks demonstrate lower dialysis adequacy and more cardiac health sequelae. Whites are transplanted quicker than blacks. In children remaining on dialysis, 36 month survival is near 90% in both blacks and whites. Further study is needed to understand these disparities and to ensure optimal outcomes for all chronically dialyzed children.

	N	White	Black	Hispanic	Other
Dialysis Registrants	8923	49%	24%	19%	8%

Health-Related Quality of Life for Pediatric Patients with ESKD: A Systematic Review and Meta-Analysis of the PedsQL™

Kush Doshi,[1] Rupesh Raina,[1,2] Kar Hui Ng,[3] Vera Koch,[4] Girish C. Bhatt,[7] Sidharth K. Sethi,[5] Maria E. Ferris.[6] *[1]Cleveland Clinic Akron General, Akron, OH; [2]Akron Children's Hospital, Akron, OH; [3]National University of Singapore, Singapore, Singapore; [4]Universidade de Sao Paulo, Sao Paulo, Brazil; [5]Medanta The Medicity, Gurgaon, India; [6]The University of North Carolina at Chapel Hill Division of General Pediatrics and Adolescent Medicine, Chapel Hill, NC; [7]All India Institute of Medical Science - Bhopal, Bhopal, India.*

Background: Health-related quality of life (HRQoL) studies demonstrate the impact of end-stage kidney disease (ESKD) on children's physical and psychosocial development. While several instruments measure HRQoL, few have standardized domains specific to pediatric ESKD. This review examines the published literature on the HRQoL among children with ESKD across differing renal replacement therapy (RRT) modalities, providing insight into the holistic care for these patients.

Methods: We conducted a literature review on pediatric HRQoL using the PedsQL™ 4.0 Generic Core Scale and the PedsQL™ 3.0 ESKD Module among 5 to 18-year-old patients. We queried PubMed, Embase, Web of Science, CINAHL, and Cochrane databases. Retrospective, case-controlled, and cross-sectional studies encompassing self/parent-reported PedsQL™ dimensional and total HRQoL scores were collected.

Results: Of 435 identified studies, 14 met the inclusion criteria. Meta-analysis demonstrated a significantly higher total HRQoL for healthy patients over those with ESKD [SMD: 1.44 (95% CI: 0.78 - 2.09); p<0.001] and across all dimensional scores. In addition, kidney transplant patients report a significantly higher total HRQoL than those on dialysis [PedsQL™ GCS, SMD: 0.33 (95% CI:0.14 - 0.53); p<0.001] and [PedsQL™ ESKD, SMD: 0.65 (95% CI: 0.39 - 0.90); p<0.001]. Kidney transplant patients also reported greater physical health scores than those on dialysis in self and parent/proxy reports of the PedsQL™ GCS [SMD: 0.51 (95% CI: 0.32 – 0.69); p<0.001] and [SMD: 0.30 (95% CI: 0.01 – 0.59); p=0.041], respectively.

Conclusions: Patients with ESKD report lower HRQoL in physical and psychosocial domains when compared to healthy controls. Pediatric transplant recipients showed better total HRQoL than dialysis patients, regardless of the specific modality, as observed on both PedsQL™ scales. This analysis demonstrates the need to identify areas of impaired functioning and produce congruent clinical recommendations.

Quality of Life Domains	Standardized Mean Difference (95% CI)	P	I^2 (95% CI); p-value
PedsQL™ 4.0 Generic Core Scales Total HRQoL			
Control (n=533) vs ESKD (n=330)	1.44 (0.78 - 2.09)	<0.001	93.36% (83.97% - 97.25%); p<0.0001
Transplant (n=285) vs Dialysis (n=192)	0.33 (0.14 - 0.53)	<0.001	27.89% (0.00% - 68.88%); p=0.2155
PedsQL™ 3.0 ESKD Module			
Transplant (n=148) vs Dialysis (n=127)	0.65 (0.39 - 0.90)	<0.001	0.00% (0.00% - 79.73%); p = 0.4249
Peritoneal Dialysis (n=49) vs Hemodialysis (n=17)	0.86 (0.27 - 1.45)	0.005	0.00% (0.00% - 21.0%); p=0.5150

SA-PO370

Clinical Outcomes in Children on Maintenance Dialysis: A Report of the North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) Registry

Ankana Daga,[1,2] Kathleen Altemose,[3] Sara A. Boynton,[4] Alicia Neu,[4] Michael J. Somers.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Indiana University School of Medicine, Indianapolis, IN; [4]The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: The NAPRTCS dialysis registry includes data on 8923 children receiving chronic dialysis.

Methods: Children on maintenance dialysis at any NAPRTCS center are eligible for registry enrollment. Data is collected at dialysis initiation and at 6-month intervals until dialysis termination. Clinical characteristics and outcomes compared across eras: 1992-2000, 2001-2010, 2011-2020.

Results: Hemodialysis (HD) as the initiating dialysis modality increased (34% in 1992-2000 versus 54% in 2011-2020), while peritoneal dialysis (PD) decreased (66% to 40%). HD catheters are placed in the jugular vein more often (87% in 2010-2020 vs 51% in 1992-2020). Use of double cuffed swan neck PD catheters placed with a downward oriented exit site increased over time (5% to 25%). Mean eGFR at dialysis initiation increased from 9.2 (1992-2000), to 11.2 (2011-2020) ml/min/1.73M2. Obesity has increased over time (17% affected 2010-2020). Hypertension was common regardless of the era (35% in 2010-2020 vs 39% for entire cohort). Height remains suboptimal, with average height Z scores of -1.34 within a month of dialysis initiation falling to -1.62 at 24 months, with growth hormone use in 30% of PD and 16% of HD children. Survival at 36 months of dialysis was > 90% with children initiating dialysis > 6 years old vs 77% initiating < 1 year old. A Cox proportional hazards model adjusted for age at initiation showed survival improved with initiation after 2000 (p<0.01). Infection accounted for 22% of deaths on dialysis in 1992-2000 but only 15% in 2011-2020, whereas cardiopulmonary causes of death stayed steady at 22%. Death from infection was higher in PD vs HD (23% vs 12%, p <0.01), though annualized rates for peritonitis fell from 0.93 (95%CI: 0.89-0.98) between PD initiations in 1992-1996 to 0.28 (0.21-0.35) between 2017-2022.

Cumulative incidence of transplant from the deceased donor waiting list increased, from 0.80 (95% CI: 0.75-0.84) in 1992-2000 to 0.91 (0.81-0.96) in 2011-2020.

Conclusions: Although survival on chronic dialysis has improved significantly over 30 years, hypertension, obesity, and growth delay in dialyzed children remain common morbidities. Infection rates and related mortality has decreased, but cardiopulmonary mortality has not, highlighting areas that can be improved upon in the future.

SA-PO371

Follow-Up of Low Estimated Glomerular Filtration Rate (eGFR) in Children in the US Military Health System (MHS)

James D. Oliver,[1] Gregory H. Gorman,[2] Robert Nee,[1,3] Susan R. Mendley,[4] Hava Marneweck,[5] Amanda Banaag,[5] Alain K. Koyama,[6] Yoshihisa Miyamoto,[6] Fang Xu,[6] Meda E. Pavkov,[6] Tracey L. Koehlmoos.[1] *[1]Uniformed Services University of the Health Sciences, Bethesda, MD; [2]Defense Health Agency, Falls Church, VA; [3]Walter Reed National Military Medical Center, Bethesda, MD; [4]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [5]Henry M Jackson Foundation for the Advancement of Military Medicine Inc, Bethesda, MD; [6]Centers for Disease Control and Prevention, Atlanta, GA.*

Background: For children, calculation of eGFR from serum creatinine (sCr) is typically not available in the electronic record and clinicians may fail to recognize an abnormal eGFR in the absence of previously known kidney disease. We retrospectively analyzed the extent of this issue in a large diverse pediatric population using the MHS Data Repository.

Methods: We extracted data for 1,561,622 children ages 1–17 enrolled in the MHS from 2016-2019, using the CKiD U-25 equation to calculate eGFR. Low eGFR was defined as the first occurrence of either <75 or <60 mL/min/1.73m^2. Follow-up was defined as a repeat sCr ≤90 days after the low eGFR. Children with > 8 sCr measurements or with the first low eGFR obtained ≤90 days from the end of 2019 without follow-up were excluded from analysis.

Results: sCr was measured in 128,033 (8.2%) of children. After exclusions there was at least one eGFR <75 and one <60 mL/min/1.73m^2 in 15,395 (12.0%) and 3168 (2.5%) children, respectively (Table). Follow-up sCr ≤90 days after low eGFR was performed infrequently; it was obtained in 9.7% vs 12.4% of children with eGFR <75 vs. <60 mL/min/1.73m^2, respectively. First follow-up sCr at >90 days were obtained in 13.2% vs.11.6% of children, and no follow-up labs were obtained in 77.1% vs. 76.1%. For eGFR <75 mL/min/1.73m^2, absence of follow-up labs within 90 days was associated with female sex (odds ratio [OR], 95% confidence interval [CI]=1.2, 1.1–1.3), ages 5–9 vs. 1–4 (OR, 95%CI=1.2, 1.03–1.4), ages 10–13 vs. 1–4 (OR, 95%CI=1.3, 1.1–1.6), and Black vs. White race (OR, 95%CI=1.2, 1.1–1.4). Sex, age, and race were not associated with lack of follow-up labs for GFR <60 mL/min/1.73m^2.

Conclusions: In the MHS, follow-up measurements of decreased eGFR in children were infrequent, suggesting a gap in recognition of reduced kidney function and a potential area for improvement. *The views expressed in this abstract are those of the authors and do not reflect the official position of the Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., the Department of Defense, the Department of Health and Human Services, or the US Government.*

Pediatric Nephrology Workforce in the United States and Access to Waitlist Registration in Children with ESKD

Gabriela Accetta Rojas, Charles E. Mcculloch, Adrian Whelan, Timothy P. Copeland, Alexandra Bicki, Sophia Giang, Barbara A. Grimes, Elaine Ku. *University of California San Francisco, San Francisco, CA.*

Background: Nephrology is one of the pediatric subspecialties with the lowest workforce density in the US with minimal improvements noted over the last two decades. Pediatric nephrologists (PN) are critical partners in preparing children for kidney transplantation (KT), which is the preferred treatment modality. We hypothesized that geographic variations in the density of PN could associate with variations in the time to waitlist registration and living donor kidney transplantation (LDKT).

Methods: Retrospective cohort study of children <18 years who developed ESKD between 2016 to 2019 according to the United States Renal Data System. The number of active PN per state was estimated by the American Board of Pediatrics (ABP) in 2022 and state population <18 years was estimated by US Census Bureau Population Estimates in 2021. We examined the association between density of PN per 100,000 children and time to waitlist registration and LDKT using Cox models. Odds of preemptive waitlisting was examined using logistic regression models. All models used cluster (state) robust standard errors.

Results: We included 3,442 children, of whom 2,319 (67.4%) were waitlisted for kidney transplantation. The median density of PN/100,000 children/state was 0.85 (IQR 0.56 -1.19 (see Figure). The median time to waitlist registration was 0.65 years (IQR 0.32-1.16). Children residing in states with > 1 PN/100,000 had a 64% better access to waitlisting (HR:1.64, 95% CI 1.41-1.90); 2.8 times higher odds of preemptive waitlisting (OR:2.80, 95%CI 1.66-4.72) compared with children residing in states with < 0.4 PN/100,000; and 2.31 higher hazard of LDKT (HR: 2.31, 95% CI 1.40-3.82).

Conclusions: Lower density of pediatric nephrologists is associated with worse access to waitlist registration. Further studies to examine the implications of workforce availability and care of children with kidney disease are warranted.

Funding: NIDDK Support

Lipid Levels in Pediatric Dialysis Patients with Glomerular and Non-Glomerular Disease

Edward M. Zitnik, Marciana Laster. *University of California Los Angeles, Los Angeles, CA.*

Background: Children on dialysis have a 10-fold increase in cardiovascular disease (CVD) mortality when compared to the general population. The development of CVD in dialysis patients is in part attributed to progressive blood vessel calcification from CKD-MBD. Patients on dialysis are also more likely to have dyslipidemia, which further increases their risk of cardiovascular disease. While the prevalence of dyslipidemia in adult dialysis patients has been described, there is limited data on risk factors for pediatric dyslipidemia.

Methods: 2,043 pediatric patients (≤21 years) receiving maintenance hemodialysis (HD) or peritoneal dialysis (PD) with at least one lipid panel measurement were obtained from USRDS between 2001 and 2016. Disease etiology was classified as glomerular (n=1,029), non-glomerular (n= 701) and unknown (n= 313) and comparisons were made across etiologies. Linear regression models determined the relationship between disease etiology and log-transformed LDL, HDL, triglyceride (TG) and total cholesterol (TC) levels drawn within 12 months of USRDS entry.

Results: The median(IQR) age of the cohort was 13 (17, 19.4). The majority of the cohort received HD as a primary modality and there were no differences between ESKD etiologies. Adjusting for age, gender, race/ethnicity, modality, time with ESKD and using non-glomerular etiology as the reference, glomerular disease [%(95% CI)] was associated with 21%(14.8, 26.6) higher LDL, 19%(14.7, 23.8) higher TC, and 22.3% (15.5, 29.5) higher TG (p<0.0001 for all). There was no significant difference in HDL.

Conclusions: Pediatric dialysis patients with ESKD from glomerular causes have higher levels of Total Cholesterol, LDL, and Triglycerides compared to children with ESKD from non-glomerular causes. The long-term impact of this unfavorable lipid profile requires further investigation.

Table 1: Baseline cohort characteristics

Persistent Increase in Serum Ferritin Levels Despite Converting to Permanent Vascular Access in Pediatric Hemodialysis Patients: Pediatric Nephrology Research Consortium Study

Ali Mirza Onder,[1] Matthew M. Grinsell,[2] Craig B. Langman.[3] Pediatric Nephrology Research Consortium. *[1]Nemours Children's Hospital Delaware, Wilmington, DE; [2]University of Utah Health, Salt Lake City, UT; [3]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Our objective was to examine the change in serum ferritin levels after successful conversion to PVA among children who started hemodialysis (HD) using TCC.

Methods: Retrospective chart reviews were completed on subjects from 20 pediatric HD centers. All patients used TCC prior to PVA. Serum ferritin levels were collected at the creation of PVA and for two years thereafter. Statistical methods included hypothesis testing and statistical modeling after adjusting for relevant demographic variables.

Results: There were 11 (11%) arteriovenous grafts (AVG) and 87 (89%) arteriovenous fistulae (AVF). Their mean TCC use before PVA creation was 10.4± 17.3 months. Serum ferritin at PVA creation was elevated at 562.64± 492.34 ng/ml, further increased to 753.84± 561.54 ng/ml (p= <0.001) at first year and remained significantly elevated at second year 759.60 ± 528.11 ng/ml (p= 0.004). The serum ferritin levels did not show statistically significant linear association with respective serum hematocrit values. In a multiple linear regression model, there were three predictors of serum ferritin at first year PVA follow-up which showed significant association; steroid-resistant nephrotic syndrome as primary etiology (β = -438.93; 95% CI: [-845.41, -32.46]; p=0.035), being from a center enrolling >10 cases (β = 319.85; 95% CI: [2.02, 637.68]; p=0.049) and baseline serum ferritin level (β = 17.96; 95% CI: [3.38, 32.53]; p=0.017).

Conclusions: Increasing serum ferritin after conversion to PVA is concerning. This increase is not associated with serum hematocrit trends. Future studies should investigate the correlation of serum transferrin saturation and ferritin levels in pediatric HD patients.

Exploring the Value of Assessing Hydration and Nutritional Status with Bioelectrical Impedance Analysis in Pediatric Chronic Dialysis

Qian Shen, Hong Xu, Wei Yuan. *Children's Hospital of Fudan University, Shanghai, China.*

Background: There is a lack of domestic and international clinical studies on the assessment of the hydration and nutritional status of children on dialysis by bioimpedance analysis-body composition monitor (BIA-BCM).

Methods: Children treated on dialysis in the nephrology department of the Children's hospital of Fudan University between July 1, 2021 and December 31, 2022 were assigned. A total of 100 children were described before and after 3 days of their dialysis, including basic information, biochemical indicators, imaging findings, and BIA-BCM indicators, exploring the correlation between BIA-BCM indicators and clinical indicators.

Results: Totally, 86 children with peritoneal dialysis and 14 children with hemodialysis were included. In peritoneal dialysis group, 19.77% and 36.05% had mild and severe water overload ; reduced LTI in 41.54% and increased LTI in 10.77%. In hemodialysis group, 35.71% with mild and severe water overload each; 3 cases with reduced LTI (Fig1). There was a significant linear relationship between BIA-BCM hydration indicators and clinical hydration indicators, and BIA-BCM nutritional indicators and clinical nutritional indicators (Fig2).

Conclusions: BIA-BCM can help guide the adjustment of clinical treatment regimens, and chronic dialysis children have some degree of improvement in hydration and nutritional status.

Barriers to Growth Hormone (GH) Use in Children with CKD

Isabella M. Hendrickson, Caleb Berta, Alicia Diaz-Thomas, Margaret C. Hastings. *The University of Tennessee Health Science Center College of Medicine, Memphis, TN.*

Background: GH is safe and effective in improving height in children with CKD. The purpose of this study was to identify barriers to GH use for the treatment of short stature in children with CKD.

Methods: Retrospective chart review identified children treated in the nephrology clinic at Le Bonheur Children's Hospital with estimated glomerular filtration rates (eGFR) ≤ 60 ml/min/1.73 m² via bedside Schwartz equation between January 1, 2017 until December 31, 2021. Males > 15 years old, females > 14 years old, and children < 3 years old were excluded. All children on GH at the most recent visit were included regardless of age, eGFR, or height percentile. Children having serum creatinine and height recorded within 7 days of one another during the study period were assessed. Barriers were evaluated for children not on GH with height percentiles ≤ 5%.

Results: 94 children were identified with eGFR ≤ 60 ml/min/1.73m². The cohort was 30% female, 51% black/African American, 41% white, 5% Hispanic/Latino, and had a median age of 11 years. Obstructive uropathy (27%), renal dysplasia (19%), and focal segmental glomerulosclerosis (13%) were the most common causes of CKD. 80 (85%) were not on GH and 14 (15%) were prescribed GH. Of the 14 patients on GH, 13 (93%) were male and 11 (79%) were white. Of the children not prescribed GH, 25 children (31%) had height percentiles ≤ 5% making them candidates for GH; there were 14 (56%) females, 13 (52%) black/African American, 9 (36%) white, and 2 (8%) Hispanic/Latinos in this group. Barriers identified were missed appointments/lost to follow up (8), severe developmental delay (7), severe hyperparathyroidism (4), delayed growth not identified by clinician (2), perceived adverse reaction (1), liver transplant (1), family declined treatment (1), and family reported not able to obtain (1).

Conclusions: Education on the importance of routine follow up appointments with more aggressive attempts to reschedule missed appointments may be beneficial in improving use of GH in children with CKD. Additionally, further education of families may lead to better control of hyperparathyroidism and other sequelae of CKD. The utility of GH therapy in children with severe neurologic impairments and CKD deserves further study. Finally, higher use of GH in white male children may suggest racial and gender inequality in provision of this treatment.

SA-PO378

Cognitive and Social Functioning of Infants and Preschoolers with Mild to Moderate CKD

Stephen R. Hooper,[1] Rebecca J. Johnson,[2] Marc Lande,[3] Lyndsay Harshman,[4] Sharon M. Bartosh,[5] Cynthia Wong,[6] Joann M. Carlson,[7] Camille Wilson,[8] Anne E. Dawson,[8] Stephen J. Molitor,[9] Matthew Matheson,[10] Bradley A. Warady,[2] Susan L. Furth.[11] CKiD Study. *[1]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [2]Children's Mercy Kansas City, Kansas City, MO; [3]University of Rochester Medical Center, Rochester, NY; [4]University of Iowa Hospitals and Clinics, Iowa City, IA; [5]University of Wisconsin-Madison, Madison, WI; [6]Stanford University School of Medicine, Stanford, CA; [7]Rutgers Robert Wood Johnson Medical School, Piscataway, NJ; [8]Nationwide Children's Hospital, Columbus, OH; [9]Medical College of Wisconsin, Milwaukee, WI; [10]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [11]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Previously published data from the observational CKiD Study showed average neurocognitive function for a combined sample of infants and preschoolers with CKD, although 20% to 37% were deemed at-risk for selected neurodevelopmental difficulties (e.g., executive dysfunction). The current study expands upon previous findings with increased sample size and the examination of infants separately from preschool-age children.

Methods: Participants were 38 infants (Mean age=1.8 yrs) and 225 preschoolers (Mean age=4.8 yrs) recruited by CKiD Study sites. Infants were 76% male, with a median eGFR=49; preschoolers were 73% male, with a median eGFR=53. Measures included the Mullen Scales of Early Learning for infants, and the Wechsler Preschool and Primary Scale of Intelligence IV (WPPSI-IV) for preschoolers. Participants across both age bands received the parent-completed Ages & Stages Questionnaire: Social Emotional (ASQ:SE). Covariates included age, sex, maternal education, eGFR, hypertension, anemia/ESA use, proteinuria, seizure history, and abnormal birth history. Multivariate and logistic regressions were employed.

Results: After adjustment for covariates, infant Mullen Receptive Language (p=.02) and Expressive Language (p=.03) scores dropped with every 10% decline in eGFR. For the preschoolers, a 10% decline in eGFR (p=.004) and a doubling of proteinuria (p=.0002) were each associated with lower WPPSI-IV Verbal IQ. On the parent-completed ASQ:SE for the combined sample, about 13% were deemed at-risk for social-emotional problems, although the doubling of proteinuria was associated with at-risk status (p=.01).

Conclusions: CKD progression was associated with lower language-related abilities for infants and preschoolers, and this represents a novel finding in the CKD neurodevelopmental literature. The rate of parental concerns for social-emotional difficulties was equivalent to what might be expected in the typical population, although the doubling of proteinuria was associated with at-risk social status. Results highlight the need for early identification and ongoing developmental surveillance of young children with mild to moderate CKD, with further attention being devoted to early language and social development.

Infectious Complications with Two Different Induction Regimens After Pediatric Kidney Transplantation

Jayanthi Chandar,[1,2] Marissa J. Defreitas,[1,2] Vaka Sigurjonsdottir,[1,2] Chryso P. Katsoufis,[1] Wacharee Seeherunvong,[1] Carolyn L. Abitbol,[1] Gaetano Ciancio.[1,2] University of Miami. *[1]University of Miami, Miami, FL; [2]Miami Transplant Institute, Miami, FL.*

Background: Pediatric kidney transplant recipients are vulnerable to clinically significant viral replication (VR) because of their need for intense induction and ongoing need for maintenance immune suppression (ISP). In this single-center study we compare the incidence of VR with CMV, EBV, parvovirus, BKV and infectious complications on an induction regimen with anti-thymocyte globulin (ATG) consisting of 3 mg/kg (HiATG) versus <3mg/kg (LoATG) and those who did not receive ATG (NoATG).

Methods: Retrospective analysis was performed in 59 patients with isolated kidney transplants from January 2018 to December 2021. The protocol for HiATG was a cumulative dose of 3mg/kg in the years 2018 -2019 which changed to 1 mg/kg in 2020-2021 for LoATG. Those with low pre-transplant vaccine response and/or low CD4 counts received NoATG. Induction ISP included basiliximab and methylprednisolone. VR was defined if PCR was > 137 copies/ml. Discontinuation of anti-metabolites or specific treatment for viral infection defined viral disease. Rejection was confirmed by kidney biopsy.

Results: Median age was 14 years (IQR: 9.5-17). There were no significant differences in the incidence of VR and rejection between HiATG and LoATG in the first 6 post-transplant months. All patients in NoATG had VR (See Table). Opportunistic infections were observed more often in NoATG. Although steroid avoidance was possible in LoATG and HiATG, time to steroid withdrawal was longer in LoATG (p = 0.02). Leukopenia was more prevalent in HiATG. After 6 months of transplant, VR occurred in 4 patients in each of HiATG and LoATG groups with one patient developing post-transplant lymphoproliferative disease during a mean follow-up period of 33±14 months.

Conclusions: Infectious complications occur in all induction regimens. In addition, maintenance ISP contributes to lowering host immunity. Differences in host response are likely to play a significant role in propensity to infections, highlighting the importance of individualizing ISP.

Clinical Characteristics in the First 6 Post-transplant Months

Norovirus Gastroenteritis in Pediatric Kidney Transplant Recipients: A Pediatric Nephrology Research Consortium Study

Sarah J. Kizilbash,[1] Ziou Jiang,[2] Rachel M. Engen.[1] *[1]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN; [2]University of Wisconsin-Madison, Madison, WI.*

Background: Norovirus can cause debilitating diarrhea in transplant recipients. Herein, we describe the clinical course and complications of norovirus infection in children with a kidney transplant.

Methods: Four transplant centers participated in this study. We included kidney transplant recipients who developed norovirus infection (confirmed by stool polymerase chain reaction or viral culture) between 1/1/2013 and 12/1/2019. Study variables are summarized as median and proportions. The estimated glomerular filtration rate (eGFR) was determined using the modified Schwartz equation. Acute kidney injury (AKI) was defined based on a change in eGFR per the pRIFLE criteria.

Results: Our cohort included 40 patients, 33 (82.5%) requiring hospitalization. The median age at transplant was 5.4 years (IQR:2.2, 1.2). Thirty-one patients (77.5%) were white, and 26 (65.0%) were male. The median time to diarrhea onset after transplant was 1.9 years (IQR:0.8, 3.8). The median diarrhea duration was 16 days (IQR:6.0,41.5), and that of hospitalization was 3 days (IQR: 2.0,8.0). During the norovirus infection, 17.5% developed neutropenia, 15% had a urinary tract infection, 17.5% had BK DNAemia, and 20% had EBV DNAemia. Furthermore, 52.5% developed AKI. We found no sustained decline in the median eGFR 12 months after diarrhea resolution (Table 1). Of the patients in the cohort, 2 lost their graft 6.8 and 30.0 months after the onset of diarrhea.

Conclusions: Norovirus can cause prolonged diarrhea in pediatric kidney transplant recipients complicated by AKI, neutropenia, and opportunistic infections. We found no sustained decline in eGFR over a 12-month follow-up. Multicenter, randomized controlled trials are needed to determine the most appropriate management strategy in children.

Clinical Characteristics and T-Cell Exhaustion in BK Polyomavirus Infection After Pediatric Kidney Transplantation

Ching-Yuang Lin. *Children's Hospital, China Medical University, Taiwan, Taichung, Taiwan.*

Background: BK virus (BKV) is a significant cause of chronic kidney injury in kidney transplant recipients that results in allograft loss. Inhibitory receptors PD-1 and Tim-3 play a crucial role in regulating CD8 T cell function during chronic infection. The study's aim 1 was to determine the clinical characteristics of those who had BK viremia versus those who did not. Aim 2 was to document correlation between exhausted PD-1 and Tim-3 exhausted T cells during chronic BKV infection.

Methods: The retrospective case-control study was conducted from January 2008 to July 2022. The subjects were composed of a total of 32 pediatric KTRs and 12 with BKV viremia, in which 5 of 12 had BKVN were obtained. Peripheral blood mononuclear cells (PBMCs) were collected during episodes of BKV viremia. PD-1, Tim-3, and CD8 T cells were evaluated by multiparameter flow cytometry.

Results: BKV viremia was observed in 12/32 (37.5%) and BKVN in 5/32 (15.6%). Induction therapy was not significantly different between BKV and non-BKV viremia groups. The mean time for BK detection was 4.1 months after renal transplantation. Percent rise in serum creatinine correlated with intensity of viral load. The first-line therapy after identification of BKV viremia was a decreased dosage in Tacrolimus (100%) and intravenous immunoglobulin, and discontinuing mycophenolate mofetil. When reduction in immunosuppressant was not sufficient to decrease viral load, 4/12 (33.3%) of patients received leflunomide. High expression of PD1 and Tim-3 on CD8 cells with more severe T cells exhaustion was noted during chronic BKV infection. The treatment resistance was also accompanied with persistent high level of PD-1 and Tim-3 expression on CD8 T cells. There was no difference in the percentage of graft survival between BKV viremia and non-BKV viremia after 8 years' follow-up.

Conclusions: Patients with the highest viral loads and longest duration of BKV viremia are at risk of BKVN. Expression of PD-1, Tim-3 and CD8 T cell indicates chronic T cell partial exhaustion. BKV viremia and CD8 T cell exhaustion may be a surrogate marker for adjusting immunosuppressant reduction and intravenous immunoglobulin treatment.

Use of the Seraph® 100 Microbind® Affinity Blood Filter in an Adolescent Patient with Disseminated Adenoviral Disease

David S. Li, Thomas M. Burke, Jodi M. Smith, Daryl M. Okamura, Shina Menon. *University of Washington School of Medicine, Seattle, WA.*

Introduction: Disseminated adenovirus infection can lead to high mortality and morbidity in immunocompromised patients. The Seraph® 100 Microbind® Affinity Blood Filter (Seraph 100) is a hemoperfusion device designed to adsorb pathogens when added to extracorporeal circuits. It has emergency use authorization for the treatment of COVID-19. Preclinical tests show a 62% reduction of adenoviral (ADV) load with Seraph 100, but this has not been reported in pediatrics.
