Results: Two base models that captured the overall trend of TKV and eGFR were examined and the one with a lower Akaike Information Criteria (AIC) score was chosen. Covariates were: Age of diagnosis, baseline age, baseline eGFR, and baseline log(TKV) as continuous covariates Race, sex, and presence of hypertension at baseline as categorical covariates Age of diagnosis, baseline age, baseline TKV, and sex as covariates for the TKV longitudinal model Baseline age, baseline eGFR, race and baseline TKV as covariates for the eGFR longitudinal model For the time-to-event model, the Weibull distribution was selected based on the lowest AIC (best fit) before incorporating longitudinal markers. A graphical user interface (GUI) for the CTE tool was constructed for the creation of virtual simulations of disease progression. The tool models different trial durations, population sizes, and hypothetical magnitude of drug effects on TKV/eGFR progression and predict their impact on ESRD.

Conclusions: A quantitative tool can be utilized to model disease progression trajectories in defined ADPKD subpopulations and potentially simulate impact on ESRD based on theoretical drug effects on TKV/eGFR progression. The tool may be beneficial in clinical trial design to ultimately benefit ADPKD patients.

Kynurenines and Change in Body Mass Index in Autosomal Dominant Polycystic Kidney Disease

Kristen L. Nowak, Zhiying You, Cortney Steele, Berenice Y. Gitomer, Michel Chonchol, Jelena Klawitter. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: We have previously described that overweight and obesity are associated with kidney disease progression in individuals with early-stage autosomal dominant polycystic kidney disease (ADPKD). We have also reported dysregulated kynurenine metabolism, which associated with kidney disease severity, in early-stage patients with ADPKD. As the tryptophan-kynurenine pathway has been reported to be dysregulated in obesity, and kynurenines can induce and potentiate oxidative stress and

inflammation, we hypothesized that baseline kynurenine circulating concentrations would associate with change in BMI patients with ADPKD.

Methods: 357 participants with ADPKD and estimated glomerular filtration rate (eGFR) >60 ml/min/1.73m^2 who participated in HALT Study A and had repeated measurements of kynurenines, BMI, and covariates were included. Twelve key tryptophan metabolites were previously measured in plasma using a validated liquid chromatography-mass spectrometry assay. The time-varying associations between kynurenines (individual mean and mean change over time) and change in BMI over 48-months were assessed using linear mixed effects regression models.

Results: Mean±s.d. age was 38±8 years, eGFR was 90±17 ml/min/1.73m^2, and height-adjusted total kidney volume was 724±413 ml/m^2, baseline BMI was 27.0±4.8 kg/m^2. Greater individual log-transformed mean concentrations of kynurenic acid (b-estimate 1.71 [0.41, 3.01]), and quinolinic acid (β-estimate 2.13 [0.00, 4.25) and a lower log-transformed mean change in picolinic acid over time (β-estimate -0.52 [-0.13, -0.95]) were associated with greater increase in BMI after adjustment for demographics, study randomization, eGFR, baseline height-adjusted kidney volume, and genotype.

Conclusions: Several kynurenines were associated with change in BMI in ADPKD patients. Further research should evaluate whether kynurenines could serve as a biomarker of obesity-associated kidney growth in patients with ADPKD.

Assessing Formoterol Treatment in a Mouse Model of Autosomal Dominant Polycystic Kidney Disease

Brennan Winkler, Mykhailo Fedoriuk, Xiaofeng Zuo, Peifeng Deng, Wayne R. Fitzgibbon, Oleg Palygin, Joshua H. Lipschutz. *Medical University of South Carolina, Charleston, SC.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a disease caused by mutations in the genes PKD1 and PKD2 that results in cyst growth within the kidney and over time leads to renal failure. Tolvaptan is currently the only drug approved for treating ADPKD, but it is only modestly effective and has significant side effects. ADPKD is associated with metabolic dysfunction. Treating the metabolic dysfunction in ADPKD may be therapeutic. A metabolic modulator, formoterol, is a beta-2 adrenergic receptor agonist commonly prescribed for chronic obstructive pulmonary disease. Our previous research has demonstrated the effectiveness of formoterol in treating some forms of chronic kidney disease (CKD). Metabolic dysfunction is thought to be corrected by formoterol's ability to stimulate mitochondrial biogenesis. We hypothesize that formoterol treatment in a mouse model of ADPKD will be therapeutic in reversing, stopping, or slowing disease progression.

Methods: RC/RC mice, a model of ADPKD generated using mutations in PKD1 from a human family, will be treated using osmotic mini pumps filled with formoterol for six months at 1 mg/kg body weight/day after they reach the age of three months. Pumps will be exchanged 4-6 times over the course of treatment with blood and urine collections at each surgery for further analysis. Cohorts of 12 males and 12 females will be treated to address any sex differences in treatment; 6 mice treated and 6 mice untreated/receiving vehicle (DMSO) in each cohort. Mice will be weighed weekly. MRIs will be performed at three months and at end of the experiment on a representative sample of the mice to assess cyst burden. After six months of treatment the mice will be sacrificed, and the kidney, liver, heart, and spleen will be harvested for histological, protein, and nucleic acid-based analyses. Formoterol will also be tested in the PCK rat model of PKD.

Results: Mice Males: To date, a trend toward lower kidney/body weight (p=0.28) and liver/body weight (p=0.07) ratios is observed in the formoterol-treated compared to the vehicle-treated mice, which may indicate decreased cystogenesis. Females: In progress **Rats** In progress.

Conclusions: Preliminary data suggest that formoterol may have an effect on cyst growth, though additional cohorts of treated and untreated mice need to be studied.

TH-PO418

Validation of the Mayo Imaging Classification System for Predicting Renal Outcome in ADPKD

Thomas Bais, Paul Geertsema, Martine G. Knol, Maatje D. van Gastel, Esther Meijer, Ron T. Gansevoort. On Behalf of the DIPAK Consortium. *Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: The Mayo Imaging Classification is used to predict the rate of disease progression in patients with autosomal dominant polycystic kidney disease (ADPKD). The goal of this study was to validate its ability to predict renal prognosis in a large cohort of patients with ADPKD.

Methods: Included were ADPKD patients with 'typical' disease, at least one height-adjusted total kidney volume (HtTKV) measurement, ≥3 eGFR estimates and ≥1 year follow-up. The stability of the classification, kidney growth rate and eGFR decline rate were calculated for each Mayo HtTKV class at various timepoints. The observed eGFR decline rate at these timepoints were compared to the values predicted by the Mayo Clinic formula for future eGFR. Kaplan-Meier survival analysis was performed to predict end stage kidney disease (ESKD) using Mayo HtTKV class as a predictor variable.

Results: We included 619 patients with a mean age of 47 ± 11 years and an eGFR of 63 ± 25 ml/min/1.73m^2 at baseline. The majority of patients (70.0 - 88.9%) remained in their baseline Mayo HtTKV class after 6 years of follow-up. The mean eGFR decline and TKV growth rates during a mean follow-up duration of 5.0 ± 2.2 years were -3.26 ± 2.49 ml/min/1.73m^2/year and 5.29 ± 3.97 %/year, respectively. There was considerable variation in kidney growth and eGFR decline rates within each Mayo HtTKV class. The observed eGFR decline at follow-up was not significantly different from the predicted values for Mayo HtTKV classes 1A, 1B, 1C and 1D. However, the observed eGFR decline of Mayo HtTKV class 1E was less than predicted. This was also observed in patients aged <40 years at baseline and in patients with *PKD2* mutations. The classification was a strong predictor for ESKD.

Conclusions: The Mayo Imaging Classification demonstrates acceptable stability over time and is predictive of the rate of eGFR decline albeit with wide inter-individual variations. The ability to predict future eGFR decline for individual patients might be improved by developing equations that include additional prognostic covariates.

TH-PO419

Applicability of Mayo's Autosomal Dominant Polycystic Kidney Disease Prognostic Tool in the Southeast Asian ADPKD Population

Chye Chung Gan,[1,2] En Thong Goh,[2] Shok H. Ooi,[2] Wai Ling Leong,[1,2] Peng Loon Cheah,[2] Anushya Vijayananthan,[1,2] Soo Kun Lim.[1,2] *[1]University of Malaya Faculty of Medicine, Kuala Lumpur, Malaysia; [2]University of Malaya Medical Centre, Kuala Lumpur, Malaysia.*

Background: Mayo autosomal dominant polycystic kidney disease (ADPKD) prognostic tool revolved around the height-adjusted total kidney volume ($HtTKV_0$) measurement using MRI at a single point of time adjusted with age_0 and it was recognized as a strong predictor for kidney disease progression in patients with ADPKD. This study reports 24-month prospective longitudinal studies examining the applicability of the Mayo ADPKD prognostic tool in the Southeast Asian cohort in a tertiary center in Malaysia.

Methods: Convenience sampling was completed on March 2021. Patients were subjected to a single non-contrasted T2W-MRI kidney scan using the ellipsoid method with subsequent yearly blood samples collected for analysis. Total kidney $volume_0$ (TKV_0) was measured by 2 radiologists and the average of 2 results was recorded. Correlation of glomerular filtration rate generated from the Mayo ADPKD prognostic tool ($eGFR_{Mayo}$) and serum estimated glomerular filtration rate of patients according to 2009 $CKD\text{-}EPI_{creatinine}$ ($eGFR_{2009CKD\text{-}EPI}$) were tested with Spearman correlation coefficient and Bland-Altman analysis.

Results: A total of 50 patients were enrolled with a median age of 39.5 years (33.5, 58.0) and predominantly female (54%), and of Chinese (60%) ethnicity. Median TKV_0 was 1233.8cm^3 (697.2, 1995.8) and $HtTKV_0$ was 727.9ml/m (447.0, 1180.9). Three patients dropped out at month 24. $eGFR_{Mayo}$ correlated very strongly with $eGFR_{2009CKD\text{-}EPI}$ during the 24 months study with R_{S0}=1.000 (bias of -0.196, precision=0.395), R_{S12}=0.972 (bias of -0.204, precision=8.300), and R_{S24}=0.952 (bias of 4.670, precision=10.930) respectively, p<0.001. $eGFR_{Mayo}$ demonstrated an accuracy of 42.6 – 98% within 10mls/min/1.73m^2 of serum $eGFR_{2009CKD\text{-}EPI}$.

Conclusions: Mayo's ADPKD prognostic tool demonstrated its applicability to the Southeast Asian ADPKD population with a very strong correlation to $eGFR_{2009CKD\text{-}EPI}$, low bias, and high precision. Long-term data with a larger sample size needs to be evaluated in future studies.

Funding: Government Support - Non-U.S.

Spearman correlation coefficient & Bland-Altman analysis

Variables	Sample size, n	Spearman's correlation coefficient (Rs)	p-value	Bias (Mean difference)	Precision (±1.96SD of Mean Difference)	Accuracy (P10),%
eGFR Mayo* vs eGFR 2009CKD-EPI at 0 month	50	1.000	0.000	-0.196	0.395	98
eGFR Mayo* vs eGFR 2009CKD-EPI at 12 months	50	0.972	0.000	-0.204	8.300	58
eGFR Mayo* vs eGFR 2009CKD-EPI at 24 months	47	0.952	0.000	4.670	10.930	42.6

Tolvaptan Use and Prescribing Patterns in Patients with Autosomal Dominant Polycystic Kidney Disease: A Multicenter Real-World Experience

Vinamratha Rao,[1] Abrar Alshorman,[1] Shahed Ammar,[2] Kerri A. McGreal,[1] Franz Winklhofer,[1] Lama A. Noureddine,[2] Diana I. Jalal,[2] Michelle A. Fravel,[2] Alan S. Yu,[1] Reem Mustafa.[1] *[1]University of Kansas School of Medicine, Kansas City, KS; [2]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the most common genetic disease leading to End Stage Kidney Disease. Tolvaptan was approved and is being used to treat patients with rapidly progressing disease. In this study we describe the real-world experience of Tolvaptan use among patients with ADPKD.

Methods: We retrospectively identified adult patients with ADPKD enrolled in the Risk Evaluation and Mitigation Strategy (REMS) program and treated with Tolvaptan at the University of Kansas Medical Center (KUMC) and University of Iowa Hospitals and Clinics (UIHC) from 2018 to 2023. The investigators abstracted data and treating physicians reviewed and confirmed the data. We performed descriptive analysis of the patients' demographics, baseline labs, Tolvaptan prescribing trends, reasons for stopping treatment, and frequency of imaging surveillance.

Results: The study includes 134 patients, 115 from KUMC and 19 from UIHC. The average age of start of Tolvaptan treatment was 42.67 and 36.17 years respectively for KUMC and UIHC. Male to female ratio was approximately 1:1 for KUMC and 1:2 for UIHC. In the KUMC cohort, 87% were Caucasian, and the remaining 13% comprised of African American and Hispanic ethnic groups. In the UIHC cohort, 95% were Caucasian. By March 2023, 63% and 58% remained on Tolvaptan and of the KUMC and UIHC

cohorts respectively. The two major reasons for discontinuing Tolvaptan included intolerance of polyuria and polydipsia (26% in KUMC and 50% in UIHC) and renal transplantation (17% in KUMC and 13% in UIHC). The average fluid intake was 5.23 and 3.36 Liters respectively in the KUMC and UIHC cohorts. The starting dose combination of 45 mg (AM)/15 mg (PM) was prescribed to most patients at both KUMC (90%) and UIHC (89%). For many patients, prescribing physicians had to considerably titrate Tolvaptan doses to moderate side effects.

Conclusions: The findings of this descriptive study provide valuable insights into the real-world use of Tolvaptan in treating patients with ADPKD. A higher percentage of patients with ADPKD are discontinuing Tolvaptan compared to trials findings due to polyuria and polydipsia. The study also highlights the need for considerable titration of Tolvaptan dose to manage symptoms.

TH-PO421

Kidney Function Decline in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Patients: Assessment of Real-World Effectiveness of Tolvaptan

Ronald D. Perrone,[1] Sasikiran Nunna,[2] Hema K. Gandhi,[2] Ancilla Fernandes,[2] Diana Garbinsky,[3] Xiaolei Zhou.[3] *[1]Tufts Medical Center, Boston, MA; [2]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [3]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC.*

Background: In clinical trials, tolvaptan led to a slower decline in kidney function (vs placebo) among ADPKD patients at risk of rapid progression. The objective of the current study is to evaluate real-world effectiveness of tolvaptan by comparing annual rate of change in kidney function, as measured by eGFR, in adult ADPKD patients treated with and without tolvaptan.

Methods: From May 2019 to September 2022, 57 US nephrologists completed a web-based survey using medical records of ADPKD patients treated with tolvaptan for ≥2 year (cases). A cohort of ADPKD patients in Mayo class 1C to 1E not treated with tolvaptan was obtained from CRISP, HALT-PKD (data provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases) and OVERTURE studies (controls). Cases and controls were matched 1:1 on baseline age, gender and chronic kidney disease (CKD) stage. Kidney function decline was compared between cases and controls using mixed models, which included treatment, time, and a treatment-by-time interaction as fixed effects and patient-specific intercepts and slopes (for time) as random effects.

Results: Of the 149 cases treated with tolvaptan, controls matched for age, sex and CKD stage were identified for 110 cases. Among these 110 matched pairs, the majority were male (60%), aged 43 (SD: 10.1) years on average, and 76% were in CKD stage 3a or earlier. Mean eGFR at baseline was 60 mL/min/1.73m^2 among cases and 63 mL/min/1.73m^2 among controls. The annual change in eGFR was -2.23 mL/min/1.73m^2 among cases vs -3.62 mL/min/1.73m^2 among controls with a statistically significant difference of 1.40 mL/min/1.73m^2 per year (95% CI: 0.05, 2.74, p =0.042). A second analysis, whereby cases and controls were matched on baseline age, gender and eGFR resulted in 98 matched pairs. In comparison of the 98 matched pairs tolvaptan was associated with a trend in reduction of decline rate by 1.18 mL/min/1.73m^2 per year (95% CI: -0.22, 2.58, p =0.097).

Conclusions: In the current analysis, tolvaptan showed real world effectiveness in slowing decline in eGFR when compared to matched historical controls, consistent with its efficacy in clinical trials.

TH-PO422

Liver Safety of Tolvaptan in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD): Interim Data from a European Union Post-Authorization Safety Study (EUPASS)

Retesh K. Kumar,[1] Emanuel Lohrmann,[1] Ada Ezenekwe,[2] Sasikiran Nunna,[2] Ancilla Fernandes,[2] Thomas Jaeger,[1] Linda Mccormick,[2] Vinu George.[2] *[1]Otsuka Pharmaceutical Europe Ltd, Wexham, United Kingdom; [2]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ.*

Background: After risk of drug-induced liver injury was detected during tolvaptan clinical development for the treatment of ADPKD, a real-world pharmacovigilance study was required as a condition of EU regulatory approval. We provide an interim-analysis of 6-years of liver safety data from EUPASS.

Methods: This is an interim analysis from a prospective, observational study enrolling patients prescribed tolvaptan for ADPKD in everyday clinical practice. Data are obtained through physician records collected as part of regular standard of care. Per the prescribing label, liver enzymes are monitored monthly for the first 18 months of treatment and once every 3 months thereafter, and patients and providers are required to report adverse events suggestive of liver injury. The data collection period was Oct 2016–Apr 2022. An independent hepatic adjudication committee (HAC) evaluates all DILI cases in EUPASS.

Results: At data cutoff, 2,074 patients had received at least one dose of tolvaptan (median follow-up, 528 days). Alanine aminotransferase (ALT) or aspartate aminotransferase (AST) levels ≥3 times upper limit of normal (ULN) were found for 65 patients (3.1%). Among these patients, 35 (1.7%) had elevation of ALT/AST > 3 to ≤ 5 times ULN, 21 (1.0 %) had elevation of > 5 to ≤ 10 times ULN, 9 (0.4 %) > 10 times ULN. Tolvaptan was interrupted or withdrawn in 59/65 (90.8%) participants with confirmed ALT/AST ≥3 times ULN, with most transaminase elevations and adverse events resolved or resolving at data cutoff. No laboratory results met criteria for high-risk liver injury (Hy's Law). As per the assessment of HAC, there was no dose-response relationship.

Conclusions: Regular monitoring facilitates prompt detection of liver adverse events and intervention to reduce risk of severe injury. Data from interim analysis indicate that monitoring and risk minimization measures are effectively mitigating the risk of liver injury. No Hy's law cases/deaths have been reported.

TH-PO423

Integrating Multi-Omics for Precision Medicine: Identification of Drug Targets and Biomarkers for ADPKD from Large Patient Cohorts

Philipp Skroblin, Hendrik Urbanke, Ricardo Castro, Jürgen Stumm, Maximilian Naujock, Mitja Mitrovic, I-Ju Lo, Michaela Bayerlova, Manuel Landesfeind, Sven Sauer, Antje Schmidt, Olivier Radresa, Uwe Andag. *Evotec International GmbH, Goettingen, Germany.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic cause of kidney failure. There is an unmet medical need for biomarkers (early diagnosis, reliable prognosis) and for effective and safe therapy. Especially research on the molecular drivers of ADPKD progression is challenging due to the lack of available biopsies. An integrative approach utilizing patient samples and ADPKD models can bridge this gap.

Methods: Blood samples from NURTuRE-CKD participants (200 ADPKD, 2,000 other CKD) were subjected to genotyping and deep mRNA-Seq. Selected serum and urine samples were analyzed by proteomics and metabolomics. Whole-exome sequencing (WES) data were provided by the NURTuRE consortium. Cyst-forming renal organoids were differentiated from human iPSCs carrying a loss-of-function mutation in PKD1 and subjected to snRNA-Seq.

Results: In NURTuRE omics data we observed that: (1) ADPKD patients' blood transcriptomes constitute a cluster that is distinct from age-, sex- and eGFR-matched non-ADPKD samples (other CKD), (2) several proteins are differentially abundant in ADPKD vs. other CKD urine proteomics, (3) among NURTuRE-CKD patients, WES revealed carriers of PKD1 and PKD2 pathogenic mutations who had previously not been diagnosed with PKD and may represent early or pre-onset cases of ADPKD. To provide more insight into early disease mechanisms, we performed snRNA-Seq of human iPSC-derived cyst-forming renal organoids. To leverage their combined power, we used these datasets reflecting different aspects of the disease to build a multi-layered similarity network while maintaining source information. This network was incorporated into a larger graph database, which allows for the expansion of feature information and the generation of embeddings for biological interpretation facilitated by machine learning.

Conclusions: Our integrated multi-omics analysis framework utilizes patient samples and cyst-forming organoids to enable the analysis of molecular mechanisms underpinning ADPKD, especially in early disease stages. This will facilitate the discovery of diagnostic or prognostic biomarkers and novel targets.

TH-PO424

Effects of Salt and Protein Intake on Polyuria in Tolvaptan-Treated ADPKD Patients: A Randomized Controlled Trial

Paul Geertsema, Iris W. Koorevaar, Karin Ipema, Bart J. Kramers, Niek F. Casteleijn, Ron T. Gansevoort, Esther Meijer. *Universitair Medisch Centrum Groningen, Groningen, Netherlands.*

Background: The only renoprotective treatment in Autosomal Dominant Polycystic Kidney Disease (ADPKD) is a vasopressin V2-receptor antagonist (V2RA). However, aquaresis-associated side effects limit tolerability. We investigated whether salt and protein intake influence urine volume and aquaresis-related endpoints in V2RA-treated ADPKD patients.

Methods: In this randomized, controlled, double-blind, crossover trial, ADPKD patients treated with a maximally tolerated dose of a V2RA were included. While on a low salt (≈6 g/24h) and low protein (≈0.8 g/kg/24h) diet, patients were given additional salt and protein during a baseline study period to mimic regular intake, which was replaced by placebo during four 2-week periods: low salt/low protein, low salt/regular protein, low protein/regular salt and regular protein/regular salt intake in random order. Primary endpoint was change in 24h urine volume. Secondary endpoints were change in quality of life, measured glomerular filtration rate (mGFR), blood pressure and copeptin level.

Results: Twelve patients (49±8 years, 25.0% male, mGFR 59±23 mL/min/1.73m^2) were included. Baseline salt- and protein intake was 10.8±1.3 g/24h and 1.2±0.2 g/kg/24h. During the low salt and low protein treatment periods, intake significantly decreased to 5.8±1.6 g/24h and 0.8±0.1 g/kg/24h respectively. Baseline 24h urine volume (5.9±1.2 L) diminished to 5.2±1.1 L (-11%, p=0.004) on the low salt & low protein and to 5.4±0.9 L (-8%, p=0.04) on the low salt intake. Reduction in 24h urine volume tended to be greater in patients with lower urine osmolality (-16 vs -7%, p=0.1). Polyuria QoL scores improved with changes in urine volume. mGFR decreased on the low salt & low protein intake, while mean arterial pressure did not change during the study periods. Plasma copeptin decreased significantly during low salt and low protein periods.

Conclusions: Changes in intake of salt and protein have only a minor effect on urine volume in V2RA-treated ADPKD patients. In subjects with most complete vasopressin blockade, i.e. those with the lowest baseline urine osmolarity, this antipolyuric effect tended to be most pronounced. Reduction of osmolar intake decreased plasma copeptin and might therefore improve the renoprotective effect of a V2RA.

TH-PO425

Eight Years of Canadian Real-World Assessment of Tolvaptan in ADPKD: C-MAJOR Study and Safety Monitoring and Distribution Program

Philip McFarlane,[1,2] Daniel G. Bichet,[4] Ahsan Alam,[5] Luc Bergeron,[3] Sylvie Boutin,[3] Annick Laplante.[3] *[1]University of Toronto, Toronto, ON, Canada; [2]St. Michael's Hospital, Toronto, ON, Canada; [3]Otsuka Canada Pharmaceutical Inc, Saint Laurent, QC, Canada; [4]Universite de Montreal, Montreal, QC, Canada; [5]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.*

Background: Tolvaptan is approved in Canada for slowing renal function decline and kidney enlargement in patient with ADPKD. As required by Health Canada, a patient registry study evaluating long-term clinical outcomes (C-MAJOR) and a hepatic safety monitoring and distribution program (HSMDP) to mitigate risk of liver injury were implemented. The aim of this interim analysis is to describe patient characteristics at tolvaptan initiation from the C-MAJOR study and to report on liver transaminase elevation rates and treatment persistence through the HSMDP.

Methods: C-MAJOR is a non-interventional, observational, multi-centre study of ADPKD patients treated with tolvaptan. HSMDP ensures tolvaptan is dispensed under controlled liver function monitoring.

Results: As of February 2023, 469 patients were enrolled in C-MAJOR. At baseline, 51% were female, with a mean (SD) age of 45 (12) years, BP 129 (13)/83 (10) mmHg and eGFR 64 (28) mL/min/1.73 m². Overall, 68% were in early CKD stages 1, 2 and 3a. Total kidney volume was 1963 (1538) mL, 80% had a family history of ADPKD, 38% had a family history of early end-stage kidney disease, and 91% were at high risk of disease progression (Mayo Imaging Class 1C-D-E). The most common clinical manifestations were hypertension (84%), hepatic cysts (71%) and kidney pain (24%). From the HSMDP, 82 (3.4%) of the 2418 patients who initiated tolvaptan reported an elevation of transaminases (>3x ULN), with 11 (0.45%) meeting guidelines for permanent discontinuation. No cases of drug-induced liver injury were reported. Occurrence of ALT/AST levels greater than 3x ULN were seen up to 81 months post tolvaptan initiation and of these, 32% of the episodes occurred following the first 18 months of treatment. Treatment persistence rates at 12, 24 and 36 months were 84%, 77% and 72%, respectively.

Conclusions: This analysis provides Canadian real-world evidence that most ADPKD patients treated with tolvaptan are at high-risk of disease progression and three-year treatment persistence is similar to phase III study data. The HSMDP in Canada has been effective at avoiding the incidence of drug-induced liver injury associated with tolvaptan.

Development Program of 2-deoxy-D-glucose (2DG) for the Treatment of ADPKD

Alan S. Yu,[1] Marco Chiaravalli,[2] Matteo Federici,[2] Carolyn J. Vivian,[3] Scott J. Weir,[3] Alessandra Boletta.[2] *[1]University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; [2]IRCCS Ospedale San Raffaele, Milano, Italy; [3]University of Kansas Institute for Advancing Medical Innovations, Kansas City, KS.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is characterized by the growth of fluid-filled kidney cysts due to abnormal epithelial proliferation. We have demonstrated that ADPKD cyst epithelial cells undergo metabolic reprogramming with increased aerobic glycolysis (Warburg effect) and so are exclusively dependent on glucose for energy production. This can be exploited to treat ADPKD using an analog of glucose, 2-deoxy-D-glucose (2-DG), that inhibits glycolysis. We have shown that 2DG is effective at slowing cyst growth in both rapid and slowly progressive mouse PKD models. 2DG has previously been tested in over 200 normal human volunteers and cancer patients in both single and continuous daily dosing for up to 3 months and shown to be safe and well tolerated at doses up to 45 mg/kg/day.

Methods: We now present a new development program to advance 2DG for treatment of ADPKD. Preclinical investigational new drug (IND)-enabling activities are underway or will begin soon, including refinement of the dose-response relationship, chronic GLP toxicology studies in rodent/non-rodent species, synthesis of GMP-grade batches of drug product, and discussions with regulatory authorities.

Results: Our first-in-human study is proposed to be a multicenter Phase 1B uncontrolled, multiple ascending dose clinical trial. ADPKD patients aged 18–60 yr with eGFR >60 mL/min/1.73 m² will be enrolled in cohorts of 3 and administered single daily oral doses of 2DG for 2 weeks. The primary objective will be to assess the safety and tolerability of 2DG in ADPKD patients and to determine a recommended Phase 2 dose. The secondary objectives will be to determine the pharmacokinetics of 2DG and to identify candidate metabolic response biomarkers in patient blood and urine.

Conclusions: The results of this study will determine whether it is justified to proceed to a clinical proof-of concept study, and will also inform the design of such a trial.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a hereditary disease that leads to kidney failure (ESKD), typically in the fifth decade of life. Given the variability between individuals in the rate of progression to ESKD there is significant unmet need for an accurate prognostic model that can predict the course of disease early in individual patients. CRISP IV is the longest extant ADPKD cohort (21 years), providing a unique opportunity to determine the association between clinical observations early in the disease and hard clinical outcomes.

Methods: Data collected from participants in the CRISP and HALT-A studies between 2001 and 2022 were modeled using multivariable Cox proportional hazards. The outcome was a composite of kidney failure (dialysis or kidney transplant) and eGFR <15 mL/min/1.73 m². Candidate dependent variables were picked on the basis of face validity, and selected for inclusion in the model by iterative forward selection.

Results: Of 759 included participants with a median follow-up of 8.2 years, 123 (16.2%) reached the composite endpoint. A prognostic model was built using 5 essential variables. Four clinical variables (serum CO_2, hemoglobin, BMI, diastolic BP) were found to add independently to this model.

Conclusions: We have developed a prognostic model that can predict kidney failure in an ADPKD patient over a time horizon of 15 years. The next step is to validate this in an external ADPKD registry cohort and create a risk calculator.

Baseline Characteristics of Participants in Statin Therapy in Patients with Early-Stage ADPKD Clinical Trial

Berenice Y. Gitomer, Wei Wang, Diana George, Kristen L. Nowak, Mallory Britz, Jelena Klawitter, Anna Jovanovich, Zhiying You, Beverly Farmer, Michel Chonchol. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: At present tolvaptan is the only agency approved therapy to slow kidney disease in patients with faster progressing autosomal dominant polycystic kidney disease (ADPKD). However, aquaretic side effects limit use for some patients, underscoring the need for identification of additional ADPKD therapies. We previously showed that pravastatin treatment slowed kidney cystic disease progression in children and young adults with ADPKD. In order to assess whether pravastatin slows disease progression in an adult population with ADPKD we designed a randomized double blind placebo-controlled trial (NCT03273413).

Methods: 150 subjects with an ADPKD diagnosis and early stage kidney disease (eGFR ≥ 60 ml/min/1.73m²) were included in the study. Subjects were recruited nationally and study visits were conducted at the University of Colorado Renal Research Clinic. Baseline visits were ongoing between 2017 and 2022. All participants were randomized to receive either study drug, 40 mg of pravastatin or matching placebo each day for a 2-year period. Baseline assessments included demographics, medical history, total kidney volume (TKV) and renal blood flow (RBF) by magnetic resonance imaging, Glofil-125

(Iothalamate-125) nuclear medicine assessment of measured GFR (mGFR) and routine blood chemistries including creatinine for eGFR by CKD-Epi equation.

Results: Participant mean age and standard deviation was 40 ± 10 years and 65% of subjects were female. There was good agreement between baseline eGFR (90 ± 20 ml/min/1.73m^2) and mGFR (92 ± 20 ml/min/1.73m^2) r = 0.7, P< 0.0001. Renal blood flow (682 ± 193 ml/min/1.73m^2) was positively correlated with both eGFR (P<0.0001) and mGFR (P<0.0001) and negatively correlated with natural log height corrected TKV (P< 0.004) Median height corrected TKV ml/m (IQR) 687 (468,1026).

Conclusions: The target goal for subject recruitment was attained. Subject recruitment spanned a longer than expected period due to travel and University restrictions related to the COVID-19 epidemic. The clinical trial is currently ongoing with the last participant scheduled to complete the end-of-study 2-year visit in March 2024.

How Well Do Risk Assessment Guidelines Perform for ADPKD?

Mauricio A. Miranda Cam, Muhammad T. Hassan, Saima Khowaja, Xuewen Song, York P. Pei. *University Health Network, Toronto, ON, Canada*.

Background: The approval of Tolvaptan for treatment of ADPKD heralds a new era when mechanism-based therapy is now possible. However, Tolvaptan is an expensive drug associated with potentially serious side-effects and is currently reserved for patients at high-risk for progression to ESKD. Two sets of risk assessment guidelines for ADPKD are now available based on the consensus of two panels of nephrologists from Canada and Europe. However, how well do these guidelines perform in risk assessment has not been formally assessed.

Methods: We conducted a prospective study in 474 patients with typical imaging pattern of ADPKD by MRI who also had detailed clinical and laboratory data. We used age- and height-adjusted total kidney volume to derive the Mayo Clinic Imaging Class as a "gold-standard" for risk assessment (i.e. low-risk: 1A-1B; high-risk: 1C-1E). We then applied the revised Canadian guidelines (Can J Kidney Health Dis. 2018) and the updated European guidelines (NDT 2022) to our patient cohort to assess their performance.

Results: The study cohort consisted of 286/474 (60%) high-risk patients with MCIC 1C-1E. Applying the updated Canadian risk assessment algorithm resulted in exclusion of 245/474 (52%) patients including 86/286 (30%) of the high-risk patients. The resultant cohort (229/474) was enriched with 88% high-risk patients but also included 12% of low-risk patients. The updated European guidelines provide a 3-step hierarchal algorithm, when applied resulted in exclusion of 55% (157/286) of high-risk patients. During the last step, 122 patients could not be classified due to a lack of eGFR slope information. The resultant cohort (180/474) was enriched with 72% high-risk patients but also included 28%(51/180) of low-risk patients.

Conclusions: Risk assessment in ADPKD is evolving process that needs to be redefined by new clinical data and test technologies. Clinical guidelines should be evaluated using real-life data and those that enrich high-risk patients while minimize low-risk patients have most clinical utility.

Identification and Characterization of Biomarkers from Cell-Free DNA Methylation in ADPKD Patients

Xiaoyan Li,[1,2] Xia Zhou,[1,2] Christian Hanna,[1,3] Peter C. Harris,[1,2] Xiaogang Li.[1,2] *[1]Department of Internal Medicine, Mayo Clinic, Rochester, MN; [2]Department of Biochemistry and Molecular Biology, Mayo Clinic, Rochester, MN; [3]Division of Pediatric Nephrology, Mayo Clinic, Rochester, MN.*

Background: ADPKD is caused by mutations of PKD1/PKD2. However, there is no proper biomarker for this disease. Recently, circulating cell-free (cf) DNA has attracted attention as biomarkers in the context of prediction, prognostication, and monitoring of drug response in human diseases.

Methods: We isolated cfDNA from plasma and urine and performed EM-Sequencing to identify cfDNA methylation signatures and the differential methylation regions (DMRs) with 5% methylation difference between the pediatric ADPKD patients and age-matched healthy individuals. The DMRs associated signaling pathways were analyzed with gene set enrichment analysis (GSEA).

Results: We identified 2,054 and 30,511 DMRs in cfDNA from plasma and urine, in which 1,409 (69%) and 24,707 (81%) DMRs were aligned to protein-coding genes, 43 (3%) and 7453 (30%) DMRs were located on the promoters of those protein-coding genes, and 26 of 43 (60%) and 7365 of 7453 (99%) DMRs were hypomethylated in ADPKD patients. The criteria used to identify DMRs as biomarkers include that, 1) their methylation is three times more than the initial 5% differential methylation in ADPKD patients versus healthy controls in either plasma or urine; 2) they are located to the promoter regions of protein-coding genes; and/or 3) they are constantly hypo- or hyper-methylated in both plasma and urine. We identified 7 hypo- and 5 hyper-methylated DMRs in plasma only, and 1754 hypo- and 55 hypermethylated DMRs in urine only, and those DMRs only matched criteria 1 and 2. Importantly, we identified 19 DMRs in both plasma and urine, and 10 of these 19 DMRs matched all three criteria. These 10 DMRs associated protein-coding genes encode inflammatory cytokine (CD70), metabolic related proteins (PON1, LOXL1, CERS3, ENOSF1), neurological synapse related factor (SDK1), epigenetic regulators (PRDM8, CMTR2) and transcriptional regulators (CIZ1, NBL1), which were all hypomethylated and their mRNA levels were increased in *Pkd1* mutant mouse kidneys. The diverse function of these 10 proteins/factors and the associated pathways supports the roles in regulation of cyst growth in ADPKD.

Conclusions: This study identifies cfDNA methylation signatures and the differential methylation regions in ADPKD patients, and the 10 candidate DMRs and the associated genes and pathways are potential biomarkers and novel mechanisms for ADPKD progression.

Evaluation of Tolvaptan Effect in Autosomal Dominant Polycystic Kidney Disease (ADPKD) Using Inverse Probability of Censoring Weighting for Long-Term Extension Data

Huan Jiang, Zhen Zhang. *Otsuka America Pharmaceutical Inc, Princeton, NJ.*

Background: In long-term extension (LTE) clinical trials switching treatment arms is common among placebo participants. Inverse Probability of Censoring Weighting (IPCW) was invented to recreate balanced treatment arms by assigning weights to patients without switching. Another possible issue is no comparators exist during LTE trials, leading to bias in comparisons between treatments when including LTE data. In this research, we aim to create a control group for treatment comparison and determine whether IPCW decreases bias raised from crossover in LTE data.

Methods: Using data from TEMPO 3:4 trial and its LTE TEMPO 4:4, we created a control group for placebo druing LTE, calculated weights using IPCW, and conducted analyses: 1) estimation of time to end stage kidney disease (ESKD) using Cox regression models; (2) estimation of average decline in eGFR between placebo and tolvaptan using mixed-effects models.

Results: IPCW method performed well in reducing errors from unbalanced treatment arms and determining effectiveness of tolvaptan with a decreased hazard ratio(HR) in Model 1(0.17 with 95% CI (0.05, 0.54)) compared to HRs estimated in Model 2, which ignored crossover and analyzed as intention-to-treat (ITT) (0.38 with 95% CI (0.20, 0.75)) and Model 3, a time-varying Cox regression model (0.22 with 95% CI (0.09, 0.56)) (Table 1). Cox regression models were adjusted by baseline age, eGFR, creatinine, sex, race, PKD diagnosed before age 35, and TKVs over time. It also adjusted biases well in Model 4 (-4.22 ml/min/1.73 m^2 per year for placebo; -2.93 ml/min/1.73 m^2 per year for tolvaptan) on average eGFR decline, compared to Model 5, which excluded placebo patients from LTE and longer years were used to estimate tolvaptan effects, and Model 6 using ITT method mentioned in Model 2 (Table 2). Mixed-effects models were used without adjustment.

Conclusions: In Cox regression and mixed-effects models, IPCW reduced bias in estimating long-term effects from crossover after creating a control group for placebo patients.

Computable Phenotype to Identify ADPKD Patients, A Validation Study

Shahed Ammar,[1] Kathleen Borghoff,[2] Ibrahim El Mikati,[3] Vinamratha Rao,[3] Abrar Alshorman,[3] Reem Mustafa,[3,4] Diana I. Jalal,[1,5] Lama A. Noureddine.[1] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]University of Nebraska Medical Center Department of Internal Medicine, Omaha, NE; [3]University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; [4]McMaster University, Hamilton, ON, Canada; [5]Iowa City VA Medical Center, Iowa City, IA.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common inherited kidney disease. Patients with ADPKD are at high risk of end-stage kidney disease as the disease lacks a cure. It is important to facilitate the recruitment of ADPKD patients in clinical trials. Here, we sought to validate a computable phenotype based on the ICD-9/10 codes for ADPKD in the electronic medical record (EMR).

Methods: We retrospectively identified 495 patients with ICD-9/10 for ADPKD or renal cysts and were following up at the University of Iowa Hospitals and Clinics (UIHC). We conducted a chart review to verify if they had ADPKD. We stratified patients into four groups: Group A, following in the nephrology clinic with ICD-9/10 codes of ADPKD; Group B, following in the nephrology clinic with ICD-9/10 codes for renal cysts; Group C, following in the non-nephrology clinic with ICD-9/10 codes for ADPKD; and Group D, following in the non-nephrology clinic with ICD-9/10 codes for renal cysts.

Results: Of the 495 patients, 134 (27%) patients were evaluated in the nephrology clinic and 360 (73%) in the non-nephrology clinic. A total of 117 patients had ICD-9/10 codes for ADPKD, where 108 (92%) had confirmed ADPKD and 9 (8%) didn't have ADPKD. A total of 377 had ICD-9/10 codes for renal cysts, where only 1 (0.3%) had

ADPKD, while 376 (99.7%) didn't have ADPKD. The overall sensitivity of the ICD-9/10 codes for ADPKD was 92.3% and the specificity was 99.7%. In the nephrology clinic, the sensitivity was 94.6% and the specificity was 100%. In the non-nephrology clinic, the sensitivity was 88.4% and the specificity was 99.7% (Figure.1).

Conclusions: Utilizing ICD-9/10 to identify patients with ADPKD is of excellent overall sensitivity, specificity, PPV, and NPP. The sensitivity tends to be higher in the nephrology clinic Vs non-nephrology clinic.

TH-PO433

Omics Profiling of Tolvaptan-Treated Autosomal Dominant Polycystic Kidney Disease Patients

Tzongshi Lu,[1,2] Jiun-Chi Huang,[1,3] Yi Li.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Kaohsiung Municipal Siaogang Hospital, Kaohsiung, Taiwan.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a life-threatening genetic kidney disease and the fourth leading cause of kidney failure. Dialysis or transplant are current treatments for end-stage ADPKD patients, and no other ideal efficient therapeutic strategy exists. The selective vasopressin V2-receptor antagonist, Tolvaptan, was used to treat hyponatremia in heart failure but was approved by FDA for ADPKD treatment in 2018; however, there are limitations for ADPKD patients to receive Tolvaptan treatment and its significant side effects severely affect patient's life quality. In this study, we use omics tools to discover potential therapeutic targets with fewer side effects for ADPKD patients.

Methods: Tolvaptan was started with the 45-0-15 dose, then titrated to 60-0-30 after two months. Blood and urine were collected before Tolvaptan treatment and 2, 3, 6, 9, and 12 months after treatment. Omics profiling was performed using SureSelect XT HS2 mRNA Library Preparation kit (Agilent, USA) and sequenced on Nextseq. Differential expression analysis was performed using StringTie and DEseq2 with Welgene Biotech's in-house pipeline. Genes with p-value < 0.05 and > 2.0-fold changes were considered significantly differentially expressed. Functional enrichment assay was performed using cluster Profiler v3.6.

Results: Our data indicate that cytoskeleton-regulating proteins and junctional proteins: NBPF10, RGPD2, MYH1, NPIPB9, SLC9B1P1, and TUBB7P were involved in the regulation of cystogenesis in Tolvaptan-treated ADPKD patients. In addition, the downstream junctional and cytoskeleton regulating genes of the above proteins (Log2 ratio: CRB3, 11.01; CLDN10,10.09; MAPK10, 7.34; FGF17, 9.47; MYH14, 7.04) were significantly ($p<0.05$) preserved after Tolvaptan treatment that may be involved in the regulation of calcium, Rho GTPases, and PAK Pathway signaling. Furthermore, Hypoxanthine, Creatine, L-a-aminobutyric acid, and Trimethylamine N-oxide were significantly decreased in our metabolomics data analysis, showing paracellular transportation in kidney cells was inhibited.

Conclusions: Our data shows Tolvaptan treatment regulates the integrity of tight junctions and paracellular transportation of kidney cells. It elucidates the possible targets in inhibiting side effects and provides novel therapeutic targets that may be served in ADPKD treatments with fewer side effects.

Association Between PKD1 Truncating Mutations and Accelerated eGFR Decline in ADPKD Patients: Implications for Early Identification and Intervention

Hamad Ali,[1,2] Barrak Alahmad,[3,2] Yousif Bahbahani,[2,4] Sarah R. Senum,[5] Mohamed Abu-Farha,[2] Jehad Abubaker,[2] Fahd Al-Mulla,[2] Peter C. Harris.[5] *[1]Kuwait University Health Sciences Centre, Safat, Kuwait; [2]Dasman Diabetes Institute, Kuwait City, Kuwait; [3]Harvard University, Cambridge, MA; [4]Kuwait Ministry of Health, Safat, Kuwait; [5]Mayo Clinic Minnesota, Rochester, MN.*

Background: ADPKD severity varies due to allelic and genic heterogeneity. Identifying patients at risk of rapid disease progression may improve outcomes. This study aims to explore the association between PKD1 types (truncating vs. non-truncating) mutations & rate of eGFR decline in ADPKD patients.

Methods: This study followed up 42 PKD1-ADPKD patients with clinically & genetically confirmed diagnoses for an average of 6.6±3.8 years. Renal function tests were performed annually, and eGFR was calculated using the CKD-EPI Creatinine Equation (2021).

Results: Patients with PKD1 truncating mutations had a more rapid rate of eGFR decline per year (-4.7 ml/min/1.73 m2 per year) compared to patients with PKD1 non-truncating mutations (-3.5 ml/min/1.73 m2 per year) ($P<0.001$).

Conclusions: This study highlights the association between PKD1 truncating mutations & a more rapid rate of eGFR decline in ADPKD patients. Identifying patients with potential rapid disease progression may aid in early intervention & better disease management to improve outcomes.

Funding: Government Support - Non-U.S.

Analysis of ADPKD progression per PKD1 mutation type

	Effect Estimate	95% CI	P

Comparison of the Total Kidney Volumes Using the Ellipsoid Equation and Manual Segmentation in ADPKD

Hyun Bae Jang,[1] Caroline Reinhold,[2] Ahsan Alam.[2] *[1]McGill University, Montreal, QC, Canada; [2]McGill University Health Centre, Montreal, QC, Canada.*

Background: Total kidney volume (TKV) is an important prognostic biomarker of disease progression in autosomal dominant polycystic kidney disease (ADPKD). The gold standard of manual segmentation TKV (mTKV) is time and labour-intensive. The ellipsoid equation TKV (eTKV) is commonly used in clinical practice, but assumes uniform growth of the kidneys. Our study examined the correlation between the eTKV and mTKV and we examined cases individually where there was misclassification.

Methods: We analyzed coronal T2-weighted MRI slices for 143 patients with ADPKD from a single centre. eTKV was determined using standard orthogonal measurements. The ground truth mTKV was performed by a single trained individual. Pearson's correlation coefficient was calculated and a Bland-Altman analysis was performed. A confusion matrix was generated to illustrate the misclassification in the Mayo Imaging Classification (MIC) between the two approaches. We explored cyst imaging features where the difference in TKV methods was ≥20%.

Results: The mean age of the cohort was 45 (SD 15), 46% were male, hypertension prevalence was 71%, the median eGFR was 76 ml/min/1.73m^2 (IQR 46-107), height-adjusted TKV was 865 mL/m (IQR 490-1307), and tolvaptan use was 45%. The correlation coefficient between both TKV measures was 0.96. The Bland-Altman analysis showed wide limits of agreement [-40.43%, 25.15%], and 24 patients were reclassified by one MIC risk category. Of the 25 patients (17%) who exhibited ≥20% difference between the two measures, 23 patients were characterized as having large exophytic cysts.

Conclusions: The eTKV is efficient and generally reliable for calculating TKV, but it may lose accuracy in patients with large exophytic cysts. Further study should explore the association of exophytic cysts with kidney disease progression. Understanding whether exophytic cysts should be included in the TKV estimation may aid in risk stratification.

Confusion Matrix of Mayo Imaging Class Determined By Total Kidney Volume Using Ellipsoid Equation (eTKV) and Manual Segmentation (mTKV)

		eTKV					
		1A	1B	1C	1D	1E	2

Prognosis of Polycystic Kidney Disease: FinnGen Study

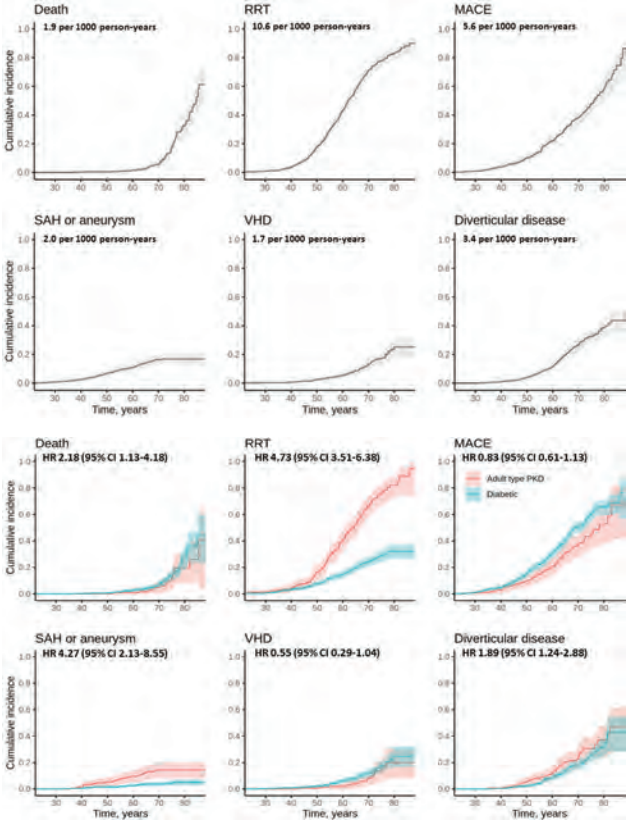
Tomas J. Visser,[1] Tapio Hellman,[2] Anni Kauko,[3] Matias Simons,[4] Timo Jahnukainen,[5] Jaakko Helve,[6] Patrik Finne,[5] Daniel Gordin,[5] Teemu Niiranen.[3] *[1]Helsingin yliopisto, Helsinki, Finland; [2]TYKS Turu yliopistollinen keskussairaala, Turku, Finland; [3]Turun yliopisto, Turku, Finland; [4]University Hospital of Heidelberg, Heidelberg, Germany; [5]HUS-yhtyma, Helsinki, Finland; [6]Finnish Registry of Kidney Diseases, Helsinki, Finland.*

Background: The extra-renal complication risk and progression rate of autosomal dominant polycystic kidney disease (PKD) are incompletely understood. We assessed the clinical outcomes of PKD in the FinnGen study, which covers nearly 10% of the Finnish population (N=473681).

Methods: PKD patients and clinical outcomes were identified using ICD diagnosis codes. The outcomes of interest were death, start of dialysis or transplantation (RRT), major adverse cardiovascular events (MACE), subarachnoid hemorrhage (SAH) or cerebral aneurysms, valvular heart disease (VHD, defined as valvular regurgitation), or diverticular disease. In a smaller sample with data available for estimated glomerular filtration rate (eGFR), we compared the risk of adverse outcomes and kidney function decline in PKD patients and controls (diabetes mellitus [DM] patients) using multivariable-adjusted Cox regression and repeated linear mixed models. The cases and controls were matched with a ratio of 1:4 by age, sex and eGFR.

Results: The study sample included 674 PKD patients. The incidence of clinical outcomes in these patients is reported in Figure 1. The risk of adverse outcomes in PKD patients (N=173) compared to DM patients (N=692) is reported in Figure 2. The risk of death, RRT, SAH or cerebral aneurysms, and diverticular disease was greater in PKD patients compared to DM patients ($p<0.02$ for all). The eGFR decreased more rapidly in PKD patients compared to DM patients (-2.31 [95% CI, -2.41 to -2.22] vs -1.62 [95% CI, -1.67 to -1.56] ml/min/1.73 m^2 per year, $p<1x10^{-16}$).

Conclusions: In this large register study, PKD patients demonstrated a greater risk for most adverse outcomes and a more rapid kidney function decline compared to DM patients.



TH-PO437

A Serum Proteomic Study Identifies Novel Biomarkers for Autosomal Dominant Polycystic Kidney Disease

Xia Zhou, Xiaoyan Li, Xiaogang Li, Peter C. Harris. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ADPKD is a genetic disorder characterized by cyst growth and expansion, and inflammation and renal fibrosis leading to kidney failure. The disease course of ADPKD is highly variable depending on the gene, mutation, and other factors. Better methods to measure disease progression, such as serum biomarkers, are urgently needed in ADPKD to complement total kidney volume data.

Methods: The level of 1500 circulating proteins in serum samples from 45 ADPKD patients with an eGFR ≥ 15 ml/min/1.73m^2 (4 subgroups based on eGFR, CKD1-4) and 12 healthy individuals were measured using the SOMAscan proteomics platform. Differentially expressed proteins (DEPs) were analyzed by Go and KEGG enrichment analyses. Differentially expressed genes in kidneys of *Pkd1$^{flox/flox}$:Pkhd1-Cre* mice were identified by RNA-seq.

Results: A total of 155 proteins were upregulated and 49 proteins downregulated in patients with ADPKD and CKD3 compared to healthy individuals ($p < 0.05$). DEPs were associated with several signaling pathways, including cytokine-cytokine receptor interactions, TGF-β signaling, complement and coagulation cascades, TNF signaling, cancer, lipid regulation, and atherosclerosis. Potential individual serum biomarkers were identified by the following criteria: 1) more than >20% increase in CKD2 versus healthy control; 2) more than two-fold increase in CKD4 versus healthy control; and 3) the change of protein level was associated with a decline of eGFR. A total of 31 proteins were identified, including the inflammatory biomarkers (MIC-1, TNFR-I, TNFR-II, TNFRSF21, IGFBP-6, and TGF-bRIII), fibrosis biomarkers (MMP-7, MMP-3, Edostatin, WFDC2), and other biomarkers (Resistin, EPHB4, EFNB2, and CAD17). Specifically, the level of MMP-7 was increased 1.8-, 3.2-, 6-, and 8.2-fold in ADPKD patients with CKD1-4, respectively. Among the 155 upregulated and 49 downregulated proteins, the mRNA levels of 55 and 11 genes were similarly increased or decreased in mouse PKD kidneys. These results suggest that these specific upregulated and downregulated proteins are altered in the kidney and can also be tested as urinary biomarkers.

Conclusions: Our study identified several potential diagnostic biomarkers in ADPKD. The TNFR-I, TNFR-II, MMP-7, and WFDC2 have been reported as prognostic biomarkers in CKD, but the other inflammatory and fibrotic biomarkers are novel for ADPKD.

TH-PO438

Changes in Tubular Biomarkers with Dietary Intervention and Metformin in Patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Wei Wang, Zhiying You, Cortney Steele, Berenice Y. Gitomer, Michel Chonchol, Kristen L. Nowak. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Tubular biomarkers, which reflect tubular dysfunction or injury, are associated with incident chronic kidney disease and kidney function decline. Several tubular biomarkers have also been implicated in progression of ADPKD. We evaluated changes in tubular biomarkers in four groups of patients with ADPKD who participated in one of two clinical trials (metformin therapy and diet-induced weight loss), based on evidence suggesting that such interventions could reduce tubule injury.

Methods: 66 participants (26M/40F) with ADPKD and estimated glomerular filtration rate (eGFR) >30 ml/min/1.73m^2 who participated in either a 12-month metformin clinical trial (n=22 metformin [max dose 2,000 mg/d]; n=23 placebo) or 12-month dietary weight loss study (n=10 daily caloric restriction [DCR; 34% restriction]; n=11 intermittent fasting [IMF]; 3x/wk) were included in assessments of urinary tubular biomarkers (kidney injury molecule-1 [KIM-1], fatty-acid binding protein [FABP], interleukin-18 [IL-18], monocyte chemoattractant protein-1 [MCP-1], neutrophil gelatinase-associated lipocalin [NGAL], clusterin, and human cartilage glycoprotein-40 [YKL-40]; normalized to urine creatinine), at baseline and 12 months. The association of baseline levels with change in height-adjusted total kidney volume (htTKV) and eGFR, with covariate adjustment, was also assessed.

Results: Mean±s.d. age was 48±8 years, eGFR was 71±16 ml/min/1.73m^2, and baseline BMI was 30.5±5.9 kg/m^2. None of the tubular biomarkers changed with any intervention as compared to placebo. Tubular biomarkers were not associated with change in eGFR or htTKV over one year, after adjustments for demographics, group assignment, and clinical characteristics (Table).

Conclusions: In this cohort of patients with ADPKD, tubular biomarkers did not change with dietary-induced weight loss or metformin, nor did they associate with kidney disease progression.

Funding: NIDDK Support

Tubular Biomarker (log-adjusted)	Adjusted association with change in htTKV (B-estimate [95% CI])	Adjusted association with change in eGFR (B-estimate [95% CI])
KIM-1	4.3 (-1.1, 9.6)	2.1 (-6.4, 10.6)
FABP4	0.52 (-3.2, 4.3)	-2.3 (-7.5, 2.9)

Evaluation of the Predictive Ability and Concordance of Prognostic Scores for Rapid Progression in ADPKD: A Multicenter Cohort

Irene Capelli,[1,2] Valeria Aiello,[1,2] Elhussein A. Elhassan,[3,4] Katherine A. Benson,[4] Carlotta P. Cristalli,[1] Anna Vella,[1] Francesca Ciurli,[2] Francesca Montanari,[1] Gaetano La Manna,[1,2] Jan Halbritter,[5] Peter J. Conlon.[3,4] *[1]IRCCS Azienda Ospedaliero-Universitaria di Bologna, Bologna, Italy; [2]Universita degli Studi di Bologna, Bologna, Italy; [3]Beaumont Hospital, Department of Nephrology and Transplantation, Dublin, Ireland; [4]Royal College of Surgeons in Ireland Faculty of Medicine and Health Sciences, Dublin, Ireland; [5]Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: ADPKD is characterized by the progressive development of bilateral renal cysts, resulting in enlargement of the kidney volume and ESKD. ERK-NET assessed Tolvaptan indications according to 3 algorithmic criteria: total kidney volume (HtTKV) and Mayo Clinic Imaging Class (MCIC), rate of decline in eGFR, and the Predicting Renal Outcome in Polycystic Kidney Disease (PROPKD) score. These scores are alternatively used to define rapid progressor (RP) patients. The aim of this study is to evaluate and improve the concordance of sensitivity and specificity of MCIC and PROPKD predictive abilities for rapid disease progression.

Methods: Data from 3 centers (Bologna, Dublin, Berlin/Leipzig) were assessed. We defined RP with: eGFR slope ≥3 mL/min/1.73m^2/ yearly over 4 years, or MCIC classes 1C-D-E, or PROPKD score (7-9). Descriptive statistics were used to summarize clinical parameters. The concordance between MCIC and PROPKD was assessed using Kappa statistics. In *PKD1* missense variants, the REVEL score was obtained and treated as a continuous variable; score greater than 0.65 were considered 'pathogenic' and regarded as *PKD1*-truncating variants for PROPKD score calculation.

Results: We evaluated 298 ADPKD patients, demographic and clinical data are summarized in Tab 1. After 4 yr of follow-up, MCIC (p 0,041), HBP (p 0,031), and urological events (p<0.001) result were statistically significant on multivariate analysis (Tab 1). Assessment of RP using PROPKD and MCIC scores yielded Kappa Cohen of 0,149; 47.9% (*n*=143) were concordant, 49,32 % (*n*=148) patients identified as RP for MCIC were non- RP for PROPKD, while 2.3% (*n*=7) of PROPKD score considered RP using PROPKD score were considered non-RP using MCIC classes. Following the reclassification of *PKD1* missense variants by REVEL score, K of Cohen improved to 0.174, and PROPKD becomes predictive of RP also at multivariate (p 0.010).

Conclusions: Concordance between scores results low (K of Cohen 0,149). PROPKD is more selective compared to the Mayo. Nevertheless, PROPKD allows the identification of some RP patients excluded from MCIC. The combined use of scoring may increase the ability to identify progressive patients. REVEL score could improve the agreement.

TH-PO440

Impact of the 2021 Glomerular Filtration Rate Estimation Equation in a Cohort of White Polycystic Kidney Disease Patients

Yasar Caliskan,[1] Abdullah Ozkok,[3] Nilüfer Alpay Kanitez,[4] Ozgur A. Oto,[2] Safak Mirioglu,[2] Serra Artan,[2] Ahmet B. Dirim,[2] John C. Edwards,[1] Halil Yazici,[2] Krista L. Lentine.[1] *[1]Saint Louis University School of Medicine, Saint Louis, MO; [2]Istanbul Universitesi, Fatih, Turkey; [3]Yeditepe Universitesi, Istanbul, Turkey; [4]Koc Universitesi, Istanbul, Turkey*.

Background: New estimated glomerular filtration rate (eGFR) equations removed race adjustment, but the impact of this removal on prediction of chronic kidney disease (CKD) staging for autosomal dominant Polycystic Kidney Disease (ADPKD) patients is unknown. We aimed to investigate the impact of new eGFR equations on CKD staging and their associations with clinical characteristics in ADPKD patients.

Methods: We examined data for 288 consecutive White patients with ADPKD [mean age 53±16; 158 (54.9%) women, 130 (45.1%) man] through chart review between 2000-2013 with a median 9-yr follow-up (IQR, 6-12 yrs). We computed changes in eGFR resulting from substituting the CKD-EPI 2009 equation for the 2021 equation and the consequent reclassification into different CKD Stages according to KDIGO 2012 classification. Correlates of eGFR changes during follow up are also studied.

Results: Compared to the 2009 equation, CKD-EPI 2021 yielded a higher baseline eGFR, with a median of 2.67 mL/min/1.73 m^2 (IQR 1.43-3.43) and higher last visit eGFR with a median 2.64 mL/min/1.73 m^2 (IQR 1.24-3.65). Among the cohort of ADPKD patients, 9% (n=26) were reclassified into a higher category of eGFR, as were the following proportions by baseline (2009 equation) stage: from CKD stage 2, 9.1% (n=6) from CKD stage 3, 9.4% (n=3) from stage 4 and 12.8% (n=6) from stage 5. No patient was re-classified into a more severe CKD stage. Based on last visit eGFR, CKD stage was also reclassified into a higher category in 13.3% (n=6) from CKD stage 2, 12.5% (n=6) from stage 3, 10% (n=2) from stage 4 and 7.9% (n=3) from stage 5. The median change in eGFR over median 9 years (follow-up - baseline value) calculated by CKD-EPI 2009 and CKD-EPI 2021 was -8.5 mL/min/1.73 m^2 (IQR 0.5-22.1) and -7.9 mL/min/1.73 m^2 (IQR 0.5-22.7), respectively. Among the baseline clinical characteristics, smoking was significantly correlated with eGFR decline during follow up (CKD-EPI 2009, r=0.0186, p=0.016; CKD-EPI 2021, r=0.186, p=0.018).

Conclusions: Implementing the CKD-EPI 2021 equation in a Caucasian ADPKD population, would increase eGFR by a modest amount. A significant proportion of the population would be re-classified into a higher eGFR category, with a consequent decrease in the prevalence of stage 5 CKD.

TH-PO441

Impact of the COVID-19 Pandemic on Health Care Utilization and Behaviors in Adults with ADPKD

Anthony Atalla, Alok Shetty, Terry J. Watnick, Stephen L. Seliger. *University of Maryland School of Medicine, Baltimore, MD*.

Background: The impact of the COVID-19 pandemic on those with chronic diseases was pervasive, affecting healthcare seeking behaviors, and medication and access to care. The impact of COVID-19 on adults with ADPKD is uncertain.

Methods: Participants were recruited from 223 adult ADPKD patients without ESRD in a study at the University of Maryland. N=66 patients participated in a questionnaire from July 2022-December 2022 about PKD-related complications, COVID infections, healthcare seeking behaviors, and care avoidance before and after March 2020.

Results: N=34(51.5%) of participants reported a positive COVID-19 test result. N=29(44%) reported frequent concern about contracting COVID-19. Those who avoided medical care at least once (n = 17, 26%) had similar demographics and PKD severity to those who did not but reported greater telehealth utilization and use of non-prescribed medication for COVID-19 prevention. They were also more likely to have contracted COVID-19 (Table). Among the N=53 who reported very good or excellent PKD disease management pre-pandemic, N=47(94%) reported no significant change during the pandemic.

Conclusions: Among a sample of ADPKD patients with well-managed disease, there was no significant decline in self-reported PKD management during the pandemic. However, more than 1 in 4 reported avoidance of care and were more likely to have utilized telehealth and been infected with COVID-19. Future studies should investigate care avoidance in PKD patients whose care is not as easily transitioned to telehealth.

Funding: NIDDK Support

Characteristics of Participants with and without new avoidance of healthcare during COVID pandemic

	No avoidance (n=49)	Healthcare avoidance (N=17)	p-value
Age (yrs)	45.5 (14.0)	47.8 (11.4)	0.5
Male	22 (45%)	7 (41%)	0.99
White	44 (90%)	16 (94%)	0.99
College Education	40 (82%)	15 (88%)	0.7
eGFR (ml/min/1.73m2)	77.9 (32.4)	67.6 (31.2)	0.3
htTKV (cc/m)	670 [439, 1279]	838.6 [658.2, 1108.9]	0.3
Flank Pain	21 (43%)	9 (53%)	0.6
UTIs	24 (49%)	12 (71%)	0.3
Often or Always Concerned about COVID	21 (43%)	8 (47%)	0.8
Use of non-prescribed meds for COVID prevention	4 (8%)	6 (35%)	0.01*
COVID infection during pandemic	21 (43%)	13 (77%)	0.02*
Telehealth Use during pandemic	21 (43%)	13 (77%)	0.002*

TH-PO442

Evaluation of Autonomic Modulation in Normotensive Autosomal Dominant Polycystic Kidney Disease Patients

Daniel R. Rocha, Milene S. Ormanji, Ana Cristina Matos, Cassia T. Bergamaschi, Ruy R. Campos, Bruno M. Silva, Ita P. Heilberg. *Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil*.

Background: Autonomic cardiovascular dysregulation has been described among Autosomal Dominant Polycystic Kidney Disease (APDKD) patients exhibiting hypertension and reduced kidney function. The present study aimed to evaluate the involvement of the sympathetic nervous system (SNS) preceding the onset of hypertension and kidney dysfunction.

Methods: We measured resting Heart Rate Variability (HRV) and systolic and diastolic arterial blood pressure (sBP and dBP) for five minutes in *Finapres*® device and cardiovascular reactivity after sympathoexcitatory stimuli: Stroop colored word test (SCWT), cold pressor test (CPT), and isometric handgrip (HG). Baroreflex sensitivity (BRS) was analyzed through the Valsalva maneuver (VM). Thirteen (13) ADPKD normotensive patients (5M/ 8F, 25.9±5.7 years old) and 13 healthy subjects (HS, 6M/7F, 26.1±4.6 yrs), eGFR of 104.8±18.6 and 104.9±11.0 mL/min/1.73m2, respectively, were included.

Results: Mean values of HR, BP, and HRV parameters at resting were not statistically different between groups. Although resting systolic BP (sBP) was similar for both groups, mean peak-phase-II-sBP and nadir-phase-III-sBP during VM were significantly higher in ADPKD versus HS (165.9±20.1 vs 142.5±19.7 and 140.2±11.7 vs 116.9±15.8 mmHg, p<0.05, respectively). Absolute differences between mean values of HR before and during CPT (at 2 minutes) were bigger in the ADPKD group (8.7±5.3 vs 2.9±5.6 bpm, p<0.05). Absolute differences between mean values of sBP and dBP before and during HG test (at 2 minutes) were smaller in ADPKD group than HS for sBP (11.8±8.1 vs 21.6±13.9 mmHg, p<0.05) and dBP (8.1±7.9 vs 14.7±8.1 mmHg, p<0.05). Absolute differences between mean values of HR during HG test and at 2 minutes of the recovery period were smaller in ADPKD than HS (-3.4±5.6 vs -10.5±9.0 bpm, p<0.05). Responses of HR and BP to SCWT did not differ between groups.

Conclusions: Preliminary data from VM and CPT as well as the delay in BP and HR returning to basal values observed in HG test suggested an increase in sympathetic drive in ADPKD normotensive patients. An additional number of patients need to be further evaluated to confirm present findings.

TH-PO443

A Diagnosis of Depression/Anxiety Is Associated with More Rapid eGFR Decline in Autosomal Dominant Polycystic Kidney Disease

Kathryn E. Simmons,[1] Lawrence S. Ullman,[1] Neera K. Dahl.[2] *[1]Yale School of Medicine, New Haven, CT; [2]Mayo Clinic Department of Internal Medicine, Rochester, MN.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is the leading genetic cause of kidney failure. 22-60% of patients with ADPKD are diagnosed with depression, which is associated with worse physical health and decreased dietary compliance with ADPKD guidelines. Depression in chronic kidney disease patients is associated with increased all-cause mortality, but the impact of mental health on ADPKD progression has not been assessed.

Methods: We identified ADPKD patients seen at Yale Nephrology from 2016 to 2021 and retrospectively collected demographic, medical history, and clinical data through automated query and manual chart review. Patients were separated into two groups, those diagnosed with depression and/or anxiety (DA), and those without a diagnosis of depression and/or anxiety (NDA). Estimated glomerular filtration rate (eGFR) was calculated using the 2021 CKD EPI Creatinine equation. Differences between groups were assessed through chi-squared and Student's T-test, and the impact of DA on kidney function decline, represented by average change in eGFR, was assessed through simple and multiple linear regression.

Results: There were 49 (26%) patients with DA, and 140 (74%) patients without. DA patients were more likely to be female (p=0.0044), younger (p=0.044), have higher body mass index (BMI) (p=0.021), and be diagnosed with obstructive sleep apnea (p=0.046). There were no differences between Mayo Imaging Classification (MIC) or genotype between the groups, though tolvaptan use was more common in the NDA group (p=0.021). DA diagnosis was not linked to more rapid eGFR decline (p=0.672) with simple linear regression. However, DA was a significant predictor for rapid eGFR decline (p=0.019) on multivariable regression when controlling for factors linked to disease progression, including ADPKD genotype, MIC, kidney stones, hypertension, and diabetes, as well as age, sex, and BMI.

Conclusions: DA is significantly correlated with rapid eGFR decline in ADPKD patients in addition to traditional risk factors such as genotype, age and MIC. Future investigations may help determine if the impact of DA on eGFR decline is through a clinical, psychological, and/or behavioral mechanism.

Pregnancy and Its Association with Total Kidney Volume in Nulliparous Women with Autosomal Dominant Polycystic Kidney Disease

Bang Zheng, Berenice Y. Gitomer, Kristen L. Nowak, Zhiying You, Michel Chonchol. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: There is mounting evidence of metabolic dysregulation contributing to polycystic kidney disease (PKD) progression. The maternal metabolic changes during pregnancies are well described, but the relationship between pregnancy and changes in total kidney volume in women with PKD is unclear. In this study, we tested the hypothesis that a pregnancy carried to live delivery in nulliparous PKD women is associated with a greater increase in total kidney volume than in non-pregnant PKD women.

Methods: Using data from the University of Colorado PKD registry from 1985 to 2004, a total of 6 nulliparous PKD women with pre and post-kidney ultrasound measurements for their first pregnancy met the inclusion criteria for the study (cases). Using a pool of 172 women with PKD but without pregnancy, we selected 6 for matches for the PKD women with pregnancies (controls). These women were matched 1:1 by age, race, and eGFR (calculated by the MDRD equation). A two-sample T-test was performed to compare the yearly change in height-adjusted total kidney volume (htTKV), calculated by ellipsoid formula, between cases and controls. Analyses were further adjusted for history of hypertension.

Results: Of the PKD women with pregnancies, the mean (SD) age and mean (SD) eGFR before pregnancy was 26±3 yrs and 79±22 mL/min/1.73m^2, respectively. The median (IQR) htTKV for cases and controls were 288 [248-366] and 350 [240-515]ml/m^2, respectively. The follow-up median duration was 7.00 [2.1-9.5] yrs, for women with and without pregnancies. The yearly percent change (median; IQR) in htTKV in PKD women with and without pregnancies was 14.2 [7.1-15.8] and 7.1 [1.4-8.6]%, respectively (p=0.11). Results remained unchanged after adjustment for history of hypertension.

Conclusions: Nulliparous PKD women demonstrated a faster increase in htTKV after pregnancy than non-pregnant PKD participants; however, it was not statistically significant. Further studies looking at the effect of pregnancy on PKD progression are needed.

Deciphering the Chronology of Cystogenesis and Metabolic Reprogramming

Daniel Spies,[1,2] Sara Clerici,[1,2] Laura Cassina,[2] Marco Chiaravalli,[2] Alessandra Boletta.[2] Unit of Cystic Kidneys Disorders - Alessandra Boletta Lab. *[1]Universita Vita Salute San Raffaele, Milano, Italy; [2]IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: ADPKD is among the most prevalent monogenic diseases. Multiple relevant orthologous animal models were generated over the years and helped defining mechanism of disease progression and identifying therapies able to retard end-stage-kidney-disease. However, the initial stages of renal cystogenesis have been poorly defined. Identification of the cellular alterations occurring at the onset of cystogenesis would provide important information on mechanism of disease and possibly help designing better therapies targeting initiating events and being more effective.

Methods: Mutant kidneys have been characterized by IHC and IF analysis. Single cell dissociation was performed pairing mechanical and enzymatic approaches. PARSE single cell combinatorial barcoding RNA sequencing was performed on 10k cells from P54 control kidneys, with a depth of 50k reads/cell

Results: We have developed a tamoxifen-inducible *Pkd1* animal model (TmKspCrePkd1fl/fl) carrying a fluorescent switch cassette (mT/mG) that allows identification of cells in which the Cre recombinase has been activated to study the initiating events in cystogenesis. Induction by 3 low dose injections of Tamoxifen resulted in full penetrance (cyst formation) within two weeks. 5 days after the last injection we identified renal tubules completely green, but not cystic, while 8 days post injection green cells started to form cysts. A pilot scRNA-seq of WT cells confirmed the capability to capture and distinguish induced from non-induced cells as well as the higher sequencing depth and reduced contamination of the combinatorial scRNA-seq approach.

Conclusions: Our inducible Pkd1 KO model enables the determination and characterization of both pre-cystic and cystic time windows, as well as the selection of low abundant pre-cystic mutant cells due to our colorSwitch reporter cassette. Comparison of mutant cells involved in cyst initiation and expansion will permit the exact determination of new mechanisms as well as therapeutic windows that allow tailoring of treatments to the corresponding metabolic stage of each cell-type. The experimental analysis is ongoing.

TH-PO446

Financial Implications of Genetic Testing in Nephrology: A Real-Life Evaluation of the Costs Related to Podocytopathy and Collagenopathy Diagnosis

Luigi Cirillo,[1,2] Tommaso Mazzierli,[1] Jacopo Lomi,[1] Eleonora Superchi,[1] Valentina Raglianti,[2,1] Gianmarco Lugli,[1] Samuela Landini,[1] Viviana Palazzo,[1] Benedetta Mazzinghi,[1] Paola Romagnani,[2,1] Francesca Becherucci.[2,1] *[1]Meyer Children's Hospital IRCCS, Firenze, Italy; [2]Universita degli Studi di Firenze Dipartimento di Scienze Biomediche Sperimentali e Cliniche Mario Serio, Firenze, Italy.*

Background: Collagenopathies and podocytopathies significantly contribute to CKD. Despite concerted efforts to enhance genetic testing guidelines, a data vacuum persists concerning the economic burden for diagnosis these diseases impose on healthcare systems. This study aims to shed light on healthcare resources utilization and the accompanying financial burden attributable to diagnosing these diseases, using real-world data. Moreover, we sought to evaluate the potential cost savings associated with using early genetic testing in diagnostic trajectories.

Methods: In this multicentric, retrospective study we enrolled all patients with a conclusive genetic diagnosis of podocytopathy and collagenopathy, from our tertiary hospital from Jun 2014 to Dec 2022, as previously described. Direct medical costs from clinical onset to conclusive genetic diagnosis, including medication use, in-hospital visits, invasive procedures, blood sampling, imaging studies, hospital admissions, and genetic tests, were recorded from patient clinical records. These costs were subsequently compared to those anticipated under a 'exome first' approach, involving a basic panel of tests followed immediately by genetic testing within a one-year follow-up period.

Results: The study included 43 patients (23 female), with 22 diagnoses of podocytopathies and 21 of collagenopathies. Over a median follow-up period of 3.5 years; patients required a wide range of resources consumption. Overall, the direct medical costs totaled 98,252 euros for medications, 4,125 euros for in-hospital visits, 68,138 euros for biopsies, 68,926 euros for blood tests, 2,560 euros for urinalysis, 9,023 euros for imaging, and 146,000 euros for genetic testing. Remarkably, the annual cost per patient averaged 3,897 euros, aligning closely with the cost of adopting the 'exome first' approach.

Conclusions: Our study underscores the significant unnecessary treatments and costs associated with the existing diagnostic approach for collagenopathies and podocytopathies. By adopting an early genetic testing strategy, we can mitigate this burden and reallocate resources more efficiently, providing valuable insights for healthcare policymakers.

Large-Scale Case-Control Exome-Wide Association Study Identifies Known and Novel Susceptibility Genes for Idiopathic Nephrotic Syndrome

Juntao Ke,[1] Gundula Povysil,[1] Shirlee Shril,[6] Yask Gupta,[1] Matthias Kretzler,[2] Krzysztof Kiryluk,[1] Moin Saleem,[3] Rasheed A. Gbadegesin,[4] Matt G. Sampson,[6] Ali G. Gharavi,[1] Martin Pollak,[5] Friedhelm Hildebrandt,[6] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]University of Michigan, Ann Arbor, MI; [3]University of Bristol, Bristol, United Kingdom; [4]Duke University, Durham, NC; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]Boston Children's Hospital, Boston, MA.*

Background: The genetic causes of idiopathic nephrotic syndrome (INS) have traditionally been studies using family-based approaches and comprehensive association studies across the age of onset, response to therapy, and ancestries are lacking.

Methods: We conducted an exome sequencing (ES) study on 5,262 children and adult cases with INS caused by focal segmental glomerulosclerosis or minimal change disease, including 1,998 steroid sensitive cases (SSNS) and 3,264 cases that were not known to be responsive to steroids (either steroid resistant or untreated/unknown). Per-gene burden of rare coding variants was assessed by exome-wide collapsing analysis comparing the above 5,262 cases and 28,637 population controls with ES data under dominant and recessive models. Analyses were conducted on the entire dataset and then again after removal of cases harboring diagnostic/pathogenic Mendelian mutations in known FSGS genes and *APOL1* high-risk genotypes.

Results: In the analysis on the entire cohort, we identified and retrieved association for many of the known FSGS genes, including *WT1* (best $P = 1.09 \times 10^{-23}$; OR= 15.64), *COL4A5* (best $P = 2.37 \times 10^{-17}$; OR= 9.83), *INF2* (best $P = 1.87 \times 10^{-11}$; OR= 12.22), and several others, under dominant models, and *NPHS1* (best $P = 1.56 \times 10^{-21}$; OR= 25.18), *NPHS2* (best $P = 3.93 \times 10^{-15}$; OR= 30.58), *SMARCAL1* (best $P = 9.91$ x 10-9; OR= 31.97) and several others, under a recessive model. This analysis re-classified *CD2AP* as an autosomal recessive cause of INS, and points to mutations in *CLN5* and *OCRL* as common causes of FSGS phenocopies. Removal of solved cases and re-analysis prioritized 5 novel genes that exceeded the 5% false discovery rate (FDR), one gene that represented a phenotypic expansion of a known Mendelian neurodevelopmental disease, and three genes for which mouse models of the orthologues display glomerulopathy. Three of them are novel candidates for steroid resistant NS and two for SSNS.

Conclusions: These findings expand our understanding of the genetic underpinning of INS, identify novel candidate genes, and highlight the high genetic heterogeneity of disease. Genetic and functional validation studies of these results are ongoing.

TH-PO448

Genotype-First Analysis in an Unselected Health System-Based Population Reveals Variable Penetrance of COL4A5 Variants

Alexander R. Chang, Mckenzie R. Zellers, Kaushal V. Solanki, Bryn S. Moore, Tooraj Mirshahi. *Geisinger Health, Danville, PA.*

Background: Current literature suggests that nearly all hemizygous males with *COL4A5* mutations (i.e. X-linked Alport Syndrome [AS]) progress to end-stage kidney disease (ESKD) though most data come from selected cohorts.

Methods: We used exome sequencing data from the Geisinger MyCode DiscovEHR study, an unselected health system-based cohort with exome sequencing and electronic health record data to identify patients with *COL4A5* variants reported as pathogenic (P) or likely pathogenic (LP) in ClinVar. Phenotypic data sources included the United States Renal Data System (USRDS), ICD codes, blood and urinalysis data. Patients were categorized into Kidney Disease Improving Global Outcomes (KDIGO) risk categories using estimated glomerular filtration rate (eGFR) and albuminuria (preferentially) or urine dipstick protein data.

Results: Out of 174,418 participants, there were 24 hemizygous males (mean age 53.8 [SD 19.5] years) and 55 heterozygous females (mean age 59.8 [SD 17.6]) with a P/LP *COL4A5* variant, including Gly624Asp (n=48) and 9 missense and 4 protein truncating variants. Overall, 41% of males had KDIGO severely increased risk category and 4% of females had severely increased risk category with lower severity for Gly624Asp than other variants **(Figure)**. In logistic regression analyses adjusted for age, sex, and race, hemizygous males and heterozygous females were at increased risk of ESKD (females: OR 5.2, 95% CI: 1.2, 21.3; males: OR 36.1, 95% CI: 14.5, 89.7). Few had been diagnosed with Alport Syndrome (21% of males, 9% of females). Only 45% of individuals had completed albuminuria screening, and ~1/3 were taking renin angiotensin aldosterone system (RAAS) inhibitors.

Conclusions: In an unselected cohort, we demonstrate a wider spectrum of kidney severity in men and women than has been described previously with variability by genotype. Future studies are needed to determine whether early genetic diagnosis can improve outcomes in Alport Syndrome.

Small but Clinically Relevant Contribution of Copy Number Variations (CNVs) to Idiopathic Nephrotic Syndrome

Tze Yin Lim,[1,2] Yask Gupta,[1] Juntao Ke,[1] Adele Mitrotti,[1,3] Gina Jin,[1] Matt G. Sampson,[4] Moin Saleem,[5] Ali G. Gharavi,[1] Martin Pollak,[6] Friedhelm Hildebrandt,[4] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]Universita degli Studi di Torino, Torino, Italy; [3]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [4]Boston Children's Hospital, Boston, MA; [5]University of Bristol, Bristol, United Kingdom; [6]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Idiopathic Nephrotic Syndrome (INS) is a frequent cause of kidney failure. The utility of genetic diagnostics within the context of rare variants affecting Mendelian NS-associated genes have been demonstrated on patients with various kidney disease. Nevertheless, genetic studies have overwhelmingly assessed the contribution of single nucleotide variants while the contribution of rare Copy Number Variations (CNV) to INS remains poorly understood.

Methods: We conducted chromosomal DNA microarray (CMA) genotyping on a multi-ethnic cohort of 3,600 INS patients across ages of onset and response to immunosuppressive therapy. An interim analysis of 2,230 INS cases was conducted. To extract CNVs, we used PennCNV with default parameters. Predicted CNVs were annotated against the CNV start and stop boundaries of 221 known Genomic Disorders (GD) and a curated list of 126 genes that, when mutated, are known to cause INS/FSGS or a phenocopy of it. A subgroup analysis will be conducted after the removal of solved cases via exome sequencing, partitioning by age of onset, response to therapy, and genetic ancestry.

Results: 18 of 2,230 INS individuals (0.8%) carried a GD-CNV without significant enrichment for a particular subcategory. Notably, we identified 6 (0.3%) individuals with smaller deletions that encompassed INS-associated genes for which a loss-of-function mechanism of disease determination is known: *NPHS1* (N=2), *FRAS1*, *HNF1B*, *LMX1B*, and *WDR73*.

Conclusions: This interim analysis showed that the overall CNV diagnostic rate for INS is relatively low, (< 2%), but should not be overlooked since these variants add to the overall genetic diagnostic workup and have direct implications in clinical management for NS (ex steroid avoidance) and risk stratification for extra-urinary complications associated to these variants.

TH-PO450

The Polygenic Burden of Rare Variants Predicts Onset of CKD in the UK Biobank

Ricky Lali,[1,3] Caitlyn Vlasschaert,[2,4] Matthew B. Lanktree.[1,3] *[1]McMaster University, Hamilton, ON, Canada; [2]Queen's University, Kingston, ON, Canada; [3]McMaster University Department of Health Research Methods Evidence and Impact, Hamilton, ON, Canada; [4]Queen's University Department of Medicine, Kingston, ON, Canada.*

Background: Genetic contributors to chronic kidney disease (CKD) have been explored through monogenic mechanisms by rare mutations and polygenic mechanisms through the aggregate impact of many small-effect common variants. In this work, we test whether a polygenic burden of rare variants across numerous genes contributes to CKD by constructing a rare variant polygenic risk score (rvPRS).

Methods: We first conducted a discovery exome-wide association study (ExWAS) of rare protein-truncating variants with a calculated severe CKD phenotype based on eGFR below 30 ml/min/1.73m2 using a discovery set of 834 cases and 147,855 British European controls in the UK Biobank (UKB). After excluding known Mendelian CKD genes, an rvPRS was constructed of 124 nominally significant ($P<0.05$) *risk* genes associated with severe CKD. As such, the effect conferred through rvPRS124 would not be driven through underlying monogenic mechanisms. We then tested the predictive power of rvPRS124 using a validation set consisting of 688 independent CKD events in the UKB.

Results: In the validation set, rvPRS124 conferred a 21% increase in hazard for incident CKD onset with one rare protein-truncating allele (HR=1.21; 95%CI, 1.01-1.46; P=0.045) after adjusting for age, sex, the first 5 principal components of ancestry, and pertinent clinical risk factors including obesity, myocardial infarction, and smoking. Individuals with 2 or more rvPRS124 alleles (N=1,352) had a 10-fold increase in hazard

for CKD onset compared to individuals with no rvPRS124 variants (HR=10.0, 95% CI, 2.5-39.4; P=1.3 x 10-3). No single gene in rvPRS124 replicated an association with CKD after adjusting for multiple hypothesis testing (P<4x10-4; 0.05/124), which emphasizes the importance of rare variant polygenic mechanisms underlying CKD. Lastly, through 1000 permutations of random gene sets, we show that the association of rvPRS124 with CKD was specific to the selected genes used to construct the score and not solely due to the gene count (P<0.05).

Conclusions: Using the UKB, we demonstrate a cumulative impact of rare protein-truncating variants in genes not known to have monogenic effects on CKD. An omnigenic score, incorporating established clinical risk factors and both Monogenic and common variant polygenic effects, should also include the polygenic burden of rare variants in non-Mendelian CKD-related genes.

TH-PO451

Unraveling the Unknown: A Few Illustrative Examples of the Utility of Genetic Testing for CKD

Steffi Sathiyaraj, Yariana E. Rodriguez Ortiz, Angelina Edwards, Tariq Shafi. *Houston Methodist, Houston, TX*.

Introduction: Genetic testing can offer critical insight into diagnosing disease states that were previously challenging to identify. In the context of CKD, genetic testing using commercially available panels can provide valuable information to guide personalized treatment decisions. We highlight three cases seen in our clinic over the past six months that illustrate the value of genetic testing for CKD.

Case Description: Case 1: 75- year-old self-identified Black male presented to the clinic with elevated creatinine and significant history of treatment-resistant hypertension and hypokalemia. Subsequent workup was consistent with Primary Hyperaldosteronism (plasma aldosterone-renin ratio, 58). Genetic testing, pursued initially to identify glucocorticoid remediable hyperaldosteronism, revealed a CACNA1H mutation, consistent with Type 4 Familial Hyperaldosteronism. Case 2: 56-year-old self-identified Black male with a history of ischemic cardiomyopathy and orthotopic heart transplant seven years ago was evaluated for worsening creatinine. A renal biopsy showed secondary focal segmental glomerulosclerosis and hypertensive arteriosclerosis attributed to calcineurin inhibitors. Genetic testing revealed APOL1 homozygosity with G1/G1alleles. Case 3: 41-year-old self-identified Black female was evaluated for persistent albuminuria and intermittent hematuria over several years with stable serum creatinine. She had no significant medical co-morbidities or family history. Genetic testing revealed COL4A3 mutation, seen with Alport's syndrome without sensorineural hearing loss.

Discussion: In summary, these cases highlight the tremendous clinical utility of genetic testing in a CKD clinic. As genetic testing technologies continue to advance and emerge for specific renal diseases, such as APOL1-mediated CKD, routine genetic testing for patients with CKD is worth considering.

TH-PO452

Reclassification of Genetic Diagnoses: Need for Structure in Re-Evaluation of Genetic Findings

Clara Schott,[1,2] Cadence Baker,[2] Samantha Colaiacovo,[2] Dervla M. Connaughton.[1,2] *[1]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada*.

Introduction: Constant advances and emerging data in genomic medicine causes classification of genetic findings to be dynamic. In kidney disease (KD) alone, the number of single gene disorders are increasing, with over 600 genes described thus far. Genetic variant pathogenicity is classified according to the American College of Medical Genetics (ACMG) guidelines. Although the ACMG guidelines provide a classification with >95% certainty, variants of unknown significance (VUS), which do not have enough information to classify, may be reclassified when more information becomes available. The ACMG guidelines suggest that all new data should be incorporated into the genetic evaluation as it becomes available. This includes, but is not limited to, any new patient specific clinical information, family data, and population and case data in the literature. Currently, there are no protocols guiding when and how often to reevaluate genomic data. We present a case which highlights the importance of periodic genetic re-evaluation in a living donor post kidney donation.

Case Description: A 45-year-old female donated her left kidney as a non-directed altruistic donor. At the time of donor assessment, her creatinine was normal (60-70mmol/L), however, she had persistent microscopic hematuria. Given a positive family history of KD in a maternal uncle, genetic testing was performed. This revealed a variant of unknown significance (VUS) in COL4A4 c.3307G>A, p.G1103R. Since a VUS is not considered a clinically actionable finding, she elected to proceed with donation. Unfortunately, 5-years post-donation, she had progressive rise in creatinine (125 umol/L). An updated pedigree analysis now revealed that two of her children had developed KD and hearing impairment, prompting reanalysis. New clinical data and additional data in literature supported pathogenicity of this variant warranting reclassification to pathogenic, supporting a familial diagnosis of Alport Syndrome.

Discussion: We show that reevaluation of patient genomics can lead to reclassification of previously identified variants, which can have significant clinical implications for the patient and at-risk family members. This case highlights both the importance of re-analysis of genomic data and the clinical implications of establishing a genetic diagnosis for family screening and decision making for transplants.

TH-PO453

The Role of Whole-Exome Sequencing in Diagnosis of Genetic Disorders: A Case Report of a Novel Mutation in the Fibrinogen A-Alpha Chain Gene

Roxana A. Jurubita, Bogdan Obrisca, Lungu I. Adrian Catalin, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania*.

Introduction: Hereditary fibrinogen amyloidosis (AFib) was first characterized in 1993 in a Peruvian kindred. Patients with AFib present with renal disease and typically progress to ESRD. We describe a case of Afib with a novel mutation in the FGA gene identified by whole-exome sequencing (WES).

Case Description: A 51-year-old male patient presented to the nephrology clinic for the evaluation of a nephrotic range-proteinuria (5.4 g/day) and decreased eGFR (35 ml/min/1.73m^2). His family history was notable for stage V CKD of unknown cause (patient's mother). His past medical history is remarkable for a ruptured spleen and splenectomy following a minor trauma, two years prior to current evaluation. The initial work-up was negative for autoimmune disorders, hepatitis serology, malignancy screening, monoclonal gammopathy. The kidney biopsy revealed severe amyloid deposition with striking glomerular enlargement and almost complete obliteration of the normal architecture, without vascular or interstitial involvement. The reevaluation of splenic tissue did also reveal extensive amiloyd deposition. The bone marrow biopsy was negative and the patient didn't have any prior history of a chronic inflammatory process (serum amyloid A protein was slightly increased, 19 mg/L). Typing of amyloid by immunohistochemistry (IHC) could not reliably differentiate between AA amyloidosis and AFib. Because the initial genetic testing for hereditary amyloidosis (including testing for SAA1 promoter gene) was negative, a WES was further performed. The patients was identified to be heterozygous for two variants of uncertain significance (VUS) of FGA gene, c.1676A>T, p. (Glu559Val) and c. 967C>G, p. (Pro323Ala).

Discussion: This case report illustrates the limitations of amyloid typing by IHC and the role of WES in identifying novel mutations in hereditary amyloidosis. The patient was heterozygous for two VUS of FGA gene, of which the c.1676A>T, p. (Glu559Val) has been previously reported in two German sisters with AFib, while the c. 967C>G, p. (Pro323Ala) has not been reported in the medical literature. Despite that both variants were reported to be VUS, the correlation with the patient's family history and the severity of renal and splenic involvement further outlines that these variants are clinically significant.

TH-PO454

An Unusual Genetic Etiology for Adult-Onset FSGS

Khalid A. Mohamed,[1] Ahmed E. Subahi,[2] Hanna Almoaswes,[1] Siddhartha D. Bajracharya,[1] Rajesh Mohandas.[1] *[1]LSU Health New Orleans, New Orleans, LA; [2]Beaumont Hospital Dearborn, Dearborn, MI*.

Introduction: Focal segmental glomerulosclerosis (FSGS) is a histological pattern that is commonly associated with nephrotic syndrome and characterized by damage to the podocyte cytoskeleton. Genetic FSGS results from mutations in genes encoding podocyte proteins, particularly those predominantly expressed in the slit diaphragm. Here we discuss a case of genetic FSGS associated with mutation of a gene predominantly expressed in the proximal tubules.

Case Description: A 31-year-old African American male was referred to the renal clinic for evaluation of stage IV chronic kidney disease (CKD) and nephrotic range proteinuria. He had a history of well-controlled hypertension (not on any antihypertensives) and non-obstructive nephrolithiasis. Given proteinuria of more than 3 grams, suggesting glomerular disease and uncertain etiology of his CKD, a renal biopsy was performed. Biopsy revealed focal segmental glomerulosclerosis and severe interstitial fibrosis with tubular atrophy. Given the patient's age and the unclear etiology of his FSGS, genetic testing was conducted, which revealed a homozygous mutation in the CLCN5 gene, consistent with Dent Disease type 1.

Discussion: Dent Disease type-1 is a rare X-linked recessive disease due to mutations in the CLCN5 gene that encodes for the electrogenic Cl-/H+ exchanger. It usually manifests with proximal tubular dysfunction including low-molecular-weight proteinuria, hypercalciuria, nephrolithiasis, and progressive CKD. A novel mutation (L521F) in the CLCN5 gene has been reported to cause defects in podocyte transport and FSGS. However, the L521F mutation is usually not associated with hypercalciuria or nephrolithiasis. Our patient had evidence of both glomerular and tubular involvement. Our case demonstrates the value of genetic testing in patients with CKD of uncertain etiology, particularly in younger patients or those with unusual presentations. Understanding the genetic basis of kidney disease can lead to novel discoveries in renal physiology.

TH-PO455

Monogenic Causes Identified in 30.70% of Children with Steroid-Resistant Nephrotic Syndrome: A Single-Centre Study

Luyan Zhang, Bixia Zheng, Aihua Zhang. *Children's Hospital of Nanjing Medical University, Nanjing, China*.

Background: Steroid resistant nephrotic syndrome (SRNS) is the second most common cause of end-stage kidney disease in children, mostly associated with focal segmental glomerulosclerosis (FSGS). Advances in genomic science have enabled the identification of causative variants in 20 – 30% of SRNS patients.

Methods: We used whole exome sequencing (WES) to explore the genetic causes of SRNS in children. Totally 101 patients with SRNS, and 13 patients with subnephrotic proteinuria and FSGS were retrospectively enrolled in our hospital between 2018 and 2022. For the known monogenic causes analysis, we generated a known SRNS gene list of 71 genes through reviewing the OMIM database and literature.

Results: Causative variants were identified in 30.70% of our cohort, and the most frequently mutated genes in our cohort were WT1 (7/33), NPHS1 (3/33), ADCK4(3/33), TRPC6(3/33) and ANLN (3/33). Five patients carried variants in phenocopy genes, including MYH9, MAFB, TTC21B, AGRN, and FAT4. The variant detection rate was the highest in the two subtype groups with congenital nephrotic syndrome and syndromic SRNS. In total 68.75% of variants we identified were novel, and have not been previously reported in literature.

Conclusions: Comprehensive genetic analysis is key to realizing the clinical benefits of a genetic diagnosis. We suggest that all children with SRNS undergo genetic testing, especially those with early onset and extrarenal phenotypes.

TH-PO456

Genetic Causes of Focal Segmental Glomerulosclerosis in Koreans

Hyeri Shin,[1] Naye Choi,[1] Hyeonju Lee,[1] Ji hyun Kim,[3] Hajeong Lee,[4] Yo Han Ahn,[1,2] Jin-Soon Suh,[5] Hee Gyung Kang.[1,2] *[1]Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea; [4]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [5]Catholic University of Korea Bucheon Saint Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea.*

Background: Focal segmental glomerulosclerosis (FSGS) is a relatively common pathologic findings of nephrotic syndrome or chronic kidney disease (CKD) presenting proteinuria. Genetic FSGS, usually not responding to immunosuppressive medications, is more common in younger patients and those who have a family history of kidney disease. Common genetic causes of FSGS include mutations reported COL4A mutations in families, but those of Korean population have not been well investigated.

Methods: The Korean Genetic Kidney Disease Cohort study is enrolling patients with kidney diseases of presumably genetic origin since 2021. Clinical characteristics of the cases were collected by the referring physicians and the genomic DNA of the enrolled cases were sequenced by multiple parallel sequencing of whole exome sequencing. Pathogenicity of variants were interpretated according to the American College of Medical Genetics (ACMG) guideline referring the resources of gnomAD (genome Aggregation Database), ClinVar (National Center for Biotechnology Information ClinVar Database), VarSome and other in silico prediction tools.

Results: Of a total 453 prospective cases of the our cohort, 124 cases (27.4%, Male:Female 64:60, mean age of diagnosis 20.8 year (range 0-78.7 years)) had pathological diagnosis of FSGS. Among them, 20.9% had a positive family history. Genetic diagnosis was obtained in 40.3% (n=50), among which COL4A3-5 (n=8) were the most commonly found causative gene, followed by NPHS1 (n=6), PAX2 (n=5), WT1 (n=4), COQ6/8B (n=4), NUP107 (n=3), TRPC6 (n=3), LAMA5 (n=2), MYH9 (n=2), MAFB (n=1). Gene testing changed the diagnosis in 8 (FSGS to Alport syndrome (AS)), lead to extrarenal manifestation screening in 8 (AS, PAX2, MYH9, and MAFB), and provided information on potential treatment (coenzyme Q10) in 4 with COQ6/8b mutations.

Conclusions: We found that proportions of causative genes in Korean FSGS are different from previous results of Western countries. Similar to the literature, gene testing was useful in obtaining more precise diagnosis and guiding management.

TH-PO457

Getting the Full Picture: Identifying Cases with Multiple Genetic Diagnoses Using Comprehensive Renal Gene Testing

Emily Hendricks, Tessa R. Pitman, Margaret Westemeyer, Akash Anand, Megan M. Hager, Sumit Punj, Quinn P. Stein. *Natera, Inc., Austin, TX.*

Background: Comprehensive genetic testing can provide genetic diagnoses for kidney disease of unknown etiology and those with unexpected phenotypes due to multiple genetic causes.

Methods: Analysis of 42,221 samples tested with the Renasight™ test was performed to identify cases with diagnostic findings in ≥ 2 genes. The cases were categorized based on: 1) disease penetrance: high (variants are expected to cause the condition) or susceptible (variants provide risk for disease development) and/or 2) disease phenotypic presentation: a) distinct phenotypes (2 conditions with dissimilar symptoms), b) same phenotype (2 distinct conditions with the same symptoms), c) combined phenotype (2 distinct genes that interact to cause the same disease (Digenic)).

Results: A total of 818 cases with multiple positive results spanning 130 genes (787 dual and 31 triple) were found, accounting for 7.7% of all tests with a positive result. Of the 369 different gene combinations identified, 274 occurred only once. The most common positive gene result was *APOL1* (344, 42.1%), among which, additional positive findings included: high penetrance genes with expected distinct phenotypes (28.9%), *TTR* (associated with cardiac amyloidosis; 9.5%) and other susceptibility genes (1.2%). Multiple positive findings among the non-*APOL1* cases (56.4%) included those with 2 high penetrance genes that cause distinct phenotypes (35.3%), cases with both a high penetrance gene and a susceptibility gene (8.91%), and cases with a *TTR* finding and a second high penetrance gene (7.2%). Digenic findings comprised 3.8% of all multiple positive cases and those with two separate gene findings that independently cause the same phenotype comprised 1.2% (Table).

Conclusions: We found that 7.7% of patients with genetic kidney disease had multiple etiologies that encompassed a wide range of genes and combinations demonstrating that comprehensive genetic testing is crucial for identifying the full range of genetic causes of kidney diseases that may be missed by traditional testing methods.

	Result Category	Number of Cases (%)
Triple positives		31 (3.8%)
Dual positives	**APOL+**	**325 (39.7%)**
	a. *APOL1* + high penetrance gene (e.g. *COL4A3, PKD*)	237 (28.9%)
	b. *APOL1* + *TTR*	78 (9.5%)
	c. *APOL1* + susceptibility gene	10 (1.2%)
	Non-*APOL*	**462 (56.4%)**
	a. 2 high penetrance genes, separate phenotypes	289 (35.3%)
	b. Susceptibility (e.g. *ABCC8*, complement) + high penetrance gene (e.g. *COL4A3, PKD, HBB*)	73 (8.9%)
	c. *TTR* + high penetrance gene (e.g. *COL4A3, PKD, HBB*)	59 (7.2%)
	d. Digenic (e.g *COL4A3* + *COL4A4*)Genes that cause same phenotype (e.g. *PKD1/PKD2*)	31 (3.8%)

Table: Summary of the dual and triple positive findings results

TH-PO458

Genome-Wide DNA Methylation Association Study Identifies DNA Methylation Associated with ESRD

Xiaohong Zhou.[1,2] *[1]Guangdong Provincial People's Hospital, Guangzhou, China; [2]Guangdong-Hong Kong Joint Laboratory on Immunological and Genetic Kidney Diseases, Guangzhou, China.*

Background: Kidney disease is a progressive condition afflicting >10% of the general population worldwide, of which progression to end-stage renal disease (ESRD) caused poor quality of life and significant premature mortality. Defining DNA methylation biomarkers and understanding their roles in ESRD may help develop preventive and therapeutic strategies for kidney disease progression.

Methods: We conduct a blood-based genome-wide DNA methylation association study of ESRD in 2 independent cohorts (consisting of 1924 samples) from China and Singapore. Two-sample summary-level Mendelian randomization analysis was performed to evaluate the causality of the associations between methylation at DMP and kidney function (eGFR/eGFR decline). We also attempted to identify the candidates of ESRD-related genes underlying the significant associations by integrating the regulatory information from multiple public and published datasets. Using publicly available tools, we analyzed drug candidates for prevention or treatment of CKD progression based on ESRD-related genes.

Results: We identified a total of 922 differentially methylated positions (DMPs) at genome-wide significance ($P < 9e-8$). Regulatory function analysis of these DMPs have implicated 1255 candidate ESRD-related genes, which are enriched for biological processes related to immunity, GTPase activator activity, and signal complex assembly. All the candidate genes were enriched in key regulatory elements for gene function, including accessible chromatin elements. Of these candidate ESRD-related genes, some are the targets of investigational or approved drugs. Mendelian randomization revealed some causal association between DMPs and kidney function (eGFR/eGFR decline).

Conclusions: Our study demonstrated that DNA methylation play a significant role in the progression of kidney disease. Our study has not only identified DMPs as potential biomarkers for predicting renal progression and further implicated genes as potential therapeutic targets for ESRD treatment.

TH-PO459

Aberrant Splicing Caused by Intronic Variants Positioned at Third to Fifth Nucleotides in COL4A5

Hideaki Kitakado,[1] Yuya Aoto,[1] Eri Okada,[1,2] Yuta Ichikawa,[1] Yu Tanaka,[1] Chika Ueda,[1] Ryota Suzuki,[1,3] Atsushi Kondo,[1] Nana Sakakibara,[1] Tomoko Horinouchi,[1] Kandai Nozu.[1] *[1]Kobe Daigaku, Kobe, Japan; [2]Tsukuba Daigaku Fuzoku Byoin, Tsukuba, Japan; [3]Hokkaido Daigaku Daigakuin Igaku Kenkyuin, Sapporo, Japan.*

Introduction: Alport syndrome is an inherited kidney disease caused by the variants of *COL4A3, COL4A4,* or *COL4A5*, which encode type IV collagen. Among them, approximately 80% of cases have X-chromosome-linked pathogenic variants of *COL4A5*. According to recent advances in genetic analysis, a number of novel variants have been detected in Alport syndrome. It has been already known that single nucleotide substitutions in the introns positioned at 1st and 2nd from the last nucleotide of exons always cause aberrant splicing in general.

Case Description: Methods: We extracted intronic 11 variants positioned at 3rd, 4th, and 5th from the last nucleotide of exons in *COL4A5*, in our Alport syndrome cohort from January 2006 to July 2022. We performed minigene in-vitro splicing assays, and if available, we also performed messenger RNA (mRNA) sequences obtained from patients' samples. Results: The variants' positions are as follows; 3rd in three, 4th in two, and 5th in six patients. All 11 patients had hematuria, and at least 9 of them had also proteinuria. The minigene splicing assay revealed aberrant splicing, particularly upstream entire exon skipping in all variants. Moreover, the results of mRNA sequences in six cases were consistent with those of the minigene splicing assay results.

Discussion: This study revealed that the intronic variants positioned at 3rd, 4th, and 5th from the last nucleotide of exons in *COL4A5* are highly likely to cause aberrant splicing. It is also revealed that the hybrid minigene splicing assay may be useful, especially when patients' samples were not available for mRNA sequences. Intronic variants close to the exons are likely to be pathogenic and when those intronic variants are detected pathogenicities need to be evaluated.

TH-PO460

Monogenic Disease Variants in the Swiss Kidney Stone Cohort and Stone-Free Controls

Johannes Muench,[1,2] Joana F. Silva,[2] Elena M. Cabello,[2] Isabel Rubio-Aliaga,[1] Daniel G. Fuster,[3,4] Florian Buchkremer,[5] Grégoire Wuerzner,[6] Alexander Ritter,[7] Beat Roth,[8] Olivier Bonny,[9,4] Carsten A. Wagner,[1,4] Ruxandra Bachmann-Gagescu.[2] *[1]Universitat Zurich Physiologisches Institut, Zurich, Switzerland; [2]Institute of Medical Genetics, University of Zurich, Zurich, Switzerland; [3]Department of Nephrology & Hypertension, University Hospital Bern, Bern, Switzerland; [4]National Center of Competence in Research NCCR Kidney, Zurich, Switzerland; [5]Division of Nephrology, Cantonal Hospital Aarau, Aarau, Switzerland; [6]Lausanne University Hospital, Service of Nephrology and Hypertension, Lausanne, Switzerland; [7]Department of Nephrology, University Hospital Zurich, Zurich, Switzerland; [8]Department of Urology, CHUV, University of Lausanne, Zurich, Switzerland; [9]Hopital Fribourgeois, Fribourg, Switzerland.*

Background: With a lifetime prevalence of 10%, kidney stones (KS) are among the most common diseases. KS disease (KSD) has a complex pathogenesis influenced by a variety of factors, including dietary intake, fluid consumption, metabolic abnormalities, and a genetic predisposition. A thorough understanding of both the genetic and biochemical factors is crucial for a better diagnosis, therapy and prevention. However, data from larger cohorts with KSD with detailed profiling are scare.

Methods: The Swiss Kidney Stone Cohort (SKSC) is a multicenter longitudinal observational study consisting of two distinct groups: Kidney stone formers (KSF) and matching non-KSF (NKSF; status confirmed by low-dose CT scan). Blood and urine samples were collected at baseline (KSF, NKSF) and periodically over a 3-year period (KSF). Exome sequencing was performed in all participants, and variants in established KSD genes were assessed according to the ACMG/AMP criteria with subsequent genotype/phenotype analysis for KSF and NKSF.

Results: 731 KSF and 201 NKSF were included. A diagnosis of monogenic KSD was established in 10.1% of KSF. (Likely) pathogenic variants were predominantly located in genes encoding proteins involved in phosphate/calcium metabolism (*SLC34A1*, *SLC34A3*, *ALPL*, *CYP24A1*) or cystinuria (*SLC3A1*, *SLC7A9*). Of note, 4.5% of NKSFs also carried (likely) pathogenic variants in KSD genes and displayed matching biochemical parameters (e.g., NKSF with *SLC34A1* variants had comparable reduction of TmP/GFR). In addition, our longitudinal follow-up revealed that among KSFs, patients with monogenic KSD showed a significantly steeper decrease in eGFR over a 36-month period (ΔeGFR -4.9 vs. -2.0 mL/min/1.73 m^2, p=0.027).

Conclusions: The SKSC is the hitherto largest genetically analyzed KS cohort, accompanied by a control group of confirmed NKSF. The comparison with NKSFs, who also carried (likely) pathogenic variants in KS genes, suggests that KS occurrence may depend on additional factors that may be either genetic (additional rare or common variants) or environmental. Additionally, the results from genetic analysis in KS genes can help identify patients at higher risk for a faster decline in kidney function.

Funding: Government Support - Non-U.S.

TH-PO461

Mayo Clinic Experience with TRPC6 Mutations Using Clinical Whole Exome Sequencing

Poemlarp Mekraksakit,[1] Silvia Titan,[1] Fernando C. Fervenza,[1] Ladan Zand,[1] Lynn D. Cornell,[1] Arvind K. Garg,[2] Mireille El Ters,[1] Marie C. Hogan.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mayo Clinic Health System, La Crosse, WI.*

Background: Integration of genomic and research testing and multidisciplinary evaluation in a nephrology cohort with CKD of unknown etiology or suspected monogenic disease provides a diagnosis in approximately a third of families in our center. The TRPC6 gene, a member of the transient receptor potential (TRP) superfamily of cation-selective ion channels, encodes the slit diaphragm-associated canonical TRP cation channel C6 protein expressed in podocytes. Around 20 missense mutations have been reported, including nine gain-of-function and five loss-of-function mutations that affect TRPC6 channel activity. We present our experience at the Mayo Nephrology Clinic with cases of proteinuric chronic kidney disease found to have TRPC6 variants.

Methods: Testing utilized kidney/nephrotic disease panels, single gene analysis, or analysis of kidney-related genes from exome sequencing. The Nephrology Genomics Board, composed of nephrologists, geneticists, and pathologists, interpreted the patients' clinical and genetic data. Kidney biopsy was performed for most patients. Variant classification followed the 2015 guidelines from the American College of Medical Genetics and Genomics and the Association for Molecular Pathology.

Results: Eight probands, all adults, were identified with TRPC6 variants and proteinuric CKD. All variants clustered in Exons 1, 2, and 13. We provided a definitive genetic diagnosis for three probands with pathogenic or likely pathogenic variants, one of which has not been reported previously. In addition, five cases had variants of interest, and among them, three had other first-degree family members with CKD as well. One of the cases with a positive family history had a sibling who was accepted for kidney donation after the donor tested negative for TRPC6 variants.

Conclusions: In summary, TRPC6-related CKD diagnoses have diagnostic and prognostic implications, enabling a more precise diagnosis and changes in management, including the evaluation of safety for living kidney donation. Furthermore, further studies on the functional analysis of TRPC6 variants may provide new insights into diagnostic precision and the mechanisms of the disease.

Age of genetic testing	c. change	p. change	Allele frequency (GNOMAD)	Functional evidence	ESRD	Pathogenicity	Family history

LP: Likely pathogenic; VUS: Variant of undetermined significance

TH-PO462

TRPC6 Nephropathy: An International Registry of Prevalence and Outcome

Susan M. McAnallen,[1,2] Elhussein A. Elhassan,[1] Eoghan White,[1] Kendrah O. Kidd,[3] Rasheed A. Gbadegesin,[4] Anthony J. Bleyer,[3] Peter J. Conlon.[1] TRPC6 Research Group. *[1]Beaumont Hospital, Dublin, Ireland; [2]Saint James's Hospital, Dublin, Ireland; [3]Wake Forest University School of Medicine, Winston-Salem, NC; [4]Duke University School of Medicine, Durham, NC.*

Background: Monogenic forms of focal segmental glomerulosclerosis(FSGS) represent an important subset of patients with nephrotic syndrome. They often have an ominous clinical course reaching end-stage renal disease(ESRD) at a young age. Variants in *TRPC6*(a non-selective calcium channel) have been described to cause autosomal dominant ESRD. Most have been described as "activating"variants, resulting in increased influx of calcium into the podocyte, precipitating the sclerosing process.*TRPC6* is a rare disease with many cases reported to date arising from a large New Zealand kindred. Recently, a compound targeting*TRPC6*has entered clinical trial-making understanding the natural history all the more important.

Methods: We established a*TRPC6*collaborative research group&developed a questionnaire focusing on natural history, variability in phenotype&gene variants. This has been circulated internationally to professionals involved in inherited kidney disease, nephrologists worldwide&those who have previously published on*TRPC6*.

Results: To date, we have received responses involving38patients worldwide(Europe, UK, Asia, Australia, New Zealand, North America and Africa) from 21 families, identifying 17 variants. The majority are missense, with commonest variants located on exons 2&13. Average age of genetic testing-32 years old. All but three patients experienced symptoms before the age of 40(six were 10 years old or younger). Presentation varied from microalbuminuria to anasarca&pre-eclampsia;most presenting with nephrotic syndrome, six presented with ESRD. Four patients were found to have hearing impairment.18patients underwent renal biopsy, 14(78%) demonstrated FSGS. 19patients progressed to ESRD-median age of 29 years old.12 patients have undergone transplantation(10 of which are still functioning). Three patients have had recurrence of nephrotic syndrome, two of which still have graft function. The third patient lost graft function after two years, aged 28. One patient died from complications related to dialysis. To the best of our knowledge the remaining are alive with self-supporting renal function&varying degrees of CKD.

Conclusions: *TRPC6* is a rare cause of monogenic ESRD presenting with nephrotic syndrome. The condition shows considerable variability in disease progression. New treatments are becoming available in effort to reduce immunosuppression burden.

TH-PO463

The Natural History and Genetics of TRPC6-Associated Podocytopathy

Benjamin Wooden,[1] Gina Jin,[1] Yask Gupta,[1] Ken Saida,[2] Adele Mitrotti,[6] Krzysztof Kiryluk,[1] Dominick Santoriello,[1] Vivette D. D'Agati,[1] Ali G. Gharavi,[1] Moin Saleem,[3] Rasheed A. Gbadegesin,[4] Friedhelm Hildebrandt,[2] Martin Pollak,[5] Simone Sanna-Cherchi.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]Boston Children's Hospital, Boston, MA; [3]University of Bristol, Bristol, United Kingdom; [4]Duke University School of Medicine, Durham, NC; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: Pathogenic variants in TRPC6 account for a small but significant proportion of inherited podocytopathy. TRPC6 podocytopathy is caused mainly by gain-of-function mutations increasing the open probability of the encoded channel, making it potentially amenable to inhibitory drug therapy. Understanding the natural history and spectrum of genetic variation is therefore of considerable importance. Here, we report on the outcome data and mutational spectrum of a large cohort of patients with TRPC6-associated podocytopathy.

Methods: A cohort of 86 patients with TRPC6 variants and proteinuric kidney disease from 51 families was assembled. All patients underwent exome/genome sequencing and targeted Sanger sequencing. Affected regions of the TRPC6 protein were visualized using the cBioPortal mutation mapper, and predicted effects of mutations on the TRPC6 protein were generated using several validated in silico scoring systems (REVEL, CADD, PrimateAI, and Polyphen-2). Clinical data were collected and used for genetic correlations.

Results: 33 independent TRPC6 variants were identified. The majority of variants had high pathogenicity scores, though only 45% of them have existing ClinVar annotation. Variants were clustered in 3 regions, with one cluster in the early ankyrin repeat, a second in the transient receptor ion channel (TRP_2) domain, and a third at the C-terminal end. Within the cohort, age of onset of kidney disease ranged from <1 year to 53 years, with a median of 19 years. Data regarding progression to ESRD were available for 65% of patients; of these, 68% developed ESRD, with a median age of 31 years (ranging from 1 to 57 years).

Conclusions: TRPC6-associated podocytopathy is a rare cause of genetic FSGS. We have assembled a large cohort of patients, demonstrating high intra- and inter-familial variability in age at presentation and outcomes, and that the resulting kidney disease is progressive and frequently results in ESRD. Granular clinical genetic and kidney pathology correlations are ongoing.

TH-PO464

Five Cases with MAFB Variants

Yu Tanaka,[1] Nana Sakakibara,[1] Yooka Nam,[2] Takaaki Kigoshi,[3] Yoichiro Ikeda,[4] Yuta Ichikawa,[1] Hideaki Kitakado,[1] Chika Ueda,[1] Ryota Suzuki,[5] Eri Okada,[6] Atsushi Kondo,[1] Tomoko Horinouchi,[1] Tetsuji Inagaki,[3] Naoya Morisada,[1] Kandai Nozu.[1] *[1]Kobe Daigaku, Kobe, Japan; [2]Matsudo City General Hospital, Matsudo, Japan; [3]Miyagi Kenritsu Kodomo Byoin, Sendai, Japan; [4]Tokyo Daigaku, Bunkyo-ku, Japan; [5]Hokkaido Daigaku, Sapporo, Japan; [6]Tsukuba Daigaku, Tsukuba, Japan.*

Introduction: The pathogenic variants in *MAFB* gene cause multicentric carpal tarsal osteolysis syndrome (MCTO) (OMIM: # 166300), an N-terminal variant characterized by progressive destruction of the bones, and Duane retraction syndrome (DRS) (OMIM: # 617041), a C-terminal variant characterized by congenital eye movement abnormalities, whose inheritance pattern is autosomal dominant. Nephropathy have been reported in about half of the patients with MCTO and in five patients in three families with DRS. Only one case with DRS family history of nephropathy without extrarenal manifestations (isolated-FSGS) has been reported in the past.

Case Description: Five cases with pathogenic variants in *MAFB* were diagnosed in our department, four with MCTO and one with isolated-FSGS. Among four cases with MCTO, case1 showed congenital nephrotic syndrome (CNS), case 2 nephrotic syndrome, case 3 persistent proteinuria, and case 4 bone lesions, respectively. Genetic analysis revealed heterozygous missense variants in all four cases with MCTO (case 1 and 2: c. 212 C > T, p. (Pro 71 Leu), case 3: c. 188 C > A, p. (Pro 63 Gln), and case 4: c. 188 C > G, p. (Pro 63 Arg)), all of which were de novo variants and N-terminal side. Case 1, case 2, and case 3 developed nephropathy at the ages of 0 months, 1 year 11 months, and 3 years, and led to end-stage kidney disease (ESKD) at the ages of 6 months, 3 years and 20 years, respectively. On the other hand, the isolated-FSGS patient has developed persistent proteinuria since12 years old, but his renal function was still normal at the age of 19. Genetic analysis revealed a novel heterozygous missense variant at c. 755 C > G, p. (Ala 252 Gly) which was a de novo variant and C-terminal side.

Discussion: Case 1 was the youngest case of developing ESKD and the first case manifesting CNS. In case 5, who was the isolated-FSGS case, a variant near the DRS hotspot was identified, but no eye movement abnormalities were observed. This case is the second case showing isolated nephropathy among cases with *MAFB* variants. MCTO should be included in the differential diagnosis as a cause of CNS disease. Isolated-FSGS may be a new phenotype of *MAFB* abnormalities different from MCTO and DRS.

TH-PO465

RAAS Inhibition Delays Onset of Nephrotic Syndrome due to TRPC6-Mediated FSGS: A Case Report of a Sibling Pair

Ashley W. Carver, Dorey A. Glenn, Katherine D. Westreich. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Introduction: Transient receptor potential channel (TRPC6) is a slit diaphragm protein located on the podocyte, and a known genetic cause of focal segmental glomerulosclerosis (FSGS). Upregulation of TRPC6 channel activity is proposed to disturb podocyte structure, leading to proteinuria. ACE inhibitors (ACEi) demonstrate reno-protective benefits, reduction in proteinuria, and are commonly used to reduce proteinuria in FSGS. Here we describe progression to symptomatic nephrotic syndrome in a sibling pair with TRPC6 mediated steroid resistant FSGS as a function of early vs. late initiation of ACEi.

Case Description: Sibling A, the older of the two affected siblings, presented to care at 3 years of age with generalized edema, hypoalbuminemia (1.6g/dL), and nephrotic range proteinuria (UPCR 35mg/mg). Family history revealed that the child's father had end stage kidney disease of unclear etiology at the age of 3 years. Genetic testing of the child and parents demonstrated an autosomal dominant mutation in TRPC6 ((c.523C>T) [p.R175W]). Sibling A was unresponsive to steroids and cyclosporine and progressed to dialysis dependence due to fluid overload and pulmonary edema. Sibling A underwent kidney transplantation without recurrence of proteinuria. Sibling B, whose genetic diagnosis was made shortly after birth, was immediately started on RAAS inhibition, which was then maximally up-titrated (0.6mg/kg) as tolerated by blood pressure. He eventually underwent unilateral nephrectomy at age 4 to aid with proteinuria reduction. At age 5, nephrectomy of the remaining kidney was pursued with transition to peritoneal dialysis and preparation for kidney transplant. The age at dialysis dependence was 3 years in Sibling A and 5.5 years in Sibling B.

Discussion: In summary, this report describes delay in progression to symptomatic nephrotic syndrome in a child with TRPC6 mutation due to early exposure to ACEi. The reno-protective mechanisms of ACEi are not fully understood and include proteinuria reduction and anti-fibrotic effects. Angiotensin II has been described to cause upregulation of TRPC6, thus aggressive blockade of this pathway may be a unique benefit to patients with TRPC6 mutations. A comparison of the siblings reported here would suggest that ACEi may significantly delay symptomatic nephrotic syndrome when started early and dosed maximally.

TH-PO466

Clinical and Genetic Characteristics of INF2-Related Monogenic FSGS

Eoghan White,[1] Elhussein A. Elhassan,[1] Susan M. McAnallen,[1] Sofia C. Jorge,[2] Julia Hoefele,[3] Eloise Colliou,[4] Peter J. Conlon.[1] *[1]Beaumont Hospital, Dublin, Ireland; [2]Hospital de Santa Maria, Lisboa, Portugal; [3]Technische Universitat Munchen, Munchen, Germany; [4]Centre Hospitalier Universitaire de Toulouse, Toulouse, France.*

Background: Focal segmental glomerulosclerosis (FSGS) is a histological lesion with diverse aetiologies. Although monogenic forms of FSGS are characterized by a grim clinical course, resulting in early end-stage renal disease (ESRD), they often remain underdiagnosed. Disease-causing variants in INF2 (inverted formin 2), which encodes an essential actin regulatory protein, have been identified as the most common cause of dominantly inherited FSGS; however, the disease has a highly heterogeneous clinical presentation and progression.

Methods: To describe the natural history of *INF2*-related FSGS, we established a *INF2* research group and produced an e-survey describing the clinical outcomes (age at presentation, disease trajectory, histological diagnosis) and genetic data (exon location, and functional domains).

Results: We have received responses from 9 European centers and collected data from 53 patients (21 families), 22 (41.5%) of these cases have not previously been published. The age of initial presentation was 26.3 ± 12.8 years, with the majority of patients presenting with proteinuria and/or edema. Among the 25 patients (47.2%) who underwent kidney biopsy, FSGS accounted for 64% of the histopathologic diagnoses. Of the available data, 18 had reached end-stage kidney disease with a mean time to ESKD of 7.8 years from the presentation. Ten patients have undergone transplantation, and 8 patients had associated Charcot-Marie Tooth Neuropathy. Most families [19/22; 86.4%] had missense variants spanning exons 2 to 4 that localize to a diaphanous inhibitory domain.

Conclusions: *INF2* is an increasingly recognized cause of monogenic kidney disease that can lead to ESKD and has an important impact on responses to treatment. Continued efforts are required to determine phenotype variability and disease severity of *INF2*-related FSGS globally.

TH-PO467

Novel Double-Dominant Mutations of COL4A4 Gene Causing Alport Syndrome in a Hispanic Family

Basant Hamed, Shikha Rijal, Aarthi Sriram, Anil K. Mongia. *SUNY The State University of New York, Brooklyn, NY.*

Introduction: Autosomal recessive (AR) and Autosomal dominant (AD) disease account for 10-15% and 20-30% respectively of patients with Alport syndrome due to genetic defects in either the COL4A3 or COL4A4 genes. Here we report family of four patients with microscopic hematuria and proteinuria caused by 2 novel mutations of COL4A4 gene.

Case Description: We present a 13-year-old male patient who was presented with microscopic hematuria and proteinuria since the age of 4. Patient had normal audiology and ophthalmologic examination and normal renal function including serum creatinine. His brother, mother, and father had microscopic hematuria but no other symptoms. Genetic testing was performed for all four individuals using Next Generation Sequencing (NGS, Illumina) and confirmed COL4A4 gene mutation with 2 novel variants that is predicted to disrupt the canonical splice acceptor site for exon 9 and 29. The first intronic variant, *NM_000092.5:c.559-2A>T,* is predicted to abolish canonical splice acceptor activity while the second intronic variant, *NM_000092.4:c.2545+2T>G,* alters the highly conserved splice donor site for exon 29 and is predicted by all four splice site prediction tools queried to abolish canonical splice donor activity. Both variants are expected to result in altered function of the COL4A4 gene product as a result of aberrant splicing. Of these mutations, our patient has bi-paternally inherited variants with compound heterozygosity, while the rest of his family showed only one pathogenic variant, which can explain the severity of his microscopic hematuria and proteinuria.

Discussion: Here we report unusual double dominant inheritance pattern in a 13 year old boy who has inherited defective genes from both affected parents. These type of patients may have worst prognosis than other forms of Alport syndrome. Current classification needs to be revised in view of newer genetic information.

Clinical features and genetic findings in a family with Alport syndrome

Subject	I (index case)	II (brother)	III (father)	IV (mother)
Sex	M	M	M	F
Age	13	23	54	52

Therapeutic Strategies for PodR138Q Nephrotic Syndrome

Pei-Chen Lu,[1,2] Gavin I. Welsh,[1] Moin Saleem.[1] [1]*University of Bristol, Bristol, United Kingdom;* [2]*Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan*.

Background: The most common missense mutation in podocin, Pod^{R138Q}, results in steroid-resistant nephrotic syndrome. Pod^{R138Q} causes the podocin to be trafficked incorrectly resulting in it being trapped in ER and degraded leading to aberrant function of the slit diaphragm. Understanding the mechanism of this mis-trafficking and degradation may lead to new therapeutic strategies for treating this disease.

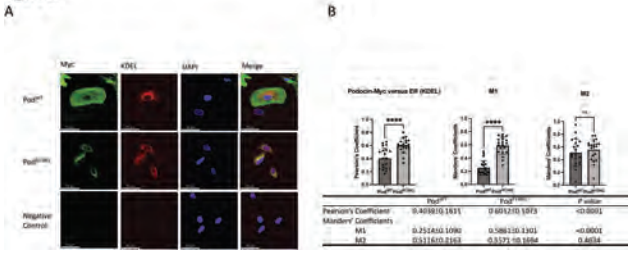
Methods: Both Pod^{WT} and Pod^{R138Q} were overexpressed in immortalized human podocytes. These cells were treated with MG132 (proteosome inhibitor), bafilomycin A1 (lysosome inhibitor), and kifunensine (Kif) (ER mannosidase I inhibitor). Podocin localization/tyrafficking was analyzed by western blotting and immunofluorescence.

Results: Pod^{R138Q} had higher co-localization coefficients with ER than Pod^{WT} (Fig 1). Pod^{WT} was mainly degraded by the lysosome, and Pod^{R138Q} degraded only by the proteosome (Fig 2A, 2B). Blocking podocin proteosomal degradation with MG132 resulted in Pod^{R138Q} being localized to plasma membrane lipid rafts (Fig 2C). Kif leads to the accumulation of high mannose N-glycan podocin (Fig 2B). High mannose N-glycan Pod^{R138Q} had affinity to calnexin (Fig 2D), and this implies that Pod^{R138Q} is degraded via ER-associated degradation (ERAD).

Conclusions: Pod^{WT} is mainly degraded by the lysosome whereas Pod^{R138Q} undergoes ERAD. By using a proteasome inhibitor, Pod^{R138Q} can be rescued correctly trafficked to lipid rafts. This finding could suggest a new therapeutic target for medical intervention for Pod^{R138Q} nephrotic syndrome.

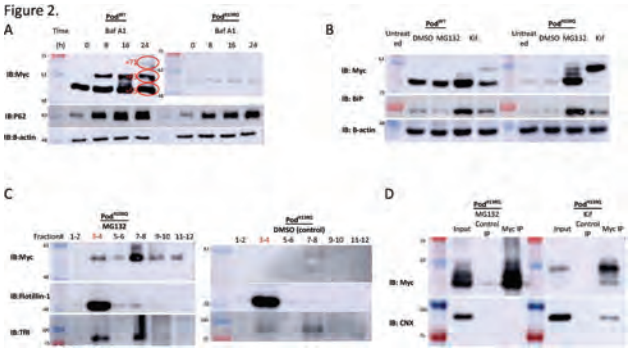
Funding: Private Foundation Support

Figure 1.



The colocalization coefficients between podocin and ER.

Figure 2.



Podocin treated by bafilomycin A1, MG132, and Kif (2A, 2B). Sucrose gradient centrifugation showed MG132 treated Pod^{R138Q} in lipid rafts (2C). Co-IP showed high mannose Pod^{R138Q} interacting with calnexin (2D).

TH-PO469

Efficacy and Mechanism of Dapagliflozin in Alport Syndrome

Qimin Zheng, Shuwen Yu, Tong Jun, Yuanmeng Jin, Zhengying Fang, Qinjie Weng, Wen Du, Junru Li, Pan Xiaoxia, Xiangchen Gu, Jingyuan Xie. *Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China*.

Background: Alport syndrome(AS) is a hereditary kidney disease caused by *COL4A3/4/5* mutation. Currently, the standard therapy is merely RAASi, thus new treatment for AS is urgently needed. SGLT2 inhibitor has been approved for the treatment of diabetic nephropathy and chronic kidney disease, while its therapeutic effect on AS is unknown.

Methods: We conducted an observational, single-arm, prospective study based on AS patients with heterozygous mutations of COL4A3/A4/A5 from May 1, 2021, to August 1, 2022, in Shanghai Ruijin Hospital. Participants were treated with dapagliflozin 10mg per day. Proteinuria and serum creatinine were assessed every 3 to 6 months. We also investigated the effect of dapagliflozin on AS mice. *Col4a3* p.C1615Y homozygous mutant mice were used as an AS model. Mutant and wild-type mice(16-17-week -old) were administered with dapagliflozin (10mg/kg), or vehicle in drinking water, and the blood, urine, and kidney samples were collected after 28 days of treatment.

Results: Nine AS patients with heterozygous mutations of COL4A3/A4/A5 were included in this study. There are five males and four females, the average age was 40 years, and all patients were followed up 12 (11.5-17.0) months. The urine protein was 1.66 (1.06-1.90) g at baseline and 0.70 (0.50-2.21) g at the last follow-up time, with a 58% decrease from baseline. The eGFR at last time was 72.5 (61.7-80.1) ml/min/1.73$m^{2.}$ no statistical significance was shown compared with the baseline 66.3 (55.7-101.5) ml/min/1.73m^2. No adverse events were observed in these patients. Consistent with the observational study, the animal study also showed that Dapagliflozin significantly alleviated proteinuria (urinary albumin creatinine ratio). We also observed that mutant mice treated with dapagliflozin exhibited significantly reduced transcript levels of renal proinflammatory cytokines and fibrotic markers, including Ccl2, Ccl5, Cxcl10, Vimentin, and Col1a1 as compared to vehicle-treated mutant mice. These data were also supported by H&E and F4/80 IHC staining showing decreased immune cell infiltration in kidney tissues of dapagliflozin-treated mutant mice.

Conclusions: Altogether, these results suggest that dapagliflozin is a promising treatment for AS patients, and further studies are required to elucidate the precise mechanism of SGLT2 inhibitors on retarding AS progression.

Phenotypic Spectrum Analysis and Molecular Mechanism Study of PAX2 Variants in the Chinese Population

Qian Shen, Hong Xu, Man Q. Sun. *Children's Hospital of Fudan University, Shanghai, China*.

Background: Congenital anomalies of the kidneys and urinary tract (CAKUT) is the leading cause of renal failure in children. Dysfunction of transcription factors can cause human and mouse CAKUT. Variants in *PAX2* gene are widely reported to cause CAKUT with or without optic nerve abnormalities (Renal coloboma syndrome, RCS). Interestingly, heterozygous variants in *PAX2* gene were also reported to cause Focal Segmental Glomerulosclerosis (FSGS). However, the mechanism is not well studied.

Methods: Variants in *PAX2* gene and phenotypic spectrum from 16 individuals were summarized. Functional effects of different *PAX2* variants were confirmed by constructing wild-type and mutant *PAX2* overexpression plasmids. Minigene splicing assay was performed to test function of splicing variants. The plasmid of mutant *PAX2* gene associated with FSGS was also transfected into human podocytes. Meanwhile, we further performed RNA-seq to analysis the different signaling between different phenotype.

Results: A total of 16 individuals with 12 different variants *PAX2* variants were included in this study. Among them, nonsense mutations (5/16, 31%) were the main type of variation. One variant caused FSGS phenotype. In vitro study, nonsense mutations produces truncated proteins and damaging the protein stability. Different *PAX2* gene variant proteins all significantly reduced the expression level of *PRS4*-luc. Both c.43+1G>A and c.213-2A>G in *PAX2* gene demonstrated abnormal splicing of mRNA. The FSGS phenotype-associated *PAX2* gene variant c.975C>A mainly shows damage to podocytes dominated by mitochondrial dysfunction. Furthermore, by RNA-seq, we showed *PAX2* gene mutations associated with CAKUT phenotype, mainly involved in PI3K-Akt signaling pathway, neural development, extracellular matrix and other factors, while FSGS phenotype-associated *PAX2* gene variants, mainly involved in cell adhesion, actin cytoskeleton related to podocyte development.

Conclusions: Our study showed different *PAX2* gene variants cause different phenotype. Functional study showed *PAX2* gene mutations associated with CAKUT phenotype are mainly involved in PI3K-Akt molecular pathways, neural development and other factors, while *PAX2* gene mutations associated with FSGS phenotype are mainly involved in cell adhesion, actin cytoskeleton and the development of podocytes.

TH-PO471

A New BMP-4 Gene Mutation Associated with Adult Focal Segmental Glomerulosclerosis (FSGS)

John A. Szendrey, Daniel L. Landry, Spencer Hodgins, Jeffrey Mulhern, Sana Fatima, Gregory L. Braden. Kidney Care & Transplant service of New England. *UMass Chan Med School-Baystate, Springfield, MA*.

Introduction: FSGS has been associated with numerous gene defects in children, adolescents & adults. We describe a new BMP-4 gene mutation associated with adult onset FSGS treated successfully with combined supratherapeutic ACE inhibitors with an ARB.

Case Description: In 1994 a 40 year(yr) old non-smoking obese man developed nephrotic syndrome & hypertension. His daily urine protein excretion was 3.6 gms, iothalamate gfr 81 ml/min, s creatinine 1.2 mg/dl, s albumin 3.0 gm/dl & cholesterol 400 mg/dl. He had no signs of systemic diseases. C3 & C4 complements, ANA, ANCA, immunofixation, hepatitis A, B & C were normal. A renal biopsy showed: Light: 3/16 glomeruli with focal glomerular sclerosis & moderate tubular & interstitial sclerosis. IF: completely negative. EM: increased measangial matrix with focal foot process fusion, thickened basement membranes & no immune deposits. A Dx of FSGS. NOS possibly due to obeisty was made. He was treated with supratherapeutic lisinopril 40 mg bid and valsartan 160 mg a day for 30 years despite retraction of the Lancet COOPERATE trial in 2012. His decrease in gfr over 29 yrs was only 1.8 ml/mim/yr. His urine protein decreased to 1 gm after 6 yrs & was only 1 gm/d until 2015 when it increased to 1.5 gm/d, & then to 2.2 gm in 2022. His gfr gradually declined to 65 ml /min in 2000, 50 ml/min in 2010, 36 ml/min in 2015 & 29 ml/min in 2023. A Renasight gene panel (Natera, Austin, TX) showed: a c 124G>C (pAla 42 Pro) mutation, codon 42 missense on exon 3 guanine for cytosine.

Discussion: Loss of function mutations in BMP-4 are associated with CAKUT. A BMP-4 gain of function mutation in animal studies shows increased SMAD which inhibits podocyte VEGF leading to shrinkage & immature glomeruli (H.Euda, JASN

19:685, 2008). In addition Iv and intravitreal VEGF inhibitors in humans can cause FSGS (CC Estrada JASN 30:187, 2019). We conclude that the BMP-4 mutation in our pt could lead to inhibition of intraglomerular VEGF inducing FSGS. Supratherapeutic ACE inhibitors with an ARB may slow the loss of gfr in FSGS & could be used as a control for a study against sparsentan for FSGS.

TH-PO472

ADCK4 Nephropathy in Identical Siblings

Shun Manabe,[1,2] Moe Kawashima,[1,2] Kawachi Keiko,[1,2] Koji Kanai,[1] Takayasu Mori,[3] Sekiko Taneda,[2] Takahito Moriyama,[4] Junichi Hoshino.[2]
[1]Tokyo Rosai Hospital, Ota-ku, Japan; [2]Tokyo Women's Medical University, Shinjuku-ku, Japan; [3]Tokyo Medical and Dental University, Bunkyo-ku, Japan; [4]Tokyo Medical University, Shinjuku-ku, Japan.

Introduction: *ADCK* mutations are recently documented cause of coenzyme Q10 (CoQ10) nephropathy, which emerges during adolescence and progresses to end-stage renal disease in early adulthood. Here, we present the identical twin sisters who were diagnosed with ADCK nephropathy, exhibiting divergent clinical severity.

Case Description: The elder twin displayed proteinuria (0.5 g/day), and kidney biopsy revealed focal segmental glomerulosclerosis (FSGS) during her mid-10s. During initial pregnancy, urinary qualitative tests yielded results ranging from 0 to 2+. During subsequent pregnancy, in late 20s, proteinuria gradually escalated to 3 to 4+. Six months post-delivery, the lab results were as follows: albumin 4.3 g/dL, estimated glomerular filtration rate (eGFR) 126 ml/min/1.73, and urine protein-to-creatinine ratio (UPCR) 3.0 g/gCr. Kidney biopsy demonstrated FSGS (NOS variant) along with mitochondrial accumulation within the podocyte. Despite the initiation of steroid, including pulse steroid therapy, and cyclosporine, proteinuria persisted. Four years later, immunosuppression was discontinued. In late 30s, UPCR increased to 3.6 g/gCr, prompting the reintroduction of steroid, cyclosporine, and rituximab. Although UPCR gradually declined to 1.0 g/gCr, eGFR decreased to 50 ml/min/1.73. Due to steroid-resistant proteinuria, progressive renal dysfunction, pathological findings, and a familial history of FSGS, genetic analysis was conducted, revealing a homozygous pathogenic mutation in *ADCK4*. Administration of CoQ10 resulted in complete remission of proteinuria (UPCR < 0.3 g/gCr) and restoration of renal function (eGFR 71 ml/min/1.73). The younger twin also exhibited proteinuria (0.4 g/day), and kidney biopsy demonstrated FSGS during her mid-10s. She had no history of pregnancy, delivery, or comorbidities. At the age of 39, her renal function remained preserved, with an eGFR of 92 ml/min/1.73 and UPCR of 0.23 g/gCr.

Discussion: ADCK4 nephropathy represents a renal-limited subtype of CoQ10 nephropathy, exhibiting a favorable response to CoQ10 supplementation. Therefore, it is crucial to comprehend the clinical characteristics to facilitate genetic testing in appropriate instances. Our case study vividly illustrates a wide spectrum of clinical severity, even in identical twins, thus emphasizing the influence of environmental factors on the exacerbation of ADCK4 nephropathy.

TH-PO473

Colocalization of Genetic Associations with Plasma and Urine Proteins Provide Insights into Renal Protein Handling and Related Clinical Outcomes

Oleg Borisov, Stefan Haug, Nora Scherer, Sara Monteiro-Martins, Yong Li, Anna Kottgen. *Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany.*

Background: Genetic mechanisms underlying tubular handling of proteins in the kidney can provide valuable insights into the pathogenesis of kidney-related diseases. We generated urine proteomics data and integrated it with large-scale proteomics, genomics, and biobank data to test whether genetic influences on protein levels are shared between plasma and urine, hypothesizing that shared signals represent filtered or tissue-shared proteins secreted into the urinary tract.

Methods: We employed genome-wide association study (GWAS) results of 364 plasma proteins measured in 35,559 Icelanders with significant ($p<2e-9$) associations in 2,279 genomic regions. We extracted respective regions from GWAS of 353 proteins measured in urine of 754 participants of the German Chronic Kidney Disease study and conducted genetic colocalization analyses for plasma-urine protein pairs. To link the results with clinical outcomes, we additionally incorporated genetic associations with 1,419 medical conditions from the UK Biobank (N=400,000).

Results: Strong evidence for colocalization was detected for 105 of 2,371 plasma-urine pairs, suggesting a single causal genetic variant affecting both plasma and urine protein levels. The proportion of pairs consisting of the same protein was significantly higher among the colocalizing pairs (23/105, 21.9%) than among all pairs (54/2371, 2.3%; p=5e-13), and included known and emerging biomarkers such as GDF15 for adverse kidney outcomes. We further detected 3,001 colocalized pairs of plasma protein and clinical outcome (out of 37,030), entailing kidney diseases, of which 1,141 (38%) enlisted plasma proteins that also colocalized with urine proteins. Interesting examples encompassed a shared genetic basis for urine and plasma levels of Kidney Injury Molecule-1 (HAVCR1), hypertension and kidney stones, as well as for prostate-specific microseminoprotein beta in urine and plasma and prostate cancer.

Conclusions: We report colocalizing proteins that share genetic architecture in plasma and urine, additionally linking them to medical conditions. The generated resource can reveal circulating biomarkers of diseases that are also informative when quantified in urine, and will facilitate a deeper understanding of renal protein handling and its link to kidney diseases.

Molecular Mechanisms of Novel NPHS2 Pathogenic Variants and Proposed Therapeutic Interventions

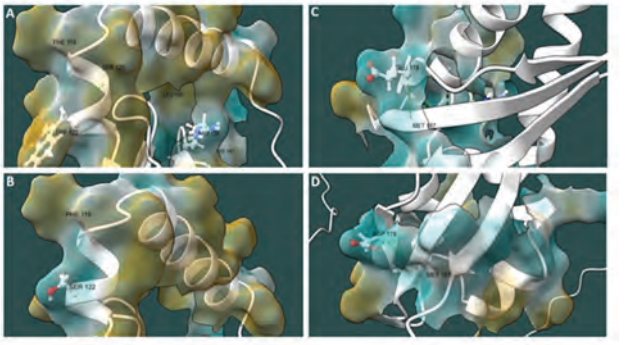
Asmaa S. Abu-Maziad. *The University of Arizona Health Sciences, Tucson, AZ.*

Background: The human *NPHS2* gene encodes podocin protein, an essential component of GBM. Mutations in *NPHS2* causes steroid-resistant FSGS/nephrotic syndrome. Podocin signaling is essential to the structure and function of glomerular podocytes. Defining the molecular dysfunctions of this novel *NPHS2* mutations is imperative to improving our understanding of the dynamic roles of podocin protein and potential therapeutic interventions.

Methods: We study the molecular and biochemical properties of the *NPHS2* pathogenic variants and podocin protein using patient-derived induced pluripotent stem cell (piPSC) and reprogrammed podocytes. To further study the implications of the W122S mutation, *in silico* analysis was performed. ColabFold was used to predict the structure of wild-type podocin and W122S mutated podocin.

Results: Try122 is located in podocin's transmembrane region, where the protein inserts itself into the inner leaflet of the plasma membrane. It is here where podocin recruits nephrin and CD2AP into lipid rafts, forming a multiprotein signaling complex. This complex was found to be integral in the formation of the podocyte's actin cytoskeleton. Given its predicted location on the outer surface of the transmembrane region of podocin, Try122 supports podocin's ability to embed itself in the plasma membrane.

Conclusions: Distinct differences in lipophilicity and structure of the transmembrane domain are revealed. Further work using our patient's derived stem cell will allow us to understand the signaling cascade and therapies.



Structure prediction results of wild type podocin residues and their respective mutations. Visualized with hydrophobicity maps on surfaces and contacted residues. A. Transmembrane tryptophan 122 contacting Ser120 and Phe119. B. Podocin mutant W122S contacting Phe119 and losing contact with Ser120. Distinct differences in lipophilicity and structure of the transmembrane domain are visible. C. Glutamic acid 178 protrudes from PHB domain and contacts Met187. D. E178D mutant shows a similar structure to wild type form and maintains contact with Met187.

TH-PO475

Molecular Mechanisms of Neonatal-Onset WT1-Related Glomerulopathy

Lily Hiltebeitel,[1] Jie Yang,[2] Yu Cao,[2] Xing Zhang,[2] Xiaodong Cheng,[2] Friedhelm Hildebrandt,[1] Nina Mann.[1] *[1]Boston Children's Hospital, Boston, MA; [2]The University of Texas MD Anderson Cancer Center Children's Cancer Hospital, Houston, TX.*

Background: Human mutations in *WT1*, or *Wilms' tumor 1*, lead to severe, progressive glomerulopathy marked by heavy proteinuria and progression to end-stage renal disease (ESRD). A subset of patients with *WT1* variants present at birth with rapid progression to renal failure. We sought to determine the genotypic spectrum and molecular mechanisms causing neonatal onset *WT1*-related disease.

Methods: We performed a systematic literature review of neonatal-onset (<1 month of age) *WT1*-related glomerulopathy and of all cases with the *WT1* p.Arg467Trp or p.Arg467Gln variants. Cell biological techniques were utilized to assess the cellular localization, DNA binding, and transcriptional activity of wild type and mutant WT1 proteins.

Results: We identified 21 cases with pathogenic *WT1* variants who had disease onset by 1 month of age and ESRD by 6 months. 17/21 (80%) cases had mutations at one of two DNA-binding residues: p.Arg439 (n=10) and p.Arg467 (n=7). Notably, there was enrichment for the p.Arg467Gln variant (n=6) and no cases with the p.Arg467Trp variant, which is a common mutational hot-spot. We found that nearly all individuals with the p.Arg467Gln variant developed early onset renal failure (median age at ESRD 1.2 months, n=15), while those with the p.Arg467Trp variant had a more variable disease course (median age at ESRD 21.6 months, n=40). *In vitro* studies showed that the wild type WT1 protein (in the -KTS isoform) localized diffusely within the cell nucleus, while both the p.Arg467Gln and p.Arg467Trp mutant proteins (in the -KTS isoform) localized to nuclear subdomains and failed to activate transcription. The p.Arg467Gln and p.Arg467Trp mutant proteins also have significantly reduced DNA binding, suggesting that these mutations do not function in a dominant manner via activation of aberrant transcriptional pathways.

Conclusions: *WT1* mutations at the p.Arg439 and p.Arg467 loci are associated with neonatal-onset disease and early progression to ESRD. The p.Arg467Gln variant leads to more severe disease than the p.Arg467Trp variant but there was no functional difference between the two mutant proteins with regards to cellular localization or DNA binding. Further studies will be needed to better elucidate the mechanisms of neonatal-onset WT1-related glomerulopathy.

Rescue Mechanism for Glomerular Endothelial Lipid Metabolic Dysfunction in Alport Syndrome

Hasmik Soloyan,[1] Matthew E. Thornton,[2] Geremy Clair,[4] Janielle M. Cuala,[2] Qi Zhang,[1] Senta K. Georgia,[1,2] Paolo Cravedi,[3] Stefano Da Sacco,[1,2] Laura Perin,[1,2] Sargis Sedrakyan.[1,2] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of Southern California Keck School of Medicine, Los Angeles, CA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Pacific Northwest National Laboratory, Richland, WA.*

Background: Glomerular endothelial dysfunction plays a key role in the development of chronic kidney disease (CKD). In Alport syndrome (AS, caused by mutations in collagen IVα3α4α5) damage to the glomerular endothelial cells (GEC) occurs before onset of heavy proteinuria and is characterized by altered fenestration size and glycocalyx deposition. Despite this evidence, the role of GEC in Alport progression is poorly understood. Here, we elucidate the role of lipids in GEC injury in an animal model of AS, and the potential of using amniotic fluid stem cell (AFSC) derived extracellular vesicles (EVs) as a rescue strategy to restore glomerular homeostasis.

Methods: The phasor approach to FLIM (fluorescent lifetime imaging microscopy) was applied to evaluate the metabolic changes in the kidneys (and particularly in the glomeruli and GEC) of AS and WT mice. GEC isolated by FACS from tdTomato-reporter AS and WT mice at 4-months of age were compared by bulk RNA-seq and lipidomics. In vitro, silencing experiments on primary human GEC were performed to study the role of fatty acid synthase (FASN) in GEC metabolic dysfunction. FASN-carrying AFSC-EVs and control nanoparticles were applied both *in vitro* and *in vivo* to restore lipid homeostasis in GEC.

Results: In AS mice, RNAseq analysis of GEC revealed changes in the metabolic genes, (including FASN) and pathways associated with uptake, synthesis and oxidation of fatty acids. FLIM studies showed that changes in the metabolic fingerprint of the GEC correlated with increasing age and severety of disease in AS mice. Lipidome analysis found high abundance of triglycerides in GEC isolated from AS. We confirmed accumulation of lipid droplets in the glomeruli of AS mice, as well as in FASN KO human primary GEC, *in vitro*. These results suggest potential mitochondrial dysfunction in GEC. AFSC-EVs treatment restored lipid homeostasis in GEC, both *in vitro* and *in vivo*.

Conclusions: We report for the first time a lipid metabolic dysfunction in Alport GEC, and the ability of AFSC-EVs to rescue this phenotype. Therefore, better understanding of the role of GEC in AS could lead to the development of targeted new therapies for the treatment of this and other forms of CKD.

Apolipoprotein M Treatment Restores Kidney Function in Mouse Model of Alport Syndrome

Judith T. Molina David,[1,2] Matthew Tolerico,[1,2] Jin Ju Kim,[1,2] Yelena Drexler,[1,2] Sandra M. Merscher,[1,2] Alessia Fornoni.[1,2] *[1]University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL; [2]Peggy and Harold Katz Family Drug Discovery Center, UM, Miami, FL.*

Background: Studies suggest that altered Apolipoprotein M (APOM) expression is associated with dyslipoproteinemia, atherosclerosis and possibly diabetes, obesity, and inflammation. However, little is known about the role of APOM in the kidney. We previously reported decreased glomerular APOM expression in glomerular diseases. ApoM is a protein linking cholesterol and sphingolipid metabolism, which are both important players in the development of glomerular injury in Alport Syndrome (AS) among other glomerular disorders. Here we test the hypothesis that systemic replacement of ApoM in AS protects from the development of kidney failure.

Methods: To study the role of APOM in the kidney, we analyzed renal APOM expression in a mouse model of progressive renal disease associated with Alport Syndrome (Col4a3 KO mice). We found reduced mRNA and protein expression of APOM in the kidneys of Col4a3 KO mice. To investigate if APOM replenishment would improve renal function in this mouse model, we injected Col4a3 KO mice with recombinant human APOM (rh-APOM). Three groups of mice were studied: (1) Col4a3 +/+ (WT) + vehicle, (2) Col4a3 -/- (KO) + vehicle, and (3) Col4a3 -/- (KO) + rh-ApoM. rh-APOM was administered by weekly intraperitoneal injection starting at 4 weeks of age and until sacrifice at 8 weeks of age.

Results: APOM mRNA and protein expression were markedly reduced in glomeruli and podocytes from Col4a3 KO mice compared to WT mice. Treatment of Col4a3 KO mice with rh-APOM normalized renal APOM levels and prevented the development of renal failure (serum BUN and creatinine), proteinuria (urinary albumin/creatinine ratio), and protected from the development of glomerulosclerosis, tubular atrophy and dilation.

Conclusions: Our results suggest that restoring renal APOM levels in an experimental model of AS protect from renal failure and that treatment with rh-APOM may represent a novel therapeutic strategy for the treatment of glomerular diseases.

TH-PO478

Exploring the Molecular Basis of Ramipril-Induced Nephroprotection in Alport Syndrome

Tomohiko Yamamura, Emily Williams, Mychel R. Morais, Rachel Lennon. *Wellcome Trust Centre for Cell Matrix Research, Manchester, United Kingdom.*

Background: Renin-angiotensin system inhibitors such as angiotensin-converting enzyme Inhibitors (ACEi) play a central role in the treatment of CKD, and they are known to reduce proteinuria and extend kidney survival in Alport syndrome. This beneficial effect has been explained by the reduction of intraglomerular pressure and the inhibition of inflammation and subsequent fibrosis. However, the actual molecular changes induced by ACEi in the kidneys are yet elucidated.

Methods: The ACEi ramipril was administered orally (n=10 each) to a mouse model of Alport syndrome (Col4a5 knockout). Treatment was initiated at five weeks (early treatment group) or ten weeks (late treatment group) and continued until 16 weeks of age, with comprehensive evaluation including functional studies, imaging and mass spectrometry-based proteomic analysis kidney tissue.

Results: The mean urinary albumin-creatinine ratio ± SEM was significantly lower ($p<0.01$) in both the early treatment group (1417±470.3) and the late treatment group (2984±1116) compared to the no-treatment group (8902±1320). No significant differences were observed between the early and late treatment groups. Although serum BUN was not significantly different between the no-treatment and treatment groups, light microscopy showed that the early-treatment group had less cellular infiltration of the interstitial area than the no-treatment and the late-treatment group. Proteomic analysis revealed distinct proteomic profiles not only between Alport mice and wild-type mice but also between ACEi-treated Alport mice and non-treated Alport mice. With pathway enrichment analysis, we found significant enrichment for terms associated with chaperonin-mediated protein folding, extracellular matrix organisation and glycosaminoglycan metabolism in ACEi-treated mice compared to untreated mice.

Conclusions: The present study indicates that the molecular mechanisms of the nephroprotective effects of ACEi, such as the reduction of proteinuria and improved histological findings in the Alport mouse, involve proteins related to chaperonin-mediated protein folding, extracellular matrix organisation and glycosaminoglycan metabolism pathways in the kidney.

Adult Male Patient of C1q Nephropathy with Heterozygous Pathogenic COL4A4 Variant

Kasumi Konishi,[1] Takuya Fujimaru,[1,2] Chiharu Aizawa,[1] Nozomi Kadota,[1] Yugo Ito,[1] Masahiko Nagahama,[1] Fumika Taki,[1] Takayasu Mori,[2] Eisei Sohara,[2] Shinichi Uchida,[2] Masaaki Nakayama.[1] *[1]St. Luke's International Hospital, Tokyo, Japan; [2]Tokyo Medical and Dental University, Tokyo, Japan.*

Introduction: Autosomal dominant Alport syndrome (ADAS) is a disease with heterozygous pathogenic *COL4A3* or *COL4A4* variants. ADAS is considered to have a better renal prognosis than X-linked Alport syndrome and less likely to develop focal and segmental glomerulosclerosis. However, ADAS could predispose to IgA glomerulonephritis (IgAN). We report an adult male patient of C1q nephropathy with ADAS.

Case Description: A 47-year-old man admitted our hospital for renal biopsy. He had hematuria and proteinuria since childhood. Six years before admission, he had hypertension and chronic kidney disease (serum Cr was around 2.5 mg/dL). His maternal grandmother, maternal aunt, son, and daughter had hematuria. No one, including him, suffered from hearing loss. One year before admission, his renal function deteriorated (Cr 3.37 mg/dL) and severe proteinuria appeared (5–7 g/day). Renal biopsy showed that 25% of glomeruli had global sclerosis and 60% had segmental glomerulosclerosis. Immunofluorescence shows global granular mesangial staining for C1q and IgM. Electron microscope revealed diffuse intra-membranous deposits with GBM thickening. Genetic analysis showed that he had heterozygous pathogenic variant in *COL4A4* (c.2510G>C: p.Gly837Ala). We diagnosed him as C1q nephropathy with ADAS and started 1 mg/kg of corticosteroid for C1q nephropathy. We added cyclosporine after 1 month of treatment due to refractory proteinuria. However, because cyclosporine worsened renal function and he suffered from avascular necrosis of femoral head, immunosuppressive therapy was tapered.

Discussion: As far as we know, this is the first case of C1q nephropathy with ADAS. ADAS may also predispose to glomerulonephritis other than IgAN. Additionally, concomitant glomerulonephritis could worsen renal prognosis in ADAS patients.

TH-PO480

Genotype-Phenotype Correlations in Alport Syndrome: A Single-Center Experience

Stefan N. Lujinschi, Bogdan Obrisca, Bogdan Sorohan, Roxana A. Jurubita, Alexandra Vornicu, Gener Ismail. *Fundeni Clinical Institute, Bucharest, Romania.*

Background: Alport syndrome is a common and heterogeneous genetic kidney disease, oftentimes leading to end-stage kidney disease (ESKD). Due to the growing availability of genetic testing, understanding the interplay between genetic and clinical features has become essential for individualized prognostication.

Methods: This is a single-center, retrospective study that included 36 adults with type IV collagen mutations. Our scope was to describe how genetic features influence renal survival, i.e., the age at renal replacement therapy initiation.

Results: A total of 28 different mutations were identified, out of which 8 had not been previously described. Mutations affecting each of the type IV collagen α chains were equally prevalent (33.3%). Six patients had multiple mutations. One patient had mutations involving all α chains. Five patients also had mutations involving podocyte and glomerular basement membrane proteins, but with no significant differences regarding proteinuria and renal survival. Most patients had a family history of kidney disease (71%). The most prevalent clinical picture was nephritic syndrome (64%), followed by isolated hematuria (24%). One third of the subjects had extrarenal manifestations, such as hearing loss (28.6%) and eye abnormalities (7.1%). There were no significant differences in laboratory findings at diagnosis between patients with COL4A3, COL4A4 and COL4A5 mutations. Eighteen patients presented with (41.6%) or later developed (8.3%) ESKD at a median age of 25.5 years old (IQR, 21.5-37.25). Six patients underwent kidney transplant. Overall kidney survival was 40.55 years (95% CI, 35.55-45.55). COL4A4 group displayed a significantly better renal survival when compared to COL4A3 (p=0.027). Hearing loss was associated with a significantly poorer renal prognosis (p<0.001). For a subgroup where follow-up data were available (44.4%), the 5-year renal survival was 68.6% and in patients with multiple mutations, a lower renal survival at 27 months was noticed (p=0.014).

Conclusions: In our study, COL4A3 mutations, presence of multiple mutations and a personal history of hearing loss were associated with a poorer renal prognosis.

TH-PO481

The NOX Inhibitor Setanaxib Combined with Ramipril Reduces Glomerular Function Decline and Fibrosis in a Mouse Model of Alport Syndrome

Thierry Christophe,[1] Maryline Fresquet,[2] Mychel R. Morais,[2] Craig Lawless,[2] Rachel Lennon.[2] *[1]Calliditas Therapeutics AB, Stockholm, Sweden; [2]Wellcome Centre for Cell-Matrix Research, Division of Cell Matrix Biology and Regenerative Medicine, School of Biological Sciences, Faculty of Biology Medicine and Health, The University of Manchester, Manchester, United Kingdom.*

Background: Alport syndrome is a rare genetic disorder, which presents in childhood or adolescence. It is caused by genetic variants affecting type IV collagen, leading to progressive kidney damage. Setanaxib, an NADPH oxidase (NOX) inhibitor, has been shown in preclinical models to reduce inflammation and fibrosis – mechanisms known to play a role in Alport syndrome disease progression. In this study, we assessed the therapeutic potential of setanaxib in a mouse model of Alport syndrome.

Methods: Four-week-old *Col4a3* -/- mice on 129/SvJ background (n=10 per group) were given 10 mg/kg ramipril (an ACE inhibitor [ACEi]) in drinking water, 60 mg/kg setanaxib once daily by gavage, setanaxib and ramipril combined, or vehicle, over 4 weeks. At the end of the study, kidneys were analyzed by imaging and proteomics.

Results: Urinary albumin levels and albumin/creatinine ratio were reduced at 6 and 8 weeks of age in mice receiving ramipril alone, with a further reduction seen in mice receiving setanaxib and ramipril combined (Fig. 1A,B). Histologic analysis indicated that setanaxib and ramipril combined also significantly decreased glomerular sclerosis (scored by a pathologist) and overall fibrosis (Fig. 1C-E). Proteomic and *in silico* analyses also reported increased detection of glomerular basement membrane and collagen proteins with setanaxib and ramipril combined.

Conclusions: These results indicate that setanaxib, when combined with the standard of care ACEi, induced mechanisms that reduced the decline in glomerular function and fibrosis in a well-established mouse model of Alport syndrome.

Funding: Commercial Support - Calliditas Therapeutics

TH-PO482

Beyond COL4A: Combined Renal Histopathology and Genetic Testing Reveals the Genetic Complexity of Thin Glomerular Basement Membrane Disease

Cristian Riella,[1] Dan Colombo,[1] Guilherme Taborda Ribas,[3] Isaac E. Stillman,[1] Helmut G. Rennke,[2] Peter G. Czarnecki.[1,2] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Brigham and Women's Hospital Department of Medicine, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Improved access to genetic testing is changing the diagnostic landscape of chronic kidney disease (CKD). While renal histopathology represents the current gold standard in the differential diagnosis of CKD, the incremental diagnostic yield of genetic testing remains unknown. We aim to investigate the combined diagnostic yield of histopathology and genetic testing, and we seek to identify novel correlations between genotypes and histopathologic phenotypes.

Methods: We identified 114 patients from two academic medical centers in Boston, MA, who underwent both, kidney biopsy and kidney panel genetic testing between 1/1/2020 and 5/1/2023. We assessed pathologic diagnosis and quantifiable ultrastructural phenotypes. We then analyzed corresponding genotypes for diagnostic variants and variants of uncertain significance (VUS). Variants were grouped by genes associated with CAKUT and podocytopathy (or steroid resistant nephrotic syndrome, SRNS).

Results: Glomerular basement membrane thinning was found in 47/114 patients, representing the most common ultrastructural abnormality. We found 16 COL4A variants in 14 patients with GBM abnormalities (8 diagnostic variants, 8 VUS). The remaining patients with GBM abnormalities had variants in dominant CAKUT genes (14 variants in 12 patients) and dominant SRNS genes (15 variants in 13 patients). 4 patients had exclusively recessive SRNS variants identified. In 8 patients, GBM abnormalities did not correlate with any variant of the above categories. 12/18 patients with COL4 variants had ultrastructural evidence of segmental or diffuse podocyte foot process effacement, and 5/18 had a diagnosis of primary FSGS.

Conclusions: In our retrospective cohort of patients who underwent kidney biopsy and genetic testing, thin glomerular basement membranes represented the most common ultrastructural finding. In only one third of these patients, a COL4A variant was found. Variants in dominant CAKUT and SRNS genes were the next most common findings, reflecting the genetic complexity of TBMD beyond COL4A mutations, and suggesting alternative mechanisms of disease causation. Genetic testing for COL4A variants alone would have missed the diagnosis of TBMD in 68.9% of cases, while 3.5% of test results were found to be false positive.

Diagnostic Utility of Characterizing Glomerular Basement Membrane (GBM) Collagen IV Changes by Quantitative Immunofluorescence in Paraffin Sections from FSGS Patients Carrying COL4A3/4/5 Variants

Pongpratch Puapatanakul,[1,2] Suramath Isaranuwatchai,[3,2] Ankanee Chanakul,[2] Jerasit Surintrspanont,[2] Kroonpong Iampenkhae,[2] Kanya Suphapeetiporn,[2] Vivek Charu,[4] Hani Suleiman,[1] Kearkiat Praditpornsilpa,[2] Jeffrey H. Miner.[1] *[1]Washington University in St Louis, St Louis, MO; [2]Chulalongkorn University, Bangkok, Thailand; [3]Chulabhorn Hospital, Bangkok, Thailand; [4]Stanford University School of Medicine, Stanford, CA.*

Background: Variants in COL4A3/4/5 genes are the most common genetic abnormalities associated with FSGS patients without typical Alport syndrome (AS), linking glomerular basement membrane (GBM) collagen IV (colIV) aberrations and podocytopathy. However, variant pathogenicity is often unclear.

Methods: We developed a new method of immunofluorescence staining for collagen α5(IV) and α1/2(IV) on kidney paraffin sections and used Airyscan confocal microscopy to assess colIV levels in 17 idiopathic FSGS patients with pathogenic/likely pathogenic (P/LP) variants, variants of uncertain significance (VUS), and likely benign (LB) variants in *COL4A3/4/5* genes, respectively. Samples from 2 nephrectomies, 3 transplant surveillance biopsies, and 6 biopsies from FSGS patients without *COL4A* variants were used as controls.

Results: Our approach demonstrated collagen α3α4α5(IV) and α1α1α2(IV) in the GBM as two distinct layers, which enabled quantitative comparisons (Figure 1). The ratios of the mean fluorescence intensities of collagen α5(IV) to α1/2(IV) (α5:α1/2 FI ratios) and the ratios of the thicknesses of α5(IV) to α1/2(IV) (α5:α1/2 thickness ratio) were calculated to represent the level of collagen α3α4α5(IV) in relation to α1α1α2(IV). α5:α1/2 FI and thickness ratios were comparable across the control samples (mean ratios 1.36±0.9 and 1.97±0.63, respectively), while both ratios were drastically decreased in all patients with P/LP variants (mean ratios 0.19±0.08 and 0.94±0.48, respectively) confirming the validity of the approach. We then identified 3 VUS patients with significantly reduced α5:α1/2 FI and thickness ratios, suggesting these variants could in fact be pathogenic.

Conclusions: Our approach can serve as a new diagnostic tool to identify the subgroup of FSGS patients with underlying pathogenic *COL4A* variants, which can be confirmed with genetic testing. This may help guide immunosuppressive therapy for FSGS.

Funding: NIDDK Support

Sex Differences in Glomerular Protein Expression in Mice with Autosomal Recessive Alport Syndrome

Emine B. Caparali,[1,2] Vanessa S. De Gregorio,[2,3] Akanchaya Rana,[4] Joanna Cunanan,[2,3] Sofia Farkona,[2,1] Ana Konvalinka,[1,3] Moumita Barua.[1,3]
[1]University Health Network, Toronto, ON, Canada; [2]Toronto General Research Institute, Toronto, ON, Canada; [3]University of Toronto, Toronto, ON, Canada; [4]Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada.

Background: Alport syndrome (AS) is a monogenic disorder that leads to progressive kidney disease, ear, and ocular abnormalities. It is caused by pathogenic variants in *COL4A3*, *COL4A4*, or *COL4A5*, which encode the α3, α4, and α5 chains of type IV collagen. *COL4A3* and *COL4A4* reside on chromosome 2q36, while *COL4A5* is on the X chromosome. We evaluated for sex differences in mice with autosomal recessive AS.

Methods: We compared differences in global protein expression in isolated glomeruli between 1-day old male and female *Col4a3* knockout (KO) and wildtype (WT) mice with mass spectrometry (MS). MaxQuant was used for analysis and statistical tests were done on Perseus. Pathway analysis was performed using Gene Ontology.

Results: At postnatal day 1 (P1), we observed more severe disease in male compared to female *Col4a3* KO mice, as evidenced by higher urine albumin-creatinine ratios (uACR) (1088 mg/mmol vs. 875.6 mg/mmol, p=0.4). 309 significantly differentially expressed proteins in the glomerulus were identified, of which 208 were downregulated and 101 were upregulated in male *Col4a3* KO mice. We also compared P1 WT male and female mice and no differentially expressed protein was detected at baseline. Interestingly, the well-known podocyte apical surface transmembrane sialoglycoprotein, podocalyxin, was upregulated in males compared to female *Col4a3* KO mice. Pathway analysis showed that *Col4a3* KO male mice also had decreased biological processes suggestive of impaired glomerular structure maintenance such as actin filament bundle assembly, cell morphogenesis involved in differentiation and endoplasmic reticulum-nucleus signaling pathway. By contrast, pathways including peptide biosynthetic process and ATP biosynthetic process were found to be increased in male *Col4a3* KO mice, possibly due to increased compensatory mechanisms.

Conclusions: One day old male compared to female *Col4a3* KO mice display more severe disease. Podocalyxin has been reported to be excreted in urine due to podocyte loss and we postulate that its upregulation in male *Col4a3* KO mice may represent compensation. Overall, glomerular proteomic comparison highlights biological pathways that can explain phenotypic differences between male and female mice with autosomal recessive AS, though its mechanistic drivers are unclear.

TH-PO485

Frequency of Diagnostic Variants of Kidney Disease in Diabetic Kidney Disease Patients: A Single-Center Investigation

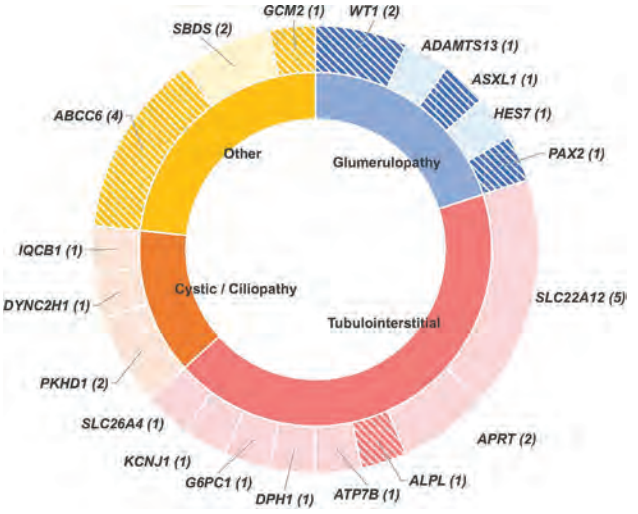
Toyohiro Hashiba,[1] Yuka Sugawara,[1] Yosuke Hirakawa,[1] Dai Sato,[1] Reiko Inagi,[2] Masaomi Nangaku.[1] *[1]Division of Nephrology and Endocrinology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan; [2]Division of Chronic Kidney Disease Pathophysiology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan.*

Background: Involvement of rare variants in the pathogenesis of lifestyle diseases has not been investigated in detail. The past research showed that diagnostic variants were detected only in 1.6% of cases with diabetic kidney diseases (DKD) (NEJM, 2019), but there was no mention of which cases should be genetically tested. Therefore, we performed a whole genome sequence (WGS) based analysis of pathogenic single nucleotide variants (SNVs) of DKD patients to extract the characteristics of cases with pathogenic SNVs.

Methods: We performed WGS for Japanese patients with clinically diagnosed-DKD. Variants were processed with GATK Best Practices. We defined target variants as those included in the 625 genes associated with Mendelian nephropathy and genitourinary diseases (same as analyzed genes in NEJM 2019) and classified as pathogenic or likely pathogenic by ACMG criteria. Target variants were classified into four categories: glomerulopathy, tubulointerstitial, cystic/ciliopathy, and others.

Results: Of the 79 participants, 66 (84%) were males, 70.3±0.8 ages, and 9 (11%) had a family history of kidney diseases. A total of 25 patients (32%) had the target variants, all heterozygously. There were no significant differences in clinical information such as level of albuminuria between cases with and without the target variants. There were 10 cases with the variants in genes *WT1*, *ASXL1*, *PAX2*, *ALPL*, *ABCC6*, and *GCM2*, which reportedly show an autosomal dominant (AD) manner of inheritance. Only 2 of these 10 cases had a family history of kidney disease.

Conclusions: Among clinically diagnosed Japanese DKD patients, a considerable number had kidney-related pathologic variants, which were unexpectedly large compared to the previous report. It was difficult to determine from clinical presentation or family history which cases had the target variants.



Gene names of the detected target variants are shown along with their category classification and the number of persons with them. Stripes indicate AD pattern of inheritance.

TH-PO486

Mouse and Human Studies Support DSTYK Loss of Function as a Low Penetrance and Variable Expressivity Risk Factor for Urinary Tract Anomalies and Movement Disorders

Jeremiah Martino,[1] Qingxue Liu,[1] Katarina Vukojevic,[2] Juntao Ke,[1] Atlas Khan,[1] Velibor Tasic,[3] Gian Marco Ghiggeri,[6,7] Krzysztof Kiryluk,[1] Cathy L. Mendelsohn,[4] Vivette D. D'Agati,[5] Ali G. Gharavi,[1] Simone Sanna-Cherchi.[1] *[1]Columbia University Department of Medicine, New York, NY; [2]Sveuciliste u Splitu Medicinski fakultet, Split, Croatia; [3]Medical Faculty of Skopje, University Children's Hospital, Skopje, Macedonia (the former Yugoslav Republic of); [4]Columbia University Department of Urology, New York, NY; [5]Columbia University Department of Pathology and Cell Biology, New York, NY; [6]Division of Nephrology and Renal Transplantation, IRCCS Instituto Giannina Gaslini, Genoa, Italy; [7]Laboratory of Molecular Nephrology, IRCCS Instituto Giannina Gaslini, Genoa, Italy.*

Background: Previous work identified rare variant in *DSTYK* in humans with congenital anomalies of the kidney and urinary tract (CAKUT). *DSTYK* coding variants exist at low frequency in the general population, complicating genetic interpretation. Mouse and human studies were used to clarify the association, penetrance and expressivity of *DSTYK* variants.

Methods: We phenotypically characterized *Dstyk* knockout mice on 3 genetic backgrounds (C57BL/6J, FVB/NJ and C3H/HeJ). We expanded, characterized and re-sequenced the original family segregating the *DSTYK c*.654+1G>A splice-site variant (referred to "splice variant" below). *DSTYK* loss-of-function (LOF) and the splice-site variants were annotated in individuals across different phenotypes: a) CAKUT, b) Epilepsy, and c) amyotrophic lateral sclerosis (ALS) vs. controls. PheWAS analysis was performed using UKBB data.

Results: C57BL/6J *Dstyk*$^{-/-}$ mice exhibited a 23% penetrance of obstructive uropathy (OU). FVB/NJ *Dstyk*$^{-/-}$ mice showed a similarly low penetrance, but with added phenotypes of hypoplasia and partial duplication of the kidney and proximal ureter. C3H/HeJ mutants showed a 40% penetrance of OU, but with mild-to-moderate severity. Expansion, re-analysis and re-sequencing of the original family segregating the rare splice-site variant showed low penetrance and no alternative genetic causes for CAKUT. LOF *DSTYK* variant burden showed significant excess for CAKUT (OR=9.13, P=6.50x10^{-3}), and Epilepsy (OR=6.20, P=1.35x10^{-2}), vs. controls. Enrichment analysis for the splice variant was significant for epilepsy (OR= 6.04, P=1.72x10^{-2}). Literature review and exploratory PheWAS supported association with neurological disorders.

Conclusions: Mouse and human data support causality for *DSTYK* LoF variants. Large sequencing studies (e.g. >200,000 cases) are required to fully assess the contribution of *DSTYK* rare variants to lowly-penetrant underlying traits with relatively common population prevalence such as obstructive uropathy. Therefore, while *DSTYK* LoF variants should not be used to ascertain diagnosis or risk stratification, they may be used in clinical settings when coupled with inheritance information and clinical plausibility.

TH-PO487

Tofacitinib Suppresses JAK/STAT Pathway Hyperactivity Ex Vivo in Pediatric Focal Segmental Glomerulosclerosis

Carol L. Shen, Ashley Richardson, Marta Martin-Fernandez, Louise Malle, Sofija Buta, Aum Patel, Haylen Rosberger, Jean Lim, Michael E. Horesh, Jeffrey Saland, Dusan Bogunovic. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Focal segmental glomerulosclerosis (FSGS) accounts for approximately 20% of cases of pediatric nephrotic syndrome and is the leading cause of end-stage renal disease among glomerular disorders in the US. Primary FSGS is thought to be caused by a circulating factor which causes podocyte, glomerular and endothelial injury, and presumably immune dysregulation. There is growing evidence that the JAK/STAT pathway is involved in various kidney diseases, however, its role in FSGS has not been thoroughly studied. We recently identified JAK1 gain-of-function mutation in a pediatric patient with membranous nephropathy and multisystem immune dysregulation, which was successfully treated with a JAK inhibitor. We hypothesized that JAK/STAT pathway hyperactivity may play a role in the pathogenesis of pediatric primary FSGS, and may be suppressed by *ex vivo* JAK inhibition.

Methods: We recruited eleven individuals age 2-18yr with primary FSGS and ten age- and sex-matched healthy controls. Mass cytometry (CyTOF) with antibodies against STAT proteins was performed on heparinized whole blood samples to characterize JAK/STAT pathway activity in immune cell subsets. Multiplex immunoassay was performed on plasma samples to quantify circulating cytokine levels. Plasma from patients were added to healthy control peripheral blood mononuclear cells (PBMCs) and treated with or without tofacitinib for 4 hours, followed by CyTOF.

Results: The JAK/STAT pathway is overactive in 60% patients despite immunosuppression, predominantly showing increased phosphorylated STAT3 (pSTAT3) activity in T cell subsets. The level of STAT3 phosphorylation in T cells predicts lower kidney function, lower serum albumin, and increased proteinuria 1 year later. IL6 and IL17 which stimulate STAT3 phosphorylation are increased in patient plasma. Tofacitinib treatment of healthy control PBMCs incubated with patient plasma leads to reduction in pSTAT3 activity in T cell subsets, particularly in CD4+ T cells.

Conclusions: JAK/STAT pathway overactivity is present in pediatric patients with primary FSGS and predicts future severity of disease. JAK/STAT hyperactivity is likely driven by cytokine signaling and may be targeted by JAK inhibition.

TH-PO488

Validation of Multiple Office Blood Pressure Measurement: A Novel Tool for Evaluating Blood Pressure in Children

Daniele Rossetti,[1] Maria Cristina Mancuso,[1] Giacomo Tamburini,[1] Antonio Vergori,[2] Alice Monzani,[3] Thomas Ria,[4] Valentina Capone,[1] Gianluigi Ardissino.[1] On Behalf of the CHIld Project. *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Aziende Socio Sanitarie Territoriale dei Sette Laghi, Varese, Italy; [3]Azienda Ospedaliero Universitaria Maggiore della Carita, Novara, Italy; [4]Presidio Ospedaliero Universitario "Santa Maria della Misericordia", Udine, Italy.*

Background: Blood pressure measurement (BPM) is a common procedure in clinical practice, but it can be challenging to obtain reliable values in children. Casual office BPM (gold standard) is all but accurate and ABPM may be difficult to perform or even misleading. Multiple Office Blood Pressure Measurement (mOBPM) was developed at our Center in 2010 for evaluating BP with serial and automated measurements (≥10 in at least 30 min) using standard oscillometric devices. BP values were uploaded in a software and coefficient of variation (CV) was calculated after excluding outlier values (<5th and & >95th centile of the recorded values).

Methods: The present study compares results obtained with mOBPM vs ABPM in children addressed to our Center for suspected arterial hypertension (AH). Given that children develop myocardial hypertrophy soon after the development of AH, Cardiac Mass Index (CMI) was used as gold standard to categorize patients as hypertensive or normotensive.

Results: Twenty-five children were enrolled. AH was confirmed by increased CMI in 5 (20%) of them. ABPM identified 11 (44%) hypertensive children vs 12 (48%) identified by mOBPM. Sensitivity and specificity were 60% and 60% using ABPM vs 100% and 65% using mOBPM. PPV and PNV were 27% and 86% vs 42% and 100%, respectively.

Conclusions: The present analysis shows that mOBPM is more reliable than ABPM in the diagnosis of AH in children. We recommend the routine use of mOBPM for measuring BP since ABPM may lead to wrongful diagnosis, can provide misleading results because of children discomfort and is more time-consuming.

TH-PO489

Evaluating Pediatric Hypertension According to Different Guidelines Using a Multi-Institutional Electronic Health Record Database

Wei-Ting Liao, You-Lin Tain. *Chang Gung Memorial Hospital Kaohsiung Branch, Division of Pediatric Nephrology, Kaohsiung, Taiwan.*

Background: Childhood hypertension is associated with cardiovascular morbidity and adult mortality. However, the burden of pediatric hypertension in Taiwan remains unclear.

Methods: We conducted a cross-sectional study using outpatient blood pressure (OBP) measurements obtained in routine care visits from the Chang Gung Research Database between 2009 and 2018 to evaluate guideline defined hypertension and patient-related factors of pediatric hypertension. Additionally, we examined the agreement on hypertension between the 2017 American Academy of Pediatrics Guidelines and the 2004 Fourth Report.

Results: In total, 12,469 children and adolescents who underwent three separate >= 3 OBP measurements over 33,369 person-years with a total of 95,608 BP measurements in an outpatient setting were analyzed. According to the 2017 American Academy of Pediatrics (AAP) guidelines, the rate of pediatric hypertension in the study setting ranged from 0.78–5.95 per 1000 persons between 1 and 17 years of age. Perfect agreement existed between the thresholds of the two guidelines for defining hypertension in 1-7, 8-12 and 13-17 years of age groups (all k static >=0.85), but the use of AAP threshold classified more children as having hypertension. Children and adolescents with hypertension often had complex chronic diseases and required substantial healthcare services in outpatient, emergency, and inpatient settings.

Conclusions: The present study provides evidence of guideline-based pediatric hypertension. The study results highlight the importance of regular blood pressure monitoring to identify and management of hypertension in children and adolescents. Further research is required to investigate the effect of new thresholds on the identification of target organ damage in pediatric age.

Funding: Private Foundation Support

Comparison of pediatric hypertension defined by 2004 and 2017 versions of guidelines in three age groups

Age group, year	Number of participant	2004 Fourth Report		2017 AAP guideline		Differences	
		Number of case	Event rate / 1000 persons	Number of case	Event rate / 1000 persons	Kappa (95% CI)*	Agreement (%)**
1-7	495,962	375	0.76	387	0.78	0.98 (0.97-0.99)	99.58
8-12	255,615	523	2.05	573	2.24	0.94 (0.94-0.96)	99.11
13-17	218,368	1185	5.43	1300	5.95	0.85 (0.84-0.87)	97.44

American Academy of Pediatrics (AAP)

*Cohen's Kappa estimate >0.8 indicates perfect agreement

** Agreement (%) between two guidelines was calculated with as (number of cases + number of non-cases agreed in both guidelines/total participants)

Hypertension Associated with Hyper-Reninemic Hyperaldosteronism After COVID-19 Infection in a Pediatric Patient

Devyani Sivakumar,[1,2] Vivian Shi,[3] Mohammed Khurram Faizan.[1,4] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI; [3]Stanford Medicine, Stanford, CA; [4]Hasbro Children's Hospital, Providence, RI.*

Introduction: COVID-19 was a leading cause of death among children and adolescents from Aug 2021 through Jul 2022, ranking 8th for all causes and 1st for infectious causes **[Kompaniyets, 2022][1]**. Children and adolescents are at risk for certain post-COVID complications. **[Tadeo, 2023][2] [Flaxman, 2023][3]**. In a prospective multicenter study in Turkey, 28% of the children ages 10-18 yrs had abnormal blood pressure 8 weeks after a mild COVID-19 infection, of whom 39.2% had stage 1 HTN **[Uysal, 2022][4]**. The pathophysiology of SARS-CoV-2 associated hypertension (HTN) remains unclear **[Kukarni, 2022][5]**.

Case Description: A 13-yr-old male with no significant past medical history presents to the pediatric nephrology clinic for evaluation of HTN. He had COVID infection 9 mths ago and was noted to be hypertensive since then. He was asymptomatic. Vitals notable for BP 142/87 mmHg, BMI 31 kg/m^2. Exam was normal. Labs revealed normal CBC, urinalysis, lytes, creatinine, TSH, serum metanephrine levels. Renin [4.2ng/mL/h] and aldosterone [37.6 ng/dL] levels were elevated. Renal US with doppler was unremarkable. MRA abdomen was negative for renal artery stenosis. 24-hour ABPM showed a daily average 135/70 mmHg and night average 140/73 mmHg. He was started on lisinopril with improvement in BP.

Discussion: Angiotensin converting enzyme 2 (ACE2), which is utilized by SARS-CoV-2 for entry into host cells, is widely expressed in the lungs, kidneys, testes, gut, adipose tissue, and brain. Infection within host cells mediates RAS overactivation. One hypothesis is that the increased activity of the ACE/AngII/AT1R axis or the decreased activity of the ACE2/Ang-(1–7)/Mas Receptor axis generates pulmonary and neurogenic HTN **[3]**. We were able to rule out secondary causes in our patient with hyper-renninemic hyperaldosteronism and clinical response to lisinopril further supports this proposed mechanism. In a retrospective and prospective cohort study of adult patients, 21.6% patients had uncontrolled HTN requiring treatment, 23 days post-discharge from the hospital or ER for COVID infection **[Wrona, 2022][6]**. In a cross-sectional study in Korea, an increase in the prevalence of HTN was observed among youths during the pandemic **[Song, 2019][7]**. There are limited studies available in pediatric patients in comparison to adults assessing prevalence and risk factors for HTN post COVID infection.

TH-PO491

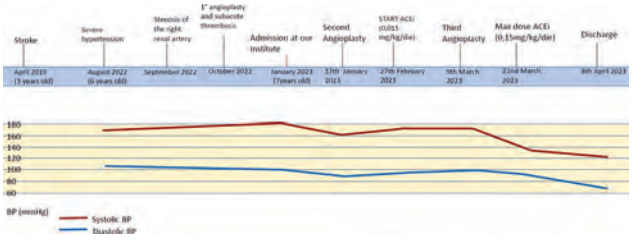
Melorheostosis and Renal Artery Stenosis in Solitary Kidney: A Pediatric Case

Carolina Bigatti,[1] Gabriele Mortari,[2] Andrea Angeletti,[1] Francesca Lugani,[1] Martino Cheli,[1] Gianluca Caridi,[1] Enrico E. Verrina,[1] Gian Marco Ghiggeri,[1] Alberto Magnasco,[1] Maddalena Lancieri,[1] Barbara Lionetti,[1] Edoardo La Porta.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy.*

Introduction: Melorheostosis is a rare bone dysplasia characterized by irregular hyperostosis of bones, diagnosed by typical radiological signs. Additionally, soft tissue changes have been described. We present a patient with melorheostosis and severe hypertension due to angioplasty-resistant renal artery stenosis (RAS) of the solitary kidney.

Case Description: A 7-years-old girl presented with severe hypertension. She had a history of stroke, absence of left kidney and scoliosis. In 2022, due to severe RAS she underwent percutaneous cutting balloon angioplasty with improvement on blood pressure control. Few days later the occurrence of subacute thrombosis was treated by drug eluting stent. MRI imaging of the spine revealed evidence of bony aspects compatible with melorheostosis. She was considered not suitable for vascular surgery and proposed to our Institution for nephrectomy or renal transplant. In our Institute she was treated with 9 antihypertensive drugs without reaching pressure control. Kidney ultrasound demonstrated in-stent fracture with severe restenosis. Two additional percutaneous angioplasties were attempted with no significant improvement. Then we introduced ACE inhibitor (ACEi) titrated to benefit on blood pressure control without compromising kidney function. Her blood pressure is now acceptable.

Discussion: Melorheostosis is associated with different malformation of soft tissue: we present the first case of melorheostosis with RAS in solitary kidney patient. RAS causes activation of RAAs to increase renal blood flow, leading to high blood pressure. The use of ACEi in patients with RAS is controversial: it acts directly on the causative mechanism of hypertension, but it leads to a reduction in the kidney blood flow, with the risk of developing acute kidney damage. Given the poor response to several angioplasties, we started with Ramipril at very low dose progressively increased until 0.11 mg/kg/die. She is treated now with 5 antihypertensive drugs, with better pressure control.



TH-PO492

Renal Autotransplant in a Pediatric Patient with Neurofibromatosis Type 1 (NF1) and Renal Artery Stenosis (RAS)

Morgan E. Beebe, Samantha J. Wala, Mahmoud Kallash, Jaimie D. Nathan, Sara K. Rasmussen. *Nationwide Children's Hospital, Columbus, OH.*

Introduction: Patients with NF1 are at increased risk for developing HTN, with RAS being the most common etiology. When medication fails, surgery may be indicated. We present a case of a 6-year-old boy with NF1 and RAS whose HTN was refractory to medical therapy and balloon dilation, but successfully treated with renal autotransplant.

Case Description: A 6-year-old boy with NF1 presented to our nephrology clinic with HTN. While his laboratory findings were unrevealing, computed tomography angiography (CTA) of the renal vessels revealed high-grade stenosis of the proximal right renal artery. He subsequently underwent arterial dilation and balloon angioplasty performed with IR. Following this, he presented in hypertensive urgency on dual-medical therapy. Repeat CTA redemonstrated severe right-sided stenosis; IR deemed the patient inappropriate for re-intervention. With 45% function of the right kidney on MAG-3 scan, our surgical colleagues offered renal autotransplant for consideration, which the family accepted. Six months postoperatively, his antihypertensive burden decreased from four-drug therapy to amlodipine monotherapy, with home blood pressures averaging 100/60 mmHg.

Discussion: Patients with NF1 are at increased risk of developing HTN. In those with RAS, a stepwise treatment approach from least-to-most invasive is preferred. If multidrug therapy and endovascular interventions fail, nephrectomy is then considered. Because stenosis may recur in the remaining kidney, renal autotransplant can be a preferred intervention for the treatment of refractory HTN with RAS in patients with preserved renal function. While more technically challenging in pediatric patients, this intervention confers the benefit of retaining the native kidney.

TH-PO493

Clinical Characteristics of Korean Pediatric Renovascular Hypertension According to Underlying Diseases

Jinwoon Joung, Heeyeon Cho. *Samsung Medical Center, Gangnam-gu, Seoul, Republic of Korea.*

Background: Previously, Moyamoya disease (MMD) has been suggested as the most common cause of renovascular hypertension (RVH) in Korean children. The *ring finger protein 213* (*RNF213*) has also been reported to be a causative gene of systemic vasculopathy in East Asia which results in MMD and RVH. This study aimed to evaluate the clinical characteristics of RVH and to compare the outcomes according to underlying diseases in Korean children.

Methods: A retrospective study was performed in patients who were diagnosed RVH at age under 18 years in Samsung Medical Center from 2010 to 2022. Medical records including sex, age, gene study, location of vascular lesion, treatment modalities and response to treatment were reviewed. *RNF213*-related vasculopathy designates systemic vasculopathy involving intracranial, renal, and pulmonary arteries with defined *RNF213* mutation. According to underlying diseases, patients were grouped as *RNF213*-related vasculopathy (group 1, n=17), atypical vasculopathy (group 2, n=14), and others including congenital anomalies of kidney and urinary tract (CAKUT) and solid tumor (group 3, n=10).

Results: A total of 41 pediatric patients (19 males and 22 females, mean age of 10.1±4.8 years) were included. The mean value of initial blood pressure (BP) was 162/96 mmHg. Twenty five children were incidentally detected hypertension without symptoms while 15 patients showed neurological symptoms. Five patients were diagnosed RVH prior to MMD. Twenty patients underwent percutaneous transluminal angioplasty (PTA), 3 patients received bypass surgery, and 3 patients were done nephrectomy. Target organ damage was found in 15 patients (36.6%). Ostial vascular involvement was notably prevalent in group 1. For response to treatment, BP and stenotic lesions were poorly controlled in group 1 and 2 while overall outcome was relatively favorable in group 3. However, no statistical differences were revealed for the location and level of stenosis, treatment modalities, and outcomes between 3 groups.

Conclusions: The *RNF213*-related vasculopathy including MMD is the most common cause of RVH in Korean children in association with ostial vascular lesions. PTA and bypass surgery are mostly performed for patients with *RNF213*-related or atypical vasculopathy and clinical outcomes are relatively poor in these patients compared to other underlying diseases such as CAKUT or solid tumor.

TH-PO494

Blood Pressure Control in Pediatric Hemodialysis: Data from the SCOPE Collaborative

Celina Brunson,[1] Troy Richardson,[2] Donna J. Claes,[3] Heather L. Wasik,[4] Mark Mitsnefes,[3] Sarah J. Swartz,[5] Rebecca Ruebner,[6] Donald J. Weaver,[7] Alicia Neu,[6] Bradley A. Warady.[8] *[1]Children's National Hospital, Washington, DC; [2]Children's Hospital Association, Overland Park, KS; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]SUNY Upstate Medical University, Syracuse, NY; [5]Texas Children's Hospital, Houston, TX; [6]Johns Hopkins University, Baltimore, MD; [7]Wake Forest University School of Medicine, Winston-Salem, NC; [8]Children's Mercy Kansas City, Kansas City, MO.*

Background: The Standardizing Care to Improve Outcomes in Pediatric End Stage Kidney Disease (SCOPE) Collaborative is a quality improvement initiative focused on improving care of children on dialysis. Accurate blood pressure (BP) measurement is a focus of SCOPE as hypertension and cardiovascular disease is a leading cause of morbidity and mortality for children on dialysis.

Methods: Twenty centers collected two post-hemodialysis (HD) BP measurements per week for two weeks of each month using a standardized procedure (BP measurement bundle) to characterize the BP of children on HD from 4/1/2019-3/31/2022. The measurements were conducted via either oscillometric or manual methods. Hypertension was classified using the 2017 AAP hypertension guidelines.

Results: A total of 2,390 BP evaluation forms from 294 HD patients ≥3 years of age have been submitted to date. There were 4,713 weekly BP measurements. 1,457 (31%) measurements were from patients aged 3-12 years and 3,256 (69%) measurements were from patients aged 13 years and older. BP medications were prescribed at the time of 56% of measurements. Overall, 2,432 (52%) of the BP readings were abnormal. The majority (58.5%) of measurements in the 3-12 year olds were consistent with either Elevated, Stage I or Stage II hypertension. In the patients 13 years and older, 48.5% of measurements were abnormal, with 35% of the readings in Stage I/II hypertension. More than 70% of the abnormal readings were based only on oscillometric measurement. 891 (18.9%) of all BP measurements were manual. In 41% of instances when a manual BP was repeated after an oscillometric reading, the BP classification changed, in 33% there was an increase in the BP classification, while the classification improved in 67% of cases.

Conclusions: The prevalence of elevated BP/hypertension is high amongst pediatric HD patients in the SCOPE collaborative when using a standardized BP measurement procedure and despite the use of antihypertensive therapy. While most of the BP classifications were based on oscillometric measurements instead of manual readings, the latter may help inform treatment decisions. Additional efforts by SCOPE will help to further define a clinically practical strategy for BP assessment in children on HD as a prelude to addressing therapeutic BP management.

TH-PO495

Prevalence of Masked Hypertension and Its Association with Target Organ Damage in Children: A Systematic Review and Meta-Analysis

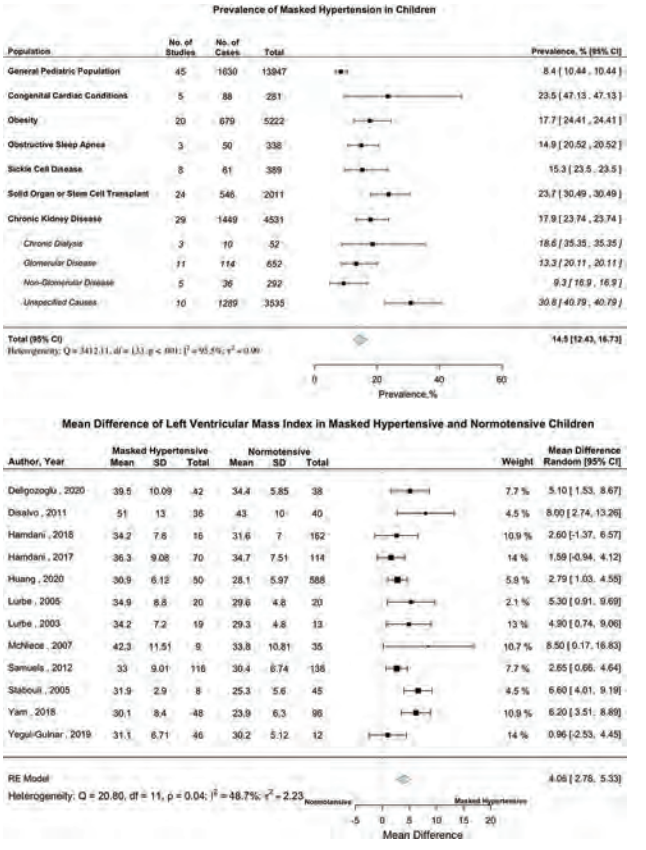
Andrew Yu,[1] Jason Chung,[2] Cal Robinson,[3] Lauren Sheffield,[4] Prathayini Paramanathan,[5] Mark Mitsnefes,[6] Rulan S. Parekh,[7] Manish Sinha,[8] Janis M. Dionne,[9] Rahul Chanchlani.[10] *[1]University of Alberta Faculty of Science, Edmonton, AB, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [3]The Hospital for Sick Children, Toronto, ON, Canada; [4]McMaster University, Hamilton, ON, Canada; [5]All Saints University School of Medicine, Roseau, Dominica; [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [7]Women's College Hospital, Toronto, ON, Canada; [8]Evelina London Children's Hospital, London, United Kingdom; [9]BC Children's Hospital, Vancouver, BC, Canada; [10]McMaster Children's Hospital, Hamilton, ON, Canada.*

Background: We investigate the prevalence of pediatric masked hypertension (MH) in children with various comorbid conditions and compare the risk of target organ damage in children with MH and normotensive children.

Methods: A systematic literature search on nine databases included English publications from 1974-2023. MH was defined based on ambulatory blood pressure monitoring. LVMI was indexed to subject height and body surface area (g/m$^{2.7}$). LVH was defined by the 95th percentile pediatric reference range, or a pediatric or adult cut-off. Correlation coefficients were transformed and pooled using a random effects model.

Results: Of 8996 screened studies, 12 studies and 2028 children were included. MH prevalence was highest among those with chronic kidney disease (CKD) (18%), congenital cardiac conditions (24%), obesity (18%), and solid-organ or stem-cell transplant (24%). LVMI was elevated in the MH group (mean=35.48 g/m$^{2.7}$) compared to the normotensive group (mean=31.10 g/m$^{2.7}$), with a mean difference of LVMI was 4.06 g/m$^{2.7}$ (95% CI:2.78-5.33) (fig). MH children were at 2.37 (95% CI: 1.41, 3.97) increased odds of LVH compared to normotensive children.

Conclusions: MH is common among children with congenital cardiac conditions, solid organ or stem-cell transplant, CKD, and obesity, and is associated with increased risk of LVH. These findings emphasize the importance of early screening, diagnosis, and treatment of hypertension in these high-risk children.



TH-PO496

Risk of Target Organ Damage in Pediatric CKD Patients with Ambulatory Hypertension: A Systematic Review and Meta-Analysis

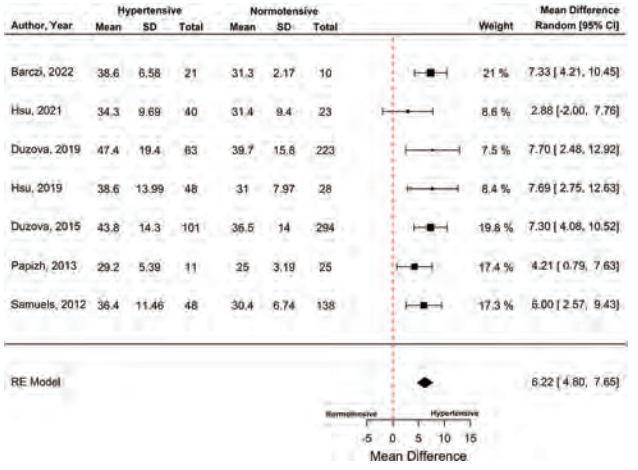
Jason Chung,[1] Cal Robinson,[2] Andrew Yu,[3] Lauren Sheffield,[4] Manish Sinha,[5] Janis M. Dionne,[6] Mark Mitsnefes,[7] Andrew M. South,[8] Rulan S. Parekh,[9] Myanca D. Rodrigues,[10] Damien G. Noone,[2] Rahul Chanchlani.[11] *[1]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [2]The Hospital for Sick Children, Toronto, ON, Canada; [3]University of Alberta, Edmonton, AB, Canada; [4]McMaster University, Hamilton, ON, Canada; [5]Evelina London Children's Hospital, London, United Kingdom; [6]BC Children's Hospital, Vancouver, BC, Canada; [7]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [8]Wake Forest University School of Medicine, Winston-Salem, NC; [9]Women's College Hospital, Toronto, ON, Canada; [10]McMaster University, Hamilton, ON, Canada; [11]McMaster Children's Hospital, Hamilton, ON, Canada.*

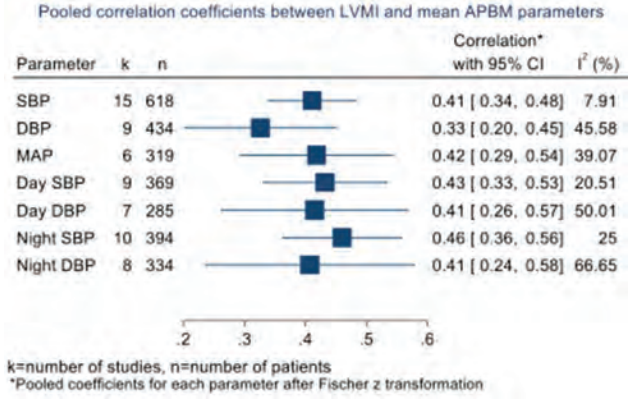
Background: The objective of this systematic review is to determine the association between ambulatory hypertension and left ventricular mass index (LVMI) as well as ambulatory blood pressure monitoring (ABPM) parameters in youth with CKD.

Methods: A systematic literature search on 9 databases included English publications from 1974-2022. LVMI was indexed to subject height and body surface area (g/m$^{2.7}$). Correlation coefficients were transformed and pooled using a random effects model.

Results: Of 1,128 screened studies, 16 studies and 2,254 children and adolescents were included. LVMI was elevated in the hypertensive group compared to the normotensive group (mean difference: 6.22 g/m$^{2.7}$, 95% CI: 4.80-7.65). Hypertensive children were at 3.34 (95% CI: 2.38-4.68) increased odds of left ventricular hypertrophy compared to normotensive children. Estimates of pooled correlation coefficients demonstrated nighttime systolic (r=0.46, 95%CI: 0.36, 0.56) and daytime systolic (r=0.43, 95%CI: 0.33-0.53) BP to have the strongest positive linear relationship to LVMI.

Conclusions: Pediatric CKD patients with ambulatory hypertension especially during nighttime are at significant risk of increased LVMI. Adequate blood pressure control among children with CKD is imperative to avoid the risk of target organ damage and future cardiovascular disease.





TH-PO497

Association of Isolated Nocturnal Hypertension (INH) and Target Organ Damage in Light of the 2022 American Heart Association (AHA) Pediatric Ambulatory Blood Pressure Monitoring (ABPM) Guidelines

Taylor A. Hill-Horowitz, Penina Feldman, Rachel Frank, Laura J. Castellanos, Pamela Singer, Christine B. Sethna, Abby M. Basalely.
Cohen Children's Medical Center, Queens, NY.

Background: Pediatric INH, previously defined by the 2014 guidelines as sleep blood pressure (BP) >95th%ile for sex and height, is associated with increased risk of target organ damage (TOD). In 2022, AHA guidelines lowered sleep BP thresholds to 110/65mmHg. The aim was to determine the association of INH and TOD according to the new guidelines.

Methods: A retrospective chart review of ABPMs from adolescents 13-21 years old between 2015-2022 was performed. ABPM phenotypes were normotension, INH, isolated daytime hypertension (HTN), and sustained day-night HTN. The primary exposure was INH, defined as sleep BPs ≥110/65mmHg with wake BPs <130/80mmHg. Echocs performed within 6 months of ABPM were reviewed. The primary outcome was left ventricular hypertrophy (LVH), defined as LVMI >95th%ile. Pearson's chi-squared, Wilcoxon rank-sum, and logistic regression were utilized as appropriate.

Results: Of 353 ABPM reports (median age 16, 73% male), 25% (N=89) classified as INH by 2014 guidelines, while 45% (N=115) classified as INH by 2022 guidelines. Hypertensive sleep BPs bordered the 110/65mmHg cutoff; median systolic BP was 116mmHg [IQR 112,122] and median diastolic BP was 62mmHg [58,68] (Table 1). Echos were available for 60% of the cohort (N=154) and 57% (N=65) of INH. LVH prevalence according to ABPM phenotype was 40% (26/65) of INH, 33% (2/6) of isolated daytime HTN, and 46% (38/83) of sustained day-night HTN. Any HTN was associated with >2x increased odds of LVH [OR=2.5 95%CI(1.2-5.2)], but there was no association of INH with LVH as compared to normotension.

Conclusions: Lack of association between INH and LVH may reflect the increased sensitivity of 2022 AHA guidelines to diagnose nocturnal HTN. LVH was less prevalent among INH as compared to other hypertensive phenotypes. While the cohort was small, these findings may inform future studies of how clinicians should manage INH.

ABPM Phenotypes					
Variables*†	Normotension (N=98)	Isolated Nocturnal Hypertension (N=115)	Isolated Daytime Hypertension (N=9)	Sustained Day-Night Hypertension (N=131)	P-Value

Sleep-Disordered Breathing, Risk of Target Organ Injury, and Role of Obesity in Youth Referred for Hypertension Disorders

Donald J. Weaver,[1] Rahul Chanchlani,[2] Stefan Kiessling,[3] Margaret Murphy,[3] Sandeep K. Riar,[4] Christine B. Sethna,[5] Ikuyo Yamaguchi,[6] Andrew M. South.[7] *[1]Levine Children's Hospital, Charlotte, NC; [2]McMaster University, Hamilton, ON, Canada; [3]University of Kentucky, Lexington, KY; [4]Emory University School of Medicine, Atlanta, GA; [5]Cohen Children's Northwell Health Physician Partners Pediatric Nephrology and Kidney Transplant, Queens, NY; [6]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [7]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Sleep-disordered breathing (SDB) has adverse consequences on blood pressure regulation in adults, but its relationship with target organ injury (TOI), especially in youth, is less clear. Our objective was to determine if SDB is associated with higher risk for TOI in youth referred for hypertension disorders and if obesity magnified this risk.

Methods: Interim cross-sectional analysis of baseline data from the multisite Study of the Epidemiology of Pediatric Hypertension Registry (SUPERHERO) which retrospectively collects electronic health records data using biomedical informatics scripts. Inclusion criteria were initial visit for hypertension disorder based on ICD-10 codes between 1/1/2015 and 12/31/2022 and age <19 years. Exclusion criteria were kidney transplant, dialysis, or pregnancy per ICD-10 codes at the index visit. Exposures were ICD-10 code-defined SDB, and obesity by body mass index percentile was our effect modifier. Outcomes were ICD-10 code-defined heart and kidney TOI at the index visit. We used unadjusted generalized linear models.

Results: In this analysis of 11,580 participants, mean age was 12.0 ± 5 years, 52% had obesity, 4% has SDB, and 8 % had TOI (Table). Compared to participants without SDB, those with SDB had a 57% lower risk of TOI (RR 0.43, 95% CL 0.26 to 0.69). Obesity was associated with a lower magnitude of association, though not significantly (interaction *p*-value 0.08).

Conclusions: In a large multisite registry of youth referred for hypertension disorders, participants with an ICD-10 code for SDB at baseline had a lower risk of TOI by ICD-10 code. Next steps include better defining our exposure and outcome. Further studies are needed to determine if clinical interventions that impact sleep health can mitigate future cardiovascular risk in youth.

Urinary Biomarkers in Neonates Born to Mothers with Preeclampsia

Vimal Master Sankar Raj, Praveen Kumar, Diana L. Warnecke. *University of Illinois Chicago College of Medicine at Peoria, Peoria, IL.*

Background: Effects of preeclampsia on renal development or function in newborns are unknown. We hypothesized that the circulating factors causing endothelial dysfunction and impaired renal function in mothers with preeclampsia may adversely affect fetal kidneys.

Methods: All newborns with gestational age ≥32 weeks were eligible. Moms with known renal abnormalities on function or structure on prenatal ultrasound, nephrotoxic medication exposure as well as babies born with low APGAR scores, fetal distress were excluded. Bag urine samples were stored at -70° C and assayed using commercially available ELISA kits for Cystatin C,Nephrin, KIM – 1 and Klotho. Urinary creatinine and protein contents were measured using standard techniques. Comparisons between the groups were made using t-tests or Wilcoxon Rank Sum Test. For categorical variables, Chi-square or Fisher's exact analyses were used.

Results: The baseline characteristics of 68 mothers and their newborns were comparable to each other. Urine protein and creatinine were significantly higher (Table1) while Klotho levels were significantly lower in study group. Urinary Nephrin was higher in study infants but the difference was not statistically significant (p value 0.053). There was no correlation between maternal urinary protein/creatinine ratio and levels of urinary biomarkers in their infants.

Conclusions: This cross-sectional study on urinary biomarkers among infants born to preeclampsia mothers has shown high urinary protein in the study group over control. Urinary klotho levels were also significantly lower in the study infants mirroring the existing knowledge of low klotho levels with acute renal injury and advanced CKD. Levels of urinary nephrin urinary KIM-1 and cystatin C level were not statistically different between the two groups. Further prospective studies tracking renal function, proteinuria and blood pressure measurement can provide clues to the significance of these urinary biomarkers as early screening tools for CKD in infants born to mothers with preeclampsia.

Urinary biomarkers

Biomarker	Mother Preeclampsia + (%) N = 34	Mother Preeclampsia - (%) N =34	P value
Total Protein (mg/dl) Median (IQR)	37.1 (14.4 to 53.5)	20.3 (7.5 to 30.0)	0.04
Creatinine (mg/dl) Median (IQR)	63.4 (25.2 to 96.6)	24.8 (19.8 to 44.2)	0.008
Cystatin C (ng/ml) Median (IQR)	2.4 (1.2 to 6.2)	7.59 (1.1 to 33.8)	0.12
KIM-1 (ng/ml) Median (IQR)	0.035 (0.0045 to 0.20)	0.074 (0.0045 to 0.30)	0.16
Nephrin (µg/ml) Median (IQR)	0.56 (0.06 to 1.90)	0.15 (0.066 to 0.53)	0.053
Klotho (pg/ml) Median (IQR)	3.08 (3.08 to 21.28)	17.03 (3.08 to 92.36)	0.0032

TH-PO500

Association Between Birth Weight Z-Score and Blood Pressure in 9- to 10-Year-Old Icelandic Children

Asdis H. Sigurdardottir,[1] Olafur S. Indridason,[1] Sigurdur S. Stephensen,[1,2] Thordis J. Hrafnkelsdottir,[1,2] Vidar O. Edvardsson.[1,2] *[1]Landspitali, Reykjavik, Iceland; [2]Haskoli Islands, Reykjavik, Iceland.*

Background: Low birth weight has been associated with adverse cardiovascular outcomes, including an increased risk of hypertension later in life. The aim of this study was to examine the association between birth weight (BW) indices and blood pressure (BP) in a cohort of healthy 9-to 10-year-old Icelandic school children.

Methods: Icelandic children aged 9-10 years underwent 4 seated BP measurements in 2009. BP percentiles and z-scores were calculated from the average of the 4 measurements. Height and weight were measured, and information on birth weight and gestational age was obtained from the Icelandic Birth Registry. Birth weight z-score was calculated based on a standardized growth chart by Niklasson & Albertsson-Wikland. Pearson correlation coefficient and multivariable linear regression were used for statistical analysis.

Results: Of 892 children with complete data, 458 were girls (51.3%). The mean BP in girls was 111/63 mm Hg and 112/64 mm Hg in boys. The mean BW was 3688 ± 586 g for girls and 3750 ± 644 g for boys. A significant negative correlation was observed between BW and systolic BP z-score (r= -0.09, p=0.001), and between BW z-score and systolic BP z-score (r= -0.09, p=0.006). There was a negative correlation between the diastolic BP z-score and both BW and BW z-score (r= -0.09, p=0.005, and r= -0.10, p=0.003). The relationship was stronger in girls for both BW and z-score (r= -0.11, p=0.024 and r= -0.10, p=0.036) than in boys (r= -0.07, p=0.14 and r=-0.08, p=0.11). When adjusted for body mass index (BMI) z-score, there was a significant association between BW z-score and systolic BP z-score (beta= -0.12, p<0.001) and diastolic BP z-score (beta= -0.08, p<0.001) in girls. In boys the adjusted association was significant for BW z-score and systolic BP z-score (beta= -0.07, p=0.024), but the association with diastolic BP z-score was of borderline significance (beta= -0.04, p=0.05). Neither BW nor the BW z-score significantly correlated to absolute blood pressure values in children.

Conclusions: This study suggests that low birth weight may be an important predictor of elevated BP in children and indicates the importance of BP follow-up of low-birth-weight infants.

TH-PO501

Association of Psychosocial and Neurocognitive Dysfunction in Pediatric Hypertension

Vanessa Thiel, Anne E. Dawson, Mahmoud Kallash, Camille Wilson. *Nationwide Children's Hospital, Columbus, OH.*

Background: Pediatric hypertension (HTN) is a significant problem, with incidence of elevated BP increasing over time. Cardiac end organ damage of HTN is well-documented but only recently has attention turned to its neurocognitive effects. Researchers have previously demonstrated significantly lower performance on neurocognitive testing in children with primary HTN compared to normotensive controls and have reviewed the effects of HTN on attention and anxiety/depression. The goal of this study is to further identify the common neuropsychological concerns that are prevalent in children with HTN, and to clarify the neuropsychological factors associated with HTN concerns.

Methods: This is a retrospective chart review of outpatient pediatric nephrology patients (n=197) who received an ambulatory blood pressure monitor and neuropsychological screening measures between 6/2020 and 8/2021.

Results: The study included 197 subjects who completed ABPM placement and neuropsychological screening. There was no specific correlation between ABPM data and clinical levels of anxiety, depression, or ADHD hyperactivity symptoms. HTN and ADHD inattentive symptoms were significantly associated. Elevated systolic BP load, elevated diastolic BP load, and mean arterial pressure were all associated with areas of executive functioning and learning concerns, inclusive of working memory and mathematics skills (all p's <0.05). Systolic BP load was also associated with problems in factual memory, sequential processing, and problem-solving.

Conclusions: This study highlights the relation between pediatric HTN and neurocognitive concerns, but does not clarify concerns for psychological symptoms. The findings assert the potential need to implement behavioral health and neurocognitive screenings when concerns for elevated BP are present to activate immediate and effective intervention for BP management. Further analysis will continue to characterize specific aspects of HTN, patient demographics, and neuro/psychological symptom elevations.

TH-PO502

Prematurity and Low Birth Weight Associate with Adolescent Hypertension in a Large Nationwide Cohort

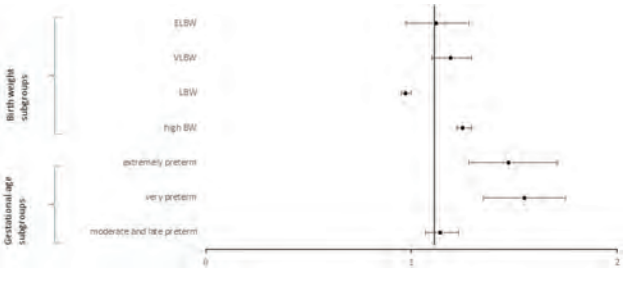
Shimrit Tzvi-Behr, Efrat Benshalom, Yaacov Frishberg. *Shaare Zedek Medical Center, Jerusalem, Israel.*

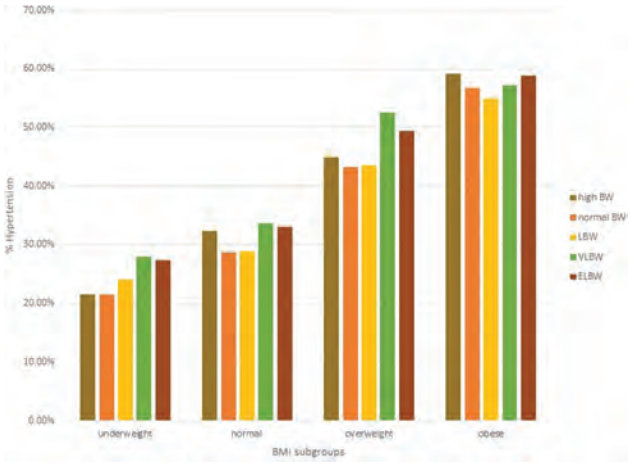
Background: prematurity is a global burden occuring in ~ 11% of total deliveries. Chronic kidney disease (CKD), due to incomplete nephrogenesis and acute kidney injury episodes, can be a long term complication of prematurity. The aim of this study is to explore the risk of having hypertension or proteinuria, as CKD manifestations, in adolescents born prematurely or small for gestational age in a large nationwide cohort.

Methods: Study population included potential recruits that were examined in an Israel Defence Forces (IDF) medical facility between November 2005 and October 2018. Clinical, demographic and anthropometric data were retrieved from the IDF medical files electronic system. Data regarding gestational age at delivery, retrieved from the Israeli Ministry of Health database, was available for adolescents born between January 1993 to December 2000.

Results: Study cohort included 513,802 participants, aged 17.3±0.9 years. 48,994 individuals had data regarding gestational age at birth (38.8 ± 2.99 weeks). Adolescents born as very- and extremely preterm infants had 55% and 47% greater risk for having hypertension, respectively. Being born with very or extremely low birth weights have an OR of 1.19 and 1.12 for adolescent hypertension, respectively (figure 1). Within the overweight and obese adolescents, comparison between different birth weight groups revealed higher hypertension prevalence in adolescents born as low, very low and extremely low birth weights (figure 2).

Conclusions: Our study demonstrated a higher trend for adolescent hypertension in very premature infants and in infants born with very and extremely low birth weight. These adolescents should be monitored for signs of CKD in order to treat and delay its progression.





TH-PO503

Association Between Epigenetic Age Acceleration at Extremely Preterm Birth and Systolic Blood Pressure in Adolescence

Anisha R. Gerber, Kyle R. Roell, Katelyn Huff, Michael O'Shea, Rebecca Fry, Keia Sanderson. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Epigenetic age deviation from chronologic age is associated with poor cardiovascular (CV) outcomes in adults. No studies have evaluated this association in children born preterm, who are at risk for advanced epigenetic gestational age (eGA) and poor CV outcomes. Our objective was to examine the association between epigenetic gestational age acceleration (eGAA) and adolescent systolic blood pressure (SBP) in individuals born extremely preterm.

Methods: This is a secondary analysis of the Extremely Low Gestational Age Newborn study. Participants were born <28 weeks' gestation and had placental DNA quantification at birth and 3 manual blood pressures measured during follow up at 15-17 years old. eGA was estimated using the Robust Placental Clock (RPC). eGAA was calculated as residuals from a linear regression of predicted RPC eGA on chronologic gestational age (GA). Mixed effects models were fit to assess association between eGAA and average adolescent SBP. A minimally sufficient adjustment set, identified using a directed acyclic graph, included maternal factors (health insurance, years of education, marital status, prenatal smoking, pre-pregnancy body mass index (BMI) > 30 kg/m^2, diabetes, hypertension) and birth weight for GA.

Results: 202 study participants had data for eGA and adolescent SBP. 34% had elevated SBP > 120mmHg, and 52.6% were male. 67% with elevated SBP were male, 27.8% had mothers with hypertension, and 25% had mothers with BMI > 30 kg/m^2. In the overall sample, we found no association between eGAA and adolescent SBP (p=0.539). When stratified by sex, for every 1 week acceleration in eGA, adolescent males had an increase of 3.32mmHg in SBP (p=0.04; Table 1).

Conclusions: Epigenetic gestational age acceleration at birth is associated with significant increase in SBP in adolescent males but not females who were born extremely preterm. The kidney is key in regulating blood pressure, so future research includes evaluating kidney-specific epigenetic changes at preterm birth and CV outcomes.

Females, adjusted	-1.002	-3.068, 1.006

TH-PO504

Disparities in Medication Fill Duration in Pediatric Hypertension

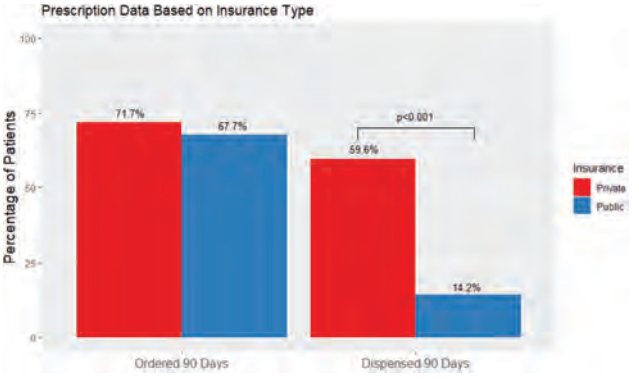
Meghan M. Mclaughlin, Conrad D. Gleber, Marc Lande. *University of Rochester, Rochester, NY.*

Background: Medication nonadherence is a barrier to blood pressure control. The CDC recommends prescribing 90-day fills for maintenance medications yet antihypertensives are often dispensed as 30-day fills due to insurance limits. This increases the burden of pharmacy visits, a contributor to nonadherence. We observed how often antihypertensives are dispensed as a 30-day supply despite a prescription for longer duration and the impact of 30-day vs 90-day fills on adherence.

Methods: This retrospective cohort study included patients with hypertension (HTN) seen in our Pediatric Nephrology Clinic over a 3 year period. For each patient, antihypertensive medication days prescribed was compared to days dispensed using pharmacy refill and insurance claim data. Proportion of days covered (PDC) was calculated to estimate medication adherence.

Results: A total of 449 patients (61% primary HTN, 39% secondary HTN) had 4,492 prescription orders and 8,800 dispenses over the 3-year period. While 36% of prescriptions were ordered for ≥90 days only 12% were dispensed for ≥90 days and 70% of patients had at least one prescription for ≥90 days but only 37% of patients had at least one dispense for ≥90 days. In addition, 35% of patients had a fill discrepancy (prescribed but never received a 90-day fill). There was no difference in likelihood of being prescribed a 90-day fill by insurance type (public vs private, OR = 0.82, p = 0.35) but patients with public insurance were less likely to be dispensed a 90-day fill (OR = 0.126, p <0.001) and more likely to have a fill discrepancy (OR = 6.02, p <0.001). Patients who received at least one 90-day fill had better adherence rates (median PDC, 77.5% vs 58.1%, p <0.001).

Conclusions: Longer fill duration is associated with better adherence with antihypertensive medication in pediatric patients. However, patients are often dispensed only 30-day fills despite a 90-day prescription. Patients with public insurance are markedly less likely to be dispensed 90-day fills, a modifiable barrier to improving adherence in disadvantaged youth.



TH-PO505

A Systematic Review of Efficacy and Safety of Dialysis Modalities in Neonates/Children with Inborn Errors of Metabolism

Manan Raina,[1] Raghav Shah,[2] Kush Doshi,[3] Pranjal Sharma,[2] Sidharth K. Sethi.[4] *[1]Hawken High School, Cleveland, OH; [2]Northeast Ohio Medical University, Rootstown, OH; [3]Cleveland Clinic Akron General, Akron, OH; [4]Medanta The Medicity Medanta Institute of Kidney and Urology, Gurugram, India.*

Background: Inborn errors of Metabolism (IEM) are due to mutations that involve aberrations in the metabolism of macromolecules and synthesis of essential compounds, especially hyperammonia. Treatment of IEM typically involves RRT initiation. Our systematic review in neonates and children investigates survival rates and ammonia level reduction in varying RRT modalities (CRRT, HD, PD).

Methods: The literature search was conducted through PubMed, Web of Science, and Embase. The search terms included 'neonates' and 'pediatric' linked with 'IEM' and the varying RRT modalities. The studies included entailed survival rate and ammonia level data in patients with IEM with an intervention of RRT. Analysis variables included efficacy outcomes [% reduction in ammonia (RIA) from pre-dialysis to post-dialysis and time to 50% RIA] and mortality among neonates with IEM on different dialysis modalities. The data was analyzed using R version 3.1.0.

Results: A total of 38 studies were included, with a total sample size of 697. The mortality was observed to be lower among neonates with IEM receiving CRRT vs. PD or HD. The pooled proportion (95% CI) of mortality of those who got CRRT was 25.4% (21.26% - 29.91%) [I^2: 44.6%; p=0.0117. Those who received PD was 36.64% (30% - 43.6%) [I^2: 39.5%; p=0.0579; And those who received HD was 35.9 % (26.5% - 46.2%) [I^2: 18.0%; p=0.2876. The mean (SD) time to 50% RIA level was seen to be higher with CAVHD or CVVHD vs. HD [3.4 (4.1) or 4.3 (3.5) vs. 1.6 (0.4)] hrs. The time to 50% ammonia reduction was significantly lower with CVVHDF vs. PD [median (IQR): 6 (6–9.5) vs. 14 (6–30) hrs; p=0.01, CVVH vs. PD [mean (SD): 4.4 (1.5) vs. 16.3 (10.9) hrs; p=0.042] and CVVHD vs. PD [4.7 (2.5) vs. 13.5 (6.2) hrs; p<0.0001. Likewise, the mean (SD) time to 50% decline in plasma ammonia or leucine levels with CVVHD (n=7) vs. PD (n=5) [7.1 (4.1) vs. 17.9 (12.4) hrs; p<0.02.

Conclusions: Results indicate that the efficacy of the mean % RIA is superior in CRRT. Comparing time to 50% RIA levels, CRRT is superior to PD, while HD appears slightly superior to CRRT. Findings show lower mortality among patients with IEM who received CRRT vs. PD or HD. In conclusion, PD has been shown to be less effective compared to HD and CRRT. The ability to reduce ammonia quicker by HD is also associated with a greater risk of mortality than CRRT.

TH-PO507

Phosphate-Containing vs. Phosphate-Free Solutions in Pediatric Continuous Renal Replacement Therapy: A WE-ROCK Study

Faizeen Zafar,[1] Katja M. Gist,[1] Javier A. Neyra,[2] David T. Selewski,[3] Huaiyu Zang,[1] Nicholas J. Ollberding,[1] Shina Menon.[4] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]The University of Alabama at Birmingham, Birmingham, AL; [3]Medical University of South Carolina, Charleston, SC; [4]Seattle Children's Hospital, Seattle, WA.*

Background: Hypophosphatemia is common in patients on continuous renal replacement therapy (CRRT), and is associated with adverse outcomes (prolonged mechanical ventilation (MV) and longer ICU stay). We aimed to compare outcomes between commercially available phosphate-containing (1 mmol/L, PHOS+) and phosphate-free (PHOS-) solutions in pediatric CRRT patients.

Methods: The Worldwide Exploration of Renal Replacement Outcomes Collaborative in Kidney Disease (WE-ROCK) is a 32-center registry of patients aged 0-25 years treated with CRRT for acute kidney injury or fluid overload (FO). This analysis excluded patients with incomplete CRRT fluid data or those receiving pharmacy-compounded solutions with variable phosphate concentrations. Primary outcomes were 28-day MV- and ICU-free days. Multivariable regression analyses were conducted for outcome comparisons.

Results: We included 410 patients; median age 8.2 years (IQR 1.6-14.1y). Of these, 43.4% (178/410) received PHOS+. The PHOS+ group had a higher %FO (7.2% vs. 5.4%, p=0.009) and lower MV rate at CRRT initiation (64% vs. 82%, p<0.001). There was no difference in PELOD and vasoactive inotropic score between the groups. Both groups received a similar dose of CRRT (42 vs 48 ml/kg/h, p=0.4) although the duration was longer for the PHOS+ group (7 vs 4d, p<0.001). The PHOS+ group had less incident hypophosphatemia (<2.5 mg/dl) during CRRT compared to the PHOS- group (20% vs. 33%, p=0.007). However, there were no differences in 28-day MV- and ICU-free days and 90-day mortality between the 2 groups in unadjusted and adjusted analyses (Table).

Conclusions: PHOS+ (1 mmol/L) CRRT solutions reduced incident hypophosphatemia in this pediatric cohort but did not associate with reduction in 90-day mortality or less ventilator or ICU resource utilization.

Table. Multivariable analysis for 28-day ventilator- and ICU-free days*

Variable	ICU-free days** OR (95% CI)	Ventilator-free days** OR (95% CI)
Age	0.81 (0.59-1.11)	1.09 (0.71-1.68)
Sepsis†	1.20 (0.82-1.77)	0.97 (0.67-1.40)
PELOD-2 score†	**0.30 (0.16-0.55)**	**0.31 (0.21-0.48)**
% Fluid overload†	**0.57 (0.41-0.78)**	0.96 (0.84-1.10)
VIS†	0.92 (0.71-1.20)	0.89 (0.74-1.07)
CRRT dose, mL/kg/hr	1.01 (0.95-1.07)	0.98 (0.93-1.03)
CRRT duration, days	**0.27 (0.15-0.49)**	0.82 (0.69-0.98)
Hospital size, small vs. medium	0.68 (0.31-1.49)	1.23 (0.51-2.99)
Hospital size, small vs. large	2.01 (0.81-4.97)	0.89 (0.49-1.62)
Phosphate-free vs. phosphate-containing CRRT solution	1.11 (0.49-2.54)	0.98 (0.71-1.35)

CI, confidence interval; CRRT, continuous renal replacement therapy; ICU, intensive care unit; OR, odds ratio; PELOD-2, pediatric logistic organ dysfunction-2 score; VIS, vasoactive inotropic score.

*OR and 95% CI were obtained by semiparametric ordinal regression accounting for nesting of patients within centers via the Huber-While cluster sandwich estimator of variance, where OR <1 indicated association with a worse clinical outcome (i.e., increased healthcare utilization). The model adjusted for all the listed covariates. For continuous predictors such as age, the OR was computed by comparing the 75th percentile to the 25th percentile of the variable.

†Determined at CRRT initiation

**Significant predictors marked in bold

Multivariable analysis for 28-day ventilator- and ICU-free days

TH-PO508

Regional Citrate Anticoagulation in Continuous Renal Replacement Therapy in Children: Opportunities for Optimization

Danilo Santana, Caroline S. Ortega, Lilian C. Nóbrega, Michele Luglio, Andreia Watanabe, Werther B. Carvalho. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: Regional citrate anticoagulation (RCA) is based on blood citrate concentration of 3-4 mmol/L to reach post filter ionized calcium (Cai) of 0,25-0,40 mmol/L in continuous hemodiafiltration (CVVHDF). However, it can lead to metabolic complications of citrate accumulation.

Methods: From May 2019 to Dec 2022, 5,5% (109/1970) of patients admitted in a PICU were submitted to CVVHDF using RCA with 2,2% citrate. 25 patients were excluded for CVVHDF <24h, and 3 others for prior CVVHDF. Data related to minimum magnesemia was analyzed to sensitize the results.

Results: From the 81 patients included, 56,8% were girls, the age was 4.2 years (1.1-12.8) and the weight 13 kg (8,1-36,3). Organic dysfunctions were cardiovascular in 64,2%, pulmonary in 70,4% and hepatic in 65,4%, and the mortality rate was 51.9%. Hypomagnesemia (Mg<1,7mg/dL) was observed in 64% of patients, and the minimum magnesemia was 1,6mg/dL (1,4-1,8), where blood flow rate was 6ml/kg/min (3,4-7,5), the replacement+dialisate fluid rate of 65 ml/kg/h (47-92), blood citrate concentration of 1,7 mmol/L (1,4-2,6), citrate dosage of 0,6mmol/kg/h (0,35-0,85), reaching CaT/Cai (citrate GAP) of 2,01 (1,89-2,03). Only 4 patients presented citrate acummulation (citrate GAP >2,5). Patients <1 years of age reached larger blood flow rate [7,7 (6,7-11,7) vs 4,8 (3-6,5), p<0,001], smaller blood citrate concentration [1,5 (1,4-1,9) vs 1,9 (1,4-2,80), p=0,048], larger citrate dosage [0,75 (0,64-1,09) vs 0,53 (0,32-0,77), p=0,008], and larger citrate GAP [2,14 (1,96-2,33) vs 1,96 (1,79-2,09), p=0,035]. Blood citrate concentration tended to be smaller in the circuits with <36 horas of duration (48,7%), [1,7mmol/L (1,3-2,0) vs 1,9 (1,4-2,8) vs p=0,062], and no difference was observed in the citrate dose (p=0,117) or post filter Cai (p=0,385).

Conclusions: The low circuit patency obtained is probably associated with the low blood citrate concentration used. Children <1 year of age presented good tolerance to high doses of citrate, with a low rate of citrate accumulation. It is possible that children tolerate citrate dosages of 0,6-0,85 mmol/kg/h, reaching blood citrate concentration of 3mmol/L by adjusting the blood flow rate to 2-5 ml/kg/min, improving circuits patency without major metabolic consequences.

TH-PO509

Longitudinal Trends in Pediatric Hospitalizations Complicated by AKI in the United States

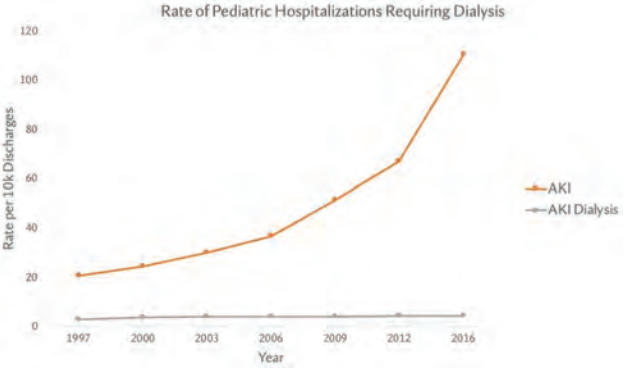
Alexander J. Kula,[1] Shina Menon.[2] *[1]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [2]Seattle Children's Hospital, Seattle, WA.*

Background: There are limited national data describing longitudinal trends of pediatric acute kidney injury (AKI) and AKI requiring dialysis (AKI-D) We aimed to characterize rates of pediatric AKI and AKI-D across the United States over a 20-year period.

Methods: We analyzed data from the Kids Inpatient Database (KID) from 1997 to 2016. AKI was identified using International Classification of Diseases Clinical Modification (ICD-CM) codes, 9th Revision (1997-2012) and 10th Revision (2016). Use of dialysis during hospitalization was assessed using procedure codes. We excluded pediatric hospitalization for uncomplicated, term newborn birth. Weighted data was used to estimate national yearly incidence totals and rates.

Results: Over the study period, there was a weighted total of 49,228,048 pediatric discharges, 22,059,242 of which were included in the final analysis. Nationwide, the yearly incidence of AKI and AKI-D increased from 1997 (AKI**:** 8340 cases/year, AKI-D: 1049 cases/year) to 2016 (AKI: 43,053 cases/year, AKI-D: 1656 cases/year). The rates of hospitalizations with AKI and AKI-D also increased from 1997 (cases/10k discharges [95%CI]: AKI: 20.7 [20.2, 21.1], AKI-D: 2.6 [2.4,2.8]) to 2016 (AKI: 111 [110, 112], AKI-D: 4.2 [4.0, 4.5]) (**Figure 1**).

Conclusions: This analysis of KID shows an increase in the absolute number, and the rate of pediatric hospitalizations complicated by AKI and AKI-D 1997 to 2016. While some of the increase may be explained by an increase in awareness and documentation, there is a near 3-fold increase in rates of AKI-D. More detailed analysis are needed to evaluate the reasons behind this. Given our understanding of the long-term impact of AKI, it is important to assess for preventable causes and to optimize care of those with AKI and AKI-D.



TH-PO510

Long-Term Outcomes After Pediatric Non-Dialysis-Treated AKI: A Population-Based Cohort Study

Cal Robinson,[1] Nivethika Jeyakumar,[2] David J. Askenazi,[3] Akash Deep,[4] Amit X. Garg,[2] Stuart Goldstein,[5] Jason H. Greenberg,[6] Cherry Mammen,[7] Danielle M. Nash,[8] Rulan S. Parekh,[1,9] Samuel A. Silver,[10] Ron Wald,[11] Michael Zappitelli,[1] Rahul Chanchlani.[12] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]ICES Western, London, ON, Canada; [3]The University of Alabama at Birmingham, Birmingham, AL; [4]King's College London, London, United Kingdom; [5]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [6]Yale University, New Haven, CT; [7]BC Children's Hospital, Vancouver, BC, Canada; [8]London Health Sciences Centre, London, ON, Canada; [9]Women's College Hospital, Toronto, ON, Canada; [10]Queen's University, Kingston, ON, Canada; [11]St Michael's Hospital, Toronto, ON, Canada; [12]McMaster Children's Hospital, Hamilton, ON, Canada.*

Background: Acute kidney injury (AKI) is common in hospitalized children. Dialysis-treated pediatric AKI is associated with long-term chronic kidney disease (CKD), hypertension, and death. We aim to evaluate the outcomes after non-dialysis-treated AKI, which are uncertain.

Methods: Retrospective cohort study of all hospitalized children (0-18yr) surviving non-dialysis-treated AKI from 1996-2020 in Ontario, identified via provincial administrative health databases. Children with prior kidney replacement therapy (KRT; dialysis or transplant), CKD, or AKI were excluded. Cases were matched with up to four hospitalized controls without AKI by age, neonatal status, sex, index year, ICU admission, cardiac surgery, malignancy, hypertension, and a propensity score for AKI. Children were followed until death (2.9%), provincial emigration (5.3%), or March 2021 (91.8%). The primary outcome was major adverse kidney events (MAKE; composite of death, chronic KRT, or *de novo* CKD).

Results: A total of 4173 pediatric AKI survivors were matched to 16,337 hospitalized controls. Baseline covariates were well-balanced after propensity score matching. Median age was 8yr (IQR 1-15); 706 (16.9%) AKI cases were neonates. During median 9.7-year follow-up, 17.6% of AKI survivors developed MAKE vs 4.6% of controls (HR 4.3, 95%CI 3.9-4.8, p<0.001). AKI cases had higher rates of chronic KRT (2.2% vs 0.2%; HR 12.8, 95%CI 8.5-19.4), CKD (15.9% vs 2.0%; HR 8.8, 95%CI 7.7-10.0), hypertension (16.8% vs 7.7%; HR 2.4, 95%CI 2.2-2.7), and subsequent AKI (5.7% vs 1.5%; HR 4.0, 95%CI 3.4-4.8), but no mortality difference (2.7% vs 2.9%; HR 1.0, 95%CI 0.78-1.16).

Conclusions: Children with non-dialysis-treated AKI are at increased long-term risk of CKD, chronic KRT, hypertension, and subsequent AKI vs hospitalized controls.

Reducing AKI in Critically Ill Pediatric Patients: An Improvement Project Targeting Nephrotoxic Medication Exposures

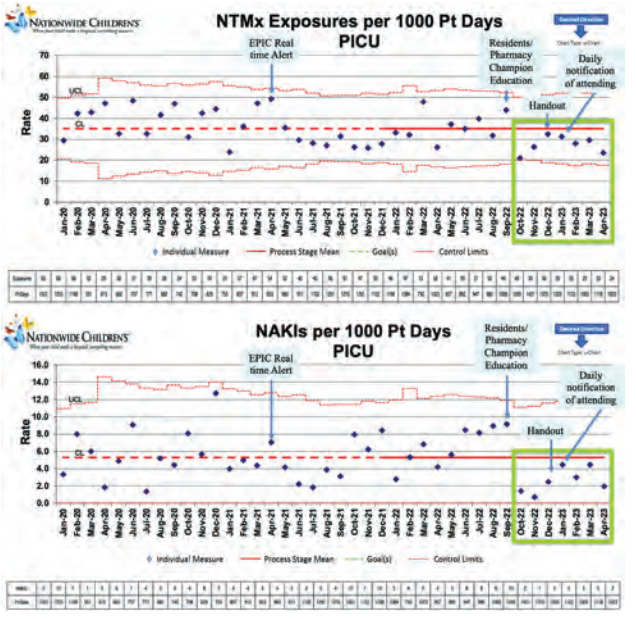
Natalie R. Capretta,[1] W. Joshua Frazier,[1,2] Jeffrey Lutmer,[1,2] Cheryl Sargel,[1] Lindsay Kalata,[1] Robert J. Gajarski,[1,2] Diana Zepeda-Orozco.[1,2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Acute kidney injury (AKI) occurs commonly in critically ill hospitalized pediatric patients, is associated with nephrotoxic medication exposure and is independently associated with worse clinical outcomes. Our pediatric intensive care unit (PICU) utilized the multicenter Nephrotoxic AKI (NAKI) quality improvement project to increase awareness of nephrotoxic medication exposures, develop interventions, and reduce NAKI.

Methods: A multi-phased approach was used to increase education and recognition surrounding nephrotoxic medication exposures in the PICU and their role in subsequent AKI. Monthly resident physician education was provided by our unit-based clinical pharmacist, and an informational handout was created and reviewed monthly during resident PICU orientation. A third phase included a clinical pharmacist notification to attending physicians of patients meeting exposure criteria with acceptable alternatives to nephrotoxic drugs and suggestions for AKI monitoring.

Results: Our cohort included 39,181 patient days admitted to the PICU at our institution between October 1st 2022 and April 30th 2023. A total of 225 unique patients met nephrotoxic exposure criteria leading to 21 AKI episodes. We reduced nephrotoxic medication exposure rates by 25% from 36.73 to 27.39 per 1000 patient days and NAKIs by 51% from 5.43 to 2.64 per 1000 patient days.

Conclusions: Interventions to decrease AKI successfully in critically ill patients required a multi-phased approach including recurrent education efforts and pharmacy-driven daily physician alerts. Organizational implementation of these interventions is ongoing.



TH-PO512

GUIDANCE: Primary Results of a Prospective, Observational Clinical Study Evaluating the Performance of Urinary Neutrophil Gelatinase-Associated Lipocalin (NGAL) in the Risk Assessment of AKI in Pediatric ICU Patients

Stuart Goldstein,[1] Shina Menon,[2] Katja M. Gist,[3] Megan Soohoo,[3] Natasha Afonso,[4] David M. Kwiatkowski,[5] Christopher W. Mastropietro,[6] David J. Askenazi,[7] Hostensia M. Beng,[8] Sarah J. Kizilbash,[9] Abby M. Basalely,[10] Avi Traum,[11] Julie C. Fitzgerald.[12] The GUIDANCE Investigators. *[1]Cincinnati Children's Hospital, Cincinnati, OH; [2]Seattle Children's Hospital, Seattle, WA; [3]Children's Hospital of Colorado, Aurora, CO; [4]Texas Children's Hospital, Houston, TX; [5]Lucile Packard Children's Hospital School, Palo Alto, CA; [6]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [7]Children's of Alabama, University of Alabama at Birmingham, Birmingham, AL; [8]East Carolina University Brody School of Medicine, Greenville, NC; [9]University of Minnesota Children's Hospital, Minneapolis, MN; [10]Cohen Children's Medical Center, Queens, NY; [11]Boston Children's Hospital, Boston, MA; [12]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: Acute kidney injury (AKI) has been associated with prolonged hospital stays, future progression to chronic kidney disease, and a 25-80% risk of in-hospital death in critically ill patients. Our ability to treat this condition is lacking, partially due to our inability to detect AKI early. We sought to validate the clinical cut-off value for neutrophil gelatinase-associated lipocalin (NGAL) in pediatric patients. Here, we report the clinical performance of NGAL as a risk assessment marker for AKI in GUIDANCE, a validation study completed in support of an FDA submission.

Methods: Children (aged ≥ 90d to 22 yr) admitted to an intensive care unit (ICU) with a urine sample collected within 24 hours of admission were eligible. Eligible patients must have had either mechanical ventilation, vasoactive medication administration, solid organ or bone marrow transplantation, OR hypotension within 24 hours of admission. Urine NGAL was measured using a particle-enhanced, turbidimetric, NGAL assay. Serum creatinine (SCr) was measured on days 1, 2, and 3 to determine stage 2 or 3 SCr-AKI per KDIGO guidelines. Independent adjudication by three clinical experts assessed for AKI within 48-72 hours using SCr measurements and clinical information but did not have access to NGAL results. NGAL positivity was defined as a urine concentration ≥125 ng/mL based on a prior derivation study.

Results: Six hundred sixty patients were screened, and 514 were evaluable per the study protocol. Forty-seven patients (9.1%) developed stage 2 or 3 AKI; 36 of these patients were NGAL-positive. The sensitivity, specificity, negative predictive value, and positive predictive value for the NGAL test ≥125 ng/mL was 76.6% (36/47), 86.8% (406/468), 97.6% (406/416), 36.7% (36/98), respectively. The diagnostic performance of NGAL as demonstrated by an area under the ROC was 0.86 (95%CI, 0.80-0.92).

Conclusions: These data demonstrate that a particle-enhanced, turbidimetric, NGAL assay performs well early in ICU course to aid in risk assessment for stage 2 or 3 AKI in critically ill children.

Does Kidney Echogenicity Correlate to eGFR in Pediatric AKI?

Shrea Goswami, Michelle C. Starr, Daniel Cater, Andrew L. Schwaderer.
Indiana University School of Medicine, Indianapolis, IN.

Background: Kidney ultrasound echogenicity is a subjective finding reported by radiologists however it may be more clinically useful if quantified. The objective is to investigate if ultrasonographic parameters of the kidney correlates to estimated glomerular filtration rate (eGFR) in pediatric AKI.

Methods: Retrospective study in a tertiary children's hospital. Ultrasounds of 35 subjects were identified with AKI at the time of CKRT initiation. Three distinct areas of the kidney cortex and liver were cropped. Using Adobe Photoshop software a gray scale pixel density value was quantified. An inverse ratio of the kidney to liver mean pixel densities was the quantified echogenicity index (EI). The kidney lengths, age, weight, height, race/ethnicity, percent fluid overload (%FO), seurm albumin and time on CKRT were entered into a multivariate calculator. The difference between the mean measured and predicted right and left kidney lengths was the kidney length ratio (KLR).

Results: 35 subjects were analyzed. The median age was 10 years (range 2-16) and 54% were male. Heatmap correlation analysis revealed statistically significant negative correlations for mean EI with eGFR and BMI (r = -0.36 [p-value 0.03]: and -0.35[p-value 0.04], respectively). KLR showed negative correlation with BMI and age (r= -0.46 [p-value 0.005] and r = -0.38[p-value 0.0025], respectively). The % of FO significantly correlated with decreasing size and BMI. The AUC for EI with eGFR <90ml/min/1.73m^2 and <60ml/min/1.73m^2 was 0.7 (p-value 0.08 and 0.02, respectively). EI < 1.17 predicted eGFR < 90 with sensitivity of 46.2% (95% CI 29%-65%) and specificity of 88.9% (CI 57%-99%). Similarly, for eGFR <60 with sensitivity of 55.0%(CI 34%-74%) and specificty of 86.7%(CI 62%-98%). AUC for KLR was 0.6 and statistically insignificant.

Conclusions: Increased kidney echogenicity appears to be a more accurate correlate with decreased kidney function than increased kidney size.

Correlation plot for data. Significant values highlighted in yellow.

TH-PO514

Is Kidney Echogenicity an Early Indicator of AKI Recovery?

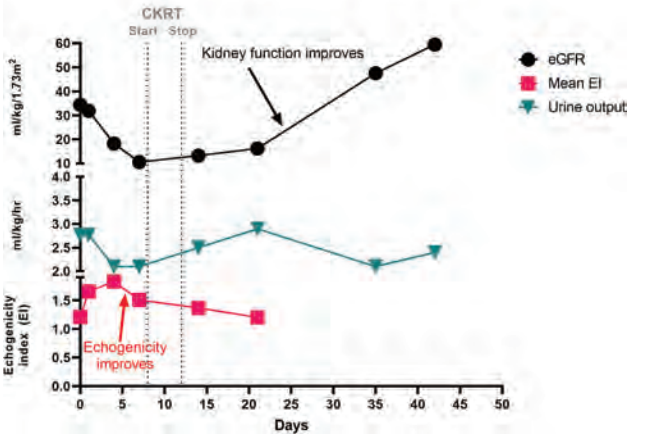
Shrea Goswami, Michelle C. Starr, Daniel Cater, Andrew L. Schwaderer.
Indiana University School of Medicine, Indianapolis, IN.

Introduction: Kidney ultrasound echogenicity is a subjective finding reported by radiologists however it may be more clinically useful if quantified. We present a case report of a 15-year-old girl with acute kidney injury (AKI).

Case Description: 15-year-old girl was diagnosed with AML requiring treatment with a tyrosine kinase inhibitor, gilteritinib. Within two weeks of receipt of this agent she developed severe non-oliguric AKI, likely from medication induced thrombotic microangiopathy. Her baseline serum creatinine was 0.40 mg/dL with a peak of 6.83mg/dL, necessitating CKRT for 5 days. She was receiving serial abdominal ultrasounds for concerns for venous occlusive disease at the same time. Mean echogenicity (EI) was obtained by quantifying the grey scale pixel density of value of the right kidney cortex compared to the liver using adobe photoshop software. Serial echogenicity index (mean EI) of the kidney cortex, weekly urine output (ml/kg/hour) and estimated glomerular filtration rate (eGFR) was collected during hospitalization. It appears that mean EI peaked on day 4 while eGFR was the lowest. Subsequently EI improved on day 7 while the eGFR had sustained improvement between days 21-42.

Discussion: To our knowledge we are not aware of any reports studying kidney echogenicity as a marker for kidney recovery and raises the possibility that it may improve before other markers. EI as an early indicator of kidney recovery needs to be prospectively evaluated compared to other markers such as urine NGAL and, in oliguric patients, increasing urine output.

Fig. 1: Mean EI, urine output and eGFR during hospitalization



Clinical timeline of key parameters relevant to kidney recovery.

TH-PO515

Epidemiology and Outcome of AKI in Hospitalised Children in Australia

Madeleine S. Didsbury,[1,2] Ben Gelbart,[3,4] Peter R. Summers,[2,3] Daryl R. Cheng,[2,3] Thomas A. Forbes,[1,3] Catherine Quinlan,[1,5] Joshua Y. Kausman,[1,3] Emily See.[1,5]
[1]Department of Nephrology, The Royal Children's Hospital, Melbourne, VIC, Australia; [2]Centre for Health Analytics, The Royal Children's Hospital, Melbourne, VIC, Australia; [3]Murdoch Children's Research Institute, Parkville, VIC, Australia; [4]Paediatric Intensive Care Unit, The Royal Children's Hospital, Melbourne, VIC, Australia; [5]School of Medicine, University of Melbourne, Melbourne, VIC, Australia.

Background: Available estimates of the burden of acute kidney injury (AKI) in hospitalised children are inconsistent and the prognostic implications of its severity, duration, and frequency are poorly understood. Additionally, lack of hospital data on AKI impacts service provision and planning.

Methods: We used our electronic medical record to capture the epidemiology and outcome of AKI in a cohort of children aged between 1 month and 18 years who were hospitalised for at least 24 hours at a quaternary paediatric centre in Melbourne, Australia, between 1 January 2017 and 31 December 2021. AKI was examined according to phenotype in terms of KDIGO stage, duration (transient <48 h, persistent 48 h to 7 d, or acute kidney disease), and frequency. The primary outcome was 30-day mortality. Secondary outcomes included resource utilisation, hospital outcome, and major adverse kidney events at 30 days (MAKE30).

Results: A total of 4,214 AKI episodes occurred, involving 3,134 admissions for 1,540 children (incidence 16%; 17.77 episodes per 1000 patient-days). Most AKI was stage 1, transient, and occurred as a single episode. AKI was associated with an increased risk of 30-day mortality (aOR 3.93, 95% CI 2.77 to 5.58). Compared to children without AKI, children with AKI had a higher odds of ICU admission (aOR 3.40, 95% CI 3.13 to 3.69), mechanical ventilation (aOR 2.05, 95% CI 1.76 to 2.41), vasoactive drugs (aOR 3.76, 95% CI 3.28 to 4.30), and extracorporeal membrane oxygenation (aOR 32.37, 95% CI 15.73 to 66.60). Children with AKI were also more likely to die in hospital (aOR 5.98, 95% CI 4.29 to 8.35), be discharged to rehabilitation (aOR 2.03, 95% CI 1.66 to 2.47), or develop a MAKE30 (aOR 40.35, 95% CI 29.63 to 54.94) compared to children without AKI, when adjusted for ICU status and age. Most adverse events had a graded association with AKI stage and AKI duration; the association between AKI frequency and outcome is less clear.

Conclusions: AKI occurs commonly in hospitalised children and is associated with increased mortality and, among survivors, greater hospital resource utilisation. There was a graded increase in the magnitude of the association with increasing AKI severity and duration. This analysis could be automated and repeated over time to measure the impact of interventions to detect and reduce AKI.

TH-PO516

Predictors for the Development of CKD Stage 2 or Higher in Repeat Pediatric Heart Transplant Recipients

Melvin Chan. *University of Colorado, Denver, CO.*

Background: There is little data on the risk factors for developing chronic kidney disease (CKD) in repeat pediatric heart transplant recipients.

Methods: All repeat heart transplants (RT) at our center from 1995-2021 were reviewed. Renal function was determined by estimated glomerular filtration rate (eGFR) derived from CKiD U25 calculator using creatinine at each hospital and clinic visit.

The stages of acute kidney injury (AKI) were in accordance with the Kidney Disease: Improving Global Outcomes (KDIGO) serum creatinine criteria. Independent samples t-test was conducted on the development of CKD stage 2 or higher and the following variables: pre-transplant eGFR; post-transplant eGFR at 1-3 months; ages at first heart transplant (FT) and RT; time between transplants; gestational age; weight category prior to transplant; and number of AKIs between FT and RT. Multivariate logistical regression was performed for significant variables.

Results: A total of 43 RT were included in this cohort, with a majority being Caucasian and mean age of 14 years old. Median follow-up time was 3 years. Univariate analysis showed significant associations between development of CKD stage 2 or higher and the following variables: pre-transplant eGFR, post-transplant eGFR at 1-3 months, the number of stage 2 and 3 AKIs between FT and RT. Multivariate logistic regression showed that post-transplant eGFR at 1-3 months (OR 0.92) and number of stage 2 and 3 AKIs (OR 21.5) remained significant, with an AUC of 0.91, sensitivity of 0.97, and specificity of 0.60.

Conclusions: Our preliminary data shows the post-transplant eGFR at 1-3 months and number of stage 2 and 3 AKIs are predictors for the development of chronic kidney disease stage 2 or higher. More research is needed to look at predictors for development of advanced chronic kidney disease to inform transplant teams when a repeat heart transplant or a dual heart and kidney transplant can be done.

Table 1. Predictors for Development of Chronic Kidney Disease Stage 2 or Higher

Variables	Univariate Analysis	Multivariate Analysis	
	p-value	OR	p-value
Pre-transplant eGFR	0.002		
Post-transplant eGFR at 1-3 months	0.001	0.92	0.031
Number of stage 2 and 3 AKIs	0.013	21.5	0.015

Figure 1: Univariate Predictors of Developing Chronic Kidney Disease, Stage 2 or Higher

AKI in Pediatric Heart Transplant Patients with a Ventricular Assist Device (VAD)

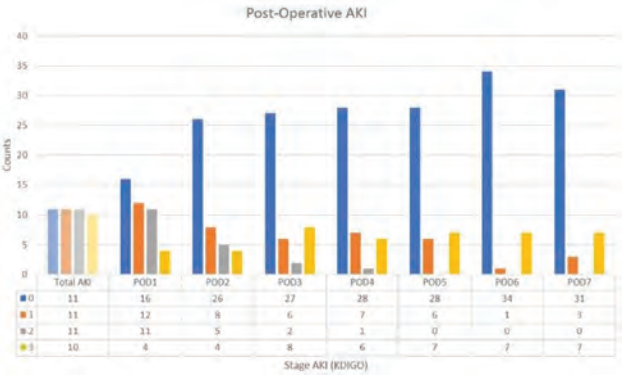
Deirdre Bartlett,[1,2] Jamie Penk,[1] Brian Madden,[1] Alexander J. Kula.[1] *[1]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [2]Stanley Manne Children's Research Institute, Chicago, IL.*

Background: Acute kidney injury (AKI) is common and an independent risk factor for prolonged hospitalization, development of CKD, and mortality in critically ill children undergoing cardiac surgery. AKI following heart transplant (HTxp) has not been as well studied, and even less is known in patients bridged with ventricular assist device. The VAD population warrants further attention given unique risk factors of prolonged mechanical circulatory support, multiple surgeries requiring cardiopulmonary bypass, and nephrotoxic treatments pre- and post- HTxp including diuretics and immunosuppression. Our study aimed to address this knowledge-gap by describing rates of AKI following HTxp in VAD dependent pediatric patients at time of surgery.

Methods: We performed an observational, retrospective study. Included patients met the following criteria: received HTxp at our institution during the past 5 years, age <18 years, use of VAD at time of HTxp, and at least 1 creatinine value in the first 7 postoperative days. GFR estimated using bedside Schwartz equation. AKI stages defined by KDIGO creatinine criteria. Primary outcome was incidence of AKI in the first week following HTxp.

Results: Out of 140 HTxp performed, 43 (31%) met inclusion criteria. Mean pre-Txp GFR was 142 mL/min/1.73m2. 11% (5/43) had CKD not requiring dialysis and 4.7% (2/43) were on dialysis entering transplant. During the first 7 post-operative days, 74.42% (32/43) developed any AKI, 48.84% (21/43) developed severe AKI (stage 2-3) and 16.27% (7/43) required dialysis. Multivariate analysis will be performed to determine significantly associated risk factors.

Conclusions: Our study demonstrates pediatric HTxp recipients with VADs may have a high burden of AKI and severe AKI. The incidence of AKI in our cohort was much higher compared to previously published rates in other pediatric cardiac surgeries. Kidney care may need to be prioritized in VAD patients following HTxp. We plan to work to identify modifiable risk factors for post-transplant AKI in VAD patients in ongoing research.



TH-PO518

Outcomes of Simultaneous Heart-Kidney vs. Sequential Heart-Kidney Transplantation in Children

Ruchi Mahajan, Michael D. Evans, Sarah J. Kizilbash. *University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Heart transplant (HTx) recipients frequently require kidney transplantation for concomitant advanced chronic kidney disease. Data on simultaneous (HTx and Kidney Transplant (KTx) at the same time) versus sequential {HTx performed before KTx} HTx and KTx in children are limited. Herein, we compare KTx outcomes between the two groups.

Methods: We used the Scientific Registry of Transplant Recipients (SRTR) to identify all pediatric (age < 21 years) Htx recipients who also received a KTx within 10 years of the HTx. We divided the study cohort into two: simultaneous heart/kidney and sequential heart/kidney recipients. We compared continuous and categorical variables using the Wilcoxon rank sum test and chi-square test. We compared patient and death-censored graft survival between simultaneous and sequential KTx recipients using the Cox regression, adjusting for age at the KTx, sex, race, pretransplant dialysis, donor type, and prior KTx. All analyses were performed in R, and a p-value of < 0.05 was considered statistically significant.

Results: Our analysis cohort included 165 recipients (79 for sequential and 86 for simultaneous). Table 1 is baseline characteristics of the cohort. We found no difference in patient survival (aHR: 0.97; 95% CI: 0.39, 2.41; p = 0.95) but better death-censored graft survival in sequential heart/kidney recipients compared with simultaneous heart/kidney recipients (aHR: 4.26; 95% CI: 1.21, 14.9; p = 0.02).

Conclusions: Pediatric HTx/KTx recipients who receive the KTx after their HTx have a better death-censored kidney allograft survival compared with those who receive KTx simultaneously with the heart transplant. Children with less significant kidney dysfunction at the time of HTx evaluation should be considered for a sequential heart/kidney transplant.

Baseline Characteristics of Patients undergoing Sequential versus Simultaneous Heart Kidney Transplantation.

Demographic Characteristics	Sequential heart and kidney transplant N = 79	Simultaneous heart and kidney transplant N = 86	p Value
Median Age at kidney Tx (years)	17.00 [13.00, 21.00]	16.00 [12.00, 18.75]	0.015

New Treatments, New Challenges: Nephrotoxicity-Associated Naxitamab in Pediatric Patients with High-Risk Neuroblastoma

Alvaro Madrid Aris,[1] Pedro Arango Sancho.[1,2] *[1]Hospital Sant Joan de Deu, Barcelona, Spain; [2]Pediatric Cancer Center Barcelona, Barcelona, Spain.*

Background: Neuroblastoma is the most common extracranial solid tumor in pediatrics, having a poor survival in high- risk (HR) tumors. Naxitamab(hu3F8) is a humanized monoclonal antibody anti-dysialoganglioside (GD2) approved for treatment

of > 1 year-old and adults with refractory/relapsed HR-neuroblastoma limited to bone or bone marrow. Our hospital has been the first center (2017) worldwide use it (clinical trials/compassionate use), obtaining excellent results.

Methods: Retrospective descriptive study including 244 patients (41% female-101-and 59% male-143-) using Naxitamab (monotherapy and/or associated with chemotherapy) from June 2017 to current day (6 years) in whom renal involvement and/or hypertension (HT) was evaluated.

Results: Mean age was 8 years, presenting nephrotoxicity of some type up to 26.6%(65):HT(11.9%/29), acute renal damage(ARD10.2%/25) and proteinuria(5.3%/13), developing all of them during the infusion or the first 3 cycles. In case of HT, only in 6 patients an ABPM was performed, observing:2 nocturnal-HT,2 diurnal-HT without specific-pattern and 2 disautonomic-pattern, not previously observed. Among the ARD, all cases were tubular except for one patient who presented clinical-analytical pattern of acute tubule- interstitial nephritis(AIN). Eight of them(32%) presented possible confounding factors in the development of(previous chemotherapy, ibuprofen or radiotherapy). Among patients with proteinuria(none nephrotic range): 38% tubular, 38% glomerular and 23% mixed.2 patients presented ARD+AHT and 3 a combination of AHT+ARD+proteinuria. Of these last, all of them received prior chemotherapy, leaving 2 of them with chronic renal damage(CKD stage 2 and 3).67 patients(27.4%) died due to progression of their underlying disease.

Conclusions: Management of HR-neuroblastoma remains a daily challenge. Naxitamab is an emerging therapy in this type of tumors, although there are few studies describing its AE. Previous studies of our group in mice explain the involvement of the myelin sheaths of the autonomic nervous system with this drug, which could explain, among others, the dysautonomic pattern of blood pressure presented. Short- and long-term follow-up, the systematic performance of ABPM and the use of early markers of renal damage, could lead to a more efficient management of complications derived from this new treatment.

TH-PO520

Incidence of Nephromegaly Following Hematopoietic Stem Cell Transplantation in Children and Young Adults

Raed Bou Matar. *Cleveland Clinic, Cleveland, OH.*

Background: Hematopoietic stem cell transplantation (HSCT) is an effective treatment for a variety of malignancies, metabolic and autoimmune diseases. Complications of HSCT include infections, veno-occlusive disease, mucositis, hemorrhagic cystitis, and graft-versus-host disease. Nephromegaly, along with other abdominal organomegaly, has been reported in the literature but the incidence and clinical significance is unknown.

Methods: Children and young adults (age ≤ 19 years) who underwent HSCT over a 10-year period (2011 to 2021) were screened for the study. Patients were included if they underwent a kidney ultrasound pre-HSCT and within 3 months post-HSCT. We retrospectively collected data that included demographics, type of HSCT, conditioning regimen and primary diagnosis. Data extracted from ultrasound reports included kidney length, presence, and severity of hydronephrosis and other renal anomalies. Other data points collected included HSCT source, conditioning regimen, and concurrent renal anomalies. The primary outcome of the study was the kidney length percentile for patient's age as measured by ultrasound before and within 3 months after the HSCT. Paired t-test was used for comparison of continuous data and Chi-Square test for comparing proportions.

Results: Twenty-seven patients met the inclusion criteria for the study. Median age was 7 years (20 months to 19 years) with 41% females. The kidney length percentile was significantly increased post-HSCT (79.3, IQR 71.5 - 98.7) as compared to pre-HSCT (72.4, IQR 44.9 - 97.2, p = 0.03). The percentage of patients with unilateral nephromegaly was 51.8% pre and 59.3% post HSCT (p = 0.58). The percentage of patients with bilateral nephromegaly was 14.8% pre and 29.6% post-HSCT (p = 0.19). No statistically significant differences were detected when groups were stratified by age, sex, primary diagnosis, HSCT source, conditioning regimen, and presence of other renal anomalies.

Conclusions: In this cohort of children and young adults, kidney length percentiles for age significantly increased post-HSCT. The mechanism and clinical significance of this increase requires further investigation.

TH-PO521

Epidemiology and Outcomes of AKI and Dialysis After Bone Marrow Transplant in Pediatric Patients

Omer S. Ashruf,[1] Zara C. Orozco,[1] Imad U. Haq,[1] Zaid Ashruf,[1] Sidharth K. Sethi,[3] Rupesh Raina.[2,4] *[1]Northeast Ohio Medical University, Rootstown, OH; [2]Cleveland Clinic Akron General, Akron, OH; [3]Medanta The Medicity Medanta Institute of Kidney and Urology, Gurugram, India; [4]Akron Children's Hospital, Akron, OH.*

Background: Acute kidney injury (AKI) is a common post-operative complication of bone marrow transplantation (BMT) in pediatric patients, with high mortality and morbidity. However, little is known about the epidemiologic characteristics. We assessed the characteristics, risk factors, and outcomes of BMT-induced AKI and the incidence, prevalence, and mortality of dialysis in the pediatric population.

Methods: Using patient data from TriNetX, a platform of health record data from 101 healthcare organizations, two cohorts were identified using ICD-10/lab/procedure/prescription codes: <18y/o patients with AKI within 30 days of BMT, and <18y/o patients who underwent BMT excluding AKI. Cohorts were 1:1 propensity matched for age, sex, and race. Outcomes assessed were: characteristics, risk factors, and clinical outcomes (hospitalization, emergency department [ED] visit, intensive care unit [ICU] admit, and mortality) after 6 and 12 months and incidence, prevalence, and mortality of dialysis patients post-AKI. Risk ratio (RR) and hazard ratio (HR) with 95% confidence intervals (95% CI) and Kaplan-Meier analysis were conducted.

Results: After matching, 524 pediatric patients were included. Characteristics, risk factors, and outcomes are in **Table 1**. Patients with AKI had higher rates of all clinical outcomes and greater mortality risk: 12.8% reduction in survival probability at 6 months and 14.6% at 1 year, **Figure 1**. The incidence of dialysis post-BMT and AKI was 4.3% at 1 year and 10.6% at 5 years, while the prevalence was 12.8% at 1 year and 14.6% at 5 years. Survival probability was 11.9% below the control cohort.

Conclusions: We found BMT-induced AKI and dialysis led to worse clinical outcomes in child patients. Further research is needed to develop preventive/management strategies for this high-risk population.

Long-Term Kidney Outcomes of Pediatric Acute Lymphoblastic Leukemia Survivors

Camille Laroche,[1] Jean-Philippe Roy,[1] Gabriel Cote Corriveau,[1] Daniel Sinnett.[2] *[1]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada; [2]Centre de Recherche du Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.*

Background: Hypertension (HTN) and chronic kidney disease (CKD) have been described in pediatric cancer survivors but renal outcomes following childhood acute lymphoblastic leukemia (cALL), the most frequent pediatric cancer, remain poorly defined. We aimed to determine the prevalence of abnormal estimated glomerular filtration rate (eGFR) and HTN among cALL survivors in the short- and long-term and assess potential associations with clinical characteristics prior to end of treatment.

Methods: This is a retrospective cohort study of 237 cALL survivors with no prior kidney disease. Clinical, imaging, and laboratory data were documented from cALL diagnosis to end of treatment (1987-2010) and at study follow-up (2013-2015). Logistic regression models were used to examine relationships between clinical characteristics and kidney outcomes.

Results: 49.8% of the cohort were males and median age at diagnosis was 4.8 (IQR = 3.0-9.8) years. By end of treatment, HTN and acute kidney injury (AKI) were diagnosed in 15.3% and 34.2% of patients respectively. Stage 1 AKI represented 77.8% of all AKI episodes. Initial ultrasound findings suggestive of leukemic kidney infiltration (LKI) and tumor lysis syndrome (TLS) were associated with higher AKI risk. HTN risk was higher among children younger than 5 years old (OR 2.3; 95% CI 1.1-4.8), those with LKI (3.5; 1.5-7.9), and who had AKI (2.5; 1.2-5.2). Median length of follow-up was 15.0 (11.6-19.7) years, with median age of 21.4 (16.8-25.9) years old. High blood pressure values suggesting HTN were recorded in 11.5% of patients. Mean eGFR was 100.3±15.7 ml/min/1.73m^2, with no difference between patients who had previous severe AKI episodes versus not. 27.1% of the cohort met criteria for stage 2 CKD (eGFR < 90 ml/min/1.73 m^2). CKD at long-term follow-up was not associated with number of AKI episodes, AKI severity, nor HTN prior to end of treatment. Prior severe AKI episodes were associated with high blood pressure at follow-up (5.1; 1.7-15.2).

Conclusions: Attention may be warranted for patients with ultrasound findings suggestive of LKI and TLS prior to end of treatment. cALL survivors who had severe AKI would benefit from long-term blood pressure monitoring. All cALL survivors should have their kidney function monitored as over 1 in 4 had stage 2 CKD by early adulthood, regardless of previous AKI or HTN diagnoses.

TH-PO523

Severe AKI and CKD Are Common in Children with Veno-Occlusive Disease Following Bone Marrow Transplantation

Kylie Culley, April Rahrig, Courtney M. Rowan, Jodi L. Skiles, David S. Hains, Michelle C. Starr. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Veno-occlusive disease (VOD) is a life-threatening complication occuring after bone marrow transplantation (BMT). The prevalence and severity of short and intermediate kidney outcomes is unknown.

Methods: Single center retrospective cohort of children with VOD following BMT from 2010-2020 (N=44). Primary outcome was treatment with kidney replacement therapy (KRT). Secondary outcomes included severe AKI and CKD at 1 year post BMT.

Results: Severe AKI developed in 35 (80%) of children with VOD and KRT was used in 21 (48%). Childen receiving KRT were younger (p=.041) and had lower pre-BMT eGFR (p=.032). Children receiving tacrolimus for GVHD prophylaxis (p<.001), shorter time to VOD diagnosis (p=.021), and more fluid overload (p=.001) were more likely to require KRT (**Table**). 33 (75%) survived to discharge. Of those receiving KRT, 13 (62%) survived to discharge. One year following BMT, 19 patients (43%) had died. Of those alive at 1 year, 9 (36%) had CKD and 9 (36%) had hypertension (**Figure**).

Conclusions: Despite high mortality, severe AKI and KRT in children with VOD is no longer universally fatal. In those that survive, CKD is common. We describe patient and treatment factors associated with KRT. Further study is needed to assess the causality, such as fluid overload and target interventions, such as diuretic therapy and individualized fluid management, in this high-risk patient population.

Renal Vein Thromboses: A 10-Year Review of a Tertiary Pediatric Center Practice

Ashish Patel, Miriam Cynan, Alexander D. Lalayiannis. *Birmingham Women's and Children's NHS Foundation Trust, Birmingham, United Kingdom.*

Background: Renal vein thrombosis (RVT) is a rare diagnosis predominantly affecting neonates. Although uncommon, there is long-term risk of hypertension (HTN) and chronic kidney disease (CKD). RVT tends to be unilateral (70% of cases) but extension of thrombosis is common (52% of cases). There are many risk factors predisposing to RVT including genetic thrombophilia mutations. Current management is based solely on expert opinion or small observational studies with no consensus. The choice and length of anticoagulation, if used, is variable and recommendations vary.

Methods: We reviewed our practice of RVT at a single tertiary pediatric nephrology center in the United Kingdom. We carried out a retrospective review of RVT cases over the past 10 years to evaluate our practice and develop local consensus on management.

Results: 18 patients were screened, with 14 patients eligible for inclusion. Nearly all patients identified were neonates, diagnosed with RVT at a median age of 3 days. Our review found a higher proportion of cases having bilateral RVT (57%) compared to unilateral (43%), with associated thromboses occurring in 71% of cases. 86% of cases received anticoagulation initially with low molecular weight heparin (LMWH)/enoxaparin (50%), unfractionated heparin (42%) or alteplase (8%). Long term anticoagulation was predominantly LMWH (62.5%) with others receiving warfarin (25%) and one case receiving rivaroxaban. Duration of anticoagulation varied between 1 week to 6 months. Most children (79%) were investigated with a thrombophilia screen, and 45% of those investigated had a gene mutation identified (2 with prothrombin mutation and 3 with factor V Leiden mutation). Mortality was high (21%) with long term outcomes of HTN (50% of cases) and CKD (43% of cases) being common at 3 and 6 month follow up.

Conclusions: Our review, although small, highlighted the variability in RVT presentation and management. There were more cases of bilateral RVT with a high index of associated thrombus formation in our population. Most cases received anticoagulation, but we recognise the variation in practice and length of therapy. We highlight the need for thrombophilia screening as well as monitoring for long-term sequalae like HTN and CKD. We recommend that larger international studies or an RVT registry are needed to achieve consensus on management between pediatric haematology and nephrology.

TH-PO525

Congenital Single Kidney, Inferior Vena Cava Abnormality, and Bilateral Ileo-Femoral Deep Vein Thrombosis: A Case of KILT Syndrome

Amy Hearn,[1] Smita Gunda.[2] [1]*Queen Elizabeth Hospital King's Lynn NHS Foundation Trust, King's Lynn, United Kingdom;* [2]*Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom.*

Introduction: KILT (kidney and inferior vena cava (IVC) abnormalities with leg thrombosis) syndrome is a rare condition comprising of renal defects, IVC abnormalities and venous thrombosis. There is limited knowledge about its pattern of presentation, management, and prognosis.

Case Description: We present a 30-year old lady who was referred to us with microscopic haematuria, single kidney on recent imaging and normal renal function. She later developed bilateral ileo-femoral DVT. In 2016, she presented to her General Practitioner with bilateral loin pain and positive urine dip. Computed tomography (CT) urogram was performed due to pyelonephritis revealing a solitary left hypertrophied kidney, hence referred to our renal clinic. She had normal renal function, no proteinuria or hypertension so renal biopsy was not clinically indicated. Renal function and urine parameters were therefore monitored annually. She presented to the Accident & Emergency department in August 2022 with pelvic inflammatory disease then developed a rigid left calf. Ultrasound Doppler demonstrated extensive DVT involving the popliteal femoral axis and anti-coagulation was commenced. Haematology screen was negative. She re-presented with right thigh pain in September 2022. CT abdomen-pelvis showed bilateral DVTs extending into the iliac veins and IVC as well as an IVC anatomical variant. In view of her having a single kidney, IVC abnormality and leg thrombosis a diagnosis of KILT syndrome was made. She has since developed a pulmonary embolism despite oral anti-coagulation.

Discussion: Most reported cases present with leg thrombosis and are later found to have absent/hypoplastic kidney. Our patient presented with a single kidney and no known history of thrombosis. The presentation therefore seems to be varied and a high degree of clinical suspicion is necessary. Could we have prevented DVT if we had imaged her

IVC anatomy as workup for the single kidney? Perhaps. We feel KILT syndrome should be included in the differential diagnosis of young patients with renal defects to prompt consideration of CT imaging of the IVC. Early detection may prevent renal hypoplasia with vascular intervention. There is no consensus of prevention or management of DVTs in KILT syndrome. Therefore, long-term anticoagulation and more follow up is required.

TH-PO526

Res(e)t and Relaxation: Intractable Hypernatremia

Rishil Patel, Nithiakishna Selvathesan, Subhrata Verma, Caoimhe Costigan, Mathieu J. Lemaire. *The Hospital for Sick Children, Toronto, ON, Canada.*

Introduction: Sodium and water homeostasis is regulated by vasopressin (AVP) release from the anterior pituitary and its antidiuretic action on the kidney. Osmoreceptors detect changes in plasma tonicity. The osmotic threshold (or osmostat) for AVP release is ~285 mOsmol/kg H_20.

Case Description: A 3-y boy with global developmental delay, cerebral palsy and G-tube dependence presented with pneumonia. The plasma sodium (PNa) improved from 154mmol/L to 151mmol/L with increased water intake. On follow up, PNa was 157mmol/L: he was admitted for further investigations. There was persistent sialorrhea and diaphoresis, but no medication changes, excess water losses or increased salt intake. He had stable vitals, 100g drop in weight and unremarkable examination. With no intervention, repeat bloodwork showed PNa 150mmol/L, plasma osmolality (POsm) 309 mOsm/kg H20, urine osmolality (UOsm) 1019 mOsm/kg and FeNa 0.5%. All other serum electrolytes and renal indices were unremarkable. Active increase in free water intake above his usual total fluid intake resulted in a PNa nadir of 146mmol/L, with urine osmolality of 187 mOsm/kg. These data show evidence of free water loss while still hypernatremic. After returning to his TFI, PNa settled around 151 mmol/L, with UOsm 600 mOsm/kg, and has remained stably high ever since.

Discussion: We describe a case of hypertonic hypernatremia and concomitant highly concentrated urine, indicating excellent urinary concentrating ability and adequate ADH production, effectively ruling out diabetes insipidus. Once PNa dropped below 150mmol/L (but never less than 146), enhanced free water excretion was invariably observed. We hypothesized that these findings are in keeping with an osmostat that is reset at a higher POsm to trigger ADH release: a rarer form of reset osmostat (RO), which is more commonly associated with hyponatremia (type C SIADH). We estimate that the threshold is ~150mmol/L instead of the usual 145. The etiology remains unclear with no hypothalamic lesion and no evidence of anterior pituitary dysfunction, and perhaps long term hypodipsia contributed. An overview of published literature on reset osmostat hypernatremia will be discussed. RO should be considered when dealing with a patient with an unusually difficult-to-control dysnatremia, when there is evidence of normal kidney function, and intact urine diluting and concentrating ability.

TH-PO527

Prediction of Ionized Hypocalcemia by Anion Gap and Its Components in Children Admitted to the Intensive Care Unit: A Retrospective Cohort Study

Jmal Alhaj, Anil K. Mongia, Oluwatoyin F. Bamgbola. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: The diagnosis of ionized hypocalcemia based on total serum calcium can be misleading. Correction of total calcium for hypoalbuminemia may be erroneous because calcium binds to other anions outside of the serum albumin. In this study, we tested the hypothesis that a correction of total serum calcium for anion gap and its components would improve the accuracy of a non-invasive diagnosis of ionized hypocalcemia in pediatric patients admitted to the ICU.

Methods: This is a retrospective study of patients aged 1 month to 21 years who were admitted to PICU at SUNY Downstate Medical Center between 2016-2020. All patients who had measurements of basic metabolic panel and blood gas analysis respectively taken within 60 minutes of each other were included. Logistic regression analysis for the prediction of ionized hypocalcemia using either the anion gap (AG model), its ion components (Na, Cl, and CO2; ion model), total serum calcium, and serum albumin as independent variables were performed.

Results: Compared with the AG model, the ion model was a better predictor of ionized hypocalcemia. The value of area-under-the-curve (ROC) was 0.85 ($p < 0.005$) for AG model and 0.9 ($p < 0.005$) for the ion model (Figure 1). Both parameters were more predictive of ionized hypocalcemia than the albumin-adjusted calcium method with the value of the ROC of only 0.8 ($p < 0.05$), Figure-1.

Conclusions: A correction of the total serum calcium for the anion gap and its components [sodium, chloride, and CO2] respectively improved the ability to diagnose ionized hypocalcemia non-invasively in pediatric patients admitted to ICU.

Clinical Features of Cystinosis and Practice Patterns: A Report of the NAPRTCS Cystinosis Registry

Reeti Kumar,[1] Kathleen Altemose,[2] Laurel K. Willig,[3] Bradley A. Warady,[3] Jodi M. Smith.[4] NAPRTCS. *[1]Duke University Health System, Durham, NC; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Children's Mercy Kansas City, Kansas City, MO; [4]University of Washington School of Medicine, Seattle, WA.*

Background: The NAPRTCS Cystinosis Registry was established to describe the clinical features of cystinosis in children and young adults and the associated practice patterns of providers.

Methods: Subjects ≤ 25 yrs of age with cystinosis at any NAPRTCS center are eligible for enrollment. Demographic and clinical data from time of diagnosis, time of registry enrollment, and every 6 months thereafter are collected.

Results: To date, data from 91 subjects from 30 centers diagnosed between 12/1999 and 8/2022 are available. Patient demographics and clinical features are shown in Table 1. Reported medications at diagnosis included cystine lowering medications (81.3%), cysteamine eye drops (35.2%), and phosphorus and potassium supplementation (42.9%, 40.7%) (Table 2). Procysbi use progressively increased following FDA approval in 2013. Median creatinine at registry entry and 36 months post enrollment was 0.64 mg/dL (eGFR 76.4 ml/min/1.73m^2) and 0.79 mg/dL (66.1 ml/min/1.73m^2), respectively. At registry entry, almost half the patients (48.9%) had a g-tube and photophobia was reported in 25.3%. Over 90% of patients were at grade level with 34.1% receiving special services. The most common subspecialty visits were ophthalmology (28.9%), endocrinology (25.6%), and GI (17.8%).

Conclusions: Children with cystinosis present early in life with the majority diagnosed before 2 years of age. Patients typically experience 5 months of symptoms prior to diagnosis, with failure to thrive present in more than 50%. Children and young adults with cystinosis have complex care needs which are often met through multispecialty care providers.

Updates on Renal Amyloidosis in Children and Adolescents

Asma B. Shaoba, Oluwatoyin F. Bamgbola. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: Amyloidosis affects individuals with eastern Mediterranean ethnicity; however, worldwide manifestation is frequent because of worldwide human migration. Although renal amyloidosis (RA) is a potentially fatal disease, it is relatively rare in children and adolescents. Its early manifestation as nephrotic syndrome may be mistaken for a minimal change disease. Familiarity with its geographical spread and pattern of presentation may enhance diagnostic awareness. For this purpose, we embarked on a PubMed search for articles on pediatric RA.

Methods: We searched the PubMed and Embase databases from 1960 to 2022 for relevant original articles including case reports and case series on RA in children and adolescents.

Results: RA occurred (n = 679) commonly among a population affected by familial Mediterranean fever (FMF) (n = 2812) who are mostly residents of Turkey (n = 1907) and Armenia (n = 836). The second most common cause of RA was idiopathic juvenile arthritis (JIA) (n = 139). Other reported causes were tuberculosis (TB) (n = 10) and epidermolysis bullosa (EB) (n = 13). In general, there was often renal remission following early diagnosis and treatment of FMF, JIA, and TB. The poor response to treatment in EB frequently resulted in end-stage kidney disease and fatal outcomes. There were only 6 cases of hereditary RA, three of which were due to ALys amyloid deposition. There was a single report of ALECT2 disease.

Conclusions: Most cases of pediatric RA were due to auto-inflammatory syndrome. Acquired causes were mostly due to JIA. Early treatment frequently resulted in renal remission. Finally, resources for modern genetic diagnosis most likely influenced the prevalence and geographical spread of the disease. Ref Picken MM. Current Understanding of Systemic Amyloidosis and Underlying Disease Mechanisms. Am J Cardiol. 2022;185: S2-S10.

Summary Data of Renal Amyloidosis (RA) from Original articles (OA), Case reports (CR), and Case series (CS) in Children and Adolescents.

Primary pathology/ type of amyloidosis	Gender ratio	Mean age (yrs.)	Publication types (n = no. of subjects with RA)
Tuberculosis	3M 3F 4NR	12.8	5CR, 1CS (n = 10)
Neutropenia	0M 6F	13.5	6CR (n = 6)
Hodgkin's Lymphoma	2M 2F	9.5	4CR (n = 4)
Recessive dystrophic Epidermolysis bullosa	9M 4F	14.3	7CR (n = 10)
Juvenile Idiopathic Arthritis	25M 24F 90NR	8.9	3OA, 2CS, 14CR (n = 139)
Inflammatory bowel disease	2M 1F	12.6	3CR (n = 3)
Chronic granulomatous disease	2M 1NR	15	3CR (n = 3)
Tumor Necrosis Factor Receptor Periodic Syndrome.	19M 16F	8.4; mean age RA = 35	1OA, 4CR, 1CS (n = 35)
Familial Mediterranean fever (FMF)	442M 368F	10.7	13CR 9OA, 4CS (FMF n = 2812; RA n = 679)
Mevalonate kinase deficiency (MKD)	64M 63F	8.2	9CR, 3CS, 1OA (MKD n = 149; RA n = 13)
Hereditary amyloidosis (3ALys; 3AFib)	4M 2F	14.1	6CR (n = 6)

Elevated Serum Gd-IgA1/s.IgA Levels and Not Serum Gd-IgA1 Alone Is an Independent Risk Factor for Composite Outcome in South Asian IgA Nephropathy (IgAN)

Suceena Alexander, Selvin Sundar Raj Mani, Santosh Varughese, George John. GRACE-IgANI. *Christian Medical College Vellore, Vellore, India.*

Background: The role of serum Gd-IgA1 in a prospective longitudinal South Asian IgAN cohort **(GRACE-IgANI)** and the impact of immunosuppression is not known.

Methods: We measured serum galactose-deficient IgA1 (s.Gd-IgA1) levels in 170 IgAN patients, 40 disease controls, and 27 healthy controls by KM55 ELISA (IBL international GmBH, Germany) at baseline. Longitudinal measurements were made at 1 year and 2 years in a subgroup of 117 IgAN patients who received a short course of immunosuppression. The baseline associations and the usefulness of s.Gd-IgA1 as a diagnostic and prognostic biomarker was assessed.

Results: s.Gd-IgA1 had significant positive correlation with serum immunoglobulin A (s.IgA) (r=0.6, n=170, p<0.001). Neither s.Gd-IgA1 nor s.Gd-IgA1/s.IgA ratio was a diagnostic marker for IgAN. s.Gd-IgA1/s.IgA ratio had stronger baseline and longitudinal associations than s.Gd-IgA1 alone. Elevated s.Gd-IgA1/s.IgA ratio was significantly associated with baseline clinical and histopathological indices of activity and chronicity. In the subgroup that received immunosuppression, there was significant decrease in both s.Gd-IgA1 and s.IgA at 1 year. The mean time to the composite outcome was significantly shorter for each quartile increase in s.Gd-IgA1/s.IgA ratio by Kaplan-Meier survival analysis [<1.3: vs. 1.3-1.7 HR 3.3 (95% CI 1.2-9.1), 1.7-2.3 HR 4.3 (95% CI 1.6-11.9), >2.3 HR 6.2 (95% CI 2.4-16.2), p<0.001]. Higher median s.Gd-IgA1/s.IgA ratio was as an independent predictor for composite outcome by Cox proportional-hazards (HR 2.3, 95% C.I. 1.2-4.5, p=0.01) model and outperformed 24-hour urine protein.

Conclusions: We have shown for the first time in IgAN with South Asian ethnicity, the relevance of proportion of s.Gd-IgA1 to total serum IgA for risk stratification, its association with prognosis and its longitudinal changes with immunosuppression. The results need to be externally validated.

Claudin-1 Is a Therapeutic Target for Crescentic Glomerulonephritis

Geoffrey Teixeira,[1] Jean-Daniel Delbet,[2] Vincent Anquetil,[1] Alberto Toso,[1] Stephen Toovey,[1] Luigi Manenti,[1] Roberto Iacone,[1] Jesper Kers,[3,4] Ton J. Rabelink,[3] Kevin Saitoski,[2] Thomas F. Baumert,[5,6] Ariela Benigni,[7] Susanna Tomasoni,[7] Giuseppe Remuzzi,[7] Thomas Cagarelli,[8] Marco Prunotto,[9] Solange Moll,[8] Pierre-Louis Tharaux.[2] *[1]Alentis Therapeutics, Allschwil, Switzerland; [2]Paris Centre de Recherche Cardiovasculaire, Paris, France; [3]Leids Universitair Medisch Centrum, Leiden, Netherlands; [4]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands; [5]Universite de Strasbourg, Strasbourg, France; [6]Institut Universitaire de France, Paris, France; [7]Istituto di Ricerche Farmacologiche Mario Negri, Milano, Italy; [8]Hopitaux Universitaires Geneve, Geneve, Switzerland; [9]Universite de Geneve Section des Sciences Pharmaceutiques, Geneve, Switzerland.*

Background: Crescentic glomerulonephritis (CGN), encompasses a large spectrum of kidney diseases characterized by extensive epithelial cell proliferation forming crescents and renal fibrosis. Current therapies for CGN do not directly target the deleterious response of resident kidney cells. Claudin-1 (CLDN1), a transmembrane protein involved in epithelial tight junctions, can, in pathological conditions, be exposed outside the tight junctions and mediate pro-fibrotic pathways and extracellular matrix (ECM) remodelling. We have developed ALE.F02, a first-in-class monoclonal antibody (mAb) highly specific in targeting CLDN1 exposed outside the tight junctions. ALE.F02 exhibited an excellent safety profile with evidence of on-target biological activity in first-in-human clinical trial. This study investigated the functional role of CLDN1 in proliferative glomerular parietal epithelial cells (PEC) as a therapeutic target for ANCA-associated vasculitis (AAV), Lupus Nephritis (LN) and crescentic IgA nephropathy (IgAN).

Methods: CLDN1 expression in renal tissues of CGN patients was analyzed using immunohistochemistry, immunofluorescence and spatial transcriptomics. Correlations between CLDN1 expression, disease biomarkers and crescent evolution were studied. Spatially resolved molecular roadmap from CLDN1+ crescentic glomeruli were conducted. Proof-of-concept studies using anti-CLDN1 mAb were performed in preclinical models of CGN.

Results: In tissues (n=100+) of CGN patients, exposed CLDN1 was highly expressed by cellular and fibro-cellular crescents. Multi-color immunofluorescence of CGN patients revealed up-regulated CLDN1 expression by activated PEC. CLDN1 upregulation was associated with high plasma levels of renal disease biomarkers (CD44, CXCL12, MMP7). Spatial transcriptomics analysis highlighted the association between CLDN1+ crescentic glomeruli and ECM proteins. Proof-of-concept studies in CGN mouse models showed that treatment with anti-CLDN1 mAb reduced proteinuria and fibrosis biomarkers.

Conclusions: Our results suggest a functional role for CLDN1 in the pathogenesis of CGN, providing preclinical proof-of-concept for ALE.F02 as a novel therapeutic approach in patients with CGN.

TH-PO532

Elevated Levels of IL-6 in IgA Nephropathy Patients Are Induced by an Epigenetically Driven Mechanism Modulated by Viral and Bacterial RNA

Fabio Sallustio, Angela Picerno, Maria Teresa Cimmarusti, Francesca Montenegro, Alessandra Stasi, Francesco Pesce, Vincenzo Di leo, Loreto Gesualdo. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: Immunoglobulin A nephropathy (IgAN) is the most frequent primary glomerulonephritis characterized by the presence of IgA immune complexes in the glomeruli. Newly, the role of IL-6 in pathogenesis is becoming increasingly important but reason why levels of IL-6 are elevated in IgAN patients is not well understood. One attainable hypothesis comes out from our recent whole genome DNA methylation screening in IgAN patients, that identified, among others, a hypermethylated region comprising Vault RNA 2-1 (VTRNA2-1), a non-coding RNA.

Methods: Total RNA were isolated from PBMCs of IgAN patients, transplanted IgAN patients (TP-IgAN), non-IgAN transplanted patients (TP) and healthy subjects (HS). VTRNA2-1, CREB and PKR transcripts were evaluated by RT-PCR. Total and phosphorylated PKR, CREB and Il-6 proteins were evaluated by ELISA. Poly (I:C), a synthetic analogue of dsRNA, and Pfizer-BioNTech COVID-19 vaccine were used to transfect patient PBMCs. PKR inhibitor imoxin (C16) 1 μM was used to stimulate patient PBMCs.

Results: Here we confirm that VTRNA2-1 is low expressed in IgAN subjects compared to HS and we found that also in transplanted IgAN patients (TP-IgAN), compared to non-IgAN transplanted patients (TP), the VTRNA2-1 transcript was expressed at level very low. We found that in IgAN patients with downregulated VTRNA2-1, PKR is overactivated, coherently with the role of the VTRNA2-1 that binds to PKR and inhibits its phosphorylation. The loss of the VTRNA2-1 natural restrain caused the activation of CREB by PKR, a classical cAMP-inducible CRE-binding factor interacting with a region of the IL-6 promoter and leading to IL-6 production, both in IgAN and in TP-IgAN patients. PKR is normally activated by bacterial and viral RNA and we found that both the RNA poly(I:C) and the COVID-19 vaccine stimulation significantly increase the IL-6 levels in PBMCs from HS but had an opposite effect in those from IgAN patients.

Conclusions: In conclusion, the discovery of the upregulated VTRNA2-1/PKR/CREB/IL-6 pathway in IgAN patients may provide novel approach to treat the disease and may be useful for development of precision nephrology and personalized therapy, possibly by checking the VTRNA2-1 methylation level in IgAN patients.

Topological Analysis of High-Resolution Spatial Transcriptomics Reveals Immune Glomerular Architecture of Lupus Nephritis

Katherine R. Bull,[1,2] Katherine Benjamin,[3] Aneesha Bhandari,[1] Zhouchun Shang,[5,6] Yanan Xing,[5,6] Yanru An,[5] Nannan Zhang,[7] Ulrike Tillmann,[3,4] Heather A. Harrington.[3] Oxford Kidney Pathology Research Group and Oxford Mathematics Institute. *[1]University of Oxford Nuffield Department of Medicine, Oxford, United Kingdom; [2]Churchill Hospital Oxford Kidney Unit, Oxford, United Kingdom; [3]University of Oxford Mathematical Institute, Oxford, United Kingdom; [4]Isaac Newton Institute for Mathematical Sciences, Cambridge, United Kingdom; [5]BGI Group, Shenzhen, China; [6]Chinese Academy of Sciences, Beijing, China; [7]Bejing Genomics Institute-Qingdao, Qingdao, China.*

Background: To develop targeted treatments for immune complex diseases such as lupus nephritis (LN) we need to understand immune and renal cell interactions. The advent of spatial sub-cellular resolution whole transcriptome technologies offers the potential to study cell distribution within glomeruli, but requires new mathematical approaches. Conventional 'fixed-window' approaches bin data across spots, discarding the granularity of a high-resolution platform and missing small or rare cells such as immune infiltrates.

Methods: Murine kidneys treated with topical imiquimod or vehicle were prepared for single nuclei RNA sequencing (snRNA-Seq, 10x Genomics) and 200nm spot spatial transcriptomics (STOmics, Beijing Genomics Institute) and analysed (Seurat, RCTD). We developed topological automatic cell type identification (TopACT), combined with multiparameter persistent homology (MPH) to quantify multiscale spatial cell organization. TopACT independently classifies and annotates spot level cell type using a dynamic local neighbourhood.

Results: On synthetic data imputed from renal snRNA-Seq, TopACT produced high accuracy spot-level cell type annotations in comparison to fixed-window approaches. In murine kidney, TopACT spatially resolved individual immune cells in LN, enriched within glomeruli, where the average MPH landscape indicated large loops of immune cells (Fig 1A). This leads to the prediction, driven by spatial data, and confirmed by CD45 immunofluorescence, of a peripheral ring structure of glomerular immune cells in LN (Fig 1B and C).

Conclusions: Our multiscale method for topological automatic cell classification improves accuracy of cell-type information for subcellular resolution spatial transcriptomics, and detects the spatial arrangement of glomerular immune cells in LN. TopACT is generalisable, flexible and has potential for further application to 3D or spatiotemporal data.

ACE in Granulocytes Has a Protective Role in Crescentic Glomerulonephritis via Complement Lectin Pathway Independent of Angiotensin II

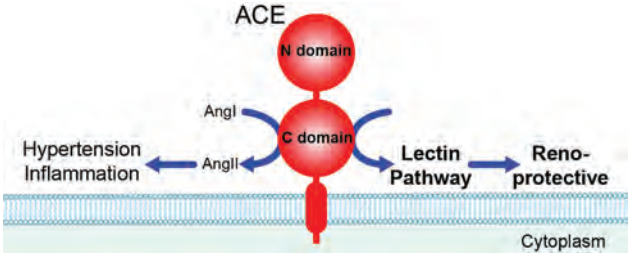
Suguru Saito, Narihito Tatsumoto, Michifumi Yamashita. *Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: ACE is a well-known enzyme to regulate blood pressure and inflammation, and structurally having two enzymatic domains: N-domain and C-domain. Its C-domain regulates blood pressure by producing angiotensin II in renin-angiotensin system. We recently reported a novel function of ACE: ACE overexpressed neutrophils have a protective role in immune complex (IC)-mediated crescentic glomerulonephritis (GN) via complement C3b-CR1/2 axis, efficiently removing IC deposits. Here, we show that ACE C-terminal catalytic domain is responsible for the renoprotective role in myeloid cells in crescentic GN via lectin pathway.

Methods: We induced the nephrotoxic serum nephritis (NTN) in C57Bl/6 (WT), Jwt mice that overexpressing ACE in myeloid cells (neutrophils and monocytes/macrophages), Jcko mice that overexpressing C-domain knockout ACE in myeloid cells, and Jnko mice that overexpressing N-domain knockout ACE in myeloid cells, and evaluated renal function and histology (crescent formation and fibrinoid necrosis). In addition, we examined complement pathway activation in vitro and blood angiotensin II level.

Results: 7 days after induction of NTN, Jwt mice showed less severe proteinuria and mild histological glomerular damages, showing overexpressed ACE in neutrophils and monocytes/macrophages has the protective role in IC-mediated crescentic GN. When we induced NTN in Jcko mice and Jnko mice, Jcko mice lost the renoprotective effects and Jnko mice still showed the severe glomerular damage. These data clearly showed that ACE C-domain, but not N-domain, has the renoprotective role. Regarding complement activation, recombinant ACE activated lectin pathway, but not classical and alternative pathways. Given the normal blood pressure level and the normal plasma angiotensin II level in all these mouse strains, the ACE C-domain mediated renoprotective effect is independent of angiotensin II.

Conclusions: ACE C-domain in granulocytes has a protective role in crescentic glomerulonephritis via complement lectin pathway independent of Angiotensin II.



Dual effects of ACE C-domain in kidney disease

TH-PO535

Integrin β6 Regulates Tubuloglomerular Feedback Through the NKCC2-COX2/nNOS Pathway

Jianyong Zhong, Haichun Yang, Agnes B. Fogo. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Integrin β6 (β6) is a protein expressed in some tubules and macula densa cells, which activates transforming growth factor-β (TGF-β). Our previous studies showed that $\beta6^{-/-}$ mice exhibit milder tubulointerstitial fibrosis but more severe glomerulosclerosis than wild type (WT) after 5/6 nephrectomy. This study aimed to explore the involvement of macula densa integrin β6 in the dysfunction of tubuloglomerular feedback.

Methods: We first knocked down β6 in mouse macula densa cells (MMDD1) and exposed them to high salt. The expression of Oxidative Stress Responsive Kinase 1 (OXSR1), a regulator of NKCC2 activity, was assessed by qPCR. The protein

expressions of NKCC2, COX2, and nNOS were analyzed by western blot. We then measured renal clearance before and after acute volume expansion in $\beta6^{-/-}$ and WT mice.

Results: Immunostaining showed that integrin β6 and NKCC2 colocalized on the cell membrane of MMDD1. Knockdown of β6 significantly increased the expression of OXSR1 and NKCC2 and induced more nNOS and less COX2 compared to WT cells. High salt reduced COX2 and increased nNOS protein expression in WT, which was not changed in β6 knockdown cells. In vivo, following acute volume expansion with 3% of body weight volume of isotonic saline over 5 min, blood pressure decreased minimally and similarly in both groups at 15 min and recovered to the baseline level at 30 min after volume expansion. GFR of WT mice increased at 30 minutes and returned to baseline at 90 min. In contrast, integrin β6 knockout mice reached peak GFR at 60 min, but ultimately returned to baseline at 90 min.

Conclusions: These findings suggest that integrin β6 regulates tubuloglomerular feedback through the NKCC2-COX2/nNOS pathway. The dysfunction of tubuloglomerular feedback induced by β6 knockout on macula densa cells may contribute to the observed mismatch in tubulointerstitial fibrosis and glomerulosclerosis in $\beta6^{-/-}$ mice after 5/6 nephrectomy.

TH-PO536

Lambda Light Chain Predominance Links C1q Deposition to Endocapillary Hypercellularity in IgA Nephropathy

Eva Baier, Bjoern Tampe. *Universitatsmedizin Gottingen Klinik fur Nephrologie und Rheumatologie, Gottingen, Germany.*

Background: Involvement of the complement system is a key driver of immune complex-mediated nephritogenicity in immunoglobulin A nephropathy (IgAN), being the most prevalent primary glomerulopathy worldwide. Despite growing insights on the pathophysiological relevance of lambda (λ) light chain (LC) predominance in IgAN, implications of glomerular complement deposition remain largely elusive. Therefore, we here aimed to systematically assess the correlative pattern of clinicopathological findings and glomerular complement C1q and C3c deposits in λ-LC predominant biopsy-proven IgAN.

Methods: A total of 37 patients with biopsy-proven IgAN obtained between 2016 and 2021 were retrospectively included in a single center observational study. Clinical data assessment comprised age, sex, serum creatinine levels, blood urea nitrogen, eGFR, complement C3/ C4 and proteinuria. Oxford-scored lesions mesangial (M) and endocapillary hypercellularity (E), segmental sclerosis (S), tubular atrophy (T), crescentic formations (C), and other lesions scored analogous to the Banff classification were evaluated. Immune histochemistry-detected glomerular deposits of complement factors C1q/ C3c and kappa (κ)/ λ LCs were semiquantitatively scored. Two groups were formed according to the λ-LC status: λ-LC positive (*n=20*) and λ-LC negative (*n=17*). Clinicopathological correlations were analyzed in both groups regarding glomerular C1q and C3c deposits by means of multivariable linear regression.

Results: Enrolled patients featured a median creatinine level of 1.5 mg/dL. C1q and C3c deposition featured no significant association with serum parameters indicative of kidney injury or proteinuria. We identified endocapillary hypercellularity to feature the strongest association with glomerular C1q deposition in the λ-LC positive group (ρ=0.7; β=0.745, *p<0.001*). In the λ-LC negative group, a significant correlation of C3c deposition and mesangial hypercellularity was identified (ρ=0.6; β=0.762, *p<0.001).*

Conclusions: We here show a correlative pattern of λ LC-associated deposition of complement factors C1q and C3c in distinct histopathological features of IgAN implying an involvement of the classical pathway in the preset of λ-LC predominance.

Classical Monocyte-Derived and Lipid-Associated TREM2+ Macrophages Orchestrate Inflammatory and Fibrotic Processes in ANCA-Associated Glomerulonephritis

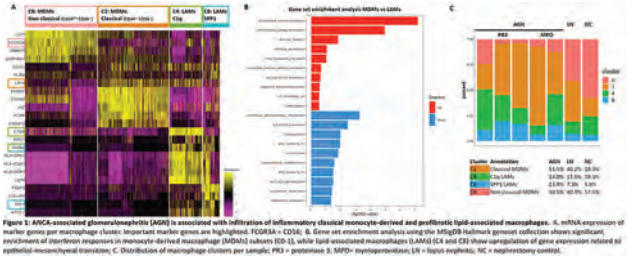
Yosta Vegting,[1] Aldo Jongejan,[2] Annette E. Neele,[3] Nike Claessen,[4] Jesper Kers,[4,5] Joris Roelofs,[4] Sandrine Florquin,[4] Johan willem V. Heijden,[6] Liffert Vogt,[1] Frederike J. Bemelman,[1] Menno de Winther,[3] Perry Moerland,[2] Marc Hilhorst.[1] Hilhorst Group. *[1]Amsterdam UMC, University of Amsterdam, Department of Internal Medicine, Section of Nephrology, Amsterdam Cardiovascular Sciences, Amsterdam Infection and Immunity, Amsterdam, Netherlands; [2]Amsterdam UMC, University of Amsterdam, Dept. of Epidemiology & Data Science (EDS), Bioinformatics Laboratory, Amsterdam, Netherlands; [3]Amsterdam UMC, University of Amsterdam, Department of Medical Biochemistry, Amsterdam Cardiovascular Sciences, Amsterdam Infection and Immunity, Amsterdam, Netherlands; [4]Amsterdam UMC, University of Amsterdam, Department of Pathology, Amsterdam Cardiovascular Sciences, Amsterdam, Netherlands; [5]Leiden University Medical Center, Department of Pathology, Leiden, Netherlands; [6]Spaarne Gasthuis Hospital, Department of Internal Medicine, Hoofddorp, Netherlands.*

Background: ANCA-associated glomerulonephritis (AGN) associates with a high risk of end-stage kidney disease. Kidney macrophage infiltration is one of the main histological hallmarks of vasculitic lesions and is strongly linked to disease activity. The role of kidney macrophages in local inflammation remains unclear. Here we investigate kidney macrophage diversity and function.

Methods: Single cell transcriptome analysis of $CD45^+$ immune cells from freshly retrieved kidney biopsies of 5 AGN patients, 1 disease-control with class 2 lupus nephritis (LN), and 1 nephrectomy control (NC) was performed using 10X Genomics technology. Myeloid cells were selected and subsequently reclustered to identify disease-specific macrophage subtypes and functionality was assessed by a gene set enrichment analysis (GSEA). Validation studies were performed using flow cytometry and immunohistochemistry.

Results: Focused analysis identified 2 monocyte-derived macrophage (MDMs) clusters and 2 new $TREM2^+$ lipid-associated macrophage (LAMs) subtypes, $C1Q^+$ and $SPP1^+$/Osteopontin$^+$ LAMs **(panel A)**. GSEA revealed increased interferon responses in MDMs compared to LAMs **(panel B)**, and increased TNFa signaling via NFkB in classical MDMs compared to non-classical MDMs. $SPP1^+$ LAMs showed upregulation of gene sets related to fibrosis and cell cycle. Evaluating kidney macrophage subsets between diseases revealed increased % classical MDMs and LAMs in AGN (respectively, 52% and 38%) compared to NC tissue (18% and 24%) **(panel C)**. Flow cytometric analysis identified a similar increase in peripheral blood classical monocytes during active disease (P<0.0001).

Conclusions: Classical MDMs and LAMs are the main kidney macrophage subsets present in AGN. Classical MDMs drive inflammation, whereas $SPP1^+$ $TREM2^+$ LAMs orchestrate fibrosis. Targeting these specific macrophage subsets may potentially reduce acute kidney injury and long-term fibrosis.



TH-PO538

Evaluation of Intrarenal Plasmacytoid Dendritic Cells in Active Lupus Nephritis

Brad H. Rovin,[1] Samir V. Parikh,[1] Su Jing Chan,[2] Luke Jandreski,[2] Kyle Ferber,[2] Catherine Barbey,[3] Taylor L. Reynolds.[2] *[1]The Ohio State University Wexner Medical Center Department of Internal Medicine, Columbus, OH; [2]Biogen Inc, Cambridge, MA; [3]Biogen Inc, Baar, Switzerland.*

Background: Interferon-alpha (IFNα)-responsive genet expression is highly upregulated in the kidneys of patients with active lupus nephritis (LN). Infiltrating plasmacytoid dendritic cells (pDCs) have been postulated to be a source of intrarenal IFNα. In this study we quantified intrarenal pDCs in patients with LN and correlated infiltration with histologic activity and chronicity.

Methods: Immunohistochemistry (IHC) for BDCA-2, a marker of pDCs and a subset of dendritic cells was used to visualize intrarenal pDCs. All pDCs within a biopsy were counted and the average number of glomerular pDCs and the number of tubulointerstitial pDCs per unit area were determined. The NIH activity and chronicity indices were calculated. IHC for MX1, an IFNα-inducible protein was used to characterize the interferon response.

Results: We studied 18 patients with proliferative (70% (n=12)) or proliferative + membranous LN (30%, n=6), 60% (n=11) of whom were de novo diagnoses and 40% (n=7) carried an LN diagnosis for 1-6 years. Patients were biopsied for suspected LN flare. pDCs were found mainly as individual cells within the tubulointerstitium in these kidney biopsies, and were seldom seen within glomeruli. In some biopsies, aggregations of pDCs were found in areas of tubulointerstitial inflammation or surrounding glomeruli. A median (range) of 0 (0-0.82) pDCs/glomerulus and 2.7 (0.77-49) pDC/mm^2 of tubulointerstitium were found. There was no evidence of an association between tubulointerstitial pDCs and serum creatinine, proteinuria, activity index, or chronicity index. MX1 immunoreactivity was found in abundance throughout the kidney, including glomerular and tubular epithelial cells, glomerular and tubulointerstitial endothelial cells, vascular wall smooth muscle cells, and infiltrating inflammatory cells.

Conclusions: pDCs are thought to be the major source of IFNα in the kidneys of patients with LN. If this is true, our data suggest that very few infiltrating pDCs are needed to initiate a robust IFNα response within the kidneys.

The Balance Between STAT3 and Glutathione Metabolism Is Required for Parietal Cell Activation and Proliferation in Proliferative Glomerulopathies

Joseph Kim,[1] Yogesh Gowthaman,[1] Yiqing Guo,[1] Robert Bronstein,[1] Andrew Chow,[1] Sandeep K. Mallipattu.[1,2] *[1]Stony Brook University Hospital, Stony Brook, NY; [2]Northport VA Medical Center, Northport, NY.*

Background: STAT3 signaling is activated in podocytes and parietal epithelial cells (PECs) in murine models of proliferative glomerulopathy and in human RPGN and subtypes of FSGS. We previously showed that podocyte-specific loss of STAT3 preserves podocyte loss and attenuates PEC activation. However, the mechanism by which STAT3 activation triggers PEC activation, proliferation, and crescent formation and whether its inhibition as a therapeutic target in proliferative glomerulopathies remains poorly understood.

Methods: PECs were treated with increasing doses of IL-6 (5, 10, 20, 40ng/ml) to explore the role of STAT3 activation in cell viability. We generated mouse PECs with deletion of STAT3 using Crispr/Cas9. MTT assay was performed on Cas9 (wildtype) and STAT3 knockout (STAT3-/-) PECs. Cell migration of Cas9 and C7 cells were measured using a scratch assay. Mitochondrial respiration, glycolytic rate, and ATP production were performed using seahorse analyzer. Glutathione, superoxide, and reactive oxygen species (ROS) levels were measured. RNA sequencing was conducted in the Cas9 and STAT3-/- PECs. PEC-specific STAT3-/- mice were generated as well as STAT3 inhibitor treatment in mice post-nephrotoxic serum (NTS) administration.

Results: STAT3-/- PECs exhibited reduced cell proliferation, activation, oxygen consumption, and ATP production. RNAseq demonstrated a downregulation of differential expressed genes (DEGs) involved in glutathione metabolism with an upregulation in focal adhesion DEGs. STAT3-/- PECs had reduced cellular glutathione pool leading to increased levels of superoxide levels leading to increased oxidative stress and DHE expression. In silico analysis showed that pSTAT3 occupies the promoter region of key glutathione synthesis genes, suggesting potential direct regulation. PEC-specific STAT3-/- mice or treatment with STAT3 inhibitor reduced proteinuria, PEC activation (CD44, Akap12), crescent formation with increased oxidative stress (8-oxo-G, OGG1) as compared to their respective controls post-NTS treatment.

Conclusions: To date, this is the first study to demonstrate the mechanism by which STAT3 activation in PECs enhances glutathione metabolism to maintain a balance in ROS and exacerbate PEC activation and crescent formation in proliferative glomerulopathies.

Association of a New Variant of Complement Regulator FHR2 with C3 Glomerulopathy

Peter F. Zipfel,[1] Luce Perie,[1] Thorsten Wiech.[2] *[1]Leibniz-Institut fur Naturstoff-Forschung und Infektionsbiologie eV Hans-Knoll-Institut, Jena, Germany; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany*.

Background: C3 glomerulopathy (C3G) is caused by a dysregulation of the complement system leading to C3 deposition and formation of glomerular deposits. Several C3G patients harbor mutations or copy number variations in the human Factor H (*FH*) and/or Factor H-Related (*FHRs*) genes. Therefore, FH and FHRs are emerging immune targets for inhibition of the complement cascade, as well as markers to monitor patients on complement regulatory drugs to test their efficiency.

Methods: Here, we focused our study on FHR2, known to inhibit *in vitro* formation of the terminal complement complex. We identified new variants for the *FHR2* gene in a cohort of C3G patients and performed detailed functional studies on the novel variant FHR2$_{L46}$, which has the Pro at position 46 replaced by Leu. Patients with FHR2$_{L46}$ variant presented increased FHR2 plasma level, as compared to controls and displayed FHR2 deposits in glomeruli. We generated a recombinant FHR2$_{L46}$ mutant protein to gain insight into the effect of this novel FHR2 variant on complement regulation.

Results: As the amino acid exchange occurred in the first short consensus repeat (SCR1), we first tested if the Leu at position 46 altered FHR2 homodimerization and heterodimerization of FHR2 with FHR1 and FHR5. We observed that FHR2$_{L46}$ binds significantly less to FHR2 and FHR1 but more to FHR5. Furthermore, FHR2$_{46L}$ acquired the capacity to bind to cell surfaces by interacting with glycosaminoglycans heparin and malondialdehyde (MDA)-modified amino group (MAA) epitopes. FHR2$_{L46}$ also bound substantially more to necrotic cells compared to wild-type FHR2 (FHR2$_{WT}$). In contrast, no difference was observed between FHR2$_{L46}$ and FHR2 WT binding to C3 and C5.

Conclusions: Taken together, the present study identified a novel FHR2$_{L46}$ variant in a C3G patient and suggests that the FHR2$_{L46}$ mutant forms stable oligomers with FHR5 and enhances complement activation.

An Integrated Proteome-Transcriptome Organoid Atlas Illuminates Core Concepts of Kidney Disease

Moritz Lassé,[1] Jamal El Saghir,[2] Celine C. Berthier,[2] Sean Eddy,[2] Matthew Fischer,[2] Matthias Kretzler,[2] Jennifer L. Harder,[2] Markus M. Rinschen.[1] *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Division of Nephrology, Department of Internal Medicine, University of Michigan, Ann Arbor, MI.*

Background: The use of kidney organoids as a model for studying kidney disease shows great promise, but their potential is limited by our limited understanding of the proteins they express and their functional profiles. In this study, we aimed to address this limitation by examining the proteome and transcriptome of organoids throughout their culture period and in response to TNFα, a cytokine stressor.

Methods: In our study, we employed proteomic analysis to compare kidney organoids with other established model systems and native tissues, including native glomeruli and cultured podocytes. We examined the developmental trajectory of organoids and explored their innate immune responses, thereby expanding the applicability of organoids as a valuable model system in the field of nephrology. Additionally, we performed a comprehensive comparison of our proteomic data with both bulk and single-cell transcriptomics data, providing a more comprehensive understanding of the molecular landscape of kidney organoids.

Results: We found that older organoids displayed increased accumulation of extracellular matrix while showing decreased expression of glomerular proteins. By integrating single-cell transcriptome data, we discovered that most changes in the proteome were localized to podocytes, tubular cells, and stromal cells. Treatment of the organoids with TNFα resulted in the differential expression of 322 proteins, including cytokines and complement components. Importantly, the transcript expression of these 322 proteins was significantly higher in individuals with poorer clinical outcomes in proteinuric kidney disease. Notably, key proteins associated with TNFα (C3 and VCAM1) were found to be increased in both human tubular and organoid kidney cell populations, indicating the potential of organoids to advance the development of biomarkers. VCAM1 was localized to the descending thin limb (DTL) of proteinuric patients with kidney disease.

Conclusions: By integrating various “omic” layers of kidney organoids, incorporating a relevant cytokine stressor, and comparing with human data, we highlight the significance of kidney organoid modeling in understanding and studying complex human kidney disease.

Identification of Conserved Gene Expression Changes Across Common Glomerular Diseases by Spatial Transcriptomics

Jeongmin Cho,[1] Sehoon Park,[1] Jung Hun Koh,[1] Yaerim Kim,[2] Hajeong Lee,[1] Seung Seok Han,[1] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Keimyung University Daegu Dongsan Hospital, Daegu, Republic of Korea*.

Background: Glomerular diseases encompass a group of kidney diseases that may share common gene expression pathways. We aimed to analyze glomerular-specific gene expression profiles across various glomerular diseases.

Methods: We performed spatial transcriptomic profiling using formalin-fixed paraffin-embedded kidney biopsy specimens of controls and patients with five types of glomerular diseases using the GeoMx Digital Spatial Profiler. We identified common differentially expressed genes (DEGs) across glomerular diseases and performed Gene Ontology (GO) annotation using the ToppGene suite.

Results: A total of 35 DEGs were consistently downregulated in glomeruli across the disease compared to the control, while none of the DEGs were consistently upregulated. Twelve of 35 downregulated DEGs, including the two hub genes FOS and JUN, were annotated with molecular function GO terms related to DNA-binding transcription factor activity. The annotated biological process GO terms included response to lipid-related (17/35 DEGs), response to steroid hormone (12/35 DEGs), or cell cycle regulation (10/35 DEGs).

Conclusions: Identifying common DEGs by spatial transcriptomic analysis provides insights into underlying molecular mechanisms of glomerular diseases and may lead to novel assessment or therapeutic strategies.

Generation of CX3CR1-Expressing T Regulatory Cells Using Retroviral Transduction

Paul Diefenhardt,[1,2] David L. Puetz,[1,2] Bastian Trinsch,[1,2] Jasper F. Nies,[1,2] Claudio Sierra Gonzalez,[2] Bernhard Schermer,[1,3] Paul T. Brinkkoetter,[1,2] Thomas Benzing,[1,2] Sebastian Braehler.[1,2] *[1]Universitatsklinikum Koln, Koln, Germany; [2]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [3]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: T cells play a central role in the pathogenesis of acute glomerulonephritis. Studies in rodent models as well as observations in patients suggest an imbalance of pro-inflammatory T effector cells and anti-inflammatory T regulatory cells (Treg), resulting in autoimmune-mediated glomerular injury. Increasing the numbers of T regulatory cells in the inflamed kidney might restore the T cell balance and, thus, attenuate disease. This could be achieved by transfusion of Tregs equipped with specific chemokine receptors to increase their migration into the inflamed kidney. In this regards, the CX3CR1-CX3CL1 axis represents a promising target, as it has been implicated in a variety of inflammatory diseases in the kidney.

Methods: The nephrotoxic nephritis model (NTN) is used to assess the distribution of CX3CL1 in the kidney using IHC stainings. The expression of CX3CR1 on renal and splenic immune cells during homeostasis and NTN is analysed using flow cytometry. Standard cloning techniques are used to design a retroviral vector for transduction of naïve murine T cells.

Results: Flow cytometry analysis after 7 days of nephrotoxic nephritis reveal CX3CR1 expression mostly on macrophages and classical dendritic cells Type 2 in the kidney and spleen. Renal and splenic T cells, on the other hand, express less CX3CR1, with about 20% of cytotoxic T cells and 10-15% of Tregs and Th17 cells expressing the receptor. Immunohistochemistry reveals increased Fractalkine expression in nephritic kidneys compared to healthy controls. To generate induced Tregs expressing CX3CR1, the protein coding sequences for CX3CR1 or eGFP were linked with a P2A site to the sequence for FOXP3 and introduced into a MSCV retroviral vector system. This vector will be used for transfection of the Pheonix-Eco packaging cell line to produce virions for subsequent transduction.

Conclusions: The expression of CX3CL1 is upregulated in nephritic kidneys and might therefore represent a promising point of action to increase renal migration of ex vivo induced T regulatory cells. A viral vector was successfully cloned to generate CX3CR1 expressing Tregs. Future experiments will validate the suppressive function of these Tregs in vitro and in vivo. Ultimately, the therapeutic potential in attenuating NTN will be assessed.

TH-PO544

Comparing Different Pathogenic Patterns Between Immunoglobulin A Nephropathy and Lupus Nephritis Using Integrated Bioinformatics Analysis

Haidong Zhang, Yue Wang, Zhenling Deng. *Department of Nephrology, Peking University Third Hospital, Beijing, China.*

Background: Immunoglobulin A nephropathy **(**IgAN) and lupus nephritis (LN) are the most common primary and secondary glomerular diseases, respectively, sharing several similarities in clinical presentations. Common pathogenic mechanisms in IgAN and LN have been well established by previous studies. However, it is confusing how these two independent diseases carrying distinct pathological features are manifested considering the similarities between them. Therefore, different mechanisms of the pathogenesis between IgAN and LN were compared in this study.

Methods: Glomerular gene expression profiling data were acquired from the Gene Expression Omnibus (GEO) database. R packages were used for the data processing. Least Absolute Selection and Shrinkage Operator (LASSO) regression analysis and multivariate logistic regression analysis were used to construct models predicting IgAN and LN. Cibersort processed the analysis of immune cell infiltration in IgAN and LN. RT-qPCR was used to validate the gene expression in the human renal mesangial cells (HRMC).

Results: In the regressing predicting models based on differentially expressed genes (DEG) and weighted correlation network analysis (WACNA), retinoic acid receptor γ (RARG) and prolactin releasing hormone (PRLH) were independent risk factors for IgAN, and HECT domain and RCC1-like domain-containing protein 5 (HERC5) and interferon stimulated exonuclease gene 20 (ISG20) were independent risk factors for LN. GO analysis revealed that DEGs mostly correlated to IgAN in the "salmon" module in WGCNA were enriched in ligand-receptor activity induced cellular growth and development, and DEGs mostly correlated to LN in the "red" module were enriched in nucleic acid/nucleotide binding-induced type I interferon related activity and response to virus infection. Immune infiltration analysis showed CD4+ T-cells and M2 macrophage abundance in the glomerular compartment in IgAN and LN, respectively. The expression of RARG in HRMC was significantly elevated after stimulation of immune complexes (IC) from IgAN patients, staphylococcus aureus cell protein C (SAC) and interleukin 6 (IL-6).

Conclusions: IgAN and LN carry distinct molecular patterns in the pathogenesis, in which overexpression of RARG might be responsible for mesangial proliferation in IgAN.

Characterization of Cell Surface Glycophenotypes of IgA1-Secreting Cells Reveals Distinct Subpopulations and Correlation with Glycosylation of Galactose-Deficient IgA1 in IgA Nephropathy

Taylor Person,[1,2] Shigeaki Nakazawa,[3] Dana V. Rizk,[2] Bruce A. Julian,[2] Jan Novak,[1] Colin Reily.[2] *[1]The University of Alabama at Birmingham Department of Microbiology, Birmingham, AL; [2]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [3]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu Igaku Senko Kikan Seigyo Gekagaku Hinyoki Kagaku, Suita, Japan.*

Background: IgA nephropathy (IgAN) is an autoimmune disease in which the autoantigen, IgA1 with some *O*-glycans deficient in galactose (Gd-IgA1), is recognized by IgG autoantibodies, and some of the resultant immune complexes deposit in the glomeruli to induce kidney injury. Elevated levels of Gd-IgA1 in the circulation of IgAN patients predict worse outcomes. However, Gd-IgA1 represents only a small portion of total circulatory IgA1. We hypothesize that specific subpopulations of IgA1-secreting cells produce most of the Gd-IgA1. Here, we report that certain cell-surface glycophenotypes correlate with Gd-IgA1 production.

Methods: Immortalized IgA1-producing cells derived from peripheral-blood cells of IgAN patients and healthy controls were live-sorted for IgA^+ populations and separated into PNA-low and high subpopulations (PNA lectin is specific for galactose(Gal)-b1,3*N*-acetylgalactosamine(GalNAc) disaccharide of glycoconjugates). These subpopulations were then incubated for 48 h with a mixture of pro-inflammatory cytokines (IL-4, IL-6, IL-21, CD40L; 50 ng/mL each). Live cells were treated with sialidase (to remove sialic acid that may be attached to Gal, GalNAc, or both), then stained with PNA, HPA (lectin specific for GalNAc), and antibody specific for IgA, followed by flow cytometry analysis. Amounts of IgA1 and Gd-IgA1 secreted into the cell-culture medium were determined by ELISA.

Results: Cell-surface glycosylation of $IgA1^+$ sorted cells was dynamic after expansion of subpopulations. IgA cell-surface expression also changed after the expansion of cells. The frequency of IgA^- cells correlated with Gd-IgA1, irrespective of IgA1 sialylation or IgA production ($p<0.01$; $n = 5$). Additionally, cell-surface HPA reactivity of PNA-high cells exclusively increased after treatment with sialidase, and negatively correlated with degree of sialylation of secreted Gd-IgA1 ($p<0.01$; $n=5$).

Conclusions: We found an inverse correlation of cell-surface GalNAc sialylation with Gd-IgA1 sialylation in PNA-high cells. This observation suggests that some glycosyltransferase pathways are regulated by distinct mechanisms with different impact on cell-surface glycophenotypes and IgA1-glycosylation.

Nucleotide-Sensing TLR9/TLR7 System Is a Potential Therapeutic Target for IgA Nephropathy

Mingfeng Lee,[1] Hitoshi Suzuki,[1,2] Ryousuke Aoki,[1] Rina Kato,[1] Yusuke Fukao,[1] Maiko Nakayama,[1] Yoshihito Nihei,[1] Toshiki Kano,[1] Yuko Makita,[1] Yusuke Suzuki.[1] *[1]Juntendo University Faculty of Medicine, Tokyo, Japan; [2]Juntendo Daigaku Igakubu Fuzoku Urayasu Byoin, Urayasu, Japan.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis worldwide. Galactose-deficient IgA1 (Gd-IgA1) is a key effector molecule in the pathogenesis of IgAN. Previous reports indicated that toll-like receptor (TLR)9 and TLR7 are involved in synthesizing Gd-IgA1. TLR9 and TLR7 recognize microbial DNA and RNA, respectively. Several clinical trials suggested hydroxychloroquine (HCQ), known to suppress TLR9/TLR7, might effectively treat IgAN. The present study aimed to clarify whether TLR9/TLR7 could be the therapeutic targets for IgAN.

Methods: First, we divided the ddY mice, the spontaneous IgAN model, into the control group, HCQ administered group, CpG-ODN (ligand of TLR9) nasally administered group, CpG-ODN + HCQ group, Imiquimod (ligand of TLR7) nasally administered group, and Imiquimod + HCQ group, respectively. We analyzed the serum aberrantly-glycosylated IgA, IgG-IgA immune complexes (IC), proteinuria, and renal pathology. Next, we cultured the splenocytes of ddY mice with CpG-ODN or Imiquimod. We analyzed the effect on the synthesis of aberrantly-glycosylated IgA. Finally, we cultured tonsillar mononuclear cells (TMCs) from IgAN patients with CpG-ODN or Imiquimod. We analyzed the cellular expression of C1GaLT1, an enzyme involved in IgA1 glycosylation, and the supernatant Gd-IgA1 levels.

Results: The mice administered with CpG-ODN or Imiquimod showed elevated serum levels of aberrantly-glycosylated IgA and IgG-IgA IC. Furthermore, these mice showed aggravated proteinuria. Renal pathological findings further confirmed glomerular mesangial proliferation accompanied by significant IgA/IgG/C3 depositions. The mice co-administered with HCQ did not show the changes that CpG-ODN or Imiquimod induced. The splenocytes of ddY mice significantly elevated IL-6, known to affect IgA glycosylation, and promoted aberrantly-glycosylated IgA when stimulated by CpG-ODN or Imiquimod. In the human studies, stimulation with CpG-ODN or Imiquimod let the cultured TMCs promote IL-6 synthesis, downregulated C1GaLT1 and consequently enhanced the production of Gd-IgA1.

Conclusions: Present data suggested that nucleotide-sensing TLR9/TLR7 are involved in the pathogenesis of IgAN and might be the candidates for disease-specific therapeutic targets.

TH-PO547

Differentiating Lupus Nephritis Classes Using Peripheral Blood DNA Methylation

Christine Y. Bakhoum,[1] Sophia Faulkner,[1] Joachim H. Ix,[2] Dennis G. Moledina,[1] Mathieu F. Bakhoum.[1] *[1]Yale University, New Haven, CT; [2]University of California San Diego, La Jolla, CA.*

Background: Approximately 60% of patients with systemic lupus erythematosus (SLE) develop nephritis. Histologically-determined disease classification provides clinically actionable information including administration of kidney-specific immunosuppression. Given the pivotal role of autoimmunity in SLE, we hypothesized that DNA methylation patterns of immune cells could distinguish between the different lupus nephritis classes.

Methods: We identified 25 participants from the Yale Kidney Biobank with biopsy-confirmed lupus nephritis. DNA was extracted from blood buffy coat. DNA methylation was analyzed using Illumina MethylationEPIC V2.0, surveying > 935,000 CpG loci. β-values (percent methylation) were derived using the R Sesame package. KEGG pathway enrichment and differential methylation analyses were performed, comparing class II participants to those with more advanced nephritis (III, IV, V).

Results: We identified 3 participants with class II disease, and 22 participants with classes III, IV, or V disease. Enrichment analysis identified differential methylation in Rap1 signaling, focal adhesion, and MAPK signaling pathways between the two groups (q-values < 0.001). Participants with advanced lupus nephritis exhibited *ERK* hypermethylation and *RAP1* hypomethylation compared to those with class II. We identified 5 CpG loci that were differentially methylated between the two groups (adjusted p-values < 0.05). Unbiased hierarchical clustering based on the top 25 differentially methylated loci revealed that those with class II nephritis have distinct methylation profiles as compared to those with more advanced nephritis (Figure 1).

Conclusions: Our findings suggest that DNA methylation patterns in immune cells may distinguish between lupus nephritis classes, potentially guiding the decision to conduct a kidney biopsy. The observed methylation differences in ERK and RAP1 pathways, which have been implicated in SLE pathophysiology, among advanced lupus nephritis classes may provide valuable insights into disease pathogenesis.

Funding: NIDDK Support, Private Foundation Support

Figure 1. Heatmap demonstrating hierarchical clustering of samples based on top 25 differentially methylated loci between participants with class II vs. those with class III, IV, or V nephritis.

Deciphering the Contribution of Inflammatory Macrophages to Focal Segmental Glomerulosclerosis

Jasper F. Nies,[1,3] Claudio Sierra Gonzalez,[3,4] Paul Diefenhardt,[1,3] He Chen,[4] Bernhard Schermer,[1,4] Thomas Benzing,[1,3] Martin Kann,[1,3] Paul T. Brinkkoetter,[1,3] Christian Kurts,[2] Sebastian Braehler.[1,3] Nephrolab Cologne. *[1]Universitatsklinikum Koln, Koln, Germany; [2]Universitatsklinikum Bonn, Bonn, Germany; [3]University of Cologne Center for Molecular Medicine Cologne, Cologne, Germany; [4]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: Focal segmental glomerulosclerosis (FSGS) refers to a histologic pattern of glomerular injury that can result from heterogenous disease entitites, which in turn respond differently to therapeutic regimens. Causes for FSGS include immunological diseases that respond to immunosuppressive treatments. Modern biotechnological tools allow us to characterize diseases resulting in an FSGS pattern in detail with the prospect of providing pathophysiology-based precision medicine for the patients.

Methods: We used a genetic model (heterozygous compound mutations in *Nphs2)* that causes a slowly progressive FSGS phenotype with a strong intraglomerular immune cell infiltrate. In order to characterize these immune cells in depth and to identify glomerular communication patterns, we employed bulk and single nucleus RNA sequencing of glomerular isolates, flow cytometry, and immunohistochemistry.

Results: We identified myeloid cells to be the most abundant immune cells in diseased glomeruli. A macrophage subpopulation with an M2-like, tissue-remodeling transcriptomic signature significantly expanded over time, which correlates with proteinuria. We confirmed such intraglomerular infiltration of macrophages by immunohistochemistry, and detected macrophages in the tubulointerstitium at a later stage of the disease. snRNAseq-based ligand-receptor-target gene network analysis indicated progressively altered signaling between glomerular cells resulting in a pro-fibrotic inflammatory milieu characterized by strong signaling activity of the TGFb-superfamily and upregulation of CC-chemokines and matrix metalloproteinases. Intriguingly, fractalkine (CX3CL1), a macrophage recruiting chemokine, was strongly upregulated at an early stage of the disease. Immuno-staining localized fractalkine to glomerular endothelial cells while flow cytometry showed significant upregulation of its receptor CX3CR1 on macrophages.

Conclusions: In this model, a mutation in a slit-diaphragm protein results in a glomerular fibro-inflammatory phenotype with strong macrophage infiltration that may be linked to fractalkine. Based on these results, our project might provide the rationale for new therapeutic approaches in FSGS.

TH-PO549

Identifying Targetable Renal Immune Pathways in Lupus Nephritis

Aneesha Bhandari, Richard J. Cornall, Katherine R. Bull. *University of Oxford, Oxford, United Kingdom.*

Background: Lupus Nephritis (LN) is characterised by renal immune-complex (IC) deposition, how these deposits trigger inflammatory mediators, and signalling between resident and recruited cells is unclear. Mouse lupus models share clinical features of human disease including renal involvement. Using single nuclei RNA sequencing (snRNA-seq), we compare two models of early LN, to identify disease drivers, potential therapeutic targets, and to establish an approach translatable to human kidney.

Methods: Kidney sections from autoimmune MRL/lpr mice aged 15-weeks, or Balb/c mice treated for 8 weeks with topical TLR7 agonist (IMQ) and respective controls, were processed for histology, immunofluorescence (IF), flow cytometry and snRNA-seq (10x genomics).

Results: IMQ kidneys showed IC deposition, mesangial expansion, and endothelial proliferation consistent with class-II LN. MRL/lpr mice additionally developed crescents, and class-III LN. Transcriptomic data from 92k nuclei identified clusters corresponding to resident and immune populations. Early S1/S2 proximal tubule segments were identified as interferon (IFN) susceptible targets in both models. Intrarenal T, B, and myeloid cells were enriched in diseased mice. MRL/lpr mice had the largest immune infiltrate, including NK and CD8 T cells expressing markers of cytotoxicity and exhaustion (Gzma, Pdcd1). Integrated analysis with human immune renal LN single cell data (Arazi et al., 2019), showed overlap with MRL/lpr phenotype with cytotoxicity and exhaustion

signatures (GZMA, PDCD1) identified in the NK and CD8 T cell clusters. Shared disease phenotypes across models included increased CD11b^{hi} renal resident macrophage populations, expressing genes implicated in phagocytosis, efferocytosis (Mertk, Lrp1) and IFN responses (Stat1), with trajectory analysis suggesting these arise from increased patrolling non-classical monocytes, and highlighting targets to inhibit monocyte infiltration.

Conclusions: Integrated kidney snRNA-seq in two LN models delineates a shared immune signature, with interactions with stromal, tubular, and glomerular cells important in early disease perpetuation and damage. Our comprehensive kidney single nuclei approach is generalisable, suggests candidate genes for rescue experiments and can be applied to human renal tissue.

TH-PO550

Urinary Extracellular Vesicles Reveal Distinct Biological Effects of Voclosporin in the Treatment of Lupus Nephritis

Martijn H. van Heugten,[1] Kuangyu Wei,[1,2] Hester van Willigenburg,[1] Fatih Demir,[3] Linda M. Rehaume,[4] John Viel,[4] Markus M. Rinschen,[3] Ewout J. Hoorn.[1] *[1]Erasmus MC Afdeling Inwendige Geneeskunde, Rotterdam, Netherlands; [2]Tri-Service General Hospital, Taipei, Taiwan; [3]Aarhus Universitet, Aarhus, Denmark; [4]Aurinia Pharmaceuticals Inc, Victoria, BC, Canada.*

Background: In the Phase 2 AURA-LV and Phase 3 AURORA 1 trials the novel calcineurin inhibitor voclosporin significantly increased complete renal response rates compared to placebo, both including mycophenolate mofetil and low-dose steroids. We further explore this treatment response by analyzing urinary extracellular vesicles (uEV), which are secreted by kidney cells and have the potential to provide a non-invasive read-out of cellular processes.

Methods: We isolated uEV from biobanked spot urine samples collected from patients with active lupus nephritis (LN) treated with voclosporin or placebo in AURORA 1 (n=60 per arm). uEVs were isolated at baseline and at the end of treatment using a differential ultracentrifugation protocol. Proteomes were quantified by tandem mass spectrometry on a Thermo Exploris480 with a data-independent acquisition strategy. Data was analyzed with Spectronaut and proteins with a log2-fold change >1 and q-value <0.05 considered significant. Pathway analysis was performed using the Reactome database.

Results: We identified 3708 proteins in uEV. At baseline 545 proteins were different in patients who responded to voclosporin. Pathway analysis linked these proteins to neutrophil degranulation, selenoamino acid metabolism, and Robo-receptors. Previous work on Robo-signaling showed it controls leukocyte infiltration and podocyte function in kidney injury and is increased in LN, while selenoamino acids are key to cellular antioxidant defenses and control Akt signaling through calcineurin. 732 proteins significantly changed in the patients who responded to voclosporin. Pathway analysis for voclosporin-altered proteins showed enrichment of the complement C2 and C4 pathways, while Fc-gamma receptor phagocytosis and tyrosine kinase signaling changed in patients responding to placebo. Neutrophil degranulation was changed by both voclosporin (61 proteins) and placebo (52 proteins), but involved different proteins (15 shared).

Conclusions: Using mass spectrometry of uEV we identified potential non-invasive biomarkers for treatment response to voclosporin in patients with LN. In addition, we were able to characterize the altered processes in the patients responding to voclosporin, which included complement and a specific change in neutrophil-associated proteins.

Active CD11b Targets TLR7-Driven Inflammation to Reduce suPAR Levels and Kidney Damage in Lupus Nephritis

Viviana Jimenez,[1] Veronica Villanueva,[1] Xiaobo Li,[1] Khulood Alzahrani,[1] Hafeez Faridi,[2] Vineet Gupta.[1] *[1]Rush University Medical Center, Chicago, IL; [2]Chicago State University College of Pharmacy, Chicago, IL.*

Background: Lupus nephritis (LN) is a common end-organ injury resulting from systemic lupus erythematosus (SLE). CD11b heterodimerizes with b2 integrin to form the CD11b/CD18 receptor on surface of leukocytes that is essential for their normal functions. Genome-wide association studies revealed a number of single nucleotide polymorphisms (SNPs) in the ITGAM gene, that codes for CD11b, associate with SLE and LN. Prior studies have shown that several coding SNPs in CD11b reduce integrin function and increase Toll like receptor (TLR)-dependent inflammatory signaling. However, it is not clear if ITGAM SNPs also correlate with various kidney disease biomarkers, such as suPAR, and what the underlying mechanism could be. Additionally, it is not known if activation of CD11b would be able to reduce these biomarkers and kidney injury in vivo.

Methods: We used a combination of in vitro and in vivo assays. A macrophage cell line as well as primary macrophages were utilized and treated with TLR7 agonists. Two orthogonal approaches, genetic and pharmacologic, were utilized to activate CD11b and measure its effect on TLR7-dependent inflammatory signaling in myeloid cells in vitro and in LN models in vivo. Additionally, we utilized the MRL/lpr mice, a genetic model which shares many features and organ pathology with SLE, and a newly developed humanized mouse model of LN to mechanistically define role of CD11b activation in disease control.

Results: TLR7-stimulation increased suPAR levels in wild type cells in vitro and in vivo. Absence of CD11b (using CD11b knock out) exacerbated response. Conversely, CD11b activation using an oral agonist or a genetic mutation in CD11b significantly reduced suPAR and reduced proteinuria and LN pathology. CD11b activation also reduced splenomegaly and infiltration of CD11b+ inflammatory cells in the kidney. Mechanistically, CD11b activation reduced TLR7-dependent activation of NFkB to suppress suPAR generation.

Conclusions: We demonstrate that CD11b activation reduced TLR7-dependent suPAR levels in models of LN. These studies provide further support for CD11b activation as a therapeutic strategy for LN.

In Vitro Expansion of Regulatory T Cells Restores Functional Capacity in ANCA Vasculitis

Meghan E. Free, Sandra H. Elmore, Dominic J. Ciavatta, Ronald Falk. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: ANCA vasculitis is an autoimmune disease characterized by loss of tolerance to one of two main ANCA autoantigens, myeloperoxidase or proteinase 3. Broad immune system dysfunction is exhibited within relapses of disease which includes regulatory T cell (Treg) dysfunction. Previously, our group and others have demonstrated that Tregs are functionally deficient and unable to restrain effector T cell proliferation and cytokine production in ANCA vasculitis.

Methods: Tregs defined as CD4+, CD127low, CD25high, and CD45RA+ were sterile sorted from cryopreserved peripheral blood mononuclear cells. Sorted Tregs were then expanded in vitro with combinations of supplemental IL-2 and stimulation from CD3/CD28 Dynabeads for 14 days. After the 14 day expansion, Tregs were analyzed for phenotype and function was assessed by in vitro suppression assays.

Results: After 14 day expansion, Tregs from both healthy controls and patients with ANCA vasculitis expanded between 500-2000 fold over day 0 starting material. Expanded Tregs maintained >95% FOXP3+ protein expression and surface markers of CD25high, CD127low. Healthy control Tregs had potent suppressive capacity with >90% suppression of effector T cells. Expanded Tregs from ANCA vasculitis patients varied in their suppressive capacity from 30% suppression to >60% suppression of effector T cells. Variances in degrees of suppression may be due to clinical activity status and/or medication regimen at time of sample.

Conclusions: Tregs taken directly ex vivo from ANCA vasculitis patients fail to suppress effector T cell function. We have utilized a Treg expansion protocol that yields highly pure Tregs with 500-2000 fold expansion of numbers of Treg cells. Importantly, these expanded Tregs are functionally able to suppress autologous and allogeneic effector T cell proliferation. These studies are foundational for future trials of Treg expansion to maintain remission in ANCA vasculitis.

Autoantibodies Against Laminin-521 Are Pathogenic in Anti-Glomerular Basement Membrane Disease

Huang Kuang,[1] Congrong Shen,[1,2] Xiao Y. Jia,[1] Zhao Cui,[1] Ming-Hui Zhao.[1] *[1]Peking University First Hospital Department of Nephrology, Beijing, China; [2]China-Japan Friendship Hospital, Beijing, China.*

Background: We previously demonstrated that laminin-521 is a novel autoantigen within the GBM and that antibodies to laminin-521 are present in about one-third of patients. However, definitive evidence for a pathogenic role of these antibodies has been lacking.

Methods: In this study, a rare case of atypical anti-GBM disease whose serum was negative for anti-a3(IV)NC1 antibody prompted us to investigate the possible presence of autoantibodies binding to laminin-521. Additionally, WKY rats were immunized with recombinant human laminin-521 to test the pathogenicity of antibodies to laminin-521 *in vivo*. Disease control and negative control rats were immunized with recombinant human α3(IV)NC1 and phosphate-buffered saline, respectively.

Results: The patient was diagnosed with a kidney biopsy. Circulating autoantibodies reactive exclusively to laminin-521 were confirmed in this patient. Immunoblot results reveal circulating IgG from this patient binds α5 and γ1 chains. A decrease in antibody levels was observed and was associated with improved clinical presentation after plasmapheresis. In rats immunized with laminin-521, but not in negative controls, severe proteinuria, crescentic glomerulonephritis, IgG deposits, complement activation, and infiltration of T cells and macrophages were observed. Lung hemorrhage occurred in 75.0% (6/8) of rats. Besides, sera and kidney elutes from laminin-521 immunization rats demonstrated a high level of IgG binding to laminin-521 but not to human α3(IV)NC1, while the opposite was observed in human α3(IV)NC1-immunized rats.

Conclusions: Patient data and animal studies imply a causative role of autoantibodies against laminin-521 in the development of anti-GBM disease and aid in the understanding of its etiology.

TH-PO554

Galectin-3 Involved in the Development of IgA Nephropathy

Shuk-Man Ka,[1] Yu-Ling Chou,[1] Ann Chen.[2] *[1]National Defense Medical Center, Taipei, Taiwan; [2]Hualien Tzu Chi Hospital Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan.*

Background: IgA nephropathy (IgAN) is the most common type of glomerulonephritis that frequently progresses to end-stage renal disease. However, the molecular pathogenesis underlying IgAN remains largely unknown. This study investigated the role of galectin-3 (Gal-3), a galactoside-binding protein in IgAN pathogenesis.

Methods: Two complementary mouse IgAN models, a model induced with TEPC-15 hybridoma using Gal-3 knockout (KO) mice, and a spontaneous IgAN model of "grouped" ddY (gddY) mice were employed.

Results: Gal-3 expression increased with disease severity in the glomeruli, peri-glomerular regions, and some renal tubules in both the inducible and spontaneous IgAN models. Gal-3 KO in the TEPC-15 hybridoma-induced IgAN mice significantly improved proteinuria and renal function and reduced severity of renal pathology, including neutrophil infiltration and decreased differentiation of Th17 cells from renal-draining lymph nodes, despite increased percentages of regulatory T cells. Gal-3 KO also inhibited the NLRP3 inflammasome, yet it enhanced autophagy and improved renal inflammation and fibrosis. Moreover, administration of 6-de-O-sulfated, N-acetylated low-molecular-weight heparin, a competitive Gal-3 binding inhibitor, restored renal function and improved renal lesions in passive IgAN mice.

Conclusions: These results suggest that Gal-3 is critically involved in IgAN pathogenesis by activating the NLRP3 inflammasome and promoting Th17 cell differentiation. Therefore, targeting Gal-3 action may represent a new therapeutic strategy for treatment of this renal disease.

TH-PO555

Mice with a Pax2 Missense Variant Are Susceptible to Experimental FSGS and Display Impaired Glomerular Repair

Joanna Cunanan,[1,2] Bedra U. Sharif,[1] Sriya Rajyam,[1] Khalil Udwan,[1,2] Akanchaya Rana,[1] Vanessa S. De Gregorio,[1,2] Samantha Ricardo,[1,2] Emine B. Caparali,[1] Rohan John,[3] Sofia Farkona,[1] Ana Konvalinka,[1,2] Astrid Weins,[4,5] Martin Pollak,[6,5] Moumita Barua.[1,2] *[1]Toronto General Research Institute, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada; [4]Brigham and Women's Hospital, Boston, MA; [5]Harvard Medical School, Boston, MA; [6]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: FSGS is a form of chronic kidney disease characterized by podocyte loss. Our team previously reported that *PAX2* pathogenic missense variants account for 4% of adults with FSGS. PAX2 regulates glomerular development and its expression persists in adult parietal epithelial cells (PECs), postulated to serve as a reservoir for cells including podocytes. We hypothesize that in humans and mice with pathogenic *PAX2* missense variants, PEC-mediated podocyte regeneration is impaired.

Methods: FSGS induced by Adriamycin was performed on wildtype mice and mice with a *Pax2* missense variant (termed *Pax2*^{MV}). Kidney tissue were analyzed by histology and immunostaining. Glomeruli were isolated and subjected to mass spectrometry (MS), analyzed by Gene Ontology (GO) Enrichment Analysis. Kidney tissue from relatives with *PAX2*-associated FSGS was also analyzed.

Results: At embryonic day 16.5, mouse wildtype kidneys showed overlapping expression of PAX2 and WT-1 in the condensed mesenchymal cells until PEC and podocyte differentiation, supporting a close lineage relationship. *Pax2*^{MV} had reduced nephron number but displayed only minor differences in glomerular function at baseline. Adriamycin-injured *Pax2*^{MV}mice showed more severe FSGS compared to wildtype, including decreased podocyte numbers and increased albuminuria. Adriamycin-injured *Pax2*^{MV}mice showed PAX2-expressing glomerular tuft cells, which were rarely observed in injured wildtype and were similar to histological findings from *PAX2*-associated FSGS patients, suggesting a role of these ectopic *PAX2*-expressing cells in pathogenesis. GO processes obtained from isolated glomeruli demonstrated maladaptive repair in *Pax2*^{MV}, including increased epithelial cell migration, decreased cell adhesion, de-regulated actin cytoskeleton dynamics, and in-utero embryonic development; while GO terms of normal repair mechanisms including regulation of cell morphogenesis, cell adhesion, cell-cell junction assembly, and actin cytoskeleton organization were enriched in wildtype.

Conclusions: Our findings support decreased glomerular regeneration in *Pax2*^{MV} mice compared to wildtype. We are next pursuing glomerular single-cell RNA sequencing to characterize the role of PECs in this process.

TH-PO556

Molecular Imaging of Kidney C3d Deposits to Monitor Lupus Nephritis

Felix Poppelaars,[1] Brandon Renner,[1] Catherine A. Foss,[2] Jennifer Laskowski,[1] Vojtech Petr,[1] Liudmila Kulik,[1] Martin G. Pomper,[2] V. M. Holers,[1] Joshua M. Thurman.[1] *[1]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [2]Johns Hopkins University, Baltimore, MD.*

Background: Early identification of lupus nephritis (LN) is crucial in managing inflammation that could lead to chronic injury and kidney failure, but clinical signs and laboratory tests don't reliably predict histology in LN. Our work focused on using molecular imaging of renal C3d deposition to detect LN at an early stage.

Methods: Biopsy reports were retrospectively analyzed from LN patients to study the link between C3 staining intensity and histology. We also created a monoclonal antibody (mAb 3d29) against human C3d, that cross-reacts with mouse but doesn't bind intact C3. Next, we stained kidney tissue from LN patients and MRL/lpr mice (a model of LN). Lastly, we generated imaging probes from the mAb 3d29 to quantify C3d deposits by optical and positron emission tomography (PET) imaging in live mice.

Results: In LN biopsies, the intensity of C3 deposition correlated with histology. By immunostaining, our mAb 3d29 detected glomerular C3d in kidney samples from MRL/lpr mice and LN patients. In MRL/lpr mice, glomerular C3d deposits were seen at 8 weeks when mice had no histological/functional signs of kidney disease. C3d deposition stepwise increased at 12, 16, and 20 weeks, but showed a decrease at 24 weeks. Next, we performed optical imaging using the 3d29 mAb in *Cfh*-/- mice, a model of C3 glomerulopathy. Imaging demonstrated high intensities in their kidneys, whereas low signal or only background was detected in wild-type and *C3*-/- mice. As C3d deposition is an early disease event in MRL/lpr mice, we tested if early C3d imaging could predict future disease severity. Preliminary experiments in MRL/lpr mice suggested that renal C3d deposition detected by imaging at 8 weeks correlated with increased disease activity at 16 weeks. PET imaging in MRL/lpr and control mice with the radiolabeled 3d29 mAb showed similar results.

Conclusions: Renal C3d deposition seems a biomarker of disease activity in LN, and molecular imaging of C3d could be helpful to monitor disease activity in LN patients.

Enhanced Growth of Gut Bacteria Muribaculaceae Reduces Inflammation and Kidney Injury in an Experimental Model of Anti-Neutrophil Cytoplasmic Antibody Vasculitis

Kim M. O'Sullivan, Matthew Snelson, Diana S. Tan, Jenny Nguyen, Anne Le, U-Shane S. Huang, Melinda T. Coughlan. *Monash University, Clayton, VIC, Australia.*

Background: The gut microbiome is a critical factor influencing immune homeostasis. Reduced microbial diversity in the gut has been associated with the increasing prevalence of autoimmune diseases. Notably, the family *Muribaculaceae* has declined within the human microbiome in the industrialised world, and studies have linked its reduced abundance to disease. We investigated the role of the declining *Muribaculaceae* family in ANCA-associated vasculitis (AAV). We hypothesized that dietary supplementation with resistant starch (RS) a fermentable substrate for gut bacteria would enhance the growth of anti-inflammatory short chain fatty acid (SCFA) producing bacteria (including *Muribaculaceae)* which would mitigate neutrophil activation and ameliorate kidney inflammation in AAV.

Methods: Using an experimental model of ANCA vasculitis, we assigned mice to treatment groups receiving a diet supplemented with 15% RS (n=8) or a calorie-matched control diet (n=8). Additionally, another cohort of mice was randomized to receive either a control vehicle (n=8), or SCFAs acetate (n=8), butyrate (n=8), or propionate (n=8) orally.

Results: 16S rRNA analysis (Illumina miseq) analysis of the caecal contents revealed that the RS diet induced significant alterations in the gut microbiota consortium, characterized by a notable expansion of SCFA-producing bacteria from the *Bacteroidaceae* and *Muribaculaceae* families. The ratio of firmicutes/bacteriodota an indication of gut dysbiosis was reversed in the mice on the RS diet. RS treated mice all had significant diminution of inflammation, with a reduction in glomerular injury, neutrophil, macrophage and CD4 T cell recruitment. Mice in the RS treatment group had significantly reduced dendritic cell activation in the draining lymph nodes with a decrease in MHCII and CD80 expression. Albuminuria was significantly decreased in the RS group ($p < 0.05$). SCFAs alone were not as efficient as RS supplementation in reducing glomerular injury and leukocyte infiltration.

Conclusions: Our findings highlight the therapeutic potential of SCFA production through RS fermentation or direct administration of SCFAs in ANCA vasculitis. These interventions represent possible novel adjunct therapies for reducing inflammation in vasculitis.

TH-PO558

Targeting Tissue-Specific T Cell Plasticity by Pooled Single-Cell CRISPR Screening in Preclinical Mouse Models

Malte Hellmig, Kristoffer Riecken, Hans-Joachim Paust, Yu Zhao, Saskia-L. Jauch-Speer, Varshi Sivayoganathan, Shuya Liu, Thorsten Wiech, Tobias B. Huber, Stefan Bonn, Samuel Huber, Ulf Panzer, Christian F. Krebs. *Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: Treatment of autoimmune diseases demands a shift from unspecific immunosuppression towards targeted therapies. This could be achieved by turning pro-inflammatory T helper cells into anti-inflammatory subsets. However, the molecular

pathways involved in T cell plasticity and stability are not fully understood. Single cell CRISPR-screens are a powerful tool to simultaneously analyze the impact of multiple genes on cellular phenotypes.

Methods: By combining single cell gene expression analysis and T cell receptor sequencing, we uncover Th17 to Th1 cell plasticity in the human kidney in renal autoimmunity. To investigate the molecules involved in T cell plasticity in disease settings, we established *in vivo* single cell CRISPR droplet sequencing (iCROP-seq).

Results: By applying this technique to *in vivo* models of inflammatory diseases in the kidney and intestine, we demonstrate that CRISPR-induced alterations in T cell polarization can be identified and ranked according to corresponding transcriptional perturbations. In particular, we targeted pro-inflammatory Th17 cells in models of immune-mediated diseases and quantified polarization biases into Th1 and regulatory T cells.

Conclusions: iCROP-seq will facilitate the identification of therapeutic targets by highly efficient functional stratification of genes and pathways in a disease- and tissue-specific manner.

Funding: Government Support - Non-U.S.

TH-PO559

Proliferative Glomerulonephritis with Monotypic Immunoglobulin Deposits (PGNMID) and Preeclampsia

Mukaish Kumar,[1] Vivette D. D'Agati,[2] Sharon E. Maynard.[1] [1]*Lehigh Valley Health Network, Allentown, PA;* [2]*Columbia University Medical Center, New York, NY.*

Introduction: We report the case of a pregnant woman presenting with hypertension, nephrotic range proteinuria and hematuria. Kidney biopsy revealed glomerular thrombotic microangiopathy (TMA) and underlying PGNMID with IgG1-k deposits.

Case Description: A 33-year-old woman presented at 21 weeks' gestation with new-onset hypertension. She had a history of prior preterm preeclampsia and obesity s/p gastric sleeve surgery. Physical exam was normal except for blood pressure 141/111 mmHg. Kidney function was normal. UA showed hematuria and proteinuria, with UPCR of 3.7 g/day. Fetal ultrasound showed severe fetal growth restriction (FGR). ANA, Anti-dsDNA, Anti-PLA2R Ab were negative, and complements were normal. She had persistent proteinuria and microscopic hematuria on multiple UAs from 5 years prior to pregnancy. Kidney biopsy was done at 23 weeks' gestation to evaluate for glomerular disease vs. preeclampsia. Light microscopy showed glomerular endotheliosis with a membranoproliferative pattern, consistent with preeclampsia. IF showed mesangial and segmental glomerular capillary wall staining for IgG1 and k with negative λ, consistent with proliferative glomerulonephritis with monotypic IgG-k deposits (PGNMID). SPEP and immunofixation was negative for a monoclonal protein. Testing for HBV, HCV, and HIV was negative. At 24 weeks, labor was induced for worsening transaminitis. Due to severe FGR, neonatal resuscitation was not attempted. At 3 weeks postpartum, her BP and proteinuria improved (UPCR 1.3g/day). Kidney function remained normal.

Discussion: To our knowledge, this is the first reported case of PGNMID with preeclampsia. There is 1 report of PGNMID in pregnancy, but without preeclampsia. As in our case, IF showed IgG1- k, and there was no monoclonal protein detected. PGNMID was first described in 2004 as an endocapillary proliferative or membranoproliferative glomerulonephritis related to monoclonal IgG deposition. Most (70%) patients with PGNMID do not have a detectable circulating monoclonal protein in the serum or urine. In such cases, treatment directed at a hypothesized underlying clone may still be considered. In our patient, preeclampsia complicated the clinical presentation and obscured the pathologic findings of PGNMID. Kidney biopsy assisted in confirming the diagnosis of preeclampsia, allowing appropriate management when preeclampsia progressed.

TH-PO560

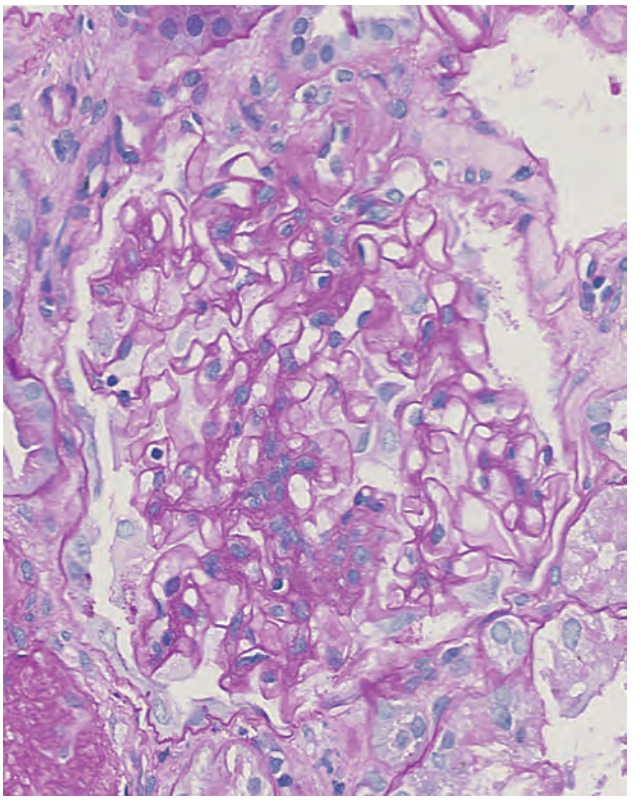
Gross Hematuria and Proteinuria in Myelofibrosis: A Curious Case of Myelofibrosis-Related Glomerulopathy

Robin Edwin, Jobira A. Woldemichael, Kevin Dao, Mohid Mirza, Alison J. Fletcher, Alexei V. Mikhailov. *Atrium Health Wake Forest Baptist, Winston-Salem, NC.*

Introduction: Renal involvement in myeloproliferative disease is rare and presents with proteinuria, nephrotic syndrome, and renal insufficiency. Renal damage can be due to renal extramedullary hematopoiesis (EMH) and glomerulopathy. Renal EMH presents as infiltration of the interstitial, functional damage of parenchyma and vessels and sclerosing mass-like lesions causing hydronephrosis and renal insufficiency.

Case Description: 69 year old male patient with JAK2 mutated Polycythemia Vera progression to Myelofibrosis; admitted for respiratory failure with lobar pneumonia. Patient was on Ruxolitinib for 7 years. Baseline creatinine was 1.43mg/dL. Patient had an AKI with creatinine of 4 mg/dL attributed to contrast use and hypotension. During the hospital course, the patient developed an acute onset colicky flank pain associated with frank hematuria. CT imaging and renal duplex ultrasound were normal except for hepatosplenomegaly. Additional testing showed proteinuria (3.7g/g). Numerous dysmorphic RBCs and muddy brown casts present on microscopy. Serology for proteinuria were non-revealing. Renal biopsy showed diffuse moderate acute tubular injury, glomerulopathy with mesangial expansion, thickened glomerular capillary walls and megakaryocytes consistent with myeloproliferative neoplasm related glomerulopathy. The patient did not require dialysis. His hematuria and creatinine improved to 1.6 mg/dL. Patient remains on Ruxolitinib and received splenic radiation for symptomatic splenomegaly.

Discussion: Patient with myeloproliferative disease presenting with AKI, proteinuria, hematuria and acute abdominal colicky pain should raise suspicion of myeloproliferative related glomerulopathy.



Mesangial expansion and hypercellularity on light microscopy on Periodic Acid-Schiff stain.

TH-PO561

Scleroderma-Associated Kidney Disease: A Case Series

Tara O'Sullivan,[1,2] Darragh O'Donoghue,[1,2] Andrew J. Redmond,[1,2] John G. Ryan,[1,2] Sarah M. Moran,[1,2] James Gleeson,[1,2] Adeel R. Ahmed.[1,2] [1]*University College Cork, Cork, Ireland;* [2]*Cork University Hospital, Cork, Ireland.*

Introduction: Scleroderma is a rare multisystem disorder categorised into limited and diffuse subtypes. Recognised renal manifestations of scleroderma include renal crisis (SRC) and ANCA associated vasculitis. We present three differing cases of scleroderma associated renal disease.

Case Description: Case 1: 64 year old normotensive female with systemic sclerosis developed AKI and microangiopathic haemolytic anaemia. ANCA and ANA were negative. IgG Kappa paraprotein detected (9.7g/L). Bone marrow biopsy showed 7.2% plasma cells. Renal biopsy demonstrated intraglomerular thrombotic microangiopathy, without onion-skinning or involvement of interlobular or arcuate arteries. Treatment was targeted at the plasma cell clone. **Case 2:** 53 year old female with CREST presented with hypertension (BP 231/124mmHg) and developed AKIN3. She was anti-centromere positive. Renal biopsy demonstrated thrombotic microangiopathy, with onion-skin appearance of arterioles. She was treated as SRC with captopril, leading to improvement in renal function. **Case 3:** 75 year old female with limited systemic sclerosis admitted with nephrotic syndrome. She was hypertensive but did not tolerate RAAS inhibition. Urinary PCR was 873.6mg/mmol. Renal biopsy demonstrated a cellular form of focal segmental glomerulosclerosis, without tip lesions. Corticosteroids were avoided due to risk of precipitating SRC. She was treated with tacrolimus, which reduced proteinuria to the sub-nephrotic range.

Discussion: These cases demonstrate three different presentations of scleroderma associated renal disease. The intraglomerular distribution of TMA in Case 1 is more consistent with MGRS rather than SRC, in the context of a paraprotein. While there is one published case of SRC in a patient with concurrent scleroderma and monoclonal gammopathy, SRC is less frequent in seronegative scleroderma. SRC presenting in CREST, as in case 2, is unusual as it is more commonly reported with diffuse scleroderma, and anti-centromere antibodies have a negative association. In the final case, primary FSGS is a highly atypical manifestation of limited systemic sclerosis. The contrasting pathologies highlight the diagnostic value of kidney biopsy in scleroderma patients presenting with renal impairment, and its importance in guiding treatment.

TH-PO562

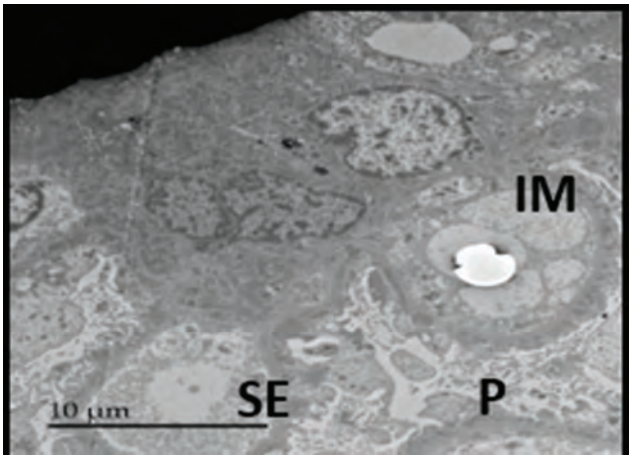
Unique Case of Silicosis Leading to Several Autoimmunities: Rheumatoid Arthritis and Membranous Lupus Nephritis

Assaf Potruch, Momen Abbasi, Anat A. Hershko Moshe, Roy Abel.
Hadassah University Medical Center, Jerusalem, Israel.

Introduction: Silicosis is a fibrotic lung disease caused by the inhalation of free crystalline silica, and is the oldest pulmonary occupational hazard known. Silica exposure has been linked to several other conditions including infections, malignancies and autoimmunity.

Case Description: A 41-year-old male, marble factory worker, lung silicosis diagnosed by biopsy on 2012. ANA, dsDNA, anti-Smith and RF were all negative than. in 2017 due to symmetrical arthritis and newly positive RF rheumatoid arthritis was diagnosed, and he was treated with steroids, hydroxychloroquine and methotrexate. Patient currently presented with arthralgia, peripheral edema, and almost 10 Kg gain during a month. He was not taking any medical treatment at that time. lab results indicated normal renal function, a low serum albumin (23g/L), and nephrotic range proteinuria (7.4 g/g). ANA, anti-Smith, anti-SSA were positive, and C3 was low. Renal biopsy revealed rigid glomerular capillary walls with tiny discreate deposits in the outer aspect of the GBM, a "full house" pattern immunofluorescence, and increased mesangial matrix (M) with numerous electron dense deposits, intramembranous (IM) and subepithelial deposits (SE) interposition of glomerular basement membrane material (spikes), and effacement of foot processes (P) were seen at EM(figure), compatible with membranous pattern injury of SLE. Patient received steroids hydroxychloroquine and MMF treatment.

Discussion: Silicosis is associated with impaired immune system, high risk for pulmonary infections malignancies and more. It is also associated with inflammatory diseases such as RA, scleroderma and mixed connective tissue disease. Autoantibodies as anti-DNA and anti-SSA/B occur in a higher frequency in individuals exposed to silica than general population. Renal involvement secondary to silica has been seen in the past, however this is the first description of membranous lupus nephritis after silica exposure.



TH-PO563

Unusual Presentation of Proliferative Glomerulonephritis with Monoclonal Immunoglobulin Deposits (PGNMID)

Christopher T. Banach,[1] Kiran M. Goli,[1] Preyas Vaidya,[1] Aedan Olaso,[2,1] Glen S. Markowitz.[3] *[1]Lehigh Valley Health Network, Allentown, PA; [2]Valley Kidney Specialists PC, Allentown, PA; [3]Columbia University Irving Medical Center, New York, NY.*

Introduction: Proliferative glomerulonephritis with monoclonal immunoglobulin deposits (PGNMID) is a recent entity of monoclonal gammopathy of renal significance (MGRS) due to monoclonal immunoglobulin (mIg) deposits in the glomerulus leading to kidney injury. However, clinical or laboratory evidence of cryoglobulinemia needs to be ruled out. We describe a unique case of PGNMID with pathologically similar to infection related GN but with laboratory evidence of positive type II cryoglobulinemia and anti-smooth muscle antibodies.

Case Description: A 29-year-old obese male with hypertension and type 2 DM was admitted for AKI in the setting of nausea, vomiting, diarrhea & NSAID use. Creatinine (Cr) was 2.5 mg/dl with a baseline of 0.9 mg/dl. He received IV hydration and Cr improved to 1.8-1.9 mg/dl. However, further work up revealed microscopic hematuria & nephrotic syndrome with UPCR of 10 g/g. Serologic workup revealed positive ANA (1: 160). SPEP did not show monoclonal protein spike. Type II cryoglobulin with monoclonal IgG lambda and polyclonal IgG with a titer of 20 mg/dL was detected. Kidney biopsy showed PGNMID with monotypic IgG3-lambda shaped subepithelial deposits concerning for "infection-related glomerulonephritis". Extensive infectious workup was negative. Hematologic evaluation did not reveal an underlying lymphoproliferative disorder. Rheumatologic workup showed elevated anti smooth muscle antibody (1:320). After 2 weeks, proteinuria improved significantly to 1.9 g/g but Cr increased to 2.3 mg/dl with persistent microscopic hematuria. Patient was then started on Prednisone 1 mg/kg. Cr improved to 2.0 mg/dl and UPCR 0.6 g/g after about 1 week of high dose steroids. He is doing better clinically but microscopic hematuria persists.

Discussion: We describe a unique case with pathologic evidence of PGNMID with subepithelial hump deposits suggestive of infection, monotypic composition of the deposits (IgG3-lambda) suggestive of possible underlying dysproteinemia but also with laboratory evidence of mixed cryoglobulinemia which also raises the possibility of an unusual pattern of cryoglobulinemic GN. Interestingly, anti-smooth muscle antibodies are also positive which raises a suspicion of sub clinical autoimmune hepatitis which can be associated with mixed cryoglobulinemia. This case emphasizes the importance of a thorough serologic workup, despite having biopsy results.

TH-PO564

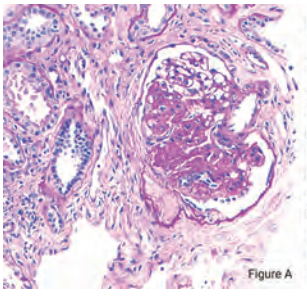
Semaglutide (Ozempic), a Possible Cause of Focal Segmental Glomerulosclerosis (FSGS)

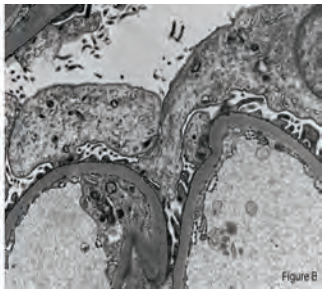
Jahanzeb Khan,[1] Luis A. Juncos,[1] Umair Ali,[1] Sehrish W. Bukhari,[2] Mariam Khalid,[1] Nasir Khan.[1] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Kidney Care Center, Little Rock, AR.*

Introduction: Semaglutide use has been increasing rapidly because of its beneficial effects on diabetes control, cardiovascular protection, and weight loss. Adverse renal events are rare. We present a case of semaglutide-associated FSGS.

Case Description: A 55-year-old nondiabetic female with history of end stage kidney disease secondary to IgA nephropathy treated by kidney transplantation 3 years earlier. Her baseline serum creatinine was 1.2 mg/dL and she had no proteinuria. She was initiated on Semglutide for weight loss. Soon after starting. 0.5 mg weekly, she developed proteinuria; UPC (urine protein to creatinine ratio) =400 mg/mg. The association was not suspected and so her dose was increased to 1.0 and then 2.0 mg weekly. The increases in Semaglutide dose coincided with worsening UPC 3300 mg at 2 months and 9 g/g at 4 months. She was subsequently admitted due to progressive edema and dyspnea; her 24 hour urine protein was 16 g/g now. Her serum creatinine remained at 1.2-1.5 mg/dL while her albumin and LDL levels were 1.7 and 303 mg/dL, respectively. She remained on Tacrolimus, Mycophenolate and Prednisone throughout. Blood tests for HIV, hepatitis, drug use and APOL1 gene were negative. A kidney biopsy showed FSGS on light microscopy (figure A), moderate to marked segmental foot process effacement by electron microscopy (figure B).

Discussion: To the best of our knowledge, this is the first case of FSGS that appears to be associated with the Semaglutide use. While we did not establish causality, the time course and progression of proteinuria raise the possibility that Semaglutide was the trigger. The mechanism is unknown but Semaglutide therapy is known to induce formation of anti-Semaglutide antibodies in up to 1% of patients. The clinical significance of this immune response is unknown but raises the possibility that it could have led to the formation of a circulating glomerular permeability factor that caused the FSGS. Identification of more cases may allow for further investigations into the potential causality and mechanisms of Semaglutide-associated FSGS.





TH-PO565

Type II Cryoglobulinemic Glomerulonephritis in a Patient with Marginal Zone Lymphoma

Devyani Sivakumar, Senin Shah, Manini Vishwanath. *Brown University, Providence, RI.*

Introduction: Cryoglobulinemia is rare and clinically significant in about 1 in 100,000. Renal involvement is seen in 30-60% cases and is especially associated with type II cryoglobulinemia. In a study of 80 patients with noninfectious biopsy proven mixed cryoglobulinemic glomerulonephritis, 7 patients had marginal zone lymphoma.

Case Description: A 76-year-old female with history of marginal zone lymphoma since 2019, managed conservatively, presented to the hospital with dyspnea on exertion, fatigue, 20 lbs weight gain and leg edema for 2 months. She had 3 recent hospitalizations for similar complaints and had been managed with diuretics and antibiotics, with no improvement. She was hypertensive to 167/86 mmHg, exam showed bilateral cervical lymphadenopathy and 2+ pitting pedal edema up to the groin. Labs revealed Cr 1.51 mg/dl [baseline 0.6-0.9 mg/dl]. UA positive for protein, albumin 2.4 g/dl and UPCR 9 g. Low complements with C3 at 33 mg/dl and C4 <3 mg/dl. Serology revealed ANA reactive [1:5120] and anti dsDNA negative. HIV, Hepatitis B and C were non-reactive. Kappa/Lambda ratio 1.68 with IF positive for monoclonal IgM kappa and potential monoclonal lambda free light chain. Immunoglobulin levels notable for elevated IgM at 1349 mg/dl. Cryoglobulin positive at 790 UL cryo/mL with isotype positive for weak monoclonal IgM kappa. Kidney biopsy showed membranoproliferative glomerular injury pattern with immune complexes which stained for IgM [3+], IgG [2+], C3 [2+], C1q [2+], kappa [2+], lambda light chains [1+]. A diagnosis of paraneoplastic

type II cryoglobulinemia related to marginal zone lymphoma was made. She started treatment with rituximab, cyclophosphamide and dexamethasone and responded well with improvement in symptoms and renal function.

Discussion: Noninfectious type II cryoglobulinemic glomerulonephritis associated with marginal zone lymphoma is uncommon. In a retrospective multicenter survey of 242 cases of noninfectious mixed cryoglobulinemic vasculitis, 22 cases had marginal zone lymphoma and renal involvement was seen in 84 cases. Management and prognosis is dependent on disease severity and involves treatment of underlying cancer. Although our patient responded well to treatment, there was a 2 month delay in diagnosis despite recurrent hospitalizations. It is important to highlight this association and the clinical presentation.

TH-PO566

ANCA-Associated Pulmonary Renal Syndrome with Immune Complex Deposition

Alexander N. Fleischhacker, Shane W. Quo, Carlos A. Fernandez Bojanini, Aakash Padodara, Jorge L. Ajuria. *University of Miami Health System, Miami, FL.*

Introduction: Pulmonary renal syndrome (PRS) is a highly morbid condition in which rapid identification and empiric therapy is critical.

Case Description: A 55 year old female with a past medical history of hypertension, rheumatoid arthritis not on any active therapy, and CKD3 diagnosed 6 months ago, presented to the ED for 2 days of hemoptysis and hematuria. She denied any recent upper respiratory symptoms or fevers. She also developed constant, non radiating, epigastric pain with 2 episodes of blood streaked emesis. She denied any new medications. Because her symptoms were unremitting and she became dyspneic, she presented to the ED. On arrival, she was tachypneic at 34 respirations per minute and hypoxic to 84%. She had a hemoglobin of 6.4. Her creatinine was 8.96 with a baseline of 1.5. On urinalysis, she had 3+ protein, 3+ blood, 6-9 WBCs, >100 RBCs, no casts or dysmorphic RBCs were noted. A chest x-ray showed severe, diffuse pulmonary infiltrates. Given concern for acute glomerulonephritis (GN) with associated PRS, she was started on empiric pulse dose steroids with 1 gram of methylprednisolone IV daily for 3 days as well as plasmapheresis with FFP and cyclophosphamide. Subsequent workup showed a positive MPO-ANCA serology. Complement c3 and c4 levels were low. Anti-GBM was negative. ANA was positive at 1:1280 with a speckled, nuclear pattern. Anti-DS DNA was not detected. Anti streptolysin O antibodies were in the normal range. Serologies for HIV and hepatitis were unremarkable. Kidney biopsy revealed diffuse sclerosing and focal proliferative GN with 30 percent crescents and severe interstitial inflammation. There was also immune complex deposition.

Discussion: ANCA associated GN is most often pauci immune and concurrent immune complex GN is unusual but has been reported in 5-14 percent of patients with ANCA positive GN. When ANCA associated GN presents with immune complex deposition, vasculitis involvement is most often exclusively renal. In our case, the patient had both pulmonary and renal involvement. Recognition of MPO ANCA associated GN with concomitant immune complex deposition is important as it has been associated with worse renal outcomes. Moreover, while a link between ANCA positivity and rheumatoid arthritis has previously been established, RA related renal dysfunction is typically not rapidly progressive.

TH-PO567

A Case of ANCA-Associated Vasculitis with IgG4-Related Disease Treated with the C5a Receptor Inhibitor Avacopan

Akiko Kudo,[1] Akihiro Fukuda,[1] Jun Okita,[1] Hiroki Uchida,[1] Takeshi Nakata,[1] Noriko Uesugi,[2] Hirotaka Shibata.[1] *[1]Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan; [2]Department of pathology, Fukuoka University, Fukuoka, Japan.*

Introduction: Complement is important in the immune system against infection but complement hyperactivation can cause complement-related disease, such as systemic lupus erythematosus. Recently, the C5a inhibitor avacopan was developed for treating antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). IgG4-related disease (IgG4-RD) is often associated with hypocomplementemia. C5a inhibitors may be effective in treating IgG4-RD, but this not been reported. We report the first case of AAV with IgG4-RD treated with avacopan.

Case Description: A 69-year-old man was admitted to our hospital because of fever, weight loss, anemia and urinalysis abnormalities. A blood test showed mild kidney dysfunction and elevated CRP, MPO-ANCA and serum IgG4 levels. An enhanced computed tomography (CT) scan showed bilateral renal swelling and multiple low-density lesions in the renal cortex. A renal biopsy showed pauci-immune type crescentic nephritis with necrotizing vasculitis. There was also prominent infiltration of IgG4-positive plasma cells with interstitial fibrosis called “storiform fibrosis,” which led to the diagnosis of coexistence of AAV and IgG4-RD. Remission induction therapy with glucocorticoids (GCs) and rituximab was followed by maintenance therapy with avacopan. One month later, the Birmingham vasculitis activity score (BVAS) improved from 15 to 0. Six months later, the renal low-density lesions on CT scan disappeared. GCs were tapered early with concomitant use of avacopan, and remission was maintained.

Discussion: Avacopan is a selective C5a receptor antagonist that blocks the inflammatory neutrophil response, including degranulation and release of reactive oxygen species. In the ADVOCATE study, avacopan was noninferior in the treatment response compared with GCs, and superior in reducing relapse and GC toxicity. GCs are the first-line treatment for IgG-RD, but the optimal treatment is unclear. Serum C5a levels in IgG4-RD were reported to be significantly higher than those in healthy donors and decreased at remission. These data suggest that avacopan may have been effective for not only AAV, but also for IgG4-RD, in our case.

TH-PO568

Infection-Related Glomerulonephritis (IRGN) due to Gordonia Bacteremia in an Immunocompetent Patient with a Femoral Catheter

Emmanuel A. Aydin-Ghormoz, Andrea R. Lightle, Mauricio Monrroy. *Albany Medical College, Albany, NY.*

Introduction: Gordonia species rarely cause human infection, though cases of bacteremia in immunocompromised patients with endovascular devices have been reported. These may be under-recognized as blood cultures (BC) can be negative until 4 or more days after incubation. We report a case of IRGN secondary to Gordonia bacteremia in an immunocompetent patient with a chronic femoral catheter.

Case Description: A 61-year-old woman with complex regional pain syndrome on buprenorphine infusion via femoral catheter presented to our hospital with AKI on outpatient labs. She had been hospitalized 1 year prior with a diffuse macular rash while on Bactrim for cellulitis. At that time, she was febrile with negative BC and low C3/C4. Skin biopsy showed leukocytoclastic vasculitis (LCV), presumed to be drug-induced. Rash resolved with broad-spectrum antibiotics (Abx). At the current presentation, creatinine was 5.37mg/dL. UA showed 1+ protein and innumerable RBCs. C3 was low and rheumatoid factor (RF) was elevated. Renal biopsy showed diffuse proliferative crescentic immune-complex GN with full house staining pattern suspicious for lupus nephritis, though all serologies (except RF) returned negative. She developed fever after routine femoral catheter exchange and BC were sent. Steroid therapy was started for suspected autoimmune GN when BC were negative for 2 days. Unfortunately, after a sneezing spell she developed a spontaneous left subdural hematoma (SDH) with active bleeding requiring craniotomy. By then, BC (2 sets) grew Gordonia polyisoprenivorans at 3 days. Abx were started. Steroids were stopped. She briefly required hemodialysis but had rapid renal recovery with Abx. Unfortunately, she had further intracranial complications including transtentorial herniation and persistent comatose state. Family elected to continue all care. She was discharged to a nursing facility.

Discussion: The patient’s AKI and biopsy findings were attributed to IRGN. There was suspicion her spontaneous SDH was secondary to vascular mycotic infection from Gordonia bacteremia, and prior LCV may have been a manifestation of chronic bacteremia. Clinicians should have a high index of suspicion for slow-growing bacterial infections as an etiology of IRGN in unexplained glomerular disease, especially in patients with indwelling central catheters.

TH-PO569

Wunderlich Syndrome with Polyangiitis Overlap: A Diagnostic Challenge

Christopher Savvides,[1] Komal Paradkar,[1] Marguerite Linz,[1] Nishigandha Pradhan.[1,2] *[1]University Hospitals, Cleveland, OH; [2]Case Western Reserve University, Cleveland, OH.*

Introduction: Spontaneous renal hemorrhage, called “Wunderlich syndrome”, is a rare complication of vasculitides, especially polyarteritis nodosa (PAN). We present a patient with spontaneous renal hemorrhage with polyangiitis overlap syndrome.

Case Description: A white male in his 70s presented with leg pain, weakness, and oliguria. He noted worsening bilateral hearing loss and recurrent sinusitis over 6 months and involuntary 30 lb. weight loss over 3 months. Serum BUN/creatinine were 168 mg/dl/11.2 mg/dl and hemodialysis was started. Initial CT scan of abdomen was negative. He developed new onset left sided abdominal pain after 3 days. Repeat CT scan of abdomen showed bilateral renal hematomas (Fig. A) and multiple left renal aneurysms concerning for PAN (Fig. B) on CT angiogram. pANCA titer was 1:320 (<1:20) with anti-MPO titer of 134 AU/ml (0-19). He met classification criteria for both PAN and Microscopic Polyangiitis (MPA) (Table 1). Kidney biopsy was deferred due to high bleeding risk. Hearing improved after pulse methyl prednisone followed by oral prednisone, cyclophosphamide, and plasma exchange but he remains dialysis dependent six months after discharge.

Discussion: We describe a challenging case with features of both PAN and MPA with bilateral spontaneous renal hemorrhages which precluded tissue diagnosis. This clinical presentation is most consistent with “polyangiitis overlap syndrome” which has not been previously described in association with Wunderlich syndrome. Renal hemorrhage should be considered in patients with ANCA associated vasculitides or polyangiitis overlap syndromes with acute abdominal pain.

1990 ACR Criteria for Classification as PAN (least 3 of 10 criteria)	2022 ACR/EULAR Criteria for Classification as MPA, (total score ≥5)
Unexplained weight loss > 4kg	pANCA or anti-MPO antibodies positive (+6)
Myalgias (excluding shoulder or hip girdles), muscle weakness	
BUN >40 mg/dL or serum creatinine >1.5 mg/dL	
Characteristic arteriographic abnormalities not from noninflammatory disease processes	

Table 1

Fig. B

TH-PO570

A Rare Feature of Myeloperoxidase (MPO)-Positive Crescentic Glomerulonephritis (GN) and Neural Epidermal Growth Factor-Like 1 (NELL-1) Protein Positive Membranous Nephropathy (MN) in Mantle Cell Lymphoma (MCL)

Erik Mai, Waleed A. ElSheikhMohammed, Milos N. Budisavljevic, Evelyn Bruner. MUSC Nephrology. *Medical University of South Carolina, Charleston, SC.*

Introduction: MCL is a B-cell non-Hodgkin's lymphoma that can have renal involvement via infiltration, immune complex (IC), or complement-mediated (CM) GN. Typical IC-positive GN lesions include proliferative GN with monoclonal IgG deposits (PGNMD), C3GN, and MN. Antineutrophilic Cytoplasmic Antibody (ANCA) associated GN is now recognized to link with preceding or concurrent malignancy. Our case features a rare presentation of acute kidney injury (AKI) caused by MCL infiltration, coexisting MPO-ANCA associated crescentic GN, and NELL-1 positive MN.

Case Description: 61-year-old previously healthy male presented with intermittent fever, night sweats, maculopapular rash with bullae, anasarca and a 30 lbs weight loss. He was hypertensive and labs revealed anemia, thrombocytopenia, Strep. Agalactiae bacteremia, active urine sediment and severe AKI needing dialysis. Also notable was hypoalbuminemia 1.9 g/dL with proteinuria 9 g/g. Imaging revealed splenomegaly, diffuse lymphadenopathy, and normal-sized kidneys. Nephritic labs showed positive ANCA with MPO antibody specificity, low C3 and C4 levels, and normal kappa lambda light chain ratio. Bone marrow biopsy confirmed MCL with blastoid features. Renal biopsy showed crescentic GN, polyclonal IgG, C3, C1q, Kappa and Lambda along the tubular basement membrane, positive NELL-1 staining, and lymphomatous infiltration. Steroids and Rituximab were used as induction therapy without plasmapheresis. Rituximab continued as part of MCL chemotherapy. His renal function improved and dialysis was stopped. At 8 months creatinine was 2.9 g/dl with partial nephrosis remission (UPCR 1.3 g/g and albumin 3.3 g/dL).

Discussion: We describe a rare AKI in lymphoma presentation with MCL infiltration, MPO positive crescentic GN, and NELL-1 associated MN. To our knowledge no such case has been reported. The association between NELL-1 and malignancy is established, but it's unclear if this association with MPO ANCA is coincidental. Early identification through kidney biopsy and initiation of cancer treatment may alter the renal and patient overall prognosis. Our patient responded well to Rituximab and steroids, but the success of standard guideline therapy and the possibility of complete remission require further investigation.

TH-PO571

Idiopathic Multicentric Castleman's Disease (iMCD)-TAFRO Syndrome with Atypical Renal Biopsy Findings

Ciara L. Chen, Karen Strenge, Trevor W. Tobin. *Eisenhower Army Medical Center, Fort Gordon, GA.*

Introduction: Idiopathic Multicentric Castleman's Disease (iMCD) is a rare lymphoproliferative disorder characterized by enlarged lymph nodes in HHV-8 negative patients. It is associated with fevers, weight loss, hepatosplenomegaly, cell line dyscrasias, and organ dysfunction. One subtype of iMCD is TAFRO syndrome, characterized by the presence of thrombocytopenia, anasarca, myelofibrosis, renal dysfunction, and organomegaly. We report a patient who presented with a seronegative proliferative glomerulonephritis and was subsequently diagnosed with iMCD-TAFRO syndrome.

Case Description: A 47-year-old male with no past medical history presented to the hospital with non-specific lab abnormalities. Vital signs showed new hypertension, tachycardia, and intermittent fevers. Physical exam noted diffuse anasarca. Laboratory investigation revealed elevated inflammatory markers, new anemia, and acute renal injury. He did not have nephrotic syndrome per urine protein quantification. Urine microscopy revealed microscopic hematuria with hyaline and granular casts. Glomerulonephritis serologic evaluation was negative. Rapidly progressive renal failure necessitated initiation of renal replacement therapy and pulse dose steroids. Renal biopsy revealed a proliferative glomerulonephritis without crescents or segmental necrosis. Immunofluorescence demonstrated trace focal mesangial granular deposits of IgM and C3. Electron microscopy showed moderate foot process effacement without subendothelial or mesangial deposits. Other evaluations included a PET/CT scan, bone marrow biopsy, and cervical lymph node biopsy. Pending lymph node biopsy results, IV cyclophosphamide was started for presumed seronegative ANCA vasculitis. Results from the cervical lymph node biopsy were consistent with iMCD. The patient was transitioned to siltuximab with a prednisone taper.

Discussion: iMCD-TAFRO syndrome can present with proliferative glomerulonephritis. While this patient presented with common clinical findings of iMCD, renal biopsy results were atypical relative to prior reports of a MPGN or TMA-like histopathology. iMCD-TAFRO syndrome may not always conform to typically seen patterns. Diagnosis requires a high index of suspicion and should be considered for glomerulonephritis with non-specific biopsy findings in the context of a systemic inflammatory disease.

TH-PO572

Bacterial Endocarditis with Strongly Positive Anti-PR3 ANCA

Andrew Slater. *University of Florida, Gainesville, FL.*

Introduction: ANCA-associated rapidly progressive glomerulonephritis (GN) should be identified and treated promptly. There are however infectious mimickers of ANCA-associated GN that may present only as a lack of complete pauci-immunity on biopsy. When lack of pauci-immunity is present, it should alert the clinician to a careful search for a causative infectious agent and to reconsider immunosuppressive therapy.

Case Description: A 64-year-old man with a mechanical mitral valve presented with dyspnea and acute kidney injury preceded by months of fatigue and weight loss. He was treated as decompensated heart failure. His first blood culture was negative. Subsequently, microscopic urinalysis showed dysmorphic red blood cells. Serological testing resulted with anti-PR-3 antibody at 955 AU/cc, anti-MPO within the reference range. Renal biopsy was consistent with crescentic GN, but lacking was complete pauci-immunity with mesangial staining for IgG (trace), IgM (1+), C3 (2-3+), C1q (2+). It was thought that he had a PR-3 associated RPGN. HCV, HBV, Anti-GBM antibodies and HIV serologies were negative. He began steroids, rituximab and cyclophosphamide. Subsequently, mixed cryoglobulin testing returned positively. The components C3 and C4 were low. Immunosuppression was discontinued and further infectious workup was repeated. Quantiferon GOLD testing was negative. Four of four blood cultures grew Staph. epidermidis. As he's a cat owner, Bartonella and Coxiella serologies were sent. Bartonella henselae IgM and IgG were both strongly positive, while Q-Fever IgM was less so. Echocardiogram demonstrated a mitral valve vegetation and CT of the abdomen showed splenic infarction (initial Echo and CT negative). He was started on treatment for S. epidermidis bacteremia and B. henselae, both of which could have been the causative agent of endocarditis. He eventually developed uremia and started kidney replacement therapy. He remains dialysis dependent.

Discussion: The decision to initiate immunosuppression is not light. Bartonella henselae has been shown to present as a rapidly progressive GN that mimics ANCA-associated GN through concomitantly elevated PR3-ANCA antibodies. Coxiella burnetii is a documented causative agent of mixed cryoglobulinemia. A level of suspicion for infectious disease should be maintained when pauci-immunity is absent despite clinically rapidly progressive GN in the setting of strong ANCA serological positivity.

TH-PO573

A Vexing Case

Dhara Dave, Grace L. Malvar, Gilbert W. Moeckel, Anushree C. Shirali. *Yale School of Medicine, New Haven, CT.*

Introduction: In 2020, somatic mutations in UBA1, an X-linked gene that encodes enzyme E1 necessary for ubiquitination, were described in patients with an adult-onset inflammatory syndrome called VEXAS (Vacuoles, E1 enzyme, X-linked, Autoinflammatory, and Somatic). It has diverse systemic presentations and kidney manifestations are not well-characterized. We describe a patient who developed proliferative crescentic glomerulonephritis (GN) with deposits coincident with diagnosis of VEXAS.

Case Description: A 75-year-old male with hypertension and alcohol use disorder was admitted for worsening pancytopenia and acute kidney injury. 2 months prior he reported otitis externa and biopsy-proven atopic dermatitis responsive to steroids. Workup for pancytopenia including prior bone marrow biopsy (BM) was negative. Physical exam: BP 142/88 mmHg, normal heart, lung, abdomen and skin exam. Labs on admission: WBC 5200/μL, Hb 6.9g/dL, Platelets 133000/μL, Cr 1.96 mg/dL (baseline 0.8 mg/dL). Urinalysis: 2+ protein, 3+ blood, pyuria. Urine protein creatinine ratio 3.77. Serologies for complement, cryoglobulins, and ANCA were negative. Kidney biopsy

displayed proliferative necrotizing and crescentic GN with subendothelial deposits and lymphoplasmacytic infiltrate. IF staining: 3+ IgM, 3+ IgA, 1+ IgG, 1+ lambda. Review of prior BM biopsy showed cytoplasmic vacuoles in erythroid and myeloid precursors. Genetic screen positive for somatic UBA1c mutation. He was treated with steroids, mycophelonate and tocilizumab with partial response of declining creatinine and proteinuria.

Discussion: Limited data on kidney manifestations in VEXAS include MPO-positive necrotizing and crescentic GN, acute tubulointerstitial nephritis, and isolated interstitial infiltrate with MPO-positive and CD68+ myeloid cells. The present case adds to this data in describing a serology-negative necrotizing and crescentic GN. VEXAS syndrome represents dysregulated immune activation that leads to auto-immune organ injury. The kidney-specific pathological mechanisms of VEXAS syndrome are unknown but proposed theories include: cytokine-mediated tubular injury activating endothelial cells, recruitment of myeloid cells leading to further inflammation, and dysregulated neutrophil extracellular traps. Further research into how VEXAS syndrome involves the kidney is critical to targeted therapies for kidney disease in patients with this multi-system inflammatory syndrome.

TH-PO574

Hepatic Glomerulopathy After Liver Transplant: An Unexplored Clinical Entity

Aseel Zghayer, Ewa Borys, Maria M. Picken, Kavitha Vellanki. *Loyola University Health System, Maywood, IL.*

Introduction: Hepatic glomerulopathy, also known as hepatic glomerulosclerosis is a secondary glomerular process that occurs in the context of liver failure and cirrhosis. Pathogenesis involves acquired LCAT (Lecithin–Cholesterol Acyltransferase) deficiency as the enzyme is mainly synthesized in the liver. Deposition of lipid particles in glomerular basement membrane (GBM) similar to those seen in congenital LCAT deficiency is pathognomonic. Here, we present a unique case of persistent hepatic glomerulopathy post liver transplant.

Case Description: A 58-year-old man s/p liver transplant with prior h/o alcoholic cirrhosis complicated by hepatocellular carcinoma presented to nephrology clinic for evaluation of persistent proteinuria post liver transplant. His immunosuppression includes tacrolimus and mycophenolate and BP is well controlled. Work up revealed nephrotic range proteinuria (approx. 4 gm/gm creatinine), rest is shown in Table 1. Kidney biopsy revealed deposition of lipid particles in glomerular basement membrane and metastatic micro-calcifications (Image 1).

Discussion: Hepatic glomerulopathy is an unexplored clinical entity which is characterized by deposition of small, irregular partially electro-lucent lipid particles in the subepithelial, intramembranous, subendothelial and mesangial regions as seen in our patient. The prevalence of hepatic glomerulopathy in liver disease is not known, nor is the clinical course post liver transplantation. To our knowledge, our case is the first to be reported in literature of persistent findings post liver transplantation. We believe raising awareness of the disease entity will help in understanding the clinical course and exploring treatment options.

Lab	Patient values	Reference range	Lab	Patient values	Reference range

TH-PO575

Mycobacterium simiae: A Rare Cause of Renal AA Amyloidosis

Momen Abbasi, Assaf Potruch, Ophir Eyal. *Hadassah University Medical Center, Jerusalem, Israel.*

Introduction: *Mycobacterium Simiae* is a prevalent nontuberculous mycobacterium (NTM) that can become pathogenic to immunocompetent individuals with underlying lung disease. Rarely, untreated chronic NTM infections can result in AA amyloidosis.

Case Description: 74-year-old male with COPD presented with weight loss, nocturnal fever, elevated ESR and anemia. Cultures, serology tests, and GeneXpert for tuberculosis were negative. Normal FLC ratio. Borderline paraprotein detected only in serum. PET-CT showed increased uptake in upper right lung, small mediastinal and hilar lymph nodes. He was treated pneumonia. M. simiae grew in two sputum cultures after 4 weeks, repeated cultures were advised but not done. 5 months later patient presented with severe nephrotic syndrome, albumin <20 g/L and protein/creatinine ratio 20.8 g/g. Borderline paraprotein reported only in urine. Normal FLC ratio. Kidney biopsy was consistent with renal AA amyloidosis by immunostaining and lack of light chain restriction. PET CT revealed consolidations in right lower lobe and cavitations in both lower lobes. BM biopsy exposed dysplastic changes. Diagnosis of systemic AA Amyloidosis due to untreated M. simiae infection was made. He was treated with azithromycin, ciprofloxacin, cotrimoxazole but succumbed to his disease.

Discussion: NTM rarely cause amyloidosis with 5-8 years interval between NTM diagnosis and amyloidosis development after which mean survival time is 10 months. We believe that M. *simiae* caused amyloidosis in this case because of longstanding inflammation and negative extensive workup for other causes. We found only one case of AA amyloidosis associated with M. *simiae* lung infection with renal involvement but no nephrotic syndrome described. We present a rare case of nephrotic syndrome due to AA amyloidosis associated with *M. simiae* infection. Despite prolonged inflammation, M. simiae was diagnosed 5 months prior to AA amyloidosis diagnosis. Treatment was started late in the course of the disease and despite that he died within few weeks. This highlights the importance of early diagnosis and treatment of active M. *simiae* infection.

TH-PO576

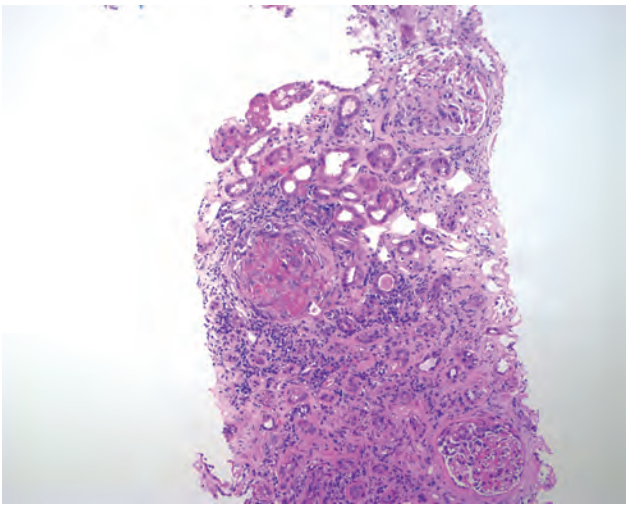
Looking at ANCA Vasculitis

Saher Aslam,[1] Haris H. Chaudhry,[2] Eric Magliulo,[1] Kirk W. Foster,[1] Felipe S. Naranjo.[1] *[1]University of Nebraska Medical Center, Omaha, NE; [2]Creighton University School of Medicine, Omaha, NE.*

Introduction: Anti-neutrophilic cytoplasmic antibody (ANCA) associated vasculitis is a group of autoimmune diseases that can cause inflammation and damage to small blood vessels throughout the body. Inflammatory eye disease is described in 50% to 60% of patients with ANCA-positive vasculitis, and for 8% to 16% of patients, it is an initial manifestation.

Case Description: A 74-year-old man with a history of gout, chronic sinusitis, and chronic kidney disease (G3a) presented to the clinic with worsening kidney function and proteinuria without hematuria. He was seen by Ophthalmology a few months prior for scleritis and was treated with a short course of NSAIDs, with the improvement of his symptoms. The initial workup was unremarkable. Kidney biopsy showed a lesion of focal segmental sclerosis with obliteration of the capillary lumen, mild interstitial fibrosis, and tubular atrophy, immunofluorescence was negative and electron microscopy with rare small dense deposits. The patient was started on SGLT-2 inhibitors. Renal function continued to deteriorate. The patient's condition was complicated by acute bronchitis, diffuse anterior scleritis, and acute kidney injury, laboratory work was significant for positive ANCA antibodies with elevated PR3 antibodies. A repeat kidney biopsy revealed necrotizing crescentic glomerulonephritis. He was treated with IV steroids, rituximab and ultimately required dialysis.

Discussion: Renal involvement is a significant feature of ANCA vasculitis and can lead to acute kidney injury or chronic renal failure if left untreated. Clinicians should consider ANCA vasculitis in the differential diagnosis of patients presenting with scleritis, especially in those with renal dysfunction even with partial or complete resolution in ocular symptoms. Early diagnosis and treatment are essential in preventing irreversible organ damage and improving patient outcomes.



Biopsy with PAS stain showing crescent formation consistent with ANCA vasculitis

TH-PO577

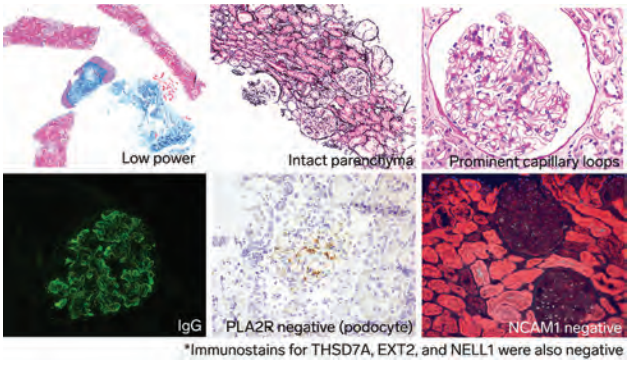
Membranous Nephropathy Associated with Alemtuzumab

Raja Ravender,[1] Chaitanya A. Pal,[1] Chandra Kumar Mallick Kodavanti,[1] Saeed K. Shaffi,[1] Darren W. Schmidt,[1] J. Pedro Teixeira,[1] Tiffany Caza,[2] Pablo Garcia.[1] UNMH/Arkana Team. *[1]The University of New Mexico, Albuquerque, NM; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Alemtuzumab is a humanized anti-CD52 monoclonal antibody approved for multiple sclerosis. We present a case of membranous nephropathy associated with alemtuzumab use.

Case Description: A 20-year-old woman with a seven-year history of multiple sclerosis was referred to nephrology due to new-onset nephrotic range proteinuria nine months after receiving her first cycle of alemtuzumab. She took no other medications. Vitals were stable with trace lower extremity edema. Spot urine protein- and albumin- to creatinine ratios were 4.63 g/g and 3481 mg/g, respectively. Serum creatinine was 0.4 mg/dL with serum albumin 2.1 g/dL. Hepatitis B and C, HIV, C3 and C4 complement, kappa/lambda ratio, anti-GBM antibody, rheumatoid factor, antinuclear antibody, antineutrophil cytoplasmic antibody, and anti-phospholipase A2 receptor (PLA2R) antibody were all negative. Renal biopsy revealed membranous nephropathy, with negative immunohistochemical stains for PLA2R, thrombospondin type-1 domain-containing 7A, exostosin 2, and neural epidermal growth factor-like 1. Alemtuzumab was held. Rituximab was initiated as it is effective for membranous nephropathy or multiple sclerosis, and we await the renal and neurologic response.

Discussion: Alemtuzumab depletes B and T lymphocytes and can produce side effects associated with immune reconstitution, with thyroid toxicity seen in up to 30% of patients. However, nephrotoxicity is rare (5/1485 patients, 0.3%). Mechanisms underlying kidney-related side effects from alemtuzumab use are not fully understood but may be linked to the anti-CD52 immunomodulatory effect on B and T cell lymphocytes. The autoimmune diseases observed after administering alemtuzumab are predominantly antibody-mediated and appear to respond to B-cell depletion, suggesting that rituximab may be a potentially effective therapy.



TH-PO578

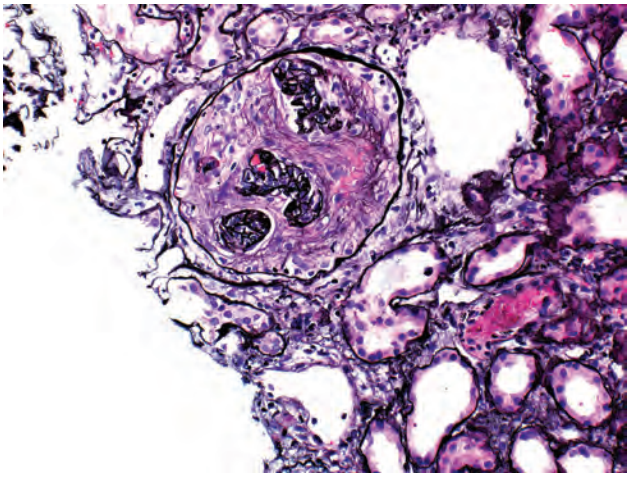
Crescenteric Glomerulonephritis Leading to Diagnosis of Culture Negative Endocarditis

Huanchun N. Lai.[1,2] *[1]McLaren Health Care Corp, Flint, MI; [2]Michigan State University, East Lansing, MI.*

Introduction: Infective endocarditis-associated glomerulonephritis (IEAGN) as the initial presentation leading to diagnosis of afebrile, culture negative and negative serologic workup endocarditis.

Case Description: A 64-year-old male with history of CAD s/p remote CABG and hypertension presented with cough, dyspnea and worsening lower extremity edema. He was found to have a serum creatinine of 2.27mg/dL, hematuria and nephrotic range proteinuria 4.1g raising concerns for glomerular etiologies. Serologic workup showed mildly positive ANA 1:80, normal C3 and C4, ANCA, MPO, PR3, SPEP, and K/L ratio all negative, and no Bence Jones proteins. Hep B and C studies were negative. Outpatient kidney biopsy was obtained and demonstrated crescenteric glomerulonephritis on light microscopy with C3 dominant deposits on immunofluorescence favoring infection-associated glomerulonephritis and raising question for endocarditis. Patient readmitted for further inpatient workup. TEE showed evidence of vegetation on right coronary cusp. Blood culture negative. Histoplasmosis, Bartonella, and Q fever, Antistrep O, HIV, mycoplasma, and legionella were all negative. The patient was treated with six weeks of intravenous ceftriaxone followed with prednisone taper. Patient had improvement of symptoms and improvement of renal function.

Discussion: IEAGN develops as sequalae of acute or subacute endocarditis. In literature there has not been a case with acute renal injury with proteinuria and hematuria as the initial presentation of endocarditis. This case highlights the importance of renal biopsy in guidance of treatment of cresenteric glomerulitis in a case of culture negative, serology negative endocarditis.



Necrotizing cresenteric glomerulonephritis seen with Jones silver stain. Active crescents involve 55-60% of non-obsolescent glomeruli sampled for light microscopy.

TH-PO579

Truly a Catastrophe: A Case of Severe Anti-Phospholipid Syndrome in the Setting of Lupus

Shilpa Pedapati, Golnaz Vahdani. *Banner University Medical Center Tucson, Tucson, AZ.*

Introduction: Antiphospholipid syndrome(APS) is characterized by venous or arterial thrombosis in the presence of antiphospholipid antibodies. It can occur as a primary vs secondary condition in which its associated with inflammatory disorders like systemic lupus erythematosus(SLE). APS related kidney disease can manifests itself in various ways from non-inflammatory occlusive diseases with arterial and venous thrombosis, TMA as well as glomerular diseases. Lupus can affect kidneys in the form of glomerulopathies in addition to TMA. It is important to distinguish inflammatory versus thrombotic lesions in order to ensure timely diagnosis and initiation of emergent management.

Case Description: 49-year-old female with a history of SLE not on any immunosuppression was admitted due to diarrhea and was found to have severe acute renal failure with a creatinine of 13. Serologies demonstrated low C3 and C4, Positive ANA, double-stranded DNA, cardiolipin IgG antibody, beta-2 glycoprotein IgG and c-ANCA. Duplex was negative for renal artery stenosis or renal vein thrombosis. She was initiated on hemodialysis secondary to volume overload. Anticoagulation was also initiated due to new diagnosis of bilateral upper extremity deep vein thrombosis. Kidney biopsy performed demonstrating chronic TMA in the glomeruli, negative for acute thrombi, crescents/features of lupus or a full house pattern on immunofluorescence. MR angio was also obtained in the setting of concern for APS showing complete intraluminal thrombus occlusion of aorta at the level of renal arteries down to the bifurcation, with occlusion of the right renal artery and narrowing of left renal artery. Due to concern for catastrophic APS she was promptly started on plasmapheresis and steroids. She remained

dialysis dependent and had recurrent hospitalizations for pulmonary edema secondary to hypertension, and eventually underwent aortoiliac bypass with improvment of hypertension and remained dialysis dependent.

Discussion: Renal prognosis remains poor in patients affected by SLE in the presence of aPLs and may lead to ESRD. Prompt initiation of anticoagulation, Immunosuppression and plasmapheresis remains the mainstay of treatment. Having a high index of suspicion is very important to diagnose thrombotic lesions as it affects not only kidney outcomes but also contributes to overall morbidity and mortality.

TH-PO580

Association of Preterm Birth with Adverse Outcomes of Glomerular Disease in Children and Adults in the CureGN Cohort

Jaya Isaac,[1] Jonathan P. Troost,[3] Yujie Wang,[3] Kelly Garrity,[4] Rick Kaskel,[1] Rasheed A. Gbadegesin,[2] Kimberly J. Reidy.[1] *[1]Children's Hospital at Montefiore, New York, NY; [2]Duke University, Durham, NC; [3]University of Michigan, Ann Arbor, MI; [4]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: While some studies of children with nephrotic syndrome have demonstrated worse outcomes in those born preterm vs. term, there is little data on associations of preterm birth with kidney and cardiovascular outcomes in adult-onset glomerular disease.

Methods: We performed a cross-sectional and longitudinal survival analysis of participants in the Cure Glomerulonephropathy (CureGN) cohort with birth history data. Preterm (<37 weeks gestation) was compared to term (≥37 weeks gestation). Baseline characteristics and cardiovascular outcomes were compared using Chi-square and Mann Whitney testing. A survival analysis and adjusted Cox proportional hazards model was used to examine a composite outcome of 40% decline in estimated glomerular filtration rate (eGFR) or progression to End Stage Kidney Disease (ESKD). An adjusted logistic regression model was used to examine remission of proteinuria.

Results: More pediatric than adult participants in CureGN were born preterm: 12.8% (118/919) vs. 7.69% (117/1521) (p<0.001). Adults born preterm had a higher prevalence of Focal Segmental Glomerulosclerosis (FSGS) (35% vs. 25%, p=0.01) and *APOL1* high risk genotype (9.4% vs 4.2%, p=0.01) as compared to adults born term. Pediatric participants born preterm were more likely to have hypertension at enrollment (p=0.001). While there was no difference in eGFR at enrollment, participants born preterm had a shorter time interval to a 40% eGFR decline/developing ESKD after biopsy (p=0.001). In adjusted analysis, preterm participants were 28% more likely to develop 40% eGFR decline/ESKD (p=0.008) and 38% less likely to attain complete remission of proteinuria (p=0.006). There was no statistically significant difference in ever having hypertension or other cardiovascular events between the two groups.

Conclusions: Preterm birth was a risk factor for adverse outcomes in this heterogenous cohort of children and adults with glomerular disease. Children born preterm were more likely to have baseline hypertension while adults born preterm were more likely to have an *APOL1* high risk genotype and FSGS. Even in analyses adjusted for FSGS and *APOL1* risk status, there was a faster progression of chronic kidney disease in those born preterm. Low nephron endowment and other perinatal exposures may account for these differences.

Inpatient and Outpatient Service Review of a Greek Reference Centre for Glomerular Diseases

Aglaia Chalkia,[1] Christos Koutsianas,[2] Panagiota E. Giannou,[1] Christina Tsalapaki,[2] Margarita Mpora,[1] Harikleia Gakiopoulou,[3] Konstantinos Tsioufis,[4] Dimitrios Vassilopoulos,[2] Dimitrios I. Petras.[1] *[1]Nephrology Department, Hippokration General Hospital, Athens, Greece; [2]2nd Department of Medicine and Laboratory, Clinical Immunology - Rheumatology Unit, National and Kapodistrian University of Athens School of Medicine, Hippokration General Hospital, Athens, Greece; [3]1st Department of Pathology, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece; [4]1st Department of Cardiology, National and Kapodistrian University of Athens School of Medicine, Hippokration General Hospital, Athens, Greece.*

Background: The glomerulonephritis (GN) is a rare and complicated disease with high demand of hospital resources while the chronic kidney disease and end-stage renal disease present increased prevalence in these patients.

Methods: We retrospectively assessed the inpatient and outpatient service for patients with GN, who have been followed-up at a Greek reference centre for GN, during the pre-Covid-19 period 2018-2020.

Results: 267 patients (median age 65±23 years) included. All patients underwent a kidney biopsy by the nephrologist without complications. ANCA associated GN (18%), Focal Segmental Glomerulosclerosis/Minimal Change Disease (17.5%), IgA nephropathy (17%), Membranous Nephropathy (12.6%), Lupus Nephritis (5%), Membranoproliferative GN (3%), Fibrillary GN (3%), Monoclonal Gammopathy of Renal Significance (3.3%) and IgG4-related disease (2%.) were encompassed. We reported median 75 new patients per year. Regarding the inpatient service, we observed an increasing trend to the hospitalizations during this period (274, 452, 461 hospitalizations in 2018, 2019, 2020 respectively). The AAV was the most common disease of hospitalizations through this period (53% in 2018, 33% in 2019, 39% in 2020), whereas the second most common was the FSGS/MCD (28% in 2018, 13% in 2019, 23.8% in 2020). The outpatient's service review also revealed an increasing number of visits per person per year (279, 456 and 464 total visits in 2018, 2019 and 2020 respectively). The disease with the highest number of visits per person was reported the AAV (median 3.25 visits per patient per year). All the patients treated in collaboration with a multidisciplinary team, consisting of nephrologist, rheumatologist, cardiologist, and pathologist. Finally, we reported complete response at 76% of the patients and in terms of renal improvement, 46% presented eGFR≥60ml/min/1.73m^2, 45% eGFR<60ml/min/1.73m^2 and only 9% progressed to ESRD after the first year of treatment.

Conclusions: The patients with GN present an increased need for hospitalization and regular outpatient visits. In addition to the medical treatment, the favourable outcome depends on a well-organized inpatient and outpatient service provided by a multidisciplinary team.

TH-PO582

Histopathology Findings and Outcomes of Non-Nephrotic Range Proteinuria in Adults and Children

Ai Itoku,[1] Lihong Bu,[2] Wei Hao,[4] Rick Kaskel,[1] James M. Pullman,[1] Kimberly J. Reidy.[3] *[1]Children's Hospital at Montefiore, New York, NY; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Montefiore Medical Center, New York, NY; [4]University of Michigan, Ann Arbor, MI.*

Background: While there are clinical practice recommendations for nephrotic syndrome (NS), the approach to diagnosis and management of non-nephrotic range proteinuria (NNP) is not well defined. We hypothesized that histopathologic diagnosis would differ between subjects with NNP compared to NS, and that renin-angiotensin aldosterone system (RAAS) blockers would be associated with complete or partial remission in subjects with NNP.

Methods: This is a secondary analysis of the Nephrotic Syndrome Study Network (NEPTUNE) cohort. We included adult and pediatric NEPTUNE participants who did not receive treatment for NS prior to screening, and who presented with urine protein creatinine ratio (UPCR) ≧ 0.5 g/g up to < 2 g/g in children and < 3 g/g in adults at the time of screening. A NS comparison group was identified using clinical diagnoses of NS and/or UPC ≧ 2 g/g in children and untreated adults with UPC ≧ 3 g/g at screening. Histopathologic diagnoses were compared by Chi-Square test between NNP and NS cohorts. In longitudinal analyses, we examined the associations of covariates with complete or partial remission and eGFR decline during the follow up period in NNP using generalized estimating equation.

Results: More than half of adult and children presenting with NNP were classified as overweight/obese and had high blood pressure. Subjects presenting with NNP were more likely to have FSGS than those presenting with NS [In adults, 37.1% in NNP vs 29.3 % in NS (p=0.002). In children, 41.2% in NNP vs 18.1% in NS (p<0.0001).] In those with NNP, histopathology diagnosis of FSGS (vs diagnosis of other) [OR=3.27, p=0.03] and/or high blood pressure at baseline [OR=0.51, p=0.02] predicted decrease rate of remission. In those with NNP, histopathology diagnosis of IgAN (vs FSGS) and/or overweight/obesity at baseline predicted faster eGFR decline [-8.63 ml/min/year (p=0.038), -7.04 ml/min/year (p=0.021) respectively]. While this study had a limited sample size, RAAS therapy was not statistically significantly associated with either remission or eGFR in this cohort.

Conclusions: This study supports the need for kidney biopsy in subjects presenting with NNP. Further study/clinical trials are needed to identify the effective therapies for subjects with NNP.

TH-PO583

Edema and the Risk of Thromboembolic Complications in Nephrotic Syndrome: A Cohort Study

Sarah Kelddal,[1,2] Bawer J. Tofig,[3,4] Erik L. Grove,[4,5] Anne-Mette Hvas,[6] Christian F. Christiansen,[7,5] Henrik Birn.[1,5] *[1]Aarhus Universitetshospital Afdeling Nyresygdomme, Aarhus, Denmark; [2]Aarhus University Department of Biomedicine, Aarhus, Denmark; [3]Regionshospitalet Godstrup Afdeling Hjertesygdomme, Herning, Denmark; [4]Aarhus Universitetshospital Afdeling Hjertesygdomme, Aarhus, Denmark; [5]Aarhus Universitet Institut for Klinisk Medicin, Aarhus, Denmark; [6]Aarhus Universitet Faculty of Health, Aarhus, Denmark; [7]Aarhus University Hospital Department of Clinical Epidemiology, Aarhus, Denmark.*

Background: Nephrotic syndrome (NS) is defined by severe albuminuria, hypoalbuminemia, and edema; however, the prevalence of edema with nephrotic range albuminuria and the associated risk of complications is unclear. We examined edema prevalence and the association between edema, mortality, and thromboembolic events (TE) in a cohort of NS patients.

Methods: A cohort study including patients being hospitalized or treated in outpatient clinics with a urine albumin-creatinine ratio (uACR) > 2,200 mg/g and plasma-albumin < 30 g/L in the Central Denmark Region between 2015-2022. Patients were identified from the central laboratory database by screening all recorded uACR and p-albumin measurements. We further collected demographics and outcomes and reviewed all medical records to examine if edema was present at time of NS diagnosis. Patients were followed until death or end of study.

Results: Among 806 included patients with nephrotic range albuminuria, 459 (61.4%) had edema at time of diagnosis. A total of 34 (4.2%) arterial TE (ATE) and 23 (2.6%) venous TE (VTE) were observed during follow-up (Table 1). Patients with edema

had a lower incidence rate of ATE compared to those without edema (10 vs 28 per 1000 person-years), while the incidence rate of VTE did not differ between groups. All-cause one-year mortality was higher in the edema group (33.7% vs 25.7%).

Conclusions: Edema was prevalent at the time of diagnosis and was associated with an increased all-cause one-year mortality despite lower risk of ATE. Additional analyses are needed to explore this association and to determine the prognostic relevance of edema in the diagnosis of NS.

Corticosteroid Dose and Risk of Infection in Children and Adults with Glomerular Disease: An Analysis of the CureGN Study

Dorey A. Glenn,[1] Calvin Andrews,[2] Jarcy Zee,[4,3] Sarah Mansfield,[2] Michelle M. O'Shaughnessy,[5] Andrew S. Bomback,[6] Keisha L. Gibson,[1] Larry A. Greenbaum,[7,8] Laura H. Mariani,[9] Ronald Falk,[1] Susan L. Hogan,[1] Amy K. Mottl,[1] Michelle Denburg.[4,3] On Behalf of the CureGN Consortium. *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]Galway University Hospitals, Galway, Ireland; [6]Columbia University, New York, NY; [7]Children's Healthcare of Atlanta Inc, Atlanta, GA; [8]Emory University, Atlanta, GA; [9]University of Michigan, Ann Arbor, MI.*

Background: Corticosteroid (CS) exposure is associated with risk of infection leading to increased morbidity and mortality in patients with glomerular disease (GD). We describe longitudinal CS exposure and measure its association with risk of infection in the Cure Glomerulonephropathy (CureGN) study.

Methods: CureGN is a prospective cohort study of patients with biopsy-proven primary GD. CS dose and duration were abstracted from participant medical records at interval study visits and harmonized to prednisone (oral) and methylprednisolone (IV) dose equivalents. Marginal structural models (MSM) were used to estimate effects of CS dose (see Figure), with or without other IS exposure, on hazards of first infection-related hospitalization or ED visit, adjusting for baseline age, race, sex, ethnicity, GD subtype, comorbid conditions, and time-varying markers of disease activity [eGFR, UPCR, and serum albumin].

Results: Of 2568 participants (43% female, 35% <18 years), 446 (17%) experienced a first infection over a median follow-up of 58 months (IQR 32-77). Children and adults were exposed to CS for 14% and 9% of their follow-up time, respectively. Median daily exposure to oral and intravenous CS was 13 mg (IQR 5-32) and 65 mg (IQR 40-500) in children and 10 mg (IQR 5-22) and 125 mg (IQR 125-125) in adults. In a multivariable MSM model, low, medium, and high dose CS exposure was associated with 1.22 (95% CI 0.53-2.84), 3.06 (95% CI 1.84-5.10), and 3.03 (95% CI 1.64-5.59) times higher hazards of infection without concurrent IS, and 2.30 (95% CI 1.40-3.77), 2.71 (95% CI 1.75-4.21), and 3.66 (95% CI 2.35-5.71) times higher hazards of infection with concurrent IS, compared to no IS exposure.

Conclusions: Medium and high dose CS independently increase risk of infection when used alone. When used in combination with other IS, all doses of CS increase risk of infection. These results can inform clinical care and highlight the importance of CS sparing medication regimens for patients with GD.

TH-PO585

Influenza Vaccine Administration and Effectiveness Among Patients with Glomerular Disease

Dorey A. Glenn,[1] Virginia Pate,[2] Ronald Falk,[1] Emmanuel B. Walter,[3] Michelle Denburg,[4,5] Susan L. Hogan,[1] Amy K. Mottl,[1] J. Bradley Layton.[6] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]The University of North Carolina at Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; [3]Duke University, Durham, NC; [4]The Children's Hospital of Philadelphia, Philadelphia, PA; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]RTI Health Solutions Research Triangle Park, Research Triangle Park, NC.*

Background: Influenza contributes to excess healthcare utilization and morbidity in individuals with glomerular disease (GD). Immune responses to influenza vaccination in individuals with GD may be attenuated by immune dysregulation and immunosuppressant use. We evaluated the effectiveness of influenza vaccination among patients with GD.

Methods: Individuals with primary GD were identified within the Merative MarketScan Claims & Encounters database and followed across annual influenza seasons until disenrollment or 2020. Influenza vaccination, influenza and influenza-like infections, and covariates were ascertained using ICD-9/10-CM-based definitions from medical and prescription claims. Influenza seasons (2010-2019) were analyzed individually by comparing the incidence rates of infection in vaccinated and unvaccinated individuals. Propensity score weighting was used to balance the distribution of potential confounders across vaccination status. Cox proportional hazards models were used to estimate vaccine effectiveness (VE=1-hazard ratio). We then compared years with a close match between vaccine composition and circulating influenza strains (2010-2013, 2015-2018), with a mismatched "control" season (2014). We used a weighted Cox model with an interaction term between vaccination status and vaccine match grouping to estimate the relative VE in matched vs. mismatched seasons.

Results: 46,010 influenza person-seasons were analyzed from 17,219 individuals (mean age 45 years (SD 17), 43% female), including 10,535 and 35,475 person-seasons from vaccinated and unvaccinated individuals, respectively. The mean proportion of individuals vaccinated per season was 23% (range 19-25%). VE estimates for individual seasons ranged from -74 to 66% for influenza and -58 to 29% for influenza-like infection. In the pooled analysis comparing matched vs. mismatched seasons, vaccination was modestly protective for both influenza (VE 17%, 95% CI -38 to 50) and influenza-like infection (VE 14%, 95% CI -24 to 41%).

Conclusions: Rates of influenza vaccination are suboptimal among patients with GD. Despite potential confounding by indication and uncaptured vaccinations and infections, these data suggest that protection from influenza after vaccination may be poor, leading to excess infection-related morbidity in this vulnerable population.

TH-PO586

Patterns of Disease Progression Among Children and Adults with IgA Nephropathy/Vasculitis in CureGN

Dorey A. Glenn,[1] Ashley W. Carver,[1] Margaret Helmuth,[3] Abigail R. Smith,[3] Pietro A. Canetta,[6] Cynthia C. Nast,[4] Heather N. Reich,[7] Carla M. Nester,[5] Myda Khalid.[2] On Behalf of the CureGN IgA Working Group. *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Cedars-Sinai Medical Center, Los Angeles, CA; [5]University of Iowa Hospitals and Clinics, Iowa City, IA; [6]Columbia University, New York, NY; [7]Toronto General Research Institute, Toronto, ON, Canada.*

Background: IgA nephropathy (IgAN) is the most common glomerular disease world-wide. Identifying demographic and clinical characteristics that place patients at increased risk for disease progression is critical for optimizing therapeutic interventions and targeting clinical trials.

Methods: CureGN is a multi-center cohort study of children and adults with biopsy-proven glomerular disease, including 823 patients with IgA nephropathy/vasculitis with nephritis (IgAN/IgAVN). We used latent class analysis to segregate 316 incident and prevalent patients, with at least 4 UPCR measurements within the first 2 years of their follow-up, into 3 groups based on longitudinal UPCR trajectories over 2 years. Using Cox proportional hazard models, we then modeled disease progression, defined as the composite outcome of 40% eGFR decline or kidney failure (initiation of dialysis, transplant, or 2 eGFRs <15ml/min/1.73m^2), as a function of UPCR trajectory group while adjusting for age, eGFR at enrollment, use of immunosuppression, RAAS blockade, and IgAN/IgAVN status.

Results: 149 incident and 167 prevalent patients (enrolled <6 months and > 6 months from biopsy (max 5 years), respectively) were followed for a median of 6.1 (IQR 4.5,6.9) years. Three groups were identified based on UPCR trajectories (Figure). Among incident patients, those with the highest UPCR (group 3) demonstrated faster eGFR decline (median (IQR) decline -4.0 (-7.3,-0.1) ml/min/1.73m^2/year compared to +1.3 (-2.0,+3.1) in group 1 and -0.9 (-3.9,+1.7) in group 2) and had 5.4-times higher hazard of progressing to the composite outcome compared to Groups 1+2 combined (p=0.0016). Among prevalent patients, those with the highest UPCR (Group 3) had 3.9-times higher hazard of progressing to the composite outcome (p=0.0049). No association between immunosuppression use and the composite outcome was detected.

Conclusions: In both incident and prevalent IgAN/IgAVN cohorts proteinuria trajectories define patients into distinct clinical groups and are a strong independent predictor of disease progression.

TH-PO587

Frequency and Risk Factors for Glucocorticoid-Induced Diabetes Mellitus: The Japan Nephrotic Syndrome Cohort Study

Hidekazu Ikeuchi,[1] Keiju Hiromura,[1] Ryohei Yamamoto,[2] Naoki Nakagawa,[3] Yoshitaka Isaka.[2] *[1]Gunma Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Maebashi, Japan; [2]Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan; [3]Asahikawa Ika Daigaku, Asahikawa, Japan.*

Background: Glucocorticoid (GC)-induced diabetes mellitus (GIDM) is one of the major complications of glucocorticoid treatments. The study aims is to examine the incidence and risk factors for GIDM among patients (pts) with primary nephrotic syndrome in Japan.

Methods: We conducted a *post-hoc* analysis of the Japanese Syndrome Cohort Study (JNSCS), a nationwide prospective study of primary nephrotic syndrome. 374 pts who received renal biopsy between 2009 to 2010 were enrolled in JNSCS. After excluding 151 pts (no data for baseline HbA1c, no GC use, and already diabetes at baseline), 223 pts (104 male) were included. GIDM was defined when pts started diabetes medication within 6 months of GC treatment.

Results: Baseline clinical data were as follows: mean age 54.6±20.0 years, mean body mass index 23.4±3.6, eGFR 65.6±37.2 ml/min/1.73m^2, and HbA1c 5.2±0.4%. GIDM was developed in 50 pts (22.4%) in 223 total pts, 14 pts (14.2%) in 98 minimal change diseases pts, 27 pts (30.3%) in 89 membranous nephropathy pts, 9 (33,3%) in 27 focal segmental glomerulosclerosis pts, and 0 pts (0%) in 9 other diseases pts. Multiple logistic regression analysis revealed age≥65 years and HbA1c≥5.6% before treatment are risk factors for the development of GIDM (Figure). Among 43 GIDM pts whose data were available, 15 pts (34.9%) discontinued diabetes medications within 2 years. There were no significant differences for adverse events (death, infections, vascular thrombosis, cardiovascular) and renal outcomes (complete remission, relapse, renal function deterioration) between patients with or without GIDM during 2 years after treatment.

Conclusions: About 20% of patients developed GIDM during the treatment of primary nephrotic syndrome in Japan. Older age and higher HbA1c levels at baseline are the risk factors for GIDM. One-third of GIDM patients could discontinue diabetes medications during 2 years after treatment.

Mood Changes Associated with High-Dose Corticosteroids in Adults with Glomerular Disease

Fergus Daly,[1,2] Sinead Stoneman,[1] Michael Clarkson,[1] Michelle M. O'Shaughnessy,[1,3] Sarah M. Moran.[1] The Cork Kidney Research Group. *[1]University College Cork, Cork, Ireland; [2]Beaumont Hospital, Dublin, Ireland; [3]Galway University Hospitals, Galway, Ireland.*

Background: Glomerulonephritis (GN) can be caused by a variety of underlying conditions, many of which are treated with high dose corticosteroids. There is a paucity of knowledge regarding the frequency, severity, and predictors of neuropsychiatric toxicity from high-dose corticosteroids in adults with glomerular diseases.

Methods: We conducted a prospective, survey-based study of adults with newly diagnosed or relapsing biopsy-proven minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), IgA nephropathy (IgAN), and membranous nephropathy (MN). Institutional ethical approval was granted. Three identical questionnaires were provided for self-completion at enrolment, 2- & 12-weeks post-enrolment. The questionnaire was adapted from two existing surveys, developed and validated to measure mania (Altman Self-Rating Mania Scale) and depression (Patient Health Questionnaire – 9).

Results: 30 patients were enrolled. Biopsy diagnoses included: MN (10), MCD (9), FSGS (4) and IgAN (7). 60% (18) were new diagnoses. 43% (13) had a prior psychiatric diagnosis (depression (8), anxiety (4), post traumatic stress disorder (1)) The median age was 54 years. There was no significant difference between groups in proteinuria or GFR at baseline level, however serum albumin was lower in the steroid treated group (25g/L vs 32g/L). 47% (14) of participants received corticosteroids, while the remainder(non-exposed: n=16) received no form of immunosuppressive therapy during their 12-weeks of enrolment. *Mania:* ASRM scores at 2-weeks were significantly higher in the corticosteroid-exposed group compared to the immunosuppressant-naïve control group (p <0.001). Patients treated with corticosteroids experienced a mean ASRM score increase from baseline of 9 (standard deviation = 4.2) at 2-weeks, whereas their non-exposed counterparts experienced a negligible change. *Depression:* A significant between-group difference in PHQ-9 (depression) scores at 12-weeks was observed with the corticosteroid group recording higher scores (p < 0.001).

Conclusions: Patients with glomerular disease treated with corticosteroids experienced significant increases in mania scores at early stages of their treatment course, while depression predominated at later stages of treatment course.

Humanization and Telehealth for Improving Patient-Reported Outcomes in Glomerular Diseases: The Human-C Project

Miguel Uriol Rivera, Elena Serén. *Hospital Universitario Son Espases, Palma, Spain.*

Background: Glomerular diseases (GD) encompass rare diseases that predominantly affect young and working-age individuals, often requiring off-label therapies. These conditions necessitate personalized and ongoing monitoring, which can impact patients' quality of life (QoL). The implementation of telehealth should be tailored to individual patient profiles, while nurse coaching support can identify patients' personal and occupational needs, and reinforce effective communication. This study reports the outcomes of implementing telehealth and nurse coaching support (Humanization Coaching Project: Human-C Project) in a glomerular disease unit.

Methods: Objective: Evaluate the effect of the Human-C Project on patient-reported outcomes (PROMs) and patient-reported experience measures (PREMs) in GD patients, including during the COVID-19 pandemic. Telehealth via WhatsApp and nurse coaching support were introduced in November 2019, incorporating virtual visits. A nurse conducted interviews using Promis-29 and SF-36 questionnaires. In February 2023, an online survey with 15 items (including questions from Promis-29, SF-36, and nurse coaching) was administered to 233 patients.

Results: In 2019, 2,432 visits were recorded, reducing by 7% in 2020 (2,251 visits), with 37% being virtual. Eighty-nine patients responded to the questionnaire. The questionnaire covered domains such as employment status, disease knowledge, social

function, psychological health, medical appointments, and therapy preferences. Key findings included: working-age patients (87%), inadequate disease knowledge (16%), fatigue (53%), sleep issues (50%), dissatisfaction with work performance (40%), and reduced activity due to emotional problems (34%). Following the Human-C Project, 85% reported adequate healthcare team access during the pandemic, and 72% reported improved QoL.

Conclusions: Glomerular disease patients face QoL challenges, but the Human-C Project, along with telehealth, provides specific care perspectives and improves QoL. These findings have important implications for healthcare systems, even in crises like the COVID-19 pandemic.

TH-PO590

Adverse Educational Outcomes in Glomerular Disease

Kelly Garrity,[1] Nathaniel Putnam,[2] Eloise Salmon,[2] Susan F. Massengill,[3] Elaine S. Kamil,[4] Myda Khalid,[5] Jaya Isaac,[6] Kelsey L. Richardson.[7]
[1]University of California Los Angeles, Los Angeles, CA; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Atrium Health, Charlotte, NC; [4]Cedars-Sinai Medical Center, Los Angeles, CA; [5]Indiana University School of Medicine, Indianapolis, IN; [6]Montefiore Health System, Bronx, NY; [7]Oregon Health & Science University, Portland, OR.

Background: Research on kidney disease's cognitive impacts in youth has largely focused on CAKUT patients due to the extent of brain development in the first 5 years of life. Our prior research found decreased high school diploma/GED attainment in those with adolescent Glomerular Disease (GD) onset. However, school impacts range beyond diploma attainment. No studies have analyzed the likelihood of patients with renal disease onset solely after age 5 reporting any adverse educational impact. Objective: Determine the prevalence of any educational impact on GD patients diagnosed between ages 5-19 and which factors might contribute.

Methods: CureGN prospective cohort study participants with Minimal Change Disease(MCD), Focal Segmental Glomerulosclerosis(FSGS), Membranous Nephropathy(MN), or IgA Nephropathy(IgAN) diagnosed between ages 5-19(n= 817) were included in the analysis, with the outcome defined as any self reported educational impact. Odds ratios(OR) based on General Estimating Equations were used to determine predictors of educational impact. Predictors of interest included race-ethnicity, child (5-12) vs adolescents (13-19) GD onset, parental education, adherence, APOL1 high risk allele, disease type, sex, and number of coexisting conditions.

Results: 43%(348/817) reported GD ever impacted their education. Table 1 shows OR of the educational impact of predictors.

Conclusions: GD impacts a high percent of patients' educations, even with onset after age 5. Having coexisting conditions and Black race(reference White) increased the likelihood while IgAN(reference MCD) decreased the likelihood of reporting an educational impact. The racial disparity in educational outcomes and the underlying causes of GD's adverse educational outcomes warrant more research.

TH-PO591

Assessment of Medication Adherence Among Adults with Glomerular Disease

Jill Krissberg,[1,2] Margaret Helmuth,[3] Abigail R. Smith,[3] Tetyana L. Vasylyeva,[6] Bruce M. Robinson,[3] Richard A. Lafayette,[4] Katherine R. Tuttle.[5]
Cure Glomerulonephropathy Network. *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]Stanford University School of Medicine, Stanford, CA; [5]University of Washington, Seattle, WA; [6]Texas Tech University Health Sciences Center, Lubbock, TX.*

Background: Patients with glomerular disease (GD) face challenges taking complex and potentially toxic medication regimens. This study assessed medication adherence in adults with GD and associations with demographic, socioeconomic and disease-related factors.

Methods: CureGN is a multinational prospective cohort study of prevalent patients with biopsy proven GD. Nonadherence is assessed at enrollment and follow-up visits. We compared patient and disease characteristics at enrollment and probability of nonadherence during follow-up across self-reported racial and ethnic groups. We used multivariable mixed effects logistic regression models to explore associations between race and ethnicity and odds of nonadherence, serially adjusting for potential confounders.

Results: In 1,550 adults with GD (66% White, 15% Black, 10% Asian, 9% Hispanic, 56% male, median age 42 years; 64% privately insured (US); at enrollment, median estimated glomerular filtration rate 73.2mL/min/1.73m2, median urine protein-to-creatinine 1.5g/g), 914 (59%) reported at least one non-adherence response over a median 53 (28, 72) months follow-up time where a median 4 (2, 6) surveys were completed. Odds of non-adherence were higher for Black vs. White adults (OR 1.70, 95% CI 1.24-2.33), for public insurance (US) (OR 1.45, 95% CI 1.06-1.98), and for moderate or greater edema (OR 1.45, 95% CI 1.13-1.86). While forgetfulness was the most common stated reason for medication non-adherence (60%), Black adults were most likely to cite side effects (23% for Black adults vs 17% for overall cohort), cost (7% vs 3%), and feeling well (12% vs 8%) as reasons for non-adherence.

Conclusions: Non-adherence to medication is common in adults with GD. Black compared to White adults had higher odds of non-adherence, with side effects, cost, and feeling well all more commonly indicated as reasons. Interventions to target these reasons across racial and ethnic groups may help improve medication adherence.

A New Mexico-Based Kidney Biopsy Registry Data Analysis

Saeed K. Shaffi,[1,2] Brent Wagner.[1,2] *[1]Raymond G. Murphy VA Medical Center, Albuquerque, NM; [2]University of New Mexico School of Medicine, Albuquerque, NM.*

Background: The frequency of biopsy-proven renal parenchymal diseases in the U.S. Southwest is unknown which is summarized in this study.

Methods: The University of New Mexico Kidney biopsy registry is a data repository from 2002 to 2019. We abstracted the primary diagnoses from the biopsy report with natural language processing and reviewed them to ensure data accuracy. We reported the initial primary diagnosis if the subsequent diagnoses were congruent in patients with multiple biopsies. Continuous and categorical data were reported as median (IQR) and n (%). We plotted time trends for each diagnosis.

Results: Of the 1204 unique native kidney biopsies, cancer and diabetic glomerulosclerosis were the most frequent diagnoses (Figure 1). The majority self-identified as Hispanic or American Indian. Biopsy frequency increased with time. Patients with cancer were the oldest at the time of biopsy while those with lupus nephritis were the youngest ($p < 0.001$). A higher frequency of cancer and diabetic glomerulosclerosis was noted with time (Figure 2).

Conclusions: We used natural language processing to analyze kidney biopsy registry data in a predominantly Hispanic or American Indian cohort and identified disease frequency. This registry will facilitate the study of renal parenchymal disease's natural history and outcomes.

Development of a Patient-Reported Outcome for Older Children and Adults with Nephrotic Syndrome as Part of "Preparing a Clinical Outcomes Set for Nephrotic Syndrome" (Prepare-NS)

Eloise Salmon,[1] Kayla Sifre,[1] Courtney N. Hurt,[2] Rebecca Scherr,[1] Patrick H. Nachman,[4] David T. Selewski,[3] Noelle E. Carlozzi,[1] Jin-Shei Lai,[2] John D. Peipert.[2] *[1]University of Michigan, Ann Arbor, MI; [2]Northwestern University Feinberg School of Medicine, Chicago, IL; [3]Medical University of South Carolina, Charleston, SC; [4]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN.*

Background: Individuals with nephrotic syndrome (NS) experience fluid overload (FO) which can impact health-related quality of life (HRQOL). In partnership with the Food and Drug Administration (FDA), Prepare-NS aims to create and validate clinical outcome assessments (COAs) of FO in NS for use in drug development.

Methods: Context of use includes the following NS diagnoses: FSGS, minimal change disease, childhood-onset (not biopsied), membranous nephropathy, and IgM nephropathy. Participants with swelling in the past 90 days and not on dialysis volunteered via study website to complete an interview and consent (parental for participants under 18) was obtained. Concept elicitation interviews occurred via Zoom or phone and discussed how NS impacts functioning. Interview transcripts were coded in NVivo by two independent raters according to established standards for qualitative analysis. Recurring themes informed the conceptual model.

Results: To date, 25 participants have completed interviews. Image 1 shows participant demographics. Themes overall were consistent among age, sex, race, and diagnostic subgroups. Image 2 shows the conceptual model.

Conclusions: FO impacts HRQOL in the domains of physical function, fatigue, pain, sleep disturbance, gastrointestinal symptoms, appetite loss, and other essential functions. The next phase of Prepare-NS will be to develop the PRO inclusive of items to assess the impact of FO that is likely to be modifiable in NS disease modifying drug development.

Patterns of Acute Care Utilization and Health-Related Quality of Life in Primary Glomerulonephropathy Patients

Chien-Wen Yang,[1] Qian Liu,[2] Dorey A. Glenn,[3] Michelle Denburg,[4] Jarcy Zee.[1,2] *[1]University of Pennsylvania, Philadelphia, PA; [2]The Children's Hospital of Philadelphia Research Institute, Philadelphia, PA; [3]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [4]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: The relationship between acute care utilization and health-related quality of life (HRQOL) in patients with GN is unclear. We hypothesize that the number of acute care events (ACE) will be associated with worse HRQOL among adults and children in CureGN.

Methods: CureGN is a prospective observational cohort of primary GN including minimal change disease, IgA nephropathy/vasculitis, focal segmental glomerulosclerosis, and membranous nephropathy. Linear mixed effect models were used to explore the association between HRQOL and the number of ACE (hospitalizations and emergency room visits) within the prior 3 months. HRQOL was self-reported for adults and children ≥8 years old and reported by parent proxy for children <11 using the PROMIS instrument. Models were adjusted for potential confounders, including HRQOL measures before the 3-month ACE period, comorbidities, socioeconomic factors, and medication exposure.

Results: Among 2393 patients, 1282 experienced at least one ACE with an incidence of 75 events per 100 person-years. Infection, gastrointestinal and cardiovascular events were the most common diagnoses (15, 9, and 6 events per 100 person-years, respectively). Among adults and children ≥8, a greater number of ACE was associated with worse fatigue ($p<0.001$), general physical health ($p<0.001$), mobility ($p=0.001$), and global health ($p=0.005$). Among proxy-reported PROMIS measures, a greater number of ACE was associated with worse fatigue ($p=0.001$), mobility ($p<0.001$), and global health ($p<0.001$).

Conclusions: Having more ACE was associated with worse HRQOL in several physical health domains among patients with GN. Our study reinforces the healthcare burden of GN and helps identify risk factors for deterioration in the patient experience.

Funding: Other NIH Support - pharmacoepidemiology T32

Table. A Summary Table of the Association Between Number of 3-Month Acute Care Events and Each Domain of PROMIS Scores.

PROMIS Domain	β Coefficient (95%CI)	p value
Self-reported		
Anxiety	0.11 (-0.35, 0.57)	0.629
Fatigue	1.09 (0.51, 1.67)	<0.001
Sleep impairment	-0.09 (-0.77, 0.58)	0.790
General mental health	-0.42 (-1.02, 0.18)	0.168
General physical health	-1.24 (-1.81, 0.68)	<0.001
Mobility	-1.73 (-2.72, 0.75)	0.001
Global health	-1.52 (-2.58, -0.45)	0.005
Proxy-reported		
Fatigue	1.81 (0.76, 2.86)	0.001
Mobility	-1.64 (-2.38, -0.90)	<0.001
Global health	-1.85 (-2.82, -0.88)	<0.001

*The coefficient represents the change in the PROMIS score for each one count increase in ACE.
*Adjusted for age, sex, level of education, insurance type, country of residence, time from biopsy to enrollment, prior PROMIS scores, years from time of biopsy, student-employment status, number of comorbidities, edema status, weight status, eGFR, urine protein creatinine ratio, serum albumin and immunosuppressant exposures.

TH-PO595

Health-Related Quality of Life (HRQoL) in Adults with Primary Glomerular Diseases in India

Amritesh Grewal, Bhavik Bansal, Arunkumar Subbiah, Dipankar M. Bhowmik, Sanjay K. Agarwal, Soumita Bagchi. *All India Institute of Medical Sciences, New Delhi, India.*

Background: There is paucity of information about the health-related quality of life (HRQOL) of patients with glomerular diseases.

Methods: We used PROMIS 29 v2.1 (Patient-Reported Outcomes Measurement Information System) tool to assess the HRQoL impact of primary glomerular diseases in adult patients, under the following domains: physical function, anxiety, fatigue, depression, sleep disturbance, ability to participate in social roles and activities, and pain interference in daily activities. A composite score representing the patient's global HRQoL was calculated using T scores (mean=50, standard deviation=10) of individual domains derived from patient responses. Multivariable linear regression models were evaluated for all domains and composite scores independently.

Results: 301 patients were recruited (100 minimal change disease/focal segmental glomerulosclerosis, 75 membranous nephropathy, 109 IgA nephropathy, and 17 membrano-proliferative glomerulonephritis). Mean T-scores were: physical function - 48 (47.6-49.9), fatigue - 48.7 (47.6-49.9), anxiety - 51.4 (50.3-52.6), sleep impairment - 44 (42.9-45), depression - 50.1 (49-51.2), ability to participate in social roles and activities - 55.6 (54.5-56.7), hindrance in daily activities due to pain - 51 (50-52). Worse physical function was significantly associated with female sex (β=3.28), low eGFR (<60ml/min/1.73m^2) (β=2.45), unemployed status (β=2.12), obesity (BMI>30) (β=4.4), and edema (β=2.71); fatigue with female sex (β=4.9), low eGFR (β=3.51) and obesity (β=7.41); anxiety with recent steroid use (β=2.61), female sex (β=3.74), and low eGFR (β=2.74) and sleep impairment with recent steroid use (β=3.46), female sex (β=2.56), lower eGFR (β=3.37) and edema (β=4.02). Depression was higher with obesity (β=5.0) and low eGFR (β=2.4) and pain interference with female gender (β=5.95), low eGFR (β=2.38), and obesity (β=4.0). Decreased ability to perform social roles was seen in females (β=4.6), and obese individuals (β=2.58). Lower composite scores (worse global quality of life) were associated with female sex (β= 3.65), lower eGFR (β= 3.14), and obesity (β=4.02).

Conclusions: Glomerular diseases adversely impact quality of life. Female sex, lower renal function, obesity, clinically apparent edema, and recent steroid use correlate with higher morbidity.

TH-PO596

Association Between Social Vulnerability, Environmental Burden, and Kidney Outcomes Among Individuals with Glomerular Disease: Results from the Cure Glomerulopathy Network (CureGN)

Loryn W. Dass,[1] Abigail R. Smith,[2] Jill Krissberg,[3] Chia- Shi Wang,[5] Bruce M. Robinson,[2] Rasheed A. Gbadegesin,[1] Gaurav Dave,[4] Keisha L. Gibson.[4] *[1]Duke University School of Medicine, Durham, NC; [2]University of Michigan, Ann Arbor, MI; [3]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [4]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Emory University School of Medicine, Atlanta, GA.*

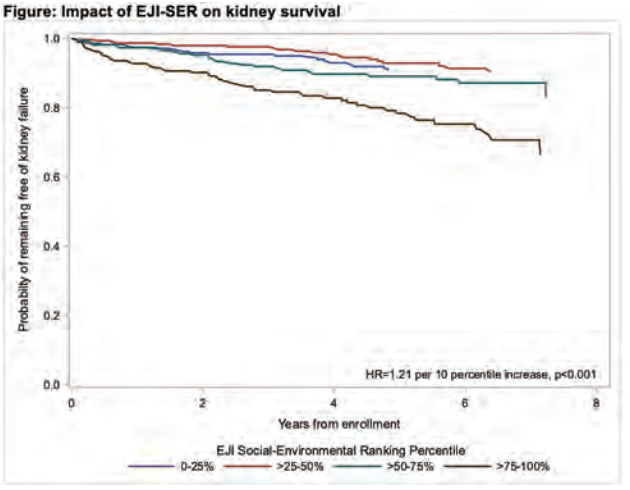
Background: The CDC Environmental Justice Index Social-Environmental Ranking (EJI-SER) combines a Social Vulnerability Module (SV) with an Environmental Burden Module (EB) to characterize cumulative environmental and social burden at the census tract level. With this analysis, we evaluate the association between EJI-SER and kidney outcomes in patients with glomerular disease (GD).

Methods: CureGN is an observational cohort study of adults and children with biopsy-proven GD. EJI-SER is percentile ranking by census tract, with higher score indicating more severe SV and EB burden. Associations between EJI-SER and its components with kidney failure (initiation of kidney replacement therapy, transplant, or 2 eGFRs <15ml/min/1.73m^2) and longitudinal eGFR were tested using multivariable Cox regression and linear mixed models, respectively, adjusted for demographics, histologic diagnosis, eGFR and urine protein to creatinine ratio at enrollment, and time from biopsy to enrollment.

Results: Among 1,131 participants with census tract data, median follow-up was 5.1 years (IQR 3.0-6.6) and median age at biopsy was 24 with 5% Asian, 18% Black, and 70% White. Median EJI-SER was 0.49 (IQR 0.26-0.75). EJI-SER was associated with higher hazard of kidney failure (adjusted HR 1.12 per 10 percentile increase [95% CI, 1.04-1.20]) and lower eGFR (mean eGFR 9.3 ml/min/1.73m^2 lower for EJI-SER >75th versus ≤25th percentile, p<0.001).

Conclusions: As captured by EJI-SER, higher environmental and social burden are associated with lower eGFR and higher risk of kidney failure in the CureGN cohort. This first use of the EJI-SER in GD demonstrates the need for additional investigation into drivers of disparities in GD and policies and resources that address these structural inequities.

Figure: Impact of EJI-SER on kidney survival



TH-PO597

Humanistic Burden of Rare Kidney Diseases: Understanding the Impact of IgA Nephropathy (IgAN) and FSGS on Patients and Care Partners Study (HONUS): Preliminary Results for FSGS in the United States (US)

Justyna Szklarzewicz,[1] Mark E. Bensink.[2] On Behalf of HONUS Advisory and Study Team Members. *[1]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [2]Travere Therapeutics Inc, San Diego, CA.*

Background: FSGS is known to cause significant clinical and economic burden, however, less is known about the humanistic burden associated with the disease. HONUS is a multi-national, cross-sectional survey study to evaluate humanistic burden of rare kidney diseases, including FSGS.

Methods: The study recruited adult patients with their care-partners, and parents of youth (8-17 years) with FSGS or IgAN. The survey collects data on demographic/clinical characteristics, health-related quality of life (HRQoL, 12-Item Short Form Survey [SF-12], PedsQL) and disease impact on employment (Work Productivity and Activity Impairment [WPAI]). This preliminary analysis uses US data collected from FSGS adult patients, their care-partners, and parents of youth with FSGS by April 2023. Data were evaluated descriptively.

Results: The analysis included 76 adult FSGS patients and their care-partners, and 29 parents of youth with FSGS (proxy for pediatric patients). Most patients were Caucasian (adults, 68%; pediatric, 69%) and female (adults, 76%; pediatric, 59%), with a mean age of 44 years (adults) and 12 years (pediatric). Most adult patients were in CKD stages 3-5 (3, 26%; 4, 4%; 5, 25%); 13% had received transplant. For adult patients, mean SF-12 physical and mental component scores (PCS, MCS) were 41.5 and 44.5, respectively, lower (reflecting worse HRQoL) than previously published mean scores (MCS and PCS of 50) for the US general population. Parents of pediatric patients reported a mean total PedsQL (parent proxy) score of 65.8, lower (reflecting worse HRQoL) than previously published scores (parent proxy range: 82-88) for healthy US pediatric populations. Adult patients reported 39% activity impairment and 28% overall work productivity loss due to FSGS-related reasons, while care-partners/parents of adult and pediatric patients reported overall work productivity loss of 15% and 31%, respectively, due to FSGS-related reasons.

Conclusions: Both adult and pediatric patients with FSGS experience impaired HRQoL compared to the US general population, impacting adult work productivity and that of care-partners and parents.

Kidney Diseases Associated with Inflammatory Bowel Disease

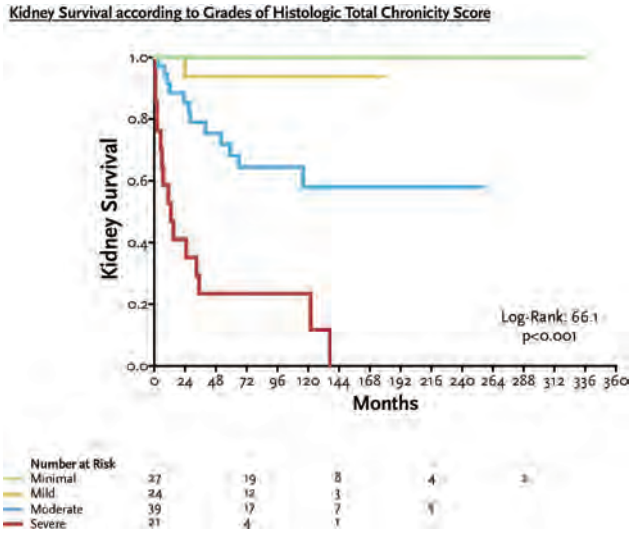
Federico Yandian,[1] Fernando Caravaca-Fontan,[2] Loren P. Herrera Hernandez,[3] Maria Jose Soler,[4] Sanjeev Sethi,[3] Fernando C. Fervenza.[5] *[1]Department of Nephrology, Hospital de Clínicas "Dr. Manuel Quintela", Montevideo, Uruguay; [2]Instituto de Investigación Hospital "12 de Octubre", Madrid, Spain; [3]Mayo Clinic Department of Laboratory Medicine and Pathology, Rochester, MN; [4]Vall d'Hebron University Hospital, Universitat Autònoma de Barcelona, Barcelona, Spain; [5]Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.*

Background: Kidney disease is a well-known extra-intestinal manifestation associated with intestinal bowel disease (IBD), with different underlying etiologies. Little is known about the overall outcomes and predictors.

Methods: Retrospective, observational, cohort study. Patients with previous diagnosis of IBD in whom a kidney biopsy was performed at Mayo Clinic between 1994–2022, were included. Kidney transplant patients were excluded. The main outcomes were kidney failure (defined as eGFR<15 ml/min/1.73m²) and kidney function recovery at last follow-up (categorized as ≥75%, 25–75%, <25% of baseline eGFR).

Results: From a total cohort of 318 patients, 111 patients with IBD and long-term follow-up available were selected (45 ulcerative colitis and 66 Crohn's disease), with a mean age 48±17 years (40% females). Sixty-eight (61%) were under treatment with 5-ASA. IgA nephropathy, chronic interstitial nephritis and acute interstitial nephritis were the most common diagnoses (22%, 19%, 13%). Median eGFR at presentation was 30 [IQR17–54] ml/min/1.73m² and urinary protein-to-creatinine ratio 0.8 [0.3–3.4] g/g, with no differences between type of IBD. During a median follow-up of 59 (12–109) months, 29 (26%) patients progress to end-stage kidney disease (ESKD). By multivariable Cox regression analysis, the main predictors of kidney failure were age (HR: 1.04; p=0.002), baseline eGFR (HR: 0.94; p=0.003) and histologic total chronicity score (HR: 4.01; p<0.001). 26 (24%), 19 (17%), and 66 (59%) achieved complete, partial or no remission/recovery of kidney function, respectively. Global survival (ESKD+death) was significantly better in patients who achieved complete/partial recovery of kidney function.

Conclusions: One-fourth of patients with kidney disease associated with IBD progress to ESKD, and the main determinants of this outcome is age, baseline eGFR and degree of chronicity in kidney biopsy.



TH-PO599

Kidney Disease Outcomes in Patients with Inflammatory Bowel Disease

Manish K. Saha,[1] Duvuru Geetha,[2] Louis-Philippe Laurin,[3] Simon Leclerc,[3] Ronald Falk,[1] Susan L. Hogan,[1] Amy K. Mottl,[1] Yichun Hu,[1] Vimal K. Derebail.[1] *[1]University of North Carolina, Chapel Hill, NC; [2]Johns Hopkins University, Baltimore, MD; [3]Universite de Montreal, Montreal, QC, Canada.*

Background: Patients with inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC) may have extra-intestinal manifestations (EIM). The prevalence of histologic patterns of kidney disease seen in IBD patients is known, but clinical characteristics and long-term kidney outcomes remain ill-defined.

Methods: We performed a multi-center, retrospective, study of IBD patients who had a kidney biopsy across 3 centers. Inclusion criteria were: (i) IBD diagnosis based on clinical/histological characteristics and (ii) kidney biopsy with pathology report available. Baseline clinical data were analyzed for the whole cohort while outcomes were evaluated in those with available follow-up. Between groups, comparisons for continuous variables were made using Wilcoxon two-sample test and Fisher's exact test for categorical values.

Results: The frequency of various glomerular (GN), tubulointerstitial (TIN), and vascular (VD) processes are listed in Table 1. Patients with VD were older compared to other groups. At presentation, proteinuria was higher in patients with GN compared to those with TIN [2.13 (0.84, 4.07) vs. 0.30 (0.25, 1.25) p<0.05] and kidney function was worse in those with TIN compared to GN (3.10 [1.98, 4.50] vs. 2.10 [1.20, 3.11], p=0.05]). TIN occurred in 3 treatment naïve patients. In median follow-up of >3 years, 6 of 35 (17%) GN patients, 1 of 8 (12.5%) TIN, and 2 of 4 (50%) VD patients developed ESKD.

Conclusions: Patients with IBD may have varying forms of CKD including GN, and routine monitoring of kidney function is essential for early diagnosis and treatment. TIN may occur as an EIM independent of sulfasalzine therapy. Future studies are required to understand plausible shared immunopathogenesis.

Table 1 Frequency of various kidney diseases in patients with IBD

	CD+UC+IBD@ n=96	CD n=56	UC n=36
IgAN	18	11	6
FSGS	10	6	3
Amyloidosis-MGRS	8	5	3
ANCA-vasculitis	8	3	5
Other GN	12	5	7
TIN	14	8	5
VD	12	8	4
Others	9	6	3

@IBD - 4 patients had IBD without distinctive features of CD/UC -- 1 each had IgAN, FSGS, TIN, ATN

4 patients in CD and 1 in UC group had only ATN; MGRS=monoclonal gammopathy of renal significance, ANCA=Anti-neutrophil cytoplasmic antibody; Others: neoplasm, non-specific interstitial fibrosis

TH-PO600

Frequency of Adverse Events and Risk of Relapse Following SARS-CoV-2 Vaccination in Patients with Glomerular Diseases: A Multicentre Retrospective Study

Sophia Lionaki,[1,2] Kriki Pelagia,[3,4] Smaragdi Marinaki,[5] Dimitra Gkalitsiou,[6] Evangelia Dounousi,[7,8] Sofia Flouda,[1] Vassilios Liakopoulos,[9] Vasileios Vaios,[9] Angeliki Sardeli,[1] Ioannis Bellos,[10,5] Zoi Kleinaki,[2,5] Giannakopoulos Panagiotis,[1,10] Louiza Gkika,[7,8] Marios Papasotiriou,[11] Aliki I. Panagoutsos,[4,3] Ioannis Boletis.[2,5] *[1]Panepistemiako Geniko Nosokomeio Attikon, Athens, Greece; [2]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [3]University of Thrace, Alexandroupolis, Alexandroupolis, Greece; [4]Demokriteio Panepistemio Thrakes, Komotini, Greece; [5]Laiko Geniko Nosokomeio Athenon, Athens, Greece; [6]Geniko Nosokomeio Athenon Giorgos Gennematas, Athens, Greece; [7]Panepistemio Ioanninon, Ioannina, Greece; [8]Panepistemio Ioanninon Tmema Iatrikes, Ioannina, Greece; [9]Aristoteleio Panepistemio Thessalonikes, Thessalonike, Greece; [10]Ethniko kai Kapodistriako Panepistemio Athenon, Athens, Greece; [11]Panepistemio Patron, Patra, Greece; [12]Panepistemiako Geniko Nosokomeio Erakleiou Iatrike Yperesia, Heraklion, Greece.*

Background: Sars-cov2 vaccination has altered the natural course of COVID-19. We aimed to explore the frequency of adverse events of vaccination in patients with glomerular diseases (GD) including the risk of GD relapse afterwards.

Methods: Patients were included if they had biopsy-proven GD and received at least one dose of sars-cov2 vaccine. Patients who ended up in ESKD prior to vaccination or received a GD diagnosis after vaccination were excluded. We recorded demographics, histopathological diagnosis, immunosuppressive regimens, GD outcome before and after vaccination, and adverse events associated with the vaccine. Outcomes of GD included remission, relapse, treatment resistance, ESKD, and death. The rate of GD relapse post vaccination was estimated among patients who had achieved remission.

Results: 315 patients with biopsy-proven GD prior to sars-cov2 vaccination were included, with a mean age of 51(36-63) years at the time of diagnostic biopsy, of whom 142(45.1%) were males. Patients received a median of 3(3-4) vaccine doses. The median time from the diagnostic kidney biopsy to the 1st vaccine dose was 48.9(19.8-106.2) months. Among 255 patients with known GD status at vaccination, 139 (44.1%) were on immunosuppressive therapy, 224(87.8%) were on remission and 31(12.2%) were still active. 66(21.0%) patients reported systemic side effects (fever, arthralgias, myalgias) and 122(38.7%) local side effects (pain, swelling, itching, edema) associated with the vaccination. Renal function and 24-hour proteinuria remained stable after vaccination. Among patients in GD remission at vaccination, 23(9.0%) experienced a relapse during a follow up time of 18.2(15.5-20.1) months. Of those, 8 (7.8%) were on immunosuppression and 15 (18.1%) were not (p=0.058). The mean time to GD relapse following vaccination was 2.5(1.2-6.4) months.

Conclusions: According to the findings from this cohort, vaccination against sars-cov2 appears safe for patients with GD, with no significant impact in renal function or the probability for relapse.

TH-PO601

Outcomes of COVID-19 Infection in Patients with ANCA-Associated Vasculitis Receiving Avacopan Therapy

Faten Aqeel,[1] Reza Zonozi,[2] Anushya Jeyabalan,[2] Gabriel Sauvage,[2] John Niles,[2] Duvuru Geetha.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Harvard University, Cambridge, MA.*

Background: The complement C5a-C5aR signaling axis plays a crucial role in the pathogenesis of ANCA-associated vasculitis (AAV) and COVID-19 infection. Avacopan, a C5aR antagonist is approved as an adjunct therapy for remission induction in AAV. Vilobelimab, a C5a antibody was granted Emergency Use Authorization by the FDA for severe COVID-19 infection. In AAV, COVID-19 infection poses an increased mortality risk. Additionally, the risk of severe COVID-19 infection is increased in patients receiving rituximab and glucocorticosteroids.

Methods: We performed an observational, retrospective study examining outcomes of patients with AAV treated with avacopan and who had COVID-19 infection. Data on ANCA type, immunosuppressive treatment, COVID-19 course, and COVID-19 vaccination status were retrieved after a review of the electronic medical records.

Results: A total of 7 patients were included. The mean (SD) age was 65.1 (±17.5) years old. Four patients had MPO-AAV and 3 patients had PR3-AAV. Two patients had a relapsing disease, and the rest had a new diagnosis of AAV. Six patients received at least 3 COVID-19 vaccines and a single patient received two COVID-19 vaccines. Five patients received a combination of rituximab, cyclophosphamide, glucocorticoids, and avacopan, whereas 2 patients received rituximab, glucocorticoids, and avacopan. The mean (SD) time from the date of initiation of induction immunosuppression to avacopan initiation was 20 (±21.5) days. The mean (SD) time from avacopan initiation to COVID-19 infection was 110 (±62) days. At the time of COVID-19 infection, all patients remained on rituximab therapy. The mean (SD) time between the last rituximab dose and the onset of COVID-19 infection was 63.8 (±57.1) days. Avacopan was continued in all patients. COVID-19 treatment included Paxlovid (n=3), Bebtelovimab (n=1), Molnupiravir (n=1), remdesivir and dexamethasone (n=1), and no treatment (n=1). All patients had mild symptoms except one patient who was hospitalized and died from severe COVID-19 infection.

Conclusions: COVID-19 clinical course appears to be mild in the majority AAV patients treated with avacopan, with a single patient experiencing severe COVID-19 infection and death. More studies are needed to explore the interplay between C5a blockade and infectious complications from SARS-CoV-2.

TH-PO602

Analysis of Clinical Features in ANCA-Associated Rapidly Progressive Glomerulonephritis Treated with Avacopan: A Single-Center Experience in Japan

Soko Kawashima. *Kyorin Daigaku Igakubu Fuzoku Byoin, Mitaka, Japan.*

Background: Although avacopan (AVA) has recently become available as an induction therapy of ANCA-associated vasculitis, but the use of corticosteroid has not been established. Therefore, we conducted a retrospective analysis of the clinical database of ANCA-associated rapidly progressive glomerulonephritis (ANCA-RPGN)-patients in our hospital with a reduced regimen of corticosteroids.

Methods: All patients met the CHCC classification criteria for MPA and GPA at disease onset. Seven patients [3(43%) females)] followed for at least 12 weeks since Aug 2022 (up to Apr 2023) were analyzed for clinical course, including remission rates. Remission was defined as Birmingham Vasculitis Activity Score (BVAS) 0. GC Pulse, RTX, and AVA were used for induction therapy. PSL was begun at a dose of 0.4-1.0 mg/kg/day and then tapered off at 12 weeks.

Results: AVA was used in 12 patients with AAV, of whom 7 presented with RPGN. Of the 7 patients with renal involvement (4 MPO-MPA, 2 MPO-GPA and 1 PR3-GPA), 6 newly diagnosed and 1 relapsing disease received a remission induction. The mean age was 70.0±12.1 years, mean BVAS was 16.4±3.1, prednisolone (PSL) was 52.1±17.8 mg/day. At the start of AVA, s-Cr was 2.3±1.1 mg/dL, eGFR was 25.0±11.8 ml/min/1.73m^2, CRP was 1.9±3.1 mg/dL and the dose of PSL was 37.1±17.0 mg/day. At week 12 and 24, percentages of participants who could discontinue PSL were 43%, 60% and remission rates were 100%, 80%, respectively. There were no serious adverse events and no patients requiring maintenance dialysis. At week 12 and 24, doses of PSL were 3.6±4.5/1.5±2.2 mg/day, s-Cr were 1.6±0.6 /1.7±0.7 mg/dL, eGFR were 34.2±14.2 /35.6±17.7 ml/min/1.73m^2 and CRP were 2.7±6.7/0.11±0.09 mg/dl, respectively.

Conclusions: These results showed that AVA may be effective and have acceptable safety profiles in relatively elder AAV-RPGN patients in daily practice in Japan.

TH-PO603

Treatment, Relapse, and Complications of Myeloperoxidase (MPO) and PR3 ANCA-Associated Glomerulonephritis: Report from an Australian Centre

Ken W. Chau,[1,2] Tien K. Khoo,[2,3] Alfred K. Lam,[2] Dwarakanathan Ranganathan.[1,2] *[1]Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Griffith University, Gold Coast, QLD, Australia; [3]University of Wollongong, Wollongong, NSW, Australia.*

Background: ANCA-associated vasculitis is a group of autoimmune vasculitides of unknown aetiology, with different phenotypic manifestations. Myeloperoxidase (MPO) and Proteinase 3 (PR3) have emerged as two main serological subtypes and growing evidence reported differences between their disease characteristics. We investigate the disease manifestation, progression and complications in patients with biopsy-confirmed ANCA-associated glomerulonephritis (AAGN).

Methods: This retrospective study was performed at the Royal Brisbane and Women's Hospital, a major tertiary hospital with a population catchment of approximately 1,030,006 people in North Brisbane, Australia. Patients with pauci-immune glomerulonephritis confirmed on kidney biopsy between 1st January 2005 to 1st October 2021 were identified. Clinical data were collected via medical records.

Results: A total of 1,433 kidney biopsy results were reviewed. 80 cases of pauci-immune AAGNs were identified. Majority were MPO-positive AAGN (53/80), as opposed to PR3-positive disease (21/80). 5/80 were ANCA negative and 1/80 did not have ANCA serology available. Pulmonary involvement rates in PR3 and MPO AAGN were similar at 29% (6/21) and 30% (16/53) respectively. Majority patients (58/73) had induction treatment with cyclophosphamide. More patients on cyclophosphamide developed malignancy compared to the patients on alternative therapy (14% (8/58) vs 5% (1/22), p=0.43). Approximately one in five (17/80) patients had a relapse over the study period. More relapses occurred in PR3 than MPO disease (38% (8/21) vs 13% (7/53), p=0.02). Most relapses (12/17 cases) occurred within 2 years of diagnosis. The longest time to relapse was 12 years. Numerous AAGN cases developed deep vein thrombosis or pulmonary embolism (8/80). The risks were higher in PR3 compared to the MPO group (3/21 vs 4/53, RR 1.89). Malignancy was common (16/80). No difference was observed between MPO and PR3 subgroups (21% vs 24%). 56% (9/16) of malignancies were diagnosed after AAGN diagnosis.

Conclusions: This is the first study in Australia that reports on AAGN outcomes and disease associations. Both, MPO and PR3 AAGN are associated with pulmonary involvement. PR3 AAGN is associated with a significantly higher relapse rate compared to MPO disease, this finding is consistent with other cohort studies in Europe.

TH-PO604

Burden of Infection-Related Hospitalization and the Impact of Multidisciplinary Care in ANCA-Associated Vasculitis: A Retrospective Cohort

Emily K. Yeung, A. Richard Kitching, Michael Gingold, Kevan Polkinghorne, Jessica Ryan. *Monash Health, Clayton, VIC, Australia.*

Background: ANCA associated vasculitis (AAV) is managed with combination immunosuppression. Infections are the most common cause of excess morbidity and mortality. Multidisciplinary clinics have improved outcomes in several chronic diseases but have not been evaluated in AAV.

Methods: A retrospective cohort study was performed of patients diagnosed with AAV at Monash Health in Melbourne, Australia between January 1, 2000 and February 28, 2018, excluding children and those with EGPA. Hospitalization rate was calculated as number of hospitalized patients out of those at risk excluding day admissions. Survival analysis was performed, with subjects entering analysis at diagnosis.

Results: Of 165 patients, 22 were hospitalized for infection within the first 12 months of AAV diagnosis with a hospitalization rate of 15 per 100 person-years. Median length of stay was 9.4 days. Hospitalization rate for infection did not change with vasculitis clinic establishment in 2014 (18 per 100 person-years pre vs. 8 per 100 person-years post, p=0.10). After infection, kidney disease (excluding routine dialysis), cardiovascular disease, and disease relapse accounted for the greatest burden of hospital days. Hospitalization rate for any cause reduced from 70 per 100 person-years before clinic establishment to 51 per 100 person-years after (p=0.02). Those with MPA were at comparable risk of death to those with GPA (HR 1.22, 95% CI 0.53-2.80). Where known, the most common cause of death was infection, followed by kidney failure (dialysis non-commencement for medical or social reasons), and malignancy within the first 12 months of AAV diagnosis.

Conclusions: Establishment of a multidisciplinary vasculitis clinic was associated with a significant reduction in hospitalization rate for any cause, with a trend toward a reduction in hospitalization rate for infection. Infection was the most common cause of death.

Table 1: Demographics & Characteristics of Included Patients

	MPA n=112	GPA n=53	p-value
Age*	63.4 (60.7-66.0)	54.7 (50.0-59.3)	<0.001
Male	59 (52.7)	36 (67.9)	<0.001
System involvement			
Renal	104 (92.8)	38 (71.7)	0.001
Dialysis	49 (43.8)	16 (30.2)	0.001
ESKD**	37 (33.0)	11 (20.8)	0.001
Ear/Nose/Throat	12 (10.7)	27 (50.9)	0.001
Lung	39 (34.8)	33 (62.3)	0.001
Eye	2 (1.8)	9 (17.0)	0.001
Arthritis	13 (11.6)	13 (24.5)	0.04
Neurological	8 (7.1)	5 (9.4)	0.85
Gastrointestinal	6 (5.4)	4 (7.5)	0.25
Skin	11 (9.8)	8 (15.1)	0.05
Subglottic stenosis	0 (0)	0 (0)	

Note: values are mean (95% CI) or number (%)
No Aboriginal/Torres Strait Islander patients in the cohort
*Age at AAV diagnosis in years
**ESKD defined as requiring dialysis for >/= 90 days

TH-PO605

Changing Phenotypes and Clinical Outcomes over Time in Microscopic Polyangiitis

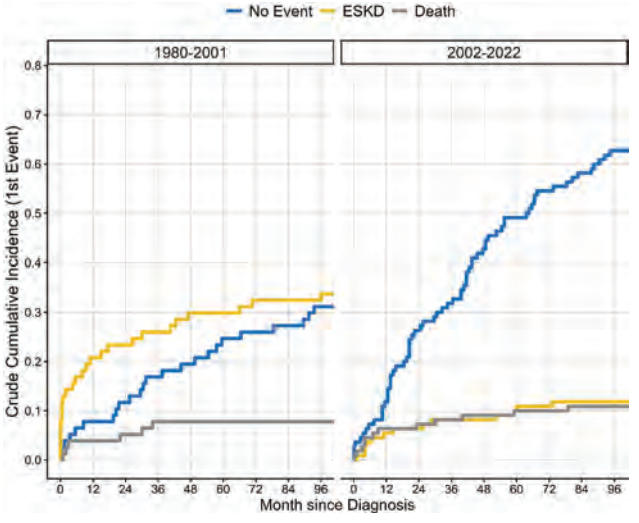
Martina Uzzo,[1,2] Umberto Maggiore,[3] Filippo M. Sala,[1,4] Francesco Reggiani,[2,5] Vincenzo L'Imperio,[6] Marta Calatroni,[2,5] Gabriella Moroni,[2,5] Renato A. Sinico.[2] *[1]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [2]Nephrology and Dialysis Unit, IRCCS Humanitas Research Hospital, Milano, Italy; [3]Nephrology and Dialysis Unit, Department of Medicine and Surgery, University of Parma, Parma, Italy; [4]Nephrology and Dialysis Unit, IRCCS Fondazione San Gerardo dei Tintori, Monza, Italy; [5]Department of Biomedical Sciences, IRCCS Humanitas Research Hospital, Milano, Italy; [6]Department of Medicine and Surgery, Pathology, University of Milano-Bicocca, IRCCS Fondazione San Gerardo dei Tintori, Monza, Italy.*

Background: Diagnosis and management of Microscopic Polyangiitis (MPA) have evolved considerably over the last decades, but it is unknown whether clinical, histological presentation and patient and renal outcomes have changed accordingly.

Methods: We compared clinical-histopathological characteristic at diagnosis, and the risk of death and of end stage kidney disease (ESKD) in patients diagnosed with MPA between 1980 and 2022, after grouping them in two periods (p): p1980–2001 and p2002–2022. We compared the mortality rate between the two periods using Kaplan-Meier estimator and Cox-regression and competing risks of ESKD and death using the Aalen-Johansen estimator, Fine-Gray multiple regression and multi-state models.

Results: Out of 187 patients, 77 were in p1980-2001, and 110 in p2002-2022. Patients in p2002-2022 were older (66.2(14.0) vs 57.7(15.8); P<0.001), had a better kidney function (eGFR 25.9(24.8) vs 21.5(28.2) mL/min/1.73m^2; P=0.011) and a lower prevalence of the Berden sclerotic class (4.8 vs 18.2%; P=0.006). Despite a similar crude and adjusted patient survival, the risk of ESKD decreased during p2002-2022, compared to p1980-2001 (0.30 [95%CI:0.16-0.57; P<0.001]) (**Figure**). The result remained significant after accounting for death after ESKD in multistate models and after adjusting for potential confounders (0.33 [95%CI:0.18-0.63; P<0.001]).

Conclusions: Clinical presentation of MPA has become less severe over the last decades, leading to a reduced risk of ESKD, despite a comparable risk of death. Older age, changing clinical patterns and better kidney function at the time of diagnosis do not fully account for the reduction in ESKD, which may be instead related to new induction and maintenance therapies as well as to a greater awareness of the disease.



TH-PO606

Non-Lupus Full House Nephropathy: A Debatable Entity

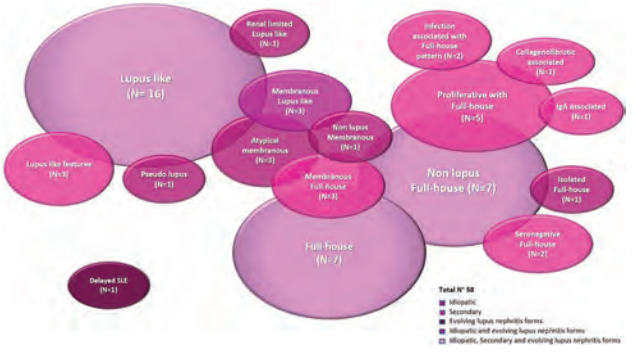
Martina Uzzo,[1,2] Andreas Kronbichler,[3] Federico Alberici,[4] Ingeborg M. Bajema.[2] *[1]Department of Medicine and Surgery, University of Milano-Bicocca, Monza, Italy; [2]Department of Pathology and Medical Biology, University of Groningen, University Medical Center, Groningen, Groningen, Netherlands; [3]Department of Internal Medicine IV, Medical University, Innsbruck, Austria; [4]Nephrology Unit, University of Brescia, Azienda Socio Sanitaria Territoriale Spedali Civili, Brescia, Italy.*

Background: Lupus nephritis (LN) is characterized by a variety of light microscopic findings on kidney biopsy and a full house (FH) pattern at immunofluorescence/immunohistochemistry. A FH pattern and lesions consistent with LN, in a patient without clinical and laboratory features of SLE have led to the descriptive term non-lupus full house nephropathy (NLFHN). We performed a systematic review focussing on NLFHN nomenclature, clinical findings and outcome.

Methods: In a reiterative process, all identified terms for NLFHN and other MeSH terms were searched in PubMed. 346 records were screened according to inclusion and exclusion criteria. The 58 records identified were published between 1982 and 2022 and 60.3% were case reports. The available clinical data of patients from different reports were collected and analysed.

Results: NLFHN was addressed with 22 different names: the same name used by different authors could refer to different entities (Figure 1). We identified 148 patients: 75(50.7%) were males; median age 35(23-58) years. Creatinine and proteinuria at onset were 1.4(0.8-2.5) mg/dL and 5.7(2.7-8.8) g/day. Less than 1/3 of patients achieved complete renal response (CRR). A clear causative agent was identified in 50 patients, mainly infective (50%). Secondary NLFHN were acute, non-relapsing diseases with lower renal function at onset compared to the idiopathic ones (P=0.001). Among the 57 patients with idiopathic NLFHN, CRR was comparable between patients treated with immunosuppression (IS) and supportive therapy; however, proteinuria and creatinine at onset were higher in patients treated with IS (P=0.089 and P=0.066). Only 8 patients developed SLE after a median follow-up of 5.0(1.9-9.0) years.

Conclusions: Despite increasing interest, the place of NLFHN among glomerular diseases is still uncertain, which complicates treatment decisions. Confusion arises by the lack of high-quality evidence and the lack of consensus on nomenclature. The description of three pathogenic categories is a step forward towards a shared framework of this rare entity.



TH-PO607

The Clinical Value of Monoclonal Protein in ANCA-Associated Vasculitis with Renal Involvement

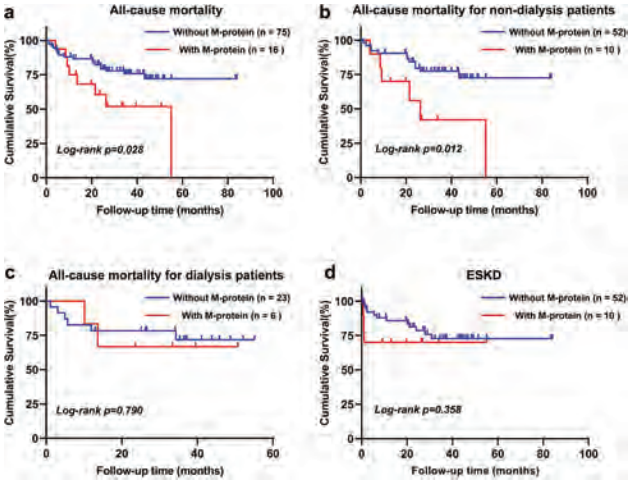
Yue Wang, Jiachuan Xiong. *Army Medical University Xinqiao Hospital, Chongqing, China.*

Background: The value of monoclonal protein (M-protein) in antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) patients with renal involvement has not been investigated.

Methods: We analyzed AAV patients with renal involvement from 2013 to 2019 in our center. Patients with immunofixation electrophoresis were divided into M-protein positive group and M-protein negative group. The clinicopathological features and outcomes of the two groups were compared.

Results: Ninety-one AAV patients with renal involvement were enrolled for analysis, and 16 patients (17.6%) had a positive test for M-protein. Compared with M-protein negative patients, M-protein positive patients had lower hemoglobin (77.6 *vs.* 88.4 g/L, $p = 0.016$), MCHC (313 *vs.* 323 g/L, $p = 0.002$), serum albumin (29.4 *vs.* 32.5 g/L, $p = 0.026$) and complement 3 (C3) (0.66 *vs.* 0.81 g/L, $p = 0.047$), while higher platelets (252 *vs.* 201 10^9/L, $p = 0.048$) and incidence of pulmonary infection (62.5% *vs.* 33.3%, $p = 0.029$). However, renal pathological features between the two groups had no significant difference. In addition, during a median follow-up of 33 months, Kaplan-Meier survival analysis showed that, compared with M-protein negative patients, M-protein positive patients had a higher risk of all-cause mortality (log-rank test, $p = 0.028$), especially for patients who were not dialysis-dependent at the time of admission (log-rank test, $p = 0.012$).

Conclusions: Our results indicate that M-protein is associated with different clinicopathological features and increased all-cause mortality in AAV patients with renal involvement. Testing M-protein and rigorous diagnosing of the significance of the presence of M-protein may be helpful for assessing the survival of AAV patients with renal involvement.



TH-PO608

Impact of Sex in Clinical Presentation and Outcomes of Patients with ANCA-Associated Vasculitis with Severe Kidney Diseases

Marta I. Casal Moura,[1,2] Marc Patricio-Liébana,[3] Dalia Zubidat,[1] Maria Jose Vargas-Brochero,[1] Nancy Daniela Valencia-Morales,[1] Miriam Machado,[1] Sana Abouzahir,[1] Ladan Zand,[1] Ulrich Specks,[1] Sanjeev Sethi,[1] Fernando C. Fervenza,[1] Maria Jose Soler.[3] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Universidade do Porto Faculdade de Medicina, Porto, Portugal; [3]Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: The impact of sex in the clinical presentation and outcomes of patients with anti-neutrophil cytoplasmic antibodies (ANCA) associated vasculitis (AAV) with glomerulonephritis (AAV-GN) has not been studied, particularly in patients with severe kidney involvement (eGFR<15mL/min/1.73m^2).

Methods: A retrospective cohort study on MPO-or PR3-ANCA patients with AAV (MPA or GPA) and eGFR<15 ml/min/1.73 m^2 or ESKD at presentation. Clinical presentation and outcomes were analyzed according with sex.

Results: We analyzed 166 patients with biopsy proven active AAV-GN and eGFR<15mL/min/1.73m^2 at diagnosis:78(47%) females and 88(53%) males. Arterial hypertension was more frequent in males (85.2%vs.70.5%,p=0.022). Median serum creatinine (SCr) was higher in males when compared with females (5.2[IQR 4.2-7.4]vs.3.6[IQR 2.8-5.1]mg/dL, p<0.001) but there were no differences in eGFR at presentation (9.9vs.12.1 mL/min/1.73m^2, p=0.053). There were no differences between groups in age at diagnosis, GPAvs.MPA, ANCA specificity, frequency of alveolar hemorrhage, BVAS score, chronicity score or crescentic features on kidney biopsy. Males received IV methylprednisolone more frequently (84.1%vs.69.2%,p=0.023), but other therapies were similar. Most patients who started dialysis within 4 weeks were males(53.4%vs.30.8%,p=0.003), however the rate of progression to ESKD at 12 months between groups was similar(p=0.186). When analyzing only the 71 patients that started dialysis within 4 weeks, infections at 12 months were more common in females (75.0%vs.36.2%,p=0.017). Rate of dialysis initiation or progression to ESKD was not different between males(n=61.7%) vs. females (n=62.5%) being on dialysis at 12 months. By multivariable logistic regression, factors related with dialysis initiation within 4 weeks in our cohort were SCr(OR1.478,[95%CI1.231-1.776],p<0.001), alveolar hemorrhage(OR2.726,[95%CI 1.099-6.763],p=0.031) and PR3-ANCA(OR3.155,[95%CI 1.485-6.702],p=0.003) adjusted to sex.

Conclusions: In our cohort, males presented with higher SCr, and dialysis was started within 4 weeks more frequently but outcomes were not different. Females had increased frequency of infections at 12 months.

TH-PO609

A Retrospective Observational Study of the ANCA-Negative Renal Vasculitis Cohort in the National Rare Kidney Disease Registry

Sorcha O'Brien,[1] Sinead Stoneman,[2] Mark A. Little,[3] Allyson C. Egan.[1] *[1]Tallaght University Hospital, Dublin, Ireland; [2]University College Cork, Cork, Ireland; [3]The University of Dublin Trinity College, Dublin, Ireland.*

Background: A recent single centre study reported that ANCA-negative pauci-immune glomerulonephritis (PIGN) presents in younger patients, with higher end-stage kidney disease (ESKD) risk, despite lacking differences in histopathology. Fewer extra-renal manifestations were observed. The aim of this study was to review ANCA negative vasculitis PIGN outcomes in the Irish Rare Kidney Disease Registry.

Methods: Of 616 patients with PIGN in the registry, 13 were ANCA-negative (defined as negative on anti-MPO and anti-PR3 immunofluorescence / ELISA), with PIGN confirmed on kidney biopsy. Data collection included demographics, biopsy results, management, and outcomes.

Results: The mean age was 56.8 years (SD 12.85). 4 patients had renal limited disease. Most common other symptom/ system involved included: constitutional (n=4) and ENT (n=4), muco-cutaneous/ophthalmic (n=2), chest (n=2), neurological (n=1), abdominal (n=1). The mean estimated glomerular filtration rate (eGFR) at diagnosis was 19.4ml/min/1.73m (SD 19.9). Mean creatinine was 423µmol/L (SD 259.9). 8 patients had UPCR documented, with the mean UPCR recorded as 543.2 (SD 747.3). Applying the Berden score to 11 participants: 6 focal, 3 mixed, 1 crescentic, 1 sclerosed were observed. 10 of 13 patients received immunosuppression. Induction treatment included Methylprednisolone (n=7), Cyclophosphamide (n=7), Rituximab (n=2), oral prednisolone (n=3), and PLEX treatment (n=1). 9 patients were continued on maintenance treatment: oral prednisolone (n=6), Azathioprine (n=5), Mycophenolate Mofetil (n=3), Cyclophosphamide (n=1), Rituximab (n=1). 4 patients were on renal replacement therapy (RRT) at diagnosis, 1 patient developed end-stage kidney disease (ESKD). 10 patients achieved remission, 1 did not. 3 had documented relapse. 1 patient died within 5-years of diagnosis.

Conclusions: ANCA-negative vasculitis with renal involvement requires early detection and treatment to prevent kidney disease progression. Renal disease may occur as a single manifestation or as part of a multi--systemic presentation, underscoring the importance of organ surveillance. Further elucidation of the pathogenesis and prognostic markers of relapse in ANCA negative vasculitis, will play a key role in improving outcomes.

TH-PO610

Impact of Reclassification by the 2022 ACR/EULAR Classification Criteria on the ANCA-Associated Vasculitis Study Population

Jolijn R. van Leeuwen, Sophia L. Hafemann, Ton J. Rabelink, Yoe Kie Onno Teng. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: In 2022 the American College of Rheumatology (ACR) and European Alliance of Associations for Rheumatology (EULAR) presented new classification criteria for the three subsets of antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV): granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and Eosinophilic Granulomatosis with Polyangiitis (EGPA). Our aim was to assess the impact of the new 2022 ACR/EULAR classification criteria on future GPA, MPA and EGPA studies.

Methods: An established, single center cohort of patients with a clinical AAV diagnosis in a tertiary academic hospital was used as source population. Clinical diagnosis and disease characteristics at time of diagnosis were collected by manual review and matched to the novel 2022 ACR/EULAR classification criteria for GPA, MPA or EGPA. Patients with an unspecified AAV diagnosis and patients with insufficient clinical data for the time of diagnosis were excluded.

Results: We included 183 GPA, 54 MPA and 27 EGPA patients. In total 32/264 (12%) patients were reclassified. 22/183 (12%) clinical GPA patients were reclassified: 11 (6%) as MPA and 11 (6%) were unclassified. 3/54 (9%) MPA patients were reclassified: 1 (2%) as GPA and 2 (4%) were unclassified. 7/27 (25%) EGPA patients were reclassified: 3 (11%) as GPA and 4 (15%) patients were unclassified. One clinical GPA patient could be classified as both GPA and MPA. After reclassification, PR3+ patients remain predominantly GPA (from 97 to 99%), MPO+ patients are more often considered MPA (from 64% to 75%) and ANCA- patients can often not be classified (29%). Focusing on risk factors for relapse, an often used endpoint in clinical trials, we identified an enrichment of PR3 positivity in GPA patients (+12%) and of pulmonary involvement in MPA patients (+10%) after reclassification.

Conclusions: With 12% reclassification the 2022 ACR/EULAR classification criteria will impact inclusion in future studies. Reclassification is often based on ANCA serology and impacts the distribution of typical risk factors for disease relapse in MPA and GPA subgroups.

TH-PO611

Canadian Society of Nephrology Commentary on the 2021 KDIGO Glomerulonephritis Guidelines and 2023 ANCA/Lupus Updates

Arenn S. Jauhal,[1] Reem Mustafa,[2] Anna T. Mathew,[3] Michelle A. Hladunewich.[4] Canadian Society of Nephrology Glomerulonephritis Working Group. *[1]University Health Network, Toronto, ON, Canada; [2]University of Kansas School of Medicine, Kansas City, KS; [3]St Joseph's Healthcare Hamilton, Hamilton, ON, Canada; [4]Sunnybrook Health Sciences Centre, Toronto, ON, Canada.*

Background: The Canadian Society of Nephrology (CSN) completes commentary on published Kidney Disease Improving Global Outcomes (KDIGO) Guidelines. In 2021, KDIGO published Glomerulonephritis (GN) guidelines with recent 2023 guideline updates. KDIGO guidelines includes Recommendations and practice points (PP), which are used when there is insufficient evidence for a Recommendation. In this article we describe the process and highlight findings of the CSN commentary on the KDIGO GN guidelines.

Methods: The CSN established a working group including adult and pediatric nephrologists, pharmacists, pediatricians, pathologists, and patient partners with expertise in GN across Canada. The working group aimed to review guideline's relevance and applicability to the Canadian context when caring for patients with GN. Recommendations from the KDIGO 2021 GN guidelines (including 2023 lupus and ANCA updates) were assessed with a standardized survey assessing whether working group members agreed or not with the Recommendation with focus on highlighting specific Canadian context that may impact the recommendation. Recommendations attaining <80% consensus or

those with comments pertaining to important considerations to the Canadian context were specifically discussed. Practice points were discussed amongst working group members and relevant PP were highlighted.

Results: This commentary highlights the impact of the KDIGO GN guideline Recommendations and PP on GN care in Canada. In general, the CSN working group agrees with most of the guideline statements by KDIGO. This commentary highlights the uptake of certain PP including lack of evidence, practice variation, and areas of controversy. Health equity and virtual medical care were important issues impacting GN care in Canada.

Conclusions: Canadian Society of Nephrology GN working group generally agrees with the KDIGO GN guidelines and recent lupus nephritis and ANCA updates, and highlights areas relevant to the Canadian healthcare for patients with GN.

Funding: Government Support - Non-U.S.

TH-PO612

Prevalence and Outcomes of Anti-Glomerular Basement Membrane Disease with and Without Secondary Glomerular Pathologies

Nattawat Klomjit,[1] Mariam P. Alexander,[2] Ladan Zand.[3] *[1]Division of Nephrology and Hypertension, University of Minnesota, Minneapolis, MN; [2]Depatment of pathology and laboratory medicine, Mayo Clinic, Rochester, MN; [3]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN.*

Background: Anti-glomerular basement membrane (Anti-GBM) disease is a rare but devastating autoimmune kidney disease. Anti-GBM disease can co-exist with several other glomerular pathologies, but little is known about the frequency of these associated pathologies and patients' renal outcomes compared to patients who have anti-GBM disease alone.

Methods: We retrospectively evaluated Mayo Clinic Renal Pathology Database and included patients (age ≥ 18 years) with a diagnosis of anti-GBM disease on a native kidney biopsy who were treated at the Mayo Clinic from 2000 to 2021. Detailed pathological findings were collected from renal pathology reports. Clinical characteristics and outcomes were collected from review of medical records.

Results: Total of 209 anti-GBM cases were identified and of these, 49 cases (23.4%) were treated at Mayo Clinic (internal), whereas 160 cases (76.6%) only had their biopsy reviewed at Mayo Clinic but were treated elsewhere (external). Of 209, 191 were typical anti-GBM (91.4%) and 18 (8.6%) were atypical anti-GBM. Of typical anti GBM cases (n=191), 119 (62.3%) had no other glomerular pathology, 53 cases (27.8%) also had anti-neutrophilic cytoplasmic antibody (ANCA)-associated glomerulonephritis (GN), 10 cases (5.2%) had membranous nephropathy (MN), 6 cases (3.1%) had IgA nephropathy, 3 cases (1.6%) had thrombotic microangiopathy (TMA) and 1 case (0.5%) had fibrillary glomerulonephritis). ANCA-GN patients were significantly older than patients with anti-GBM alone and had significantly higher serum creatinine (SCr) compared to patients with associated MN. Those with MN had significantly higher urinary protein compared to those with anti-GBM alone and those with ANCA-GN. Patients with ANCA-GN had the highest degree of sclerosis compared to other pathologies. Of the 49 internal cases, 32 (65.3%) required dialysis upon presentation and 91.7% survived at 1 year. Of those who required dialysis, only 9.1% discontinued dialysis. There were no different in the outcomes between groups.

Conclusions: Concomitant glomerular pathology is common among patients with anti-GBM disease and can occur in up to 40% of patients. ANCA-GN accounts for over 70% of those co-existing pathologies. Clinical characteristics may potentially serve as clues to look for secondary pathologies in patients who present with anti-GBM disease.

TH-PO613

Clinical Courses in IgA Vasculitis with Nephritis Underwent Tonsillectomy

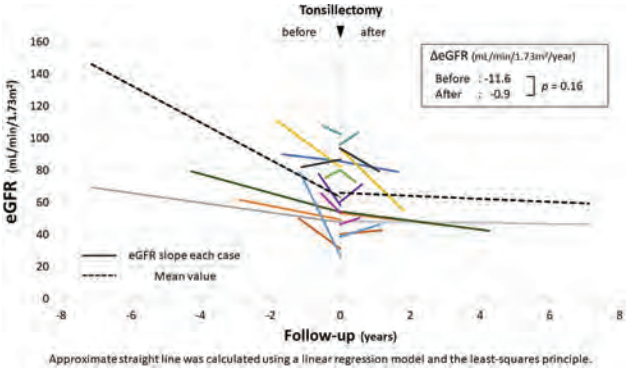
Eisuke Kubo, Kotaro Haruhara, Hirokazu Marumoto, Takaya Sasaki, Masahiro Okabe, Shinya Yokote, Hiroyuki Ueda, Nobuo Tsuboi, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

Background: Adult-onset IgA vasculitis (IgAV) frequently presents with kidney involvement and is often associated with unfavorable clinical courses. There is no established treatment in IgAV with nephritis (IgAVN) other than renin-angiotensin-aldosterone inhibitors and corticosteroids. Although tonsillectomy is one of the treatment options in primary IgA nephropathy, the efficacy of tonsillectomy in IgAVN has not been determined to date.

Methods: Adult patients with biopsy-proven IgAVN who received tonsillectomy at 6 hospitals in Japan from 2015 to 2022 were recruited. Changes in hematuria, time-averaged urine protein-to-creatinine ratio (UPCR), estimated glomerular filtration rate (eGFR), and serum IgA were evaluated before and after tonsillectomy. Hematuria remission and proteinuria remission were defined as three consecutive urinary RBC<5/HPF and UPCR<0.3g/g for at least 6 months, respectively.

Results: A total of 12 patients with IgAVN who underwent tonsillectomy were identified. The median observation periods before and after tonsillectomy were 20.7 months and 48.6 months, respectively. Corticosteroids were prescribed before and after the tonsillectomy in 5 (42%) and 7 (58%) patients, respectively. After the tonsillectomy, both hematuria score (median 4.25 versus 2.5) and time-averaged UPCR (median 0.63 versus 0.28 g/g) decreased. Five patients achieved hematuria remission and nine patients achieved proteinuria remission and only one patient showed a recurrent urine abnormality. The eGFR slope was changed from mean -11.6 to -0.9 mL/min/1.73m^2/year before and after tonsillectomy. Serum IgA after tonsillectomy also changed compared with before (median 394 versus 296 mg/dL).

Conclusions: Adult IgAVN patients who underwent tonsillectomy had relatively favorable clinical courses with improved urinary findings and eGFR slopes. The prospective controlled trial is needed to confirm the efficacy of tonsillectomy in IgAVN.



TH-PO614

Predictors of Major Adverse Kidney Disease Events in a Real-World Population with IgA Nephropathy

Katherine R. Tuttle,[1,2] Lindsey M. Kornowske,[1] Cami R. Jones,[1] Kenn B. Daratha,[1] Radica Z. Alicic,[1,2] Joshua J. Neumiller,[3] Mark E. Bensink,[4] Wu Gong,[4] Keith C. Norris,[5] Susanne B. Nicholas.[5] CURE-CKD. *[1]Providence Health and Services, Spokane, WA; [2]University of Washington School of Medicine, Seattle, WA; [3]Washington State University, Pullman, WA; [4]Travere Therapeutics Inc, San Diego, CA; [5]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: IgA nephropathy (IgAN) is a glomerular disease that may progress to kidney failure. While albuminuria or proteinuria and reduced kidney function are associated with greater risk, other predictors are less clear. The study aim was to use a real-world population to assess clinical predictors of major adverse kidney disease events (MAKDE) in IgAN.

Methods: The study population was derived from electronic health records data in the Center for Kidney Disease Research, Education, and Hope (CURE-CKD) Registry at Providence and UCLA Health systems. Demographics, clinical characteristics, and prescriptions were obtained for adults ≥18 years old with a diagnosis code for IgAN in 2016-2020. Kaplan Meier survival analysis and Cox proportional hazards models evaluated MAKDE: 40% eGFR decline, eGFR <15 mL/min/1.73 m^2, and administrative codes for kidney failure, dialysis, or transplant.

Results: Patients with IgAN (N=1,099) were 50% women (n=554) and 55±18 (mean±SD) years old. At baseline, mean eGFR was 77±28 mL/min/1.73 m^2 (Chronic Kidney Disease Epidemiologic equation 2021); median urine albumin/creatinine ratio (UACR) and urine protein/creatinine ratio (UPCR) were 119 (interquartile range 30-518) mg/g and 0.7 (0.3-1.9) g/g. Renin angiotensin system (RAS) inhibitors and corticosteroids were prescribed to 49% (n=538) and 25% (n=278), respectively. MAKDE occurred in 13% (n=144) by 3 years. Predictors of MAKDE were Asian race, hospitalization, diabetes, RAS inhibitor use, and lower baseline eGFR (**Figure**). In a sensitivity analysis model including baseline UACR or UPCR measurements (n=335), levels above versus below the median had an adjusted hazard ratio of 2.10 (95% confidence interval 1.07-4.11).

Conclusions: MAKDE were common in patients with IgAN. Asian race and illness severity reflected by hospitalization, diabetes, and RAS inhibitor use, as well as reduced kidney function and albuminuria or proteinuria, predicted these events.

TH-PO615

ESKD and CKD Progression Among a Diverse Immunoglobulin A Nephropathy (IgAN) Population

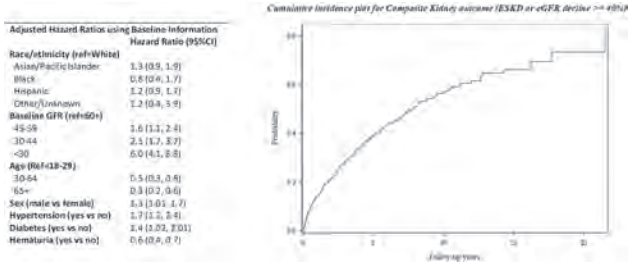
John J. Sim,[1] Qiaoling Chen,[1] John M. Chang,[1] Nancy Cannizzaro,[1] Dilip Makhija,[2] Sandipan Bhattacharjee,[2] Ancilla Fernandes,[2] Cibele S. Pinto,[2] Asher D. Schachter,[3] Mohit Mathur.[3] *[1]Kaiser Permanente Southern California, Pasadena, CA; [2]Otsuka America Pharmaceutical Inc, Rockville, MD; [3]Visterra Inc, Waltham, MA.*

Background: IgAN is the most common glomerulonephritis and a leading cause of ESKD but real-world data on natural history of the disease are sparse. This study evaluated kidney outcomes among a diverse IgAN population in an integrated US health system.

Methods: Longitudinal cohort study (1/1/2000-12/31/2021) was performed within Kaiser Permanente Southern California members with biopsy proven primary IgAN. Secondary IgAN was excluded. Kidney outcome was a composite of ESKD (dialysis or transplant) and/or CKD progression. Patients were followed from index biopsy until kidney outcome and censored for mortality, disenrollment, or end of study. Multivariable Cox regression was used to estimate hazard ratios (HR).

Results: Among 687 patients with IgAN, mean age was 45.5 (SD 14.7) yrs. with 52% males, 40% Hispanic/Latino, 30% Asian/Pacific Islander, 24% White, 3% Black, and 39% with eGFR<45). At biopsy, mean eGFR was 58 and mean urine protein creatinine ratio (uPCR) was 2.5 g/g. A total of 270 (39%) had a kidney outcome (39 ESKD, 231 CKD progression) with median time to outcome of 1.3 years (2.4 years among eGFR>30 patients). Median time to ESKD was 2.6 years (4.7 years among eGFR>30 patients). The composite kidney outcome rate was 96.8 (per 1,000 person-years) without significant influence of race/ethnicity. ESKD incidence rate was 56.1 (per 1,000 person-years), also without significant influence of race/ethnicity over the median follow-up duration of 3.4 years. Baseline eGFR, male sex, hypertension, diabetes, hematuria, and age>65, were identified as predictors of ESKD and CKD progression.

Conclusions: Among a diverse IgAN population within a real-world environment, we observed a high rate of kidney outcomes in patients with lower eGFR and hypertension, but no difference across race/ethnic groups. Additional analysis evaluating effect of uPCR and treatment on kidney outcomes is ongoing.



TH-PO616

Clinical Burden of IgA Nephropathy (IgAN) in the United States: A Retrospective Electronic Medical Record (EMR) and Claims Analysis

Briana C. Ndife,[1] Carolina A. Aldworth,[1] Jennifer Nguyen,[1] Stephen W. Olson,[1] Elizabeth Nagelhout,[2] Marley K. Boyd,[2] Deval Gor.[2] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Genesis Research LLC, Hoboken, NJ.*

Background: IgAN is a complement-mediated kidney disease with a highly variable risk of disease progression; some patients already exhibit loss of kidney function at diagnosis. This analysis described the demographic and clinical characteristics of patients with IgAN in the US and estimated the proportion of patients at high risk of IgAN progression despite treatment with supportive care.

Methods: This was a retrospective cohort study of patients with IgAN aged ≥12 years using the HealthVerity database comprised of EMR, claims and lab data between 01-01-2016 and 09-30-2022. Demographic and clinical characteristics of patients who had been in the database for ≥12 months continuously before the date of their first IgAN SNOMED diagnosis code (index date) were examined. Patients at high risk of IgAN progression were defined as having proteinuria ≥1.0 g/g despite receiving supportive care (defined as ≥1 record of ACE inhibitors and/or ARBs within 12 months of the index date), and/or SGLT-2 inhibitors.

Results: Among 1,541 patients with IgAN included in the final analysis, mean ± SD age was 43.8±14.5 years and 53% were male. Of 918 patients with available data, 62.1% had stage ≥3 CKD at index. Mean ± SD eGFR was 67±33 mL/min/1.73m^2 and mean ± SD proteinuria was 1.9±1.9 g/g. Overall, 1.8% of patients had previously undergone a kidney transplant. Comorbidities were common, including hypertension (62.5%) and Type 2 diabetes (13.8%). Overall, 814/1,541 patients (52.8%) were treated with ACE inhibitors or ARBs (with or without SGLT-2 inhibitors) within 12 months post-index. Of patients with proteinuria data, the proportion of patients at high risk of IgAN progression despite supportive care at 6 months (±3 months) post-index was 46/109 (42.2%); at 12 months (±3 months) post-index, this proportion was 32/95 (33.7%).

Conclusions: In a cohort of patients with IgAN using real-world EMR and administrative claims data, comorbidities and advanced kidney disease were common. About half of these patients were receiving ACE inhibitors or ARBs (with or without SGLT-2 inhibitors) within 12 months after diagnosis, and half remained at high risk of progression at 6 months. These data highlight the need for novel therapies in IgAN.

TH-PO617

Design and Rationale for PERFORM Patient Registry™: An Observational Cohort of Patients Utilizing TARPEYO® for Immunoglobulin A Nephropathy (IgAN) in the United States

Mit M. Patel,[1] Danni Zhao,[2] Nancy D. Lin,[2] Ian C. Bonzani,[2] Elena Koshkina,[2] Warren P. Brooks.[1] *[1]Calliditas NA Enterprises Inc., New York, NY; [2]IQVIA Inc., Durham, NC.*

Background: Immunoglobulin A Nephropathy (IgAN) is a rare autoimmune disease characterized by the deposition of galactose-deficient IgA1 in the mesangial area of the glomeruli. Up to 50% of patients with IgAN are at risk of developing ESRD within ten to twenty years of diagnosis with poor survival outcomes. TARPEYO® (budesonide) was the first US FDA approved treatment (accelerated approval granted in December 2021) to reduce proteinuria in adults with primary IgAN at risk of rapid disease progression, generally a urine protein:creatinine ratio (UPCR) ≥1.5 g/g. Given the rarity and progressiveness of IgAN, an understanding of real-world treatment patterns and patient outcomes is warranted. The PERFORM Patient Registry™ uses a novel direct-to-patient approach to capture electronic health data and patient-reported data in real-world patients with IgAN who are utilizing TARPEYO.

Methods: Adult participants (≥ 18 years) with at least one dispensed prescription of TARPEYO will self- enroll in the registry online via the IQVIA Integrated Health Platform study application. This approach includes participant consent to sharing of their electronic health data (electronic medical records [EMR], TARPEYO dispensing claims) and collection of electronic participant-reported data (including the participant reported outcome [ePRO] of EQ-5D-5L). Participants will be followed up for a minimum of 36 months, until their withdrawal of consent or the end of the registry, whichever occurs first.

Results: This study will describe data obtained via the online study application for eligible participants. Additional exploratory analyses include characterization of the IgAN-treated participant population in terms of demographic and clinical characteristics, patterns of TARPEYO treatment utilization and clinical management of the disease over time.

Conclusions: This is the first direct to patient real-world registry of patients with IgAN utilizing TARPEYO. Patient recruitment via Version 1.0 of the registry began in December 2022 and the full registry Version 2.0 is expected to launch in May 2023.

TH-PO618

Levels of Socioeconomic Deprivation Are Associated with Worse Kidney Outcomes in Patients with IgA Nephropathy: Data from UK RaDaR

Jonathan Barratt,[1] David Pitcher,[2] Katie Wong,[2,3] Liz Lightstone,[4] Daniel P. Gale.[2,3] *[1]University of Leicester, Leicester, United Kingdom; [2]UK Kidney Association, Bristol, United Kingdom; [3]University College London, London, United Kingdom; [4]Imperial College London, London, United Kingdom.*

Background: The UK National Registry of Rare Kidney Diseases (RaDaR) recruits adults and children with biopsy-proven primary IgA nephropathy (IgAN) and eGFR <60 mL/min/1.73m^2 or proteinuria ≥0.5g/24h from 107 adult and paediatric kidney units across the UK, including retrospective and prospective data. Given the well established gradient between greater socioeconomic deprivation and worse health, in this study we aimed to determine whether socioeconomic deprivation influenced the risk of developing kidney failure in IgAN.

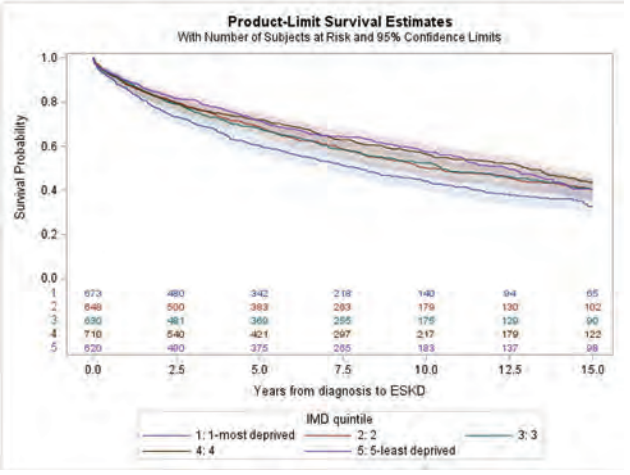
Methods: Deprivation quintile was derived using patient postcodes matched to Index of Multiple Deprivation (IMD) scores. Kidney survival from diagnosis was analysed using Kaplan Meier methods and Cox regression. The event was initiation of kidney replacement therapy, censored for death.

Results: The characteristics of 4,127 IgAN patients in RaDaR by IMD quintiles are shown in the **Table**. There was a clear association between risk of development of kidney failure and deprivation quintile (**Figure**) with the most deprived IgAN patient group exhibiting significantly faster progression. HR for kidney failure after adjustment for age, eGFR at diagnosis and gender for IMD1 vs 3 quintile: 1.46 (1.15-1.84), p=0.0017.

Conclusions: Outcomes in this large IgAN cohort have been published and shown to be poor with few patients expected to avoid kidney failure in their lifetime. This analysis demonstrates even worse outcomes if more socioeconomically deprived & highlights the need to develop strategies to ensure equity of access not only to early diagnosis but also to the new therapies that are showing promise in preventing kidney failure in IgAN.

IMD Quintiles	Age at diagnosis (median, 25th & 75th pctl)	Gender (M/F) (% IMD quintile)	White/ non-White (%)	eGFR at diagnosis (median, 25th & 75th pctl)	Time to kidney failure (median, 95% CI)
1- most deprived	38.9 (28.4, 51.2)	67.3/32.7	75.2/25.8	38 (21, 69)	7.9 (6.9, 9.3)
3	41.0 (29.4, 51.9)	69.9/30.1	86.2/13.8	39 (22, 70)	10.4 (9.0, 12.6)
5- least deprived	41.6 (30.6, 55.0)	74.3/25.7	88.5/11.5	37 (22, 68)	12.4 (11.1, 13.5)

Figure: Kaplan Meier plot showing time from diagnosis to ESKD, censoring for death



TH-PO619

Long-Term Renal Survival in Patients with IgA Nephropathy: A Systematic Review and Meta-Analysis

Huijian Zhang, Guisen Li. *Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.*

Background: IgA nephropathy (IgAN), a primary glomerular disease named more than 50 years ago, is still one of the main causes of end-stage renal disease (ESRD) worldwide. Patients with ESRD incurred higher yearly costs and bear great financial pressure. Assessment of trends in renal survival could indicate whether changes in treatment strategies have resulted in improved long-term renal outcomes.

Methods: We searched the PubMed, Embase and Cochrane Database for cohort studies and clinical trials on renal survival with IgAN from their inceptions to November 2021. The outcome was defined as a composite of any of the following: doubling of serum creatinine level, 50% decline in estimated GFR (eGFR), or end-stage renal disease (ESRD). We extracted data on 3-year, 5-year, and 10-year renal survival in IgAN. Besides, we separately analyzed studies from developed countries and developing countries. We also analyzed the effect of proteinuria on long-term renal survival.

Results: We included 146 articles that reported on 98,334 patients from 1988 to 2021. The 3-year, 5-year and 10-year renal survival were 94.12% [95% confidence interval (CI) 94.08% to 94.16%], 88.64% (95% CI: 88.58% to 88.70%) and 77.46% (95% CI: 77.34% to 77.59%), respectively. In the past few decades, there have been no significant changes in 3-year and 5-year renal survival in IgAN patients. However, the 10-year renal survival of IgAN had gradually decreased since the late 1990s. Survival in developed countries was higher than in developing countries and fluctuate less. Furthermore, when proteinuria was < 1.0 g/24h, renal survival was improved.

Conclusions: We found that long-term renal survival was not increased over the years in IgAN. And the renal survival was lower in developing countries than in developed countries. The proteinuria was crucial in long-term prognosis of IgAN. When proteinuria was < 1g/24h, long-term renal survival was significantly improved. These results could be used to counsel patients on long-term renal survival and know the trend of survival in developed and developing countries.

TH-PO620

Characteristics and Outcomes of IgA Nephropathy in the Canadian Province of Manitoba

Bryce Barr,[1] Oksana Harasemiw,[1] Ian W. Gibson,[1] Olivier Tremblay-Savard,[2] Navdeep Tangri.[1] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]University of Manitoba Faculty of Science, Winnipeg, MB, Canada.*

Background: Immunoglobin A (IgA) nephropathy is a common primary glomerulonephritis with variable clinical presentation. The aim of the current study was to characterize the population of patients with IgA nephropathy in the Canadian province of Manitoba.

Methods: In this retrospective, population-based cohort study, we identified all patients with biopsy-proven IgA nephropathy in the province of Manitoba, Canada between July 1, 2002 and December 31, 2019. Natural-language processing software was used for data extraction from pathology reports, which was then linked to administrative data via the Manitoba Centre for Health Policy. Descriptive statistics are presented to describe the patient population.

Results: We identified 366 patients (mean age at biopsy 43.2 years, 39.6% females). Mean estimated glomerular filtration rate (eGFR) at biopsy was 50 mL/min/1.73m^2, and mean urine albumin-to-creatinine ratio was 167.7 mg/mmol. Of the 122 patients with Oxford scores, 29 (23.8%) had M1, 46 (37.7%) had E1, 107 (87.7%) had S1, 29 (23.9%) and 43 (35.3%) had T1 and T2, respectively, while 33 (27%) had either C1 or C2. When stratifying by income quintiles, 31.7% of patients were in the lowest income quintile versus 9.6% in the highest. Comparing eras (2002-2010 versus 2011-2019), receipt of disease-modifying treatment within 6 months of biopsy remained stable for renin-angiotensin system inhibitors (69.6 vs 69.7%), anti-blood pressure medications (57.8 vs 60.6%) and glucocorticoids (23.0 vs 20.4%). Statin use increased significantly between periods (13.3% vs 29.0%, p<0.001). Patients were more likely to receive glucocorticoids if they had Oxford scores M1 versus M0 (41.4 vs 18.3%, p=0.01), E1 versus E0 (37.0 vs 15.8%, p=0.0078), or C1+2 versus C0 (51.5 vs 13.5%, p<0.0001). Over a median of 5.6 years of follow-up, 163 (44.5%) patients developed kidney failure and 69 (18.9%) patients died.

Conclusions: In this cohort, IgA nephropathy was associated with substantial risk of kidney failure and mortality. This study demonstrated the feasibility of using natural language processing as a data extraction technique, and will facilitate further epidemiologic research in this cohort. The study was limited by small sample size, incomplete Oxford scoring and lack of blood pressure data.

Analysis of the Real-World Management of IgA Nephropathy (IgAN) Patients in Five European Countries

Philipp Csomor,[1] Tucker B. Hurtado,[2] Chris Dudzenski,[2] Lucy Santos.[1] *[1]CSL Vifor, Glattbrugg, Switzerland; [2]Spherix Global Insights, Exton, PA.*

Background: Immunoglobulin A nephropathy (IgAN) is the most common form of primary glomerulonephritis worldwide. Current treatment strategies focus on controlling blood pressure and minimising proteinuria. This study investigated the real-world management of IgAN in five European countries through a physician questionnaire and patient chart review.

Methods: From 21 Dec 2022 to 6 Feb 2023, physicians from France, Germany, Italy, Spain and the UK completed a questionnaire on IgAN management, and patient charts from their centres were analysed. Physicians had to have ≥50 CKD stage 1–4 patients under their management, including ≥4 IgAN patients not on dialysis. Patients had to be ≥12 years, diagnosed with IgAN, not be on dialysis and have an eGFR ≥15 mL/min/1.73m^2.

Results: Participating physicians (N=261) each saw a mean of 30 IgAN patients in the past year. Patients audited as part of the study (N=473) were mostly male (71%), 78% were Caucasian, mean age was 47 years and 57% were in CKD stage 3. The mean time since referral to their current physician was 4.2 years. Proteinuria was >1 g/day in 66% of patients at referral and in 50% of patients at the current assessment (N=403 with both referral and current values). This was despite 92% of patients currently taking an ACE inhibitor and/or ARB, 43% taking an SGLT2 inhibitor and 16% taking a steroid. Physicians considered rate of eGFR decline to be moderate in 19% and fast in 6% of patients. However, among patients with eGFR values over 2 years (N=293), rate of eGFR decline was 3 mL/year in 12%, 4–5 mL/year in 16% and ≥6 mL/year in 19% of patients. Relapse occurred at least once in 54% of patients; steroid therapy was used to control the most recent relapse episode in 60% of patients. Most physicians (78%) agreed that they would prefer to administer therapies specifically approved for IgAN and 66% agreed that there is a lack of non-immunosuppressive treatments for IgAN.

Conclusions: Many patients with IgAN continue to have persistent proteinuria despite ACE inhibitor/ARB treatment, and progressive disease is common. Overall, this study indicates that there is a need for more effective treatment strategies to reduce proteinuria and disease progression in patients with IgAN.

Comparing Proteinuria and Kidney Survival in FSGS and IgA Nephropathy (IgAN): A NEPTUNE Analysis

Laura H. Mariani,[1] Jonathan P. Troost,[1] Wu Gong,[2] Mark E. Bensink,[2] Ambarish Athavale,[6] Pietro A. Canetta,[3] Vimal K. Derebail,[4] Yelena Drexler,[5] Howard Trachtman.[1] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Travere Therapeutics Inc, San Diego, CA; [3]Columbia University, New York, NY; [4]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]University of Miami School of Medicine, Miami, FL; [6]University of California San Diego, La Jolla, CA.*

Background: Changes in disease activity markers are important outcomes for clinical trials in rare proteinuric kidney disease. While novel therapies may be effective in multiple etiologies, the relationship between proteinuria and kidney survival has not been directly compared across diseases.

Methods: We studied children and adults with FSGS or IgAN enrolled in Nephrotic Syndrome Study Network (NEPTUNE) at the time of clinically indicated biopsy and followed prospectively with proteinuria and eGFR at each study visit. We tested the association between lowest proteinuria within 12 months (mo) after biopsy and the time to composite of ESKD/40% eGFR decline using Kaplan-Meier method.

Results: 211 FSGS and 58 IgAN patients were included. Compared to IgAN, FSGS patients had higher baseline eGFR, UPCR and obesity rates, but similar age and blood pressure. Relative change in proteinuria was -42% vs -39% by 12mo and -42% vs -63% by 24mo in FSGS and IgAN, respectively, but a significant proportion with either diagnosis did not achieve complete remission (Fig 1). Associations between higher protieinuria in 12mo and shorter kidney survival time were similar across diseases (Fig 2).

Conclusions: Lower proteinuria by 12mo after biopsy was associated with similar improvement in kidney survival in FSGS and IgAN. A substantial proportion of patients under usual care have high proteinuria at 24mo, highlighting unmet need for new treatments.

Sex Differences in Lupus Nephritis: A Meta-Regression Analysis

Salman B. Mahmood,[1] Muhammad Aziz,[2] Deepthi C. Malepati,[1] Wade M. Lee-Smith,[3] Justin Clark,[4] Ann M. Brearley,[4] Patrick H. Nachman.[1]
[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]The University of Toledo Medical Center, Toledo, OH; [3]The University of Toledo Libraries, Toledo, OH; [4]University of Minnesota Twin Cities School of Public Health, Minneapolis, MN.

Background: More frequent and severe lupus nephritis (LN) has been reported in men compared to women, but data are limited and inconsistent. We performed a meta-analysis to compare the histopathologic findings and outcomes between men and women with biopsy-proven LN (BPLN).

Methods: We conducted a systematic search of electronic databases through 2021 using the terms "lupus nephritis" and "sex/gender". Screening was limited to studies of adult patients with BPLN. We compared the biopsy findings and outcomes between the sexes. Pooled odds ratios (OR) with 95% confidence intervals (CI) were generated, and meta-regression performed to assess the impact of several covariates, using random-effects models.

Results: 25 studies were included (1210 men and 6635 women). 20 studies reported kidney histopathology, 11 kidney outcomes and 8 mortality rates. Men had a higher OR for class IV±V LN (1.26, 95% CI: 1.01-1.56) and the composite kidney outcome (doubling serum creatinine, kidney replacement therapy or eGFR<15 ml/min) (2.20, 95% CI: 1.59-3.06) and a lower OR for complete remission (0.52, 95% CI: 0.39-0.68) (Fig. 1). Meta-regression did not reveal statistically significant study-level relationships between sex differences in any of the covariates and the composite kidney outcome (Table 1).

Conclusions: Our analysis confirms the association between male sex and increased LN severity as well as worse kidney outcomes. Larger prospective studies are needed to validate this association and inform treatment strategies that may hold unique value for this high-risk population.

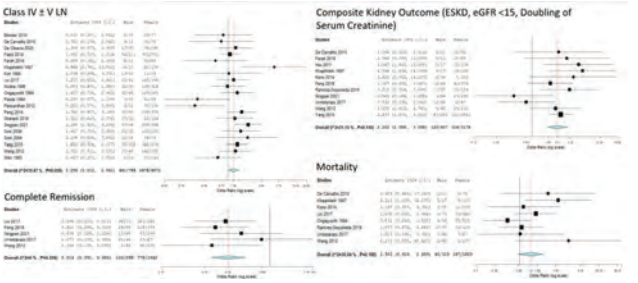

Figure 1. Forest plots showing the estimated OR with 95% CI for men with BPLN compared to women.

Characteristic	exp (β_1)	95% CI	p-value	Sample Size
Mean Difference in Age, years	1.02	0.91, 1.14	0.8	10
Mean Difference in Baseline Creatinine	3.00	0.64, 14.1	0.2	7
Mean Difference in Proteinuria	1.28	0.91, 1.80	0.2	7
Mean Difference in Activity Index	1.08	0.73, 1.57	0.7	6
Mean Difference in Chronicity Index	1.33	0.53, 3.34	0.5	6
Mean Difference in LN disease duration, months	1.01	0.93, 1.10	0.9	4
OR Diffuse Proliferative LN (class IV ± V)	1.15	0.92, 1.44	0.2	6
OR Complete Remission	0.13	0.01, 1.24	0.076	4
OR Hypocomplementemia (Low C3 or C4)	1.29	0.93, 1.80	0.13	4
OR Cyclophosphamide use	1.08	0.96, 1.21	0.2	5

TH-PO624

Factors Predictive of Infections over Time in Lupus Nephritis Patients: Data from a Single-Center Retrospective Cohort

Wenhao Zhang, Zhiming Ye. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Infection is a common complication among patients with lupus nephritis (LN) who started treatment. Previous studies have shown that infection has become the leading cause of death in patients with LN. Therefore, early identification of risk factors for infection in LN patients is of great significance for complication prevention and improvement of prognosis. The aim of this study was to explore the clinical predictors of infection in patients with LN.

Methods: Patients who were diagnosed with LN and treated with immunosuppressive therapy at Guangdong Provincial People's Hospital from 2000 to 2020 were enrolled. Demographics, laboratory data, glucocorticoid dosage, antimalarial usage, immunosuppressive agents and infection details were included. Cox regression model was adopted to identify risk factors of infection. Both Univariable and multivariable analyses were performed.

Results: 1. A total of 374 LN patients were enrolled, of which 85.3% (n=319) were female. The average age was 30±12 years and the age ranged from 5 to 81 years. The mean of height was 1.58±0.99m and weight was 51.62±9.87kg. 219 patients (58.6%) with LN developed infection during follow-up, of which 111 (29.7%) were severe infection. 2. In order to compare changes of variables from 3 months, 6months and 12months after treatment, our study conducted cox regression analysis. We also conducted ROC and showed the AUC respectively (0.798, 0.700 and 0.521). Multivariable analysis demonstrated that IgM (HR=1.288,95%Cl : 1.074-1.544,p=0.006) and free light chain λ (HR=1.783,95%Cl : 1.000-3.177,p=0.050) were predictive factors of infection while after 3month treatment, anti-dsDNA reduction(HR=0.728,95%Cl : 0.563-0.924,p=0.016) and hemoglobin increase(HR=0.790,95%Cl : 0.652-0.958,p=0.017) were protective.

Conclusions: Our study showed that the incidence of infection in LN patients during treatment was high. Changes of variables in 3months after treatment had the most significant influence on infection and severe infection. High levels of IgM and serum free light chain λbefore treatment increase the risk of infection and dsDNA antibodies decreased and hemoglobin increased at the third month of treatment, were protective

TH-PO625

Cardiovascular and Renal Risks of Tacrolimus in Lupus Nephritis: A Long-Term Retrospective Cohort Study

Mieke van Schaik, Edwin Bredewold, Merel Priester, Wieneke Michels, Ton J. Rabelink, Joris I. Rotmans, Yoe Kie Onno Teng. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Systemic lupus erythematosus is associated with an increased risk of cardiovascular disease. Tacrolimus is a calcineurin inhibitor that finds its origin in solid organ transplantation, but is also effectively used in lupus nephritis. In a transplant setting,

tacrolimus is associated with an increased cardiovascular risk, including nephrotoxicity, hypertension, dyslipidemia and hyperglycemia. In lupus nephritis the use of tacrolimus is off-label, and since head-to-head comparisons and long-term evaluations are lacking, its safety profile is less well-defined. Our objective was to investigate the long-term effects of tacrolimus on cardiovascular and renal outcomes in lupus nephritis patients.

Methods: In a retrospective, single-center cohort study, all adult lupus nephritis patients treated in the Leiden University Medical Center between 2004 and 2023 were investigated and dichotomized based on the prescription of systemic tacrolimus. We evaluated the Framingham risk score and the occurrence of cardiovascular events, diabetes, dyslipidemia, and change in kidney function.

Results: Of 223 patients that were enrolled in the study, 45 (20.2%) were ever prescribed tacrolimus. The remaining 178 patients had never been prescribed calcineurin inhibitors and were assigned to the control group. There was an equal incidence of cardiovascular events in both groups. The 10-year risk of coronary heart disease was significantly lower in the tacrolimus group, although this could largely be contributed to the age difference between the groups. Tacrolimus use was an independent predictor of eGFR decline, but this did not result in larger incidence of end-stage kidney disease during the follow-up period. There was no difference in the occurrence of diabetes or dyslipidemia between the groups, although there was a significant increase in HbA1c in the tacrolimus group.

Conclusions: Tacrolimus may have nephrotoxic and modest diabetogenic effects in lupus nephritis patients. Caution when prescribing tacrolimus and vigilance towards these possible side effects when continuing tacrolimus treatment as maintenance treatment is advised. However, further prospective studies in larger cohorts are necessary to confirm these findings and further assess the side-effects of tacrolimus in lupus nephritis patients.

TH-PO626

Exostosin 1-/Exostosin 2-Positive Membranous Lupus Nephritis Is Associated with a Favorable Kidney Prognosis

Fernanda Zavala Miranda,[1,2] Ana M. Sobrino,[1] Oscar Pena,[1] Abril A. Pérez Arias,[1] Sofia E. M. Macedo,[1] Bernardo Juarez Cuevas,[1] Norma O. Uribe-uribe,[1] Juan M. Mejia-Vilet.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Universidad Nacional Autonoma de Mexico, Ciudad de Mexico, Mexico.*

Background: 30-35% of patients with membranous lupus nephritis (MLN) are positive for the exostosin 1/2 (EXT1/2) staining. Previous studies have suggested that positive EXT1/2 stain is associated with better response to therapy, kidney prognosis, and low rates of transition to proliferative nephritis. We evaluated the prevalence of EXT1/2 staining in our cohort of pure MLN and its association with response to therapy and long-term kidney outcomes.

Methods: Retrospective cohort study. From 100 patients with membranous nephropathy we evaluated 53 patients with pure MLN and follow-up >5 years. EXT1/2 was detected by immunohistochemistry. We compared the clinical and histopathological presentation of EXT1/2 positive and negative patients. The kidney outcomes of response to therapy, 40% decline in eGFR, doubling of serum creatinine, and kidney failure were assessed by survival analyses.

Results: Fourteen (26%) MLN patients had positive EXT1/2 staining. Patients with positive EXT1/2 staining were younger and had a higher eGFR at presentation. There were no differences in complete or partial response between both groups (log-rank p=0.118 and p=0.412, respectively). Over a median follow-up of 118 months (IQR 73-172), none of the EXT1/2 positive and 9 of the EXT1/2 negative patients progressed to 40% decline of the eGFR with 5- and 10-year 40% eGFR decline rates of 0% and 0%, and 16% and 26%, respectively (log-rank p=0.046, Figure 1). No differences were observed in progression to doubling of serum creatinine or kidney failure. All patients were alive at the last date of follow-up.

Conclusions: EXT1/2 positive MLN is associated with similar response to therapy than EXT1/2 negative MLN, but better long-term kidney prognosis.

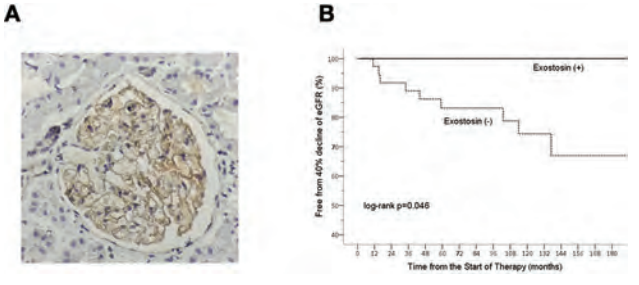

Figura 1. Glomerular EXT1/2 immunohistochemistry (A) and kidney outcome of 40% decline in eGFR according to EXT1/2 staining.

TH-PO627

The Impact of Late Renal Biopsy on Renal Survival in Patients with Lupus Nephritis

Mariana Nunes, Lectícia Jorge, Luis Yu, Viktoria Woronik, Cristiane B. Dias. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: Brazil is the American country with the highest African ancestry. In lupus nephritis (LN) it is possible to observe differences in incidence and even severity according to the location and characteristics of the population studied. This study aims to describe the clinical-epidemiological profile and the influence of late diagnosis in patients with LN at the Nephrology Service of the Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, between the period from 1999 to 2015.

Methods: Retrospective descriptive observational study of patients diagnosed with LN and biopsied before six months of the onset of LN symptoms compared to those biopsied after six months or more than of the onset of symptoms.

Results: The total sample size was 398 patients. FAN was positive in 94.1% of patients, anti-DNA in 77.7% and anticardiolipin in 27.1%. The full-house pattern was observed in 124 patients (33.7%). Considering the time from the onset of LN-related symptoms until the kidney biopsy, in 47.5% this time was less than 6 months (early group) and in 52.5% this time was greater than or equal to 6 months (late group). The chronicity index was lower in the group biopsied less than 6 months, 2(1-4) vs 3(2-5), p= 0.003, with a higher activity index in this same group (5 (3-8) vs 4 (3-6), p= 0.006). The chronicity index had a positive correlation with initial, 3-month, 6-month and 5-year creatinine after renal biopsy, with r=0.56 and p< 0.0001, r=0.51 and p<0.0001, r=0.51 and p<0.0001 and r=0.38 and p<0.0001, respectively. Fifty-three patients progressed on dialysis over five years of follow-up and in uni and multivariate analysis late renal biopsy and chronicity index starting at 4 were independent factors for this worse outcome.

Conclusions: This study showed that renal outcomes in renal replacement therapy or chronic kidney disease were associated with delayed renal biopsy and higher chronicity index at diagnosis. Late biopsy comes from a delay in referral to a tertiary hospital nephrologist and therefore a delay in diagnosis and initiation of appropriate treatment for that patient.

TH-PO628

Comparison of Renal Outcomes Between Primary Membranous Nephropathy and Membranous Lupus Nephritis: A Prospective Multicenter Study

Hyunglae Kim, Yong Kyun Kim. *The Catholic University of Korea St Vincent's Hospital, Suwon, Gyeonggi-do, Republic of Korea.*

Background: Primary membranous nephropathy (PMN) and membranous lupus nephritis (MLN) are autoimmune disorders characterized by immune complex deposit in the glomerular basement membrane. The optimal immunosuppressive regimen for these conditions remains undefined, and limited research exists on their renal outcomes.

Methods: This study included 108 patients with PMN and 43 patients with MLN (23 Class V only, 20 Class V + III or IV) diagnosed through renal biopsy at eight South Korean hospitals from September 2015 to April 2022. All patients received standard immunosuppressive therapy, including glucocorticoids with additional agents such as calcineurin inhibitors, mycophenolate mofetil, or cyclophosphamide. Renal outcome was assessed by comparing serum creatinine levels at baseline and one year, adjusted to baseline levels. The response rate was defined as CR (<0.5g/g reduction in proteinuria), PR (≥50% reduction in proteinuria), and TF (failure to achieve CR or PR). Median follow-up period for was 11 months in both PMN and MLN.

Results: PMN patients exhibited older age (57.5±12.9 vs 37.4±14.1, p<0.001), higher male proportion (86.1% vs 37.0%, p<0.001), higher BMI (26.0±4.6 vs 23.0±5.1, p=0.002), increased prevalence of hypertension (50% vs 16.3%, p<0.001), higher serum creatinine (0.9±0.4 vs 0.7±0.3, p=0.03), decreased albumin (2.6±0.7 vs 2.9±0.7, p=0.041), and increased urine protein creatinine ratio (6.1±3.6 vs 4.4±4.8, p=0.015) compared to MLN patients. After one year, in multivariated regression analysis, PMN patients showed that the increase rate of serum creatinine was higher than MLN patients (22.4% vs 11.7%, p=0.027), indicating worse renal function in the PMN group, while the reduction rate of proteinuria was similar in both groups (57.6% vs 61.7%, p=0.306). Response rates (CR+PR) and treatment failure rates (TF) did not significantly differ between the two groups (PMN: CR+PR=77.8%, TF=22.2%; MLN: CR+PR=76.7%, TF=23.3%; p=0.891).

Conclusions: This study showed the comparable response rate between PMN and MLN patients after treatment with immunosuppression. However, PMN patients had more deteriorated renal function compared to MLN patients during the median follow-up period of 11 months. Further evaluation with longer follow-up is necessary to gain comprehensive insights into renal outcomes in these patient groups.

TH-PO629

Clinical Outcome of NELL1-Associated Membranous Nephropathy

Raja Ramachandran,[1] Mayuri Trivedi,[2] Ritambhra N. Duseja,[1] Vinod Kumar,[1] Harbir S. Kohli.[1] *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]Lokmanya Tilak Municipal General Hospital and Lokmanya Tilak Municipal Medical College, Mumbai, India.*

Background: Neural epidermal growth factor-like 1 -associated membranous nephropathy (NELL1 MN) is related to multiple secondary causes, including malignancy and intake of complementary and alternative medicines. The association of CAM intake to NELL1 MN is well-reported in India. However, the outcome of the NELL1 MN remains to be determined.

Methods: We analysed retrospectively clinicopathologic features of NELL1 MN and compared them to non-M-type Phospholipase A2 receptor (PLA2R)/NELL1 MN from our PGIMER-primary MN registry and LTMC, Mumbai. We express the data as numbers, percentages, mean ± standard deviation (range) for normally distributed variables and median and interquartile range, otherwise.

Results: A total of 21 patients had NELL1 MN; the median age, proteinuria, creatinine, and albumin were 37 (26.5,55.5) years, 6.7(3.9,10.5) g/day, 1 (0.7,1.4) mg/dl and 2.4 (1.9,2.7) g/dl, respectively. 14(67%) patients received a modified Ponticelli regimen. For comparison, we included 21 consecutive patients of non-PLA2R/NELL1 MN. The median age, proteinuria, creatinine and albumin were 41 (30,54) years, 5.3 (2.7,8.7) g/day, 1 (0.7,1.3) mg/dl and 2.4 (1.9,3.0) g/dl, respectively. 14 (67%) had a history of CAM intake in the NELL1 MN group, which was higher than the non-PLA2R/NELL1 MN group (p<0.001); the malignancy work-up was negative in all the cases. The requirement for immunosuppressive therapy was higher in the NELL1 MN group compared to the non-PLA2R/NELL1 MN group (p=0.04). In the NELL1 MN group, we lost two patients to follow-up after a median follow-up of 18 (10,28) months; 15 (79%) patients achieved remission. Two patients died due to infectious complications. 78% and 65% of the patients in the NELL1 and non-PLA2R/NELL1 MN achieved remission (p=0.48).

Conclusions: The present report highlights the association of NELL1 MN with CAM intake compared to non-PLA2R/NELL1 MN. Three-fourths of the NELL1 MN responded to in-sighting drug withdrawal/ immunosuppressive therapy.

TH-PO630

Kidney Outcomes in Self-Reported Black Patients with Primary Membranous Nephropathy in the Cure Glomerulonephropathy Study (CureGN)

Margaret Helmuth,[1] Salem Almaani,[2] Isabelle Ayoub,[2] Dhruti P. Chen,[3] Leonela A. Villegas,[4] Cynthia C. Nast,[5] Bruce M. Robinson,[6] Vimal K. Derebail,[3] Andrew S. Bomback,[7] Louis-Philippe Laurin.[8,9] Cure Glomerulonephropathy Study. *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]The Ohio State University Wexner Medical Center, Columbus, OH; [3]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Connecticut Children's Medical Center, Hartford, CT; [5]Cedars-Sinai Medical Center, Los Angeles, CA; [6]University of Michigan, Ann Arbor, MI; [7]Columbia University, New York, NY; [8]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [9]Universite de Montreal, Montreal, QC, Canada.*

Background: Primary membranous nephropathy (pMN) is a common cause of nephrotic syndrome in adults. Disease progression in Black versus non-Black patients with pMN remains to be fully characterized.

Methods: CureGN is an ongoing multi-center prospective, observational cohort of children and adults with biopsy-proven pMN or 3 other primary glomerular diseases. First diagnostic biopsies were performed between 2010 and 2023. For this analysis, we report baseline clinical data at enrollment, proportion of time on immunosuppression during follow-up, and incident rates for kidney failure and 40% eGFR decline. Time to kidney outcomes was estimated using adjusted Cox proportional hazards models.

Results: As of May 2023, 608 pMN patients were enrolled (580 with available follow-up data). Of those, 93 were self-reported Black/African American race: median age 52 (IQR, 37-64); 39% female; and median follow-up time of 4.4 yrs. Among 444 pMN patients genetically sequenced, 12 (3%) had 2-high risk APOL1 alleles; of the 73 pMN patients with self-reported Black/African American race who were sequenced, 11 (15%) had 2-high risk APOL1 alleles.

Conclusions: In patients with pMN, self-reported Black race appears to be strongly associated with worse kidney outcomes despite having similar eGFR at enrollment. Additional analyses including assessment of genetic factors are underway to gain understanding of determinants of this observed association.

Funding: NIDDK Support

	Black (N=93)	Non-Black (N=515)
Median eGFR at enrollment (mL/min/1.73m^2) (IQR)	76.5 (51.2-103.9)	78.4 (52.6-101.0)
Median urine protein to creatinine ratio at enrollment (IQR)	4.3 (1.5-8.2)	2.7 (0.7-6.3)
Proportion of time on any immunosuppression during study follow up (%)	27	28
Kidney failure rate (per participant year)	0.053	0.016
eGFR decline >40% rate (per participant year)	0.082	0.033
Kidney outcomes (Black vs. Non-Black)	**HR (95% CI)**	**p-value**
Kidney Failure	3.3 (1.6-6.6)	0.0008
Kidney Failure & eGFR decline >40%	2.4 (1.4-3.9)	0.0007
Complete Remission*	0.7 (0.4-1.1)	0.1

All models are adjusted for sex, age at biopsy, immunosuppression use prior to biopsy, UPCR at enrollment, eGFR at enrollment and time from biopsy to enrollment. *Among those who entered the study not in complete remission. eGFR = estimated glomerular filtration rate (per CKiD-U25 if age <25 years or CKD-EPI-2021).

TH-PO631

Membranous Nephropathy Outcomes Among Children and Adults: Cure Glomerulonephropathy Study (CureGN)

Leonela A. Villegas,[1,2] Margaret Helmuth,[3] Vimal K. Derebail,[4] Isabelle Ayoub,[5] Salem Almaani,[5] Bruce M. Robinson,[6] Louis-Philippe Laurin,[7] Meryl Waldman.[8] *[1]Connecticut Children's Medical Center, Hartford, CT; [2]UConn Health, Farmington, CT; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]University of North Carolina Wilmington, Wilmington, NC; [5]The Ohio State University Wexner Medical Center, Columbus, OH; [6]University of Michigan, Ann Arbor, MI; [7]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada; [8]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Membranous nephropathy (MN) is a rare entity in children, whereas it's one of the most common causes of primary nephrotic syndrome in adults. There are limited data on disease progression in children, as well as uncertainty about differences between childhood vs adult-onset MN.

Methods: CureGN is a multi-center prospective, observational cohort of individuals with biopsy-proven glomerular diseases. For this analysis, baseline clinical data and proportion of time on immunosuppression (IS) across study follow up were reported. Cox proportional hazard models were used to estimate time to kidney outcomes, and linear mixed models to assess estimated glomerular filtration rate (eGFR) trajectories. Models were adjusted for sex, age at biopsy, IS prior to biopsy, urine protein to creatinine ratio (UPCR), eGFR, and time from biopsy to enrollment.

Results: Among 608 MN participants (580 with ≥1 follow-up visit), 54 (9%) had childhood-onset MN (age <18 at time of biopsy) with characteristics including: 48% female, median age 14 years (IQR, 12-17), and 15% self-identify as Black. Overall, childhood-onset MN had an increased risk of end stage kidney disease (HR, 5.1; 95% CI, 1.45-18) in comparison to adults. The eGFR decline was steeper in children (-3.75 (±0.87) ml/min/1.73m2 per year) than adults (-0.14 (±0.78) ml/min/1.73m2 per year) (p<0.0001).

Conclusions: Despite potential for remission, children with MN had steeper eGFR decline and faster time to kidney failure than adults. Additional data are needed to extend our understanding of determinants of disease and outcomes to guide therapies and inform practice guidelines.

The Epidemiology of Primary Membranous Nephropathy: A Single-Centre Study over Two Decades

Joshua Storrar, Rajkumar Chinnadurai, Philip A. Kalra, Smeeta Sinha. *Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom.*

Background: Membranous nephropathy is the commonest cause of nephrotic syndrome in non-diabetic White adults over the age of 40, and can be either primary (pMN) or secondary. Management aims to induce remission- spontaneously with supportive care, or with immunosuppression (IS). Here, we describe the natural history of this condition in a large tertiary centre in the UK.

Methods: 178 patients with pMN were identified over 2 decades. We collected data on demographics, baseline laboratory values, treatment received and outcomes including progression to renal replacement therapy (RRT) and mortality. Analysis was performed on the whole cohort and specific subgroups.

Results: Median age was 58.3 years with 63.5% male. Median baseline eGFR was 76.7mls/min/1.73m^2 and urine protein-creatinine ratio 664g/mol. Remission (partial or complete) was achieved in 134 (75.3%), either spontaneous in 60 (33.7%) or after treatment with IS in 74 (41.6%), and of these 57 (42.5%) relapsed. Progression to RRT was seen in 10.1% with mortality in 29.8%. Those who went into remission had improved outcomes compared to those who did not (less progression to RRT [4.5% vs 28%] and death [20.1% vs 67%]). Those classified as high risk as per KDIGO also had worse outcomes than those at low risk (mortality seen in 52.6% vs 10.8%, p<0.001).

Conclusions: We provide a comprehensive epidemiologic analysis of pMN at a large tertiary UK centre. Only 10.1% progressed to RRT (much lower than classically reported). For novelty, the KDIGO risk classification was linked to outcomes, highlighting its utility for identifying patients most likely to progress. The Salford glomerulonephritis research group was supported by an unrestricted project grant from CSL Vifor.

Characteristics of Membranous Nephropathy Patients Presenting with an Arterial or Venous Thromboembolism: A Retrospective Cohort Study

Ruben Visch, Jack F. Wetzels, Anne-Els van de Logt. *Radboudumc, Nijmegen, Netherlands*.

Background: Membranous nephropathy (MN) is associated with a very high risk for developing arterial (ATE) or venous (VTE) thromboembolism. A previous study suggested an association between high PLA2Rab titers and ATE/VTE risk. We aimed at comparing MN patients with ATE/VTE at presentation versus MN patients without.

Methods: A total of 508 incident nephrotic MN patients were enrolled in this study. Nephrotic patients with ATE/VTE from six months prior and up to two weeks after the diagnosis of MN were defined as cases. Controls were MN patients without ATE/VTE. Differences in baseline data and outcome were studied.

Results: Twenty-five patients (5%) with ATE (n=6) or VTE (n=19) at presentation were compared to 483 patients without ATE/VTE. Baseline characteristics are presented in table 1. Approximately 75% of patients were PLA2Rab positive. There were no differences in PLA2Rab titer nor in severity of nephrotic syndrome between patients with or without ATE/VTE (Table). During follow-up (median 28.5 [11.7 – 66.4] months), 64% in the VTE/ATE group was treated with immunosuppressive therapy, compared to 58% in the control group (p = .713). Spontaneous remissions occurred in three patients in the ATE/VTE group.

Conclusions: We could not confirm the association between higher PLA2Rab levels and presentation with ATE/VTE. All patients were severely nephrotic, likely explaining the futility of serum albumin. Better biomarkers of thrombotic risk are needed.

Table 1. Baseline characteristics of the studied MN patients with and without an ATE or VTE at presentation

Baseline characteristics	With ATE/VTE (n=25)	Without ATE/VTE (n=483)	p Value
Gender (male, n (%))	20 (80)	336 (70)	0.375
Age (years)	55 ± 13	55 ± 15	0.999
PLA2R-related M (n, %)	20 (80)	358 (74)	0.673
sCreatinine (umol/l)	102 [81-149]	91 [77-113]	0.263
sAlbumine (g/L)	18 [14-24]	20 [16-24]	0.187
UPCR (g/10 mmol)	8.0 [5.9-9.9]	6.9 [5.0-10.3]	0.269
PLA2R-ab titer (RU/ml)*	91 [50-153]	87 [22-218]	0.604

*aPLA2R titers at presentation were available for 16 and 360 patients in the cases and control groups respectively.

TH-PO634

A Nomogram Prediction Model for Treatment Failure in Primary Membranous Nephropathy

Chanyu Geng,[1,3] Yunlin Feng.[1,2] *[1]Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]University of Electronic Science and Technology of China, Chengdu, China*.

Background: The natural course of primary membranous nephropathy (PMN) is heterogeneous. Immunosuppressive therapy is recommended to PMN patients at risk for renal function deterioration. Prediction model for treatment failure of PMN has been rarely reported.

Methods: This study retrospectively included PMN patients diagnosed by renal biopsy in Sichuan Provincial People's Hospital from January 2017 to December 2020. Information of clinical characteristics, laboratory test, pathological examination, and treatment was collected. The outcome was treatment failure at the end of twelve months. Simple logistic regression was used to identify candidate predictive variables. Forced-entry stepwise multivariable logistic regression was used to develop the prediction model, of which the performance was evaluated using AUC, calibration plot, and DCA analysis. Internal validation was performed using bootstrapping method.

Results: A total of 310 patients were recruited in this study. The comorbidity rates of hypertension and diabetes were 37% (112/310) and 11% (33/310), respectively. At renal biopsy, the medium levels of eGFR, serum creatinine, serum albumin, proteinuria and PLA_2R antibody were 102.3 ml/min/1.73m^2, 70.1 µmol/L, 24.3 g/L, 5.9 g, and 35.48 RU/ml. 116 patients achieved the outcome. Forced-entry stepwise multivariable logistic regression indicated that PLA_2R antibody (OR=1.002, 95%CI: 1.001-1.003, P=0.002), renal interstitial inflammatory cells infiltration (OR=1.935, 95%CI: 1.393-2.478, P=0.017), and C3 deposit on immunofluorescence (OR=0.294, 95%CI: -0.928-1.515, P=0.049) were the three independent risk factors for treatment failure of PMN. The final prediction model has an AUC (95% CI) of 0.653(0.590-0.717) and a net benefit in the range of 23%-77%.

Conclusions: PLA_2R antibody, renal interstitial inflammatory cells infiltration, and C3 deposit on immunofluorescence were the three independent risk factors for treatment failure at 12 months in PMN. Our prediction model may help to identify patients with risk of treatment failure thus avoid unnecessary drug exposure and side effects.

Interim Analysis of Dapagliflozin in Inactive Lupus Nephritis Cross-Over Randomized Trial

Gisele Vajgel, Carlos R. Silva Miranda Filho, Camila B. Oliveira, Denise M. Costa, Braziliano M. da Silva Júnior, Camilla A. de Lima, Paula S. Sandrin-Garcia, Lucila Maria Valente. *Universidade Federal de Pernambuco, Recife, Brazil*.

Background: Clinical trials with sodium-glucose co-transporter 2 (SGLT2) inhibitors have demonstrated to slow the progression of CKD but excluded Lupus Nephritis (LN) patients. This study will assess efficacy and safety of dapagliflozin in inactive LN with residual proteinuria.

Methods: The present cross-over RCT(RBR-3vcg568) is including adults with chronic LN class III or IV(+/-V), proteinuria >500mg/24h and eGFR ≥20ml/min in maintenance therapy. RAASi should be stable >4w. We exclude patients with recurrent urinary infections; biopsy with active LN (AI>2) and use of induction therapy in the last 12mo, including CNI; and prednisone ≥20mg/d. Patients are randomized to receive dapagliflozin 10mg on top of standard of care (SoC) therapy or not. After 24w the groups are switched off. Primary endpoint is reduction of proteinuria compared to baseline at 6 and 12mo. Secondary endpoints are changes in weight and blood pressure and number of infections. The sample size was calculated for 28 patients enrolled for 80% power to detect a 25% relative risk reduction in proteinuria (α=0.05).

Results: From 87 screened class III or V(+/-V) LN patients in maintenance therapy, we excluded 67 due to active LN, low proteinuria or low eGFR. We have included 20 patients that were randomized 1:1. There were 18 (90%) women, mean age was 39.5y (±11.1), 1 (5%) had diabetes, median eGFR was 49.5ml/min (40.8-113.8), median proteinuria was 1133mg/24h (833.8-1749), 1 (5.5%) had low C3 or C4, all patients had SLEDAI ≤6 and used MMF≤2g/day. We analysed 6 and 7 patients from initial dapa and 6 and 4 patients from initial SoC after 3 and 6mo, respectively. Although the sample was not powered to compare the groups, initial results showed lower proteinuria in both groups at 3 and 6mo compared to baseline but did not show differences between them. Dapagliflozin was well tolerated, there were no infection episodes during the follow-up,

no weight and blood pressure changes, but 5 (45.4%) patients with dapagliflozin had symptoms of hypotension.

Conclusions: We expect that the complete results of this trial will help to evaluate whether the SGLT2 inhibitor, added to LN maintenance therapy, could safely reduce the residual proteinuria of inactive LN patients.

Current Status of Treatments for IgA Nephropathy in Japan: A Descriptive Study Using Claims Database

Keiichi Matsuzaki,[1] Mami Ishida,[2] Tateki Kumakura,[3] Takashi Sozu,[4] Hitoshi Suzuki,[5] Yusuke Suzuki.[6] *[1]Department of Public Health, Kitasato University School of Medicine, Sagamihara, Japan; [2]Department of Medical Informatics and Clinical Epidemiology, Kyoto Prefectural University of Medicine, Kyoto, Japan; [3]Department of Information and Computer Technology, Tokyo University of Science Graduate School of Engineering, Tokyo, Japan; [4]Department of Information and Computer Technology, Faculty of Engineering, Tokyo University of Science, Tokyo, Japan; [5]Department of Nephrology, Juntendo University Urayasu Hospital, Urayasu, Japan; [6]Department of Nephrology, Juntendo University Faculty of Medicine, Tokyo, Japan.*

Background: Several questionnaire-based studies have clarified the current status of treatment for IgA nephropathy (IgAN) in Japan. However, there have been few studies on based on the medical claims records. The aim of this study is to clarify the current treatment status for IgAN using the medical claims database in Japan.

Methods: Medical claims data were retrieved from JMDC (Tokyo, Japan). To interpret the medical claims data, we used the International Classification of Diseases, Tenth Revision codes (ICD-10) for disease, Anatomical Therapeutic Chemical (ATC) codes for drugs, names of the medical practice for treatment procedure, respectively. First, we extracted the claims who had disease code of IgAN from April 2014 to October 2020 (31282 patients, 469173 receipts). Then, we included the patients aged between 18 and 80 years at the index date with confirmed IgAN diagnosis at least 6 months of continuous insurance coverage/enrollment after the index date. We defined the newly diagnosed IgAN patients as those who underwent renal biopsy and confirmed IgAN more than twice (at least once as the "main disease"). Treatment patterns were categorized by ATC codes and names of the medical practice. Patient who occurred in severe infectious disease was defined as recorded the sequential organ failure assessment score in hospital record.

Results: Among the 4554 included patients, 2200 patients (48.3%) received the corticosteroids. Of those, severe infectious disease occurred in only 8 patients (0.17%). Renin-angiotensin system inhibitors (RAS-I) were used in 2682 patients (58.9%). Women aged 18-29 years had a lower prescription rate of RAS-I (30.2%) than other groups. Of the 805 patients were newly diagnosed IgAN (49.6% men; mean age 44.9), 396 patients (49.2%) underwent the tonsillectomy and 684 patients (85.0%) underwent the corticosteroid therapy including the oral corticosteroid alone respectively. Tonsillectomy with corticosteroid pulse therapy was the most commonly chosen initial treatment procedure (358 patients: 44.5%).

Conclusions: Tonsillectomy with corticosteroid pulse therapy was the standard treatment in Japan.

TH-PO637

Clinical Manifestation and Prognosis of Membranous Nephropathy in Patients with Primary Sjögren Syndrome

Fangxing Hou, Linfeng Zou, Xiaoxiao Shi, Peng Xia, Yan Qin, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Glomerulonephropathy (GN) in primary Sjögren's syndrome (pSS) was rare. We aimed to compare the clinical features and prognosis between patients with membranous nephropathy and pSS (pSS-MN) and idiopathic MN (iMN) patients.

Methods: From January 1993 to September 2022, at Peking Union Medical College Hospital, we enrolled 96 pSS-MN patients diagnosed with renal pathology and the revised version of the American-European Consensus Group. The control group was 150 iMN patients diagnosed with renal pathology and positive serum anti-M-type phospholipase A2 receptor (PLA2R) antibody.

Results: Compared to the iMN patients, the pSS-MN patients were older, predominantly females (80.2% vs. 44.7%, $P < 0.05$), with lower 24h urine proteins, higher serum IgG levels, more anemia, and hypocomplementemia. pSS-MN patients had lower ratios of positive serum anti-PLA2R antibody (34.0% vs. 59.1%) and positive tissue PLA2R antigen (65% vs. 87.3%) (both $P < 0.05$). During the median time of 22 months, treated with a combination of glucocorticoids, immunosuppressive agents (cyclophosphamide, calcineurin inhibitors, tripterygium glycosides), or rituximab, the patient's eGFR remained normal. Moreover, the 24h urine proteins decreased from 3.1 g/d to 0.8 g/d.

Conclusions: We reported the largest cohort of pSS-MN patients displayed more pronounced immunological anomalies, with a lower prevalence of positive serum anti-PLA2R antibody and tissue PLA2R antigen than the iMN patients, and responded well to the treatment with stable eGFR.

Funding: Government Support - Non-U.S.

TH-PO638

Membranous Nephropathy: A Retrospective Observational Study in a Single Renal Unit

Mei Y. Tan, Elshaeima Mohammed, Richard J. Fluck, Khai Ping Ng. *Royal Derby Hospital, Derby, United Kingdom.*

Background: Membranous Nephropathy (MN) is a common cause of nephrotic syndrome in adults. The diagnosis and treatment paradigms for MN have evolved with the identification of PLA2R autoantibodies and evidence for the use of Rituximab. We aim to retrospectively examine the treatments and outcomes of all adults diagnosed with MN in a single renal centre, March 2013 to March 2023.

Methods: Patients' demographics, clinical presentation, treatments, full remission (FR), partial remission (PR), relapse, renal outcome and complications were collected via electronic health records.

Results: In total, 75 patients were identified with 13 diagnosed as secondary MN. Of the 58 patients with primary MN, their mean age was 57 (SD=14) years with 72% male and 35% positive serum anti-PLA2R. At diagnosis, their mean eGFR was 68 (SD=27) ml/min, uPCR 781 (SD=557) mg/mmol, serum albumin 20 (SD 6) g/L. 98% received RAAS inhibitor. Ten patients (17%) achieved FR or PR without further need of immunosuppressive therapy (IS). Of the 48 patients, the median time from diagnosis to start of IS was 2 (IQR 4) months. The majority (63%) received oral cyclophosphamide and prednisolone (CYP) as first line IS, whilst 19%, 15% and 4% received calcineurin inhibitor (CNI), prednisolone only and Rituximab, respectively. After first IS, 26% and 24% achieved FR and PR. 23 patients (47%) required second course of IS whilst 11 and 5 patients required third and fourth courses of IS, respectively. Relapses occurred in 29% of the patients. Overall, the mean eGFR at 6 months, 12 months, 2 years and 5 years was 64, 61, 62, 56 ml/min, two progressed to kidney failure and five died. The FR and PR rates were 41%, 37% following CYP, 47%, 11% following CNI and 27%, 64% following Rituximab. Pancytopenia (n=1), deranged liver function test (n=2), recurrent or opportunistic infections (n=3) and malignancies (n=4) were reported amongst those who received CYP. No significant complications were reported with Rituximab since its first use in October 2020.

Conclusions: In this cohort of MN, their overall long-term renal outcome was favourable. Although the FR rate was < 50%, progression to kidney failure was rare. Relapses remain a challenge. IS is complicated by infection and neoplasia. Biologics and diagnostics may refine therapy options in the future.

The Natural History of Focal and Segmental Glomerulosclerosis (FSGS)

Ali Poyan-Mehr,[1] Tingting Li,[2] Raymond K. Hsu,[3] Tripti Singh,[4] Nidia C. Messias,[2] Nasim Wiegley,[6] Kuang-Yu Jen,[6] Stewart H. Lecker,[5] Swati Arora,[9] Dia R. Waguespack,[7] Amanda Tchakarov,[7] Nancy D. Mendelssohn,[1] Divya Seth,[3] Iyad S. Mansour,[8] Timothy Legenzoff,[9] Tejwinder S. Sandhu,[1] Alice J. Drozd,[1] Jose D. Mena,[5] Ria S. Sood,[1] Gabriela Sanchez,[1] Jennifer Yip,[1] Isaac E. Stillman.[10] *[1]The Permanente Medical Group Inc, San Francisco, CA; [2]Washington University in St Louis, St Louis, MO; [3]University of California San Francisco, San Francisco, CA; [4]University of Wisconsin-Madison, Madison, WI; [5]Beth Israel Deaconess Medical Center, Boston, MA; [6]University of California Davis, Davis, CA; [7]The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX; [8]Banner University Medical Center Tucson, Tucson, AZ; [9]Allegheny Health Network, Pittsburgh, PA; [10]Mount Sinai Health System, New York, NY.*

Background: FSGS is the tissue manifestation of various kidney diseases that ultimately lead to end-stage kidney disease in most patients. Their rare and heterogeneous presentations and unpredictable responses to therapies pose a tremendous challenge. Here we report on one of the most extensive natural history studies of patients with a biopsy diagnosis of FSGS.

Methods: Nine collaborating sites are enrolling 800 patients with primary, genetic, or FSGS of unknown cause (Fig. 1A) diagnosed between Jan. 1, 2000, and Aug. 1, 2021. The time of the first kidney biopsy is the index date, flanked by pre-biopsy baseline patient characteristics and longitudinal follow-up data of outcomes of interest (Fig. 2B & C).

Results: We have collaboratively created a decentralized registry with 366 data elements for patients with glomerular diseases, secured regulatory approval for deidentified data sharing, and enrolled 103 eligible patients to date.

Conclusions: Large retrospective studies of rare diseases face difficult-to-overcome challenges, including variability in data, uniform definitions, and a need for a regulatory framework for data sharing. Here, we have leveraged a decentralized registry to exchange deidentified patient information, creating a large multi-site retrospective study for patients with FSGS across highly diverse populations and healthcare settings.

Funding: Commercial Support - Travere Therapeutics

Adult patients (age ≥18 years) with a tissue diagnosis of FSGS based on a native kidney biopsy performed during the study period who have a minimum of one-year clinical follow-up data.

Inclusion criteria:

- A tissue diagnosis of FSGS (native kidney biopsy report), with any degree of foot process effacement that is suspected to be due to "primary FSGS"
- A tissue diagnosis of FSGS (native kidney biopsy report), suspected to be "secondary FSGS," however without any apparent histological or clinical evidence of a secondary cause.
- Genetic podocytopathies

Exclusion criteria:

- Type 1 DM or uncontrolled DM2 (HbA1c >8% or 64mmol/mol) at time of kidney biopsy
- History of HIV, HepB, or HepC infection
- Presence of any systemic autoimmune disorders such as lupus, IgA, ANCA GN, MGRS, etc.
- Presence of any secondary cause such as morbid obesity (BMI>40 kg/m2), COVID19 associated FSGS, inherited basement membrane disorders, drug-induced FSGS (including but not limited to bisphosphonates, cocaine, heroin, and anabolic steroids)
- Collapsing FSGS

Figure 1. Study population inclusion criteria

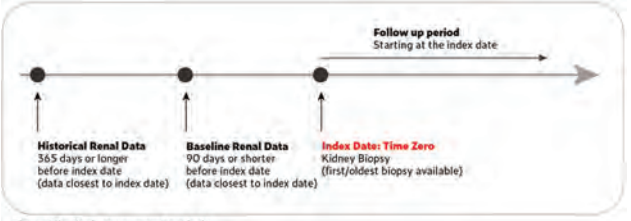

Figure 2A. Study assessment periods

Outcome	Definition
eGFR	Percent change in eGFR from baseline at years one, three, and five. eGFR is calculated using the new creatinine-based equation to estimate GFR without race
Slope of eGFR	Slope of eGFR assessed at years one, three, and five.
Proteinuria	Percent change in proteinuria from baseline at years one, three, and five, post biopsy.
Time to partial remission	The probability of achieving a UPCR ≤1.5 g/g and a >40% reduction from baseline in UPCR at years one, three, and five.
Time to complete remission	The probability of achieving no proteinuria (UPCR <0.2 g/g or ACR < 30, or dipstick trace or negative for protein) at years one, three, and five.
Time to MAKE (Major Adverse Kidney Events)	The probability reaching a confirmed 40% change in eGFR, end-stage renal disease (ESRD), or death. (ESRD is defined as initiation of renal replacement therapy [RRT], kidney transplantation, or eGFR <15 mL/min/1.73 m2 at years one, three, and five from the index date
eGFR decline	The probability reaching a confirmed 40% change in eGFR
End-stage renal disease (ESRD)	ESRD is defined as initiation of renal replacement therapy [RRT], kidney transplantation, or eGFR <15 mL/min/1.73 m2 at years one, three, and five from the index date
Renal death	Deaths that result from renal failure and immediate sequalae of this, such as uremia, hyperkalemia leading to cardiac arrest, acute kidney injury.
Time to MACE	The probability of major adverse cardio-vascular events defined as nonfatal stroke, nonfatal myocardial infarction, and cardiovascular death at years one, three, and five from the index date.
Hospitalizations	Frequency and duration of hospitalizations
Cardiovascular death	Deaths that result from an MI, sudden cardiac death, death due to heart failure, death due to stroke, death due to cardiovascular procedures, death due to cardiovascular hemorrhage, and death due to other cardiovascular causes
All cause death. Time to event.	Any death. Mortality risk at years one, three, and five from the index date.

Figure 2B. Outcomes of interest.

TH-PO640

Incidence Rates of Primary Focal Segmental Glomerulosclerosis (FSGS) Within a Diverse Adult Southern California Population, 2010-2021

Mercedes A. Munis,[1] Qiaoling Chen,[1] T. M. Hill,[2] Teresa N. Harrison,[1] Sandipan Bhattacharjee,[2] Asher D. Schachter,[3] Ancilla Fernandes,[2] Min Zhuo,[3] John J. Sim.[1] *[1]Kaiser Permanente Southern California, Pasadena, CA; [2]Otsuka Pharmaceutical Development and Commercialization Inc, Princeton, NJ; [3]Visterra Inc, Waltham, MA.*

Background: FSGS is a leading cause of end-stage kidney disease. However, little epidemiologic data exist exploring the specific FSGS subtypes that increases the importance of understanding this rare disease and subsequent management strategies. The goal of this study was to estimate the incidence of FSGS and primary FSGS among a large diverse population in the United States.

Methods: A retrospective cohort study within Kaiser Permanente Southern California was performed among patients (age ≥18yrs) with renal biopsy-proven FSGS between 2010-2021. Presumed primary FSGS consisted of biopsies with FSGS as the principal diagnosis. Manual chart reviews were then performed to confirm primary FSGS with extensive foot process effacement (FPE) of ≥80%. Patient demographics were assessed during the 1 year prior to date of biopsy (index date). Annual incidence rates (per 100,000 person-years) were calculated after adjusting to 2020 US census.

Results: Among 7,115,249 unique persons, we identified 3,839 patients with biopsy-proven FSGS. Of 1,509 presumed primary FSGS, 640 (42.4%) were confirmed primary FSGS (mean age [SD] 55.5 years [17.9], 56.4% male, 35.8% Hispanic/Latino, 28.8% White, 17.8% Asian/Pacific Islander, 15.9% Black). The adjusted annual incidence rates of primary FSGS ranged from 1.3 – 2.4 per 100,000 person-years (Table 1). The highest mean primary FSGS incidence rates per 100,000 person-years were among Black (3.4), Asian (2.7), and Pacific Islander (2.8) patients (Table 2).

Conclusions: Among a racially/ethnically diverse population, primary FSGS accounted for 16.7% of all biopsy-proven FSGS. Our findings suggest that primary FSGS remains a rare disease but varies across race/ethnicity. Proper identification of primary FSGS in patients may help facilitate tailoring therapeutic options.

Demographic, Clinical Characteristics, and Treatment Outcomes of C3 Glomerulopathy in China: A Nationwide Retrospective Cohort Study

Sheng Nie,[1] Shiyu Zhou,[1] Qi Gao,[1] Ping Li,[2] Fei Gao,[2] Shaosen Zhang.[2] *[1]Southern Medical University Nanfang Hospital, Guangzhou, China; [2]Beijing Novartis Pharma Ltd, Beijing, China.*

Background: As a rare glomerular disease, there is limited data on the demographic, clinical characteristics, and treatment outcomes of C3 glomerulopathy (C3G) in China.

Methods: Patient medical records were retrospectively collected from 24 regional central hospitals across China, from 2013 to 2021. Descriptive analysis was performed on clinical characteristics, treatment, and outcomes. χ^2 test was performed to analyze the difference between children and adult groups.

Results: 470,000 patients with chronic kidney disease (CKD) were enrolled, of which 102 patients were C3G confirmed by renal biopsy. Among them, 9 were diagnosed with dense deposit disease and 93 were diagnosed with C3 glomerulonephritis. At the time of diagnosis, 46.2% of C3G patients had an eGFR<60 ml/min/1.73m^2, 47.1% had low serum complement C3, 48.8% had low serum C4, 22.5% had abnormal blood/urine protein electrophoresis, and 3% had elevated serum globulin. Besides C3 deposition, 4.9% and 12.7% of patients combined IgA and IgG deposition in pathological immunofluorescence, respectively. Compared to children, adult patients tended to present severe symptoms at diagnosis (Table 1). 55 patients (53.9%) received treatment with RASI, while 48 (47.1%) patients received glucocorticoids and 24 patients combined glucocorticoids with other immunosuppressants (cyclosporine, etc.). 16 patients were followed up for more than one year. Among them, 2 patients showed ≥40% decrease in eGFR from baseline, and 3 patients developed end stage renal disease (ESRD) within one year.

Conclusions: C3G has heterogeneous clinical characteristics, and adult patients presented more serious symptoms at diagnosis. Gaps are identified for C3G patients standardized treatment in China, and targeted therapy is urgently needed.

Characteristics of Patients with Complement 3 Glomerulopathy (C3G) in a US Multi-Center Assessment

Briana C. Ndife,[1] Carolina A. Aldworth,[1] Kathleen Murphy,[1] Jennifer Nguyen,[1] Irina Pivneva,[2] Marie Louise Edwards,[2] Annika Anderson,[2] James Signorovitch,[2] Pietro A. Canetta.[3] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Analysis Group Inc Boston, Boston, MA; [3]Columbia University Irving Medical Center, New York, NY.*

Background: C3G is characterized by C3 deposition in the glomeruli caused by abnormal activation of the alternative complement pathway. There are no approved therapies for C3G. Despite supportive care, C3G remains a progressive form of kidney disease, with novel treatments needed to improve outcomes. Contemporary datasets on the clinical burden of patients with C3G are limited. Using real-world evidence from electronic medical records, this study describes the characteristics of patients diagnosed with C3G in the US.

Methods: This was a retrospective cohort study of patients included in the US Optum Life Science clinical electronic health record database who were aged ≥12 years at C3G diagnosis (per ICD-10 or SNOMED; index date) between 01/2015 and 06/2022. Patients had continuous clinical activity ≥12 months before (baseline) and ≥6 months after (follow-up) index date, and were followed until death or data end. Patient and clinical characteristics at index date were evaluated using descriptive statistics.

Results: Of 284 patients in the final sample, 78% were White, 11% African American, 2% Asian, and 10% other/unknown. Mean age ± SD was 49 ± 21 years, 50% were male, and 136/228 (60%) had stage ≥3 CKD at index. At baseline, mean Charlson Comorbidity Index (CCI) score ± SD was 2.3 ± 2.7. Of comorbidities included in the CCI, the most common included chronic pulmonary disease (25%) and diabetes without chronic complication (20%). At baseline, hypertension (65%) was the most common C3G-related comorbidity; 10% of patients had undergone dialysis and 12% kidney transplant. Obesity (BMI ≥30) was recorded in 100/249 patients (40%). Common C3G-related treatments at baseline included corticosteroids (54%), ACE inhibitors (41%), ARBs (26%) and immunosuppressants (21%). At baseline, proteinuria was assessed in 126 patients (44%); mean protein/creatinine ratio ± SD was 2.9 ± 3.9 g/g. Of 100 patients (35%) with available data, 34% had complement C3 level <77 mg/dl.

Conclusions: This contemporary assessment of patients with C3G from a national US cohort identified a population that presented with multiple comorbidities and advanced kidney disease around the time of diagnosis.

TH-PO643

CKD Progression in Patients with Complement 3 Glomerulopathy (C3G) in a US Multi-Center Assessment

Briana C. Ndife,[1] Carolina A. Aldworth,[1] Kathleen Murphy,[1] Jennifer Nguyen,[1] Irina Pivneva,[2] Marie Louise Edwards,[2] Annika Anderson,[2] James Signorovitch,[2] Pietro A. Canetta.[3] *[1]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [2]Analysis Group Inc Boston, Boston, MA; [3]Columbia University Irving Medical Center, New York, NY.*

Background: Patients with C3G have high rates of progression despite treatment. Using electronic medical record data, this study characterized disease progression in a US cohort of patients with C3G.

Methods: This was a retrospective cohort study of de-identified patients within the US Optum Life Science clinical electronic health record database, aged ≥12 years at C3G diagnosis (per ICD-10 or SNOMED) between Jan 2015–Jun 2022. Index date was the date of diagnosis. Patients had continuous clinical activity ≥12 months before (baseline) and ≥6 months after (follow-up) index. Patients were followed until death or data end. Patient and clinical characteristics were assessed using descriptive statistics, and time to CKD progression using Kaplan–Meier analyses.

Results: Of 284 patients in the final sample, mean age ± SD was 49 years ± 21; 136/228 (60%) had stage ≥3 CKD at index. During follow-up, 115/188 patients (61%) progressed to a higher CKD stage than at index, and/or to kidney failure; median time to progression was 12.6 months (95% CI: 9.4, 17.7). At 6 and 12 months, 38% and 48% of patients, respectively, had a progression of CKD stage. In progressors (n=115), mean age was 54 years and mean Charlson Comorbidity Index (CCI) score was 2.8; in non-progressors (n=73), mean age was 48 years and mean CCI score was 1.8. Among progressors and non-progressors, 14% and 6% of patients, respectively, were African American, had hypertension (79% and 55%), and had prior kidney transplant (10% and 3%) at baseline. At index, 68/115 (59%) of progressors and 28/73 (38%) of non-progressors had CKD stage ≥3. Within 90 days of index, a higher proportion of progressors relative to non-progressors were treated with ACE inhibitors (31% and 22%) or ARBs (23% and 14%). Up to 90 days after index, mean ± SD protein:creatinine ratio was 2.3 ± 2.6 g/g in 21 assessed non-progressors and 3.7 ± 5.0 g/g in 53 assessed progressors. The proportion of patients with complement C3 level <77 mg/dL at baseline was 15/47 (32%) among progressors and 9/24 (38%) among non-progressors.

Conclusions: Patients with C3G progress rapidly despite supportive care. Noted differences between progressors and non-progressors warrant further investigation.

Qualitative Analysis Reveals Insights to Meet the Needs of Patients with C3 Glomerulopathy (C3G)

Ryan Woolley, Stephanie C. Olebara, Melanie Paris, Michael Spigler. *American Kidney Fund, Rockville, MD.*

Background: C3 glomerulopathy (C3G), a rare condition characterized by abnormal regulation of the alternative complement pathway, results in kidney function impairment that can progress to end-stage renal disease. Published evidence of the patient experience in managing this rare condition is scarce. Therefore, the American Kidney Fund (AKF) sought to gain insight into the unique needs and challenges of people affected by C3G by convening a focus group of patients and caregivers.

Methods: Through convenience sampling via a C3G social media page, 8 participants were recruited for a virtual, 60-minute focus group. Six participants were adults diagnosed with C3G and two were caregivers of children with C3G. The focus group was recorded and transcribed, then analyzed for key themes using thematic analyses.

Results: Findings revealed 3 overarching themes: limited C3G awareness among health care providers, a lack of patient-friendly C3G education material, and a need to stay connected to the community. Participants faced challenges identifying health care providers knowledgeable about C3G and with experience treating patients with C3G leading several to travel far for their care. Many also discussed their struggle with finding accessible educational information and having to navigate complex scientific literature to learn more about their condition and treatment options. Social support needs were also identified including connecting with others with this rare condition and seeing progress being made with advancements in treatments and ongoing trials.

Conclusions: C3G educational resources written in plain language, especially targeted at newly-diagnosed patients, are needed. Additionally, increased HCP education and better avenues for identifying HCPs well-versed in C3G will help patients feel more confident in their care and management plans. Lastly, finding avenues to connect patients and share insights from clinical trials and ongoing advancements will help to relieve the emotional burden felt by patients and caregivers. As part of this effort, AKF is developing a C3G education campaign centered around tackling these barriers. Gathering patient input is imperative to ensure educational resources are meaningfully tailored to patient needs and values to improve health outcomes.

Patient Characteristics and Renal Outcomes of C3 Glomerulopathy (C3G) and Immune Complex Membranoproliferative Glomerulonephritis (IC-MPGN) in the UK: A Retrospective Analysis of 287 Patients in the UK National Registry of Rare Kidney Diseases (RaDaR)

Lewis Downward,[1] Katie Wong,[1,2] Clare Proudfoot,[4] Nicholas Webb,[4] Edwin K. Wong,[3] Daniel P. Gale.[1,2] *[1]Rare Renal Disease Registry, Bristol, United Kingdom; [2]University College London Research Department of Renal Medicine, London, United Kingdom; [3]National Renal Complement Therapeutics Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle upon Tyne, United Kingdom; [4]Novartis AG, Basel, Switzerland.*

Background: Membranoproliferative glomerulonephritis (MPGN) is a rare, chronic kidney condition that encompasses immune-complex MPGN (IC-MPGN) and C3 glomerulopathy (C3G). There is limited literature on treatments and outcomes in MPGN.

Methods: This is a descriptive, retrospective study of patients recruited to RaDaR with C3G or IC-MPGN confirmed on biopsy or clinical records. Kaplan-Meier analysis and logrank statistic were used to investigate time to kidney failure and linear mixed effects models to investigate annual estimated glomerular filtration rate (eGFR) slope by disease subtype.

Results: 287 patients were included in these analyses: 135 (47%) had confirmed C3G and 152 (53%) IC-MPGN. Median age at diagnosis was 14 years for C3G patients and 23 years for IC-MPGN patients. The majority of patients in the C3G and IC-MPGN cohorts were white (74% and 79% respectively). 53% of the IC-MPGN cohort and 45% of the C3G cohort were male. C3G patients had faster annual eGFR decline compared to IC-MPGN patients (5.1 vs 3.4 mL/min/1.73m2/year), although no significant difference was found in the time from diagnosis to kidney failure (median time to kidney failure 8.3 vs 11.1 years for C3G and IC-MPGN respectively, p-value 0.14, Figure 1). Of 141 patients with medication data, 51 (36%) were adult and 90 (64%) were paediatric at diagnosis. 58% of these patients were given RAS blockade (ACE-I/ARBs), and 46% were given corticosteroids as their initial treatment (Figure 2).

Conclusions: RaDaR is a large and robust data source allowing investigation into C3G/IC-MPGN natural history. We found heterogeneity of current treatment approaches in this cohort and rapid progression to kidney failure despite current treatments.

TH-PO646

Persistence of Signs and Symptoms in Treated Patients with C3 Glomerulopathy (C3G): Evidence from Real-World Data

Richard A. Lafayette,[1] Susanna Libby,[2] Katharina Pannagl,[3] Briana C. Ndife,[4] Serge Smeets,[5] Kathleen Murphy,[4] Jonathan de Courcy,[2] Clare Proudfoot.[5]
[1]Stanford University School of Medicine, Stanford, CA; [2]Adelphi Real World, Bollington, United Kingdom; [3]Novartis Pharmaceuticals UK Ltd, London, United Kingdom; [4]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [5]Novartis Pharma AG, Basel, Switzerland.

Background: Complement 3 glomerulopathy (C3G) is a rare kidney disease, with an estimated incidence of 1-2/million/year. C3G is associated with a high risk of disease progression; approximately 50% of patients reach kidney failure within 10 years of diagnosis. This analysis aimed to describe C3G signs and symptoms (S&S) in treated patients.

Methods: Data were drawn from the Adelphi C3G Disease Specific Programme, a cross-sectional survey of C3G-treating nephrologists in US, EU5 (France, Germany, Italy, Spain, UK), China and Japan between August 2022 and April 2023. Nephrologists completed structured forms for consecutive patients presenting with C3G. The forms included demographics, C3G treatment history and clinical information including S&S.

Results: 111 nephrologists completed records for 385 C3G patients (US 100, EU5 189, China 60, Japan 36). Of the 288 receiving treatment at time of survey, median patient age was 41.0, 60% were men, 83% had C3 glomerulonephritis and 16% had dense deposit disease. 60% (173) of patients had been on treatment for <1 year, 21% (61) between 1-2 years and 19% (54) >2 years, median treatment duration was 43.2 weeks. Despite currently receiving treatment, most patients had S&S at time of survey. This was consistent in patients with a longer treatment duration. Common S&S experienced were proteinuria, hypertension, fatigue, and hematuria (**Table 1**). Around one third of patients had a CKD stage between 3b and 5, regardless of number of years on treatment. Of those patients treated for >2 years, 44% had ≥1g proteinuria/day where reported.

Conclusions: Despite treatment, C3G S&S persist in the majority of patients. Proteinuria remains high in many patients, increasing risk of progression to kidney failure. This shows a need for targeted treatments for C3G.

TH-PO647

Real-World Time to Diagnosis in C3 Glomerulopathy (C3G)

Richard A. Lafayette,[1] Katharina Pannagl,[2] Briana C. Ndife,[3] Serge Smeets,[4] Kathleen Murphy,[3] Jonathan de Courcy,[5] Susanna Libby,[5] Clare Proudfoot.[4]
[1]Stanford University, Stanford, CA; [2]Novartis Pharmaceuticals UK Ltd, London, United Kingdom; [3]Novartis Pharmaceuticals Corporation, East Hanover, NJ; [4]Novartis Pharma AG, Basel, Switzerland; [5]Adelphi Real World, Bollington, United Kingdom.

Background: Complement 3 glomerulopathy (C3G) is a rare kidney disease, with an estimated incidence of 1-2/million/year. C3G is associated with a high risk of disease progression, approximately 50% of patients reach kidney failure within 10 years of diagnosis (Dx). Delayed dx may lead to poor prognosis. This analysis aims to better understand the diagnostic pathway in C3G.

Methods: Data were drawn from the Adelphi C3G Disease Specific Programme, a cross-sectional survey of C3G-treating nephrologists in US, France, Germany, Italy, Spain, UK (EU5), China and Japan between August 2022 and April 2023. Nephrologists completed forms for consecutive patients presenting with C3G. The forms included demographics, clinical information and reasons for diagnostic delay.

Results: 111 nephrologists completed records for 385 C3G patients (EU5 189, US 100, CN 60, JP 36). Median patient age at time of Dx was 38.8, and 59% were male. Median time from symptom onset to the patient's first physician consultation was reported for 78% of patients. In the EU5 (n=150) this was 4.1 weeks (IQR: 0.3-8.7), in the US (n=63) and China (n=59) this was 4.4 weeks (IQR US: 1.3-6.4, IQR CN: 1.3-12.4), and Japan (n=30) 6.8 weeks (IQR: 4.1-17.6). Median time from first physician consultation to confirmed C3G Dx was reported for 85% of patients. Half of the patients received Dx within 4.6 weeks, 10% experienced a much longer period (**table 1**). Reasons for a delay >4 weeks between first consultation and Dx were reported for 54% of patients (n=206). Waiting to conduct biopsy (39% EU5, 38% US, 27% China and 45% Japan) and waiting for biopsy results (33% EU5, 20% US, 38% China and 32% Japan) were the most common causes. When (e)GFR was recorded at Dx (84%), 43% of patients were at CKD stages 3b-5 (GFR <45 mL/min/1.73 m2).

Conclusions: While half of patients with C3G receive a diagnosis within 4-6 weeks of presentation, 1 in 10 wait over 21 weeks. During this time patients may progress to later stages of CKD. Accelerating Dx may improve prognosis for some patients.

The Idiopathic Hypocryoglobulinemia as an Emerging Membranoprolipherative Glomerulonephritis

Dario Roccatello, Roberta Fenoglio. *University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy.*

Background: A considerable number of patients with high clinical suspicion for cryoglobulinaemic vasculitis either show negative results for the detection of cryoglobulins or show only trace amounts which cannot be characterized for composition. We aimed at establishing whether the failure to detect or the detection of trace amounts of cryoglobulin with conventional methods either identifies a peculiar subset of low level cryoglobulinaemia (from now on hypocryoglobulinaemia) or represents a separate entity.

Methods: Using a modified precipitation technique in hypo-ionic medium, we prospectively identified between 2008 and 2021 237 patients (median age 60.8 years [22-97], 137 females) having <0.5% cryocrit and clinical suspicion of autoimmune disorder.

Results: 54 out of 237 patients (22.7%) had a history of HCV infection. 169 out of 237 patients (71%) had an established underlying disease, while 68 patients (28.6%) (median age 62.9 years [29-93], 35 females) did not show either laboratory markers or clinical symptoms consonant with an underlying aetiology. These 68 cases with only trace amounts of cryoglobulins were defined as having a putatively idiopathic hypocryoglobulinaemia. Nineteen of these 68 patients (27.9%) had a history of HCV infection. Twenty-four patients out of 68 (35.3%) were positive for rheumatoid factor (RF), while 25 (36.7%) patients had signs of complement consumption, and 36 (52.9%) had increased inflammatory indexes. Seven patients only had arthralgia and constitutional symptoms while 61 out of 68 (89.7%) presented with at least one of the three cardinal signs of cryoglobulinaemic vasculitis including skin lesions, peripheral nerve involvement, and glomerulonephritis. Seventy-five percent of the subjects had type III hypocryoglobulins. In patients with hypocryoglobulinaemia the histologic features of glomerulonephritis (also examined by electron microscopy) resembled those of mixed cryoglobulinaemia-associated glomerulonephritis.

Conclusions: In conclusion, hypocryoglobulins are often polyclonal and are mainly unrelated to HCV infection. Patients who present high clinical suspicion for vasculitis, especially glomerulonephritis and yet test negative for cryoglobulinaemia detected by standard techniques, could require deeper investigation even in the absence of HCV infection, RF activity or signs of complement consumption.

TH-PO649

Prognostic Factors and Outcomes of a Large Brazilian Retrospective Cohort of Renal Amyloidosis

Valkercyo A. Feitosa, Elieser H. Watanabe, Precil D. Neves, Talita S. Siqueira, Luiz F. Onuchic. LIM/29 – Laboratório de Nefrologia Celular, Genética e Molecular. *Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil.*

Background: To date, no large studies have characterized the epidemiology and outcomes of the main types of renal amyloidosis in Brazil or Latin America.

Methods: This retrospective cohort study evaluated 81 patients with biopsy-proven renal amyloidosis, diagnosed from January 1999 to December 2022. Follow-up started at kidney disease presentation and ended at death or December 2022. Clinical presentation, including age, serum creatinine, proteinuria and amyloid type, as well as survival and prognostic factors were analyzed.

Results: From the initial 81 patients, 76 had definite biopsy-proven renal amyloidosis and were analyzed. AL amyloidosis was the most frequent type (68.4%). AA amyloidosis was present in 14.5% and was mainly related to rheumatological diseases (7/11) and familial Mediterranean fever (2/11). Hereditary forms accounted for 11.8% of cases (10.5% AFibE545V, 1.3% ATTRV30M), and the type was inconclusive in 5.3%. The etiologic type was classified as confirmed in 43.1% and probable in 56.9%. AL was associated with lower serum albumin and higher degree of proteinuria compared to the other types. Patients with AL amyloidosis almost always presented with nephrotic syndrome, unlike patients with the AFib amyloidosis, who most often presented with isolated proteinuria and hypertension. The diagnosis of AA was frequently established before 40 years of age (45.5%) and more often displayed glomerular detection of C3 (70.0% in AA, 22.9% in AL and 11.1% in AFib/ATTR). During follow-up, 67.3% of AL, 54.5% of AA and 66.7% of AFib+ATTR progressed to ESKD, and 57.7% of AL, 36.3% of AA, and 22.2% of AFib+ATTR died; median kidney survival was 10 (1-154), 21.5 (1-117) and 56 (10-146) months, respectively (p=0.024). eGFR<60mL/min/1.73m^2 at diagnosis (HR 6.50 [95% CI, 1.73-24.40]) and shorter time from symptoms to diagnosis (HR 1.07 [95% CI, 1.01-1.13]) were identified as risk factors for progression to ESKD.

Conclusions: Our data broadly characterized the types of renal amyloidosis in this large cohort and revealed that most cases were AL amyloidosis, which was associated with worse kidney and overall survival. Our findings suggest that clinical presenting features can often distinguish the types. Hereditary forms should be considered when confirmation of AL cannot be obtained and a chronic inflammatory disease is not diagnosed.

TH-PO650

Fibrinogen A Alpha-Chain Amyloidosis: A Brazilian Reality

Valkercyo A. Feitosa, Elieser H. Watanabe, Vivian C. Dourado, Precil D. Neves, Luiz F. Onuchic. *Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil.*

Background: Fibrinogen A α-chain amyloidosis (AFib amyloidosis) results from mutations in the fibrinogen A α-chain gene (*FGA*) and is the most common form of hereditary renal amyloidosis.

Methods: We characterized the natural history and long-term outcomes of AFibE545V amyloidosis in patients diagnosed by clinical presentation, renal biopsy and/or genetic testing at the University of São Paulo Medical Center from 2014 to 2022.

Results: A total of 47 patients from 15 unrelated families with AFib amyloidosis were diagnosed by genetic testing, all heterozygous for the p.E545V variant: 31 (66%) with clinical manifestation and 16 (34%) with no clinical manifestation. During the follow-up, 31 developed kidney disease at a mean age of 55.0±10.4 years. Clinical presentation consisted of proteinuria (67.7%), hypertension (84%), and kidney failure (39.3%). Nineteen (61.3%) patients progressed to end-stage kidney disease (ESKD) at a mean of 62.0±10.7 years, with a mean kidney survival of 45.5±38,7 months. The rate of estimated glomerular filtration rate (eGFR) decline was 8.45±6.41 mL/min/1.73m^2/year. Multivariate analysis showed that eGFR <60 mL/min/1.73m^2 at diagnosis was an independent risk fator for progression to ESKD (HR 5.45 [95% CI, 1.04-28.68]). 11.5% of the patients underwent chemotherapy treatment, even without evidence of plasma cell disorder. Only 9 (60%) of the unrelated probands had a family history of CKD or amyloidosis. Differences in penetrance rate were observed according to the age of the patients: 77.4% (>50 years) vs 22.6% (<50 years), p=0.028.

Conclusions: AFibE545V amyloidosis showed significantly variable penetrance according to age range. In patients with hypertension, proteinuria, and progressive renal impairment, one should consider this diagnosis to carry out targeted genetic testing for AFib, particularly for the p.E545V variant, especially in family members of identified cases. This procedure would avoid inappropriate treatment.

TH-PO651

The Clinico-Pathologic Characteristics of Patients with Fibrillary Glomerulonephritis

Omar Osman,[1] Hanny Sawaf,[1] Tariku T. Gudura,[1] Leal C. Herlitz,[1] Ali Mehdi,[1] Surafel K. Gebreselassie,[2] Shane A. Bobart.[2] *[1]Cleveland Clinic, Cleveland, OH; [2]Cleveland Clinic Florida, Weston, FL.*

Background: Fibrillary glomerulonephritis (FGN) is a rare glomerular disease with lack of sufficient understanding of the disease pathogenesis. As a result, there is a lack of good evidence to guide therapy.

Methods: We identified patients with FGN from the Cleveland Clinic Kidney Biopsy Epidemiology Project from January 2015 to March 2023. Retrospective chart review was performed to obtain demographic and clinical characteristics.

Results: From 45 patients with FGN, 30 patients had sufficient data. 70% were female and 86% self-reported as white. The median age was 64 years. Clinical features at kidney biopsy were: hypertension (100%), acute or chronic kidney disease (100%), hematuria (76%), proteinuria (60%), nephrotic syndrome (48%). Hypocomplementemia was identified in one case. Work up for secondary associations revealed, M protein (20%), Hepatitis C virus infection (16%), autoimmune conditions (23%) and solid tumor malignancy (10%). Mean serum creatinine and proteinuria at biopsy were 2.7mg/dl (0.7-10) and 3.6 gm/dl (0.1-8.7) respectively. Regarding pathology, pure mesangial (90%) followed by endocapillary hypercellularity (6.7%) were the most common patterns of injury. The majority of patients (76%) had moderate to severe interstitial fibrosis and tubular atrophy and 13% had crescents. DNAJB9 was tested on 2 samples, both were positive. 86% of patients had positive IF staining for IgG/C3/K/L with the majority of IgG staining being described as a smudgy pattern. EM showed mesangial pattern deposition and GBM thickening in more than 80% of patients. Regarding treatment and outcomes, most patients were treated with non-immuno-modulatory antiproteinuric agents. Of 7 patients treated with immunosuppressive therapy, 5 patients received Rituximab. During an average of 24 months (0-70) follow up for 13 patients with data, 23% had partial remission (proteinuria reduction > 50% with stable eGFR), 23% had persistent disease, and 53% (7) progressed to ESKD. Aside from a positive correlation between creatinine during biopsy and ESRD, no predictive variables were identified on univariate and multivariable analysis.

Conclusions: FGN is a rare glomerular disease with poor renal outcomes. Treatment strategies vary. Prospective, multicenter studies are necessary to better understand the disease pathogenesis and identify appropriate therapy.

Post-Transplant Recurrence of Glomerular Diseases: Analysis of the CureGN Database

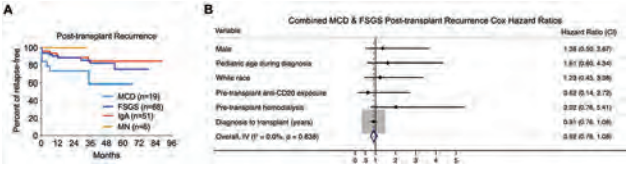
Orhan Efe,[1] Guilherme Taborda Ribas,[1] Maria Larkina,[2] Ayman Al Jurdi,[1] Frank E. Hullekes,[1] Laura H. Mariani,[2] Leonardo V. Riella.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]University of Michigan, Ann Arbor, MI.*

Background: Post-transplant recurrence of glomerular diseases is one of the leading causes of kidney graft failure. Identification of risk factors and predictive biomarkers are needed to guide management.

Methods: CureGN is a prospective multicenter international consortium of patients with biopsy-proven minimal change disease (MCD), focal segmental glomerulosclerosis (FSGS), IgA nephropathy/vasculitis (IgAN), and membranous nephropathy (MN). We included pediatric and adult patients from CureGN who underwent deceased or living kidney transplantation. The primary outcome was the risk of post-transplant recurrence. Recurrences were evaluated using a log-rank test. For secondary outcomes, clinical features of recurrent and non-recurrent patients were compared by t-test, Mann-Whitney, or Fisher's exact test. Risk factors of post-transplant recurrence were analyzed by Cox regression.

Results: A total of 144 patients were enrolled, including 19 MCD, 68 FSGS, 51 IgAN, and 6 MN. Overall, the mean age was 29.7±18.8, 46 (32%) were pediatric, 87 (60%) were male, and 88 (61%) were White. During a mean follow-up of 31.9±20.7 months, post-transplant recurrence occurred in 32%, 15%, and 12% of MCD, FSGS, and IgAN patients, respectively. None of the MN patients had a recurrence. In MCD and FSGS, the mean time to recurrence was 7.8±13.5 and 14.7±18.6 months, respectively **(Fig.1A)**. In the combined analysis of MCD and FSGS, none of the variables were associated with increased risk of recurrence (**Fig.1B**). All of the recurrent patients had dialysis pre-transplant, while 64% in the non-recurrent group (P = 0.002). For IgAN, the mean time to recurrence was 10.9±12.6 months and there was a tendency toward less White and more pre-transplant dialysis in the recurrent group. Overall, having a recurrence was associated with decreased post-transplantation eGFR in FSGS (HR 15.1, CI 13-17.3) and IgAN (HR 27, CI 22.4-31.7) in linear regression after adjusting for time.

Conclusions: In the diverse CureGN cohort, post-transplant recurrence was most common in MCD, followed by FSGS and IgAN. The recurrence of FSGS and IgAN was associated with reduced kidney graft function.



TH-PO653

Clinical Characteristics and Risk Factors Analysis on a Cluster of Patients with Acquired Solitary Kidney

Zhou Jing,[1,2] Huiming Wang.[1] *[1]Wuhan University Renmin Hospital, Wuhan, China; [2]Wuhan University, Wuhan, China.*

Background: Patients with acquired solitary kidney (ASK), including those who underwent unilateral nephrectomy and those presented with non-functional unilateral kidney atrophy due to acquired causes. While the long term outcome of ASK patients remains an issue of debate. The aim of this study was to observe the clinical characteristics of ASK patients and identify the risk factors for poor prognosis.

Methods: We performed a retrospective analysis on a case series of ASK patients once hospitalized in Renmin Hospital of Wuhan University, China, from January, 2011 to November, 2022. Preoperative and postoperative clinical and demographic data were collected until last admission, Univariate and multivariate Logistic regression models were used to analyze the risk factors for patients with postoperative eGFR <60 mL/min. Kaplan–Meier cumulative prevalence curves were used to compare the incidence of ESRD in different groups of ASK patients.

Results: 1. We enrolled 336 ASK patients in this study. Among them, 220 (65.5%) cases underwent unilateral nephrectomy due to hydronephrosis126 (37.5%) or renal cancer 94 (28.0%), the rest 116 (34.5%) patients were with unknown causes. The median age at diagnosis was 51.50 years old (IQR 42.02, 62.00), and after the median follow-up time of 6 years (IQR 3,12.75), the prevalence of hypertension, diabetes, anemia, hyperuricemia, hematuria and proteinuria were 43.8%, 15.7%, 40.8%, 37.8%, 71.1% and 44.3%, respectively. 2. K-M survival curve showed that ASK patients with hypertension, hyperuricemia, anemia, age at diagnosis ≥60 years, U-TP>2g/d were more likely to progress to ESRD. 3. Multivariate logistic regression analysis showed the risk factors which independently associated with the decreased eGFR including the age at diagnosis ≥60 years, follow-up time >10 years, hypertension, anemia, hyperuricemia, U-TP>2g/d, contralateral kidney operation history.

Conclusions: In conclusion, the ASK patients with underlying comorbidities, appears to be more susceptible in the long-term. It is particularly significant to have a strict and routine follow-up for ASK patients in high-risk.

TH-PO654

Belimumab for Recurrent Lupus Nephritis After Kidney Transplant

Mark D. Kilpatrick,[1,2] Gaurav Gupta,[1] Jason M. Kidd.[1] *[1]Virginia Commonwealth University, Richmond, VA; [2]Thomas Jefferson University Hospital, Philadelphia, PA.*

Introduction: A 31-year-old woman with a history of end stage kidney disease (ESKD) due to systemic lupus erythematosus (SLE) glomerulonephritis (Class IV/V) underwent deceased donor pediatric en bloc kidney transplant. Nine months after transplant, she developed proteinuria with 2.2 g/g on a spot urine protein to creatinine ratio. Serum creatinine was stable at 1.3 mg/dl and she was maintained on tacrolimus 4 mg twice daily, mycophenolate mofetil 360 mg twice daily and prednisone 5 mg daily. She had no prior history of rejection.

Case Description: Renal biopsy was performed and showed focal, active nephritis with mesangial hypercellularity and inflammatory cells in the endocapillary space, consistent with class III+V lupus nephritis with an activity score of 3/24. Given the recurrence of SLE nephritis despite treatment with immunosuppression, treatment with belimumab was initiated at 200 mcg weekly given subcutaneously. Six months after starting treatment, proteinuria had decreased to 0.2 g/g with stable kidney function. Repeat kidney biopsy revealed class II and class V lupus nephritis with improvement in activity index to 0/24.

Discussion: Recurrence of SLE nephritis after transplant has been shown to increase the risk of graft loss[1]. Management of recurrence varies by provider but can involve steroids and alteration of the immunosuppressive regimen[2]. Belimumab is a fully human IgG1λ recombinant monoclonal antibody directed against B-lymphocyte Stimulator (BlyS) that binds to endogenous B-cell activating factor, leading to B-cell apoptosis and diminished autoantibody production. Use has been shown to reduce disease activity and flares in patients with SLE[3]. When added to standard therapy for lupus nephritis, belimumab has been shown to improve the chances of a renal response[4]. The addition of belimumab should be considered in patients with recurrent lupus nephritis after kidney transplant. 1 Contreras G, et al. Recurrence of lupus nephritis after kidney transplantation. Belimumab-Induced Delirium and Behavioral Changes in a Patient with Lupus Nephritis: A Case Report

Sahibzadi Noor,[1] Roy O. Mathew,[1,2] Amir Abdi Pour,[1] Sayna Norouzi.[1] *[1]Loma Linda University, Loma Linda, CA; [2]VA Loma Linda Healthcare System, Loma Linda, CA.*

Introduction: Belimumab is a monoclonal antibody against B-lymphocyte stimulator, approved by the United States Food and Drug Administration in 2011 for patients with active systemic lupus erythematosus or active lupus nephritis who are receiving standard therapy. Here, we describe a rare case of a patient developing delirium and behavioral changes after subcutaneous (SC) belimumab initiation.

Case Description: A 65-year-old female with lupus nephritis Class IIIC was started on SC belimumab due to progressive proteinuria while taking prednisone 40 mg daily, mycophenolic acid 180 mg twice daily and hydroxychloroquine 200 mg twice daily. After starting SC belimumab, the patient developed intermittent confusion, forgetfulness and aggressive behavior e.g., inability to recognize her daughter, yelling at others without reason, refusal to go to church despite being an active and regular member previously, and inability to recognize and use common household items. After she threatened to jump out of a moving car when her demands were not met, her husband took her to the emergency room. In the ER, initial laboratory workup and intracranial imaging were unremarkable. Patient was advised to discontinue belimumab and was discharged home. The symptoms resolved completely one to two days after discontinuing SC belimumab. The patient continues to take prior immunosuppressive therapy.

Discussion: Based on the timing of symptom onset, negative head imaging, unremarkable laboratory workup and immediate resolution after discontinuing belimumab, the symptoms were most likely caused by SC belimumab. She has tolerated both oral and intravenous pulse steroids without any adverse effects, thus ruling out steroids as a possible cause. Literature review showed that intravenous belimumab has been associated with depression, anxiety and suicidality, however, SC belimumab resulted in less psychiatric events than placebo (1). We believe this is the first case of SC belimumab induced delirium and behavioral changes with immediate resolution after cessation. It is important to educate patients and caregivers about such symptoms. This should be verified in post-marketing surveillance of belimumab as well as specific surveillance during clinical trial follow up.

TH-PO656

The Effect of Voclosporin as Monotherapy in Treating Lupus Nephritis

Thu L. Nguyen. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: The current standard of care for lupus nephritis typically involves the use of combination therapy with immunosuppressive medications, such as mycophenolate mofetil (MMF) or cyclophosphamide, along with low-dose corticosteroids. While these medications can be effective in treating lupus nephritis, they are also associated with a range of potential side effects. We present a case of a young female patient who had multiple recurrent infections while on MMF which prompted conversion to voclosporin monotherapy with success in maintaining complete remission.

Case Description: We present a case of a 21 year old African American female with a past medical history of systemic lupus erythematosus (SLE), diagnosed at the age of 18, complicated by lupus nephritis (LN) class III. The patient was initially treated with a combination of mycophenolate mofetil (MMF), low-dose corticosteroids and hydroxychloroquine. Despite achieving partial remission with this treatment, the dose of MMF had to be reduced due to recurrent infections and persistent leukopenia. Voclosporin was eventually added to the regimen with the aim of achieving complete remission. However, MMF was eventually discontinued as the patient continued to have complications. The patient was continued on voclosporin monotherapy with low-dose prednisone for a total of 12 months, during which she achieved complete remission of her LN, with a stable serum creatinine and undetectable proteinuria.

Discussion: Lupus nephritis is a serious complication of SLE, and its treatment often requires the use of immunosuppressive medications, such as MMF and cyclophosphamide which bring with them a wide range of side effects including infections and myelosuppression. Voclosporin is a novel calcineurin inhibitor that has shown promise as a potential treatment for LN. It has been shown to be effective and well-tolerated in combination with MMF and low-dose corticosteroids in the AURA-LV and Aurora 1 trials. This case report demonstrates that voclosporin monotherapy may be an effective and safe treatment option for LN along with low-dose prednisone for LN in patients who are unable to tolerate or have contraindications to other immunosuppressive medications.

TH-PO657

A Rare Complication of Prolonged Immunosuppression in Lupus Nephritis

Andrea Broka,[1] Merryl Terry,[2] Nasim Wiegley.[1] *[1]UC Davis Health, Sacramento, CA; [2]UCSF Medical Center, San Francisco, CA.*

Introduction: Epstein-Barr virus (EBV) is a well-recognized virus associated with lymphoproliferative disease (LD). Immunodeficiency and immunosuppression can lead to the reactivation and replication of the virus, increasing the likelihood of malignancy. We present a case of a patient with Lupus nephritis (LN) patient on long-term immunosuppression presenting with non-transplant-associated central nervous system (CNS) LD.

Case Description: A 35-year-old woman with frequently relapsing LN Class IV on mycophenolate mofetil (MMF), Plaquenil and prednisone for 15 years presented with numbness and weakness in the left side of her face and arm. MRI head showed bilateral supratentorial enhancing lesions (Fig 1). Positive dsDNA Ab, reduced C3, normal C4, EBV positive in cerebrospinal fluid, blood viral load <750 units/ml. CNS lesion biopsy confirmed iatrogenic EBV-associated LD (Fig 2). MMF was discontinued. Rituximab was started for the management of LD with resolution of the symptomatology. To date, lupus nephritis has remained quiescent on Rituximab.

Discussion: EBV-associated LD is influenced by the level of immune suppression and reduced surveillance by T cells. Certain medications can impede the proliferation of lymphoblastoid cell lines, and others affect T-cell function. In vitro and animal model studies have shown that prolonged use of MMF was associated with diminished recovery of Vδ2+ T cells and increased occurrence of EBV reactivation. MMF, commonly used in autoimmune diseases, may unmask an inherent susceptibility of the CNS for immunosuppression-related LD. While LD is frequently considered after organ transplantation, it is less often considered in non-transplant immunosuppressed patients. A high index of suspicion is needed when caring for non-transplant immunosuppressed patients presenting with primary CNS symptoms. Prompt evaluation is necessary to distinguish between lupus cerebritis and LD to individualize care and improve patient outcomes.

Combined Diagnosis of Proliferative Lupus Nephritis and Tuberculosis Infection: A Treatment Dilemma

Francis N. Atemnkeng,[1] Michelle L. Kirk,[1] James M. Pullman,[2] Michael D. Klein,[1] Savneek S. Chugh,[1] Sanjeev Gupta.[1] *[1]Westchester Medical Center, Valhalla, NY; [2]Montefiore Medical Center, New York, NY.*

Introduction: The treatment of tuberculosis (TB) infection (previously termed latent TB) during the induction phase of treatment for proliferative lupus nephritis (LN) is challenging. The use of high dose immunosuppression (IS) can cause TB disease. Rifamycin-based treatment for TB infection can also lead to major drug-drug interaction as rifampin can reduce the serum levels of mycophenolate mofetil (MMF), hence the level of IS.

Case Description: A 38-years-old Mexican male who presented with lower limb edema. Initial labs showed leukocytosis and acute kidney injury with nephrotic syndrome. Blood cultures grew Streptococcus pyogenes. Workup for glomerulonephritis (GN) revealed a positive ANA and hypocomplementemia, consistent with immune complex mediated GN. He received antibiotics for a total of 14 days. The urine protein/creatinine ratio (UPCr) one week later increased to 36.9 g/g from 3.2 g/g. Kidney biopsy demonstrated class III+V LN with 5/22 globally sclerosed glomeruli, 4 with segmental endocapillary hypercellularity with 2 cellular crescents on light microscopy and full house staining on immunofluorescence. Electron microscopy demonstrated mesangial, intramembranous, and sup-epithelial electron dense deposits and extensively effaced foot processes. The patient was discharged on conservative anti proteinuric therapy, as well as MMF. Routine TB screening with Quantiferon was positive, so he was started on rifampin and isoniazid. Follow-up 1 month later demonstrated UPCr of 1.76 g/g with no signs of TB disease.

Discussion: The term latent TB was changed to TB infection because these patients are infected with viable mycobacteria in various stages of containment by the host immune system. Therefore, during the induction phase of treatment of LN, with use of high dose IS, the presence of TB infection presents a high risk of progression to TB disease. We found no case reports of simultaneous diagnosis of proliferative LN and TB infection. Treatment literature is obtained from transplant patients diagnosed with TB infection, where rifampin was found to lower the level of MMF. Therefore, we suggest close follow-up of these patients to rule out TB disease and non-response to LN treatment during each visit.

TH-PO659

A 35-Year History of Lupus Nephritis Without Renal Fibrosis or Scarring: How Is This Possible? Exostosin 2

Eibhlin S. Goggins,[1] Joel D. Murphy,[2] Corey J. Cavanaugh.[1] *[1]University of Virginia, Charlottesville, RI; [2]Arkana Laboratories, Little Rock, AR.*

Introduction: Recently, Exostosin 1/Exostosin 2 (EXT1/2) was identified as a novel antigen in membranous nephropathy associated with autoimmune disease, particularly lupus nephritis (LN). These patients have distinct clinical features, notably favorable outcomes despite high proteinuria. Current guidelines provide treatment recommendations for patients with LN. However, whether these represent the best approach to the subgroup of patients with EXT1/2+ LN remains elusive.

Case Description: A 54-year-old female with a 35-year history of class IV & V LN presented with proteinuria/hematuria along with hair loss and rash. The patient was not on any immunosuppressive drugs and was taken off hydroxychloroquine 2 years prior for retinal toxicity. History was significant for HTN, osteoporosis hypovitaminosis D, AVN of hips and knees, nephrolithiasis, HLD, glaucoma, and hysterectomy for uterine fibroids. Serology showed negative ANA (previously positive), positive anti-dsDNA, low C3, and low C4. Kidney biopsy revealed membranous LN Class V with EXT2+, PLA_2R-, THSD7A-, NELL1- staining. Notably, a near total lack of fibrosis or glomerulosclerosis was observed. Treatment was reinitiated with mycophenolate mofetil and tacrolimus for nephrotic syndrome, and losartan for HTN.

Discussion: Our patient has a long history of recurrent LN, with a notable lack of renal fibrosis or sclerosis. Further investigations revealed EXT2 positivity. Despite evidence demonstrating a favorable renal prognosis associated with EXT1/2+ LN, it is unclear whether these patients remain susceptible to other diseases, as persistent proteinuria can affect other clinical outcomes. Our patient had a recurrence of disease in the context of no immunosuppressive therapy. Without further evidence, we favor a standard approach to immunosuppressive therapy (as in EXT1/2 negative counterparts). We believe EXT1/2 immunohistochemical phenotyping of patients with LN should be performed to aid in our understanding of this subgroup. There are many outstanding questions regarding EXT1/2 and this case underscores the need for more research to help guide treatment practices.

TH-PO660

DNAJB9-Associated Fibrillary Glomerulonephritis with Systemic Lupus Erythematosus: A Case Series

Abhishek Nimkar, Nerihan Hadji, Kenar D. Jhaveri, Yihe Yang. *Northwell Health, New Hyde Park, NY.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare primary glomerular disease with DNAJB9 positivity. We report 2 cases with lupus nephritis and FGN.

Case Description: Case 1: A 53-year-old woman with history of systemic lupus erythematosus (SLE), hypertension and depression presented severe proteinuria. The patient was diagnosed with SLE 20 years ago, her last lupus flare was 5 years ago. Over the course, her proteinuria worsened with spot urine protein-creatinine ratio (UPCR) was elevated at 3.54 with serum creatinine stable at 0.47mg/dl. Hep B and C, HIV, ANCA and PLA2R antibodies are negative. SLE serologies were not active. Serum C3 (148mg/dl) and C4 (42mg/dl) were in range. The serum light chain kappa/ lambda ratio was 1.05. She was on MMF and hydroxychloroquine. A kidney biopsy confirmed lupus

nephritis membranous type/ class V and glomerular dense fibrillary deposits suggestive of fibrillary glomerulonephritis. DNAJB9 antibody staining was positive. Patient received rituximab infusion therapy (1gm X 2 doses). Two months of follow up showed improvement in UPCR (0.9) with stable serum creatinine at 0.41mg/dl. One year out, the patient remains in remission. Case 2: A 65-year-old female with SLE (diagnosed ~40 years ago), hypertension and arthritis who presented with rising serum creatinine at 2.4 mg/dl. Her UPCR was stable at 0.3. Serological work up was negative. Serum C3 complement levels were mildly low (74mg/dl) and serum C4 complement levels were in range (18mg/dl). The Serum light chain kappa/ lambda ratio was 1.86. The patient was on MMF. Her BP was elevated, and lower extremity edema was present on exam. Kidney biopsy showed fibrillary glomerulonephritis with mesangioproliferative pattern and abundant electron dense material with fibrillary substructure infiltrating mesangium and glomerular basement membranes. mmunohistochemical staining of DNAJB9 was positive in glomeruli. Patient received rituximab infusion therapy. 9 months follow up showed stable UPCR (0.2) with elevated but stable serum creatinine at 1.86mg/dl. Her BP improved without any medications and clinically lower extremity edema disappeared. There was no progression of disease.

Discussion: The association between SLE and DNAJBP associated FGN is unclear. Rituximab may serve as a potential treatment strategy.

TH-PO661

Is It Rhabdomyolysis or Is It Lupus? A Case of Dual Presentation of New-Onset Lupus

Hira Tahir, Farah Daccueil. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: Acute kidney injury in unconscious patients has a wide range of differential diagnoses; rhabdomyolysis is a common consequence. However, acute lupus nephritis is rarely the most common presentation of an unconscious patient. Here we report diagnosis of lupus nephritis with severe rhabdomyolysis.

Case Description: A 40-year-old male with no medical history presents after being found down. Per a friend, for past few weeks, patient had been feeling ill with several Urgent Care visits for fever, prescribed multiple rounds of antibiotics with no improvement. On admission his speech was slurred, and he had bruising over his arms, dry mouth and lips, with blue extremities. Social history was noted for smoking 20 pack years, occasional marijuana uses and micro-dosing mushrooms. Physical exam was significant for bilateral lower extremity reticular rash and severe cyanosis of fingers and toes. Admissions labs had severe electrolyte abnormalities: Na 116 mmol/L, K 6.2 mmol/L, Cl 79 mmol/L, HCO3 16 mmol/L, BUN 105 mg/dL and Cr 3.26 mg/dL, calcium 6.8 mg/dL, albumin 1.9 g/dL, PO4 10.0 mg/dL, CPK 6533 IU/L, uric acid 12.3 mg/dL, urinalysis with large blood, 1 RBC, 100 protein, trace LE, negative nitrites and 1 WBC, urine Pr/Cr 0.41 g/dL and negative urine culture. Urine drug screen was positive for cannabinoids only. Blood gas showed pH 7.17, pCO2 46.1 mmHg, pO2 33 mmHg and HCO3 17 mEq/L. US revealed bilateral DVTs. CT was grossly unremarkable. Due to worsening electrolytes and creatinine, renal replacement therapy was started. Additional labs including C3, C4, ANA, anti-dsDNA, SM/RNP Ab and chromatin Ab were consistent with Lupus. Pulse dose steroids were initiated, and renal biopsy results revealed acute tubular injury with myoglobin casts and class II lupus nephritis. After pulse dose steroids and 2 weeks of intermittent hemodialysis, kidney function improved substantially. Due to severe digit necrosis, patient required fingertip amputations. The patient was started on low dose mycophenolate and discharged with close outpatient follow-up.

Discussion: Rhabdomyolysis is known to occur in unconscious patients with severe AKI (1). Few case reports diagnose new-onset lupus with concomitant rhabdomyolysis with renal failure requiring dialysis. Additionally, the widespread skin involvement and digit amputation made diagnosis and management for this case difficult and thought provoking.

TH-PO662

Not All Lupus Nephritis Is "Complement"-ary

William M. Parkinson,[1] Ryan Rayman,[1] Andy Guan,[1] Thomas S. Denapoli,[2] Jesse M. Wickham.[1] *[1]Brooke Army Medical Center, Fort Sam Houston, TX; [2]Pathology Reference Laboratory, San Antonio, TX.*

Introduction: Lupus nephritis (LN) is a common but serious manifestation of Systemic Lupus Erythematous (SLE) that can lead to high morbidity and mortality, ultimately affecting up to 50% of patients with SLE. Typically, LN presents early in the clinical course of SLE, often within the first 3 years after diagnosis. Although the clinical manifestations of LN vary greatly, from nearly asymptomatic to rapidly progressive glomerulonephritis (RPGN), the typical presentation of LN includes edema, hypertension, proteinuria, and microscopic hematuria in patients with known SLE. We present a case with a classical presentation of lupus nephritis that did not follow the typical serologic findings.

Case Description: A 19-year-old white female with no significant past medical history presented to her primary care with 6-month history of intermittent bilateral itching leg pain and a 20lb weight gain. She initially attributed her leg pain to a high level of physical activity. Pain was worse between her knees and ankles and only temporarily alleviated with rest, massage, and ice. Over the past month, she developed new bilateral swelling in her legs. She denied history of recent illness, chest pain, SOB, congestion, malar rash, photosensitivity, oral ulcers, joint pains, or any history of kidney disease. Initial labs were significant for elevated lipid panel, ESR, and TSH with hypoalbuminemia. Urine analysis showed 3+ proteinuria with micro positive for >50% dysmorphic RBC and acanthocytes. Complements were normal suggesting against lupus nephritis. However, subsequent ANA came back positive with dsDNA 36 and anti-chromatin. The patient underwent a kidney biopsy and was diagnosed with Class IV +V lupus nephritis.

Discussion: In the work up of Nephritic syndrome we classically teach a targeted approach to serologic testing to avoid unnecessary (and potentially costly) labs. Complements are often used in the initial lab work up to assist in limiting serologic labs as a differentiating factor between complement mediated/immune complex mediated glomerulonephritis. In the above case, we initially had a lower suspicion for lupus nephritis due to normal complements. We were later surprised to find + ANA and biopsy confirmed class IV +V lupus nephritis. This case highlights the need to keep a broad differential diagnosis in the work up of Nephritic syndrome, and the limitations of Complement.

TH-PO663

A Rare Case of "Lupus-Like" Glomerulonephritis Presenting as Pulmonary Renal Syndrome (PRS)

Mingyue He,[1] Sheetal Koul,[2] Iris J. Lee.[2] *[1]Temple University Hospital, Philadelphia, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: PRS is a life-threatening condition characterized by rapidly progressive glomerulonephritis (RPGN) and diffuse alveolar hemorrhage (DAH). The main causes of PRS include ANCA associated vasculitis (AAV), anti-GBM disease, or immune complex-mediated glomerulonephritis (GN). Herein, we present a rare case of PRS with positive P-ANCA, but a "full house" crescentic GN on renal biopsy, with a negative ANA panel.

Case Description: A 59-year-old female with history of osteoarthritis presented with productive cough and dyspnea for two days. CT chest showed bibasilar ground glass opacities. Extensive infectious workup was negative. On the third day, she developed fever, hemoptysis, and rapidly progressive dyspnea necessitating intubation. Bronchoscopy revealed DAH. Her creatinine increased from 2.2 mg/dl on admission (baseline Cr 0.93 mg/dl) to 4.5 mg/dl within one week. Urinalysis revealed significant proteinuria (300 mg/dl) and RBC 40-60/HPF. Serologic workup revealed a high P-ANCA titer (> 1:640) and an elevated myeloperoxidase (MPO) antibody of 13. Anti-GBM, ANA, and anti-dsDNA were negative. Complements were normal. Kidney biopsy showed 19/69 glomeruli with cellular/fibrocellular crescent formation. Immunofluorescence (IF) revealed an intense "full house" staining. She was treated with plasmapheresis, steroid, and cyclophosphamide, resulting in the resolution of respiratory failure and improvement in Cr to 2.7 mg/dl upon discharge.

Discussion: Our patient's clinical picture supports a diagnosis of AAV with renal involvement, which typically presents as a pauci-immune crescentic GN with negative IF on biopsy. The presence of a "full house" IF pattern, suggestive of Lupus nephritis, was unexpected in this case. While P-ANCA can be found in 10% of patients with SLE, the absence of ANA excludes the patient from meeting the new EULEAR/ACR criteria for SLE diagnosis. SLE/AAV overlap syndrome has been reported as a rare entity, with biopsy features of both diseases. In such cases, the presence of ANCA antibody is often associated with more active lupus disease, higher ds DNA antibody levels, and worse renal function. Our case suggests the potential for AAV to overlap with other autoimmune syndromes, highlighting the importance of further studies to validate this association and develop a treatment strategy.

TH-PO664

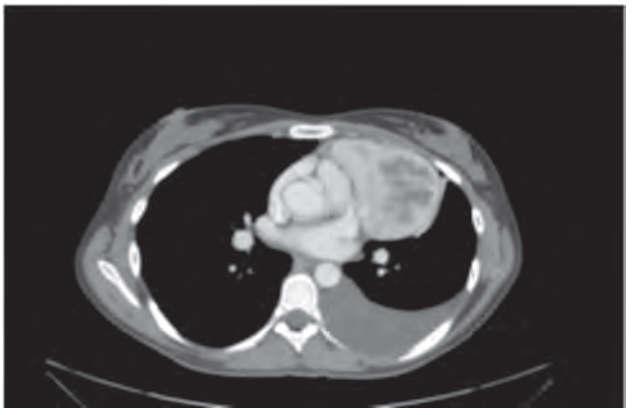
Diagnostic Challenges in Lupus: Systemic Lupus Erythematosus Initially Presenting as Unicentric Castleman Disease

Allison Miller, Vanderlene L. Kung, Ruchi Thanawala, Rupali S. Avasare. *Oregon Health and Science University, Portland, OR.*

Introduction: Multiple conditions mimic Castleman Disease (CD), a group of lymphoproliferative disorders, including infection, neoplams and autoimmune disease. There is well-described clinical overlap between systemic lupus erythematosus (SLE) and CD as both can manifest with lymphadenopathy, proteinuria and positive anti-nuclear antibody (ANA) serology. Distinguishing between these two entities can be a vexing process and requires a multidisciplinary approach to care.

Case Description: A 23 year-old woman presented with dyspnea. Chest imaging revealed a large mediastinal mass and pleural effusion (Figure 1). The mass was resected and the patient was diagnosed with HHV-8 and EBV-negative CD. A clinician noted persistent hypoalbuminemia and discovered 8.2 grams per day of proteinuria despite surgical management. Work up included a kidney biopsy that showed a "full house" immune complex-mediated glomerulonephritis with focal activity, endocapillary hypercellularity and large subendothelial deposits. Serologic testing revealed positive ANA, anti-double-stranded DNA antibody and hypocomplementemia. The patient's final diagnosis was revised to SLE and she achieved remission with immunosuppressive therapy.

Discussion: To our knowledge, this is the first reported case of unicentric CD mimicking SLE in a patient with nephrotic syndrome. Because unicentric CD is managed with surgery alone, this report highlights the need for a broad diagnostic workup to rule out similarly presenting diseases with vastly different treatments. In this patient, workup for nephrotic syndrome prompted kidney biopsy and serologic testing that was essential for establishing the correct diagnosis and management.



TH-PO665

Guillain-Barre Syndrome Presenting Alongside Lupus Nephritis: Case and Management

Puja Mehta,[1] Randy L. Luciano,[1] Abinet M. Aklilu,[1] Grace L. Malvar.[2] *[1]Yale School of Medicine, New Haven, CT; [2]Yale School of Medicine, New Haven, CT.*

Introduction: Systemic Lupus erythematosus (SLE) can affect any organ system including the nervous system. However, peripheral nervous system involvement occurs in less than 10% of cases. We present here a case of Guillain-Barre syndrome (GBS) coexisting in a patient with undiagnosed new onset lupus nephritis.

Case Description: The patient is a 21-year-old female with past medical history of well controlled skin-limited SLE treated with hydroxychloroquine who presented with two weeks of ascending bilateral muscle weakness and the inability to ambulate in the setting of a recent gastrointestinal infection. Due to high suspicion for Guillain-Barre syndrome (GBS), she was started on plasmapheresis (PLEX) and pulse dose steroids. Despite completing 5 sessions of PLEX, her condition worsened and required mechanical ventilation due to respiratory muscle involvement. She further developed locked-in-syndrome. She, then completed 5 days of IVIG without any improvement. On day 13, she was noted to have acute kidney injury (AKI) with nephrotic range proteinuria, along with rare dysmorphic RBCs on urine sediment. Serology was positive for an SLE flare including hypocomplementemia, elevated ANA titer, and a positive dsDNA antibody. A kidney biopsy demonstrated full house immunofluorescence, with electron microscopy revealing subepithelial deposits and mesangial dense deposits, consistent with lupus nephritis, class V. Despite treatment with steroids, she quickly developed non-oliguric AKI, requiring hemodialysis. She was started on mycophenolate mofetil along with prednisone, resulting in recovery of kidney function within one month of initiating immunosuppression. However, she had much slower recovery in GBS symptoms, resolving 6 months after initial presentation.

Discussion: It is difficult to speculate which came first: GBS or lupus nephritis, since we know GBS can be initial presentation for lupus nephritis, however, GBS can trigger lupus nephritis as well through aberrant immune activation. However, when GBS coexists with lupus nephritis, its treatment is controversial, with standard treatment (PLEX +/- IVIG) being less effective. Currently no specific guidelines exist to treat GBS in such situations, however, cyclophosphamide with corticosteroids is considered first line of treatment, with mycophenolate mofetil, as in this case, an alternative treatment option.

TH-PO666

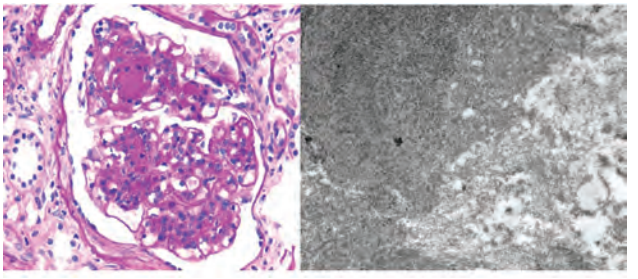
Cardiac Failure in Fibrillary Glomerulopathy Associated with Systemic Lupus Erythematosus

Carina S. Zapata Beltrán,[1] Elisa M. Guerrero Gonzalez,[1] Giovanna Y. Arteaga Muller,[1] Mara C. Olivo Gutierrez,[1] Ricardo A. Garza Treviño,[1] Daniela C. Elvir,[1] Joary Vargas Santana,[1] Virgilia Soto.[2] *[1]Hospital Universitario José Eleuterio González, UANL, Monterrey, Mexico; [2]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico.*

Introduction: SLE involves the kidneys in a large percentage of cases, and less frequently, there is the presence of myocardial damage with a prevalence of 8-25%.

Case Description: This is a 42-year-old male with a past medical history of pleural tuberculosis diagnosed three years ago, presenting with refractory exudative left pleural effusion, dyspnea, and pleuritic pain. He also has a three-year history of type 2 diabetes mellitus. His current symptoms as the same previously additional bilateral pleural effusion (transudate), intolerance to lying down, no peripheral edema, no retinopathy on fundoscopy. Laboratory findings included Hb of 11.7 g/dL, normo-normo anemia, eGFR by CKD-EPI of 28 mL/min/1.73m2, proteinuria of 8.9 g/24hrs with an inverted albumin/globulin ratio. Echocardiogram showed an ejection fraction of 23%. Only ANAs (1:640) and anti-U1-RNP (>200) antibodies were positive. C3 and C4 were normal. Renal biopsy showed negative staining with Congo red, indicating glomerulonephritis due to immune complexes with a membranoproliferative and nodular pattern. Immunofluorescence revealed a diffuse, global, and granular full house pattern, electron microscopy revealed fibrillary deposits measuring 10-20 nm.

Discussion: The presence of antibodies anti-U1-RNP and the occurrence of myocarditis are related to autoimmune activity against striated muscle. Myocarditis occurs in 5% to 10% of patients with SLE and most cases are asymptomatic and it can progress to heart failure. Atypical serology, unusual clinical presentation, and nodular biopsy make the diagnosis challenging, requiring electron microscopy for the diagnosis.



The mesangium shows diffuse expansion of the matrix with predominantly global proliferation, which gives some glomeruli a hiperlobulated appearance with the presence of acellular nodules.There are subendothelial and mesangial deposits of fibrils measuring 10-20 nm.

TH-PO667

Lupus Nephritis Complicated by Atypical Hemolytic Uremic Syndrome and Heterozygous Deletion in CFHR1-CFHR3 Successfully Treated with Ravulizumab

Sahar Amin,[1] Barry M. Wall,[1,2] Dhirisha Bhatt,[1] Geeta G. Gyamlani.[1,2] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN.*

Introduction: Atypical hemolytic uremic syndrome (aHUS) involves unchecked activation of the alternative pathway leading to deleterious action of complement on the endothelium. Failure to control complement activation is often due to inherited or acquired deficiencies of complement regulatory proteins, including Factor I, Factor H, Membrane Cofactor Protein, and CD46.

Case Description: 21 year old female with history of SLE presented with acute kidney injury (AKI) with an active urine sediment. Kidney biopsy showed diffuse lupus nephritis class IV and thrombotic microangiopathy (TMA). She was started on mycophenylate (MMF) 1g bid which she received for 2 wk, but was off for 4 wk, as she was not able to fill her medications, leading to admission for worsening AKI. Laboratory: hemoglobin 6.1gm/dl, platelet 185,000/ul, serum creatinine 7.25 mg/dl, UPCR 3.5 g/g, low C3 (57mg/dl), LDH 472 IU/l, haptoglobin 36 mg/dl, 2-3 schistocytes noted on blood smear. She was Induced with solumedrol and Myfortic 720 mg BID. Five sessions of plasmapheresis (PLEX) were done due to TMA biopsy findings. She developed microangiopathic hemolytic anemia (MAHA), severe thrombocytopenia, tonic-clonic seizures, and required hemodialysis. ADAMTS 13 level was normal and anti-phospholipid studies were negative. Given the high suspicion of atypical HUS, ravulizumab was added to her regimen. Hemoglobin and platelet count normalized after 2 weeks. She remained dialysis dependent for 6 weeks. Renal function improved and serum creatinine has remained stable at 3.0 mg/dl off dialysis. Genetic testing revealed compound heterozygosity for exon 2-6 deletion in CFHR1 and exon 1-6 deletion on CFHR3.

Discussion: The coexistence of atypical HUS with mutations in complement regulatory proteins and lupus nephritis is rare. Our patient had a successful outcome with addition of ravulizumab. Initial treatment with plasma exchange and conventional therapy with MMF and glucocorticoids did not improve MAHA, thrombocytopenia, or kidney function.

TH-PO668

A Do-Not-Miss Diagnosis: Thrombotic Thrombocytopenic Purpura in Systemic Lupus Erythematosus

Andrew Yanik, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Thrombotic thrombocytopenic purpura (TTP) is a rare complication of systemic lupus erythematosus (SLE) associated with high mortality. We report the case of a patient with SLE complicated by the development of fatal TTP.

Case Description: A 42-year-old male with history of SLE presented to an outside hospital endorsing three days of hematuria, hematemesis, dysarthria, malaise, and cutaneous changes for one week. His objective data there was pertinent for platelets (PLT) of 2 k/uL, creatinine of 2.38 mg/dL (baseline 0.8), and CT evidence of perinephric stranding. On arrival to our hospital, he was tachycardic, tachypneic, afebrile, and normotensive. Examination revealed jaundice with diffuse ecchymoses, and a normal neurological status. Laboratory studies on arrival were pertinent for undetectably low PLT count, hemoglobin 8.4 g/dL, creatinine 2.55 mg/dL, total bilirubin 3.6 mg/dL (direct 1.0), haptoglobin 20 mg/dL (ref 30-200), schistocytes on blood smear, LDH 3,433 U/L, D-dimer 38.5 ug/mL, fibrinogen 603 mg/dL, PT of 15.2 s, PTT of 34 s, and a normal vitamin B12. The patient's mental status rapidly worsened in the ensuing hours, and he developed hypoxic respiratory failure with a serum lactate of 12 mmol/L. He was moved to the intensive care unit to start empiric therapeutic plasma exchange (TPE). His ADAMTS13 activity level resulted at <5% (ref >61%) and notably the ADAMTS13 inhibitor activity was elevated. Prior to initiation of TPE, however, the patient was found unresponsive and in cardiac arrest. After forty minutes of advanced cardiovascular life

support effort, the patient was pronounced deceased just twelve hours after admission. Autopsy showed platelet-rich microthrombi in multiple organs, severe thrombocytopenia, and no deep vein thrombi most consistent with TTP.

Discussion: Thrombotic microangiopathies (TMA) are rare clinical syndromes characterized by thrombocytopenia, microangiopathic hemolytic anemia, and microvascular thrombus formation leading to end-organ damage. TTP is a rare and often lethal complication of SLE (sTTP) and its diagnosis is challenging due to the significant overlap in signs and symptoms. As illustrated by this case, severe thrombocytopenia in a patient with SLE should raise concern for sTTP as any delay in its diagnosis can be fatal. Early diagnosis and prompt initiation of treatment including therapeutic plasma exchange is crucial.

TH-PO669

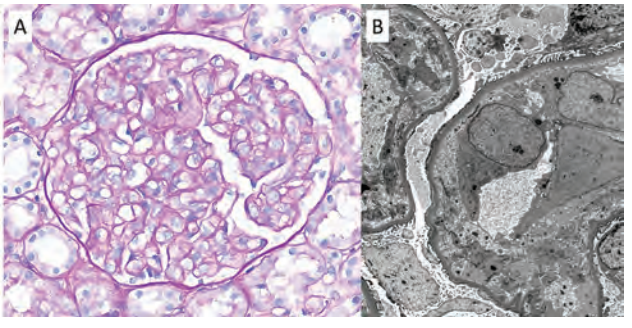
Effective Treatment of Renal Thrombotic Angiopathy due to Idiopathic Multicentric Castleman Disease with Rituximab

Hima B. Doppalapudi,[1,2] Luis B. Caraballo,[1,2] Vijay K. Vanguri,[1,2] Kenneth M. Ralto.[1,2] *[1]UMass Memorial Health, Worcester, MA; [2]University of Massachusetts Chan Medical School, Worcester, MA.*

Introduction: Idiopathic multicentric Castleman disease (iMCD) is a rare, benign lymphoproliferative disorder. Renal involvement in iMCD is uncommon but is usually associated with thrombotic microangiopathy, and effective therapies have not been rigorously studied. First-line therapy includes steroids and monoclonal antibodies targeting IL-6. We present a case of iMCD with renal involvement unresponsive to siltuximab but responsive to rituximab.

Case Description: A 36-year-old gentleman presented with shortness of breath, edema, lymphadenopathy, and fevers and was found to have a serum creatinine (sCr) of 2.5 mg/dL. Urine sediment showed muddy brown casts and he had subnephrotic range proteinuria. A renal biopsy showed acute microangiopathy with diffuse glomerular endotheliosis and minimal fibrosis. A subsequent inguinal lymph node biopsy showed reactive lymphoid hyperplasia with some changes suggestive of Castleman disease. He was initiated on steroids and sCr improved to 0.94 mg/dL. One year after the initial presentation, he was re-admitted with dyspnea and acute kidney injury (AKI). A repeat renal biopsy showed chronic angiopathic changes accompanied by scattered endotheliosis and mild fibrosis, and he was placed on a prednisone taper with improvement in his renal function. Given his recurrent disease, he was started on siltuximab and received 3 doses. He failed to respond to this and was transitioned to rituximab with subsequent resolution of his AKI, proteinuria, and lymphadenopathy.

Discussion: Renal involvement in severe cases of iMCD is rare but is usually associated with microangiopathy and endothelial injury; however, little is known about the most effective treatment. Siltuximab is often the first-line therapy, but there is limited data for patients who do not respond. Second-line therapies include chemotherapy, immunomodulators, and immunosuppressants. Our case demonstrates improvement in renal function and resolution of proteinuria with rituximab.



TH-PO670

Atypical Hemolytic Uremic Syndrome with Normal Complement Studies in a Patient with Complement Factor I Deficiency

Brian Monk, Danielle C. Foster, Mohammad Atari, Mohamed Hassanein. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Atypical hemolytic uremic syndrome (AHUS) is a type of thrombotic microangiopathy (TMA) that presents with organ dysfunction, particularly involving the kidney. AHUS occurs due to dysfunction in the alternative complement pathway and occurs sporadically, secondary to malignancy, drugs, or autoimmune diseases, or can be inherited. We present a rare case of AHUS due to a genetic mutation in complement factor I (CFI) and normal complement studies.

Case Description: A 27-year-old female with uncontrolled hypertension (HTN) was admitted for hypertensive emergency (blood pressure 211/119) and acute kidney injury (Cr 15.4 mg/dL, baseline 3 mg/ dL). Further workup showed hemoglobin 8.2 g/dL (ref: 11.2-15.7 g/dL), platelets 78 K/uL (ref: 182-369 K/uL), low haptoglobin, and elevated LDH. Infectious and autoimmune processes were ruled out. Compliment levels C3 and C4 were normal. While awaiting an AHUS complement panel, she required dialysis and underwent a kidney biopsy which showed TMA with 40% interstitial fibrosis and 60% acute tubular injury. Eculizumab therapy was initiated for suspicion of AHUS based on biopsy findings. A few days later, AHUS panel came back showing no abnormalities in the alternative complement pathway, except elevated C5b-9. After discharge, she was found to have a heterozygous mutation of the CFI gene which has been associated with autosomal dominant AHUS. Eculizumab therapy was continued and the patient was monitored closely outpatient.

Discussion: In the setting of normal complement studies, one cannot rule out AHUS as the primary cause of TMA. If the index of suspicion is high, it is recommended to start empirical Eculizumab and send off genetic studies to rule out a genetic cause of the AHUS, which may prevent unnecessary cessation or delay in Eculizumab therapy, and hence improve outcomes.

TH-PO671

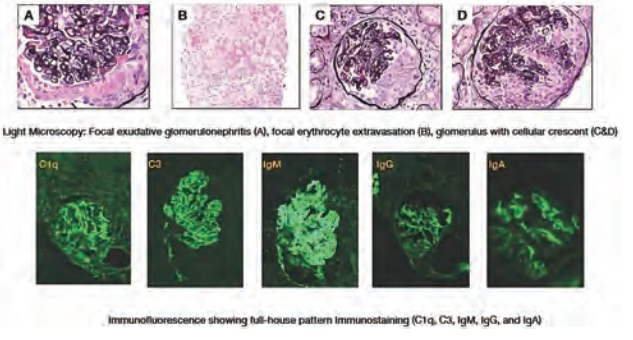
Unusual Presentation of ANCA-Associated Vasculitis with Full-House Pattern Immunostaining

Brian Monk, Suhaib F. Al-Sawajneh, Timothy E. Yen, Mohamed Hassanein, Mohammad Atari. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Pauci-immune glomerulonephritis is the most common cause of rapidly progressive glomerulonephritis (RPGN) mainly secondary to antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV). Typically, renal involvement lacks the presence of immune deposits. Here we present a case of AAV-induced RPGN with a full-house pattern immunofluorescence (IF).

Case Description: A 35-year-old male with a history of uncorrected congenital heart disease presented to the hospital with lower extremitiy edema. Evaluation revealed AKI with serum creatinine 5.43 mg/dL, urine analysis with >100 RBCs (0-4), +50 protein with sub-nephrotic range proteinuria. Autoimmune workup was positive for ANA 1:160 (speckled pattern), low C3 70mg/dL (90-180 mg/dL), positive PR3-ANCA >8U (<0.4U), and P-ANCA, but negative MPO-ANCA and C-ANCA. Anti-dsDNA, anti-histone antibodies, anti-smith, anti-GBM, viral panel, and protein electrophoresis all were normal. Kidney biopsy showed necrotizing crescentic glomerulonephritis with variable para-medullary inflammation strongly suggesting ANCA vasculitis. IF showed a full-house pattern (IgG, IgM, IgA, C3, C1q, kappa, and lambda). Treatment with Rituximab and pulse steroids followed by steroids taper was initiated. Unfortunately, the patient passed away.

Discussion: Renal involvement by AAV typically has no or few immune deposits. Full-house immunofluorescence has been rarely reported in the setting of ANCA vasculitis and it is unusual. Although histopathology in our patient is suggestive of AAV, the presence of full house pattern on IF with positive serum ANA is concerning for possible overlap syndrome where lupus and ANCA vasculitis accompany. Despite the absence of anti-dsDNA and anti-smith, still, lupus cannot be ruled out. This case is one of a few reported cases having AAV with RPGN presentation and concomitant full-house pattern in kidney biopsy, possibly representing lupus/AAV overlap.



TH-PO672

Thrombotic Microangiopathy Associated with Exostosin-1-Associated Membranous Nephropathy: Case Report

Gisele Vajgel,[1] Lucas S. Xavier,[1] Italo R. Alves,[1] Thais O. Santos,[1] Camila B. Oliveira,[1] Aureli N. Machado,[2] Lucila Maria Valente,[1] Denise M. Costa.[1] *[1]Hospital das Clinicas, Recife, Brazil; [2]Fundação de Hematologia e Hemoterapia de Pernambuco, Recife, Brazil.*

Introduction: Thrombotic Microangiopathy (TMA) is characterized by the association of microangiopathic hemolytic anemia (MAHA), thrombocytopenia, associated to target organ damage. Its association with Membranous Nephropathy (MN) is rarely described. We report an atypical case of TMA with Exostosin 1-associated MN.

Case Description: A previously healthy 15-years-old woman presented with vomiting and seizures associated with MAHA, thrombocytopenia, hematuria and creatinine (sCr) 2.2 mg/dL. She had low serum complement level and negative viral serologies, ANA and anti-DNAds. PLASMIC score was five. Due to moderate suspicion of Thrombotic Thrombocytopenic Purpura (TTP), the patient was treated with Methylprednisolone 1g/day for three days, followed by Prednisone 1mg/Kg/day and Rituximab (500mg/wk - 4 weeks), in addition to plasmapheresis. On the 4th day of hospitalization, she developed refractory hypervolemia and worsening of renal function, requiring hemodialysis during 4 weeks. She has improved renal function and MAHA, but remained with nephrotic syndrome (peripheral edema, albumin 3.3g/dL, proteinuria 6.1g/day) associated to hematuria. A renal biopsy was performed showing subacute TMA associated with stage II MN, with granular deposits of IgG (3+/3+) and C3 (traces) in the glomerular basement membrane. Immunohistochemistry of the renal tissue was PLA2R-negative and

positive for Exostosin-1, IgG1, IgG2 and IgG4. On further investigation, she had positive p-ANCA and Anti-DNA, but negative ANA and APS antibodies. ADAMTS13 activity (4 weeks after Rituximab) was normal. The patient progressively decreased proteinuria and sCr, but after 4 months, she relapsed with peripheral edema, proteinuria 8.0 g/day and albumin 3.4 g/dL. Due to her previous good response to Rituximab, a new cycle of medication was scheduled.

Discussion: Despite MN being a frequent cause of nephrotic syndrome, few cases are reported in association with TMA. Auto-immune secondary causes of MN should be screened in young ladies. Since both conditions can be mediated by immune complexes, it is possible that autoantibodies caused the deposition of subepithelial immune complexes as well as the complement activation and endothelial injury which are responsible for TMA in our patient.

TH-PO673

Thrombotic Microangiopathy Secondary to Acute Pancreatitis: A Rare Association

Ojaswi S. Tomar, Anuja Java. *Washington University in St Louis, St Louis, MO.*

Introduction: Thrombotic microangiopathy (TMA) due to acute pancreatitis is rare with only 35 cases reported since 1978. The diagnosis requires a high index of suspicion and if not managed timely, can lead to severe morbidity and mortality. Here we report a case of TMA due to acute pancreatitis that was promptly recognized and successfully treated with Eculizumab.

Case Description: A 58-yo woman presented with one-day history of abdominal pain, nausea and vomiting after ingesting seafood. She was Jehovah's witness. Labs on admission showed an elevated lipase, 1900 U/L (13-60 U/L). Serum creatinine was at baseline (1.7 mg/dl). Treatment for acute pancreatitis was initiated. Two days later, serum creatinine increased to 8 mg/dl. Labs also showed features of microangiopathic hemolytic anemia and thrombocytopenia (Hgb 4 g/dl, platelet 46 K/uL, haptoglobin < 10 mg/dl, lactate dehydrogenase 2424 U/L). Schistocytes (>10/hpf) were present on peripheral smear. ADAMTS13 activity was normal. C3 was low normal at 99 mg/dl (normal range, 90-180 mg/dl) and C4 was normal. TMA was suspected and eculizumab started on day 7. Two days after starting eculizumab, platelet count improved to 128 K/uL, hemoglobin to 7 g/dl, LDH was 800 U/l and haptoglobin normalized. She remained dialysis dependent on discharge but 4 weeks later renal function recovered and she came off dialysis. Serum creatinine 6 weeks later is 3.6mg/dl. She remains on eculizumab. Genetic testing did not show any pathogenic mutations.

Discussion: Pancreatitis can occur in 2% of cases due to TMA, but pancreatitis causing TMA is exceedingly rare. In cases where TMA causes acute pancreatitis, it precedes the onset of pancreatitis, whereas, when acute pancreatitis causes TMA, it manifests typically 2-3 days after the pancreatitis (as in our case). The etiology of TMA after pancreatitis is speculated to be due to inflammatory mediators causing vascular endothelial injury, transient complement activation and ADAMTS13 inhibition. Eculizumab has been shown to shorten renal and hematological recovery but only reported in 3 of 35 cases. Most patients can stop the drug after 3-6 months. Importantly, in our case, we treated with eculizumab since she was Jehovah's witness and refused plasma exchange. AKI in acute pancreatitis can have a broad differential but early recognition of TMA-induced AKI can be lifesaving.

TH-PO674

A Rare Presentation of Genetic Complement-Mediated Thrombotic Microangiopathy

Allaa Almoushref, Maria Sokola, Karlo Toljan, Zeshaun Khawaja, Tarek Ashour. *Cleveland Clinic, Cleveland, OH.*

Introduction: Complement genetics has recently gained prominence in understanding the pathogenesis of complement mediated thrombotic microangiopathy (CM-TMA) and the development of a specific therapy that is potentially lifesaving. We present a rare case of ischemic cortical infarcts concurrently with CM-TMA, successfully treated with eculizumab.

Case Description: A 46-year-old male with a history of hypertension and chronic type B aortic dissection presented to the hospital for evaluation of presyncope and paraparesis. Labs showed profound renal failure with serum creatinine (sCr) of 14 mg/dl (baseline 1.14 mg/dl about 4 years before his presentation). A urinalysis showed > 300 mg of proteins, urine Pr/Cr of 8.0, and > 25 non dysmorphic RBCs/HPF. The patient was started on hemodialysis for worsening uremia, and shortly he developed ischemic stroke symptoms. MRI of the brain showed acute multifocal ischemic infarcts. Additional testing showed anemia, thrombocytopenia, elevated lactate dehydrogenase, low haptoglobin, and schistocytes in the peripheral smear. ADAMTS13 was normal. Further workup and serologies for possible infectious or autoimmune diseases were negative. SPEP was normal. A kidney biopsy showed thrombotic microangiopathy with negative immunofluorescence. Additional testing of complement factors showed elevated factor H, C3a, and C5a, with a normal CH50, and factor B, supporting CM-TMA diagnosis. The patient was started on an induction dose of eculizumab and remained on a maintenance dose every two weeks. Genetic testing showed homozygous deletion of CFHR1, supporting the long-term use of a C5 inhibitor. The patient started to show signs of renal recovery. Hemodialysis was discontinued 6 weeks after initiation, and sCr improved and remained stable around 2.4 mg/dl while on eculizumab. Over a 2-year follow-up, hemoglobin and platelets normalized, and neurologic recovery was full.

Discussion: CM-TMA is caused by dysregulation of the alternative pathway. Eculizumab, a humanized anti-C5 monoclonal antibody, is effective in terminating the microangiopathic hemolytic activity in patients with CM-TMA. Early identification and treatment of this disease can be life-saving. We also highlight the importance of genetic testing as it can guide long-term treatment plans. Patients with high-risk variants and severe disease manifestations may need a prolonged treatment period.

Avelumab-Induced Thrombotic Microangiopathy: A Case Report

Jessica M. Nino, Ryan Wong, Erika R. Bracamonte, Bijin Thajudeen. *Banner University Medical Center Tucson, Tucson, AZ.*

Introduction: Monoclonal antibodies against programmed cell death 1 (PD-1) can improve outcomes in many advanced cancers, including ovarian carcinoma. Despite such advantages, these agents are associated with various immune-related adverse events. We report a case of TMA after chemotherapy using Avelumab.

Case Description: A 56-year-old female, with a medical history of stage 3 ovarian cancer and hypertension was referred by her oncologist due to worsening kidney function. Her cancer was initially treated with carboplatin, paclitaxel, and veliparib for a total of 6 cycles. Therapy was changed to bevacizumab due to worsening disease but was suspended when the patient developed secondary hypertension. Subsequently, Avelumab was initiated. A slow rise in creatinine was noted two months after starting Avelumab. A renal biopsy showed acute on chronic thrombotic microangiopathy. Although there was anemia, no hemolysis or thrombocytopenia was noted. Supplementary work up including ADAMS 13, APLA, and autoimmune workup were normal. In the setting of possible atypical HUS secondary to PD 1 inhibitor exposure, eculizumab was initiated. In the most recent follow-up, kidney function has been steadily improving reaching a range between 1.7-2.0 mg/dl.

Discussion: Although TTP associated with Avelumab is reported, HUS associated with Avelumab has not been reported so far. Possible mechanisms of kidney injury that have been proposed: include excessive inflammatory cytokine production, and enhancing complement-mediated inflammation. Prompt discontinuation of the offending agents along wth initiation of complement inhibitory therapy is key to the successful management.

TH-PO676

ANCA Glomerulonephritis: Uncommon Presentation as Renal Masses

Suhaib F. Al-Sawajneh, Brian Monk, Mohamed Hassanein, Bushra Syed, Neville R. Dossabhoy, Yoshitsugu Obi. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: Antineutrophil cytoplasmic antibodies (ANCA)-associated vasculitis (AAV) can manifest with diverse systemic symptoms and commonly affects the kidneys, causing necrotizing glomerulonephritis (GN). Here, we report a rare case of AAV presenting as renal cortical masses.

Case Description: A 70-year-old male presented with fatigue, loss of appetite, and a 50-lb weight loss over six months. Initial laboratory workup was unremarkable including normal serum creatinine and urinalysis. CT scan showed non-specific bilateral pulmonary nodules and a 'rind' of abnormal soft tissue surrounding the abdominal aorta. Three months later, follow-up CT scan revealed worsening peri-aortic soft tissue thickening (max 3 cm) and the development of bilateral renal cortical masses (largest measuring 2.5 cm). Further workup showed positive p-ANCA with elevated MPO levels (>8.0 U; ref. <0.4 U), CRP (72 mg/dL; ref. <0.5 mg/dL), and mildly elevated IgG4 (137 mg/dL, ref. 2.4–121 mg/dL). Two kidney biopsies were obtained. The standard core biopsy showed plasma cell-rich infiltrates without IgG4 positivity, while the fine needle aspiration (FNA) to a renal mass showed focal necrotizing and crescentic GN with granulomatous vasculitis. Induction therapy with high-dose steroids and rituximab was initiated. Steroid dosage was tapered over a year, and maintenance rituximab doses were adjusted based on CD19+/CD20+ cell counts and MPO-ANCA titers. The patient has remained in clinical remission, without hematuria, proteinuria, or elevated serum creatinine over 4 years.

Discussion: AAV can form inflammatory masses in various organs, including kidneys, pancreas, orbit, and peri-aortic soft tissue, akin to IgG4-related disease. In a recent case series, patients with ANCA-associated renal masses often had elevated serum IgG4 levels or increased tissue IgG4+ plasma cells. Few cases had normal urinalysis and serum creatinine despite biopsy findings of crescentic GN, as in our case. Our case is particularly unique: (1) repeated CT scans confirmed rapid development and progression of renal masses and peri-aortic soft tissue thickening; and (2) crescentic GN was detected in FNA of the renal mass but not in the core biopsy. In patients with suspected AAV and renal masses, kidney biopsy is essential to establish the diagnosis and rule out cancer and infection before starting immunosuppression.

TH-PO677

ANCA-Negative Vasculitis Leading to Intrauterine Fetal Demise

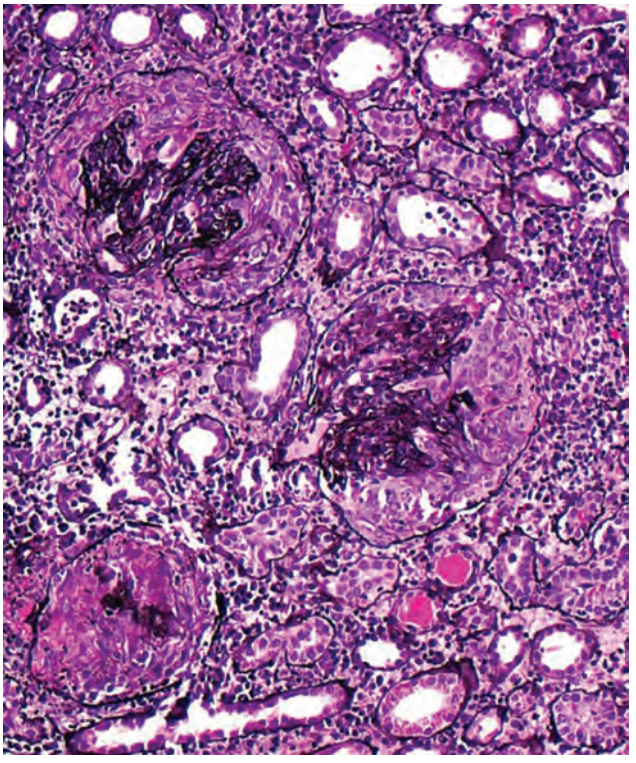
Dhirisha Bhatt,[1,2] Sahar Amin,[1,2] Barry M. Wall,[2] Alice Chedid.[1] *[1]The University of Tennessee Health Science Center College of Medicine, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN.*

Introduction: ANCA-negative pauci immune crescentic glomerulonephritis is a relatively rare subtype of RPGN, accounting for ~10-30% of cases. ANCA-negative vasculitis complicating a pregnancy course is even more rare. We present an interesting case where fetal demise at 20 weeks was the first manifestation of ANCA vasculitis.

Case Description: A previously healthy 16-year-old, G1P0 at 20 weeks of gestation, presented with vaginal bleeding and lower limb edema of 3-4 days duration. No further

PMH except a recently completed antibiotic course 3 weeks ago for a URI. She was afebrile, HR 116/min, BP 158/110mmHg, SpO2 97% on RA. Lab workup WBC 8.4, Hgb 7.0, platelets 207, Na 136, K 4.4, HCO3 17, BUN 76, Cr 9.4 mg/dl (no baseline), and albumin 2.6 g/dl. UA: microscopic hematuria, 3+ protein. UPCR 6.3 g/g. UDS negative. Autoimmune workup was all negative including PR3/MPO. Trans-abdominal US showed fetal demise for which she underwent emergent vaginal delivery. From a kidney standpoint, the patient required hemodialysis on admission for volume overload. Given her severe anuric AKI, she underwent a kidney biopsy that showed: Diffuse necrotizing and crescentic glomerulonephritis, pauci immune, 23/24 glomeruli with cellular crescents and fibrinoid necrosis. The patient was treated with pulse steroids, rituximab 1 gram x 2, and plasmapheresis every other day for total of 7 sessions. She became non-oliguric; however, remained dialysis-dependent at the time of transfer to a pediatric hospital.

Discussion: We present a challenging case of ANCA-negative vasculitis complicating pregnancy leading to fetal demise. Our patient was managed similarly to an ANCA-positive vasculitis. We wonder if adding aserum creatinine to the routine urinalysis as part of first-trimester screening would have led to earlier diagnosis and changed this unfortunate outcome.



Cellular crescents

TH-PO678

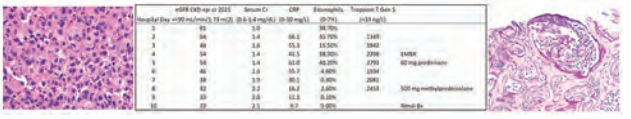
Where Have All the Eos Gone? Long Time Passing or in the Heart? ANCA-Associated Crescentic Glomerulonephritis Presenting with Eosinophilic Myocarditis

Mohammad I. Khan,[1,2] Kunal Parekh,[3] Lisa Kim.[3,2] *[1]Hawaii Residency Programs Inc, Honolulu, HI; [2]University of Hawai'i at Manoa John A Burns School of Medicine, Honolulu, HI; [3]Queen's Medical Center, Honolulu, HI.*

Introduction: Eosinophilic granulomatosis with polyangiitis (EGPA) may be diagnosed from other small vessel vasculitides by clinical criteria. Its rare presentation as an acute coronary syndrome in a community setting makes this an unfamiliar entity. New therapies in IL-5 and complement pathways are recent tools to reduce immunosuppression but trials have mixed results or must be used "off-label" for EGPA due to its variable presentation. We present a case of EGPA in which avacopan was initiated for compassionate use.

Case Description: A 69 year old male with history of asthma presented to his PCP with 3 days of constant left sided chest pain radiating to the back. Transfer to our institution showed cardiac MR consistent with subendocardial infarct and suspicion for eosinophilic myocarditis as peripheral eosinophilia was elevated to 38.7% (absolute eosinophils 2250/mm^3). Endomyocardial biopsy was performed showing sheet-like histiocytic cell proliferation with abundant eosinophilic inflammation (Figure 1). Methylprednisolone 500 mg was initiated for presumed eosinophilic myocarditis. Urinalysis was notable for 51-100 rbc and renal biopsy was performed. A diagnosis consistent with pauci-immune necrotising crescentic glomerulonephritis was made but eosinophils were absent. cANCA was positive at 1:320. The patient received rituximab and discharged with steroid taper but was rehospitalized for Klebsiella and Pseudomonas pneumonia and severely reduced eGFR of 9 mL/min/1.73 m^2. Cyclophosphamide was initiated with another round of high dose steroids but dialysis was started by week 9 of his original presentation. On day 58, the patient started avacopan 30 mg BID. Although he eventually became dialysis independent he continued to experience complications from infections and entered hospice 8 months after the diagnosis of EGPA.

Discussion: EGPA may affect multiple organs and therefore requires rapid recognition with aggressive treatment and coordination from specialists. However, complications often occur with sustained immunosuppression as our case demonstrates. The use of new agents for this rare cause of ANCA associated glomerulonephritis must further be studied.



TH-PO679

Avacopan and ANCA

Sadia S. Hussaini, Janany J. Sabescumar. *University of Rochester Medical Center, Rochester, NY.*

Introduction: ANCA-negative vasculitis, although rare, is associated with increased morbidity and mortality. In this case report, we present a patient with ANCA-negative vasculitis and highlight the use of the novel agent Avocopan.

Case Description: A seventy-four-year-old male with a medical history of hypertension, insulin-dependent diabetes, and coronary arterial disease presented to urgent care with symptoms of shortness of breath, cough, lower extremity swelling, and a rash on his buttocks. He was thought to have multifocal pneumonia and heart failure. Despite initial treatment, his edema worsened, and subsequent laboratory tests showed an increase in serum creatinine from 1.7 mg/dL to 3.75 mg/dL. Urinalysis revealed microscopic hematuria and proteinuria quantified at 8.89 g/day. Concerns arose regarding rapidly progressive glomerulonephritis, and a secondary serological workup yielded largely negative results, including ANCA. A kidney biopsy was performed, revealing pauci-immune crescentic glomerulonephritis of the focal necrotizing type with moderate activity and minimal chronicity. The patient underwent Rituximab induction therapy along with steroids for maintenance. However, due to worsening edema, hypertension, hyperglycemia, and weight gain a decision was made to switch the patient to Avacopan. At six months follow up, the patient's serum creatinine reduced to 1.89 mg/dL, and proteinuria decreased to 0.81 g.

Discussion: The standard approach to ANCA-mediated vasculitis has involved the use of glucocorticoids in combination with Rituximab or cyclophosphamide. However, a novel agent called Avacopan has emerged as a promising alternative. Avacopan specifically targets the alternative complement pathway, which is believed to play a role in the pathogenesis of ANCA vasculitis. In our case of ANCA-negative vasculitis the patient responded well to Avacopan therapy, achieving remission with minimal proteinuria. References: Jayne et Al. Avacopan for the Treatment of ANCA-Associated Vasculitis. NEJM 2021 Feb 18 384:599-609. Jennette JC, Nachman PH. ANCA Glomerulonephritis and Vasculitis. TH-PO680

ANCA Vasculitis in a Patient with Significant Silica Exposure

Nivetha Subramanian, Shuchi Anand. *Stanford Medicine, Stanford, CA.*

Introduction: Exposure to free crystalline silica (silicon dioxide) is classically associated with an array of lung diseases. It has also been associated with ANCA vasculitis. Here we describe a case of ANCA vasculitis attributed to silicosis, a diagnosis that occurred through multi-disciplinary involvement.

Case Description: A 37-year-old male with no past medical history presents with one year of cough and hemoptysis. For the past 20 years, he has worked as a granite cutter, installing counter tops; he smokes 2-3 cigarettes per day. He was found to have a creatinine of 2.5 mg/dL (0.8 mg/dL eight months ago). Labs were notable for nephrotic range proteinuria of 5 g/g creatinine and 3+ hemoglobinuria with 13 RBCs/HPF but normal complements and negative rheumatoid factor, HIV, and anti-HCV. He had positive MPO/P-ANCA, dsDNA, and ANA. CT chest without contrast showed numerous nodules. After discussion between nephrology, rheumatology, infectious disease, and pulmonology, he was admitted for expedited kidney biopsy and bronchoscopy. Kidney biopsy revealed glomerulonephritis with 30% active crescents and both IgG and C3 deposition, not entirely typical for lupus or ANCA vasculitis but concerning for drug-induced or infection-associated ANCA. Bronchoscopy showed hemosiderin laden-macrophages but BAL was inconsistent with diffuse alveolar hemorrhage and negative for tuberculosis through AFB stain and culture. Since his quantiferon was positive and he had immigrated from a TB-endemic region, concern for miliary tuberculosis was high, so he underwent VATS lung biopsy which was consistent with silicosis based on pathology demonstrating nodular aggregates of dust-laden macrophages, fibrosis, and birefringent particles. A diagnosis of ANCA vasculitis associated with silicosis was made. He received

rituximab but experienced a severe infusion reaction so treatment was changed to cyclophosphamide and high-dose steroids with improvement in his creatinine although without return to baseline. He is also receiving treatment for latent tuberculosis.

Discussion: Silica exposure has been described in the literature to cause a variety of autoimmune conditions including ANCA vasculitis and lupus although the mechanism is unclear. Our patient's occupational exposure and biopsies support this diagnosis. This case highlights the importance of a thorough exposure history and multi-disciplinary engagement to arrive at a diagnosis.

TH-PO681

Obinutuzumab in Combination with Avacopan in Rituximab-Resistant ANCA-Associated Vasculitis (AAV)

Yeshwanter Radhakrishnan, Ulrich Specks, Fernando C. Fervenza, Ladan Zand. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Rituximab (RTX) is now considered the standard for induction (along with glucocorticoid) and maintenance therapy of patients with AAV. We report 2 patients with AAV who had active disease despite RTX therapy and were successfully treated with combination of Obinutuzumab (OBZ) (a type II anti-CD20) and Avacopan (C5aR antagonist).

Case Description: Patient 1: 80-year old female with a 10-year history of microscopic polyangiitis treated with mycophenolate (MPA) (for 6 years) and prednisone (PRED). She relapsed after being off immunosuppression for 2 years and was re-initiated on MPA therapy. Due to lack of response, she was switched to RTX induction 1g x 2 doses 2 weeks apart with PRED. At the time of RTX induction, serum creatinine (Scr) was 1.5 with MPO-ANCA titers > 8.0 U and hematuria (3-10 RBC/HPF). She was continued on RTX maintenance therapy (1g) every 6-months. However, despite RTX therapy (18 months) and CD20+ B cell of zero, she had rising Scr 2.1 mg/dL with persistent hematuria and MPO titers > 8.0 U. Repeat biopsy showed active necrotizing glomerulonephritis (GN). Therefore, she received OBZ 1g x 2 doses 2weeks apart with Avacopan 30 mg twice daily. At last follow up (9 months after OBZ), her Scr is stable at 2.0 mg/dL, hematuria completely resolved and MPO is down to 1.1 U. She has not experienced any adverse events. Patient 2: 47-year-old female was diagnosed with AAV after presenting with a Scr of 2.6, hematuria (3-10 RBC/HPF), MPO titers > 8.0 U and a biopsy that showed pauci-immune necrotizing GN. She was initially treated with RTX 375 mg/m^2 weekly for 4 doses and PRED. She was continued on RTX (1g) every 6 months. Although her Scr initially improved to 1.5 mg/dL, her MPO remained persistently > 8.0. Subsequently, she was noted to have a worsening Scr that peaked at 2.4 mg/dL with hematuria (100/HPF) and MPO > 8.0 U despite therapy with RTX. CD20+ B cells were zero. A repeat kidney biopsy showed active necrotizing GN. She received 1 dose of OBZ 1g, Avacopan 30 mg twice daily and prednisone. Six months following OBZ, Scr is stable at 2.2 mg/dL, hematuria resolved and MPO titers are down to 5.8 U.

Discussion: OBZ with Avacopan can be an effective strategy in AAV patients resistant to RTX. The efficacy of this combination should be evaluated through a randomized clinical trial to determine outcomes and adverse effects.

TH-PO682

Infection-Related ANCA-Negative Pauci-Immune Glomerulonephritis

Mohammad A. Sohail, Jonathan J. Taliercio, Kristen Tomaszewski, Ali Mehdi. *Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Introduction: Infection-related glomerulonephritis (IRGN) is typically an immune-complex mediated disease characterized by a diffuse proliferative process with mesangial, subendothelial and subepithelial deposits comprised of various combinations of IgM, IgG, IgA and C3. However, other forms of IRGN have also been reported, including those with a pauci-immune crescentic pattern of injury. The overwhelming majority of pauci-immune GN cases are associated with the presence of anti-neutrophil cytoplasmic antibodies (ANCA). However, approximately 2-10% of these patients may be ANCA negative, and here, we present two cases of IRGN, which were ANCA-negative, and demonstrated a pauci-immune crescentic pattern of injury.

Case Description: Table 1 describes the clinical characteristics, histologic features and outcomes for two patients who initially presented with acute kidney injury, were subsequently diagnosed with ANCA-negative pauci-immune crescentic GN on kidney biopsy and after further evaluation for secondary causes of pauci-immune GN, were found to have bacterial aortic/mitral valve endocarditis.

Discussion: This case series depicts two patients who developed ANCA-negative pauci-immune GN in association with bacterial endocarditis. The largest case series of 74 patients with ANCA-negative pauci-immune GN included 9 cases that were infection-related. 54% of these patients had extra-renal involvement and 23% of them required dialysis at diagnosis. The diverse glomerular presentations in association with infections have significant clinical implications since the prompt recognition of an underlying systemic infection is crucial to avoid inadvertent immunosuppressive therapy. It is imperative for clinicians to screen for occult infections not only when an immune-complex GN is seen, but also when a pauci-immune process is identified on a kidney biopsy.

Table 1

Clinical Characteristics	Case 1	Case 2
Age (Years) / Sex	69 / Female	59 / Female
Clinical Manifestations	Exertional Dyspnea and Lower Extremity Edema	Progressive Weight Gain, Exertional Dyspnea and Lower Extremity Non-Blanching Petechial Rash
Serum Creatinine on Initial Presentation (Baseline Creatinine) (mg/dL)	4.1 (1.0)	3.0 (0.6)
Urinalysis Urine Protein/Creatinine Ratio (mg/mg)	Microscopic Hematuria (>25 RBCs/HPF) (Dysmorphic RBCs) 0.45	Microscopic Hematuria: (>25 RBCs/HPF) (Dysmorphic RBCs) 0.95
Available Serologic Testing	ANA Negative ANCA Negative Low Serum C3 (71 mg/dL) Low Serum C4 (7 mg/dL)	Polyclonal IgG Type 3 Cryoglobulinemia IgM Lambda M-Protein ANA Negative ANCA Negative Low C3 (79 mg/dL) Normal C4 (24 mg/dL)
Blood Cultures Echocardiogram Findings	Streptococcus Mutans Mitral/Aortic Valve Vegetations	Streptococcus Mitis Mitral Valve Regurgitation Mitral/Aortic Valve Vegetations
Histologic Features on Kidney Biopsy	Pauci-Immune GN Endocapillary Hypercellularity Cellular/Fibrous Crescents with Necrosis Moderate IFTA	Pauci-Immune GN with Trace IgA, C3 and C1q Endocapillary Hypercellularity Cellular Crescents Severe IFTA
Clinical Outcomes	S/P Mitral and Aortic Valve Replacement Initiated KRT at the time of kidney biopsy Repeat kidney biopsy 1 month later showed focal global glomerulosclerosis without ongoing proliferative activity Last Follow-Up: remains KRT-dependent 4 months following valvular surgery	S/P Mitral Valve Replacement and Aortic Valve Repair Initiated KRT immediately after valvular surgery Subsequent kidney recovery with cessation of KRT one week after initiation Last Follow-Up: remains liberated from KRT with serum creatinine 1.23 mg/dL 3 months following valvular surgery

Interstitial Fibrosis and Tubular Atrophy (IFTA); Kidney Replacement Therapy (KRT)

TH-PO683

An Unusual Case of ANCA Vasculitis Coexisting with Membranous Nephropathy due to Cocaine Use

Marjorie Mailing Flores Chang, William M. Paredes, Hamed Sarikhani, Jamil Ibrahim, Bessy Suyin Flores Chang. *SBH Health System, Bronx, NY.*

Introduction: Membranous nephropathy (MN) is one of the leading entities causing nephrotic syndrome. Cocaine is associated with leukocytoclastic vasculitis, rhabdomyolysis, and ANCA-associated vasculitis (AAV) with pauci-immune necrotizing glomerulonephritis**.** We are reporting a rare case of a patient with rapidly progressive focal necrotizing & crescentic and sclerosing glomerulonephritis coexisting with MN in the setting of cocaine use.

Case Description: 51 yo male with Heart Failure reduced EF 30%, ANCA-associated MPA with focal segmental pauciimmune glomerulonephritis, Rheumatoid arthritis, polysubstance use (cocaine, alcohol) presents with dyspnea and lower extremity edema. BP 149/110, HR 100 beats/min, RR 18 respirations/min, T 97.7 Fahrenheit, O2 96% on room air Blood work showed macrocytic anemia of 8.1k with MCV 97.3, platelets: 256k, sodium: 139 mg/dL, potassium: 5.1 mg/dL, bicarbonate: 16, serum creatinine: 2.8 mg/dL, albumin: 1.9. BNP: 6992. UA >500 protein, moderate blood and RBCs 9, total protein creatinine ratio 3.88 g. Urine toxicology positive for cocaine and marihuana. C4 low 4, C3 low 68, ANA negative, RF negative, DsDNA: <1, P-ANCA 1:640, Myeloperoxidase ab elevated. Patient was admitted due to HF exacerbation and started on intravenous furosemide. Kidney biopsy showed Membranous, focal necrotizing crescentic and sclerosing glomerulonephritis. Treatment with steroids and immunosuppressive therapy with Rituximab and cyclophosphamide which he completed and discharged home. Returned to the ED 2 weeks later with clinical signs of fluid overload, anemia, and worsening kidney function requiring blood transfusion and subsequently started on dialysis. Hospital course was complicated with sepsis due to pneumonia and 7.5 cm abscess-like fluid collection posterior the bladder, abdominal tap positive for resistant Enterococcus faecium and ESBL positive, cyclophosphamide was discontinued and started on IV broad spectrum antibiotics. Ultimately patient succumbed to the disease.

Discussion: Coexistence of ANCA vasculitis with MN due to cocaine use is not frequently reported in the literature, effect of cocaine in the kidney has multiple pathophysiological mechanisms, causing AKI but very few includes MN intention of this abstract is to make physicians aware of this for the future and warrant further investigation.

TH-PO684

Late-Onset Hydralazine-Associated Immune-Complex Glomerulonephritis with Overlap ANCA and Lupus Nephritis Features

Liana Srisawitri. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Hydralazine is one medication that has been long associated with drug-induced lupus and also antinuclear cytoplasmic antibodies (ANCA) vasculitis. We present an unusual case of an 83-year-old patient with hydralazine-associated glomerulonephritis (GN) with overlap features of ANCA vasculitis and lupus nephritis.

Case Description: The patient presented with hemoptysis with blood clot and estimated half a cup of red blood. She has history of hypertension and atrial fibrillation. Patient has had dyspnea on exertion, cough, nausea, and fatigue for 3 months. CT chest showed bronchial opacification, airspace disease, and mild fibrosis. Patient had remote 20 pack-year history of smoking. Her medications include hydralazine 50 mg 3 times a day for more than 10 years. Hemoglobin (Hgb) was 6.4 g/dL (down from 9.3 g/dL 1 month prior). Serum creatinine (Cr) was 2.3 mg/dL up from 1.4 one month prior and 0.7 six months prior. C3 and C4 70 and <8 mg/dL. Urinalysis showed 6-10 WBC and 50-100

RBC/hpf with dysmorphic RBCs and RBC casts. Urine protein/Cr ratio was 0.62 g/g. ANA 1:640, anti-dsDNA indeterminate, p-ANCA 1:640, MPO Ab 7.2 AI, PR-3 Ab >8.0 AI, anti-histone Ab 4.4 U. Kidney biopsy showed mild mesangial hypercellularity on light microscopy and mild mesangial deposits on electron microscopy. Immunofluorescence showed 1-2+ IgA, IgM, C3 diffuse granular deposits. Patient was given pulse IV methylprednisolone for 3 days, followed by slow taper prednisone. Cr peaked at 3.3 mg/dL and improved to 2.1 mg/dL upon discharge.

Discussion: Patient's presentation of pulmonary renal syndrome is common in ANCA vasculitis, supported by the high p-ANCA, MPO Ab, and PR-3 Ab However, the classical findings of ANCA vasculitis with purely pauci-immune necrotizing and/or crescentic GN were not found. Instead, glomeruli showed mild IgA-predominant deposits. Low complements and elevated ANA and anti-histone Ab suggest hydralazine-induced GN. Ten years of hydralazine use confers a high cumulative dose, in contrast to a review of 12 cases of hydralazine-associated ANCA vasculitis showed median drug duration of 22 months. In a review of 7 cases of drug-induced lupus nephritis, the duration was >12 months for most patients. In summary, this case may be an atypical hydralazine-induced GN with overlapping lupus and ANCA serology but with dominant IgA deposits.

TH-PO685

"Atypical" Atypical Anti-Glomerular Basement Disease

Sandipan Shringi,[1,2] Kammi J. Henriksen,[3] Ankur Shah.[1,2] *[1]Brown University Warren Alpert Medical School, Providence, RI; [2]Rhode Island Hospital, Providence, RI; [3]University of Chicago Department of Pathology, Chicago, IL.*

Introduction: Anti-glomerular basement membrane (anti-GBM) disease frequently presents as rapidly progressive glomerulonephritis due to autoantibodies directed toward the alpha 3 NC 1 domain of type IV collagen, found in the glomerular and alveolar basement membrane. In atypical anti-GBM disease, serum antibodies are negative, but the biopsy shows linear IgG staining. Clinically, it presents with an indolent renal limited course and good prognosis.

Case Description: A 36-year-old woman with a history of HIV, hypertension, diabetes mellitus type 2, asthma, obesity, and fatty liver presented with elevated creatinine, hematuria, and proteinuria. She developed foamy and dark urine six months before referral. HIV was stable with an undetectable viral load, CD 4 count 190 cells/mm^3 on dolutegravir-rilpivirine. Physical examination was unremarkable. Presentation labs were BUN 34, sCr 1.91 mg/dL, urinalysis with 3+ blood, 100 protein, albuminuria 3087mg/g. C3 143mg/dl, C4 28 mg/dl, and serologies included negative ANCA, MPO, PR3, and anti-GBM. Kidney biopsy demonstrated an active necrotizing and crescentic glomerulonephritis involving 36% of the sampled glomeruli, as well as older fibrous crescents in 27% of the glomeruli. There was patchy interstitial nephritis and mild interstitial fibrosis and tubular atrophy. Direct immunofluorescence demonstrated linear staining of the GBMs for IgG (3+) and kappa (2-3+) and lambda (3+) light chains. There were no electron-dense deposits by electron microscopy. The patient was started on treatment with solumedrol and cyclophosphamide. After the development of diffuse alveolar hemorrhage, 6 sessions of plasmapheresis were performed. sCr peaked at 3.6 with improvement to 2.2 since. ESR/CRP were used as surrogates of disease activity, owing to the lack of ability to monitor antibody titers.

Discussion: Atypical GBM was thought to have an indolent disease course without crescent formation on light microscopy, but more recent literature has shown crescents in pathology and progression to ESKD. Diffuse alveolar hemorrhage has not been reported to our knowledge. Management of atypical anti-GBM is complicated, owing to the lack of ability to monitor serum levels of antibodies. It is important for treating clinicians to be aware of the evolving landscape of this entity and of the difficulties in treatment including decisions regarding plasmapheresis and methods to monitor disease activity.

TH-PO686

Pulmonary Renal Syndrome Caused by Seronegative Anti-Glomerular Basement Membrane (GBM) Disease

Mohamed Modar Abidian,[1] Santhoshi R. Bavi,[2] Atiya Chachar,[3] Anum Bilal.[1] *[1]Emory University, Atlanta, GA; [2]Ascension Saint Joseph - Chicago, Chicago, IL; [3]Tanner Health System, Villa Rica, GA.*

Introduction: Anti-GBM disease is a common cause of crescentic RPGN with or without pulmonary hemorrhage. We present an unusual case of pulmonary renal syndrome caused by biopsy proven anti-GBM disease without serum anti-GBM antibodies (Ab).

Case Description: A 50 YO F with history of asthma and suspected PE on apixaban presented with dyspnea and found to have hypoxia with bilateral lung opacities and AKI (SCr 1.7, baseline 0.6) Urinalysis showed hematuria and nephrotic-range proteinuria of 3.8 gm/gm. Initial serologic workup for infectious and autoimmune etiologies was negative, particularly ANCA <1:20 and anti-GBM Ab 0.5 units (normal range: 0.0-0.9). A renal biopsy showed diffuse necrotizing crescentic GN involving 50% of glomeruli with linear IgG deposits along the GBM. Prompt treatment with high dose steroids, cyclophosphamide and plasmapheresis was initiated along with supportive care. Clinical course was complicated by severe hemoptysis leading to hypoxia and cardiac arrest that necessitated VV ECMO support and CRRT after ROSC. Bronchoscopy showed blood in the airway but no active hemorrhage and repeated anti-GBM Ab remained within reference range. Given severe hypoxemia, 13 additional TPE sessions were done along with CYC and steroids. Later on, pulmonary function improved significantly allowing for ECMO decannulation. However, RRT-requiring AKI persisted without renal recovery.

Discussion: We present a rare case of pulmonary renal syndrome caused by seronegative anti-GBM disease occur in only 2-3% of cases. The diagnosis relies on the detection of anti-GBM Ab along with biopsy-proven crescentic necrotizing GN and/or alveolitis but serum Ab can be negative in rare cases due to low test sensitivity, antibodies to atypical GBM epitopes, or non-IgG anti-GBM Ab. The absence of alveolar hemorrhage on initial presentation with negative serology makes the diagnosis challenging, thus kidney biopsy becomes critical for early diagnosis and salvage treatment. Given the rarity of seronegative anti-GBM disease, there is no data on management and prognosis and the renal outcome of this case is undetermined.

TH-PO687

Ureteral Obstruction as a Risk Factor for Anti-Glomerular Basement Membrane (GBM) Disease

Megan Dunleavy,[1] Satoru Kudose,[3] Solomon Dawson,[1,2] Vinay Srinivasan.[1,2] *[1]Cooper University Health Care, Camden, NJ; [2]Rowan University Cooper Medical School, Camden, NJ; [3]Columbia University, New York, NY.*

Introduction: Anti-glomerular basement membrane (anti-GBM) disease has an incidence of 0.5–1 per million population; possible triggering factors including smoking & hydrocarbon exposure. Limited data also suggests a link between obstructive uropathy & the development of anti-GBM antibodies. We present a case of a 77-year-old male with chronic bilateral hydroureteronephrosis who subsequently developed anti-GBM disease & was successfully treated with a combination of steroids, cyclophosphamide, & plasmapheresis.

Case Description: A 77-year-old male with history of Chronic Kidney Disease Stage 3a presented for a routine outpatient evaluation; he was asymptomatic at time of presentation. Laboratory evaluation was notable for a serum creatinine of 4.42 mg/dL that had increased from 1.31 mg/dL seven months earlier. Urine microscopy showed numerous dysmorphic RBCs/HPF raising concern for a rapidly progressive glomerulonephritis (RPGN) prompting inpatient admission. CT imaging studies were notable for chronic bilateral hydroureteronephrosis dating back for at least two years. His serologic evaluation was negative with the exception of anti-GBM antibody that was positive at 1.8 U. Repeat imaging showed continued bilateral hydronephrosis initially delaying kidney biopsy however NM MAG3 scan did not reveal a high-grade urodynamic obstruction. After urologic evaluation, the patient underwent a native kidney biopsy confirming anti-GBM disease. He received pulse dose steroids, followed by cyclophosphamide, Prednisone taper, & 14 sessions of plasmapheresis. His serum creatinine has nadired at 2.6 mg/dL & anti-GBM antibodies are now undetectable.

Discussion: Anti-GBM antibodies target a cryptic α3 antigen of the non-collagenous 1 domain of type IV collagen. It is hypothesized that disruption of this domain, exposing the α-3 chain, is required for anti-GBM antibodies to develop. While several environmental triggers have been implicated in this process, ureteral obstruction & hydronephrosis remain an under-recognized & poorly understood trigger. Although challenging due to the rare nature of this disease process, further studies are needed to elucidate the nature of this relationship.

TH-PO688

Clinical Characterization and Outcomes of Lupus Nephritis in the Colombian Caribbean: Data from the Lupus Nephritis Register (RENELUP)

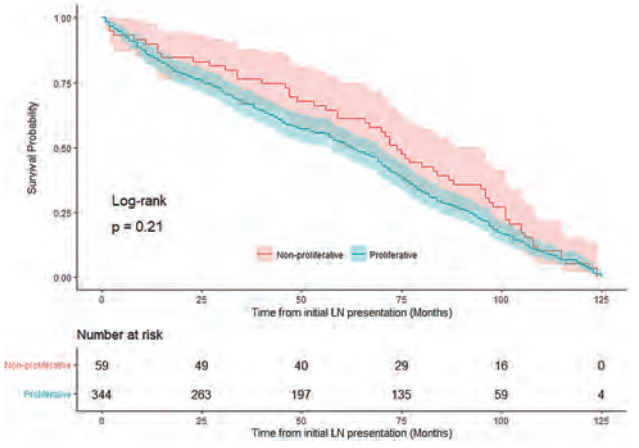
Gustavo Aroca Martinez,[1] Alex Dominguez-Vargas,[2] Henry J. Gonzalez Torres,[1] Carlos G. Musso,[1] Maria G. Sanguino,[2] Maria D. Velez,[1] Lorena Gomez Escorcia,[1] Maria F. Palma,[1] Camilo J. Roncallo,[3] Carlos J. Sepulveda Ospino,[1] Manuela Vallejo Patiño,[1] Jesús A. Orozco,[4] Hernando R. Ricardo Garcia,[3] Natalia Barraza,[3] Alvaro A. Martinez Bayona,[1] Jesús D. Puche Padilla,[5] Eduardo Egea Bermejo,[2] Gloria Garavito De Egea,[2] Elkin Navarro Quiroz,[1] Zilac Espitaleta,[1] Andres Cadena Bonfanti,[1] Jorge R. Fontalvo.[1] *[1]Universidad Simon Bolivar Facultad de Ciencias de la Salud, Barranquilla, Colombia; [2]Universidad del Norte Division Ciencias de la Salud, Barranquilla, Colombia; [3]Clinica de la Costa Ltda, Barranquilla, Colombia; [4]Universidad Nacional de Colombia Facultad de Medicina, Bogota, Colombia; [5]Universidad Libre - Campus Barranquilla, Barranquilla, Colombia.*

Background: LN is a severe manifestation of SLE, impacting outcomes directly and indirectly through therapy. LN varies across populations. Registries are crucial for understanding LN and assessing therapies. This study evaluates LN in RENELUP to assess its status in the Colombian Caribbean.

Methods: A multicenter cohort of 579 LN patients enrolled from 2008 to 2023. RENELUP, a JAVA-based web app, recorded demographic data, severity, outcomes, treatments, and mortality. Patients were grouped into Proliferative (Class III-IV) and Non-Proliferative (Class I-II-V) LN using ISN/RPS criteria. Chi-square/Mann-Whitney U tests evaluated renal survival using Kaplan-Meier estimator.

Results: Most patients were female (87%). Mean age was 41.1±13.1 years. Proliferative LN class IV was the main profile (62%). Proliferative LN had higher serum creatinine, proteinuria, activity index compared to Non-Proliferative LN ($p<0.05$). Hematuria, chronicity, low C3/C4, and clinical response were similar between LN classes. Overall SLEDAI-2K was 15.4±2.5. MMF (64%) was used as main induction therapy. Renal survival comparable based on serum creatinine at first presentation ($p>0.05$).

Conclusions: Our study provides insights into LN in the Colombian Caribbean. Predominant proliferative LN Class IV with significant renal involvement was observed. Moderate disease activity and MMF as main induction therapy highlight clinical management in this population, emphasizing the importance of patient registries for monitoring disease and treatment outcomes.



TH-PO689

Vitamin D Levels on Lupus Nephritis: Profile of a Large Brazilian Academic Center

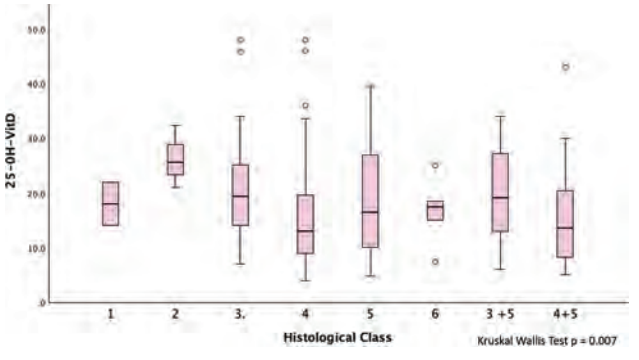
Liliana M. Kassar, Washington A. Freire Filho, Felipe Carvalho Barros Sousa, Fernando L. Strufaldi, Karoline W. Silva, Ana Teresa P. Vieira, Cristiane B. Dias, Luis Yu, Lectícia Jorge. *Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil.*

Background: Lupus nephritis is present in most patients with lupus. It is believed that the imbalance between pro-inflammatory and anti-inflammatory factors is responsible for its manifestation. Vitamin D is known for its anti-inflammatory activity and plays a regulatory role in cytokine production. Therefore, we tested the association between the level of 25-OH-Vitamin D, histological class, activity index and degree of proteinuria in patients from a large Brazilian academic center.

Methods: Patients diagnosed with lupus nephritis between January 2012 and December 2018 were included. Variables evaluated were age, gender, creatinine, estimated glomerular filtration rate (eGFR) by CKD-EPI, proteinuria, histological class and serum level of 25-OH-Vitamin D at the time of kidney biopsies.

Results: 253 kidney biopsies were performed during this period, 86% in women. The mean age was 31 years (13-70), creatinine 1.3 mg/dL (0.32-8.04), eGFR of 57.9 mL/min (6.2-165.3), proteinuria of 2.7g (0.07-10.7) and level of 25-OH-Vitamin-D 17 (4-48). Spearman's correlation between Vitamin D levels and proteinuria was -0.338 with $p<0.001$. The association between levels of vitamin D, histological class of lupus nephritis and activity index > 9 was significant ($p= 0.007$ and p 0.003, respectively), with the lowest median found in class IV. We didn't find associations between vitamin D levels and thrombotic microangiopathy.

Conclusions: Low levels of vitamin D were found in patients with more severe histological class, higher activity index and higher proteinuria, which may be involved as a risk factor for the inflammatory imbalance present in lupus and disease activity.



TH-PO690

Incidence of Primary Immunoglobulin A Nephropathy (IgAN) Among a Diverse Population in the United States

John J. Sim,[1,2] Qiaoling Chen,[1] John M. Chang,[1] Nancy Cannizzaro,[1] Dilip Makhija,[3] Ancilla Fernandes,[3] Sandipan Bhattacharjee,[3] Cibele S. Pinto,[3] Asher D. Schachter,[4] Mohit Mathur.[4] *[1]Kaiser Permanente Southern California, Pasadena, CA; [2]Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; [3]Otsuka America Pharmaceutical Inc, Rockville, MD; [4]Visterra Inc, Waltham, MA.*

Background: IgAN is a leading cause of primary glomerular disease and end stage kidney disease (ESKD) with a 10-year risk of chronic kidney disease (CKD) progression of up to 40%. Global incidence is estimated at 2-5 cases per 100,000 people. US data suggest lower rates but varies by race/ethnicity. We examined incidence of primary IgAN, leveraging a diverse, contemporary cohort from a single integrated health system in California.

Methods: A retrospective cohort was studied (1/1/2010-12/31/2021) of Kaiser Permanente members with biopsy proven IgAN, excluding secondary IgAN. Annual IgAN incidence rates were standardized by age, sex, and race/ethnicity according to the 2020 US Census using the American Community Survey (ACS). Primary IgAN rate was calculated for 2010-2021 and stratified by race/ethnicity. We estimated IgAN prevalence by using mean annual incidence x estimated disease duration.

Results: A total of 606 primary IgAN patients were identified with mean age (SD) of 46 years (15.0) with males (51.2%), Hispanic/Latinos (38.6%), Asian/Pacific Islanders (30.4%), Whites (25.6%), and Blacks (3.1%). The average annual incidence rate (per 100,000 person-years) of primary IgAN was 4.5, 1.7, 1.2, and 0.6 among Asian/Pacific Islanders, Hispanic/Latino, Whites, and Blacks, respectively. The mean annual IgAN incidence of 1.4 per 100,000 person-years equates to an adjusted IgAN prevalence estimate of 40 per 100,000 persons (incidence x estimated disease duration of 28.5 years for IgAN patients).

Conclusions: Our findings show a mean annual IgAN incidence of 1.4 per 100,000 person-years. Asian/Pacific Islander and Hispanic/Latino had the highest incidence rate of IgAN. Whether the clinical course and response to treatment for IgAN patients varies by race/ethnicity warrants further investigation.

Funding: Commercial Support - Otsuka Pharmaceuticals

Table 1: Prevalence Rate of Primary IgAN by Race/Ethnicity (2010-2021)

Race/Ethnicity	Total patients	Number of Patients	Rate per 100,000	2020 US Census Adjusted
	7128506	606	8.5	
White	2210545	155	7	
Black	499249	19	3.8	
Hispanic	2519144	234	9.3	
Asian/Pacific Islander	716038	184	25.7	
Other/Unknown	1183530	14	1.2	
Overall, 2010-2021	7128506	606	8.5	8.1

Calculated as number of IgAN patients divided by members during 2010-2021, and then standardized by age, sex and race/ethnicity according to the 2020 US Census data.

Table 2: Incidence Rate of Primary IgAN (2010-2021)

			Primary IgAN		
Year	Number of Patients	Person-year	Incident cases	Crude rate (95% CI)	Standardized* Rate (95% CI)
2010	2784574	2440317	48	2 (1.5, 2.6)	1.8 (1.3, 2.4)
2011	2904383	2568616	42	1.6 (1.2, 2.2)	1.6 (1.2, 2.1)

Average 2010-2021				1.7 (0.9, 2.4)	1.4 (0.8, 2.0)

*Standardized by age, sex and race/ethnicity based on US population of 2020 ACS estimates. Note: Incidence rate per 100,000 person-year

TH-PO691

The Epidemiology of ANCA-Associated Vasculitis over Two Decades at a Large Tertiary Centre

Joshua Storrar, Sayyid M. Raza, Rajkumar Chinnadurai, Smeeta Sinha, Philip A. Kalra. *Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom.*

Background: ANCA-associated vasculitis (AAV) is a systemic condition affecting small blood vessels and commonly causes kidney disease. It has a reported incidence of around 20-25 per million per year. Here we aimed to describe its epidemiology at our renal centre over a 23-year period and to compare granulmatosis with polyangiitis (GPA) and miroscopic polyangiitis (MPA).

Methods: We identified all patients with AAV between January 2000 and December 2022 through our biopsy database and electronic patient record (EPR). The cohort after exclusions totalled 278. We collected baseline demographic data, baseline laboratory values, treatment received and outcomes including progression to renal replacement therapy (RRT), relapse rates and mortality.

Results: Median age of the cohort was 63.5 years, 52.5% were male and 92.4% White. GPA was seen in 49.3% and MPA in 42.1%. Median eGFR at presentation was 18mls/min/1.73m^2. RRT at presentation occurred in 19.4%. Relapse occurred in 23%, progression to RRT in 26.6% and 1-year mortality was 3.2%. Median follow up duration was 54 months. Those with GPA were younger, had higher incidence of ENT disease at presentation, were more likely to relapse and had greater 1- and 5- year survival. Mortality rate per hundred person years improved from 2010 onwards.

Conclusions: This is one of the largest retrospective observational studies conducted on AAV, which reports real world epidemiology of this rare condition. AAV presents with advanced renal disease and there remain important differences in presentation and outcomes between GPA and MPA. The Salford glomerulonephritis research group was supported by an unrestricted project grant from CSL Vifor.

Ofatumumab: A Therapeutic Option for Secondary Membranous Nephropathy in Adults

Monarch Shah, Lalida Kunaprayoon, Corey J. Cavanaugh. *University of Virginia, Charlottesville, VA.*

Introduction: B-cell targeting therapies like cyclophosphamide and rituximab are integral in treating many glomerulopathies like FSGS, lupus nephritis, and high-risk membranous nephropathy (MN). Newer B cell targeting therapies like ofatumumab has infrequently been used in MN, although trials are ongoing. Much less is known about their use in secondary MN. We describe the use of ofatumumab in two cases of secondary MN.

Case Description: We retrospectively analyzed two cases of MN treated with ofatumumab. The first case was a 53-year-old woman with nephrotic syndrome and a history of biopsy-proven MN with kappa predominance staining on immunofluorescence and a co-occurring MGUS (IgG Kappa) with a B-cell lymphocytosis with a kappa restricted B-cell. She was thus diagnosed with monoclonal gammopathy of renal significance and treated with 3 cycles of Cyclophosphamide after insurance denied her rituximab. Unfortunately, she relapsed 1 year later and was treated with ofatumumab, 300mg day 1, and 700mg day 14. Her proteinuria responded from 3.32g to 0.44 grams proteinuria 2 months after infusion. Case 2 was a 48-year-old female with profound nephrotic syndrome (56g/24-hour urine collection, serum albumin 1g/dL) refractory to cyclophosphamide combined with steroids and rituximab. She then developed anaphylaxis to rituximab on subsequent infusions and was switched to ofatumumab. She received 100 mg on day 1, 700mg on day 21, and 700 mg on day 35 for cycle 1, then 300 mg weekly for 1 month on cycle two (6 months after cycle 1). Patient 1 saw complete renal remission and patient 2 had a partial response with a reduction from 10.8 grams proteinuria to 3.6 g pr/cr ratio with normalization of serum albumin.

Discussion: This case series has shown that ofatumumab is a viable option for patients with secondary MN. The novel anti-CD20 monoclonal antibody like ofatumumab can become another option for patients who have refractory disease despite completing historical therapies like rituximab and cyclophosphamide. It also provides an agent for patients who have allergies to rituximab. More options for novel B-cell targeting therapies should be explored for secondary MN. Future clinical trials would be helpful to establish its efficacy and safety profile.

TH-PO693

Obinutuzumab with Tacrolimus as a Bridge for Membranous Nephropathy

Himanshu Patel, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Introduction: Treatment of Membranous Nephropathy (MN) has been improving over the past several years. Obinutuzumab, a monoclonal antibody that targets CD20 on B-cells, is another potential therapeutic approach under investigation. Currently, Obinutuzumab is approved for the treatment of specific tumors such chronic lymphocytic leukemia.

Case Description: We describe a 64-year-old male with a history of benign essential hypertension, stage 3a chronic kidney disease presenting with worsening proteinuria. Eight years prior to presentation, he was diagnosed with MN, and at that time, he was anti-Phospholipase A2 Receptor (PLA2R) antibody negative with 4gm of proteinuria. He was started on tacrolimus and got 1 year of treatment leading to remission. He relapsed months after stopping tacrolimus and his PLA2R antibody titers rose to 11 RU/mL with worsening proteinuria. He was started on cyclosporine and continued it for over 7 years and was discontinued a year before presentation. At the time of presentation, he had 3gm of proteinuria and was started on dapagliflozin and two infusions of rituximab with 1gm each two weeks apart with some initial allergic reaction but then completed the infusions without complications. A year later, he relapsed and PLA2R antibodies rose to 23.5 RU/mL and proteinuria of 11gm. He was given two infusions of Obinutuzumab with 1gm each two weeks apart given his sub-optimal prior response to rituximab and allergic reaction to the drug along with a tacrolimus bridge. His proteinuria improved to 2gm with serum a creatinine of 1.2mg/dL. He was taken off tacrolimus few months post Obinutuzumab treatment. He continues SGLT2i and ARB therapy as well.

Discussion: Obinutuzumab is a more potent anti B cell agent that may be a promising therapy for MN. Using Obinutuzumab along with tacrolimus as a bridge to get the response of MN may serve as a potential long-term therapy for MN.

TH-PO694

EXT-1 Membranous Glomerulonephropathy

Elizabeth Pabon-Vazquez, Vatsalya Kosuru. *Augusta University Medical College of Georgia, Augusta, GA.*

Introduction: Membranous nephropathy is one of the most common causes of nephrotic syndrome in adults. The most common etiology is autoimmune condition and identification of pertinent antigens could help in the management of the disease.

Case Description: This is the case of a 33y/o male with past medical history of chronic inflammatory demyelinating polyneuropathy and recurrent pulmonary embolism on apixaban. Patient presented to emergency department complaining of worsening pleuritic chest pain and shortness of breath of one day of evolution. He was also tachycardic, tachypneic and had bilateral lower extremity edema. Laboratory evaluation was remarkable for >600protein and 0-3RBCs on urine dipstick. Renal panel showed creatinine of 1.27mg/dL and albumin of 1.7g/dL. The patient was admitted for recurrent unprovoked pulmonary embolism despite being on anticoagulation therapy and nephrotic syndrome. Initial workup for nephrotic syndrome reported 24-hour urine protein of 20,570mg. Further work up was negative for diabetic disease, hepatitis panel, HIV panel, complements, PLA2R antibodies and lupus nephritis. However, serologic markers ANA, RNP70 Ab and U1 RNP Ab were positive consistent with mixed connective tissue disease. During hospitalization, the patient developed an acute kidney injury with creatinine elevated to 2.65mg/dL, and renal biopsy was performed. Kidney biopsy showed acute tubular injury and exostosin-1 associated membranous glomerulopathy. The patient was treated with two doses of 1g rituximab, prednisone, and losartan. At subsequent clinic follow up, patient's spot urine protein-creatinine ratio was improved to 3.4g. Renal function is stable with creatinine of 1.13mg/dL and albumin improved to 2.3g/dL.

Discussion: Exostosin 1 and 2 are novel proteins seen in secondary membranous nephropathy associated with autoimmune diseases, especially lupus nephritis. Our patient's case is unique as his serology is positive for mixed connective tissue disease with no extra-renal manifestations and this is the first case reported of the association of MN with mixed connective tissue disease. Due to rarity of disease and lack of standard therapy we have opted for rituximab treatment based on literature review. After the initial course of rituximab treatment, our patient showed significant improvement in proteinuria to sub-nephrotic range. He is currently on medical management with losartan.

TH-PO695

Membranous Nephropathy in Kimura Disease: A Case Report and Literature Review

Motoki Murata, Kenichi Koga, Kensei Yahata. *Department of Nephrology, Osaka Red Cross Hospital, Osaka, Japan.*

Introduction: Kimura disease (KD) is a chronic benign granulomatous disease characterized by the formation of indistinct masses in the subcutaneous soft tissues and lymph nodes of the head and neck region. Approximately 20% of patients with KD have renal disease, with 60-80% reportedly having nephrotic syndrome. Membranous nephropathy (MN) is one of the major pathologies of renal diseases in KD; however, the underlying mechanism remains unknown.

Case Description: We herein present a 28-year-old male diagnosed with KD after biopsy of a left lower eyelid mass 11 years earlier. Two months before his presentation, proteinuria was noted for the first time. He visited our hospital with edema in the lower legs and scrotum. A blood test showed a serum creatinine level of 0.95 mg/dL and serum

albumin level of 0.9 g/dL. Urinalysis showed heavy proteinuria (7.22 g/gCr) without hematuria. Renal biopsy revealed spike formation by PAM staining and granular deposits of IgG and C3 in the glomerular basement membrane by direct immunofluorescence microscopy (IF). Electron microscopy showed subepithelial electron dense deposits (EDD). The serum anti-phospholipase A2 receptor (PLA2R) antibody was negative, while IF staining for PLA2R was positive in the glomerular basement membrane. The patient was diagnosed with PLA2R-associated MN.

Discussion: Target antigens in MN, such as PLA2R, were recently identified in both primary and secondary MN. Our literature review on MN in KD including 14 cases revealed that most cases showed subepithelial EDD without subendothelial EDD (Table). This result strongly suggests the involvement of autoantibodies on the surface of podocytes in its pathogenesis. In the present case, PLA2R staining was positive on the glomerular basement membrane. A literature review revealed that PLA2R staining was only performed on 3 out of the 14 cases investigated, and was positive in 2. Further studies on the antigens responsible are needed to elucidate the underlying pathogenesis.

Case No.	Sex	Age (years)	U-pro (g/day)	Serum anti-PLA2R Ab	Glomerular PLA2R Ag	EDD

TH-PO696

An Interesting case of Membranous Nephropathy in a Patient with Diffuse Alveolar Hemorrhage and Cocaine Use: A Case Report

Kadambari Jangam,[1] Nangali S. Srinivasa.[2] *[1]UPMC McKeesport, McKeesport, PA; [2]UPMC East, Monroeville, PA.*

Introduction: Membranous nephropathy (MN) is a common cause of nephrotic syndrome in adults. 70-80% of the cases are primary. We present a case of primary membranous nephropathy in a patient with cocaine use disorder presenting with diffuse alveolar hemorrhage and acute renal injury.

Case Description: A 60-year-old woman with a medical history of HTN, asthma, and cocaine use presented with left-sided chest pain after a mechanical fall following alcohol and cocaine consumption. Trauma work-up: no fracture. CT chest: multifocal pneumonia. Serum Cr: 3.25(baseline: 0.8-1.2), UA: mild proteinuria-30 mg/g, no casts. Her hospital course was complicated by severe ARDS requiring intubation, septic shock, and worsening renal function with oliguria. Repeat UA: proteins>300mg/g, no casts. Serum Cr: 2.25/BUN: 53/K+: 5.4/HCO3: 21. Hemodialysis(HD) was initiated for volume overload. Bronchoscopy showed diffuse alveolar hemorrhage. Serology: positive ANA(1:40), anti-RNP/Sm antibody(3.1). RF complement levels, anti-MPO, ANCA, lupus antibodies, lupus anticoagulant antibodies, Sjogren's antibodies, anti-JO-1, scleroderma, anti-proteinase-3 antibody, anti-DNAase, anti-smooth muscle, anti-GBM, cryoprecipitate, RPR test, IgG, IgM antibodies were negative. Hepatitis B core antibody, CMV DNA was positive. VATS biopsy demonstrated scattered hemorrhagic infarct with organizing pneumonia. Kidney biopsy revealed stage 3/4 membranous nephropathy with focal segmental sclerosis. Presence of co-dominant IgG1 and IgG3 subclass and IgG4 and PLA2R staining of the GBM immune deposits, and few mesangial immune complex deposits. CPK: normal. Anti-PLA2-R resulted in positive. Following high-dose steroids, she is now on steroid taper and on intermittent HD due to poor renal recovery.

Discussion: Diffuse alveolar hemorrhage and nephrotic range proteinuria prompted testing to rule out pulmonary-renal syndromes, which were unsatisfactory; a mildly positive ANA could be secondary to an acute illness. Electron microscopy and immunofluorescence findings of kidney biopsy were inconsistent. IgG1 and IgG3 subclass staining of the GBM immune deposits suggested lupus membranous nephropathy; IgG4 and PLA2R staining suggested primary membranous nephropathy. Despite risk factors for secondary MN(Hep B positive, levamisole with cocaine exposure) a positive Anti-PLA2-R made the diagnosis of primary MN.

TH-PO697

THSD7A-Related Membranous Nephropathy (MN) in a Patient with Prostate Adenocarcinoma

Harpreet Kaur. *Alameda Health System, Oakland, CA.*

Introduction: Thrombospondin type-1 domain- containing 7A (THSD7A) is a transmembrane protein expressed on the podocytes that serves as an auto-antigen in patients with membranous nephropathy. We report a case of kidney biopsy proven THSD7A associated MN in a 69-year-old Vietnamese male with history of metastatic prostate adenocarcinoma and chronic Hepatitis B.

Case Description: A 69-year-old male admitted for weight loss was found to have retroperitoneal lymphadenopathy, diffuse mixed sclerotic and lytic lesion, and enlarged prostate. He underwent EUS with FNA of retroperitoneal adenopathy which showed metastatic prostate cancer. Then two months later, patient presented with marked anasarca for two weeks. He was afebrile, normotensive and saturating well on RA. Labs notable for albumin 1.6, UA with >1000 mg/dL proteinuria, urine protein/creatinine 18.68, Hepatitis B surface antigen reactive, Hepatitis B core antibody reactive, and PSA 833. Phospholipase A2 Receptor (PLA2R) antibody was negative and THSD7A antibody was positive. Subsequently had a kidney biopsy which showed membranous nephropathy, grade I. He was initially suspected to have secondary MN due to cancer and untreated HBV, but kidney biopsy stain pattern more reflective of primary THSD7A MN likely related to his cancer. He was started on both Hepatitis B treatment (with Entecavir) and prostate cancer (with Lupron and Enzalutamide), Bumex, Metolazone and anticoagulation with Lovenox. While waiting for Rituximab approval, patient was started on Ponticelli regimen [Protocol: cyclophosphamide and alternate with prednisone for 6 months total (month 1, 3, 5, prednisone 0.5kg/day, then 2, 4, 6 cyclophosphamide 2mg/kg/day), with Bactrim prophylaxis]. Once the Rituximab was approved, Ponticelli regimen was stopped after the first month and prednisone was tapered. He has finished Rituximab induction therapy and currently on every 6 months maintenance. Current urine protein/Creatinine ratio remains elevated at 13. Hepatitis B is well-controlled and PSA is now 0.5.

Discussion: In a meta-analysis of 10 studies involving 4121 participants, the prevalence of THSD7A was on average 3% in all patients and higher at 10% in PLA2-R patients. Another study discovered that 8 of 40 patients developed a malignancy within a median time of 3 months from diagnosis of MN. Thus it is important to screen and monitor for malignancies in THSD7-A positive MN patients.

TH-PO698

A Case of Coexisting Primary Membranous Nephropathy and Dermatomyositis

Kavita Mistry, Stewart H. Lecker. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Dermatomyositis (DM) is an inflammatory disorder of the skin and skeletal muscle characterized by cutaneous eruptions and myositis. DM is associated with malignancy, interstitial lung disease, esophageal dysmotility and cardiac complications. Unlike other connective tissue diseases, DM does not classically feature renal involvement, although several small case series and retrospective analyses have described a small minority of patients with DM who develop renal pathologies, including ATN in the setting of rhabdomyolysis as well as various glomerular diseases.

Case Description: A 56-year-old African American woman presented with one week of leg swelling. Vital signs were remarkable for hypertension to systolic BPs of 170s, and exam was remarkable for prominent facial edema and 3+ bilateral lower extremity edema, with skin hyperpigmentation on the face, neck, chest and upper arms. Creatinine was at her baseline of 0.7 mg/dL. U/A revealed 4+ blood and 4+ protein, quantified at 10.2 g/g. Urine microscopy revealed lipid casts and <1 isomorphic RBC/hpf. Nephrology and rheumatology were consulted and recommended workup as follows: C3 and C4 normal, SPEP negative, serum anti-PLA2R IgG negative, HIV and hepatitis B/C serologies negative, ANA positive 1:1280 nuclear fine speckled pattern. She had negative dsDNA, anti-Sm, centromere B, RNP, anti-SCL 70, anti-SS-A, anti-SS-B, anti-cardiolipin and anti-B2 glycoprotein antibodies. CPK was sent on account of 4+ blood on U/A with relative paucity of RBC on microscopy and was elevated at 1249 IU/L. Myositis panel was sent and returned positive for anti-MI2 alpha and beta antibodies, consistent with DM. A renal biopsy was performed and revealed membranous nephropathy (MN). Although serum anti-PLA2R IgG was negative, the biopsy stained positive for anti-PLA2R IgG, suggesting primary MN. Comprehensive malignancy evaluation was performed given the close association of both membranous nephropathy and dermatomyositis with cancers and was negative. The patient was started on rituximab for management of MN and prednisone for management of DM.

Discussion: To our knowledge, this is the third case report describing coexisting primary MN and DM in the absence of underlying malignancy. The biological basis for the coexistence of these two pathologies in a single patient remains to be elucidated, although can be presumed to result from a breakdown of immune tolerance.

TH-PO699

Not So "Golden": A Case of Mercury-Associated NELL-I-Positive Membranous Nephropathy

Nazli Atefi,[1] Amanda M. Tuchler,[1] Hassan Syed,[1] Taylor Douglas,[1] Cinthia Drachenberg,[1] Joshua D. King.[1,2] *[1]University of Maryland School of Medicine, Baltimore, MD; [2]Maryland Poison Center, Baltimore, MD.*

Introduction: Mercury is a heavy metal that exists in various forms and can be encountered through multiple pathways of exposure. Inorganic mercury is associated with glomerular disease - particularly membranous nephropathy (MN) - as well as peripheral neuropathy. In recent years, inorganic mercury in skin lightening creams has been associated with neural epidermal growth factor-like 1 protein (NELL-1) positive MN; very few cases are reported from the United States. We report a case of skin lightening cream-associated mercury toxicity and NELL-1 positive MN.

Case Description: A 41-year-old female with type 2 diabetes who emigrated from Afghanistan 2 years prior presented with 6 months of progressive leg edema, worsening proteinuria, and long-standing peripheral neuropathy. Four months before presentation, albumin/creatinine ratio (ACR) was 6,050 mg/g; immediately before presentation, ACR was 17,862 mg/g. Subsequent 24-hour urine protein was measured at 37.1 grams. Serum creatinine was 0.6 mg/dL. On initial presentation, skin lightening cream use was queried;

the patient produced a container of "Golden Pearl" beauty cream, found by the FDA to contain 12,000 ppm mercury, which she regularly used. Her blood and urine mercury levels were found to be elevated. Serologic studies included multiple negative serologic studies including anti-phospholipase A2 receptor (PLA2R) antibodies. The patient was admitted to the hospital and treated with furosemide. A kidney biopsy was performed and was notable for MN, staining negative for anti-PLA2R and positive for NELL-1. Chelation with succimer was unable to be initiated due to cost; treatment with steroids is being arranged.

Discussion: Mercury-associated MN generally has a favorable prognosis with discontinuation of mercury use; steroids and chelation are the most common therapies utilized in the literature. Skin lightening creams may be used in the United States by immigrants from regions in which they are routinely used. In patients presenting with unexplained proteinuria from areas of the world where mercury-containing products are used, particularly with peripheral neuropathy, mercury toxicity should be considered and skin lightening cream use should be queried. Mercury-associated MN has an emerging association with NELL-1; mercury screening may be warranted in patients with NELL-1 positive MN.

TH-PO700

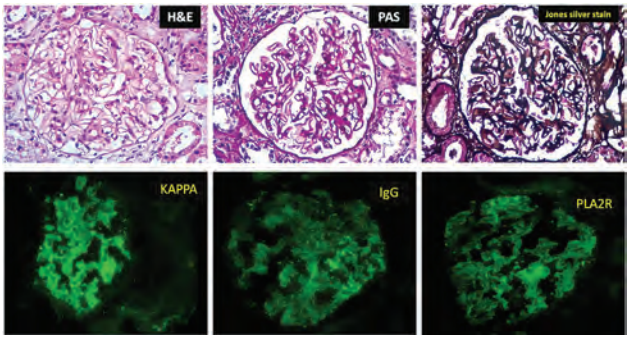
An Unusual Presentation of a Common Disease: Primary Membranous Glomerulopathy with Light-Chain Deposits: Case Report

Rodolfo A. Moreno,[1,2] Guillermo Navarro Blackaller,[3] Werner De león,[4] David A. Armas.[1] *[1]Centro Medico Militar, Guatemala, Guatemala; [2]Universidad Mariano Galvez de Guatemala Facultad de Ciencias Medicas y de la Salud, Guatemala, Guatemala; [3]Hospital Civil de Guadalajara Unidad Hospitalaria Fray Antonio Alcalde, Guadalajara, Mexico; [4]SERPAT, Guatemala, Guatemala.*

Introduction: Membranous glomerulopathy (MG) is a common cause of nephrotic syndrome (NS) caused by the formation of immune complexes along the subepithelial slope of the glomerular basement membrane (GBM) and considered as the main cause of idiopathic NS in adults. Deposits of light chain isotype are rarely seen.

Case Description: A 56-year-old Guatemalan male patient with a 3-month history of lower-limbs edema. No previous medical history. On first evaluation presented AKI with SCr of 1.58mg/dl associated with proteinuria (12.8gr/day), hematuria (5 RBC/HPF) and oval fatty bodies and fat droplets. Laboratories with hyperlipidemia (cholesterol 692mg/dl, triglycerides 396mg/dl), C3-C4 normal, FANA+ 1:80, ANCAs, HIV, HBV, HCV, rheumatoid factor were negatives and serum anti-PLA2R+ (353 RU/ml (positive >20)), serum and urine electrophoresis negative for monoclonal protein. Kidney biopsy was performed and reported homogenous thickening of the GBM with mesangial proliferation; Jones stain with pin hole pattern on the capillary wall. Negative for endocapillary or extra capillary hypercellularity, double contours or interstitial fibrosis IF: IgG (+), IgM (+), Kappa (++) and PLA2R (++) with granular pattern in GBM. The patient is on RAASi with losartan 100mg/day while decides to accept rituximab protocol. With improvement of SCr (1.04mg/dl) controls after 1-month but still with nephrotic range proteinuria.

Discussion: The pathophysiology of MG results from the formation of immune complexes, predominantly by polytypic deposits along the subepithelial slope of the GBM. Usually, these immune complexes are against PLA2R and HTSD7A but about 10% of patients with typical PMN are negative for both antibodies making it probable that more autoantibodies to podocyte antigens will be found such as light-chain deposits. Though, positive serum antiPLA2R suggest a primary etiology, the rarely seen deposition of single IgG subclass should prompt a clinical workup to exclude the presence of an underlying etiology.



TH-PO701

"Finding the Bright Side": A Case Series of Spontaneous Remission in NELL1 Membranous Nephropathy

Ion D. Bucaloiu, Lakshna Sankar, Kartik Kalra. *Geisinger Health, Danville, PA.*

Introduction: Neural tissue encoding protein with EGF- like repeats (NELL1) has been identified as a target antigen in membranous nephropathy (MN). It can be primary or associated with malignancies, stem cell transplant, de novo in kidney transplant, drugs, autoimmune diseases and infections.

Case Description: Four patients of Caucasian origin with age ranging from 50 - 71 years presented with nephrotic syndrome (Table 1). At presentation, all had urine protein creatinine ratios above 5 g/g creatinine. Immunological work up was negative. Kidney biopsy was positive for NELL1 associated MN. Infectious work up including hepatitis panel, human immunodeficiency virus (HIV) and rapid plasma regain (RPR) were negative. Screening for underlying malignancy including computed tomography (CT) of chest, abdomen and pelvis, pap smear, mammogram and colonoscopy was unremarkable. Careful review of home medications list showed no indigenous medications except for one patient who was on lipoic acid for a duration of 1 year which was stopped after the diagnosis of NELL1 MN. Supportive care such as renin-angiotensin blockade (RAAS) and diuretics were initiated with periodic monitoring of renal functions and proteinuria (Table 1). All 4 patients went into remission within 3 – 6 months.

Discussion: Spontaneous remission (30% of the patients) is a well-known characteristic of MN. Patients with persistent nephrotic range proteinuria are at risk of progression to end stage kidney disease and may require immunosuppression therapy. Several studies showed that a higher percentage of NELL1 MN cases are associated with malignancies (up to 30%) compared to MN associated with other antigens (PLA2R and THSD7A). Our case series suggests that NELL1 MN without underlying malignancy might experience spontaneous remission without need for immunosuppression. After excluding malignancy, a conservative strategy including maximizing RAAS blockade with serial monitoring of kidney function and proteinuria for 3-6 months may be appropriate in NELL1 MN.

Table 1: Clinical characteristics of NELL1 membranous nephropathy

Patients	Age, gender and demographics	Creatinine in mg/dL (reference range 0.5 – 1 mg/dL)	Proteinuria (Urine protein creatinine ratio in mg/g)	Albumin in g/dL (reference range 3.8 – 5 g/dL)	Serum PLA2R IFA (Immunofluorescence)	Renal biopsy	Supportive care (RAAS blockade +/- diuretics)	Time to remission Complete / Partial
Case 1	50-year-old Caucasian female	0.9	5200	3.5	Negative	Membranous glomerulopathy, NELL1 positive; PLA2R, THSD7A, EXT 2 were negative.	Lisinopril 30 mg daily, cessation of lipoic acid	6 months
Case 2	68-year-old Caucasian male	1.2	6235	3.2	Negative	Membranous glomerulopathy, NELL1 positive; PLA2R and THSD7A were negative.	Losartan 100 mg daily	2 months
Case 3	70-year-old Caucasian male	1.0	9124	2.7	Negative	Membranous glomerulopathy, NELL1 positive; PLA2R and THSD7A were negative.	Losartan 100 mg daily, Lasix 40 twice daily	3 months
Case 4	71-year-old Caucasian female	0.8	17,245	2.9	Negative	Membranous glomerulopathy, NELL1 positive; PLA2R, THSD7A, SEMA3B and EXT2 were negative.	Losartan 25 mg daily, Torsemide 20 mg daily	6 months

I Am the Lucky Third: Spontaneous Resolution of High-Risk Membranous Nephropathy

Wadhah M. Bin Homam,[1] Fatima Ayub,[1] Ahmed Elkalashy,[1] Md R. Hasan,[2] Joseph H. Holthoff.[1] UAMS Internal Medicine/Nephrology. *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Arkansas College of Osteopathic Medicine, Fort Smith, AR.*

Introduction: The 2021 KDIGO guidelines for the treatment of high-risk and very high-risk membranous nephropathy (MN) involve angiotensin-converting enzyme inhibitors (ACEi) or angiotensin receptor blockers, and intense immunosuppression with rituximab or combination of cyclophosphamide and steroids. Typically, these immunosuppression regimens are initiated immediately in high-risk and very high-risk MM. Here we present a case of very high-risk MN nephropathy who achieved spontaneous with only conservative management.

Case Description: A 28-year-old male with no significant past medical history presented with acute onset of left flank pain and lower limb swelling for 3 weeks. Pertinent lab workup showed proteinuria of 28 grams/day, serum albumin of 1.1g/dL, and normal serum creatinine. CT angiogram showed bilateral renal veins thrombosis extending to the inferior vena cava. The serological workup for glomerulonephritis came back positive for anti-PLA2R antibodies, hence diagnosing him with primary MN. Renal biopsy further confirmed MN and PLA2R stain was diffusely positive The patient underwent an interventional radiology-guided thrombectomy. Given the severity of his clinical picture and following a detailed discussion of the risks versus benefits of different protocols of immunosuppressants, a pulsed dose of methylprednisolone was administered followed by oral prednisone for modified Ponticelli regimen, but the patient later refused cyclophosphamide due to the risk of infertility and agreed with initiating of rituximab. However, the prior authorization for rituximab was unsuccessful, and the patient was discharged on a tapered course of prednisone, lisinopril, and apixaban. At six-month follow-up, proteinuria was reduced to 1.6 g/d and renal function remained stable.

Discussion: Here we present a case of very high-risk MN in which the patient achieved spontaneous remission and remained in partial remission at the 6-month follow-up visit. Cases such as this highlight the fact that risk stratification in MN is based on criteria at the time of initial diagnosis, when in fact the disease may follow a dynamic and changing course over time. Just as low and moderate risk patients may ultimately progress to renal failure, here we present a case of very high risk MN that ultimately achieved remission without intensive immune suppression.

TH-PO703

An Unlikely Culprit: A Case of Membranous Nephropathy with Celiac Disease

Sneha M. Vaddadi, Katherine D. Wick, Kuang-Yu Jen, Niti Madan. *UC Davis Health, Sacramento, CA.*

Introduction: Membranous nephropathy is a cause of nephrotic syndrome, categorized as primary (e.g. anti-PLA2R-associated) or secondary (due to autoimmune conditions, malignancy). There are a few case reports demonstrating an association between membranous nephropathy and celiac disease, an autoimmune disorder affecting the small intestine with the ingestion of gluten, however, this association has not been well established. We present a case of secondary membranous nephropathy with celiac disease and subsequent complete remission with the treatment of the underlying disease.

Case Description: A 46-year-old female initially presented for evaluation of the nephrotic syndrome with a urine protein to creatinine ratio 8.6 g/g and serum albumin of 1.8 g/dL. Workup for viral, autoimmune and malignant etiology significant only for evidence of prior Hepatitis B infection and positive surface antibodies. A kidney biopsy demonstrated evidence of early-stage membranous nephropathy without secondary features. Tissue PLA2R staining and Anti-PLA2 antibody testing were negative. The patient was diagnosed with primary membranous nephropathy due to negative secondary workup. Cyclosporine and low-dose prednisone treatment for 1 year resulted in partial remission. The patient then got diagnosed with Celiac Disease. She transitioned to a gluten-free diet with continued conservative management with an angiotensin-converting enzyme (ACE) inhibitor resulting in complete remission of her disease.

Discussion: Celiac disease has been associated with IgA nephropathy; its presentation with IgG membranous nephropathy is not well-established. With an otherwise negative workup and despite biopsy results without secondary features, the etiology of the glomerular disease in this case was likely celiac disease given the complete remission only after dietary modification. This case demonstrates a potential novel association between the autoimmune condition celiac disease and secondary membranous nephropathy.

TH-PO704

Unveiling a Novel Link: A Case of Secondary FSGS with Anti-MDA5 Amyopathic Dermatomyositis

Sneha M. Vaddadi, Shubha Ananthakrishnan, Niti Madan, Kuang-Yu Jen, Nasim Wiegley. *UC Davis Health, Sacramento, CA.*

Introduction: Amyopathic dermatomyositis is a cutaneous predominant form of dermatomyositis, characterized by the biomarker anti-MDA5 antibody. Extra-dermatologic involvement has been shown within the pulmonary, vascular, or articular systems. No known reports demonstrate an association between this rarer form of dermatomyositis and glomerular disease. We report a case of anti-MDA5 dermatomyositis associated focal and segmental glomerulosclerosis (FSGS), treated with immunosuppressive therapy targeting the underlying autoimmune condition.

Case Description: A 56-year-old Black man with confirmed anti-MDA5 positive amyopathic dermatomyositis diagnosed via skin biopsy and otherwise negative myositis panel presented for nephrotic syndrome and acute kidney injury evaluation. Labs showed serum creatinine of 2.04 mg/dL (baseline 0.8), urine protein to creatinine ratio >7 g/g, serum albumin of 2.6 g/dL, and urinalysis without cellular sediment. A native kidney biopsy was performed, showing features of FSGS on light microscopy (LM), negative immunofluorescence (IF), with segmental foot process effacement and the presence of tubuloreticular inclusions on electron microscopy (EM). Malignancy workup was negative. The patient was treated with high-dose prednisone and mycophenolate mofetil (MMF) for targeted treatment of both dermatomyositis and FSGS, with subsequent improvement to partial remission in the first 6 months.

Discussion: To our knowledge, this is the first reported case of kidney involvement with amyopathic dermatomyositis. With an otherwise negative workup for other viral or malignant causes, the likely etiology of secondary FSGS was this autoimmune condition. MMF, a common treatment for dermatomyositis, was utilized in this case for targeted treatment of both dermatomyositis and FSGS and resulted in improved proteinuria and partial remission of nephrotic syndrome.

TH-PO705

Compressed and Concomitant Cyclophosphamide with Prednisone for Membranous Nephropathy: Low Doses for Very-High-Risk Patients

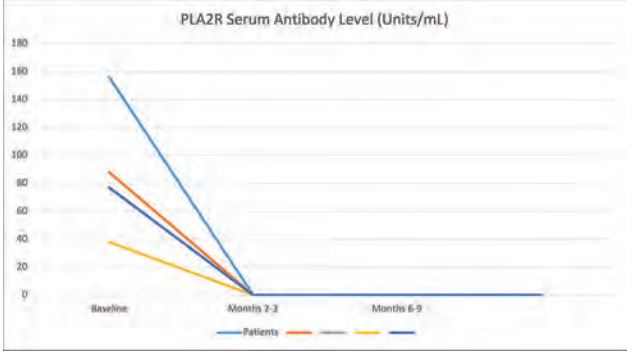
Benjamin Silverberg, Corey J. Cavanaugh. *University of Virginia, Charlottesville, VA.*

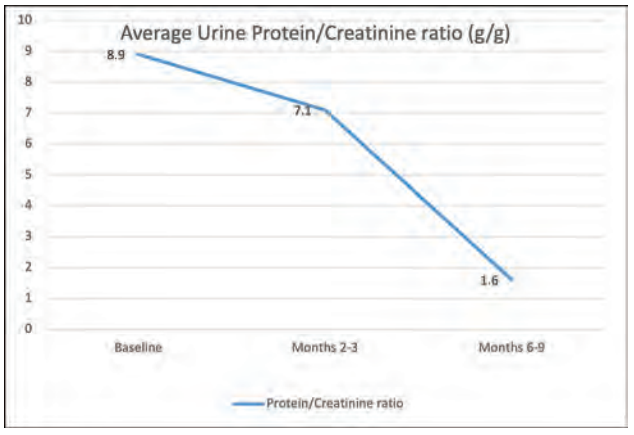
Introduction: Immunosuppressive therapy for primary membranous nephropathy (MN) has undergone significant change in the last 5 years. The "modified Ponticelli" regimen for MN is the recommended therapy for very high-risk MN according to KDIGO guidelines. The regimen consists of alternating cycles of cyclophosphamide and corticosteroids for a total of 6 months and comes with dose-dependent side effects such as cytopenias, infections, and malignancy. Here, we describe our experience with compressed and concomitant CYC/GC in very high-risk patients.

Case Description: We retrospectively analyzed 4 cases of PLA2R-positive membranous nephropathy with very high-risk features treated with concomitant prednisone 0.5mg/ kg tapered with oral cyclophosphamide 1.5-2mg/kg daily over 3-4 months. All patients were male between the ages 36-62. Clinical data, including serum PLA2R-AB levels and UPCR, were collected over the treatment period and 6 months after completion (Images 1 and 2). All patients had complete or partial remission at 9-12 months follow-up. No cytopenias or infections were observed. One patient developed steroid-related diabetes.

Discussion: Compared to the 24-week modified Ponticelli regimen, our doses of GC were lower, with a shorter duration of therapy and without any loss in efficacy (Table). A compressed and concomitant CYC/GC regimen in very high-risk patients with PLA2R membranous nephropathy is safe and effective in this limited case series.

	Compressed CYC/Pred	Modified Ponticelli (for a 60kg patient)
Average total CYC dose	11.21g	10.8-13.5g
Average total GC dose	1965mg	11.4g
Total duration of therapy	13.75 weeks	24 weeks





TH-PO706

FAT1 as an Antigen in Antibody-Mediated Rejection-Associated Membranous Nephropathy

Laith Al-Rabadi,[1] Tiffany Caza,[2] Christopher P. Larsen,[2] Laurence H. Beck.[3]
[1]University of Utah Health, Salt Lake City, UT; [2]Arkana Laboratories, Little Rock, AR; [3]Boston Medical Center, Boston, MA.

Introduction: Membranous nephropathy can be a manifestation of antibody mediated rejection (ABMR). While recurrent membranous nephropathy has been mostly attributed to PLA2R, the targeted antigen in ABMR-associated membranous remains unknown. FAT1 has been recently found to be an antigen in post hematopoietic stem cell transplant but not in de novo membranous nephropathy related to ABMR.

Case Description: Patient has evidence of ABMR evidenced by presence of peritubular capillaritis, glomerulitis, and positive donor specific antibody (HLA DQ1 11,000). In addition to microcirculation inflammation, membranous nephropathy was identified on kidney biopsy. Serum from the patient with De novo membranous MN recognizes HGE at a high molecular weight band (higher than THSD7A and PLA2R). We sought to investigate whether FAT1 can be the targeted antigen given the high molecular weight on western blotting. Immunostaining revealed a granular pattern of FAT1 along the capillary wall.

Discussion: FAT1 can be the antigen implicated in membranous nephropathy related to ABMR. We are currently screening a larger cohort to validate our findings.

TH-PO707

Disseminated Nocardiosis in an Immunosuppressed Patient with Membranous Nephropathy

Samia Ait Faqih, Krishnamoorthy Sundara Raman, Alaedin Shurrab. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: Nocardiosis is a rare life-threatening opportunistic infection which has been reported in association with immunosuppressed patients. The diagnosis is challenging because of the insidious onset of symptoms with a subacute course that progresses over several weeks. Misdiagnosis and late treatment can lead to fatal consequences. We report a new case of disseminated nocardiosis (lungs, brain, eyes and joints) in a patient diagnosed with membranous nephropathy. We also review the literature and analyze the clinical characteristics and modalities of treatment of nocardiosis.

Case Description: A 49-year-old Eritrean man diagnosed with nephrotic syndrome secondary to primary membranous nephropathy with high risk progression factors. He was started on immunosuppression along with general supportive measures. He presented to the Accidents & Emergency department with fever, fatigue, productive cough, red eyes and right knee swelling since the preceding week. He was found to have pneumonia, bilateral uveitis and right septic arthritis. He had arthroscopic drainage and washout of the knee. Cultures of sputum, blood and joint came back positive growing Nocardia otitidiscaviarum. CT brain imaging revealed left occipital ring enhancing lesions with surrounding edema without mass effect suggesting brain abscess. Patient was started on Trimethoprim/Sulfamehtoxazole based on sensitivity testing and this was continued for 12 months. Immunosuppression was also stopped once the diagnosis was made and he had shown signs of remission around the same time. Patient responded very well to antibiotics and fully recovered.

Discussion: Immunosuppression is the most important predisposing factor for systemic nocardiosis. Poor outcome is mostly found in immunocompromised patients which can be improved by early detection and administration of the correct antibiotic regimen. More studies on nocardiosis are required to better identify risk factors associated with morbidity /mortality and to develop effective methods of prevention of the disease.

TH-PO708

Primary Sjögren Syndrome (pSS) with PLA2R-Associated Membranous Nephropathy (MN)

Mingyue He,[1] Iris J. Lee.[2] *[1]Temple University Hospital, Philadelphia, PA; [2]Lewis Katz School of Medicine at Temple University, Philadelphia, PA.*

Introduction: pSS is an autoimmune disorder characterized by lymphocytic infiltration of exocrine glands. Renal involvement occurs in 5% of pSS cases. The prevalent renal pathology associated with pSS is tubulointerstitial nephritis, with less frequent glomerular manifestations, mainly membranoproliferative glomerulonephritis. pSS is also a recognized cause of secondary MN. Herein, we present a rare case of co-occurrence of pSS and primary MN with negative serum PLA2R antibody (Ab) but positive tissue PLA2R Ab.

Case Description: A 27-year-old female with a history of pSS on plaquenil was referred to a Nephrology clinic for subnephrotic proteinuria of 1.5 gm. Urinalysis revealed no microscopic hematuria. Her creatinine was 0.54 mg/dl with no evidence of renal tubular acidosis or nephrolithiasis. Immunological markers including ANA, dsDNA, and serum PLA2R Ab were negative. Complements were normal. HIV, HBV, and HCV tests were negative. Kidney biopsy showed MN with positive immunofluorescence for IgG, C3, and PLA2R. One year later, her proteinuria decreased to 0.47 gm with preserved renal function without treatment. Her serum PLA2R Ab remained negative.

Discussion: This case poses a diagnostic challenge as to whether the observed MN is primary or secondary to pSS. Serum PLA2R Ab is associated with MN development and has high sensitivity (78%) and specificity (99%) for primary MN. Although PLA2R Ab detection has been reported in secondary MN cases such as sarcoidosis (55%), it is largely absent in rheumatic disease-associated MN, especially lupus MN (<5%). The absence of serum PLA2R Ab in this case aligns with the "kidney as sink" hypothesis, proposing that early-stage disease may show negative serum levels due to high Ab affinity for tissue antigens. Despite having persistent negative serum PLA2R Ab levels, our patient demonstrated positive tissue PLA2R Ab staining. Moreover, PLA2R Ab levels are also indicative of disease prognosis. In our case, the patient, with persistently negative serum PLA2R Ab, exhibited a significant spontaneous reduction in proteinuria. Her remission occurred in the absence of any pSS therapy, suggesting a coincidental occurrence of MN and pSS. Our case highlights that primary MN can coexist with other autoimmune diseases, emphasizing the need to distinguish primary from secondary MN due to potential differences in management strategies, where PLA2R Ab detection can be insightful.

TH-PO709

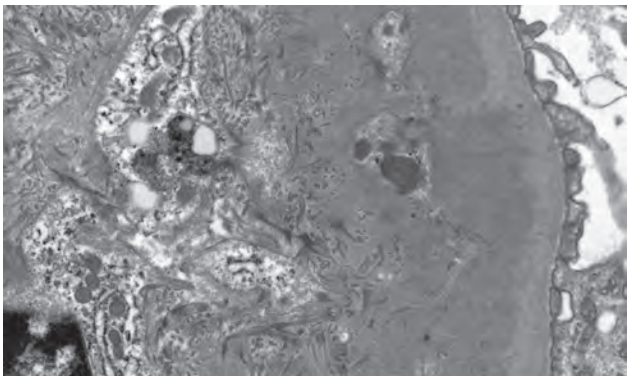
A Case of Rapidly Progressive Glomerulonephritis due to Superimposed IgA Nephropathy on Collagenofibrotic Glomerulopathy

Shoko Ochiai, Masao Kikuchi, Koichi Kaikita, Shouichi Fujimoto. *Miyazaki Daigaku, Miyazaki, Japan.*

Introduction: Collagenofibrotic glomerulopathy (CFG) is a rare disease characterized by the accumulation of type III collagen in the glomerulus. CFG and IgA nephropathy (IgAN) may coexist coincidentally, but there have been no reports presenting rapidly progressive glomerulonephritis (RPGN). Here, we report the case that developed in RPGN and was diagnosed with active IgAN accompanied by CFG.

Case Description: A 69-year-old Japanese woman complained of new-onset fatigue and generalized edema lasting one month. She had a history of rheumatoid arthritis for about 20 years and had been administered etanercept, a TNFα inhibitor, for eight years. Her serum creatinine (SCr) level used to be around 1.5 mg/dL. On admission, She exhibited gross hematuria, an elevated SCr (5.8 mg/dL), a decreased serum albumin (2.63 g/dL), a weight gain (+10 kg), and was clinically diagnosed with RPGN and nephrotic syndrome. Histological examination revealed active IgAN with positive KM55(galactose deficient(Gd)-IgA1) and superimposed CFG. She temporarily needed hemodialysis, but with steroid pulse therapy and cyclophosphamide, her SCr improved to 2.66 mg/dL, and hematuria was also resolved.

Discussion: This is the first report of RPGN caused by IgAN superimposed on CFG. In IgAN, IgA deposition in the capillary wall have been reported to have a poor renal prognosis. In this case, the presence of type III collagen in the mesangial region promoted IgA deposition in the capillary wall and induced RPGN. Furthermore, this is the first case in which etanercept induced IgA nephropathy with Gd-IgA1. The mechanism of action of TNFα inhibitor-induced IgAN may be the generation of anti-drug antibodies to the glycan structures of the TNFα inhibitors. This cross-reacts with Gd-IgA1 and forms a large antigen-antibody complex, and then may have caused IgAN. Despite the rare and complex diseases, we believe the appropriate interpretation of renal biopsy findings contributed to effective treatment and favorable renal outcomes.



TH-PO710

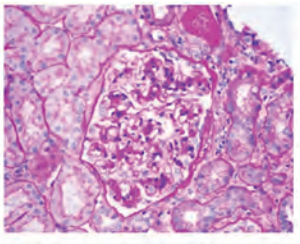
A Novel Case of IgA Nephropathy Relapse Secondary to Adalimumab

Christopher D. Naranjo,[1,2] Margarita D. Almeida,[1,2] Mary Sifain,[1,2] Chavely Valdes Sanchez,[1,2] Zachary Kornblum,[1,2] Marco A. Ladino Avellaneda.[1,2] University of Miami/Miami VAMC Fellowship Program. *[1]University of Miami School of Medicine, Miami, FL; [2]Miami VAMC, Miami, FL.*

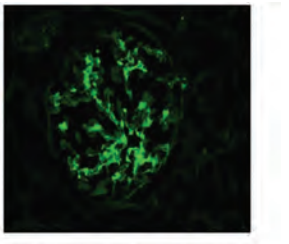
Introduction: IgA nephropathy is the most diagnosed glomerulonephritis worldwide. Biologic agents including tumor necrosis factor alpha (TNFa) inhibitors have been identified as a potential cause for IgAN and on our patient, recurrence.

Case Description: The patient is a 35 year old male with biopsy proven IgA nephropathy diagnosed 4 years prior to current presentation. Initially, the patient was found to have microscopic hematuria and proteinuria on routine urinalysis. Kidney biopsy was performed at that time and demonstrated focal fibrocellular and fibrous crescentic disease. He was treated with glucocorticoid therapy and RAAS blockade, leading to full remission. He had underlying uveitis managed with Rituximab and Methotrexate, then Adalimumab. On the current presentation, the patient reported an isolated episode of hematuria 2 months prior. Creatinine increased to 1.6 mg/dL from 1.1 mg/dL 4 months prior. A urinalysis demonstrated > 500 mg of albuminuria and 57 RBC/hpf. Spot urine protein to creatinine ratio was 526 mg/g. A second kidney biopsy showed light microscopy demonstrated mesangial hypercellularity. Electron microscopy revealed patchy effacement of podocyte foot processes.

Discussion: We report a case of IgA nephropathy, which was initially treated with glucocorticoid therapy, leading to a sustained remission. Later, the patient was started on Adalimumab due to uveitis. IgAN relapsed after taking Adalimumab for 6 months. On diagnosis, the patient was started on Mycophenolate Mofetil as a steroid sparing strategy. The patient deferred repeat treatment with glucocorticoid therapy. The patient was treated supportively with RAAS blockade and SGLT2i, with good anti-proteinuric response. This is a novel case of recurrence of IgA nephropathy, as there is scant literature available that studies IgA Nephropathy related to Adalimumab. Furthermore, physicians must be aware of this potential side effect when prescribing Adalimumab, particularly in patients with underlying IgA nephropathy.



Light microscopy (PAS stain): Mesangial hypercellularity and endocapillary hypercellularity.



Immunofluorescence: Granular mesangial staining for IgA.

TH-PO711

IgA Nephropathy and IgA Vasculitis, Two Sides of the Same Coin: A Rare Case of Rapidly Progressive IgA Nephropathy with IgA Vasculitis of the Skin

Christopher Grivas,[1] Marwa Abdalla,[2] Donghyang Kwon,[2] Chanigan Nilubol.[2] *[1]Georgetown University School of Medicine, Washington, DC; [2]MedStar Georgetown University Hospital, Washington, DC.*

Introduction: IgA Nephropathy (IgAN) is the most common type of primary glomerular disease worldwide. About 25-30% of IgAN patients develop end-stage kidney disease within 20-25 years. IgA vasculitis (IgAV) is a small-vessel vasculitis that affects multiple organs including the skin and kidneys. Renal involvement occurs in 45 to 85% of adults with IgAV. Despite the similarities between IgAN and IgAV, most IgAN trials excluded those with vasculitis. Here we report a case of rapidly progressive glomerulonephritis (RPGN) secondary to IgAN in a patient presenting with IgAV involving the skin.

Case Description: A 44-year-old Asian man with hypertension, gout, anemia, hypothyroidism and alcoholic cirrhosis presented with profuse epistaxis and pruritic skin rash. The physical examination was notable for palpable purpuric rash on all extremities. His blood urea nitrogen and serum creatinine were 90 and 4.8 mg/dL. His serology tests were negative. C3 was low at 50 mg/dL. He had microscopic hematuria and proteinuria. A skin biopsy showed superficial perivascular lymphohistiocytic infiltrate with perivascular fibrin and 2+ IgA staining. The patient received methylprednisolone and was initiated on hemodialysis. A kidney biopsy showed focal proliferative glomerulonephritis with approximately 18% active cellular crescents in conjunction with ubiquitous IgA mesangial deposits.

Discussion: The pathophysiology of both IgAN and IgAV is based on the multi-hit hypothesis involving galactosidase deficient IgA and complement pathways. The histologic differentiation between the two diseases remains impossible. Despite the possibility of secondary IgAN from cirrhosis, the evidence of IgAV in the skin of our patient suggested a primary systemic disease. The therapy for IgAN with RPGN is methylprednisolone followed by a combination of oral or intravenous cyclophosphamide and corticosteroids. Rituximab has been reported previously in treatment of IgAV. Due to concerns for cyclophosphamide hepatotoxicity and non-adherence, we recommended rituximab for our patient. He remained dialysis dependent at the date of this report. This report calls for the inclusion of IgAN with IgAV on future clinical trials and a more specific therapeutic guideline for this subgroup of patients.

TH-PO712

Minimal Change Nephrotic Syndrome in an Elderly Female with Acute Onset Type 1 Diabetes

Shinichiro Koga.[1,2] *[1]Section for Nephrology & Hypertension, Department of Medicine, Tokyo Metropolitan Police Hospital, Tokyo, Japan; [2]Department of Diabetes & Endocrinology, Tokyo Hospital, Japan Organization for Occupational Health & Safety, Tokyo, Japan.*

Introduction: Concurrent type 1 diabetes (T1D) and idiopathic nephrotic syndrome (NS) is rare, and most previously reported cases were in children. Recently, a younger adult who developed minimal change NS (MCN) several months after acute-onset of T1D was reported 1). Moreover, human leukocyte antigen (HLA) A24, Bw52, Bw61, DR2 and DR9 has been described to be associated with both T1D and renal disease 2).

Case Description: An Asian 78-year-old female with anti-glutamic acid decarboxylase (GAD) 65 antibody-positive acute onset T1D, anti-thyroperoxidase antibody-positive Hashimoto thyroiditis, and fatty liver disease, diagnosed them three years ago then treated with mdi insulin and po levothyroxine 3), was admitted again to our section due to bilateral leg edema as well as remarkable body weight gain. Her serum albumin was decreased to 1.8 mg/dL. Laboratory data show Hb 12.2 g/dL, TP 4.7 g/dL, Cr 1.11 mg/dL, eGFR 36.8 ml/min/1.73m^2, Na 132 mEq/L, K 5.7 mEq/L, Tchol 353 mg/dL, LDL-c 165 mg/dL, fT4 0.90 ng/dL, TSH 13.81 mU/L, HbA1c 6.9 %, normo-complement proteins, D-dimer 9.23 μg/mL**,** UACR < 30 mg/gCr, UP 7.9 g/gCr with selectivity index 0.18, β2-microglobulin 27 mg/L. Serum antibodies were positive in GAD 604 U/mL, TPO 168 IU/mL, Tg 123 IU/mL, whereas was negative in MPO/PR3-ANCA, GBM, nor staff as paraproteinemia. No deep vein thrombosis nor malignancy was shown in non-enhanced computed tomography imaging. Kidney biopsy detected minor glomerular abnormalities with 1/10 obsolescence glomeruli; No Kimmelstiel-Wilson nodule was shown. Diagnosis of MCN was made with incidence described above. Her HLA typing was A24, A26, B62, B54, and DR9. Given methylpredonisolone (mPSL) 500 mg/day intravenously for three days, then PSL 40 mg/day orally, CR was acheived but fastly relapsed twice so added po 75 mg cyclosporin A. Five weeks after admission, she discharged with po 25mg PSL plus 75 mg cyclosporin A, mdi 50 units/day insulin with po 50 mg SGLT2i ipraglifrozin, and 25 μg levothyroxin.

Discussion: The patient maintained remission with cyclosprin A; not required temporal hemodialysis 1)2) nor LDL-apheresis 1). HLA subtype was partially coincide in aged case 2) but not in young adult case 1). Th 1/2 predominance in T1D/MCN should have discussed 1)2). TH-PO713

Rituximab in the Treatment of Thymoma-Related Minimal Change Disease

Yuxin Nie. *Zhongshan Hospital Fudan University, Shanghai, China.*

Introduction: Thymoma may cause autoimmune-related kidney disease. This article presents two cases of thymoma-related kidney disease treated with oral prednisone in combination with rituximab. Remission of proteinuria were achieved, and shrinkage of the thymoma mass was observed on the CT scan.

Case Description: Case 1: A 67y male was admitted because of foamy urine and edema. Lab tests revealed hypoalbuminemia and proteinuria. Scr increased progressively, while auto-immune antibodies were negative. Chest CT showed a mass in the anterior mediastinum. The patient underwent a right posterior hepatic lobectomy in 2020. The pathology revealed a thymoma type B2. Other past history includes hypertension and diabetes. Based on the patient's clinical manifestations, history of thymoma, and renal biopsy, the patient was diagnosed as thymoma-related minimal change disease, acute interstitial inflammation, diabetic nephropathy, and hypertensive kidney injury. Methylprednisolone was administered 240mg/d *3d, followed by prednisone 30mg/d and rituximab 375mg/m^2/week *4 weeks. Remission was achieved one month after completion of the RTX course. Surprisingly, the thymoma shrank on the CT scan. **Case 2**: A 67y male was admitted because of foamy urine and edema. Lab tests showed a 24h urine protein of 8.78g. Plasma albumin was 16.9g/L, eGFR was 53mL/min/1.73 m^2.

The patient claimed a history of thymoma, and underwent thymectomy in 2014. PET-CT showed left pleural, left phrenic angle and cardiophrenic angle lymph node, and anterior chest wall subcutaneous metastases. The patient claim a history of hypertension. The final diagnosis based on clinical manifestations and renal biopsy was thymoma-related MCD, hypertensive kidney injury, and AIN. Steroid therapy (methylprednisolone 120mg/d*3d, followed by prednisone 40mg/d) combined with RTX (375mg/m^2/week *4weeks) was administered. The patient's proteinuria gradually decreased two months after RTX treatment, the urine protein was 0.67 g/24h at the latest follow-up. In addition, there was remission of the patient's thymoma metastasis.

Discussion: Experience in treating thymoma-related nephropathy with RTX is limited, our cases report the effectiveness of RTX in both MCD and thymoma. This report provide a new approach for treating thymoma-related kidney disease, especially for those who are not suitable for surgery.

TH-PO714

Collapsing Focal Segmental Glomerulosclerosis in a Patient with Hemophagocytic Lymphohistiocytosis

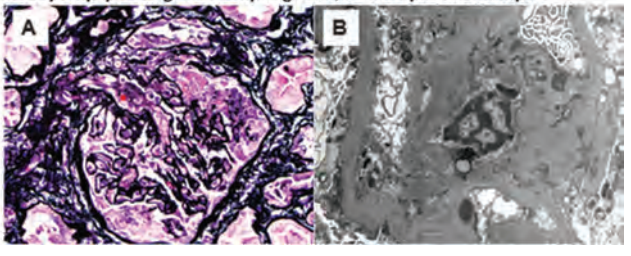
Belen A. Nunez,[1] Steven Salvatore,[2] Edgar A. Jaimes,[1,2] Aisha Shaikh.[1,2]
[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY.

Introduction: Hemophagocytic lymphohistiocytosis (HLH) is a systemic inflammatory disorder caused by the activation and proliferation of nonmalignant macrophages. HLH-associated podocytopathy is very rare. Here, we report a case of HLH-associated collapsing focal segmental glomerulosclerosis (FSGS).

Case Description: A 46-year-old black man with plasma cell leukemia presented to the hospital with a fever and dyspnea. CT scan showed bibasilar lung consolidation and antibiotics were started. He had anemia (hemoglobin 5 g/dl), thrombocytopenia (platelets 10,000 K/µl) and high ferritin (129,379 ng/ml), lactate dehydrogenase (3707 U/L), triglycerides (294 mg/dl), and soluble IL2 Receptor (2145 pg/ml). Based on these findings, a diagnosis of HLH was made. On admission, urine analysis showed 30 mg/dL protein; on hospital day #5, the urine-spot-protein-creatinine ratio (UPCR) was 60 g/g; urine albumin-creatinine-ratio was 25 g/g, and UPEP/IF revealed a monoclonal band with an M-spike of 8.3 mg/dl. Serum creatinine (SCr) rose to 3.8 mg/dl. One gram of solumedrol was administered daily for three days, followed by oral prednisone 60 mg daily. Kidney biopsy showed collapsing FSGS with rare sub-epithelial humps and no evidence of paraprotein disease. Blood cultures and tests for HIV, parvovirus, CMV, EBV, and SARS-CoV-2 were negative. Genotyping for APOL-1 risk alleles is pending. Two weeks following steroid initiation, UPCR improved to 1.5 g/g, and SCr was 1.2 mg/dl.

Discussion: Here, we report a case of HLH-associated collapsing FSGS with sub-epithelial humps. No infectious cause was identified, but the presence of sub-epithelial humps suggests an infectious trigger for HLH. HLH is characterized by cytokine release, which induces podocyte injury. HLH-associated collapsing FSGS occurs in black individuals with APOL-1 mutation. In a large case series of HLH-associated glomerular diseases[1], the mortality rate was 64%, and kidney recovery was rare. The rapid improvement in proteinuria and AKI in collapsing FSGS, as observed in this patient, is very rare. [1] Nephrotic syndrome associated with hemophagocytic syndrome. Kidney Int. 2006.

Kidney biopsy findings. A. Collapsing FSGS, B. Sub-epithelial humps



TH-PO715

Collapsing Glomerulopathy: A Case Series

Harsha Nnss, Varun Kumar Bandi, Sindhu Chaganti. *Dr Pinnamaneni Siddhartha Institute of Medical Sciences & Research Foundation, Vijayawada, India.*

Introduction: Collapsing glomerulopathy (CG) is a rare variant of FSGS and is associated with rapid progression to ESRD. We present a series of three cases of CG.

Case Description: Case 1: A 32-year woman presented with acute pulmonary edema. She had tachycardia, stage II hypertension, and diffuse lung crepitations. On evaluation, she had global hypokinesia of left ventricle with ejection fraction of 25%, acute kidney injury (creatinine -3.6mg/dl) with a small right kidney (6.5cm). Her sputum culture grew multidrug-resistant Klebsiella pneumoniae. She was treated with Polymyxin B, diuretics, and three anti-hypertensives. There was no evidence of renal artery stenosis on doppler. Left renal biopsy was done, which showed collapsing glomerulopathy with IgA nephropathy, and was started on oral steroids. At 3 months, her BP is controlled on one drug, creatinine is 2.8mg/dl. Case 2: A 55-yr male presented with nephrotic syndrome. He had well-controlled diabetes and hypertensive. His creatinine worsened from 3.5 to 6.4mg/dl. Renal biopsy showed collapsing glomerulopathy with diabetic nephropathy, RPS class 3. He was treated with oral steroids but had no recovery and is dialysis dependent. Case 3: A 46-year-old man presented with umbilical hernia. He was found to have nephrotic syndrome, right renal mass, and renal failure. A well-defined lobulated heterogeneously enhancing lesion with cystic areas was seen arising from the lower pole of the right kidney, suggestive of renal cell carcinoma. Left renal biopsy showed collapsing glomerulopathy with diabetic nephropathy, RPS class III. He underwent right partial nephrectomy, which showed renal cell carcinoma–Clear cell variant. At 3 months, he has no edema, normal serum Albumin, and creatinine.

Discussion: We present a series of collapsing GN, with varying outcomes. Case 1 had partial recovery, case 2 had rapid progression, and case 3 had complete recovery. The etiology could be probably uncontrolled hypertension and IgA nephropathy in case 1, Case 2 was idiopathic, and Case 3 was malignancy related.

	Age (years) /Sex	Creatinine (mg/dl)	Outcome	Etiology	Histology
Case 1	32/F	3.6	Creatinine- 2.8	IgAN, HTN	Mesangial hypercellularity. Segmental sclerosis with adhesions to Bowmans capsule in one glomerulus, collapse of capillary tuft with hyperplasia of overlying podocytes in one glomerulus
Case 2	55/M	6.4	ESRD	Idiopathic	Kimmelstiel Wilson nodules are noted. Mesangiolysis and capillary tuft collapse with the overlying podocytes hyperplasia seen in two glomeruli. Microaneurysmal dilatation of capillaries is seen. 40-55% interstitial fibrosis and tubular atrophy. Diffuse lymphoplasmacytic infiltrate is seen in interstitium.
Case 3	46/M	2.1	Recovered	Renal Cell carcinoma	Diffuse and nodular mesangial matrix expansion. Occasional Kimmelstiel Wilson nodules. Segmental collapse of the capillary tuft with hyperplasia of overlying of podocytes in one glomerulus. There is microaneurysmal dilatation of some capillaries. 25-30% interstitial fibrosis and tubular atrophy.

TH-PO716

Membranoproliferative Glomerulonephritis Associated with Hemophilus parainflunezae Endocarditis: A Rare Presentation

Momina Amjad, Mauricio Monrroy. *Albany Medical Center, Albany, NY.*

Introduction: We present a case of acute renal failure due to diffuse membranoproliferative glomerulonephritis in the setting of HACEK organism mitral valve infective endocarditis (IE).

Case Description: A 56-year-old with year old male with no significant past medical history was transferred to the ICU for renal failure, anemia and hypotension. He had a three month history of fevers, night sweats, reddish brown urine and 15 Ib weight loss. Physical exam was notable for confusion, respiratory distress on 14 liters oxygen, a pansystolic murmur over the mitral area and +2 bilateral pedal edema. He had profound microcytic anemia on initial presentation with a hemoglobin of 4 g/dL, alongside leukocytosis 29 10x9/L. Metabolic panel was notable for Creatinine 5.28, BUN 162, PO4 10.2 and albumin 2.6. He underwent continuous renal replacement therapy (CRRT) for uremic encephalopathy in the setting of hypotension. Further investigation revealed 2.5g proteinuria ove 24 hours and RBC casts in the urine analysis. C3 was 38.4 mg/dL, C4 was undetectable and rheumatoid factor was more than 115. Hepatitis C was not detected and other rheumatologic serologies were unremarkable. The patient was started on empiric plasmapheresis for concern of cryoglobulinemic glomerulonephritis (GN). A transthoracic echocardiogram showed a large mitral valve (MV) vegetation, severe MV regurgitation, and a small pericardial effusion. Blood cultures grew gram negative rods after 79 hours, which were finalized to Hemophilus parainfluenzae. Plasmapheresis was stopped. Due to persistent encephalopathy, MRI brain was obtained which showed septic emboli. His kidney biopsy revealed diffuse membranoproliferative GN with C3/IgM strongly positive. His final diagnosis was mixed cryoglobulinemia and MPGN in the setting of Hemophilus endocarditis. He was maintained on IV ceftriaxone and eventually underwent surgical mitral valve replacement.

Discussion: Acute renal failure related to IE-associated glomerulonephritis (IEAGN) has been reported in literature, with varying pathophysiological mechanisms, including one third of patients having anti-neutrophil cytoplasmic antibody (ANCA) positivity. To our knowledge, there are no reported cases of IE caused by HACEK organisms associated with MPGN. This case highlights a unique presentation that may be missed.

TH-PO717

Cryofibrinogen-Associated Membranoproliferative Glomerulonephritis

Minah Kim,[1] Chang Seong Kim,[2,3] Hong Sang Choi,[2,3] Eun Hui Bae,[2,3] Seong Kwon Ma,[2,3] Soo Wan Kim,[2,3] Sang Heon Suh.[2,3] *[1]Chonnam National University Hwasun Hospital, Hwasun-gun, Jeollanam-do, Republic of Korea; [2]Chonnam National University Medical School, Gwangju, Republic of Korea; [3]Chonnam National University Hospital, Gwangju, Republic of Korea.*

Introduction: Cryofibrinogenemia is a rare disorder caused by deposition of cryofibrinogen. Various clinical manifestations associated with cryofibrinogenemia. Although the kidney can be a target organ, but there are few reports. We describe a case of cryofibrinogen-associated glomerulonephritis in old man with prolonged diabetes.

Case Description: A 74-year-old man with diabetes mellitus visited the emergency department with generalized edema and weakness since 1 week. Serum creatinine level was 3.9 mg/dL (up from a baseline 6 mo earlier 1.2 mg/dl), and urinalysis revealed microscopic hematuria and nephrotic-range proteinuria (5.15 g/day in 24-h urine sample). Kidney biopsy, performed to ascertain the exact cause of acute kidney injury with nephrotic-range proteinuria, revealed basement membrane thickening, mesangial matrix prominence, marked inflammation, and endocapillary hypercellularity under light microscopy. Immunofluorescence microscopy showed no staining for immunoglobulin G. Electron microscopy revealed subendothelial and mesangial deposits with large-bore multilayered tubular structures (Figure 1a) that were further evaluated and comprised

an abnormal protein that precipitated when the plasma, but not serum, was stored at 4'C and redissolved at 37'C(Figure 1b). Liquid chromatography-tandem mass spectrometry revealed fibrinogen-α, -β, and -γ chains, and fibronectin. Despite adequate hydration, the patient's renal function did not improve, and prednisolone (1 mg/kg/day) therapy was initiated and continued for 3 months, whereby the serum creatinine decreased to 1.9 mg/dL. However, the renal function of the patient decreased gradually thereafter to eventual kidney failure that necessitated hemodialysis.

Discussion: Cryofibrinogenemia can induce several organ dysfunctions, manifesting as mostly dermatological symptoms, as well as kidney involvement. Distinctive ultrastructure findings of large microtubular structures on electron microscopy, plasma cryoprecipitates when cold, and proteomic analysis are crucial for diagnosing cryofibrinogen-associated glomerulonephritis.

Unraveling the Mystery: A Case of Cryoglobulinemia

Shilpa Pedapati, Jessica M. Nino, Asma Rashid, Elvira González Negrete, Iyad S. Mansour, Erika R. Bracamonte, Bijin Thajudeen. *Banner University Medical Center Tucson, Tucson, AZ.*

Introduction: Cryoglobulinemia is a systemic inflammatory syndrome that generally involves small-to-medium vessel vasculitis due to cryoglobulin-containing immune complexes. The classification distinguishes three subtypes of cryoglobulinemic diseases. But at the same time, there are rare instances where there could be misleading classification of the disease due to the presence of two different underlying disorders. Here we report a case of type 2 cryoglobulinemic membranoproliferative glomerulonephritis with a detectable monoclonal IgM kappa in serum.

Case Description: A 70-year-old gentleman with a past medical history of chronic myelogenous leukemia presented with epigastric abdominal pain and melena. He was diagnosed with liver cirrhosis and spontaneous bacterial peritonitis. Additional workup revealed active hepatitis C infections, acute kidney injury with hematuria, sub-nephrotic proteinuria, active sediment on urine microscopy, elevated RF, serum immunofixation showing monoclonal gammopathy, IgM, kappa type and urine immunofixation with lambda light chain band. A kidney Biopsy was performed that showed cryoglobulinemic glomerulonephritis. Due to monoclonal gammopathy, hematology performed a bone marrow biopsy, which returned 2-3% plasma cells. The diagnosis was felt to be more consistent with mixed/Type 2 Cryoglobulinemia secondary to HCV infection. The monoclonal gammopathy and the presence of Kappa-restricted B cells were felt to be an association rather than the cause of cryoglobulinemia. Therefore, he was not treated further with plasma cell-directed therapy. He received treatment with Rituximab, plasmapheresis, and steroids.

Discussion: This case highlights the importance of differentiating between different types of cryoglobulinemia that determines appropriate therapy. Detectable monoclonal gammopathy can be found in the serum of patients with type II cryoglobulinemic glomerulonephritis. Although lymphoproliferative disorders are more closely related to type I cryoglobulinemia, it is essential to exclude monoclonal gammopathy in patients with mixed cryoglobulinemic glomerulonephritis to reveal hidden lymphoproliferative disease before the diagnosis of essential cryoglobulinemia can be made. This has implications for the management of such patients.

TH-PO719

Interstitial Inflammation and C3 Glomerulopathy Secondary to an Autoinflammatory Syndrome

Manish K. Saha,[1] Joshua Rivenbark,[1] Beatriz Caceres-Nazario,[1] Alessia Buglioni,[2] Samuel M. Rubinstein.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Dual presence of histiocytic interstitial inflammation and C3 glomerulopathy (C3GN) are uncommon. We report a rare case of non-Langerhans cell histicoytosis associated acute kidney injury (AKI).

Case Description: A 71-yr-old male was admitted to the hospital with anasarca and generalized weakness. Laboratory data were significant for anemia, AKI, hypercalcemia, and trace monoclonal IgA lambda. Autoimmune and infectious workup was unrevealing. PET scan revealed hypermetabolic extensive infiltration of kidneys, perirenal space, and mild bilateral hydronephrosis. Bone marrow biopsy demonstrated hypercellular marrow without evidence of neoplasm. Vacuolization was not demonstrated in neutrophils. Kidney biopsy showed C3GN. Interestingly, a cluster of interstitial CD68-positive and Langerin-negative histiocytes was present. C3GN was thought to be inactive in the absence of active urine sediment. Biopsy of the perinephric mass showed fibroconnective tissue primarily composed of histiocytes, without evidence of neoplasm. IgG4 and EBV staining were negative. Further evaluation led to the identification of a pathogenic variant in the *UBA1* gene p.(M41) – a somatic variant which may result in promotion of pro-inflammatory gene expression, and implicated in the pathogenesis of VEXAS (Vacuoles, E1 enzyme, X-linked, autoinflammatory, somatic mutation) syndrome, a recently described autoinflammatory disease. The patient's clinical presentation in the setting of a pathogenic *UBA1* variant was consistent with VEXAS syndrome. Speculatively, the alternate complement pathway, could have been activated by the inflammatory mediators or IgA lambda protein, leading to C3GN (C3 Nef antibody was negative, normal C3/C4). AKI was determined to be multifactorial and hypercalcemia was secondary to cytokine-mediated increased calcitriol synthesis by monocytes. This patient was treated with oral glucocorticoid and anti-IL-6 receptor monoclonal antibodies, with marked improvement in clinical status, inflammatory markers, kidney function, and metabolic uptake on follow-up PET scan.

Discussion: Acute interstitial inflammation with infiltration of non-Langerhans cell histiocytes due to VEXAS syndrome is a rare cause of AKI. A high degree of suspicion is required to diagnose VEXAS which carries significant mortality and morbidity without prompt treatment.

TH-PO720

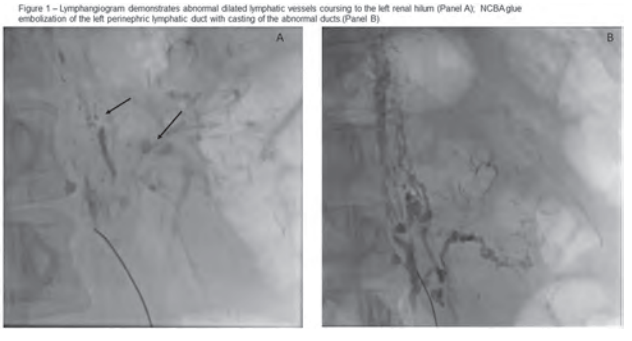
Nephrotic Range Proteinuria with White, Cloudy Urine

Manish K. Saha,[1] Megan Asher,[2] Elizabeth A. McInnis,[1] Nicole Keefe,[1] David Friedlander,[1] Vimal K. Derebail.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]University of Pennsylvania, Philadelphia, PA.*

Introduction: Nephrotic range proteinuria may be due to a myriad of glomerular pathologies. While rare, non-glomerular etiologies can produce high grade proteinuria in the absence of significant glomerular pathology.

Case Description: A 30-year-old male was evaluated for nephrotic range proteinuria and hypoalbuminemia. Physical examination was unremarkable. Laboratory data showed Creatinine 1.1 mg/dl (eGFR 100 ml/min/1.73m^2), urine to protein creatinine (UPCR) ratio of 9 g/g, UACR at 183 ug/mg, serum albumin 2.7 g/dl. The urine was "cloudy," and sediment analysis demonstrated no acanthocytes or lipid-laden oval fat bodies. Kidney biopsy showed normal glomeruli by light microscopy with unremarkable immunofluorescence staining and no significant glomerular abnormalities by electron microscopy. Additional studies were performed in our research laboratory to determine the cause of urinary turbidity. Upon addition of ether (a fat solvent), clearing of "cloudy" centrifuged urine occurred with layering of fat globules at the bottom. With addition of Sudan III stain, a red-stained fatty layer accumulated upon centrifugation. Urine assessed in a clinical laboratory showed elevated levels of triglyerceride, cholesterol, and chylomicrons. Filariasis serologies were negative. The patient was diagnosed with chyluria based on the urine TG level and ether test. MR lympangiography showed abnormally dilated lymphatic channels in the left paraspinal region communicating with the left kidney. He underwent lymphangiogram with N-butyl cyanoacrylate glue embolization of the left perinephric lymphatic duct, and within 12 hours, the urine cleared to clear yellow.(Figure 1) Repeat labs 1 month after embolization showed UPCR of 0.07 g/g and serum albumin of 4.2 g/dl.

Discussion: Chyluria is a rare cause of nephrotic range proteinuria. Urine color and turbidity, absence of oval fat bodies, and non-selective proteinuria were early diagnostic clues, with urine TG confirming the diagnosis. Microscopic examination of the urine sediment is essential in evaluating patients with proteinuria.



TH-PO721

Compassionate Use of Pegcetacoplan in a Patient with C3 Glomerulopathy: A Case Report

Sahibzadi Noor,[1] Roy O. Mathew,[2,1] Amir Abdi Pour,[1] Sayna Norouzi.[1] *[1]Loma Linda University, Loma Linda, CA; [2]VA Loma Linda Healthcare System, Loma Linda, CA.*

Introduction: Pegcetacoplan is a C3 complement inhibitor which is approved by the United States Food and Drug Administration for paroxysmal nocturnal hemoglobinuria and geographic atrophy secondary to macular degeneration. It is undergoing a phase III trial (Valiant trial, NCT05067127) which is assessing subcutaneous pegcetacoplan in patients with C3 glomerulopathy (C3G) or immune-complex mediated glomerulonephritis. Here, we discuss the case of a patient who did not qualify for the trial but was approved for compassionate use of pegcetacoplan.

Case Description: A 26-year-old female was diagnosed with biopsy proven C3G with negative genetic testing. Over the course of about one and a half year, her renal function had deteriorated from estimated glomerular filtration rate (eGFR) of 64 to 22 ml/min/m^2 , with proteinuria progressing from 1.5 to 2.7 gm/day, while being on prednisone and mycophenolic acid (MFA). Due to the inability to tolerate MFA (MFA induced colitis on colon biopsy), she was transitioned to tacrolimus and prednisone. The patient kept being hospitalized frequently due to acute kidney injuries (AKI), with five admissions over four months. Patient was not a candidate for the Valiant trial due to eGFR < 30 ml/min/m^2, 76% glomerular sclerosis (GS) and 60% interstitial fibrosis and tubular atrophy (IFTA) on the last biopsy. Therefore, a request for compassionate use of pegcetacoplan was submitted. It was approved after four months and started in September 2022. While being on pegcetacoplan for six months, the patient's renal function remained stable (eGFR 19-22 ml/min/m^2, proteinuria 0.5-0.7 gm/day) and she did not require any hospitalizations. The medication was well tolerated without any serious adverse effects. In March 2023, the patient progressed to end stage renal disease (ESRD) and was started on hemodialysis.

Discussion: There is currently no approved therapy for C3G. Our patient had frequent episodes of AKI, multiple hospitalizations and did not meet the criteria for Valiant trial due to her low GFR. We believe pegcetacoplan might have delayed her progression to ESRD, improved her quality of life by avoiding hospitalizations and allowed her time to get listed for transplant. Further studies are needed to evaluate the efficacy and safety of pegcetacoplan in advanced C3G.

TH-PO722

C3 Glomerulonephritis and Thrombotic Microangiopathy in a Patient with C3 Nephritic Factor

Manaf Aljishi,[1] Nicole Isbel,[1] Dev K. Jegatheesan,[1] Vishwas Raghunath.[2]
[1]Princess Alexandra Hospital, Woolloongabba, QLD, Australia; [2]Ipswich Hospital, Ipswich, QLD, Australia.

Introduction: Complement-mediated kidney diseases include thrombotic microangiopathy (TMA), and C3 glomerulonephritis (C3GN). TMA can occur due to complement dysregulation manifesting as hemolytic anemia, thrombocytopenia and kidney dysfunction. C3GN develops due to mesangiocapillary C3 accumulation. We report a case where both conditions developed in the same patient.

Case Description: A 36-year-old woman presented with shortness of breath and generalised edema. She had a history of hepatitis C infection. Laboratory testing showed creatinine 2.1mg/dL (eGFR 30 mL/min/1.73m2) and albumin 19 g/L. Urinalysis showed hematuria and protein/creatinine ratio (uPCR) 1,100 g/mol. Hepatitis C viral load was 5.52 x 10^6 IU/m. Other viral, autoimmune, cryoglobulin and paraprotein tests were negative. C3 was low 0.22 g/L (0.9-1.8). C4 was normal. Kidney biopsy showed mesangial and endocapillary hypercellularity with double contours. IF showed granular C3 deposition in capillary and mesangium. EM showed subendothelial deposits, consistent with membranoproliferative glomerulonephritis. Renal parameters did not improve with hepatitis C treatment. C3 Nephritic Factor (C3NeF) was positive and Prednisolone and Mycophenolate were thus commenced with improvement of creatinine to 1.4 mg/dL and uPCR to 192 g/mol. One year later the patient presented with dyspnea, kidney failure (creatinine 14.1mg/dL) and features of TMA, with haemoglobin 63 g/L and platelets 133 x 109/L. Haptoglobin was low (0.26 g/L) and blood film showed schistocytes. ADAMTS13 level was normal. Hemodialysis commenced and Eculizumab was given with improvement in hematological parameters only. Complement genetic analysis (aHUS, C3GN) panel was negative. At four-year follow up, the patient remains dialysis-dependent.

Discussion: TMA and C3GN are disorders caused by complement defects, with the former from membrane-anchored complement activation and the latter from fluid-phase complement activation. C3NeF is a stabilizing antibody against the C3 convertase complex, a common step in multiple complement pathways, leading to complement-mediated disorders. Our patient had both TMA and C3GN. This illustrates the complexity and overlap of complement pathways.

TH-PO723

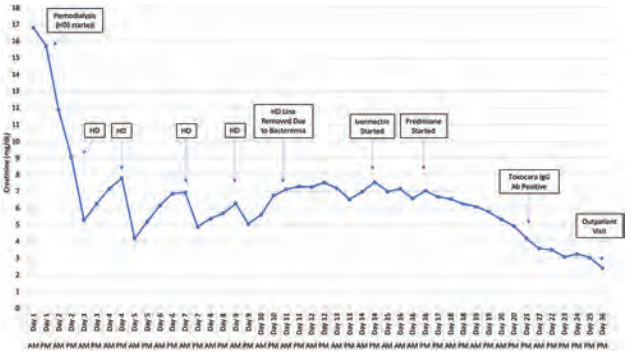
A Case of AKI Secondary to Toxocara-Induced C3 Glomerulonephritis

Kristine Huang, Malek Ayoub, Scott C. Stockholm, Patricia F. Kao.
Washington University in St Louis, St Louis, MO.

Introduction: C3 glomerulonephritis (C3GN) is a rare form of glomerulonephritis that can occur secondary to infection. We present a case of biopsy-confirmed C3GN in a patient with AKI requiring dialysis and positive Toxocara IgG Ab who achieved partial remission with steroids.

Case Description: A 59-year-old male with hypertension and diabetes mellitus presented with a week of anasarca and oliguria after a 3-month trip to Cuba. Physical exam was notable for bilateral 4+ pitting edema up to his hips. Labs demonstrated a Cr of 16.81 mg/dL (1.16 mg/dL 16 months prior) and eosinophilia 1.9K/cumm. Urinalysis revealed 3+ protein, 21-50 WBC/hpf, >50 RBC/hpf, and a 24-hour urine protein of 5.4 grams. Notable serologic workup included elevated DNASE B Ab, ANA 1:160, and low serum C3. Hemodialysis (HD) was started for diuretic resistant oliguric AKI. His course was complicated by MRSA bacteremia necessitating a line holiday, during which time his urine output improved and his Cr and azotemia spontaneously stabilized without further HD. A kidney biopsy showed C3GN, 2/10 globally sclerotic glomeruli, moderate interstitial fibrosis, 40% tubular atrophy, and moderate hyaline arteriosclerosis. Initial infectious workup was negative. Given the biopsy results and persistence of Cr ~7 mg/dL, oral prednisone 60mg daily was initiated. ID recommended 2 days of empiric Ivermectin while awaiting results of a parasitic workup. His Cr steadily decreased to ~3 mg/dL on steroids. Toxocara IgG Ab subsequently resulted positive. There were no acute signs of Toxocariasis, so albendazole was not started. His Cr continued to improve at discharge.

Discussion: Toxocariasis, a parasitic helminth infection, can cause eosinophilia and is important to consider when evaluating for C3GN, even without active signs of infection. It is typically diagnosed with an ELISA Ab assay and treated with albendazole. Prednisone may be added for severe systemic involvement. Patients without active Toxocariasis, significant sclerosis, or fibrosis on renal biopsy may have good renal recovery after prompt steroid treatment.



TH-PO724

A Case of AA Amyloidosis Associated with "Skin Popping" Heroin

Marimar Contreras Nieves,[1] Belal I. Hakim.[2] *[1]Stanford University, Stanford, CA; [2]Santa Clara Valley Medical Center, San Jose, CA.*

Introduction: The differential diagnosis for renal disease in patients with substance use disorder can be broad. Etiology can be related to the substance itself, a contaminant of the substance, or a transmitted disease. The renal complications can be acute or chronic and include glomerular, interstitial, and vascular diseases. This case highlights the importance of distinguishing by kidney biopsy between different etiologies in patients with substance abuse.

Case Description: A 62-year-old man with history of Hepatitis C (treated 8 months prior), treated latent TB, chronic left ankle ulcer, and substance use disorder presented to the emergency room with right calf pain for 4 days. Per patient, he used heroin via "skin popping" a couple of times since his pain was severe, but denied using for 15 years prior. Exam with hyperkeratotic plaques on right ulnar palm, left heel ulcer, and lower extremity edema. He was found to have a new deep vein thrombosis in the right popliteal and posterior tibial veins. His laboratory workup revealed a serum creatinine of 5.5 mg/dL from 1.0 mg/dL 5 months prior, urinalysis with 3+ protein and 2+ blood, and 14.8 grams of urine protein per 1 gram of urine creatinine. Hepatitis C viral load was undetectable. Other workup resulted during the hospitalization including HIV, Hep B, cryoglobulins, Anti-GBM, complements, ANCA, ANA, and dsDNA were negative. He had an abnormal SPEP and elevated free light chains ratio. Kidney biopsy revealed AA amyloidosis with preserved glomeruli and tubulointerstitial fibrosis less than 30%. Although serum creatinine did not significantly change during hospitalization, he remained with good urine output and did not develop indications to start dialysis.

Discussion: Given the broad differential diagnosis in patients with substance abuse, it is key to differentiate between them with a kidney biopsy. Renal amyloidosis should be considered in the differential diagnosis of heroin users when they present with proteinuria and renal impairment. Untreated skin and soft tissue infections can cause persistent inflammation that trigger AA amyloidosis. Unfortunately, injection drug users who develop AA amyloidosis are usually diagnosed late when the renal disease is advanced. There are no proven treatments currently. However, some have suggested that AA amyloidosis may be preventable and potentially reversible if the inflammatory stimulus is eliminated early.

TH-PO725

AL Kappa Amyloidosis with Rapidly Unfavorable Evolution: A Case of Renal, Hepatic, and Muscular Involvement with POEMS Syndrome and Unusual Autoantibody Activity

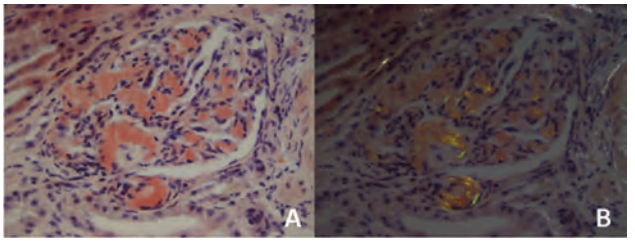
Rossana Cazzato, Giovanni Maria Rossi, Paolo Greco, Caterina Maccari, Umberto Maggiore, Enrico Fiaccadori, Francesca Di Mario. *Parma University Hospital, Parma, Italy.*

Introduction: AL amyloidosis arises in the setting of plasma cell discrasia, with deposition of amyloidogenic misfolded immunoglobulin-free light chains in peripheral tissues resulting in progressive organ dysfunction. Involved organs include kidneys, heart, liver, nervous system and gastrointestinal tract.

Case Description: We report the case of a 61-year-old man who presented with hypotension, alternating diarrhea and constipation, muscle pain, paraesthesias, and a monoclonal IgG kappa component with altered free light chain ratio, nephrotic syndrome and acute kidney injury requiring haemodialysis. After renal and bone marrow biopsies a diagnosis of AL k amyloidosis was reached **(Fig. 1)**. Evidence of persistently elevated levels of liver function tests and creatine phosphokinase led to consideration of amyloid infiltration in the liver and muscle, confirmed by biopsies. Clinical management was complicated by the presence of hypopituitarism associated with MRI changes consistent with hypophysitis. High-titer anti-cardiolipin IgG and anti-β2 glycoprotein IgG was

observed, despite the absence of thrombotic lesions on whole-body CT images. The patient was started on a cyclophosphamide-bortezomib-dexamethasone-daratumumab regimen, interrupted after four cycles, following the patient's death only one month after the onset of nephrotic syndrome.

Discussion: We described a rare case of systemic amyloidosis with a rapidly unfavorable outcome with abrupt disease onset, in which organ involvement has rapidly progressed to multiorgan failure. If we exclude central nervous system involvement, polyendocrinopathies may be explained by concomitant POEMS. The significance of autoantibody positivity in the absence of clinical autoimmunity remains unclear, and raises the suspicion of a false positivity due to molecular mimicry.



Kidney biopsy: (A) Glomerulus and arteriole with amorphous material in mesangial areas and the arteriolar wall respectively stains positive with Congo red and shows apple-green birefringence in polarized light, consistent with amyloid (B).

TH-PO726

Nephrotic Syndrome due to AA Amyloidosis Associated with Cystic Fibrosis: A Case Report

Washington A. Freire Filho, Tassila G. Maia, Diogo Campos, Isabela C. Salgado, Liudmila G. de Menezes, Livia B. Cavalcante, Luis Yu. *Universidade de Sao Paulo Hospital das Clinicas, São Paulo, Brazil.*

Introduction: Cystic fibrosis (CF) is an autosomal recessive and multisystemic disease that predominantly involves the respiratory and digestive tracts. New drugs for treatment and early recognition have recently increased survival of the patients, leading to a chronic inflammation environment, introducing renal AA amyloidosis as a possible complication.

Case Description: A 28-year-old male with cystic fibrosis, mild malnutrition and recurrent pneumonia was admitted for treatment of infectious decompensation and investigation of anasarca that started 1 month earlier. He underwent antibiotic treatment with resolution of the infectious condition. Concerning the edemigenic syndrome, echocardiogram and abdominal ultrasound indicated normal results; spot urine revealed 6.41g of protein and no hematuria or pyuria. Urine protein-creatinine ratio in isolated sample was 7.5g/g; 24-hour proteinuria: 4.56g; serum albumin of 1.8g/dL; LDL 191mg/dL; triglycerides 248mg/dL. Serologies for hepatitis B, hepatitis C and HIV, and both FAN and ANCA resulted negative. Urinary protein electrophoresis showed no alteration. Renal biopsy presented mesangial expansion with amorphous eosinophilic pale material, PAS negative, with birefringence on analysis under polarized light in sections stained with Congo red (fig1). Amyloid A antigen test was performed, which resulted positive in arteriole walls. Gathering all of this information, the patient obtained a presumptive diagnosis of AA amyloidosis secondary to CF.

Discussion: CF may rarely complicate with AA amyloidosis. Amyloid deposits occur mainly in the liver, spleen and kidneys. This complication reflects a history of recurrent infections and successive inflammatory insults. AA amyloidosis presents itself as a poor prognostic factor and patients with CF and 24h-proteinuria > 1g or nephrotic syndrome should mandatorily perform a renal biopsy.

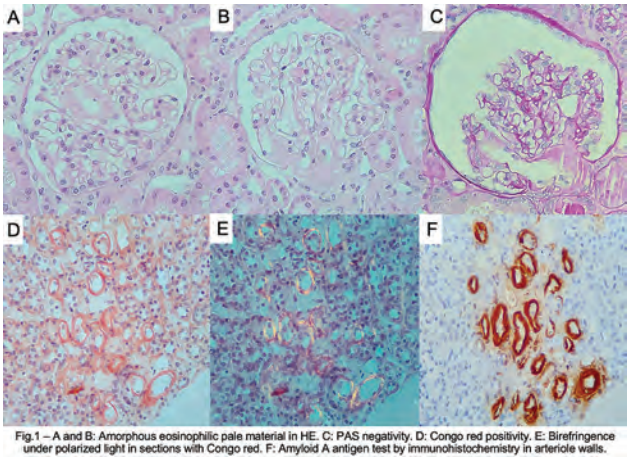


Fig.1 – A and B: Amorphous eosinophilic pale material in HE. C: PAS negativity. D: Congo red positivity. E: Birefringence under polarized light in sections with Congo red. F: Amyloid A antigen test by immunohistochemistry in arteriole walls.

TH-PO727

A Rare Case of Paraneoplastic Scleroderma Renal Crisis in a Patient with Squamous Cell Carcinoma of the Tongue

Marwa Abdalla, Garrett Durbin, Donghyang Kwon, Michael J. Choi, Negiin Pourafshar. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Scleroderma Renal Crisis (SRC) is a life-threatening emergency that presents with hypertension, Acute Kidney Injury (AKI) and Thrombotic Microangiopathy (TMA) in patients with Systemic Sclerosis (SSc). It is associated with 20% mortality at 6 months and 19-40% of patients requiring long term dialysis[1,2]. Paraneoplastic Scleroderma Renal crisis (PSRC) is a rare subset of SRC that has been reported previously[3]. We report a rare case of PSRC without history of SSc in a patient with squamous cell carcinoma of the tongue.

Case Description: 61-year-old male with history of squamous cell carcinoma of the tongue on radiotherapy presented for evaluation of decreased oral intake for few days. He was noted to have tachycardia and hypertension (BP167/109 mmHg). Labs showed anemia, thrombocytopenia and serum creatinine of 1.5mg/dL (baseline 1mg/dL). Urinalysis showed small blood and 30 mg/dL protein with granular casts. Renal ultrasound was unremarkable. The patient was treated initially for a presumed acute tubular injury (ATN) from prolonged pre-renal state. Due to worsening renal function with a creatinine 8.9 mg/dL the patient was initiated on hemodialysis. A renal biopsy was obtained revealing a widespread prominent mucoid intimal hyperplasia with severe occlusion and secondary changes of bloodless glomeruli. Mesangial lysis, acute tubular injury with focal ATN and minimal interstitial inflammation was seen. Repeat physical exam revealed thickening of the skin of the hands. Further testing revealed evidence of schistocytes, elevated LDH and positive RNA polymerase III. A diagnosis of PSRC was made and the patient was started on captopril. The patient continued to be dialysis dependent at the time of discharge.

Discussion: Paraneoplastic SCR has been reported in a few cases of lung, breast and abdominal cancers[3]. The pathogenesis is postulated to be related to cancer induced profibrotic cytokines and growth factors leading to renal vascular damage[3]. To our knowledge, there are no reported cases of squamous cell cancer associated PSCR. Our case adds to the literature of the rare PSCR in this patient population. This case highlights the importance of considering PSCR in the differential diagnosis of cancer patients presenting with AKI, TMA and higher than baseline blood pressure measurements.

TH-PO728

A Case of Fibrillary Glomerulonephritis Presenting as Rapidly Progression Glomerulonephritis in a Patient with Untreated Hepatitis C

Aadil Kaisani, Mohammed Mahgoub, Mohammed A. Sayeed Khan, Nimrit Goraya. *Baylor Scott and White Central Texas, Temple, TX.*

Introduction: Fibrillary glomerulonephritis (FGN) is a rare progressive disease accounting for 0.5% to 1.4% of all native kidney biopsies. The diagnosis is established with renal biopsy demonstrating randomly oriented fibrils ranging 15-25 nm on electron microscopy, and negative Congo red staining. Recent discovery of DNAJB9 as a biomarker has been reliable for diagnosis, although its role in pathogenesis remains unclear. It is strongly associated with underlying malignancy, monoclonal gammopathy, autoimmune disease or infections. Prognosis remains poor with no established clinical guidelines to optimize therapy. Here, we describe a case of FGN presenting with rapidly progressive glomerulonephritis and crescents on biopsy in a patient with untreated Hepatitis C.

Case Description: A 64 yo. M with significant past medical history of hypertension, cirrhosis secondary to untreated Hepatitis C and methamphetamine who presented with dyspnea. Initial work up showed AKI with creatinine of 4.52 mg/dL. Urinalysis displayed hematuria and UPCR of 7.04 g/g, raising suspicion for an underlying GN. Serological work including anti-GBM, ANCA, Cryoglobulin, RF, HIV, Hepatitis A and B were negative. Hepatitis C antibody was positive, with quantitative RNA greater than 300,000 IU/mL. Electron microscopy from biopsy revealed randomly oriented fibrils of ~ 15nm in diameter throughout the glomeruli. IF revealed IgG, C3, kappa/lambda light chains in the mesangium and along the GBM. IHC analysis showed negative Congo red and positive DNAJB9. Of the 46 glomeruli analyzed, 7 demonstrated cellular and fibrocellular crescents. Biopsy findings were consistent with FGN. He was started on pulse dose steroids followed by a taper and cyclophosphamide. Due to worsening renal function and volume overloaded state, he required initiation of dialysis. Despite starting treatment for Hepatitis C, there has been no evidence of renal recovery.

Discussion: Overall prognosis for FGN remains poor with approximately 40-50% of patients progressing to ESRD. Our case highlights the challenges with recognition and management of FGN as a cause of RPGN since clinical presentation is similar to other recognized etiologies. Despite treatment of RPGN and Hepatitis C, our patient had progression of disease emphasizing need for further trials and novel therapies.

TH-PO729

An Atypical Case of IgG4-Related Disease (IgG4-RD) Manifesting as Extensive Abdominal Periarteritis and Membranous Nephropathy (MN): A Case Report and Literature Review

Minami Matsumoto, Shinya Yamamoto, Hideki Yokoi, Motoko Yanagita. *Kyoto Daigaku, Kyoto, Japan.*

Introduction: IgG4-RD is a progressive immune-mediated fibrotic disease characterized by tumor-like mass formation in many affected organs. Tubulointerstitial nephritis (TIN) with increased IgG4-positive plasma cells is the dominant feature of IgG4-related kidney disease. Here we present an atypical case of IgG4-RD, and a literature review of 18 cases on IgG4-related MN.

Case Description: A 71-year-old man with a peptic ulcer was admitted with acute-onset leg edema and nephrotic syndrome. The laboratory data revealed serum albumin 1.9 g/dL, creatinine 1.1 mg/dL, and urinary protein 9.3 g/gCr. The renal biopsy showed granular staining in the capillary walls for IgG (IgG1>4) and negative PLA2R staining, suggesting secondary MN. Computed tomography (CT) scans revealed extensive wall thickening around the iliac and splenic arteries, and superior and inferior mesenteric arteries with dilatation. The findings of periarteritis, high serum IgG4 and IgE levels, and numerous IgG4-positive cells infiltration to interstitium led to the diagnosis of IgG4-RD. Other etiologies causing vascular lesions such as lymphoma, and polyarteritis nodosa, were incompatible with the clinical findings. We chose low-dose prednisolone because this patient had a peptic ulcer and high doses of prednisolone may promote aneurysm formation in IgG4-related arteritis. After the initiation of prednisolone (10 mg) and ARB, he achieved partial remission of proteinuria. We successfully controlled IgG4-RD and avoided the recurrence of peptic ulcers.

Discussion: In this case, nephrotic syndrome and the absence of typical manifestations, such as pancreatitis and sialadenitis made the diagnosis of IgG4-RD challenging. It was also unique in that extensive arteritis was confined to a major branch of the abdominal aorta, not the aorta itself. These features suggest a new phenotype of IgG4-RD. Our literature review of 18 cases on IgG4-related MN, including 1 case with aortitis, demonstrated that 10 cases achieved complete remission, and 8 achieved partial remission of proteinuria with various treatments such as corticosteroids, cyclophosphamide, and rituximab. Although the number of affected organs had no relation with the response of proteinuria, the complication of TIN had an association with a good response.

TH-PO730

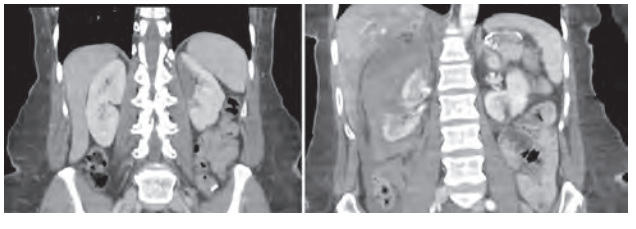
A Case of Renal Infarcts Followed by Renal Hematoma: The Importance of Angiography in the Diagnosis of Polyarteritis Nodosa

Erica Marnet, Kaltrina Sedaliu. *Bridgeport Hospital, Bridgeport, CT.*

Introduction: A renal infarct (RI) may go undiagnosed given its non specific symptoms; abdominal or flank pain, nausea and vomiting. Classically, it is attributable to cardiovascular causes, such as atrial fibrillation (AF), or to coagulopathies. Frequently, however, no underlying etiology is ascertained. Polyarteritis nodosa (PAN) is a medium vessel vasculitis not associated with antineutrophil cytoplasmic antibodies. Biopsy demonstrating necrotizing arteritis is the gold standard for diagnosis, and when it cannot be secured, angiography is an important tool to establish the diagnosis, exhibiting aneurysms or segmental stenosis of intraabdominal arteries.

Case Description: A 52-year old female, with a past medical history of abdominal pain with prior extensive work up, presents with acute on chronic abdominal pain, nausea, vomiting and 6 kg weight loss. Work up revealed a left RI. Telemetry was negative for AF, as a transesophageal echocardiogram for left ventricle thrombus. Her hospital stay was complicated by ongoing abdominal pain, repeated imaging showing a new large right RI. Hypercoagulable work up was negative. However, It was believed she was high risk for recurrent thrombosis, thus, initiated on Apixiban. After two weeks, she returns with abdominal pain and was discovered with a large right pericapsular hematoma with possible active bleeding. Given hemodynamic instability, she underwent a right renal angiogram that showed severe irregularity with multifocal areas of stenoses, dilatations and microaneurysms, also, large areas of devascularization, consistent with PAN. Hepatitis B sorology showed prior immunization. She was treated with pulse dose steroid therapy and IV cyclophosphamide (total of 5 infusions), followed by PO prednisone 1mg/kg. Her abdominal pain ultimately resolved and she experienced no further thrombotic events.

Discussion: The underlying etiology of RI requires compressive investigation. Proper treatment warrants an evidence based practice. PAN is a rare entity, however usually complicates with RI. This case highlights the importance of prompt recognition, appropriate diagnostic investigation, and timely treatment.



TH-PO731

Histiocytic Glomerulopathy

Marwa Ahmed,[1] Jason M. Kidd,[1] Samih H. Nasr,[2] Lihong Bu.[2] *[1]Virginia Commonwealth University Health System, Richmond, VA; [2]Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Direct glomerular involvement by activated histiocytes is a rare histopathologic finding and may be associated with cryoglobulinemic glomerulonephritis, Langerhans cell histiocytosis (LCH) and hemophagocytic lymphohistiocytosis (HLH). We present a case of histiocytic glomerulopathy without a readily identifiable systemic cause.

Case Description: A 67-year female with recent cholecystectomy presented with abdominal pain and nausea. She was noted to have elevated alkaline phosphatase levels (1000 U/L) but with normal AST/ALT. She subsequently developed anasarca and anuric kidney failure requiring dialysis. Kidney biopsy showed diffuse macrophage foam cells positive for CD68 in glomeruli (image-1). Immunohistochemistry stains for CD1a and Langerin were negative making Langerhans cell histiocytosis unlikely. A bone marrow biopsy showed rare hemophagocytic macrophages. A broad serologic work up was performed and was mostly unremarkable. Although serology showed elevated IL-2 receptor alpha, hyperferritinemia, hypertriglyceridemia, and bone marrow with hemophagocytic macrophages; she did not meet full criteria for HLH. Due to concern for hypersensitivity reaction to metal clips placed during her cholecystectomy, she underwent laparoscopic removal. She was started on high dose methylprednisolone and then oral prednisone. Renal function improved and dialysis was discontinued.

Discussion: Histiocytic glomerulopathy is a rare entity categorized by the presence of macrophages in glomeruli. We present an idiopathic case which may have been triggered by a hypersensitivity reaction. Treatment options are limited and include steroids, plasmapheresis, and intravenous immunoglobulins (IVIG). Our patient responded to steroids in addition to removal of a potential underlying trigger. Six weeks after her initial presentation she remains off dialysis with excellent renal function.

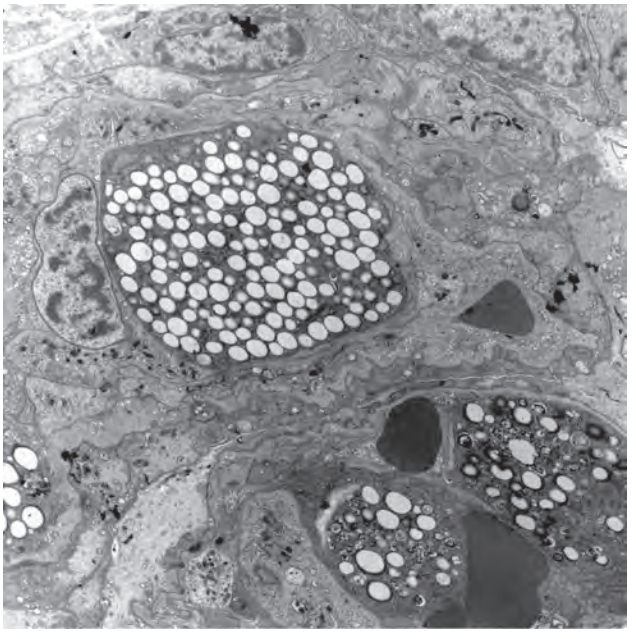


Image-1

TH-PO732

Tick-Borne Disease and Kidney

Ramandeep Kaur, Mushfique Choudhury, Jason R. Pettus, Thomas M. Kaneko, Clay A. Block. *Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: A case of IgA nephropathy presenting coincidentally with Lyme disease.

Case Description: A previously healthy 41-year-old man presented with 5 days of chest pain, fever, erythematous skin rash, myalgias and painless gross hematuria. Laboratory data showed serum creatinine of 1.22 mg/dL (reference range 0.8-1.5) and CRP of 44.4 mg/L (reference range < 4.9). Urine microscopy showed 8 WBC/HPF and 20 RBC/HPF including acanthocytes. Urine protein-creatinine ratio was 0.8. Creatinine kinase, P-ANCA, C-ANCA, MPO Ab, and PR3 Ab were negative. Lyme IgG and IgM were positive and consistent with active infection with B. burgdorferi. A renal biopsy was performed for persistent microscopic hematuria. Light microscopy was normal, but immunoflorescence (IF) showed 4+ mesangial granular staining for IgA, 2+ kappa and 3+ lambda. C1q, IgG, fibrinogen, albumin were negative. Electron microscopy (EM) confirmed electron dense para-mesangial deposits. A diagnosis of IgA nephropathy was made. In addition to Doxycycline, he was treated with steroid taper and lisinopril. One year later, his urine protein-creatinine ratio is <0.1 and CRP is <3.0 mg/L.

Discussion: Lyme Disease can trigger IgA nephropathy and should be considered in tick exposure. Patients presenting with hematuria and/or proteinuria may be tested for acute Lyme disease.

TH-PO733

A Podocyte-Specific Injury Mouse Model with Inducible Yamanaka Factors

Katharina Lemberg, Selina Hölzel, Florian Buerger, Gijs A. Franken, Caroline M. Kolvenbach, Ken Saida, Daanya Salmanullah, Konstantin Deutsch, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Ectopic expression of the *Yamanaka* transcription factors *Oct4, Klf4, c-Myc* and *Sox2* (OKMS) can reprogram somatic cells into pluripotent stem cells *in vitro* (Takahashi *Cell* 126, 2006). As shown recently for different tissues, *in vivo* expression of those factors can enhance regeneration and improve outcome after injury through partial cellular re-programming (Hishida *Cell Rep*. 39, 2022), even in non-mitotic cells (Lu *Nature* 588, 2020). In order to apply this approach to podocytes and examine effects of OKMS on podocyte regeneration, we employed a podocyte-specific injury model (Guo *J Am Soc Nephrol* 23, 2012) and crossed it with a conditional and inducible OKMS mouse model, thereby generating podocyte-specific expression of the *Yamanaka* factors.

Methods: We crossed the previously published inducible diphtheria toxin receptor-mouse (Buch *Nat Methods* 2, 2005) with a Podocin-Cre recombinase mouse (Moeller *Genesis* 35, 2003), and further with the ROSA26-rtTA(neo); OKMSCh250-mouse (JAX stock #031012). We induced OKMS-expression *in vitro* in extracted primary podocytes, as well as *in vivo* by 7-day application of doxycycline via drinking water. Furthermore, we determined urine albumin/creatinine ratios (ACR) and obtained histological samples to evaluate the extent of kidney injury after intraperitoneal diphtheria toxin (DT) injection in 5 different doses.

Results: To determine if OKMS can be induced, expression was first tested *in vitro.* Primary podocytes from $OKMS^{tg/WT}$; $rtTA^{fl/WT}$; Podocin-Cre^{+} - mice showed increasing *Oct4* and *Sox2* expression over time, but no expression of *Nanog* after 6 days and no decrease in podocyte-specific markers, whereas primary podocytes from a $OKMS^{tg/tg}$; $rtTA^{fl/WT}$; Podocin-Cre^{+} - mouse exhibited expression of *Nanog*, as well as a decrease of *Nphs1* and *Nphs2*, but an increase in *WT1*. *In vivo*, administration of 10 μg/kg and 7.5 μg/kg DT led to proteinuria with ACR levels over 50 g/g after 4 days as well as glomerulosclerosis and tubular casts on light microscopy after 4 weeks. Administration of 5 μg/kg, 2.5 μg/kg and 1.25 μg/kg showed later onset (d6), lower levels and, after 14 days, a reduction of proteinuria.

Conclusions: We, hereby, provide a suitable mouse model to study the effect of *Yamanaka*-expression in a podocyte-specific injury model.

TH-PO734

Deficiency of Melanocortin 5 Receptor Exacerbates Proteinuria and Podocytopathy upon Glomerular Injury

Bohan Chen, Yan Ge, Lance D. Dworkin, Rujun Gong. *The University of Toledo Department of Medicine, Toledo, OH.*

Background: Converging evidence suggests that therapeutic targeting of nonsteroidogenic melanocortinergic pathways represents a novel strategy for treating proteinuric glomerulopathies. However, the type of melanocortin receptor (MCR) mediating this beneficial effect remains controversial and uncertain. Recent work indicates that MC5R is expressed in glomerular cells and MC5R signaling may be involved in glomerular pathobiology. This study examined the possible effect of MC5R ablation in nephrotoxic serum (NTS)-elicited podocytopathy.

Methods: NTS nephritis was induced in MC5R knockout (KO) mice and wild-type (WT) littermates. Additional WT mice received treatment with a highly selective MC5R agonist or vehicle before NTS injury. Proteinuria, podocyte injury and glomerular damage were evaluated early in the heterologous phase of NTS nephritis.

Results: Despite no discernible phenotypes under physiological conditions, KO mice sustained exacerbated glomerulopathy upon NTS injury, as shown by heavier albuminuria. This was associated with worsened glomerular pathology, characterized by glomerular hypercellularity, swelling of glomerular endothelial cells, and fibrinoid necrosis of glomerular capillary tufts, although glomerular depositions of the glomerular basement membrane-reactive heterologous rabbit IgG and the C5b-9 membrane attack complex along the glomerular capillary loops were found to be comparable between the WT and KO groups after NTS insult. In parallel, KO mice exhibited more severe podocytopenia than WT mice after NTS injury, as evidenced by reduced numbers of WT-1 positive cells in glomeruli, as well as worsened podocyte injury, marked by loss of glomerular expression of podocyte homeostatic proteins such as podocin and synaptopodin. Conversely, to test if activation of MC5R signaling is sufficient to protect against NTS-elicited podocytopathy, WT mice with NTS nephritis were subjected to MC5R agonism by using a peptidomimetic selective agonist. This resulted in an attenuated proteinuria and an improved podocyte injury, as evidenced by preserved expression of podocyte marker proteins.

Conclusions: Our findings suggest that MC5R-mediated melanocortinergic signaling protects against proteinuria and podocytopathy upon glomerular injury, and may be harnessed as an actionable target for treating proteinuric glomerulopathies.

TH-PO735

Lower NBL1 Increases Kidney Function in a Glomerular Damage Model

Rei Bufi,[1,2] Susan M. Sheehan,[1] Ron Korstanje.[1] *[1]The Jackson Laboratory, Bar Harbor, ME; [2]UConn Health, Farmington, CT.*

Background: Increased serum levels of neuroblastoma suppressor of tumorigenicity 1 (NBL1) have been associated with a faster decline in kidney function in patients with diabetic nephropathy (DN), and *in vitro* experiments suggest higher NBL1 levels lead to podocyte apoptosis. We aim to test whether there is a causal relationship between NBL1 and CKD by manipulating *Nbl1* expression.

Methods: We generated an *Nbl1* heterozygous knockout (HET) model in the C57BL/6J background (homozygous knockout is not viable) and confirmed lower NBL1 levels in these mice. We tested two kidney damage models. In the first model, we induced tubular damage using a low-dose cisplatin protocol. In the second model, we induced glomerular damage by introducing a *Col4a5* mutation through breeding.

Results: In our tubular damage model, we did not find differences in renal phenotypes between the HET mice and wildtype (WT) littermates. Bulk RNA-seq also showed no differences between the two groups. However, in our glomerular damage model, HET mice have a higher glomerular filtration rate than their WT littermates. The kidneys show no difference in glomerular damage at the gross histological level, but a more detailed study of the podocytes is ongoing. In addition, bulk RNA-seq showed approximately 130 differentially expressed genes between the two groups, including *Jun, Junb, Fos, Fosb, Egr1, Egr2,* and *Egr3,* which encode transcription factors implicated in the pathogenesis of DN.

Conclusions: Our preliminary results suggest that NBL1 is causal for decreased kidney function only in the model defined by glomerular pathology. Our next steps aim to determine what drives increased NBL1 expression, and the source of serum NBL1.

TH-PO736

Podocyte-Specific NRF2 Activity Protects Against Adriamycin-Induced Kidney Injury

Hannah L. Hartman,[1] Corry D. Bondi,[1] Jiaxuan Wang,[1] Roderick J. Tan.[1,2]
[1]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [2]Veterans Health Administration, Pittsburgh, PA.

Background: NRF2 is a key regulator of antioxidant and detoxification pathways in the kidney. KEAP1 is an endogenous inhibitor of NRF2. Various cellular stressors alter KEAP1 binding to NRF2, leading to NRF2 nuclear translocation and upregulation of target antioxidant and detoxification genes. Unexpectedly, NRF2 enhancers increased proteinuria in CKD clinical trials. Our prior work also demonstrated that global NRF2 enhancement exacerbates proteinuria in mouse models of glomerular disease. The kidney cell(s) mediating these effects are not known. Since podocytes are key cells maintaining the glomerular filtration barrier, we hypothesized that podocyte-specific NRF2 activity exacerbates proteinuria and glomerular injury.

Methods: We generated podocyte-specific KEAP1 knockout mice (Podo-KEAP1 KO) by crossing *Podocin-Cre* mice with *Keap1* floxed mice. These mice exhibit increased NRF2 activity only in podocytes. We subjected Podo-KEAP1 KO and control littermates to either adriamycin or chronic angiotensin II infusion to induce glomerular injury and proteinuria. Kidney injury was assessed by histologic, biochemical, and molecular indices.

Results: Contrary to our expectations, Podo-KEAP1 KO mice were protected against adriamycin-induced kidney injury, as demonstrated by lower levels of proteinuria, the injury marker NGAL, and fibrosis. Results from glomerular isolates reveal significantly increased antioxidant (*Nqo1* and *Cat*) and a trend to decreased inflammatory responses (*IL-1β*) that may protect Podo-KEAP1 KO mice from adriamycin injury. However, in the angiotensin II model there was neither improvement nor worsening of disease.

Conclusions: Although prior work demonstrated that global NRF2 enhancement worsens proteinuric CKD, we now show that podocyte-specific NRF2 enhancement protects against adriamycin-induced injury. This may be due to a specific effect of podocyte NRF2 activity to reduce glomerular oxidative stress in this model. Lack of effect in the angiotensin II model suggests a different mechanism of injury. Non-podocyte effects must also mediate CKD exacerbation in both models when NRF2 is globally enhanced. Future studies will determine the cell- and disease-specific effects of NRF2 in CKD and whether podocyte-specific NRF2 can be targeted therapeutically.

14-3-3 Proteins Stabilize Vimentin and Actin Filaments to Maintain Primary and Foot Processes in Podocyte

Hidenori Yasuda, Yoshiyasu Fukusumi, Ying Zhang, Hiroshi Kawachi.
Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.

Background: 14-3-3 proteins are a ubiquitously expressed family of adaptor proteins. Despite exhibiting high sequence homology, several 14-3-3 isoforms have isoform-specific binding partners and roles. We reported that 14-3-3β interacts with FKBP12, a binding protein of tacrolimus, and synaptopodin (Syp) to maintain the structure of actin fibers in podocytes (Yasuda et al., FASEB J, 2021). However, the functions of 14-3-3 proteins in podocyte are not fully elucidated. The precise localization and differential role of 14-3-3 isoforms in glomeruli are also unclear.

Methods: mRNA expression of 14-3-3s in kidneys was analyzed with RT-PCR, and their localization was investigated with immunohistochemical analyses. The interaction of 14-3-3s was analyzed by immunoprecipitation assay with the lysate of cultured podocytes and HEK-transfected cells. The effect of 14-3-3 isoform-specific siRNAs was analyzed in cultured podocytes. The expression of 14-3-3s in podocyte injury models was analyzed.

Results: 14-3-3β and 14-3-3σ were abundantly expressed in glomeruli. 14-3-3β in glomeruli was restricted in podocytes. 14-3-3σ in glomeruli was expressed in podocytes and mesangial cells. 14-3-3β was dominantly co-localized with FKBP12 in the foot processes, and a part of 14-3-3β was co-localized with Par3 at the slit diaphragm. 14-3-3β interacted with Par3, and the interaction was decreased by the transfection of FKBP12. The interaction of Par3-Par6 was enhanced by the treatment of 14-3-3β siRNA (3 times to normal, $p<0.05$). The structure of F-actin was deranged (score 1.8 vs. 3.1 of normal, $p<0.05$), and process formation was impaired (46.5% to normal, $p<0.005$) in the podocytes treated with 14-3-3β siRNA. 14-3-3β and Syp expression was decreased in podocyte injury models. 14-3-3σ in podocytes was expressed in the primary processes. 14-3-3σ interacted with vimentin but not with the actin-associated proteins FKBP12 and Syp. The structure of vimentin fibers was deranged (65.2% to normal, $p<0.05$), and process formation was impaired (40.1% to normal, $p<0.005$) in the podocytes with 14-3-3σ siRNA. 14-3-3σ and vimentin expression was increased in the early phase of podocyte injury but was decreased in the late stage.

Conclusions: 14-3-3 proteins play the roles in maintaining the primary and foot processes by stabilizing vimentin and actin filaments in podocyte.

COVID-19 Unmasking Concurrent IgA Nephropathy and Minimal Change Disease

Rachel J. Roan, Jason N. Lam, David Chang. *Temecula Valley Hospital, Temecula, CA.*

Introduction: The existence of concurrences of Minimal Change Disease (MCD) and IgA nephropathy (IgAN) is exceedingly rare. This is an unusual case of COVID-19 unmasking a dual glomerulopathy of MCD and IgAN.

Case Description: 54-year-old Asian female presented with flu-like symptoms, worsening anasarca, and bubbly urine. She was hemodynamically stable on room air. Exam was pertinent for lung crackles, edematous eyelids, and +2 lower extremities edema. Labs showed BUN 50mg/dL, creatinine (Cr) 2.9mg/dL, and albumin 0.8mg/dL. Baseline Cr was 0.61mg/dL. Urine analysis showed >300mg/dL proteins with large blood and dysmorphic RBC. A spot urine protein 5065.9 mg/dL and Cr 389 gm/dL. COVID-19 was positive. Glomerulonephritis panel was negative. Kidney biopsy under immunofluorescence microscopy showed diffuse segmental granular mesangial staining +2 IgA. Electron Microscopy showed extensive effacement of podocyte foot processes (> 90%) with dense deposits in the mesangium. Concurrence of IgAN and MCD was diagnosed and she was started on prednisone and lisinopril.

Discussion: This highlights the rarity of the co-existence of two glomerular diseases with COVID-19. We postulate the likelihood that our patient had long-standing IgAN given the disease's indolent course, followed by the development of MCD from COVID-19 infections. There have been similar cases showing the concurrence of the two diseases, but there has been no report with COVID-19 infection. After treating the patient with steroids for total of 3 months, our patient was able to successfully remain in remission.

Selected Renal Cells Express a Podocyte-Parietal Epithelial Cell Transcriptome

Prakash Narayan, Andrew T. Bruce, Tim A. Bertram, Deepak Jain.
ProKidney, Winston-Salem, NC.

Background: Selected renal cells (SRCs) express podocyte, ureteric bud and cap mesenchyme markers and in models of chronic kidney disease (CKD) their administration is associated with improved glomerular barrier function, renal filtration, and preservation of renal microarchitecture and glomerular integrity. We tested the hypothesis that SRCs

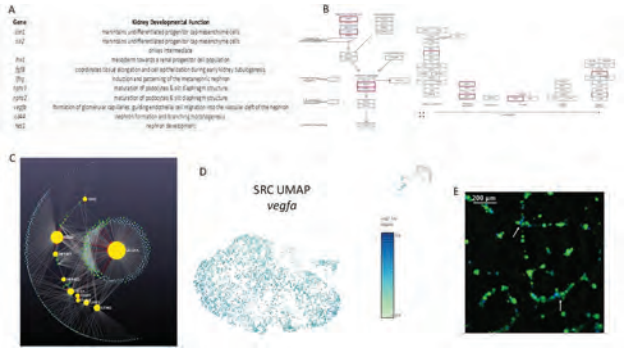
share a podocyte-parietal epithelial cell (PEC) transcriptome associated with renal repair and restoration.

Methods: The intersection set of podocyte-PEC genes (literature) and directionally aligned SRC genes were seeded into miRNet and Cytoscape for visualization of the shared transcriptome and identification of its functional attributes. Human SRCs (National Disease Research Interchange kidneys) were submitted to scRNA-seq to map gene expression and placed in culture and the supernatant queried for secreted vascular endothelial growth factor A (VEGFA) and its angiogenic activity using a human umbilical vein endothelial cell (HUVEC) tube formation assay.

Results: *osr1*, *six2*, *lhx1*, *fgf8*, *lfng*, *nphs1*, *nphs2*, *vegfa*, *cd44* and *hes1* are expressed by both podocyte-PEC and SRCs and involved in kidney developmental functions including maintenance of undifferentiated nephron precursors, tube and nephron formation, maturation of the glomerular barrier and formation of the glomerular capillary bed (A, B). *Vegfa* emerged as the hub gene within this network (C). SRCs expressed *vegfa* (D) and secreted VEGFA (0.75 to 3.02 ng/mL, mean=1.45 ng/mL) whose angiogenic activity was evidenced by HUVEC tube formation (E).

Conclusions: A *Vegfa* anchored podocyte-PEC transcriptome expressed by SRCs may recapitulate events associated with kidney development and mediate the preservation or improvement of glomerular integrity, renal microarchitecture and renal filtration observed in CKD models.

Funding: Commercial Support - ProKidney



(A, B) SRCs express podocyte-PEC genes involved in kidney development including glomerular development. (C) The shared podocyte-PEC and SRC transcriptome. (D) *Vegfa* is expressed by SRCs whose secreted gene product is associated with tube formation in HUVECs (E, arrows).

TH-PO740

Podocyte Density, Rather than Podocyte Number per Glomerulus, Is Associated with Kidney Outcomes in Obesity-Related Glomerulopathy

Kotaro Haruhara,[1,2] Yusuke Okabayashi,[1] Takaya Sasaki,[1] Eisuke Kubo,[1] Vivette D. D'Agati,[3] John F. Bertram,[2] Nobuo Tsuboi,[1] Takashi Yokoo.[1]
[1]Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan; [2]Department of Anatomy and Developmental Biology, Monash Biomedicine Discovery Institute, Monash University, Clayton, VIC, Australia; [3]Columbia University Irving Medical Center, New York, NY.

Background: Obesity-related glomerulopathy (ORG) is a slowly progressive glomerular disease occurring in obese individuals. Podocyte injury and subsequent podocyte depletion are regarded as key processes in ORG progression. However, no previous study has assessed the longitudinal association between podometrics and long-term kidney outcomes in ORG.

Methods: Podocyte number per glomerular volume (podocyte density) and podocyte number per glomerulus (podocyte number) in ORG patients were estimated using model-based stereology. The associations between these podometrics at the diagnostic biopsy and subsequent kidney outcomes (30% decline in eGFR) were examined by log-rank tests and Cox proportional hazard analyses.

Results: Forty-one ORG patients with median age of 47 years, eGFR 63 mL/min/1.73m^2 were analyzed. At biopsy diagnosis, ORG patients with podocyte density below the median value were older, predominantly male, and had larger body surface area, higher proteinuria, larger glomeruli, and lower podocyte number than ORG patients with higher podocyte density. During a median follow-up period of 3.9 years, 16 (39%) ORG patients reached a 30% decline in eGFR. Kidney survival in patients with lower podocyte density was significantly worse than in patients with higher podocyte density ($P = 0.001$), but there was no significant association between kidney survival and lower vs higher podocyte number ($P = 0.3$). Cox hazard analyses showed that podocyte density, but not podocyte number, was associated with kidney outcome after adjustment for clinical factors, including age, sex, proteinuria, and eGFR.

Conclusions: Our results indicate that lower podocyte density, rather than lower podocyte number, is a high-risk factor for progression of ORG. Confirmation in other ORG cohorts and potential generalizability to other glomerular diseases will require further studies.

Deletion of Neph1: Important for Renal Filtration but Critically Decisive for Patterning of the Enteric Nervous System

Bernhard Dumoulin,[1,2] Badr Khbouz,[1,2] Tobias B. Huber,[1,2] Florian Grahammer.[1,2]
[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Hamburg Center for Kidney Health, Hamburg, Germany.

Background: The immunoglobulin superfamily (IgSF) is a diverse group of proteins defined by the presence of one or more immunoglobulin domains. Nephrin (*NPHS1*) and Neph1 (*NEPH1*) are two well-known members of the IgSF in the kidney. They are expressed on podocytes where they form the slit diaphragm through homophilic interactions between neighboring foot processes. While many reported mutations for *NPHS1* cause early-onset albuminuria leading to kidney failure, only two *NEPH1* mutations have been reported, resulting in later-onset albuminuria progressing to chronic kidney disease. Knockout (ko) models for *Nphs1* and *Neph1* both show albuminuria and perinatal death. However, it is unclear whether death is caused by the kidney phenotype. Nephrin is expressed in podocytes, pancreas, and cerebellum, while Neph1 has a broader expression in podocytes, lung, brain, heart, skeletal muscle, liver, pancreas, and gut.

Methods: Podocyte specific conditional ko of *Nphs1* and *Neph1*, constitutive ko of *Nphs1* and *Neph1*, expression analysis using in-situ hybridization. Perinatal mice underwent μMRI analysis and examination of the olfactory bulb (OB) and enteric nervous system using immunofluorescence (IF) and 3D reconstruction.

Results: By utilizing podocyte specific conditional ko models of *Nphs1* and *Neph1*, we can demonstrate that while *Nphs1*^{Pod} mice die perinatally, *Neph1*^{Pod} mice are viable with a median survival of 4.5 months, indicating that the kidney phenotype is not the cause of perinatal death. We found increased expression of *Neph1* in the OB of mouse embryos. Shortly after birth, we found Neph1 at the axon terminals of primary olfactory sensory cells in the ventromedial zone of the OB. We used olfactory marker protein (OMP) as an indirect marker for disturbed axonal guiding and found a condensed layer of OMP with insufficient transport to the specific glomeruli in *Neph1*$^{-/-}$ mice. Furthermore, μMRI of perinatal *Neph1*$^{-/-}$ mice revealed widened, fluid filled bowels. Using IF, we found a much wider ganglion network of the enteric nervous system in ileum and colon of *Neph1*$^{-/-}$ mice, suggesting a disturbed regulation of peristalsis.

Conclusions: We believe, this offers a plausible rationale for the perinatal mortality observed in *Neph1*$^{-/-}$ mice, as well as the low occurrence and hypomorphic characteristics of NEPH1 variants found so far in humans.

Identification of Intercellular Communication Involved in the Progression of Tubulointerstitial Fibrosis Common to Podocyte Injury and Ischemia-Reperfusion Injury Models

Atsuhiro Imai, Isao Matsui, Hiroki Okushima, Yusuke Katsuma, Ayumi Matsumoto, Satoshi Minami, Takeshi Yamamoto, Kazunori Inoue, Yoshitaka Isaka. *Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu Igaku Senko, Suita, Japan.*

Background: Tubulointerstitial fibrosis (TF) is the final common pathway of progressive chronic kidney disease. The fibrogenic niche, a specialized microenvironment that triggers the differentiation of myofibroblasts (MF), is one of the critical therapeutic targets for TF. However, it remains uncertain what kind of intercellular communication shapes the fibrogenic niche.

Methods: Podocyte-specific *Tln1* knockout (*Tln1* KO) in C57BL/6J background mice (*Tln1*$^{fl/fl}$ *Nphs2*^{rtTA} *TetO - Cre*) and an ischemia-reperfusion injury (IRI) model on C57BL/6 wild-type mice were used as animal models for TF. *Tln1*$^{WT/WT}$ *Nphs2*^{rtTA} *TetO - Cre* mice and sham-operated mice served as the controls. Kidney samples were collected on day 10 and week 5 after initiation of doxycycline induction for *Tln1* KO mice and on days 2, 5, and 14 for the IRI model. The kidney samples were subjected to several analyses, including single-cell RNA sequencing (scRNA-seq).

Results: Histological examinations and real-time PCR analyses confirmed the development of TF lesions at week 5 in *Tln1* KO mice and at day 14 in the IRI model. scRNA-seq analyses of a combined dataset from the two animal models identified 21 cell clusters. As TF progressed, clusters of injured proximal tubules (Inj-PT), impaired Henle's loops, MFs, and inflammatory cells appeared in common in both animal models. CellChat analyses of the inter-cluster communication revealed the closest communication between the Inj-PT and MF clusters. The communication between these two clusters included *Spp1-Itgb1/5* and *Pdgfa/b-Pdgfrb*, *Mdk-Sdc1/2/4*, and *Bmp6-Acvr1* signaling. The Inj-PT cluster expressed high levels of *Havcr1* that encodes kidney injury molecule 1.

Conclusions: These results indicated that *Havcr1*-positive proximal tubular cells communicate strongly with myofibroblasts in both animal models. Although further experiments are required, these intercellular communications may contribute to developing a fibrogenic niche.

TH-PO743

Interleukin (IL)-27-Induced Podocyte Injury in Minimal Change Nephrotic Syndrome (MCNS)

Chang-Yien Chan,[1,2] Henry H. Yang,[3] Yaochun Zhang,[1,2] Liangjian Lu,[2] Sharon Teo,[2] Kar Hui Ng,[1,2] Hui Kim Yap.[1,2] *[1]National University of Singapore Yong Loo Lin School of Medicine, Singapore, Singapore; [2]Khoo Teck Puat-National University Children's Medical Institute, National University Health System, Singapore, Singapore; [3]Cancer Science Institute of Singapore, Singapore, Singapore*.

Background: We have previously demonstrated that relapse in MCNS was associated with decreased monocyte expression of CD14 and downregulation of proinflammatory cytokines in lipopolysaccharide-stimulated monocytes. This study aimed to identify the dysregulated monokines in disease relapse and subsequently to investigate the proteinuria-inducing mechanism in an experimental rat model and cultured human podocytes.

Methods: Monocytes were isolated from 5 MCNS patients in relapse (MCNSrelapse) and remission (MCNSrem) using monocyte isolation kit II. Monocyte transcription profile was performed using Illumina Human Ref8 chips. Plasma IL-27 levels were measured in 14 MCNS patients in relapse and remission and 20 healthy controls. Experimental rat model was created through electroporation of IL-27 plasmid DNA in Wistar rats. The role of IL-27 in human podocytes was examined through cell RhoA/Rac1 and STAT1/3 activities. Statistical analysis was done using Mann-Whitney test and Wilcoxon signed rank test for paired data.

Results: Monocyte transcriptome in MCNSrelapse involved regulation of IL-1 signaling, RhoGTPases regulation of actin cytoskeleton, toll-interleukin receptor (TIR)-domain-containing adapter-inducing interferon-β (TRIF) and IFN-induction pathways. Analysis of monokine gene expression showed 2.7-fold increase in *IL27* expression in MCNSrelapse. Plasma IL-27 levels were also significantly higher in MCNSrelapse (1.56±0.19ng/ml) compared to MCNSrem (0.95±0.13ng/ml) (P<0.05) and controls (0.89±0.14ng/ml) (P≤0.01). Similarly, in an IL-27 overexpression rat model, both 24-hour urine albumin excretion (409±34 *vs* 251±34μg/24h, P=0.005) and plasma triglyceride levels (36±2 *vs* 27±2mg/dL, P=0.02) were significantly higher at Day 70, compared to control rats. This was associated with upregulation of glomerular pSTAT3 expression in IL-27 transfected rats. Additionally, IL-27 stimulation in human podocytes resulted in phosphorylation of both STAT1 and STAT3 as well as 1.56-fold increase in activated Rac1 levels.

Conclusions: corroborated in the IL-27 overexpression rat model demonstrating podocyte injury possibly through activation of STAT3 and Rac1 as shown on podocyte culture experiments.

TH-PO744

Disrupting Circadian Control of Autophagy Induces Podocyte Injury and Proteinuria

Lulu Wang, Han Tian, Junwei Yang, Lei Jiang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China*.

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage-renal disease. The decrease in podocyte number or density is associated with DKD progression. Currently, there is a lack of effective methods of protecting podocytes or improving damage. The circadian clock exists with a wide range of biological process and controls numerous aspects of physiology to adapt the daily environmental changes caused by Earth's rotation. The renal clock plays an important role in maintaining tubular function, but its effect on podocytes remains unclear.

Methods: Adult C57BL/6J mice and podocyte specific *Clock* knockout mice (podocyte-*Clock*$^{-/-}$) were used to construct the type II diabetes model in vivo. Primary podocytes were cultured in 30mM high glucose. Chromatin immunoprecipitation (CHIP) qPCR analysis and dual-luciferase reporter gene assay were used to elaborate association between *Clock* and autophagy.

Results: The rhythmic oscillations of *Clock* were disappeared in high glucose treated podocytes and in glomeruli from diabetic mice. The podocyte specific *Clock* knockout mice at age 3 months and 8 months showed deficient autophagy, loss of podocytes and increased albuminuria. Chromatin immunoprecipitation (CHIP) sequence and PCR analysis indicated *Clock* binding to the promoter regions of Becn1 and Atg12. ChIP-qpcr analysis also confirmed the binding of *Clock* and autophagy gene promoter reduced when exposed to high glucose. Deletion *Clock* in podocyte could aggravate podocyte injury and proteinuria in diabetic mice. The autophagy in podocyte-*clock*$^{-/-}$ diabetic mice was lower than that of control diabetic mice.

Conclusions: Our findings demonstrate that *clock*-dependent regulating autophagy is essential for podocyte survival. The loss of circadian control autophagy plays an important role of podocyte injury and proteinuria.

Funding: Government Support - Non-U.S.

TH-PO745

Reduced Glycolytic ATP Production Is Responsible for Irreversible Podocyte Injury in Nephrotic Syndrome

Masahiro Sugimura, Kayaho Maeda, Yuka Sato, Noritoshi Kato, Tomoki Kosugi, Shoichi Maruyama. *Department of Nephrology, Nagoya University Graduate School of Medicine, Nagoya, Japan*.

Background: Energy metabolism is essential for cellular function and homeostasis, and the kidney is a high energy-consuming organ, making it susceptible to injury during aberrant energy metabolism. Podocyte energy metabolism is also critical for homeostasis under physiological condition, but its role in stress condition, especially in nephrotic syndrome involving circulatory permeability factors, is unclear. Therefore, to clarify the role of energy metabolism in injured podocytes, we examined changes in podocyte energy metabolism by circulating humoral factors of minimal change disease (MCD) or focal segmental glomerulosclerosis (FSGS).

Methods: Cultured human podocytes were treated with biopsy-proven MCD and FSGS patients' or healthy subjects' sera, analyzed for cell apoptosis by flow cytometry, and real-time ATP production rates in glycolysis and mitochondrial respiration using a Seahorse Extracellular Flux Analyzer. In addition, metabolomic analysis of serum-treated podocytes by GC-MS was performed to obtain an overview of energy metabolism. Isolated mouse glomeruli from Adriamycin nephropathy were also evaluated.

Results: FSGS patients' sera significantly induced apoptosis in human podocytes compared to MCD patients' or healthy subjects' sera. There was a correlation between decreased glycolytic ATP production and the rate of cell apoptosis in podocytes treated with FSGS patients' sera. In addition, treatment with low concentrations of glycolytic inhibitors further induced podocyte apoptosis, despite increased mitochondrial ATP production in podocytes treated with MCD patients' sera. Metabolomic analysis also showed that glycolytic metabolites were reduced in podocytes treated with FSGS patients' sera compared to MCD. Glycolytic enzymes were also decreased in mouse glomeruli isolated from Adriamycin nephropathy.

Conclusions: These data suggest that irreversible podocyte injury is associated with disruption of metabolic compensatory mechanisms, particularly reduced glycolytic ATP production.

Funding: Government Support - Non-U.S.

STING Activation by Mitochondrial DNA Triggers Podocyte Injury in Diabetic Kidney Disease

Antonio M. Fontanella, Rachel Njeim, Judith T. Molina David, George W. Burke, Sandra M. Merscher, Alessia Fornoni, Alla Mitrofanova. Katz Family Division of Nephrology and Hypertension. *University of Miami School of Medicine, Miami, FL*.

Background: Diabetic kidney disease (DKD) remains the most common cause of end stage kidney disease in the USA, and is characterized by mitochondrial dysfunction, increased circulating serum mtDNA levels, and activation of STING, a DNA-sensing innate immune adaptor, expressed in podocytes. Mitochondrial DNA (mtDNA) has been previously described to activate STING signaling in renal tubular cells in DKD, leading to autoinflammation. We hypothesize that loss of mitochondrial transcription factor A (TFAM) and impairment of PTEN-induced putative kinase 1 (PINK1) mediated mitophagy triggers mtDNA leakage and causes podocyte injury in DKD.

Methods: 16-week-old control (db/+) and diabetic (db/db) mice were used. Glomeruli were isolated to determine the expression of OXPHOS complex subunits, TFAM, PINK1 and TOM20, a biomarker for mitochondrial mass. Mitochondrial morphology was evaluated by TEM. Free mtDNA levels were measured in plasma, urine and cytosolic fractions from kidney cortex. Treatment with nuclear DNA (nDNA) or mtDNA was performed *in vitro*(10 ng, 30 min) using immortalized control human podocytes and *in vivo* (5 mg/kg, 24h) using control and STING knockout mice, followed by pSTING/STING expression and phenotypical analyses.

Results: We found that db/db mice have decreased glomerular TFAM expression and increased PINK1 expression in the mitochondrial fraction of db/db mice kidney cortices. Mitochondria morphology was indicative of dysfunction on TEM analysis, which was confirmed by increased expression of OXPHOS complex II (SDHA), and loss of mitochondrial mass marker TOM20. Db/db mice were also found to have increased mtDNA in the cytosol of kidney cortices, as well as in blood and urine. Treatment with mtDNA led to increases in pSTING expression *in vitro* and the development of albuminuria and foot process effacement *in vivo*, while STING -/- mice were protected from renal injury.

Conclusions: Our data suggest that loss of TFAM accumulation of PINK1 contribute to pathologic leakage of mtDNA into the circulation and cytosol causing albuminuria and podocyte injury.

RIPK3 Promotes Mitochondrial Fission and Dysfunction via PGAM5-Drp1 Signaling During Diabetic Podocyte Injury

Jeong suk Kang,[1] Nam-Jun Cho,[1] Seong Woo Lee,[1,2] Ji-Hye Lee,[3] Samel Park,[1] Hyo-Wook Gil,[1] Seung Seob Son,[1,2] Donghyeong Lee,[1,2] Hee Seul Jeong,[1,2] Eun Young Lee.[1,2] *[1]Department of Internal Medicine, Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea; [2]BK21 Four Project, College of Medicine, Soonchunhyang University, Cheonan, Republic of Korea; [3]Department of Pathology, Soonchunhyang University Cheonan Hospital, Cheonan, Republic of Korea.*

Background: Receptor-interacting protein kinase (RIPK)3 is an essential molecule for necroptosis and its role in kidney fibrosis has been investigated using various kidney injury models. However, the relevance and the underlying mechanisms of RIPK3 of podocyte injury in DKD are poorly understood. In this study, we investigated the role of RIPK3 in kidney injury of DKD and elucidated the underlying mechanism.

Methods: We evaluated the association of RIPK3 on clinical indices of DKD in the kidneys from diabetic patients and animals. To investigate the role of RIPK3 in glomerular damage of DKD, diabetes was induced by a high-fat diet in *Ripk3* knockout (KO) mice and cultured podocytes were stimulated with high glucose with or without RIPK3 inhibitor GSK872.

Results: RIPK3 level was upregulated in podocytes and plasma from human DKD cohort. Such upregulation was correlated with podocyte loss, albuminuria, and poor renal outcome. RIPK3 deficiency in DKD mice improved albuminuria, podocyte numbers, and renal histopathological features including foot process effacement and glomerular basement membrane (GBM) thickening. Increased mitochondrial fragmentation, upregulated mitochondrial fission-related proteins such as phosphoglycerate mutase family member 5 (PGAM5) and dynamin-related protein 1 (Drp1), and mitochondria dysfunction were decreased in RIPK3-depleted diabetic podocytes both *in vitro* and *in vivo*. By contrast, RIPK3 overexpression was sufficient to decrease oxygen consumption rate and increase PGAM5 expression and mitochondrial fragmentation due to mitochondrial translocation of Drp1.

Conclusions: RIPK3 is associated with diabetic podocytopathy, likely by regulating mitochondrial fission via PGAM5-Drp1 signaling. Targeting RIPK3 might be a promising therapeutic option for treating DKD.

TH-PO748

Dapagliflozin Exerts Senomorphic Effects on Adriamycin-Induced Podocyte Injury via Modulation of Complosome

Giuseppe Castellano,[1,2] Min Li,[1] Deborah Mattinzoli,[1] Silvia Armelloni,[1] Masami Ikehata,[1] Carlo Alfieri.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: Recent clinical and experimental studies demonstrate that Sodium-glucose co-transporter 2 inhibitors (SGLT2i) exert reno- and cardiovascular protection independently of the hypoglycaemic effect. SGLT2i treatment rapidly reduces proteinuria preserving renal function in the long term. The mechanisms underlying the renal protection of SGLT2i are not fully understood. PODOs are the cornerstone of the glomerular filtration barrier, and podocytopathy is the principal cause of proteinuric glomerular diseases such as FSGS. In the present study, we attempt to verify if SGLT2i have a direct effect on Podocytes (PODO) after Adriamycin (ADR) injury investigating the underlying mechanisms.

Methods: Human-immortalized PODO and glomerular endothelial cells were used. Expression of SGLT2 Nephrin, Synaptopodin, p53, and $p21^{WAF1}$ on PODO was investigated with immunofluorescence (IF), Western Blotting (WB), and quantitative PCR (qPCR). After ADR damage, the SGLT2i (Dapagliflozin, Dapa) at 100 nM was used to treat PODO. The PODOs' actin cytoskeleton was evaluated. A PODO-endothelial cell co-culture device was used to test the albumin permeability (P_{alb}). Intracellular Complement activation (Complosome) was analysed by confocal microscopy.

Results: PODOs express SGLT2 receptor. Dapa significantly decreased P_{alb} provoked by ADR (ADR, 17%±5; ADR+Dapa, 2.5%±1, P<0.05) in vitro. Dapa repairs ADR-induced PODO injury by recovering of PODOs' F-actin, increasing Nephrin (mRNA: ADR, 0.04±0.01; ADR+Dapa, 0.29±0.13; P<0.05; protein: ADR, 0.21±0.02; ADR+Dapa, 0.57±0.3: P<0.05) and Synaptopodin (mRNA: ADR, 0.34±0.2; ADR+Dapa, 1.13±0.2; P<0.05; protein: ADR, 0.06±0.01; ADR+Dapa, 0.13±0.02; p<0.05). Importantly, Dapa down-regulates nuclear p53 (protein: ADR, 7.56; ADR+Dapa, 4.69) and $p21^{WAF1}$ (ADR, 1.93; ADR+Dapa, 0.76). Moreover, we found that ADR actives complosome with a significant increase in intracellular C5a but not C3a. Dapa can inhibit intracellular C5a activation, shifting from the intracellular compartment to the outer cellular membrane.

Conclusions: SGLT2i exerts senomorphic effects restoring ADR-induced PODO inflammation and counteract Podo senescence. The underlying mechanisms could be the inhibition of Complosome activation at the C5a level.

TH-PO749

The IgG Glycome Predicts Nephritis and Leads to Podocyte Injury in Systemic Lupus Erythematosus (SLE)

Rhea Bhargava,[1,2] Rohit Upadhyay,[1] Scott E. Wenderfer,[3] Jing Chen,[1] George C. Tsokos.[2] *[1]Tulane University School of Medicine, New Orleans, LA; [2]Beth Israel Deaconess Medical Center, Boston, MA; [3]The University of British Columbia, Vancouver, BC, Canada.*

Background: Lupus nephritis (LN) occurs in 50% of patients with systemic lupus erythematosus (SLE) for which we lack biomarkers, and an understanding of its pathogenesis. We have previously demonstrated that IgG in LN is aberrantly glycosylated and can injure podocytes.

Methods: We evaluated the IgG glycome by N-glycan profiling in a pediatric cohort of 40 children with SLE and 20 paired pre and post treatment LN samples using LS-MS Mass Spectrometery. We used enzymatic treatments to evaluate the role of glycans in podocyte injury. Data were analyzed using GEE analysis, Spearman test, t-test and regression analysis. Podocyte phenotype was evaluated by wound healing assay, cytoskeleton evaluation (F-actin) and podocyte specific proteins by RT-PCR and western blotting.

Results: We found that the overall glycosylation was reduced 6 months post treatment in patients with LN. Furthermore, those decorated with terminal galactose were increased while those with terminal sialic acid were reduced. In addition, neutral glycans were increased after treatment while negatively charged glycans were decreased. To evaluate whether these differences were due to treatment rather than LN activity, we analyzed the IgG glycome in SLE without LN, LN, LN in remission 6-month after treatment. We found that neutral glycans and negatively charged glycan chains changed with LN activity. Furthermore, the presence or absence of sialic acid and galactose correlated with parameters that influence active nephritis (renal SLEDAI, dsDNA, C3, cellular crescents and proteinuria). A switch from tri to bi -antennary complex type N-Glycans was noted in those with decling GFR. More interestingly, treatment of IgG with PNGase- F, which removes glycan chains, prevented cytoskeleton and motility changes in podocytes that were induced in LN. In addition, nephrin expression was preserved following PNG-ase treatment.

Conclusions: The IgG glycome in pediatric SLE patients is altered and is further aberrantly glycosylated in LN. The magnitude of change is associated with LN activity. More importantly, the glycans on IgG can lead to podocyte injury in LN. Our data shed light on the role of IgG glycosylation in the development of podocyte injury and propose the development of approaches using the IgG glycome to diagnose and monitor LN. Further, it highlights IgG glycosylation as an important pathogenic mechanism in LN.

Downregulation of TRPM4 and Consequent Increase in TRPC6 Activity Are Critical Initiation Events Leading to Podocyte Injury

Ying Zhang, Yoshiyasu Fukusumi, Hidenori Yasuda, Mutsumi Kayaba, Hiroshi Kawachi. *Department of Cell Biology, Kidney Research Center, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: TRPM4 was identified as a molecule downregulated in PAN nephropathy, a mimic of MCNS, by RNA-seq analysis. TRPM4, a member of TRP channels, is a monovalent cation channel, which facilitates Na+ influx, and consequently suppresses Ca2+ influx. We have reported that TRPM4 is restrictedly expressed at podocytes in glomeruli, and is mainly localized at the surface of the foot process just above the slit diaphragm. However, the function of TRPM4 in podocyte is not elucidated yet. TRPC6, a Ca2+ channel localized at the slit diaphragm, is also a member of TRP channels. It is accepted that increase in TRPC6 activity plays a critical role in several types of podocyte injury. However, no studies on the association of TRPM4 with TRPC6 have been reported.

Methods: Variants expression of TRPM4 was analyzed with RNA materials of human cultured podocyte. To analyze the relation between TRPM4 and TRPC6, gene silencing studies with siRNA were performed with cultured podocytes. The effect of 9-phenanthrol, a specific TRPM4 inhibitor on the expression of TRPC6 was analyzed. The kinetics of the expressions of TRPM4, TRPC6, and podocyte functional molecules were analyzed in cultured podocytes treated with adriamycin, a reagent that is capable of inducing FSGS-like podocyte injury by injection into rats.

Results: A unique TRPM4 variant, lacking exon 17, was expressed in podocytes. The expression of TRPC6 was altered in TRPM4-knockdowned podocytes, but TRPM4 expression was not altered in TRPC6-knockdowned podocytes. The 9-phenanthrol treatment clearly promoted the expression of TRPC6 (139.76% ± 5.49%, P < 0.05). TRPM4 was clearly downregulated (62.25% ± 7.74%, P < 0.01) and the expression of TRPC6 was increased (120.27 % ± 31.23%) at 14 hours after adriamycin treatment. At this time point, neither any morphological alterations nor altered expressions of podocyte functional molecules were detected yet.

Conclusions: The depletion assays with siRNAs suggested that TRPM4 is an upstream regulator of TRPC6. The study with 9-phenanthrol clearly showed that functional loss of TRPM4 promoted TRPC6 expression. It is conceivable that downregulation of TRPM4 and consequent increase in TRPC6 activity are critical initiation events leading to podocyte injury. TRPM4 is available as an early marker to detect podocyte injury.

TH-PO751

Nephrin, Podocin, and Neph1 Encoding mRNAs Are Dysregulated by Alternative Polyadenylation During Podocyte Injury

Monoj K. Das,[1] Amy Webb,[2] Claire Bryant,[3] Claire L. Moore,[4] Shipra Agrawal.[1]
[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]The Ohio State University, Columbus, OH; [3]Forge Biologics, Columbus, OH; [4]Tufts University, Medford, MA.

Background: Podocyte injury and proteinuria are hallmark characteristics of glomerular disease. Nephrin, Podocin and Neph1 are critical regulators of the structure and function of podocytes and the glomerular filtration barrier. We hypothesized that these important components of the slit diaphragm could be dysregulated at the level of mRNA processing during podocyte injury and glomerular disease.

Methods: Glomerular alternative mRNA polyadenylation was detected using APATrap analyses of the RNASeq data from puromycin aminonucleoside (PAN) and adriamycin (ADR)-induced nephropathy models of podocyte injury and glomerular disease, mimicking human minimal change disease (MCD) and focal segmental glomerulosclerosis (FSGS), respectively.

Results: *Nphs1* (encoding for Nephrin) mRNA presented with a significant shift from proximal to distal usage of the polyadenylation [p(A)] site in its 3' untranslated region (3' UTR) in both PAN (12.7% shift vs healthy control) and ADR (24% shift vs. healthy control) -induced glomerular disease models. The Nphs1 mRNA p(A) shift to distal site and lengthening of the 3'UTR during injury was also validated by 3' Rapid Amplification of cDNA Ends assay. In contrast, a reverse shift was detected on the *Nphs2* (encoding for Podocin) mRNA in the ADR-induced nephropathy model (9.2% shift vs healthy control) only. The p(A) shift in *Nphs1* mRNA to a more distal site during injury results in introduction of target sites for miRNAs (miR-376a-5p, miR-466c-5p and miR-466d), which might affect its localization, stability and translation. Neph1 mRNA also showed a shift to a more distal site (~13% shift vs healthy control) in both PAN and ADR -induced glomerular disease models, exposing additional 415 nucleotides to miRNA targeting. On the other hand, a shift in *Nphs2* p(A) site from distal to proximal during injury results in introduction of the p(A) site in its last coding exon upstream of the STOP codon, which might affect its stability by the mRNA non-STOP decay pathway.

Conclusions: Alternative mRNA polyadenylation of *Nphs1, Nphs2 and Kirrel* mRNAs during podocyte and glomerular injury could result in their altered levels or function, with potential implications towards the dysregulation of podocyte structure and function and disruption of glomerular filtration barrier.

Podocyte Injury in Human Primary Membranous Nephropathy: Evidence Supporting a Role for Complement

Valentina Bruno,[1] Carolina G. Ortiz-Sandoval,[1] Sarah M. Moran,[2] Daniel C. Cattran,[3] Christoph Licht.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]University College Cork, Cork, Ireland; [3]Toronto General Research Institute, Toronto, ON, Canada.*

Background: Primary membranous nephropathy (PMN) is the leading cause of nephrotic syndrome in adults and a common cause of end-stage kidney disease (ESKD). The Heymann's nephritis rat model of PMN shows that proteinuria is complement-mediated. However, the pathogenetic role of complement in human PMN remains unclear. We aim to demonstrate that complement activation can have both structural and functional effects on podocytes.

Methods: An in-vitro model of immortalized human podocytes (from Moin Saleem, Bristol, UK) was used for all the experiments. Cells were exposed to 25% serum of 19 PMN patients (from the Toronto Glomerulonephritis Registry). Complement deposition was detected by immunofluorescence (IF). As positive control, cells were pre-sensitized with anti-CD59 and exposed to 25% normal human serum (NHS) to induce complement activation. Changes in intracellular calcium were monitored using a fluorescent dye (Fluo 8-AM), acquiring images every 20 seconds (up to 10 minutes) by confocal microscopy. Calcium effects on mitochondrial membrane potential were measured by flow cytometry. Intracellular adenosine triphosphate (ATP) changes were analyzed by bioluminescence. Actin cytoskeleton re-arrangements were evaluated by IF. Wound healing assays were performed to study functional effects on cell migration.

Results: Incubation with 25% PMN serum led to deposition of both C3b and C5b9 on the cell surface, which was significantly higher compared to controls ($p < 0.05$). Complement activation induced a significant rise in the intracellular calcium levels. Loss of mitochondrial membrane potential was also observed, together with intracellular ATP decrease, disruption of the actin cytoskeleton and impaired cell migration. Effects of both structure and function of podocytes were reversed by inhibition of the terminal complement pathway.

Conclusions: Complement is active in PMN, leading to both structural and functional effects on podocytes. Effects can be reversed by inhibition of the terminal complement pathway. Further studies are needed to fully understand the consequences of complement activation on the podocyte energy machinery and the rationale for the use of complement inhibitors in PMN. Our research may identify novel molecular treatment targets with the potential of improved patient outcomes and quality of life.

TH-PO753

Podocyte Injury Marker EGR1 in Lupus Nephritis

Masahiro Okabe,[1] Kentaro Koike,[1] Nobuo Tsuboi,[1] Taiji Matsusaka,[2] Takashi Yokoo.[1] *[1]Jikei University School of Medicine, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan.*

Background: We have discovered that early growth response 1 (EGR1) is expressed in injured podocytes from an early stage in animal studies. Additionally, we have observed that EGR1 expression in podocytes correlates with proteinuria, urinary nephrin/podocin mRNA levels, and glomerular podocin expression in patients with glomerular diseases. These findings suggest that EGR1 could potentially serve as a marker of podocyte injury. The objective of this study is to investigate the relationship between EGR1 expression in podocytes and the activity of lupus nephritis (LN).

Methods: We recruited patients diagnosed with LN by kidney biopsy at Jikei University Hospital, Tokyo, between January 2001 and March 2020. Patients under 20 years and those with fewer than 8 glomeruli were excluded. We collected the SLE disease activity index (SLEDAI), estimated glomerular filtration rate (eGFR), and urinary protein excretion (UPE) levels from the patients' medical records during kidney biopsy. We measured the percentages of glomeruli with podocytes expressing EGR1 (%EGR1glo), sclerotic glomeruli (%GS), glomeruli with endocapillary hypercellularity (%Endo), and glomeruli with cellular/fibrocellular crescents (%Cres), as well as tubulointerstitial damage from the kidney biopsy specimens. %EGR1glo was compared with these parameters using Spearman's rank correlation coefficient, and %EGR1glo between LN classes was compared using the Kruskal-Wallis test. Multiple comparison corrections were conducted using Holm-Bonferroni method.

Results: Seventy-five patients were included in this study (84% female, median age 38 [interquartile range 31–50] years, SLEDAI 17 [14–22], eGFR 86 [60–103] mL/min/1.73 m^2, UPE level 1.49 [0.57–3.23] g/d, and %EGR1glo 14.3 [8.8–28.6]%). LN classes were 4% Class I, 8% Class II, 44% Class III, 36% Class IV, and 8% Class V. %EGR1glo showed correlations with SLEDAI, eGFR and UPE level (rho = 0.419, -0.358, and 0.45; P = 0.003, 0.018, and <0.001, respectively). In the histological analysis, %EGR1 was significantly higher in Class IV than in the other classes (vs Class I + II, P <0.001; vs Class III, P <0.001: and vs Class V, P = 0.004). %EGR1glo correlated with %Endo and %Cres (rho = 0.566 and 0.586; P <0.001 and <0.001, respectively), but not with %GS or tubulointerstitial damage.

Conclusions: EGR1 expression in podocytes was associated with the activity of LN, especially with acute lesions.

Podocyte Injury Induces Rapid Collagen Degradation Within Mesangial Cells

Taiji Matsusaka. *Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan.*

Background: Glomerulosclerosis, characterized by accumulation of extracellular matrix (ECM) proteins, is primarily caused by podocyte injury. In our investigation of mouse model of podocyte injury, we frequently observed mesangiolysis in sclerotic glomeruli. Our hypothesis is that mesangial collagen undergo degradation subsequent to podocyte injury. This study aimed to characterize the process of collagen degradation following podocyte injury.

Methods: Podocyte injury was induced in transgenic mice expressing hCD25 in podocytes through the injection of hCD25-directed immunotoxin, LMB2. Denatured collagen was visualized using Collagen hybridizing peptide (CHP), a specific binder of unfolded collagen chains, and imaged with LSM880. Collagenolytic activities was assessed by quenched fluorogenic DQ-Gelatin or DQ-Collagen IV.

Results: CHP staining was intensified in glomeruli seven days after the induction of podocyte injury preceding the establishment of sclerotic lesions. The intensity of glomerular CHP staining correlated with the severity of glomerular injury and was localized in mesangial cells labeled by Itga8. Notably, intense glomerular CHP staining was absent in decellularized sections, while hydroxyproline (HP) staining persisted (Figure). The primary CHP staining was partially co-localized with MEK1/2 or GAPDH, but not with LAMP1, a lysosome marker, or with ERp72, an ER marker, suggesting that CHP is present in the cytoplasm. Collagenolytic activity in glomeruli with podocyte injury was found to be elevated in parallel with CHP staining.

Conclusions: These findings indicate that podocyte injury triggers and promotes degradation of collagen and accumulation of denatured collagen within mesangial cells. Further investigation is required to elucidate the detailed process involved.

The Mouse Nephrotoxic Serum (NTS) Model to Screen Novel Drugs for Reversal of Podocyte Injury

Simon A. Hinke, Cassandre Cavanaugh, Matthew M. Rankin, Rong Meng, Katharine D'Aquino, Pavlos Pissios, Andrea R. Nawrocki. *Janssen Research and Development LLC, Spring House, PA.*

Background: Kidney podocyte drug targets are being studied for treatment of diabetic kidney disease (DKD) and chronic kidney disease (CKD), requiring screening models to triage agents for efficacy testing. Nephrotoxic serum (NTS) causes nephritis driven by immune complex-mediated inflammation of the kidneys. Methods of induction vary widely: kidney immunogen used, source of serum, presence of adjuvant or pre-immunization, dose of NTS, and/or mouse strain. A new batch of commercially available NTS (Probetex, San Antonio, TX) has been validated for rats but not mice. Characterization of this mouse model will facilitate rapid screening podocyte targeting agents for DKD/CKD.

Methods: An IV dose range of new Probetex NTS was tested in four strains of mice. Female C57Bl/6 and DBA/1 mice were chosen for more testing. Kidney injury model induction was tested using single or multiple sequential daily NTS injections. Disease model severity was assessed measuring serum creatinine, BUN, urine albumin to creatinine ratio (UACR) and Luminex Kidney Injury Panels. Upon establishing mouse strain sensitivity to NTS, the effect of clinically approved standard of care agents lisinopril or losartan to preserve kidney function was assessed.

Results: One dose of new NTS did not replicate reported body weight effects in mice; small UACR effects were noted but less than published literature. In contrast, two or three daily NTS injections caused an increase serum creatinine, BUN and UACR, with sensitivity of DBA1 mice being greater than C57 mice. Comparing fold-increase in UACR to PBS control mice, two doses of NTS induced 6.8±1.7 and 149±64 fold-increases, and three doses of NTS induced 217±36 and 292±117 fold-increases, in C57 and DBA1 mice respectively. Lisinopril or losartan treatment were both able to attenuate the NTS-induced kidney injury by over 65%, as assessed by UACR changes, in either 2- or 3-dose NTS injury paradigms in DBA1 mice, with a concomitant improvement in tissue histopathology.

Conclusions: The new Probetex NTS was validated for use in mice to generate a screening model for podocyte injury. The differential sensitivity of C57 vs DBA1 mice, and the ability to alter the disease severity in each model by modifying the NTS-injection protocol will permit tailoring the degree of injury relevant to the research question.

Nucleophosmin Translocation Detects Early Podocyte Injury

Seiya Urae, Zhiyong Wang, Sudhir Kumar, Joel M. Henderson, Steven C. Borkan, Laurence H. Beck. *Boston University, Boston, MA.*

Background: Podocyte loss is common in diverse glomerular diseases. However, the lack of injury markers limits elucidation of the pathophysiologic processes that cause podocyte loss. Nucleophosmin (NPM) mediates regulated kidney cell death, and its translocation from the nucleus to the cytosol is an early marker and trigger of ischemic injury in tubular epithelial cells. Based on these observations, we tested the hypothesis that NPM translocation reflects podocyte injury. In our preliminary study, we detected NPM translocation as a novel marker of podocyte injury in cell injury models, and in human glomerular disease.

Methods: In vitro, podocytes were exposed to diverse insults known to injure podocytes including oxidative stress, adriamycin, and hyper-osmolarity. NPM translocation was evaluated by immunofluorescence and immunoblotting of cytosolic podocyte extracts. To assess NPM translocation in humans, kidney biospy tissue from diabetic nephropathy patients was stained for NPM and established podocyte markers.

Results: NPM translocation was detected in cultured podocytes after oxidative stress, or exposure to either adriamycin, or hyper-osmolarity (Figure 1). Podocyte NPM translocation was also observed in patients with established diabetic kidney disease (Figure 2).

Conclusions: NPM translocation reflects acute podocyte injury in vitro and podocyte injury in diabetic glomerulopathy. Regulated cell death mediated by NPM may be a primary pathologic mechanism of podocyte loss. NPM is also a rational therapeutic target in glomerular diseases to reduce the dropout of the limited number of podocytes residing in the human kidney.

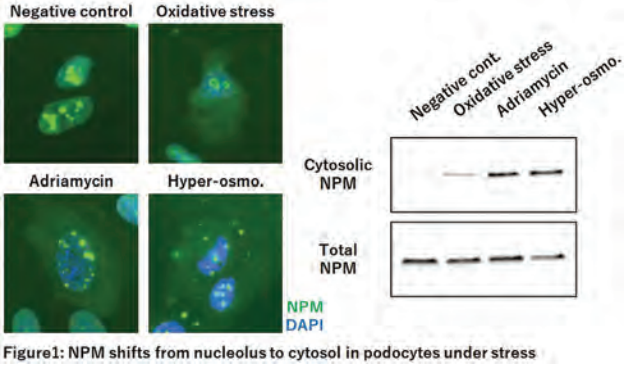

Figure1: NPM shifts from nucleolus to cytosol in podocytes under stress

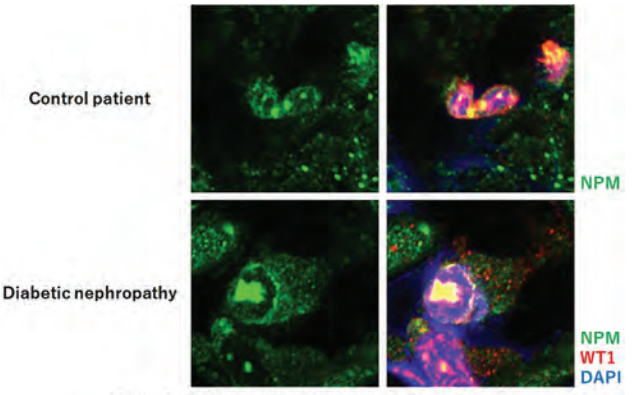

Figure 2: NPM translocation in diabetic nephrpathy

TH-PO757

Targeting Membrane Lipid Peroxidation Rescues Podocyte Dysfunction in Cystinosis

Sante Princiero Berlingerio,[1] Sarah Tassinari,[2] Tjessa Bondue,[1] Angela Ferrulli,[1,3] Celien Lismont,[1] Marc Fransen,[4] Sara Cairoli,[5] Fanny O. Arcolino,[6] Lambertus P. Van den heuvel,[1,7] Benedetta Bussolati,[2] Elena Levtchenko.[6] *[1]Katholieke Universiteit Leuven Groep Biomedische Wetenschappen, Leuven, Belgium; [2]Universita degli Studi di Torino Dipartimento di Biotecnologie Molecolari e Scienze per la Salute, Torino, Italy; [3]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [4]Katholieke Universiteit Leuven Groep Biomedische Wetenschappen, Leuven, Belgium; [5]Ospedale Pediatrico Bambino Gesu, Roma, Italy; [6]Amsterdam Universitair Medische Centra, Duivendrecht, Netherlands; [7]Radboud Universiteit, Nijmegen, Netherlands.*

Background: Cystinosis is a rare, incurable, autosomal recessive lysosomal storage disease caused by mutations in the *CTNS*$^{-/-}$ gene and leading to lysosomal cystine accumulation in all cells of the body. While cystinosis is considered as a prototype of proximal tubular dysfunction, the disease also affects glomerular podocytes and presents with increased podocyte losses into urine and glomerular proteinuria at early disease stages. Cysteamine, the current standard of care treatment, decreases lysosomal cystine accumulation but does not reverse podocyte injury. Thus, we aimed at investigating other pathogenic mechanisms than mere cystine accumulation involved in glomerular dysfunction in cystinosis.

Methods: Immortalized cystinosis patient-derived podocytes, healthy podocytes and *CTNS*$^{-/-}$ knockdown podocytes were used and the results were validated in our newly in-house developed fluorescent ctns$^{-/-}$ zebrafish larvae model (l-fabp:DBP-eGFP;CTNS). To understand the impaired podocyte functionality, static and dynamic permeability assay, tracer metabolomics analysis (LC-MS), flow cytometry, RT-qPCR, western blot, chemical and dynamic roGFP2 redox-sensing fluorescent probes were used.

Results: Cystinosis podocytes present decreased adhesion, increased permeability and enhanced ferroptosis cell death caused by an accumulation of mitochondrial ROS-driven lipid membrane peroxides. Moreover, these cells show fragmented mitochondrial network with impaired energy and TCA cycle metabolism and decreased expression of superoxide scavenging enzyme SOD2. Targeting mitochondrial ROS with MitoTEMPO in combination with cysteamine or lipid peroxidation with Liproxstatin-1 improved podocytes dysfunction *in vitro* and rescued proteinuria in cystinosis zebrafish larvae.

Conclusions: Mitochondrial dysfunction leading to increased ROS production and subsequent lipid peroxidation drive podocyte detachment and ferroptosis and plays a key role in podocyte injury in cystinosis. Targeting these mechanisms represents a new therapeutic prospective for nephropathic cystinosis.

TH-PO758

Exploring the Pathogenicity of an Anillin Coding Variant in Proteinuric Kidney Disease

Matthew Fischer,[1] Zie Craig,[2] Damian Fermin,[1] Celine C. Berthier,[1] Jamal El Saghir,[1] Maria Larkina,[1] Sean Eddy,[1] Matthias Kretzler,[1] Ann L. Miller,[2] Jennifer L. Harder.[1] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]University of Michigan Department of Molecular Cellular and Developmental Biology, Ann Arbor, MI.*

Background: Mutations in slit diaphragm proteins and regulators of actin dynamics are implicated in the pathogenesis of proteinuric kidney disease (protKD). Coding variants of Anillin (ANLN), a scaffolding protein found at slit diaphragms, have been associated with FSGS, but mechanisms are unknown. The aim of this study is to investigate the pathogenicity of ANLN coding variants identified in individuals with protKD.

Methods: Expression of ANLN relative to proteinuria was assessed in bulkRNAseq profiles of microdissected kidney tissues from NEPTUNE (n=238 glom, n=316 tub) and living donor (n=8, 10) cohorts. WGS data in NEPTUNE (n=620) were interrogated for ANLN coding variants; allele frequencies were compared to gnomeAD. Kidney organoids

(hKO) were generated from an iPSC line from a NEPTUNE participant harboring an ANLN coding variant and scRNA-seq (Sc) performed. Cell junction integrity and cytoskeletal dynamics were assessed by IF and live imaging in *Xenopus laevis* embryonic epithelial cells following morpholino knockdown of ANLN and replacement with ANLN WT or coding variant.

Results: Kidney tissue ANLN mRNA expression correlated with UPCR and negatively with eGFR. Ten previously uncharacterized variants of ANLN were found in 16 NEPTUNE individuals; 6 harbored one missense mutation (rs141247770) resulting in an I1109V substitution in the pleckstrin homology (PH) domain, which binds phospholipids. Sc profiling of hKO ANLN I1109V versus WT epithelial cells revealed perturbation of YAP and MAPK8 signaling pathways. Live imaging of *X. laevis* embryos expressing the ANLN variant revealed disrupted tight junction (ZO-1) integrity plus abnormalities in junctional F-actin and cell size and shape.

Conclusions: Our protKD cohort data are consistent with prior animal models showing that perturbed ANLN expression is associated with kidney disease. Functional studies in hKO and *Xenopus* models harboring the ANLN variant within the PH domain revealed disrupted cell-cell junction integrity, cytoskeletal dynamics, cytokinesis, and several dysregulated signaling pathways. Together, our findings reveal that alterations in both ANLN expression levels and function are critical in the pathogenicity of proteinuric kidney disease.

A Modular Intracellular Hierarchical-Responsive Nanocarrier Enables Dual Targeting for High Therapeutic Efficacy in Kidney Diseases

Aiqing Li, Zeng Tao. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: Single-drug nanocarriers that can improve targeting capability and reduce drug toxicity compared with free drugs demonstrate a promising strategy for disease treatment. However, due to cell heterogeneity during disease progression, dose-induced drug resistance, and instability of nanocarriers in the blood circulation, achieving dual targeting of different injured cell subsets while reducing drug dosage and maintaining treatment efficacy remains challenging. In addition, developing nanocarriers is a complex and time-consuming process; there is a desire for a universal nanocarrier for various diseases, especially complex diseases. Here, we have successfully designed a modular nanocarrier capable of co-delivering drugs with a reduced effective dosage of one-tenth that of single-drug nanocarriers.

Methods: The dual-drug targeting nanoparticles consist of three main modules: a PLGA nanoparticle, an antibody, and two drugs. We first constructed a 400 nm PLGA nanoparticle encapsulating drug A. Then, the podocyte-specific antibody Nephrin was modified onto the nanoparticle surface. Finally, drug B was coupled to the antibody. The dual-targeting dual-drug nanoparticles were injected into mice to evaluate their toxicity compared with free drugs. We explored the targeting of the nanoparticles using organ imaging and other methods. We established three kidney disease models in mice to compare the effects of dual-targeting nanoparticles at different concentrations.

Results: Dual-targeting nanoparticles loaded with different drugs demonstrated dual targeting of glomeruli and tubules. To treat acute kidney injury, the nanocarriers encapsulated rapamycin and dexamethasone acetate; for PAN, the drugs were rapamycin and captopril; and for the ccRCC model, gefitinib and glutathione were chosen as the targeted antitumor drugs. For different diseases, lesions were significantly treated with different drug combinations. We observed reduced tubular injury in the acute kidney injury model, recovered podocyte foot processes in the PAN model, and reduced cancer foci in the ccRCC model. These results show that dual-drug loaded nanomaterials have an excellent ability to address complex disease presentations.

Conclusions: The dual-drug delivery system can flexibly adapt to treating various diseases by modifying the particle size, surface antibodies, and drugs.

Oxysterol-Binding Protein-Like 7 Deficiency in CKD

Jeffrey D. Pressly,[1,2] Mario Schiffer,[4,3] Sandra M. Merscher,[1,2] Alessia Fornoni.[1,2] *[1]University of Miami Katz Family Division of Nephrology and Hypertension, Miami, FL; [2]University of Miami, Miller School of Medicine, Peggy and Harold Katz Drug Discovery Center, Miami, FL; [3]Mount Desert Island Biological Laboratory, Salsbury Cove, ME; [4]Universitatsklinikum Erlangen Medizinische Klinik 4 Nephrologie und Hypertensiologie, Erlangen, Germany.*

Background: OSBPs have been implicated in various processes such as cholesterol transfer from the endoplasmic reticulum to the Golgi, and cholesterol efflux. Previous studies have shown that OSBPL7 deficiency leads to decreased autophagy in other cell types, which may impact lipid trafficking and podocyte function. The purpose of this study is to investigate the role of OSBPL7 in chronic kidney disease and its potential as a therapeutic target. OSBPL7's involvement in autophagy and endoplasmic reticulum stress suggests that its deficiency may contribute to the development of CKD.

Methods: The study utilized immortalized mouse podocytes and a Tg[l-fabp: DBP:eGFP] zebrafish model to investigate the effects of OSBPL7 deficiency on the development of renal dysfunction in podocyte disease and measure the integrity of glomerular filtration. We determined OSBPL7 protein levels in metabolic and non-metabolic mouse models of CKD using western blot. OSBPL7 deficient podocytes and zebrafish were generated and the impact of OSBPL7 deficiency on ER stress markers, autophagy, lipid droplets, and proteinuria was analyzed.

Results: The results show that OSBPL7 protein levels were reduced in the renal cortex of metabolic and non-metabolic mouse models of CKD. OSBPL7 deficiency leads to an increase in apoptosis levels and ER stress markers in podocytes and a decrease in autophagic flux. Additionally, an increase in lipid droplet levels is observed in OSBPL7 deficient podocytes, but this increase was found to be cholesterol independent. Knocking down OSBPL7 expression in Tg[l-fabp:DBP:eGFP] zebrafish leads to increased proteinuria and a slight edema phenotype. The findings suggest that OSBPL7 plays a critical role in the regulation of autophagy and ER stress in podocytes and contributes to the progression of CKD.

Conclusions: This study sheds light on the important role of OSBPL7 in podocytes and its potential as a therapeutic target in CKD. The results indicate that OSBPL7 deficiency may lead to lipid accumulation inside the podocyte and contribute to the proteinuria observed in CKD. Further studies are needed to fully understand the mechanisms and to develop potential therapeutic strategies for treating CKD. In summary, this study provides new insights into the role of OSBPL7 in chronic kidney disease and directly implicated OSBPL7 deficiency to proteinuria in a zebrafish model.

Steroid-Dependent Minimal Change Disease in an Adult Responsive to Rituximab

William J. Assante, Aromma Kapoor. *Westchester Medical Center Health Network, Valhalla, NY.*

Introduction: The patient is a 30M diagnosed at age 27 with minimal change disease. His clinical course was complicated by multiple relapses following an initial treatment with full dose steroids (60mg per day) per clinical guidelines. He ultimately progressed to steroid dependent disease. Consequently, the patient was prescribed Rituximab, to which he showed a clinical and serologic response, with almost full remission of proteinuria.

Case Description: The patient was diagnosed with minimal change disease in 2019, and he was treated with a course of full dose steroids by his primary nephrologist. However, after steroids were tapered off, the patient suffered three more relapses of his minimal change disease over the course of the ensuing fourteen months. After the last relapse, steroids were unable to be weaned (remained on 5 mg PO daily). A CT scan of the chest returned unremarkable for lymphadenopathy or any findings suspicious for lymphoma. The patient sought a second opinion with a nephrologist at Westchester Medical Center. Upon initial evaluation in November 2020, urine protein to creatinine ratio (UPCR) was 3mg/g, with creatinine 1.06. He continued the aforementioned maintenance dose of prednisone 5mg PO daily. On follow-up in July 2021, the patient endorsed frothy urine, lower extremity swelling, and twenty pound weight gain. The patient had increased his dose of prednisone to 10mg PO daily prior to the appointment. Creatinine 0.86 and UPCR 4mg/g. Once again, he was started on full dose steroids for treatment, with subsequent improvement in proteinuria. However, by April 2022, the patient once again endorsed lower extremity swelling and frothy urine while on steroids. A repeat biopsy was performed that showed minimal change disease, with 40-89% effacement of the podocyte foot processes. The patient was subsequently given two doses of Rituximab 1gm IV for steroid dependent minimal change disease. Steroids were discontinued. Upon follow-up in February 2023, the patient's creatinine was 1.1 and UPCR 0.04mg/g.

Discussion: Minimal change disease is a rare clinical entity in adult patients. The patient in this case presented with relapsing minimal change disease (confirmed by two separate biopsies) that ultimately became steroid dependent. This case provides an example of successful response to Rituximab as an alternate agent for minimal change disease in treatment resistant cases.

TH-PO762

Uncovering the Role of Cyclin G-Associated Kinase (GAK) in Regulating the Podocyte Cytoskeleton

Patricia Bunda, Xuefei Tian, Kazunori Inoue, Shuta Ishibe. *Yale University, New Haven, CT.*

Background: Podocytes are terminally differentiated epithelial cells that are integral components of the glomerular filtration barrier (GFB). These cells have specialized interdigitating structures called foot processes, characterized by an extensive network of actin filaments. Damage to podocytes leads to cytoskeletal reorganization and morphological changes, which ultimately result to foot process effacement and disruption of the GFB. In 2020, our group previously identified subsets of chronic kidney disease (CKD) patients with significantly reduced expression of cyclin G associated kinase (GAK).

Methods: We subsequently generated a podocyte specific *Gak* knockout mouse (*Gak*$^{fl/fl}$ *Pod-Cre-Dtr*^{fl}) mice, which developed foot processes effacement, progressive proteinuria, and profound glomerulosclerosis. To further interrogate the role of GAK in podocytes, we utilized a mouse model, which enables transgenic expression of a truncated GAK protein consisting only of the 62-kDa C-terminus end (*Gak*-C62$^{+/-}$). We then generated the C62/*Gak* KO mouse model by crossing the *Gak*-C62$^{+/-}$ mouse to our podocyte specific *Gak* KO mouse.

Results: Interestingly, our preliminary data showed that the C62/*Gak* KO mice rescued the proteinuria and glomerulosclerosis phenotypes, and podocyte foot processes were also maintained, suggesting a novel role of the C-terminal domains of GAK in cytoskeletal regulation in podocytes. Furthermore, *in vitro* analysis of cell morphology indicates disruption of cytoskeletal structure of *Gak* KO podocytes compared to wildtype controls. *Gak* KO podocytes form long spindles as opposed to the stellate shaped wildtype

podocytes. This morphological change in vitro was again rescued in podocytes isolated from the C62/*Gak* KO mouse. To elucidate the mechanism of rescue, we also performed a co-immunoprecipitation combined with shotgun proteomics experiment to identify potential binding partners of the C-terminus end of GAK. Remarkably, our results suggest a novel interaction between GAK and lymphocyte-specific protein 1 (LSP1), a known actin-binding partner, which was the top hit.

Conclusions: Together, these results further support the integral role of GAK, specifically its 62-kDa C-terminus in regulating actin dynamics in podocytes and may provide a novel target for treating CKD that specifically addresses podocyte dysfunction.

Soluble CD93 Contributes to Podocyte Activation in Minimal Change Disease

Colin D. Bauer,[1] Federica Piani,[2] Miguel A. Lanaspa,[2] Ana Andres-Hernando,[2] Petter Bjornstad,[1] Kazunari Kaneko,[3] Joshua M. Thurman,[2] Richard J. Johnson,[2] Gabriel M. Cara-Fuentes.[1] *[1]Children's Hospital Colorado, Aurora, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Kansai Daigaku, Suita, Japan*.

Background: Minimal Change Disease (MCD) is considered a podocytopathy, but subtle endothelial injury may also be present. CD93, a protein primarily expressed in endothelium, mediates focal adhesion kinase (FAK) activation in endothelium and can be shed during inflammation. We tested the hypothesis that glomerular endothelium releases CD93 that in turn activates podocyte FAK in MCD.

Methods: We tested for CD93 in human kidney tissue (immunofluorescence), urine and sera (ELISA) from 27, 57 and 48 children, respectively, with MCD during relapse. Patients without glomerular disease served as controls (n=9 for kidney tissue, n=19 for soluble CD93). We cultured human glomerular endothelial cells (GEnC) with human sera and measured CD93 (extracellular domain) in cell lysates by western blot. Additionally, we exposed GEnC to human sera and, following washing steps, we measured CD93 (ELISA) in serum-free supernatants. By co-immunoprecipitation, we studied CD93 and podocyte β1 integrin interaction. Human podocytes were also treated with recombinant CD93 (rCD93) and human sera, with β1 integrin (Mab13) and CD93 blocking antibodies, respectively, and we assessed FAK activation by western blotting.

Results: Compared to controls, CD93 expression was higher in MCD glomeruli and colocalized with endothelium ($p<0.0001$). Soluble CD93 was higher in urine (~10 fold) and serum (~1.5 fold) from MCD patients in relapse compared to controls ($p<0.0001$ for both). MCD sera in relapse stimulated cultured human GEnC to release CD93. CD93 was higher in supernatants and lower in cell lysates from GEnC previously exposed to MCD sera in relapse compared to controls ($p<0.01$). rCD93 bound to podocyte β1 and medaited FAK activation (Figure 1a, $p<0.05$ at 6 hours). MCD sera in relapse caused podocyte FAK activation, which was mitigated by adding a CD93 antibody to sera (Figure 1b, $p=0.01$).

Conclusions: MCD sera trigger the release of soluble CD93 from GEnC and this, in turn, contributes to podocyte activation.

The Direct Effect of Mycophenolate Mofetil on Podocytes in Nephrotoxic Serum Nephritis

Agnes Hackl,[1,2] Eva Nüsken,[1] Seif El Din Abo Zed,[1,2] Eva Wiesner,[2] Claudia Dafinger,[2,1] Katrin Bohl,[2] Matthias Hackl,[2,3] Kai D. Nüsken,[1] Lutz T. Weber.[1] *[1]Department of Pediatrics, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany; [2]CECAD, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany; [3]Department 2 of Internal Medicine, Faculty of Medicine and University Hospital Cologne, University of Cologne, Cologne, Germany*.

Background: Mycophenolate mofetil (MMF) is applied in proteinuric kidney diseases, but the exact mechanism of its effect on podocytes is still unknown. Our previous *in vitro* experiments suggested that MMF can ameliorate podocyte damage *via* restoration of the Ca^{2+}-actin cytoskeleton axis. The goal of this study was to characterize podocyte biology during MMF treatment in proteinuric glomerulopathy.

Methods: Nephrotoxic serum (NTS) nephritis (NTN) was induced in three-week old wild-type mice. On day 3, half of the mice were treated with MMF (100 mg/kgBW/d p.o.) for one week. On day 10, we performed proteomic analysis of glomeruli as well as super-resolution imaging of the slit diaphragm. For multiphoton imaging of Ca^{2+} concentration ($[Ca^{2+}]_i$), the experimental design was repeated in mice expressing podocyte-specific Ca^{2+} sensor.

Results: MMF ameliorated the proteinuria induced by NTS. We identified significant changes in the abundance of proteins involved in Ca^{2+} signaling and actin cytoskeleton regulation, which was further confirmed by direct $[Ca^{2+}]_i$ imaging in podocytes showing decreased Ca^{2+} levels after MMF treatment. This was associated with a tendency to restoration of podocyte foot process structure.

Conclusions: Here, we provide evidence that MMF has a substantial direct effect on podocytes. MMF contributes to improvement of $[Ca^{2+}]_i$ and amelioration of the disorganized actin cytoskeleton in podocytes. These data extend the knowledge of direct effects of immunosuppressants on podocytes that may contribute to a more effective treatment of proteinuric glomerulopathies with the least possible side effects.

TH-PO765

Loss of PRDM16 Aggravated Podocytopathies by Regulating Insulin Signaling

Qian Yuan, Ben Tang, Chun Zhang. *Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*.

Background: Podocytopathies are kidney diseases that are characterized by proteinuria or nephrotic syndrome due to direct or indirect podocyte injury. Our lab has investigated the effect of tubular PRDM16 on renal fibrosis. And we found that the expression of PRDM16 was abundant in healthy podocytes, however, decreased greatly in injured podocytes. In this study, we aim to clarify the function of PRDM16 on podocyte injury.

Methods: The expression of PRDM16 in the podocytes of podocytopathies patients and mice was detected by Western Blot, qPCR and Co-immunofluorescence staining. Podocyte-specific PRDM16 knockout mice were generated, and Streptozotocin-induced diabetic nephrology (DN) model was established. Kidneys, urine, and blood were collected. Lentivirus was used to overexpress PRDM16 in podocytes, and FSGS and DN animal models. Western Blot, qPCR, IHC, IF, electron microscope, urinary albumin to creatine ratio (ACR), Masson's staining, and PAS staining were used to verify the podocytes-protected role of PRDM16 in vivo and in vitro. RNA-sequencing, glucose intake assay, glycolysis detecting with seahorse bioanalyzer, ChIP, Co-IP, and luciferase assay were used to clarify the mechanism of PRDM16 on insulin signaling.

Results: The results showed PRDM16 was decreased markedly in the podocytes of Podocytopathies patients and mice. Renal injection with PRDM16 overexpression lentivirus decreased proteinuria and podocyte injury of Adriamycin nephropathy and DN mice. Podocyte-specific PRDM16 knockout diabetic mice showed more severe proteinuria and podocyte injury compared to $PRDM16^{fl/fl}$ diabetic mice. RNA-sequencing results revealed that insulin signaling changed obviously in PRDM16 overexpression podocytes. And we verified that PRDM16 promoted the transduction of insulin signaling and glucose metabolism by inhibiting the Ser307 phosphorylation of insulin receptor substrate-1(IRS-1) which was recognized and degraded by the ubiquitin-proteasome system. The mechanism of PRDM16 regulating the phosphorylation of IRS-1 was inhibiting the transcription of serine-threonine kinase, IKK-β.

Conclusions: Loss of PRDM16 in podocytes aggravated podocyte injury by inhibiting insulin signaling and successive glucose metabolism. Mechanistically, PRDM16 blocked the Ser307 phosphorylation of IRS-1 by downregulating the transcription of IKK-β.

PFKFB3 Downregulation Aggravates Angiotensin II-Induced Podocyte Detachment

Zhaowei Chen, Xiaoxiao Huang, Guohua Ding. *Renmin Hospital of Wuhan University, Wuhan, China*.

Background: Podocytes are known to play a critical role in the maintenance of normal glomerular filtration. However, the exact mechanism of podocyte loss remains unclear. Fructose-2,6-biphosphatase 3 (PFKFB3) is a bifunctional enzyme and has been demonstrated to play a crucial role not only in glycolysis, cell proliferation, and cell survival but also in cell adhesion. The purpose of this study is to evaluate the role of PFKFB3 in Angiotensin II (Ang II)-induced kidney injury.

Methods: Immunohistochemical staining and immunofluorescence double staining techniques were employed to determine the localization of PFKFB3 in podocytes. Western blot analysis was performed to assess the expression levels of PFKFB3, p-talin1, and ITGB1 in glomeruli. The adhesive capacity of podocytes was assessed using an adhesion assay. Western blot was conducted to evaluate the expression levels of p-talin1 and ITGB1 in podocytes. Flow cytometry was employed to assess the impact of PFKFB3 on podocyte apoptosis. To examine the impact of PFKFB3 on podocyte adhesion under Ang II treatment, pEnCMV-PFKFB3 plasmid and PFKFB3 siRNA were transfected into podocytes.

Results: PAS and HE staining of mouse kidney sections revealed significant glomerulosclerosis in the Ang II-infused mice. Urinary protein examination demonstrated that the angiotensin II-infused mouse model exhibited higher levels of proteinuria. Immunofluorescence staining and immunofluorescence double staining revealed that Ang II inhibited the PFKFB3 expression in both the cytoplasm and nucleus of cultured human podocytes. Western blot experiments further confirmed that Ang II inhibited PFKFB3, p-talin1, and ITGB1 expression in glomeruli. In vitro study, adhesion assay demonstrated that Ang II stimulation of podocytes resulted in decreased adhesion compared to the control groups. Inhibition of PFKFB3 further enhanced the suppression of p-talin1 and ITGB1 expression in podocytes induced by Ang II. Additionally, stimulation of podocytes with Ang II suppressed PFKFB3, leading to podocyte apoptosis. All these effects were significantly exacerbated following transfection with PFKFB3 siRNA. However, the overexpression of PFKFB3 alleviated these effects.

Conclusions: These findings suggest that Ang II leads to the decrease in podocyte adhesion by suppressing PFKFB3 expression and indicates a potential therapeutic target for podocyte injury in CKD.

TH-PO767

MHC Class I Molecules and Dendrin Are Upregulated in Primary FSGS Podocytes

Dries Deleersnijder,[1] Dora Bihary,[2] Ben Sprangers,[3] Björn K. Meijers,[1] Diether Lambrechts,[2] Amaryllis H. Van Craenenbroeck.[1] *[1]Katholieke Universiteit Leuven, Leuven, Belgium; [2]Vlaams Instituut voor Biotechnologie KU Leuven Center for Cancer Biology, Leuven, Belgium; [3]Ziekenhuis Oost-Limburg, Genk, Belgium.*

Background: The pathophysiology of primary focal segmental glomerulosclerosis (FSGS) is incompletely understood, and differentiation between FSGS subtypes remains challenging. We used single-cell transcriptomics to identify new pathways that are specifically deranged in primary FSGS podocytes.

Methods: We performed single-nucleus RNA-sequencing (10x Genomics Chromium) on cryopreserved kidney biopsy cores from patients with primary FSGS (n=9, all nephrotic), maladaptive FSGS (n=9, none nephrotic), proteinuric controls (PLA2R-positive membranous nephropathy, n=3), and healthy controls (pre-perfusion biopsies, n=4).

Results: We identified 194,594 nuclei, of which 3,660 were podocytes expressing canonical marker genes **(Figure 1A)**. Differential gene expression analysis between primary FSGS podocytes (n=1,635 nuclei) and all other podocytes (n=2,025 nuclei) showed significant upregulation of genes encoding major histocompatibility complex (MHC) class I proteins (*HLA-A, HLA-B, HLA-E, B2M*) and dendrin (*DDN*) (**Figure 1B-C**). Overexpression of MHC class I molecules has previously been observed in autoimmune diseases such as diabetes mellitus[1]. We hypothesize that presentation of self-antigens in primary FSGS podocytes via MHC class I proteins may either be an initiating event, triggering production of a pathogenic permeability factor, or alternatively an adaptive response to earlier podocyte injury. Dendrin, which interacts with slit diaphragm proteins, translocates to the nucleus in injured podocytes, triggering apoptosis in mouse models of FSGS[2], thereby making it a promising new target in human primary FSGS.

Conclusions: MHC class I molecules and dendrin represent two novel differentially expressed pathways that could aid in further distinguishing different FSGS subtypes.

Shear Stress on Podocyte Foot Processes Arising from Flow in Filtration Slits Studied by Numerical Flow Simulations

Alexander Fuhrmann,[1] Balazs Pritz,[1] Karlhans Endlich,[2] Wilhelm Kriz.[3] *[1]Karlsruher Institut fur Technologie, Karlsruhe, Germany; [2]Universitatsmedizin Greifswald, Greifswald, Germany; [3]Universitat Heidelberg, Heidelberg, Germany.*

Background: The glomerular filtration barrier is exposed to flow dynamic forces arising from filtration pressure (tensile stress) and filtrate flow (shear stress). Filtrate flow acts on podocyte cell bodies in Bowman's space and on foot processes (FPs) lining the filtration slit. Besides a previous estimate of 8 Pa (Endlich & Endlich, *Semin. Nephrol.* 2012), the magnitude of shear stress to FPs remains unknown.

Methods: We used numerical flow simulations to study forces arising from glomerular filtration. Simulations were run with a realistic model of a filtration unit and the corresponding filtration parameters of the rat kidney. The filtration unit consists of fenestrated endothelium, the GBM, and two opposing halves of FPs bridged by the slit diaphragm (SD). The GBM and SD were regarded as porous media.

Results: Modeling the GBM and SD as one homogenous porous medium, a peak wall shear stress of 65.2 Pa acting on FPs in the filtration slit was found; pressure dropped by 2.5 mm Hg across the SD. Increasing filtration slit width from 30 to 40 nm reduced peak wall shear stress by only 9% to 59.4 Pa. Modeling GBM and SD as two separate homogenous porous media with an increased viscous resistance of the SD further increased the pressure drop across the SD, but also wall shear stress on FPs. Two factors were revealed that may account for the high levels of wall shear stress: 1) convergence of filtrate flow out of the GBM into the filtration slit (similar to a nozzle), 2) transition from a porous medium (GBM, SD) with a rather uniform velocity profile into free flow (Bowman's space) with a developing parabolic velocity profile.

Conclusions: Our data demonstrate that FPs are likely to experience high levels of wall shear stress in the filtration slit that markedly exceed levels of endothelial wall shear stress. Shear stress on FPs represents the only flow dynamic force that directly tends to disconnect viable podocytes from the GBM—a hallmark of podocyte loss in many glomerular diseases.

TH-PO769

YAP and TAZ in Podocytes: Twins Distinguished by Single-Nucleus Transcriptomic Analysis

Lioba Ester,[1,2] Inês Cabrita,[1,2] Michel T. Ventzke,[1,2] Eva Wiesner,[1,2] He Chen,[1,2] Thomas Benzing,[1,2] Martin Kann,[1,2] Bernhard Schermer.[1,2] *[1]Universitatsklinikum Koln, Koln, Germany; [2]Exzellenzcluster CECAD in der Universitat zu Koln, Koln, Germany.*

Background: Podocyte homeostasis and the maintenance of the filtration barrier relies on the balanced activity of YAP and TAZ, the two effectors of the Hippo signaling pathway. Previous studies showed an increase of YAP and TAZ during glomerular disease. Additionally, specific deletion of YAP and TAZ in adult podocytes increases susceptibility to induced injury, suggesting a protective role. However, the exact molecular mechanisms underlying these observations remain unclear. Here, we investigate the individual roles of YAP and TAZ in podocytes *in vivo*.

Methods: We generated genetic mouse models in which YAP, TAZ, or both were knocked out specifically in podocytes (pKO). The mice were deeply characterized including kidney function, slit diaphragm morphology and survival. To gain insights into pathomechanisms leading to podocyte disease and to differentiate processes unique for YAP or TAZ we performed single nuclei RNA Sequencing (snRNASeq) of isolated glomeruli of mice of different ages and stages of disease.

Results: YAP pKO mice present a heterogenous disease onset until 12 weeks old, with a phenotype resembling focal segmental glomerulosclerosis (FSGS) with proteinuria and reduced slit diaphragm length. TAZ pKO mice displayed a tendency towards a reduced slit diaphragm length without developing proteinuria. Notably, when breeding mice to obtain both YAP and TAZ knockout alleles, no viable offspring was produced with less than two of the four YAP/TAZ alleles, suggesting compensational mechanisms. Immunostainings supported this hypothesis. The snRNASeq analysis revealed similar patterns in the YAP and TAZ pKO mice, further confirming their overlapping functions. Subsequent cell communication network analysis provided first evidence on disturbed signaling pathways that could contribute to the phenotypic differences observed between YAP and TAZ pKO mice.

Conclusions: While YAP and TAZ have a high level of similarity and are considered homologous twins, their roles in podocytes are distinct, as only the specific deletion of YAP leads to FSGS. Strikingly, combined YAP/TAZ activity above a certain threshold is indispensable for podocyte homeostasis, as the combined knock out is not viable. With this study we apply snRNASeq to elucidate shared, unique and compensatory functions of YAP and TAZ in podocyte homeostasis and injury.

TH-PO770

Multi-Ethnic Genome-Wide Association Study (GWAS) for Idiopathic Nephrotic Syndrome Identifies Susceptibility Loci Across the Life Span, Response to Therapy, and Genetic Ancestry

Yask Gupta,[1] Juntao Ke,[1] Gundula Povysil,[1] Michelle Mcnulty,[2] Gina Jin,[1] Matthias Kretzler,[3] Krzysztof Kiryluk,[1] Ali G. Gharavi,[1] Rasheed A. Gbadegesin,[4] Moin Saleem,[5] Martin Pollak,[6] Friedhelm Hildebrandt,[2] Matt G. Sampson,[2] Simone Sanna-Cherchi.[1] *[1]Columbia University, New York, NY; [2]Boston Children's Hospital, Boston, MA; [3]University of Michigan, Ann Arbor, MI; [4]Duke University, Durham, NC; [5]University of Bristol, Bristol, United Kingdom; [6]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Large-scale genetic association studies for idiopathic nephrotic syndrome cause by focal segmental glomerulosclerosis and minimal change disease are lacking, especially for forms of disease that are unresponsive to immunosuppressive treatment. To address this knowledge gap, we conducted a large-scale genome-wide association study (GWAS) for common variants with paired exome sequencing in order to assess the complex polygenic architecture of non-Mendelian INS.

Methods: This study consists of 5,600 INS cases across the life span, genetic ancestry, and response to therapy, compared to over 50,000 genetically matched controls. More than 80% of cases had paired exome or genome sequencing. GWAS was conducted first on the entire cohort and then in subgroups based on age of onset, ancestry, and response to therapy. Analyses were conducted again after removal of cases harboring diagnostic/pathogenic Mendelian mutations in known FSGS genes and *APOL1* high-risk genotypes. Ancestry specific GWAS were conducted using Regenie and Saige, metanalyses were conducted using Metal and TransMeta.

Results: Trans-ethnic metanalysis of all cases irrespective of age of onset and response to therapy showed the known association of *APOL1*, driven by individuals of recent African ancestry (OR= 2.67, P= 4.24 x 10^{-61}), association with the *HLA-DQA1* locus (OR=1.49, P= 5.91 x 10^{-24}) and with chromosome 4 (*LDB2*; OR=1.34, P= 4.48 x 10^{-9}). After removal of cases harboring pathogenic mutations causing Mendelian forms of

FSGS and *APOL1* HR genotypes, the strength for association to chromosome 4 increased and a novel locus on chromosome 15 reached genome-wide significance (*ADAMTSL3*; OR=1.53, P=2.73 x 10^{-08}). Ancestry-specific and sub-phenotype analyses according to the age of onset and response to glucocorticoid treatment resulted in validation and replication of loci for SSNS (*e.g. CALHM6, CLEC16A*), and several novel HLA loci (for adult SSNS and non-Mendelian SRNS).

Conclusions: Interim results demonstrate multiple novel loci for INS, including pleiotropic risk alleles that predispose to NS across different sub-phenotypes, and loci specific to ancestry, age of onset, and response to therapy.

TH-PO771

Regulation of Podocyte Adhesion by SEL1L-HRD1 ERAD via Integrin

Xiaoqiong Wei, You Lu, Ling Qi. *University of Michigan, Ann Arbor, MI.*

Background: Podocytes are specialized epithelial cells crucial for the kidney glomerular filtration barrier. They form interdigitating foot processes with neighboring podocytes in the kidney glomerulus to filter the blood. Adhesion of podocytes to glomerular basement membrane (GBM) is key to the formation of foot process and filtration function. Impairment of this process causes podocyte detachment, proteinuria and glomerulosclerosis in humans. While homeostasis in the endoplasmic reticulum (ER) has been generally recognized as important for cellular function, our understanding of ER homeostasis in podocytes remains unclear. Endoplasmic reticulum-associated degradation (ERAD) is the primary mechanism for the clearance of misfolded ER proteins by cytosolic proteasomal degradation. The SEL1L-HRD1 protein complex represents the most conserved ERAD pathway. However, the role of SEL1L-HRD1 ERAD in podocyte function remains poorly understood.

Methods: The podocyte-specific SEL1L-deficient mice were generated. Mouse body weight and survival curve were recorded. Urine samples from mice at 1, 3, and 5 weeks of age were collected to assess the abundance of albumin and WT1. Kidneys from wild-type (WT) and SEL1L-deficient mice were collected for ultrastructure observation by scanning electron microscopy (SEM) and transmission electron microscopy (TEM), the abundance and cellular location of the integrin subunit ITGA3 by immunofluorescence staining and western blot.

Results: Compared with WT mice, SEL1L-deficient mice showed lower body weight and premature renal failure with a median lifespan of 14 weeks. More albumin and detached podocytes were observed in SEL1L-deficient mice. Moreover, SEL1L-deficient mice showed damaged glomeruli and severe foot process effacement based on SEM and TEM. In terms of molecular mechanism, ITGA3, an important podocyte adhesion receptor, was accumulated in the ER, not exit to podocyte membrane, in the absence of SEL1L-ERAD.

Conclusions: Our data demonstrate SEL1L-ERAD regulates podocyte attachment on the glomerular basement membrane via degrading misfolded integrin subunit, ITGA3.

TH-PO772

Identification of Circular Dorsal Ruffles as Signal Platforms for the AKT Pathway in Glomerular Podocytes

Sei Yoshida. *Nankai University, Tianjin, China.*

Background: Circular dorsal ruffles (CDRs) are rounded membrane ruffles induced by growth factors to function as precursors of the large-scale endocytosis called macropinocytosis. In addition to their role in cellular uptake, recent research using cell line systems has shown that CDRs/macropinocytosis regulate the canonical AKT/mTORC1 growth factor signaling pathway. However, as CDRs have not been observed in tissues, their physiological relevance has remained unclear. Here, we first report that CDRs are expressed in glomerular podocytes *ex vivo* and *in vivo*, and we visually captured the transformation process to macropinocytosis.

Methods: Ultra-high resolution scanning electron microscopy (SEM) and confocal microscopy were used to see if CDRs are expressed at the surface of mouse glomerulus and isolated glomeruli. Podocyte cell line MPC5 was used for further imaging analysis as well as biochemical assays to test if CDRs regulate the Akt/mTORC1 pathway.

Results: High-resolution SEM of mouse kidney tissue showed that glomerular podocytes displayed CDR-like structures *in vivo* (Fig. 1A, arrows). In total, 21 glomeruli from five mice were examined using SEM. CDR-like structures formed in 25.38% of the podocytes (n=528). Moreover, epidermal growth factor (EGF) and platelet-derived growth factor (PDGF) induced CDRs in MPC5 cells. Inhibition of CDRs significantly mitigated GF-induced AKT phosphorylation and attenuated mTORC1 activation in cells. Confocal microscopy showed that AKT signaling components localized to CDRs. Importantly, we utilized isolated mouse glomeruli for *ex vivo* experiments and found that podocytes express CDRs as macropinocytic cups after EGF stimulation (Fig. 1B, arrows), regulating the AKT pathway.

Conclusions: Our results demonstrate the physiological role of CDRs as signal platforms for the AKT/mTORC1 pathway in podocytes at the tissue level. As mTORC1 plays critical roles in podocyte metabolism and aberrant activation of mTORC1 triggers podocytopathies, the outputs from this study strongly suggest that targeting CDR formation could represent a potential therapeutic approach for these diseases.

Dual Deletion of Guanylyl Cyclase-A and p38 Mitogen-Activated Protein Kinase (MAPK) in Podocytes with Aldosterone Administration Causes Glomerular Intracapillary Thrombi

Sayaka Sugioka,[1] Hiroyuki Yamada,[2] Akira Ishii,[1] Yukiko Kato,[1] Ryo Yamada,[1] Keita P. Mori,[1] Shoko Ohno,[1] Takaya Handa,[1] Akie Ikushima,[1] Takuya Ishimura,[1] Taiji Matsusaka,[3] Motoko Yanagita,[1] Hideki Yokoi.[1] *[1]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Primary Care & Emergency Medicine, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Department of Molecular Life Sciences, Tokai University School of Medicine, Isehara, Japan.*

Background: Previously, we demonstrated that podocyte-specific guanylyl cyclase-A (GC-A; natriuretic peptide receptor 1; NPR1) conditional KO (pod-GC-A cKO) mice with aldosterone exhibit podocyte injury, and that pharmacological inhibition of p38 MAPK ameliorates it. However, the effects of genetic deletion of p38 MAPK in podocytes have been unknown.

Methods: We generated podocyte-specific p38 MAPK and GC-A double cKO (pod-double cKO) mice, and treated them with aldosterone and high salt without nephrectomy (B-ALDO). Next, we focused on PAI-1 (SERPINE1) and administered PAI-1 neutralizing antibody to pod-double cKO mice. *In vitro*, we examined human podocytes in which p38 MAPK was deleted by CRISPR/Cas9 system and GC-A was suppressed by siRNA. Then, we cultured human p38 MAPK-null podocytes transfected with si-*NPR1* in the upper layer and wild-type glomerular endothelial cells (GE) in the lower layer, with PAI-1 inhibitor in the transwells.

Results: Unexpectedly, B-ALDO-treated pod-double cKO mice resulted in elevation of serum Cr, massive albuminuria and severe foot process effacement in addition to intracapillary fibrin thrombi indicating endothelial damage. PAI-1 was increased in podocytes and treatment with PAI-1 neutralizing antibody ameliorated intracapillary thrombus formation in B-ALDO-treated pod-double cKO mice. *In vitro*, knockout of p38 MAPK and suppression of GC-A in human cultured podocytes upregulated *SERPINE1*, *TGFB1*, and *FN1*. Deletion of p38 MAPK and inhibition of GC-A in podocytes in the upper layer upregulated *TGFB1* in the GE in the lower layer, indicating that some humoral factors derived from podocytes could work as cell-to-cell mediators. The treatment with PAI-1 inhibitor decreased *TGFB1* in both podocytes and GE.

Conclusions: Podocyte-specific deletion of p38 MAPK and GC-A exacerbated glomerular endothelial cell injury as well as podocyte damage which was ameliorated by PAI-1 neutralizing antibody. PAI-1 in podocytes is one factor that disrupts the podocyte-endothelial crosstalk, suggesting that p38 MAPK and GC-A play indispensable roles in podocytes.

TH-PO774

Podocyte Infolding Glomerulopathy: Insights from Proteomics by Laser Microdissection and Mass Spectrometry

Ling Hong,[1,2] Zhihua Zheng,[1] Wenfang Chen.[2] *[1]The Seventh Affiliated Hospital, Sun Yat-sen University, Shenzhen, China; [2]The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China.*

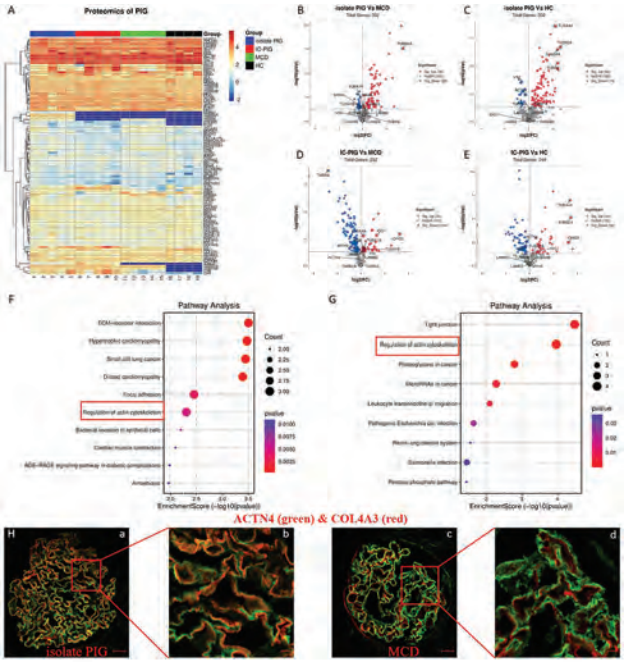
Background: Podocyte infolding glomerulopathy (PIG) is a newly recognized rare glomerular injury. The potential mechanism of this injury pattern remains unclear.

Methods: 10 cases diagnosed with PIG and 5 minimal change disease (MCD), 4 donor kidney biopsy specimens at Kingmed Diagnostics were analyzed by laser scanning microdissection and mass spectrometry (LMD/MS). The clinicopathological features, especially the ultrastructural changes were reviewed.

Results: 10 cases were divided into 2 groups according to immunofluorescence, IC-PIG (coexisting with immune-complex associated glomerulonephritis), and isolate PIG (without immunoglobulin or complement deposition). The underlying disease of IC-PIG included lupus nephritis in 4 cases, and membranous nephropathy in 1 case, while no known underlying disease was found in 5 cases of isolate PIG. Immunoglobulin gamma-1 heavy chain (IGG1) and Immunoglobulin heavy constant gamma 3 (IGHG3) showed significant differences in the IC-PIG group compared with the other two control groups. The differentially expressed protein, α-actinin4 (ACTN4), was detected by LMD/MS in 10 PIG glomeruli (P=0.005) compared with 9 controls, among the top 20 proteins. The displacement of ACTN4 into the GBM was confirmed by the confocal microscope. Interestingly, Tubulin Beta-4 Chain (TUBB4A) was only detected in the isolate group

compared with IC-PIG, normal donor kidney and MCD among the identified 302 proteins. Regulation of actin cytoskeleton signaling was screened out by the Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment.

Conclusions: PIG is a rare morphological change of podocyte injury with heterogeneous diseases. Podocyte cytoskeletal protein ACTN4 and TUBB4A were dysregulated which may involve in the mechanism of podocyte injury.



Mass spectrometry and confocal imaging.

Single-Cell Transcriptional Analysis Reveals the Effect of Anti-PLA2R and Anti-THSD7A Sera on Human Glomerular Cells

Stefano Da Sacco,[1] Qi Zhang,[1] Coralien Vink-van Setten,[3] Jack F. Wetzels,[3] Paolo Cravedi,[2] Laura Perin.[1] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Radboud Universiteit, Nijmegen, Netherlands.*

Background: Primary membranous nephropathy (MN) is a leading cause of nephrotic syndrome in adults due to the deposition of anti-podocyte antibodies in the glomerular subepithelial space. Several podocyte proteins have been identified as targets of these autoantibodies, with PLA2R and THSD7A the most prominent. We investigated the specific effect of anti-PLA2R and anti-THSD7A on glomerular cells using single cell transcriptomics on a human glomerulus-on-a-chip (GOAC) system.

Methods: GOACs were generated using human primary podocytes and glomerular endothelial cells and cultured with human serum from MN patient with anti-PLA2R or anti-THSD7A antibodies for 72 hours. Sera from healthy individuals were used as a control. Samples from three different individuals were used for each group. Albumin leakage assay was performed on GOAC to confirm injury. Single cell RNA-seq analysis (scRNA-seq) was performed on cells retrieved from the GOAC. Downstream analyses were done using UMAP, gene and pathway enrichment, and intra- and inter-cluster comparative transcriptomics.

Results: Exposure to anti-PLA2R and anti-THSD7A sera from MN patients induced injury on the GOAC as confirmed by albumin leakage. scRNA-seq analysis showed robust activation of the complement pathway in both cohorts. Preliminary analysis also suggested activation of podocyte injury pathways with changes in genes involved in slit diaphragm formation being more prominent in cells exposed to anti-THSD7A sera vs the anti-PLA2R. At the same time, GEC displayed an enrichment in genes involved in proliferation and metabolic changes under both conditions compared to healthy sera, suggesting a broader effect of MN sera that extends beyond direct podocyte damage.

Conclusions: The combined use of the GOAC and transcriptomics studies allows to investigate molecular and transcriptional changes affecting podocytes and GEC when both exposed to MN sera. This approach can help unraveling glomerular mechanisms of injury in MN, thus providing potential new targets for the treatment of nephropathies and other glomerular diseases.

Multi-Institutional Study of Anti-Nephrin Autoantibodies in Post-Transplant Focal Segmental Glomerulosclerosis Recurrence

Yoko Shirai,[1] Kenichiro Miura,[1] Kiyonobu Ishizuka,[1] Taro Ando,[1] Shoichiro Kanda,[2] Junya Hashimoto,[3] Yuko Hamasaki,[3] Kiyohiko Hotta,[4] Kenji Tanabe,[1] Tomoko Takano,[5] Motoshi Hattori.[1] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Tokyo Daigaku, Bunkyo-ku, Japan; [3]Toho Daigaku, Ota-ku, Japan; [4]Hokkaido Daigaku, Sapporo, Japan; [5]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.*

Background: Post-transplant recurrence of focal segmental glomerulosclerosis (rFSGS) is a major challenge in kidney transplantation. Recently, we reported very early pathological changes in podocytes and possible roles of circulating anti-nephrin antibodies (abs) in a patient with rFSGS (Hattori et al, Am J Transplant, 2022). To confirm these preliminary results, we performed a multi-institutional study.

Methods: 14 Japanese kidney transplant recipients with childhood-onset primary FSGS who had stored plasma samples and graft biopsy specimens were analyzed. All patients underwent whole exome sequencing and no pathogenic variants in FSGS-related genes were identified. Circulating anti-nephrin abs were measured by ELISA and the cut off levels were defined as 231 U/mL, the maximum antibody levels among the controls (9 genetic FSGS patients, 13 membranous nephropathy patients, 4 lupus nephritis patients and 13 healthy controls). Dual immunofluorescence staining of nephrin and IgG or ShcA, an adaptor protein of phosphorylated nephrin, was performed using the structured illumination microscopy.

Results: There were 10 rFSGS and 4 non-recurrent (non-rFSGS) patients. In rFSGS patients, median (interquartile range) anti-nephrin abs before transplant or during a post-transplant recurrence were markedly high at 950 (839, 1323) U/mL. Graft biopsies showed punctate IgG deposition co-localizing with nephrin that showed altered localization and increased expressions of ShcA. Eight of 10 rFSGS patients achieved remission, and graft biopsies after remission showed normal nephrin expression and no signals for IgG and ShcA. Anti-nephrin abs decreased to 261 (121, 398) U/mL in 4 patients with available samples at remission. In non-rFSGS patients, anti-nephrin abs were comparable with the controls regardless of the timing of sample collection. Their graft biopsies showed normal nephrin expression and no signals for IgG and ShcA.

Conclusions: Our results suggest that anti-nephrin abs are associated with rFSGS via nephrin phosphorylation. Larger studies including other ethnicities are required to confirm this finding and to determine the prevalence and incidence of post-transplant FSGS recurrence associated with anti-nephrin abds.

Exosomes Play a Pivotal Role in Linking Proteinuria to Glomerulosclerosis by Mediating Podocyte-Mesangial Communication

Zhao Liu, Xi Liu, Youhua Liu. *Southern Medical University Nanfang Hospital, Guangzhou, China.*

Background: Podocyte injury is the primary feature of the vast majority of glomerular diseases, while mesangial cell activation is the hallmark of glomerulosclerosis. How these two types of cells communicate in glomerular disease remains elusive. Exosomes act as membranous vesicle carriers and are involved in the pathogenesis of kidney disease by shuttling proteins and other materials between donor and recipient cells. Here, we tested whether exosomes play a role in mediating podocyte-mesangial communication in glomerular disease.

Methods: Exosomes secreted by injured podocytes were purified by differential centrifugation and characterized using nanoparticle tracking analysis and transmission electron microscopy. Differentially expressed proteins from podocyte-derived exosomes were analyzed by protein microarray, and sonic hedgehog (Shh) was identified as one of the most regulated proteins in the exosomes from injured podocytes. The potential role and mechanism by which exosomal-Shh mediates communication between podocytes and mesangial cells was investigated *in vitro* and *in vivo*.

Results: *In vitro*, we found an increased production of exosomes in mouse podocyte cells (MPC5) stimulated by angiotensin II (Ang II). Shh and activated N-Shh were encapsulated in exosomes isolated from Ang II-treated MPC5 cells (Ang II-Exo). The Ang II-Exo were able to induce the activation and proliferation of rat mesangial cells (RMC). In contrast, inhibition of exosome secretion with dimethyl amiloride, depletion of exosomes from conditioned medium or knockdown of Shh expression abolished the ability of Ang II-Exo to induce RMC activation. *In vivo*, the injection of podocyte-derived exosomes exacerbated glomerulosclerosis, which was negated by inhibitors of Shh signaling. Furthermore, blocking exosome secretion also ameliorated glomerulosclerosis following Ang II and adriamycin injury in mice.

Conclusions: Podocyte-derived exosomes play a critical role in mesangial cell activation and glomerulosclerosis by carrying Shh ligands. Therefore, strategies targeting exosomes may be a novel way to treat proteinuric kidney disease.

TH-PO778

Identification of Novel Small Molecules for Podocytopathies Using a High-Throughput Screen for KLF15 Agonists

Andrew Chow,[1] Yiqing Guo,[1] Nehaben A. Gujarati,[1] Bhaskar Das,[2] Sandeep K. Mallipattu.[1] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]Long Island University, Brookville, NY.*

Background: Krüppel-Like Factor 15 (KLF15) is a glucocorticoid-responsive, zinc-finger transcription factor that is critical for maintenance of podocyte differentiation. Previous studies demonstrate that podocyte-specific induction of *KLF15* attenuated kidney injury and improved overall survival in proteinuric murine models. Here, we developed a high-throughput screen (HTS) to identify novel KLF15 agonists for podocytopathies.

Methods: We developed a HTS using human podocytes expressing a dual reporter, firefly luciferase reporter directed at the *KLF15* promoter and renilla luciferase, and tested the NCI small molecule library (2642 compounds). Hit-to-lead optimization was conducted using a Structure-Activity Relationship (SAR) study. Lead KLF15 agonists were tested in cultured human podocytes and the proteinuric murine models: LPS, Nephrotoxic Serum (NTS) Nephritis, and HIV-1 transgenic (Tg26) mice.

Results: HTS assay exhibited high reproducibility with low variability (signal to background ~ 3.22 and a low Z-score ~ 0.56). We identified 16 hits with > 2.5-fold change in *KLF15* reporter activity and an EC_{50} < 100nM. Based on cell viability and "lead likeness" of the hits, SAR study was conducted to synthesize novel leads with improved efficacy and low cell toxicity. The novel lead, BT503, demonstrated improved cell viability in cultured human podocytes and reduced proteinuria and podocyte effacement in mice treated with LPS. BT503 treatment in NTS and Tg26 mice also attenuated kidney injury (proteinuria, serum creatinine, urea nitrogen), podocyte and glomerular injury, and interstitial fibrosis. Concurrent treatment with BT503 in cultured human podocytes and mice also reduced the dexamethasone dose required to restore podocyte injury. Subsequent RNA-sequencing, in-silico drug-docking studies, and western blot analysis in cultured podocytes demonstrate that the salutary effects of BT503 and induction of KLF15 are mediated through NF-kB signaling.

Conclusions: To date, this is the first study to develop a KLF15 HTS using human podocytes to identify and optimize novel small molecules, and subsequently demonstrate their therapeutic efficacy in cultured podocytes and proteinuric murine models with a mechanism of action.

SGLT2 Inhibitor Suppresses Progression of Obesity-Related Nephropathy Induced by Podocyte Hypertrophic Stress

Miho Suzuki, Akihiro Fukuda, Ryo Kurimoto, Hiroki Uchida, Akiko Kudo, Takeshi Nakata, Hirotaka Shibata. *Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan.*

Background: We recently reported that podocyte hypertrophic stress occurred relatively early during the onset of nephropathic progression in a rat model of type 2 diabetes-related nephropathy. In this study, we evaluated the progression of obesity-related nephropathy (ORN) caused by podocyte hypertrophic stress and the efficacy of an SGLT2 inhibitor (SGLT2i) in obese rat models.

Methods: To investigate the ORN progression, we used 8-week-old Zucker fatty (ZF) rats exhibited non-diabetic obesity model (n = 6), and Zucker lean (ZL) rats as a control model (n = 6). Kidney biopsies and urine samples were collected at 16, 24, and 32 weeks of age. Next, to investigate the effect of an SGLT2i, ZF rats were divided into two groups (SGLT2i: n = 6, non-treated: n = 6); beginning at 12 weeks of age, both groups were fed the same amount of diet. From 24 weeks of age, the SGLT2i group received canagliflozin 10 mg/kg/day for 8 weeks. Kidney tissues and urine samples were collected at 32 weeks of age. We measured urinary sediment podocin (U-sed pod) mRNA using qRT-PCR, glomerular volume (GV), podocyte volume (PV), and podocyte density (PD) to evaluate the podocyte injury.

Results: ZF rats were significantly heavier than ZL rats during the entire observation period. The urinary protein (UP) excretion level in ZF rats began to significantly increase at 16 weeks of age and became 20-fold greater than the level in ZL rats at 32 weeks of age. Significant increases in the GV, PV, and U-sed pod mRNA level, along with a decrease in PD, were observed in ZF rats from 16 to 32 weeks of age. Neither non-treated nor SGLT2i groups were hyperglycemic, and no changes in blood pressure occurred during the observation period. Compared with non-treated group, SGLT2i group exhibited significant weight loss, approximately 50% decrease in UP, significant reductions in the GV and PV, an increased PD ($p < 0.01$), and decreased U-sed pod mRNA ($p < 0.01$). SGLT2i group exhibited a significant increase in urinary sodium excretion ($p < 0.01$) and restored creatinine clearance to the level in control group.

Conclusions: Quantitative and morphological assessment of podocytes suggest that podocyte hypertrophic stress causes ORN progression. An SGLT2i may suppress podocyte hypertrophic stress by inhibiting glomerular hyperfiltration, and progression of ORN.

Cross-Talk of Injured Podocytes with Parietal Epithelial Cells Through Wnt4/β-Catenin Signaling

Christoph Daniel,[1] Eike Schwartze,[1] Eva Pfister,[1] Nicole Endlich,[3] Vedran Drenic,[3] Stuart J. Shankland,[2] Jeffrey W. Pippin,[2] Maike J. Buettner,[1] Kerstin U. Amann.[1] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]University of Washington, Seattle, WA; [3]Universitat Greifswald, Greifswald, Germany.*

Background: With changing demographics, chronic kidney disease (CKD) and its treatment have become a major public health concern. However, glomerulopathies such as FSGS have limited treatment options. Therefore, understanding the pathogenesis of these lesions, including gender differences, is critical to expanding therapeutic options.

Methods: Here we investigated podocyte injury and crosstalk with parietal epithelial cells (PECs) using both male and female transgenic rats expressing the human diphtheria toxin receptor (hDTR) in podocytes under the control of the podocin promoter. Podocyte injury was induced by injection of diphtheria toxin and disease progression/repair was assessed on days 3, 7, 14, 21. 28 and 42 by immunohistochemistry and real-time PCR. An in vitro podocyte injury model and PECs were used to further investigate the mechanisms of cellular crosstalk.

Results: After injection of diphtheria toxin into transgenic animals, we observed a loss of WT1-positive podocytes starting on day 7. The percentage of glomeruli with FSGS lesions and the number of Pax8-positive PECs on the glomerular tuft increased with time and correlated significantly ($r=0.927$, $p<0.001$). Interestingly, proteinuria at day 14 was approximately twice as high in males, and FSGS lesions and Pax8-positive cells on the tuft tended to be higher in males compared to females. From d14, both glomerular mRNA and protein expression of Wnt4 were increased, which was more pronounced in male animals. Wnt4 was localized in podocytes and beta-catenin in Pax8-positive lesions as shown by confocal microscopy. The Wnt4 target gene CD44 was strongly upregulated at d7 after model induction and then slowly increased after an initial decrease until the end of the experiment (d42). In cell culture, we confirmed that injured podocytes expressed and secreted Wnt4. Cell culture supernatants stimulated the expression of Wnt target genes Axin2 and beta-catenin in PECs but not in podocytes.

Conclusions: Taken together, these data suggest that the canonical Wnt/b-catenin axis plays a critical role in the crosstalk between PECs and injured podocytes and the subsequent migration of PECs onto the tuft. Furthermore, gender-specific differences in podocyte injury and regeneration appear to be, at least in part, Wnt4-mediated.

TH-PO781

Association of Minimal Change Nephrotic Syndrome with Mitochondrial Dysfunction in a Rat Model

Yuko Fujii,[1] Hideki Matsumura,[1] Tomoko Tanaka,[1] Satoshi Yamazaki,[1] Akihiko Shirasu,[2] Hyogo Nakakura,[1] Akira Ashida.[1] *[1]Osaka Ika Yakka Daigaku, Takatsuki, Japan; [2]Shiritsu Hirakata Byoin, Hirakata, Japan.*

Background: In recent years, it has been reported that mitochondrial dysfunction is associated with various renal diseases. However, the relationship between minimal-change nephrotic syndrome (MCNS) and mitochondrial dysfunction remains unclear. Here, using a rat model of MCNS, we examined changes in glomerular mitochondrial damage in response to increased urinary protein.

Methods: To prepare this MCNS model, male Wistar rats aged 6 weeks (n=18) each received a subcutaneous injection of 50 mg/kg puromycin aminonucleoside on day 1 and were euthanatized on days 4, 7, and 10 (n=6, respectively). Whole-day urine samples were collected from the rats on the day before euthanasia, and glomerulus and plasma samples were taken on days 4, 7, and 10 for measurement of protein, creatinine, markers of lipid peroxidation, and mitochondrial DNA content. The experimental protocol, including ethical aspects, was approved by the Osaka Medical and Pharmaceutical University Animal Care and Use Committee (approval number: 21096-A).

Results: Daily urinary protein excretion showed a gradual increase on days 3, 6, and 9 (median 18.1, 95.8, 279.1; interquartile range (IQR) 10.3-23.2, 74.3-103.0, 181.0-366.3 mg/dL, respectively; p=0.0006). The levels of plasma 4-hydroxynonenal were significantly lower on days 4 and 7 than on day 10 (median 0.73, 1.06, 3.29; IQR 0.48-1.12, 0.87-1.23, and 2.65-4.26 mg/mL; p=0.002). From day 4 to day 10, mitochondrial DNA levels decreased gradually (median 3278, 2867, 2369; IQR 3,200-3,360, 2,530-3,090, 2,068-2,937 pg/mL; p=0.01). There was a strong negative correlation between the amount of daily proteinuria and glomerular mitochondrial DNA content (r= -0.718, p= 0.008). Furthermore, glomerular mitochondrial damage was studied using transmission electron microscopy.

Conclusions: In this MCNS rat model, urinary protein excretion increased as glomerular mitochondrial dysfunction worsened. This suggests that glomerular mitochondrial dysfunction may be closely related to the pathogenesis of MCNS.

TH-PO782

Ezetimibe Restores the Communication Between Lipid Droplets and Mitochondria via Modulation of Plin5

Jin Ju Kim,[1] Judith T. Molina David,[1] Rachel Njeim,[1] Jeffrey H. Miner,[2] Sandra M. Merscher,[1] Alessia Fornoni.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Podocyte lipid accumulation contributes to glomerular diseases such as diabetic kidney disease (DKD) and Alport Syndrome (AS). These excess lipids, such as cholesterol and fatty acids, are esterified and stored as cholesterol ester and triglyceride in lipid droplets. Excessive FFA catabolism resulting from excessive lipolysis of TG is a major contributor to cell lipotoxicity. Perilipin 5 (PLIN5) is an LD-related protein that plays a critical role in regulating TG lipase activity and the interactions between LD and mitochondria, where it protects mitochondria from excessive exposure to FFA. Here we test the hypothesis that PLIN5 expresses in podocytes and that PLIN5 deficiency in AS causes excessive TG breakdown and the loss of LD-mitochondrial contact, thus contributing to kidney failure.

Methods: *In vitro,* Immortalized AS podocytes and WT podocytes were established and characterized in our laboratory by breeding the Col4a3KO mice (Jackson Laboratory) to H-2kb-tsA58 transgenic mice (Charles River). PLIN5 expression was determined by RT-PCR and western blot analysis in podocytes from Col4a3KO mice when compared to controls. TG lipolysis and FFA quantification were determined and normalized to protein content. LD-Mitochondrial contact was determined by TEM analysis. PLIN5 expression was studied in kidney cortexes, and the effect of Ezetimibe on PLIN5 modulation, on LD-Mitochondrial contact, and on podocyte injury was studied *in vitro* and *in vivo*.

Results: We demonstrate that PLIN5 is expressed in podocytes, and the expression of PLIN5 is significantly decreased in AS podocytes compared to WT podocytes ($p<0.01$). AS podocytes also showed significantly increased rates of TG lipolysis ($p<0.05$), intracellular free fatty acids ($p<0.05$), and apoptosis ($p<0.01$) when compared to WT podocytes. AS podocytes had a reduced number of LD-mitochondrial contacts ($p<0.05$), implying apoptosis. Moreover, Ezetimibe, which restored LD-Mitochondrial contact *in vitro* ($p<0.05$) and improved kidney function *in vivo*, was found to restore PLIN5 expression *in vitro* and *in vivo* ($p<0.05$).

Conclusions: Our study suggests that podocyte PLIN5 deficiency causes podocyte injury in AS through excessive TG lipolysis and inefficient FA transfer from LD to Mitochondria. Ezetimibe improves LD-mitochondria communication by restoring PLIN5 expression.

TH-PO783

Expression Evaluation of TRPC6 and PODXL Genes in Podocyte Cell Culture After Albumin Overload with and Without Puromycin-Aminoglycoside Damage

Mara S. Guaragna,[1,3] Marcela L. Souza,[1] Adriana S. Torsoni,[2] Vera Maria S. Belangero,[3] Maricilda P. de Mello.[1] *[1]State University of campinas, Center for Molecular and Genetic Engineering (CBMEG), Campinas, Brazil; [2]State University of Campinas, School of applied sciences, Limeira, Brazil; [3]Universidade Estadual de Campinas Faculdade de Ciencias Medicas, Campinas, Brazil.*

Background: Proteinuria is a prognostic marker for kidney disease and one of the main symptoms of podocytopathies. This study aimed to evaluate the relative expression of *TRPC6* and *PODXL* genes after albumin overload in podocytes *in vitro.*

Methods: Human podocyte cultures were exposed to progressive 0, 3, 20 and 40 mg/mL of albumin for 24h without and with 15 ug/uL exposure to puromycin aminoglycoside (PAN) for 12h. qPCR was performed with RPLP0 as endogenous control. The phenotype recovery was evaluated, either with gradual (removing 25% every 24h of total overload) or abrupt (removing all albumin in the first 24h) regression conditions. SDS-page and Western Blot were performed to evaluate protein expression. Statistical analysis was performed with ANOVA and Tukey's *a posteriori* test ($p<0.05$) (n=5).

Results: The rate of *PODXL* gene transcript was higher than control in 40 mg/mL of albumin without PAN and in 0, 20 and 40 mg/mL of albumin with PAN ($p<0.0001$). Phenotype recovery was observed after gradual removal of albumin overload at 20 mg/mL with PAN. Similar results were observed for protein expression, both in progressive and regressive conditions ($p<0.05$). For *TRPC6* gene, there was a decrease in expression after progressive albumin exposure with 3, 20 and 40 mg/mL without PAN ($p<0.0001$) and an increase expression in 20 and 40 mg/mL with PAN treatment ($p<0.0001$). Phenotype recovery was observed in gradual and abrupt regressive conditions.

Conclusions: When podocytes are injured, podocalyxin is released in vesicles that are excreted in the urine and used as an early glomerular disease biomarker. Therefore, we believe that this mechanism might explain why the phenotype was not recovered in the 40 mg/mL condition. Regarding *TRPC6*'s increased expression after PAN exposure, it might increase Ca^{+2} influx leading to apoptosis, aggravating podocyte damage after proteinuria insult.

Funding: Government Support - Non-U.S.

TH-PO784

Defects in CLVS1 Gene Increase Glycolytic Activity in Cultured Human Podocytes

Brandon M. Lane,[1,2] Adolya M. Moore,[3] Sue Zhang,[3] Hariel G. Peters,[3] Guanghong Wu,[1,2] Megan Chryst-Stangl,[1,2] Rasheed A. Gbadegesin.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]Duke Molecular Physiology Institute, Durham, NC; [3]Duke University, Durham, NC.*

Background: Increased oxidative stress is a common feature of chronic kidney disease. We have shown that the homozygous H310Y variant in the gene encoding clavesin-1 (*CLVS1*) is a cause of steroid sensitive nephrotic syndrome and disrupts podocyte endocytosis as well as binding of clavesin-1 to an antioxidant transporter. Human podocyte cells lines with CLVS1 knockout (KO) and homozygous H310Y knockin (KI) displayed increased levels of reactive oxygen species (ROS) and apoptosis that could be rescued by treatment with corticosteroids as well as ROS inhibitors. However, the precise effects of CLVS1 deficiencies on the metabolic profile of podocytes is unknown.

Methods: To identify differences in podocyte metabolic function due to deficiencies in *CLVS1*, we used an Agilent Seahorse XF Analyzer to examine *CLVS1* KO, homozygous *CLVS1* H310Y KI, corticosteroid treated *CLVS1* H310Y KI, and control podocytes. Assays designed to measure ATP production, mitochondrial respiration, and glycolysis were used to examine differences between cell groups (N=15 for each).

Results: *CLVS1* KO and H310Y KI podocytes displayed a more energetic cell phenotype compared to controls that included a higher level of overall ATP production and increased glycolytic activity ($p<0.0001$ for each). An almost two-fold increase in glycolysis, glycolytic capacity and glycolytic reserves were observed in KO and KI podocytes compared to controls ($p<0.0001$ for each). These levels were unaffected by steroid treatment. Differences in mitochondrial respiration were relatively minimal between control and *CLVS1* KO or KI podocytes. However, increases in non-glycolytic acidification and non-mitochondrial oxygen consumption were observed in KO and KI podocytes ($p<0.0001$ for each), suggesting that additional physiological abnormalities may be present as well.

Conclusions: Defects in *CLVS1* increase glycolysis-mediated ATP production in podocytes. Glycolysis is a key component of podocyte metabolic activity, particularly in foot process regulation and elevated ROS levels can induce a shift towards increased glycolytic activity. However, further studies are required to determine if this altered metabolic activity contributes to podocyte dysfunction due to deficiencies in *CLVS1* or if it is a survival response to other cellular abnormalities including increased ROS levels.

TH-PO785

Elucidation of the Molecular Mechanism of Albuminuria Improvement by Nonsteroidal Mineralocorticoid Receptor (MR) Antagonists Focusing on Podocyte Calcium (Ca2+) Dynamics

Tsukasa Iwakura, Kengo Kidokoro, Seiji Kishi, Hajime Nagasu, Naoki Kashihara, Tamaki Sasaki. *Kawasaki Ika Daigaku, Kurashiki, Japan.*

Background: MR activation in podocytes has been linked to the progression of glomerular and podocyte injuries in diabetic kidney disease (DKD). In the FIDELIO-DKD study, non-steroidal MR inhibitors showed a significant reduction in the development of renal outcomes compared to placebo. However, there are still many unknown aspects regarding MR activation in DKD. Transient Receptor Potential Canonical (TRPC)s, a Ca^{2+} channel in podocytes, has been implicated in various kidney diseases, including hereditary nephrotic syndrome. We hypothesized that increased TRPC activity and expression due to MR activation in podocytes contribute to glomerular damage in DKD. We investigated the molecular mechanism of finerenone's effect on improving albuminuria in DKD.

Methods: C57BL/6 mice (control) and diabetic Akita mice (Akita) were used in the study. Four groups were created: Control-Nx (Nx; one nephrectomized), Control-Nx+HS (high salt diet), Akita-Nx+HS, and Akita-Nx+HS+finerenone. The mice were sacrificed at 17 weeks of age, and specimens and tissues were analyzed. In vivo imaging using a two-photon laser microscope was performed to confirm changes in albumin leakage from glomeruli. Additionally, cultured podocytes were used to assess the effect of aldosterone (Aldo) stimulation on TRPC5 expression, reactive oxygen species (ROS) production, Ca2+ influx, and actin rearrangement. Podocin-GCaMP5/tdTomato mice, which specifically express the calcium sensor protein GCaMP in podocytes, were used to study the effect of Aldo stimulation on Ca2+ influx.

Results: The Akita-Nx+HS group exhibited abnormal podocyte morphology and significantly increased albuminuria. Increased intraglomerular ROS production was observed, along with clear albumin leakage from glomeruli. In cultured podocytes, Aldo stimulation induced increased TRPC5 protein expression, ROS production, Ca2+ influx, and actin rearrangement. Similar Ca2+ influx was observed in Podocin-GCaMP5/tdTomato mice. These changes were ameliorated by MR and TRPC5 inhibitors.

Conclusions: The study demonstrated that MR activation in podocytes contributes to glomerular damage in DKD through increased TRPC5 channel expression and activity. MR inhibitors like finerenone improve podocyte Ca2+ dynamics and reduce damage in DKD.

TH-PO786

Multidimensional Characterization of Renal Biopsies Integrating Podocyte Morphology with Clinical and Histopathological Features

Johannes Pospiech,[1] Tobias Bohnenpoll,[1] Philipp Skroblin,[1] Tim Endlich,[2] Olivier Radresa,[1] Nicole Endlich,[2] Uwe Andag.[1] *[1]Evotec International GmbH, Gottingen, Germany; [2]NIPOKA GmbH, Greifswald, Germany.*

Background: Podocyte foot process effacement and loss of glomerular filtration slits are common pathological changes observed in many chronic kidney diseases (CKD). Accurate measurement of podocyte morphology requires electron microscopy or advanced super-resolution light microscopy. Here, we used three-dimensional-structured illumination microscopy (3D-SIM) to quantify glomerular filtration slits in residual diagnostic biopsies of the NURTuRE CKD cohort. We integrated this measure of podocyte foot process morphology with other clinical and histopathological features to enable future precision diagnostics and patient stratification strategies.

Methods: Histological sections of formalin-fixed, paraffin-embedded kidney biopsies were stained for podocin and nephrin and analyzed using the 3D-SIM Podocyte Exact Morphology Measurement Procedure (PEMP). Filtration slit densities (FSD) and filtration slit lengths (FSL), which describe the density and extent of the glomerular filtration network, were derived from a median of 17 glomeruli per sample for 69 NURTuRE CKD patients of various etiologies.

Results: Quantification of podocyte morphology revealed different patterns of intra- and intersample variance with distinct, etiology-dependent distributions, likely reflecting common disease mechanisms. While samples from primary glomerular diseases showed a reduced median FSD and FSL with low intrasample variance, samples from secondary glomerular diseases showed high intrasample variance, suggesting distinct patterns of glomerular injury and disease progression. Moreover, podocyte morphology was strongly correlated with urinary protein and albumin creatinine ratios, but independent of other histopathological features, including glomerulosclerosis ratios and interstitial fibrosis and tubular atrophy scores.

Conclusions: Assessment of podocyte morphology in NURTuRE kidney biopsies supports FSD and FSL as independent and precise histopathological estimators of foot process effacement and glomerular integrity, revealing etiology-specific features of disease. Further integration of clinical time series and renal survival data, will uncover the potential of PEMP for kidney precision diagnostics and risk prediction.

Role of Colony-Stimulating Factor-1 Receptor in Driving Parietal Epithelial Cell Activation in Focal Segmental Glomerulosclerosis

Ana Amaya-Garrido,[1] Nuria Doladé Masot,[1] Anna Manonelles,[2] Cristian Varela,[1] Sergi Codina Sanchez,[2] Carlos Couceiro Monteagudo,[1] Josep M. Cruzado,[2] Anna Sola.[1] Endogenous Renal Regeneration, Inflammation and Aging (Nephrology and Renal Transplantation Group). *[1]Institut d'Investigacio Biomedica de Bellvitge, Barcelona, Spain; [2]Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Spain.*

Background: Parietal epithelial cells (PECs) are renal progenitor cells similar to bone marrow stem cell niches. In focal segmental glomerulosclerosis (FSGS), activated PECs contribute to extracellular matrix deposition. Colony stimulating factor-1 (CSF-1), a hematopoietic growth factor, acts through its specific receptor, CSF-1R, and has been implicated in various glomerular diseases. However, its role in PEC activation is still unknown. In this study, we studied the CSF-1/CSF-1R pathway in dysfunctional activation of PECs in FSGS.

Methods: CSF-1R expression was assessed in FSGS patient biopsies and in adriamycin (ADR)-induced FSGS mouse model. ADR-induced animals were further treated with specific CSF-1R inhibitors, GW2580 or Ki20227 (n=5-7). CSF-1R expression, localization in the glomerulus and its relevance to glomerulosclerosis were examined, as well as de novo CD44 formation and its correlation with the ERK1/2 pathway. Human kidney progenitor cells were treated with CSF-1 (n=6/group) to observe migration and proliferation changes and to identify potential key interactors of CSF-1 through RNAseq. Genes of interest were validated in the FSGS model.

Results: CSF-1R was upregulated in PECs and podocytes in FSGS biopsies. *In vitro*, results showed that PECs constitutively expressed CSF-1R. CSF-1 treatment induced CSF-1R upregulation and transcriptional changes in genes associated with PEC activation. CSF-1/CSF-1R activated the ERK1/2 pathway, upregulated CD44 while both ERK and CSF-1-R inhibitors reduced CD44 expression. CSF-1 promoted PEC proliferation and migration while suppressing podocyte differentiation. These results were validated in the ADR-induced FSGS model. Treatment with specific CSF-1R inhibitors demonstrated strong therapeutic effects. CSF-1 also promoted interferon (IFN)-related gene transcription in human PECs.

Conclusions: This study provides the first evidence of the involvement of the CSF-1/CSF-1R pathway in PEC activation in FSGS and suggests potential therapeutic use of CSF-1R inhibitors in FSGS treatment.

TH-PO788

AMPK Activation Ameliorates Angiotensin II-Induced Downregulation of Podocyte ZO-1

Tae-Sun Ha. *Chungbuk National University, Cheongju, Chungcheongbuk-do, Republic of Korea.*

Background: Angiotensin II (Ang II) promotes the development and progression of proteinuria and renal diseases and induces podocyte apoptosis. ZO-1 (zonular occludens-1) protein as a component of the slit diaphragm plays a pivotal role in glomerular permeability by connecting slit diaphragm structure and actin cytoskeleton. AMP-activated protein kinase (AMPK), as a sensor of cellular energy status, has been known to play an important role in the pathophysiology of metabolic diseases, including diabetes, and its renal complications. We investigated the role of AMPK on the changes of ZO-1 of podocyte induced by Ang II.

Methods: Mouse podocytes were incubated in media containing various concentrations of Ang II and AMPK-related agents. The changes of ZO-1 and permeability were observed by confocal imaging, western blotting, and permeability assay in the presence of Ang II.

Results: Ang II induced the fusion of microvilli and the gap pores on podocytes, which were improved by AICAR, an AMPK activator. Ang II also reduced and disrupted the intercellular ZO-1 staining, resulting in increased podocyte intercellular permeability. The intensities of fluorescences and bands of ZO-1 protein were decreased by Ang II in a dose-dependent manner by confocal microscopy and western blot analysis, respectively. AICAR and metformin, AMPK activators, ameliorated the abnormal distributional changes and the protein of ZO-1. Losartan, Ang II type I receptor blocker, also ameliorated the decrease of ZO-1 protein.

Conclusions: Our findings suggest that Ang II induces the relocation and suppression of podocyte ZO-1 via Ang II type 1 receptor which is ameliorated by AMPK-activating agents.

TH-PO789

Pre-Transplant Nephrin Autoantibodies Predict Post-Transplant Recurrent Focal Segmental Glomerulosclerosis (FSGS)

Astrid Weins,[1] Aghiles Hamroun,[2] Francois Provot,[2] Keith H. Keller,[3] Jean-Baptiste Gibier,[2] Andrew J. Watts.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Centre Hospitalier Universitaire de Lille, Lille, France; [3]Broad Institute, Cambridge, MA.*

Background: Recurrent Focal Segmental Glomerulosclerosis (FSGS) following renal transplant occurs commonly and can lead to early graft failure. Evidence supports a recipient derived circulating factor(s) that leads to early post-transplant recurrence however its identity has remained elusive. The recent discovery of nephrin autoantibodies in minimal change disease (MCD) lead us to hypothesize that nephrin autoantibodies pre-transplant may predict early recurrence in FSGS.

Methods: Single center retrospective study of 16 consecutive patients undergoing renal transplant for biopsy proven primary podocytopathy from the Centre Hospitalier Regional Universitaire de Lille between 2012 and 2019. Circulating anti-nephrin antibodies were evaluated pre-transplant by indirect ELISA. Recurrent FSGS was diagnosed on biopsy and the presence of nephrin antibodies was evaluated by immunofluorescence (IF).

Results: The median age of disease onset and transplant were 19 years (IQR 8.5-31.25) and 31 years (IQR 23.5-43.75) respectively. Disease recurrence was seen in half of the patients and occurred early, within 1 day, in 62.5% (n=5/8). One quarter (n=4/16) of the patients were serologically positive for nephrin autoantibodies at the time of transplant (Fig 1) and as expected, this was universally associated with disease recurrence (n=4/4) and constituted the majority, 80% (n=4/5) of those with early recurrence. There was complete concordance with anti-nephrin antibodies in the renal biopsies. Approximately one third (n=5/16) of the patients underwent pre-transplant plasma exchange (PE) and the majority (n=4/5) were serologically negative for nephrin autoantibodies. Post-transplant recurrence occurred in 2 of 5 patients and one of them was anti-nephrin antibody positive despite pre-emptive PE.

Conclusions: The presence of circulating nephrin autoantibodies at the time of transplant was universally associated with post- transplant early recurrence and were identified within the kidney disease. Our findings support an important role for nephrin autoantibodies in the pathogenesis of recurrent FSGS. In those patients undergoing pre-emptive PE this is would be an important biomarker to guide treatment as one patient who recurred despite PE has persistent circulating nephrin autoantibodies.

Characterization of a Novel Human Podocyte Cell Line as a Model for CKD Drug Development

Gang Zheng,[1] Shuyu Ren,[2] Eugene Myshkin,[1] Shanker Kalyana-Sundaram,[1] Nikolay O. Bukanov,[1] Maria Chiara Magnone.[1] *[1]Janssen Research and Development LLC, Raritan, NJ; [2]Pfizer Inc, New York, NY.*

Background: Podocytes are terminally differentiated epithelial cells which act as a crucial component to form the glomerular filtration barrier. There are a number of challenges in working with human and mouse podocytes in culture for drug discovery programs as most cell lines do not present a typical podocyte morphology that is comparable with the in vivo situation, and some of the podocyte markers are not expressed in these cell lines. In this study, we characterized a novel human podocyte cell line

PODO/TERT 256 from Evercyte that has several advantages over long-standing SV40 T antigen immortalized podocytes. We completed further evaluation of this cell line as a potential tool for target validation and drug discovery.

Methods: The mRNA expression of podocyte markers was detected using qPCR and the protein expression was confirmed by western blotting and immunofluorescence staining of cultured podocytes. Comparative RNA profiling with other cell lines was assessed by RNA-seq. The effect of podocyte injury was assessed using puromycin aminonucleoside. The cell viability study and adhesion assay were quantified using CellTiter-Glo. The adhesion of podocytes was evaluated using Laminin, a ligand for Integrin $\alpha 3\beta 1$.

Results: We showed, that in PODO/TERT 256 cell line, the key podocyte markers *NPHS1, SYNPO, PODXL, WT-1, KIRREL, KIRREL3* were detectable by qPCR. Expression of the nephrin, podocin, synaptopodin and podocalyxin proteins were confirmed by western blotting. The localization to the cellular membrane for synaptopodin and nephrin was confirmed by immunofluorescent staining. RNA profiling study indicated that this cell line possesses podocyte characteristics. Nephrin expression was stimulated by 12-O-tetradecanoylphorbol-13-acetate (TPA) and suppressed by glucose. The cells demonstrated susceptibility to puromycin aminonucleoside (PAN) induced injury. Cell adhesion assays confirmed the suitability of this novel podocyte cell line for functional studies.

Conclusions: Characterization of novel podocyte cell line PODO/TERT 256 (Evercyte) confirmed expression of multiple podocyte-specific markers on RNA and protein levels. This new podocyte cell line will become a powerful tool for identification of the novel therapeutic targets and discovery of the new drugs for CKD.

TH-PO791

Urinary Podocin Cell Count in Relation to Glomerular and Tubular Damage Markers in Patients with Primary Nephrotic Syndrome

Bartholomeus T. van den Berge,[1,2] Anne-Els van de Logt,[1] Jitske Jansen,[3,2] Bart Smeets,[2] Jack F. Wetzels,[1] Rutger J. Maas.[1] *[1]RadboudUMC Department of Nephrology, Nijmegen, Netherlands; [2]RadboudUMC Department of Pathology, Nijmegen, Netherlands; [3]RWTH Aachen Institute of Experimental Medicine and Systems Biology, Aachen, Germany.*

Background: Progressive renal failure in patients with glomerular disease is driven by podocyte depletion. Several methods have been proposed to monitor urinary podocyte loss. Here, we investigated the process of podocyte depletion in patients with primary membranous nephropathy (MN) by flow cytometric detection of Podocin-positive cells in urine.

Methods: We included 27 patients with MN. Urinary cell pellets were processed and stained for Podocin and subsequently counted using FACS. Urinary protein and creatinine levels were determined from the same portion of urine. Normal values of urinary Podocin-positive cells were obtained in urine samples of 13 healthy controls.

Results: Mean urinary podocyte count (Podocin-positive cells) was significantly higher in patients compared to healthy controls. Podocyte excretion showed significant correlations with urinary protein ($r = 0.71$), glomerular damage marker IgG ($r = 0.75$) and the tubular damage markers α1-microglobulin ($r = 0.66$) and β2-microglobulin ($r = 0.43$), all corrected for creatinine.

Conclusions: Urinary excretion of Podocin-positive podocytes was significantly increased in patients with MN, and correlated significantly with protein/creatinine ratios and glomerular and tubular damage markers. We conclude that this method can be used to monitor the process of podocyte depletion, and potentially the impact of treatment. We are planning prospective studies to evaluate the prognostic value of urinary Podocin$^+$ podocyte excretion in patients with PNS.

Value of Repeat Renal Biopsies in Lupus Nephritis in Two Large Inner-City Hospitals in New York

Nang San Hti Lar Seng,[1,2] Rosalba Y. Santana De Roberts,[1,2] Anitha Ramu,[3,2] Gopisree Peringeth,[1,2] Ladan Golestaneh,[3,2] Belinda Jim.[1,2] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Montefiore Medical Center, New York, NY.*

Background: Class transition is common in lupus nephritis (LN) patients and may affect treatment. While the initial biopsy is indicated for the diagnosis, the role of repeat renal biopsies during renal flares is controversial. We retrospectively evaluated the histopathological and treatment changes associated with repeat renal biopsies in LN patients.

Methods: Fifty-six LN patients with at least 2 renal biopsies were included at Jacobi Medical Center and Montefiore Medical Center in Bronx, NY. Statistical analysis was performed using STATA 18 (StataCorp).

Results: The study cohort consisted of 80.4% (45/56) female, 48.2% (27/56) Black, and 42.8% (24/56) Hispanic patients, with a mean age of 26.4 ± 13.1 at the initial biopsy. The most common LN classes were proliferative, accounting for 62.9% and 80.8% of the identified classes in the 1st and 2nd biopsies respectively. There were no differences between the mean activity indices between the 1st and 2nd biopsies (1.89 ± 2.11 vs 2.10 ± 2.07, p =0.666). Mean chronicity indices were significantly higher in the 2nd vs. 1st biopsies (5.05 ± 2.60 vs 2.69 ± 2.19, p <0.001). Class switch occurred in 52% (26/50) of the repeat biopsies. Among the proliferative classes, 35% (11/31) had class switch within the proliferative categories (mixed class to III or IV or vice versa, or III to IV or vice versa), 6% (2/31) transitioned to class V, and 3% (1/31) to class II. Eighty percent (8/10) of the mixed III/IV+V class remained histologically unchanged in the repeat biopsies. Among non-proliferative classes, 75% (6/8) transitioned to proliferative classes (III, IV, or III/IV+V). Class switch during flares occurred more frequently in the non-proliferative classes compared to the proliferative classes (63% vs 45%, p=0.013). In the end, 64% of patients had escalation in their immunosuppression, 17% had de-escalation, and 19% had no change.

Conclusions: Repeat biopsies were found to be particularly important in those with non-proliferative class of LN at the initial biopsy since transition to proliferative class occurred in a majority of these cases. Further, a class switch occurred in more than half the patients and a majority of the patients had an escalation of therapy, suggesting the benefit of repeat biopsies during flare in our largely minority population.

TH-PO793

Identification of Unique Molecular "Fingerprints" of Systemic Lupus Erythematosus (SLE) and Evaluation of Kidney Function Using Urine Raman Spectroscopy and Chemometrics

Ryan S. Senger,[1] Kathleen E. Sullivan,[2] Kelly Maurer,[2] Amr Sayed Issa,[1] John L. Robertson.[1] *[1]Virginia Polytechnic Institute and State University College of Engineering, Blacksburg, VA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA.*

Background: SLE, a pan-systemic inflammatory disease, can have a deleterious effect on renal function. Timely detection and management of renal dysfunction is highly desirable, since many patients develop disease at an early age and inflammatory nephropathies can be relentlessly progressive.

Methods: We developed a Raman spectroscopic technology (Rametrix® molecular urinalysis) to detect SLE systemic/renal effects by analysis of patient urine. It is based on chemometric analysis of the Raman spectrum of urine and detects metabolomic differences. The technology is not designed specifically to detect cell degradation products (DP), such as nucleic acid DPs, but can be harnessed to probe and quantify these. We hypothesized that SLE would alter urine composition and that Rametrix® analysis could detect renal dysfunction via urine molecular 'fingerprinting'. We applied Rametrix® analysis on 587 urine specimens collected from 82 patients with biopsy-proven (80/82) and/or laboratory-validated SLE markers. Patients were 8-21 years of age (median age 14.5) and 77.5% female. Most patients were African-American (183/587), Latino (162/587) or Caucasian (129/587). Serial longitudinal urine samples were obtained on multiple individuals. A renal SLEDAI-2K score was correlated to Rametrix® findings. Using chemometric analysis of urine Raman spectra, we compared SLE urine spectra with urine spectra from urine of healthy controls (203), patients with CKD (20), COVID19 patients (118), bladder cancer patients (19) and Lyme disease patients (20).

Results: Rametrix® molecular urinalysis distinguished SLE-associated changes in urine composition with predictive metrics (accuracy, sensitivity, specificity, PPV, and NPV) ranging between 73-97%. A correlation between changes in urine Raman spectra and physician assessment of disease (SLEDAI-2K) was also found through computational analysis. Urine spectra from SLE and COVID19 patients showed notable Raman spectral similarities, suggesting common inflammatory pathways (interferonopathies).

Conclusions: Raman molecular urinalysis can be useful to detect and manage SLE and renal dysfunction.

Funding: Commercial Support - Rametrix Technologies, Inc.

TH-PO794

Establishment of Diagnostic Criteria for Tubulointerstitial Nephritis with IgM-Positive Plasma Cells (IgMPC-TIN)

Naoki Takahashi, Yudai Nishikawa, Yuki Watanabe, Sho Nishikawa, Kazuhisa Nishimori, Sachiko Fukushima, Mamiko Kobayashi, Hideki Kimura, Kenji Kasuno, Masayuki Iwano. *Fukui Daigaku, Fukui, Japan.*

Background: We proposed the IgMPC-TIN disease concept in 2017, and this disease concept is gradually gaining recognition in Japan. However, there are no clear diagnostic criteria for diagnosing IgMPC-TIN. We attempted to develop diagnostic criteria for IgMPC-TIN from both clinical and histological parameters or from only clinical parameters using cases collected from multiple institutions.

Methods: A total of 118 renal biopsy samples were collected from 61 patients with suspected IgMPC-TIN and 57 patients with other interstitial lesions from our hospital and national collaborating centers, and we performed double staining (IgM and CD138) using the immunoenzymatic method. Patients with M protein in their blood or urine and patients with diabetes mellitus were established as exclusion criteria. Then several nephrologists classified each case that did not meet the exclusion criteria from +3 (typical IgMPC-TIN) to −3 (not IgMPC-TIN at all). Based on 49 cases judged as +3 and 56 cases judged as −3, a decision tree-based diagnostic algorithm was created in JMP. Finally, the sensitivity and specificity of the diagnostic criteria created were calculated.

Results: In the diagnostic criteria consisting of histological and clinical parameters, the most important requirement was a maximum IgMPC infiltration count of ≥20/high magnification field of view (7400 μm^2). The next most important requirement was the presence of urinary sugar, and the next requirement was the presence of primary biliary cholangitis (PBC). For diagnostic criteria consisting only of clinical parameters, the most important requirement was a serum IgM level of 267 or higher, followed by the presence of Fanconi syndrome. Sensitivity and specificity of each diagnostic criterion were 97.9 and 100% for histological and clinical parameters and only for clinical parameters. Although we consider diagnostic criteria that include histological parameters to be the gold standard, diagnostic criteria based solely on clinical parameters are also sufficiently accurate.

Conclusions: We analyze the clinical characteristics of IgMPC-TIN cases and develop criteria for the diagnosis of IgMPC-TIN based on histological and clinical parameters.

Funding: Government Support - Non-U.S.

TH-PO795

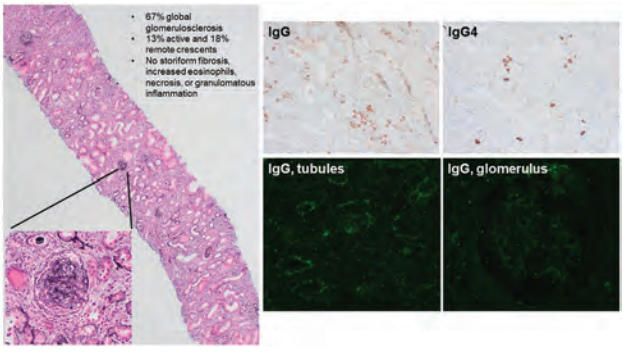
ANCA-Associated Kidney Disease in a Child with History of Presumed IgG4-Related Disease

Ileisa Oleson, Adeline L. Fecker, Kelsey L. Richardson, Abbie R. Bauer, Nicole K. Andeen, Vanderlene L. Kung. *Oregon Health & Science University, Portland, OR.*

Introduction: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) and IgG4-related disease (IgG4-RD) are immune disorders with distinctions in pathogenesis, prognosis, and management, that can share clinical and laboratory features. While ANCA positivity excludes IgG4-RD in the 2019 ACR/EULAR classification, this criterion is not uniformly applied, and AAV can form inflammatory masses in various organs and show increase in IgG4+ plasma cells, similar to IgG4-RD. This case highlights challenges in AAV and IgG4-RD diagnoses in a child.

Case Description: A 5-year-old female with previously normal kidney function presents with nausea, diarrhea and acute kidney injury with hematuria and proteinuria. Her only medical history is of a left orbital mass a year ago, diagnosed as IgG4-RD based on elevated serum IgG (1270 mg/dL) and biopsy with sclerosing fibrosis with IgG4+ plasma cells and eosinophils, and treated with steroids with complete mass resolution. On this admission, she has a positive MPO ANCA (1:80) with pertinent negatives of normal serum C3, C4, total IgG, and IgG4, and negative ANA and anti-dsDNA. A kidney biopsy shows chronic active pauci-immune crescentic glomerulonephritis and acute tubulointerstitial nephritis with up to 14 IgG4+ plasma cells/40X field, IgG4+/IgG+ plasma cell ratio up to 25%, and focal tubular basement membrane (TBM) deposits (Image). She is treated with pulse steroids and rituximab with no kidney function improvement, in contrast to most cases of IgG4-RD.

Discussion: Pauci-immune crescentic GN with positive ANCA are characteristic for kidney AAV, and in retrospect, suggest the orbital mass may have represented the initial manifestation of AAV despite orbital mass histology with increased IgG4+ plasma cells and elevated serum IgG4 at diagnosis. The additional features of TBM deposits and increased IgG4+ plasma cells in the kidney biopsy highlight further potential for confounding morphologic overlap between AAV and IgG4-RD, for which correlation with ANCA testing is essential.



TH-PO796

Interstitial ANCA-Associated Vasculitis Associates with Severe Kidney Injury Independent of Glomerulonephritis

Bjoern Tampe. *Universitatsmedizin Gottingen, Gottingen, Germany.*

Background: Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) is a small vessel vasculitis affecting multiple organ systems, including the kidney. Although crescentic ANCA glomerulonephritis (GN) is a common histological finding reflecting glomerular small vessel vasculitis, it is reasonable that manifestation of AAV could also contribute to interstitial small vessel vasculitis. Therefore, we here aimed to expand our current knowledge focusing on interstitial vasculitis in ANCA GN by systematic histological scoring of vascular lesions analogous to Banff.

Methods: A total number of 49 kidney biopsies with confirmed renal involvement of AAV at the University Medical Center Göttingen were retrospectively included between 2015 till 2020. A renal pathologist evaluated all biopsies and was blinded to clinical data collection and analysis.

Results: Since previous studies established that crescentic ANCA GN associates with severe kidney injury and acute deterioration of kidney function in AAV, we first systematically scored interstitial vasculitis in association with requirement of renal replacement therapy (RRT). Among all active and chronic tubulointerstitial lesions analogous to the Banff scoring system, the only association between severe kidney injury requiring RRT was observed for interstitial vasculitis in AAV reflected by peritubular capillaritis (ptc, p=0.0002) and arteritis (v, p=0.0069), affecting 5/49 (10.2%) and 11/49 (22.4%) of renal biopsies, respectively. Interestingly, no association between interstitial vasculitis (ptc and v correlating with severe kidney injury) and any glomerular lesion in ANCA GN (also correlating with severe kidney injury) was observed, thereby confirming that interstitial vasculitis contributes to severe kidney injury independent of ANCA GN. By contrast, short-term renal recovery from RRT was equal in both groups, suggesting a distinct association with acute decline of kidney function at disease onset.

Conclusions: Taken together, by using the Banff scoring system we here expand our current knowledge of renal interstitial lesions in AAV revealing peritubular capillaritis and arteritis as important histological alterations associated with severe kidney injury in a considerable subset of AAV.

TH-PO797

Transthyretin Amyloidosis with Biopsy-Proven Renal Involvement

Roberta Fenoglio. *University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy.*

Background: Systemic amyloidosis is a cluster of disorders characterized by tissue deposition of amyloid (highly ordered fibrils composed of low molecular weight subunits of a variety of proteins). Transthyretin (TTR) amyloidosis (ATTR) is either an autosomal dominant inherited condition (ATTRv, where v stands for "variant") or a non hereditary disease due to misfolding of wild-type TTR (ATTRwt). ATTR is likely underdiagnosed due to its clinical variability and lack of specific symptoms or biomarkers. The first aim of the study is to emphasise the importance of suspecting ATTR when facing certain clinical manifestations in association with renal impairment and urinary abnormalities. Furthermore, renal biopsy provides crucial information for a correct diagnosis and treatment approach.

Methods: We report 5 cases of biopsy-proven renal ATTR deposition in patients presenting with mild to moderate renal impairment and mild urinary abnormalities. The TTR precursor has been confirmed in kidney specimens by immunohistochemistry. Genotyping was carried out in every patient.

Results: The presence of amyloid was found in all patients, with different distribution (#1-3 pericapsular and vascular; #2 vascular; #4 mesangial, vascular, in tubular basement membrane and in the interstitium of cortex and medulla; #5 pericapsular, vascular and interstitial). On genetic analysis three patients were wild-type (#1-2-5), one carried the c.424G>A (p.(Val142Ile)) mutation (#3) and the last one the Val30Met mutation (#4).

Conclusions: Suspicion of ATTR should be considered in patients with increase in serum creatinine, mild proteinuria and cardiac and peripheral nerve symptoms. This can be of utmost importance in elderly patients in whom a monoclonal gammopathy of undetermined significance can co-exist and drive a wrong diagnosis of primary light chain amyloidosis (AL), that could lead the clinician to undertake inappropriate treatments. Renal biopsy and genetic sequencing are both critical in diagnosing ATTR. Finally, we suggest distinguishing in the context of the ATTR deposition disease an ATTR nephropathy characterized by mesangial accumulation of amyloid, that impacts functional and urinary assessment, from isolated deposition in small vessels without specific clinical consequences, albeit critical for ATTR diagnosis.

TH-PO798

Microplastics: First Proteomic Analysis on Kidney Tubular Cells

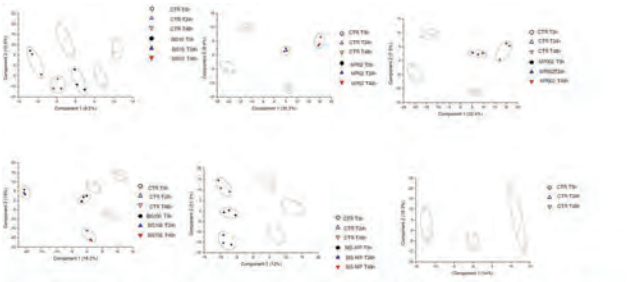
Edoardo La Porta,[1] Maurizio Bruschi,[1] Giovanni Candiano,[1] Cristina Artini,[2] Daniela Verzola,[3] Sara Massardo,[2] Paolo Cravedi,[4] Pasquale Esposito,[2] Andrea Angeletti,[1] Francesca Lugani,[1] Carolina Bigatti,[1] Enrico E. Verrina,[1] Gian Marco Ghiggeri,[1] Stefano Alberti,[2] Micaela Gentile.[4] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Universita degli Studi di Genova, Genova, Italy; [3]Universita degli Studi di Genova, Genova, Italy; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Microplastics (fragments < 5 mm in diameter) and nanoplastics (< 1 μm) are ubiquitous in the environment. Microplastics (MPs) absorb environmental pollutants, such as bisphenol A (BPA), and release them into tissues increasing their toxicity. Their presence has been proved in human blood and human tissues, such as placenta and lung, and in cirrhotic liver. Biological effects of MPs are inflammation, oxidative stress and alteration of metabolic pathways. We performed proteomic analysis to evaluate the toxicity of polyethylene (PE) and bisphenol-A (BPA) MPs on renal tubular cells (HK2).

Methods: HK-2 cultures were exposed to BPA, PE Microspheres (PE-MP) and MP combined with BPA. We performed a proteomic analysis by mass spectrometry (MS). Analysis of data were performed using unsupervised hierarchical clustering using multidimensional scaling, non-linear support vector machine (SVM) learning, and partial least squares discriminant analysis. In SVM learning, a fourfold cross-validation approach was applied to estimate the prediction and classification accuracy.

Results: Analysis showed a clear differentiation of the HK2 proteome based on conditioning and identified a "core" of proteins, significant at ANOVA and above the 95th percentile for "fold increase" and significant at T-test compared with controls, highly discriminatory between groups. A final set of 5 proteins was selected to be validated for distinguishing features. PPIAL4C accelerate the folding of proteins. Nephronectin is involved in cellular adhesion. GDF15 is a markers of stress conditions. IGFBP7 is a biomarker of acute kidney damage. CDKN1C is a negative regulator of cell proliferation.

Conclusions: MP and BPA significantly modify the protein expression in renal tubular cells. These findings highlight the urgent need for additional research into the toxic effects of plastic debris on human kidneys and the eventual link to kidney diseases.



Multidimensional scaling. Highly performance discrimination of all the experimental groups, different conditions and times compared with controls

Magnetic Resonance Imaging Contrast Agents: Confounded Exposures Matter

Brent Wagner,[1,2] G. P. Escobar,[1,3] Tamara A. Howard,[3,1] Abdul Mehdi S. Ali,[4,1] Joshua Deaguero,[1,3] Karol Dokladny.[1,3] Kidney Institute of New Mexico. *[1]Kidney Institute of New Mexico, Albuquerque, NM; [2]New Mexico VA Health Care System, Albuquerque, NM; [3]University of New Mexico Health Sciences Center, Albuquerque, NM; [4]University of New Mexico, Albuquerque, NM.*

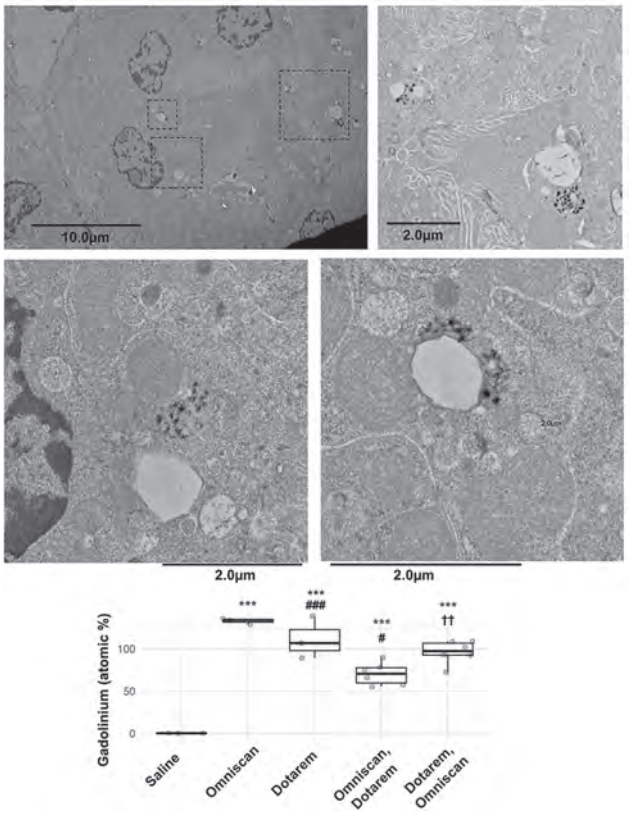
Background: Gadolinium-induced systemic fibrosis involves the monocyte chemoattractant protein-1/C-C chemokine receptor 2 pathway. Observational analyses measuring the risk of nephrogenic systemic fibrosis universally discounted exposures to multiple brands. The patients who contact the Kidney Institute of New Mexico report exposure to various brands or American College of Radiology Group 2 agents. Using our rodent model, we examined the pathology and metal retention of combined Group1/2 exposures.

Methods: We treated rodents for one week with Omniscan and three weeks of Dotarem (and vice versa) according to our standard, published protocols. Specimens were analyzed using conventional histology and electron microscopy. We quantified gadolinium with ICP-MS (Nexion 300D, Perkin-Elmer).

Results: Confounded treatments (Omniscan followed by Dotarem or vice versa) led to the formation of intracellular nanoparticles in the renal proximal tubules.

Conclusions: Measuring the incidences of gadolinium-induced complications has been artificially reduced by excluding confounded contrast agent exposures. Our results demonstrate that Le Chatellier's principle must be entertained in estimating the risk from magnetic resonance imaging contrast agents. Because routine magnetic resonance imaging contrast agent administration leads to gadolinium-rich nanoparticles in the brain and the kidney, defending particular brands is a fragile position.

Funding: NIDDK Support, Other NIH Support - UL1TR001449, Veterans Affairs Support, Private Foundation Support



Mixed exposures to class 1 and 2 magnetic resonance imaging contrast agents (Omnisan, Dotarem) led to intracellular gadolinium-rich nanoparticles in the renal proximal tubule. Transmission electron microscopy, Hitachi H7700. Kidney gadolinium levels were similarly elevated regardless of the magnetic resonance imaging contrast agent treatment group. *** P < 0.001, ANOVA, TukeyHSD.

TH-PO800

Intersectin 1 and Intersectin 2 Localize with IgG Deposition in Glomeruli

Naonori Kumagai, Tomomi Kondo, Yuji Matsumoto, Yohei Ikezumi. *Fujita Ika Daigaku, Toyoake, Japan.*

Background: Intersectin 1 (ITSN1) and intersectin 2 (ITSN2) are multifunctional proteins and are causative gene for steroid-sensitive nephrotic syndrome. However, their expression in glomeruli remains unclear. IgG deposition cause glomerular injury and play a pivotal role in glomerular diseases such as membranous nephropathy and lupus nephritis. However, the molecules associated with IgG deposition remain unclear.

Methods: ITSN, ITSN2, and IgG were co-stained with immunofluorescence staining for renal biopsy specimens of pediatric patients with glomerular diseases such as steroid sensitive nephrotic syndrome, steroid resistant nephrotic syndrome, IgA nephropathy, Henoch-Schonlein nephropathy, membranous nephropathy, and lupus nephritis.

Results: ITSN1 and ITSN2 stained at the same site and with the same intensity as IgG regardless of the type of disease. In membranous nephropathy and lupus nephritis, ITSN1 and ITSN2 stained strongly at the IgG stained site with the same intensity as IgG, especially in glomerular capillary. In other kidney diseases such as IgA nephropathy, Henoch-Schonlein nephropathy, steroid sensitive nephrotic syndrome, and steroid resistant nephrotic syndrome, ITSN1 and ITSN2 stained weakly at the IgG stained site with the same intensity as IgG.

Conclusions: ITSN1 and ITSN2 seem to express in glomeruli in response to IgG deposition, since they stain at the IgG stained site with the same intensity as IgG regardless of the type of disease. They are considered commonly associated with IgG deposition regardless of the type of disease, which cause glomerular injury. It remains to elucidate the pathophysiological role of ITSN1 and ITSN2 in glomerular injury caused by IgG deposition.

Fast Molecular Profiling of Kidney Biopsy Tissue by Gene Profiling from Biopsy Transport Medium

Ziyang Li,[1] Jan A. Bruijn,[1] Hans J. Baelde,[1] Jesper Kers.[1,2] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Molecular assessment by targeted gene profiling of kidney biopsy tissues is gaining traction in kidney pathology, particularly kidney transplant biopsies (e.g. with the Nanostring B-HOT panel). A critical downside of molecular assessment from FFPE tissues is its turnaround time and same-day diagnostics is currently not feasible. Timely and tailored treatment requires the support of faster and more sensitive molecular assessment and we therefore studied the use of biopsy transport medium (BTM) used to transfer kidney biopsies from the clinic to the pathology ward.

Methods: We utilized tumor-free tissues from complete nephrectomy to cut tissues into small strips, imitating the size of a renal biopsy. These biopsies were stored in PBS to mimic the process of biopsies transport at our department. We optimized RNA isolation by comparing different RNA isolation methods, centrifuge speeds, and storage times of the biopsies in the BTM. We checked the quantity and integrity of the RNA and performed qPCR with different biomarkers. We validate the reliability of BTM by comparing gene expression in BTM and frozen tissues from the same kidney. Finally, from a cohort of regular biopsies, RNA was isolated.

Results: Our results showed that different RNA isolation methods, centrifuge speeds, and different storage time up to 24 hours did not have a significant effect on RNA quality and yield. In a preliminary assessment, we were able to measure cell-specific genes by RT-PCR, representing T cells, B cells, macrophages, and even podocytes. The average RNA yield from regular biopsies was 165ng with RIN values around 7. As an example, CD68 expression of BTM correlated with the CD68 expression of tissue from their corresponding kidneys (N=5, r= 0.902, p<0.05).

Conclusions: Our results demonstrate that we can obtain relatively large amounts of RNA with sufficient quality from BTM, and that gene expression analysis from BTM is practically feasible as we were able to measure the expression levels of cell-specific genes within 5 hours after arrival. BTM represents an interesting new source for rapid molecular assessment and a potentially feasible alternative to molecular assessment on FFPE tissues without the need for an extra biopsy core. Further research should validate its potential in discriminating clinically relevant diagnosis and/or quantification of disease activity.

Development and Validation of a Multilayer Segmentation Model to Quantify Chronic Changes on Kidney Biopsy

Muhammad Sohaib Asghar,[1] Lucas Stetzik,[2] Jaidip M. Jagtap,[1] Laura Barisoni,[3] Mariam P. Alexander,[1] Fadi E. Salem,[4] Maxwell L. Smith,[5] Andrew Janowczyk,[6,7] Aidan F. Mullan,[1] Aleksandar Denic,[1] Andrew D. Rule.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Aiforia Technologies, Cambridge, MA; [3]Duke University, Durham, NC; [4]Mayo Clinic in Florida, Jacksonville, FL; [5]Mayo Clinic Arizona, Scottsdale, AZ; [6]Emory University, Atlanta, GA; [7]Georgia Institute of Technology, Atlanta, GA.*

Background: Semiquantitative visual assessment of chronic structural changes is clinically relevant but has limited reproducibility. To better quantify chronicity, we developed a multilayer artificial intelligence (AI) model for the automated detection of glomerular, tubulointerstitial, and vascular chronic changes.

Methods: HistoQC was first applied to 1258 whole slide images (WSI) generated by multisite multi-scanner Aging Kidney Anatomy study to curate the dataset and to ensure representative variability. Aiforia Create, an AI-based interactive tool, was then used on 193 PAS-stained whole slide images (WSI) from 99 kidney tumor patients and 94 living kidney donor biopsies. This approach uses an iterative process to assign classes (semantic segmentation or object detection with instance segmentation) across nested layers. A total of 20,509 objects or regions were manually annotated to train the model. To validate the model, an independent test set of 10 WSIs (5 kidney tumor patients and 5 kidney donors) were annotated independently by 7 human validators and by the AI model. Then, for all 203 WSIs, the objects and regions detected by the AI model were used to calculate chronic changes. These were correlated with similar measures of chronic changes derived independently using human annotations.

Results: The final model assigned 20 classes across 9 nested layers (**Figure 1**). The F1 score for AI vs human was 95% and for human vs human was 96%. The correlation between AI model vs human measures was r=0.92 for glomerular volume, r=0.90 for cortex per glomerulus, r=0.92 for % globally sclerotic glomeruli, r=0.82 for AI % tubular atrophy vs. human % interstitial fibrosis/tubular atrophy, and r=0.72 for % artery stenosis from intimal thickening.

Conclusions: A multilayer AI model for the segmentation of 20 different classes on PAS-stained WSIs facilitate the quantification of kidney chronicity indices.

On-Site Evaluation of Renal Biopsy Specimens: Impact on Diagnostic Yield in the Absence of Nephropathologists

Esra Ekiz, Tariq A. Mu'Amar, Suhaib A. Andrabi, Leroy Herbert. *Harlem Hospital Center, New York, NY.*

Background: Renal biopsy is a crucial procedure for diagnosing kidney diseases, and the quality of obtained tissue samples is essential for accurate diagnosis. On-site evaluation of biopsy specimens has been shown to increase the diagnostic yield. However, there is a trend of omitting on-site assessment when a nephropathologist is not readily available, leading to decreased yield. We hypothesized that evaluation of biopsy specimens by a nephrologist en-suite would improve specimen adequacy in the absence of a pathologist.

Methods: Electronic medical records of patients who underwent kidney biopsy from 2019 to 2022 were reviewed. Demographic, clinical, and biopsy-related data were collected. Biopsy specimens were evaluated by a nephrologist on-site, and the final pathology report was provided by different pathologists. Adequacy of the specimens was assessed based on the number of glomeruli observed under light microscopy, immunofluorescence, and electron microscopy.

Results: The average age of the study sample was 50, range between 20-72 years of age. 19 of all patients were women. 5 out of 30 biopsies were performed under CT-guidance. Adequate number of glomeruli were found in 27 biopsies; 2 of them had 6 glomeruli in LM, the other had a total of 3 glomeruli. A minimum of 1 glomerulus was available for IF and EM. 2 specimen were deemed adequate by ephrologist but inadequate by patholgist. 1 specimen was deemed inadequate by both nephrologist and pathologist. Average glomerular yield was 26. Median glomerular yield was 40 glomeruli total. The most common pathologic diagnoses were secondary FSGS and diabetic nodular glomerulosclerosis.

Conclusions: Adequate biopsy samples are crucial for accurate diagnosis and monitoring of kidney disorders. Previous studies have shown that on-site assessment of biopsy specimens improves yield outcomes. In this study, evaluation of specimens by a nephrologist en-suite showed nearly 100% correspondence with pathologists' assessments. Our findings suggest that nephrologists' evaluation of gross biopsy specimens can positively impact biopsy yield in institutions lacking nephropathologists. Further research with larger cohorts is needed to validate these findings and assess the generalizability of this approach.

TH-PO804

Biopsy Features of Initial KPMP Participants with CKD and Diabetes or Hypertension

Christine P. Limonte,[1] Yunbi Nam,[1] Zoltan G. Laszik,[2] Laura Barisoni,[3] Joel M. Henderson,[4] Gearoid M. McMahon,[5] Isaac E. Stillman,[6] Jonathan J. Taliercio,[7] Miguel A. Vazquez,[8] Brooke Berry,[1] Emilio D. Poggio,[7] Charles E. Alpers,[1] Sylvia E. Rosas,[9] Ian H. de Boer.[1] For the Kidney Precision Medicine Project. *[1]University of Washington, Seattle, WA; [2]University of California San Francisco, San Francisco, CA; [3]Duke Medicine, Durham, NC; [4]Boston University School of Medicine, Boston, MA; [5]Brigham and Women's Hospital Department of Medicine, Boston, MA; [6]Beth Israel Deaconess Medical Center, Boston, MA; [7]Cleveland Clinic, Cleveland, OH; [8]The University of Texas Southwestern Medical Center, Dallas, TX; [9]Joslin Diabetes and Endocrinology Research Center, Boston, MA.*

Background: The Kidney Precision Medicine Project (KPMP) is obtaining kidney biopsies in people with common causes of CKD and AKI for complete clinical, histopathological, and molecular characterization. Here we report findings from the first set of adjudicated CKD biopsies.

Methods: KPMP enrolled adults with CKD and diabetes or hypertension with eGFR 30-59ml/min/1.73m^2, UACR >30mg/g, or UPCR >150mg/g. Standardized clinicopathological adjudication by KPMP nephrologists and kidney pathologists was completed for 39 participants enrolled 2019-2022. Clinicians completed surveys to assess impacts of biopsy results on diagnosis and management.

Results: Participants' mean age was 59 years, 59% were female. Mean eGFR was 53ml/min/1.73m^2 and median UACR was 96mg/g. Among participants with diabetes and CKD (N=28), 15 (54%) had a primary diagnosis of diabetic nephropathy, 3 (11%) had vascular nephrosclerosis, 2 (7%) had other glomerular diseases, and 8 (29%) participants had non-specific biopsy findings for which no primary diagnosis could be determined. Among those enrolled with hypertension and CKD (N=11), 5 (46%) had vascular nephrosclerosis and 6 (55%) had non-specific findings. A range of glomerular, tubulointerstitial, and vascular findings was observed (**Table**). 26% of clinicians stated results were different than expected and 77% stated results affected prognostic discussions.

Conclusions: Kidney biopsies in people with common causes of CKD show a broad range of histopathology and may have clinical utility. Unexpected and non-specific findings precluding a definitive diagnosis are often present. Biopsies influenced prognostic discussions between participants and their providers.

Automated Foot Process Width (FPW) Measurements Using a Deep Learning (DL) Model Are Interchangeable with Stereology and Correlate with Kidney Functional and Structural Variables

David D. Smerkous,[1] Michael Mauer,[2] Camilla Tøndel,[3] Einar Svarstad,[3] Robert G. Nelson,[4] Behzad Najafian.[1] *[1]University of Washington, Seattle, WA; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Universitetet i Bergen, Bergen, Norway; [4]NIDDK, Phoenix, AZ.*

Background: Increased FPW is a key measure of podocyte (PC) health and injury. Unbiased stereology, the current gold standard, is time consuming and not widely available. To address this, we developed a DL model for automated FPW measurement.

Methods: A U-Net variant model was trained to semantically segment the PC-glomerular basement membrane interface (PGBMI) and filtration slits. A cloud-based application was developed for users to upload systematic electron microscopy (EM) images, view and download the results. The model was applied to EM images of biopsies from Fabry disease (FD) patients (n=56), type 2 diabetes (T2D) (n=15), minimal change disease (n=10), and controls (n=17). The results were compared with unbiased stereology measurements by expert technologists (ET).

Results: DL and ET FPW measurements were correlated and not statistically different in all of the groups. Bland-Altman plot confirmed method interchangeability. FPW measurement time/biopsy was reduced from ~8 hours (ET) to <1 min (DL). In male (M) FD patients, both DL and ET measured FPW correlated directly with age, urine protein/creatinine (PCR), podocyte volume (VPC) and volume of FD inclusions per PC [V(Inc/PC)]; However, only DL FPW correlated inversely with PC numerical density. In female (F) FD patients, only DL FPW directly correlated with PCR, VPC and V(Inc/PC). In the T2D group, both DL and ET FPW correlated directly with fractional volume of mesangial matrix per glomerulus. However, only DL FPW directly correlated with urine

albumin/creatinine, and fractional volume of mesangium per glomerulus, and VPC, and inversely with glomerular filtration surface density.

Conclusions: Our novel and validated DL model for EM FPW measurements can make this important biomarker widely accessible for research and clinical applications.

Clinical Relevance of Computationally Derived Spatial Relationships Between Interstitial Fibrosis and Tubular Atrophy (IFTA) and Peritubular Capillary Features

Yijiang Chen,[1] Bangchen Wang,[2] Dawit S. Demeke,[3] Fan Fan,[1] Celine C. Berthier,[4] Jeffrey B. Hodgin,[3] Andrew Janowczyk,[5,8] Laura Barisoni,[2,6] Anant Madabhushi.[5,7] *[1]Case Western Reserve University Department of Biomedical Engineering, Cleveland, OH; [2]Duke University Department of Pathology, Durham, NC; [3]University of Michigan Department of Pathology, Ann Arbor, MI; [4]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [5]Emory University, Atlanta, GA; [6]Duke University Department of Medicine, Durham, NC; [7]Atlanta Veterans Administration Medical Center, Atlanta, GA; [8]University Hospital of Geneva, Geneva, Switzerland.*

Background: The status of the tubulointerstitium and microvasculature is clinically relevant in glomerular diseases. While extent of interstitial fibrosis and tubular atrophy (IFTA) and peritubular capillaries (PTC) shape are independently associated with glomerular disease progression, the prognostic relevance of PTC shape features stratified by IFTA remains unknown.

Methods: N = 344 PAS-stained whole slide images (114 MCD/MCD-like, 132 FSGS, 61 MN and 37 IgAN) from the NEPTUNE/CureGN datasets were manually segmented for cortex and IFTA. A deep learning model was applied for PTC segmentation. The WSIs were split into training (S_t) and testing (S_v) datasets (1:1). 100 pathomic features quantifying cortical PTC shape were extracted from PTCs in IFTA and non-IFTA regions. Clinical outcome was defined as 40% eGFR decline or kidney failure. Lasso regression models were constructed on S_t, identifying top PTC shape features in IFTA and non-IFTA regions. The same features and model parameters were applied on S_v for independent validation. A prognostic model built with IFTA cortical density alone was created for comparison. Cox proportional hazards models and KM curves were used to evaluate prognostic relevance of the models.

Results: PTC shape features in IFTA regions were prognostic of disease progression, while PTC shape features in non-IFTA regions were not. The association between cortical IFTA density and disease progress was included for comparison (Figure 1). The top PTC shape features selected from IFTA regions are listed in Table 1.

Conclusions: IFTA density and PTC shape characteristics in IFTA regions are biomarkers of disease progression in patients with glomerular diseases. These results suggest that PTCs within IFTA regions tend to undergo morphologic changes, and these morphologic features are associated with kidney failure.

Funding: NIDDK Support, Other NIH Support - NIH-NCI

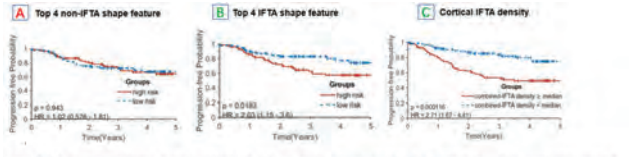

Figure 1: Cox Proportional Hazards model Visualized with KM Curves: (A) showing non-IFTA PTC shape model without significant association with disease progression ($p > 0.05$), (B) IFTA PTC shape feature based model and (C) Cortical IFTA density model showing significant association with disease progression ($p < 0.05$)

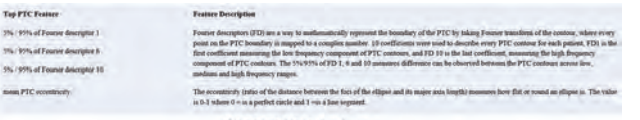

Top PTC Feature	Feature Description
5% / 95% of Fourier descriptor 1	Fourier descriptors (FD) are a way to mathematically represent the boundary of the PTC by taking Fourier transform of the contour, where every point on the PTC boundary is mapped to a complex number. 10 coefficients were used to describe every PTC contour for each patient. FD1 is the first coefficient measuring the low frequency component of PTC contours, and FD 10 is the last coefficient, measuring the high frequency component of PTC contours. The 5%/95% of FD 1, 6 and 10 measures difference can be observed between the PTC contours across low, medium and high frequency ranges.
5% / 95% of Fourier descriptor 6	
5% / 95% of Fourier descriptor 10	
mean PTC eccentricity	The eccentricity (ratio of the distance between the foci of the ellipse and its major axis length) measures how flat or round an ellipse is. The value is 0-1 where 0 = is a perfect circle and 1 =is a line segment.

Table 1: Top IFTA PTC shape feature descriptors

A Comparison of Artificial Intelligence (AI) vs. Human-Derived Measures of Nephron Size

Jaidip M. Jagtap,[1] Andrew Janowczyk,[2] Aleksandar Denic,[1] Yijiang Chen,[4] Muhammad Sohaib Asghar,[1] Sumana Ramanathan,[1] Aidan F. Mullan,[1] Timothy L. Kline,[1] Bradley J. Erickson,[1] Laura Barisoni,[3] Andrew D. Rule.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Emory University, Atlanta, GA; [3]Duke University, Durham, NC; [4]Case Western Reserve University, Cleveland, OH.*

Background: Enlarged nephrons as detected by glomerular volume and cortex per glomerulus (reciprocal of glomerular density) on kidney biopsy are prognostic for progressive CKD but require stereological calculations based on tedious human annotations. We sought to compare clinical associations with nephron size as calculated by AI versus human.

Methods: PAS-stained wedge section whole slide images (WSI) from nephrectomies (N=932) were manually annotated for cortex and non-sclerosed glomeruli using ImageScope software. A previously developed AI model for glomerular segmentation (NEPTUNE study) was applied to the same WSI. A threshold of 2000 μm2 for the smallest glomerular profile excluded false positives with the AI model. Spatial intersection statistics were compared between AI and human derived segmentations. Clinical correlations and the risk of progressive CKD (kidney failure or a 40% decline in eGFR sustained for at least 3 months) was assessed using AI versus human derived glomerular volume and cortex per glomerulus.

Results: The intersection between AI and human annotations of glomeruli had a Dice of 96%, precision of 99%, and recall of 93%. Glomerular volume was larger by AI than human (.0030 vs .0027 mm3, p<0.001) as was cortex per glomerulus (.080 vs .077 mm3, p<0.001). There were 52 progressive CKD events. Correlation of clinical characteristics with AI vs human estimates of glomerular volume is shown in the Table. The risk of progressive CKD with glomerular volume (per SD) was 1.76 (95%CI 1.41-2.19) by AI and 1.89 (95%CI 1.61-2.23) by human and with cortex per glomerulus (per SD) was 1.82 (95%CI 1.49-2.21) by AI and 1.71 (95%CI 1.52-1.93) by human.

Conclusions: The AI approach provides efficient quantification of nephron size measures comparable to a human approach.

Funding: NIDDK Support

Characteristics correlated with glomerular volume

	Human r (p value)	AI r (p value)
Age	-.09 (.009)	-.13 (.0001)
Male	.23 (<.0001)	.23 (<.0001)

Spatial Transcriptomic Analysis Reveals Altered Gene Expression in Glomerular Parietal Epithelial Cells Following Tubular Injury

Haichun Yang,[1] Jianyong Zhong,[1] Shilin Zhao,[1] Angela R. Kruse,[2] Morad C. Malek,[2] Jeffrey M. Spraggins,[2] Agnes B. Fogo.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Vanderbilt University, Nashville, TN.*

Background: In our previous study, we observed that acute tubular injury leads to the activation and transdifferentiation of parietal epithelial cells (PECs), resulting in a decrease in the ratio of columnar to flat PECs. In this study, our objective was to investigate the spatial transcriptomics of PECs following tubular injury.

Methods: We conducted experiments using wild-type (WT) mice and transgenic mice expressing the diphtheria toxin (DT) receptor in proximal tubular epithelial cells (PTECs). The mice were injected with DT at week 0 and week 1 and sacrificed after 6 weeks. Paraffin-embedded tissue sections were analyzed using the NanoString GeoMx DSP platform.

Results: Using fluorescent antibodies, we successfully isolated glomerular tuft and PECs and performed GeoMx spatial transcriptomics analysis. Principal component analysis (PCA) clearly distinguished tuft and PECs in both DT-treated and normal mice. In DT-treated PECs, we observed increased expression of 153 genes, including osteopontin (*OPN*), which showed enrichment in pathways related to actin cytoskeleton regulation, apelin signaling, the citric acid cycle, and respiratory electron transport. Immunostaining revealed that osteopontin was undetectable in PECs of WT mice, whereas its expression was significantly increased at week 3 and week 6 after tubular injury in DT-treated mice.

Conclusions: Our findings indicate that proximal tubular injury affects glomerular PECs, leading to their activation and altered gene expression. This study suggests potential pathways involved in the communication between tubular and glomerular compartments.

Histopathological Description of Sickle Cell Nephropathy of the Arab-Indian Haplotype

Basil Alnasrallah,[1] Shatha A. Alfaraj,[1] Abdullah Alqawain,[1] Zainab A. Al Khuraidah,[1] Eman Alabbad,[1] Mohammed Aljishi,[1] Ahmad A. Alnasser,[1] Jafar M. Al Rubh,[1] Manaf Aljishi,[2] Husam Alzayer.[3] *[1]Qatif Central Hospital, Qatif, Saudi Arabia; [2]Saudi German Hospital Dammam, Dammam, Saudi Arabia; [3]Saudi Arabia Ministry of Health, Riyadh, Saudi Arabia.*

Background: Sickle cell disorders are a group of autosomal recessive disorders characterized by the presence of the hemoglobin S (HbS) variant, which leads to sickling and hemolysis of the red blood cells. The inheritance of one variant gene, sickle cell trait (SCT), leads to a carrier state and milder form of the disease while having 2 genes leads to the more aggressive state of sickle cell disease (SCD). The main variants of HbS genes are the haplotypes present in the African race and the Arab-Indian (AI) haplotype, found in Saudi Arabia and central India. Sickle Cell Nephropathy (SCN) has been well characterized in the population of African descent. However, the histopathological changes of SCN have not been described in the patients of AI haplotype.

Methods: This was a single-center retrospective analysis of all adult patients with sickle cell disorders (SCD/SCT) who underwent a kidney biopsy from January 2012 until May 2023. Histological specimens were retrieved and examined by a research histopathologist. Clinical and biochemical data were collected and analyzed at the time of biopsy and last follow-up.

Results: 22 kidney biopsies were identified, 5 of which were excluded due to active lupus nephritis leaving 17 biopsies (12 SCD and 5 SCT). The mean age was 44 +/- 10 years, 8 were females (47%). The main indications for biopsy were unexplained raised creatinine (4/17) and proteinuria (13/17). The median hemoglobin S in SCD and SCT was 81% and 26%, respectively. Changes suggestive of SCN were only observed in SCD; the main findings were tubular hemosiderosis (92%), global sclerosis (83%), glomerular hypertrophy (75%), sickled RBCs (58%), FSGS lesions (42%), and duplication of the glomerular basement membrane (33%). None of the findings from SCT biopsies were consistent with SCN changes (2 diabetic glomerulosclerosis, 1 chronic glomerulonephritis, 1 normal glomerular architecture, and 1 cortical necrosis).

Conclusions: In patients with Sickle cell disorder in Saudi Arabia, where the AI haplotype is predominant, the SCN histopathological changes were largely similar to the ones previously reported with the haplotypes in the African race. These changes were only present in SCD and are likely to reflect the nature of the repetitive damage.

TH-PO810

Influence of Hospital Practices on Native Glomerular Pathologic Patterns: Insights from the Largest Kidney Biopsy Cohort in Thailand

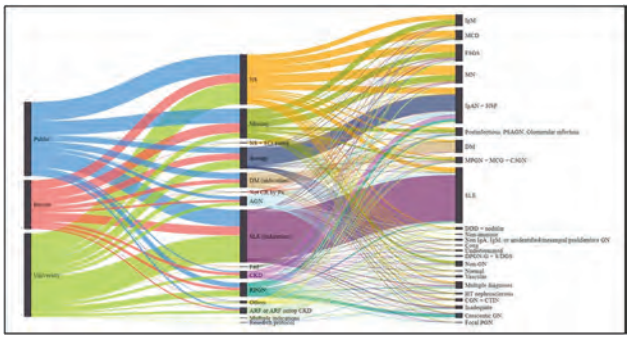
Talerngsak Kanjanabuch,[1,2] Suramath Isaranuwatchai,[3] Theerachai Thammathiwat,[4] Vijitr Boonpucknavig,[5] Tanawin Nopsopon.[1,6] *[1]Chulalongkorn University Faculty of Medicine, Bangkok, Thailand; [2]Center of Excellence in Kidney Metabolic Disorders, Faculty of Medicine, Chulalongkorn University, Pathum Wan, Thailand; [3]Chulabhorn Hospital, Bangkok, Thailand; [4]Naresuan University Faculty of Medicine, Phitsanulok, Thailand; [5]Bangkok Hospital, Bangkok, Thailand; [6]Brigham and Women's Hospital, Boston, MA.*

Background: We sought to explore the effects of kidney biopsy and glomerular pathologic patterns using the largest Thailand kidney biopsy registry.

Methods: Records of kidney biopsy registries from the Chulalongkorn University (one of the biggest university-based hospitals in Thailand) and the Kidney Center Bangkok Hospital (a center providing kidney pathologic diagnosis for all private and public hospitals in Thailand) between 2000 and 2014 were analyzed and classified into three groups: university practice (U), private practice (Pv), and public practice (Pb). Records from pediatric patients, kidney transplant recipients, repeated biopsies, and insufficient clinicopathologic diagnosis were excluded from the study**.** One-way ANOVA was conducted to compare continuous variables among hospital types while Chi-Squared test and Fisher's exact test were used for categorical variables.

Results: Out of 6,995 native kidney biopsies, 5,007 were eligible for analysis from 62 provinces covered all regions of Thailand over 15 years. University hospitals performed the highest number of kidney biopsies, followed by public and private hospitals. The three most common indications across all practice groups were nephrotic syndrome (NS), systemic lupus erythematosus (SLE, e.g., suspected lupus nephritis, morphologic diagnosis before making treatment decisions), and asymptomatic urinary abnormalities. U had a significantly higher proportion of biopsies due to SLE than the others (Image 1). In contrast, Pv performed biopsies with more indication of asymptomatic urinary abnormalities and unknown CKD than the others. Lupus nephritis was the most common pathological finding in U and Pb groups, while the Pv group was IgA nephropathy corresponding to the indications for biopsy.

Conclusions: The prevalence of pathologic diagnosis patterns is correlated well with the biopsy indication. Our findings highlight the influence of hospital practices on kidney biopsy indications and glomerular diagnoses.



TH-PO811

Unusual Pathogens in Usually Encountered Infections in ESRD

Bahaar S. Athavale, Hardik Shah, Akshay P. Ramteke, Dilip Kirpalani. *Bombay Hospital and Medical Research Centre, Mumbai, India.*

Introduction: In this case series of ESRD patients, we aim to highlight serious infections caused by pathogens hitherto not commonly encountered in India.

Case Description: *Aeromonas hydrophila*, found in aquatic environment was isolated from biopsy of non healing leg wound (prior cultures being negative) in a transplant recipient, who responded only after an appropriate 6 week antibiotic course. *Serratia marcescens*, found in water and soil, was isolated from BAL of a transplant recipient with cavitatory pneumonia and from a tunnelled catheter in a HCV positive patient on MHD with CRBSI. Both patients did not exhibit positive cultures from prior samples and responded only to Meropenem (other higher antibiotics being resistant). *Morganella morganii*, part of normal flora in humans, was grown from tunnelled catheter of a patient on MHD with fever of unknown origin (other workup of FUO being inconclusive), needing catheter removal due to pan resistance. *Elizabethkingia meningoseptica*, a commensal in healthcare facilities, was isolated from non tunnelled HD catheter, and needed Colistin therapy as the only available choice. *Geotrichum species*, a contaminant of fruits & vegetables was finally isolated from tunnelled catheter of a patient with CRBSI with 2 negative blood cultures previously over 3 weeks. A 54/F patient needed CAPD catheter removal due to Candida tropicalis infection and 3 months later needed tunnelled catheter removal due to Candida parapsilosis (a common skin flora and a subungual proliferator) infection. Both above organisms were resistant to Azoles and Echinocandins.

Discussion: These unusual organisms residing in soil, water, disinfection solutions and surfaces in dialysis units need active surveillance and timely microbiological detection as they are likely to increase morbidity and mortality in ESRD. Tackling the double whammy of newer pathogens and depleting arsenal of sensitive antibiotics is a big challenge in developing countries. High index of clinical suspicion and state of the art diagnostic facilities for detecting causative pathogens is the need of the hour.

TH-PO812

Renal Malakoplakia: A Rare Disease Causing Acute Renal Failure

Zoya Ladiwala, Harsha Adnani. *Luminis Health Anne Arundel Medical Center, Annapolis, MD.*

Introduction: Malakoplakia is a rare chronic inflammatory condition characterized by granulomatous lesions, frequently involving the kidneys. We present a case of renal malakoplakia in the setting of Escherichia coli (E.coli) bacteremia leading to acute renal failure.

Case Description: A 36-year-old woman presented with vomiting and shortness of breath. Initial evaluation revealed hypotension, tachycardia, leukocytosis (22,000/μL), and acute kidney injury with elevated creatinine (6.4 mg/dL from a baseline of 0.6 mg/dL). Urinalysis showed blood, leukocytes, bacteria, and a urine protein/creatinine ratio of 31 mg/mg. Computed tomography scan indicated fatty hepatomegaly and globular nephromegaly. Urine and blood cultures grew E. coli. The patient was treated for septic shock with antibiotics and vasopressors. However, she developed oliguric acute renal failure and required continuous renal replacement therapy. A left kidney biopsy was pursued to evaluate the nephromegaly, which revealed multifocal microabscesses, parenchymal necrosis, fibrosis, calcifications, and an inflammatory infiltrate with histiocyte predominance, consistent with malakoplakia. Von Kossa stain confirmed the presence of numerous Michaelis-Gutmann bodies. Renal mercaptoacetyltriglycine 3 scan showed differential function of 25% in the left kidney and 75% in the right kidney. Despite prolonged antibiotic therapy, the patient continued to experience volume overload, persistent leukocytosis, bacteremia, and fungemia. Given the higher disease burden in the left kidney, she underwent a radical left nephrectomy for source control. Postoperatively, her clinical condition improved, and she was discharged on suppressive minocycline.

Discussion: The pathogenesis of malakoplakia involves impaired bactericidal capacity of macrophages. Michaelis-Gutmann bodies, characterized by calcium and iron deposits, are pathognomonic. Diagnosis is challenging due to variable clinical presentations and imaging findings resembling malignancy. Renal biopsy remains the gold standard for definitive diagnosis. Given its rarity, evidence-based treatment is limited; however, a general approach includes systemic antibiotics and surgical excision. Renal malakoplakia poses clinical challenges in differentiating from other infections and tumors. Early diagnosis through biopsy is crucial for prompt treatment and to prevent long-term morbidity and mortality.

TH-PO813

Infection as a Trigger of Acute, Transient Glomerular Deposition of Clonal Immunoglobulins

Bangchen Wang,[1] Micah Schub,[1] Derrick Robinson,[2] David N. Howell.[1]
[1]Duke University, Durham, NC; [2]Novant Health, Wilmington, NC.

Introduction: Glomerular deposition of clonal IgM, frequently in the form of intracapillary pseudothrombi, can be seen in Waldenström macroglobulinemia (WM) and type 1 cryoglobulinemia (CG). Both are typically associated with B-cell lymphomas, particularly lymphoplasmacytic lymphoma (LPL). While infection is a frequent trigger of mixed (type 2 and 3) CG, its association with type 1 CG is uncommon. We report two cases in which striking lambda-restricted IgM deposits and acute kidney injury (AKI) occurred in the setting of systemic infections, with prompt resolution on treatment of the infection.

Case Description: Patient 1 was a 57-year-old female who presented with AKI following bowel perforation, treated with resection and antibiotics. Serum protein electrophoresis (SPEP) showed IgG kappa and IgM lambda M-proteins, without history of lymphoma. Patient 2 was a 59-year-old female with a 9-year history of an untreated, quiescent mature B-cell lymphoma, who presented with AKI, nephrotic range proteinuria, and hematuria, alongside a recent sore throat, presumptively treated with antibiotics for a respiratory infection. Her lab findings showed hypocomplementemia and faint IgM-lambda M-protein on SPEP. Neither patient was tested for cryoglobulins. Renal biopsies for both patients revealed glomerular capillary loops distended by abundant amorphous, eosinophilic and PAS-positive material, which stained strongly for IgM and lambda light chain on immunofluorescence and was granular and lacked substructure by electron microscopy. These findings were initially interpreted as concerning for renal manifestations of WM. However, after further investigation, neither patient exhibited LPL, and both patients experienced recovery of renal function following treatment of their respective infections (patient 2 also received a short course of steroids). Notably, patient 1 was diagnosed with a diffuse large B-cell lymphoma several years later.

Discussion: While infection may not be the root cause of clonal immunoglobulin production, these two cases suggest that it may serve as a trigger for glomerular deposition of clonal IgM in patients predisposed by underlying lymphoma. WM was initially suspected in both patients; however, the rapid normalization of renal function after resolution of infection indicates that they had undiagnosed type 1 CG triggered by infection.

TH-PO814

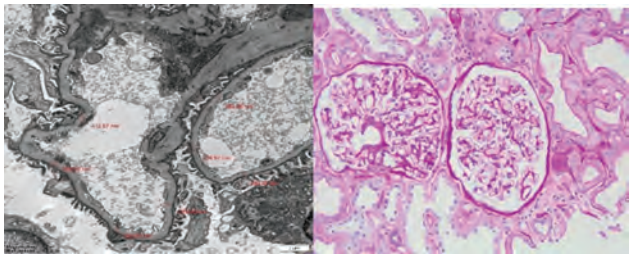
Nephropathy of Prematurity and the Crucial Role of Kidney Biopsy

Mohammad AL Wahadneh,[1] Hadi Dahhan,[2] Divya Ravi,[1] Ala Dahhan.[1]
[1]Rochester Regional Health, Rochester, NY; [2]Plainview Hospital, Plainview, NY.

Introduction: Nephrogenesis, the creation of nephrons, typically concludes before birth, yet in preterm infants it can extend up to 40 days post-birth. Nevertheless, these late-forming nephrons mature prematurely and remain abnormal. The exact influence of premature birth on nephrogenesis remains unclear. In light of this, we share a case of a young woman with signs of nephropathy attributed to her premature birth.

Case Description: A 22-year-old female with migraines and high blood pressure (230/150 mmHg) presented at an emergency department. Initial tests revealed normal CBC and CMP, but with elevated BUN (62 mg/dL) and creatinine (2.8 mg/dL). Mild proteinuria and a few red blood cells were noted. A renal ultrasound only found a small cyst in the right kidney. No stenosis was found, leading to further diagnostic workup. By the 5th day, with improved kidney function and controlled blood pressure, a renal biopsy was performed due to unclear AKI cause. The biopsy findings indicated acute tubular injury and Glomerulomegaly with secondary focal global and segmental glomerular sclerosis (Figures 1, 2). As the patient had no history of drug abuse, the prospect of premature birth was considered, which she confirmed, leading to the diagnosis of Chronic Kidney Disease due to nephropathy of prematurity

Discussion: This case is unique due to hypertension and renal failure in a patient with a normal workup and kidney size. Nephropathy of prematurity should be considered in young adults presenting with renal failure and benign urinary findings. This case underlines the importance of vigilant follow-ups for early detection of renal diseases in young adults with proteinuria and high blood pressure but normal kidney size. The case raises the question of whether monitoring renal function in premature infants should be extended into adulthood. Kidney biopsy remains the definitive method for diagnosing unexplained CKD, emphasizing the role of vigilant follow-ups and consideration of underlying renal disease in young adults with proteinuria, high blood pressure, and normal kidney size.



Dilated flat tubules and glomerulomegaly. Rare focal scarringno electron-dense deposits.

TH-PO815

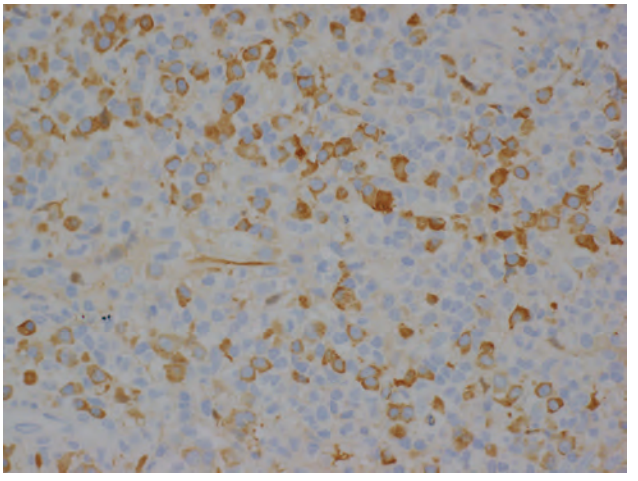
Systemic Immunoglobulin G4-Related Disease

Jacob R. Henderson, Karl B. Pembaur. *The Christ Hospital, Cincinnati, OH.*

Introduction: Immunoglobulin G4-Related Disease (IgG4-RD) is an autoimmune condition that can result in systemic fibrosis and organ damage. Clinical manifestations include lymphadenopathy, atopy like symptoms, and is often found incidentally on imaging with diffuse or focal organ lesions. Serological findings can include elevated levels of immunoglobulins and low complement levels. A tissue biopsy is needed for diagnosis revealing IgG4 lymphoplasmacytic infiltration with variable degrees of fibrosis.

Case Description: A 79 year-old male with a PMHx of HTN, biliary stricture, asthma, and BPH presented with generalized fatigue, pruritus, and difficulty initiating urination for one month. Labs revealed an AKI (Cr 5.19, BUN 47; UA - mild proteinuria), transaminitis (AST 322, ALT 460, ALP 796, TBili 4), and anemia (Hgb 11.2). MRCP revealed a biliary duct stricture, chronic pancreatitis, and soft tissue swelling representing retroperitoneal fibrosis. ERCP with biliary stent placement and biopsies were performed, revealing lymphoplasmacytic infiltration and diffuse fibrosis. Renal biopsy revealed diffuse interstitial inflammatory IgG4 lymphoplasmacytic infiltration with interstitial nephritis. Total protein and globulin levels were elevated. SPEP/IFE revealed increased gamma globulins (2.1) with no monoclonality. Immunoglobulin G4 was elevated at 266.2 (4-86), IgG1 was elevated at 1185 (282-395), and low C4 levels.

Discussion: The patient was diagnosed with IgG4-RD and started on immunosuppression with solumedrol and rituximab, complement levels were used to track responsiveness to treatment. Repeat serologic tests after immunosuppression revealed normalization of IgG4, IgG1 and complement levels, with a CD19/20 count of zero, showing that his IgG4-RD was in remission. Early recognition and treatment of IgG4-RD is of upmost importance due to a fibrotic transition that is poorly responsive to treatment with resultant end organ damage.



Renal biopsy demonstrating IgG4 plasma cells.

TH-PO816

Proliferative Glomerulonephritis with Monoclonal IgG1λ Deposits, Characterized by Intracapillary λ-Containing Macrophages Infiltration

Natsumi Kasahara,[1] Ryo Nishioka,[1] Daichi Kaikoi,[2] Anri Mori,[1] Hiromitsu Akamatsu,[1] Hiroaki Saito,[1] Hajime Sanada,[1] Yoshinori Takahashi,[1] Shunsuke Tsuge,[1] Satoshi Hara,[1] Kiyoaki Ito,[1] Ichiro Mizushima,[1] Mitsuhiro Kawano.[1] *[1]Kanazawa Daigaku Fuzoku Byoin, Kanazawa, Japan; [2]Toyama Kenritsu Chuo Byoin, Toyama, Japan.*

Introduction: Monoclonal gammopathy of renal significance (MGRS) encompasses kidney disorders caused by monoclonal proteins. We report a rare case of proliferative glomerulonephritis with monoclonal IgG1λ deposits (PGNMID) in a patient with monoclonal gammopathy of undetermined significance (MGUS). Notably, the case is characterized by the infiltration of intracapillary macrophages containing λ immunoglobulin.

Case Description: A 69-year-old Japanese female with MGUS presented with renal dysfunction and proteinuria. She had a history of persistent proteinuria (urinary protein 3.4 g/g Creatinine), microscopic hematuria, and kidney dysfunction (serum Creatinine 1.3 mg/dL) for the past 2 years. Due to refractory symptoms, she was admitted to our hospital. On admission, her urinary protein was 1.1 g/day, with microscopic hematuria, and serum Creatinine 1.9 mg/dL. Immunofixation analysis detected monoclonal IgGλ in both serum and urine, while cryoglobulins were absent. Renal biopsy revealed diffuse endocapillary proliferative glomerulonephritis with subendothelial deposition. Immunofluorescence demonstrated IgG1, C3, and λ deposition with an infringe pattern, confirming the diagnosis of PGNMID. Remarkably, the intracapillary cells exhibited a foamy appearance and showed double positivity for CD68 and λ. Electron microscopy confirmed electron dense deposits (EDD) in the subendothelial area, and intracapillary foam cells contained EDD. Due to the presence of other life-threatening factors, the patient received renal protection therapy without anti-tumor treatment. Over a four-year period, renal dysfunction progressively worsened, with a serum creatinine level of 2.9 mg/dL and persistent proteinuria.

Discussion: We present a rare case of PGNMID characterized by the infiltration of intracapillary monoclonal λ-containing macrophages. The underlying pathophysiology remains unknown, but it may share similarities with crystal-soring histiocytosis, where macrophages engulf monoclonal immunoglobulins. To our knowledge, only one similar case has been previously, suggesting that this histological finding could represent a novel manifestation of MGRS.

TH-PO817

How Factor H Deficiency Triggered Atypical Hemolytic Uremic Syndrome (aHUS) in a New Mother

Thien Ho, Erik Mai, Evelyn Bruner, Milos N. Budisavljevic. *Medical University of South Carolina, Charleston, SC.*

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is a rare form of thrombotic microangiopathy (TMA) causing dysregulation of the alternative complement system. aHUS presents with microangiopathic hemolytic anemia (MAHA), thrombocytopenia, and organ damage, notably, renal failure requiring dialysis. Morbidity and mortality is preventable as treatments are now available. Yet, treatment is often delayed as aHUS is viewed as an exclusion diagnosis. Prior studies have shown that aHUS is associated with many genetic mutations of complement proteins. Of these, Factor H (CFH) were found in 25% of cases. We present an aHUS case of CFH deficiency in a postpartum patient.

Case Description: A 26 year old healthy female, who one week ago had a normal term vaginal delivery, presented with hypertensive emergency, MAHA, thrombocytopenia, and renal failure requiring dialysis. Initial labs showed deficient C3 levels and normal C4 levels. Plasmapheresis was started for suspicion of Thrombotic Thrombocytopenic Purpura. Therapy was stopped when her ADAMTS13 returned normal. She was screened for infections, drugs, and malignancy, all were negative. A renal biopsy showed TMA with 10% cortical necrosis. Results of her complement panel showed dysregulation of the alternative pathway: low CFH and low alternative pathway levels. She was diagnosed with aHUS and treated with a C5 Inhibitor, Eculizumab. Eculizumab was given weekly and after her third dose, her hemolytic labs improved. After her 4th dose, her renal function was near complete recovery and dialysis stopped. Her dose now was every two weeks for a minimum of six months.

Discussion: C5 inhibitors have hugely improved renal survival. Our patient received Eculizumab with promising renal recovery. A 2010 study of 100 females with aHUS showed that 48% of cases involved CFH mutations. Another study assessed 273 aHUS patients and 139 had CFH dysfunction. We are learning that the defect affects more than one area on the CFH gene. Thus, the location of dysfunction affects the severity and treatment response making aHUS much more challenging to standardize.

Genetic defect	Frequency	Response to short-term plasma therapy	Long-term outcome	Outcome after kidney transplantation
CFH	20–30%	Rate of remission: 60% (dose- and timing-dependent)	Rate of death or ESRD: 70–80%	Rate of recurrence: 80–90%
CFI	4–10%	Rate of remission: 30–40%	Rate of death or ESRD: 60–80%	Rate of recurrence: 80–90%
CFHR1 & 3 with CFH autoantibodies	6%	Rate of remission: 70–80%	Rate of death or ESRD: 30–40%	Rate of recurrence: 20%
MCP	10–15%	No indication for therapy	Rate of ESRD or death: <20%	Rate of recurrence: 15–20%
CFH	1–2%	Rate of remission: 30%	Rate of death or ESRD: 70%	Recurrence in one case
C3	5–10%	Rate of remission: 40–50%	Rate of death or ESRD: 60%	Rate of recurrence: 40–50%
THBD	5%	Rate of remission: 60%	Rate of death or ESRD: 60%	Recurrence in one case

Figure 1: Summary of Clinical Outcomes From Complement Genetic Defects in Atypical Hemolytic Uremic Syndrome

TH-PO818

Lanthanum Gastropathy in Gastrectomy Specimen: A Case Report

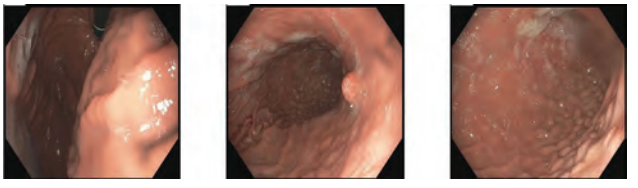
Erika M. Dorff, Sarah Y. Liu, Amer K. Abu Alfa, Wasef Abu- Jaish. *University of Vermont Medical Center, Burlington, VT.*

Introduction: Lanthanum carbonate is a non-calcemic phosphate binder that is used in end-stage renal disease (ESRD.) It has few adverse effects due to its poor systemic absorption. Gastrointestinal lanthanum deposition was first reported in 2015 and is likely due to alterations in epithelial permeability from inflammation in chronic kidney disease. Endoscopy findings include gastritis, erosions, ulcerations, and polyps, with a diffusely white mucosa and fine granular deposits. It is challenging to detect these findings in cases with minimal microscopic deposition and may be missed on biopsy.

Case Description: A 36-year-old with ESRD secondary to hypertension was started on lanthanum in 2017. She was evaluated by bariatric surgery in 2019 for sleeve gastrectomy and endoscopy was completed as part of the pre-operative workup. Findings were significant for gastritis and multiple gastric polyps. Biopsies demonstrated aggregates of histiocytes with granular eosinophilic material in the lamina propria. She underwent sleeve gastrectomy in 2022 in which the excised portion showed similar histiologic findings. There have been no further studies or adverse events reported since the surgery.

Discussion: This case allows for the evaluation of a gross specimen as there have been no reports to date describing lanthanum gastropathy in specimens larger than biopsy. Not all patients taking lanthanum undergo endoscopic and histologic evaluation, but studies have found deposits in 60-85% of those evaluated. One case report found concurrent neoplastic changes, though this is the only description of such. The findings in this case were not consistent with neoplasm despite prolonged lanthanum use, but further studies must be conducted to determine long-term effects in patients with ESRD.

Gastrectomy gross specimen



Endoscopic findings

TH-PO819

Development of a Predictive Model for Assessing the Risk of Severe Renal Fibrosis in Kidney Biopsy

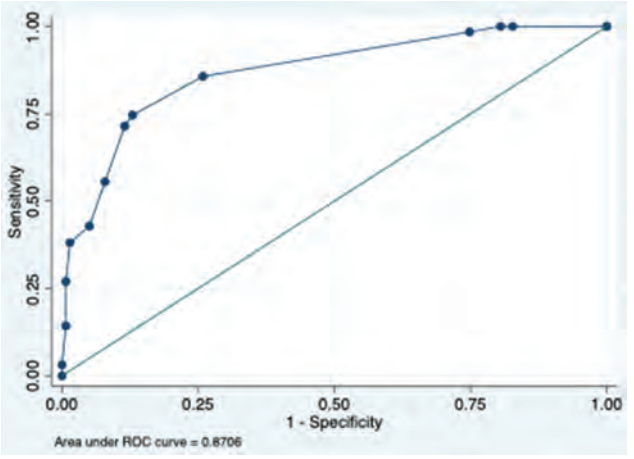
Ittikorn Spanuchart,[1] Veeraphol Tungphaisal,[2] Kanin Thammavaranucupt.[3] *[1]University of Michigan, Ann Arbor, MI; [2]Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand; [3]Chakri Naruebodin Medical Institute, Bang Phli, Thailand.*

Background: Kidney biopsy is an essential diagnostic tool for various kidney diseases, but its clinical utility may be limited in cases of severe fibrosis, coupled with an increased risk of bleeding. Although several clinical parameters are used to predict the extent of renal fibrosis, a validated predictive model has not yet been established. This study aimed to construct a predictive model for assessing the risk of severe renal fibrosis.

Methods: Medical records of patients who underwent native kidney biopsies at Ramathibodi Hospital between January 2017 and December 2021 were reviewed. Severe renal fibrosis was defined as interstitial fibrosis and tubular atrophy (IFTA) greater than 50% or glomerulosclerosis greater than 50% on the pathology report. Clinical data, laboratory results, and ultrasonographic parameters were collected. Multivariable logistic regression analysis was performed to build the predictive model, and its discriminative performance was assessed using the receiver operating characteristic (ROC) curve. The internal validity of the model was evaluated through bootstrapping techniques.

Results: Among 202 patients, 31% exhibited severe renal fibrosis. The predictive model incorporated five significant predictors: nocturia, CKD, anemia, kidney length, and loss of corticomedullary differentiation. The model had an area under the ROC curve of 0.87 (95% CI: 0.818-0.923). The scoring model ranged from 0 to 18, with a score of 10 or higher indicating a positive likelihood ratio of 26 for severe fibrosis prediction. Internal validation using bootstrap resampling yielded an optimism of 0.024, with a shrinkage factor of 0.869.

Conclusions: The developed predictive model, utilizing routine clinical parameters, has demonstrated exceptional discriminative ability and ease of use in predicting renal fibrosis. It holds great potential in assisting clinicians with risk stratification and the planning of kidney biopsies.



TH-PO820

Left Ventricular Diastolic Dysfunction by Echocardiography Is a New Predictor of Delayed Graft Function

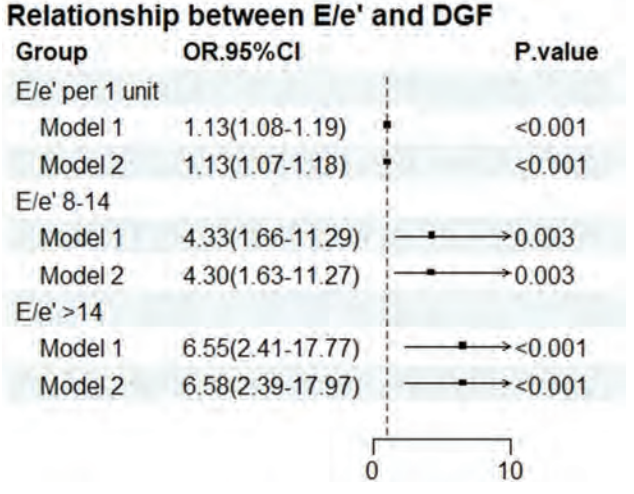
Linhui Huo, Hongli Jiang. *The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China.*

Background: Diastolic dysfunction (DD) is a common complication among end-stage renal disease (ESRD) patients. The ratio of early transmitral flow velocity (E) to early diastolic velocity (e') of the mitral annulus (E/e') is related to left ventricular (LV) diastolic dysfunction (LVDD). Delayed graft function (DGF) is a detrimental complication after kidney transplantation (KT). It is unclear whether increased E/e' predisposes a recipient to DGF.

Methods: A total of 574 patients were enrolled in this retrospective study. Two-dimensional echocardiography and Doppler imaging were performed. Multivariate logistic regression analyses were performed to calculate the OR (95%CI) for DGF. Model 1 included variables with P<0.05 in the multivariate logistic regression analyses. Model 2 was adjusted for demographic data (age and sex) and operation data (warm ischemia time and cold ischemia time). Model 3 (reference model) includes all the variables in Model 2 except E/e'. Discrimination was assessed by AUCs. Model performance was also evaluated by continuous net reclassification index (cNRI) and integrated discrimination improvement (IDI).

Results: 93 patients (16.25%) developed DGF. E/e' was higher in DGF patients(14.07±6.16 vs. 11.51±4.23, P<0.001). Per 1 unit E/e' increase (OR 1.16; 95%CI, 1.1-1.23) and higher E/e' categories (8≤E/e' ≤14 OR 6.51; 95%CI, 2.38-17.80; E/e' >14 OR 6.58; 95%CI, 2.39-17.97) were associated with DGF. After adjusting for other covariates, the relationship between E/e' and DGF remained significant (adjusted OR 1.13; 95%CI, 1.07-1.18). Compared with Model 3, Model 2 had better discrimination and reclassification (cNRI, 46.48%; 95% CI, 24.61%- 68.34%; IDI, 4.36%; 95% CI, 1.81%-6.91%).

Conclusions: Our study found that higher E/e' was an independent predictor of DGF. This may provide an important perspective on the management of waiting list patients. Our results recommend that clinicians should take measures to lower E/e' before transplantation to lower DGF risks.



TH-PO821

Pre-Transplant Daratumumab (Dara) and Kidney Transplant Rejection

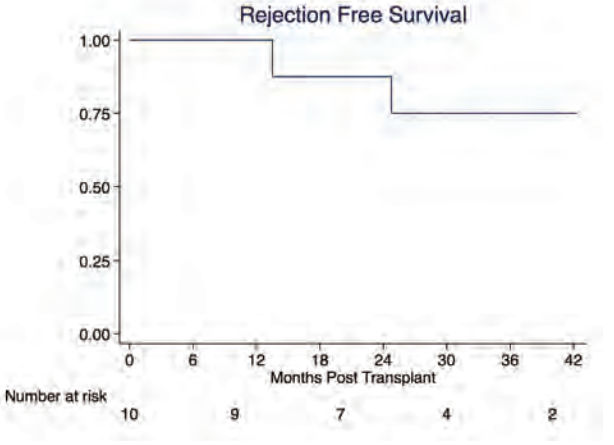
Hatem Amer, Elena-Bianca Barbir, Mireille El Ters, Nelson Leung. *Mayo Clinic Department of Internal Medicine, Rochester, MN.*

Background: This study examined the post-kidney transplant outcomes of patients who received Dara, a monoclonal antibody against CD38 positive cells, pre-transplant. Concerns exist that Dara may increase the risk of rejection.

Methods: We identified solitary kidney allograft recipients who received Dara within 180 days pre-transplant in our center. Clinical and laboratory data were abstracted from the chart. Protocol biopsies are routine in our practice.

Results: Ten patients met inclusion criteria. Mean age was 60 (±10) range 36-73 years, there were 7 males, and 7 received a living donor transplant. Induction was with Basiliximab in 7, Alemtuzumab in 2 & Anti-thymocyte globulin in 1. Maintenance immunosuppression consisted of ± corticosteroids, tacrolimus, mycophenolate mofetil in 9 patients, Belatacept replaced tacrolimus in one patient and in one patient sirolimus was substituted for tacrolimus 26 months post-transplant due to microangiopathy. Last dose of dara was 22 (16,30) days prior to transplant. Three patients resumed dara: 11, 24, and 244 days post-transplant. Follow-up was 32 (± 16) months. One patient did not undergo protocol biopsies due to systemic anticoagulation. The remainder had protocol biopsies at the predetermined time points. No graft losses occurred during follow-up. Two patients had subclinical borderline changes (i0, t1) at one year, and (i1, t3) on the two-year protocol biopsy. The latter, after reduction in immunosuppression due to CMV infection **(Fig1)**. Another patient developed severe BK nephropathy that required significant immunosuppression reduction.

Conclusions: In our series of 10 patients, we did not observe any clinical acute cellular rejections. Two patient had subclinical borderline changes, one- and two-years post-transplant. Daratumumab did not appear to increase the risk of rejection.



Rejection free (including borderline changes) kidney graft survival.

TH-PO822

Role of Angiopoietins in Cardiovascular Disease (CVD) Outcomes of Kidney Transplant Recipients

Liam Brown,[1] Natalie Gendy,[2] Mary Kate Staunton,[1] Kanika K. Garg,[1] Yu Yamamoto,[1] Wassim Obeid,[3] Andrew Bostom,[4] Sherry Mansour.[1] *[1]Yale School of Medicine, New Haven, CT; [2]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [3]Johns Hopkins University, Baltimore, MD; [4]Brown University, Providence, RI.*

Background: Kidney transplant recipients have 30 times the risk of dying from cardiovascular disease (CVD). We tested the role of 2 vascular biomarkers, angiopoietin-1 and angiopoietin-2 (angpt-1, -2), in the development of CVD in deceased donor kidney transplant recipients.

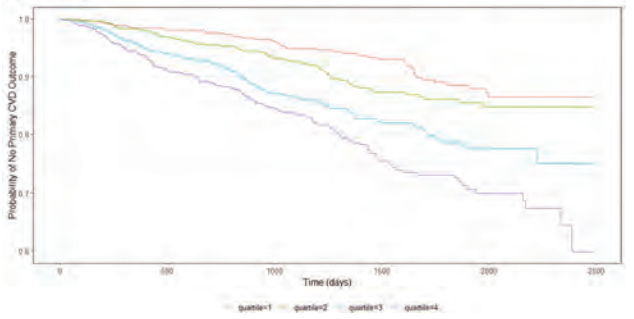
Methods: This is an ancillary analysis of the FAVORIT study, evaluating the associations between baseline levels of angpt-1 and angpt-2 in the development of CVD and the secondary outcomes of graft failure (GF) and death in 2000 recipients. We used a Cox regression analysis to test the associations between biomarker quartiles and outcomes.

Results: Median age of participants was 52 IQR [45, 59] years with 37% women and 73% identifying as white. Median time from transplantation to biomarker measurement was 3.99 IQR [1.58, 7.93] years. Median time to the development of CVD was 3.7 IQR [2.89-5.25] years. Angpt-1 was not significantly associated with outcomes. Higher levels of angpt-2 (quartile 4) as compared to quartile 1 had about 2 times the risk of CVD, GF and death [aHR 1.85 (1.25 - 2.73), *P*<.01; 2.24 (1.36 - 3.70), *P*<.01; 2.30 (1.48 - 3.58), *P*<.01, respectively, (Figure 1)].

Conclusions: Angpt-2 may identify high-risk kidney transplant recipients for the development of CVD. This may aid in tailoring follow-up after transplantation to reduce the risk of CVD.

Funding: NIDDK Support

Figure 1. Kaplan-Meier curve of the probability of not developing CVD stratified by Angpt-2 quartiles



The red line represents the probability of not developing CVD in patients with quartile 1 of angiopoietin-2 concentrations. Quartiles 2,3, and 4 are represented by the green, blue, and purple lines respectively. We adjusted for demographics (age, sex, race, and ethnicity); CVD related factors (hypertension, diabetes mellitus, body mass index, history of CVD, baseline estimated glomerular filtration rate); transplant-related variables (pancreas transplant, and graft vintage at randomization); medications (lipid lowering drugs, cyclosporine, tacrolimus, sirolimus, mycophenolate, azathioprine, and prednisone); and urine albumin-to-creatinine ratio and randomization status.

TH-PO823

Impact of Hyperparathyroidism and Its Different Subtypes on Long-Term Graft Outcome: A Single Transplant Center Cohort Study

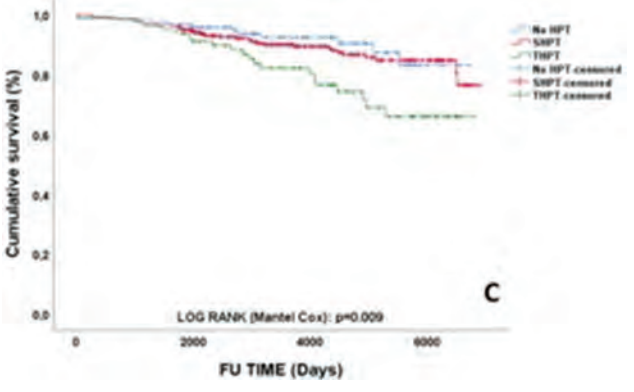
Carlo Alfieri,[1,2] Paolo Molinari,[1,2] Anna Regalia,[1] Anna Maria Pisacreta,[1,2] Elisa Cicero,[1,2] Giulia V. Re Sartò,[1,2] Giuseppe Castellano.[1,2] *[1]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Universita degli Studi di Milano, Milano, Italy.*

Background: We studied the association between parathormone (PTH) levels and long-term graft loss in RTx patients (RTx-p).

Methods: We retrospectively evaluated 871 RTx-p, transplanted in our unit from Jan-2004 to Dec-2020 assessing renal function and mineral metabolism parameters at 1, 6 and 12 months after RTx. Graft loss and death with functioning graft during follow-up (FU, 8.3[5.4-11.4] years) were checked.

Results: At month-1, 79% had HPT, of which 63% with secondary HPT (SHPT) and 16% tertiary HPT (THPT); at month-6, HPT prevalence was 80% of which SHPT 64% and THPT 16%; at month-12 HPT prevalence was 77% of which SHPT 62% and THPT 15%. A strong significant correlation was found between HPT type, PTH levels and graft loss at every time point. Mean PTH exposure remained strongly and independently associated to long-term graft loss (OR 3.1 [1.4-7.1], p=0.008). THPT was independently associated with graft loss at month-1 when compared to HPT absence and at every time point when compared to SHPT. No correlation was found with RTx-p death. Discriminatory analyses identified the best mean PTH cut-off to predict long-term graft loss to be between 88.6 and 89.9 pg/ml (AUC=0.658). Cox regression analyses highlighted that THPT was strongly associated with shorter long-term graft survival at every time point considered (Figure 1, PTH status at 12-months after KTx).

Conclusions: High PTH levels, and especially tertiary HPT during 1st year of RTx seem to be associated with long-term graft loss.



Survival analyses of long-term graft outcomes according to PTH status at 12-months after KTx

TH-PO824

Acute Phosphate Nephropathy: A Preventable Cause of AKI Among Kidney Transplant Recipients

Johanna Marie S. Orejo, Sandeep Ghai, Jean M. Francis, Melinda K. Solomon. *Boston Medical Center, Boston, MA.*

Introduction: Acute Kidney Injury (AKI) after a kidney transplant is an extreme emergency. It is associated with allograft loss and increased morbidity. Prompt recognition of reversible causes of AKI is important to prevent graft loss. We present a case of a kidney transplant patient who developed AKI secondary to acute phosphate nephropathy.

Case Description: A 37-year-old male with end-stage renal disease secondary to hypertension underwent a deceased donor kidney transplant. His pre-operative laboratory results include calcium of 8.2 mg/dl, phosphorus of 6.6 mg/dl, PTH of 855 pg/ml, and 25-hydroxyvitamin D of 18.6 ng/ml. His phosphate binder Sevelamer was discontinued after the transplant. He had an immediate graft function and an uncomplicated post-operative course. He was discharged on hospital day 4 with a creatinine of 1.1 mg/dl and phosphorus of 2 mg/dl. His immunosuppressants include Tacrolimus 7 mg twice daily, Myfrotic 720mg twice daily, and Prednisone 5mg daily. On follow-up, his blood work showed stable renal function but worsening hypophosphatemia of 1.4 mg/dl. He was initiated on oral phosphate supplementation. Two weeks later, he has a progressive worsening of AKI with creatinine trending up to 3 mg/dl. Due to concern for acute rejection, a kidney biopsy was performed which showed acute tubular injury with focal tubular necrosis, focal tubular subepithelial tubular calcium phosphate deposition, and calcium phosphate casts. There was no evidence of T-cell or Anti-body mediated rejection. Phosphate supplementation was discontinued which subsequently improved the patient's allograft function with his creatinine reaching a nadir of 1.8 mg/dl 3 months later.

Discussion: Hypophosphatemia is commonly seen after kidney transplantation. This case highlights that acute phosphate nephropathy secondary to oral phosphate repletion may cause AKI among kidney transplant patients. Nephrologists should be vigilant in managing hypophosphatemia following a kidney transplant. Unless hypophosphatemia is life-threatening, we recommend conservative management including high dietary phosphate intake. Oral phosphate supplementation should only be considered in patients who are symptomatic with persistent severe hypophosphatemia and once a patient is initiated, careful monitoring of serum phosphate level and kidney function is recommended.

TH-PO825

Rapid Point-of-Care Capillary Blood Assays for Monitoring Cystatin C Levels in Kidney Transplant Recipients

Trong Nguyen,[1] Maria Ortega,[1] Emily Vuu,[1] Rahul Ganguli,[1] Andrea C. Daza Aguilar,[2] Ekamol Tantisattamo,[2] Yalcin Kulahci,[4] Fatih Zor,[4] Vijay S. Gorantla,[4] Connie Rhee,[2] Kamyar Kalantar-Zadeh.[3] IOS. *[1]Intelligent Optical Systems, Inc., Torrance, CA; [2]University of California Irvine, Irvine, CA; [3]Harbor-UCLA Medical Center, Torrance, CA; [4]Wake Forest Institute for Regenerative Medicine, Winston-Salem, NC.*

Background: Frequent monitoring of tacrolimus (TAC), an FDA-approved immunosuppressant, and estimated glomerular filtration rate (eGFR) in kidney transplant recipients (KTRs) are necessary to prevent allograft rejection and toxicity. We propose to use cystatin C (CysC) concentration as a marker for estimating eGFR for KTRs; CysC concentration is independent of age, sex, and muscle mass, making it a valuable predictor of nephrotoxic risks associated with TAC in KTRs. IOS has partnered with UCI Nephrology and WFIRM to develop a novel point-of-care (POC) enhanced lateral flow assay (ELFA) platform to determine levels of CysC from fingerstick capillary blood.

Methods: ELFA performance was assessed using standard calibration curves (SCCs) with spiked whole blood samples at various CysC levels. Method validation involved 17 KTRs, comparing ELFA measurements on fingerstick blood samples (n=3) to standard lab measurements of CysC from venous blood. Samples were collected from the same KTRs before their next TAC dose. A comparison of ELFA CysC and lab serum assumed a 50% hematocrit correction. Pearson correlation and Bland-Altman analysis determined the agreement between ELFA and clinical laboratory methods.

Results: SCCs indicated ELFA performs well in the 0-6 mg/L range for CysC. ELFA and standard lab measurements strongly correlated with r=0.88. Bland-Altman analysis showed a mean difference (bias) of 0.13 mg/L for CysC between the two methods.

Conclusions: The ELFA platform delivers minimally invasive, convenient sampling in a POC device using capillary fingerstick blood from KTRs, and provides accurate, rapid measurements of CysC that have demonstrated good repeatability and strong correlation with laboratory standard reference measurements.

Performance of GFR Estimating Equations in Kidney Transplant Recipients of Various Races

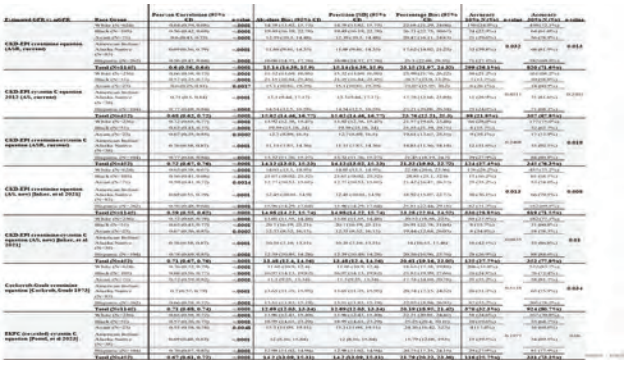
Pooja Budhiraja,[1] Richard J. Butterfield,[1] Raymond L. Heilman,[1] Musab S. Hommos,[1] Hay Me Me,[1] Wisit Cheungpasitporn,[2] Salah B. Alajous,[1] Tejas S. Khurana,[1] Hasan Khamash.[1] *[1]Mayo Clinic Arizona, Scottsdale, AZ; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: We compared the performance of various estimated Glomerular filtration rate (eGFR) equations in kidney transplant recipients of different races.

Methods: This single-center study compares eGFR with measured GFR at 1-year post-transplant.

Results: There were 1145 subjects with 1-year eGFR and mGFR data. Whites made up 54%, followed by Hispanics (23%), Blacks (9%), Native Americans (7%), and Asians (6%). Among Whites, 2021 CKD-EPI creatinine cystatin C-based equations outperformed others [r=0.72, 95% CI (0.65, 0.78)]. The Cockcroft-Gault creatinine equation was the best correlated, least biased, and most accurate (83.7% A30). In Blacks, both 2009 CKD-EPI [r=0.56, 95% CI (0.42,0.68)] and 2021 CKD-EPI [r=0.56, 95% CI (0.41, 0.68)] had a weak correlation. The new EKFC (rescaled) cystatin C equation did not perform better in blacks than the 2021 CKD-EPI creatinine or 2012 CKD-EPI cystatin C-based equations. Cockcroft-Gault creatinine equation had the best correlation [r=0.68, 95% CI (0.56, 0.77)], followed by the 2021 CKD-EPI creatinine-cystatin C equation (0.63, 95% CI (0.43, 0.77). Among Hispanics, cystatin C and combined creatinine cystatin C-based equations were superior, with the 2021 CKD-EPI creatinine-cystatin C equation being the most accurate (84.6%) and highly correlated [r=0.78 (0.69, 0.85)]. In Native Americans, the creatinine-cystatin and EKFC cystatin c equations achieved the highest 30% accuracy (>85%).

Conclusions: The study suggests that combined equations of creatinine-cystatin C performed better than creatinine-based equations and the cystatin C-based equations in all races. EKFC rescaled cystatin equation performed better than 2021 CKD EPI. There was no substantial difference between the 2009 CKD EPI and the new 2021 CKD-EPI equation, which does not factor in race.



TH-PO827

eGFRcr, eGFRcys, Muscle Mass, and All-Cause Mortality in Kidney Transplant Recipients: Post-Hoc Analyses from a Randomized Controlled Trial

Gabriel A. Curran,[1] Jane D. Mcneilly,[2] Alastair J. Rankin,[2] Kaitlin J. Mayne,[1,3] Elbert Edy,[4] Patrick B. Mark,[1,2] Jennifer S. Lees.[1,2] *[1]University of Glasgow, Glasgow, United Kingdom; [2]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [3]University of Oxford, Oxford, United Kingdom; [4]Manchester University NHS Foundation Trust, Manchester, United Kingdom.*

Background: We explored eGFRcr, eGFRcys and pectoral muscle cross-sectional area (PMA: a muscle mass surrogate) in kidney transplant recipients (KTR) and assessed relationships: i) between parameters and ii) with all-cause mortality.

Methods: Participants were from the ViKTORIES randomised controlled trial (ISRCTN22012044) in prevalent KTR. eGFRcr (2009) and eGFRcys (2012) were calculated from creatinine and cystatin C respectively at baseline. PMA was calculated as the mean pectoral muscle area from slice 1 (the first slice in which the full pectoral muscle became visible), 3 and 5 on non-contrast axial thoracic computed tomography (CT) scans taken at baseline. Follow-up data were extracted from the electronic record. Linear regression tested associations between eGFR measures and PMA. Cox proportional hazards models tested associations between eGFR measures, PMA and death.

Results: Of 90 ViKTORIES participants, 90 had available serum/plasma samples and 89 had CT data for analysis. Mean (±SD) age was 57.6 ± 9.6 years and 63 (70%) were male. The proportion with pre-existing cardiovascular disease (21.1%) and diabetes (22.2%) was lower than observed in UK KTR populations. Over median follow-up of 4.8 (IQR 4.5 - 5.1) years, there were 14 deaths. Mean eGFRcys (40.9 ± 18.3 mL/min/1.73m^2) was lower on average than eGFRcr (52.5 ± 21.0 mL/min/1.73m^2; Figure). PMA was inversely associated with eGFRcr (adjusted β per 1cm^2 increase in PMA: -0.326, p=0.007), but not eGFRcys (adjusted β: -0.172, p=0.165). eGFRcys (but not eGFRcr nor PMA) was significantly associated with death (aHR per 10mL/min/1.73m^2 decrease: 1.62, 95% CI 1.05-1.92).

Conclusions: In this population of KTR with lower-than-expected cardiometabolic comorbidity, eGFRcys was lower than eGFRcr, was not associated with muscle mass but was strongly associated with mortality. As seen in the general population, eGFRcys is a valuable marker to stratify risk of death in KTR.

Long-Term Outcome of Kidney Transplant Recipients with History of Complement-Mediated Thrombotic Microangiopathy

Kanza Haq,[1] Alana Dasgupta,[3] S.M. Bagnasco,[1] Umberto Maggiore,[2] Nada Alachkar.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]Azienda Ospedaliero-Universitaria di Parma, Parma, Italy; [3]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: The long-term outcome of kidney transplant recipients with history of complement-mediated thrombotic microangiopathy (cTMA) is unknown.

Methods: We retrospectively studied all kidney transplant recipients with TMA as primary disease or developed TMA post-transplant between Jan 2000 and Dec 2020 in our center. We estimated the crude survival probability via Kaplan-Meier methods starting at date of transplant until graft failure or death. The adjusted hazard ratio (aHR) associated with primary cTMA was estimated using Cox regression models with time-varying cTMA effect and biopsy diagnoses included as time-varying variables.

Results: We identified 129 patients (20 with cTMA as primary disease) who had 460 biopsies. After a mean follow-up of 4.5 years, 73 started dialysis and 22 died. Compared to others, patients with cTMA were younger both at cTMA diagnosis and at transplantation (age at diagnosis, 28.9±16.3. vs 46.5±16.0 years; P<0.001). Crude survival probability is reported in **Figure 1**. After adjusting for non-linear age, sex, ethnicity, biopsy diagnoses, cTMA was associated with 4-fold increase in the hazard of transplant failure shortly after transplant (adjusted hazard ratio (aHR): 3.97 [95%CI:1.52-10.38; P=0.005]); then, the aHR decreased by 0.87 (95%CI: 0.77-1.00; P=0.046) per year elapsed since transplantation (**Figure 2**). Banff diagnoses were all associated with increased hazard of transplant failure: grade 1 & 2 TCMR, borderline rejection, and CNI-toxicity (P<0.05), and ABMR (P=0.077), the strength of their association with transplant failure not being affected by cTMA history (P=0.38 for interaction).

Conclusions: Patients with cTMA have an increased risk of early transplant failure which vanishes with time elapsed since transplant when standard Banff diagnoses seem to take over cTMA history in determining transplant prognosis.

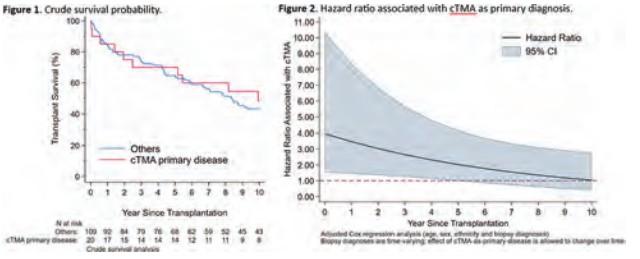

Figure 1. Crude survival probability. **Figure 2.** Hazard ratio associated with cTMA as primary diagnosis.

TH-PO829

Long-Term Outcomes Comparing Belatacept- vs. Tacrolimus-Based Maintenance Immunosuppression in Kidney Transplant Recipients: A UNOS Database Analysis

Adriana Montalvan,[1] Stalin I. Canizares Quisiguina,[1] Devin Eckhoff,[1] David D. Lee,[1] Kalathil K. Sureshkumar,[2] Bhavna Chopra.[1] *[1]Beth Israel Deaconess Medical Center, Boston, MA; [2]Allegheny Health Network, Pittsburgh, PA.*

Background: Calcineurin-inhibitors have been the mainstay of maintenance immunosuppression in kidney transplant recipients (KTRs), which is associated with nephrotoxic risks. Several immunosuppressants have been tried as nephron sparing agents but with limited success. We compared long-term outcomes of KTRs on tacrolimus (Tac) vs belatacept (Bela) based maintenance immunosuppression.

Methods: Using the UNOS Standard Transplant Analysis and Research (STAR) file to identify adult, first KTRs only from 2010 to 2022 who received induction therapy. Patients were categorized based on Tac or Bela based maintenance immunosuppression

at discharge. Multivariate cox regression models adjusting for several donor, transplant and recipient factors were used to compare graft, death-censored graft failure (DCGF) and patient death in all KTR and further stratified by donor type.

Results: A total of 194307 and 5152 patients on Tac and Bela were identified. Compared to patients discharged on Tac, subjects discharged on Bela were more likely to be older (53.5y vs 52.1y), African American (35.2% vs 27.3%), and diabetic (36.6% vs.34.5%), had greater time on dialysis (974d vs 913d), and received higher KDPI kidneys (36 vs 23) ($p<0.05$). Results of all KTRs and further stratified by donor type are shown in Table 1. Outcomes were similar in living donor KTRs; in deceased donor KTRs, Bela was associated with increased risk of death and DCGF.

Conclusions: Based on demographic and clinical data, patients discharged on Bela as maintenance therapy had higher comorbid burden. Our study found increased DCGF and patient death in the Bela group, which might be related to increased comorbidity, risk of early rejections despite the reduced nephrotoxic effects, and possibly increased viral and fungal infections associated with Bela. Retrospective nature and selection bias are major limitations of database study. Randomized controlled trials comparing Bela vs Tac are awaited.

Outcomes of all, deceased and living donor kidney recipients based on immunosuppression maintenance at discharge

	Patient Death HR (95%CI); p	Adjusted Overall Graft Failure HR (95%CI); p	Death Censored Graft Failure HR (95%CI); p
All patients Tac(n=194307) vs Bela(n=5152)	0.89 (0.82-0.97); 0.009	0.97 (0.90-1.05); 0.457	0.85 (0.78-0.94); 0.001
Deceased Donor Tac(n=3722) vs Bela(n=134583)	0.89 (0.82-0.97); 0.009	0.97 (0.90-1.05); 0.457	0.85 (0.78 - 0.94); 0.001
Living Donor Tac(n=59724) vs Bela(n=1430)	0.87 (0.74-1.03); 0.115	0.97 (0.82-1.14); 0.683	0.92 (0.75-1.12); 0.398

TH-PO830

Long-Term Outcomes Comparing Belatacept vs. Tacrolimus Stratified by Cytomegalovirus Risk in Kidney Transplant Recipients: A UNOS Database Analysis

Adriana Montalvan, Stalin I. Canizares Quisiguina, Devin Eckhoff, David D. Lee, Bhavna Chopra. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Cytomegalovirus (CMV) infection is associated with increased risk of death and significant morbidity which can cause graft loss. Some studies have shown that Belatacept (Bela) may be associated with an increased risk of CMV reactivation and infection. We analyzed the UNOS database to compare long term patient and graft outcomes comparing Tacrolimus (Tac) vs Bela based maintenance immunosuppression (IS) in Kidney Transplant Recipients (KTR) stratified by CMV risk.

Methods: Using the UNOS Standard Transplant Analysis and Research (STAR) file, we identified adult, kidney-only transplant recipients from 2010 to 2022 who received (depleting/non-depleting) induction therapy and were discharged on Tac or Bela based maintenance IS. Multivariate cox regression models adjusting for several donor, transplant and recipient factors were used to compare Tac vs Bela maintenance in KTR stratified by CMV risk; CMV low (D-/R-), CMV intermediate (R+), and CMV high risk (D+/R-). Outcome measures included overall mortality, graft, and death-censored graft failure (DCGF).

Results: A total of 196785 KTR were identified where 5046 were on Bela and 191739 on Tac at discharge. The long-term outcomes comparing Tac vs. Bela were similar in CMV low risk group, worse (DCGF and Patient) for Bela in CMV intermediate risk and DCGF was nearing significance worse for Bela in high-risk group. Results are shown in Table 1.

Conclusions: When stratifying KTR based on CMV risk, it appears that patients on maintenance Bela IS may be at increased risk for DCGF when the CMV risk increases. Lack of granularity of data on CMV infection related details, retrospective design and selection bias are limitations of this study.

Outcomes on KTR according to immunosuppression maintenance at discharge stratified by CMV risk

	Adjusted Overall Graft Failure HR (95%CI); p	Death Censored Graft Failure HR (95%CI); p	Patient Death HR (95%CI); p
CMV Low Risk Tac (n=33035) vs Bela (n=866)	1.04 (0.82-1.31); 0.749	1.31 (0.93-1.83); 0.123	1.06 (0.82-1.37); 0.661
CMV Intermediate Risk Tac (n=124730) vs Bela (n=3423)	0.99 (0.91-1.01); 0.890	0.83 (0.74-0.92); 0.001	0.89 (0.80-0.98); 0.015
CMV High Risk Tac (n=33948) vs Bela (n=757)	0.86 (0.73 - 1.02); 0.091	0.81 (0.65-1.01); 0.058	0.87 (0.71-1.05); 0.149

pos: positive | neg: negative

TH-PO831

Renal Allograft Function Outcomes After Conversion from Conventional Immunosuppression to Belatacept Plus Low-Dose Conventional Drug Regimen

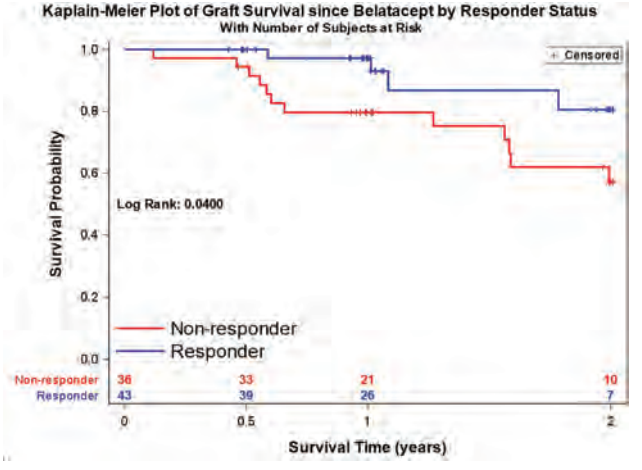
Ahsan Aslam,[1] Sharon M. Moe,[1] Yang Li,[1,2] Kathleen A. Lane,[1,2] Muhammad Y. Jan,[1] Oluwafisayo O. Adebiyi,[1] Asif A. Sharfuddin,[1] Muhammad S. Yaqub.[1] Division of Nephrology and Hypertension. *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University Richard M Fairbanks School of Public Health, Indianapolis, IN.*

Background: Calcineurin Inhibitors (CNI) and Sirolimus have been traditionally used as immunosuppressants to prevent rejection in kidney transplant recipients but they are often associated with undesirable renal and metabolic adverse effects. Belatacept which is a selective T-cell costimulation blocker does not have the undesirable AE's. Data on using Belatacept and low dose CNI/Sirolimus combination is scant. At our institution, patients are switched to this regimen if they had Slow/delayed graft function, complications related to CNIs or graft rejection while on these drugs.

Methods: It is a retrospective chart review study. We included all patients >18 years of age at Indiana University Hospital who had a Kidney transplant and were switched from Tacrolimus, Sirolimus or Cyclosporine to a combination of Belatacept and lower dose CNI/Sirolimus. 'Response' (to the addition of belatacept) was defined as >10% change in the eGFR per year from baseline (pre-belatacept values) over 2 years. Logistic regression models were performed.

Results: N=79 Mean Age=53 years. History of deceased donor kidney transplant= 64 %. Response was observed in 54% of patients with improved eGFR by 6 months ($p= 0.003$) and sustained by 2 years eGFR of 49.1+/-19.5 vs. 35.3 +/-11.4 ($p = 0.04$). The mean duration of dialysis in responders vs. non responders was 32 and 52 months, respectively ($p= 0.057$) and there was no difference in tacrolimus levels post conversion. By univariate anlayses, non-response was significantly associated with retransplant (OR= 4.93) and higher level of proteinuria (OR= 1.51), and history of graft rejection before belatacept (OR= 3.45).

Conclusions: Belatacept in combination with low dose conventional immunosuppression appears to be a favorable option in patients with slow/delayed graft function or intolerance to conventional drugs at their therapeutic levels.



TH-PO832

Safety of Belatacept as a Maintenance Immunosuppressive Therapy in Kidney Transplantation: A Systematic Review and Meta-Analysis

Ibrahim Tawhari. *King Khalid University, Abha, Saudi Arabia.*

Background: Although calcineurin inhibitors (CNIs) are used as the standard maintenance immunosuppressive therapy after kidney transplantation, they are associated with nephrotoxicity and long-term renal allograft loss. Recent randomized controlled trials (RCTs) showed that using Belatacept (Bela) as an alternative to CNIs is associated with improves renal functions. However, there has been conflicting data about the risk of adverse outcomes such as infections and malignancies.

Methods: A systematic search for RCTs assessing the safety and efficacy of Bela in adult kidney transplant recipients was conducted in multiple online databases including Google Scholar and PubMed. RStudio was used for statistical analysis. Results are expressed as relative risk ratio (RR) and 95% confidence interval (CI).

Results: Five RCTs were included in our meta-analysis. The results showed no significant difference between the Bela and CNIs based-regimen in terms of renal allograft loss (RR= 0.77, 95% CI 0.52 – 1.09), cytomegalovirus (CMV) viremia (RR= 0.0.98, 95% CI 0.47 – 1.30), BK viremia (RR= 0.83, 95% CI 0.35 – 2.02), and malignancy (RR= 1.31, 95% CI 0.81 – 2.13). There was a significant increase in the risk of post-transplant lymphoproliferative disorder (PTLD) (RR= 3.87, 95% CI 1.08 – 13.82), but the majority of those patients were Epstein-Barr virus (EBV) seronegative.

Conclusions: Overall, the use of Bela as maintenance immunosuppressive therapy in kidney transplantation was generally safe and with no substantial increase in the risk of infection or malignancy. There was an increased risk of PTLD associated with this regimen in patients with EBV-negative serology. Avoiding Bela in EBV-negative patients may help lower this risk.

TH-PO833

Expanded One-Year Experience of Bimonthly Belatacept

Johanna L. Christensen, Randi Thompson, Ryan Winstead, Layla Kamal, Gaurav Gupta. *VCUHealth, Richmond, VA.*

Background: Belatacept (bela) is a common immunosuppressive (IS) drug in kidney transplant (KT). We have over 300 KT patients on bela. Our initial cohort of expanded 2 monthly belatacept had favorable results so we expanded our cohort from 18 to 34 patients, and continued monitoring until year post conversion.

Methods: 34 patients at high risk of infection were included who were beyond one year from transplant and had no donor specific antibody (DSA) or prior episodes of rejection. They had stable allograft function and maintenance IS included bela 5mg/kg monthly, median mycophenolate mofetil dosing of 1g daily and prednisone 5mg daily. We monitored donor derived cell free DNA (ddcfDNA; Allosure), DSA, total IgG level, and CD4 counts at baseline and then at 2, 4, 6, and 12 months. Repeated measures ANOVA was used to assess statistical changes with multiple comparisons adjusted with Tukey-HSD.

Results: 20/34 (59%) patients were African American. The mean time on bela at initiation was 48.1± 30.0 months. The estimated glomerular filtration rate (eGFR; Mean± SE) did not change significantly between initiation and month 12 (43.5 ± 3.3 vs 46.3± 6.6 ml/min). There was no significant change in ddcfDNA between months 0 (0.23± 0.03%), 2, 4 and 6 (0.20±0.06%) months, though at month 12 there was an uptrend in mean ddcfDNA in 10 patients that have achieved this interval (0.43± 0.06%). There was no difference in absolute CD4 count; mean± SE between month 0 and 12 (326 ± 33.9 vs 368.7 ± 72.5; p= 0.94) and similar results were noted for IgG levels (939.5.2± 57.2 vs 861.0 ± 124.2; p=0.72). 1 patient developed low grade DSA at 6 months, which resolved spontaneously. 1 patient underwent biopsy for proteinuria which showed advanced diabetic nephropathy. One patient underwent biopsy for acute rise in ddcfDNA with DSA, which showed antibody mediated rejection, which resolved after intensive therapy and return to monthly bela infusions. There were no graft losses.

Conclusions: This report evaluating q2m bela, in a carefully selected and monitored cohort, demonstrates low risk of rejection with change in dose interval. There was no significant change in DSA or ddcfDNA or incidence of major opportunistic infections. Long term outcome monitoring is needed, and close interval assessment of ddcfDNA and DSA is critical for management of these patients in order to reduce the risk of acute rejection.

TH-PO834

Comparisons of Clinical Outcomes Between Hypertensive and Normotensive Living Kidney Donors: A Nationwide Prospective Cohort Study

Yu ho Lee,[1] So-young Lee,[1] Hyeyun Jeong,[1] Jin sug Kim,[2] Jihyun Baek,[1] Hyaemin Lee,[1] Hyeon Seok Hwang.[2] *[1]CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [2]Kyung Hee University Medical Center, Dongdaemun-gu, Seoul, Republic of Korea.*

Background: Living kidney donors with hypertension is potential candidates to solve the imbalance between supply and demand for renal transplantation. However, the safety of hypertensive donor is not sufficiently ensured after donor nephrectomy and there are limited studies, which compare the clinical outcomes between hypertensive and normotensive donors.

Methods: All data from this study were obtained from the Korean Organ Transplantation Registry. A total 642 hypertensive donors and 4,848 normotensive living kidney donors were included from May 2014 to December 2020.

Results: Compared to normotensive donors, hypertensive donors had lower eGFR before nephrectomy and remained lower after kidney transplantation. However, the risk of eGFR below 60 ml/min/1.73 m²(adjusted HR, 0.87; 95% CI 0.70-1.09; P = 0.217) or below 45 ml/min/1.73 m²(adjusted HR, 1.52; 95% CI 0.79-2.94; P = 0.209) was not significantly increased in hypertensive donors after multiple adjustment. When comparing the rate of eGFR decline between the hypertensive and normotensive donors, there was no significant difference (adjusted unstandardized β, -0.19; -1.15 – 0.76, P = 0.691). The incidence of proteinuria occurrence in hypertensive donor was increased, and it tended to increase even after 4-5 years. Hypertensive donors were found to have significantly more proteinuria than normotensive donors (adjusted HR, 1.77; 95% CI 1.10-2.85; P =0.020).

Conclusions: Our study indicated that the risk of proteinuria after donation was increased in hypertensive donor, while it was not translated into significant decline in renal function. The careful monitoring for proteinuria should be required in hypertensive donor after nephrectomy.

TH-PO835

Tegoprubart for the Prevention of Rejection in Kidney Transplant: Update of Emerging Data from an Ongoing Trial

John S. Gill,[1] Jeffrey D. Bornstein.[2] *[1]St Paul's Hospital, Vancouver, BC, Canada; [2]Eledon Pharmaceuticals, Irvine, CA.*

Background: Tegoprubart is a monoclonal antibody directed against the CD40 ligand (CD40L), a key mediator of co-stimulation. Inhibition of CD40L should result in a decrease in both cell and antibody mediated immunity and create a more tolerogenic immune environment. Tegoprubart has been shown to be effective in animal models and is currently being studied in kidney transplant recipients. It is being assessed to determine whether it can provide similar prevention of rejection as tacrolimus with superior graft function.

Methods: 12 adults receiving a kidney transplant from either a living or deceased donor will be enrolled. To be eligible, this must be their first transplant, they must be seropositive for EBV, free of donor specific antibodies, have low panel reactive antibodies, and the organ cannot be from an extended criteria donor or have a prolonged cold ischemia time. All participants will receive rATG and a regimen consisting of tegoprubart 20 mg/kg IV administered every 3 weeks after initial loading, mycophenolate and corticosteroids. The primary endpoint is safety at one year. Secondary endpoints include characterizing the pharmacokinetic profile of tegoprubart, the incidence of biopsy proven rejection (BPAR) and changes in estimated glomerular filtration rate (eGFR).

Results: As of the abstract submission deadline, May 2023, 5 participants have been transplanted, and 3 are ongoing. No participant has experienced rejection. One discontinued due to an SAE of BK viremia and another for mild alopecia and fatigue. BK viremia was the only SAE reported to date, and the drug appears safe and well tolerated. Participant information is summarized in Table 1, and mean eGFR is summarized in Figure 1.

Conclusions: Improved graft function may improve long term outcomes in kidney transplantation. It is postulated that tegoprubart could be an alternative therapy for prevention of rejection in kidney transplant recipients. Data to date are encouraging, with no rejections, a good safety profile and excellent allograft function.

Anti-Thymocyte Globulin vs. Alemtuzumab Induction and Associated Complications in Kidney Transplantation: A 20-Year Multi-Center Experience

Sundus Sardar,[1,2] Abdel-Rauof M. Akkari,[1,3] Mohammad Gul Yousaf Khan,[1,3] Ronald P. Miller,[1,2] Nasrollah Ghahramani.[1,3] *[1]Penn State College of Medicine, Hershey, PA; [2]Penn State Health Milton S Hershey Medical Center, Hershey, PA; [3]Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Background: Antibody-depleting immunosuppression such as anti-thymocyte globulin (ATG) and alemtuzumab are commonly-used induction therapies after kidney transplantation, and may result in varying rates of associated complications including, but not limited to, acute or delayed allograft rejection, leukopenia, sepsis, allograft failure, CMV infection, BK virus nephropathy, or death.

Methods: We performed a retrospective multi-center cohort study using TriNetX, a global federated health research network, providing access to electronic medical records across large healthcare organizations [HCOs] grouped into Global Collaborative Network including 97 HCOs. We identified 4,920 propensity-matched kidney transplant recipients inducted with ATG (n=2460) or alemtuzumab (n=2460) between Jan 2003-2023 from 26 HCOs in 13 countries, compared for clinical outcomes with risk analysis and Kaplan-Meier survival analysis.

Results: Kidney allograft rejection occurred in 1,159(47.1%) patients with alemtuzumab induction as compared to 794(32.3%) patients in ATG cohort(RR=1.460;95%CI 1.36-1.57). Severe sepsis confirmed in 160(6.5%) patients with alemtuzumab vs 179(7.27%) in ATG group(RR=0.894;95%CI 0.73-1.09). With alemtuzumab, 908(36.9%) patients developed leukopenia vs 741(30.1%) patients in ATG cohort(RR=1.225;95%CI 1.13-1.33), and 135(5.48%) died in alemtuzumab group vs 176(7.15%) in ATG group(RR=0.77;95% CI 0.617-0.953). Kidney transplant failure (KTF) was confirmed in 1090(44.3%) patients in alemtuzumab group and 724(29.4%) patients in the ATG group (RR=1.506, 95% CI 1.396-1.624), with graft survival of 53.06% and 67.80% in alemtuzumab vs ATG cohorts, respectively(HR=1.68;95%CI 1.53-1.85; p=0.004). CMV disease confirmed in 860(34.9%) with alemtuzumab induction vs 693(28.8%) in ATG group(RR=1.241;95%CI 1.14-1.35). With alemtuzumab induction, BK virus nephropathy was diagnosed in 370(15.0%) vs 265(10.7%) in ATG group(RR=1.396;95%CI 1.21-1.74).

Conclusions: Kidney transplant patients with alemtuzumab induction had significantly increased risk of rejection, leukopenia, transplant failure, CMV infection, and BK virus nephropathy. Risk of death is significantly less in the alemtuzumab group as compared to ATG group. No significant difference in severe sepsis between alemtuzumab and ATG cohorts.

Incidence and Outcomes of Post-Transplant Lymphoproliferative Disorder After Kidney Transplantation: A 20-Year Multi-Center Experience

Sundus Sardar, Abdel-Rauof M. Akkari, Mohammad Gul Yousaf Khan, Nasrollah Ghahramani. *Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Background: Post-transplant lymphoproliferative disorder (PTLD) is a rare complication following solid-organ transplantation, involving a spectrum of lymphocytic and/or plasmacytic proliferations in immunosuppressed patients. While often associated with Epstein-Bar Virus (EBV) reactivation, the pathogenesis and risk factors of PTLD are not clearly understood; its clinical manifestations are diverse, and management is challenging with focus on immunosuppression reduction, chemoradiotherapy or surgical resection of localized lesions, while aiming to preserve graft function.

Methods: We performed a retrospective multi-center cohort study using TriNetX, a global federated health research network providing access to electronic medical records across large healthcare organizations (HCOs). We identified 163,826 post-kidney transplant patients from January 15 2003-2023 from 89 HCOs in 13 countries. Patients with confirmed diagnosis of PTLD (n=2181) and those without PTLD (n=161,645) post-renal transplantation were assessed for clinical outcomes including death and kidney transplant failure (KTF) with risk analysis and Kaplan-Meier survival analysis.

Results: Among 163,826 post-renal transplant recipients, 2,181 (1.3%) were identified with confirmed diagnosis of PTLD and 161,645 (98.6%) did not develop PTLD. At the time of transplant, the PTLD group was younger($p<0.0006$), more likely to have received a previous transplant($p<0.0001$), and on an immunosuppressive agent($p<0.0001$). Of those who developed PTLD, 534 (24.4%) died as compared to 23,824 (14.7%) in non-PTLD group; survival rate was 55.87% in PTLD vs. 44.79% in non-PTLD cohort [HR=0.434, 95% CI 0.398-0.473, p = 0.00). Risk difference for death in patients without PTLD vs. with PTLD was -0.097 [RR=0.602, 95% CI -0.116, -0.079; p=0.00]. KTF was confirmed in 34,643 (21.4%) in non-PTLD vs 600 (27.5%) in PTLD group. KTF risk in patients without PTLD and with PTLD was 0.214 and 0.275, respectively, with graft survival of 54.06% and 55.55% in non-PTLD vs. PTLD cohorts, respectively [HR=0.652, 95% CI 0.602-0.707, p=0.008].

Conclusions: Younger age, previous transplant and being on an immunosuppressive agent at time of kidney transplant is associated with occurrence of PTLD. Additionally, PTLD is associated with increased risk of graft failure and death.

TH-PO838

Histological Analysis of Protocol Biopsies and Outcomes in ABO-Incompatible Renal Transplants: A Single-Centre Prospective Study from West India

Aniketh Prabhakar,[1] Sishir D. Gang.[2] *[1]Sigma Hospital, Mysore, India; [2]Mulijibhai Patel Urological Hospital, Nadiad, India.*

Background: ABO Incompatible renal transplants(ABOiKtx) provide a viable option to increase donor pool for ever increasing need. Outcomes are comparable to ABO compatible counterparts. Limited data exist regarding role of Protocol Biopsies and the impact of histological changes on the outcomes of ABO incompatible renal transplants.

Methods: We Included all ABO incompatible renal transplant patients from April 2017 and have completed 6 months of follow up till march 2019. A Protocol biopsy was done when eligible at 3 and 12 months post transplant. All the patients were analyzed for outcomes. Mehtodology for Biopsy: Biopsy samples were processed at our hospital, 2 cores were taken for histology and IF, C4D done by IF. Protocol biopsies were assessed and deemed adequate for interpretation by pathologists and graded according to the revised Banff classification 2017.

Results: 34 patients who underwent ABOiKTX between April 2017 to March 2018 were included. 23/34 patients underwent biopsies at 3 months[17 protocol and 6 indication biopsy(5 didnot consent, 2 were on antiplatelets, and 4 grafts were lost)] and20/23 at 12 months[17 protocol and 3 indication biopsy(2 graft were lost and one was on antiplatelets)]. Protocol biopsies revealed no subclinical rejections. 3/17 and 8/17 had C4d positivity without rejection at 3 and 12 months respectively. Presence of C4d at 3 months did not significantly influence GFR or Chronicity on biopsy at 12 months. Analysis of indication biopsies 6/23 revealed 1 IFTA,1 ABMR 4 TCMR at 3 months. Overall 6 patients had TMA on biopsies(Indication biopsies) over 1 year follow up. At 1 year Patient survival was 94% and death censored graft survival of 87% (Causes- Graft artery thrombosis, HUS and Rejections). Subgroup analysis revealed no difference in graft outcomes with lower or higher doses of Rituximab for desesnitization (p= 0.6).

Conclusions: Presence of C4D positivity or Tubulo-interstitial inflammation at 3 months was not associated with reduced GFR or increased fibrosis at end of 1 year. Lack of subclinical rejections were encouraging. Those with normal biopsies at 3 months had good outcomes at 1 year. Graft Survival and patient survival were comparable with other centres.

TH-PO839

Clinical Outcomes and Health Care Resource Utilization Associated with Post-Transplant Neutropenia Among Kidney Transplant Recipients: A Real-World Evidence Study

Qinghua Li,[1] Vladimir Turzhitsky,[1] Pamela Moise,[1] Kaylen Brzozowski,[2] Irina Kolobova.[1] *[1]Merck & Co Inc, Rahway, NJ; [2]TriNetX LLC, Cambridge, MA.*

Background: Cytomegalovirus (CMV) remains one of the leading opportunistic infections after kidney transplantation (KT). Valganciclovir is the preferred drug for CMV prophylaxis, but neutropenia limits its use. The objective of this study was to examine the differences in clinical outcomes and HCRU among KT recipients (KTRs) with and without PTN.

Methods: This retrospective cohort study utilized the TriNetX Dataworks – USA Network, a federated network of de-identified electronic health record data for over 86 million patients in the US. Adult KTRs who received their first KT between 1/1/2012 and 9/30/2020 and valganciclovir/ganciclovir within 30 days post-KT were included. PTN was defined by laboratory ANC of <1000 cells/μl. We ran Chi-square tests for categorical variables and t-tests for continuous variables.

Results: Among 8,791 KTRs included in this study, 2,149 (24.4%) developed PTN. ***Table 1*** presents the comparison on clinical and HCRU outcomes. A higher proportion of KTRs with PTN had CMV infections/disease (12.1% vs. 4.4%), other opportunistic infections (e.g., bacterial septicemia (13.1 vs 8.4%)), graft rejection (30.5% vs. 25.8%), graft loss (7.6% vs. 5.2%), new-onset of diabetes mellitus (32.8% vs. 21.5%), and received dialysis (30.5% vs 25.8%) within 1 year post-KT. KTRs with PTN (vs. without) were more like to have hospitalizations (63.1% vs. 55.9%), ER visits (37.5% vs. 32.0%), outpatient visits (mean number of visits: 39.3 vs. 33.0), blood transfusions (23.5% vs. 20.1%), and G-CSF use (54.2% vs. 5.2%).

Conclusions: KTRs with PTN tended to experience more opportunistic infections, worse graft outcomes and higher HCRU. The findings suggest the need for treatment options to reduce the risk of PTN among KTRs to improve clinical outcomes and reduce HRCU post-KT.

Funding: Commercial Support - Merck & Co. Inc

Table 1: Clinical Outcomes and HCRU within 1 Year Post-KT

Clinical outcomes and HCRU	With PTN N (%) /Mean (SD)	Without PTN N (%) /Mean (SD)	P-value
	2,149 (24.4%)	6,642 (75.6%)	
Clinical outcomes			
Opportunistic infections			
CMV infection/disease	259 (12.1%)	292 (4.4%)	<0.01
Viral infections (non-CMV)	976 (45.4%)	2296 (34.6%)	<0.01
Bacterial infections	335 (15.6%)	679 (10.2%)	<0.01
Septicemia	281 (13.1%)	555 (8.4%)	<0.01
Fungal infections	356 (16.6%)	774 (11.7%)	<0.01
Graft Outcomes			
Graft rejection	656 (30.5%)	1,712 (25.8%)	<0.01
Graft loss	163 (7.6%)	348 (5.2%)	<0.01
Dialysis	600 (27.9%)	1,607 (24.2%)	<0.01
HCRU			
Hospitalization	1,357 (63.1%)	3,713 (55.9%)	<0.01

G-CSF	1,165 (54.2%)	346 (5.2%)	<0.01

TH-PO840

Association of Metformin with Rejection and Graft Survival in Kidney Transplant Recipients Taking Tacrolimus with Post-Transplantation Diabetes Mellitus

Jaeyun Lee,[1] Jiyun Jung,[2] Haeyon Cho,[1] Dongyeon Lee,[1] Jae Yoon Park,[2] Hyosang Kim.[1] *[1]Asan Medical Center, Songpa-gu, Seoul, Republic of Korea; [2]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: Tacrolimus is a pivotal maintenance immunosuppressive drug in kidney transplantation (KT). Although diabetogenic property of tacrolimus is still an inevitable concern, it can reduce the risk of acute rejection and improve graft survival. Metformin, despite limited randomized controlled trial, has been found to be safe and effective in patients with post-transplantation diabetes mellitus. We aimed to investigate the effect of metformin on acute rejection and graft survival in kidney transplant recipients taking tacrolimus.

Methods: A number of 410 PTDM patients prescribed tacrolimus between 2000 and 2018 were collected. We conducted propensity score matching between the metformin and non-metformin group and evaluated the effects of metformin on the occurrence of T-cell mediated rejection and antibody-mediated rejection, and graft survival.

Results: Among 410 patients taking tacrolimus, 273 patients were treated with metformin for the average of 3.8 years. After 1:1 matching, cumulative incidences of TCMR (p=0.029) and graft failure (p=0.025) in the metformin group was lower than the non-metformin group, while no significant difference was observed in ABMR. Metformin use was associated with a reduced risk of TCMR (HR 0.40, 95% CI 0.18-0.90, p=0.026) and graft failure (HR 0.32, 95% CI 0.14-0.72, p=0.006). There was no significant difference in tubulitis, interstitial inflammation, and endarteritis scores of TCMR between the metformin and the non-metformin group.

Conclusions: Our study demonstrates that combination therapy with metformin and tacrolimus in KT recipients with PTDM is associated with a lower risk of acute rejection and graft failure.

Triple Jeopardy: Trialled Thrice in the Same Crime

Fatima Ayub,[1] Md R. Hasan,[2] Nasir Khan,[1] Wadhah M. Bin Homam,[1] Venkata R. Manchala.[1] *[1]University of Arkansas for Medical Sciences, Little Rock, AR; [2]Arkansas College of Osteopathic Medicine, Fort Smith, AR.*

Introduction: Post-transplant lymphoproliferative disorder (PTLD) is a life threatening complication following solid organ transplantation. PTLD covers a wide range of lymphomas, however the most common is the B-cell type. While majority of the cases are associated with Epstein-Barr virus (EBV) infection, about 20 % of the PTLD can occur in EBV seronegative patients. Hemophagocytic lymphohistiocytosis (HLH) is a syndrome of excessive immune activation that can rapidly progress to multisystem organ failure and is mostly associated with infections and malignancies. Only two cases of HLH associated with EBV negative PTLD in a renal transplant patient have been reported in the literature. Hereby, we present an extremely rare (third) case of EBV-negative PTLD complicated by HLH in a kidney transplant recipient.

Case Description: 41 year old male with history of deceased donor kidney transplant for hypertensive nephrosclerosis about 10 years ago presented to the emergency department with complains of fever, fatigue and diarrhea for 3 weeks. His maintenance immunosuppression included tacrolimus, prednisone and mycophenolate. On presentation, he was hypotensive and febrile. Initial labs showed leukocytosis, anemia, thrombocytopenia, acute kidney injury, hypoglycemia, and severe lactic acidosis. The patient was started on broad spectrum antibiotics. Further work up revealed an undetected plasma EBV. His tremendously high serum ferritin, lactate dehydrogenase, triglycerides, soluble IL-2 receptor levels and abdominal imaging revealing splenomegaly did raise concern for HLH secondary to an underlying malignancy. He underwent bone marrow biopsy which showed findings consistent with diffuse large B cell lymphoma (DLBCL). He subsequently received 6 cycles of chemotherapy with R-CHOP (Rituximab, Cyclophosphamide, Doxorubicin, Vincristine, and Prednisone) regimen resulting in complete remission of DLBCL.

Discussion: The incidence of PTLD in adult kidney transplant recipients ranges from 1-3%. The principal risk factors for PTLD include degree of immunosuppression and the EBV serologic status of the recipient. Clinical manifestations are non-specific and highly variable. B cell lymphoma with HLH in kidney transplant recipients is a rare entity and associated with a high mortality of >50%. Therefore, a high index of clinical suspicion and prompt initiation of chemotherapy is the key.

TH-PO842

CD8+ T Cells and Subpopulations as Potential Predictors for Cytomegalovirus (CMV) Viremia in Kidney Transplantation

Max Schuller, Agnes A. Mooslechner, Konstantin A. Kloetzer, Philipp Eller, Kathrin Eller. *Medizinische Universitat Graz, Graz, Austria.*

Background: CMV viremia is associated with reduced graft survival in kidney transplant recipients, despite potential prevention by antiviral prophylaxis. Identification of patients at risk remains a key challenge in transplant nephrology. Here, we examined the predictive value of pretransplant $CD8^+$ T cell subtype immunophenotyping on CMV viremia after transplantation.

Methods: Flow cytometric analysis of peripheral blood leukocytes and $CD8^+$ T cell subpopulations was performed shortly before transplantation (timepoint V1) in 65 kidney transplant recipients. CMV viremia was defined as above 100 CMV copies/ml in at least one PCR during the first year of transplantation.

Results: CMV viremia (CMV+) was frequent (n= 33, 50.8%) in our cohort. After one year, eGFR was worse in CMV+ compared to CMV- patients (1.66 vs. 1.25ml/min/1.73m^2, p<0.001), underlining its detrimental effect on graft function. Overall, pre-transplant frequencies of $CD3^+CD8^+$ in lymphocytes (19.7% vs. 15.4%, p=0.05) and $FoxP3^+CD25^+$ in $CD3^+CD8^+$ T cells (1.45% vs. 0.74%, p<0.01) were significantly higher in CMV+. Absolute numbers of leukocytes (4145/µl vs. 5249/µl, p=0.01), granulocytes (2576/µl vs. 3317/µl, p=0.01) and monocytes (222/µl vs. 315/µl, p=0.01) were lower in CMV+. Although not generally regarded as risk factor, women were disproportionally affected by CMV in our cohort (16 CMV+ in 25 women, 64% vs. 17 CMV+ in 40 men, 42.5%). Although we are limited by a small sample size, we sought to explore potential sex-specific risk factors for CMV within the peripheral blood at V1: For men, $CD3^+CD8^+$ T cells were increased in those who latter developed CMV viremia (21% vs. 15.2%, p=0.04). $FoxP3^+CD25^+$ in $CD3^+CD8^+$ T cells were elevated (1.19% vs. 0.71%, p=0.01), and monocytes (211/µl vs. 358/µl, p=0.02) were decreased in women, who became CMV+.

Conclusions: Pre-transplant predictors of CMV viremia within the peripheral leukocyte and $CD8^+$ T cell pool may aid in selecting patients for antiviral prophylaxis. While $CD8^+$ T cells are generally regarded as cytotoxic, expansion of regulatory subtypes like $FoxP3^+CD25^+CD8^+$ T cells may render individuals susceptible to infections. Our findings further hint towards sex-specific differences in immune cell abundance and function, which ought to be confirmed in a larger cohort.

TH-PO843

A National Retrospective Cohort Study of BK Viraemia in Renal Transplant Recipients

Michelle Clince,[1] Vicki K. Sandys,[1] Fidelma Fitzpatrick,[1] Caoimhe Brennan,[2] Peter Conlon,[1] Patrick O'kelly,[1] Peter J. Conlon.[1] *[1]Beaumont Hospital, Dublin, Ireland; [2]UCD Center for Research in Infectious Diseases, Dublin, Ireland.*

Background: BK nephropathy is an important cause of graft dysfunction and graft loss. Treatment options are limited and involve immunosuppression reduction. In Ireland, post-transplant BK DNA is checked monthly between months 1-6 and thereafter at month 9 and 12. We examine incidence, risk factors and effect of BK viraemia on long-term graft survival.

Methods: A national retrospective cohort study of renal transplant recipients in the first 12 months post-transplant between 2011-2021 was performed using data from the National Renal Transplant Registry and the National Virus Reference Lab. Patients were followed up for a minimum of 3 months and BK viraemia was defined as >5000 DNA copies per ml (CPM). A cox proportional hazards model was used to assess risks associated with BK viraemia. Statistical analysis was performed using Stata 16 SE.

Results: Of 1319 transplanted patients, BK surveillance rates were high across all nephrology centres (96-99% of patients had results available as per monitoring protocol). 179,14% of recipients developed BK viraemia with peak levels occuring at two months and levels falling to 1000 CPM by six months. Rates of BK viraemia were higher in males than females, 145 per 1000 patients (95% CI 121-175) versus 103 per 1000 patients (95% CI 76- 141). Highest rates of BK viraemia were seen in ages 49-59 (190 per 1000 patients, 95% CI 146-247). Higher rates of biopsy-proven rejection at one year (HR 1.65 CI 1.01-1.77 p-value 0.044) was associated with BK viraemia. Neither pGEN >95% (HR 1.04 CI .61- 1.77 p value 0.896) or delayed graft function (HR1.01 CI 0.68-1.49 p-value 0.969) was associated with the development of BK viraemia. At one year the average serum creatinine was 115umol/L in recipients without BK-viraemia versus 126umol/L in those with BK-viraemia (p value 0.0017). Kaplan-Meier survival graphs demonstrated no difference in renal graft survival in those with BK viraemia than those without at 10 years. (p-value 0.37).

Conclusions: No significant difference in graft survival was observed in those who developed BK viraemia in the first 12 months post-transplant over a decade of transplantation in Ireland. The next step of this analysis is the examine the effect of immunosuppression changes on the development of donor specific antibodies.

TH-PO844

A Comparison of BK Polyomavirus Nephropathy Between Native and Allograft Kidneys

Tong Wu, Shicong Yang, Wenfang Chen. *The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China.*

Background: BK polyomavirus nephropathy (BKVN) has emerged as an important but uncommon cause of renal dysfunction and loss in allograft kidney and native kidneys from hematopoietic stem cell transplant recipients (HSCTRs). Yet it is unclear whether there is difference between these two populations on the clinicopathological features and renal outcomes.

Methods: Patients diagnosed as BKVN by renal biopsy from 2019 to 2022 were collected for a retrospective cohort study. The patients were divided into native kidney group (including 7 HSCTRs) and allograft kidney group (including 50 KTRs).

Results: By the time of diagnosis, the median age of native kidney group was younger than that of allograft kidney group (median 14.4 vs. 35.3y, *P*<0.001). There

was no difference of time interval from transplantation to diagnosis between the two groups (median 12.0 vs. 11.0 months, *P*=0.742). The native kidney group had higher i, ci, ct scores (Banff 2019) and percentage of SV40-T positive tubules (all *P*<0.05). More positive SV40-T glomerular parietal epithelial cells was found in native than in allograft kidney group (*P*<0.05). In a 1:1 propensity score matching by age, the native kidney group also showed higher i score, higher proportion of SV40-T positive tubules and advanced AST stage patients than allograft kidney group (all *P*<0.05). The rate of eGFR decline was greater in native than allograft kidney group (median -1.82 vs.0.44 ml/min per 1.73 m2/year, *P*=0.044; Fig A). One year cumulative renal failure rate after BKVN diagnosis was 57.1% in native and 4% in allograft kidney group (*P*<0.001; Fig B). The risk of progression to renal failure was significantly higher in BKVN of native than BKVN of allograft kidney (HR, 0.02; 95% CI, 0.00-0.59; *P*=0.025). Multivariate Cox regression analysis demonstrated that advanced AST stage was independently associated with worse renal outcome (HR, 2.36; 95% CI, 1.05-5.33; *P*=0.038).

Conclusions: BKVN of native kidneys in HSCTRs have a poorer renal survival than allograft kidney, which may correlate with more severe tubulointerstitial chronic lesions and higher tissue polyomavirus load at the time of renal biopsy.

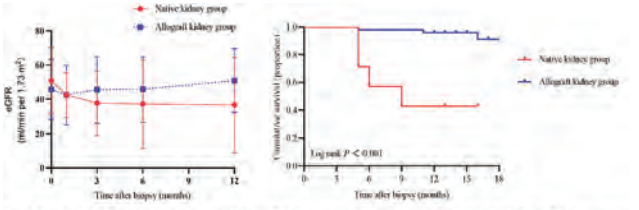

Fig A. Trend of eGFR over time in native and allograft kidney group. B. Renal survival in native and allograft kidney group.

TH-PO845

Increased Incidence of Kaposi Sarcoma Among African and Hispanic Kidney Transplant Recipients

Lindsay M. Pattison, Michelle Toker, Luz E. Liriano-Ward, Yorg Al Azzi, Maria Ajaimy, Enver Akalin, Swati Jain, Beth N. Mclellan, Cindy T. Pynadath. *Montefiore Medical Center, Bronx, NY.*

Background: Post-transplant Kaposi's sarcoma (PTKS) is a rare complication among transplant patients. However, the incidence of PTKS is 100-500 times higher than Kaposi's sarcoma (KS) in the general population. There have been no retrospective analyses characterizing increased incidence of PTKS among racial minorities in the U.S.

Methods: We performed an IRB-approved retrospective analysis of all adult patients greater than 18 years of age diagnosed with KS at Montefiore Medical Center. We reviewed electronic medical records based on ICD-9/10 code between the dates of 01/01/2014 – 09/01/2022 and identified 80 patients with KS, 10 of which were diagnosed with PTKS. Nine patients with PTKS after kidney transplant were included and 1 patient with PTKS after bone marrow transplant was excluded.

Results: Of the 9 patients that received kidney transplants and subsequently developed PTKS, 3 were female and 6 were male. All patients were minorities, with 6 African American and 3 Hispanic patients. Median age at transplantation was 60 years (range 44-70). Average time elapsed between transplant and PTKS development was 832.3±834.97 days (range 125-2630). Anatomic locations of PTKS lesions in patients included lower extremities (n=5), upper extremities (n=3), lymph nodes (n=3), kidney (n=1), and lung (n=1). Immunosuppression included tacrolimus (n=9), mycophenolate (n=7), cyclosporine (n=1), and steroids (n=10). After PTKS diagnosis, 7 patients had immunosuppression switched to sirolimus, 1 patient had tacrolimus and mycophenolate reduced, and 1 patient expired before treatment modification. All patients continued steroids. Four patients required additional treatment including radiotherapy (n=2), excision (n=1), and excision and imiquimod (n=1). One patient experienced PTKS recurrence approximately 18 months after initial resolution. Mortality was high (44%), and 4 patients died at a median of 95 days (range 19-1760) after diagnosis.

Conclusions: This study demonstrates high mortality rate in PTKS patients in minority kidney transplant recipients.

TH-PO846

Efficacy and Safety of Sodium-Glucose Cotransporter-2 Inhibitor in Diabetic Kidney Transplant Recipients: A Case-Control Study

Ashraf A. Ibrahim, Mohamed Y. Ali, Ali Mahgoub, Rasha Mohamed Abdul Rahman, Mohamed Abdelhalim, Ahmed F. Hamdi, Tarek A. Ghonimi, Tarek A. Fouda, Mohammed E. Hussain, Mostafa Elshirbeny, Fatima B. Eltayeb, Musab Elgaali, Shaimaa A. Arroub, Rania A. Ibrahim, Essa Abuhelaiqa, Abdullah I. Hamad, Hassan A. Al-Malki, Mohamad M. Alkadi. *Hamad Medical Corporation, Doha, Qatar.*

Background: KDIGO guidelines recommend initiating sodium-glucose cotransporter 2 inhibitors (SGLT2i) in diabetic chronic kidney disease (CKD) patients for its cardiovascular and renal protective effects. However, up till now, there are no recommendations regarding its use in diabetic kidney transplant recipients (KTR). The aim of this study was to determine the efficacy and safety of SGLT2i in diabetic KTR.

Methods: This was a retrospective case-control study. Cases (diabetic KTR using SGLT2i) and controls (diabetic KTR not using SGLT2i) were matched for recipient age, gender, year of transplant, and donor type. This study has been approved by Hamad general hospital research center. MRC-01-23-077

Results: There were 78 cases and 78 controls. The mean follow-up period in cases and controls was 23.9 and 24.1 months, respectively. Both groups had similar baseline graft function and HbA1c. Compared to controls, cases had a statistically significant reduction of BMI (-1.1 vs. +0.23; P<0.001). There was also a trend for better graft function and diabetes control, but it did not reach statistical significance. Both groups had similar adverse events such as AKI, UTI, cardiovascular and cerebrovascular complications (figure 1).

Conclusions: SGLT2i use in diabetic KTR was associated with a significant reduction in BMI and a trend for better kidney function and diabetes control. Longer prospective randomized controlled trials are needed to confirm their safety and efficacy outcomes in KTR.

Funding: Government Support - Non-U.S.

Figure 1: Efficacy and safety of SGLTi in diabetic KTR

Variables	Cases (n=78)	Controls (n=78)	P value

Economic Impact of Dementia After Kidney Transplantation: A Matched Cohort Analysis

Krista L. Lentine,[1] David Axelrod,[3] Huiling Xiao,[1] Mara McAdams-DeMarco,[2] Yusi Chen,[2] Sunjae Bae,[2] Yasar Caliskan,[1] Dorry L. Segev,[2] Mark Schnitzler.[1] *[1]Saint Louis University, Saint Louis, MO; [2]New York University, New York, NY; [3]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Dementia risk is increased among patients with kidney disease, including kidney transplant (KTx) recipients, and is assocaited with adverse outcomes. To date, the cost implications of dementia after KTx are not well described.

Methods: We examined USRDS data (2006–2016) to compare costs incurred in the care of Medicare-insured KTx recipients with diagnosed dementia vs. matched controls, based on payments on Medicare claims. KTx recipients age 65+ years with post-KTx dementia were identified by diagnosis codes and matched to recipients without dementia, based on propensity score for dementia using recipient (demographic and clinical), donor, and transplant factors. Average costs per month, marginal costs per month, and cumulative costs were compared after the dementia diagnosis vs after equivalent time post-KTx in the controls.

Results: We identified 1,556 KTx recipients with dementia after KTx (mean time to diagnosis: 4.2±2.8) and 3,112 controls. Cases and controls were well balanced with regard to baseline factors, including mean age (70.3±4.2 vs 70.1±4.0 yrs.), sex (37.7% vs. 35.8% women), race (26.0% vs. 25.5% African American), and cause of ESKD (46.2% vs. 46.3% diabetes). Monthly costs approaching a dementia diagnosis rose to peak of ~$9,229, and exceeded that of cases over 36 mos. of follow-up (**Fig. A**). The marginal cost impact of dementia diagnosis ranged from $6,215 to $945 (**Fig. B**). At 36-mo. post dementia diagnosis, dementia patients incurred $34,034 (95% CI $12,192–$60,816) more costs than those without dementia. Higher spending occurred despite substantially lower survival in patients with dementia vs. matched controls.

Conclusions: KTx recipients with dementia incur higher costs of care and experience lower survival compared to matched controls. Further research is needed to develop care pathways to optimize clinical and economic outcomes of KTx recipients with dementia.

Transition of Care of Stable Kidney Transplant Patients to Referring Nephrologists: A National Survey of US Transplant Centers

Krista L. Lentine,[1] Neeraj Singh,[2] Kenneth J. Woodside,[3] Kennan R. Maher,[4] Tarek Alhamad,[5] Roy D. Bloom,[6] Darshana M. Dadhania,[7] Mona D. Doshi,[8] Ronald Parsons,[9] Gaurav Gupta,[10] Amy D. Waterman,[11] Bekir Tanriover,[12] Gary G. Singer,[13] Prince M. Anand.[14] *[1]Saint Louis University, Saint Louis, MO; [2]Willis-Knighton Health System, Shreveport, LA; [3]Gift of Life, Ann Arbor, MI; [4]Willis-Knighton, Shreveport, LA; [5]Washington University in St Louis, St Louis, MO; [6]University of Pennsylvania, Philadelphia, PA; [7]Cornell University, Ithaca, NY; [8]University of Michigan, Ann Arbor, MI; [9]Emory University, Atlanta, GA; [10]Virginia Commonwealth University, Richmond, VA; [11]Houston Methodist, Houston, TX; [12]Banner University Medical Center Tucson, Tucson, AZ; [13]Midwest Nephrology, St. Louis, MO; [14]Medical University of South Carolina, Charleston, SC.*

Background: Transition of care from transplant centers (TC) to referring nephrologists is critical for long-term care of kidney transplant (KTx) recipients. We conducted a national survey to assess opinions and experiences of TC staff related to care graduation processes.

Methods: After IRB approval, staff at U.S. adult kidney TC were surveyed using the Qualtrics survey platform (4/5/22–10/31/22). Respondents were invited via email and professional society list-servs. If >1 survey was submitted for a TC, a selection hierarchy was utilized (e.g. prioritizing nephrologists).

Results: Respondents represented 55% of YC (n=108) and 67% of national KTx volume. The majority of respondents (78%) were nephrologists. Full graduation to referring nephrologists was reported by 37% of TC, while 48% reported partial graduation with ongoing co-management. Rationales for graduation included patient travel distance (64%), maintenance of referral base (58%), continuity of care (58%), and TC burden (54%) (**Fig. A**). Common reasons cited by TC for post-graduation return of care included worsening renal function (80%), malignancy (66%), opportunistic infection (63%), local nephrologist availability (58%), and pregnancy planning (57%) (**Fig. B**). Additional staff were cited by 78% of TC as needed to enable TC perpetual care, with 70% expressing need for more clinicians. Nearly 50% thought more physical space or telemedicine are required.

Conclusions: Graduation of KTx patients is common, with half of TC using joint-care. With continued growth of the KTx population, expanded opportunities related to transplant care for the general nephrology community are essential.

TH-PO849

Transition of Care of Successful Kidney Transplant Patients from the Transplant Center: A National Survey of Referring Nephrologists

Krista L. Lentine,[1] Prince M. Anand,[2] Kenneth J. Woodside,[3] Roy D. Bloom,[4] Neeraj Singh,[5] Tarek Alhamad,[6] Matthew Cooper,[7] Darshana M. Dadhania,[8] Mona D. Doshi,[9] Gaurav Gupta,[10] Ronald Parsons,[11] Bekir Tanriover,[12] Amy D. Waterman,[13] Gary G. Singer.[14] *[1]Saint Louis University, Saint Louis, MO; [2]Medical University of South Carolina, Charleston, SC; [3]Gift of Life, Ann Arbor, MI; [4]University of Pennsylvania, Philadelphia, PA; [5]Willis-Knighton Health System, Shreveport, LA; [6]Washington University in St Louis, St Louis, MO; [7]Froedtert Hospital, Milwaukee, WI; [8]Cornell University, Ithaca, NY; [9]University of Michigan, Ann Arbor, MI; [10]Virginia Commonwealth University, Richmond, VA; [11]Emory University, Atlanta, GA; [12]Banner University Medical Center Tucson, Tucson, AZ; [13]Houston Methodist, Houston, TX; [14]Midwest Nephrology Associates, St. Louis, MO.*

Background: We conducted a national survey of nephrologists to assess opinions and experiences related to the process of returning kidney transplant (KTx) patients from the transplant center ("graduating") to referring nephrologist care.

Methods: After IRB and Renal Physicians of America (RPA) approval, RPA members were surveyed using the Qualtrics electronic survey platform during October, 2022.

Results: The majority of the 105 respondents self-identified as private practice general nephrologists (78%). While 40% of respondent practices were within 10 miles of a transplant center (TC), >30% were more than 50 miles from a TC (**Fig. A**). Post-graduation visits were most frequently reported as every 3 mos. (51%) or every 6 mos. (29%), with lab draw intervals more frequent (monthly 32%, every 2 mos. 11%, and every 3 mos. 33%). Practices that did not accept patients back when ready for graduation (n=15) most typically cited the inability to work closely with the TC (67%) or inadequate staffing/resources for immunosuppression monitoring (53%); time commitment (40%) and patient complexity (33%) were less frequent concerns. Clinicians reported referring KTx recipients back to TC for management after graft dysfunction (79%), cancer (51%), pregnancy planning (41%), or fever (21%) (**Fig. B**).

Conclusions: Despite many general nephrologists being relatively close to a TC, most care for KTx patients. As expected, allograft dysfunction often leads to referral back to the TC after graduation. Nephrologists who do not accept KTx patients have concerns about communication with the TC or lack of office resources--both of which TC can actively help develop.

Outcomes of Living Related Kidney Donors in a Tertiary Care Kidney and Liver Transplant Facility of a Developing Country

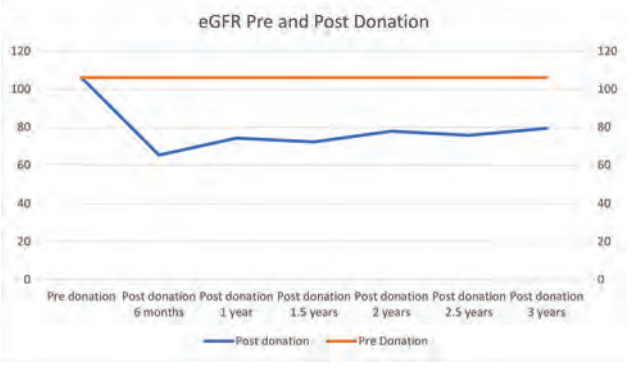
Maria Ijaz,[1] Tahreem Afroz,[1] Hafiz I. Ahmad,[1] Adil Manzoor,[1] Muhammad Awais,[3] Syed Rizwan A. Bokhari.[2] *[1]Pakistan Kidney and Liver Institute & Research Center, Lahore, Pakistan; [2]University of Rochester Medical Center, Rochester, NY; [3]University Hospital Kerry, Tralee, Ireland.*

Background: The long-term effects of unilateral nephrectomy for the live kidney donors are a neglected area of study in the developing countries. In Western countries like US, there is extensive data on living donor outcome through National Health and Nutrition Examination Survey (NHANES III), while no such resource is available in Pakistan. The purpose of this study is to evaluate the outcome of kidney donors at a large public sector Academic hospital, Pakistan Kidney and Liver Institute, Lahore.

Methods: One hundred and thirty-two successive donors with living donor nephrectomies (during March 2018 to Feb 2021) were enrolled in this prospective observational study. Off these, 100 donors were successfully followed up once every six months for total of six encounters in 3 years. Outcome included short and intermediate term effects of unilateral nephrectomy on donor physical parameters (blood pressure and BMI), kidney function (serum creatinine, eGFR) and glycaemic status (HbA1c) by comparing pre and post donation data. Estimated glomerular filtration rate (eGFR) was calculated using CKD-EPI (Chronic Kidney Disease Epidemiology Collaboration) equation.

Results: Out of 100 living donors followed, 51 were male. All donors were in age range of 18-69 years with mean age 30-49 years. Left donor nephrectomy was performed in 89 (89%) patients. Mean diastolic blood pressure was slightly decreased and mean HbA1C pre and post donation were not statistically significant. Mean eGFR value before nephrectomy was 106.1ml/min and it dropped by 38% (65.2 ml/min) at 6 months. The eGFR then increased by 12% at 1year, 10% at 1.5 years, 16% at 2 years, 14% at 2.5 years and 18% (79.3ml/min) at 3 years post nephrectomy.

Conclusions: We hereby conclude that living kidney donation resulted in initial decline in the renal function because of loss of one kidney. Subsequently, taking post-donation value of eGFR at 6 months as baseline, it gradually increased by 18% at 3 years.



TH-PO851

Prevalence and Correlated Factors of Vascular Calcification and Vascular Stiffness in Kidney Transplant Patients

Peachaphol Chongvoranond, Monravee Tumkosit, Jeerath Phannajit, Natavudh Townamchai, Somchai Eiam-Ong, Kearkiat Praditpornsilpa, Yingyos Avihingsanon, Paweena Susantitaphong. *King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Mineral and bone disorders related with chronic kidney disease (CKD) increased risk of vascular health in both CKD and dialysis patients, leading causes of morbidity and mortality. Although, kidney transplantation (KT) is the best way to treat end stage kidney disease and some important risk factors might be improved after KT, the prevalence of vascular diseases seems to be persistently high in KT recipients. Early detection, prevention and optimal management is the key to attenuate vascular diseases in KT.

Methods: This cross-sectional study was conducted in 400 KT recipients who received KT for at least 1 year and followed up at King Chulalongkorn Memorial Hospital. Plain film of lateral abdomen was done to assess the presence of vascular calcification (Abdominal aortic calcification scores) while cardio-ankle vascular index was performed to evaluate vascular stiffness. Severe vascular calcification was defined by using abdominal aortic calcification scores ≥ 5.5. Baseline characteristics, laboratory data, and medications were collected for evaluation of important risk factors by multivariable logistic regression analysis.

Results: 400 KT recipients were enrolled in this study. The prevalence of severe vascular calcification and vascular stiffness were 35.94% and 27.75%, respectively. By multivariable logistic regression, diabetes mellitus and post parathyroidectomy were correlated with severe vascular calcification (OR 2.299; 95%CI 1.036-5.100, OR 7.668; 95%CI 2.928- 20.082, respectively). Systolic blood pressure, mean arterial pressure and severe vascular calcification were related with vascular stiffness (OR 0.960; 95%CI 0.928-0.992, OR 1.085; 95%CI 1.038-1.133, OR 2.256; 95%CI 1.223-4.162, respectively) while elderly was correlated both severe vascular calcification and vascular stiffness (OR 1.108; 95%CI 1.074-1.142, OR 1.094; 95%CI 1.057-1.133, respectively).

Conclusions: The prevalence of vascular calcification and vascular stiffness were still high in KT recipients. Optimal management of important risk factors including mineral bone disorders (CKD-MBD) before and after KT, diabetes and blood pressure control should be highlighted to attenuate cardiovascular diseases in KT recipients.

TH-PO852

Calciphylaxis in Kidney Transplantation Recipients

David J. Stoy, Tripti Singh, Ali I. Gardezi, Fahad Aziz. *University of Wisconsin-Madison, Madison, WI.*

Background: Calciphylaxis, also called calcific uremic arteriolopathy (CUA), is a rare vascular disorder of subcutaneous microcirculation calcification and thrombosis. CUA results in painful non-healing necrotic ulcers and often portends poor outcomes. Minimal data exist describing post-kidney transplant calciphylaxis's incidence, management, and long-term outcomes. Herein we describe a series of calciphylaxis in kidney transplant recipients.

Methods: Single-center observational cohort study of patients who received kidney transplantation (KT) between 1/1/1994 and 1/1/2023 and who developed calciphylaxis at any time after transplant with a functional kidney allograft.

Results: During the 29-year study period, nine patients had biopsy-proven calciphylaxis (CUA). Six patients had kidney transplant (KT) alone, two had a simultaneous pancreas and KT, and one had simultaneous liver and KT. None of the patients had a preemptive KT; only one received a living donor transplant. The mean age at the time of KT was 41 ± 13.4 years, and the mean at the time of calciphylaxis diagnosis was 45 ± 16.5 years. All patients received lymphocyte-depleting induction (anti-thymocyte globulin) at the time of transplant. The mean duration on dialysis before KT was 3.4 ± 2. The mean time from transplant to the diagnosis of CUA was 4 ± 6.4 years); six patients developed CUA within twelve months of KT. Only one patient had a history of calciphylaxis before the transplant. At the time of CUA diagnosis, the mean eGFR was 57 ± 23 mL/min/1.73 m2; the mean for calcium was 10 ± 0.7, phosphorous was 3.6 ± 1, and iPTH was 212 ± 284 pg/ml. Location of CUA was distal lower extremity in seven patients. Eight patients required debridement, and four patients received sodium thiosulphate. Six patients were concurrently on anticoagulation at time of CUA diagnosis. Before 2001, three of four patients recieved parathyroidectomy. After 2001, one of five patients had parathyroidectomy. The mean follow up after the calciphylaxis diagnosis was 3 ± 3.2 years. At the last follow-up, three patients lost their kidney allograft, and four died.

Conclusions: Post-transplant calciphylaxis is rare and associated with high mortality and allograft loss. More extensive studies are needed to examine this condition's risk factors and management.

TH-PO853

Hypercalcemia of Humoral Malignancy After Kidney Transplant

Srinath Tripuraneni, Amer A. Belal, Rohan V. Mehta, Alfonso Santos. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: Hypercalcemia of humoral malignancy (HHM) occurs due to a tumor-produced parathyroid hormone-related peptide (PTHrP) and is associated with increased morbidity and mortality. HHM typically presents with severe hypercalcemia (>13 mg/dl), decreased or normal parathyroid hormone (PTH), and elevated PTHrP with variable serum 25 hydroxy vitamin D levels. Although HHM has been associated with renal, bladder, breast, ovarian carcinomas and squamous cell carcinomas of the lung, head, and neck, it can very rarely can present with squamous cell carcinoma of the skin. We describe a case of HHM in a Kidney Transplant (KT) Recipient (KTR).

Case Description: A 41-year-old Black man with a history of KT in early 2019, ESRD from Hypertension and Dysplastic Kidneys with a baseline serum creatinine of 1.8-2.2 mg/dL was admitted for a groin mass. Relevant medical history included failed KT (2005), tertiary hyperparathyroidism s/p two lobe parathyroidectomy in 2018 (on sensipar), with baseline serum calcium 9.0-10.0mg/dL and baseline PTH of 200-400 pg/mL. The patient noted a perineal mass about two months prior to admission, that developed into a purulent and bleeding ulcer. Home medications included monthly Belatecept infusions, Mycophenolate 750 mg BID, and prednisone 5 mg daily. Laboratory data included serum creatinine 2.6 mg/dL, serum calcium 11 mg/dL, 25-OH vitamin D 18.71 ng/mL, and PTH of 133 pg/mL. Intravenous fluids were initiated, and a punch biopsy was performed by Dermatology. On post-admission day 7 with serum Calcium of 14.1 mg/dL, ionized calcium of 2.1 mmol/L, calcitonin was administered and sensipar was increased to 60 mg BID. Punch biopsy reported a well-differentiated squamous cell carcinoma, which was excised 10 days after admission. Serum Calcium dropped to 11.9 mg/dL, 4 days after surgery. PTHrP obtained before excision returned elevated at 60.2 pmol/L, while serum creatinine remained baseline. Serum Calcium had normalized to 9.2 mg/dL, about 4 weeks after surgery.

Discussion: HHM has been associated with solid organ cancers but can occur with dermatologic malignancies. Clinicians should be aware of the possibility of HHM as a rare complication of squamous cell skin cancer. In patients with tertiary hyperparathyroidism, it can present with severe hypercalcemia, non-suppressed PTH, and an elevated PTHrP.

TH-PO854

Hypercalcemia as a Rare Manifestation of Pneumocystis jirovecii Pneumonia

Aayush Mittal, Mohamad H. Beidoun, Jose L. Valdes, Andrew Peleman, Snigdha Reddy, Anita K. Patel. *Henry Ford Hospital, Detroit, MI.*

Introduction: Pneumocystis Jirovecii pneumonia (PJP) is a fungal infection which disproportionally affects immunocompromised individuals. We present two cases of PJP associated with hypercalcemia and acute kidney injury (AKI) in renal transplant recipients (RTR).

Case Description: Case 1: A 40-year-old male RTR patient presented with one-week of fever, cough, and shortness of breath. CT Chest showed peripheral ground-glass opacities. Patient remained febrile, tachycardic, and hypoxic. Given the clinical presentation and Fungitell > 500 pg/mL, treatment for PJP was started with Atovaquone and steroids. Hypercalcemia (ionized calcium 1.62 mmol/L) was reported with routine workup insignificant for pharmacological or alternate underlying conditions. PTH was suppressed at 6 pg/mL and 1,25 DiHydroxyvitamin D was elevated above 200 pg/mL. 25-Hydroxy Vitamin D levels were within normal limits. Due to lack of improvement in hypercalcemia with IV hydration, Denosumab was prescribed with improvement in serum calcium levels. Bisphosphonates were contraindicated with renal dysfunction. Case 2: A 63-year-old male RTR patient presented with a three-week history of fatigue, cough, and chills. Workup similarly revealed PJP, hypercalcemia, and AKI with an elevated 1,25 DiHydroxyvitamin D. Due to failed treatment with IV Saline, Miacalcin, and Ketoconazole, Denosumab was used with improvement in Hypercalcemia. Clinical improvement of PJP reported with Primaquine and Clindamycin.

Discussion: Two renal transplant patients, on immunosuppressive medications, presented with AKI, hypercalcemia, and PJP. This hypercalcemia is believed to be due to an alveolar macrophage mediated process, increasing 1-a-hydroxylase activity and elevating 1,25-DiHydroxyvitamin D. Both patients responded favorably to denosumab, a RANK-L inhibitor which prevents osteoclast activation. PJP was suspected based on bilateral ground-glass opacities on imaging, elevated fungitell, and presence of dry cough in an immunocompromised patient. LDH was not elevated in Case 1, as sensitivity of LDH elevation in non-HIV patients with PJP is as low as 63%. Clinical improvement noted with treatment of PJP. Hypercalcemia is a unique presentation of PJP in renal transplant recipients. Early intervention is recommended given the potential for continued alveolar macrophage mediated Hypercalcemia and AKI.

TH-PO855

Greater Incidence of Severe Hyperparathyroidism Requiring Early Parathyroidectomy After Kidney Transplantation in Patients Previously Under Etelcalcetide than Cinacalcet

Arnaud Devresse, Philippe Delaey, Johann Morelle, Danai Faitatzidou, Miren Iriarte Abril, Nada Kanaan, Antoine Buemi, Michel Mourad, Tom Darius, Eric Goffin, Michel Y. Jadoul, Laura Labriola. *Cliniques universitaires Saint-Luc, Brussels, Belgium.*

Background: Etelcalcetide is a novel and highly effective intravenous calcimimetic agent used to reduce intact parathyroid hormone (iPTH) levels in patients on maintenance hemodialysis (HD). The clinical impact of discontinuing etelcalcetide at the time of kidney transplantation has not been investigated yet.

Methods: We retrospectively reviewed all patients who received a kidney transplant at our institution between January 01st, 2015 and December 31st, 2022. The incidence of parathyroidectomy and the evolution of calcium, phosphate, and intact PTH after transplantation was analyzed according to the history and type of calcimimetic treatment before transplantation (cinacalcet versus etelcalcetide versus none). Kaplan-Meier estimates and Cox regressions were applied to assess the time to post-transplant parathyroidectomy.

Results: Overall 372 patients (aged 53 [IQR 42-62] years) were included. At the time of transplantation, 35, 75, and 262 patients were treated with etelcalcetide, cinacalcet or no calcimimetic, respectively. After a median follow-up of 1064 (IQR 367-1658) days, the incidence of parathyroidectomy in the etelcalcetide *vs*. cinacalcet *vs*. no calcimimetic groups was 29% (n=10) vs 12% (n=9) vs 1% (n=2), respectively (p<0.001). Etelcalcetide was associated with an increased incidence of parathyroidectomy after transplantation, both in unadjusted analyses and after adjustment for age, sex and hemodialysis vintage (HR 91.0, 95% CI 19.1-493.9, p<0.001). The incidence of parathyroidectomy was related to etelcalcetide dosage (6/11 [54.6%] in patients with ≥10 mg vs 4/24 [16.7%] in patients with < 10 mg/dialysis session, p= 0.02). Moreover, calcium levels were higher (2.81 [IQR 2.60-2.99] mMol/L vs 2.63 [IQR 2.58-2.72] mMol/L, p<0.001) and parathyroidectomy was performed earlier (median 80 *vs.* 480 days, p<0.001) in the etelcalcetide compared with the cinacalcet group. Long-term graft function, graft loss and mortality were similar between groups.

Conclusions: Etelcalcetide use during maintenance HD is associated with an increased incidence of early parathyroidectomy after transplantation compared to cinacalcet or no calcimimetic.

TH-PO856

0-ABDR Mismatch Transplants Do Not Confer Additional Immunologic Protection in Non-White Recipients

Jillian Caldwell, Gomathy Parvathinathan, Margaret R. Stedman, Patrick Ahearn, Jane C. Tan, Xingxing S. Cheng. *Stanford University School of Medicine, Stanford, CA.*

Background: In kidney transplants, matching donor and recipient human leukocyte antigen (HLA) alleles reduces allorecognition and eases reliance on immunosuppression. We hypothesize that 0-antigen mismatch transplants provide stronger protection against graft loss in racial minorities in whom systemic barriers to healthcare may explain higher rates of graft failure.

Methods: We included adult, single-organ, US deceased-donor kidney transplants from 2007-2016. We examined time-to-allograft failure (competing risk of death) using imputed Kaplan Meier and Weibull models. Degree of HLA mismatch (0- vs. ≥1-mismatch) was the main exposure. Models were adjusted for potential confounders and included an interaction term between mismatch and recipient race. Additional analyses were stratified by recipient race (white vs. non-white).

Results: We analyzed 102,114 transplants over a median of 5.6 years (16,862 graft loss events, 18,994 deaths). White recipients comprised 59,254 transplants (7628 0-mismatch) vs. 42,860 non-white recipients (1439 0-mismatch). In the cohort, 0-antigen mismatch was associated with improved graft survival (subdistribution hazard ratio [sHR] 0.80, 95% CI [0.75-0.85]) and was similar after adjusting for covariates. In crude models the effect of 0-antigen mismatch was more pronounced in white (sHR 0.78 [0.72-0.83]) vs. non-white recipients (sHR 0.88 [0.79-0.99], interaction p-value 0.03). This was attenuated after adjusting for covariates (sHR 0.78 [0.73-0.84]) vs sHR 0.87 [0.77-0.98], interaction p-value 0.09, Figure 1).

Conclusions: 0-antigen mismatch transplants were associated with a 20% risk reduction in graft loss. In non-white recipients the protective effect of 0-antigen mismatch transplants was not enhanced vs. white recipients. This may be due to the degree of mismatch at other HLA alleles and minor antigens, or due to systemic barriers to healthcare borne by minority recipients.

TH-PO857

Effectiveness and Safety of Denosumab on Osteoporosis Treatment in Kidney Transplant Recipients

Woo Yeong Park, Yaerim Kim, Jin hyuk Paek, Kyubok Jin, Seungyeup Han. *Division of Nephrology, Department of Internal Medicine, Keimyung University School of Medicine, Keimyung University Dongsan Hospital, Daegu, Republic of Korea.*

Background: It is known that the use of immunosuppressive agents influences the bone status of kidney transplant recipients (KTRs). In particular, glucocorticoids, the main immunosuppressants, can induce osteoporosis in KTRs. Denosumab, a potent antiresorptive agent, has been reported to increase bone mineral density (BMD), but the clinical impact and safety of denosumab on osteoporosis in KTRs remain controversial.

Methods: We analyzed 98 KTRs who used denosumab from 2018 to 2023. We investigated the change of BMD, chemical parameters, allograft function, tacrolimus trough level (TTL), complications of denosumab, fracture risk assessment tool (FRAX) score, acute rejection within 1 year and graft failure and death.

Results: Mean T-scores at 1-year post-denosumab were significantly increased comparing to mean T-scores pre-denosumab at the femur neck and spine area, respectively (-2.68±0.68 vs. -2.81±0.68, P<0.001; -2.78±0.96 vs. -3.21±1.00, P<0.001). The levels of calcium and phosphorus were significantly decreased and those of vitamin D were significantly increased at 1-year post-denosumab, but there were no significant differences in PTH, allograft function and TTL. There were no recurrent fractures among the 12 KTRs with a history of fracture, but 3 de novo fractures happened. Cardiovascular event occurred in 3 patients. Denosumab-induced hypocalcemia developed in 8 patients, but severe hypocalcemia was observed in only 1 patient. Acute kidney injury did not happen.

Urinary tract infection (UTI) was in 17 patients. Arthralgia occurred in 4 patients. Median 10-year probability of a major osteoporotic fracture and hip fracture by FRAX tool was significantly decreased after denosumab. Acute rejection within 1 year after denosumab developed in 3 patients. There was no graft failure and no patient death.

Conclusions: The use of denosumab in KTRs is effective and safe for the treatment of osteoporosis and prevention of fracture, but it should be carefully monitored for complications, especially, UTI.

Funding: Government Support - Non-U.S.

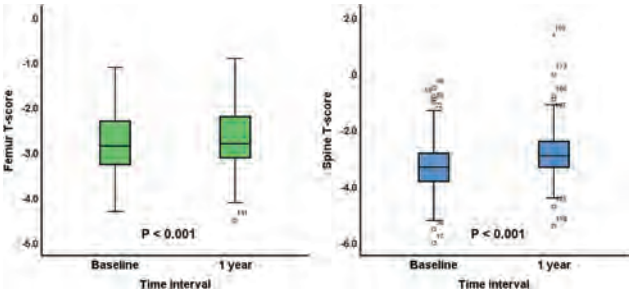

Figure 1. Mean T score of femur and spine at denosumab and 1 year after denosumab

TH-PO858

Correlates of Bone Mineral Density and Fractures in Kidney Transplant Recipients

Sujay D. Paudel,[1,2] Thai Nguyen,[1,2] Enrica Fung.[1,2] *[1]Loma Linda University, Loma Linda, CA; [2]VA Loma Linda Healthcare System, Loma Linda, CA.*

Background: Although kidney transplant recipient are known to be at high risk for bone disease, the optimal timing of testing for bone health and risk factors for osteodystrophy remain unclear.

Methods: We conducted a retrospective analysis of 65 patients from the Veterans Affairs at Loma Linda, California who underwent at least one DEXA scan after receipt of kidney transplantation.

Results: The mean age of our cohort was 64.0+/-12.2 and was predominantly male. Most patients received a combination of calcineurin inhibitor, antimetabolite and steroids for immunosuppression. Thirty patients had normal DEXA scans, while 25 patients were osteopenic and 10 were osteoporotic by DEXA; and 11 had documented fracture(s). Many patients received calcium and vitamin D prophylaxis but few received bisphosphonates or calcimimetics post transplant. (Table 1) In a multivariate model, after adjusting for age, dialysis vintage and other characteristics, we found that female gender was correlated with higher risk of fractures. In the same model, there was also a trend towards diabetes and high PTH (>300) predicting higher risk of fractures although this relationship did not reach statistical significance.

Conclusions: Despite the prevalence of bone disease among kidney transplant recipients, we found that a significant portion of such patients may not be receiving optimal therapy. Further studies are needed to establish effective treatments and determine the optimal monitoring frequency of bone parameters.

Association Between Hemoglobin Levels and Hypercalcemia due to Persistent Hyperparathyroidism in Kidney Transplant Recipients

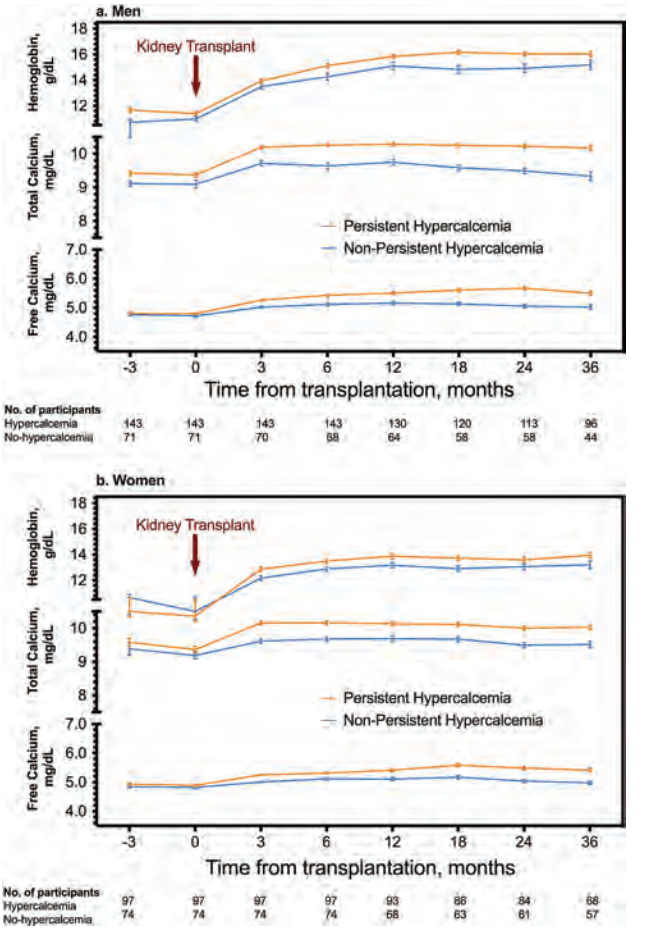
Gabriel Cojuc,[1,2] Alfonso Gindl-Bracho,[1] Sophia Albarran Munoz,[1] Cielo E. Linares Perez,[1] Nathalie D. Pichardo,[1] Lluvia A. Marino-Vazquez,[1] Luis E. Morales-Buenrostro,[1] Juan Carlos Ramirez-Sandoval.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Red de Universidades Anahuac, Naucalpan de Juarez, Mexico.*

Background: Hypercalcemia has emerged as a potential non-traditional factor associated with erythrocytosis following transplantation. We hypothesized that hypercalcemia due to persistent hyperparathyroidism is positively correlated with hemoglobin levels in kidney transplant recipients (KTRs).

Methods: We conducted a prospective cohort study investigating the trajectory of hemoglobin in KTRs with and without persistent hypercalcemia (free calcium >5.2 mg/dL in ≥80% of measures). We performed mixed model analyses adjusting for potential confounders.

Results: We included 385 subjects. Persistent hypercalcemia was present in 66% (56% male, median age 36 [IQR 28-48] years, median follow-up 4.1 [IQR 1-8.2] years). KTRs with hypercalcemia due to persistent hyperparathyroidism had a mean increase in hemoglobin levels of 0.76 g/dL/year (95% CI 0.45-1.08) compared to KTRs without hypercalcemia, 0.80 (95% CI 0.32-1.27) g/dL/year for males and 0.36 (95% CI 0.16-1.08) g/dL/year for females. Hypercalcemia was significantly associated with post-transplant erythrocytosis according to the WHO (47% vs. 24%, OR 2.8, 95% CI 1.8-4.4) and altitude-adjusted criteria (22% vs. 10%, OR 2.5, 95% CI 1.2-4.5). The significance of the effect of hypercalcemia on hemoglobin levels was consistent after adjusting for potential confounders.

Conclusions: Hypercalcemia due to persistent hyperparathyroidism after kidney transplantation was significantly associated with higher hemoglobin levels and an increased likelihood of developing post-transplant erythrocytosis.



The trajectory of hemoglobin, total calcium, and free calcium in KTRs with and without persistent hypercalcemia.

TH-PO860

Incidence, Risk Factors, and Outcomes of Post-Transplant Erythrocytosis Among Simultaneous Pancreas and Kidney Transplant Recipients

Mina L. Gibes, Brad C. Astor, Jon S. Odorico, Didier A. Mandelbrot, Sandesh Parajuli. *University of Wisconsin-Madison School of Medicine and Public Health, Madison, WI.*

Background: Post-transplant erythrocytosis (PTE) is a common condition after kidney transplantation. In the current era of immunosuppressive medication and management, the incidence, risk factors and outcomes of PTE among simultaneous pancreas and kidney (SPK) transplant recipients is poorly defined.

Methods: We analyzed all SPK transplant recipients at our center between 1998 to 2021. PTE was defined as at least 2 consecutive hematocrit (Hct) levels of > 51% within the first 2 years of transplant. Controls were selected at a ratio of 3:1 at the time of PTE occurrence using event density sampling. Risk factors for PTE and graft survival were examined.

Results: Of 887 SPK recipients, 108 (12%) developed PTE a median of 273 days (IQR: 159.5-393) after transplantation. The incidence rate of PTE was 7.5 per 100 person-years. Multivariable analysis found increased incidence associated with being on dialysis before transplant (HR: 3.15, 95% CI: 1.67-5.92, p<0.001), nonwhite donor (HR: 2.14, 95% CI: 1.25-3.66, p=0.006), female donor (HR: 1.50, 95% CI: 1.0-2.26, p=0.05), and male recipient (HR: 2.33, 95% CI: 1.43-3.70, p=0.001). The 108 cases of PTE were compared to 324 control recipients without PTE. PTE was not associated with pancreas graft failure (HR: 1.36, 95% CI: 0.51-3.68, p=0.53) or kidney graft failure (HR: 1.16, 95% CI: 0.40-3.42, p=0.78).

Conclusions: In the modern era of immunosuppression, PTE is still a common complication among SPK recipients. Likely due to proper management, PTE among SPK recipients was not associated with adverse graft outcomes.

TH-PO861

Cytomegalovirus-Associated Pulmonary Embolism

Mohamed J. Kassim,[1,2] Richard S. Spong.[1,2] *[1]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN; [2]M Health Fairview University of Minnesota Medical Center East Bank, Minneapolis, MN.*

Introduction: Thromboembolism has been associated with acute CMV infection or reactivation in transplant recipients. Here, we present a case of a young man with no apparent risk of a hypercoagulable state who developed a PE in the setting of a significant CMV viral load.

Case Description: The patient is a 24-year-old male with a PMH of ESRD secondary FSGS, status post LDKT 7 months earlier. Induction was with anti-TG and basiliximab, follow by maintenance immunosuppression. He was CMV and EBV IgG antibody positive at the time of transplant and did receive 3 months of prophylaxis with oral valganciclovir. The patient presented to the hospital with complaints of gastrointestinal symptoms, dyspnea, and pleuritic chest pain. He reported having watery diarrhea for over 10 days, as well as nausea, vomiting, chills, fatigue and an episode of fever to 102F. A few days prior to his admission, he developed pleuritic chest pain and dyspnia. Physical examination was unremarkable except for dry mucous membranes and low BP, which improved with volume resuscitation. CT angiogram revealed a right middle, lower segmental and sub-segmental pulmonary emboli with partial occlusion. Stool studies were normal. CMV PCR of the blood was positive with more than 222,000 copies. EBV PCR blood was negative. He was started on a therapeutic heparin drip and was transitioned to Apixaban prior to discharge. Induction dosing of IV ganciclovir was started for CMV viremia which continued upon discharge.

Discussion: The etiology of acute PE in our patient is believed to be triggered by the CMV infection. It has been reported in the medical literature that CMV can cause endovascular injury that can lead to thrombus formation and embolization. CMV reactivation is mostly seen in CMV discordant recipients (D+/R-), however, CMV reactivation can occur, albeit less frequently and at a lower viral load in seropositive recipients, as in this case. Latent CMV has been found on the endothelial cells of both venous and arterial vascular walls. It has been postulated that CMV-infected endothelial cells increase the expression of tissue factor II, which is involved in hemostasis and thrombus formation. CMV and other enveloped viruses have phosphatidylserine-like procoagulant activity on their surfaces which predispose to thrombus formation. In conclusion, acute CMV infection is a risk factor for thrombosis in transplant recipients and immunocompromised patients.

TH-PO862

Trend in Utilization and Transplant Outcomes of COVID-19-Positive Deceased-Donor Kidneys

Mengmeng Ji,[1] Amanda J. Vinson,[2] Su-Hsin Chang,[1] Massini Merzkani,[1] Krista L. Lentine,[3] Yasar Caliskan,[3] Tarek Alhamad.[1] *[1]Washington University in St. Louis, St. Louis, MO; [2]Dalhousie University, Halifax, NS, Canada; [3]Saint Louis University, Saint Louis, MO.*

Background: While the pandemic of coronavirus disease-19 (COVID-19) enters a new phase and the proportion of individuals with a prior COVID-19 diagnosis grows, the national trend in utilization and medium-term outcomes of kidney transplantation (KT) from COVID-19 positive donors remain unknown. This study evaluated the trend in utilization and KT outcomes of kidneys from donors with active or resolved COVID-19.

Methods: This retrospective cohort study used Standard Analysis and Research (STAR) data from 3/1/2020 to 3/30/2023. The exposure was donor SARS-CoV-2 NAT results, i.e., positive NAT within 7 days as active COVID-19, and positive NAT 7 days before procurement as resolved COVID-19. Kidney non-utilization, graft failure, all-cause death, acute rejection in six months, length of hospital stay (LOS), and delayed graft function (DGF). Multivariable logistic regression for kidney non-utilization, rejection, and DGF, multivariable linear regression for LOS, and Cox analyses for graft failure and all-cause death were performed. All models were adjusted for inverse probability treatment weighting.

Results: The likelihood of non-utilization of kidneys from active or resolved COVID-19+ donors declined over time. During 2020-2022, kidneys from COVID-19+ donors had a higher risk of non-utilization compared to kidneys from donors without COVID-19. In 2023, kidneys from active or resolved COVID-19+ donors were no longer associated with higher risk of non-utilization. No higher risk of graft failure was found in KT recipients receiving active COVID-19+ kidneys (adjusted hazard ratio [aHR], 1.03; 95% CI, 0.78-1.37) or resolved COVID-19+ kidneys (aHR, 1.10; 95% CI, 0.88-1.39). Donor COVID-19 positivity was not associated with all-cause death, longer LOS, higher risk of acute rejection, neither DGF.

Conclusions: This cohort study found that the non-utilization rate of kidneys from COVID-19+ donors declined over time and donor COVID-19 positivity was not associated with inferior KT outcome within 2 years post-transplantation.

Table: Non-utilization of active and resolved COVID-19 positive kidneys and transplant outcome, OPTN 2020-2023

	Kidney Discard[a] Odds Ratio (95%CI)					Transplant Outcomes[b] Hazard Ratio (95% CI)	
	Overall	2020 (Mar-Dec)	2021	2022	2023 (Jan-Mar)	Kidney graft failure	Patient death
COVID-negative	Ref.	Ref.	Ref.	Ref.	Ref.	Ref.	Ref.
Active COVID-19 positive	1.55 (1.38, 1.76)	11.26 (2.29, 55.38)	2.09 (1.58, 2.79)	1.47 (1.28, 1.70)	1.07 (0.75, 1.63)	1.03 (0.78, 1.37)	1.17 (0.84, 1.66)
Resolved COVID-19 positive	1.31 (1.16, 1.48)	3.87 (1.26, 11.90)	1.94 (1.54, 2.45)	1.09 (0.99, 1.28)	1.18 (0.80, 1.73)	1.10 (0.88, 1.39)	0.95 (0.70, 1.28)

[a]Adjusted for donor characteristics, including age, sex, race and ethnicity, body mass index, presence of diabetes, presence of hypertension, donation after cardiac death, cause of death, serum creatinine level, hepatitis C virus status, and kidney donor profile index score.

[b]Adjusted for donor characteristics (age, sex, race and ethnicity, body mass index, presence of diabetes, presence of hypertension, donation after cardiac death, and kidney donor profile index score), recipient characteristics (age, sex, race and ethnicity, education attainment, insurance status, body mass index, presence of diabetes, dialysis duration, peak panel reactive antibody level, organ share type, and days on waiting list before transplant), and transplant characteristics (blood type compatibility, human leukocyte antigen matching, cytomegalovirus concordance status with donors, cold ischemia time, center volume of COVID-19 positive KTs, and year of transplant).

TH-PO863

Sequelae of Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) Among Kidney Transplant Recipients: A Large Single-Center Experience

Emily E. Zona,[1] Mina L. Gibes,[1] Asha S. Jain,[1] Juan S. Danobeitia,[2] Jacqueline Garonzik Wang,[2] Didier A. Mandelbrot,[2] Sandesh Parajuli.[2] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]University of Wisconsin-Madison, Madison, WI.*

Background: Kidney transplant recipients (KTR) are a vulnerable immunocompromised population at risk of severe disease and mortality from COVID-19. We characterized the sequelae of infection in KTRs at our center.

Methods: We studied all adult KTRs who had their first episode of COVID-19 between 04/2020 and 04/2022 and at least 12 months of follow-up (unless graft failure or death). Outcomes of interest included risk factors for hospitalization, all-cause mortality, and COVID-19-related mortality.

Results: Of 979 KTRs, 381 (39%) were hospitalized due to their first episode of COVID-19. There were some differences in baseline characteristics: those hospitalized had advanced age at COVID-19 diagnosis (59.8 (12.9) vs. 53.7 (12.6), p<0.001), were more likely to be male (63% vs. 55%, p=0.02), non-white (28% vs. 16%, p<0.001), have diabetes mellitus as a cause of ESKD (33% vs. 14%, p<0.001), and less likely to be living donor recipients (35% vs. 48%, p<0.001). In multivariate analysis, risk factors for hospitalization included advanced age at COVID diagnosis (HR: 1.03, 95%CI: 1.02-1.04), male recipient (HR: 1.29, 95%CI: 1.04-1.60), nonwhite recipient (HR: 1.48, 95%CI: 1.17-1.88), and diabetes as a cause of ESRD (HR: 1.77, 95%CI: 1.41-2.21). Vaccination against COVID-19 protected against risk of hospitalization (HR: 0.73, 95%CI: 0.59-0.90), risk for all-cause mortality (HR: 0.52, 95%CI: 0.37-0.74), and risk for COVID-related mortality (HR: 0.47, 95%CI: 0.31-0.71). Risk factors for both all-cause and COVID-related mortality in the multivariate analyses included advanced age (HR: 1.05, 95%CI: 1.03-1.07; HR: 1.04, 95%CI: 1.02-1.05), hospitalization (HR: 6.76, 95%CI: 3.43-13.28; HR: 24.3, 95%CI: 6.9-85.7), and respiratory symptoms for hospital admission (HR: 2.29, 95%CI: 1.42-3.68; HR: 2.73, 95%CI: 1.52-4.89). Furthermore, additional risk factors for all-cause mortality in multivariate analysis included being a nonwhite recipient (HR: 1.46, 95%CI: 1.01-2.12) and diabetes as a cause of ESKD (HR: 1.42, 95%CI: 1.0-2.01), with being a recipient of a living donor as protective (HR: 0.69, 95%CI: 0.48-1.0).

Conclusions: Hospitalization due to COVID-19 is associated with increased mortality. Vaccination against COVID-19 is a protective factor against hospitalization and mortality.

TH-PO864

A Rare Case of Malakoplakia in a Renal Transplant Patient

Victor E. Serrano-Santiago,[1] Roberto L. Collazo-Maldonado,[1,2] Muhammad R. Qureshi.[1,2] *[1]Methodist Dallas Medical Center, Dallas, TX; [2]Dallas Nephrology Associates, Dallas, TX.*

Introduction: Malakoplakia is a rare condition that affects immunocompromised patients, typically resulting in chronic inflammation, infections, and increased risk of bleeding in the affected tissues due to impaired bacterial clearance. Here we present a case of malakoplakia in a renal transplant patient that was complicated by bleeding and ultimately resulted in renal graft loss.

Case Description: A 70 y/o man presented to the emergency room with abdominal pain, fullness, and an acute kidney injury. He had a medical history of end-stage renal disease due to obstructive uropathy, deceased-donor renal transplantation in 2022 with anti-thymoglobulin induction, and was currently on triple immunosuppression with tacrolimus, mycophenolate, and prednisone. Abdominal computed tomography showed a large irregular mass in the right pelvis involving the right ureter, bladder, and renal transplant. Biopsy showed malakoplakia with chronic and acute inflammation, and ultimately grew *Bacillus* species. A drain was placed, and the patient was discharged with four weeks of piperacillin/tazobactam. Four months later, the patient was admitted with hypotension and abdominal pain. Abdominal imaging showed a subcapsular hematoma in the native right kidney originating from the malakoplakia lesion and extending into the right ureter, which required interventional radiology embolization. Imaging showed malakoplakia was still present throughout the native urinary tract. Immunosuppression was further reduced on discharge and suppressive antibiotics were continued to allow for adequate clearance of the chronic infection. The patient was ultimately readmitted with worsening kidney disease and restarted on dialysis. Malakoplakia findings were still present and largely unchanged on imaging. Immunosuppression was completely stopped and antibiotics were continued. The patient is currently undergoing nutritional optimization and chronic suppressive antibiotic therapy with the aim of pursuing surgery to remove the native urogenital tract.

Discussion: Here we show a case of malakoplakia in a renal transplant patient that required reduction of immunosuppression and subsequently led to graft function loss. Malakoplakia must be considered when imaging findings consistent with post-transplant lymphoproliferative disorder are seen in the urogenital tract.

TH-PO865

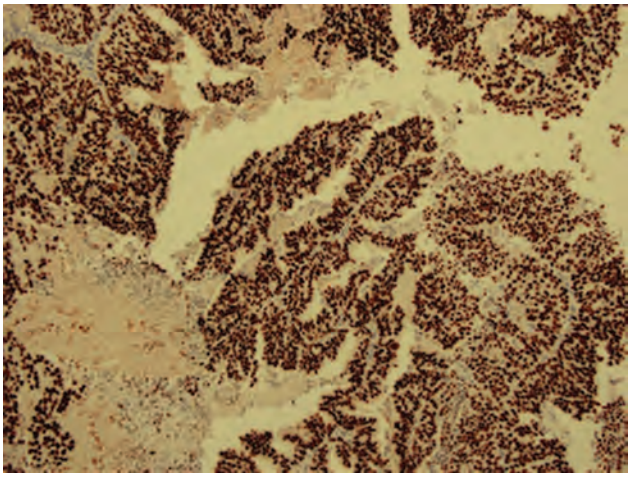
Urothelial Tumor in Transplant Patient with BK Nephropathy

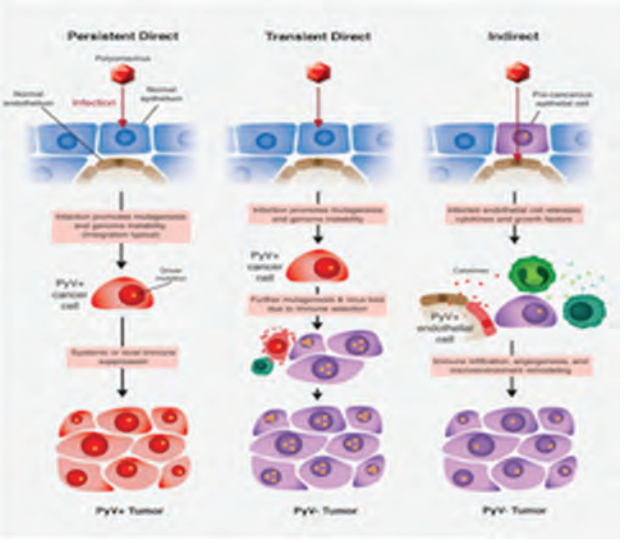
Sai Srikar VankadariVenkata,[1] Thomas H. Waid,[2] Hasan Fattah,[2] Ana L. Castellanos,[2] Fritz E. Lower,[2] Protima Rayapati,[2] Sravanthi Paluri.[2] *[1]Stanley Medical College, Chennai, India; [2]University of Kentucky Medical Center, Lexington, KY.*

Introduction: BK is a dsDNA virus in polyomaviridae family. BK does not cause disease in immunocompetent hosts. However BK can get activated in immunocompromised & cause BK nephropathy, ureteric stenosis in renal Tx, hemorrhagic cystitis in HSCT and rarely associated with urothelial carcinoma. We present a case of urothelial cancer in patient with persistent BK viremia, presenting with new onset microscopic hematuria.

Case Description: A 62 y/o WM with a history of LDKT in 2016, on Prograf, MMF, steroid. He developed BK viremia & nephritis 2 years postTx. Appropriate reduction in IS was implemented, along with wkly IVIG. His allograft function remained stable with CKD3b. BK viremia remained stable in the range of 40K -100K. He was found to have Microscopic Hematuria in 2022, cystoscopy revealed 2 Invasive Papillary bladder cancer which stained positive for BK by SV40 stain.

Discussion: BK Nephropathy is known cause of allograft loss, BK virus related malignancy is rarely reported & discussed. It is unclear if higher risk of Urothelial cancer in these immunocompromised hosts is directly related to IS & BK merely is an innocent bystander but new reports suggest role of BK in tumorigenesis. BK surveillance is recommended for upto 3 yrs post Tx. Our patient did not have any risk factors for bladder tumors other than persistent BK & IS meds. Persistent BK viremia and microscopic hematuria in transplant patients warrant further workup for urothelial cancers.





TH-PO866

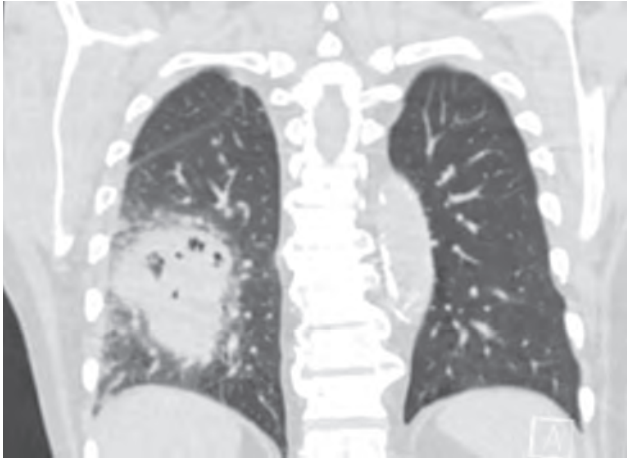
Mystery Lung Mass in a Kidney Transplant Recipient

Russell Leong,[1] Connor J. Grantham,[1] Trey H. Richardson,[1] Beatrice P. Concepcion.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of Chicago Pritzker School of Medicine, Chicago, IL.*

Introduction: The differential for lung masses in solid organ transplant recipients is broad. It includes infections particularly fungal and mycobacterial infections, malignancy, and recurrence of underlying systemic disease (e.g.GPA). The overlapping clinical and radiographic findings make diagnosis challenging.

Case Description: This is a 64-year-old female with ESKD due to hypertension who underwent a deceased donor kidney transplant with Alemtuzumab and methylprednisolone induction. She received sulfamethoxazole-trimethoprim for *Pneumocystis* prophylaxis. She was maintained on tacrolimus, mycophenolate mofetil, and prednisone. She had no prior episodes of rejection. She presented one-year post-transplant with 20-lb weight loss, fevers, generalized weakness, and productive cough. CT chest revealed a large right lung mass. Sputum and BAL cultures grew *Nocardia* nova. Transbronchial needle aspiration of the mass was negative for malignancy. She was treated with imipenem/cilastin and trimethoprim-sulfamethoxazole. Her mycophenolate mofetil was held. She subsequently improved clinically with marked improvement of radiographic findings.

Discussion: Nocardia is a low virulence organism found in soil and water. It is a rare life-threatening opportunistic infection that affects the lung, brain, and skin. It is more common in solid organ transplants recipients and usually presents 1-2 years post-transplant. Pulmonary nocardia presents with non-specific clinical symptoms. Imaging typically shows cavitary lesions. The risk of nocardiosis increases with net immunosuppression, rejection episodes, and time since transplantation. Prophylaxis with trimethoprim-sulfamethoxazole covers nocardia. This case demonstrates the importance of high index of suspicion for nocardia and a low threshold to send testing for sputum AFB/culture and to pursue early bronchoscopy/BAL. Timely diagnosis and initiation of treatment allow for a good clinical outcome such as what was achieved in this case.



TH-PO867

Complete Remission of Donor-Derived Metastatic Urothelial Carcinoma After Transplant Nephrectomy and Discontinuing Immunosuppression

Ebenezer A. Dawodu,[1,2] Barry M. Wall,[1,2] David S. Rustom,[1,2] Manish Talwar.[1,3] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]VA Memphis Medical Center, Memphis, TN; [3]Methodist Le Bonheur Healthcare, Memphis, TN.*

Introduction: De novo urothelial carcinoma is associated with kidney transplant and tends to present with advanced disease at diagnosis. We present a case of donor derived metastatic urothelial carcinoma with complete remission following transplant nephrectomy and withholding immunosuppression.

Case Description: A 55-year-old male with ESRD secondary to hypertensive nephropathy was on dialysis from 1992 -2005 and underwent deceased donor kidney transplant in 2005. Dual kidney transplant was performed due to donor's smoking history and donor finding of > 10% glomerulosclerosis. He did well post-transplant, baseline creatinine, 1.3 mg/dL. He developed allograft dysfunction with biopsy showing BK Polyoma Nephropathy in 2006. In 2021, he presented with bilateral flank pain and gross hematuria for 1 week. Urine cytology was positive for urothelial carcinoma. Bladder and prostatic urethra biopsies and right native renal pelvis washing were negative for carcinoma. Cytology from superior transplant kidney demonstrated high-grade urothelial carcinoma. PET CT in June 2021 showed abdominopelvic retroperitoneal nodal metastatic disease extending cephalad into the right retrocrural region with relative sparing of the pelvic nodal chains and focal hypermetabolism of the left adrenal gland, presumed to be metastatic. Both transplant kidneys were surgically removed in June 2021. Lymph node dissection and adrenalectomy were not performed due to position and proximity to the aorta. A 5 x 4 cm high grade urotheilial carcinoma with lymphovascular invasion was present in the pelvis of the superior allograft. BK virus DNA was undetectable in 2021. Immunosuppressive therapy included CNI, mycophenylate, and low dose prednisone. Immunosuppression was discontinued after resuming hemodialyis. Patient did not receive chemotherapy. Subsequent PET CT scans as recently as March 2023 demonstrated complete remission of metastatic disease. Cell-free DNA was < 0.12%, below the threshold for detection, supporting the absence of tumor.

Discussion: We report a case of complete remission of donor derived metastatic urothelial carcinoma following transplant nephrectomy and immunosuppression withdrawal. Future research should explore the balance between innate immunity as a protective factor against malignancy and immunosuppression to prevent rejection.

TH-PO868

When the Diagnosis Is Skin Deep: A Case of Cutaneous Chromoblastomycosis in a Patient with Kidney Transplant

Maryn Gardner, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Chromoblastomycosis, caused by fungi from the Herpotrichiellaceae family, primarily affects skin and soft tissues. Although it's prevalent in tropical and subtropical regions, U.S. cases have been reported. The disease presents various dermatologic lesions and can, in rare cases, affect lungs, bones, and brain. Treatment includes physical interventions, antifungal therapy, and is notoriously difficult due to frequent relapses and possible bacterial infections.

Case Description: A 67-year-old male kidney transplant recipient with a history of end-stage kidney disease from hypertension presented with a persistent, expanding skin lesion on his right anterior leg. Despite being non-pruritic, non-painful, and without any surrounding inflammation, his interest in gardening raised suspicion. A skin biopsy confirmed the diagnosis of chromoblastomycosis. The patient began itraconazole treatment, resulting in slow lesion improvement.

Discussion: Melanized fungal infections, such as chromoblastomycosis, are infrequent, particularly in temperate climates, making diagnosis challenging. This case illustrates the necessity of an early skin biopsy for accurate diagnosis. Immunocompromised patient, are at an elevated risk of disseminated disease. Thus, early diagnosis and treatment are critical to reduce potential morbidity and mortality.

TH-PO869

Case of Kidney Allograft Failure: A Pandora Box

Lakshna Sankar, Pooja Sanghi. *Geisinger Health, Danville, PA.*

Introduction: Post kidney transplant acute kidney injury could be due to drug toxicity, recurrence of primary disease, transplant rejection and vascular complications.

Case Description: 43 year old male with end stage kidney disease secondary to IgA nephropathy status post living related kidney transplant from an outside hospital in 2011, presented with shortness of breath of 1 week duration. He was on mycophenolate mofetil 500 twice daily and tacrolimus 3 mg twice daily. On clinical examination, he appeared hypervolemic. Review of labs showed elevated creatinine of 21.4 mg/dl (baseline 1.8 mg/dl) and was started on hemodialysis. Serology, infectious work up and echocardiogram were unremarkable. Tacrolimus level was supratherapeutic at 11 ng/ml. A doppler ultrasound showed large parenchymal arteriovenous fistula (AVF) in the midpole (Figure 1A). He underwent transplant arteriogram and was successfully embolized (Figure 1B). Subsequently, allograft biopsy showed recurrence of Ig A nephropathy, acute T-cell mediated rejection Banff criteria grade 1A, interstitial fibrosis and tubular atrophy of 70%, features suggestive of chronic thrombotic microangiopathy and glomerular sclerosis favoring chronic calcineurin inhibitor toxicity (Figure 2 A-C). Given the severity of scarring in the kidney, we did not treat him for rejection, as the adverse effects outweighed the benefits.

Discussion: Incidence of AVF in kidney allograft ranges from 0.5-16.9%; they can be traumatic (after biopsy), congenital or from the donor kidney. Our patient never had a biopsy since his transplant. Thus it is possible that this was donor derived. He was asymptomatic all these years till the AVF was diagnosed in his allograft and endovascularly ligated. Kidney biopsy revealed a myriad of other etiologies that ultimately lead to his graft failure. This case brings on a better insight to causes of allograft failure highlighting the gargantuan effort in evaluation and management of complications in a transplanted kidney.

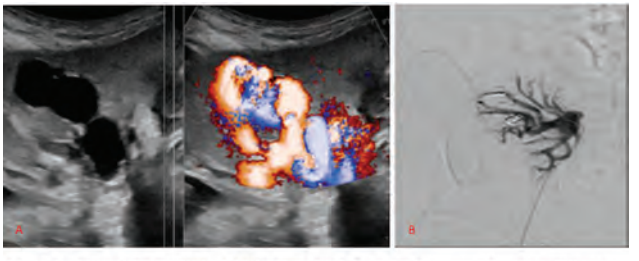

Figure 1: A - Ultrasound kidney transplant with doppler showing AVF; B - Post transplant arteriogram showing coil embolization

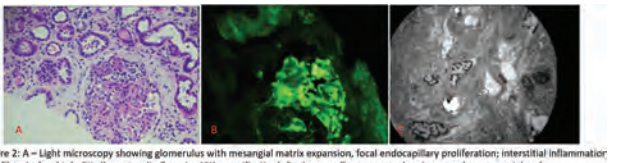

Figure 2: A – Light microscopy showing glomerulus with mesangial matrix expansion, focal endocapillary proliferation; interstitial inflammation and fibrosis, focal tubulitis (hematoxylin & eosin, 40X magnification); B – Immunofluorescence showing granular, mesangial and focal capillary loop fluorescence with IgA (3+); C - Electron microscopy showing subendothelial deposits.

TH-PO870

Impact of Area Deprivation Index on Early Stages in the Kidney Transplantation Process

Andrew J. Snyder,[1] Anna M. Morenz,[2] Jordan Nichols,[1] Omri Ganzarski,[1] Andre Dick,[3] James D. Perkins,[3] Nicole J. Kim,[2] Yue-Harn Ng.[2] *[1]University of Washington School of Medicine, Seattle, WA; [2]University of Washington Department of Medicine, Seattle, WA; [3]University of Washington Department of Surgery, Seattle, WA.*

Background: Socioeconomic factors play major roles in kidney transplantation (KT) access and outcomes but are difficult to identify. Area Deprivation Index (ADI) is a measure of socioeconomic conditions at the census block group level. We hypothesized that ADI may be a useful tool to identify patients at risk for inequities in the KT process. We investigated whether ADI was associated with attendance at KT clinic and subsequent waitlisting (WL).

Methods: We performed a retrospective cohort study of adults referred for KT evaluation from 1/1/15 -12/31/21. We compared clinical and sociodemographic characteristics between patients who were 1) seen vs. not seen in KT clinic and 2) WL vs. not WL. Wilcoxon rank sum test for continuous variables and chi-square test for categorical variables were used. Multivariable logistic regression analysis was performed to examine the association between ADI and WL.

Results: 2,284 patients were referred for KT evaluation during the study period. Patients from the most vulnerable neighborhoods (ADI 44-100) were less likely to be seen following referral (31% vs 26%; p=0.008). 1,691 (74.0%) patients attended KT evaluation, of these patients, 643 (38%) were waitlisted for KT. Residents in the highest ADI quartile (44-100) had a 38% less odds of being WL relative to the residents in the lowest ADI quartile (1-18) (OR 0.62, 95% CI 0.45-0.87; p=0.005).

Conclusions: Patients residing in higher ADI neighborhoods are at increased risk of not being seen in KT clinic and not being WL after KT evaluation. These findings suggest that ADI may be a useful marker to proactively identify patients at risk for early inequities in advancement through the KT process and could help guide early intervention efforts to ensure a more equitable evaluation process.

Unraveling the Hemodialysis Patient Network: Results from the Social Network and Renal Education (SNARE) Transplant Intervention

Alec Gayner,[1] Avrum Gillespie,[1] Peter P. Reese,[2] Crystal A. Gadegbeku,[1] Hannah Calvelli,[1] Heather M. Gardiner,[1] Edward L. Fink.[3] *[1]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [2]Hospital of the University of Pennsylvania, Philadelphia, PA; [3]Temple University, Philadelphia, PA.*

Background: In-center Hemodialysis (HD) is a unique therapy occurring in a group setting, facilitating patient social network formation. Social networks are a key social determinant of health, amenable to intervention if influential members are identifiable. The goal of our study is to determine whether patients who are more clustered (a network member whose alters are interconnected) vs. more central (a network member who has multiple alters who are not interconnected) within HD networks are more likely to disseminate the COmmunicating About Choices in Transplant (COACH) intervention. This intervention has been shown to improve knowledge, communication skills, and behaviors regarding living/deceased-donor kidney transplantation (KT).

Methods: For this pilot network intervention clinical trial (NCT03536858), in a North Philadelphia HD clinic, the Monday, Wednesday, Friday patients were stratified to centrality spread and Tuesday, Thursday, Saturday to clustering spread. Outcomes including number of transplant evaluation steps completed, change in KT knowledge, self-reported KT conversation self-efficacy, and living donation requests were assessed using repeated questionnaire data and chart review prior to the intervention, at 3-months, and 9-months post-intervention. Data analysis was performed using *t*-tests, repeated measures ANOVA, and Fisher's exact test.

Results: Twenty-eight transplant-eligible patients completed the study. Groups (centrality N=11; clustering N=17) did not differ significantly in demographic or clinical variables. The clustering group completed more KT evaluation steps (+0.79 ± 1.72 vs -0.38 ± 1.3, p=0.02) and reported higher conversation self-efficacy scores than the centrality group (21± 2.6 vs.16 ± 1.4, p=0.03). The difference in living KT requests was not significant (3 vs 1, p=0.5). No differences were observed in knowledge outcomes.

Conclusions: Selection of patients with the highest clustering yielded more efficient dissemination of the COACH intervention. Notably, this network intervention improved transplant behaviors but not knowledge, indicating a peer-network imitation effect on behaviors without changing knowledge. Further research is indicated to assess these effects in a larger population and with expanded network targeting strategies.

Disparities in Access to Kidney Transplantation for Asian, Hispanic, and Black Candidates

Maya N. Clark-Cutaia,[1,2] Gayathri Menon,[2] Yiting Li,[2] Byoungjun Kim,[2] Stephen P. Wall,[2,3] Melissa D. Hladek,[4] Tanjala S. Purnell,[5] Dorry L. Segev,[2] Mara McAdams-DeMarco.[2] *[1]New York University Rory Meyers College of Nursing, New York, NY; [2]New York University Grossman School of Medicine, New York, NY; [3]New York University Ronald O Perelman Department of Emergency Medicine, New York, NY; [4]Johns Hopkins University School of Nursing, Baltimore, MD; [5]Johns Hopkins University Center for Teaching and Learning, Baltimore, MD.*

Background: Disparities in access to kidney transplantation (KT) for minoritized end-stage kidney disease (ESKD) patients are persistent and pervasive. The distinct points along the KT continuum where disparities are most prominent are poorly understood, however their identification is crucial for developing targeted interventions. We quantified disparities from ESKD diagnosis to listing and first KT for Asian, Hispanic, and Black candidates, compared to White candidates.

Methods: Engaging USRDS data, we identified 2,200,356 adults with initial ESKD diagnosis between 1999-2019**.** We used Fine and Gray sub-distribution hazards models, adjusted for age, sex, race/ethnicity, comorbidities, primary health insurance, to determine adjusted sub-hazards ratio (aSHR) of listing after ESKD diagnosis, and KT after listing, with death as a competing risk. We tested the proportional hazards assumption using complementary log-log plots and Schoenfeld residuals.

Results: White candidates were more likely to be waitlisted and transplanted than candidates of other racial/ethnic groups. Waitlisted White candidates were also more likely to receive KT, especially LDKTs (Black aSHR (95% confidence interval (CI)): 0.33 (0.32-0.35); Hispanic aSHR (95%CI): 0.66 (0.64-0.69); Asian aSHR (95%CI): 0.45 (0.42-0.47)) and pre-emptive KTs (Black aSHR (95%CI): 0.53 (0.47-0.60); Hispanic aSHR (95%CI): 0.65 (0.56-0.75); Asian aSHR (95%CI): 0.47 (0.38-0.58).

Conclusions: The field of transplantation should engage communities to identify interpersonal, community, and societal barriers to access to KT among minoritized candidates.

Effect of Kidney Allocation System (KAS) Policy on Renal Transplantation in Elderly Recipients

Tahir A. Jatoi, Sandeep R. Sasidharan, Mohammad W. Abushawer, Fausto R. Cabezas, Angelika C. Gruessner, Subodh J. Saggi, Moro O. Salifu.
SUNY Downstate Health Sciences University, New York City, NY.

Background: Prior to 2015 KAS policy creation and implementation, there were inordinate number of kidneys being allocated to recipients who were not matched appropriately to enhance the longevity of the transplanted organ. Our aim was to analyze the impact of KAS policy on patient mortality.

Methods: This study includes retrospective analysis of primary DDRT patients age ≥ 65 years reported to UNOS/OPTN and performed between 2010 and 2022. Patients were divided into preKAS and KAS group by dialysis status. Comprehensive univariate and multivariable analyses were performed.

Results: There were 34717 patients analyzed. Fig1 shows the changes in factors over time. The number of transplants increased significantly as well as the number of preemptive transplants. The wait time decreased significantly and the number of Black and Hispanic recipients increased significantly. Fig1 shows patient and graft survival at 3 years. During the KAS era outcomes declined. The analysis showed an increased Relative Risk for transplants during KAS (RR: 1.39,1.32-1.46) while the outcome for preemptive transplants is significantly lower (RR: 0.68,0.64-0.73).

Conclusions: The number of kidney transplants in this elderly transplant group increased over time which offers an increased life-expectancy. While overall the mortality risk could not be reduced, a shorter waitlist time was noted, which is important. This analysis also shows the importance of early transplantation in this age group to reduce mortality.

Geographic Proximity to Donor Care Units Among Deceased Organ Donors After Brain Death

Emily A. Vail,[1,2] Vicky Tam,[3] Richard Hasz,[4] Peter Abt,[1,5] Peter P. Reese,[1,5] Niels D. Martin,[1] Kim M. Olthoff,[1,5] Vishnu S. Potluri.[1,2] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Leonard Davis Institute of Health Economics, Philadelphia, PA; [3]The Children's Hospital of Philadelphia, Philadelphia, PA; [4]Gift of Life Donor Program, Philadelphia, PA; [5]Penn Transplant Institute, Philadelphia, PA.*

Background: The National Academies recommend that all United States (US) organ procurement organizations (OPOs) operate deceased donor care units (DCU) but adoption is incomplete. Donors in hospitals at greater distances from DCUs may be less likely to transfer. We sought to characterize the geographic proximity of donors in hospitals to operating DCUs as a proxy for nationwide DCU access.

Methods: Retrospective analysis of all adult deceased donors after brain death with recovery dates Jan 2010 - Jun 2022 in Organ Procurement and Transplantation Network data. Driving times and distances between donor hospitals and DCUs were measured using ArcGIS road network software. We defined geographic proximity to a DCU by estimated driving times; primary outcome was drive time <2 hours (feasible for ground transport). We estimated the number of donors who would gain access to DCUs if OPO donor service area boundaries were ignored.

Results: Among 92 085 donors in 2574 hospitals, 42 302 (42.0%) were managed in one of 25 OPOs with DCUs. Among donors in those areas, a majority (86.7%, 36 687 donors in 999 hospitals) were within 2 hours' driving distance of a DCU. Rates of DCU proximity varied by OPO (median 43.5% (IQR 0-67.8%) of donors per OPO). When OPO area boundaries were ignored, 8164 additional donors in 229 hospitals were within 2 hours' distance of at least one DCU (Fig 1). Donor characteristics were similar between groups.

Conclusions: Less than half of donors were within 2 hours drive of a DCU. Proximity rates rates varied across donor service areas. A substantial number of donors were in hospitals proximate to an existing DCU in a neighboring area. OPOs may consider collaborating to transfer donors from hospitals in nearby areas or opening additional DCUs. Future work is needed to understand whether, and how, optimally located DCUs may improve kidney donation and transplantation outcomes.

Using Machine Learning to Identify People Considering Living Kidney Donation on Reddit

Amy D. Waterman,[1] Joshua E. Nielsen,[2] LaShara A. Davis,[1] Xiaoyu Chen,[2] Monica Gentili.[2] *[1]Houston Methodist Hospital, Houston, TX; [2]University of Louisville, Louisville, KY.*

Background: Machine learning (ML) strategies may help to identify potential kidney recipients and living kidney donors on online digital platforms, who are considering living kidney donation (LKD), to target helpful information to them. Our study's aims were to: (1) Identify people sharing their personal LKD experiences on the digital platform Reddit, (2) Determine whether ML models could distinguish between simplified or more nuanced labels.

Methods: A multidisciplinary team of engineers and transplant experts created and piloted a user labeling system to code 3,292 posts created by Reddit users from 2010-2023 using 3 simplified labels and six nuanced labels (Table). To validate the system, four team members independently labeled the same 100 posts manually, and definitions were refined until reaching unity. The remaining 3,192 posts were manually labeled using refined definitions. We explored the ability to automate this classification process using an ML model known as Bidirectional Encoder Representations from Transformers (BERT). Two models were trained to predict simplified and nuanced labels, respectively. Exploratory work using ChatGPT was also included for automatic classification.

Results: The BERT model accurately classified the simplified labels with 87% accuracy, but when trained to classify all six nuanced labels, was only able to perform with 67.1% accuracy. Preliminary experiments using ChatGPT showed poorer alignment with automated user labeling than ML models (69% and 45.3% for simplified and nuanced labels, respectively).

Conclusions: Using expert defined classification criteria combined with ML methods, it is possible to identify those who may be interested in LKD on digital platforms. Current methods perform better on more simplified classifications, but improvements can be made and advances in ML may increase the predictive power of future models. Future work will explore ways to enhance the BERT method using integration with ChatGPT.

Type of Post	Simplified Type	Number (%)	Example Post
Current Direct – Personally involved with LKD at present	**Current**	363 (11.0%)	A friend of mine is in need of a kidney. My first instinct is to offer one of mine. I have Googled and read LOTS of info. What would you do? Have you donated a kidney? What am I missing?
Current Indirect – Secondhand experience with LKD at present	**Current**	177 (5.4%)	I need help finding a kidney for my dad.
Past Direct – Personally involved with LKD in the past	**Past**	164 (5.0%)	Eight years ago today, I donated a kidney to a friend. Ask me anything.
Past Indirect – Secondhand experience with LKD in the past	**Past**	58 (1.8%)	[Here's a] picture of my dad and the woman who donated a kidney to save his life.
General Commentary/Hypothetical	**Impersonal**	159 (4.8%)	If you donate a kidney, then later your only one starts to fail, would you be put on a higher priority?
News/Noise	**Impersonal**	2371 (72.0%)	Story: A man donated his kidney to his wife of 51 years after finding out he's her perfect match.

TH-PO876

Sociodemographic Barriers to Interest and Pursuit of Living Donation Among ESKD Patients

Adam G. Walker,[1] Scott Sibbel,[1] William D. Maixner,[2] Carey Colson,[1] Michael O'Shea,[2] Steven M. Brunelli,[1] Francesca Tentori.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Living donor kidney transplants result in better patient and graft survival compared to deceased donor kidney transplants. Despite these benefits, only 23% of all kidney transplants in 2022 were from a living donor. To provide insight of potential barriers to living donation, we quantified the associations of interest in, and pursuit of, living donor transplant with geographic, demographic, and socioeconomic factors among end-stage kidney disease (ESKD) patients.

Methods: This was a retrospective study of 151,656 adult ESKD patients on dialysis for whom preferences and potential pursuit of transplant status were documented. Publicly available data sources were used for classification of socioeconomic status. Outcomes considered were interest in living donation and separately, pursuit of a living donation. Associations between patient characteristics and outcomes were quantified with odds ratios and 95% confidence intervals derived from multivariate logistic regression models assuming a binomial distribution.

Results: For the 59,893 patients in whom interest was recorded, 11,675 (19.5%) were interested in living donor transplant. Among those interested, 7,376 (63.2%) reported having pursued a living donation. The following factors were associated with interest in living donation: age at dialysis start, race/ethnicity, sex, diabetes status, insurance type at dialysis start, kidney education attendance, and poverty level. The following factors were associated with pursuit of a living donation: age at dialysis start, race/ethnicity, and insurance type at dialysis start. Both interest and pursuit of living donation varied by state, but no obvious regional trends were observed.

Conclusions: Our results identify subgroups of patients who could potentially benefit from additional education regarding living donor transplant. This information may be useful in the design of interventions to increase living donor kidney transplantation rates.

Variable/Category	Interest in Living Donation Odds Ratio (95% CI)	Pursuit of Living Donation Odds Ratio (95% CI)

TH-PO877

Experiences of Ethnically Diverse Living Kidney Donors

Miriam E. Velez-Bermudez, Heidi Rishel Brakey, Larissa Myaskovsky, Mark L. Unruh, Pooja Singh, Nancy Pandhi. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Living kidney donors enter the donation process in good health but are often ill-prepared to face any negative outcomes following donation. Adverse post-donation outcomes are more prevalent among ethnic minorities. We aimed to provide an in-depth description of ethnically diverse donors' positive and negative outcomes to inform development of an online module of lived experiences.

Methods: We used the DIPEx (database of individual patient experiences) method to conduct in-depth individual interviews with a diverse sample of donors. This method combines in-depth patient interviews with rigorous systematic, purposeful sampling and qualitative analysis. All interviews were conducted by a primary and secondary interviewer and analyzed by a qualitative research team.

Results: Fourteen donors (9 women; 8 White, 5 Hispanic, 1 Native American) completed narrative interviews. Findings highlight the critical role of social support in validating the decision to donate and aiding post-donation recovery. Participants felt compelled to donate to prevent dialysis use or death for their recipient. Although familial duties seemed to motivate donation for Hispanic and Native American women, a call to action as a healthy individual was a greater motivator among the White donors. Most (n=13) felt well-supported by healthcare providers throughout the entire pre-donation period, though three participants reported erroneously being told they had developed kidney disease in primary care due to a lack of clarity regarding post-donation clinical care. Among directed donations (n=12), most reported either no change or improvement in the relationship to the recipient. Many donors (n=11) experienced unanticipated outcomes post-donation, including minor complications (e.g., constipation, fatigue, pain), moderate complications (e.g., hernia, gout), or emotional distress (e.g., depression, mourning loss of kidney). Despite these adverse outcomes, all participants were enthusiastic about donation and reported no regrets.

Conclusions: Adverse outcomes post-donation did not preclude living donors' enthusiasm and support of donation; therefore, greater transparency about post-donation outcomes is warranted. An online DIPEx module presenting these diverse experiences may enhance awareness and understanding of the donation process for future living kidney donors.

TH-PO878

Healthcare System Intervention Changed Negative Perceptions of Healthcare in Kidney Transplant Candidates

Miriam E. Velez-Bermudez,[1] Yuridia Leyva,[1] Jamie M. Loor,[1] Mary Amanda Dew,[2] Yiliang Zhu,[1] Mark L. Unruh,[1] L. Ebony Boulware,[3] Amit D. Tevar,[2] Larissa Myaskovsky.[1] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]UPMC, Pittsburgh, PA; [3]Wake Forest University School of Medicine, Charlotte, NC.*

Background: The kidney transplant (KT) evaluation process is lengthy for patients but even longer for Black patients. One potential reason for these longer times is past negative experiences with healthcare contributing to mistrust toward healthcare systems. We examined whether engaging in a streamlined evaluation process at a transplant center reduced negative perceptions of the healthcare system among Black patients.

Methods: We recruited patients undergoing KT evaluation, and the intervention occurred during the evaluation period. We collected survey responses at T1 (before evaluation initiation) and T2 (following KT evaluation completion). Surveys assessed experience of discrimination in healthcare, perceived racism in healthcare, medical mistrust, and trust in physician. Regression analyses adjusted for baseline characteristics. We examined whether negative perceptions of healthcare changed from T1 to T2 among White and Black participants.

Results: The final sample included 883 participants (658 White, 225 Black). White participants consistently had lower scores for discrimination, racism, and mistrust but higher scores for trust in physician, compared to Black participants, across both time points (all $p<.001$). Interaction effects indicate that White participants experienced a significant reduction in discrimination, racism, and mistrust scores at T2, and Black participants experienced a significant reduction in discrimination, mistrust, and trust in physician scores at T2 (all $p<.05$). The difference in change-in-perception scores between Whites and Blacks was statistically significant for trust in physician ($p = .012$).

Conclusions: A coordinated healthcare system intervention reduced perceptions of discrimination, racism, and mistrust in patients undergoing KT evaluation, but results varied by race. Future work will ascertain whether perceptions of discrimination, racism, and mistrust are associated with faster time to KT waitlisting, treatment adherence, and quality of life post-transplant.

TH-PO879

Disparities in Phase Progression in Kidney Transplant Evaluation

Adarsh Ramakrishnan, Syed A. Husain, Kristen L. King, Miko Yu, Demetra Tsapepas, Sumit Mohan. Columbia University Renal Epidemiology (CURE). *New York-Presbyterian Columbia University Medical Center, New York, NY.*

Background: Inequity in access to kidney transplantation by race/ethnicity is a significant challenge. In this study, we evaluate the association between race and progression to subsequent phases of transplant in patients being evaluated for a kidney transplant.

Methods: We conducted a retrospective cohort study of patients undergoing kidney transplant evaluation at our center from 2020-2023. Using time-to-event analyses, we examined the time to reaching the next phase of transplant by self-identified patient racial group. Patients determined to be ineligible for listing were censored at committee review date while remaining patients were censored at the end of the study period. We then created a multivariate Cox proportional hazards model to assess the association between race and phase progression while controlling for age, gender, employment status, cause of end-stage renal disease, and insurance type.

Results: We identified 957 patients who were evaluated for kidney transplant with a documented race. Of these, 9% were Asian, 28% were Black/African American, 29% were Hispanic/Latino and 35% were White. Median progression time from evaluation to listing was 181 days and listing to transplant was 264 days. The unadjusted probability of progressing from evaluation to listing was significantly different between all four racial groups (p<0.0001), but there was no difference in progressing from listing to transplant (p=0.12) (Figure). In adjusted models, Black/African American patients had 37% lower rate of progressing from evaluation to listing (p=0.0001) and 35% lower rate of progressing from listing to transplant (p=0.01) compared to White patients, and Hispanic/Latino patients had 34% lower rate of progressing from evaluation to listing (p=0.0005) compared to White patients.

Conclusions: Disparities in progression from evaluation to waitlisting contribute to racial disparities in kidney transplant access.

Public Survey of Financial Incentives for Kidney Donation

Amgad E. El Agroudy. *Arabian Gulf University, Manama, Bahrain.*

Background: With the increasing prevalence of end-stage kidney disease in Bahrain, kidney donation is of vital importance. In this study we want to assess how financial incentives will influence peoples' views and decisions regarding kidney donation. The aim is to establish strategies to increase the number of kidneys for transplantation in Bahrain.

Methods: We adapted a previously established questionnaire on financial incentives for living kidney donations. The questionnaire assessed the public opinion in Bahrain on how kidney donation can be influenced by two different financial incentives, namely 10,000 BHD and life-long health insurance. We collected a convenient sample of 446 participants by distributing an electronic version of the questionnaire. SPSS-23 software was used for data entry and analysis.

Results: Of the total participants 39% were male and 61% were female. Eighty-percent of the participants believed that their chances for kidney donation will not increase in turn of receiving a financial compensation, while 20% of them believed that it will increase. Our study found that generally married participants (70%) find it a preferable development for health insurance companies to offer financial compensation for kidney donation, while non-married participants (30%) found it not a preferable but also not an adverse development (P-value 0.038). Furthermore, there is a positive correlation between age and preferable views toward financial incentives to increase kidney donation (P-value <0.001).

Conclusions: Although financial incentives for kidney donation might encourage a minority of the population, the majority may not be influenced by implanting a financial incentives' system for kidney donation.

Neighborhood Deprivation and Access to Living Donor Kidney Transplantation: Reducing Health Care Disparities

Byoungjun Kim,[1] Gayathri Menon,[1] Yiting Li,[1] Maya N. Clark-Cutaia,[2] Dorry L. Segev,[1] Mara McAdams-DeMarco.[1] NYU Langone Center for Surgical & Transplant Applied Research. *[1]New York University Grossman School of Medicine, New York, NY; [2]New York University Rory Meyers College of Nursing, New York, NY.*

Background: Living donor kidney transplantation (LDKT) offers better health outcomes for individuals with end-stage kidney disease (ESKD). Deprived neighborhoods have low socioeconomic status, limited social cohesion, and reduced access to health care. However, the role of neighborhood deprivation on access to LDKT is understudied.

Methods: We used SRTR data to identify 510,674 non-Hispanic (NH) White, NH Black, NH Asian, and Hispanic KT candidates (age≥18) who were listed for first KT from 1995-2021. The National Cancer Institute's Neighborhood Deprivation Index (NDI) was averaged at the ZIP code level using population weights from the American Community Survey. Proportional hazards models were used to determine the likelihood of LDKT across tertiles of NDI, adjusting for clinical and neighborhood-level factors.

Results: Candidates residing in high-deprivation (HD) neighborhoods had a lower access to LDKT than those in low-deprivation (LD) neighborhoods (adjusted hazard ratio (aHR)=0.80, 95% confidence interval (CI): 0.79-0.82); notably, Black candidates living in HD neighborhoods had 37% lower access to LDKT than those in LD neighborhoods (aHR=0.63, CI: 0.60-0.67). Similarly, Asian and Hispanic candidates living in HD neighborhoods had 22% (aHR: 0.78, CI: 0.70-0.88) and 21% (aHR: 0.79, CI: 0.75-0.83) lower access to LDKT, respectively, relative to White candidates.

Conclusions: Neighborhood deprivation is associated with decreased access to LDKT, particularly among Black candidates. Identification of structural factors impacting healthcare access in disadvantaged neighborhoods can be used by policymakers and healthcare providers to develop interventions to address barriers and disparities in LDKT access.

Ongoing Sex Disparities in Living Kidney Transplantation: A UNOS Analysis

Fausto R. Cabezas, Sandeep R. Sasidharan, Mohammad W. Abushawer, Tahir A. Jatoi, Moro O. Salifu, Angelika C. Gruessner, Subodh J. Saggi. SUNY Downstate Nephrology Division. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: In the United States, the prevalence of chronic kidney disease (CKD) is higher in females (16.2%) than in males (13.4%). Studies in Asia and Mexico have shown that females comprised 62% to 69% donors and were LKDT recipients in only 20% of cases. Disparities are not fully explained by socio-cultural or biological factors. Outdated U.S. data showed a lower rate of LDKT in females. We aim to explore current trend of LDKT in the US.

Methods: We queried the UNOS database for all adult primary single organ LDKTs from 2011 to 2022. We excluded deceased donor recipients which has been previously described. Comprehensive univariate and multivariate analyses were performed to describe changes and risk factors.

Results: There were 60,865 LDKTs, 36% were female recipients and 63.5% were donors (Table 1). The likelihood to receive a LDKTA decreased with increasing age. Black females were more likely to be donorsreceive a LD KTA when compared to white females (OR 1.4 [1.3-1.5] <0.001). Female donors recipients were less likely to be biologically related to male recipients to receive a nonbiologically related KTA (OR 0.89 [0.86-0.93] <0.001). Furthermore, female recipients were longer on the transplant waiting list and were more likely to have a higher a cPRA (OR 6.2 [6.2-7.3] <0.001). Female to Male donors accounted for 40.6% of donors, this trend remained stable throughout the study period.

Conclusions: Females are more likely to be donors than LDKTA recipients and face longer times in the transplant waiting list. Black females were more likely to be donors and less likely to be recipients when compared to white females. The sex disparities in KT

listing and LKDT remains. However, socio-cultural factors, as well as biological factors influencing such disparities are yet to be elucidated. Data informed policy is warranted to bridge the sex disparities in LKDT.

Use of "Marginal Kidneys" to Improve Access to Care: No Adverse Impact on Short-Term Outcomes

Fausto R. Cabezas, Sandeep R. Sasidharan, Mohammad W. Abushawer, Tahir A. Jatoi, Mariana S. Markell, Caroline L. Rochon. *SUNY Downstate Health Sciences University, New York City, NY.*

Background: In an effort to improve both equity and utility of organ allocation, the current kidney allocation system (KAS) assigns kidneys from donors with higher kidney donor profile index (KDPI) to recipients with a lower expected posttransplant survival (EPTS) score and vice versa. However, many kidneys with a high KDPI (especially >80%) are discarded for fear of poor outcomes. This study examines our experience with high KDPI kidneys.

Methods: We queried our transplant QI database for all adult primary deceased kidney donor transplants (DDKT) from 2022-2023. The cohort was dichotomized based on high vs lower KDPI (>80% vs.<80%). One-year mortality and allograft failure were compared across groups.

Results: Of 115 DDKT, 81.7% were African-American, 46% were females, median age was 60 years. The recipients with a KDPI < 80% represented 70%. Recipients with a KDPI >80 % were older (66 vs. 57), had longer ischemic times (26.6 hours vs. 23.8 hours) and had a slightly higher EPTS (64% vs. 68%) when compared to the lower KDPI group (table 1). Recipients in the high KDPI group had similar rates of mortality and marginally lower delayed graft function (DGF), these differences were not statistically significant when compared to recipients with a KDPI <80%.

Conclusions: -In keeping with the KAS, organs from donors with KDPI <80% were more likely to be allocated to younger highly sensitized recipients. -Mortality and graft failure at 1-year pos-transplant did not differ between recipients of KDPI >80% vs. <80% kidneys despite the older age of the high KDPI recipients. -The high DGF rate in our low KDPI group was likely to be due to our acceptance of allografts from donors with acute kidney injury in an effort to transplant recipients who were ranked lower. -Our results suggest that high KDPI kidneys should be utilized although the early transplant period requires a strong multidisciplinary transplant team to guarantee good outcomes in underserved communities with low rates of DDKT such as ours.

Living Kidney Donation in the United States from 2017 to 2022

Fawaz Al Ammary,[1] Hayden R. Troutt,[1] Deidra C. Crews,[2] Abimereki Muzaale.[2] *[1]University of California Irvine, Irvine, CA; [2]Johns Hopkins University, Baltimore, MD.*

Background: Living kidney donation has not recovered to pre-pandemic rates. To inform the national efforts for increasing living kidney donation rates in the United States, we sought to characterize post-pandemic trends to guide future interventions.

Methods: We studied a US national registry (SRTR) of 35,511 living kidney donors from 2017 to 2022 (median age [IQR], 44 years [34-54], 64% female, 71.8% White, 15.2% Hispanic, 8.4% Black, 4.6% Asian donors). We used Poisson regression models to describe changes in the number of donors in 2020-2022 vs. 2017-2019 by donor-recipient relationship and race/ethnicity.

Results: Among biologically related donors aged <34, 35-4, ≥50 years the number of White donors aged <34, 35-49 and ≥50 decreased by 13%, 13%, and 18%, and Black donors aged <34, 35-49 years decreased by 27% and 22. Among unrelated donors <35, 35-49, ≥50 White donors decreased by 13% across age groups and Black donors <34 decreased by 49%. Among spousal donors aged 35-49 and ≥50 White donors decreased by 21% and 23% and Black donors decreased by 44% and 38% Among kidney-paired donors White donors ≥50 increased by 18%, and Hispanic donors aged <34 and ≥50 increased by 31% and 65%. No significant changes were observed for Asian donors across these described subgroups.

Conclusions: The decline in living kidney donation in the wake of the pandemic was driven by White and Black donor subgroups, warrantying targeted efforts to uncover what new barriers may be responsible for these observations.

Living Kidney Donors' Perspectives of Telemedicine Video Visits for Donor Evaluation: A Qualitative Study

Fawaz Al Ammary,[1] Ellie Kim.[2] Transplant Qualitative Research Collaborative. *[1]University of California Irvine, Irvine, CA; [2]Johns Hopkins University, Baltimore, MD.*

Background: Living kidney donor evaluation is a complex multiphase process that takes approximately one year. It requires in-person visits where access to a transplant center becomes a barrier for willing candidates. Telemedicine via synchronous video enhances care coordination of donors. We conducted a qualitative study to understand donors/donor candidates' perceptions of telemedicine in donor evaluation.

Methods: We conducted in-depth, semi-structured interviews between 11/23/2021 and 03/17/2022. We interviewed 20 donors/donor candidates who completed their evaluation via telemedicine or in-person visits at a tertiary transplant center in Baltimore, Maryland. Interviews were analyzed using thematic analysis.

Results: Participants reported the following: 1) Telemedicine reduces travel time and travel-related expenses. 2) Telemedicine requires less time commitment compared to in-person, which allowed for more flexibility with scheduling their visit and made it easier to take less time off work. 3) Telemedicine reduced the burden of arranging for child and family care. 4) Interest in having introductory information provided prior to their visit. 5) Some concerns about telemedicine visit privacy and security. 6) Suggestions for using visual aids to facilitate the information shared during their visit. 7) Preferences in telemedicine versus in-person based on the providers' roles, specifically noting that they would prefer to meet the surgeon in-person. 8) Differences in levels of personal connectedness and communication. 9) Advantage of telemedicine allowing family and significant others to attend their visits.

Conclusions: Our findings provide information about donors/donor candidates' experiences and attitudes toward using telemedicine for donor evaluation. The reported views help inform a care coordination model in the donor evaluation process to enhance engagement of donor candidates and support completion of their evaluation.

Automated 3D Cortical Thickness Measurements from CT Images: A Novel Predictor of Low Kidney Function in Living Kidney Donors

Timothy L. Kline, Adriana Gregory, Panagiotis Korfiatis, Andrew D. Rule, Aleksandar Denic. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: The kidney cortex volume can be quantified on contrast-enhanced CT and is prognostic for chronic kidney disease (CKD) outcomes. Reduced cortical thickness is routinely reported from kidney ultrasound, however, cortical thickness is highly variable throughout the cortex and can be difficult to estimate from 2D images. Additionally, the relative contributions of cortical thickness and cortical volume to CKD risk are unclear.

Methods: This study examined a cohort of 1,132 living kidney donors with robust cortico-medullary differentiation on contrast-enhanced CT of the kidneys. AI techniques first separately segmented the cortex and medulla. Automated post-processing was employed to measure kidney length and volume of cortex. Then a distance map-based method was used to calculate average, maximal, and summed cortical thickness of the retained kidney. Cox proportional hazards models assessed the risk of measured glomerular filtration rate (mGFR)<60ml/min/1.73m^2 after donation with all five kidney cortex measures in analyses that were unadjusted and adjusted for cortex volume.

Results: Higher levels of all five AI-derived kidney cortex measures correlated with higher pre-donation mGFR (r_s=0.15-0.33, p<.0001). In unadjusted analyses, lower levels of all cortex measures associated with onset of a mGFR<60ml/min/1.73m^2 at a median 4 months post-donation. After adjusting for cortex volume, lower sum of cortex thickness and higher mean cortex thickness associated with onset of a mGFR<60ml/min/1.73m^2.

Conclusions: At the same level of cortex volume, a donor with lower total cortex thickness is at a higher risk for lower kidney function. Decreased total cortical thickness relative to total cortical volume may better detect loss of nephrons from nephrosclerosis than does cortical volume alone.

Funding: NIDDK Support

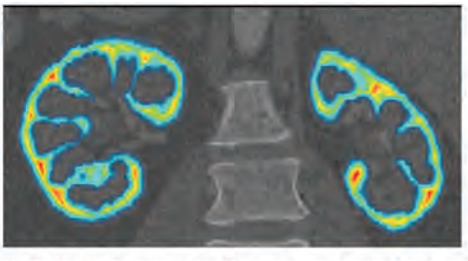

Figure. Example CT image with distance map of kidney cortex (displayed as a color overlay) used to derive cortical thickness.

Table. Imaging biomarkers as predictors of GFR<60ml/min/1.73m^2 in short-term donor follow up.

Median follow-up of 4.4 months by clinical care (n=1132)	Unadjusted		Adjusted for cortex volume	
	OR (95%CI)	P value	OR (95%CI)	P value
Cortex volume	0.43 (0.36-0.50)	<0.0001	---	---
Kidney length	0.65 (0.57-0.74)	<0.0001	0.98 (0.83-1.15)	0.82
Cortex thickness, sum	0.63 (0.55-0.72)	<0.0001	0.75 (0.65-0.87)	0.0002
Cortex thickness, average	0.84 (0.73-0.96)	0.01	1.41 (1.19-1.67)	<0.0001

TH-PO887

Beliefs and Intention to Organ Donation

Sami A. Alobaidi. *University of Jeddah, Jeddah, Saudi Arabia.*

Background: Efforts to increase organ donation globally have not been successful, as seen in the low donor rates in Middle Eastern countries like Saudi Arabia, despite advanced healthcare systems and supportive government policies. Multiple factors, including psychosocial, cultural, religious, and structural elements, influence organ donation rates, some of which are unique to Saudi Arabia. The theory of planned behavior (TPB) is used to study how attitudes, beliefs, and norms affect organ donation intention and practice. This study explores normative, behavioral, and control beliefs among Saudi Arabian residents.

Methods: This was an online survey conducted from June to December 2021 using a Google form questionnaire among residents of Saudi Arabia. The survey covered demographic factors and explored normative, behavioral, and control beliefs related to organ donation.

Results: This study received 1245 valid responses. Among the study participants, only 19.6% were willing to register as an organ/tissue donor. The intention for organ donation showed a statistically significant positive association with beliefs that organ donation is a good thing (123.51, df: 4, p<0.001), could save somebody's life (81.38, df: 4, p<0.001), could have a positive impact on life after death (114, df: 4, p<0.001), and that the provision of better social support to the family of the deceased can increase organ donation (68.43, df: 4, p<0.001). Knowledge about family objections (190.76, df: 4, p<0.001), transplantation process (179.35, df: 4, p<0.001), religion's view (120.345, df: 4, p<0.001), and registration facilities (241.64, df: 4, p<0.001) increased willingness to donate organs. Worry about receiving less care (OR=4.25, 95% CI 1.57-11.51), belief in better social support increasing donation (OR=10.49, 95% CI 1.56-70.43), and concern for family emotions during donation (OR=4.37, CI 1.57-12.23) strongly predict intention to donate organs.

Conclusions: The study finds a positive correlation between normative/behavioral beliefs and definite intention for organ donation in the Saudi population. Control beliefs show a negative correlation. Promoting awareness about the organ donation process, including religious permissibility, is needed to increase donation rates.

TH-PO888

Procurement Retardation Improves Organ Recovery

Chloé Samson,[1,2] Sarah Drouin,[1,2] David Buob,[3,1] Juliette Hadchouel,[1,2] Pierre Galichon.[1,2] Mécanismes de l'insuffisance rénale aigüe et réparation. *[1]INSERM U1155, Paris, France; [2]Sorbonne Universite, Paris, France; [3]Assistance Publique - Hopitaux de Paris, Paris, France.*

Background: The conditioning of the donor is crucial to avoid delayed graft function (DGF), which occurs in nearly 30% of cases and is associated with graft loss. A third of brain-dead donors have a recovered cardiac arrest (RCA), thus leading to a first episode of renal ischemia before procurement. Even if ischemia is known to be deleterious, studies conducted so far did not find an association between the donor's RCA and DGF. We hypothesize that the time interval (TRCA) between the RCA (1st ischemia) and the graft's procurement (2nd ischemia) could influence the function and survival of the graft. Using the French CRISTAL database, we found that a TRCA shorter than 3 days is associated with an increased risk of DGF. Several data suggest that proliferative cells are more sensitive to stress than non-proliferative ones. Given that an acute injury induces the proliferation of tubular cells, a procurement occurring during the proliferative phase of the tubular epithelium induced by the RCA-mediated ischemia could favor DGF. We used a mouse model to test this hypothesis and identify mechanisms responsible for the increased risk of DGF after an 'early' 2nd ischemia.

Methods: To mimic the situation of a donor with RCA, we performed two renal ischemias separated by either 2 or 5 days ('early' and 'late' 2nd ischemia), using a vascular occluder we recently developed. We evaluated the Glomerular Filtration rate (GFR) 24h after each ischemia by measuring the transcutaneous excretion kinetics of FITC-sinistrin (MediBeacon®). The histological analysis was carried out 24h after the 2nd ischemia by evaluating (i) the tubular injury and (ii) the cellular response using markers of proliferation (BrdU) and cell death (TUNEL).

Results: Comparably to the human data, the GFR following an early 2nd ischemia is lower than after a late 2nd ischemia. There was also a trend towards increased tubular lesions in the early group compared to the late one. Our future goal is to examine the effects of inhibiting proliferation after an early 2nd ischemia on the function and structure of the kidney (short & long-term after ischemias).

Conclusions: Our results suggest that delaying kidney procurement after RCA could ameliorate the function and survival of the graft. Given that it concerns a frequent situation, our study could improve the quality of grafts by recommending an optimal time interval for procurement after an RCA.

TH-PO889

Health-Related Quality of Life in Altruistic vs. Directed Kidney Donors

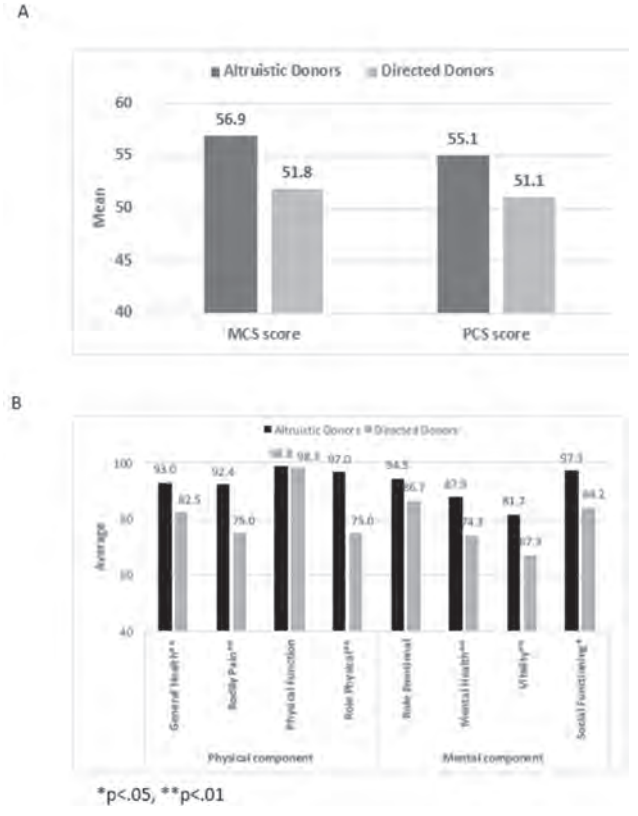
Tamar Hod,[1] Assaf Vital,[2] Enosh M. Askenasy,[3] Ronen Ghinea,[3] Eytan Mor.[3] *[1]Tel Aviv University, Tel Aviv, Israel; [2]Ariel University, Ariel, Israel; [3]Sheba Medical Center, Tel Hashomer, Israel.*

Background: Despite the significant increase in the rate of living kidney donation, there has been a lack of sufficient investigation into the post-donation health related quality of life (HRQoL) of altruistic donors (ADs) in comparison to directed donors (DDs).

Methods: We analyzed 112 living kidney donors (82 ADs and 30 DDs) who completed a SF-12 questionnaire and four supplementary questions. We compared the PCS and MCS scores between the two groups and examined secondary outcomes such as admission length of stay (LOS), time to return to normal activity and to physical activity, pre- and post-donation exercise rates, and physical activity continuation post-donation.

Results: Living kidney donors had higher mean PCS-12 and MCS-12 scores compared to the general population, with significantly higher scores in ADs than DDs ($p<0.001$). ADs returned to physical activity sooner than DDs (45 vs. 60 days), exercised more before and after donation, and continued post-donation. ADs had shorter admission LOS (3.4 vs. 4.4 days, $p<0.001$). Multivariable regression analyses revealed donation type and WBC count predicted PCS-12 score (altruistic vs. DDs: +2.69 (1.02), $p=0.01$) and donation type predicted MCS-12 score (altruistic vs. DDs: +4.43 (1.53), $p=0.005$). Altruistic donation type predicted a shorter LOS (by 0.78 days, $p<0.001$) and the odds of having PCS-12 and MCS-12 scores above 50 were almost 10 and 16 times higher in ADs, respectively ($p<0.05$).

Conclusions: ADs exhibit significantly higher physical and mental HRQoL compared to DDs post-donation, indicating the safety and potential benefits of promoting altruistic donation. However, it is essential to maintain a careful selection process to prevent any harm and ensure that donors' genuine desire to help others is not exploited.



SF-12 questionnaire results

TH-PO890

Comorbidity and Multimorbidity Burden in Living Kidney Donors

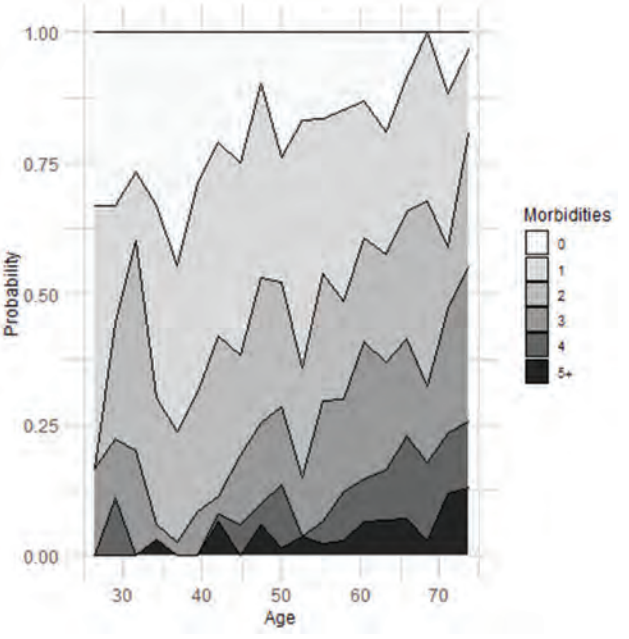
Ngan Lam. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: After donation, living donors may develop one or more risk factors that increase the likelihood of subsequent cardiac and kidney adverse events.

Methods: We conducted a cross-sectional, population-based cohort study using linked healthcare databases to study 979 living kidney donors who had donated between 1994 and 2019 in Alberta, Canada. The primary outcome was the presence or history of cardiac and kidney comorbidities, as of March 31, 2020. Cardiac comorbidities included hypertension, diabetes, or major cardiovascular events (myocardial infarction, stroke, or transient ischemic attack). Kidney comorbidities included sustained low eGFR (<45 mL/min/1.73 m^2), moderate-severe proteinuria, or kidney stones. Secondary analyses included the presence of other comorbidities, such as cancer, depression, and chronic pain.

Results: The median time since donation was 13 years (IQR 7–19). Of the cardiac comorbidities, hypertension was the most common (31%), followed by diabetes (7%), then major cardiovascular events (5%). Both hypertension and diabetes were present in 5% of donors. For the kidney comorbidities, a history of kidney stones was the most common (12%), while low eGFR (5%) and proteinuria (4%) were uncommon. For the other comorbidities, chronic pain (40%) was most common, followed by depression (36%). Overall, approximately three-quarters of donors had at least 1 comorbidity with the proportion of donors with multimorbidity (≥2 comorbidities) rising with increasing age.

Conclusions: Comorbidity and multimorbidity in the living kidney donor population rises with increasing age. The results of this study may inform long-term follow-up care of donors by identifying those who may benefit most from periodic health reviews.



TH-PO891

Sex Disparity and Kidney Function in Living Kidney Donors

Ekamol Tantisattamo,[1,2] Voramol Rochanaroon,[3] Wanprapit Noree,[4] Ben Thiravetyan,[5] Thanathip Suenghataiphorn,[5] Urairat Chuenchaem,[6] Narathorn Kulthamrongsri,[5] Thitiphan Srikulmontri,[7] Chanokporn Puchongmart,[5] Piengpich Naunsil,[8] Possawat Vutthikraivit,[9] Manasawee Tanariyakul,[10] Thiratest Leesutipornchai,[10] Jathurong Kittrakulrat,[11] Sasithorn Kunupakan,[1,12] Phuuwadith Wattanachayakul.[1,5] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Tibor Rubin Veterans Affairs Medical Center, Veterans Affairs Long Beach Healthcare System, Long Beach, CA; [3]Rayong Hospital, Rayong, Thailand; [4]Police General Hospital, Bangkok, Thailand; [5]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [6]Bumrungrad International Hospital, Bangkok, Thailand; [7]Siriraj Health Science Education Excellence Center, Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [8]Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand; [9]Phramongkutklao College of Medicine, Mahidol University, Bangkok, Thailand; [10]University of Hawaii John A. Burns School of Medicine, Honolulu, HI; [11]Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [12]Ramathibodi Excellent Center for Organ Transplantation, Bangkok, Thailand.*

Background: While a sex disparity in chronic kidney disease exists, it remains unclear if there is a disproportionate difference in kidney function following kidney donation.

Methods: A retrospective cohort study using OPTN/SRTR includes adult living kidney donors (LKD) undergoing donation between June 1972 and September 2022. The time-to-event of >35% rise in post-donation serum creatinine (SCr) from pre-donation SCr between female and male LKD was investigated by multiple Cox proportional hazard regression.

Results: In a cohort of 136,814 living kidney donors, mean±SD age was 42±12 years and 61% were female. Out of 103,938 LKD with post-donation SCr data at 6, 12, or 24 months, 75,343 (72%) experienced the event within a median time to follow-up of 6.3 months (IQR 4.1, 8.7). The incidence rate of the event was 0.09 person-months. The mean and median pre-donation SCr was 0.85±0.19 and 0.80 mg/dL, respectively with notably female and male mean pre-donation SCr were 0.77±0.14 and 0.99±0.17 mg/dL, respectively (mean difference of 22%; (95%CI 0.22, 0.22; P <0.001). Compared to female LKD, male LKD had a 12% significantly higher risk of experiencing an increased post-donation SCr >35% (HR 1.12; 95%CI 1.10, 1.13; P <0.001). After adjusting for age, race/ethnicity, U.S. citizenship, education level, history of pre-donation hypertension, pre-donation BMI, SBP, DBP, post-donation proteinuria, and the interaction term between sex and pre-donation SCr (≤0.8 or >0.8), male LKD remained at a significantly higher risk for the event (HR 1.42; 95%CI 1.36, 1.47; P <0.001). Furthermore, pre-donation SCr was identified as an effect modifier with an increased risk of rising SCr >35% observed in male LKD with pre-donation SCr >0.8 mg/dL ($P_{interaction}$ <0.001).

Conclusions: Male LKD with pre-donation SCr >0.8 mg/dL are at a higher risk of experiencing an increased post-donation SCr >35% compared to female LKD regardless of other pre- and post-donation factors. Despite women contributing as LKD more than men, addressing the underlying causes of sex disparity may provide the opportunity to increase donations while taking precaution for high-risk population.

TH-PO892

Changes in Sex Lives Pre- and Post-Kidney Transplantation

Natasha Gupta, Yi Liu, Mara McAdams-DeMarco. *New York University Grossman School of Medicine, New York, NY.*

Background: Sexual dysfunction among patients with kidney disease (KD) is common. Although studies have demonstrated improvements in sexual function after kidney transplantation (KT), the impact of KD on patients' sex lives pre- and post-KT is unknown.

Methods: We leveraged a prospective cohort of 497 adult KT recipients who responded to the Kidney Disease Quality of Life questionnaire from 2014 to 2022 at Johns Hopkins. Adjusted logistic regression models were used to estimate characteristics associated with self-reported sexual bother due to KD pre-KT, and sexual bother pre- and 3 years post-KT was compared using a Chi-squared test. We estimated unadjusted trajectories of the prevalence of sexual bother due to KD pre- and post-KT using mixed-effect logistic models. We also assessed the prevalence of sexual activity pre- and 3 years post-KT.

Results: The mean age was 52.2 ± 13.5 years, 37.0% were female, 43.1% were Black, 59.6% were partnered, and 41.6% were prior or current smokers. Overall, 43.5% (26.6% of females and 53.4% of males) had sexual bother due to KD pre-KT versus 22.8% (14.8% of females and 26.9% of males) 3 years post-KT (p=0.001). Pre-KT, participants who were male (adjusted odds ratio [aOR]=3.08 [95%CI:2.02-4.69]), non-Black (aOR=1.65 [95% CI:1.09-2.51]), partnered (aOR=1.93 [95% CI:1.27-2.93]), or prior or current smokers (aOR=1.65 [95% CI: 1.10-2.47]) had significantly more sexual bother. Estimated sexual bother due to KD improved significantly over time across all subgroups (Table 1). Overall self-reported sexual activity within the past month also increased significantly from 39.9% pre-KT to 44.0% 3 years post-KT (p=0.009). Both male and female participants had similar increases in sexual activity from pre- to 3 years post-KT (males: 39.6% to 44.0%, p=0.045; females: 40.3% to 44.0%, p=0.178), though the increase was only statistically significant among male participants.

Conclusions: Sexual bother due to KD is common and improves significantly after KT for patients across varying subgroups. The impact of KD on patients' sex lives can be mitigated by KT.

Funding: Other NIH Support - National Institute on Aging, National Center for Advancing Translational Sciences (KL2TR001446).

Table 1: Estimates of sexual bother due to kidney disease pre-kidney transplantation (KT) and at various time points post-KT. Estimates of percent who report sexual bother and annual change in percent who report sexual bother were obtained using mixed-effect logistic models. Percentages are transformed from log odds.

Candidates were enrolled at admission for KT. The percentages were estimated for a reference "standard population": Age >60 years, non-Black, male, partnered, prior or current smoker, less than high school education, Charlson Comorbidity Index>1.0 (pre-KT median), and time on dialysis>2.2 years (pre-KT median)

TH-PO893

Care Considerations and Management of Transgender Individuals After Kidney Transplantation: A Single Institution Experience and Literature Review

Pragati Basera,[1] Manish Anand,[2] Amit Govil,[2] Shikha Jaiswal.[2] *[1]King George's Medical University, Lucknow, India; [2]University of Cincinnati, Cincinnati, OH.*

Introduction: It is estimated that there are 0.04% to 0.06% transgender people in the United States. More than 4000 of them are affected by End Stage Kidney Disease (ESKD). There are limited studies on transgender patients undergoing kidney transplantation, and there is little awareness about the challenges faced by them. We describe 2 cases at our center highlighting this and review available literature.

Case Description: Case #1: 48-year-old Trans-female, with past medical history of ESKD secondary to IgA nephropathy and major depressive disorder(MDD), underwent Deceased Donor Kidney Transplant (DDKT) in 2018. Course was notable for recurrent Herpes labialis. Patient reported onset of gender dysphoria 6 months post-transplant. Patient sought gender-affirming care and started transdermal estradiol, finasteride and cosmetic hair removal. Counseling, screening for sexually transmitted infections, and age-appropriate cancer screening were done at each visit. MDD and medication adherence improved significantly. Renal function has remained stable. **Case #2:** 57-year-old Trans-male with ESKD secondary to polycystic kidney disease, underwent DDKT in 2016. Patient reported onset of gender dysphoria in early childhood and took depot medroxyprogesterone since puberty to suppress menstruation. 3 years post-transplant, patient sought gender-affirming care, started testosterone injections, and had bilateral mastectomy. Post this, patient developed polycyathemia, and most recently was diagnosed with osteoporosis. Renal function has remained stable and medication adherence has been good.

Discussion: Transitioning through gender-affirming care can be stressful for a Transgender person. In the early peri-transplant phase, estrogen may lead to venous thromboembolic events and allograft loss. When used with calcineurin inhibitors (CNI) or Bactrim, androgen-lowering agents like spironolactone can increase hyperkalemia risk. Erythropoiesis is stimulated by androgenic therapy and may increase polycythemia risk. Gender-affirming surgeries can cause urological complications. Regular screening for osteoporosis and sexually transmitted infections, as well as psychotherapeutic support, is necessary. As hormone therapy can affect muscle mass and body composition, it is recommended to use a non-sex-dependent estimation of GFR using cystatin C.

TH-PO894

Kidney Allograft Outcomes Are Similar in Recipients with Living Donors with Hematuria Compared with Recipients with Living Donors Without Hematuria

Tripti Singh, Krista Brackman, Brad C. Astor, Didier A. Mandelbrot. *University of Wisconsin-Madison, Madison, WI.*

Background: The impact of hematuria in living kidney donors on future donor outcomes has been previously described; but to the best of our knowledge, no previous studies have examined the impact of such hematuria on recipient outcomes. In this study, we study the allograft outcomes in recipients who received an allograft from living donors with persistent microscopic hematuria.

Methods: All adult kidney transplant recipients at our program between 1/1/2000-6/30/2022 who received allograft from living donor with urine microscopy showing >5 RBC's/HPF[DM1] in their pre-donor evaluation were included in this study. This cohort was compared to recipients with living donors without hematuria during the same time period. Primary outcomes were allograft failure (defined as re-transplant or return to dialysis) and death censored allograft failure.

Results: 112 recipients that received their allograft from a living donor with microscopic hematuria were identified and compared to 1967 recipients that received their allograft from a living donor without microscopic hematuria. Mean recipient age was 51.7 (±14.1) years compared to 50.3 (±13.9) years of donors with hematuria and without hematuria respectively. 40% of recipients were females and 9% were non-white in both groups. Mean age of donors with hematuria and without hematuria was 43.8 (±11.3) years and 44.9 (±11.6) years respectively. There were a total of 773 allograft losses which includes death and 411 death censored graft losses among 2079 kidney transplant recipients. The risk of graft loss (HR 1.06 95% C.I. 0.79, 1.44; p-value 0.67) and death censored graft loss (HR 0.91 95% C.I. 0.59, 1.41; p-value 0.67) was similar in recipients with living donors with hematuria compared to recipients with living donors without hematuria. The risk of graft loss was similar even after adjustment for donor age, donor race, donor sex, recipient age, recipient race, recipient sex and HLA mismatch between the two groups.

Conclusions: The risk of graft failure and death censored graft failure was similar among recipients who received their graft from living donors with hematuria compared to living donors without hematuria.

TH-PO895

Impact of Suspensions and Reactivations from Waitlist on Quality of Life in Canadian-Australasian Randomised Trial of Screening Kidney Transplant Candidates for Coronary Artery Disease (CARSK)

Karan K. Shah,[1] Kristy Robledo,[1] Bree Shi,[2] John S. Gill,[3] Tracey Ying,[2] Melanie Wyld,[4] Rachael L. Morton.[1] *[1]NHMRC Clinical Trials Centre, The University of Sydney, Sydney, NSW, Australia; [2]Renal Department, Royal Prince Alfred Hospital, The University of Sydney, Sydney, NSW, Australia; [3]Division of Nephrology, St. Paul's Hospital, University of British Columbia, Vancouver, NSW, Australia; [4]Centre for Transplant and Renal Research, Westmead Hospital, Sydney, NSW, Australia.*

Background: There is limited information on individuals' health-related quality of life (HRQoL) on the waiting list for a kidney transplant. Understanding the HRQoL among patients undergoing suspensions and reactivations could shed light on their experiences and the impact of illness burden.

Methods: The HRQoL among eligible participants (not transplanted or deceased within 12 months) was assessed using the EuroQoL 5 domains, five levels (EQ-5D-5L) questionnaire administered at baseline, 6 and 12-months. The HRQoL index ranged from 0 (dead) to 1 (full health). Within these 6-month intervals, the effect of waitlist suspensions and reactivations on HRQoL was examined using Generalized Estimating Equations models. Factors associated with HRQoL such as age, sex, ethnicity, dialysis modality, time on dialysis, diabetes status, cause of end-stage kidney disease, prior kidney transplant, baseline EQ-5D score, and waitlist status (never suspended, suspended but not reactivated, suspended and reactivated) were investigated.

Results: 1,457 patients from Australia (32%), New Zealand (17%), and Canada (51%) were recruited. From baseline to 12 months, 1,013 patients were suspended, 170 patients were suspended and not reactivated, and 187 were suspended and reactivated. Average age was 54 years (SD 12), 63% males, 35% diabetics. Of these, 671 (46%) were managed with facility-based hemodialysis, 247 (17%) with home hemodialysis, and 539 (37%) with peritoneal dialysis. On average, patients spent 1,039 days on dialysis. The mean EQ5D index at baseline, 6 months, and 12 months was 0.87 (SD 0.14), 0.89 (SD 0.13), and 0.89 (SD 0.14), respectively. Compared with patients not suspended, those who were suspended and not reactivated had a lower mean EQ5D index (0.042, 95% CI 0.014 to 0.070, p = 0.004).

Conclusions: Our findings indicate that patients' suspension from the waitlist due to health factors making them unfit for a deceased donor kidney transplant significantly impacts their self-reported HRQoL.

Adjusted Mean EQ5D index

Visits	Never suspended	Suspended and not reactivated	Suspended and reactivated
6 months	0.891 (95% CI 0.842 - 0.940)	0.849 (95% CI 0.798 - 0.900)	0.878 (95% CI 0.829 - 0.928)
12 months	0.887 (95% CI 0.838 - 0.935)	0.845 (95% CI 0.794 - 0.895)	0.874 (95% CI 0.825 - 0.923)

TH-PO896

Patient and Provider Discordant Perspectives on Patient Transplant Experiences

Dennis Hood,[1] Lauren Andracchio,[2] Melanie Paris,[2] Michael Spigler.[2] *[1]Equa Solutions, Germantown, MD; [2]American Kidney Fund, Rockville, MD.*

Background: While transplant is the optimal treatment for end stage kidney disease (ESKD), there is a kidney shortage. In 2022, over 4000 people died waiting for a transplant. Both patients and providers have unique vantage points of patient transplant challenges. To gain insight from both perspectives, the American Kidney Fund (AKF) conducted qualitative research with each group.

Methods: AKF hosted 2, 90-minute focus groups (FG) of 6 transplant patients/donors and 6, 60-minute in-depth interviews (IDI) with 4 renal specialists and 2 patients unable to attend FG. Sixteen IDI and 10 FG open-ended questions were asked to reveal participants' unique perspectives on challenges accessing transplant, process awareness, helpful resources, and transplant information-sharing methods. IDI and FG were recorded, transcribed, and analyzed using a deductive approach via concept-driven coding in NVivo. Themes were indicated by frequency of mentions (FM).

Results: AKF identified 7 themes: challenges, empowerment, resources, post-transplant experiences, pre-transplant experiences, living donor, and educational material mechanics. Distinctions in patient and provider conversations were on patient challenges, living donor and post-transplant experiences. Provider discussions on patient challenges focused on "maintaining health" or difficulties maintaining waitlist eligibility, attending appointments, and taking medications (FM=24) while patient challenge discussions were on finding a donor (FM=11). For useful patient resources, providers (FM=8) and patients (FM=18) discussed "doctors, clinical team," yet patients also valued "mentors, peers" (FM=15) and "support groups" (FM=10). Conversations on post-transplant patient experiences were limited, but providers emphasized the patients' need to "maintain health" (FM=4) and prepare for post-transplant life (FM=4), while patients mentioned "recovery process" (FM=1).

Conclusions: Qualitative results reveal discordant focuses between patient and provider on patient transplant challenges, donor experiences, and post-transplant life. Given the limited sample, future research is needed to further understand what causes the differences in perspectives. This research would bring insight into patient barriers and ways to augment patient and provider education materials to bring a unified approach to transplant.

TH-PO897

Higher Dialysis Facility Patient-to-Nurse Staffing Ratio Is Associated with Lower Hazard of Kidney Transplantation Among Adolescents and Young Adults

Alexandra Bicki,[1] Charles E. Mcculloch,[2] Barbara A. Grimes,[1] Elaine Ku.[2] *[1]University of California San Francisco, San Francisco, CA; [2]University of California San Francisco, San Francisco, CA.*

Background: Higher patient-to-nurse ratios at dialysis facilities have been associated with worse patient outcomes in older adults. We aimed to examine if this nurse staffing ratio is associated with access to kidney transplant in children and young adults.

Methods: This is a retrospective analysis of the US Renal Data System, of patients 12-30 years who initiated dialysis from 2005-2019 at US dialysis facilities. Cox models were used to relate the primary exposure (patient-to-nurse ratio at the dialysis facility) to receipt of kidney transplant (either living or deceased donor).

Results: 51,419 individuals were included (74% were ≥22 years, 84% initiated with hemodialysis). Median staffing ratio was 14 patients per 1 nurse (IQR 10:1 to 19:1). Over a median follow-up time of 2.4 years, 53% of those <22 years vs. 34% of those ≥22 years received a kidney transplant. In adjusted analysis, each doubling of the patient-to-nurse ratio at a facility resulted in 15% lower hazard of transplantation (HR 0.85; 95% CI: 0.84-0.87). There was an interaction ($p<0.001$) by age at dialysis initiation, such that the association between higher patient:nurse ratio and access to transplantation was more pronounced in those 12-21 years (HR 0.79, 95% CI: 0.77-0.82) vs. 22-30 years (HR 0.96, 95% CI: 0.94-0.99).

Conclusions: Adolescents and young adults receiving care from facilities with higher patient-to-nurse ratio had lower hazard of transplantation compared to those receiving care facilities with lower staffing ratios. Low dialysis nurse staffing ratios may represent a crucial facility characteristic that promotes successful kidney transplantation, particularly for adolescents.

TH-PO898

Understanding Barriers and Strategies to Increase Pancreas Transplantation: A Delphi Survey of US Transplant Professionals

Krista L. Lentine,[1] Kennan R. Maher,[1] Kenneth J. Woodside,[2] Ronald Parsons,[3] Matthew Cooper,[4] Darshana M. Dadhania,[5] Mona D. Doshi,[6] Rachel C. Forbes,[7] Martha Pavlakis,[8] Neeraj Singh,[9] Deirdre L. Sawinski,[5] David Axelrod.[10] *[1]Saint Louis University, Saint Louis, MO; [2]Gift of Life, Ann Arbor, MI; [3]Emory University, Atlanta, GA; [4]Froedtert Hospital, Milwaukee, WI; [5]Cornell University, Ithaca, NY; [6]University of Michigan, Ann Arbor, MI; [7]Vanderbilt University, Nashville, TN; [8]Beth Israel Lahey Health, Cambridge, MA; [9]Willis-Knighton Health System, Shreveport, LA; [10]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: To better understand barriers to expanding U.S. pancreas transplantation (PTx) practice, and the anticipated impact and feasibility of potential strategies to address, we conducted a modified Delphi survey of professional and patient stakeholders.

Methods: An electronic survey was distributed to 53 stakeholders, including surgeons, nephrologists, endocrinologists, OPO professionals, and patients, who participated in a national workshop in Boston, MA (distrubution: 6/25/22-8/14/22) Participants ranked the importance of 16 barriers to PTx, and the anticipated feasibility and impact of associated strategies, using 9-point Likert scales. Consensus was defined *a priori* as when ≤30% responded outside an item's Interquartile Range (IQR).

Results: Of 16 analyzed barriers, 8 met consensus as 'very important', incl.: candidate medical and psychosocial complexity, inadequacy of available tools to assess and transmit quality information, allocation delays, financial barriers, inadequate provider and patient education, and insufficient number of trained surgeons. While no strategy met consensus as 'very feasible', 15 strategies met consensus as 'very impactful' (**Table: Highest Impact X Feasibility subset**). 1 strategy was ranked as both 'very important' and 'very feasible': OPOs should provide real-time access to allograft imaging to improve acceptance decisions.

Conclusions: While stakeholders generally agree on barriers to PTx utilization, a diversity of strategies may be impactful and feasible, including focus on improving organ assessment, logistics of the organ recovery operation and allocation, and mitigation of financial disincentives for organ utilization.

Pre-Transplant Biomarkers of Cellular Senescence Are Associated with Death with Function After Kidney Transplantation

Elizabeth C. Lorenz,[1] Andrew J. Bentall,[2] Byron H. Smith,[2] Walter Park,[2] LaTonya J. Hickson,[3] Andrew D. Rule,[2] Nathan Lebrasseur,[2] Mark D. Stegall.[2] *[1]Baylor College of Medicine, Houston, TX; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Mayo Clinic in Florida, Jacksonville, FL.*

Background: Cellular senescence has associated with aging and medical risk in non-transplant populations. The goal of this study was to examine the relationship between pre-transplant biomarkers of cellular senescence and death with function after kidney transplantation.

Methods: We conducted a prospective, observational cohort study involving consecutive adult patients who received a kidney transplant at Mayo Clinic in Minnesota between 1/2006 and 12/2018. We measured biomarkers of cellular senescence in pre-transplant serum. Cox analyses, Kaplan Meier survival analyses, and gradient boosting machine modeling were used to examine the relationship between biomarkers and death with function after kidney transplantation.

Results: Our cohort consisted of 1,595 kidney transplant recipients, of whom 62.9% were male and 83.2% were non-Hispanic white. Over a mean follow-up time of 7.4 ± 3.9 years, 19.7% of patients (n=315) experienced death with function. Higher levels of growth differentiation factor-15 (GDF-15), interleukin-6 (IL-6), monokine induced by gamma interferon (MIG), and soluble tumor necrosis factor receptor-1 (sTNF-R1) were associated with death with function. Adding these biomarkers to a clinical Cox model improved the C-statistic for death with function from 0.732 to 0.750, while using a gradient boosting machine modeling approach instead improved the C-statistic to 0.768.

Conclusions: Pre-transplant biomarkers of cellular senescence predict death with function after kidney transplantation. Measuring serum concentrations of GDF-15, IL-6, MIG, and sTNF-R1 may help risk stratify kidney transplant candidates.

Graft Outcomes in Spousal Donor Kidney Transplantation: Impact of Donor-Recipient Sex Mismatch

Seyoung Ryou, Seunghyeok Choi, Hanbi Lee, Chul Woo Yang, Byung ha Chung. *Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

Background: Despite increasing demand for kidney transplantation (KT) due to the rising prevalence of end-stage kidney disease (ESKD), the shortage of kidney donors remains critical. Spousal donors have emerged as an essential source for living donor kidney transplantation (LDKT) in modern nuclear families. Given that patients' sex is a biological characteristic, the mismatch between the donor and recipient's sex can potentially affect the survival and function of the transplanted kidney. Moreover, female recipients are exposed to donor HLA antigens during pregnancy, increasing the immunological risk. We aim to investigate the impact of donor-recipient sex mismatch on the outcomes of spousal donor kidney transplantation.

Methods: We analyzed 456 spousal donor kidney transplantation (SDKT) recipients at Seoul St. Mary's Hospital from 1986 to 2022. Recipients were categorized based on immunological risk determined by Panel Reactive Antibody. Among the 367 standard-risk SDKT recipients, 75 were husband-to-wife (H2W) and 292 were wife-to-husband (W2H). In the high-risk group of 89 SDKT recipients, 55 were H2W and 34 were W2H. We assessed graft survival and allograft rejection based on donor-recipient sex mismatch.

Results: Long-term graft survival and the incidence of biopsy-proven acute rejection (BPAR) with 1 year after KT were comparable between H2W and W2H recipients in standard-risk group (10-year survival rate: 90.7% vs. 87.6%, p value = 0.428; incidence of BPAR: 3% vs. 7%, p value = 0.178). In the high-risk group, long-term graft survival was similar between H2W and W2H recipients (83.6% vs. 91.2%, p-value=0.593), while H2W recipients showed a higher incidence of BPAR within 1 year after KT compared to W2H recipients (3% vs. 17% p value = 0.044), mainly due to acute antibody-mediated rejection (AAMR).

Conclusions: Our findings indicate that donor-recipient sex mismatch does not have a significant impact on graft survival. However, among high-risk SDKT recipients, H2W SDKT recipients exhibited a higher risk of AAMR compared to W2H SDKT recipients, who face similar immunological risks. H2W SDKT recipients with a high immunological risk should receive careful management through personalized desensitization protocols and tailored immunosuppressant strategies to reduce the incidence of AAMR following KT.

TH-PO901

Risk of Symptomatic Kidney Stones After Kidney Donor Evaluation in Stone Formers

Mira T. Keddis,[1] Nan Zhang,[1] Jaxon Quillen,[1] Matthew R. D'Costa,[2] Hasan Khamash,[1] Caroline Jadlowiec,[1] Hani Wadei,[3] Ivan E. Porter,[3] Andrew D. Rule.[2] *[1]Mayo Clinic, Scottsdale, AZ; [2]Mayo Foundation for Medical Education and Research, Rochester, MN; [3]Mayo Clinic, Jacksonville, FL.*

Background: There are limited data on outcomes of kidney donor candidates with nephrolithiasis. We sought to identify risk factors for symptomatic kidney stone events after donor evaluation.

Methods: A survey was sent in 2022 to 446 adults with self-reported history or CT imaging evidence of nephrolithiasis at the time of kidney donor evaluation at Mayo Clinic (3 sites) between 2000 and 2016. The survey queried post-evaluation symptomatic (renal colic or gross hematuria) kidney stone events, complications, and management. Analyses assessed differences in stone burden between approved and denied donors and risk factors associated with symptomatic stone events.

Results: Survey was completed by 161 (36%) of 446 kidney donor candidates with kidney stones, of whom 113 were approved and 48 were denied for donation. 26 (16%) experienced a symptomatic stone event after donor evaluation and this occurred more frequently in denied vs approved donors (27% vs 12%, p=0.019), in the first 4 years after evaluation (19% vs 1%, p<0.001). Factors associated with denial for donation included presence of medullary sponge kidney, ≥2 stones on CT imaging, presence of bilateral kidney stones, and diameter of largest stone ≥3mm. [Table 1] There was no difference in medical management, surgical/procedural management, or reported development of chronic kidney disease between the two groups. Risk factors for symptomatic stone events after evaluation include bilateral kidney stones (p<0.001), kidney stone diameter≥3mm (p=0.019), younger age (p=0.008), and ≥2 stones on CT imaging (p=0.003).

Conclusions: Our findings identified kidney stone characteristics associated with denial for donation and risk for symptomatic stone event after donor evaluation that may better inform donor candidates of the risk for symptomatic stone events. The lack of significant differences in management and complications between approved and rejected donor candidates questions current approaches to denial based on stone risk.

Table 1. Baseline characteristics of donor candidates comparing those who were approved vs denied donation.

	Approved (N=113)	Denied (N=48)	P-value
Medullary sponge kidney	7%	19%	0.046
≥2 stones on CT imaging	27%	52%	0.004
Bilateral kidney stones	11%	40%	<0.001
Mean diameter of largest stone on CT ≥3mm	25%	42%	0.039
Symptomatic stone event before evaluation	20%	15%	0.787
Symptomatic stone event after evaluation	12%	27%	0.019

TH-PO902

Risk of Developing CKD Following Live Kidney Donation: A Prospective Observational Study

Naduni Erandika,[1,2] Rajitha A. Abeysekera,[2] Sulochana Wijetunge,[2] Hemalika T. Abeysundara,[3] Nishantha Nanayakkara.[1] *[1]National Hospital Kandy, Kandy, Sri Lanka; [2]University of Peradeniya Faculty of Medicine, Peradeniya, Sri Lanka; [3]University of Peradeniya Faculty of Science, Peradeniya, Sri Lanka.*

Background: Chronic Kidney Disease (CKD) is a major concern among live kidney donors. Understanding the risk factors to development of CKD is crucial for optimizing donor selection and post-donation management. This study is aimed to identify the incidence and risk factors associated with development of CKD after one year kidney donation.

Methods: This prospective observational study was conducted using 57 live kidney donors at the National Hospital, Kandy, Sri Lanka. Pre-operative demographic, clinical and pre-implantation kidney biopsy (bx) findings of live donors were examined. We evaluated the estimated glomerular filtration rate (eGFR) using Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation. Donors who had eGFR of less than 60 mL/min per 1.73 m2 at one-year post kidney donation considered as development of CKD among kidney donors.

Results: The mean age of the participants was 47.8 years, with males representing 50.9% (n=29) of the study cohort. 19.3% (n=11) of the donors developed CKD at the end of one year post donation. According to Kaplan-Meir analysis, there is a significant decrease in survival of donors with smoking (p=0.001), alcohol consumption (p=0.016), past medical history of hypertension (p=0.002), presence of donor/recipient relationship, (p=0.018), more than 50 years of age (p=0.005), presence of tubular atrophy (TA) (p=0.001), interstitial fibrosis (p=0.006), interstitial inflammation (p=0.007 and high activity index (p=0.04) in pre-implantation bx. Logistic regression analysis showed that, presence of TA (p=0.007) in histology and having a related donor (p=0.009) had 2.4 and 2.5 times higher risk of developing CKD at final follow-up respectively.

Conclusions: Incidence of development of CKD was high among live kidney donors in a cohort of Sri Lanka with highest risk of being presence with TA in pre-implantation bx and presence of being related kidney donor. These findings emphasize the requirement of a better biomarker to predict the risk of complications as the kidney biopsy is not applicable to do in routine practice. Indeed, the implementation of targeted interventions and follow-up protocols can potentially mitigate the risk of CKD progression among live kidney donors.

TH-PO903

Impact of Donor Warm Ischemia Time on Graft Survival for Donation After Circulatory Death Kidney Transplantation

Donna Marie L. Alvino, Sumedh Kaul, Aaron Fleishman, Martha Pavlakis, David D. Lee. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: To meet demands for kidney transplantation (KT), expanded donor criteria has increased utilization of donation after circulatory death (DCD) donors. Due to ischemic injury associated with DCD organ procurement, the impact of donor warm ischemia time (DWIT) on long-term graft survival has been a notable topic of interest; yet our understanding of this impact on KT outcomes remains limited. Herein, we seek to investigate the impact of DWIT on rates of graft failure after DCD KT.

Methods: Retrospective analysis was conducted on donors and recipients of DCD KT utilizing the Standard Transplant Analysis and Research (STAR) dataset. Demographic data were analyzed and probability of one-year graft failure was assessed based on increasing DWIT using mixed effects logistic regression, stratifying by Kidney Donor Profile Index (KDPI).

Results: From January 2010 to August 2020, 17,169 donors and 22,096 recipients of DCD KT were studied. KPDI decreased from 47% for patients with DWIT 0-45 minutes to 36.5% for DWIT >90 minutes (Table 1). When stratified by KDPI, the impact of increasing DWIT >90 minutes for low KDPI (<50%) recipients was minimal. High KDPI (>50%) recipients demonstrated higher probability of one-year graft failure with increasing DWIT up to 30 minutes compared with low KDPI recipients, but this effect plateaued (Figure 1). No increased probability of graft failure in DWIT >60 minutes was apparent, though confidence intervals widened.

Conclusions: For low KDPI (<50%) kidneys, impact of prolonged DWIT (>60 minutes) on graft survival is minimal, likely reflecting the resilience of higher quality renal allografts to ischemic insult over time. Caution should be taken in considering KT of high KDPI (>50%) kidneys with prolonged DWIT given overall lack of confidence in the existing dataset.

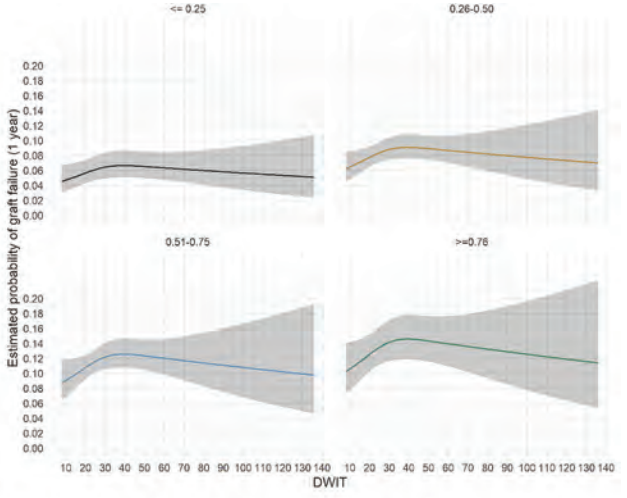

Figure 1. Death-censored probability of graft failure at one year following kidney transplantation with respect to increasing dWIT, stratified by very low (<=0.25), low (0.26-0.50), high (0.51-0.75) and very high (>=0.76) KDPI values

TH-PO904

Association of Pre-Donation Kidney Length with Estimated Glomerular Filtration Rate in Living Kidney Donors

Sasithorn Kunupakan,[1,2] Phuuwadith Wattanachayakul,[1,3] Jathurong Kittrakulrat,[1,4] Ekamol Tantisattamo.[1,5] *[1]University of California Irvine, Irvine, CA; [2]Synphaet Ramintra Hospital, Bangkok, Thailand; [3]Mahidol University, Salaya, Thailand; [4]Chulalongkorn University, Bangkok, Thailand; [5]VA Long Beach Healthcare System, Long Beach, CA.*

Background: The compensatory mechanism increases estimated glomerular filtration rate (eGFR) after unilateral native nephrectomy. Predicting post-living kidney donation eGFR may depend on pre-donation factors, including kidney length. We aimed to examine the association between kidney length and post-donation eGFR.

Methods: A single-center cross-sectional study included adult living kidney donors (LKD) between February 2015 and January 2023. The association between the pre-donation kidney length (by CT scan)/height ratio (LHR) of the remaining kidney and post-donation eGFR was examined by multiple linear regression analyses.

Results: Of 136 LKD, the mean±SD age was 47±12 years and 59% were female. The median (IQR) of LHR was 6.34 (6.07, 6.71) cm/m. Mean pre-donation creatinine clearance (CrCl) were 130.9±32.8 ml/min, followed-up (F/U) eGFR at 1 wk, 6-, 12-, and 24-mos post-donation were 67.8±15.1, 70.7±16.2, 71.3±15.4, and 73.6±16.3 ml/min/1.73 m^2, respectively. The eGFR increased from quartile 1 to 4 of LHR for all F/U periods (P_{trend} <0.001, 0.004, 0.004, and 0.003; Figure 1A). Each 0.1 cm/m increase in LHR was associated with 0.9 – 1.2 ml/min/1.73 m^2 greater eGFR of all post-donation F/U periods with the lowest and highest eGFR at 12 and 24 mos, respectively(β (95%CI) $_{1wk}$ 11.8 (6.1, 17.5); β_{6mo} 11.3 (4.7, 17.9); β_{12mo} 9.3 (3.2, 15.5); β_{24mo} 12.0 (4.8, 19.2); Figure 1B-1D). After adjusting for age, sex, race, pre-donation BMI, CrCl, urinary microalbumin:urinary creatinine ratio, systolic and diastolic blood pressures, the magnitude and direction of the LHR – eGFR association remains (β_{1wk} 11.2 (5.8, 16.7); β_{6mo} 12.1 (6.5, 17.8); β_{12mo} 10.5 (4.6, 16.3); β_{24mo} 15.1 (7.7, 22.5)). There was no effect modification observed in all major covariates for the LHR – eGFR association.

Conclusions: Pre-donation LHR is positively associated with post-donation eGFR during 24 mos F/U, suggesting its relevance in selecting potential LKD with low eGFR.

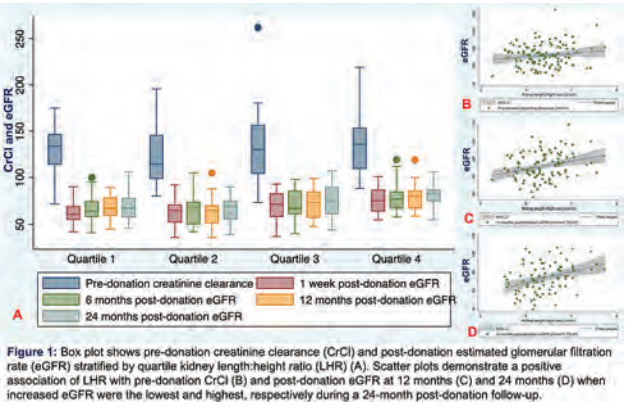

Figure 1: Box plot shows pre-donation creatinine clearance (CrCl) and post-donation estimated glomerular filtration rate (eGFR) stratified by quartile kidney length:height ratio (LHR) (A). Scatter plots demonstrate a positive association of LHR with pre-donation CrCl (B) and post-donation eGFR at 12 months (C) and 24 months (D) when increased eGFR were the lowest and highest, respectively during a 24-month post-donation follow-up.

TH-PO905

Males Show Greater eGFR Recovery than Females Following Kidney Donation

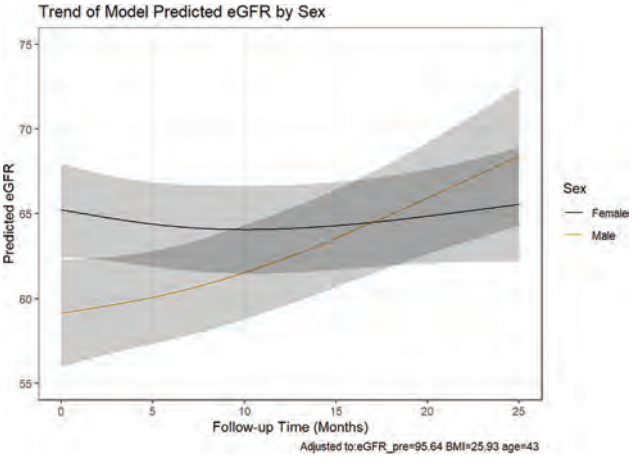
Austin M. Hilvert, Jared V. Grice, Trey W. Mcgonigle, Shi Huang, Niketna Vivek, Hamideh Ale Ali, Beatrice P. Concepcion, Anthony J. Langone, Heidi M. Schaefer, Rachel C. Forbes. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Living donor kidney transplantation is the optimal treatment for end-stage kidney disease and requires donor risk assessment. More data is needed to understand kidney function recovery after donation. We aimed to assess the impact of BMI, age, and sex on post-donation estimated glomerular filtration rate (eGFR) in kidney donors over 2 years.

Methods: We analyzed data from 178 kidney donors who underwent living donor nephrectomy at a single medical center between Nov. 2017 and Jan. 2022. Follow-up visits occurred at approximate 1-month, 6-month, 12-month, and 24-month intervals. eGFR was calculated using the CKD-EPI equation (2021) at each timepoint. We utilized Friedman's test to identify variations in eGFR over the follow-up periods. Relationships between post-donation eGFR and BMI, age, and sex were explored using a generalized least squares model with AR1 error structure. The resulting relationships were plotted using model-estimated eGFR values.

Results: The study included 57 male and 121 female kidney donors. Median pre-donation eGFR was similar for males and females (98.85 vs 94.59, p=0.184). Pre-donation eGFR, BMI, and age did not significantly affect eGFR trajectories (p=0.89, p=0.37, and p=0.17, respectively). However, sex appears to significantly affect eGFR trajectories. As seen in Figure 1, despite the initially lower eGFR (59.13 vs. 65.21, p<0.001), males showed a significantly greater eGFR recovery than females through 24-month follow-up (p=0.003).

Conclusions: Our study suggests that male kidney donors recover kidney function to a greater degree than females after donation. These findings may have implications for donor evaluation, pre-operative patient counseling, and sex-specific monitoring. Further studies are needed to investigate underlying mechanisms and potential interventions to enhance eGFR recovery in both male and female kidney donors.



TH-PO906

Safety of Low-Dose ACE Inhibition in Living Kidney Donors

Ankur Chaudhary, Ashok K. Yadav, Vivek Kumar, Harbir S. Kohli, Kajal Kamboj. *Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: ACE inhibitor (ACEi) medications have positive effects on vascular function separate from their anti-hypertensive effects. We evaluated the safety of low dose ACEi, (Ramipril 1.25mg) in kidney donors and impact on flow mediated dilatation (FMD) at 6 months post donation.

Methods: In an open label, randomized control trial, all prospective living renal donors, 18-60 years, with no hypertension or allergy to ACEi were enrolled. Baseline eGFR and FMD were recorded, and subjects were randomized (1:) at the time of discharge to receive either daily dose of 1.25 mg of Ramipril or no medication. Repeat measurement of FMD and eGFR was done at 6 months after kidney donation. Subjects were withdrawn from the study during follow up if serum creatinine increased by >25% as compared to baseline, or serum potassium rose to >5.5 mEq/L, or systolic blood pressure (SBP) fell to <90 mm Hg or fell by >25% as compared to baseline.

Results: Total 59 subjects were enrolled and randomized. 29 and 30 participants were allocated to the Ramipril and Control arm respectively. At 6 month, 19 subjects in the intervention arm and 23 subjects in the control arm completed follow up (Figure 1). One participant in intervention arm developed side effect (increase in serum creatinine >25% from baseline). In the control arm, 2 subjects had a rise in serum creatinine. Mean difference in eGFR was 25.4±16.3ml/min/1.73m2 in intervention arm while 26.0±17.1ml/min/1.73m2 in the control arm (p=0.909). The mean difference in FMD at 6 months vs baseline in intervention arm was 3.63±10.76% while in control arm was -2.62±10.28% (p=0.098).

Conclusions: Use of ramipril in dose of 1.25 mg once every day in living kidney donors was safe. A trend in improvement in vascular function (increase in FMD) was noted in intervention arm suggesting further study the effect of ACEi on vascular function in post kidney donation with adequate sample size.

TH-PO907

Vertebral Fracture Risk Is Increased Among Living Kidney Donors 25 Years After Donation: Survey-Based Study

Hilal Maradit Kremers,[1] Brandon R. Grossardt,[1] Bertram L. Kasiske,[2] Arthur J. Matas,[3] Sundeep Khosla,[1] Walter K. Kremers,[1] Hatem Amer,[1] Rajiv Kumar.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Hennepin Healthcare System Inc, Minneapolis, MN; [3]Regents of the University of Minnesota, Minneapolis, MN.*

Background: Living kidney donors may have an increased risk of fractures due to reductions in renal mass, lower concentration of 1,25-dihydroxyvitamin D, secondary increases in parathyroid hormone and bone turnover markers. We compared the long-term risk of fractures among living kidney donors with matched controls from the general population.

Methods: Surviving kidney donors from 3 transplant centers completed a survey about bone health and history of fractures. Age, sex, and race-matched non-donor controls without a history of comorbidities that would have precluded kidney donation were identified from population-based resources and completed the survey. The proportion of persons reporting fractures was compared using standardized incidence ratios (SIR).

Results: A total of 1,930 donors and 1,615 controls responded to the survey. Average time between donation/index date and survey date was 24.8 years for donors and 27.3 years for controls. At the time of the survey, donors were 1.1 years younger than the controls (67.4 vs 68.5 years). Although the overall rate of fractures in donors was significantly less than in controls (SIR 0.91; 95% CI 0.82-0.99), there were significantly more vertebral fractures in donors than in controls (SIR 1.43; 95% CI 1.06-1.86) and more hip fractures in women donors compared to controls (SIR 1.90; 95% CI 1.01-3.26).

Conclusions: Our findings suggest excess vertebral fractures in both men and women and excess hip fractures in women among living kidney donors compared to controls after 25 years of follow-up.

Funding: NIDDK Support

Harnessing Synergies, Healthy Heart, Allograft Optimized: The Positive Impact of Arteriovenous Fistula (AVF) Closure After Kidney Transplant

Zeeshan Azeem, Prince M. Anand. *Medical University of South Carolina, Lancaster, SC.*

Introduction: The AVF remains the preferred vascular access for hemodialysis (HD) and after kidney transplant (KT) for future graft failure but consensus on ligation or preservation of AVF after KT is lacking. While AVF ligation offers established cardiovascular benefits, its impact on allograft function is uncertain with conflicting outcomes (improvement vs deterioration). We present a case of improved allograft function following AVF ligation prompted by symptomatic AVF aneurysm.

Case Description: A 60-year-old male underwent a deceased donor KT for end-stage renal disease secondary to type II diabetes mellitus on 10/03/2022. Prior to a KT patient had a left upper extremity AVF as HD access. Pre-transplant echocardiogram (ECHO) showed an ejection fraction of 60% and mild pulmonary hypertension (RVSP-36mmHg). The postoperative course was complicated by delayed graft function with rapid progressive weight gain despite optimal diuretics with limited salt intake, normal urine output, and elevated creatinine (1. 8-2.4mg/dl- nadir 1.6mg/dl). The immunosuppression regimen was changed from Tacrolimus-based therapy to IV Belatacept without any significant improvement in creatinine. Additionally, worsening swelling at the site of AVF three months post-transplant necessitated a surgical consult. Following AVF ligation due to a symptomatic aneurysm, weight and creatinine improved remarkably accompanied by symptomatic improvement. ECHO and renal allograft resistive indices post-AVF ligation are pending.

Discussion: Our case highlights that risk-benefit assessment of AVF closure after kidney transplantation requires contextual evaluation via a possible scoring system and/or a multi-disciplinary committee to ensure informed decision-making and to optimize primary cardiac and secondary outcomes.

TH-PO909

High Coronary Artery Calcium Score Is Associated with an Increased Risk of Death in Patients Evaluated for Kidney Transplant

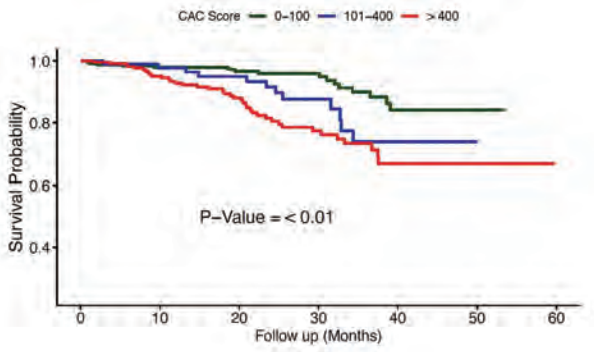
Nagaraju Sarabu, Yasolatha Chalicheemala, Himabindu Yerneni, Arksarapuk Jittirat, Sadeer Al-Kindi, Percy Adonteng-Boateng. *University Hospitals, Cleveland, OH.*

Background: Coronary artery calcification (CAC) is a marker of coronary artery disease which is related to increased risks of cardiovascular complication in kidney transplant recipients. Over the past 5 years, our transplant center has utilized CAC score for cardiac risk stratification in pre-evaluation of kidney transplant. This is a single center, retrospective observational study to evaluate the association between CAC score and death from any cause among kidney transplant (KT) evaluations.

Methods: Retrospective observational study including adults, > 40 years, evaluated for a KT between January 1, 2018, and December 31, 2022. All-cause mortality was ascertained through electronic medical records and the Ohio death index. CAC scores were grouped into low (0-100), medium (100-400), and high (>400). Cox proportional hazard models were used to explore the relationship between CAC score and the mortality.

Results: Of the 570 subjects included, 345 (60%) were male, 272 (48%) were of white race, and 245 (43%) were black. The mean age was 57.8 years. CAC scores were: 247 (43%) low, 91(16%) medium, and 232 (41%) high. The median follow-up for the entire cohort was 22.4 months (IQR 21.4 months). During the study period, 71(12.4%) received kidney transplants, and 67(11.7%) died. Multivariate Cox model showed high CAC score (> 400) was associated with a high hazard of death (HR 3.29, 95% CI: 1.71-6.32).

Conclusions: High CAC score is independently associated with death from any cause in patients evaluated for a kidney transplant. Transplant centers should consider closely monitoring patients with high CAC scores to ensure better performance in the Organ Procurement and Transplant Network metric of waitlist mortality.



Kaplan-Meier Curves of Death from Any Cause by Coronary Artery Calcium (CAC) Score Categories

TH-PO910

Impact of Recipient Hepatitis C Virus (HCV) Sero-Status on the Outcomes Following Kidney Transplantation from HCV Viremic Donors in the Era of Directly Acting Anti-HCV Agent Use

Kalathil K. Sureshkumar,[1] Bhavna Chopra,[3] Rita L. McGill.[2] *[1]Allegheny Health Network, Pittsburgh, PA; [2]University of Chicago Pritzker School of Medicine, Chicago, IL; [3]Beth Israel Deaconess Medical Center, Boston, MA.*

Background: Kidneys from hepatitis C virus (HCV) infected donors were historically utilized for transplantation into HCV seropositive recipients and in recent years with the availability of highly effective directly acting anti-HCV (DAA) agents into HCV-naive recipients. We aimed to look at the trend in the use of kidneys from HCV infected donors stratified by recipient HCV sero-status and compared transplant outcomes with respect to recipient HCV sero-status.

Methods: OPTN/UNOS files were used to identify all HCV viremic donors for whom each kidney was transplanted into a first-time kidney-only recipient with a known HCV sero-status from 01/2015 to 12/2022. Length of stay (LOS), delayed graft function (DGF), time to death and graft failure were assessed. Marginal models with robust sandwich estimators were used to account for clustering by donor, allowing odds ratio (OR) for DGF and hazard ratios (HR) for graft failure, death-censored graft failure and death to be calculated within a mate-kidney frame work. Models were adjusted for multiple recipient and transplant related variables.

Results: Median study follow up was 22 (10-35) months. There were 3524 recipients of matched HCV+ donor kidneys and 80.5% of recipients were HCV-. There was an increase in HCV+ donor kidney availability over time from 116 in 2015 to 614 in 2022. HCV+ to HCV- transplantation increased from 6% of all kidneys in 2015 to 95% in 2022. LOS was similar for HCV+ [5 days (4-6)] vs. HCV- [4 days (3-6)] recipients (p=0.7). Transplant outcomes for HCV+ (n=688) vs. HCV- (n=2836) recipients are shown in the table.

Conclusions: Our analysis showed increasing utilization of HCV+ (viremic) kidneys over time with preferential use in HCV- recipients more recently. Similar graft and patient outcomes of HCV+ kidney transplantation into HCV+ vs. HCV- recipients likely reflect availability of DAA agent. Our study demonstrates reduced accessibility of HCV+ kidneys for HCV+ recipients in recent years despite equivalent outcomes.

Outcome	Univariate		Adjusted	
	OR (95% CI)	P	OR (95% CI)	P
Delayed graft function	1.32 (0.83-2.11)	0.2	1.25 (0.72-2.17)	0.4
	HR (95% CI)	P	HR (95% CI)	P
Graft failure	0.86 (0.68-1.56)	0.2	0.81 (0.62-1.04)	0.1
Death-censored graft failure	1.08 (0.70-1.66)	0.7	0.98 (0.62-1.54)	0.9
Death	0.82 (0.64-1.05)	0.1	0.81 (0.61-1.07)	0.1

TH-PO911

Phospholipase A2 Receptor Antibody (PLA2Rab) Epitope Spreading (ES) Associates with Recurrent Membranous Nephropathy (MN)

Hatem Amer,[1] Mireille El Ters,[1] Laurence H. Beck,[2] Fernando C. Fervenza.[1] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Boston University, Boston, MA.*

Background: Anti-PLA2Rab ES has been associated with higher anti-PLA2R ab titers, more severe disease, greater likelihood of progression to ESRD, and need for higher doses of Rituximab. The objective of this study was to determine if epitope spreading associates with recurrent MN post kidney transplant (KTx).

Methods: Pre-transplant serum from 23 KTx recipients with ESKD due to MN was analyzed by ELISA and Western blot for presence of anti-PLA2R abs and ES. Recurrence was diagnosed by protocol biopsies and proteinuria measurements.

Results: Age 50.9± 12.8 year, 65.2% males, 82.6% received a kidney from a living donor, 43.5% were preemptive transplants. There were no demographic differences between those with positive anti-PLA2Rab or not, nor those with ES vs. not. PLA2Rab was detected in 14 (60.9%) patients. Epitope spreading was present in 6/14 (42.9%) of those: 100% if PLA2Rab>150RU, 50% if >50 <150 RU, and 20% if < 50RU. One was positive for CTLD1-3 and one for CTLD4-8 with the remainder co-positive. PLA2Rab+ patients were more likely to recur HR 8.8 (1.13, 68.00). In PLA2Rab+, ES associated with increased risk of recurrence HR 15.2 (1.7, 133.3) unadjusted and 9.8 (1.03, 94.1) adjusted for PLA2Rab level. Seven patients required therapy with Rituximab for recurrent MN with no graft loses.

Conclusions: ES of PLA2Rab associates with a higher likelihood of post KTx recurrence of MN and may be useful to determine in those with PLA2Rab < 150 RU.

Social Support and Dietary Behaviors Among Adults with ESKD and Obesity

Bengucan Gunen,[1] Ann C. Klassen,[1] Brandy-Joe Milliron,[2] Jasmine M. Sweeting,[4] Joanna H. Lee,[3] Jennifer R. Haileselasse,[1] Sneha S. Hingorany,[3] Meera N. Harhay.[3] *[1]Drexel University Dornsife School of Public Health, Philadelphia, PA; [2]Drexel University College of Nursing and Health Professions, Philadelphia, PA; [3]Drexel University College of Medicine, Philadelphia, PA; [4]Jefferson Health, Wayne, PA.*

Background: End stage kidney disease (ESKD) patients with obesity (~40% of the dialysis population) have unique challenges with weight management and diet. Few studies have explored the role of different types of social support in achieving optimal dietary intake and renal dietary adherence.

Methods: We conducted semi-structured, 60-90-minute phone interviews in 2020-21 with 40 adults with ESKD and obesity (body mass index, BMI, ≥30 kg/m^2). Participants were recruited from dialysis centers and patient networks in 22 states, using purposive sampling for geographic and demographic diversity. Interviews were audio recorded and transcribed verbatim. A coding framework was developed by an interdisciplinary team including a nephrologist, a nutrition scientist, and a social scientist. By memoing patient narratives on the role of social support in dietary behaviors, codes were finalized to include sources of social support (family, friends, community members, fellow patients) and types of social support (emotional, appraisal, instrumental, informational). Patient typologies based on social support levels were identified to explain patterns of dietary behaviors.

Results: Mean age of participants was 55 years; average BMI was 39.5kg/m^2, 58% of patients were female, 35% were Black/African American, 60% had diabetes. Participants reported receiving the most varied types of social support from family members in their household, while also accessing emotional support from fellow patients, and informational and appraisal support from online communities. Qualitative data analyses identify patient typologies based on social support levels to explain patterns of dietary behaviors. Using behavior change theory and study data, the included figure illustrates how social support influences diet adherence.

Conclusions: Social support buffers the negative health consequences of adverse life events and helps patients with self-management, with implications for renal diet adherence and promoting healthy diets among patients with ESKD and obesity.

TH-PO913

Comparing the Value of Periodic Assessment of Three Objective Nutrition Scores on the Prognosis of Hemodialysis Patients: A Multicenter Longitudinal Study

Qian Wang, Zengchun Ye, Hui Peng. *The Third Affiliated Hospital of Sun Yat-Sen University Lingnan Hospital, Guangzhou, China.*

Background: The prognostic value of objective nutrition scoring tools for longitudinally assessing the relationship between nutritional status and prognosis in hemodialysis patients remains unclear. In this multicenter retrospective cohort study, the prognostic nutritional index (PNI), controlling nutritional states scores (CONUT), and geriatric nutritional risk index (GNRI) were used to longitudinally evaluate nutritional status, and their predictive values for all-cause and cardiovascular mortality were compared.

Methods: Hemodialysis patients from four hospitals were included in the study, and laboratory data and nutrition scores were collected at the start of dialysis, 6 months, 12 months, and 18 months of dialysis. A joint model was used to analyze the relationship between changes in the three nutritional scores and patient prognosis, and area under the curve (AUC) was used to compare their predictive values.

Results: Of the 863 patients included in the study with a median follow-up of 37 months, 23.8% died during follow-up, with 14% being cardiovascular deaths. Malnourished patients had a higher risk for all-cause and cardiovascular mortality. Dynamic changes in PNI and GNRI scores were significantly associated with a reduced risk of all-cause and cardiovascular mortality. Longitudinal increases in PNI and GNRI scores were associated with a 4% and 3% reduction in all-cause(PNI: hazard ratio [HR], 0.96; 95%confidence interval [CI], 0.95-0.98. GNRI: HR, 0.97; 95% CI, 0.96-0.98) and cardiovascular mortality risk(PNI: HR, 0.96; 95% CI, 0.94-0.98. GNRI: HR, 0.97; 95% CI, 0.95-0.98) respectively, with increasing dialysis duration. CONUT score changes were not significantly associated with all-cause death and cardiovascular mortality. The AUC of three joint models showed that GNRI (0.8925) score showed higher predictive accuracy for all-cause than PNI(0.8315) and CONUT(0,852). Similar results were found for the three scores regarding cardiovascular mortality.

Conclusions: Malnutrition strongly associates with increased all-cause and cardiovascular mortality in hemodialysis patients. Regular assessment of nutritional status using GNRI has higher predictive accuracy than CONUT score and PNI score for all-cause and cardiovascular mortality in patients with MHD.

TH-PO914

Effect of Geriatric Nutritional Risk Index (GNRI)-Based Stratified Diet Intervention on Nutritional Status and Self-Efficacy of Elderly Patients with Maintenance Hemodialysis

Ying Wang, Bing Zhuang, Fangfang Xu, Junwei Yang, Hong Ye. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: To explore the effect of stratified dietary intervention based on geriatric nutritional risk index (GNRI) on nutritional status and self-efficacy in elderly patients with continuous hemodialysis (MHD).

Methods: A total of 60 elderly patients with MHD from the Second Affiliated Hospital of Nanjing Medical University from January 2020 to January 2021 were randomly selected and divided into an intervention group and a control group by random number table method, with 30 cases in each group. The control group implemented conventional intervention measures, and the intervention group implemented GNRI stratified dietary intervention based on conventional intervention measures. The nutritional status of the two groups before and after 3 months of intervention, including the score of the subjective global assessment (scored patient-generated subjective global assessment, PG-SGA), body mass index (body mass index, BMI) and triceps skin triceps skin fold (TSF), self-efficacy [general self-efficacy scale (GSES) score, dietary treatment attitude [the attitude scale for the dietary therapy of hemodialysis] patients, ASDTH) score], quality of life [kidney disease quality of life short form (KDQ) score] changes.

Results: After 3 months of intervention, the intervention group PG-SGA score, BMI, TSF, Event coping, goal achievement and individual problem solving, ASDTH score and KDQ score were higher than those of the control group ($t = 5.450, -2.199, -3.510, -5.122, -5.142, -5.085, -4.280, -4.959$; respectively; $P < 0.001, 0.032, 0.001, P < 0.001, P < 0.001, 0.001, P < 0.001$ and $P < 0.001$.

Conclusions: GNRI stratified dietary intervention can improve the nutritional status of elderly MHD patients, help to enhance their self-efficacy, improve Diet therapy attitude, improve the quality of life, has high clinical application value.

Veteran Diet Quality and Associations of Unprocessed Plant Nutrients on Vascular Function

Luis M. Perez,[1] Taylor Struemph,[2] Heather Farmer-Bailey,[2] Anna Jovanovich.[2,1] *[1]VA Eastern Colorado Health Care System, Aurora, CO; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Over 500,000 Veterans have chronic kidney disease (CKD) with higher incidence (16-36%) than the general population. Most CKD is caused by diabetes and associated with hypertension and cardiovascular disease. Dietary changes may prevent, delay, or manage hypertension, diabetes, and CKD. Poor dietary quality and low adherence to recommended diets is common in CKD. The purpose of this study was to describe diet quality and cross-sectional associations of plant-based diet components with vascular function measures in Veterans with CKD.

Methods: We conducted a secondary analysis of baseline data from the Phosphate Lowering in CKD Trial (NCT02209636) that recruited 66 Veterans with CKD stage 3b-4. Primary study outcomes were vascular function measures, carotid-femoral pulse-wave velocity (PWV) and flow mediated dilation (FMD). We calculated plant-based diet components from 3-day dietary records by linking the Food and Nutrient Database for Dietary Studies with food composition data provided by the USDA Nutrient Database for Standard Reference. We classified food and nutrient degree of processing by the NOVA diet classification system. Analysis included basic descriptive statistics and paired T-tests to compare nutrient intake above/below the median with PWV and FMD.

Results: Mean±SD ultra-processed calories was 64.3±15.1% of total intake and animal protein was 52.3±19.6% of total protein intake. Mean ± SD combined processed/ultra-processed nutrients intake was: 72.4±17.8% of total sodium (2,358g), 56.2±14.9% of total potassium (1,191g), 64.1±16.5% of total phosphorus (743g). No participants were Dietary Approaches to Stop Hypertension (DASH) diet adherent (1.3±0.9 points of 9) and the Healthy Eating Index score was 48.9±11.7 (out of 100). Individuals with unprocessed plant protein above the median intake had lower PWV (996.5±237.1 m/s) than those below the median intake (1223.5± 09.1 m/s, p=0.04). Those with unprocessed plant phosphorus above the median intake also had lower PWV (979.2±233.8 m/s) than those below the median intake (1241.8±399.4 m/s, p=0.02).

Conclusions: Veterans in the Phosphate Lowering in CKD Trial had low dietary quality, however, those who consumed more unprocessed plant protein and phosphorus had better vascular function at baseline. These results indicate opportunities for nutritional intervention and future research.

Dietary Patterns and Kidney Function in West Africans with CKD

Edward P. Kwakyi,[1] Titilayo O. Ilori,[2] Runqi Zhao,[2] Rulan S. Parekh,[3] Ifeoma I. Ulasi,[4] Dwomoa Adu,[1] Adaobi Solarin,[5] Yemi R. Raji,[6] Manmak Mamven,[7] Diane C. Mitchell,[8] Sushrut S. Waikar,[2] Akinlolu Ojo,[9] Rasheed A. Gbadegesin.[10] *[1]University of Ghana School of Medicine and Dentistry, Accra, Ghana; [2]Boston University School of Medicine, Boston, MA; [3]Women's College Hospital, Toronto, ON, Canada; [4]University of Nigeria, Nsukka, Nigeria; [5]Lagos State University Teaching Hospital, Lagos, Nigeria; [6]University of Ibadan College of Medicine, Ibadan, Nigeria; [7]University of Abuja, Abuja, Nigeria; [8]Texas A&M University System, College Station, TX; [9]University of Kansas School of Medicine, Kansas City, KS; [10]Duke University School of Medicine, Durham, NC.*

Background: There is little known about the impact of dietary patterns on chronic kidney disease (CKD) in West Africa. Our study describes associations of dietary patterns with estimated glomerular filtration rate (eGFR) and is the first study to do so in a well-phenotyped West African CKD cohort.

Methods: We analyzed participants in the Diet, Apolipoprotein L1 and CKD (DCA) study from 7 centers in West Africa (Ghana and Nigeria). Data from 24-hour dietary recalls were categorized into 32 food groups and 3 dietary patterns were derived via principal component analysis (PCA). Using mixed effect linear regression models, we estimated the b coefficients and 95% confidence intervals for quartiles of the dietary patterns and eGFR (2009 CKD-EPI equation, not corrected for race).

Results: Among 583 people with a mean age of 49±17 years and 51% males, the mean eGFR and median 24-hour urine protein were 68±39 mL/min/1.73m^2 and 0.31(IQR=0.13-1.07) g respectively. We identified the **Dried Fish and Oil dietary pattern, Poultry and Cereal dietary pattern** and the **Fruit and Cereal dietary pattern**. Compared to Q1 (lowest consumption) of the Poultry and Cereal pattern, higher quartiles were associated with higher eGFR in the unadjusted model (p for trend<0.001, **Table 1**). Adjusting for covariates attenuated the association. Age was associated with the Poultry and Cereal dietary Pattern (-0.02, $p < 0.001$). No other dietary patterns were associated with eGFR.

Conclusions: In our cross-sectional analyses, there was no association of dietary patterns with eGFR. Future studies on diet quality and nutrient contents and CKD progression in Africans are needed. Our next steps are to investigate other factors associated with dietary patterns in our population (aside from age) and examine longitudinal associations of dietary patterns with CKD progression.

Funding: NIDDK Support

TH-PO917

Dietary Sodium and Potassium Intake Estimations in Different Stages of CKD by Multiple 24-Hour Urine Collections

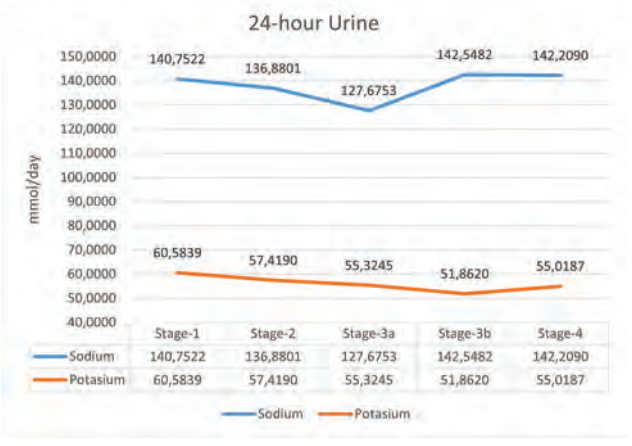
Mustafa Arici, Berat Baran, Samed Önder, Sevilay Karahan, Elif A. Bulut, Helin Kinaci, Fatma Sule Dayanc, Onat Silleli, Ozan Uysal, Elif Emirsuleymanoglu. *Hacettepe Universitesi Tip Fakultesi, Ankara, Turkey*.

Background: Dietary sodium (Na) and potassium (K) intake in chronic kidney disease (CKD) patients can be calculated most accurately by multiple 24-hour urine (24hU) samples. While Na intake targets are known, optimal K intake according to different stages of CKD is not known. We aimed to examine how much Na intake met the guideline recommendations and the effect of K intake on serum K values in CKD patients.

Methods: This retrospective cohort study was based on 253 stable patients (who collected 5 or more 24hU between 2012-2022) at different stages of CKD. Clinical data was obtained through database of Hacettepe University Hospitals. 24hU sodium (24hUNa) and potassium (24hUK), serum Na, K and creatinine (Scre) values were analyzed. Generalized linear model for analysis of parametric variables was used.

Results: There was a total of 3493 urinary Na values from a mean of 13 collections in 253 patients. Mean 24hUNa was 134.3 +-70,5 mmol/d. Only 32.7% (n=1142) were below the recommended target of 100 mmol/d. There was a total of 1959 urinary K values from a mean of 14 collections in 135 patients. Mean 24hUK was 58,3 +-22 mmol/d. 24hUNa and 24hUK excretion according to the CKD stages was shown in Figure. There was no correlation between CKD stages and 24hUNa and 24hUK excretion. Scre values and 24hUNa values were inversely proportional, with beta:-0.001 and p:0.04. Scre values and 24hUK values showed an inverse correlation, with beta: -0.007 and p:0.00. When serum K values and 24hUK values were analyzed, beta is negligible, p:0.884. No statistically significant correlation was found between serum K values and 24hUK values.

Conclusions: 24hUNa levels with recommended Na targets is present only in one third of the samples. The lack of relation with serum K and 24hUK values needs further studies to define an optimal K intake in different stages of CKD.



TH-PO918

Effects of High Dietary Salt on Immunome and Microbiome Composition: Results from a Randomized Clinical Trial

Hendrik Bartolomaeus,[1] Harithaa Anandakumar,[1] Chia-Yu Chen,[1] Anja Mähler,[1] Dominik N. Müller,[2] Sofia K. Forslund,[2] Nicola Wilck.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Max-Delbruck-Centrum fur Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany*.

Background: Increased dietary salt intake ranks among the most prominent nutritional risk factors worldwide and has been tied to arterial hypertension and all-cause mortality. The mechanisms responsible are incompletely understood and have recently been extended to include inflammatory and microbiome-associated mechanisms. Building on our preliminary data, the present study investigates whether a moderate increase in salt intake in healthy subjects primes host physiology to a more transiently unstable state, potentially leading to changes in the microbiome-immune axis.

Methods: We conducted a prospective, randomized, double-blinded trial to evaluate the effect of high dietary salt in healthy participants (NCT03024567), where the intervention group (n = 19) was given 6g of salt (NaCl) in addition to their daily normal salt intake, essentially doubling the recommended salt intake against a placebo group (n=19) for 14 days. Clinical parameters, stool, and PBMC were collected at baseline and day 14. Shotgun metagenomic sequencing, metabolomics (stool and serum), and single-cell sequencing (Cellular Indexing of Transcriptomes and Epitopes by Sequencing (CITEseq)) of whole PBMC and CD4+ T cells (~150k single cells) was performed.

Results: Our results confirm previously established findings showing an increase in the dissimilarity of the microbiome composition (Jensen-Shannon Divergence) under a high salt diet. Differential abundance of the microbiome's functional space, as quantified by functional gut-specific modules, picked up a salt-specific module (M00494, NatK-NatR (sodium extrusion) two-component regulatory system) in the salt intervention group. A short-chain fatty acid-specific module (MF0128, Propionate conversion to succinate) was reduced in the salt arm. CITEseq revealed a significant amount of differently expressed genes (DEGs) solely in the salt group. We found 602 DEG in naïve conventional T cells (Tconv) and 202 DEGs in non-naïve Tconv, e.g. belonging to NF-kB and T cell receptor signaling pathways.

Conclusions: Our placebo-controlled study is the first to utilize different omics techniques to investigate and identify high-salt-induced changes in the microbiome and immunome in healthy individuals that may be relevant to the development of pathological conditions in the long term.

TH-PO919

High-Salt and Low-Salt Diets Can Modulate Kidney Immune Cells and Endothelial Cells

Kyungho Lee,[1] Junseok Jeon,[1] Hojin Jeon,[1] Jihoon Ko,[2] Jung eun Lee,[1] Wooseong Huh,[1] Yoon-Goo Kim,[1] Hye Ryoun Jang.[1] *[1]Samsung Medical Center, Cell and Gene Therapy Institute, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea; [2]Gachon University, Seongnam-si, Gyeonggi-do, Republic of Korea*.

Background: Kidney immune cells and endothelial cells mediate kidney ischemia-reperfusion injury and can affect kidney transplant outcomes. We aimed to study the effect of changes in dietary salt intake on kidney immune cells and endothelial cells in experimental models and kidney transplants.

Methods: We treated C57BL/6 mice with normal diet, low-salt diet, or high-salt diet and obtained kidneys after 6 weeks of allocated diets. Kidney sections were stained for CD45. To compare intrarenal sodium buffer, glycosaminoglycan (GAG) concentration was measured with kidney protein extracts. Lymphocytes isolated from kidneys were analyzed by flow cytometry. Human kidney transplant tissues obtained at 2 weeks after kidney transplantation by a protocol biopsy were stained with CD45 and CD31 and analyzed per donors' pre-donation 24h urine sodium levels. Induced pluripotent stem cell-derived endothelial cells (iPSC-ECs) from healthy individuals and end-stage kidney disease (ESKD) patients were treated with additional sodium, and proliferation was assessed.

Results: Mice kidneys from high-salt diet group had higher kidney leukocytes ($CD45^+$) than those from normal diet group (1.9±0.3% vs 0.9±0.1%, P=0.043). Kidney GAG level was lower in high-salt diet group than in low-salt group (41.0±3.1 vs 48.3±1.3 ng/mg, P=0.004). Both low-salt and high-salt diets increased effector-memory $CD4^+$ T cells (normal 44.2±2.6%; low-salt 57.1±3.5%, P=0.020; high-salt 62.1±2.5% of $CD4^+$ T cells, P=0.002) and mature B cells (70.0±1.5%; 79.1±1.4%, P=0.001; 76.7±1.6% of $CD19^+$ cells, P=0.015), whereas decreased naïve $CD4^+$ T cells (45.9±2.1%; 32.7±3.2%, P=0.016; 27.8±3.1% of $CD4^+$ T cells, P=0.001) in kidneys. Human kidney transplants from donors under low-salt diet exhibited lower leukocytes ($CD45^+$, 0.3±0.1% vs 0.9±0.3%, P=0.019) and higher capillary density ($CD31^+$, 29.0±2.2% vs 16.1±1.8%, P=0.009) than those from donors under high-salt diet. The proliferation of iPSC-ECs from healthy individuals and ESKD patients after hypoxia was reduced under higher sodium concentrations.

Conclusions: High-salt and low-salt diets seem to exert adverse effects on kidney immune cell numbers and phenotypes as well as endothelial cells. Modulation of kidney microenvironment by modifying dietary salt intake could be a potential strategy to improve kidney transplant outcomes.

TH-PO920

Dietary Potassium and Fiber Intake and Health-Related Quality of Life in a Multicenter Prospective Hemodialysis Cohort

Yoko Narasaki,[1] Kamyar Kalantar-Zadeh,[2] Seung Hyeok Han,[3] Tae ik Chang,[4] Diana S. Kalantar,[1] Tracy Nakata,[1] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]Yonsei University, Seoul, Seoul, Republic of Korea; [4]National Health Insurance Service, Wonju, Gangwon-do, Republic of Korea*.

Background: Guidelines recommend dietary potassium (K) restriction in ESKD patients due to concerns about hyperkalemic CV events. However, K-rich foods tend to be from heart-healthy sources with high fiber content. We examined the relationship of dietary K and fiber intake with health-related quality of life (HRQOL) in a prospective HD cohort.

Methods: Among 583 HD patients from the multicenter NIH MADRAD cohort recruited across 16 outpatient dialysis clinics, information regarding dietary K intake was obtained using protocolized Food Frequency Questionnaires (FFQs) and HRQOL was assessed using Short Form 36 surveys administered over 10/2011-9/2022. We examined associations of dietary K intake categorized as tertiles with HRQOL using linear mixed

effect models. We also examined different pairings of dietary K and fiber intake across four exposure groups (low K/low fiber, low K/high fiber, high K/low fiber, high K/high fiber) with HRQOL.

Results: In expanded case-mix + laboratory analyses, the highest tertile of absolute dietary K intake was associated with better trajectory of physical functioning and physical component scores (PCS) over time (ref: lowest tertile): Estimates (β) (95%CI) +8.33 (+3.59, +13.08) and +1.48 (-0.13, +3.09) (Fig A). Similarly, the highest dietary K tertile in residual models were associated with better trajectory of PCS and energy/fatigue (Fig B). In adjusted analyses of pairings of dietary K/fiber intake in the absolute (Fig C) and residual models (Fig D), patients with high K/high fiber intake had better physical functioning and PCS vs. those with low K/low fiber intake.

Conclusions: In a prospective HD cohort, higher dietary K and fiber intake were associated with better HRQOL, particularly related to physical function domains. Further studies are needed to determine the causal mechanisms linking dietary intake and physical function in this population.

TH-PO921

Different Effects of Dietary Selenium on All-Cause Mortality According to the Baseline Characteristics Based on the Nationwide Population Study: Results from the NHANES, 1999-2016

Yaerim Kim,[1] Jeonghwan Lee,[2] Kyubok Jin,[1] Woo Yeong Park,[1] Dong Ki Kim,[3] Chun Soo Lim,[2] Jung Pyo Lee.[2] *[1]Keimyung University School of Medicine, Daegu, Daegu, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [3]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: As an antioxidant, selenium has a beneficial role in human health including metabolism and thyroid function. Based on the metabolism process, kidney function status has a potential role in the bioavailability of dietary selenium. Herein, we aimed to evaluate the impact of dietary selenium on all-cause mortality in different baseline characteristics including kidney function status.

Methods: We used data from the US National Health and Nutrition Examination Survey 1999-2016. Based on a 1-day 24-hr dietary recall, the intake of selenium was divided by quintile; the third quintile was regarded as a reference. Baseline characteristics included kidney function, body mass index, and alcohol consumption status. We used a multivariate Cox proportional hazard model to identify the impact of selenium on all-cause mortality.

Results: A total of 41,423 subjects were included in the study. The risk for all-cause mortality was significantly increased in subjects included in the 1st quintile (adjusted hazard ratio [aHR] 1.12, 95% confidence interval [CI] 1.03-1.21) after adjustment with age, gender, ethnicity, education, income, comorbidities (hypertension, diabetes), BMI, total calorie intake, laboratory results (hemoglobin, serum albumin, total cholesterol, serum glucose, and estimated glomerular filtration rate). In subgroup analysis, lower intake of selenium increased mortality in subjects with eGFR ≥60 mL/min/1.73 m2 (aHR 1.14, 95% CI 1.03-1.27), BMI 25-30 kg/m2 (aHR 1.24, 95% CI 1.08-1.43), and moderate to heavy drinker (aHR 1.27, 95% CI 1.11-1.44). Selenium intake and blood level of selenium showed a positive correlation, and it was prominent in subjects with eGFR <60, BMI 25-30, and non-drinkers. The impact of the blood level of selenium on all-cause mortality was the same as the results in selenium intake.

Conclusions: Deficiency in selenium intake and lower levels of blood selenium significantly increased all-cause mortality, especially in subjects with preserved kidney function, overweight, and moderate to heavy drinkers.

Diet and the Discrepancy Between Cystatin C- and Creatinine-Based eGFR in Middle-Aged and Older Community-Dwelling Japanese Adults

Keiko Kabasawa,[1] Yumi Ito,[1] Hideyuki Kabasawa,[1] Ribeka Takachi,[2] Kazutoshi Nakamura,[1] Junta Tanaka,[1] Ichiei Narita.[1] *[1]Niigata University, Niigata, Japan; [2]Nara Women's University, Nara, Japan.*

Background: Discrepancy between creatinine-based eGFR ($eGFR_{creat}$) and cystatin C-based eGFR ($eGFR_{cys}$) is associated with kidney health and frailty. Dietary factors may affect serum creatinine concentration, but little is known about the association between diet and eGFR discrepancy.

Methods: Baseline data from a Japanese community-based cohort (age 40–97 years) comprising 3,029 men and 3,115 women were analyzed. We cross-sectionally assessed nutrients and food groups derived from a food frequency questionnaire adjusted by energy intake, using the residual method. eGFR was calculated according to the equation developed for the Japanese population, using creatinine and cystatin C. Discrepancy between $eGFR_{creat}$ and $eGFR_{cys}$ was assessed as $eGFR_{cys}$ divided by $eGFR_{creat}$, with $eGFR_{cys}$ / $eGFR_{creat}$ > 1.4 used as an outcome variable in this study. The association between diet and eGFR discrepancy was analyzed using logistic regression analysis, with adjustment for potential confounders according to sex.

Results: eGFR discrepancy ($eGFR_{cys}$ / $eGFR_{creat}$ >1.4) was observed in 9.3% of men and 14.5% of women, with a median $eGFR_{creat}$ and $eGFR_{cys}$ of 73.9 (interquartile interval: 64.1, 84.7) and 84.7 (72.7, 97.0) in men, and 73.7 (64.8, 83.6) and 87.3 (76.4, 98.6) in women, respectively. In the multivariable logistic regression model, protein, phosphorus, vitamin D, and fish intakes were positively and carbohydrate and grain intakes were negatively associated with eGFR discrepancy in men, while energy, potassium, and phosphorus intakes were positively and carbohydrate and grain intakes were negatively associated with eGFR discrepancy in women (Table).

Conclusions: This study found that some dietary features were associated with the eGFR discrepancy in men and women. The results suggest that not only whole protein intake but also its sources and other dietary features should be taken into account when considering kidney health.

Funding: Government Support - Non-U.S.

Table: Multivariable logistic regression analysis of diet and eGFR discrepancy by sex.

eGFR discrepancy was defined as $eGFR_{cys}$ / $eGFR_{creat}$ > 1.4. The multivariable adjusted model included age, smoking status, drinking habits, exercise habits, body mass index, diabetes, hypertension, and $eGFR_{creat}$. Nutrients and food groups were adjusted by energy intake using the residual method and treated as quartiles in the logistic regression model.

Men	Adjusted odds ratio [95%CI]	Women	Adjusted odds ratio [95%CI]
Protein	1.16 [1.02, 1.33]	Energy	1.16 [1.04, 1.29]
Phosphorus	1.17 [1.02, 1.33]	Potassium	1.13 [1.01, 1.26]
Vitamin D	1.27 [1.12, 1.45]	Phosphorus	1.13 [1.01, 1.26]
Fish	1.26 [1.11, 1.44]	Carbohydrate	0.89 [0.80, 0.99]
Carbohydrate	0.83 [0.73, 0.94]	Grain	0.89 [0.80, 0.99]
Grain	0.82 [0.72, 0.93]		

TH-PO923

Association of Obesity, Metabolic Syndrome, and Diabetes with CKD in Men and Women: National Health and Nutrition Examination Survey (NHANES), 2003-2020

Chyng-Wen Fwu,[1] Julia Barthold,[2] Paul L. Kimmel,[2] Jenna M. Norton,[2] Susan R. Mendley,[2] Robert A. Star,[2] Ivonne H. Schulman.[2] *[1]Social & Scientific Systems, Inc., a DLH Holdings Corp (DLH) company, Silver Spring, MD; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Associations between chronic kidney disease (CKD), obesity, and metabolic syndrome (MetS) have been documented previously, but how these associations vary across obesity/metabolic phenotypes in males and females has not been evaluated extensively.

Methods: Data were analyzed for 8,586 male and 8,420 non-pregnant female adults (≥20 years), from the 2003-2020 cycles of the NHANES. CKD (defined as albuminuria and/or eGFR<60ml/min), MetS (defined as ≥3 of the following: hypertension, prediabetes, hypertriglyceridemia, low HDL cholesterol, and/or central obesity), and obesity (BMI≥30) were identified by physical examination and/or results from fasting laboratory samples. Diabetes was identified by self-report, prior diagnosis, and/or high fasting glucose or hemoglobin A1C. Participants without diabetes were further categorized according to 4 obesity/metabolic phenotypes: metabolically healthy non-obese (MHNO), metabolically unhealthy non-obese (MUNO), metabolically healthy obese (MHO), and metabolically unhealthy obese (MUO). Multivariable-adjusted logistic regression models were used to examine the relationship of CKD with obesity/metabolic phenotypes using appropriate sampling weights.

Results: The prevalence (95% CI) of CKD for male and female diabetics was 36.7% (33.6-39.8) and 35.9% (32.2-39.9), respectively. The prevalence of CKD for male and female MUNO was 13.2% (10.6-16.5) and 21.0% (18.0-24.3), respectively; for MUO 10.9% (9.1-13.1) and 14.8% (12.9-16.9); for MHNO 5.6% (4.9-6.5) and 9.6% (8.5-10.9); and for MHO 4.6% (3.4-6.2) and 8.4% (6.6-10.7). CKD was associated with the metabolically unhealthy phenotypes in males [adjusted odds ratio: MUNO 1.94 (1.41-2.68) and MUO 1.83 (1.40-2.38)], but only with MUNO [1.50 (1.12-1.99)] among females.

Conclusions: These findings suggest different associations between MetS and CKD between males and females. Understanding how sex-specific differences, such as sex hormones, modulate the interaction between obesity/metabolic phenotypes and CKD may provide additional avenues for prevention and treatment.

TH-PO924

Ketogenic Diet Mitigates Renal Fibrosis and Partially Preserves Kidney Function in Nephrotoxic Serum Nephritis

Konstantin A. Kloetzer, Max Schuller, Marcell Krall, Katharina Artinger, Corinna Schabhüttl, Agnes A. Mooslechner, Hansjörg Habisch, Tobias Madl, Alexander R. Rosenkranz, Philipp Eller, Kathrin Eller. *Medizinische Universitat Graz, Graz, Austria.*

Background: Ketogenic diet (KD) has garnered medical interest due to its potential health benefits in various diseases including a significant regulatory impact on inflammatory processes. Our study examined the effects of a KD on an experimental mouse model of immune-complex-mediated glomerulonephritis (GN).

Methods: Male C57BL/6 mice were put on a KD or continued with standard chow (SC) three days after the induction of nephrotoxic serum nephritis (NTS). Mice were observed for 21 days post-induction. Key parameters like the albumin-to-creatinine ratio (ACR) in spot urine and kidney histology were evaluated. Further, we transitioned mice back to SC on day 21 and observed them for an additional 5 weeks. During this period, kidney function was monitored using transdermal glomerular filtration rate measurement devices. Kidney fibrosis was assessed using Sirius Red staining. To thoroughly examine the molecular mechanisms associated with a ketogenic diet, we employed a multifaceted approach incorporating comprehensive immunophenotyping of blood and lymphatic tissues via flow cytometry and immunohistochemistry, renal NMR spectroscopy (metabolomics), and renal bulk RNA-sequencing.

Results: KD significantly reduced levels of albuminuria. We noticed fewer crescents and lower PAS scores, indicating an improved glomerular phenotype in the KD group, but a trend toward increased tubular injury and tubular fat deposition. Mice switched back to SC after the initial KD phase demonstrated a reduction in kidney fibrosis and preserved kidney function with regression of the tubular fat deposits. KD mice showed major systemic immunological and metabolic adaptions like a reduction in blood leukocyte numbers and an increase in the concentration of renal ketone bodies. We further observed an increase of renal neutrophil infiltrates and changes in bulk inflammatory signatures including a decrease in *Mpo* expression. Notably, transcriptomics analysis revealed a decrease in extracellular matrix production.

Conclusions: A therapeutic KD was protective in a mouse model of GN, leading to a reduction in albuminuria, preserved kidney function, and reduced renal fibrosis. Further research is needed to fully understand these protective mechanisms.

Dietary Acid Reduction with Either Fruits and Vegetables or Oral NaHCO3, Adjuvant to Angiotensin-Converting Enzyme Inhibition, Slows Progression of Macroalbuminuric Stage G1 CKD

Nimrit Goraya,[1] Jan Simoni,[2] Maninder Kahlon,[3] Nazan Aksan,[4] Donald E. Wesson.[3] *[1]Baylor Scott and White Central Texas, Temple, TX; [2]Texas Tech University System, Lubbock, TX; [3]The University of Texas at Austin, Austin, TX; [4]The University of Texas at Austin Dell Medical School, Austin, TX.*

Background: Patients with macroalbuminuric (urine albumin-to-creatinine ratio > 200 mg/g creatinine) chronic kidney disease (CKD) are at increased progression risk despite angiotensin converting enzyme inhibition (ACEI). As high acid-producing diets are associated with risk for CKD progression, we tested the hypothesis that dietary acid reduction with either base-producing fruits and vegetables (F+V) or oral NaHCO3 (HCO3) slows progression in macroalbuminuric CKD with initially normal eGFR (> 90 ml/min/m2 or stage G1).

Methods: One hundred fifty-three macroalbuminuric, non-diabetic G1 participants on ACEI were randomized to F+V (n=51) in amounts to reduce dietary potential renal acid load 50%, oral NaHCO3 (HCO3, n=51) 0.4 meq/Kg bw/day, or no additional intervention (Usual Care, n=51). They were followed annually for 5 years, measuring eGFR and these urine parameters per g creatinine: albumin (Ualb), N-acetyl-D-glucosaminidase (UNAG, indicator of tubulointerstitial injury), angiotensinogen (UAGT, index of kidney angiotensin II), and isoprostane 8-isoprostaglandin F2α (U8-iso, index of systemic oxidative stress). Mixed linear regressions with random person intercepts tested differential group trajectories, p-values from the relevant interaction terms are included below.

Results: We highlight group differences at year-5 for brevity and provide p-values from the full model. For F+V and HCO3 relative to UC, 5-year eGFR was higher ([mean (SE)], F+V [96.5(0.79)], HCO3 [95.9 (0.96)] vs. UC [92.1 (1.23), ml/min/1.73 m2, ps<0.001]). 5-year Ualb and UNAG were lower in F+V and HCO3 than UC (Ualb, F+V [306 (8.5)], HCO3 [308 (8.4)], UC [416 (15)], mg/g, ps<0.001); UNAG, F+V [2.5 (0.05)], HCO3 [2.5 (0.05)], UC [2.8 (0.06)], U/g, ps<0.001). Additionaly, 5-year UAGT and U8-iso were lower in F+V and HCO3 than UC (UATG, F+V [20.9 (0.32)], HCO3 [20.6 (0.35)], UC, [23.1 (0.40), µg/g, ps<0.001]; 8-iso, F+V [1.08 (0.02)], HCO3 [1.06 (0.02)] vs. UC [1.27 (0.03)], µg/g, ps<0.001]).

Conclusions: Dietary acid reduction with either F+V or NaHCO3, adjunctive to ACEI, yielded better eGFR preservation than UC in macroalbuminuric G1 CKD, associated with reductions of indicators of kidney angiotensin II and systemic oxidative stress, each potential mediators of CKD progression.

TH-PO926

The Relevance of a Personalized Low-Normal Protein High-Calorie Diet in Nephrectomized Patients for Renal Cell Carcinoma (RCC): Myth or Reality?

Francesco Trevisani,[1] Matteo Paccagnella,[2] Francesco Fiorio,[1] Fabiana Laurenti,[3] Riccardo Vago,[1] Federico Di Marco,[1] Matteo Floris,[4] Umberto Capitanio,[1] Michele Ghidini,[5] Ornella Garrone,[5] Andrea Salonia,[1] Francesco Montorsi,[1] Arianna Bettiga.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Fondazione ARCO, Cuneo, Italy; [3]Universita degli Studi dell'Aquila - Polo Coppito, L'Aquila, Italy; [4]Azienda Ospedaliera Brotzu, Cagliari, Italy; [5]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.*

Background: Nutritional therapy (NT) based on a controlled protein intake represents a cornerstone in the management of CKD. However, if a CKD patient is at the same time affected by cancer, oncologists suggest a diet based on high protein intake to avoid malnutrition. International guidelines are not diriment in this asset of patients. In particular, no clear nutritional management is established in the radical nephrectomy (RN) patients for RCC. The aim of our study was to investigate the efficacy of a Low-Normal Protein High Calorie (LNPHC) diet in a consecutive RN cohort of RCC pts using an integrated nephrologist and nutritionist approach.

Methods: A consecutive cohort of 40 nephrectomized pts for RCC was enrolled in a tertiary institution between 2020-2022. Inclusion criteria: Age >18 years old, eGFR<60 ml/min/1.73,RN for RCC. An initial nephrological and nutritional evaluations were performed and then a conventional CKD LNPHC diet integrated with aproteic foods (0,7-1 g/Kg/die: calories: 30-35 kcal per kg body weight/die) for a period of 6 months (+/- 2 moths). MST, Body Mass Index (BMI), Phase Angle (PA), Fat Mass percentage (FM%), Fat-Free Mass Index (FFMI), body cell mass index (BCMI), extracellular/intracellular water ratio (ECW/ICW), waist/hip circumference ratio (WHC), lab test exams and clinical variables were examined at baseline and after 6 months. Statistical analysis: Kruskal-Wallis rank sum test; Data analysis: R programming language and RStudio integrated development environment.

Results: Descriptive analysis is showed in Table 1. Our results clearly highlighted that LNPHC was able to generate a significant improvement in several nutritional parameters (Tables 2 and 3). Moreover, LNPHC was responsible for a significant decrease of urea.

Conclusions: LNPHC represents a new important therapeutic strategy to apply in the onco-nephrological patients with solitary kidney due to renal cancer.

Descriptive Analysis of Renal Function and Potential Renal Acid Load in Adult Patients with Long-term Home Parenteral Nutrition Support: A Retrospective Study

Paramat Thimachai.[1,2] *[1]University of Alberta, Edmonton, AB, Canada; [2]Phramongkutklao Hospital, Bangkok, Thailand.*

Background: Home parenteral nutrition (HPN) is an established therapy for chronic intestinal failure (CIF). The relationship between CIF and HPN with renal function and kidney disease has yet to be well described in this population. Our study aims to describe chronic kidney disease (CKD) with renal function and potential acidosis load in patients who received long-term HPN.

Methods: We conducted a retrospective study in Edmonton, Alberta. Adult patients aged ≥18 who visited the HPN clinic between Jan 2022 and Mar 2023 were enrolled. The patient admitted to the program for less than six months was excluded. Electronic medical records were reviewed for five years to collect demographic data, the presence of CIF, HPN indications and prescription, the presence of CKD and renal functions. The primary outcome was the estimated glomerular filtration rate (eGFR) with its change after admission to the program and potential total acids load (PTAL). Secondary outcomes included predicted pH, amino acids, glucose, lipid, electrolytes, trace elements, acetate concentration and estimated osmolality load in TPN prescription.

Results: Sixty-one adult patients were included in the study. The mean age was 59.20 ± 11.51 years old, 27.9 % were male and short bowel syndrome was noted in 59%; the most common cause of short bowel syndrome was Crohn's disease. Diabetes mellitus was 16.4 %, Hypertension was 39.3%, and CKD was 47.5%. The most common cause of CKD was nephrolithiasis. The duration of HPN was 6.03 years. An average eGFR was 84.51 ± 27.09 ml/min/1.73 m^2 with a mean change of -2.69 ± 3.21 ml/min/1.73 m^2/year, and the incident rate of rapid GFR decline was 27.9% in five-year follow-up. The median amount

of amino acids was 1.19 (0.85, 1.55) g/kg/day. The average pH of the TPN solution was 5.33 ± 0.36. The median of PTAL was 71.43 (48.35, 95.05) mmol/bag without statistical correlation with CKD when normalised by body weight.

Conclusions: The prevalence of CKD in the HPN was higher than in the general population, with a high rate of eGFR decline. The study showed no statistical correlation between PTAL and CKD in those patients. A prospective study with different GFR measurements should be conducted for the accuracy of eGFR and to demonstrate risk factors for the deterioration of renal function.

Do Protein Intake, Serum Bicarbonate, and Inflammatory Markers Explain the Associations of Advanced CKD with Muscle Wasting?

Farahnaz Akrami, Ravinder Singh, Robert E. Boucher, Guo Wei, Augustine Takyi, Azeem M. Mohammed, Amara Sarwal, Sydney E. Hartsell, George Bissada, Srinivasan Beddhu. *University of Utah Health, Salt Lake City, UT.*

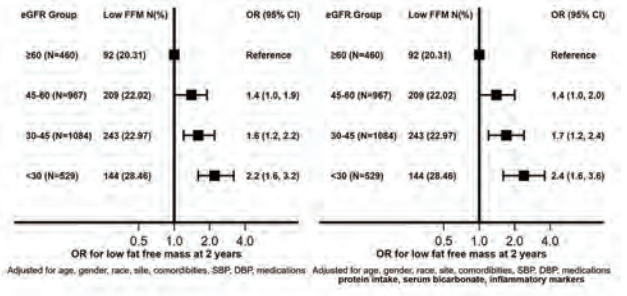
Background: Muscle wasting is a significant concern in individuals with chronic kidney disease (CKD) as it adversely affects their overall well-being and increases the risk of mortality. Low protein intake, metabolic acidosis and systemic inflammation are considered to be some of the main drivers of muscle wasting in CKD. Therefore, we examined in the Chronic Renal Insufficiency Cohort (CRIC), whether these factors explain muscle wasting in CKD.

Methods: We included 3040 eligible CRIC participants. Baseline protein intake was determined from dietary protein intake. Serum bicarbonate was used as marker of acid-base status. Serum hsCRP, IL6, fibrinogen, TNFa and IL1beta were used to derive a previously published CRIC inflammatory score. Muscle wasting was defined as gender specific lowest quartile of fat-free mass estimated from bioelectrical impedance analysis (BIA) at month 24 visit. We investigated the association between low fat-free mass (FFM) and eGFR groups using logistic regression, with covariate adjustment for age, gender, race, site, comorbidities, SBP, DBP, and medications. With additional adjustment for baseline protein intake, serum bicarbonate, and inflammatory score, we examined whether the associations of CKD stages with low FFM at month 24 were attenuated.

Results: Mean baseline age was 58 ± 11 years, 56% were male, 40% were black, and mean eGFR was 45 ± 15. Mean weight was 91 ± 23 kg and mean FFM was 61 ± 16 kg. n multivariate logistic regression model, more advanced CKD was associated with significantly higher risk of low FFM (Figure 1 Panel A). These associations persisted after adjusting for baseline protein intake, serum bicarbonate, and inflammatory score (Figure 1 Panel B).

Conclusions: More advanced CKD is strong predictor of muscle wasting. These associations are not fully explained by protein intake, serum bicarbonate and inflammatory markers. Further studies are needed to unravel the mechanisms of muscle wasting in CKD.

Funding: NIDDK Support



TH-PO929

Evaluation of Protein Malnutrition in CKD Patients on Low-Protein Diet

Arianna Bologna,[1,2] Nadia Edvige Foligno,[1,2] Giuseppe Vezzoli.[1,2] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy.*

Background: Low-protein diet is considered crucial to slow down kidney function deterioration in patients with chronic kidney disease and control metabolic variables such as serum phosphate, urea and bicarbonate. However, low-protein diet may result in malnutrition if patients do not respect nutritional prescription. Thus, the present study examined the risk of protein malnutrition in CKD patients who started a low-protein diet.

Methods: Anthropometric variables, blood variables, nutrient intake and body composition were measured in 40 patients with CKD stage 4-5 (M/F 23/17; age 70±15 years; body weight 70±17 kg) before and after 3-months of a low-protein diet (0.6 g/kg; energy intake 30 Kcal/kg). Nutrient intake was estimated with a food frequency questionnaire; body fat mass (FM), free-fat mass (FFM) and skeletal muscle mass normalized to height^2 (SMI) were assessed using bioimpedentiometry analysis.

Results: In the whole sample, after a 3-month diet protein intake decreased from 0.85±0.24 to 0.71±0.20 g/kg (p<0.001) without a decrease in calory intake (22.3±5.9 and 21.5±4.9 kcal/kg). The diet induced a decrease in body weight (70±17 to 69±16 kg; p<0.001), BMI (26.5±6.4 to 25.9±6.2 kg/m^2; p=0.001), FM (21±10 to 20±10 kg; p=0.003), serum urea (168±48 to 134±43 mg/dl; p<0.001). Eight patients (20%; 4 diabetics) had a protein intake lower than 0.6 g/kg after 3-months of diet. Compared with patients having a higher protein intake, these patients showed lower protein intake at baseline (0.71±0.21 vs 0.89±24 g/kg; p=0.05) and serum albumin (36.3±2.7 vs 40.5±3.2 g/l; p=0.012). Their protein intake after the diet was significantly lower than that at baseline (0.53±0.2 vs 0.71±0.21 g/kg; p=0.016). They also showed a significant decrease in SMI (9.5±1.9 to 8.5±1.8; p=0.003). Conversely, the other 32 patients did not change SMI (9.2±2 to 9,2±2 kg/m^2), but significantly decreased FM (23±11 to 21±11 kg; p=0.002) and increased phase angle (4.2±0.9 to 4.6±0.9; p=0.017).

Conclusions: Protein malnutrition may occur during a low-protein diet in CKD patients with a low consumption of proteins before starting this diet. Nutritional analysis is necessary to identify CKD patients at risk of protein malnutrition and to adequately follow up CKD patients on low protein diet.

Phosphorous Balance Calculator, an Individualized Tool for Treatment of Hyperphosphatemia in Hemodialysis Patients: A Randomized Clinical Trial

Mengjing Wang, Jing Chen. *Huashan Hospital, Fudan University, Shanghai, China.*

Background: Lack of evaluations of the dietary phosphorus and dialysis phosphorus removal in daily clinical practice are the common obstacle to assess phosphorus balance and control phosphorus in hemodialysis patients. We aimed to investigate whether the individualized therapy using phosphorus balance calculator improves phosphorus control.

Methods: A randomized, open-lable, multicenter, 4-week clinical trial was conducted. 119 patients aged 18 to 85 years old and with serum phosphorus level higher than 1.45mmol/l from 3 university teaching hospitals in Shanghai were enrolled and randomized in a 1:1 ratio to individualized (n=60) or conventional therapy (n=59). The primary outcome was the serum phosphorus concentration after 4-week treatment.

Results: Among 119 randomized participants (mean age, 62 years; 68 male[57%]), 116 completed the trial. By using the phosphorus balance calculator, the individualized group achieved a better phosphorus equilibrium state, significantly reduced the serum phosphorus (1.62±0.45mmol/l versus 1.85±0.45 mmol/l, *P*=0.006), increased the proportions of patients achieving target serum phosphorus range (41% versus 18%, *P*=0.006), and had greater adjusted mean difference in change in serum phosphorus over the 4 weeks (-0.47 versus -0.23mmol/l, *P*=0.010) when compared to conventional therapy.

Conclusions: Phosphorus balance calculator was proved to improve serum phosphorus control in patients undergoing maintenance hemodialysis, offering a new tool for managing refractory hyperphosphatemia.

Funding: Government Support - Non-U.S.

Exposure Estimates of Both Inorganic and Organic Phosphate-Containing Food Additives in US Grocery Household Food Sales in 2022 Validates Need for Labeling Phosphorus Content

Jaime Uribarri,[1] Elizabeth K. Dunford,[2] Mona S. Calvo.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]The George Institute for Global Health, Newtown, NSW, Australia.*

Background: A new paradigm based on the degree of food processing to assess the health of dietary patterns has replaced the traditional approach based on the nutrient content of the foods consumed. Dietary patterns where ultraprocessed foods (UPF) dominate are linked to adverse health conditions including CKD, CVD and mortality. Industrial use of food additives is a hallmark of UPF with 60% of foods purchased by Americans containing food additives, a 10% increase in use since 2001. Use of phosphate (PO_4) additives in UPF is a possible mechanism underlying CKD and other conditions by contributing to the total excessive dietary PO_4 intake. Average underestimated intake of 1400 mg P/d by the general public was significantly linked to increased mortality.

Methods: Since no databases exist to estimate phosphate additive intake from processed foods, our objective was to use 2 proxy methods to estimate exposure to all commonly used PO_4-containing food additives, both inorganic salts and less studied organic PO_4 additives (e.g., lecithins, phosphated modified starches). We used household grocery product food label information from USDA's Branded Food Product Database (BFPD) to estimate the number of foods being sold to American consumers that contain inorganic and organic PO_4 additives in foods (Table). Sales data from Euromonitor International were then used to identify products sold by the top 25 food and beverage manufacturers in the US. The proportion of products from these top 25 manufacturers that contained both organic and inorganic phosphates was also determined.

Results: Only 3% of products in the BFPD displayed P content compared to 5% in foods from the top 25 manufacturers. Both proxy measures showed a much higher proportion of products contained inorganic and organic additives than what displayed P on the label.

Conclusions: These findings justify the need for P content labeling of foods to accurately link the health consequences of excessive P intakes in CKD and the general public.

No. of Grocery Foods	USDA BFPD N=396,062 (% total number)	Top 25 Grocery Producer Sales N=36,763 (% matched foods)
No. with Inorganic PO4 additives	77,659 (20%)	11,209 (30%)
No. with Inorganic & Organic PO4 additives	140,111 (35%)	20,741 (56%)
No. Total Data Set with P on Label	12,046 (3%)	1,888 (5%)

TH-PO932

Inorganic Phosphate Additives in US Household 2022 Product Sales from the Top 25 Grocery Store Food Manufacturers: An Existential, Pervasive Risk Factor for CKD

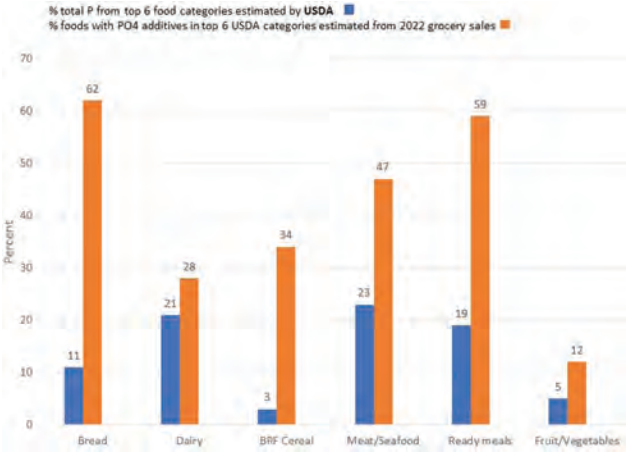
Mona S. Calvo,[1] Elizabeth K. Dunford,[2] Jaime Uribarri.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]The George Institute for Global Health, Newtown, NSW, Australia.*

Background: Restricting dietary phosphorus (P) intake is critical to managing CKD and is an important therapeutic personal action CKD patients can take to slow the progression of kidney failure, hyperphosphatemia and cardiovascular disease. Limiting dietary P intake is not a simple task of consuming less natural food sources rich in P (red meats, dairy) since the use of inorganic phosphate (PO_4) additives to process a variety of foods can contribute significant P hidden in processed food. Additives present a unique problem different from natural organic protein and lipid bound P in foods. PO_4 additive salts are rapidly dissociated in stomach acidity, absorbed quickly and can acutely disrupt serum P homeostasis and hormonal dysregulation linked to cardiovascular disease and mortality. Control of P intake is further complicated by the unknown extent of exposure to these PO_4 additives from packaged food and beverage products.

Methods: To estimate exposure to PO_4 additives, we examined ingredient labels of US household packaged products from the top 25 food and beverage manufacturers to identify the total number of food products containing PO_4 additives across USDA's 23 food categories. USDA identifies 6 food categories contributing the majority of total P intake (81%); however, this is thought to be mostly natural P as additive contribution is rarely included.

Results: Using category-level sales data as a proxy for actual intake of foods with PO_4 additives, we show the % of foods that contained PO_4 additives in the 6 categories (Figure). More than 50% of bread, processed meats and ready meals contained PO_4 additives. USDA survey intakes of total P are thought to significantly underestimate total P when PO_4 additive use is not included.

Conclusions: Our findings support this claim of underestimated total P intake, showing evidence of the wide spread use of PO_4 additives in the foods contributing the most P to daily intake.



TH-PO933

Calcium- and Iron-Based Phosphate Binders Impact the Gut Microbiome in Rats with CKD

Annabel Biruete,[1,2] Shruthi Srinivasan,[2] Kalisha O'Neill,[2] Henriette De loor,[3] Pieter Evenepoel,[3,4] Kelly Swanson,[5] Neal X. Chen,[2] Sharon M. Moe.[2] *[1]Purdue University, West Lafayette, IN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Katholieke Universiteit Leuven, Leuven, Belgium; [4]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [5]University of Illinois Urbana-Champaign, Urbana, IL.*

Background: Limited studies suggest that phosphate binders may impact the gut microbiome. Our objective was to examine the effects of a calcium-based binder and an iron-based binder on the cecal microbiota and gut-derived uremic toxins in a rat model of progressive CKD.

Methods: Rats with normal kidney function (NL) were compared to rats with CKD (Cy/+ male rats): 1) control (CKD), 2) 2% ferric citrate (CKD + FC), 3) 2% calcium gluconate in water (CKD +Ca). Rats consumed the treatments for 10 weeks (18 to 28 weeks of age; mild to moderate/advanced CKD, respectively). The V4 region of the 16S rRNA gene was sequenced from cecal digesta and analyzed using QIIME2. Serum gut-derived uremic toxins were quantified using ultra-performance liquid chromatography-tandem mass spectrometry.

Results: Richness of the microbiota (alpha-diversity) was similar between groups, but overall microbial composition (beta-diversity) was different from each other. At the phylum-level, all CKD rats had lower relative abundance of Firmicutes, and CKD+Ca had higher Bacteroidetes. At the genus-level, CKD+FC had a higher relative abundance of *Akkermansia,* unclassified Desulfovibrionaceae, and *Clostridium,* and a lower relative abundance of *Allobaculum, Bifidobacterium,* and *Lactobacillus.* CKD+Ca had higher relative abundance of unclassified Lachnospiraceae and *Blautia.* Indoxyl sulfate and p-cresyl sulfate were elevated in CKD but were not affected by phosphate binders. However, phenyl sulfate and phenyl glucuronide were lower in CKD+Ca.

Conclusions: Calcium- and iron-based phosphate binders altered the gut microbiota, but only the calcium-based binder impacted phenyl-derived uremic toxins.

Funding: NIDDK Support, Other NIH Support - NIAMS T32, Commercial Support - Keryx pharmaceuticals for parent study.

Effects of Curcuma longa L. and Green Propolis Extract-Loaded Microcapsules Supplementation on Inflammation in Hemodialysis Patients

Denise Mafra,[1,2] Isadora Britto,[1] Marcia M. Ribeiro,[1] Bruna R. de Paiva,[2] Jessyca S. Brito,[1] Karla thais R. Teixeira,[2] Livia D. Alvarenga,[1,2] Heloiza Couto,[2] Tuany R. Chermut,[2] Virgílio P. Delgado,[3] Danielle F. Cunha,[3] Marcelo Ribeiro-Alves,[5] Andresa Berretta,[4] Ludmila F. Cardozo,[2] Paulo emílio C. Leite.[2] Renal Nutrition - UFF. *[1]Universidade Federal do Rio de Janeiro Centro de Ciencias da Saude, Rio de Janeiro, Brazil; [2]Universidade Federal Fluminense, Niteroi, Brazil; [3]Renal Assistencia Medica, Rio de Janeiro, Brazil; [4]ApisFlora, Ribeirão Preto, Brazil; [5]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil.*

Background: Nutritional interventions with food that contains bioactive compounds such as *Curcuma longa L.* and propolis can mitigate inflammation in patients with CKD on hemodialysis (HD). Although broadly available, there are limitations in using these bioactive compounds when ingested in their traditional forms. In this way, the microencapsulation process of these natural compounds can be a good alternative. This longitudinal, double-blind, placebo-controlled study aims to evaluate the effects of *Curcuma longa L.* and green propolis extract-loaded microcapsules supplementation on inflammatory markers in HD patients.

Methods: Patients were randomized into two groups: Intervention (137mg/d of *Curcuma longa L.* and 500mg/d of concentrated and standardized green propolis extract EPP-AF®, Apis Flora, Brazil) as microcapsules administrated hard vegetable capsules or placebo for eight weeks. The levels of inflammatory biomarkers (IL-5, GM-CSF, TNF-α, IL-1B, IL-13, IL-4, MCP-1, IL-8, MIP-1, IL-10, G-CSF, IL-7, IL-12 and IL-17) were analyzed by multiplex assay (Bio-Plex Magpix®). C-reactive protein (CRP) was analyzed using a Bioclin device. All analyses were adjusted according to age, sex, BMI and time on HD.

Results: 38 patients completed the study; 18 patients in the intervention group (49 ± 18.6 yr.; BMI 21.6 ± 5.2Kg/m^2; 8 men) and 20 in the placebo group (49 ± 16.2 yr.; BMI 24.4 ± 3.4Kg/m^2; 10 men). After supplementation, MIP-1 and CRP plasma levels were significantly reduced (**Fig 1**).

Conclusions: Supplementation with 137 mg/d of *Curcuma longa L.* and 500mg of microencapsulated EPP-AF® green propolis extract in hemodialysis patients for eight weeks significantly reduced MIP-1 and CRP values, evidencing the potential anti-inflammatory effects of the supplement.

Funding: Government Support - Non-U.S.

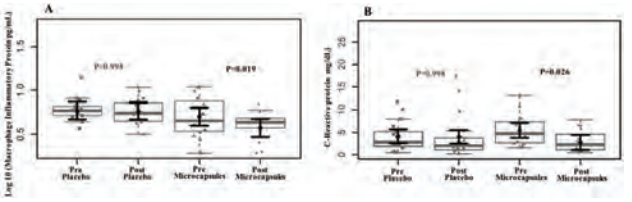

Fig 1. There was evidence of reduced plasma levels of MIP-1 (A) and CRP (B) after microcapsules with turmeric and propolis supplementation.

Does Dark Chocolate Intake Influence Magnesium Status in Hemodialysis Patients?

Denise Mafra,[1,2] Julie Ann Kemp,[2] Susane Fanton,[2] Beatriz G. Baptista,[2] Marcia M. Ribeiro,[1] Marcelo Ribeiro-Alves,[3] Ludmila F. Cardozo.[2] Renal Nutrition - UFF. *[1]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil; [2]Universidade Federal Fluminense, Niteroi, Brazil; [3]Fundacao Oswaldo Cruz, Rio de Janeiro, Brazil.*

Background: Magnesium (Mg^{2+}) is a fundamental mineral that maintains cell function. Magnesium deficiency can be observed in patients with CKD and is associated with increased inflammation, disease progression, and mortality. Studies have shown that patients with high Mg^{2+} serum levels have shown better survival. Dark chocolate is an excellent source of magnesium and polyphenols. Thus, the study aimed to evaluate the effects of 70% cocoa chocolate on magnesium plasma levels in patients with CKD on hemodialysis (HD).

Methods: These are secondary analyses from a previous controlled pilot study that included 59 CKD patients undergoing HD. Patients were allocated into two groups; the chocolate group received 40 grams of 70% cocoa chocolate during HD sessions (3 times a week) for two months. The control group did not receive any intervention. Routine biochemical parameters, including potassium, phosphorus and Mg^{2+}, were evaluated by a colourimetric test using a commercial kit (Bioclin®).

Results: Thirty-five patients in the chocolate group (17 women, 53.4 ± 12.9 years) and 11 in the control group (4 women, 46.7 ± 10.9 years) completed the study. The median of Mg^{2+} serum levels was 2.4 (0.4) mg/dL, with no significant differences between the groups. After two months of supplementation, there was no change in potassium and phosphorus plasma levels, but the Mg^{2+} serum levels were significantly increased in the chocolate group **(Figure 1)**.

Conclusions: Dark chocolate intake increased the Mg^{2+} serum levels in patients with CKD on HD. Therefore, dark chocolate might be a promising nutritional strategy to improve Mg^{2+} levels in patients with CKD on HD. The offered dose was safe, not altering plasma phosphorus and potassium levels.

Funding: Government Support - Non-U.S.

Febuxostat vs. Allopurinol in CKD Patients: Observational Study on Cardiovascular Events and Deaths

Miho Otani,[1] Sae Shinomiya,[1] Yasutaka Ihara,[1] Ryota Kawai,[1] Hisako Yoshida,[1] Kazuhiko Tsuruya,[2] Ayumi Shintani.[1] Osaka Metropolitan University, Dept of Medical Statistics. *[1]Osaka Koritsu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Osaka, Japan; [2]Nara Kenritsu Ika Daigaku Igakubu Igakuka Daigakuin Igaku Kenkyuka, Kashihara, Japan.*

Background: Recent trials have investigated the effects of urate-lowering agents, such as febuxostat and allopurinol. The CARES trial (2018) reported higher all-cause deaths with febuxostat compared to allopurinol. Then the FAST trial (2020) showed that febuxostat did not increase cardiovascular events nor deaths compared to allopurinol. However, these trials did not include severe chronic kidney disease patients, leaving uncertainty regarding febuxostat's efficacy in this population. Moreover, high prevalence of hyperuricemia in severe chronic kidney disease patients, we aimed to assess febuxostat's impact on cardiovascular events and deaths in this population.

Methods: We conducted an observational study using Japanese nationwide administrative data. Patients aged over 60 years with chronic kidney disease (eGFR<60ml/min/1.73 m^2), including severe CKD (eGFR <30), prescribed either febuxostat or allopurinol were identified. The outcomes were cardiovascular events (myocardial infarction, cerebral infarction, unstable angina requiring urgent revascularization) and all-cause deaths. We did intention-to-treat analysis, in which we ignored switching of drugs, using Cox proportional hazard regression models.

Results: A total of 4,793 patients were enrolled: febuxostat group (n = 3,783; median age 74 years; 2,479 [65.5%] men; 1,455 [38.5%] with diabetes; median eGFR 22.8ml/min/1.73m^2; median urate 8.3mg/dl) or allopurinol group (n = 596; median age 75 years; 426 [71.5%] men; 185 [31%] with diabetes; median eGFR 28.5ml/min/1.73m^2; median urate 7.3mg/dl). With respect to cardiovascular events and deaths, febuxostat (1032 patients [0.035 events per 100 patient-years]) was superior to allopurinol (227 patients [0.042 events per 100 patient-years]; adjusted HR 0.861 [95% CI 0.741 – 1.001]).

Conclusions: This analysis using Japanese nationwide data suggested that febuxostat seemed to decrease cardiovascular events and deaths compared to allopurinol in chronic kidney disease patients.

TH-PO937

Antioxidative Effects of Molybdenum and Its Association with Reduced Prevalence of Hyperuricemia in the Adult Population

Boram Weon,[1,2] Wencheng Jin,[1,3] Ara Ko,[2] Jeonghwan Lee.[1,3] *[1]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea; [2]Seoul National University Hospital Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea; [3]Seoul National University College of Medicine Department of Internal Medicine, Jongno-gu, Seoul, Republic of Korea.*

Background: The relationship between molybdenum and kidney-related disease outcomes, including hyperuricemia, is not well investigated. This study aims to determine whether molybdenum and its antioxidative property are associated with systemic inflammation and kidney-related disease parameters including hyperuricemia.

Methods: Urinary molybdenum's epidemiological relationship to hyperuricemia and kidney-disease related outcomes was evaluated in 15,370 adult participants in the National Health and Nutrition Examination Survey (NHANES) collected between 1999 and 2016. Individuals' urinary molybdenum levels were corrected to their urinary creatinine concentrations. The association between urinary molybdenum-to-creatinine ratio and kidney-disease related outcomes were assessed by multivariable linear and logistic regression analyses, adjusting for covariates including age, sex, ethnicity, diabetes mellitus, hypertension, body mass index, and estimated glomerular filtration rate. Antimony and tungsten were used as control trace metals. Experimentally, HK-2 cell was used to assess molybdenum's antioxidative properties. HK-2 cells were challenged with H2O2-induced oxidative stress. Oxidative stress was measured using a fluorescent microplate assay for reactive oxygen species (ROS) and antioxidation levels were assessed by measuring the expression of manganese superoxide dismutase.

Results: In the adult NHANES population, urinary molybdenum-to-creatinine ratio was significantly associated with decreased serum uric acid (β, -0.119; 95% CI, -0.148 to -0.090) concentrations, and decreased prevalence of hyperuricemia (OR, 0.73; 95% CI, 0.64-0.83) and gout (OR, 0.71; 95% CI, 0.52-0.94). Higher urinary molybdenum levels were associated with lower levels of systemic oxidative stress (gamma-glutamyltransferase levels; β, -0.052; 95% CI, -0.067 to -0.037) and inflammation (C-reactive protein levels; β, -0.184; 95% CI, -0.220 to -0.148). In HK-2 cells under H2O2-induced oxidative stress, molybdenum upregulated manganese superoxide dismutase expression and decreased oxidative stress.

Conclusions: Urinary molybdenum levels are associated with decreased prevalence of hyperuricemia and gout in adult population. Molybdenum's antioxidative properties might have acted as an important mechanism for the reduction of systemic inflammation, ROS, and uric acid levels.

TH-PO938

Characterizing the Metabolic Response of the Zebrafish Kidney to a High-Calorie Diet

Evan Zeitler,[1] Ronald Falk,[1] Susan J. Sumner.[2] UNC Kidney Center. *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Obesity is an epidemic risk factor for the development of chronic kidney disease. Obesity induces systemic changes in metabolism; its effect on kidney metabolism specifically is not known.

Methods: We treated zebrafish for 8 weeks with a control (ND) and a high calorie (HC) diet and performed an untargeted metabolomic analysis on the kidney tissue of fish using ultra-high performance liquid chromatography coupled mass spectrometry. We used mummichog and gene set enrichment analysis to uncover differentially affected metabolic pathways.

Results: Overfed zebrafish were heavier and had larger kidneys. Kidney metabolomes differed significantly **(Figure 1A)**, and 235 metabolites were significantly different between groups (125 upregulated in high calorie diet, 110 downregulated) **(Figure 1B)**. Analysis of specific metabolites suggested alterations in tryptophan

metabolism, purinergic signaling and fatty acid oxidation **(Figure 1C-E)**. Pathway analysis demonstrated alterations in metabolic pathways including glycolysis and fatty acid synthesis **(Figure 2A-B)**.

Conclusions: Our findings show that diet induced obesity leads to metabolic changes in the kidney tissue and implicate metabolic pathways including glycolysis and tryptophan metabolism in the pathogenesis of obesity related kidney disease, demonstrating the power of untargeted metabolomics to identify pathways of interest by directly interrogating kidney tissue.

Diet Significantly Influences the Induction of Endoplasmic Reticulum Stress (ERS) in the Kidneys of Male C57Bl/6 Mice

Joseph C. Gigliotti,[1] Jeffrey F. Houghton,[1] Joseph W. Brewer.[2] *[1]Liberty University College of Osteopathic Medicine, Lynchburg, VA; [2]Edward Via College of Osteopathic Medicine - Auburn Campus, Auburn, AL.*

Background: Previous studies have associated ERS with different forms of kidney disease, but it is unclear whether ERS influences renal physiology in normal, non-diseased states. Previous work has suggested an interaction exists between diet and ERS in other organs. Therefore, this study aimed to determine if diet alters the severity of tunicamycin (TUN)-induced ERS in male C57Bl/6 mice.

Methods: Weanling male C57Bl/6 mice were randomly assigned to receive one of three diets: chow, commercially available Western Diet (WD), or a novel Americanized diet (AD) formulated to match 50th percentile nutrient intake in humans. After 6-weeks, mice were injected with TUN (1 mg/kg, IP), or saline, to induce ERS. 24-hours later, mice were euthanized, and plasma and kidneys were collected. Plasma BUN and creatinine were quantified using commercially available assays and mRNA expression of ERS-related genes was quantified using commercially available PCR arrays. All data were analyzed using GLM procedures and significance identified with $P<0.05$.

Results: Mice fed the WD had the greatest body weight and adiposity ($P\leq0.002$). TUN alone did not influence either measure, but a significant diet*TUN interaction was observed where only mice fed WD had a 20% reduction in body weight and adiposity ($P\leq0.01$) with TUN. TUN reduced ($P<0.001$) BUN (20.6±0.7 mg/dL) as compared to control mice (28.0±0.0.8), and a diet*TUN interaction was observed with mice fed AD having lower ($P<0.001$) BUN with TUN. Diet alone had no effect on BUN ($P=0.3$), but plasma creatinine was higher in mice fed AD regardless of TUN (0.65±0.04 mg/dL, $P=0.005$). Neither diet or TUN influenced renal inflammation by CD45$^+$ mRNA expression. Diet alone significantly ($P<0.05$) influenced the expression of 30% (26 of 84) of the quantified ERS-related genes, and a significant diet*TUN interaction was observed in 14 genes. Generally, mice fed the AD had greater change in ERS-related genes with TUN.

Conclusions: These data highlight an interaction between diet and ERS on renal function in a non-disease setting. Our data suggest that diet, formulated to model typical American intakes, modulates the expression of ERS-related genes. Further studies are needed to validate these findings and understand their physiologic significance.

TH-PO940

Alterations in Jejunal Transcriptome of Mice on High Fructose Diet Recapitulate Those of Jejunal Organoids in Obese Individuals

Manoocher Soleimani,[1,2] Sharon L. Barone,[1,2] Christos Argyropoulos,[2] Marybeth Brooks,[1,2] Julie G. In,[2] Kamyar A. Zahedi.[1,2] *[1]New Mexico VA Health Care System, Albuquerque, NM; [2]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Metabolic syndrome (MetS) is manifested by visceral obesity, hypertension, and insulin resistance. The markedly increased incidence of MetS over the last 4 decades correlates with enhanced consumption of fructose and sucrose (a fructose/glucose disaccharide); yet, the pathogenesis of hypertension in MetS remains speculative. Increased consumption of fructose and sucrose activates molecules/pathways that enhance salt and carbohydrate absorption in the small intestine that are critical to the development of salt-overload and hypertension in MetS.

Methods: Jejunal transcriptomes of mice fed high fructose (HF) or high glucose (HG) at 60% vs. control for 2 weeks were compared to those of jejunal organoids from obese individuals (OI) (BMI>35) vs. lean subjects (BMI<25). Differentially expressed transcripts (DET) and activated pathways were identified. Northern/western blot analyses and immunofluorescence labeling were performed to verify the results.

Results: Expression of GLUT5 robustly increased in jejunum of OI and HF mice. The expression of PAT1 (SLC26A6), the Cl^-/HCO_3^- exchanger, which works with NHE-3 to absorb salt in the small intestine, was significantly increased along with ATP1B1 (the Na^+/K^+ ATPase B1 subunit) in OI and HF mice but not in HG mice. The expression levels of SGLT1, GLUT2, ATP1A1, INS2, and LEP significantly increased in OI, HF and HG groups. Mice on HG diet showed enhanced expression of MR (mineralocorticoid receptor) and SGK1 in jejunum, signifying NHE3 activation. KEGG enrichment analysis indicates that pathways critical to the development of obesity, diabetes, and hypertension are activated in OI, HF, and HG.

Conclusions: Robust expression of GLUT5, PAT1, and ATP1B1 in jejunum of OI and mice on HF diet strongly points to enhanced fructose and salt absorption in individuals with MetS. A similar activation of ATP1A1, GLUT2, and SGLT1 in OI, HF or HG points to additional pathways for salt and glucose/fructose absorption. Enhanced fructose or sucrose consumption in the setting of enhanced salt intake activates salt absorption in the small intestine, and can lead to a state of salt overload and hypertension in MetS/obesity.

Kynurenine 3-Monooxygenase Limits De Novo NAD+ Synthesis Through Dietary Tryptophan in Cultured Renal Proximal Tubule Epithelial Cells

Yougang Zhai, Rong Meng, Jose A. Chavez, Andrea R. Nawrocki, Alessandro Pocai, Lifeng Wang, Li-Jun Ma. CVMR-PH Discovery, Janssen Research & Development LLC. *Janssen Research and Development LLC, Raritan, NJ.*

Background: Nicotinamide adenine dinucleotide (NAD^+) is an essential coenzyme involved in regulation of mitochondrial function. Depletion of kidney NAD^+ levels has been linked to acute kidney injury (AKI). The *de novo* NAD^+ can be synthesized through the tryptophan-kynurenine pathway. Renal proximal tubular epithelial cells (RPTECs) are susceptible to diverse injuries in AKI and maybe important for de novo NAD+ generation. However, despite feeding cultured RPTECs with isotope labeled tryptophan, we were unable to detect the synthesis of NAD^+. To address this, we aim to investigate whether the use of 3D culture of primary human RPTECs can enhance *de novo* NAD^+ synthesis.

Methods: Primary hRPTECs were cultured in ULA plates for 4 days to form spheroids. Gene expression levels were assessed by qPCR. Human Kynurenine 3-monooxygenase (hKMO) was overexpressed in hRPTEC spheroids through transduction of Adv-hKMO vector. Cells were treated with isotope-labeled Tryptophan (*Trp) or isotope-labeled 3-hydroxyanthranilic acid intermediate (*3HAA). The relative concentrations of intracellular *Trp, $*NAD^+$ and metabolite intermediates in the hRPTEC spheroids were analyzed by LC-MS/MS.

Results: 3D culture of primary human RPTECs led to a significant increase in the expression of tubular marker genes and enzyme genes involved in *de novo* NAD^+ synthesis. However, *de novo* NAD^+ synthesis was not detected. To investigate why 3D tubular cells were unable to metabolize Trp beyond kynurenine (KYN) metabolite, supplement of *3HAA to hRPTEC 3D spheroids was applied and resulted in its effective incorporation into $*NAD^+$. Furthermore, overexpressing KMO, the enzyme responsible for converting KYN to 3-hydroxykynurenine (3HK), achieved successful rescue of *de novo* NAD^+ synthesis through Trp in the hRPTEC 3D spheroids.

Conclusions: Our data demonstrate that 1) *in* cultured primary RPTECs, the tryptophan-kynurenine pathway loses its function for *de novo* NAD^+ synthesis, 2) the downregulation of a key enzyme gene *KMO* disrupts the conversion of KYN to 3HK in the pathway.

Glucocorticoid Treatment Induces Lymphatic Dysfunction via ATP-Sensitive Potassium Channel

Jianyong Zhong, Haichun Yang, Elaine L. Shelton, Valentina Kon. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Previously, we showed proteinuric disease impairs lymphatic vessel function. Glucocorticoid (GC) therapy is a cornerstone treatment of proteinuric diseases but commonly increases adiposity. Since lymphatics are the principal conduit for transport of lipoprotein particles and clearance of excess lipids, adiposity has been proposed as an indicator of impaired lymphatic function. We investigated whether glucocorticoids directly disrupt lymphatic integrity and function.

Methods: We exposed cultured lymphatic endothelial cells (LECs) to dexamethasone (DXMS) or control medium and assessed relevant parameters including proliferation, migration, and expression of tight junction protein-1 (*TJP1*), vascular endothelial growth factor receptor 3 (*VEGFR3* or *flt4*), and caspase 2/3/9 (*caps2/3/9*) genes. Ex vivo myography studies evaluated DXMS effects on dynamics by exposing isolated rat mesenteric lymphatic vessels to increasing concentrations of DXMS. We also studied mesenteric lymphatic dynamics in vessels harvested from rats receiving daily DXMS or vehicle x 2 weeks. Finally, we evaluated effects of chronic DXMS exposure on response to vasoactive agents: L-NAME, PGE_2, furosemide, and pinacidil, an ATP-sensitive potassium channel (K_{ATP}) agonist.

Results: Our findings revealed that DXMS significantly reduces proliferation, migration, and *TJP1* gene expression in LECs, while enhancing *Flt4* gene expression. DXMS did not alter apoptosis of LECs. In mesenteric lymphatic vessels isolated from normal rats, DXMS increased frequency and end-systolic diameter (ESD), along with decreased amplitude of contraction (AMP) and ejection fraction (EF) with little effects on end-diastolic diameter (EDD). Similarly, vessels from DXSM-treated rats had decreased AMP and EF vs vehicle-treated rats. Moreover, chronic exposure to DXMS dramatically diminished responsiveness to pinacidil when compared to vessels of control rats, suggesting that DXMS can alter lymphatic function via modulation of K_{ATP} channels.

Conclusions: Our data suggest the novel observations that glucocorticoids are powerful modulators of lymphatic vessel function, lymphatic endothelial cell integrity and growth. These alterations may contribute to impaired lipid clearance and visceral adiposity commonly associated with glucocorticoid therapy in the context of proteinuric kidney disease.

Environmental Circadian Disruption Accelerates 5/6 Nephrectomy-Induced Chronic Kidney Injury in Mice

Lihong Chen,[1] Jiayang Zhang,[1] Guangrui Yang.[2] *[1]Dalian Medical University, Dalian, China; [2]Shanghai University of Medicine and Health Sciences, Shanghai, China.*

Background: Circadian disruption such as shift work, jet lag, has gradually become a global health issue and is closely associated with many metabolic disorders. The effect and mechanism of circadian disruption on renal injury and chronic kidney disease (CKD) remains poorly understood. Here, we evaluated the effect of environmental light/dark shifting on the progression of chronic renal injury in CKD mice.

Methods: Mice were subjected to 5/6 nephrectomy and then exposed to either a standard 12h light/12h dark (12L/12D) cycle or weekly light-dark cycle reverse (LDDL) or weekly 6h phase advance (6h advance) for 3 months. Plasma and kidney tissues were harvested for renal function and histological examination. RNA-seq and untargeted metabolomics were performed for mechanistic investigation.

Results: The results showed that 3-month light interference by weekly LDDL significantly exacerbated renal dysfunction, accelerated renal injury, and promoted renal fibrosis in mice with 5/6 nephrectomy, while light interference by weekly 6h phase advance failed to worsen renal function and kidney injury. RNA-seq and untargeted metabolomics results revealed significant upregulation of genes related to inflammatory response and immune cell chemotaxis, while obvious downregulation of genes and metabolites related to energy metabolism was indicated in the LDDL-conditioned CKD kidneys. Consistently, the renal content of ATP was decreased and ROS production was increased in the residual kidney tissues of the LDDL-challenged CKD mice.

Conclusions: We concluded that circadian disruption by environmental light interference may aggravate chronic kidney injury by facilitating inflammatory response and suppressing energy metabolism in the CKD kidneys. Targeting the circadian machinery and keeping routine light-dark cycles may represent promising approaches for the prevention and treatment of CKD.

TH-PO944

Decreased TFH, GCB, PC, and Increased TFR Cell Frequencies in Spleen of Mice Fed with a Glutamine-Free Diet

Li-Shiuan Yang,[1,2] Chung Ying Tsai,[2] Huang-Yu Yang.[1,2] *[1]Chang Gung University, Taoyuan, Taiwan; [2]Chang Gung Memorial Hospital Linkou, Taoyuan, Taiwan.*

Background: We investigated the effects of a glutamine (Gln)-free diet (GFD) and the Gln analog 6-Diazo-5-oxo-L-norleucine (DON) on immune cell populations in mice. Specifically, T follicular helper cells (TFH), T follicular regulatory cells (TFR), germinal center B cells (GCB), and plasma cells (PC) in spleen. Additionally, we assessed the impact of CD4-specific GLS1 deficiency (KO) on TFH frequency and evaluated the therapeutic effects of GFD and DON in a lupus mouse model.

Methods: Animal and Groups: Eight-week-old WT B6 male mice were divided into four groups: chow+PBS or DON, GFD+PBS or DON. After 2-week treatment, mice immunized with LPS-OVA Alum and sacrificed 7.5 days later. **Cell Frequencies:** Flow cytometry was performed to determine the TFH, TFR, GCB, and PC frequencies. **CD4 T cell-GLS1 KO:** $GLS1^{f/f}CD4\text{-}cre^{0/0,\ Tg/0}$ mice were utilized. **Lupus Mouse Model and Therapeutic Interventions:** 1. Five- to six-month-old MRL/lpr mice were used and divided into two groups: GFD-fed mice and DON-treated mice. 2. Cell frequencies in spleen and kidney were determined. 3. Serum anti-ANA, anti-dsDNA, and IgG1 antibodies were measured. 4. Kidney sections were examined for anti-glomerulus IgG deposition.

Results: Effects of GFD and DON on T and B Cell Frequencies 1. Mice treated with chow+DON, GFD+PBS or DON exhibited decreased TFH, GCB, and PC frequencies compared to chow+PBS mice. 2. GFD+PBS treatment led to the highest frequency of TFR cells among all groups. **CD4 T Cell-GLS1 KO and TFH Frequency** CD4 T cells with GLS1 KO showed a primary reduction in TFH frequency. **Therapeutic Effects of GFD and DON in Lupus Mice** 1. Mice with GFD or DON exhibited amelioration of lupus symptoms. 2. TFH and PC frequencies in spleen were reduced in GFD-fed mice. 3. GFD and DON treatments resulted in lower level of serum anti-ANA, anti-dsDNA, and IgG1 antibodies. 4. DON treatment significantly reduced the total frequency of kidney infiltrated lymphocytes.

Conclusions: Our findings demonstrate that a GFD can decrease TFH, GCB, and PC cell frequencies, while increasing TFR cell frequency in spleen of mice. CD4 T cell-specific GLS1 KO primarily reduces TFH frequency. Furthermore, both GFD and DON show therapeutic effects in ameliorating lupus symptoms in the MRL/lpr mouse model. These results suggest the potential of manipulating Gln metabolism as a therapeutic strategy for autoimmune diseases like lupus.

Dietary Supplementation with Bacillus Superoxide Dismutase Protects Against Kidney Ischemia Reperfusion Injury in Mice

Jihyun Yang,[1,2] Ko Yoon Sook,[2] Lee Hee Young,[2] Young Eun Choi,[2] Suk Min Chung,[2] Sungyeon Kim,[2] Myung-Gyu Kim,[2] Sewon Oh,[2] Sang-Kyung Jo.[2] *[1]Kangbuk Samsung Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: Superoxide dismutase (SOD) is a metalloenzyme that play an important role in antioxidant defense against oxidative stress. Bacillus strains are known to produce manganese containing SOD (Mn-SOD) and thus have been shown to have protective effect in inflammatory bowel disease animal model. Based on recent data showing the important role of gut dysbiosis, aberrant gut mucosal immunity as well as well-known oxidative stress in kidney injury, we investigated the renoprotective potential of orally administered enteric-coated SOD protein purified from *Bacillus amyloliquefaciens* (SOD-BA) in kidney ischemia/reperfusion injury (IRI) in mice.

Methods: Six week old C57BL/6 male mice were fed with SOD-BA 24 hours prior to IRI. Serum BUN, creatinine and histologic alterations as well as oxidative stress, inflammation in kidney tissue were determined. Gut microbiome analysis, permeability, epithelial damage as well as various antioxidant enzymes including catalase and SOD activity were also determined.

Results: Oral supplementation of SOD-BA conferred significant renoprotective effect in kidney IRI and this was associated with significantly increased level of SOD levels in kidneys. Gut microbiota structure in SOD-BA +IRI group was clearly distinguished from that of IRI group in principal coordinate analysis, showing that the relative frequency of family Porphyromonadaceae, Muribaculaceae and Bacteroidacea increased. SOD-BA administration also led to decreased colon epithelial apoptosis with partial restoration of gut permeability. Despite significant renoprotective effect, there was no difference in colon and kidney inflammation.

Conclusions: SOD-BA could be served as an orally available, potent antioxidant in the prevention and treatment of acute kidney injury. Our data showed a therapeutic potential of gut bacterial product in kidney IRI that can overcome the safety issue regarding the use of probiotics.

Case Report on Successful Treatment of Life-Threatening Anemia in ESRD Patient on Maintenance Hemodialysis Who Is a Jehovah Witness and Refusing Blood Transfusion

Omar N. Elhawary,[1,2] Sandeep R. Sasidharan,[1,2] Syeda S. Bukhari,[1,2] Isha Puri,[1,2] Mary C. Mallappallil.[1,2] Kings County Team. *[1]SUNY Downstate Health Sciences University, Brooklyn, NY; [2]Kings County Hospital Center, Brooklyn, NY.*

Introduction: Anemia is prevalent in patients with advanced chronic kidney disease (CKD) and end-stage renal disease (ESRD) who undergo regular hemodialysis. This is primarily attributed to reduced production of erythropoietin by the kidneys. Existing guidelines recommend managing anemia when the hemoglobin (Hgb) is below 11 g/dL by administering intravenous iron and erythropoietin injections. In cases who have severe anemia with hemoglobin levels below 7-8 g/dL and experience symptoms, blood transfusion is typically recommended. Blood transfusions help in correcting anemia, alleviating symptoms, and enhancing tissue oxygenation. However, providing appropriate treatment for anemia becomes challenging when patients refuse blood transfusion due to religious beliefs, such as our patient. In our case report, we present a successful treatment approach for severe anemia in an ESRD patient without utilizing blood transfusions.

Case Description: 60-year-old woman with history of Hypertension, ESRD on hemodialysis (HD) due to Systemic lupus erythematosus with failed kidney transplant presented with altered mentation. She was found hemodynamically unstable, in atrial-flutter requiring ablation and cardiac monitoring on admission. She had a long hospitalization with Hgb at presentation~9. It gradually went down to 4.8 over 3 weeks. Due to her religious beliefs as a Jehovah's witness, she declined blood transfusion. To treat her anemia, we initiated a daily treatment regimen consisting of short-acting erythropoietin alfa at a dose of 40,000 Units for seven days, along with daily intravenous iron sucrose at 100 mg. After one week of this treatment, the patient's hemoglobin level improved to 11.5 g/dL and felt markedly better.

Discussion: For Jehovah Witness patients undergoing HD, who have severe anemia and decline blood transfusions, we suggest initiating a daily, short-term treatment of erythropoietin alfa at a dosage of 40,000 U, alongside intravenous iron, for a duration of one week. If the patient is already receiving long-acting darbepoetin alfa, it is advised to transition to short-acting erythropoietin alfa. This approach may also be applied for preoperative management of significant anemia, regardless of whether the patients are receiving renal replacement therapy or not.

TH-PO947

SGLT2i-Induced Erythrocytosis Unveiling Heterozygous Hereditary Hemochromatosis (HH) Gene Mutation in an Individual with CKD

Kamilya Schumacher,[1] Elvira O. Gosmanova.[2,1] *[1]Albany Medical College, Albany, NY; [2]Albany Stratton VA Medical Center Albany, Albany, NY.*

Introduction: SGLT2i were shown to increase hemoglobin (Hb) levels in clinical trials. We report a case of symptomatic erythrocytosis in an individual treated with SGLT2i empagliflozin who was later found to have a HH gene mutation.

Case Description: This was a 72-yo male with CKD and baseline serum creatinine (SCr) of 2.1mg/dL (eGFR 33mL/min/1.73m^2), controlled type 2 diabetes (A1C 6.9%) and hypertension. Empagliflozin 12.5mg daily was initiated due to persistent grade A3 proteinuria (uACR ~1.5g/g) despite daily combination of losartan 100mg and spironolactone 25mg. Hb and hematocrit (Hct) were 16.8g/dL (normal 13.5-17) and 49.5% (normal 38-50) at the time of SGLT2i start. The patient had no history of obstructive sleep apnea. There was a remote history (>30 years ago) of smoking. Over the years, he had intermittent mild Hb elevation in 17-17.5g/dL range. At that time, erythropoietin level was normal and polycythemia vera was excluded. Within 6 months of empagliflozin initiation, Hb (Hct) gradually rose to 20g/dL (59.3%) despite advice to maintain adequate hydration. The patient reported worsening fatigue and diffuse myalgias. Physical examination and vital signs were normal. Transferrin saturation (Tsat) was 30%. Ferritin was 145ng/mL. SCr rose to 2.6mg/dL (eGFR 25 ml/min/1.73m^2). Screening for HH in the nephrology clinic revealed H63D heterozygosity in the HFE (Hemostatic Iron regulator) gene and negative C282Y gene mutation. Two serial phlebotomies were performed and lead to the normalization of Hb (Hct) to 16.5g/dL (48%), resolution of symptoms, and an improvement in SCr to 2.0mg/dL (eGFR 35 ml/min/1.73m^2). Tsat and ferritin remained stable. Empagliflozin was continued for renoprotection. Monthly phlebotomy was continued to maintain adequate Hb.

Discussion: SGLT2i reduce risk of anemia in patients with CKD. Their use may also be associated with erythrocytosis. The presence of underlying heterozygous HH gene mutation was likely predisposing risk factor of SGLT2i-induced erythrocytosis. This case suggests that periodic monitoring of Hb level should be considered. Additionally, screening for HH could be offered to patients with SGLT2i-induced erythrocytosis to implement phlebotomy if a HFE gene mutation is detected. Stopping SGLT2i will likely lower Hb to baseline, but it will also remove their cardiorenal benefits.

TH-PO948

Successful Treatment of Anemia with Roxadustat in a Hemodialysis Patient Following Erythropoietin-Induced Pure Red Cell Aplasia

Pearl Pai,[1,2] Xuejuan Ma,[1,4] Xiaowei Chen,[1,3] Wenjuan Zhu,[1] Liwen Cui.[1] *[1]The University of Hong Kong-Shenzhen Hospital, Shenzhen, China; [2]The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong; [3]Guangzhou Medical University, Guangzhou, China; [4]Jinan University, Guangzhou, China.*

Introduction: Erythropoietin (EPO) antibody (Ab)-induced Pure Red Cell Aplasia (PRCA) is a rare condition. Treatment usually requires immediate withdrawal of EPO and treatment with immunosuppression or renal transplantation. Here, we present the successful treatment of a case of EPO Ab-induced PRCA with cyclosporin (CyA) and Roxadustat, a hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI).

Case Description: A 58-year-old man developed kidney failure as a result of diabetes mellitus. In July 2021, shortly before he began dialysis, he was commenced rHuEPO (Jimaixin, epoetin-α, KexingBio, Shandong, China) subcutaneously 5000 IU twice a week. He began hemodialysis (HD) in November 2021. He was switched to intravenous rHuEPO (6000 IU) (Yipuding, epoetin-α, NCPC GenetechBio, Hebei, China) once a week. His Hb increased to 116 g/L in the first 3 months but fell to 75 g/L 6 months into HD. 3½ weeks later, he presented with a pneumonia and a Hb of 48 g/L. He was treated with antibiotics and was transfused. His EPO was stopped. He was started on Roxadustat. 18 days later, his Hb fell to 38 g/L, his reticulocytes was 2900/uL. A bone marrow (BM) biopsy showed a proliferative active BM but reduced erythropoiesis and an erythroid precursor of 7%. A diagnosis of EPO Ab-induced PRCA was suspected. However, an anti-EPO Ab ELISA test later turned out negative. Some likely causes of PRCA such as lymphoproliferative disorder, parvovirus B19 infection, thymoma and systemic autoimmune disease were excluded. The Roxadustat was discontinued. A second BM biopsy showed a erythroid precursors of 5.2%. The suspicion of a EPO Ab-induced PRCA was maintained. The patient was commenced CyA 3mg/kg/day and was given 25 more units of blood over 2 months. The reticulocyte counts took 3 months to recover to normal. The patient was recommenced on Roxadustat 100 mg TIW and his Hb stabilized.

Discussion: Even though the anti-EPO Ab was negative by ELISA assay in our case, the clinical course, with markedly reduced reticulocyte count <10000/ul, a BM biopsy revealing reduced erythroblasts only, and its subsequent response to CyA, were in keeping with EPO Ab-induced PRCA. Anti EPO Ab assay is not always positive in EPO Ab-induced PRCA. Our case illustrates that treatment with Cyclosporin and a switch to Roxadustat are useful in treating EPO Ab-induced PRCA.

TH-PO949

Risk Factors Involved in Erythropoietin Resistance in Patients with CKD in a Hemodialysis Unit

Juan D. Diaz Garcia, Diana Maldonado Tapia, Enrique F. Morales Lopez, Jose L. Ortega, Francisco J. Hernandez Copca, Beatriz R. Cerezo Samperio, Irving G. Ramirez, Julio C. Nieto, Abel Humberto V. Compean, Mario Alamilla-Sanchez. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

Background: Recombinant human erythropoietin is administered to patients with end-stage chronic kidney disease for the treatment of anemia. However, there are different factors that generate resistance to this treatment. This paper seeks to evaluate the impact of a structured team approach for the management of anemia in erythropoietin-resistant hemodialysis patients.

Methods: Prospective study of 18 months. A total of 27 patients in a hemodialysis unit of a reference center, where erythropoietin resistance was defined as those patients who had erythropoietin >300 units/kg/week. Hemoglobin, iron indices, parathyroid hormone, folate, vitamin B12, and reticulocyte counts were determined at baseline. Said previous parameters were followed every 6, 12 and 18 months. The target hemoglobin was 10-12 g/dl. All factors potentially contributing to erythropoietin resistance were evaluated and, if possible, treated every 4 weeks by a specialized nephrology team. Downward erythropoietin dose adjustments of 12.5 to 25% to the nearest 1000 units were considered if the underlying causes of resistance could not be identified or reversed, or if hemoglobin exceeded the target level.

Results: Parathormone levels and iron deficiency were the predominant treatable factors associated with erythropoietin resistance. At 4 months, mean erythropoietin dose decreased significantly from 469 to 319 units/kg/week ($p < 0.001$) and mean hemoglobin increased significantly from 10.6 to 11.6 g/dl ($p = 0.023$), a At 8 months, the patients had erythropoietin doses of less than 300 units/kg/week, reaching target hemoglobin levels.

Conclusions: A structured team approach of nephrologists and a monthly adaptation with an individualized management of the patient managed to significantly reduce the dose of erythropoietin with an improvement in serum hemoglobin reaching the objectives set in the international guidelines, identifying and solving the factors involved.

TH-PO950

3-Carboxy-4-Methyl-5-Propyl-2-Furanpropionate (CMPF), an Endogenous Protein-Bound Uremic Solute, Renders Erythrocyte Osmotically More Fragile, Possibly Through a Piezo1 Pathway

Beatriz Akemi K. Van Spitzenbergen,[1] Gabriela Ferreira Dias,[2] Nadja Grobe,[2] Andrea N. Moreno-Amaral,[1] Peter Kotanko.[2,3] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Shortened red blood cell (RBC) life span contributes to renal anemia and may be caused by uremia-induced premature RBC death (eryptosis). Recently, it was hypothesized that the uremic solute CMPF interacts with the Piezo1 mechanoreceptor on the RBC surface due to CMPF's structural similarity with Jedi1, a well-characterized synthetic Piezo1 agonist (Kotanko *et al*., 2022). In this study, we compared the effects of Jedi1 and CMPF on RBC osmotic fragility.

Methods: RBC from 5 healthy subjects were incubated for 30 min with CMPF or Jedi1 (both at concentrations of 87 μM) in phosphate-buffered saline with 4% human serum albumin. RBC incubated without CMPF or Jedi1 were negative controls. Subsequently, RBC suspensions were incubated in NaCl solutions of increasing osmolarity (NaCl 3 to 9 g/L). Free hemoglobin was measured in the supernatant by spectrophotometry at 540 nm. The data were fitted to a 4-parameter logistic regression curve to obtain the osmotic fragility index (IC50). IC50 is defined as the NaCl concentration that causes 50% hemolysis.

Results: RBC incubation with CMPF or Jedi1 increased IC50 (i.e., increased osmotic fragility) when compared to the negative control (Table 1). The IC50 increase was most pronounced in RBC incubated with CMPF.

Conclusions: Our findings suggest that CMPF - an endogenous metabolite and uremic solute - may increase RBC osmotic fragility, possibly through a Piezo1 pathway. Understanding the molecular mechanisms involved may aid the developing new therapeutic approaches to renal anemia.

Table 1 – RBC osmotic fragility index (IC50) under different experimental conditions

Experimental condition	IC50 mean±SD (95% CI)	Mean IC50 difference (95%CI) to controls	p-value
Negative control	4.57 ± 0.31 (4.18 – 4.97)	Not applicable	Not applicable
Jedi1 (87μM)	5.02 ± 0.28 (4.66 – 5.37)	0.45 (0.06 – 0.83)	0.031
CMPF (87μM)	5.57 ± 0.39 (5.09 – 6.06)	1.00 (0.61 – 1.38)	0.002

TH-PO951

A Retrospective View of the Relationship of Soluble Fas with Anemia and Outcomes in CKD

Jessica L. Andrade,[1] Otavio H. Clemente,[1] Beatriz M. Silva,[1] Adelson Rodrigues,[1] Abolfazl Zarjou,[3] Miguel Angelo Goes.[2,1] *[1]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [2]Sociedade Beneficente Israelita Brasileira Albert Einstein, Sao Paulo, Brazil; [3]The University of Alabama at Birmingham Center for the Study of Community Health, Birmingham, AL.*

Background: Anemia is common in chronic kidney disease (CKD) and is related to serum levels of soluble Fas (sFas), which are associated with resistance to erythropoietin (EPO). The study objeticves to compare clinical data and serum levels of sFas, EPO, and pro- inflammatory markers between non-dialytic CKD patients and healthy individuals. To assess the relationship of serum EPO and sFas between these patients with and without anemia.

Methods: Retrospective study of 58 CKD patients under conservative treatment and 20 healthy individuals. Complete blood count, renal function, serum EPO, sFas, and inflammatory markers (CRP, IL-6, and IFN-γ) were compared at baseline. We then analyzed these variables between patients who progressed to anemia and those without anemia. We evaluated the frequency of outcomes in these patients with elevated sFas levels. We performed a multivariate analysis of factors associated with anemia.

Results: CKD when compared to healthy individuals had lower eGFR (35.7 ±2.5 vs 89.7 ±3.32 ml/min; p<0.001), and Hb (12.8 ±0.27 vs 14.4 ± 0.25 g/dl; p=0.003), major inflammatory markers, sFas (2894 ±172 vs 1136 ±97pg/ml; p<0.001), and EPO/Hb (8.76 ±1.16 vs 4.90 ± 0.58 IU/mg/dl; p=0.003). CKD with anemia, when compared to non-anemic individuals, had lower eGFR (27.7 ±1.72 vs 54.9 ±5.26; p<0.001) and higher sFas/ eGFR (150.9 ±16.6 vs 45.2 ±9.95; p<0.001), EPO/Hb (10.3 ±1.56 vs 5.12 ±0.69; p=0.04) and sFas (3339 ±181 vs 1820 ±240; p=0.001). We found an independent association in the multivariate analysis of serum sFas levels with long-term renal anemia sFas (OR 4.322, 95% CI, 1464-12.753; p=0.008).

Conclusions: As an elective risk factor, serum sFas levels were independently associated with long-term renal anemia.

TH-PO952

Depression and Anxiety Are Associated with Iron Deficiency Anemia for Patients with Stages 2-4 CKD

Ilgin Genc, Muhammed Hakan Aksu, Saliha Yildirim, Emre Yasar, Ozant Helvaci. *Gazi Universitesi Tip Fakultesi, Ankara, Turkey.*

Background: Neuropsychiatric disorders, mainly cognitive decline, depression, and anxiety, are more common in CKD patients. The association between iron deficiency anemia (IDA) and cognitive decline is well-known for this population. For patients without CKD, IDA is associated with depression and anxiety. However, the link between depression, anxiety, and IDA is not clear in subjects with non-dialysis-dependent CKD. In this work, we aimed to evaluate the association above.

Methods: We selected a cohort of patients with stable stage 2-4 CKD and assessed them with Beck's depression inventory (BDI) and Beck's anxiety inventory (BAI). We excluded patients with acute kidney injury or decompensation, hematological/ solid malignancies, and those suffering from psychological trauma. A diagnosis of schizophrenia, major depression, and bipolar disorder or using antidepressant/ antipsychotic drugs were reasons for exclusion. We also did not include those needing EPO or those with other causes of anemia.

Results: Two hundred patients were included in the final analysis. 76 of 200 (38%) patients were anemic. Patients with anemia were older and had worse GFR. BDI scores were worse for patients with anemia. Furthermore, with a cut-off of eleven for BDI, 31,7% of patients in non-anemic and 51,4% of patients in anemic groups deserved further evaluation for clinical depression. The difference was significant (p=0,007). Univariate analysis did not reveal a relationship between BDI and hemoglobin, transferrin saturation, and ferritin levels. A multivariate analysis was not undertaken due to the low number of patients. A subgroup analysis of anemic patients also showed that patients who had received iron, despite being still anemic, had lower BDI scores compared to those with untreated anemia (p<0,001) BAI scores were similar between groups. In addition, frequencies of minimal, mild, moderate, and severe anxiety were similar. However, in subgroup analysis, patients who had received iron despite being still anemic had lower BAI scores than those with untreated anemia.

Conclusions: Our work hints at a viable link between depression, anxiety, and IDA in subjects with Stage 2-4 CKD. However, this study is observational and thus only can generate a hypothesis. Prospectively designed studies on iron replacement may further elaborate our understanding of these associations.

TH-PO953

Red Blood Cell Transfusion Rates in the Early Dialysis Period: Comparing Hemodialysis (DOPPS) and Peritoneal Dialysis (PDOPPS) in an International Setting

Angelo Karaboyas,[1] Charlotte Tu,[1] Anna Richards,[2] Jake N. Hunnicutt,[3] Timothy Pham,[3] Elke Schaeffner,[4] Elham Asgari,[5] Antonio A. Lopes,[6] Jeffrey Perl,[7] Roberto Pecoits-Filho.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]GSK plc, Brentford, United Kingdom; [3]GSK, Collegeville, PA; [4]Charite Universitatsmedizin Berlin, Berlin, Germany; [5]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [6]Universidade Federal da Bahia, Salvador, Brazil; [7]St Michael's Hospital, Toronto, ON, Canada.*

Background: The transition to dialysis is a period of clinical instability during which red blood cell transfusion (RBCT) use may be indicated. Given key differences in pre-dialysis nephrologist care and anemia management between patients who initiate hemodialysis (HD) and peritoneal dialysis (PD), patterns in RBCT rates in the early dialysis period should be investigated.

Methods: We used data from 22,643 in-center HD patients from 20 countries in the Dialysis Outcomes and Practice Patterns Study (DOPPS) phases 5–7 (2012–2022) and 3557 PD patients from 6 countries in the Peritoneal DOPPS (PDOPPS) phase 1 (2014-2018). In these prospective cohort studies, RBCT receipt (yes/no) was prospectively captured each month, with rates presented by time since dialysis initiation (vintage).

Results: Hemoglobin levels measured within 30 days after dialysis initiation were lower in HD (mean 9.5; 37% <9 g/dL) vs. PD (mean 10.8; 12% <9 g/dL) patients. The RBCT rate (per 100 patient-years) was 74.0 during the first 90 days of HD vs. 12.7 during the first 90 days of PD. After 90 days, RBCT rates were very similar in the HD (21.0) vs. PD (20.8) populations. These patterns – relatively lower RBCT rates during the early PD period but higher RBCT rates during the early HD period – were consistently observed across countries, with rates generally stabilizing after the first 9–12 months of dialysis (Figure 1).

Conclusions: Using uniform and standardized RBCT capture across countries and modalities, this study showed high RBCT rates in the first few months of HD, but not PD, therapy, likely reflecting differences in patient profiles. When considering the short-term and long-term risks of RBCT, awareness of this relationship may help inform anemia management before, during, and after this important transition period to reduce the need for RBCT intervention.

Hemoglobin Level Variability and Infectious Risk in Hemodialysis Patients in the Era of Long-Acting Injectable Erythropoiesis-Stimulating Agents

Hiroshi Nishi,[1] Jui Wang,[2] Yoshihiro Onishi,[2] Masaomi Nangaku.[1] *[1]Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan; [2]iHope International, Kyoto, Japan.*

Background: Target hemoglobin level is suggested in the management of chronic kidney disease. However, hemoglobin levels often fall below or exceed the target range. Past retrospective cohort studies of patients undergoing hemodialysis with conventional short-acting erythropoiesis stimulating agents found that hemoglobin level fluctuations predicted mortality and cardiovascular adverse events; thereafter long-acting agents have been widely available.

Methods: We adopted Cox regression models to evaluate associations between hemoglobin level variability and all-cause death, hospitalization, and cardiovascular, thrombotic, or infectious adverse event outcomes in 3,063 hemodialysis patients' data from the Japanese Dialysis Outcomes and Practice Patterns Study from 2012 to 2018.

Results: All-cause mortality was lowest in the first quartile and tended to be higher in the groups with greater hemoglobin variability (hazard ratio: 95% confidence interval for the fourth quartile of an absolute value of hemoglobin variability: 1.44 [0.99–2.08], p for trend = 0.056). Intriguingly, infectious event incidence was higher than the first quartile for the second through fourth quartiles (p for trend <0.01). The association was more pronounced in patients with lower serum ferritin levels or with iron supplementation. However, cardiovascular and thrombotic event incidence was not associated with hemoglobin variability.

Conclusions: Maintenance hemodialysis patients on erythropoiesis stimulating agent treatment with higher hemoglobin variability are at higher risk for all-cause mortality and particularly infectious events.

Hemoglobin Variability in Hemodialysis Patients Improves Under Individualized Anemia Therapy

Doris H. Fuertinger,[1] David J. Joerg,[1] Kevin Ho,[4] Lin-Chun Wang,[2] Lela Tisdale,[2] Xiaoling Ye,[2] Stephan Thijssen,[2] Peter Kotanko.[2,3] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Fresenius Medical Care North America, Waltham, MA.*

Background: Anemia is a common complication in patients receiving hemodialysis. Anemia treatment with erythropoiesis-stimulating agents (ESAs) is challenging and Hgb outcomes vary widely in clinical practice. In a randomized controlled clinical trial (RCT), we investigated the impact of an individualized anemia therapy tool on hemoglobin (Hgb) variability.

Methods: Patients were randomized 1:1 to be treated with an individualized ESA dose recommendation tool (intervention (INT) group) or an anemia management protocol (standard of care (SoC) group) for 26 weeks; 82 patients completed the study (INT: N=40, SoC: N=42). The recommendation tool utilized a previously validated physiology-based model of anemia to estimate key patient-specific physiological characteristics, such as red blood cell lifespan, to create a digital twin from recent routine clinical data (Fuertinger et al., PLOS ONE 13(4):e0195918, 2018). Based on the patient's digital twin, individual ESA dose recommendations for methoxy polyethylene glycol-epoetin beta were generated to target a Hgb window of 10-11 g/dL.

Results: Interpatient variation in mean Hb levels over the study period was smaller in the INT group than in the SoC group (Variance 0.15 vs 0.66 g^2/dL^2, F-test, p<0.001) while the mean shifted to the center of the target range (10.5 vs 10.8 g/dl). The distributions of mean monthly Hgb levels progressively narrowed in the INT group over time (see Fig. 1, left panel). Further, intrapatient Hgb variability, defined as the standard deviation around the mean Hgb levels, improved in the INT group compared to the SoC group (median [IQR]: 0.7 [0.3] vs 0.9 [0.6] g/dL, Wilcoxon-rank sum test, p=0.001) (see Fig 1, right panel).

Conclusions: The RCT results suggest that the individual ESA recommendations of the anemia therapy tool improves inter- and intrapatient Hgb variability, while also bringing mean Hgb levels into the desired target range.

Funding: Commercial Support - Fresenius Medical Care

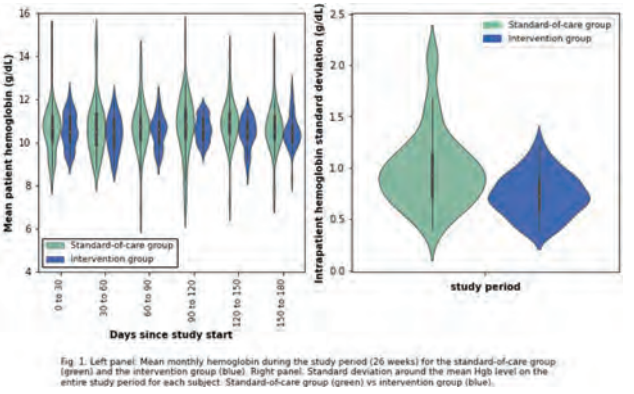

Fig. 1. Left panel: Mean monthly hemoglobin during the study period (26 weeks) for the standard-of-care group (green) and the intervention group (blue). Right panel. Standard deviation around the mean Hgb level on the entire study period for each subject. Standard-of-care group (green) vs intervention group (blue).

TH-PO956

Hemoglobin Variability Is Associated with Nutritional Status in Hemodialysis Patients Undergoing Darbepoetin-Alfa Treatment

Juyoung Jung,[1,2] Dong-jin Oh,[1,2] Hye Min Choi,[1,2] Young Eun Kwon,[1,2] Song in Baeg.[1,2] *[1]Myongji Hospital, Goyang, Gyeonggi-do, Republic of Korea; [2]Hanyang University College of Medicine, Seongdong-gu, Seoul, Republic of Korea.*

Background: Anemia is common in hemodialysis (HD) patients, and their response to erythropoietin (EPO) treatment is inconsistent. Fluctuations in hemoglobin levels, known as Hb variability, occur during EPO therapy. This study investigated the association between EPO responsiveness, Hb variability, and nutritional status in HD patients undergoing NESP® (darbepoetin-alfa; Kyowa Kirin Korea Co., Ltd.) treatment.

Methods: This prospective study enrolled 98 adult HD patients (age >20 years, HD vintage >6 months). The target Hb level followed Korean reimbursement guidelines (10-11 g/dL). NESP® dosage adjustments were based on monthly Hb measurements. EPO resistance index (ERI) was calculated as the average weekly NESP® dose divided by Hb level. Hb variability was assessed using Hb-Coefficient of Variation (Hb-CV) with over 24 monthly Hb data points. Nutritional parameters, including body mass index (BMI), fat tissue index (FTI), lean tissue index (LTI), body cell mass index (BCMI), and phase angle (PhA), were evaluated using BCM® (Fresenius Medical Care a Deutschland GmbH, Germany). Clinical and biochemical parameters were also considered.

Results: The study comprised patients with a mean age of 64.0±11.9 years, of which 55.0% were male. HD vintage averaged 54.9±46.8 months, and the follow-up duration was 79.3±47.9 months. Mean Hb level was 10.7±1.3 g/dL. Patients were divided into tertiles based on ERI and Hb-CV. The average ERI was 0.02±0.01, 0.04±0.01, and 0.07±0.03 in ERI-T1, ERI-T2, and ERI-T3, respectively. The ERI-T3 group exhibited lower Hb levels (p=0.038) and higher EPO doses (p=0.001). ERI-T3 correlated with lower PhA (p=0.044), BMI (p=0.001), and FTI (p=0.046). The Hb-CV-T3 group displayed lower BMI (p=0.002) and FTI (p=0.002). FTI was negatively correlated with ERI (r= -0.193, p=0.046) and Hb-CV (r= -0.268, p=0.005) and positively correlated with age (r=0.197, p=0.017) and female sex (r=0.386, p=0.001). Multiple linear regression analysis indicated a negative association between FTI and ERI (β= -0.218, p=0.014) as well as Hb-CV (β= -0.181, p=0.039). Age (β= 0.197, p=0.017) and female sex (β= 0.386, p=0.001) were positively associated with FTI.

Conclusions: Higher EPO resistance and Hb variability were associated with compromised nutritional status, particularly reduced fat tissue, in HD patients on darbepoetin-alfa.

TH-PO957

Red Blood Cell Distribution Width-Coefficient of Variation as an Indicator of the Requirement for and Efficacy of Daprodustat in Hemodialysis Patients Switching from Erythropoietin-Stimulating Agents

Kenichi Morii,[1,2] Toshiki Doi,[1,2] Yoshiko Nishizawa,[1] Kazuomi Yamashita,[1] Kenichiro Shigemoto,[1] Sonoo Mizuiri,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: Red blood cell distribution width (RDW) is an index of red blood cell volume variability and is used as a marker of iron deficiency anemia. In both hemodialysis and chronic kidney disease patients, a high RDW is associated with a higher mortality risk. Indicators of the requirement for and efficacy of daprodustat have not been reported previously. Therefore, we investigated whether the RDW-coefficient of variation (CV) is an indicator of the requirement for and efficacy of daprodustat when switching from erythropoietin-stimulating agents (ESAs) to daprodustat in patients undergoing maintenance hemodialysis.

Methods: This historical cohort study included 37 patients undergoing maintenance hemodialysis and who switched from ESAs to daprodustat at our affiliated institutions.

The patients were divided into two groups by an RDW-CV cut-off of 14.2%. Propensity score matching was performed by sex, diabetes mellitus, iron sufficiency, albumin concentration, and C-reactive protein concentration. We examined whether there was a difference in the requirement for daprodustat and in the hypoxia-inducible factor prolyl hydroxylase inhibitor resistance index (HRI; defined as daprodustat dose / dry weight / hemoglobin) after 6 months between the two groups.

Results: In the two groups of patients matched for background factors by propensity scores (10 patients with an RDW-CV of ≤14.2%, 10 patients with an RDW-CV of >14.2%), significant differences were observed in both the requirement for daprodustat (4.4 mg at an RDW-CV of ≤14.2%, 8.0 mg at an RDW-CV of >14.2%; $P < 0.05$) and HRI (0.0068 at an RDW-CV of ≤14.2%, 0.0120 at an RDW-CV of >14.2%; $P < 0.05$) after 6 months.

Conclusions: RDW-CV is an indicator of the requirement for and efficacy of daprodustat in hemodialysis patients switching from ESAs.

TH-PO958

High Hemoglobin and High ESA Responsiveness Are Good Prognostic Factors in CKD Patients: An Attribute-Based Analysis Using a Cross-Classification Approach in the BRIGHTEN Study

Hiroshi Kataoka,[1] Terumasa Hayashi,[3] Masaomi Nangaku,[2] Ichiei Narita,[4] Tatsuo Kagimura,[5] Kosaku Nitta,[1] Junichi Hoshino.[1] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Tokyo Daigaku Daigakuin Igakukei Kenkyuka Naikagaku Senko, Bunkyo-ku, Japan; [3]Osaka Kyuseiki Sogo Iryo Center, Osaka, Japan; [4]Niigata Daigaku, Niigata, Japan; [5]Iryo Innovation Suishin Center, Kobe, Japan.*

Background: The BRIGHTEN study, a multicenter, prospective, observational study for patients with non-dialysis-dependent chronic kidney disease with renal anemia, reported the initial erythropoiesis-stimulating agent (ESA) response index (iEResI) to be positively associated with male sex, low hemoglobin (Hb) and iron supplementation, and darbepoetin alfa (DA) administration frequency, suggesting that the iEResI could associated with 'adequacy of anemia treatment'.

Methods: We analyzed the data for the 1,480 patients registered in the BRIGHTEN study. The primary outcome was progression of renal dysfunction. The iEResI was calculated by dividing Hb changes resulting from 12-week DA administration by the weight-adjusted total dose of DA administered in that period. Cross-classification (4 groups) of sex × 65 years was used for analysis per attribute.

Results: The baseline Hb levels were similar in all groups, ranging between 9.7–9.9 g/dL, regardless of sex or age. The DA dose/kg was the lowest in men <65 years (0.80 μg/kg/12 weeks) and the highest in women >65 years (1.08 μg/kg/12 weeks), whereas iEResI was the highest in men <65 years (0.61) and the lowest in women >65 years (0.45). The Kaplan–Meier survival curves indicated that men <65 years and women >65 years had the worst and best renal prognoses, respectively, among the cross-classified sub-cohorts. Multivariate Cox analyses in the present study revealed that high levels of Hb (hazard ratio [HR] 0.75, P<0.001) and high levels of iEResI (HR 0.77, P=0.002) were associated with good renal prognosis. Notably, when divided into four subgroups for cross-classification, anemia was associated with renal prognosis in three subgroups: men <65 years, men >65 years, and women >65 years, whereas iEResI was associated with renal prognosis only in men <65 years. In men <65 years, iEResI (HR 0.63, P=0.030), Hb (HR 0.65, P<0.001), eGFR (HR 0.91, P<0.001), and urinary protein excretion (HR 1.12, P<0.001) were associated with renal prognosis.

Conclusions: Anemia and ESA response index (iEResI) were associated with renal prognosis, suggesting that anemia treatment may improve renal prognosis. Cross-classification clarified that men <65 years may benefit more from anemia treatment than other patients.

TH-PO959

Patient-Reported Outcomes in a Real-World Study of Anemia of CKD in the Middle East and Africa

Mustafa Arici,[1] Saeed Al-Ghamdi,[2,3] Alain G. Assounga,[4] Ahmed El-Koraie,[5] Abigail Mcmillan,[6] Budiwan Sumarsono,[7] Martin Blogg,[8] Daniel B. Ng,[7] Elvira Lansang.[7] *[1]Hacettepe University Faculty of Medicine, Ankara, Turkey; [2]King Abdulaziz University, Jeddah, Saudi Arabia; [3]King Faisal Specialist Hospital & Research Center, Jeddah, Saudi Arabia; [4]University of KwaZulu-Natal, Durban, South Africa; [5]Alexandria University, Alexandria, Egypt; [6]Adelphi Real World, Bollington, United Kingdom; [7]Astellas Pharma Singapore Pte Ltd, Singapore, Singapore; [8]Astellas Pharma Europe Ltd, Addlestone, United Kingdom.*

Background: Anemia is a common complication of chronic kidney disease (CKD) that can negatively impact quality of life. Treatment satisfaction of patients with anemia of CKD living in the Middle East or Africa was explored.

Methods: SATISFY was a real-world study in Egypt, Saudi Arabia, South Africa and Turkey (1 Jun–1 Sep 2022). Physicians and patients completed cross-sectional surveys of treatment perceptions; patients' clinical characteristics were recorded via retrospective review of medical records. Eligible physicians were nephrologists with ≥1 year of experience. Eligible patients were aged ≥18 years with CKD stage 3b–5 at anemia diagnosis and ≥2 years of follow-up data. Data were analyzed descriptively.

Results: In total, 217 physicians and 766 patients (457 [60%] non-dialysis dependent; 286 [37%] dialysis dependent; 23 missing [3%] at data extraction) completed surveys. Mean patient age (standard deviation) was 48 (14) years; 457 (60%) were male. Treatment satisfaction was high (89% of physicians and 84% of treated patients [n=478] were satisfied/very satisfied). Overall, 24% of treated patients had severe-to-very severe anemia symptoms, 15% reported worsening symptoms since initiating most recent treatment and 38% had quite-to-very bothersome side-effects (**Figure**). Over 80% of both patients and physicians reported that physicians made the final treatment decisions.

Conclusions: Despite high treatment satisfaction, patients with anemia of CKD in the Middle East and Africa reported high symptom burden, treatment side-effects and worsening of symptoms, suggesting a high unmet need.

Funding: Commercial Support - Astellas Pharma Singapore Pte Ltd.

Figure 1. Patient global impressions of symptom severity, change in symptoms since initiating most recent treatment and treatment tolerability (proportion of patients)

Data shown are for patients who were receiving treatment or on treatment holiday at time of data extraction.

DD, dialysis dependent; NDD, non-dialysis dependent; Patient Global Impressions of Severity (PGI-S), severity of anemia symptoms within 7 days prior to data collection; PGI-C, Patient Global Impressions of Change (PGI-C), change in anemia symptoms since patients started their current treatment; Patient Global Impressions of Treatment Tolerability (PGI-TT), how bothersome side-effects of current treatment were within the 7 days prior to data collection.

Physical Quality of Life, Anemia, and Iron Stores Among Incident Peritoneal Dialysis Patients: Preliminary Findings from a Multinational Observational Study

Peter G. Pecoits,[1,2] Vladimir Rigodon,[1,3] Yue Jiao,[3] John W. Larkin,[3] Franklin W. Maddux,[4] Peter Kotanko,[5,6] Roberto Pecoits-Filho,[1,2] Thyago P. Moraes,[1,2] Murilo H. Guedes.[1,2] *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]EPICENTER- Center for Epidemiology and Clinical Research, Curitiba, Brazil; [3]Fresenius Medical Care, Waltham, MA; [4]Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany; [5]Renal Research Institute, New York, NY; [6]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Adequate hemoglobin (Hb) and iron reserves are vital for tissue/organ functions, and impaired oxygen delivery and iron availability can lead to fatigue and reduced exercise tolerance, ultimately impacting a patient's quality of life (QoL). We aimed to describe biomarkers of anemia and iron stores across different thresholds of KDQOL Physical Component Summary (PCS) scores in patients starting peritoneal dialysis (PD).

Methods: We used data on incident PD patients from a cohort in Brazil (BR) and the United States (US) during Dec 2004-Jan 2011. Patient, lab, and medication data was compared by PCS categories representing an individual's physical well-being/ functioning. PCS scores were categorized as ≤35 (low PCS), >35 to ≤40 (moderate-low PCS), >40 to ≤50 (moderate-high PCS), >50 (high PCS).

Results: Demographics for patients who started PD (BR=2,022; US=1,657) were consistent between countries for mean age (BR=57.3 & US=55.6 years) and albumin (both 3.7 g/dL), yet there were more males (BR=45% vs US=54%) and patients of a white race (BR=62% vs US=72%) in the US. Mean PCS scores were slightly higher in BR (41.2) vs the US (38.4). Patients in BR had higher TSAT values (43%) vs the US (30.5%). Erythropoietic stimulating agents (ESA) use was higher in the US (90%) than in BR (35%), as was IV iron use (BR=35% vs. US=42%). Across both cohorts, patients with lower PCS tended to be older, with lower albumin and higher ferritin. While use of ESA tended to be a little higher among patients with lower PCS, Hb and TSAT were similarly distributed across groups in both cohorts (**Figure 1**).

Conclusions: Physical QOL among patients starting PD in BR and the US appeared to be related to age, nutrition, and ferritin levels. Patients with low PCS scores had relatively preserved iron stores compared to those with better PCS. Results may suggest inflammation could be a driver of lower quality of life in patients with adequate TSAT and Hgb levels.

TH-PO961

Treatment Patterns and Clinical Events in Non-Dialysis-Dependent CKD Patients with Elevated C-Reactive Protein and Anemia: A Nationwide Hospital-Based Cohort Study in Japan

Kanae Yoshikawa-Ryan,[1] Suguru Okami,[1] Sachiko Tanaka-Mizuno,[2,3] Hidetoshi Uenaka,[3] Takeshi Kimura,[3] Yosuke Ishida,[1] Glen James,[4] Takanori Hayasaki,[1] Takahiro Kuragano.[5] *[1]Bayer Yakuhin Kabushiki Kaisha, Osaka, Japan; [2]Kyoto Daigaku, Kyoto, Japan; [3]Real World Data Co. Ltd., Kyoto, Japan; [4]Bayer AG, Leverkusen, Germany; [5]Hyogo Ika Daigaku, Nishinomiya, Japan.*

Background: Treating anemic CKD patients with inflammation (identified from increased CRP) is challenging due to associated ESA resistance. Contemporary evidence for anemia management and clinical event risk in NDD-CKD patients with elevated CRP are limited.

Methods: A retrospective cohort study was conducted using a Japanese nationwide EMR-based hospital database in adult patients with stage≥3a NDD-CKD and Hb<11g/dL (January 2013–November 2021; N=26,626). Serum CRP was collected during the baseline period. Anemia treatment patterns (initiation and discontinuation) and clinical events including all-cause mortality, CV events, dialysis introduction, hospitalization for AKI, and RBC transfusion were assessed.

Results: 9086 (34.1%) had normal CRP (<0.3mg/dl, mean 0.1mg/dL), 13,642 (51.2%) had elevated CRP (≥0.3mg/dl, mean 5.4mg/dL), and 3898 (14.6%) had no CRP measurements. Compared to normal CRP, patients with elevated CRP had lower Hb (9.8 vs 10.0g/dL), higher ferritin (212.4 vs 140.9ng/mL), and lower TSAT (23.7 vs 27.5%). The cumulative incidence of anemia treatment initiation within 12 months was lower in patients with elevated CRP (34.1 vs 39.0%), including ESA 23.0%, iron oral 16.5% iron iv 6.0%, and HIF-PHI 0.1%. Anemia treatment discontinuation within 12 months was higher in patients with elevated CRP (88.9 vs 86.9%) including ESA 95.4%, iron oral 81.1%, iron iv 99.3%, and HIF-PHI 60.0%. Incidence rates (per 100 person-years) for all clinical events were higher in patients with elevated CRP. (Fig)

Conclusions: The proportion of patients with elevated CRP was high in anemic NDD-CKD. Combination of anemia and elevated CRP was associated with adverse effects. Despite a significantly higher rate of RBC transfusion, many patients remain untreated and for those treated discontinuation was high in both groups.

TH-PO962

Contemporary Treatment Patterns of Clinically Meaningful Anemia Among Non-Dialysis-Dependent CKD Patients in the United States

Junjie Ma,[1] Najma Saleem,[1] Carol Moore,[1] Yinkang Duan,[2] Renee Jaramillo,[2] Robert D. Toto,[3] Matthew R. Weir,[4] Jeffrey S. Berns,[5] Richard A. Lafayette,[6] Jeffrey Petersen.[1] *[1]Amgen, Inc, Thousand Oaks, CA; [2]SimulStat Inc, Solana Beach, CA; [3]The University of Texas Southwestern Medical Center, Dallas, TX; [4]University of Maryland School of Medicine, Baltimore, MD; [5]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [6]Stanford University, Stanford, CA.*

Background: Anemia is a common complication in non-dialysis dependent chronic kidney disease (NDD-CKD) patients, and the appropriate management of anemia is important. This study aimed to describe the treatment patterns of clinically meaningful anemia in line with the KDIGO guidelines [90-day average hemoglobin (Hb) level ≤ 10g/dL after the first date of Hb < 12 g/dL following CKD diagnosis] and the characteristics of NDD-CKD patients with clinically meaningful anemia using Optum Electronic Health Records (EHR) database in the United States (US).

Methods: The data source was Optum EHR which had 73 million patients with at least 1 year of data available from January 1, 2015 to December 31, 2021. NDD CKD patients with anemia (≥ 3 eGFR results <60 mL/min/1.73 m^2 on separate dates) were included in the analysis. Among those patients, the treatment patterns of anemia were described, including the use of erythropoiesis-stimulating agents (ESA), intravenous (IV) iron, and red blood cell (RBC) transfusion.

Results: The study included 14,922 NDD-CKD patients with clinically meaningful anemia. 46.3% were men, mean age was 73.8 ± 10.3 years. Comorbidities were common, with hypertension in 74.1%, peripheral vascular disease in 24.2%, and coronary artery disease in 27.2%. The average baseline eGFR was 44.3 ± 12.8 mL/min/1.73m^2. The average baseline Hb level was 9.2 ± 0.6 g/dL. 96.3% had average baseline Hb between 8.0g/dL to 9.9g/dL, 3.7% in the range of 6.5 g/dl to 7.9g/dl, and 0.1% below < 6.5 g/dL. In this study, IV iron was prescribed to 18.4%, RBC transfusion to 24.6%, and ESAs to 4.8% as first anemia treatment. Throughout the study period, 24.9%, 33.1% and 9.5% of NDD CKD patients received one or more prescriptions of IV iron, RBC transfusion, and ESAs. However, 52.2% did not receive any prescription of IV iron, RBC transfusion, or ESAs after anemia diagnosis.

Conclusions: A substantial proportion of contemporary NDD-CKD patients with clinically meaningful anemia in the US were not receiving treatment. Blood transfusions were prescribed in more than 20% of patients as the first anemia treatment which potentially may be avoidable.

TH-PO963

Anemia Management in Non-Dialysis CKD Patients

Anum Bilal, Yvette T. Johnson, Anju A. Oommen. *Emory University, Atlanta, GA.*

Background: Anemia is common in CKD and is closely associated with advanced stages of CKD. KDIGO recommends treating iron deficiency when TSAT is below 30% and administering ESA when Hb levels drop below 10 mg/dL. Current guidelines suggest maintaining Hb levels between 10-11.5 mg/dL. Despite this, anemia in CKD is often undertreated. This initiative aims to improve anemia management by addressing ESA hypo-responsiveness, administrative gaps, and missed treatments through quality improvements.

Methods: Our quality improvement project aimed to improve anemia management with two goals: 1) Increase Hb levels above 10 g/dL in at least 90% of patients on ESA for six months or more; 2) Decrease transfusion and hospitalization rates by 10%. To achieve these goals, we made minor changes in our clinic and utilized a new EMR system introduced in October 2022. The EMR system allowed for easy scheduling of follow-ups and labs, reducing administrative errors, and ensuring timely interventions. We upgraded the nursing ESA protocol by adding labs to screen for B12 and folate deficiencies. Nurses received re-education on ESA use and anemia management. Nurse Practitioner clinic was

utilized to provide frequent follow-up for patients on home ESA, with a specific Retacrit protocol created for them. We maintained an "ESA panel" list to monitor and review patients on both home and in-clinic ESA for follow-up and outcomes.

Results: The intervention phase started in February 2022, and we anticipate results in the coming months. Data extraction from the EMR system spanned its entire duration to measure changes over the last three quarters. Among the 4,000 clinic patients, 1,722 were diagnosed with anemia based on the ICD codes. Preliminary analysis shows a decrease in blood transfusions from 43 in the first quarter to 30 in the current quarter. Nephrology-ordered iron infusions decreased from 60 to 30, while the use of Retacrit increased from 8 to 17. These initial findings suggest the impact of our interventions on anemia management, but further analysis and evaluation are required to determine the full extent of improvements achieved.

Conclusions: Our study highlights the inadequate management of anemia in CKD patients, leading to avoidable healthcare utilization and compromising the chances of successful transplantation. Improved anemia management is urgently needed to address these concerns and optimize patient outcomes.

TH-PO964

Red Blood Cell Transfusion Use in Dialysis-Dependent Patients with Anemia of CKD in the United States: A Systematic Literature Review

Anna Richards,[1] Anadi Mahajan,[2] Lakshmi R. Gajjala,[2] Supriya C. Desai,[2] Saifuddin Kharawala,[2] Jake N. Hunnicutt.[3] *[1]GSK, Brentford, United Kingdom; [2]Bridge Medical Consulting Ltd, Richmond, United Kingdom; [3]GSK, Collegeville, PA.*

Background: Anemia of chronic kidney disease (aCKD) occurs frequently in dialysis-dependent (DD) patients (pts). Management includes iron supplementation, erythropoiesis-stimulating agents, and when clinically indicated, red blood cell transfusions (RBCT). There are limited collated data on RBCT use in the US; thus, a systematic literature review evaluating frequency, predictive factors, complications, healthcare resource use and costs was undertaken.

Methods: A comprehensive literature search for studies published between 1980 and June 2022 was conducted in Embase, MEDLINE and gray literature sources, to identify real-world (RW) studies and randomized controlled trials (RCTs) reporting RBCT use in US DD CKD pts. Titles and abstracts were reviewed against pre-defined criteria. Results were summarized descriptively.

Results: Of 182 relevant studies identified, 37 RW studies and 22 RCTs reported data in DD CKD US pts. In RW studies, overall frequency of RBCT use ranged from 0.0–66% (n=26); for hemodialysis (HD) pts 0.0–66% (n=19); peritoneal dialysis (PD) pts 5.5–7% (n=1); and HD and PD patients 1.4–35.5% (n=4). Rates of RBCT per 100 person-years (PY) in DD CKD pts ranged from 1.1–504 (n=12); for HD pts 1.1–148.4 (n=10); PD pts 28.8–504 (n=2); and HD and PD pts 19.2–49.7(n=1). RBCT use varied by population, pt factors and study design. For the 22 RCTs (single country [n=7], multi-country [n=15]), overall frequency of RBCT use ranged from 0.7–62%; for HD pts 1.2–62% (n=11); and HD and PD pts 0.7–21.1% (n=10), comparable to RW studies. Rates of RBCT per 100 PY ranged from 3.5–10.3 among HD and PD pts (n=3); no HD only/PD only studies were found. Predictors of RBCT based on quantitative multivariable analysis were identified in 6 RW studies; 5 reported RBCT complication data; 2 HCRU data and 2 direct costs associated with RBCT use and complications.

Conclusions: RBCTs form part of aCKD management in DD CKD US pts, with higher rates in RW studies than in RCTs, although frequencies were comparable. Factors accounting for the variations in frequency, and predictive factors for RBCT use were identified. There are limited data on complications, HCRU and costs of RBCT.

TH-PO965

Hemoglobin (Hgb) Targets in Hemodialysis (HD) Patients: What Is the Optimal Target Range?

Jochen G. Raimann,[1] Ariella E. Mermelstein,[1] Tomislav Kovacevic,[4] Jeffrey L. Hymes,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Vifor Pharma Management Ltd, Glattbrugg, Switzerland.*

Background: Based on RCTs a hgb target range between 10 to 11 g/dL is mandated in the US. Retrospective analyses have shown lower hospitalization and death rates with higher values. We investigated the association between all-cause mortality hazard ratio (HR) and time spent outside the target range.

Methods: We studied incident HD patients (pts) initiated on a long-acting ESA (Mircera; Vifor) within the first 90 days. In pts with at least 12 hgb during the 6-months baseline (BL), we quantified the patient-individual area under the target excursion curve (AUC) 'above' and 'below' the target range (10 to 11 g/dL). We used these metrices as predictors in proportional hazard models predicting HR in the following 18 months. We fitted the HR as a spline function of mean BL hgb. We built an additional model, adjusted for race, sex, age, diabetes, serum albumin and phosphorus, as spline functions in a bivariate fashion as a function of AUC above and below as a contour plot. Sensitivity analyses considering cumulative ESA doses, iron status, vintage, excursion frequency, nutrition and inflammation were performed.

Results: We studied 64,042 pts out of 517,860 pts. We found a preferable target range to be between 10.3 and 12.2 g/dL (**Figure 1**). AUC 'below' in the presence of low AUC 'above' conferred a higher risk of death, whereas a higher AUC "above" only started to increase risk only at around 150 g/dLxdays (**Figure 2**). Sensitivity analyses did not change the interpretation.

Conclusions: A wider and higher target range associates with more favorable outcomes. Limitations of retrospective research apply. Adequately powered and designed experimental studies are needed. **Figure 1:** HR as a function of mean BL hgb levels. **Figure 2:** HR as a function of AUC above and below.

TH-PO966

The Setting of Administration of Erythropoiesis-Stimulating Agents Among Home Dialysis Patients in a Mid-Sized Dialysis Provider

Eric D. Weinhandl,[1,2] Wael F. Hussein,[1,3] Gopa B. Green,[1] Graham E. Abra.[1,3] *[1]Satellite Healthcare, San Jose, CA; [2]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [3]Stanford University School of Medicine, Stanford, CA.*

Background: For patients undergoing home hemodialysis (HHD) or peritoneal dialysis (PD), an erythropoiesis-stimulating agent (ESA) may be administered by healthcare professionals during clinic visits or self-administered at home. The latter option may be convenient for patients, including those with long travel time to the clinic, but may increase the risk of nonadherence. We assessed the incidence and predictors of self-administration of ESAs among home dialysis patients.

Methods: We analyzed the electronic health records of Satellite Healthcare, a mid-sized, not-for-profit dialysis provider. In 2021 and 2022, we identified all administered doses of epoetin alfa and darbepoetin alfa among home dialysis patients. For each administered dose, we identified the prescribed frequency of administration, the home dialysis modality (HHD, PD), and months since home dialysis initiation, as well as the age, sex, and race/ethnicity of the patient. We fit a logistic regression of self-administration of the ESA, using generalized estimating equations to account for intra-patient correlation.

Results: The cohort comprised 1984 patients and 54,301 ESA dose administrations. Overall, 42.0% of ESA doses were self-administered. In HHD patients, 78.1% of doses were self-administered; in PD patients, the corresponding statistic was 25.0%. Use of darbepoetin alfa, relative to epoetin alfa, was not associated with self-administration (adjusted odds ratio, 0.88; 95% CI, 0.56-1.37). Relative to once-monthly dosing, adjusted odds ratios of self-administration were 2.04 (95% CI, 1.70-2.45) with every-other-week dosing, 3.27 (2.64-4.05) with once-weekly dosing, and 4.84 (3.49-6.73) with multiple doses per week. Neither age nor sex was associated with self-administration, but relative to non-Hispanic White patients, Asian patients were less likely to self-administer ESAs (adjusted odds ratio, 0.52; 95% CI, 0.32-0.86). Each one-month increment in home dialysis duration was associated with 3% higher adjusted odds of self-administration.

Conclusions: Among contemporary home dialysis patients, self-administration of ESAs is common with HHD and uncommon with PD. Increased frequency of ESA administration and longer duration of home dialysis were associated with higher odds of self-administration, whereas Asian race was associated with lower odds.

TH-PO967

Randomized Assessment of Auryxia® Therapy for In-Center and Home Dialysis Patients

Varshasb Broumand,[1] F. David Newby,[2] Stephanie Brillhart,[3] Martha Block,[3] Amanda Leppink,[3] Mark D. Danese,[4] Geoffrey A. Block.[3] *[1]South Texas Renal Care Group, San Antonio, TX; [2]Nephrology and Hypertension Specialists, PC, Dalton, GA; [3]US Renal Care, Plano, TX; [4]Outcomes Insights Inc, Calabasas, CA.*

Background: Auryxia (ferric citrate) is an FDA approved iron-based phosphate binder for adults with dialysis-dependent chronic kidney disease. This study investigated the impact of Auryxia as primary phosphorus lowering therapy on utilization of erythropoiesis-stimulating agent (ESA) and intravenous (IV) iron.

Methods: In this randomized, open-label, active-controlled, multicenter study (NCT04922645), subjects receiving ESA and either in-center hemodialysis or home dialysis were randomized 1:1 to Auryxia (starting dose of 6 tablets per day) or remain on standard of care (SOC) phosphate lowering therapy for up to 6 months. Dose adjustments were at investigator discretion to achieve target serum phosphorus. The primary endpoint was difference in change from baseline (BL, Month -3 to Day 1) to efficacy evaluation period (EEP, Months 4-6) in mean monthly ESA and IV iron doses between groups. Secondary endpoints included difference in proportion with Hb ≥10.0g/dL and serum phosphate ≤5.5 mg/dL.

Results: 209 subjects were randomized to Auryxia (n=103) or SOC (n=106). The two groups had generally similar baseline characteristics, although atherosclerotic CV disease and congestive heart failure were more common in the SOC group. During the EEP, the mean treatment difference in ESA administration was -31 mcg/month (p=0.02). A non-statistically significant change in mean monthly IV iron administration of -37 mg/month (p=0.17) was observed. Mean Hb, TSAT, and ferritin all increased from BL to the EEP in the Auryxia vs. SOC group. The proportion of subjects with Hb ≥10.0 g/dL and serum phosphate ≤5.5 mg/dL did not differ between groups. Three subjects stopped Auryxia due to GI intolerance (n=2) or adverse events (n=1). Serious adverse events (SAEs) occurred in 39% of subjects receiving Auryxia vs. 59% in those receiving SOC. No related SAEs were reported. Fewer patients randomized to Auryxia experienced CV (8.7% vs. 13.2%) or infectious (8.7% vs. 17.9%) SAEs.

Conclusions: Treatment with Auryxia as compared to remaining on SOC phosphate binders resulted in increased Hb, increased iron stores, statistically significantly less average monthly ESA use and a non-statistically significant reduction in monthly IV iron use.

TH-PO968

Survey of Erythropoiesis-Stimulating Agent (ESA) Use in Non-Dialysis-Dependent CKD (NDD-CKD) in Civilian vs. Military Practice

Robert Nee,[1,2] James D. Oliver,[2] Tracey L. Koehlmoos,[2] Christina M. Yuan.[1,2] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]Uniformed Services University of the Health Sciences, Bethesda, MD.*

Background: There is a paucity of data on barriers to ESA use in the pre-dialysis chronic kidney disease (CKD) population. In the context of universal health care coverage within the Military Health System (MHS), we evaluated ESA use in patients with stage 3-5 NDD-CKD among nephrologists practicing in military facilities vs. former military nephrologists practicing in the civilian sector.

Methods: We conducted an anonymous online survey of nephrologists assigned to military facilities and graduates of the Walter Reed Nephrology fellowship program from 1988-2022 who have transitioned to civilian practice (n=104).

Results: The response rate was 63/104 (61%) with a 95% complete rate. Most of the respondents (97%) were in active clinical nephrology practice; 53% were in military facilities and 41% in civilian practice. Fifty-two percent of military and 29% of civilian nephrologists estimated that 5%-10% of their NDD-CKD patients were receiving ESA therapy (p=0.09). Sixty-eight percent of military nephrologists vs. 58% of civilian nephrologists would start an ESA if the hemoglobin (Hgb) ≤ 9 g/dL (p=0.46). Sixty-eight percent of military nephrologists vs. 62% civilian nephrologists targeted a Hgb between 10-11 g/dL on ESA (p=0.69). Patients had their ESA administered in the clinic, at home, or in both settings in 42%, 10%, and 45%, respectively, in military practice vs. 38%, 8% and 42%, respectively, in civilian practice (p=0.49). Compared to military nephrologists, civilian nephrologists were more likely to identify low reimbursement rate (29% vs. 0%, p=0.0013), drug cost and affordability (54% vs. 0%, p<0.001), and restriction on ESA formulations by health insurance (38% vs. 3%, p=0.001) as barriers to ESA therapy. Military nephrologists were more likely to report that there were no particular barriers to ESA therapy compared to their civilian counterparts (52% vs. 12%, p=0.002).

Conclusions: Although the practice patterns of ESA therapy in NDD-CKD are comparable between military and civilian nephrologists who had similar training/background, the former group experiences less barriers to implementing therapy in the MHS. *Disclaimer: The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy of the Department of Defense or the U.S. Government.*

TH-PO969

Conversion from Darbepoetin Alfa to Epoetin Alfa in a Multi-Center Cohort of In-Center Hemodialysis Patients

Gopa B. Green,[1] Sheila Doss-McQuitty,[1] Dongyang Shang,[1] Steven Chang,[3] Alex Yang,[3] Eric D. Weinhandl.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [3]Xelay Acumen, San Mateo, CA.*

Background: Over the past two decades of anemia treatment, many dialysis patients have been converted from a short-acting erythropoiesis-stimulating agent (ESA) to a long-acting ESA. However, there is little data about conversion of a population in the opposite manner, from a long-acting ESA to a short-acting ESA. We investigated the initial results of conversion of a population of in-center hemodialysis patients from darbepoetin alfa to epoetin alfa in early 2023.

Methods: During January and February 2023, 69 outpatient hemodialysis centers at Satellite Healthcare converted from first-line anemia treatment with darbepoetin alfa (*Aranesp*) to treatment with epoetin alfa (*Epogen*). Patients were converted according to a protocol-based dosing algorithm derived from the *Aranesp* package insert and published studies. To assess changes in anemia-related parameters before and after conversion, we analyzed hemoglobin, ESA dose, transferrin saturation, and ferritin in patients who completed ≥4 hemodialysis treatments during a 2-week period of each month from July 2022 to April 2023; the period comprised the prescheduled week of blood draws and the week thereafter.

Results: On average, monthly cohorts included 6633 patients, among whom 6193 (93.4%) completed ≥4 treatments during the 2-week observation period. In 2022, 5.0% of ESA-treated patients received epoetin alfa, 94.8% received darbepoetin alfa, and 0.2% received both agents. In February 2023, 99.3% of ESA-treated patients received epoetin alfa, 0.4% received darbepoetin alfa, and 0.3% received both agents; by April, 99.6% received epoetin alfa. The distribution of hemoglobin was stable during and after the conversion process (table). The ratio of mean weekly epoetin alfa dose (IU) in February 2023 to darbepoetin alfa dose (mcg) in 2022 was 309; from February to April, mean weekly epoetin alfa dose decreased 3%. From December 2022 to March 2023, distributions of transferrin saturation and ferritin shifted modestly downward.

Conclusions: A protocol-based ESA dosing algorithm can be used to convert in-center hemodialysis patients from darbepoetin alfa to epoetin alfa in a short timeframe, without disruption of the hemoglobin distribution.

	Jul-Dec 2022	Jan 2023	Feb 2023	Mar 2023	Apr 2023

Efficiency and Efficacy of Anemia Therapy with Epoetin Beta: Results from a Randomized Controlled Trial of Therapy Software vs. Standard of Care

David J. Joerg,[1] Doris H. Fuertinger,[1] Kevin Ho,[2] Lin-Chun Wang,[3] Lela Tisdale,[3] Xiaoling Ye,[3] Stephan Thijssen,[3] Peter Kotanko.[3,4] *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Fresenius Medical Care North America, Waltham, MA; [3]Renal Research Institute, New York, NY; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Anemia is common in patients on hemodialysis (HD) and typically treated with erythropoiesis-stimulating agents (ESA). Recurrent ESA dose adjustments are challenging due to delayed effects on patient hemoglobin (Hb) levels and interpatient variability in ESA responsiveness. We developed a novel software providing personalized ESA-dose recommendations based on a mathematical model of anemia. Here, we report results from a randomized controlled trial, comparing the software versus standard-of-care (SOC) anemia treatment in using ESAs efficiently to bring patients' Hb levels into a given target range.

Methods: We enrolled 96 subjects on HD; 82 of them completed the study. Patients were randomized to be managed by our anemia therapy software (intervention group, "INT", 40 patients) or continued SOC treatment (42 patients). For 26 weeks, the software generated biweekly patient-specific ESA recommendations to target a Hb of 10–11 g/dL. Recommendations were passed on to clinicians.

Results: In the SOC group, mean Hb levels across the study period showed a negative dependence on the mean amount of ESA per month (Fig. 1A) and total number of ESA administrations during the study period (Fig. 1B). In the INT group, this effect was significantly reduced (Fig. 1). The mean amount of ESA per kg patient weight was also significantly reduced in the INT group (INT: 1.1 [0.6–1.5] mcg/30 days/kg, median [IQR]; SOC: 1.5 [0.9–2.1] mcg/30 days/kg; Wilcoxon rank-sum test, p=0.031) while the number of ESA administrations within the study period was comparable in both groups (INT: 9 [6-10]; SOC: 8 [6-10]; Wilcoxon rank-sum test, p=0.76).

Conclusions: Trial results suggest that our therapy software utilizes ESA more efficiently and controls Hb levels better at low and high ESA dose levels than SOC treatment, while requiring less ESA per kg patient weight and a comparable number of ESA administrations.

Funding: Commercial Support - Fresenius Medical Care

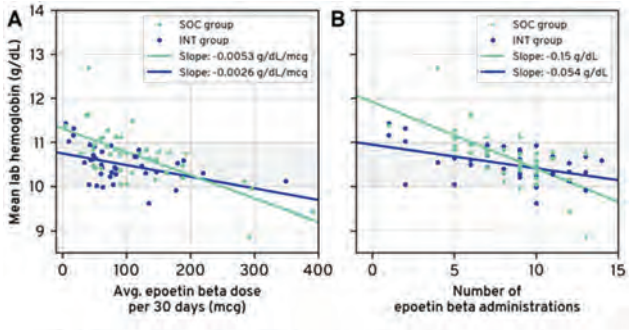

Fig. 1: Mean lab hemoglobin within the study period (26 weeks) vs. (A) avg. epoetin beta dose per 30 days and (B) number of epoetin beta administrations for the intervention (INT) group (blue) and the standard-of-care (SOC) group (green). Dots show patient-individual data points, lines show linear regressions. Data points of 3 patients who received zero administrations were excluded from the analysis (intervention group: 2; SoC group: 1).

TH-PO971

Medication Evaluation of Early Post-Transplant Anemia Management

Estefany Yanqui,[1] Allyson M. Kluener,[1,2] Nicholas J. Parrish,[1] Madison Cuffy,[1] Amit Govil.[1] *[1]University of Cincinnati Health, Cincinnati, OH; [2]The Christ Hospital, Cincinnati, OH.*

Background: Post-transplant anemia (PTA) is a common phenomenon in kidney transplant recipients (KTR). There are currently no consensus guidelines for PTA, however patients are commonly treated with erythropoiesis-stimulating agents and receive iron deficiency correction. Dosing and duration for these regimens remain unclear. The purpose of this study is to evaluate the efficacy of erythropoietin use and intravenous iron supplementation on hemoglobin in KTR with PTA.

Methods: This is a single center, retrospective cohort study from 10/1/2021 – 4/1/2022. Primary outcome was hemoglobin at 6 months in KTR who received ESA, iron sucrose or neither. Secondary outcomes included kidney function, iron studies, transfusions, dapsone use > 7 days post-transplant. All continuous data was analyzed using a student T-test. All categorical data was analyzed using a chi square test.

Results: Ninety-seven KTR were included in our final analysis. A total of 59 (60.8%) of KTR received either ESA alone or in combination with IV iron. Hemoglobin and renal function trends over time are represented on Figure 1 and 2. Of note, 16 (42.1%) of the patients who did not receive ESA or IV iron were living donor transplant recipients. There was no difference in hemoglobin outcomes at 6 months in patients who received IV iron repletion with ESA versus ESA alone (Figure 3). Patients who received IV iron < POD 30, had significantly higher Hgb outcomes than those who got IV iron >POD 30 (Figure 4). Dapsone use >7 days was associated with significantly reduced Hgb during the duration of use (Figure 5).

Conclusions: Patients with PTA did not show additional hemoglobin increases when given any ESA as compared to those who received no ESA. Differences in treatment groups including higher numbers of deceased donors and poor graft function may have contributed to the poor response to ESA. A prospective, randomized study is warranted for the best use of these interventions in a judicious manner.

TH-PO973

Hospitalizations and Red Blood Cell (RBC) Transfusions in Patients with Dialysis-Dependent-CKD (DD-CKD) on Auryxia® Compared with Other Phosphate Binders

F. David Newby,[1] Varshasb Broumand,[2] Stephanie Brillhart,[3] Martha Block,[3] Amanda Leppink,[3] Mark D. Danese,[4] Geoffrey A. Block.[3] *[1]Nephrology and Hypertension Specialists, PC, Dalton, GA; [2]South Texas Renal Care Group, San Antonio, TX; [3]US Renal Care, Plano, TX; [4]Outcomes Insights, Inc, Calabasas, CA.*

Background: Auryxia (ferric citrate) is an FDA approved iron-based phosphate binder for adults with dialysis-dependent chronic kidney disease (DD-CKD). Primary efficacy results of this study of Auryxia as phosphorus lowering therapy compared to standard of care (SOC) in patients with CKD undergoing dialysis showed a statistically significant reduction in erythropoiesis-stimulating agents (ESAs) and a reduction in intravenous (IV) iron. Here, we further explore hospitalizations and red blood cell (RBC) transfusions.

Methods: This open-label, active-controlled, multicenter study (NCT04922645), in subjects receiving ESA and either in-center or home dialysis, were randomized 1:1 to receive Auryxia or remain on SOC phosphorus-lowering therapy for up to 6 months. Dose adjustments were at investigator discretion to achieve target serum phosphorus. The primary endpoint was the difference in change from baseline (BL, Month -3 to Day 1) to efficacy evaluation period (EEP, Months 4-6) in mean monthly ESA and IV iron doses between groups. Safety and exploratory analyses estimated the rate of hospitalizations, hospital days, RBC transfusion, and units of packed red blood cells (PRBC) per person-month from day 1 through the end of study.

Results: 209 subjects were randomized to Auryxia (n=103) or SOC (n=106). The two groups had generally similar baseline characteristics, although atherosclerotic CV disease and congestive heart failure were more common in the SOC group. Hospitalization event rates per 100 person-months were 7.4 and 10.6 in the Auryxia (40 events) and SOC (63 events) treatment groups, respectively. Subjects in the Auryxia group had 60 hospitalization days per 100 person-months compared to 82.6 days in the SOC group. RBC transfusion rates per 100 person-months were 1.5 and 4.2 in the Auryxia (8 events) and SOC (25 events) treatment groups, respectively. The rates of PRBC transfusions, per 100 person-months were 2.4 and 7.1 with Auryxia (13 units) and SOC (42 units), respectively.

Conclusions: Treatment with Auryxia as compared to remaining on SOC phosphate binders resulted in lower hospitalization rates, fewer hospitalization days, fewer RBC transfusions and fewer PRBC units used.

Validate Optimal Iron Management When Using Hypoxia-Inducible Factor-Prolyl Hydroxylase Domain Inhibitor (HIF-PHI) in Renal Anemia: Excessive Iron Administration Is Unnecessary

Chie Ogawa,[1,2] Ken Tsuchiya,[3,2] Kunimi Maeda.[1,2] *[1]Maeda Institute of Renal Research, Kawasaki, Japan; [2]Biomarker Society, INC, Kawasaki, Japan; [3]Department of Blood Purification, Tokyo Women's Medical University, Tokyo, Japan.*

Background: Hypoxia-inducible factor prolyl hydroxylase domain inhibitors (HIF-PHIs), new therapeutic agent for renal anemia, shows its effects through a mechanism not only by transcription factor-mediated erythropoietin production but also by iron metabolism. Therefore, although the importance of iron supplementation has been emphasized, it is presumed that iron utilization is also promoted endogenously and that a mischievous iron overdose is not necessary. In the present study, we examined optimal iron management under HIF-PHI administration.

Methods: The subjects were 30 maintenance hemodialysis patients who switched from darbepoetin alfa (DA) to Roxadustat (Rox). To examine iron kinetics during the switchover, reticulocyte hemoglobin content (CHr), which reflects recent Hb synthesis, was measured in addition to conventional iron-related parameters. The iron-regulated hormone hepcidin was also measured. Iron deficiency was defined as CHr<32.0 pg. ROC curves were used to determine cut off values for the point at which CHr sufficiency was met.

Results: After the switching to Rox, there was a significant increase in Hb and RBC and a decrease in ferritin and hepcidin (all, $p<0.01$), suggesting increased iron demand. In the results of the ROC curve with the endpoint CHr≥32pg on Day0, cutoff values for s-ft and TSAT were respectively 49.7 ng/mL and 21.6% on Day 0 and 35.5 ng/mL and 16.2% on Day 28. With the endpoint CHr ≥ 32.0 pg on Day 28, cutoff values for s-ft and TSAT on Day 0 were 81.6 ng/mL and 23.9%, respectively. In a patient with s-ft 184 ng/mL and TSAT 10.6%, there was a rapid increase in Hb from 8.0 to 10.0 g/dL after 2 weeks of switching.

Conclusions: The present study suggests that a serum ferritin of at least 81.6 ng/mL at the time of switching, and most recently 35.5 ng/mL, may avoid iron deficiency when switching from DA to Rox. Iron deficiency is pointed out to increase the risk of thrombosis due to hypercoagulability and increased platelet count. In our previous report (Acta Haematol 2022), the cutoff value of ferritin for platelet increase was 77.2 ng/ml (area under the curve 0.76, 95% CI 0.55 – 0.96) when ROX was administered. Moreover, it has also been shown that functional iron deficiency with ferritin sufficiency may result in a rapid rise in Hb. Thus, the amount of iron required at the time of switchover may be less than expected.

TH-PO975

A Regional Perspective of Hypoxia-Inducible Factor-Prolyl Hydroxylase (HIF-PH) Inhibitors in Dialysis

Meghan Weiss, Chris Dudzenski, Stephen Regan. *Spherix Global Insights, Exton, PA.*

Background: Hypoxia-inducible factor prolyl hydroxylase enzyme inhibitors (HIF-PHI) were developed as an alternative to erythropoiesis-stimulating agents (ESA) to treat anemia in chronic kidney disease (CKD) patients. As of fielding, daprodustat was the only approved HIF-PHI in the United States (US) and roxadustat and vadadustat were approved in the European Union (EU); all agents are indicated to treat dialysis patients, while only roxadustat is approved to treat CKD non-dialysis patients in the EU. This analysis of nephrologist attitudes provides insight into regional perceptions of HIF-PHIs as a treatment option for dialysis patients.

Methods: Responses were collected via online surveys with 207 US-based nephrologists (February 2023) and 208 EU-based nephrologists (March through April 2023). Additional insights were captured via an independent, retrospective chart audit of 1,282 CKD non-dialysis patient records collected from 263 EU-based nephrologists (December 2021 through February 2022). EU countries surveyed included the UK, Germany, Italy, France, and Spain.

Results: To date, roxadustat has experienced slow uptake among EU nephrologists, with physicians reporting that 6% of their HD patients and 8% of their PD patients are currently on therapy. In the CKD non-dialysis setting, audited patient records reveal that roxadustat treatment rates are even lower at 3.5%, with increased use as patients progress in their CKD. As of fielding in the US, daprodustat had not been officially launched; however, 52% of physicians report that they are likely to be more reserved and selective in their prescribing once it is available, relying heavily on peers and KOLs for guidance. US physicians also expect that availability and dialysis center protocols will be key drivers of adoption. Looking towards future use, 55% of EU nephrologists report that the advantages of roxadustat outweigh the potential risks in dialysis patients, compared

to 44% of US physicians believing the same for daprodustat. Most nephrologists across regions (70% EU, 55% US) indicate they are anxious to gain clinical experience with the drugs.

Conclusions: Despite recognition of the benefits of HIF-PHIs in dialysis patients, slow adoption of roxadustat in the EU and hesitancy among US-based nephrologists to prescribe daprodustat may stifle treatment evolution in the anemia space, with ESAs likely to remain the standard of care in the dialysis setting.

TH-PO976

Efficacy and Safety of Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors (HIF-PHIs) in Patients with CKD: Metanalysis of Phase 3 Randomized Controlled Trials

Roberto Minutolo, Carlo Garofalo, Silvio Borrelli, Luca De Nicola. *Universita degli Studi della Campania Luigi Vanvitelli Scuola di Medicina e Chirurgia, Napoli, Italy*.

Background: HIF-PHIs are new therapeutic agents for anemia of CKD. We evaluated by metanalysis and meta-regression efficacy and safety of HIF-PHIs in patients with CKD-related anemia.

Methods: We selected phase-3 RCTs comparing HIF-PHIs and ESA in dialysis and non-dialysis CKD patients. Efficacy outcomes were the changes from baseline of hemoglobin (Hb), iron parameters and intravenous iron dose; safety outcomes included cancer, major adverse cardiovascular events (MACE), MACE+ (MACE plus hospitalization for HF, unstable angina or thromboembolism), thrombotic events (deep vein thrombosis, pulmonary embolism), artero-venous fistula (AVF) thrombosis, and death.

Results: In 26 RCTs (N=24,387 patients) included, comparators were long-acting ESA (darbepoetin or CERA) in 17 RCTS and short-acting ESA (epoetin-α or-β) in 9 trials. Summary of difference between HIF-PHI and ESA for efficacy and safety is depicted in Figure 1. Random effect meta-analysis of unstandardized mean difference between HIF-PHIs and ESAs showed a significant change from baseline in Hb levels. Meta-regression analysis showed significantly higher Hb change for HIF-PHIs in younger patients and in studies using short-acting ESA as comparator (+0.21 g/dL, 95%CI, 0.12-0.29 vs -0.01, 95%CI, -0.09-0.07 in studies using long-acting ESA, P<0.001). Heterogeneity was not affected by type of HIF-PHIs. In comparison with ESAs, HIF-PHIs induced a significant decline in hepcidin and ferritin and a significant increase in serum iron and TIBC; IV iron dose was lower with HIF-PHI. Rate ratio of cancer, MACE, MACE+, thrombotic events and death did not differ between HIF-PHIs and ESAs.

Conclusions: In comparison with ESA therapy, HIF-PHIs are effective in correcting anemia and improving with a significant impact on iron metabolism without notable difference among various agents. No safety signals emerge with use of HIF-PHIs.

	HIF-PHI versus ESA	P
EFFICACY [Mean changes from baseline (95%CI)]		
Hemoglobin (g/dL)	0.10 (0.02-0.17)	**0.012**
Hepcidin (ng/mL)	-19.2 (-28.5 to -9.9)	**<0.001**
Serum iron (µg/dL)	9.7 (5.7 to 13.8)	**<0.001**
Total Iron Binding Capacity (µmol/L)	36.3 (31.9 to 40.7)	**<0.001**
Transferrin Saturation (%)	-0.3 (-1.7 to 1.0)	0.636
Ferritin (ng/mL)	-16.8 (-32.4 to -1.3)	**0.034**
IV iron dose (mg/week)	-3.4 (-6.2 to -0.5)	**0.020**
SAFETY [rate ratio (95%CI)]		
Cancer	0.93 (0.76-1.13)	0.520
MACE	1.00 (0.94-1.07)	0.905
MACE+	1.01 (0.95-1.06)	0.875
Thrombotic/pulmonary embolism events	1.08 (0.84-1.38)	0.967
Artero-venous fistula thrombosis	1.02 (0.93-1.13)	0.227
All-cause death	1.02 (0.95-1.13)	0.670

Summary effects of HIF-PHIs compared with ESA on efficacy and safety measures

TH-PO977

Evaluating the Outcomes of Roxadustat Treatment for Anemia in Dialysis-Dependent CKD: A Systematic Review and Meta-Analysis

Muhammed Khaled Elhadi Elfaituri, Taha K. Elfaituri, Hazem Faraj, Ahmed Msherghi. *University of Tripoli Faculty of Medicine, Tripoli, Libya*.

Background: Chronic kidney disease (CKD) patients often grapple with anemia, a complication that severely impinges on their quality of life and overall prognosis. Roxadustat, an innovative oral hypoxia-inducible factor prolyl hydroxylase inhibitor, has emerged as a potential solution to this pervasive issue. However, its effectiveness and safety need to be comprehensively analyzed. This study aims to investigate the efficacy and safety of Roxadustat for anemia in CKD patients.

Methods: We systematically searched PubMed, Web of Science, and Cochrane Library databases until October 2022. We sought randomized controlled trials (RCTs) that compared Roxadustat with Epoetin Alfa or a placebo in dialysis-dependent CKD patients. The primary outcomes were changes from baseline in hemoglobin, hepcidin, ferritin, and transferrin saturation (TSAT) levels. Secondary outcomes were the incidence of adverse and major adverse events. The data were aggregated using a random-effects model and expressed as standardized mean differences (SMDs) for continuous outcomes or relative risks (RRs) for dichotomous outcomes. The meta-analysis was executed using R version 4.0.3, employing the metafor and meta packages.

Results: We included five studies comprising 3,478 participants (1,847 administered Roxadustat and 1,631 given Epoetin Alfa or a placebo). Roxadustat was found to significantly enhance hemoglobin (SMD: 0.32, 95% CI: 0.12-0.52, $p < 0.01$, I^2=39%) and lower hepcidin levels (SMD: -0.29, 95% CI: -0.45- -0.14, $p < 0.01$, I^2=23%) from baseline, as compared to the control group. However, changes in ferritin (SMD: 0.03, 95% CI: -0.17-0.24, $p = 0.76$, I^2=0%) and TSAT levels (SMD: 0.14, 95% CI: -0.07-0.34, $p = 0.19$, I^2=0%) were not statistically significant. Adverse events (RR: 1.02, 95% CI: .96-1.07, $p = 0.5$, I^2=33%) and major/critical adverse events (RR: 1.05, 95% CI: 0.96-1.16, $p = 0.3$, I^2=20%) were marginally more frequent in the Roxadustat group, but these differences lacked statistical significance.

Conclusions: Roxadustat may potentially elevate hemoglobin and decrease hepcidin levels in dialysis-dependent CKD patients. However, its effects on ferritin and TSAT levels are unclear. Future, more extensive studies are needed to validate these findings and determine Roxadustat's optimal use.

TH-PO978

Roxadustat vs. Erythropoiesis in the Nephroprotection Treatment of Patients with CKD and Anemia

Yan Ouyang, Hong Ren, Jingyuan Xie, Xiaocen Fu, Xiao Li, Weiming Wang, Nan Chen. *Shanghai Jiao Tong University Medical School Affiliated Ruijin Hospital, Shanghai, China*.

Background: Roxadustat has been approved for patients with chronic kidney disease(CKD) and renal anemia in China since 2019. It is now widely used around the world. Although studies have found that roxadustat may improve tissue fibrosis, inflammation, and oxidative stress, there have been few studies on its nephroprotection. We aim to elucidate the nephroprotection of roxadustat versus erythropoiesis-stimulating agent (ESA) in CKD patients with anemia.

Methods: We conducted a retrospective cohort study of CKD patients with anemia diagnosed in ruijin hospital between January 2010 and December 2022. CKD patients aged 14 years at diagnosis, coexisting with anemia, an estimated glomerular filtration rate(eGFR) greater than 15 ml/min/1.73m^2, 24-hour urine protein, follow-up data, and received roxadustat three times a week or ESA, were included. The patients were 1:1 assigned to two groups by propensity score matching based on indicators including sex, age, eGFR, 24-hour urine protein and follow-up time. The primary outcome was composite renal endpoint defined as a 50% decline in eGFR and end-stage kidney disease (ESKD).

Results: A total of 288 patients were included after PSM. The significantly lower incident of composite renal outcomes in the roxadustat group compared with the ESA group were observed (39.58% *vs.* 26.39%, p=0.017). By multivariate Cox regression analysis, roxadustat was associated with a lower risk for the composite kidney outcomes compared to ESA (HR=0.61, 95% CI: 0.40-0.94, p=0.023) after adjusting for age, gender, baseline eGFR, 24-hour urine protein, MAP, and hemoglobin. Moreover, subgroup analysis showed similar results in different subgroups defined by hyperlipidemia, high urine acid. Notably, in the roxadustat group, eGFR decreased at a slower rate than in the ESA group [median eGFR slope: -2.14 *vs.* -7.46 ml/min/1.73m^2/yrs, p=0.099]. We found that roxadustat group had a higher hemoglobin level than the ESA group (110.64±17.13 *vs.* 104.33±23.14 g/L, p=0.04). Compared to the ESA group, the roxadustat group had more 50% decline in proteinuria after 12 months (43.06% *vs.* 29.86%, p=0.02).

Conclusions: Roxadustat is superior than ESA in treating CKD patients combined with anemia, especially for nephroprotection. Our findings need to be validated in further.

TH-PO979

Efficacy and Safety of Desidustat for the Treatment of Anaemia in Patients with CKD: A Retrospective, Open-Label, Single-Centre Study

Ashwinikumar Khandekar. *Kingsway Hospitals, Nagpur, India*.

Background: CKD is associated with an increased risk of anaemia, significantly impacting patients' quality of life. Current therapy includes injectable erythropoiesis-stimulating agents which have limitations and safety concerns. Desidustat has shown promise in stimulating endogenous erythropoiesis and addressing anaemia in CKD. This study assesses the real-world clinical efficacy & safety of the desidustat treatment in CKD patients with anaemia.

Methods: This is a retrospective, observational, open-label, single-centre, single-arm study of CKD anaemic patients. Patients were administered with desidustat 100mg orally thrice a week for a period of 24 weeks. 83.3% of patients received 300mg/ week dose of desidustat as starting dose. Dose adjustment was done every 4 weeks as per the Hb level of the patients. The primary outcome was to assess the change in the Hb from baseline to the end of 24 weeks and the secondary outcome was the evaluation of AEs if occur.

Results: Out of 84 patients, 51.2% were previously on ESA therapy, 48.8% were treatment naïve, 38.1% were on dialysis and 56% non-dialysis patients. The results show statistically significant improvement in mean Hb level at the end of 24 weeks (1.306g/dL; p<0.01). Within groups including - treatment naïve patients, patients previously on ESA, non-dialysis and on dialysis patients improvement in mean Hb from baseline to end of 24 weeks was statistically significant, with most significant improvement seen in treatment naïve patients (p<0.01) and non-dialysis patients (p<0.01), the improvement in mean Hb values being 9.5±0.91 to 11.3±0.87, 9.7±1.16 to 11.2±0.87 respectively. The serum potassium showed mild variation from a mean of 4.7±0.80 to 4.8±0.47. AEs were observed in 13.1% patients, including AV Fistula failures (4.8%), LVF (2.4%), Arterial thrombosis (1. 2%), DVT (1.2%), Acute Pancreatitis (1.2%), Haemorrhagic stroke (1.2%) and Transaminitis (1.2%).

Conclusions: The short-term desidustat treatment demonstrated statistically significant improvement in Hb levels in patients. Therefore, making it a viable alternative

to current treatment options. Since the present study was retrospective in nature the causality assessment was not assessed. Hence, further research is needed to gather long-term data and compare the cardiovascular safety of desidustat with the injectable ESAs.

A National, Multi-Center, Prospective Study Evaluating the Long-Term Safety and Effectiveness of Roxadustat for Anemia Treatment in Patients with CKD (ROXSTAR Registry)

Xiaoying Du,[1] Yaomin Wang,[1] Qi Guo,[1] Changyun Qian,[2] Yiqing Wu,[2] Shuting Pan,[2] Jianghua Chen.[1] *[1]Kidney Disease Center, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China; [2]FibroGen, Shanghai, China.*

Background: Anemia is associated with increased morbidity/mortality in chronic kidney disease (CKD) patients. Roxadustat (RXD) stimulates erythropoiesis & has demonstrated effectiveness for anemia treatment. We conducted a real-world clinical study on the safety/effectiveness of RXD for CKD-associated anemia (CKD-anemia) treatment & its effect on quality of life (QOL).

Methods: This phase 4, prospective, clinical study enrolled patients aged ≥18 years with CKD-anemia (with or without dialysis) in 61 centers in China. Patients received a starting dose of 70–120-mg RXD orally thrice a week for 52 weeks. Primary & secondary outcomes were long-term safety & effectiveness. Safety assessments included the number of patients with treatment-emergent adverse events (TEAEs). Effectiveness was assessed by hemoglobin (Hb) change from baseline & percentage of patients with mean Hb >100 g/L. QOL was assessed by changes from baseline at 24 weeks in the Short Form (SF)-36 Vitality (V) & Physical Functioning (PF) subscales & self-reported Rapid Assessment of Physical Activity (RAPA) scores.

Results: Of 2024 patients enrolled, 1830 were RXD-naïve, 193 were previously RXD-treated, & 1 was unknown. In total 2021 (99.9%) received ≥1 RXD dose (hemodialysis: n=851 [42.1%]; peritoneal dialysis: n=676 [33.4%]; non-dialysis-dependent: n=494 [22.4%]) & 1592 (78.8%) completed the study. The mean±standard deviation (SD) age was 50.2±13.5 years, the weekly RXD dose was 254.13±103.16 mg & 53.8% were male. In total 1643/2021 patients (81.3%) reported TEAEs (hyperkalemia, 15.4%; upper respiratory tract infection, 10.0%; peripheral oedema, 5.2%) & 219 (10.8%) patients had drug-related TEAEs (nausea, 1.3%; hypertension, 1.0%; insomnia, 0.9%). TEAEs led to death in 38 patients (1.9%), but none were deemed related to RXD. In RXD-naïve patients (n=1804), the mean±SD Hb increased by 14.28±0.38 g/L over weeks 36–52. From weeks 24–52 the mean percentage of patients with Hb >100 g/L was 86.3% in RXD-naïve patients & 85.9% in treated patients (baseline, 45.6% & 61.1%). There were no changes in QOL at 24 weeks.

Conclusions: RXD had tolerable safety & increased Hb to >100 g/L in >85% of patients over 24–52 weeks; these results support RXD treatment for CKD-anemia patients in a real-world setting.

Low vs. Standard Starting Dose Oral Roxadustat for Treating Anemia in Chinese Patients with CKD on Dialysis: A Prospective, Randomized Clinical Trial

Bi-Cheng Liu,[1] Yan Tu,[1] Yan Xu,[2] Li Yao,[3] Bei ru Zhang,[4] Tiekun Yan,[5] Aiping Yin,[6] Xinzhou Zhang,[7] Min Yang,[8] Jun Liu,[9] Caili Wang,[10] Xiaomei Peng,[11] Wang Jianqin,[12] Wei Niu,[13] Wenqing Jiang.[13] *[1]Institute of Nephrology, Zhongda Hospital, Southeast University School of Medicine, Nanjing, China; [2]The Affiliated Hospital of Qingdao University, Qingdao, China; [3]The First Hospital of China Medical University, Shenyang, China; [4]Shengjing Hospital of China Medical University, Shenyang, China; [5]Tianjin Medical University General Hospital, Tianjin, China; [6]The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [7]Shenzhen People's Hospital, Shenzhen, China; [8]The First People's Hospital of Changzhou, Changzhou, China; [9]Southern Medical University Nanfang Hospital, Guangzhou, China; [10]The First Affiliated Hospital of Baotou Medical College of Inner Mongolia University of Science and Technology, Baotou, China; [11]The People's Hospital of Guangxi Zhuang Autonomous Region, Nanning, China; [12]Lanzhou University Second Hospital, Lanzhou, China; [13]FibroGen China, Beijing, China.*

Background: Part 1 of this phase 4 study (NCT04059913) descriptively evaluated the efficacy and safety of a one dose step lower roxadustat starting dose in Chinese chronic kidney disease patients receiving dialysis as compared to the approved standard starting dose.

Methods: ESA naïve and previously ESA-treated patients on dialysis were randomized to receive a standard or lower roxadustat starting dose TIW for 20 weeks, titrated to maintain hemoglobin (Hb) within 100–120 g/L. The primary endpoints were the proportion of ESA-naïve patients achieving Hb≥110 g/L in the first 20 weeks and the proportion of ESA-treated patients achieving mean Hb≥100 g/L averaged over week 17 - 21 visit. Other efficacy endpoints include change from baseline (CFB) in Hb over week 17-21 etc. Adverse events (AEs) were monitored and assessed.

Results: Among 318 patients randomized to the lower vs. standard starting dose (ESA-naïve: 57 vs. 56; ESA-treated: 103 vs. 102), baseline characteristics including overall Hb (ESA-naïve: 87.73 vs. 86.17 g/L; ESA-treated: 104.81 vs. 105.34 g/L) were generally comparable. Numerically comparable proportions of low and standard dose patients within the ESA naïve and ESA-treated groups achieved the pre-defined Hb target levels (ESA naïve: 77.2% vs. 73.2%; ESA-treated: 82.5% vs. 79.0%). The mean Hb CFB to the average over week 17-21 visits were also comparable (ESA-naïve:20.7 g/L vs. 21.6 g/L; ESA-treated:4.9 g/L vs. 6.0 g/L). Treatment-emergent AEs (TEAEs) were comparable between treatment arms.

Conclusions: One dose level lower roxadustat starting dose showed similar efficacy and safety profile as compared to the approved standard starting dose in Chinese CKD patients receiving dialysis.

Real-World Clinical Use of Roxadustat in Patients with Anemia of CKD: Interim Results from a Post-Marketing Surveillance Study in Japan

Shusaku Abe,[1] Haruko Sugamori,[1] Yusuke Tanaka,[1] Kazuhiko Tsuruya.[2] *[1]Astellas Pharma Inc, Tokyo, Japan; [2]Nara Medical University, Nara, Japan.*

Background: Roxadustat is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI) approved in Japan to treat anemia of non-dialysis-dependent (NDD) or dialysis-dependent (DD) chronic kidney disease (CKD). A post-marketing surveillance study is underway in Japan to examine the safety and effectiveness of roxadustat in real-world clinical use. Here, we report the results of a planned interim analysis from this study.

Methods: This open-label, non-comparative, non-interventional observational study had an observation period of 104 weeks. Eligible patients had anemia of CKD and were naive to roxadustat. Enrollment began in June 2020 (DD CKD patients receiving hemodialysis [HD] or peritoneal dialysis [PD]) and January 2021 (NDD CKD), with a planned interim analysis as of December 16, 2022. Incidence of adverse drug reactions (ADRs), including specified safety outcomes, and change in mean hemoglobin (Hb) level were reported descriptively after 12 weeks of roxadustat treatment.

Results: In total, 1468 patients (safety analysis population: NDD: 768; HD: 608; PD: 90; 2 patients received both HD and PD) were analyzed. A total of 839 patients (57.2%) switched from erythropoiesis-stimulating agents (ESA) to roxadustat, 16 patients (1.1%) concomitantly used ESA and roxadustat, 586 patients (39.9%) were ESA-naive, 23 patients switched from a HIF-PHI (1.6%), and 4 (0.3%) were missing data for prior ESA use. ADRs and serious ADRs occurred in 17.03% and 6.54% (overall), 13.02% and 3.52% (NDD CKD), 20.39% and 9.70% (HD), and 25.56% and 10.00% (PD), respectively (**Table**). Mean Hb level (g/dL) changed from 9.82 at baseline to 11.79 (NDD CKD), 9.83 at baseline to 11.06 (HD), and 10.22 at baseline to 11.21 (PD) after 12 weeks of roxadustat treatment.

Conclusions: The results from this interim analysis of a post-marketing surveillance study in Japan found that the incidence of ADRs was similar to the known roxadustat safety profile and showed the effectiveness of roxadustat in patients with anemia of CKD in clinical practice for up to 12 weeks.

Funding: Commercial Support - This study was funded by Astellas Pharma, Inc.

Table. Incidence of ADRs and Serious ADRs

	Overall Population N=1468			NDD Patient Population N=768			HD Patient Population N=608			PD Patient Population N=90

TH-PO983

Safety and Efficacy of Vadadustat Thrice Weekly in Patients with Anemia due to Dialysis-Dependent CKD

Hakan R. Toka,[1] Wenli Luo,[2] Irfan Ullah,[2] Zhihui (Sunny) Yang,[2] Zhiqun Zhang,[2] Steven K. Burke.[2] *[1]Nova Clinical Research, Bradenton, FL; [2]Akebia Therapeutics Inc, Cambridge, MA.*

Background: Vadadustat (VADA) is an oral hypoxia-inducible factor prolyl hydroxylase inhibitor (HIF-PHI). This study investigated the efficacy and safety of conversion from the long-acting IV erythropoiesis-stimulating agent methoxy polyethylene glycol-epoetin beta (CERA; MIRCERA®) to oral VADA thrice weekly (TIW) for the maintenance treatment of anemia in patients with dialysis-dependent chronic kidney disease (DD-CKD).

Methods: This randomized (1:1:1), open-label, active-controlled, sponsor-blinded trial compared VADA, at starting doses of 600 mg and 900 mg TIW, and CERA treatment in patients with DD-CKD for up to 52 weeks. Primary and secondary endpoints were mean change in hemoglobin (Hb) from baseline to the primary evaluation period (PEP; weeks 20–26) and secondary evaluation period (SEP; weeks 46–52), respectively (noninferiority margin, –0.75 g/dL). Other key endpoints included the proportion of patients requiring red blood cell (RBC) transfusions during the PEP and those with Hb levels >11g/dL and 12g/dL. Treatment-emergent adverse events (TEAEs) and serious TEAEs were reported as primary safety endpoints.

Results: VADA TIW (n=304) was noninferior to CERA (n=152) for mean change in Hb from baseline during the PEP (least-squares mean difference: –0.33 g/dL; 95% CI: –0.53, –0.13) and SEP (–0.33 g/dL; 95% CI: –0.56, –0.09). The percentage of patients receiving RBC transfusions during the PEP was 3% for both groups. The proportion of patients with Hb levels >11g/dL and 12g/dL were lower in the VADA group (61.6% and 20.5%, respectively) vs the CERA group (78.2% and 30.6%, respectively). VADA and

CERA had similar incidences of TEAEs and serious TEAEs. The proportion of patients with TEAEs resulting in death was 9% in the VADA group and 11% in the CERA group. The most common TEAEs were COVID-19 and diarrhea in both groups. Incidence of cardiac arrest was more common in the CERA group (7.3%) compared to the VADA group (1.7%). No differences in abnormal liver enzymes were observed between treatment groups.

Conclusions: VADA TIW was noninferior to CERA in Hb efficacy. VADA had a lower proportion of patients with Hb excursions compared to CERA. The incidence of TEAEs and serious TEAEs was similar between VADA and CERA.

Effects of Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors on Copper Metabolism and Association with Organ Damage in CKD

Tomofumi Moriyama, Kensei Taguchi, Goh Kodama, Kei Fukami. *Division of Nephrology, Department of Medicine, Kurume University School of Medicine, Kurume, Japan.*

Background: Excess copper accumulates in visceral organs throughout the body producing reactive oxygen species which ultimately causes organ damage. In patients with chronic kidney disease (CKD), excess copper accumulation is known to be a risk factor for worsening renal function. HIF-PhD inhibitors are recently used to treat renal anemia worldwide. Several studies have demonstrated that HIF-PhD inhibitors affect iron kinetics. Meanwhile, there are few reports on copper metabolism. In the present study, we investigated whether HIF-PhD inhibition has an impact on copper metabolism in CKD rodents model and patients with CKD or patients with peritoneal dialysis (PD).

Methods: 7 patients with advanced CKD and 9 patients with PD were enrolled in the present study. Serum copper, iron, and zinc were evaluated before and 3 months after the initiation of HIF-PHD inhibitors. In vitro, CuSO4 was administered to cultured proximal tubules to explore whether excess cooper accumulation causes cellular damage. In vivo experiments, GSK360A, a HIF-PHD inhibitor, GSK360A plus HIF-1α inhibitor, or GSK360A plus HIF-2α inhibitor were injected into C57BL/6J mice after induction of CKD by repeated low dose cisplatin injections to examine which HIF compartment is involved in cooper metabolism.

Results: Serum copper was elevated after the treatment with HIF-PhD inhibitors in patients with advanced CKD (104±5→131±24 μg/dL) and PD (101±15→148±20 μg/dL). Meanwhile, serum iron and zinc concentration were not affected by HIF-PhD inhibitors. In vitro experiment, co-incubation with CuSO4 increased α-SMA and cleaved caspase3, suggesting that excess cooper causes fibrotic pathway and ultimately cell death. In vivo experiment, serum copper was elevated in CKD rodents when compared to control, which was further enhanced by treatment with GSK360A. Pharmacological inhibition of HIF-1α did not affect GSK360A-induced increase in copper accumulation, suggesting that HIF-2α might be involved in copper metabolism in response to HIF-PhD treatment.

Conclusions: Copper accumulation can be induced by HIF-PhD inhibitors which might be associated with renal fibrosis and cell death. HIF-2α might mediate copper metabolism in response to HIF-PhD inhibitors.

Anemia Treatment Among Prevalent Hemodialysis and Peritoneal Dialysis Patients in the United States

Jiannong Liu,[1] Julie Rouette,[2] Suying Li,[1] Sally Wetten,[3] Haifeng Guo,[1] Gema Requena,[3] George Mu,[4] Liyuan Ma,[4] Jolyon Fairburn-Beech,[3] David T. Gilbertson,[1] Anna Richards,[3] James B. Wetmore.[1,5] *[1]Chronic Disease Research Group, Hennepin Healthcare Research Institute, Minneapolis, MN; [2]GSK, Montreal, QC, Canada; [3]GSK, Brentford, United Kingdom; [4]GSK, Collegeville, PA; [5]Division of Nephrology, Hennepin Healthcare, Minneapolis, MN.*

Background: This study aims to assess anemia treatment in chronic kidney disease (CKD) patients (pts) undergoing dialysis to understand the evolving landscape of CKD anemia management.

Methods: Using USRDS data, we conducted an observational, descriptive cohort study of adults (≥18 years) receiving dialysis on Jan 1, 2018 (index) and with 6 months of Medicare fee-for-service coverage pre-index. Pts with prior kidney transplant, cancer, and hospitalization for heart failure, myocardial infarction, or stroke in the previous month were excluded. Follow-up was from index until death, loss of Medicare coverage, kidney transplantation, or Dec 31, 2019. Use of erythropoiesis-stimulating agents (ESA), IV iron, and blood transfusions were assessed during follow-up. ESA, iron use, and transfusions were identified by a combination of HCPCS codes, ICD-10-PCS procedure codes, and/or revenue center codes. ESA use was calculated as days covered/week (total days covered by ESA divided by follow-up time in weeks; 3 epoetin alfa administrations covered 7 days; 1 darbepoetin for 14 days), IV iron calculated as number of administrations per week, and transfusions as number per 100 person-years. Overall rates were calculated as weighted mean of pt-level rates using follow-up as weight.

Results: Overall, 209,408 pts were on HD and 20,647 on PD; median follow-up was 24.0 months (HD, IQR: 14.6–24.0; PD, 13.0–24.0), PD pts were younger (median age 62.2 vs 64.7 yrs). More PD pts were White (53.5 vs 39.1%), higher income (34.0 vs 48.7% with Medicare/Medicaid dual enrollment), and with glomerulonephritis as the cause of end-stage kidney disease (15.2 vs 8.5%). PD pts had fewer comorbidities and shorter dialysis duration (median 2.7 vs 3.9 yrs). During follow-up (**Table**), PD pts had lower ESA and IV iron use (1.24 vs 2.64 days of ESA coverage/week; 0.15 vs 0.48 iron administrations/week) and a higher transfusion rate (38.3 vs 32.4 /100 person-years).

Conclusions: In this descriptive study, PD pts had lower ESA and iron use and a higher transfusion rate than HD pts during follow-up. Anemia management may need improvement among PD patients.

Funding: Commercial Support - Funded by GSK (Study 217316)

TH-PO986

Effect of Multiple Doses per Day vs. Daily vs. Alternate Day Oral Iron Therapy in Iron Deficiency Anemia with CKD

Nilang G. Patel,[1,2] Scott Silvey,[1,2] Pradeep Arora.[3,4] *[1]Virginia Commonwealth University, Richmond, VA; [2]VA Richmond Medical Center, Richmond, VA; [3]University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY; [4]VA Western New York Healthcare System, Buffalo, NY.*

Background: We investigated the effect of 2-3 times a day (typical clinical practice) vs. once-a-day vs. alternate-day oral iron administration on the improvement of Hgb and iron indices in patients with Iron deficiency anemia (IDA) & CKD.

Methods: Retrospective observational study of the veterans with IDA [defined as Hgb < 12 g/dL and either 1.) iron saturation < 20% or 2.) ferritin < 50 micrograms/L] and CKD [defined by eGFR < 60 ml/min/1.73m²] who received the first index outpatient prescription of oral iron for 90 days with one additional refill within 120 days from 2009-2019. Patient were classified into three groups: daily (once-a-day), multi-doses per day (> = 2-3 times per day) and alternate-day dose based on their oral iron dosing schedule. Groups were analyzed with longitudinal mixed effects models to estimate mean improvement (change-from-baseline) in Hgb & iron indices over the course of the time.

Results: 25,882 veterans were included in final cohort. Table 1 shows baseline characteristics & change in Hgb & iron indices at 90 & 210 days. Figure 1 shows estimated Hgb improvement in different groups. Hgb & iron indices significantly improved in multi-dose iron group compared to the daily group. Alternate day group showed slower pace of improvement in Hgb & iron indices. After adjusting all covariates, it did not affect the final results.

Conclusions: All different oral iron strategy improves Hgb & iron indices over time, although, multi-dose per day strategy improves at a much faster pace. The choice of oral iron therapy should depend on the rapidity of response desired, & patient preference due to adverse effects.

Long-Term Safety of Hypoxia-Inducible Factor Prolyl Hydroxylase Inhibitors in CKD: A Systematic Review and Meta-Analysis of Randomized Trials

Jeffrey Ha,[1,2] Swapnil Hiremath,[3] Min Jun,[1,2] Suetonia Palmer,[4] David C. Wheeler,[5] Daniel W. Coyne,[6] Vlado Perkovic,[1,2] Sunil Badve.[1,2] *[1]The George Institute for Global Health, Newtown, NSW, Australia; [2]University of New South Wales, Sydney, NSW, Australia; [3]University of Ottawa, Ottawa, ON, Canada; [4]University of Otago, Dunedin, New Zealand; [5]University College London, London, United Kingdom; [6]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Hypoxia-inducible factor (HIF) prolyl hydroxylase inhibitors are an oral treatment for anemia of chronic kidney disease (CKD). We assessed long-term safety of HIF prolyl hydroxylase inhibitors in CKD.

Methods: In this systematic review and meta-analysis, MEDLINE, Embase and Cochrane databases were searched to March 2023. Randomized trials comparing HIF prolyl hydroxylase inhibitors with an erythropoiesis-stimulating agent (ESA) or placebo with ≥48 weeks of follow-up were eligible. Major adverse cardiovascular events (MACE), individual components of composite cardiovascular endpoints, thrombotic events, and non-cardiovascular adverse events were evaluated. We conducted analyses separately in people with CKD treated with dialysis and those not treated with dialysis (PROSPERO registration CRD42021278011).

Results: Twenty-five trials involving 26,478 participants proved eligible. Of these, 13 trials were conducted in 13,230 participants with dialysis-dependent CKD, and 12 trials involved 13,248 participants with CKD not requiring dialysis. There was no evidence that HIF prolyl hydroxylase inhibitors and ESA had different effects on MACE in people with dialysis-dependent CKD (relative risk [RR] 0.99, 95% CI 0.92 to 1.08) and non-dialysis CKD (RR 1.08, 95% CI 0.95 to 1.22). Similarly, there was no evidence that HIF prolyl hydroxylase inhibitors and placebo had different effects on MACE (RR 1.10, 95% CI 0.96 to 1.27) in people with non-dialysis CKD. The lack of difference between HIF prolyl hydroxylase inhibitors and ESA or placebo was observed for individual components of MACE, and for cardiovascular death. The safety of HIF prolyl hydroxylase inhibitors for other outcomes was similar to ESA in dialysis-dependent CKD. In non-dialysis CKD, dialysis access thrombosis, infections, hyperkalemia and seizures occurred more frequently in the HIF prolyl hydroxylase inhibitor group than the placebo group. In non-dialysis CKD, esophageal or gastric erosion was more frequent with HIF prolyl hydroxylase inhibitors than ESA.

Conclusions: The long-term effects of HIF prolyl hydroxylase inhibitors were similar to ESA in dialysis-dependent CKD. However, HIF prolyl hydroxylase inhibitors increased the incidence of some adverse outcomes in non-dialysis CKD.

TH-PO988

The Effect of Sodium-Glucose Cotransporter 2 Inhibitors on Hemoglobin Levels in Patients with CKD

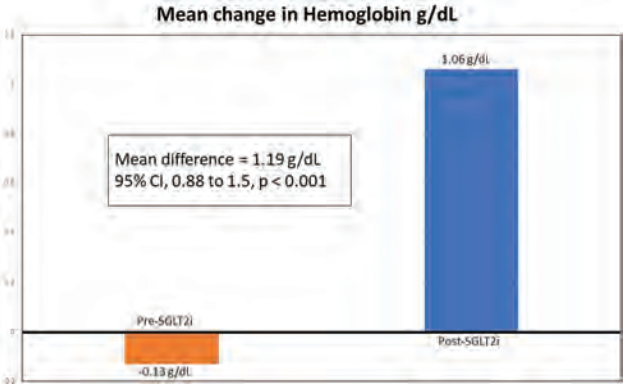
Carmen E. Cervantes,[1] Tareq Hanouneh,[2] Veena K. Acharya,[1,3] Jonathan G. Lim,[1,3] Hyung M. Lim,[1,3] Mohamad A. Hanouneh.[1,3] *[1]Johns Hopkins University, Baltimore, MD; [2]Mayo Clinic in Florida, Jacksonville, FL; [3]Nephrology Center of Maryland, Baltimore, MD.*

Background: Sodium-Glucose Cotransporter 2 Inhibitors (SGLT2is) confer kidney and cardiovascular protection in patients with chronic kidney disease (CKD). Some studies have analyzed the effects of SGLT2is on hemoglobin levels. Potential mechanisms for rising hemoglobin include hypoxia-induced activation of HIF2α, hepcidin inhibition resulting in iron metabolism modulation, and hemoconcentration. We aimed to assess the effect of SGLT2is on hemoglobin levels in CKD patients.

Methods: We conducted a retrospective study in patients seen in a community nephrology practice with eGFR 25-90 ml/min per 1.73 m^2 who received either dapagliflozin 10 mg daily or empagliflozin 10 mg daily between 1/2022 and 9/2023. The primary outcome was the mean difference in hemoglobin levels 8 months prior and 8 months post initiation of SGLT2i therapy.

Results: Among 402 patients screened from 1/2022 to 9/2023, 72 were prescribed either dapagliflozin 10 mg daily or empagliflozin 10 mg daily, with a mean eGFR of 51.2 ml/min/1.73 m^2. Of those 72 patients, 46 (63.88%) were male and 26 (36.11%) female. No one received any iron supplements or erythropoietin therapy. The mean hemoglobin level 8 months before initiating SGLT2i therapy was 12.8 g/dL, with a mean drop of 0.13 g/dL (95% CI, –0.32 to +0.06) in 8 months. Eight months following the addition of SGLT2is, patients experienced an increase in hemoglobin levels of 1.06 g/dL (95% CI, 0.88 to 1.25). Overall, we observed a mean hemoglobin difference of 1.19 g/dL (95% CI, 0.88 to 1.5, $p < 0.001$) before and after initiating SGLT2i therapy. (Figure 1)

Conclusions: The use of either dapagliflozin or empagliflozin for eight months resulted in a significant elevation in hemoglobin levels in patients with CKD. Larger prospective trials can help better understand the size of the effect and confirm the mechanisms that explain this finding. Elevation of hemoglobin with SGLT2is may be closely linked to the reduction of cardiovascular mortality and heart failure hospitalization risk.



TH-PO989

Utility of a Novel Point-of-Care Test for Albuminuria in Communities at High Risk for CKD

Somkanya Tungsanga,[1,2] Win Kulvichit,[1] Sadudee Peerapornratana,[1] Kearkiat Praditpornsilpa,[1] Aminu K. Bello,[2] Nattachai Srisawat.[1] *[1]Chulalongkorn University, Bangkok, Thailand; [2]University of Alberta, Edmonton, AB, Canada.*

Background: Albuminuria is a key prognostic marker in chronic kidney disease (CKD). Reliable testing tools for albuminuria and are scarce in many world settings due to limited availability and cost. We tested the utility of novel and low-cost point-of-care test (POCT) for albuminuria to asymptomatic individuals at high risk of CKD in Thailand.

Methods: A community-based cohort study of 2,307 adults with hypertension, diabetes, and/or over age 60 in Ban Phaeo District, Samut Sakhon Province, Thailand. We measured serum creatinine and urine albumin-creatinine ratio (UACR) using a POCT urine albumin strip test (Albii®, K. BioSciences, Bangkok, Thailand) and urine dipstick test for protein, and validated with standard laboratory measures. To confirm the chronicity of abnormalities, participants with albuminuria, regardless of eGFR or patients with eGFR <60 ml/min/1.73m^2 at the first screening (suspected CKD) received follow-up tests for CKD risk. CKD was defined based on standard criteria.

Results: At baseline, 468 participants had reduced eGFR and/or albuminuria. Follow ups were conducted with 260 participants 3 months later, and 140 were confirmed with CKD (Figure 1). Among those diagnosed with CKD, 68 had albuminuria (UACR ≥30mg/g) with normal eGFR, 49 had impaired eGFR without albuminuria, and 22 had both albuminuria and impaired eGFR (Figure 2). The median eGFR was 93.23 [87.82, 98.73] ml/min/m^2, and the median UACR was 9.15 [5.09, 20.96] mg/g for all participants. The POCT urine albumin strip showed a sensitivity of 0.86, specificity of 0.98, and accuracy of 0.96 compared to the standard UACR. Conversely, the POCT urine dipstick for protein had poor sensitivity, positive predictive value, and accuracy. The test results and interpretation were mailed to each participant in a sealed envelope. Participants identified with CKD were advised to attend the outpatient kidney clinic at the district hospital for appropriate management to slow CKD progression.

Conclusions: The urine albumin strip test is a highly effective tool for conducting point-of-care screening for early CKD among high-risk populations. Given the test's low cost- and ease of use, it can facilitate the implementation of large-scale and affordable early detection programs for CKD.

Micral-Test® Strip to Detect Albuminuria Among Patients with CKD Risk Factors

Xi Yan Ooi, Wanting Weng, See Cheng Yeo. *Tan Tock Seng Hospital, Singapore, Singapore.*

Background: CKD is often asymptomatic and remains undiagnosed in its early stages. Screening and early identification of CKD allows implementation of treatment to delay progression and prevent adverse outcomes. To improve screening uptake and decrease screening cost in primary care, we piloted a 2 stage-screening strategy:pre-screening using microalbuminuria (Micral-Test®) strips, and confirmatory laboratory testing for positive results. In this study, we examined the testing characteristics of this screening strategy.

Methods: We provided Micral-Test® strips to 15 General Practitioners in Singapore. Individuals with these risk factors were offered screening:diabetes mellitus(DM), hypertension(HT), BMI>27.5kg/m^2, age>60 years, cardiovascular/cerebrovascular disease, family history of kidney disease or smoking history. Patients with positive test were offered a specialist review for confirmation of albuminuria. We calculated a minimum sample size of 97 is needed to achieve 10% margin error and 95% confidence interval.

Results: 209 patients were recruited between April 2022 to April 2023; 72% had HT and 23% had DM. 111(53%) were screen positive and 43% of screen-positive subjects

did not follow up with confirmatory testing. Of the 63 patients who proceeded with a confirmatory urine albumin-creatinine ratio test, 37(58.7%) had confirmed albuminuria; 29 moderately increased albuminuria and 8 severely increased albuminuria. The positive predictive value (PPV) of Micral-test was highest in patients with DM, with or without other comorbidities, and is relatively low in patients without any comorbidities(age>60 years only).

Conclusions: Majority of patients with risk factors for CKD have undiagnosed albuminuria. Our study suggests that Micral-test® strip can be used as an effective screening tool for albuminuria especially in patients with DM. There remains a large proportion of patients with screen positive results that declined further follow-up; further education and screening strategy should target this group for better CKD identification.

Funding: Commercial Support - AstraZeneca

Test characteristics in different subpopulations

Population	Screen positive(%)	PPV(%)
All	53.1	58.7
Diabetes Mellitus	77.6	80.8
Hypertension	53.0	58.8
Diabetes mellitus, hypertension and age>60 years old	74.1	77.8
Age>60 years old only	33.3	0

TH-PO991

Trace Proteinuria Is a High-Risk Marker for Developing ESRD and for Shortening the Lifespan: Findings from an 18-Year Follow-Up Cohort with Half a Million Asian Participants

Min Kuang Tsai,[1,2] Chi Pang Wen.[2] *[1]Taipei Medical University, Taipei, Taiwan; [2]National Health Research Institutes, Zhunan, Taiwan.*

Background: Trace proteinuria, obtained by urine dipstick, has not received its due attention in clinic visits. It was particularly overlooked in the younger people, even though it had three times more trace proteinuria than the elderly. This study aims to investigate its role in kidney diseases such as End Stage Renal Disease and its association with mortality outcomes and life-shortening effects in a large Asian cohort.

Methods: A cohort of 646,987 adults, who have undergone health screening programs successively since 1994, were followed for a median of 18 years. Through encrypted identification numbers, 49,216 deaths and 4,101 ESRD cases were identified. Dipstick, in contrast to the old color-comparison method, is a semi-automated computer-assisted urinalysis system. Results reported as trace, 1+, 2+, and more. The association between proteinuria, ESRD, and mortality risks was evaluated using Cox proportional hazards models.

Results: Trace proteinuria existed around 5% among healthy adults, contributed to nearly half of all CKD (9.5%), with younger adults (age <60 years) having a threefold higher prevalence than the elderly (age ≥60 years). Trace proteinuria significantly increased the risk of ESRD independent of eGFR, with up to 4-5 folds in normal eGFR subjects. The HR was 3.54, 95% CI: 2.67, 4.69 when eGFR ≥ 90 ; HR: 3.86, 95% CI: 3.08, 4.84 when eGFR 60-89; HR: 12.26, 95% CI: 9.24, 16.28 when eGFR 45-59; HR: 44.60, 95% CI: 31.39, 60.55 when eGFR 30-44 ml/min/1.73m^2) when compared with negative proteinuria. Participants with trace proteinuria also had a significantly higher risk of all-cause mortality (HR: 1.48, 95% CI: 1.42, 1.54), and associated with a reduction in life expectancy of up to 4-5 years. Dipstick tests demonstrated relatively high sensitivity (84%) and specificity (96%) in detecting microalbuminuria.

Conclusions: Trace proteinuria, overlooked in the clinics, was associated with a 4-5 fold increase in developing ESRD later in life and a shortened lifespan of five years, with nearly 50% increase in all-cause mortality. Trace proteinuria can be screened easily in the clinic or among the public with a dipstick, an inexpensive test with instant results. More than 80% with microalbuminuria in an apparently healthy population could be identified.

TH-PO992

Cost-Effectiveness of Home-Based Screening for Albuminuria in the General Population in the Netherlands

Dominique van Mil,[1,2] Xavier G. Pouwels,[3] Lyanne M. Kieneker,[1] Ronald W. van Etten,[4] Birgitte M. Evers-Roeten,[5] Marc Thelen,[6,7] Marc H. Hemmelder,[8] Ron T. Gansevoort,[1] Hendrik Koffijberg.[3] *[1]University Medical Centre Groningen, Department of Nephrology, Groningen, Netherlands; [2]University Medical Centre Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, Netherlands; [3]University of Twente, Health Technology and Services Research Department, Enschede, Netherlands; [4]Amphia Hospital, Department of Internal Medicine, Breda, Netherlands; [5]General Practice Tholos, Zevenbergen, Netherlands; [6]Amphia Hospital, Result Laboratory for Clinical Chemistry, Breda, Netherlands; [7]Radboud University Medical Centre, Department of Laboratory Medicine, Nijmegen, Netherlands; [8]Maastricht University Medical Centre, Department of Internal Medicine, Maastricht, Netherlands.*

Background: Screening the general population for albuminuria may identify individuals at high risk of chronic kidney disease (CKD) events and cardiovascular disease (CVD) and allow early preventive interventions. Previous studies on the cost-effectiveness of albuminuria population screening were inconclusive, modelled screening by family physicians, and included only CKD events. We evaluated the cost-effectiveness of home-based general population screening for increased albuminuria to prevent CKD and also CVD events.

Methods: We developed an individual-level health-state transition model to assess cost-effectiveness from the Dutch healthcare perspective with a lifetime horizon. Inputs were based on the THOMAS study, a prospective study in which we screened the general population aged 45-80 years, published in Lancet 2023. THOMAS consisted of a home-based albuminuria screening and subsequent elaborate screening of individuals with elevated albuminuria for CKD and CVD risk factors, to be treated by their family physicians. Risks of CKD and CVD events were calculated by simulating albuminuria and eGFR progression and the SCORE2 algorithm. Treatment relative risk reduction, quality of life weights, resource use, and cost inputs were obtained from the literature. Outcomes included the number of events, total costs, quality-adjusted life years (QALYs), and incremental cost-effectiveness ratio (ICER) of screening versus usual care (no screening), based on probabilistic analysis.

Results: The relative reduction in lifetime dialysis, kidney transplantation, non-fatal myocardial infarction, non-fatal stroke, and fatal CVD events of screening was respectively 11%, 12%, 6%, 5%, and 2%. The incremental costs and QALYs of screening were €1,584 and 0.18 QALYs. This resulted in an ICER of €8.689/QALY, which would be considered cost-effective at the Dutch willingness to pay threshold of €20.000/QALY. The probability of screening being cost-effective for this threshold was 96%. Screening was more cost-effective in subjects aged 65-80 years, compared to those aged 45-65, and if implementation of care after screening was improved.

Conclusions: Home-based screening for increased albuminuria to prevent cardiovascular and chronic kidney disease events is likely cost-effective.

TH-PO993

Screening for Urine Protein as a Risk Factor for ESRD Using a Large Claims Database

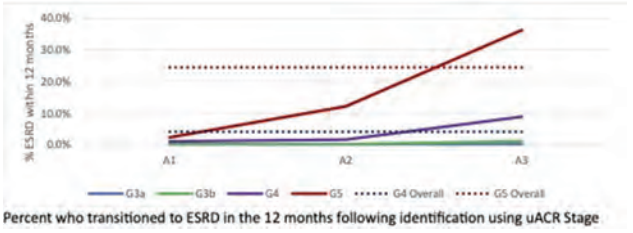
Rahul Dhawan, Ashley Crossman, Lisa M. Latts, Gregory Wysocky. Optum Kidney Solutions: Nurses, Product Team and the OHS Medical Office Team. *Optum Inc, Eden Prairie, MN.*

Background: Proteinuria screening serves as a crucial diagnostic tool in identifying chronic kidney disease (CKD) and mitigating the risk of progression to end-stage renal disease (ESRD). Timely detection and intervention can enhance patient outcomes and provide cost savings, as proteinuria serves as a predictor for ESRD and all-cause mortality rates.

Methods: A large health insurance claims database was used to analyze the relationship between estimated glomerular filtration rate (eGFR), urine albumin-creatinine ratio (uACR), and the progression to ESRD in a population of Medicare members with CKD stages 3a to ESRD during the index month of January 2021. The analysis included data from the 12 months prior to the index month to determine the presence or absence of proteinuria and data from the 12 months following the index month to determine ESRD transition. Data from 32,194 individuals was included. Sources included Medicare claims, labs, and demographics.

Results: Of the 32,194 members in this analysis, 47% were female and the average age was 57.3 years. Thirty-six percent of individuals who had eGFR stage G5 and A3 (severely increased) degree of proteinuria in the twelve months starting January 2021 progressed to ESRD. Twenty-three percent of individuals with eGFR stage G5 patients without proteinuria screening progressed to ESRD. Eighteen percent of the population had proteinuria screening and 22.9% of these patients were CKD 3B, 12.1% were stage 4, and 13.8% were stage 5. Of these patients, 26% were A3, 42% were A2 (Moderately increased) and 32% were A1 (Normal to mildly increased).

Conclusions: Proteinuria screening can provide an early warning of CKD that may progress to ESRD and potentially allow for risk mitigation. In this analysis, more than one-third of CKD G5A3 patients progressed to dialysis within a year. Prompt detection of patients with proteinuria and management, coupled with adherence to ACE and SGLT2 inhibitors, may curtail progression. Utilizing a health plan database is a useful tool to identify individuals who have proteinuria and are at risk of CKD progression and earlier diagnosis can lead to improved outcomes and delay in CKD progression.



Percent who transitioned to ESRD in the 12 months following identification using uACR Stage

TH-PO994

Development of a New Equation for Estimated 24-Hour Proteinuria: Modified Urine Protein-Creatinine Ratio Adjusted by Urinary Creatinine Excretion

Masahiro Eriguchi, Riri Furuyama, Takaaki Kosugi, Takayuki Uemura, Hiroyuki Tamaki, Hikari Tasaki, Masatoshi Nishimoto, Hideo Tsushima, Kaori Tanabe, Keisuke Okamoto, Ken-ichi Samejima, Kazuhiko Tsuruya.
Nara Medical University, Kashihara, Japan.

Background: Instead of the 24h proteinuria, the urinary protein-to-creatinine ratio (Up/Ucr) in spot urine, based on the assumption of 24h urinary creatinine excretion (CER) of 1 g/day, is widely used in clinical practice. However, the actual CER is often deviated from 1g/day because it is affected by individual muscle mass and kidney function, and Up/Ucr is often not accurately estimated for 24h proteinuria.

Methods: Data from a prospective observational study in patients with chronic kidney disease or cardiovascular disease in our hospital were used. Patients with both 24h urine collection and spot urine the day after 24h urine collection were included. First, we examined the relationship between Up/Ucr in 24-hour urine collection and UP/Ucr in spot urine, and then created estimated CER using age, sex, and serum creatinine. Finally, a modified Up/Ucr equation was developed adjusting for estimated CER and the relationship between Up/Ucr in 24-hour urine and UP/Ucr in spot urine.

Results: Among 1031 patients, 813 patients for whom spot urine and 24h urine data were available were included in the analyses of this study. Up/Ucr in spot urine increased by 7% compared to Up/Ucr in 24h urine, and both were closely associated with each other (R2=0.90), suggesting an increase in proteinuria due to exercise in spot urine at hospital visit as compared with 24h urine. Mean CER for males and females was 1.04 and 0.69 g/day, respectively, meaning 4%-overestimation in males and 31% underestimation in females when using Up/Ucr compared with measured 24h proteinuria. CER was also negatively associated with older age especially >60 years and increased in serum creatinine. The mean difference from measured 24h proteinuria for Up/Ucr in spot urine was -45.4% and that for modified Up/Ucr was -21.2% (P <0.001). The numbers within 15% and 30% of measured 24h proteinuria was 17% and 34% for Up/Ucr in spot urine, respectively and 24% and 46% for modified Up/Ucr, respectively (P <0.001).

Conclusions: Using spot urine immediately after 24-hour urine collection and estimated CER, a modified Up/Ucr equation was newly developed, which could be more useful in clinical practice than classical Up/Ucr.

TH-PO995

Disparities in Etiologic Classification of CKD

Benjamin Silverberg,[1] Wei Yu,[1] Fei Heng,[3] Omar J. Ahsan,[1] Alan T. Kelley,[2] Alfred K. Cheung,[2] Julia J. Scialla,[1] Guofen Yan.[1] *[1]University of Virginia, Charlottesville, VA; [2]University of Utah Health, Salt Lake City, UT; [3]University of North Florida, Jacksonville, FL.*

Background: Understanding the etiology of CKD is critical for targeted therapy. No prior study has evaluated disparities in assigning an etiology for CKD in practice. Due to widely described health disparities in CKD, we hypothesized that etiologic assignment would be lower for patients of Black race, Hispanic ethnicity, and female sex.

Methods: We identified adults in the Veterans Health Administration who had incident CKD stage G3 or higher (G3+) from 2005-2015. Incident CKD G3+ was defined as the first occurrence of two eGFRs <60 ml/min/1.73m^2 >90 days apart. Patients with ICD-9/ICD-10 codes for general CKD (i.e., 585.X; N18.X) before the index date were excluded. Using 290 specific ICD-9/ICD-10 codes (e.g., N03.3) classified in 6 etiologic domains (diabetic, hypertensive/vascular, obstructive/urologic, glomerular, cystic/congenital, tubulointerstitial), we identified specific etiologic diagnoses of CKD within 3 yrs before or after incident CKD G3+. Logistic regression was used to evaluate disparities in assignment of a specific etiologic code by race/ethnicity and sex, stratified by age. We adjusted for geographic region, year of incident CKD, and comorbidities.

Results: Out of 452,851 patients (438,414 male/14,437 female), 42.5% received an etiologic assignment. Contrary to our hypothesis, rates of etiologic assignment among patients of non-Hispanic Black race or Hispanic ethnicity were higher compared to non-Hispanic White race/ethnicity. We found consistently lower rates of etiologic assignment among females compared to males in all age groups (**Table**).

Conclusions: Efforts are needed to improve the assignment of etiology of CKD, particularly among female Veterans. More work is needed to evaluate rates of specific etiologies and their accuracy in CKD.

Funding: NIDDK Support

Table. Adjusted odds ratios (95% confidence intervals) of etiologic assignment within 3 years before or 3 years after incident CKD

	Overall	Age group 18-44	Age group 45-64	Age group 65-74	Age group 75 and above
Female vs Male	0.47 (0.45-0.48)	0.51 (0.40-0.64)	0.43 (0.41-0.45)	0.49 (0.45-0.53)	0.53 (0.48-0.58)
Asian, Native Hawaiian/Pacific Islander vs White	1.09 (1.03-1.15)	1.54 (0.72-3.27)	1.12 (1.01-1.25)	1.07 (0.96-1.18)	1.04 (0.94-1.15)
Black vs White	1.56 (1.53-1.59)	1.59 (1.27-1.99)	1.70 (1.65-1.76)	1.51 (1.46-1.56)	1.39 (1.34-1.44)
Hispanic vs White	1.17 (1.13-1.21)	1.76 (1.12-2.74)	1.33 (1.25-1.41)	1.15 (1.08-1.22)	1.02 (0.96-1.09)
American Indian/Alaska Native vs. White	1.11 (1.01-1.22)	1.68 (0.44-6.42)	1.09 (0.93-1.27)	1.14 (0.98-1.33)	1.10 (0.91-1.33)
Multiple or other races vs. White	1.04 (0.98-1.09)	0.85 (0.46-1.55)	1.09 (1.00-1.19)	1.05 (0.96-1.14)	0.97 (0.88-1.07)

Incorporation of Cystatin C in Estimating Kidney Function: Real-World Experience in Sweden

Shoshana Ballew,[1] Yingying Sang,[1] Josef Coresh,[1] Edouard Fu,[2,3] Juan J. Carrero,[3,4] Morgan Grams.[5] *[1]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD; [2]Brigham and Women's Hospital Department of Medicine, Boston, MA; [3]Karolinska Institutet, Stockholm, Sweden; [4]Karolinska Institutet Institutionen for kliniska vetenskaper Danderyds sjukhus, Stockholm, Sweden; [5]New York University, New York, NY.*

Background: Cystatin C is a filtration marker that, when used in combination with serum creatinine, provides a more precise estimate of GFR than using serum creatinine alone. However, many US physicians are unfamiliar with cystatin C and guidelines are vague on use of cystatin C as an adjunct test. Cystatin C has been routinely tested in Sweden for over a decade.

Methods: Using routine clinical data collected from 2010-2018 in the Stockholm Creatinine Measurements (SCREAM) project, we investigated rates of routine outpatient cystatin C testing over time as well as clinical care and patient characteristics associated with cystatin C testing. We used logistic and Cox proportional hazards regressions, stratified by ACR testing status, to further examine associations with cystatin C testing.

Results: Among the 1.37M adult individuals with serum creatinine tested, 11.2% also had serum cystatin C tested. The annual rate of cystatin C testing ranged between 4-7% each year. Those who had both markers tested were more likely to be older, male, have a lower eGFRcr, have more comorbidities, and more likely to have an ACR test. Among those with ACR testing, we found higher odds for a lower eGFRcr and, much higher risks of KFRT for the same level of eGFRcr in the population with cystatin C testing compared to those without. Among those without ACR testing, we found higher odds for older age and anemia, similar KFRT risk, but higher mortality risk among those with cystatin C testing compared to those without.

Conclusions: Cystatin C testing in Sweden followed two distinct patterns: for those at heightened risk of kidney failure (who were also receiving albuminuria testing) and for older adults who were more likely to have anemia and at higher risk of mortality. This study provides a real-world account of cystatin C testing and supports the utility of cystatin C for clinical practice.

TH-PO997

Cystatin C as a Marker for GFR Estimation in Clinical Populations: A Systematic Review

Ogechi M. Adingwupu,[1] Ernesto R. Barbosa,[2] Paul M. Palevsky,[4] Joseph A. Vassalotti,[3] Andrew S. Levey,[1] Lesley A. Inker.[1] CKD-EPI. *[1]Tufts Medical Center, Boston, MA; [2]Tufts University School of Medicine, Boston, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]VA Pittsburgh Healthcare System, Pittsburgh, PA.*

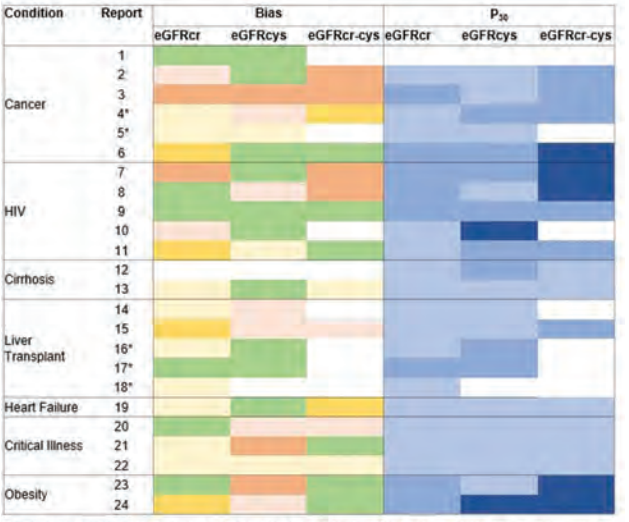
Background: GFR estimated using creatinine (eGFRcr) is often inaccurate in populations with acute and chronic illness. The accuracy of GFR equations that use cystatin C (eGFRcys) or creatinine-cystatin C (eGFRcr-cys) is not well studied in these populations.

Methods: Using a systematic review, we identified 21 studies of populations with comorbid illnesses that evaluated eGFRcr and eGFRcys compared to measured GFR (mGFR) using standardized assays for the markers: cancer (5); HIV (5); cirrhosis (2); liver transplant (3); heart failure (1); critical illness (3); and obesity (2). The performance of each equation was the unit of analyses ("report"). We assessed equation performance using bias as the median or mean difference between eGFR and mGFR, and accuracy as the percentage of eGFR within 30% of mGFR (P_{30}).

Results: eGFRcr had more reports of moderate-to-large bias than for eGFRcys and eGFRcr-cys, and of overestimation, than underestimatation, of mGFR. There were large inconsistencies in the relative performance of eGFRcr vs eGFRcys even for populations with the same illness. eGFRcr-cys was most accurate in populations with cancer, HIV and obesity, but did not perform consistently better in cirrhosis, liver transplant, heart failure and critical illness populations. Notable limitations are that participants were selected because of concern for inaccurate eGFRcr, and most studies had small sample sizes, limiting generalizability.

Conclusions: eGFRcr-cys improves GFR estimation in populations with a variety of acute and chronic illnesses, supporting current recommendations for more frequent use of cystatin C into more clinical practice. These data provide early evidence base for indications for cystatin C.

Funding: NIDDK Support



*Children only studies. Green indicates small bias, -5 to +5 mL/min/1.73m². Dark peach indicates medium underestimate, bias of -5 to -10 mL/min/1.73m². Light peach indicates large underestimate, bias > -10 mL/min/1.73m². Dark yellow indicates medium overestimate, bias of 5 to 10 mL/min/1.732m². Light yellow indicates large overestimate, bias >10 mL/min/1.73m². Dark blue indicate high accuracy, P_{30} > 90%. Medium blue indicates moderate accuracy, P_{30} of 80 to 90 %; light Medium blue indicates low accuracy, P_{30} < 80%.

TH-PO998

Estimating GFR from Cystatin C Without Including a Sex Variable: CKD-EPI 2023 Equation

Lesley A. Inker. CKD-EPI. *Tufts Medical Center, Boston, MA.*

Background: Use of a binary sex variable in eGFR equations may limit their use in gender subgroups. There are smaller differences between sex groups in cystatin C than creatinine independent of GFR. Other research groups have developed equations to estimate GFR using cystatin without sex [Pottel et al, NEJM 2023; Grubb et al, Clin Chem 2014]. We developed a CKD-EPI cystatin C equation that does not include a variable for sex and evaluated its performance in an external validation population.

Methods: Using the same population (5,352 participants from 13 studies) used for development of the current equation that includes age and sex (CKD-EPI 2012 eGFRcys AS), we developed a new eGFR cystatin C equation without sex (CKD-EPI 2023 eGFRcys A). We used least squares linear regression of measured GFR (mGFR) vs serum cystatin C and age on the logarithmic scale, with separate slopes for cystatin C at low vs. high values using the same spline knot as the 2012 equation (0.8 mg/L), and assessed model performance using root-mean-square error (RMSE). We assessed performance in the CKD-EPI 2021 external validation population (4,050 participants from 12 studies) using bias (systematic error, mL/min/1.73m^2) as the median difference between mGFR and eGFR, and accuracy as the percentage of eGFR within 30% of mGFR (P_{30}).

Results: In the development and validation population, 2,245 (42%) and 1,557 (38%) were female, respectively. Removing the sex variable led to a minimal increase in RMSE overall and in both sex subgroups (Table). In the external validation population, removing the sex variable led to a small increase in bias in both subgroups, with greater decrease in accuracy for females vs males although at levels considered acceptable (P_{30} >80%).

Conclusions: The availability of acceptably accurate eGFRcys equations that do not include a sex variable provides an option to use in people whose gender identification differs from their sex assigned at birth. Further studies can explore the impact of using these equations in the general population.

Performance of CKD-EPI 2012 and 2023 cystatin C eGFR equations

Equations	Development (13 Studies) mean (SD) mGFR 68 (39) mL/min/1.73m² and age 47 (15) years.	External Validation (12 Studies) mean (SD) mGFR 76 (30) mL/min/1.73m² and age 57 (17) years.	
	RMSE (95%CI)	Bias (95%CI)	P30 (95%CI)
Overall	**N=5,352**	**N=4,050**	
CKD-EPI 2012 AS	0.224 (0.217, 0.231)	0.6 (0.1, 1.1)	88.2 (87.2, 89.2)
CKD-EPI 2023 A	0.226 (0.220, 0.233)	0.9 (0.3, 1.3)	86.3 (85.3, 87.4)
Female	**(n=2,245, 42%)**	**(n=1,597, 38%)**	
CKD-EPI 2012 AS	0.231 (0.219, 0.244)	-1.1 (-1.8, -0.5)	88.7 (87.1, 90.3)
CKD-EPI 2023 A	0.235 (0.223, 0.248)	**-3.7 (-4.5, -3.0)**	**84.8 (83.0, 86.6)**
Male	**(n=3,107, 58%)**	**(n=2,493, 62%)**	
CKD-EPI 2012 AS	0.219 (0.211, 0.226)	1.8 (1.2, 2.5)	88.0 (86.7, 89.2)
CKD-EPI 2023 A	0.220 (0.213, 0.228)	**3.6 (3.0, 4.3)**	87.3 (86.0, 88.6)

A positive and negative value for bias indicates underestimation and overestimation of mGFR, respectively. Bold font indicates non-overlapping 95% confidence intervals compared with the CKD-EPI 2012 AS (reference equation).
Confidence intervals were calculated using bootstrap resampling with 2000 replicating samples. Equations are below:
CKD-EPI 2023: For Scys ≤0.8 mg/L, eGFR = 129 x (Scys/0.8)$^{-0.523}$ x 0.9962^{Age}; and for Scys >0.8 mg/L, eGFR = 129 x (Scys/0.8)$^{-1.328}$ x 0.9962^{Age}
CKD-EPI 2012: For Scys ≤0.8 mg/L, eGFR = 133 x (Scys/0.8)$^{-0.499}$ x 0.9962^{Age} x 0.932[If female]; and for Scys >0.8 mg/L, eGFR = 133 x (Scys/0.8)$^{-1.328}$ x 0.9962^{Age} x 0.932[If female]

TH-PO999

Effect of Race-Free Estimated Glomerular Filtration (eGFR) Equation on CKD Prevalence in the US Military Health System (MHS)

James D. Oliver,[1] Robert Nee,[1,2] Hava Marneweck,[4] Amanda Banaag,[4] Alain K. Koyama,[3] Meda E. Pavkov,[3] Tracey L. Koehlmoos.[1] *[1]Uniformed Services University of the Health Sciences, Bethesda, MD; [2]Walter Reed National Military Medical Center, Bethesda, MD; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]Henry M Jackson Foundation for the Advancement of Military Medicine Inc, Bethesda, MD.*

Background: The 2021 Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equation removed race as a factor in the calculation of eGFR. We assessed the potential impact on CKD prevalence using the MHS Data Repository, a large network health care database covering a diverse population comparable to the US general population.

Methods: We extracted MHS data from 2016-2019 for adults age ≥18. We compared CKD prevalence using eGFR calculated from the 2009 race-adjusted vs. the 2021 race-free CKD-EPI equations. Race was classified as Black or non-Black and was imputed in 23.7% of the population. CKD stages 3-5 was defined as eGFR < 60 mL/min/1.73m² for ≥90 days. We evaluated addtional population changes at eGFR thresholds (<45, <30, <20 mL/min/1.73m2) important for clinical decision-making.

Results: The study included 1,970,433 adults with median (IQR) age 40 (29–55) yrs, 49.2% female, and 18.0% Black adults. With the 2021 equation, Black adults with CKD increased from 5828 to 8928, a change in crude prevalence from 1.6 to 2.5% (Table). Non-Black adults with CKD declined from 43,126 to 30,932, a crude prevalence change from 2.7 to 1.9%. The Black adult population with eGFR <60, <45, <30, and <20 mL/min/1.73m² increased by 53.2%, 29.0%, 18.6%, and 28.7%, respectively while that for non-Black adults declined by –28.3%, –26.6%, –26.0%, and –27.8%, respectively. Cumulatively, 44.4% of Black adults with CKD and 42.1% of non-Black adults with CKD were reclassified across eGFR strata.

Conclusions: The new eGFR equation in the MHS will reclassify many Black adults to new or more advanced CKD stages, with the opposite effect on non-Black adults. The impact on time to diagnosis, clinical management, and outcomes is unknown but there may be shifts in referral patterns to nephrology, dialysis, and transplant services. Ongoing surveillance of CKD is warranted. *The views expressed in this abstract are those of the authors and do not reflect the official position of the Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., the Department of Defense, the Department of Health and Human Services, or the US Government.*

TH-PO1000

Potential Implications of 2021 CKD-EPI Equation in Patients with CKD from British Columbia, Canada

Mohammad Atiquzzaman, Lee Er, Ognjenka Djurdjev, Micheli U. Bevilacqua, Peter C. Birks, Michelle M. Wong, Adeera Levin. *BC Provincial Renal Agency, Vancouver, BC, Canada.*

Background: One in 10 British Columbians has kidney disease. The implications of implementing 2021 CKD-EPI equation in British Columbia (BC) is unknown. This was investigated in a population-level cohort of CKD patients from BC, Canada.

Methods: CKD patients aged ≥19 years and registered in the "Provincial Renal Program" on March 31, 2023 (index date) were included. Patients needed to have ≥1 serum creatinine recorded within 1 year before index date. We excluded patients who received transplantation before index date. We calculated eGFR using CKD-EPI 2009 and 2021 equations, and estimated the mean difference in eGFRs and corresponding Kidney Failure Risk Equation (KFRE) 2-year risks by age and sex. We assessed the implications in two clinical aspects: (1) reclassification between eGFR categories (G1-G5) (2) reclassification between KDIGO risk categories (low, moderately increased, high and very high risk). Finally, we investigated patient characteristics among those who were reclassified in eGFR categories (switcher; yes/no).

Results: Study sample included 16,037 patients, median age 74 years, 54% male. Compared to 2009 equation, eGFR calculated using 2021 equation was on average 1.80-2.60 ml/min higher in women and 2.86-3.33 ml/min higher in men. The 2021 equation downgraded the CKD severity with highest % of patients downgraded in G5 category (Fig.1). In KDIGO risk categorization, ~4% of patients in the very high risk group were reclassified to a lower risk group. The switchers appeared to be older male, majority (~43%) were in eGFR category G4 followed by 27% in G3b. KFRE 2-year risk score calculated using eGFR from 2021 equation was lower compared to that of estimated using eGFR from 2009 equation, median (IQR) in difference was -0.854 (-2.516, -0.258). Difference was larger in males.

Conclusions: The eGFR calculated using CKD-EPI 2021 was higher compared to 2009 equation. A large number (~17%) of patients currently under the care of nephrologists in BC would have categorically less severe CKD. The implications of this on resource utilization, care plans and outcomes are unknown.

CKD EPI 2021 Equation for Estimation of Glomerular Filtration Rate (eGFR) Has Good Efficacy to Predict Clinical Outcomes in a Large Prospective Cohort of Adult Koreans

So Young Jang, Ho Jun Chin. *Seoul National University Bundang Hospital, Seongnam, Republic of Korea.*

Background: A new eGFR equation using serum creatinine (CKD-EPI 2021) without race were developed by Chronic Kidney Disease Epidemiology Collaboration in 2021. We projected the changes of eGFR, CKD prevalence, and incidence of end stage renal disease (ESRD) and mortality in a large prospective cohort of adult Koreans who had voluntary health check-ups, using current (CKD-EPI 2009) and new equation (CKD-EPI 2021).

Methods: We included 112,772 adult participants, aged 18 years or older, who had voluntary routine health check-ups at three medical centers in Korea from 2003 to 2009. We compared the difference of eGFR and predictability of mortality and ESRD between eGFR values calculated by CKD-EPI 2009 and 2021. The incidence of mortality data was extracted from Statistics Korea and the ESRD data from the ESRD registry of the Korean Society of Nephrology.

Results: At baseline study, there were 60,723 males (53.8 %). The value of IDMS-traceable serum creatinine was 0.86 ± 0.21 mg/dl. Levels of eGFR at baseline study were 93.5 ± 15.6 ml/min/1.73 m² by CKD-EPI2009, and 97.1 ± 15.0 ml/min/1.73 m² by CKD-EPI2021. CKD stage was improved in 11,828 (10.5%) participants using eGFR calculated by CKD-EPI 2021 instead of CKD-EPI 2009, however, only 0.63 % of participants with eGFR <60 ml/min/1.73 m² by CKD-EPI equation was reclassified into eGFR ≥60 ml/min/1.73 m² by CKD-EPI 2021. During 11.6 ± 2.0 years, 3354 (3.00 %) subjects were dead and 151 (0.13%) subjects had end stage renal disease (ESRD) before death. Any eGFR or stage of eGFR was an independent risk factors to ESRD or mortality estimated by Cox's hazard proportional model adjusted by related factors. AUC to estimate renal survival by eGFRs was not different between eGFRs by CKD-EPI2021 and CKD-EPI2009 [0.739 (0.687-0.790) vs 0.740(0.688-0.792), p=0.170]. p<0.001]. AUC to estimate survival by eGFRs calculated through CKD-EPI equation was slightly higher than that by CKD-EPI2021 equation [0.673(0.664-0.682) vs 0.667(0.658-0.676), p<0.001], however, the difference of AUC was negligible [standard error of AUC difference by two eGFRs; 0.96 (95% CI; 0.006-0.007)].

Conclusions: The eGFR calculated by CKD-EPI2021 was higher compared to eGFR calculated by CKD-EPI2009. The power to estimate renal survival was not different between eGFRs by CKD-EPI2021 and CKD-EPI2009.

TH-PO1003

Identifying CKD Stage 3 with Excess Disease Burden

Stanley D. Crittenden,[1] Lihao Chu.[2] *[1]Evergreen Nephrology, Nashville, TN; [2]Rubicon Founders, Nashville, TN.*

Background: Chronic kidney disease (CKD) is a widely prevalent disease with heterogeneous disease progression. Current practice guidelines recommend nephrology referral when patients are diagnosed with CKD stage 4. Prior studies suggest earlier referral to nephrologists can improve health outcomes for patients with chronic kidney disease (CKD), however claims-based methods to identify high-risk CKD stage 3 patients remain lacking. We assessed cost, utilization, and disease progression in patients with various stages of CKD, including an identified subset of patients with CKD stage 3 and common medical comorbidities.

Methods: This is a retrospective study of Medicare fee-for-service beneficiaries with CKD stages 3-5. We identified seven comorbidities with high prevalence in patients with progressive CKD and segmented beneficiaries with CKD stage 3 based on the presence of

these comorbidities. Outcomes including costs, utilization, and disease progression were then compared across beneficiaries with different stages of CKD.

Results: We identified that beneficiaries with CKD stage 3 and at least one of the selected comorbidities (CKD stage 3-plus), represented 35.4% of all beneficiaries with CKD stage 3. The CKD stage 3-plus cohort had cost and utilization patterns that were more similar to beneficiaries with CKD stages 4 and 5 compared to beneficiaries with CKD stage 3 without the selected comorbidities.

Conclusions: Our findings demonstrate the use of a claims-based algorithm to identify patients with CKD stage 3 that are high cost and at risk of disease progression, highlighting a potential subset of patients who might benefit from earlier nephrology intervention.

TH-PO1004

Undiagnosed Early CKD in Patients with Hypertension and Cardiovascular Disease in the United States

Navdeep Tangri,[1] Pamela R. Kushner,[2] Salvatore Barone,[3] Matthew Arnold,[4] Hungta (tony) Chen,[3] Christian S. Alvarez.[3] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]University of California Irvine, Irvine, CA; [3]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD; [4]BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom.*

Background: Chronic kidney disease (CKD) is a growing public health issue and widely under-recognized in the United States. Hypertension (HTN) and cardiovascular diseases (CVD) are well-known risk factors for CKD; and KDIGO recommends screening in both high-risk groups. Early diagnosis of CKD and active management can slow disease progression and improve outcomes, but the prevalence of undiagnosed early-stage CKD in patients with comorbidities other than type 2 diabetes (T2D) has not been reported. This analysis assessed the prevalence of undiagnosed stage 3 CKD in patients with HTN and CVD in the absence of T2D.

Methods: Data were extracted from the US TriNetX database. Patients were aged ≥18 years with 2 consecutive estimated glomerular filtration rate (eGFR) results ≥30 and <60mL/min/1.73m^2 recorded 91-730 days apart between 2015 and 2020. Undiagnosed CKD was defined as the absence of a CKD diagnosis code any time before and up to 6 months after the second eGFR (index date). The analysis cohorts included patients with the following at or before index: 1) HTN ICD 9/10 diagnosis code but not for T2D; 2) HTN or atherosclerotic cardiovascular disease (ASCVD) ICD 9/10 diagnosis code but not for T2D; 3) HTN or heart failure (HF) ICD 9/10 diagnosis code but not for T2D; and 4) ICD 9/10 diagnosis code for T2D.

Results: In the absence of T2D, the proportion of undiagnosed stage 3 CKD in patients with HTN was 68.4% (95%CI: 68.2%, 68.7%). Similar proportions were observed in patients with either HTN or ASCVD (68.7%, 95%CI: 68.4%, 69.0%), and with HTN or HF (68.6%, 95%CI: 68.3%, 68.8%). These proportions were greater than those with undiagnosed stage 3 CKD and T2D (51.7%, 95%CI: 51.3%, 52.0%) (**Figure**).

Conclusions: A high prevalence of undiagnosed CKD in patients with existing HTN and CVD in the absence of T2D was observed in a large contemporary US database. These results highlight an opportunity to increase early identification of CKD in people with high-risk comorbidities other than T2D in order to implement targeted evidence-based therapies to slow progression of CKD and improve patient outcomes.

Renal Protective Treatment Use for Non-Diabetic CKD in Japan, Sweden, and the United States

Navdeep Tangri,[1] Maria K. Svensson,[2] Johan Bodegard,[3] Samuel Adamsson Eryd,[3] Marcus Thuresson,[4] Tadashi Sofue.[5] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Department of Medical Sciences, Renal Medicine, Uppsala University, Uppsala, Sweden; [3]CVRM Evidence, BioPharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden; [4]Statisticon AB, Uppsala, Sweden; [5]Department of Cardiorenal and Cerebrovascular Medicine, Kagawa University, Kagawa, Japan.*

Background: Chronic kidney disease (CKD) is an underdiagnosed disease affecting 10% of people worldwide. Appropriate management of CKD delays progression and reduces its burden. Renin–angiotensin system inhibitors (RASis) have been the mainstay of CKD treatment until recently. Here we describe the use of RASis and the sodium–glucose co-transporter-2 inhibitor dapagliflozin in a contemporary population of patients with CKD.

Methods: This study used secondary data extracted from electronic health records or claims data sources. Adult patients with CKD (either two estimated glomerular filtration rate [eGFR] measurements ≥ 90 days apart of which both were ≤ 60 mL/min/1.73 m^2 or an eGFR ≤ 60 mL/min/1.73 m^2 followed by a CKD diagnosis) who were new RASi or dapagliflozin users during 2021–2023 were included. Patients with type 1 or gestational diabetes, stage 5 CKD or on dialysis were excluded. RASi and dapagliflozin doses and persistence were assessed in the year following initiation.

Results: Overall, 159 220 patients were included (Japan, 57 222; Sweden, 10 861; USA, 91 137). Median ages were 75, 72 and 72 years, and 63%, 66% and 52% were males in Japan, Sweden and the USA, respectively. Of patients without type 2 diabetes, a high proportion receiving dapagliflozin remained on the evidence-based 10 mg target dose (Figure). A large proportion of patients treated with RASis received low doses. At 12-month follow-up, dapagliflozin persistence was approximately 65%, 80% and 55% in Japan, Sweden and the USA, respectively, and was 34%, 75% and 64% for RASi, respectively.

Conclusions: CKD treatment with dapagliflozin was associated with a high likelihood of receiving and remaining on target dose compared with RASi treatment. Efforts to maintain patients on renal protective treatment are needed.

Prevalence of Antihypertensive Use in CKD

Navdeep Tangri,[1] Pamela R. Kushner,[2] Salvatore Barone,[3] Matthew Arnold,[4] Hungta (tony) Chen,[3] Eric T. Wittbrodt.[3] *[1]University of Manitoba, Winnipeg, MB, Canada; [2]University of California Irvine, Irvine, CA; [3]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD; [4]BioPharmaceuticals Medical, AstraZeneca, Cambridge, United Kingdom.*

Background: Treatment-resistant hypertension (TRH) is a comorbidity of concern in patients with chronic kidney disease (CKD) and elevates the risk of cardiovascular events. The aim of this analysis was to identify the prevalence of antihypertensive medication (AHM) use in patients with persistent TRH concurrent with CKD, overall and stratified by CKD stage.

Methods: The study cohort was comprised of adults with CKD in the US TriNetX database between 2008 and 2020. CKD index was defined as the second of two consecutive eGFR measurements <75 ml/min/m^2 between 91-730 days apart or ICD-9/10 code of CKD or dialysis. Patients with ≥1 systolic blood pressure (SBP) ≥130 mm Hg within 6 months before or any time after index were included, and of these, TRH was defined as taking ≥3 AHM classes. The number of AHM prescribed 0 to ≥4 were described overall and by CKD stage. A sensitivity analysis using SBP ≥140 mm Hg was also performed.

Results: In the cohort with CKD and SBP ≥130 mm Hg (N = 109,385), mean (SD) age was 64 (13) years, 57% were female, and 77% were White and 20% were Black. Median (IQR) SBP measurements was 3 (1,5). Proportion of patients with TRH was 18.6% overall, and by CKD stage was 13.8% (S1 and 2), 21.5% (S3), 35.7% (S4), and 37.5% (S5). These proportions were modestly increased in the sensitivity analysis.

Conclusions: In a large real-world cohort, TRH was detected in nearly 1 in 5 individuals with CKD, and no AHM use was observed in nearly half of CKD patients with elevated SBP. An opportunity clearly exists for improved management of TRH in order to avoid adverse clinical outcomes in this high-risk population.

The Prevalence of CKD in Australian Primary Care: Analysis of a National General Practice Dataset

Min Jun,[1,2] James Wick,[3] Brendon L. Neuen,[1] Sradha S. Kotwal,[1] Sunil Badve,[2] John P. Chalmers,[1] Meg Jardine,[4] Vlado Perkovic,[2] Martin P. Gallagher,[1] Paul E. Ronksley.[3] *[1]The George Institute for Global Health, Newtown, NSW, Australia; [2]University of New South Wales, Sydney, NSW, Australia; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [4]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia.*

Background: CKD prevalence in Australia varies substantially across reports. Using a large, nationally-representative general practice data source in Australia, we determined the contemporary prevalence and staging of CKD in Australian primary care.

Methods: We performed a retrospective, community-based observational study using healthcare data from MedicineInsight, a national general practice data source in Australia. We included all adults with ≥1 visit to a general practice participating in MedicineInsight and ≥1 serum creatinine measurement (with or without a UACR measure) between 2011-2020; n=2,720,529 patients. CKD prevalence was estimated using 3 definitions: (1): an eGFR (mL/min/1.73m^2) <60 or an eGFR ≥60 with a UACR (mg/mmol) >2.5 for M and >3.5 for F, (2) 2 consecutive eGFR measures <60, ≥90 days apart or an eGFR ≥60 with a UACR >2.5 for M and >3.5 for F and (3) 2 consecutive eGFR measures <60, ≥90 days part and/or 2 consecutive UACR measures >2.5 for M and >3.5 for F ≥90 days apart. Patient characteristics were assessed across the 3 definitions.

Results: CKD prevalence progressively increased over the 10-year study period, irrespective of the method used to define CKD. The annual prevalence of CKD varied across the 3 CKD definitions, with definition 1 resulting in the highest estimates. In 2020, CKD prevalence in the study cohort was 8.4% (n=123,988), 4.7% (n=69,110) and 3.1% (n=45,360) using definitions 1, 2 and 3, respectively. The number of patients with UACR measurements was low such that, among those identified as having CKD in 2020, only 3.8%, 3.2% and 1.5% respectively, had both eGFR and UACR measures available in the corresponding year. Patients in whom both eGFR and UACR measurements were available mostly had moderate or high risk of CKD progression (83.6%, 80.6% and 76.2%, respectively). Comorbid burden in patients with CKD was also frequently observed.

Conclusions: In this large, nationally-representative study, we observed an increasing trend in CKD prevalence in primary care settings in Australia. Most patients with CKD were at moderate to high risk of CKD progression with a significant comorbid burden. These findings highlight the need for early detection and effective management to slow progression of CKD.

Predictors of Differences in Cystatin C- and Creatinine-Based eGFR

Debbie Chen,[1,2] Kaiwei Lu,[3] Rebecca Scherzer,[1] O. Alison Potok,[4] Jennifer S. Lees,[5] Patrick Mark,[5] Joachim H. Ix,[4] Michael Shlipak,[6,1] Michelle M. Estrella.[6,1] *[1]University of California San Francisco, San Francisco, CA; [2]Genentech Inc, South San Francisco, CA; [3]Northern California Institute for Research and Education, San Francisco, CA; [4]University of California San Diego School of Medicine, La Jolla, CA; [5]University of Glasgow, Glasgow, United Kingdom; [6]San Francisco VA Health Care System, San Francisco, CA.*

Background: Large differences between eGFR based on cystatin C (eGFRcys) and creatinine (eGFRcr) are common. A comprehensive evaluation of factors that account for these differences is needed to guide the interpretation of discrepant eGFR values.

Methods: We randomly divided the study population of 468,969 UK Biobank participants into 2 nonoverlapping cohorts, 80% for model training and 20% for model testing. In the training set, we used Bayesian model averaging to identify a parsimonious set of predictors among 34 candidate variables, including sociodemographic, lifestyle, physical and clinical factors of large eGFRdiff. Large eGFRdiff was defined as eGFRcys minus eGFRcr <-15 (negative eGFRdiff) or ≥15 mL/min/1.73 m^2 (positive eGFRdiff). We incorporated the identified set of predictors into a multinomial logistic regression model to estimate the odds of negative or positive eGFRdiff. We assessed model performance in the test set.

Results: The mean age was 56y; 46% were male. The overall mean ± SD of eGFRcys was 88±16 and eGFRcr was 95±13 mL/min/1.73 m^2; 25% of participants had negative eGFRdiffs and 5% had positive eGFRdiff. Strong predictors of negative eGFRdiff included older age, male sex, South Asian ethnicity, current smoker (vs. never smoker); history of thyroid dysfunction, chronic inflammatory disease, steroid use, higher waist circumference and body fat, and UACR >300 mg/g (Table 1). Odds ratio estimates for these predictors were largely inverse of those for positive eGFRdiff. The model's AUC was 0.75 in the test set, with good calibration (1.00).

Conclusions: This study highlights the multitude of demographic, lifestyle, and health characteristics associated with wide eGFRdiff. These results may help clinicians to interpret discrepant eGFRcys and eGFRcr values.

Funding: NIDDK Support, Veterans Affairs Support

Mapping CKD Prevalence Burden in a Reportedly High Australian Health District Region

Hicham I. Cheikh Hassan,[1,3] Kelly Lambert,[2] Stephen Moules,[2] Brendan J. Mcalister,[3] Karumathil Murali.[1,3] *[1]University of Wollongong Faculty of Science Medicine and Health, Wollongong, NSW, Australia; [2]University of Wollongong, Wollongong, NSW, Australia; [3]Illawarra Shoalhaven Local Health District, Wollongong, NSW, Australia.*

Background: Chronic kidney disease (CKD) affects 10% of the worldwide population but varies globally and regionally. In Australia, it ranges from 3% to 20%, with reports indicating a high prevalence of almost 20% among Illawarra and Shoalhaven Local Health District (ISLHD) residents. We aimed to determine the true prevalence of CKD among ISLHD residents and to identify potential risk factors.

Methods: Retrospective cohort longitudinal analysis on data from adult patients (>18 years of age), who attended an ISLHD facility between January 2008 and December 2017. Data variables included baseline demographics, comorbidities (defined from international classification of disease [ICD 10AM]), and CKD status defined using ICD-10AM codes or two creatinine or urine protein measurements, within 3-12 months apart, confirming CKD as per Kidney Disease Improving Global Outcome (KDIGO) definitions. Proportion of CKD in each suburb was calculated to identify suburbs with low and high prevalence of CKD. We preformed multivariate Cox proportional hazard analysis to determine CKD risk among the ISLHD suburbs, using time to CKD as an endpoint. Variables known to influence CKD risk (such as age, diabetes, hypertension, history of acute kidney injury) were included in the analysis.

Results: In total 135,585 patients were followed up for 580,118 patient years. Mean age was 53 (standard deviation 21.2) years and the most common comorbidity was hypertension (26%), diabetes (14%) and coronary artery disease (10%). CKD affected 9% of the population with an incidence of 2 per 100 patient year. CKD patients were more likely

to have, compared to non-CKD patients, a history of hypertension (43% vs 25%) diabetes (18% vs 12%) and acute kidney injury (20% vs 9%), *P*<0.001. The CKD prevalence differed highly across the 80 suburbs within the region, ranging from 4% to 24%. However, multivariate cox regression analysis which included risk factors known for CKD, found none of the suburbs had a statistically significant CKD risk above the known average.

Conclusions: Despite reports to the contrary, ISLHD CKD prevalence is within the national average. The large variability among the ISLHD suburbs can be explained by known risk factors and older age.

TH-PO1010

Prevalence and Outcomes of CKD in England (CaReMe CKD UK)

Ruiqi Zhang,[1] Jil Billy Mamza,[1] He Gao,[1] Kiera C. Lochead,[1] Nicola Milne,[2] Bhautesh D. Jani,[3] James A. Chess,[4] Smeeta Sinha,[5] Naresh Kanumilli,[6] Patrick B. Mark.[7] CaReMe CKD UK. *[1]Medical and Scientific Affairs, BioPharmaceuticals Medical, AstraZeneca, London, United Kingdom; [2]Northenden and Brooklands Primary Care Network, Manchester, United Kingdom; [3]School of Health and Wellbeing, University of Glasgow, Glasgow, United Kingdom; [4]Department of Nephrology, Abertawe Bro Morgannwg University Health Board, Swansea, United Kingdom; [5]Salford Royal Hospital, Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom; [6]Northenden Group Practice, Manchester, United Kingdom; [7]School of Cardiovascular and Metabolic Health, University of Glasgow, Glasgow, United Kingdom.*

Background: The CaReMe CKD study indicates that one in ten adults in Europe and Canada likely have chronic kidney disease (CKD). In England, 6.5% of the population has been diagnosed with CKD, but rates of possible and undiagnosed cases remain unknown. To address this, we updated the analysis with more comprehensive electronic health records (EHR) to determine the prevalence of diagnosed and potentially undiagnosed CKD and associated clinical adverse outcomes in England.

Methods: Patients were identified using linked national EHR (Clinical Practice Research Datalink, Hospital Episode Statistics and Office for National Statistics) by either having a CKD diagnosis or a single pathological value of eGFR <60 ml/min/1.73 m2 or urine albumin-creatinine ratio (UACR) ≥30 mg/g before 1st November 2020. CKD stages were defined in accordance with Kidney Disease: Improving Global Outcomes (KDIGO) criteria. CKD was categorized into three groups based on laboratory values or diagnosis codes (Figure). One year cardiovascular and renal event rates were determined using the first recorded in-hospital diagnosis at the main position.

Results: In a background population of 10,363,493, the prevalence of possible CKD was 9.2% (mean age 71, 55% women, 32% diabetes, 46% using renin-angiotensin-aldosterone system inhibitors); while one out of three did not have a corresponding CKD-specific diagnostic code, half could not be confirmed with KDIGO criteria. Prevalence of CKD was consistently higher in females across definitions. Among CKD patients confirmed by KDIGO criteria, the majority (64%) were in KDIGO stage 3A, 3% were stages one or two. Adverse events were common and 6.7%-8.7% died annually (Figure).

Conclusions: One in ten adults in England is affected by CKD, which leads to significant adverse outcomes. Diagnosis rates underestimates the actual prevalence of CKD. There is significant public health potential to identify and treat those who currently remain undiagnosed.

Funding: Commercial Support - AstraZeneca

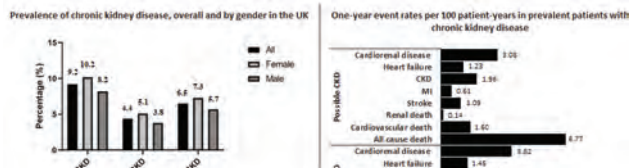

Figure. CKD: chronic kidney disease. Possible CKD: patients with a CKD diagnosis or one pathological UACR or eGFR measurement. Measured CKD: patients with KDIGO confirmed CKD using UACR and eGFR. Diagnosed CKD: patients who have a registered CKD diagnosis. UK: United Kingdom.

Event rates: the first event registered between index and the end of follow-up or death were defined by the first recorded in-hospital diagnosis of CKD (including diabetic kidney disease, acute kidney failure, CKD, unspecified kidney disease, hypertensive kidney failure and dialysis), HF (including hypertensive HF), stroke (including ischaemic and haemorrhagic stroke), myocardial infarction and peripheral artery disease, as the main diagnosis. Cardiorenal disease reflected as a diagnosis of HF or CKD as first diagnosis.

Prevalence, outcomes and definitions.

TH-PO1011

Prevalence and Progression of Kidney Diseases Among Ethiopian Immigrants Compared with Other Immigrant and Native Populations in Israel

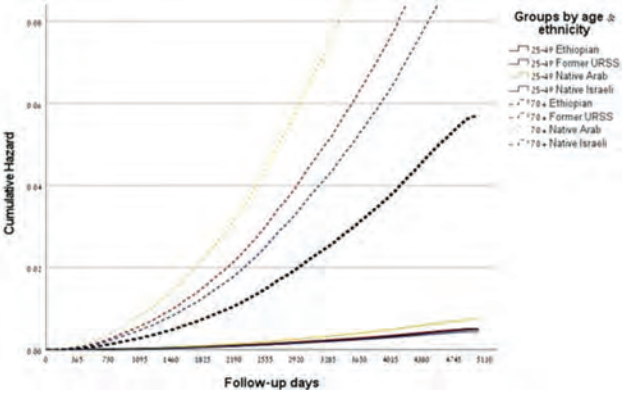
Yael Einbinder,[1] Tzipi Hornik-Lurie,[1] Keren Cohen - Hagai,[1] Sydney Benchetrit,[1] Tomas Karpati.[2] *[1]Meir Medical Center, Kfar Saba, Israel; [2]Holon Institute of Technology, Holon, Israel.*

Background: The worldwide prevalence of kidney disease in the Ethiopian population is unknown. This study assessed the prevalence of CKD and risk-factors for progression among Ethiopian immigrants compared to Soviet Union immigrants, as well as Israeli-born Jewish and Arab population.

Methods: The study included all people above 25 years old who were insured by Clalit Health Services from 01/01/2007 until 31/12/2017, and had more than two plasma creatinine measurements at least 28 days apart, which demonstrated similar CKD stage. Follow-up was until 31/12/2020. Primary outcome was at least 50% decrease in estimated glomerular filtration rate (eGFR) calculated with CKD-epi equation. Cox regression model was used to analyze risk-factors for CKD progression.

Results: The study included 1,734,501 people, of whom 41,260 (2.4%) were Ethiopian immigrants, mean age 44.8±16.6 years, baseline eGFR 111.1±16.5 ml/min/1.73m^2; 273,476 (15.8%) former Soviet Union immigrants, mean age 56.3±18.1 years, baseline eGFR 88.2±22.5 ml/min/1.73m^2; 366,789 (21.1%) native Israeli Arabs, mean age 42.5±14.5 years, baseline eGFR 107.9±18.8 ml/min/1.73m^2, and 1,052,976 (60.7%) native Israeli Jews, mean age 43.1±14.3 years, baseline eGFR 102.6±18.7 ml/min/1.73m^2. (p<0.001 for age and eGFR). Decrease in eGFR ≥50% was documented in 38,913 (2.2%) people: 573 (1.4%) were Ethiopian immigrants. Cox regression model was performed in three age groups: Ethiopian ethnicity was associated with higher risk for CKD progression in the young group (<50 years), HR 1.70 (95% CI: 1.54-1.90, p <0.001), but had no effect in the 50 to 70 years age group, HR 1.14 (95% CI: 1.05-1.24, p =0.098) and had a protective effect in the older, ≥70 years group, HR 0.62 (95% CI: 0.57-0.68, p <0.001).

Conclusions: Young Ethiopian immigrants had higher risk for CKD progression which was absent among older Ethiopian immigrants, suggesting a genetic/familial etiology or adaptive factors. Further research is desirable.



TH-PO1012

National Trends in the Prevalence of CKD Among Korean Adults, 2007-2020, Including the COVID-19 Pandemic: A Korean Representative Serial Study

Kyunghwan Jeong,[1] Soo-Young Yoon,[1] Dae Kyu Kim,[1] Hyo Jin Lee,[1] Yang Gyun Kim,[2] Jin sug Kim,[1] Ju young Moon,[2] Hyeon Seok Hwang.[1] *[1]Kyung Hee University Hospital, Dongdaemun-gu, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: Little is known about the prevalence of chronic kidney disease (CKD) during the coronavirus disease 2019 (COVID-19) pandemic, as well as the pandemics' impact on CKD diagnosis. We aimed to investigate the long-term trends in CKD prevalence throughout the pre- and early pandemic periods in adults using a nationwide serial survey from South Korea.

Methods: We used data from 108,152 Korean adults from 2007 to 2020 obtained from a representative longitudinal serial study. We defined CKD as a condition when the participant's estimated glomerular filtration rate was <60 mL/min/1.73 m^2, one-time spot proteinuria was ≥1+ on a urinary dipstick test according to recent guidelines, or previous diagnosis of CKD. We examined the overall trends in the prevalence of CKD during the study period and the impact of the early pandemic on the prevalence of CKD.

Results: Among the included adults (n=80,010), the overall national prevalence of CKD was 6.2%. The trend slope gradually increased from 2007 to 2019, however, there was a sudden decrease in 2020 (2007–2010, 5.1% [95% confidence interval (CI), 4.7–5.5]; 2017–2019, 7.1% [95% CI, 6.6–7.6]; pandemic period, 6.5% [95% CI, 5.7–7.3]; and β_{diff}, -0.19; 95% CI, -0.24–-0.13). The prevalence of CKD among younger adults and those with poor medical utilization significantly decreased during the early pandemic.

Conclusions: This study was the first large-scale study to investigate the longitudinal prevalence of CKD from 2007 to 2020. Further research is needed to fully understand the exact causes for this decline and to identify healthcare policy strategies for preventing and managing CKD.

TH-PO1013

Prevalence and Risk Factors for CKD and CKDu in León, Nicaragua

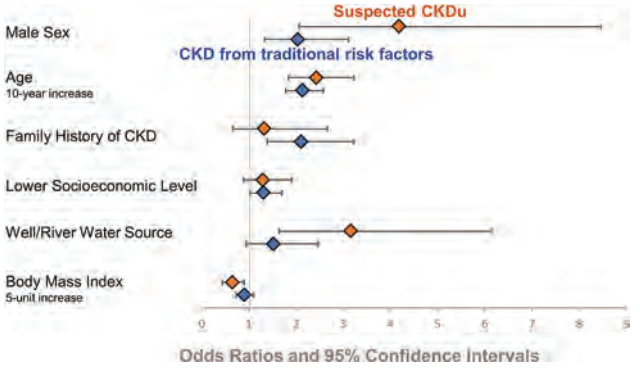
Anna Strasma,[1] Ángel F. Mejía,[2] Aurora Aragon,[3] Indiana M. López,[3] Lawrence Park,[4,1] Susan L. Hogan,[5] Nathan M. Thielman,[4,1] Christina M. Wyatt,[1,6] Marvin A. Gonzalez.[7,3] *[1]Duke University School of Medicine, Durham, NC; [2]Microbiology Research Institute, National Autonomous University of Honduras, Tegucigalpa, Honduras; [3]WUQU' KAWOQ, Maya Health Alliance, Tecpán, Guatemala; [4]Duke Global Health Institute, Durham, NC; [5]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [6]Duke Clinical Research Institute, Durham, NC; [7]University College London Research Department of Renal Medicine, London, United Kingdom.*

Background: CKD of unknown etiology (CKDu) disproportionately affects young people in Central America who lack traditional CKD risk factors (diabetes and hypertension) and is instead linked to heat stress, occupational and environmental exposures, nephrotoxic medications, and/or genetic conditions. This study aimed to estimate the prevalence of CKD and to identify risk factors for traditional CKD and CKDu in Nicaragua.

Methods: Surveys and assessment for CKD markers in urine and serum were performed in 15-59 year olds in households of the León municipality of Nicaragua. The survey included questions on demographics, health behaviors, occupation, and medical history. Participants with CKD were subdivided into traditional CKD and suspected CKDu based on history of diabetes, hypertension, or other specified conditions. A multinomial logistic regression model was used to identify factors associated with traditional CKD and CKDu, compared to the non-CKD reference group.

Results: In 1795 study participants, CKD prevalence was 8.6%. Prevalence in males was 2-fold higher than females (12% vs 6%). Of those with CKD, 30% had suspected CKDu. Both traditional CKD and CKDu were associated with male sex and increasing age. Traditional CKD was associated with a family history of CKD and lower socioeconomic status, while CKDu was associated with non-treated water sources and a lower body mass index.

Conclusions: Both traditional CKD and CKDu are significant burdens in this region. Our study supports previous hypotheses of CKDu etiology and emphasizes the importance of CKD screening.



Odds ratios and 95% confidence intervals from a multinomial logistic regression model for CKD from traditional risk factors and suspected CKDu compared to the non-CKD reference group.

TH-PO1014

CKD of Unknown Origin (CKDu) Is Associated with Subclinical Rhabdomyolysis

Magdalena Madero,[1] Richard J. Johnson,[2] Catharina Wesseling,[3] Ana K. Fernandez Yepez,[1] L. Gabriela Sanchez-Lozada,[1] Jason R. Glaser,[3] Ilana Weiss,[3] Bernardo Rodriguez-Iturbe.[1,4] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]University of Colorado, Denver, CO; [3]La Isla Foundation, Ada, MI; [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico.*

Background: CKDu is a type of chronic kidney disease, unrelated to diabetes and hypertension, mostly described in young sugar cane workers in El Salvador, Nicaragua and Mexico (Mesoamerican Nephropathy). Many etiologies have been assessed, including pesticides, heavy metals, silica, fructose-rich soft drinks, tobacco use, nutritional factors, and strenuous work in hot climate. Occupational heat stress is now an accepted key etiologic factor, but pathophysiologic pathways need further clarification. The role of rhabdomyolysis has been considered but myoglobin levels are unknown and serum creatine kinase (CK) levels during the harvest season are only mildly elevated.

Methods: We determined serum myoglobin (ng/ml, electrochemiluminescence immunoassay), CK (units/L) and creatinine (Scr, mg/dl) before (Pre) and after (Post) a 5 to 12 hour working shift in 109 sugar cane cutters (1 female), 19-78 years old from Tierra Blanca, Veracruz, a previously identified hot spot region for CKDu.

Results: Levels (mean±sem) of myoglobin (Pre=33.2±1.42; Post=60.0±5.02; p<0.0001), CK (Pre=164.8±9.24; Post=218.9±12.10; p<0.0001) and Scr (Pre=0.98±0.053; Post=1.17±0.058, p<0.0001) increased significantly (paired T test) during the working shift. There was a direct linear correlation between the increment in Scr and both the increments in CK (n=104, r2=0.161; p<0.0001) and myoglobin levels (n=104; r2=0.284; p<0.0001 (Figure).

Conclusions: The serum levels of myoglobin and CK are below the levels usually reported in rhabdomyolysis-related acute kidney injury. Nevertheless, subclinical rhabdomyolysis occurs daily during the harvest season in sugar cane workers and the role of repeated mild episodes of rhabdomyolysis in CKDu deserves to be investigated.

TH-PO1015

Long-Term Exposure to High Perceived Temperature and Risk for Mortality Among CKD Patients

Ara Ko,[1] Jeonghwan Lee,[2] Jung Pyo Lee.[2] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: Risks for climate change is emerging and interest in health risks from high temperature exposure is growing. The perceived temperature (PT) is an equivalent temperature based on a complete heat budget model of the human body. We aimed to analyze the effect of PT on the overall mortality among chronic kidney disease (CKD) patients.

Methods: A total of 32,870 patients with CKD in Seoul participated in a retrospective cohort (2001-2018) at three medical centers. PT during summer season was calculated using meteorological factors including air temperature nearby automated weather station, dew point temperature, wind velocity, and total cloud amount. We assessed the association of PT using Kriging spatial interpolation on mortality in CKD patients in the time-varying Cox proportional hazard model that was adjusted for sex, age, body mass index, hypertension, diabetes mellitus, estimated glomerular filtration rate, smoking, alcohol consumption, and education level.

Results: During the 6.14 ± 3.96 years of follow-up, 3,863 deaths (13%) were observed. In multivariable analysis, average level of PT (hazard ratio (HR) 1.292, 95% confidenc interval (CI) 1.255-1.331) and maximum level of PT (HR 1.356, 95% CI 1.309-1.404) showed increased risk for overall mortality among CKD patients. The c-index for mortality was high in the order of PT, temperature, discomfort index, and heat index (average level, 0.790, 0.785, 0.785, and 0.784; maximal level, 0.790, 0.784, 0.782, and 0.781). When stratified by age, diabetes mellitus, and estimated glomerular filtration rate, CKD patient with old age (age above 65 years old), without diabetes mellitus, and estimated glomerular filtration rate above 60 ml/min/1.73 m2 showed higher c-index levels. In addition, the risk for death in winter and spring seasons was also proved as significant with HR of 1.152 (95% CI 1.088-1.220) and 1.067 (95% CI 1.014-1.123) compared with the summer and autumn season mortality with according to HR of 1.401 (95% confidence interval 1.313-1.496).

Conclusions: Long-term exposure to high perceived temperature during summer season increase the risk of mortality among CKD patients.

TH-PO1016

Long-Term Exposure to Low Perceived Temperature in Winter Increases the Risk of Death in CKD Patients

Ara Ko,[1] Jeonghwan Lee,[2] Jung Pyo Lee.[2] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Seoul National University Seoul Metropolitan Government Boramae Medical Center, Dongjak-gu, Seoul, Republic of Korea.*

Background: Because of the rapid climate change, global interest about its impact on human health has been heightened. Perceived temperature (PT) is defined as a temperature that reflects the actual effect of temperature on the human body by considering the wind speed, amount of clouds, and humidity information. Due to the insufficiency of data on the health effects of long-term exposure to low temperature in chronic kidney disease (CKD) patients, we aimed to analyze the effect of PT in winter on the overall mortality among CKD patients.

Methods: 32,870 CKD patients in Seoul participated in a retrospective cohort at three medical centers. PT was calculated by the Staiger's equation, using the temperature of a nearby automated weather station, dew point temperature, wind velocity, and cloud amount. PT is interpolated using Kriging method and mortality was assessed by using the time-varying Cox proportional hazard model. The Cox regression model was used to assess the PT corresponding to the temperature for cold wave watch or warning.

Results: During the 6.14 ± 3.96 years of follow-up, 6,147 (18.7%) deaths were observed Since 2000, maximal and average PT had not significantly been changed. In multivariable analysis, the hazard ratio (HR) of maximum PT was 1.091 (95% confidence interval (CI) 1.073-1.109, p-value 0.<0001), and HR of average, minimal PT were 1.042 (CI 1.018-1.065, p-value 0.0004), 1.036 (CI 1.022-1.049, p-value <0.0001) respectively. The maximum PT had the highest C-index for mortality (0.783), followed by the risk of average and minimum PT (0.780). In addition, each PT for cold wave watch and warning were -21.86°C, -25.63°C. The cold wave warning at a PT of -25.63°C indicated the risk of death as HR 1.874 (CI 1.806-1.944, p-value<0.0001) and c-index 0.807.

Conclusions: Exposure to lower PT during winter season could increase the risk of mortality among CKD patients.

TH-PO1017

Particulate Matter and Risk of CKD: A Global Exposure-Response Analysis

Feifei Zhang. *Peking University Health Science Center, Beijing, China.*

Background: Associations between particulate matter (PM) air pollution and chronic kidney disease (CKD) have been increasingly reported, yet the exposure-response association is insufficiently estimated. This study aimed to combine all available associations between PM of two different sizes ($PM_{2.5}$ and PM_{10}) and CKD to generate exposure-response functions over concentrations experienced by populations in the globe.

Methods: Based on data from two prospective, population-based cohorts in the United Kingdom and China (UK biobank and China Health and Retirement Longitudinal Study), we used the shape constrained health impact function to generate exposure-response functions between both $PM_{2.5}$ and PM_{10} and CKD within each country. We then collected additional data on $PM_{2.5}$-CKD and PM_{10}-CKD associations from published literature and used the global exposure mortality model to construct exposure-response functions for CKD over a full range of global $PM_{2.5}$ and PM_{10} concentrations.

Results: In the United Kingdom, the exposure-response functions for both $PM_{2.5}$ and PM_{10} and CKD showed a linear association at lower concentrations and then a sublinear association at higher concentrations. In China, the risk of CKD also increased linearly with the increasing $PM_{2.5}$ and PM_{10} at lower concentrations, but the associations for both air pollutants did not reach the statistical significance. After combining with all other published associations, the exposure-response function revealed a near linear association of the natural log relative risk of CKD with $PM_{2.5}$ (**Figure 1a**) and a sublinear association with PM_{10} (**Figure 1b**), respectively.

Conclusions: Both $PM_{2.5}$ and PM_{10} exposure increased the risk of CKD, particularly at higher concentrations. Our findings highlight the urgency for air pollution management in areas with severe PM pollution to protect kidney health.

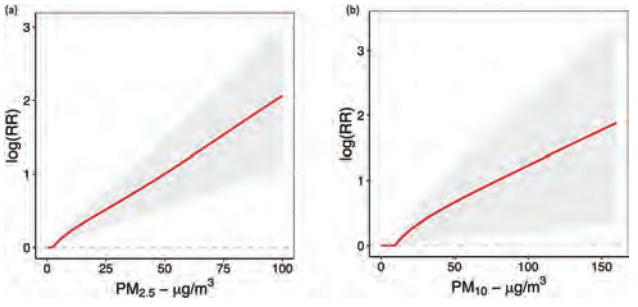

Figure 1 Exposure-response relationships between particulate matter and chronic kidney disease. (a) $PM_{2.5}$, (b)PM_{10}. Red line represents the log (relative risk) and grey shaded area represents its 95% confidence intervals.

Exposure to Organic Pollutants in Adults with CKD: A Pilot Study

Howard Trachtman,[1] Wenbo Wu,[2] Kurunthachalam Kannan,[3] Zhongmin Li,[3] Vineet Kumar Pal,[3] Sunmi Lee,[2] David M. Charytan.[2] *[1]University of Michigan, Ann Arbor, MI; [2]New York University, New York, NY; [3]Wadsworth Center, Albany, NY.*

Background: In pediatric patients with chronic kidney disease (CKD), exposure to organic pollutants is associated with intra-renal oxidant stress and tubular injury; however, the impact on longitudinal estimated glomerular filtration rate (eGFR) or proteinuria is minimal. Less is known about the adverse effects of exposure to these chemicals in adults with CKD.

Methods: In this pilot study, we utilized HPLC-MS/MS to measure urinary concentrations of bisphenols, phthalates, organophosphate pesticides, polycyclic aromatic hydrocarbons, melamine, and cyanuric acid at years 1, 3 and 5 after enrollment in 40 adults with CKD from the Chronic Renal Insufficiency Cohort (CRIC) study. We assessed associations with clinical kidney and cardiovascular outcomes, cardiovascular function markers, markers of mineral and bone metabolism, and baseline and longitudinal trajectory of eGFR and proteinuria.

Results: Mean baseline eGFR and urinary protein:creatinine ratio were 33 ml/min/1.73 m^2 and 0.58 mg:mg, respectively. Of 52 compounds assayed, 30 were detectable in ≥50% of participants. Urinary chemical concentrations were comparable in CKD patients to healthy subjects from contemporaneous National Health and Nutrition Examination Survey (NHANES) cohorts. Phthalates were the only class with a trend towards higher exposure in CKD patients. In a univariate analysis of time updated exposure to the individual compounds, there was a wide range of association with changes in kidney function. There was an inverse relationship between the level of exposure and eGFR slope for select compounds in the chemical classes including bisphenol F, mono-(3-carboxypropyl) phthalate, mono-benzyl phthalate, mono-[2-(carboxymethyl) hexyl] phthalate, and melamine. There were no significant associations between organic pollutant exposure and cardiovascular outcomes.

Conclusions: Simultaneous measurement of multiple organic pollutants in adults with CKD is feasible. Exposure levels are comparable to that in the healthy population. A subset of contaminants may be associated with more rapid deterioration in kidney function especially in the phthalate class. Our findings provide a useful reference for future studies of the impact of organic pollutant exposure in the CKD population.

The Increased Burden of CKD in Young Adults with Questionable Levels of Education and Health Literacy

Varsha Kumar,[1,2] Anita K. Patel.[2,1] *[1]Wayne State University School of Medicine, Detroit, MI; [2]Henry Ford Health System, Detroit, MI.*

Introduction: This case highlights the harmful effects of unsatisfactory healthcare education that may contribute to poor patient insight in certain communities across the United States.

Case Description: This patient is a 29-year-old G4P2113 black female with a past medical history of uncontrolled hypertension(HTN), chronic kidney disease(CKD), and morbid obesity. Her health insurance is managed by Medicaid. At age 17, she had her 1st spontaneous vaginal delivery(SVD) in the emergency department(ED) with no prenatal care(PNC). Urinalysis(UA) during her 3rd trimester was significant for 3+ proteinuria. She was discharged with normal blood pressure(BP). The patient was noncompliant with post-partum follow-up. Her 2nd term SVD was at age 18 with limited PNC(2 ED visits were for severe HTN and proteinuria was noted). BP at discharge was normal but she had proteinuria. In the next 5 years, she lost her 3rd pregnancy. At age 25, she presented for an annual GYN exam where she was diagnosed with HTN and given NifedipineCC. ED visits documented that she had no primary care provider(PCP) and showed CKD stage 3A. A year later, she returned to the ED with uncontrolled HTN to confirm her 4th pregnancy. She had CKD stage 3B with 2+ proteinuria and a GFR of 43mL/min. She was admitted to labor and delivery and had a preterm SVD. When seen post-partum, the patient was in denial about her diagnosis of CKD. She did not comply with a renal diet and refused anti-hypertensives. To date, she does not have a PCP or nephrologist although she was referred and told about the gravity of the diagnosis.

Discussion: Many factors contributed to the progression of this patient's illness: individual, interpersonal, societal and institutional factors. This patient lacked insight into the consequences of proteinuria and HTN that progressed to CKD. She had 3 children without family support. Her early pregnancies interfered with her high school education. We believe that her low socioeconomic status(SES) and domicile negatively impacted her access to a healthy diet. Her race, gender and SES predispose her to poorer health outcomes(HO). The effect of her education and health literacy highlights the impact of healthcare on young adults: It must be further studied to provide focused upstream interventions. An education program incorporating health literacy in high school may help prevent adverse HO.

TH-PO1020

First Detection of Microplastics Fragments in Human Urine and Kidney Tissues

Sara Massardo,[1] Edoardo La Porta,[2] Enrico E. Verrina,[2] Francesca Lugani,[2] Stefano Alberti,[1] Claudia Caboni,[1] Matteo Santostefano,[3] Daniela Verzola,[4] Pasquale Esposito,[4,5] Gianluigi Zaza,[6] Cristina Artini.[1,7] *[1]Chemistry and Industrial Chemistry Department, University of Genoa, Genova, Italy; [2]UOC Nephrology, IRCCS Istituto Giannina Gaslini, Genova, Italy; [3]PM_TEN Srl, Genova, Italy; [4]Department of Internal Medicine, University of Genoa, Genova, Italy; [5]IRCCS Ospedale Policlinico San Martino, Genova, Italy; [6]Nephrology and Dialysis Unit, Department of Medical and Surgical Sciences, University of Foggia, Foggia, Italy; [7]CNR-ICMATE, Genova, Italy.*

Background: Microplastics (MPs) are small plastic particles (< 5 mm) continuously released into the environment, contaminating natural habitats. Humans are constantly exposed to this kind of pollution: studies proved the presence of MPs in their lungs, liver, placenta, blood, and breast milk. To date, risks related to the uptake of plastic fragments are not well clarified, but their correlation with emerging diseases of unknown etiology cannot be *a priori* excluded. Due to an epidemic of Chronic Kidney Disease (CKD) that steadily increases over the decades and emerging new diseases worldwide as CKD of uncertain etiology (CKDu), the presence of MPs in human urines and kidney was investigated, to clarify their contribute to kidney damage.

Methods: MicroRaman spectroscopy is a technique of election for MPs detection in different matrices, thanks to its high sensitivity towards different polymers and its

high spatial resolution. Urine samples from healthy individuals and kidney tissues from nephrectomies were collected, digested in a KOH 10% solution, and filtered. Particles retained on the surface of the filters were analysed with a Renishaw System 2000 Raman imaging microscope (633 nm laser source). The collected spectra were investigated, to determine the nature of the detected particles.

Results: This study revealed the presence of different polymer fragments in both urines and kidneys (polyethylene, polystyrene, and styrene-isoprene gum, Figure 1), as well as pigments residuals (*e.g.*, hematite, Cu-phthalocyanine (blue), and cerulean blue).

Conclusions: This study revealed for the first time the presence of microfragments of materials of anthropogenic origin (polymers, pigments, and inorganic particles) in human kidney and urine. The current investigation laid the foundations for further studies on the mechanisms of renal clearance and deposition of these particles, and on their possible role in promoting kidney damage.

Sample;total n	Positive samples;total particles	Particle Material

TH-PO1021

Association of Co-Exposure to Cadmium and Lead with CKD and Cardiovascular Disease (CVD) Comorbidity in US Adults: NHANES 2003-2018

Meda E. Pavkov,[1] Michael D. Lewin,[2] Babatunde Y. Alli,[3] Anne L. Sowell,[1] Youn K. Shim.[2] *[1]Centers for Disease Control and Prevention, Atlanta, GA; [2]Agency for Toxic Substances and Disease Registry, Atlanta, GA; [3]McGill University, Montreal, QC, Canada.*

Background: Environmental exposure to cadmium (Cd) and lead (Pb) have been implicated in both CKD and CVD. The two metals can be detected together at or above the respective population medians in 45% of the US population 6 years and older. Although both metals exhibit similar renal pathology and toxic mechanisms, the relationship between the metal mixture and the CKD and CVD comorbidity is not clear. The objective of this cross-sectional study was to examine the associations of Cd and Pb exposure with CKD and CVD outcomes and to see if the two metals are independently associated with the outcomes.

Methods: We included data from the National Health and Examination Survey (NHANES) 2003-2018 participants 20 years and older with urine Cd, blood Pb, serum creatinine, and urine albumin/creatinine measurements (n=12,851). Pregnant women and participants with CKD stage 5 were excluded. We used generalized logistic regression to calculate adjusted odds ratios for CVD, CKD, or both CKD and CVD relative to none of these co-morbidities. We tested for interactions, both on multiplicative and additive scales, between the two metals with and without other covariates (gender, race/ethnicity, attained education, smoking, alcohol use, body mass index (BMI), and quadratic age).

Results: Both multiplicative and additive interaction effects were not statistically significant at the p-value of 0.05 level. It is possible that our sample size was too small to detect the effect. The final model included urine Cd, blood Pb, gender, race/ethnicity, education, smoking, alcohol use, BMI, and quadratic age. The Cd effect was statistically significantly associated with CKD+CVD (OR=1.19, 95%CI=1.03-1.38, p=0.02) after adjusting for the effect of Pb and other covariates, whereas Pb was significantly associated with CKD (OR=1.22, 95%CI=1.07-1.39, p=0.003) and CVD+CKD (OR=1.39, 95%CI=1.16-1.65, p=0.0004) after adjusting for the effect of Cd and other covariates.

Conclusions: These results suggest that the effects of Cd and Pb are independent each other, and more pronounced in participants who had both CKD and CVD, supporting their role as risk factors even at exposures below the levels typically associated with occupational hazards. However, reverse causation because of underlying kidney damage cannot be ruled out.

TH-PO1022

Association Between Blood Cadmium Level and Kidney Function: Analysis of NHANES 2017-2020

Phuuwadith Wattanachayakul,[1] Pongprueth Rujirachun,[2] Chawin Lopimpisuth,[3] Pakin Lalitnithi,[4] Natchaya Polpichai,[5] Ekamol Tantisattamo.[6,7] *[1]Albert Einstein Healthcare Network, Philadelphia, PA; [2]Mahidol University Faculty of Medicine Siriraj Hospital, Bangkok, Thailand; [3]University of Miami Health System, Miami, FL; [4]St Elizabeth's Medical Center, Brighton, MA; [5]Weiss Memorial Hospital, Chicago, IL; [6]University of California Irvine, Irvine, CA; [7]VA Long Beach Healthcare System, Long Beach, CA.*

Background: Recent studies have highlighted the significant impact of cadmium toxicity on various organs, including kidneys and the cardiovascular system, whether the association between a wide range of cadmium levels from normal to high toxic levels and kidney function remains unclear.

Methods: A cross-sectional study involving participants (≥ 18 years old) in the 2017 - 2020 NHANES was examined by using multiple linear regression analysis for the association between blood cadmium levels (Cd) and kidney function measured by serum creatinine level (SCr).

Results: Of 12,102 participants with Cd results, the mean ± SD age was 37+/-24 years old, and 50.6% were female. White accounts for 33%, followed by Black (25%), Mexican American (13%), and Asian (10%). The Median (IQR) SCr was 0.82 (0.68 - 0.98) mg/dL. We stratified the participants into four quartiles based on their Cd results; the average Cd for each quartile was 0.08, 0.16, 0.29, and 0.93 ug/L, respectively (Figure 1). We found that Q2, Q3, and Q4 participants had significantly higher SCr values of 0.06, 0.08, and 0.14 mg/dL, respectively than those in Q1. (β SCr Q2: 0.06, 95%CI 0.02, 0.09; Q3: 0.08, 95%CI 0.05, 0.12; Q4: 0.14, 95%CI 0.11, 0.17). After adjusting for age, gender, race, BMI, smoking status, high systolic blood pressure (<130 vs.>130 mmHg), diabetic status, and urine albumin creatinine ratio, individuals in the Q3 and Q4 still had significantly higher SCr levels of 0.04 mg/dL. (β SCr Q3: 0.04, 95%CI 0.01,0.07; Q4: 0.04, 95%CI 0.01, 0.07).

Conclusions: Our study found a positive correlation between blood cadmium levels and the risk of declining kidney function, even within the normal range that is not considered toxic. However, future longitudinal studies are required to elucidate this relationship.

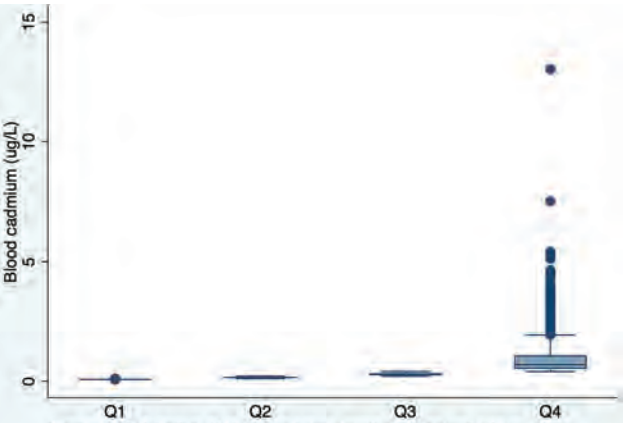

Figure 1: Distribution of blood cadmium levels categorized into quartiles.

TH-PO1023

Nonlinear Associations Between Serum Manganese with CKD: Results from Two Nationwide Studies in the United States and China

Yang Li. *Zhongshan Hospital Fudan University, Shanghai, China.*

Background: This study aimed to better evaluate the association between serum manganese (Mn) and chronic kidney disease (CKD) by using data from the US National Health and Nutrition Examination Survey (NHANES) and the Chinese Longitudinal Healthy Longevity Study (CLHLS).

Methods: A total of 15411 and 451 participants were selected from NHANES and CLHLS, respectively. The primary diagnosis of CKD was defined as eGFR <60 mL/min/1.73m^2 and urinary albumin-creatinine-ratio (ACR) ≥30 mg/g. Multivariable regression and threshold analyses were used to assess the associations between Mn level and CKD.

Results: The prevalence of CKD was estimated to be 8.1% in NHANES and 47.7% in CLHLS. After adjusting for covariates, participants with the highest quartile (Q4) of Mn had an increased likelihood of CKD than those with Q1 (OR=0.67, 95% CI 0.55-0.82 in NHANES, and OR=0.31, 95% CI 0.16-0.58 in CLHLS). The non-linear associations revealed that the OR values of CKD were decreased with Mn before reaching the threshold (OR=0.64 per 1 μg/L increase of Mn in NHANES and 0.98 in CLHLS). The trends of protective effects then became flat with no longer significance. This association remained robust by using the continuity of eGFR and ACR as the outcome. Exploration analysis showed that superoxide dismutase (SOD) mediated 6.7% of the effect of Mn levels on CKD.

Conclusions: The higher Mn concentration was significantly associated with a lower prevalence of CKD through different non-linear patterns.

TH-PO1024

Comparison of National and Global Utilization Trends of Sodium-Glucose Cotransporter 2 Inhibitors (SGLT2i) and Glucagon-Like Peptide 1 Receptor Agonists (GLP-1RA) in CKD

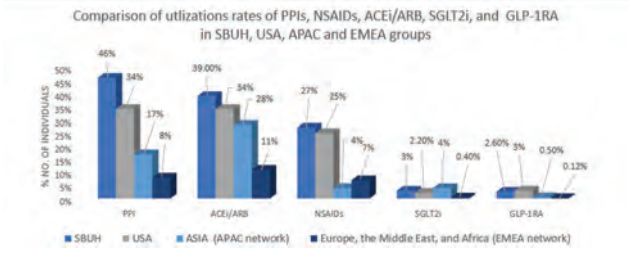
Iqra Nawaz, Sakil A. Bhuiyan, Fatima Sheikh, Sandeep K. Mallipattu.
Stony Brook University, Stony Brook, NY.

Background: Despite the mounting evidence demonstrating the reno and cardiovascular benefits of SGLT2i and GLP-1RA in diabetic and non-diabetic CKD, there appears to be a degree of therapeutic inertia in using these agents in routine clinical practice. The assessment of the utilization rates and practice patterns of these drugs in patients with CKD remains scarce.

Methods: We used TriNetX Analytics, including Stony Brook Healthcare, US-network, AMA (Asia), and EMEA (Middle east, Europe, Africa) collaborative networks. The estimated glomerular filtration rate (eGFR) mL/min/1.73 m2 (CKD-EPI equation) lab values and the KDIGO eGFR classification were used to define the CKD stages. Individuals with age > 18 years with ambulatory visits (CPT 1013626) from 2000 to 2022 were included. Patients with end-stage renal disease (CPT 1019051), acute kidney injury (ICD-10-CM N17), and kidney transplant recipients (CPT 50380) were excluded.

Results: SGLT2i and GLP-1RA use were highest among non-Hispanic white males (55% vs 55%) with Type 2 DM (86% vs 79%) and Hypertension (87% and 82%). The use rates of ACEi/ARB were noticeably low among all cohorts; 34% (280,0219) in the US, 28% (77,011), and 11% (38,599) in the AMA and EMEA groups. In the AMA group, the SGLT2i use rate was 4% (11,786), and the lowest prescription rate was noticed in the EMEA group at 0.40% (1681). The prevalence of GLP-1RA use was relatively higher in Stony Brook and US cohorts, 2.60% (4370) and 3% (230,925), as compared to AMA and EMEA groups at 0.50% (1763) and 0.12% (431), respectively.

Conclusions: Despite the high national and global burden of CKD, the prescription rates of ACEi/ARBs are alarmingly low. In contrast, a relatively high prevalence of potential nephrotoxins (i.e., NSAIDs and PPIs) use has been noticed. Overall national and global SGLT2i and GLP-1 RA utilization rates have increased over the last few years. However, the use rates of these agents are still significantly suboptimal among CKD patients.



TH-PO1025

Predictors and Outcomes of Discontinuation of Sodium-Glucose Co-Transporter 2 Inhibitors (SGLT2is) in CKD

L Parker Gregg,[1,2] Peter Richardson,[2] Vijay Nambi,[1,2] Michael E. Matheny,[3,4] Salim S. Virani,[5] Sankar D. Navaneethan.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]Vanderbilt University Medical Center, Nashville, TN; [4]VA Tennessee Valley Healthcare System, Nashville, TN; [5]The Aga Khan University, Karachi, Pakistan.*

Background: SGLT2is decrease the progression of CKD and improve cardiovascular outcomes. However, their utilization remains low. Little is known about treatment discontinuation and its associations with patient characteristics and outcomes.

Methods: We identified adults with CKD stages 3-4 receiving care at Veterans Affairs (VA) facilities from 2005-2022 from the VA Corporate Data Warehouse. Individuals who had an incident prescription for an SGLT2i were included, with the date of prescription considered the index date. The primary outcome was treatment discontinuation, defined as an interruption in SGLT2i prescription for at least 90 days. Cox proportional hazards regression identified factors associated with time to treatment discontinuation. Cox proportional hazards regression treating SGLT2i discontinuation as a time-varying covariate assessed the association of treatment discontinuation with time to all-cause death.

Results: Of 96,345 individuals who received an SGLT2i, 97% were male, 71% were White, 24% were Black, 71% were age ≥70, and 84% had CKD stage 3a. Discontinuation (at least once) occurred in 35,953 (37%) SGLT2i users over a median (IQR) of 1.01 (0.58, 1.74) years of follow up. Black race, female sex, younger age, and more advanced stage of CKD were associated with SGLT2i discontinuation (**Figure**). There were 8698 deaths. SGLT2i discontinuation, included as a time-varying covariate, was associated with all-cause death (HR 1.57 [95% CI 1.49, 1.66], P<0.0001) independent of age, sex, race, CKD stage, medical comorbidities, and concomitant medication use.

Conclusions: Discontinuation of SGLT2is is common and is associated with an increased risk of mortality. Further studies to understand the reasons for SGLT2i discontinuation (both temporary and permanent), and additional efforts to improve adherence are warranted.

TH-PO1026

ACEi/Angiotensin Receptor Blocker (ARB) Prescribing Practices and Patient Experiences in CKD: A Qualitative Study of Clinicians and Patients

L Parker Gregg,[1,2] Jennifer Arney,[3] Sheena R. Wydermyer,[2] Michael A. Herrera,[1] Peter Richardson,[2] Michael E. Matheny,[4,5] Julia Akeroyd,[1] Glenn T. Gobbel,[4] Adriana Hung,[4,5] Salim S. Virani,[6] Sankar D. Navaneethan.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Michael E DeBakey VA Medical Center, Houston, TX; [3]University of Houston Clear Lake, Houston, TX; [4]Vanderbilt University Medical Center, Nashville, TN; [5]VA Tennessee Valley Healthcare System, Nashville, TN; [6]The Aga Khan University, Karachi, Pakistan.*

Background: Angiotensin converting enzyme inhibitors (ACEi) and angiotensin receptor blockers (ARB) improve clinical outcomes but are underutilized in chronic kidney disease (CKD). Little is known about reasons for discontinuation and lack of reinitiating these medications, which contributes to underutilization.

Methods: We conducted in-depth interviews with a multi-profession sample of clinicians and patients with documented ACEi/ARB side effects in the past 6 months. Participants were recruited from 2 Veterans Affairs (VA) healthcare systems. We used inductive and deductive qualitative data analysis approaches to identify themes related to experiences with ACEi/ARB. Thematic analysis focused on prescribing decisions and practices, clinical guidelines, and perception of side effects. Data were analyzed as they amassed. Recruitment was stopped at the point of thematic saturation.

Results: Participants included 15 clinicians (primary care, geriatrics, cardiology, and endocrinology; 8 physicians, 3 NPs/PAs, 4 clinical pharmacists) and 10 patients (mean age 69 years, 40% men). Clinicians prescribe ACEi/ARB for blood pressure control and kidney protection, and many emphasized the role these agents play in diabetes management. Clinicians described providing comprehensive patient education about CKD and ACEi/ARB. However, patient interviews revealed knowledge gaps about CKD and the need for ACEi/ARB, with many patients unaware of their CKD diagnosis or why they had been prescribed ACEi/ARB. Clinicians' drug management strategies and understanding of prescribing guidelines varied widely. They identified structural and patient-level barriers to prescribing, and many endorsed the development of a decision support tool to facilitate ACEi/ARB prescribing and management (Figure).

Conclusions: Our qualitative exploration of clinicians' and patients' experiences with ACEi/ARB will inform the development of a decision support tool to improve prescription rates of these agents for patients with CKD.

Funding: Veterans Affairs Support

Patient- and Provider-Related Factors Associated with Changes in Antihypertensive Treatment in CKD

Margaux Costes-Albrespic,[1] Sophie Liabeuf,[2,3] Solene M. Laville,[2] Denis Fouque,[4,5] Maurice Laville,[4] Luc Frimat,[6] Roberto Pecoits-Filho,[7] Oriane Lambert,[1] Benedicte Stengel,[1] Ziad Massy,[8] Bénédicte Sautenet,[9] Natalia Alencar de Pinho.[1] *[1]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [2]Centre Hospitalier Universitaire Amiens-Picardie, Amiens, France; [3]Universite de Picardie Jules Verne, Amiens, France; [4]Cardiovasculaire Metabolisme Diabetologie et Nutrition, Pierre Benite, France; [5]Centre Hospitalier Lyon-Sud, Pierre-Benite, France; [6]Centre Hospitalier Regional Universitaire de Nancy, Nancy, France; [7]Arbor Research Collaborative for Health, Ann Arbor, MI; [8]Hopital Ambroise-Pare, Boulogne-Billancourt, France; [9]Centre Hospitalier Regional Universitaire de Tours, Tours, France.*

Background: Despite the existence of effective antihypertensive drugs, blood pressure (BP) remains off-target in a large number of CKD patients. We aimed to assess patient- and provider-related factors associated with changes in antihypertensive drug prescription in CKD.

Methods: We included 2,755 patients with CKD stages 3–4 and hypertension, under nephrology care, from the French CKD-REIN cohort study. We collected all drug prescriptions over 5 years and classified antihypertensive drugs in 14 mutually exclusive classes. We estimated cause-specific hazard ratios (HR) of add-on and withdrawal of antihypertensive drugs associated with patient- and provider-related factors by using hierarchical shared-frailty models, and accounting for clustering at the nephrologist level.

Results: At baseline, 81% of the patients (median age, 69; 66% men; mean eGFR 33 mL/min/1.73 m2) had BP ≥ 130/80 mmHg. Over a median 5-year follow-up (IQR 4.6-5.2), the rates of any antihypertensive drug class change, add-on, withdrawal, and switch were 50, 23, 25, and 4 per 100 person-years, respectively. In multivariable models, drug add-on hazard was higher for older patients (HR, 1.11; 95% confidence interval [CI], 1.04-1.18), for those with higher BMI (HR, 1.04 95% CI, 1.01-1.07), and poor medication adherence (HR, 1.39; 95% CI, 1.10-1.68). Drug withdrawal hazard was higher for patients with cardiovascular history (HR, 1.19 95% CI, 1.04-1.35), and those with shorter formal education (HR, 1.23; 95% CI, 1.02-1.45 for 9-11 years versus ≥12). The higher the number of nephrologist visits, the higher the add-on and withdrawal hazards (HR for ≥4 versus none, 1.50; 95% CI 1.14-1.86 and 1.57; 1.24-1.90, respectively). Associations with withdrawals and add-ons of antihypertensive drug prescriptions and the number of other physicians' visits differed according to their specialty.

Conclusions: Our findings highlight the dynamics of antihypertensive drug prescriptions in the search for BP control, with heterogeneity in practices among the multiple physicians involved in the care of CKD patients.

TH-PO1028

Association Between Reduced RAASi Therapy and Progression to ESKD in Hyperkalemic CKD Patients

Anjay Rastogi,[1] Charles Pollack,[2] Eva Lesén,[3] Abiy Agiro,[4] Matthew Arnold,[5] Naru Morita,[6] Krister Järbrink,[3] Toyoaki Murohara,[7] Eiichiro Kanda.[8] *[1]Department of Medicine, David Geffen School of Medicine at the University of California Los Angeles, Los Angeles, CA; [2]Department of Emergency Medicine, University of Mississippi School of Medicine, Jackson, MS; [3]CVRM Evidence, AstraZeneca, Gothenburg, Sweden; [4]Renal Payer Evidence, AstraZeneca, Wilmington, DE; [5]Real World Science and Digital, AstraZeneca, Cambridge, United Kingdom; [6]CVRM Medical Affairs, AstraZeneca, Osaka, Japan; [7]Department of Cardiology, Nagoya University Graduate School of Medicine, Nagoya, Japan; [8]Department of Medical Science, Kawasaki Medical School, Okayama, Japan.*

Background: Renin-angiotensin-aldosterone system inhibitor (RAASi) therapy is renoprotective in patients (pts) with chronic kidney disease (CKD) but increases hyperkalemia (HK) risk. Despite recommendations to maintain RAASi using novel anti-HK treatment, RAASi therapy is often limited/withdrawn in pts with HK. This observational study investigates risk of progression to end-stage kidney disease (ESKD) associated with HK-related RAASi reduction in CKD.

Methods: Data from hospital records/claims from the US (Optum's de-identified Market Clarity Data) and Japan (Medical Data Vision) were analyzed. Pts with CKD Stage 3/4 and baseline RAASi use with an HK episode (ICD-10 code E87.5) during July 2019–Sept 2021 (US)/May 2020–Sept 2021 (Japan) were included. Based on RAASi prescriptions 3 months (mo) before vs after the HK episode, pts were categorized as down-titrated, discontinued, or maintained treatment. Risk of progression to ESKD (diagnosed CKD Stage 5/ESKD or dialysis initiation) within 6 mo in pts who down-titrated/discontinued vs maintained RAASi was assessed.

Results: In total, 11,873 (US) and 1427 (Japan) pts were included. Mean age was 71 (US) and 76 (Japan) years; 52% and 66%, respectively, were male. In the US, 7506 pts filled a RAASi prescription within 3 mo prior to index event and had ≥3 mo follow-up; of these, 33% discontinued and 6% down-titrated. Of the corresponding 1179 pts in Japan, 27% discontinued and 5% down-titrated. Risk of progression to ESKD was 70–74% higher in all pts who discontinued, and 60% higher in US pts who down-titrated vs maintained RAASi (**Table**).

Conclusions: HK-prompted RAASi therapy reduction is associated with increased risk of progression to ESKD, indicating a need for improved guideline adherence in managing HK to maintain RAASi therapy.

Funding: Commercial Support - AstraZeneca

Risk of progression to ESKD in patients with CKD Stage 3/4 who discontinued or down-titrated vs maintained RAASi therapy following an HK episode

Association Between Hyperkalemia, CKD Progression, and All-Cause Mortality: The REVOLUTIONIZE II Study

Abiy Agiro,[1] Alexandra Greatsinger,[2] Jingyi Chen,[2] Erin Cook,[2] Fan Mu,[2] Angela Zhao,[2] Elaine M. Louden,[2] Ellen Colman,[1] Pooja N. Desai,[1] Glenn Chertow.[3] *[1]AstraZeneca Pharmaceuticals LP, Wilmington, DE; [2]Analysis Group Inc Boston, Boston, MA; [3]Stanford University, Stanford, CA.*

Background: The association of hyperkalemia (HK) with progression of chronic kidney disease (CKD) has not been well studied. This real-world study described and compared CKD progression and mortality among patients with HK and matched patients without HK.

Methods: Adults with stage 3b or 4 CKD with HK (defined as serum K>5.0 mmol/L and a HK diagnosis) and matched patients without HK were identified from the Optum de-identified Market Clarity database (1/2016-8/2022). Index date was the first eligible CKD diagnosis. Time to CKD progression (defined as stage 4 or 5 CKD, provision of dialysis, or kidney transplantation) and time to death were compared between cohorts using cause-specific Cox proportional hazard models reported as hazard ratios (HR) and 95% confidence intervals (CI). Subgroup analyses were conducted by CKD stage and renin-angiotensin-aldosterone system inhibitor (RAASi) use.

Results: 6,619 matched pairs were included in the overall sample. Mean age was 74.5 years, 47% male, 76% white, and 71% had stage 3b CKD at index date. Among all groups, patients with HK had statistically significantly higher rates of CKD progression (overall: HR 1.60 [95% CI 1.50, 1.71], p<0.001) (**Figure 1**). Patients with HK also had higher rates of all-cause mortality than patients without HK in the overall cohort (1.09 [1.02, 1.16]), RAASi subgroup (1.14 [1.05. 1.23]) and CKD stage 3b subgroup (1.11 [1.03, 1.20]) (all p<0.01).

Conclusions: Patients with HK experienced significantly higher rates of CKD progression and all-cause mortality compared to patients without HK, with consistent findings irrespective of use/non-use of RAASi.

Prevalence of Elevated Serum Potassium in CKD Population by KDIGO Risk and eGFR Categories in a Representative US Population: NHANES 1999-2018

Ajay K. Singh,[1,2] Zihe Zheng,[1] Youssef M. Farag.[3,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Among patients with CKD, hyperkalemia has been independently associated with poorer outcomes. However, the prevalence, risk factors, and severity of hyperkalemia in the US by demographic groups, KDIGO risk categories, eGFR categories and levels of albuminuria have not been reported.

Methods: We used data of 101,316 participants from the National Health and Nutrition Examination Survey (NHANES) between 1999 to 2018. We calculated 20-year weights to account for the complex survey design and the oversampling of certain age and minority groups. We defined and examined hyperkalemia by different levels of elevated serum potassium > 5.0, >5.5, and >6 mmol/L. Univariate and multivariate regression analysis was performed to identify independent predictors for hyperkalemia. Each model was adjusted for age, gender, race/ethnicity, diastolic blood pressure, hypertension, diabetes, HbA1c, hemoglobin, triglyceride, and CVD history. In the model of eGFR as exposure, UACR was additionally adjusted and in the model of UACR as exposure, eGFR was additionally adjusted.

Results: In a nationally representative sample of US adults with CKD, the prevalence of mild hyperkalemia (K>5.0 mmol/L) was 2.46%, moderate hyperkalemia (K>5.5 mmol/L) was 0.43%, and severe hyperkalemia (K>6 mmol/L) was rare at 0.06% (Table). While mild hyperkalemia was common in patients with KDIGO very high-risk category (9.72%) and in eGFR <15 to 29 ml/min/1.73m^2 (15.67%), severe hyperkalemia was rare at 0.54% and 1.45%, respectively. Both KDIGO risk and eGFR categories independently predicted mild and moderate hyperkalemia.

Conclusions: Mild hyperkalemia is relatively common in patients with advanced CKD, although not as high as previously reported in unweighted samples of CKD patients. Severe hyperkalemia is rare. The most important predictors of hyperkalemia are high and very high KDIGO risk categories as well as eGFR of <15-29 ml/min/1.73m^2.

Instantaneous and Persistent Elevation of Serum Potassium and Progression of CKD

Jinwei Wang, Fang Wang, Ming-Hui Zhao. *Peking University First Hospital, Beijing, China.*

Background: The adverse effect of hyperkalemia on chronic kidney disease (CKD) progression has not been well studied.

Methods: The study population was recruited from outpatients of Peking University First Hospital for patients with CKD G1-4 between 2010 and 2020. Those with ≥2 measurements of serum potassium during the first year after recruitment (baseline period) were included in the analysis. Instantaneous hyperkalemia was defined as occurrence of serum potassium≥5.0 mmol/L for once or lasting for < 3 months, while persistent hyperkalemia as repeated occurrence lasting for ≥ 3 months. The initiation of kidney replacement therapy (KRT) was followed after baseline period until death, loss of follow-up or Dec. 31 of 2020. Cox proportional hazards regression model was used to estimate the association between exposure and outcome, while linear mixed effects model to estimate the slope of estimated glomerular filtration rate (eGFR) with interactions between time and hyperkalemia status indicating difference of slope. Two-sided P<0.05 was statistically significant.

Results: A total of 527 patients were included in the analysis, with mean age of 56±16 years and 54.7% of male. CKD stage 1, 2, 3 and 4 accounted for 3.6%, 12.0%, 55.4% and 29.0% of the patients. There were 331, 85 and 111 patients with no, instantaneous and persistent hyperkalemia, respectively. During a mean follow-up of 4.45±3.27 years, 61 events of KRT occurred. Hyperkalemia was associated with higher risk of KRT (Figure 1). After multivariable adjustment, both instantaneous hyperkalemia and persistent hyperkalemia were associated with increased risk of KRT (hazard ratio: 2.43 [95%CI: 1.14-5.18] and 2.86 [95%CI: 1.48-5.54], respectively) and higher rate of eGFR decline (-2.23 and -3.92 versus -1.97 ml/min/1.73m^2/year).

Conclusions: Hyperkalemia, especially persistent status, was associated with higher risk of CKD progression among patients with CKD.

Performance of the European Kidney Function Consortium (EKFC) Creatinine-Based Equation in American Cohorts

Pierre Delanaye,[1] Andrew D. Rule,[2] Elke Schaeffner,[3] Etienne Cavalier,[1] Ulf Nyman,[5] Jonas Björk,[5] Hans Pottel.[4] EKFC (European Kidney Function Consortium). *[1]Universite de Liege, Liege, Belgium; [2]Mayo Clinic Minnesota, Rochester, MN; [3]Charite Universitatsmedizin Berlin, Berlin, Germany; [4]Universite de Liege, Liege, Belgium; [5]Lunds Universitet, Lund, Sweden.*

Background: The new creatinine-based European Kidney Function Consortium (EKFC) equation has been developed and validated in datasets of European subjects. This equation is based on rescaled creatinine, with the rescaling factor (Q-value) which is the median normal value of serum creatinine in a given population. The EKFC equation performed well across the whole age spectrum. However, the validation was limited in Black and non-Black Americans.

Methods: Cross-sectional analysis with separate pooled datasets for validation from 9 US research and clinical studies with measured GFR, age, sex, and self-reported race available. Two strategies were considered with population specific Q-values in Black and non-Black men and women ($EKFC_{PS}$) or a race-free Q value ($EKFC_{RF}$) which is the mean of the Q values obtained in Black and non-black populations. Performance (bias, precision and accuracy within 30% (P30) was compared with the CKD-EPI_{2021} equation.

Results: In the whole adult population (n=12,854), the $EKFC_{PS}$ equation showed no statistical bias (0.14 95%CI [-0.07;0.35] mL/min/1.73m2), and the statistical bias of the $EKFC_{RF}$ (0.74 [0.51;0.94] mL/min/1.73m2) was closer to zero than the CKD-EPI_{2021} equation (1.22 [0.99;1.47]) mL/min/1.73m2]. The percentage of estimated GFR within

30% of measured GFR was similar for CKD-EPI$_{2021}$ (79.2% [78.5%-79.9%]) and EKFC$_{RF}$ (80.1% [79.4%-80.7%]) but improved with the EKFC$_{PS}$ equation (81.1% [80.5%-81.8%]).

Conclusions: The EKFC-equation can be used in the USA to estimate GFR incorporating either self-reported race or unknown race at the patient's discretion per hospital registration records. The performance of the EKFC equation is as at least good as the CKD-EPI$_{2021}$ equation.

Table: Performance of the CKD-EPI$_{2021}$ and EKFC equations to estimate glomerular filtration rate

TH-PO1033

New Argentine Equation to Estimate the Glomerular Filtration Rate

Pehuén Fernández,[1,2] María Laura Nores,[3] Pablo R. Lujan,[1] Sofia Naser,[1] Javier De Arteaga,[1,2] Jorge de la Fuente,[1,2] Walter Douthat,[1,2] Carlos R. Chiurchiu.[1,2] *[1]Hospital Privado Centro Medico de Cordoba, Cordoba, Argentina; [2]Instituto Universitario de Ciencias Biomedicas de Cordoba, Cordoba, Argentina; [3]Universidad Nacional de Cordoba, Cordoba, Argentina*.

Background: Latin Americans are poorly represented in the current glomerular filtration rate equations (eGFR), so their predictions are difficult to extrapolate in our population. Objetive: to develop a new equation to estimate GFR based on data from Argentina and compare its performance with those currently available.

Methods: Cross-sectional study. We included all adults whose GFR was measured with urinary clearance of iothalamate (mGFR) between 2007 and 2017 (development sample–DS-, n=583). The chosen equation was based on a quasi-likelihood model with identity variance function and logarithmic link to predict mGFR from the square root of creatinine, age, sex, monoren, albumin and the logarithm of urea. Later, an independent sample was added between 2018 and 2019 (temporary validation sample -TVS-, n=78). The performance of the new equation was compared with the previous ones (MCQ, MDRD 4 and 6, CKD-EPI 2009 and 2021) in the DS (by 10-fold cross-validation) and in the TVS.

Results: There were no differences in the baseline characteristics in both samples and they presented a wide range in the mGFR (1.9-186.6 ml/min/1.73 m^2). Within the previous equations, CKD-EPI (2009 and 2021) obtained the best performance (comparator). In the DS, Argentine Equation (AE) presented a lower RMSE, higher P15, bias median closer to zero, and a higher %CC compared to CKD-EPI 2009. In addition, from Q1, M, and Q3 of the bias, a greater shift to the left of CKD-EPI 2009. Compared with CKD-EPI 2021, AE obtained a median bias closer to 0, and in the rest of the metrics it was slightly lower, although very similar (table 1). In the TVS, AE presented a lower RMSE, higher r, P30 and %CC compared to CKD-EPI in its two versions. In addition, it presented a median bias closer to 0 and a higher P15 compared to CKD-EPI 2009.

Conclusions: AE presented a better global performance to estimate GFR in residents of Argentina compared to the currently equations.

Table 1. Performance of the equations in the development sample (by 10-fold cross validation) and in the temporary validation sample.

	RMSE	Bias (Q1 / Q3)	P15	P30	r	%CC
Development Sample by 10-fold cross validation (n=583)						
CKD-EPI 2009	18.3	-4.3 (-13.8 / 6)	58	84.4	0.868	73.6
CKD-EPI 2021	17.9	-0.6 (-10.1 / 9.5)	61.2	83.7	0.869	73.9
AE	18	-0.3 (-10.1 / 9)	60.7	83.2	0.867	73.8
Temporary Validation Sample (n=78)						
CKD-EPI 2009	16.8	-4.6 (-16.2 / 2.4)	57.7	88.5	0.882	70.5
CKD-EPI 2021	15.4	-1.1 (-12.4 / 6.4)	61.5	85.9	0.887	74.4
AE	15	-1.1 (-12.1 / 6.9)	60.2	89.7	0.894	79.5

RMSE= Root mean squared error, Bias= Median difference between the estimated and measured GFR; Q1 and Q3= 1th and 3th quartile; P15 and P30= % of the eGFR within ±15 or 30% of the mGFR; r= Pearson's correlation coefficient; %CC= Percentage of patients correctly classified in CKD stages; AE= Argentine Equation

TH-PO1034

Performance Evaluation of CKD-EPI Equations for Estimated Glomerular Filtration Rate Compared with Inulin Clearance in Koreans

Jeongmin Cho,[1] Ran-hui Cha,[2] Dong Ki Kim,[1] Ho Jun Chin.[3] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]National Medical Center, Jung, Seoul, Republic of Korea; [3]Seoul National University Bundang Hospital, Seongnam, Republic of Korea*.

Background: A race-free glomerular filtration rate (GFR) estimation equation has recently been developed. However, the performance of the new Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) equations needs to be evaluated in Asian populations.

Methods: We performed a cross-sectional study at a single center in South Korea. The measured GFR (mGFR) was determined based on systemic inulin clearance. The GFR was estimated using the following five CKD-EPI equations incorporating creatinine (cr), cystatin C (cys), and cystatin C and creatinine (cr-cys): 2009 CKD-EPIcr, 2012 CKD-EPIcr-cys, 2012 CKD-EPIcys, 2021 CKD-EPIcr, and 2021 CKD-EPIcr-cys.

Results: The bias of 2009 CKD-EPIcr (2.24) and 2012 CKD-EPIcr-cys (6.74) were lower than those of 2021 CKD-EPI equations (5.40 and 10.54 mL/min/1.73 m^2). The accuracy of the five eGFR equations measured as the percentage of study participants with eGFR values within 30% of the mGFR of original CKD-EPIcr and CKD-EPIcr-cys were higher than those of 2021 equations (85.4 vs. 83.3% and 84.1 vs. 80.8%). The overall concordance rate between mGFR and estimated GFR was higher in the 2009 CKD-EPIcr (0.393) and 2012 CKD-EPIcr-cys (0.473) than in the 2021 CKD-EPIcr-cys (0.372 and 0.456). The CKD prevalence in 2009 CKD-EPIcr, 2021 CKD-EPIcr, 2012 CKD-EPIcr-cys, and 2021 CKD-EPIcr-cys was 54.8%, 51.0%, 47.7%, and 44.8%, respectively.

Conclusions: Our study demonstrated better performance of the original CKD-EPIcr and CKD-EPIcr-cys equations than the 2021 new CKD-EPI equations. We do not recommend the adoption of the new CKD-EPI equations in Korea.

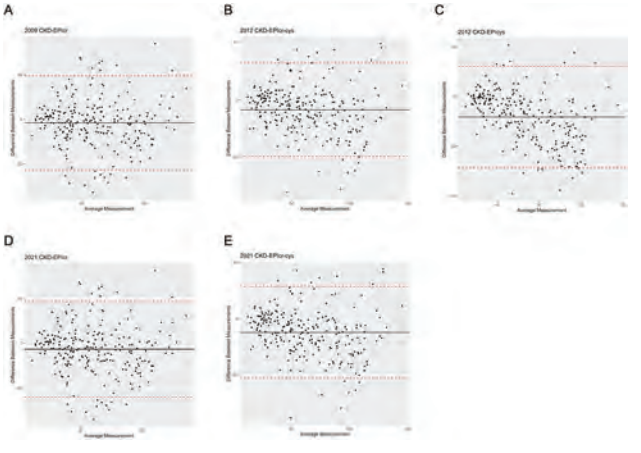

Figure 1. Bland-Altman plots for the concordance rate between mGFR and eGFR.

Equations	Intercept (95% CIs)	Slope (95% CIs)	[a]Median bias (95% CIs)	[b]Accuracy, %		
				15%	30%	50%
2009 CKD-EPIcr	20.01 (13.37–26.65)	0.61 (0.51–0.71)	2.24 (-8.83–17.39)	79.5	85.4	91.2
2012 CKD-EPIcr-cys	9.98 (4.89–15.07)	0.71 (0.64–0.78)	6.74 (-2.81–20.80)	75.3	84.1	91.6
2012 CKD-EPIcys	12.75 (7.80–17.70)	0.57 (0.52–0.63)	16.07 (2.23–38.91)	57.7	64.9	73.6
2021 CKD-EPIcr	19.40 (12.6–26.21)	0.59 (0.5–0.69)	5.40 (-6.04–20.40)	76.2	83.3	89.1
2021 CKD-EPIcr-cys	8.44 (3.29–13.58)	0.70 (0.64–0.77)	10.54 (0.30–24.37)	69.0	80.8	87.4

TH-PO1035

The Impact of Muscle Mass on eGFR Accuracy with Creatinine and Cystatin C

Rouvick Gama,[1,2] Kathryn Dalrymple,[1] Emmanuel Mangahis,[1,2] Kate Bramham,[1,2] Sharlene A. Greenwood.[1,2] *[1]King's College London, London, United Kingdom; [2]King's College Hospital NHS Foundation Trust, London, United Kingdom.*

Background: The use of creatinine (Cr) for estimating glomerular filtration rate (eGFR) is limited by non-GFR factors such as muscle mass, diet and drugs. Calculating lean tissue mass (LTM), a surrogate for muscle mass, or cystatin-c (Cys-c) – an alternative filtration marker unaffected by muscle mass or diet - may improve GFR estimation. We explored the relationship between LTM and eGFR accuracy using Cr and/or Cys-c, compared to measured GFR (mGFR) at multiple timepoints.

Methods: Participants with CKD were recruited. Demographics (age, sex, ethnicity) and 0, 6- and 12-month weight (kg), LTM (kg), mGFR, Cr and Cys-c were recorded. eGFR was calculated using the Modification of Diet for Renal Disease (MDRD), European Kidney Function Consortium (EKFC), CKD Epidemiology Collaboration (CKD-EPI) 2009, 2012 and 2021 equations for Cr, Cys-c and combined Cr-Cys-c. The relationship between LTM, mGFR and eGFR equations were assessed using beta coefficient. Association at baseline and over 12 months with LTM was assessed using regression analysis and multilevel mixed-effects linear regression respectively.

Results: Of 41 participants, 28 (68.3%) were male and mean age was 53.2 ± 14.1 yrs. Baseline median (IQR) weight, LTM and mGFR were 85.5kg (71.2, 104.4), 44.3kg (36.5, 53.6) and 35 mL/min/1.73m^2 (23.0, 46.0) respectively. Baseline LTM (kg) was associated with higher values of mGFR-eGFR beta-coefficients for all Cr based equations ($p<0.05$). LTM as percentage of weight was weakly associated with CKD-EPI 2021 Cr equation (0.66; 95% CI 0.01-1.31;$p<0.05$). Cys-c eGFR equations compared with mGFR showed no significant associations with LTM. At 12 months, there was also a significant relationship between mGFR-eGFR Cr-based beta-coefficients (figure 1).

Conclusions: LTM was associated with Cr-based eGFR's relationship with mGFR. There was no significant association involving Cys-c based equations, providing further evidence of independence of muscle mass, making its use more appealing in specific cohorts (e.g. liver cirrhosis, malignancy). Analysis of a larger cohort may allow a factor for LTM to further improve eGFR equation accuracy.

Impact of Obesity on the Associations of Cystatin C-Based eGFR with Clinical Outcomes

Debbie Chen,[1,2] Rebecca Scherzer,[1] Joachim H. Ix,[3] Holly J. Kramer,[4] Deidra C. Crews,[5] Girish N. Nadkarni,[6] Orlando M. Gutierrez,[7] Titilayo O. Ilori,[8] Alexander L. Bullen,[3] Pranav S. Garimella,[3] Michael Shlipak,[9,1] Michelle M. Estrella.[9,1] *[1]University of California San Francisco, San Francisco, CA; [2]Genentech Inc, South San Francisco, CA; [3]University of California San Diego, La Jolla, CA; [4]Loyola University Health System, Maywood, IL; [5]Johns Hopkins University, Baltimore, MD; [6]Mount Sinai Health System, New York, NY; [7]The University of Alabama at Birmingham, Birmingham, AL; [8]Boston University, Boston, MA; [9]San Francisco VA Health Care System, San Francisco, CA.*

Background: Cystatin C-based eGFR (eGFRcys) has stronger associations with adverse clinical outcomes than creatinine-based eGFR (eGFRcr). Obesity may be associated with higher cystatin C levels, independent of kidney function, but whether obesity affects the prognostic utility of eGFRcys is unknown.

Methods: This prospective cohort study included 27,249 US adults enrolled in the Reasons for Geographic and Racial Differences in Stroke study between 2003 and 2007. We constructed multivariable Cox and Fine-Gray models with multiplicative interaction terms to investigate whether waist circumference (WC) quartiles modified associations of eGFR with risks of all-cause mortality, ESKD, incident atherosclerotic cardiovascular disease (ASCVD), and incident heart failure (HF).

Results: Participants had a mean age of 65 y; 54% were women, and 41% were Black. Baseline prevalence of abdominal obesity (WC ≥88 cm for women or ≥102 cm for men) was 48% and obesity (BMI ≥30 kg/m^2) was 38%. During a median follow-up time of 12.1 years, 9350 (34%) participants died, 511 (2%) developed ESKD, 2271 (11%) had an incident ASCVD event, and 1053 (4%) had an incident HF hospitalization. In adjusted analyses (Table 1), each 15-mL/min/1.73 m^2 lower eGFRcys was associated with higher risk of mortality in each WC quartile (Q1: HR 1.10 [1.15, 1.24]; Q2: HR 1.22 [1.18, 1.26]; Q3: HR 1.20 [1.16, 1.24]; Q4: 1.19 [1.15, 1.23]). WC did not modify associations of eGFRcys with mortality (p-interaction >0.05). Similarly, WC did not modify associations of eGFRcys with the other outcomes (all p-interactions >0.05). Compared with eGFRcr, eGFRcys had stronger associations with mortality in all WC quartiles ($p<0.001$ in all quartiles).

Conclusions: The association of eGFRcys with adverse outcomes did not differ by WC. Among individuals with obesity, cystatin C may be used to examine associations of eGFR with important clinical adverse outcomes related to kidney disease.

Indexing to Body Surface Area Diminishes GFR Estimation and Increases CKD Staging in Overweight and Obese Population

Juan P. Huidobro,[1] Rodrigo Sepúlveda,[1] Jorge E. Vega.[2,3] *[1]Pontificia Universidad Catolica de Chile, Santiago, Chile; [2]Universidad de Valparaiso, Valparaiso, Chile; [3]Hospital Naval de Vina del Mar Almirante Nef, Vina del Mar, Chile.*

Background: Estimated glomerular filtration rate (eGFR) is usually indexed to a standard body surface area (BSA) of 1.73m^2. This allows comparing values of individuals of different sizes but can potentially affect eGFR in individuals with extreme BSA. We aimed to evaluate the differences in eGFR with and without indexing for BSA in a cohort of ambulatory patients with different body mass index (BMI) and how indexing affects CKD classification.

Methods: 390 patients of a nephrological clinic were evaluated with ambulatory 24-hour creatinine clearance (CrCl) and their demographic and anthropometric data was registered in an anonymous database. Patients were divided in 3 groups according to BMI (18-24.9; 25-29.9; ≥30 kg/m^2). GFR was estimated with MDRD-4, CKD-EPI 2009 and 2021 equations, with and without indexing to 1.73m^2. CKD classification was also performed with and without indexing eGFR.

Results: 224 of 390 patients were men (57.4%).103 (26.4%) had normal BMI (group 1), 193 (49.5%) were overweight (group 2) and 94 (24.1%) were obese (group 3). The difference between non-indexed and indexed CrCl was +2.2 ml/min, - 2.9 ml/min y – 9.3 ml/min in groups 1, 2 and 3, respectively. Using MDRD-4, CKD-EPI 2009 and 2021 equations, the differences were -2.0, -2,1 and -2,2 in group 1; +2.2, +2,3 and +2,5 in group 2; and +7.3, 7,6 and +8.0 ml/min in group 3. Non-indexed eGFR was significantly higher in obese patients ($p<0.001$). Classification of CKD was significantly affected by removing indexing using CKD-EPI 2021 equation, with almost 20% of the patients switching stage of CKD (17.5% group 1, 18.7% group 2 and 12.8% group 3). Diagnosis of GFR <60 mL/min was more frequent when GFR estimation was indexed in overweight and obese patients (15% and 13.3% more, respectively). Converserly, removing indexing reclassifies 11.7% of patients with normal BMI into GFR <60 mL/min.

Conclusions: Indexing to standard BSA lowers eGFR in overweight and obese patients, leading to a higher prevalence of < 60 ml/min CKD diagnosis.

TH-PO1038

Potential Value of Near Real-Time Transdermal GFR Measurement: Estimated GFR Results by CKD-EPI Serum Creatinine Misclassifies CKD Stage in One of Three Adults

Stuart Goldstein,[1,2] Richard B. Dorshow.[2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]MediBeacon, St.Louis, MO.*

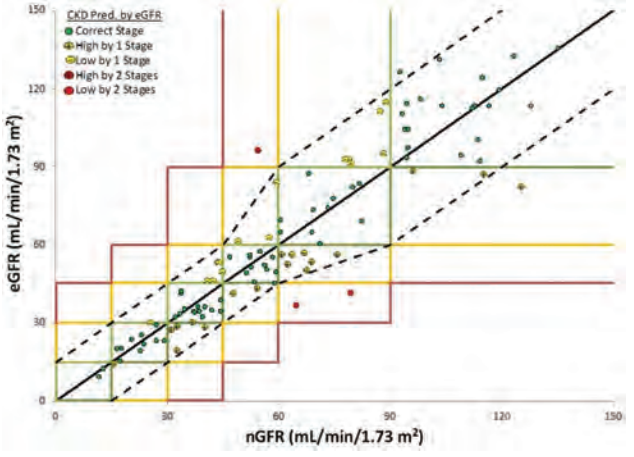
Background: Currently, chronic kidney disease is most often staged using the serum creatinine-based CKD-EPI equation to estimate GFR (eGFR). Serum creatinine is confounded by several well-known factors including chronic inflammation, muscle mass, medications, tubular SCr secretion and hydration status. Available measured GFR methods are challenged by need for multiple blood draws, radiological equipment and time or prolonged urine collections which are unreliable. We have previously shown our plasma GFR assessment (nGFR) with novel fluorescent tracer agent, relmapirazin (also known as MB-102 in the literature), demonstrates outstanding correlation with iohexol measured GFR in Phase I and II studies (n=120 patients, r^2=0.99). We have also previously shown transdermal MB-102 GFR assessment (tGFR) shows outstanding correlation with MB102 nGFR (r^2=0.95), and can report GFR within 90-120 minutes at the bedside. We assessed the agreement between nGFR and eGFR in the 120 Phase I and II subjects.

Methods: This prospective study evaluated nGFR with the MediBeacon Inc system in 120 adult patients with CKD Stages 1-4. MB-102 distributes in body tissues over 90-

120 minutes and starts to be cleared solely by glomerular filtration. We compared the CKD Stage by CKD-EPI and nGFR using plasma measurements MB-102 over 8-12 hours.

Results: Data from all 120 subjects (64 female, median age 55.5 years, median BMI 29 kg/m^2) were available for analysis. Reported patient race was White (69), Black (48), American Indian/Alaskan Native (2), Asian (1) and all 6 of the Fitzpatrick Skin Scales were represented. **Figure 1** shows that nGFR and CKD-EPI eGFR differed by at leas one CKD Stage in 32% and at least CKD Stages 4% of the time. Over- and underestimation of CKD was evenly divided.

Conclusions: CKD-EPI eGFR misclassifies true GFR based CKD stage in more than 1/3 of patients. We have completed a Phase II study comparing nGFR to tGFR to demonstrate accurate near real-time GFR assessment at the bedside.



TH-PO1039

Machine Learning and Multiparametric MRI for Noninvasive Diagnosis of the Etiology of CKD

Tsutomu Inoue,[1] Eito Kozawa,[1] Masahiro Ishikawa,[2,1] Hiroaki Amano,[1] Wakako Kosakai,[1] Yusuke Watanabe,[1] Koji Tomori,[1] Naoki Kobayashi,[1] Hirokazu Okada.[1] *[1]Saitama Ika Daigaku, Iruma-gun, Japan; [2]Kinki Daigaku, Higashiosaka, Japan.*

Background: Multiparametric magnetic resonance imaging (MRI) has the potential to provide various types of biological information about the kidney. In this study, we aimed to diagnose the underlying etiology of chronic kidney disease (CKD) non-invasively by combining MRI images and machine learning.

Methods: T1-weighted images (water-weighted images using the Dixon method), T1 value maps, T2* value maps of blood oxygen level-dependent MRI, perfusion maps of arterial spin-labeling, fractional anisotropy value maps from diffusion tensor imaging, and apparent diffusion coefficient value maps from diffusion-weighted imaging were used. We calculated the cortical values and cortical-medullary gradients using a 12-layer concentric object method. We created a multiclass classifier using a support vector machine and features such as MRI measurement values, age, estimated glomerular filtration rate (eGFR) at the time of imaging, and hemoglobin value. K-fold cross-validation was used to evaluate classifier accuracy.

Results: A total of 197 patients [60.9 ± 14.9 years old, 65.0% male, 15.2% with diabetic kidney disease (DKD), 34.0% with chronic glomerulonephritis (CGN), 50.8% with nephrosclerosis (NS), and a mean eGFR of 42.3 ± 22.2 ml/min/1.73 m^2] were included. After model optimization, we obtained a relatively good overall accuracy of 0.65, and area under the curve values of 0.72 for DKD, 0.76 for CGN, and 0.73 for NS on the receiver operating characteristic curve. There were some estimation errors, particularly in cases diagnosed with DKD by physicians, and accuracy of the estimation tended to be low. Among cases of DKD, there were also cases that showed imaging characteristics similar to those of NS or CGN, suggesting an overlap of pathologies.

Conclusions: Conventional and functional kidney MRI and machine learning/augmented intelligence diagnosis have the potential to be useful noninvasive diagnostic tools, and further improvements in accuracy can be achieved by refining the features. We observed some cases diagnosed with DKD by nephrologists based on the clinical course and results of blood/urine test that showed MR imaging characteristics resembling those of NS or CGN. Kidney biopsy or renal MRI may be effective for accurate diagnosis and determination of an appropriate treatment plan.

TH-PO1040

Feasibility and Safety of Percutaneous Kidney Biopsy in Small Kidneys: Breaking the Paradigm

Ivan Zepeda Quiroz,[1] Jose D. Juarez Villa,[1] Brenda Cortez,[1] Omar H. Sanchez Vazquez,[2] Alejandro Garcia Rivera,[2] Victor H. Gomez Johnson,[1] Bernardo Moguel.[1] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

Background: Percutaneous kidney biopsy (PKB) is a vital diagnostic tool, there are absolute and relative contraindications. Kidney size considered a relative contraindication due to poor accessibility and risk of complications, therefore, there is no consensus regarding the best approach in this setting.

Methods: Retrospective cross sectional at the Interventional Nephrology Department of the Instituto Nacional de Cardiologia Ignacio Chavez. Patients older than 16 years old who had kidney length of ≤ 8 cm and underwent a PKB of native kidneys from July 2019 to December 2022 were included. Sampling was performed in real time guided by ultrasound. For the comparative analysis, the Chi-square or Fisher's exact test were used for qualitative variables, and the T-student or Mann-Witney U test for quantitative variables, according to their distribution.

Results: 25 patients were included, 19 women and 6 men. The mean age was 42.3 ± 18.04. The mean kidney length was 7.56 ±0.33 and the mean width was 4.2 cm. All patients received only one puncture, with an average of 12 glomeruli. The mean serum creatinine was 1.94 mg/dL. Minor complications occurred in 5 patients, perirenal hematoma 3, hematuria in 1, and hematoma plus hematuria in 1 patient. Histological examination showed FSGS in 36% of cases, lupus nephritis in 20%, other glomerular diseases in 16%, crescentic glomerulonephritis in 16%, and tubulointerstitial nephritis in 12%. Management was modified in 64% of cases. A bivariate analysis was performed for complications versus without complications based on clinical and ultrasound characteristics, where statistical significance was found for complications with pre-biopsy DBP of 89 ± 5.80 mmHg (p>0.001).

Conclusions: PKB in small kidneys is a feasible and safe procedure when properly planned, providing an adequate sample in all cases, with an insignificant number of minor complications, and that is clinically relevant.

TH-PO1041

Quantifying the Delay from Laboratory-Based Detection to Diagnosis of CKD in the United States

Satabdi Chatterjee,[1] Adrian R. Levy,[2] Bonnie M. Donato,[1] Ling Zhang,[1] Sydnie Stackland,[3] Csaba P. Kovesdy.[4] *[1]Boehringer Ingelheim Pharmaceuticals Inc., Ridgefield, CT; [2]Dalhousie University, Halifax, NS, Canada; [3]Panalgo LLC, Boston, MA; [4]The University of Tennessee Health Science Center, Memphis, TN.*

Background: While delays from chronic kidney disease (CKD) onset to diagnosis are common, these delays have yet to be quantified. The study objective was to quantify the delay from laboratory-based physiologic detection (using eGFR) to diagnosis of CKD (using ICD 9/10 code).

Methods: A retrospective cohort study was conducted using 2009 -2020 Optum® Market Clarity data. Individuals aged 18 years and older, who had two laboratory records showing eGFR < 60 mL/min/1.73 m^2, 3-12 months apart, were included. The second eGFR < 60 was defined as the index date. Patients with pre-existing ICD code of CKD during the 12-month pre-index period (baseline), or before the first eGFR <60 were excluded. Individuals were followed from the index date until a diagnosis of CKD or censoring (date of death, end of follow-up, or disenrollment). Cohorts were stratified by the presence or absence of comorbid diabetes and heart failure (HF) at baseline. Survival analysis was performed to evaluate the factors associated with delays in diagnosis, for overall and stratified cohorts.

Results: A total of 1.39 million adults with laboratory evidence of CKD (mean (±SD) age 71 (±10); 63% women; 87% Caucasian) were included. Over 90% of them were in KDIGO stage 3, 5% in stage 4 and 1% in stage 5. Overall, 62% of individuals had neither diabetes nor HF, 24% had diabetes, 8% had HF, and 6% had both. The mean follow-up was 2.7 (SD 2.4) years. Overall, the median time to CKD diagnosis was 469 days (interquartile range [IQR]: 120-1062); time to CKD diagnosis was 537 days (IQR: 152-1163) among those without diabetes or HF, 449 days (IQR: 114-1007) among those only with diabetes, 319 days (IQR: 62-793) among those with only HF, and 270 days (IQR: 54-694) among those with both diabetes and HF. Factors associated with longer time to CKD diagnosis included: absence of diabetes or HF; less severe CKD; younger age; female sex; and Caucasian race.

Conclusions: In a large cohort of individuals with laboratory-based evidence of CKD, the time to diagnosis was delayed, on average, by over a year. In light of newer therapies that can slow kidney disease progression and reduce cardiovascular complications, these findings reinforce the need for early recognition of CKD that would inform optimal guideline-based treatment and improve outcomes in these patients.

TH-PO1042

Exploring the Spectrum of Retroperitoneal Fibrosis

Nityasree Srialluri, Dustin Le, Grace A. Molano, Mohamed G. Atta. *Johns Hopkins Medicine, Baltimore, MD.*

Background: Retroperitoneal fibrosis (RPF) is a rare disease characterized by fibroinflammatory tissue surrounding the abdominal aorta and iliac arteries. Due to the nonspecific nature of its clinical presentation, diagnosis is challenging and often delayed. This study aims to comprehensively analyze the clinical characteristics, treatment approaches, and renal outcomes in a diverse cohort of RPF patients.

Methods: Electronic Health Records of patients who underwent evaluation for RPF between 01/2015 to 09/2022 at Johns Hopkins Hospital were reviewed to collect data on baseline demographics, clinical information, laboratory findings, imaging results, histopathology, and outcomes. Follow-up was from the first nephrology visit until end of study or last follow-up.

Results: 43 patients underwent evaluation for RPF. The most common lesion was idiopathic RPF which was present in 23 (54%) patients (mean age: 62 years, 48% Male; 35% Black, mean eGFR: 58 ml/min/1.73m^3), followed by Erdheim Chester Disease (ECD) in 4 (9%) patients (mean age: 68 years, 75% Male, 0% Black, mean eGFR: 81 ml/min/1.73m^3), and IgG4 disease in 4 (9%) patients (mean age: 58 years, 100% Male, 75% Black, mean eGFR: 58 ml/min/1.73m^3). The remaining 7 (16%) patients (mean age: 62 years, 57% Male, 43% Asian, mean eGFR: 74 ml/min/1.73m^3) had diverse diagnoses, including Follicular Lymphoma, Secondary RPF (from asbestos and Renal Cell Carcinoma), Non-Langerhans Cell Histiocytosis, Thrombosed Aneurysm, and Adnexal Cyst. 5 (12%) patients are currently under evaluation. Common symptoms included pain (flank, abdominal, or back), emesis, and ≥ 5lb weight loss. Imaging showed hydronephrosis in most patients and periaortic findings in those with IgG4 disease and idiopathic RPF. 19 (44%) patients had acute kidney injury at diagnosis. In the first year, 17 (74 %) idiopathic RPF patients received medical therapy (Mycophenolate, Rituximab, Tamoxifen, or Steroids), and patients who tolerated medical therapy had stable or improved disease outcomes. IgG4 disease and ECD patients received immunosuppressants and ECD-specific treatment after biopsy confirmation resulting in improved or stable disease during follow-up.

Conclusions: This study offers valuable insights on diagnosing, managing, and evaluating patients with RPF and related conditions. Our diverse cohort enhances understanding of this rare disease and informs clinical decision-making in RPF cases.

TH-PO1043

Bilateral Multiple Renal Arteries as a Cause for Renal Infarction

Mit A. Chauhan,[1,2] Heli Bhatt,[3,4] Pooja Malhotra.[1,2] *[1]Saint Michael's Medical Center, Newark, NJ; [2]New York Medical College, Valhalla, NY; [3]Texoma Medical Center, Denison, TX; [4]Texas College of Osteopathic Medicine, Fort Worth, TX.*

Introduction: Atrial fibrillation is the most common cause of renal infarction followed by valvular or ischemic heart disease, and coagulopathy. However, when all tests are unremarkable, renovascular abnormalities must be kept in the differential. We present one such case of bilateral double renal artery as a likely cause of renal infarction.

Case Description: Forty-six-year-old male with no known past medical history presents to the emergency department for sudden onset left lower quadrant pain radiating to left flank and thigh, severe, 10/10, constant and progressively worsening. Patient denies any dysuria, hematuria, or change in urine output. Patient is hemodynamically stable. The physical exam elicited left sided flank tenderness, left testicular tenderness without swelling or evidence of varicose veins. Lab results showed elevated white blood cell count of 16.5, normal BUN and creatinine. The erythrocyte sedimentation rate was normal. ECG showed normal sinus rhythm with early repolarization pattern. CT abdomen pelvis with IV contrast showed multiple medium sized wedge-shaped parenchymal hypodensities in the left kidney. Complete renal ultrasound denoted occult findings of renal infarction. MRI angiogram of the abdomen with contrast showed two renal arteries bilaterally and reaffirmed renal infarctions in the left upper, middle, and lower kidney. Transthoracic and transesophageal echocardiograms were unremarkable for cardiac thrombosis. Pharmacological nuclear stress test was normal. The patient was started on therapeutic anticoagulation, initially on heparin drip and subsequently discharged on Rivaroxaban. C3 complement was 232 and C4 Complement was 54. Anti-nuclear antibody, lupus anticoagulant, Protein C & S, beta-2 glycoprotein antibodies, Anticardiolipin antibody, and rheumatoid factor were unremarkable.

Discussion: This case is unique because this patient has double bilateral renal arteries which is anatomically rare. Predominantly, there are two renal arteries, originating from the aorta. Few are seen to have double renal arteries and rarely bilaterally. To the best of our knowledge, multiple renal arteries have not been reported as a cause of renal infarction. Therefore, we emphasize renal anatomical abnormalities as an etiology of renal infarction, given all other hypercoagulable work up and cardiac work up is unremarkable.

TH-PO1044

Clinical Course and Recurrence in TAFRO Syndrome: A Case Series Analysis

Yusuke Yoshimura, Hiroki Mizuno, Naoki Sawa. *Toranomon Byoin Bunin, Kawasaki, Japan.*

Background: TAFRO syndrome is a rare systemic inflammatory disease characterized by five manifestations: thrombocytopenia, anasarca, fever/inflammation, renal insufficiency/reticulin fibrosis of the bone marrow, and organomegaly. It is considered a severe subtype of idiopathic multicentric Castleman disease (iMCD), with the potential for dire outcomes such as hemodialysis or death. Despite prior reporting on TAFRO syndrome's clinicopathological features, its long-term clinical course remains unknown. This study presents a case-series analysis of ten patients with TAFRO syndrome, exploring the long-term prognosis and recurrence of TAFRO syndrome.

Methods: We conducted a retrospective case-series study of patients with TAFRO syndrome at Toranomon Hospital or Toranomon Hospital Kajigaya from January 2012 to June 2021. Diagnosis was based on the criteria proposed by Nishimura *et al*. We collected clinicopathological data from medical records. Clinical course analysis was performed, with the diagnosis day defined as Day 1.

Results: A total of 10 patients were enrolled. All patients were Japanese, with a median follow-up period of 1,636 days (185 – 3,566). All patients underwent corticosteroid treatment, with 9 out of 10 receiving tocilizumab (TCZ) therapy. Rituximab and cyclosporin A were added in 4 and 1 patients, respectively. Recurrence occurred in 2 cases after reducing the TCZ dosage. By contrast, 2 patients maintained long-term remission after terminating all medications. One patient died due to severe pneumonia during immunosuppressive therapy.

Conclusions: The study revealed the potential for disease recurrence in TAFRO syndrome, particularly following TCZ dosage reduction. These findings suggest that the diathesis of TAFRO syndrome may persist long after the initial onset of the disease, and insufficient maintenance therapy could trigger a relapse. On the other hand, some patients maintained long-term remission even after stopping TCZ, indicating the possible varying degrees of IL-6 contribution to the etiology of TAFRO syndrome. Further studies are needed to enhance our understanding of this rare disease's pathogenesis and to optimize its stratified management.

TH-PO1045

The Crash-Lander Advanced Renal Disease Study (CLARD) Study

Ihab El Madhoun, Rony Pulikkan, Mourad Bouarour, Krishnakumar Karipoth, Saad Mahi, Shibu Jacob, Ahmed Emam. *Al Wakra Hospital- HMC, Al Wakra, Qatar.*

Background: Advanced renal disease (ARD) patients can present very late which carries a high risk of morbidity and mortality. Patients with ARD need dialysis support and treatment to be planned ahead. The aim of this study is to review the characters, presentation, renal replacement therapy requirement and outcome of advanced renal diseases cases who required unplanned dialysis in our institution.

Methods: All adult patients who presented acutely to our secondary care Al Wakra Hospital, Hamad Medical Corporation Qatar with serum creatinine >1000mmol/L between 1/1/2016 to 31/12/2022 reviewed. Their initial presentation and need for urgent dialysis, comorbidities, clinical and biochemical parameters, duration of hospital stay have been studied. We intend to assess their outcome with regards to dialysis need, morbidity and mortality during admission and 90 days after presentation. Data collected from the hospital electronic health records.

Results: Out of initially screened 340 patients, 172 fulfilled the inclusion criteria.149 (86%) were males. The mean age was 47 years. 144 (83%) required dialysis during their admission. 12 (6.9%) patients improved without the need for dialysis and 16 (9.3%) patients refused dialysis. 64 (37.2%) patients were sick enough to require ICU/HDU admission. Most patients (93%) managed with hemodialysis. 94 (65%) required temporary vascular access, 38 (26%) Permcath, 9 (6%) peritoneal catheter and only 3 (2%) AVF. The main renal disease was Diabetes in 47 (27.3%) patients, unknown in 49 (28.5%) patients and Hypertension in 26 (15%) patients. 66 (38%) patients were diabetic. 68 (39%) patients had previous encounter with nephrologist sometime in the past. Out of the dialyzed patients, 122 (85%) required to be on long term dialysis. Length of hospital stay was 2 weeks, 1 week and 3 weeks for 60 (34%), 57 (33%) and 26 (15%) patients, respectively. Out of the172 patients, on day 90 from admission, 94 (55%) patients were alive, 3 (2%) expired and 75 (43%) lost follow up.

Conclusions: - Crash- lander ARD is not uncommon in day to day practice and carries high morbidity and represent a heavy burden on health system. - 85% of patients with presenting creatinine > 1000mmol/L will need long term renal replacement therapy. - Despite the severity of the presenting illness, there was low mortality rate for the patients on 90 days follow up.

Clinical Characteristics, Comorbidities, and Management of Patients with CKD: Insights from iCaReMe Global Registry

Carol A. Pollock,[1] Kamlesh Khunti,[2] Hiddo J. Heerspink,[3] Antonio Nicolucci,[4] Shashank R. Joshi,[5] Peter Fenici,[6] Susana Goncalves,[7] Luong Nguyen Cong,[8] Hardik Vasnawala,[9] Ahmed Hadaoui.[10] *[1]Kolling Institute of Medical Research, St Leonards, NSW, Australia; [2]University of Leicester, Leicester, United Kingdom; [3]Department of Clinical Pharmacy and Pharmacology University Medical Center Groningen, Groningen, Netherlands; [4]Center for Outcomes Research and Clinical Epidemiology, Pescara, Italy; [5]Lilavati Hospital & Research Centre), Mumbai, India; [6]AstraZeneca Italy, Milan, Italy; [7]AstraZeneca Argentina, Buenos Aires, Argentina; [8]AstraZeneca Vietnam, Ho Chi Minh City, Viet Nam; [9]AstraZeneca India, Bangalore, India; [10]AstraZeneca Algeria, Algiers, Algeria.*

Background: CKD is recognized as a global health concern with an increased prevalence, and attributable morbidity and mortality particularly in low- and middle-income countries where there is a need to better understand clinical characteristics, and risk factors for CKD within the Cardiovascular Renal Metabolic Continuum. iCaReMe

registry is an opportunity to fill this knowledge gap by providing a comprehensive global real-world data source on patients' characteristics, disease management and outcomes. The objective of our analysis is to describe clinical features, major risk factors, and management of CKD patients based on data from the iCaReMe Registry.

Methods: iCaReMe Global Registry (NCT03549754) is a multinational, prospective, observational study to assess the management and quality of care of patients with CKD, T2D, HTN, and/or HF. We present baseline cross-sectional descriptive analysis of the CKD cohort enrolled from February 2018 to December 2022.

Results: Overall, 2977 adults with CKD (mean age 60.6 years, 54.6% male) were enrolled in 21 countries* across the six WHO regions**. DKD and HKD were the most common etiologies. HTN, T2D, dyslipidemia, HF were present in 80.2%, 72.1%, 44.1% and 35.3% of patients respectively. Mean UACR was 556.7 mg/g available in 891 (30%) patients and mean eGFR was 46.1ml/min/1.73m^2 reported in 2492 (83.7%) patients. ACEi or ARB were prescribed to 37.8% of patients, and 20.6% received an SGLT2i.

Conclusions: Our results highlight opportunities to improve CKD management particularly in patients with CVD multimorbidity and advanced CKD by enhancing the use of albuminuria monitoring and the adoption of evidence-based treatments.

Clinical Characteristics and Treatment Pattern in Patients with CKD: Real-World Insights from iCaReMe Registry-Middle East and Africa (MEA) Cohort

Mustafa Arici,[1] Sola Aoun Bahous,[2] Kuven Naidu,[3] Hiba M. Barghouthi,[4] Arif A. Nooryani,[5] Jemima H. Kamano,[6] Ahmed Reja,[7] Mohamed Salah Eldin,[8] Necmi Eren,[9] Susana Goncalves,[10] Luong Nguyen Cong,[11] Ahmed Hadaoui.[12] *[1]Hacettepe University Medical Faculty, Ankara, Turkey; [2]Lebanese American University School of Medicine, Beirut, Lebanon; [3]Life Glynnwood Hospital, Benoni, South Africa; [4]Abdali Medical Center, Amman, Jordan; [5]Al Qassimi Hospital, Sharjah, United Arab Emirates; [6]Moi Teaching and Referral Hospital, Eldoret, Kenya; [7]Addis Ababa University College of Health Sciences, Addis Ababa, Ethiopia; [8]National Institute of Urology and Nephrology, Cairo, Egypt; [9]Kocaeli University, Kocaeli, Turkey; [10]AstraZeneca Argentina, Buenos Aires, Argentina; [11]AstraZeneca Vietnam, Ho Chi Minh City, Viet Nam; [12]AstraZeneca Algeria, Algiers, Algeria.*

Background: The global burden of CKD has witnessed a nearly 30% rise in past 30 years with increasing prevalence of hypertension (HTN) and type 2 diabetes (T2D). The MEA region shares disproportionate burden of CKD with paucity of data on patients' characteristics and management. The iCaReMe Global Registry (NCT03549754 multinational, prospective, observational study) aims to generate real world data on characteristics, management patterns, and outcomes in patients with CKD, T2D, HTN, or HF.

Methods: Baseline cross sectional descriptive analysis of clinicodemographic characteristics and treatment patterns in CKD patients enrolled from MEA region in the iCaReMe registry between February 2018 and December 2022.

Results: 1629 adults with CKD (mean±SD age; 59.7±14.5years, 56.1% male) were enrolled from 8 MEA countries (Egypt, Ethiopia, Jordan, Kenya, Lebanon, South Africa, Turkey, and United Arab Emirates). HTN (75.6%), T2D (54.4%) and HF (36.4%) were the most common comorbidities. UACR and eGFR were available in 31.7% and 79.1% of patients, respectively while 10.9% had both. The prevalence of KDIGO GFR G3-5 was 77.0% and albuminuria A2/A3 was 72.5%. The medications included ARB (26.5%) and ACEi (11.0%); about 19.6% were on SGLT2i. (Figure)

Conclusions: Most of the enrolled patients were at high/very high risk of CKD progression. Only one third had UACR testing. Less than one third received optimal guideline-directed medical therapy (GDMT). Our results highlight underutilization of UACR screening and suboptimal adherence to GDMT in patients with CKD in the MEA region.

Impact of CKD on Patients' Health-Related Quality of Life: Results from PaCE-CKD, a Multinational Survey

Juan Jose Garcia Sanchez,[1] Janani Rangaswami,[2] Mai-Szu Wu,[3] Ciro Esposito,[4] Richard Hull,[5] Steven J. Chadban,[6] Hesham M. Elsayed,[7] Helmut Reichel,[8] Ricardo Correa-Rotter,[9] Surendra Pentakota,[1] Bronwyn West,[10] Richard Mellor,[10] Thames Kularatne,[10] Simon Fifer.[10] *[1]AstraZeneca PLC, Cambridge, United Kingdom; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC; [3]Taipei Medical University, Taipei, Taiwan; [4]Universita degli Studi di Pavia, Pavia, Italy; [5]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [6]Royal Prince Alfred Hospital, Camperdown, NSW, Australia; [7]Ain Shams University Faculty of Medicine, Cairo, Egypt; [8]Nephrologisches Zentrum Villingen Schwenningen, Villingen-Schwenningen, Germany; [9]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [10]CaPPRe: Community and Patient Preference Research, Sydney, NSW, Australia.*

Background: Chronic kidney disease (CKD) has a substantial burden on patients' health-related quality of life (HRQoL). The aim of this study was to quantitatively determine the effect of CKD on patient HRQoL from early disease to kidney failure in a multinational setting.

Methods: A cross-sectional survey enrolled individuals with CKD in the US, UK, Germany and Mexico. HRQoL was assessed using the EQ-5D-5L instrument, scoring problems in five domains – anxiety/depression, mobility, pain, self-care, and usual activities. EQ-5D index scores were estimated by the inclusion of local tariffs. Scores were compared against a general population cohort, matched in sample size and key demographic characteristics (e.g. sex, age).

Results: Patients were enrolled from the US (n=199), UK (n=212), Germany (n=201) and Mexico (n=204). Inclusion criteria included patients with CKD stages 1-5 and those receiving dialysis. Of patients enrolled, a proportion were dialysis dependent (DD) in the US (32.2%), UK (54.8%), Germany (42.3%) and Mexico (56.9%). Across all countries, patients received haemodialysis more commonly than peritoneal dialysis and the majority were on treatment for less than five years. Patients with CKD had a 28% reduction in mean EQ-5D-5L scores than the general population in all settings. Patients in the UK experienced the lowest EQ-5D scores with a 32% reduction and mean index scores of 0.64 [0.27] versus 0.95 [0.08]. Patients in Mexico and the UK receiving dialysis had lower mean [SD] EQ-5D-5L scores than non-dialysis dependent (NDD) patients (0.66 [0.21] vs 0.74 [0.18]; 0.60 [0.25] vs 0.68 [0.27] respectively). There was no difference in HRQoL between DD and NDD patients in the US and Germany. Patients with CKD had problems in all five EQ-5D domains, with an 88% increase in reporting related to usual activities. Results for other countries will also be presented at Kidney Week.

Conclusions: This survey provides evidence across multiple countries on the HRQoL decrement associated with CKD. Evidence based policy interventions should be aimed towards slowing CKD progression to improve patient quality of life.

PaCE-CKD: Health-Related Quality of Life of Caregivers of Individuals with CKD: Results from a Multinational Survey

Ricardo Correa-Rotter,[1] Richard Hull,[2] Hesham M. Elsayed,[3] Janani Rangaswami,[4] Ciro Esposito,[5] Mai-Szu Wu,[6] Helmut Reichel,[7] Juan Jose Garcia Sanchez,[8] Steven J. Chadban,[9] Surendra Pentakota,[8] Bronwyn West,[10] Richard Mellor,[10] Thames Kularatne,[10] Simon Fifer.[10]
[1]National Institute of Medical Sciences and Nutrition Salvador Zubiran, Mexico City, Mexico; [2]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [3]Ain Shams University Faculty of Medicine, Cairo, Egypt; [4]The George Washington University School of Medicine and Health Sciences, Washington, DC; [5]Universita degli Studi di Pavia, Pavia, Italy; [6]Taipei Medical University, Taipei, Taiwan; [7]Nephrologisches Zentrum Villingen Schwenningen, Villingen-Schwenningen, Germany; [8]AstraZeneca PLC, Cambridge, United Kingdom; [9]Royal Prince Alfred Hospital, Camperdown, NSW, Australia; [10]CaPPRe: Community and Patient Preference Research, Sydney, NSW, Australia.

Background: Patients with chronic kidney disease (CKD) often rely on informal caregivers such as friends and relatives for support with their condition. The study aim was to measure the multinational impact of CKD on caregiver health-related quality of life (HRQoL) versus the general population.

Methods: A non-interventional survey enrolled unpaid caregivers from the UK, US, Mexico and Germany. A cohort representing the general population was also enrolled, matched for key demographics. HRQoL was measured by the EQ-5D-5L instrument which scored health across five domains: mobility, self-care, pain, usual activities, and anxiety/depression. Local tariffs were used to estimate ED-5D index scores. The CarerQol-7D instrument measured the impact of caregiving for patients with CKD and were compared against published estimates in other disease contexts.

Results: Surveys enrolled caregivers from the UK (n=116), US (n=113), Mexico (n=138) and Germany (n=99). Caregivers typically cared for a parent (36.5%) or spouse/partner (30.2%). Most caregivers cared for dialysis dependent patients (UK: 67.2%; US: 81.4%; Mexico: 65.2%; Germany: 64.6%). Support for patients typically comprised of taking medications (86.9%) and transport to/from hospital appointments (85.6%). In all countries, caregivers experienced worse health states and lower mean [SD] EQ-5D-5L scores, with caregivers in Mexico scoring 15% lower than the general population (0.79 [0.18] versus 0.94 [0.07]). Caregivers reported more problems across all EQ-5D-5L domains, most commonly in carrying out usual activities, and experiencing pain, anxiety, and depression. Caregivers in CKD had worse weighted average CarerQoL-7D scores (69.2) across all countries versus caregivers for patients with breast cancer (92.4) and hip fractures (83.7). Results for other countries will be also presented at Kidney Week.

Conclusions: The study explores an aspect of the broader societal burden of CKD, demonstrating a significant impact to caregivers' HRQoL. Strategies to address the growing burden of CKD should take its indirect effect on caregivers into consideration.

Aversive Response Against High Salt Taste Is Disturbed in CKD Patients

Natsuko Okuno,[1] Yusuke Kohama,[2] Keiichi Tamagaki,[1] Hiromu Taguchi,[2] Takashi Hirao,[2] Tetsuro Kusaba.[1] *[1]Department of Nephrology, Graduate school of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]House Foods Group Inc., Tokyo, Japan.*

Background: Reducing salt intake is a vital lifestyle modification in the management of hypertension. Initiatives aimed at reducing salt intake are based on the premise that we prefer salt, but we exhibit an aversive response against high salt taste. It is postulated that salt intake behavior is influenced by the balance between attraction to low salt taste and aversion to high salt taste. However, aversion to high salt has not been quantitively investigated in both healthy individuals and CKD patients.

Methods: As a pilot study, we performed a salt taste test on 125 healthy volunteers, wherein we devised nine different concentrations of NaCl (ranging from 0.3% to 20%). The participants placed a filter paper containing each solution on their tongues, and we assessed the recognition threshold as a parameter of taste accuracy, and "minimum aversion level" for the concentration at which the initial dislike sensation emerged. Based on the results of the pilot study, a definition of "lack of salt taste aversion" was determined, and the same test was conducted on 70 CKD patients.

Results: In the pilot taste test conducted on 125 healthy subjects, the number of subjects exhibiting an aversive reaction increased with higher salt concentrations. The threshold for normal taste perception was arbitrarily defined as 10% NaCl, with approximately half (47.2%) of the healthy subjects displaying an aversive reaction. Among the 70 CKD patients, only 30% could recognize salt taste at 0.6% NaCl, which is considered normal, and 10% of CKD patients could not recognize salt taste even at the highest concentration of 20% NaCl, suggesting that taste perception is significantly impaired in CKD patients. Age and the use of dentures were factors associated with lower taste perception thresholds in patients. A high proportion (84%) of CKD patients exhibited decreased aversive reactions to high salt taste, with gender and denture usage being associated factors.

Conclusions: This study confirmed the anticipated aversive response to high salt taste in humans and demonstrated its attenuation in CKD patients, implying that CKD patients have reduced resistance to high salt intake. When implementing salt reduction strategies in clinical practice, it is crucial to pay attention to the decrease in aversive response to high salt taste as well as the increase in salt preference.

Concordance Between Patient-Reported Symptoms and Provider Documentation During Ambulatory Nephrology Encounters

Kendra E. Wulczyn,[1] Mallika L. Mendu,[2,3] Sahir Kalim.[1,4] *[1]Massachusetts General Hospital Division of Nephrology, Boston, MA; [2]Nephrology Division, Department of Medicine, Brigham and Women's Hospital, Boston, MA; [3]Office of the Chief Medical Officer, Brigham and Women's Hospital, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: Accurate assessment is the first step toward management of the symptom burden faced by many patients with CKD, but whether symptoms are being routinely discussed during ambulatory nephrology encounters is uncertain. We compared patient self-reporting of 3 common CKD symptoms with providers' documentation from the concomitant encounter note.

Methods: From 2016 to 2020, adult patients treated at a single, ambulatory, academic nephrology practice were asked to complete the Kidney Disease Quality of Life (KDQOL) instrument prior to visits. The KDQOL queries symptom severity over the prior 4 weeks, with Likert-scale response options ranging from 1 to 5. We restricted the present analysis to the symptoms of fatigue, pruritus, and dyspnea and defined a patient-reported symptom as a response of "moderately bothered (3)" or greater. Provider documented symptoms were determined by manual search of the visit note associated with each KDQOL response for the terms fatigue, pruritus, and dyspnea and their synonyms.

Results: Over 4 years, a total of 441 adult patients completed 556 KDQOL surveys. The average eGFR was 36 ± 18 mL/min/1.73 m^2, and the median time between KDQOL completion and the clinic visit was 4.2 hrs (IQR 0.1 – 125 hrs). Rates of patient-reported, moderate or greater fatigue, pruritus, and dyspnea were 28%, 18%, and 20%, respectively. Agreement between patient-reported and provider-documented symptoms was low (Figure 1). Cohen's kappa, a coefficient of agreement corrected for random chance, was 0.17 (standard error [SE] 0.04) for fatigue, 0.07 for pruritus (SE 0.03), and 0.29 (SE 0.04) for dyspnea, suggesting fair agreement at best.

Conclusions: Rates of physician documentation of fatigue, pruritus, and dyspnea are considerably lower than rates of patient-reporting of the same symptoms. Tools for standardizing symptom assessment in routine nephrology care are needed to help close this gap.

Funding: NIDDK Support

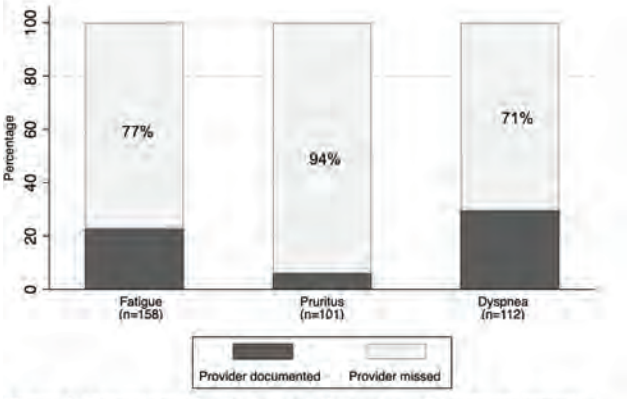

Figure 1. Percentage of patient-reported symptoms (≥moderate severity using the KDQOL) missed (in light grey) and identified (in dark grey) by physicians during the associated clinical encounter. This figure is restricted to instances in which the patient positively reported a symptom (numbers shown beneath each symptom)

TH-PO1052

Implications of the Acute and Chronic GFR Slopes for Time-to-Event End Points in Clinical Trials of CKD

Tom Greene,[1] Lesley A. Inker,[2] Hiddo J. Heerspink.[3] CKD-EPI(CT).
[1]University of Utah Health, Salt Lake City, UT; [2]Tufts Medical Center, Boston, MA; [3]Universiteit Groningen Afdeling Gezondheidswetenschappen, Groningen, Netherlands.

Background: In a companion abstract, we apply a multivariable model to relate treatment effects on the established clinical endpoint (CE) based primarily on serum creatinine (SCR) doubling to treatment effects on the acute (evaluated prior to 3 months) and chronic (evaluated after 3 months) GFR slopes across 66 randomized treatment comparisons (RTCs). Here, we apply the same model to alternative time-to-event (TTE) endpoints defined by progressively larger GFR declines, including the established CE as a special case.

Methods: For each RTC, we used mixed effects models and Cox regression, respectively, to estimate treatment effects on the acute and chronic GFR slopes, and on four TTE endpoints (Table heading, expressed as log hazard ratios). We then used multivariable Bayesian meta-regressions to relate the treatment effects on each TTE endpoint jointly to the treatment effects on the acute and chronic slopes.

Results: Treatment effects on the acute and chronic slopes jointly predicted treatment effects on each TTE endpoint with high accuracy (all trial-level R^2s ≥ 0.91). After accounting for the treatment effect on the chronic slope, a 1 ml/min/1.73m^2 greater negative acute effect led to a positive shift in the HR (against the treatment) by 15.4%, 11.4%, and 5.7%, respectively, for TTE endpoints based on 30% GFR decline, SCR doubling, and KFRT and GFR ≤ 15 ml/min/1.73m^2, showing that the role of the acute slope substantially attenuated for TTE endpoints based on larger GFR decline.

Conclusions: Acute effects have a small but measurable impact on KFRT or GFR decline to less than 15 ml/min/1.73m^2 after accounting for the chronic slope. However, relative to their small impact on progression to kidney failure, the role of the acute effect is moderately overstated by the established CE based on SCR doubling, and more severely by TTE endpoints based on 30% or 40% GFR decline.

Funding: Private Foundation Support

KFRT: Kidney Failure with Renal Replacement Therapy

TH-PO1053

The Clinical Implications of Acute and Chronic GFR Slope in Clinical Trials of CKD

Tom Greene,[1] Lesley A. Inker,[2] Hiddo J. Heerspink,[3] CKD-EPI(CT).
[1]University of Utah Health, Salt Lake City, UT; [2]Tufts Medical Center, Boston, MA; [3]Universiteit Groningen Afdeling Gezondheidswetenschappen, Groningen, Netherlands.

Background: Randomized trials for CKD traditionally use the established clinical endpoint (CE) of kidney failure or doubling of serum creatinine as the primary outcome. These are late events in CKD, thus requiring trials with long follow-up or restriction to patients with rapidly progressive or advanced disease. GFR slope has been proposed to circumvent these limitations, but acute effects often complicate interpretation. We use a multivariable model to resolve ambiguities from acute effects.

Methods: Using individual patient data from 66 randomized treatment comparisons (RTCs), we used mixed effects models to estimate treatment effects on the acute (baseline to 3 months) and chronic GFR slopes (after 3 months), and Cox regression to estimate treatment effects on the CE (hazard ratios (HRs)). We used a multivariable Bayesian meta-regression to relate the treatment effects on the CE jointly to the treatment effects on the acute and chronic slopes.

Results: Across the 66 RTCs, the multivariable model showed that optimally weighting the acute and chronic slopes accurately predicted the treatment effects on the CE, with a trial-level R^2 (95% Bayesian credible interval) of 0.95 (0.78,1.00). For a fixed treatment effect on the chronic slope, each 1 ml/min/1.73m^2 greater acute GFR decline for the treatment vs. the control *increased* the HR for the CE by 11.3%, in the direction against the treatment. For a fixed acute effect, each 0.75 ml/min/1.73m^2/year greater treatment effect on the chronic slope *reduced* the HR for the CE by 22.8%, in favor of the treatment. The Figure shows the model's decomposition of the estimated treatment effects on the CE into separate components due to the acute and chronic slopes for each RTC.

Conclusions: Treatment effects on both the acute and chronic slopes are strong, independent determinants of the treatment effect on the CE. Optimal weighting of the acute and chronic slopes accurately predicts treatment effects on the CE.

Association Between Initial Dip and Long-Term Prognosis After Dapagliflozin Administration in Patients with CKD

Rina Kawano,[1] Nobuhito Hirawa,[1] Aiko Haruna,[1] Tatsuya Haze,[2] Akira Fujiwara,[1] Kouichi Tamura.[2] *[1]Yokohama Shiritsu Daigaku Fuzoku Shimin Sogo Iryo Center, Yokohama, Japan; [2]Yokohama Shiritsu Daigaku, Yokohama, Japan.*

Background: Renoprotective effects of dapagliflozin (sodium glucose transporter 2 inhibitor) have been reported in several randomized controlled trials. The main mechanism considered is correction of hyperfiltration, which can be observed as an acute decline in eGFR referred to as "initial dip". While association between initial dip and long-term renal prognosis have been reported, no consistent conclusions have been reached. We aimed to investigate this relationship in real-world clinical practice.

Methods: We performed a retrospective observational cohort study of patients at Yokohama City University Medical Center in Japan. Patients administered to dapagliflozin between May 2014 thru December 2022 were included. Excluding those with eGFR over 90 or less than 15mL/min/1.73m^2 at baseline, history of kidney transplant, dialysis, or cancer, and those with dosage changes of dapagliflozin, 146 patients had complete data at baseline, 4 weeks, and 12 months, and were applicable for this study. We defined initial dip as eGFR decline from baseline to 4 weeks. Chronic change, which reflect long-term renal prognosis, was defined as eGFR decline from 4 weeks to 12 months. The association between initial dip and chronic change was examined using linear regression models. Also, eGFR changes between a year before and after starting dapagliflozin were compared for those whose data were available. (n=74)

Results: Absolute eGFR changes before and after starting dapagliflozin were -4.8±9.6 and -1.5±8.3mL min/1.73m^2 per year, respectively. ($p<0.05$) Long term renoprotective effect of dapagliflozin was observed regardless of initial dip. Furthermore, Pearson's correlation coefficient revealed that the degree of initial dip and chronic change were inversely correlated ($r=-0.37$, $p<0.001$). Multivariate regression analysis demonstrated initial dip was an independent determinant factor for chronic change. ($p<0.001$)

Conclusions: The real-world clinical data showed that the greater the initial dip, significantly smaller the subsequent decline in eGFR. Renoprotective effect of dapagliflozin was observed regardless of initial dip.

TH-PO1055

Caffeine Effects on eGFR Dip in Patients Who Started SGLT2 Inhibitors

Zach Kisley, John C. Edwards, Sandeep Singh Dhindsa Dhindsa, Krista L. Lentine, Amy Mosman, Amanda J. Kalishman, Aliza Anwar Memon, Paul Kunnath, Emily Wood, Kana N. Miyata. *Saint Louis University School of Medicine, Saint Louis, MO.*

Background: Sodium-glucose cotransporter-2 inhibitors (SGLT2i) have widespread effects including antihyperglycemia, renoprotection, and cardioprotection. Renoprotection is thought to be mainly mediated by a reduction in glomerular filtration rate (GFR) via tubuloglomerular feedback (TGF), which is referred to as the GFR "dip". Adenosine plays an important role in signal transmission in the TGF mechanism and caffeine is a nonselective adenosine receptor antagonist. We hypothesized that patients with high caffeine intake have reduced eGFR dip after starting SGLT2i compared to patients with no or small caffeine intake.

Methods: This is a retrospective cohort study conducted at Saint Louis University. Caffeine consumption was collected via survey. Retrospective chart review was performed to trend creatinine before and 1-2 months after the initiation of SGLT2i. Inclusion criteria included adult patients receiving SGLT2i regardless of indication (diabetes mellitus, heart failure, or chronic kidney disease) and eGFR ≥30 ml/min/1.73 m^2 at the time of initiation. Student's t test was used to analyze differences of eGFR change (% change from the baseline) between patients with high caffeine intake and low caffeine intake. Pearson's correlation coefficient was used to analyze correlation between caffeine intake and eGFR change.

Results: The survey was collected from 36 patients (N=13 on Dapagliflozin, N=22 on Empagliflozin, and N=1 on Ertugliflozin). The mean age of the study cohort was 62.9±11.1 years old and 58.3% were female. The median eGFR at SGLT2i initiation was 50 ml/min/1.73 m^2. Top quartile caffeine takers (≥400 mg/day, N=9) had significantly lower % eGFR dip compared to the low caffeine takers (<400mg/day, N=27); 0.46±12.51 % vs 11.83±14.45%, respectively ($p<0.05$). In a subgroup analysis of those who were not on loop diuretics, which could affect TGF, % eGFR dip was inversely correlated with the caffeine intake (N=24, $r=-0.55$, $p<0.01$).

Conclusions: Our study shows that caffeine consumed at high levels (above 400mg daily) can mitigate the eGFR dip after SGLT2i initiation. Further study is needed to assess its long-term effects on SGLT2i's renoprotective property.

TH-PO1056

Clinical Characteristics and Predictors of Glomerular Filtration Rate Decline in Patients with CKD of Unknown Etiology (CKDu) in Agricultural Communities of Odisha, a CKDu Hotspot

Priti Meena, Sandip Panda, Paromita Das, Anish Garg. *All India Institute of Medical Sciences - Bhubaneswar, Bhubaneswar, India*.

Background: Chronic Kidney Disease of Unknown Etiology (CKDu) is characterized by the absence of traditional risk factors for CKD such as diabetes mellitus hypertension, and glomerulonephritis. Odisha in India has been identified as a potential 'hotspot' for CKDu.

Methods: Patients aged 18–60 years who met clinical criteria for CKDu from 1st April 2021 to 31st April 2023 were enrolled in the study. A kidney biopsy was performed according to the feasibility. The study's primary objective is to describe the clinical characteristics and predictors for glomerular filtration rate (eGFR) decline.

Results: A total of 120 patients were enrolled in the study. The mean age of participants was 39.78 ± 8.85 years, with 85 % males. About 96.3% of cases belonged to rural areas, 90 % belonged to lower socioeconomic classes, and only 3 % had a family history of diseases. 75.4 % were farmers, exposure to agrochemicals was reported in 20.4% of cases; and 25.7 % of patients had no formal education. 40% and 25% of the participants were of CKD stage 3 and stage 4 respectively. The mean hemoglobulin level and uric acid levels were 10.3/ dl and 5.9 mg/ dl respectively. A kidney biopsy was performed on 20 patients. Histopathology was predominantly interstitial fibrosis with mononuclear infiltration, tubular atrophy, and global glomerulosclerosis. After adjustments for confounding factors, predictors of GFR decline were found to be baseline GFR, baseline serum albumin, low haemoglobin, and male sex.

Conclusions: There is a need for a multipronged approach to address the CKDu epidemic, particularly in CKDu hotspots. The need to take steps to increase awareness, prevention, appropriate screening, and surveillance is imperative.

TH-PO1057

Associations Between Albuminuria and Clinical Outcomes in Patients with CKD with and Without Diabetes: New Insights from DAPA-CKD

Dominique van Mil,[1] Priya Vart,[1,2] Meir Schechter,[1,3] Niels Jongs,[1] Glenn Chertow,[4] Ricardo Correa-Rotter,[5] Anna Maria Langkilde,[6] Peter Rossing,[7,8] Robert D. Toto,[9] David C. Wheeler,[10] Hiddo J. Heerspink.[1,11] *[1]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]Department of Internal Medicine, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [3]Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel; [4]Stanford University School of Medicine, Stanford, CA; [5]The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; [6]BioPharmaceuticals R&D AstraZeneca, Gothenburg, Sweden; [7]Steno Diabetes Center Copenhagen, Copenhagen, Denmark; [8]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [9]Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [10]Department of Renal Medicine, University College London, London, United Kingdom; [11]The George Institute for Global Health, Newtown, NSW, Australia*.

Background: Albuminuria is a strong determinant of kidney and cardiovascular (CV) risk in patients with chronic kidney disease (CKD) with and without type 2 diabetes (T2D). Early albuminuria reduction may be an indicator of decreased risk. In the DAPA-CKD trial, dapagliflozin reduced the risk of kidney and CV events in patients with CKD with similar effects in those with and without T2D. We examined risk associations between baseline and early changes in albuminuria and kidney outcomes in patients with CKD with and without T2D.

Methods: In DAPA-CKD, 4304 patients with and without T2D with urinary albumin-to-creatinine ratio (UACR) 200-5000 mg/g and eGFR of 25–75 mL/min/1.73m² were randomized to receive dapagliflozin 10 mg or placebo daily, on top of standard of care, and followed for a median 2.4 years. We assessed associations among baseline UACR, early change in UACR (baseline to Month 4), and the primary outcome (≥50% eGFR decline, end-stage kidney disease, death from a kidney or CV cause) using multivariable adjusted Cox regression analyses.

Results: Every doubling of baseline UACR was associated with a near doubling of risk: hazard ratio (HR) 1.89 (95% confidence interval [CI] 1.71–2.08) in patients with T2D and 1.84 (95% CI 1.54–2.20) in those without T2D. Dapagliflozin reduced UACR (placebo-adjusted) from baseline to Month 4 by 35.7% (95% CI 29.0–42.5) in participants with T2D and 19.7% (95% CI 10.6–28.8) in those without T2D, with a large between-individual variation in both treatment groups. The HR for every 50% decline in UACR from baseline to Month 4 was 0.86 (95% CI 0.79–0.93) and 0.70 (95% CI: 0.59–0.83) in participants with and without T2D, respectively.

Conclusions: In patients with CKD with and without T2D, higher baseline albuminuria was associated with a higher risk of progressive kidney disease or cardiovascular death, and early albuminuria reduction was associated with a decreased risk. Because dapagliflozin reduced clinical outcomes in patients with and without T2D but reduced albuminuria to a larger degree in those with T2D, these findings suggest that the clinical benefits gained via dapagliflozin's albuminuria-reducing effects are more potent among patients with T2D.

Mediators of the Kidney Protective Effects of Dapagliflozin in Patients with CKD with or Without Type 2 Diabetes

Meir Schechter,[1,2] Niels Jongs,[1] Glenn Chertow,[3] John McMurray,[4] Ricardo Correa-Rotter,[5] Peter Rossing,[6,7] Anna Maria Langkilde,[8] Robert D. Toto,[9] David C. Wheeler,[10] Hiddo J. Heerspink.[1,11] *[1]Department of Clinical Pharmacy and Pharmacology, University Medical Center Groningen, Groningen, Netherlands; [2]Faculty of Medicine, Hebrew University of Jerusalem, Jerusalem, Israel; [3]Stanford University School of Medicine, Stanford, CA; [4]Institute of Cardiovascular and Medical Sciences, University of Glasgow, Glasgow, United Kingdom; [5]The National Medical Science and Nutrition Institute Salvador Zubiran, Mexico City, Mexico; [6]Steno Diabetes Center Copenhagen, Gentofte, Denmark; [7]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [8]BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [9]Department of Internal Medicine, UT Southwestern Medical Center, Dallas, TX; [10]Department of Renal Medicine, University College London, London, United Kingdom; [11]The George Institute for Global Health, Newtown, NSW, Australia*.

Background: The DAPA-CKD trial demonstrated that dapagliflozin attenuates progression of chronic kidney disease (CKD) in patients with and without type 2 diabetes. This post-hoc analysis assessed possible mediators of the observed kidney protective effect.

Methods: In DAPA-CKD, 4304 patients with an estimated glomerular filtration rate (eGFR) 25–75 mL/min/1.73m² and urine albumin-to-creatinine ratio (UACR) 200–5000 mg/g were randomized to receive dapagliflozin 10 mg or placebo. The primary outcome was a composite of sustained ≥50% eGFR decline, end-stage kidney disease, or kidney or cardiovascular death. We considered biomarkers that were significantly affected by dapagliflozin versus placebo over time, as assessed using mixed effect model for repeated measures: UACR, hematocrit, HbA1c, blood pressure (systolic [SBP] and diastolic [DBP]), serum sodium and potassium, and body weight. We calculated the proportion of the effect of dapagliflozin explained by the change in each biomarker by fitting a multivariable-adjusted, time-dependent, Cox model, adjusted for baseline sex, age, body mass index, eGFR, SBP, and UACR. We estimated confidence intervals using 1000-iterations bootstrap. Analyses were repeated by type 2 diabetes status.

Results: Compared with placebo, dapagliflozin reduced UACR (29.3% [95%CI: 25.2–33.1]), SBP (2.9mmHg [2.3–3.6]), DBP (1.0mmHg [0.6–1.4]), HbA1c (0.08% [0.03–0.14]), serum potassium (0.035mEq/L [0.012–0.057]) and body weight (0.85kg [0.61–1.08]), and increased hematocrit (2.3% [2.1–2.5]) and serum sodium (0.14mEq/L [0.02–0.26]). The effect of dapagliflozin on the primary outcome was explained by changes in hematocrit (35.5% [95%CI 24.3–69.0]), UACR (35.4% [23.0–52.8]), and SBP (4.9% [1.3–9.1]), but not through the other tested biomarkers. The proportion of dapagliflozin's effect explained by change in hematocrit was 31.2% (20.0–70.3) in participants with type 2 diabetes, and 32.4% (14.3–76.5) in those without type 2 diabetes. The respective proportions explained by the change in UACR were 41.7% (26.1–75.9) and 16.6% (3.2–34.4).

Conclusions: The kidney protective effect of dapagliflozin in patients with CKD is associated with its effects on albuminuria and hematocrit.

Inflammatory Cytokines and Adipokines in Obese Patients with and Without CKD

Sandeep Mahajan, Arunkumar Subbiah. *All India Institute of Medical Sciences, New Delhi, India*.

Background: Global epidemic of obesity & metabolic disorders are fuelling increasing cases of CKD worldwide. Besides having higher incidence of DM & hypertension, obesity is independent risk factor for CKD. Mechanisms involved are poorly studied, though obesity related inflammation mediated by shift in adipokine and cytokine production towards pro-inflammatory state is implicated. We in this case control study looked at important pro-inflammatory mediators (leptin, IL-6, TNF-α) and anti-inflammatory mediators (adiponectin, IL-10) in obese with & without CKD, non-obese CKD & healthy controls.

Methods: 50 consenting subjects in each group were studied. Besides detailed history, co-morbidity charting, BMI calculation; serum levels of HsCRP, adipokines (leptin & adiponectin) & cytokines (IL-6, TNF-α & IL-10) were assessed using commercially available ELISA kits.

Results: Table shows demographic, clinical & study parameters of each group. Patient groups had similar representation of DM & were slightly older than controls. Obese subjects with & without CKD had higher HsCRP, leptin & IL6 than controls & CKD patients, with obese patients with CKD showing maximum aberrations. Adiponectin concentration was higher in patients with obesity alone but suppressed in patients with obesity & CKD.

Conclusions: Inflammation & pro-inflammatory *milieu* as evidenced by high levels of Hs-CRP, IL-6 & leptin and low levels of adiponectin might be important drivers for obesity related complications like CKD. Larger, prospective studies are required to confirm the same.

Funding: Government Support - Non-U.S.

Association of N-Terminal Pro-Brain Natriuretic Peptide (NT-proBNP) with the Progression of CKD in Indian CKD Cohort

Ashok K. Yadav,[1] Monica Kundu,[2] Arpita Ghosh,[2] Vivek Kumar,[1] Vivekanand Jha.[2] Indian Chronic Kidney Disease Study Group. *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]The George Institute for Global Health India, New Delhi, India.*

Background: It has been shown that elevated NT-proBNP levels are associated with the progression of kidney disease and may serve as a prognostic marker. This study aims to determine the association between baseline levels of NT-proBNP with renal and cardiovascular outcomes in CKD patients in the Indian Chronic Kidney Disease (ICKD) Study.

Methods: The study encompassed 783 individuals diagnosed with mild to moderate CKD, enrolled in ICKD study, followed up for mean duration of 4.89 years. Unadjusted and adjusted Cox proportional hazard models were used to study the association of time to occurrence of events: Major adverse kidney events (MAKE), end stage kidney disease (ESRD), ≥50% decline in eGFR, all-cause mortality, and cardiovascular (CVD) mortality. In assessing CVD mortality as a primary focus, deaths resulting from renal causes were considered as competing events. Similarly, when examining 50% eGFR decline, ESRD, and MAKE as key outcomes, non-renal deaths were treated as competing events.

Results: In the study cohort, mean age of patients was 48 years, 35% were women and the mean eGFR at baseline was 46 mL/min/1.73m^2. 249 (32%) developed MAKE and 197 (25%) progressed to ESKD. Median (IQR) level of NT-proBNP at the baseline was 4.65 (1.63, 16.36) ng/ml. Similar association was found for unadjusted and adjusted Cox proportional hazard models suggesting that increase in the levels of NT-proBNP is associated with higher risk of MAKE (1.16; 1.01-1.34) and ESKD (1.19; 1.01-1.41) (Table 1). However, no significant association was found between the levels of NT-proBNP with respect to death and 50% eGFR decline.

Conclusions: This study establishes the evidence that higher levels of NT-proBNP at baseline is a risk factor for CKD progression.

Funding: Government Support - Non-U.S.

Intact Fibroblast Growth Factor 23 and Progression of CKD

Ashok K. Yadav,[1] Monica Kundu,[2] Arpita Ghosh,[2] Vivek Kumar,[1] Vivekanand Jha.[2] Indian Chronic Kidney Disease Study Group. *[1]Post Graduate Institute of Medical Education and Research, Chandigarh, India; [2]The George Institute for Global Health India, New Delhi, India.*

Background: Elevated levels of fibroblast growth factor 23 (FGF23) are associated with mortality in patients with end-stage kidney disease. Still, its relationship with adverse kidney outcomes in the early stages of chronic kidney disease is unknown. We investigated the association of intact FGF23 with the progression of CKD in the Indian Chronic Kidney Disease (ICKD) Study.

Methods: The study includes a subset of adult participants with mild to moderate CKD enrolled in ICKD study. Linear regression model was used to study the association between baselines levels of intact FGF23 and estimated glomerular filtration (eGFR) decline in the study period, adjusting for other covariates including age, gender, baseline eGFR, blood pressure, tobacco consumption and urine albumin-to-creatinine ratio. Further, to assess the association between FGF23 levels with respect to time-to-event adverse outcomes of interest, namely, major adverse kidney events (MAKE), end stage kidney disease (ESRD), ≥50% decline in eGFR, all-cause mortality, and cardiovascular (CVD) mortality, Cox proportional hazard models were used. Competing risk analysis was taken into account while fitting Cox models.

Results: A total of 605 individuals with mild to moderate CKD were included in this analysis. Mean age of the CKD patients of age was 48 years, and baseline mean eGFR was 45.8 mL/min/1.73m^2. Mean (SD) follow up duration of the study was 5.33 (2.37) years with median (IQR) baseline level of intact FGF23 as 111 (78, 163) pg/ml. Baseline levels of intact FGF23 were significantly and positively associated with eGFR decline in the study period (p=0.02). Unadjusted and adjusted Cox regression models indicated that higher levels of FGF 23 were significantly associated with greater risk of MAKE (1.34; 1.15-1.56), 50% eGFR decline (1.25; 1.06 - 1.49) and ESKD (1.35; 1.13-1.62) (table 1).

Conclusions: Among individuals with mild to moderate CKD, baseline levels of intact FGF-23 are independently associated with the adverse kidney outcomes of CKD.

Funding: Government Support - Non-U.S.

Association Between Plasma Uric Acid Levels and Mortality and Cardiovascular Outcomes According to Kidney Function

Hae Sang Park,[1] Ji Eun Kim.[2] *[1]H Plus Yangji Hospital, Seoul, Republic of Korea; [2]Korea University Guro Hospital, Seoul, Republic of Korea.*

Background: Plasma uric acid levels rise with worsening renal function, but it is not known whether uric acid levels affect the risk of death and cardiovascular disease according to renal function.

Methods: We conducted a multicenter retrospective observational cohort study based on data from the Observational Medical Outcomes Partnership Common Data Model. Adult non-dialysis patients with at least one measurement of serum uric acid levels during study period were screened, and the participants were classified according to their estimated glomerular filtration rate (eGFR); eGFR >= 60 ml/min/1.73m2 (high eGFR) and eGFR < 60 ml/min/1.73m2 (low eGFR). Primary outcome of this study was all-cause mortality. And secondary outcomes were the development of myocardial infarction requiring coronary intervention and heart failure.

Results: We included 240197, 84858, and 59044 participants from three centers. In multivariable Cox regression analysis, uric acid level showed J-shaped association with all-cause mortality risk in both high and low eGFR groups. In pooled analysis for three centers, pooled hazard ratios for mortality in uric acid levels > 10 mg/dL compared to uric acid levels 6-7mg/dL were 1.8 (1.36-2.39) and 2.0 (1.51-2.65) in low and high eGFR groups, respectively. The risk for myocardial infarction was neither associated with uric acid levels in low and high eGFR groups from all three centers. The risk for heart failure showed linear association with uric acids levels, especially in high eGFR groups, and this finding was consistent in three centers.

Conclusions: Plasma uric acid levels showed J-shaped association with mortality regardless of eGFR status, while it showed linear association with heart failure in high eGFR participants

Elevated Serum and Urinary Secreted Protein Acidic and Rich in Cysteine (SPARC) Levels Are Novel Biomarkers of Kidney Fibrosis Severity

Niu Yangyang. *Shanghai Tongji Hospital, Shanghai, China.*

Background: Interstitial fibrosis is the main determinant of the progression of chronic kidney disease (CKD), and noninvasive identification of interstitial fibrosis is a major challenge. We aimed to explore the diagnostic value of serum and urinary secreted protein acidic and rich in cysteine (SPARC) in kidney fibrosis.

Methods: 674 renal biopsy CKD patients in 1 clinical center serving as the training cohort (n = 322) and in 3 clinical centers serving as the validation cohort (n = 352). The serum and urinary SPARC levels were measured at the time of kidney biopsy. *In vivo* and *in vitro* kidney fibrosis models were also applied to confirm the role of SPARC.

Results: Increased SPARC expression was found in kidney fibrosis tissues. Higher serum and urinary SPARC levels were detected in the kidney fibrosis group than nonkidney fibrosis group. The higher levels of serum SPARC were associated with increasing severity of kidney fibrosis. Moreover, the serum SPARC level had a higher area under the receiver operating characteristic curve (AUC-ROC) (AUC 0.86) than urinary SPARC and the estimated glomerular filtration rate (eGFR). The combination of serum

SPARC, urinary SPARC and eGFR could increase the AUC-ROC for kidney fibrosis from 0.86 to 0.90. The diagnostic performance of serum or urinary SPARC were consistent in the validation cohort. *In vivo* and *in vitro* kidney fibrosis models also confirmed the upregulation of SPARC expression.

Conclusions: Serum and urinary SPARC levels may be potential biomarkers for kidney fibrosis, which may be helpful for the noninvasive diagnosis of kidney fibrosis.

Serum Myostatin Is Independently Associated with Endothelial Dysfunction in Non-Dialysis CKD Stages 3 to 5

Ho-Hsiang Chang,[1] Yu-Hsien Lai,[1,2] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Myostatin expressed by skeletal muscle cells where it limits muscle growth and promotes protein breakdown and may have a role in obesity, insulin resistance, cardiovascular disease. However, its relationship with endothelial function in patients with chronic kidney disease (CKD) remains inconclusive. This study aimed to investigate the association between serum myostatin levels and endothelial function in patients with stages 3–5 CKD.

Methods: Fasting blood samples were obtained from 136 CKD patients. Serum myostatin levels were determined using the enzyme-linked immunosorbent assay. The endothelial function, demonstrated as a vascular reactivity index (VRI), was measured noninvasively through digital thermal monitoring test. The serum myostatin levels were determined using commercially available enzyme-linked immunosorbent assays. In this study, VRI < 1.0 was used as the poor vascular reactivity, 1.0 ≤ VRI < 2.0 was used as the intermediate vascular reactivity, and VRI ≥ 2.0 was used as the good vascular reactivity.

Results: 25 CKD patients (18.4%) were categorized as poor vascular reactivity (VRI < 1.0), 63 CKD patients (46.3%) were categorized as intermediate vascular reactivity (1.0 ≤ VRI < 2.0), and 48 CKD patients (35.3%) had good vascular reactivity. Older age (p = 0.026), higher serum blood urea nitrogen (p = 0.020), creatinine (p = 0.021), urinary protein-to-creatinine ratio (UPCR, p = 0.015), and higher serum myostatin level was associated, while lower estimated glomerular filtration rate (eGFR) was associated with poor vascular reactivity. After multivariable forward stepwise linear regression analysis noted that older age (β = –0.331, adjusted R^2 change = 0.081, p < 0.001), serum creatinine (β = –0.273, adjusted R^2 change = 0.070, p = 0.001) and log-transformed myostatin level (β = –0.256, adjusted R^2 change = 0.057, p = 0.002) were significantly and independently negatively associated with VRI values in patients with CKD.

Conclusions: Myostatin together with old age and serum creatinine is negatively associated with VRI values and is a potential endothelial function modulator and a valuable biomarker of endothelial dysfunction in patients with CKD.

TH-PO1065

Lower Estimated Glomerular Filtration Rate Is Associated with Cognitive Decline and Longitudinal Structural Brain Changes over Six Years

Shady Rahayel,[1,2] Remi Goupil,[1,2] Suzanne Dominique Genest,[1,2] Florence Lamarche,[1,2] Mohsen Agharazii,[1,2] Francois Madore.[1,2] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Hopital du Sacre-Coeur de Montreal Centre de Recherche, Montreal, QC, Canada.*

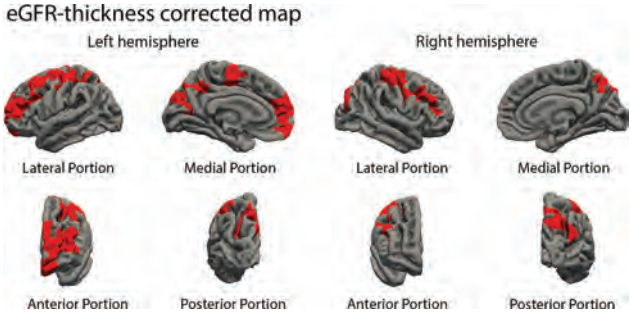
Background: Chronic kidney disease (CKD) is characterized by albuminuria and/or reduced estimated glomerular filtration rate (eGFR). CKD is linked to cognitive deficits and structural alterations, such as brain atrophy. The mechanisms connecting decreased kidney function, cognitive impairment, and brain function are not yet fully understood. Here, we examined the correlation between eGFR, cognition, and longitudinal brain structure.

Methods: We analyzed a population-based sample of 15,897 participants (53.9 ± 7.5 years old, 49% women) from the CARTaGene cohort in Quebec, Canada. We conducted multivariate linear regressions to explore the relationship between baseline eGFR and cognitive performance. Vertex-based cortical surface analysis was done on the T1-weighted brain MRI scans acquired in 1367 participants six years after baseline to examine whether cortical thickness associated with baseline eGFR adjusting for age, sex, body mass index, vascular risk factors, and white matter lesion volume. Gene set enrichment analysis was done to identify the genetic features of regions where eGFR associated with thickness.

Results: Cognitive performance declined with decreasing eGFR after adjusting for age, sex, income, education, smoking, alcohol intake, vascular risk factors, body mass index, and psychoactive medication use (P<0.001). Lower eGFR associated with cortical thinning in frontal and posterior regions and with increases in the temporal and cingulate areas (Figure 1). Brain regions exhibiting lower eGFR-associated thinning were enriched for mitochondrial gene expression, whereas regions with increased thickness were enriched for genes involved in protein-containing complex remodeling, with apolipoprotein E and angiotensinogen being key elements.

Conclusions: Baseline eGFR is associated with cognition and longitudinal brain structural changes in regions with specific gene expression characteristics.

Funding: Government Support - Non-U.S.



Brain maps showing the regions where lower eGFR was significantly associated with cortical thinning.

Kynurenine Metabolism and Neurocognition in CKD: CRIC Study

Hassan Gorji,[1] Jason W. Yang,[1] Mary Hannan,[2] Jiang He,[3] Lindsay M. Miller,[1] Anna V. Mathew,[4] Stephen L. Seliger,[5] Manjula Tamura,[6] Rupal Mehta,[7] Peter Kotanko,[8] Joachim H. Ix,[1] Eugene P. Rhee,[9] Rakesh Malhotra.[1] CRIC Writing Group. *[1]University of California San Diego, La Jolla, CA; [2]University of Illinois Chicago, Chicago, IL; [3]Tulane University School of Medicine, New Orleans, LA; [4]University of Michigan Michigan Medicine, Ann Arbor, MI; [5]University of Maryland School of Medicine, Baltimore, MD; [6]Stanford University School of Medicine, Stanford, CA; [7]Northwestern University Feinberg School of Medicine, Chicago, IL; [8]Renal Research Institute, New York, NY; [9]Mass General Brigham Inc, Boston, MA.*

Background: Kynurenine metabolites and chronic kidney disease (CKD) are independently linked with neurocognitive dysfunction. We examined the associations between the Tryptophan (TRP) and Kynurenine (KYN) metabolites with neuro-cognitive function in CKD patient in the Chronic Renal Insufficiency Cohort (CRIC).

Methods: CRIC participants with data on TRP and KYN metabolites and cognitive tests were included in the analysis. TRP and KYN and its metabolites (kynurenic acid (KYNA) and Quinolinic acid (QYN)) were measured at baseline using mass-spectrometry. The neurocognitive tests included Modified Mini Mental State Examination (MMSE), Trail Tests A and B, Buschke Selective Reminding, Category fluency and Boston Naming. Cognitive tests were measured at baseline and then every 2 years thereafter for 10 years. Linear regression and linear mixed models were used for analysis. Model was adjusted for demographics, co-morbidities and eGFR.

Results: Among 240 participants, mean age was 62±8 yrs and 66% had CKD stage 3. TRP levels were lower (p<0.001) whereas KYN, KYNA and QYN levels were greater (p <0.001) for more advanced CKD stage. In fully adjusted regression model, lower TRP levels were associated with poor performance on the Boston, verbal, MMSE, recall and Trail-A and B tests. In contrast, higher QYN levels were associated with lower MMSE, recall and higher trail-A and trail-B score (Figure). These findings were similar in longitudinal analysis over mean follow-up of 10 years.

Conclusions: Our study indicates disturbed metabolism of the KYN pathway in CKD. Low levels of TRP and high QYN levels were related with worse neuro-cognitive function, independent of eGFR. Interventions to modulate the KYN pathway may improve cognition in CKD.

Table. Cross-sectional analysis of Tryptophan and Kynurenine metabolites with neuro-cognition and depression in CRIC

	Beta coefficient	95% CI	P value
	BOSTON

Impaired Incretin Homeostasis in Non-Diabetic Moderate-Severe CKD

Armin Ahmadi,[1] Jennifer E. Norman,[1] Madelynn Tucker,[1] Jorge Gamboa,[3] Bethany P. Cummings,[1] Ian H. de Boer,[2] Baback Roshanravan.[1] *[1]University of California Davis, Davis, CA; [2]University of Washington, Seattle, WA; [3]Vanderbilt University, Nashville, TN.*

Background: Incretin hormones are critical regulators of insulin secretion and glucose homeostasis. Little is known about the incretin response in CKD. We hypothesized that CKD is associated with impaired incretin secretion during oral glucose tolerance testing (OGTT).

Methods: We performed a cross-sectional study of 59 people with non-diabetic CKD (eGFR<60 ml/min per 1.73 m^2) and 39 healthy control participants (eGFR>60 ml/min per 1.73 m^2). We measured total area under the curve (tAUC) of plasma glucagon-like peptide-1 (GLP-1) and glucose-dependent insulinotropic polypeptide (GIP) during a 2-hour OGTT. We used linear regression adjusting for demographic, body composition, and lifestyle factors.

Results: Mean age of CKD patients was 64±14 yrs with 51% females versus 61±12 yrs with 44% females among controls. The mean eGFR in CKD participants was 38 ± 13 compared to 89 ± 17 ml/min per 1.73 m^2 in controls (**Table 1**). GLP-1 tAUC and GIP tAUC were higher in CKD than controls with a mean of 3420 ± 1948 versus 2384 ± 1546 pM*120min (*P*=0.03), and 79400 ± 38670 versus 53994 ± 28191 pg/ml*120min (*P*=0.01), respectively (**Figure 1**). After adjustment, CKD was associated with estimated 1032 pM*120min greater GLP-1 (95% CI 74, 1989) and 19103 pm/ml*120min greater GIP (95% CI 4116, 34090) compared to control. There were no differences in insulin secretion and glucose tolerance between CKD and controls.

Conclusions: CKD is associated with increased incretin hormone levels during OGTT but no difference in insulin secretory response. Further studies are needed to investigate pancreatic response to incretin hormones in CKD.

Funding: NIDDK Support

Table 1. Participant characteristics.

Characteristics	Controls (n=39)	CKD (n=59)
Age	61.0 (12.4)	63.6 (13.9)

TH-PO1068

Choroidal and Retinal Thinning in CKD Are Modifiable with Treatment and Independently Associate with eGFR Decline

Tariq E. Farrah,[1,2] Dan Pugh,[1,2] Fiona A. Chapman,[1,2] Peter J. Gallacher,[1,2] Neeraj Dhaun.[1,2] *[1]The University of Edinburgh Centre for Cardiovascular Science, Edinburgh, United Kingdom; [2]Department of Renal Medicine, Royal Infirmary of Edinburgh, Edinburgh, United Kingdom.*

Background: Cardiovascular disease is the commonest complication of chronic kidney disease (CKD). As estimated glomerular filtration rate (eGFR) declines, cardiovascular risk increases. There is an unmet need for novel biomarkers that reliably track kidney injury, demonstrate treatment-response, and predict patient outcomes. We investigated the ability of retinal optical coherence tomography (OCT) to achieve these ends.

Methods: Patients with stable, pre-dialysis CKD (including those with a kidney transplant), patients with kidney failure undergoing kidney transplantation, living kidney donors, and healthy volunteers were recruited into a series of prospective, cross-sectional, and longitudinal studies. We used the SPECTRALIS OCT machine to examine retinal thickness, macular volume, and choroidal vascular layer thickness.

Results: Compared to healthy volunteers, macular volume was reduced in CKD patients (health *vs.* CKD: 8.73±0.36 mm^3 *vs.* 8.44±0.44 mm^3, p <0.001). Kidney transplant recipients also had a reduced macular volume compared to health of a similar magnitude to that seen in CKD patients. The choroid was thinner in CKD patients (health *vs.* CKD, macular locations I, II and III: 234±80mm *vs.* 197±85mm, 319±93mm *vs.* 274±93mm, 292±83mm *vs.* 262±84mm, p <0.01 for each). Conversely, patients with a kidney transplant had choroidal thicknesses similar to healthy levels, suggesting reversal of thinning. In those with CKD, the degree of choroidal thinning related to increasing age (r= -0.25, p =0.008), falling eGFR (r=0.30, p =0.001) and severity of kidney scarring (r= -0.60, p <0.001). Patients undergoing kidney transplantation (n=25) demonstrated rapid choroidal thickening (~10%) that was maintained at 1-year post-transplant. These patients also demonstrated increases in both retinal thickness and macular volume over this period. Conversely, kidney donors (n=22) demonstrated gradual choroidal thinning over 1-year but there were no changes in retinal thickness or macular volume. In patients with CKD (n=289), both retinal and choroidal thickness independently associated with eGFR decline over 2 years.

Conclusions: These observations highlight the potential for retinal OCT to act as a non-invasive monitoring and prognostic biomarker of kidney injury. Larger, longer-term clinical trials are now warranted.

Disease Progression in Patients with Two APOL1 Variants and Proteinuric CKD from the AASK, CRIC, and FSGS-CT Datasets

Michael Lipkowitz,[1] George Manos,[2] Prasad L. Gawade,[2] Will A. Eagan,[2] Yuan Yang,[2] Ogo I. Egbuna,[2] Glenn Chertow.[3] *[1]Georgetown University Medical Center, Washington, DC; [2]Vertex Pharmaceuticals Incorporated, Boston, MA; [3]Stanford University School of Medicine, Palo Alto, CA.*

Background: Two variants in *Apolipoprotein L1* (*APOL1*) lead to proteinuric chronic kidney disease (CKD) referred to as APOL1-mediated kidney disease (AMKD). Disease progression in persons with two *APOL1* variants and proteinuric CKD is not well-understood.

Methods: We analyzed data from non-diabetic patients with two *APOL1* variants and proteinuric CKD enrolled in the African American Study of Kidney Disease and Hypertension (AASK), Chronic Renal Insufficiency Cohort (CRIC) study, and Focal Segmental Glomerulosclerosis Clinical Trial (FSGS-CT). The analysis included participants in AASK and CRIC with urine protein to creatinine ratio (UPCR) ≥0.7 g/g and participants in FSGS-CT with UPCR ≥1.0 g/g. Baseline age, sex, UPCR, and estimated glomerular filtration rate (eGFR) were determined at enrollment. For each data

set, we derived an annual eGFR slope estimate as related to persistent proteinuria, median time to end-stage kidney disease (ESKD), and median time to composite clinical outcome based on a decline of ≥30% from baseline in eGFR, the onset of ESKD, or death.

Results: A total of 38 patients from AASK, 47 patients from CRIC, and 27 patients from FSGS-CT were found to have two *APOL1* variants, CKD, and proteinuria. The estimated annual eGFR slope in AASK, CRIC, and FSGS-CT was -5.80, -8.55, and -19.08 mL/min/1.73m²/year, respectively. Across all studies, patients had a median time to ESKD of <4 years and a median time to composite clinical outcome of ≤2.14 years.

Conclusions: These results highlight the rapid rate of decline in kidney function in patients with AMKD relative to other glomerular diseases and may inform the design of clinical trials testing the safety and efficacy of APOL1-targeted therapies.

Rapidly Increased Pattern of Erythropoiesis–Stimulating Agent (ESA) Resistance Is a Predictor of Poor Renal Prognosis in Predialysis CKD Patients: BRIGHTEN Study Subanalysis

Shinya Kawamoto,[1,2] Takao Masaki,[2] Shoichi Maruyama,[2] Akane Yamakawa,[2] Tatsuo Kagimura,[2] Ichiei Narita.[2] *[1]Dokkyo Ika Daigaku Nikko Iryo Center, Nikko, Japan; [2]BRIGHTEN Study, Tokyo, Japan.*

Background: As CKD progresses, Hb level becomes sluggish in pre-dialysis CKD patients even though the dosage of ESA increases. We investigated whether renal prognosis can be predicted from transition pattern in ESA resistance as a sub-analysis of the BRIGHTEN study.

Methods: The ESA Resistance Index (ERI) was defined as Darbepoietin (DA) dosage/Hb. After the start of DA administration, ERI measured over time and renal events (dialysis initiation/ kidney transplantation) were investigated. The onset relationships were analyzed with Joint latent class models for longitudinal and time-to event data. The Kaplan-Meier method was used to estimate renal survival curves for each ERI transitional pattern. The patient background was compared.

Results: During an average observation period of 3.5 years in 1625 patients, renal events in 517 dialysis initiation and 18 kidney transplantation were analyzed. ERI transition pattern were divide into 3 classes: ERI unchanged Class A (1237 patients, Hb 9.9g/dL, Cr 2.6mg/dL), moderately increased ClassB (274 patients, Hb 9.6g/dL, Cr 3.6mg/dL), and rapidly increased Class C (114 patients, Hb 9.4g/dL, Cr 3.8mg/dL). Class C showed significant poor renal survival curve in 3 groups, and Class B showed intermediate(P<0.0001). The median renal survival time was 1.09 years in Class B, and 0.61 years in Class C. Between Class B and C, though there was no significant difference in Cr levels at the start of DA, Class C showed significant higher ERI throughout all observation period, higher rate of hypertension and ischemic heart disease.

Conclusions: (Discussion) In HD patients, several studies showed that the ESA resistance is an independent predictor of mortality. On the other hand, in pre dialysis CKD patients, a few reports showed the relationship between ESA resistance and mortality, cardio-renal outcome. The BRIGHTEN study of 1724 Japanese was the largest study and found that reduced initial responsiveness to DA was a risk factor for cardio-renal outcomes. In this sub-analysis, even if the initial response is good, rapidly increased ESA resistance during the course of CKD indicates poor renal prognosis. (Conclusion) Rapidly increased pattern of ESA resistance is a predictor of poor renal prognosis in pre-dialysis CKD.

Baloxavir Marboxil (BXM) Treatment of Influenza in Renally Impaired Patients: Post Hoc Analysis of CAPSTONE-2

Colleen Collins,[1] Steven E. Cagas,[1] Jian Han,[1] Marie-Laure Delporte,[2] Sylvie Retout.[3] *[1]Genentech Inc, South San Francisco, CA; [2]F. Hoffmann-La Roche Ltd, Basel, Switzerland; [3]F. Hoffmann-La Roche Ltd, Paris, France.*

Background: Renally impaired patients (pts) have a higher mortality rate from influenza vs pts without renal impairment. In the US, oseltamivir (OSL) is used for influenza but requires dose adjustment for pts with creatinine clearance (CrCl) <60 mL/min. CAPSTONE-2 (NCT02949011), a global phase 3 study of BXM vs OSL vs placebo (PBO) in high-risk pts ≥12 years with influenza, demonstrated the efficacy and safety of prompt single dose BXM treatment: median time to improvement of influenza symptoms (TTIIS) was (BXM vs OSL vs PBO) 73.2 vs 81.0 vs 102.3 h; no new safety signals were identified. This post hoc analysis examined BXM efficacy and safety in renally impaired pts with influenza.

Methods: In CAPSTONE-2, pts received a single oral dose of BXM (40 mg: <80 kg, 80 mg: ≥80 kg), OSL 75 mg twice daily for 5 days or PBO and were to be excluded if CrCl was <60 mL/min (<30 mL/min for Japan). At the time of enrolment, a small cohort of renally impaired pts was deemed eligible for inclusion as judged by the PI and were included in the intention to treat infected (ITTI) population. For this study, renal impairment was CrCl <55 mL/min. Endpoints were TTIIS, time to alleviation of symptoms (TTAS), time to cessation of viral shedding (TCVS) and safety.

Results: Overall, 89/1153 (7.7%) renally impaired pts were in the ITTI population; 33/384 (8.6%), 23/386 (6.0%), and 33/383 (8.6%) received BXM, OSL or PBO, respectively. For renally impaired pts, median TTIIS was numerically shorter for BXM (62.4 h [95% CI 29.2–86.2]) vs PBO (92.2 h [44.0–115.9]; p=0.1602) and similar vs OSL (69.4 h [45.5–123.2]; p=0.2061) with similar results for median TTAS (BXM: 62.4 h [29.2–86.2] vs PBO: 92.2 h [44.0–115.9]; p=0.1602; OSL: 78.2 h [48.8–123.2]; p=0.0729). Median TCVS was significantly shorter for BXM (48 h [24–72]) vs PBO (120 h [96–168]; p=0.0016) and OSL (96 h [96–144]; p=0.0029). Overall, 54 (34.2%) pts had ≥1 adverse event.

Conclusions: In this analysis of renally impaired pts (CrCl 21.7 to 54.9 mL/min), there was clinical benefit of single dose BXM with a similar median TTIIS and TTAS as well as significantly better median TCVS vs OSL; analysis of the safety data from this small cohort did not identify any new safety concerns.

Real-World Effectiveness and Tolerability of Bictegravir/Emtricitabine/Tenofovir Alafenamide (B/F/TAF) in Treatment-Experienced (TE) People with HIV with a History of CKD

Ansgar Rieke,[1] Joss De Wet,[2] Vincenzo Esposito,[3] Ana Silva-Klug,[4] Itzchak Levy,[5,6] John S. Lambert,[7,8] Marta Boffito,[9,10] Berend van Welzen,[11] Rachel Rogers,[12] Nathan Unger,[12] Tali Cassidy,[13] Rebecca Harrison,[13] Christine Katlama.[14] *[1]Gemeinschaftsklinikum Mittelrhein, Kemperhof Koblenz, Koblenz, Germany; [2]Spectrum Health, Vancouver, BC, Canada; [3]Infectious Diseases and Gender Medicine Unit, Cotugno Hospital, AO dei Colli, Naples, Italy; [4]HIV and STD Unit (Infectious Disease Service), Hospital Universitari de Bellvitge-Bellvitge Biomedical Research Institute (IDIBELL), L'Hospitalet de Llobregat, Barcelona, Spain; [5]Infectious Disease Unit, Sheba Medical Center, Tel Hashomer, Israel; [6]Sackler Medical School, Tel Aviv University, Tel Aviv, Israel; [7]Mater Misericordiae University Hospital, Dublin, Ireland; [8]University College Dublin School of Medicine, Dublin, Ireland; [9]HIV Department, Chelsea and Westminster Hospital Foundation Trust, London, United Kingdom; [10]Department of Infectious Diseases, Imperial College London, London, United Kingdom; [11]Department of Infectious Diseases, University Medical Centre Utrecht, Utrecht, Netherlands; [12]Gilead Sciences, Inc., Foster City, CA; [13]Gilead Sciences, Stockley Park, United Kingdom; [14]Infectious Diseases Department, Sorbonne University, Hôpital Pitié-Salpêtrière, Paris, France.*

Background: TAF-containing regimens, eg B/F/TAF, are approved in the US in people with an estimated CrCl ≥30 mL/min and have demonstrated comparable long-term renal safety vs non–tenofovir-based regimens. No proximal renal tubulopathies have been reported in 26 TAF trials or in a trial rechallenging those with history of tubulopathy on tenofovir disoproxil fumarate.

Methods: We investigated the renal safety profile and efficacy of B/F/TAF in the BICSTaR study, in which 963 TE participants with HIV switched from current antiretroviral therapy (ART) to B/F/TAF.

Results: Of 843 participants with baseline (BL) eGFR data available, 90 had CKD (MDRD eGFR <60 mL/min/1.73 m²), 83% were male and 85% were non-Black. More participants with vs without BL CKD were >50 yrs old (79% vs 43%; P<0.001), had ≥1 cardiovascular condition (54% vs 20%; P<0.001), diabetes mellitus (12% vs 6%; P=0.029) and hypertension (44% vs 16%; P<0.001). Those with vs without BL CKD had longer prior exposure to ART and time from diagnosis to B/F/TAF initiation (Table). Drug-related (DR) AEs were reported in 16% of people with BL CKD vs 15% in those without. A single DR renal AE (RAE) was reported in 1 person with BL CKD (proteinuria, drug continued); there were no DR RAE discontinuations or serious DR RAEs. Median eGFR was stable through 24 months for people with BL CKD (Fig.).

Conclusions: B/F/TAF was effective and safe with respect to renal outcomes in this real-world study in TE people with HIV and CKD switching to B/F/TAF, supporting use of TAF-based regimens in people with eGFR <60 mL/min/1.73 m^2.

Table: Baseline Characteristics and 24-Month Effectiveness and Safety Outcomes

	eGFR <60 mL/min/1.73m^2 (N=90)	eGFR ≥60 mL/min/1.73m^2 (N=753)	P-value*
Baseline Characteristics			
HIV-1 RNA, n (%)†: <50 c/mL / ≥50 c/mL	80 (93) / 6 (7)	676 (92) / 60 (8)	0.704

Comparative Effectiveness of Opioids vs. Non-Opioid Analgesics on the Risk of ESRD and Mortality Among US Veterans with CKD and Chronic Pain

Satya Surbhi,[1] Yamini Mallisetty,[1] Prabin Shrestha,[1] Keiichi Sumida,[1] Fridtjof Thomas,[1] Kamyar Kalantar-Zadeh,[2] Csaba P. Kovesdy.[1,3] *[1]The University of Tennessee Health Science Center, Memphis, TN; [2]University of California Irvine, Irvine, CA; [3]VA Memphis Medical Center, Memphis, TN.*

Background: Pain is common among individuals with CKD, in whom commonly used analgesics such as NSAIDs are often contraindicated. Opioids can be an alternative, but they are associated with unwanted adverse effects, leaving patients with few choices for analgesia. Non-opioid non-NSAID analgesics (e.g., gabapentin, acetaminophen, antipyrine) represent potential alternative choices, but their long-term outcomes in CKD. We compared the association of chronic opioid vs. non-opioid analgesics with end-stage kidney disease (ESKD) and all-cause mortality among patients with CKD and chronic pain.

Methods: We examined patients with CKD (defined as two or more eGFR <60 or UACR >30) and chronic pain (defined as 2 or more pain scores ≥7, 90 to 365 days apart). Chronic opioid and non-opioid analgesic use was defined as at least one 30-day supply in the one-year period following the second pain score. The association of opioid vs. non-opioid use with ESKD and mortality was examined using Kaplan-Meier estimates and multivariable adjusted Cox proportional hazards models.

Results: The total sample included 16,494 patients, of which 13,631 (82.6%) used non-opioid and 2,863 (17.4%) used opioid analgesics. Overall, patients were 69.1±11.7 years old, 96% were men, and 19% were African American, with a mean baseline eGFR of 66±22 and with 38% with UACR of >30. Opioid use (vs. non-opioid use) was associated with significantly higher risk of mortality, but not with the incidence of ESKD (Table).

Conclusions: The use of opioid analgesics was associated with higher risk of mortality among patients with CKD and chronic pain. Additional studies are needed to examine whether non-opioid analgesics could be considered as safer agents for chronic pain management among patients with CKD.

A Multi-Omics Approach to Renal Epithelial Senescence Urinary Biomarker Discovery

David P. Baird,[1] Maximilian Reck,[3] Ross A. Campbell,[1] Eoin D. O Sullivan,[1] Marie Docherty,[1] Jamie P. Traynor,[2] Patrick B. Mark,[2] Jeremy Hughes,[3] Laura Denby,[3] Bryan Conway,[3] Katie J. Mylonas,[1] David A. Ferenbach.[1] Ferenbach. *[1]The University of Edinburgh Centre for Inflammation Research, Edinburgh, United Kingdom; [2]University of Glasgow, Glasgow, United Kingdom; [3]The University of Edinburgh The Queen's Medical Research Institute, Edinburgh, United Kingdom.*

Background: Epithelial senescence is proposed as a driver of kidney fibrosis with senescent cell (SC) depletion improving outcomes. There are no non-invasive biomarkers for quantifying renal SCs. We used samples from patients with kidney disease and cultured human renal proximal tubular epithelial cells (hRPTECs) to identify urinary biomarkers of renal tubular senescence (rtSCs).

Methods: hRPTEC senescence was induced *in vitro* using 10Gy irradiation. Bulk RNAseq was performed comparing SCs with proliferating controls (n=5/group). Immunofluorescence staining for p21CIP1, Ki67 and tubular markers CD10/CKPAN was performed in human kidney tissue from 131 CKD patients. P21CIP1 (+) / Ki67 (neg) tubular cells were classified as senescent (expressed as % of all tubular cells). In subgroup 1 (collected in Edinburgh, n=51), LC-MS studies were performed on matched urine samples. Proteins qualified as candidate biomarkers if they predicted the level of histological senescence in multivariate linear regression models alongside baseline eGFR, age and ACR and were upregulated in senescence transcriptomically. Candidate biomarkers were validated in subgroup 2 (collected in Glasgow, matching baseline characteristics to subgroup 1, n=53) that had both urine and kidney tissue available.

Results: *In vitro:* Irradiation increased mRNA levels of *CDKN1A* and reduced *LMNB1* and *MKI67* in keeping with senescence induction. *In vivo*: rtSCs increased with age (rho = 0.58, p<0.001) and inversely with baseline eGFR (rho = -0.48, p<0.001). 331 proteins were detected by LC-MS. 5 candidate biomarkers were identified; 3 of which remained highly correlated with and predictive of histological senescence in the validation subgroup (fig. 1) [not named pending patent applications].

Conclusions: We have identified and validated 3 urinary biomarkers of senescence. These could aid patient selection for clinical trials of senolytic treatments in kidney disease.

Prognostic Comparisons of Carbamylated Albumin and Homocitrulline-Two Circulating Markers of Protein Carbamylation in CKD

Aya Awwad,[1,2] Eugene P. Rhee,[2,1] Morgan Grams,[3] Hernan Rincon-Choles,[4] James H. Sondheimer,[5] Jiang He,[6] Jing Chen,[6] Chi-yuan Hsu,[7,8] Vasan S. Ramachandran,[9] Paul L. Kimmel,[10] Anders H. Berg,[11] James P. Lash,[12] Mengyao Tang,[2,1] Sahir Kalim.[2,1] *[1]Harvard Medical School, Boston, MA; [2]Massachusetts General Hospital, Boston, MA; [3]New York University, New York, NY; [4]Cleveland Clinic, Cleveland, OH; [5]Wayne State University, Detroit, MI; [6]Tulane University, New Orleans, LA; [7]University of California San Francisco, San Francisco, CA; [8]Kaiser Permanente, Oakland, CA; [9]Boston University, Boston, MA; [10]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [11]Cedars-Sinai Medical Center, Los Angeles, CA; [12]University of Illinois Chicago, Chicago, IL.*

Background: Protein carbamylation, a urea driven post-translational protein modification, associates with adverse outcomes in CKD. Circulating markers of carbamylation include carbamylated albumin (C-Alb) and homocitrulline (HCit, carbamylated lysine), but prognostic comparisons between the 2 have never been made. Demonstrating comparability of the 2 markers could facilitate study comparisons and support HCit use from existing databases (HCit is a common analyte on metabolomic platforms). We thus compared the prognostic performance of C-Alb and HCit in a prospective CKD cohort.

Methods: Baseline C-Alb and HCit levels were assayed using mass spectrometry (Broad Institute Metabolomics Platform for HCit) in 1659 patients with CKD stages

2-4 enrolled in the Chronic Renal Insufficiency Cohort (CRIC) study. We compared associations to the endpoints of death and end stage kidney disease (ESKD). Adjusted Cox proportional hazard models (including eGFR and proteinuria) and C-statistics were used to compare the prognostic performance of each marker.

Results: Participant demographics included mean (SD) age 57 (10.7) years; 712 (42.9%) females; 704 (42.4%) White. Participants in the highest quartile across the two-biomarkers had similar baseline characteristics (e.g., serum urea nitrogen for HCit was 45 [35-58] mg/dL, for C-Alb 44 [34-58] mg/dL). The 2 markers showed a correlation coefficient of 0.64, P<.001, (HCit was the strongest correlate to C-Alb amongst >400 analytes from the Broad platform). In multivariable adjusted Cox models, on a continuous scale or in quartiles, HCit and C-Alb showed similar increase in the risk of either death or ESKD with increasing risk observed at higher levels (HR for death in 4th quartile compared to the 1st was1.86 (95% confidence interval [CI]:1.26-2.77) for HCit, and 1.90 (1.36-2.65) for C-Alb. The top quartile of both biomarkers had a similar but distinct HRs for ESKD with overlapping CIs. Measures of model performance showed significant and identical improvements when each carbamylation biomarker was added to fully adjusted models.

Conclusions: HCit was similar to C-Alb across multiple prognostic assessments, thus may have potential to be utilized like C-Alb in CKD clinical outcomes studies.

TH-PO1076

CKD Progression with Remote Pulmonary Artery Pressure (PAP) Monitoring in Heart Failure (HF)

Deepthi Gunasekaran, Lawrence S. Ullman, Abinet M. Aklilu, Jeffrey M. Turner. *Yale University, New Haven, CT.*

Background: CardioMEMS HF system is FDA approved for remote monitoring of PAP in patients with NYHA class III HF to reduce HF hospitalizations. Subgroup analysis of the CHAMPION trial with CKD patients reported a mean estimated glomerular filtration rate (eGFR) change of 1.0±14.48 ml/min/1.73m^2 in 6 months in the CardioMEMs group and was similar in controls. Limited data is available on the role of remote PAP monitoring on kidney function in a real-world population that includes patients with advanced CKD over longer follow up.

Methods: This is a retrospective observational study where we included patients with CKD (eGFR <60 ml/min/m^2 for atleast 90 days as screened by a nephrologist) and HF who were managed with the CardioMEMs HF system. Patients on dialysis, kidney and heart transplant recipients were excluded. Baseline characteristics were collected at the time of CardioMEMs implant. Outcome characteristics were collected after 2 years. Primary outcome was a composite of >40% decline in GFR, need for dialysis or transplant, and death.

Results: Baseline characteristics are summarized in table 1. Of 42 patients, 73.8% had NYHA Class III HF, 71.4% were diabetic and 90.5% were hypertensive. 20 (47.6%) reached the primary composite outcome. 9 (21.4%) had >40% decline in eGFR, 4 (9.5%) required chronic dialysis and 10 (23.8%) died. While 18 (42.9%) patients developed progression of kidney disease, 17 (40.5%) patients had an improvement in their eGFR. Of those, 10 (23.8%) improved by more than 20%. The median change in eGFR at 2-yrs was +11.81% (16.88, 34.7). Median number of hospitalizations was 5.0 (3.0,7.0).

Conclusions: In this cohort of adults at high risk for renal progression at the time of cardioMEMs insertion, we observed an improvement in eGFR despite the expected renal progression. A larger study with a control group is warranted to better understand the impact of remote PAP monitoring on CKD progression.

Cytomegalovirus Exposure in Nontransplant, Critically Ill CKD Patients

Dinesh Khullar, Scienthia Sanjeevani, Rahul Grover, Gagan Chhabra, Sahil Bagai, Prof Narinder P. Singh, Anish K. Gupta. *Max Super Speciality Hospital, Dehli, India.*

Background: This study aimed to provide a comprehensive understanding of the incidence, and prevalence and to determine whether CMV infection had any significant impact on the clinical course and prognosis of non-transplant CKD patients in the intensive care unit setting.

Methods: A prospective study involved 94 patients with known cases of CKD stage 3 and above admitted to ICU due to acute illness or comorbidities. CKD Patients who had received corticosteroids, cytotoxic therapy, immunosuppressive medications, or had undergone solid organ or bone marrow transplantation were excluded. In our case, at the end of 3 weeks, the prevalence of CMV infection was defined as the percentage of patients who had the infection at that time, and incidence was defined as the percentage of patients who developed the infection at any point between the time of admission and 3 weeks. At 0, 1, and 3 weeks, a quantitative RT PCR analysis for CMV DNA was conducted. The primary outcome was to evaluate the incidence and prevalence of CMV infection. The secondary outcome was to assess the effect of CMV infection on patient outcomes, hospital stay, and 30-day mortality.

Results: The prevalence of CMV infection was 9.57% with an incidence of 10.63 per 1000 patients. The mean age of CMV-infected patients was slightly higher (58.22± 8.829 vs 56.9 ± 7.638, p 0.148) compared to CMV non-infected. There was no significant difference in gender or the number of comorbidities between the two groups. The most common admitting diagnosis in both groups was sepsis (88.8% and 72.9%). The severity of the disease was higher in CMV-infected patients (p 0.044). CMV infection was associated with longer lengths of ICU stay but did not significantly impact hospital stay or 30-day mortality.

Conclusions: CMV infection is not uncommon among critically ill patients, irrespective of their immune status. It can occur in CKD patients even in the absence of overt immunodeficiency. The acquisition of CMV infection appears to be associated with the severity of illness in the ICU and is linked to higher morbidity. Such studies would provide valuable insights into the relationship between CKD and CMV, shedding light on associated risks and potential interventions.

TH-PO1078

Clinical Utility of Tenascin-C Levels in Patients with CKD

Zhen Yu Z. Lim, Hazirah Mohamad, Gek Cher Chan, Boon Wee Teo. *National University Hospital, Singapore, Singapore.*

Background: Tenascin-C (TNC), an extracellular matrix protein, is a novel biomarker associated with kidney fibrosis. Within the kidney, it activates fibroblasts and induces epithelial-mesenchymal transition. Increased levels of TNC have been seen in kidney biopsies of patients with chronic kidney disease (CKD). Current literature lacks studies evaluating TNC and associations with clinical parameters and clinical outcomes.

Methods: We retrieved prospectively collected 24-hour urinary and plasma samples from 126 CKD patients and 99 healthy participants. TNC levels were assayed using IBL Tenascin-C Large (FNIII-B) assay kit. TNC concentration was assessed for associations with serum creatinine, cystatin-C, eGFR albuminuria, and rate of eGFR decline. Other factors evaluated include age, gender and body mass index. Differences in TNC concentration between groups were compared using analysis of variance, chi-squared tests. Univariate analysis was performed to assess correlation between TNC and variables of interest. Multiple regression analysis was performed to identify predictors of eGFR decline/year. Significance was taken at $P < 0.05$.

Results: CKD patients versus healthy participants: age (59 vs. 42), gender (44% female vs. 51%), non-smokers (78% vs. 81%), BMI (27.7 vs. 24.8), eGFR (45 vs. 100mL/min/1.73m2), serum creatinine (171 vs. 69 μmol/L). 24-hour urinary concentration of TNC is elevated in CKD patients (1.45 vs. 0.32ng/ml, p<0.001). It is associated with

serum creatinine levels (p<0.001), serum cystatin-C levels (p<0.001), eGFR (p<0.001) and albuminuria (<0.001). Urinary TNC concentration is highest in patients with diabetes mellitus (DM, n=52), followed by non-DM (n=43) and healthy controls (n=92). (1.86, 0.95, 0.32ng/ml, p<0.001). In CKD patients, urinary TNC concentration is associated with rate of eGFR decline/year (p<0.001). Plasma TNC concentration was not associated with eGFR, albuminuria and GFR decline.

Conclusions: 24-hour urinary tenascin C level offers novel clinical utility in management of patients with CKD. Early detection of high risk CKD patients will allow for earlier intervention and may serve to delay ESKD onset.

The Effect of Fibrates on Kidney Function: A Systematic Review and Meta-Analysis

Saif Ali,[1] Fangwen Zhou,[1] Leo B. Morjaria,[1] Syed A. Irfan,[1] Sofia A. Platnick,[2] Lonnie Pyne.[1] *[1]McMaster University, Hamilton, ON, Canada; [2]Wilfrid Laurier University, Waterloo, ON, Canada.*

Background: Randomized controlled trials (RCTs) have investigated the effects of fibrates on cardiovascular events. Fibrates are known to cause an acute decline in estimated glomerular filtration rate (eGFR) but their long-term effect on kidney function is unclear. Some trials have indicated that following the acute decline fibrates improve the long-term rate of eGFR decline. We conducted a systematic review and meta-analysis to elucidate the impact of fibrates on kidney function.

Methods: This review was prospectively registered on PROSPERO (CRD42023377211) and conducted according to the PRISMA 2020 guidelines. Literature searches were conducted in MEDLINE, EMBASE, CINAHL and Scopus. Inclusion criteria were RCTs in adults comparing fibrates to placebo or active comparator that reported eGFR at at least two timepoints. Screening, data extraction and risk of bias assessments were conducted in-duplicate. Random-effects, restricted maximum likelihood, inverse variance meta-analyses were used to pool treatment effects. Primary outcomes included the effect on acute change in eGFR (defined as within the first 4 months), chronic eGFR slope (defined as the eGFR slope following the acute period) and post-washout eGFR. Additional outcomes were change in albuminuria and the incidence of ESRD.

Results: Fifteen (N=16,957) eligible RCTs were included. When compared to control, fibrates led to an acute decline in eGFR (MD -9.53 ml/min/1.73 m2; 95% CI -12.12 to -6.94) that was present at the end of the study period as well (MD -6.29 ml/min/1.73 m2; 95% CI -14.64 to -2.06). Based on the data available, we were unable to meta-analyze the effect of fibrates on chronic slope. However, two RCTs reported a beneficial effect of fibrates on chronic eGFR slope (-1.19 vs -2.03 ml/min/1.73 m2 per year and -0.27 vs -1.26 ml/min/1.73 m2 per year, p<0.001). Following washout, fibrates improved eGFR as compared to control (MD 3.60 ml/min/1.73 m2; 95% CI 0.02 to 7.17). Fibrates reduced albuminuria (MD -0.17 mg/g; 95% CI -0.25 to -0.10). There was no statistically significant effect on ESRD (RR 0.93; 95% CI 0.71 to 1.22).

Conclusions: Fibrates cause an acute decline in eGFR and an improvement in the rate of eGFR decline thereafter. Further studies are needed to determine the long-term impact of fibrates on renal function.

TH-PO1080

Non-Skeletal, as Opposed to Skeletal, Alkaline Phosphatase Associates with Mortality in Patients with CKD Not Yet on Dialysis

Dieter Smout,[1,2] Hanne S. Joergensen,[1,3] Björn K. Meijers,[1,2] Sander Dejongh,[1] Etienne Cavalier,[4] Mathias Haarhaus,[5,6] Amaryllis H. Van Craenenbroeck,[1,2] Pieter Evenepoel.[1,2] Nephrology and Renal Transplantation Research Group - KU Leuven. *[1]Katholieke Universiteit Leuven, Leuven, Belgium; [2]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven, Leuven, Belgium; [3]Aarhus Universitetshospital, Aarhus, Denmark; [4]Universite de Liege, Liege, Belgium; [5]Karolinska Universitetssjukhuset, Stockholm, Sweden; [6]Malmo universitet, Malmo, Sweden.*

Background: High total alkaline phosphatase (ALP) levels associate with increased mortality in patients with chronic kidney disease (CKD). The underlying mechanisms remain poorly understood. Emphasis has been on the skeletal fraction and its link with accelerated vascular calcification, but intestinal and liver ALP may be implicated given their role in the detoxification of bacterial endotoxins. This study aimed to identify the ALP fraction driving the association with mortality in CKD.

Methods: Demographics, Framingham risk factors, total and bone-specific ALP, and parameters of inflammation (CRP) and metabolic endotoxemia (lipopolysaccharide binding protein (LBP)) were assessed in 432 patients with CKD grade 1-5. Non-skeletal ALP levels were estimated as residuals of linear regression (according to Filipowicz et al. CJASN 2013). Mortality data were censored at time of renal replacement therapy or loss of follow up.

Results: Median age was 63 years, 54% were men, 19% had diabetes, and 31% had cardiovascular disease. During a median follow-up of 8.0 years, 131 patients died. High total and non-skeletal ALP were significant and independent predictors of increased all-cause mortality risk, while bone ALP was not predictive (Table). Total and non-skeletal ALP were independent determinants of elevated CRP (>10 mg/L) after adjusting for demographics and eGFR. Non-skeletal ALP was also independently associated with high LBP (Figure).

Conclusions: Non-skeletal ALP drives the association of total ALP with all-cause mortality in patients with CKD not yet on dialysis. We speculate that inflammation and metabolic endotoxemia are implicated in the poor outcomes seen with elevated total ALP.

Funding: Government Support - Non-U.S.

Table. Cox proportional hazard model showing association of serum ALP and mortality

Kidney Clearances of Protein-Bound Uremic Toxins in Various Stages of CKD and Their Predictive Role for Clinical Prognosis

Danshu Xie, Mengdi Jiang, Jiaolun Li, Feng Ding, Wenji Wang. *Shanghai Ninth People's Hospital, Shanghai, China.*

Background: Studies on the characteristics of 24-hour kidney clearances of protein bound uremic toxins (cPBUTs) in patients with CKD are limited.

Methods: Patients with non-dialyzed CKD from 2018 to 2020 were enrolled. The concentrations and 24-hour kidney clearances of indole sulfate (IS), p-cresol sulfate (pCS), and indole-3-acetic acid (IAA) among different CKD stages and levels of proteinuria were analyzed. 186 patients were followed up until September 2022. The primary and secondary outcomes were renal and hospitalization events, respectively.

Results: This was a single-center prospective cohort. The 24-hour kidney clearances of IS, IAA and pCS (cIS, cIAA and cPCS) decreased with eGFR (CKD5 VS CKD1: IS, 2.2 ml/min VS 26.7 ml/min; pCS, 1.8 ml/min VS 18.4 ml/min; IAA, 2.1 ml/min VS 12.1 ml/min). Only cIAA was positively correlated with level of proteinuria in CKD1 and CKD5 (p= 0.003; p= 0.007). The cPBUTs could effectively predict renal events (cIS: area under the curves [AUC]=0.764, p<0.001; cIAA: AUC=0.624, p=0.026; cPCS: AUC=0.657, p=0.006). Higher kidney clearance of PBUTs were associated with increased cumulative renal event free survival rates (Figure 1). Increased cIS and cIAA were associated with reduced renal events' risk ratio respectively in adjusted Cox regression models (cIS, hazard ratio [HR], 0.957, p=0.029; cIAA, HR 0.925, p=0.014). The cIAA was also associated with hospitalization risk ratio (HR, 2.55; p = 0.024) (Table 1).

Conclusions: The clearances of IS and IAA decreased with eGFR decline. They were independent predictors of worse prognosis.

Funding: Government Support - Non-U.S.

Table 1. Multivariate Cox regression analysis of renal and hospitalization events related to PBUTs

Characteristics		Renal Events HR (95% CI)	p Value	Hospitalization Events HR (95% CI)	p Value
cIS (ml/min)					
	Unadjusted	0.927(0.887,0.969)	0.001	0.970(0.952,0.989)	0.002
	Adjusted	0.957(0.920,0.995)	0.029	0.982(0.961,1.00)	0.106

Association Between Declining Kidney Function and Abdominal Aortic Calcification: Insights from NHANES Study

Pratiksha Singh, Priyaranjan Kata, Sujata Pandey, Carlos Valladares, Song Peng Ang, Jose I. Iglesias. *Rutgers Health, Community Medical Center, Toms River, NJ.*

Background: Abdominal Aortic Calcification (AAC) is a strong predictor of cardiovascular disease (CVD), which is affected by age. Gender, comorbidities, inflammation, smoking, phosphate and chloride levels, and the presence of chronic kidney disease (CKD). The exact mechanism of increased risk of AAC in CKD remains unclear, but bone and mineral metabolism and endothelial dysfunction are stipulated causes. With this in mind, we analyzed the NHANES database, which provided measurements of AAC.

Methods: 3140 subjects from the NHANES 2013-2014 dataset were included in the analysis of 40 demographic, clinical, and laboratory variables that were evaluated using univariate and multivariate analysis. Variables found to be significantly associated with AAC were included in a stepwise forward logistic regression analysis. Additionally, K means cluster analysis was performed in 2,943 subjects.

Results: Severe AAC was present in 423 subjects (13%). Stepwise forward logistic regression analysis demonstrated that Caucasian race, older age, smoking, coronary artery disease, and hypertension were associated with increased risk of AAC. In contrast, higher eGFR and higher serum chloride were associated with decreased risk. K means cluster analysis identified 3 clusters, C1, C2, and C3, representing 61%, 1%, and 38% of subjects, respectively. Compared to C2 and C3, subjects in C1 had lower AAC, higher eGFR, a lower degree of proteinuria, lower neutrophile lymphocyte ratio (NLR), higher klotho levels, and younger age.

Conclusions: A higher eGFR is independently associated with reduced risk of AAC in individuals, even in the presence of traditional risk factors. In addition, several phenotypes can be classified mainly on renal function parameters, inflammation (lower NLR), higher Klotho levels, and glomerular injury. Early interventions to maintain eGFR in individuals with traditional risk factors may improve CVD outcomes.

Impact of CKD on Complications of Hypertensive Emergency

Akil S. Kavcar,[1] Husam El Sharu,[1] Omar Khdeir,[1] Anish Surapaneni.[2] *[1]East Carolina University Brody School of Medicine, Greenville, NC; [2]Prima Healthcare, Westland, MI.*

Background: Hypertension in chronic kidney disease (CKD) is primarily volume-dependent. We sought to examine the impact of CKD on the development of complications in hospitalizations with hypertensive emergency.

Methods: We conducted a retrospective cohort study using the National Inpatient Sample from 2016-2019. We used the International Classification of disease-10 to identify hospitalizations with hypertensive emergency and then stratified them based on whether they had CKD. We used Chi-square and t-test to compare categorical and continuous outcomes, respectively. Multivariate regression analysis was used to adjust for confounders. Adjusted odds ratios (aOR) were reported with 95% confidence intervals (CI) and results were considered statistically significant if P values <0.05.

Results: Among the 750,595 total hospitalizations with hypertensive emergency 335,805 had CKD. The mean age was 63 (without CKD) VS 61 (with CKD). Of those with CKD, 45% were African Americans and 35% were Caucasians. After adjusting for patient demographics, comorbidities, and hospital characteristics those with CKD had higher odds of developing acute kidney injury (aOR: 2.85, p<0.001, CI: 2.77 - 2.94), acute pulmonary edema (aOR: 1.94, p<0.001, CI: 1.79 - 2.09), and retinal hemorrhage (aOR: 1.96, p<0.001, CI: 1.36 - 2.81). CKD was associated with lower odds of developing aortic dissection (aOR: 0.44, p<0.001, CI: 0.4 - 0.5), subarachnoid hemorrhage (aOR: 0.34, p<0.001, CI: 0.32 - 0.35), and acute ischemic stroke (aOR: 0.42, p<0.001, CI: 0.4 – 0.44). There was no statically significant difference in the odds of developing acute coronary syndrome (aOR: 1.03, p=0.395, CI: 0.96 - 1.1) and posterior reversible encephalopathy syndrome (aOR: 1.06, p=0.226, CI: 0.96 - 1.18).

Conclusions: Among hospitalizations with hypertensive emergency, CKD was associated with higher odds of acute kidney injury, acute pulmonary edema, and retinal hemorrhage.

TH-PO1084

Influence of Impaired Renal Function on the Efficacy and Safety of Intravenous Thrombolytic Therapy with Tenecteplase vs. Alteplase in Patients with Acute Ischaemic Stroke

Yu Wu, Yilun Zhou. *Beijing Tiantan Hospital, Beijing, China.*

Background: Data about intravenous thrombolysis (IVT) therapy among stroke patients with chronic kidney disease (CKD) are limited, especially for tenecteplase. We aimed to investigate the impact of renal dysfunction on efficacy and safety of tenecteplase versus alteplase in patients with acute ischemic stroke (AIS) based on the TRACE-2 trial.

Methods: A total of 1,412 thrombolysis-eligible patients with AIS were randomly assigned to intravenous tenecteplase or alteplase within 4.5 hours of symptom onset. Patients were categorized by their eGFR ≥90 (normal), 60-89 (mild CKD), and <60mL/min/1.73 m^2 (moderate CKD). The primary efficacy outcome was the proportion of participants who had a mRS score of 0–1 at 90 days. The primary safety outcome was symptomatic intracranial haemorrhage (ICH) within 36 h.

Results: Patients across the renal function strata did not have a statistically significant difference in primary efficacy outcomes with tenecteplase therapy versus alteplase (normal: RR 1.07, 95% CI, 0.97-1.18; mild: RR 1.14, 95% CI, 0.95-1.37, moderate: RR 0.86, 95% CI, 0.59-1.27) with no significant interaction between renal dysfunction and treatment assignment ($P_{interaction}$ = 0.55). The safety outcomes including proportions of symptomatic ICH ($P_{interaction}$ = 0.55) or rates of mortality ($P_{interaction}$ = 0.65) were also not different between the two treatments based on renal function.

Conclusions: CKD did not modify the treatment effect of tenecteplase versus alteplase. IVT with tenecteplase for AIS had the same efficacy outcomes compared with alteplase without increasing ICH, mortality and other bleeding events in reduced renal function, thus these patients should not be excluded from tenecteplase treatment.

Funding: Government Support - Non-U.S.

Efficacy outcomes at 3 months according to 3 eGFR category

	eGFR(mL/min/1.73m2)	Tenecteplase,%	Alteplase,%	Effect size	P value	Interaction P value
mRS score 0-1 at 3 months	≥90	302(65.51)	293(61.17)	1.07(0.97-1.18)	0.53	0.55
	60-89	114(58.76)	86(51.5)	1.14(0.95-1.37)	0.13	
	<60	21(46.67)	26(52.0)	0.86(0.59-1.27)	0.74

	<60	2(1 to 4)	1(0 to 4)	0.82(0.40-1.68)	0.59	

TH-PO1085

Rapid Serologic Response of Patients with Advanced CKD to HepB-CpG Vaccination

Christopher Yang, Anip Bansal. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Vaccination against Hepatitis B virus (HBV) is recommended in patients with CKD who are at risk for progressive kidney disease due to risk from sporadic outbreaks in hemodialysis units. There are 3 recommended HBV vaccines available in the US: Recombivax-HB, Engerix-B and Heplisav-B (HepB-CpG). HepB-CpG has been reported to have improved immunogenicity, especially in groups known to have low responses historically e.g. patients with CKD and ESKD.

Methods: The following retrospective cohort study is an analysis of sero-response rates to HepB-CpG in the outpatient CKD clinic at the University of Colorado hospital. All patients with documented administration of at least one dose of HepB-CpG between January 1, 2021 to December 31, 2022 were included in this study.

Results: 96 patients at our clinic received at least one dose of the HepB-CpG vaccine. Of these 96 patients, 67 patients had a follow-up hepatitis B surface antibody (HepBsAb) titer measured. Common reasons for non-measurement of follow up titers included death, start of kidney replacement therapy and loss to follow up. Of the 67 patients with measured follow up titers, there was an 80% (53/67) serologic response (HepBsAb > 10mIU/ml) after 1-3 doses of the vaccine (scheduled to be given at 0, 1 and 6 months). There was similar serologic response between CKD stages [CKD5: 22/27 (81%), CKD4: 22/27 (81%), CKD3b: 7/9 (77%), CKD1-CKD3a: 1/2 (50%)]. Only 2 of these patients required more than one series for a serologic response. Of the 14 non-responders who received at least two doses of the HepB-CpG vaccine, 6 patients were solid organ transplant recipients on immunosuppression (5 liver, 1 kidney), 2 patients had active multiple myeloma, and 2 patients had solid organ malignancies.

Conclusions: In our real world clinical experience, HepB-CpG produces a rapid serologic response in advanced CKD patients requiring less doses compared to the high dose of the traditional HBV vaccines (Engerix or Recombivax-HB). Ongoing immunosuppression and active malignancy were the common causes of response failure.

TH-PO1086

Prevalence and Factors Associated with Hyperkalemia in Outpatients with CKD

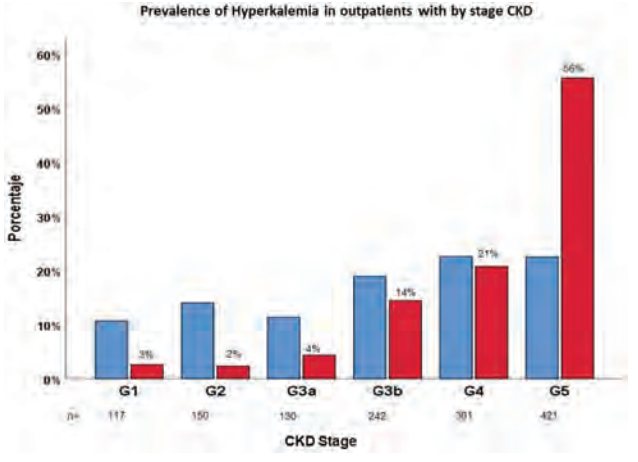
L. M. Perez-Navarro, Rafael Valdez-Ortiz, Juan Reyna-Blanco. *Hospital General de Mexico Dr Eduardo Liceaga, Ciudad de Mexico, Mexico.*

Background: Hyperkalemia (HK) is a frequent complication of chronic kidney disease (CKD), with a prevalence of between 14-20%, which is associated with different factors, such as the use of some antihypertensives (ARA's, IECAS), age, gender, Diabetes Mellitus (DM), cancer. Our aim was to determine the prevalence and factors associated with HK in patients with CKD.

Methods: Transversal study. Patients with CKD who attended the nephrology service of the Hospital General de México during the period Feb 2019 to August 2022 were included. The prevalence and factors associated with HK (K>5) by CKD stage were estimated using regression logistics (95% CI).

Results: 1368 patients were included, with an average age of 55.2±18.8 years; 51% of the population female. The time of suffering from CKD was 1 year (RIQ 2); 16% (223) are in renal replace therapy (93% HD). 74% were overweight or obese, with a mean BMI of 27.1±5.4. The main comorbidities were anemia (55%), hyperuricemia (52%), hypertriglyceridemia (50%), DM (46%), Hypertension (26%). The prevalence of HK was 25% (347), Figure 1. The factors associated with HK by CKD stage were stage 3a, DM (OR 7.5, 1.6-34.7), the use of IECAS (OR 3.7, 12-11.2) and hypertension (OR3.5, 1.1-10.9); in stage 3b, DM (OR 2.06, 1.1-3.8), AINES (OR 2.5, 1.04-6.2, 0.04), Glucose >100 ml/DL (OR 2.01, 1.04-3.8); stage 4 used ARAS (OR 3.9, 1.3-11.3); and in Stage 5 was identified the male gender (OR 1.6, 1.13-2.45) and being on HD (OR 1.8, 1.2-2.7).

Conclusions: HK presented a high prevalence in our population, which increases the risk of death, cardiovascular disease, and hospitalization. An intentional search is necessary from the early stages of CKD, as well as the different associated factors according to the CKD stage.



TH-PO1087

Proximal Tubular Secretory Clearance Is Preserved in Cirrhosis

Michael L. Granda, Eric Luitweiler, Cary H. Paine, Raimund T. Pichler, Lena Sibulesky, Bryan R. Kestenbaum. *University of Washington, Seattle, WA.*

Background: Cirrhosis promotes substantial changes in the metabolic and circulatory milieu, leading to vasoconstriction of the kidney arterioles and a consequent reduction in the glomerular filtration rate (GFR). Liver disease further leads to the retention of toxic metabolites that may impair proximal tubular functions. We tested whether cirrhosis is associated with alterations in tubular secretory clearance in patients referred for liver transplantation.

Methods: We recruited 39 outpatients with end stage liver disease undergoing workup for transplantation. We selected 58 control subjects without liver disease, matched to patients with cirrhosis by their estimated GFR (±10 ml/min/1.73m^2). We estimated tubular secretory solute clearance based on 24-hour urine and plasma concentrations of endogenous solutes measured by LC/MS. We determined the mean fold-difference of secretory clearance using regression of log-transformed clearances and adjusted for eGFR, age, and sex.

Results: Cirrhosis patients were characterized by a mean Child-Pugh 7.9±1.8 or moderate (B) liver disease, 72% male, age 57 ±9 years, and eGFR 65.6 ±19.7 ml/min/1.73m^2. Tubular secretory clearances of most endogenous solutes was equal to or higher in patients with cirrhosis compared to control persons (Fig. 1), which persisted after adjustment for eGFR, age, and sex (Tab. 1). The plasma concentrations of many solutes were substantially lower in cirrhosis (Fig. 2).

Conclusions: In contrast to our hypothesis, proximal tubular secretory clearance is largely preserved or increased in outpatients with cirrhosis. Cirrhosis patients had substantially lower plasma levels of many solutes despite similar kidney function.

Perceptions About Influenza and COVID-19 Vaccines Among People with CKD: CRIC Study

Junichi Ishigami,[1] Bernard G. Jaar,[1] James P. Lash,[2] Jing Chen,[3] Lawrence J. Appel,[1] Deidra C. Crews,[1] Kristin Riekert,[1] David W. Dowdy,[1] Kunihiro Matsushita.[1] *[1]Johns Hopkins University, Baltimore, MD; [2]University of Illinois Chicago, Chicago, IL; [3]Tulane University, New Orleans, LA.*

Background: Vaccine uptake in people with CKD is suboptimal. Understanding reasons for not getting vaccinated ("non-vaccination") could inform programs seeking to address these concerns.

Methods: In a subset of Chronic Renal Insufficiency Cohort (CRIC) Study participants, we administered a survey on perceptions about influenza and COVID-19 vaccines. Survey development followed the Health Belief Model, including themes of perceived risk, perceived benefits and harms, and cues to action. Response was based on a 5-level Likert scale (strongly agree, agree, neutral, disagree, strongly disagree). The odds of agreeing to each statement in the questionnaire (strongly agree/agree vs. others) were compared between those who did and did not have non-vaccination status, defined as never having received either an influenza vaccine in the last 5 years or a COVID-19 vaccine at any point preceding the survey.

Results: Between July 2022 and March 2023, 199 participants completed the survey (age 71 years, 42% female, 45% Black race, mean eGFR 50 ml/min/1.73m^2); 24 (12%) and 35 (18%) had influenza and COVID-19 non-vaccination status. For both vaccines, agreeing that benefits are exaggerated, that people are lied to about the risks of vaccines, and that vaccines cause side effects were associated with higher odds of non-vaccination; whereas agreeing that vaccines prevent people from becoming seriously ill was associated with lower odds of non-vaccination (Figure). Agreeing that the vaccine causes people to get COVID-19, and that people who had influenza do not need the influenza vaccine, were associated with their non-vaccination status.

Conclusions: Among people with CKD, negative perceptions about vaccine safety and benefits were associated with non-vaccination status. Effectively communicating accurate information tailored by vaccine type may be essential to improve vaccination uptake in people with CKD.

Funding: NIDDK Support

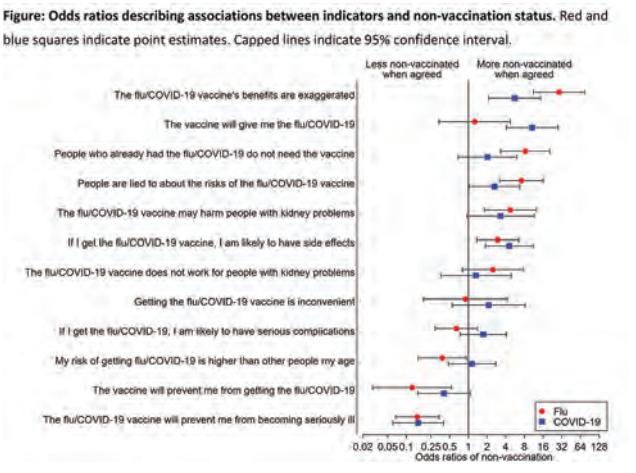

Figure: Odds ratios describing associations between indicators and non-vaccination status. Red and blue squares indicate point estimates. Capped lines indicate 95% confidence interval.

Evaluating the Effect of COVID-19 Pandemic on Anxiety in Solid Organ Transplant Recipients

Jad Fadlallah, Ana M. Samudio, Katalin Groe, Mursal Jahed, Istvan Mucsi. Kidney Health Education and Research Group. *University Health Network, Toronto, ON, Canada*.

Background: The impact of the SARS-CoV-2 on mental health, specifically on anxiety symptoms may be pronounced among solid organ transplant recipients (SOTRs), who are immunocompromised and at a higher risk of infection. This study aims to assess the impact of the pandemic on anxiety symptoms in SOTRs.

Methods: Cross-sectional convenience sample of adult kidney, kidney-pancreas, liver and kidney-liver transplant recipients, recruited in studies validating PROMIS tools between 1997-2023. Demographic data are self-reported, clinical data is from health records. Patients completed the PROMIS-29 anxiety v2.0 using 4-item SF or CAT, scored on a T-score metric, where higher score indicates more anxiety symptoms. In our primary analysis, we compare anxiety between patients who completed the questionnaires prior to the pandemic (PRE) vs after the onset of the pandemic (POST). In our secondary analysis, we further divide our POST group into those who were transplanted before (POST-B) and those who were transplanted after the pandemic (POST-A), to further delineate the potential association between the pandemic and anxiety symptoms. Scores were compared using two-sample t-test and linear regression adjusted for organ type, age, sex, ethnicity, education, marital status, economic disadvantage, comorbidity, time since transplant, serum albumin and hemoglobin.

Results: Of 682 participants, 422 (62%) were male, mean(SD) age was 53(15) years. In our primary analysis, mean(SD) PROMIS-29 anxiety scores were higher in POST vs PRE (54[9] vs 52[9], p=0.004). POST anxiety scores were significantly higher in the fully adjusted regression model (coefficient[95% CI]: 2.9[0.9,4.9], p=0.007). In our secondary analysis, the fully adjusted regression model showed that the timing of transplant (prior to or after COVID onset) status was associated with anxiety scores (reference: PRE): POST-A (coefficient[95%CI]: 4.2[0.8,7.6], p=0.019), POST-B (2.4[0.6,5.4]).

Conclusions: Anxiety scores collected in this sample of SOTRs were higher after the onset of the pandemic. These findings suggest that mental health support for SOTRs is relevant and important in the context of the pandemic. Longitudinal studies can assess the development of anxiety symptoms in the future.

TH-PO1090

Psychological Impact After the COVID-19 Epidemic on Hemodialysis Patients in China: A Multi-Center Cross-Sectional Study

Junru Wang,[1,2] Nan Wang.[3] *[1]Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Chengdu, China; [2]Chinese Academy of Sciences Sichuan Translational Medicine Research Hospital, Chengdu, China; [3]Chengdu Second People's Hospital, Chengdu, China*.

Background: Patients on hemodialysis often suffer from anxiety, depression and sleep disturbances. The questionnaire was used to assess the anxiety, depression,insomnia and social support of Chinese hemodialysis patients after the novel coronavirus disease (COVID-19) epidemic period.

Methods: Sent self-questionnaire to hemodialysis patients to record demographic and clinical information and use Generalized Anxiety disorder 7(GAD-7), Insomnia Severity Index(ISI), Patient Health Questionnaire 9(PHQ-9), Perceived social support scale(PSSS) to investigate the anxiety, sleep, depression and social support. We used logistic regression to analyses independent factor of anxiety, sleep, depression and social support**.**

Results: A total of 1044 questionnaires were collected. 480 cases (46.0%) had mild or higher anxiety, 480 cases (46.0%) had mild or higher insomnia, 927 cases (88.8%) had mild or higher depression, and among which 85.1% had suicidal tendency. 1044 cases (100%) had various degrees of social support. Work status, comorbid underlying diseases, COVID-19 vaccination, social support, depression, and insomnia are independent risk factors for anxiety. Marriage, residence, anxiety, and insomnia are independent risk factors for depressive. Comorbid underlying diseases, COVID-19 infection, anxiety, depression and social support are independent risk factors for insomnia. Comorbid underlying diseases, COVID-19 infection, COVID-19 vaccination, anxiety, depression and insomnia are independent risk factors for social support in hemodialysis patients. (P<0.05).

Conclusions: After the COVID-19 epidemic period, there is a high incidence of anxiety, depression, and sleep disorders in hemodialysis patients, and what needs to be concerned is 85.1% of depressed patients expressed suicidal tendencies. Although hemodialysis patients all have varying degrees of social support, which need more attention.

TH-PO1091

Dynamic Changes of Cycle Threshold Values and Chest CT Quantification in a Prospective Cohort of Hemodialysis Patients with SARS-CoV-2 Omicron Variant

Ze Li,[1,2] Haifan Xing,[1] Ying Fan.[1] *[1]Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Hainan General Hospital, Haikou, China*.

Background: Hemodialysis patients are at high risk of severe forms of SARS-CoV-2 infection due to their impaired immunity. Earlier warning and intervention may help to avoid adverse outcome. We aim to study the clinical characteristics, dynamic changes of cycle threshold (Ct) values and chest CT quantification in hemodialysis patients with SARS-CoV-2 Omicron variant and to explore the risk factors affecting the outcome in these patients.

Methods: We performed a single center, prospective study in Shanghai sixth People's hospital, a designated hemodialysis center. Clinical information, laboratory results, dynamic Ct values and AI based chest CT quantitative parameters were collected. Primary endpoint was defined as death or ICU admission. Patients were prospectively followed up from the first day of admission until they reached the endpoint or were discharged from hospital. Patients were divided into mild group and severe group according to the exposure to outcome or not. All aforementioned data were compared and analyzed and generalized estimating equation (GEE) was used to identify risk factors from the cohort.

Results: A total of 161 hemodialysis patients with SARS-CoV-2 Omicron variant were included and followed up (median 62 days), among which 31 patients reached the endpoint. Compared to mild group, severe group had a lower Ct value in Day 4. Ct values of the two groups tended to be equal after Day 4. In CT quantitative parameters, severe group had higher thin-section CT scores (TSS), higher percentage of ground glass opacity (GGO) volume (PGV) and higher percentage of consolidation volume (PCV). Both PGV and PCV values got faster growth from Day 0 to Day 4 in severe group than those in mild group, which kept continuously increasing at Day 7 in patients with poor outcome. Multivariate GEE showed age, PCV and phosphorus were independent risk factors for death or ICU admission in hemodialysis patients with Omicron variant, while albumin and lymphocyte count were protecting factors.

Conclusions: Our new findings suggest early and dynamic monitoring of Ct values and AI based chest CT quantitative parameters could be helpful to assess the survival and outcome in hemodialysis patients with SARS-CoV 2 Omicron variant. Optimizing dialysis strategies and improving nutritional status are important in these patients.

Incorporation of Chest Computed Tomography Quantification to Predict Outcomes in Hemodialysis Patients with COVID-19

Haifan Xing,[1] Ze Li,[1,2] Ying Fan.[1] *[1]Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China; [2]Hainan General Hospital, Haikou, China*.

Background: Patients undergoing maintenance hemodialysis are vulnerable to coronavirus disease 2019 (Covid-19) with a higher risk of hospitalizations and mortality. Early identification and intervention is important to prevent the disease progression in these dialysis patients with Covid-19.

Methods: A total of 186 Covid-19 patients from a hemodialysis center in Shanghai 6th People's hospital, China were enrolled between March 2021 and June 2021. 70% of patients (n = 130) were randomly selected in the training set for the establishment of a prognostic nomogram. 30% (n = 56) were included for the validation of the predictive model. Artificial intelligence (AI) based parameters of chest computed tomography (CT) were quantitated; demographic features, comorbidities and laboratory examination items were screened using univariate and multivariate Cox regression analyses to construct a nomogram predicting the risk of death or transferring to ICU within 28 days in hemodialysis patients with COVID-19. The concordance statistics (C- statistics) and calibration curves were used to assess model performance.

Results: The recruited patients had a median age of 65 years (IQR 56-73 years) and 58.6% of participants were male. Median time on dialysis was 4 years (IQR 2-8 years). 81.2% dialyzed through arteriovenous fistula. Age, diabetes mellitus, serum phosphorus, lymphocyte count and thin-section CT scores were identified as independent prognostic factors ($p < 0.05$) which were further incorporated into the nomogram. The C-statistics were 0.865 and 0.748 in the training and validation sets, respectively. Calibration plots show good agreement between expected and actual outcomes.

Conclusions: This is the first study to develop a reliable nomogram using clinical indicators and AI based CT image parameters to predict outcome and survival probabilities in hemodialysis patients with COVID-19. This model could be helpful to clinicians in treating SARS-CoV-2 infection, managing serum phosphorus and adjusting the dialysis strategies in these patients to against severe-critical disease progression.

TH-PO1093

Safety and Efficacy of Pre-Exposure Prophylaxis with Tixagevimab/ Cilgavimab (Evusheld) in Patients with Glomerular Diseases Who Received Rituximab

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy.*

Background: Patients on B-cell depleting agents may have a suboptimal response to vaccination, placing them at a higher risk of contracting SARS-CoV-2 or suffering from a more severe prognosis. Indeed, available data on pre-exposure prophylaxis with tixagevimab/cilgavimab (Evusheld) in subjects with glomerular diseases (GD) who received rituximab is limited.

Methods: We conducted a prospective study analyzing the safety and efficacy of tixagevimab/cilgavimab for pre-exposure prophylaxis in patients with GD who received rituximab in the previous 12 months. Rate of symptomatic infections and hospitalizations were compared to patients with GD treated with rituximab who refused to receive tixagevimab/cilgavimab.

Results: Tixagevimab/cilgavimab was administered to 22 patients (12 females, mean age 58,4±19, 6 years) with GD diagnoses including membranous nephropathy, lupus nephritis, ANCA-associated vasculitis and focal segmental glomerulosclerosis. No patient treated with tixagevimab/cilgavimab experienced symptomatic infection with SARS-CoV-2 during the follow-up (mean observation time follow-up was 112 ± 23 days), while 11 out 28 controls (39,3%) reported a symptomatic infection (p=0,001), requiring hospitalization in 2 cases. Reported adverse events were mild, namely self-limiting headache (4), discomfort at the injection site (3), flu-like symptoms/myalgia (3), and fever (1). No serious adverse event, (e.g., cardiac events, anaphylaxis) was reported.

Conclusions: Pre-exposure prophylaxis with tixagevimab/cilgavimab (Evusheld) seems safe and lowering of about 40% the risk of symptomatic SARS-CoV-2 infection in vaccinated subjects with GD who received anti-CD20 therapy. Possible applications in the subset of patients who need immunosuppressive therapy, especially with Rituximab, in a pandemic setting might be envisaged.

TH-PO1094

Effect of Remdesivir on Long-Term Adverse Cardiac and Kidney Outcomes in Patients with COVID-19 and Impaired Kidney Function

Qiyu Wang, James Dinulos, Duru E. Cosar, Ian A. Strohbehn, Sophia Zhao, Meghan E. Sise. *Massachusetts General Hospital, Boston, MA.*

Background: Patients (pts) who survive COVID-19 are at increased risk for cardiac and kidney sequelae. We sought to determine if the use of remdesivir in pts with underlying kidney impairment who were hospitalized for COVID-19 is associated with differences in long-term cardiac and kidney adverse outcomes.

Methods: We performed a propensity-score matched cohort study to compare the risk of major adverse cardiovascular events (MACE), major adverse kidney event (MAKE), slope of eGFR decline among pts hospitalized for COVID-19 with admission eGFR<60mL/min who received remdesivir versus historical comparators admitted prior to EUA for remdesivir (Figure 1). Among pts surviving 30 days and followed up to 18 months, we used Cox proportional hazards model to predict risk of hospitalization/death from MACE and MAKE; we used mixed effect linear model to estimate the eGFR decline slope.

Results: Among the 412 pts who survived >30 days (N=162 for remdesivir-treated cohort, N=250 for historical comparators, variable matching used, Figure1), mean age was 71(SD13), 55% were male, 18% were black, 11% required mechanical ventilation and mean admission creatinine was 1.5mg/dL (1.3 – 2.0). By 18 months, there was no significant difference in MACE or MAKE between the two groups. However, remdesivir use was associated with a significant attenuation of eGFR decline between 30 days to 18 months (-0.77 vs. -2.81 mL/min/year) (Table1).

Conclusions: Among pts with underlying kidney impairment hospitalized for COVID-19 who survived >30 days, remdesivir use was not associated with reduction of MACE or MAKE. However, there was attenuation of eGFR decline in pts treated with remdesivir.

Funding: Commercial Support - Gilead Science

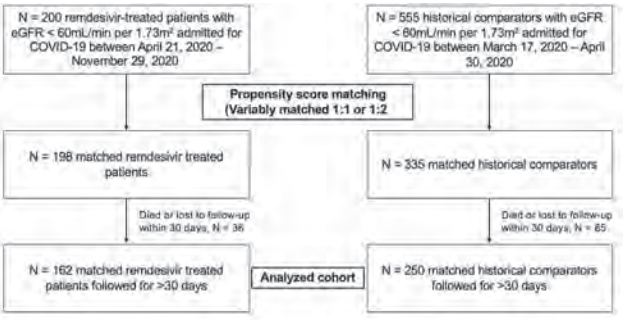

Figure 1: Patient flow: We matched patients across independent variables associated with remdesivir administration, including age, sex, race/ethnicity, sequential organ failure assessment (SOFA) score at admission, presenting creatinine, history of diabetes, hypertension, cardiovascular disease, chronic kidney disease and ESKD status, prior solid organ transplantation, and number of inpatient and outpatients encounters within MGB within 1 year prior to COVID-19. We performed variable 1:1 or 1:2 nearest-neighbor matching without replacement with a caliper of 0.1 standard deviation of the propensity score.

Unadjusted Model	eGFR slope	95% CI		p value
All patients survived ≥30 days (n=384)				
Controls	-2.90	-3.93	-1.86	<0.01
Remdesivir	-0.74	-2.01	0.53	
Multivariable Model*	**eGFR slope**	**95% CI**		**p value**
All patients survived ≥30 days (n=384)				
Controls	-2.81	-3.85	-1.78	0.01
Remdesivir	-0.77	-2.03	0.50	

Table 1. Slope of eGFR (mL/min/1.73m²/year) of the 384 patients without ESKD at baseline. Sensitivity analysis of only paired patients (N=336) revealed similar findings. The multivariable model is adjusted for age, sex, black race, diabetes, hypertension, coronary artery disease, congestive heart failure, solid organ transplant, requiring mechanical ventilation within 72 hours, SOFA score, admission serum creatinine, frequency of overall and inpatient encounters in the year prior to admission for COVID-19.

TH-PO1095

Safety and Efficacy of Nirmatrelvir/Ritonavir in Patients with Moderate-Severe CKD with COVID-19: A Real-World Data Study

Omer S. Ashruf,[1] Zara C. Orozco,[1] Imad U. Haq,[1] Zaid Ashruf,[1] Rupesh Raina.[2,3] *[1]Northeast Ohio Medical University, Rootstown, OH; [2]Cleveland Clinic Akron General, Akron, OH; [3]Akron Children's Hospital, Akron, OH.*

Background: Chronic kidney disease (CKD) is a mortality risk factor for COVID-19, predisposing patients to poor clinical outcomes. Nirmatrelvir/ritonavir (Nm/r) is currently the most effective oral antiviral agent for COVID-19, with 89% reduction in hospitalization and mortality. The U.S. Food and Drug Administration advised against Nm/r in severe CKD patients due to lack of study. In this propensity-matched retrospective study, we assess side effects, efficacy, and severity of clinical outcomes in Nm/r-treated moderate-severe CKD patients with COVID-19.

Methods: Patient data was accessed from TriNetX, a platform that aggregates health record data of over 123 million patients. The experimental group consisted of Stage 3-5 CKD patients, with 2 separate eGFR measurements of <60 mL/min/1.73m², prescribed Nm/r after COVID-19 infection. The control cohort was any non-CKD patient with COVID-19 prescribed Nm/r. Cohorts were 1:1 propensity matched for age, sex, race, and comorbidities: diabetes mellitus, hypertension, ischemic heart disease, heart failure, cerebrovascular disease, respiratory disease, smoking, and alcohol use. Outcomes assessed were COVID-19 rebound within 5-14 days, side effects within 5-35 days, and clinical outcomes (hospitalization, emergency department (ED) visit, intensive care unit (ICU) admit, and mortality) within 35 days. Odds ratio (OR) and hazard ratio (HR) with 95% confidence intervals (95%CI) and Kaplan-Meier analysis were calculated.

Results: After matching, 2,491 patients were included in the analysis. Moderate-severe CKD patients were at greater risk of developing nausea/vomiting (OR 4.32, 95%CI 2.35-7.93), diarrhea (OR 2.78, 95%CI 1.64-4.72), and fatigue (OR 1.78, 95%CI 1.23-2.55). These side effects were associated with lower survival probability within 35 days, by 2.1%, 1.6%, and 1.5%, respectively. CKD patients were also at greater risk of COVID-19 rebound (OR 1.33, 95%CI 1.08-1.65), hospitalization (HR 5.75, 95%CI 4.06-8.15), and ED visit (HR 1.68 95%CI 1.29-2.17).

Conclusions: Our findings show that moderate-severe CKD patients fare greater risk of side effects, COVID-19 rebound, and severe outcomes compared to non-CKD high-risk groups even after Nm/r. Providers should counsel patients and monitor the side effect profile and risk of COVID-19 rebound in Nm/r treated CKD patients.

Outcomes of Nitrelmivir-Ritonavir in Patients with Advanced CKD and COVID-19

Gordon C. Chan, Jack K. Ng, Cheuk-Chun Szeto, Kai Ming Chow. *The Chinese University of Hong Kong Faculty of Medicine, Hong Kong, Hong Kong.*

Background: Patients with chronic kidney disease (CKD) are vulnerable to severe novel coronavirus-2019 infection (COVID-19). Nirmatrelvir-ritonavir is an effective oral antiviral therapy, but it is not recommended in patients with eGFR < 30 ml/min/1.73m².

Methods: This is a prospective interventional trial that included COVID-19 patients with eGFR < 60 ml/min/1.73m² including dialysis. A 5-day course of nirmatrelvir-ritonavir was prescribed at a modified dosage. The adverse event, viral response and disease rebound were compared between high (> 30 ml/min/1.73m²) and low eGFR (< 30 ml/min/1.73m²). We further compare the treatment failure rate with a cohort treated with molnupiravir.

Results: 59 of the 85 participants had stage 5 CKD and were on dialysis. 9.4% had adverse events, which were comparable between eGFR groups. The viral load significantly reduced on day 5, 15 & 30 (p < 0.001 for all), including the low eGFR group (Fig 1). 10 patients had virological rebound, though was transient and asymptomatic. The rate of adverse clinical outcome was significantly lower compared to molnupiravir users (6.8% vs 21.7%, p = 0.01, Fig 2), and the significance persisted in the multivariate model (odds ratio 0.16, 95% confidence interval 0.04 – 0.71, p = 0.016).

Conclusions: Modified dose of nirmatrelvir-ritonavir is well-tolerated and effective in patients with COVID-19 and CKD including dialysis.

TH-PO1097

A Meta-Analysis to Evaluate the Safety of Remdesivir in Patients with Reduced Renal Function

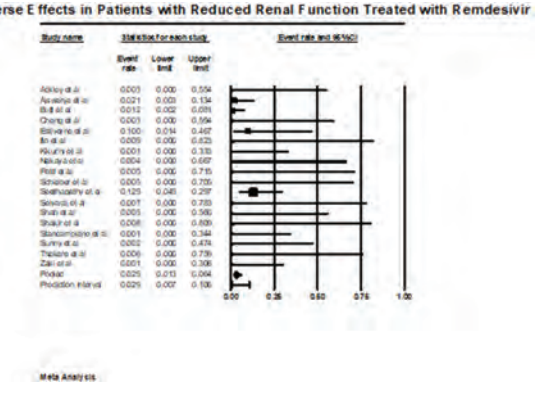
Deepak Chandramohan,[1] Divya Chandramohan,[2] Apoorv Deotare,[1] Ashwini S. Pujari,[1] Sreekant Avula.[3] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]The University of Texas at San Antonio, San Antonio, TX; [3]University of Minnesota Twin Cities School of Medicine, Minneapolis, MN.*

Background: Remdesivir is approved by the U.S. FDA for treating coronavirus disease-2019 (COVID-19). However, the clinical trials assessing remdesivir's efficacy did not include patients on dialysis and those with an estimated glomerular filtration rate (eGFR) of <30 mL/min/1.73 m2. Sulfobutylether-β-cyclodextrin (SCEBD), the solubilizing excipient used in intravenous formulations could accumulate in renal tubules causing further renal dysfunction. We performed a meta-analysis to find the safety profile of this therapeutic agent.

Methods: We systematically searched PubMed, Google Scholar, EMBASE, Cochrane, Web of Science and Clinical trials.gov from inception to January 2023 to identify studies with CKD and ESRD patients over 18 years of age with COVID-19 who received Remdesivir therapy. Using a random effects model, proportional effect sizes were calculated. The heterogeneity between study-specific estimates was assessed by the I^2 statistics. The primary outcome were the pooled rates of liver failure, renal failure and serious adverse effects. Secondary outcomes assessed were requirements of oxygen, mechanical ventilation, and mortality rate.

Results: Eighteen studies (764 patients) met the inclusion criteria. 58.3% (95% CI: 49.5-66.6; I^2= 76.9%) were males. 82.6% (95% CI: 65.3-92.3; I^2= 87.7%) were ESRD on dialysis. Severe liver failure occurred in 1.6% (95% CI:0.6-3.9; I^2= 0%). The rate of renal failure in eGFR of <30 mL/min/1.73 m2 was 8.9% (95% CI:4.6-16.5; I^2= 0%). The pooled proportion of all serious adverse effects due to remdesivir was 2.9% (95% CI:1.3-6.4; I^2= 7.8%). 17.7% (95% CI: 13.0-23.7; I^2= 62.5%) were on mechanical ventilation. The mortality rate in CKD and ESRD patients treated with remdesivir was 26.8% (95% CI: 21.1- 33.5; I^2= 65.4%).

Conclusions: The use of remdesivir in CKD and ESRD is relatively safe from our meta-analysis. Randomized clinical trials are needed to further evaluate the safety and other adverse effects of remdesivir in this population.



TH-PO1098

Remdesivir in COVID-19 Patients with Kidney Disease: A Study on the Renal Function and Outcomes

Crystal G. Lagura, Jennifer Ivy Togonon-Leaño. *Southern Philippines Medical Center, Davao City, Philippines.*

Background: The COVID-19 pandemic has high mortality rates in patients with kidney disease. Remdesivir, an antiviral nucleotide prodrug, showed to shorten time to recovery in adults hospitalized with COVID 19. However, individuals with kidney disease were not included in clinical trials, thus when emergency use authorization was granted, it was recommended to avoid use in patients with eGFR <30mL/min "unless benefit outweighs the risk". In this study, we aim to determine the effect of Remdesivir on renal function and outcomes among COVID19 patients with kidney disease.

Methods: This retrospective study included the following: >18 years old, RT-PCR confirmed COVID19 infection treated with Remdesivir and who were confirmed to have kidney disease.

Results: There were 106 patients included; the mean age was 62.25±13.96 years old, more than half of the population were males (53%). The majority of the population had acute kidney injury (70.7%) while the rest had chronic kidney disease and 25% underwent renal replacement therapy. Most of them were classified as severe (66%) and critical (25%) COVID infection. To determine effects on renal function laboratory parameters were determined at baseline and after completion of treatment. There was an overall significant improvement in eGFR (<0.01), albuminuria (0.013) and in acid-base balance (0.003) and odds ratio showed that none of the demographic, clinical and laboratory profile significantly increased the chance of death in terms of overall clinical outcome. In terms of overall clinical outcome, this study had a mortality rate of 4.9% as 5 out of 106 patients expired.

Conclusions: Use of Remdesivir in patients with kidney disease was not associated with renal function deterioration. Contrary to concerns there was rather an overall significant improvement in eGFR, degree of albuminuria and acid-base balance after treatment regardless of their disease severity and its use in patients on hemodialysis have not shown any detrimental impact on mortality.

TH-PO1099

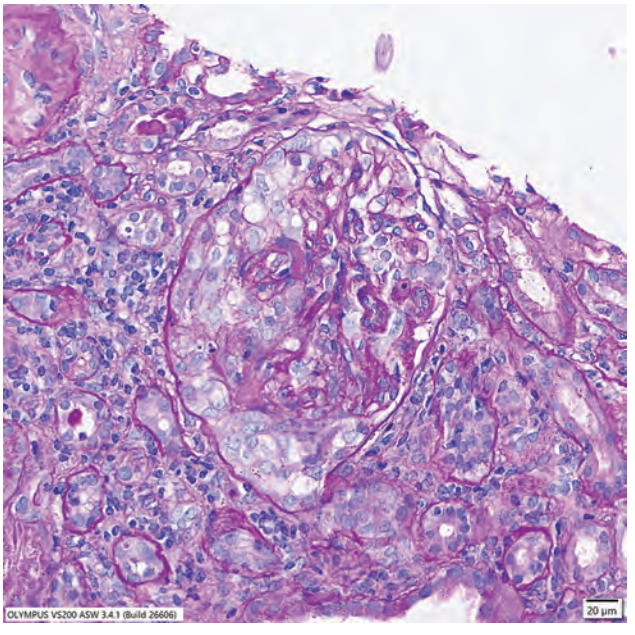
COVID-19-Associated C-ANCA Vasculitis

Pradeep Vaitla,[1] Mohammad Atari,[1] Sanjana Kapoor,[1] Prathap Simhadri.[2]
[1]The University of Mississippi Medical Center, Jackson, MS; [2]Advent Health, Daytona Beach, FL.

Introduction: Anti-neutrophil cytoplasmic antibody (ANCA) associated vasculitis is a group of systemic vasculitis that causes inflammation and destruction of the small and medium-sized blood vessels and can cause acute renal failure. SARS-CoV-2 (COVID-19) has been shown to increase the risk for autoimmune diseases. We present a case of C-ANCA vasculitis a few weeks after COVID-19 infection which was successfully treated with steroids and Rituximab.

Case Description: 87-year-old female with hypertension presented with generalized weakness, malaise, and myalgias. She had COVID-19 infection with bronchitis symptoms a few weeks before the presentation. She has no history of kidney disease; labs showed creatinine of 2.99 mg/dl, BUN of 36 mg/dl with eGFR of 14. Urine dipstick showed 3+ proteinuria and 3+ hematuria. Labs showed serum Anti-proteinase-3 antibody titers of 1:946, C-ANCA titers of 1:1280, and myeloperoxidase, P-ANCA were negative. Renal biopsy showed necrotizing and crescentic glomerulonephritis. Immunofluorescence: granular mesangial and capillary loop staining with 3+ staining for IgG, IgM, C3, kappa, and lambda. Infection-related crescentic vasculitis was considered and ruled out with negative blood and urine cultures. She was given pulse dose steroids and four weekly doses of Rituximab. Prednisone was tapered to 10 mg daily over 8 weeks. She had significant improvement with her generalized weakness, anemia, and myalgias. Even though her eGFR recovery (17) was marginal, proteinuria and hematuria resolved completely and ANCA titers improved which indicates improving vasculitis activity.

Discussion: A few cases of COVID-19-associated ANCA vasculitis have been reported but data regarding management is scarce. Our case highlights the safety and efficacy of prompt Rituximab and steroid therapy in patients with COVID-associated ANCA vasculitis.



TH-PO1100

A Case of Newly Diagnosed Systemic Lupus Erythematosus and Lupus Nephritis After COVID-19 Infection

Nicole A. Clarke,[1] Gabriela Dande,[1,2] Saul N. Gonzalez Montalvo.[1] *[1]Larkin Community Hospital Inc, South Miami, FL; [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Introduction: Systemic Lupus Erythematosus (SLE), the most common form of lupus, is a chronic autoimmune inflammatory disease with clinical manifestations affecting any organ. Kidney involvement is seen in about 50% of patients, leading to CKD or ESKD. The year 2019 brought on a pandemic caused by the virus Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Here we illustrate a case of SLE and lupus nephritis with clinical manifestations discovered after COVID-19 infection.

Case Description: A 39-year-old Hispanic male presented to our institution with abdominal pain associated with nausea and vomiting, recurrent skin rash, hematuria, weight loss of 40 pounds over the past several months and joint pains. Prior to this admission, he had multiple visits to the hospital for abdominal pain, general malaise, and joint pain that started about 9 months after a 5-day course of COVID-19 infection; and subsequently diagnosed with urticarial vasculitis with colitis during one of his hospital admissions. Physical examination was notable for tenderness to the epigastric and periumbilical region, and multiple umbilicated papules of the elbows and palms and tense bulla of the left third digit. His laboratory findings revealed elevated creatinine, anemia and urinalysis showed hematuria. Previous autoimmune workup was positive for ANA, ds-DNA, Sjogren's antibodies and low C3 and C4 complements. His CT abdomen without contrast showed a thickened terminal ileum with inflammatory changes consistent with colitis. Skin biopsy findings were consistent with small vessel vasculitis. Subsequent renal biopsy confirmed immune complex – mediated glomerular nephritis with full house tubular inclusions and subepithelial deposits consistent with membranous lupus nephritis. He was treated with IV methylprednisolone, PO prednisone, with plans for starting Cyclophosphamide.

Discussion: The link between lupus and colitis is rare in the literature. Similarly, the link between lupus and COVID-19 is also rare with only case reports of both scenarios currently existing. This and other case reports in the literature hopes to spark the discussion and later the investigation as to the possible reasons for both occurrences.

TH-PO1101

COVID-19 Vaccination (VAX) and Infection (INF)-Related Glomerular Diseases (GNs)

Phuong-Chi T. Pham,[1] Vinod K. Valluri,[1] Golriz Jafari,[1] Anita Kamarzarian,[1] Kulwant S. Bath,[1] Masoud Haghi,[1] Phuong-Thu T. Pham.[2] *[1]UCLA Medical Center Olive View, Sylmar, CA; [2]University of California Los Angeles, Los Angeles, CA.*

Background: There have been numerous reports of GNs associated with both COVID-19 VAX and INF. We performed a systematic review per PRISMA involving reported COVID-19 VAX and INF-associated GN cases to explore for supportive evidence of a cause-and-effect rather than a fortuitous relationship.

Methods: We searched NLM, EMBASE, and the World Health Organization COVID-19 database for case reports and series, and observational studies for reported VAX or INF-associated GNs.

Results: Of 1261 articles identified, 117 articles were included. Fifty-eight articles pertained to infection- and 59 to vaccine-related GNs. Among vaccine-related GNs, the top 3 diagnoses were IgA nephropathy (IgAN, 35 out of 111 cases, 31.5%), anti-neutrophil cytoplasmic antibody-associated GN (ANCA, 23 out of 111, 18.9%), and minimal change disease (MCD, 23 out of 111, 18.9%). Among infected patients, the top 3 were focal segmental glomerulosclerosis (FSGS, 90 out of 162, 55.6%), ANCA-associated GN (34 out of 162, 21.0%), and IgAN (12 out of 162, 7.4%). The distributive patterns of reported GNs associated with the VAX and INF differ significantly compared with that in the pre-COVID era, where excluding diabetic glomerulosclerosis, the top 3 GNs globally were FSGS 17.4%, IgAN 16.5%, and MN 12.1%.

Conclusions: Based on the pathogenesis of GNs and systemic immune response to COVID-19 VAX and INF and the observed differences in GN patterns among pre-COVID era, VAX, and INF-reported GN cases, we suspect that the relationship betweent VAX and INF-reported GNs were directly causal rather than coincidental.

GN	Pre-COVID global distribution (%)	COVID-19 vaccine n (%)	COVID-19 infection n (%)
Focal segmental glomerulosclerosis	17.4	3 (2.7)	90 (55.6)
IgA nephropathy/Henoch Schonlein purpura	16.5	35 (31.5)	12 (7.4)
Diabetic kidney disease	13.9	0 (0)	0 (0)
Membranous nephropathy	12.1	10 (9)	6 (3.7)
Lupus nephritis	12.2	4 (3.6)	1 (0.6)
ANCA	6.2	21 (18.9)	34 (21)
Minimal change disease	5.2	21 (18.9)	2 (1.2)
MPGN/C3GN	3	3 (2.7)	0 (0)
Renal amyloid	2.9	1 (0.9)	1 (0.6)
TTP/HUS	2.5	4 (3.6)	12 (7.4)
Others	8.1	9 (8.1)	4 (2.5)
Total	100	111 (99.9)	162 (100)

Impact of COVID-19 Infection in a Glomerular Disease Unit

Miguel Uriol Rivera, Felipe I. Ojeda, Estela M. Ródenas, Aina Obrador, Sonia Jimenez. *Hospital Universitario Son Espases, Palma, Spain.*

Background: COVID-19 infection poses a significant global health challenge, yet its impact on glomerular disease patients (GDP) remains understudied. This research aims to investigate the mortality and chronic renal replacement therapy (CRRT) rates among GDP, identify predictive factors, and explore the influence of proteinuria on the evolution of estimated glomerular filtration rate (eGFR).

Methods: This retrospective study compares the annual eGFR changes in GDP before and after COVID-19 infection. The study period spans from January 10, 2020, to July 28, 2022. Proteinuria was defined as a urine protein/creatinine ratio exceeding 0.2 mg/mg.

Results: Among the 302 GDP included, 64 (21%) contracted COVID-19. The mean age was 47 years. Sex: Females 31 (48%) patients. Infection rates were 9% in 2020, 28% in 2021, and 63% in 2022. Of the infected patients, 12 (19%) either died

(9) or initiated CRRT (3). Age, eGFR, and proteinuria at admission were identified as independent predictive factors for death or the need for chronic renal replacement therapy. Hospitalization was required for 21 (33%) patients, with 6 necessitating intensive care unit admission. Excluding those who died or initiated CRRT, 52 patients were followed up for an average duration of 17 months (ranging from 9 to 40 months). During this period, the annual mean change in eGFR between the pre- and post-COVID-19 infection periods was -10.3 mL/min/1.73m2 (95% confidence interval: -17.9 to -2.8, P=0.008). At the time of infection, eGFR decreased by 6.8 mL/min/1.73m2 (3.9 to 9.8). Patients without proteinuria experienced eGFR recovery, while those with proteinuria exhibited a progressive decline in eGFR (Figure 1).

Conclusions: Twelve (19%) GDP patients either died or initiated CRRT, with age, eGFR, and proteinuria serving as significant predictor factors. The trajectory of eGFR shifted following COVID-19 infection in GDP, with proteinuria notably contributing to a progressive and accelerated decline in eGFR.

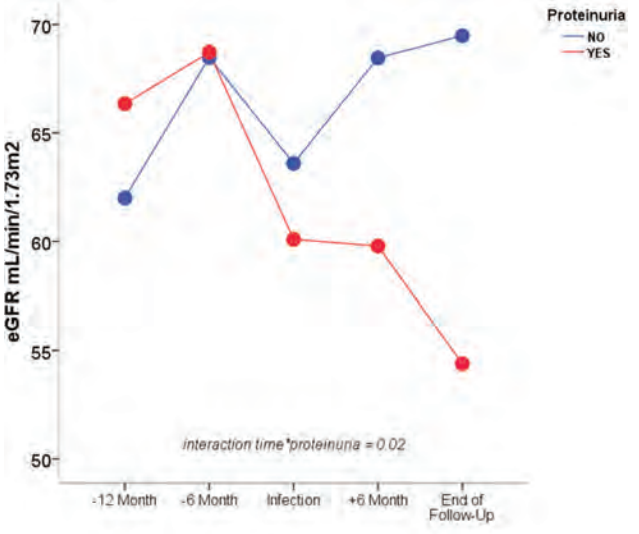

Figure 1

TH-PO1103

Risk Factors for the Relapse and Aggravation of Patients with Primary Membranous Nephropathy After COVID-19 Infection

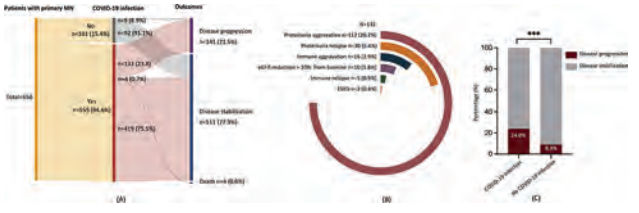
Yue Shu, Zhao Cui. *Peking University First Hospital Department of Nephrology, Beijing, China.*

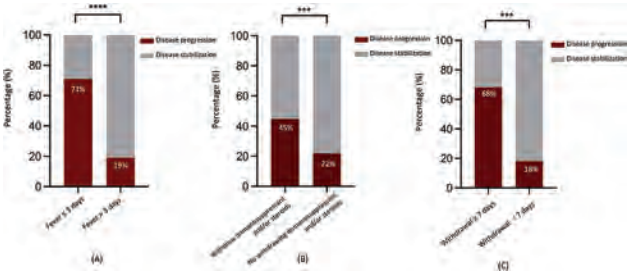
Background: Relapse cases of membranous nephropathy (MN) and other glomerular diseases have been reported after the infection of COVID-19. The risk factors for MN disease progression after COVID-19 infection need to be clarified.

Methods: A retrospective study were conducted from November 11th, 2022 to February 22nd, 2023 on 656 consecutive patients with biopsy-proven primary MN who had been treated and followed up for more than 6 months. Logistic regression analyses were performed to identify the risk factors.

Results: 555 (84.6%) patients underwent COVID-19 infection. Among them, 112 (20.2%) patients experienced urinary protein aggravation > 50% from the baseline, including 30 (5.4%) patients with relapse of nephrotic syndrome. 16 (2.9%) patients got immune aggravation with the increase of anti-PLA2R levels and five (0.9%) patients got immune relapse with antibody reoccurrence. Ten (1.8%) patients got kidney dysfunction with eGFR reduction > 30% from the baseline, among them two (0.4%) patients progressed into ESKD. Four (0.7%) patients died of respiratory failure. Taken together, 132 (24%) patients experienced disease progression after COVID-19 infection. Multivariate logistic analysis showed that the longer duration of fever (OR 1.118, 95% CI 1.029-1.356, *P*=0.018), the withdrawal of immunosuppressants and/or steroids (OR 2.571, 95% CI 1.377-4.799, *P*=0.003) and the longer time of withdrawal (OR 1.113, 95% CI 1.045-1.186, *P*=0.001) were independent risk factors for MN progression.

Conclusions: The findings proposed an active anti-virus treatment and no or shorter time of immunosuppressants withdrawal for a better prognosis of kidneys on the clinical practice of MN patients with COVID-19 infection.





TH-PO1104

A Case of Membranous Nephropathy and Collapsing Focal Segmental Glomerulosclerosis After COVID-19 mRNA Vaccination

Mark Rudy, B. Peter E. Sawaya, Sadiq Ahmed. *University of Kentucky College of Medicine, Lexington, KY.*

Introduction: The mRNA COVID-19 vaccines have been an effective method for combating the deadly COVID-19 virus. In the literature, there are case reports of glomerulopathies developing after vaccination. It is important to be aware of this potential association to allow for prompt investigation and treatment. We highlight a case of combined membranous nephropathy and collapsing focal segmental glomerulosclerosis in a 36-year-old male after mRNA COVID-19 vaccination.

Case Description: A 36-year-old white male was referred to our clinic for nephrotic syndrome. He developed symptoms of lower extremity edema and fatigue two months after receiving the second dose of an mRNA COVID-19 vaccination. He did not seek medical care at that time. After 11 months he had laboratory studies that showed a serum creatinine of 0.78 mg/dL, serum albumin of 1.6 g/dL, PLA2R antibody titer of 108 Ru/mL, and 24-hour urine with > 15 grams of protein. A kidney biopsy showed membranous glomerulopathy Stage II-III with frequent segmental sclerosis with collapsing features as well as severe interstitial inflammation. He was treated with ACE-I, statin, and two infusions of 1-gram Rituximab given two weeks apart. 6 months after his treatment, his serum albumin was 3.1 g/dL, PLA2R antibody titer was 10 RU/mL, and urine protein to creatinine ratio was 6.1 g/g and his lower extremity edema and fatigue markedly improved.

Discussion: This case illustrates an unusual combination of membranous nephropathy, collapsing FSGS and interstitial inflammation after receiving COVID-19 mRNA vaccination with partial response to Rituximab at 6 months. Membranous nephropathy and FSGS have been reported after COVID-19 vaccines or infection, but the combination is rarely seen in the literature. This case emphasizes the need for awareness of the diversity of glomerulopathies associated with the COVID-19 mRNA vaccination.

TH-PO1105

Case of Membranous Nephropathy (MN) After COVID-19 Vaccine

Tahir A. Jatoi, Sandeep R. Sasidharan, Omar N. Elhawary, Mohammad W. Abushawer, Sonalika Agarwal, Mary C. Mallappallil, Isha Puri. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Covid vaccines are considered the best approach to prevent SARS-CoV-2 infection. There are few biopsy proven cases reported of glomerular pathology associated with COVID-19 vaccines. Here we present a case of primary membranous nephropathy (anti-PLA2R positive) that developed after Pfizer-BioNTech COVID-19 vaccine.

Case Description: 56 y-o M with history of HTN and recent PE with negative hypercoagulability work up, on Eliquis presented with complaints of leg and orbital

edema for 6 weeks. He had similar complaints few months ago and presented to an outside hospital when he was diagnosed with PE. He reported that he first noted swelling in his lower extremities after the first dose of covid vaccine which worsened after he received the second dose. Labs showed a Serum Creatinine of 1.3 mg/dl, urine protein>300, Serum albumin 1.7 mg/dl, HbA1c of 5.8, Spot UPCR was 6.8 g/g and anti-PLA2R titers were 539. Renal biopsy was done which showed positive granular capillary wall staining for PLA2R1 (2+) and mild interstitial fibrosis with tubular atrophy. Immunofluorescence was positive for IgG, C3, Kappa and Lambda light chains. Electron Microscopy showed glomerular subepithelial dense deposits, with slight mesangial expansion and epithelial foot process effacement diagnostic for stage 1 MN and ATN. He was treated with supportive measures initially and later switched to Rituximab infusion for two doses after biopsy confirmed MN. He had poor response and his UPCR remained >10g/d. Tacrolimus was subsequently added for persistent proteinuria but without sufficient response. He was then started on a cyclical corticosteroids and Cyclophosphamide with successful achievement of remission.

Discussion: MN accounts for 20-30% of Nephrotic syndrome cases. Anti-PLA2R antibodies are identified in 70-80% of primary MN cases. Given recent reports of de-novo glomerular diseases after receiving COVID-19 vaccines in depth studies of vaccinated patients are needed to establish a causal relationship.

New Onset of Membranous Nephropathy and Renal Vein Thrombosis After SARS-CoV-2 Infection

Areebah Qadir,[1] Aamna F. Hameed,[2] Mohammad R. Khan,[1] Aemen S. Khakwani,[3] Nabiha Mustafa,[1] Sadaf Munir,[4] Usman A. Khan.[5] *[1]Bakhtawar Amin Medical and Dental College, Multan, Pakistan; [2]Shifa College of Medicine, Islamabad, Pakistan; [3]Suburban Community Hospital, Norristown, PA; [4]CMH Multan Institute of Medical Sciences, Multan, Pakistan; [5]University of Oklahoma and VA Medical Centre, Oklahoma City, OK.*

Introduction: COVID-19 was identified as a cause of a cluster of pneumonia cases in the province of Wuhan in China in 2019 and soon was declared a pandemic by WHO in February 2020. Though COVID-19 is mainly a pulmonary disease, there have also been reports of extrapulmonary manifestations of the disease affecting the renal system, among other systems. We present a unique case of a patient diagnosed with membranous nephropathy post-COVID-19 infection.

Case Description: A 37-year-old man presented to the Emergency department with primary complaints of hematuria, fever, and right lower quadrant abdominal pain. Recent past medical history revealed mild Covid-19 infection with resolution in 2 weeks. Laboratory analysis showed creatinine at 1.8mg/dL, protein to creatinine ratio of 9.5g/g, and albuminuria of 12g/L. Doppler of both kidneys showed right renal vein thrombosis. Biopsy on day 4 showed thickening of the basement membrane with PLA2R staining positive. The patient was started on ACE inhibitors and rituximab for 14 days. After following the prescribed regimen, the patient showed complete resolution of proteinuria, with normal creatinine function.

Discussion: Membranous nephropathy can be primary PLA2R+ or secondary, and COVID-19 infection and immunization have recently been linked to its increased incidence. Podocytes, neutrophils, airway epithelial cells, and macrophages all express PLA2R-Antigen, and upon getting triggered by a foreign antigen such as COVID-19 these cells release extracellular vesicles containing PLA2R or cause the longitudinal release of PLA2R by engendering extracellular traps, subsequently exciting B lymphocytes to produce PLA2R-Antibody. Additionally, the oxidative environment induced by inflammatory cytokines may result in longstanding expression of PLA2R pathogenic epitopes and increase their ability to bind to circulating antibodies. We believe a recent COVID-19 infection, triggered this cascade in our young 37-year-old patient and resulted in nephrotic syndrome, albuminuria, membranous nephropathy, and renal vein thrombosis.

TH-PO1107

Series of Glomerular Diseases Developed After COVID-19 mRNA Vaccination

Kenichiro Abe,[1] Hitoshi Suzuki,[1,2] Yukako Umezawa,[1] Hitomi Hirose,[1] Takeo Koshida,[1] Tomomi Hirasawa,[1] Arisa Kato,[1] Hiromitsu Fukuda,[1] Hisatsugu Takahara,[1] Yusuke Suzuki.[2] *[1]Juntendo Daigaku Igakubu Fuzoku Urayasu Byoin, Urayasu, Japan; [2]Juntendo Daigaku Igakubu Daigakuin Igaku Kenkyuka, Bunkyo-ku, Japan.*

Introduction: The coronavirus disease 2019 (COVID-19) vaccine has been proven effective in preventing severe COVID-19 infection. Meanwhile, many vaccine-related adverse events have been reported with the increasing use of messenger RNA (mRNA)-based COVID-19 vaccines. In fact, cases of vaccine-related new-onset and relapsing glomerular diseases, including minimal change disease (MCD), anti-neutrophil cytoplasmic autoantibody-associated vasculitis, immunoglobulin (Ig)G4-related disease, and IgA nephropathy (IgAN), have been reported. Here, we report 40 patients who developed glomerular diseases after COVID-19 mRNA vaccination.

Case Description: We evaluated the clinical characteristics, vaccine types, and clinical outcomes of 40 patients whose urinalysis indicated proteinuria and/or occult blood after COVID-19 mRNA vaccination. For a definitive diagnosis, we performed a renal biopsy and evaluated their histological findings. Out of 40 patients, 27 (67.5%) were female, and 13 (32.5%) were male. The median patient age was 41 years (range, 15–78). Seventy-five percent of patients received BioNTech Pfizer vaccines, and 25% received Moderna vaccines. Gross hematuria was observed in 85% of patients, and 15% presented with nephrotic syndrome. Twenty-seven patients (67.5%) were diagnosed as IgAN by renal biopsy, while the remaining were diagnosed with MCD, TAFRO syndrome, membranous nephropathy, proliferative glomerulonephritis with monoclonal Ig deposits, thrombotic microangiopathy, and anti-glomerular basement membrane disease. Four patients with IgAN who previously diagnosed and underwent treatment showed exacerbation of urinary abnormalities.

Discussion: Various glomerular diseases developed after COVID-19 mRNA vaccination. However, the mechanisms underlying mRNA vaccine induced kidney disease remain unclear. Several hypotheses have been proposed regarding the mechanism by which an mRNA vaccine triggers an adaptive immune response to display its protective effect, which may stimulate a hyperinflammatory condition. Further studies are necessary to elucidate the underlying biological mechanisms and identify the exact causal relationship.

TH-PO1108

The Severity of Microscopic Hematuria in IgA Nephropathy Correlates with the Incidence of Gross Hematuria Following SARS-CoV-2 mRNA Vaccination

Shinya Yokote, Nobuo Tsuboi, Akihiro Shimizu, Masahiro Okabe, Kotaro Haruhara, Takaya Sasaki, Hiroyuki Ueda, Takashi Yokoo. *Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan.*

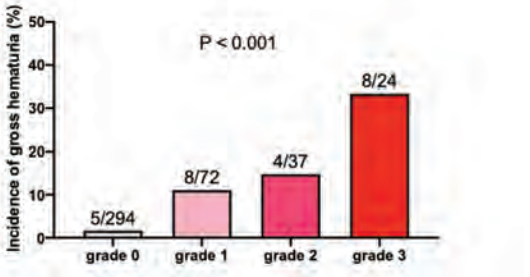
Background: Since the initiation of a global vaccination program against the COVID-19 pandemic, numerous cases of newly diagnosed or worsening immunoglobulin A nephropathy (IgAN) with gross hematuria have been reported following SARS-CoV-2 mRNA vaccination. Recent case studies have indicated a possible link between baseline urinary findings and the appearance of gross hematuria following SARS-CoV-2 mRNA vaccination.

Methods: Outpatients with biopsy-proven IgAN aged 18 years or older were included in this study. The association between pre-vaccination microscopic hematuria (urine sediment < 5 /HPF) or proteinuria (< 0.3 g/gCr) and post-vaccination gross hematuria was retrospectively analyzed.

Results: A total of 417 IgAN patients (mean age, 51 years; 56 % female; eGFR, 58 mL/min/1.73 m^2) were included. The frequency of post-vaccination gross hematuria was higher in patients (20/123; 16.3%) with pre-vaccination microscopic hematuria than in patients (5/294; 1.7%) without pre-vaccination microscopic hematuria ($p < 0.001$). There was no association between pre-vaccination proteinuria and post-vaccination gross hematuria. After adjustment for potential confounders such as gender (female), age group (< 50 years), eGFR category (≥ 60 mL/min/1.73m^2), and prior tonsillectomy or corticosteroid therapy, microscopic hematuria was still associated with post-vaccination gross hematuria (OR 8.98, $p < 0.001$). Notably, as the severity of pre-vaccination microscopic hematuria increased, the incidence of post-vaccination gross hematuria increased (**Figure 1**).

Conclusions: These results suggest that baseline microscopic hematuria predicts gross hematuria after SARS-CoV-2 mRNA vaccination in patients already diagnosed with IgAN. The correlation between the severity of pre-vaccination microscopic hematuria and the incidence of post-vaccination gross hematuria suggests that IgAN disease activity is involved in this association.

Figure 1



The red blood cell (RBC) count in the urinary sediment was graded as follows: 0, <5 RBC/high-power field (HPF); 1, 5–19 RBC/HPF; 2, 20–49 RBC/HPF; and 3, ≥50 RBC/HPF.

TH-PO1109

Elucidating the Mechanism of Gross Hematuria in IgA Nephropathy: Analysis of the Biomarkers in Patients with Gross Hematuria After COVID-19 Vaccination

Ryousuke Aoki,[1] Yoshihito Nihei,[1] Keiichi Matsuzaki,[2] Masao Kihara,[1] Hitoshi Suzuki,[1] Yusuke Suzuki.[1] *[1]Juntendo Daigaku, Bunkyo-ku, Japan; [2]Kitasato Daigaku Igakubu, Sagamihara, Japan.*

Background: Gross hematuria (GH) is observed shortly after an upper respiratory tract infection in 30–40% of the patients with immunoglobulin A nephropathy (IgAN), however, its mechanism is unclear. Recently, several reports showed the cases with GH after vaccination against coronavirus disease 2019 (COVID-19) in patients with IgAN. Here, we sought to clarify the mechanism of GH in IgAN by detailing the clinical characteristics and measuring serum and urinary galactose-deficient IgA1 (Gd-IgA1), which are known to be associated with development of IgAN, in patients with GH after COVID-19 vaccination. We conducted a prospective cohort study of 82 patients who presented with GH after COVID-19 vaccination.

Methods: All the patients visited either Juntendo University Hospital or Juntendo University Urayasu Hospital between May 11, 2021, and July 31, 2022. We collected the serum and urine samples at the time of the first presentation to the hospital with GH (GH 0) and six months after GH (GH 6). IgA1 were measured by enzyme-linked immunosorbent assays.

Results: We found that majority of patients who developed GH after COVID-19 vaccination were females (58 patients, 71%). GH was observed after the second or subsequent vaccinations in most patients (75 patients, 92%). Among the 82 patients, 22 had been already diagnosed with IgAN or IgA vasculitis (IgAV) prior to vaccination. In the remaining 60 patients, 42 performed kidney biopsies, who were all diagnosed with IgAN or IgAV. Although serum Gd-IgA1 were comparable throughout the observation period (GH 0: 5135.7 ng/mL; interquartile range [IQR] 3930.3-6914.4 ng/mL vs. GH 6: 5354.8 ng/mL; IQR, 4288.5-7937.9 ng/mL; p=0.319), urinary Gd-IgA1 was increased at the time of GH (GH 0: 42.7ng/mL; IQR, 21.6-110.1 ng/mL vs. GH 6: 31.7ng/mL; IQR, 12.8-93.9 ng/mL; p=0.030). These data suggests that deposition of Gd-IgA1 in the glomeruli was enhanced by COVID-19 vaccination by a mechanism other than increasing serum Gd-IgA1.

Conclusions: Our cohort study suggests that GH in IgAN is triggered by some alternations in glomerulus itself that facilitate the deposition of Gd-IgA1. Increased incidence of GH after COVID-19 vaccination in females and after the second or subsequent vaccinations may help to clarify the mechanism of GH in detail.

TH-PO1110

COVID-19 Vaccination Implications for Individuals Receiving Anti-Complement Therapy During the SARS-CoV-2 Pandemic

Tanya Srivastava,[1] Jason G. Gnasigamany,[3] Snehal Shrivastava.[2] *[1]Dr. D.Y Patil Medical College, Hospital and Research Centre, Pune, India; [2]East Texas Kidney Specialist, Longview, TX; [3]CHRISTUS Good Shepherd Health System, Longview, TX.*

Introduction: Treatment of complement mediated thrombotic microangiopathy (CM-TMA) with anti-complement agents such as Eculizumab during the COVID-19 Pandemic posed unique clinical decision making challenges in the area for COVID vaccination.

Case Description: A 36 year old African American lady, presented to the obstetric ER for hypertension and underwent emergency C-section due to fetal distress. Postoperative course was complicated by blood loss and oliguric acute renal failure. Based on lab data and clinical findings, diagnosis of CM-TMA was made. Genetic testing revealed heterozygosity for c.989-78G>A (rs1962149) variant of MCP/CD46 haplotype. Patient received transient hemodialysis for uremia and definitive treatment with anti-complement therapy- Eculizumab which resulted in complete renal recovery and remission for a 15 month follow up period. Due to ongoing COVID-19 pandemic, patient expressed interest in obtaining COVID vaccine for protection of herself and her newborn infant. After review of literature and observing her clinical progression, patient received 2 doses of mRNA vaccines: first dose administered 15 days after the final eculizumab infusion; and the second dose, three weeks after 1st dose. Her renal function and CM-TMA parameters were closely monitored post vaccination without event. The antibody response to vaccination could not be tested.

Discussion: Concurrent administration of COVID-19 vaccine with anti complement therapy poses special clinical challenges due to lack of conclusive data and guidance. SARS-CoV-2 virus, mRNA and adenovirus vaccines have shown to trigger Microangiopathic Hemolytic anemia (MAHA) and CM-TMA. Additionally, inconclusive data exists regarding the use of Eculizumab in the treatment of COVID-19. Data regarding strength of immune response after vaccination while on therapy is also limited. Due to increasing use of anti-complement therapies, we call for further research to aid development of guidelines for timing of covid vaccination. Such data will not only be useful in timely administration of preventive vaccination but also guide further management of complement mediated disorders.

TH-PO1111

Collapsing FSGS in a Patient with Post-COVID-19 Infection

Fazal Khan, Pablo D. Tzorin, Evgeni Mirkin, Harold G. Jarrell, Jonathan Martinez. *St. Francis Emory Healthcare, Columbus, GA.*

Introduction: Focal segmental glomerulosclerosis accounted for about one sixth of cases of nephrotic syndrome prior to the COVID pandemic. This disease is focal, involving some glomeruli, and segmental, involving part of the glomerulus. Patients may present with either nephrotic or nephritic syndrome. This abstract describes a 40-year-old Caucasian female who presented post-COVID pandemic with nephrotic range proteinuria after being asymptomatic for the past 14-years. Renal biopsy revealed collapsing glomerulopathy. This case demonstrates CKD patient post-COVID that presented with nephrotic range proteinuria, however non-uremic and not on dialysis despite worsening laboratory findings. Kidney failure in the form of COVID associated nephropathy (COVAN) is associated with increased morbidity and mortality. Few large cohort studies of kidney biopsies from patients with COVID-19 have been completed-to-date.

Case Description: A 40-year-old Caucasian female with a history of Hypertension, Vitamin-D deficiency, CKD stage 5 and nephrotic range proteinuria with a baseline creatinine around 2 mg/dL for the last 14-years presented asymptomatically with a serum creatinine of 4.5-4.9 mg/dL after approximately 1-year hiatus due to the COVID pandemic. Renal biopsy was performed and revealed collapsing glomerulopathy with focal segmental glomerulosclerosis. A biopsy approximately 15 years ago showed unremarkable pathological findings. She started treatment with repository corticotropin injection with subsequent development of anasarca and interval elevation in creatinine to 6 mg/dL. Treatment was stopped. She remained non-oliguric with close monitoring and supportive management of her co-morbidities.

Discussion: The progress of our patient's sub-nephrotic range proteinuria and CKD before and after COVAN with transition into nephrotic range proteinuria and without ATN findings shows the unique presentation of individuals with COVID associated FSGS. There is still yet to be understood regarding the mechanism in which patient present with worsening prognosis depsite remaining Non-oliguric and non-uremic. Few studies have shown an endpoint in the understanding and management of COVID FSGS and despite different treatment therapies available, COVID-FSGS remains yet to be fully understood. Patients infected with COVID-19 may present with mimicking features of commonly presenting renal pathology.

TH-PO1112

Risk Factors for Post-COVID-19 Incident CKD in the National COVID Cohort Collaborative

Spencer Krichevsky,[1] Farrukh M. Koraishy,[1] David H. Ellison,[2] Feifan Liu,[3] Rajiv Saran,[4] J. Brian Byrd,[4] Yun Jae Yoo,[5] Joel H. Saltz,[1] Richard L. Zhu,[6] Sandeep K. Mallipattu,[1] Yun Han,[4] Chirag R. Parikh.[6] *[1]Stony Brook University, Stony Brook, NY; [2]Oregon University System, Portland, OR; [3]University of Massachusetts System, Boston, MA; [4]University of Michigan, Ann Arbor, MI; [5]Emory University, Atlanta, GA; [6]Johns Hopkins University, Baltimore, MD.*

Background: COVID-19 has been associated with accelerated GFR decline in hospitalized patients (pts), but prior studies are limited by cohort sizes, duration of follow-up and geo-specificity. Moreover, characterization of incident CKD in non-hospitalized patients with COVID is lacking.

Methods: Electronic health record data were obtained from 77 health systems in the United States in the National COVID Cohort Collaborative. Adults diagnosed with COVID between Mar 1, 2020, and Oc 1, 2022, and without pre-COVID CKD, were evaluated for incident post-COVID CKD until Dec 31, 2022. CKD was identified via outpatient eGFR measurements or diagnosis (dx) codes. Multivariable (MV) models were applied to analyze risk factors like demographics (age, sex, race/ethnicity), geographical regions (Midwest, Northeast, South, West), hospitalization, AKI, and a reported diagnosis (U09.9) of long-COVID (PASC).

Results: Among 3.7m pts, 76k (2%) had incident post-COVID CKD. Of these pts, 55k (73%) were not assigned a CKD dx code but met requirements for eGFR-based CKD. In MV models, incident CKD was associated with older age, male sex, and Black and Native Hawaiian or Pacific Islander race (compared to White). Compared to pts never hospitalized during follow-up, event rates for incident CKD for pts hospitalized during the COVID dx were significantly higher (11.4 vs 28.7 /1000 patient-years [pt-yrs]). Among hospitalized pts, those with AKI (vs no AKI) had an even higher rate of incident CKD (98.3 vs 21.2 /1000 pt-yr). In MV analyses, when compared to pts never hospitalized, those hospitalized during COVID with AKI had much higher incidence of

CKD (hazard ratio [HR] 3.82, p <0.001). The adjusted odds ratios for incident CKD were higher in the West (1.32, p<0.001) and South (1.03, p<0.001) and lower in the Northeast regions (0.94, p<0.001) compared to the Midwest. In a sub-cohort of 1.5mpts evaluated at U09.9-reporting sites, PASC was associated with a moderately higher HR for incident CKD (1.41, p<0.001).

Conclusions: In one of the largest studies on this topic, we observe that incident CKD in pts with COVID was underdiagnosed and influenced by geographical region, hospitalization and AKI. Pts with PASC had higher rates of CKD compared to those without.

FR-PO001

A Network-Based View of AKI and CKD at Cell Subtype and Spatial Niche Resolution

Xi Chen,[1,2] Rachel S. Sealfon,[1,2] Weiguang Mao,[1,2] Zhicheng Pan,[1,2] Blue Lake,[3,4] Rajasree Menon,[5] Ricardo Melo Ferreira,[6] Ahmed Naglah,[7] Paul M. Palevsky,[8] Jose Torrealba,[9] Chirag R. Parikh,[10] Sylvia E. Rosas,[11] Krzysztof Kiryluk,[12] Jennifer A. Schaub,[5] Laura Barisoni,[13] Pinaki Sarder,[14] Jeffrey B. Hodgin,[5] Michael T. Eadon,[6] Sanjay Jain,[15] Matthias Kretzler,[5] Olga Troyanskaya.[1,2] KPMP. *[1]Flatiron Institute, New York, NY; [2]Princeton University Princeton Center for Quantitative Biology Lewis-Sigler Institute for Integrative Genomics, Princeton, NJ; [3]Altos Labs Inc, Redwood City, CA; [4]University of California San Diego Department of Bioengineering, San Diego, CA; [5]University of Michigan Medical School, Ann Arbor, MI; [6]Indiana University School of Medicine, Indianapolis, IN; [7]University of Florida Department of Medicine, Gainesville, FL; [8]University of Pittsburgh School of Medicine, Pittsburgh, PA; [9]The University of Texas Southwestern Medical Center Medical School, Dallas, TX; [10]The Johns Hopkins University School of Medicine, Baltimore, MD; [11]Joslin Diabetes Center, Boston, MA; [12]Columbia University Irving Medical Center, New York, NY; [13]Duke University, Durham, NC; [14]University of Florida, Gainesville, FL; [15]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Understanding functional relationships between genes and their regulators and how they are altered in acute kidney injury (AKI) and chronic kidney disease (CKD) is a crucial challenge. New computational methods are necessary to elucidate disease-specific gene regulation and function in spatial context.

Methods: We develop a computational framework to integrate spatial transcriptomics with single cell multiomics data (Table 1) and infer disease-associated gene networks at spatial niche and cell type resolution. We identify spatial niches using a biological-knowledge-informed matrix decomposition method, align single-cell multiome data with spatial transcriptome data, and infer functional regulatory relationships between genes using an integrated Bayesian framework.

Results: Using glomerular identification as an example, the spatial transcriptome-based niche pattern is concordant with image-based digital pathology. We build functional regulatory gene networks for ~50 kidney cell subtypes for each disease state. Focusing on the adaptive proximal tubule (aPT) networks, we rank >13000 gene ontology terms based on their differential network connectivity between disease states. The terms with highest differential connectivity include regulation of nephron tubule epithelial cell differentiation (CKD vs AKI), phospholipase A2 inhibitor activity (reference vs. AKI), and regulation of kidney size (CKD vs. reference). The regulatory networks mediated by HNF4A and NFKB1 in aPT cells are further validated on independent single cell data (Lake et al 2023). These disease-associated cell type networks are aligned to spatial niches, enabling a spatially-resolved, cell-type specific characterization of molecular pathways in kidney disease.

Conclusions: Our framework provides a network-based view of molecular differences between kidney disease states, cell subtypes, and spatial niche patterns.

FR-PO002

Integrative Metagenomic, Metabolomic, and Deep Immune Profiling Reveal Coordinate Effects on Host-Microbe Interactions in CKD

I-Wen Wu.[1,2] *[1]Chang Gung Memorial Hospital, Keelung, Keelung, Taiwan; [2]Chang Gung University College of Medicine, Taoyuan, Taiwan.*

Background: Perturbation of gut dysbiosis is present in chronic kidney disease (CKD) and associated with a sophisticated milieu of metabolic and immune dysregulation. However, the underlying host-microbe interaction is unclear.

Methods: We performed multi-omics measurements, including systems-level gut microbiome, targeted serum metabolome, and high-dimensional immunotyping, in a cohort of 72 CKD patients and 20 controls.

Results: Our analyses on functional profiles of gut microbiome showed that loss of renal function decreased the diversity and abundance of carbohydrate-active enzyme (CAZyme) genes, but increased the abundance of antibiotic resistance, nitrogen cycling enzyme, and virulence factor genes. Models generated using measurements of circulating metabolites (amino acids, bile acids, and short-chain fatty acids) or immunotypes were predictive of renal impairment but less so than many of the taxonomic or functional profiles derived from gut microbiota, with the CAZyme genes being the top performing model to accurately predict early stage of diseases. Correlation analyses among different omics parameters revealed coordinated host-microbe relationships in CKD. Specifically, significant correlations were identified with circulating metabolites by several taxonomic and functional profiles of gut microbiome, while immunotype features were only moderately associated with the abundance of microbiome-encoded metabolic pathways and serum levels of amino acids.

Conclusions: Our multi-omics integration revealed signatures of the systems-level gut microbiome in robust associations with host-microbe co-metabolites and renal function, highlighting potential etiological and diagnostic implications in CKD.

Funding: Private Foundation Support, Government Support - Non-U.S.

Developing a Kidney Genetics Registry Within an Electronic Medical Record

Asheeta A. Gupta,[1,2] Ciara Mcdonnell,[1] Josiah Shanks,[1] Grainne H. Butler,[1,2] Kushani C. Jayasinghe,[3] Catherine Quinlan.[1,2] *[1]The Royal Children's Hospital Melbourne, Parkville, VIC, Australia; [2]Murdoch Children's Research Institute, Parkville, VIC, Australia; [3]Monash Health, Clayton, VIC, Australia.*

Background: Dynamic patient registries within the electronic medical record (EMR) can provide security in a clinical setting by using existing tools to automate database compilation, reducing the time burden required to populate information whilst maintaining the accuracy of patient lists and data entry. A kidney genetics registry within the EMR facilitates decision-making that directly affects clinical care whilst concurrently contributing to a better understanding of disease processes and therapeutic approaches. We present our approach to the development of an EMR-embedded kidney registry in a tertiary pediatric setting highlighting the implementation challenges of amalgamating clinical data from multiple platforms.

Methods: An encounter-based EPIC registry was designed and created in collaboration with the Centre of Health Analytics for all patients referred to the Kidney Genetics clinic at the Royal Children's Hospital, Melbourne from February 2016 to present. Metrics for data capture included demographic information, growth parameters, clinical diagnoses, non-genetic diagnostic test results (including imaging and histopathology), and surveillance (including clinical parameters, hematological and biochemical test results). Triggers to warrant genetic re-evaluation or clinical intervention were included. A subsequent validation study was performed with a manually collated cohort of patients.

Results: The complete registry consisted of 516 patients (median age at presentation of 24 months). Challenges included the identification of appropriate patients, inclusion of genetic results from external laboratories, manual validation of non-machine-readable genetic reports, and the concurrent use of paper-based family genetic files. Sequencing was undertaken in the form of a clinical exome or whole exome sequencing with or without microarray depending on clinical indication. A genetic diagnosis was found in 88/212 (41.5%), variants of uncertain significance in 16/212 (7.5%), and incidental findings in 2/212 (0.94%).

Conclusions: Obtaining a genetic diagnosis can instigate a precision medicine approach, aiding risk stratification, tailored surveillance, initiation of disease-modifying therapies, and transplant planning. Combining genetic results with real-time monitoring of patients has the potential to streamline and automate this process.

ADPKD Predictor: A Cloud-Based Prognostic Tool for Autosomal Dominant Polycystic Kidney Disease

Vincenzo Carbone,[1] Matteo Gazzin,[1] Roberta Bursi,[1] Riccardo Magistroni,[2] Cristiana Corsi.[3] *[1]InSilicoTrials Technologies, Trieste, Italy; [2]Università di Modena e Reggio Emilia, Modena, Italy; [3]University of Bologna, Bologna, Italy*.

Background: Total Kidney Volume is accepted by FDA and EMA as a prognostic biomarker for ADPKD and is currently used to select patients eligible for drug treatment. We developed ADPKD Predictor, a user-friendly cloud-based tool for fast and accurate estimation of disease classification and progression, based on advanced image processing techniques.

Methods: The tool was designed on Microsoft Azure Cloud to facilitate the use of a MATLAB algorithm to automatically detect kidneys and cysts contours from MRI data (Figure 1). TKV is automatically calculated and ADPKD Imaging Classification, eGFR, GFR Category, eligibility for drug treatment and estimated effect are obtained (Figure 2).

Results: The proposed solution is extremely fast and precise compared to manual segmentation (absolute mean error 2.4% ± 2.7%), and more accurate than ellipsoid-based method, resulting in a manifold reduction of misclassification error (2.5%). No numerical expertise, software or hardware is required since computations run remotely in the cloud.

Conclusions: ADPKD Predictor provides a fast and reproducible assessment of risk classification and disease progression. It is extremely useful to researchers and clinicians for effective stratification of patients, hence supporting correct therapy administration.

Using Deep Learning to Determine Kidney Function Decline in Patients with ADPKD

Hyun Bae Jang,[1] Caroline Reinhold,[2] Keyhan Najafian,[4] Farhad Maleki,[3,2] Ahsan Alam.[2] *[1]McGill University, Montreal, QC, Canada; [2]McGill University Health Centre, Montreal, QC, Canada; [3]University of Calgary, Calgary, AB, Canada; [4]University of Saskatchewan, Saskatoon, SK, Canada*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is associated with progressive kidney cyst growth, eventually leading to kidney failure in many patients. The current risk stratification tool uses height-adjusted total kidney volume (TKV) by age. However, it does not include clinical or other imaging features that may contribute to kidney function decline. In this study, we developed a deep learning classifier that integrates clinical and imaging features to predict rapid estimated GFR (eGFR) decline in patients with ADPKD.

Methods: We included 120 patients with confirmed ADPKD with at least one MRI scan and at least 3 serial eGFR measures. An eGFR decline of 4 mL/min/1.73 m² per year or greater was defined as rapid progression. We tripled the sample size by extracting the largest manually segmented 2D MRI slice and its two neighbouring slices for each patient and assigning the corresponding clinical features. Pixel-level and spatial-level transformations were applied to the images to enhance our deep model's generalizability and robustness. The model consisted of three components: 1) EfficientNet-b2, 2) FuseNet, and 3) Classifier with the train:validation:test split of 63:17:20. The EfficientNet-b2 extracted 1000 features from each MRI slice. The FuseNet performed feature fusion on 15 clinically relevant features associated with ADPKD. The feature maps obtained from both models were concatenated and fed into the Classifier. Weighted-average F1 and AUC scores and the confusion matrix were used to assess the model's performance.

Results: The mean age of the study cohort was 46 years (SD 14), 54% were male, 95% were non-Black, hypertension prevalence was 79%, the median eGFR was 67 ml/min/1.73 m² (IQR 45-99), height-adjusted TKV was 940 mL/m (IQR 542-1373), tolvaptan use was 53%, and the Mayo Imaging Class was 8%, 17%, 40%, 23%, 10%, and 2% for 1A, 1B, 1C, 1D, 1E and class 2, respectively. The weighted-average F1 and AUC scores and the true positive and true negative values were 0.88, 0.88, 0.88, and 0.88 on the validation set, respectively and 0.83, 0.83, 0.86, and 0.80 on the test set.

Conclusions: Our study demonstrates that a deep learning approach which integrates clinical information with MRI features can successfully classify patients at risk for rapid eGFR decline. Further validation in an external cohort is required.

In Silico Drug Repurposing of Aquaporin 1

Aled R. Lloyd, Karl Austin-Muttitt, Jonathan G. Mullins. Genome and Structural Bioinformatics Group, Swansea University Medical School. *Swansea University, Swansea, United Kingdom*.

Background: Drug repurposing is the identification of new therapeutic targets for existing licensed medicinal compounds. We have developed protocols and programs for an *in silico* high-throughput repurposing screen using structural modelling, docking, and molecular dynamics (MD). Uniquely our approach uses a bespoke interface on Google Colab for graphic processing units (GPU's) to run the MD simulations. We describe its application to human aquaporin 1 (AQP1).

Methods: The library of British National Formulary listed compounds was obtained from NCBI PubChem. I-TASSER was used to generate monomeric structural models and Modeller for assembling oligomers. PLANTS was used for docking simulations. CHARM-GUI and bespoke software were used to prepare membrane-bound systems to run in GROMACS using GPU's in Google Colab. 20 nanosecond simulations were undertaken (300 Kelvin and 1 bar) to discriminate between binding and non-binding events.

Results: Complete monomeric and tetrameric structural models of human AQP1 were obtained incorporating chains of water molecules traversing the pores. Docking studies of 1002 drug compounds at the cytoplasmic opening of AQP1 identified 200 compounds binding in the pore. 45 compounds exhibited a higher calculated binding energy higher than the known binder furosemide and underwent further testing using

MD. The 20 nanosecond MD simulations distinguished the compounds which were not binding and elucidated the dynamics of the binders. A noteworthy finding was that furosemide induced a conformational change in the cytoplasmic chain.

Conclusions: We have developed a robust docking-MD protocol for high throughput repurposing screening. We have demonstrated that shorter simulations than previously published can reliably detect active binding conformations and identify compounds that could interact with human AQP1. Several commonly used medications exhibited stable interactions including furosemide, gabapentin, pregabalin, pravastatin and esmolol.

Histopathological Prediction of CT-Based Radiomic Imaging Biomarkers in Native Kidney Biopsies

Ji Eun Kim, Kipyo Kim. *Inha University Hospital, Incheon, Republic of Korea.*

Background: In recent years, there has been a growing interest in radiomics as a quantitative approach for image analysis. This study aims to explore the relationship between radiomic features extracted from CT scans and histological findings obtained from kidney biopsies.

Methods: We retrospectively enrolled participants who underwent abdomen CT scan within 7 days before native kidney biopsy. Three-dimensional kidney segmentation was performed in two different methods; the entire kidney parenchyma and isovolumumic cortical area. We extracted various radiomics features such as shape, first-order, and texture features from the CT images. The histological findings were assessed using a semiquantitative scoring system, which assigned severity grades to various parameters including interstitial fibrosis (IF), tubular atrophy (TA), glomerulosclerosis (GS), interstitial inflammation (II), and arterial intimal thickening (IT).

Results: Total of 124 patients were included in the main analysis. The ROC curve analysis of the extracted radiomic features revealed higher AUC values for moderate IF, TA, and II in both the total kidney parenchyma and cortex. However, the ability to distinguish GS and IT was relatively lower. The most discriminatory features extracted from total kidney for IF and TA were GLCM IDMN (LLH-wavelet) and GLCM IDN (LLH-wavelet), with the AUCs approximately 0.83. For the kidney cortex, GLRLM GLNU (HLL-wavelet), GLDM DE (HLL-wavelet), and GLRLM RV (HLH-wavelet) had the texture features with the highest AUCs for IF and TA, with the AUCs of 0.84-0.88. Texture features extracted from kidney cortex showed higher correlation with histologic features. We found that CT-based texture features consist of volume-dependent and independent components. Volume-independent texture features extracted from kidney cortex showed more a higher degree of correlation with chronic histologic scores.

Conclusions: In conclusion, our findings suggested the potential of CT-based radiomics in predicting chronic histological findings in kidney biopsies.

Figure 1. The associations between interstitial fibrosis scores and representative texture features with high ROC-AUC values. (A) and (B) from the entire kidney parenchyme. (C) and (D) from cortical area. The associations between IF scores and (E) wavelet-HLL_glrlm_GrayLevelNonUniformity (F) wavelet-HLH_glrlm_RunVariance.

Assessment of Hemodialysis Arteriovenous Shunt (AV Shunt) Sounds by Using a Novel Electronic Stethoscope and Machine Learning Techniques

Hiroko Inagaki,[1,2] Hiroki Tamura,[3] Hiromu Takeguchi,[4] Yutaka Endou,[5] Fukumoto Hiroyuki,[6] Yasuomi Tanaka,[7] Kazuya Kibune,[8] Masao Kikuchi,[2] Shouichi Fujimoto.[1,2] *[1]Department of Medical Environment Innovation, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan; [2]Division of Nephrology and Dialysis, University of Miyazaki Hospital, Miyazaki, Japan; [3]Faculty of Engineering, University of Miyazaki, Miyazaki, Japan; [4]Graduate School of Engineering, University of Miyazaki, Miyazaki, Japan; [5]Miyazaki Seikyo Hospital, Miyazaki, Japan; [6]Miyazaki Association Clinical Engineering Technologists, Miyazaki, Japan; [7]Togo Medikit Co., Ltd., Hyuga, Japan; [8]Department of Clinical Engineering Section, Tokatsu Dialysis Hospital & Clinic, Matsudo, Japan.*

Background: Hemodialysis AV shunt management is performed by screening for auscultated shunt sounds. However, determining stenosis with a stethoscope requires skill, and it is difficult to make assessment objectively and quantitatively. We linked the echo findings of AV shunt to audio data obtained from a novel electronic stethoscope (Togo Medikit Co., Ltd., Japan) and used these data to train AI, and then developed software that estimated two labels with AI. In this study, the usefulness of this software in clinical settings was examined by comparing the rating of trained staffs and AI for auscultatory sounds.

Methods: The quality and intensity of the shunt sounds were evaluated in six levels each by trained staff just before and after dialysis by auscultation mainly just above the shunt creation site. At the same time, 20 seconds of shunt sound data were electromagnetically recorded from each patient by a novel auscultation device. The sound quality rating by the staffs was 0~3 as bad, 4-5 as good, while the electromagnetically recorded sound data was rated as normal or abnormal using the developed software. Match rate, sensitivity, and specificity by both evaluation methods were calculated.

Results: We compared the ratings of trained nurses and AI for 191 auscultatory sounds. The matching rate between the two was 66.0%. 83.3% of the subjects were calculated as abnormal by AI, when trained staff judged as “bad”. 94.1% of the subjects were judged “good” by trained staff, when AI calculated as normal. Contrary to expectations, the rate of AI judging as normal was higher after dialysis than before, even though the intensity of the shunt sound was weaker after dialysis. When echo examination showed shunt blood flow reduction, it was more likely to be judged as abnormal by AI compared to the judgment by the staff.

Conclusions: In this study, AI rating for AV shunt sounds was considered to be at an acceptable level for clinical use. However, there are differences between trained staff and AI results for “normal” results. This reason for this may be that the AI label is based on the echo. This evaluation method using a new device is expected to become more useful with additional AI learning.

FR-PO013

eGFR Trajectories Among Children with CKD Using a Multi-Institutional Electronic Health Record Database

Jarcy Zee,[1,2] Caroline A. Gluck,[3] Mitchell Maltenfort,[2] Amy Goodwin Davies,[2] Ryan Webb,[2] Miranda J. Higginbotham,[2] Elana Dicocco,[2] Vikas R. Dharnidharka,[7] Keith A. Marsolo,[8] Priya S. Verghese,[6] Rebecca Ruebner,[5] Dorey A. Glenn,[4] Alicia Neu,[5] Michelle Denburg.[2,1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]The Children’s Hospital of Philadelphia, Philadelphia, PA; [3]Nemours Children’s Hospital Delaware, Wilmington, DE; [4]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Johns Hopkins Medicine, Baltimore, MD; [6]Ann and Robert H Lurie Children’s Hospital of Chicago, Chicago, IL; [7]St Louis Children’s Hospital, St Louis, MO; [8]Duke University School of Medicine, Durham, NC.*

Background: Progression of pediatric chronic kidney disease (CKD) is highly variable across patients and may be nonlinear over time. This study’s objective was to describe eGFR trajectories among a large, unselected cohort of children with CKD.

Methods: Using electronic health records from 16 healthcare institutions within PCORnet, a computable phenotype was implemented to identify children ages 1-18 with mild to moderate CKD (two eGFRs between 30-90 mL/min/1.73m^2 at least 90 days apart). Latent class mixture models were used to identify classes of eGFR trajectories from cohort entry until dialysis, transplant, or last follow-up.

Results: N=17,168 children with CKD were grouped into four eGFR trajectory classes [Figure]. Class 1 (“steep decline”) contained N=499 (2.9%) patients with mean eGFR at cohort entry of 66.4 and a steep, nonlinear decline in eGFR. Class 2 (“moderate decline”) had N=6,661 (38.8%) patients with mean entry eGFR of 59.2 and a moderate, nonlinear decline. Class 3 (“stable”) had N=7,999 (46.6%) patients with mean entry eGFR of 78.1 and little change in eGFR over time. Class 4 (“improvement”) had N=2,009 (11.7%) patients with mean entry eGFR of 79.5 and an increase in eGFR. Class 1 (steep decline) patients had more clinic visits and hospitalizations and a larger proportion on anti-hypertension medications, whereas those in Class 4 (improvement) were slightly younger.

Conclusions: Four distinct classes of eGFR trajectories were identified among children meeting criteria for CKD stage 2-3. Over half were in stable or improving eGFR subgroups, and only a small proportion exhibited steep decline. These subgroups provide a real-world, multi-institutional characterization of eGFR trajectories among children with mild-moderate CKD.

Regulation of the Adaptive Proximal Tubule Cell State by ELF3, KLF6, and KLF10

Debora L. Gisch,[1] Blue Lake,[2] Jeannine M. Basta,[3] Michelle Pherson,[4] Ying-Hua Cheng,[1] Ricardo Melo Ferreira,[1] Daria Barwinska,[1] Mahla Asghari,[1] Tarek M. El-Achkar,[1] Shamim Mollah,[3] Jonathan Himmelfarb,[5] Matthias Kretzler,[6] Pierre C. Dagher,[1] Sanjay Jain,[3] Michael I. Rauchman,[3] Michael T. Eadon.[1] KPMP. *[1]Indiana University School of Medicine, Indianapolis, IN; [2]San Diego Institute of Science, Altos Labs, San Diego, CA; [3]Washington University in St Louis School of Medicine, St Louis, MO; [4]Saint Louis University, Saint Louis, MO; [5]University of Washington, Seattle, WA; [6]Michigan State University, East Lansing, MI.*

Background: Gene regulatory regions modulate gene expression and maintain cell function. In response to injury, the proximal tubule (PT) undergoes adaptation, including differentiation or epithelial to mesenchymal transition, resulting in successful or failed repair. Single-cell multiome, whole genome bisulfite sequencing (WGBS), and CUT&RUN were used to study the regulatory control of the PT as it undergoes this adaptation.

Methods: Single-cell multiome with ATAC-seq data was generated and analyzed for 12 kidney tissue samples. TRIPOD and scMEGA were used for analysis. Celloracle *in silico* perturbation tested DEG changes after the knockout of transcription factors (TFs). scMEGA was used to map TF activity in spatial transcriptomics samples (N=3). Regulatory relationships were characterized by WGBS and CUT&RUN.

Results: Between the PT-S12 and aPT, we observed 25,356 DARs and 4194 DEGs at adj-P<0.05. aPT marker genes like *TPM1* were targeted by the TFs *ELF3, KLF6,* and *KLF10* which also cross-regulated each other, suggesting a regulatory network of adaptation in the PT. The TF *ELF3* targeted 316 DARs of the aPT, including 248 in positively regulated genes. *In silico* perturbation resulted in the downregulation of *TPM1* and other aPT genes such as *VCAM1* and *ITGB8*. The correlation matrix estimated by scMEGA for *ELF3* transcription factor activity predicted that 495 genes are bound by *ELF3* with a correlation >90%. By transferring these labels to spatial transcriptomics samples, colocalization of TF activity was identified in injured cortical regions with PT. By WGBS and CUT&RUN, the *TPM1* peak 106234, targeted by *ELF3* was an active promoter with reduced DNA methylation.

Conclusions: *ELF3, KLF6,* and *KLF10* contribute to the PT's adaptative response to injury as a regulatory network, specifically localized to the PT.

Evaluating the Impact of a Tailored Electronic Medication Management System on Anemia Management in Outpatient Hemodialysis Patients

Xiaohua Sheng, Niansong Wang. *Department of Nephrology, Shanghai Sixth People's Hospital Affiliated to Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: The prevalence of Medication-related problems (MRPs) in outpatient hemodialysis patients, especially in anemia management, is high. We developed a tailored electronic medication management system for outpatient hemodialysis (the New System) and evaluated its impact on anemia management.

Methods: The New System was collectively developed by our hospital and Spectrum Healthcare, building on the existing electronic information system. We compared the percentage of patients with hemoglobin, ferritin, transferrin saturation within the KDIGO recommended range, and cardiovascular events six months before (control period) and after (study period) the implementation of the New System.

Results: Using the New System, physicians perform evaluations and prescribe medications based on patients' lab reports. After patient payment and pharmacist review, medications are auto-allocated to a virtual pharmacy in the Hemodialysis Center. The New System then generates a medication form before each dialysis session for nursing staff. On dialysis days, the system displays the predetermined prescriptions. After administration by nurses, the system auto-deducts the used medication. The control period included 285 patients (190 males and 95 females, aged 62.4±13.2 years), and the study period included 278 patients (193 males and 85 females, aged 62.8±13.2 years). Compared with the control period, the percentage of patients at the study period with hemoglobin (40.2% [687/1710] vs 47.8% [797/1668], P<0.001), ferritin (31.2% [178/570] vs 39.0% [217/556], P=0.006), transferrin saturation (58.6% [334/570] vs 64.7% [360/556], P=0.034) within the KDIGO recommended range was higher. The occurrence of cardiovascular events during the study period was 11.2% (31/278), which was lower (P=0.043) compared to the control period where it was 16.5% (47/285).

Conclusions: The implementation of the New System in the Hemodialysis Center improves anemia management in outpatient hemodialysis patients. The study hints that an electronic medication management system tailored for outpatient hemodialysis holds potential in addressing partial MRPs.

Deep Learning Model for Evaluating Histopathology of Acute Renal Tubular Injury

Hyeongwan Kim, Yujin Jung, Woong Park, Jihyun Yeom, Soo jin Lee, Yujin Shin, Won Kim. *Jeonbuk National University Hospital, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: Acute tubular injury is the most common cause of acute kidney injury (AKI). Histopathological diagnosis may help distinguish between the different types of acute kidney injury and aid in treatment. Currently, no studies have utilized deep learning models to assist in the histopathological diagnosis of acute kidney injury. The aim of this study is to perform histopathological segmentation to identify the four structures of acute renal tubular injury using deep learning models.

Methods: We use a segmentation model (glomerulus, healthy tubules, tubules with cast, and necrotic tubules) to classify tubule-specific injuries after cisplatin treatment. A total of 45 whole slide images with 400 generated patches are used in the segmentation model and 27,478 annotations are created for four classes, namely glomerulus, healthy tubules, necrotic tubules and tubules with cast. A segmentation model was developed utilizing the DeepLabV3 architecture with the MobileNetv3-Large backbone to accurately identify four histopathological structures associated with acute renal tubular injury in mouse PAS-stained samples. In the segmentation model for four structures, the highest Intersection over Union and the Dice coefficient are obtained for the segmentation of the "glomerulus" class, followed by "necrotic tubules," "healthy tubules," and "tubules with cast" classes.

Results: The overall performance of the segmentation algorithm for all classes in the test set includes an Intersection over Union of 0.7968 and Dice coefficient of 0.8772. The Dice scores for the glomerulus, healthy tubules, necrotic tubules, and tubules with cast are 91.78 ± 11.09%, 87.37 ± 4.02%, 88.08 ± 6.83%, and 83.64 ± 20.39%, respectively.

Conclusions: The utilization of deep learning in a predictive model has demonstrated promising performance in accurately identifying the histopathological structures of injured renal tubules. These results may provide new opportunities for applying the proposed methods to more effectively evaluate renal pathology in the future.

FR-PO017

Proximal Tubule Neighborhood in AKI, CKD, and Healthy Control Kidney Tissue Using Spatial Transcriptomics

Mahla Asghari,[1] Ricardo Melo Ferreira,[1] Ying-Hua Cheng,[1] Debora L. Gisch,[1] Daria Barwinska,[1] Angela R. Sabo,[1] Matthias Kretzler,[2] Jonathan Himmelfarb,[3] Pierre C. Dagher,[1] Seth Winfree,[4] Sanjay Jain,[5] Tarek M. El-Achkar,[1] Michael T. Eadon.[1] KPMP. *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Michigan, Ann Arbor, MI; [3]University of Washington School of Medicine, Seattle, WA; [4]University of Nebraska Medical Center, Omaha, NE; [5]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: The interaction of proximal tubules (PTs) with neighboring immune, stromal, and endothelial cells may impact their physiological functions. Using spatial transcriptomics (ST), we sought to establish the spatially anchored microenvironments of the PT across kidney samples in chronic kidney disease (CKD), acute kidney injury (AKI) and healthy human kidney biopsy samples.

Methods: We interrogated 23 samples from the HuBMAP, Kidney Precision Medicine Project (KPMP) and Biopsy Biobank Cohort of Indiana with Visium ST. Cell labeling was performed using a transfer score methodology of the publicly available snRNAseq atlas. Label score vectors were utilized to cluster and identify niches in R. Pathway analysis was performed in PathfindR.

Results: Clustering revealed 33 distinct PT neighborhood clusters with colocalization of injured PTs, stromal cell and immune cell dominant PT neighborhoods. The adjusted p-value of 0.05 was considered as the significance threshold. Adaptive PT (aPT) enriched clusters in AKI revealed increases in injury, repair, and immune responses compared to normal PTs. Pathway enrichment displayed activation of ERK1/2 cascade, TOR signaling, neutrophil chemotaxis, positive regulation of interleukin−2 production and T cell receptor signaling pathways. CKD samples were enriched for B and plasma cell niches. Upregulation of immunoglobulin genes and pathways contributing to activation of complement cascade were observed in CKD.

Conclusions: Distinct cell type compositions were identified within normal and disease cell clusters. ST facilitated spatial anchoring of cells within the kidney. The neighborhood analyses of PTs in disease and health provide insights into alteration of cell networks in kidney disease.

Funding: NIDDK Support

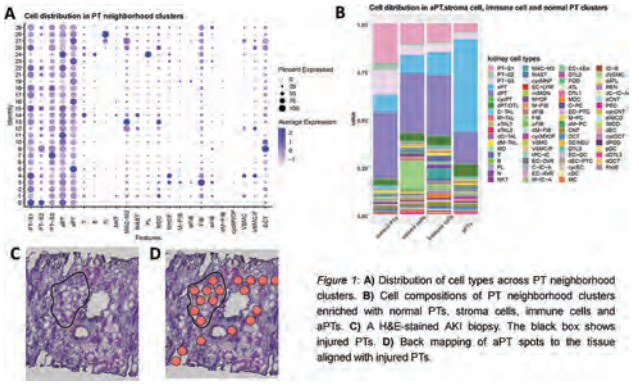

Figure 1: **A)** Distribution of cell types across PT neighborhood clusters. **B)** Cell compositions of PT neighborhood clusters enriched with normal PTs, stroma cells, immune cells and aPTs. **C)** A H&E-stained AKI biopsy. The black box shows injured PTs. **D)** Back mapping of aPT spots to the tissue aligned with injured PTs.

FR-PO018

Capturing Spatial Transcriptomics Around Cysts with Deep Learning and Image Processing Is a Novel Method to Reveal Therapeutic Targets in ADPKD

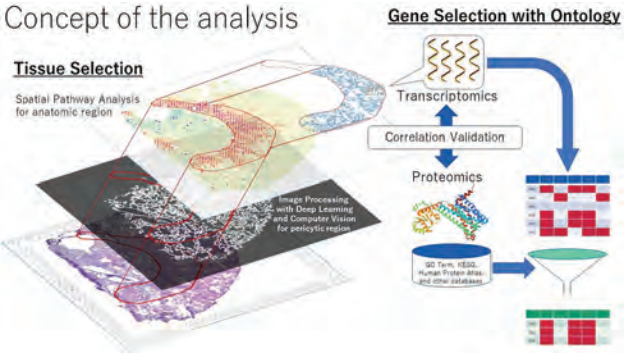
Yoshifumi Uesumi, Yasuhiro Ichida, Kohji Nagano, Naoshi Horiba. *Chugai Seiyaku Kabushiki Kaisha, Chuo-ku, Japan.*

Background: There are still many unknowns in ADPKD. Current therapies are not sufficiently effective. To search for new therapeutic targets, we examined the mechanism of PKD progression in pericystic areas using a new method that integrates histology, proteomics, spatial transcriptomics, GO (gene ontology) analysis, analysis of DEG (differentially expressed genes), deep learning, and image processing.

Methods: DBA/2J as a normal control mouse and DBA/2FG-pcy as a PKD model mouse were used for the analysis. Frozen kidneys of mice were subjected to proteomic measurement by LC-MS. Spatial transcriptomic measurement (Visium, 10X Genomics) and H&E staining were performed using formalin-fixed, paraffin-embedded samples. Image regions of tissues and cysts were obtained with a deep learning program. The pericystic tissue area was further clarified with image processing. Barcoded spots of Visium in this area were fixed by superimposing the spot locations over the images of the pericystic areas and genetically classifying them with GO analysis or cluster analysis. Barcoded spots were also obtained in the corresponding area in normal control mice to obtain DEG in pericystic areas. GO terms were organized for new criteria to exclude inflammatory or fibrosis genes which are usually upregulated in PKD tissues and include membrane protein genes.

Results: In a mouse model of PKD, proteomics and spatial transcriptomics suggested that genes and proteins were generally present in a constant ratio. We identified the pericystic tissue areas with methods described above. A group of genes was identified by DEG analysis of Barcoded spots in these areas. A list of histopathology-related genes was created by filtering these genes through pre-designed selection criteria.

Conclusions: We created a new list of genes associated with pericystic regions but unrelated to all-kidney tissue that could be involved in PKD progression. We will conduct more detailed investigations on the genes in this list to identify therapeutic targets.



FR-PO019

Interactive Visualization of Kidney Structural Segmentations and Associated Pathomic Features on Whole Slide Images

Mark Keller,[1] Nicholas Lucarelli,[2] Yijiang Chen,[3] Bangchen Wang,[4] Charles E. Alpers,[5] Andrew Janowczyk,[6] Jeffrey B. Hodgin,[7] Samuel Border,[2] Sayat Mimar,[8] Ahmed Naglah,[8] Nikki Bonevich,[9] Ulysses G. Balis,[7] Jonathan Himmelfarb,[10] Matthias Kretzler,[9] Laura Barisoni,[4,11] Nils Gehlenborg,[1] Pinaki Sarder.[8] The Kidney Precision Medicine Project (KPMP). *[1]Harvard Medical School Department of Biomedical Informatics, Boston, MA; [2]University of Florida Department of Biomedical Engineering, Gainesville, FL; [3]Case Western Reserve University Center for Computational Imaging and Personalized Diagnostics, Cleveland, OH; [4]Duke University Department of Pathology - Division of AI and Computational Pathology, Duhram, NC; [5]University of Washington Department of Laboratory Medicine & Pathology, Seattle, WA; [6]Emory University Department of Biomedical Engineering, Atlanta, GA; [7]University of Michigan Department of Pathology, Ann Arbor, MI; [8]University of Florida Department of Medicine - Quantitative Health, Gainesville, FL; [9]University of Michigan Department of Medicine - Division of Nephrology, Ann Arbor, MI; [10]University of Washington Kidney Research Institute, Seattle, WA; [11]Duke University Department of Medicine - Division of Nephrology, Durham, NC.*

Background: The Kidney Precision Medicine Project (KPMP) is a collaborative study generating histology images and spatial molecular data from patient biopsies. To enable seamless study of whole slide images (WSI) and derived data, it is important to integrate solutions for navigation and visualization into computational pipelines.

Methods: We built a pipeline to (a) apply previously developed segmentation models of kidney structures on KPMP PAS-stained WSIs, including for globally/non-sclerotic glomeruli, arteries/arterioles, tubules, peritubular capillaries (PTC), interstitial fibrosis and tubular atrophy (IFTA), and the cortical interstitial fractional space (Ginley et al., bioRxiv 2023); (b) extract quantitative features from these structures; and (c) load these data in Vitessce (http://vitessce.io), a web-based framework for visualization and analysis of bioimaging data.

Results: Segmented KPMP WSIs linked to corresponding extracted features are visualized using quantitative colormaps and statistical plots such as histograms, violin plots, and bar charts. As a use case, we explore the spatial relationship between different structures and associated features (i.e., aspect ratio of PTCs in IFTA and non-IFTA regions).

Conclusions: Image analysis methodologies paired with web-based visualization tools allow for the interactive examination of renal morphometry. These tools enable KPMP investigators and a broader public to exploit WSI-extracted data for integration with other omics data and hypothesis generation and testing.

Funding: NIDDK Support

Self-Supervised Learning Applied to Kidney Histomorphology in Whole Slide Images

Krutika Pandit,[1] Nicolas Coudray,[1] Adalberto Claudio Quiros,[2] Aditya L. Surapaneni,[1] Avi Z. Rosenberg,[3] Katalin Susztak,[4] Morgan Grams,[1] Aristotelis Tsirigos.[1] *[1]New York University, New York, NY; [2]University of Glasgow, Glasgow, United Kingdom; [3]Johns Hopkins University, Baltimore, MD; [4]University of Pennsylvania, Philadelphia, PA.*

Background: Current approaches to characterize medical imaging data typically use some degree of supervision, relying heavily on expert annotation. Pathologist reads can have high inter-observer variability. A supervised model built on these reads will mimic the idiosyncrasies of the expert and may perpetuate inter-observer inconsistencies. Supervised approaches also require time-consuming and meticulous labeling on the input images. Given the limitations, supervised learning may not be optimal for unbiased and generalizable characterization of histologic patterns in the kidneys, which are complex.

Methods: Histomorphological Phenotype Learning leverages the latest advances in self-supervised learning (SSL), the Barlow-Twins method, to learn representations of image tiles that are later clustered by the Leiden method, a state-of-the-art community detection algorithm. This strategy was used to discover de novo clusters of morphologically similar tissue from 254 whole slide images (WSIs) of the kidney without any prior diagnostic information from pathologists. These clusters were then projected onto validation (N = 254), test (N = 255), and external validation (N = 113) sets, visually inspected across sets, and correlated with expert-provided histology scores. Additionally, elastic net models were trained to predict histology scores using proportion of patients' tiles in each cluster.

Results: Visual inspection of representative tiles from clusters revealed comparable histologic patterns across sets. Clusters that were visually indicative of disease were positively correlated with fibrosis; clusters representing healthy tissue were negatively correlated with fibrosis (Figure 1). The best-performing elastic net model used 17 clusters to predict percent fibrosis (R^2 in test set = 0.81).

Conclusions: In this study, we demonstrated the application of SSL to characterize WSIs of the kidney. Features extracted from this approach were associated with and demonstrated good prediction of expert-provided histology scores. Subsequent work will link clusters to gene expression and metabolic processes.

FR-PO021

Diverse Immune, Stromal, and Vascular Niches Along the Cortico-Medullary Axis of the Human Kidneys by Integrating 10 Different Modalities Performed on the Same Tissue Block

Seth Winfree,[1] Blue Lake,[2] Ricardo Melo Ferreira,[3] Anthony A. Fung,[4] Angela R. Sabo,[3] Madhurima Kaushal,[5] Daria Barwinska,[3] Bo Zhang,[4] Joseph Gaut,[5] Kun Zhang,[2,4] Lingyan Shi,[4] Michael T. Eadon,[3] Tarek M. El-Achkar,[3] Sanjay Jain.[5] HuBMAP. *[1]University of Nebraska Medical Center, Omaha, NE; [2]Altos Labs Inc, Redwood City, CA; [3]Indiana University School of Medicine, Indianapolis, IN; [4]University of California San Diego, La Jolla, CA; [5]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Methods to delineate cell types and microenvironment using multiple modalities (DNA, RNA, protein and metabolites) across cortico-medullary axis and that are applicable in a clinical setting are needed to understand cellular basis of kidney disease.

Methods: Multimodal assays were performed on same or sequential sections using an innovative freezing and processing method on prechilled metal blocks: 1) 10X multiome (snRNAseq and snATACseq on same cell, 280μm), 2) Light microscopy (5μmH&E, 5μmPAS), 3) 10X VISIUM and H&E (spatial transcriptomics, 10μm), 4) CODEX (40plex antibody panel for nephron, immune, endothelial, stromal and kidney injury, 10μm) and H&E, 5) Label free imaging with Stimulated Raman Scattering (SRS) microscopy on the same section as CODEX to generate lipids, extracellular matrix and pseudo-H&E data. Integration of modalities used molecular, cellular, and morphological bridges across kidney functional tissue units (FTUs).

Results: The tissue processing pipeline was feasible with multiple omic and spatial technologies from the same block at multiple institutions with passing QC for each assay. 10X multiome data from ~200K nuclei (12 donors) identified more than 25 immune, 20 stromal and 20 endothelial cell identities with clear zonation along the cortico-medullary axis. Novel niches of several fibroblast and immune cells were identified using VISIUM integrated with CODEX where 3.9 million cells (5 donors, 30 cell types based) on protein markers showed distinct zonation and higher protein-to-lipid ratio and increased lipid saturation in podocytes and mesangial cells versus distal tubules were seen in CODEX-SRS mapping.

Conclusions: This work outlines the collection and construction of a multimodal atlas of the human kidney from same tissue by 1) Integrating multimodal single cell and FTU spatial map using less than half depth of a kidney biopsy is feasible and compatible in a clinical setting, 2) Identifying zonation of interstitium and vascular cell diversity along the cortico-medullary axis by multiple modalities, 3) RNA-protein-lipid-ECM-histology mapping in millions of cells, neighborhoods and FTUs.

Accuracy of Bayesian Improved First Name Surname Geocoding (BIFSG) for Race and Ethnicity Imputation in a Kidney Care Management Program to Assess Racial Disparities

Liana D. Bruce, Christopher S. Krasniak, Cliff S. Eddings, Brandon Phan, Bassem Mikhael, Joe Kimura. *Somatus, McLean, VA.*

Background: Self-reported race and ethnicity data are ideal for classifying race and ethnicity to improve equity and close health outcome disparities, but these data have low response rates, typically <20%. Our goal was to validate race and ethnicity imputed using the BIFSG algorithm against self-reported data in a kidney care management population.

Methods: Patients are assessed at baseline and responses classified into six Office of Management and Budget standardized combined categories. We applied RAND's indirect estimation method to generate estimates based on first names, surnames, and ZIP Codes. Accuracy, specificity, sensitivity, and positive predictive value (PPV) were then calculated to compare BIFSG-imputed values with self-reported values in a validation subsample.

Results: 53,695 (16%) of 326,679 patients self-reported race/ethnicity. BIFSG predicted 269,354 (82%) of the overall population, including 44,964 of the self-report cohort. After imputation, 278,085 (85%) of patients had non-missing race/ethnicity. Overall imputed value accuracy compared to self-report was 99%. PPV was highest for Hispanic and lowest for American Indian or Alaskan Native, while accuracy was highest for Native and lowest for White.

Conclusions: Imputation of race/ethnicity can improve analyses of health disparities in kidney disease. The BIFSG imputation model obtained highly accurate (99%) predictions of race and ethnicity in a large chronic kidney disease population, increasing coverage of racial identity from 16% to 85%. The BIFSG algorithm could be supplemented with additional sources eg, historical records to impute residual missing values. Incorporating additional data and advanced machine learning models will improve predictions to better track health disparities.

Prediction of Individual Educational Attainment in ESKD Patients Using Zip Code-Derived Measures

Kullaya Takkavatakarn,[1,2] Yang Dai,[1] Huei Hsun Wen,[1] Girish N. Nadkarni,[1] Lili Chan.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: Social determinants of health (SDOH) are associated with various health outcomes. Area-level SDOHs based on patients' zip codes or census tracts have been commonly used in research instead of individual SDOH. Previous work showed that zip code-derived SDOH measures were inaccurate in highly heterogeneous urban neighborhoods. Therefore, we aimed to predict individual SDOH by using machine learning.

Methods: We used data from ESKD patients ≥ 25 years old enrolled in two studies at Mount Sinai in NY. All patients completed a questionnaire regarding the highest level of education, age, gender, and race/ethnicity. We used data from the American Community Survey to achieve the zip code-derived education based on the patient's zip code, gender, and race/ethnicity. We tested several machine-learning algorithms, including Naïve Bayes, decision tree, and random forest (RF). We then developed three multi-class prediction models to predict individual educational attainment. Model 1 used only zip code-derived education. Model 2 included model 1 + demographic variables and comorbidity. Model 3 included model 2 + neighborhood SDOHs (GINI and dissimilarity indices). The cohort was divided into 75/25 training and test sets, and 5-fold cross-validation was employed.

Results: A total of 603 ESKD patients were identified. The mean age was 58±12 years, 55% of patients attained less than high school, 32% completed high school, and 13% had a bachelor's degree or higher. Only 31% of zip code-derived education accurately matched actual education. The RF model has the best overall performance. Using RF, model 1 enhanced accuracy to 51% with an AUROC of 0.62 (95%CI 0.53 to 0.67). Model 3 demonstrated the highest accuracy (59%) and AUROC (0.71, 95%CI 0.63 to 0.77) (Figure 1).

Conclusions: Combining zip code-derived educational attainment with demographic data and neighborhood SDOH measures can improve the prediction of individual education in ESKD patients. This may improve the performance of models that incorporate SDOH as a feature.

Uncovering Subgroups of Diabetic Deceased Donor Kidney Transplant Recipients with Differing Outcomes Using Consensus Cluster Analysis

Supawit Tangpanithandee,[1,2] Charat Thongprayoon,[1] Jing Miao,[1] Caroline Jadlowiec,[4] Shennen Mao,[5] Michael A. Mao,[5] Napat Leeaphorn,[5] Pattharawin Pattharanitima,[3] Pajaree Krisanapan,[1,3] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand; [3]Thammasat University Faculty of Medicine, Khlong Nueng, Thailand; [4]Mayo Clinic, Phoenix, AZ; [5]Mayo Clinic, Jacksonville, FL.*

Background: Diabetic donor kidney transplants have inconsistent clinical outcomes, possibly due to population heterogeneity. This study aimed to use an unsupervised machine learning approach to cluster recipients of diabetic deceased donor kidney transplants and identify subgroups with higher risk of inferior outcomes and associated variables.

Methods: The study analyzed recipient-, donor-, and transplant-related characteristics of 7,876 recipients of diabetic deceased donor kidney transplants from 2010 to 2019 in the OPTN/UNOS database. Consensus cluster analysis was performed to identify important characteristics of each assigned cluster and compare posttransplant outcomes between the clusters.

Results: The analysis identified three clinically distinct clusters. Cluster 1 (N=2,903) recipients were characterized by the oldest age (64±8 years) and highest rate of comorbid diabetes mellitus (55%). They were more likely to receive kidney allografts from older donors (58±6.3 years) with hypertension (89%), meeting ECD status (78%), having a high rate of cerebrovascular death (63%) and carrying a high-KDPI (KDPI ≥85%) (77%). Cluster 2 (N=687) recipients were younger (49±13 years) and all were re-transplant patients with higher PRA (88 [IQR 46, 98]), receiving kidneys from younger (44±11 years), non-ECD deceased donors (88%) with low number of HLA mismatch (4 [IQR 2, 5]). The cluster 3 cohort was characterized by first-time kidney transplant recipients (100%) who received kidney allografts from younger (42±11 years), non-ECD deceased donors (98%). Compared to cluster 3, cluster 1 had a higher incidence of primary non-function, delayed graft function, patient death, and death-censored graft failure, while cluster 2 had a higher incidence of delayed graft function and death-censored graft failure but comparable primary non-function and patient death.

Conclusions: An unsupervised machine learning approach identified three clinically distinct clusters of diabetic donor kidney transplant patients with differing outcomes. The study suggests opportunities to improve utilization of high KDPI kidneys coming from diabetic donors in recipients with survival-limiting comorbidities, such as those observed in cluster 1.

Exploring the Diversity of Clinical Profiles and Outcomes in Kidney Transplant Recipients with Limited Education Using Clustering Analysis

Supawit Tangpanithandee,[1,2] Charat Thongprayoon,[1] Jing Miao,[1] Caroline Jadlowiec,[3] Shennen Mao,[4] Michael A. Mao,[4] Napat Leeaphorn,[4] Pajaree Krisanapan,[1,5] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Mahidol University Faculty of Medicine Ramathibodi Hospital, Bangkok, Thailand; [3]Mayo Clinic, Phoenix, AZ; [4]Mayo Clinic, Jacksonville, FL; [5]Thammasat University Hospital, Khlong Nueng, Thailand.*

Background: Education level has been identified as a potential predictor of post-transplant outcomes for kidney transplant recipients. However, there is a lack of research focusing on recipients with lower education levels and their unique clinical characteristics. Therefore, the objective of our study was to utilize unsupervised machine learning techniques to cluster kidney transplant recipients with lower education levels.

Methods: We performed consensus clustering analysis on 20,474 kidney transplant recipients with education levels below college/university using recipient, donor, and transplant data from the OPTN/UNOS database (2017-2019). We identified significant characteristics for each cluster and compared posttransplant outcomes.

Results: Most recipients had completed high school (86%) and were non-white (64%). We identified four clusters: Cluster 1 comprised young, non-diabetic patients receiving kidneys from young, non-hypertensive, non-ECD deceased donors with lower KDPI. Cluster 2 included preemptive or early dialysis initiators, predominantly white, receiving kidneys from living donors. They showed better outcomes. Cluster 3 consisted of young kidney re-transplant recipients with higher PRA and fewer HLA mismatches. Cluster 4 involved older, diabetic patients receiving kidneys from lower-quality donors. Cluster 2 exhibited the best outcomes, while clusters 1, 3, and 4 had higher risks of graft failure and patient mortality.

Conclusions: Unsupervised machine learning successfully clustered kidney transplant recipients with lower education levels into four distinct groups, each with unique clinical profiles and varying posttransplant outcomes. Cluster 2 demonstrated the best outcomes, while clusters 1, 3, and 4 had higher risks of graft failure and patient mortality. These findings have implications for personalized care and risk stratification in kidney transplant recipients with lower education levels.

Interpretable Machine Learning-Based Individual Analysis of AKI in Immune Checkpoint Inhibitor Therapy

Minoru Sakuragi,[1,2] Eiichiro Uchino,[1,2] Noriaki Sato,[1,2] Takeshi Matsubara,[2] Ryosuke Kojima,[1] Motoko Yanagita,[2,3] Yasushi Okuno.[1] *[1]Department of Biomedical Data Intelligence, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [2]Department of Nephrology, Graduate School of Medicine, Kyoto University, Kyoto, Japan; [3]Institute for the Advanced Study of Human Biology (ASHBi), Kyoto University, Kyoto, Japan.*

Background: Acute kidney injury (AKI) is a critical complication in immune checkpoint inhibitor (ICI) therapy. Since the etiologies of AKI in cancer therapy vary among patients, clarifying AKI causes in individuals is critical for optimal cancer treatment. Although it is essential to individually analyze ICI-treated patients for underlying pathologies existing behind each AKI onset occurring at different times, these analyses have not been realized with conventional clinical research methods.

Methods: We created a dataset from the electronic medical records (EMR) of 616 patients who received ICI therapy at the Kyoto University Hospital from July 2014 to September 2019. AKI was defined by serum creatinine changes based on the KDIGO guideline. We developed a gradient-boosting decision tree-based machine learning (ML) model continuously predicting AKI within 7 days from each time point, using 287 clinical variables obtained from EMR as input features. We noted that the temporal changes in individual predictive reasoning in AKI prediction models represented the key features contributing to each AKI prediction, and clustered AKI patients based on the pattern of features with high predictive contribution quantified in time-series by SHapley Additive exPlanations (SHAP), a model interpretation framework. We searched for common clinical backgrounds of AKI patients in each cluster, compared with annotation by three nephrologists.

Results: One hundred and twelve patients (18.2%) had at least one AKI episode. They were clustered per key features and their SHAP value patterns, and the nephrologists assessed the clusters' clinical relevance. Receiver operating characteristic analysis revealed that the area under the curve was 0.880. Patients with AKI were categorized into four clusters with significant prognostic differences (p=0.010). The leading causes of AKI for each cluster, such as hypovolemia, drug-related, and cancer cachexia, were all clinically interpretable, which conventional approaches cannot obtain.

Conclusions: Our results enabled us to clarify the background of AKI development in ICI-treated patients with complicated AKI risks and suggested the potential for applying ML prediction models as interpretable artificial intelligence to medical care, which had been a challenge to explainability.

FR-PO027

Development, Implementation, and Outcome of Telemedicine to Improve Access to Renal Health During the COVID-19 Pandemic at the National Kidney and Transplant Institute (NKTI)

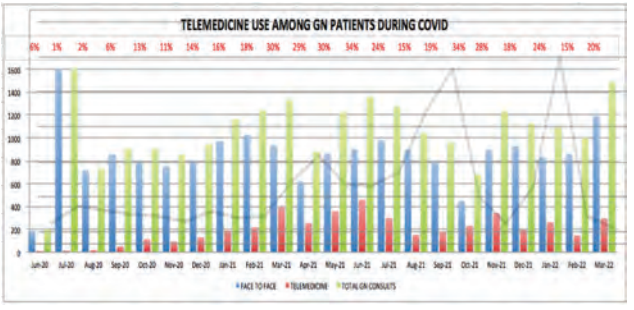
Melchor A. Altillero. *National Kidney and Transplant Institute, Quezon City, Philippines.*

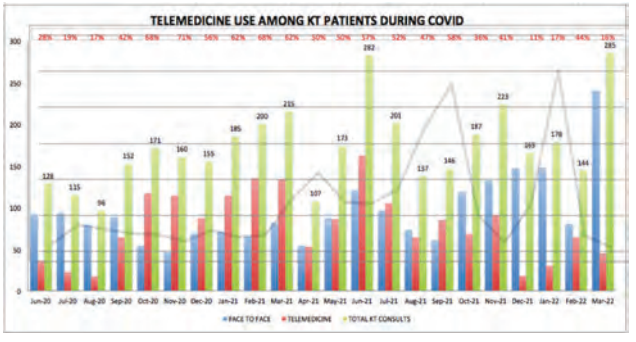
Background: With health care facilities becoming high risk places during the COVID pandemic, NKTI has developed adjustments in the provision of healthcare for out-patient consultation during the pandemic. This study aims to describe the development, implementation and outcome of telemedicine among service renal patients of Adult Nephrology Department in NKTI Out-Patient Service (OPS).

Methods: A hybrid model of telemedicine and ambulatory visits was utilizing synchronous video consults integrated with electronic medical records (EMR). Data were collected from the NKTI-OPS and Adult Nephro System including e-survey forms to assess patient satisfaction.

Results: Comparing with pre-pandemic, a 29% decrease in the mean service renal patient consultation/month was noted, with 28% and 50% reduction in GN and KT respectively. During the 4-month dry run of the program, the GN telemedicine utilization was only 4% while 27% for KT. With the full operation by October 2020, an increase of telemedicine usage was observed for both GN and KT consults with a high percentage among KT 68% vs 34% in GN patients. Majority of patients who utilized telemedicine were within 30-40 age group with comparable demographics between sex. Telemedicine was used by patients in almost all regions in the Philippines. Over-all patient satisfaction rate was 95.2%.

Conclusions: Delivering telehealth consultation to renal patients in our Institute during the COVID-19 pandemic demonstrated that it is feasible and well accepted alternative in augmenting patient care.





FR-PO028

Using Telemedicine Compared with Face-to-Face Visits for Outpatient Management in CKD Patients

Nichapat Apibankurukit, Anan Chuasuwan. *Bhumibol Adulyadej Hospital, Bangkok, Thailand.*

Background: In the recent past, Coronavirus disease 2019 (COVID-19) was a pandemic. Telemedicine is thought to be used for outpatient management in chronic kidney disease (CKD) patients because we want to reduce hospital visits and congestion in CKD clinic to decrease the risk of COVID-19 infection in CKD patients. This study aimed to compare the effectiveness of telemedicine with face-to-face visits for outpatient management in CKD patients.

Methods: A non-inferiority, non – randomized open-label controlled trial in a CKD clinic at Bhumibol Adulyadej Hospital, Bangkok, Thailand from January 2022 to January 2023. The patients were divided into 2 groups, using telemedicine and face-to-face visits. The primary outcome was to compare the percentage change of eGFR-EPI between the two groups.

Results: There were 32 patients in both the telemedicine and face-to-face visit groups. The majority were male 60.9%. The mean age was 72.2 ± 11.2 (SD) years. CKD KDIGO stage 4 was the majority by 56.2% and mean eGFR-EPI was 24.6 ± 9.9 (SD) ml/min/1.73 m^2. The eGFR increased by 2.1% in the telemedicine group and decreased by 2.1% in the face-to-face visits group (p 0.374). There was no difference between the two groups in all-cause mortality, hospitalization, emergency department visits, renal replacement therapy initiation rate, co-morbidities and CKD complications controlled, adherence, and satisfaction with the service. Telemedicine had higher quality of life, measured from the EQ-5D scales (69.5 vs 58.4 scores, $p = 0.009$), and used shorter timing in the visit (52.5 vs 189.5 minutes, $p < 0.001$) than the face-to-face visits group.

Conclusions: Compared to face-to-face visits, telemedicine for outpatient management in CKD patients is not inferior in the percentage change of eGFR, co-morbidities, and CKD complications. Telemedicine tends to have a better quality of life, shorten the timing of the visit, and lower travel costs to the hospital.

Funding: Government Support - Non-U.S.

The difference in change of eGFR between the telemedicine group and face-to-face visits groups at 2, 4, and 6 months in follow-up times.

Integration of CODEX and Brightfield Histology for Cell Type Segmentation and Classification Using Deep Learning

Nicholas Lucarelli,[1] Seth Winfree,[2] Angela R. Sabo,[3] Samuel Border,[1] Daria Barwinska,[3] Zoltan G. Laszik,[4] Michael T. Eadon,[3] Tarek M. El-Achkar,[3] Sanjay Jain,[5] Pinaki Sarder.[6] *[1]University of Florida Department of Biomedical Engineering, Gainesville, FL; [2]University of Nebraska Medical Center Department of Medicine, Omaha, NE; [3]Indiana University Department of Medicine - Division of Nephrology and Hypertension, Indianapolis, IN; [4]University of California San Francisco Department of Pathology and Laboratory Medicine, San Francisco, CA; [5]Washington University in St Louis Department of Medicine Division of Nephrology, St. Louis, MO; [6]University of Florida Department of Medicine - Quantitative Health, Gainesville, FL.*

Background: Cell types in a biopsy provide information on disease processes or organ health. Multiplex imaging technologies like CODEX provide spatial context to protein expression and detect cell types in a tissue sample. New CODEX workflows allow for hematoxylin and eosin (H&E) staining on the same sections. Deep learning can automate the process of image analysis, saving time. We seek to segment and classify cell nuclei from renal tissue sections using deep learning with CODEX generated cell labels as a ground truth.

Methods: Images consisted of brightfield H&E whole slide images (WSIs) from two institutions, collected from human reference kidneys. Nuclei were segmented using deep learning, and CODEX markers were measured for each nucleus. Cells and their markers were clustered in an unsupervised manner and assigned labels according to upregulated markers and biological priors. Cell types included: proximal tubules, distal tubules connecting tubules and collecting ducts, thick ascending limb, podocytes, endothelium, vessels, and immune cells. Cell maps were used to train a Deeplab V3+ semantic segmentation model. Classification was assessed in hold-out slides from CODEX generated sections.

Results: Two segmentation models were trained on WSIs from each institution. For the model trained on 3 sections containing ~3.9M cells, we achieved a balanced accuracy of 0.68, and for the model trained on ~350k cells from 11 sections, we achieved 0.75.

Conclusions: We were able to automatically segment and classify nuclei from various cell types directly from H&E stained WSIs. In future work, we seek to extend these segmentations to typical WSIs in renal pathology, with no prior molecular interrogation.

Comparison of a Deep Learning Model with Human Expert Annotations for Segmentation of Kidneys, Tumors, and Cysts in Routine CT Imaging Exams

Timothy L. Kline, Cole J. Cook, Adriana Gregory, Jason R. Klug, Theodora A. Potretzke, Eyal Ron, Naoki Takahashi, Bradley J. Erickson, Abhinav Khanna, Vidit Sharma, Bradley Leibovich. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: This study explores if a deep learning model for automatic kidney, tumor, and cyst segmentation from abdominal CT images can match interrater agreement.

Methods: A deep learning model was developed to segment the kidneys, tumors, and cysts from abdominal CTs. The training/validation set consisted of 1003 images from 479 unique subjects. A urologic oncologist with expertise in renal tumor evaluation and treatment (reference standard) and two radiology residents with experience in general abdominal CT imaging manually segmented 30 images, a held-out test set subset. Segmentation overlap between the reference standard and residents, or AI segmentations was assessed via the Dice coefficient. Confidence intervals (CI) for the probability the Dice coefficient between the reference standard and AI segmentation was larger than the with the residents based on a Mann Whitney U equivalence test were generated for left kidney, right kidney, tumor, and cyst.

Results: The mean and standard deviation of the Dice coefficients between reference standard and residents (AI) were 0.91±0.03 (0.93±0.03) for left kidney, 0.92±0.02 (0.94±0.02) for right kidney, 0.80±0.23 (0.86±0.18) for tumor mask, and 0.24±0.35 (0.42±0.37) for cyst mask, 0.81±0.24 (0.83±0.23) (see Figure 1). The 90% CIs tended to be greater than 0.5 in all cases but the tumor masks (see Table), suggesting the AI is often performing within expected interrater agreement.

Conclusions: A fully automated kidney, tumor, and cyst segmentation algorithm was trained and evaluated against three independent readers. The AI algorithm was found to compare similarly to interrater agreement.

Table 1: The estimated probability (point estimate) and corresponding 90% confidence interval for the probability a given Dice coefficient between the reference standard (urologic oncologist) and the AI segmentation is greater than or equal to the Dice coefficient between the reference standard and the two residents for each mask type (whole mask or individual connected component/lesion) and mask label (left kidney, right kidney, tumor, and cyst). Note 90% CIs were constructed based on a Mann Whitney U equivalence test with a level of significance of 0.05. If the 90% CI exceeds 0.5, the AI is performing within interrater agreement. This is the case for all but the tumor lesion masks, which are likely close to interrater agreement.

Mask Type	Mask Label	Point Estimate	90% CI
Whole	Left Kidney	0.746	[0.650, 0.841]
	Right Kidney	0.804	[0.716, 0.892]
	Tumor	0.581	[0.477, 0.685]
	Cyst	0.874	[0.812, 0.936]
Individual Lesion	Tumor	0.556	[0.450, 0.661]
	Cyst	0.839	[0.790, 0.888]

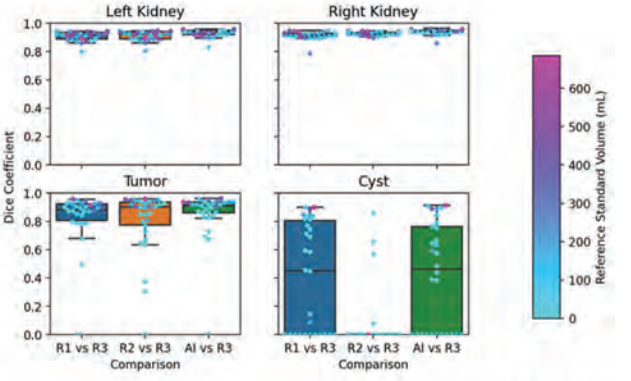

Figure 1: Box plots of the Dice coefficients based on the comparison (reader 3 is the reference standard) for the whole mask. Note the individual points are color coded based on the reference standard volume for the whole mask.

Development and Evaluation of a Vision Transformer-Based Machine Learning Model for Improved Nephron Segmentation in Kidney Disease Analysis

Zhongwang Li, Keith Siew, Stephen B. Walsh, Simon Walker-Samuel. London Tubular Centre. *University College London, London, United Kingdom.*

Background: Impacting over 20 million globally, kidney diseases mostly stem from nephron lesions. Nephrons' complex tubular structure complicates 3D pathology assessment. We've created a workflow merging optical clearing and AI to automate and improve this process. Optical clearing transfer samples transparent for accurate nephron mapping. Light-sheet microscopy visualizes these structures, but precise segmentation is required for measurements like tubule volume. Our proposed vision transformer-based machine learning model automates these measurements, assisting diagnosis and offering gene expression insights. This adaptable method extends to other tubular tissues, promising wider benefits.
