Methods: We collected 36 quarter-mouse-kidney light-sheet microscopy images, each 2048x2048 pixels, with a depth range of 700-1200 pixels. Images are splitted into blocks and individually segmented. Each block is treated as a 2D image series. Adjacent images' local features and segmentation results are encoded using a convolutional neural network. The transformer encoder/decoder processes high-level contextual representations, while the convolutional decoder recovers spatial dimensions and generates a tubule probability map. The final segmentation mask is derived from a normalized output probability map, and blocks are reassembled into an original-size image. Segmentation results can be visualized and validated using VR.

Results: Amid ongoing data annotation, preliminary tests of our model on a synthetic dataset of 6000 images showed promising results. After ten epochs of training on 4800 images, it demonstrated an IoU score (Intersection over Union, a measure of the overlap between the predicted segmentation and the ground truth) of 93%, Binary Accuracy (percentage of correctly predicted data points out of all predictions) of 98%, and F1 Score (100% indicates a more robust prediction) of 96% on a validation set of 1200 images.

Conclusions: Despite synthetic data's simplicity, our model's promising performance implies its potential with real-world data. We'll keep refining the model and, once enough real-world data is annotated, we'll test and compare it with baseline models like the Classical 3D Convolutional Neural Network. At that point, we'll release the model's structure, code, annotated data, and performance results.

FR-PO032

Automated Pipeline for Peritubular Capillary Inflammation Scoring

Akshita Gupta,[1] Samuel Border,[2] Marco Delsante,[3] Sayat Mimar,[4] Anindya S. Paul,[4] Avi Z. Rosenberg,[3] Pinaki Sarder.[4] *[1]University of Florida Department of Health Outcomes and Biomedical Informatics, Gainesville, FL; [2]University of Florida Department of Biomedical Engineering, Gainesville, FL; [3]Johns Hopkins University Department of Pathology, Baltimore, MD; [4]University of Florida Department of Medicine - Quantitative Health Section, Gainesville, FL.*

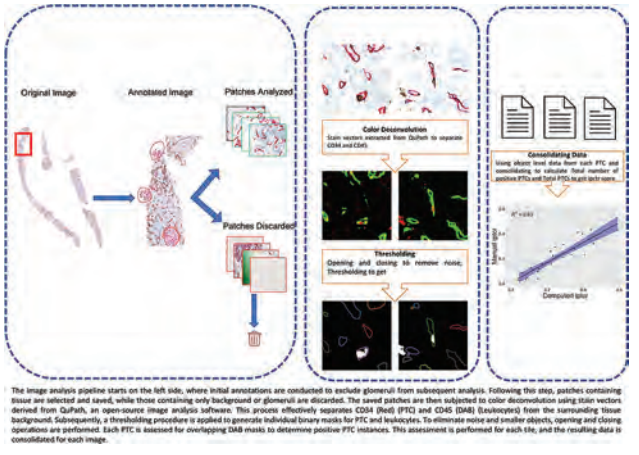
Background: Antibody-mediated rejection (AMR) can occur after kidney transplantation and is characterized by immune cell-mediated microvascular injury in response to donor-specific antibodies (DSA) and results in progressive graft survival and function. Using dual immunostaining for endothelium (anti-CD34)/leukocytes (anti-CD45), we identified peritubular capillaries (PTCs) and intracapillary leukocytes to determine the inflamed peritubular capillary ratio (*iptcr*), a quantitative Microvascular Inflammation (MVI) score that in a previous study correlated with renal graft failure and DSA strength.

Methods: Initially, we selected our stain vectors through QuPath. Used them to implement color deconvolution to separate CD34 (Red) (PTCs) and CD45 (DAB) (leukocytes). Thresholding and noise removal techniques were applied to each WSI to segment PTCs and leukocytes. The *iptcr* was determined by the ratio of total leukocyte (>1 cell) containing PTCs to total PTCs. Automated iptcr scores were compared to ground truth iptcr from manual scoring.

Results: There was a high correlation between pathologist and automated *iptcr* score (R-square: **0.83**). Perhaps even more important automated iptcr was **4X** faster versus manual pathologist scoring for each WSI.

Conclusions: Our automated approach based on using a relatively simple analytical pipeline (intensity transformation/enhancement, texture analysis, binarization, and morphological processing) makes iptcr scoring feasible. Our early results demonstrate the potential of the *iptcr* score pipeline as an efficient supplementary tool for improved AMR evaluation to replace the current discontinuous scoring system in place. Further validation and exploration of larger cohort are warranted.

Funding: NIDDK Support



The image analysis pipeline starts on the left side, where initial annotations are conducted to exclude glomeruli from subsequent analysis. Following this step, patches containing tissue are selected and saved, while those containing only background or glomeruli are discarded. The saved patches are then subjected to color deconvolution using stain vectors derived from QuPath, an open-source image analysis software. This process effectively separates CD34 (Red) (PTC) and CD45 (DAB) (Leukocytes) from the surrounding tissue background. Subsequently, a thresholding procedure is applied to generate individual binary masks for PTC and leukocytes. To eliminate noise and smaller objects, opening and closing operations are performed. Each PTC is assessed for overlapping DAB masks to determine positive PTC instances. This assessment is performed for each tile, and the resulting data is consolidated for each image.

FR-PO033

Multimodal Data Analysis with Spatial Transcriptomics

Samuel Border,[1] Nicholas Lucarelli,[1] Ahmed Naglah,[2] Sayat Mimar,[2] Tarek M. El-Achkar,[3] Sanjay Jain,[4] Ricardo Melo Ferreira,[3] Michael T. Eadon,[3] Pinaki Sarder.[2] *[1]University of Florida Department of Biomedical Engineering, Gainesville, FL; [2]University of Florida Department of Medicine - Quantitative Health Section, Gainesville, FL; [3]Indiana University School of Medicine Department of Medicine Division of Nephrology, Gainesville, FL; [4]University of Washington St Louis Department of Medicine Division of Nephrology, St. Louis, MO.*

Background: Spatial transcriptomics (ST) methods have provided researchers the ability to link morphological observations in histology with molecular mechanisms. This expanded view has great potential in a clinical setting towards improving patient stratification and treatment design. However, it is difficult for a human to handle all of these data. Machine Learning (ML) methods are specially equipped to handle dense datasets, exhibiting high performance on image-related tasks. ML can be used to provide details about cell populations and their cell states in non-specially prepared tissues.

Methods: We first built a visualization tool, *FUSION*, that allows users to examine the distribution of cell types and their states across functional tissue units. Users can also select regions of interest over which to aggregate ST data. We then made a prediction model (*SpotNet*) to characterize cellular information from histology tissues. Our model uses a ResNet50 encoder and a set of branched layers to predict cell types and states. Two models were trained using glomerulus and tubule-specific cells. There were more tubules than glomeruli. A dynamic patching approach greatly increased the diversity of our training data without substantial augmentation. Predictions made on a patch-level were converted into heatmaps for visualization of cell type localization.

Results: *FUSION* is deployed on the web for public access. *SpotNet* achieved a Mean Absolute Error (MAE) of 6.4±3.2%, 10.1±1.8%, 1.2±1.16%, 11.9±4.2% on prediction of 6 cell types and 4 cell states for glomeruli and 12 cell types and 4 cell states for tubules respectively. Predicted cell localizations overlapped well with ground truth.

Conclusions: We present a method for interactive viewing of ST data and a novel ML model for prediction and interpretation from images. Integration of this model into our visualization platform will enable highly granular analysis of histology.

FR-PO034

The Acceptability and Usability of My Kidneys & Me, a Digital Self-Management Health Intervention for CKD

Courtney J. Lightfoot, Thomas J. Wilkinson, Matthew Graham-Brown, Alice C. Smith. *University of Leicester, Leicester, United Kingdom.*

Background: The use of digital health interventions (DHIs) to provide education and support has rapidly increased, especially in the post-COVID era, due to potential cost-effectiveness and ease of equitable delivery. We co-developed My Kidneys & Me (MK&M), an educational self-management DHI for CKD. Here we report the usage metrics of MK&M during a 20-week evaluation.

Methods: As part of a randomized trial, participants at 26 UK sites were given access to MK&M for 20-weeks. MK&M provided online education sessions (underpinned by behaviour change theory), and digital applications to track goals, symptoms, physical activity, and clinical measures. Access to and usage data of MK&M were collected, alongside perceived usefulness (scored from 0 (not useful at all) to 10 (very useful)). Frequency analysis identified the frequency and length of time spent on MK&M sessions.

Results: 281 patients received MK&M (age 60.8±12.8 years, 58% male, eGFR 38.9±18.5 ml/min/1.73m^2). 205 (73%) used MK&M at least once. The median number of logins per person was 10.0 (IQR 4.0-28.0). The median time per login was 12 mins (IQR 7-25 mins). 'The kidneys' was the most accessed session (n=152 participants). Table 1 displays top three sessions by total number times accessed and total duration spent on session. All sessions scored ≥7/10, with 'Kidney disease and general health' considered the most useful session (8.7/10). Goal setting was considered the most useful tracker (8.5/10) and symptoms the least (6.7/10).

Conclusions: MK&M was well received and utilised by participants. Our findings show that people with CKD are capable and willing to use DHIs for kidney health. Identification of real-life usage and usability issues will help refine MK&M, improving the content and delivery before clinical implementation.

Top three sessions by the total number of times session accessed and total duration of time spent on the session per participant

	Total number of times session accessed per participant		
	Session title	Median (n)	IQR
1	Managing my symptoms	15	15-17
2	How to move more and be active	13	13-18
3	Treatment options available	13	13-15
	Total duration of time spent on session per participant		
	Session title	Median (mins)	IQR
1	Kidney disease and general health	11	6-22
2	Kidney disease	11	6-17
3	Treatment options available	9	5-16

NB. IQR: interquartile range

FR-PO035

Tracking the 3D Architecture of Hundreds of Nephrons and Peritubular Capillaries in Health and Disease Using Light Sheet Microscopy and Deep Learning

Chetan Poudel,[1] Ruben M. Sandoval,[2] Madeline K. Wong,[1] Jonathan T. Liu,[1] Joshua C. Vaughan.[1] Vaughan Lab. *[1]University of Washington, Seattle, WA; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Until recently, it has been practically impossible to study whole kidney nephrons and peritubular capillaries throughout the many millimeters of tissue necessary to examine them in their entirety. This technical limitation has obscured correlations and causal relationships between different parts of the same nephron, and between nearby nephrons and vasculature in cases of injury. Our study will use recent technical breakthroughs in 3D imaging, tissue clearing, and artificial intelligence to study thick specimens and process large datasets. We aim to establish a 3D connectivity map of hundreds to thousands of nephrons and study the coupling of injuries between glomeruli, tubules, adjacent nephrons, and peritubular capillaries at different stages of chronic kidney disease.

Methods: We used in vivo antibody labeling and solvent-based clearing to uniformly stain and clear whole mouse kidneys, which were then imaged on a custom-built lightsheet microscope with sub-cellular spatial resolution. We processed the 3D fluorescence data using a human-in-the-loop AI method, a deep-learning-based supervised image segmentation that allows for scaling up to large volumes and segmenting many nephrons at a time.

Results: From a single fluorescence label, our deep learning segmentation model traced hundreds of whole nephrons in 3D. We also used vasculature labeling to visualize and quantify the characteristics of the peritubular capillary network around the nephrons. So far, we have generated 3D renderings of nephrons and connectivity maps, and performed associated morphometrics (length, volume, tortuosity) for nephrons in healthy kidneys.

Conclusions: We have developed a pipeline using 3D imaging and artificial intelligence to extract relevant 3D features in hundreds of whole nephrons and capillaries in the same tissue. We will apply this framework to study the spatial correlations of injuries at various timepoints in models of chronic kidney diseases, such as focal segmental glomerulosclerosis and ischemia-reperfusion injury.

Data-Driven Disease Detection: A Learning Health System

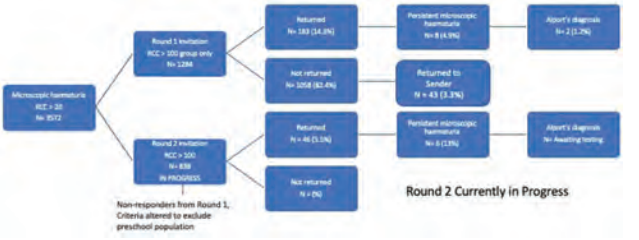
Grainne H. Butler,[1,2] Josiah Shanks,[3,4] Casie East,[1] Saravanan Satkumaran,[1] Catherine Quinlan.[3,2] *[1]Centre for Health Analytics, Royal Children's Hospital Melbourne, Melbourne, VIC, Australia; [2]Murdoch Children's Research Institute, Parkville, VIC, Australia; [3]The Royal Children's Hospital Melbourne, Parkville, VIC, Australia; [4]The University of Melbourne Department of Paediatrics, Parkville, VIC, Australia.*

Background: Achieving pre-clinical diagnosis in time to change the course of disease is the promise of data analytics and genomic medicine. Our Kidney Genomics Clinic(KGC) showed a high diagnostic yield for Alport syndrome(AS) in a pediatric cohort with persistent microscopic haematuria. Early diagnosis of AS in childhood offers an opportunity to start treatment and delay progression. Large studies of variant databases have shown heterozygous pathogenic variants in COL4A3/COL4A4 are present in 1 in 106 and pathogenic variants in COL4A5 in 1 in 2320. Despite guidelines and education, referral rates remained static and follow up rates were low. We created a digital health solution using data analytics of the electronic medical record(EMR) to identify children with an incidental finding of microscopic haematuria and offer early genomic diagnosis to those at risk of AS.

Methods: EMR databases were interrogated using Microsoft SQL to identify patients with incidental findings of microscopic haematuria and no prior or subsequent results below the threshold(20 RCC). Patients were stratified according to levels of haematuria and those with pyuria excluded. Patients were contacted with a letter outlining the need for repeat testing utilising bulk communication and ordering functions within the EMR. All those with persistent microscopic haematuria were offered genomic sequencing through the KGC. We developed a suite of web-based resources to enhance recruitment and webpage analytics were monitored for views and engagement. As a learning health system, we sought to integrate feedback and lessons learned to iteratively improve each round of patient contact.

Results: Figure 1

Conclusions: Direct patient contact through the EMR is feasible and acceptable demonstrating how digital health strategies can be employed to solve problems in healthcare. Response rates using postal contact are poor; alternate modes of communication may improve uptake. Lessons learned from this will be utilized to develop a prospective strategy automating the process for recall of future findings of microscopic haematuria.



FR-PO037

ToxiPedia: A Website Research and Education Tool on Uremic Toxins

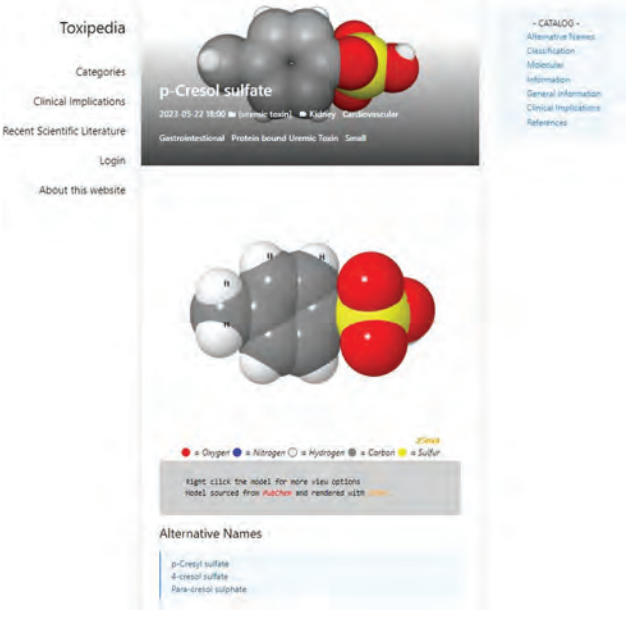
Noble B. Tabibian,[1] Carlos Orantes,[2] Victor Gura.[1,3] Wearable Artificial Organs. *[1]University of California Los Angeles, Los Angeles, CA; [2]Wearable Artificial Organs Inc, Los Angeles, CA; [3]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Mounting evidence suggests that current understanding of uremic toxicity is limited. As many different uremic toxins are being identified there is a need for research tools to better study, classify and analyze the different molecules implicated in uremic toxicity, their origin, chemical structure, metabolism, and ill effects. ToxiPedia, is an encyclopedic free access website, to be used as a tool to store all information on each toxin, its effects, chemical structure, metabolomic, proteomic, and toxicological classifications, and other pertinent information. It may also provide a continuously updated resource for researchers to study and analyze uremia. The clinical impact of uremic toxins will also be retrievable. The website aims to serve as an educational and research tool to improve renal replacement therapies that eliminate these toxins, improve the quality of life, and reduce morbidity and mortality.

Methods: The website is designed with a website generator to allow physicians and researchers to easily contribute to it. An advisory committee will validate the project to provide independent guidance and expert advice to improve the project before it is completed, along with a peer review process for every page. As new data on uremic molecules develops researchers can update and revise relevant pages to keep the website up to date.

Results: Online free acccess catalogue of Uremic Toxins allows retreiving all relevant information on Uremic Toxins.

Conclusions: This website may close current knowledge gaps and improve the accessibility of information on uremic toxins. It will also provide a much-needed resource to organize the large mass of emerging data on the uremic syndrome, causes, mechanisms, and complications. It is hoped that Toxipedia will contribute to more knowledge and better treatment of uremic toxicity.



FR-PO038

Perceived Value of Advance Care Planning Documents in the Electronic Health Record: A Qualitative Study of Chief Medical Information Officers, Clinicians, and Patients with CKD

Kristen Kennefick,[1] Daniel E. Weiner,[2] Keren Ladin.[1] DART Team.
[1]Tufts University, Medford, MA; [2]Tufts Medical Center, Boston, MA.

Background: Older adults with advanced chronic kidney disease (CKD) are at high risk for hospitalization, serious complications, cognitive decline, and death. Despite this, advance care planning (ACP) remains low among this population. Barriers to ACP completion and the impact of ACP availability in the electronic health record (EHR) are not well understood.

Methods: Qualitative study using semi-structured interviews (March 2022-March 2023) with purposively sampled patients (CKD stage 4-5 patients, age ≥50), chief medical information officers (CMIOs), and clinicians. Participants discussed EHR-related barriers and facilitators to ACP completion and accessibility. Audio recordings were transcribed verbatim and a thematic analysis was conducted.

Results: 72 participants (29 clinicians, 11 CMIOs, 33 patients) completed interviews. Among clinician and CMIO participants, 33% were women and 43% were from the Northeast. Among patients, 36% were women, 39% identified as Black, and mean age was 70 ± 9 years. Four themes with subthemes emerged: 1) Challenges to ensuring patient autonomy (document ownership, evolving patient preferences, ensuring preferences are actionable); 2) Valuable ACP requires interoperability (lack of standardized ACP protocols, variable access across settings, limited infrastructure and incentives, policies for improving interoperability); 3) Complexity of timing (in-the-moment decision-making, clinical triggers for ACP, opportunities for automation and improved workflow); and 4) Consequences of inconsistent ACP protocols (discordant care, overconfidence that patient wishes are known).

Conclusions: The perceived value of ACP is negatively impacted by inconsistent accessibility of ACPs across settings. Recommendations for increasing the reliability of ACP at the time of need include encouraging patient ownership of ACP documents; ensuring revisions occur regularly and are reconciled in the EHR; institution-level training on storage and documentation of ACP in the EHR; employing available EHR tools such as trigger messages; and introducing financial incentives for sharing across institutions.

FR-PO039

Implementing a Supportive Information System for the Vaccination Program of CKD Patients: Project from the Regional Nephrology Program, Military Hospitals, Taif Region, Saudi Arabia

Najlaa AlMalki, Hichem Abidi. *Al Hada Armed Forces Hospital, Taif, Saudi Arabia*.

Background: Vaccination rates remain particularly low in chronic kidney disease (CKD) patients, with diminished immune responsiveness due to delayed vaccination. Based on an in-depth review of vaccination-related processes, this project aimed at ensuring CKD patients timely receive all recommended vaccines, while boosting vaccination culture among healthcare providers, and implementing information system support for smoothly shared documentation through the continuum of care.

Methods: An in-depth review of national and international guidelines related to the vaccination of CKD patients was undertaken. Existing local policies were reviewed in comparison. Additionally, real-life practices were scrutinized to understand the level of adherence to policies, physicians' vaccination culture, prescription and administration of vaccine processes, and the information systems that underlay them.

Results: Standardizing and centralizing electronic vaccine prescription and documentation was one of the specific objectives of the project. Different, non-linked supports -electronic and paper- were used in the different nephrology units, which resulted in siloed in-unit data, that was impossible to be shared instantly or consulted remotely. The absence of a defined process in the clinics hindered vaccine prescribing for outpatients. Prescribing was standardized by adding vaccines to the regular medication form on the electronic medical record (EMR). To standardize documentation, the EMR native pediatric vaccination form was upgraded to hold adult vaccines. A reminder -that would pop up whenever the EMR is opened- was added to the system to help staff carry out planned vaccination. The preventive medicine (PM) vaccination clinic was linked to the information system to support the vaccination of nephrology outpatients. The clinic was mapped with an individual code, allowing for referral and booking, and for full access of the PM nurses to the prescription information and to the newly created vaccination form for documentation.

Conclusions: A coherent information system, that allows for readily available and smoothly shared information, is an essential component to support the development of a comprehensive vaccination program for chronic kidney disease patients through their continuum of care.

FR-PO040

Have You Googled Your Kidney? Interpretation of Google Trends Data During World Kidney Day

Chrystel Pawly,[1] Maroun Ibrahim,[2] Armenia Mordan.[1,3] *[1]Yale University Department of Internal Medicine, New Haven, CT; [2]Lebanese American University School of Medicine, Byblos, Lebanon; [3]Waterbury Hospital, Waterbury, CT.*

Background: World Kidney Day (WKD) is a global campaign conducted yearly in March to raise awareness of the importance of kidney disease. Analysis of the public's online interest may provide insight into the effectiveness of such awareness efforts. Our objective is to evaluate the impact of WKD by examining the temporal correlation between online searches related to kidney disease and the WKD campaign.

Methods: Using Google Trend (Gtr), we performed a retrospective study looking at relative search volumes (RSVs) of terms related to kidney disease from January 2006 to April 2023 in the USA. The search terms' RSVs during March of each year were compared to the other months. Pearson correlation coefficient was used to determine the statistical significance of the change in the RSV of WKD and its related search terms such as "Kidney Disease", "Chronic Kidney Disease", "Kidney damage", "Acute Kidney Injury", and "Dialysis".

Results: Throughout the years, an upward trend was observed in the RSVs of WKD and its associated terms. However, no consistent statistically significant correlation was found between the RSVs of WKD and related terms during March compared to the other months of the year. There were isolated statistically positive correlations found in March 2023 between RSVs for WKD, "dialysis," and "kidney disease" ($p=0.04$ and $p=0.019$, respectively), as well as an isolated positive correlation in March 2019 with the term "kidney disease" ($p=0.006$). Surprisingly, the data showed a significant negative correlation ($p=0.039$) between WKD and "Kidney Failure" for all the years analyzed.

Conclusions: Studies with similar designs have shown solid statistical correlations between the public's online queries and the Pink October campaign for breast cancer and the GoRedW campaign for heart disease. The interpretation of these findings suggests that these campaigns have successfully raised public awareness. Our study found an inconsistent positive correlation between WKD and specific terms over the years within our study period. Moreover, a negative correlation was noted with "Kidney Failure" for all years. Our research emphasizes the need for more studies on creating and executing awareness campaigns for kidney disease that can achieve the same success as those for other similarly burdensome illnesses.

FR-PO041

Characterizing the Genetic Architecture of Rare Glomerulonephropathy Disease: The Landscape of RNA Binding Protein Dysregulation

Tess A. Marvin,[1] Aviya Litman,[1] Chen Wang,[2] Chandra L. Theesfeld,[1] Laura H. Mariani,[3] Krzysztof Kiryluk,[2] Matthias Kretzler,[3] Olga Troyanskaya.[4] CureGN Genetics. *[1]Princeton University Princeton Center for Quantitative Biology Lewis-Sigler Institute for Integrative Genomics, Princeton, NJ; [2]Columbia University Vagelos College of Physicians and Surgeons, New York, NY; [3]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [4]Princeton University, Princeton, NJ.*

Background: The majority of primary glomerular nephropathy (GN) cases present with either immunoglobulin A nephropathy, focal segmental glomerulosclerosis, membranous nephropathy, and minimal change disease. Despite overlapping presentations, each diagnosis may represent many distinct disease subtypes with unique etiologies. Even as most disease risk is concentrated in a small number of genes, most patients do not carry syndromic mutations in GN-associated genes. Regulatory mutations that alter the magnitude or spatiotemporal aspect of expression may contribute to the genetic architecture of disease. RNA binding proteins (RBPs) regulate the life cycle of the RNA molecule (e.g. alternative splicing). Here we employ a genome-wide analysis of >67 million mutations in WGS of GN patients from the Cure Glomerulonephropathy (CureGN) cohort using a set of RBPs and their target sites to characterize the role RBPs play in the GN disease.

Methods: To assess the pathogenic contribution of RBP dysregulation to GN, we identified the functional impact of GN patient variants on RBP binding profiles using Seqweaver, a deep learning framework for predicting variant dysregulation for over 200 RNA-binding protein models with single nucleotide sensitivity. To determine if there are global signals of RBP dysregulation across the CureGN cohort, we identified trends in RBP disease impact scores across the patient variants. A pipeline was designed to select high-impact variants that are disease specific to identify mechanisms of disease. Beyond looking at individual genes and variants in isolation, we utilized a network-based approach to nominate active disease processes at a pathway level.

Results: We observed genes enriched for predicted high-impact variants from different patients (e.g. *VAV3*), and together, the rare variants associated with GN GWAS genes had significantly higher average disease impact than control variants associated with all other genes. Importantly, we also observed significant enrichment of RBP impact in kidney cell types. Seqweaver variant predictions provide hypotheses for biochemical mechanisms that explain GWAS association signals.

Conclusions: These findings suggest that RBP regulatory mutations of known kidney disease genes may harbor substantial disease risk.

FR-PO042

Vascular Calcification Heterogeneity Evaluated by Deep Radiomics Based on Chest Radiography

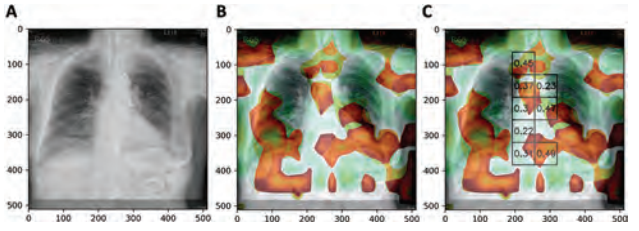
Chia-Ter Chao. *National Taiwan University Hospital, Taipei, Taiwan.*

Background: Vascular calcification (VC) is regarded a systemic pathology involving most arterial segments. Recent studies suggest that calcification heterogeneity exists, meaning that VC involves different wall components and locations, indicating diverse calcification patterns. We previously established a chest radiography-based radiomic approach for identifying VC. In this study, we aimed to evaluate whether radiographic calcification heterogeneity existed, in the form of different VC distributions between those with and without chronic kidney disease (CKD).

Methods: We devised a classification method using the attention mechanism of a deep learning neural network, whose architecture was first trained in a large chest radiography dataset, and then used as an initialization for the target domain with fine-tuning. We divided substrate images into subdivisions with grids and numeric values showing the radiomics features guided by deep learning attention mechanism. Boxes were used to indicate regions more significantly attentioned in patients with at least stage 3b CKD comparing to those in non-CKD populations. We visualized the attention of the network and extracted attentional areas.

Results: We analyzed chest radiography images from 11,106 general population (3.3% with VC) and 59 stage 3b or higher CKD patients (61% with VC). We examined the differentially attentioned areas between CKD and non-CKD patients after deep learning (Figure 1A, overlapping images). Activated areas, or differentially calcified areas in CKD patients included the ascending aorta, carotid vessels, and inter-diaphragmatic areas of thoracoabdominal aortas (Figure 1B). Quantitative analysis revealed inter-diaphragmatic areas exhibited the highest radiomic feature values, followed by carotid vessels and ascending aorta region (Figure 1C).

Conclusions: Using deep radiomics, we demonstrated specific aortic segments and branch arteries to be more significantly affected by VC among CKD patients than those without. Calcification heterogeneity can be detected using deep radiomics.



FR-PO043

Automated Detection of Renal Contrast Phases

Seyed Moein Rassoulinejad Mousavi, Bardia Khosravi, Alexander Weston, Hillary Garner, Naoki Takahashi, Timothy L. Kline, Bradley J. Erickson. Mayo AI Lab. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Renal contrast phases are vital for evaluating renal function, assessing pathology, detecting abnormalities, and formulating treatment plans. In this study, we utilized a combination of deep learning (DL) and regression techniques to identify contrast agents in CT scans and determine the specific stages of contrast-enhanced (CE) renal imaging. Initially, DL was employed to differentiate between CE and non-CE scans. For scans with administered contrast agents, a random forest regression model was trained to predict the complete range of values associated with the contrast phases. This approach allows for a more precise analysis of the continuous chronological sequence of contrast phases, rather than relying on predefined categories like classification.

Methods: The DL model is trained using a ConvNeXt-Femto architecture to classify CE and non-CE renal imaging. We used 3033 CT scans from 1017 patients with renal cell cancer. Using a segmentation model the left and right kidney were segmented. We selected five 2D slices of renals for classification: the middle slice based on the right kidney, two slices above, and two slices below. This simplified the input data while leveraging renal image characteristics. Features extracted from DL were used as input for a regression task using random forest to associate a value with each contrast phase based on chronological sequence aspects of renal enhancement. We employed five-fold cross-validation for training, using a sixth fold as the test set.

Results: The models performed well both in contrast detection and phase association tasks. The DL achieved an accuracy of 98% in classifying CE versus non-CE. For predicting other contrast phases, the model had a mean absolute error (MAE) of 0.34 on the test set. The model effectively associates numerical values with the eight contrast phases from “early corticomedullary” to “late pyelographic”, enabling characterization of renal contrast enhancement patterns.

Conclusions: Coupling DL and regression, proved to be highly effective in automating the detection of contrast agents in CT scans and accurately determining the specific stages of CE in renal imaging. This approach enables comprehensive analysis of the continuous chronological sequence of contrast phases, surpassing the limitations of predefined categories typically used in classification.

FR-PO044

Characterizing Urinary Tract Infections and Their Treatment Pathways EHR

Ning Shang, Katherine Xu, Krzysztof Kiryluk. *Columbia University, New York, NY.*

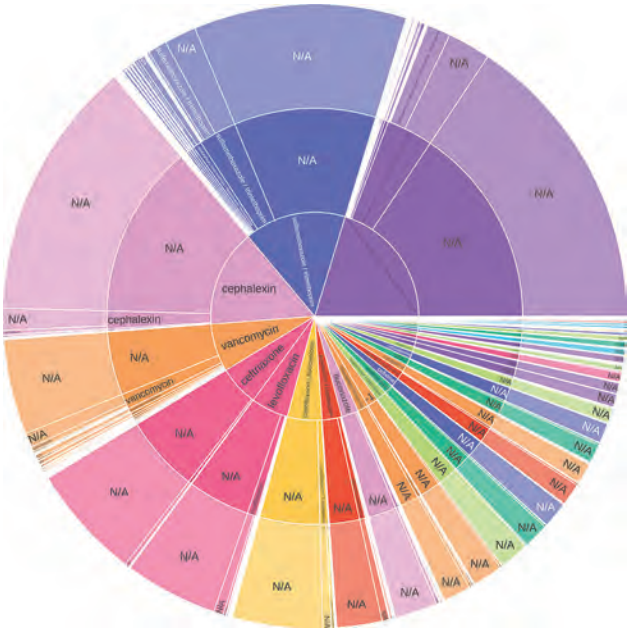
Background: UTIs are one of the most common infections worldwide. UTI epidemiology studies show a 27% recurrent rate in women within 6 months after the first UTI. Hence UTI early diagnosis and systematic treatment are very important. This project studies antibiotics treatment pathways (medication usage sequence) using big data.

Methods: We developed an electronic UTI phenotype identifying UTI by having at least 1 diagnosis/positive urine culture. It can further subgroup UTI as having a single episode of UTI or recurrent UTIs using 1-week time window to define each episode. UTI treatment pathways were analyzed for those who had at least one antibiotic in EHR. The patient had to have at least a 1-year of data in the database before the first UTI occurrence to be included. The medications were defined by ingredients using RxNorm and were grouped to drug class using ATC. The medications were extracted, and then ordered by first exposure. The sunburst plots were generated to visualize the pathways.

Results: Analyzing ~5M CUIMC EHR spanning back to 1980s, we identified 176,533 UTI patients (71% single vs 29% recurrent), consistent with prior reports. Among them, 112,126 patients qualified for this analysis. Recurrent UTIs patients were younger than single UTI patients (48 vs 53 years). The prevalence of female UTI was significantly higher than male UTI (female in overall 83%, in single UTI 82%, in recurrent UTI 87%). The five most commonly used antibiotics were nitrofurantoin monohydrate (24%), cephalexin (23%), nitrofurantoin/tetracaine (22%), ceftriaxone (18%), sulfamethoxazole/trimethoprim (17%) (Fig 1).

Conclusions: We designed a new electronic phenotype to detect single and recurrent UTI events. This algorithm can be useful for big data approaches to studies of UTI epidemiology and treatment patterns.

Funding: Other NIH Support - National Human Genome Research Institute (NHGRI)



4 level treatment pathways for UTI. The inner circle shows the first relevant medication that the patient took, and so forth. N/A means no drug.

FR-PO045

A Machine Learning Approach to Differentiating Between Typical Diabetic Nephropathy (DN) and Atypical DN with Podocytopathy in Periodic Acid-Schiff (PAS)-Stained Whole Slide Images of the Kidneys

Myles Joshua T. Tan,[1] Avi Z. Rosenberg,[2] Anindya S. Paul,[3] Seung Seok Han,[4] Pinaki Sarder.[3] *[1]University of Florida Department of Electrical & Computer Engineering, Gainesville, FL; [2]Johns Hopkins University Department of Pathology, Baltimore, MD; [3]University of Florida Department of Medicine - Quantitative Health Section, Gainesville, FL; [4]Seoul National University Department of Internal Medicine, Seoul, Republic of Korea.*

Background: Diabetic nephropathy (DN) is a leading cause of end-stage kidney disease. Other podocytopathies may occur in the setting of diabetes, leading to atypical presentations and potential responsiveness to immunosuppressants. Differentiation between typical and atypical cases is infeasible with light microscopy alone. We show that atypical DN with other podocytopathy can be differentiated from typical cases by uncovering clusters in a 2D projection of quantitative morphological features of glomeruli.

Methods: 99 PAS-stained whole slide images of DN kidney biopsies (91 typical; 8 atypical) were fed into a deep learning model to segment glomeruli, from which

315 morphological features were quantified. Features were categorized according to compartment: global, PAS-positive (P), luminal (L), nuclear (N), both P & L, both P & N, and both L & N. They were further categorized according to type: morphological, size, color, radial, relative distance, textural. Points representing cases in a 315-dimensional hyperplane (1 dimension per feature) were projected onto 2D while preserving high-dimensional clusters using uniform manifold approximation and projection.

Results: Points representing typical DN cases clustered separately from atypical cases (top of projection). See Fig. 1.

Conclusions: Since some podocytopathies in the setting of DN respond to immunosuppressants, our approach could inform treatment in DN cases with suspicion of co-occurring podocytopathy. Given the infrequency of atypical cases and the overwhelming background diabetes, data are scarce. Future research may identify features that contribute to the clustering and to understand how morphology can inform diagnosis.

Funding: NIDDK Support

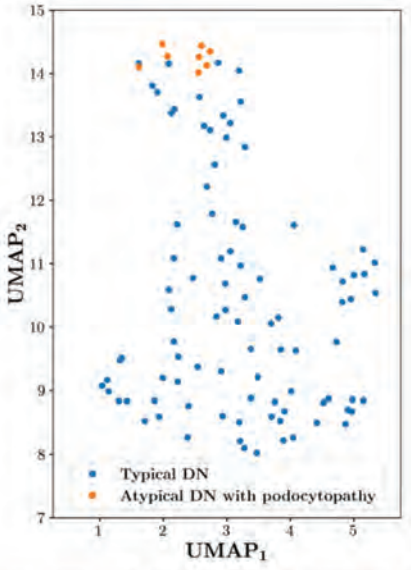


Fig. 1: Two-dimensional uniform manifold approximation and projection (UMAP) of 315 morphological image features of glomeruli from 99 cases of diabetic nephropathy [DN; (91 typical, 8 atypical)]. Points representing typical DN cases (blue points) occupied the greater part of the projection and clustered separately from atypical cases (orange points; top of projection). This illustrates that atypical DN cases with other podocytopathies could be differentiated using quantitative morphological features of glomeruli extracted from PAS-stained whole slide images of DN kidney biopsies.

FR-PO046

Symptom Trajectories in the Electronic Health Record During the Transition to Dialysis

James B. Wetmore,[1,2] Kirsten L. Johansen,[1,2] David T. Gilbertson,[2] Nicholas S. Roetker.[2] *[1]Hennepin Healthcare System Inc, Minneapolis, MN; [2]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN.*

Background: How symptoms recorded in the electronic health record (EHR) change during the transition to dialysis has not been fully explored.

Methods: Using Optum's de-identified Integrated Claims-Clinical Dataset, we identified individuals with CKD stages 4-5 who transitioned to dialysis. We searched clinical notes for symptoms, identified by natural language processing, recorded across weekly intervals in the 6 months before and after dialysis initiation. We estimated changes in the odds of a symptom being recorded with an interrupted time series analysis using segmented logistic regression.

Results: The cohort comprised 728 individuals (mean age 67.7 ± 13.1 years, 44.0% women, 55.9% White and 29.9% Black). During the 6 months prior to dialysis initiation, 83.3% were recorded as having pain, 68.4% had fatigue/weakness, 66.3% had shortness of breath, 60.6% had nausea/vomiting, and 37.1% had difficulty concentrating. Before initiation, odds of an individual being recorded as having pain increased (slope: OR 1.02 per week, 95% CI 1.01 – 1.03); dialysis initiation was associated with a decrease (intercept change: OR 0.70, 95% CI 0.60 – 0.83). After initiation, odds of pain were unchanged (post-dialysis slope: OR 1.00 per week, 95% CI 0.99 – 1.01), although this represented a trajectory change relative to the pre-dialysis period (change in slope: OR 0.98 per week, 95% CI 0.96 – 0.99). For fatigue/weakness, odds increased before initiation (OR 1.03 per week, 95% CI 1.02, 1.04), but decreased upon initiation (OR 0.62, 95% CI 0.52 – 0.76) and thereafter over time (OR 0.98 per week, 95% 0.97 – 0.99), representing a reduction in slope relative to the pre-dialysis period (OR 0.95 per week, 95% CI 0.94 – 0.97). Patterns for shortness of breath, nausea/vomiting, and difficulty concentrating were similar to those of fatigue/weakness.

Conclusions: Natural language processing can be used to study symptom changes recorded in individuals with advanced CKD.

Funding: NIDDK Support

FR-PO047

Performance of Large Language Models in Self-Assessment Questions for Nephrology Board Renewal: Comparative Study of ChatGPT (GPT-3.5, GPT-4) and Bard

Ryunosuke Noda, Yuto Izaki, Fumiya Kitano, Jun Komatsu, Daisuke Ichikawa, Yugo Shibagaki. *St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: The GPT series, Large Language Models (LLMs) pre-trained on vast data, have highly influenced recent Natural Language Processing advances. While GPT-4 demonstrated high accuracy in US law and medical exams, its performance in specialized areas like nephrology is unclear. This study aimed to compare ChatGPT (GPT-3.5, GPT-4), Bard, and their potential clinical applications in area of nephrology.

Methods: In this study, 99 questions from the "Self-Assessment Questions for Nephrology Board Renewal" from the years 2018-2022 were presented to two versions of ChatGPT plus (GPT-3.5, GPT-4), and Bard. The prompts were presented in Japanese, beginning with "I will now present a problem related to kidneys. Please answer in the form of 'answer', 'explanation'." Questions that included images only used the text of the question as input. We calculated the overall correct answer rates for the five years and each year, and checked whether they exceeded the pass criterion of a correct answer rate of ≥ 60%. We also conducted a comparative study of the correct answer rates by category and image presence. Statistical analysis was performed using Chi-square tests and Fisher's exact tests.

Results: The overall correct answer rates for GPT-3.5, GPT-4, and Bard were 31.3% (31/99), 54.5% (54/99), and 32.3% (32/99), respectively, thus GPT-4 showed significantly higher accuracy than GPT-3.5 ($p < 0.01$) and Bard ($p < 0.01$). While GPT-3.5 and Bard did not meet the pass criteria in any year, GPT-4 met the pass criteria in three years. GPT-4 showed significantly higher accuracy in clinical questions and non-image questions compared to GPT-3.5 ($p = 0.01$, $p < 0.01$) and Bard ($p = 0.02$, $p < 0.01$). No significant differences were observed between GPT-3.5 and Bard in any analysis.

Conclusions: GPT-4 significantly outperformed GPT-3.5 and Bard in overall accuracy, clinical, and non-image queries. It met Japanese Nephrology Board renewal standards in three of five years, with future improvement expected in image input and nephrology-specific fine-tuning. These findings underline the potential application of LLMs in nephrology and their pros and cons. As LLMs advance, nephrologists should understand their performance and reliability for future applications.

FR-PO048

External Validation of a Machine Learning Model for Progression of CKD in the CREDENCE and CANVAS Trials

Navdeep Tangri,[1] Thomas W. Ferguson,[1] Ryan J. Bamforth,[1] Clare G. Arnott,[2] Kenneth W. Mahaffey,[3] Hiddo J. Heerspink,[4] Vlado Perkovic,[2] Brendon L. Neuen.[2] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]Stanford Medicine, Stanford, CA; [4]Universitair Medisch Centrum Groningen Afdeling Cardiologie, Groningen, Netherlands.*

Background: Sodium glucose cotransporter 2 inhibitors (SGLT2i) are indicated for slowing progression of chronic kidney disease (CKD). A previously validated machine learning model (Klinrisk model) accurately predicts 40% decline in eGFR or kidney

failure using routinely collected laboratory data. We sought to validate this model in the pooled CANVAS/CREDENCE trials.

Methods: The CANVAS/CREDENCE trials evaluated the effects of the SGLT2i canagliflozin on cardiorenal outcomes in patients with type 2 diabetes at high cardiovascular risk or with CKD. We validated the Klinrisk model for prediction of CKD progression, defined as greater than 40% decline in eGFR or kidney failure. The model applies results from complete blood cell counts, chemistry panels, comprehensive metabolic panels, and urinalysis. Model performance was assessed up to 3 years (median follow up 2.4 years) with the area under the receiver characteristic operating curve (AUC), Brier scores, and calibration plots of observed and predicted risks. We compared performance of the model to standard of care using eGFR (G1-G4) and urine ACR (A1-A3) KDIGO heatmap categories.

Results: Among 14,464 patients in CANVAS/CREDENCE, we found the Klinrisk model provided excellent discrimination for CKD progression (696 events at 2 years), with an AUC of 0.81 (95% confidence interval 0.78 – 0.83) for prediction of the outcome at 1 year, increasing to 0.88 (0.86 – 0.89) at 3 years. Brier scores were 0.020 (0.018 – 0.022) at 1 year, increasing to 0.056 (0.052 – 0.059) at 3 years. Calibration was satisfactory, with minor overprediction in patients randomized to canagliflozin. Compared to the KDIGO heatmap, the Klinrisk model had improved performance at every interval (Table 1).

Conclusions: The Klinrisk machine learning model using routinely collected laboratory features was highly accurate in its prediction of CKD progression in the CANVAS and CREDENCE trials.

Table 1. Results of model performance

	Klinrisk model	Klinrisk model	eGFR and ACR categories (KDIGO heatmap)	eGFR and ACR categories (KDIGO heatmap)
Time frame, years	AUC (95% CI)	Brier score (95% CI)	AUC (95% CI)	Brier score (95% CI)
1	0.81 (0.78 - 0.83)	0.020 (0.018 - 0.022)	0.74 (0.71 – 0.76)	0.021 (0.018 – 0.023)
2	0.85 (0.84 - 0.87)	0.042 (0.039 - 0.046)	0.79 (0.78 – 0.81)	0.046 (0.042 – 0.050)
3	0.88 (0.86 - 0.89)	0.056 (0.052 - 0.059)	0.83 (0.81 – 0.84)	0.063 (0.059 – 0.067)

Brier scores range from 0 to 1, with lower values representing higher accuracy.

FR-PO049

The KIDNEE Club: An Acceptability and Feasibility Study of a Preclinical Medical Student Experience in a Pediatric Dialysis Unit Pilot Program

Sarah Couser, Lisa E. Herrmann, Robin Hurdle, Meredith P. Schuh.
Cincinnati Children's Hospital Medical Center, Cincinnati, OH.

Background: Recently, concerns have developed over the sustainability of the pediatric nephrology workforce. Studies indicate that preclinical exposure may impact medical students' interest in field specialization. Seeking to provide early pediatric nephrology exposure to medical students, we implemented an educational intervention to pair preclinical students with pediatric dialysis patients, called the KIDNEE (Kids In Dialysis, Nephrology Exposure and Education) club. We aimed to study the acceptability and feasibility of this pilot intervention for the students, patients, and unit staff.

Methods: For the 2022-23 academic year, seven first year medical students were paired with pediatric dialysis patients. Students met with their "match" once weekly during dialysis sessions. We distributed surveys to participants six months after program implementation to assess feasibility and acceptability of this pilot program. Surveys, based on a previously published Likert scale tool assessing student and parent impression of a preclinical exposure program, were iteratively revised after review by medical education experts. Surveys were distributed via REDCap to the medical students, staff, and patients/families who participated in the program.

Results: From October 2022-April 2023, the 7 medical students spent ~173 hours in the dialysis unit. All (100%) students, 8 of 24 (33%) dialysis staff, and 2 of 7 (28%) patients/families responded to the survey. Students reported increased interest in caring for children with kidney disease after participation in the KIDNEE Club. Staff and parents unanimously reported students were helpful to patients and played an important role in patient's overall happiness. They all reported that they would recommend the KIDNEE club to other families. One parent reported that the program "improved my child's mood and maybe made it easier for the necessary care to take place because he was more cooperative/motivated."

Conclusions: Preliminary data suggests the KIDNEE club pilot was both feasible and acceptable for students, staff, and patients/families. As our results are limited by small sample size given the pilot nature of the program, future study is needed with program expansion and longitudinal assessment of the impact on students' career trajectories.

FR-PO050

Overview and Outcomes of the Kidney STARS Program

Lili Chan,[1] Leticia Rolon,[2] Molly Rubin,[3] Keisha L. Gibson,[4] Ursula C. Brewster,[5] Robert S. Hoover,[6] Stephen M. Sozio.[7] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]University of California San Francisco School of Medicine, San Francisco, CA; [3]American Society of Nephrology, Washington, DC; [4]University of North Carolina Wilmington, Wilmington, NC; [5]Yale School of Medicine, New Haven, CT; [6]Tulane University, New Orleans, LA; [7]Johns Hopkins University, Baltimore, MD.*

Background: The ASN Kidney Students and Residents (STARS) program was founded to increase interest in Nephrology careers. In addition to tailored events and networking opportunities, this program provides travel support and complimentary registration to attend the Annual Meeting during ASN Kidney Week. Understanding the impact of Kidney STARS participation on recruitment of trainees into the nephrology workforce is critical.

Methods: We tracked medical students (MS) and residents (PGY) STARS participants from 2009-2017 using Doximity, ABIM, and ABP by searching for the participants' first and last names. Two reviewers validated the search results. MS began to be accepted into the program in 2010. Those that participated multiple times were logged in their first year of participation only. Participants who were still in training at the time of tracking (e.g., MS or PGY), were international participants, or were unable to be validated by the reviewers were excluded from final analysis. Starting in 2010, assessment of participant interest in nephrology pre- and post- participation was obtained via a post-Kidney Week survey.

Results: There have been 1,624 STARS participants over those nine years, of which 1,128 were included in our tracking metrics. MS made up 26% of the participants while PGY constituted 74%. 52% of participants completed a fellowship in nephrology (Figure 1A). A larger proportion of PGY participants chose a career in nephrology compared to MS participants (64% vs. 18%, P<0.001) (Figure 1B) with significantly higher odds (OR 8, 95% CI 5.8-11.2). While MS had lower pre- and post- interest than residents (Pre 6.2 vs. 7.7, P<0.001 and Post 7.4 vs. 8.9, P<0.001), relative change in interest was higher in MS (19 vs. 15.3, P=0.007) (Figure 1C).

Conclusions: The ASN Kidney STARS program has been adapted to include diverse levels of learners, has built programs in mentorship, and has refined its approaches. The program has been successful with more than half of participants in the STARS program completing a fellowship in nephrology. Continued investment into the Kidney STARS program is critical to attracting trainees into nephrology.

Reimagining Safety in the Learning Environment: A Grounded Theory Exploration of Identity Safety in Clinical Medical Students

Justin L. Bullock,[1,2] Javeed Sukhera,[3] Amira del Pino Jones,[4] Timothy G. Dyster,[5] Jonathan S. Ilgen,[1] Tai M. Lockspeiser,[4] Pim Teunissen,[2] Karen E. Hauer.[5] *[1]University of Washington, Seattle, WA; [2]Universiteit Maastricht, Maastricht, Netherlands; [3]Hartford HealthCare Institute of Living, Hartford, CT; [4]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [5]University of California San Francisco, San Francisco, CA.*

Background: Trainees in nephrology who identify as underrepresented in medicine and/or international medical graduates are at high risk for identity threats such as stereotype threat and microaggressions. Identity threats impair learning and erode well-being. In contrast to identity threat, less is known about how learners experience feelings of safety regarding their identity. This exploratory study aims to develop a theory of identity safety in the clinical learning environment.

Methods: This multi-institutional, qualitative interview study was informed by constructivist grounded theory and critical pedagogy. Participants were clinical students at three US medical schools. Investigators purposively sampled interviewees based on their responses to an 11-item survey with an open-ended question soliciting students' personal identities and their scores on the racial/ethnic and gender Stereotype Vulnerability Scales. The investigators interviewed, coded, constantly compared, and continued sampling in alignment with grounded theory. The team engaged in critical reflexivity throughout the analytic process to enrich data interpretations.

Results: Sixteen diverse students were interviewed. We organized their identity salient experiences into identity safety, identity threat, and threat mitigation. Identity safety occurred when learners existed as their authentic selves without feeling the need to monitor others' perception of their identities. This arose when: 1) learners demonstrated agency to leverage their identities for patient care, 2) others upheld their personhood and saw them as unique individuals, and 3) learners felt they belonged. Participants experienced identity threat when they experienced stereotype threat or interpersonal threat. Threat mitigation occurred when someone intervened against an identity threat, dampening but not eliminating the impact of the identity threat.

Conclusions: Identity safety may foster learning by liberating learners from self-monitoring, insulating them from identity threats, and enabling them to leverage their identities to contribute to patient care.

FR-PO052

Building Diagnostic Schemas Improves Resident Confidence in Managing AKI

Colton Jensen, Varun Agrawal. *University of Vermont, Burlington, VT.*

Background: The complexity of nephrology has been identified as a major contributing factor as to why fewer resident physicians are pursuing it as a career. Improving resident comfort and knowledge about nephrology topics, particularly acute kidney injury (AKI), is imperative to decreasing resident perception of their difficulty. There is a paucity of data on effective teaching methods for AKI for resident physicians. Therefore, we designed and tested a workshop where interns build an AKI diagnostic schema to see if that improved their comfort with the topic.

Methods: The workshop took place during dedicated didactic time for interns at an academic hospital's internal medicine residency. They received a pre-workshop survey that explored their perceived knowledge of AKI etiology, diagnosis, and management as well as their comfort level with explaining AKIs to patients and medical students. Interns were briefed on how to use diagnostic schemas and together constructed one for AKI (pre-renal, intrinsic, and post-renal causes). They then underwent didactics on pathophysiology, clinical manifestations, diagnostic work up, and management of AKI using this schema. Finally, the group used the schema to map out a general approach for a patient presenting with an AKI and answered practice questions. Finally, they took a post-workshop survey with the same questions as the pre-survey.

Results: 12 interns completed the pre-workshop survey and 15 completed the post-workshop survey. In the pre-survey, only 25% of the interns "agreed" or "strongly agreed" they felt comfortable working up and managing a patient with an AKI and only 16% had an organized approach compared to 80% of interns in the post-survey for both responses. 8% and 16% of interns felt comfortable explaining AKIs to patients and medical students, respectively, which improved to 73% and 57% after the workshop.

Conclusions: Internal medicine interns felt more confident diagnosing and managing AKI as well as discussing it with their patients and medical students after building and practicing with a diagnostic schema. Though this study was limited by study size and lack of control group, it serves as a first step in collecting data and exploring effective teaching methods for common nephrology topics, with the crucial goal to increase resident comfort level with kidney disorders and bolster interest in nephrology.

FR-PO053

Handout on Over-the-Counter Medication Safety in CKD Improves Internal Medicine Resident Confidence and Knowledge

Surekha U. Annadanam, Michael Heung, Nidhi Sukul, Rachel L. Perlman, Julie A. Wright Nunes. *University of Michigan, Ann Arbor, MI.*

Background: Drug-related nephrotoxicity can lead to acute kidney injury, chronic kidney disease (CKD) progression, or even end stage kidney disease. There are limited electronic medical record (EMR)-based educational materials with information on over-the-counter (OTC) medication safety for patients with CKD. The goal of our study was to introduce an EMR-based educational handout to internal medicine resident physicians and evaluate whether their knowledge and confidence in OTC medication safety counseling for CKD changed following.

Methods: Internal medicine and internal medicine-pediatric (med-peds) residents at the University of Michigan were recruited to participate in the introduction and training for the EMR-based handout. The handout was previously developed by experts in nephrology for use during patient-provider encounters. Pre-tests and post-tests were administered prior to and immediately after review of the handout. Resident confidence was gauged using survey questions with item responses consisting of a 7-point Likert scale. Differences in proportions were assessed using chi-squared tests. This project was IRB approved.

Results: 35 residents completed training for the EMR-based handout: mean (SD) age was 28.3 years (1.8) and 46% were female. Ninety-four percent were general internal medicine and 6% were med-peds residents. Comparing pre-test and post-test scores, a higher proportion of residents correctly identified medication safety profiles for patients with CKD following training: low dose aspirin (pre-test = 57.1% vs post-test = 94.3%, $p < 0.01$), antihistamines (71.4% vs 97.1%, $p < 0.01$), guaifenesin (74.3% vs 97.1%, $p = 0.01$), dextromethorphan (40.0% vs 88.6%, $p < 0.01$), and Pepto-Bismol (68.6% vs 91.4%, $p = 0.03$). A higher proportion noted concerns with pseudoephedrine (68.6% vs 94.3%, $p = 0.03$) and Kaopectate (42.9% vs 100.0%, $p < 0.01$) for routine use in patients with CKD. Following training, residents felt more confident in their knowledge (4.2 vs 6.3, $p < 0.01$) and in counseling patients with CKD on OTC medication safety (4.0 vs 6.2, $p < 0.01$).

Conclusions: One-time didactic training using an EMR-based handout about OTC medication safety enhanced resident knowledge and confidence in counseling patients with CKD.

FR-PO054

Career Development in Nephrology: A Pilot Fellowship Mentorship Program

Rachel Hilburg, Laura Watabu, Amanda K. Leonberg-Yoo. *University of Pennsylvania, Philadelphia, PA.*

Background: Mentorship programs can improve career enhancement for trainees and mutually benefit the mentor. Structured mentorship programs in graduate medical education have been shown to enhance the training experience and are met with high satisfaction. We implemented a structured 2-year mentorship program in the nephrology fellowship at the University of Pennsylvania from 2021-2023.

Methods: Between 2021 and 2023, nephrology faculty volunteered as mentors. Faculty created career and special interest profiles. Fellows reviewed faculty profiles and ranked mentor preferences, which program leadership used to create mentor-mentee pairs. Pairs met quarterly throughout the academic year and participated in professional development sessions (Figure). End of year feedback was obtained using anonymous surveys to assess satisfaction and effectiveness of the program using Likert scales (1-6, extremely dissatisfied to extremely satisfied, extremely ineffective to extremely effective). This program was deemed exempt by the University of Pennsylvania IRB.

Results: 34 mentor-mentee pairs were created between 2021-2023. 22 fellows (65%) and 22 faculty (65%) responded to anonymous surveys. Average overall program satisfaction score among fellows was 5.0/6.0 (SD 1.1), and among faculty was 3.9 (1.2). Fellows were satisfied with support of their professional aspirations (avg 5.3, SD 1.1). Faculty were satisfied with mentor resources (avg 4.3, SD 1.1). Perceived effectiveness of mentorship among fellows was satisfactory across all domains (Table).

Conclusions: The nephrology fellowship mentorship program at the University of Pennsylvania was met with active participation and high overall satisfaction. Limitations include survey response rates and assessment of attitudes rather than professional outcomes. Based on the pilot program, we will continue to evolve the professional development sessions and faculty resources to meet the needs of the fellows.

Table: Perceived effectiveness of mentorship domains among fellows, 2021-2023 (22 Respondents)

	Clinical Skills Advancement No. (%)	Career Planning No. (%)	Networking No. (%)	Sponsorship & Advocacy No. (%)	Research Productivity No. (%)	Professionalism* No. (%)
Effective (Likert 4-6)	21 (95)	20 (91)	20 (91)	20 (91)	18 (82)	20 (91)
Ineffective (Likert 1-3)	1 (5)	2 (9)	2 (9)	2 (9)	4 (18)	2 (9)

*Professionalism domain explored mentoring on handling sensitive or challenging issues

Figure: Mentorship Program Schedule

	Session #1	Session #2	Session #3	Session #4
Year 1	Introduction	Strength Assessment	Career Panel	CV Workshop
Year 2	Getting/Giving Advice	Goal Setting	Nephrology Boards Planning	Concluding Session

FR-PO055

Creation and Validation of a Formative Assessment Tool for Nephrology Fellows' Clinical Reasoning in a National Cohort

Suzanne Boyle,[1] James R. Martindale,[2] Andrew S. Parsons,[2] Stephen M. Sozio,[3] Rachel Hilburg,[4] Jehan Z. Bahrainwala,[4] Lili Chan,[5] Lauren D. Stern,[6] Karen M. Warburton.[2] *[1]Lewis Katz School of Medicine at Temple University, Philadelphia, PA; [2]University of Virginia School of Medicine, Charlottesville, VA; [3]Johns Hopkins Medicine, Baltimore, MD; [4]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Boston University School of Medicine, Boston, MA.*

Background: Deficits in clinical reasoning are common among graduate medical learners. We created and validated an instrument to assess clinical reasoning in a national cohort of first-year nephrology fellows and established performance thresholds for remedial coaching.

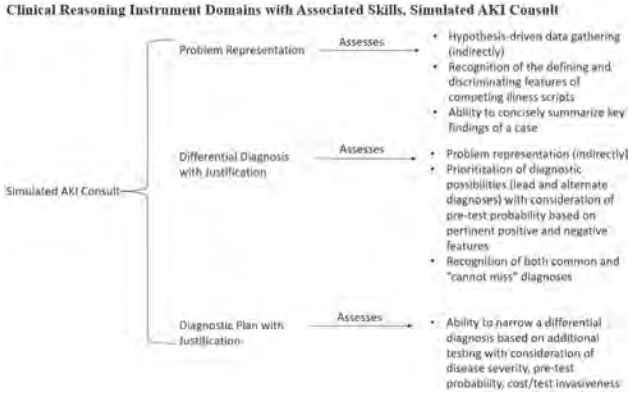
Methods: Experts in nephrology education and clinical reasoning remediation designed an instrument to measure clinical reasoning through a written patient-encounter note from a web-based, simulated AKI consult (https://sites.temple.edu/rene/case-2/). The instrument measured clinical reasoning in three domains (Problem Representation, Differential Diagnosis with Justification, Diagnostic Plan with Justification). Inter-rater reliability was established in a pilot cohort of first-year fellows using a two-way random effects agreement intraclass correlation coefficient (ICC) model. The instrument was then administered to a larger cohort of first-year fellows to establish performance standards for coaching using the Hofstee method.

Results: Both the pilot cohort (n=15 fellows; 4 training programs) and study cohort (n=61 fellows; 20 training programs) were representative of first-year nephrology fellows nationwide. The ICCs for Problem Representation, Differential Diagnosis, and Diagnostic Plan were 0.90, 0.70, and 0.50. Passing thresholds (% total points) in Problem

Representation, Differential Diagnosis, and Diagnostic Plan were 59%, 57%, and 62%. Fifty-nine percent (n=36) met the threshold for coaching in at least one domain.

Conclusions: We provide validity evidence for a simulated AKI consult for formative assessment of clinical reasoning in nephrology fellows. The majority met criteria for coaching in at least one of three reasoning domains, demonstrating a need for assessment and instruction in clinical reasoning.

Funding: Private Foundation Support



The simulated consult measures three domains, which map to a part of the linear clinical reasoning pathway.

FR-PO056

A Qualitative Analysis of Advanced Training in Glomerular Diseases: Results from a Program Directors' Survey

Kenar D. Jhaveri,[1] Insa M. Schmidt,[2] Jun Oh,[4] Laurel J. Damashek,[5] Koyal Jain.[3] International Glomerular Diseases Society Education Committee. *[1]Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY; [2]Boston University, Boston, MA; [3]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [4]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [5]International Society of Glomerular Disease, Boston, MA.*

Background: Several centers around the world offer either an extra year of training in glomerular disease (GD) or focus on specialized GD training during nephrology fellowship. Data on the successes and limitations of advanced fellowship programs or focused training in GD is scant.

Methods: As part of the education committee of the International Society of Glomerular Disease (ISGD), we conducted a 10-question survey of all program directors that offer an advanced year in GD training. Open-ended questions were used to evaluate measures of success and challenges of each program and data were analyzed using thematic content analysis.

Results: 15 programs responded to the survey (>90% response rate). 6/15 programs have had GD specific training for over 15 years; and the remaining ranged from 5-15 years. The majority of the programs were in USA (10/15) and 5/15 programs were located in Europe. 11/15 program graduates entered academia. All had a renal pathologists. The majority (9/15) of programs did not have a formal fellowship curriculum. Fig 1 and Fig 2 discuss success and challenges programs faced with GD fellowships. Success was noted as having departmental resources, multidisciplinary teams and local expertise in GD and protected time for research. Challenges included funding, interest in nephrology, visa issues, lack of resources for patient education in GD.

Conclusions: There is a lack of GD focused training programs in nephrology. Data from this study can help to inform the development of new guidelines and educational curricula for trainees and highlight the need to foster international collaborations that can provide peer support, aid with funding, and promote GD research.

FACTORS CONTRIBUTING TO GD PROGRAM SUCCESS	
Multidisciplinarity	"[We have a] close collaboration with rheumatology and immunology." "We have an interdisciplinary (Nephrology, Rheumatology, Dermatology and OB/GYN) lupus clinic." "We do offer a combined pediatric adult GN clinic [and] training in kidney biopsy." "[We have] nephropathology [as part of the program]." "Integration of our clinics with rheumatology and pulmonary as there is significant overlap in the systemic diseases that result in GD."
Institutional support for research	"Protected time for Clinician Scientists to study GNs and more." "Clinical research opportunities for interested fellows."
Local expertise	"Program directors completed GN fellowships at other institutions." "Multiple faculty members devoted to GN." "Our success is due to massive expertise locally in GN."
Educational curricula	"Dedicated GN clinics that GN fellow attends with 2 attendings allowing for different perspectives on management." "A 2-year fellowship for more longitudinal exposure, and it is tied to doing a Master's degree in clinical epidemiology with a large focus on research." "There is lots of flexibility for fellows to be able to attend on service or join the nephropathology department."
Patient-related factors	"Clinically we have a lot of patients coming to our institution and that provides a wealth of knowledge and experience for our GN fellows." "Wide variety of referral cases." "Large and diverse patient population"

Fig 1

CHALLENGES FOR GD PROGRAMS	
Financial resources/funding	"Finding money to pay fellow salaries." "[Get] funding for an additional year of training in glomerular disease." "Funding - we don't have specific funding for fellowships; hence our "fellows" have to do a lot of ordinary renal residency work. [There's] great demand for properly funded GN fellowships."
Political factors/ US immigration	"Inability to recruit fellows with visas." "Inability to hire J-visa candidates." "Interested people are often from overseas and as there is clinical work, state board licensure becomes an issue."
Declining interest in nephrology and nephrology research	"The number of young doctors interested in nephrology is gradually decreasing." "Appointment of young physicians due to the burden of this specialty [is difficult]." "Finding fellows who want to do basic, translational, and clinical research..." "Identifying nephrology fellows interested and dedicated to doing 2 years of extra training."
Healthcare and patient-related factors	"Many of our patients are non-English speaking with limited health literacy, which complicates understanding of diagnosis and potential treatment options." "Reimbursement of biologicals [is an issue]."

FR-PO057

Results and Economic Benefits of the Implementation of an Interventional Nephrology Program in a Third-Level Center in Mexico City

Fernando A. Cuellar-Gonzalez,[1,2] Sebastian Consuegra-Flores,[1,2] Mauricio Arvizu Hernández.[1,2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Tecnologico de Monterrey - Campus Ciudad de Mexico, Ciudad de Mexico, Mexico.*

Background: Diagnostic and Interventional Nephrology (DIN) is an area of great interest and growth, it has shown great operational utility in the departments. Since 2015, a DIN program has been started in our center, with an area of ultrasound equipment and procedures. It has shown significant benefits for patients and in the training of nephrology residentss, mainly in renal graft biopsies (RGB), vascular access (VAs) and kidney biopsies (KB).

Methods: A retrospective, observational and descriptive study. RGB procedures (January/2015-May/2023) and VAs (July/2017-May/2023) were included; RGBs are performed on an outpatient basis; VAs with USG guidance, without fluoroscopy, with local anesthesia.

Results: A total of 4,092 procedures were performed, 2,167 RGBs (52.9%); 931 (22.7%) VAs for HD and KB 994 (24.2%). The most frequent indication for RGB was by protocol 699 (32.2%) and the presence of DSAs 586, (27%); 2115 (97.6%) were successful, and there were 52 complications (2.3%), 8 (0.3%) serious. Of the VAs, 601 (64.5%) were non-tunneled catheters (NTC) and 327 (35.1%) tunneled catheters (TC); the most frequent indications were chronic HD 438 (47%) and uremic syndrome 161 (17%); there were 57 complications (6.1%), 1 death. The economic burden reduction (EBR) was US $318.83 for each RGB and a total of US $690,904 (in 8 years). The EBR of the NTC VAs was US $140.59 per procedure, and a total of US $84,494 and for each TC the savings were US $179 with a total of US $58,533 (in 7 years). The EBR of the KB was US $214.25 per procedure, and a total US $212,964. The EBR of all procedures was US $1,046,895.

Conclusions: The implementation of the NDI program has yielded significant cost reductions of at least US $1,046,895 while ensuring the safety and well-being of patients. Beyond its financial impact, the program has also had broader benefits, including the advancement of resident training and the establishment of a specialized diploma in interventional nephrology of comprehensive 6-month training program and university validity, equips aspiring interventional nephrologists with essential skills and knowledge, solidifying its value in the field of nephrology education and practice.

FR-PO058

Nephrology Associate Program Director and Core Faculty Survey: Protected Time for Training Program Administration

Christina M. Yuan,[1] Brian Y. Young,[2] Maura A. Watson,[1] Amy N. Sussman.[3] *[1]Walter Reed National Military Medical Center, Bethesda, MD; [2]University of California Davis School of Medicine, Sacramento, CA; [3]The University of Arizona Health Sciences, Tucson, AZ.*

Background: In 2024-25, the Accreditation Council for Graduate Medical Education (ACGME) will require core faculty to have 4 hrs/week of protected time for program administration. Associate program directors (APDs) must receive 4 hrs/week (more if >6 fellows). Program directors (PDs) surveyed in April 2022 reported protected time for core faculty was a median 1.5 hrs/week (39% had none) and a median 4 hrs/week for APDs.

Methods: In a follow-up survey of all US adult nephrology PDs (March 2023), we asked PDs to forward an anonymous survey link to APDs/core faculty, and to indicate how many were sent. We asked APDs and core faculty how much protected time they had, to indicate their program-related tasks, and estimate time needed to perform them.

Results: 57/149 (38%) of PDs forwarded the link to 454 faculty. Response was 27% (121/454); 87% completion. 52/57 PDs who forwarded the link had an APD; 94% (49/52) responded. 50% of PDs reported their APD had <4 hrs/week protected time. 37% had none. APDs had a median 2 hrs/week (IQR 0,4), and estimated needing 5 hrs/week (IQR 4.25,8) to effectively fulfill their role, regardless of program size. 67/402 (17%) core faculty responded. PDs reported faculty protected time was 2 hrs/week (IQR 0,4). 41% had none. Core faculty had a median 0.5 hours/week (IQR 0-2.75), and estimated needing

4 hrs/week (IQR 2.25, 5.75) to effectively fulfill their role, regardless of program size. 90-100% taught fellows during clinical rotations. >95% gave lectures; >85% attended conferences; >95% did fellow evaluations. 73% of APDs and 56% of faculty assisted in fellow remediation. 90% participated in recruitment; >85% mentored scholarly work; >60% mentored quality/safety training. APDs commonly managed rotations (62%) and wellness events (55%). 27% of APDs and 20% of faculty were at high risk for emotional exhaustion, reporting feeling "burned out from my work" daily or a few times a week.

Conclusions: APDs and core faculty have little protected time for program administration/didactic teaching, despite contributing substantially in these areas. About 40% have none. They estimate needing 4-5 hrs/week to effectively do their work, regardless of program size. *The views expressed in this abstract are those of the authors and do not necessarily reflect the official policy of the Department of Defense or the U.S. Government.*

FR-PO059

A Comparative View of Early Career and Established Nephrologist Perspectives

Stephen Regan. *Spherix Global Insights, Exton, PA.*

Background: As nephrologists transition from fellowship to an established clinical practice, their perspectives change regarding areas of interest, perceived unmet needs, and approaches to treatment. This analysis of nephrology fellows, early career, and established nephrologists reveals differences in viewpoints based on tenure.

Methods: Responses were collected from established nephrologists with over 10 years in practice (n=50), new nephrologists with 2 to 5 years in practice (n=37), and current nephrology fellows (n=44) via an online survey in August 2022. Respondents were required to spend at least 70% of their professional time in a clinical setting seeing patients.

Results: Glomerular diseases are a top area of interest for nephrologists, regardless of their tenure. Nuances exist in other areas, as established and new nephrologists show a greater interest in critical care nephrology (60% new, 50% established) and hypertension (38% new, 50% established) compared to fellows (41% and 25%, respectively). While 45% of current fellows rank dialysis/modalities within their top three areas of interest, nearly half feel unprepared to manage peritoneal dialysis patients, and this only increases to 79% for home hemodialysis patients. Interestingly, despite encouragement within the industry to transition more dialysis patients to home modalities, new and established physicians show greater interest in other topics. Perspectives on unmet needs for new therapeutic agents to treat specific conditions also differ by tenure. AKI is perceived as having a high unmet need by 64% of established nephrologists, compared to 27% of new nephrologists and 41% of fellows. Within glomerular diseases, newer practitioners perceive a greater unmet need for IgA nephropathy (39% fellows, 41% new), while only 16% of established nephrologists share the same sentiment. KDIGO guidelines are followed more closely by fellows, 91% of whom report that they always reference them when making treatment decisions. Established and new nephrologists instead rely more heavily on their own clinical experience.

Conclusions: As a nephrologist's career progresses, their interests become narrower and more specialized based on clinical experience. Nephrology fellows often express more innovative views but many report feeling ill-prepared for the movement of dialysis patients to home modalities.

FR-PO060

Institute of Nephrology

Mihran V. Naljayan,[1,2] Mackenzie Cecil,[1] Tim Mcdevitt,[1] Adam J. Weinstein.[1]
[1]DaVita Inc, Denver, CO; [2]Louisiana State University, Baton Rouge, LA.

Background: Home dialysis has shown to have potentially positive clinical and lifestyle impacts for many patients such as preserving residual kidney function or flexibility with schedules when compared to in-center hemodialysis (ICHD). However, peer-reviewed research suggests that nephrologists receive inadequate exposure to home dialysis during their fellowships, creating a barrier to increasing the use of home dialysis. Moreover, use of home dialysis in the US is lower than in many other developed countries. It is therefore crucial to improve nephrologists' competence in home dialysis as a way to improve patient care and access. We are addressing these challenges with a new virtual educational platform for nephrologists, advanced practice providers and nephrology fellows: the Institute of Nephrology (IoN).

Methods: IoN offers online courses on a variety of home dialysis topics, selected based on numerous interviews and surveys of practicing nephrologists. Content is self-paced to accommodate physicians' busy schedules and aligns with nephrologists' preference for interactive, case-based content. Nationally-recognized home dialysis experts developed the content on subjects such as mitigating peritoneal dialysis (PD) transfer to ICHD, peritonitis, Home dialysis prescription optimization, embedded PD catheters, and urgent start PD. Additionally, the courses are accredited for Continuing Medical Education and Maintenance of Certification credit, allowing nephrologists to satisfy licensure requirements while building knowledge in home dialysis.

Results: In the first three months after the launch, 600 of nephrologists have accessed IoN. The most popular topic has been Urgent Start PD, an important area for increasing the number of patients starting on PD and helping patients be successful on that modality. IoN users have varied widely in their familiarity with home dialysis: while 2/3 of users have > 20% of their patients on home dialysis, 25% of users have no patients treating on home dialysis.

Conclusions: The early results of IoN suggest that there is appetite in the nephrologist community for more education on home dialysis. Nephrologists play a vital role in supporting their patients' modality selection and treatment; resources such as IoN empower nephrologists to address gaps in nephrology fellowships in a single platform dedicated to home dialysis education and may improve the utilization of home dialysis in the US.

FR-PO061

AKI Education of Internists: A Needs Assessment

Sahil P. Sanghani,[1] Michael Heung,[2] Patricia F. Kao.[3] *[1]Washington University in St Louis John T Milliken Department of Medicine, Saint Louis, MO; [2]University of Michigan Michigan Medicine, Ann Arbor, MI; [3]Washington University in St Louis, St Louis, MO.*

Background: Acute kidney injury (AKI) is one of the most common complications of hospitalized patients. The pooled incidence in North America is estimated to be 22.3%, and the rate of AKI has been increasing. Many patients with AKI are managed by internists during and after hospitalization. As the Society of General Internal Medicine (SGIM) and the Society of Hospital Medicine (SHM) are major internal medicine meetings focusing on high-yield education for internists, we examined the prevalence of AKI-related education at their annual meetings.

Methods: This is a retrospective review of SGIM Annual Meeting session titles, session agendas, and accepted abstracts, and SHM Converge accepted abstracts from 2018-2022. SHM session titles and agendas are not publicly available. Any session title or description, or abstract containing keywords "kidney," "renal," or "nephrology" was manually reviewed by authors for relevance to: A) prevention of AKI, B) treatment of AKI, C) post-AKI care. Descriptive analysis was performed.

Results: Among 5203 research abstracts presented at SGIM and SHM national meetings from 2018-2022, a total of 259 (5.0%) abstracts contained one or more keywords. Of the keyword positive abstracts, 57 (1.1% of the total abstracts) were related to AKI (Figure). Of those, 38 abstracts (67%) were related to prevention of AKI, 7 abstracts (12%) were related to treatment of AKI, and 12 abstracts (21%) explored post-AKI care. Among the 1022 sessions at SGIM and their descriptions in that timeframe, only 2 contained the keywords, neither of which were directly related to prevention, treatment, or management of AKI.

Conclusions: Despite the clinical importance of AKI and the fact that patients with AKI are frequently managed by internists, we identified no SGIM Annual Meeting sessions dedicated to AKI education over a 5-year period. Between SGIM and SHM, only 1% of accepted abstracts over the last 5 years were related to AKI, with a nominal decline in number since 2019. These findings suggest a substantial need to increase AKI education opportunities for internists.

FR-PO062

Insights from the ASN Kidney Week 2022 Point-of-Care Ultrasound Precourse

Abhilash Koratala,[1] Nathaniel C. Reisinger.[2] *[1]Medical College of Wisconsin, Milwaukee, WI; [2]University of Pennsylvania, Philadelphia, PA.*

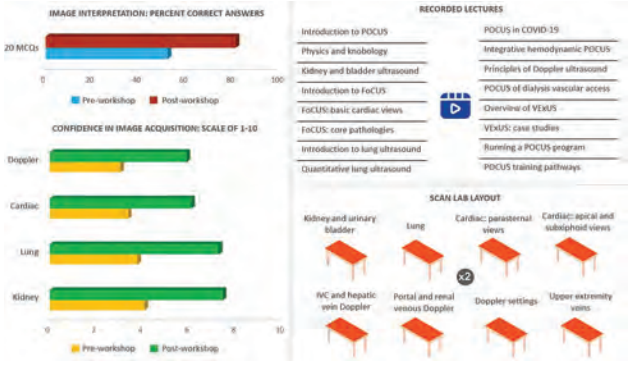
Background: A multi-organ point of care ultrasound (POCUS) precourse was offered at the ASN Kidney Week in November 2022 with the objective of introducing core theoretical concepts and image acquisition techniques to practicing nephrologists and trainees, co-chaired by the authors. We share some insights from the course.

Methods: The course was limited to 80 registrants and had full attendance. It was conducted in hybrid format consisting of on-demand virtual content and an in-person hands-on workshop. The virtual content comprised of video lectures listed in the Figure, which were provided to the registrants prior to workshop. The in-person workshop consisted of a refresher lecture and hands-on practice on healthy subjects. 2 identical scanning rooms (40 attendees per room) were set up with 8 stations each teaching a predefined sonographic application (see Figure). We conducted anonymous pre- and post-course surveys to assess the impact of the training on participants' knowledge, confidence, and satisfaction.

Results: The pre- and post-course surveys were answered by 60 and 46 registrants respectively (response rate of 75% and 57.5%). The mean % of correct answers on the pre-course survey (image interpretation) was 51.9 ± 20.4, which significantly increased to 81 ± 13.1 on the post-test ($p<.001$). Similarly, the self-reported confidence in image acquisition improved from 3.56 ± 0.4 to 6.66 ± 0.7 on a scale of 1-10 ($p<0.001$) after

the workshop. 41.9% of the post-course survey respondents felt that the course met their expectations whereas 51.2% reported it exceeded their expectations. Most attendees reported lack of protected time, inadequate expert supervision and limited availability of ultrasound mahines as barriers to continued POCUS practice at their institutions.

Conclusions: The POCUS course led to significant improvement in the knowledge and confidence of the participants. Nonetheless, as we cannot expect anyone to master physical examination by attending a one- or two-day workshop, same applies to POCUS and continued hands-on practice is the key to achieving mastery.



FR-PO063

Nephrologist-Led Cardiac Point-of-Care-Ultrasound (POCUS) Workshop Using High-Fidelity Simulation: Insights and Observations

Abhilash Koratala, Hari R. Paudel, Kevin R. Regner. *Medical College of Wisconsin, Milwaukee, WI.*

Background: Cardiac point of-care-ultrasonography (POCUS) is an integral component of bedside volume status assessment. We sought to explore the effectiveness of a short simulation-based POCUS workshop for medical students taught by a nephrologist.

Methods: Workshops were conducted for two different groups of 4th year medical students with a total of 25 attendees. The workshop consisted of a 1-hour lecture followed by 15 minutes of cardiac anatomy simulation and a 2-2.5-hour hands-on session in the simulation laboratory [Fig 1]. An anonymous pre-course survey comprising of 10 questions assessing the interpretation of common greyscale POCUS findings encountered in patients with undifferentiated hypotension was performed. A post-course exam and feedback survey were also administered.

Results: 23 and 20 students answered the pre- and post-course surveys, respectively. The mean total score on the pre-test was 63.8% ± 13.6%, which significantly increased to 91.5% ± 10.5% on the post-test (P<.001). 90% of the respondents strongly agreed that the cardiac anatomy simulation improved their understanding of the cardiac sonographic anatomy. 75% strongly agreed that the hands-on simulation enhanced their confidence in image acquisition and interpretation. 70% said they would choose nephrology elective if POCUS training was integrated with it [Fig 2].

Conclusions: A Nephrologist-led diagnostic POCUS workshop using simulation techniques is effective may increase medical student interest in Nephrology elective rotations

FR-PO064

Simulation of Ultrasound-Guided Renal Biopsy Using a Novel Custom-Made Training Model

Ji Hwan Kim, Jinha Jang, In Soo Kim, Jung Nam An, Jwa-kyung Kim, Sung Gyun Kim, Hyungseok Lee. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

Background: Kidney biopsy is a critical procedure in nephrology fellowship training, necessitating extensive simulation to prevent biopsy-related complications. There's a need to practice optimizing ultrasound imaging and guiding the biopsy needle to target points in real-time images. We introduce a novel, cost-effective renal biopsy training model.

Methods: We developed a model using Konjac jelly and soft-boiled chicken or duck eggs to simulate ultrasound-guided renal biopsy. The soft-boiled eggs' yolk and egg white were distinctly depicted in grayscale images due to their differences in echogenicity, resembling the renal sinus and corticomedullary area of the kidney's lower pole (Figure 1A). Trainees were instructed to sample the egg white selectively. The biopsied yolk and egg white samples were easily distinguishable with the naked eye (Figure 1B), allowing trainees to verify if the sample was successfully obtained from the target with immediate feedback. The materials were readily available, and the model was easy to construct and reproduce. Trainees were able to simulate the operation of biopsy devices, optimize ultrasound imaging, and guide the biopsy needle in real time.

Results: Nephrology fellows underwent the simulation training using the model before performing kidney biopsies on patients. After implementing this curriculum, a total of 186 kidney biopsies were performed from March 3, 2022, to May 20, 2023. Biopsies were conducted with a 16-gauge needle under ultrasound guidance. There were no failed procedures. Complications included three minor hematomas that resolved with bed rest and one arteriovenous fistula that was treated with coil embolization. In pre- and post-training surveys, trainees' confidence levels in performing renal biopsies significantly improved.

Conclusions: This novel model may assist nephrology fellows in familiarizing themselves with biopsy procedures and enhancing their skills before commencing renal biopsies in a clinical setting.

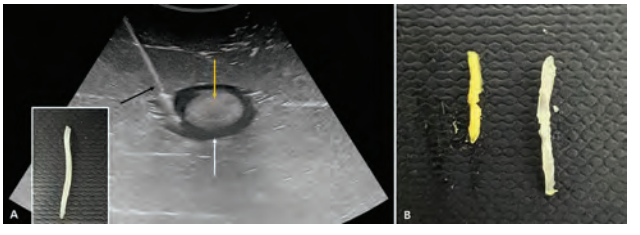

Figure 1.A. A duck egg embedded in Konjac jelly (white arrow: the egg white, yellow arrow: the yolk, black arrow: biopsy needle). B. the yolk (left) and egg white (right)

FR-PO065

Virtual Nephron: Assessment of a Virtual Reality (VR) Educational Tool

Elias Bassil,[1] Ali Mehdi,[1] Susana Arrigain,[2] Jesse D. Schold,[2] John R. Sedor,[1] Joseph V. Nally,[1] John F. O'Toole,[1] S. Beth Bierer,[1] Jonathan J. Taliercio,[1] Georges Nakhoul.[1] *[1]Cleveland Clinic, Cleveland, OH; [2]University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Recent technological advancements within the VR sphere have allowed for the development of innovative technological tools. Using funding from ASN's Bennett Clinical Scholars Program, we developed a 3D VR physiology course and assessed its efficacy on learners' knowledge gains.

Methods: Internal medicine PGY1 residents were randomized into 2 groups: a VR group (exposed to the VR session) and a traditional group (received a printed script of the VR learning course). The VR session consisted of a 3D review of water and electrolyte transport across the nephron and of the mechanism of action of diuretics. Within a week of the intervention, both groups underwent a 2-hour seminar on physiology of solute/water transport and diuretics. Knowledge acquisition and retention were assessed with a test administered immediately after the conclusion of the 2-hour seminar and repeated within 6-12 weeks. The 40-question test was issued using the secure platform RedCAP. Tests were anonymous, thereby preventing paired test comparisons. We used independent t-tests to compare the number of correct answers and the percent correct between the VR and traditional groups. Initial and follow up tests were evaluated separately.

Results: Of the 188 PGY1 residents who were scheduled and randomized to participate, 117 completed the initial testing. Sixty-four were randomized to the VR group and 53 were randomized to the traditional group. 51.3% of participants were males and average age was 27.3±2.0 years old. Initial test results showed higher scores among VR compared to the traditional group (76.5% correct vs. 68.8%, Table 1). Seventy-eight PGY1s participated in the follow up testing (46 VR group vs. 32 traditional group). Results of the follow up test showed no significant difference in test results. Test score results are summarized in Table 1.

Conclusions: The 3D VR platform appeared to have improved short-term learning but without improving long-term retention. A larger student cohort with longer term follow up will help assess the long-term impact of VR technology and its effect on transfer of learning.

Table 1. Test results by group participation

Initial Test Score Results	Overall (N=117)	VR (N=64)	Traditional (N=53)	p-value
Score out of 40 questions, Mean ± SD	29.2±5.0	30.6±4.4	27.5±5.3	<0.001
Percent correct, Mean ± SD	73.0±12.6	76.5±11.1	68.8±13.2	<0.001
Follow up Test Score Results	**Overall (N=78)**	**VR (N=46)**	**Traditional (N=32)**	**p-value**
Score out of 40 questions, Mean ± SD	26.2±5.0	26.6±5.2	25.6±4.7	0.40
Percent correct, Mean ± SD	65.5±12.5	66.5±13.0	64.1±11.7	0.40

FR-PO066

Success of Virtual Patient Simulation at Improving Management of CKD-Associated Pruritus

Amy Larkin, Donald Blatherwick. *Medscape Education, New York, NY.*

Background: We sought to determine if online, virtual patient simulation (VPS)-based continuing medical education (CME) can improve performance of nephrologists and primary care physicians (PCPs) related to comprehensive management of chronic kidney disease sssociated pruritus (CKD-aP).

Methods: The intervention comprised two different patients presenting at a given time points in a VPS platform that allows learners to order lab tests, make diagnoses, and prescribe treatments similar to actual practice. Tailored clinical guidance (CG), based on current evidence, was provided after each decision, followed by the opportunity to modify the decision. Decisions were collected post-CG and compared with each user's baseline (pre-CG) using a McNemar's test to determine *P* values. The activity posted September 2022; initial data were collected through December 2022.

Results: 281 nephrologists and 234 PCPs completed the activity (all decisions within at least 1 case) and were included. Case 1: 13% increase of nephrologists (67% pre-CG vs 80% post-CG; P<.001) and 11% increase of PCPs (76% pre-CG vs 87% post-CG; P<.01) who ordered a patient health questionare-9 (PHQ-9) assessment 28% increase of nephrologists (56% pre-CG vs 84% post-CG; P<.001) and 29% increase of PCPs (45% pre-CG vs 74% post-CG; P<.01) who diagnosed CKD-aP 46% increase of nephrologists (6% pre-CG vs 52% post-CG; P<.001) and 45% increase of PCPs (0% pre-CG vs 45% post-CG; P<.001) who ordered difelikefalin for a patient with CKD-aP 37% increase of nephrologists (11% pre-CG vs 48% post-CG; P<.001) and 38% increase of PCPs (10% pre-CG vs 48% post-CG; P<.001) who ordered an antileptic agent for a patient with CKD-aP Case 2: 24% increase of nephrologists (51% pre-CG vs 75% post-CG; P<.001) and 30% increase of PCPs (47% pre-CG vs 77% post-CG; P<.001) who diagnosed CKD-aP 38% increase of nephrologists (16% pre-CG vs 54% post-CG; P<.001) and 35% increase of PCPs (13% pre-CG vs 48% post-CG; P<.001) who treated CKD-aP.

Conclusions: VPS that immerses and engages specialists in an authentic and practical learning experience can improve evidence-based clinical decisions related to comprehensive management of CKD-aP.

FR-PO067

Providing Patient-Centric Education in Type 2 Diabetes and CKD: The "YOU" Project™

Pablo E. Pergola,[1] Cynthia Ramos,[1] Norma A. Rosales,[1] Jeannine Oconnor,[2] Edmund H. Doherty.[3] *[1]Renal Associates PA, San Antonio, TX; [2]CTI BioPharma Corp, Seattle, WA; [3]Bluejay Medical Affairs Consulting, Dallas, TX.*

Background: Recently, we have seen many new and impactful therapeutic options to treat Type 2 Diabetes (T2D) and Chronic Kidney Disease (CKD). Clinicians are challenged to educate patients with TD2 and CKD during a limited appointment time. To address this, we created a simple patient-centric education tool to help them understand the factors impacting their disease, treatment guidelines, and medication options to positively impact disease progression. We assessed how the tool impacted patient knowledge.

Methods: As of this submission, 43 patients with CKD completed a questionnaire PRE (5 questions) and POST (7 questions) clinic visit to assess knowledge.

Results: See Table.

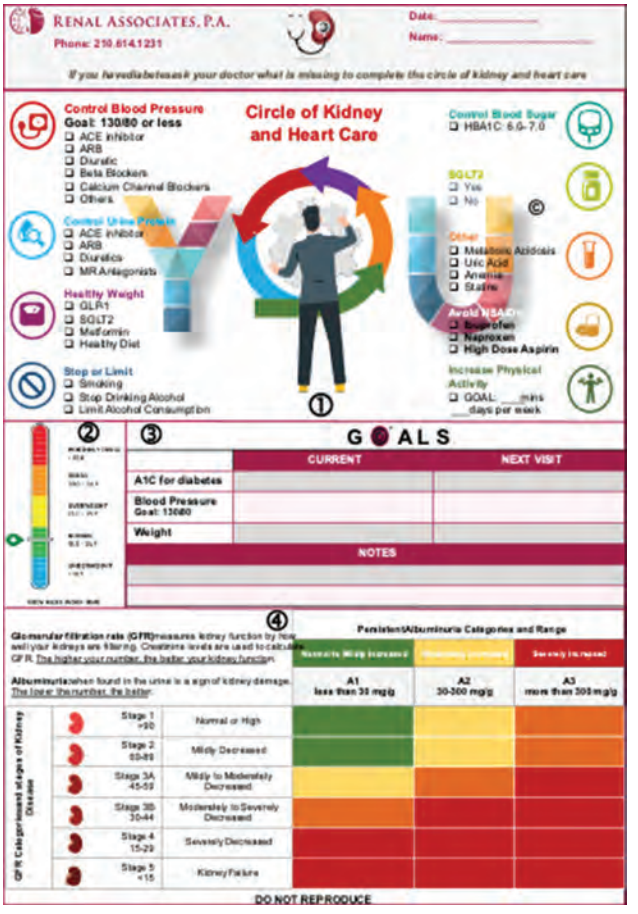
Conclusions: The "YOU" patient education tool was well received by patients and allowed clinicians to cover a broad range of information efficiently. All patients showed consistent improvement in their knowledge of disease state, laboratory values, factors that can delay progression, and various medications used, while having a guide to take home and track progress. Patients will be followed, and long-term benefits described in a future publication.

Funding: Clinical Revenue Support

RESULTS

QUESTION	PRE-TEST	POST-TEST	% CHANGE
I am very clear in my understanding of the stage of my kidney function	3.8	4.8	+20%
I am very clear in my understanding of how to protect my kidneys	3.9	4.7	+16%
I am very clear in my understanding of my blood pressure, labs and which medications manage it	4.1	4.7	+12%
I am very clear in my understanding of how to manage excess protein in the urine	2.8	4.0	+24%
I am very clear in my understanding of how to control diabetes (blood sugar)	3.4	3.9	+10%
(POST ONLY) The tool that the Doctor provided helped me to better understand my medical conditions and how to better manage it	Very Helpful: 31 Patients Helpful: 12 Patients		
(POST ONLY) What section of the tool did you find most useful?	The YOU Circle: 28 Patients GFR: 12 Patients Goals: 2 Patients BMI: 1 Patient		

5 = Strongly Agree, 4 = Agree, 3 = Neither or N/A, 2 = Disagree, 1 = Strongly Disagree. Note: It is very likely that patients overestimated their knowledge base when being asked pre-test questions. 43 patients agreed that the "YOU" educational tool improved their comprehension and understanding of kidney disease.



FR-PO068

EMR-Based CKD Patient Education and Decision Support in Primary Care Improves Patient Satisfaction

Julie A. Wright Nunes,[1] Akinlolu Ojo,[2] Corey C. Powell,[1] Audrey Fan,[1] Anita M. Devine,[1] Tammy Ellies,[1] Katie Grzyb,[1] Luis M. Garcia-Guzman,[1] Andrea L. Oliverio,[1] Emily P. Chen,[1] Angela Fagerlin.[3] *[1]University of Michigan, Ann Arbor, MI; [2]University of Kansas School of Medicine, Kansas City, KS; [3]University of Utah Health, Salt Lake City, UT.*

Background: We pilot-tested an EMR-based CKD patient education and decision support tool in primary care. Systems engineering optimized seamless integration into clinical workflow.

Methods: With input from patients and providers we developed an EMR-based patient education and decision support tool called an Encounter Decision Intervention (EDI). The EDI was designed to be used during primary care encounters when patients and providers discussed a CKD diagnosis and decided on management steps. Patients were enrolled into an intervention (received EDI) or control group (did not receive the EDI) using a prospective, cross-sectional design. Measurement of outcomes occurred after patient visits via validated surveys of patient perceived and objective kidney disease knowledge, CKD-specific stress, and satisfaction. Chi-square tests, t-tests, and Kruskal-Wallis were used to detect associations between outcomes and measured characteristics, as appropriate.

Results: Seventy-four patients completed the pilot study (37 per group). There were no statistically significant differences in patient characteristics between groups, nor were there statistically significant differences in overall kidney objective knowledge (mean (SD) of 67 % correct (15)), perceived knowledge (mean (SD) out of 4 total, 3.0 (2.1)) or CKD-specific stress (1.9 (0.7)). Satisfaction scores with provider communication, care, and providers themselves were all significantly higher in the intervention group: The proportion of participants rating satisfaction with provider communication as all 5's (scale 1-5), showed n= 16 (43%) in usual care and 30 (81%) in the EDI group, p=0.0016. For satisfaction with care, 26 (70%) in usual care and 35 (95%) in the intervention group rated all 5's, p=0.012. The proportion of patients rating all 5's for satisfaction of providers themselves were 29 (78%) in the usual care group and 36 (97%) in the EDI group, p = 0.028. All three satisfaction scores remained statistically significant in multivariate analysis. Patients rated use of the EDI high (4.1 (out of 5) CI 3.8-4.4).

Conclusions: The EDI was seamless to care delivery and associated with more patients who were very satisfied with provider communication, overall care, and the primary care providers themselves.

FR-PO069

A Pilot Plant-Based Cooking Class to Improve CKD Patient Education

Linda-Marie U. Lavenburg, Alayna L. Letteri, Manisha Jhamb. *University of Pittsburgh, Pittsburgh, PA.*

Background: Diet has a crucial role in chronic kidney disease (CKD) management, but patients experience barriers such as limited knowledge, cooking skills, and conflicting dietary restrictions with other comorbidities. We previously designed and implemented a plant-based cooking class for nephrology providers to unify counseling to the updated Kidney Disease Outcomes Quality Initiative dietary guidelines. We adapted feedback from the provider classes to design and pilot a CKD plant-based cooking class for patients aimed at making CKD education more actionable compared to the conventional lecture-based format.

Methods: A renal dietitian and chef created a menu of plant-based meals and modified recipes to minimize sodium and ensure low to moderate phosphorus, potassium, and protein content. We recruited adult (age ≥ 18 years) patients and their support persons from a university-affiliated nephrology clinic and a local dialysis unit. We administered a pre-class phone survey to determine baseline cooking skills, meal planning, and understanding of a CKD diet. The 3-hour hands-on CKD cooking class was led by a chef and included a knife skills component. During the class, two nephrologists and a renal dietitian provided practical education on a plant-based kidney friendly diet. Recipe cards with nutrient content and estimated price per meal were provided. Participants completed a satisfaction survey at the cooking class. We present descriptive statistics of the baseline and satisfaction surveys.

Results: Of 11 participants who completed two surveys and attended the pilot CKD plant-based cooking class, 9 were female, 6 were black, and 7 had CKD stage ≥ 3, which included 3 who are dialysis-dependent. At baseline, 73% of respondents reported intermediate to advanced cooking skills, but 45% were not confident in their ability to describe a diet good for kidney health. All 11 class attendees reported high satisfaction and 91% reported improved understanding of a CKD diet, a high likelihood of changing eating patterns and attending another class.

Conclusions: A hands-on plant-based cooking class is an accepted and effective method to improve understanding of a healthful CKD diet and provide actionable steps to adopt plant-based eating. A follow-up survey will assess if participants actually changed their diet, and future classes will provide opportunity to collect additional participant feedback.

Patient Questions Related to Peritoneal Dialysis: An Analysis of Online Search Data

Kavya M. Shah,[1] Anthony Zhong,[2] Monica Taing,[3] Li-Li Hsiao.[4] *[1]Harvard University, Cambridge, MA; [2]Harvard Medical School, Boston, MA; [3]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada; [4]Brigham and Women's Hospital Department of Medicine, Boston, MA.*

Background: End-stage renal disease patients must often decide whether to receive peritoneal dialysis (PD) or hemodialysis (HD), and much of the academic literature has focused on comparing quality of life differences between PD and HD. However, the type of information that patients themselves seek when considering PD is relatively unknown. As more patients utilize the Internet to access health information, understanding PD search trends can help identify areas for targeted improvement in patient education. Here, we address this knowledge gap by characterizing online search data related to PD.

Methods: In May 2023, Google search data based on the term "Peritoneal Dialysis" were analyzed using "Search Response" (https://searchresponse.io/), a search engine optimization tool. Searches were performed for the most common People Also Ask (PAA) questions against a dataset of over 150 million queries, and the top 100 PAA questions relevant to the "Peritoneal Dialysis" keyword were ranked based on popularity. Two reviewers (AZ and MT) independently grouped the questions into categories adapted from standards in the literature, and a third reviewer (KMS) resolved any discrepancies.

Results: The Search Response tool generated 1,747 PAA questions for "Peritoneal Dialysis." Coding of the top 100 questions revealed that the greatest number of questions related to Procedure (41) (e.g., "What are the steps in peritoneal dialysis?"), Complications (14) (e.g., "What are the side effects of peritoneal dialysis?"), Definition (10) (e.g., "What are the types of peritoneal dialysis?"), Prognosis (8) (e.g., "How long can you live on peritoneal dialysis?"), Quality of Life (8) (e.g., "Can you swim with a peritoneal dialysis catheter?"), and then Comparison to Other Forms of Dialysis (6) (e.g., "Which is better hemodialysis or peritoneal dialysis?"). Thirteen questions were uncategorized (e.g., "How long is training for peritoneal dialysis?").

Conclusions: The most common theme for questions related to PD was Procedure, which reveals a knowledge gap in the procedural aspects of PD. While it is important to compare different treatment options from a quality of life standpoint, providers should take steps to thoroughly educate patients about the procedural details surrounding PD (e.g., the equipment used or the steps involved in PD) to address patients' most common questions and informational needs.

FR-PO071

Investigating Online Search Trends to Improve Patient Education in Nephrolithiasis

Kavya M. Shah,[1] Anthony Zhong,[2] Monica Taing,[3] Li-Li Hsiao.[4] *[1]Harvard University, Cambridge, MA; [2]Harvard Medical School, Boston, MA; [3]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada; [4]Brigham and Women's Hospital Department of Medicine, Boston, MA.*

Background: Nephrolithiasis can cause severe pain and affects one in ten individuals globally. Successful treatment requires patient cooperation, and managing the condition can be complex. While a variety of interventions ranging from citrate supplements to hydrochlorothiazide to shock wave lithotripsy exist, patients' informational needs for nephrolithiasis are not well understood within the literature. As an increasing number of patients turn to the Internet for health information, analyzing search trends offers an opportunity to identify knowledge gaps and improve health literacy. Here, we characterize online search data related to nephrolithiasis to inform efforts to improve targeted patient education.

Methods: In May 2023, Google search data based on the term "Kidney Stones" were analyzed using "Search Response" (https://searchresponse.io/), a search engine optimization tool. Searches were performed for the most common People Also Ask (PAA) questions against a dataset of over 150 million queries, and the top 100 PAA questions relevant to the "Kidney Stones" keyword were ranked based on popularity. Two reviewers (AZ and MT) independently grouped the questions into categories adapted from standards in the literature, and a third reviewer (KMS) resolved any discrepancies.

Results: The Search Response tool generated 19,376 PAA questions for "Kidney Stones." Coding of the top 100 questions revealed that the greatest number of questions related to Management and Nutrition (31) (e.g., "What is the best food to eat when you have kidney stones?"), Treatment and Medication (25) (e.g., "What is the best treatment for kidney stones?"), Definition, Diagnosis, and Symptoms (20) (e.g., "What are the 4 types of kidney stones?"), and then Causes, Risk Factors, and Prevention (15) (e.g., "What are the main causes of kidney stones?"). Nine questions were uncategorized (e.g., "How painful is a stent for kidney stones?").

Conclusions: The most common themes for questions regarding nephrolithiasis were Management and Nutrition, followed by Treatment and Medication; Definition, Diagnosis, and Symptoms; and Causes, Risk Factors, and Prevention. Therefore, targeted provider information about nutrition and other lifestyle interventions should be prioritized to address patients' most common concerns regarding nephrolithiasis, and may help improve health literacy for this widespread condition.

FR-PO072

Enhancing Patient Education: ChatGPT's Potential in Addressing Dialysis FAQs

Paul W. Davis, Iasmina Craici, Pajaree Krisanapan, Supawit Tangpanithandee, Charat Thongprayoon, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Patient education empowers those with ESKD to understand and navigate their treatment options. FAQs websites are valuable resources for information on dialysis, but AI's effectiveness in addressing patient queries about dialysis remains unexplored. ChatGPT, an AI model powered by natural language processing, has shown promise in providing accurate information across varied domains. This study evaluates ChatGPT's performance in delivering accurate patient education on dialysis.

Methods: A total of 57 patient questions related to dialysis were collected from the official Mayo Clinic website for the purpose of patient education. These questions were categorized into five steps: original questions, paraphrased questions with different interrogative adverbs, paraphrased questions with incomplete sentences, paraphrased questions with misspelled words, and paraphrased questions with verbs and prepositions removed. ChatGPT (March 23 Version) generated responses to each question; the accuracy of its answers was evaluated by nephrologists and compared with the FAQs website.

Results: ChatGPT consistently demonstrated high accuracy by providing correct responses to all 57 questions across various complexity levels and paraphrasing variations. ChatGPT's answers to patient FAQs for 1) original questions, 2) paraphrased questions with different interrogative adverbs, 3) paraphrased questions with incomplete sentences, 4) paraphrased questions with misspelled words, and 5) paraphrased questions with verbs and prepositions removed were all consistently accurate. However, there was one inconsistent response to "what are the requirements for a patient undergoing hemodialysis?"; ChatGPT initially provided the expected requirements related to patient behavior but later included technical requirements for patient dialysis candidacy.

Conclusions: These results highlight the ChatGPT's accuracy in providing education on dialysis across different complexity levels and variations in question paraphrasing, indicating that it has the potential to serve as a valuable resource for patient information on dialysis, supplementing FAQs websites. However, one inconsistency calls for refinement to ensure accurate information. With improvements, AI models potentially can significantly contribute to patient education, further empowering those with ESKD.

Abstract Withdrawn

FR-PO074

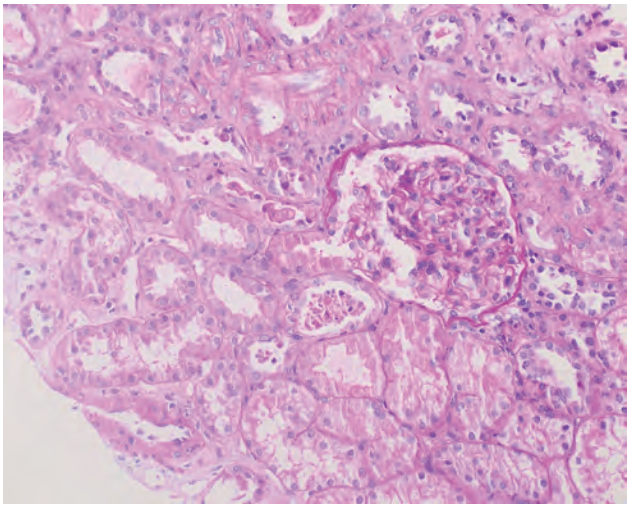
The Cautionary Tale of Co-Administrating Piperacillin-Tazobactam and Vancomycin

Abraham Bell, Gautam Maddineni, Katarzyna Karpinska-Leydier, Ross Huff, Stefan Milutinovic, Tamim Ghith. *Florida State University College of Medicine, Tallahassee, FL.*

Introduction: Vancomycin and piperacillin-tazobactam (Zosyn) are commonly used antibiotics for their broad spectrum of antimicrobial coverage. However, their combined use has been associated with an increased risk of acute renal injury. Despite the widespread use of these antibiotics, there are only a few reported cases where a kidney biopsy was performed to investigate the cause of renal injury.

Case Description: This report presents a unique case of a 40-year-old man with acute refractory diverticulitis who developed acute kidney injury after being treated with vancomycin and piperacillin-tazobactam. The patient had failed outpatient therapy of ciprofloxacin and metronidazole, had a high white blood cell count, and was clinically septic. The infectious disease consultant started the patient on a combination of antibiotics to provide broad coverage of anaerobes and VSE gram positives. Over several days, the patient's creatinine levels increased, leading to the diagnosis of acute kidney injury. Interestingly, the patient had no prior history of renal conditions, and a kidney biopsy was performed to investigate the cause of kidney failure. The biopsy showed acute tubular necrosis (ATN) and mild acute tubulointerstitial nephritis (ATIN). The patient progressed to end-stage renal disease (ESRD) and required hemodialysis but recovered after three months and is now dialysis-free.

Discussion: The findings from this case highlight the importance of carefully weighing the risks and benefits of using antibiotics that have a higher incidence of causing acute kidney injury. In this case, the ability to perform a kidney biopsy allowed for a more accurate diagnosis of kidney failure and highlighted the importance of continued research into the mechanisms behind vancomycin-induced renal injury.



Diffuse ATN and ATIN

FR-PO075

Utility of Urinary Microscopy Score to Identify Patients with Subclinical AKI and Subsequent Clinical AKI

Rolando Claure-Del Granado,[1,2] Diego Torrico-Moreira,[1,2] Jason W. Yang,[3] Pei Lun Lee,[3] Rakesh Malhotra,[3] Jingyao Zhang.[3] *[1]Division of Nephrology, Hospital Obrero No 2 - CNS, Cochabamba, Bolivia, Plurinational State of; [2]Universidad Mayor de San Simon Facultad de Medicina, Cochabamba, Bolivia, Plurinational State of; [3]University of California San Diego School of Medicine, La Jolla, CA.*

Background: ADQI group has proposed a new AKI classification to recognize early stage of AKI termed subclinical (1S) using functional and structural biomarkers. However, these novel structural biomarkers are not available in resource-limited settings. We propose that urinary sediment score (USS), which reflects kidney structural damage could detect subclinical AKI and subsequent development of clinical AKI.

Methods: We included 103 consecutive hospitalized patients who were at moderate to high-risk of AKI using AKI Risk Assessment algorithm (Rizo-Topete et al. Blood Purif. 2017;43(1-3):82-88). Fresh urine was obtained and examined and urine sediment was assigned a score (Perazella et al. score Clin J Am Soc Nephrol 2010 Mar;5(3):402-8.) from 1 to 3 at admission, at 48 hours and at day 7. Renal function was followed up daily up to 7 days. We defined subclinical AKI (ADQI stage 1S) as a urinary sediment score (USS) ≥2 in the absence of rise in serum creatinine (sCr). Clinical AKI was defined by KDIGO sCr criteria and classified using the new propossed ADQI classification (1A, 1B, 2A, 2B, 3A or 3B) depending on the presence or absence of elevated damage (USS) or functional (sCr) biomarkers. We analyzed the predictive value of this scoring system for the subsequent development of clinical AKI, need of kidney replacement therapy (KRT) and mortality.

Results: Among 103 patients, 38% (39/103) have a USS ≥ 2 and were classified as AKI-1S. At 48 hours, 80% (31/39) patients of the AKI-1S group developed clinical AKI. At 7 days, only 9 % of patients with a USS ≤ 1 developed clinical AKI vs. 75% of AKI-1S patients; $p < 0.0001$. A USS ≥ 2 at admission have a good performance in predicting clinical AKI with a ROC-AUC 0.84 (95% CI 0.75-0.92); $p < 0.0001$. Need of KRT (10.3% vs. 1.6%; $p = 0.05$) was higher in patients with AKI-1S vs. patients with normal kidney function who later developed clinical AKI. Mortality was also higher in patients who developed AKI-1S versus patients with normal kidney function at admission (43.6% vs. 14.6%; $p = 0.008$).

Conclusions: Urine sediment score can identify early phase of AKI and will be useful tool to refine the diagnostic and staging criteria for AKI especially in resource-limited settings.

FR-PO076

A Case of Semaglutide-Associated Severe AKI in an Immunocompromised Patient

Devang B. Patel, Amalia Restrepo, Karthik Kovvuru, Juan Carlos Q. Velez, Swetha Rani Kanduri. *Ochsner Medical Center, New Orleans, LA.*

Introduction: Glucagon-like peptide 1 receptor agonists (GLP-1RAs) have been FDA approved for weight loss and are increasingly prescribed for patients with diabetes or obesity. So far, only 3 cases of semaglutide associated acute kidney injury (AKI) were reported. Herein, we report a unique case of a patient with heart transplant who developed rapid worsening of renal function after an increased dose of semaglutide.

Case Description: A 61-year-old woman presented to the hospital with 4 weeks of decreased appetite, 2 weeks of nausea, vomiting and diarrhea. Five months prior to the index hospitalization, semaglutide 0.25 mg was prescribed and the dose was eventually up titrated to 1 mg, 5 weeks prior to the presentation. Symptoms began 1 week after the dose

of semaglutide was increased to 1 mg. Medical history pertinent for heart transplantation, type 2 diabetes mellitus (T2DM) and chronic kidney disease (CKD) 3b. Laboratory data at the time of admission revealed elevated serum creatinine (Scr) of 12.5 mg/dL (baseline 1.5 mg/dL), blood urea nitrogen of 83 mg/dL, tacrolimus level of 2.4 ng/mL, urine protein to creatinine ratio (UPCR) of 1.83 g/g. Urinalysis positive of 1+ protein, 2+ blood and 4 red blood cells per high-power field. Urine microscopy revealed hyaline, granular and a few muddy brown casts. Serological evaluation for acute glomerulonephritis, CMV, EBV, BK PCR resulted negative. Kidney ultrasound was normal. Semaglutide was held on admission and IV fluids were started without improvement in Scr. Kidney biopsy was perfomed and revealed acute tubular injury (ATI) with diffuse flattening of tubular epithelium and brush border attenuation, chronic striped fibrosis secondary to long term exposure to calcineurin inhibitors (CNI) and mild diabetic nephropathy. No immune complex or paraprotein deposits identified by IF or EM. Patient had gradual recovery of renal function with a Scr down to 1.6 mg/dL on last follow up.

Discussion: GLP-1RAs agonists can be associated with severe volume depletion from suppressed appetite and intractable vomiting, predisposing to ischemic ATI. Patients with solid organ transplant and on CNI could be particularly vulnerable. Clinicians should ensure adequate oral intake before escalating the doses and plan a close follow-up.

FR-PO077

GLP-1 Agonists-Associated Kidney Toxicities

Rimda Wanchoo, Purva D. Sharma, Vipulbhai Sakhiya, Kenar D. Jhaveri. *Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY.*

Background: Data on kidney related side effects of GLP-1 agonists have not been well defined. Sparse case reports of AKI have been reported.

Methods: We reviewed the FDA adverse event reporting system (FAERS) and queried for kidney adverse events associated with GLP-1 agonists (semaglutide, exenatide, tirzepatide, liraglutide, albiglutide, dulaglutide, Ozempic, Bydureon, Mounjaro, Victoza, Tanzeum, Trulicity, Saxenda, Byetta) between 2010 and 2022 using search terms all related to AKI, electrolyte disorders and hypertension. SAS enterprise guide v7.12 was used to pull data and analysis.

Results: In the last 12 years, a total of 2375 total kidney related adverse events were reported to the FAERS in reference to GLP-1 agonists. AKI was the most common with 58.65% with equal distribution for male's vs females. HTN(22.02 %) was the next most common event followed by hyperkalemia as the most common electrolyte disorder. Most of the other electrolyte disorders and capillary leak syndrome were uncommon. (Figure). Limitations: The events are reported by providers and/or patients and therefore could have a reporting bias. It is not possible to determine whether an event is truly caused by the drug as opposed to the underlying disease or concomitant medications or by prior drugs administered to these patients. In addition, we cannot get an accurate assessment of incidence rate.

Conclusions: As GLP-1 agonists are being used for DMII and weight loss, as nephrologists we need to be aware of AKI as a potential adverse event associated with this class of agents. The mechanism of injury needs to be determined.

Name of Medication Class	Reaction	Male (N=1023) n (%)	Female (N=1160) n (%)	Missing (N=192) n (%)	Overall (N=2375) n (%)

FR-PO078

In Search of Declining Weight, a Significant Decline in Kidney Function: A Rare Case of Liraglutide-Induced Interstitial Nephritis

Deepika Jain, Ramsha Riaz, William P. Ott, Subash Sapkota. *Jersey City Medical Center, Jersey City, NJ.*

Introduction: Liraglutide is a glucagon-like peptide-1 (GLP-1) agonist known to improve glycemic control in diabetics and result in weight loss. There are reports of GLP-1 agonists causing acute interstitial nephritis (AIN) primarily in the setting of preceding gastrointestinal symptoms or pre-existing chronic kidney disease (CKD). We present a case of rapid decline in renal function one month after starting liraglutide with concomitant use of an angiotensin-receptor blocker (ARB).

Case Description: A 50 year-old Caucasian male with history of hypertension, dyslipidemia, obesity presented to the hospital for acute renal failure noted as an outpatient from a baseline creatinine of 1.15 mg/dL and GFR 78 mL/min/1.73m^2. Patient was asymptomatic without any hematuria, dysuria, decreased urinary output, rashes, or respiratory complaints. Home medications included olmesartan-HCTZ 40/25 mg, pravastatin 80 mg, and the recent addition of Liraglutide (Saxenda) one month ago to aid with weight loss. Labs on presentation were notable for significant renal dysfunction with BUN/Creatinine of 53/4.71 mg/dL and eGFR 14 mL/min/1.73m2. Urinalysis showed a protein of 100 mg/dL (1-2+) and protein-creatinine ratio of 9.04 mg/mg. Further work-up including ANA, anti-GBM Ab, HIV, ANCA, Ds-DNA Ab, C3/C4 was normal. A renal biopsy showed interstitial inflammatory infiltration, focal interstitial edema, and mild tubular injury. No evidence of acute glomerulonephritis, immune complex glomerulopathy, or paraprotein related nephropathy was identified. Patient was extensively counseled to discontinue use of both ARB and liraglutide, however he declined to stop liraglutide since he had been achieving excellent weight loss results.

Discussion: Drug-induced AIN is often considered when unexplained renal insufficiency is detected or when an abnormal urinalysis is noted in someone who has been exposed to medications known to cause AIN, with renal biopsy being the gold standard investigation to make a definitive diagnosis. Our case highlights a patient with no CKD and GI symptoms with rapid elevation of creatinine following initiation of liraglutide for weight loss. This effect seems to have been compounded by existing use of ARB, which highlights importance of closer and more frequent monitoring of patients on GLP-1 agonists to prevent unwarranted adverse effects.

FR-PO079

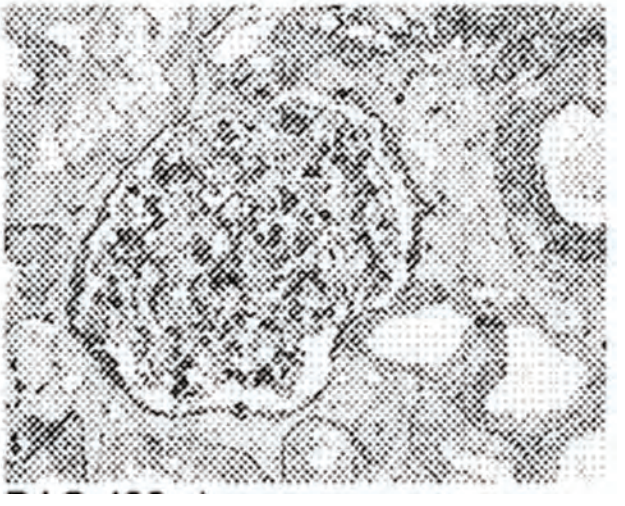
Nonsteroidal Anti-Inflammatory Drug (NSAID)-Induced Acute Tubular Injury with Eosinophiluria

Shereen Naccour, Muhammad H. Siddiqi, Faiza Khan. *Baptist Hospitals of Southeast Texas, Beaumont, TX.*

Introduction: Age, Diabetes and Hypertension are major risk factors of AKI resulting in hospitalizations. Age adjusted acute kidney injury hospitalizations increased by 230% between 2000-2014 and are mostly related to drugs. We share an interesting/atypical presentation of drug induced Acute Tubular Injury causing Eosinophiluria.

Case Description: 74 year old male with history of hypertension presented with chest pain, lower extremities edema, shortness of breath and a diffuse rash which started one day ago following Ketorolac injection for back pain. Vital signs on presentation showed blood pressure of 95/65 and tachycardia. Physical exam revealed a diffuse erythematous rash, mild wheezes in bilateral lungs and anasarca. Laboratory studies were only remarkable for serum creatinine 1.8 (baseline 1.0), blood urea nitrogen 41, white blood cells 21.9, eosinophils 32.3%. Echocardiogram, electrocardiogram, renal parenchyma ultrasound, venous doppler ultrasound of lower extremities and chest X-Ray were unremarkable. Further evaluation showed random urine creatinine 274.8, urine protein 19, spot UPCR 500 and urinalysis showed eosinophiluria. Skin biopsy revealed spongiotic dermatitis with eosinophils. Kidney biopsy showed acute tubular injury, mild interstitial fibrosis, tubular atrophy and was negative for AIN. Patient was started on steroids and responded well to the treatment.

Discussion: NSAIDs cause renal complications including AKI & AIN due to a reduction in renal blood flow, tubular obstruction through crystal deposition, direct cytotoxicity and cell-mediated immune injury. AIN usually necessitates renal biopsy and may require high-dose steroids and/or immunosuppressants. Patients manifest allergic features such as fever, rash and eosinophilia after initiating NSAIDs. Although eosinophiluria is often present in cases of AIN, its sensitivity is 60% as it also occurs in other renal diseases associated with AKI.



Biopsy shows tubular atrophy & interstitial fibrosis

FR-PO080

Renal Tubular Injury Biomarkers in the Early Detection and Diagnosis of Drug-Induced AKI: IMI/SAFE-T/TransBioLine

Michael Strader,[1] Xavier Benain,[4] Stefan Sultana,[3] Nunzio Camerlingo,[2] Patrick T. Murray.[1] *[1]University College Dublin, Dublin, Ireland; [2]Pfizer Inc, New York, NY; [3]AstraZeneca PLC, Cambridge, United Kingdom; [4]Sanofi SA, Paris, France.*

Background: Drug induced kidney injury (DIKI) is a common adverse outcome in clinical practice and clinical trials. Serum creatinine (Scr) and urine output are "gold" standard biomarkers used to diagnose and stage acute kidney injury (AKI), limited by their sensitivity and delayed detection of measurable change from time of injury. Novel AKI biomarkers with more proximal times to onset are increasingly recognized as clinically useful for earlier detection of AKI.

Methods: IMI/SAFE-T analyzed data from 2 different clinical trial cohorts — (i)105 oncology patients (normal baseline eGFR) receiving their 1st dose of IV cisplatin (≥65 mg/ m2/ cycle); (ii) 20 patients with similar cancers treated with non-nephrotoxic agents. Blood and urine samples were collected for all participants. 3 blinded expert nephrologists adjudicated presence or absence of AKI. Biomarkers (adjusted for Ucreat for urine biomarkers) maximum change from baseline accuracy — area under the ROC (AUROC), sensitivity, specificity, and 95% confidence intervals — for Cisplatin treated and AKI cases versus non-treated patients were then estimated for 3 standard biomarkers or 8 novel biomarkers.

Results: Individual novel biomarkers exceeded performance in treated vs non-treated control patients and in AKI-adjudicated vs non-treated control patients. Well performing novel biomarker median time-to-peak value was 1-3 days vs. standard biomarkers (7 days). Combination of biomarkers has also the potential to increase sensitivity and specificity of detecting AKI (exploratory result not shown in abstract).

Conclusions: Multiple individual novel urine biomarkers (uαGST, uKIM1, uOPN) exceeded performance and/or signalled AKI onset prior to individual standard biomarkers (Screat, eGFR, uALB).

Individual and Combined Biomarkers Performance in Cisplatin Treated and AKI adjudicated Patients vs. Non-Treated Patients

		Treated vs non-treated		AKI vs non-treated	
Biomarker	Number of non-treated subject	Number of treated subjects	AUROC and 95% CIs	Number of AKI subjects	AUROC and 95% CIs
uOPN	17	88	0.95 [0.90;0.98]	58	0.96 [0.92;0.99]
uKIM1	17	88	0.95 [0.87;0.99]	58	0.96 [0.89;1.00]

FR-PO081

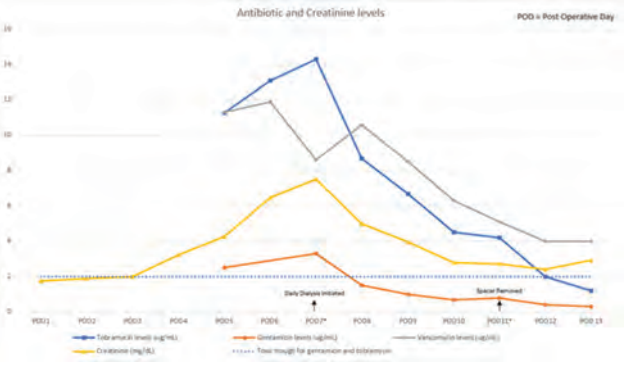
Severe AKI due to Antibiotic Loaded Cement Spacer of Knee

Salman A. Millwala, Evan Finger, Larab L. Giniyani, Jordan L. Rosenstock. *Northwell Health, New York, NY.*

Introduction: Periprosthetic joint infection after total knee arthroplasty is frequently treated with a two-stage revision involving an antibiotic-loaded acrylic bone cement spacer (ALCS) placed in the joint space for infection control weeks before placement of a new prosthesis. The antibiotics within the spacer are expected to remain localized, but studies have found that systemic absorption can occur and can be associated with acute kidney injury (AKI). However, many cases are associated with confounding factors such as the concomitant use of nephrotoxic intravenous antibiotics or associated sepsis, and only rarely have patients required dialysis treatment. We present a case of a 71 year old male who developed AKI on chronic kidney disease (CKD) requiring hemodialysis due to toxic antibiotic exposure from ALCS placement.

Case Description: Our patient had a history of hypertension and CKD 3, who had developed a joint infection with methicillin sensitive staph aureus. An ALCS containing vancomycin, tobramycin and gentamicin using standard doses was placed. Five days post operatively creatinine was 4.1 mg/dl, from 1.75 mg/dl the day of the surgery. Antibiotics levels were sent, tobramycin and gentamicin levels were elevated at 13 mcg/ml and 2.5 mcg/ml respectively (Figure). Despite daily hemodialysis (HD), tobramycin levels remained in toxic range, prompting spacer exchange with a spacer containing 3 grams of cefazolin. He required 8 weeks of HD before recovering.

Discussion: Previous studies have shown a risk for developing new AKI after exposure to antibiotics in bone cement spacers of 14-27% with increased risk in those patients with underlying CKD. Tobramycin appears to be strongly linked but concomitant gentamicin in the ALCS may increase the risk. Clinicians should be cognizant of the potential of serious nephrotoxicity from the antibiotics in the ALCS, especially when they are at high doses in patients with underlying CKD. Combined aminoglycoside antibiotics may exacerbate the risk.



FR-PO082

Validation of Urine Clusterin and MCP1 in Predicting Drug-Induced AKI

Yi Da, Nor Islya Emma Othman, Akalya K Akalya, Wei Zhen Hong, Liang Piu Koh, Horng-Ruey Chua. *National University Hospital, Singapore, Singapore.*

Background: We have published that elevated urine clusterin, MCP1, β2MG, KIM1 and cystatin-C predict drug-induced AKI in patients receiving nephrotoxic drugs(vancomycin, aminoglycosides and calcineurin inhibitors) with a 1–3 day lead-time. We aim to validate the best-performing biomarkers for drug-induced AKI prediction in susceptible patients.

Methods: The reproducibility of the five proposed urine biomarkers to predict AKI in 13 drug-induced AKI patients and 13 controls was determined, to curate the best-performing three biomarkers using a multiplex assay. A prospective single-centre study of 137 patients receiving nephrotoxic drugs was subsequently conducted. Urine samples were collected 2–5 days before AKI onset by KDIGO criteria or before the end of nephrotoxic therapy in non-AKI patients. The primary analysis was the ability of the selected biomarkers to predict AKI with a 2-day lead time using individual ELISA.

Results: Urine clusterin, MCP1, β2MG yielded consistent AKI prediction with respective AUCs of 86%, 75%, 74%, and were superior to that of KIM1 and cystatin-C in the initial 26 patients. Of the validation cohort of 137 patients, 28% developed AKI. AKI and non-AKI patients had a similar mean age of 55 years, with AKI patients having a higher baseline eGFR than non-AKI patients (104 vs 98 mL/min/1.73m^2 respectively, p=0.01). Median levels of biomarkers were higher in eventual AKI cases vs non-AKI patients (p<0.0001 for clusterin and MCP1, p=0.03 for β2MG). Their AUC for AKI prediction was 73(64-82)% with clusterin, 77(68-86)% with MCP1, and 62(51-72)% with β2MG. We determined threshold levels of clusterin and/or MCP1 for optimal AKI prediction.

Conclusions: Urinary clusterin >150 ng/mL or MCP1 >200 pg/mL predicts drug-induced AKI, with best precision achieved by further elevations of both biomarkers.

Apixaban in CKD, a Life-Threatening Cause of Pericardial Bleed with Resultant Acute Tubular Necrosis (ATN) and Dialysis Dependency

Zahoor U. Rehman,[1,2] Ashok P. Chaudhari,[1,2] Donald I. Baumstein.[1,2]
[1]New York City Health and Hospitals Metropolitan, New York, NY; [2]New York Medical College, Valhalla, NY.

Introduction: Bleeding is a common complication associated with oral anticoagulants. It can be revealed or concealed, including upper and lower gastrointestinal hemorrhage, central nervous system macro and microbleeds, and bleeding in the genitourinary system. After a thorough literature search, we found no reported case of a large pericardial bleed causing cardiac tamponade. Therefore, we report a case of a large pericardial bleed that caused tamponade, which resulted in ATN in a patient with chronic kidney disease (CKD) who then required dialysis.

Case Description: A 77-year-old Chinese woman with a history of diabetes mellitus type-2, hypertension, atrial fibrillation, left middle cerebral artery stroke status post thrombectomy, and CKD with a baseline creatinine of 1.8 mg/dl (two months prior) was brought to the emergency department (ED) due to elevated blood urea nitrogen (BUN) and creatinine. On arrival at the ED, her creatinine was elevated at 8.3 mg/dl, BUN at 76 mg/dl, and hemoglobin at 7.0 g/dl, with normal platelet and white cell count. She was alert but not oriented and had jugular venous distension, with a blood pressure of 100/60 mmHg. EKG showed no acute changes, a chest x-ray revealed a globular heart, and the septic workup was negative. Echocardiogram demonstrated severe pericardial effusion with right ventricular collapse. She was taking Apixaban 5 mg twice daily. Renal failure workup was all negative or normal, including autoimmune and hepatitis profile, infection, and myeloma screening. Pericardial bleed was suspected in light of an acute drop in hemoglobin, so a pericardial window was made, and a 2-liter bloody effusion was drained on day-1 with a total of 4 liters over a week. Pericardial fluid was negative for atypical cells, gram stain, AFB stain, QuantiFERON, and viral PCRs, and cultures were negative for bacteria and fungi.

Discussion: Oral anticoagulants can cause a potentially life-threatening pericardial bleed and resultant cardiac tamponade. Though apixaban and other non-vitamin K analogs require less monitoring than warfarin and may be associated with lesser chances of bleeding, however, it can cause a large pericardial bleed and can lead to shock and ATN. Care should be exercised in prescribing apixaban to patients who have an increased risk of bleeding, especially those with CKD.

FR-PO084

Validation of a Six-Point Bedside Risk Score for Prediction of AKI After Transcatheter Aortic Valve Replacement

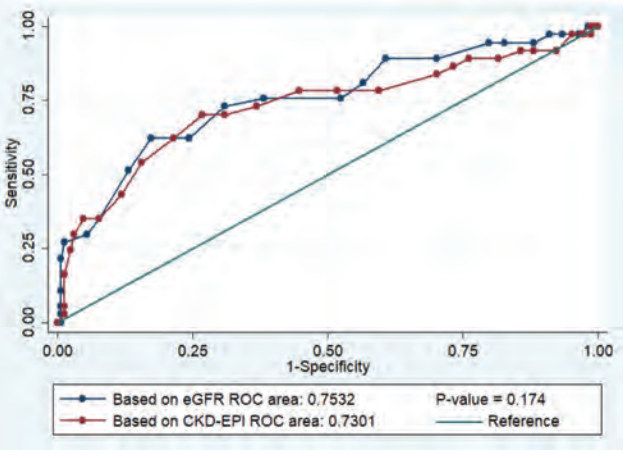
Jenn Danielle M. Gargar, Annabelle S. Lim, Gwen R. Marcellana, Fabio Enrique B. Posas, Kahlil Carlo A. Cruz. *St. Luke's Medical Center Global City, Metro Manila, Philippines.*

Background: Post-transcatheter aortic valve replacement (TAVR) acute kidney injury (AKI) is a significant complication linked to increased mortality, dialysis rates and myocardial infarction underscoring the need for a reliable prediction tool. Zivkovic et al. (2018) developed a bedside risk score with six pre-procedural variables (NYHA class, non-femoral access, valve-in-valve procedure, hemoglobin level, creatinine clearance, weight) to predict post-TAVR AKI. Validation of this score improve evidence for wider adoption in patient care.

Methods: A retrospective analysis of 205 patients who had TAVR was done. Patient characteristics were compared between AKI and non-AKI groups. Diagnostic accuracy was assessed using the receiver operating characteristics curve.

Results: AKI incidence was 18%. Significant AKI predictors were NYHA class (OR: 2.1170; p=0.001), non-femoral access site (OR: 2.6672; p=0.021), elevated baseline creatinine (OR: 4.1459; p<0.001), decreased hemoglobin levels (OR: 0.6319; p<0.001), eGFR<30 (OR: 0.9634; p<0.001). Age, gender and contrast volume showed no differences. AKI group had higher 10-year follow-up mortality (54.05% vs 31.55%, p=0.010), with 40% of AKI group mortalities occurring in the first year post-TAVR compared to 20% in non-AKI. Post-TAVR dialysis was higher in the AKI group (immediately after: 18.9%, 1 year post-TAVR: 16.2% vs. 0.0% respectively, p<0.001). The bedside risk score demonstrated promising discrimination (AUROC 0.75, accuracy of 69.76%), with a 23.43% increased odds of AKI per score increase.

Conclusions: Zivkovic et al.'s risk score shows promise in predicting post-TAVR AKI and can improve patient care through targeted monitoring and intervention. Guideline development for timely nephrology referral based on the risk score will optimize outcomes for high-risk patients.



Area under the ROC curve of Bedside Risk Score

From Mega Men to Mega Kidney Failure

Crystal Wong,[1] Mahad Malik,[1] Georgina Ang,[1] Musa Njeru.[2] *[1]Department of Medicine, Long Island Jewish Forest Hills, Donald & Barbara Zucker School of Medicine at Hofstra/Northwell, Forest Hills, NY; [2]Department of Nephrology, Long Island Jewish Forest Hills, Donald & Barbara Zucker School of Medicine at Hofstra/Northwell, Forest Hills, NY.*

Introduction: Acute interstitial nephritis (AIN) is a type of acute kidney injury associated with the presence of inflammatory infiltrates and interstitial edema. It accounts for 15-27% of biopsies in the category of acute kidney injuries and 1-3% of all renal biopsies. AIN can be caused by infections, systemic disease, idiopathic causes, but drug-induced AIN accounts for over 75% of the cases. Common offending agents are antibiotics, NSAIDs, allopurinol, furosemide, and omeprazole. Here, we describe a case of AIN caused by an over-the-counter (OTC) supplement requiring emergent dialysis.

Case Description: A 50-year-old male without known medical history nor supplement intake, presented with generalized abdominal pain. Upon evaluation, he was afebrile and hemodynamically stable. Serum creatinine was noted to be 17.8 with a GFR of 3 on admission. A right femoral temporary catheter was placed for emergent dialysis. Serological markers were obtained and resulted as negative. He underwent multiple dialysis sessions and his creatinine improved from 17.8 to 7.18. He had lower back pain during his hospitalization with negative findings on lumbosacral spine x-ray. His kidney biopsy showed severe acute tubulointerstitial nephritis with acute tubular injury. During an outpatient visit, he admitted to taking a dietary supplement called Mega Men. The supplement was discontinued and a prednisone taper was started. The last dialysis session was 1 month after his admission, and the patient's creatinine stabilized to a new baseline of 1.38.

Discussion: The case above highlighted a drug induced AIN caused by a non-FDA-approved OTC supplement. With an abundance of easily accessible supplements, it is critical to consider AIN as a diagnosis in those with an acute worsening of renal function as 40% of AIN cases require dialysis. Drug induced AIN presents with a multitude of non-specific symptoms such as fever, rash, arthralgia and in this case abdominal pain and lower back pain. Although duration of use and severity of renal failure are not strongly correlated, the first step after suspecting AIN is removal of the offending agent. A few days after the onset of interstitial inflammation, irreversible fibrosis follows. Early treatment with steroids is recommended to minimize the irreversible renal damage.

FR-PO086

Evaluation of Risk Stratification for AKI: A Comparative Analysis of EKFC, 2009, and 2021 CKD-EPI Glomerular Filtration Estimating Equations

Jeongmin Cho,[1] Jung Hun Koh,[1] Yaerim Kim,[2] Dong Ki Kim,[1] Sehoon Park.[1]
[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Keimyung University Daegu Dongsan Hospital, Daegu, Republic of Korea.

Background: The adoption of the 2021 CKD-EPIcr equation for glomerular filtration rate (GFR) estimation provided race-free eGFR calculation. We aimed to evaluate the differences in acute kidney injury (AKI) risk discrimination power according to 2009 and 2021 CKD-EPIcr, and EKFC equations.

Methods: We performed a retrospective observational study within a tertiary hospital from 2011 to 2021. AKI was defined according to KDIGO serum creatinine criteria. GFR estimates were calculated by three GFR estimating equations: 2009 and 2021 CKD-EPIcr, and EKFC. AKI risk discriminative performances were evaluated with area under receiver operator curves (AUROC) and net reclassification improvement.

Results: A total of 187,139 individuals, including 27,447 (14.7%) of AKI and 159,692 (85.3%) of control, were enrolled. In multivariable regression prediction model, 2009 CKD-EPIcr model (0.7583 [0.755 – 0.7617]) showed superior performance in AKI prediction than 2021 CKD-EPIcr (0.7564 [0.7531 – 0.7597], <0.001) or EKFC model in AUROC (0.7577 [0.7543 – 0.761], <0.001). In reclassification of AKI, 2021 CKD-EPIcr and EKFC models showed a worse classification performance than 2009 CKD-EPIcr model. (-7.24 [-8.21 – -6.21], -2.38 [-2.72 – -1.97] %).

Conclusions: Regarding AKI risk stratification, the 2009 CKD-EPIcr equation showed better discriminative performances compared to 2021 CKD-EPIcr equation.

	AUC	*Comparison of AUC		
		A vs. B	A vs. C	B vs. C
2009 CKD-EPIcr	0.7583 (0.755 – 0.7617)			
2021 CKD-EPIcr	0.7564 (0.7531 – 0.7597)	<0.001	<0.001	<0.001
EKFC	0.7577 (0.7543 – 0.761)			

Figure 1. Performance of GFR estimating equations in classifying AKI using Multivariable ROC-AUC

	Proportion of participants correctly reclassified		NRI, % (95% CI)	AKI reclassified (N)
	AKI reclassified, % (95% CI)	Non-AKI reclassified, % (95% CI)		
2009 CKD-EPIcr vs.				
2021 CKD-EPIcr	-4.43 (-5.54 – -3.46)	-2.8 (-2.94 – -2.64)	-7.24 (-8.21 – -6.21)	1,136 (887 – 1,421)
EKFC	-2.40 (-2.75 – -1.99)	0.02 (0.00 – 0.04)	-2.38 (-2.72 – -1.97)	615 (510 – 705)

Influence of Acute Kidney Disease on the Incidence of AKI and Patient Outcomes in Critically Ill Patients Admitted to the Intensive Care Unit

Harin Rhee, Dong Eon Kim, Eunmi Jo, Yeji Lee, Taeil Kim, Il Young Kim.
Pusan National University School of Medicine, Busan, Republic of Korea.

Background: The Kidney Disease: Improving Global Outcomes (KDIGO) clinical practice guideline for acute kidney injury (AKI) proposed the concept of acute kidney disease (AKD), however, its impact on critically ill patients is rarely studied. The aim of this study is to investigate the influence of baseline AKD on the incidence of AKI and patient outcomes in critically ill patients admitted to intensive care unit (ICU).

Methods: This is a retrospective study based on the electronic medical record-extracted ICU cohorts in two 3rd affiliated hospitals in South Korea. We retrospectively categorized baseline kidney function status as no kidney disease (NKD), AKD, and chronic kidney disease (CKD) based on the eGFR levels. AKI was defined based on the KDIGO serum creatinine criteria. The outcome measurements were the incidence of AKI in the ICU and in-hospital mortality.

Results: A total of 7,153 patients were included. The median age was 67 (18-110) years, and 57.6% were male. In all, baseline NKD, AKD, and CKD were seen in 4,792 (66.6%), 926(12.9%), and 1,465(20.5%) patients, respectively. During the ICU stay, AKI was observed in 2,461(34.4%) patients, which was more frequent in AKD [OR 2.354(1.996-2.776)] and CKD [OR 2.347(2.028-2.716)] compared to NKD (Fig 1A). During the median 16(9, 23) days of hospital stay, 819(11.4%) were dead. The in-hospital mortality rate was 1.546(1.328-1.800) folds higher in patients with AKI regardless of the baseline kidney function status, whereas, in patients without AKI, the risk of mortality was 2.176(1.625-2.915) folds higher in AKD compared to NKD (Fig 1B).

Conclusions: AKD was observed in 12.9% of ICU-admitted patients, and it was associated with a higher risk for incident AKI and in-hospital mortality. This study implies the significance of recognizing AKD in the management of ICU patients.

Community-Acquired AKI: A Prospective Case-Control Study

Telma H. Ragnarsdóttir,[1,2] Margret Kristjansdottir,[1] Gisli Gislason,[1,2] Margret O. Tomasdottir,[2,3] Vicente Sanchez-Brunete,[1] Olafur H. Samuelsson,[1] Runolfur Palsson,[1,2] Olafur S. Indridason.[1] *[1]Landspitali, Reykjavik, Iceland; [2]Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland; [3]Heilsugaesla Hofudborgarsvaedisins, Reykjavik, Iceland.*

Background: Acute kidney injury (AKI) is a common clinical entity in the hospital setting but data on community-acquired AKI is lacking. The aim of this study was to examine the causes and risk factors for community acquired AKI.

Methods: This was a prospective case-control study in which serum creatinine (SCr) of all individuals admitted to the emergency department (ED) of Landspitali–The National University Hospital of Iceland were examined for the presence of AKI. We present data from January 1 until March 3, 2020, May 19 until September 21, 2020, and February 1 until June 15, 2021. The study was paused between these periods due to the COVID-19 pandemic. Patients who met the SCr component of the KDIGO criteria for AKI were invited to participate. Randomly selected control cases (1:2) were paired according to age, sex, and date of ED visit. Participants answered questions about their medical history and use of medications, including over the counter (OTC) drugs. Past medical history was obtained from electronic medical records. Conditional logistic regression was used to identify factors associated with AKI.

Results: A total of 602 AKI cases were identified in 574 persons during the study period, 488 of whom participated (512 cases). The mean (±SD) age of AKI cases and controls was 67.1±16.6 years and 67.2 ±16.2 years, respectively; 48% of cases and controls were female. AKI cases were significantly more likely than controls to have used non-steroidal anti-inflammatory drugs (NSAID) (26.0% vs 18.0%, p=0,001) in the week preceding the ED visit, particularly OTC NSAID (23.3% vs 15.9%, p<0.001). In adjusted analysis, AKI was associated with vomiting (odds ratio [OR] 2.62, 95% confidence interval [CI] 1.95-3.53), diarrhea (OR 1.35, 95% CI 1.04-1.75), urinary retention (OR 1.86, 95% CI 1.32-2.62) and use of NSAID (OR 1.60, 95% CI 1.18-2.23), diuretics (OR 1.48, 95% CI 1.12-1.99) or ACEi/ARB (OR 1.49, 95% CI 1.12-1.99). A statistically significant relationship was not observed for diabetes, hypertension, vascular- or chronic kidney disease.

Conclusions: Volume depletion and the use of NSAID and ACEi/ARB seem to play a major role in the development of AKI in the community setting. Use of OTC NSAID is surprisingly frequent and should be addressed considering serious adverse effects.

Funding: Government Support - Non-U.S.

FR-PO089

The Association Between Skeletal Muscle Mass and Survival/Renal Recovery from Dialysis in Patients with Sepsis-Associated AKI Receiving Continuous Renal Replacement Therapy

Do Kyun Kim, Kyu Won Jang, Bon Jin Koo, Byung Min Ye, Seo Rin Kim, Il Young Kim, Dong Won Lee, Soo Bong Lee. *Pusan National University Yangsan Hospital Nephrology Clinic, Yangsan, Republic of Korea.*

Background: Lower skeletal muscle mass at intensive care unit (ICU) admission has been associated with poor outcomes. In this study, we investigate the independent association between computed tomography (CT)-measured skeletal muscle mass and survival, as well as renal recovery from dialysis, in patients with sepsis-induced acute kidney injury (SIAKI) who are undergoing continuous renal replacement therapy (CRRT).

Methods: In this retrospective study, a total of 618 patients with SIAKI who CRRT in our ICU were included. Within three days prior to ICU admission, all patients underwent abdominal CT scans. The cross-sectional area of skeletal muscle at the 3rd lumbar vertebra was measured, and the skeletal muscle index (SMI), a normalized measure of skeletal muscle mass, was calculated. Patients were categorized into sarcopenia and non-sarcopenia groups using Korean-specific cutoffs of SMI.

Results: Out of the 618 patients included in the study, 301 expired within 28 days of ICU admission. Non-survivors exhibited a higher prevalence of sarcopenia and SMI compared to survivors. The results of multivariable Cox regression analysis revealed that sarcopenia independently predicted 28-day mortality (hazard ratio [HR]: 2.66; 95% confidence interval [CI]: 1.42–2.38; P < 0.001). Among the survivors, sarcopenia was independently associated with a lower likelihood of renal recovery from dialysis within 28 days of ICU admission (HR: 0.42, 95% CI: 0.26–0.68; P < 0.001). Kaplan-Meier analysis demonstrated that sarcopenic patients had lower rates of survival and renal recovery from dialysis within 28 days of ICU admission compared to non-sarcopenic patients.

Conclusions: This study demonstrated that sarcopenia assessed by CT-derived skeletal muscle mass was independently associated with both survival and renal recovery from dialysis in patients with SIAKI receiving CRRT. These findings highlight the potential value of sarcopenia as a prognostic tool in this patient population.

FR-PO090

The Significance of Initial Emergency Room Six-Hour Urine Volume for Survival in Critically Ill Patients Receiving Continuous Renal Replacement Therapy

Kyungho Park,[1] Yunkyeong Hwang,[1] Heewon Park,[1] Suyeon Han,[1] Hye Rim Park,[2] Eu Jin Lee,[1] Hae Ri Kim,[3] Youngrok Ham,[1] Kiryang Na,[1] Kang Wook Lee,[1] Dae Eun Choi.[1,2] *[1]Chungnam National University Hospital, Daejeon, Republic of Korea; [2]Department of Medical Science, Chungnam National University, Daejeon, Republic of Korea; [3]Chungnam National University Sejong Hospital, Sejong, Republic of Korea.*

Background: The impact of initial emergency room(ER) factors on survival and renal function in critically ill patients receiving continuous renal replacement therapy(CRRT) has been poorly understood. This study aimed to investigate whether initial factors in ER have an influence on the survival and renal recovery of critically ill patients undergoing CRRT.

Methods: This retrospective single-center study included 332 critically ill patients who were admitted to intensive care units and received CRRT via the ER between March 1, 2018, and May 31, 2021. Various clinical parameters, such as urine output, estimated glomerular filtration rate (eGFR), and serum neutrophil gelatinase-associated lipocalin (NGAL), were assessed. The primary outcomes measured were the mortality rates at 30 days and 90 days, while the secondary outcomes focused on the duration of dialysis-free periods at 30 days and 90 days.

Results: The group with low urine output (LUO), defined as < 0.5 mL/kg/hr x 6 hours, displayed a significant association with both 30-day and 90-day mortality rates. The results of multivariable Cox regression analysis indicated that the LUO group had a significantly higher risk of 30-day mortality and 90-day mortality (hazard ratio, 1.935 and 2.141, respectively) compared to the high urine output (HUO) group, defined as ≥ 0.5 mL/kg/hr x 6 hours. There was no significant correlation between 30-day or 90-day mortality rates and initial eGFR or plasma NGAL levels. In critically ill patients undergoing CRRT, the HUO group and the group with initial eGFR ≥ 30 ml/min/1.73m2 were associated with a decreased 30-day and 90-day dialysis-free duration. However, serum NGAL levels did not show a significant association with 30-day and 90-day renal replacement therapy free duration.

Conclusions: The initial urine volume in ER emerges as a crucial factor for both 30-day and 90-day mortality rates in critically ill patients receiving CRRT.

FR-PO091

Impact of Fluid Balance After Sepsis-Associated AKI on Development of Persistent AKI

Hannah Kittrell,[1] Wonsuk Oh,[1] Roopa D. Kohli-Seth,[1] Girish N. Nadkarni,[1] Ankit Sakhuja.[2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]West Virginia University, Morgantown, WV.*

Background: Persistent AKI (pAKI), defined as AKI lasting ≥48h is seen in over half the patients with sepsis associated AKI (SA-AKI). Fluid overload is common in patients with SA-AKI and is associated with worse outcomes. It is however unclear if net fluid balance within 48h after onset of SA-AKI (NFB-48) is associated with development of SA-pAKI.

Methods: We conducted a retrospective study using MIMIC IV database. We identified adult patients (≥18y) with sepsis who developed AKI within 48 hours of ICU admission. We defined AKI using both creatinine and urine output based KDIGO criteria. We then identified association between NFB-48 (used as tertiles) with development of SA-pAKI using logistic regression adjusted for demographics, comorbidities, SOFA score, vital signs, laboratory measurements, vasopressors and mechanical ventilation use.

Results: Of 10,739 SA-AKI patients, 62.2% developed SA-pAKI. In comparison with patients whose SA-AKI resolved within 48h, those with SA-pAKI had higher max creatinine level (1.1 vs 1.7 mg/dL; p<0.001), higher SOFA score (4.3 vs 6.3; p<0.001), more use of vasopressors (28% vs 47%; p<0.001) and mechanical ventilation (38% vs 56%;p<0.001). They also had a higher NFB-48 (0.4 vs 1.7L; p<0.001). On adjusted analysis positive NFB-48 was significantly associated with increased odds of developing SA-AKI in a stepladder pattern (Table 1).

Conclusions: We have shown that positive NFB within 48 hours after onset of SA-pAKI is significantly associated with development of SA-pAKI. The study underscores the need for optimal fluid balance in patients with SA-AKI.

Funding: NIDDK Support, Other NIH Support - WO: T32DK007757 TL1DK136048, AS: 1K08DK131286, GN: R01DK108803 U01HG007278 U01HG009610 U01DK116100

The Impact of C-Reactive Protein-to-Albumin Ratio on Mortality in Patients with AKI Requiring Continuous Kidney Replacement Therapy: A Multicenter Retrospective Study

You Hyun Jeon, Seong-Wook Lee, Hee-Yeon Jung, Sun-Hee Park, Chan-Duck Kim, Yong-Lim Kim, Jang-Hee Cho, Jeong-Hoon Lim. *Kyungpook National University Hospital, Daegu, Republic of Korea.*

Background: The C-reactive protein-to-albumin ratio (CAR) is a prognostic marker in various diseases that represents patients' inflammation and nutritional status. Here, we aimed to investigate the prognostic value of CAR in critically ill patients with severe acute kidney injury (AKI) requiring continuous kidney replacement therapy (CKRT).

Methods: We retrospectively collected data from eight tertiary hospitals in Korea from 2006–2021. The patients were divided into quartiles according to CAR levels at the time of CKRT initiation. Cox regression analyses were performed to investigate the effect of CAR on in-hospital mortality. The mortality prediction performance of CAR was evaluated using the area under the curve (AUC), net reclassification improvement (NRI), and integrated discrimination improvement (IDI).

Results: In total, 3995 patients who underwent CKRT were included, and the in-hospital mortality rate was 67.3% during the follow-up period. The 7-day, 30-day, and in-hospital mortality rates increased toward higher CAR quartiles (all *P*<0.001). After adjusting for confounding variables, the higher quartile groups had an increased risk of in-hospital mortality (quartile 3: adjusted hazard ratio [aHR], 1.15, 95% confidence interval [CI], 1.02–1.30, *P*=0.023; quartile 4: aHR, 1.33; 95% CI, 1.18–1.50, *P*<0.001). CAR combined with APACHE II or SOFA scores significantly increased the predictive power compared to each severity score alone for the AUC, NRI, and IDI (all *P*<0.05).

Conclusions: A high CAR is associated with increased in-hospital mortality in critically ill patients requiring CKRT. The combined use of CAR and severity scores provides better predictive performance for mortality than the severity score alone.

Clonal Hematopoiesis of Indeterminate Potential Is Associated with AKI

Caitlyn Vlasschaert,[1] Bryan R. Kestenbaum,[2] Samuel A. Silver,[1] Jianchun Chen,[3] Elvis A. Akwo,[3] Pavan K. Bhatraju,[2] Ming-Zhi Zhang,[3] Shirong Cao,[3] Ming Jiang,[3] Aolei Niu,[3] Edward D. Siew,[3] Holly J. Kramer,[4] Anna Kottgen,[5] Nora Franceschini,[6] Bruce M. Psaty,[2] Alvaro Alonso,[7] Dan Arking,[8] Josef Coresh,[8] Christie Ballantyne,[9] Morgan Grams,[1] Matthew B. Lanktree,[10] Michael J. Rauh,[1] Alexander Bick,[3] Raymond C. Harris,[3] Cassianne Robinson-Cohen.[3] *[1]Queen's University, Kingston, ON, Canada; [2]University of Washington, Seattle, WA; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Loyola University Chicago, Chicago, IL; [5]Albert-Ludwigs-Universitat Freiburg Universitatsklinikum Freiburg, Freiburg, Germany; [6]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [7]Emory University, Atlanta, GA; [8]Johns Hopkins University, Baltimore, MD; [9]Baylor College of Medicine, Houston, TX; [10]McMaster University, Hamilton, ON, Canada.*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is a recently recognized risk factor for several chronic diseases of aging including cardiovascular disease and chronic kidney disease. In these contexts, clonal populations of mutated myeloid cells contribute to end-organ damage through inflammatory dysregulation. We recently identified CHIP as a novel risk factor for AKI: it was associated with an increased risk of incident AKI in ICD code-based prospective clinical data from three large cohorts totalling nearly half a million individuals (adjusted hazard ratio: 1.26, 95% CI: 1.19–1.34).

Methods: In the current work, we sought to investigate determine whether CHIP was associated with impaired functional recovery from AKI. We first examined the association between CHIP and AKI recovery in the ASSESS-AKI cohort. We then assessed long-term post-AKI outcomes in a mouse model of CHIP (partial *Tet2*$^{-/-}$ bone marrow transplant) subjected to ischemia reperfusion injury.

Results: We identified that certain subtypes of CHIP exhibited a non-resolving pattern of injury and had poorer long-term outcomes after AKI. At 28 days post-ischemic injury, we observed higher levels of kidney injury markers KIM-1 and NGAL as well as more kidney fibrosis in the CHIP mice compared to wild type mice. Kidney macrophage infiltration was markedly increased in CHIP mice at this timepoint, and concomitant upregulation of pro-inflammatory and fibrotic signaling pathways was noted.

Conclusions: This work identifies CHIP as a novel and potentially targetable risk factor for impaired recovery from AKI.

Genome-Wide Association Study (GWAS) in Critically Ill Sepsis Patients Identifies Single Nucleotide Polymorphisms (SNPs) Associated with AKI by Multiple Definitions

Todd A. Miano, Michael G. Shashaty, John P. Reilly, Tiffanie Jones, Rui Feng, Alexandra P. Turner, Thomas Dunn, Caroline Ittner, Brian J. Anderson, Jason Christie, Heather Giannini, Katalin Susztak, Nuala J. Meyer. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Identifying replicable genetic variants associated with AKI has been challenging, potentially related to differences in AKI definition across studies. We conducted GWAS of AKI, defined multiple ways, in critically ill sepsis patients.

Methods: We included 1955 critically ill patients without ESKD enrolled in a sepsis cohort from 2011-2020. We extracted genomic DNA from whole blood and genotyped with the Affymetrix Axiom TxArray. We defined AKI using 1) Kidney Disease Improving Global Outcomes (KDIGO) creatinine (Cr) criteria which include both worsening and rapidly resolving AKI, and 2) Acute Kidney Injury Network (AKIN) Cr criteria which require Cr increase from admission. We used PLINK to conduct additive multivariable logistic regression, adjusting for age, sex, and principal components, stratified by European (n=1312) or African (n=643) ancestry (EA, AA). We assessed SNPs associated with AKI at $p<5x10^{-5}$ by one definition for significance at $p<5x10^{-3}$ by the other.

Results: AKIN-AKI occured in 43% of EA patients and 45% of AA patients, while KDIGO-AKI occured in 58% of EA patients and 63% of AA patients. In AAs, 21 had $p<5x10^{-5}$ for AKIN-AKI and 18 for KDIGO-AKI; 4 SNPs were associated with the other AKI definition at $p<5x10^{-3}$ (Table). *NOD1* encodes a bacterial pattern-recognition receptor that initiates inflammation. *ERO1B* encodes an oxidoreductase in the endoplasmic reticulum that regulates reactive oxygen species production. In EAs, 14 SNPs had $p<5x10^{-5}$ for AKIN-AKI and 11 for KDIGO-AKI; none were associated with the other AKI definition at $p<5x10^{-3}$. However, NKAIN2 is extensively expressed in the kidney and is associated with glomerular filtration rate in children, while rs10031539 (*KCNIP*) is associated with CKD.

Conclusions: We identified SNPs associated with both KDIGO and AKIN defined AKI that may be pathophysiologically relevant.

Funding: NIDDK Support, Other NIH Support - NHLBI

Association of Angiotensin-Converting Enzyme Inhibitor/Angiotensin Receptor Blocker Use with Kidney Diseases Among Long-COVID and Non-Long-COVID Adults: Retrospective Cohort Study of Real-World Data

Yue Zhang, Djibril Ba, Nasrollah Ghahramani, Vernon M. Chinchilli. *Penn State College of Medicine, Hershey, PA.*

Background: Angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin II receptor blockers (ARBs) are widely prescribed for hypertension. In vitro studies have suggested that ACEIs/ARBs upregulate ACE-2 expression, the receptor for SARS-CoV-2 entry, particularly in kidneys. It was hypothesized that the risk of kidney diseases may be elevated in individuals with Long COVID receiving ACEI/ARB therapy. The objective of this research is to examine the relationship between ACEI/ARB usage and the occurrence of acute kidney injury (AKI) in both Long COVID and non-Long COVID populations.

Methods: A retrospective cohort study using TriNetX datasets was conducted, with diagnoses of long COVID and kidney outcomes identified via International Classification of Diseases 10th revision (ICD-10) codes. Four cohorts were built: long COVID ACEI/ARB users (LCAU), long COVID non-users (LCAN), non-long COVID ACEI/ARB users (NLCAU), and non-long COVID ACEI/ARB non-users (NLCAN). Multivariable stratified Cox proportional hazards regression models were used to analyze the relationships. Meanwhile, we also compared the hazard ratio of AKI, CKD, and MAKE between ACEI/ARB and an active comparator, calcium channel blockers (CCB).

Results: A total of 164,070 qualified participants were included from 10/01/2021 to 02/14/2023, with 10,627 long COVID patients and 12,574 ACEI/ARB users. After controlling for demographics, drug histories, and comorbidities, ACEI/ARB use did not significantly impact the risk of AKI, CKD, and MAKE, when comparing LCAU to LCAN, and NLCAU to NLCAN. However, an increased AKI risk was associated with long COVID when comparing LCAN to NLCAN (aHR, 1.61; 95% CI, 1.27 – 2.06). No significant difference in HR of each kidney outcome between ACEI/ARB and CCB was found in both long COVID and non-long COVID cohorts.

Conclusions: ACEI/ARB use does not appear to elevate the incidence of AKI in comparison to non-users and active comparators for both Long COVID and non-Long COVID participants. Instead, it is Long COVID that has been associated with an increased risk of AKI.

FR-PO096

Prevention of Renal Damage Caused by Activation of Rhabdomyolysis-Induced Inflammasome

Maria Angeles Gonzalez-Nicolas Gonzalez,[1,2] Blanca Humanes Sanchez,[1,2] Alberto Lazaro Fernandez.[3,4] Renal Physiopathology Laboratory. *[1]Instituto de Investigacion Sanitaria Gregorio Maranon, Madrid, Spain; [2]Hospital General Universitario Gregorio Maranon, Madrid, Spain; [3]Universidad Complutense de Madrid Facultad de Medicina, Madrid, Spain; [4]Department of Physiology, Complutense University of Madrid, Madrid, Spain.*

Background: Rhabdomyolysis (RM) is a clinical and biochemical syndrome characterized by skeletal muscle rupture and massive release of cellular components including myoglobin (MG), which causes one of the most serious complications, acute renal failure (ARF) by direct cytotoxicity and tubular obstruction due to precipitation of MG itself. The heme group induces an inflammatory response by activation of the NLRP3 inflammasome, release of different cytokines and the phenotype changes of proinflammatory (M1) to antiinflammatory (M2) macrophages. Cilastatin, a renal dehydropeptidase-I inhibitor, has demonstrated its usefulness in the protection of ARF induced by nephrotoxic drugs due to interference with lipid rafts. We evaluate if cilastatin is able to block inflammasome activation and protect from RM-induced renal damage.

Methods: RM was induced in Wistar rats by administering in the hind legs with 50% glycerol (or vehicle to the control group). Cilastatin (150 mg/kg) or its vehicle, was administered immediately and every 24h after RM induction. Renal damage was assessed 48h after glycerol/vehicle administration by measuring serum levels of creatinine, potassium, LDH, blood urea nitrogen (BUN) and glomerular filtration rate (GFR), as well as morphology in renal tissue and ferric iron, specific biomarkers of inflammasome activation, also phenotype change in macrophages.

Results: RM worsened renal function compared to the control group, which was confirmed by the presence of severe morphological changes and iron accumulation in tubular cells, as well as a statistically significant increase of the biomarkers of inflammasome and cytokines levels, along with a change in phenotype M1 to M2. Cilastatin treatment completely prevented renal dysfunction, restored significantly all other parameters to levels found in the control groups, and reduced many of the histological symptoms of renal damage.

Conclusions: Our results support the theory of a possible use of cilastatin in the prevention and treatment of ARF-induced by RM. Therefore, cilastatin may be a very beneficial therapeutic strategy in clinical practice for patients with some type of trauma or susceptible to renal damage due to RM.

Effects of Sodium Bicarbonate on Clinical Outcomes in CKD Patients with Contrast-Associated AKI (CA-AKI): A Meta-Analysis on Randomized Controlled Trials (RCTs)

Yen Chung Lin.[1,2] [1]*Taipei Medical University Hospital, Taipei, Taiwan;* [2]*Taipei Medical University, Taipei, Taiwan.*

Background: Contrast Associated Acute kidney Injury (CA-AKI) has been linked to the causal effect in a small increase of creatinine without serious adverse outcomes. However, this transient decrement in kidney function may associate with serious adverse outcomes such as dialysis or mortality. Intravenous fluid volume expansion with sodium bicarbonate (NaBiC) were highly recommended for prevention of CA-AKI in KDIGO guidelines. However, the independent role of NaBiC in CA-AKI is not fully explored especially on patients with chronic kidney disease (CKD).

Methods: The randomized controlled trials with NaBiC supplement were compared to that of hydration in CKD patient with CA-AKI were surveyed. Electronic databases: Pubmed, Embase, Web of science, and Cochrane library were searched with predefined key words/MeSH terms to identified relevant studies. In addition, reference lists of included studies were screened manually. We conducted meta-analysis by using random effects model. The results were expressed as risk ratio for categorical outcomes with 95% confidence interval and mean difference with 95% confidence interval for continuous outcomes.

Results: A total 25 studies were included in our final analysis after screened with predefined criteria, including 4396 patient with CKD. The risk ratio of CA-AKI when comparing NaBiC to hydration is 0.74 [95% CI: 0.56, 0.97] in subgroup of early CKD (eGFR between 45-60ml/min). However, the Risk ratio of dialysis and mortality are 0.97 [95% CI: 0.46, 2.03] and 0.90 [95% CI: 0.67, 1.20] in all population, respectively. Mean difference of creatinine between NaBiC group and hydration group within 24 hours, 48 hours and 72 hours are -0.04 [95% CI: -0.17, 0.10] mg/dl, -0.02 [95% CI: -0.12, 0.08] and -0.44 [95% CI: -0.72, -0.16] mg/dl, respectively. Mean difference of eGFR within 24 hours, 48 hours and 72 hours between NaBiC and hydration group is 0.06 [95% CI: -0.23, 0.35], 0.12 [95% CI: -0.06, 0.30] and 0.67 [95%CI: 0.34, 1.01] ml/min/1.73m². Mean difference of hospital stay length is -0.55 [95% CI: -1.56, 0.47] days between NaBiC and hydration group. The funnel plot showed no bias.

Conclusions: In compared to intravenous fluid volume expansion, sodium bicarbonate may benefit in eGFR in early CKD patients, however, in regards to mortality, dialysis or hospital stay, NaBiC supplement showed no additional advantages in patients with CKD.

FR-PO098

The Use of Anti-Adrenergic Agents as a Predictor of AKI and Delayed Recovery of Kidney Function: The NARA-AKI Cohort Study

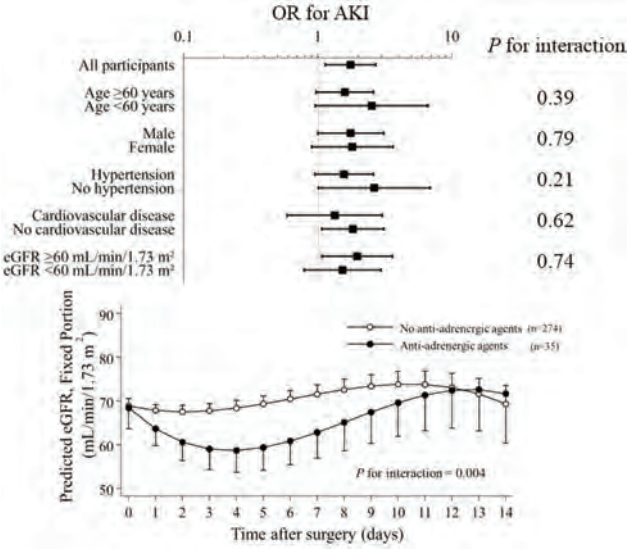
Masatoshi Nishimoto,[1] Miho Murashima,[2] Maiko Kokubu,[3] Masaru Matsui,[3] Masahiro Eriguchi,[1] Ken-ichi Samejima,[1] Yasuhiro Akai,[1] Kazuhiko Tsuruya.[1] [1]*Nara Kenritsu Ika Daigaku Fuzoku Byoin, Kashiwara, Japan;* [2]*Nagoya Shiritsu Daigaku, Nagoya, Japan;* [3]*Nara-ken Sogo Iryo Center, Nara, Japan.*

Background: Association of anti-adrenergic agents with postoperative acute kidney injury (AKI) and with trajectory of kidney function after AKI is still unknown.

Methods: In a retrospective cohort study, adults undergoing non-cardiac surgery under general anesthesia were included. Obstetric or urological surgery, missing data, or preoperative dialysis was excluded. The exposure of interest was preoperative regular use of anti-adrenergic agents. The outcomes were AKI within 1 week postoperatively and trajectories of kidney function within 2 weeks postoperatively among patients with AKI. Multivariable logistic regression models were used to examine the association of anti-adrenergic agents with AKI. Linear mixed-effects models were used to compare the trajectories of postoperative kidney function after AKI between patients with and without anti-adrenergic agents.

Results: Among 5168 patients, 245 had used anti-adrenergic agents. A total of 309 (6.0%) developed AKI, and the use of anti-adrenergic agents was independently associated with postoperative AKI even after adjustment for preoperative and intraoperative potential confounders [OR (95% CI): 1.76 (1.14–2.71)]. As a sensitivity analysis, propensity score matched analysis yielded the similar result [OR (95% CI): 1.78 (1.003–3.15)]. The association was similar across preexisting hypertension or cardiovascular disease. Analyses restricted to patients with AKI suggested that the timing and stage of AKI were similar among those with and without anti-adrenergic agents; however, the recovery of kidney function was delayed among those with anti-adrenergic agents (*P* for interaction = 0.004).

Conclusions: The use of anti-adrenergic agents was associated with postoperative AKI, and delayed recovery of kidney function after AKI. Temporary withdrawal of anti-adrenergic agents during perioperative periods may contribute to prevent AKI and shorten the duration of AKI.



FR-PO099

Metabolic Acidosis Increases the Risk of AKI in Critically Ill Patients: A Multicenter Cohort Study

Antonio Jose Inda-Filho,[1] Heitor S. Ribeiro,[1] Marvery P. Duarte.[2] [1]*University Center ICESP, Brasília, Brazil;* [2]*Universidade de Brasilia, Brasilia, Brazil.*

Background: Acute kidney injury (AKI) is a common complication in critically ill patients admitted to the intensive care units (ICU), as well as metabolic acidosis, characterized by low levels of serum bicarbonate. However, the possible association between both is not clear yet. The aim of the present study was to evaluate metabolic acidosis as a risk factor for the development of AKI.

Methods: A prospective cohort study was conducted by collecting data from three ICUs in the Federal District, Brazil. The serum bicarbonate level in the first 24 hours after ICU admission was used to define the acid-base disorders; acidosis (<22 mEq/L) and alkalosis (>26 mEq/L). The KDIGO guideline for AKI was used to define it based on serum creatinine levels. The mortality outcome was followed up to 28 days during the ICU stay. Odds ratio and Cox regression were performed with corrections for age, male sex, serum creatinine, and the presence of any comorbidity.

Results: A total of 2,732 patients (66±19 years and 55% men) were analyzed, with metabolic acidosis found in 26% (n=705) and metabolic alkalosis in 32% (n=865). Compared with the patients without acid-base disorders, those with acidosis were 81% more likely to develop AKI (OR=1.81; 95%CI:1.10–2.99), while those with alkalosis were 44% less likely (OR=0.56; 95%CI:0, 32–0.98). Both acidosis and alkalosis were not associated with increased risk of mortality (HR=1.03; 95% CI: 0.68–1.56 and 0.99; 95% CI: 0.68–1.42, respectively).

Conclusions: In critically ill ICU patients, metabolic acidosis, but not alkalosis, was associated with the development of AKI compared to the patients without acid-base disorders. On the other hand, metabolic alkalosis was a protective factor to the development of AKI. For the mortality outcome, none of the acid-base disorders was significantly associated with it.

FR-PO100

AKI in Patients with Acute Decompensated Heart Failure Undergoing Aggressive Diuresis and Its Effect on Short-Term Outcome

Anil K. Jhajhria, Manoj Singhal, Lovy Gaur, Manisha Dassi. *Max Super Speciality Hospital Vaishali, Ghaziabad, India.*

Background: Acute heart failure (AHF) patients treated with diuretics often develop worsening of renal functions with resultant acute kidney injury (AKI) during hospitalization. AKI could be a result of renal tubular injury or simply indicate a hemodynamic / functional change in glomerular filtration.

Methods: 100 AHF patients who underwent aggressive diuresis were included (excluding patients requiring inotropic support or haemodialysis). Urine NGAL was measured on the day of admission and after 72 hours. Serum creatinine was measured on day of admission, at 48 hours and at 72 hours post admission. AKI was defined as per KDIGO guideline as increase in creatinine by 0.3mg/dL or more in 48 hours or urine output < 0.5 mL/kg/h for 6 hours. All patients were contacted at 30 days and reviewed regarding requirement of readmission/mortality. Patients who developed AKI got their creatinine checked again at day 30 from the day of admission.

Results: Mean eGFR of patients was 48.1 ml/min/m2. Mean NT-proBNP was 11000 pg/ml. Mean LVEF was 43%, with 38% patients having HFrEF and 62% patients had HFpEF. Of total 100 patients, 37 developed AKI. Rise in NGAL from day 0 to day 3 was noted in 34 cases. There was no correlation found between rising creatinine levels and rising NGAL levels (including patients with AKI). Mean NT-proBNP was higher in patients with AKI as compared to those without AKI (p-value=0.048). Of 37 AKI patients,

10 (27%) patients had creatinine value at day 30 higher than at day 3, while 27 (73%) patients had creatinine value at day 30 lower than at day 3. 30 patients needed readmission within 30 days after discharge; 5 patients expired by day 30. Occurrence of AKI did not show association with readmission within 30 days or with mortality at 30 days.

Conclusions: AKI occurred in 37% patients with AHF undergoing aggressive diuresis. This AKI had no correlation with serial NGAL levels (tubular injury biomarker) but was associated with elevated baseline NT-proBNP levels. 73% AKI patients showed improvement in creatinine levels by day 30 post discharge & occurrence of AKI did not affect short term morbidity (readmission at 30 days) and mortality at 30 days. This implies that AKI in the setting of AHF & aggressive diuresis is mild, mainly functional/ hemodynamic and should not affect decisions with decongestive therapy.

FR-PO101

Analysis of Influencing Factors of Poor Prognosis in Patients with Acute Respiratory Distress Syndrome Complicated with AKI

Yue Gu,[1,2] Jing Zhou,[1,2] Shen Y. Jia,[1,2] Fengmin Shao.[1,2] *[1]Henan Provincial People's Hospital, Zhengzhou, China; [2]Zhengzhou University People's Hospital, Zhengzhou, China.*

Background: To study the influencing factors of poor prognosis in patients with acute respiratory distress syndrome (ARDS) complicated with acute kidney injury (AKI) in ICU.

Methods: Retrospective analysis was performed on patients with ARDS complicated with AKI admitted to the ICU. The stage of AKI was determined according to the change of blood creatinine value within 7 days after the diagnosis of AKI. They were divided into 28-day survival group (28-S) and 28-day death group (28-D) according to their survivalist 28 days. Multivariate COX regression analysis was used to analysis of influencing factors of 28-day death in patients with ARDS complicated with AKI.

Results: 265 patients with ARDS complicated with AKI has a median age of 68 (54,75) years old. 154 patients died within 28 days(58.1%). Compared to the 28-S group, age, proportion of renal function early unrecovered, proportion of combined coronary heart disease, proportion of combined malignant tumor, acute physiology and chronic health evaluation scoring system II, proportion of pulmonary ARDS, proportion of positive fluid balance accumulated on day 2 of ICU admission, proportion of severe AKI, blood lactic acid of the 28-D group were higher (P<0.05). The arterial partial pressure of oxygen, arterial oxygen saturation, oxygenation idex of the 28-D group were lower (P<0.05). Multivariate COX regression analysis showed that renal function early unrecovered (HR=1.936, 95%CI 1.238~3.027, P=0.004), combined malignant tumor (HR=1.983, 95%CI 1.301~3.023, P=0.001), positive fluid balance accumulated on day 2 of ICU admission (HR=1.428, 95%CI 1.013~2.015, P=0.042), oxygenation index(HR=0.647, 95%CI 0.447~0.937, P=0.021) were independent influencing factors for the 28-day death in patients with ARDS complicated with AKI.

Conclusions: Renal function early unrecovered, combined malignant tumor, positive fluid balance accumulated on day 2 of ICU admission, oxygenation index decreased are associated with poor prognosis in patients with ARDS complicated with AKI.

Funding: Government Support - Non-U.S.

Influencing factors of 28-day death in ARDS patients complicated with AKI

Factors	Multivariate COX regression analysis		
	P-value	HR	95%CI
Renal Function Early Unrecovered(Yes/No)	0.004	1.936	1.238~3.027
Combined Malignant Tumor(Yes/No)	0.001	1.983	1.301~3.023
Positive Fluid Balance Accumulated on Day 2 of Icu Admission(Yes/No)	0.042	1.428	1.013~2.015
Oxygenation Index(Every 1mmHg increase)	0.021	0.647	0.447~0.937

Building a Prediction Model for Postoperative AKI Using Machine Learning: The CMC-AKIX Model

Jeeyoung Yoon,[1] Ji Won Min,[2] Suyeon Hong,[3] Tae Hyun Ban,[4] Eun Sil Koh,[5] Byung ha Chung,[6] Yong Kyun Kim,[7] Seok Joon Shin,[1] Hye Eun Yoon.[1] The Catholic University of Korea. *[1]Catholic University of Korea Incheon Saint Mary's Hospital, Incheon, Republic of Korea; [2]Catholic University of Korea Bucheon Saint Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea; [3]Uijeongbu Saint Mary's Hospital, Uijeongbu, Republic of Korea; [4]Catholic University of Korea Eunpyeong St Mary's Hospital, Seoul, Republic of Korea; [5]Catholic University of Korea Yeouido Saint Mary's Hospital, Seoul, Republic of Korea; [6]Seoul Saint Mary's Hospital, Seoul, Republic of Korea; [7]Catholic Univeristy of Korea Saint Vincent Hospital, Suwon, Republic of Korea.*

Background: Postoperative acute kidney injury (AKI) is associated with increased mortality and morbidity in patients undergoing surgeries performed under general anesthesia. There are several models that predict postoperative AKI risk, but most are single-center studies that need external validation.

Methods: In this retrospective cohort analysis, we included noncardiac surgeries performed between 2009 and 2019 at 7 university hospitals in South Korea. Postoperative AKI was defined as an increase of serum creatinine at least 1.5 times the baseline value or initiation of renal replacement therapy within 30 days of the postoperative period. We tested 6 machine learning prediction models: deep neural networks (DNN), logistic regression, decision tree, random forest, light gradient boosting machine (GBM), and naïve Bayes, and compared model performance using the area under the curve (AUC) of the receiver-operating characteristic.

Results: A total of 239,267 surgeries were included, and 7,935 postoperative AKI events (3.3%) occurred. The 6 different statistical analysis methods were run on various combinations of 40 independent preoperative predictors that we had selected. Model 1 included all variables, Model 2 included variables that had been significantly associated with postoperative AKI in previous studies, and Model 3 included variables that were found significant on multivariate analysis. Among them, Model 1 run on DNN (AUC = 0.821) and light GBM (AUC = 0.823) and Model 3 run on DNN (AUC = 0.807) demonstrated the best prediction performance.

Conclusions: We have developed a high-performance risk prediction system for postoperative AKI that can be easily applied using preoperative patient characteristics and laboratory data.

FR-PO103

Acute Kidney Disease in Outpatient Setting: Epidemiological Insights from National Digitalized Big Data Practice

Hsiu-Yin Chiang, Zi-Han Lin, David R. Chang, Chin-Chi Kuo. *China Medical University Hospital, Taichung, Taiwan.*

Background: The burden of acute kidney disease in outpatients (AKD_{OPT}) is largely unknown due to health data silos and its asymptomatic nature. We established an Acute Kidney Injury Detection System (AKIDS) that integrates local electronic medical records and National Health Insurance Cloud to screen for AKD_{OPT}, and enable risk-based referrals in real-time.

Methods: AKIDS was integrated into the backend of outpatient HIS during 2017.12-2020.05. AKD_{OPT} within 180 days prior to a clinic visit is defined as the percent change between the max and min of (1) serum creatinine (SCr) >50%, or (2) eGFR >35%. AKD_{OPT} is considered deteriorating if the last two SCr decreased by >0.3 mg/dL; otherwise, it's termed stable. We ensured a 1-year follow-up by including adult patients with the first AKD_{OPT} occurring during 2017.12-2019.06 and without ESRD or cancer. One-year composite kidney outcome (CKO) was defined as having ESRD or ≥40% drop of outpatient eGFR during follow-up. All-cause mortality was determined by National Death Registry. Multivariable Cox proportional modeling was used to estimate the risk of outcomes associated with AKD_{OPT}.

Results: The monthly cumulative incidence density of AKD_{OPT} was 6.9 to 8.1% (**Figure**). AKD_{OPT} patients had significantly higher 1-year CKO (1.8 vs 0.2%) and mortality (8.2 vs 1.4%), compared with those without. Of 79838 outpatients, 15.7% had AKD_{OPT} (12.7% stable; 3.0% deteriorating). Multivariable analysis found that AKD_{OPT} was significantly associated with increased 1-year risk of CKO by 5-fold (adjusted HR [aHR]=5.2; 95% CI=4.0-6.8) and mortality by 3-fold (2.6 [2.4-2.9]). The risk of 1-year CKO for deteriorating AKD_{OPT} (7.6 [5.5-10.5]) was higher than that for stable AKD_{OPT} (4.4 [3.3-5.8]).

Conclusions: By integrating national–local data and creating a kidney data ecosystem, we conducted the first study to fully characterize the epidemiologic profile of AKD_{OPT}—a obscured AKI phenotype. This study illustrates the potential of healthcare big data in transforming global approaches to AKD patterns and prevention.

Novel Data-Driven Phenotyping to Support Genome-Wide Association Study (GWAS) Exploration in AKI

Michael E. Matheny,[1,2] Jacklyn N. Hellwege,[1,2] Bethany Birkelo,[1,2] Sharidan Parr,[3] Andrew J. Vincz,[1,2] Trey H. Richardson,[2] Adriana Hung,[1,2] Digna R. Velez edwards,[1,2] Edward D. Siew.[1,2] Million Veterans Program Initiative. *[1]VA Tennessee Valley Healthcare System, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]VA Nebraska-Western Iowa Health Care System, Omaha, NE.*

Background: Traditional phenotyping may have limited sensitivity for detecting meaningful phenotypes. Machine learning may detect patterns of variables for novel phenotype identification. We applied this approach to identify phenotypes of acute kidney injury (AKI).

Methods: A cohort of VA patients hospitalized from 2002-2019 was aggregated. AKI was defined as KDIGO Stage 1 or greater during hospitalization. 5,515 data features including individual demographics, laboratory tests, medications, and billing codes were used to calculate longitudinal curves anchored on each patient hospitalization, and endophenotypes inferred with Independent Component Analysis (ICA). Ten iterations from

200,000 randomly selected hospitalizations with AKI were analyzed, resulting in 11,985,029 learning instances. GWAS was performed on 167,051 MVP patient hospitalizations with and without AKI were scored for each phenotype. Each patient was represented only once with that patient's hospitalization being randomly selected. Single variant linear regression analyses were performed using imputed data, adjusting for sex, age, the top 10 principal components, stratified by HARE race/ethnicity, followed by meta-analysis. Phenotypes were retained if they had at least 1 significant SNPs and inflation between 0.98-1.1.

Results: 2,137 distinct phenotypes were identified. 50 phenotypes with data patterns potentially relevant to AKI were selected by expert adjudication. Nine of 50 phenotypes were retained. We selected two phenotypes, one clinically consistent with patterns of acute glomerulonephritis (AG) and one with cardiorenal syndrome (CS). The former was associated with serum complement and albumin levels, hyperlipidemia, and acute/chronic hepatitis C. The latter was characterized by acute on chronic heart failure, elevated BNP, and acute renal failure (ARF) codes. The presence of ARF in both phenotypes enriched for intrinsic/more severe injury. Two loci with AG (HLA and COL4A2), and one locus (FANCL) with CS reached genome-wide significance.

Conclusions: An entirely data-driven process can identify both well-established and potentially novel endophenotypes of AKI that can be explored for clinically provocative features. These findings show promise for novel phenotype discovery and significant genetic association detection.

FR-PO105

Time to Blood Pressure Control and Blood Pressure Targets Significantly Impact Mortality Among Veterans Following AKI

Benjamin R. Griffin, Mary V. Sarrazin, Masaaki Yamada, Qianyi Shi, Meenakshi Sambharia, Melissa L. Swee, Diana I. Jalal. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Acute kidney injury (AKI) complicates 20-25% of hospital admissions, and is associated with increased long-term mortality. Effective blood pressure (BP) control following AKI may improve outcomes, but appropriate BP targets and optimal timing of BP medication initiation are unclear.

Methods: This retrospective cohort analysis included adult Veterans admitted from 2013 to 2018 with in-hospital AKI and ≥1 blood pressure measurement within 30 days of discharge. Systolic BP control was treated as time dependent and categorized as <120, 120-129, and 130-139, relative to >140 mm HG. The primary outcome was time to death. Cox Proportional Hazards regression was adjusted for demographics, chronic lung disease, unexplained weight loss, dementia, congestive heart failure (CHF), hematocrit, blood urea nitrogen, bilirubin, and albumin. [YM1] To evaluate the impact of BP control over time, we calculated hazard ratios (HR) at 7 different timepoints (30, 60, 90, 120, 180, 270, and 365 days after discharge).

Results: A total of 97,376 Veterans were included and 14,819 (15%) died within 1 year of discharge. The cohort had high rates of hypertension (85%), CHF (28%), and diabetes mellitus (19%). All BP categories <140 mmHg had significantly reduced HRs for mortality relative to uncontrolled BP, but the 130-139 mmHg group had the lowest HRs (Table). For all BP categories, hazard ratios relative to uncontrolled BP were lowest at the 30-day mark and increased over time (Table).

Conclusions: Among post-AKI Veterans, BP control within 30 days of discharge was associated with reduced mortality, but this benefit was attenuated over time. All BP targets were superior to blood pressure >140 mmHg, but the 130-139 mmHg group had the lowest risk of death at each timepoint. These findings highlight the importance of achieving BP control promptly post-AKI and suggest that targeting a systolic BP of 130-139 is ideal.

Table. Hazard Ratios and 95% confidence intervals for mortality over time, by blood pressure category

		Systolic Blood Pressure (mmHg)			
		<120	120-129	130-139	>=140
Days From Hospital Discharge	30	0.66 (0.66-0.67)	0.56 (0.56-0.57)	0.47 (0.46-0.48)	Reference
	60	0.69 (0.68-0.69)	0.59 (0.59-0.60)	0.50 (0.49-0.50)	Reference
	90	0.71 (0.71-0.71)	0.62 (0.61-0.62)	0.52 (0.52-0.53)	Reference
	120	0.74 (0.73-0.74)	0.65 (0.64-0.65)	0.55 (0.55-0.56)	Reference
	180	0.80 (0.79-0.80)	0.71 (0.71-0.72)	0.62 (0.61-0.62)	Reference
	270	0.89 (0.89-0.89)	0.82 (0.81-0.82)	0.72 (0.72-0.73)	Reference

AKI Increase the Risk of Fractures: A Retrospective Cohort Study of an Australian Health District

Hicham I. Cheikh Hassan,[1,2] Karumathil Murali,[1,2] Kelly Lambert,[3] Stephen Moules,[3] Brendan J. Mcalister,[4] Bridie S. Mulholland,[1] Judy Mullan.[1] *[1]University of Wollongong Faculty of Science Medicine and Health, Wollongong, NSW, Australia; [2]Wollongong Hospital, Wollongong, NSW, Australia; [3]University of Wollongong, Wollongong, NSW, Australia; [4]Illawarra Shoalhaven Local Health District, Wollongong, NSW, Australia.*

Background: Kidneys play an important role in maintaining bone mineral balance and bone health. However, this may be disrupted following an acute kidney injury (AKI), affecting bone health. We hypothesized that AKI increases the risk of fractures and investigated this association.

Methods: Retrospective cohort study utilising adult (>18 years of age) patient-data (January 2008-December 2017), from an Australian Local Health District. AKI was based on serum creatinine measurements consistent with Kidney Disease Improving Global Outcome (KDIGO) AKI definition or international classification of disease (ICD) 10AM AKI code. Demographics, comorbidities and fractures were also extracted from ICD codes. Adjusted time-varying (time to AKI) Cox proportional hazards was used to determine the risk for future fractures (hazard ratio [HR], 95% confidence intervals [CI]) after AKI uring no AKI history as a reference. Variables in multivariable analysis included those associated with fractures such as age, gender, history of chronic kidney disease, hypertension, diabetes, cardiac history, cancer and osteoprosis. Sensitivity analysis using only biochemistry confirmed AKI was also undertaken.

Results: Of 139,080 patients; 19,188 (13.8%) had AKI; 14,914 (10.7%) experienced a fracture. Median time to fracture following AKI was 4.2 [Interquartile range 2.3,6.6] years. Crude fracture incidence for the cohort was 27.9/1,000 patient-years (95% CI 27.5-28.3). Fracture incidence was higher in the AKI group (44.5, 95% CI 42.6-46.5) compared to the non-AKI group (26.6, 95% CI 26.2-27.1) (P<0.001). In unadjusted analysis AKI was significantly associated with a risk of fracture (HR 2.1, 95% CI 2.0-2.2,P<0.001), which persisted in multivariate analysis (HR 1.2, 95%CI 1.1-1.3,P<0.001). Sensitivity analysis showed similar estimates (univariate analysis HR 1.4, 95% CI 1.4-1.5, P<0.001 and multivariate analysis HR 1.1, 95%CI 1.0-1.2, P=0.007).

Conclusions: In a large cohort of patients representing an Australian local health district, AKI was found to be associated with an increased risk of fractures. This association should be further examined and verified in other patient cohorts.

FR-PO107

Assessment of Individualized Mean Perfusion Pressure Target for Cardiac Surgery-Associated AKI: PrevHemAKI Trial

Alicia M. Andújar, Jose Rios, Gastón J. Piñeiro, Esteban Poch. *Hospital Clinic de Barcelona, Barcelona, Spain.*

Background: Retrospective studies support that mean perfusion pressure (MPP) deficit in cardiac surgery patients is associated with a higher incidence of post-operative acute kidney injury. The aim of our study was to apply an algorithm based on MPP = mean arterial pressure (MAP)-central venous pressure (CVP) in the postoperative period of cardiac surgery patients to determine whether management with an individualized target compared to standard treatment reduces the incidence of acute kidney injury (CC-AKI).

Methods: Randomized controlled trial of patients undergoing cardiac surgery with extracorporeal circulation between October 2019 and September 2022. Inclusion criteria were: adults with valve replacement and/or bypass surgery intervention with Leicester score >30. Patients were randomized to follow target of MPP >75% baseline vs standard follow-up during the first 24h.

Results: 98 patients were recruited, 82.7% male with mean age 72.96 +- 7.25 years and eGFR of 55.3 +/-16.6 ml/min. 49 were randomized to the intervention arm and 49 to the standard treatment arm. Mean MAP during the intervention was higher in the intervention group (73.6/75.9 p=0.008), with no differences in mean MAP and MPP of the first 24h (75.5 vs 76.7, p=0.32 and 66.5 vs 67.5, p= 0.375 respectively) although a higher use of noradrenaline was found in the intervention arm (38.78 vs 63.27, p= 0.026). The percentage of time with MPP<75% baseline was similar in both groups (21.5/21.4%, p=0.811). Mean 24h fluid balance was similar (331 [-384-1206] vs 26 [-984-999], p=0.154). The incidence of CC-AKI was 36.7% (72.2% of them stage 1), with no differences between both groups but with a tendency to a higher incidence of AKI in the presence of PPM deficit of >20% (p=0.064).

Conclusions: There was a tendency to a higher incidence of AKI if MPP deficit >20% but individualized hemodynamic management based on MPP compared to standard treatment did not reduce the incidence of AKI associated to cardiac surgery in our study. Larger cohorts are needed in order to confirm these findings.

Real-World Evidence on the Impact of Incident AKI on Mortality, Healthcare Resource Utilization, and Costs Among Patients Undergoing Cardiac Surgery with Cardiopulmonary Bypass (CPB) from US Hospitals

Richard W. Declue,[1] Jonghanne Park,[1] Seth Emont,[2] Zhun Cao,[2] Manu Tyagi,[2] Craig B. Lipkin,[2] Vivek B. Ajmani,[2] Peggy H. Wong,[1] Matthew D. Breyer,[1] Victor Dishy,[1] Hideo Makimura.[1] *[1]Janssen Research and Development LLC, Raritan, NJ; [2]Premier Inc, Charlotte, NC.*

Background: AKI is among the most common complications in hospitalized patients, including 100,000 US cases per year in patients undergoing CPB. AKI is underdiagnosed and its severity is not routinely captured by ICD-10 codes. Therefore, we used serum creatinine (SCr) values (i.e., KDIGO criteria) to evaluate the true impact of AKI on mortality, healthcare resource utilization (HCRU), and costs among inpatients undergoing CPB.

Methods: Using an all-payer US hospital-based database, this retrospective cohort study included adult patients undergoing CPB with an index visit between January 2018 and December 2020. All-cause death, HCRU, and index hospitalization costs were described by AKI stage. Incident AKI and staging were defined by KDIGO criteria and/or an ICD-10 (or dialysis procedure) code at index. Propensity score matching was used to create matched cohorts to address differences in demographic and clinical characteristics between patients with severe AKI (stage 2/3) and no or mild AKI (stage 1). A comparison by presence vs absence of AKI by ICD-10 code was done as a reference.

Results: More severe AKI was associated with higher risk of death and greater HCRU (Table). Adjusted analysis indicated independent associations of severe AKI with 34.1x and 2.5x higher odds of death and 30-day readmission, mean LOS increase of 9.8 days, and mean increased costs of $58.4k compared to confirmed non-AKI or AKI stage 1. The impact of severe AKI was underestimated for ICD-10 AKI diagnosis vs. absent: 9.3x and 1.9x higher odds of death and 30-day readmission, mean LOS increase of 5.4 days, and mean increased costs of $25.5k.

Conclusions: Severe AKI in patients undergoing CPB is associated with significantly high mortality, HCRU, and cost compared to no or mild AKI. ICD-code based definition can underestimate the impact of AKI.

Funding: Commercial Support - Janssen Research & Development

Mortality, HCRU, and Costs by AKI stage

AKI Stage	Mortality at Index (%)	30-Day Readmission (%)	Index LOS (Mean Days)	Index Hospitalization Costs (Mean)
Confirmed non-AKI	0.4	8.9	8.9	$43,960
Stage 1	2.6	15.0	13.1	$63,486
Stage 2	13.3	22.0	20.8	$101,569
Stage 3 w/o dialysis	17.8	22.2	21.9	$104,465
Stage 3 w/ new dialysis	39.2	26.2	26.1	$166,222

FR-PO109

Renal Functional Reserve After AKI Predicts Adverse Outcomes at 180 Days

Vongsatorn Tiabrat, Nattachai Srisawat, Nuttha Lumlertgul, Kearkiat Praditpornsilpa, Somchai Eiam-Ong, Yingyos Avihingsanon, Sadudee Peerapornratana. *King Chulalongkorn Memorial Hospital, Bangkok, Thailand.*

Background: There is a lack of evidence to guide optimal post-acute kidney injury (AKI) care. Renal functional reserve (RFR) measures the capacity of the kidney to increase glomerular filtration rate (GFR) under various physiologic stresses and is potentially a marker to predict the susceptibility to injury and refine the recovery of kidney function. We aim to examine the association between post-AKI RFR and major adverse kidney events at 180 days after hospital discharge ($MAKE_{180}$) including death, new kidney replacement therapy, and persistent renal dysfunction.

Methods: We enrolled patients with baseline eGFR of >60 mL/min/1.73 m^2 who survived from moderate to severe AKI with eGFR of >30 mL/min/1.73 m^2 at hospital discharge between November 2021 to March 2023. RFR was measured by using intravenous amino acid infusion at 1 and 3 months after discharge. Primary end point is the predictive performance of post-AKI RFR for $MAKE_{180}$. Secondary end points include the performance of RFR to predict recurrent AKI and incident chronic kidney disease (CKD) within 6 months.

Results: Among 56 AKI survivors enrolled, median RFR at 1 and 3 months after AKI are significant lower in those who developed $MAKE_{180}$ compared with those who did not (0.86 (4.6-10.6) vs 13.48 (8.6-21.8) mL/min/1.73 m^2, p=0.002 and -0.69 (-4.67-3.5) vs 17.57 (10.83-38.1) mL/min/1.73 m^2, p=<0.001, respectively). Patients with $MAKE_{180}$ had RFR declination (negative difference RFR), in contrast, those without $MAKE_{180}$ had RFR improvement over 3 months (-4.39 (-7.42-0.64) vs 14.34 (9.7-22.14) mL/min/1.73 m^2, p=<0.001). The RFR at 1 and 3 months could predict $MAKE_{180}$ with an AUC of 0.77 (95% CI, 0.62-0.93) with the cut-off value of 8.3 mL/min/1.73 m^2 (sensitivity 76%, specificity 74%) and AUC of 0.91 (95% CI, 0.81-1) with the cut-off value of 8.6 mL/min/1.73 m^2 (sensitivity 93%, specificity 83%), respectively. Those who developed incident CKD and recurrent AKI had a significantly lower post-AKI RFR at 1 and 3 months and predicted incident CKD and recurrent AKI with good AUC.

Conclusions: Post-AKI RFR is highly predictive of poor kidney outcomes at 6 months. Larger prospective studies are warranted to explore the association between a reduced RFR and poor outcomes in post-AKI survivors.

FR-PO110

The Incidence, Aetiology, and Short-Term Outcomes of AKI in Adults

Alaeldin Abdalla,[1] Adeel R. Ahmed,[2] Muniza Satti,[3] David Lappin.[1] *[1]Galway University Hospitals, Galway, Ireland; [2]University College Cork, Cork, Ireland; [3]University of Galway, Galway, Ireland.*

Background: Acute Kidney Injury (AKI) is a common clinical syndrome in hospitalized patients associated with an increased risk of poor prognosis and mortality. We aimed to identify the incidence, aetiology, and short-term outcomes of adults with AKI on presentation to the hospital.

Methods: Data were prospectively collected over a two-month period. The patients were followed till the time of discharge from the hospital. Patients admitted over two months were investigated, and those with AKI as defined by the Kidney Disease: Improving Global Outcomes (KDIGO) criteria) were identified at the time of admission. Patients with known End Stage Renal Disease (ESRD) on dialysis, renal transplant, Paediatric, and Gynaecology admissions were excluded. Data was collected from the admission records in the emergency department, medical notes, laboratory system and discharge summaries.

Results: There were a total of 2847 patients admitted over the study period, and 2397 were reviewed. The incidence of AKI was 5.92% (n=142). In the AKI population, 54.22% were males and 45.77% were females. The mean±standard deviation(SD) age was 74.6±14.7 years. Chronic kidney disease was present in 53.52%. The mean±SD creatinine at baseline (pre-admission) was 106±47.1umol/L(1.2±0.53mg/dL), at presentation 190±91.1umol/L (2.15±1.44mg/dL), and 127±67.2umol/L(1.44±0.76mg/dL) on discharge. The most common aetiology of AKI was a decrease in effective circulating volume (prerenal)(78.17%) secondary to primarily sepsis (44.36%), decompensated heart failure(4.96%), acute coronary syndrome(6.34%), stroke or seizure(7.4%), gastrointestinal bleed(4.22%) and diabetic ketoacidosis (3.52%). Obstructive nephropathy was present in 9.15%. Polypharmacy contributing to AKI was present in 61.97%. The median length of stay was 8 days (inter-quartile range 5 to 13 days). Renal replacement was required in 13.38%, and 11.27% were admitted to the intensive care unit. On discharge from the hospital, complete renal recovery was seen in 57.75%, residual renal impairment in 22.54% and dialysis dependence in 5.63%. The all-cause mortality was 6.34%.

Conclusions: The incidence of AKI was 5.92% in the study population. Sepsis was a common aetiology. A large proportion of patients had residual renal impairment on discharge, indicating high morbidity with AKI.

FR-PO111

Clinical Characteristics and Outcomes in AKI in Non-Critically Ill Patients

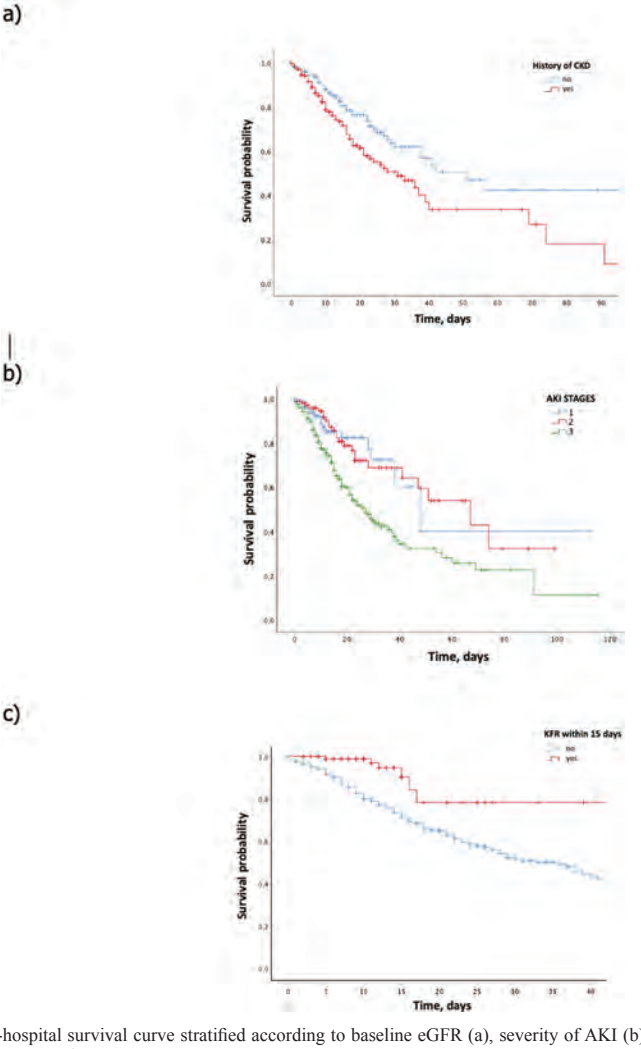
Marco Fiorentino, Sebastiano Nestola, Loreto Gesualdo. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: Although many studies have been focused on critically ill patients in ICUs, AKI occurs even in non-critical care settings. Epidemiological data of AKI outside the ICU are not well investigated. We aim to describe main features and outcomes of AKI in non-critically ill patients in our teaching hospital.

Methods: We performed a retrospective analysis including AKI patients referred to nephrology consultation in a 6-month period at AOU Policlinico, Bari, Italy. We analyzed the main features of AKI episodes, including AKI stages, the need for dialysis, mortality rate and factors associated to kidney function recovery (KFR).

Results: Among 899 patients referred for nephrologists, 415 (46%) were evaluated for AKI. 52.5% of AKI episodes were classified as KDIGO Stage 3, and 54 patients (13%) required RRT. In-hospital mortality was 36.9%, higher in patients with pre-existing CKD, in patients with stage 3 AKI and among those who did not present KRF. Cox analysis showed a higher mortality risk for older age (HR 1.032, 95%CI 1.012–1.053, p=0.002) and pre-renal AKI (HR 2.823, 95%CI 1.219-6.536, p=0.015), while KFR was associated to lower mortality (HR 0.246, 95%CI 0.098-0.615, p=0.003). KFR was observed in 197 patients (47.5%) mainly in patients with mild AKI (stage 1 62.6% vs stage 2 57.6% vs stage 3 36.8%, p<0.001). Higher baseline eGFR (OR 1.025, 95%CI 1.014-1.036, p<0.001) was associated with KFR. Severe AKI was independently associated with lower probability of KFR (OR 0.420, 95%CI 0.248-0.711, p=0.001).

Conclusions: AKI episodes outside the ICU are severe and associated with a high mortality rate even outside the ICU. A timely nephrologist consultation is important to limit AKI severity.



In-hospital survival curve stratified according to baseline eGFR (a), severity of AKI (b) and kidney function recovery (c)

FR-PO112

Development and Feasibility of a Remote Patient Monitoring Program for AKI Survivors

Mariam Charkviani, Andrea G. Kattah, Jennifer A. Ferguson, Kianoush Kashani, Kristin C. Mara, Heather P. May, Lindsey M. Philpot, Swetha Reddy, Jordan K. Rosedahl, Andrew D. Rule, Erin F. Barreto. *Mayo Clinic Minnesota, Rochester, MN.*

Background: One-third of acute kidney injury (AKI) survivors lack appropriate follow-up after hospital discharge. Remote patient monitoring (RPM) may improve post-discharge care quality. We report an AKI RPM program's development and preliminary feasibility.

Methods: Mayo Clinic launched an AKI RPM program in October 2021 for individuals who experienced AKI with a nephrology consultation during a hospitalization. Once enrolled, patients were discharged with RPM technology (e.g., blood pressure cuff, scale), and vital signs and symptoms were monitored daily. In-center laboratory assessments were scheduled weekly. RPM nurses evaluated the data daily and adhered to prespecified protocols for alerts and care escalation management. Patients were followed for up to three months. Individuals graduated from the AKI RPM program if they remained dialysis independent, with a stable creatinine for 2 consecutive weeks, and no urgent or emergent results in the prior week. Feasibility was defined as the proportion of enrolled patients who submitted at least one set of vitals or symptom data after program initiation.

Results: Of the 50 people approached, 41 (82.0%) were enrolled in RPM. The median (IQR) baseline eGFR was 37 (28, 60) mL/min/1.73m^{2,} and 83% experienced stage 3 AKI. The length of time in the program was 31 (28, 38) days. Eight (20%) patients were lost to follow-up or withdrew. Thirty (73%) individuals had at least 1 RPM alert, most for weight gain or edema. Six emergency department referrals were made for AKI RPM patients. Among the 33 patients who graduated from the AKI RPM program, 25 (76.0%) were referred to nephrology for evidence of chronic kidney disease. 17 (68%) of those individuals completed a nephrology visit within 90 days of program graduation.

Conclusions: The AKI RPM workflow was feasible and addressed a vital gap for AKI care after discharge. Digital health solutions such as RPM offer a unique opportunity to bridge the care transition from hospital to home, increase access to quality care for the most vulnerable AKI survivors, and direct the attention of nephrologists to patients most likely to benefit from specialty consultation.

FR-PO113

A Self-Funded, Value-Based, Post-AKI Care Program: Predicted vs. Observed Outcomes

Kaushal V. Solanki, Dolly A. Gotschal, Alexander R. Chang, Evan Norfolk, Gurmukteshwar Singh. *Geisinger Health, Danville, PA.*

Background: Readmissions occur in 20% patients with Acute Kidney Injury (AKI), adding $20000 in healthcare costs. While post-AKI care improves outcomes, studies are limited to non-dialysis referred patients. As one of the earliest post-AKI clinics, we set up a self-sustaining multi-disciplinary post-AKI care program.

Methods: Target population/interventions were finalized by interviewing nephrologists, patients and AKI!Now Workgroup. Since May 2022, hospitalized adults with high-risk stage 2/3 AKI at Geisinger Medical Center were identified in real-time. Those eligible were provided inpatient AKI education, nurse coordinator services, flexible scheduling, non-face-to-face care and expedited nephrology visits. Follow-up was up to 90 days post-discharge. Observed vs Predicted (Grampian-Aberdeen model) 90-day rehospitalization/mortality risk were compared.

Results: On screening 1198 patients, 303 were eligible; 195 (64.4%, 5% on dialysis) were enrolled (Fig 1) and 154 have completed 90 days. More than 95% received direct or non-face-to-face nephrology care. Fig 2 shows predicted vs observed outcomes: 90-day rehospitalization/mortality was 30.2% vs a mean risk of 45.8%. Graphical pattern suggests steady benefit lending itself to a Difference-in-Difference estimation.

Conclusions: We developed a value-based comprehensive post-AKI care model showing improvement over predicted outcomes. Our approach allows quasi-experimental analysis and could be widely applicable.

An Exploratory Needs Assessment for AKI Patient Education: Results from a Focus Group

Daniel P. Murphy,[1] Patricia F. Kao,[2] Rajit K. Basu,[3] Andrew J. Lewington,[4] Marla Levy,[5] Linda Awdishu,[6] Jorge Cerda,[7] Kathleen D. Liu,[8] Marlies Ostermann,[9] Ashita J. Tolwani,[10] Bonnie L. Freshly,[5] Michael Heung.[11] ASN AKINow Education Workgroup. *[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]Washington University in St Louis, St Louis, MO; [3]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [4]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom; [5]American Society of Nephrology, Washington, DC; [6]University of California San Diego Skaggs School of Pharmacy and Pharmaceutical Sciences, La Jolla, CA; [7]Albany Medical College, Albany, NY; [8]University of California San Francisco School of Medicine, San Francisco, CA; [9]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [10]The University of Alabama at Birmingham Department of Medicine, Birmingham, AL; [11]University of Michigan, Ann Arbor, MI.*

Background: Literature on the type, content, and effectiveness of patient education regarding acute kidney injury (AKI) is scarce. The American Society of Nephrology AKINow Education Workgroup conducted a focus group of relevant stakeholders with

AKI experience to discern major themes in the educational needs, level of resources, and opportunities in the realm of AKI-education.

Methods: The focus group was held virtually in May 2023 with participants recruited from the United States and United Kingdom. Participants included patients, physicians, nurses, pharmacists, and social workers and were divided into four breakout sessions to discuss for 40 minutes one topic each: (1) AKI-related education in the hospital and at discharge; (2) long-term education needs based on degree of AKI-recovery; (3) education in the outpatient dialysis unit regarding dialysis-requiring AKI; or (4) counseling patients at risk for AKI.

Results: Focus group participants included 7 patients, 15 nephrologists, 2 primary care physicians, 1 intensivist, 3 nurses, 6 pharmacists, and 2 social workers. Several common themes emerged, including: general lack of knowledge among the public regarding "what kidneys do;" uncertainty of what questions patients would be well-served by asking; and a desire for improved and/or more frequent communication to patients and amongst their medical team regarding updated, germane AKI-related information. Additional major themes from session 1 included: key signs/symptoms to monitor for, and clear directions to navigate clinical changes in a patient's AKI course. Major themes from session 2 included: recommended steps to improve or protect health after AKI, including medications and diet. Major themes from session 3 included: inconsistency in provider messaging around the evolving assessment of AKI-recovery vs. end-stage kidney disease. Major themes from session 4 included: the need for multimodal patient education (e.g., written and multimedia resources) in addition to education from trusted providers.

Conclusions: There is an urgent need to improve education for patients with AKI through all phases of the AKI experience and to co-produce these resources with patients.

FR-PO115

Feasibility of a Randomized Pilot Trial of a Multidisciplinary AKI Survivor Program in Primary Care

Heather P. May, Joan M. Griffin, Joseph Herges, Kianoush Kashani, Andrea G. Kattah, Rozalina G. McCoy, Andrew D. Rule, Angeliki G. Tinaglia, Erin F. Barreto. For the ACT Study Group. *Mayo Clinic Minnesota, Rochester, MN.*

Background: AKI survivor care delivery in nephrology specialty clinics has been limited by poor recruitment. The AKI in Care Transitions (ACT) Program was designed to address this barrier by facilitating kidney health follow-up within primary care. This study aimed to describe the recruitment and retention of patients in a clinical trial on the feasibility of ACT compared to usual care.

Methods: The study included adults with stage 3 AKI during hospitalization from 2022-2023 at Mayo Clinic in Rochester, MN, who were expected to discharge to home in the local area, not on dialysis. Consenting individuals were randomized 1:1 to ACT or usual care. Patients in the ACT group received education before discharge and coordination of post-discharge laboratory and clinician (primary care physician [PCP], pharmacist) follow-up in primary care within 14 days. The Usual Care group received no study-specific intervention. The percentage of AKI survivors screened, approached, and who provided consent was reported. Reasons for declining participation were recorded if volunteered. We described the proportion of patients in the ACT group in which pre-discharge education was completed and post-hospital laboratory and clinician follow-up orders were placed.

Results: An electronic health record alert identified 549 potential candidates. There were 429 exclusions based on pre-specified study criteria and 106 individuals were approached for participation. Forty-five (42%) consented to participate and were enrolled. Among 14 patients who declined with a reason, concerns about time commitment and feeling overwhelmed predominated. Of 23 ACT patients, 22 completed education, and 21 had orders placed for post-discharge follow-up. One patient withdrew from the ACT group due to feeling overwhelmed.

Conclusions: These data demonstrate the ability to recruit AKI survivors into a care transitions program within primary care. While ACT recruitment appeared more successful than in other controlled trials of nephrologist follow-up, feeling overwhelmed remained an important barrier to participation. AKI survivor interventions should be simplified where possible to limit treatment burden.

Revolutionizing AKI and Critical Care Nephrology Education: Evaluating ChatGPT's Accuracy on Core Questions

M. Salman Sheikh, Kianoush Kashani, Charat Thongprayoon, Fawad Qureshi, Juan Pablo Domecq Garces, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ChatGPT is a state-of-the-art language model with exceptional proficiency in various natural language processing tasks, including generating responses that closely mimic human-generated ones. While there is growing speculation about ChatGPT's potential to serve as a substitute for physicians in clinical settings, its proficiency in nephrology, including acute kidney injury and critical care nephrology, remains uncertain. This study aims to evaluate the performance of ChatGPT in answering core questions related to acute kidney injury and critical care nephrology.

Methods: The accuracy of ChatGPT was evaluated in answering questions related to acute kidney injury and critical care nephrology using the Nephrology Self-Assessment Program (NephSAP) and Kidney Self-Assessment Program of the American Society of Nephrology (KSAP). Questions containing images were excluded from the assessment due to current limitations in ChatGPT's image processing capabilities. One hundred ten questions were included in the evaluation, 45 from NephSAP and 55 from KSAP. Each question bank was executed twice using ChatGPT. The level of concordance between the initial and subsequent runs, which were conducted two weeks apart, was also examined.

Results: In the case of NephSAP questions, ChatGPT achieved accuracies of 55% and 69% on the initial and subsequent runs, respectively. For KSAP questions, it achieved accuracies of 46% and 40%, respectively. ChatGPT's accuracy on all 110 questions combined was 52% and 51% for the initial and subsequent runs. The overall concordance between the initial and subsequent runs was 78%, with 86 questions (78%) receiving the same response and 24 (22%) receiving different responses. Correct concordance was 57%, and incorrect concordance was 43%. Among the 24 questions with divergent responses, ChatGPT rectified 11 incorrect responses to become correct. Conversely, it changed its response from correct to incorrect in 5 out of 24 questions.

Conclusions: Our study shows that ChatGPT only responded correctly to half of the questions related to acute kidney injury and critical care nephrology with low reliability. Therefore, ChatGPT as an educational tool may not be precise or reliable, and further development may be necessary to improve its performance.

Epidemiology and Outcome of Community- and Hospital-Acquired AKI in a Developing Country

Arunkumar Subbiah, Sanjay K. Agarwal, Raj K. Yadav, Soumita Bagchi, Sandeep Mahajan, Dipankar M. Bhowmik. *All India Institute of Medical Sciences, New Delhi, India.*

Background: Acute Kidney Injury (AKI) is associated with adverse short-term and long-term outcomes in hospitalized patients. In developing countries, including India, Community acquired AKI (CAAKI) is more common than hospital acquired AKI (HAAKI) and the pattern varies with different geographical areas. This single-centre study aimed to assess the clinical spectrum, risk factors for in-patient mortality and renal outcome of patients with CAAKI compared to HAAKI.

Methods: In this prospective observational cohort study conducted in a tertiary care hospital in India, hospitalized patients with AKI were enrolled and followed-up for upto 12 months after discharge. Patients with renal dysfunction at admission or worsening renal dysfunction in the first 48 hrs of hospitalization were classified as having CAAKI while patients with renal dysfunction after 48 hours of hospitalization were classified as HAAKI. Outcome variables were in-hospital all-cause mortality, renal function (by creatinine) at discharge and on long-term.

Results: A total of 476 AKI patients were enrolled in this study; 395 (83%) were CAAKI. The mean age was 44.8±18.7 years. Sepsis (176/476; 36.9%) was the most common cause of AKI. The in-hospital mortality was 38%. The peak serum urea and creatinine was higher in patients with CAAKI than HAAKI. The need for ventilator (34.9% vs 67.9%), inotropic support (38% vs 73%) and in-hospital mortality (31% vs 73%) was more in HAAKI. Patients with HAAKI had significantly higher mortality (72% vs 31%). Age >60 yrs (HR=1.51; 95% CI,1.11–2.07), oliguria (HR=1.48; 1.05–2.10), need for ventilator (HR=2.45; 1.36–4.41) and/or inotropes (HR = 14.4; 6.28–33.05) were predictors of in-hospital mortality. Of the 295 patients discharged, 146 (30.7%) had complete renal recovery, while 149 (31.3%) had partial renal recovery. Of the 295 patients on follow-up, 211 (71.5%) patients had normal renal function, 4 (1.4%) died and 41(14%) developed CKD while 6 (2%) were dialysis dependent. All patients having CKD on follow-up were patients of CAAKI group.

Conclusions: Present cohort study with long follow-up showed that there is a definite risk of CKD in recovered patients and they should be monitored periodically. AKI in hspitalized patients still has high mortality especially in patients with HAAKI.

FR-PO118

AKI in the Surgical Ward: A Single-Center Study

Daniel Kushnir, Tatiana Tanasiychuk, Jawad Kayali, Victor Frajewicki. *Carmel Medical Center, Haifa, Israel.*

Background: Acute Kidney Injury (AKI) is a non-uncommon condition with unknown incidence, mostly it take place in hospitalized patients and it is often under recognized. AKI significantly affects short and long-term morbidity and mortality.

Methods: A retrospective single center cohort study was performed, using the electronic medical records (EMR) of the hospital. AKI was defined as an increase of serum creatinine level of at least of 0.5 mg/dl from the previous test. We identified patients with AKI during the period January 1st –December 31, 2019, hospitalized in our hospital in the non-cardiac surgical clinics during this period. Chronic dialysis patients were excluded from the analysis.

Results: The final analysis included 203 patients hospitalized in Surgical Wards. Median age of patients was 75 (20-97), while 62% were men, almost 50% were diabetics, showing a mean Charlson score of 6. Almost 50% had CKD before the hospitalization with a median eGFR 61 ml/min. Seventy seven percent of patients were operated during the hospitalization. Most (66%) of operations were non elective. In 9% cases renal replacement therapy (RRT) was performed. All of them underwent non-elective operations. Patients needing RRT were younger, with lower hemoglobin, more frequent use of nephrotoxic antibiotics, received intravascular contrast, were mechanically ventilated and hypotensive, with sepsis. All-cause 90-day mortality was 33%. All-cause 90-day mortality was higher in cases of non-elective operations, in patients with hemoglobin level less than 8 mg/dl, higher American Society of Anaesthesiologists score, and hypotension during the hospitalization. Mortality rate was lower in diabetic patients (p=0.009). Management of AKI: only 47% of patients had urinalysis, renal imaging was done in 15%, monitoring of urine output was performed in 76%. Only in one third of cases there was any addressing to AKI in the EMR, and only in 43% of AKI was a main diagnosis at discharge.

Conclusions: It seems that non-diabetic, severely anemic (hemoglobin less than 8 mg/dl) patients with high ASA Score are at higher risk to AKI. More efforts should be done to recognize high risk patients with aim to prevent AKI, and improve renal failure management in the surgical departments.

FR-PO119

Intensive Care Unit Improves Dialysis Care Quality While Reducing Costs

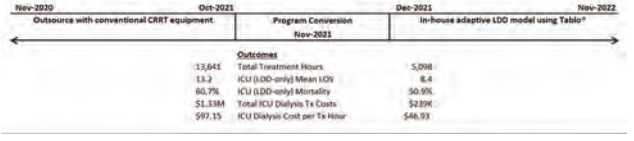
Tara E. Greenleaf Nichols,[1] David M. Doman,[1] Sherrie K. Mullen,[1] Senthil P. Ramaiyah,[1] Sandy Rowe,[1] Stephan C. Dunning.[2] *[1]Covenant HealthCare, Saginaw, MI; [2]Outset Medical, San Jose, CA.*

Background: In November 2021, a medium-size hospital ICU in Michigan initiated a quality improvement dialysis program, converting their outsourced continuous renal replacement therapy (CRRT-only) to an in-house adaptive long-duration dialysis (LDD) model, using the Tablo® Hemodialysis System (Tablo) to provide treatments >6 hours, as medically necessary. This conversion was done with the goals of (1) improving quality of care for ICU patients requiring LDD, and (2) reducing both dialysis-related nursing staff burden and dialysis treatment costs. We compared patient characteristics and treatments performed in the one year before and one year after the in-house LDD program launch.

Methods: We evaluated ICU stays requiring LDD in the one year before and after the month of the dialysis quality improvement program launch. EHR data were reviewed. compiled and analyzed by ICU staff, using MS Excel. Data include, demographics, select clinical diagnoses including kidney disease, heart failure, sepsis, and COVID. The results are presented as descriptively only. No cohort adjustments or statistical significance tests were performed.

Results: There were 145 ICU stays with 13,641 hours of CRRT among 145 pts before, and 116 ICU stays with 5,098 hours of LDD among 116 pts in the year after program launch. Mean dialysis treatment hours per patient were reduced from 93.7 to 43.1, increasing ICU nurse productivity by 50.6 hours per patient. Similar dialysis treatment time savings occurred in both COVID and no-COVID subsets. Concurrently, mean ICU length of stay for these patients declined by 4.8 days between the pre and post periods, from 13.2 to 8.4 days, respectively. Mortality declined between the periods, from 60.7% to 50.9% overall, and declining in both COVID and no-COVID subsets. Total dialysis treatment costs were reduced from $1.33M to $239k, and costs per treatment hour declined 52% from $97.15 to $46.93, in the pre and post periods, respectively.

Conclusions: Converting from an outsourced CRRT-only program to an in-house adaptive long-duration dialysis program, a medium-size hospital ICU in Michigan improved dialysis care quality and patient outcomes, while reducing costs and increasing nurse productivity.



FR-PO120

Initial Outpatient Dialysis Orders in AKI-D vs. ESKD

Ian E. McCoy,[1] Eric D. Weinhandl,[2] Wael F. Hussein,[2] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Satellite Healthcare, San Jose, CA.*

Background: Many hospitalized patients with dialysis-requiring acute kidney (AKI-D) do not fully recover renal function and are discharged to continue hemodialysis at dialysis centers oriented toward treating patients with end-stage kidney disease (ESKD). Little is known about dialysis practice patterns in this population.

Methods: We examined initial outpatient dialysis orders for 1,754 AKI-D patients initiating in-center hemodialysis between 7/1/2017 and 6/30/2022 across 67 dialysis centers operated by a medium-sized, not-for-profit dialysis provider. For comparison, 6,197 contemporary patients initiating in-center hemodialysis for ESKD were identified.

Results: Patients initiating outpatient dialysis for AKI-D and ESKD had similar demographics (mean age, 63 in AKI-D vs 64 in ESKD; 60% male in both groups) and body mass indices (mean, 29 kg/m^2 in both groups). However, mean pre-dialysis serum creatinine, interdialytic weight gain and pre-dialysis systolic blood pressure, were lower in the AKI-D group (5.3 versus 5.9 mg/dL, 0.9 versus 1.1 kg, and 135 versus 144 mmHg, respectively). Despite these differences, initial dialysis orders were similar. The initially prescribed hemodialysis frequency was 3x/week dialysis for 94% of AKI-D patients and 95% of ESKD patients. Hemodialysis session duration, dialysate sodium, and dialysate temperature were also similar.

Conclusions: Despite dissimilar medical profiles at hemodialysis initiation in the outpatient setting, initial hemodialysis orders for AKI-D and ESKD are largely the same. Greater individualization of dialysis orders may improve patient care.

Funding: NIDDK Support, Commercial Support - Satellite Healthcare, Inc, not-for-profit dialysis provider

Initial outpatient dialysis prescriptions in AKI-D and ESKD

	Incident AKI-D	Incident ESKD
Sample size (N)	1,754	6,197
Treatment frequency 3 treatments/week	94%	95%
Session duration ≥4.0 hours	20%	23%
3.5-3.9 hours	35%	37%
<3.5 hours	45%	40%
Dialysate sodium ≥140 mEq/L	9%	8%
138-139 mEq/L	52%	49%
136-137 mEq/L	30%	30%
<136 mEq/L	9%	13%
Dialysate potassium 3 mEq/L	70%	63%
2 mEq/L	29%	37%
Other	<1%	<1%
Dialysate temperature Celsius, mean (SD)	36.8 (0.5)	36.8 (0.4)

FR-PO121

Impact of Using Blood Warmer During Continuous Kidney Replacement Therapy on Hemodynamic Instability

Akshith Doddi, Aisha Abbasi, Ambika Ramesh, Safa Moursy, Ankit Sakhuja, Khaled Shawwa. *West Virginia University Health Sciences Center, Morgantown, WV.*

Background: Continuous kidney replacement therapy (CKRT) can lead to heat loss in the extracorporeal circulation. Hypothermia may have detrimental effects; however, rewarming of blood may alter vascular reactivity and induce hypotension.

Methods: We screened patients with acute kidney injury (AKI) who required CKRT between 1/1/2012 and 1/1/2021 and were admitted at a tertiary academic hospital. Intradialytic hypotension (IDH) was defined as mean arterial pressure (MAP) ≤ 60 millimetermercury (mmHg) or a decrease in MAP by ≧ 10 mmHg, systolic blood pressure (SBP) less than or equal to 90 mmHg or a decrease in SBP by ≧ 20 mmHg, or increased vasopressor requirement. These were measured in 15-minute increments and the number of episodes in each hour was recorded. The number of events was analyzed by Poisson regression with repeated-measures analysis of variance using the generalized estimation equation.

Results: There were 669 patients with AKI who required CKRT during the study period. Use of blood warmer on first day of CKRT was in 324 (48%) patients. Patients where a blood warmer was used were more likely to have required vasopressor or inotropes (56% vs 45%, p =0.003), be diagnosed with sepsis/septic shock (81% vs 74%, p=0.04), and were in a less positive fluid balance at the time of CKRT initiation (1.0 vs 1.3 L, p=0.03) compared to patients where a blood warmer was not used. The incident rate ratio for IDH during the first 24 hours of CKRT in patients where a blood warmer was used was 1.06 (95%CI 0.98; 1.13) compared to those where blood warmer was not used. After adjusting for variables that were different between the two groups and clinically relevant ones (norepinephrine equivalents, mechanical ventilation and MAP at time of CRRT initiation and ultrafiltration on CRRT day1), using a blood warmer did not increase IDH episodes. Overall, the within-subject effect of temperature on IDH on first day of CRRT was negative, meaning that higher temperature was associated with fewer IDH (relative risk of 0.94, 95% CI 0.9; 0.99 for each 10 degrees increase, p 0.007).

Conclusions: Blood warming techniques during CKRT were not associated with worsening hemodynamic instability during first day of CKRT.

FR-PO122

Impact of Ultrafiltration Rate Among Adults with AKI Treated with Continuous Renal Replacement Therapy (CRRT)

Samantha Gunning, Jay L. Koyner. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Background: Observational data supports the view that fluid removal with dialysis in critical illness confers survival benefit. The optimal fluid removal rate is unknown with some suggesting that ultrafiltration rate (UFR) greater than 1.75 mL/kg/hr may be harmful.

Methods: We conducted a single-center retrospective cohort study among adult AKI patients admitted to the intensive care unit (ICU) at University of Chicago treated with CRRT from April 1, 2016 to March 31, 2020. We collected information regarding patient demographics, severity of illness, daily fluid balance (all intakes minus outputs, inclusive of RRT), RRT ultrafiltration, and outcomes (length of stay, dialysis dependence, and mortality). We calculated UFR restricted to the first 72 hours of dialysis treatment as net ultrafiltrate (mL) per hour treatment duration adjusted for patient's baseline body weight.

Results: 742 patients had low UFR (≤1.01 mL/kg/hr), 269 had moderate UFR (between 1.01 and 1.75 mL/kg/hr), and 167 had high UFR (≥1.75 mL/kg/hr). Those with low UFR were older, had higher baseline body weight, and had less positive fluid balance in the 72 hours prior to starting dialysis. Severity of illness (SOFA) and burden of co-morbidities were not significantly different across UFR groups. Those with low UFR had a median cumulative fluid balance of 2.38 L over 72 hours, lower likelihood to remain dependent on dialysis at 90-days, and highest 90-day mortality (Table 1).

In an adjusted Cox proportional hazards model, low UFR was associated with an increased risk of 90-day mortality (HR 1.88, 95% CI 1.10-3.21 p=0.02) whereas high UFR was not significantly associated with 90-day mortality (HR 0.66, 95% CI 0.31-1.42, p=0.29).

Conclusions: Low UFR is associated with increased 90-day mortality while high UFR was not associated with 90-day mortality. Future studies should investigate the ideal UFR to improve patient outcomes.

Funding: Commercial Support - Fresenius Medical Care

Outcomes By 72 Hour Net Ultrafiltration Rate

	Low NUF <1.01 ml/kg/hr	Moderate NUF 1.01-1.75 ml/kg/hr	High NUF >1.75 ml/kg/hr	p-value
N	742	269	167	
72H Fluid Balance (L), med (IQR)	2.38 (-0.02, 5.97)	-0.62 (-3.33, 2.37)	-3.25 (-5.38, -0.35)	<0.001
72H UFR (mL/kg/hr), med (IQR)	0.39 (0.07, 0.71)	1.29 (1.14, 1.47)	2.27 (1.93, 2.76)	<0.001
ICU Days, med (IQR)	8 (3, 19)	12 (6, 24)	13 (5, 25)	<0.001
Hospital Days, med (IQR)	14 (5, 27)	19 (9, 33)	19 (9, 31)	<0.001
RRT at Day 90 (%) Survivors, N=403	31 (14.3)	13 (12.1)	16 (20.3)	0.016
90-Day Mortality (%)	525 (70.8)	162 (60.2)	88 (52.7)	<0.001

FR-PO123

Impact of Positive Fluid Balance and Timing of Renal Replacement Therapy in AKI in a Real-Life Scenario

Joaquin Rodelo Ceballos,[1,2] Jean Paul P. Gomez Gil,[1] Carlos A. Arteaga Mejía,[1] Andres A. Zapata Cardenas,[1,2] Alba L. León,[1] Fabian Jaimes.[1] *[1]Universidad de Antioquia, Medellin, Colombia; [2]Hospital Universitario San Vicente de Paul, Medellin, Colombia.*

Background: Objective: To determine if a fluid overload of less than 10% of body weight and early initiation (<12 hours) of RRT behave as an independent prognostic factor for mortality in patients with AKI KDIGO 3 in the ICU.

Methods: Retrospective cohort study that included patients hospitalized in the ICU of a hospital in Medellín-Colombia with a diagnosis of AKI KDIGO 3 and need for RRT.

Results: 278 patients with a median age of 63 years, 58.6% (163) men and 60.4% (168) diagnosed with sepsis were included. 166 (59.7%) were classified as early RRT and 112 (40.3%) as late RRT. The cumulative fluid balance was 9565 ml and 7496 ml, respectively. Mortality was 69% (192), with no significant differences according to the time of RRT (67 vs. 71%). There were no statistically significant differences between the early and late therapy group (OR adjusted 1.34, 0.65-2.75); nor in those with a percentage of accumulated fluid balance greater than 10% of body weight (OR adjusted 1.27; CI 0.73-2.23).

Conclusions: Early initiation of RRT, less than 12 hours from diagnosis, and with an accumulated fluid balance of less than 10% of body weight, did not have a lower risk of in-hospital mortality in patients with AKI KDIGO 3 in the ICU.

Variable	OR crude	OR adjusted
Early RRT	1.07 (0.56-2.06)	1.34 (0.65-2.75)

Volume Control Strategy and Patient and Kidney Survival in Sepsis-Associated AKI Receiving Continuous Kidney Replacement Therapy: A Randomized Controlled Trial

Hyojin Ahn,[1] Jun Hye Seo,[1] Cheol Ho Park,[1] Boyoung Nam,[1,2] Jaejin Ryu,[1,2] Gyu R. Kim,[1,2] Hyung Woo Kim,[1] Jung Tak Park,[1] Seung Hyeok Han,[1] Shin-Wook Kang,[1] Tae-Hyun Yoo.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Volume overload in patients with sepsis-associated acute kidney injury (AKI) requiring continuous kidney replacement therapy (CKRT) is associated with an increased risk of mortality. However, the optimal strategy for volume control and the clinical implication of achieved volume control in these patients is uncertain.

Methods: We randomly assigned patients with sepsis-associated AKI receiving CKRT accompanying volume overload with either conventional volume control strategy or bioelectrical impedance analysis (BIA)-guided volume control strategy for 3 days. The outcomes of interest were patient survival at 28 and 90 days. A *post-hoc* analysis was performed to compare patient survival according to achieved volume accumulation rate ([cumulative fluid balance during 3 days×100]/fluid overload) using multivariate Cox regression model.

Results: Of the 73 patients, 39 were randomly assigned to conventional volume control strategy, and 34 to BIA-guided volume control strategy. At 28 days after randomization, 20 (51.3%) deaths had occurred in the conventional volume control group and 19 (55.9%) deaths in the BIA-guided volume control group (*P*=0.69). There were no differences in 28-day mortality (HR, 1.19; 95% CI, 0.63–2.23) or 90-day mortality (HR, 0.99; 95% CI 0.57–1.75) between conventional volume control group and BIA-guided volume control group. In the secondary analysis, achieved volume accumulation rate was significantly associated with patient survival. Compared with the achieved volume accumulation rate of ≤-50%, the HRs (95% CIs) for the risk of 28-day mortality were 0.90 (0.16-5.02), 0.21 (0.03-1.61), and 8.08 (1.18-55.50) in that of -50–0%, 1–50%, and >50%, respectively. In addition, the HRs (95% CIs) for the risk of 90-day mortality were 1.21 (0.29-5.01), 0.55 (0.12-2.48), and 7.18 (1.58-32.51) in that of -50–0%, 1–50%, and >50%, respectively.

Conclusions: BIA-guided volume control in patients receiving CKRT due to sepsis-associated AKI with volume overload did not improve patient outcomes. In the secondary analysis, achieved volume accumulation rate was associated with patient survival.

FR-PO125

Hypotensive Episodes During Continuous Kidney Replacement Therapy and Mortality

Ambika Ramesh, Akshith Doddi, Aisha Abbasi, Ankit Sakhuja, Khaled Shawwa. *West Virginia University Health Sciences Center, Morgantown, WV.*

Background: Continuous kidney replacement therapy (CKRT) is often the preferred modality in hemodynamically unstable patients who develop acute kidney injury (AKI) and require kidney replacement therapy.

Methods: Patients with acute kidney injury (AKI) who required CKRT between 1/1/2012 and 1/1/2021 and were admitted to a tertiary academic hospital were included. We assessed the impact of hypotensive episodes on in-hospital mortality and major adverse kidney events (MAKE) at 90 days. MAKE is a composite outcome of need of kidney replacement therapy, doubling of the serum creatinine from baseline or death. Hemodynamic instability episodes were defined as mean arterial pressure (MAP) < 60 mmHg or a decrease in MAP by ≥ 10 mmHg, systolic blood pressure <90 mmHg or a decrease in SBP by ≧ 20 mHg, or increased vasopressor requirement. These were measured in 15-minute increments and the number of episodes in each hour was recorded.

Results: There were 669 patients with AKI that required CKRT during the study period. The median number of hypotensive episodes during the first 24 hours of CKRT was 51 (Interquartile range: 46-55). There were 320 (48%) who suffered in-hospital mortality. Patients who had in-hospital mortality were older (62 vs 58), and had higher SOFA score (11 vs 9), higher norepinephrine equivalent (NEE) requirement (0.16 vs 0.07 mcg/kg/min), more frequent hypotensive episodes (medians: 52 vs 49), higher lactate (6.2 vs 3.2 mmol/L), lower mean arterial pressure (MAP) (74 vs 79 mmHg) and were more likely to be requiring mechanical ventilation (81% vs 61%) at CKRT initiation compared to patients who did not suffer in-hospital mortality, p<0.001. After adjusting for age, baseline serum creatinine and SOFA score, lactate, MAP, mechanical ventilation and NEE at CKRT initiation, the number of hypotensive episodes during the first 24 hours was independently associated with in-hospital mortality (OR: 1.2, 95% CI: 1.11-1.35, p<0.001) and MAKE-90 (OR: 1.1, 95% CI 1.01-1.2, p-value=0.04) per 10 increase in hypotensive episodes.

Conclusions: Hypotension is a significant independent risk factor for in-hospital mortality and occurs frequently in patients receiving CKRT.

Association of Dynamic Hemoglobin Change and Renal Recovery in Patients with Severe AKI Requiring Continuous Renal Replacement Therapy

Areumsongi Nam,[1] Jiyun Jung,[1] Jungsoon Kim,[1] Dha Woon Im,[2] Yong Chul Kim,[2] Jangwook Lee,[1] Sung Joon Shin,[1] Jae Yoon Park.[1] Dept of Internal Medicine, Dongguk University Ilsan Hospital. *[1]Dongguk University Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [2]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Anemia in patients with severe acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) is associated with increased mortality and morbidity. However, the relevance of dynamic hemoglobin level variability (HbV) to renal recovery after AKI is still largely unknown. This study investigated the correlations between HbV and renal recovery at the time of discharge in patients with severe AKI who requiring CRRT.

Methods: We collected 1,897 AKI patients who underwent CRRT from two university hospitals between 2006 and 2021. The HbV was defined as the standard deviation (SD) and coefficient of variation (CV) during CRRT. To investigate the effects of HbV on RRT-dependence at discharge, we estimated the sub-distribution hazard ratio (HR) considering the mortality, adjusted by sex, age, charlson-comorbidity index, hypertension, SOFA, APACHE, and serum chemistry data.

Results: Of 1,897 AKI patients, 38 % were male, and the mean (standardized deviation) age was 66.1 (16.1) years. The proportion of outcome at discharge was 8% for RRT dependence, 29% for RRT independence, and 63% for mortality. The Cox regression analysis showed that HbV was positively correlated with RRT-dependence (SD, HR 0.77, 95% confidence interval [CI], 0.66 to 0.89; CV, HR 0.97; 95% CI 0.96 to 0.99).

Conclusions: This study showed that HbV during dialysis was associated with short-term renal recovery after severe AKI requiring CRRT.

FR-PO127

Association of Changes in Platelet and White Blood Cell Counts with Hospital Mortality in Patients with AKI requiring CRRT: A Multicenter Cohort Study

Chloe G. Braun,[1] Lan N. Bui,[2] Augusto Cama-Olivares,[3] Lucas J. Liu,[4] Tomonori Takeuchi,[1] Victor M. Ortiz-Soriano,[5] Joshua Lambert,[6] Ashita J. Tolwani,[1] Kianoush Kashani,[7] Javier A. Neyra.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Samford University, Birmingham, AL; [3]Universidad Peruana Cayetano Heredia, Lima, Peru; [4]University of Kentucky, Lexington, KY; [5]Brookwood Baptist Health, Birmingham, AL; [6]University of Cincinnati, Cincinnati, OH; [7]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: The relationship of platelet and white blood cell counts and adverse outcomes has been extensively studied in diverse critically ill populations. These parameters have seldom been studied in patients with AKI requiring CRRT. Given that the delivery of CRRT may directly impact these parameters, we aim to examine the association of changes in platelet and white blood cell (WBC) counts from pre-CRRT to during CRRT with hospital mortality.

Methods: Multicenter retrospective cohort study of 1,413 critically ill adult patients with AKI that required CRRT at two academic medical centers between 2011 and 2021. Platelet and WBC count change from pre- to during CRRT was assessed as a percentage and categorized by SD groups (<1 SD, within 1 SD, and >1 SD of the mean). Multivariable LASSO regression and interaction analyses were utilized to investigate associations with hospital mortality.

Results: Hospital mortality occurred in 53.2% of patients. In models adjusting for demographics, comorbidity, baseline kidney function, and SOFA scores, >1 SD platelet count drop during CRRT (>62% from pre-CRRT) was independently associated with hospital mortality (aOR: 1.82, 95% CI: 1.06, 3.13), while >1 SD WBC count increase during CRRT (>136% from pre-CRRT) exhibited non-significant increased mortality (aOR 1.41, 95% CI: 0.88, 2.29). Four high-risk patient phenotypes were identified from interaction analyses: 1. Pre-CRRT low platelet count that remained low, 2. Pre-CRRT normal platelet count with a drop of >1 SD, 3. Pre-CRRT elevated WBC count that remained high and 4. Normal or elevated pre-CRRT WBC count that increased to >1 SD.

Conclusions: In critically ill adult patients with AKI requiring CRRT, a drop in platelets and an increase in WBC from pre-CRRT to during CRRT can assist in patient phenotyping and mortality risk-classification. Further discovery and validation of relevant CRRT patient phenotypes is needed to better guide CRRT delivery.

Funding: NIDDK Support

Clinically Relevant Phenotypes

Phenotype	Pre-CRRT mean platelet count ($x10^3$)	Drop in platelets during CRRT	Pre-CRRT mean WBC count ($x10^3$)	Rise in WBC during CRRT	Observed odds of hospital mortality	Model adjusted odds (25, 75p) of hospital mortality
1 (n=71)	<55	34 to 62%	2.1 to 27	-59 to 136%	1.22	1.42 (1.07, 1.85)
2 (n=63)	55 to 263	>62%	2.1 to 27	-59 to 136%	1.74	1.61 (1.14, 2.17)
3 (n=37)	55 to 263	34 to 62%	>27	-59 to 136%	2.08	1.88 (1.13, 3.35)
4 (n=41)	55 to 263	34 to 62%	2.1 to 27	>136%	2.15	1.73 (1.22, 2.15)

Hypomagnesemia in Critically Ill Patients Undergoing Continuous and Prolonged Intermittent Kidney Replacement Therapies: Still a Matter of Debate?

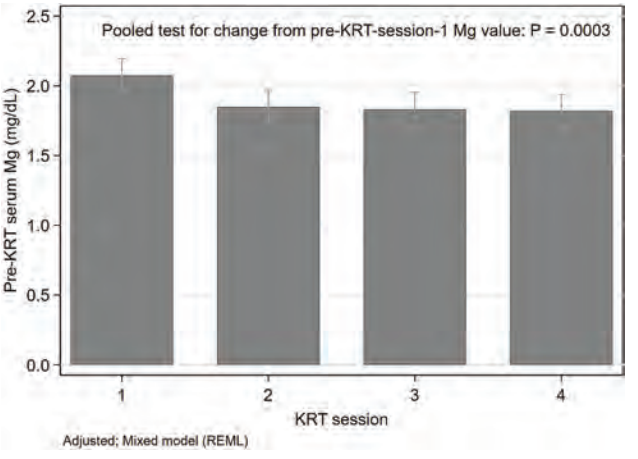
Francesca Di Mario, Umberto Maggiore, Giuseppe Regolisti, Brenda Menegazzo, Maria C. Pacchiarini, Paolo Greco, Caterina Maccari, Enrico Fiaccadori. *Parma University Hospital, Parma, Italy.*

Background: Hypomagnesemia may represent a fearsome complication in critically ill patients undergoing Continuous and Prolonged Intermittent Kidney Replacement Therapy (CKRT, PIKRT). Given its negative impact on morbidity and mortality, strategies aimed at reducing its incidence should be timely implemented. We carried out a prospective observational study aimed at assessing the incidence and outcome of hypomagnesemia in ICU patients undergoing CKRT and PIKRT with Regional Citrate Anticoagulation.

Methods: KRT was performed by the Prismax system and AN69 filters (Baxter), combining a trisodium citrate solution (Regiocit 18/0, Baxter) with a Mg-containing solution used as dialysis and/or post-dilution replacement fluid (Mg^{2+} 0.75 mmol/L; Biphozyl, Baxter). Each patient underwent 72-h CKRT or 3 consecutive 8-h SLED sessions. Mg losses were replaced, when needed, with Mg sulphate. We used linear mixed-effects and time-varying Cox multiple regression models to assess s-Mg level and its association with mortality.

Results: We enrolled 47 patients on CVVH, CVVHDF and SLED (mean APACHE II 25±7.0); s-Mg was 2.07±0.48 mg/dL at baseline and decreased by -0.25 mg/dL during KRT (P=0.0003, **Figure 1**), with the nadir being reached since the first KRT session. Hypomagnesemia (s-Mg<1.6 mg/dL) was observed, at least once, in 46.8% of patients, despite an average supplementation of 1.18 g/day. There was a trend, albeit not statistically significant, of lowest s-Mg values to be associated with increased mortality, after adjusting for potential confounders.

Conclusions: Hypomagnesemia is an incident complication of CKRT and PIKRT, mainly depending on baseline s-Mg. It seems associated with ICU mortality. Among preventive strategies, the evaluation of ionized s-Mg levels may represent a useful tool to better clarify Mg mass transfer during KRT.



FR-PO129

Magnesium Supplementation Is Associated with Reduced Mortality in AKI Requiring Continuous Kidney Replacement Therapy (CKRT)

Ryo Matsuura, Yoshifumi Hamasaki, Masaomi Nangaku, Kent Doi.
The University of Tokyo Hospital, Tokyo, Japan.

Background: Hypomagnesemia is a common electrolytic disorder and associated with mortality and delayed renal recovery in AKI patients. Although prevention and treatment of hypomagnesemia are suggested, evidence that magnesium (Mg) supplementation could improve survival is still lacking.

Methods: We retrospectively collected the data on AKI patients requiring CKRT with the support of vasopressors and/or ventilators. After excluding patients without measurement of serum magnesium at the day of CKRT start and those who died within 48 hours from CKRT start, patients were divided in two groups according to presence or absence of Mg supplementation within 48 hours of CKRT. Propensity score matching was performed using a 2:1 nearest neighbor matching algorithm. The primary and secondary outcomes were mortality and KRT free at 90 days. The association with Mg supplementation and outcomes was evaluated using a multivariable Cox regression model and a Fine and Gray model.

Results: After excluding 296 patients who died within 48 hours or did not have measurement of serum Mg, 296 patients without and 37 with Mg supplementation were eligible. After propensity score matching, 68 patients without and 34 patients with Mg supplementation were analyzed. There is no difference in age, sex, presence of sepsis, baseline kidney function, illness severity and serum magnesium. Patients with Mg supplementation received 24.4±10.6mEq of Mg during 48 hours. The mortality rate was lower in patients with Mg supplementation than in those without (Figure). Mg supplementation is inversely associated with 90-day mortality with adjusted hazard ratio of 0.38 (95%CI, 0.18 – 0.83). Mg supplementation was associated with KRT free at 90 days with hazard ratio of 2.07 (95%CI, 1.23–3.49).

Conclusions: The study using propensity score matching revealed the association of Mg supplementation with improving survival rate and renal recovery.

Calcium Balance in Slow Extended Dialysis: Effect of Regional Citrate vs. Other Anticoagulation Strategies in a Randomized Trial

Lucas B. Mota,[1] Etienne Macedo,[2] Rosa M. Moyses,[3] Maristela C. Costa,[1] Ligia C. Battaini,[1] Filomena R. Galas,[1] Jose Nicolau,[1] Silvia G. Lage,[1] Dirce M. Zanetta,[3] Emmanuel A. Burdmann,[3] Veronica T. Costa e Silva.[3]
[1]Heart Institute, São Paulo, São Paulo, Brazil; [2]University of California San Diego Department of Medicine, La Jolla, CA; [3]University of São Paulo Medical School, São Paulo, Brazil.

Background: Regional citrate anticoagulation (RCA) has been used as an alternative to heparin during slow extended dialysis (SLED) in patients with acute kidney injury (AKI). However, there is scanty data on the impact of different anticoagulation strategies on calcium balance during these procedures. This study aimed to determine calcium balance in SLED using RCA compared to saline or heparin in a crossover randomized clinical trial (RCT).

Methods: We included 20 critically ill adults with AKI who were eligible to SLED (6 to 8 hours) in a tertiary center in Brazil. They were randomized to either RCA or standard of care (heparin as the first choice or continuous saline flush, in case of heparin contraindication) in a crossover manner. Dialysis was carried out using single-pass batch equipment, until the maximum of six therapies per subject. RCA used ACD 2.2% at 3mmol/L (320mL/h), post filter calcium target 0.6 - 0.7mmol/L, and pre-filter calcium target 1.10 - 1.32mmol/L. Dialysate calcium was 1.25 mmol/L in all therapies. The primary outcome was calcium balance.

Results: In 48 procedures, 24 used citrate, and 24 used heparin or continuous saline. Each participant performed 2 (1 - 3) sessions in the protocol. Patients age was 66 (40 - 71) years, 55% men, 15% on mechanical ventilation, and 20% using vasoactive agents. All groups had a negative calcium balance, markedly in dialysis using RCA.

Conclusions: In this RCT, SLED was associated with negative calcium balance independently of the anticoagulation strategy, although calcium loss was more prominent in the RCA group. Further studies are needed to corroborate our results and investigate the determinants of calcium loss during SLED.

Funding: Government Support - Non-U.S.

Dialysis parameters (n = 48)

	CITRATE (24)	HEPARIN (14)	SALINE (10)
Blood / dialysate flow (mL/min)	180 (180 - 180)	180 (180 - 180)	180 (180 - 180)
Time (min)	420 (397 - 470)	390 (360 - 480)	420 (366 - 420)

Association Between Body Mass Index and Clinical Outcomes in Patients with AKI Requiring Continuous Renal Replacement Therapy

Hyung Duk Kim,[1] Yaeni Kim.[2] *[1]Catholic University of Korea Eunpyeong St Mary's Hospital, Eunpyeong-gu, Seoul, Republic of Korea; [2]Seoul Saint Mary's Hospital, Seocho-gu, Seoul, Republic of Korea.*

Background: Obesity is associated with higher mortality in general population. However, there has been controversy over the effect of obesity in critically ill patients. In this study, we retrospectively reviewed medical records to investigate the association between body mass index (BMI) and mortality or ESRD incidence in critically ill patients who admitted to intensive care unit (ICU) and receiving continuous renal replacement therapy (CRRT).

Methods: A total of 891 adult patients were admitted to the ICU and received CRRT at three institutions of the Catholic Medical Center from July 2012 to December 2020. Of these patients, 845 subjects were eligible for the study, excluding patients without BMI data or patients with extracorporeal membrane oxygenation (ECMO) treatment. Patients were categorized into 4 groups according to the BMI criteria of the Korean Society for The Study of Obesity (BMI less than 18.5, 18.5-22.9, 23.0-24.9, 25.0kg/m^2 or greater). The association between BMI and 1-year overall mortality and 1-year ESRD incidence were investigated.

Results: The 1-year mortality was 43.3%, 47.9%, 36.2% and 39.0% in the underweight, normal, overweight, and obese groups respectively. The mortality rate of obese patients was significantly lower than that of normal patients in Kaplan-Meier analysis (p=0.002). Multivariable logistic regression analysis showed that obese patients had a lower risk of mortality than normal group (hazard ratio [HR], 0.60; 95% confidence interval [CI], 0.42-0.85; P=0.005). The 1-year ESRD incidence was 43.6%, 37.9%, 32.4% and 25.0% in the underweight, normal, overweight, and obese groups respectively. In a multivariable logistic regression analysis adjusted for confounding factors, obesity was associated with a decreased risk of ESRD (HR, 0.56; 95% CI, 0.34-0.92; P=0.023). In subgroup analysis according to age, 1-year mortality consistently showed an inverse correlation between BMI and mortality, but ESRD incidence was inversely related with obesity only in patients with age > 65.

Conclusions: In critically ill patients admitted to ICU with AKI requiring CRRT, obesity (BMI>25.0kg/m^2) was associated with lower 1-year mortality and 1-year ESRD incidence, suggesting obesity paradox in patient survival and renal survival.

FR-PO132

Effect of Urinary Output on Withdrawal from Continuous Renal Replacement Therapy in a Tertiary Referral Center in Western Mexico

Ricardo Parra Guerra, Adriana Banda Lopez, Enrique Rojas-Campos, Luis G. Gonzalez-Correa, Mauricio Carvallo Venegas, Jorge Andrade-Sierra, Salvador Mendoza Cabrera, Miguel Acevedo, Berenice Bautista Melo, Moises Cruz Landino. *Instituto Mexicano del Seguro Social, Guadalajara, Mexico.*

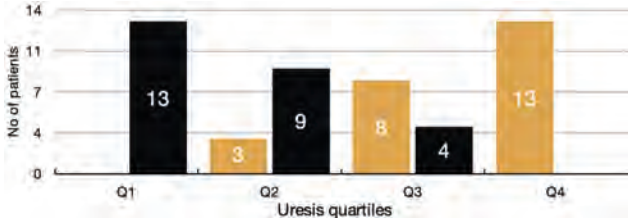
Background: The withdrawal of Continuous Renal Replacement Therapy (CRRT) in patients with severe AKI has not been standardized. New evidence suggests that releasing CRRT too soon, as well as unneeded and extended CRRT, might negatively affect the clinical course and economic cost of AKI.

Methods: A retrospective cohort of critically ill adult patients hospitalized in four intensive care units of a tertiary care center in western Mexico, who presented with acute kidney injury requiring CRRT, in which renal replacement therapy (RRT) was interrupted without the intention of migrating to another form of RRT, from January 2016 to March 2021. We defined CRRT withdrawal success as 72 h without the need for a TRR reset after CRRT discontinuation.

Results: Fifty-two patients who met the inclusion criteria were evaluated. Due to the abnormal distribution of the uresis values in both groups, it was decided to carry out the analysis by quartiles, finding the distribution regarding the success or failure of CRRT withdrawal. We found that uresis below the first quartile (<1,200 ml) was a risk factor for failure to withdraw CRRT (OR 2.85, 95% CI 1.84-4.41, p<0.001). Other variables that showed a risk of CRRT withdrawal failure in the multivariate analysis were lower systolic and diastolic blood pressure, the presence of comorbidities, more total hours of CRRT, and absence of diuretic use at the time of CRRT withdrawal.

Conclusions: A urine output of less than 1 liter was associated with almost three times the risk of failure to withdraw CRRT in our population. In turn, diuretics use

facilitated withdrawal. Urinary volumes were greater in our CRRT-withdrawing study compared to those reported in other places.



FR-PO133

Proenkephalin May Improve Strategies for Successful Weaning from RRT

Christian Nusshag,[1] David Gabriel,[1] Julia Grenz,[1] Daniel Göth,[1] Louise Benning,[1] Felix C.F. Schmitt,[2] Uta Merle,[3] Martin G. Zeier,[1] Mascha O. Fiedler,[1] Markus A. Weigand,[1] Christian Morath.[1] Nusshag Lab. *[1]Heidelberg University Hospital Department of Nephrology, Heidelberg, Germany; [2]Heidelberg University Hospital Department of Anesthesiology, Heidelberg, Germany; [3]Heidelberg University Hospital Department of Gastroenterology, Heidelberg, Germany.*

Background: Acute kidney injury (AKI) is associated with fatal outcomes, particularly in patients requiring renal replacement therapy (RRT). Conventional kidney biomarkers such as serum creatinine (SCr) are incapable of indicating kidney recovery in patients receiving RRT. Proenkephalin A (penKid) is a novel kidney biomarker with unique characteristics. We hypothesized that penKid could provide a more accurate prediction of successful weaning from RRT than established standards of care.

Methods: Measurement of penKid plasma levels were implemented in the daily blood routine at our center. In this preliminary analysis, data of 1473 patients were gathered. The start of a weaning trial was defined as 48h without RRT, and weaning was considered successful if a patient did not require RRT for five consecutive days.

Results: RRT procedures were performed in 234 patients of whom 54 patients were chronically dependent on hemodialysis prior ICU admission. Baseline and maximum penKid levels showed a stepwise increase with rising AKI stage (KDIGO criteria). Median penKid levels at RRT start were 128.2 pmol/L and increased further under RRT. In contrast, SCr levels decreased in association with RRT procedures. In patients with pre-existing chronic RRT-dependency, penKid levels were significantly higher than in patients with acute RRT requirements at any time after RRT initiation (Day 3 after RRT Start: 134.7 vs. 403.9 pmol/L), while SCr was already indifferent on day 3 (1.60 vs. 1.49 mg/dL). Differing RRT modalities had no effect on penKid levels, whereas continuous RRT forms were more effective than intermittent RRT in clearing SCr. On the day of last RRT, the area under the curve (AUC) for predicting successful RRT weaning was higher for penKid compared to UO with 0.76 (95% CI 0.58-0.94, p=0.014) and 0.74 (95% CI 0.55-0.94, p=0.039), respectively. One day earlier, predictive performance was even more favorable for penKid compared to UO (AUC 0.72 [95% CI 0.54-0.91, p=0.036] vs. 0.58 [95% CI 0.36-0.80, p=0.879]).

Conclusions: Our data suggest that penKid may provide additional information to standard of care rgarding kidney integrity under RRT, making it a valuable biomarker to predict liberation from RRT. This has large clinical implications given the importance of avoiding unnecessary RRT-procedures.

FR-PO134

Predictors of Early Peritoneal Dialysis Start in Newborns and Young Infants Following Cardiac Surgery

Ali Mirza Onder. *Nemours Children's Hospital Delaware, Wilmington, DE.*

Background: This single center, retrospective cohort study was conducted to investigate the predictors of early peritoneal dialysis (PD) start initiation in newborns and young infants undergoing cardiac surgery.

Methods: There were fifty-seven newborns and young infants. All subjects received PD catheter after completion of the cardiopulmonary bypass (CPB). Worsening postoperative (post-op) positive fluid balance and oliguria (<1 ml/kg/hour) despite furosemide were the clinical indications to start early PD (PD +). Demographic, clinical and laboratory data were collected from the pre-operative, intra-operative and immediately post-operative periods.

Results: Baseline demographic data were indifferent except that PD + group had more newborns. Preoperative serum creatinine was higher for PD + group (p= 0.025). PD + group had longer CPB time (p=0.044), longer aorta cross-clamp time (p=0.044) and less urine output during early post-op 24 hours (p= 0.008). In the univariate logistic regression model, pre-op serum creatinine was significantly associated with higher odds of being in PD+ (p= 0.021) and post-op systolic BP (p=0.018) and post-op MAP (p=0.001) were significantly associated with reduced odds of being in PD + (p= 0.018 and p= 0.001, respectively). Post-op MAP showed a statistically significant association (aOR= 0.89, 95% CI [0.81, 0.96], p=0.004) with PD + in multivariate analysis after adjusting for age at surgery.

Conclusions: : In our single center cohort, pre-op serum creatinine, post-op systolic BP and MAP were demonstrated statistically significant association with PD +. This finding may help to better risk stratify newborns and young infants for early PD start following cardiac surgery.

FR-PO135

Role of Immunomodulation Therapy with Selective Cytopheretic Device (SCD) in Reversing Acute on Chronic Liver Failure (ACLF) with Hepatorenal Syndrome (HRS) and Multi-Organ Failure

Lenar T. Yessayan, Pratima Sharma, Angela Westover, Balazs Szamosfalvi, H. David Humes. *University of Michigan, Ann Arbor, MI.*

Introduction: ACLF is a clinical disorder characterized by acute clinical deterioration in patients with pre-existing chronic liver disease. ACLF develops from systemic inflammation, often due to bacterial infections or alcoholic hepatitis, and progresses to multi-organ failure. Severe ACLF with ≥ 4 organ failure has a grave prognosis with a mortality rate at 28 days of 100%. Early liver transplant is the treatment of choice for those who are refractory to medical treatment. Intervention to modulate and lessen this systemic inflammatory state may alter the progression of multi-organ dysfunction and allow time for liver transplantation.

Case Description: Case 1. A male patient in his 30s presented with acute alcohol associated hepatitis, ACLF, HRS, and ≥4 organ failure. He required vasopressors, mechanical ventilation, and CKRT. MELD score was 38. **Case 2.** A male patient in his 60s with non-alcoholic steatohepatitis (NASH) was admitted for hypotension and decompensated cirrhosis. He required vasopressors and developed HRS. MELD score was 37. Both patients were enrolled into a clinical trial (NCT 04898010) to evaluate an extracorporeal immunomodulating device, SCD. Both patients showed rapid clinical improvement associated with a decline in elevated blood cytokine concentrations and diminution of activation levels of circulating leukocytes. On follow up Case 1 was alive at day 90 after treatment and undergoing liver transplantation evaluation and Case 2 had a successful liver transplantation 6 days after SCD therapy ended.

Discussion: The final common pathway of systemic hyper-inflammation resulting in multi-organ failure is the effector cells of the innate immunologic system. The activation of neutrophils and monocytes is the key driver of the developing hypoxic and toxic tissue damage of solid organs. The immunomodulation of these cellular elements rather than removal or inhibition of soluble cytokines or chemokines of inflammation is the critical target for effective therapy, as demonstrated with SCD treatment. These cases represent the first in human treatment of ACLF with SCD. These results suggest a role for SCD treatment in the management of HRS-AKI and ACLF as a bridge to liver transplantation.

FR-PO136

Safety Summary of the Selective Cytopheretic Device (SCD): A Review of Safety Data Across Multiple Clinical Trials in ICU Patients with AKI and Multi-Organ Failure

David Catanzaro,[1] Stuart Goldstein,[2] Lenar T. Yessayan,[3] Kevin K. Chung,[1] Emily Scribe,[1] H. David Humes.[3] *[1]SeaStar Medical, Denver, CO; [2]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [3]University of Michigan, Ann Arbor, MI.*

Background: AKI is a frequent and serious complication in critically ill patients, occurring at a rate of 1 in 5 adults and 1 in 3 children hospitalized with acute illness. AKI requiring CKRT is a significant complication in ICU patients with mortality rates exceeding 50%. A dysregulated immune response can lead to systemic inflammation caused by a hyperactivity of pro-inflammatory neutrophils & monocytes leading to tissue damage. Damage resulting from hyperinflammation associated with AKI frequently progresses to other organs, such as the heart, lung, or liver. The SCD is an investigational medical device in a new class of cell-directed extracorporeal therapies distinct from cytokine adsorbers or filters, as it targets activated leukocytes, the key cellular sources driving the hyperinflammatory process. This report summarizes safety data from the major clinical studies of the SCD across a variety of patient types with AKI and multi-organ failure.

Methods: Safety was assessed in each study through the collection of AEs & SAEs. All-cause mortality was also assessed. As all-cause mortality can help in interpreting safety, this report will also summarize survival rates in each study.

Results: Results from each of the 5 studies will be described herein, including that 5 of 6 studies had no device-related SAEs and AEs from each study were consistent with those expected in a critically-ill ICU population. Although studies were not powered to detect differences in mortality, there were trends toward higher survival rates in SCD patients vs. controls.

Conclusions: These studies support that the SCD can be added as a therapeutic intervention in critically ill AKI patient populations with additional multi-organ failure without adding additional safety risks. Any intervention with the potential to improve survival in such a critical patient population would be welcome.

FR-PO137

Sepsis-Associated AKI (SA-AKI) Requiring Kidney Replacement Therapy (KRT): Role of Hemofiltrate Reinfusion (HFR)-Supra on Inflammation and Outcome

Giuseppe Gernone, Michele Russo. *ASL Bari, Bari, Italy.*

Background: Sepsis is life-threatening organ dysfunction caused by dysregulated body response to an infection. Mortality rate ranging over 60% for septic shock. AKI is final common pathway of this immune dysregulation leading to systemic inflammation (SI) due to uncontrolled circulating levels of pro-inflammatory mediators and cytokine induced direct organ damage. KRT is often required in SA-AKI and could improve SI removing pathogens and inflammatory factors. Various blood purification techniques have been used: HCO/MCO membranes, hemoperfusion, plasma filtration/adsorption and, anecdotal, Hemo Filtrate Reinfusion Supra (HFR): endogenous reinfusion HDF based on adsorbing resin cartridge that remove pro-inflammatory cytokines but whose full spectrum is not yet know. Aim of this study is to test HFR on outcome of SA-AKI in critically ill pts.

Methods: Retrospective observational study evaluated 8 SA-AKI pts requiring RRT. All were treated with daily HFR(Bellco-Medtronic, Italy), mean of 8.3 ±5.4 treatments. We daily assessed (as mean ±SD): urea, sCr, CRP, procalcitonin (PCT), WBC, myoglobin(Myo), albumin; in addition need for vasopressor and outcome. AKI was defined according to KDIGO.

Results: The mean age was 74.1±9.4 years, 6 pts were male (75%). Over 30% obese, 20% with nephropathies, some hypertensive, with diabetes or COPD. HFR: Qb= 250 ±18.8 ml/m, TT 238.7 ±27.7m. HFR confirm valid URR, highly significant abatement of CRP (271.7 ± 68.4 *85.7 ± 61.1 p< 0.0003*), meaningful cut of PCT (65.7 ±65.9 *10.5 ±20.2 p< 0.03*) and Myoglobin (3648.5 ± 1709.2 *511.7 ± 435.9 p < 0.01*), stable Albumin. Lower need of vasopressor (13.5± 3.8 *7.5± 3.1 p < 0.002*) highlights improved hemodynamic instability with no poor intradialytic compliance. 3 pts not survived (2 for surgical, 1 for pulmonary complications) everyone else had renal recovery.

Conclusions: HFR decrease SI and support renal recovery in SA-AKI pts, even in the not survived. The sorbent cartridge remove many proinflammatory cytokines, that lead to improved MAPs and lower critical illness scores, and allow to eliminate myoglobin too. Finally HFR-Supra is the cheapest technique for SA-AKI in comparison to the other (eg CRRT, HCO, Cytosorb). There is no study on HFR in SA-AKI and very few experience on his use to hypermyoglobinemia. Larger studies need to confirm our evidence but, in the meantime, we could help to build a new scientific evidence.

FR-PO138

Plasma Cystatin C Predicts Kidney Function Recovery in Patients Requiring Continuous Kidney Replacement Therapy (CKRT) for AKI

Sarah Haeger,[1] Kayo Okamura,[1] Zhibin He,[1] Amy S. Li,[1] James F. Colbert,[1] Ruth E. Campbell,[1] Benjamin R. Griffin,[2] Sarah Faubel.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: AKI requiring KRT is a common complication in hospitalized patients that confers increased mortality. Tools to predict timing of kidney function recovery and mortality are needed. Cystatin C (CysC) is a marker of kidney function that may reflect residual kidney function while on KRT. Herein, we tested the hypothesis that lower plasma cysC concentrations would predict early kidney function recovery in patients with AKI requiring CKRT.

Methods: 51 patients without chronic kidney disease requiring CKRT for AKI were studied. Plasma was collected prior to CKRT initiation, and plasma and effluent were collected on days 1, 2, and 3 of CKRT. Two groups were studied: early kidney function recovery (EKFR, liberated from dialysis within 7 days of CKRT initiation, N = 15) and delayed kidney function recovery or death (DKFR/D, on dialysis 21 days after CKRT initiation or death prior to renal recovery, N = 36). CysC, creatinine, and blood urea nitrogen (BUN) were measured in plasma and effluent, and CKRT dose and urine output were recorded.

Results: Mean plasma cysC (mg/L) was significantly lower on days 1 (1.79 vs 2.41, p = 0.03) and 2 (1.91 vs 2.41, p = 0.03) of CKRT in patients with EKFR versus DKFR/D. There was no difference in serum creatinine or BUN between the two groups. CysC on days 1 and 2 of CKRT predicted early kidney function recovery (day 1 ROC AUC 0.765, p = 0.003; day 2 ROC AUC 0.751, p = 0.010). CKRT clearance of cysC and cysC sieving coefficient were similar between the two groups. The average cysC sieving coefficient in all patients was 0.59, 0.61, and 0.61 on days 1, 2, and 3 of CKRT respectively.

Conclusions: CysC on days 1 and 2 of CKRT predicts early kidney function recovery. The lower concentration of plasma cysC in patients with EKFR was not due to differences in CKRT cysC clearance. Since cysC is moderately cleared by CKRT, it is only predictive at early timepoints after CKRT initiation. CysC is available in clinical practice, thus measuring cysC in patients on CKRT for AKI is feasible and would fill a void in data that is needed to support discussions between clinical providers and patients regarding outcomes and prognosis.

FR-PO139

Impact of Early Renal Replacement Therapy in Leptospirosis on Mortality and Long-Term Renal Function: A Retrospective Analysis over 11 Years in Reunion Island

Marie Julien,[1,2] Yannis Lombardi,[1] Julien Jabot,[2] Cedric Rafat.[1] *[1]Hopital Tenon, Paris, France; [2]Centre Hospitalier Universitaire de La Reunion, Saint-Denis, Réunion.*

Background: Leptospirosis is a widespread zoonosis that can cause severe acute kidney injury (AKI-L) and remote chronic renal disease (CKD-L). Anecdotal evidence suggests that early renal replacement therapy (RRT) may improve mortality associated with AKI-L. Conversely, intensive care unit (ICU)-based trials, including the landmark AKIKI carried have disproved a positive impact of early RRT on patient mortality. We aimed to determine i) whether the timing of RRT positively impacts mortality ii) provide an estimation of the incidence of post-leptospirosis CKD.

Methods: We conducted a retrospective study over 11 years in Reunion Island, including adult patients with confirmed leptospirosis complicated by KDIGO 2 or 3 AKI. The primary endpoint was a composite endpoint including death and CKD-L up to 3 years after hospital discharge. Factors associated with CKD-L and death were determined using logistic regression models with different adjustment variables.

Results: Three hundred eighty patients were included, 39% of whom required RRT with a median time to initiation of 1 day (0-2 days). According to the composite criterion, the mortality rate was 4% in the study population and the incidence of CKD-L was 8%. On univariate analysis, factors associated with the composite criterion included ICU severity scores, age, baseline kidney function, oligo-anuria and the need for RRT. Using bivariate models adjusting on age or SAPS2 or prior renal function, we showed that when compared to patients who did not require dialysis, no significant difference was found between early or late dialysis initiation on the composite endpoint. Odds ratio (OR) for RRT before 24h was 5.7 (1.9-17.9) and OR for RRT after 24h was 5.7 (2.1-16.3).

Conclusions: In conclusion, leptospirosis accounts for significant CKD. Early RRT does not seem to improve the composite mortality-CKD endpoint. Further investigations are needed to substantiate the potentially protective effects of early RRT on CKD-L.

Bivariate analysis of factors associated with death or CKD at last follow-up, according to time to initiation of RRT and patients' SAPS2 score

Variable	OR	CI 95%	p
RRT < 24 hours	5.7	1.9 - 17.9	< 0.01
RRT > 24 hours	5.7	2.1 - 16.3	< 0.001
SAPS2, per unit	1.1	1 - 1.1	< 0.001

A Roadmap to Recovery: Managing AKI in a Case of Hemophilia B

Avani Kulkarni, Shrirang D. Pathak, Saurabh Saigal. *All India Institute of Medical Science - Bhopal, Bhopal, India.*

Introduction: Hemophilia, a rare inherited bleeding disorder, poses unique challenges in the management of patients requiring renal replacement therapy. Acute Kidney Injury is a serious complication that can occur in hemophilic patients following prolonged hospitalization secondary to trauma. There is limited data on the appropriate dialysis modality selection, and prescription of dialysis treatments in these patients.

Case Description: We present a case report highlighting the innovative approach adopted for the management of acute kidney injury (AKI) in a 31-year-old male hemophiliac patient with a history of abdominal trauma following a road traffic accident. The diagnostic workup revealed intra-abdominal bleeding and sepsis, leading to the development of AKI. Given the patient's complex clinical profile, a tailored approach was necessary to balance the need for renal replacement therapy while minimizing the bleeding risks associated with hemophilia. Sustained low-efficiency daily dialysis (SLEDD) was utilized for renal support, with modifications made to minimize bleeding risks. The modifications included the use of normal saline and cryoprecipitate to maintain adequate clotting factor levels, to minimize bleeding during catheter insertion and removal and to prevent coagulation of the circuit, and close monitoring of coagulation parameters throughout the dialysis sessions. 6 such dialysis sessions were done following which the acute kidney injury was resolved.

Discussion: In this case, the key challenge to overcome was concerning the use of heparin to prevent coagulation in the extracorporeal circuit, but at the same time it carried the risk of prolonging the already prolonged Actiavted Partial Thromboplastin Time (APTT). The solution was to use saline and cryoprecipitate in the process to maintain the dialysis circuit and the hemodynamic stability of the patient. The modality of choice was SLEDD, because of its capacity to offer continuous renal support while retaining a low risk of bleeding. SLEDD with modifications proved to be a safe and effective method for managing AKI in our patient. Further research is needed to establish optimal management strategies for AKI in patients with Hemophilia B.

FR-PO141

Suspected Scleroderma Renal Crisis in Patient with Severe Hypertension and AKI

Saramarina Sanchez, Satesh Saroop, Smita Padala. *HCA Florida Citrus Hospital, Inverness, FL.*

Introduction: Although rare, scleroderma renal crisis is a potentially fatal complication that affects up to 10% of patients with systemic sclerosis. The etiology of scleroderma renal crisis is poorly understood, however it is thought that vascular

endothelial injury, vascular thrombosis and arterial narrowing leads to decreased perfusion of the kidneys. This in turn activates the renin-angiotensin-aldosterone system causing severe hypertension.

Case Description: A 67 year old male with history of scleroderma, pulmonary hypertension, pulmonary fibrosis and hyperlipidemia presented with worsening shortness of breath. Initial systolic blood pressure noted to be in the 180s on occasion reaching 220s with diastolic blood pressures in the 100s. Labs significant for BUN 47, creatinine 1.6 (baseline 0.7), GFR 47 (baseline 100s), CRP 1.17, troponin 0.248, platelets 80, LDH 405, haptoglobin < 20 and urinalysis showing protein > 500 mg. Renal ultrasound showed echogenic kidneys consistent with chronic parenchymal disease. Scleroderma renal crisis was suspected and plan was to initiate captopril 6.25 mg q 4 hrs, however medication was non-formulary. Therefore, Enalapril 2.5 mg IV q 4 hrs was ordered and after 1 dose, systolic blood pressures noted to be in the 130s-150s and diastolic blood pressures in the 70s-90s. He was then started on lisinopril 5 mg po qHS and amlodipine 5 mg po daily to control his blood pressure.

Discussion: The diagnosis of scleroderma renal crisis must be considered in all patients with systemic sclerosis presenting with AKI and accelerated hypertension. Several risk factors for development of scleroderma renal crisis include renal impairment within first 5 years of disease course, scleroderma skin involvement, glucocorticoid therapy within 6 months and autoantibodies to RNA polymerase III. Scleroderma renal crisis is a diagnosis of exclusion and treatment is more likely to be effective when initiated early, therefore prompt recognition significantly improves outcomes and mortality. While the patient initially presented with typical features of scleroderma renal crisis, his hemodynamic stability and rapid response to ACEi makes it unlikely. Once the patients blood pressure was controlled, renal function significantly improved. The patients symptoms more representative of hypertensive emergency in setting of poorly managed hypertension.

FR-PO142

Ichthyosiform Sarcoidosis with Renal Involvement

Tareq Hanouneh,[1] Carmen E. Cervantes,[2] Lois J. Arend,[3] Mohamad A. Hanouneh.[2,4] *[1]Mayo Clinic in Florida, Jacksonville, FL; [2]The Johns Hopkins University School of Medicine, Baltimore, MD; [3]Johns Hopkins University, Baltimore, MD; [4]Nephrology Center of Maryland, Baltimore, MD.*

Introduction: The ichthyoses, also called disorders of keratinization, are a heterogeneous group of disorders characterized by generalized skin scaling. The great majority of ichthyoses are inherited, but acquired forms can develop in the setting of malignancy, autoimmune or infectious diseases.

Case Description: A 51-year-old man presented to the hospital for evaluation of acute kidney injury. The skin exam showed xerosis with hyperpigmented scales lesions on his arms, legs, abdomen, and back (Figure 1-A). Initial workup revealed the following: creatinine 6.27 mg/dL (baseline 0.8 mg/dL), calcium 15.1 mg/dL, PTH 9.1 pg/mL (10-55 pg/mL), vitamin D 1,25 dihydroxy 97.3 pg/mL (20-76 pg/mL), and angiotensin-converting enzyme 120 u/L (14-82 u/L). Urinalysis was positive for proteinuria with a urine protein/creatinine ratio of 900 mg/g Cr. Renal biopsy demonstrated diffuse granulomatous interstitial nephritis (Figure 2-A). Immunofluorescence showed granular capillary wall IgG. Electron microscopy showed podocyte foot process effacement and subepithelial electron-dense deposits (Figure 2-B). Skin biopsy revealed hyperkeratosis with non-necrotizing granulomas. The patient was diagnosed with ichthyosiform sarcoidosis, granulomatous interstitial nephritis, and secondary membranous nephropathy. He was started on prednisone 60 mg daily. His serum creatinine and serum calcium returned to normal with significant improvement in his ichthyosis (Figure 1-B).

Discussion: Ichthyosiform lesions are one of the extremely rare cutaneous manifestations of sarcoidosis that may precede or coincide with the diagnosis of systemic sarcoidosis. Renal manifestations include abnormal calcium metabolism, nephrolithiasis and nephrocalcinosis, acute interstitial nephritis, and membranous glomerulonephritis.

FR-PO143

Successful Management of TAFRO Syndrome-Related Renal Thrombotic Microangiopathy with Interleukin-6 Inhibitor

Ahmed I. Abdelkader, Salem Vilayet, Evelyn Bruner, Anand Achanti, Milos N. Budisavljevic. *Medical University of South Carolina, Charleston, SC.*

Introduction: TAFRO [**T**hrombocytopenia, **A**nasarca (edema, pleural effusions, ascites), **F**ever, **R**eticulin myelofibrosisis (or Renal insufficiency), and **O**rganomegaly (lymphadenopathy and hepatosplenomegaly)] that represents a severe subtype of idiopathic multicentric Castleman's disease (iMCD). Kidney involvement in TAFRO syndrome can be severe and may require hemodialysis (HD). However, detailed descriptions of this syndrome's aspect remain limited.

Case Description: A 20-year-old male presented as transfer from another hospital with anasarca, malaise, diffuse lymphadenopathy, and non-oliguric acute kidney injury. He has no past medical history. Initial concern for lymphoma; however, bone marrow biopsy, ascites, pleural fluid examination and flow cytometry were negative for malignancy. The lymph node biopsy showed diagnostic findings of Castleman disease-TAFRO variant. HHV-8, HHV-6, CMV, EBV and HIV were negative. Kidney functions continued to deteriorate driving hyperkalemia necessitated HD. Kidney biopsy was done showing thrombotic microangiopathy (TMA) with mesangiolysis. Serum Interleukin-6 (IL-6) and VEGF were high. Prednisolone was started and Siltuximab, an IL-6 monoclonal antibody, was initiated and continued at 3 weeks intervals. Patient started to improve within days after the first dose of IL-6 inhibitor and HD was discontinued along with full improvement of clinical symptoms and kidney functions.

Discussion: Rates of renal failure are much higher in TAFRO syndrome variant than typical iMCD. Histopathology of renal involvement in TAFRO syndrome has been reported in few publications. The majority have demonstrated a pattern consistent with membranoproliferative glomerulonephritis and few showed TMA. iMCD is known as hyper-IL-6 syndrome with polyclonal lymphadenopathy. Early recognition of disease and early initiation of IL-6 inhibition and glucocorticoids are of paramount importance in attaining complete.

FR-PO144

Investigating Vasopressin-Dependent Renal Medullary Osmolarity as a New Target for Renoprotection

Karen I. López-Cayuqueo, Felix Boivin, Janna Leiz, Shuang Cao, Christian Hinze, Kai M. Schmidt-Ott. Molecular Mechanisms of Kidney and Kidney Transplant Diseases. *Medizinische Hochschule Hannover, Hannover, Germany*.

Background: The renal medulla is characterized by a hyperosmolarity that depends on Avpr2 signaling. High osmolarity in the kidney medulla is required for urine concentration mechanisms. However, the role of the hyperosmolar medulla beyond electrolyte-free water reabsorption is not well understood. Here, we investigate the role of high osmolality in regulating kidney injury responses at molecular and cellular levels.

Methods: We analyzed kidneys from C57Bl/6N mice treated with tolvaptan (Avpr2 antagonist) and compared them to kidneys from control mice. Our analysis included single-nuclei and bulk RNA sequencing, in situ hybridization, and renal ischemia-reperfusion injury.

Results: Tolvaptan treatment reduced renal medullary osmolality and caused significant changes in the gene expression of tubular cells in the renal medulla. These changes included decreased expression of stress response and immune activation-related genes (such as Atf4, Ddit3, Hmgb1) and genes influenced by high tissue osmolality (such as Cryab, and Nupr1). The results were confirmed through bulk RNA sequencing and in situ hybridizations. Avpr2 antagonist treatment protected the renal medulla from fibrosis following unilateral renal ischemia-reperfusion injury.

Conclusions: Applying unbiased single-cell transcriptomics and orthogonal validation, we discovered that inhibiting Avpr2 in mice reduced the expression of osmolarity-regulated genes in tubular cells of the renal medulla, including those associated with stress and immune responses. Avpr2 inhibition protected the renal medulla from fibrosis development following ischemia-reperfusion injury. These findings suggest that targeting Avpr2-dependent medullary osmolality could be a potential strategy for renoprotection.

Caspase-3 Activation Increases with Age and Aggravates Kidney Injury After Ischemia-Reperfusion

Imane Kaci,[1,2] Shanshan Lan,[1,2] Hyunyun Kim,[1,2] Annie Karakeussian Rimbaud,[2] Francis Migneault,[2] Julie Turgeon,[2] Natalie Patey,[1,3] Mélanie Dieudé,[1,2] Marie-Josee Hebert.[1,2] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [3]Centre de Recherche du Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.*

Background: Rarefaction of peritubular capillaries (PTC) after ischemia-reperfusion injury (IRI) predicts progressive renal failure, especially in older kidneys. We previously demonstrated the importance of caspase-3-dependent microvascular damage in progressive kidney dysfunction after IRI. We also showed that renal IRI increases circulating levels of ApoExo; an immunogenic type of exosome-like vesicles produced by apoptotic endothelial cells downstream of caspase-3 activation, and characterized by the presence of LG3/perlecan autoantigen and active 20S proteasome. Here, we hypothesize that age modulates caspase-3 activation after renal IRI leading to increased release of ApoExo, enhanced PTC rarefaction, fibrosis and renal dysfunction.

Methods: Unilateral renal pedicle clamping (30 minutes) and contralateral nephrectomy were performed in young (8 weeks-old) and old (27 and 53 weeks-old) mice. ApoExo were purified from serum-free medium conditioned by apoptotic murine endothelial cells *in vitro* and injected to mice via tail vein every other day. Endpoints were assessed 21 days post-IRI. ApoExo circulating levels were measured by proteasome activity and anti-LG3 titers by ELISA. Complement deposition, caspase-3 activation, PTC rarefaction and fibrosis were assessed by immunohistochemistry. Renal function was monitored by BUN level.

Results: At baseline, old mice showed higher levels of caspase-3 activation within PTC, lower PTC density and higher anti-LG3 titers. Renal IRI led to significant increase in PTC caspase-3 activation, ApoExo and anti-LG3 circulating levels with age. PTC C4d deposition, interstitial fibrosis and renal function were worsened by age. To test the role of ApoExo in fueling maladaptive responses to IRI, young mice were injected with ApoExo to reach circulating levels observed in old mice. ApoExo injection increased anti-LG3 formation, PTC C4d deposition, caspase-3 activation, PTC rarefaction and interstitial fibrosis, and aggravated renal dysfunction.

Conclusions: Our results suggest that caspase-3 activation within PTC increases with older age leading to more ApoExo production post-IRI. The latter enhances microvascular damage and fibrosis, favoring progressive kidney dysfunction.

FR-PO146

Hypoxia-Inducible Factor-1Alpha Induces Apoptosis of Tubular Cells in Renal Ischemia-Reperfusion Injury via Regulating Glutathione-Specific Gamma-Glutamylcyclotransferase 1

Yoshitaka Kihira,[1] Takujiro Homma,[2] Yoshino Fujimura,[1] Shinji Matsunaga,[2] Eiji Sato,[1] Shuhei Tomita.[2] *[1]Fukuyama University, Faculty of Pharmacy and Pharmaceutical Sciences, Fukuyama, Japan; [2]Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan.*

Background: Renal ischemia-reperfusion (I/R) is the major cause of acute renal failure in the native and transplanted kidneys. Hypoxia-inducible factor (HIF)-1α is a transcription factor for cellular adaption to hypoxia. It is shown that HIF-1α expressed in renal tubules is up-regulated during renal ischemia and contributes to recovery of the I/R induced renal injury (IRI). However, precise mechanisms for the renal protective effect of HIF-1α in the IRI remain unclear. In the present study, we aimed to clarify the role of HIF-1α on renal IRI by employing a heterozygous HIF-1α knockout (hKO) mouse model.

Methods: Male hKO and wild type (WT) littermate mice were used for IRI model. Mice were anesthetized and the right kidney was resected. Then the left kidney was occluded with a vascular clamp at the hilus for 45 min. The clamp was removed to allow blood reperfusion. For hypoxia-reoxygenation (H/R) treatment, human renal epithelial cell line HK2 were grown to approximately 80% confluence. The culture medium was changed to DMEM without either glucose or FBS and the cells were incubated for 24 h under 1% O_2 conditions. Then, the cells were incubated in DMEM containing 10% FBS under normoxia.

Results: Serum creatinine and blood urea nitrogen in hKO mice with IRI were higher than those in WT mice, confirming that HIF-1α contributes to repair of IRI. Apoptosis is induced in early phase of IRI in WT, while it is induced in late phase in the hKO. In hKO mice, Bcl-2/Bax ratio was increased compared with that of WT mice, indicating that Bcl-2 is a cause for the temporal difference of the apoptosis induction. We found that the pro-apoptotic factor glutathione-specific gamma-glutamylcyclotransferase 1 (CHAC1) was upregulated in tubules of WT after I/R but not in those of hKO. CHAC1 knockdown in HK2 cells induced Bcl-2 upregulation after H/R treatment. These results indicate that CHAC1 regulates apoptosis induction in tubules during IRI via Bcl-2 regulation. HIF-1α knockdown with RNA interference in HK2 cells reduced CHAC1 expression after H/R treatment, indicating direct regulation of CHAC1 by HIF-1α.

Conclusions: Induction of apoptosis in the early phase of IRI is regulated by HIF-1α-CHAC1 axis, contributing to the repair of IRI.

FR-PO147

Mitochondrial Infusion Attenuates Cisplatin-Induced AKI by Inducing Mitochondrial Dynamics

Mohammad A. Afjal,[1] Amanda S. Stayton,[1] Thomas W. Horton,[1] Soumi Mazumdar,[1] Fnu Wajidunnisa,[1] Canan Kuscu,[1] Cem Kuscu,[1] Navjot Pabla,[2] Amandeep Bajwa.[1] *[1]The University of Tennessee Health Science Center Department of Surgery, Memphis, TN; [2]The Ohio State University, Columbus, OH.*

Background: Acute kidney injury (AKI) is a critical clinical condition of hospitalization with high mortality. Approximate 30% of patients treated with cisplatin (CP) develop AKI. CP affects mainly proximal tubular cells as well as tubular mitochondria and several mechanisms have been involved such as oxidative stress, apoptosis, and mitochondrial damage which leads to AKI. Mitochondrial function and homeostasis is crucial for the maintenance of renal function. In the current study, we evaluated the use of mitochondrial infusion, which could be a promising strategy to prevent CP-induced AKI. Currently it is unknown whether mitochondrial infusion will reduce alterations in mitochondria bioenergetics and dynamics in CP-induced AKI.

Methods: 10-12 wks old male mice were divided into four groups. Group I = saline, group II = 20 mpk CP, group III and IV received 20 mg/kg or 50 μg/mouse isolated healthy liver mitochondria via I.V. injection 24 hrs after CP injection (Fig 1A).

Results: Mice receiving either low dose 50 μg/mouse or high dose 20 mg/kg mitochondria had significantly reduced plasma BUN (Fig 1B) and creatinine including renal injury markers (*Kim1* and *Ngal*). The inflammatory genes such as *Tnfa* (Fig 1C), *Il6, Il1b*, *Mcp1* induced by CP were significantly reduced in both groups III and IV. Treatment with mitochondria significantly increased mitochondrial biogenesis genes *Pgc1alpha,* mitochondrial transcription factor A (*Tfam*) and antioxidant marker *Nrf2* compared to CP group.

Conclusions: Our results demonstrate that mitotherapy protects from renal injury in CP induced model of AKI. This study indicating that mitochondrial infusion could be promising therapy to protect kidneys from CP induced AKI.

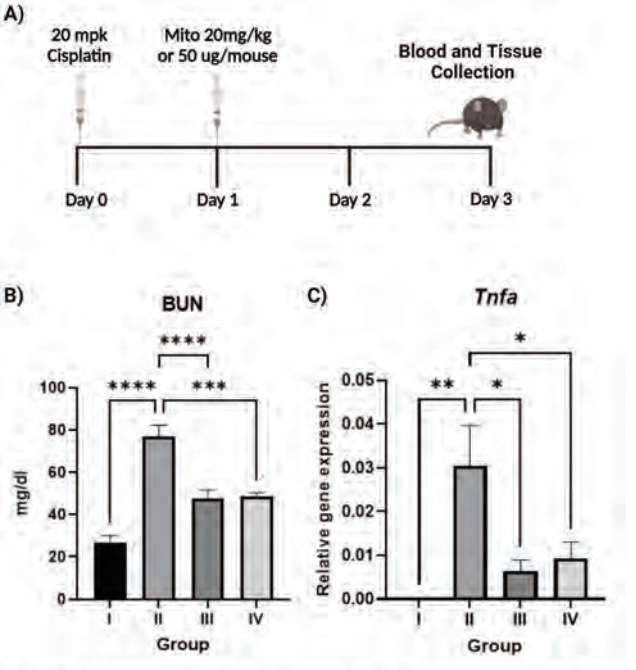

Figure 1. A) Experimental Schematic. B) BUN and C) gene level of *Tnfa. (*p ≤ 0.05; **p≤0.01; ***p≤0.001).* Group I: Saline; Group II: Cisplatin (20 mpk); Group III: CP+Mito (20 mg/kg); Group IV: CP +Mito (50 μg/mouse).

Nrf2/Keap1 Pathway Activation Improves Kidney Injury in Nephrotoxic AKI in Mice

Jianying Liu,[1] Fuyong Du,[1] Raul Camacho,[1] Katharine D'Aquino,[1] Lili Guo,[2] Rong Meng,[1] Alessandro Pocai,[1] Andrea R. Nawrocki.[1] CVMR-PH Research, Janssen Research & Development LLC. *[1]Janssen Research and Development LLC, Spring House, PA; [2]Johnson & Johnson Services Inc, New Brunswick, NJ.*

Background: Acute kidney injury (AKI) is highly prevalent and increases the risk of chronic kidney disease without treatment options. Preclinical evidence shows that regulating nuclear factor erythroid 2–related factor (Nrf2/Keap1) pathways attenuate AKI by increasing expression of anti-oxidant and anti-inflammatory genes including peroxisome proliferator-activated receptor-γ, and heme oxygenase1. To establish an

AKI model to investigate the Nrf2/Keap1 pathway, we used the Nrf2 activator CDDO-Imidazolide (CDDO-IM) to benchmark its effects in cisplatin (Sic) nephrotoxicity, cecal slurry (CS) sepsis, and ischemia reperfusion (IRI) induced AKI models in mice.

Methods: The Cis-AKI model was induced by 20 mg/kg cis in C57 mice. **The CS sepsis-AKI** was caused by a single dose of 450 ul of CS. **The IRI-AKI** was induced by bi-clamping of mouse renal pedicles for 26 min. The mice were treated with CDDO-IM (10 mg/kg, PO) prior to AKI induction. Renal function was evaluated by plasma creatinine (pCr) and expression of Nrf2 target genes (Nqo1/Txnrd1), tubular injury markers (KIM1/NGAL). Acute tubular necrosis was evaluated and scored.

Results: In the cisplatin model pCr levels increased from d1 through d4 indicating acute kidney injury. Pre-treatment of mice with CDDO-IM significantly reduced the pCr levels through d4 (pCr 0.32±0.047 in CDDO-IM vs. Vehicle 0.98±0.23 mg/dl; p<0.001). Txnrd1 was upregulated while kidney injury markers KIM1 and NGAL were downregulated. Furthermore, tubular necrosis was reduced indicating CDDO-IM prevented tubular injury and improved recovery from AKI. Unexpectedly, pre-treatment with CDDO-IM did not attenuate kidney injury in the CS or IRI model despite clear enhancement of NRF2 target expression. In contrast, Dexamethasone significantly improved renal function in sepsis and IRI mouse models of AKI.

Conclusions: The protective effect of Nrf2 activator CDDO-IM was evaluated in commonly used AKI models. CDDO-IM pretreatment significantly attenuated plasma biomarkers and tubular necrosis in cis, but not in sepsis or IRI related AKI in mice. The reasons for the model differences are unclear but could be related to the timing of Nrf2 activation in relation to the induction and disease progression, the severity of injury and potentially altered kidney exposures due to AKI.

Recombinant Sestrin2 Ameliorates Oxidative Stress, Mitochondrial Damage, and Renal Dysfunction in Contrast-Induced AKI

Hyewon Oh. *Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Although the use of iodinated contrast agents is at times essential for accurate disease diagnosis, contrast-induced acute kidney injury (CI-AKI) is a possible complication. The pathogenesis of CI-AKI has not yet been fully elucidated, but increased oxidative stress is thought to be one important cause and mitochondrial damage is thought to accompany the consequences of oxidative stress. Sestrin2 is activated by many stress factors that have been associated with oxidative stress and mitochondrial damage.

Methods: In vivo experiments, C57BL/6 mice were divided into; control, recombinant sestrin2 (RS), CI-AKI and CI-AKI with RS groups. We examined the blood analysis, oxidative stress, mitochondrial damage and CT scans.

Results: Our results showed that RS decreases oxidative stress in the CI-AKI model. Mitochondrial damage presenting as morphological changes were alleviated and ATP synthesis was restored after administration of RS. Also, the decreases in relative blood volume significantly increased compared to the CI-AKI group after RS administration in the CT scan. Finally, renal injury markers also decreased and kidney function was preserved with RS. These results suggested that RS can mitigate the deterioration of renal function in CI-AKI model.

Conclusions: Sestrin2 could mitigate mitochondrial damage and apoptosis by regulating oxidative stress in a contrast-induced acute kidney injury model.

Dissecting the Role of Tubular Manganese Superoxide Dismutase (MnSOD): Mitochondrial Oxidative Metabolism Disruption as an Adaptive Mechanism

Gabriela Vasquez Martinez,[1] Gabriel Mayoral Andrade,[1] Birong Li,[1] Ashley R. Jackson,[1,2] Kranti A. Mapuskar,[3] Douglas R. Spitz,[3] Bryan Allen,[3] Diana Zepeda-Orozco.[1,2] *[1]Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH; [3]University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Manganese superoxide dismutase (MnSOD) is an antioxidant enzyme that catalyzes the conversion of superoxide ($O_2^{\cdot-}$) to hydrogen peroxide (H_2O_2) in the mitochondrial matrix. Tubular MnSOD deletion results on renal histolgical abnormalities including tubular dilation, epithelial cell enlargement, and casts formation within the tubular lumen. However, there is no significant difference in serum creatinine or survival compared to WT mice suggesting that tubular MnSOD deletion leads to an adaptive response in mitochondrial metabolism that prevents renal dysfunction.

Methods: We developed a doxycycline-inducible pan-tubular MnSOD knock-out (Pax8rtTA-TetOcre-MnSODfl/fl, tMnSOD-KO). Mice were induced with doxycycline at 6 weeks of age, and seven months later we measued serum electrolytes and blood urea nitrogen (BUN). Transdermic glomerular filtration rate (tGFR) (WT=5 *vs.* KO=7) was evaluated prior to euthanasia. Whole kidney homogenates were used to measure mitochondrial electron transport chain (ETC) and tricarboxylic acid cycle (TCA) activities by spectrophotometric analysis and western blots (WT=11 *vs.* KO=5).

Results: No significant difference in serum electrolytes, tGFR, and BUN were noted between tMnSOD-KO and WT littermates. tMnSOD-KO and WT had no significant difference in citrate synthase activity, a surrogate marker of mitochondrial content. tMnSOD-KO kidneys demonstrated a decrease in ETC-Complex I and ETC-Complex II protein expression and activities. In contrast, ETC-Complex III and Aconitase activities were increased in the KO kidneys.

Conclusions: Tubular MnSOD deletion results in disruption of mitochondrial oxidative metabolism as well as TCA cycle enzymes 7 months post induction with preserved renal function. Future studies will provide insight into the implications of an adaptive response of mitochondrial oxidative metabolism in response to kidney injury.

TRPA1 Promotes Cisplatin-Induced AKI by Regulating the Endoplasmic Reticulum Stress-Mitochondrial Damage

Wei Qin,[1] Fei Deng,[1,3] Heping Zhang,[2] Wei Zhou,[4] Shijie Ma,[4] Yuwei Kang,[5] Wei Yang,[5] Liangbin Zhao.[6] *[1]West China Hospital of Sichuan University, Chengdu, China; [2]Affiliated Hospital of North Sichuan Medical College, Nanchong, China; [3]Chengdu Jinniu District People's Hospital, Chengdu, China; [4]University of Electronic Science and Technology of China, Chengdu, China; [5]The Affiliated Hospital of Southwest Medical University, Luzhou, China; [6]Hospital of Chengdu University of Traditional Chinese Medicine, Chengdu, China.*

Background: Cisplatin (DDP) is a widely used and effective chemotherapeutic agent against cancer. However, nephrotoxicity is one of the most common side effects of DDP, and it can proceed to acute kidney injury (AKI). The aim of this study was to investigate the mechanism of TRPA1 in promoting DDP-induced AKI through modulation of the endoplasmic reticulum stress (ERS)-mitochondrial damage.

Methods: A DDP-induced HK-2 cell model in vitro and mouse model in vivo were established and treated with the TRPA1 antagonist (HC-030031). We also used TRPA1 agonists, and treated with ERS inhibitors or GRP75 inhibitors. Renal function, histopathological changes, apoptosis, ERS and mitochondria-related proteins expression, mitochondrial changes, calcium ion concentration, cell proliferative activity, mitochondrial membrane potential (MMP), ATP, and ROS levels were also evaluated.

Results: DDP increased Scr and BUN levels, caused renal tissue injury and cell apoptosis, decreased ERS-related proteins GRP78, CHOP, and GRP75. The mitochondrial fusion-related proteins OPA1, MFN1, and MFN2, and mitochondrial division-related proteins p-DRP1 and MFF were elevated, DDP lead to mitochondrial dysfunction, and increased calcium ion concentration. In addition, DDP inhibited cell proliferation activity, decreased MMP and ATP levels, and increased ROS levels. In contrast, HC-030031 had protective effects against DDP-induced ERS and mitochondrial dysfunction

in vivo and *in vitro*. Futhermore, TRPA1 agonists promoted mitochondrial dysfunction via mitochondria-associated endoplasmic reticulum membrane. ERS inhibitors and GRP75 inhibitors increased cell proliferation activity, reduced cell apoptosis, and modulated ERS-mitochondrial damage and calcium overload to improve cell injury.

Conclusions: TRPA1 promotes DDP-induced AKI by regulating the ERS-mitochondrial damage.

FR-PO152

Long Noncoding RNA GSTM3P1 Induces mir-668 Degradation to Promote Ischemic AKI

Qingqing Wei,[1] Emily X. Huo,[2] Zheng Dong.[1,3] *[1]Augusta University, Augusta, GA; [2]Augusta Preparatory Day School, Martinez, GA; [3]Charlie Norwood Department of Veterans Affairs Medical Center, Augusta, GA.*

Background: Long non-coding RNAs (lncRNAs) play pivotal roles in ischemic acute kidney injury (AKI). Our study has identified a lncRNA, GSTM3P1, to be induced by hypoxia and to significantly enhance renal proximal tubular cell apoptosis post ATP depletion. Its mouse homologue, gstm2-ps1, exhibited a similar injurious role and induced in C57BL/6 mouse proximal tubules after 30-minute ischemia and 3-hour reperfusion. Proximal tubular specific depletion of gstm2-ps1 significantly protected mice from ischemic AKI. Our research also suggests a potential mechanism of GSTM3P1 to target a renal protective microRNA mir-668 by co-precipipation in the RNA-induced silencing complex.

Methods: A binding site of mir-668 in GSTM3P1 was confirmed through luciferase assay. However, unlike the routine lncRNA/microRNA sponge and neutralization, GSTM3P1 overexpression resulted in the degradation of mature mir-668 without affecting its primary transcript or precursor. Mutation of the mir-668 binding site in GSTM3P1 counteracted the mir-668 degradation. Thus, we hypothesized that GSTM3P1 induces mir-668 degradation through target-directed microRNA degradation (TDMD), a new regulation pathway for lncRNAs to suppress microRNAs.

Results: Accordingly, an HEK cell line with ZSWIM8 (a key TDMD complex component) knockout was established. In comparison to the wild type HEK cells, ZSWIM8 knockout hindered the mature form mir-668 degradation by GSTM3P1. Furthermore, to protect kidneys from ischemic AKI, we tested the effect of gstm2-ps1 knockdown. In vitro in cultured mouse proximal tubular cells (BUMPT), gstm2-ps1 siRNAs significantly suppressed ATP depletion-induced apoptosis. In vivo, C57BL/6 male mice were treated with negative control or gstm2-ps1 siRNAs and subjected to 25-minute bilateral kidney ischemia and 48-hour reperfusion injury. Compared to the negative control group, gstm2-ps1 knockdown exhibited significantly protection by reducing BUN and serum creatine levels. The histological examination indicated profound suppression of renal tubular necrosis and apoptosis, and a substantial decrease in renal tubular NGAL induction post injury.

Conclusions: In conclusion, lncRNA GSTM3P1/gstm2-ps1 contributes to renal proximal tubular cell death and ischemic AKI by binding to and inducing mir-668 degradation via TDMD. GSTM3P1/gstm2-ps1 can be a potential therapeutic target for mitigating ischemic AKI.

Activation of Branched Chain Amino Acid (BCAA) Catabolism Protect Against AKI

Samaneh Gholami, Sandeep K. Mallipattu, Sian Piret. *Stony Brook University, Stony Brook, NY.*

Background: BCAA (Valine, Leucine and Isoleucine) catabolic defects are implicated to be determinates of multiple diseases, however it is poorly studied in kidney injuries. Acute kidney injury (AKI) is a major risk factor for development of renal fibrosis and chronic kidney disease (CKD) but there are currently no therapies available to slow or reverse this process. AKI particularly affects proximal tubule cells (PT) and results in fundamental alterations in cellular metabolism. We previously showed that BCAA catabolic enzymes are downregulated in mice treated with the PT-specific toxin aristolochic acid I (AAI) to induce AKI, as well as human CKD. Our aim was to determine whether pharmacological activation of BCAA catabolism using the compound BT2 attenuates AAI-induced AKI.

Methods: C57Bl/6 mice were injected with 3 mg/kg AAI to induce AKI. After evaluating the frequency and dosage of AAI to induce AKI, mice were treated with two injections of AAI three days apart plus 20 mg/kg/day BT2 or DMSO. Serum was collected for urea nitrogen and creatinine measurements, and kidneys for histology, immunofluorescence, gene expression analysis, Western blotting and measurement of BCAA concentrations.

Results: There were no functional or histological differences between controls groups treated with DMSO or BT2 at baseline. Kidney function as assessed by creatinine and BUN was significantly reduced in mice treated with AAI but improved significantly in AAI+BT2 mice. Lotus lectin staining for mature PT showed extensive loss of PT in AAI-treated mice which was significantly rescued in AAI+BT2 mice. Moreover, PT injury markers such as kidney injury molecule1 (Kim-1), vimentin (Vim) and cytokeratin 20 (KRT-20) which were induced by AAI, were also attenuated in AAI+BT2 mice. We also identified an increased BCAA accumulation in kidney cortex of mice treated with AAI compared with controls, which was attenuated in AAI+BT2 mice. Interestingly, m-TORC1 pathway showed significant increase in AAI treated mice compared to controls which may be due to leucine accumulation in PT cells, whereas phospho-mTOR was reduced in AAI+BT2 mice.

Conclusions: Pharmacological activation of BCAA catabolism attenuated AKI features in mice by improving metabolism and reducing BCAA accumulation in cells which may be toxic for PT cells.

FR-PO154

TEAD1 Regulates Cisplatin-Induced AKI

Melanie Tran, Baihai Jiao, Hao Du, Bo Song, Yanlin Wang. *University of Connecticut School of Medicine, Farmington, CT.*

Background: Cisplatin is an inorganic platinum-based chemotherapeutic agent that is widely used for the treatment of solid tumors. However, a known complication of cisplatin administration is acute kidney injury (AKI). Despite recent advances in examining the molecular mechanisms, no potential strategy exists to prevent kidney injury. In this study, we examined the role of TEA domain family member 1 (TEAD1) in the pathogenesis of cisplatin-induced AKI.

Methods: We generated proximal tubule-specific TEAD1 knockout ($TEAD1^{PKO}$) mice by crossing TEAD1 floxed mice with PEPCK-Cre mice. Ten-week-old male $TEAD1^{PKO}$ mice and $TEAD1^{f/f}$ ($TEAD1^{CON}$) mice were administered a single intraperitoneal dose of cisplatin (20mg/kg body weight), or vehicle (saline) to induce AKI. Blood and kidneys were collected at 72h for assessment of kidney function, tubular cell injury, cell death and inflammation. Lentivirus transfection was utilized to knock down the expression of TEAD1 in mouse tubular epithelial cells *in vitro*. Cells were treated with cisplatin (20μM, 24h) for determination of intracellular ROS and mitochondrial function.

Results: TEAD1 expression was upregulated in tubular epithelial cells of kidneys with cisplatin-induced AKI. $TEAD1^{PKO}$ mice treated with cisplatin had increased tubular cell damage and enhanced kidney dysfunction compared with $TEAD1^{CON}$ mice. Additionally, $TEAD1^{PKO}$ mice had augmented necroptotic cell death and inflammatory response compared with $TEAD1^{CON}$ mice treated with cisplatin. Knockdown of TEAD1 in mouse tubular epithelial cells promoted intracellular ROS levels, which was associated with reduced ATP production and impaired oxygen consumption rate.

Conclusions: Taken together, our results indicate that TEAD1 plays an important role in the pathogenesis of cisplatin–induced AKI through regulation of necroptosis and inflammation which may be associated with impaired mitochondrial function. TEAD1 may represent a novel therapeutic target for cisplatin-induced AKI.

AMPK Activation Protects Kidney Function After Renal Ischemia Reperfusion Injury in Rats

Henriette Frikke-Schmidt, Kamal A. Albarazanji, Jenson Qi, David Frederick, Fuyong Du, Rong Meng, George Ho, Andrea R. Nawrocki, Alessandro Pocai. Cardiovascular, Metabolism, Retina and Pulmonary Hypertension Therapeutic Area. *Janssen Research and Development LLC, Spring House, PA.*

Background: The kidney has a high energy demand to carry out its function, and with Acute Kidney Injury (AKI) such as ischemia reperfusion, there is profound mitochondrial damage. Adenosine Monophosphate Kinase (AMPK) is a key regulator of mitochondrial function and biogenesis. Here, we used a rat model of ischemia-reperfusion inducing AKI to explore the effect of pharmacological activation of AMPK.

Methods: Male Spraque Dawley rats were treated with a direct AMPK activator (n=12) or vehicle (n=12) one hour prior to ischemia reperfusion induced by bilateral clamping the renal pedicles for 35 minutes. Kidney functions was assessed by transcutaneous glomerular filtration rate (tGFR) measured at 5-7 hours using the Medibeacon technology, and kidney, plasma and urine were collected for analysis of plasma creatinine, urinary NephroCheck and kidney histology 7 hours post injury.

Results: Plasma creatinine and tGFR were significantly improved in the animals treated with AMPK activator compound compared to vehicle control with a 28% reduction of creatinine (1.53±0.257 versus 1.10±0.184 mg/dl, $p<0.001$) and 69% improvement in tGFR (0.0792± 0.0452 versus 0.135±0.0738 ml/min/100g bodyweight, $p<0.05$). AMPK activation improved urinary NephroCheck score (0.0764±0.0564 versus 0.00899±0.00356 $(ng/ml)^2/1000$ of IGFBP7 and TIMP2, $p<0.001$) and acute tubular necrosis in the cortex.

Conclusions: Pharmacological activation of AMPK alleviated kidney function and preserved tubular structure. These data support AMPK activation as a novel therapeutic approach for AKI.

FR-PO156

Notch Signaling Pathway Mediates Anti-Inflammatory Effects of Vagus Nerve Stimulation

Shuhei Kuwabara, William Nash, Junlan Yao, Shuqiu Zheng, Mark D. Okusa. Division of Nephrology and Center for Immunity, Inflammation, and Regenerative Medicine. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: A novel strategy for the prevention and treatment of AKI is activating the cholinergic anti-inflammatory pathway (CAP), a neuroimmune circuit. The CAP can be initiated by vagus nerve stimulation (VNS) and subsequent activation of splenic and peritoneal macrophages (MΦ), leading to suppression of pro-inflammatory cytokine production. We previously showed that an increase in hairy and enhancer of split 1 (Hes1) in peritoneal MΦ contributes to renoprotective effects of CAP. Hes1 is a transcriptional factor, and its expression is regulated by the Notch signaling pathway. However, a direct

relationship between the CAP and Notch signaling has been unclear. In the current study, we focused on Notch signaling in MΦ to unravel the detailed molecular mechanism of CAP and to determine the utility of Notch signaling in ameliorating AKI.

Methods: To test if VNS activates Notch signaling in MΦ, we performed VNS before lipopolysaccharide (LPS)-induced AKI. After LPS administration, gene expression of Notch components, cytokines, and *Kim-1* was assessed by qPCR. MΦ-specific *Notch2* KO mice (*Cx3cr1Cre; Notch2$^{fl/fl}$*) and controls (*Notch2$^{fl/fl}$*) were subjected to VNS to evaluate whether Notch2 mediates anti-inflammatory responses in MΦ. Flow cytometry analysis was performed to examine the influence of MΦ-specific Notch2 expression on immune cell subpopulations.

Results: VNS suppressed an LPS-induced upregulation of pro-inflammatory cytokines (*Tnfa, Il1b*, and *Ccl2*) in MΦ and *Kim-1* in kidneys. This event was accompanied by an increase in Notch components including *Hes1* in MΦ. After VNS and LPS treatments, BUN levels were increased in *Notch2* KO mice, compared to WT controls. Consistently, these *Notch2* KO mice showed higher levels of *Ccl2* (but not *Tnfa* and *Il1b*) and *Kim-1* expression in the MΦ and kidneys, respectively. Flow cytometry analysis revealed that under physiological conditions, Notch2 deficiency in MΦ induced a decrease in MΦ and monocyte numbers in the spleen and circulation.

Conclusions: Our findings suggest that: 1) during LPS-induced AKI, Notch2 mediates anti-inflammatory effects of VNS by suppressing *Ccl2* expression in MΦ, and 2) Notch2 in MΦ positively regulates cell subpopulations of MΦ and monocytes, which might inhibit neutrophil infiltration into the kidneys and attenuate subsequent injury.

Transient Nucleus-to-Cilium Microtubule Assemblies Initiate Senescence in Stressed Renal Epithelial Cells

Jielu H. Robichaud,[1] Yingyi Zhang,[1] Kai He,[1] Chuan Chen,[1] Yan Huang,[1] Zheng Dong,[2] Kun Ling,[1] Jinghua Hu.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Augusta University, Augusta, GA.*

Background: Cellular senescence plays a critical role in diminishing regenerative capacity and exacerbating kidney injury. In previous research, we demonstrated that the translocation of a ciliary protein, FBF1, to promyelocytic leukaemia nuclear bodies (PML-NBs) is crucial for inducing senescence in stressed human cells. However, how FBF1 translocates into the nucleus upon exposure to stressors remain elusive.

Methods: Human renal cortical tubular epithelial cells (RCTE) were exposed with irradiation, inflammatory cytokines, or oxidative stress to induce cellular senescence. Senescent level was determined using Senescent Associated (SA)-b-Gal staining, and protein and RNA levels of senescence and SASP markers. Immunofluorescence was employed to detect sinc-MTs. Microtubule assembly was disrupted in RCTE cells using Colchicine or knockdown CDK5RAP2. Knockdown of the tubulin glutamylases were performed to investigate the role of polyglutamylation in sinc-MT-mediated senescence induction. Western blotting, confocal imaging, and super-resolution Structure Illumination Microscopy (SIM) were used to determine the expression and subcellular localization of key components. Protein-protein interaction were analyzed through APEX2 based BioID analysis and confirmed by exogenous and endogenous immunoprecipitation assays.

Results: Here, we discovered a novel phenomenon that, in renal epithelial cells, irreparable stressors induce a transient assembly of nucleus-to-cilium microtubule assays (sinc-MTs), which are highly polyglutamylated, unconventionally polarized with minus-ends nucleating near the nuclear envelope and plus-ends anchored below the ciliary base. KIFC3, a minus-end-directed kinesin, is recruited to cilia base in stressed cells and use centrosomal protein CENEXIN1 as an adaptor to translocate FBF1 towards the nucleus along sinc-MTs. Deficiency of KIFC3 or CENEXIN1 abolishes both FBF1 translocation and senescence initiation in stressed cells.

Conclusions: Collectively, we elucidate the mechanistic insights into the essential role of a stress-induced sinc-MTs in transducing stress-induced ciliary signals into the nucleus to initiate senescence program in damaged renal epithelial cells. Our findings highlight the potential of targeting cilia as a therapeutic strategy for senescence-related kidney diseases.

FR-PO158

The Effects and Mechanism of Circadian Rhythm on Contrast-Induced Renal Injury

Shuqing Yang, Lei Jiang, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The circadian clock of mammals regulates various life activities. As an important metabolic organ in the body, the kidney exhibits a certain diurnal pattern in glomerular filtration function and ion transport of renal tubules. In view of the huge basic population of using contrast agents for diagnosis and treatment, as well as the potential long-term risks of renal diseases, contrast-induced acute kidney injury (CI-AKI) is a clinical problem that cannot be ignored. Although the pathogenesis of CI-AKI has been partially understood, the role and mechanism of circadian rhythm in contrast agent renal injury is still unknown.

Methods: The study retrospectively analyzed 33 patients undegoing percutaneous coronary angiography and coronary angioplasty in the cardiovascular center of our hospital from October 2020 to June 2022. In addition, all the mice were injected with 10 g/kg Iohexol through the tail vein at ZT0 or ZT12, respectively and sacrificed 24 hours later.

Results: The change of serum neutrophil gelatinase-associated lipocalin (NGAL) in the morning group (7:00~13:00) was higher than that of the afternoon group (13:00~20:00). The injection of Iohexol at ZT0 had almost no significant effects on the renal tissue of mice. While the injection of Iohexol at ZT12 increased the expression of kidney injury molecule 1 (KIM1), NGAL and lipid peroxidation products and reduced the expression of glutathione peroxidase 4. Knockdown of *Clock* in primary proximal renal tubular cells decreased the expression of *Nrf2* and its downstream antioxidant target genes, while over-expression of *Clock* restored the expression of *Nrf2*. Finally, 4-octyl itaconate was intraperitoneal injected to upregulate the expression of NRF2 at ZT12, which alleviated the renal tubular injury caused by Iohexol.

Conclusions: The study shows the circadian clock regulates NRF2 mediated antioxidant response, which in turn leads to diurnal differences in contrast-induced renal injury.

Autophagy-Associated FIP200 Protects Renal Tubules Against Apoptosis Following Renal Ischemia-Reperfusion Injury

Yi Li, Li Wang. National Natural Science Foundation of China (82270729, U21A20349) and Key R&D projects in Sichuan Province (2021YFS0372, and 2021YFS0370). *Department of Nephrology, Sichuan Provincial People's Hospital, Sichuan Clinical Research Center for Kidney Diseases, University of Electronic Science and Technology of China, Chengdu, China.*

Background: Acute kidney injury (AKI) easily progresses to chronic kidney diseases. Renal ischemia-reperfusion injury (IRI) is an important cause of AKI. The pathogenesis of renal IRI is complex, and its pathological characteristics mainly include renal tubular epithelial cell injury. Apoptosis is one of the main mechanisms of hypoxia-induced renal tubular epithelial cell death. Autophagy regulates apoptosis and plays a key role in the development of renal IRI. FAK family-interacting protein of 200 kDa (FIP200) is a crucial component of the ULK-1-Atg13-FIP200 complex formed in mammalian cells upon autophagy induction. However, the precise mechanisms of FIP200 in renal IRI-mediated AKI remains elusive.

Methods: The Billups hypoxic modular systemwas used to establish the hypoxia/reoxygenation (H/R) cell model in HK2 cells. Cells were maintained under hypoxia for 5 min, 30 min, 45 min, 1 h, 2 h, 4 h, 6 h, and 24 h, and then reoxygenated for 24 h. Cells in the control group were not subjected to hypoxia then reoxygenation. All animal studies were approved by the Ethics Committee of Sichuan Provincial People's Hospital (approval No. L201735). Twenty-four wild-type mice were divided into 8 groups, and the renal pedicles of their left kidney were clamped with microvascular forceps. Then, 12 FIP200 conditional knockout (FIP200loxp-/loxp--Ggt cre/mice) mice in the renal tubular epithelial cell, in parallel to 12 wild-type mice, were randomly divided into renal IRI group and sham operation group.

Results: The expression of the autophagy-related protein FIP200 was up-regulated in vivo and in vitro after renal IRI or hypoxia/reoxygenation (H/R). Mice with conditional FIP200 knockout in renal tubules showed severe renal tissue damage after IRI. Overexpression and knockdown of FIP200 in HK2 cells revealed its protective effects on H/R injury of renal tubular epithelial cells. FIP200 could interact with HMGB1 by immunoprecipitation assays and biolayer interferometry. FIP200 could induce autophagy by regulating the competitive binding of HMGB1 and autophagy-related factors.

Conclusions: Our data indicate that FIP200 has an important role in preventing renal tubular cell damage and death following renal IRI, and might be a novel potential target for prevention and treatment of AKI caused by IRI.

FR-PO160

JMJD3 Activation Contributes to Renal Protection and Regeneration Following AKI in Mice

Chao Yu,[1] Jianjun Yu,[1] Shougang Zhuang.[2] *[1]Tongji University School of Medicine, Shanghai, China; [2]Brown University Warren Alpert Medical School, Providence, RI.*

Background: We have recently demonstrated that Jumonji domain-containing protein D3 (JMJD3), a histone demethylase of histone H3 on lysine 27 (H3K27me3), is protective against renal fibrosis, but its role in acute kidney injury (AKI) remains unexplored.

Methods: Murine renal tubular epithelial cells (mRTECs) were treated with GSK or siRNA specific for JMJD3. A folic acid (FA)-induced AKI murine model was created by peritoneal injection of FA at 250 mg/kg and a biliteral I/R murine models were established by occluding with a non- traumatic vascular clamp for 35 minutes in mice.

Results: Injury to the kidney upregulated JMJD3 and induced expression of H3K27me3, which was coincident with renal dysfunction, renal tubular cell injury/apoptosis and proliferation. Blocking JMJD3 activity by GSKJ4 led to worsening renal dysfunction and pathological changes by aggravating tubular epithelial cell injury and apoptosis in both murine models of AKI. JMJD3 inhibition by GSKJ4 also reduced renal tubular cell proliferation and suppressed expression of cyclin E, phosphorylation of CDK2, but increased p21 expression in the injured kidney. Furthermore, inactivation of JMJD3 enhanced I/R- or FA-induced expression of TGF-b1, vimentin and Snail, phosphorylation of Smad3, STAT3 and NF-kB and increased renal infiltration by F4/80 (+) macrophages. Finally, GSKJ4 treatment caused a further downregulation of Klotho, BMP-7, Smad7 and E-cadherin, all of which are associated with renal protection and anti-fibrotic effects.

Conclusions: These data provide strong evidence that JMJD3 activation contributes to renal epithelial tubular cell survival and regeneration after AKI.

Funding: Government Support - Non-U.S.

MLL1 Activation Contributes to Renal Protection and Regeneration Following AKI Induced by Folic Acid and Ischemia/Reperfusion

Xiying Hou,[1] Shougang Zhuang.[2] [1]*Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China;* [2]*Department of Medicine, Rhode Island Hospital, Brown University, Providence, RI.*

Background: Mixed lineage leukemia 1 (MLL1) is a methyltransferase that induces histone H3 lysine 4 trimethylation (H3K4me3) and exerts its functional roles by interacting with multiple subunits including WD repeat-containing protein 5 (WDR5) and Menin. In this study, we investigated the role and mechanisms of MLL1 in murine models of acute kidney injury (AKI) induced by folic acid (FA) and ischemia/reperfusion (I/R).

Methods: A folic acid (FA)-induced AKI murine model was created by peritoneal injection of FA at 250 mg/kg and a biliteral I/R murine models were established by occluding with a non- traumatic vascular clamp for 35 minutes in mice.

Results: Injury to the kidney elevated expression of MLL1, Menin, WDR5 and H3K4Me3, which was accompanied by increased serum creatine (Scr) and blood urea nitrogen (BUN), renal tubular injury and apoptosis. Pharmacological inhibition of MLL1 activity with MI503 to disrupt the interaction between MLL1 with Menin further increased Scr and BUN levels, enhanced expression of neutrophil gelatinase associated lipocalin and kidney injury molecule-1, and induced more apoptosis in the kidney following FA and I/R injury. In contrast, MI503 decreased the expression of vimentin and proliferating cell nuclear antigen. Similarly, treatment with MM102 to disrupt the interaction between MLL1 and WDR5 also worsened renal dysfunction, aggravated tubular cell injury and apoptosis, and inhibited cellular dedifferentiation and proliferation in mice following FA injection. Moreover, MI503 inhibited FA-induced phosphorylation of epidermal growth factor receptor (EGFR), signal transducer and activator of transcription 3 and extracellular signal-regulated kinase-1/2 in injured kidneys.

Conclusions: Collectively, these data suggest that MLL1 contributes to renal protection and functional recovery and promotes renal regeneration through a mechanism associated with activation of the EGFR signaling pathway.

Histone Methyltransferase SMYD2 Promotes AKI and Renal Regeneration by Activating Epidermal Growth Factor Receptors

Xiying Hou,[1] Shougang Zhuang.[2] [1]*Department of Nephrology, Shanghai East Hospital, Tongji University School of Medicine, Shanghai, China;* [2]*Department of Medicine, Rhode Island Hospital, Providence, RI.*

Background: Protein methyltransferase SET and MYND domain containing protein 2 (SMYD2) is one of the most widely studied lysine methyltransferases. It is involved in the development of numerous tumors and renal fibrosis by inducing methylation of H3K36 and H3K4 as well as multiple non-histone protiens, but its role in acute kidney injury (AKI) remains unclear.

Methods: In this study, we investigated the role and mechanism of SMYD2 in murine models of AKI induced by folic acid (FA), ischemia/reperfusion (I/R), as well as cecal ligation and puncture (CLP) using highly selective inhibitor AZ505 and renal tubular conditional knockout mice of SMYD2.

Results: Following AKI, the expression levels of SMYD2 and H3K36Me3 were significantly increased, along with the increase of serum creatinine (Scr) and urea nitrogen (BUN) levels, renal tubule cell injury and apoptosis. Administration ofAZ505 further increased levels of Scr and BUN, enhanced the expression of neutrophil gelatinase- associated lipocalin (NGAL), kidney damage molecule-1 (Kim1), and the apoptosis-related proteins such as cysteine-aspartate protease 3 (Caspase3), polyadp ribose transferase (PARP) and BAX. Conversely, pharmacological inhibition of SMYD2 reduced the expression of proliferating cell nuclear antigen and Vimentin. Similarly, conditional knockout of renal tubule SMYD2 aggravated renal impairment, tubular cell injury and apoptosis and inhibited the dedifferentiation and proliferation of renal tubular cells in mice following acute injury. Moreover, AZ505 and tubule conditional SMYD2 knockouts significantly inhibited phosphorylation of renal epidermal growth factor receptor (EGFR), Akt and extracellular signal-regulated kinase 1/2 (ERK1/2). In cultured renal tubular cells, selective inhibition of SMYD2 by AZ05 or silencing of EGFR by siRNA also resulted in decreased phosphorylation of EGFR, Akt and Erk1/2.

Conclusions: These findings suggest that the expression and activation of endogenous SMYD2 contributes to renal protection and tubular cell regeneration through a mechanism involved in the activation of EGFR signaling pathway.

Upregulating NRF2 Is a Critical Regulatory Mechanism for the Protective Effect of Ultrasound to Mitigate Sepsis-Associated AKI

Shuqiu Zheng, Junlan Yao, Shuhei Kuwabara, William Nash, Eibhlin S. Goggins, Mark D. Okusa. *University of Virginia, Charlottesville, VA.*

Background: Sepsis-induced oxidative stress and dysfunction of innate immune response have emerged as key players in the pathogenesis of sepsis-associated acute kidney injury (S-AKI). Nuclear factor-erythroid-derived 2-related factor 2 (NRF2), a key oxidative stress regulator, has been implicated to play an important role in T cell–specific augmentation of Nrf2 to mitigate oxidative stress. Our previous studies indicated that pulsed ultrasound (pUS) can reduce inflammation and acute kidney injury in mice. We hypothesis that pUS mediated protection is associated with enhanced the expression of Nrf2 and reduced immune system dysfunction. In this study, we utilized LPS-induced S-AKI in normal and Nrf2–/– mice, and we used RAW264.7 cells to investigate the effects of pUS on LPS-induced kidney injury, macrophage filtration and NRF2. In addition, we also investigated whether pUS protection occurs through enhanced NRF2 expression and disturbed CD4+ T cells immune function in human Jurkat T cells.

Methods: C57/BL/6 mice received pUS 24 hours before LPS (5 mg/kg, ip) treatment. The parameters of pUS therapy followed the protocol we previously published. In vitro studies were performed using RAW cells and Jurkat T-cell lines, which were cultured and stimulated with LPS (100ng/ml) for 6h. NRF2 protein and mRNA expression was measured by immunofluorescence and RT-PCR respectively. Kidney injury was assessed by Kim1, cleaved-caspase-3 and plasma creatinine assay. Iba1, F4/80 and CD4+ T cells were used to evaluate immune cells/macrophage infiltration.

Results: LPS produced AKI and macrophage/lymphocyte filtration in WT mice with a dramatic decline of NRF2. Furthermore, pUS-treated mice with high Nrf2 expression had fewer Iba1+ and F4/80+ macrophage infiltration in the kidney and CD4+ T cells in Jurkat T cells and attenuated sepsis-induced AKI. In contrast, LPS stimulus induced greater infiltration of microphages, as well as more early time and more severe renal injury in Nrf2–/– mice compared with litter mate control mice. pUS attenuated S-AKI.

Conclusions: These results suggest that upregulating Nrf2 antioxidant defenses in kidney and in T cells are essential for ultrasound to attenuate oxidative stress-induced AKI. Our results reveal a novel mechanism for pUS protection from kidney injury during S-AKI.

AKI-Induced Senescence as a Key Player in CKD Progression: Insights from an Aristolochic Acid Mouse Model

Peng Gao,[1,2] Schrodinger C. Cenatus,[1,2] Nathalie Henley,[2] Jonatan Barrera-Chimal,[2] Casimiro Gerarduzzi.[1,2] [1]*Universite de Montreal Faculte de Medecine, Montreal, QC, Canada;* [2]*Hopital Maisonneuve-Rosemont Centre de Recherche Axe de Nephrologie, Montreal, QC, Canada.*

Background: Senescence is a persistent cell cycle arrest accompanied by a senescence-associated secretory phenotype (SASP). The role of tubular senescence in driving chronic kidney disease (CKD) following acute kidney injury (AKI) remains controversial due to the multiple animal models used and different timepoints of senescent cell depletion. To accurately represent a direct injury induction of tubular senescence, we utilized a mouse model of Aristolochic acid (AA), a nephrotoxicant known in the clinical setting to promote DNA damage specifically in tubular epithelial cells (TECs). Our model of persistent injury following AA-induction of AKI leads to tubular senescence and allows to study diverse timepoints of CKD progression.

Methods: An AKI to CKD model was created by a single intraperitoneal injection of 5 mg/kg of AA into male C57BL/6 mice. *In vitro* studies utilized 1-10ug/ml AA, and HK-2 (human proximal tubule cell line), mTECs (primary mouse TECs), and NRK-49F (kidney fibroblast cell line). Senolytics (ABT-263) were used to eradicate senescent cells, while senomorphics (Metformin) inhibited SASP.

Results: *In vivo*: Compared to the control, AA-induced tubular senescence as early as 7 days post-injury, as shown by increased p53, p21, p16, γH2AX expression, and β-Gal activity in tubules. AA-treated mice displayed CKD signs of tubular damage and tubulointerstitial fibrosis. Timing of senolytic treatment affected therapeutic outcomes, with early clearance of senescent cells post AA injection protecting against fibrosis. Clearance of SASP factors using Metformin from day 3 post AA injection mitigated renal fibrosis and senescent burden. *In vitro*: AA-induced senescence in HK-2 and mTECs. Senescent HK-2 cell-derived conditioned medium promoted epithelial-to-mesenchymal transition in HK-2 cells and fibroblast-to-myofibroblast transition in NRK-49F cells, which was reversed by Metformin treatment.

Conclusions: Using a model of specific tubular DNA damage, our data reveal that: i) TEC senescence is a key link in the AKI to CKD transition; ii) Precise timing of senescent cell removal by senolytic treatment is critical to achieving therapeutic benefits; iii) Therapeutic inhibition of SASP by senomorphics reduces renal fibrosis and senescence, offering a potential alternative to senolytics.

Spns2 Deficiency Protects the Mouse Kidneys During Ischemia-Reperfusion Injury

Sylvia Cechova, Junlan Yao, Yugesh Kharel, Kevin Lynch, Mark D. Okusa. *University of Virginia School of Medicine, Charlottesville, VA.*

Background: Spns2 (Spinster homolog 2) is transmembrane protein that transports sphingosine 1-phosphate, a bioactive lipid that acts as an extracellular ligand and intracellular second messenger in a variety of biological functions. In the present study, we investigated the effect of inducible global *Spns2* deletion or pharmacological inhibition of Spns2 in mouse kidneys after bilateral ischemia-reperfusion injury (IRI).

Methods: *Ubiquitin-CreERT2*;*Spns2*$^{fl/fl}$ mice (*iSpns2*^{UBCKO}) and *iSpns2*$^{fl/fl}$ littermates were injected with tamoxifen (1 mg, i.p.) daily for 5 days and rested for 2 weeks before 28 min ischemia followed by 24 h reperfusion. C57BL/6 mice were pre-treated 24 h before IRI with Spns2 inhibitor (SLF1081851, 10 mg/kg, i.p.) or vehicle. Relative kidney *Spns2, Ngal, Kim1, Cxcl1, and Cxcl10* mRNA expression were estimated by qPCR and neutrophil infiltration by immunofluorescence labeling using Ly6G clone1A8 antibody.

Kidney injury was evaluated by measuring plasma creatinine (PCr) and BUN and by scoring acute tubular necrosis (ATN) in H&E stained sections.

Results: Relative kidney mRNA of *Spns2* in *iSpns2^{UBCKO}* mice after tamoxifen treatment was significantly reduced compared to *iSpns2$^{fl/fl}$* mice: 0.5±0.1 vs. 1.0±0.1, P=0.006. After IRI, the increase in mRNA of kidney injury markers *Ngal* and *Kim1* and PCr and BUN in *iSpns2$^{fl/fl}$* mice were significantly reduced in *iSpns2^{UBCKO}* mice (4.2±0.7 vs. 1.40±0.2, P=0.0023; 38.8±8.3 vs. 2.4±1.0, P=0.0042; 9±0.1 vs. 0.4±0.1, P=0.0017; and 186.7±13.3 vs. 56.6±11.4, P<0.0001). *Cxcl1* and *Cxcl10* mRNA and kidney neutrophil infiltration were similar in *iSpns2^{UBCKO}* and *iSpns2$^{fl/fl}$* mice after IRI. ATN scores for *iSpns2$^{fl/fl}$* vs. *iSpns2^{UBCKO}* were 57.6±3.6 vs.10.1±1.6 (P<0.0001). The increase in PCr and BUN in C57BL/6 mice was reduced significantly by SLF1081851 (1.4±0.3 vs. 0.4± 0.1, P=0.007; 159.7±15.0 vs. 79.9±18.9, P=0.006). SLF1081851 decreased ATN score compared to vehicle (42.8±9.4 vs.14.9±4.3, P=0.027).

Conclusions: Our results demonstrate that genetic global deletion or pharmacological inhibition with a selective Spns2 inhibitor protects kidneys from IRI, suggesting that SPNS2 can serve as a potential target to prevent AKI.

Targeted IRAK4 Degradation Impairs Kidney Stromal Cell Myddosome Signaling and Reduces Tubulointerstitial Fibrosis in AKI

Marta López-Marfil,[1,2] Xichi Wang,[1] Diana O. Lopez Cantu,[1] Jocelynn G. Colunga Minutti,[1] Antonio Esquivel-Herrera,[1] Reza Abdi,[3] Dario R. Lemos.[1,4] *[1]Renal Division, Brigham and Women's Hospital, Boston, MA; [2]Universitat de Barcelona, Barcelona, Spain; [3]Transplantation Research Center, Renal Division, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: Renal fibrosis is a process of pervasive interstitial scarring driven by kidney stromal fibrogenic cells. Previous data have indicated that inflammatory signaling via the fibrogenic cell myddosome complex is critical for kidney fibrosis development. Within the myddosome, modulation of interleukin-1 receptor associated kinase 4 (IRAK4) by small molecule kinase inhibitors reduces fibrosis, but has limited anti-inflammatory effect, indicating that the IRAK4 scaffold function is sufficient for canonical activation of NF- kB.

Methods: Here we used a novel strategy to abrogate IRAK4 by means of targeted ubiquitination followed by proteasomal degradation. We tested the antifibrotic and anti-inflammatory activity of an IRAK4 degrader molecule in vitro and in vivo in a model of acute kidney injury in mice.

Results: Incubation with degrader resulted in abrogation of IRAK4 protein levels, and reduced formation of myddosome complex in primary kidney fibrogenic cells. In human kidney organoids, IRAK4 degradation reduced both extracellular matrix deposition, as well as fibrosis gene expression caused by nephron tubule damage. Further, the treatment resulted in inhibition of NF-kB activation and downstream inflammatory cytokine expression. In vivo, the IRAK4 degrader showed increased efficacy compared to the small molecule kinase inhibitor CA-4948 in ameliorating fibrosis and inflammation following ischemia/reperfusion injury.

Conclusions: Collectively, our results indicate that targeted degradation of IRAK4 is a superior therapeutic approach to kinase inhibitors for the treatment of renal fibrosing disorders.

mRNA Editing via the Apobec1 Gene Promotes Recovery from AKI

Xiaojia Guo,[1] Heino Velazquez,[1,2] Leyuan Xu,[1] Zhongshan Cheng,[1] Tian-Min Chen,[1] Yuan Tian,[1] Joerg Bewersdorf,[1] Valerie Blanc,[3] Nicholas Davidson,[3] Robert L. Safirstein,[1,2] Gary V. Desir.[1,2] *[1]Yale School of Medicine, New Haven, CT; [2]VA Connecticut Healthcare System West Haven VA Medical Center, West Haven, CT; [3]Washington University in St Louis, St Louis, MO.*

Background: Cisplatin (CP) and Ischemia/reperfusion Injury (IRI) induces AKI whereby proximal tubules (PT) undergo necrosis. We now examine the role of Apobec1, which regulates mitochondrial metabolism and cell fate, in the recovery from these forms of AKI.

Methods: Wild type (WT) and Apobec1 knockout (KO) mice received CP 15 mg/kg or were subjected to 20min IRI. Renal function, histology, mRNA, protein, lipids, and RNA sequencing were analyzed and compared. Bone marrow-derived macrophages (BMDM) were isolated from mice treated with or without CP, and their morphology, polarization, and cytokines secretion were analyzed.

Results: Apobec1 KO resulted in more severe CP-AKI as compared to WT (plasma creatinine (pCr): 2.07 mg/dL ± 0.59 vs 0.23 ± 0.09, p < 0.01 in WT) and IRI-AKI (pCr: 1.34 ± 0.22 vs 0.75 ± 0.06, p<0.05 in WT). Inflammatory cytokines were markedly increased in the Apobec1 KO animals after CP. The kidneys of Apobec1 KO showed greater necrosis, neutrophil invasion, activated T cells, elevated markers of injury, as macrophages were unexpectedly reduced. Apobec1 KO BMDM failed to polarize to M1 phenotype in vitro and to home to the kidney in vivo. High resolution microscopy of BMDM isolated from KO AKI animals revealed reduced mitochondria numbers and altered mitochondrial structure as compared to WT AKI animal. Activation of both AMPK α and β was observed in Apobec1 KO AKI, suggesting increased mitochondrial fatty acid oxidation. Mutational and pathway analysis of apobec1 derived mRNA editing differences in WT AKI and Apobec1 KO AKI showed Apobec1 potentially edits genes involved in oxidative stress, inflammation, sterol regulatory element-binding protein signaling, apoptosis and ferroptosis. Overexpression of Apobec1 in PTs in vitro reduced the ferroptosis regulator Acsl4 expression. The Apobec1 KO phenotype in CP-AKI could be rescued by intravenous injection of either BMDMs isolated from WT animals, or of the mitochondrial uncoupler BAM15.

Conclusions: We have identified Apobec1 as a crucial gene regulating the stress response to AKI. The absence of Apobec1 provoked greater oxidant stress and prevented the homing of macrophages to the injured kidney, thus preventing repair and regeneration. Increasing Apobec1 activity could be an effective strategy to reduce or prevent AKI.

FR-PO168

Meprin β Activity Modulates Cellular Proliferation via Trans-Signaling IL-6-Mediated AKT/ERK Pathway in Ischemia/Reperfusion (IR)-Induced Kidney Injury

Shaymaa Abousaad,[1] Faihaa Ahmed,[2] Ayman Abouzeid,[1] Elimelda M. Ongeri.[1] *[1]North Carolina Agricultural and Technical State University, Greensboro, NC; [2]NC State University, Raleigh, NC.*

Background: Inflammation plays a central role in the progression of kidney injury induced by ischemia/reperfusion (IR). Meprin metalloproteinases have been implicated in the pathophysiology of IR-induced kidney injury. We previously showed that meprin β modulates cellular survival (BCL-2) through IL-6/JAK/STAT signaling pathway in IR-induced kidney injury. However, it's not known how meprin β modulation of the IL-6 signaling pathway impacts the cellular proliferation in IR-induced AKI. IL-6 trans-signaling induces proliferation through either MAPK/ERK or PI3K/AKT pathway or in crosstalk with AKT/ERK. PCNA is a cellular proliferation marker that is induced through activation of the IL-6 signaling pathway. The goal of the current study was to determine how meprin β modulation of the IL-6 signaling pathway impacts downstream cellular proliferation in IR-induced kidney injury.

Methods: We used the unilateral IR as a model of renal inflammation in wild-type (WT) and meprin β knockout (βKO) male mice, with the contralateral kidneys serving as controls. The mice were sacrificed at 96 h post-IR, and kidney tissue processed for evaluation by RT-PCR and immunohistochemistry. Statistical analysis of data utilized two-way ANOVA.

Results: Our PCR data showed significant increase in mRNA levels for IL-6 and PCNA in WT and βKO mice at 96 h-post IR when compared to WT control kidneys. Immunohistochemical data showed significant increases in IL-6, PCNA, p-AKT and p-ERK in select tubules in both genotypes at 96 h post-IR compared to control kidneys. Data from immunofluorescence of kidney tissues showed that the levels of IL-6, PCNA, p-AKT and p-ERK were higher in meprin β-expressing proximal tubules (PTs), at 96 h post-IR when compared to the distal kidney tubules (DTs), which lack meprins. High levels of IL-6 were also present in the lumen of PTs and DTs from WT and βKO kidneys at 96 h post-IR, suggesting increased release into filtrate and subsequently into urine. However, high levels of PCNA, p-AKT and p-ERK were present in the lumen of PTs only from both genotypes at 96 h post-IR.

Conclusions: In conclusion, our data shows that meprin β activity modulates cellular proliferation via trans-signaling IL-6-mediated AKT/ERK pathway in IR-induced kidney injury.

Kidney Metabolomics of NHERF1 Deficiency

Eleanor D. Lederer,[1,2] Kenneth B. Gagnon.[1] *[1]The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; [2]North Texas Veterans Affairs Health Care System, Dallas, TX.*

Background: Mice lacking NHERF1 (Na^+-hydrogen exchanger regulatory factor isoform 1) show increased susceptibility to toxin-induced acute kidney injury (AKI) associated with increased activity of enzymes of the pentose phosphate pathway. We hypothesize that NHERF1 deficiency results in altered kidney cell metabolism associated with enhanced injury response. To test this hypothesis, we performed targeted metabolomic analysis of kidney cortex of wild type (WT) and NHERF1 knockout littermates (KO) in response to saline (vehicle; V) or cisplatin (C).

Methods: 5 WT and 5 KO littermate mice underwent IP injection with either saline or 20 mg/kg body weight of cisplatin (n=20). Kidneys were harvested after 72 h for metabolite extraction with HPLC-grade methanol. Ultrahigh-performance liquid chromatography tandem mass spectrometry performed by the UTSW Metabolomics Core within the Dept of Biochemistry identified over 140 metabolites in the four experimental groups: WTV; WTC; KOV; and KOC.

Results: Principal component analysis demonstrated significant variance between all four experimental groups implicating both NHERF1 absence and cisplatin-induced AKI in metabolic shift. A clear separation was seen between WTV and KOV. Enrichment and Pathway Analysis comparing WTV/KOV demonstrated enrichment of metabolites associated with methylhistidine and glycerophospholipid metabolism, phosphatidylcholine biosynthesis, and the pentose phosphate pathway. After cisplatin, major differences were noted between WTC and KOC in metabolites associated with lipid and phospholipid biosynthesis, nucleotide sugar metabolism, and mitochondrial electron transport chain.

Conclusions: NHERF1 deficiency alters carbohydrate and lipid metabolism similar to what is seen in response to kidney disease such as diabetes and uninephrectomy and alters metabolic response to injury. Whether these metabolic changes are due to deficient nutrient uptake or altered intracellular pathway integrity and how these changes predispose to acute injury are unknown.

Altered Lipid Metabolism Exacerbates Endotoxin-Associated Kidney Injury in Diabetes

Thomas De Luca, Danielle Janosevic. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Diabetes is a risk factor for endotoxin-associated acute kidney injury (sAKI). In a non-comorbid murine model of sAKI, we previously identified that renal tissue plays a role in the mediation of innate immune responses and cell-specific temporal changes in the lipid metabolism transcriptome, culminating in organ failure (16 hr) followed by recovery (24 hr). Bioactive lipids (bL) are spatially and functionally dysregulated in both diabetes and sepsis and play diverse roles in immunity, inflammation, and kidney injury, with ceramide at the nexus of sphingolipid metabolism. We hypothesized that metabolic dysregulation of bL mediates sAKI in the diabetic milieu.

Methods: Lipopolysaccharide (LPS) was given intravenously (iv) to diabetic (BKS.Cg-Dock7m+/+ Leprdb/J) mice (db) and littermates (db+) sacrificed at 0 (baseline), 16 (injury), 24 hr (recovery) after LPS iv, serum, kidneys collected. Serum creatinine (Scr) quantified (MS). ScRNAseq: dissociated kidneys sequenced (10x Chromium) and clustered (Seurat). Cryogel mounted tissue (15 uM) imaged and untargeted DESI-MSI and analysis performed (positive and negative ion modes, m/z range: 100-1,200, Cardinal MSI), attributions assigned (Lipid Maps Structural Database and Human Metabolome Database).

Results: Db at 24 hr (vs. 0 hr) had persistent renal injury (Kim1 Log_2FC 8.32±1.01, Scr 0.38±0.34) vs. db+ (Kim1 Log_2FC 3.51± 0.58, Scr (0.10 ± 0.01). In db (vs db+), putative C16 ceramide remained elevated in the renal medulla (16, 24 hr), reduced levels of protective C24 ceramide in the cortex (0 hr). In db (0-24 hrs) there was significantly altered metabolism of glycerophospholipids (i.e., phosphoinositols), fatty acyls, sterols, compared to db+. Db scRNAseq at 16,24 hrs had decreased expression in glycosphingolipid-metabolic enzymes (Glb1) in proximal tubule and similar changes in ceramide synthases (e.g., Cers 1-6), sphingosine 1-phosphate receptors involved in sAKI inflammatory and immune responses.

Conclusions: We identified several classes of deregulated lipids and altered transcriptomic expression of associated enzymes in db mice which exhibited persistent renal injury. This may lead to the deregulation of cellular function and thus, maladaptive recovery from sAKI in db. Additional work to identify ions/genes of interest and their similarities with the human metabolome will be necessary to determine causality.

FR-PO171

Proteomics and Metabolomics Conjoint Analysis Revealed Mitochondrial Function and Metabolic Disorders in Sepsis-Induced AKI

Jiatong Xu, Xiaoxiao Shi, Jiaying Li, Yan Li, Huadong Zhu, Limeng Chen. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: Sepsis-induced acute kidney injury (S-AKI) is a severe and life-threatening condition with high morbidity and mortality and poses a significant risk of chronic kidney disease. However, the early diagnosis and precaution of S-AKI remain challenged due to lacking effective diagnostic biomarkers and treatment targets.

Methods: We established an S-AKI mouse model using intraperitoneal injection of lipopolysaccharide (LPS) and control mice with 0.9% saline (both n=5). After 24 hours, the mice were euthanized to collect blood and kidney samples. The kidney proteins and dissolved metabolites were analyzed using liquid chromatography-tandem mass spectrometry. We integrated proteomics and metabolomics analysis approaches through various bioinformatic analyses, including Gene Set Enrichment Analysis (GSEA), protein and protein interactions (PPI), and MetaboAnalyst analysis.

Results: A total of 5185 proteins were identified in the kidney, including 353 upregulated and 166 downregulated proteins in S-AKI mice compared with the control group. The GO and KEGG analysis of the differentially expressed proteins (DEPs) indicated that downregulated proteins in S-AKI kidneys were primarily involved in mitochondrial functions such as mitochondrial translation and mitochondrial respiratory chain complex assembly. The hub proteins in PPI networks were mainly involved in the mitochondrial electron transport chain. The GSEA also indicated that mitochondrial dysfunction was an incredibly crucial facilitator for S-AKI development. S-AKI kidneys had 111 increased and 66 decreased metabolites compared to the control group. MetaboAnalyst enrichment analysis suggested that S-AKI mainly caused disorders of central carbon metabolism (such as transfer of acetyl groups into mitochondria, Warburg effect, and citric acid cycle), amino acid metabolism, and nicotinate and nicotinamide metabolism.

Conclusions: Proteomics and Metabolomics conjoint analysis provides new insights and a more comprehensive understanding of the pathophysiology of S-AKI with mitochondrial function and metabolic disorders, contributing to new diagnostic biomarkers and therapeutic targets.

FR-PO172

USP13 Targets MCL-1 to Protect Mitochondria-Attenuating AKI

Qian Wang, Weiwei Xia, Yue Zhang, Aihua Zhang, Zhanjun Jia. *Nanjing Medical University, Nanjing, China.*

Background: Acute kidney injury (AKI)is a severe clinical syndrome with high mortality. Thus, investigation on its mechanism and drugable targets is of importance. Here we investigated the novel role and mechanism of ubiquitin specific proteases 13 (USP13) in AKI.

Methods: Eight weeks old WT and $USP13^{+/-}$ mice were subjected to cisplatin and folic acid (FA) to induce AKI. Rapid injection of USP13 plasmids via tail vein was applied to overexpress USP13 in kidney. The serum and kidney tissues were collected for analysis. In vitro cells were used for the mechanistic study.

Results: Immunofluorescence showed that USP13 was expressed in the kidney tubular epithelial cell of human and mouse. In WT mice, cisplatin or FA strikingly enhanced serum BUN, Cys C and Cr, which were further enhanced in $USP13^{+/-}$ mice by around 15% to 30%, respectively. Meanwhile, $USP13^{+/-}$ mice with AKI showed aggravated mitochondrial injury in kidney. In contrast, overexpression of USP13 in kidney significantly protected against AKI and mitochondrial damage. Furthermore, the mechanistic study suggested that USP13 deubiquitinated and stabilized myeloid cell leukelia-l (MCL-1) to protect mitochondria under AKI, thus resulting in a protection against AKI. Finally, pharmacological inhibition of USP13 by spautin-1 (10mg/kg, I.P., daily) also worsened AKI.

Conclusions: USP13 could deubiquitinate and stabilize MCL-1 to protect against mitochondrial injury and AKI. Targeting USP13 could be a potential strategy in treating AKI.

FR-PO173

Ultrastructural Analysis of AKI due to Rhabdomyolysis

Seira Orihara, Yuta Miyake, Tomotaka Miura, Ayumi Kuroda, Kodai Suzuki, Chihiro Takada, Hideshi Okada. *Gifu University Graduate School of Medicine, Gifu, Japan.*

Background: Rhabdomyolysis (RM) develops due to being caused by skeletal muscle damage. The breakdown products are released into the bloodstream and filtered by glomeruli, causing tubular obstruction and inflammation due to protein precipitation. These injured the renal tubular and endothelial cells of the kidney and lead to acute kidney injury (AKI). However, the mechanism is still unclear. In this study, we analyzed the ultrastructure of the renal tubular and the endothelial glycocalyx in RM with scanning electron microscopy (SEM).

Methods: Ten-week-old male C57BLB6 mice were injected intramuscularly into the left thigh of the mice at a dose of 5 mL/kg of 50% glycerol after 24 hours of fasting to create an RM model mouse. The mice that survived were euthanized 96 hours after injection, and then kidney specimens and blood samples were obtained. To investigate the ultrastructure of the kidney, the glycocalyx fixation method, and the conventional fixation method were performed. Mice were perfused with a solution composed of glutaraldehyde with/without lanthanum nitrate at a steady flow rate.

Results: Serum blood urea nitrogen and creatinine were significantly elevated in the RM group. SEM analysis revealed that renal tubules are nourished by capillaries flowing through their interstices, and in normal kidneys, tubules and capillaries exist in close contact. However, in AKI induced by RM, a gap with fibrosis is created around the capillaries, creating a distance between the capillaries and the tubules. The surface of the proximal tubular cells in normal kidneys is densely packed with microvilli of unequal length and thickness, forming a brush border. In RM, microvilli on the surface of the proximal tubules had disappeared and their density was sparse. Under the RM condition, the endothelial glycocalyx was disrupted compared to the control group.

Conclusions: In conclusion, our data have shown the renal tubular and the vascular endothelial glycocalyx were injured and the newly formed gap creates a distance between them.

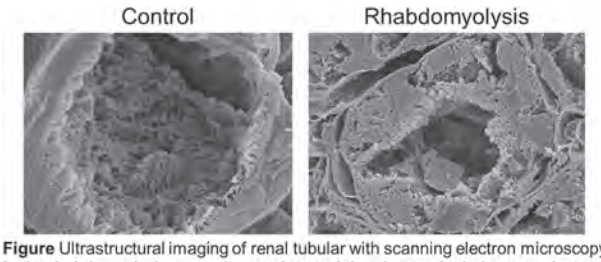

Figure Ultrastructural imaging of renal tubular with scanning electron microscopy. In the rhabdomyolysis group, it was observed that the renal tubular were destroyed, and the nucleus prolapsed.

FR-PO174

Following AKI, Transcriptional Expression of Repair Genes Are Differentially Regulated By 5-HT1F Receptor Agonism

Paul Victor Santiago Raj,[1] Kevin A. Hurtado,[1] Jaroslav Janda,[1] Rick G. Schnellmann.[1,2] *[1]The University of Arizona College of Pharmacy, Tucson, AZ; [2]Southern Arizona VA Health Care System, Tucson, AZ.*

Background: Acute kidney injury (AKI) is often accompanied by a persistent reduction in mitochondrial function, fatty acid oxidation and vascular injury. We have shown that the FDA-approved 5-HT_{1F} receptor agonist lasmiditan stimulates mitochondrial biogenesis (MB), decreases vascular injury, and accelerates renal recovery in a mouse model of AKI. Given recent studies reporting conserved cellular responses and profiling successful and failed repair genes following AKI, we sought to explore the role of lasmiditan on these repair genes.

Methods: Male 8-week-old C57B/6J mice were administered 0.3 mg/kg lasmiditan or vehicle daily beginning 24h after ischemia/reperfusion-induced AKI (I/R-AKI) and continuing for 144h (n=6/group). The kidneys were collected and gene and protein expression of select repair genes analyzed in renal cortices.

Results: Serum creatinine and kidney injury marker 1 (KIM1) were maximally elevated 24h after IR-AKI. Lasmiditan treatment decreased serum creatinine and KIM1 compared to vehicle by 144h after I/R-AKI. qRT-PCR analysis 24h following I/R-AKI revealed decreased expression of successful repair genes *ACSM2a, LRP2, SLC5A12* and *HNF4A,* and increased expression of failed repair genes *VCAM1, LCN2, RELB* and *KCNIP4* in the renal cortex of injured mice. Lasmiditan treatment increased successful repair gene expression compared to vehicle treatment by 144h after I/R-AKI; but had no effect on failed repair genes. These findings were confirmed using immunoblot analysis.

Conclusions: While these data support lasmiditan-induced regulation of successful repair genes following I/R-AKI, contributing to increased fatty acid metabolism, reabsorption of lactate, and decreased inflammation, the mechanism remains unclear. Continued use of this approach will allow us to identify and assess key genes responsible for pathophysiological changes during AKI, other renal pathologies, and the effects of drugs stimulating repair/recovery.

FR-PO175

Protective Effect of Piperazine Ferulate on AKI in Septic Rats

Xinyu Liu, Jiangang Wang, Di Li, Mengyuan Deng, Qianqian Li, Xingxing Ding, Qi Liu. *Nanyang Central Hospital, Nanyang, China.*

Background: Ferulic acid piperazine is widely used in chronic nephritis and nephrotic syndrome in clinical practice. The aim of this study was to investigate the role of ferulic piperazine (PF) in sepsis-induced acute kidney injury (AKI) rats and its mechanism.

Methods: The sepsis-induced AKI model in male SD rats was prepared by cecum ligation puncture (CLP) method. The animals were randomly divided into five groups: normal group, sham-operated group, CLP group and two PF-treated groups, and PF was administered by gavage at a dose of 50 and 100 mg / kg, respectively. Renal index, serum creatinine, blood urea nitrogen and NGAL were measured to evaluate renal function. PAS staining was used to observe renal histopathological changes. Serum inflammatory mediators (PCT, IL-6) levels were measured to assess serum inflammation levels; oxidative stress indicators (T-SOD, CAT, MDA, GSH-PX) were measured to assess body redox activity and oxidative stress levels. western blot was used to detect the expression levels of nuclear factor E2-related factor 2 (Nrf2) protein and au-rich element (ARE) binding factor 1 (AUF1) protein expression levels.

Results: PF treatment significantly reduced renal index and serum creatinine, urea nitrogen, and NGAL levels in rats. PF was also effective in ameliorating renal pathological damage. PF treatment was observed to suppress renal inflammation by reducing PCT and IL-6 levels. PF treatment restored the decrease in serum GSH-PX (glutathione peroxidase), CAT (catalase) and T-SOD (total superoxide dismutase), while also modulating the elevation of MDA (malondialdehyde). In addition, PF treatment significantly enhanced the expression of Nrf2 and AUF1 proteins in the kidney.

Conclusions: PF has a potential therapeutic effect on AKI in septic rats, and its activity may be related to the activation of anti-inflammatory and antioxidant effects of Nrf2 and AUF1 proteins.

The Novel Dual-Effect Disintegrin, ARGD-RR, Attenuates AKI to CKD in Ischemic-Reperfusion Injury Models

Chih-Kang Chiang, Shing-Hwa Liu. *National Taiwan University College of Medicine, Taipei, Taiwan.*

Background: Acute kidney injury (AKI) can lead to the development of renal fibrosis, ultimately resulting in chronic kidney disease (CKD) and end-stage renal disease (ESRD). Platelet activation has been identified as a key factor in the pathophysiology of AKI, triggering the formation of neutrophil extracellular traps (NETs), which exacerbate tubular necrosis and renal inflammation. Previous studies have demonstrated that antagonists or inhibitors of platelet activation hold promise as therapeutic interventions in AKI models induced by ischemia/reperfusion (I/R). Here, we tested whether the novel dual-effect disintegrin, ARGD-RR attenuated AKI to CKD in Ischemic-Reperfusion Injury.

Methods: In this study, we evaluated the therapeutic efficacy of a novel anti-platelet activation peptide called ARGDRR in a unilateral ischemic-reperfusion injury (uIRI) model. ARGDRR is a snake venom-derived dual-effect disintegrin-ARGDRR peptide that exhibits high affinity for binding to αIIbβ3 and αvβ3. Following ischemic-induced kidney injury, ARGDRR was administered, and we assessed renal dysfunction, renal fibrosis, and cell senescence after a 15-day period. Additionally, we examined the extent of platelet activation and NET formation in AKI.

Results: The mRNA levels of platelet glycoprotein IIb-GPIIIa (Itga2b and Itgb3) progressively increased in the uIRI kidney from day 1 to day 15, accompanied by platelet aggregation and neutrophil infiltration. Administration of ARGDRR ameliorated renal dysfunction, fibrosis, and cell senescence in the transition from AKI to CKD. Moreover, ARGDRR modulated platelet-neutrophil interaction and inhibited NET formation in AKI.

Conclusions: Our findings provide compelling evidence that the disintegrin-ARGDRR peptide holds significant potential for renal protection in the transition from AKI to CKD by inhibiting platelet activation and NET formation. These results contribute to the advancement of therapeutic strategies for AKI and CKD treatment.

Renal Tubular Epithelial Cells RIPK3 Promote AKI Progressing to CKD

Zhiyong Xie, Wei Dong, Yingwen Chen, Luan Li, Xinling Liang. *Division of Nephrology, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China.*

Background: Acute kidney injury (AKI) could increase the risk of long-term chronic kidney diseases (CKD) but its exact mechanism is still unclear. The purpose of this study was to clarify the role and mechanism of renal tubular epithelial cells RIPK3 in the AKI to CKD progression.

Methods: We evaluate the role of renal tubular epithelial cells RIPK3 through detecting its expression in renal puncture tissue and AKI to CKD progression animal model. The role of RIPK3 in promoting AKI-to-CKD transition and G2/M cell cycle arrest was evaluated using transgenic mice with specific knockout of proximal renal tubular epithelial cells RIPK3 or intervention of RIPK3 inhibitor GSK'872. Co-Immunoprecipitation and pull-down experiments were used to explore the interaction between the phosphorylated RIPK3 and CDK1. The mechanism that RIPK3 promote AKI to CKD transition through regulating G2/M cell cycle arrest were explored in vitro rescue experiments.

Results: Renal tubular epithelial cells RIPK3 was up-regulated in renal puncture tissues of CKD patients after cardiac surgery-associated AKI and AKI to CKD progression animal models. GSK'872 intervention or specific knockout of proximal renal tubular epithelial cells RIPK3 could attenuate renal interstitial fibrosis and G2/M phase cell cycle arrest. Co-Immunoprecipitation and pull-down experiments confirmed that phosphorylated RIPK3 and CDK1 could bind directly. siRNA inhibiting the expression of CDK1 could attenuate the reno-protective effect of GSK'872 intervention or RIPK3 silence after intervention of TGF-β.

Conclusions: Renal tubular epithelial cells RIPK3 is up-regulated and activated during the AKI to CKD progression and drive the AKI progressing to CKD. The possible mechanism may be that RIPK3 can inhibit the activity of CDK1, and mediate the G2/M cell cycle arrest of renal tubular epithelial cell, which could provide a new theoretical and therapeutic target for delaying the AKI to CKD progression.

FR-PO178

Decoy Receptor 2 Promotes Tubular Maladaptive Repair by Inhibiting Hmgcs2-Induced β-Hydroxybutyrate Production Following AKI

Jia Chen, Kehong Chen, Yani He. *Department of Nephrology, Daping Hospital, Army Medical University, Chongqing, China.*

Background: Tubular maladaptive repair after acute kidney injury (AKI) leads to chronic kidney disease or end-stage renal disease. However, the underlying mechanism remains unclear. The expression of DcR2 was abnormally increased in renal tubules in patients of AKI, and associated with renal prognosis. Similar results were found in moderate and severe ischemia-reperfusion injury and cisplatin-induced AKI mouse models.

Methods: Similar results were found in moderate and severe ischemia-reperfusion injury and cisplatin-induced AKI mouse models. Proteomics analysis and validation study showed that DcR2 mediated maladaptive repair by regulating the expression of Hmgcs2 (a rate-limiting enzyme of endogenous ketogenesis) and the levels of renal beta-hydroxybutyrate (β-OHB). Hmgcs2 inhibition or deletion aggravated kidney damage and

repressed renal repair. Nonetheless, β-OHB administration ameliorated these phenomena. Moreover, PTEC-specific DcR2/Hmgcs2 double deletion decreased β-OHB levels, which inhibited FOXO3 by regulating histone acetylation, thereby boosting tubular maladaptive repair.

Results: DcR2-GFP transgenic mice showed that DcR2 was specifically expressed in proximal tubular epithelial cells (PTECs) following AKI, and PTEC-specific deletion of DcR2 improved renal repair and prognosis by alleviating kidney damage, inhibiting cell senescence, promoting cell proliferation and regeneration, and repressing renal fibrosis.

Conclusions: These findings suggest that DcR2/Hmgcs2/β-OHB/FOXO3 signaling mediates tubular maladaptive repair and targeting DcR2 may enhance renal repair and improve AKI prognosis.

FR-PO179

Irisin Modulates Renal Ischemia-Reperfusion Injury by Upregulating Mitochondrial Autophagy Marker Protein LC3

Cui Yu. *Kidney Disease Center, the First Affiliated Hospital, Zhejiang University School of Medicine, Hangzhou, China.*

Background: Acute kidney injury (AKI) is a clinical syndrome with a high incidence and increased cost and mortality for hospitalized patients, and are still lacking of effective therapeutic drugs. Irisin has been reported to have inhibitory effects on cellular inflammation, reduced cell apoptosis, and antioxidant stress in various diseases. But it is still unknown whether Irisin has therapeutic effects after ischemic AKI.

Methods: We evaluated the serum Irisin levels and their correlation with renal function in AKI patients and healthy control groups. We constructed a mice model of ischemia-reperfusion(I/R) kidney injury and administered exogenous Irisin toinvestigated the potential therapeutic effects and mechanisms through a series of experimental techniques such as renal tubular microperfusion.

Results: We found that the Scr level in the AKI patient was significantly higher thanthat in the healthy control group (256.8 ± 30.5 vs 61.9 ± 10.5 umol/L, P<0.0001), the BUN level was significantly higher (17.1 ± 6.5 vs 5.1 ± 1.0 mmol/L, P<0.0001), and the Irisin level was significantly reduced (39.9 ± 8.2 vs 76.7 ± 13.8 ng/ml, P<0.0001). We found that exogenous Irisin reduced the renal damage indicators in mice model. The stability of mitochondrial JC-1 membrane potential increased and the ROS decreased after H/R in the Irisin treatment group. Irisin up-regulated the expression of renal mitochondrial autophagy related proteins PINK1 and PARK2 and marker protein LC3, enhanced mitochondrial autophagy, and down regulated the activation of NLRP3 inflammasome.

Conclusions: This study suggests that Irisin may serve as a potential biomarker of ischemic AKI. Irisin has therapeutic effects on renal IRI, and its protective effect may be related to enhancing mitochondrial autophagy by upregulating mitochondrial autophagy marker protein LC3. This study provides theoretical support for Irisin as a therapeutic drug for ischemic AKI.

HNF4α Links PGC1α to Quinolinate Phosphoribosyl Transferase (QPRT) and De Novo NAD+ Biosynthesis

Amanda J. Clark,[1,2] Samir M. Parikh.[1,3] *[1]The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX; [2]The University of Texas Southwestern Medical Center Department of Pediatrics, Dallas, TX; [3]University of Texas Southwestern, Department of Pharmacology, Dallas, TX.*

Background: De novo NAD+ biosynthesis is suppressed in acute kidney injury (AKI), particularly the bottleneck enzyme Quinolinate Phosphoribosyl Transferase (QPRT), leading to NAD+ reduction and accumulation of upstream metabolites. We previously showed that QPRT is regulated by PPARgamma coactivator 1 alpha (PGC1a), a transcriptional co-activator that regulates many genes involved in metabolism and mitochondrial biogenesis. A transcription factor (TF) linking PGC1a and QPRT has not been identified.

Methods: The ENCODE TF Database was compared with Biogrid and the Human Reference Protein Interactome to identify TFs that interact with PGC1α and bind *QPRT*. Expression of PGC1α, HNF4α, and QPRT was assessed with qPCR. Compartment-specific NAD+ was measured using transfected biosensors. ATP and ChIP qPCR was measured via commercial assay.

Results: Analysis of public datasets identified HNF4α and RXRA as candidate TFs modulating QPRT via PGC1α. We focused on HNF4α as no RXRA mutations associate with kidney disease. HNF4α was suppressed in AKI proportionally to QPRT (R^2=0.5, P<0.01). HNF4α overexpression increased QPRT expression (1.27 fold change [FC], p<0.01), and HNF4α mirrored both QPRT and PGC1α with increased cellular NAD+ and ATP with HNF4α overexpression (NAD+ in cytoplasm 1.08FC, p<0.001; mitochondria 1.06FC, p<0.05; nucleus 1.09FC, p<0.05) (ATP 1.08FC, p<0.001) and decreased NAD+ and ATP with siHNF4α (NAD+ in cytoplasm 0.86FC, p<0.001; mitochondria 0.89FC, p<0.05; nucleus 0.86FC, p<0.05) (ATP 0.91FC, p<0.01). ChIP qPCR showed that HNF4α binds the *QPRT* locus in kidney (12.7FC over IgG) proportionally with PGC1α expression (R^2=0.58, p<0.05). Finally, siHNF4a co-transfected with PGC1α plasmids prevented PGC1α-induced increase in QPRT expression (PGC1α overexpression = 1.34FC increase in QPRT, p<0.001; PGC1α overexpression with siHNF4α = 1.1 FC in QPRT, p=0.19).

Conclusions: HNF4α is a known regulator of metabolic pathways in the liver and a critical component of kidney cell differentiation, but few studies have examined the role of HNF4α in adult kidney. This is relevant as recent multi-omics investigations have identified HNF4α recovery after injury as a critical feature of "recovered" tubular cells. In summary, the present results identify a transcriptional mechanism for HNF4α in regulating de novo NAD+ biosynthesis suppression in AKI.

FR-PO181

Tryptophan Metabolism in AKI: A New Target in Kidney-Brain Axis

Maria Teresa Cimmarusti,[1] Alessandra Stasi,[1] Rossana Franzin,[1] Marco Fiorentino,[1] Francesco Staffieri,[1] Alberto M. Crovace,[2] Monica Campioni,[1] Fabio Sallustio,[1] Paola Pontrelli,[1] Antonio Crovace,[1] Loreto Gesualdo.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Universita degli Studi di Sassari, Sassari, Italy.*

Background: Partial recovery following AKI could lead to long-term consequences that predispose to chronic dysfunction and may also accelerate neurocognitive decline. Kidney-brain axis seems to play a pivotal role leading to detrimental outcome for AKI patients. Many studies suggest a high relationship between kidney damage and brain dysfunction even after AKI resolution. Patients who suffered AKI may afterward show a disturbance of arousal called brain-fog. Although advances in understanding the pathophysiology of AKI and brain dysfunction, there are no available preventive and therapeutic strategies. Recent findings have revealed link existing between dyslipidemia/low HDL levels and Kynurenine pathway (KP) alterations that lead to the production of neuroactive metabolites: kynurenine (KYN) and quinolinic acid (QA).

Methods: Sepsis-induced AKI (SI-AKI) was induced in a porcine model by intravenous infusion of a saline solution containing 300 µg/kg of LPS. After injection, 12 animals were treated with different doses of recombinant HDL (rHDL) (20-40mg/kg), while 6 animals did not receive treatment (LPS group). Animals were sacrificed after 24h from the start of experimental procedure.

Results: Endotoxemic pigs developed oliguric AKI with increased tubular and glomerular damage and interstitial inflammatory infiltrate. rHDL treatment decreased the inflammatory process and tubular damage, preventing AKI, especially in 40mg/kg rHDL group. The rate-limiting step of KP, the Indolamine-2,3-dioxygenase 1 (IDO1) enzyme is upregulated during inflammation in sera and brain tissue, and has been linked to cognitive dysfunction. In our model, LPS induced an increased activation of IDO-1 gene expression at brain level in endotoxemic animals, meanwhile it appears to be reduced in both treated arms (p<0.005). Sera from the rHDL group showed a significant reduction in IDO1 activity (KYN/Trp ratio) (p<0.05) and QA levels (p<0.005) compared with the LPS group. Moreover, a significant decrease of both systemic and brain IL-6 levels was observed after rHDL treatments.

Conclusions: Our data indicated that HDL-enhancing therapies may decrease the inflammatory response, the retention of waste products and neuroactive compounds, improving renal and cognitive function in SI-AKI.

FR-PO182

Metabolomics Screen in Cilia-Deficient Cells Identifies Tryptophan Metabolism as a Possible Mechanism for Cilia-Dependent Cyst Growth

Kasey Lerner, Brennan Winkler, Xiaofeng Zuo, Kelly R. Misare, Jessica H. Hartman, Joshua H. Lipschutz. *Medical University of South Carolina, Charleston, SC.*

Background: Primary cilia and mitochondria are involved in polycystic kidney disease (PKD). We showed that knockdown (KD) or ciliary targeting sequence mutation (cts-mut) of Exoc5, a central exocyst complex component, resulted in cilia loss while Exoc5 overexpression (OE) resulted in longer cilia. Ift88 knockout (KO) also resulted in cilia loss which was reversed by Ift88 rescue.

Methods: Seahorse assays and metabolic profiling were performed on canine (MDCK control, Exoc5 cts-mut, KD, OE) and murine (Ift88 KO, rescue) kidney cells.

Results: Seahorse assays showed lower basal respiration (BR), maximal respiration (MR), and spare respiratory capacity (SRC) in Exoc5 KD and Exoc5 cts-mut compared

to control MDCK cells. Conversely, Exoc5 OE cells had higher BR, MR, and SRC. MR and SRC were also lower in Ift88 KO than rescue cells. A metabolomics screen showed tryptophan increased in Exoc5 KD and Exoc5 cts-mut cells by 58- and 113-fold compared to control. In Exoc5 OE cells, tryptophan decreased 59%. Similarly, tryptophan increased by 21% in Ift88 KO cells. Kynurenine is directly downstream of tryptophan and decreased by 83% and 20% in Exoc5 KD and cts-mut cells, and increased by 25% in Exoc5 OE cells. In Ift88 KO cells kynurenine decreased by 49%.

Conclusions: Kynurenine drives oxidative stress and mitochondrial dysfunction and was higher in MDRD Study participants with ADPKD compared to other CKD, and patients with ADPKD had higher plasma levels compared to healthy individuals which increased with disease progression. Nguyen et al (2022, *JCI Insight*) found decreased tryptophan and increased kynurenine in Pkd1 RC/RC mice. This is the opposite of what we found following cilia loss. IDO1 converts tryptophan to kynurenine. When Nguyen et al pharmacologically inhibited or genetically knocked out IDO1, cystogenesis decreased. In 2013 Ma et al (2013, *Nature Genet*) showed that cilia loss suppresses cyst growth in ADPKD mouse models. Shao et al (2020, *Kidney Int*) showed that Ift88 KO slowed cyst growth in a PKD1 mouse model. Therefore, we hypothesize that cilia loss inhibits cystogenesis by increasing tryptophan and decreasing kynurenine. These findings highlight a link between cilia and mitochondrial function and suggest that tryptophan metabolism via IDO1 could be a novel target for ADPKD treatment.

FR-PO183

Loss of Pax2 and Pax8 Induces Resistance to Ischemia in S3 Proximal Tubule

Madison C. McElliott, Asha C. Telang, Edgar A. Otto, Abdul A. Soofi, Greg R. Dressler, Jeffrey A. Beamish. *University of Michigan, Ann Arbor, MI.*

Background: Pax2 and Pax8 are two highly homologous transcription factors regulating kidney development and are re-expressed during acute kidney injury (AKI) and repair. Our aim was to determine whether Pax2 and Pax8 are necessary to regenerate new proximal tubule cells after ischemic AKI.

Methods: Pax mutations were targeted to the proximal tubule, the primary site of injury in ischemic AKI, using floxed Pax2 and Pax8 conditional alleles and a phosphoenolpyruvate carboxykinase (PEPCK) Cre driver. Control mice included PEPCK-Cre but wild type Pax2 and Pax8 loci. All animals expressed a GFP-Cre reporter to track Cre activity. No gross differences in kidney function or histology were observed at baseline. Mutant and control mice were subjected to unilateral ischemia-reperfusion injury (uIRI) with simultaneous contralateral nephrectomy. Samples were analyzed at various post-injury time points. Nuclei from whole kidneys of uninjured mutant and control mice were analyzed using single nucleus RNA sequencing (snRNA seq).

Results: Mice with proximal tubule Pax2 and Pax8 deletion were protected from both acute and chronic injury as measured by serum BUN, histological injury score, and expression of injury markers. Differences manifested as early as 6 h after injury, suggesting an inherent resistance to ischemia. Pre-injury snRNA seq revealed that mutant mice developed a unique population of S3 proximal tubule cells which was confirmed by immunostaining for cluster specific markers and invariably stained for GFP, marking Cre-mediated Pax2 and Pax8 deletion. The transcriptional profile of mutant S3 cells were strongly enriched in genes associated with a range of conditions that protect against ischemic injury including hypoxic preconditioning, caloric restriction, and female sex.

Conclusions: Our data indicate that neither Pax2 nor Pax8 is necessary for repair after ischemic AKI. On the contrary, Pax protein loss induced protection against ischemic injury by promoting a transcriptional program that strongly overlaps with other conditions that confer protection. These findings highlight critical genes and pathways that determine sensitivity to ischemic AKI and suggest a novel role for Pax proteins in the proximal tubule.

FR-PO184

Alternative Splicing Generates an Intracellular Uromodulin Isoform that Mediates Mitochondrial Function and Is Up-Regulated in AKI

Azuma Nanamatsu, Kaice A. LaFavers, Radmila Micanovic, Virginie Lazar, George Rhodes, Shehnaz Khan, Robert L. Bacallao, Pierre C. Dagher, Takashi Hato, Tarek M. El-Achkar. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Uromodulin (UMOD), a glycoprotein exclusively produced by renal tubular cells, is known to protect against acute kidney injury. Previous research has mainly focused on the secreted UMOD; however, the significance of intracellular UMOD has not been described.

Methods: We performed long-read RNA sequencing on human and mouse kidneys to explore alternative splicing variants of UMOD. RT-PCR and Sanger sequencing were conducted to validate the expression of the identified variant. The expression of the variant in mice after renal ischemia-reperfusion injury was quantified using RT-qPCR. To assess the localization and function, cDNA of the variant was overexpressed in kidney epithelial cells, and Western blotting, immunofluorescence, LDH assay, and Mito Stress Test were performed.

Results: Long-read RNA sequencing revealed a novel alternative splicing variant of UMOD, referred to as UMOD-AS, both in humans and mice. The existence of UMOD-AS mRNA was confirmed by RT-PCR and Sanger sequencing. UMOD-AS mRNA was up-regulated after renal ischemia-reperfusion injury, whereas canonical UMOD was down-regulated. In the cellular model, UMOD-AS localized in the cytoplasm, whereas canonical UMOD localized at the membrane and was secreted extracellularly. Interestingly, UMOD-AS-expressing cells showed better cell viability than canonical UMOD-expressing cells. Mito Stress Test suggested UMOD-AS up-regulates mitochondrial function compared to canonical UMOD.

Conclusions: UMOD-AS is an intracellularly-localized and cellular-protective isoform of UMOD. Notably, the localization and regulatory mechanisms of UMOD-AS are contrasted with canonical UMOD. Alternative splicing of UMOD may be a novel protective mechanism in acute kidney injury.

Kidney Mitochondrial DNA Contributes to Circulating IL-6 in Sepsis-Associated AKI

Alice Shen, Avnee J. Kumar, Joachim H. Ix, Prabhleen Singh, Mark Hepokoski. *University of California San Diego, La Jolla, CA.*

Background: Increased circulating cell-free mitochondrial DNA (CCF-mtDNA) and acute kidney injury (AKI) are associated with mortality in sepsis, but the role of CCF-mtDNA in the pathogenesis of sepsis-associated AKI (S-AKI) remains unclear. We hypothesized that CCF-mtDNA released from the injured kidney contributes to the systemic inflammatory response via IL-6 in S-AKI.

Methods: CCF-mtDNA isolated from the plasma of mice exposed to sepsis by cecal ligation and puncture (CLP) vs sham control (N=5-6/group) were sequenced and quantified by droplet digital PCR. Single nucleotide polymorphisms (SNPs) identified in the isolated mtDNA were compared to those found in the heart, kidney, liver, and lung of individual mice to infer tissue origin. In in-vitro studies, mouse bone marrow cells were treated with CpG (positive control), kidney mtDNA, or mitochondrial damage-associated molecular patterns (mtDAMPs) with and without DNase or toll-like receptor-9 inhibitor. IL-6 concentrations were compared across groups. In in-vivo studies, mice were injected with saline vs kidney mtDAMPs with and without DNase, and IL-6 concentrations were compared. Finally, CCF-mtDNA levels were quantified in the plasma of septic human subjects with and without AKI.

Results: CCF-mtDNA was significantly increased in the plasma of CLP mice compared to controls. Three out of five mice analyzed had unique SNPs in mtDNA fragments indicating kidney origin of release. In both in-vitro and in-vivo studies, exposure to kidney mtDAMPs led to increased IL-6 release, which was attenuated by treatment with TLR-9 inhibitor or DNase (Figure A). In human studies, plasma CCF-mtDNA levels were significantly increased in patients with S-AKI compared to those with sepsis without AKI, and increased CCF-mtDNA significantly correlated with plasma IL-6 (Figure B/C).

Conclusions: CCF-mtDNA released from the kidney contributes to increased plasma IL-6 in sepsis. Preserving kidney mitochondrial integrity, preventing mtDNA release, or clearing circulating mtDNA are translational avenues to pursue to decrease mortality from S-AKI.

FR-PO186

Renal Congestion Exacerbates Sepsis-Induced AKI in Mice

Itaru Nakamura,[1] Yuhei Kirita,[2] Keiichi Tamagaki,[2] Tetsuro Kusaba.[2] [1]*Department of Nephrology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan;* [2]*Kyoto Prefectural University of Medicine, Kyoto, Japan.*

Background: Recent epidemiological studies demonstrated that renal congestion is a major factor in the development of renal dysfunction associated with heart failure. We previously established a novel unilateral renal congestion mouse model wherein the inferior vena cava was constricted between both renal veins, and reported its impact on the exacerbation of renal ischemia-reperfusion injury. However, the impact of renal congestion on septic AKI, the most common cause of AKI, is unclear.

Methods: We instigated sepsis via cecal ligation and puncture (CLP) in a unilateral renal congestion model. We comprehensively analyzed the pathophysiology of exacerbation of septic AKI by renal congestion, especially focused on the toll-like receptor (TLR) 2, a receptor of the innate immune system.

Results: After the induction of CLP in the unilateral renal congestion model, the transient decline in blood pressure was observed at 3 and 6 hours after CLP. Ultrasonography revealed the persistent dilation of renal veins in the congested kidney for a duration extending up to 7 days post-CLP. Histological analysis at day 7 exhibited marked fibrosis in the group subjected to congestive heart failure + CLP, while qPCR assays indicated upregulation of fibrosis markers including Col1a1, Acta2, Tgfb1, and Fn1.

At acute phase after procedures, extensive tubular damage with macrophage infiltration was noted in congestion + CLP group. qPCR demonstrated the upregulation of tlr2, in addition to inflammatory cytokines (Tnf, Ccl2). To further investigate the mechanistic insights focusing on the TLR2, we conducted CLP and renal congestion in TLR2-KO mice. Blood pressure transiently decreased at 3 and 6 hours after CLP, mirroring the response observed in WT mice. At 1 day post-CLP, tubular injury was exacerbated in the TLR2-KO group in comparison to the WT group, and qPCR analysis revealed an increase in Havcr1 expression and a decrease in Lrp2 expression, indicating that TLR2 might exert the inhibitive role on the exacerbation of sepsis-induced AKI by renal congestion.

Conclusions: This study using the combination of CLP and novel renal congestion model demonstrated the increased renal venous pressure may have contributed to the exacerbation of the AKI by inducing a reduction in renal perfusion following CLP, thereby implicating the involvement of TLR2 in this process.

FR-PO187

Anti-Inflammatory and Renal Protective Mechanisms by Controlling Parasympathetic and Sympathetic Balance

Ryusuke Umene,[1,2] Chia-Hsien Wu,[2] Kenta Torigoe,[3] Kumiko Muta,[3] Tomoya Nishino,[3] Tsuyoshi Inoue.[2] *[1]Department of Nephrology, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan; [2]Department of Physiology of Visceral Function and Body Fluid, Graduate School of Biomedical Sciences, Nagasaki University, Nagasaki, Japan; [3]Department of Nephrology, Nagasaki University Hospital, Nagasaki, Japan.*

Background: Acute kidney injury (AKI) lacks effective treatment. To understand renal homeostasis and develop therapeutic strategies, we investigate renal protection and anti-inflammatory effects mediated by the autonomic nervous and immune systems. Vagus and sympathetic nerve activation provide kidney protection, and stimulating both nerves yields synergistic anti-inflammatory effects in macrophages. However, achieving this synergy through autonomic nerve stimulation in vivo remains uncertain. This study aims to determine the optimal autonomic balance for kidney protection and explore in vivo autonomic nerve stimulation as a novel renal disease treatment.

Methods: *In vitro* experiments treated RAW 264 cells and HK-2 cells with autonomic nerve stimulants, assessing changes in renal injury markers, cytokines, and cellular properties. GTS-21 (α7nicotinic acetylcholine receptor: α7nAChR agonist) and salbutamol (β2 adrenergic receptor: β2AR agonist) were used. *In vivo* experiments used LPS-induced septic mice or renal ischemia-reperfusion injury as AKI models. Macrophage-specific α7nAChR and/or β2AR knockout mice were used to examine parasympathetic and sympathetic nerve stimulation effects on the kidney.

Results: *In vitro*, combining GTS-21 and salbutamol with LPS showed concentration-dependent, synergistic anti-inflammatory effects in RAW 264 cells. LPS and salbutamol treatment of HK-2 cells resulted in a concentration-dependent decrease in NGAL. Simultaneous administration of both agonists tended to further decrease NGAL expression. However, *in vivo* experiments with septic mice did not demonstrate synergistic anti-inflammatory effects when GTS-21 and salbutamol were administered together. Additionally, LysM-Cre: α7nAChR/β2AR flox mice showed attenuated renal injury compared to controls in bilateral ischemia-reperfusion injury.

Conclusions: Simultaneous parasympathetic and sympathetic stimulation synergistically reduced inflammation in macrophages and tubular cell damages. However, *in vivo* experiments did not support this synergistic effect. Autonomic nerve stimulation appears to have indirect anti-inflammatory and renal protective effects mediated by the immune system, as well as direct protective effects on the kidney. Maintaining a precise balance of these effects is crucial for biological homeostasis.

miR-486-5p Protects Against Ischemic AKI and Prevents Transition to CKD

Adrianna Douvris,[1,3] Jose L. Vinas,[2] Joe A. Zimpelmann,[1] Alex Gutsol,[1] Dylan Burger,[2,1] Kevin D. Burns.[2,3] *[1]University of Ottawa, Ottawa, ON, Canada; [2]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [3]Department of Medicine in Ottawa, Ottawa, ON, Canada.*

Background: Recovery from acute kidney injury (AKI) is associated with increased risk for progressive chronic kidney disease (CKD). We previously showed that microRNA (miR)-486-5p protects against kidney ischemia-reperfusion (IR) injury in mice, with targeting of *phosphatase and tensin homolog* (*PTEN*) and downregulation of proximal tubular genes involved in apoptosis and tumor necrosis factor signaling. In cultured human endothelial cells however, miR-486-5p inhibits endothelial nitric oxide synthase (eNOS) expression. Here, we studied the effects of miR-486-5p on IR AKI and CKD development in rats with a focus on vasculature.

Methods: Kidney IR injury was induced in male rats by bilateral renal pedicle clamping followed by reperfusion. Lipid-encapsulated miR-486-5p (0.5mg/kg) was injected i.v. at the start of reperfusion. Outcomes were assessed after 24hr and 10 weeks. Kidney blood flow was measured by laser doppler flowmetry. Endothelium-dependent mesenteric artery reactivity was evaluated by myography.

Results: In rats with IR AKI, miR-486-5p preserved regional kidney blood flow at 24hr ($p<0.01$,n=7) and prevented increases in plasma Cr ($p<0.001$,n=10), neutrophil and macrophage infiltration, and apoptosis. miR-486-5p had no effect on kidney *PTEN* expression, but inhibited IR-induced expression of eNOS and intercellular adhesion molecule (ICAM)-1. At 10 weeks, while rats with IR alone had normal plasma Cr, kidneys displayed decreased peritubular capillary density with increased interstitial collagen, α-smooth muscle actin$^+$ myofibroblasts, and F4/80$^+$ macrophages. These changes were inhibited by miR-486-5p (CD31, collagen $p<0.0001$, n=6-8). Although blood pressure was similar across rat groups, IR inhibited endothelium-dependent vasorelaxation in mesenteric arteries at 10 weeks, which was prevented by miR-486-5p. Delayed administration of 2 doses of miR-486-5p (96hr, 3 weeks after IR) had no effect on capillary density, kidney fibrosis, blood pressure, or endothelial function.

Conclusions: In rats, early administration of miR-486-5p prevents kidney IR injury and preserves regional blood flow despite reduction in eNOS expression. miR-486-5p also protects against CKD development and associated endothelial dysfunction. The results suggest that miR-486-5p is a promising therapy for the prevention of ischemic AKI and its complications.

Reno-Protective Effect of Haptoglobin and Hemopexin by Inhibiting Ferroptosis in Ischemic Reperfusion AKI

Ye Eun Ko,[1,2] Boyoung Nam,[2,3] Gyu R. Kim,[1,2] Jaejin Ryu,[1,2] Hyung Woo Kim,[1,2] Jung Tak Park,[1,2] Seung Hyeok Han,[1,2] Shin-Wook Kang,[1,2] Tae-Hyun Yoo.[1,2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Institute of Kidney Disease Research, College of Medicine, Yonsei University, Seoul, Republic of Korea; [3]Severance Biomedical Science Institute, College of Medicine, Yonsei University, Seoul, Republic of Korea.*

Background: Recent studies showed that cell free hemoglobin (CFH) increases in patients with sepsis and after heart surgery, which may cause acute kidney injury (AKI). Since CFH contains catalytically active iron, iron-dependent cell death, CFH related iron-dependent cell death, ferroptosis may induce AKI. This study investigates the reno-protective effect of haptoglobin (Hp) and hemopexin (Hx), which scavenge CFH, in an experimental AKI model.

Methods: Ischemic reperfusion injury (IRI) animal models were used as AKI animal models. After 2, 4, 6, 8, and 24 hours, CFH and hemin levels were evaluated in both the control and IRI groups. In addition, the IRI models were treated with different doses (25, 50, 100, and 200 mg/kg) of Hp or Hx via intravenous injection 30 minutes prior to IRI surgery. CFH, hemin, and kidney injury markers, as well as an oxidative stress marker, and ferroptosis markers were evaluated 24 hours later. Furthermore, kidney injury score was evaluated from kidney tissues based on the percentage of cell necrosis, loss of brush border, cast formation, and tubule dilatation.

Results: CFH and hemin levels increased in the IRI group at each hour compared to the control. Injection of Hp decreased CFH levels regardless of the dosage, while injection of Hx decreased hemin levels compared to the IRI group. Creatinine, BUN, NGAL, and MDA levels showed increases in the IRI group compared to the control. Treatment with Hp or Hx resulted in decreases in creatinine, BUN, MDA, and kidney injury score across all dosage compared to the IRI group. NGAL levels showed a decrease in all drug injection groups except for the Hp 25mg/kg group compared to the IRI group. In the IRI group, the mRNA expression of cystine/glutamate antiporter system Xc− decreased compared to the control, while ferritin heavy chain 1 increased. However, treatment with Hp or Hx resulted in an increase in cystine/glutamate antiporter system Xc− mRNA expression and a decrease in ferritin heavy chain 1 compared to the IRI group.

Conclusions: Hp and Hx, scavenger proteins, may aid as preventive agents for ischemic reperfusion AKI by inhibiting ferroptosis.

FR-PO190

Reduced Perivascular Cell Dynamin-Related Protein 1 (Drp1) Protects Against AKI and CKD in Mice

Eibhlin S. Goggins, Nabin Poudel, Junlan Yao, Shuqiu Zheng, Mark D. Okusa. *UVA Health, Charlottesville, VA.*

Background: Mitochondrial dysfunction has been implicated in the pathogenesis of AKI and CKD. We have previously demonstrated that proximal tubule deletion of *Drp1* attenuated progressive kidney injury and fibrosis after ischemia-reperfusion injury (IRI). The role of *Drp1* and mitochondrial dysfunction in kidney perivascular cells (PVCs) during AKI and CKD has not been explored.

Methods: PVC specific germline (*Foxd1-Cre;Drp1$^{+/-}$*, *Foxd1-Cre;Drp1$^{-/-}$*) or inducible (*Pdgfrβ-CreERT2;Drp1$^{+/-}$*, *Pdgfrβ-CreERT2;Drp1$^{-/-}$*) *Drp1* heterozygote and knockout mice and respective littermate controls (WT) were generated. *Foxd1-Cre;Drp1$^{+/-}$*, *Foxd1-Cre;Drp1$^{-/-}$* and WT male and female mice were injected with folic acid (FA, 250 mg/kg i.p.). 24 and 48 hours later, mice were evaluated for kidney injury by plasma creatinine (PCr) and BUN and *Kim-1* and *Ngal mRNA*. In another model of AKI, *Pdgfrβ-CreERT2;Drp1$^{+/-}$*, *Pdgfrβ-CreERT2;Drp1$^{-/-}$* and WT male mice underwent bilateral kidney IRI (bIRI, 26 min). In a model of the AKI to CKD progression, *Foxd1-Cre;Drp1$^{+/-}$*, *Foxd1-Cre;Drp1$^{-/-}$* and WT male and female mice were injected with FA and followed for 14 days. Mice were evaluated for kidney fibrosis by mRNA levels of fibrosis genes (*Col1α1, Fn1)* and Masson's trichrome staining.

Results: 24 hours after FA, both male and female WT mice displayed a rise in plasma creatinine and BUN which was significantly attenuated in mice with partial deletion of PVC *Drp1* (*Foxd1-Cre;Drp1$^{+/-}$*). In contrast, mice with a full deletion of *Drp1* in PVCs (*Foxd1-Cre;Drp1$^{-/-}$*) displayed an increased susceptibility to injury in male mice and increased mortality in females. 14 days after FA, *Foxd1-Cre;Drp1$^{+/-}$* mice had reduced kidney fibrosis histologically and by mRNA levels of *Col1α1* and *Fn1* compared with WT and *Foxd1-Cre;Drp1$^{-/-}$* mice. After bIRI, both *Pdgfrβ-CreERT2;Drp1$^{-/-}$* and *Pdgfrβ-CreERT2;Drp1$^{+/-}$* mice had a decrease in plasma creatinine compared with WT controls.

Conclusions: Reduced expression of *Drp1* in PVCs had a protective effect during AKI and CKD, suggesting that PVC *Drp1* could serve as a therapeutic target. Although *Pdgfrβ-CreERT2;Drp1*$^{-/-}$ mice were protected from injury, *Foxd1-Cre;Drp1*$^{-/-}$ mice displayed increased susceptibility to injury. Studies to understand the effect of timing, cellular expression and level of *Drp1* reduction on AKI and CKD outcomes are ongoing.

FR-PO191

ATF3 Ameliorates Ischemic Kidney Damage by Controlling the Cross-Talk Between Immune and Kidney Cells

Andrea Paolini, Abhijeet Todkar, Johannes Wiegel, Toma A. Yakulov, Gerd Walz. *Albert-Ludwigs-Universitat Freiburg Universitatsklinikum Freiburg, Freiburg, Germany.*

Background: Acute kidney injury (AKI) is a leading cause of death. The molecular pathophysiological mechanisms of AKI remain only partially understood, and targeted therapies to facilitate recovery from renal failure are still elusive.

Methods: To find central signaling pathways that drive kidney regeneration, we performed single-cell RNA sequencing (scRNA-seq) after laser-induced injury of zebrafish pronephric tubules, and explored the function of *Atf3* in three different *Atf3*-deletion models, subjecting *Atf3*$^{f/f}$*Pax8-rtTA*TetO-Cre*, *Atf3*$^{f/f}$**Cx3cr1-Cre*, and *Atf3*$^{f/f}$**Ksp-Cre* mice to unilateral nephrectomy followed by ischemia-reperfusion injury (IRI). To determine the role of ATF3 in IRI, kidney cells were subsequently analyzed by histology, flow cytometry, bulk-/scRNA-seq, and CUT&RUN experiments.

Results: Depletion of zebrafish *atf3* by morpholino oligonucleotides compromised the repair process after pronephros injuries. While *Pax8*- or *Cx3cr1*-mediated deletion of *Atf3* did not affect renal function, *Ksp-Cre*-mediated *Atf3* loss intensified the renal failure after IRI in mice. The absence of *Atf3* in distal nephron segments reduced the expression of crucial chemokines including *Cxcl10*, resulting in decreased numbers of infiltrating F4/80^{+} macrophages and deficient macrophage "M2" polarization. Using RNA sequencing and CUT&RUN techniques, we found that ATF3 directly regulates *Umod* (Uromodulin), and promotes its secretion via increased *Kcnj1* (ROMK) expression after IRI. Gene Ontology enrichment analysis of the immune cell populations confirmed the downregulation of leukocyte migration, cytokine production, and cell-cell adhesion. CellChat analysis identified a weakened interaction between immune cells and the tubular epithelial cells of the thick ascending limb (TAL).

Conclusions: *Ksp-Cre*-mediated excision of *Atf3*, primarily affecting ATF3 production in the TAL, worsens renal failure after IRI. Loss of ATF3 affects the expression of several immune regulatory factors including Uromodulin, which is known to promote an anti-inflammatory macrophage phenotype. Our analyses reveal that ATF3 protects the kidney against ischemia by controlling the cross-talk between immune and kidney cells.

Pathomics Reveals Histomorphological Recovery During Nephrectomy-Induced Kidney Repair

Elien Van Campen,[1,2] Lies Moonen,[1] Peter Boor,[2] Benjamin A. Vervaet.[2,1] Laboratory of Pathophysiology and Laboratory of Nephropathology. *[1]Universiteit Antwerpen Faculteit Farmaceutische Biomedische en Diergeneeskundige Wetenschappen, Wilrijk, Belgium; [2]Universitatsklinikum Aachen, Aachen, Germany.*

Background: Acute kidney injury (AKI) is a common disease, that can progress to chronic kidney disease (CKD). Nephrectomy (Nx)-induced repair describes the phenomenon of a remarkable functional and structural recovery of unilateral AKI upon removal of the contralateral healthy kidney. The underlying mechanisms remain largely unknown and a thorough analysis of structural recovery remains challenging. Therefore, we applied next generation morphometry and pathomics to comprehensively quantitate structural alterations in a validated model of Nx-induced repair after left unilateral ischemia reperfusion injury (UIRI).

Methods: C57BL/6J mice were divided into 3 groups: UIRI+Sham (n=54), UIRI+Nx (n=36), or healthy controls (n=6). Kidneys of all mice were acquired at days 1 to 7 and days 21, and 42 after UIRI (n=6/timepoint). Sham-surgery or Nx of the right kidney were performed 3 days after UIRI. Digitized PAS-stained tissue sections (whole slide images) were analysed using our pathomics pipeline.

Results: Quantitative pathomics on over 706090 tubules revealed a progressive decay of overall tubular area after UIRI with a loss of 22% by day 42 compared to controls. In accordance with tubular atrophy, tubular cross-sectional diameters (μm) and sizes (μm^2) became smaller after UIRI by 15% (diameter) and 32% (size) of control values from day 3 onwards. Nx prevented these changes, minimizing loss of tubular area to 5%. The mean tubular diameters and areas were comparable to control values, although their overall distribution changed from a bimodal (healthy control) to a unimodal distribution appearance, originating from the dimensional differences of cortical and medullary tubules. After UIRI, interstitial area steadily increased to 20% above controls by day 21. Nx abrogated this progression, with an interstitial area remaining stable at an average of 6.5% above controls.

Conclusions: Large-scale, automated quantification of structural alterations revealed the distinct histopathological fates of an acute injured kidney in comparison to its rescue by nephrectomy. These data show the utility of pathomics to investigate spatiotemporal histological shifts during kidney injury and repair.

FR-PO193

Inhibition of Histone Methyltransferase SET8 Attenuates Renal Tubular Cell Apoptosis by Restoring PTEN in Cisplatin-Induced AKI

Xu Yang,[1] Shougang Zhuang.[2] *[1]Department of Medicine, Rhode Island Hospital/Alpert Medical School, Brown University, Providence, RI; [2]Brown University, Providence, RI.*

Background: SET8 is a histone H4K20 monomethyltransferase that regulates transcriptional and posttranslational modifications, heterochromatin formation, genomic stability, and cell cycle progression. Numerous studies have shown that SET8 is involved in various pathophysiological events, including cancer, inflammatory responses and metabolic disorders. However, its role in acute kidney injury (AKI) remains unexplored.

Methods: In this study, we aimed to investigate the role and mechanism of SET8 in cisplatin-induced AKI using a murine model and cultured renal epithelial cells.

Results: SET8 and its downstream histone H4 lysine 20 methylation (H4K20me1) expression were highly increased in cultured murine proximal tubule epithelial (TKPT) cells and kidneys from mice treated with cisplatin, along with decreased expression of phosphatase and tensin homolog (PTEN) and increased phosphorylation of p53 (p-p53). Pharmacologic inhibition of SET8 with UNC0379, a specific inhibitor, or siRNA-mediated silencing of SET8 suppressed apoptosis, p-p53 and preserved PTEN expression in TKPT cells exposed to cisplatin. Similarly, administration of UNC0379 in cisplatin-injected mice also improved renal function, attenuated tubular injury and inhibited apoptosis, which was coincident with repressing expression of SET8, H4K20me1 and p-p53, and restoring PTEN. Moreover, inhibition of PTEN with bpv (HOpic) or silence of PTEN aggravated cisplatin-induced apoptosis without affecting expression of SET8, H4K20me1. In contrast, inhibition of p53 with pifithrin-alpha (PFA) or silence of p53 lowered cisplatin-induced apoptosis without affecting expression of SET8, H4K20me1 and PTEN.

Conclusions: These findings indicate that SET8 relieved renal apoptosis induced by cisplatin by upregulating PTEN, which in turn repressed p53, and suggest that SET8 may serve as a novel therapeutic target for cisplatin-induced AKI by attenuating apoptosis and restoring PTEN expression.

Lats2 Ablation Exacerbates Severe Ischemia/Reperfusion-Induced Renal Maladaptive Repair Through the Upregulation of p53

Chi Zhang,[1,2] Zhihuang Zheng,[1,2] Huijuan Wu,[3] Jun Liu.[1,2] *[1]Shanghai General Hospital, Shanghai, China; [2]Shanghai Jiao Tong University School of Medicine, Shanghai, China; [3]Fudan University School of Basic Medical Sciences, Shanghai, China.*

Background: Incomplete recovery of AKI can lead to long-term functional deficits and CKD. The Hippo pathway plays a regulatory role in the pathogenesis and repair of AKI and CKD progression. LATS2, a negative regulator of YAP in the Hippo pathway, has been proved to have a strong association with cell apoptosis independent of YAP. p53 has been known to mediate the progression of cell apoptosis and maladaptive kidney repair after AKI. Nevertheless, the relationship between LATS2 and p53 in post-AKI renal maladaptive repair remains far from clear.

Methods: We established proximal tubule *Lats2* conditional knockout (*Lats2*-CKO) mouse models. Then we constructed a mouse model of maladaptive kidney repair after severe kidney injury (unilateral I/R-induced AKI) on both *Lats2*-CKO and WT mice, and assessed the fibrotic state, inflammatory cellular infiltration, apoptosis and p53 expression in post-AKI kidney tissue. Next, we used the pharmacological p53 inhibitor Pifithrin-α (PFT-α) to treat post-IRI mice for 14 days. Hypoxia and reoxygenation (H/R) was used to mimic I/R in vitro.

Results: At 14 days after I/R, *Lats2*-CKO mice represented more severe tubulointerstitial damage than WT mice. Masson trichrome, Sirius red staining, and α-SMA staining suggested that fibrosis is exacerbated in renal maladaptation in response to *Lats2* knockout. F4/80 and CD3 renal positive staining indicated more severe I/R-induced macrophage and T cell infiltration in *Lats2*-CKO mice. Moreover, we found that proximal tubule-specific Lats2 knockout upregulates p53 expression, and also induces upregulation of p21 and Bax and downregulation of Bcl-2 and Bcl-xL, accompanied by higher rate of cellular apoptosis. *In vivo* administration of PFT-α in post-IRI mice reduced renal fibrosis, immune cell infiltration and apoptosis in both *Lats2*-CKO and WT group. Interestingly, *in vitro* experiments showed that *Lats2* overexpression elevated p53 expression under vehicle condition, whereas suppressed p53 expression with H/R treatment, which indicated that H/R stress could revert the role of *Lats2* on modulating p53 expression.

Conclusions: This study indicates that specific *Lats2* knockout on renal proximal tubular epithelial cells exacerbates tubulointerstitial fibrosis, immune cell infiltration, apoptosis in ischemic AKI-induced tubular maladaptive repair through the upregulation of p53.

Renal Protection Driven by Peroxisome Activity, Proximal Tubule Park7, and Protein Succinylation

Katherine Pfister,[1,2] Victoria Young,[4] Anne C. Silva Barbosa,[1] Eric S. Goetzman,[2,1] Birgit Schilling,[3] Sunder Sims-Lucas.[1,2] *[1]University of Pittsburgh, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA; [3]Buck Institute for Research on Aging, Novato, CA; [4]Lake Erie College of Osteopathic Medicine Bradenton Campus, Bradenton, FL.*

Background: Acute Kidney injury (AKI) is an unfortunately frequent disease acquired during hospitalization with nearly 1 in 5 patients exhibiting some form of AKI. With the recent COVID-19 epidemic increasing instances of hospitalization, the burden that AKI and ensuing Chronic Kidney Disease (CKD) has on healthcare underlines the critical need for early detection, protection, and treatment for AKI. To attenuate AKI occurrence therapeutically we need a better understanding of the physiological and cellular mechanisms underlying damage. The most pronounced effect of AKI is on the Proximal Tubule Epithelial Cells (PTECs) which have the highest metabolic activity and are therefore most susceptible to damage after ischemia, sepsis, or transplant stress. This damage causes an increase in radical oxygen species, oxidative protein stress, and decreased functionality of mitochondrial Fatty Acid Oxidation (FAO) enzymes.

Methods: Our approach to protect from long-lasting tissue damage is by modulating the metabolic regimen and activating FAO in peroxisomes, a normally underused metabolic organelle. Large classes of proteins can be modulated rapidly and reversibly through the activity of enzymes that ligate Posttranslational Modifications (PTMs). We have previously shown that succinylation of lysine residues on metabolic proteins can be protective during AKI, specifically when the activity of the desuccinylase Sirtuin 5 is inhibited.

Results: Maintenance of the succinylome in Sirtuin 5 knockout tissue requires the activity of a second PTM ligating enzyme, the deglycase Park7. Park 7 is activated by oxidative stress and has been linked to apoptotic protection and minimizing CKD through reduction of Advanced Glycation Endproducts. Mass spectrometry analysis of kidney lysates point towards a protective combination of activated Park7 and deactivated Sirtuin 5 increasing peroxisomal FAO. This relationship is confirmed by the use of a diet-induced peroxisome upregulation using dicarboxylic acid (DCA) supplementation. The protection seen with DCA after AKI is significantly dependent on functioning Park7.

Conclusions: We conclude that a rapid and effective target for AKI treatment can be found by analyzing and maintaining the succinylome of PTECs and we hope to harness this mechanism to develop novel therapies for AKI.

Funding: NIDDK Support

FR-PO196

Scleroderma Renal Crisis: A Nephrologist's Enigmatic Therapeutic Dilemma

Macaulay A. Onuigbo,[1,2] Nicholas Krant,[1] Steven Bair.[2] *[1]University of Vermont Larner College of Medicine, Burlington, VT; [2]University of Vermont Medical Center, Burlington, VT.*

Introduction: Scleroderma Renal Crisis (SRC), occuring in 5-20% of patients with systemic scleroderma, typically presents with hypertensive urgency, acute kidney injury (AKI), microangiopathic hemolytic anemia and renal thrombotic microangiopathy. SRC is one of the very few times when AKI treatment calls for aggressive ACE inhibition, especially with Captopril. We describe fatal SRC, more than 20 years after initial diagnosis, AKI requiring hemodialysis despite escalated oral Captopril therapy for hypertension. She died 10 days after starting hemodialysis.

Case Description: A 71-year-old female with scleroderma since 2000 and treated intracranial oligodendroglioma since 2010 was admitted in late December 2022, with abdominal pain and decreased appetite. Blood pressure was 186/109 mm Hg, pulse 108/min and pulse ox 94% on room air. She was diagnosed with SRC – hypertension, microangiopathic hemolytic anemia, elevated LDH, +1 schistocytes, AKI with more than doubled creatinine to 2.21 mg/dL, UACR 935 ug/mg, >50 RBC/HPF and >50 WBC/HPF. Escalated oral Captopril was initiated. PLASMIC score was 4 points, low probability for TTP. ADAMTS13 was 53%, nondiagnostic. Hypertension was controlled on 137.5 mg Captopril TID + Nifedipine 60 mg BID. She was discharged, after 3 weeks, with stabilized blood pressure, stable creatinine at 4 mg/dL, and urine output of 1 L/day. Six days later, she was readmitted with worsening hypoxia, hyperkalemia 5.9 mmol/L, and creatinine of 5.12 mg/dL, which improved with fluid resuscitation. Potassium improved with oral sodium zirconium cyclosilicate. Kidney biopsy demonstrated thrombotic microangiopathy. She was treated for hypotension. Intermittent hemodialysis was started for worsening AKI and uremic encephalopathy. The patient passed away nine days after starting hemodialysis.

Discussion: SRC is an early complication of systemic sclerosis (SS), usually within one year of diagnosis. This case corroborates the difficulty in treating SRC-induced hypertension and resultant kidney damage. Our patient was atypical, with SRC occurring more than 20 years after diagnosis, hence the need for heightened vigilance. SRC was previously the leading cause of death in SS; the prognosis improved significantly with the introduction of ACE inhibitors. Despite adequate management of hypertension, our patient ultimately succumbed to her disease.

FR-PO197

Ascites and Bilateral Hydronephrosis

Brian D. Remillard, Ramandeep Kaur, Micaela M. Dickinson, Clay A. Block, Eric K. Hoffer. *Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Tense ascites resulting in bilateral hydronephrosis documented by antegrade nephrostograms before and after large-volume paracentesis (LVP).

Case Description: A 63-year-old man presented with cirrhosis presented with ascites, confusion and oliguria. Initial laboratory evaluation revealed elevated blood urea nitrogen 91 mg/dL and creatinine 5.97 mg/dL. Three months earlier, these were 7 mg/dL and 0.97 mg/dL, respectively. Ultrasound showed massive ascites and bilateral grade 2 hydronephrosis. A urinary catheter yielded 100 mL of urine. Computed Tomography confirmed bilateral hydronephrosis. It was hypothesized that massive ascites was the cause of the hydronephrosis. Antegrade nephrostogram found absent flow and fixed narrowing at the pelvic brim. The initial left renal pelvis pressure measured 15 mmHg. After LVP of 5 liter, renal pelvis pressure was 0 mmHg and fluoroscopy demonstrated ureteral peristalsis with antegrade flow into the bladder with resolution of the narrowed segment. Retroperitoneal ultrasound four days later confirmed resolution of hydronephrosis.

Discussion: Resolution of the elevated collecting system pressure and outflow obstruction after paracentesis supported tense ascites as the etiology for the acute kidney injury.

Pre-paracentesis

Post-paracentesis

Plasma Cell-Rich Acute Interstitial Nephritis in VEXAS: An Under-Recognized Disease Feature

Kambiz Kalantari, Loren P. Herrera Hernandez, Lihong Bu, Samih H. Nasr, Lynn D. Cornell, Kenneth Warrington, Abhishek Mangaonkar, Mrinal Patnaik, Matthew J. Koster. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: VEXAS syndrome (Vacuoles, E1 enzyme, X-linked, Autoinflammatory, Somatic) is a recently identified autoinflammatory disease with a large variety of disease manifestations. While recurrent fever, auricular chondritis, recurrent venous thromboembolism/thrombophlebitis, inflammatory skin lesions, ocular inflammation and cytopenias have been well-described, understanding of kidney manifestations is limited.

Case Description: Methods: Medical records of all patients with genetically confirmed VEXAS syndrome were reviewed for evidence of AKI or abnormal urinalysis. Patients who met the KDIGO criteria for AKI for at least two consecutive measurements of serum creatinine or cystatin C were considered as having AKI. Biopsy specimens (n = 4) were reviewed by four experienced nephropathologists. Clinical and laboratory features at disease onset and at time of AKI diagnosis were abstracted from direct chart review. **Results:** Among a cohort of 69 patients (all men, mean age 71 ± 9) with VEXAS syndrome, 16 (23%) developed AKI (mean age 75 ± 9) at some point during their follow up. A review of urinary findings revealed microscopic hematuria, mild proteinuria, and pyuria in 100%, 100% and in 82% of cases, respectively. Four patients had undergone renal biopsy for AKI. One patient had features of peri-tubular capillaritis and has been previously described. Three patients were found to have biopsy confirmation of interstitial nephritis (IN). All three patients had IN (acute in 2 and active chronic in 1) with plasma cell-rich infiltrate and tubulitis. Immunofluorescence was negative and electron microscopy did not show glomerular or extraglomerular immune deposits. Prednisone was initiated in all patients with biochemical improvement in renal function and resolution of urinary findings, however, AKI recurred following reduction in prednisone dose below 10-15 mg/day.

Discussion: AKI from Plasma cell-rich IN is an under-recognized feature in patients with VEXAS. AKI in VEXAS responds well to treatment with corticosteroids. Recurrence is common with lowering corticosteroids dose. Further investigations to Identify targeted, effective therapies is necessary.

FR-PO199

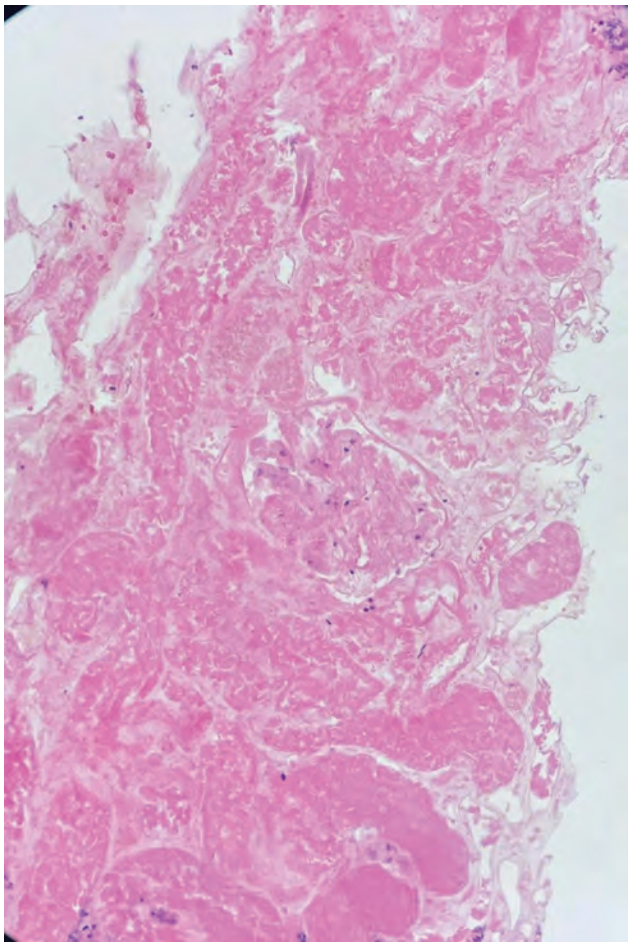
Renal Cortical Necrosis in Sickle Cell Trait

Basil Alnasrallah,[1] Shatha A. Alfaraj,[1] Jafar M. Al Rubh,[1] Osama A. Alkhamis,[1] Manaf Aljishi,[2] Husam Alzayer.[3] *[1]Qatif Central Hospital, Qatif, Saudi Arabia; [2]Saudi German Hospital Dammam, Dammam, Saudi Arabia; [3]Saudi Arabia Ministry of Health, Riyadh, Saudi Arabia.*

Introduction: Sickle cell disease (SCD) is a monogenic disorder characterized by an abnormal hemoglobin molecule due to a single nucleotide substitution in the β-globin gene. A homozygous inheritance causes sickling and hemolysis of erythrocytes and, subsequently, ischemia and end-organ damage. The heterozygous inheritance results in sickle cell trait (SCT) with a milder phenotypic presentation. We report a rare biopsy-proven renal cortical necrosis (RCN) in a patient with SCT.

Case Description: A 40-year-old male presented with severe, non-radiating lower abdominal pain and had lower abdominal tenderness on examination. His creatinine was 530 mmol/L. The urinalysis showed moderate pyuria and hematuria with negative urine culture. The urine protein:creatinine ratio was 1040 mg/g and his lactate dehydrogenase was 1209 units/L. The vasculitic and viral screens were negative, with normal complement levels. His hemoglobin electrophoresis showed a hemoglobin S of 31%. A kidney ultrasound showed normal size and morphology of both kidneys. A kidney biopsy showed diffuse extensive coagulative necrosis in the cortex, where the tubules and glomeruli were lined by pale ghost cells with pyknotic nuclei, there was marked interstitial inflammatory infiltrate composed predominantly of neutrophil ghosts. The immunofluorescence stains were negative. The patient's creatinine gradually improved over a 6-month period down to 176 mmol/L.

Discussion: Recurrent vaso-occlusive crises in SCD lead to many kidney manifestations, including RCN. Due to the relatively low levels of hemoglobin S, individuals with SCT rarely experience clinical manifestations. To the best of our knowledge, RCN has not been reported before in SCT.



H&E Stain showing necrotic areas with ghost outlines of glomeruli and tubules, and loss of cellular details

FR-PO200

Amoxicillin-Induced Crystalline Nephropathy

Cyril Mousseaux,[1,2] Ellie Tang,[2] Maxime Tristant,[1] Laurent Mesnard,[1,2] Yosu Luque,[1,2] Cedric Rafat,[1] David Buob,[1,2] Emmanuel Letavernier.[1,2]
[1]Assistance Publique - Hopitaux de Paris, Paris, France; [2]INSERM, Paris, France.

Introduction: Amoxicillin-induced crystalline nephropathy (AICN) is characterized by the sudden onset of acute kidney injury (AKI) and microscopic examination of the urine revealing characteristic birefringent needles under polarized light. Surprisingly, the presence of intratubular amoxicillin crystals is not reported. We report here the first case of intrarenal deposits of amoxicillin crystals.

Case Description: A 55-year-old woman was referred for AKI within one week of the initiation of amoxicillin antibiotic therapy for mitral endocarditis. She was euvolemic and had no fever, tachycardia, or rash. Urine analysis revealed no signs of leukocyturia or hematuria. The initial serum creatinine level was 5.42 mg/dL and the urine protein/creatinine ratio was 1 g/g. Complement and serum electrophoresis results were within normal range. Renal ultrasound was unremarkable. Urine microscopy after amoxicillin withdrawal did not reveal any crystals. Renal biopsy detected elongated optically empty formations within the tubular lumen, suggesting the presence of material dissolved during sample preparation. Further examination of the frozen fragment of the kidney biopsy specimen under polarized light revealed numerous intratubular birefringent structures. Scanning electron microscopy confirmed the presence of crystals within the tubular lumen, suggesting amoxicillin crystallization. The definitive proof that these crystals were composed of amoxicillin was obtained through attenuated total reflectance (ATR)Fourier-transform infrared spectroscopic analysis of frozen kidney biopsy sections.

Discussion: Despite being one of the most frequent crystalline nephropathies, the presence of intratubular crystals of amoxicillin in situ has yet to be documented. This case highlights several important messages. First, the processing of kidney biopsies can cause dissolution of crystals, emphasizing the need for systematic analysis of frozen tissue under polarized light in suspected cases of crystalline nephropathy. Second, infrared spectroscopic analysis plays a crucial role in identifying the causative substance. Finally, the presence of crystals in urine is transient and crystalluria analyses may be negative if not performed during exposure to amoxicillin.

Dual Autoimmune Processes, One IgG4 Stain

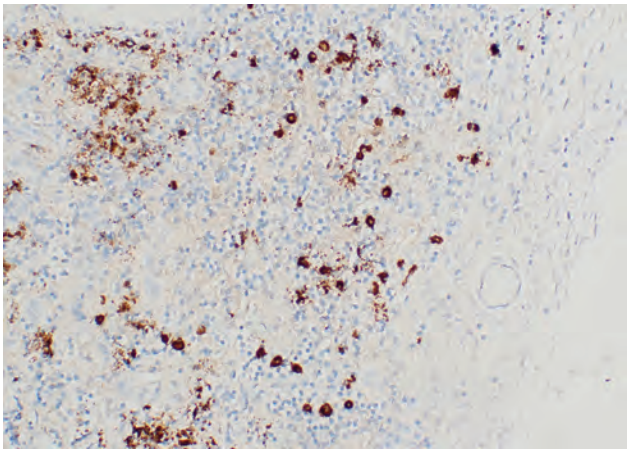
Claire F. Schretlen,[1] Timothy M. Chow,[1] Silvia Malvica,[1,2] Farah Abifaraj.[1]
[1]Johns Hopkins Medicine, Baltimore, MD; [2]Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy.

Introduction: IgG4-related disease (IgG4-RD) is an idiopathic immune-mediated fibroinflammatory disease often targeting the pancreas, kidney, retroperitoneum, and salivary glands. Pathology shows lymphoplasmacytic infiltrate with IgG4 plasma cells, storiform fibrosis, and obliterative phlebitis. We present an atypical presentation of a disease still being elucidated.

Case Description: A 30-year-old female with cirrhosis due to autoimmune hepatitis with primary sclerosing cholangitis overlap (AIH-PSC) and CKD stage III due to previous acute kidney injury (AKI) presented with new AKI (creatinine 3.3 mg/dl) during liver transplant evaluation. Serologic studies (table 1) showed elevated IgG with IgG4 predominance. Radiologic findings included retroperitoneal lymphadenopathy and groundglass pulmonary nodules. Although liver biopsy had not shown IgG4 plasma cell predominance, kidney biopsy revealed global glomerulosclerosis, interstitial fibrosis without storiform pattern, IgG4/IgG ratio of at least 30%, and >10 IgG4-plasma cells per high powered field (fig 1). She was treated for IgG4-RD with steroids and rituximab. Kidney function and pulmonary imaging improved dramatically within 6 months.

Discussion: This is a rare case of IgG4-RD in a young female with AIH-PSC without all characteristic pathologic findings. Diagnosis should be based on clinical, serological, radiological, and pathologic evidence. Underlying autoimmune disease may correlate with development of IgG4-RD.

Serologic Tests	Results	Normal range
Anti-neutrophil antibody (ANA) titer	>1:640	negative
Perinuclear anti-neutrophil cytoplasmic antibody (p-ANCA) titer	>1:640	negative
Myeloperoxidase (MPO) IgG	69 units	<20.0 units
Proteinase-3 (PR3) IgG	139.6 units	<20.0 units
Anti-double stranded DNA (Anti-dsDNA) titer	1:80	negative
Total IgG	6249 mg/dl	610-1616 mg/dL
IgG4	436.9 mg/dl	3.9-86.4 mg/dL



FR-PO202

Oxalate Nephropathy: An Insidious Cause of Renal Insufficiency

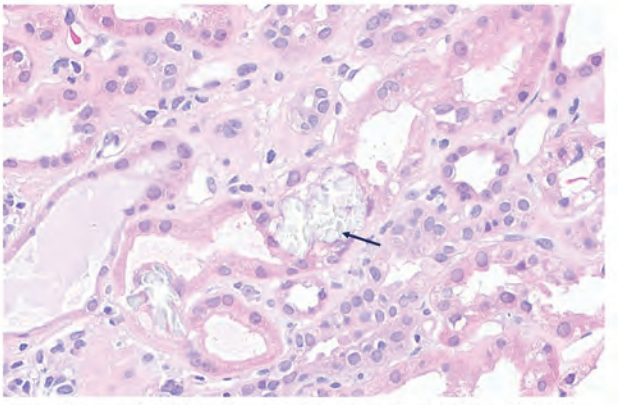
Alex D. Tarabochia, Jason R. Pettus, Roy Rajan. *Dartmouth Health, Lebanon, NH.*

Introduction: Oxalate nephropathy is caused by urinary super saturation of calcium oxalate, crystal formation with obstruction of tubules and deposition into the renal parenchyma.

Case Description: Patient is a 73-year-old male with Crohn's disease, distant history of oxalate renal stones 5 years ago, and hypertension referred for chronic kidney disease (CKD) with baseline serum creatinine (Cr) of 1.6 with stable Cr for more than a year, which increased to 2 over the period of six months. Blood pressure (BP) was at goal and he had not had a Crohn's flare in four years. Renal ultrasound (US) was negative for obstruction but did show small, non-obstructing (8mm on the left, 7mm on the right) renal stones in the bilateral lower renal poles. Specific gravity was 1.015, calcium was 8.5, protein: creatine (UPC) ratio was 0.1, and urine sediment was unremarkable with light microscopy. Routine labs were obtained one month later and serum Cr was 6.5. His symptoms were remarkable for fatigue and confusion. Pertinent medical history and repeat renal imaging were unremarkable. Specific gravity was 1.014 on urinalysis; calcium, UPC and light microscopy were unremarkable. The lack of obvious findings and lack of improvement with IV hydration prompted renal biopsy which showed tubular atrophy (15%) with diffuse calcium oxalate deposition and minimal acute tubular injury. Twenty-four-hour urine collection showed low urine citrate (113mg/day) and high urine oxalate (92 mg/day). He was started on potassium citrate and was instructed to increase fluid intake after which Cr improved to 2.5 over a period of two months.

Discussion: This case illustrates the insidious nature of oxalate nephropathy where the ongoing, mild super saturation leads to CKD and an acute super saturation leads to AKI. Risk factors include dehydration, high oxalate diet, and disorders with malabsorption

of fat including Crohn's disease which leads to saponification and increased oxalate absorption. The case highlights the importance of biopsy to distinguish this from other forms of AKI and 24-hour urine studies to manage stone formation.



Arrow pointing towards oxalate crystals in renal tubule with necrotic renal tubular epithelial cells.

FR-PO203

Allopurinol-Associated Renal Necrotizing Vasculitis

Zachary Appelbaum, Abdallah Sassine Geara, Yonghong Huan, Matthew Palmer. *Penn Medicine, Philadelphia, PA.*

Introduction: Allopurinol is a xanthine oxidase inhibitor frequently used in the treatment of gout, a common comorbidity in patients with chronic kidney disease (CKD). Post-marketing studies of allopurinol reported a higher incidence of acute kidney injury (AKI) with acute interstitial nephritis representing the most reported histologic finding. We report a case of allopurinol-associated renal vasculitis in a patient with diabetic kidney disease (DKD).

Case Description: A 68-year-old African American female with a history of DKD, hypertension, and gout was referred to the Emergency Room for nausea and AKI. Her baseline serum creatinine (sCr) was approximately 2.6 mg/dL and increased to 4.02 mg/dL on presentation. Two months prior to presentation, the patient was initiated on allopurinol therapy for gouty arthritis. Other notable findings were elevated liver enzymes and a diffuse purpuric rash. Serologic work-up revealed negative for ANCA, normal complement levels, and negative viral serologies. Because the AKI did not improve with hydration and cessation of allopurinol, a kidney biopsy was performed. The biopsy showed focal vasculitis with fibrinoid necrosis superimposed on a background of diabetic nephropathy with severe interstitial fibrosis and hypertension related arterial sclerosis. Review of the immunofluorescence did not reveal any staining for immunoglobulins, complement, or light chains. This biopsy was most consistent with necrotizing vasculitis. A prednisone taper was initiated for presumed allopurinol induced necrotizing vasculitis. The patient had improvement of kidney function and was subsequently discharged without requiring kidney replacement therapy.

Discussion: Rash is a known adverse effect of allopurinol therapy, and the majority of these cutaneous reactions improve with discontinuation of allopurinol therapy. The risk of severe adverse reactions is increased in patient of African, Korean, Chinese or Thai ancestry due to the high incidence of individuals who carry the HLA-B*5801 variant allele. Allopurinol-associated renal necrotizing vasculitis is likely a presentation of this type of severe hypersensitivity reaction. Upon initiation of allopurinol, especially the patients at high risk of cutaneous reactions should be counseled regarding this risk and instructed to promptly discontinue the medication and inform the treating provider if a rash is present.

FR-PO204

Tubulointerstitial Nephritis and Uveitis Syndrome (TINU)

Alina Hasan, Jamal Abu-Khaled, Anusha Alam, Krishna Pothugunta. *Corewell Health, Royal Oak, MI.*

Introduction: Tubulointerstitial Nephritis and Uveitis Syndrome (TINU) is a rare, self-limiting interstitial nephritis and bilateral anterior uveitis.[1] Here, we describe an interesting case of TINU.

Case Description: A 42-year-old woman with no significant medical history presented to the hospital with acute kidney injury (AKI). She was noted to have elevated creatinine (Cr) of 2.2mg/dL with a baseline of 0.7-0.9mg/dL. Urinalysis was positive for blood (3+) and protein (30 mg). She reported using naproxen for menstrual cramps. Physical exam was negative for skin rash or lower extremity edema. Family history was significant for sarcoidosis. During inpatient stay, labs revealed urine protein to creatinine ratio (Pr:Cr) was 0.97 g/g. Serological work up was negative for ANA, ANCA, anti GBM, MPO, PR-3 and PLA2R. Complement levels were normal. Serum protein electrophoresis (SPEP) was negative for monoclonal protein. Free light chain ratio was elevated but acceptable for renal function. Urine eosinophils were negative. Kidney ultrasound (US) showed normal sized kidneys with normal echotexture and no evidence of hydronephrosis. Kidney biopsy showed acute interstitial nephritis. She received prednisone 60 mg daily which was tapered over 4 weeks. Cr improved to 1mg/dl on outpatient labs. She developed anterior uveitis after tapering the steroids and was prescribed methyl prednisone by ophthalmology. Repeat urinalysis showed significant pyuria with no nitrites nor proteinuria and Pr:Cr at 0.19 g/g. Repeat SPEP was negative. IgG4 subclasses were normal. Sjrogen antibodies, HLA B27 screening, Lyme's serology, quantiferon TB were all negative. ACE levels and 1,25 vit D levels were normal. Previous chest x-ray was negative for any hilar lymphadenopathy. Repeat renal biopsy showed resolving tubulointerstitial nephritis, however increased chronicity with moderate interstital fibrosis compared to mild previously.

Discussion: TINU is a diagnosis of exclusion[2,3] confirmed with renal biopsy. Management includes steroids with some severe cases requiring steroid sparing immunomodulators. Recurrence is common in the 1st few months to 2 years of stopping therapy.[3] **Conclusion:** An unexplained AKI that has been thoroughly worked up, in the presence uveitis, should prompt consideration for TINU, especially if it's been steroid responsive and recurring after its discontinuation.

FR-PO205

Use of Anti-C5 Inhibitor Leading to Renal Recovery in Combined Typical and Atypical Hemolytic Uremic Syndrome (HUS)

Man Kit Michael Siu, Antoney J. Ferrey, Ekamol Tantisattamo. *University of California Irvine, Irvine, CA.*

Introduction: Hemolytic uremic syndrome (HUS) is classified as typical vs atypical with very different approaches to management. Only around 10% of cases are atypical HUS, a rare disease with poor outcome caused by uncontrolled activation of the alternative complement pathway. Here we present a case of a patient admitted for AKI requiring initiation of dialysis with clinical features suggestive of both typical and atypical HUS manifestation. Use of anti-C5 inhibitor, Eculizumab, ultimately provided full renal recovery.

Case Description: Patient is a 43 female, with no significant past medical history, and presented with nausea, vomiting, and bloody diarrhea. On admission, found to be in oliguric acute kidney injury (AKI), with hospital course complicated by worsening renal function and mental status requiring initiation of dialysis for clearance and volume optimization. Additional work up was significant for thrombocytopenia, elevated LDH, undetectable haptoglobin, with rare schistocyte concerning thrombotic microangiopathy (TMA). ADAMSTS13 29, given >10, not suggestive of TTP. O157:H7 grew on chromogenic agar with testing positive for Shiga toxin. As such, etiology of AKI initially thought secondary to typical HUS. However, given hemolytic anemia, thrombocytopenia, and kidney dysfunction, atypical HUS is still within the differential. Case discussed among transfusion medicine and nephrology team and patient was managed as atypical HUS with monoclonal anti-C5 inhibitor, Eculizumab 900mg weekly. Subsequent TMA complete genetic panel equivocal, but did show heterozygous missense for C5 polymorphism. Pt saw significant renal recovery after 4 doses of Eculizumab and was no longer dialysis dependent.

Discussion: Eculizumab is recommended as first-line treatment for atypical HUS; but its use in typical HUS has been controversial. However, our case illustrates the difficult but importance of early consideration of aHUS in patients presenting with TMA. More importantly, we highlight that near-normal renal recovery may be attained with eculizumab in adults even after a dependence on dialysis.

FR-PO206

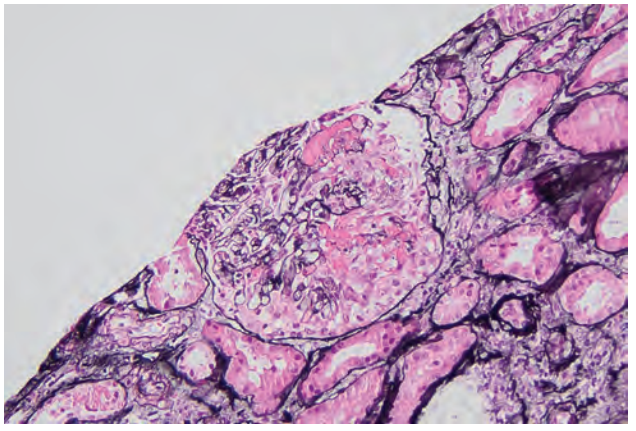
Heuristic Is a Good Clinical Servant but a Bad Master: A Case of Delayed Diagnosis of Granulomatosis with Polyangiitis

Percy Adonteng-Boateng, Meghan Kapp, Lavinia A. Negrea. *University Hospitals, Cleveland, OH.*

Introduction: Failure to connect the different and sometimes scattered symptoms of systemic vasculitis may result in delayed diagnosis of severe illnesses like Granulomatosis with Polyangiitis (GPA).

Case Description: 51-year-old male treated for CAP/sinusitis at an outside hospital 3 weeks prior and readmitted with diarrhea, hemoptysis, nausea, vomiting, dark stools, joint pains, epistaxis, and purpuric skin rash on extremities. Infectious work up, ANA with reflex, C3, C4, and hepatitis panel were unremarkable, but cANCA was positive at 1:160. Lactoferrin and calprotectin were elevated. CT abdomen was suggestive of colitis. Patient started on IV solumedrol for presumed inflammatory bowel disease (IBD) versus vasculitis, and transferred to our facility for GI evaluation. Serum creatinine rose from 1.0 to 1.8 mg/dl. UA showed hematuria, pyuria but no proteinuria. Colonoscopy with biopsy showed ulcerated mucosa without viral inclusions or features of IBD. Skin biopsy showed leukocytoclastic vasculitis. Working diagnosis was Henoch Schonlein Purpura, patient changed to oral steroids with plans for outpatient dermatology follow up. Kidney function however worsened so nephrology was consulted and a kidney biopsy pursued. This showed pauci-immune necrotizing crescentic GN. Therefore, patient was diagnosed with GPA and IV solumedrol and Rituximab were started. His clinical manifestations improved, but kidney function did not. He underwent PLEX. Creatinine plateaued at 5 mg/dl. At outpatient follow up visit, it decreased from 5.0 to 3.2 mg/dl. Patient reported feeling overall well with no symptoms recurrence.

Discussion: Recognizing the clinical presentations of rare diseases like ANCA associated vasculitis may help clinicians diagnose and promptly initiate of immunosuppressive therapy while awaiting kidney biopsy. This may yield better kidney prognosis.



Jones' silver stain 200x: Glomerulus demonstrating breaks in the GBM with associated fibrinoid necrosis.

FR-PO207

Weil Disease as a Cause of Electrolyte Wasting and AKI

Kavita Mistry, Jeffrey H. William. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: Leptospirosis is a spirochetal illness that can manifest as a severe syndrome of Weil's disease, characterized by oliguric AKI, liver injury, jaundice, anemia, thrombocytopenia, rhabdomyolysis and pulmonary edema. AKI in Weil's disease is multifactorial, resulting from direct action of spirochetes on renal tissue, rhabdomyolysis, ATN and AIN.

Case Description: A 67-year-old woman from Haiti residing in the Boston area presented with lower extremity myalgias and weakness. Physical exam revealed scleral icterus and 4/5 muscle strength in the proximal lower extremities. She was found to have oliguric AKI with creatinine of 5.9 mg/dL, potassium of 4.3 mEq/L, phosphorus of 1.3 mg/dL and calcium of 8.2 mg/dL. LFT abnormalities included ALT 187 IU/L, AST 278 IU/L, total bilirubin 10.6 mg/dL and direct bilirubin 9.5 mg/dL. CPK was elevated at 3439 IU/L. CBC was remarkable for white blood cell count 19.8 K/uL, hemoglobin 8.9 g/dL and platelet count 23 K/uL. Reticulocyte count was low at 0.3% with haptoglobin 364 mg/dL and LDH 313 IU/L. INR and PTT were normal. ANA was negative. U/A revealed 1+ glucose, 3+ blood and 3+ protein (quantified at 4.7 g/g) with 10-15 isomorphic RBC/hpf, few granular casts and several renal tubular epithelial cells on microscopy. Infectious Diseases was consulted, and initially had low pre-test probability for infection given that the patient was afebrile and had been living in Massachusetts for 6 months, however recommended testing for leptospirosis, Dengue, chikungunya and tickborne diseases. Leptospira IgM returned positive with high titer of 12,800 for L. interrogans on MAT confirmatory testing. The patient was diagnosed with Weil's disease and was treated with ceftriaxone with normalization of laboratory parameters and symptoms.

Discussion: This patient's presentation of oliguric AKI with relatively preserved potassium and hypophosphatemia is characteristic of leptospirosis-associated renal injury, which is often preceded by electrolyte wasting that is thought to result from leptospire-induced changes in expression of tubular transport proteins along the nephron. It is important to maintain a high index of suspicion for leptospirosis in patients who present with AKI and evidence of electrolyte wasting, and in patients who present with direct hyperbilirubinemia out of proportion to other LFT abnormalities, even in the absence of exposure and recent travel history.

FR-PO208

Putting the Pieces Together: A Multifaceted Elevation in Creatinine

Devam Parghi,[1] Saikiran Mandyam,[1] Juhi Patel,[2] Jocelyn Z. Medal,[3] Priyanka Patel,[1] Nowoghomwenma C. Ibie.[1] *[1]Southeast Health, Dothan, AL; [2]Rutgers New Jersey Medical School, Newark, NJ; [3]Alabama College of Osteopathic Medicine, Dothan, AL.*

Introduction: Goody Powder is OTC medicine containing aspirin, caffeine, and acetaminophen. When taken in excess and combined with alcohol it can induce undesirable elevations in blood pressure that can exacerbate renal dysfunction in an already compromised kidney. It can also cause severe gastric irritation with the risk for gastrointestinal bleeding. GI bleed could lead to blood loss, uremia, and dehydration. Furthermore, caffeine and alcohol exhibit diuretic properties intensifing dehydration and exacerbate AKI through the reduction of blood volume. Although aspirin and alcohol have been linked to kidney damage, there are few case reports demonstrating the rapid progression to ESRD.

Case Description: 33 y/o African American male BMI 37 and no reported PMH presented with complaints of fatigue, generalized weakness, nausea, vomiting, and diarrhea x 1 month. Reported daily episodes of vomiting with intermittent hematemesis. He also complains of dizziness, abdominal pain, decreased urine output. He denies fever, chills, chest pain, or dyspnea. The patient also reports prior heavy drinking with multiple alcoholic beverages/day till recently, and combining it with Goody powders for his abdominal pain. BP 175/88, HR 96. Lab Na 131, K 6.0, bicarb 6, BUN 238, creatinine 50, and eGFR 1, Hb 6.6. The patient was admitted for further workup where electrolytes were replenished, his hypertensive emergency was appropriately controlled, and he underwent dialysis. A renal biopsy demonstrated accelerated hypertension as one of the prime causes for his renal failure.

Discussion: Even though Goody Powders' controlled use is generally safe, its combined use with alcohol possibly accelerated the progression to ESRD in our patient. This patient possibly had baseline CKD due to uncontrolled hypertension that was never controlled but in the setting of above, he progressed to ESRD rather quickly. Also, he had concurrent hemolysis secondary to severe hypertension on top of potential GI bleed. It is important to note that combining caffeine with alcohol can have contradictory CNS manifestations especially when uremia sets in. Therefore, timely identification of metabolic abnormalities along with prompt management is crucial. Patient education should be emphasized to avoid prior behaviors and to avoid further damage.

FR-PO209

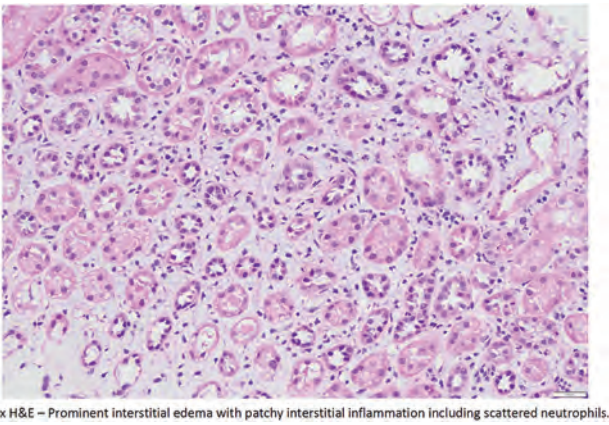
An Uncommon Presentation of Cocaine-Induced Acute Interstitial Nephritis

Dhruv Bakshi, Deep Phachu. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Cocaine induced kidney injury may occur through multiple mechanisms including rhabdomyolysis, thrombotic microangiopathy, glomerulonephritis, vasculitis, and renal infarction. Acute interstitial nephritis (AIN) is characterized by inflammatory infiltrates in the kidney interstitium sparing the glomeruli, that may occur from systemic autoimmune disorders, infection or drug-related mechanisms. Cocaine-induced AIN is a rare entity that has been poorly studied.

Case Description: A 45-year-old male was brought to the ER after being found unresponsive. He had acute kidney injury with a creatinine of 4, lactic acidosis, creatine kinase greater than 40,000 IU/L and urine toxicology positive for cocaine. Manual urine microscopy showed occasional non-dysmorphic RBCs and no WBCs. The patient was treated with IV fluids without renal replacement therapy. After regaining consciousness, he communicated a prolonged history of cocaine use but no kidney injury. He was treated for myoglobin-related toxic kidney injury from rhabdomyolysis. Over the next few days, his creatinine plateaued around 4 despite volume resuscitation. On hospital day 15, a kidney biopsy revealed acute tubular injury with myoglobin casts, and prominent interstitial edema with inflammation suggestive of interstitial nephritits. This was presumed to be cocaine-induced AIN.

Discussion: The most common presentation of AIN is rash and fever (25-40%), with laboratory findings of acute kidney injury, eosinophilia (35-60%) and sterile pyuria (75-85%). The classical triad of fever, eosinophilia and AKI are present in <10% of all cases. A definitive diagnosis is made by a kidney biopsy which shows interstitial infiltrates and edema. In our patient, while diagnosis was confirmed with a classical picture on biopsy, the patient did not have any evidence of pyuria or eosinophils. This suggests that in a patient with cocaine overdose who shows non-improvement in creatinine, interstitial nephritis may be considered despite absence of classical clinical findings.



20x H&E – Prominent interstitial edema with patchy interstitial inflammation including scattered neutrophils.

FR-PO210

Acute Hyperoxaluria in Setting of Hereditary Spherocytosis Presenting as a Rapidly Progressive Glomerulonephritis (RPGN)

Barbara C. Mcmullan, Anna M. Burgner. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Hereditary spherocytosis (HS) is the most common inherited hemolytic anemia. Characteristic symptoms include anemia, jaundice, and splenomegaly. Clinical severity is variable with most remaining well compensated. Common complications include cholelithiasis, hemolytic episodes, and aplastic crisis. Despite causing hemolytic anemia, kidney injury is rarely associated with this disease.

Case Description: A 32-year-old female with HS developed hemolytic crisis and AKI and was aggressively resuscitated. She had evidence of a rapidly progressive glomerulonephritis (RPGN) by labs, see Table 1. She was treated empirically with steroids and underwent kidney biopsy on hospital day 5. Biopsy results showed diffuse calcium oxalate crystals with minimal glomerular injury, see figure 1. Day 1 post biopsy

she required dialysis for metabolic derangements. With normalization of electrolytes and clearance of oxalate, she was able to cease dialysis with excellent kidney recovery.

Discussion: The source of acute oxalosis was unknown. Erythrocytes carry oxalate but intact red blood cells do not increase risk of crystal formation. Red cell membrane fragments have been shown to promote oxalate crystal growth and aggregation up to 2.5 fold. However, she had a history of prior hemolytic episodes without AKIs or nephrolithiasis. We ruled out causes of oxalate including history of bariatric surgery and ethylene glycol poisoning. We learned that 2 days prior to admission she had received an infusion containing 2500mg vitamin C (Myers cocktail). We postulate that hypervitaminosis C in setting of hemolytic anemia caused acute oxalate crystal deposition with subsequent kidney failure. Various infusions have become readily available with minimal medical oversight, thus history taking remains paramount to patient care.

Atypical Hemolytic Uremic Syndrome from Recent HIV Diagnosis

Omar Khan,[1] Wafa Mehboob,[1] Hamad Patel,[1] Fakhar Ijaz.[2] *[1]Arkansas College of Osteopathic Medicine, Fort Smith, AR; [2]CHI St Vincent Infirmary, Little Rock, AR.*

Introduction: Atypical Hemolytic Uremic Syndrome (aHUS) is a rare thrombotic microangiopathic disorder characterized by reduced platelet counts, thrombocytopenia, and hemolytic anemia, often leading to kidney failure. It is associated with dysfunction of the Complement Alternative Pathway, and unlike Typical TMA, ADAMTS 13 activity levels are not low. While HIV-induced TMA has been documented, information on HIV-induced aHUS is limited. In this case, we present a rare instance of a patient with aHUS who was recently diagnosed with HIV.

Case Description: A 50-year-old male African American patient was recently diagnosed with HIV, with a CD4 count of 4 and a CD8 count of 158. He arrived at the hospital with complaints of abdominal pain, nausea, vomiting, generalized fatigue, and confusion. His Initial Lab results showed thrombocytopenia (plt:53k), anemia (Hgb:8), acute kidney injury (Cr:20, BUN:156), and accelerated hypertension. Tests for viral hepatitis, ANA, ANCA, and Syphilis were negative. The patient's renal biopsy revealed possible TMA with interstitial fibrosis and fibrin deposition. Plasmapheresis was initiated based on suspected TTP. Hemodialysis was started due to worsening renal failure and anuria. His ADAMTS13 levels were not low, suggesting atypical HUS. The patient's management was changed to Eculizumab therapy where his clinical condition and renal function improved after two doses. His dialysis was eventually discontinued.

Discussion: Existing literature links HIV with typical TMA, but no reports mention HIV-induced Atypical HUS. This case reveals a rare presentation of aHUS following a recent HIV diagnosis. HAART therapy is typically recommended but may take time to show clinical benefit, potentially leading to long-term dialysis due to irreversible scarring. This report demonstrates Eculizumab as an effective rapid therapy for acute TMA, allowing patients to improve without requiring long-term dialysis.

FR-PO212

Intraperitoneal Urinary Leak Presenting as Severe AKI After Robotic-Assisted Laparoscopic Radical Prostatectomy (RALRP)

Laith Alzyood,[1,2] Mahmoud Ali,[3] Neelja D. Kumar.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY; [3]St Barnabas Hospital, Bronx, NY.*

Introduction: About one in five hospitalizations is complicated by AKI, and patients with urological diseases are at higher risk of developing AKI, but severe AKI is a rare event after prostate surgery. We present a unique case of AKI following RALRP.

Case Description: A 60-year-old male with hypertension, type 2 diabetes, prostate cancer and normal kidney function at baseline, presented with severe lower abdominal pain six days after RALRP. His surgical drains were removed a day prior to presentation, but his urinary catheter was maintained. Abdominal exam revealed a tender right lower abdomen and clean surgical sites. He was afebrile, blood pressure was 149/86 mmHg, and pulse was 94 beats/minute. A non-contrast abdominopelvic computed tomography (CT) showed a pelvic hematoma to the right of the urinary bladder with small locules of gas. There was also a lower density fluid collection in the surgical bed. His serum creatinine was 1.72 mg/dL, potassium was 4.2 mEq/L, and blood urea nitrogen was 22 mg/dL. Hemoglobin was 10 g/dL. WBC, platelet count, creatinine kinase and coagulation profile were all within normal limits. Urinalysis was positive for blood, but negative for infection. The patient had worsening abdominal distension and pain and an abdominal ultrasound showed a new development of moderate ascites. At that time, patient also had doubling of his serum creatinine to 4.21 mg/dL while maintaining adequate urine output. Abdominal paracentesis performed in the left lower quadrant aspirated 2 liters of bloody fluid. Analysis of the peritoneal fluid showed creatinine of 10.4 mg/dL. A CT cystography confirmed a vesicourethral urinary leak with expansion into the peritoneal cavity. A pelvic drain was placed, resulting in normalization of serum creatinine and resolution of abdominal ascites.

Discussion: RALRP has become the dominant surgical approach for radical prostatectomy in the United States. Vesicourethral urinary leak is a common complication following RALRP, but the reported incidence of expansion of those leaks into the peritoneum was 1% and <0.5% required CT-guided drainage. Our case is unique given the acute presentation of severe non-oliguric AKI after RALRP with development of ascites after removal of the surgical drain resulting in pseudo-AKI from increased creatinine absorption through the peritoneal membranes.

FR-PO213

A Case of AKI due to Letermovir and Tacrolimus Interaction

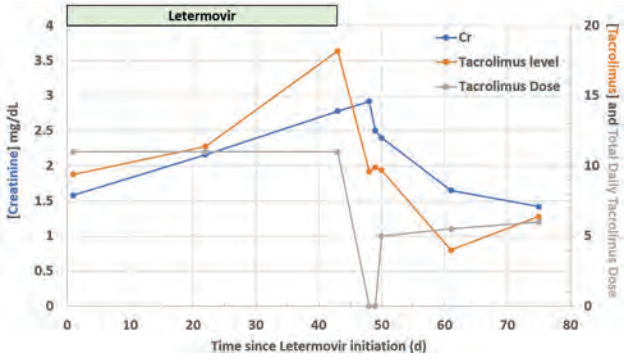
Farid Arman, Anna Krieger, Jessica Hedvat, Russell J. Crew, Jacob Stevens. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Cytomegalovirus (CMV) is a significant pathogen causing morbidity and mortality among solid organ transplant recipients. Valganciclovir (VGC) and ganciclovir are first line for prophylaxis and treatment. Their use is limited by bone marrow toxicity, particularly leukopenia, and by viral resistance. Letermovir (LET) is a terminase complex inhibitor approved for CMV prophylaxis in hematopoietic stem cell transplant patients. Unlike VGC and ganciclovir, it doesn't have myelosuppressive properties. It is also a moderate inhibitor of cytochrome P450 3A4, which metabolizes commonly used immunosuppressive (IS) tacrolimus (TAC). One study suggests a TAC dose reduction of about 30% may be needed after starting LET.

Case Description: Our patient is a 68-year-old male with non-ischemic cardiomyopathy status post orthotopic heart transplant (CMV+/-) now with CKD (serum creatinine (SCr) 1.4-1.6 mg/dL) complicated by recurrent CMV viremia treated with VGC. His IS regimen included TAC with stable levels for several months. At 2.5 years after transplant, he developed leukopenia prompting a switch from VGC to LET. At visits

0, 3, and 6 weeks after LET initiation, SCr was 1.6, 2.2, and 2.8 mg/dL, respectively (see figure 1) with gradually increasing TAC levels (peak 18 ng/mL at week 6). He did not have any other new medications, diarrhea, abnormal liver tests or other explanation for the change in TAC level. He was admitted for AKI evaluation and workup was unrevealing. AKI was felt to be due to TAC nephrotoxicity secondary to drug-drug interaction with LET. LET was discontinued, TAC was reduced, and SCr improved. In subsequent outpatient visits, SCr returned to baseline and TAC dose had to be increased, confirming that LET was likely the etiology.

Discussion: To our knowledge, this is the first reported case of AKI following the initiation of LET with concurrent TAC use. Transplant physicians should be aware of this interaction and consider more frequent TAC level monitoring in the first month of starting or stopping LET.



FR-PO214

AKI and Hypercalcemia: A Complicated HIV Story

Yara Bilen, Ali Mehdi, George Thomas, Dania Salih Bacha, Michael W. George. *Cleveland Clinic, Cleveland, OH.*

Introduction: HIV causes kidney injury through direct viral effects, antiviral therapies, immune reconstitution, and superimposed infections. We report a case of kidney dysfunction in the setting of HIV/AIDS and disseminated mycobacterial avium complex (MAC) infection.

Case Description: A 23-year-old male with history of HIV/AIDS was admitted with acute kidney injury (AKI) and hypercalcemia (hyperCa) after outpatient evalutation for failure to thrive and lymphadenopathy. Creatinine peaked at 2.48mg/dL from a baseline of 1. HyperCa and hyperphosphatemia were noted at 13.5 and 5.2mg/dL respectively. Urinalysis showed 2+ protein with a UPCR of 0.6. Sediment analysis revealed muddy brown casts. Kidney US showed non-obstructing renal calculi without hydronephrosis. Workup showed low PTH levels, 25-OH Vitamin D of 26.8ng/mL (nl: 31-80) and 1,25-Dihydroxyvitamin D of 58.4pg/mL (nl 19.9-79.3). PTHrP was elevated at 4.1pmol/L (nl: 0-2.3). Per chart review, patient had a diagnosis of disseminated MAC and a recent kidney biopsy that showed acute on chronic interstitial nephritis. At that time, his AKI was attributed to MAC and antibiotics were started. Subsequently, patient had worsening adenopathy concerning for lymphoma, but a follow up biopsy could not be obtained. His symptoms were suggestive of uncontrolled MAC so the antibiotics and HIV therapy were adjusted. His AKI was thought to be related to the hyperCa which in turn was hypothesized to be related to the granulomatous infection due to activated vitamin D. The elevated PTHrP remained of concern. The hyperCa was managed with IV fluids and pamidronate. Patient was discharged on optimized HIV and MAC therapy with improvement of calcium level and kidney function. 9 months after admission, creatinine was down to 1.23 with a calcium of 9.7.

Discussion: HyperCa is a rare but potentially serious complication of disseminated MAC infection, with incidence ranging from 5 to 20%. The mechanism is thought to be due to increased 1-alpha hydroxylase expression in activated macrophages. A similar mechanism explains hyperCa seen with lymphomas. In the setting of HIV in general, and AIDS particularly, hyperCa should trigger an in-depth evaluation for an underlying granulomatous or lymphomatous disorder. Improvement generally follows treatment of the underlying pathology.

FR-PO215

Nivolumab-Induced Acute Interstitial Nephritis

Zaid A. Elkarmi, Tina Kochar, Muhammad Rawala, Alokika Patel. *The University of Texas Medical Branch at Galveston, Galveston, TX.*

Introduction: Nivolumab, an anti-programmed death – 1 (PD-1) monoclonal antibody, is an immune checkpoint inhibitor that has recently been approved for use as treatment for various cancers including melanoma, renal cell carcinoma, non-small cell lung cancer and squamous cell carcinoma. However, immune checkpoint inhibitors have been linked to a different array of immune related side effects affecting dermatological, gastrointestinal, endocrinological, hepatic, and renal systems. There have been a few documented occurrences of nephrotoxic side effects.

Case Description: We present a case of a 73-year-old male patient who was diagnosed with clear cell renal cell carcinoma with extensive necrosis, lung metastasis and renal vein thrombosis in 08/2021. The patient was started on Cabozatinib chemotherapy with initial good response. The patient was started on Nivolumab in 01/2023 in combination with lower dose of Cabozatinib as the response to cabozatinib was suboptimal. Two months after starting Nivolumab the patient was admitted with c/o right flank pain. He was found to have evidence of acute kidney injury (AKI). BMP showed a creatinine of 7.21 mg/dl, BUN 57, Na 134 mg/dl, K 5.7 mg/dl. Urinalysis showed 30 mg / dl proteinuria, 4 rbc / hpf, +1 blood, and urine spot protein to creatinine ratio was 1 gm / gm. CBC revealed a normal white blood cell count and no eosinophilia. Soon after admission the patient developed uremic symptomatology and had to be initiated on Hemodialysis and a renal biopsy was planned. Renal biopsy report was consistent with signs of acute interstitial nephritis with associated tubulitis, normal appearing glomeruli, negative immunofluorescence, and minimal intimal fibrosis. The patient was started on intravenous methylprednisolone 2 mg / kg for a total of 3 days followed by oral prednisone 1 mg / kg. Kidney function slowly improved and stabilized after 2 weeks with a creatinine of 4.4 mg / dl with no need for further hemodialysis sessions.

Discussion: It is challenging to differentiate between cases of AIN versus acute tubular necrosis (ATN), which occur commonly in patients with cancer. The following case report highlights AIN as a cause of AKI in patients receiving Nivolumab and how good clinical judgement along with timely intervention can lead to reversal of dialysis dependent AKI

FR-PO216

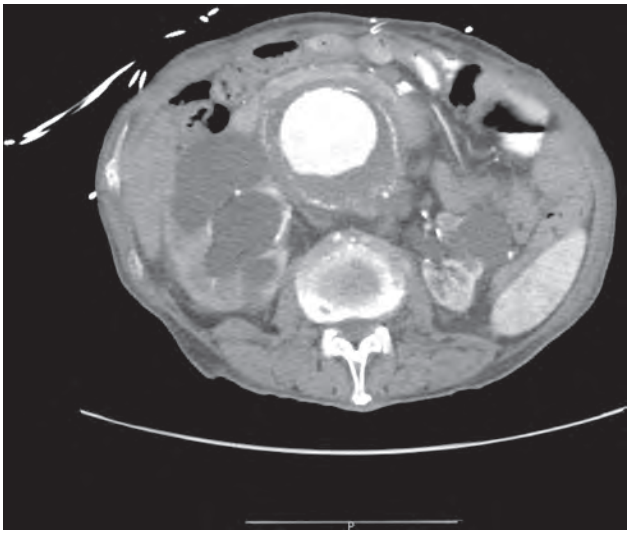
Giant Abdominal Aortic Aneurysm (AAA): A Rare Cause of Obstructive Nephropathy

Nora H. Hernandez Garcilazo, Ursula C. Brewster. *Yale School of Medicine, New Haven, CT.*

Introduction: Obstructive nephropathy (ON) accounts for 5-10% of all cases of AKI. The most common causes include benign prostatic hyperplasia, kidney stones or malignancy. Only few cases have been reported of ON caused by a large abdominal aortic aneurysm (AAA) producing ureteral compression. We present the case of a patient whose severe renal failure only became evident after presenting to the hospital with impending AAA rupture.

Case Description: A 72-year-old male with long-term tobacco use and no medical care for >15 years presented with abdominal pain and dyspnea. He denied any fever, chills, nausea, vomiting, diarrhea, or poor oral intake. In ED, blood pressure was 163/93, but otherwise stable. Blood work showed a creatinine 14.0 mg/dl, BUN 149 mg/dl, K 5.3 mmol/L, CO2 6 mmol/L, anion gap 29, and normal LFTs. CT without contrast revealed an impending aortic rupture with aneurysmal dilation measuring 8.6 x 10.6 cm in axial diameter causing severe right-sided hydronephrosis and mildly atrophic left kidney. Dialysis was initiated for optimization of acid-base status for emergent endovascular repair. The next day he underwent percutaneous stent graft repair and had a right nephrostomy tube placed resulting in complete resolution of right hydronephrosis. Urine output improved; however, clearance was still impaired so dialysis was restarted and continued without adequate renal recovery.

Discussion: AAA is a rare and potentially fatal cause of ON. AAAs larger than 8 cm carry an annual rupture risk of 30-50%. Once this occurs mortality risk is extremely high, making emergency surgery the only alternative. Our patient's case posed an added level of complexity as he was found to have acute renal failure requiring emergent dialysis for pre-op optimization. Although exceedingly rare, it is important to keep in mind aortic aneurysms as a cause of ON with the major difference from most other causes being the critical role prompt treatment plays in patients' survival.



AAA causing severe hydronephrosis

FR-PO217

Renal Limited IgG4-Related Disease: A Unique Clinical Entity

Aseel Zghayer, Julia Schneider. *Loyola University Health System, Maywood, IL.*

Introduction: IgG4 related disease (IgG4-RD) is an immune mediated fibroinflammatory conditions that can affect many organs including kidneys, where involved organs share core pathologic, clinical and serological similarities. IgG4-related

kidney disease (IgG4-RKD) is a part of spectrum of IgG4-RD and more than 90% of patients with IgG4-RKD have manifestations of extrarenal involvement. Here, we describe a rare case where kidney is the sole organ involved in IgG4-RD.

Case Description: A 74-year-old man with history of long standing hypertension was admitted after a routine blood test showed acute kidney injury, serum creatinine 5.4 mg/dl, was 1.3 mg/dl two years prior. Work up is shown in Table 1. BP was uncontrolled on admission and patient was asymptomatic. CT abdomen/pelvis did not show any abnormalities. Kidney biopsy revealed diffuse interstitial fibrosis and tubular atrophy involving 90% of the cortical parenchyma, and immuno-labeling showed diffuse IgG4-positive plasma cells in the interstitium with 17-31 cells/HPF in most concentrated areas (Image 1).

Discussion: Tubulointerstitial nephritis (IgG4-TIN) is the most common renal manifestation of IgG4-RKD, it may present as acute or chronic renal insufficiency. Diagnosis of IgG-4 TIN is challenging without the presence of other extra-renal manifestations of IgG4-RD. IgG4 staining should be considered in TIN with presence of plasma cell infiltrates. To the best of our knowledge, our case is first to be reported in literature for isolated IgG4-TIN. Greater clinical awareness of this entity will lead to early diagnosis and early intervention.

FR-PO218

Point-of-Care Ultrasound (POCUS) in Metastatic Ovarian Carcinoma: Kidney Injury and Inferior Vena Cava (IVC) Compression

Amulya Rajagopal, Ryan Goleniak, Lalathaksha Murthy Kumbar. *Henry Ford Hospital, Detroit, MI.*

Introduction: Acute renal failure in metastatic cancer is common, with various causes. Point-of-care ultrasound (POCUS) aids in identifying complications like pleural effusions, edema, and thrombosis. Its utilization is validated both inpatient and outpatient, enhancing diagnostic capabilities at the bedside.

Case Description: A 65-year-old female with active metastatic serous ovarian carcinoma of Müllerian origin presented with progressive dyspnea on exertion and lower extremity edema over one month. Her treatment history included Doxil/Bevacizumab with partial response, followed by Carboplatin/Taxol/Avastin and Niraparib with disease progression. Surgical intervention was not an option. Vital signs were significant for tachycardia. Physical examination findings included diminished lung sounds in the left base, distended abdomen, and 3+ pitting edema up to the knees bilaterally. Laboratory workup showed acute kidney injury with creatinine 2.11 mg/dL (baseline 0.9-1.0 mg/dL) that had been gradually increasing over 6 months. Urinalysis revealed >300 mg/dL protein with a urine protein-to-creatinine ratio of 1.44 g/g. CT chest ruled out pulmonary embolism but revealed a moderate to large left pleural effusion. Intravenous diuretic therapy initially improved symptoms, but renal function subsequently worsened. POCUS demonstrated a patent but collapsible inferior vena cava (IVC) and an abdominal mass compressing the IVC. MRI confirmed flattening of the IVC throughout the abdomen with slit-like narrowing at the level of renal veins, attributed to mass effect from a large left hemiabdominal mass displacing bowel loops. Creatinine stabilized at 1.9 mg/dL, and the patient was discharged with daily furosemide for symptom management and volume status optimization.

Discussion: Acute kidney injury due to metastatic mass compression of the IVC is an uncommon but important complication to consider. Compression of the IVC by an abdominal mass can contribute to renal impairment and venous congestion. POCUS is a valuable tool for assessing the IVC and identifying IVC compression, CT or MRI can provide further confirmation. In such cases, diuretic therapy should be used judiciously, with careful consideration of the patient's renal function and overall clinical status. Management of edema and venous congestion in such cases should focus on optimizing volume status and providing symptomatic relief.

FR-PO219

Severe Hypothyroidism May Contribute to AKI but Not Hyponatremia: A Case Report

Nicholas J. Carbajal, Swetha Rani Kanduri. *Ochsner Health, New Orleans, LA.*

Introduction: Hypothyroidism is commonly encountered in patients with chronic kidney disease but rarely contributes to acute kidney injury. Majority of the published cases of acute kidney injury (AKI) have associated rhabdomyolysis secondary to severe hypothyroidism. In addition, hypothyroidism work up is typically included as a standard practice in the etiology of hyponatremia. Herein, we report a severe case of hypothyroidism resulting in AKI without associated rhabdomyolysis or hyponatremia.

Case Description: An 89-year-old woman presented to emergency department with a chief complaint of left-sided hip pain following mechanical fall. Review of systems positive for fatigue and constipation. Medical history was pertinent for CKD IIIb, hypothyroidism and hypertension. Physical examination revealed persistent bradycardia (HR;30-50 bpm) and 2+ bilateral lower extremity edema. Telemetry additionally demonstrated intermittent sinuses pauses. Laboratory data at the time of admission revealed serum creatinine (Scr) of 1.8 mg/dL (baseline 1.3 mg/dL), thyroid stimulating hormone (TSH) of 298 uIU/mL, free T_4 < 0.40 ng/dL and total T_3 < 40 ng/dL, creatinine phosphokinase (CPK) was 404 U/L and serum sodium was 136 mmol/L. Urine analysis consistent with 1+protein, no blood and urine sediment notable for waxy and granular casts. Urine protein: creatinine ratio (UPCR) was 0.28 mg/dL and a kidney ultrasound was negative. Other serologies including AST, ALT, cortisol resulted negative. Upon further inquiry patient mentioned of missing several doses of levothyroxine as she ran out of several medications. Patient was started on intravenous (IV) fluid supplementation and high doses of IV levothyroxine. Meanwhile, with persistent bradycardia, a pacemaker was implanted. She had gradual resolution of her symptoms and thyroid function tests with thyroid hormone supplementation. Her Scr returned closed to baseline and she was eventually discharge on levothyroxine dose of 88 mcg daily with close follow up.

Discussion: Severe hypothyroidism can cause AKI secondary to associated cardiac conduction abnormalities and hemodynamic alteration, even in the absence of rhabdomyolysis. In addition, the traditional teaching of hypothyroidism as a cause of hyponatremia is a very rare entity.

FR-PO220

An Atypical Case of Typical Hemolytic Uremic Syndrome (HUS)

Mark N. Massoud, Gurbir S. Sehmbey, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Typical hemolytic uremic syndrome (HUS) is a rare cause of thrombotic microangiopathy in adults. Predominantly a pediatric disease, typical HUS is caused by Shiga toxin producing Escherichia Coli. We present the case of an adult with typical HUS.

Case Description: A 60 years old woman with history of type 2 Diabetes Mellitus and no kidney disease was admitted to the ICU with a 5 day history of nausea, vomiting and bloody diarrhea. Her workup revealed colitis with sepsis, AKI, and thrombocytopenia. Platelet count was 61,000/mL and plummeted to 33,000/mL during the course. Serum creatinine on admission was 2.8 mg/dL and peaked to 6.0 mg/dL with progression to anuric renal failure over 3 days. Hemoglobin dropped from 16.9 g/dL on admission to a nadir of 6.6 mg/dL over 6 days requiring RBC transfusion. Features of non immune hemolytic anemia were detected including very low haptoglobin level (<1 mg/dL), elevated LDH level of 2301 IU/L and negative Coomb's test. Peripheral smear was notable for schistocytes. DIC panel with coagulation studies and fibrinogen levels were normal. The patient received IVF resuscitation and was started on antibiotics with IV ceftriaxone and metronidazole. Shortly after admission she developed seizure and required intubation. She received hemodialysis for renal failure. The combination of MAHA, thrombocytopenia and AKI warranted consideration for TTP. ADAMTS 13 level was ordered and the patient was started empirically on plasma exchange pending ADAMTS13 level. Urine microscopy showed extensive granular casts. ADAMTS 13 came back normal (45%) and plasma exchange was discontinued. Shiga toxin-producing E Coli PCR was positive in the stools. Renal function improved and dialysis discontinued after 3 sessions. Thrombocytopenia completely resolved with improvement in anemia and a creatinine at discharge of 3.42 mg/dL.

Discussion: Typical HUS caused by shiga-like toxin producing enteric organisms is most commonly encountered in children but can affect all ages and should be suspected when a patient presents with bloody diarrhea, MAHA, thrombocytopenia, AKI and neurological symptoms. The differential should always include TTP and empiric plasma exchange should be pursued while awaiting ADAMTS 13 levels as delaying treatment for TTP could be devastating. It is important to note that AKI, especially severe, is not a prominent feature of TTP and should warrant consideration of alternative diagnosis.

FR-PO221

Oliguric AKI Developed After Toxic Ingestion of Tribulus/Drug-Induced Liver Injury (DILI)

Kevin M. Stephenoff, Ranil N. DeSilva. *UPMC, Pittsburgh, PA.*

Introduction: Liver disease is associated with multiple mechanisms of acute kidney injury (AKI). Bile cast nephropathy is a relatively rare (but potentially underdiagnosed) cause without great treatment options. Also, many non-tested supplements are available and widely used - some which may have a toxic effect on the kidneys and lead to AKI.

Case Description: A 46 year old male with AFib, bipolar disorder, and normal baseline kidney and liver function was admitted with severe cholestatic liver injury and developed an oliguric AKI. He had 5 weeks of progressive jaundice, fatigue, weight loss, and poor oral intake. Total bilirubin peaked at 48.5 mg/dl. Liver biopsy was consistent with drug induced liver injury suspected to be from a supplement obtained on Amazon called Tribulus used a "testosterone booster". Kidney function consistently worsened after admission as the patient became nearly anuric. Urine Na 62 meq/L and multiple reviews of the urine sediment showed bile casts without other granular casts. Kidney biopsy was deferred due to patient preference. Patient's mental status worsened and hemodialysis was initiated for potential uremic symptoms. Workup was initiated for potential liver transplantation. In an attempt to decrease inflammatory mediators contributing to liver disease, plasmapheresis was started which also had the effect of significantly reducing the serum bilirubin levels. Urine output drastically improved after plasmapheresis and no further hemodialysis sessions were needed as renal function recovered. Liver function also improved with supportive care.

Discussion: This case demonstrates a severe oliguric AKI in the setting of Tribulus injection and DILI with eventual recovery that was caused most likely by one of two mechanisms: 1. Direct tubular damage due to toxic drug effects or 2. Bile cast nephropathy that interesting may have resolved after plasmapheresis significantly decreased the serum bilirubin level. Further investigation into the toxic effects on renal tissue from over the counter supplements is warranted. It is unclear if the improvement in renal function was the direct results of plasmapheresis – though if the clinical findings are highly concerning for bile cast nephropathy in a severe AKI, plasmapheresis may be considered to lower serum bilirubin and potentially improve renal function when AKI is caused by bile cast nephropathy.

FR-PO222

Bartonella Endocarditis-Associated Glomerulonephritis Presenting as Acute Renal Failure

Abraham Z. Cheloff,[1,2] Shawn Wen,[1,2] Caitlin Driscoll.[1,2] *[1]New York City Health and Hospitals Bellevue, New York, NY; [2]NYU Langone Health, New York, NY.*

Introduction: Acute kidney injury (AKI) in the setting of mitral valve endocarditis is often due to cardiorenal syndrome secondary to valvular dysfunction. We report a case of acute renal failure caused by Bartonella endocarditis-associated glomerulonephritis.

Case Description: A 28-year-old man from Nicaragua with a history of mitral valve replacement presented with left arm weakness. Brain MRI revealed a subacute right parietal lobe infarct. TTE and TEE showed thickened mitral valve leaflets and a high transvalvular pressure gradient, consistent with prosthetic valve endocarditis. Empiric antibiotics were initiated. Cultures remained negative throughout admission. On hospital day (HD)13, Bartonella henselae IgG was >1:2560, and antibiotics were changed to rifampin and doxycycline. Creatinine on admission was 1.3 (baseline 0.8), and stabilized at 1.1. On HD13, the patient's Cr uptrended to 1.5. Concurrently, he developed acute hypoxemic respiratory failure with evidence of volume overload, initially thought to be cardiorenal syndrome and the patient was diuresed. Despite reaching euvolemia, his Cr continued to uptrend to 6.4. UA with moderate hematuria and proteinuria. 24-hour protein was 1.3g. FeUrea was 47%, which was less consistent with pre-renal AKI and prompted an intrinsic AKI workup. Results notable for positive ANA, low C3 and C4, and positive PR3, which led to the clinical diagnosis of infectious glomerulonephritis. Renal biopsy to confirm the diagnosis was deferred in favor of definitive treatment with mitral valve replacement. The patient's creatinine improved to 2.9 after surgery, and he was discharged with a presumed diagnosis of C3-mediated Bartonella glomerulonephritis. He continued 3 months of doxycycline and 6 weeks of rifampin and his creatinine normalized within 2 weeks of discharge.

Discussion: Acute renal failure in the setting of endocarditis can be multifactorial, and it can be challenging to determine the etiology. The concomitant development of respiratory failure, valvular dysfunction, and acute renal failure was initially compelling for cardiorenal syndrome. However, worsening renal function after achieving euvolemia, along with positive PR3, hypocomplementemia, proteinuria, and hematuria in the setting of Bartonella endocarditis was later more consistent with infectious glomerulonephritis that resolved upon definitive treatment.

FR-PO223

Ciprofloxacin-Induced Crystal Nephropathy Is a Rare Cause of Reversible AKI

Rujuta R. Patil, Yuan Huang, Michelle H. Pengshung, Kelly D. Smith, Laura Mayeda. *University of Washington, Seattle, WA.*

Introduction: Ciprofloxacin is a commonly used antibiotic that is generally well tolerated. Acute kidney injury (AKI) related to ciprofloxacin is most commonly due to allergic interstitial nephritis or acute tubular injury (ATI). Additionally, ciprofloxacin-induced crystal nephropathy has been described as a rare cause of AKI. We present two patient cases of AKI due to crystal nephropathy after exposure to ciprofloxacin.

Case Description: Case 1. A 71-year-old female with a history of hypertension, diabetes, and metastatic endometrial cancer presented with a sudden elevation in serum creatinine (Cr) to 9.26 mg/dL from her baseline of 0.9 mg/dL. She had recently received treatment for a urinary tract infection, first with nitrofurantoin and then with ciprofloxacin 500mg twice daily for 7 days for persistent dysuria. On presentation, the patient was non-oliguric, normotensive, and well appearing without symptoms. Urine pH was 5.8 on urinalysis with minimal proteinuria. Urine microscopy at the time showed white blood cells and no evidence of ATI. Kidney biopsy demonstrated ATI, with birefringent crystalline material in several tubules. The cause of AKI was determined to be ciprofloxacin-induced crystal nephropathy. The patient remained non-oliguric and AKI resolved with supportive care over the next 3 weeks. Case 2. A 77-year-old female with a history of hypertension and chronic hypokalemia initially presented with diarrhea, abdominal pain, and new ascites. After one oral dose of metronidazole and ciprofloxacin 500mg for possible diverticulitis, the patient re-presented with decreased urine output and foamy urine. During the hospitalization, Cr increased from a baseline of 0.8 mg/dL four days prior to admission to peak at 8.07 mg/dL. Kidney biopsy demonstrated widespread ATI with interspersed pigmented and polarizable crystalline material within the tubules, likely ciprofloxacin-induced crystal nephropathy. Cr improved without intervention and was 2.06 mg/dL two weeks later at hospital discharge.

Discussion: We present two cases of elderly female patients with abrupt onset AKI due to ATI with crystal nephropathy after treatment with ciprofloxacin. In both cases, the patients recovered with supportive care and dialysis was not needed. Providers should be aware of ciprofloxacin-induced crystal nephropathy as a rare cause of AKI.

FR-PO224

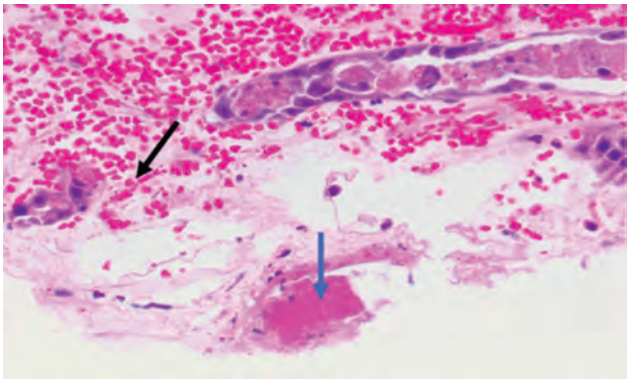
Thrombotic Microangiopathy from Chafing Fuel Intoxication

Nazanin Vaghari Mehr, Grace L. Malvar, Deepthi Gunasekaran, Shuta Ishibe, Gilbert W. Moeckel. *Yale School of Medicine, New Haven, CT.*

Introduction: Diethylene glycol (DEG) is widely used as an industrial diluent in chafing fuel, brake fluids, wallpaper strippers etc. Mass poisonings with high fatalities have been reported. Here we report a rare and unusual case of Thrombotic Microangiopathy (TMA) in a patient who ingested chafing fuel.

Case Description: A 58-year-old male with alcohol use disorder presented with five days of vomiting, diarrhea and altered mental status. His wife reported severe alcohol cravings and ingestion of hand sanitizer (isopropyl alcohol) and chafing fuel (DEG). He was anuric with creatinine of 8.2, a pH of 6.87, bicarb of 2 mmol/L, anion gap of 44 and osmolal gap of 45. Toxicology screen was negative. He was admitted to the intensive care unit for emergent hemodialysis. Hemodialysis was continued as there was no evidence of renal recovery. He then developed hypertension and thrombocytopenia. Peripheral smear was without schistocytes, LDH was elevated and haptoglobin was low. C3 was mildly decreased. C4, CH50, HIT antibody panel and ADAMTS13 activity were within normal limits. A kidney biopsy was performed on day 5 *(see figure)* which showed thrombotic microangiopathy and diffuse acute tubular injury. On day 6, he developed severe neurological defects including slurred speech, facial droop and progressive cranial neuropathies. He required mechanical ventilation for airway protection. He failed an empiric trial of steroids and expired on day 19.

Discussion: AKI in DEG toxicity is linked to high mortality rates and dialysis dependency. Typical Kidney biopsy lesions are extensive necrosis of the proximal tubule, severe interstitial hemorrhage and hyaline casts. In our case, TMA can be attributed to DEG in the absence of other causes. Vascular injury from necrotic glomeruli or direct endothelial injury from DEG are possible mechanisms. In DEG poisoning, TMA should be considered as a potential life-threatening complication.



Fibrinoid necrosis of arteriole (blue arrow). RBC fragments (black arrow).

FR-PO225

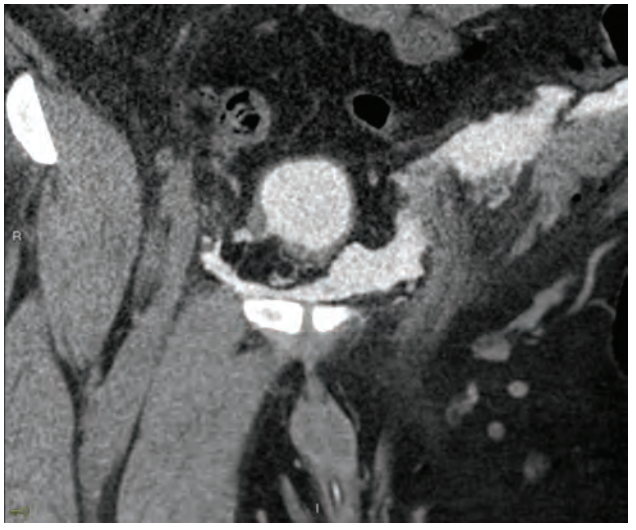
Pseudo-Renal Failure After Laparoscopic Hernia Repair

Nazanin Vaghari Mehr,[1] Susan T. Crowley.[1,2] *[1]Yale School of Medicine, New Haven, CT; [2]Veterans Health Administration, Washington, DC.*

Introduction: Bladder wall rupture cause high mortality if not diagnosed urgently. It can lead to extravasation of urine in peritoneum followed by anuria, abdominal pain, rise in serum Creatinine and be misdiagnosed as acute renal failure. We report a rare case of pseudo-renal failure in the setting of bladder wall rupture following laparoscopic repair of umbilical and bilateral inguinal hernia.

Case Description: 50 year old man with seizure disorder presented for laparoscopic repair of bilateral inguinal hernia and umbilical hernia. He was admitted for observation due to self limited seizure. Labs showed rise in creatinine of 2.4 mg/ dL. Patient developed urinary retention and required straight catheterization. Serosanguis drainage from lower surgical port site developed. His abdominal pain increased significantly and Creatinine continued to rise to 3.4 mg/dL. Nephrology was consulted for presumed acute renal failure. Patient had continued urinary retention with minimal improvement with foley placement on POD 3. Surgical port site drainage Urea and Cr were 81 and 14.2 mg/dL respectively. A CT cystogram showed bladder wall rupture and fluid extravasation to pre-peritoneal space. Serum Creatinine returned to baseline (0.9 mg/dL) immediately post bladder wall repair.

Discussion: Bladder rupture and urinary ascites can cause pseudo-renal failure in presence of normal renal function. Urinary ascites alters concentration gradient of peritoneal fluid and serum resulting in rapid increase of serum urea and creatinine while maintaining normal GFR. We suggest pseudo-renal failure consideration when suspecting urinary ascites as well as using peritoneal urea and creatinine to help diagnosis. Urgent Cystoureterogaphy is key for bladder rupture diagnosis and urgent bladder repair along with foley placement to relieve obstruction is essential to avoid further complications and rapid return of labs to baseline.



FR-PO226

Lysozyme Nephropathy: A Rare Cause of Progressive Kidney Disease

Preyas Vaidya,[1] Christopher T. Banach,[1] Kathryn E. Ussai,[1] Dominick Santoriello,[2] Sharon E. Maynard.[1] *[1]Lehigh Valley Health Network, Allentown, PA; [2]Columbia University Irving Medical Center, New York, NY.*

Introduction: A progressive decline in renal function with sub-nephrotic proteinuria in a diabetic is usually attributed to DKD. Lysozyme nephropathy is a rare cause of progressive decline in renal function with only a few underreported cases in the literature mostly in patients with hematological malignancy. AKI is seen in one-third of patients with hematological malignancy and has a negative impact.

Case Description: An 84-year-old male with stage 4 chronic kidney disease, type 2 diabetes mellitus, and chronic anemia on ESA was admitted with an upper GI bleed. He had hemorrhagic shock leading to acute tubular injury. Urinalysis showed trace protein with no RBCs on the microscopic sediment exam. A serologic workup was negative except for positive ANA and hepatitis B surface antibody, which had been previously negative. He had anemia and severe leukocytosis (WBC > 65 K/mm^3). His kidney function gradually improved over 2 weeks. Following hospital discharge, the patient was readmitted with worsening kidney function and a high anion gap metabolic acidosis. The urine sediment showed granular casts. A kidney biopsy was performed, which showed moderate (30-40%) tubulointerstitial scarring and patchy proximal tubular degenerative changes, consistent with acute and chronic tubulointerstitial nephropathy. Refractile, hypereosinophilic intracytoplasmic protein droplets were noted in the proximal tubular cells, which showed immunohistochemical reactivity for lysozyme. Immunofluorescent staining for kappa and lambda was negative.

Discussion: Lysozyme, also called muramidase, is a basic, cationic protein, primarily produced by monocytes/macrophages, salivary gland acinar cells, Paneth cells, and other cell types. Lysozyme is filtered by the glomerulus and reabsorbed by the proximal convoluted tubule where tubular injury occurs. Lysozyme nephropathy is seen with myeloid leukemias, myeloproliferative, myelodysplastic disorders, granulomatous disease, inflammatory bowel disease, and malignancy. This patient had leukocytosis with myelocytes on the smear which might have reflected underlying hematologic malignancy. A diagnostic evaluation was deferred as he was not a candidate for therapy based on age and comorbidities. Subsequently, his kidney function continued to decline. He opted for conservative management of end-stage kidney disease and hospice care.

FR-PO227

Thrombotic Microangiopathy from Metastatic Signet Ring Cell Carcinoma

Maria Christina Victoria M. Capistrano. *Tufts Medical Center, Boston, MA.*

Introduction: Thrombotic microangiopathy (TMA) as a paraneoplastic syndrome is rare and outcomes can be devastating. We present a case of TMA as an initial presentation of metastatic signet ring cell carcinoma (SRCC).

Case Description: Our patient is a 36-year-old female with a history of type 2 diabetes mellitus who presented with 3 weeks of dyspnea, cough and hemoptysis, then respiratory failure requiring intubation. Chest CT scan showed bilateral parenchymal mosaic attenuation. Her hemoglobin and platelets decreased to 7.8 g/dL and 68,000/μL, from 10.3 g/dL and 111,000/μL, respectively. Other work up include: MCV 82 fL, WBC 13,100/μL, LDH 18, 238 U/L, haptoglobin <10 mg/dL, Coomb's negative, schistocytes on peripheral smear, fibrinogen 80 mg/dL, protime 14.7 seconds, INR 1.52, aPTT 40 seconds, potassium 8.4 mmol/L, creatinine 2.61 mg/dL, bicarbonate 9 mmol/L and lactate 19.1 mmol/L. She received FFP, PRBC and platelets. ADAMST13 was sent but plasmapheresis was initiated immediately. She was anuric and required CRRT. Despite the transfusions, her hemoglobin and platelets worsened at 5.3 mg/dL and 19,000//μL. She developed diffuse mottling and critical limb ischemia. After the 3rd hospital day, she was made comfort measures only. The autopsy showed metastatic poorly differentiated colon adenocarcinoma with signet-ring cell component, with diffuse bone marrow involvement.

Discussion: The management of secondary TMA, such as DIC, pre-eclampsia, severe hypertension, are focused on the underlying cause. Metastatic carcinoma with bone marrow involvement can be an obscure differential and can prove fatal if undetected. The mechanism of how TMA occurs is not clear but there may be a role in mucin production from the signet ring cell subtype which causes endothelial cell dysfunction and thus causing thrombus formation. Bone marrow involvement generates abnormal angiogenesis that damages blood vessels and causes release of Ultra Large Von Willebrand Factor multimers, which has been implicated in the pathogenesis of MAHA. Metastatic malignancies have been misdiagnosed as TTP does not respond to plasmapheresis, had more respiratory symptoms and higher LDH. TMA as a paraneoplastic syndrome ultimately requires prompt chemotherapy and/or resection. Mucin producing tumors have been reported to present initially as TMA but by the time the diagnosis is made, it has widely metastasized and prognosis is notably poor.

FR-PO228

Metformin-Associated Lactic Acidosis: A Mimicker of Acute Mesenteric Ischemia

Nang San Hti Lar Seng,[1,2] Luis C. Despradel,[1,2] Belinda Jim.[1,2] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Introduction: Metformin-associated lactic acidosis (MALA) is a rare life-threatening complication of metformin. Metformin is renally excreted with a major precipitating factor for MALA being acute kidney injury (AKI). The clinical presentation of MALA is similar to that of acute mesenteric ischemia though imaging is usually negative. Here we present a case of MALA masquerading as acute mesenteric ischemia and intra-abdominal sepsis.

Case Description: A 52-year-old female with a history of HTN, Type 2 DM on metformin, CKD of unclear baseline presented with vomiting, poor oral intake, and abdominal pain for 2 days with finger-stick glucose of 35 mg/dL. She denied fever, chills, urinary symptoms, diarrhea, or overdose of metformin. Her initial vitals were T 95.6 degree Fahrenheit, BP 171/96, HR 91, RR 16, and SpO2 100% on room air. The physical examination showed only dry oral mucosa. Laboratory values were significant for potassium 6.8 mEq/L, serum creatinine 7.9 mg/dL, blood urea nitrogen 61 mEq/L, glucose 49 mg/dL, bicarbonate 5.0 mEq/L, anion gap 45.9 mEq/L, venous blood gas with pH 7.0, PCO2 21 mmHg, lactate >17 mmol/L, white blood cell 17.7/nL. CT of the abdomen showed thickened small bowel loops and a questionable single loop of small bowel with pneumatosis. The patient was admitted for sepsis in the setting of presumed ischemic bowel. However, the surgery service discounted this diagnosis as they felt that there was no pneumatosis upon their review and that the thickened loops of bowel can be due to enteritis. She was empirically treated with intravenous piperacillin/tazobactam. Given AKI and severe lactic acidosis, a metformin level was sent. The patient was treated with 2 sessions of hemodialysis. When blood and urine cultures returned negative, antibiotics were discontinued. Her renal function improved to a serum creatinine of 1.6 mg/dL 2 weeks later, at which time the metformin level returned to be elevated at 27 mcg/ml (therapeutic level 1-2 mcg/ml).

Discussion: Our case highlights that MALA can be confused with ischemic bowel on clinical presentation with abdominal pain, lactic acidemia and suggestive CT findings of pneumatosis intestinalis. Thus, high clinical suspicion and prompt treatment with renal replacement therapy is needed to avoid unnecessary surgery even without resulted metformin levels.

FR-PO229

Severe Hypothyroidism Presenting as Rhabdomyolysis and Acute Tubular Necrosis

Sameen Aamer, Muhammad Ali Butt, Brandon T. Dunmyre. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Hypothyroidism often manifests with a broad range of muscular symptoms: cramping, generalized weakness, and diffuse myalgias. Rhabdomyolysis is a rare manifestation of severe hypothyroidism resulting in profound acute tubular necrosis

via myoglobin induced renal vasoconstriction, proximal tubule necrosis, and distal tubular obstruction. We present a case of acute tubular necrosis caused by rhabdomyolysis secondary to severe hypothyroidism.

Case Description: A 62-year-old female with past medical history of coronary artery disease, type II diabetes mellitus and hypothyroidism presented with fatigue, shortness of breath, fifteen pound weight gain and decreased appetite for a month. She reported myalgias and non-compliance with oral synthroid for seven months. Vital signs revealed normothermia without bradycardia. Physical exam was unremarkable. Laboratory work revealed elevated creatinine kinase (CK) 59,952 U/L, creatinine 6.37 mg/dL (baseline 0.8-1), very low free T4 <0.1 and very high TSH >1000. Urinalysis was positive for blood with minimal red blood cells, and urine sediment revealed granular casts. Treatment with intravenous fluids and synthroid significantly improved the TSH (75.9 mIU/L) and CK (10,791 U/L) on admission day ten. Renal function slowly improved over the hospitalization course with serum creatinine trend 6.37 mg/dL to 3.8 mg/dL on discharge with concurrent non-oliguric urine output. She was discharged home with oral thyroid hormone replacement therapy. She demonstrated complete renal recovery on outpatient follow up with serum creatinine 0.72 mg/dL, normal CK levels 31 U/L and thyroid function panel (TSH 0.97, free T4 1.5).

Discussion: The precise mechanism of hypothyroidism-induced rhabdomyolysis is unclear, however, it is thought to be related to impaired glycogenolysis or mitochondrial oxidation. This case is unique as there are no previously reported instances of patient sustaining such severe hypothyroidism-induced rhabdomyolysis (serum CK 400x upper limit of normal), and ATN in the absence of underlying chronic kidney disease. Therefore, prompt diagnosis, identification of causative factor, and timely treatment are crucial to prevent long-lasting renal injury in this disease. It also emphasizes medication compliance, patient education, and considering hypothyroidism in the differential diagnosis of rhabdomyolysis for improved patient outcomes.

FR-PO230

Oxalate Nephropathy: A Studded Case of AKI

Sissmol Davis,[1] Deep Phachu,[2] Jessica L. Hata,[3] Astrid Weins,[3] Ashish Verma,[2] Hemant Magoo.[2] *[1]JJM Medical College, Davangere, India; [2]Central Mass Nephrology, Worcester, MA; [3]Brigham and Women's Hospital, Boston, MA.*

Introduction: Oxalate nephropathy (ON) is a rare manifestation of hyperoxaluria which can present as acute kidney injury (AKI) with the possibility of rapid progression to end stage kidney disease. We present a case of AKI with ON on biopsy.

Case Description: A 64-year-old male with obesity, type 2 diabetes mellitus and hypertension presented with nausea and unsteady gait. He has AKI with a serum creatinine (Cr) of 9.4 mg/dL on admission with a baseline Cr of 0.8 mg/dL 3 months prior. Clinical history did not reveal a cause for AKI. Urine studies showed the occasional granular cast but no dysmorphic RBCs, proteinuria or pyuria. Serological workup including antinuclear antibody, anti-neutrophilic cytoplasmic antibody, and serum monoclonal testing were unremarkable. He underwent kidney biopsy due to inadequate improvement of renal function with intravenous fluids. Kidney biopsy (Figure 1) showed widespread calcium oxalate deposition in the tubules (renal oxalosis) with associated mild acute tubular injury and mild interstitial nephritis. Genetic testing did not show a known mutation associated with Primary Hyperoxaluria.

Discussion: Primary Hyperoxaluria is due to a genetic defect leading to abnormal oxalate handling. Secondary Hyperoxaluria (SH) occurs due to excessive dietary oxalate intake and/or gastrointestinal disorders that increase absorption of oxalate or oxalate precursors, such as inflammatory bowel disease. Both diabetes mellitus (DM) and obesity have also been associated with increased urinary oxalate excretion. We assume that our patient suffered from SH with both obesity and DM playing a role. Although significantly less common than other causes of acute kidney injury, ON should be included in the differential for AKI of unclear etiology, especially in patients with concurrent DM and obesity.

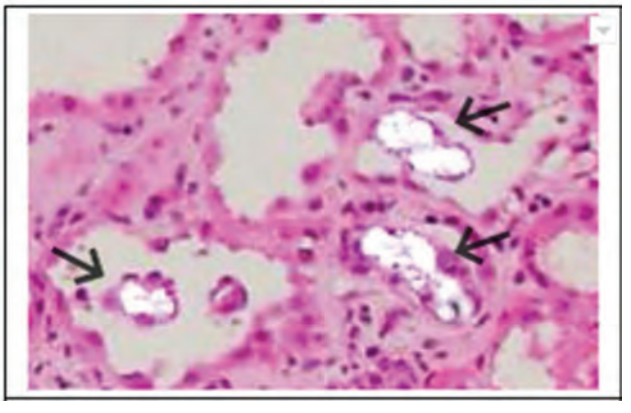


Figure 1: Widespread calcium oxalate deposition within the renal tubules under polarized light (arrows).

FR-PO231

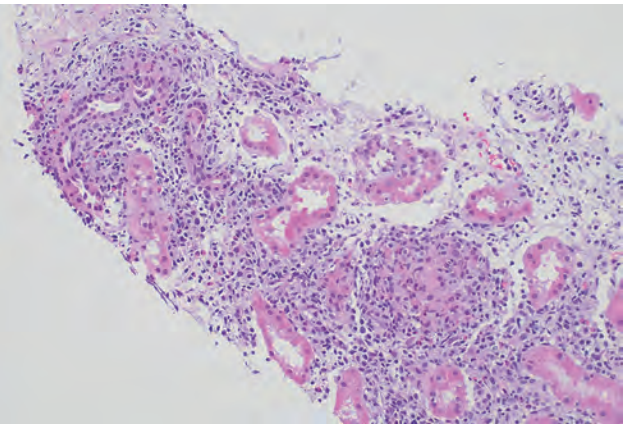
Say "No" to the DRESS (Drug Reaction with Eosinophilia and Systemic Symptoms)

Hannah R. Miller, Tyler Sims, Sam Beavin. *University of Kentucky College of Medicine, Lexington, KY.*

Introduction: Healthy 25-year-old with rash due to DRESS and acute kidney failure due to granulomatous acute interstitial nephritis in the setting of EBV and RSMF infection.

Case Description: A 25-year-old woman with history of paroxysmal SVT and migraines was seen outpatient and treated with amoxicillin/clavulanic acid for suspected bacterial pharyngitis with lymphadenopathy. Four days later, she developed a pruritic rash on hands and shins that spread diffusely. Hospital workup showed positive IgM titers for Rocky Mountain Spotted Fever and IgG titers for Ebstein-Barr Virus. Patient started on topical steroids and doxycycline for suspected RMSF. She then developed flu-like symptoms and oliguria with severe kidney failure. Kidney function worsened to a peak creatinine of 11.71 mg/dL. Kidney US demonstrated increased parenchymal echogenicity, and UA was unremarkable. Hospital day 4 kidney biopsy showed severe tubular interstitial nephritis with substantial eosinophils in interstitium and formulation of granulomas. She was treated with IV methylprednisolone for 3 days and then switched to oral prednisone with significant improvement in kidney function.

Discussion: This case revealed the rare pathological finding of granulomatous tubulointerstial nephritis on kidney biopsy and rapid improvement of kidney function with high dose steroids. The presentation was mostly likely due to DRESS from the amoxicillin with associated AIN. Cases of AIN with granulomatous inflammation are not common and account for < 1% of all kidney biopsy findings (1). Most often this pattern is associated with antibiotics, NSAIDS and diseases such as sarcoidosis, TB, fungal infections and GPA (Shah S. 2015). Glucocorticoids were the treatment of choice as patient achieved resolution of both her DRESS and acute kidney failure with avoidance of dialysis.



Kidney Biopsy at 20X Magnification

FR-PO232

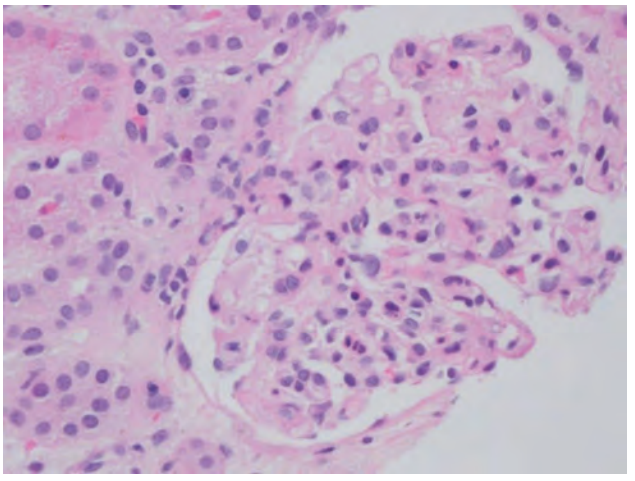
Infection-Related Glomerulonephritis

Dominik Thomas, Monica P. Revelo Penafiel, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Infection-related (IE) glomerulonephritis (GN) can be associated with viral or bacterial infections and vary from asymptomatic microscopic hematuria to rapidly progressive GN with acute kidney injury requiring emergent dialysis. This patient presents with months of nonspecific symptoms and developed rapidly worsening renal function. He was ultimately found to have bacterial endocarditis.

Case Description: 50 year old male presented with progressive functional decline, cough, and unintentional weight loss in the setting of pancytopenia for 6 months and worsening creatinine (Cr) and hematuria over the preceding two weeks. He saw hematology and underwent imaging and bone biopsy with negative results. Serum Cr on admission was 2.75mg/dl but two weeks prior was 0.73 md/dl. UA showed 50-100 RBCs and urine microscopy revealed numerous dysmorphic RBCs. Urine protein to creatine ratio was 2974 mg/g (15-68mg/g). Renal biopsy showed endocapillary proliferative GN with dominant C3 deposits, a fibro-cellular crescent and patchy mixed interstitial inflammatory infiltrate with focal acute tubular injury. Infectious workup resulted in positive blood cultures for streptococcus mutans. He was started on Ceftriaxone. Transesophageal echocardiogram showed mobile mass on the posterior leaflet measuring 1.2 x 0.3 cm. He underwent mitral valve replacement. Cr trended down to 0.75 mg/dl along with improving proteinuria and hematuria.

Discussion: Sub acute bacterial endocarditis can present with non specific symptoms delaying diangosis. Treatment of IE-associated GN includes antibiotics and sometimes valve replacement. Control of the infection may not always be associated with a favorable outcome. One case series shows 21 percent of patients died; of the surviving patients, 10 percent progressed to end-stage kidney disease, 37 percent had persistent kidney function impairment, and only 32 percent had complete kidney recovery. Early recognition and prompt treatment is crucial for recovery.



H&E stain

FR-PO233

Pneumocystis jirovecii Pneumonia-Induced Hypercalcemia

Dominik Thomas, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: A growing number of case reports demonstrate the relationship between non-parathyroid mediated hypercalcemia preceding or occurring in conjunction with a diagnosis of Pneumocystis jirovecii pneumonia (PJP). Most cases described in literature occur in kidney transplant patients. We present a patient with heart transplant with nonspecific symptoms, acute kidney injury and hypercalcemia.

Case Description: 63 year old female with history of breast cancer status post chemoradiation with anthracycline induced cardiomyopathy requiring orthotopic heart transplant two years earlier presented with fever, chills, weight loss and fatigue for two months. She reported in addition a dry cough with increasing shortness of breath. She presented with a serum creatinine (SCr) of 5.23mg/dl, up from a baseline of 2.2 mg/dl. Creatinine improved to 4.1mg/dl after intravenous hydration. Admission urinalysis unremarkable. Renal US was with increased bilateral echogenicity. Serum Calcium was 12.9 mg/dl on admission with PTH of 7 pmg/ML (15-65 pmg/mL) and 1,25 Vitamin D of 87pg/mL. (19.9-79.3 pg/mL). CT chest demonstrated patchy ground glass opacities throughout the lungs. Infectious work up revealed Beta-D-Glucan >500. A bronchoscopy with BAL was performed and returned positive for PJP on PCR. She was started on atovaquone with improvement in symptoms. Cr trended down to baseline with resolution of hypercalcemia.

Discussion: Hypercalcemia related to PJP is thought to be associated via 1α-hydroxylase enzyme-dependent mechanism causing extra-renal production of 1α-hydroxylase. Some reports of PJP revealed the presence of inflammatory granulomas rich in macrophages and monocytes that are capable of vitamin D activation and thereby inducing hypercalcemia. The majority of cases are described in kidney transplant recipients possibly suggesting a susceptibility in these patients for developing PJP-related hypercalcemia but PJP can occur with any solid organ transplant.

FR-PO234

Unresolving AKI Diagnosed as a Case of Tubulo-Interstitial Nephritis with Uveitis Syndrome

Pabitra Adhikari, Raj Devani, Prithul Koirala. *Ascension Saint Francis, Evanston, IL.*

Introduction: Tubulo-interstitial nephritis and uveitis (TINU) is a very rare condition and till now around 250 cases have been reported so far. The pathogenesis of TINU syndrome remains unclear. Patients usually present with non-specific symptoms like nausea, vomiting and the ocular symptoms of uveitis might not always coincide with the diagnosis of acute kidney injury (AKI). The diagnosis can be easily missed with the clinical picture overlapping with prerenal etiology of AKI.

Case Description: We report a case of a 67-year-old female with a past medical history of diabetes mellitus, hyperlipidemia, hypertension, Grave's disease status post ablation presenting with nausea and vomiting for a few days. She was found to have acute kidney injury (AKI) with creatinine level of 2.06 mg/dl and was initially treated with intravenous fluids (IVF) as it was presumed to be prerenal with vomiting. However, the AKI did not improve with IVF and. Initial laboratory work ups were unremarkable to determine the etiology of AKI. Complete blood count showed a slightly raised eosinophil percentage of 5.7% (reference range less than 5%). Urinalysis demonstrated red blood cells (RBCs) of 6-10/ high power field (hpf) and glycosuria. On the third day of hospitalization, the patient had bilateral eye pain, redness and blurring of vision which was diagnosed as bilateral uveitis with posterior vitreous detachment. On further investigation, the patient had elevated urine Beta 2 Microglobulin of 3,704 ug/L (reference range 0-300 ug/L) and subsequent renal biopsy revealed tubulo-interstitial nephritis and diabetic glomerulopathy Class 2A thus confirming the diagnosis. Ocular symptoms improved with topical steroids and renal function continued to platue for few weeks. Patient did not require systemic steroids. On regular oupatient follow up renal fuction continued to improve but did not reach the baseline.

Discussion: TINU syndrome is a diagnosis of exclusion and can not be diagnosed by a single test. All the patients with suspected TINU syndrome do not undergo renal biopsy as kidney function usually improves with supportive treatment. Elevated urinary beta-2 microglobulin level is associated with TINU syndrome. Some severe cases might need systemic steroid therapy. It requires very high index of suspicion for timely diagnosis and management to prevent long term complications.

FR-PO235

Olaparib Associated AKI: Real or Fake?

Tyler W. Clay, Madeline Kirby, Negiin Pourafshar. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Olaparib is a chemotherapy drug used in the treatment of metastatic ovarian and breast cancer. Olaparib, an inhibitor of human Poly-(ADP-ribose)-polymerase (PARP), is the first PARPi approved for the treatment of metastatic ovarian cancer. Olaparib has been associated with increases in serum creatinine thought to be due to a non-pathologic mechanism. As the renal function of oncology patients can affect their course of care, distinguishing pathologic kidney injury from non-pathologic laboratory changes is important.

Case Description: A 61-year-old woman with non-insulin dependent type II diabetes and hypertension was receiving chemotherapy for metastatic ovarian cancer with carcinomatosis. Baseline creatinine was 0.8 mg/dl with eGFR 67 ml/min. She received paclitaxel and then was started on Olaparib. Her creatinine rose over the course of several months to a peak of 2.0 mg/dl and eGFR of 28 ml/min. Urinalysis was negative. Urine protein-creatinine ratio was 55 mg/gm. Renal imaging was negative. Subsequent serum cystatin C was normal at 1.11 mg/l and eGFR of 63ml/min. This suggested Olaparib caused a non-pathologic increase in serum creatinine. Patient continued therapy and future kidney function evaluation used cystatin C.

Discussion: This case showcases the importance of distinguishing between pathologic and non-pathologic increases in serum creatinine in cancer patients. As kidney damage can alter the pharmacodynamics of chemotherapy drugs and alter the available pharmacologic options for individuals undergoing cancer treatment, determining the cause of alterations in serum creatinine is critical. Olaparib's effect on serum creatinine is thought to be due to interactions with creatinine secreting transporter proteins on the apical membrane of the proximal tubule. Interactions with these transporters can falsely increase the serum creatinine without intrinsically altering renal function. Cystatin C is freely filtered by the glomerulus without utilizing transporter proteins, therefore it is not affected by the use of Olaparib. A recent case series showed a 14% increase in creatinine in 66 patients receiving Olaparib without significant changes in cystatin-C measurements. In this patient with sustained elevation in creatinine but normal cystatin C following Olaparib treatment, the likely mechanism of an elevated creatinine was non-pathologic effects of Olaparib.

FR-PO236

Kidney Replacement Therapy and Death in Patients with Hyperuricemic AKI Treated with Rasburicase

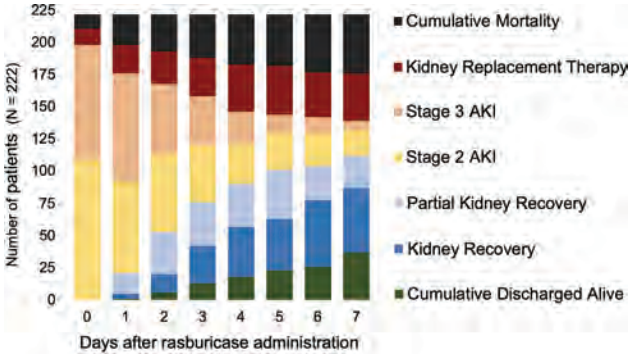
Robert M. Hayden,[1] Rafia W. Ali,[1] Ritu Seethapathy,[2] Ian A. Strohbehn,[2] Shruti Gupta,[1] Meghan E. Sise,[2] David E. Leaf.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Massachusetts General Hospital, Boston, MA.*

Background: Rasburicase is highly effective at rapidly lowering plasma uric acid levels in patients with cancer who develop tumor lysis syndrome and is the standard-of-care for preventing hyperuricemic AKI in this setting. However, few studies have examined the clinical outcomes of rasburicase-treated patients who already had AKI at the time of rasburicase receipt.

Methods: In this multicenter cohort study involving seven hospitals within the Mass General Brigham health care system (Boston, MA), we identified 222 adult inpatients from 2015-2020 with hyperuricemia (uric acid ≥8.0 mg/dL), active malignancy, and moderate-to-severe AKI (KDIGO stage 2 or 3) at the time of rasburicase administration. The primary outcome was kidney replacement therapy or death (KRT/death) within 7 days following rasburicase receipt. We used multivariable logistic regression to identify independent risk factors for KRT/death.

Results: A total of 83 of 222 patients (37%) progressed to KRT/death, 27 (12%) had persistent stage 2 or 3 AKI, 75 (34%) had partial or full kidney recovery, and 37 (17%) were discharged alive by day 7 (**Figure**). Independent risk factors for KRT/death were AKI stage 3 (odds ratio [OR] 2.11 [95% CI, 1.13-3.93]), admission to an ICU (OR 4.12 [95% CI, 1.94-8.74]), and elevated blood lactate (OR 5.10 [95% CI, 2.0-12.98] and 2.07 [95% CI, 1.05-4.10]) for lactate >5.0 and 1.3-5.0 mmol/L, respectively. The incidence of KRT/death ranged from 11% among patients with no risk factors to 81% among those with multiple risk factors.

Conclusions: Short-term clinical outcomes are poor among patients with cancer and hyperuricemic AKI treated with rasburicase, particularly among those with severe AKI, elevated blood lactate, and in the ICU. Additional data are needed to assess the efficacy of rasburicase in improving clinical outcomes in patients who already have AKI at the time of its administration.



Outcomes

FR-PO237

Incidence of AKI with Immune Checkpoint Inhibitors: A Five-Year Retrospective Review

Blathnaid O'Connell, Catherine M. Brown. *University Hospital Waterford, Waterford, Ireland.*

Background: Immune checkpoint inhibitors (ICPIs) are one of the most commonly prescribed cancer treatments. ICPIs prolong overall & progression-free survival in patients with a wide range of malignancies, but also cause AKIs. This can lead to dose delays, discontinuation of therapy, and prolonged courses of immunosuppression. The reported rate of ICPI-AKI is variable, ranging from 3%-7%. Use of ICPIs has increased significantly in recent years. The aim of this study was to describe the incidence & stages AKI associated with ICPIs, over a 5 year period.

Methods: Patients receiving ICPIs between 2016-2021 in University Hospital Waterford (UHW), were identified using the UHW oncology database. Data were then linked to our institutional electronic patient record to obtain laboratory data and kidney biopsy results. Medical charts were reviewed to obtain data on concurrent medications and treatment received for ICPI-AKIs. AKI was defined as per the KDIGO criteria.

Results: 202 patients commenced ICPIs, with a mean age of 69 & a male preponderance (1.6:1). 20.3% of patients experienced an AKI, & of those, 19.5% had eosinophilia. The incidence of AKI & eosinophilia differed by agent. AKI rates differed by agent; Pembrolizumab 21.2%, Nivolumab 20.9%, atezolizumab 10.8%, durvalumab 33.3% & ipilimumab 33.3%. Anti-CTL4 ICPIs had a higher rate of AKI compared to PD-1 ICPIs at 25% & 21%. 83% had a stage 1 AKI, 7% had a stage 2 AKI & 10% had a stage 3 AKI. Stages differed by agent. 71.4% with a stage 2 or 3 AKI received steroids, & 1 patient received infliximab. Only 1 patient had a renal biopsy, reporting ATN. The average time to develop an AKI was 85.7 days (ranging 7 to 314 days).

Conclusions: This demonstrates a considerable burden of AKI in patients on ICPIs. Incidence of AKI in our cohort is higher than previously reported, at 20.3%, but the majority were stage 1. Only 1 patient underwent a biopsy. Previously, biopsies were the standard of care, however current ASCO guidelines recommend empiric treatment. A high index of suspicion should be maintained throughout duration of treatment, even in patients established on ICPIs, due to the variation in time to develop an AKI after treatment initiation. The use of ICPIs is increasing & it is important to monitor for renal toxicity. Close monitoring of renal function, early recognition & management of AKI can prevent long-term renal damage and improve outcomes.

FR-PO238

AKI and Acute Kidney Disease After Radical Cystectomy for Muscle-Invasive Bladder Cancer: Two Underestimated but Dangerous Threats

Francesco Trevisani,[1] Mattia Longoni,[1] Alessandra Cinque,[2] Matteo Floris,[3] Andrea Salonia,[1] Francesco Montorsi.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Biorek srl, Milan, Italy; [3]Azienda Ospedaliera Brotzu, Cagliari, Italy.*

Background: Radical cystectomy (RC) represents the first line surgical treatment for muscle-invasive bladder cancer (MIBC), a worldwide increasing malignant neoplasm. However, RC represents the most complex and invasive surgery in urology, characterized by significant morbidity and mortality. Among RC patients, the incidence of post-operative acute kidney injury (AKI) and Acute kidney disease (AKD) is still not clear, due to the paucity of data. Aim of the study was to evaluate the incidence of AKI and AKD after RC.

Methods: A consecutive cohort of 839 patients who underwent RC for MIBC in a tertiary institution between 2010 and 2022 was collected. All clinical variables, comorbidities, surgeries techniques and oncological regimen were reported pre and after surgery. Serum creatinine and eGFR using CKD-EPI formula were collected at baseline pre-operative and in the acute setting at 24h, 48, 72h, 6 days for the AKI onset, and after 9,12,15,18,21,24,27,30,45, 60, 75, 90 days for the AKD establishment. Fisher's exact test; Wilcoxon rank sum test; Pearson's Chi-squared test were used for the statistical analysis.

Results: General characteristics of patients included in the study are summarized in Table 1. Surprisingly, a very high rate of both AKI (30%) and AKD (50%) was reported in the total cohort of patients, with an augmented incidence in the elder pts, low pre-operative eGFR, pre-existing CKD, BMI > 24, robotic surgery and hypertensive pts in the multivariate analysis (table 2). Moreover, stage II and III of both AKI and AKD affected a non-negligible percentage of patients, requiring advanced nephrological medical treatments and prolonged hospitalization.

Conclusions: AKI and AKD are very common but hidden side effects in the RC for MIBC. Therefore, a personalized nephrological counseling both in the pre and post -surgery asset is necessary to reduce morbidity and mortality.

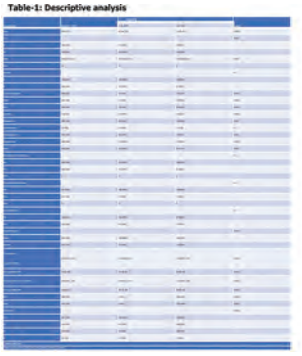


Table-1: Descriptive analysis

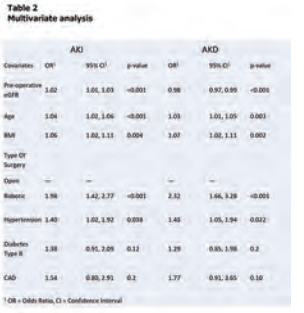

Table 2

GFR in the Era of Precision Medicine: A Face to Face Between Measured GFR (mGFR) and Estimated GFR (eGFR) in Onconephrology

Francesco Trevisani,[1] Giulia Quattrini,[1] Alessandra Cinque,[2] Umberto Capitanio,[1] Fabiana Laurenti,[3] Andrea Salonia,[1] Arianna Bettiga,[1] Giorgio Pizzagalli,[1] Francesco Montorsi,[1] Federico Di Marco.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Biorek srl, Milan, Italy; [3]Universita degli Studi dell'Aquila - Polo Coppito, L'Aquila, Italy.*

Background: Onco-nephrological patients deserve the highest attention in term of personalized medicine. Acute and chronic renal damages represent common major side effects, often as a results of drugs renal toxicities due to false dosage based on GFR. Therefore, a reliable assessment of renal function is mandatory. Aim of this study was to determine the extent of the error of eGFR common formulas compared to mGFR in onco-nephrology.

Methods: A consecutive cohort of 701 onco-nephrological patients (pts) was collected to compare the most used eGFR formulas (MDRD, CKD-EPI SCr 2012, CKD-EPI 2021 SCr, CKD-EPI Cys 2012, CKD-EPI Cys 2021, CKD-EPI Cys/SCr, Cockroft-Gault) with mGFR method (Iohexol Plasma Clearance). True positives and False positives were classified in CKD stages based on eGFR and mGFR. Comparisons between groups were performed using Wilcoxon ranks sum test for numerical variables and Pearson's Chi square test for categorical ones.

Results: Clinical data: overall median age was 66 years, median BMI 25, Male: 536, F: 165, Diabetes: 10.9%, Hypertension: 53.8%, CKD stage I: 3.7%, II: 25.5%, IIIA: 28%, IIIB: 27.5%, IV: 13.4%, V: 1.74%, mean Creatinine: 1,44 mg/dl, cystatin: 1,24. We reported a huge discrepancy between the eGFR formulas and mGFR values, suggesting the essential role of mGFR in the clinical decision making algorithm (Figures 1 and 2).

Conclusions: eGFR formulas showed a non-negligible error in all CKD stages classification in comparison to mGFR. In the onconephrological asset, the use of mGFR should be mandatory to obtain a tailored management.

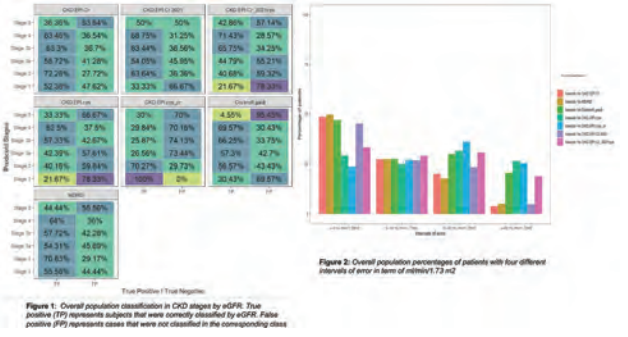

Figure 1: Overall population classification in CKD stages by eGFR. True positive (TP) represents subjects that were correctly classified by eGFR. False positive (FP) represents cases that were not classified in the corresponding class

Figure 2: Overall population percentages of patients with four different intervals of error in term of ml/min/1.73 m2

FR-PO240

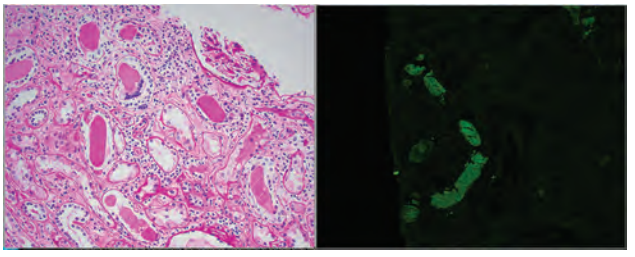
Myeloma Cast Nephropathy in an HIV Patient with AKI

Christian Nehme, Mrinalini Sarkar. *University of California Los Angeles, Los Angeles, CA.*

Introduction: HIV is associated with a multitude of renal pathologies that can involve the glomeruli, tubule, and interstitium. HIV is rarely associated with monoclonal gammopathy. We present a case of myeloma cast nephropathy in an HIV patient presenting with an AKI.

Case Description: 58-year-old male patient with a past medical history of well controlled HIV and CKD with a baseline creatinine of 1.3 mg/dL presented to the hospital with abnormal labs. His creatinine was 7.1 mg/dL. Hemoglobin was 7.1 g/dL. Patient reported generalized weakness of 2 weeks duration. On presentation, patient's vital signs and physical exam were unremarkable. Repeat labs revealed a BUN of 61 mg/dL, creatinine of 6.9 mg/dL, and hemoglobin of 6.7 g/dL. Patient received IV hydration in the ER with no significant improvement in creatinine and was admitted for further workup. Workup included SPEP which showed a monoclonal band in the gamma region; 9.2 g/dL. IgG was 10703 mg/dL and serum free kappa/lambda was 733.43. Renal biopsy showed light chain cast nephropathy, kappa light chain type in addition to minimal global glomerulosclerosis, mild interstitial fibrosis and mild to moderate arteriosclerosis. Multiple myeloma was suspected and was confirmed on bone biopsy which showed myeloma with kappa-restricted plasma cells, involving 80-90% of cellularity. Patient was started on daratumumab/bortezomib/dexamethasone for treatment of multiple myeloma. Over a month, his creatinine has steadily decreased down to 2.6 mg/dL.

Discussion: HIV can commonly cause focal segmental glomerulosclerosis, collapsing variant. It is also known to cause pan-nephropathy including glomerular, interstitial, and tubular pathology. HIV can also be associated with polyclonal hypergammaglobulinemia though monoclonal gammopathy and myeloma cast nephropathy are rare. Treating the underlying multiple myeloma can help improve kidney disease. Clinicians should have a broad differential for AKI, including multiple myeloma, in HIV patients especially if they present with anemia as treating the underlying etiology is essential in treating the kidney disease.



Atypical casts on light microscopy and Kappa light chain on immunofluorescence

Onconephrology and AKI: A University Hospital Experience

Andrea C. Valenca, Alline Oliveira, Joseph L. Nascimento, Thiago M. Lacerda, Klebson F. Feijo de Melo, Italo R. Alves, Ana Paula Gueiros. *Hospital das Clinicas, Recife, Brazil.*

Background: Acute kidney injury (AKI) is prevalent in cancer patients and associated with poor outcomes. The aim of this study was to assess the clinical profile and outcomes of patients with cancer and AKI followed up in our onconephrology department.

Methods: This was a cross-sectional, retrospective study. The medical records of AKI patients were reviewed from January 2018-December 2022. AKI was diagnosed according to KDIGO. COVID-19 patients were excluded.

Results: We assessed 340 patients, 50% were male, with a median age of 62 years. The mean follow-up was 15 days. Seventy-eight percent of the patients presented with a solid tumor. The main associated cancers were: digestive tract (27.6%), cervix (15.3%) and lymphoma (12.4%). Comorbidities: hypertension (50%), diabetes mellitus (25%), and chronic kidney disease (24%). Around a third of patients were in ICU and 34% had sepsis. The AKI types were: intrinsic renal (38%), prerenal (31%) and obstructive (27%). Most patients (72%) were non-oliguric. Laboratory tests: creatinine (Cr mg/dL) on admission (CrA) 1.6 and Cr at the first nephrology visit (CrN) 2.7. Hyponatremia (sodium <135 mg/dL) was observed in 53% of patients. The median level of hemoglobin was 8.9 g/dL and albumin 2.9 g/dL. Renal replacement therapy (RRT) was required for 37% of patients. Patients on RRT differed from those who did not, by age (59 x 64; p=0.006), being in ICU (64 x 40; p<0.001), CrA (2.25 x 1.57; p=0.002), CrN (3.7 x 2.5 ; p<0.001), sepsis (50% x 24%; p<0.001), urine output (mL) (405 x 1300; p <0.001), sodium (133 x 135; p=0.034), potassium (mg/dL) (4.8 x 4.5; p= 0.008) and phosphorus (mg/dL) (4.6 x 3.9; p<0.001). In the multivariate analysis, CrN was the only independent risk for RRT (OR 12.6, CI 2.77 – 113; p=0.005). Thirty-five percent of patients died, and mortality was higher in those who underwent RRT (56% vs. 22%, p<0.001). Only 26% of patients fully recovered and 4% remained on RRT.

Conclusions: AKI in cancer patients is associated with high mortality. The clinical profile of cancer patients is unfavorable, with a high prevalence of hyponatremia, anemia and malnutrition. A late referral to a nephrologist is associated with higher rate of RTT and a poor prognosis.

FR-PO242

Impact of Race on Renal Recovery in Patients with New Diagnosis of Multiple Myeloma and AKI Requiring Dialysis

Swetha Rani Kanduri, Devang B. Patel, Prarthana Somaiah, Natalia R. Nombera, Ambuga Badari, Juan Carlos Q. Velez. *Ochsner Medical Center, New Orleans, LA.*

Background: Renal involvement is reported in about 20-50% of the patients with multiple myeloma. Although renal recovery is associated with improved survival, it is unclear whether a disparity exists among Black and White races with new diagnosis multiple myeloma (NDMM) and renal recovery. Additionally, factors associated with the probability of renal recovery are not clearly understood.

Methods: A retrospective review of medical records was conducted searching for cases of NDMM with acute kidney injury (AKI) needing renal replacement therapy (RRT) at Ochsner Medical Center over a 10-year period. Patients with relapses were excluded. We aimed to identify number of patients achieving RRT independence by race, mean time to renal recovery by race, and factors associated with RRT independence for the entire cohort.

Results: A total of 54 patients (27 Black and 27 White) were included. The mean age was 63 years, 63% males. Six (11%) had overt albuminuria. RRT independence was achieved in 9/27 (33%) Blacks and 6/27 (22%) Whites. Among those who recovered, 3/9 (33%) Blacks were alive at last follow-up compared to 5/6 (83%) Whites *(p=0.06)*. The mean time to renal recovery was 33 vs. 22 days in Blacks and Whites respectively (*p=0.48*). The mean *kappa* value before RRT initiation was 310 mg/dL for those who recovered vs 1024 mg/dL for those who did not (*p=0.015*), whereas the mean *lambda* value was 383 mg/dL in those who recovered vs 755 mg/dL in those who did not *(p=0.09*). Other variables, serum creatinine (*p=0.90*), urine protein/creatinine (*p=0.42*), LDH (*p=0.45*) B_2-microglobulin (*p=0.48*) were not different between groups. High risk cytogenetics {t(4:14), t(4:16), t(14,20), gain (1q21), del (1p), del (17p)} were reported in 3/15 (20%) in recovered vs 11/39 (28%) non-recovered (*p=0.55*)

Conclusions: A trend for better survival off RRT was observed in White patients with NDMM. However, limited number of patients with RRT recovery limited the analysis. Otherwise, no difference in renal recovery was observed between Black and White patients. In addition, high *kappa* light chain burden was associated with lower probability of renal recovery. Further studies are needed to expand upon these observations.

FR-PO243

Immobilization-Associated Hypercalcemia in Patients with Malignancy in the Hospital Setting: A Cohort Study

Swetha Rani Kanduri, Ana I. Stark, Alexander M. Smith, Walter Lam, Juan Carlos Q. Velez. *Ochsner Medical Center, New Orleans, LA.*

Background: Malignancy-associated hypercalcemia (MAH) is not uncommon in patients with cancer. Direct bone invasion (primary bone cancer, bone metastasis, multiple myeloma) and humoral hypercalcemia (elevated PTH, PTH-related peptide (PTHrP) and calcitriol) are the predominant etiologies. Although a significant proportion of patients with malignancy have poor functional status, immobilization-associated hypercalcemia (Immob-HCa) is not well recognized in this population. We examined the relative contribution of Immob-HCa to all causes of MAH in the hospital setting.

Methods: A retrospective review of medical records was conducted searching for cases of MAH over a 3-year period. Hypercalcemia was defined as serum calcium >11.0 mg/dL. *Definite* Immob-HCa was defined as presence of immobility >1 week prior to admission or ECOG score >4, needing complete assistance, combined with absence of disqualifying laboratory data (PTH >60 ng/dL, 1,25 vitamin D >70 pg/mL, 25 vitamin D >80 ng/mL, PTHrP >2.5 pmol/L) monoclonal gammopathy, lytic lesion by imaging or alternative etiology (sarcoidosis, exposure to thiazide, or calcium or vitamin D supplementation). *Probable* Immob-HCa was defined as documented immobility and absence of alternative etiology, but incomplete laboratory data.

Results: A total of 145 patients with in-hospital MAH were identified. The median age was 68 (33-92), 45% women, 64% white, 31% self-identified black; median peak serum calcium was 12.1 (11.2-17.8) mg/dL. High ionized calcium was verified in 41 (28%) cases. 74 (51%) had evidence of bone metastasis (including primary bone cancer), multiple myeloma accounted for 7 (5%) cases, elevated PTH for 10 (7%) cases, PTHrP for 11 (7%) and elevated calcitriol for 3 (2%) cases. One case was categorized as *Definite* Immob-HCa and 4 cases as *Probable* Immob-HCa. The etiology of MAH was undetermined in 35 (24%) cases. Thus, Immob-HCa accounted for up to 4% (5/145) of in-hospital MAH. Concomitant acute kidney injury (AKI) was present in 3 out of 5 (60%) cases of Immob-HCa.

Conclusions: Immob-HCa accounted for approximately 1 in 29 of cases of in-hospital MAH and is accompanied by AKI in about half of the cases. Notably, incomplete diagnostic work up for MAH was common and may underestimate the incidence of Immob-HCa.

FR-PO244

AKI and Anemia Are Common in Patients with Sarcopenia and CKD Receiving Carboplatin, Pemetrexed, and Pembrolizumab for Advanced Non-Small-Cell Lung Cancer

Nurit S. Katz, Lea Mantz, Paul Hanna, Tianqi Ouyang, Florian J. Fintelmann, Meghan E. Sise. *Mass General Brigham Inc, Boston, MA.*

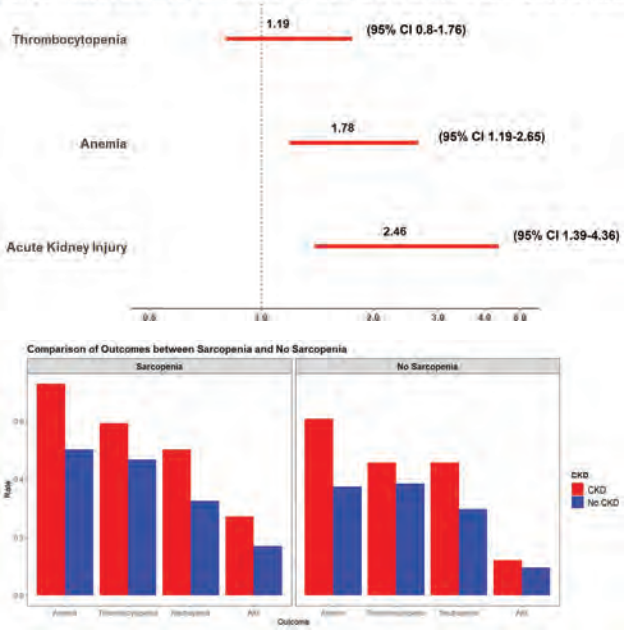
Background: Carboplatin, pemetrexed, and pembrolizumab (triplet therapy), which are first line treatment in advanced non-small cell lung cancer (aNSCLC) may cause acute kidney injury (AKI) and cytopenias. Carboplatin and pemetrexed are renally cleared and require dose adjustments in patients with reduced estimated glomerular filtration rate (eGFR), which may be overestimated in patients with sarcopenia. We hypothesized that patients with sarcopenia treated with triplet therapy have increased risk for AEs.

Methods: In this retrospective cohort study for adults with aNSCLC who received triplet therapy (2016-2022), we performed body composition analysis of T10 or L3 vertebral level on routine CT scan obtained within 90 days of treatment using a validated deep learning pipeline. Sarcopenia was defined using sex-specific cutoffs for skeletal muscle index (SMI). AEs included AKI, anemia, thrombocytopenia or neutropenia. We fit multivariable logistic regression to determine the association between sarcopenia and each AE, adjusting confounders. We assessed the rates of AE in patients with sarcopenia and without sarcopenia with or without CKD.

Results: 595 patients were included, mean age 65.9 ± 9.7, 51.4% female. 28.6% met CT-criteria for sarcopenia. 66.9% had one or more AEs. Patients with sarcopenia had increased odds of AKI and anemia (**Figure 1**), adjusted for confounders. Patients with concomitant sarcopenia and CKD had the highest rates of AEs (**Figure 2**).

Conclusions: Patients with aNSCLC and sarcopenia are at increased risk for AEs from triplet therapy, possibly due to eGFR overestimation and failure to appropriately dose-reduce chemotherapy.

Figure 1: Adjusted odds ratio for adverse outcomes in patients with sarcopenia receiving triplet therapy.



FR-PO245

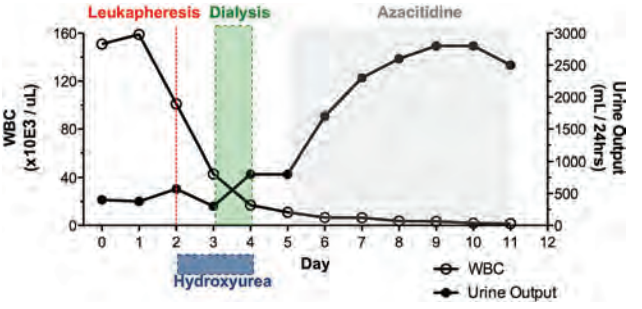
Role of Leukapheresis in the Management of AKI Associated with Hyperleukocytosis of Acute Myeloid Leukemia (AML)

Sherif Badra, Jusong Choi, Chintan V. Shah. *University of Florida, Gainesville, FL.*

Introduction: The rates of AML patients with hyperleukocytosis range from 8–12%. Due to very high early mortality rates, as high as 50% during 30 days after presentation, hyperleukocytosis—especially if complicated by leukostasis—is a hematologic emergency that requires prompt treatment. The role of leukapheresis remains controversial due to the lack of strong data. Hereby, we report a case of acute kidney injury (AKI) that resolved after one session of leukapheresis.

Case Description: A 73-year-old male presented to the hospital with abdominal pain, nausea, vomiting, and generalized fatigue of 2 weeks duration. He was found to have a WBC count of 159,000/μL with 98% peripheral blasts concerning for acute leukemia. On admission, nephrology was consulted for oliguric AKI without evidence of sepsis or hypotension. Urine microscopy revealed a few granular casts suggestive of ATN. The patient did not meet Cairo-bishop criteria for tumor lysis syndrome (TLS). The patient was initiated on hydroxyurea. Due to a lack of improvement in oliguric AKI after four days of presentation and without any other identifiable cause than cytostasis, he underwent one session of leukapheresis (Figure 1). This was followed by two consecutive sessions of dialysis for uremic encephalopathy. Two days later, his urine output increased to about 1.8 L with remarkable kidney function improvement, and he didn't require further dialysis. Unfortunately, the patient passed away after six weeks of a complicated hospital course and withdrawal of care with comfort measures.

Discussion: Renal failure can occur due to leukostasis from hyperleukocytosis in acute leukemia as a result of tubular and glomerular dysfunction. The exact mechanism is unknown but possibly due to mechanical obstruction from less deformable leukemic blasts, the release of proinflammatory cytokines, and matrix metalloproteinases that damage endothelial cells. No current guidelines exist for the treatment of renal injury in this setting. Our case suggests leukapheresis should be considered a therapeutic option for such patients.



FR-PO246

AKI due to Chronic Lymphocytic Leukemia Infiltration with Necrotizing Granulomas

Erika D. Critell, Amy Yau, Laura Biederman. *The Ohio State University, Columbus, OH.*

Introduction: Chronic lymphocytic leukemia (CLL) can commonly affect the kidneys. In autopsy findings, leukemic infiltration can be seen in up to 64-90% of cases, but direct involvement to the renal parenchyma causing acute kidney injury (AKI) is rare. In addition to leukemic inflammation, non-necrotizing granulomatous interstitial nephritis has been described.

Case Description: A 61 year old male with a past medical history of type 2 diabetes mellitus, ulcerative colitis, and immunoglobulin heavy chain variable region gene (IgHV) mutated CLL (not previously requiring therapy) presented in the outpatient setting with creatinine elevation from 1.0 mg/dL to 1.9 mg/dL. Work up revealed normal kidney size and new proteinuria of 493mg/24 hours. The creatinine rise was seen alongside a rise in his white blood cell (WBC) count from baseline 13-19 K/uL to 24-39 K/uL. Renal biopsy revealed leukemic infiltration with cells staining positive for CD20 and CD5 indicating direct involvement of the renal parenchyma along with necrotizing granulomas. The granulomas were found to be non-infectious, indicating a severe form of inflammation. He was started on acalabrutinib and obinutuzumab with hopes for AKI resolution.

Discussion: Other case reports note the appearance of necrotizing granulomatous inflammation seem to affect younger men; additionally, there is no correlation with WBC. Most cases have complete to partial renal recovery after initiation of chemotherapy, however case reports suggest patients with granulomatous inflammation may have a poorer response. The mechanism of renal injury is not clear. Some suggest leukemic cells secrete monoclonal immunoglobulins whereas others suggest renal damage from a hypersensitivity reaction to leukemic cells. Of note, previous case reports did not classify IgHV mutation status, which is now routinely evaluated for. Renal biopsy remains critical to diagnose this potentially reversible, specific, and rare cause of acute renal failure and dictate initiation and guidance of chemotherapy.

Association Between Cancer and AKI Among Medicare Fee-for-Service Beneficiaries, 2006-2014

Yoshihisa Miyamoto, Linda J. Andes, Alain K. Koyama, Fang Xu, Meda E. Pavkov. *National Center for Chronic Disease Prevention and Health Promotion Division of Diabetes Translation, Atlanta, GA.*

Background: Acute kidney injury (AKI) is a heterogeneous syndrome characterized by an abrupt decline in kidney function. Although patients with cancer are likely to be susceptible to AKI, population-based incidence of AKI in patients with cancer is not well understood in the US.

Methods: We conducted a population-based retrospective cohort study among Medicare fee-for-service beneficiaries who were continuously enrolled for six-years, including an initial one year cancer-free window before the index year. The index year was defined by a new cancer diagnosis. Follow-up started with the index year and ended at the time of AKI, death, or censoring at the end of five years. We defined incident cancer

by the presence of two ICD-9 CM diagnosis codes in an outpatient setting or one ICD-9 CM inpatient code. A control group without cancer represented patients without any cancer diagnoses over the same time period, matched on age, sex, and race and ethnicity. The main outcome was time to AKI or death. All-cause death date was ascertained using the National Death Index. Association between cancer and AKI was assessed by cause-specific hazard and Fine-Gray competing risk models.

Results: We identified 5,613,285 Medicare fee-for-service beneficiaries with incident cancer and the same number of matched controls. Beneficiaries with cancer were at greater risk of AKI (unadjusted hazard ratio [HR]=1.66) and death (HR=2.83). The associations were significant after adjustment for covariates (HR=1.38 and HR=2.53, respectively). When death was modeled as a competing risk, unadjusted subdistribution hazard ratio (SHR) of AKI in patients with vs. without cancer was 1.20, and the adjusted SHR was 0.98. All outcomes were significant due to the large sample size.

Conclusions: Medicare fee-for-service beneficiaries with cancer were at greater risk of AKI, compared with those without cancer. However, because the cause-specific association of cancer with death was stronger than that with AKI, impact of cancer on cumulative incidence of AKI indicated by SHR was not notable.

FR-PO248

Mortality of Patients with Cancer and AKI: What Are the Lessons?

Alline Oliveira, Andrea C. Valenca, Joseph L. Nascimento, Thiago M. Lacerda, Klebson F. Feijo de Melo, Italo R. Alves, Ana Paula Gueiros. *Hospital das Clinicas, Recife, Brazil.*

Background: Acute kidney injury (AKI) is a prevalent complication in cancer patients, contributing to mortality. This study aimed to assess factors associated with the mortality of patients with cancer and AKI monitored in the onconephrology clinic of a university hospital.

Methods: This was a cross-sectional, retrospective study. Medical records were reviewed of patients monitored from January 2018 to December 2022. Patients with COVID-19 were excluded. AKI was defined according to KDIGO criteria. The final creatinine (CrF mg/dL): last value measured before discharge or death; oliguria: diuresis <400 mL/24h. A comparative analysis was performed of patients who died and survivors. Univariate and multivariate analyzes were used in the search for risk factors for death. The impact was assessed of hyperphosphatemia (phosphorus>4.5mg/dL) and hyponatremia (sodium<135mEq/L) on mortality.

Results: A total of 340 patients (50% male), with a median age of 62 years, were studied. The mean follow-up time was 15 days. Most patients (78%) presented solid tumors. Types of AKI were: intrinsic renal (38%), prerenal (30%), and obstructive (27%). Outcome data were available on 336 patients. One hundred and eighteen patients (35%) died. Patients who died differed from survivors by being in ICU (55% x 17%; p<0.001), intrinsic renal AKI (57% x 27%; p<0.001), sepsis (58% x 19%; p<0.001), urine output (mL) (500 x 1050; p<0.001), need for renal replacement therapy (RRT) (60% x 25%; p<0.001), CrF (3.2 x 1.5; p<0.001), phosphorus (4.6 x 4.0; p=0.018) and albumin (g/dL) (2.8 X 3.0; p=0.046). In the univariate analysis, the following were associated with mortality: not being in ICU (OR 0.17; p<0.001), CrF (OR 2.26; p<0.001), intrinsic renal AKI (OR 3.47; p<0.001), no sepsis (OR 0.17; p<0.001), non- oliguric (OR 0.31; p<0.001), phosphorus (OR 1.2; p=0.023) and no need for RRT (OR 0.22; p<0.001). In the multivariate analysis, only CrF was an independent risk factor for death (OR 7.51; p=0.009). Hyperphosphatemia was associated with mortality (p=0.006), but hyponatremia was not (p=0.8).

Conclusions: We confirmed the high mortality rate of patients with cancer and AKI. The severity and persistence of AKI are determinants of mortality. Hyperphosphatemia seems to be a predictor of mortality in cancer patients with AKI.

FR-PO249

Lymphocytic Infiltrates on Kidney Biopsy of a Patient with AKI and Chronic Lymphocytic Leukemia: Interstitial Nephritis or Infiltration by Leukemia?

Christopher D. Naranjo, Chavely Valdes Sanchez, Yiqin Zuo, Jair Munoz Mendoza. *University of Miami, Coral Gables, FL.*

Introduction: Chronic lymphocytic leukemia (CLL) is the most common adult leukemia. AKI has been reported in patients with CLL due to hypercalcemia, tumor lysis syndrome, or obstructive nephropathy. Infiltration of organs by CLL can occur, however, kidney involvement is unusual.

Case Description: A 60-year-old female with history of hypertension on treatment with lisinopril and HCTZ, gastroesophageal reflux recently on esomeprazole, and CLL with trisomy 12 and 14:19 translocation, on treatment with Ibrutinib for 5 years, was found to have worsening kidney function. In the ER, she reported abdominal discomfort and bloating for one month. On physical exam she had bilateral lower extremity edema. Three months earlier, she had a creatinine of 0.98 mg/dL. On current presentation, her creatinine was 5.27 mg/dL and potassium was 2.9 mmol/L. UA revealed proteinuria and pyuria. Spot UPCR was 400 mg/g. A kidney ultrasound showed normal size kidneys. A kidney biopsy was performed which showed acute granulomatous tubulointerstitial nephritis (TIN) with extensive interstitial lymphocytic infiltrate and scattered interstitial eosinophils. Evaluation by a hematopathologist confirmed involvement of renal parenchyma by CLL. By immunohistochemistry, lymphoma cells were positive for PAX5, CD20, and CD5. Treatment was initiated with prednisone. Ibrutinib was discontinued and she was started on Obinutuzumab and Venetoclax. 4 weeks later, her creatinine improved to 1.26 mg/dL and urinalysis was negative for proteinuria or pyuria.

Discussion: This case illustrates the importance of a multidisciplinary collaboration and high degree of suspicion when lymphocytic infiltrates are seen in a kidney biopsy of patients with CLL. The presence of TIN with eosinophils may indicate allergic TIN in this case due to either HCTZ or esomeprazole, but the presence of malignant cells due to CLL is the most likely contributor to the AKI. Mechanistically, AKI secondary to infiltrative disease secondary to CLL is poorly understood with one report hypothesizing tubular microvascular compression and infiltration-associated inflammatory response. Recognition of this phenotype of infiltrative disease in patients with CLL is vital for timely treatment.

FR-PO250

Clonal Hematopoiesis of Indeterminate Potential Is Associated with Kidney Disease Progression in a Multi-Cohort Meta-Analysis of Individuals with CKD

Caitlyn Vlasschaert,[1] Yang Pan,[2] Varun S. Rao,[2] James E. Hixson,[3] Michael R. Chong,[4] Elvis A. Akwo,[5] Md Mesbah Uddin,[6] Zhi Yu,[6] Do-Kyun Kim,[3] Manjula Tamura,[7] Debbie L. Cohen,[8] Jiang He,[9] Changwei Li,[9] Zeenat Y. Bhat,[10] Panduranga S. Rao,[10] Alexander Bick,[5] Bryan R. Kestenbaum,[11] Guillaume Pare,[4] Michael J. Rauh,[1] Adeera Levin,[12] Pradeep Natarajan,[6] James P. Lash,[2] Cassianne Robinson-Cohen,[5] Matthew B. Lanktree,[4] Tanika Kelly.[2] *[1]Queen's University, Kingston, ON, Canada; [2]University of Illinois System, Urbana, IL; [3]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [4]McMaster University, Hamilton, ON, Canada; [5]Vanderbilt University Medical Center, Nashville, TN; [6]Harvard Medical School, Boston, MA; [7]Stanford University, Stanford, CA; [8]University of Pennsylvania, Philadelphia, PA; [9]Tulane University, New Orleans, LA; [10]University of Michigan, Ann Arbor, MI; [11]University of Washington, Seattle, WA; [12]The University of British Columbia, Vancouver, BC, Canada.*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is a common inflammatory condition of aging caused by acquired mutations in blood stem cells. CHIP causes myriad end-organ damage, including a doubling of the risk of cardiovascular disease independent of traditional risk factors. We have recently shown associations for CHIP with acute kidney injury and with kidney function decline in the general population, with a greater effect for CHIP driven by mutations in genes other than *DNMT3A* (non-*DNMT3A* CHIP). Longitudinal kidney function endpoints in individuals with pre-existing chronic kidney disease (CKD) and CHIP have been examined in two previous studies, which reported conflicting findings and were limited by small sample sizes.

Methods: In this study, we examine the prospective associations between CHIP and CKD progression events in four cohorts of CKD patients: the Chronic Renal Insufficiency Cohort (CRIC), the African American Study of Kidney Disease (AASK), the Canadian study of prediction of death, dialysis and interim cardiovascular events (CanPREDDICT), and BioVU (total N = 4853). The primary outcome was CKD progression (composite of 50% kidney function decline or end-stage kidney disease). Analyses were adjusted for age, age^2, sex, self-reported race, and the following baseline parameters: eGFR, proteinuria, smoking status, BMI, diabetes status, hypertension, and cardiovascular disease history.

Results: Across all cohorts, the average age was 67.4 years, the average baseline eGFR was 41.2 ml/min/1.73m^2, and 25% had CHIP. In a random-effects meta-analysis, non-*DNMT3A* CHIP was associated with a 59% increased risk of incident CKD progression (HR 1.59, 95% CI: 1.01-2.51). This effect was slightly more pronounced in the subgroup with baseline eGFR ≥ 30 ml/min/1.73m^2 (HR 1.77, 95% CI: 1.06-2.98).

Conclusions: Non-*DNMT3A* CHIP is a potentially targetable novel risk factor for CKD progression in a multi-cohort meta-analysis.

5HT-1F Agonist-Mediated Protection Against Cisplatin-Induced Nephrotoxicity Is Abolished in a Murine Model of Lung Cancer

Andrew Orwick, Leah J. Siskind. *University of Louisville, Louisville, KY.*

Background: Anti-cancer drug-induced acute kidney injury (AKI) is a persistent problem. Cisplatin is a prominent example of this, 30% of patients develop AKI after a single dose and have an increased risk of chronic kidney disease (CKD). The mechanism driving the AKI to CKD transition in the repeated low-dose cisplatin (RLDC) model is not fully understood. Mitochondrial dysfunction plays a critical role in the transition from AKI to CKD. The role of kidney mitochondrial dynamics/quality control in the RLDC model is currently unknown. Preclinical cisplatin toxicity studies have been completed mostly in mice without cancer. The lack of appropriate preclinical models has led previous research down doomed pathways.

Methods: The objective of this study was to determine if nephroprotective strategies in mice without lung cancer will still protect mice with lung cancer. Eight-week-old B6129 mice with and without lung cancer were administered Cisplatin (7mg/kg) or saline via intraperitoneal (i.p.) injection once a week for four weeks. Following the first dose of cisplatin, mice were administered LY344864 (2mg/kg) or saline 6 days a week via i.p. injection. We pharmacologically induced mitochondrial biogenesis to increase kidney mitochondrial content to determine if this pathway will protect from cisplatin-induced nephrotoxicity.

Results: Stimulating mitochondrial biogenesis increased kidney mitochondrial content and reduced loss of kidney function, kidney injury, inflammation, and

development of fibrosis from RLDC in mice without cancer. However, these effects are nullified when the experiment was repeated in mice with subcutaneous lung cancer.

Conclusions: Previous clinical trials on nephroprotective agents have failed, and we propose that poorly representative mouse models may be responsible for misleading preclinical research. Our development of clinically relevant models of cisplatin-induced nephrotoxicity provides a foundation for developing nephroprotective agents that can be used as adjunctive therapy for cancer patients receiving cisplatin.

FR-PO252

Gut Microbiota and Kidney Injury After Allogeneic Hematopoietic Cell Transplantation (allo-HCT)

Matthew Abramson,[1,2] Insara Jaffer Sathick,[1,3] Andrea Knezevic,[1] Edgar A. Jaimes.[1,3] *[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY; [3]Weill Cornell Medicine, New York, NY.*

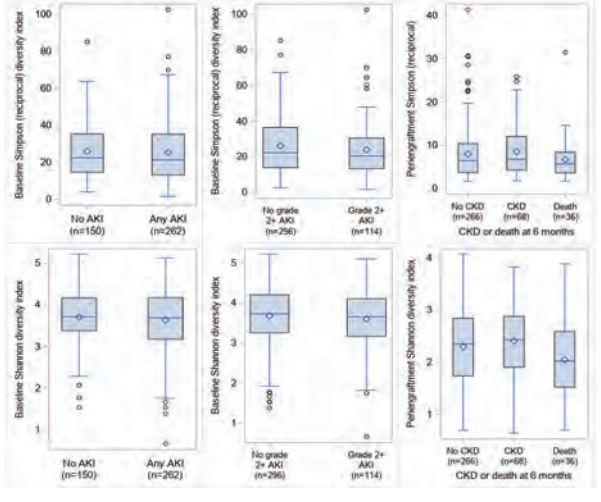
Background: Acute kidney injury (AKI) is a common complication of allo-HCT associated with an increase in non-relapse mortality. In contrast, higher diversity of gut microbiota at neutrophil engraftment is associated with lower mortality. We aimed to study the association of changes in gut microbiome diversity in an allo-HCT cohort who developed post-transplant AKI or CKD.

Methods: We performed a single-center study of 419 allo-HCT recipients from 2014-2017 at Memorial Sloan Kettering Cancer Center with analysis of gut microbiome diversity. We defined AKI and CKD based on KDIGO criteria and eGFR using the CKD-EPI equation. We defined gut microbiome diversity using Shannon and Simpson reciprocal diversity indices (DI), with higher levels indicating more diverse microbiota. We used Wilcoxon rank-sum test to compare baseline DI (within 7 days of HCT conditioning) between patients who did and did not develop AKI by 100 days post-HCT, and peri-engraftment DI (median DI in days 7-21 post-HCT) between those who did and did not develop CKD at 6 months.

Results: Simpson reciprocal and Shannon DI were 21.8 (IQR: 13.7, 35.2) and 3.7 (IQR: 3.2, 4.2) at baseline, and 6.3 (IQR: 3.7, 10.4) and 2.3 (IQR: 1.7, 2.8) at peri-engraftment, respectively. Of the 419 patients, 263 (63%) developed AKI; 114 (27%) was Stage 2+. CKD occurred in 68 patients (18%) at 6 months. There were no significant differences in microbiome DI at baseline or peri-engraftment in patients who developed AKI or CKD, compared to those who did not (all p>0.05, Figure 1).

Conclusions: Our findings do not support the existence of a link between baseline or peri-engraftment gut diversity and the risk for development of AKI or CKD in patients undergoing allo-HCT. This study highlights the complex and multifactorial etiology of AKI in allo-HCT recipients and the need for additional prospective and mechanistic studies.

Figure 1. Baseline and peri-engraftment Simpson reciprocal and Shannon diversity indices by any AKI in 100 days post-HCT and CKD at 6 months.



FR-PO253

Multiple Cancers Alters Renal Physiology and Induces Kidney Injury and Inflammation

Dana Hammouri, Leah J. Siskind. *University of Louisville, Louisville, KY.*

Background: The altered physiology of cancer patients and their unique susceptibility to kidney disease has led to the rapidly growing specialty of Onconephrology. Cancer patients often have decreased kidney function, and drug-induced acute kidney injury (AKI) is common and remains a hurdle. Drug-induced AKI can interrupt therapy and reduce overall survival. Our lab has recently shown that lung-cancer enhances the nephrotoxicity of cisplatin. Additionally, we were able to show that lung-cancer alone alters kidney physiology. However, we are unaware if this phenomenon is exclusive to the model we tested. In this study we used multiple cancer types to determine if kidney function, injury, and inflammation are being altered by subcutaneous cancer alone.

Methods: Eight- to ten-week-old B6;129 mice were randomly assigned into six group of non-cancer and various other cancer types. In the cancer groups, cancer cells were injected subcutaneously and followed for tumor size. Animals were euthanized once tumor size met necessary endpoint per IACUC protocol.

Results: Different cancer types have varying effects on altering kidney function, injury and inflammation. Metastatic lung cancer induces the largest changes, compared to non-metastatic lung cancer. Additionally, melanoma increased urinary NGAL, but did not increase KIM-1 expression.

Conclusions: The presence of subcutaneous tumors is sufficient to alter kidney biology, induces renal injury and inflammation and reduce renal function. Further studies will need to be conducted to elucidate the mechanism behind these changes. Understanding the tumor-kidney crosstalk may provide mechanistic insights and uncover novel therapeutic targets for onconephrology patients.

FR-PO254

Urine EGF and TNFR2: A Pilot Study of Novel Biomarkers to Predict Long-Term Renal Outcomes in Pre-Clinical Model of Cisplatin-Induced Chronic Kidney Injury

Claudia A. Mosquera Vasquez,[1] Gabriela Vasquez Martinez,[1] Gabriel Mayoral Andrade,[1] Ahmed S. Zeid,[1] Diana Zepeda-Orozco.[1,2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University College of Medicine, Columbus, OH.*

Background: Cisplatin is associated with development of chronic kidney disease (CKD) and hypertension affecting around 45% of pediatric oncology patients. Novel urine biomarkers may allow early identification of patients at risk of CKD progression. Urine EGF (uEGF) has been shown to be an independent predictor of CKD progression in humans with an inverse correlation between uEGF and estimated glomerular filtration rate (GFR) decline. Tumor Necrosis Factors Receptor 2 (TNFR2) is a promising biomarker of inflammation with higher levels associated with increased risk of CKD progression. Murine cisplatin pre-clinical models result in long-term renal function decline and could facilitate identification of biomarkers to predict CKD progression.

Methods: Ten-week-old C57Bl6J male mice received 3 weekly intraperitoneal (IP) injections of cisplatin 8 mg/kg/dose vs 0.9% NaCl control (n = 18/group). Urine was collected at 14 days and 3 months after initial cisplatin dose, and transdermal GFR (tGFR) measurements were performed at 3 and 6 months after initial cisplatin dose. uEGF (ELISA, MEG00, R&D Systems) and uTNFR2 (R-PLEX assay, MESO QuickPlex SQ instrument) were measured according to manufacturer's instructions. tGFR analysis was performed calculating FITC-sinistrin clearance after retroorbital injection. Veterinarian Pathologist quantified tubular injury, inflammation and fibrosis in kidney sections (score 0-4).

Results: Survival was 89% (control 94% vs 83% cisplatin). At 6 months, cisplatin treated mice had lower tGFR, and higher tubular injury, interstitial fibrosis, and inflammation on histological analysis. Cisplatin treated mice had significant reduction in uEGF at 14 days, and 3 months and a significant increase in uTNFR2 at 14 days compared to control group (p<0.05 2way ANOVA). There is a significant negative correlation between uEGF at 3 months and tubular injury, inflammation, and fibrosis at 6 months and a positive correlation with tGFR at 6 months. There is a significant positive correlation between uTNFR2 at 14 days and tubular injury, glomerular changes, and fibrosis at 6 months (Pearson, p<0.05).

Conclusions: uEGF and uTNFR2 could be promising early biomarkers to predict CKD in pre-clinical models of cisplatin-induced CKD.

FR-PO255

Atypical Presentation of Renal Amyloidosis in a Patient with Plasma Cell Dyscrasia (PCD)

Priyal Sakhuja, Randolph A. Hennigar, Rula A. Abdulrahman. *Stony Brook University Hospital, Stony Brook, NY.*

Introduction: Amyloidosis (AD) is deposition of abnormal proteins that can lead to organ dysfunction. Light chain AD (AL amyloidosis) is the most common systemic form. This is commonly associated with PCDs such as multiple myeloma (MM). This case focuses on a patient with IgA PCD who develops an atypical presentation of renal AD.

Case Description: 76-year-old male with hypertension, diabetes, hyperlipidemia, coronary artery disease, heart failure, atrial fibrillation, urinary bladder AD and chronic kidney disease (CKD) was seen at CKD clinic. Cr was 1.8-2.0 mg/dl. Urinalysis with no hematuria, urine protein to creatinine ratio (UPCR) was 621 mg/g. SPEP signified M-spike and immunofixation with IgA-kappa monoclonal protein bands. Patient was referred to

hematology. Serum IgA was 952 mg/dL (103-591) with elevated kappa/lambda ratio 4.48 (0.53-1.51). Bone marrow biopsy showed 15-20% plasma cells and was negative for AD. PET CT with no lytic lesions. He was diagnosed with IgA PCD. MM labs remained stable with no treatment planned. Renal biopsy was indicated to rule out monoclonal gammopathy of renal significance. Urine immunofixation showed monoclonal IgA band and repeat UPCR was 132 mg/g. Biopsy revealed amyloid deposition limited to few glomeruli and arterioles with greater kappa than lambda light chains. Given IgA-kappa paraproteinemia, AL-type amyloidosis was the favored diagnosis.

Discussion: AD has a strong association with PCD. This case highlights an atypical presentation of renal AD which often presents with significant amounts of proteinuria and primarily affect the glomeruli. About 65% of patients with renal AD are afflicted with nephrotic syndrome. When amyloid deposition is found in the tubulointerstitial (TI) compartments, proteinuria is not a common feature. Additionally, lambda light chains are seen more often than kappa light chains as they are more amyloidogenic. Our case is atypical due to the absence of massive proteinuria and predominance of kappa light chains. Insignificant proteinuria can often be due to deposits confined to the TI or vascular compartments, however our patient had deposits in the glomeruli. Thus, it is important to note that even in the absence of significant proteinuria, a patient with known PCD with renal dysfunction, may still undergo renal biopsy. The histological findings can also vary despite the degree of proteinuria.

FR-PO256

Use of Radioactive Iodine in the Management of Thyroid Cancer in Those with Low-Clearance CKD/ESKD

Darragh O'Donoghue, Michael Clarkson. *Cork University Hospital, Cork, Ireland.*

Background: Radioactive iodine (RAI) is a key adjuvant treatment of differentiated thyroid cancers. Iodide is cleared by the kidney which leads to complexities in the treatment of patients with end-stage kidney disease (ESKD) due to prolonged circulation of RAI.

Methods: A structured multidisciplinary care pathway was created for those receiving RAI with ESKD, involving Nephrology, Radiation Oncology, Medical Physics, and Biomedical Engineering. A shielded room is used for RAI with the addition of mobile shielding for staff to reduce staff exposure during dialysis. Alterations for water treatment were made to deliver ultrapure water suitable for HD. Patients were dialysed in isolation until levels <30MBq (1.5µSv/hr). Safety protocols for radiation protection for staff and dialysis waste management were implemented.

Results: **Case One** 47 year old man with invasive follicular thyroid carcinoma in the setting of CKD stage 4 (eGFR of 17ml/min/1.73m2). Following thyroidectomy, an avid focus present in left thyroid bed requiring treatment with RAI. He underwent radioactive iodine ablation therapy with a reduced dose protocol of 1.1 GBq. Levels were closely monitored and graphed compared to a normalised dose rate for those without renal impairment. His clearance was in line with the expected rate. **Case 2** 50 year old man with recurrent papillary thyroid carcinoma on a background of ESKD on HD. Initial treatment with surgery and RAI in 2017. He represented with recurrent nodal disease and underwent a neck dissection. RAI treatment was planned. Dialysis was arranged prior to treatment to familiarise staff with the new unit. He received a 50% reduction in RAI with a dose of 1.850 GBq. Following treatment, he underwent dialysis at 14 hours post treament then every 48 hours. His levels were reduced by >50% with each dialysis session (Figure).

Conclusions: RAI can be safely administered to patients with low clearance CKD/ESKD with the implementation of a structured care pathway utilising a multidisciplinary approach.

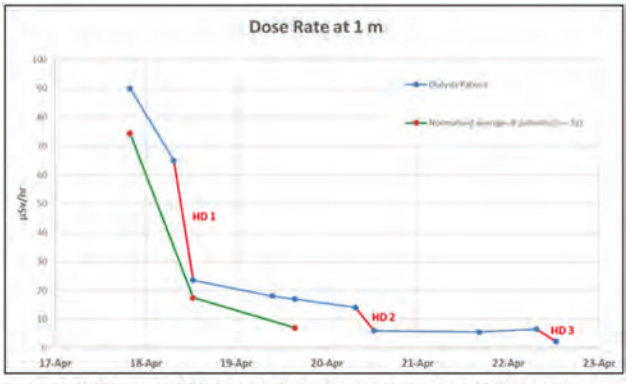

Figure 2. Clearance of RAI for Case 2 as compared to clearance of other cases

FR-PO257

Non-Proteinuric CKD: An Atypical Presentation of Multiple Myeloma

Chrystel Pawly,[1,2] Andrew Donati.[3] *[1]Yale University Department of Internal Medicine, New Haven, CT; [2]Waterbury Hospital, Waterbury, CT; [3]CT Kidney and HTN Specialists LLC, Waterbury, CT.*

Introduction: Light chain deposition disease (LCDD) is characterized by overproduction and deposition of monoclonal light chain immunoglobulins. LCDD usually has prominent kidney involvement; including proteinuria and kidney failure characterized by nodular glomerulosclerosis and tubular basement membrane thickening. Here we highlight an atypical presentation of biopsy proven kappa type LCDD without significant glomerular proteinuria in a patient found to have Kappa restricted Multiple myeloma (MM).

Case Description: Our patient is a 64-year-old male with medical history of asthma, hyperlipidemia, and tobacco use disorder (remission for 9 yr). He presented to nephrology clinic for evaluation of confirmed isolated elevation in creatinine of 2.1 (BUN 21) with normal CBC, electrolytes, total protein and albumin. History was negative for NSAID use, OTC supplements, frequent UTI or nephrolithiasis. There was no family history of CKD or ESKD. His only medication was Fluticasone-Vilanterol. His vital signs and physical exam were unremarkable. Urinalysis was negative for protein, but trace blood was noted. ANA, ANCA, C3/C4, RF, and viral hepatitis serologies were negative. UACR 10mcg/mg and UPCR 0.2mg/mg. SPEP was normal. Kappa FLC 273 mg/L, Lambda FLC 26.1 mg/L, Ratio 10.46. Renal imaging was notable for multiple bilateral cysts without evidence of enhancing lesion, stones or hydronephrosis. Renal biopsy was ultimately performed, and it revealed LCDD Kappa type, interstitial fibrosis/tubular atrophy of 70-80% with moderate arterio- and arteriolosclerosis. Bone marrow biopsy revealed normal cellular marrow with trilineage hematopoiesis and increased plasma cell (20% by CD 138 immunostaining). Flow cytometry revealed monoclonal kappa restricted plasma cell population. PET/CT was normal, implying that the kidneys were the sole site of the disease. He was started on cyclophosphamide, bortezomib and dexamethasone (CyBorD) and creatinine eventually improved. UACR increased slightly to 25mcg/mg.

Discussion: Kidney biopsy is almost always essential when the origin of CKD is unknown. Among patients newly diagnosed with MM, 20-50% have either AKI or CKD at the time of diagnosis. Early recognition and treatment of an underlying plasma cell disorder is important in preserving kidney function. This case highlights the importance of thorough workup for monoclonal gammopathy despite absence of typical presenting features.

FR-PO258

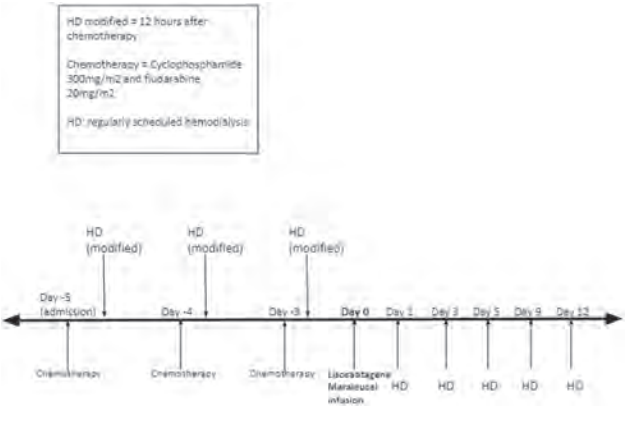
Chimeric Antigen Receptor T-Cell Therapy in a Dialysis Patient with Lymphoma

Muhammad Mire, Jay L. Koyner, Marco A. Bonilla Arevalo, Jennifer Collins, Peter Riedell. *University of Chicago Division of the Biological Sciences, Chicago, IL.*

Introduction: Chimeric antigen receptor T-cell (CAR-T) therapy has become a revolutionary cancer therapy for multiple subtypes of hematologic malignancies. Despite this, CAR-T use in End Stage Kidney Disease (ESKD) patients is limited. We describe the successful administration of CAR-T therapy in a patient with ESKD.

Case Description: A 60-year-old female with a history of hypertension, heart failure, ESKD on hemodialysis (HD), and diffuse large B cell lymphoma (DLBCL) from an underlying chronic lymphocytic leukemia (CLL) was admitted for CAR-T therapy. Prior to the receipt of CAR-T, she received three days of lymphodepleting chemotherapy consisting of Cyclophosphamide (660 mg/24 hours) and dose-reduced fludarabine(20 mg/m2). During this regimen, she underwent HD on 3 consecutive days, approximately 12 hours after her fludarabine infusions. Following CAR-T infusion, the patient resumed her traditional 3 times per week HD schedule. The patient's course was complicated by pancytopenia, lasting for 13 days. The patient experienced Grade 2 cytokine release syndrome (CRS), and was treated with one dose of tocilizumab on Day 11 post CAR-T. At the time of the last follow-up, the patient remains with ESKD on HD, and is still in remission 12 months after CAR-T.

Discussion: When performing HD, timing is essential to limit toxicity and minimize drug removal prior to CAR-T infusion, while also not eliminating the drug prior to its distribution and onset of action. Given the uncertainties of HD timing, drug removal, and the apparent increased risk of complications, further investigations are needed to determine the ideal treatment strategies in patients with ESKD. Future efforts to elucidate the impact of lymphodepleting chemotherapy on cytokine profiles and other factors in patients with ESKD will help inform management strategies. Collaborative efforts and standardized protocols are needed to better define the optimal HD timing in CAR-T recipients.



FR-PO259

Daratumumab Monotherapy in Severe Patients with AL Amyloidosis and Biopsy-Proven Renal Involvement

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *University Center of Excellence on Nephrologic, Rheumatologic and Rare Diseases, Coordinating Center of the Interregional Network for Rare Diseases of Piedmont and Aosta Valley, San Giovanni Bosco Hub Hospital, University of Turin, Turin, Italy.*

Background: Daratumumab is an anti-CD38 monoclonal antibody recently approved as a first-line therapy on top of standard therapy for the treatment of multiple myeloma and AL amyloidosis. The following data describe the good results reported by our group and the long-term experience achieved in recent years on the efficacy of daratumumab used in monotherapy.

Methods: We described 17 patients (pts) treated with Daratumumab alone, 24 iv administration at a dose of 16 mg/kg. All of them had an histological confirmation and staging of renal involvement and were ineligible for ASCT. Pts could either be naïve or refractory. When feasible, the patient who underwent the whole cycle of therapy underwent a second kidney biopsy at the end of the treatment.

Results: The mean age at diagnosis was 73 years. 16/17 pts had proteinuria that was associated with renal function impairment in 11. 2 pts were on dialysis at the time of therapy initiation. 9 pts completed the treatment; 13 over 17 underwent at least 12 infusions. At the 12th administrations 84,6% of pts had an overall hematological response. 46,5% of pts achieved a complete hematological response, 38% had a very good partial response, and 15.5% were non responders. 5/13 had already achieved an organ response.; the 2 pts who were in dialysis at the time of therapy initiation, remained on dialysis. 7/9 achieved a renal response. Proteinuria decreased rom 6,02 to 1,28 g/die ($p < 0.005$) with stabilization/improvement of sCr. 8/9 pts with cardiac involvement obtained at least amelioration. At the end of follow-up 5 pts have persistent hematological and renal response. 1 pt with initial partial response had a relapse. The last pt is still alive and is currently being treated with a second line of therapy, because no hematologic or organ response was achieved with Daratumumab. 7 pts underwent a second kidney biopsy at the end of the treatment. Histological findings showed stable deposits in 6 over 7 cases, while the last one showed a reduction in the extention and amount of amyloid deposits.

Conclusions: Our data, based on the real life experience of our center, suggest that daratumumab monotherapy may represent an effective therapeutic option, capable not only of inducing a substantial improvement in the renal status in pretreated or naïve pts, but also of limiting progression of amyloid deposition.

FR-PO260

Onconephrology: The Role of Kidney Biopsy in the Management of Side Effects of Targeted Therapies

Roberta Fenoglio, Savino Sciascia, Dario Roccatello. *CMID-Nephrology and Dialysis - San Giovanni Bosco - Turin, Torino, Italy.*

Background: The introduction of innovative therapies, resulting from revisiting cancer as a disease of the immune system, has changed the scenario of complications. These new classes of drugs, such as targeted therapies and immune checkpoint inhibitors, assure substantial advantages in cancer therapy, despite some side affecting various organs, including the kidney. Histological evaluations of kidney disorders induced by targeted/immunotherapy are limited.

Methods: In this study we examined the histological features of patients treated with new cancer agents who underwent kidney biopsy for new onset kidney failure and/or urinary abnormalities.

Results: The cohort included 30 adult patients. The most frequently administered therapies were immunotherapy (30%), targeted therapy (26.7%), immunotherapy plus targeted therapy (13.3%), immunotherapy plus chemotherapy (13.3%), targeted therapy plus chemotherapy (16.7%). The most common histological finding was tubular interstitial nephritis (30%) that was associated with acute tubular necrosis in 4 cases, and thrombotic microangiopathy (23.3%). After kidney biopsy, 16 of the 30 patients were treated according to the histological diagnosis. Fourteen patients were treated with steroids. One patient with membranous nephropathy was treated with a single dose of rituximab. A patient with severe thrombotic microangiopathy requiring dialysis received a treatment with eculizumab for 3 months. Overall some renal response was obtained in all patients treated with glucocorticoids, while complete kidney response was achieved in the patient treated with rituximab. Cancer treatment was resumed without change in 21 out of 30 patients.

Conclusions: Kidney biopsy is critical for the management of kidney toxicities and should be strongly encouraged for patients showing adverse kidney effects of novel cancer agents.

FR-PO261

Cancer Status and Mortality in Older Hemodialysis Patients: Data from a Korean Society of Geriatric Nephrology Retrospective Cohort

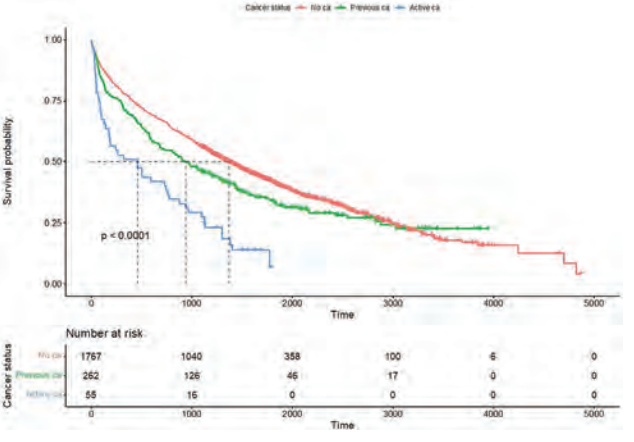
Seongmin Kang,[1] Yu Ah Hong,[2] Woo Yeong Park,[3] Jang-Hee Cho,[4] In O Sun,[5] Won Min Hwang,[6] Soon hyo Kwon,[7] Kyung Don Yoo.[1] *[1]University of Ulsan, Ulsan, Republic of Korea; [2]Catholic University of Korea Daejeon St Mary's Hospital, Daejeon, Republic of Korea; [3]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea; [4]Kyungpook National University Hospital, Daegu, Republic of Korea; [5]Presbyterian Medical Center, Jeonju, Jeollabuk-do, Republic of Korea; [6]Konyang University Hospital, Daejeon, Republic of Korea; [7]Soonchunhyang University Hospital, Yongsan-gu, Seoul, Republic of Korea.*

Background: Our study probed the correlation between cancer presence and mortality rates in elderly patients on hemodialysis, a link that is currently underexplored despite established associations between cancer, age, and chronic kidney disease (CKD).

Methods: We conducted a retrospective, multicenter cohort study through the Korean Society of Geriatric Nephrology. This study encompassed 2,085 patients aged 70 or above who commenced hemodialysis from 2010 to 2017. We employed the Kaplan-Meier survival estimator and Cox proportional hazards regression analysis to assess all-cause mortality.

Results: Among our cohort, 262 patients (12.6%) had a cancer history, while 55 patients (2.6%) were managing active cancer. Over a median follow-up period of 3.2 years, 1,357 deaths (65.1%) occurred. The active cancer group revealed significantly higher all-cause mortality in comparison to those with a cancer history or no cancer (85.5% vs 68.3% vs 64.0%; p<0.002). Kaplan-Meier analysis underscored this mortality disparity among the groups ($p < 0.001$, log-rank test). Further, the multivariate Cox regression analysis, post-adjustment for clinical variables, evidenced a strong correlation between active cancer and all-cause mortality (HR:1.89; 95%CI: 1.36–2.64; $p < 0.001$). However, a history of cancer did not significantly raise overall mortality (HR:1.07; 95%CI: 0.90–1.28; $p = 0.448$).

Conclusions: Elderly patients on hemodialysis with active cancer demonstrated a higher mortality rate compared to those with a history of cancer or no cancer. Interestingly, cancer survivors exhibited a mortality risk akin to those never diagnosed with cancer. Thus, elderly cancer survivors may be viable candidates for dialysis.



Pairwise log rank test showed all between-group comparisons significant.

FR-PO262

Cancer Screening for Dialysis Patients

Wern Lynn Ng,[1] Gabriela M. Calderon Barahona,[1] Carlos Fernando Ortega C. Girón,[1] Evelyn J. Calderon Martinez,[1] Adan M. Cuevas Velazquez,[1] Adalberto E. Guzman,[1] Amna Afreen,[1] Moe P. Htoo,[1] Si Yuan Khor,[2] Anas Atrash.[1] *[1]UPMC Harrisburg, Harrisburg, PA; [2]Michigan State University, East Lansing, MI.*

Background: Routine cancer screening is not recommended for end stage renal disease (ESRD) patients due to their high mortality rate. The current status of cancer screening in this population remains uncertain, and routine screening is deemed cost-ineffective. False-positive test outcomes may lead to unwarranted medical interventions, overtreatment, and psychological distress, highlighting the need for careful consideration in implementing such screening measures.

Methods: Among 340 ESRD patients at UPMC Harrisburg, 136 were ineligible, resulting in a cohort of 204 patients. Descriptive analysis reported categorical variables as number (percent). Group differences were assessed using chi-square tests, employing Fisher exact test for frequencies ≤5. A p-value <0.05 indicated statistical significance. SAS 9.4 (SAS Institute, Cary NC) was used for all analyses.

Results: Among the cancer screening rates examined, including breast cancer, colon cancer, prostate cancer, and cervical cancer, there was no statistically significant difference observed between patients who died from cancer-related causes and those who

died from non-cancer related causes. However, it is worth noting that the screening rate for lung cancer displayed a statistically significant difference between these two groups.

Conclusions: Cancer screening in ESRD patients should be tailored on anticipated survival, transplant eligibility, and cancer risk. However, this study is limited by small sample sizes. Larger patient cohorts are needed to provide more representative results. A personalized approach to cancer screening, considering specific risk factors and projected lifespan, is crucial in ESRD patients. Further retrospective studies are necessary.

	cancer related death		Non-cancer related death		p-Value

FR-PO263

Futility of Dialysis in Patients with Tumor Lysis Syndrome in Advanced Hematological Malignancy: A Case Series

Ashley Golbus, Evelyn Bruner, Blaithin A. McMahon. *Medical University of South Carolina, Charleston, SC.*

Background: Acute kidney injury (AKI) can occur as result of tumor lysis syndrome (TLS) in patients with an underlying hematological malignancy. In TLS, hyperuricemia and hyperphosphatemia can cause crystal nephropathies. In patients with advanced malignancies, excess lactic acid production occurs as neoplastic cells preferentially undergo anaerobic glycolysis, known as the Warburg effect, resulting in type B lactic acidosis. These patients typically are hemodynamically stable. While dialysis is frequently used in the management of TLS, data on outcomes of these patients with advanced hematological malignancy would aid in deciding utility of dialysis. The purpose of our study is to assess mortality outcomes in patients with an advanced hematological malignancy with TLS, type B lactic acidosis, and AKI to better determine the utility and outcomes of dialysis in this cohort.

Methods: For this case series we used the TriNetX search, then refined our cohort to only include patients with type B lactic acidosis and excluded patients with AKI also due to hypotension/hypoperfusion. We identified 10 patients admitted to the Medical University of South Carolina between 2014 and 2022 with an underlying hematological malignancy with type B lactic acidosis, TLS, and AKI. Renal outcomes were assessed based on death, dialysis, and transfer to hospice through 6 months.

Results: Death occurred in 100% of patients with an underlying hematological malignancy presenting with TLS, type B lactic acidosis and AKI, with median time from onset of TLS to death of 4.5 days (SD 55). 70% of patients began dialysis with median time to initiation following TLS diagnosis of 1 day (SD 1.3), and median time to death following dialysis initiation of 2 days (SD 25.4). Median pH was 7.29 (SD 0.08), median lactate 8.6 (SD 5.6), LDH 5817 (SD 7558), uric acid 15.45 (SD 7.34), peak SCr 3.7 (SD 1.53), phosphorous 8.6 (SD 3.5).

Conclusions: Patients in our cohort had very poor rates of survival and dialysis did not appear to change outcomes. Given poor outcomes in these patients we suggest dialysis may have limited utility in our cohort and the focus of care should be comfort.

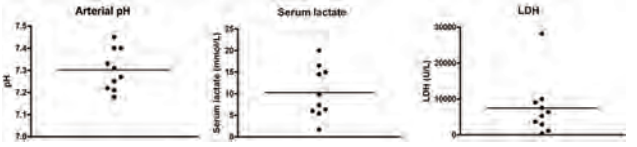

Figure 1. Median peak arterial pH, serum lactate, and LDH of each patient.

FR-PO264

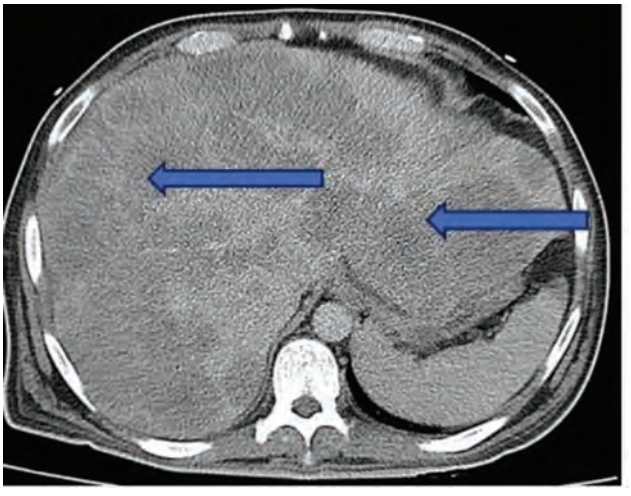
Type B Lactic Acidosis Secondary to Metastatic Liver Cancer in the Setting of Normal Renal Function: A Case Report

Tracy-Ann Poyser, Chidinma P. Amakiri, Steven Pham. *Unity Health White County Medical Center, Searcy, AR.*

Introduction: Lactic acidosis occurs when lactate levels are greater than 4 mmol/L. It is due to an overproduction of lactate or decreased metabolism. There are two types, Type A and Type B. Type B is more common in hematological conditions, such as multiple myeloma, leukemia, and lymphoma.

Case Description: We present a case of a 43-year-old male with Type B lactic acidosis secondary to stage IV colon cancer with metastasis to the liver. Computed Tomography scan of the abdomen and pelvis showed extensive hepatic metastasis with marked hepatosplenomegaly and mild ascites. He had a lactic acid of 16.5 mmol/L, glucose of 52 mg/dl, and bicarbonate of 8 mEq. He received aggressive fluid resuscitation, IV antibiotics, and bicarbonate supplementation. However, his lactic acid worsened, requiring urgent dialysis. Despite dialysis, he showed no significant improvement, and was placed on hospice.

Discussion: Type B lactic acidosis can arise as a complication of solid and, more commonly, hematological malignancies, such as multiple myeloma, lymphoma, and leukemia. It is a rare complication that requires prompt diagnosis and treatment of the underlying condition. Treatment modalities, such as hemodialysis and chemotherapy, have been studied, but the prognosis remains poor. Our patient with type B lactic acidosis received hemodialysis, sodium bicarbonate, and glucose supplementation with marginal initial improvement, followed by worsening lactic acidosis. Due to the late stage of his cancer, chemotherapy was not beneficial. There is a paucity of information due to the rarity of studies on severe lactic acidosis. More studies are needed to better understand the pathogenesis of type B lactic acidosis secondary to hematological malignancies to improve patient outcomes.



Imaging showing extensive liver metastasis with significant hepatosplenomegaly and ascites.

FR-PO265

Beyond Tumor Regression: Exploring the Fatal Consequences of Immune Checkpoint Inhibitor (ICI)-Induced Triple M Syndrome and Myoglobin Nephropathy

M. Salman Sheikh, Raad B. Chowdhury, Nelson Leung. *Mayo Clinic Minnesota, Rochester, MN.*

Introduction: Immune checkpoint inhibitors (ICIs) have revolutionized cancer therapy. Despite showing remarkable tumor regressions and anti-tumor efficacy, these agents can also lead to life-threatening immune-related adverse events (irAEs). One exceedingly rare irAE is ICI-induced myocarditis with myositis/myasthenia overlap, also known as Triple M Syndrome. We present a case of Triple M Syndrome with acute kidney injury and provide a review of the clinical course.

Case Description: A 76-year-old male with melanoma was treated with a single dose of adjuvant Nivolumab. Two weeks later, he was admitted with sudden-onset angina, respiratory failure requiring emergent intubation, and neurological symptoms.

Physical exam revealed bilateral ptosis, diplopia, and proximal muscle flaccid paralysis. Laboratory workup was notable for increasing troponins to 4783ng/L, markedly elevated liver enzymes, and elevated creatinine kinase (CK) of 6806 U/L. Serum myoglobin was elevated to 3799 mcg/L, aldolase was 100 U/L, and acetylcholine receptor antibodies were detected. EKG did not show ischemic features. Electromyography demonstrated significant abnormalities. The patient was diagnosed with ICI-induced myocarditis, myositis, and myasthenia gravis. Pulse dose steroid therapy was administered followed by plasma exchange. Persistent elevation of serum and urine myoglobin, even after CK normalization, resulted in pigment nephropathy requiring continuous renal replacement therapy (CRRT). Anti-thymoglobulin was administered for refractory irAE- but no benefit was observed. He ultimately expired. Autopsy revealed severe tubular injury with myoglobin casts, no ICI related interstitial findings, and focal lymphocytic myocarditis.

Discussion: This case presents Triple M Syndrome, an irAE characterized by myocarditis, myositis, and myasthenia overlap. The patient exhibited profound elevation in troponin and myoglobin levels, while CK levels were less remarkable. This suggests a predominant myocardial injury with a lesser extent of skeletal muscle involvement. Important to note is that the diagnosis of myositis relied on troponin and CK, while CK and myoglobin were necessary for diagnosing myoglobin pigment nephropathy. In summary, recognizing Triple M Syndrome as an irAE causing renal injury from myoglobin, and not necessarily only interstitial disease, is crucial.

FR-PO266

Ifosfamide-Induced Fanconi Syndrome: A Complication that Cannot Be Overlooked

Italo R. Alves, Lucas S. Xavier, Andrea C. Valenca, Denise M. Costa, Thais O. Santos, Ana Paula Gueiros. *Hospital das Clinicas, Recife, Brazil*.

Introduction: Fanconi syndrome (FS) is a severe dysfunction of the proximal tubule, which causes urinary loss of glucose, amino acids, phosphorus, bicarbonate and potassium. Ifosfamide (IFO)-induced FS is reported in 1.4-5% of children being treated for solid tumors, but few cases have been reported in adults. We describe a case of FS in an adult who was taking IFO for sarcoma treatment.

Case Description: A male, aged 29, diagnosed with cervical fibrosarcoma at the age of 13. In September 2021, with the third recurrence of the disease, he initiated chemotherapy (CT) with IFO, vincristine and actinomycin D. On the 24th week of CT, after 48g/m^2 of IFO, the patient presented muscle weakness and renal dysfunction (Cr mg/dL 1.3), and CT was suspended. In September 2022, six months after interrupting CT, he was admitted with disabling muscle weakness (unable to walk) and polyuria (8.0 L/day). Laboratory: Cr 4.2; potassium (mEq/L) 2.6, phosphorus (mg/dL) 1.7, pH 7.19, bicarbonate (mEq/L) 13, chlorine 113 mEq/L, sodium 135 mEq/L, anion gap 12; urine: density 1007, glucose 4+ (normal blood glucose), no hematuria, 24h proteinuria 1.3 g/day, potassium in isolated sample 59 mEq/L and phosphorus excretion fraction 94%. After correcting electrolytes and metabolic acidosis, the patient's weakness improved significantly, urine output normalized and Cr was 3.2. He is currently undergoing outpatient follow-up, using chelated phosphorus, potassium citrate, sodium bicarbonate and potassium chloride. January 2023 exams: Cr 3.3, phosphorus 3.2, potassium 4.6, bicarbonate 18.

Discussion: IFO toxicity appears to be dose dependent and occurs mainly with cumulative doses greater than 45 g/m^2. It is believed that IFO nephrotoxicity is due to the action of metabolites, acrolein and chloroacetaldehyde in the renal tubules. It is important that oncologists and nephrologists are aware of the possibility of FS and nephrogenic diabetes insipidus with the use of IFO, so as to avoid serious and fatal complications. Our patient presented muscle weakness and altered renal function, IFO was suspended, but FS was not diagnosed at the time. We emphasize the importance of monitoring renal function and electrolytes in cancer patients undergoing CT, mainly because a wide range of old and new drugs is available.

FR-PO267

Prevalence of Cisplatin-Induced Nephrotoxicity in an Inner-City Population in the Bronx, New York

M Bakri Hammami,[1,2] Paola Gudino,[1] Juan Diego Rodriguez Salazar,[1] Charan T. Vegivinti,[1] Anjali Acharya.[1] *[1]New York City Health and Hospitals Jacobi, Bronx, NY; [2]Mayo Foundation for Medical Education and Research, Rochester, MN*.

Background: Cisplatin is a commonly used chemotherapeutic agent with known nephrotoxicity. Studies evaluating its nephrotoxicity in minorities are limited. We assessed the incidence of kidney injury among our adult patients receiving cisplatin.

Methods: Retrospective review of records for adult patients receiving cisplatin from Jan 2021 to Jan 2023 was conducted. Serum Creatinine (SCr) and estimated glomerular filtration rate (eGFR) were obtained at baseline and within 30 days after cycles 1, 2, and 3 of Cisplatin. KDIGO definition was used to diagnose AKI.

Results: Of the 47 patients included in the analysis, 51.1% were male (n=24), median (range) age was 58 years (19-78). 42.6% were Black (n=20), 21.3% White (n=10) and others consisting of Pacific Islanders, American Indians, and Asians represented 36.2% (n=17). 80% of whites were Hispanic. The median number of cisplatin cycles was 4 (range: 1-11). Median baseline eGFR and SCr was 99.7ml/min and 0.80 g/dl, respectively. Blacks had a mean baseline GFR of 86.1ml/min, while non-Blacks had a mean of 100.86 ml/min (t=2.223, p=0.031). The median eGFR and SCr at the last follow-up after cisplatin was 77.80 ml/min and 0.99 g/dl, respectively. 10.6% of the patients developed AKI after the first dose of Cisplatin. There was no statistically significant correlation between race, sex, BMI or the use of immune checkpoint inhibitors and development of AKI. Repeated measures ANOVA test was conducted to evaluate the change in patients' creatinine when measured before cisplatin, after 1st, 2nd and 3rd cycle. The results indicated a statistically significant rise in creatinine level following cisplatin therapy [Wilks' Lambda = 0.003, F (1, 26) = 13.7, $\eta^2 = 0.44$].

Conclusions: Our retrospective study in a minority based, low socioeconomic status adult population highlights the progressive risk of kidney injury following each cycle of cisplatin therapy, indicating risk for chronic dose-dependent cisplatin-induced nephrotoxicity. Patients from low socioeconomic backgrounds and minority populations may be at higher risk for renal dysfunction and progression to CKD. Further prospective studies targeting this specific population are warranted to validate these findings and develop tailored interventions to reduce cisplatin-induced nephrotoxicity.

FR-PO268

FGFR Inhibitors in Cholangiocarcinoma and Urothelial Bladder Cancer Resulting in Hyperphosphatemia, Low Parathormone, and High Calcitriol: The Side Effects of FGF23 Blockade

Germana A. Brito,[1] Benedito J. Pereira,[1] Aline L. Baptista,[1] Maria de Nazaré S. Poluboiarinov,[1] Rosa M. Moyses.[2] *[1]ACCamargo Cancer Center, Sao Paulo, Brazil; [2]Universidade de Sao Paulo Hospital das Clinicas, Sao Paulo, Brazil*.

Introduction: Hyperphosphatemia is the most frequent adverse event in patients treated with FGFR (fibroblast growth factor receptor) inhibitors. FGF23 and FGFR1 play key roles in phosphate homeostasis and hyperphosphatemia results from FGFR1 inhibition.

Case Description: Case series of patients with urothelial bladder cancer and cholangiocarcinoma (CCA) taking FGFR inhibitors (erdafitinib or futibatinib) at AC Camargo from July 2021 - February 2023. Creatinine, serum phosphate, parathyroid hormone (PTH), 1,25-dihydroxyvitamin D (1,25 vitD), 24h urinary phosphate level were measured after 4 weeks of therapy. As described in the table below, we included 4 patients with cholangiocarcinoma and 2 with urothelial bladder cancer. Hyperphosphatemia occurred in 100% of the patients, with serum phosphate ranging from 6 to 7.5 mg/dl, accompanied by decreased urinary phosphate. PTH was suppressed in 2 of the patients, whereas high 1,25 vitD was seen in half of them. Hyperphosphatemia caused a temporary interruption of treatment, to control serum phosphate. Also, phosphate binders were administered to all patients. Acetozolamide was admistered to patients 3 and 4, but had no effect on serum phosphate and caused worsening of dry mouth and metabolic acidosis. Ungual lesions were present in all cases and eye toxicities, such as serous retinal detachment, were seen in 4.

Discussion: FGFR1 blockade caused by FGFR inhibitors is associated with hyperphosphatemia, hypophosphaturia, high 1,25 vitD and PTH suppression, as described in animal models of FGF23 blockade. The metabolic changes caused by these drugs are a undesirable, but important side effects that might limit their use in many patients affected by cancer with genetic alterations in FGFRs.

Age/Sex	Cancer	Genetic alteration	Creat (mg/dl)	iCalcium (mmol/L)	P (mg/dl)	1,25 vitD (pg/ml)	PTH (pg/ml)	Urinary P (mg/24h)
62; M	Urothelial	FGFR3-TACC3	1,6	1.40	6.1	n/a	56	n/a
61; F	CCA	FGFR2	0.9	1.41	7.0	47	20	30
52; F	CCA	FGFR2-BICC1	0.7	1.35	6.9	123	67	365
73; M	CCA	FGFR2	1.6	1.31	6.0	93	107	155
67; M	Urothelial	FGFR3	1.3	1.28	7.5	n/a	17	103
75; F	CCA	FGFR2	0.8	1.20	6.1	17	40	36

CCA = cholangiocarcinoma; P = Phosphate; iCa = Ionized Calcium; Creat = creatinine; 1,25 vitD = 1,25-dihydroxyvitamin D; n/a = not available

FR-PO269

Abiraterone-Associated Syndrome of Mineralocorticoid Excess (SAME)

Chandra Kumar Mallick Kodavanti,[1] Raja Ravender,[1] Saeed K. Shaffi.[2] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]Raymond G Murphy Department of Veterans Affairs Medical Center, Albuquerque, NM*.

Introduction: We present a patient with abiraterone-associated SAME and discuss its pathophysiology and treatment.

Case Description: A 77-year-old man with metastatic prostate adenocarcinoma was treated with abiraterone 1 gram daily. Prednisone 5 mg daily was added 3 months later. Soon after chemotherapy initiation, his plasma potassium declined (Figure 1), and did not improve despite potassium replacement requiring hospitalization. He was volume overloaded with signs of urinary potassium wasting (Table 1). Further investigations revealed an ACTH (adrenocorticotropic hormone) mediated SAME. Discontinuation of abiraterone with amiloride use improved serum potassium and decreased kaliuresis.

Discussion: Abiraterone acetate is a drug that irreversibly inhibits Cytochrome P450c17 with the suppression of 17 α-hydroxylase (17α-OH) and C17,20-lyase and is used for the treatment of prostate cancer. The inhibition of 17α-OH in the Zona Fasciculata causes an ACTH-mediated SAME due to accumulation of corticosterone and deoxycorticosterone. Therefore, it is co-administered with prednisone to inhibit ACTH. However, low-dose prednisone may not effectively suppress ACTH in all the patients on abiraterone. High dose steroids or spironolactone use is discouraged as they may be associated with worse outcomes. Potassium wasting can be managed effectively with

amiloride and low-dose steroids. Despite prednisone use, the possibility of abiraterone inducing SAME should be entertained in patients with hypertension, volume-overload, and/or hypokalemia.

Laboratory values

ACTH (pg/dl) (Ref 6-50) 220, Plasma Aldosterone Concentration (ng/dl) <1, Plasma Renin Activity (ng/ml/hr) 0.13, Plasma Corticosterone (ng/dl) (Ref AM 59-1293) >10,000, Deoxycorticosterone (ng/dl) 100, Plasma Total CO2 (mEq/L) 32 Arterial pH 7.46, Spot urine K/cr (mEq/gm): on day of admission - 206 and 4 days later while on amiloride- 59

Lysozyme Toxicity Causing Proximal Tubulopathy in Patient with Acute Monocytic Leukemia

Gurbir S. Sehmbey, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Acute leukemia is a common malignancy that is often associated with acute kidney injury. While rare, lysozyme-induced nephropathy can occur in patients with monocytic leukemia. This condition is caused by overproduction of lysozyme, which is released into blood circulation, filtered by the glomerulus, and reabsorbed by the proximal tubule. The resulting tubular injury can lead to renal insufficiency and electrolyte imbalances.

Case Description: 22 years old male was admitted to the hospital with fever. Upon admission, labs revealed marked leukocytosis, white blood cell count of 114.94 k/uL. Bone marrow biopsy confirmed a diagnosis of acute monoblastic/monocytic leukemia. The patient was noted to have acute kidney injury with serum creatinine of 1.48 mg/dL. Urine microscopy was with numerous granular casts and few eumorphic red blood cells. Kidney ultrasound showed normal-sized kidneys, increased parenchymal echogenicity and no hydronephrosis. After rapid resolution of AKI to a baseline creatinine of 0.6mg/dL patient was noted to have hypokalemia with serum potassium of 3.2 mmol/L, hypophosphatemia with phosphorus of 1.4 mg/dL (normal range 2.2-4.5mg/dL) and uric acid levels of 1.3 mg/dL (normal range of 3.5-8.5mg/dL). Given the high percentage of blasts and monocytes, lysozyme-induced nephropathy with Fanconi syndrome was considered. Fractional excretion of potassium was > 10%, indicating increased renal loss of potassium. Additional testing revealed elevated serum lysozyme levels (>10.00 ug/mL; normal range 0 – 2.75 ug/mL), supporting a diagnosis of lysozyme-induced nephropathy. Patient was started on aggressive fluid hydration; electrolytes were replaced. The patient was eventually started chemotherapy with normalization of white blood cell count and renal function.

Discussion: Lysozyme-induced nephropathy is a rare complication of acute or chronic monocytic neoplasms associated with overproduction of lysozyme resulting in elevated serum and urine levels. Lysozyme is freely filtered by the glomerulus and reabsorbed in the proximal tubule. Lysozyme can be toxic to proximal tubule cells leading to acute tubular injury, renal insufficiency, hypokalemia due to renal potassium wasting and Fanconi syndrome. Kidney biopsy can be helpful to establish a diagnosis. Recognition of this rare etiology for AKI is important and may guide management of acute and chronic leukemias.

FR-PO271

Imatinib-Associated Fluid Retention

Dhara Dave,[1] Kerolos N. Abdelmalek,[3] Zonghan Dai,[2] Tarek H. Naguib.[2] *[1]Yale School of Medicine, New Haven, CT; [2]Texas Tech University Health Sciences Center School of Medicine, Amarillo, TX; [3]Community Regional Medical Center, Fresno, CA.*

Background: Imatinib is one of the first tyrosine kinase inhibitors and is used in several conditions based on effects on receptors like BCR-ABL, the platelet-derived growth factor receptor (PDGFR), and stem cell factor (SCF)/c-kit tyrosine kinases. It has been associated with fluid retention (FR) and the mechanism behind this is largely unknown. Here we provide laboratory data that suggests imatinib affects aquaporin 2 (AQP2) expression proposing a theory behind imatinib associated FR.

Methods: Mouse kidney inner medullary collecting duct cell line (IMCD-3) cells are grown on coverslips in 24-well plate with DMEM containing 10% fetal bovine serum to 95% confluency. The cells are starved in 1 ml/well plain DMEM F12 medium for 2 hours prior to treatment. They are then treated with DMSO as control or with either 5 μM imatinib for 1 hour or 100 nM AVP for 30 min. After treatment, cells are washed, fixed, permeablized, and incubated with anti-aquaporin 2 antibody and Alexa Flor Goat anti-rabbit IgG 488. The cells are counter-stained by DAPI to visualize nuclei and stained coverslips then are mounted to slides and visualized under fluorescence microscope.

Results: IMCD-3 cells express AQP2 with an even distribution in cytosol and membrane in untreated control cells. Stimulation of IMCD-3 with vasopressin promotes a dramatic membrane distribution of AQP2. Similar to vasopressin, treatment of IMCD-3 cells with imatinib also induced a profound membrane distribution.

Conclusions: To our knowledge, this is the first evidence that treatment of IMCD-3 with imatinib enhances AQP2 membrane distribution. The bidirectional control of AQP2 trafficking from cytoplasm to the apical plasma membrane is regulated by vasopressin/vasopressin receptor (VP/VPR) pathway and filamentous actin (F-actin) polymerization/depolymerization. The signaling pathways can be activated by growth factor receptors such as EGFR and PDGFR which also cross-talk to VP/VPR. Abl tyrosine kinases likely play important roles as downstream receptors in regulating actin cytoskeleton remodeling and intracellular trafficking. Activation of Abl tyrosine kinases increases cell surface expression of EGFR. Therefore, inhibition of Abl tyrosine kinases by imatinib may lead to blockade of the EGF/EGFR signaling that regulates AQP2 distribution and FR. Further study of Abl signaling as a potential regulator in AQP2 trafficking is warranted.

The Conundrum of Normal Kidney Endothelial HLA-DR Clarified by Checkpoint Inhibitor Toxicity: A Role for Microvascular Endothelium in Peripheral Tolerance

Kimberly A. Muczynski. *University of Washington, Seattle, WA.*

Background: Years ago we reported high constitutive expression of HLA-DR on microvascular endothelial cells of normal human kidney in the absence of inflammation. This surprised us and seemed incongruent with what is known about HLA class II antigen processing. Peptides bound to class II molecules are derived from the uptake of extracellular proteins which get processed intracellularly and then exported to the cell surface bound to HLA-DR where they can be recognized by specific T cell receptors. Would it, therefore, not be dangerous to have kidney endothelial cells constitutively express HLA-DR on their surface where they might encounter and activate circulating T cells?

Methods: We used flow cytometry and and T cell activity assays to investigate the role of HLA-DR on human kidney microvascular endothelial cells (KMEC).

Results: First, we show T cell proliferation and gamma interferon secretion of sensitized T cell when influenza hemagglutinin peptide is presented by KMEC of the appropriate HLA-DR specificity. Blockade of CD58 or HLA-DR reduces T cell activation while blockade of CD274 (PD-L1) enhances activation. **Second**, T cell co-stimulatory and inhibitory molecules on normal native and transplanted kidneys are identified by flow cytometry. CD274 expression is high on all KMECs and T cells within the kidney express CD279 (PD-1). **Third,** biopsies of acute kidney injury associated with checkpoint inhibitors that block the PD-1, PDL-1 axis show an intense perivascular lymphocytic infiltrate. **Finally,** human fetal kidneys express endothelial HLA-DR and CD274 at a similar time in development suggesting a fundamental property of the endothelial cells rather than resulting from an immune response.

Conclusions: Taken together, we propose a mechanism of peripheral tolerance whereby KMEC HLA-DR limits activation of sensitized T cells, even if a bound peptide is recognized, because of the constitutive high-co-expression of CD274 (PDL-1).

Acute Interstitial Nephritis and Its Recurrence due to BRAF-MEK Inhibitors for Melanoma

Zahraa Khan,[1] Surya V. Seshan,[1] Ilya Glezerman.[2] *[1]Weill Cornell Medicine, New York, NY; [2]Memorial Sloan Kettering Cancer Center, New York, NY.*

Introduction: The efficacy of BRAF – MEK inhibitor therapy on survival in advanced melanoma has resulted in its widespread use. We describe two cases of biopsy proven Acute Interstitial Nephritis from BRAF-MEK inhibitors.

Case Description: *Case One* 51 year-old with melanoma, on binimetinib and encorafenib for two years developed acute kidney injury with creatinine of 2 mg/dL from

baseline of 0.76 mg/dL two weeks ago. Labs revealed leukocytosis to 17,000, urinalysis with 41 WBC, 3 RBC, urine protein-creatinine 1.5 g/g, urine albumin-creatinine 44 mg/g and a negative urine culture. Encorafenib and binimetinib were held. Other work up revealed total protein 7 g/dL, elevated globulin 4.9 mg/dL 1, ANA 1:640, anti-dsDNA 1:80, anti-RF 23 IU/mL. Kidney biopsy revealed AIN. Prednisone was initiated at 1mg/kg/day, with return of baseline kidney function in four weeks, at which time prednisone was tapered off. She is undergoing surveillance monitoring for melanoma off BRAF-MEK inhibitors, with plan to switch to alternative drug within the class should there be recurrence of disease. *Case Two* 64-year-old with metastatic melanoma on vemurafenib and cobimetinib for six months developed AKI with creatinine of 4 mg/dL from baseline of 1.2 mg/dL. Kidney biopsy revealed AIN. She was treated with prednisone 1 mg/kg/day and switched to encorafenib and binimetinib. Two months later, she developed another AKI, presumably AIN and steroids were prescribed. She was switched to immunotherapy, however due to progression of melanoma dabrafenib and trametinib was initiated, this time with prophylactic low dose prednisone at 10 mg daily. Her kidney function is improved with creatinine of 2 mg/dL and CKD stage 4.

Discussion: We report the first case series of AIN after BRAF-MEK inhibitors for advanced melanoma. We describe our approach to therapy which includes initial treatment with steroids to suppress the immune response, followed by switch to alternative drug, possibly within the same class. However, as described in case two, our patient developed an immune reaction to the second agent as well suggesting that the reaction is likely a class effect. This was offset by prophylactic low dose of steroids given at the time of re-initiating treatment with a BRAF-MEK inhibitor.

FR-PO274

An Unusual Case of Acute Tubulointerstitial Nephritis (ATIN) with CD8-Positive Cytotoxic T Cell Infiltrate

Maria Triantafyllou,[1] Steven Salvatore,[2] Insara Jaffer Sathick.[1] [1]*Memorial Sloan Kettering Cancer Center, New York, NY;* [2]*Weill Cornell Medicine, New York, NY.*

Introduction: ATIN is a cause of acute kidney injury (AKI) characterized by tubulointerstitial inflammatory infiltrate, primarily lymphocytic and eosinophilic. We present a case of ATIN with an almost exclusive CD8+ cytotoxic T-cell infiltrate.

Case Description: A 65-year-old man with history of hypertension, nephrolithiasis, prostate cancer treated with brachytherapy, smoldering myeloma, thymoma s/p thymectomy, CD8+ granulomatous lymphadenitis on lymph node biopsy 2 years earlier and family history of autoimmunity presented with AKI amid NSAID use. Exam was normal. Patient discontinued NSAIDs. Work-up revealed proteinuria 378mg/d, serum creatinine 2.6(baseline 1.3)mg/dl, free lambda light chains on UPEP, serum lambda15mg/dl, K/L ratio 0.03 (stable). Urinalysis depicted protein 100mg/dL without abnormal cells or casts. HIV, hepatitis B/C, HTLV-I/II serologies, Parvo, CMV, AAV and EBV PCR were negative. c-ANCA was positive, ANA, dsDNA, PR-3, MPO antibodies negative, complements were normal. Kidney biopsy showed severe ATIN with CD8+ dominant T cell infiltrate, moderate interstitial fibrosis, no immune complex or amyloid deposition or glomerular crescents. Suspicion for a T-cell lymphoproliferative disorder was entertained. Hematologic workup was negative for thymoma recurrence or myeloma progression including flow cytometry. T-cell receptor studies were polyclonal. Patient was started on prednisone, creatinine improved to 2mg/dl after 2 weeks.

Discussion: This is a case of ATIN with an almost exclusively, atypical CD8+ cytotoxic T-cell infiltrate. Based on prior history, we suspect the underlying cause may be autoimmune dysregulation or T cell disorder. A careful workup to rule out active viral infections and underlying hematologic disorder was performed before starting immunosuppression with close follow up.

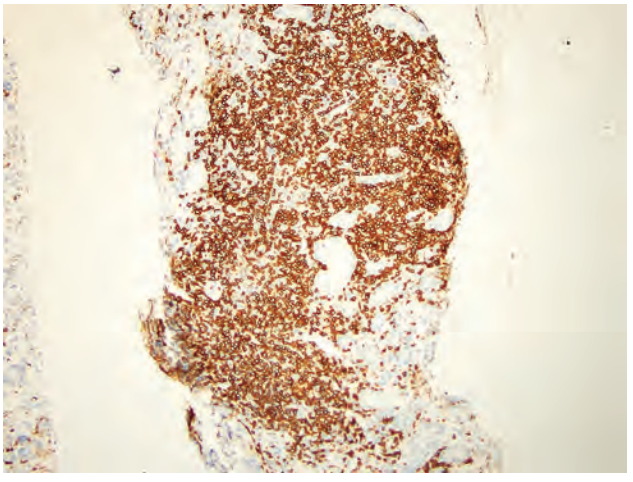

Figure 1. Renal biopsy illustrating tubulointerstitial nephritis with CD8 cytotoxic T cell infiltrate, CD8 IHC x20

FR-PO275

Pauci-Immune Necrotizing and Crescentic Glomerulonephritis due to Pembrolizumab

Divya Sharma Divyadarshini,[1] Gargi Sharma Priamvada.[2] [1]*The University of Oklahoma Health Sciences Center, Oklahoma City, OK;* [2]*East Carolina University, Greenville, NC.*

Introduction: Immune checkpoint inhibitors (ICI) have trailblazed the treatment of cancer in the past decade. However, these drugs are marred with occurrence of Immune-related Adverse Effects (irAEs). Most commonly reported renal irAE is acute tubulointerstitial nephritis(AIN). Lately, cases of acute kidney injury(AKI) from podocytopathy and glomerulonephritis with ICI are noted but true incidence is likely underestimated from missed diagnosis and under-reporting. We present an illustrative case of an elderly female with a rare manifestation of AKI during treatment with pembrolizumab(Keytruda) with complete recovery due to prompt diagnosis and effective therapy.

Case Description: 74-year-old female undergoing treatment for metastatic squamous cell carcinoma of head and neck presented to Nephrology clinic for evaluation of AKI, hematuria and new-onset proteinuria. 15 days ago, she received a third dose of Keytruda. Creatinine had rapidly risen to 2.8mg/dL from baseline 0.5mg/dL. Urine protein-creatinine ratio of 1.6g/g, urine sediment with numerous acanthocytes and RBC casts. Renal biopsy showed acute pauci-immune focal necrotizing glomerulonephritis with 30% cellular crescents, granular mesangial staining for IgM and C3 on immunofluorescence and foot process effacement by electron microscopy. Keytruda was discontinued;she was treated with methylprednisolone, cyclophosphamide and rituximab. Kidney function normalized within 8 weeks.

Discussion: The case highlights importance of clinical suspicion and knowledge of the heterogeneity of pathological findings with renal irAEs on ICI therapy. Emerging data suggest incidence of AKI from 2-20% with Keytruda, a highly selective monoclonal IGg4-kappa antibody against PD – 1 receptor. Renal irAEs can occur during and upto 2 months after therapy cessation. Many times, AKI is presumptively treated with steroids for AIN. The presence of glomerular hematuria, proteinuria or persistent AKI despite steroids warrants a renal biopsy as most patients can recover completely with early diagnosis and prompt treatment and possibly tolerate rechallenge of ICI.

FR-PO276

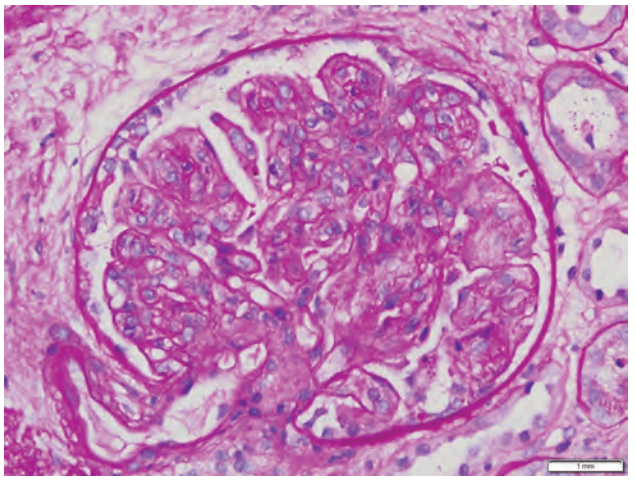
Membranoproliferative Glomerulonephritis (MPGN) Associated with Atezolizumab

Fnu Parveen. *Baylor College of Medicine, Houston, TX.*

Introduction: Immunotherapy is a revolutionary approach to cancer management, particularly in advanced malignancies that have progressed despite traditional chemotherapy. Atezolizumab is a humanized monoclonal antibody immune checkpoint inhibitor that binds to programmed death ligand 1 (PD-L1) to selectively prevent the interaction between the PD-1 and B7.1 receptors. We present a unique case of a patient with acute kidney injury associated with nephrotic syndrome after starting atezolizumab for metastatic pancreatic carcinoma.

Case Description: 64 year old female with a past medical history significant for stage 1A endometrial cancer status post (s/p) total abdominal hysterectomy, biliary obstruction s/p stent for locally advanced unresectable pancreatic duct adenocarcinoma FOLFIRINOX completed chemoradiation. She was enrolled in i LOKON - 001 immunotherapy trial with oncolytic virus + atezolizumab + abraxane + gemcitabine and received 9 cycles. She was admitted for her complaints of shortness of breath and bilateral pedal edema. Her had hypertensive urgency with anasarca on clinical exam. Labs showed acute kidney injury with urinalysis positive for protein and blood. Further work up revealed nephrotic range proteinuria with UPCR 8 g/g. ANA, complements, Urine electrophoresis were negative. Serum electrophoresis showed IgG kappa monoclonal band. Anti-PLA2R receptor normal. Renal vein doppler was negative for renal vein thrombosis. Renal biopsy showed MPGN with full house pattern, immune complex deposit in subendothelium thought to be from atezolizumab. She was taken off the immunotherapy trial and started on diuretics and steroids with significant improvement in her proteinuria and anasarca.

Discussion: Nephrotic syndrome (NS) in this patient was thought to be related to atezolizumab as secondary work up for MPGN was all negative. NS resolved after stopping atezolizumab and starting steroids which is suggestive of atezolizumab related nephrotoxicity.



FR-PO277

Acute Tubulointerstitial Nephritis and Minimal Change Disease After Administration of Lenalidomide

Xuanling Du, Charles Russell, Naveen Punchayil Narayanankutty. *University of South Florida, Tampa, FL.*

Introduction: Several case reports have raised concern regarding association between lenalidomide and acute tubulointerstitial nephritis (ATIN) or minimal change disease (MCD), mostly described in patients with plasma cell dyscrasia. Here we report a case of concomitant ATIN with MCD after lenalidomide initiation for a patient with myelodysplastic syndrome (MDS).

Case Description: A 68-year-old male with a history of MDS, hypertension, and coronary artery disease presented with a 2-week history of right flank pain, anasarca, and dark urine. He reported a 40-pound weight gain since the symptoms began. He had been taking lenalidomide for 7 months and was awaiting allogeneic hematopoietic stem cell transplantation. He was taking ibuprofen 2-3 tabs (200mg) per week over the last few years and denied other medication changes or contrast exposure. On admission, serum creatinine was 6.9 mg/dl (baseline 0.6-0.8 mg/dl) with albumin of 1.5 g/dL (baseline 3.5 g/dL). A urinalysis showed a specific gravity of 1.045, 51-100 WBC/hpf, 51-100 RBC/hpf, and many granular casts. Urine protein quantification was > 2000 mg/dl. Renal ultrasound showed medical renal disease. Hospital course was complicated by continued renal deterioration requiring initiation of hemodialysis. His renal biopsy showed mild acute tubulointerstitial nephritis with scattered eosinophils and some chronic ischemic changes. Ultrastructural studies revealed diffuse podocyte injury and extensive foot process effacement consistent with minimal change disease. The patient was started on prednisone 60mg daily with an ensuing taper initiated at discharge. At 13 weeks the patient reported near total renal recovery with cessation of hemodialysis needs.

Discussion: Lenalidomide has been reported to induce ATIN. To the best of our knowledge, there is only one case report of MCD associated with lenalidomide administration in a patient with Waldenström macroglobulinemia. NSAIDs can cause acute renal failure, ATIN and nephrotic syndrome, including MCD. NSAID-associated MCD may be present with or without ATIN, usually after long-term use. The elements of the history in our case suggests that consistent use of lenalidomide might have triggered the development of MCD with concurrent ATIN on a background of minimal NSAID use. Furthermore, rarely has MCD been reported in the setting of both MDS and lenalidomide exposure.

FR-PO278

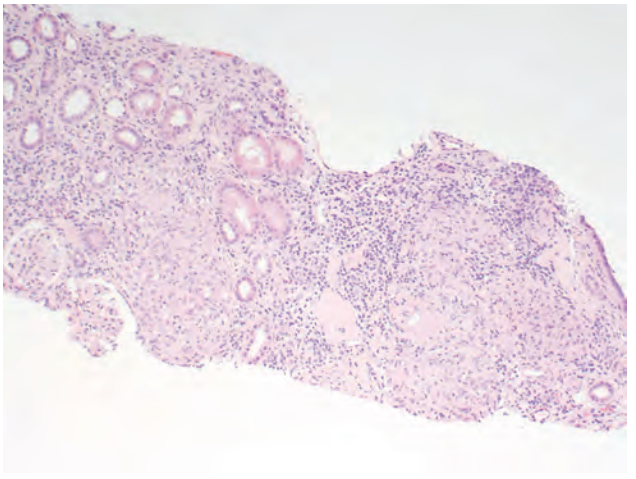
Immunotherapy-Related Renal Sarcoidosis in a Patient with Metastatic Melanoma

Avinash Rao Ullur, Rohan John, Abhijat Kitchlu. *University of Toronto, Toronto, ON, Canada.*

Introduction: Immune checkpoint inhibitors (ICIs) are widely used as standard of care therapy in management of metastatic melanoma. There have been various reported kidney complications associated with these treatments, though immunotherapy-related sarcoid-like reactions (SLRs) with kidney involvement are rare.

Case Description: A 57-year-old lady was diagnosed with metastatic melanoma stage IV and received first line Ipilimumab/Nivolumab followed by Nivolumab monotherapy q3 weekly. Her therapy was interrupted by an asymptomatic rise in serum creatinine (sCr) from a baseline of 0.9 mg/dL to 2.14 mg/dL with an incidentally detected serum calcium (sCa) of 13.23 mg/dL. She was managed with hydration & bisphosphonates. As sCr and sCa remained elevated with further ICI challenges, her treatment was changed to targeted therapy with oral Dabrafenib/Trametinib. Her melanoma remained in remission, but she persisted to have high sCr and sCa. Metabolic work-up revealed presence of hypercalciuria and elevated serum 1,25-(OH)2 vitamin D. A CT chest was suspicious for granulomatous disease, but bronchoalveolar lavage result was equivocal. The patient underwent a kidney biopsy which revealed findings consistent with sarcoidosis. She initially responded to oral steroids. As her disease remained steroid dependent, therapy was switched to oral mycophenolate mofetil. Patients' sCr has remained stable at 1.5 mg/dL after 4 months of follow up.

Discussion: In the presented case, it appears that renal SLR was related to immunotherapy as kidney dysfunction and hypercalcemia occurred after the patient was initiated on treatment. Renal SLR may also have been perpetuated with continuation of the treatment with targeted therapy, as Dabrafenib/Trametinib treatment has also been associated with SLR. In such situations, treating SLRs with steroids or immunosuppressive agents may be a reasonable option to allow continuation of therapy.



Interstitial nephritis with non-necrotizing granulomas.

FR-PO279

Acute and Chronic Kidney Dysfunction Associated with Anaplastic Lymphoma Kinase (ALK) Inhibitors

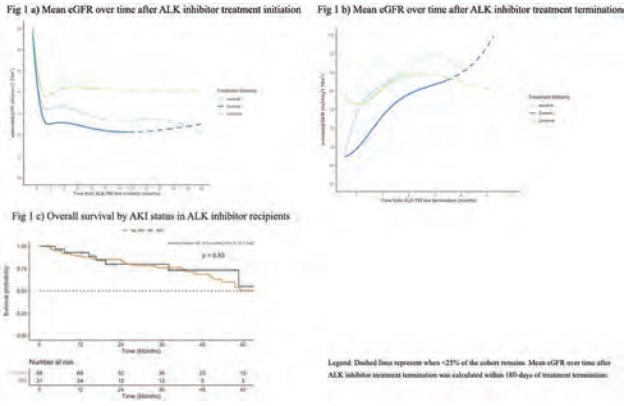
Avinash Rao Ullur,[1,2] Louis Pinard,[3] Louis C. Everest,[2] Khaleeq Khan,[2,4] Luna J. Zhan,[2,4] Geoffrey Liu,[2,4] Abhijat Kitchlu.[1,2] *[1]University of Toronto, Toronto, ON, Canada; [2]University Health Network, Toronto, ON, Canada; [3]Universite de Montreal, Montreal, QC, Canada; [4]Princess Margaret Hospital Cancer Centre, Toronto, ON, Canada.*

Background: Anaplastic Lymphoma Kinase (ALK) inhibitors have marked activity against ALK-positive non-small cell lung cancers (NSCLC). Kidney adverse effects of ALK inhibitors have been increasingly reported, though some may relate to impairment of creatinine secretion.

Methods: We performed a retrospective observational study of patients who received ALK inhibitors for NSCLC between 2010-2022. The primary outcome was incidence of acute kidney injury (AKI) within 90 days of ALK start, and chronic kidney disease (CKD) during treatment. AKI and CKD were defined via KDIGO criteria, using the creatinine-based CKD-EPI equation. We performed logistic regression for AKI risk factors and used Kaplan-Meier analysis to assess overall survival (OS) by AKI status. Spline curves were generated to estimate eGFR means over time.

Results: Among 149 Stage IIIB/IV NSCLC patients, median age was 60 years; 56% were female; 269 different TKIs were initiated: Alectinib (n=118), Ceritinib (n=30), Brigatinib (n=27), Crizotinib (n=68) and Lorlatinib (n=26). There were a total of 22 (15%) AKI events in the 90 days after initiating ALK inhibitors with 5 patients requiring treatment change due to kidney function. Figure 1 shows eGFR changes after ALK inhibitor initiation and termination. A total of 25(17%) patients developed CKD, 9 leading to treatment change. The mean eGFR for patients on Alectinib and Ceritinib was generally lower than Crizotinib. Age, hypertension, and diabetes were associated with AKI [adjusted OR (95%CI): 1.04 (1.00,1.08), 3.74 (1.50,9.54), 4.20 (1.55,11.2)]. OS did not differ by AKI status (Figure 1c).

Conclusions: There was a substantial number of AKI/CKD events observed, with a minority resulting in treatment change. Mean creatinine-based eGFR declined in the first 3 months post-ALK inhibitor start, but most patients had mild CKD during treatment, with eGFR recovering post-drug cessation. AKI did not impact OS. Our findings suggest that most patients may continue ALK TKI therapy despite kidney function changes.



FR-PO280

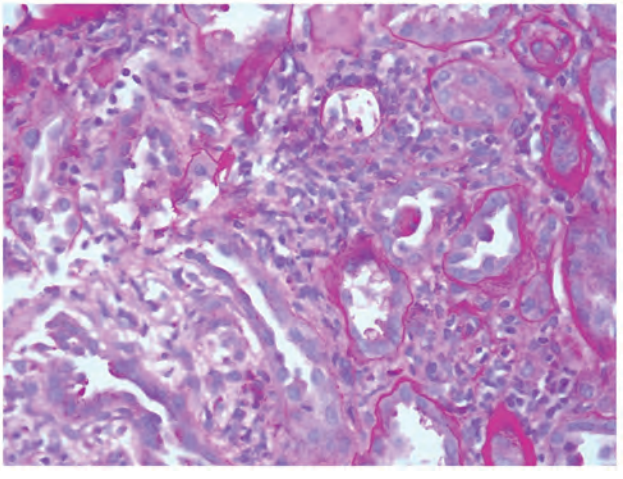
A Case of Acute Interstitial Nephritis Associated with Belvarafenib, a Novel pan-RAF Kinase Inhibitor for Metastatic NRAS Mutant Melanoma

Nabil Abu Amer, Carmen Avila-Casado, Abhijat Kitchlu. *University Health Network, Toronto, ON, Canada.*

Introduction: Belvarafenib is a potent oral type II pan-RAF kinase inhibitor that inhibits B-Raf V600E- and C-Raf-mediated signal transduction pathways and mutated Ras proteins, thereby demonstrating growth suppression of cancer with RAF or RAS mutation. This novel therapy has limited known adverse effects, with no reported kidney-related adverse events. Here, we present a case of interstitial nephritis associated with Belvarafenib treatment.

Case Description: A 79-year-old woman was diagnosed with stage IV melanoma (wild-type BRAF) with NRAS mutation on the pan-RAF agent (Belvarafenib). Eight months into the treatment, she presented to the melanoma clinic with nausea, fatigue, and severe weakness. The patient was pale on physical examination, and her vital signs were normal. Laboratory investigations revealed a serum creatinine of 260 μmol/L (from baseline 90 μmol/L) and protein trace in urinalysis with no leukocyturia or hematuria. Urine microscopy showed granular casts consistent with acute tubular necrosis. The kidney function was not improved despite hydration and discontinuing Belvarafanib. A kidney core biopsy revealed acute interstitial nephritis drug-related and acute tubular injury. She was treated with prednisolone1 mg/kg with improved renal function.

Discussion: Acute renal injury, particularly acute interstitial nephritis, is not a recognized side effect of Belvarafenib. This is the first reported case of a pan-RAF agent kidney adverse effects manifested by AIN and ATI. A literature review reported no renal adverse effects associated with pan-RAF agents. Belvarafenib is a novel agent; further research and time are required to determine its adverse effects incidence. However, clinicians must remain vigilant about the potential kidney adverse effects of this agent and consider a kidney biopsy to assess AIN in patients whose AKI does not respond promptly to discontinuing Belvarafenib and supportive care.



FR-PO281

Gemcitabine Hemolytic Uremic Syndrome (HUS) Associated with a New Complement Factor B (CFB) Mutation Successfully Treated with Eculizumab

Stephanie Lawanto, Spencer Hodgins, Daniel L. Landry, Jeffrey Mulhern, Gregory L. Braden. *UMass Chan Med School-Baystate, Springfield, MA.*

Introduction: Gemcitabine(G) HUS often causes chronic kidney disease or ESRD. We describe a patient(pt) who received a large cumulative dose of G who had a CFB mutation which caused dialysis dependency treated with eculizumab(E) successfully allowing cessation of dialysis.

Case Description: A 46 yr old woman with ER/PR positive & HER/2 negative breast cancer metastatic to her spine, liver and thoracic nodes was given G, 1500 mg on days 1 & 8 of ever 3 week cycle. After receiving 28040 mg/m2 of G she developed a BP of 160/100mmHg, dyspnea, an increase in serum creatinine from 1.3 to 3.7 mg/dl and MAHA with a Hg of 5.4 gm/dl, platelets 100,000, haptoglobin < 10 mg/dl, and LDH of 1046 IU/L & schistocytes on blood smear. C3 & C4 and ADAMTS13 were normal. Hepatitis A B&C, ANA, anti-DNA, cryos, ANCA, Shiga toxin, cardiolipin ab, rheumatoid factor, immunofioxation, INR, PTT, platelet antibodies, DAT, & direct coombs were all normal. After 2 plamaphareses a renal biopsy showed: Light: endothelial swelling, thickening of glomerular basement membranes, with double contours & intraluminal thrombi. IF :no tissue. EM: corrugated basememnt membranes with total foot process fusion and no immune deposits. She rapidly progressed to hemodialysis. Complement gene sequencing (Invitae, San Francisco, CA) showed a CFB mutation c.1937A>C (p.Tyr646Ser). She then received E 900 mg iv weekly x 4 & 1200 mg every other week for 4 months. MAHA quickly abated & after 3 months dialysis was stopped with a creatinine of 1.8 mg/dl. She died 4 months later from her cancer.

Discussion: We believe G-HUS occurs from a 2 hit hypothesis. G induces apoptosis & cell death in cultured bovine endothelial cells (AJ van Hall Cell Signal 34:86, 2017). This in the renal vessels coupled with a gain of function mutation in CFB could be enough to induce HUS. Several studies suggest E can treat G-HUS but they did not study complement mutations. Any pt with G-HUS should have complement gene testing performed & if positive E can induce MAHA remission & reverse dialysis dependency.

FR-PO282

Hyperacute Immune Checkpoint Inhibitor-Associated Acute Tubulointerstitial Nephritis (ICI-ATIN) Followed by ICI-Renal Tubular Acidosis (RTA): A Case Report

Hui Zhuan Tan,[1] Ravindran Kanesvaran,[2] Yi Chye Law,[2] Joycelyn Jie Xin Lee.[2] *[1]Singapore General Hospital, Singapore, Singapore; [2]National Cancer Center Singapore, Singapore, Singapore.*

Introduction: Hyperacute renal immune-related adverse events (irAEs) are rare. Immune-checkpoint inhibitor related renal tubular acidosis (ICI-RTA) has been described, but its true incidence is unknown. We report a case of biopsy proven hyperacute ICI-related acute tubulo-interstitial nephritis (ICI-ATIN) with probable ICI-RTA developing after completion of steroid therapy.

Case Description: A 67-year-old Skih male was referred for non-oliguric KDIGO 3 AKI (sCr 219μmol/L; baseline sCr 62μmol/L) and fever occurring 9 days after his first cycle of ipilimumab and nivolumab for treatment of metastatic clear cell renal cell carcinoma. Investigations showed pyuria (urinary leukocytes 168/μL) and subnephrotic range proteinuria (uPCR 2.42g/g). C-reactive protein was raised at 205mg/L. Renal obstruction was excluded. There was no exposure to nephrotoxic drugs. Empirical broad-spectrum antibiotics was commenced. Progression of AKI (peak sCr 351μmol/L) prompted the initiation of prednisolone (60mg/day) for treatment of presumptive ICI-ATIN, once infection screen returned negative. ATIN was subsequently confirmed on kidney biopsy. Favourable response was observed, and prednisolone was tapered over 6 weeks. ICI was not resumed. Tyrosine kinase inhibitor was commenced. Gradually worsening hypokalemia, normal-gap metabolic acidosis, hypophosphatemia were observed shortly after completion of steroid therapy. RTA was clinically suspected. However, concurrent pulmonary infection contraindicated further steroid therapy. Electrolyte/alkali replacement was commenced. Gradual dose de-escalation, but not cessation, of replacement was successful during 8 months of follow-up.

Discussion: ICI-ATIN should be suspected in all patients on ICI with AKI, regardless of timing of presentation. Differentials of AKI with fever in this context include sepsis-associated AKI, cytokine release syndrome and ICI-ATIN. Diagnosis may be challenging without kidney biopsy. An early, empiric trial of steroids may be considered as soon as infection is excluded. Limited evidence suggests that patients with hyperacute irAE(s) may develop further toxicities despite steroid therapy and cessation of ICI. ICI-RTA was a probable differential in our case. Steroid therapy remains the mainstay of treatment of ICI-RTA. It is uncertain if ICI-RTA can be transient or will persist as a chronic toxicity in patients managed without steroids.

FR-PO283

Colony-Stimulating Factor 1 Receptor Inhibitor (PLX3397) Attenuates Kidney Injury and Fibrosis Caused by Repeated Low-Dose Cisplatin

Naoki Hayase,[1] Cathy Sung,[2] Xuzhen Hu,[1] Peter S. Yuen,[1] Lisa Cunningham,[2] Robert A. Star.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]National Institute on Deafness and Other Communication Disorders, Bethesda, MD.*

Background: Cisplatin is a standard drug to treat many solid organ cancers. However, cisplatin can cause significant side effects including irreversible hearing loss and short-term (AKI) and long-term (fibrosis) renal impairment. Fernandez *et al* found that a mouse model of repeated low dose cisplatin (RLDC) treatment exhibited significant hearing loss and loss of cochlear mechanosensory hair cells. The colony-stimulating factor 1 receptor inhibitor PLX3397 ablated cochlear macrophages (>95% of immune cells in cochlea) and prevented hearing loss and hair cell loss. A recent report suggested that depletion of resident macrophages may mitigate renal fibrosis in the RLDC model. Therefore, we hypothesized that PLX3397 also would protect against cisplatin-induced nephrotoxicity.

Methods: CBAJ/CX3CR1GFP/+ (het) mice were used to label macrophages with GFP. Mice underwent three cycles of cisplatin treatment (3 mg/kg/day I.P. cisplatin for 4 days followed by a 10-day recovery). We fed mice with vehicle- or PLX3397-formulated chow one week prior, and then via daily oral gavage during the cisplatin cycles. We harvested kidneys, blood, and inner ears at 20 days after the last cisplatin injection for histological and biochemical analyses. Tissue platinum (cisplatin) was measured by inductively coupled plasma mass spectrometry.

Results: Mice that received cisplatin had increased plasma BUN and NGAL levels. In addition, cisplatin-treated mice had significant tubular injury and fibrosis, while administering PLX3397 significantly improved all parameters. We found that cisplatin increased CX3CR1+ cells in the kidney (without vs. with cisplatin, 8.6 ± 1.3 vs. 20.2 ± 2.6 cells/high-power field (HPF), n = 4-5/group, p = 0.001). We confirmed that PLX3397 treatment ablated CX3CR1+ cells in the kidney (Cisplatin without vs. with PLX3397, 20.2 ± 2.6 vs.1.5 ± 0.6 cells/HPF, n = 4-5/group, p < 0.001). Moreover, PLX3397 markedly prevented the accumulation of platinum in the kidney.

Conclusions: PLX3397 treatment mitigated cisplatin-induced kidney injury and renal fibrosis via ablation of renal CX3CR1+ cells. Additionally, PLX3397 treatment also decreased accumulation of cisplatin in the kidney. The pathogenetic roles of CX3CR1+ cells in cisplatin-induced nephrotoxicity of the RLDC model need to be elucidated in future studies.

FR-PO284

IgA Glomerulonephritis in the Setting of Immune Checkpoint Inhibitor Use Successfully Treated with Rituximab

Madison B. Calder, Nasim Wiegley, Kuang-Yu Jen, Shubha Ananthakrishnan, Lindsey R. Goetz. *University of California Davis School of Medicine, Sacramento, CA.*

Introduction: IgA nephropathy (IgAN) is the most common glomerulonephritis worldwide, and occurs as either a primary autoimmune response or secondary to other pathology. Immune checkpoint inhibitor (ICI) therapy has improved the prognosis for many patients with advanced cancers, but despite the benefits, immune-related adverse effects remain common. We report a case of ICI-associated IgAN successfully treated with rituximab.

Case Description: A 73-year-old White man with hepatocellular carcinoma on nivolumab was initially referred for acute kidney injury (AKI). History and physical, serology, urine, and imaging was unrevealing. Steroids were deferred, serum creatinine (sCr) partially recovered, and nivolumab was resumed. Four months later, he developed recurrent, now dialysis-dependent AKI along with gross hematuria and nephrotic range proteinuria. Kidney biopsy demonstrated a proliferative, crescentic glomerulonephritis with both IgA and C3 deposition (**Figure 1**). Nivolumab was discontinued, glucocorticoids were administered without improvement, and rituximab was initiated. Five months later, he discontinued dialysis with recovery of sCr and proteinuria to baseline levels.

Discussion: Rituximab has been shown to be effective for IgA vasculitis affecting the kidney, but has yet to demonstrate consistent benefit in primary IgAN. Case reports of IgAN affecting kidney transplant recipients report positive outcomes, possibly due to a B-cell depleting effect within the enhanced post-transplant immunologic milieu. Our case illustrates a potential role for rituximab in salvage therapy for ICI-related IgAN, where it may act similarly to provide a "check" to the amplified immune response caused by immune checkpoint disruption. Nephrologists and oncologists must remain aware of ICI-associated glomerular disease and maintain a low threshold to obtain a kidney biopsy when the presentation is atypical for AIN.

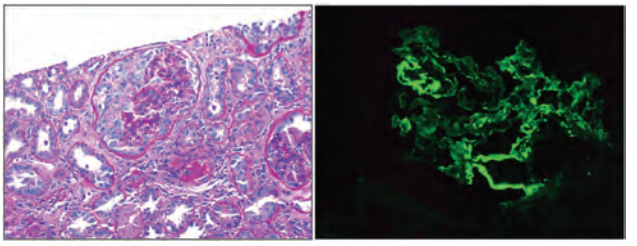

Figure 1. Native kidney biopsy demonstrating crescentic glomerulonephritis in the setting of active ICI use (left, light microscopy) with strong IgA staining (right, immunofluorescence).

FR-PO285

Allograft Rejection Following Immune Checkpoint Inhibition After Renal Transplantation: An In-Depth Analysis of PD-1, PDL-1, and CTLA-4 Checkpoint Inhibitors

Sundus Sardar,[1,2] Abdel-Rauof M. Akkari,[1,2] Mohammad Gul Yousaf Khan,[1,2] Naman Trivedi,[1,2] Nasrollah Ghahramani.[1,2] *[1]Penn State College of Medicine, Hershey, PA; [2]Penn State Health Milton S Hershey Medical Center, Hershey, PA.*

Background: Immune checkpoint inhibitors (ICIs) have emerged as one of the most pivotal therapeutic agents in tumor immunotherapy, and now used in solid-organ transplant recipients as salvage therapy post-tumor recurrence or for management of secondary tumors. However, ICI-associated allograft rejection has surfaced as a particular concern in solid-organ transplant recipients.

Methods: We performed a retrospective multi-center cohort study using TriNetX, a global federated health research network providing access to electronic medical records across large healthcare organizations (HCOs) grouped into a network called Global Collaborative Network of 105 HCOs from 14 countries. We identified 164,034 post-renal transplant recipients without ICI use and 247 patients receiving ICI after transplant until May 11 2023 from 37 HCOs. Post-kidney transplant recipients in propensity-matched groups receiving either ICI or non-ICI regimen (n=247 each) were assessed for allograft rejection within first year of ICI exposure as compared to first-year allograft rejection in non-ICI group, with risk analysis and Kaplan-Meier survival analysis as relevant, with further analysis of renal allograft rejection in propensity-matched cohort comparisons with PD-1, PDL-1 and CTLA-4 inhibition.

Results: Kidney allograft rejection within 1 year occurred in 14.9% of patients in the non-ICI cohort as compared to 11.33% in the ICI exposure group (RR=1.32; 95%CI 0.83-2.09). In renal transplant recipients on PD-1 versus CTLA-4 checkpoint inhibition, allograft rejection was confirmed in 30.3% of patients in each cohort (RR=1; 95%CI 0.48-2.08). Allograft rejection noted in 71% patients in CTLA-4 vs. PDL-1 cohorts(RR=1; 95%CI 0.63-1.59), and 50% of patients in PD-1 vs. PDL-1 cohort (RR=1; 95%CI 0.54-1.86). Our study demonstrates there was no significant difference in renal allograft rejection between ICI and non-ICI cohort.

Conclusions: After propensity matching, ICI exposure post-renal transplant was not associated with acute allograft rejection within one year of ICI exposure. Our analysis of allograft rejection with one-year exposure of either of three ICI classes did not reveal superior (or inferior) association as compared to first-year allograft rejection post-renal transplant in non-ICI cohort.

FR-PO286

Focal Segmental Glomerulosclerosis (FSGS) Associated with Chimeric Antigen Receptor T-Cell (CAR-T) Therapy

Paloma C. Orozco Scott, Matthew Abramson. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: CAR-T therapy was first used to treat pediatric leukemia, and has since expanded to other hematologic malignancies. The most common adverse reactions include cytokine release syndrome (CRS) and neurotoxicity. Acute kidney injury (AKI) has been reported in up to 30% of adult patients post CAR-T. Treatment for CRS is non-standardized but may include tocilizumab or steroids. The mechanism behind CAR-T associated AKI is not well elucidated, given small retrospective studies lacking biopsy data. With increasing popularity of CAR-T therapy, better understanding the etiology and character of CAR-T associated kidney injury may improve kidney outcomes.

Case Description: We present a case of a 47-year-old man with IgA Kappa multiple myeloma, hypertension, and diabetes, with normal proteinuria at baseline. As part of a clinical trial, he received CAR-T therapy (ciltacabtagene autoleucel). He developed CRS on day 6, and was treated with tocilizumab and anakinra. Four days after infusion there was a gradual increase in serum creatinine (SCr) from baseline 0.9 to 1.35mg/dL, downtrending to 0.99mg/dL after one month. The patient also developed hypoalbuminemia, hyponatremia, and hypophosphatemia during his course, which improved by discharge. 24-hour urine protein one month post CAR-T was 2.6 grams, and subsequent UPCR peaked at 2.56 g/g three months post CAR-T. Kidney biopsy performed at that time showed FSGS, not otherwise specified (NOS) variant, without immune deposits or substantial interstitial scarring, and with preserved podocyte foot processes. The patient was treated conservatively with losartan, and subsequent UPCR improved to 0.17 g/g by 7 months post CAR-T.

Discussion: This is the second case report of biopsy-proven FSGS after CAR-T in the literature. In contrast to the other case, our patient did not have interstitial inflammation or complete podocyte foot-process effacement, suggesting against primary FSGS, nor did he develop oliguria or edema. The presentation of new-onset proteinuria was temporally related to the CAR-T infusion, possibly representing either a CRS-related global or an off-target local inflammatory response. This case highlights the importance of understanding of CAR-T's effects on the kidney. A limitation of our case is the lack of APOL-1 testing to investigate as a second-hit phenomenon.

FR-PO287

Preliminary Open-Labeled Study to Examine the Effect of Cilastatin on the Pharmacokinetics of Cisplatin in Patients with Lung Cancer Undergoing Cisplatin-Based Chemotherapy

Hideyuki Kabasawa,[1] Michihiro Hosojima,[1] Sawako Goto,[2] Satoshi Watanabe,[3] Takahiro Tanaka,[4] Nobutaka Kitamura,[4] Ichiei Narita,[5] Toshiaki Kikuchi,[3] Akihiko Saito.[2] *[1]Department of Clinical Nutrition Science, Niigata University, Niigata, Japan; [2]Department of Applied Molecular Medicine, Niigata University, Niigata, Japan; [3]Department of Respiratory Medicine and Infectious Diseases, Niigata University, Niigata, Japan; [4]Clinical and Translational Research Center, Niigata University Medical and Dental Hospital, Niigata, Japan; [5]Division of Clinical Nephrology and Rheumatology, Niigata University, Niigata, Japan.*

Background: In animal studies, the nephrotoxicity of cisplatin (CDDP) is reduced by cilastatin (CS), which is thought to be related to the function of the endocytosis receptor megalin in proximal tubular cells, and CS may antagonize megalin and reduce the nephrotoxicity of CDDP. CS is approved as a combination drug (Thienam®, imipenem–cilastatin sodium), not as a single agent, and its effects on the pharmacokinetics of CDDP in humans have not been examined. To evaluate the pharmacokinetics and safety of CDDP when Thienam® is administered during chemotherapy including CDDP in patients with non-small cell lung cancer (NSCLC).

Methods: Patients, aged >20 years but not >70 years with advanced stage NSCLC not amenable to surgery or radical irradiation, who had not previously received chemotherapy and had an eGFR of 60 mL/min/1.73 m^2 or higher, were included. Patients were administered pembrolizumab (200 mg/body) and pemetrexed (500 mg/m^2) followed by intravenous Thienam® and then CDDP (75 mg/m^2). The primary endpoint was the pharmacokinetics of CDDP in combination with CS, which was evaluated with serum platinum concentrations.

Results: Patients were sequentially administered 0, 0.5, and 1.0 g of Thienam®, and a total of nine patients, three in each group, were enrolled in the study. The median age was 65 (range, 47–70) years and eight (89%) patients were men. The stages were unresectable stage III in one, stage IVA in four, and stage IVB in four patients. The Cmax was 2.44±0.09, 2.61±0.34, and 2.43±0.26 μg/mL, T1/2 was 114.9±14.5, 114.6±31.7, 76.8±3.4 h, and area under the curve (AUC) was 8574±1418, 8184±2480, and 7764±1217 μg/mL min in the 0, 0.5, and 1 g thienam groups, respectively. No serious adverse events occurred; only one case of grade 3 or higher adverse event (leukopenia) occurred, which was thought to be due to chemotherapy.

Conclusions: In chemotherapy, including CDDP administered to chemotherapy-naive patients with advanced NSCLC, the T1/2 and AUC of serum platinum concentration were decreased, particularly in the high-dose thienam group. It might be due to the suppression of megalin-mediated renal uptake and retrieval of CDDP by CS (Trial registration: jRCTs031180329).

FR-PO288

Refractory Hypokalemia due to a Rare Paraneoplastic Syndrome

Aiman Ajaz, Muhammad S. Ajmal. *Baylor College of Medicine, Houston, TX.*

Introduction: Renal potassium wasting can occur due to a variety of etiologies. Understanding the pathway resulting in potassium wasting is critical to treating and ultimately correcting the acid/base and electrolyte derangements seen in these cases.

Case Description: We present a case of a 54 year old female with newly diagnosed high grade metastatic neuroendocrine tumor (NET) admitted for intractable diarrhea improving after octreotide administration. Her labs, however, showed persistence of severe hypokalemia and metabolic alkalosis despite aggressive repletion. Urine electrolytes suggested renal potassium wasting with undetectable renin and aldosterone levels. Further workup showed elevated urine and serum cortisol levels with elevated adrenocorticotropin hormone (ACTH) which failed to be suppressed with dexamethasone suppression testing (DST), suggesting a paraneoplastic etiology for ACTH release. Due diligence was taken to ensure that ACTH release was not from a primary pituitary tumor by obtaining imaging and appropriate hormonal workup. It was determined that elevated cortisol exerts aldosterone-like effects on the mineralocorticoid (MRA) receptor resulting in renal potassium and hydrogen loss. The patient was started on spironolactone and ketoconazole in addition to oral potassium repletion with gradual improvements in serum potassium levels.

Discussion: As this case highlights, it is critical to understand the relationship between cortisol and the MRA receptor in addition to determining the cause for hypercortisolism which can be ACTH dependent or independent. Once it's determined to be ACTH dependent, DST is performed. Failure to suppress cortisol with dexamethasone administration suggests paraneoplastic, autonomous ACTH release which can then stimulate cortisol synthesis in the adrenals via the steroid synthesis pathway. Cortisol, at high levels, acts upon the MRA receptor resulting in hypokalemic metabolic alkalosis. Targeting therapy by blocking the MRA receptor with spironolactone and inhibiting cortisol synthesis in the steroid synthesis pathway with ketoconazole ultimately lead to improvement in serum potassium levels in addition to oral repletion.

FR-PO289

One-Year Experiences of an Onconephrology Outpatient Clinic in New York

Rahul Maheshwari, Matthew Abramson, Priya Deshpande. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Onconephrology is an emerging field within nephrology, as novel treatments in oncology have unique implications for kidney disease and care. Consequently, dedicated onconephrology clinics have been established to facilitate interdisciplinary care. However, there are no descriptions of actual onconephrology clinic experiences in the US. We report our patient characteristics during the first year of our onconephrology clinic.

Methods: The onconephrology clinic operates one half-day per week since December 2021 and is staffed by two nephrologists. We performed retrospective chart reviews of all patients seen in the first 12 months of operation, collecting patient characteristics, referral indications, primary malignancy, and referral information.

Results: 88 patients were seen with a mean age of 65.4 years, and 52% were male. The average GFR at initial visit was 44 mL/min. CKD stage at the time of initial visit was 3% CKD I, 20% CKD II, 15% CKD IIIa, 30% CKD IIIb, 26% CKD IV, and 6% CKD V (albuminuria data not reliably available at initial visit). Patients had 25 distinct primary malignancies; the most common were 35% multiple myeloma, 13% MGUS, and 13% lung cancer. 74% of referred patients had CKD. Other reasons for referral included 28% AKI, 15% proteinuria, 7% hyperkalemia, 6% TMA, 5% hyponatremia, 2% hypomagnesemia, and 1% hypertension, referred by 45 distinct providers. Median time from referral to consult for non-CKD referrals was 19 days (IQR 11-43). 40% of patients had Medicaid insurance. 15% of patients seen underwent a kidney biopsy.

Conclusions: Our experiences with an onconephrology outpatient clinic in New York highlight the diverse patient population and range of kidney-related issues encountered in this setting. The majority of referrals were for CKD, with multiple myeloma as the most common malignancy. These findings underscore the importance of collaboration between oncology and nephrology specialists to provide optimal care for patients with cancer-related kidney diseases. Further studies may provide insight into the long-term outcomes and best practices for managing these complex patients.

Current and future areas of inquiry for onconephrology clinics

FR-PO290

Association of Proton-Pump Inhibitor Use and Immune Checkpoint Inhibitor-Associated AKI: Evidence from a Meta-Analysis

Arjunmohan Mohan,[1] Pajaree Krisanapan,[2] Supawit Tangpanithandee,[2] Charat Thongprayoon,[2] Wisit Cheungpasitporn,[2] Sandra Herrmann.[2] Mayo Clinic Rochester. *[1]Nazareth Hospital, Philadelphia, PA; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Immune checkpoint inhibitors (ICIs) have revolutionized cancer treatment but their use is associated with immune-related adverse events (irAEs), including kidney injury. Proton pump inhibitors (PPI) are commonly prescribed medications independently associated with kidney injury. Understanding the relationship between ICI-associated acute kidney injury (ICI-AKI) and PPI use is crucial for optimizing patient management and minimizing complications.

Methods: To explore the association between ICI-AKI and PPI use, a comprehensive literature review was conducted. Databases including MEDLINE and EMBASE were systematically searched for articles published until January 2023. Studies reporting the incidence and risk of ICI-AKI in patients receiving ICIs, with or without concomitant PPIs, were identified and included in our analysis. Pooled odds ratios (ORs) and 95% confidence interval (CI) were calculated using a random-effect, generic inverse variance method of DerSimonian and Laird.

Results: A total of 13 studies, involving 9371 patients, were included. The overall incidence of AKI from all-cause was 51.0% (95%CI, 32.9-68.9%) among patients on PPIs and 49.0% (95%CI, 31.1-67.1%) among those not on PPIs. Focusing specifically on ICI-AKI, the incidence was 59.0% (95%CI, 49.9-67.4%) among patients on PPIs, compared to 38.7% (95%CI, 30.7-47.4%) in those not on PPIs. Importantly, our analysis revealed a significant association between PPI use and the risk of ICI-AKI, with a pooled OR of 2.51 (95% CI 1.24-5.11). These findings indicate a higher likelihood of developing ICI-AKI when using PPIs.

Conclusions: In conclusion, our meta-analysis provides further evidence of an increased risk of ICI-AKI associated with the use of PPIs. Clinicians should exercise

caution and try to avoid prescribing PPIs in patients undergoing ICI therapy, as these medications may potentially incite renal irAEs.

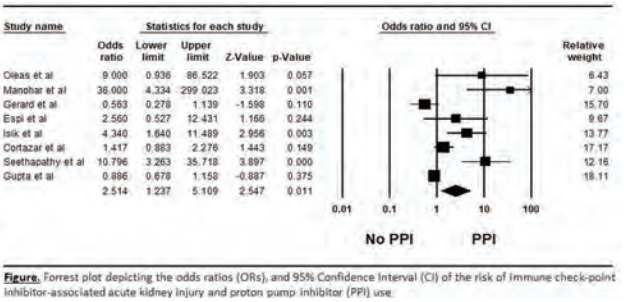

Figure. Forrest plot depicting the odds ratios (ORs), and 95% Confidence Interval (CI) of the risk of immune check-point inhibitor-associated acute kidney injury and proton pump inhibitor (PPI) use.

FR-PO291

Exploring the Biology of Non-Cleavable Klotho

Johanne V. Pastor, Orson W. Moe. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Klotho is a type-I transmembrane protein that is a cell maintenance and cytoprotective factor. Klotho protein is primarily expressed in the kidney, but it is also found in the brain, parathyroid gland, and reproductive organs. Klotho protein exists in membrane-bound and soluble forms. Membrane- Klotho acts as a co-receptor for fibroblast growth factor (FGF)23, while the soluble form of Klotho circulates and acts systemically on distant organs. Known secretases cleave the membrane klotho to produce the soluble forms of circulating Klotho. The relative contribution of the two forms of Klotho to biology and pathobiology is not known as experimental genetic manipulation of Klotho affects both forms. Low circulating levels of Klotho is associated with numerous disorders, including chronic kidney disease, cardiovascular disease, and cognitive impairment. To dissociate the function of two forms of Klotho, we aim to generate a non-cleavable form of the Klotho protein (NCK), which will provide us with the means the creation to create of a murine model to study physiology and pathophysiology.

Methods: Using previously published data and our own mutational analysis of the putative cleavage sites, we finalized on one mutant called non-cleavable Klotho (NCK) mKLd^{L9}-956-S958L, with the replacement of 9 aa at 956LGSGTLGFR-to GGLGGGSGG and expressed it in HEK293 cells.

Results: We proceeded to test that NCK is: 1. Expressed normally and trafficked to cell surface, 2. Functionally intact. 3. Indeed, NCK expression in cells and cell surface is comparable to WT Klotho (immunoblot, immunocytochemistry, and surface biotinylation), and. NCK is functionally intact as evident by its ability to sustain FGF23 signaling (FGF23-induced phospho-ERK/total ERK. There is no detectable NCK in the supernatant despite abundant cell surface expression. The data supports a NCK that is trafficked to the cell membrane, functionally intact, but not released from the cell surface.

Conclusions: A mouse model of NCK replacing WT Klotho is being generated which will provide a valuable tool for studying the physiological and pathological roles of membrane vs. soluble Klotho protein.

FR-PO292

Partial Klotho Deletion in the Renal Distal Segment Does Not Affect Ca2+ Handling

Teodora Grigore, Malou Zuidscherwoude, Caro Bos, Hannes Olauson, Joost Hoenderop. *Radboudumc, Nijmegen, Netherlands.*

Background: Klotho is a protein important in health and disease, as decrease of circulating Klotho levels is correlated with age increase and chronic kidney disease (CKD) progression. This highlights Klotho as a potential early biomarker for CKD, as well as a potential therapeutic strategy to improve health and lifespan of patients. Klotho influences renal electrolyte handling by modulating renal reabsorption of phosphate (PO_4^{3-}) and calcium (Ca^{2+}) through Ca^{2+} channel TRPV5 and Na^+/Pi co-transporter NPT2a, and by interacting with renal phosphaturic hormone fibroblast growth factor-23 (FGF23).

Methods: The mouse model with a partial deletion of Klotho (*Ksp-KL*$^{-/-}$) in the distal convoluted tubule (DCT) was generated using the Cre-Lox recombination system, and was characterized with a disrupted mineral metabolism, with hyperphosphatemia, elevated FGF23 levels and decreased parathyroid hormone levels. An interventional study was performed on *Ksp-KL*$^{-/-}$ mice by subjecting the mice to a 0.02% Ca^{2+} diet for 3 weeks immediately after weaning. 24-hour urine and blood samples were collected using metabolic cages, and kidney and intestines were processed and relevant gene expression levels were analysed (qPCR). This study aimed to assess Ca^{2+} handling in Ca^{2+}-deficient *Ksp-KL*$^{-/-}$ mice to increase our understanding of electrolyte disturbance.

Results: Urinary, serum and fecal Ca^{2+} levels were not influenced by the Ca^{2+} deficient diet or the genotype of the animals. Renal expression of *Klotho*, *Trpv5* and *Npt2a* was not significantly changed in *Ksp-KL*$^{-/-}$ mice compared to *Ksp-KL*$^{+/+}$ mice. Intestinal expression of *Trpv6* and *Npt2b* did not indicate a compensation towards intestinal electrolyte handling.

Conclusions: Partial deletion of Klotho (21%) in the DCT does not affect renal or intestinal Ca^{2+} handling, contrary to the global deletion of Klotho. We speculate that this may be due to insufficient challenge on the Ca^{2+} metabolism of the mice, as well as residual Klotho amounts that are sufficient to maintain normocalcemia and normocalciuria.

FR-PO293

Molecular Characterisation of Novel Klotho Variants Identified in Patients with Ca2+ Disturbances

Teodora Grigore,[1] Asha Bayliss,[2] Mark Stevenson,[2] Malou Zuidscherwoude,[1] David J. Carey,[4] Jeremy S. Haley,[4] Diane T. Smelser,[4] Hannes Olauson,[3] Joost Hoenderop,[1] Rajesh V. Thakker.[2] *[1]Radboudumc, Nijmegen, Netherlands; [2]University of Oxford, Oxford, United Kingdom; [3]Karolinska Institutet, Stockholm, Sweden; [4]Geisinger Health, Danville, PA.*

Background: CKD is the long-term loss of kidney function, which exerts multiple repercussions on other numerous organs, including the cardiovascular system. The progression of CKD is significantly associated with decreased serum levels of Klotho and elevated serum levels of FGF23, however the precise underlying molecular mechanisms are yet unsolved. Although CKD has a high heterogeneity in molecular changes, the disruption of the Klotho-FGF23 axis is a common feature, considering that the decline in serum levels of Klotho as the disease progresses is constant in all stages of CKD. Klotho is a protein with a large ectodomain that can get cleaved and released into circulation. Expressed in the proximal and distal tubules, Klotho is demonstrated to affect renal PO_4^{3-} excretion by interacting with NPT2a and reabsorption of Ca^{2+} by anchoring TRPV5.

Methods: The Klotho variants (c.1151T>C, c.1489T>C, c.1819A>G, c.2069C>T, c.2590G>A, c.2620G>A, c.3008A>G) were identified in a cohort by whole-exome sequencing. The variants were transiently transfected in HEK293 cells. The variants were characterized by investigating the shedding pattern, conditional cleavage, presence on the cell surface, cellular localization and co-localisation with TRPV5.

Results: Full-length shed Klotho (±130 kDa) and Klotho domains (±60 kDa) can be cleaved and identified by Western blotting. All results are compared to the wild-type Klotho condition. c.1151T>C, c.2590G>A and c.2620G>A do not show full-length shed Klotho nor shed Klotho domains, whereas c.1819A>G seems to have a lower molecular weight of the shed Klotho domain. In accordance with previous results, c.1151T>C, c.2590G>A and c.2620G>A show no surface expression on the cellular membrane. The variants c.1151T>C and c.2620G>A appear to have a diffused cytoplasmic localization, in contrast to wild-type Klotho, which has a membranous localization.

Conclusions: Our study indicates that the novel identified Klotho variants have an effect on the expression and shedding of Klotho, which directly affect the serum levels of circulating Klotho, leading to a potential decrease in circulating Klotho levels. These recent findings should allow for novel investigations on the effect of Klotho shedding in CKD.

FR-PO294

Bone-Specific Overexpression of Membrane Klotho Induces FGF23

Hirotaka Komaba, Masato Ohtsuka, Chigusa Ishioka, Abul Fajol, Yosuke Nakagawa, Naoto Hamano, Abd Aziz Ibrahim, Takehiko Wada, Masafumi Fukagawa. *Tokai University School of Medicine, Isehara, Japan.*

Background: Klotho, either membrane-bound or soluble (or cleaved) form, acts as a coreceptor that enhances the binding affinity of FGF23 to FGF receptors (FGFRs). Soluble Klotho has been shown to potently stimulate FGF23 production in osteocytes through a yet unknown mechanism, but little is known about the role of membrane Klotho in the regulation of FGF23 production.

Methods: We generated and characterized a novel mouse strain with targeted overexpression of membrane Klotho in the osteoblast lineage, driven by the 2.3-kb Col1a1 promoter.

Results: The transgenic mice are born alive and initially indistinguishable from their control littermates, but they show growth delay and die within a few days. Overexpression of membrane Klotho in osteoblasts/osteocytes resulted in a tremendous increase in serum intact FGF23 (>1500 fold) and bone Fgf23 mRNA (>400 fold), accompanied by reduced levels of 1,25-dihydroxyvitamin D and PTH, reduced Napi2a, and elevated Cyp24a1. Treatment of these mice with an FGF-receptor blocker markedly and dose-dependently suppressed the increased bone Fgf23 expression. Using primary osteoblasts isolated from the transgenic mice, we also show that the increased Fgf23 expression during osteogenic differentiation is primarily mediated by FGFR-dependent activation of the MAPK pathway.

Conclusions: These results suggest that membrane Klotho stimulates FGF23 production in osteoblasts/osteocytes, presumably by forming a positive feedback loop mediated by the FGF23-Klotho-FGFR signaling complex. Thus, membrane Klotho expressed in bone cells functions as an amplifier of FGF23 production.

FR-PO295

Merged In Vitro/In Vivo RNAseq/ATACseq Pinpointed FGF23 Target Genes Dysregulated with Klotho Deletion in Kidney Single-Cell Subpopulations

Emmanuel Solis, Kayleigh N. Jennings, Megan L. Noonan, Rafiou Agoro, Yamil Marambio, Sheng Liu, Jun Wan, Kenneth E. White. *Indiana University School of Medicine, Indianapolis, IN.*

Background: FGF23 controls phosphate and vitamin D synthesis in the kidney via its co-receptor αKlotho (KL), however, the cellular responses to FGF23 during normal and disease states are not fully understood. We hypothesize that FGF23 induces unique and generalized changes in transcription and genomic accessibility within specific nephron cell populations.

Methods: HEK293 cell line stably expressing membrane Klotho (HEK-mKL cells) was treated with FGF23 (50 ng/mL) for 4 and 16 hours, then processed for ATACseq and

RNAseq libraries. Differentially expressed genes were validated by qPCR as well as in an independent single-cell 10X Multiomics dataset from KL-KO mice. Dimensionality reduction via Uniform Manifold Approximation and Projection (UMAP) was used to identify distinct nephron cell types.

Results: HEK-mKL cell groups treated with FGF23 displayed clear segregation for both RNAseq and ATACseq following principal component analysis (PCA), with 9 and 7-fold increases in MAPK target genes *EGR1* and *FOS*. Vitamin D 24-hydroxylase *CYP24A1* (2-fold) and *VDR* (1.5-fold) increased at 4 and 16 hours, supporting this model. ATACseq showed FGF23 rapidly influenced genomic regions to control MAPK signaling as demonstrated by opening chromatin accessibility of an *EGR1* distal enhancer by 4h. In confirmation, HOMER motif discovery predicted enrichment in transcription factor binding for MAPK targets *FOS*, *JUN*, *AP1*, and *EGR1* across the genome (P<0.05). At both 4 and 16h, FGF23 bioactivity was associated with novel induction of ETV transcription factor family mRNAs (*ETV1* (3.7-fold), *ETV4* (8-fold), and *ETV5* (7.5-fold). Furthermore, FGF23 bioactivity increased the expression of *ETV1/4/5* target genes *MMP1*, *PTGS2*, and *VEGF*. Conversely, *in vivo*, 10X Multiome analysis of KL-KO mouse kidney proximal tubule-S1/S2 cells showed a 27% decrease in *Etv5* mRNA. Further, *Etv1* expression and chromatin accessibility decreased by 70% and 92%, respectively, contrary to the increase of these key factors with FGF23 treatment.

Conclusions: A unique combination of unbiased *in vitro* ATACseq/RNAseq pinpointed novel FGF23-induced transcriptional and genomic reprogramming. Translation to *in vivo* kidney cell subpopulations demonstrated these changes may influence cell-specific outcomes in FGF23-related diseases.

FR-PO296

Skeletal Muscle Is a Novel Source of FGF23 in Mouse Models of CKD

Kylie Heitman, Madison Thomas, Abul Fajol, Qing Li, Svetlana Komarova, Christopher Yanucil, Matthew S. Alexander, Christian Faul. *The University of Alabama at Birmingham Department of Cell Developmental and Integrative Biology, Birmingham, AL.*

Background: Fibroblast growth factor 23 (FGF23) increases renal phosphate (Pi) excretion, & beginning in early stages of CKD, FGF23 levels rise progressively in an attempt to maintain normal Pi levels. Pi is a potent inducer of FGF23 in bone. Previous studies suggested that bone might not be the sole source for systemic FGF23 elevations in CKD. Here we study whether mouse models of hyperphosphatemia express FGF23 in skeletal muscle (SM) & whether Pi treatments of cultured myotubes (MT) induce FGF23 expression.

Methods: C2C12 MT & primary mouse MT were treated with 1-12 mM Pi for 24 hours, followed by qPCR expression analysis of FGF23. MT were grown in chamber-slides, treated with Pi, & immunostained with anti-FGF23. We analyzed four models of hyperphosphatemia: two CKD models, i.e. mice with global deletion of collagen 4a3 (Col4a3-/-) & wildtype mice receiving an adenine-rich (0.2%) diet for 14 weeks, & two non-CKD models--a klotho deficient mouse & wildtype mouse receiving a high Pi (3%) diet for 3 & 6 months. We also studied Col4a3-/- mice receiving a low Pi (0.2%) diet for 7 weeks. Furthermore, we generated mice with SM-specific deletion of FGF23 (FGF23fl/fl;HSA-Cre+) & administered an adenine-rich or a high Pi diet for 14 weeks or 6 months, respectively. We studied FGF23 expression in SM by qPCR, ELISA & immunofluorescence microscopy, as well as serum levels of FGF23 & Pi.

Results: Pi treatments increased FGF23 expression in C2C12 MT & primary mouse MT in a dose-dependent manner. In all four mouse models we detected FGF23 in SM tissue on mRNA & protein level. When Col4a3-/- mice received a low Pi diet, FGF23 expression was reduced. FGF23fl/fl;HSA-Cre+ mice on an adenine or a high Pi diet had significantly lower FGF23 mRNA & protein levels in SM & reduced serum FGF23 levels, when compared to control mice on the same diet.

Conclusions: Mouse models with hyperphosphatemia produce FGF23 in SM tissue in the presence & absence of CKD. SM-derived FGF23 significantly contributes to the hyperphosphatemia-associated elevations in serum FGF23 levels. Our ongoing studies aim to determine whether SM-derived FGF23 has paracrine effects, & for example contributes to SM atrophy that we have detected in these mouse models. Furthermore, we will determine if SM-derived FGF23 has endocrine effects & increases renal Pi excretion.

FR-PO297

Glycerol-3-Phosphate Is an Independent Predictor of FGF23 Levels in Hemodialysis Patients

Yosuke Nakagawa,[1] Hirotaka Komaba,[1] Masatoshi Ito,[2,3] Chigusa Ishioka,[1] Naoto Hamano,[1] Yusuke Tomita,[3] Michio Nakamura,[3] Takatoshi Kakuta,[4] Masafumi Fukagawa.[1] *[1]Tokai Daigaku Igakubu Jin Naibunpi Taisha Naika, Isehara, Japan; [2]Sei Marianna Ika Daigaku, Kawasaki, Japan; [3]Tokai Daigaku Igakubu Daigakuin Igaku Kenkyuka, Isehara, Japan; [4]Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan.*

Background: FGF23 levels are markedly elevated in kidney failure, but the mechanisms for the increased FGF23 production is incompletely understood. Emerging evidence shows that kidney-derived glycerol-3-phosphate (G-3-P), a byproduct of glycolysis, serves as a key mediator of FGF23 production in response to dietary phosphate loading. However, little is known about the role of G-3-P in kidney failure.

Methods: We measured serum G-3-P levels by LC/MS in 35 healthy individuals and 650 hemodialysis (HD) patients enrolled in the Tokai Dialysis Prospective Cohort Study. We employed multivariable linear regression to explore whether hyperphosphatemia is associated with increased G-3-P levels in HD patients. We next examined whether serum G-3-P is a determinant of FGF23 levels, independent of known regulators of FGF23 such as serum phosphorus, calcium, PTH, iron metabolism, and inflammation.

Results: The median serum G-3-P level in HD patients was 220 ng/mL (interquartile range [IQR], 118-325 ng/mL), which was 2.2-fold higher than that in healthy individuals (98 ng/mL; IQR, 80-129 ng/mL; $P < 0.001$). Patients with higher G-3-P were younger; were more likely to be male; were less likely to have diabetes; had higher body mass index and higher serum albumin, creatinine, phosphorus, and total cholesterol; and were more often prescribed calcium carbonate and cinacalcet. Higher serum phosphorus was strongly associated with higher G-3-P; this association was unchanged after multivariate adjustment and was significant even when the analysis was restricted to patients undergoing dialysis for more than 10 years. In univariate analyses, higher serum phosphorus, calcium, intact PTH, and G-3-P, and active vitamin D use were each significantly associated with higher FGF23. In multivariate analyses, G-3-P was identified as one of the independent predictors of FGF23. Further adjustment fortransferrin saturation, ferritin, and C-reactive protein did not qualitatively change these findings.

Conclusions: These findings suggest that even in patients with kidney failure, G-3-P is increased by phosphate retention and serve as a regulator of FGF23 production. Additional studies are needed to test these hypotheses and to explore whether the apparently non-functioning kidney still has the capacity to produce G-3-P.

FR-PO298

Multi-Trait Analysis of Mineral Metabolism Markers Identifies Novel Genetic Associations for FGF23

Cassianne Robinson-Cohen,[1] Nicholas Vartanian,[1] Elvis A. Akwo,[1] Farzana Perwad.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]University of California San Francisco, San Francisco, CA.*

Background: Genome-wide association studies (GWAS) have identified numerous genetic loci associated with mineral metabolism markers but have exclusively focused on single-trait analysis. In this study, we performed a multi-trait analysis of GWAS data of mineral metabolism markers, exploring overlapping genetic architecture between the traits, to identify novel genetic associations for fibroblast growth factor 23.

Methods: We applied multi-trait analysis of GWAS (MTAG) to genetic variants common to GWAS of 5 genetically correlated mineral metabolism markers (phosphorus, FGF23, calcium and PTH) in European-ancestry subjects. We integrated information from the UKBioBank GWAS for phosphate and calcium (n=366,484), and two GWAS from the CHARGE consortium for PTH (n=29,155) and FGF23 (n=16,624).

Results: MTAG increased the effective sample size for all mineral metabolism markers, to n=50,325 for FGF23. After clumping, MTAG identified independent genome-wide significant SNPs for all traits, including 47 loci for FGF23. Many of these loci have not been previously reported in single-trait analyses, including loci involved in inflammation, lipid metabolism, glucose metabolism, and bone health.

Conclusions: MTAG boosted the number of genome-wide significant loci FGF23. Our findings highlight the importance of performing multi-trait analysis in GWAS studies of mineral metabolism markers to identify novel genetic associations. These genetic loci may provide insight into the biological mechanisms underlying mineral metabolism and may have implications for the development of therapies for mineral-related disorders.

Activation of Fatty Acid β-Oxidation in Proximal Tubular Epithelial Cells Is an Intrinsic Mechanism for Suppressing Phosphorus-Induced Kidney Injury

Yusuke Katsuma, Isao Matsui, Atsuhiro Imai, Hiroki Okushima, Ayumi Matsumoto, Kazunori Inoue, Yoshitaka Isaka. *Osaka Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Suita, Japan.*

Background: Excess phosphorus is known to induce kidney injury. The kidneys are the primary organ that excretes phosphorus and are exposed to a phosphorus burden. Thus, it may be difficult for the kidneys to maintain their function over a lifetime unless they have some counteracting mechanisms against the phosphorus burden. This study aimed to clarify how the kidneys counteract the phosphorus burden.

Methods: Six-week-old male C57BL/6 mice were randomly divided into Ctrl and Phos groups. Mice in the Ctrl and Phos groups were fed with a 0.85% phosphorus diet and a 3.0% phosphorus diet, respectively. Since renal fibrosis was not observed in both groups 3 weeks after the start of dietary intervention, we assumed that the kidney was in

the stress compensation period and performed single-cell RNA seq (scRNA-seq) analysis at this point. The results obtained from scRNA-seq analysis were validated in vivo and vitro experiments.

Results: Kidney component cells were classified into 12 clusters and analyzed differentially expressed genes (DEGs) between the Ctrl and Phos groups in each cluster. Since the highest number of DEGs were detected in the S1/S2 segments of the proximal tubules (Prox_S1/S2), we focused on the Prox_S1/S2. Kyoto Encyclopedia of Genes and Genomes pathway analyses demonstrated that genes related to fatty acid β-oxidation (FAO) were the top activated pathway in the Prox_S1/S2 cluster of the Phos group. Single-cell regulatory network inference and clustering analyses identified peroxisome proliferator-activated receptor α (PPARα) as one of the most activated transcription factors that regulate the gene network in the Prox_S1/S2 cluster of the Phos group. Immunohistochemistry and western blot of the kidney showed up-regulated PPARα and carnitine palmitoyltransferase 1A (CPT1A), a rate-limiting enzyme of FAO, in the Phos group. In vitro experiments using cultured proximal tubular epithelial cells (PTECs) revealed that phosphorus directly increases CPT1A expression. Etomoxir, a CPT1 inhibitor, significantly reduced cell viability of PTECs only under high phosphorus conditions.

Conclusions: The activation of FAO is an intrinsic defensive reaction against phosphorus-induced cytotoxicity in PTECs.

FR-PO300

Calcimimetic Treatment Reduces Progression of High Phosphate-Induced Tubular Injury in Mice

Maren Leifheit-Nestler, Franziska Walles, Beatrice Richter, Nina Weingärtner, Jan H. Braesen, Dieter Haffner. *Hannover Medical School, Hannover, Germany*.

Background: High phosphate stimulates fibroblast growth factor 23 (FGF23) and both factors are discussed to promote chronic kidney disease progression. Recently, we demonstrated that a high phosphate diet (HPD) in mice leads to increased serum phosphate and Fgf23 levels and a Stat3/Kim-1-mediated proximal tubule injury and tubulointerstitial fibrosis. In parallel, inflammatory processes in the renal parenchyma with induction of MCP-1 (monocyte chemoattractant protein-1; *Ccl2*) and accumulation of macrophages as well as the development of perivascular tertiary lymphoid structures (TLS) in the medullary-cortical junction could be demonstrated in HPD mice. Calcimimetics show both cardio- and nephroprotective effects. Administration of etelcalcetide in hemodialysis patients results in a reduction of FGF23 and slower progression of left ventricular hypertrophy. Cinacalcet stabilizes podocyte function in mice. We therefore postulated that calcimimetics also have a beneficial effect on the progression of HPD-induced renal damage and the maturation of TLS in mice.

Methods: To investigate whether calcimimetic treatment positively affects kidney health, we induced kidney disease in male C57BL/6 mice by the use of a 2% HPD in comparison to a 0.8% phosphate control diet (Ctrl). After four months of dietary intervention, one HPD-fed group was concomitantly treated with 1 mg/kg body weight/day etelcalcetide (Etl) for further two months. At the end, blood and urine were taken and kidneys were harvested for histological and transcriptional analysis.

Results: Therapy with Etl reduced HPD-induced Fgf23 levels but had no effect on elevated serum phosphate levels. Etl reduced activation of the renal Stat3/Kim-1 signaling cascade and decreased HPD-mediated tubule damage. Furthermore, Etl significantly suppressed mRNA expression of *Ccl2* and the macrophage-specific marker *Adgre1* compared with the HPD group without therapy. Etl had no effect on the development and maturation of renal TLS in the HPD group, which were characterized by $CD3^+$ T cells, $CD45R^+$ B cell clusters, IgD-secreting cells, $CD138^+$ plasma cells, and podoplanin$^+$ cell networks.

Conclusions: Etl therapy reduces FGF23 levels and slows progression of tubule injury in mice on HPD. Maturation of renal TLS remains unaffected by Etl, which may be attributed to persistent hyperphosphatemia.

FR-PO301

Activation of the IKK2-NFkB Pathway in Vascular Smooth Muscle Cells (VSMCs) Inhibits Vascular Calcification and Stiffness in CKD by Reducing the Secretion of Apoptosis-Mediating Calcifying Extracellular Vesicles

Makoto Miyazaki. *University of Colorado Anschutz Medical Campus, Aurora, CO*.

Background: Medial calcification is a major risk factor of cardiovascular mortality, particularly for patients with chronic kidney disease (CKD). IKK2-NFkB pathway mediated-inflammation in vascular smooth muscle cells (VSMCs) has been proposed to be an etiologic factor in vascular calcification. However, the VSMC-specific role of the IKK2-NFkB pathway in vascular calcification remains to be elucidated.

Methods: To study the role of the IKK2-NFkB pathway in vascular calcification, we used Cas9-CRISPR and Cre-loxP techniques to delete several key genes in the IKK2-NFkB pathway from cultured VSMCs and mice, respectively.

Results: CKD significantly induced inflammatory factors in VSMCs through activation of the IKK2-NFkB pathway. Unexpectedly, however, CRISPR-mediated knockouts of IKK2, RelA and NFKB1 in VSMCs all exacerbated osteogenic differentiation and mineralization of cultured VSMCs. In vivo studies showed that Cre-mediated VSMC-IKK2 deficiency aggravated vascular calcification and aortic stiffness in CKD mice, whereas the activation of NFkB by VSMC-IkB deficiency attenuated CKD-dependent medial calcification and vascular stiffness. Inhibition of the IKK2-NFkB pathway induced apoptosis of VSMCs in vitro and in vivo by reducing anti-apoptotic gene expression. In addition, increased calcifying extracellular vesicles through the inhibition of the IKK2-NFkB pathway induced mineralization of VSMCs.

Conclusions: Taken together, this study unexpectedly reveals that activation of the IKK2-NFkB pathway in VSMCs plays a protective role in CKD-dependent vascular calcification by reducing the release of apoptotic calcifying extracellular vesicles.

Hypo-Osmotic Condition Accelerates Calcification of Extracellular Matrix in Cultured Vascular Smooth Muscle Cells

Shumei Matsueda,[1] Shunsuke Yamada,[2] Kumiko Torisu,[1] Takanari Kitazono,[1,2] Toshiaki Nakano.[1] *[1]Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu Daigakuin Igaku Kenkyuin, Fukuoka, Japan; [2]Kyushu Daigaku Byoin, Fukuoka, Japan*.

Background: Hyponatremia, one of the most frequently observed electrolyte disorders in patients with chronic kidney disease (CKD), is associated with increased mortality. Basic studies have shown that lower sodium levels or osmolar conditions in the culture media induce cell damages, oxidative stress, and apoptosis: the latter two are also shown to accelerate vascular calcification (VC), a critical complication in CKD patients. It is unknown whether hyponatremia or low osmolar condition plays roles in the pathogenesis of VC.

Methods: Human vascular smooth muscle cells (VSMCs) and dissected mouse aortic rings were cultured with calcifying medium, which was supplemented high calcium and phosphate. Sodium and other osmotic substances were further added to confirm their impact on VC and phenotypic changes of VSMCs. To determine the main signaling pathway of VC in relation to osmotic stress, we performed microarray analyses. Rac1-Akt pathway and sodium-calcium co-transporter (NCX1) were investigated. The effect of osmolarity on calciprotein particles formation (CPP) was also confirmed.

Results: The lower osmolarity in the culture media exacerbated calcification of the extracellular matrix in cultured VSMCs as well as cultured mouse aortic rings. Conversely, the higher osmotic condition induced less calcification. Activation of Rac1-Akt signaling pathway, oxidative stress, CPP generation, and osteochondrogenic differentiation of VSMCs were identified as underlying mechanisms of VC acceleration mediated by low osmotic medium. Furthermore, sodium-dependent transcellular calcium efflux through NCX1 induced by high osmotic condition was proposed as mechanisms to prevent VC.

Conclusions: Our data suggest that a lower osmolarity including hyponatremic condition accelerates high-phosphate-induced VC by activating multiple cell-mediated processes and approach to avoid hypoosmotic condition would be important to prevent VC in CKD.

FR-PO303

Role and Mechanism of Interaction Between Autophagy and Ferroptosis in Regulating Osteogenic Transformation of Vascular Smooth Muscle Cells in Vascular Calcification

Li Wang, Yi Li. *Department of Nephrology, Sichuan Provincial People's Hospital, Sichuan Clinical Research Center for Kidney Diseases, University of Electronic Science and Technology of China, Chengdu, China*.

Background: Vascular calcification could cause death in chronic kidney diseases (CKD) patients, however, its pathogenesis is not clear. Osteogenic transformation of vascular smooth muscle cells (VSMCs) is key to vascular calcification in CKD, but its mechanism has not been fully elucidated. Our previous study has found an interaction between autophagy and ferroptosis involving osteogenic transformation of VSMCs in vascular calcification. This study aimed to elucidate the role of interaction between autophagy and ferroptosis in regulating osteogenic transformation of VSMCs.

Methods: We used the 5/6 nephrectomy rat model with a diet of 1.2 % phosphate at 16 weeks. Rat VSMCs were treated with supplemented medium β-glycerophosphate and CaCl2 for 7 days. All experiments were approved by the ethics committee of Sichuan Provincial People's Hospital (No. 2017. 36). And we measured autophagy and ferroptosis in CKD vascular calcification. Full-length transcriptome sequencing was performed upon rattus abdominal aortic tissues. After bioinformatics analysis with the results of sequencing, we verified the role of interaction between autophagy and ferroptosis in regulating osteogenic transformation of VSMCs in vascular calcification by molecular biology methods.

Results: The oxidative stress effect was enhanced with vascular calcification in CKD, accompanied by ferroptosis and autophagy in VSMCs. Full-length transcriptome sequencing results indicated differential expression that were related to ferroptosis and autophagy pathways significantly enriched, including significantly upregulated expression of Runx2, Atg7 and ATG5, RAB7A, ARNTL, HSP90, LAMP2A and Beclin-1 in VSMC. Protein-protein interaction analysis showed there were interactions among the differentially expressed genes that were related to autophagy and ferroptosis. Multispectral fluorescence imaging showed that the expressions of GPX4 and Sm22α decreased and the expressions of NCOA4, Smarca4 and Runx2 increased in calcified vessels of CKD.

Conclusions: These findings shed light on the role of interaction between autophagy and ferroptosis in regulating CKD-associated vascular calcification. Further studies are needed to explore the precise mechanism of interaction between autophagy and ferroptosis in CKD vascular calcification.

FR-PO304

Reversibility of Vascular Calcifications

W. Charles O'Neill, Xiaonan H. Wang, Mervyn N. Weitzmann. *Emory University School of Medicine, Atlanta, GA.*

Background: Mechanisms of vascular calcification have been extensively studied but little is known about resorption of existing calcifications, which has important therapeutic implications. Current data suggest that vascular calcification is largely irreversible but potential mechanisms for resorption that could be exploited have not been explored. To this end, resorption of calcifications was examined in human arteries implanted subcutaneously in mice or cultured with macrophages, and compared to bone particles and hydroxyapatite (HA).

Methods: Calcified human arteries were obtained from amputation specimens and calcification was quantified by μCT before and after implantation. Devitalized bone particles were obtained by pulverizing mouse femurs in liquid N_2 after removal of marrow, and HA was obtained commercially. Calcium content was measured after acid extraction. Standard histology protocols were used and activity of tartrate-resistant acid phosphatase (TRAP), a marker of osteoclasts, was measured in Triton extracts. Arteries or bone particles were cultured with macrophages from mouse spleens in the presence of M-CSF and TNFα +/- receptor activator of nuclear factor κ-B ligand (RANKL) to induce osteoclast formation.

Results: There was no decrease in arterial calcifications up to 6 weeks after implantation (+2.8 ± 0.6%) and only slight, insignificant resorption of bone particles after 7 weeks (-10 ± 8%). By contrast, only 24 ± 7% of hydroxyapatite remained after 7 weeks. Osteoclasts were not observed in any implant although TRAP-negative multinucleated giant cells were observed in HA implants. Calcified arteries cultured with macrophages for 9 days showed a 34 ± 4% increase in medium calcium (p=0.01) consistent with resorption, without enhancement by RANKL. Findings were similar with bone particles.

Conclusions: Hydroxyapatite is resorbed in vivo by macrophages in an osteoclast-independent manner. This does not occur with vascular calcifications in vivo but can occur in vitro with added macrophages, suggesting that vascular calcification is not reversible in vivo due to the failure to form functional osteoclasts or recruit macrophages. Similar findings in bone particles suggest that this extends to other forms of biomineralization. Further studies are needed to determine the properties of vascular calcifications that prevent recruitment of resorptive cells and identify strategies to overcome this.

In the CKD-MBD Absent Vascular Disease, CKD Decreases Cardiac Mitochondrial Function and Activin A Is an Activator of Skeletal Activin Receptor Signaling

Matthew J. Williams,[1] Carmen M. Halabi,[1] Hartmut H. Malluche,[2] Keith A. Hruska.[1] *[1]Washington University in St Louis, St Louis, MO; [2]University of Kentucky, Lexington, KY.*

Background: The CKD-MBD is an important factor in the cardiovascular mortality associated with CKD. The cardiac component of the CKD-MBD has not been studied in the absence of vascular disease.

Methods: We developed an animal model of the CKD-MBD without associated vascular disease. We randomized CKD Alport mice into two groups – treatment with a monoclonal Ab to activin A (CKD-AB) or an isotype matched IgG (CKD-IgG).

Results: The Alport- AB and IgG mice had CKD equivalent to human stage 4-5 CKD. PTH and FGF23 levels were one log order elevated, and circulating sclerostin was elevated. Activin A was strongly induced in the kidneys. Aortic Ca levels were not increased in the CKD mice. The CKD mice were not hypertensive, and there was no cardiac hypertrophy. Freshly excised cardiac tissue respirometry (Oroboros) revealed that ADP minus Palmitoyl Carnitine stimulated O2 flux was diminished from 52 to 22 pmol/mg ($p<0.05$) (Figure 1). RNA seq of cardiac tissue from CKD-IgG mice showed significantly decreased levels of cardiac mitochondrial oxidative phosphorylation genes. In the skeleton, the Activin A antibody decreased the effect of CKD to stimulate osteoclast number and eroded surfaces along with a decrease in the stimulation of osteoclast driven remodeling. Immunohistochemical detection of osteocytic sclerostin was increased in the CKD-IgG mice, and the antibody treatment had no effect.

Conclusions: Two important advances in the pathophysiology of the CKD-MBD are reported here. The first, that cardiac mitochondrial respiration is impaired in CKD of Alport mice in the absence of vascular disease. This is the first report of the direct effect of CKD on cardiac respiration. Secondly, we demonstrate the role of activin A in renal osteodystrophy pathogenesis. Activin A becomes the third renal produced factor after the Wnt inhibitors and klotho to contribute to the CKD-MBD.

Funding: NIDDK Support

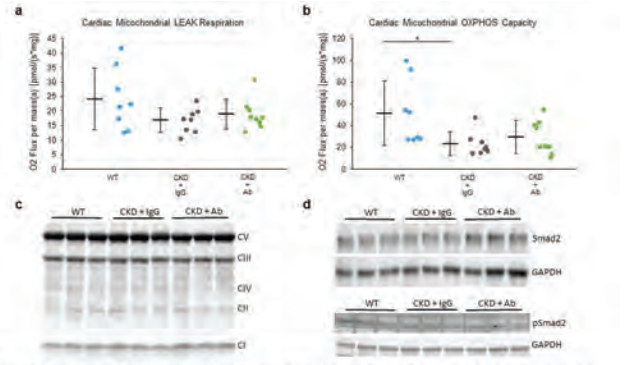

Figure 1. Cardiac mitochondrial function and oxidative phosphorylation by high resolution respirometry. a) Addition of palmitoyl carnitine and malate to permeabilized cardiac fibers to measure LEAK respiration. (**b**) Sequential addition of ADP to cardiac muscle fibers to measure fatty acid oxidative phosphorylation (OXPHOS) capacity. Cardiac fibers from 225 do Alport mice (CKD IgG) had significantly reduced rates of fatty acid oxidative phosphorylation compared to cardiac muscle fibers from WT mice. Inclusion criteria for the respirometry cohort were WT mice with BUN (mg/dL) <35 and CKD and CKD + antibody treatment mice with BUN >60. Data was limited to cardiac fibers with cytochrome c stimulated oxygen flux increase <35%. * $p<0.05$. Significance determined using the Kruskal-Wallis Test followed by pairwise comparisons with Bonferroni correction. Data represented as mean ± SD. (**c**) Cardiac mitochondrial complex I-V levels. (**d**) cardiac smad2 and psmad2 levels.

4-[(Methylthio)-Phenylthio]-Methan Bisphosphonate Improves Bone Elastic Mechanical Properties in Uremic Rats

Junichiro J. Kazama,[1] Yoshiko Iwasaki,[2] Shoichiro Horita,[1] Guy Watanabe,[1] Keiko Suzuki.[3] *[1]Fukushima Kenritsu Ika Daigaku, Fukushima, Japan; [2]Nihon Bunri University, Oita, Japan; [3]Showa Daigaku Daigakuin Shigaku Kenkyuka, Ota-ku, Japan.*

Background: Recent clinical studies no longer reveal a strong relationship between parathyroid function and fracture risk in patients on maintenance hemodialysis therapy. However, fracture risks in this patient population remains high. We have previously reported that oxidative stress-derived deterioration in bone elastic material properties could induce bone fragility in uremic conditions. The compound 4-[(methylthio)-phenylthio]-methan bisphosphonate(MPMBP)is a non-nitrogen-containing bisphosphonate, exhibiting little anti-osteoclastic activity, with an antioxidant methylthio phenylthiol group on its side chain.

Methods: An adenine-containing chew was fed to 9-week-old Sprague-Dawley male rats for 7weeks, and the treatment groups were administered 0.6 or 1.2 mg/kgBW of MPMBP subcutaneously once per week.

Results: The serum creatine levels were elevated by 2-3 folds in the adenine-fed rat groups more than those in the non-adenine-fed groups. Subsequently, the bone turnover rate was significantly elevated in the adenine-fed rat groups, while the mineral densities of femoral bone decreased regardless of MPMBP administration. Furthermore, the amount of malondialdehyde content in the tibia increased to 3-fold more in the adenine-fed groups than that in the non-adenine-fed groups. Additionally, MPMBP decreased the malondialdehyde content in a dose-dependent manner. In the adenine-fed rats, the pentosidine/amino ratio, monitored by Raman spectroscopy, significantly increased; however, MPMBP administration decreased it in a dose-dependent manner. Finally, the femoral bone storage module that was reduced to approximately half its value in the non-adenine-fed rats was almost completely recovered by MPMBP administration.

Conclusions: According to the nature of bisphosphonates, most of the MPMBP molecules administered were immediately delivered to the calcified tissue. The accumulated MPMBP molecules could scavenge reactive oxygen species, forming an antioxidant barrier around the bone. The barrier aided in oxidative stress-derived non-physiological collagen crosslink formation and reduced osteocyte apoptosis-dependent apatite disorientation, thus improving the bone elastic material properties. MPMBP exhibits the potential to serve as a new therapeutic device for uremic bone owing to a novel pharmacological mechanism.

Parathyroid Hormone (PTH) Promotes the Release of H+ by Osteoclasts via the ATF3/V-ATPase Signaling Pathway

Shuting Deng. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Persistently high levels of parathyroid hormone (PTH) promote osteolysis in patients with end-stage renal disease (ESRD). It is an important part that release of hydrogen ions (H^+) by osteoclasts leads to hydroxyapatite crystal dissolution in osteolysis, which is closely related to the proton pump (V-ATPase) on the osteoclast membrane. Activating Transcription Factor 3 (ATF3) initiates the differentiation and activation of osteoclasts. This experiment aimed to investigate that PTH promotes the release of H^+ by osteoclasts via the ATF3/V-ATPase a3 signaling pathway.

Methods: Chromatin immunoprecipitation(ChIP) assay was used to examine the binding of ATF3 and V-ATPase a3 in mouse osteoclasts. With the stimulation of PTH, we used RT-qPCR and western blot to detect the expression of ATF3, V-ATPase a3 and the expression of V-ATPase a3 which treated with silencing and overexpression of ATF3. After PTH treatment in osteoclasts, we used BCECF-AM probe to detect the pH with silencing and overexpression of ATF3, and the stronger the green fluorescence, the lower the pH, which indirectly reflected the release of H^+ by osteoclasts.

Results: ChIP assay proved that ATF3 binds to the V-ATPase a3(Figure1 A-B). PTH promoted the expression of ATF3 and V-ATPase a3(Figure1 C-F), and weakened green fluorescence of the cell, increasing the release of H^+ by osteoclasts. After PTH treatment in osteoclasts, silencing ATF3 can decrease the expression of V-ATPase a3 and the release of H^+ by cells but enhance green fluorescence in osteoclasts (Figure2), while overexpression of ATF3 can increase the expression of V-ATPase a3.

Conclusions: ATF3 is a transcription factor of V-ATPase a3. PTH promotes the expression of ATF3 and V-ATPase a3, which then facilitates the release of H^+ by osteoclasts.

FR-PO308

The Influence of MUC1 on Mg2+ Handling

Tracey Lam, Mohammad M. Al-bataineh, Allison L. Marciszyn, Lorena Ye, Amrit Singh, Paul A. Poland, Carol L. Kinlough, David R. Emlet, Evan C. Ray, Rebecca P. Hughey. *University of Pittsburgh, Pittsburgh, PA.*

Background: Numerous genomic studies find an association between the common *MUC1* polymorphism rs4072037 (minor allele frequency 21-47%) and circulating Mg^{2+} levels. This polymorphism in exon 1 of *MUC1* alters mRNA splicing, elongating the N-terminus of mature MUC1. It is referred to as the long-signal peptide variant (LSP), as compared to the short-signal peptide variant (SSP). Although human genome association studies have found an association between the LSP variant and hypomagnesemia, no studies have demonstrated an effect of MUC1 on Mg^{2+} balance. MUC1 is known to enhance cell surface localization of Ca^{2+}-selective TRP channels (TRPV5 and TRPV6). MUC1 is co-expressed with the Mg^{2+}-selective channel, TRPM6 in the kidney's distal convoluted tubule (DCT). TRPM6 is a key mediator of renal Mg^{2+} handling. Reduced TRPM6 cell surface expression in response to blockage of the epidermal growth factor receptor (EGFR), leads to urinary Mg^{2+} wasting and hypomagnesemia. We hypothesized that MUC1 influences TRPM6 cell surface expression, contributing to renal tubular reabsorption of Mg^{2+}, and that LSP-MUC1 does this less effectively than SSP-MUC1.

Methods: We examined plasma Mg^{2+} levels in *Muc1*$^{-/-}$ mice and studied MUC1 and TRPM6 expression in polarized MDCK cells and in human kidney tissue samples.

Results: We find that *Muc1*$^{-/-}$ mice are hypomagnesemic. In polarized MDCK cells in culture, MUC1 co-immunoprecipitates with TRPM6 and its binding partner, TRPM7. MUC1 enhances cell surface expression of TRPM6 and TRPM7. Although the majority of MUC1 is expressed at the apical surface of polarized epithelial cells, a small fraction is expressed basolaterally, where EGFR is located. Both in MDCK cells and in human kidney tissue, that fraction of MUC1 is reduced in the LSP variant as compared to the SSP variant. EGFR is more heavily phosphorylated in response to basolateral EGF in MDCK cells expressing SSP-MUC1 compared with LSP-MUC1, suggesting that SSP-MUC1 enhances activation of the EGFR receptor, promoting activation of TRPM6.

Conclusions: These studies provide a mechanistic explanation for the influence of MUC1 upon Mg^{2+} homeostasis. On-going studies are exploring the specific importance of kidney tubule MUC1 for TRPM6 activity and Mg^{2+} balance and EGFR-dependence of differences in TRPM6 cell surface expression associated with the LSP vs SSP MUC1 variants.

Lactating Kidneys Upregulate Expression of Cell Proliferation Genes and TRPM6 in the Distal Convoluted Tubule (DCT), Suggesting DCT Hyperplasia

Lorena Ye,[1] Hyun Jun Jung,[2] Tracey Lam,[1] Ivy Liu,[1] Andrew Gordon,[1] Allison L. Marciszyn,[1] Mohammad M. Al-bataineh,[1] Rebecca P. Hughey,[1] Paul A. Welling,[2] Evan C. Ray.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Johns Hopkins University, Baltimore, MD.*

Background: Lactating females provide large quantities of minerals to nursing offspring, including Ca^{2+}, but also Mg^{2+}. Lactation-associated Ca^{2+} conservation is stimulated when parathyroid hormone (PTH)-related peptide from the mammary gland activates renal tubular PTH receptors, promoting Ca^{2+} channel expression. However, mechanisms responsible for Mg^{2+} conservation are not described.

Methods: Female C57Bl/6 mice were mated and monitored for parturition. To normalize milk-demand, litters were culled to 4 pups at post-partum day 2 (P2). Urine was collected from P12 or nulliparous females. Mice were euthanized, and blood and kidneys harvested. Bulk RNA-Seq was performed in whole kidneys.

Results: Lactation reduced urinary Ca^{2+} and Mg^{2+}, even though circulating Ca^{2+} and Mg^{2+} were similar or higher, consistent with increased tubular reabsorption. We asked whether acute PTH receptor (PTHR) stimulation reduced urinary Mg^{2+} excretion. Acute treatment of animals with 1-34 PTH accelerated phosphorus excretion and delayed Ca^{2+} excretion, as expected, but had no net effect on Mg^{2+} excretion. Transcriptomic analysis in kidneys from lactating dams revealed increased mRNA encoding the Mg^{2+}-selective ion channel, TRPM6, exclusively expressed in the distal convoluted tubule (DCT). Transcript levels of proteins involved in paracellular transport (claudins 10, 16, and 19) were not significantly different. Kidneys from lactating dams were heavier, suggesting tissue hypertrophy. Segment-specific transcripts from the proximal convoluted tubule (PCT) and DCT were up-regulated, consistent with an increase in cell number in these tubule segments. Transcripts encoding numerous cell cycle-associated proteins also increased, including CDC20, cyclin-dependent kinase 1, cyclin D1, and cyclin D3. Cyclin D1 protein abundance also increased. In the early DCT, where TRPM6 is expressed, more cells from lactating than nulliparous females stained positive for cyclin D1.

Conclusions: These suggest that DCT hyperplasia may contribute to lactation-associated conservation of essential minerals.

Magnesium Decreases Urine Supersaturation but Not Calcium Oxalate Stone Formation in Genetic Hypercalciuric Stone-Forming Rats

Qiaoli Li,[1] Nancy S. Krieger,[2] Lee Yang,[3] John R. Asplin,[3] David A. Bushinsky.[2] *[1]Thomas Jefferson University, Philadelphia, PA; [2]University of Rochester, Rochester, NY; [3]Laboratory Corporation of America Holdings, Itasca, IL.*

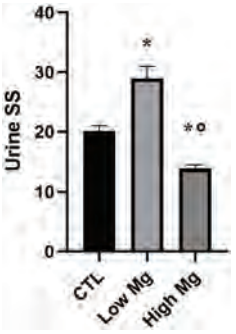
Background: This study assessed the effect of oral magnesium on urine parameters and stone formation in a genetic hypercalciuric stone-forming (GHS) rat model of human idiopathic hypercalciuria.

Methods: When fed the oxalate precursor, hydroxyproline, every GHS rat develops calcium oxalate stones. These rats, fed a normal calcium (Ca) and phosphorus (P) diet with hydroxyproline, were divided into three groups of ten rats per group: control diet with 4.0 g/kg MgO, low MgO diet (0.5 g/kg), and high MgO diet (8.0 g/kg). At baseline and at 6 weeks, twenty-four-hour urines were collected, and urine chemistry and supersaturation were determined. Stone formation was quantified.

Results: After six weeks those fed the low Mg diet had a significant reduction in urinary Mg and those fed the high Mg diet had a significant increase in urinary Mg compared to those fed the control diet. Dietary Mg did not alter urine Ca excretion while the low Mg diet led to a significant fall in urinary Ox. The low Mg diet increased urinary NH_4 and decreased urinary citrate while the high Mg diet reduced urinary NH_4 and increased urinary citrate. Urine supersaturation with respect to calcium oxalate was significantly increased with low Mg, whereas urine supersaturation was significantly decreased with high Mg. Neither a low nor high Mg diet altered kidney stone formation.

Conclusions: In genetic hypercalciuric stone-forming rats, dietary Mg significantly altered urinary CaOx supersaturation; a low Mg diet increased and a high Mg diet decreased CaOx supersaturation. There was no effect of dietary Mg on stone formation within 6 weeks of treatment.

Funding: NIDDK Support



Urine supersaturation (SS) of CaOx was differentially regulated by Mg. Results are mean ± SEM. $^{*}P < 0.05$ versus CTL; $^{o}P < 0.05$ versus low Mg.

FR-PO311

Subdued Limits E. coli Infection and Ca-Oxalate Crystallization in Drosophila Renal Tubules

Orestes Foresto-Neto,[1] Daniel R. Turin,[1] Heather L. Holmes,[1] Carmen J. Reynolds,[1] Mariah L. Arneson,[1] Muthuvel Jayachandran,[1] Julian A. Dow,[3] John C. Lieske,[1] Eva Furrow,[2] Michael F. Romero.[1] *[1]Mayo Clinic College of Medicine and Science, Rochester, MN; [2]University of Minnesota Twin Cities College of Veterinary Medicine, Saint Paul, MN; [3]University of Glasgow, Glasgow, United Kingdom.*

Background: Anoctamins (ANO) are Ca^{2+}-activated phospholipid scramblases, Ca^{2+}-activated Cl^{-} channels or both. Pathogenic ANO4 changes have been identified in dogs with calcium oxalate (CaOx) stones, and ANO4 protein expression is decreased in urinary extracellular vesicles of human CaOx stone formers. In *Drosophila* Malpighian tubules (MTs), *subdued* (ANO4-homolog) has these functions and participates in host defense against gram-negative bacteria. Urinary inoculation of mice with uropathogenic *E. coli* (UPEC) increases intrarenal CaOx crystallization. Thus, we investigated the interaction of *subdued* and UPEC for promoting *Drosophila* MT CaOx crystallization.

Methods: C724:Gal4, Uro:Gal4, and CG10116:Gal4 flies were crossed with UAS:subdued-RNAi flies to knockdown (KD) MT *subdued* in MT-stellate cells (SC), MT-principal cells (PC), or midgut cells (MG), respectively, with or without UPEC:eGFP. *Ex vivo*, dissected MTs were submerged for 90 min in a 10mM NaOx+UPEC:eGFP solution. *In vivo*, flies were fed a diet supplemented with 20mM NaOx+UPEC:eGFP for 4 days.

Results: SC *subdued*-KD slightly increased UPEC infection but did not change *ex vivo* or *in vivo* crystallization. PC *subdued*-KD facilitated UPEC invasion and increased crystal formation during short-term *ex vivo* assays. Neither crystal formation nor aggregation were changed by PC *subdued*-KD alone despite prolonged NaOx feeding *in vivo*. However, when UPEC was introduced with the NaOx diet, larger CaOx crystals were developed in MT of *subdued*-KD compared to wild-type flies. MG *subdued*-KD substantially increased UPEC presence in the MT lumen, nonetheless, this did not change CaOx crystallization in feeding experiments.

Conclusions: *Drosophila* are a useful genetic tool to study bacterial infection and CaOx crystallization. *subdued* KD in PCs or SCs, or UPEC infection alone did not change MT CaOx crystallization. However, the combination of PC *subdued*-KD and UPEC feeding *in vivo* increased bacterial infection and MT crystal formation with aggregation. These data suggest a role for ANO4 in bacterial-related human lithiases. U54-DK100227, R01-DK092408, F32-DK128987, FAPESP (2022/01226-1), ULTR002494, Mayo Foundation.

FR-PO312

SLC26A6 Plays a Major Role in Release of Soluble Oxalate from Macrophages Following Internalization of Calcium Oxalate Crystals

Ana C. Najenson,[1] Teresa R. Wagner,[2] Sebastian Bachmann,[3] Robert B. Thomson,[4] Felix Knauf,[1,4] Peter S. Aronson.[4] *[1]Department of Nephrology and Medical Intensive Care, Charité - Universitätsmedizin Berlin, Berlin, Germany; [2]NMI Natural and Medical Sciences Institute at the University of Tübingen, Reutlingen, Germany; [3]Institute of Functional Anatomy, Charité - Universitätsmedizin Berlin, Berlin, Germany; [4]Department of Internal Medicine, Section of Nephrology, Yale University School of Medicine, New Haven, CT.*

Background: Accumulating evidence indicates that macrophages play an important role in recovery from oxalate-induced nephropathy. *In vitro* studies showed that macrophages can engulf and dissolve calcium oxalate crystals. *In vivo* models demonstrated that decreased renal macrophage infiltration is accompanied by increased crystal deposition, suggesting involvement of macrophages in removing oxalate crystals. Despite these findings, the mechanisms mediating crystal clearance by macrophages remain unknown. We previously showed that macrophages express transporter SLC26A6. SLC26A6 functions as a Cl-oxalate exchanger in macrophages. Our studies indicated that under steady-state conditions, SLC26A6 mediates net oxalate efflux and prevents intracellular oxalate accumulation in macrophages. In the present work, we analyzed the role of SLC26A6 in mediating the release of soluble oxalate from macrophages following internalization of calcium oxalate crystals.

Methods: Primary murine wild-type (WT) and Slc26a6-deficient ($Slc26a6^{-/-}$) macrophages were exposed to calcium oxalate crystals for up to 48 hours. Internalization of oxalate crystals by macrophages was analyzed by transmission electron microscopy (TEM). After crystal uptake, macrophages were washed and re-incubated in an oxalate-free medium. Release of soluble oxalate after crystal internalization was measured as appearance of oxalate in the supernatant by use of an enzymatic assay.

Results: We found that WT and $Slc26a6^{-/-}$ macrophages are equally capable of oxalate crystal internalization. The presence of soluble oxalate increases with time in the supernatant of both WT and $Slc26a6^{-/-}$ macrophages after preloading with oxalate crystals. When compared with WT macrophages, macrophages from $Slc26a6^{-/-}$ mice showed greatly reduced release of soluble oxalate after 48 hours.

Conclusions: Our findings indicated that soluble oxalate is released from macrophages following internalization of calcium oxalate crystals. $Slc26a6^{-/-}$ macrophages demonstrated greatly reduced soluble oxalate release compared to WT macrophages. We therefore concluded that Slc26a6 plays a major role in the release of soluble oxalate from macrophages following internalization of calcium oxalate crystals.

Gender Difference in Plasma and Urinary Oxalate Levels in a Mouse Model for Primary Hyperoxaluria Type 1

Hatim A. Hassan,[1] Gaurav Baranwal,[1] Marina Subramaniam,[1] Ananta Prasad Arukha,[1] Soorih Shaikh,[1] Mohamed Subahi,[1] Mohammed H. El Nayir,[1] Destiny Regalia,[1] Dawood Al Dawood,[1] Mmanuel A. Dumenya,[1] Jayanta Roy-Chowdhury.[2] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Mutations in the alanine–glyoxylate amino transferase gene (Agxt) cause primary hyperoxaluria type I (PH1). A mouse model for PH1 was previously reported, with males having ~17.6% higher urine oxalate compared to females.

Methods: mRNA and protein expression levels were assessed by qPCR and immunoblotting.

Results: We now observed that males have significantly higher (~1.7-fold) urine oxalate compared to females (24-h urine oxalate in μg/g body weight: wild-type = 1.60±0.18; males = 6.69±0.32; females = 3.89±0.14). Males also have significantly higher (2.1-fold) plasma oxalate (μM: males = 4.86±0.86; females = 2.35±0.39). We first confirmed that the observed gender difference in oxalate levels is not due to differences in genotyping by showing that both males and females are homozygous for $Agxt^{-/-}$. Anion transporters SLC26A1 (A1) and SLC26A6 (A6) play important roles in oxalate homeostasis. Proximal tubular oxalate secretion involves oxalate entry into the cell from blood via A1, and then its secretion into the urine via A6. A gender difference in liver and kidney A1 protein expression exists (with no change in mRNA), where higher A1 expression is observed in male compared to female rats and is associated with significantly higher plasma (~1.8-fold) and urine (~2-fold) oxalate levels in males (including high renal oxalate secretion). Male rats also have higher liver sulfate-oxalate exchange, which could lead to elevated plasma oxalate. We therefore examined whether gender differences in A1 and/or A6 expression contribute to the observed differences in urine and plasma oxalate levels in PH1 mice. Compared to males, females have significantly reduced kidney A6 mRNA (44.6%, using qPCR) and total glycosylated A6 protein (>40%) expression. There were no significant differences in liver and kidney (~19% reduction) A1 mRNA expression levels. We could not assess A1 protein expression due to lack of working antibodies, with reduced expression expected based on data from rats.

Conclusions: We conclude that male PH1 mice have significantly higher urine and plasma oxalate levels compared to females, and that differences in kidney A6 and/or A1 (liver and/or kidney) expression potentially contribute to the observed gender difference.

FR-PO314

Uremic Toxin Indoxyl Sulfate (IS) and Parathyroid Hormone (PTH) Interact and Affect Osteocyte Signaling and Function

Neal X. Chen, Kalisha O'Neill, Sharon M. Moe. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Osteocytes are the master regulator of bone remodeling, and studies in CKD patients and animals show defective osteocyte function and maturation regardless of the PTH level suggesting other CKD specific factors may affect osteocytes. Indoxyl sulfate (IS) has been shown to have an effect on osteoclasts and osteoblasts, but the IS effect on osteocytes has not been evaluated. IS is a potent endogenous ligand for aryl hydrocarbon receptor (AhR) which is critical in the removal of toxins and can lead to inflammation, changes in steroid hormones and altered MAP kinase signaling.

Methods: We therefore evaluated the effect of IS with and without PTH on differentiation, signaling, and mineralization in mature osteocytes (day 35) and in early osteocytes when mineralization is occurring (day 14) using IDG-SW3 cell line.

Results: The results demonstrated that in mature osteocytes, the addition of IS for 24 hrs dose dependently increased the expression of bone forming genes SOST and Dkk1, bone resorbing genes RANKL/OPG ratio and oxidative stress genes NOX1 & NOX4 (all $P<0.01$) but no effect on FGF23. In contrast, PTH treatment for 24 hrs decreased SOST by 135 fold, Dkk1 by 155 fold ($p<0.01$) and increased RANKL/OPG ration by 1080 fold ($p<0.001$) with no effect on NOX. IS, but not PTH, inhibited MAP kinase activity (ERK1/2; $p <0.002$) and induced AhR activity assessed by downstream CYP1A1 (increased by10 fold) & CYP1B1 (increased by 4.5-fold) ($p<0.001$). Thus, in mature osteocytes, PTH and IS have opposing effects on osteocyte genes, oxidative stress, mediated by different mechanisms. To assess the impact of IS and PTH on mineralization, osteocytes were treated with IS or PTH alone or together for 14 days. IS and PTH both decreased alkaline phosphatase activity and together reduced further. IS also reduced mineralization but PTH had no effect. PTH increased cAMP secretion by 90%, whereas IS decreased cAMP secretion by 60% alone and significantly reduced PTH induced cAMP secretion in osteocytes ($p<0.002$).

Conclusions: In conclusion, IS and PTH have additive effects to inhibit early osteocyte mineralization, and opposing effects on mature osteocyte signaling and the gene expression involved in regulation of bone remodeling and differentiation. These results indicate IS is a major uremic toxin affecting osteocytes.

Evaluation of Mineral and Bone Metabolism in Living Kidney Donors: A 10-Year Follow-Up

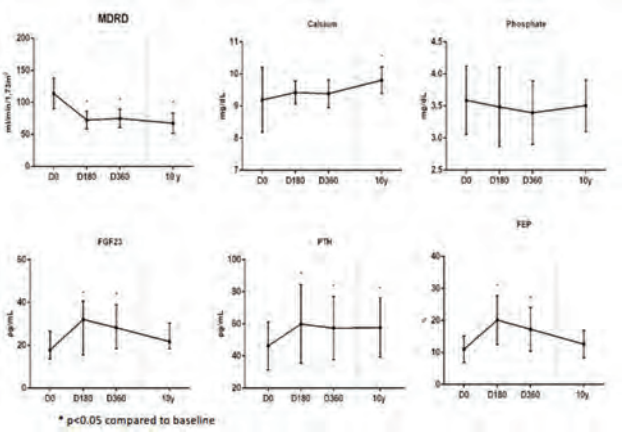
Eduardo J. Duque,[1] Gustavo Ferreira,[1] Ivone B. Oliveira,[1] Wagner Dominguez,[1] Fabiana Agena,[1] Vanda Jorgetti,[1] Francine Lemos,[1] Myles Wolf,[2] Elias David-Neto,[1] Rosa M. Moyses.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Duke University, Durham, NC.*

Background: Living kidney donors (LKD) experience an abrupt decline in glomerular filtration rate (GFR) resulting in abnormalities of mineral and bone metabolism (MBD), and this may have implications for the skeletal health. We prospectively studied acute and long term MBD adaptation of LKD from two kidney transplant centers (Brazil and USA).

Methods: We have measured renal function and MBD parameters longitudinally after live kidney donation (KD, baseline – D0, day 1, 14, 180 and 360 post-operatively) in 74 live donors (40ys, 73% female, 54% Brazilian). A subset of 20 brazilian LKD were reassessed after 10 years of KD.

Results: At baseline, Brazilian LKD presented lower FGF23 (20.8 vs 80.1 pg/mL*) and higher PTH (47.4 vs 40.1*) than their US counterparts. GFR decreased 41% just after KD, but improved 11% during the first year. PTH increased on D1 (65±30 vs D0 44±14 pg/mL*), as well as FGF23, which remained significantly higher at D360 (60 vs D0 44.4 pg/mL*). There was a reduction in serum phosphate (3.3±0.6 vs D0 3.7±0.5 mg/dL*) and calcium (7.9±0.5 vs D0 9.4±0.4 mg/dL*) on D1, which returned to baseline levels at D180 (3.5±0.6 and 9.4±0.5mg/dL, respectively). A higher fractional excretion of phosphate (FEP) was noted since D14. After 10 years of KD, Brazilian LKD presented a significant reduction in GFR [65 (55-69)ml/min] and in FGF23 [21.7 (18-30)pg/mL], as well as an increase in PTH [57 (42-66)pg/mL] and calcium levels. Despite that, FEP reduced and phosphate levels remained stable (figure 1). *$p<0.05$

Conclusions: The abrupt decline in kidney mass is associated with an increase in PTH and FGF23, which could not be explained by phosphate retention. In a long term evaluation, LKD showed a sustained drop in GFR, accompanied by an increase in PTH and calcium levels, while the reduction in FGF23 and FEP maintained phosphate stable.



FR-PO316

Mineral and Bone Biomarkers Associate with Adverse Cardiovascular Outcomes and Mortality Within the German Chronic Kidney Disease (GCKD) Cohort

Katharina C. Reimer,[1,2] Jennifer Nadal,[3] Heike Meiselbach,[4] Ulla T. Schultheiss,[5] Helena Stockmann,[6] Matthias Nauck,[7,8] Vera Krane,[9] Kai-Uwe Eckardt,[6,4] Markus P. Schneider,[4] Jürgen Floege,[1] Turgay Saritas.[1,2] *[1]University Hospital Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany; [2]University Hospital Aachen Institute of Experimental Medicine and Systems Biology, Aachen, Germany; [3]Institute of Medical Biometry, Informatics and Epidemiology, University Hospital of Bonn, Bonn, Germany; [4]Department of Nephrology and Hypertension, Friedrich-Alexander University Erlangen-Nuernberg, Erlangen, Germany; [5]Institute of Genetic Epidemiology, Faculty of Medicine and Medical Center - University of Freiburg, Freiburg, Germany; [6]Department of Nephrology and Medical Intensive Care, Charité – Universitätsmedizin Berlin, Berlin, Germany; [7]Institute of Clinical Chemistry and Laboratory Medicine, University Medicine Greifswald, Greifswald, Germany; [8]DZHK (German Centre for Cardiovascular Research), Partner Site Greifswald, University Medicine, Greifswald, Germany; [9]Department of Medicine I, Division of Nephrology, University Hospital Wuerzburg, Wuerzburg, Germany.*

Background: Mineral and bone disorders (MBD) in chronic kidney disease (CKD) are tightly linked to cardiovascular disease. This study aimed to compare prognostic information of nine MBD biomarkers to determine those associating best with adverse cardiovascular (CV) outcomes and mortality in pre-dialysis CKD.

Methods: In 5217 participants of the German CKD (GCKD) study, enrolled for glomerular filtration rate (GFR) between 30-60 ml/min/1.73m² or overt proteinuria, serum osteoprotegerin (OPG), fibroblast growth factor 23 (FGF23), intact parathyroid hormone (iPTH), bone alkaline phosphatase (BAP), cross-linked C-telopeptide of type 1 collagen (CTX1), procollagen 1 intact N-terminal protein (P1NP), phosphate, calcium, and 25-OH vitamin D were measured at baseline. Participants with missing values among these parameters (N = 971) were excluded. Hazard ratios (HRs) for associations of OPG, FGF23, iPTH, BAP, CTX1, P1NP, phosphate, calcium, and 25-OH vitamin D each alone and in combination, with 1) CV death, 2) non-CV death, 3) combined major adverse CV events (non-fatal MACE), and 4) hospitalization for congestive heart failure (CHF) were estimated using Cox regression analyses adjusted for major clinical risk factors for CKD.

Results: During a median follow-up of 6.5 years, 385 non-CV deaths, 173 CV deaths, 643 non-fatal major adverse CV events (MACE) and 367 hospitalizations for congestive heart failure (CHF) were observed among 4246 participants. OPG and FGF23 were associated with all outcomes, with the highest hazard ratios (HRs) for OPG. In the final Cox regression model, adjusted for CV risk factors and all other investigated biomarkers, every standard deviation increase of OPG was associated with non-CV death (HR 1.84, 95%CI 1.41-2.40), CV death (HR 2.33, 95%CI 1.61-3.38), MACE (HR 1.42, 95%CI 1.15-1.76) and hospitalization for CHF (HR 2.13, 95%CI 1.62-2.79).

Conclusions: Out of the nine biomarkers examined, stratification based on serum OPG identified CKD patients best who were at highest risk for any adverse CV outcome and mortality.

FR-PO317

Targeting Probiotics in Hyperphosphatemia for Patients with CKD

Thasinas Dissayabutra, Weerapat Anegkamol, Natthaya Chuaypen, Mana Taweevisit, Asada Leelahavanichkul. Metabolic Diseases in Gastrointestinal and Urologic System Research Unit (MEDGURU). *Chulalongkorn University, Bangkok, Thailand.*

Background: Hyperphosphatemia and secondary hyperparathyroidism are critical consequences in chronic kidney disease (CKD) patients. Current therapeutic strategies to lower serum phosphate are dietary phosphate restriction and phosphate lowering drugs.

Since increased paracellular intestinal phosphate absorption is considered a main factor for hyperphosphatemia, we designed a probiotic cocktail to promote gut barrier, which could subsequently reduce phosphate absorption.

Methods: *B. longum* TCU1 and *L. salivarius* TCUA were tested in HK2 cell model to be able to promote zonula occluding-1 (ZO-1) expression and had anti-inflammatory effects. The Cocktail A including 10^9 CFU of *B. longum* TCU1 and *L. salivarius* TCUA, inulin and chitosan oligosaccharide (COS), and Cocktail B which was Cocktail 1 added with maltodextrin were used. Cisplatin-induced CKD rats were divided into (a) Control, (b) CKD, (c) CKD with *L.* casei (commercial probiotic) (d) CKD with Cocktail A and (e) CKD with Cocktail B (n=8 each) were experimented for 12 weeks. Blood was collected to measure calcium (Ca), phosphate (P) and parathyroid hormone (PTH). Immunohistochemistry of intestinal ZO-1 was measured.

Results: All rats with CKD had higher serum creatinine than Control throughout the experiment. AT Week 4 & 8, CKD rats treated with probiotics had lower serum P than CKD rats, while week 12, only CKD rats with Cocktail A had significantly lower serum P than CKD, without serum Ca change. In addition, CLD rats with Cocktail A had lower serum PTH level than CKD rats at week 12. Intestinal ZO-1 expression in Cocktail A rats had non-significantly increased compared to the CKD rats as well.

Conclusions: Our study demonstrated the potential therapeutic effects of targeting probiotic cocktail A, which included *B. longum*, *L. salivarius*, inulin and COS, to ameliorate hyperphosphatemia and hyperparathyroidism in rats with CKD. Further study in clinical trial of targeting probiotic had been funded.

Tenapanor in Combination with Phosphate Binders Improves Short- and Long-Term Control of Serum Phosphate (sP) in Patients on Dialysis with Hyperphosphatemia

Daniel E. Weiner,[1] Robert I. Lynn,[2] David M. Spiegel,[3] Susan A. Edelstein,[3] Yang Yang,[3] David P. Rosenbaum.[3] *[1]Tufts Medical Center, Boston, MA; [2]Kidney Medical Associates, Bronx, NY; [3]Ardelyx, Inc., Waltham, MA.*

Background: Tenapanor (TEN) is a phosphate absorption inhibitor that blocks paracellular phosphate absorption by local inhibition of the intestinal sodium hydrogen exchanger isoform 3 (NHE3). In the 4-week AMPLIFY (NCT03824587) study, TEN in combination with the phosphate binder (PB) sevelamer (SEV) allowed more patients (pts) to achieve target sP. The NORMALIZE (NCT03988920) extension study was designed to help pts achieve sP ≤4.5 mg/dL (relaxed to ≤5.5 mg/dL with protocol amendment). Pts who completed the 1-year safety comparator arm (SEV) of PHREEDOM added TEN to control sP for up to 18 months. We report early and long-term control of sP in the subset of PHREEDOM pts who were inadequately controlled (sP >4.5 mg/dL) on SEV monotherapy.

Methods: 61 pts from the SEV arm of PHREEDOM (NCT03427125) entered NORMALIZE. Of these 61 pts, 43 (70.5%) had sP >4.5 mg/dL at NORMALIZE baseline when TEN 30 mg bid was added to the SEV dose. After starting TEN, SEV was decreased as long as sP was controlled, with the intention to decrease/eliminate SEV if possible. TEN could be up- or down-titrated in 10 mg increments, with a maximum dose of 30 mg bid, based on sP level and/or tolerability.

Results: Of the 43 pts entering NORMALIZE with sP >4.5 mg/dL, median baseline SEV use was 9 pills/day, dropping to 6 pills/day at the end of NORMALIZE. Percentage of pts achieving sP ≤4.5 mg/dL at each study visit is shown in the **Figure**. Adverse events reported were similar to those seen in other TEN studies; no new safety issues were identified.

Conclusions: The NORMALIZE study confirms the findings from AMPLIFY that TEN in combination with SEV enables a greater percentage of pts to achieve sP ≤4.5 mg/dL with no new safety issues. These data also demonstrate that TEN in combination with SEV can achieve long-term sP control in patients when SEV monotherapy fails to normalize sP.

Extended-Release Calcifediol Overcomes Impact of Low eGFR on Vitamin D Metabolism

Charles W. Bishop,[1] Stephen A. Strugnell,[1] Akhtar Ashfaq,[1] Joel Melnick,[3] Nilay Patel,[1] Rahul Ravipati,[1] Martin P. Petkovich.[2] *[1]OPKO Health Inc, Miami, FL; [2]Queen's University, Kingston, ON, Canada; [3]SCD Advisor, Evanston, IL.*

Background: Serum 25-hydroxyvitamin D (25D) falls below 30 ng/mL and serum 1,25-dihydroxyvitamin D (1,25D) becomes undetectable as chronic kidney disease (CKD) progresses. Cholecalciferol or ergocalciferol are widely prescribed but cannot reliably raise 25D and lower elevated parathyroid hormone (PTH). They are replaced/combined with calcitriol (or 1α-OH analog) when PTH inevitably rises, contrary to the current KDIGO guideline, with justification that too much renal CYP27B1 has been lost, limiting hormone production. Randomized clinical trials (RCTs) prove that extended-release calcifediol (ERC) safely and sufficiently raises serum 25D and 1,25D, and effectively treats elevated PTH despite declining eGFR, but the mechanism is not fully elucidated and requires further investigation.

Methods: Changes in serum $25D_3$, $24{,}25D_3$ and $1{,}25D_{(3)}$ during ERC treatment in four RCTs were compared as a function of eGFR. In one study, 80 non-CKD patients were treated for 4 weeks (wks) with 300 mcg/day (d) for three ds and 60 mg/d thereafter. In two studies (pooled), 285 non-dialysis patients with eGFR of 30.6±0.6 (mean±SE) mL/min/1.73m^2 were treated for 26 wks with 210 mcg/wk increasing, as needed, to 420. In another, 33 hemodialysis (HD) patients were treated for 26 wks with 900 mcg/wk.

Results: In these RCTs, baseline 25D was 37.7±12.1, 19.9±0.3 and 23.6±2.2 ng/mL, respectively. Mean 1,25D at baseline was inversely proportional to eGFR, ranging from 72.3±3.3 pg/mL in non-CKD patients to 9.4±1.0 pg/mL in HD patients. During treatment, mean $25D_3$ rose to >70 ng/mL with peak levels proportional to dose. Mean $1{,}25D_{(3)}$ rose linearly with $25D_3$ at similar rates in all eGFR groups but mean $24{,}25D_3$ (<2.9 ng/mL at baseline) increased at rates proportional to eGFR.

Conclusions: ERC reliably raised both serum $25D_3$ and $1{,}25D_{(3)}$, irrespective of eGFR, making it an attractive alternative to hormones for treating persistently rising PTH in CKD stages 3-4. Declining eGFR did not affect ERC's ability to increase the rate of $1{,}25D_{(3)}$ production, indicating that hormone generation occurred in extra-renal tissue. Increases in serum $24{,}25D_3$ were dependent on $25D_3$ elevation and limited by declining eGFR, suggesting that this metabolite derives solely from the kidney and is not disproportionately increased by ERC.

Comparative Effectiveness of Cinacalcet Delivered Daily at Home vs. Three Times Weekly In-Center

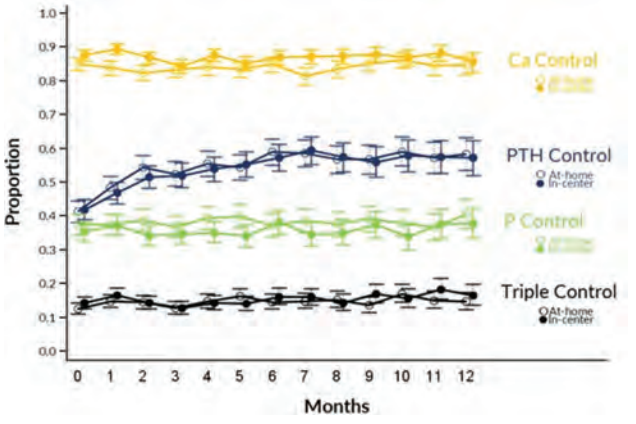
Steph Karpinski,[1,2] Gilbert Marlowe,[1,2] Carey Colson,[1,2] Kathryn Husarek,[1,2] Scott Sibbel,[1,2] Vishal N. Ratkalkar,[3,2] Francesca Tentori,[1,2] Steven M. Brunelli.[1,2] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Patient Safety Organization, Denver, CO; [3]Georgia Renal and Hypertension Care, Newnan, GA.*

Background: Chronic kidney disease-mineral and bone disorder (CKD-MBD) is a common syndrome found in end stage kidney disease (ESKD) patients and marked by dysregulation of three chemicals in the blood: calcium, phosphorus and parathyroid hormone (PTH). A recent review of the evidence showcases that treatment of CKD-MBD should be based on better control of all 3 elements. Cinacalcet, an oral calcimemetic (a PTH-lowering therapy), is one of many daily treatments that ESKD patients are often prescribed, contributing to a high total pill burden. Recent clinical trials have provided evidence that in-center administration of cinacalcet might be a safe and effective treatment option. In this study we sought to evaluate the comparative effectiveness of cinacalcet delivered daily at home versus three times weekly in-center.

Methods: This was a retrospective matched cohort study of 2,894 matched adult in-center hemodialysis patients at a dialysis provider between January 01, 2008 and September 30, 2022 who initiated their first ever calcimemetic therapy (non-exposed group: at home use or exposed group: in-center administration at the end of dialysis). Patients were matched (1:1) on: age at index date, body mass index, cinacalcet dose, and baseline phosphorous, calcium, and PTH. Patients were followed until censoring (i.e., lost to follow up) or 12 months after baseline, whichever occurred first. The primary outcome was achieving triple control of PTH, phosphorous and calcium.

Results: Fitted proportion model results show no statistical difference in achieving triple control between in-center or at home cinacalcet administration groups (Figure 1). In addition, there was no meaningful difference in control of any component.

Conclusions: In an observational, well-matched cohort administering cinacalcet in-center at the end of dialysis is non-inferior as prescribing cinacalcet for use at home.



FR-PO321

Denosumab and Fracture Events in Patients on Hemodialysis

Arisa Kobayashi,[1] Akio Nakashima,[1] Kazuhiko Kato,[1] Tatsuhiro Yaginuma,[2] Ichiro Ohkido,[1] Takashi Yokoo.[1] *[1]Tokyo Jikeikai Ika Daigaku, Minato-ku, Japan; [2]Keijin Hospital, Adachi-ku, Japan.*

Background: It is known that the risk of fracture is much higher in patients with dialysis than general population. In recent years, osteoporosis treatment has become more widespread including hemodialysis patients. However, there are few studies that analyzed the efficacy of denosumab for fracture events in hemodialysis patients.

Methods: We conducted a retrospective observational study of inpatients and outpatients at a maintenance hemodialysis facility to clarify the association between denosumab use and fracture events. The study term was from December 2013 to December 2022 and compared the incidence of fractures in the denosumab-treated and non-treated groups. The analysis was performed using the Cox proportional hazards model with the presence or absence of fracture occurrence as the objective variables and the presence or absence of denosumab use, various patient backgrounds, and laboratory values as explanatory variables.

Results: A total of 263 patients were enrolled in the study, with a mean age of 71.7 ± 12.1 years. Among them, 35.4% were female, and the median duration of hemodialysis was 48 [IQR 4-114] months. The number of patients who developed fractures was 52 in the non-treated group and 8 in the denosumab-treated group. After adjustment for factors such as age, gender, prior fracture, serum intact parathyroid hormone, serum TRACP5b and bone specific alkaline phosphatase, analysis using the Cox proportional hazards model showed that patients treated with denosumab were significantly less likely to develop fractures (HR 0.42 [95% CI: 0.18-0.98]). There were no significant differences in the incidence of hypocalcemia (OR 2.05[95%CI:0.79-5.29]. Our study has several limitations, such as single center study in Japan and small sample size, but our results have the potential to widespread fracture treatment by using denosumab for hemodialysis patients.

Conclusions: Our results suggest that denosumab may be effective in preventing fractures in hemodialysis patients. Further studies with larger sample sizes are warranted to validate and enhance the outcomes of this study.

FR-PO322

Histone Acetyltransferase p300 Inhibition Attenuates Kidney Fibrosis Under Diabetic Conditions

Gyu R. Kim,[1,2] Boyoung Nam,[1,2] Jaejin Ryu,[1,2] Ye Eun Ko,[1,2] Hyung Woo Kim,[1,2] Seung Hyeok Han,[1,2] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Jung Tak Park.[1,2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Institute of Kidney Disease Research, College of Medicine, Yonsei University, Seoul, Republic of Korea.*

Background: Diabetic nephropathy, the major cause of chronic kidney disease, is associated with progressive renal fibrosis. Transforming growth factor (TGF)-β1 plays important roles in extracellular matrix accumulation in diabetic nephropathy. Recently, acetyltransferase p300 has been shown to mediate intracellular TGF-β1 activity through facilitating Smad function. Therefore, in this study, the effect of p300 inhibition on kidney fibrosis under diabetic conditions was investigated to assess the therapeutic potential of p300 modulation.

Methods: Primary tubular epithelial cells (TECs) from C57BL/6 mice were treated with TGF-β1 with or without histone acetyltransferase p300 siRNA transfection of A485, a selective inhibitor for p300. For in vivo experiments, kidney samples were obtained from streptozotocin induced diabetic mice were administered with A485 (1mg/kg) oral gavage for 6 weeks.

Results: In vitro, TGF-β1 (5ng/ml) treatment significantly upregulated p300, PAI-1, connective tissue growth factor (CTGF), fibronectin, and type I collagen mRNA and protein expressions in TECs. These increases were attenuated significantly when TECs were transfected with p300 siRNA. Similar findings were found when the cells were treated with p300 specific inhibitor A485 (100nM). In vivo, the mRNA and protein expression of p300, PAI-1, connective tissue growth factor (CTGF), fibronectin, and type I collagen were significantly increased in kidney samples form DM mice compared to non-diabetic control mice. Oral A485 administration abrogated these increases significantly. In addition, the increased blood urea nitrogen and albuminuria levels were significantly attenuated with oral A485 treatment in the diabetic mice. Immunohistochemistry and Sirius Red staining also revealed that fibronectin expression was significantly higher and tubulointersititial fibrosis was significantly worse in diabetic mice kidneys compared with control mice. These changes were ameliorated by A485 treatment.

Conclusions: These findings suggest that inhibition of histone acetyltransferase p300 could improve diabetic-induced tubular fibrosis and may be a potential therapeutic strategy for diabetic nephropathy.

FR-PO323

Pharmacologic Pyruvate Kinase M2 Activation Maintains Mitochondrial Metabolism by Regulating the Interaction Between HIF-1α and PGC-1α in Diabetic Kidney Disease

Gyu R. Kim,[1,2] Young Su Joo,[1,2] Jaejin Ryu,[1,2] Boyoung Nam,[1,2] Jung Tak Park,[1,2] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Seung Hyeok Han.[1,2] *[1]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea.*

Background: Previous findings have indicated that pyruvate kinase isoform M2 (PKM2) activation may protect kidney injury by improving mitochondrial dysfunction and anerobic glycolysis. However, the underlying molecular mechanisms are incompletely understood. Here, we aimed to clarify mechanistic link between PKM2 and HIF-1α-mediated PGC-1α suppression in animal model of diabetic kidney disease (DKD).

Methods: In an animal DKD study, *db/db* mice were intraperitoneally injected with TEPP-46, a PKM2 activator. *In vitro*, primary cultured renal tubular epithelial cells (RTECs) from C57BL/6 mice were treated with high glucose (HG) alone and HG+TEPP-46. The interactions between HIF-1α and PGC1α were further investigated using HIF-1α overexpression and HIF-1α knockdown. PKM2 activity, energy metabolism, mitochondrial mass, dynamics, and morphology, and cell injury markers were examined.

Results: In the kidney of *db/db* mice, diabetes resulted in decreased PKM2 activation, aberrant glycolysis, impaired fatty acid oxidation, and decreased mitochondrial mass, integrity, and function. These changes were accompanied by increased HIF-1α and decreased PGC-1α levels. Increased fibrosis and apoptosis markers were observed in diabetic mice. In addition, periodic acid–Schiff (PAS) staining revealed significant tubular injury in *db/db* mice. The direct PKM2 activation by TEPP-46 treatment attenuated the dysregulated energy metabolism, mitochondrial dysfunction, and cell death. Similar alterations were also observed in HG-treated RTECs, which were restored by TEPP-46. Notably, a chromatin immunoprecipitation assay revealed that HIF-1α directly binds to the regulatory region of the *Ppargc1a* promoter and that this interaction is inversely dependent on PKM2 activation. A luciferase reporter assay showed that HIF-1α regulates the transcriptional activity of PGC-1α in a PKM2-dependent manner. Moreover, *Hif1a* overexpression suppressed PGC-1α and induced aberrant energy metabolism, mitochondrial dysfunction, and apoptosis. Conversely, these changes were reversed by HIF-1α knockdown.

Conclusions: PKM2 activation improves impaired mitochondrial metabolism and function by modulating HIF-1α and PGC-1α interactions in DKD.

FR-PO324

The Role of FRAS1 Loss of Function in Rapid Renal Decline: Insights into the Downregulation of NPR1

Tiehua Chen. *University of Utah Health, Salt Lake City, UT.*

Background: Progressive renal decline, leading to end-stage kidney disease (ESKD), is a hallmark of diabetic nephropathy. Recently, we identified a rare missense variant (p.R2516C) in the FRAS1 gene, which plays a crucial role in maintaining glomerular integrity as an extracellular matrix protein, in a family affected by both diabetes and ESKD. This study aims to investigate the impact of the p.R2516C variant on FRAS1 function and its potential involvement in the progression of ESKD.

Methods: To examine the functional consequences of the variant, we employed CRISPR-Cas9 gene editing technology to generate three distinct HEK293 cell lines. These included two FRAS1 knock-in cell lines, one harboring the p.H2520H synonymous mutation as a control and the other carrying the missense p.R2516C variant. Additionally, a FRAS1 knock-out cell line was generated. RNA sequencing was conducted on these cell lines to identify genes with differential expression patterns.

Results: Through comprehensive analysis of the RNA sequencing data, we identified 119 significantly differentially expressed genes following FRAS1 perturbation, consisting of 57 upregulated and 62 downregulated genes. Further investigation focused on the top 10 upregulated and 10 downregulated genes, which revealed NPR1 (Natriuretic Peptide Receptor A/Guanylate Cyclase A) as an intriguing downregulated candidate gene whose downregulation in diabetic nephropathy and other forms of kidney disease is further supported by publicly available transcriptomic datasets.

Conclusions: The findings of this study highlight the positive regulatory relationship between FRAS1 and NPR1, while emphasizing the contribution of FRAS1 LOF to rapid

renal decline. This study provides compelling evidence that the LOF of FRAS1 leads to the downregulation of NPR1, ultimately resulting in rapid renal decline. Given the crucial role of NPR1 in maintaining normal renal function, it represents a promising therapeutic target for individuals affected by FRAS1 LOF, diabetic kidney disease (DKD), or chronic kidney disease (CKD). Further investigations are warranted to explore the therapeutic implications of targeting NPR1 in these conditions.

Cell Surface GRP78 and α2M* Are Important Mediators of Tubulointerstitial Fibrosis in CKD

Jackie Trink, Melissa Macdonald, Bo Gao, Joan C. Krepinsky. *McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

Background: Diabetic kidney disease (DKD) is characterized by glomerular accumulation of extracellular matrix (ECM) proteins followed by the development of tubulointerstitial fibrosis. We recently showed the endoplasmic reticulum resident GRP78 translocates to the cell surface (csGRP78) in response to HG, promoting profibrotic responses in mesangial cells. We further implicated activated alpha 2 macroglobulin (α2M*) as an activator of csGRP78 signaling. Based on increased expression of this receptor-ligand pair in both DKD and non-diabetic chronic kidney disease (CKD) mouse models, we thus wanted to elucidate this signaling pathway's influence on other cell types relevant to kidney disease (proximal tubule epithelial cells (PTEC) and renal fibroblasts (RF)) as well as a potential role for TGFβ1-induced signaling.

Methods: PTEC and RF were treated with 30mM HG or 5ng/mL TGFβ1 plus csGRP78 or α2M* inhibitors. Standard molecular biology techniques were used for assessment. Immunohistochemistry staining was conducted on kidney tissues from mouse models of DKD and CKD.

Results: We observed increased localization of GRP78 to the surface of PTEC and RF with either HG or TGFβ1 stimulus. Further, α2M expression and activation were shown to be increased by both HG and TGFβ1. Inhibition of either csGRP78 or α2M* prevented HG and TGFβ1-induced ECM production (fibronectin and collagen IV). By HG treatment, downstream TGFβ1 signaling (measured by activation of Smad3) was attenuated by csGRP78 or α2M* inhibition. Interestingly, we observed no effect on Smad3 activation with csGRP78 or α2M* inhibition with TGFβ1 treatment. We hypothesized a potential role for non-canonical TGFβ1 signaling being mediated by csGRP78/ α2M*. We next assessed the known non-canonical TGFβ1 signaling molecules yes associated protein (YAP) and transcriptional co-activator with PDZ-binding motif (TAZ). Here we observed that inhibition of either csGRP78 and α2M* attenuated YAP and TAZ expression under both HG and TGFβ1 treatment. This implicates Smad-dependent and independent signaling being mediated by csGRP78/ α2M*.

Conclusions: These data support a role for csGRP78/α2M* in mediating HG or TGFβ1-induced profibrotic signaling in PTEC and RF. Inhibition of this signaling pathway represents a novel target for preventing DKD or CKD-associated fibrosis which we are currently evaluating *in vivo*.

Adam17 Inhibition Moderates Interstitial Fibrosis and Macrophage Infiltration in Type 1 Diabetes (TD1) Mouse Model

Marta Riera,[1] Cristina C. Milan,[1] Eric Galdón,[1] Claudia M. Rosco,[1] David S. García,[1] Ana A. Fajardo,[1] Vanesa Palau,[1] Maria Jose Soler,[2] Marta Crespo,[3] Clara Barrios.[3,1] GREN. [1]*Institut Hospital del Mar d'Investigacions Mediques, Barcelona, Spain;* [2]*Hospital Universitari Vall d'Hebron, Barcelona, Spain;* [3]*Hospital del Mar, Barcelona, Spain.*

Background: ADAM17 participates in the release into circulation of inflammatory and fibrotic molecules, such as TNF-a actively involved in the progression of DN. We studied the effect of specific deletion of ADAM17 in the endothelium and renal tubule in a T1DM mouse model demonstrating its participation in the progression of kidney damage. As ADAM17 is also expressed in other cell types we will study the effect of the complete deletion of Adam17 in T1DM mouse.

Methods: We studied total inducible *Adam17* knockout (ADAM17KO) male mice that were diabetic by STZ injection (DB). Glycemia, mesangial index (PAS staining), number of podocytes and positive area of a-SMA (by immunohistochemistry) were determined. We also studied the protein expression of the cytokine MCP-1 by Western Blot.

Results: The mesangial index value observed in the 20wk-DB group decreased significantly in the ADAM17KO group. Podocyte loss in DB group was not observed in the KO-DB group. For interstitial fibrosis, the intensity and location of a-SMA was significantly lower in the ADAM17KO group. In addition, the total deletion of *Adam17* partly prevented the infiltration of macrophages assessed by the expression of MCP-1 in the protein extract of the renal cortex.

Conclusions: Complete inhibition of Adam17 expression in T1DM mice prevents fibrosis progression and protects the glomerulus from hypertrophy. At the same time, it reduces macrophage infiltration, limiting the inflammatory response induced by diabetes. We demonstrate the influence of Adam17 on macrophages to reduce the expression of TNF-a partly responsible for the progression of diabetic nephropathy.

FR-PO327

Functional Coupling of ANXA1 and KCa3.1 Attenuated Renal Tubulointerstitial Fibrosis in Diabetic Kidney Disease

Li Wang, Bingbing Zhu, Shuang Liu, Yao Xingmei. *Department of Nephrology, Putuo Hospital, Shanghai University of Traditional Chinese Medicine, Shanghai, China.*

Background: Tubulointerstitial fibrosis (TIF) is the common pathway and major pathological basis for almost all kinds of renal disease including diabetic kidney disease (DKD) progress into chronic kidney disease, thus it is essential to reveal its pathogenesis. Previous research showed that up-regulation of intermediate-conductance Ca^{2+}-activated K^+ channel (KCa3.1) contribute to TIF. However, targeting the channel directly have unfortunately side-effect in clinic trials.

Methods: Molecular docking and co-immunoprecipitation were used to detect the binding capability between ANXA1 and KCa3.1. HEK293T and HK-2 cell line were cultured and transfected to confirm whether ANXA1 can be modified by SUMOylation. SUMOylation sites were predicted by SUMOsp2.0, and ANXA1 lysine residues K113, K161, K185, K257 and K312 were mutated to test the relative site change. Biotinylation assay were used to evaluate the ANXA1 activation to KCa3.1 surface expression. Western blot was used for evaluate KCa3.1-mediated TGF-β/Smad signaling activation to detect the expressions of α-SMA, fibronectin, collagen matrix and Smads.

Results: We found that ANXA1, an endogenously generated molecules that promote the physiological resolution of inflammation, could interact with KCa3.1. Mechanistic studies demonstrated that intracellular ANXA1 could be modified by SUMOylation and that SUMOylation primarily occurs at three lysine residues K113, K161, and K257 in hyperglycemia/high glucose stimulation, thereby SUMOylated ANXA1 regulating the membrane transport and lysosomal degradation of KCa3.1 channel protein, and ultimately delaying KCa3.1-mediated TGF-β/Smad activation and TIF progression in DKD state.

Conclusions: Our study suggests that ANXA1-KCa3.1 functional coupling may be a promising therapeutic strategy to mitigate DKD-induced TIF.

FR-PO328

Diet Modification to Drive Fibrotic Response in Diabetic Kidney Disease (DKD) Model

Cassandre Cavanaugh, Simon A. Hinke, Matthew M. Rankin, Rong Meng, Neetu Shukla, Andrea R. Nawrocki. CVMR & PH Discovery In Vivo Pharmacology. *Janssen Research and Development LLC, Spring House, PA.*

Background: Diabetes is a major cause of chronic kidney disease, affecting approximately 25% of diabetic patients. Several rodent models of Diabetic Kidney Disease (DKD) have been developed; however, drug discovery is hampered by the lack of preclinical rodent models with clinically relevant urinary albuminuria creatinine ratio (UACR) and/or histological fibrosis observed in humans. Here we sought to develop a new translational mouse DKD model incorporating streptozotocin (STZ)-induced hyperglycemia, mild hypertension from nitric oxide synthase inhibition, and dietary modification to drive the fibrotic response, on top of a uninephrectomized (UNx)/ hyperfiltration phenotype.

Methods: UNx Male 129S1 mice (Jackson Labs) were uninephrectomized at 7 weeks old and given STZ injections (5-40mg/kg IP) to induce diabetes. Trimethylamine n-oxide (TMAO) and Choline formulated in D12450J low fat diet (LFD) and D12492 high fat diet (HFD) for rodents (Research Diets). 100mg/L nitroarginine (L-NNA) provided in drinking water. Body weight, food intake and fed blood glucose collected weekly and urine collected biweekly for 8 weeks. At the end of treatment, animals euthanized, kidneys collected for collagen and histological analysis. Terminal plasma analyzed for blood chemistry, TMAO and circulating dietary precursors of TMAO.

Results: STZ-induced hyperglycemia confirmed in the mice (396.3±3.6mg/dL). Daily TMAO and choline intake, both LFD and HFD diet admixtures were similar (Choline: LFD 166.9±7.6g/kg; HFD 178.4±4.6g/kg; TMAO: LFD 54.1±1.8g/kg; HFD 65.2±2.6g/kg). Betaine, Carnitine and Choline dietary TMAO precursors increased in both LFD and HFD choline admixtures. TMAO did not significantly change any dietary precursor levels compared to control. UACR significantly increased after 8 weeks in both Choline supplemented, LFD (p=0.0024; 72.4±13.6) and HFD (p=0.0472; 59.7±8.2). The primary histological lesion observed was tubulointerstitial collagen thickening, seen in LFD TMAO & Choline, and HFD Choline groups.

Conclusions: Refinement of a hypertensive, diabetic, hyperfiltering mouse kidney disease model using dietary supplements to increase renal fibrosis observed to achieve comparable kidney functional impairment to that of human DKD patients, with some evidence of histological damage. This animal model may be used to assess preclinical efficacy of investigational therapies for DKD.

Loss of LRG1 Effectively Curbs Diabetes-Induced TGF-β Signaling in Glomerular Endothelial and Mesangial Cells to Attenuate Diabetic Kidney Disease (DKD)

Jia Fu,[1] Zeguo Sun,[1] Ye Feng,[1] Weijia Zhang,[1] John C. He,[1,2] Kyung Lee.[1]
[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]James J. Peters Veterans Affair Medical Center, Bronx, NY.

Background: Despite the immense burden of DKD, optimal therapies remain limited. Although TGF-β is a well-established central mediator of DKD pathogenesis, because of its pleiotropic actions in multiple organ systems, its indiscriminate blockade is not desirable. Moreover, evidence of diverse kidney cell-specific effects of TGF-β, both deleterious and protective, continues to emerge. TGF-β signaling is strongly influenced by cell type- and context-dependent regulators and determinants, and we previously showed that cell surface modulators, such as LRG1 and BAMBI, can significantly influence TGF-β signaling in kidney disease. Since LRG1 is increased in glomerular ECs in DKD, we posited that LRG1 loss may shift the balance away from excessive pathological endothelial TGF-β signaling to attenuate DKD, without a full systemic blockade of TGF-β signaling associated with unwanted side effects.

Methods: Type 1 diabetic OVE26 mice were crossed with *Lrg1*$^{-/-}$ mice to generate OVE26;*Lrg1*$^{-/-}$ mice, and DKD progression was assessed by renal function and histopathologic parameters. scRNA-seq was employed for kidney single-cell gene expression analysis of control and diabetic mice.

Results: scRNA-seq confirmed that increased LRG1 is limited to GECs in early diabetic kidneys. As anticipated, LRG1 loss significantly attenuated diabetic glomerulopathy including podocyte loss, and improved renal function. scRNA-seq analysis showed that LRG1 loss was sufficient to reverse all significant molecular pathway changes in GECs in early DKD, which were associated with the dampening of TGF-β-induced gene expression. Notably, LRG1 loss also led to a significant attenuation of TGF-β-mediated gene expression in mesangial cells of diabetic mice. These results indicate that LRG1 promotes DKD by enhancing TGF-β signaling in GECs and mesangial cells in an autocrine and paracrine manner, and indirectly via glomerular cross-talk.

Conclusions: Our study indicates that increased LRG1 directly enhances TGF-β signaling not only in GECs but also in mesangial cells in DKD, thereby exacerbating subsequent podocyte loss. LRG1 loss, while having no gross defects in mice, significantly attenuated diabetic glomerulopathy in OVE26 mice. Therefore, specific antagonisms of LRG1 may be an effective approach to curb TGF-β signaling in glomerular cells and attenuate DKD.

Nogo-B Suppresses Endoplasmic Reticulum Stress in Glomerular Endothelial Cells of Diabetic Nephropathy

Yan Zhang. *Guangdong Provincial People's Hospital, Guangzhou, China.*

Background: Diadetic vascular injuries contribute to the disease progression and glomerular endothelial cells are the critical targets of injury under hyperglycemia. Nogo-B is an endoplasmic reticulum (ER)-resident protein, which plays an important role in vascular remodeling after injury. Given the location of Nogo-B in the endoplasmic reticulum in glomerular endothelial cells, we set out to investigate whether Nogo-B is involved in the ER stress of endothelial cells in diabetic nephropathy.

Methods: The level of serum and urinary Nogo-B was measured in patients with diabetic nephropathy using ELISA. The expression of Nogo-B in the ER of endothelial cells was detected by immunofluorescence co-staining with the ER marker, PDI. The expression level of ER stress related markers GRP78 was examined using WB analysis. *In vitro*, siRNA was used to knockdown the expression of Nogo-B in Ea.hy926 under high glucose condition and RNA-seq analysis was performed. *In vivo*, AAV-induced knockdown of Nogo-B was performed in *db/db* diabetic mice for 8 weeks. The morphology phenotypes were examined by TEM.

Results: Compared with healthy control subjects, the level of serum (fig.A) and urinary(fig.B) Nogo-B was significantly increased in DN patients. *In vitro*, Nogo-B was co-localized with PDI by immunofluorescent co-labeling (fig.C). The RNA-seq results demonstrated that AGE-RAGE signaling pathway was among the top 10 activated pathways by KEGG analysis (fig.D). In high glucose cultured endothelial cells, knocking down Nogo-B caused an increase in the protein level of GRP78 (fig.E). In *db/db* diabetic mice, knocking down Nogo-B induced glomerular endothelial cell injuries (fig.F) as demonstrated by swollen changes and karyorrhexis of the cells.

Conclusions: Nogo-B, an ER-residential protein, plays a beneficial role in glomerular endothelial cells by inactivating the ER stress. Protecting the vasculature by targeting Nogo-B may serve as a potential therapeutic strategy in the treatment of DN.

Short-Chain Fatty Acids Restore Glomerular Endothelial Cell Stabilization After Exposure to Type 2 Diabetes Mellitus (T2DM) Serum, Circumventing the Reduced CPT1A Transporter

Maria Novella Nicese, Lushun Yuan, Gangqi Wang, Ton J. Rabelink, Joris I. Rotmans, Bernard van den Berg. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Renal injury is one of the major consequences for patients with type 2 diabetes mellitus (T2DM). Previously, we observed that diabetic nephropathy (DN) resulted in loss of the endothelial glycocalyx, but the molecular and metabolic mechanisms underlying this loss and in general endothelial dysfunction in T2DM remain largely unexplained. In the present study we tested the mechanistic and metabolic changes in human primary glomerular endothelial cells (huGEnCs) exposed to serum from patients with T2DM.

Methods: HuGenCs have been exposed for 4 days to T2DM serum in either static or laminar flow conditions. Cells were then used for seahorse and ECIS assays, to measure mitochondrial function and monolayer integrity, respectively. In order to visualize the monolayer, cells were stained for VE-cadherin and β-catenin. We also ran qPCR analysis to check the expression levels of endothelial and metabolic genes.

Results: qPCR data showed that huGenCs cultured with T2DM serum have an increased IL-8 mRNA expression while HAS2, HAS3, NOS3 and the fatty acid transporter CPT1A mRNA were reduced. For this reason, we performed a CPT1A knockdown to investigate the effect of the lack of this transporter in huGenCs. Monolayer resistance, either in the presence of T2DM serum or after CPT1A knockdown, was decreased. In each case, administration of the short chain fatty acids (SCFAs) butyrate and acetate restored barrier function. The beneficial effects of SCFAs on the endothelial monolayer were also confirmed when visualizing cell-cell contacts with immunofluorescence staining's for VE-cadherin and β-catenin. Using seahorse assay, we observed that SCFAs also improved fatty acid oxidation which was reduced after T2DM serum exposure.

Conclusions: SCFAs supplementation can rescue endothelial cell integrity after treatment with T2DM serum. Mechanistically, reduction of CPT1A in ECs exposed to T2DM serum revealed the importance of fatty acids for ECs homeostasis, which was confirmed by the knockdown of CPT1A. With butyrate and acetate supplementation we can circumvent this pathway and restore cellular homeostasis by improving fatty acids metabolism.

L-NAME Accelerates the Onset of Diabetic Nephropathy in Genetically Diabetic Mice

Maria Novella Nicese,[1] Angela Koudijs,[1] Reshma Lalai,[1] Joris Roelofs,[2] Roel Bijkerk,[1] Bernard van den Berg,[1] Joris I. Rotmans.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Amsterdam UMC Locatie AMC, Amsterdam, Netherlands.*

Background: Diabetic nephropathy (DN) represents one of the major causes of end stage kidney disease worldwide. Despite DN having such a high incidence, mouse models of DN rarely mimic all aspects of the human disease and usually show very slow development of DN phenotype. For this reason, in this project we aimed to develop an accelerated and reproducible rodent model of DN.

Methods: For our experiments we chose 9-week old female and male of the leptin receptor knock-out (BKS.Cg-Dock7m +/+ Leprdb/J) mice as type 2 diabetes model. As these mice are still not prone to develop severe kidney injury despite their diabetic condition, we administered the eNOS inhibitor L-NAME for 6 weeks, in order to aggravate kidney damage. Mice were divided in three groups: one vehicle control group, one receiving 40/mg/kg/day of L-NAME and one receiving 80/mg/kg/day of L-NAME dissolved in drinking water. Blood pressure and glomerular filtration rate (GFR) were measured, besides glycemia and albuminuria. At the end of the experiment, animals were killed and blood and organs collected.

Results: Mice treated with 80mg/kg/day of L-NAME showed an average increase of 10 mmHg in systolic blood pressure, with a peak of 30 mmHg increase at week 4 of treatment. Despite the increased blood pressure, three weeks of L-NAME administration

caused a significant reduction in GFR for both doses of L-NAME, with 5% reduction for the 40mg-group and 23% for the 80mg-group. No change in GFR was observed in the controls. This decrease in GFR was accompanied by a 10-fold increase in urinary albumin for both the experimental groups already after 3 weeks of treatment. PAS staining of kidney sections revealed that in particular mice treated with 80mg of L-NAME have enlarged glomeruli and a reduced glomerular capillary density, coinciding with mesangial expansion. Electron microscopy analysis showed that glomerular basement membrane (GBM) thickening was also occurring.

Conclusions: Our results show that L-NAME considerably accelerates the onset of DN in diabetic mice, with signs of kidney dysfunction already after 3 weeks. This model could be used to assess the therapeutic potential of novel interventions aimed to slow down the progression of DN.

FR-PO333

Protease-Activated Receptor-1 Deficiency Protects Against Glomerular and Endothelial Injury in Type 2 Diabetic Nephropathy

Sarah W.Y. Lok, Wai Han Yiu, Yixin Zou, Jingyuan Ma, Yuchen Feng, Kar Neng Lai, Sydney C. Tang. *The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong.*

Background: We recently showed that depletion of protease-activated receptor-1 (PAR-1) confers kidney protection in rodent models of CKD. Whether the same phenomenon may be observed in the diabetic kidney remains unknown.

Methods: We generated a novel double transgenic PAR-1 KO *db/db* mouse and observed its pathophysiology weeks in comparison to the respective wild-type and non-diabetic control animals. Fasting, non-fasting serum and urine were collected for up to week 24 of age. Vascular permeability assay of Evan's blue extravasation was performed to assess endothelial injury in the kidneys. Kidney function and histological damage were determined post-mortem. Six animals were included in each experimental group for analysis.

Results: PAR-1 deficiency significantly reduced fasting blood glucose level and glucose tolerance by OGTT associated with higher serum insulin levels in *db/db* mice. Morphologically, *db/db* control mice developed glomerular hypertrophy and tubulointerstitial damage compared to *db*/+ non-diabetic mice, whereas *db/db*;Par1$^{-/-}$ mice displayed less mesangial expansion and tubular dilation. *db/db*;Par1$^{-/-}$ mice had lower albuminuria with restoration of nephrin and WT-1 levels in the glomerulus compared to db/db controls. PAR-1 deficiency also preserved endothelial integrity and capillary permeability, along with an increase of VEGFA levels in *db/db* kidneys.

Conclusions: PAR-1 depletion confers kidney protection by reducing vascular damage and glomerular injury in experimental type 2 diabetic nephropathy. These novel findings suggest the potential of a PAR-1 targeted therapeutic strategy in diabetic nephropathy. **Funding:** Research Grants Council of Hong Kong (General Research Fund, grant no. 17118720)

Effects of a Vascular Endothelial Protein Tyrosine Phosphatase (VE-PTP) Blocking Antibody in a Mouse Model of Severe Diabetic Kidney Disease

Rajashree Rana,[1] Thomas A. Natoli,[2] Puneet Khandelwal,[3] Pavlos Pissios,[1] Abdul Bari Muhammad,[2] Vaja Chipashvili,[2] Krista P. Farrington,[2] Wen Zhou,[2] Gang Zheng,[1] Nikolay O. Bukanov,[1] Maria Chiara Magnone.[1] *[1]Janssen Research and Development LLC, Boston, MA; [2]Janssen Research and Development LLC, Cambridge, MA; [3]Janssen Research and Development LLC, Spring House, PA.*

Background: Diabetic Kidney Disease (DKD) is a disease with complex pathophysiology wherein endothelial dysfunction plays a central role in disease formation and progression. Emerging evidence emphasizes the critical role of the Tie-2 receptor and Angiopoietin 1 and 2 ligands in DKD. Tie-2 signaling is negatively regulated by the endothelial specific transmembrane Vascular Endothelial Protein Tyrosine Phosphatase (VE-PTP). Recently, it has been reported that the genetic deletion of VE-PTP provided protection from hypertension and diabetes induced renal injury in a mouse model of DKD. In the current study we investigated the efficacy of VE-PTP inhibition in a mouse model of severe DKD with an extracellular domain (ECD) targeting VE-PTP blocking antibody.

Methods: VE-PTP blocking antibody was characterized *in vitro*, *in vivo* in dermal vascular permeability assays, and in pharmacokinetic experiments. The *in vivo* proof-of-concept experiment with the VE-PTP blocking antibody and standard of care lisinopril were performed in hypertensive diabetic mice. Renin overexpression (AAV) was used to induce hypertension in db/db mice following uninephrectomy (Unx). Treatment was initiated 4-weeks after renin AAV administration and continued for another 4 weeks.

Results: Our results showed that VE-PTP inhibition with an ECD targeting VE-PTP antibody induced Tie2-phosphorylation and provided protection against VEGF-A induced vascular permeability both *in vitro* and *in vivo*. Furthermore, treatment with the VE-PTP antibody resulted in decreased kidney gene expression of endothelial activation markers *(Angpt2, Edn1, Icam1 and Vcam1)*. However, the VE-PTP blocking antibody treatment did not alter urinary albumin-to-creatinine ratio (uACR) in a severe mouse model of DKD.

Conclusions: VE-PTP inhibition with an ECD targeting antibody did not ameliorate hypertension- and diabetes-induced albuminuria in a preclinical mouse model of DKD.

Renal Lymphatics in Early Diabetic Kidney Disease: Insights from 3D Imaging and Functional Assays

Tahmina Aktar,[1] Daniyal J. Jafree,[1] Claire Walsh,[2] Luigi Gnudi,[3] David A. Long.[1] *[1]University College London Great Ormond Street Institute of Child Health, London, United Kingdom; [2]UCL Centre for Advanced Biomedical Imaging, London, United Kingdom; [3]King's College London, London, United Kingdom.*

Background: Diabetic kidney disease (DKD) is the leading cause of end-stage kidney disease, requiring dialysis or kidney transplant for patients' survival. Consequently, new treatments are urgently required. Renal lymphatics have been implicated in DKD pathogenesis, but their specific role in the early stages of disease remains unclear. This study aims to address this need using advanced 3D imaging and in vitro functional assays.

Methods: DBA/2J mice, rendered diabetic by streptozotocin (STZ), were assessed four and twelve weeks post-STZ. We measured body and kidney weight, albuminuria, and inflammatory markers, and quantified lymphatic volume, diameter, and branches using 3-dimensional imaging and computer analysis. Human dermal lymphatic cells were exposed to serum from patients with a 20-year history of Type 1 diabetes, with or without DKD (presence of albuminuria), to study possible changes in their angiogenesis and migration capacities.

Results: Although inflammation was elevated in diabetic mice at week four post-STZ, significant differences in lymphatic vessels, albuminuria, and kidney histology emerged only by week twelve. These changes included a marked expansion in lymphatic volume, diameter, and branches. Human lymphatic cells exposed to DKD$^+$ serum showed longer tube lengths, more branches, and increased migration compared to cells exposed to DKD$^-$ serum.

Conclusions: Through 3D imaging, we identify an early-stage expansion of lymphatics in DKD, coinciding with the initiation of kidney damage. Furthermore, our cellular work indicates this may be a repair response, with enhanced tube formation and migratory capabilities in lymphatic cells exposed to serum from patients with DKD. These insights indicate that modulating kidney lymphatics may represent a novel therapeutic avenue for DKD.

Funding: Private Foundation Support

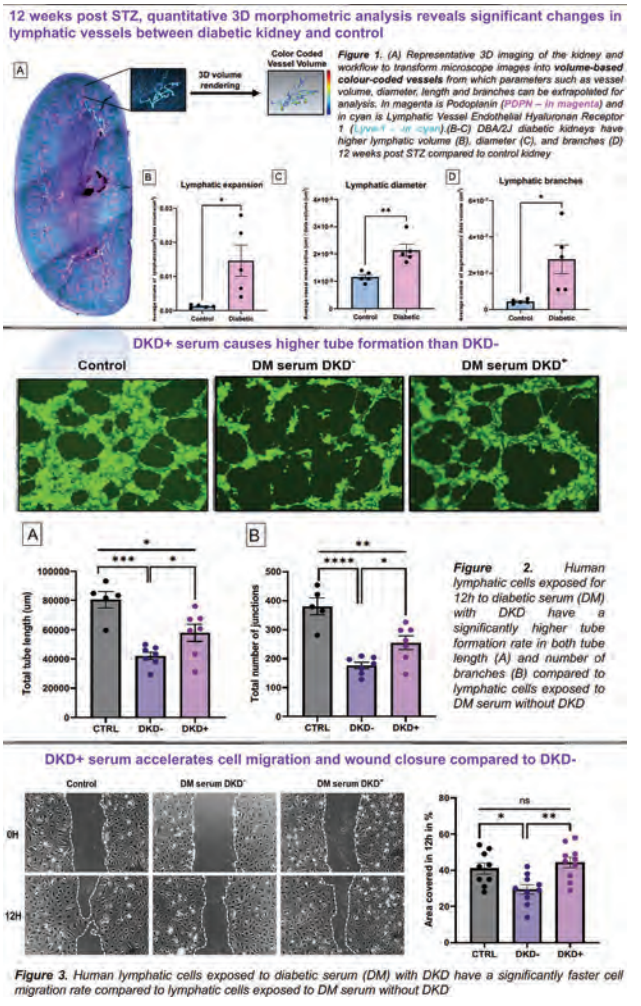

Figure 1. (A) Representative 3D imaging of the kidney and workflow to transform microscope images into volume-based colour-coded vessels from which parameters such as vessel volume, diameter, length and branches can be extrapolated for analysis. In magenta is Podoplanin (PDPN – In magenta) and in cyan is Lymphatic Vessel Endothelial Hyaluronan Receptor 1 (Lyve-1 – In cyan).(B-C) DBA/2J diabetic kidneys have higher lymphatic volume (B), diameter (C), and branches (D) 12 weeks post STZ compared to control kidney

Figure 2. Human lymphatic cells exposed for 12h to diabetic serum (DM) with DKD have a significantly higher tube formation rate in both tube length (A) and number of branches (B) compared to lymphatic cells exposed to DM serum without DKD

Figure 3. Human lymphatic cells exposed to diabetic serum (DM) with DKD have a significantly faster cell migration rate compared to lymphatic cells exposed to DM serum without DKD

Piezo1 Mediates Vasodilation Induced by Acute Hyperglycemia in Mouse Renal Arteries and Microvessels

Lingyan Fei, Zhihua Zheng, Shan Jiang. *Sun Yat-Sen University, Shenzhen, China*.

Background: Acute hyperglycemia (HG) is a risk factor for developing acute kidney injury and poor renal outcome in critically ill patients. The role of renal vasculature in this context is not clear. We hypothesize that HG-associated hyperosmolarity facilitates vasodilation through Piezo1-mediated eNOS activation.

Methods: Vasoreactivity of isolated mouse mesenteric (MA) and renal interlobar (ILA) arteries was analyzed using wire myography and that of renal afferent (AA) and efferent (EA) arterioles, and vasa recta (VR) using microvascular perfusion. Immunofluorescence and western blot were used for molecular analyses of isolated mouse blood vessels as well HUVECs.

Results: Pre-treatment with HG (44 mmol L^{-1} glucose; 4 h) increased acetylcholine (ACh)-induced relaxation in ILA and MA, which was prevented by eNOS inhibition using L-NAME. Hyperosmotic mannitol solution had a similar effect. HG induced an immediate, L-NAME-inhibitable dilation in AA, EA, and VR, whereby stronger dilation in AA compared to EA. HG also increased glomerular filtration rate in mice. In HUVECs, HG and the Piezo1 activator Yoda1 increased levels of Piezo1 protein, phosphorylated CaMKII (p-CaMKII), Akt, and p-eNOS. The HG-effect could be prevented by inhibiting Piezo1 using GsMTx4 and CaMKII using KN93. Furthermore, in arteries and microvessels, inhibition of Piezo1 using GsMTx4 prevented the HG-effect, while Yoda1 caused relaxation and dilation, respectively.

Conclusions: Results reveal that Piezo1 mediates renal vasodilation induced by hyperosmolarity in acute HG. This mechanism may contribute to the pathogenesis of renal damage by acute HG.

Podocyte-Specific Regulation of PP2A Worsens Diabetic Kidney Disease (DKD) Progression

Zhengying Fang, Kyung Lee, Ruijie Liu, John C. He. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We previously showed a critical role of protein phosphatase 2A (PP2A) in regulation of podocyte function and progression of DKD. However, PP2A is ubiquitously expressed with pleiotropic functions, limiting its role of being a DKD therapeutic target. Here, we investigated the role of a podocyte-specific regulatory subunit of PP2A, PPP2R2B in vitro and in vivo in the context of DKD.

Methods: By using PHEWAS approach, we screened the variants of genes coding for all PP2A subunits to determine their association with renal outcome in DKD patients. Knock-in (KI) mice with one of the clinical worse outcome-related *ppp2r2b* missense variants (T202M) was generated, and diabetes was induced with streptozotocin (STZ). Renal function was assessed every two weeks, and all mice were euthanized at the age of 24 weeks for examination.

Results: By PHEWAS study, several variants of *ppp2r2b* gene were found to be associated with a better or worse renal outcome in DKD patients. Interestingly, single cell transcriptomic data showed that *ppp2r2b* gene expresses mostly in human podocytes. In vitro study confirmed that *ppp2r2b* variants correlated with a better or worse clinical outcome led to an increased or decreased PP2A activity, respectively. We generated KI mice with one of the clinical worse outcome-related *ppp2r2b* missense variants (T202M). In vivo study revealed that diabetic KI mice developed significantly higher level of albuminuria in comparison to diabetic WT mice. Besides, diabetic KI mice also showed worst podocyte injury and loss, and mesangial matrix expansion. As PP2A dephosphorylates p65 NF-κB, we evaluated the phosphorylation level of p65 NF-κB in the glomeruli of these mice. Compared to wildtype mice, KI mice had a higher level of glomerular phosphorylation of p65.

Conclusions: The missense *ppp2r2b* variants were significantly associated with renal outcome in humans with DKD. KI of one of *ppp2r2b* missense variants (T202M) resulted in worsened glomerulopathy in diabetic mice. Thus, PPP2R2B, a podocyte-specific PP2A regulatory subunit, could be a better therapeutic target for DKD.

FR-PO338

Critical Role of Serum Response Factor in Podocyte Epithelial-Mesenchymal Transition of Diabetic Nephropathy

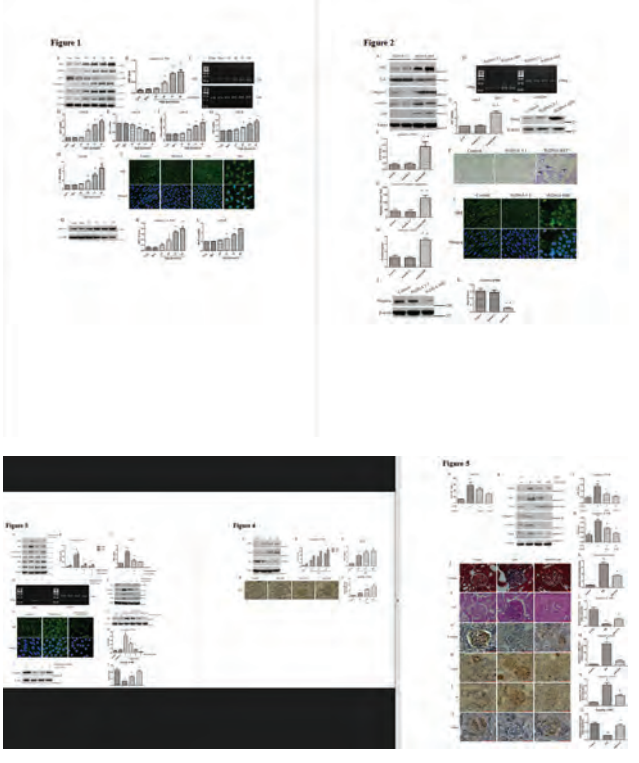
Long Zhao, Yan Xu. *The Affiliated Hospital of Qingdao University, Qingdao, China*.

Background: To investigate the expression and function of serum response factor (SRF) in podocyte epithelial–mesenchymal transition (EMT) of diabetic nephropathy (DN).

Methods: Expression of SRF, pSRF, synaptopodin, P-cadherin, ZO-1, α-SMA, FSP-1, fibronectin and collagen-1 were examined in podocytes or renal cortex following high glucose. SRF was upregulated by SRF plasmids and downregulated by CCG-1423 to investigate how SRF influence podocyte EMT in DN. Streptozocin was used to generate DM in rats.

Results: In podocytes after high glucose treatment, SRF, pSRF, α-SMA, FSP-1, fibronectin and collagen-1 increased, while synaptopodin, P-cadherin and ZO-1 declined. In vivo, CCG-1423 significantly abrogated the reduction of synaptopodin expression and the induction of SRF, collagen-1, α-SMA and FSP-1 expression in renal cortex tissues. Masson and PAS staining demonstrated that renal glomerular fibrosis was present in DM group, and after 8 weeks treatment with CCG-1423, renal glomerular fibrosis was dramatically ameliorated. In addition, CCG-1423 significantly preserved P-cadherin expression and suppressed α-SMA and FN expression in DN rats. SRF overexpression in podocytes induced expression of Snail, an important transcription factor that mediates EMT. Blockade of SRF reduced Snail induction, protected podocyte from EMT and improved proteinuria and serum albumin.

Conclusions: Together, increased SRF activity provokes podocytes EMT and dysfunction in DN. Targeting SRF by small molecule inhibitor may be an attractive therapeutic strategy for DN.



FR-PO339

Inhibition of the lncRNA 585189 Prevents Podocyte Injury and Mitochondria Dysfunction by Promoting hnRNP A1 and SIRT1 in Diabetic Nephropathy

Jinxiu Hu, Yue Liu, Huimin Chen, Zhimei Lv, Rong Wang. *Shandong Provincial Hospital, Jinan, China.*

Background: Dysfunction of podocytes has been identified as a crucial pathologic characteristic of diabetic nephropathy (DN), while the regulatory effect of long noncoding RNAs (lncRNAs) in this process has not been fully elucidated.

Methods: We conducted RNA-seq on renal tissues and identified a significantly upregulated lncRNA ENST00000585189.1 (lncRNA 585189) in patients with DN. Subsequently, we assessed its correlation with clinical indicators and demonstrated its localization with RNA-FISH. In high-glucose-induced human podocytes, the expression of lncRNA 585189 was assessed via real-time PCR and RNA-FISH. Subsequently, gain- and loss-of-function experiments detected the effect of lncRNA 585189. The expression of Desmin, ZO-1, hnRNP A1 and SIRT1 were evaluated using real-time PCR, western blot and immunofluorescence assays. Mitochondrial morphologies were evaluated using MitoTracker, while mitochondrial ROS and membrane potential were assessed using MitoSOX Red and TMRM staining. Mechanistically, bioinformatics analysis predicted the interaction between lncRNA 585189 and hnRNP A1, which was confirmed by RIP, pull-down, and EMSA assays. Moreover, the binding of hnRNP A1 to SIRT1 mRNA was validated through RIP and pull-down assays. Additionally, the stability of hnRNPA1 and SIRT1 was assessed by treatment with Cloheximide, MG-132, and Actinomycin D.

Results: lncRNA 585189 displayed a positive correlation with renal insufficiency and was found to be upregulated in both DN patients and high-glucose-induced human podocytes. Silence of lncRNA 585189 decreased the production of ROS, rescued the aberrant mitochondrial morphology and membrane potential, restored the podocyte damage caused by high glucose. Mechanistically, lncRNA 585189 binds to hnRNP A1, inducing destabilization of hnRNP A1 protein and downregulating its expression. Conversely, hnRNP A1 promotes the expression of lncRNA 585189. Furthermore, the interaction between hnRNP A1 and SIRT1 mRNA promotes the stability of SIRT1 mRNA and enhances its expression. Finally, our findings suggested that lncRNA 585189 inhibited SIRT1 expression through hnRNP A1, hindering the recovery of mitochondrial abnormalities and podocyte damage.

Conclusions: In summary, targeting lncRNA 585189 may represent a promising strategy for reversing mitochondrial dysfunction and treating DN.

FR-PO340

Stimulator of Interferon Genes (STING) Deletion Alleviates Podocyte Injury Through Suppressing Inflammatory Response in Diabetic Kidney Disease

Zhaowei Chen, Xueyan Yang, Guohua Ding. *Renmin Hospital of Wuhan University, Wuhan, China.*

Background: The stimulator of interferon genes (STING) is an adaptor protein that can drive noninfectious inflammation and pyroptosis. NLRP3-mediated inflammasome activation is an important type of inflammatory programmed death with strong pro-inflammatory activity and has been confirmed to promote a chronic inflammatory response in DKD. However, the mechanism of STING regulating immune inflammation and the interaction with NLRP3-dependent pyroptosis in the high glucose (HG) state remains unknown. The present study aims to evaluate whether STING contributes to HG-induced podocyte inflammation response through modulating NLRP3-dependent pyroptosis.

Methods: In vivo study, co-localization expression of STING and synaptopodin was evaluated in glomeruli by double immunolabeling. Western blot was performed to assess STING and inflammatory-related protein expression in glomeruli. q-PCR was used to detect inflammatory molecule expression. Transmission electron microscope (TEM) was used to identify ultrastructure changes of podocytes in diabetic mice. Pathological changes were evaluated by periodic acid-Schiff stain (PAS) or hematoxylin and eosin (HE) staining. In vitro study, podocytes were exposed to HG (40mM) for 24 h. Immunofluorescence assay and western blot were performed to evaluate STING expression. Pyroptosis and inflammatory-related molecule expression were detected by western blot and q-PCR. STING siRNA was transfected to podocytes to evaluate the effect of STING inhibition on podocyte inflammatory response under HG stimulation.

Results: Double immunolabeling of STING and synaptopodin in glomeruli was obviously increased in diabetic animals. In addition, STING protein expression was increased in diabetic mice compared with controls. Deletion of STING alleviated podocyte injury, renal dysfunction inflammation, NLRP3 inflammasome activation, and pyroptosis in diabetic mice. In cultured podocytes, STING protein expression was increased in HG-treated podocytes. Modulated STING expression by STING siRNA alleviated pyroptosis and NLRP3 inflammasome activation in HG-treated podocytes.

Conclusions: These results indicate that STING deletion suppresses podocytes inflammation response by targeting NLRP3 and provide evidence that STING may be a potential target for podocyte injury in DKD.

FR-PO341

SrGAP3 Deficiency Mediates Podocyte Injury by Promoting Cdc42 and Rac1 Activity in Diabetic Nephropathy

Yan Yang, Li Zhang, Xinling Liang. *Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guang Zhou, China.*

Background: Rho GTPase activity plays a key role in cytoskeletal rearrangement and apoptosis of podocytes in diabetic nephropathy (DN). However, the upstream regulatory mechanism directing Rho GTPases in podocytes of DN remains unclear. This study aimed to verify the expression of SrGAP3, a Rho GTPase activating protein, in kidney and its role and mechanism in podocyte injury of DN.

Methods: The level of SrGAP3 expression was analyzed using immunofluorescence in the glomerular podocytes of renal tissue from DN patients and diabetic mice with albuminuria. Albuminuria, podocyte injury and glomerular pathology were evaluated in SrGAP3 overexpression of type 2 diabetic db/db mice and STZ-induced type 1 diabetic mice. The expressions and activities of Cdc42 and Rac1 in the glomerular podocytes in vivo in diabetic mice and in vitro in podocytes exposed to either SrGAP3 knockdown or high glucose treated podocytes with SrGAP3 overexpression were detected by immunofluorescence, western blot and enzyme activity detection. Podocyte marker proteins, cytoskeleton, cell motility and apoptosis were observed in in vitro podocytes under different conditions.

Results: SrGAP3 was markedly reduced in glomerular podocytes from renal tissues of DN patients, db/db mice and STZ-induced diabetic mice with albuminuria. The albuminuria in db/db and STZ-induced diabetic mouse model was markedly attenuated after overexpression of SrGAP3 established by adeno-associated virus. This was accompanied by alleviation of basement membrane thickening, mesangial matrix expansion, and podocyte injury. The decreased expression of SrGAP3 in podocytes cultured with high glucose was upregulated after overexpression of SrGAP3, accompanied by restored decreased podocyte marker proteins, and improved actin cytoskeleton rearrangement, podocyte motility and apoptosis. Further studies found that increased activity of Cdc42 and Rac1 in podocytes in vivo and in vitro under the diabetic state were significantly inhibited after overexpression of SrGAP3.

Conclusions: SrGAP3 deficiency mediates podocyte injury of DN by promoting Cdc42 and Rac1 activation, which may provide a clinical therapeutic target for protecting podocyte injury of DN.

Podocyte-Specific Clusterin Triggers the Activation of Proximal Tubule-Specific CAMK1D Signaling to Attenuate Kidney Injury in Diabetic Kidney Disease

Nehaben A. Gujarati,[1] Bismark Owusu Frimpong,[1,2] Malaika Zaidi,[1] Sandeep K. Mallipattu.[1] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]Yale School of Medicine, New Haven, CT.*

Background: The role of podocyte-proximal tubule (PT) crosstalk in the progression of Diabetic Kidney Disease (DKD) remains understudied. Podocyte-specific overexpression of Krüppel-like factor 6 (*KLF6*), a zinc finger transcription factor, attenuated proximal tubule (PT) injury in murine DKD model. Initial snRNA-seq studies demonstrated a potential interaction between podocyte Clusterin (CLU), a secretory ligand, and proximal tubule CAMK1D. The aim of this study is to investigate the mechanism by which the podocyte primes the PT to attenuate kidney injury in DKD.

Methods: Conditioned media (CM) was collected from GFP-labeled podocytes obtained from podocyte-specific induction of *KLF6* (*KLF6*^{PODTA}) and control mice to carry out proteomic analysis and in vitro assays in primary (1°) PT. 1° PT cells were treated with control CM as well as CM blocked with CLU antibody. CAMK1D signaling was pharmacologically inhibited using STO-609, an inhibitor of the upstream kinase CAMKK. Oxygen consumption rate (OCR) was measured with seahorse analyzer. Immunofluorescence staining, western blot analysis, and pulldown assay for calmodulin were performed. Single nuclei ATAC (SnATAC) and snRNA sequencing were conducted on the kidney cortex of all mice.

Results: Immunostaining of experimental mice as well as proteomic analysis of the podocyte CM and urine, led to identification of CLU as a potential ligand for PT signaling. *KLF6*^{PODTA} CM-treated 1° PT cells demonstrated an increase in calmodulin binding affinity as well as an increase in OCR compared to control CM-treated cells in high glucose (HG) conditions, and this OCR change was abated by the addition of CLU blocking antibody. CAMK1D expression was unique to the first segment of PT in mouse as well as human tissue. 1° PT cells treated with STO-609 had a decrease in cell viability and OCR in HG conditions, a decrease in p-DRP1, and an increase in fragmented mitochondria. SnATACseq in combination with snRNAseq also validated pathways related to calcium signaling and podocyte-PT communication.

Conclusions: These data suggest that CLU secreted from podocytes attenuates mitochondrial fission in the PT by inducing CAMK1D signaling, thereby priming the PT against injury under diabetic conditions.

High Glucose-Induced Pyruvate Kinase M2 (PKM2) Tyrosine Phosphorylation Drives a Feedback Loop by PDGFRβ to Force mTORC1 Activation for Mesangial Cell (MC) Injury in Diabetic Nephropathy (DN)

Falguni Das,[1] Nandini Ghosh-choudhury,[1] Balakuntalam S. Kasinath,[1] Goutam Ghosh-Choudhury.[2] *[1]UTHSCSA, San Antonio, TX; [2]South Texas VAMC, San Antonio, TX.*

Background: Besides its role in the last step of glycolysis to produce pyruvate, increased expression and tyrosine phosphorylation of PKM2 regulate mitotic checkpoint in many cancers. We investigated the role of PKM2 tyrosine phosphorylation in DN.

Methods: MCs, OVE26 and db/db mice were employed.

Results: Incubation of MCs with 25 mM glucose (HG) increased the expression of PKM2 in a sustained manner. HG induced translocation of PKM2 into the nucleus and increased its phosphorylation at tyrosine-105 residue in both cytosol and nucleus. We have recently shown a role of PDGFRβ in DN. We hypothesized that PDGFRβ may regulate PKM2. JNJ, a PDGFRβ inhibitor, abrogated HG-stimulated PKM2 expression and tyrosine phosphorylation. Interestingly, expression of kinase dead PKM2 K367M and tyrosine phosphorylation deficient PKM2 Y105F mutants inhibited HG-induced MC hypertrophy. In contrast, overexpression of wild type PKM2 induced MC hypertrophy similar to HG treatment. Mesangial matrix expansion is an aspect of DN. Both PKM2 K367KM and PKM2Y105F mutants mitigated HG-stimulated expression of fibronectin, collagen I (α2) and PAI-1 whereas, overexpression of PKM2 had the opposite effects similar to HG. Previously, we reported that Akt/mTORC1 signaling regulates MC pathologies. We found that PKM2 K367M and PKM2 Y105F mutants suppressed HG-stimulated Akt and mTORC1 while overexpression of PKM2 increased their activities. Intriguingly, Akt and mTORC1 inhibitors MK2206 and rapamycin, respectively, suppressed expression and tyrosine phosphorylation of PKM2. While addressing the *in vivo* relevance, we found increased PKM2 expression and tyrosine phosphorylation concomitant with fibronectin, PAI-1 and collagen I (α2) expression in the renal cortex of OVE26 and db/db mice, models of type 1 and type 2 diabetes, respectively.

Conclusions: Our results identify a previously unrecognized HG-stimulated novel positive feedback loop involving PDGFRβ, activated Akt/mTORC1 and tyrosine phosphorylated PKM2 to drive MC pathologies in DN.

PTEN-Long Suppresses Proximal Tubular Epithelial Cell (PTEC) Injury in Diabetic Nephropathy (DN)

Falguni Das,[1] Nandini Ghosh-choudhury,[2] Balakuntalam S. Kasinath,[2] Goutam Ghosh-Choudhury.[1] *[1]UT Health VA Hospital, San Antonio, San Antonio, TX; [2]UT Health, San Antonio, TX.*

Background: From the same mRNA, a translational variant with CUG codon (Leu)-initiated PTEN with a 173 amino acids long N-terminus (PTEN-L) compared to canonical PTEN has recently been identified. Both PTENs provide a checkpoint against tumorigenesis. We investigated the hypothesis that PTEN-L acts as a driver of tubular injury in the progression of DN.

Methods: Human PTECs, OVE26 and db/db mice, specific antibodies, immunoblotting, PTEN-L-targeting drugs, measurement of hypertrophy and plasmid expression vector were employed.

Results: 25 mM glucose (HG) time-dependently decreased the expression of PTEN-L. PTECs predominantly express Akt-2 isoform. Concomitant with decreased PTEN-L, HG increased phosphorylation of Akt-2 and its substrate GSK3β. The anti-bacterial chromophore acriflavine (ACR) inhibits initiation from CUG codon. ACR inhibited the expression of PTEN-L. In contrast, aurin tricarboxylic acid (ATA), a potent anti-viral agent, increases translation from CUG codon and increased the expression of PTEN-L. Consequently, ACR increased Akt-2 phosphorylation/activation (p-GSK3β) similar to HG while ATA inhibited these events. These drugs had no effect on canonical PTEN expression. As Akt-2 regulates mTORC1 via phosphorylation/inactivation of tuberin and PRAS40, we determined the effect of these drugs. ACR increased their inactivating phosphorylation, resulting in activation of mTORC1, as judged by phosphorylation of S6 kinase, eEF2 kinase and dephosphorylation of eEF2; these effects were similar to HG. ATA blocked these effects induced by HG. ACR induced PTEC hypertrophy and fibronectin and PAI-1 expression similar to HG while ATA inhibited these HG-induced phenomena. To confirm the results with ATA, we used a plasmid vector expressing PTEN-L. PTEN-L suppressed HG-induced phosphorylation of Akt-2/GSK3b, resulting in inhibition of mTORC1 activity and blocked HG-induced PTEC hypertrophy and, expression of fibronectin and PAI-1. In addressing the *in vivo* relevance of our results, in the renal cortex of OVE26 and db/db mice models of type 1 and type 2 diabetes, we found decreased expression of PTEN-L concomitant with increased phosphorylation of Akt-2/GSK3b, mTORC1 activation, and fibronectin and PAI-1 expression.

Conclusions: We conclude that PTEN-L protects against PTEC injury in DN.

SIRT3 Activation with Viniferin Treatment Ameliorates Features of Diabetes-Induced Tubular Injury Through Restoration of Mitochondrial Function

Jaejin Ryu,[1,2] Jae Young Kim,[3] Boyoung Nam,[1,2] Gyu R. Kim,[1,2] Ye Eun Ko,[1,2] Hyung Woo Kim,[1,2] Seung Hyeok Han,[1,2] Tae-Hyun Yoo,[1,2] Shin-Wook Kang,[1,2] Jung Tak Park.[1,2] *[1]Department of Internal Medicine, College of Medicine, Yonsei University, Seoul, Republic of Korea; [2]Institute of Kidney Disease Research, College of Medicine, Yonsei University, Seoul, Republic of Korea; [3]Division of Nephrology, Department of Internal Medicine, National Health Insurance Service Ilsan Hospital, Goyang-si, Gyeonggi-do, Republic of Korea.*

Background: Oxidative stress and mitochondrial dysfunction are key factors inducing diabetic nephropathy. In this study, the role of SIRT3 as a regulator of mitochondrial activity and cell survival and the effect of viniferin as a SIRT3 activator were assessed in diabetes-induced tubular injury.

Methods: In vitro, NRK-52E cells treated with TGF-β-were compared with controls after SIRT3-targeted lentivirus transfection and viniferin treatment to evaluate the effect of SIRT3 overexpression. In an animal study, viniferin was injected to db/db mice for 9 weeks and to C57BL/6 mice given with unilateral nephrectomy and intraperitoneal streptozotocin injection (UNXSTZ) for 4 weeks using osmotic pump, db/m mice and C57BL/6 mice served as controls, respectively.

Results: In NRK-52E cells, TGF-β treatment resulted in decreased expression of SIRT3, in parallel with increased oxidative stress, decreased mitochondrial mass, integrity, and respiration, and increased fibrotic and apoptotic activities. SIRT3 overexpression by lentiviral transfection improved mitochondrial dynamics and cell injury, and similar alterations were observed after viniferin treatment. In kidney of db/db and UNXSTZ mice, diabetes induced downregulation of SIRT3, increased oxidative stress, decreased expressions of mitochondrial dynamic-related genes, and cell injury. SIRT3 activation by viniferin treatment restored these alterations, and tubular degeneration and fibrotic remodeling in diabetic kidney were also ameliorated by viniferin treatment.

Conclusions: This study demonstrates that SIRT3 activation by viniferin treatment improves oxidative stress and impaired mitochondrial metabolism in diabetes-induced tubular injury.

FR-PO346

Single-Cell RNA Sequencing Analysis Reveals Inhibition of Proximal Tubule mTORC1 in Myoinositol Oxygenase Knockout Mice: A Possible Mechanism for Ameliorating CKD

Isha Sharma, Yalu Zhou, Hiroshi Maekawa, Susan E. Quaggin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: MIOX is a proximal tubular specific enzyme and it catalyzes the rate limiting step of myoinositol metabolism. MIOX overexpression has been implicated in the progression of chronic kidney disease. Conversely its genetic deletion shows significant amelioration in progression of chronic kidney disease (CKD) in mouse models of diabetes.

Methods: Kidneys harvested from 6-week-old male C57BL/6J (WT) and MIOX-KO mice, fed with normal or high fat diet (HFD, 60% calories from fat) for six weeks, were analyzed. Change in body weight, blood glucose level was estimated. Single cell RNA sequence (scRNA seq) analysis was performed on libraries prepared from whole kidneys of six-week ND (normal diet) and HFD mice. We assessed pS6 level in kidneys of MIOX-KO and WT mice via immunoblotting.

Results: UMAP showed retrieval of 27 clusters which included cells of proximal tubules, loop of Henle, distal convoluted tubules, collecting duct, podocytes, stroma, vasculature, and immune cells. Pathway enrichment analysis with all cells highlighted mTORC1 signaling pathway was substantially downregulated in MIOX-KO HFD mice as compared to MIOX-KO ND mice. Conversely, mTORC1 pathway was significantly upregulated in cells from WT-HFD. Further we narrowed down the pathway enrichment analysis only to proximal tubules (PT) as MIOX is only expressed in PT cells. Beside endoplasmic reticulum stress, hypoxia, apoptosis, mTORC1 pathway was significantly downregulated in MIOX-KO-HFD mice as compared to WT-HFD and MIOX-KO ND. Immunoblotting analysis showed downregulation of p-mTORC1 in MIOX-KO mice fed with normal chow as compared to WT mice. In addition, scRNA showed that mitophagy, which is modulated by mTORC1 signaling, is induced in PT cells of MIOX-KO mice.

Conclusions: MIOX-KO reduced mTORC1 activation compared to WT following HFD. We posit that decreased activation of mTORC1 is one mechanism whereby MIOX inhibition/loss protects the kidney from injury in diabetes.

FR-PO347

Hic-5 Overexpression Drives Tubular Cell Senescence and Degeneration in Diabetic Kidney Disease

Bohan Chen, Xianhui Liang, Pei Wang. *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

Background: Emerging data suggest that tubular cell senescence plays a crucial role in the onset and development of diabetic kidney disease (DKD). However, the underlying mechanism responsible for the tubular cell senescence of DKD remains elusive. Hydrogen peroxide-induced clone 5 (Hic-5) has been shown to be associated with senescence-related genes and cell-senescent phenotypes. Ergo, this study investigated the role of Hic-5 in DKD tubular cell senescence.

Methods: The expression of Hic-5 was examined in kidney tissues of DKD patients. The effect of Hic-5 was explored in vitro in cultured tubular epithelial cells by knockdown or by forced expression of Hic-5 in diabetic milieu, or in vivo in mouse models of DKD with knockdown of Hic-5. The cell senescent phenotype, tubular degeneration or kidney injury as well as function were tested.

Results: The tubulointerstitial expression of Hic-5 was markedly increased in kidney tissues of DKD patients, as compared with healthy living donors, which was positively associated with the curated kidney-aging-related gene set "RODWELL_AGING_KIDNEY_UP", as analyzed by gene set enrichment analysis. In vitro in cultured tubular epithelial cells exposed to diabetic milieu, Hic-5 was significantly increased accompanied by increased expression of $p16^{INK4A}$, fibronectin, and increased cell senescence-associated beta-galactosidase activity as well as reduced expression of the epithelial marker E-cadherin. All these senescent phenotypes and degenerative changes were largely abrogated by knockdown of Hic-5 but reinforced by forced expression of Hic-5. In vivo in mouse models of DKD, knockdown of tubular Hic-5 expression mitigated tubular cell senescence and secretion of senescence-associated secretory phenotype including IL6, monocyte chemoattractant protein 1 and plasminogen activator inhibitor 1, concomitant with attenuated kidney function as well as decreased fibronectin and collagen I expression of the kidney.

Conclusions: Hic-5 plays an instrumental role in DKD progression by mediating cellular senescence, and thus is likely a drugable target for halting DKD progression.

FR-PO348

Inhibition of Fatty Acid-Binding Protein 4 Protects Renal Tubular Epithelial Cells and Rescues Diabetic Kidney Disease

Yen-Wen Wu,[1,2] Jaw-Wen Chen,[2,4] Ting-Ting Chang.[2,3] *[1]Far Eastern Memorial Hospital, New Taipei City, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan; [3]Department and Institute of Pharmacology, National Yang Ming Chiao Tung University, Taipie, Taiwan; [4]Healthcare and Services Center, Taipei Veterans General Hospital, Taipei, Taiwan.*

Background: Previous clinical observations have shown that increased circulating fatty acid binding protein (FABP) 4 is associated with the progression of diabetic kidney disease (DKD) in patients with type 2 diabetes. This study aimed to investigate the potential mechanistic role of FABP4 and the direct effects of FABP4 inhibition in experimental DKD.

Methods: To mimic the presence of hyperglycemia in DKD, human renal proximal tubular epithelial cells were cultured with high glucose (25 mM) for 3 days for in vitro study. In addition, Leprdb/JNarl type 2 DM mice were used for a mouse model of DKD. Mice were randomly assigned to receive an oral FABP4 inhibitor, BMS-309403, for 2 weeks.

Results: Administration of FABP4 inhibitor reduced the high glucose-induced apoptosis of renal proximal tubular epithelial cells. Furthermore, FABP4 inhibitor attenuated high glucose-induced inflammatory protein (tumor necrosis factor-α/interleukin-1β/interleukin-6) and fibrotic protein (transforming growth factor-β/collagen-1) expressions in vitro. In in vivo study, treatment of FABP4 inhibitor reduced the increase of serum blood urea nitrogen and creatinine levels in DKD mice. Moreover, the urinary albumin-to-creatinine ratio and kidney-to-body weight ratio were attenuated by FABP4 inhibitor treatments.

Conclusions: Taken together, inhibition of FABP4 could protect renal proximal tubular epithelial cells against the high glucose-induced damage in vitro and improve renal function, renal hypertrophy, and urinary albumin-to-creatinine ratios in DKD mice in vivo. Further molecular mechanistic insights may be explored to provide a novel theoretical basis for the potential therapeutic target of FABP4 in DKD.

FR-PO349

Oxidised IL-33 Mediates Proximal Tubular Injury Through the RAGE/EGFR Pathway

Elena Liarte Marin,[1] Barbara Musial,[1] Philip M. Bousfield,[1] Asha Seth,[1] Pernille B. Laerkegaard Hansen,[2] Kevin Woollard.[1] *[1]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Cambridge, United Kingdom; [2]Bioscience Renal, Research and Early Development, Cardiovascular, Renal and Metabolism (CVRM), BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden.*

Background: We previously described IL-33 role in DKD mediating glomerular endothelial inflammation through ST2 signalling and a Ph2b trial in DKD using tozorakimab (anti-IL-33 mAb) is ongoing (FRONTEIR-1). Recently, IL-33 was shown to get oxidised extracellularly ($IL\text{-}33^{ox}$) and exert distinct activity through a novel RAGE/EGFR complex to modulate lung epithelial remodelling. As ST2 and RAGE/EGFR act as putative receptors, we explored $IL\text{-}33^{ox}$ and RAGE/EGFR signalling role in kidney.

Methods: Whilst RAGE is a promiscuous receptor, blockade of RAGE signalling with a neutralising antibody prevented progression of albuminuria in the db/db uninephrectomy model. Mechanistic studies were further developed using primary human glomerular endothelial (GEC) and proximal tubular epithelial cells (PTEC) to address $IL\text{-}33^{ox}$-RAGE/EGFR pathway contribution to human DKD.

Results: GEC but not PTEC expressed ST2 and hence reduced IL-33 ($IL\text{-}33^{red}$) did not display an inflammatory response in PTEC contrary to the effects seen in GEC. However, $IL\text{-}33^{ox}$ stimulation of PTEC promoted EGF receptor activation which was inhibited by antibodies against EGFR and RAGE. $IL\text{-}33^{ox}$ led to phosphorylation of EGFR downstream signalling molecules, like ERK1/ 2 but no other MAP kinases. Data also showed $IL\text{-}33^{ox}$ upregulated epithelial injury markers (KIM-1) and inflammatory cytokine release in PTEC. Preliminary results indicated that $IL\text{-}33^{ox}$ modulates epithelial biological functions that could impact healing and reparative mechanisms in the context of DKD. Under normal culture conditions $IL\text{-}33^{ox}$ but not $IL\text{-}33^{red}$ stimulated PTEC proliferation, while under stress (serum starvation) $IL\text{-}33^{ox}$ prevented this effect. In a PTEC wound closure assay, tozorakimab facilitated wound healing suggesting oxidation inhibition of endogenously secreted IL-33 by the injured epithelium. GEC biology was assessed too. In contrast to the endothelial inflammation caused through the $IL\text{-}33^{red}$/ST2 pathway, minimal effects were observed upon $IL\text{-}33^{ox}$ stimulation.

Conclusions: Although mechanism of action of the $IL\text{-}33^{ox}$–RAGE/EGFR pathway still needs to be fully elucidated, our results suggest that $IL\text{-}33^{ox}$ can contribute to tubular epithelial repair and remodelling. Tozorakimab may therefore be beneficial in DKD by preventing $IL\text{-}33^{red}$ mediated glomerular inflammation and $IL33^{ox}$ mediated tubular injury.

microRNA (miR)-299a-5p Promotes Apoptosis of Tubular Cells Through Erk5 Inhibition

Ifeanyi K. Nmecha, Bo Gao, Melissa Macdonald, Joan C. Krepinsky. *McMaster University Faculty of Health Sciences, Hamilton, ON, Canada.*

Background: Diabetic kidney disease (DKD) is the leading cause of end stage renal failure in North America. Tubular epithelial cell apoptosis was shown to contribute to the pathogenesis of DKD by promoting interstitial fibrosis. The mechanism involves the release of cytokines and growth factors that promote interstitial inflammation and myofibroblast activation, which leads to the increased production and accumulation of extracellular matrix proteins in the interstitium. Previously, we showed that microRNA (miR) 299a-5p promotes the fibrotic response in mesangial cells. Here we studied the role of this miR in regulating tubular apoptosis.

Methods: Immortalized human kidney proximal tubular cells (HK2) were treated with high glucose (HG); miR299a-5p was detected by qPCR. HK2 cells were transfected with miR overexpression and inhibition plasmids using Transfectamine reagent. Apoptosis was detected using the Annexin V kit. Immunoblotting and immunohistochemistry were used to assess protein expression.

Results: HG increased the expression of miR299a-5p in HK2 cells. A bioinformatics screen of four databases showed that miR299a-5p targets MAP3K2, a protein kinase primarily expressed in the tubules. MAP3K2 is a major activator of extracellular signal-regulated kinase 5 (ERK 5), a known anti-apoptotic and anti-inflammatory kinase. miR299a-5p overexpression reduced the protein expression of MAP3K2 and phosphorylation of ERK5, while augmenting the expression of apoptotic markers and endoplasmic reticulum stress in response to HG. Conversely, miR299a-5p inhibition restored MAP3K2 expression and ERK5phosphorylation to basal levels, while attenuating HG-induced apoptosis. In type-1 diabetic Akita mice overexpressing TGFβ1, a model which accelerates DKD, miR299a was increased in association with reduced expression of MAP3K2 and phosphorylated ERK5.

Conclusions: These data support an important role for miR299a-5p in regulating tubular cell apoptosis in HG. Future studies will determine whether inhibition of this miR *in vivo* attenuates apoptosis and reduces tubulointerstitial fibrosis in DKD. We will also explore whether ERK5 phosphorylation may be a potential therapeutic for interstitial fibrosis.

Single Nucleus RNA Sequencing of Sglt2 Knockout Mouse Hearts Reveals Cardiac-Renal Communication

Margaret E. Fain,[1] Hiroshi Maekawa,[1] Yalu Zhou,[1] Thomas Rousselle,[2] Tanner O. Monroe,[1] Valeria R. Mas,[2] Susan E. Quaggin.[1] *[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Sodium glucose cotransporter 2 inhibitors (SGLT2is) are a class of drugs that promote glycosuria and have been shown to provide marked cardiac and renal benefit regardless of diabetes status; however, the precise mechanism of this benefit to the heart is unclear, especially given that the canonical target for SGLT2is is a cotransporter only expressed in the proximal tubule of the kidney. To investigate the broader cardiac effects of chronic Sglt2 inhibition, we conducted the first single-nucleus RNA sequencing (snRNA seq) experiment in the hearts of the SweetPee (SP) mouse model, which carries a missense mutation in the *Slc5a2* gene resulting in loss of Sglt2 expression in the proximal tubule of the kidney.

Methods: 10-week-old male SP and wildtype (WT) control littermates were fed either normal diet (ND) or high fat diet (HFD, 60% calories from fat) for 18 weeks. Hearts were processed using single-nucleus RNA sequencing (snRNA seq) and the resulting data were analyzed through the Seurat pipeline in R to identify differentially expressed genes (DEGs) and to perform pathway enrichment.

Results: Clustering revealed twenty different cell types, no one of which was significantly enriched in any of the four conditions. Replicating prior observations, *Slc5a2* was not expressed in any cardiac cell type under any condition. In the WT HFD group, genes encoding molecules involved in oxidative phosphorylation were upregulated in cardiomyocytes, alongside other metabolic genes. These changes are consistent with altered mitochondrial function. By contrast, the SP HFD showed a downregulation in genes associated with diabetic cardiomyopathy and an upregulation of angiogenic genes. The changes in the WT HFD group are predicted to be deleterious, while those in SP HFD appear to be protective, supporting a model of organ crosstalk whereby renal Sglt2 inhibition results in protective molecular changes in cardiomyocytes.

Conclusions: Here, we demonstrate for the first time that loss of function of the proximal tubule-specific Sglt2 co-transporter results in significant upregulation of cardio-protective pathways, indicating that the cardiac benefit of SGLT2is is secondary to primary effects on the kidney and not a result of off-target pharmacologic effects.

FR-PO352

SGLT2 Inhibition Causes Methionine Metabolic Modulation in Diabetic Kidney Disease

Hiroshi Maekawa, Yalu Zhou, Margaret E. Fain, Dorian Kaminski, Navdeep S. Chandel, Susan E. Quaggin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Therapeutic inhibition of the sodium glucose cotransporter 2 (SGLT2) protects the kidney although underlying mechanisms are incompletely known. We tested the hypothesis that cell-specific metabolic pathways activated by SGLT2 inhibition in diabetic kidney disease (DKD) underlie benefits.

Methods: Kidneys harvested from 10-week-old male Sglt2 mutant (MT) and wildtype (WT) mice, fed with normal or high fat diet (HFD, 60% calories from fat) for 8 or 18 weeks, were analyzed. Single cell RNA sequence (scRNA seq) analysis was performed on libraries prepared from whole kidneys. Metabolomic analysis of renal cortex was conducted by Metabolon, Inc. Two dosages (10 or 50 mg/kg BW) of Methionine Adenosyltransferase 2A inhibitor (MAT2Ai), an inhibitor of the methionine cycle, was injected into intraperitoneal cavity of WT/MT mice with prior exposure to HFD for 8 weeks. Human proximal tubular cells (HK-2), were exposed to 50 mM of D-glucose with/without 1uM of MAT2Ai or S-Adenosyl methionine (SAM) for 48hr.

Results: HFD-induced obesity was similar in both MT and WT while compensatory hyperphagia was observed in MT. Glucose intolerance occurred in mice fed HFD (WT>MT). Molecular and functional markers of kidney injury including serum creatinine, KIM-1, number of apoptotic cells and albuminuria were higher in WT>MT. Analysis of scRNA seq showed a new class of proximal tubular cells (New-PTC), predominantly found in HFD-fed WT. New-PTC showed increased expression of genes related to epithelial–mesenchymal transition (EMT), apoptosis and inflammation. Pathway enrichment analysis of metabolomic data uncovered differences in WT vs MT renal cortex; metabolites of methionine cycle including SAM were preferentially increased in HFD-fed MT. MAT2Ai abrogated renal protection with anti-inflammatory (reduced IL-6, IL-8, IL-1β and TNF) and fibrotic (reduced αSMA and SM22α) responses in MT. High glucose treatment of HK-2 recapitulated molecular changes observed in New-PTC, including markers of EMT (elevated fibronectin) and inflammation (increased IL-6, IL-8 and TNF) which could be inhibited by SAM supplementation, which enhances methionine metabolism. Conversely MAT2Ai exacerbated EMT and inflammation.

Conclusions: SGLT2 inhibition prevents the emergence of New-PTC with inflammatory and fibrotic phenotypes via methionine metabolic modulation in DKD.

FR-PO353

SGLT2 Inhibition Reveals Kidney Reconfiguration and Metabolic Interorgan Communication

Anja M. Billing,[1] Young Chul Kim,[3] Volker Vallon,[3] Markus M. Rinschen.[1,2] *[1]Aarhus Universitet, Aarhus, Denmark; [2]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [3]University of California San Diego, La Jolla, CA.*

Background: SGLT2 inhibitors, originally employed for hyperglycemia management, exhibit protective effects against renal and cardiovascular complications, irrespective of diabetes presence. The precise molecular mechanisms underlying these effects remain largely unknown and cannot be solely attributed to their primary function of inhibiting renal glucose re-absorption.

Methods: To gain insights into these mechanisms, we employed LC-MS/MS to investigate various aspects, including the proteome, phosphoproteome, gut metaproteome, metabolome, and SGLT2 interactome. For proteomics/phosphoproteomics analysis, we used TMT16-plex labeling or label-free approaches with an Exploris 480 mass spectrometer (Thermo Fisher Scientific) connected to an UltiMate3000 RSLC (Thermo Fisher Scientific) system. For untargeted metabolomics, we utilized a quadrupole time-of-flight Impact II instrument (Bruker) connected to either a Bruker Elute HPLC or an Agilent 1290 infinity HPLC device. Targeted metabolomics was conducted using a 6495C triple-quadrupole coupled to an Agilent 1290 Infinity HPLC.

Results: We performed an extensive analysis of the proteome, phosphoproteome, and metabolome following one week of SGLT2 inhibitor treatment in non-diabetic and early diabetic mice. We integrated data from multiple metabolic organs and body fluids, including the kidney, liver, heart, white adipose tissue, skeletal muscle, plasma, urine, and gut microbiota. The kidney exhibited the strongest and most significant response to SGLT2 inhibitors in terms of metabolic signaling and transporter reconfiguration. Additionally, the gut microbiome displayed a reduction in bacteria taxa capable of fermenting phenylalanine and tryptophan, resulting in lower plasma levels of uremic toxins. Among the most prominently affected metabolites was p-cresol sulfate, a finding confirmed in cohort studies involving diabetic and heart failure patients with reduced ejection fraction.

Conclusions: The metabolic communication facilitated by SGLT2 inhibitors reduced the presence of circulating waste products such as p-cresol sulfate, consequently reducing the need for renal detoxification. This, combined with decreased glucotoxicity in the proximal tubules and a broad downregulation of apical transport activity, provides a metabolic explanation for the kidney and cardiovascular protection observed.

FR-PO354

Canagliflozin Greatly Improves Mitochondrial Stress Response in Proximal Tubular Cells (PTCs) of Mice with Combined Hypertension and Type 1 Diabetes

Mayra Trentin Sonoda,[1,2] Veronique Cheff,[2] Yan Burelle,[2] Richard L. Hebert.[2] *[1]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada.*

Background: Canagliflozin (CANA) is a sodium-glucose cotransporter 2 (SGLT2) inhibitor with blood glucose lowering effects. CANA promotes kidney protection in patients with type 2 diabetes (T2D), as well as cardiovascular complications. Both diabetes and hypertension induce mitochondrial dysfunction and oxidative stress. However, it is still unclear whether CANA modulates mitochondrial function in diabetic kidney diseases.

Methods: *In vivo:* Male and female 8 weeks old genetic hypertensive mice (Lin) were subjected to daily intraperitoneal injections of streptozotocin (STZ) for 5 days. 4 weeks after the STZ injections, mice were fed either regular or CANA-infused diet for 1 week. Urinary albumin levels were determined by ELISA and urinary creatinine by colorimetric assay. Proximal tubular epithelial cells (PTCs) isolated from experimental mice were subjected to Seahorse MitoStress test. Kidney OXPHOS complexes were analyzed by Western blotting. *In vitro*: PTCs were isolated from Fvb mice, treated with 100nM Ang II + 30mM glucose for 24h, followed by treatment with 10uM CANA or vehicle for 24h.

Results: Male and females LinSTZ mice had elevated albumin to creatinine ratio (ACR), while CANA reverted the ACR increase in males (23,578 ± 7,937 vs 3,014 ± 492.5, n=4, $P<0.05$) and females (6,758 ± 906.8 vs 623.4 ± 103.8, n=3, $P<0.01$). Overall, PTCs from LinSTZ + CANA greatly improved oxygen consumption rate (OCR) throughout the mitochondrial stress test ($P<0.0001$), with significant increase in OCR after inhibition of complexes I, II, and V in males (n=4, $P<0.05$) and females (n=3, $P<0.05$). A trend to decrease protein levels of OXPHOS complexes were also observed in the kidney of LinSTZ + CANA mice (n=2-3, $P>0.08$). *In vitro*, CANA overall effect on OCR was more pronounced in males, whereas in females there was a higher response to the disruption of mitochondrial oxidative phosphorylation by FCCP ($P<0.001$).

Conclusions: Canagliflozin promoted kidney protection, shown by improvement of albuminuria in hypertensive-diabetic mice. Moreover, we show evidence of improved mitochondria function induced by CANA *in vivo* and *in vitro*. Besides the benefits related to restoration of glucose homeostasis, CANA could play a role on proximal tubular mitochondrial function and remodeling.

FR-PO355

Combination of SGLT2 Inhibition and ARB Additively Ameliorate High Glucose-Induced Epithelial-Mesenchymal Transition in HK-2 Cells

Hyo Jeong Kim, Jong Hyun Jhee, Hoon Young Choi, Hyeong cheon Park. *Gangnam Severance Hospital, Seoul, Republic of Korea.*

Background: Both angiotensin receptor blocker (ARB) and sodium-glucose co-transporter 2 (SGLT2) inhibitors have renal protective effects in diabetic kidney disease; however, their synergistic effects when used in combination are not well understood.

Methods: Human kidney-2 (HK-2) cells were divided into five groups: 1) normal glucose (NG, 5.5 mM), 2) high glucose (HG, 25 mM), 3) HG + candesartan (1μM), 4) HG + dapagliflozin (10 μM), and 5) HG + candesartan + dapagliflozin combination treatment groups. The levels of epithelial-mesenchymal transition (EMT) and inflammation markers were evaluated using real time polymerase chain reaction and western blotting. The changes in the high-mobility group box-1 (HMGB1), receptor for advanced glycation end products (RAGE), and nuclear factor kappa B(NF-kB) signaling pathways were compared among the different groups.

Results: Compared to NG, HG increased mRNA expression and proteins levels of factors associated with renal fibrosis and inflammatory response including transforming growth factor-β (TGF-β), α-smooth muscle actin (α-SMA), connective tissue growth factor (CTGF), collagen type I alpha 1 chain (COL1A1), fibronectin, and tumor necrosis factor-α (TNF-α). In addition, HG decreased the expression of E-cadherin. Treatment with candesartan or dapagliflozin effectively ameliorated these changes in mRNA and protein expressions and the effect was the greatest in combination therapy. These findings suggest that combining SGLT2 inhibitor to ARB therapy holds great promise in suppressing the progression of renal fibrosis through the inhibition of EMT. In addition, the HG group exhibited increased expressions of HMGB1, RAGE, and NF-kB, and treatment with either ARB or SGLT2 inhibitor effectively reversed the upregulation of these molecules. However, combination therapy did not significantly improve HMGB1, RAGG, and NF-kB expression compared to monotherapy.

Conclusions: Our results suggest combining SGLT2 inhibitor to ARB is more effective than the monotherapy for preventing EMT in HG stimulated HK-2 cells.

FR-PO356

Empagliflozin Rescues the Loss of Mitochondrial Mass via ERRα in Proximal Tubular Epithelial Cells from db/db Mice

Keju Yang, Hongtu Hu, Guohua Ding, Wei Liang. Division of Nephrology, Renmin Hospital of Wuhan University, Hubei, China. *Renmin Hospital of Wuhan University, Wuhan, China*.

Background: It is known that mitochondrial dysfunction of proximal tubular epithelial cells(PTECs) contributes to the pathogenesis of diabetic nephropathy. However, the ultrastructural changes of PTEC mitochondria in diabetic kidneys remain unclear. Empagliflozin(EMPA) protects the diabetic kidney via SGLT2 located only on PTECs. ERRα is highly expressed in PTECs and associated with mitochondrial biogenesis. The present study aimed to investigate the role of ERRα on mitochondrial mass in diabetic tubular injury and the mechanism of the protective effects of EMPA.

Methods: Transmission electron microscopy (TEM) was used to identify ultrastructural changes in the mitochondria of PTECs from diabetic mice and RNA sequences of isolated renal tubules was performed to identify the DEGs related to mitochondria and ERRα. The expression of ERRα was also evaluated by immunohistochemistry(IHC) and Western blot(Wb). EMPA was then administrated to db/db mice for 12 weeks and the mitochondria was assessed by TEM and the expression of ERRα was evaluated by Wb,RT-qPCR and IHC. Wb was also used to assess the expression of Fis1 and PGC1α. In HK-2 cells, High glucose(HG) or ERRα siRNA or pcDNA-ERRα or EMPA were used to modify the expression of ERRα. The mass and function of mitochondria were evaluated by Mitotracker Red and JC-1 in corresponding culture conditions.

Results: PTECs presented less mitochondrial mass and swelling mitochondria with more mitochondrial cristae fracture in 16-week-old db/db mice. RNA-sequences of isolated renal tubules from db/db mice revealed that 110 downregulated genes were related to mitochondrial function or mitochondrial energy metabolism. ERRα is among the genes with prominent changes. The downregulation of ERRα in diabetic kidney was further evaluated by Wb and IHC. In HG exposed HK-2 cells, the expression of ERRα was decreased and the mitochondrial mass and membrane potential(MMP) were inhibited. ERRα gene silencing decreased mitochondrial mass and MMP while ERRα overexpression or EMPA rescued HG-induced loss of mitochondrial mass in HK-2cells. In vivo, EMPA alleviated ultrastructural changes of PTECs and the downregulation of ERRα from db/db mice.

Conclusions: Decreased ERRα contributes to the loss of mitochondrial mass of PTECs in the early stage of diabetes and is a target of EMPA to prevent the progression of diabetes on kidney injury.

Kidney Disease Progression in Obese ZSF1 Rats Treated with the SGLT2 Inhibitor Empagliflozin

Sandra Hummelgaard,[1] Jeppe Kirchhoff,[3] Henning Hvid,[3] Simon Glerup,[1] Henrik Birn,[2] Kathrin Weyer.[1] *[1]Aarhus Universitet, Aarhus, Denmark; [2]Aarhus Universitetshospital, Aarhus, Denmark; [3]Novo Nordisk A/S, Bagsvaerd, Denmark.*

Background: The obese ZSF1 rat is a model of spontaneous diabetic kidney disease. These rats are bred from a zucker diabetic fatty female and a spontaneous hypertensive heart failure male and carry two mutations in the leptin receptor gene: *Lepr^{fa}Lepr^{cp}/Crl*. The control model for this rat is the lean ZSF1 rat (*Lepr^{fa}/Crl*). In contrast to many other animal models of kidney disease, the obese ZSF1 rat model is a slow progressing kidney disease model. In this study, we evaluated kidney disease progression in obese ZSF1 rats and for the first time investigated renal outcomes upon treatment with the SGLT2 inhibitor empagliflozin.

Methods: Lean and obese ZSF1 rats were fed with Purina #5008 diet. In the first sub-study, lean and obese animals were left untreated and regular plasma and urine samples were collected for 36 weeks. In the second sub study, obese animals were treated with empagliflozin (in feed, estimated intake: 30 mg/kg/day) or vehicle at 14 weeks of age for 15 weeks. Plasma and urine samples were collected bimonthly or monthly, respectively. Glomerular filtration rate (GFR) was measured at baseline and upon 14 weeks of treatment. Plasma and urine samples were analyzed for lipid and kidney injury markers using COBAS analysis as well as various ELISAs. Histological analyses were performed on liver and kidney tissue.

Results: Plasma cholesterol, triglycerides, glucose as well as proteinuria increased with age in obese ZSF1 rats. Urinary excretion of the kidney injury markers KIM-1 and NGAL were also elevated with age, reaching maximum concentration at age 34 weeks. Histological analyses revealed severe glomerular damage at 46 weeks of age compared to lean controls. SGLT2 inhibition with empagliflozin indeed reduced plasma glucose and triglyceride levels whereas urine volume and urinary glucose excretion were elevated.

Conclusions: Obese ZSF1 rats were hyperglycemic and hypercholesterolemic. Proteinuria increased with age in these rats, and severe glomerular damage was observed at 46 weeks of age. Empagliflozin reduced blood glucose and increased urine volume as well as glucose excretion. Future analyses investigating proteinuria, GFR as well as histological characteristics of kidney tissue are ongoing and warranted to evaluate renal outcomes upon empagliflozin treatment in obese ZSF1 animals.

Expression Profiles of Glucose Transporters Along the Nephron in Non-Diabetic and Diabetic Kidneys

Charley Cheng,[1,2] Jin Wei,[2] Jie Zhang.[2] *[1]Massachusetts Institute of Technology, Cambridge, MA; [2]Boston University School of Medicine, Boston, MA.*

Background: In non-diabetic kidneys, over 99% of filtered glucose is reabsorbed in the proximal tubule (PT), resulting in limited delivery to the distal nephron. However, in diabetic kidneys, the excessive filtration of glucose surpasses the reabsorption capacity of the PT, leading to its presence in the distal nephron. This may trigger adaptations in the distal nephron to compensate for glucose reabsorption and minimize its excretion in urine. Despite extensive research, the comprehensive expression profiles of glucose transporters along the nephron remains incompletely understood. Hence, this study aims to identify the specific glucose transporters expressed in each tubule segment and investigate alterations in their expression in diabetes.

Methods: We identified glucose transporters expressed in distinct segments of the nephron and compared their gene expression between db/m and db/db mice by analyzing the snRNA-seq data (GEO: GSE184652). Additionally, we conducted microdissection of individual nephron segments from db/m and db/db mice and measured the gene expression of glucose transporters in these isolated tubular segments using RT-PCR and qPCR. To further validate the protein expression of these glucose transporters, we performed immunofluorescence (IF) staining and Western blot (WB) assays on whole kidneys.

Results: We unveiled the expression profiles of glucose transporters in specific segments of the nephron. Specifically, Slc2a4 (GLUT4) is expressed in thick ascending limb (TAL), distal convoluted tubule (DNT), connecting tubule (CNT), and intercalated cells (IC), and Slc2a1 (GLUT1) is expressed in TAL, macula densa, DCT, CNT, pricipal cells, and IC. Furthermore, our analysis revealed an upregulation of Slc2a4 expression in the TAL (27.96%), DCT (6.10%), CNT (53.95%), and IC (6.03%) and a downregulation of Slc2a1 expression in the DCT (-50.98%), CNT (-49.05%), and IC (-10.36%) in db/db mice compared to db/m mice. Additionally, we confirmed these findings through RT-PCR and qPCR in isolated tubular segments, as well as IF staining and WB assays in whole kidneys.

Conclusions: In this study, we identified glucose transporters expressed along the nephron and compared their expression levels in db/m and db/db mice. Notably, the glucose transporter GLUT4 in the distal nephron segments appears to play a significant role in compensating for glucose reabsorption in diabetes.

Direct Effects of SGLT2 Inhibitors on Proximal Tubule Function

Wafaa N. Albalawy,[1,2] Elynna B. Youm,[1,2] Katherine E. Shipman,[2] Kimberly R. Long,[2] Youssef Rbaibi,[2] Catherine J. Baty,[2] Stephanie Mutchler,[2] Ossama B. Kashlan,[2] Ora A. Weisz.[2] *[1]University of Pittsburgh Graduate School of Public Health, Pittsburgh, PA; [2]University of Pittsburgh Department of Medicine, Pittsburgh, PA.*

Background: Sodium glucose transporter 2 inhibitors (SGLT2i) have been shown to have cardiorenal protection in patients with and without T2DM. Inhibition of proximal tubule (PT) sodium/hydrogen exchanger type 3 (NHE3), which is known to regulate endocytosis and fluid transport in the PT, has been suggested to contribute to the SGLT2i renoprotective benefits. Also, some SGLT2i have been demonstrated to activate AMPK. However, the underlying mechanisms behind the beneficial effects of SGLT2i are unknown. To circumvent the challenges of untangling the direct effects of SGLT2i on PT function in vivo, we examined the effects of gliflozins in a well-characterized and highly differentiated opossum kidney (OK) cell culture model of the PT S1 segment.

Methods: The effect of gliflozins vs NHE3 inhibitor S3226 on albumin uptake and fluid transport was quantified in OK cells. Endosomal pH was measured by fluorescence ratio imaging in OK cells treated with cana vs S3226. Effects of gliflozins, S3226, and AMPK pathway perturbants were determined by immunoblotting. 10-week-old male C57BL/6 mice were given cana or empa by oral gavage daily following vehicle gavage. Urine was collected via metabolic cages at baseline and after 24h and 48h. Creatinine and albumin were measured by ELISA.

Results: A subset of SGLT2i (cana and tofo, but not empa) impaired endocytosis and fluid transport in a dose-dependent and glucose-independent manner. Surprisingly, SGLT2i did not recapitulate the effect of S3226 on NHE3 phosphorylation or endosomal pH. Treatment with cana but not empa caused a rapid increase in AMPK phosphorylation and a reduction in phospho-S6 ribosomal protein (pS6), a downstream target of mTOR. These effects were observed at concentrations comparable to plasma levels in humans on standard doses of cana. In our mouse study, both treatment conditions led to increased urine volume compared to baseline, cana treated mice urinated significantly more than emp treated mice.

Conclusions: Differential effects of SGLT2i on fluid transport and albumin uptake in OK cell monolayers may be mediated by off-target effects on AMPK/mTOR activity. These off-target effects could contribute to the differences we observed in mice treated for short periods with cana vs empa, and could impact the renal protective mechanisms of SGLT2i in humans.

FR-PO360

A Human Single-Cell Transcriptomic Atlas Characterizes the Kidney in Diabetic Kidney Disease

Zhimei Lv, Jinxiu Hu, Rong Wang. *Shandong Provincial Hospital, Jinan, China.*

Background: Diabetic kidney disease (DKD), a common and devastating microvascular complication of diabetes, is the leading cause of end-stage renal disease (ESRD). However, the mechanisms of kidney injury in DKD are largely unknown.

Methods: To elucidate the heterogeneity and the underlying mechanisms for DKD progression, we performed single-cell RNA sequencing (scRNA-seq) on human kidneys collected from 3 DKD and 3 normal samples using 10× Genomics.

Results: A total of 51315 cells were enrolled for analyses, and nine kidney cell types and seven immune cell types were identified. The cell-type-specific changes in gene expression and signaling pathways of podocytes, fibroblasts, endothelial cells, proximal tubules and macrophages indicate abnormal regulation associated with inflammation, apoptosis, oxidative stress, extracellular matrix accumulation, fibrosis and immune activation. In particular, we show that podocytes and proximal tubules have a tremendous capacity to regenerate, which is involved in the repair of injury. Extracellular vesicles, important mediators of intercellular communication, might play vital roles in this process. In addition, we identified new candidate transcription factors responsible for the progression of DKD. We also revealed an M1-M2 hybrid pattern, in which M1 and M2 are coupled for activation in macrophages in DKD. Furthermore, we observed an increased intercellular interaction among podocytes, fibroblasts, endothelial cells, proximal tubules, and macrophages in DKD.

Conclusions: Our study advances the understanding of DKD pathogenesis and provides novel therapeutic targets for its treatment in the future.

Integrative Transcriptome and Proteome Profiling of Insulin-Resistant Kidney Cell Models and Patient Biopsies Reveals Common and Cell Type-Specific Mechanisms Underpinning Diabetic Kidney Disease

Richard Coward,[1] Abigail C. Lay,[1,2] Van Du T. Tran,[3] Viji Nair,[4] Virginie M. Betin,[1] Frédéric Burdet,[3] Florence Mehl,[3] Dmytro Kryvokhyzha,[5] Abrar Ahmad,[5] Philip A. Lewis,[1] Marieangela C. Wilson,[1] Rajasree Menon,[4] Edgar A. Otto,[4] Kate J. Heesom,[1] Helen C. Looker,[6] Robert G. Nelson,[6] Wenjun Ju,[4] Matthias Kretzler,[4] Simon C. Satchell,[1] Maria F. Gomez.[5] *[1]University of Bristol, Bristol, United Kingdom; [2]The University of Manchester Faculty of Biology Medicine and Health, Manchester, United Kingdom; [3]Swiss Institute of Bioinformatics, Lausanne, Switzerland; [4]University of Michigan Michigan Medicine, Ann Arbor, MI; [5]Lunds Universitet, Lund, Sweden; [6]National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ.*

Background: Diabetic kidney disease (DKD) is the leading cause of end stage kidney failure worldwide. It is now clear that cellular insulin resistance is a major driver of this disease.

Methods: Using established human conditionally immortalised podocytes (Pods), glomerular endothelial cells (GECs), mesangial cells (MCs), and proximal tubular cells (PTCs), we modelled both insulin sensitivity and insulin resistance and performed simultaneous transcriptomics and proteomics for integrated analysis. Our data was further compared with bulk- and single-cell transcriptomic kidney biopsy data from early- and advanced-stage DKD patient cohorts.

Results: We identified several consistent changes (individual genes, proteins, and molecular pathways) occurring across all insulin-resistant kidney cell types, which were replicated in human early- and/or advanced-stage DKD biopsies. These included the genes *CTSS*, *NRBF2*, *C3*, *CXCL1*, *TFPI2* and *PFKFB3*, and pathways related to the inflammatory response, ER stress and glycoprotein metabolism. We further identified several cell-line-specific molecular changes occurring in response to insulin resistance, which were replicated in single-cell sequencing data from DKD, together with a selective reduction in mitochondrial function in Pods, MCs and PTC, but not GECs.

Conclusions: This study provides a rich data resource to direct future studies in elucidating underlying kidney signalling pathways and potential therapeutic targets in DKD.

FR-PO362

Identification of Novel Noninvasive Biomarkers for Cadmium-Induced Renal Injury Through Transcriptome Profiling and Machine Learning

Xuefang Feng,[1] Xian Jin,[2] Rong Zhou,[1] Lei Jiang,[2] Jianyong Shou.[2] Dept of Nephrology, Yangpu Hospital, School of Medicine, Tongji University. *[1]Tongji University, Shanghai, China; [2]EnnovaBio Pharmaceuticals, Shanghai, China.*

Background: Kidney is the major toxic organ for cadmium. Once entering the body, cadmium accumulates in proximal tubule cells, resulting in the death of renal epithelial cells through necrotic or apoptotic mechanisms. Of particular interest, cadmium is closely associated with diabetes and the diabetic population is more sensitive to cadmium induced cell damage. The molecular mechanisms underlying the chronic cadmium induced toxicity and the increased susceptibly under diabetic conditions are not fully understood.

Methods: In the present study, we optimized an animal model to study chronic cadmium exposure-induced renal injury by using low dose and repetitive CdCl2 treatment. In conjunction with clinical biochemistry and histopathology, we performed whole transcriptome profiling analyses on kidney. Machine learning with cloud computing was applied to identify novel biomarkers indicative of increased susceptibility in diabetic populations with particular focus on secreted molecules.

Results: Repetitive CdCl2 exposure resulted in cadmium accumulation and remarkable renal injuries with the *ob/ob* mice manifesting increased severity of renal injury. RNA-Seq data showed that cadmium treatment induced dramatic gene expression changes correlated with the level of cadmium-induced nephrotoxicity. In order to better understand the increases susceptibility under diabetic conditions, we focused our analyses on the low dose *ob/ob* group. Canonical pathway enrichment analysis revealed key pathways such as Integrin, AP1, IL23, FRA, P53 and TAP63 pathways. Furthermore, a subset of 14 secreted molecules was found to be enriched including Il12b, Ccl2, Il1rn, Gdf15 and Il17f.

Conclusions: A subset of potential sensitive biomarkers which can be measured in peripheral for early diagnosis of cadmium-induced renal injury has been identified. Applicability of these biomarkers in clinical will be tested in human samples.

Cytochrome P450: The Metabolic Pathways and the Genetic/ Epigenetic Regulation Involved in Shaping the Story of Diabetic Kidney Disease (DKD).

Batoul Dia,[1] Elias Shamieh,[1] Sami Azar,[2] Assaad Antoine Eid.[1] *[1]American University of Beirut, Beirut, Lebanon; [2]American University of Beirut Medical Center, Beirut, Lebanon.*

Background: Cytochrome P450 (CYPs) epoxygenases metabolize arachidonic acid (AA) into 20-HETE and EETs. Our group has described the implication of CYPs and their metabolites in the pathogenesis of DKD, in experimental animal model of diabetes. Yet the correlation of these finding in human setting is under investigation. More importantly, CYPs-encoding genes possess polymorphisms that can alter the expression of these key enzymes, affecting the prognosis of patients with DKD. Herein, we hypothesize that alteration in 20-HETE and EETs levels in diabetes leads to kidney injury, and that genetic variants/epigenetic regulation of AA-metabolizing CYPs may potentiate the development of DKD.

Methods: Healthy volunteers, individuals diagnosed with type 2 diabetes (T2DM) with or without clinical manifestation of DKD were enrolled in this study. Levels of 20-HETE and EETs were assessed in the urine and plasma samples of the recruited individuals and correlated with the extent of renal injury. To detect single nucleotide polymorphisms (SNPs) in CYP4A11, CYP4F8 and CYP2B6, TaqMan PCR assay was performed on the DNA extracted from the collected blood samples.

Results: Circulating levels of 20-HETE were increased in patients with DKD when compared to T2DM patients with no clinical signs of DKD, which in turn had higher levels of 20-HETE in comparison to the healthy volunteers. This was associated with an increased expression of CYP4A11 and CYP4F8 in the human kidney biopsies of patients with DKD. In parallel, EETs levels were decreased in patients with T2DM and DKD as compared to patients with T2DM only and this was positively correlated with the decreased CYP2B6 expression in kidney biopsies of patients with DKD. Furthermore, a difference in 2 SNPs for CYP2B6 and 1SNP for CYP4A11 was observed across patients with different conditions, suggesting an increased risk with the mutant allele for diabetes and DKD.

Conclusions: This study may yield important findings about novel regulatory pathways involved in diabetes-induced renal injury and may identify novel prognostic/diagnostic biomarkers associated to CYPs pathways in DKD.

FR-PO364

Deciphering Renal Restoration: Single-Cell Transcriptional Insights from Pre- and Post-Vertical Sleeve Gastrectomy Kidney Biopsies

Abhijit S. Naik,[1] Fadhl Alakwaa,[1] Jennifer A. Schaub,[1] Phillip J. McCown,[1] Edgar A. Otto,[1] Patricia E. Ladd,[2] Tim Vigers,[2] Laura Pyle,[2] Ye Ji Choi,[2] Justin R. Ryder,[5] Frank C. Brosius,[3] Robert G. Nelson,[4] Kristen Nadeau,[2] Matthias Kretzler,[1] Petter Bjornstad.[2] *[1]University of Michigan, Ann Arbor, MI; [2]University of Colorado Anschutz Medical Campus, Aurora, CO; [3]Banner University Medical Center Tucson, Tucson, AZ; [4]National Institutes of Health, Bethesda, MD; [5]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL.*

Background: Vertical sleeve gastrectomy (VSG) attenuates the metabolic dysfunction characteristic of obesity and type 2 diabetes. The molecular mechanisms diminishing risk of kidney disease by VSG remain unclear.

Methods: Cell-type-specific differentially expressed genes (DEGs) before and 12 months after VSG (n=5 pairs) were determined from single-cell RNA sequencing (scRNAseq) of kidney biopsies. Top up-and downregulated pathways associated with VSG based on pathway enrichment of DEGs were compared with similarly curated Sodium-Glucose Cotransporter-2 inhibitor (SGLT2i) effects (https://doi.org/10.1172/JCI164486) to identify shared and unique pathways in cell types experiencing significant transcriptional changes.

Results: VSG improved UACR for all, and 75% with initial high albuminuria saw a category stepdown. Glomerular and mesangial volume decreased in the subset with kidney biopsy data. Proximal tubular cells had the most genes suppressed, while thick ascending limb cells the most enhanced, after VSG based on scRNAseq. Metabolic pathways like glycolysis, the TCA cycle, and gluconeogenesis were downregulated, while others like RTK signaling and axon guidance were upregulated across the nephron. Noteworthy transcriptional variations were seen between SGLT2i treatment and VSG (Figure).

Conclusions: scRNAseq provided insights into cell-specific effects of VSG on kidneys. Despite commonalities, VSG and SGLT2i modified distinct cell-specific signaling pathways, offering potential avenues for innovative therapeutic interventions.

FR-PO365

GDF-15 and NETosis Cross-Talk in Diabetes-Induced Renal and Cardiovascular Complications: Unraveling the Molecular Interactions

Amani W. Slika, Elio Salameh, Joseph Abourjeili, Ghiwa Sfeir, Assaad Antoine Eid. *American University of Beirut, Beirut, Lebanon.*

Background: Diabetic kidney disease (DKD) and diabetic cardiomyopathy (DCM) are severe complications of diabetes, posing significant risks of renal failure and cardiovascular events. One potential biomarker with promising implications in this context is growth differentiation factor 15 (GDF-15), a cytokine belonging to the transforming growth factor-β (TGF-β) family. Elevated levels of GDF-15 are observed in the presence of tissue injury, inflammation, and stress. Moreover, our research group has focused on exploring the relationship between neutrophil extracellular trap formation (NETosis) and the progression of injury in DKD and DCM. This article aims to elucidate the role and interplay between GDF-15 and NETosis in the development of renal and cardiac injury induced by type 2 diabetes.

Methods: T2DM was induced in C57BL/6J male black mice using the high fat diet/STZ model in two sets of experiments. In the first set, mice were divided into control, PMA-induced NETosis, T2D, and T2D treated with CLA (NETosis inhibitor) groups. In the second set, control mice, GDF-15 antibody AV-380-treated control mice (at 7.5mg/kg or 20mg/kg), T2D mice, and AV-380-treated T2D mice (at 7.5mg/kg or 20mg/kg) were utilized. Functional, histopathological, and molecular studies were performed on kidney and heart tissues from all groups.

Results: Our data demonstrate that inhibiting GDF-15 with AV-380 or NETosis with CLA can restore renal and cardiac homeostasis in T2D mice. This is evident through reduced proteinuria, glomerulosclerosis, collagen deposition in the kidneys and heart, as well as improved cardiac ejection fraction and decreased inflammatory markers in the treated diabetic mice. Importantly, NETosis inhibition attenuated the diabetes-induced overexpression of GDF-15 in kidney and heart tissues, suggesting a crosstalk between these 2 signaling molecules. Intriguingly, inducing NETosis in control mice using PMA resulted in similar renal and heart injuries observed in diabetes.

Conclusions: Our study findings provide valuable insights into the role and interplay between GDF-15 and NETosis in diabetes-related cardiac and kidney injury. Targeting the GDF-15/NETosis signaling cascade through pharmacological interventions offers a basis for future clinical studies that aim to manage diabetes-associated complications.

FR-PO366

Stress Response Protein REDD1 Sustains the Chronic Inflammatory Response in Diabetic Nephropathy

Siddharth Sunilkumar, Michael D. Dennis. *Penn State College of Medicine, Hershey, PA.*

Background: Diabetic nephropathy (DN) is one of the most common and severe complications of diabetes. We recently demonstrated a role for the stress response protein REDD1 in development of renal complications in DN. However, there remains a significant gap in our understanding of the molecular events whereby REDD1 contributes to the development of renal dysfunction. Herein, we investigated the hypothesis that diabetes-induced REDD1 expression acts to exacerbate pro-inflammatory NF-κB signaling and consequently development of renal inflammation.

Methods: REDD1$^{+/+}$ and REDD1$^{-/-}$ mice were administered low dose streptozotocin to induce diabetes. Kidneys were isolated after 16 weeks of diabetes, weighed, and analyzed for protein and mRNA expression. Spot urine albumin and creatinine levels were assayed. Kidneys were fixed and renal sections were visualized by immunofluorescence microscopy. Complementary analyses were performed with conditionally immortalized human podocyte cultures exposed to hyperglycemic conditions. Inhibition of SLGT2 or GSK3 was achieved by dapagliflozin or VP3.15 administration, respectively. Nuclear NF-κB activity was estimated by luciferase assay.

Results: Diabetes increased REDD1 expression in the kidney and promoted albuminuria and renal immune cell infiltration. In diabetic mice treated with dapagliflozin, blood glucose concentrations were reduced and both REDD1 expression and immune cell infiltration were attenuated. In contrast with REDD1$^{+/+}$ mice, REDD1$^{-/-}$ mice did not exhibit an increase in pro-inflammatory marker expression or renal macrophage infiltration with diabetes. In cultured human podocytes, exposure to hyperglycemic conditions promoted REDD1 expression, which was required for activation of both NF-κB and the NLRP3 inflammasome. Upregulated expression of NF-κB target genes and IL1β production by podocytes exposed to hyperglycemic conditions was prevented by REDD1 deletion. REDD1 acted via an Akt-GSK3β signaling axis, as GSK3β inhibition prevented diabetes-induced NF-κB activation and reduced immune cell infiltration in kidneys of diabetic mice.

Conclusions: These findings demonstrate a role for REDD1-dependent GSK3 signaling in diabetes-induced renal pathology and support the possibility that therapeutics targeting REDD1 or GSK3 could be beneficial in the context of DN.

FR-PO367

SerpinA3K Deficiency Ameliorates Diabetic Kidney Disease (DKD)

Isaac González Soria,[1,2] Axel D. Soto Valadez,[1,2] Miguel A. Martinez-Rojas,[1,2] Esmeralda Palacios-Brito,[1] Rosalba Pérez-Villalva,[1,2] Andrea Diaz-Villaseñor,[1] Norma Bobadilla.[1,2] *[1]Universidad Nacional Autonoma de Mexico, Ciudad de México, Mexico; [2]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de México, Mexico.*

Background: We showed that SerpinA3K is an early urinary biomarker of Acute Kidney Injury (AKI) to Chronic Kidney Disease (CKD) transition. SerpinA3K or anti-chymotrypsin is a serine protease inhibitor with non-canonical functions such as: antioxidant, anti-inflammatory, and anti-fibrotic in rodent diabetic retinopathy. Nevertheless, we recently showed that AKI is attenuated in SerpinA3K deficient mice by inducing higher expression of antioxidant defense, however, its involvement in CKD remains elusive. This study was designed to evaluate the impact of SerpinA3K absence in DKD.

Methods: Thirty wildtype (WT) [*SerpinA3K*+/+] and thirty knock-out (KO) [*SerpinA3K*-/-] male mice after breastfeeding were randomized in the following six groups: Standard Diet (WT+SD and KO+SD), High Fat Diet (WT+HFD and HFD+KO), and Streptozotocin (STZ) [100 mg/kg] + HFD (WT+DKD and KO+DKD). Glucose monitoring was done every 15 days. A cut-off point was established above 500 mg/dL to receive insulin 2 days per week to increase animal survival. Urine collection was done monthly. After 7 months of follow-up, each group was euthanized for kidney functional, histological, and molecular analyses. Differences between groups were analyzed through ANOVA and post-hoc testing with a significance level of $p<0.05$.

Results: HFD feeding induced obesity, hypercholesterolemia, hyperleptinemia, and hyperinsulinemia, without any differences between genotypes, but increased serum IL6 in the WT+HFD was not evident in the KO+HFD group. In addition, the WT+DKD group exhibited hyperglycemia above 500 mg/dL, since, 15 days after STZ requiring insulin, and exhibited insulin resistance (HOMA-IR). Interestingly, these effects were not seen in the KO+DKD group, in which, glycemia was below 400 mg/dL and non-insulin requirement. GFR measured by fluorescein sinistrin was significantly increased in the WT+DKD but not in the KO+DKD group. Furthermore, the WT+DKD group exhibited an increase in *Hif1a, Il6, and Tgfb1* which was not seen in the KO+DKD.

Conclusions: The absence of SerpinA3K was associated with DKD attenuation. This protective effect seems to be mediated by improving metabolic health against hyperglycemia. Nevertheless, the mechanisms and causes of this protection required further studies to deep into the role of SerpinA3K in DKD induced by STZ.

FR-PO368

Specialised Proresolving Mediators Protect the Diabetic Kidney Against Podocyte Loss

Phillip Kantharidis,[1] Madhura Bose,[1] Muthukumar Mohan,[1] Chris Tikellis,[1] Eoin Brennan,[2] Catherine Godson,[2] Mark E. Cooper.[1] Diabetes Dept. *[1]Monash University Faculty of Medicine Nursing and Health Sciences, Clayton, VIC, Australia; [2]UCD Diabetes Complications Research Centre, School of Medicine & Conway Institute University College, Dublin, Ireland.*

Background: Kidney macrophages are a heterogeneous population of cells that contribute to the chronic unresolved inflammation that underlies diabetic kidney disease (DKD). The macrophage subpopulations initiating and promoting inflammation in DKD, particularly in the glomerulus, have not been characterized. There has also been growing interest in specialised pro-resolving mediators (SPMs) such as Lipoxin A4 (LXA_4) as potential reno-protective agents. The focus of this study was to investigate the effect of LXA_4 on kidney macrophages in a model of DKD.

Methods: Six-week-old male ApoE KO mice were rendered diabetic by five daily IP injections of streptozotocin (55mg/kg). Controls received citrate buffer alone. After 10wks of diabetes, mice were randomly selected to receive twice weekly administration of either vehicle (0.02% ethanol) or LXA_4 (5µg/kg) via IP (n=30/gp) for a further 6 weeks. At endpoint, mice were culled, and kidneys collected for gene expression analysis, single cell RNA sequencing (scRNA-Seq) of glomerular cells, immunohistochemistry and histology.

Results: Diabetic mice had elevated blood glucose, glycated haemoglobin and albuminuria, as well as increased expression of fibrotic (fibronectin, Col 4a3), inflammatory markers (IL1β, TNFα, MCP1, VCAM-1, ICAM-1) compared to control. Interestingly, LXA4 resulted in reduced albuminuria, Collagen IV, inflammatory and fibrotic markers (IL1β, MCP1, ICAM1 and VCAM1) independent of any changes in metabolic parameters. scRNA-Seq of the glomerular cell populations demonstrated an increase in macrophages in kidneys of diabetic mice. These changes were associated with renal injury, including the increased expression of apoptotic markers and depletion of podocytes (reduced by 42% in diabetic versus control). LXA_4 reduced macrophage numbers and prevented podocyte loss in the diabetic kidney.

Conclusions: SPMs protect against DKD by reducing fibrotic and inflammatory signalling, as well as reducing monocyte recruitment and increased macrophage numbers in the diabetic kidney. These effects are accompanied with improved kidney function. These data further support the use of SPMs as typified by LXA_4 as a novel treatment for DKD by targeting macrophages in the kidney.

Mitochondrial Dysfunction-Related Glycogen Synthase Kinase 3β (GSK3β) Overexpression Drives Early Diabetic Tubulopathy

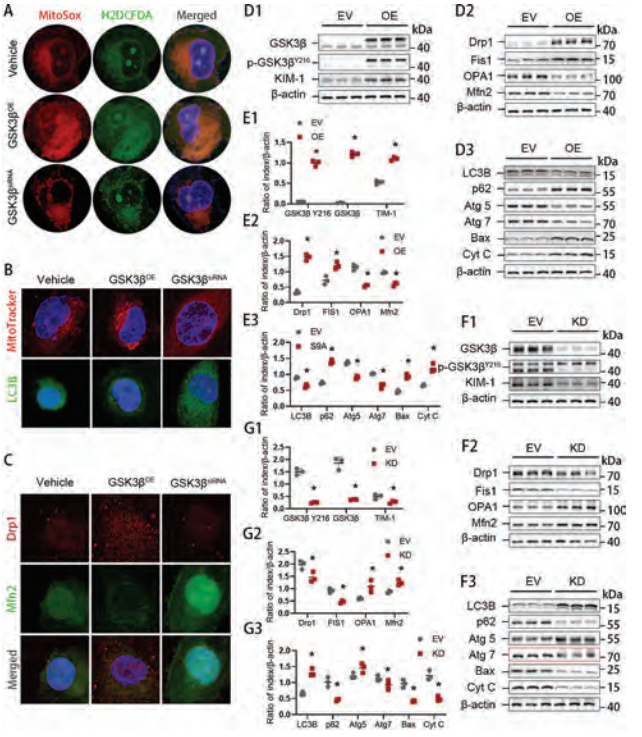
Pei Wang. *The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China.*

Background: Over these years, the traditional "glomerulocentric" paradigm of DKD has partly shifted to diabetic tubulopathy (DT) because of renal insufficiency and prognosis of patients is closely related to tubular atrophy and interstitial fibrosis. New insights indicate that mitochondria dysfunction represent an early event in DT, but the precise mechanism for such pathological process is not clear.

Methods: The present study was designed by using high-fat diet (HFD)-fed combine with STZ mice as an insulin resistance model of tubular injury in T_2DM. We also reported the expression of GSK3β in human proximal renal tubular (HK-2) cells.

Results: As a potential novel biomarker for predicting a variety of renal diseases, glycogen synthase kinase 3β (GSK3β) is overexpressed and hyperactive with mitochondrial dysfunction in proximal tubular epithelium, correlating with functional and histological signs of renal tubular injury in diabetes mellitus (DM). Moreover, tubule-specific ablation of GSK3β substantially attenuated mitochondrial damage and early tubular lesions in mice. Multiple regulatory mechanisms of mitochondrial damage, such as mitochondrial biology, mitochondrial dynamics, mitophagy and oxidative stress, are closely related to the hyperactivation of GSK3β. In addition, therapeutic targeting of GSK3β by TDZD-8 ameliorated mitochondrial dysfunction and delayed early stage of DT in mice.

Conclusions: Thus, GSK3β appears to play a key role in early DT by modulating mitochondrial dysfunction and may be an actionable target for intervention to delay DKD in advance.



GSK3β hyperactivity exacerbated HG-induced mitochondrial dysfunction in HK-2 cells

FR-PO370

ERRα Acts as a Bridge of Mitochondria and Sodium Homeostasis in Proximal Tubular Epithelial Cells Under Diabetes

Hongtu Hu, Guohua Ding, Wei Liang. *Wuhan University Renmin Hospital, Wuhan, China.*

Background: The mechanism of sodium homeostasis in diabetic kidney disease (DKD) is unclear. In previous study, we found that the expression of sodium translocation channels (ATP1A1) and the estrogen-related receptor alpha (ERRα) were decreased only in DKD renal biopsy samples. The present study aims to investigate how ERRα involves in the regulation of mitochondrial loss and sodium homeostasis in proximal tubular epithelial cells (PTEC) under diabetes condition.

Methods: ERRα and ATP1A1 proximal tubule-specific overexpression mice ($ERR\alpha^{ptKI}$, $ATP1A1^{ptKI}$) were constructed and fed with high salt (4% NaCl) or normal diet (0.8%) for 4 weeks. Sodium concentration from isolated PTEC was quantified by ionophore ICPMS analysis. The changes of renal injury markers, proximal tubular sodium-related transport channels were evaluated. In vitro study,HK-2 cells were treated with high glucose (30 mM), high salt (40 mM), and high glucose + high salt for 24 h after overexpression of ERRα and ATP1A1 using adenovirus. Sodium concentration in PTEC was observed by cellular sodium fluorescence probe, morphological changes in mitochondria were observed by TEM, and CHIP-seq analysis was carried out to evaluate the transcriptional regulation of ATP1A1 by ERRα.

Results: High salt diet accelerated the pathological injury and mitochondrial damage in PTEC and provoked sodium accumulation compared with normal diet in wild type mice. STZ-treated $ERR\alpha^{ptKI,}$ and $ATP1A1^{ptKI}$ mice with high salt diet had mild pathological injury and mitochondrial damage and less sodium concentration in PTEC when compared with STZ-treated wild-type mice. In vitro study, CHIP-seq showed that ERRα regulates its transcription by binding to the promoter of ATP1A1. Sodium concentration, mitochondrial damage, and markers of kidney injury were significantly higher in HK-2 cells treated with high glucose or high salt, and further increased in the high glucose + high salt. The above changes were alleviated by overexpression of either ERRα or ATP1A1 in HK-2 cells.

Conclusions: ERRα is an exclusive nuclear transcription factor affected by diabetes in PTEC to integrate the mitochondria and sodium homeostasis via ATP1A1, sodium loading may act as a "second strike" to promote pathological injury in PTEC under diabetic condition.

FR-PO371

Promoting Mitochondrial Dynamics by Inhibiting the PINK1/PRKN Pathway to Relieve Diabetic Nephropathy

Junyi Zhu. *University of Maryland Baltimore, Baltimore, MD.*

Background: Diabetes is a metabolic disorder characterized by high blood glucose levels and a leading cause of kidney disease. Dysfunctional mitochondria have been associated with diabetic nephropathy. However, many questions remain about the exact mechanism; its understanding is important to develop effective therapeutics.

Methods: Structure, function, and molecular pathways are highly conserved between mammalian podocytes and *Drosophila* nephrocytes Thus we used flies on a high sucrose diet to model type 2 diabetic nephropathy. We then investigated the structural and functional effects on the fly nephrocytes and their mitochondria.

Results: The nephrocytes of flies on a high sucrose diet showed remarkable levels of functional decline and decreased cell size; the flies had a shortened lifespan. Structurally, the slit diaphragm—nephrocyte filtration structure—was disorganized. At the cellular level, we found altered mitochondrial dynamics and dysfunction. Regulating mitochondrial dynamics by either genetic modification of the Pink1/Park (mammalian PINK1/PRKN) pathway or treatment with BGP-15, mitigated the mitochondrial defects and nephrocyte functional decline.

Conclusions: These findings support a role for Pink1/Park-mediated mitophagy and associated control of mitochondrial dynamics and health in diabetic nephropathy; and demonstrate that targeting this pathway might provide therapeutic benefits in type 2 diabetic nephropathy.

Obesity Augments Urinary Tract Infection Susceptibility by Activating Focal Adhesion Kinase in Kidney Intercalated Cells

Laura Schwartz,[1,2] Kristin Bender,[1] Xin Wang,[1] John D. Spencer.[1,2]
[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University College of Medicine, Columbus, OH.

Background: Obesity affects a third of the global population. Among the comorbidities linked to obesity is increased urinary tract infection (UTI) and pyelonephritis risk. The obesity mediated factors that increase UTI risk are unknown. In this study, we assess the impact of diet-induced obesity on UTI susceptibility using male and female mice. Because recent data show intercalated cells (IC) in the kidney have a key role in protecting against UTI and pyelonephritis, we also assess how diet-induced obesity effects murine IC gene expression and antibacterial defenses.

Methods: C57/BL6 male and female mice were fed a high fat diet (HFD; 60 kcal% fat) or standard diet (SD; 10% kcal fat) for 8-12 weeks. Mice were subjected to experimental UTI and infected with UPEC. UPEC burden was quantified 24 hours after infection. ICs from SD and HFD fed mouse kidneys were enriched using FACS and subjected to RNAseq. Differentially expressed genes were used to generate lists of enriched pathways and ontologies. Western blot confirmed pathway suppression or activation. To test how these pathways impact UTI outcomes, ICs were cultured to confluency, treated with target inhibitors, and challenged with UPEC.

Results: Male and female mice fed a HFD showed a 30% increase in body weight, reduced insulin sensitivity measured by glucose tolerance testing, and 10-100-fold greater UPEC burden following UTI. Changes in gene expression in ICs from HFD and SD mice diverged depending on sex. Activation of focal adhesion kinase (FAK) was consistent between sexes when comparing HFD and SD ICs. Western blot confirmed increased FAK signaling in HFD kidneys, as well as increased NFkB, a downstream FAK target. When cultured ICs were treated with the FAK inhibitor PF-573228 and challenged with UPEC, bacterial invasion was abolished.

Conclusions: These results suggest that diet-induced obesity leads to increased UTI susceptibility by activating FAK signaling in ICs. Future studies will investigate the factors regulating FAK as targets for reducing UTI risk.

Overexpression of Adiponectin, via an Adipocyte Specific Promoter, Confers Metabolic Benefits and Transient Improvements in Urine Albumin-Creatinine Ratio (UACR)

Asha Seth,[1] Mathias Liljeblad,[2] Timo N. Haschler,[1] Pernilla Tonelius,[2] Su Mi Choi,[3] Elena Liarte Marin,[3] Philip M. Bousfield,[3] James H. Kurasawa,[3] Esther Nuñez Duran,[2] Jayati Basak,[1] Alessandro Boianelli,[2] Per Svenningsen,[4] Pernille B. Laerkegaard Hansen,[2] Julie Williams,[2] Yasuhiro Ikeda.[2]
[1]AstraZeneca PLC, Cambridge, United Kingdom; [2]AstraZeneca, Gothenburg, Sweden; [3]AstraZeneca, Gaithersburg, MD; [4]Syddansk Universitet Det Sundhedsvidenskabelige Fakultet, Odense, Denmark.

Background: Adiponectin is an endocrine factor synthesized and released from adipose tissue. Clinical and pre-clinical data have linked low adiponectin levels with the acceleration of kidney disease. However, adiponectin's complex structure and multiple molecular forms have stunted therapeutic approaches to augment adiponectin signalling. We hypothesized that in-vivo overexpression of adiponectin using adipocyte specific AAV vectors would lead to extended increased systemic exposure of functional adiponectin forms.

Methods: We engineered an adipocyte-specific promoter and achieved AAV8 uptake and overexpression of adiponectin in vivo with exposure for up to 12 weeks in plasma. We evaluated the effects of adiponectin overexpression on metabolism and kidney function in the BTBR ob/ob mouse model of dyslipidaemia and diabetic kidney disease.

Results: In human glomerular endothelial cells and iPS differentiated podocytes, protective effects of adiponectin signalling were observed in in vitro disease models. Mice treated with AAV-adiponectin displayed a decrease in body weight change from the first week after treatment up to 9 weeks in BTBR ob/ob mice. In addition, adiponectin overexpression also decreased the urinary albumin to creatinine ratio 3 weeks after treatment; however, this effect was lost at later time points. At termination, AAV-adiponectin-treated obese animals had significantly decreased plasma cholesterol, liver triglyceride levels, and a decreased liver weight as a proportion of body weight. The effect of AAV-adiponectin overexpression on body weight gain was reproduced in a second study in which WT mice were treated with HFD for 10 weeks.

Conclusions: Adiponectin overexpression can reduce body weight gain and improve metabolic parameters in the liver. Overexpression of adiponectin can transiently decrease kidney damage, as assessed by UACR, but further work is required to determine how to maintain the kidney protective effects of adiponectin.

Insulin and Glucose Tolerance Assessment in Guanylyl Cyclase/ Natriuretic Peptide Receptor-A Gene-Targeted Mutant Mice

Kandasamy Neelamegam, Kailash N. Pandey. *Tulane University School of Medicine, New Orleans, LA.*

Background: Atrial natriuretic peptide (ANP), acting through the guanylyl cyclase/ natriuretic peptide receptor-A (GC-A/NPRA), is pivotal in regulating blood pressure and cardiac homeostasis. Ablation of *Npr1* (encoding NPRA) in mice exhibits hypertension and provokes congestive heart failure; however, the underlying mechanisms are not yet precisely determined. The objective of this study was to investigate whether *Npr1* plays a critical role in regulating glucose homeostasis.

Methods: The adult male (14-18 wk) *Npr1* gene-knockout haplotype (*Npr*1+/-, 1-copy), wild-type (*Npr1*+/+, 2-copy), and gene-duplicated (*Npr1*+ +/+ +, 4-copy) mice were fasted overnight (16 h) and given free access to water. The mice were administrated with glucose both orally and intraperitoneally (2 g/kg body weight) to determine the oral glucose tolerance test (OGTT) and intraperitoneal glucose tolerance test (IPGTT). For the insulin tolerance test (ITT), mice were also fasted for 16 h and then received an ip-injection of 1.0 UI/kg of insulin. Blood glucose levels were determined by performing tail bleeds at 0, 15, 30, 60, 90, and 120 min using AlphaTRAK. The non-invasive tail-cuff method determined systolic blood pressure (SBP).

Results: The results showed that administration of glucose resulted in a greater increase in blood glucose levels at 120 mins in 1-copy male mice (OGTT: 237 ± 5 mg/dL, IPGT: 246 ± 6 mg/dL, ITT; 239 ± 7 mg/dL) than 2-copy male (OGTT: 131 ± 3 mg/dL, IPGT: 126 ± 6 mg/dL, ITT; 127 ± 6 mg/dL), respectively. The blood glucose was also significantly lower in 4-copy mice (OGTT: 113 ± 5 mg/dL, IPGT: 108 ± 7 mg/dL, ITT; 107 ± 3 mg/dL) than in 2-copy mice. SBP was significantly greater in 1-copy mice (130 ± 4 mmHg) than in 2-copy mice (100 ± 3 mmHg) and significantly lower in 4-copy mice (90 ± 2) in 2-copy mice. The increase in plasma glucose levels were significantly lower in OGTT than in IPGTT.

Conclusions: NPRA markedly prevented a steep rise in blood glucose levels after glucose challenge and ameliorated glucose intolerance and insulin resistance in 2-copy and 4-copy mice than 1-copy mice. The results suggest that NPRA signaling predisposes to arterial pressure, hyperglycemia, and insulin resistance, thus *Npr1* gene might regulate blood glucose homeostasis. Supported by NIH grant DK133833.

Inhibition of Endogenous Adenine Synthesis Ameliorates Kidney Injury in db/db Mice with Type 2 Diabetes

Hak Joo Lee,[1,2] Guanshi Zhang,[1] Richard Montellano,[1] Leila Hejazi,[1] Shane Matta,[1] Jingli Gao,[1] Soumya Maity,[1] Goutam Ghosh-Choudhury,[1,2] Balakuntalam S. Kasinath,[1] Kumar Sharma.[1,2] Center for Precision Medicine.
[1]University of Texas Health San Antonio, San Antonio, TX; [2]Audie L Murphy Memorial Veterans' Hospital, San Antonio, TX.

Background: Elevation of kidney and urine adenine is associated with chronic kidney disease (CKD) including diabetes. Although adenine administration induces CKD in animal models, the effect of endogenous adenine on diabetic kidney disease (DKD) has not been studied. We hypothesize that inhibition of adenine synthesis ameliorates DKD by inhibiting mTORC in mice with type 2 diabetes.

Methods: C57BL6 WT male mice received adenine containing water or control water for 4 weeks. db/db male mice with type 2 diabetes received methylthioadenosine phosphorylase (MTAP) inhibitor or vehicle by drinking water for 8 weeks. Kidney metabolites were measured by ZipChip mass spectrometry. Mouse proximal tubule (MCT) cells were employed for *in vitro* experiments.

Results: Adenine increased albuminuria, blood urea nitrogen (BUN), kidney hypertrophy, kidney KIM-1 expression, kidney matrix protein accumulation, and kidney mTORC1 activity in WT mice. Adenine stimulated senescence-associated secretory phenotype along with reduction in *Klotho* expression in the kidney. Rapamycin (a selective inhibitor of mTORC1) inhibited adenine-induced mTORC1 activation and matrix protein accumulation in the MCT cells. MTAP inhibitor decreased kidney adenine content, serum cystatin C, albuminuria, and urine KIM-1 excretion in diabetic db/db mice.

MTAP inhibitor decreased diabetic kidney hypertrophy, KIM-1 expression, fibrosis, and mTORC1 activation in the kidney of db/db mice without changes in BUN, body weight, blood glucose level, and intake of food or water. Klotho expression was increased by MTAP inhibitor in the kidney of db/db mice. MTAP inhibitor did not affect other diabetes-related metabolites.

Conclusions: Our data suggest that elevation of adenine drives DKD which is ameliorated by inhibiting adenine synthesis in the kidney. Therefore, adenine metabolism could be used for a biomarker and therapeutic target of DKD.

Elucidating NOX5 as a Potential Therapeutic Target and a Biomarker of Kidney Disease in Diabetes

Jay C. Jha,[1] Aozhi Dai,[1] Haritha S. Ramanayaka Kankanamalage,[1] Vincent Jaquet,[3] Mark E. Cooper,[1] Karin Jandeleit-Dahm.[1,2] *[1]Monash University Department of Diabetes, Melbourne, VIC, Australia; [2]Deutsches Diabetes-Zentrum Leibniz-Zentrum fur Diabetes-Forschung an der Heinrich-Heine-Universitat Dusseldorf, Dusseldorf, Germany; [3]Universite de Geneve, Geneve, Switzerland.*

Background: Diabetes related chronic kidney disease (CKD) is the leading cause of end stage renal failure. Oxidative stress due to excessive production of reactive oxygen species plays a critical role in diabetic kidney disease (DKD). Pro-oxidant enzyme NADPH oxidase-NOX5 is considered as a major contributor of reactive oxygen species (ROS) mediated kidney damage in diabetes. We aim to identify the renoprotective effect of NOX5 inhibition in the in vitro setting of human derived renal cells and organoids exposed to diabetic milieu. We also aim to validate NOX5 as a biomarker for the early prediction of human DKD.

Methods: We examined the effect of NOX5 silencing or inhibition by NOX5-specific inhibitors on ROS formation along with markers of fibrosis, inflammation and ROS-sensitive factors in human renal cells and iPSC derived renal organoids. We assessed the expression of NOX5 in human kidney biopsies as well as in urine and serum obtained from non-diabetic and diabetic individuals by ELISA and FACS. Correlation between NOX5 level and clinical data sets including albuminuria was performed.

Results: Renal NOX5 expression was increased in diabetic patients in comparision to non-diabetic subjects. Increased expression of NOX5 was associated with upregulation of a transcription factor, EGR-1 and down regulation of an endosulfatase, SULF-1 (an enzyme which maintains the integrity of glomerular filtration barrier) in diabetes. Both genetic silencing of NOX5 in renal cells and pharmacological inhibition of NOX5 in renal cells as well as in renal organoids attenuated high glucose induced upregulation of CTGF, MCP-1, TLR-4 and EGR-1 and restored the expression of SULF-1 via reduction in ROS formation. These novel findings suggest the role for NOX5 in renal fibrosis and inflammation as well as in the regulation of EGR-1 and SULF-1 in diabetes like conditions. Moreover, increased level of NOX5 in human urine and serum was observed in diabetic individuals even in the absence of albuminuria.

Conclusions: These findings suggest that NOX5 plays a key role in human DKD by promoting inflammation and fibrosis, thereby providing the fast track validation of NOX5 specific inhibitors to combat DKD in humans. In addition, NOX5 appears to be a potential biomarker for the early detection of DKD.

FR-PO377

Novel Molecular Therapy of Diabetic Nephropathy by Repurposing Niclosamide to Modulate Renal RNA-Binding Protein HuR

Lili Zhuang, Xiao-Qing E. Tsai, Zhou Wang, Yufeng Huang. *University of Utah Health, Salt Lake City, UT.*

Background: Hu antigen R (HuR) influences the expression of genes involved in pathways critical to the pathogenesis of diabetic nephropathy (DN). We identified a FAD-approved anthelmintic drug, niclosamide (NCS), as a novel inhibitor of HuR. This study sought to determine whether HuR- targeted therapeutics with NCS are therapeutic for DN.

Methods: Four groups of uninephrectomized mice with normal control and diabetic db/db mice without treatment but being terminated at 14 and 22 wks respectively, or treated with NCS (20mg/kg daily via i.p.) from wks 18 to 22 were included.

Results: A significantly increased HuR expression was observed in diabetic kidneys from both patients and db/db mice, while the latter was inhibited by NCS treatment. Immunofluorescent staining for HuR confirmed the Western blot measurement. Untreated db/db mice developed progressive albuminuria and glomerular mesangial matrix expansion between age of weeks 14 and 22, associated with increased renal production of fibronectin and a-smooth muscle actin but decreased glomerular WT-1^{+}-podocytes and nephrin expression. NCS treatment did not affect mouse body weight but reduced blood HbA1c levels (10.8±1.0 in treated db/db vs. 13.4±0.93% in db/db, P<0.05), arrested the increases in albuminuria, markers of glomerulosclerosis and podocyte injury seen in db/db mice. Renal expressions of NF-κBp65, TNF-a, MCP-1, Nox2, and urine TBARS levels, the markers of inflammation and oxidative stress, were increased during disease progression in db/db mice, which were halted by NCS treatment (P<0.05). In addition, a downstream factor of the Wnt signaling pathway, known as WNT1-inducible signaling pathway protein 1 (WISP1), has been identified as one of key downstream mediators of HuR-dependent action and found to be markedly increased by 3.2 fold in db/db mouse kidneys at 22 wks, compared with non-diabetic controls, which was abrogated by NCS treatment, approaching to normal levels.

Conclusions: These results indicate that inhibition of HuR with NCS is therapeutic for DN through improving hyperglycemia and renal inflammation and oxidative stress. The efficacy of NCS in reducing renal WISP1 expression and action may also contribute to its reno-protective effect. Our study provides a proof-of-concept for re-purposing HuR inhibitor as a novel intervention therapy for progressive DN.

Increased Oxidative Stress with Reduced Renal PON2 in Type 2 Diabetic Nephropathy Mice

Shiyue Yu,[1,2] Xueqi Chen,[1,2] Tianyu Deng,[1,2] Zhiyun Ren,[1] Weiwan Wang,[1] Mingda Liu,[1] Xiaoyan Wang.[1,2] The Core Laboratory for Clinical Research. *[1]The Core Laboratory, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China; [2]Department of Nephrology, Nanjing BenQ Medical Center, The Affiliated BenQ Hospital of Nanjing Medical University, Nanjing, China.*

Background: Enhanced oxidative stress with excess accumulation of reactive oxygen species (ROS) triggers progression of type2 diabetic nephropathy (T2DN). However, the effects of antioxidant enzymes including paraoxonase (PON) enzyme family in T2DN are not been studied fully. Therefore, our study was conducted to investigate the alterations in renal oxidative stress, especially antioxidant enzyme expression, in T2DN mice.

Methods: 1. Mouse model: Male 6-week-old C57BL/6J mice were fed a 60% high-fat diet (HFD) for 6 weeks, and then was injected with STZ intraperitoneally at 60 mg/kg/day (T2DN, n=7) or vehicle (controls, n=5) for 3 days. Mice fed a 10% normal-fat diet (NFD) served as the background group (n=5). The mice were sacrificed at 16 weeks of HFD or NFD. 2. Cultured mouse renal proximal tubular cells (mRPTCs): the cells in low-glucose DMEM and 1%FBS were treated with 300μM sodium palmitate (PA) plus 24.5mM D-glucose or mannitol for 24h (n=4). 3. P<0.05 was considered significant for 2 group-comparison by t-test.

Results: Compared with HFD-fed mice, T2DN mice exhibited an elevated blood glucose (26.2±1.0 vs 8.7±0.6,mmol/L) together with polydipsia (13.4±1.6 vs 2.5±0.3,mL), polyphagia (4.9±0.4 vs 3.8±0.2,g), polyuria (10.6±1.5 vs 1.3±0.1,mL) and weight loss (28.2±0.7 vs 38.4±2.5,g). HOMA-IR (239.2±23.3 vs 109.5±7.8,mmol/L) and insulin tolerance test (AUC: 249±23% of control) were increased in T2DN mice with raised urine albumin-to-creatinine ratio (48.5±3.0 vs 20.8±30.7,mg/g), serum creatinine (90.7±26.6 vs 21.9±6.1,mmol/L) and urinary 8-isomeric prostaglandin (1482±86 vs 207±85,pg/mg of Cr). The staining of PAS and Masson's trichrome presented glomerular hypertrophy and collagen deposition while transmission electron microscopy revealed glomerular basement membrane thickening and podocyte fusion. Renal PON2 (66±0.03% of control) by immunoblotting was decreased while NOX1,2,4, PON1, HO1, HO2, and SODs1-3 were not affected. Except a slightly blunted response to insulin, blood glucose and renal ROS enzymes in HFD mice were not altered relative to NFD mice. PON2 was located mainly in NHE3-positive proximal tubules. Similar decrease in PON2 (73±5% of control) was also seen in cultured mRPTCs exposed to high glucose combined with PA.

Conclusions: Decreased renal PON2 may be involved in the pathogenesis of T2DN.

A Novel Method for the Analysis of Renal Sympathetic Nerve Activity (RSNA) from Multi-Fiber Nerve Recordings

Kristina Rodionova,[1] Roland Veelken,[1,2] Nada Cordasic,[1] Karl F. Hilgers,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Tilmann Ditting.[1,2] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Nurnberg, Germany.*

Background: Measurement of RSNA via bipolar electrodes from multi-fiber preparations in various species has been used for decades in the context of autonomic regulation research. Traditionally, raw neurograms are usually integrated over short time intervals and this approach works perfectly for the analysis of dynamic RSNA changes due to acute intervention. However, comparability of baseline activities between groups is limited. We present a novel analysis method, based on the raw neurogram sampled at rate of 25 kHz.

Methods: For RSNA-burst analysis a software based programmable algorithm was used. Continuous activities longer than three single spikes (i.e., >8ms) were defined as bursts, followed by silent periods with some single spikes. Approximately 10.000 bursts/rat were analyzed and burst amplitude, burst duration, burst area (i.e., duration integral), as well as the burst frequencies were analyzed.

Results: In rats with myocardial infarction (n=11) we found no difference in integrated baseline RSNA as compared to controls ((n=10). However, the new method revealed higher higher burst rate per cardiac cycle [CC] (2.65 ± 0.39 vs. 1.61 ± 0.38 bursts/CC; P<0.001) and burst frequency (15.09 ± 2.42 vs. 8.52 ±1.54 Hz; P<0.001) compared to healthy controls, indicating increased RSNA.

Conclusions: Our new method of RSNA baseline analysis was able to detect subtle differences between groups of animals that could not be detected by the traditional method of integrated RSNA analysis. Furthermore, this method has the potential to give further insights into RNSA patterns and synchronization to afferent regulatory input form the kidney itself or other organs.

FR-PO380

The Positive Effect of Renal Denervation Persists even Through Regrowth of Afferent Axons Improving Renal Afferent Nerve Activity During High Sodium Intake in Rats

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Nada Cordasic,[1] Karl F. Hilgers,[1] Peter Linz,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2]
[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Nurnberg, Germany.

Background: Previous work of ours suggests that pathologically decreased sensitivity of renal afferent neurons (reduced number of highly active tonic neurons) due to high salt diet is normalized 1 wk after renal denervation (DNX). Now we tested the hypothesis that normalized sensitivity of renal neurons persists after DNX even through regrowth of afferent axons after 12 wk. This morphological regrowth of afferent nerves 12wk after renal DNX (postDNX) was shown in a previous publication (DOI: 10.1152/ajpregu.00227.2014).

Methods: 6 male Sprague Dawley (SD) rats were put on high salt diet (HS; 8% NaCl) for 10 days. In another group of 12 rats on high salt diet (HS) left kidneys were denervated (postDNX) 12 weeks prior to examination. Rats on standard diet were used as controls. Harvested dorsal root ganglion neurons (DRG Th11-L2) with renal afferents were investigated in primary neuronal cell culture using current clamp mode to assess action potential generation during current injection and to characterize neurons as tonic highly active and phasic less active neurons.

Results: In renal neurons from rats on HS the relation of tonic to phasic neurons shifted towards less active phasic units (62% tonic neurons in control vs. 42% on HS, $p<0.05$, z-test). Denervation of the left kidney in rats on high salt diet (HS-DNX) led to a recovery of afferent renal DRG neurons after 1 wk (42% tonic neurons on HS vs. 72% tonic neurons on HS+DNX). Even 12 weeks after renal denervation this regained electrophysiological property of tonic firing persists (42% tonic neurons on HS vs. 69% tonic neurons on HS-postDNX, $p<0.05$, z-test).

Conclusions: The reduced proportion of highly active tonic neurons increased 1 wk after renal denervation to control levels. Even 12 weeks after renal denervation, this effect of renal denervation persisted, and the sensitivity of renal neurons to electrical stimuli did not change despite high-salt diet. Hence, the positive effects of renal denervation persisted even through the regrowth of renal afferent axons to the kidney.

FR-PO381

Mechanosensitive Potassium Channels in the Afferent Limb of the Cardio-Renal Baroreflex

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Karl F. Hilgers,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken,[1,2] Peter Linz.[1] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Nurnberg, Germany.*

Background: We have recently shown that the cardiorenal baroreflex (CRB) is impaired already in congestive heart failure with preserved ejection fraction. There might be a number of possibly involved mechano-sensitive channels and receptors in the afferent limb of the CRB. Since cardiac function is dependent on tight control of serum potassium levels, we tested the hypothesis that mechano-sensitive potassium channels are expressed in the afferent limb of the CRB.

Methods: We used inside-out-patches from cultured cardiac nodose ganglion neurons of rats that comprise the first neuron of the afferent limb of the CRB. The channels were activated by applying suction to the patch in a stepwise protocol.

Results: Using the pipette perfusion technique two MS channels could be distinguished: One could be blocked extracellularly with 10 μM gadolinium, a known blocker of MS ion channels. It exhibited a slope conductance of 116.4 ± 5.3 pS in symmetrical potassium concentrations. The other was not affected by gadolinium and had a slope conductance of 76.1 ± 6.5 pS. The channels exhibited also sodium- besides potassium-conductivity. The relative conductivity from potassium to sodium was 3.4 in both groups of channels, which allows membrane depolarization to levels where voltage-activated sodium-channels open.

Conclusions: Hence, through mechano-sensitive cation channels putatively also influenced by extracellular potassium concentrations, the CRB might indirectly influence serum potassium levels via altered salt and water excretion.

FR-PO382

Significance of the Nav 1.8 Voltage-Gated, Tetrodotoxin-Resistant Sodium Channel for Renal Sensoric Innervation in Mice and Rats

Kristina Rodionova,[1] Tilmann Ditting,[1,2] Kathrin Holzmann,[1] Felix R. Bach,[1] Nada Cordasic,[1] Karl F. Hilgers,[1] Peter Linz,[1] Mario Schiffer,[1] Kerstin U. Amann,[1] Roland Veelken.[1,2] *[1]Friedrich-Alexander-Universitat Erlangen-Nurnberg, Erlangen, Germany; [2]Paracelsus Medizinische Privatuniversitat - Nurnberg, Nurnberg, Germany.*

Background: Our previous work repeatedly showed that the sensory innervation of the kidney in rats has a peculiarity containing predominantly (more than 50%) highly active tonic neurons to electrical stimulation. In a previous publication (DOI: 10.1152/ajprenal.00011.2012) we demonstrated an increased mRNA expression of the TTX-resistant sodium channel Nav1.8 in renal sensory neurons. Hence, we tested the hypothesis that tonic firing pattern is related to the specific expression of $Na_v1.8$ on the cell surface of neurons with renal sensoric axons in the dorsal root ganglia (DRG Th12-L2).

Methods: Harvested dorsal root ganglion neurons (DRG Th11-L2) from male Sprague Dawley (SD) with renal afferents were investigated in primary neuronal cell culture using current clamp mode to assess action potential generation during current injection and to characterize neurons as tonic highly active and phasic less active neurons using a Nav1.8 blocker (A-803467) before and after stimulation. Further, renal DRG neurons from a Nav1.8 knock out mouse (C57BL6J-Scn10atm1Jwo) were investigated in a current clamp mode. C57BL6 mice were used as controls.

Results: At a concentration of 0.3μM the maximum AP firing frequency was blocked from 13+/- 1.1 APs/600ms to 7.6+/-1.4 APs/600ms under superfusion with a Nav1.8 blocker. No blocker effects were seen at a concentration of 0.1 μM and due to superfusion with the solvent methanol alone. The firing pattern of renal neurons in the C57BL6 mouse was similar to that in the SD rat with a dominance of the tonic highly active neurons. In a Nav1.8 knock out mouse (C57BL6J-Scn10atm1Jwo) in the population of neurons with dendrites from the kidney only a single cell out of 70 showed tonic firing behavior (control vs Nav1.8 KO mouse, z-test, $p<0.05$).

Conclusions: Under physiological conditions, renal sensory neurons exhibit predominantly a firing pattern associated with higher excitability. Our findings in this study support the significance of the TTX-resistant sodium channel Nav1.8 for the specific tonic firing pattern of neurons with renal projections. That might be of importance for pharmacological interventions to influence renal nerve activity likely involved in the control of blood pressure and cardiovascular function.

FR-PO383

The Minimal Diameter of Renal Artery Stenosis but Not Percentage Diameter Reduction Is Associated with Kidney Perfusion and Function

Arkadiusz Lubas, Anna Grzywacz, Arkadiusz Zegadlo, Stanislaw Niemczyk.
Wojskowy Instytut Medyczny - Panstwowy Instytut Badawczy, Warszawa, Poland.

Background: Renal Artery Stenosis (RAS) exceeding 50% of the lumen diameter is considered hemodynamically significant. Refractory hypertension or declining kidney function coexistence can contribute to invasive treatment. However, the different diameters of supplying arteries result in different diameters of stenoses, although they all can be estimated at 50% of the lumen diameter reduction. Thus, different diameters of stenoses can be improperly qualified for revascularization on the same decision level. The study aimed to investigate which parameter of Renal Artery Stenosis is associated with kidney perfusion and function.

Methods: Forty kidneys with single, non-hypoplastic supplying arteries were evaluated in a contrast-enhanced multidetector computed tomography (GE Discovery 750 HD) in 25 patients (11F, 14M; age 62 ±16) with hypertension and RAS suspicion. The minimal diameter (MD), percentage of diameter reduction (DR), and lumen cross-sectional area reduction (CSAR) of narrowed renal arteries, renal parenchymal blood flow (RPBF), and kidney function (CKD-EPI) were estimated.

Results: The mean values of investigated parameters were evaluated: MD 2.91 ±1.23 mm; DR 38.8 ±15.2 (range 5-73) %; CSAR 53.7 ±19.0 %; RPBF 187.7 mL/s/100g; CKD-EPI 57.9 ±29.7 ml/min/1.73 m^2. In correlation analysis, only MD was significantly associated with RPBF ($r=0.377$, $p=0.016$) and CKD-EPI ($r=0.346$; $p=0.029$), whereas DR was not correlated with these parameters ($r=-0.134$, $p=0.410$, and $r=-0.229$; $p=0.156$, respectively), and CSAR was significantly connected only with CKD-EPI ($r=-0.290$, $p=0.070$, and $r=-0.335$, $p=0.035$; respectively).

Conclusions: The absolute value of Renal Artery Stenosis minimal diameter is more closely associated with kidney perfusion and function than percentage values of diameter and lumen cross-sectional area reduction. Implementing the minimal diameter of stenosis in the renal artery revascularization criteria could improve the effectiveness of this procedure.

Vascular Dysfunction in the C57Bl/6J;Pkd1RC/RC Mouse Model of Autosomal Dominant Polycystic Kidney Disease Mimics Human Disease

Nidhi Dwivedi, Berenice Y. Gitomer, Charles L. Edelstein, Michel Chonchol, Katharina Hopp, Vienna E. Brunt. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most common genetic nephropathy characterized by progressive cyst growth in the kidney. Patients with ADPKD also present with cardiovascular diseases (CVDs), a leading cause of morbidity and mortality in this population. The majority of CVDs arise due to dysfunction of the arteries. Stiffening of the large arteries (e.g., aorta and carotids) and endothelial dysfunction are manifestations of vascular dysfunction that precede and contribute to CVDs and are often found in patients with early-stage ADPKD, even when kidney function remains preserved. The C57Bl/6J *Pkd1*$^{RC/RC}$ (RC/RC) mouse model mimics the kidney phenotype of patients with ADPKD and is widely used to study kidney pathologies of the disease, but it is unknown if the model also exhibits vascular dysfunction.

Methods: Using male RC/RC mice with mild (4mo) and moderate (8mo) kidney disease severity and age/sex matched C57Bl/6J wildtype (WT) controls, we measured aortic stiffness *in vivo* by pulse wave velocity (PWV). To investigate the contribution of structural changes in the arteries to stiffening, we also measured aortic elastic modulus by stress-strain testing (wire myography) in excised aortic rings. Lastly, we measured endothelial function as endothelium-dependent dilation (EDD) to acetylcholine in isolated carotid arteries by pressure myography.

Results: Aortic PWV was higher in RC/RC mice vs WT at both 4 (440±44 vs 346±26 cm/s, $P<0.01$) and 8mo (428±37 vs 343±30 cm/s, $P<0.01$) of age. Aortic elastic modulus

trended towards being mildly but non-significantly higher in RC/RC vs WT. Carotid artery EDD was impaired at 8mo (peak EDD: 74±6 vs 97±3%, P<0.01) but not 4mo (93±5 vs 94±2%) of age in RC/RC mice vs WT.

Conclusions: Our data suggest that the RC/RC mouse model of ADPKD presents with vascular dysfunction like that observed in patients with ADPKD. Our vascular data is in line with a prior described cardiac phenotype showing cardiac hypertrophy and echocardiographic changes in the heart in RC/RC mouse (FR-PO279 ASN 2022). Thus, this model can be utilized to study mechanisms and test novel interventions aimed to reduce CVD risk in ADPKD.

The IRE1α/XBP1s Pathway Promotes Vascular Calcification in CKD by Enhancing Oxidative Phosphorylation

Fan He,[1] Jia Shi,[2] Nan Y. Wang,[1] Gang Xu,[1] Qing Li.[1] *[1]Tongji Hospital of Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China; [2]The First Affiliated Hospital of Chongqing Medical University, Chongqing, China.*

Background: Endoplasmic reticulum stress has been reported to be linked to several vascular diseases. However, whether Inositol-requiring enzyme 1α (IRE1α) participate in vascular calcification in chronic kidney disease remains poorly understood.

Methods: The expression level of IRE1α were measured in the artery tissues of CKD patients and mice. The $Ern1^{flox/flox}$ mice were intercrossed with SMMHC-CreERT2 to obtain VSMC-specific IRE1α knockout mice ($Ern1^{flox/flox}$; SMMHC-Cre). The mice were treated with vitamin D3 to induce vascular calcification. Besides, VSMC were stimulated with high phosphate or human uremic serum to induce calcification. The calcium content and Alizarin red staining were used for analysis of calcification, and the mRNA expression level of IRE1α, XBP1s and regulated IRE1-dependent decay-related genes were measured. After transfected with Ad-XBP1s, transcriptome analysis was performed.

Results: The expression level of IRE1α were upregulated in the artery tissues of CKD patients and mice, and in high phosphate and human uremic serum-stimulated VSMC. Specific knockout of IRE1α in VSMC alleviated vascular calcification both in vivo and ex vivo, and siIRE1α attenuated VSMC calcification in vitro. The mRNA expression level of XBP1s were decreased in the aortic tissues of $Ern1^{flox/flox}$; SMMHC-Cre mice, while the expression level of regulated IRE1-dependent decay-related genes remained unchanged. Knockout of IRE1α inhibits high phosphate-induced calcification, which could be reversed by XBP1s overexpression. Overexpression of XBP1s enhanced oxidative phosphorylation of VSMC.

Conclusions: The IRE1α/XBP1s Pathway Promotes Vascular Calcification in Chronic Kidney Disease by Enhancing Oxidative Phosphorylation.

THOC5-Dependent Posttranscriptional Control Maintains Vascular Smooth Muscle Cells Homeostasis Against CKD-Related Vascular Calcification

Fan He, Anying Cheng, Yuyao Wang, Qing Li, Yongman Lv. *Tongji Hospital of Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China.*

Background: Modulation of the vascular smooth muscle cell (VSMC) osteogenic transition plays a fundamental role in CKD-associated VC. Despite transcriptional control mechanisms of VSMC osteogenic transition having been extensively studied, posttranscriptional regulation is still awaiting elucidation. In the present study, we explore the mechanism of THOC5-dependent VSMCs osteochondrogenic switching.

Methods: Von Kossa staining and immunohistochemistry staining were used to detect calcification and expression of THOC5 respectively. Thoc5 shRNA and Thoc5 overexpression lentivirus were used to modulate the expression of Thoc5. RNA-Seq combined with RIP-Seq was used to explore the target mRNAs that directly bind to THOC5, and FISH was used to confirm its subcellular localization.

Results: Immunohistochemical staining showed significantly increased THOC5 expression in the calcified artery of CKD patients. Besides, calcification-induced increase of THOC5 expression was found in both in vivo and in vitro calcification models. The overexpression of Thoc5 relieves the calcification and osteogenic differentiation of VSMCs significantly in vitro, which is mainly manifested by the reduction of calcium ion deposition and the decreased expression of osteogenic markers. Furthermore, RNA-Seq revealed that THOC5 overexpression in osteogenic-induced VSMCs closely resembled the gene expression changes induced on TGF-β treatments in cultured VSMCs. RIP-Seq was selected to detect target genes of THOC5. It was found that THOC5 directly interacts with Guanylate exchange factors (GEFs) mRNAs, and is required for their export. Thereby THOC5 maintaining RhoA GTPase activation contributes to increasing the expression of VSMCs contraction marker, which maintains the contraction phenotype of VSMCs. ROCK (Rho-kinase) inhibitor reversed the protective role of THOC5 on VC.

Conclusions: Our data introduce the binding of THOC5 to GEFs as a novel mechanism contributing to maintaining VSMCs homeostasis and imply THOC5 as a potential intervention node for vascular calcification diseases.

The Role and Mechanism of Ubiquitin-Specific Protease 25 in Cardiorenal Syndrome Type 4

Fan He, Xiaona Zhan, Yi Yang, Qing Li, Gang Xu. *Tongji Hospital of Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China.*

Background: The development of chronic kidney disease will lead to cardiorenal syndrome type 4 (CRS4). At present, there is no research on ubiquitin-specific protease 25 (USP25) in CRS4. The aim of this research was to investigate the function and mechanism of USP25 in CRS4.

Methods: C57BL/6 mice received 5/6 nephrectomy and were fed with high phosphate diet to establish the model of CRS4. The express levels of USP25 in the heart of mice in the CRS4 group and the H9C2 rat cardiomyoblast cell line treated with high phosphate (HP) was detected. The changes of hypertrophic markers and cross-sectional area of H9C2 cells in the siUSP25 + HP group were detected by qPCR and phalloidin staining. qPCR and echocardiography were used to compare the degree of cardiac hypertrophy in *usp25*$^{+/+}$-CRS4 mice and *usp25*$^{-/-}$-CRS4 mice. To prove that USP25 regulated the cardiac hypertrophy in CRS4 through PTEN/AKT signaling pathway, the effect of knockout of USP25 *in vivo* or knockdown of USP25 *in vitro* on the AKT signaling pathway in cardiomyocytes was detected by western blot. The interaction between USP25 and PTEN was verified by immunoprecipitation, and the ubiquitination level and type of ubiquitination of PTEN in cells from the siNC group and siUSP25 group were detected. The degree of cardiomyocyte hypertrophy in the plasmid-USP25+HP+PTEN inhibitor group and plasmid-USP25+HP+DMSO was detected by qPCR and phalloidin staining.

Results: The level of USP25 in the heart of mice in the CRS4 group and the cells in the HP group were increased. In H9C2 cells stimulated by HP, knockdown of USP25 *in vitro* aggravated cardiomyocyte hypertrophy. In CRS4 mice, knockout of USP25 *in vivo* aggravated cardiac hypertrophy. Knockout of USP25 *in vivo* or knockdown of USP25 *in vitro* promoted the activation of the AKT signaling pathway in cardiomyocytes. The results of immunoprecipitation suggested that USP25 interacted with PTEN. The ubiquitination level of PTEN in the siUSP25 group was higher than that in the siNC group, and the increased ubiquitination type was K63-linked ubiquitination. *In vitro*, PTEN inhibitor could attenuate the anti-hypertrophic effect of overexpression of USP25 in H9C2 cells.

Conclusions: USP25 stabilized PTEN by removing the K63-linked ubiquitin chains of PTEN, which inhibited the activation of the AKT signaling pathway and relieved cardiac hypertrophy in CRS4.

Aristolochic Acid-Induced Aortic Stiffening in Mice Can Replicate Vascular Dysfunction Seen with CKD

Vienna E. Brunt,[1] Ester Oh,[1] John R. Montford,[1,2] Anna Jovanovich,[1,2] Kristen L. Nowak,[1] Seth B. Furgeson.[1] *[1]University of Colorado Anschutz Medical Campus Division of Renal Diseases and Hypertension, Aurora, CO; [2]Rocky Mountain Regional VA Medical Center, Aurora, CO.*

Background: Cardiovascular disease (CVD) is highly prevalent in CKD and the leading cause of death. Stiffening of large arteries precedes overt CVD and contributes to the pathogenesis. It is unclear if commonly used mouse models of CKD develop arterial stiffness.

Methods: Male and female C57Bl/6J mice (n=3-8/group) received 4 doses of aristolochic acid (AA) at 2 mg/kg and 8 mg/kg, respectively. Aortic pulse wave velocity (PWV), the gold-standard measure of arterial stiffness, was assessed in anesthetized mice 7-9 weeks after AA injections. Serum, aortas, and kidneys were collected at 9 (males) or 11 (females) weeks. To determine if increases in PWV were due to structural changes in the arteries, elastic modulus (EM) was determined in aorta rings by stress-strain testing. We compared CKD-induced fold increases in aortic PWV in mice and carotid-femoral PWV in patients with stage 3-4 CKD (17M/18F; age 66±7; eGFR 38±11 mL/min/1.73 m^2) vs. age-matched controls (17M/18F; 63±7; eGFR 84±12 mL/min/1.73 m^2).

Results: Male mice developed significant CKD as assessed by renal fibrosis (hydroxyproline content 6.3±1.4 mg/g vs. 3.2±0.8 mg/g protein, p<0.05) and renal dysfunction (blood urea nitrogen [BUN] 100±23 mg/dL vs. 33±9 mg/dL, p<0.05). Both aortic PWV (441±64 vs. 342±15 cm/s, p=0.05) and EM (6,525±392 vs. 5,011±898 kPa, p=0.07) were 1.3-fold higher with AA, and this increase in aortic stiffness was comparable to that observed in male CKD patients vs. controls (1.2-fold; 1,014±229 vs. 835±130 cm/s, p<0.01). Female mice also developed renal fibrosis (hydroxyproline 11.8±3.5 mg/g vs. 4.2±0.7 mg/g protein) and renal dysfunction (BUN 41±22 mg/dL vs. 21±4 mg/dL, p< 0.05). Despite less severe renal dysfunction than males, aortic PWV (408±43 vs. 356±16 cm/sec, p=0.08) and EM (7,905±1635 vs. 5,980±1190 kPa, p=0.09) were increased (1.2- and 1.3-fold higher) comparably to male mice and to female CKD patients (1.2-fold; 907±237 vs.789±141 cm/s, p=0.08). The range of aortic stiffening in female mice was wider than males, which was also reflected in our cohort of female patients.

Conclusions: AA administration produces CKD and aortic stiffening in both male and female mice that is similar to that seen in patients with CKD. This model may be a promising pre-clinical model to test vasculoprotective therapies in patients with CKD.

FR-PO389

Histone Deacetylase 9 Contributes to Vascular Calcification in CKD

Lin Xiong, Yi Li, Li Wang, Guisen Li. *Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China*.

Background: Vascular calcification (VC) is a serious chronic kidney disease (CKD) complication. Unfortunately, there is no effective therapy for VC beyond supportive care due to the complex pathogenesis of VC. Histone deacetylase 9 (HDAC9) could regulate the transdifferentiation of vascular smooth muscle cells in atherosclerotic aortic calcification. However, the role of HDAC9 in VC upon CKD is unclear. This study aimed to investigate the role and mechanism of HDAC9 in VC upon CKD.

Methods: Rat aortic smooth muscle cells (RASMCs) were divided into the control and calcification groups. The calcification group was induced with β-glycerophosphate and $CaCl_2$. RASMCs were incubated with Alizarin Red S stain to detect calcification. RT-qPCR and WB were utilized to detect the expression level of HDAC9. 30 male wild-type Wistar rats aged from 6 to 8 weeks were randomly divided into six groups (n=5): 4- and 16-week control groups, and 4-, 8-, 12-, and 16-week VC groups. The VC model of CKD in rats was established by 5/6 nephrectomy combined with high phosphorus chow. Rat aortas were collected and stained with alizarin red to detect VC. Subsequently, the expressions of HDAC9 were detected by third-generation sequencing, immunohistochemical staining, and immunofluorescent staining.

Results: In *vitro*, alizarin red staining showed the calcificated RASMCs had more calcium salt deposits. Both WB and RT-qPCR showed the expression of HDAC9 in calcificated cells was increased. In *vivo*, alizarin red staining of the aorta showedccalcium deposition in the calcification group was significantly higher compared to control group. In the third-generation full-length transcriptome sequencing of rat aorta, the RNA expression of HDAC9 in the calcificated group increased gradually from 4 weeks to 12 weeks, and was significantly higher than that in 4- and 16-week control groups. The immunohistochemical staining and immunofluorescent staining indicated the expression of HDAC9 in the aorta of the 12-week calcification group was significantly increased, compared to the 4- and 16-week control group.

Conclusions: Histone deacetylase 9 could contribute to the development of vascular calcification in chronic kidney disease.

FR-PO390

Autophagy Attenuates Vascular Calcification by Suppressing Ferroptosis

Qing Li, Cailin Zhang, Fan He. *Department of Nephrology, Tongji Hospital of Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*.

Background: Vascular calcification (VC) is an independent risk factor for cardiovascular death in chronic kidney disease. Autophagy is reported to be protective in VC, while the mechanism is not fully elucidated.

Methods: RNA-sequencing and metabolomics of aortas from VD3-induced mice VC models (treated with or without Rapamycin) were used to identify potential signalings. RT-qPCR, Western blot (WB), and immunofluorescence staining were performed to confirm our findings, and gain-and-loss-of-function assays were conducted to validate the regulative mechanism of the involvement of ferroptosis in autophagy-mediated protective effect in VC.

Results: We revealed that high phosphate could enhance the autophagy level of vascular smooth muscle cells (VSMCs), and autophagy plays a protective role in VC. Moreover, autophagy mainly occurred on the peroxisome of VSMCs in the high phosphate circumstances, which affects the level of ferroptosis. WB of ferroptosis markers GPX4 and TRF1 in high phosphate treated VSMCs confirmed this finding. Manipulating using ferroptosis inducer can reverse autophagy-mediated VC attenuation, while ferroptosis inhibition rescues Chloroquine induced elevated level of VC.

Conclusions: Our results demonstrated that autophagy attenuates VC via preferable peroxisome inhibition, resulting in ferroptosis suppression.

The Effects of Neutrophil Extracellular Traps (NETs) on Endothelial Health and Function

Chloé Landry,[1,2] Dylan Burger.[2,1] [1]*University of Ottawa Faculty of Medicine, Ottawa, ON, Canada;* [2]*Ottawa Hospital Research Institute, Ottawa, ON, Canada*.

Background: Neutrophil extracellular traps (NETs) are intricate webs of extracellular DNA, citrullinated histones and granular protein that play an essential role in innate immunity. Dysregulation of NET formation has been implicated in acute kidney injury, lupus nephritis, and diabetic kidney disease. However, the mechanisms by which NETs contribute to kidney injury have yet to be fully elucidated. As the vasculature may represent a common pathogenic target, we examined the effect of NETs on endothelial cells *in vitro* and on *ex vivo* mesenteric artery function.

Methods: The human promyelocytic cell line, HL-60, was used to generate neutrophil-like cells *in vitro*. Differentiation was induced by incubation with 1.25% dimethyl sulfoxide (DMSO) for 5 days. Differentiated cells were then stimulated with 500 nM phorbol 12-myristate 13-acetate (PMA) for 4 hours to induce NET formation. NETs were isolated from the cell culture medium by differential centrifugation. Cultured Human Umbilical Vein Endothelial Cells (HUVECs) were treated with the isolated NETs at 0.5-500 ng/ml for 24 hours. Cell viability and proliferative capacity were measured in the treated HUVECs using an XTT and BrdU assay, respectively. Second-order mouse mesenteric arteries were harvested and mounted to a wire myograph. Vessels were treated with the isolated NETs at 15 ng/mL for 30 minutes, after which we measured vascular relaxation during chemical stimulation with acetylcholine, to assess their effect on endothelium-dependent vasorelaxation.

Results: NETs decreased HUVEC viability ~2-fold at 5 ng/ml (P=<0.0001) and dose dependently decreased proliferative capacity from 0.5-500 ng/ml, with proliferation being decreased by ~80% at 500 ng/ml. NETs also significantly impaired endothelium-dependent vasorelaxation, with relaxation being 43% lower in treated vessels at 10^{-6} M acetylcholine. This was reflected in smaller pD2 values in NET-treated vessels (5.55 vs 6.72 in control vessels) (p=0.0284).

Conclusions: These results show that NETs induce endothelial cell injury *in vitro* and impair endothelial function in intact vessels. Identifying the underlying mechanisms of NET-induced endothelial injury may help further understand their contribution to kidney and cardiovascular injury.

FR-PO392

Circadian Clock Provides Beneficial Effects Against the Endothelial Dysfunction by Regulating Porphyrins Synthesis and Heme Oxygenase-1 Expression

Hideyuki Negoro.[1,2] [1]*Harvard Medical School, Boston, MA;* [2]*The Graduate School of Project Design, Tokyo, Japan*.

Background: The circadian clock is a molecular mechanism that confers 24 hours variations in gene expression and function to regulate many physiological functions. Chronic circadian clock disruption is associated with vascular stiffness and dysfunction in endothelial signaling and responses. Heme is a ligand of REV-ERBα and REV-ERBβ which modulate circadian rhythms by binding to the ROR region of CLOCK or BMAL1 to suppress the expression of these genes. 5-Aminolevulinic acid (ALA) is the common precursor of heme. The iron ion is inserted into protoporphyrin IX to form heme in the mitochondria and incorporated into hemoproteins. Heme oxygenase-1 (HO-1) is an intracellular enzyme which catalyzes the oxidation of heme to generate ferrous iron, carbon monoxide, and biliverdin, which is subsequently converted to bilirubin. These products have anti-inflammatory, anti-apoptotic and anti-thrombotic properties. In this study, we observed if the deletion of Bmal1, a critical component of the circadian clock, can influence porphyrins and HO-1generation which play an important part in the protection of vascular diseases.

Methods: Congenic 12- to 16-week-old male, wild-type and Bmal1-KO littermate mice were generated from heterozygote breeding. To synchronize circadian rhythms, serum stimulations were performed. Cells were also pre-incubated with or without 1 mM ALA and 0.5 mM sodium ferrous citrate (SFC). We also knocked down Bmal1 to evaluate the protein levels of HO-1 expression in the knocked down cells.

Results: In aorta from Bmal1 KO mice, there was a reduction in HO-1 expression in mice with a dysfunctional circadian rhythm. Bmal1 KO mice display pre-mature aging to have a dramatic prothrombotic phenotype. This phenotype is linked to the regulation of key risk factors for cardiovascular disease. These include HO-1 which is significantly reduced in Bmal1 KO mice. ALA/SFC co-incubation affected the oscillation and phase of core clock genes to lead to increase of HO-1. HO-1 levels followed a circadian pattern, and this pattern was absent in Bmal1 KO mice.

Conclusions: These findings indicate that circadian clock provides beneficial effects against the endothelial dysfunction to promote atherogenesis by regulating Porphyrins synthesis and HO-1 expression. This study establishes a mechanistic connection between Bmal1 and cardiovascular phenotype.

FR-PO393

Renal Klotho Safeguards Platelet Lifespan in Advanced CKD Through Restraining Bcl-xL Ubiquitination and Degradation

Qigang Lan, Jinghong Zhao. *Army Medical University Xinqiao Hospital, Chongqing, China*.

Background: Thrombosis and hemorrhage as two opposite pathologies are prevalent within the chronic kidney disease (CKD) population. Platelet homeostasis, which positions centrally in their pathogenesis, varies among the CKD population, while the underlying mechanism is poorly understood.

Methods: The change character of platelet homeostasis and its association with renal Klotho deficiency were determined based on a cohort study as well as CKD mice and Klotho-deficient mice with CKD. The effects on thrombopoiesis and platelet lifespan were examined by flow cytometry and platelet transfer. The underlying mechanism was explored by proteomics, flow cytometry, western blot, and immunoprecipitation.

Results: We show that platelet count declines both in patient and mouse model with advanced CKD (Adv-CKD) and is positively associated with circulating Klotho levels. Mechanistically, we identify that ubiquitin ligase UBE2O governs Bcl-xL ubiquitination and degradation in platelets, whereas Adv-CKD-induced oxidative stress in platelets stimulates p38MAPK to promote Bcl-xL phosphorylation, which facilitates UBE2O binding to Bcl-xL and subsequent Bcl-xL degradation. Consequently, platelet lifespan is shortened in Adv-CKD, culminating in platelet count decline. However, kidney-secreted soluble Klotho protein restricts oxidative stress in platelets, thereby preserving Bcl-xL expression and platelet lifespan.

Conclusions: Our findings uncover the mechanism of platelet count decline in Adv-CKD and identify renal Klotho as a long-range regulator of platelet lifespan, which not only provide a molecular mechanism underlying CKD-associated thrombocytopenia and hemorrhage but also offer a promising therapy choice.

Funding: Government Support - Non-U.S.

Characterization of Cardiac Phenotype in Mouse CKD Models

Dickson W. Wong,[1] Burcu Yesilyurt,[1] Li Zhang,[1] Barbara M. Klinkhammer,[1] Julia Moellmann,[2] Patrick Droste,[1,3] Mathias Hohl,[4] Michael Lehrke,[2] Peter Boor.[1,3] Laboratory of Nephropathology. *[1]Institute of Pathology, University Hospital RWTH Aachen, Aachen, Germany; [2]Department of Internal Medicine I-Cardiology, University Hospital RWTH Aachen, Aachen, Germany; [3]Department of Nephrology and Clinical Immunology, University Hospital RWTH Aachen, Aachen, Germany; [4]Klinik für Innere Medizin III, IMED, Universität des Saarlandes, Homburg, Germany*.

Background: Cardiovascular disease (CVD) constitutes ~40-50% of mortality of chronic kidney disease (CKD) patients. Heart injury was described as left ventricular (LV) diastolic dysfunction, cardiac hypertrophy and fibrosis. While CKD rat models partially develop such cardiac phenotype, this is more challenging in mouse models. In this study, we aim to comprehensively examine various cardiac pathologies in two CKD mouse models.

Methods: The Col4a3$^{-/-}$ (Alport) mice, and wild-type (wt) mice on 6- or 12-weeks of mixed adenine diet (0.2% adenine + Western diet + 1.8% P) were examined for LV contractility using Millar-catheter, plasma Troponin I and BNP, and echocardiography (ECHO, Simpson's method). Heart histology, CD31 (endothelial cell) and CD45 (immune cell) were assessed.

Results: Compared to wt mice, the 8-week-old Alport mice developed CKD with histological kidney injury and fibrosis. Alport mice had decreased stroke volume, cardiac output and ejection fraction in ECHO and reduced LV relaxation in Millar-catheter measurement. The mice also showed higher plasma troponin I and BNP, reduced CD31/myocyte area ratio and increased myocardial CD45^{+} cells. Compared to the control diet, mice with mixed adenine diet at both time points showed higher serum cholesterol and phosphate and reduced calcium and histological signs of kidney injury, fibrosis and tubular atrophy. In the heart, mice with mixed adenine diet showed reduced LV contractility (ejection + relaxation phase), increased plasma Troponin I and BNP, and at 12 weeks, LV wall thickening and reduced stroke volume/cardiac output. The mice also showed increased cardiac infiltration of CD45^{+} cells and reduced CD31 expression. No overt cardiointerstitial fibrosis was observed in all models.

Conclusions: Alport mice, and mice fed with mixed adenine diet showed signs of CVD with LV dysfunction, elevated plasma cardiac injury marker, myocardial capillary rarefaction and microinflammation, while no overt fibrosis was observed. Alport mice have short lifespans thus limits the therapeutic time frame. The mixed adenine diet model further accelerates the cardiac injury onset compared to other CKD mouse models, with a good survival rate and similar physiology to CKD-CVD patients. Thus, the mixed adenine diet model with both kidney and heart injury has the potential for CKD-related CVD studies.

FR-PO395

Dysregulation of Thrombo-Inflammatory Biomarkers in ESRD and Their Potentiation with Heart Failure

Vanessa Robbin,[1] Fakiha Siddiqui,[1] Srdjan Nikolovski,[1] Madeline T. Allen,[1] Jawed Fareed,[1] Vinod K. Bansal.[2] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Medical Center Department of Nephrology, Maywood, IL*.

Background: In patients with end-stage renal disease undergoing hemodialysis (ESRD-HD), heart failure with reduced ejection fraction (HFrEF) represents a common comorbidity. Thromboinflammatory processes in both ESRD and HFrEF represent complex pathophysiology, and are demonstrated by dysregulation of thromboinflammatory biomarkers. This study aims to investigate the effects of HFrEF as a comorbidity on these biomarkers in ESRD-HD patients.

Methods: Blood samples from 71 ESRD-HD patients and 40 healthy normal controls were analyzed via commercial ELISA and other chromogenic methods for levels of angiopoietin-2, endogenous glycosaminoglycans, FABP, IL-6, LPS, free fatty acids, proBNP, TNFa, VEGF, Vit D, and vWF. Patient groups were stratified into those with or without HFrEF (EF<50%) in the 6 months prior or following the plasma collection using echocardiography records obtained via chart review.

Results: Compared to ESRD-HD alone, a significant increase ($p < 0.05$) was noted in IL-6 and proBNP, in those with ESRD-HD and HFrEF. Notably, Spearman's rank correlations were compiled for both groups, and markedly stronger correlations were noted in those with both ESRD-HD and HFrEF. Moreover, PAI-1 and tPA were higher in HFrEF group, suggesting the fibrinolytic deficit.

Conclusions: The dysregulation of thrombo-inflammatory biomarkers in ESRD-HD is amplified in comorbid HFrEF. Correlation among biomarkers in this cohort indicates the mechanisms of thrombo-inflammatory biomarker generation have an integrative process that is shared between the two conditions. The role of fibrinolytic deficit is to be further investigated.

HIF-1α/mTOR/REDD1 Pathway Modulates the Effect of Adipose Tissue-Derived Stem Cells on Kidney Disease Progression in Spontaneously Hypertensive Rats (SHRs) with Induced Visceral Obesity

Marcelo C. Batista,[1,2] Renata Nakamichi,[1] Beata M. Quinto.[1] *[1]Universidade Federal de Sao Paulo, São Paulo, Brazil; [2]Sociedade Beneficente Israelita Brasileira Albert Einstein, Sao Paulo, Brazil*.

Background: The aim of this study was to determine the effect of adipose tissue-derived stem cells (ASC) on the development of renal disease in spontaneously hypertensive rats (SHRs) fed a hypercaloric diet and if their altered lipid profile was dependent on the mTOR/HIF-1α/REDD1 pathway.

Methods: SHRs were divided into groups that received a standard or high-fat diet for 12 weeks and were later treated with ASC for 1 or 2 weeks. Lipid profile and kidney function were evaluated, as well as, the expression and production of the adipocytokines TNF-α, HIF-1α,mTOR and REDD1.

Results: A high-fat diet given to SHRs caused changes in glucose and lipid profiles resulting in insulin resistance, increase in serum levels of triglycerides and low-density lipoprotein cholesterol and decrease in high-density lipoprotein cholesterol values. We also observed an increase in the production of leptin and TNF-α and a reduction in adiponectin, with simultaneous increase in the expression of HIF-1α, mTOR and REDD1 in kidney tissue. Treatment with ASC resulted in the reversal of the kidney and metabolic dysfunction promoted by high-fat diet, with improved glucose and lipid profiles, improved renal function and reduced visceral HIF-1α, mTOR and REDD1 as well.

Conclusions: We found that treatment with ASC resulted in reversal of inflammatory-related kidney damage and metabolic imbalance in SHRs fed a high-fat diet.

Role of Ca++ Calmodulin-Dependent Kinase II in Cardiac Pathological Remodeling in Uremia

Laura Denby,[1] Shanmugakumar Chinnappa,[2,3] Azhar Maqbool,[3] Hema Viswambharan,[3] Andrew Mooney,[4] Mark J. Drinkhill.[3] *[1]The University of Edinburgh School of Biological Sciences, Edinburgh, United Kingdom; [2]Doncaster and Bassetlaw Teaching Hospitals NHS Foundation Trust, Doncaster, United Kingdom; [3]University of Leeds Faculty of Medicine and Health, Leeds, United Kingdom; [4]Leeds Teaching Hospitals NHS Trust, Leeds, United Kingdom.*

Background: Left ventricular hypertrophy is a ubiquitous finding in advanced chronic kidney disease associated (CKD) associated with high risk of heart failure. Our understanding of such pathological hypertrophy in CKD is still evolving. In this study, we set out to test the hypothesis that Ca^{++}- Calmodulin Dependent Kinase II (CAMKII) pathway, a well-recognised downstream mechanism in the genesis of myocardial pathological remodelling, is activated in uremia using a rodent model of experimental uremia.

Methods: Wistar rats had subtotal nephrectomy (STNx, n=10) or sham surgery (sham, n=8) and were followed up for 10 weeks. In vivo and in vitro cardiac assessments were performed. Cardiac tissue was extracted and protein expression of CAMKII, phosphorylated-CAMKII, and myocyte enhance factor 2 (MEF2), the target transcription factor of CAMKII, were quantified using immunoblotting. Data was analysed using an independent sample t-test with Welch's correction and expressed as mean± SEM.

Results: Serum creatinine was elevated in the STNx group (55.00±3.06 vs 32.50±1.44 µmol/L, P<0.01). Echocardiographic left ventricular mass (896.37±54.59 vs 629.81±24.27 mg) and heart weight to tibia length ratio (0.035±0.002 vs 0.027±0.001) were higher in the STNx group (both P<0.01). Furthermore, there was more myocardial fibrosis in the STNx group (4.29±0.79 vs 0.91±0.16 %, P<0.01) (Figure 1). CaMKII signalling was activated in the heart following STNx. An increase in both phosphorylated-CaMKII and total CaMKII was observed. The expression of MEF2 was also increased (Figure 1).

Conclusions: The study shows that experimental uremia induces cardiac pathological hypertrophy and there is associated activation of CAMKII-MEF2 pathway. This novel finding not only offers a mechanism of pathological hypertrophy in uremia but also a potential treatment target to prevent such hypertrophy and the subsequent myocardial dysfunction in CKD.

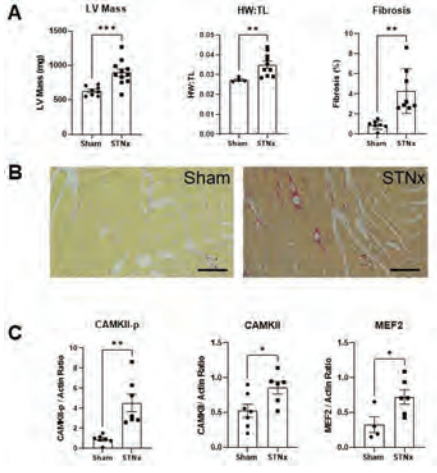

Figure 1: [A] LVmass, HW:TL and percentage cardiac fibrosis were higher in STNx group compared to Sham. [B] Picrosirius red staining of myocardium showing increased fibrosis in STNx. Scale bar 200µm [C] STNx is associated with activation of CAMKII. An increase in both phosphorylated-CAMKII and total CaMKII were observed. The expression of MEF2 was also increased. *P<0.05, **P<0.01 & ***P<0.001 on independent sample t-test. LV: left ventricle, HW:TL: heart weight to tibial length ratio.

FR-PO398

Diabetic Kidney Disease (DKD)-Induced Cardiac Damage Is Characterized and Reduced by Standard-of-Care Treatment in a Translational Diet-Induced Hypertension-Accelerated Mouse Model of DKD

Arianne Van Koppen,[1] Andrea R. Nawrocki,[2] Simon A. Hinke,[2] Harry van Goor,[3] Amélie Dendooven,[4] Tri Q. Nguyen,[5] Matthew D. Breyer,[2] Reinout Stoop.[1] *[1]TNO, Leiden, Netherlands; [2]Janssen Research and Development LLC, Boston, MA; [3]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [4]Universitair Ziekenhuis Gent, Gent, Belgium; [5]Universitair Medisch Centrum Utrecht Afdeling Pathologie, Utrecht, Netherlands.*

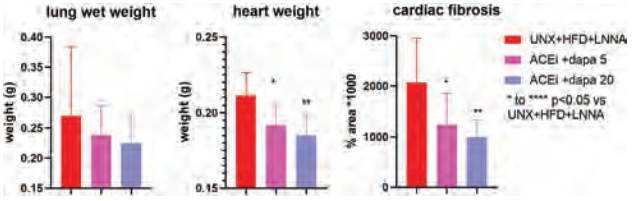
Background: Recently, we developed a diet-induced hypertension-accelerated mouse model of diabetic kidney disease characterized by progressive loss of GFR. Since cardiovascular disease is the major cause of death in CKD, we investigated the occurence of cardiac damage in this model. Additionally, we studied the efficacy of combination therapy with an ACE-inhibitor (Lisinopril) and SGLT2-inhibitor (Dapagliflozin) on cardiac damage.

Methods: Male KKAy mice underwent uninephrectomy. After recovery mice received high fat diet (45% LARD) and drinking water with or without 50 mg/L LNNA (wk0). In the intervention study, at week 4, lisinopril (2,5 mg/kg/day; drinking water) and at week 8 dapagliflozin (5 and 20 mg/kg/day;foodadmix) treatment were started. At week 16 mice were terminated and lung and heart weight and cardiac histology were determined.

Results: Upon termination, macroscopic evaluation of the hearts showed extensive scar tissue formation on the outside of the left ventricle. Histological evaluation showed the presence left ventricular hypertrophy, coronary calcification and myocardial fibrosis in male KKAy mice with UNX, HFD and LNNA. KKAy mice with UNX and HFD but without LNNA also showed myocardial fibrosis, monocyte infiltration and focal mineralization. Treatment with combination therapy reduced lung wet weight, significantly reduced heart weight and significantly decreased cardiac fibrosis. Macroscopically, less scar tissue was observed after treatment.

Conclusions: Cardiac damage is a clear feature in the KKAy mouse model of DKD, either with or without hypertension induction. Combination therapy with Lisinopril and Dapagliflozin reduced cardiac weight and cardiac fibrosis. This indicates cardiac involvement in the DKD mouse model which is clinically relevant. Studies functionally characterizing cardiac damage are currenlty ongoing.

Funding: Commercial Support - Janssen, BPM



Combination therapy with Lisinopril and Dapagliflozin shows reduced lung and heart weight and inhibited cardiac fibrosis.

FR-PO399

Combined Dapagliflozin and Eplerenone Treatment Improve Cardiorenal Function in Rats with CKD

Matthieu Soulié,[1] Manon Durand,[1] Yohan Stephan,[2] Ixchel Q. Lima Posada,[1] Roberto Palacios Ramirez,[1] Lionel Nicol,[2] Natalia Lopez-Andres,[3] Paul Mulder,[2] Frederic Jaisser.[1] *[1]INSERM U1138, Paris, France; [2]INSERM U1096, Rouen, France; [3]Navarrabiomed, Pamplona, Spain.*

Background: Patients with chronic kidney disease (CKD) present higher risk of cardiovascular (CV) complications as well as renal function decline. The DAPA-CKD trial showed reduced CV events in diabetic and non-diabetic CKD patients treated with Dapagliflozine (DAPA). Mineralocorticoid Receptor Antagonists (MRAs) have shown similar beneficial effects in diabetic CKD patients (FIDELIO-CKD & FIGARO-CKD trials) but impact in non-diabetic CKD patients is unkown. The aim of this study was to compare DAPA and Eplerenone (EPLE), alone or in combination on renal and CV functions in a non-diabetic rat CKD model.

Methods: CKD was induced in SD rats by 5/6 nephrectomy. Rats were treated with DAPA (10 mg/kg/day PO), EPLE (100 mg/kg/day PO) or the combination during 3 months after CKD induction before cardiorenal function assessment. Renal impact was assessed by histology and creatinine clearance and 24h albuminuria. Cardiac function was evaluated by cardiac echocardiography and left ventricle (LV) hemodynamics (catheterization). LV perfusion was assessed by Magnetic resonance imaging (MRI).

Results: After 3 month kidney fibrosis is decreased in the 3 treated groups compared to untreated CKD. No changes of creatinine clearance were observed while albuminuria increased in the DAPA groups with no significant effects of EPLE. The fractional shortening and the cardiac output were not modified by the treatments (not shown). Cardiac hemodynamic was improved with reduced LV end diastolic pressure (LVEDP) in the CKD rats treated with EPLE or a combination of EPLE and DAPA while LV end diastolic pressure volume relationship (LVEDPVR) was decrease by both DAPA and EPLE and further decreased by DAPA + EPLE. Decreased cardiac perfusion was prevented with EPLE alone or with the combination.

Conclusions: The use of DAPA + EPLE appears to be more effective than DAPA or EPLE alone on diastolic function in non-diabetic CKD rats while cardiac perfusion is improved by EPLE only.

Groups	Kidney fibrosis (%)	Creatinine clearance	Albuminuria (mg/24h)	LV perfusion (ml/min/g)	LV EDP (mmHg)	LV EDPVR (mmHg/RVU)
CKD	0.61±0.05	3.58±0.53	642±128	6.07±0.48	8.65±0.60	3.74±0.18

FR-PO400

Tryptophan Metabolite 3-Hydroxy Anthranilic Acid Decreases CKD-Associated Atherosclerosis

Biaoxin Chai,[1] Julian Meza,[2] Celine C. Berthier,[1] Felix H. Eichinger,[1] Jaeman Byun,[1] Anna V. Mathew.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI.*

Background: The tryptophan catabolism pathway is upregulated in chronic kidney disease (CKD), and tryptophan metabolite 3-hydroxy anthranilic acid (3-HAA) is an anti-inflammatory metabolite that has been shown to decrease atherosclerosis in preclinical and clinical models. However, the mechanistic link between 3-HAA and CKD accelerated atherosclerosis is unknown.

Methods: Twenty-four male LDLr$^{-/-}$ mice underwent 5/6 nephrectomy (CKD) and were placed on a high-fat/high-cholesterol diet (HFD) for 16 weeks. 3-HAA (200 mg/g) was injected intraperitoneally three times a week (3-HAA mice, n=12), while controls (n=12) were injected with PBS for 16 weeks. We quantified atherosclerosis with Oil Red-O staining of *en face* aortic sections at the end of 16 weeks. We used human macrophage cultures that were treated with 10μM 3-HAA and measured changes in transcriptome profiles and macrophage functions like apoptosis, phagocytosis, and cytokine profiles.

Results: 3-HAA treatment increased 3-HAA levels which negatively correlated with aortic atherosclerotic lesions in 3-HAA mice. 3-HAA treatment decreased IL-6 levels and increased IL-10 levels. 3-HAA treatment of human macrophages influences nitric oxide, platelet-derived growth factor, and CXCR3 signaling, while 3-HAA treatment had no effect on T cells. Activated human macrophage cultures reveal that 3-HAA treatment decreases macrophage apoptosis and increases phagocytosis.

Conclusions: In summary, 3-HAA treatment decreases CKD-associated atherosclerosis by its action on macrophage apoptosis, phagocytosis, cytokine profiles, and inflammatory signaling.

D4 Dopamine Receptors Regulate Insulin and Salt Sensitivities in Mice

Mingda Liu, Mingzhuo Zhang, Weiwan Wang, Ping Wang, Xiaoyan Wang. *Nanjing BenQ Medical Center, Nanjing, China.*

Background: Insulin resistance associated with dysfunction of dopamine receptors is underlined by multiple metabolic disorders including diabetes and hypertension. Dopamine D4 receptor(D4R) null mice are hypertensive.

Methods: To explore the effects of D4R on insulin resistance and hypertension, we determined the insulin/salt sensitivities, renal insulin pathway and sodium transporters in D4R null mice.

Results: Drd4$^{-/-}$ mice(14mos) had increased fasting blood glucose regardless of sex. Serum insulin levels at fasting were increased in male but not in female Drd4$^{-/-}$ mice. The male and female Drd4$^{-/-}$ mice presented a blunted blood glucose lowering effect at 30, 45 min after insulin injection (0.75U/kg,I.P). Their body weights, fasting serum total and free cholesterols, triglycerides were similar between the mouse strains. D4R agonist(PD168077,1mg/kg) increased but D4R antagonist(L745870,1mg/kg) decreased insulin sensitivity of D4$^{+/+}$ mice via osmotic mini-pumps for a week. Changing the salt intake from low to high increased mean arterial pressure by 25±4% in D4$^{-/-}$ but only by 13±1% in D4$^{+/+}$ mice while switching from high salt to low salt decreased it by 20±1% in D4$^{-/-}$ and by 11±3% in D4$^{+/+}$ mice (tail-cuff, BP-98A, Softron, Tokyo, Japan). The higher salt-sensitivity in KO than WT was also confirmed by telemetry measurements. Less increase in urinary sodium excretion was found in D4$^{-/-}$ than in D4$^{+/+}$ on high salt diet with a right-shift of pressure-natriuresis in D4$^{-/-}$. On normal salt diet Drd4$^{-/-}$ mice had decreased IRβ(19±4, % of controls, n=4)but normal protein expressions of IRα, insulin degrading enzyme, insulin substrate 1, sodium glucose transporter 2 and glucose transporters in renal cortex homogenates. D4R and IRβ were co-immunoprecipitated in immortalized mouse renal distal convoluted tubule cells and the co-immunoprecipitation was increased by D4R agonist and not altered by D4R antagonist. IRβ was co-located with the apical NKCC2 in the thick ascending limbs of the Henle's loop and NCC in the distal convoluted tubules but not with NHE3 in proximal convoluted tubules. NHE3 (126 ± 8), NKCC2 (182 ± 26) and NCC (226 ± 30) were increased in whole kidney homogenates of D4$^{-/-}$ while ENaCs and αNKA were similar between strains.

Conclusions: Therefore, D4R interacts with renal IRβ, NKCC2 and NCC, and may normalize blood pressures via reducing insulin resistance.

FR-PO402

Angiotensin II-Stimulated Superoxide Production Is Increased by a Fructose High-Salt Diet and This Contributes to Salt-Sensitive Hypertension

Beau Forester,[1] Autumn R. Brostek,[1] Agustin Gonzalez-Vicente,[1,2] Jeffrey L. Garvin.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH.*

Background: Angiotensin II (Ang-II) increases proximal tubule superoxide (O_2^-) production significantly more in rats fed a 20% fructose normal-salt diet compared to rats fed a 20% glucose, normal-salt diet. These data suggest that dietary fructose augments the sensitivity of proximal tubule O_2^- production to Ang-II. A 20% fructose high-salt (3.7% NaCl; FHS) also significantly increases systolic blood pressure (SBP), whereas 20% glucose high-salt (GHS) does not. However, it is unclear whether FHS enhances Ang-II induced oxidative stress in proximal tubules, and whether this contributes to increases in BP in this model. We hypothesized that FHS augments the ability of Ang-II to stimulate superoxide production by proximal tubules, and this contributes to fructose-induced salt-sensitive hypertension.

Methods: We measured SBP in male Sprague Dawley rats fed FHS, GHS, FHS plus 3 mM tempol (a O_2^- scavenger) in the drinking water (FHS+T), and GHS+T for 7 days. Then we measured the effect of 3.7 x 10^{-8} M Ang-II on O_2^- production by proximal tubule suspensions from rats fed GHS, FHS, and FHS+T using the lucigenin assay. This concentration was chosen because it was the lowest concentration that significantly stimulated O_2^- production by proximal tubules from rats fed FHS.

Results: FHS increased SBP by 11 ± 2 mmHg, (Day 0: 131 ± 4, Day 7: 142 ± 5 mmHg; n = 5, p < 0.01), while GHS did not (Day 0: 140 ± 3, Day 7: 137 ± 3 mmHg, n = 5). Rats fed FHS+T and GHS+T showed no significant increases in SBP (FHS+T: Δ-1 ± 5, n = 8; GHS+T: Δ-1 ± 4 mmHg, n = 6). Ang-II increased O_2^- production by 11 ± 1 relative light units (RLU)●μg protein^{-1}●s^{-1} in proximal tubules from FHS-fed rats (Basal: 53 ± 9, Ang-II: 64 ± 8 RLU●μg protein^{-1}●s^{-1}; n = 11, p < 0.01) but not in proximal tubules from rats fed GHS (Basal: 46 ± 3, Ang-II: 43 ± 5 RLU●μg protein^{-1}●s^{-1}; n = 6). Ang-II did not significantly stimulate O_2^- production by proximal tubules from rats fed FHS+T (basal: 53 ± 5, Ang-II: 51 ± 4 RLU●μg protein^{-1}●s^{-1}; n = 6). We did not measure Ang-II induced superoxide production in rats fed GHS+T because there was not a significant change in blood pressure.

Conclusions: We conclude that a FHS diet enhances the sensitivity of proximal tubule O_2^- production to Ang-II, and this contributes to fructose-induced salt-sensitive hypertension.

FR-PO403

Effects of Mild Hyperuricemia in the Progression of Salt-Sensitive Hypertension and Associated Kidney Damage

Lashodya V. Dissanayake,[1] Adrian P. Zietara,[1] Vladislav Levchenko,[1] Oleg Palygin,[2] Alexander Staruschenko.[1,3] *[1]University of South Florida, Tampa, FL; [2]Medical University of South Carolina, Charleston, SC; [3]VA James A Haley Hospital, Tampa, FL.*

Background: Increased plasma uric acid (UA) (hyperuricemia (HrU)) causes damage via crystal deposition throughout the body in gout. HrU is also a potential causal factor in hypertension (HTN) & chronic kidney disease (CKD). Whether only HrU with crystals, but not asymptomatic HrU (HrU without crystal deposition), drives the progression of HTN & CKD is controversial. Additionally, dietary salt intake is involved in blood pressure & renal function control & may affect UA levels. The renin-angiotensin-aldosterone system (RAAS) activation may trigger HTN during HrU; however, lowering UA did not affect RAAS activity in some clinical studies.

Methods: To answer the question if asymptomatic HrU in the context of salt sensitivity (SS) is a friend or foe, we explored conditions of induced mild HrU & a high salt diet on the development of HTN using Dahl SS rats & administration of either oxonic acid, a uricase inhibitor that prevents the breakdown of UA further into more soluble allantoin &/or probenecid, an inhibitor of the UA transporter Urat1, preventing UA reuptake. 8-week-old male rats were implanted with telemeters to assess mean arterial pressure (MAP). After recovery, SS rats were switched to one of 4 diets: 1) 4% NaCl high salt (HS) diet (control, N=6); 2) HS + 2% oxonic acid (treatment 1, N=7); 3) HS + 750 mg/kg Probenecid (treatment 2, N=4); or 4) HS + 750 mg/kg Probenecid + 2 % oxonic acid (treatment 3, N=3) for 3 weeks.

Results: At the endpoint, treatment group 1 had significantly higher plasma UA levels compared to the control group (2.17±0.34 vs. 0.63±0.07 mg/dl). This mild HrU was associated with attenuated progression of SS HTN while probenecid did not affect MAP & diminished the effect of oxonic acid (MAP for control & treatment 1-3 groups: 156±3, 138±3, 162±3, & 154±4 mmHg). Treatment group 1 also had a lower kidney weight/body weight ratio & lower protein cast accumulation, indicating lower kidney damage. Assessment of circulating RAAS hormones showed no treatment-specific changes.

Conclusions: These results indicate mild HrU in Dahl SS rats attenuates HTN & renal damage without affecting RAAS. Our data suggest that HrU is not inherently detrimental but beneficial to cardiovascular & kidney health under certain conditions.

FR-PO404

Angiotensin II-Induced Cellular and Transcriptional Remodeling of Mouse Kidney Stroma

Jonathan W. Nelson, Susan B. Gurley. *Oregon Health & Science University, Portland, OR.*

Background: The kidney stroma consists of perivascular cells that play multiple crucial roles. Recent data have shown that murine kidney stromal cells abundantly express the type 1a angiotensin receptor, however, how these cells respond to AngII treatment is poorly understood. Moreover, the cellular heterogeneity of the kidney stroma has been poorly characterized at the molecular level because they comprise a small percentage of kidney cells.

Methods: Pdgfrb-creERT2 mice were crossed with the INTACT mouse to create Pdgfrb-INTACT mice which express GFP connected to the nuclear envelope protein. Pdgfrb-INTACT mice were implanted with osmotic minipumps containing either saline (Veh) or Angiotensin II (AngII, 1000ng/kg/min) for 21 days. Nuclei were extracted from kidneys followed by fluorescence activated nuclei sorting (FANS) and microfluidic partitioning (10X Genomics). After sequencing the resulting cDNA libraries and deconvolution (Cell Ranger) the dataset was dimensionally reduced, integrated, and evaluated for differentially expressed genes (DEGs) with Seurat.

Results: 16449 nuclei were sequenced (9644 from Veh; 6805 from AngII). Nuclei were enriched for expression of Pdgfrb and divided into 7 populations (**Figure A**): cortical fibroblasts, medullary fibroblasts, papillary fibroblasts, adaptive fibroblasts, contractile cells, mesangial cells, and cycling cells. Veh and AngII treated nuclei were present in all cell populations (**Figure B**), but not at the same proportion. Suggestive of AngII inducing myofibroblast remodeling, there was an increase in cycling cells (5 in Veh vs. 31 in AngII) with a concurrent decrease in contractile cells (1394 in Veh vs. 607 in AngII). While each population had a unique set of DEGs, one gene that was more abundant in AngII treated cells was Pde10a.

Conclusions: The mouse kidney stroma is transcriptionally diverse with significant cellular heterogeneity. AngII treatment alters both the cellular composition of the kidney stroma as well as the genes that are expressed within each cell population, highlighting the significant impact of AngII.

FR-PO405

Evidence of Estrogen Biosynthesis in the Rat Distal Nephron

Victoria L. Nasci, Sho Sugahara, Craig R. Brooks, Eman Y. Gohar. *Vanderbilt University Medical Center, Nashville, TN.*

Background: Estrogenic signaling via renal medullary G protein-coupled estrogen receptor 1 promotes sodium excretion in female, but not male, Sprague Dawley (SD) rats implicating estrogen as a potential female-specific natriuretic factor. Recently we showed that the components of estrogen biosynthesis pathway are expressed in rat kidney suggesting the kidneys can produce estrogen locally to invoke this natriuretic response. However, the renal localization and biological activity of aromatase (ARO), the key enzyme in estrogen synthesis, are still not fully clear. The goal of this study was to determine ARO abundance, localization, binding, and levels of ARO end products in male and female SD rat kidneys.

Methods: We utilized immunohistochemistry (IHC) and immunofluorescence (IF) to determine abundance and localization, a radiotracer to evaluate in vivo binding to ARO, and mass spectrometry to measure estrogens.

Results: IHC analysis revealed ARO was most abundant in cortex (CTX) and outer medulla (OM) with a less intense signaling in the inner medulla (IM) in both sexes (male: CTX 2.4 ± 0.31, OM 1.8 ± 0.19, IM 0.6 ± 0.15 p=0.0002; female: CTX 2.6 ± 0.27 OM 2.0 ± 0.21 IM 1.2 ± 0.31 p=0.0074 Average intensity x total area mM^2). IHC analysis of male and female kidney showed the expression of ARO primarily in the distal nephron with little staining in the proximal tubule and glomeruli. IF staining for ARO and aquaporin 2 showed colocalization indicating that ARO is expressed in the collecting duct. Preliminary positron emission tomography scan of female rats following tail vein injection of [^{11}C]-cetrozole, a radiolabeled ARO inhibitor, revealed binding, indicating ARO-rich regions, within the kidneys, but not the lungs or muscle (2.9 ± 0.16 vs 0.9 ± 0.31 & 0.4 ± 0.04 respectively p=0.0063 Standard uptake value). Estradiol and estrone were present in both male and female OM isolated from flushed kidneys (estradiol; 0.9 ± 0.15 vs 1.0 ± 0.21 p=0.7627, estrone; 0.2 ± 0.05 vs 0.3 ± 0.01 pg/mg tissue p=0.0630).

Conclusions: Overall, our investigation indicates the potential of the rat collecting duct as an extragonadal site for estrogen biosynthesis. Given the critical role of the collecting duct in fine tuning of sodium excretion, improving our understanding of the contribution of kidney-derived estrogens to renal sodium handling and hypertension could reveal novel antihypertensive therapeutic avenues.

FR-PO406

Low Cl- Diet Protects from Hypertension and Cardiac Hypertrophy After AngII Infusion in Mice Preserving Natriuresis

Luis F. Michea, Jessica C. Liberona, Pablo A. Leon. *ICBM Facultad de Medicina, Universidad de Chile, Santiago, Chile.*

Background: The increase of blood caused by Angiotensin II (AngII) depends on the expansion of vascular volume and the increase of total peripheral resistance. Besides acting as a vasoconstrictor, AngII increases renal Na^+ reabsorption. Chloride is reabsorbed as the accompanying anion of Na+ and modulates natriuresis, and extracellular Cl^- affects vascular smooth muscle cell contractility. We evaluated if low dietary Cl affected the pressor response to AngII infusion, cardiac hypertrophy, natriuresis, and vascular contractility.

Methods: C56BL/6J mice were allocated to 4 experimental groups: low-Cl diet (Cl replaced by HCO3, phosphate), normal-Cl diet (NaCl), AngII infusion (1.5 mg/Kg/day osmotic minipumps) or vehicle infusion (14 days). We measured systolic blood pressure (SBP) *by* the tail-cuff method. Natriuresis after a saline load (10% of body weight, i.p.) was assessed at baseline 4 and 14 days. Na+, K+ and Cl-excretion were measured (4 hours). We also measured cardiac hypertrophy and isotonic force development in aortic rings (high extracellular K+, phenylephrine) and NO-dependent relaxation.

Results: In normal-Cl^--diet mice, AngII infusion increased SBP from 103.3±9.1 mmHg to. 145.3±3.2 mmHg (n=6 per group, P<0.01 baseline vs. 14 days). In contrast, AngII infusion did not increase SBP in low-Cl diet mice (97.8±3.6 v/s 92.71±4.7 n=6 per group, n.s baseline vs. 14 days). Low Cl diet prevented cardiac hypertrophy after AngIi infusion (14 days). Normal Cl^--diet mice presented hampered natriuretic response after AngII infusion (8.8±1.7 vs. 4.1±2.1 uEq/4h/g BW, baseline vs. 14 days respectively, P<0.01). Low- Cl^--diet prevented the decrease in natriuresis after Ang II infusion (9.6±2.7 vs. 10.69±2.09 uEq/4h/g BW, baseline vs. 14 days respectively, P<0.01). AngII infusion increased the aortic rings maximal tension in response to phenylephrine, irrespective of dietary Cl. No changes in dose response to phenylephrine or Ach-induced NO-dependent vasodilation were observed among the groups.

Conclusions: Low Cl associated to a regular Na^+ content in diet prevented the increase of blood pressure and cardiac hypertrophy in response to AngII infusion. The protective action of a low Cl^- diet may be attributed to the protection of renal natriuretic response without affecting the vascular effects of AngII.

FR-PO407

Increased Epithelial Sodium Channel (ENaC) Activity Mediates Fructose-Induced Salt-Sensitive Hypertension

Ronghao Zhang,[1] Shujie Shi,[3] Thomas R. Kleyman,[3] Agustin Gonzalez-Vicente.[1,2] *[1]Case Western Reserve University, Cleveland, OH; [2]Cleveland Clinic, Cleveland, OH; [3]University of Pittsburgh, Pittsburgh, PA.*

Background: Elevated dietary fructose causes sodium retention and salt-sensitive hypertension. In a preliminary bioinformatics study on kidney cortexes from fructose-fed rats, we found an increase in aldosterone-responsive genes, which included subunits of the Epithelial Sodium Chanel (ENaC). Regulation of ENaC in the aldosterone sensitive distal tubule involves transcriptional and post-translational mechanisms, and is key to maintain electrolyte homeostasis and blood pressure. An important post-translational regulation of α-ENaC and γ-ENaC subunits is cleavage activation by luminal and intracellular proteases. We hypothesized that "dietary fructose increases ENaC subunits expression and cleavage, thereby contributing to sodium retention and salt-sensitive hypertension".

Methods: Sprague-Dawley rats were fed with matched diets containing 4% NaCl and either 20% fructose (FHS) or glucose (GHS) for up to 11 days. Protein expression and RNA transcripts abundance were measured in the kidney cortex by Western blotting and next generation sequencing, respectively. The expression of cleaved α-ENaC and γ-ENaC subunits was measured as surrogate of ENaC activation. The effect of inhibiting ENaC on blood pressure was assessed by tail-cuff plethysmography on rats given oral amiloride for 24h.

Results: Seven days after starting the diets, FHS presented higher abundance of both α-ENaC transcripts (Scnn1a gene; $\log_2$FC = 1.04; p = 0.01, n = 6) and proteins (121±20 vs. 64±10 normalized optical density (OD); Δ 90±34 %, p < 0.03, n = 6) as compared to GHS. No differences in either protein or RNA abundance were found for γ-ENaC or β-ENaC subunits. In addition, the expression of cleaved α-ENaC protein, was higher in FHS than in GHS (85±8 vs. 58±5 OD; Δ 48±16 %, p < 0.01, n = 6). Between days 5 and 10 of dietary intervention, FHS showed significantly higher systolic pressures than GHS (144±5 vs. 127±4 mmHg; Δ17±4 mmHg, p < 0.03, n=6). Oral amiloride from days 10 to 11 reduced systolic pressure in FHS by 10±4 mmHg (paired t-test: p ≤ 0.05), while caused no significant change in GHS (paired t-test: p = 0.23).

Conclusions: Rats consuming a diet rich in fructose and sodium, present increased expression and activity of ENaC than those eating a diet matched with glucose, contributing to the salt-sensitivity of blood pressure seen in this model.

Deficiency of Peroxiredoxin-4 and Dopamine D5 Receptor Increases NLRP3-Inflammasome Activity

Jacob Q. Polzin,[1] Bibhas Amatya,[1] Laureano D. Asico,[1] Ines Armando,[1] Robin A. Felder,[2] Pedro A. Jose,[1] Hewang Lee.[1] *[1]The George Washington University School of Medicine and Health Sciences, Washington, DC; [2]University of Virginia School of Medicine, Charlottesville, VA.*

Background: Dopamine 5 receptor (D_5R) interacts with Peroxiredoxin-4 (PRDX4) to reduce oxidative stress and inflammation. *Drd5* knockout (*Drd5*$^{-/-}$) mice are hypertensive and in a state of oxidative stress and chronic inflammation. However, the gene's specific association with the regulation of inflammasomal activity in the kidney is unknown.

Methods: To investigate inflammasomal activity, the protein expressions of interleukin (IL)-1β, IL-18, and caspase-1 were quantified by immunoblotting. The *PRDX4* gene was silenced in HEK 293 cells overexpressing D_5R. *Drd5*$^{-/-}$ mice were generated as previously reported.

Results: D_5R protein expression was decreased in *PRDX4* siRNA-transfected D_5R-HEK 293 cells (*PRDX4* siRNA: 58.8±6.7% vs Mock: 100.0±9.6%, n=4), and PRDX4 protein was also reduced in the kidney cortices of *Drd5*$^{-/-}$ mice (*Drd5*$^{+/+}$: 100±12.8%, n=3; $D_5R^{-/-}$: 69.2±7.5%, n=4). In D_5R-HEK 293 cells -transfected with *PRDX4* siRNA, the protein expressions of nucleotide-binding oligomerization domain, leucine-rich repeat, and pyrin domain-containing-3 (NLRP3) were increased compared with mock-transfected cells (siRNA: 142.7±8.9%, Mock: 100±1.8%). The protein expressions of cleaved IL-1β (siRNA: 176.3±37.0%, Mock: 100.0±12.7%) and cleaved IL-18 (siRNA:710.0±214.8%, Mock: 100±8.1%) were likewise increased compared with mock- transfected cells, indicating an increase in inflammatory response due to NLRP3 activity. The increase in NLRP3 activity with silenced *PRDX4* was attenuated by tempol, a superoxide dismutase mimetic, in D_5R-HEK293 cells, indicating that oxidative stress was upstream of the increase in NLRP3-associated inflammasomal activity induced by PRDX4 deficiency. Consequently, protein expression of cleaved caspase-1 was increased in renal cortices from *Drd5*$^{-/-}$ mice (*Drd5*$^{+/+}$: 100±2.6%; *Drd5*$^{-/-}$:112.6±3.1%, n=3). Consistent with this increase, the protein expressions of cleaved IL-1β (*Drd5*$^{+/+}$: 100.0±11.1%, n=3; *Ddr5*$^{-/-}$: 152.9±13.5%, n=4), secreted IL-1β (*Drd5*$^{+/+}$: 100.0±1.5%, n=3; *Drd5*$^{-/-}$:137.4±2.2%, n=4), and cleaved IL-18 (*Drd5*$^{+/+}$: 100.0±8.3%; *Drd5*$^{-/-}$:166.0±10.4%, n=3) were also increased compared with their wild-type littermates.

Conclusions: The increase in renal inflammation associated with PRDX4 deficiency in *Drd5*$^{-/-}$ mice is due to the increase in NLRP3-inflammasome activity.

FR-PO409

Renal ABCA1 Deficiency Induces TLR4 that Regulates Epithelial Sodium Channel (ENaC)

Karin Carneiro de Oliveira,[1,2] Yuan Wei,[1,2] Robert L. Repetti,[3] Rajeev Rohatgi.[2,1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]James J Peters VA Medical Center, Bronx, NY; [3]Northport VA Medical Center, Northport, NY.*

Background: Na sensitive blood pressure (BP) and restricted cholesterol (chol) efflux are risk factors for cardiovascular mortality. In preliminary studies, renal tubular ablation of ABCA1, a chol efflux protein, leads to greater systolic BP (SBP) vs control (WT) mice, while a low Na diet quenches this difference. Moreover, toll-like receptor 4 (TLR4) is stimulated by chol and associated with Na sensitive models. We hypothesize that TLR4 contributes to cation transport in an ABCA1 deficient model.

Methods: Transgenic mice, which express a doxycycline inducible CRE in tubules, were bred with mice expressing floxed ABCA1 to produce mice deficient in ABCA1 (FF). Western blotting of kidney and cortical collecting duct (mpkCCD) cell lysate was performed. Immunofluorescence (IF) was performed on kidneys and amiloride sensitive short-circuit current (*AIsc*) measured in mpkCCD cells.

Results: Mice were fed a 1% chol diet (X 6 weeks), a low Na and a high Na diet for 1 week each and then euthanized and kidneys extracted. TLR4 expression was enhanced in FF (1.9±0.3; n=3; p<0.05) vs. WT (1.0±0.2; n=3) kidneys. Phospho-ERK(pERK) was 2.3±1.3 (p=0.052) fold greater in FF(n=5) than WT(n=5) kidneys. IF of kidneys localized pERK to CDs while TLR4 was seen in CDs and non-CDs. Next, mpkCCD cells were incubated with PSC833 (PSC, 5 μM), an ABCA1 inhibitor, which increased abundance of pERK, (1.7±0.3; n=4; p<0.05) vs. untreated cells (1.0±0.2; n=4). Dual TLR4 antagonist (TAK242 10μM) and PSC suppressed γ-ENAC expression vs. untreated and PSC alone. While TAK242 did not affect *AIsc* in untreated mpkCCD cells, TAK242 repressed *AIsc* in PSC treated mpkCCD (11.2±2.2 μA/cm^2; n=6; p<0.05) vs PSC alone (17.1±3.1 μA/cm^2). Fluid shear stress (FSS) induces pERK, and ERK inhibition suppresses flow-induced in Na absorption (Repetti et al. 2021). The role of TLR4 signaling on FSS mediated Na transport was tested in mpkCCD cells. The *AIsc* in FSS (0.4 dynes/cm^2) exposed cells was greater (40.8±2.1 μA/cm^2;n=20, p<0.05) than in static cells (26.7±1.6 μA/cm^2; n=20) and the FSS induced *AIsc* was reduced (31.5±2.6 μA/cm^2; n=18, p<0.05 vs FSS exposed cells) by TAK242.

Conclusions: ABCA1 deficiency induces TLR4 and pERK abundance in renal CD while in mpkCCD cells exposed to FSS or ABCA1 inhibition sensitizes them to TLR4 dependent *AIsc*. We speculate repression of chol efflux enhances TLR4 dependent activation of pERK and *AIsc*.

Dysregulation of the Microbiome-Immune Axis Drives Cardiovascular Pathology in Early-Onset CKD

Johannes Holle,[1] Harithaa Anandakumar,[1] Anne Dueck,[2] Julia Schlender,[1] Valentin Vecera,[1] Dominik Müller,[1] Julia Thumfart,[1] Jun Oh,[3] Hendrik Bartolomaeus,[1] Nicola Wilck.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Technische Universitat Munchen, Munchen, Germany; [3]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany.*

Background: CKD patients have a high risk for cardiovascular disease (CVD). CKD-related chronic inflammation contributes to the increased CV risk. The underlying mechanisms are incompletely understood, but gut microbial dysbiosis seems to play an important role. Here, we describe the cardiovascular and immune phenotype of children with CKD and investigate the induction of these changes by CKD-typical microbiome alterations.

Methods: We analyzed the CV phenotype by echocardiography, carotid intima-media thickness (cIMT), measurements of blood pressure (BP) and pulse wave velocity (PWV) in 38 children (normal kidney function (HC), CKD stage G3-G4 (CKD), G5 treated by hemodialysis (HD)). Additionally, we performed CITE-seq enhanced single cell RNA sequencing (scRNAseq) and flow cytometry of peripheral immune cells, targeted plasma proteomics (OLINK) and shotgun sequencing of the fecal microbiome. Lastly, from a subset of HC and HD kids, we performed fecal microbiota transplantations into GF mice and analyzed the immunophenotype and vascular function.

Results: Children with CKD showed increased BP and PWV. Our echocardiographic analysis demonstrated increased cIMT, cardiac hypertrophy and diastolic dysfunction. Immune cell analysis by flow cytometry revealed a pro-inflammatory profile with a reduction of circulating regulatory T cells. This finding could be confirmed by scRNAseq. Additionally, we identified a stage-dependent dysregulate of transcriptomes within T cell populations from CKD and HD. Using the targeted proteomics of inflammatory markers, we found 55 out of 92 measured proteins to be dysregulated, with for example an increase in TNF, PD-L1 and MCP-1. Transfer of microbiota from HD patients or HC into germ-free recipient mice (C57BL6/J) promoted early signs of immune aging and a reduced endothelial dependent vasorelaxation.

Conclusions: In the absence of traditional CV risk factors, pediatric CKD leads to a measurable alteration of the CV system. Our analysis revealed a pro-inflammatory immune cell profile. Using fecal microbiome transplantation into germ-free mice, we provide preliminary evidence for a causal role of the microbiota in promoting inflammation and CV risk. Thus, the data highlight the importance of the microbiota-immune axis in CKD.

Independent Predictors of One-Year Quality of Life Trend in a Large Population of Hemodialysis Patients: Importance of Vascular Access Management

Carla Alexandra R. Santos Araujo,[1,2] Eliana Silva,[1] Israel P. Silva,[1] Mathias Haarhaus,[1] Carlos Lucas,[1] Suzanne H. Pearce,[1] Fernando Jose G. Macario.[1] *[1]Diaverum AB, Malmo, Sweden; [2]UnIC@RISE, Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal.*

Background: Health-related quality of life (QoL) is recognized as a relevant patient-centered outcome in hemodialysis (HD). Studies evaluating the trend of QoL with time in large populations are scarce. We aimed to evaluate the changes in QoL over a one-year period in a multinational HD population.

Methods: This was a multicenter prospective observational study using a quality database from a large HD organization. All adult patients that voluntarily responded to KDQOL-36 in 2021 and 2022 were included. Mental (MCS) and Physical Composite Scales (PCS) were analyzed and divided in two groups: Group I, increase in MCS and PCS by more than 5 points; Group II, decrease in both scores. At the time of the first survey, demographic (age, gender) and clinical data (diabetes, comorbidity index - CI, vascular access) were collected. Death was registered until 6 months after the second survey. T-test and z-test were performed for group comparisons. Multivariate logistic regression, Kaplan Meyer and Cox regression for survival analysis were also used.

Results: 20 006 HD patients with valid responses to both KDQOL-36 were included. Increase on both scores was observed in 2381 patients (11.9% of surveys) and decrease in 2051 (10.3%). Group I patients were significantly younger, less diabetic, had a lower CI, higher percentage of fistulas and lower time on dialysis. A significantly higher number of deaths at 6 months were observed in Group II (6.5% vs. 4.2%, p<0.005). In multivariate analysis, age and the presence of a fistula were independently associated with global QoL improvement, whereas female gender and diabetes were independent predictors of QoL decrease. Six-month mortality was associated with worsening of QoL. Males and diabetic patients in Group I and older and diabetic patients in Group II presented significant higher hazard ratios of death.

Conclusions: In our HD population, one-year trend of QoL scores were associated with several demographic and clinical variables, allowing us to define and target specific interventions on a group at risk for rapid QoL decrease. The presence of a fistula was a predictor of QoL improvement, confirming the importance of vascular access management in the global outcomes of HD patients.

FR-PO412

One-Year Quality of Life Trend in a Large Population of Incident Hemodialysis Patients

Carla Alexandra R. Santos Araujo,[1,2] Eliana Silva,[1] Israel P. Silva,[1] Mathias Haarhaus,[1] Carlos Lucas,[1] Suzanne H. Pearce,[1] Fernando Jose G. Macario.[1] *[1]Diaverum AB, Hyllie, Sweden; [2]UnIC@RISE, Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal.*

Background: Health-related quality of life (QoL) is an important outcome in prevalent hemodialysis (HD) patients, but the evolution in the first months of treatment is still to be explored. We aimed to evaluate the 1-year changes in QoL in incident patients in a large, multinational HD population.

Methods: This was a multicenter prospective observational study. All adult patients with less than 3 months on HD that voluntarily responded to KDQOL-36 in 2021 were selected and included after the response to the 2022 survey. Mental (MCS) and Physical Composite Scales (PCS) were analyzed. At the time of the first survey, demographic (age, gender) and clinical data (diabetes, comorbidity index - CI, vascular access) were collected. T-test, z-test and multivariate logistic regression were used for statistical analysis.

Results: 1 401 HD patients with valid responses to both KDQOL-36 were included. QoL reported on HD admission was low: PCS=36.73±9.05 and MCS=44.07±10.29. In multivariate analysis, female gender and CI were independently associated with a poorer QoL at baseline, whereas diabetes was positively correlated with MCS but not with PCS. In the second survey, a significant increase in QoL was documented: PCS=38.75±9.77, p<0.01 and MCS=46.09±10.20, p<0.01. Increase in both scales after 1-year was observed in 234 patients (16.7% of surveys) and a decrease in 112 (8.0%) with the remaining presenting mixed results. The group with improvement in QoL was significantly younger, had a higher percentage of fistulas and lower prevalence of diabetes, when compared to the group with a decrease in both scales. In multivariate analysis, diabetic status was associated with PCS improvement after 1-year, whereas male gender was an independent predictor of PCS decrease.

Conclusions: In our incident HD patients, QoL was poor at baseline, but increased during the first months on dialysis. Diabetes was associated with QoL improvement, despite the low baseline values normally reported by this population, suggesting that HD may positively impact on QoL of diabetic patients with advanced renal disease. Despite the higher scores at baseline, male patients were more prone to QoL decrease during the first year, alerting for the importance of following QoL through time after the beginning of HD.

FR-PO413

Association Between Perceived Social Support and Health-Related Quality of Life in Hemodialysis Patients: Results from the TACcare Study

Sarah J. Erickson,[1] Jonathan Yabes,[2] Maria-Eleni Roumelioti,[1] Zhuoheng Han,[2] Jennifer L. Steel,[2] Mark L. Unruh,[1] Manisha Jhamb.[2]
[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]University of Pittsburgh, Pittsburgh, PA.

Background: In patients with End Stage Kidney Disease (ESKD), high symptom burden and the demands of thrice weekly hemodialysis (HD) contribute to limitations in their daily lives, including a negative impact on their interpersonal relationships. However, there is limited research exploring associations of social support with symptom burden and health related quality of life (HRQoL) among HD patients.

Methods: The Technology Assisted stepped Collaborative Care (TACcare) was a randomized controlled trial to compare the effectiveness of a stepped collaborative care intervention for symptom management in chronic in-center HD patients. The current study is a secondary, cross-sectional analyses of baseline data to examine the sociodemographic and clinical factors that affect perceived social support (Multidimensional Scale of Perceived Social Support; MSPSS), and its association with symptom burden and HRQoL (SF-12 Mental Component Score (MCS) and Physical Component Score (PCS).

Results: For the 160 randomized patients: mean (SD) age 58 ±14 years; 45% female; 28% Black, 13% American Indian, 18% Hispanic; 88 % high school education; 27% married; 4 ± 4 years on dialysis. Mean baseline levels of MSPSS from family, friends, significant other, and total were: 21.3 (5.5), 19.8 (6.1), 22.0 (5.3), and 63.1 (14.0), respectively, comparable to other chronically ill populations. High school education ($p = .04$) and being married ($p = .05$) were associated with higher total MSPSS scores. Higher MSPSS scores were correlated with lower levels of fatigue ($r = .21$, $p < .01$), pain ($r = -.17$, $p = .03$), depressive symptoms ($r = -.23$, $p < .01$), anxiety ($r = -.23$, $p < .01$), and better sleep quality ($r = -.32$, $p < .001$). Higher family, friend, significant other, and total MSPSS support scores were all associated with higher MCS ($r = .20$, $p = .01$; $r = .25$, $p < .01$; $r = .20$, $p = .01$; and $r = .26$, $p < .001$, respectively); and higher MSPSS friend support was associated with higher PCS ($r = .2$, $p = .04$). After adjusting for age, sex, race, ethnicity, and Charlson comorbidity index, MSPSS total scores were associated with MCS (beta=0.17, $p = .001$).

Conclusions: Because of the associations between MSPSS and HRQoL, particularly mental health, social support appears to be an important intervention target.

FR-PO414

Quality-of-Life Penalty Associated with Anemia of CKD in a Large Sample of Dialysis Patients

Jasmine Ion Titapiccolo,[1] Francesco Bellocchio,[1] Stefano Stuard,[1] Len A. Usvyat,[2] Luca Neri.[1] *[1]Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy; [2]Fresenius Medical Care, Waltham, MA.*

Background: Anemia of chronic kidney disease (ACD) is a common complication in dialysis and it is associated with fatigue and weakness, possibly leading to quality of life impairment. Previous reports are old and may not account for recent improvement in renal care. We used the Kidney Disease Quality of Life Short Form (KDQOL-36) questionnaire to assessing the health-related quality of life penalty associated with anemia in a large sample of dialysis patients.

Methods: We enrolled 9067 patients from 8 European countries. We assessed the severity of anemia by 5 hemoglobin concentration classes based on the last laboratory assessment available prior to survey administration. We fitted generalized linear models assessing the relationship between each KDQOL-36 subscale and the severity of ACD. We adjusted for age, vintage, gender, country of residence, and comorbidities. We accounted for multicenter design by including a random-intercept parameter. In a secondary analysis we also adjusted for ferritin and inflammatory indexes.

Results: We observed lower KDQOL-36 scores among patients with severe anemia ($p < 0.05$) (see Table 1). We observed a mild, graded association between mental composite, physical composite and symptoms scale and anemia severity. Despite statistically significant, the Quality of Life penalty associated to ACD was modest and barely clinically significant based on MCID standards. No significant differences were found in the BKD and EKD domains among the anemia groups. By adding ferritin and inflammatory indexes as confounding factors, the significance disappears in all scores.

Conclusions: Anemia of CKD is associated with modest quality of life impairment. Our study suggests that this association may be driven by iron deficiency and inflammation.

	Hb: <8 g/dl	Hb: 8-10 g/dl	Hb: 10-12 g/dl	Hb: >12 g/dl & ESA+	Hb: >12 g/dl & ESA-	p-value

QOL scores mean values in each level of anemia. Mean values are reported with corresponding confidence intervals (CI).

FR-PO415

Trust in Physicians Among Hospitalized Patients Receiving Maintenance Dialysis: Prevalence and Correlates

Spencer Dahl,[1] Musaib Syed,[1] Basil S. Kazi,[2] Fahad Saeed.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]University of Illinois Chicago, Chicago, IL.*

Background: Trust between physicians and patients is crucial for a therapeutic patient-physician relationship and effective healthcare delivery. However, there is limited research on the prevalence and correlates of physician trust in chronic disease populations, especially among acutely ill hospitalized individuals receiving maintenance dialysis.

Methods: We surveyed 223 hospitalized individuals undergoing maintenance dialysis (59% response rate) at Strong Memorial Hospital, an academic tertiary care center. Our sample included 120 patients (53%) over 65 years, 105 women (47.1%), and 91 (41%) White, 82 (37%) Black/African American and 36 (16%) patients from other self-identified racial groups. Patients had been on dialysis for an average of 3.16 years (SD ± 2.369, IQR 1-4). Physician trust was assessed using the validated Primary Care Assessment Survey (PCAS) trust scale. Dependent variables included quality of life measured by Kidney Disease Quality of Life Scale (KDQOL-36) and 30-days self-reported hospitalizations. Co-variates, included age, gender, race, education, annual household income and time on dialysis.

Results: Out of the 223 respondents, 72 (32%) reported not trusting their doctor, and 91 (41%) reported not trusting their doctor's judgments about their medical care. Linear regression analysis revealed a statistically significant correlations between trust and symptom burden subscale (estimate 0.10, CI 0.05-0.016, $p<0.0002$) and number of hospitalizations in the last 30 days (estimate -0.56, CI -1.08, -0.03, $p<0.037$). Female participants reported lower trust scores than their male counterparts (estimate -1.56, CI -3.07, -0.05, $p<0.043$).

Conclusions: Mistrust of physicians is prevalent among hospitalized patients receiving dialysis care. Hospitalized women receiving maintenance dialysis were more likely to mistrust their physicians than men. Higher trust scores were associated with lower symptom burden while lower scores were associated with greater number of hospitalizations in the last 1 month. Interventions to improve patient-physician communication and patients symptoms may improve trust.

FR-PO416

Self- and Observer-Rated Computer-Based Cognitive Function and Abilities Tests Are Valid for Dialysis Patients

Krister Cromm,[1,2] Özlem K. Tunçel,[3] Mirja Humpert,[1] Le Hong Ngoc Pham,[1] Tatiana De los Ríos,[1] Yusuf Çelik,[4] Ismail Agirbas,[5] Tugce Bedel,[3] Sibel Kaletas,[3] Gulay Asci,[3] Carrie R. Houts,[6] RJ Wirth,[6] Ercan Ok,[3] Hayriye Elbi.[3] DOPRO. *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Ege Universitesi, Izmir, Turkey; [4]Marmara Universitesi, Istanbul, Turkey; [5]Ankara Universitesi, Ankara, Turkey; [6]Vector Psychometric Group, LLC, Chapel Hill, NC.*

Background: Cognitive Function and Abilities (CFA) are important factors in health-related quality of life (HRQOL) of dialysis patients and a prerequisite for performing hemodialysis (HD) at home. Congruence of self- and observer-reported CFA is debated for assessment in clinical trials. The purpose of the study was to support the use of a CFA measure in Turkish HD patients.

Methods: We translated the 31-item PROMIS (Patient-Reported Outcomes Measurement Information System) CFA (PROMIS-CFA) subset according to FACIT methodology. PROMIS-CFA was filled in electronically by participants, Addenbrooke's Cognitive Examination-Revised (ACE-R) was assessed by psychologists at the same time during dialysis sessions. HRQOL was assessed with KDQOL-SF. Psychologist called participants on the next day for 16-item Telephone Cognitive Screen (T-Cog-S). Among 1164 patients treated in the 7 dialysis clinics, eligible patients were screened, and 151 in-center conventional HD and 26 home HD patients were randomly selected.

Results: The final sample was composed of 63 females and 114 males with an average age of 55.5±13.4. The average time since kidney disease diagnosis was 10.4±8.2 years and the average time on dialysis was 74.4±66 months. Thirty-four patients had mild cognitive impairment based on categorized ACE-R scores. The internal consistency (Cronbach's α) for the PROMIS-CFA was .96 and the observed test-retest intraclass correlation coefficient over approximately 7 days was r=.70. There were significant but low correlations (r=.2-.28) between ACE-R and PROMIS-CFA scores, but higher correlations with HRQOL (r=.15-.44). T-Cog-S significantly correlated with ACE-R (r=.55), but not PROMIS-CFA.

Conclusions: The Turkish translation of PROMIS-CFA is reliable and may support valid inferences regarding cognitive functioning and abilities in this population. Self-rated CFA is more closely related to HRQOL than observer-rated CFA. Future outcome studies should therefore include both assessments in larger samples. Telephone interviewing with T-Cog-S was not an alternative to clinical evaluation in detecting cognitive impairment due to high ceiling effects.

FR-PO417

Improved Quality of Life in Postdilution Compared to Predilution Hemodiafiltration in a European Cohort of Dialysis Patients

Mathias Haarhaus,[1,2] Carla Alexandra R. Santos Araujo,[1,3] Eliana Silva,[1] Carlos Lucas,[1] Israel P. Silva,[1] Suzanne H. Pearce,[1] Fernando Jose G. Macario.[1] *[1]Diaverum AB, Malmö, Sweden; [2]Karolinska Institutet, Stockholm, Sweden; [3]UnIC@RISE, Department of Surgery and Physiology, Faculty of Medicine, University of Porto, Porto, Portugal.*

Background: Predilution and postdilution hemodiafiltration (HDF) affect solute removal differently, but the effect on patient reported outcomes is not well described. We describe differences in quality of life in prevalent hemodialysis (HD) patients with predilution and postdilution HDF.

Methods: In a cross-sectional study of 18.018 European prevalent HD patients from an international dialysis network, we identified 5.227 patients with HDF. All 317 patients with predilution HDF were compared to 317 propensity-score matched patients with postdilution HDF. KDQOL-36 results were compared between groups. Multivariable regression models were used to identify independent predictors of symptom/problem list, physical health composite (PHC), and mental health composite (MHC).

Results: Patients were comparable with respect to age, gender, diabetes, comorbidity, vascular access, dialysis vintage, and BMI. Patients with postdilution HDF demonstrated better results for symptom/problem list, PHC, MHC, and most KDQOL SF-36 domains (Figure 1). Multivariable regression revealed independent associations of predilution HDF with lower results for symptom/problem list (coefficient B (95% confidence interval) -6.6 (-9.5 - -3.7), p<0.001), PHC (-3.1 (-4.6 - -1.6), p<0.001), and MHC (-2.4 (-4.1 - -0.7), p=0.006).

Conclusions: We demonstrate improved quality of life in postdilution, compared to predilution HDF in a cross-sectional analysis of a multinational European prevalent hemodialysis population.

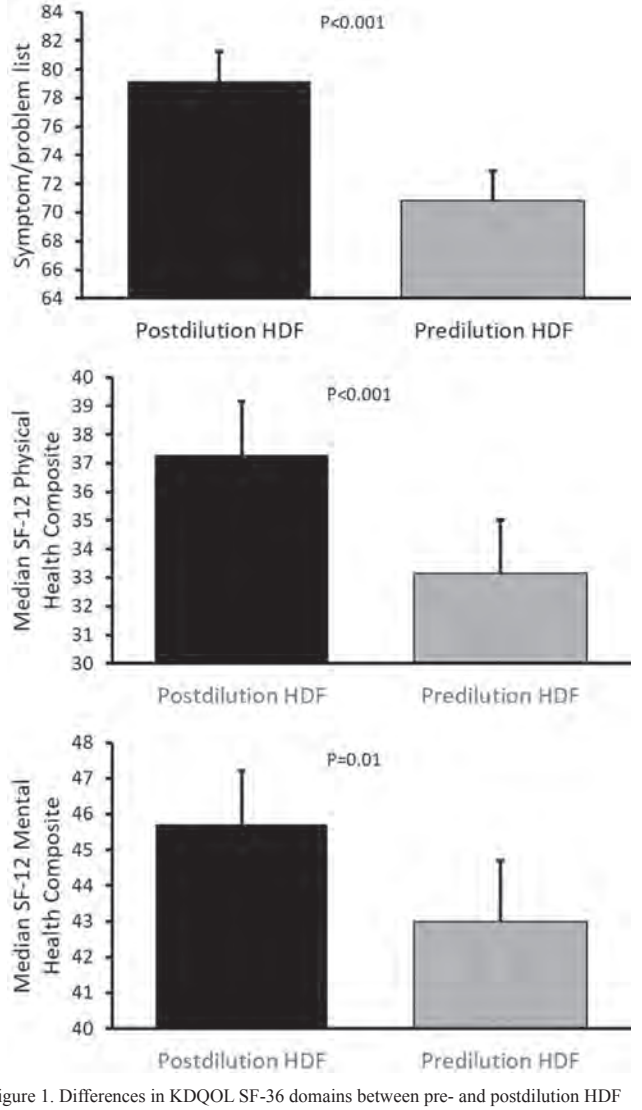

Figure 1. Differences in KDQOL SF-36 domains between pre- and postdilution HDF

FR-PO418

Psychometric Validation of the CONVINCE Inter- and Intradialytic Symptoms Questionnaire

Le Hong Ngoc Pham,[1] Krister Cromm,[2,1] Yan Zhang,[1] Anna Schappert,[2] Gregor Liegl,[2] Kathrin I. Fischer,[2] Felix Fischer,[2] Matthias Rose.[2] CONVINCE Scientific Committee and CONVINCE Investigators. *[1]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Symptom assessment, especially from the patient perspective, is crucial in dialysis treatment. A comprehensive questionnaire is needed that covers different symptom types. In the CONVINCE study, we developed a survey based on the KDQOL symptoms scale with an adapted recall period of 7 days for interdialytic symptoms and extended inter- and intradialytic (IDS) items based on literature review and patient interviews.

Methods: Patient-reported outcomes data of 1264 hemodialysis patients were extracted from CONVINCE, an international randomized controlled trial comparing high-dose hemodiafiltration with high-flux hemodialysis, including baseline and quarterly follow-up data up to 24 months. The IDS questionnaire consists of 17 items covering interdialytic symptoms (11 based on KDQOL-36) and 5 newly developed items mainly covering intradialytic symptoms. Reliability, item, and validity analyses were conducted to assess the psychometric properties of the questionnaire. Correlations between IDS and Health-Related Quality of Life (HRQL) domains, measured with the PROMIS questionnaires, were calculated.

Results: Reliability analyses showed high internal consistency, stable over time (Cronbach's α=.86 at baseline, .85-.90 for follow-up visits). Most item-total correlations yielded values from .37-.73, indicating good relationships between individual items and overall score. Item difficulty ranged from .14-.73, revealing a diverse range, ensuring coverage of the symptom spectrum. The survey also showed good validity as correlations between HRQL domains and IDS ranged from .36 to .61. Factor analyses identified 3 symptom clusters (Table 1).

Conclusions: The IDS questionnaire demonstrated good psychometric properties which supports its use in clinical and research settings. By providing a more comprehensive assessment, it is a useful improvement to the KDQOL symptoms scale. Symptoms identified with the questionnaire could be managed in clinical practice and help tailor individualized care.

FR-PO419

Patient-Perceived Benefit of Relief from CKD-Associated Pruritus

Steven Fishbane,[1] Thilo Schaufler,[2] Despina Ruessmann,[2] Isabelle Morin,[2] Frederique Menzaghi,[3] James Burton.[4] *[1]Northwell Health, Great Neck, NY; [2]CSL Vifor, Glattbrugg, Switzerland; [3]Cara Therapeutics Inc, Stamford, CT; [4]University of Leicester Department of Cardiovascular Sciences, Leicester, United Kingdom.*

Background: Chronic kidney disease-associated pruritus (CKD-aP) is a substantial burden for the physical and mental well-being of patients with kidney failure. Various instruments have been utilized to assess the impact of itch relief in clinical trials, but regular use in dialysis practice is still uncommon.

Methods: Phase-3 double-blind, placebo-controlled clinical studies KALM-1 and KALM-2 evaluated the use of IV difelikefalin (DFK) after each dialysis session for 12 weeks compared to placebo (Pbo). Itch intensity at baseline was assessed with the weekly average of the Worst Itching Intensity Numerical Rating Scale (WI-NRS, range 0 [no itch] to 10 [worst itch imaginable]) and defined as moderate (KALM-1: >4 to <7; KALM-2 ≥5 to <7; N=378) or severe (≥7; N=473). The 5-D Itch scale (range 5 to 25) assessed itch-related quality of life (QoL) and the Patient Global Impression of Change (PGIC) asked patients after 12 weeks how their itch changed (1 [very much improved] to 7 [very much worse]).

Results: A greater percentage of patients achieved a clinically meaningful improvement on the WI-NRS and 5-D Itch with DFK vs. Pbo. More patients with moderate compared to severe CKD-aP at baseline reported an improvement on the PGIC. While PGIC benefit was relatively consistent with WI-NRS and 5-D Itch for severe patients, it was 1.3 to 1.5 times higher for patients with moderate CKD-aP.

Conclusions: While relatively fewer patients with moderate vs. severe CKD-aP reported clinically meaningful improvements on validated scales WI-NRS and 5-D Itch, the share reporting that they feel very much or much improved is notably higher. Asking

patients verbally for their perceived improvement could therefore be more meaningful than clinical scales in daily dialysis practice.

FR-PO420

Exploring the Skin Symptom Cluster in a Prevalent Hemodialysis (HD) Cohort: The Dominance of CKD-Associated Pruritus and the Association with Fatigue

Katherine L. Hull,[1,2] Namrata Joshi,[1] Angus C. Jennings,[1] Roseanne Billany,[1] Daniel S. March,[1] Matthew Graham-Brown,[1,2] James Burton.[1,2] *[1]University of Leicester College of Life Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

Background: Haemodialysis (HD) patients have a high symptom burden. Dominant symptoms may precipitate or intensify others, generating a symptom cluster: the co-existence of ≥2 symptoms. This work explores the *skin symptom cluster* (itching, restless legs, skin changes, difficulty in sleeping) in prevalent HD patients.

Methods: We present prospective symptom data (POS-S Renal) from the CYCLE-HD trial (ISRCTN11299707). Spearman's rank correlations were considered, alongside linear regression (cluster sum score) and proportional odds logistic regression (fatigue sub-score), both adjusted for age, sex, dialysis vintage and BMI.

Results: 118 participants provided symptom data. 77 (65.3%) participants reported ≥2 skin cluster symptoms at baseline. There were positive correlations between each symptom in the skin cluster (all coefficients ≥0.36). A one point difference in baseline itch was associated with a 0.87 increase in total skin cluster score at 6-months; these data, as well as relationships with other symptoms in the cluster, are outlined in Table 1. 70 (59.3%) participants reported fatigue alongside ≥2 skin cluster symptoms at baseline. A unit increase in the skin cluster score at baseline was associated with a 16.1% (3.6-30.1%) higher odds of one unit increase in fatigue at 6-months.

Conclusions: Reporting of symptoms from within the skin cluster is common in the HD population. CKD-aP is the predominant symptom in predicting the persistence and exacerbation of the skin cluster. The skin symptom cluster and fatigue often co-exist and are interdependent. This highlights the importance of elucidating symptom clusters in routine care to improve management of intrusive symptoms.

Funding: Other NIH Support - CYCLE-HD was funded by the National Institute of Health and Care Research (NIHR)

FR-PO421

The Impact of Intradialytic Cycling on the Symptom of CKD-Associated Pruritus

Namrata Joshi,[1] James Burton,[1,2] Angus C. Jennings,[1] Lucy O. Abell,[1] Roseanne Billany,[1] Daniel S. March,[1] Matthew Graham-Brown,[1,2] Katherine L. Hull.[1,2] *[1]University of Leicester College of Life Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom.*

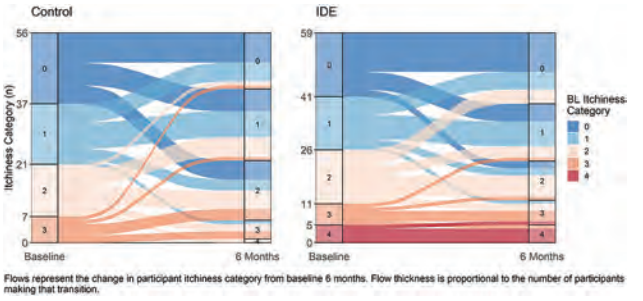
Background: CKD associated pruritus (CKD-aP) is an extremely common symptom amongst haemodialysis (HD) patients. The pathophysiology of CKD-aP is complex and multifactorial; chronic inflammation has been hypothesised as a key contributor. Individuals on maintenance HD experience high levels of chronic inflammation. Previous research has demonstrated that regular intradialytic exercise (IDE) may have an anti-inflammatory effect. This suggests that IDE may reduce levels of CKD-aP in the HD population. This work aimed to ascertain the effect of 6-months of regular IDE on CKD-aP.

Methods: Post hoc analyses of data from the CYCLE-HD (ISRCTN11299707) study. 130 HD patients were randomised to standard care or IDE for 6-months. Data regarding CKD-aP were available from 118 participants who completed the Palliative care Outcome Scale-Symptoms (POS-S) Renal at baseline and 6-months. Statistical testing included proportional odds logistic regression adjusting for baseline itch, age, sex, dialysis vintage and baseline BMI.

Results: At baseline CKD-aP was present in 68.1% of participants (control=66.1%, IDE=70.0%). CKD-aP was classified as mild (27.1%, n=32), moderate (24.6%, n=29), severe (11%, n=13), and overwhelming (3.4%, n=5). There was no statistically significant impact of group assignment on 6-month itchiness; however, the odds of a one category increase in CKD-aP severity was lower (13%) in participants assigned to the IDE group after 6-months (OR=0.87, 95% CI: 0.42, 1.81; p=0.7163). Alluvial plots (Figure) of baseline vs 6-month CKD-aP score categorised by group further demonstrated that group assignment had no marked impact on CKD-aP severity at 6-months.

Conclusions: These results demonstrate that CKD-aP is common in the HD population and 6-months of IDE did not impact on the prevalence or severity. As such, pharmacotherapy should be considered as a primary treatment option.

Funding: Other NIH Support - CYCLE-HD was funded by the National Institute of Health and Care Research (NIHR)



Alluvial plots demonstrating group assignment did not significantly impact CKD-aP severity at 6-months

FR-PO422

The Utilization of Gabapentin and Pregabalin for the Treatment of CKD-Associated Pruritus and Other Indications in Manitoba

Silvia J. Leon Mantilla,[1] Reid Whitlock,[1] Oksana Harasemiw,[2] Michelle S. DiNella,[1] Gerald Miciak,[3] Clara Bohm,[2] Paul Komenda,[2] Navdeep Tangri,[2] David T. Collister,[2] Claudio Rigatto.[2] *[1]Seven Oaks General Hospital, Winnipeg, MB, Canada; [2]University of Manitoba, Winnipeg, MB, Canada; [3]Otsuka Canada Pharmaceutical Inc, Saint Laurent, QC, Canada.*

Background: Chronic kidney disease-associated pruritus (CKD-aP) frequently affects patients on dialysis, is associated with reduced quality of life, and was identified as a research priority by patients. Until recently there were no approved treatments for CKD-aP, which was often treated with off-label therapies. Systematic reviews published in 2017-2020 identified GABA (gabapentin, pregabalin) analogues as having evidence for efficacy. This real-world study describes the prescription patterns for GABA over time and their frequency of use for CKD-aP.

Methods: Retrospective cohort study using administrative health data from Manitoba, Canada (>1.2 million residents). We included all adults (≥ 18 years) who received an incident prescription for a GABA between January 1st, 2012, and March 31st, 2022. We calculated the yearly prescription rate per new user for each GABA in total and for each of the following indications: neuropathy, seizure, fibromyalgia, restless legs syndrome (RLS), and chronic pain. Finally, we estimated the total and annual percentage of GABA prescribed for CKD-aP in the chronic dialysis population (defined as dialysis for 90 consecutive days with no gaps >15 days between sessions).

Results: In the study period, there were 125,881 GABA analogue users (adults aged 18 and over). Gabapentin was more commonly prescribed (85%) than pregabalin (15%). The number of new GABA prescriptions increased from 11,301 in 2012 to 12,031 in 2021. Only 0.7% of these were prescribed to treat CKD-aP. There were 4,028 chronic dialysis patients included. Indications for GABA prescriptions in this group were fibromyalgia (24%), seizures (12%), neuropathic pain (9%), RLS (10%) and CKD-aP (19%). Patients receiving GABA for CKD-aP were mostly men (57%) and were older (mean age 60 vs 56 years) than those in the general population. There was a decrease in the proportion of dialysis patients receiving GABA for CKD-aP from 2017 to 2020 (4% to 2.6%) with an increase in 2021 (4%).

Conclusions: GABA are rarely used for CKD-aP (0.7% of all GABA use), despite evidence of efficacy. We speculate that safety concerns may limit GABA use. Further studies of the risks:benefit of GABA analogues in CKD-aP are needed.

FR-PO423

Continued Improvement of Itch-Related Quality of Life in CKD-Associated Pruritis (CKD-aP) Patients Treated with Difelikefalin

Joel M. Topf,[1] Thilo Schaufler,[2] Meg Jardine,[3] Despina Ruessmann,[2] Isabelle Morin,[2] Frederique Menzaghi,[4] Kieran Mccafferty.[5] *[1]Oakland University William Beaumont School of Medicine, Auburn Hills, MI; [2]CSL Vifor, Glattbrugg, Switzerland; [3]NHMRC Clinical Trials Centre, Sydney, NSW, Australia; [4]Cara Therapeutics Inc, Stamford, CT; [5]Barts Health NHS Trust, London, United Kingdom*.

Background: Chronic kidney disease-associated pruritus (CKD-aP) is a serious complication seen in patients with kidney failure. Difelikefalin (DFK) has been approved to treat moderate-to-severe CKD-aP in adults on hemodialysis (HD) based on KALM-1 and KALM-2 randomized, double-blind, placebo (Pbo)-controlled phase-3 trials.

Methods: In KALM trials HD patients received either IV DFK or Pbo 3x per week (wk) for 12 wks followed by an up to 52 wks open-label extension (OLE) with all patients receiving DFK. Baseline itch intensity was defined based on the weekly average of the Worst Itching Intensity Numerical Rating Scale (WI-NRS, range 0 [no itch] to 10 [worst itch imaginable]) as moderate (KALM-1: >4 to <7; KALM-2 ≥5 to <7) or severe (≥7). Itch-related quality of life (QoL) was assessed by the validated 5-D Itch scale (range 5 to 25). This analysis assesses the 5-D Itch total score at the end of the DB period and wk 12 of the OLE.

Results: At wk 12 patients treated with DFK achieved a significantly greater improvement of QoL compared to Pbo, independent of baseline itch intensity ($p < .001$). After an additional 12 wks therapy in the OLE patients continued to improve, independent of prior exposure to DFK or Pbo and those with severe vs. moderate itch at baseline saw a numerically greater improvement of 5-D Itch scores. Differences between the groups were no longer statistically significant.

Conclusions: Patients with severe CKD-aP benefit from continued treatment with DFK. After an additional 12 wks of treatment they achieve a similar level of benefit as patients with moderate itch severity.

FR-PO424

Assessing the Quality of Life in Hemodialysis Patients with CKD-Associated Pruritus in Clinical Practice

Kamyar Kalantar-Zadeh,[1] Thilo Schaufler,[2] Joerg Latus,[3] Despina Ruessmann,[2] Isabelle Morin,[2] Frederique Menzaghi,[4] Kieran Mccafferty.[5] *[1]Harbor-UCLA Medical Center, Torrance, CA; [2]CSL Vifor, Glattbrugg, Switzerland; [3]Robert-Bosch-Krankenhaus GmbH, Stuttgart, Germany; [4]Cara Therapeutics Inc, Stamford, CT; [5]Barts Health NHS Trust, London, United Kingdom*.

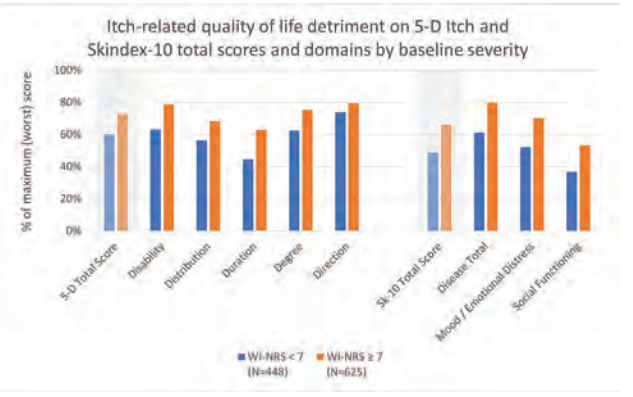
Background: The detrimental impact of chronic kidney disease-associated pruritus (CKD-aP) on the quality of life (QoL) of hemodialysis (HD) patients has been well established in epidemiologic studies. However, diagnosis of CKD-aP and its consequences is not yet routine dialysis practice and no standard instrument is established.

Methods: KALM-1, KALM-2 and 3105 are phase-3 clinical studies evaluating safety and efficacy of difelikefalin in adult HD patients with moderate to severe CKD-aP. Itch intensity at baseline was assessed with the weekly average of the Worst Itching Intensity Numerical Rating Scale (WI-NRS, range 0 [no itch] to 10 [worst itch imaginable]) and defined as moderate (KALM-1: >4 to <7; KALM-2 and 3105 ≥5 to <7; N=448) or severe (≥7; N=625). We set out to compare the association between itch severity and QoL domains in this cohort. Itch-related QoL at baseline was assessed with Skindex-10 (Sk-10; range 0 to 60) and 5-D Itch (5-D; range 5 to 25) scales with higher values indicating worse impact on itch-related QoL.

Results: Patients experiencing moderate / severe itch reported scores of 15.0 / 18.2 (5-D) and 29.3 / 39.7 (Sk-10), equivalent to 60.1% / 72.8% and 48.8% / 66.2% of the maximum for the corresponding scale respectively. Individual domains show a similar pattern. 5-D domains are relatively evenly balanced with Duration being an outlier at the lower end. Sk-10 was most influenced by the disease domain (Figure).

Conclusions: Either instrument can be useful in clinical practice: Sk-10 to complement WI-NRS with a differentiated measure of QoL and 5-D as a standalone option by combining itch intensity and impact on daily activities.

Funding: Commercial Support - CSL Vifor



FR-PO425

Real-World Experience with Difelikeaflin to Treat CKD-Associated Pruritus at a Large Dialysis Organization

Despina Ruessmann,[1] Juliana H. Oliveira,[1] Hans-Juergen Arens,[3] Rachel A. Lasky,[2] Michael S. Anger,[2] Linda Ficociello.[2] *[1]Vifor Pharma Management Ltd, Glattbrugg, Switzerland; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany*.

Background: Chronic kidney disease-associated Pruritus (CKD-aP), is a common and burdensome symptom in dialysis patients, however it is often overlooked and underestimated. Difelikefalin (DFK) has been shown in phase 3 clinical trials to decrease pruritus among hemodialysis (HD) patients with moderate to severe CKD-aP after 12 weeks of treatment. The goal of this retrospective database analysis is to assess the effectiveness and prescription pattern of DFK in reducing pruritus in HD pts in routine clinical care.

Methods: Patients (Pts) included in the analysis were Fresenius Kidney Care in-center HD pts aged 18-89 who received >1 dose of DFK before 11/15/2022 and were administered >1 Worst Itching Intensity Numerical Rating Scale (WI-NRS) assessment before first DFK administration. Pts who received >30 DFK administrations within 74-84 days were classified as Complete Regimen Group (CRG), while pts with fewer administrations were Incomplete Regimen Group (IRG). Changes in itch were measured by WI-NRS at 12 weeks compared to the baseline (before DFK start). Safety events were collected through routine post-marketing pharmacovigilance reporting methods.

Results: Patients (Pts) included in the analysis were Fresenius Kidney Care in-center HD pts aged 18-89 who received >1 dose of DFK before 11/15/2022 and were administered >1 Worst Itching Intensity Numerical Rating Scale (WI-NRS) assessment before first DFK administration. Pts who received >30 DFK administrations within 74-84 days were classified as Complete Regimen Group (CRG), while pts with fewer administrations were Incomplete Regimen Group (IRG). Changes in itch were measured by WI-NRS at 12 weeks compared to the baseline (before DFK start). Safety events were collected through routine post-marketing pharmacovigilance reporting methods.

Conclusions: At 12 weeks there is a significant difference in WI-NRS scores between CRG and IRG patients ($p<0.0001$), moreover CRG pts are more likely to continue treatment beyond 12 weeks. Confirming that treatment as prescribed in the pivotal studies ensure more pronounced itch relief and therapy adherence. A better understanding of the reasons for IRG is needed for better patient support.

FR-PO426

Characterization of Common Adverse Reactions Observed with Intravenous Difelikefalin for the Treatment of CKD-Associated Pruritus in Adults Undergoing Hemodialysis

Jayasankar K. Reddy,[1] Kieran Mccafferty,[2] Catherine Munera,[3] Frederique Menzaghi,[3] Joana Goncalves,[3] Josh Cirulli,[3] Tejas Desai,[4] Andreas Osanger,[4] Joerg Latus.[5] *[1]Wichita Falls Kidney Clinic, Wichita Falls, TX; [2]Barts Health NHS Trust, London, United Kingdom; [3]Cara Therapeutics Inc, Stamford, CT; [4]Vifor Pharma Management Ltd, Glattbrugg, Switzerland; [5]Robert-Bosch Hospital, Stuttgart, Germany*.

Background: Managing side effects associated with medications is critical for optimal outcomes. Here we describe the common adverse reactions with intravenous difelikefalin (IV DFK), a treatment approved in 2021 for chronic kidney disease–associated pruritus (CKD-aP) in adults undergoing hemodialysis.

Methods: Safety data were pooled from two randomized, double-blind, placebo-controlled phase 3 studies (KALM-1, NCT03422653; KALM-2, NCT03636269; DFK=424, placebo=424). The current analysis evaluated the safety of IV DFK administered immediately after dialysis.

Results: Common adverse reactions that occurred in ≥2% of subjects treated with IV DFK and ≥1% higher than with placebo are reported; few were categorized as severe or serious and few led to treatment discontinuation (**Table**). Median time to onset of diarrhea, dizziness, and nausea associated with DFK was 22.5, 22.0, and 39.5 days; median duration

was 3.0, 1.0, and 2.0 days, respectively. Dizziness occurred more often in subjects using concomitant CNS-depressant medications (overall relative risk [ORR] 2.09); hyperkalemia and somnolence were more frequent with concomitant opioids (ORR 1.79 and 2.73, respectively) versus without these medications.

Conclusions: IV DFK was well tolerated with most common adverse reactions reported as mild to moderate, did not lead to discontinuation compared with placebo, and rarely occurred during dialysis sessions. Diarrhea, dizziness, and nausea occurred mostly during the first month of therapy; the duration was ≤3 days, suggesting they typically resolved while IV DFK treatment was ongoing. Concomitant medication use may increase the likelihood of certain adverse reactions. These findings provide additional information to prescribers on the common side effects of IV DFK, which could improve the management of CKD-aP in dialysis patients.

FR-PO427

Burden of CKD-Associated Pruritus and Adverse Clinical Outcomes in Patients Receiving Dialysis: The SCREAM Project

Anne-Laure Faucon,[1,2] Marie Evans,[1,3] Juan J. Carrero.[1,4] *[1]Karolinska Institutet, Stockholm, Sweden; [2]Centre de Recherche en Epidemiologie et Sante des Populations, Paris, France; [3]Karolinska Institutet Institutionen for klinisk vetenskap intervention och teknik, Huddinge, Sweden; [4]Danderyds Sjukhus AB, Stockholm, Sweden.*

Background: Pruritus, a strong sensation of itching, is a common complain of patients on dialysis, but their prevalence and consequences are not well known. We aimed to quantify the burden of clinically recognized pruritus and associated adverse clinical outcomes in a region-representative cohort of patients on dialysis.

Methods: Observational study of all patients receiving maintenance dialysis in Stockholm, Sweden, during 2006-2021. Pruritus was identified by clinical diagnoses, two consecutive dispenses of pruritus-medications, or use of UV-therapy. Study outcomes were incident diagnoses of depression and sleep disorders, serious infection-related hospitalizations (composite of endocarditis, peritoneal dialysis-related peritonitis, hemodialysis / peritoneal dialysis-related catheter infection, sepsis due to *Staphylococcus Spp.*, or skin infection), and all-cause mortality. Multivariable Cox regression models with time-varying exposures explored the association between prevalent/new-onset pruritus and adverse clinical outcomes.

Results: Among 3281 dialysis patients (median age 64 years, 66% men, 69% on hemodialysis, mean dialysis vintage 2.2 years), 456 (13.8%) had pruritus at enrollment. During median follow-up of 8.3 [IQR: 4.2-13.2] years, additional 637 (22.5%) patients developed pruritus. Prevalent and new-onset pruritus patients were at a higher risk of suffering sleep disorders (N=1294, HR: 2.02 [95%CI 1.70-2.41]), developing depression (N=752, HR: 1.70 [1.40-2.07]) and being hospitalized for serious infections (composite N=872, HR: 1.40 [1.23-1.60]), the latter attributed to higher risk of catheter-related infections, peritonitis and sepsis. No association was observed with endocarditis or all-cause mortality.

Conclusions: At least one third of dialysis patients suffer from CKD-associated pruritus during their lifetime. Patients with pruritus are at increased risk of infections, depression and sleep disorders.

Larkin,[1] Bettina Griesshaber,[2] Ansgar Erlenkoetter,[3] Maria Krizsan,[4] Petra Ronova,[5] Jennifer Braun,[2] Manuela Stauss-Grabo.[2] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Fresenius Medical Care Deutschland GmbH Werk Sankt Wendel, Sankt Wendel, Germany; [4]FMC, Péterfy II. Dialízis Központ, Budapest, Hungary; [5]Fresenius Nephrocare Praha 9 - Vysocany, Praha, Czechia.*

Background: eMPORA III was a multi-center crossover trial with 4-week randomized treatment periods comparing dialyzer performance (FX CorAL 600 vs two comparable high-flux dialyzers) in post-dilution online hemodiafiltration (HDF). Primary outcome was beta-2 microglobulin (B2M) removal and self-reported itching and fatigue were also studied.

Methods: Adults on HDF were recruited from 8 centers in Europe (NCT04714281). B2M removal rate (B2M RR) 0 vs 240 min was measured in week 3 (mid-week) of each period. Pruritus Numerical Rating Scale (PNRS) & KDQOL-SF fatigue domain (questions 9a, e, g & i) were captured at baseline & end of periods. Peak/average PNRS surveys capture the worst/average itch in the prior 24 hours on a 0 (no itch) to 10 (worst itch imaginable) point scale. Fatigue survey captures the energy level in the last month on a 0 (least energy) to 100 (most energy) point scale. Analysis used mixed effects model adjusted for center and patient.

Results: Trial enrolled 82 subjects (76 ITT group, mean age 67.0±15.6 years, 26.3% female, 34.2% diabetes). FX CorAL 600 showed a +0.60±0.39% and +1.82±0.38% higher B2M RR vs FX CorDiax 600 (non-inferiority p<0.0001; superiority p=0.0606) and xevonta Hi 15 (non-inferiority p<0.0001; superiority p<0.0001). Mean peak PNRS score was 1.0±1.94, and fatigue score was 63.8±21.41 (**Figure 1**). FX CorAL 600 showed a -0.08 and +0.08 point change in peak PNRS scores vs FX CorDiax 600 (p=0.66) and xevonta Hi 15 (p=0.65); consistent findings were seen for average NRS scores. FX CorAL 600 showed a -0.01 and +0.30 point change in fatigue scores vs FX CorDiax 600 (p=0.95) and xevonta Hi 15 (p=0.86).

Conclusions: FX CorAL 600 provides a higher B2M RR than the comparators. PNRS & fatigue scores were consistent between dialyzer types. Total PNRS & fatigue values indicate mild-to-no itching and reasonable vitality among participants. Nonetheless, some unique patients reported severe itching and fatigue symptoms. Higher middle molecule clearance may not affect these outcomes. However, more studies are needed with longer follow-up should consider focusing on patients with remarkable symptoms.

Clinical Performance and Patient-Reported Sleep Quality Associated with Dialyzer Types: Results from the eMPORA III Trial

John W. Larkin,[1] Bettina Griesshaber,[2] Ansgar Erlenkoetter,[3] Petra Ronova,[4] Maria Krizsan,[5] Jennifer Braun,[2] Manuela Stauss-Grabo.[2] *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany; [3]Fresenius Medical Care Deutschland GmbH Werk Sankt Wendel, Sankt Wendel, Germany; [4]Fresenius Nephrocare Praha 9 - Vysocany, Prague, Czechia; [5]FMC, Péterfy II. Dialízis Központ, Budapest, Hungary.*

Background: eMPORA III was a prospective, multi-center, open, crossover trial with 4-week randomized treatment sequences comparing the clinical performance and hemocompatibility of dialyzers (FX CorAL 600 vs FX CorDiax 600 and xevonta Hi 15) in post-dilution online hemodiafiltration (HDF). Primary outcome of beta-2 microglobulin (B2M) removal showed FX CorAL 600 was non-inferior vs its comparators and superior vs. xevonta Hi 15. We assessed the additional patient-reported outcomes on sleep quality per Pittsburgh Sleep Quality Index (PSQI).

Methods: We recruited clinically stable adults on HDF from 8 centers in Europe (NCT04714281). PSQI was measured at baseline and at the end of each 4-week treatment sequence. PSQI survey assesses impairment of sleep quality in the prior month on a 0 (worst) to 21 (best) point scale and has 7 component subscales. PSQI scores >5 points show poor sleep quality. A linear mixed model adjusted for random effects of the center and patient estimated the effect of the dialyzer on PSQI scores.

Results: Study enrolled 82 subjects (76 in the ITT group, mean age 67.0±15.6 years, 26.3% female, 34.2% diabetes). Mean total PSQI score was 5.7±3.77 (**Figure 1**). FX CorAL 600 showed a -0.07 and -0.02 point lower PSQI scores vs FX CorDiax 600 (p=0.75) and xevonta Hi 15 (p=0.93). The 7 PSQI component scores showed consistent patterns with the total score, no differences by dialyzer.

Conclusions: PSQI scores were consistent between dialyzers. Total PSQI values indicate borderline poor sleep quality among trial participants; this appeared to be driven by small additive disturbances in all domains of component scores, especially for subjective sleep quality, latency, duration, and disturbances. FX CorAL 600 has previously shown higher B2M removal vs. comparators. Higher middle molecule clearance may not affect sleep quality outcomes, yet further studies are needed with longer follow-up times and could consider severity of symptoms (i.e., need for improvement).

Risk Factors for Impaired Cerebral Autoregulation and Its Relationship to Cognitive Decline and Brain Atrophy in Hemodialysis Patients

Max J. Goodman, Dawn F. Wolfgram. *Medical College of Wisconsin, Milwaukee, WI.*

Background: The hemodialysis (HD) population has evidence of increased cerebral atrophy and cognitive impairment. Understanding if cerebral vascular function and cerebral perfusion during HD may help us understand the pathophysiology of brain atrophy and cognitive impairment. We evaluate cerebral autoregulation (CA) during HD patients in relationship to cerebral structure and cognitive performance.

Methods: In a cross-sectional study, HD patients age 50 years and older receiving incenter HD were included. Cerebral perfusion during HD was measured using cerebral oximetry and an index of CA was calculated based on the correlation between concurrent cerebral oxygen saturation and intradialytic blood pressure. Potential risk factors for worse CA were measured through linear mixed models including patient-level random effects with a compound symmetry covariance structure to account for the correlation in repeated measures from each patient. Additionally, associations between CA and changes in neurocognitive scores as well as white and gray brain matter volumes over 12 months were measured. P-value < 0.05 was considered significant.

Results: We included 46 participants and 121 HD sessions in our analysis. The mean ± SD decline in cerebral oxygen saturation during HD was 7.02% ± 3.16%. An impaired CA index (> 0.4) was noted in 45% of HD sessions. Only diabetes mellitus as a comorbidity survived the linear mixed model method for predicting impaired CA when adjusting for demographics, albumin, dialysis treatment, and oxygen saturation with an OR 1.35 ($p < 0.01$). The Baseline CA index was negatively correlated with worse picture vocabulary scores at 12 months ($r = -0.44$, $p = 0.03$). There was no association between CA index and brain integrity including white and gray matter volume, gray matter thickness, and abnormal voxels at either baseline or 12 months.

Conclusions: Diabetes is associated with worse CA during HD. A worse (higher) CA index correlated to declining cognitive function in HD patients. Further research is needed to understand these relationships in order to reduce cerebral atrophy and cognitive impairment in HD patients.

FR-PO431

Association of Cognitive Impairment with Subsequent Cardiovascular Disease (CVD) Hospitalization: A Prospective ESKD Cohort Study

Jenny R. Park,[1,2] Michelle M. Estrella,[3,4] Jessica Fitzpatrick,[5] Bernard G. Jaar,[2] Rulan S. Parekh,[6] Jose M. Monroy-Trujillo,[2] Stephen M. Sozio.[2] *[1]Oregon Health & Science University, Portland, OR; [2]Johns Hopkins University, Baltimore, MD; [3]University of California San Francisco, San Francisco, CA; [4]San Francisco VA Health Care System, San Francisco, CA; [5]The Hospital for Sick Children, Toronto, ON, Canada; [6]Women's College Hospital, Toronto, ON, Canada.*

Background: Cognitive impairment (CI) and stroke are common among patients with ESKD receiving hemodialysis. Whether worsened CI can be a clinical indicator of increased risk of stroke and other cardiovascular disease (CVD) events in patients with ESKD is unknown.

Methods: Participants were incident hemodialysis patients from a prospective cohort study, the PACE Study. To assess CI, we used validated tests, the Multiple Mini-Mental State Exam (3MS) and Trail Making Test (TMT) Parts A and B. We used Cox proportional-hazards regression models to evaluate the association of CI at baseline with incident CVD events, adjusting for demographic characteristics, education, depression, and hypercholesterolemia.

Results: Among 568 participants, the average age was 56.3 years (SD: 13.5 years; range: 20-90 years), and most participants are black (n=393; 69.2%) or white (n=161, 28.3%). Over a median follow-up of 2.9 years, 120 (21%) CVD hospitalizations occurred among the 568 participants. Worse TMT-A scores, indicating more severe CI, were associated with subsequent CVD hospitalization on unadjusted analysis (HR=1.08; 95% CI: 1.02-1.06). Similarly, those classified as cognitively "deficient" were at higher risk for subsequent CVD hospitalization, even after further adjustments for a history of diabetes, smoking, prevalent stroke, and atrial fibrillation (HR=1.53; 95% CI: 1.13-2.08). On interaction analysis, the TMT-A scores of patients without diabetes (HR=1.38; 95% CI: 1.02-1.87) were associated with future CVD events. The 3MS test and TMT-B results did not show an association between CI and future CVD hospitalization.

Conclusions: In this study, patients with ESKD new to hemodialysis with worse TMT-A scores were more likely to have future CVD hospitalizations. Further studies should gauge whether this practical bedside test case helps predict a patient's cardiovascular risk.

FR-PO432

Plasma Refill and Changes in Cognition During Hemodialysis

Charlie Hull, (Christina) Hao Wang. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Rapid ultrafiltration during hemodialysis has been associated with impaired cerebral perfusion. The effects of dialysis-associated hypoperfusion may be enhanced during acute illness due to factors that impair the ability to refill the vascular space (i.e., plasma refill). We sought to investigate whether changes in plasma refill are associated with detectable changes in cognitive function in hospitalized patients receiving intermittent hemodialysis.

Methods: We conducted a prospective pilot study of hospitalized patients receiving intermittent hemodialysis at the University of Pennsylvania. Blood pressure was monitored every 15min throughout hemodialysis. Hematocrit monitoring (using CritLine-IV) and ultrafiltration volumes were used to calculate interval plasma refill rates. Digitized cognitive tests were administered at regular intervals during each session; specifically, the Psychomotor Vigilance Test was used to measure reaction time (delayed reaction defined as the bottom 25% or >50ms slower performance) and the Trail Making Tests A/B were used to measure executive function (impaired function defined as the bottom 25% or >10s difference in completion time). Mixed effects logistic regression was used to examine the relationship between interval change in cognitive function and plasma refill rate.

Results: In interim analysis, among 92 participants enrolled, 60 participants were able to complete at least two sets of cognitive testing. The mean age was 56.9±14.9 yr, 50.5% were female, 53% were Black and 40% were White, and 67% were receiving maintenance hemodialysis versus 33% for acute kidney injury. In the first half of hemodialysis, low plasma refill rate, defined as a plasma refill-to-ultrafiltration ratio < 0.75 was associated with delayed reaction time (OR 4.56, 95% CI 1.11-18.90, $p = 0.035$) and slower executive function but the latter did not reach statistical significance (OR 2.53, 95% CI 0.0.51-12.47, $p = 0.253$). These associations were independent of age, sex, acute versus chronic hemodialysis, and blood pressure.

Conclusions: These preliminary results offer insight into how changes in plasma refill might relate to tissue perfusion leading to detectable changes in cognition, particularly areas affected by the frontotemporal regions of the brain that are particularly susceptible to ischemic injury. Further evaluation in a larger cohort is needed to better evaluate the potential link.

FR-PO433

Sexual Dysfunction in People Treated with Hemodialysis

Daniel Cukor,[1] Stephanie Donahue,[1] Sri Lekha Tummalapalli,[2,1] Andrew Bohmart,[1,2] Jeffrey I. Silberzweig.[1,2] *[1]Rogosin Institute, New York, NY; [2]Weill Cornell Medicine, New York, NY.*

Background: End Stage Kidney disease is associated not only with increased mortality, but also with higher symptom burden, particularly for people treated with hemodialysis (HD). Sexual dysfunction (SD) is common but often underrecognized among people with kidney disease. SD is a person's inability to fully engage in sexual activities in one or more categories: desire, arousal, orgasm, and pain disorders. Reported rates of SD vary widely, between 5% - 85%.

Methods: This is a secondary analysis of a project describing symptom burden in patients on HD (Anxiety, Comorbid Depression, and Dialysis Symptom Burden) with a focus on the prevalence of sexual dysfunction. In total, 92 people being treated with hemodialysis in New York City answered questions about their sexual functioning as measured by the Dialysis Symptom Inventory.

Results: The sample was comprised of 44% women (60.8 years ± 14.1) and 56% men (60.0 years ±17.1). 38% of the total sample reported Decreased Interest in Sex (31% of the women, 45% of the men) and 32% reported Difficulty Becoming Aroused (21% of the women and 43% of the men). Of those that indicated Decreased Interest in Sex, 81% of the women and 45% of the men described being significantly bothered by it. Of those that indicated Difficulty Becoming Aroused, 25% of the women and 60% of the men described being significantly bothered by it.

Conclusions: There has been some debate as to whether decreased interest in sex should be categorized as a sexual dysfunction in people with ESKD being treated with HD. Our data find that Decreased Interest in Sex is both present and bothersome in 25% of the women surveyed and 19% of the men. Clinically significant Difficulty Becoming Aroused was reported by 5% of women and 26% of men. More detailed assessments of all the domains of SD are needed, and an exploration of the interest in intervention.

Figure 1: Prevalence and Associated Distress for Decreased Interest in Sex by Gender

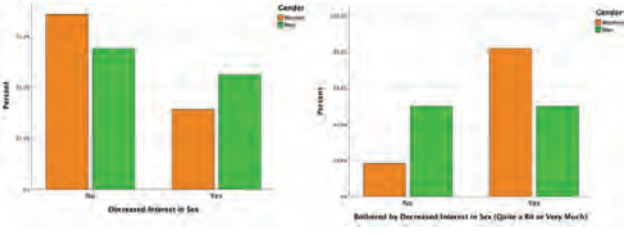

Figure 2: Prevalence and Associated Distress for Sexual Arousal Difficulty by Gender

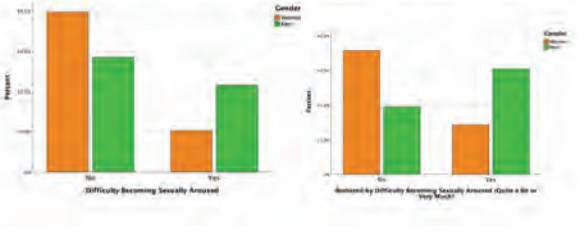

FR-PO434

Engagement in CBT-I in the SLEEP-HD Trial for People on Long-Term Hemodialysis with Insomnia

Daniel Cukor,[1] Susan M. Mccurry,[2] Tessa Rue,[2] Maria-Eleni Roumelioti,[3] Patrick J. Heagerty,[2] Mark L. Unruh,[3] Rajnish Mehrotra.[2] *[1]Rogosin Institute, New York, NY; [2]University of Washington, Seattle, WA; [3]University of New Mexico School of Medicine, Albuquerque, NM.*

Background: Patients with end-stage kidney disease treated with hemodialysis (HD) experience distressing symptoms including sleep disturbances. Unique aspects of HD treatments and schedules possibly contribute to the high prevalence of insomnia. Cognitive-behavioral therapy for insomnia (CBT-I) is a first-line therapy but largely inaccessible to HD patients, partly due to significant dialysis treatment time. CBT-I delivered by telehealth could overcome barriers to access, but the level of engagement has not been tested for these patients.

Methods: SLEEP-HD was a parallel-group randomized controlled trial (RCT) wherein 126 HD patients treated in community-based dialysis facilities in Seattle and Albuquerque were randomized 1:1:1 to 6-week treatment with telehealth delivered CBT-I, trazodone, or medication placebo. Primary goals were to compare the efficacy of a 6-week treatment with telehealth CBT-I vs. trazodone vs. placebo for the treatment of chronic insomnia at treatment conclusion and follow-up. Herein we describe data available on CBT-I engagement of the study participants.

Results: 43 SLEEP-HD participants were randomized to the 6-week CBTI telehealth intervention with 51% women and 49% men (average age: 60.1 years (SD 15.2)). The protocol called for 6 sessions over 6 weeks and 74% of participants had all 6 sessions, while 5% had none. Participants were asked to keep sleep diaries during the intervention period and 40% kept for all weeks and 19% kept none. After each session, study therapists rated their perception of the participant's level of engagement and effort in following previous week's treatment recommendations ("homework"). Engagement scores across the six sessions indicated that 98% of participants were, on average, at least somewhat engaged during the sessions and 83% were well-engaged. The average homework scores indicated that 18% of the participants were rated as not putting in significant effort, and 43% were rated as putting in considerable effort.

Conclusions: CBT-I can be demanding and patient engagement is an important part of the treatment model. In this telehealth administered CBT-I protocol adapted for people on long-term HD, overall levels of engagement in the sessions seemed high, although the level of skills practice and follow through on sleep recommendations was more limited.

FR-PO435

Reducing Frequency of Surveillance Bloodwork in Chronic In-Centre Hemodialysis (ICHD) Patients from Every Six to Eight Weeks: A Quality Improvement Study

Tina Kim, Epsita Shome-Vasanthan, Huda Al-Wahsh, Jennifer M. MacRae, Juliya Hemmett, Sophia Chou, Elena Qirjazi. *University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Regular surveillance bloodwork is vital for hemodialysis patients to monitor complications such as anemia, chronic kidney disease-mineral and bone disorder (CKD-MBD), and electrolyte abnormalities. Previous studies have shown that reducing the frequency of bloodwork from every 4 to 6 weeks did not negatively affect the achievement of anemia and CKD-MBD targets. However, the impact of further reducing routine bloodwork frequency to every 8 weeks has not been explored. This study aims to assess the impact of reducing routine bloodwork frequency from every 6 to 8 weeks in chronic in-center hemodialysis (ICHD) patients on achieving anemia and CKD-MBD targets.

Methods: In this prospective cohort study, the Alberta Kidney Care-South program, which includes 7 hemodialysis centers in Calgary, reduced routine bloodwork frequency for chronic ICHD patients from every 6 to 8 weeks. We compared the impact of this change in the intervention cohort (Dec. 1, 2020 – Nov. 5, 2022) to a control cohort (Oct. 31, 2019 – Oct. 31, 2020). Primary outcomes were proportion of patients within the target range for anemia and CKD-MBD, frequency of hyperkalemia, and cost savings attributable to the change in frequency of bloodwork. Logistic regression mixed models were used to assess the effect of reduced bloodwork frequency on the odds of achieving anemia and CKD-MBD targets, adjusted for demographic and clinical characteristics.

Results: A total of 787 control patients and 956 intervention patients were included. During the intervention period, the odds of achieving target ranges for hemoglobin, calcium, and phosphate decreased by 13% [95% CI: 0.83, 0.91] (P-value < 0.001), 17% [95% CI: 0.76, 0.90] (P-value < 0.001), and 6% [95% CI: 0.89, 1.00] (P-value = 0.050), respectively, compared to the control period. No significant change was observed in achieving target ranges for parathyroid hormone and iron saturation.

Conclusions: Reducing routine bloodwork frequency from every 6 to 8 weeks in chronic ICHD patients was associated with lower odds of achieving anemia and CKD-MBD targets. However, the clinical significance of these findings is unclear. Further studies are needed to elucidate the ideal frequency of surveillance investigations in this patient population.

FR-PO436

Impact of 10-Step Sleep Hygiene Intervention on Insomnia and Muscle Strength of ESRD Patients: A Quasi-Interventional Study

Syed Muhammad Kashif Kazmi, Muzammil Ahfaz, Misbah F. Shaikh, Umm-e Rabab, Alizeh Zaidi, Maheerah Q. Khan, Mahnoor Luni, Finza Kanwal. *NIKUD Research Hospital, a Project of the Kidney Foundation, Karachi, Pakistan.*

Background: End-stage renal disease is a significant health issue that affects millions worldwide, the 10 step sleep hygiene interventions is a simple, low-cost strategy for better sleep habits that can potentially enhance the overall health of this patient group. The purpose of this study is to evaluate the impact of a 10-step sleep hygiene intervention on hemodialysis patients and simultaneously evaluate its impact on insomnia severity and muscle power. There is dearth of research in this specific area therefore our study can provide valuable insights in this regard.

Methods: The study used a pre-post quasi-interventional design. Participants' demographic data, sleep quality, physical activity, depression score, medication and addiction history were collected using structured questionnaire before, and 1 month after the intervention. The muscle strength was measured using a handheld dynamometer. The intervention was a validated 10-step sleep hygiene strategy, which was delivered in a face-to-face physician-patient interview.

Results: Out of the 146 patients recruited, 141 completed the study. Majority of the participants were male, married, aged 35-55, had secondary education, and were retired. All of them engaged in mild physical activity, with average dynamometer readings of 10kg, and most were non-smoker with moderate insomnia, sleeping 5-6 hours per night. After the intervention, insomnia scores significantly improved (p=0.004), and muscle power saw a slight improvement. Participants transitioned from moderate to subthreshold insomnia, and average sleep duration increased to 7 hours. However, muscle strength improved in only about 15% of participants and only 8% reported some improvement in depression score.

Conclusions: The study underscores the importance of sleep hygiene in routine care for hemodialysis patients. The 10-step sleep hygiene intervention was found to effectively improve sleep quality and slightly improve muscle strength in this population. The intervention was particularly effective in reducing insomnia in women and improving muscle power in men. Younger participants(18-35 years) showed the greatest overall improvement. This suggests that tailored, age-specific sleep hygiene interventions can yield better results in the future.

FR-PO437

Holographic Biology Theory-Based Auricular Acupoint Therapy Relief Insomnia Symptoms in Hemodialysis Patients

Wu L. Li, Liang Chen. *Chongqing Traditional Chinese Medicine Hospital, Chongqing, China.*

Background: Insomnia is a common symptom among patients undergoing hemodialysis, which significantly affects their mental and physical well-being. Several studies, including DOPPS have found that sleep quality is not only related to the quality of life but also impacts patient survival rates.

Methods: A total of 42 hemodialysis patients who did not regularly take sleeping pills such as zolpidem were selected as study subjects, including 15 males (35.72%) and 27 females (64.28%), aged 46-83 years with a mean age of (63.76±2.54) years. Following the PFEIO principle, an treatment team was set up to process the treatment. Hamilton Anxiety/Depression Scale (HAMA/HAMD), polysomnography (PSG), and the Pittsburgh Sleep Quality Index (PSQI) and Sleep Rating Scale (SRSS) were used to assess sleep quality and self-rated insomnia severity. Ear acupuncture treatment was proceeded once a week, 4 weeks for a course. The TCM physician carried out a preliminary evaluation of the ears, based on tongue diagnosis, and the senior nurse performed the treatment.

Results: PSG showed that total sleep time (TST), sleep efficiency (SE), NREM stage 2 sleep as a percentage of TST (N2% of TST), NREM stage 3 sleep as a percentage of TST (N3% of TST), and REM sleep as a percentage of TST (REM% of TST) were all increased after treatment, and sleep time was longer than before treatment ($P < 0.05$). Refer to Table 1 for details. PSQI scores showed improvement in sleep quality, increase in sleep duration and efficiency, reduction in sleep disturbances, decrease in the use of hypnotic drugs, and improvement in daytime functioning. The overall score was statistically significant ($P < 0.05$). Refer to Table 2 for details. SRSS showed decrease in insufficient sleep time, significant improvement in sleep quality.

Conclusions: The application of auricular acupoint therapy based on holographic biology theory can relief insomnia symptoms and effectively improve the sleep quality of HD patients with insomnia. The therapy has the advantages of safety, convenience, and low cost, and can be easily promoted and popularized in clinical practice. However, The specific mechanism needs further study.

Comparison of PSG-related data in 42 hemodialysis patients with insomnia.

Number of cases	Group	TST	SE	N1% of TST	N2% of TST	N3% of TST	REM % of TST

FR-PO438

Frailty in Patients on Dialysis Surviving for More than 40 Years Is Common and Severe: A Nationwide Study

Suguru Yamamoto,[1] Kakuya Niihata,[2] Tatsunori Toida,[4] Masanori Abe,[3] Norio Hanafusa,[5] Noriaki Kurita.[2] *[1]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan; [2]Fukushima Medical University, Fukushima, Japan; [3]Nihon University School of Medicine, Tokyo, Japan; [4]Kyushu University of Health and Welfare, Miyazaki, Japan; [5]Tokyo Women's Medical University, Tokyo, Japan.*

Background: The number of end-stage kidney disease (ESKD) patients with a more prolonged dialysis vintage have been increasing. Recently, the Japan Society for Dialysis Therapy (JSDT) survey reporting patients on dialysis for over 40 years has been presented, and there are few reports that describe their characteristics, especially regarding physical function. This study aimed to evaluate the clinical features of ESKD patients on dialysis for 40 years or more and the associations between dialysis vintage and frailty using the JSDT Renal Data Registry database.

Methods: A cross-sectional study was conducted. The analysis included data of 227,136 patients aged over 50 on dialysis in 2018. The dialysis vintage exposure was categorized as: 0–<5 years; 5–<10 years;10–<20 years; 20–< 30 years; 30–<40 years; and above 40 (40–) years. The primary outcome was frailty, defined as grade 2 or higher according to the Eastern Cooperative Oncology Group Performance Status (ECOG PS) scale. The secondary outcome was bedridden, defined as grade 4 on the ECOG PS scale. Modified Poisson regression models adjusted for potential covariates were used to estimate the adjusted prevalence ratios (aPRs) for frailty and bedridden. The clinical characteristics of patients with dialysis vintage of 40 years or more were compared with those in other dialysis vintage categories.

Results: Total 809 (0.36%) ESKD patients were on dialysis for 40 years or more. This group showed a lower proportion of men and presence of diabetes. Histories of fractures and carpal tunnel syndrome were more frequent in the 40– years than in the other groups. The prevalence of frailty was most common in the 40– years group (54.6%), and the prevalence of bedridden was similar (9.9%). The dialysis vintage 40- years vs. 0-<5 years was associated with increased frailty (aPR [95% confidence interval]: 2.41 [2.25-2.58]), and bedridden (aPR [95% confidence interval]: 2.12 [1.72-2.60]).

Conclusions: This large nationwide study found an association between dialysis vintage and frailty in dialysis patients. Long-term dialysis therapy, particularly for over 40 years, may accelerate the decline of physical function, probably due to unmeasured dialysis-related factors.

FR-PO439

"A Ray of Hope": A Qualitative Study of Hemodialysis Patients' Attitudes Toward a Clinic-Based Animal-Assisted Intervention

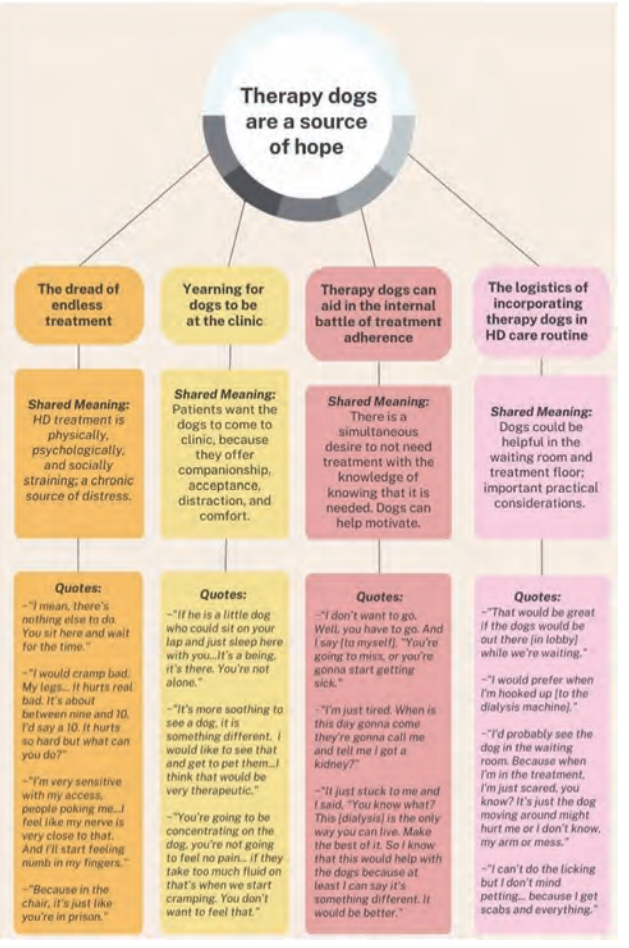
Meredith L. Stensland,[1] Adrian E. Elorriaga,[2] Martha Block,[2] Geoffrey A. Block,[2] Don D. Mcgeary,[1] Jacie Flaman,[3] Selena Lugosi.[1] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]US Renal Care Inc, San Antonio, TX; [3]The University of Texas at San Antonio, San Antonio, TX.*

Background: Adherence to one's hemodialysis [HD] regimen is paramount to overall health and well-being for individuals receiving HD in the U.S. Patients may struggle maintaining the strenuous regimen, and ways to effectively reduce rates of missed treatments are needed. The purpose of this study was to explore HD patients' attitudes toward a clinic-based animal-assisted intervention [AAI].

Methods: HD patients from 4 outpatient clinics engaged in 1-on-1 in-depth semi-structured interviews, which were audio-recorded and transcribed verbatim. Interviews took place at the dialysis clinics, including while patients were dialyzing. Within a framework of iterative content analysis, the Matrix Method was utilized in combination with line-by-line coding to thematically analyze data.

Results: Twenty patients aged 57 ± 7.93 years participated in interviews. Their narratives collectively illustrate the perceived value of AAI in the HD setting. Under the larger theme "Therapy dogs are a source of hope", there are 4 subthemes: (i) *The dread and suffering of endless treatment*; (ii) *Yearning for the presence of therapy dogs at the clinic*; (iii) *Therapy dogs can aid in the internal battle of treatment adherence;* (iv) *The logistics of incorporating therapy dogs into the HD care routine*.

Conclusions: This study improves our understanding of how HD patients feel about receiving clinic-based therapy dog visits while also offering helpful insights for implementing this intervention in future research. Incorporating therapy dogs into HD patients' healthcare routine may offer a complementary and integrative approach to improving patient outcomes. Findings highlight the importance of patient-centered care for this population.



FR-PO440

Animal-Assisted Intervention for Hemodialysis Patients' Treatment Adherence, Pain, and Depression

Meredith L. Stensland,[1] Adrian E. Elorriaga,[2] Martha Block,[2] Geoffrey A. Block,[2] Don D. Mcgeary,[1] Jacie Flaman.[3] *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]US Renal Care Inc, San Antonio, TX; [3]The University of Texas at San Antonio, San Antonio, TX.*

Background: Maintaining adherence to one's hemodialysis [HD] regimen is paramount to patients' health and well-being. The purpose of this pilot study was to evaluate the feasibility of a clinic-based animal-assisted intervention [AAI] for improving HD patients' treatment adherence, depression, and pain.

Methods: This study used a within-subject repeated measures design at 1 outpatient HD clinic with a primary outcome of unplanned missed HD treatments. Participants were prevalent HD patients, age 18+, who had depression (PHQ-2 ≥ 3), and chronic pain (Pain Enjoyment General activity score ≥ 4). Patients were randomized 1:1 into 2 groups: 1 dog visit (AAI1) or 2 dog visits (AAI2) per week for 10 weeks. The AAI took place in the waiting room immediately prior to HD; it involved socializing with and petting the dog. Patients completed pain and mood assessments before and after each dog visit. A generalized linear mixed effects model was used for data analysis.

Results: A total of 17 patients were enrolled (n= 8 AAI1, n=9 AAI2) who cumulatively received 199 of 240 possible dog visits (83%), averaging 10.8 ± 4.8 minutes each. There were 9 missed HD treatments during the trial (1 in AAI1, 8 in AAI2), while there were 30 missed treatments in the 12 weeks prior to trial (6 in AAI1, 24 in AAI2). All patients who missed at least 1 HD treatment in the 12 weeks pre-enrollment had a decrease of at least 1 fewer missed treatments during the trial. The effect estimate for the reduction in probability of missing an HD treatment in the AAI vs pre-trial was OR 0.23 (95% CI: 0.09 to 0.57), p = 0.002. Pain severity rated 0-10 scores: pre-test = M 4.38 ± 2.63, post-test = M 3.46 ±1.93 (AAI1); pre-test = M 3.52 ± 1.91, post-test = M 3.14 ±2.04 (AAI2).

Conclusions: Including therapy dogs in HD patients' healthcare routine may offer a complementary approach to improving outcomes. This safe and resource-minimal intervention received high patient approval and provides insight for determining the treatment effect of AAI in order to design larger controlled clinical trials on the clinical effectiveness of AAI.

FR-PO441

Motivational Strategies to Empower African Americans to Improve Dialysis Nonadherence

Lindsey Theut,[1] Zuri N. St. Julien,[2] Devika Nair,[2] Heather L. Prigmore,[2] Robert Greevy,[2] Marylou Wallace,[2] Rachel B. Fissell,[2] Julia Lewis,[2] Rebecca Weinand,[3] David G. Schlundt,[4] Hilary A. Tindle,[2] Collins Airhihenbuwa,[5] Kerri L. Cavanaugh,[3] Kenneth A. Resnicow,[6] Ruth Q. Wolever,[2] Ebele M. Umeukeje.[2] *[1]Creighton University School of Medicine, Omaha, NE; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University Medical Center, Nashville, TN; [4]Vanderbilt University, Nashville, TN; [5]Georgia State University, Atlanta, GA; [6]University of Michigan School of Public Health, Ann Arbor, MI.*

Background: Compared to whites, African Americans (AA) have four times the risk of ESKD. Hemodialysis (HD) nonadherence is common in AA and driven by low motivation. Motivational interviewing (MI), an evidence-based counseling style increases intrinsic motivation, and if culturally tailored, reduces nonadherence in AA. We hypothesized that culturally tailored MI would be feasible and acceptable for reducing HD nonadherence in AA.

Methods: Parallel arm [usual care (n=15) vs. MI (n=15)] pilot RCT of AA, ≥ 18 years old, who missed HD or shortened HD by 15 minutes/month during the prior 3 months. Patients randomized to MI received 6 sessions over 8 weeks, culturally tailored to prioritize contributors to nonadherence: empowerment; support network; understanding ESKD; communication & trust; mental well-being; transportation; and racial identity. Coaches were assessed via the MI Treatment Integrity (MITI) scale. Coaches and patients provided feedback regarding their experience.

Results: We enrolled 30 AA; 57% male; median age [IQR]= 57[17] years; median HD vintage [IQR] of (6.6[4.3]) and (2.2[4.9]) years in the MI and control groups respectively. Feasibility and acceptability were favorable: 76% enrollment-to-screening ratio; 73% MI attendance; 13% drop-out. Primary outcome was chart-reviewed HD adherence. In month 3 of follow-up, patients were prescribed a median [IQR] of 13 [12, 13] sessions and 2730 [2520, 3120] minutes, and completed 91.7% [80.8%, 99.1%] of prescribed HD. Patients completed 84.6% [63.6%, 92.3%] of prescribed sessions. Empowerment, support network, and understanding ESKD were most frequently discussed during MI per patients' preference. Patients reported variability in the impact of racial identity on HD adherence. Some noted having low trust *in*, and feeling intimidated *by* the health system. Most viewed MI as an effective communication style. Health coaches demonstrated high fidelity on the MITI.

Conclusions: Health coach-delivered culturally tailored MI in AA is feasible and acceptable. Next steps will assess its *efficacy* in reducing HD nonadherence in AA.

FR-PO442

Managed Care Program Improves Hospitalization Rate in ESKD Patients

Adam G. Walker,[1] Scott Sibbel,[1] Gilbert Marlowe,[1] David A. Roer,[2] Francesca Tentori,[1] Steven M. Brunelli.[1] *[1]Davita Clinical Research, Minneapolis, MN; [2]DaVita Inc, Denver, CO.*

Background: Care fragmentation, a lack of coordinated care for patients, is associated with reduced quality of care, increased costs, and poor clinical outcomes. End stage kidney disease (ESKD) patients are at increased risk of care fragmentation due to the complex collection of conditions that often accompany ESKD (i.e., diabetes, hypertension, etc.) and require care from multiple healthcare providers. Recently, managed care programs have started to defragment care for ESKD patients through collaboration across healthcare organizations in order to improve clinical outcomes. However, whether and to what degree these programs are effective is unknown.

Methods: This was a retrospective, observational study of dialysis patients with commercial or Medicare Advantage insurance treating with a dialysis provider in the United States from June 2021- June 2022. The primary exposure was enrollment in a managed care program. Expected hospitalization rates for enrolled patients were estimated by indirect standardization versus the non-enrolled patients.

Results: After accounting for differences in age, comorbidities, insurance type, and geography, we observed that enrolled patients had 0.11 admits per-patient per-year favorable hospitalization rate compared to non-enrolled patients. This resulted in an estimated 961 hospitalizations prevented among approximately 8,500 enrolled patients during the study period. Hospitalization reduction was similar between managed care programs done in partnership with government and private insurers.

Conclusions: A provider managed integrated kidney care program can be effective in improving clinical outcomes for ESKD patients for public or private payors.

FR-PO443

Perspectives on Preventability of Emergency Department Encounters for People Receiving Dialysis: A Qualitative Critical Incident Study

Meghan J. Elliott,[1,3] Paul E. Ronksley,[3] Maoliosa Donald,[3] Eddy Lang,[1] Jennifer M. MacRae,[1] Andrew Mcrae,[1,3] Shannan Love,[1] Hana Kotani,[1] Nancy Verdin,[1] Brenda Hemmelgarn.[2] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [3]University of Calgary Department of Community Health Sciences, Calgary, AB, Canada.*

Background: People receiving dialysis have disproportionately high rates of emergency department (ED) utilization. While certain conditions underlying ED encounters have been characterized as potentially preventable, little is known about how contextual factors may influence perceived need for ED care. We explored the perspectives of patients with kidney failure, their caregivers, and healthcare providers regarding the potential preventability of ED encounters.

Methods: In this qualitative critical incident study, we purposively sampled patients receiving dialysis who had received emergency care in the preceding four weeks for various acute health conditions, their informal caregivers, and healthcare providers working with dialysis patients. We conducted semi-structured interviews in person or virtually, coded transcripts in duplicate across participant roles, and generated themes through an inductive thematic analysis approach.

Results: We completed interviews with 22 patients receiving hemodialysis and peritoneal dialysis, 8 caregivers, and 30 healthcare providers from nephrology, emergency medicine, and primary care disciplines. Across roles, participants discussed aspects of acute illness unique to people receiving dialysis and emphasized coordinated care across disciplines to prevent illness onset, decompensation, and ultimately need for urgent ED management. We characterized perceived preventability of ED encounters in relation to the following themes: (1) Connectedness of the acute condition to kidney failure; (2) Care continuity and engagement; (3) Reactions and behavioural responses to the acute illness experience; (4) Access to urgent care strategies outside of the ED.

Conclusions: Patients, caregivers, and healthcare providers identified how the interplay between kidney failure, the acute illness experience, behaviours, and support structures influence the perceived preventability of ED encounters. Findings will inform coordinated approaches to averting potentially unnecessary ED use among this medically complex population.

FR-PO444

Plasma B Cell-Activating Factor (BAFF) Levels Predict the Upcoming Depressive Symptoms in Hemodialysis Patients

Woojin Jang, Dong-Young Lee. *Veterans Healthcare Service Medical Center, Seoul, Republic of Korea.*

Background: B cell activating factor (BAFF) is a cytokine that plays a role in B cells' maturation, homeostasis, and differentiation and is associated with mental disorders. Depression can often be caused by inflammation, with various cytokines playing a role. Chronic inflammation is common in hemodialysis (HD) patients, and depression is also prevalent among them. We hypothesize that BAFF may predict upcoming depressive symptoms in HD patients, so we evaluated their association.

Methods: Among 643 subjects who enrolled in a multi-center prospective HD cohort study, we investigated 72 patients who tested plasma BAFF levels, performed initial and follow-up Beck Depression Inventory, and had no depressive symptoms at first. We conducted a univariate and multivariate Cox regression analysis to calculate the hazard ratio (95% confidence interval (CI)) between upcoming depressive symptoms and BAFF levels.

Results: In both univariate and multivariate analyses, a 1 standard deviation (SD) increase in BAFF was significantly linked with a higher risk of future depressive symptoms. The HR was 1.437 (95% CI 1.034-1.996) and 1.699 (95% CI 1.037-2.784), respectively. Patients with higher BAFF levels experienced more depressive symptoms than those with lower BAFF levels for 2 years (p = 0048).

Conclusions: In HD patients, elevated levels of plasma BAFF showed a significant association with depressive symptoms up to two years later.

Hazard ratios of plasma BAFF and APRIL for depressive symptoms

	HR	95% CI	HR	95% CI
BAFF	1.437	1.034-1.996	1.699	1.037-2.784

FR-PO445

Effects of Eating Meals During Hemodialysis Treatment on Depressive Symptoms: The FrEDI Randomized Controlled Trial

Masaki Okazaki,[1,2] Connie Rhee,[1,3] Yoko Narasaki,[1] Jenny I. Shen,[4,5] Ramanath B. Dukkipati,[4,5] Tiane Dai,[4,5] Lili Tong,[4,5] Sharon G. Adler,[4,5] Joel D. Kopple,[4,5] Kamyar Kalantar-Zadeh.[3,4] *[1]University of California Irvine, Irvine, CA; [2]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [3]VA Long Beach Healthcare System, Long Beach, CA; [4]Harbor-UCLA Medical Center, Torrance, CA; [5]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA.*

Background: Approximately one-third of patients undergoing hemodialysis (HD) suffer from symptoms of depression. HD patients with low serum albumin levels who ingest high- vs. low-protein meals during HD sessions display improved their protein-energy status. We examined whether their depressive symptoms were also alleviated with intradialytic high-protein meals.

Methods: We examined data from participants in the Fosrenol for Enhancing Dietary Protein Intake in Hypoalbuminemic Dialysis Patients (FrEDI) Study (NCT01116947) who were on thrice-weekly HD with serum albumin <4.0 g/dL. Participants were randomized to receive either high-protein (50–55 g) meals or low-protein (<1 g) meals during HD treatments for 8 weeks. The primary outcome was depressive symptoms measured by the Beck Depression Inventory (BDI)-II survey at 8 weeks. Data on change in Mental Component Summary (MCS) as assessed by the SF-36 were also evaluated. Differences between pre-to-post scores within each study arm were examined using Wilcoxon signed-ranks test.

Results: Fifty-seven participants completed the BDI-II assessment. The mean (SD) age was 55 (±15) years; 56 % were female. The BDI-II score showed a statistically significant improvement among 26 participants in the high-protein meals (baseline, 11.5 [IQR, 5-20] vs. 8-weeks, 7 [IQR, 2-13], P=0.01). In the low-protein meals, BDI-II scores among 31 participants showed a trend toward improvement (baseline, 10 [IQR, 4-22] vs. 8-weeks, 6 [IQR, 1-15], P=0.077). The MCS showed no statistically significant changes either among 26 participants in high-protein meals (baseline, 37.2 [IQR, 16.5–48.7] vs. 8-weeks, 39.2 [IQR, 29.6–47.0], P=0.44) or among 31 participants in low-protein meals (baseline, 30.1 [IQR, 15.6–53.3] vs. 8-weeks, 33.4 [IQR, 16.8–48.6], P=0.97). Changes in BDI-II scores were not statistically different across meal composition.

Conclusions: Among HD patients who receive high- versus low-protein meals during thrice-weekly HD, those eating high-protein meals exhibited a significant improvement in depressive symptoms. Further clinical trials are needed to conclusively determine the efficacy and safety of intra-dialytic eating and meal provision in the dialysis clinics on patient-reported outcomes including unpleasant symptoms.

FR-PO446

Underdiagnosis of Depression in Hemodialysis Patients

Raeesa Soomar, Reena Jose, Anuj Gupta, Morgan Davis, Janos G. Hajagos, Farrukh M. Koraishy. *Stony Brook University, Stony Brook, NY.*

Background: Depression is the most common psychiatric illness among dialysis patients. It has been associated with adverse outcomes in this population, and therefore routine screening is recommended. The Patient Health Questionnaire (PHQ)-9 scale has been validated for depression screening in patients on hemodialysis (HD) in controlled studies, but it is underutilized in dialysis centers. The utility of PHQ-9 in detecting depression in HD patients without an official diagnosis and its association with psychiatric care is not well studied.

Methods: In a single center observational study of HD patients, we used PHQ-9 scores ≥ 10 as an indicator for depression. This was compared to diagnostic code-based depression diagnoses. Two-tailed t-tests were used to compare continuous variables, while Fischer's exact and Chi square tests were used to compare categorical variables.

Results: Among the 98 HD patients analyzed, the mean age was 61.5 years, mean days on HD were 2,005; 91% had hypertension, 59% diabetes and 87% had cardiovascular disease. Eighteen (18.4%) patients were diagnosed with depression using the PHQ-9. Of these, only six (33%) also had a diagnostic code-based depression diagnosis, nine (50%) had a follow-up appointment scheduled with a psychiatrist, and only five (28%) were being treated with an anti-depressant. Patients with depression were also more likely to have comorbid anxiety disorder and a greater number of previous hospitalizations (p<0.05).

Conclusions: Depression is underdiagnosed in HD patients. Better screening for depression will lead to improved medical care and potentially better health outcomes for this vulnerable population.

FR-PO447

"Dialysis Makes You Poor and Keeps You Poor": Patient Perspectives on Health-Related Social Needs and Recommendations for Interventions

Tessa K. Novick,[1] Michelle M. Osuna-Diaz,[1] Daniel Ramirez,[1] Francisco A. Barrios,[1] Deidra C. Crews,[2] Elizabeth Jacobs.[3] *[1]The University of Texas at Austin, Austin, TX; [2]Johns Hopkins Medicine, Baltimore, MD; [3]MaineHealth, Portland, ME.*

Background: Dialysis patients with low socioeconomic status have worse outcomes, which may be due to health-related social needs. Patient perspectives on the impact of social needs and how to address them have not been explored.

Methods: We interviewed 32 people with low socioeconomic status receiving in-center hemodialysis on barriers and facilitators to care with an emphasis on social needs. The interviews were conducted at three dialysis facilities in Austin, Texas, from April to July 2022. We collected demographic information, and performed thematic analysis using the constant comparative method on interviews after they were audio-recorded, translated and transcribed verbatim.

Results: Participants were mean (SD) age 56 (12) years, 18 (56%) identified as female, 15 (53%) identified as Hispanic/Latino/a/x, 30 (94%) were unemployed, 27 (94%) reported annual income <$25,000, and health-related social needs were common. Themes identified were (1) kidney failure was unexpected, (2) dialysis is detrimental, (3) powerlessness, (4) financial resource strain, (5) motivators, and (6) interventions should promote self sufficiency (Figure).

Conclusions: Dialysis exacerbates financial resource strain, and social needs exacerbate dialysis-related stress. Participants made recommendations to address social needs with an emphasis on increasing financial support and community resources for this population.

Funding: NIDDK Support

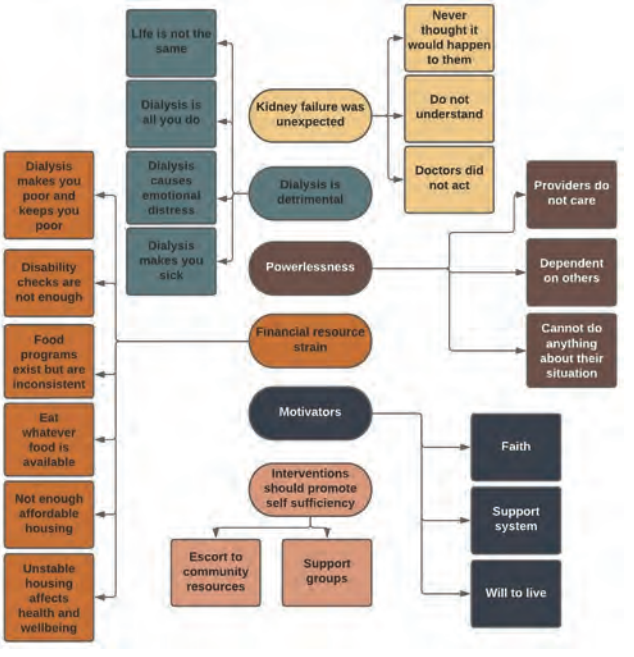

Figure. Themes and subthemes from semi-structured interviews.

FR-PO448

Advance Care Planning in Patients with Advanced CKD on Hemodialysis in the Hospital Setting

Rosa Sanchez Hernandez, Alicia B. Dahl, Rocio Z. Gonzalez-Marino, Laura Rodriguez Osorio Jimenez, Ana Muñoz Sánchez. *Hospital General de Villalba, Collado Villalba, Spain.*

Background: To explore the wishes and preferences of patients with advanced chronic kidney disease (ACKD) who receive hemodialysis through the application of the instrument "Dodecahedron of advance care planning" to improve the approach and medical care of these patients, promote communication between them and the healthcare professionals who attend to them. Advance care planning in patients with advanced chronic kidney disease on hemodialysis in the hospital setting.

Methods: Patients with advanced chronic kidney disease (ACKD) admitted to the Hemodialysis program of the General Hospital of Villalba were included. Demographic variables, knowledge about CAP and conversations about the end of life, comorbidity with the Charlson Index, and cognitive status using the Pfeiffer scale were collected. In addition, the dodecahedron of advance care planning was used as a clinical instrument through an interview.

Results: 70 patients were included; 35 completed PAC, 54.3% men and 45.7% women. Median age 72 years (44-89). Of all with Charlson Index >5, 14.2% had depression. The median dialysis time was 36 months (3-276). 100% had not discussed the end of life with their doctor, and 25.75% had with their main caregiver. 31.4% NECPAL positive. The wishes of the patients were: 91.4% "to be cared for with respect and kindness," 77.7% expect the best to be done at each moment of their illness, 25.4% did not want to talk about the end of life, 77.1% did not want to suffer in pain, 60% "not be a burden to their families," 100% wanted to die accompanied by their family. 48.6% wanted to die at home, 14% in hospital, and 37.1% did not care. 80% wanted to be connected to machines "if their recovery is reasonable," 68.6% wanted palliative sedation for refractory symptoms, 97.1% wanted to be reminded "as a good person," and 85.7% were believers that gave meaning to his illness.

Conclusions: Most patients at the end of life wish not to be a burden to their family, to die accompanied, without pain, and at home. The dodecahedron tool is helpful for CAP in HD; it facilitates communication and decision-making aspects and has a positive impact on the patient.

FR-PO449

One-Year Survival and Hospitalization After Dialysis Initiation in Patients Aged Above 75

Patrick Saudan,[1] David A. Jaques,[1] Anne Dufey Teso,[1] Fadi Haidar,[1] Belen Ponte,[1] Sebastian Carballo,[2] Sophie M. De Seigneux.[1] *[1]Service of Nephrology, Geneva University Hospitals, Geneva, Switzerland; [2]Service of General Internal Medicine, Geneva University Hospitals, Geneva, Switzerland.*

Background: Implementation of dialysis in elderly patients is debated because of an unfavourable short-term prognosis. We therefore analyzed the one-year impact on survival of planned implementation versus emergency dialysis in this population.

Methods: All patients who started maintenance dialysis in our unit during the past 21 years were reviewed. Patient's demographic and clinical characteristics were collected. Emergency implementation of maintenance dialysis was determined if there was no prior referral to a nephrologist one month before dialysis initiation.

Results: From 2000 to the end of 2021, 860 patients started maintenance dialysis in our unit, of whom 231 were aged 75 and above. Mean age was 80 ± 4 years. Hemodialysis was implemented in 83 % of the patients. There were 66% male, 41 % diabetics and median eGFR at start of dialysis was 7± 3 ml/mn. Emergency dialysis was implemented in 36% (n=81) of the patients aged 75 and above. One-year mortality was 18% in patients who had planned dialysis and 36% in patients with emergency dialysis. One-year mean survival was 327+12 days in patients with planned dialysis versus 275± 21days in those who had emergency dialysis ($p< 0.004$). In multivariate analysis including age, gender, comorbidity score and dialysis modality, prior referral was associated with a 33% decline in one-year mortality (HR: 0.67; 95% CI. 048-0.93). Hospitalization-free days within the first year after dialysis start or death were 311+60 days in referred patients versus 280± 74 days in those dialyzed in emergency ($p< 0.005$).

Conclusions: In our dialysis population, one-month referral to nephrologists prior to dialysis implementation significantly increased one-year survival and hospitalization-free days in ESKD patients aged above 75.

FR-PO450

A Nationwide Survey of Conservative Kidney Management in Japan

Ken Sakai,[1] Hirokazu Okada,[2] Naoki Kashihara.[3] *[1]Toho Daigaku, Ota-ku, Japan; [2]Saitama Daigaku, Saitama, Japan; [3]Kawasaki Ika Daigaku, Kurashiki, Japan.*

Background: Even with our best possible efforts, death is an inevitable endpoint. The age of entering dialysis has reached over 70 years/old in Japan. Withhold and withdrawal dialysis have emerged problem in elderly society. This article explains the selection and current situation of conservative kidney management (CKM) based on nationwide survey in Japan.

Methods: Quetionnaire responses were collected in 2020, based on the 2-year period status from 2018 to 2019. A web-based questionnaire was sent to all members of 4 societies (Japanese Society of Nephrology, Society for Dialysis Therapy, Association for Home Care Medicine, and Society for Pediatric Nephrology), and one response was received from each facility to avoid duplication of cases. Thus, although the exact response rate could not be counted, responses were obtained from 451 facilities.

Results: Among the responses, 299 were from hospitals, 104 were from dialysis clinics, and 37 were from visiting physicians. In the past 2 years (2018-2019), the number of patients who opted for withholding of dialysis was 917, and that for withdrawal from dialysis was 492 (1409 in total). In patients who were 80 years or older, the increase in the number of patients who opted for withholding of dialysis was substantial, with more than twice as many patients than those who opted for withdrawing from dialysis. Among patients who withheld or withdrew from dialysis, the number of patients with poor cognitive function was approximately twice that of those with good, and poor cognitive function was prominent in patients who withheld dialysis. In terms of prognosis after withholding or withdrawal of dialysis, many patients died 1 month after withholding of dialysis and 7-14 days after withdrawal from dialysis. The contents of palliative care varied but pain management was a main component: not many patients were transferred to the palliative ward or home. Relevant confirmation document were obtained, but the explanation of CKM as a therapy option was provided at the time of therapy selection in just 40% of cases.

Conclusions: CKM is not yet as well recognized as renal replacement therapy, and thus, deliberation is still required for consensus-building on CKM, as well as on ACP. Adequate time must be also spent for full SDM in the elderly Japanese dialysis population.

FR-PO451

Withdrawal from Dialysis: Seven-Year Experience in a Kidney Supportive Care Service

Kirsten S. Hepburn,[1,2] Rebecca Hudson,[1] Laura H. Austin,[1] Louise Purtell,[4,5] Monica S. Ng,[1,2] Ilse R. Berquier,[1] Katrina M. Kramer,[3] Ann Bonner,[1,4] Helen G. Healy.[1,2] *[1]Kidney Health Service, Metro North Hospital and Health Service, Brisbane, QLD, Australia; [2]Faculty of Medicine, University of Queensland, Herston, QLD, Australia; [3]Palliative and Supportive Care Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [4]School of Nursing and Midwifery, Griffith University, Southport, QLD, Australia; [5]Research Development Unit, Caboolture Hospital, Caboolture, QLD, Australia.*

Background: Withdrawal from dialysis is a common cause of death in patients on dialysis. Kidney Supportive Care (KSC) services have evolved to meet the palliative care needs of patients ceasing dialysis when it is no longer beneficial. This study examines the profile and survival of patients known to a KSC service who withdrew from dialysis.

Methods: Retrospective analysis of patients known to a KSC service between 2016 and 2023 who withdrew from haemodialysis (HD) or peritoneal dialysis (PD). Demographics including age, sex, ethnicity, and Charlson Comorbidity index (CCI) were extracted from medical records. Reason for referral to KSC and patient choices including advance care planning (ACP) documents and preferred place of death were recorded. Date of dialysis withdrawal, date and place of death; and referral to palliative care services were also collected. Results were analyzed descriptively.

Results: Over 7 years, 157 patients withdrew from dialysis with a mean age of 72.4 years (SD 9.88). 38% were female and 3% identified as First Nations people. 132 patients withdrew from HD and 25 from PD. At time of referral to KSC, the median CCI was 7 (IQR 2), 31% had either ischaemic heart or congestive cardiac failure, and 5% had a diagnosis of dementia. Patients withdrew from dialysis a median of 205 days (IQR 440) after KSC referral. Following withdrawal from HD patients survived a median of 7 days (IQR 7.75), and 6 days after withdrawal from PD (IQR 9.5). 50% of people died in an acute hospital, 24% at home and 23% in a palliative care unit (PCU). Of the 74 who had indicated preferred place of death, 35 (47%) wished to die at home; of these 16 (46%) did. Only 16 patients (22%) wished to die in a PCU, but 11 (69%) did. Surprisingly 19 patients (26%) indicated they wished to die in an acute hospital and 14 (74%) of these patients did.

Conclusions: Our results indicate that patients typically survive around one week after withdrawal from dialysis, which is consistent with current literature. Most patients died in acute care settings, which was often not in keeping with their wishes. This may have been due to acute medical complications or sudden deterioration limiting transfer to their preferred place of death. Further work is needed to understand how best to provide care that concords with end-of-life preferences.

FR-PO452

Cultural Tailoring of Motivational Strategies to Improve Hemodialysis Nonadherence in African Americans

Melissa Ma,[1] Erin Bergner,[2] Ruth Q. Wolever,[2] Kemberlee R. Bonnet,[3] Devika Nair,[2] Rachel B. Fissell,[2] Talat Alp Ikizler,[2] Kerri L. Cavanaugh,[2] Kenneth A. Resnicow,[4] Derek M. Griffith,[5] David G. Schlundt,[3] Juliet Iwelunmor,[6] Collins Airhihenbuwa,[7] Ebele M. Umeukeje.[2] *[1]California University of Science and Medicine School of Medicine, Colton, CA; [2]Vanderbilt University Medical Center, Nashville, TN; [3]Vanderbilt University, Nashville, TN; [4]University of Michigan School of Public Health, Ann Arbor, MI; [5]Georgetown University, Washington, DC; [6]Saint Louis University, Saint Louis, MO; [7]Georgia State University, Atlanta, GA.*

Background: African Americans (AA) make up 33% of patients with ESKD and, compared to white patients, have higher hemodialysis (HD) nonadherence rates. Motivational interviewing (MI) improves nonadherence, and cultural tailoring centered

on racial minorities reduces racial disparities. Informed by key themes derived from prior qualitative research focused on HD nonadherence in AA, we hypothesize that MI can be culturally tailored to improve HD nonadherence in AA.

Methods: During a facilitated community engagement studio, AA community experts (n = 7) with lived experience across each stage of kidney disease, reviewed key themes on HD nonadherence in AA. Themes were obtained from prior focus groups and interviews of 22 AA on HD, and 34 dialysis providers & researchers; mapped onto the PEN-3 cultural model; categorized as **P**erceptions (attitudes), **E**nablers (structural/societal factors), or **N**urturers (support systems); and further categorized as **P**ositive (facilitators), **E**xistential, or **N**egative (barriers). Community experts identified priority targets for an MI intervention. Health equity clinicians and researchers finalized the cultural adaptation process by examining the priority targets and providing additional input.

Results: AA community experts dentified 6 major priority targets: empowerment; support network; understanding kidney disease; communication and health system-related trust/trustworthiness; mental well-being; and transportation. Health equity researchers added racial identity as a priority target. Key themes and illustrative perspectives are shown in Table 1.

Conclusions: Use of the PEN-3 cultural model for the cultural adaptation of MI is novel. Integrating input from AA community experts and content experts with perspectives from AA on HD to identify priority targets of MI, will likely increase the potential efficacy, adoption, and sustainability of MI to improve HD nonadherence in AA.

Funding: NIDDK Support

Mapping of Themes into PEN-3 Cultural Model with Exemplar Quotes

	Perceptions Patient attitudes and beliefs	Enablers Structural and societal factors	Nurturers Patient support systems
Positive Facilitators of dialysis adherence	**SELF-ADVOCACY & EMPOWERMENT …people just understanding how motivational interviewing might empower them to think about their health and put them in the driver	**OPTIMAL MENTAL WELLBEING "Nobody wants to be the person that somebody is pointing their finger at…Because that could be the difference between life and death in some people. Because a person can get bullied for it or talked about it so much…" (Patient) *Cultural Competency	**SUPPORT NETWORK "I'm just to the point where I'm tired and I didn't want to go and I didn't want to interact. But I have a great support system at home as well as patient care to where they were all hovering with me, talking to me, and motivating me to go back to the clinic." (Patient) *Religious Support *Family Support *Peer Support
Negative Barriers to dialysis adherence	**LACK OF UNDERSTANDING OF KIDNEY DISEASE "…I think if [African Americans] were more educated on dialysis and what it does and how it works before they start dialysis, I think they will be more adherent to what	**COMMUNICATION & TRUST There may be a lack of trust… that could be a barrier… all that happened at Tuskegee and not getting the right treatment that they needed. So, there may be a cultural and historical precedent to that, in terms of relying on and believing the medical information we're giving to them now…" (Nephrologist) **TRANSPORTATION "….transportation can be kind of crazy sometimes, when you get off of dialysis, they might come pick you up a couple of hours later, you never know which way transportation's going to go." (Patient) *Finances *Representation in Healthcare	*Stigma *Diet *Lack of Provider Support

*Major themes specific to HD adherence in AA

**Major themes identified as priority targets

FR-PO453

The Impact of Depressive Symptoms on Outcomes in Incident Hemodialysis Patients

Wael F. Hussein,[1,2] Eric D. Weinhandl,[1,3] Emily Watson,[1] Graham E. Abra,[1,2] Gopa B. Green.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN.*

Background: Dialysis is associated with increased physical and psychosocial burden. This study explored the association of depressive symptoms with mortality and hospitalization among incident hemodialysis (HD) patients.

Methods: Incident in-center HD patients who began dialysis between Jan 2017 and Dec 2022 at centers managed by a mid-size non-profit dialysis provider, and who completed the PHQ2 depression screening within 150 days of initiating dialysis, were followed up for one year post-survey completion for death and for hospital admissions. Observation was continued until the end of April 2023. PHQ2 score ≥ 3 was considered positive. For time to event analysis, univariate and age- and sex-adjusted Cox regression were used, while Poisson regression was used to compute rate ratios.

Results: A total of 6,203 patients were included. Mean age was 61 ± 15 years, and 39% were female. The PHQ2 survey was positive in 230 (3.7%) patients. During follow-up, 295 (4.8%) patients died. The hazard ratio (HR) for death was 1.44 (95% CI: 0.86 -2.43) and 1.67 (95% CI: 0.99 – 2.81) in univariate and adjusted analysis respectively. The rates of hospital admissions were 1.88 per patient-year for those with a negative survey, and 1.22 for those with a positive survey (RR: 1.54, 95% CI: 1.38 – 1.72). As shown in the figure, the HR for time to first hospitalization was 1.42 (95% CI: 1.18 – 1.70) for those with a positive survey compared to those with a negative one, in both the univariate and adjusted analyses. Furthermore, patients with a positive survey spent more days in the hospital (13.08 versus 8.15 days per patient-year, RR 1.61, 95% CI: 1.54 to 1.67).

Conclusions: Depressive symptoms appear to be correlated with an increased risk of hospitalization among incident HD patients. This finding provides an opportunity to enhance patient care and potentially reduce associated healthcare costs.

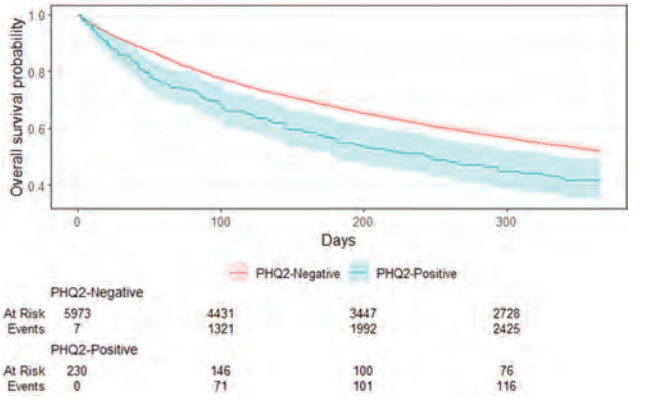

Figure: Survival of incident hemodialysis patients from completion of depression survey to first hospital admission

Palliative Care and Advance Care Planning Integration into the Dialysis Team: A Quality Improvement Intervention at a Hospital-Based Outpatient Hemodialysis Clinic

Joanna L. Martin,[1,2] Aleksandra Gmurczyk,[1,2] Joshua Hauser,[1,2] Joanna R. Varghese,[1] Julie Ozersky,[1] Tyra D. Oliver,[1] Michael J. Fischer.[1,3] *[1]Jesse Brown VA Chicago Healthcare System, Chicago, IL; [2]Northwestern Memorial Hospital, Chicago, IL; [3]University of Illinois Hospital & Health Sciences System, Chicago, IL.*

Background: Despite substantial symptom burden and high mortality, adults receiving maintenance hemodialysis (HD) infrequently utilize palliative care (PC). With mostly hospital-based outpatient dialysis clinics, Veterans Affairs (VA) is well-positioned to increase access to PC services. At a large urban VA dialysis unit, we initiated a year-long intervention to improve Life Sustaining Treatment (LST) note and advance care planning (ACP) completion.

Methods: A PC physician was integrated into the dialysis care team at the Jesse Brown VA (JBVA) Medical Center to improve LST and advance directive (AD) completion. The PC physician worked with the dialysis team to provide palliative education and refine and bolster approaches to ACP. The PC physician contacted all patients needing an AD or LST note. After 12 months, we reassessed percentages of patients with LST and AD completion. Change in proportion with note completion pre/post PC intervention was compared.

Results: Among all outpatient HD patients at the JBVA, the average age was 71 years, 85% were Black, 99% were male, and the average time on HD was 4.7 years. Frequent consultation with the dialysis social worker was essential to targeting patients for the intervention. Most patients preferred private phone calls with the PC physician to discuss ACP. Integration of a PC physician into the dialysis care team significantly increased patient completion of an AD and LST note as noted in table.

Conclusions: Integrating a PC physician into the dialysis care team led to a substantial increase in LST and advance directives for maintenance HD patients. Future PC integration plans should build on these gains in advance care planning, measure their impact on subsequent care and also extend to alleviating symptom burden.

	May 2022 (pre-PC intervention)	April 2023 (post-PC intervention)	p-value
Number of Dialysis Clinic Patients	59	70	
Patients with VA Advance Directive	38 (64%)	62 (89%)	<0.01
Patients with LST note	53 (90%)	70 (100%)	<0.01

FR-PO455

Importance of Living with a Spouse for Female Patients Undergoing Hemodialysis

Emiko Otsuka,[1,2] Mineaki Kitamura,[2] Maiko Nakamura,[1] Hiro Inoue,[1] Satoshi Funakoshi,[1] Tomoya Nishino.[2] *[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Daigaku, Nagasaki, Japan.*

Background: An increasing number of elderly people are living alone owing to the aging population, and patients undergoing hemodialysis are no exception. Generally, patients living alone have poor prognoses. However, the significance of living with a spouse for patients on hemodialysis has been unclear. Therefore, we aim to clarify such significance among Japanese patients undergoing hemodialysis.

Methods: After excluding patients with an unknown family structure, we included patients undergoing hemodialysis at Nagasaki Renal Center, Japan, during 2011 and 2012. Patients were followed up until 2021. Log-rank tests and multivariate Cox regression analyses were conducted to evaluate the patients' life prognosis.

Results: We included 333 patients undergoing hemodialysis (mean age: 67.2±13.3 years, 57% men, median dialysis vintage: 4.8 years). The proportion of those living with a spouse was 48%. The log-rank test for all patients showed that patients living with a spouse had a favorable prognosis compared with that of patients living alone (P=0.008). Notably, no significant difference was observed among male patients (P=0.22); however,

a significant difference was detected among female patients (P=0.004). Even a patients' background adjusted multivariate Cox regression analysis showed that living with a spouse reduced the risk of death (hazard ratio: 0.74, 95% confidential interval: 0.56–0.98, P=0.04).

Conclusions: Living alone was associated with poor prognosis, especially in female patients undergoing hemodialysis. The precise reason for this remains unknown. However, patients on hemodialysis living alone should not be isolated from society to improve their prognosis.

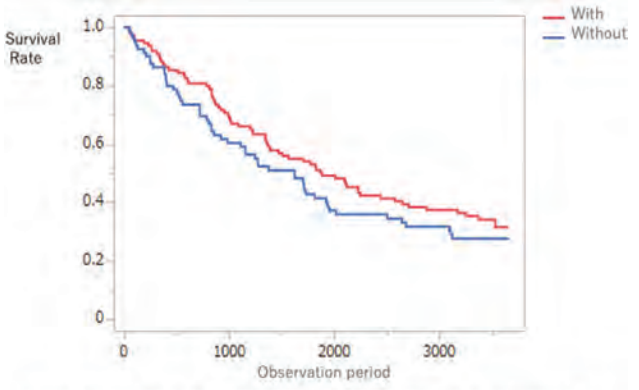

Figure2. Survival rates for those with and without a spouse in male patients undergoing dialysis.

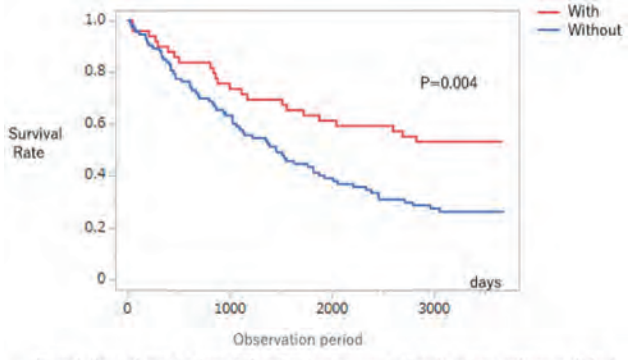

Figure1. Survival rates for those with and without a spouse in female patients undergoing dialysis.

FR-PO456

Impact of Inpatient vs. Outpatient Dialysis Transition on Survival in a National Cohort of Advanced CKD Patients

Ji Hoon Yoon,[1] Kamyar Kalantar-Zadeh,[2] Yoko Narasaki,[1] Seungsook You,[1] Andrea C. Daza Aguilar,[1] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA.*

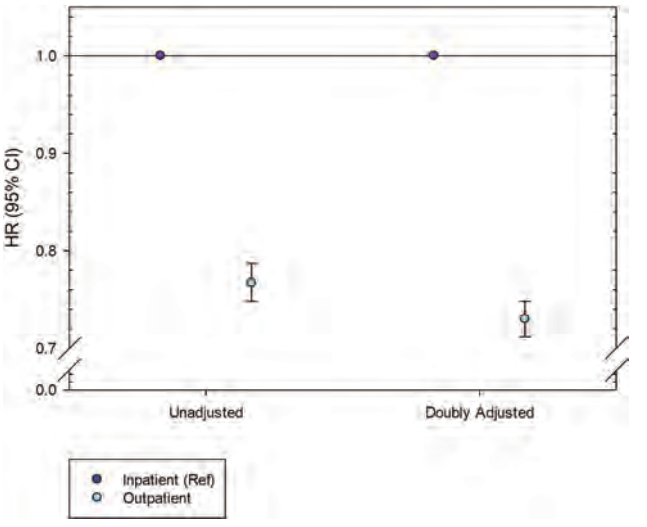
Background: Large population-based studies show advanced CKD patients transitioning to ESKD have high mortality in the first few months of dialysis initiation. It is unclear whether transitioning to dialysis in the inpatient vs. outpatient setting is associated with better survival in incident ESKD patients.

Methods: We examined advanced CKD patients (≥2 eGFRs <25 separated by ≥90 days) who transitioned to within 2-years of their 1st (index) eGFR <25 over 1/1/07-6/30/20 from the Optum Labs Data Warehouse, which contains de-identified administrative claims, including medical/pharmacy claims and enrollment records for commercial/ Medicare Advantage enrollees, and EHR data. We compared all-cause mortality in patients who transitioned to dialysis in the inpatient vs. outpatient setting matched by propensity score (PS) in a 1:1 ratio with a caliper distance of ≤0.2 to address confounding by indication in Cox models.

Results: Among 20,655 patients who were PS-matched to 20,655 patients who transitioned to dialysis in the outpatient vs. inpatient settings, respectively, outpatient dialysis transition was associated with lower mortality risk vs. inpatient dialysis transition: HR (95%CI) 0.77 (0.75-0.79). Similar findings were observed in sensitivity analyses doubly-adjusted for PS-score covariates (ref: inpatient dialysis transition): HR (95%CI) 0.73 (0.71-0.75) for outpatient dialysis transition.

Conclusions: In a national cohort of advanced CKD patients transitioning to ESKD, outpatient dialysis was associated with better survival compared with inpatient dialysis transition. Further studies are needed to determine the factors contributing to differential survival, as well as the comparative effectiveness of inpatient vs. outpatient dialysis transition on other ESKD outcomes (patient-reported endpoints, healthcare costs).

Funding: NIDDK Support



FR-PO457

Use of a Novel Machine Learning Tool ("DoWhy") to Compare Mortality Risk Between High Volume Hemodiafiltration (HV-HDF) and Hemodialysis (HD) Patients in a Large Cohort from Latin America (LA)

Adrian M. Guinsburg, Maria Ines Diaz Bessone, Jorge M. Caseiro, Jeffrey L. Hymes. *Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Since hemodiafiltration (HDF) provides higher clearance of middle molecules compared with hemodialysis (HD), several studies showed HDF may result in better outcomes than HD. However, these findings are prone to residual confounding (C) and selection bias (SB). In this study we focused on a methodology that allows to analyze differences in clinical outcomes accounting C and SB.

Methods: We included incident patients (pts) to dialysis in Fresenius Medical Care units in LA between Jan 12-Dec 22, after 90 days of treatment. Pts were classified by modality: HD or HDF (>90% in any modality). High volume HDF (HV-HDF) was considered if infusion volume >21 liters. Values were compared using t-test or Chi-square accordingly. To compare risk of death and odds to reach targets, we use a novel machine learning tool (Python library "DoWhy"), which provides interface for causal inference analysis. A model using "modality" as treatment and baseline variables as covariates was built to estimate "average treatment effect" (ATE) on outcomes of interest using propensity score stratification (PSS), which estimates the risk/odd % change between treatment and control accounting for baseline differences and SB.

Results: 99,496 pts were included (97.1% HD, 2.9% HDF, Table 1). HDF pts were younger, higher vintage and higher prevalence of male gender, diabetes, hypertension and heart disease. After PSS, ATE for mortality showed risk reduction for HDF vs HD of -4.04%, and -5.1% for HV-HDF vs HD. Odds to reach targets were increased on HV-HDF or HDF as compared to HD (Table 2).

Conclusions: Machine learning tools are an alternative when interventional studies are not available and there are unbalanced control/treated cohorts. In our study, after controlling for possible C and modelling using PSS, HDF and HV-HDF showed a reduced risk of dead and increased odds of reaching targets vs HD.

Values expressed as Mean ± SD	Total	HD	HDF	p Value
N	99496	96635 (97.1%)	2861 (2.9%)

A Qualitative Study Exploring the Role and Responsibilities of the Patient Care Technician in US Dialysis Care

Megan Urbanski,[1] Courtney E. Hoge,[1] Alexis A. Bender,[1] Jessica Joseph,[2] Kelli Collins Damron,[2] Jennifer C. Morgan,[3] Bernard G. Jaar,[4] Laura Plantinga.[1] *[1]Emory University, Atlanta, GA; [2]National Kidney Foundation, New York, NY; [3]Georgia State University, Atlanta, GA; [4]Johns Hopkins University, Baltimore, MD.*

Background: Dialysis patient care technicians (PCTs) provide essential, frontline care for patients on dialysis. We aimed to qualitatively explore perceptions of the PCT job role, responsibilities, and training among current PCTs, other staff on the dialysis care team, and patients receiving dialysis.

Methods: Focus group discussions were conducted in March-May 2023 with U.S. PCTs, dialysis staff, and patients. Participants were recruited via email invitation and social media postings from professional organizations and were purposively sampled to capture diversity in demographics and years of experience. Discussions were audio-recorded and transcribed verbatim and thematic analysis was conducted using inductive and deductive strategies.

Results: Seven focus group discussions (n=36 participants) were conducted (3 with PCTs [n=19], 2 with dialysis staff [e.g., social workers, dietitians; n=6], and 2 with patients [n=11]). Preliminary analyses revealed that, although there is agreement that PCTs play a pivotal role in dialysis care for patients and colleagues, PCTs are often perceived as "helpers" or ancillary rather than an integral part of the care team. Participants reported that PCT job training and qualifications are not standardized and are often not commensurate with job expectations and responsibilities. Additional training and continuing education are needed and desired. Participants reported that the PCT-patient relationship is deeply valued, but boundaries can be fluid and blurred due to the frequency and nature of dialysis care and differences in the perception of relationship boundaries were observed among groups. Finally, it was noted that PCTs are vulnerable to multilevel workplace safety issues (e.g., unsafe staffing ratios, violence) but feel ill-prepared to manage them.

Conclusions: Preliminary findings suggest PCTs play a multifaceted role in dialysis care that is highly valued among patients and staff, but this is not always reflected in the clinic-, organization-, or system-level policies that govern U.S. dialysis care. Future research should prioritize multilevel interventions aimed at equipping PCTs with the needed resources and support to provide quality care for patients and better prepare and integrate these critical members of the dialysis care team.

FR-PO459

A Budget Impact Model (BIM) for Expanded Haemodialysis (HDx) vs. High-Flux Haemodialysis (HF-HD) in Two Major Public Health Sectors, Kingdom of Saudi Arabia (KSA)

Konstantinos Fourtounas,[1] Mohamed C. Kechrid,[2] Mai F. Alsaqaaby,[3] Mohamed Mahsoub,[4] Sam Henderson,[4] Omneya E. Mohamed,[4] Ayman Karkar.[4] *[1]King Salman Armed Forces Hospital, Tabuk, Saudi Arabia; [2]Security Forces Hospital Program, Riyadh, Saudi Arabia; [3]IQVIA Solutions Limited Riyadh, Riyadh, Saudi Arabia; [4]Baxter AG, Dubai, United Arab Emirates.*

Background: Chronic Kidney Disease imposes economic costs on healthcare systems. The Saudi Center for Organ Transplantation (SCOT) in 2020 estimated that the number of patients undergoing dialysis (all modalities) is expected to increase by 5% per annum. Accumulation of large-size middle molecules/uremic toxins have been shown to be associated with inflammation, vascular calcification, and increased risk of cardiovascular disease. While conventional HD will clear smaller middle molecules adequately; large middle molecules can be reduced by HDx. Theranova (Baxter Healthcare Corporation, Deerfield, IL USA), a medium cut off dialyzer, allows for better clearance of large middle molecules than traditional HF-HD dialyzers.

Methods: An excel-based BIM was assessed the overall cost of HF-HD patients versus those on HDx over five-years from public payers' perspectives. Input data were retrieved via a comprehensive literature search and expert interviews. These included epidemiology data, the costs of healthcare resources utilized in dialysis sessions and dialysis related complications management including physician visits, hospitals stay, and medications.

Results: As per 2021 SCOT report, 1,862 Patients are managed in these health Sectors. HF-HD Therapy total cost per patient per year was $15,947 (US Dollars $, USD, $1 = 3.75 Saudi Riyals [SAR]), while the total cost of HDx Therapy per patient per year was $12,019. The overall cost saving per patient per year of $3,928 were driven by reductions in hospitalization, $3,619, followed by reductions in dose of Erythropoietin Stimulating Agents (ESA), $232, per patient per year. Over 5 Years the cost savings for the patients treated in these health sectors was $3.4m.

Conclusions: This study demonstrated that choosing HDx as alternative line of therapy may result in cost savings. In addition to HDx clinical benefits associated with better clearance of large middle molecules, the increased adoption of HDx with Theranova may provide further economic benefit.

Assessing the Value of an Integrated Multidisciplinary Patient Centric Program for Patients in Hemodialysis

Shaira Martinez Vaquera,[1] Sonia C. Molina,[1] Teresa Martinez Sanchez,[1] Maria Paz Sorribes López,[1] Ivan Fraile,[1] Ignacio de Leon-Ponce de Leon,[1] Oscar Martinez Perez,[2] Helena Diaz-Cuervo,[2] Jesús Cuervo,[2] Jose Maria Ordoñez Martí Aguilar,[1] Fernando Jose Gordinho R. Macario.[3] Diaverum Catalonia PCC Team. *[1]Diaverum Espana, Madrid, Spain; [2]Axentiva Solutions SL, Barcelona, Spain; [3]Diaverum Renal Services Group, Lund, Sweden.*

Background: Chronic kidney disease (CKD) constitutes a public health concern due to its notable morbidity&mortality and associated costs. The Patient Care Coordination program (PCC) provides comprehensive and personalized care to hemodialysis (HD) patients. This study evaluated the cost-effectiveness of PCC compared to standard of care (SoC).

Methods: The study included patients in 9 HD clinics (5 PCC, 4 SoC) in Catalonia, Spain, in 2020-2021. A comparative effectiveness evaluation was conducted to compare change in Individual Patient Performance Score (IPPS, score 0-100, evaluates parameters such as vascular access, adequacy of HD, anemia, mineral bone disease, arterial hypertension, nutrition/hydration status) and number of hospitalizations of PCC patients vs SoC during the first year in the program. Instrumental variables (IV) regression analysis was performed to address potential confounding; number of interactions with program specialists was a valid IV to estimate degree of PCC use. An incremental cost-effectiveness analysis (iCEA) through microsimulation was performed using the effectiveness data from the previous step, population data from the renal patient registry of Catalonia, and the cost of hospitalizations obtained from the Public Health System.

Results: 127 patients in PCC and 363 patients in SoC were included. The degree of PCC use had a positive impact on IPPS variation during the first year of the program (p= 0.012). In the iCEA the PCC program resulted in a mean gain of 3.4 additional IPPS points, a reduction of 0.2 hospitalizations per patient, and reduced mean costs of €1,265 per patient in the first year compared to SoC, resulting to be a dominant alternative (Figure 1).

Conclusions: Use of PCC resulted in positive impact in outcomes and reduced costs compared to SoC for HD patients. The PCC program represents thus a dominant alternative, with greater effectiveness and total cost savings that could sum up to €5.5 million per year in the region due to reduced hospitalizations. The findings underscore the relevance of comprehensive and personalized care in addressing the challenges of CKD and optimizing healthcare resource allocation.

Long-COVID-19 in Hemodialysis Patients: A Prospective Study

Maggie Han,[1] Lin-Chun Wang,[1] Sarah Ren,[1] Lela Tisdale,[1] Zijun Dong,[1] Chidiadi R. Nze,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Long-COVID (LC) is defined as persistent symptoms after COVID-19 infection. It has been reported that up to 40% of COVID-19 survivors experience LC (O'Mahoney et al. *The Lancet*, 2023). We aim to determine if hemodialysis (HD) patients experience LC.

Methods: HD patients diagnosed with COVID-19 via RT-PCR test were enrolled from 01 to 04 2022 from 4 clinics in New York City. COVID-19 Yorkshire Rehabilitation Scale (C19-YRS) was administered at baseline, i.e. as soon as possible after diagnosis, and 1 and 6 months after baseline. C19-YRS also asks about pre-COVID symptoms; we used that symptom severity (SS) at baseline as comparator. While SS is graded from 0-10, 10 being the worst, global health score (GH) is reported with 10 being the best. Patient data were obtained from medical records. Paired t-tests were used examine differences in SS pre- and post- COVID-19 infection. Linear and generalized mixed models were used to examine the effect of time on continuous and discrete LC SS, respectively.

Results: We studied 16 patients (58±14 years old, HD vintage 2.7±3.4 years, 56% male, 81% Black, 19% Hispanic, no diabetic, 50 % hypertensive). Baseline C19-YRS was administered 43±23 days (range 9-108) after COVID-19 diagnosis. 5 patients were hospitalized. C19-YRS results are shown in Table 1. Compared to baseline, patients experienced significantly increased dyspnea, anxiety, and PTSD at 1 month and fatigue and inability to perform personal care at 6 months. Decreased mobility and activity of daily living were also observed, though not statistically significant. Lastly, patients reported decreased GH score at months 1 and 6 compared to baseline.

Conclusions: Following COVID-19 infection, patients report worsening LC symptoms. Further studies are warranted to investigate the long-term consequences of LC in HD patients.

Risk of Hospitalization and Mortality Following Extreme Heat Events in Patients Undergoing In-Center Hemodialysis in the Western United States

Nicole E. Sieck,[1] Hyeonjin Song,[1] Jochen G. Raimann,[2] Peter Kotanko,[2,3] Franklin W. Maddux,[4] Hao He,[1] Amir Sapkota.[1] *[1]The University of Maryland, College Park, MD; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Climate change is increasing the frequency of extreme heat events (EHEs) and this trend is projected to continue into the foreseeable future. Previous research indicates that patients undergoing hemodialysis treatment are at an increased risk of both hospitalization and mortality following exposure to EHEs, although earlier analyses were limited in scope to the Northeastern U.S. Here, we investigated the risk of hospitalization and mortality following exposure to EHEs in the Western U.S. among patients that receive in-center hemodialysis treatment.

Methods: We identified EHEs as days where the daily maximum temperature (Tmax) exceeded the 95th percentile distribution of daily Tmax values specific to the location and calendar day over a 20-year baseline (1980-1999). We linked EHE data with health records of 79,963 patients undergoing in-center hemodialysis treatment at Fresenius Kidney Care clinics (*n*=191) in Washington, Oregon, and California during the warm season (May-September) of 2001-2018. We conducted a time-stratified case-crossover analysis with conditional Poisson regression to investigate the association EHE exposure and the risk of hospitalization and mortality.

Results: We observed a total of 7,242 EHE days at the county scale during the study period. EHEs were associated with a 7% higher risk of all-cause hospitalization (rate ratio (RR): 1.07, 95% CI: 1.02, 1.1), and a 6% higher risk of all-cause mortality (RR: 1.06, 95% CI: 1.00, 1.13).

Conclusions: We observed an increase in the risk of both hospitalization and mortality following EHE exposure in the Western U.S., which agrees with earlier findings from the Northeastern U.S. These findings indicate that interventions, such as the implementation of early heat warning systems, are needed to improve outcomes for patients undergoing in-center hemodialysis.

FR-PO463

Global Variability and Patterns of Use in Vascular and Peritoneal Access for Dialysis: Analysis of the ISN-Global Kidney Health Atlas Data

Samveg Shah,[1] Anukul Ghimire,[1,2] Feng Ye,[1] Somkanya Tungsanga,[1] Tushar J. Vachharajani,[3] Ikechi G. Okpechi,[1] Adeera Levin,[4] David W. Johnson,[5] Aminu K. Bello.[1] *[1]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [2]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [3]Wayne State University, Detroit, MI; [4]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [5]Princess Alexandra Hospital, Woolloongabba, QLD, Australia.*

Background: A well-functioning access (vascular or peritoneal) is key to adequate performance of dialysis. The International Society of Nephrology Global Kidney Health Atlas (ISN-GKHA) survey identified gaps in availability, patterns of use, funding models, and workforce for the provision of vascular and peritoneal accesses across countries.

Methods: Using the second iteration of the ISN-GKHA, countries were categorized by affiliations in the ISN regional boards and by World Bank income classification. Questions focused on availability of surgical aspects of care, access to education and availability of providers for the access creation.

Results: Data was available from 159 countries out of 160 that participated in the survey. Overall, public funding was available for hemodialysis (HD) central venous catheters in 92 countries (57%), for HD fistula or graft creation in 86 countries (54%), and for PD catheter surgery in 85 countries (54%). Public funding for the access types was highest in high-income countries than other country income categories. Overall, and in countries where HD was available, >75% of patients initiated HD with a temporary catheter in 21% of countries compared to patients commencing with a tunneled catheter (5%) or a fistula (5%) (Figures 1). Shortages of surgeons and radiologists were highest in low-income and lower-middle income countries.

Conclusions: There is significant variation in the availability, accessibility and patterns of use of vascular access and peritoneal catheters across countries with significant limitations in the needed workforce. In order to improve the outcomes and survival of patients on dialysis, strategies to increase the uptake of viable access are required.

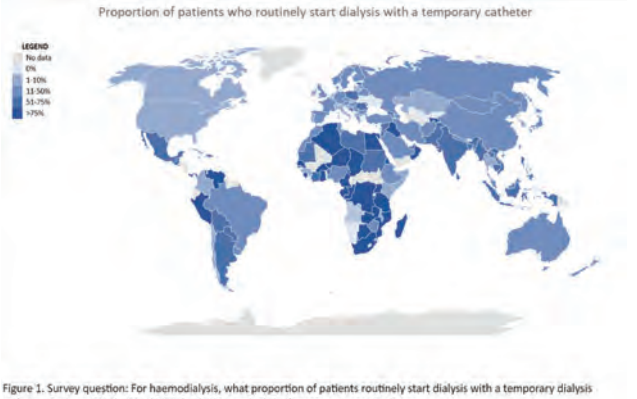

Figure 1. Survey question: For haemodialysis, what proportion of patients routinely start dialysis with a temporary dialysis catheter. Options: 0%, 1-10%, 11-50%, 51-75%, and >75%. Average response is shown.

FR-PO464

Nitric Oxide-Releasing Nanomatrix Gel Inhibits Venous Intimal Hyperplasia and Improves Vascular Remodeling in Porcine Arteriovenous Fistula (AVF)

Nguyen T. Nguyen,[1] Kevin A. Ingle,[1] Tatyana Isayeva Waldrop,[1] Bailey G. Lose,[1] Paul C. Collie,[1] William A. Gard,[1] Patrick Hwang,[2] Ho-Wook Jun,[3,2] Hannah M. Northrup,[4] Yan-Ting E. Shiu,[4] Timmy C. Lee.[1,5] *[1]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL; [2]Endomimetics, LLC, Birmingham, AL; [3]The University of Alabama at Birmingham School of Engineering, Birmingham, AL; [4]University of Utah Health, Salt Lake City, UT; [5]Birmingham Veterans Affairs Medical Center, Birmingham, AL.*

Background: Arteriovenous fistula (AVF) is the preferred vascular access for hemodialysis, but a large proportion fails to mature due to venous intimal hyperplasia (IH) formation and impaired outward remodeling. End-stage kidney disease has been linked to endothelial dysfunction characterized by reduced nitric oxide(NO) in the blood vessel. NO delivery during AVF creation may improve AVF maturation. Our study tested an NO nanomatrix gel applied perivascularly during AVF creation in a porcine AVF model.

Methods: AVFs were created in Yorkshire pigs by anastomosing the jugular vein to the carotid artery, treated with NO-releasing nanomatrix or control gel at the anastomosis, and sacrificed at day 35. Immunohistochemistry, histomorphology and hemodynamic changes were evaluated to assess the efficacy of NO gel in reducing intimal hyperplasia and promoting outward remodeling.

Results: NO gel-treated group vs control gel demonstrated significantly reduced IH($p<0.0001$) and type I collagen($p<0.05$). The patency of open lumen within AVF region was significantly higher in NO gel, along with increased blood flow and AVF diameter($p<0.05$). NO gel reduced intimal α-SMA, Vimentin, Desmin, CD68 and CD14 expression($p<0.05$).

Conclusions: AVFs applied with an NO-releasing gel reduce intimal hyperplasia and promote outward remodeling, and could serve as a therapy to promote AVF maturation.

Funding: NIDDK Support

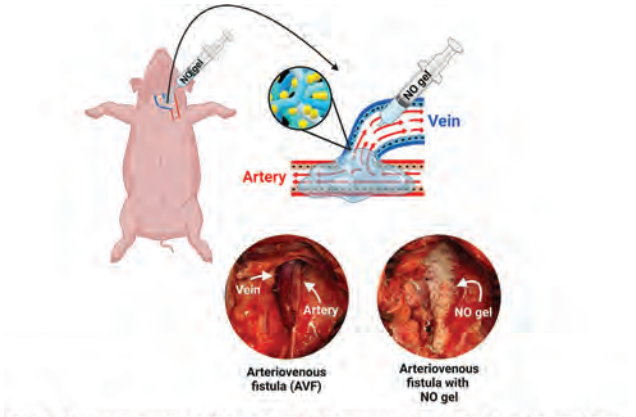

Fig.1. The NO-releasing nanomatrix gel was applied to AVF anastomosis (end jugular vein to side carotid artery)

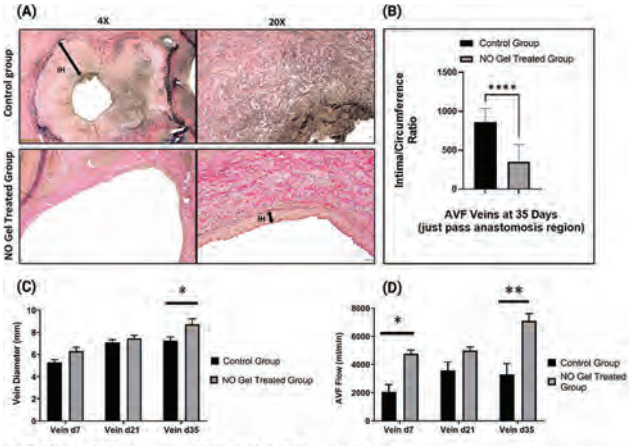

Fig.2. Effects of NO gel treatment 35 days after AVF creation in pigs
(A) Representative Van Gieson-stained cross sections show the development of venous intimal hyperplasia following 35 days post-AVF creation in the control group (note the level of aggressive intimal hyperplasia) and the NO-releasing nanomatrix gel-treated group. A visible increase in intimal thickness is observed when NO gel was not applied. Double-headed black arrows indicate intimal hyperplasia (IH) development.
(B) Morphometric analysis of intimal hyperplasia from AVF veins.
(C)(D) Quantifications of venous diameter (mm) and venous flow (ml/min) 35 days post-AVF.
All data are presented as the mean ± S.E.M. (n=3); *p<0.05 and ****p<0.0001 indicate statistical significance

FR-PO465

Contrast Venography vs. Intravenous Ultrasound in Arteriovenous Access Dysfunction

Najia Idrees,[1,2] Samir Haroon,[2] Yichi Zhang,[2] Joanna Crisa Mangio,[2] Howard J. Cabral,[2] Laura M. Dember,[3] Vipul C. Chitalia.[1,2] *[1]Veterans Affairs Boston Healthcare System, Boston, MA; [2]Boston Medical Center, Boston, MA; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Contrast venography, a standard approach for evaluating hemodialysis vascular access dysfunction, has several limitations that may be overcome by intravascular ultrasound (IVUS).

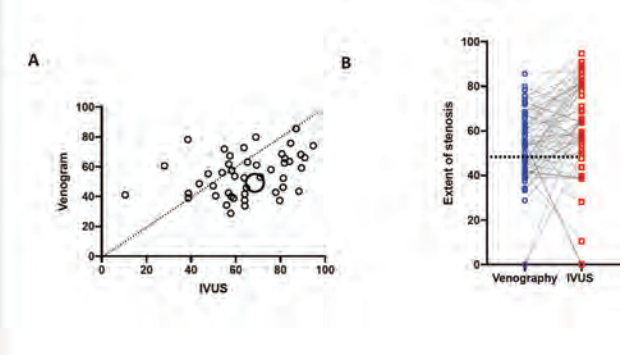
Methods: Venography and IVUS were performed in a prospective study of 41 patients with arteriovenous access dysfunction. Radiologists estimated stenosis on venograms and annotated cross-sectional IVUS images (N=250) that were used to train a deep neural network to analyze a larger set of IVUS images (N=27,315). Two measures were extracted from the IVUS images –eccentricity and homogeneity indices – characterizing stenosis shape and wall texture, respectively.

Results: Among the 33 patients with high quality images, 20 had a single stenosis and 13 had two stenoses of any severity (total of 46 stenoses). Twenty-four stenoses with >50% lumen reduction were detected by both venography and IVUS, and 14 additional stenoses were detected by IVUS but not by venography. A discordance between the two modalities was observed (McNemar ratio 7.11, p=0.0076; kappa 0.163). The severity of stenosis (%) was lower by venography (mean+SD 51.7+14.1) compared to IVUS (64.9+18.1, p=0.002). IVUS image analysis showed higher eccentricity and homogeneity indices for stenotic lesions compared to the reference segments. Metrics comparing stenoses and reference segments demonstrated substantial variability in the distribution of both indices.

Conclusions: Compared to IVUS, venography underestimated severity of stenoses in ~30% of patients presenting with arteriovenous access dysfunction. Further studies are needed to confirm the superiority of IVUS over venography and to establish the clinical utility of morphological indices for predicting stenosis progression and response to intervention.

Frequency distribution of stenoses severity detected by both modalities

Frequency of stenosis by venogram	Frequency of stenosis by IVUS		Total
	<50%	>50%	
<50%	5	14	19
>50%	3	24	27
Total	8	38	46



Disagreement between venogram and IVUS

FR-PO466

Role of Neutrophil Extracellular Traps in Vascular Access Thrombosis in Hemodialysis Patients

In Soo Kim,[1] Ji Hwan Kim,[1] Jinha Jang,[1] Sung Jin Moon,[2] Sung Gyun Kim,[1] Jwa-kyung Kim.[1] *[1]Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea; [2]Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea.*

Background: A patent vascular access (VA) is a lifeline for hemodialysis (HD) patients. However, vascular access is prone to thrombosis, which, if left untreated, can lead to permanent vascular access loss and increased mortality. Previous data have shown that neutrophil dysregulation and excessive release of neutrophil extracellular traps (NETs) may be a key mechanism in both venous and arterial thrombosis. The aim of this study is to evaluate the relationship between circulating NETs and VA thrombotic occlusion and their role in predicting permanent VA loss.

Methods: A total of 173 patients (73 arteriovenous fistula [AVF], 100 arteriovenous graft [AVG]) undergoing VA percutaneous transluminal angioplasty (PTA) with or without thrombectomy were included. Circulating nucleosome and myeloperoxidase (MPO)-DNA complexes were measured as markers of NETs. Serum von Willebrand factor (vWF) was measured as a marker of endothelial damage and thrombosis risk. VA loss was defined as access abandonment requiring dialysis catheter placement.

Results: Thrombectomy was performed in 81 patients. Patients who underwent thrombectomy were significantly older than those who underwent PTA only and used AVG more often than AVF. Circulating nucleosome levels were closely associated with MPO-DNA ($r=0.354$, $p<0.001$), serum vWF levels ($r=0.172$, $p=0.025$), and previous coronary artery disease ($r=0.226$, $p=0.003$). Nucleosome and vWF levels were significantly higher in thrombectomy cases than in PTA cases (nucleosome; 0.83 ± 0.70 vs. 0.35 ± 0.26, $p<0.001$, vWF: 9.0 ± 7.6 vs. 7.3 ± 6.2, $p=0.038$). The highest quartile of nucleosomes (Q4) was associated with an 11.4-fold increased risk of VA thrombotic occlusion ($p<0.001$). In addition, the risk of recurrent thrombotic obstruction within 6 months of PTA was also 3.1 times higher in the nucleosome Q4 group than in the Q1-3 group ($p=0.020$). During a median follow-up of 34 months, there were 25 cases of VA abandonment. The nucleosome Q4 was strongly associated with an increased risk of access loss (HR 2.56, 95% CI 1.23-7.44, $p=0.016$) even after adjustment for age, vascular access type, blood pressure, vWF, and duration of access use.

Conclusions: Higher circulating NETs are associated with thrombotic occlusion of VA and subsequent access loss in HD patients.

FR-PO467

Case Series of Real-World Use of Percutaneous Arteriovenous Fistulas in an Urban Predominantly Black US Hemodialysis Population

Gautam Yadla, Vandana D. Niyyar, Jonathan Keyes, Nathaniel Forrester, Forest Rawls, Rodella Broxton-Key, Jason Cobb. *Emory University, Atlanta, GA.*

Background: Arteriovenous fistula (AVF) is the preferred vascular access for end-stage kidney disease (ESKD), but most patients in the US start hemodialysis (HD) with a tunneled dialysis catheter. Percutaneous (pAVF) creation systems (Ellipsys and

WavelinQ) allow for non-surgical creation of AVFs. Published pAVF studies so far report higher patency rates (85-96%), less interventions, less surgical complications, and greater patient satisfaction compared to surgically created AVF. The percentage of Black patients varies from 0-20.6% in the literature, which vastly differs from our clinical population. We report a case series of real-world outcomes of pAVF in our urban predominantly Black HD patient population.

Methods: Retrospective chart review from 2021-2023 of patients from Emory Dialysis of all patients who received percutaneous AVF.

Results: Eleven patients had pAVF created by four proceduralists using either the Ellipsys or WavelinQ devices. Majority of patients were male (72.7%) and of Black race (91%). Common co-morbidities included hypertension (100%), diabetes mellitus (63.6%), and cardiovascular disease (36.4%). Mean age was 53.6 years, and the mean body mass index (BMI) was 34.6. Dialysis vintage ranged from 0.5 to 9 years, with mean duration of 2.7 years. 91% of patient had a tunneled dialysis catheter before having a fistula. Of 11 patients, 6 (54.5%) had their pAVFs functioning adequately for HD, 4 (36.4%) did not, 1 had 3 angioplasties but her pAVF was not used. Irrespective of ultimate functional patency, all required multiple interventions, with 10 of 11 patients (91%) requiring 2 or more interventions.

Conclusions: Overall, this case series provides real-world data on the use of pAVFs in an urban predominantly Black US dialysis population. To our knowledge, our study has the largest percentage of Black patients in the study population published so far. Our results indicate that though pAVFs can be successfully created in this population, a majority of patients require multiple secondary procedures, and only 54.5% were able to achieve functional patency. Further research with larger sample sizes and longer follow-up is warranted to evaluate the long-term patency rates and complications associated with pAVFs.

FR-PO468

Development of Senescence in the Rat Arteriovenous Fistula: Functional Effects of Heme

Anthony J. Croatt, Joseph P. Grande, Allan W. Ackerman, Raman D. Singh, Karl A. Nath. *Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.*

Background: As shown in our previous studies, the murine arteriovenous fistula (AVF) model in the presence of CKD (AVF-CKD) evinces markers of senescence in the venous limb [Am J Physiol Renal Physiol. 315(5):F1493-F1499, 2018]. We now assess whether an AVF fashioned in the rat also exhibits senescence, and whether heme, a prosenescent agent, alters rat AVF function.

Methods: Subtotal nephrectomy was performed in rats after which an AVF was created by anastomosing the femoral artery and vein. At 1 and 2 weeks after AVF creation, the AVF was assessed for evidence of senescence, including increased expression of cell cycle inhibitors (p16 and p21), senescence-associated β-galactosidase (SA-β-Gal) and senescence-associated secretory phenotype (SASP) factors. In additional studies, the effect of heme on AVF blood flow was assessed in the rat.

Results: One week after AVF creation, p16 and p21 mRNA levels were markedly elevated in AVF veins compared to sham veins, as were p21 protein levels; p21 protein in the AVF artery was also increased. At 2 weeks, p21 protein was again upregulated in the AVF vein and artery, and protein levels of p53, an upstream inducer of p21, were significantly increased in the AVF artery, and tended to be higher in the AVF vein ($p = 0.083$). Upregulation of SASP factors was also observed in the AVF vein at 1 week; PAI-1, IL-6, TNF-α and MCP-1 mRNA were all markedly induced compared with sham values. At this time point, miR21, (associated with vascular senescence) was also elevated in the AVF vein. Additionally, SA-β-Gal activity, an established senescence marker, was significantly increased in both the artery and vein compared to their sham counterparts at 1 and 2 weeks post AVF surgery. Finally, heme administration increased AVF blood flow at 5 days after AVF placement, but resulted in lower AVF flow rates at 3 weeks.

Conclusions: We demonstrate that the rat AVF in the presence of CKD exhibits a senescent phenotype, akin to the murine AVF-CKD model. We suggest that heme, administered over 3 weeks, reduces AVF blood flow because of its prosenescent inflammatory effects whereas an early increase in AVF blood flow results from vasodilation that this agent can induce. These results point to the need to further investigate the role of senescence in AVF function/dysfunction, and the biphasic effects of heme treatment.

Levels of Interleukin 8 and Monocyte Chemoattractant Protein-1 Are Associated with Arteriovenous Fistula Events and Upregulated in the Endothelium by Indoxyl Sulfate and TGF-β Pathway

Stanislas Bataille,[1,2] Rania Chermiti,[2,1] Philippe Giaime,[1] Nathalie Pedinielli,[1] Nathalie Mc kay,[2] Guillaume Lano,[2,3] Addi Tawfik,[2,4] Julien Mancini,[5,6] Stephane Burtey,[2,7] Laetitia Dou.[2] *[1]Institut Phocéen de Néphrologie, Clinique Bouchard, ELSAN, Marseille, France; [2]C2VN, Aix-Marseille Université, INSERM, INRAE, Marseille, France; [3]Service de Néphrologie Hémodialyse, Centre hospitalier de Bastia, Bastia, France; [4]Université Oran 1 Ahmed Ben Bella, Département de Biologie, Oran, Algeria; [5]APHM, Hop Timone, Public Health Department (BIOSTIC), Marseille, France; [6]Aix-Marseille Univ, INSERM, IRD, ISSPAM, SESSTIM, Marseille, France; [7]Centre de Néphrologie et Transplantation Rénale, APHM, Hôpital Conception, Marseille, France.*

Background: Arteriovenous fistula (AVF) failure due to stenosis or acute thrombosis is a major concern in haemodialysis (HD) patients. Intimal hyperplasia responsible for AVF stenosis can be caused by several factors like endothelial dysfunction, uremic toxins, and inflammatory/profibrotic molecules. Studies suggest that endothelium-secreted inflammatory molecules Interleukin 8 (IL8) and Monocyte Chemoattractant Protein-1 (MCP-1) trigger intimal invasion of smooth muscle cells and enhance intimal thickening. We investigated the association of IL8 and MCP-1 serum levels with AVF events in haemodialysis patients and studied the ability of the uremic toxin indoxyl sulfate to upregulate IL8 and MCP-1 expression in endothelial cells.

Methods: We conducted a retrospective observational study in 205 haemodialysis patients with AVF. In vitro, we studied the mRNA expression of IL8 and MCP-1 in endothelial cells incubated with indoxyl sulfate at uremic concentration (200μM).

Results: During the study period of 731 days, 64 patients had an AVF event defined as a composite of the first occurrence of AVF thrombosis or AVF stenosis requiring endovascular treatment. Kaplan-Meier analysis revealed that patients with serum levels of IL8 > 0 pg/ml or MCP-1> 720 pg/ml had significantly more AVF events. Serum levels of IL8 and MCP-1 were positively correlated with the levels of the pro-fibrotic molecule TGFβ1 in HD patients. In addition, serum levels of MCP-1 were positively correlated with indoxyl sulfate. In vitro, indoxyl sulfate upregulated endothelial expression of IL8 and MCP-1 by activating its receptor, aryl hydrocarbon receptor, which in turn activated the non-canonical TGFβ pathway involving TAK1, p38 MAPK, and the transcription factor AP-1. The stimulation of the TGFβ signalling pathway by TGFβ1 amplified indoxyl sulfate-mediated IL8 and MCP-1 expression.

Conclusions: We demonstrated that AVF events are associated with high serum levels of IL8 and MCP-1, which are upregulated in the endothelium by activation of the TGFβ non-canonical pathway by the uremic toxin indoxyl sulfate. Our study could provide therapeutic targets to limit intimal hyperplasia and prevent AVF events in haemodialysis patients.

Uremia and a Lack of Krüppel-Like Factor-2 (KLF-2) Are Responsible for an Inadequate Positive (Outward) Venous Remodeling in a Mouse Model of Arteriovenous Fistula (AVF) Stenosis

Jasleen Sidhu,[1] Taylor G. Lewis,[1] Christine Wai,[1] Aous Jarrouj,[1] Keith L. Saum,[1] Diego Celdran-Bonafonte,[1] Begoña Campos,[1] Eyla C. Arteaga,[1] Gang Xi,[1] Unimunkh Uriyanghai,[1] Prabir Roy-Chaudhury.[1,2] *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]VA Salisbury Healthcare System, Salisbury, NC.*

Background: Although AVFs remain the gold standard for dialysis vascular access they have a maturation failure rate of over 50% at 6 months post surgery due to a combination of neointimal hyperplasia and an inadequate positive (outward) remodeling. A central molecule in the mechanotransduction pathways responsible for outward remodeling in response to increased flow is KLF-2. In order to better understand the mechanisms of inadequate outward remodeling in AVF maturation failure we aim to describe the impact of both uremia and the absence of KLF-2 in our mouse model of AVF stenosis.

Methods: AVFs were created between the carotid artery and jugular vein in (a) non-uremic WT C57Bl/6 animals (b) uremic WT animals (c) non-uremic KLF-2 KO animals and (d) uremic KLF-2 KO animals (n=3 in each group). The degree of outward remodeling was assessed by measuring the change in the venous perimeter from the juxta-anastomotic segment (0 microns from the anastomosis) to proximal vein 1200 microns downstream (proximal) to the anastomosis, using Image J morphometry.

Results: Non-uremic WT animals had a 48% increase ($p<0.0001$) in venous perimeter across the length of the venous segment (from 0-1200 microns). In marked contrast both the KLF-2 KO animals and the uremic animals (regardless of KLF-2 presence or absence) completely lost this increase in venous perimeter (outward remodeling).

Conclusions: Our results demonstrate that KLF-2 is likely a strong driver of positive (outward) remodeling in our mouse model of AVF stenosis. At the same time uremia appears to be a strong inhibitor of outward remodeling (likely as a result of endothelial dysfunction) such that the presence or absence of KLF-2 in uremic animals does not have any impact on the remodeling process. Looking to the future our data suggest that (a) creating a local milieu around the AVF which inhibits the impact of uremic toxins and (b) upregulating KLF-2 are two molecular approaches that could reduce AVF maturation failure.

Local Sirolimus Delivery Reduces Arteriovenous Graft (AVG) Stenosis in a Pig Model

Vinay A. Sudarsanam,[1] Christine Wai,[1] Jasleen Sidhu,[1] Diego Celdran-Bonafonte,[1] Eyla C. Arteaga,[1] Gang Xi,[1] Prabir Roy-Chaudhury,[1,2] Ron Shebuski,[1] Unimunkh Uriyanghai.[1] *[1]The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC; [2]VA Salisbury Healthcare System, Salisbury, NC.*

Background: Dialysis vascular access is currently the "Achilles Heel" of hemodialysis due to the high rate of stenosis in both arteriovenous fistulae and arteriovenous grafts (AVG). AVG stenosis is due to an aggressive venous neointimal hyperplasia (NH) at the graft-vein anastomosis (GVA). Sirolimus is an anti-proliferative agent which has been shown to reduce NH in the setting of coronary stenting. We have previously developed a local sirolimus (SRL) drug eluting cuff (DEC; 2mg/month) linked to an osmotic pump that can be used to deliver high concentrations of SRL to the GVA with minimal systemic SRL exposure. We herein report on the use of the Sirolimus DEC (SDEC) versus a control solution (CDEC) in the setting of a validated pig model of AVG stenosis.

Methods: 10 AVGs (6 SDEC and 4 CDEC) were created unilaterally in Yorkshire Cross pigs. Animals underwent weekly ultrasound assessments for patency and were sacrificed at 8 weeks post surgery. At the time of sacrifice 1cm of graft downstream to the DEC and 1.5cm of downstream (proximal vein) was collected for analysis of average (avg) and maximal (max) stenosis (including any attached thrombus) across the entire graft-vein segment and also within the individual vein and graft segments, using Image J.

Results: All 10 grafts were patent at the 56 day time point. Systemic SRL levels peaked at between 0.86 and 1.6ng/ml at 3d. Percentage avg. stenosis (SDEC=30.4% vs CDEC=50.8%; p=0.025) and max. stenosis (SDEC=60.1% vs CDEC=80.6%; p=0.02) across the entire graft-vein segment was significantly reduced in the SDEC group. A similar pattern was found in the venous segment for avg. stenosis (SDEC=46.4% vs CDEC=72.9%;p=0.01) and maximal stenosis (SDEC=60.1% vs CDEC=80.6%; p=0.02) but not in the graft only segment for either avg. (SDEC=6.6% vs CDEC=22.7%;p=0.13) or max. stenosis (SDEC=9.9% vs CDEC=27.4%;p=0.19).

Conclusions: Our results (a) demonstrate the technical feasibility of using a SDEC for the local delivery of SRL to the GVA (b) document minimal systemic SRL exposure due to the SDEC device and (c) describe a significant reduction in both avg. and max. stenosis across the entire graft-vein segment. Future clinical development of the SDEC could significantly reduce AVG stenosis and make AVGs the preferred modality for dialysis vascular access.

Association Between Vascular Access Type and Health-Related Quality of Life

Jasmine Ion Titapiccolo,[1] Francesco Bellocchio,[1] Stefano Stuard,[1] Len A. Usvyat,[2] Luca Neri.[1] *[1]Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy; [2]Fresenius Medical Care, Waltham, MA.*

Background: The use of arteriovenous fistula (AVF), arteriovenous graft (AVG), or central venous catheter (CC) may differently affect patients' quality of life (QOL). We assessed the association between vascular access (VA) type and Kidney Disease Quality of Life Short Form (KDQOL-36) in a large, multinational sample of dialysis patients.

Methods: We enrolled 10148 European dialysis patients participating in the ePROM improvement program initiated in 8 European countries since September 2021. We assessed the association between the active vascular access type and KDQOL-36 subscales with generalized linear regression. All models were adjusted for potential confounders. We accounted for the multicenter design by including a random-intercept denoting patients' referral center.

Results: Catheter use was associated with statistically significant quality of life penalty in all KDQOL-36 subscales. However, the difference in score was very mild and did not reach clinical significance based on minimal clinically important difference estimation for all scales but the physical composite score (PCS12). Specifically, AVF was associated with 2-point better PCS12 scores, a small effect size difference.

Conclusions: Improving HRQOL of dialysis patients has been an elusive task as it may be associated with a multitude of factors which may require a multifaceted management approach. We found a small PCS12 advantage for AVF users which may be barely perceived as clinical important. Expanding AVF use may contribute to HRQOL improvement in combination with optimization of others modifiable clinical parameters.

QOL score	Catheter (N=2596)	Fistula (N=6379)	Graft (N=220)	p-value
BKD	37.8 (35.3-40.3)	40.3 (37.9-42.7)	37.7 (33.5-41.9)	<0.001
EKD	65.9 (63.9-67.9)	67.8 (65.9-69.7)	66.4 (63.2-69.7)	<0.001
MCS12	44.1 (43.0-45.3)	44.9 (43.7-46.0)	45.0 (43.2-46.7)	<0.05
PCS12	33.6 (31.1-36.0)	35.5 (33.0-38.0)	34.0 (31.2-36.8)	<.0001
SKD	76.2 (73.9-78.5)	77.4 (75.1-79.6)	75.6 (72.7-78.6)	<0.01

FR-PO473

Increase in Hemodialysis Initiation with a Catheter

Nicholas S. Roetker,[1] Eric D. Weinhandl,[2,3] Kirsten L. Johansen,[1,3] Jiannong Liu,[1] David T. Gilbertson,[1,3] James B. Wetmore.[1,3] *[1]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN; [2]Satellite Healthcare, San Jose, CA; [3]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Reliable vascular access is essential for hemodialysis (HD). Initiating HD with an arteriovenous (AV) access rather than a catheter is preferred for most patients. We modeled recent trends in the percentage of patients initiating HD with a catheter and no maturing AV access.

Methods: Using data from the US Renal Data System, we included all adults initiating maintenance HD between January 1, 2012 and September 30, 2022. We estimated the proportion initiating HD with a catheter only in each quarter, identifying a breakpoint in the temporal trend using segmented linear regression. We then fit a generalized piecewise linear model with a binomial distribution and identity link to estimate the temporal trend in catheter use before and after this breakpoint, with adjustment for age, sex, race/ethnicity, and seasonal effects.

Results: The analysis included 1,169,323 adults. A breakpoint was identified in March 2017 (Figure). In 2012, the overall proportion of patients initiating with a catheter only was roughly 60%. This proportion increased by 0.5% (95% CI 0.4-0.6%) per year, on average, until Q1-2017. After the breakpoint, the proportion increased more rapidly, by an average of 2.5% (95% CI 2.4–2.6%) per year, with nearly 75% of patients initiating HD with a catheter and no maturing AV access by 2022. Trends in catheter use before and after March 2017 were similar across categories of age, sex, and race/ethnicity. Other than a transient increase during Q2-2020, there was no enduring change in the pattern of catheter use during the COVID-19 pandemic.

Conclusions: We observed a concerning increasing trend in HD initiation with a catheter in the absence of a maturing permanent access between 2017 and 2022. The emergence of this trend in 2017 coincided with reductions for vascular access services in the Medicare Part B Physician Fee Schedule. Given further reductions in vascular access-related reimbursements occurred in 2023, trends in catheter use should be carefully monitored.

FR-PO474

Trends in Vascular Access Among Incident US Hemodialysis Patients Between 2015 and 2019

Michael Allon,[1] Yi Zhang,[3] Mae Thamer,[3] Deidra C. Crews,[2] Timmy C. Lee.[1] *[1]Univ of Alabama at Birmingham, Birmingham, AL; [2]Johns Hopkins Medicine, Baltimore, MD; [3]Medical Technology and Practice Patterns Institute, Bethesda, MD.*

Background: Vascular access guidelines recommend arteriovenous fistula (AVF) placement prior to hemodialysis (HD) initiation to decrease catheter (CVC) dependence. We quantified changes in vascular access between 2015-19.

Methods: Using the USRDS database, we identified 536,667 patients initiating HD from 2015-19. Patients starting HD with an AVF or with a CVC and a maturing AVF were considered to have undergone pre-HD AVF placement. We examined patient demographics, co-morbidities, functional status, insurance status, and duration of pre-HD nephrology care.

Results: AVF use at HD initiation decreased from 17% to 15% (12% relative decline) (**Fig 1**), and occurred across multiple patient subgroups. Pre-dialysis AVF placement decreased from 34 to 28% (18% relative decline). Patients with pre-dialysis AVF placement who used their AVF at dialysis initiation increased from 50 to 54%, indicating a higher AVF maturation rate. CVC use increased from 61 to 68% (11% relative increase) and AVG use remained constant at 3%. As compared to 2015, the adjusted odds ratio for initiation of HD with an AVF was 0.79 (95% CI 0.78-0.81) and for initiation with a CVC was 1.43 (1.20-1.45) in 2019. The best predictor of AVF placement and use was duration of pre-HD nephrology care. However, AVF use decreased and CVC use increased even among patients with prolonged pre-HD nephrology care (**Fig 2**).

Conclusions: AVF use decreased and CVC use increased at dialysis initiation from 2015-19.

Dialysis Access: A Post-Code Lottery? A Single-Centre Retrospective Review

Stuart R. Deoraj, Bethany J. Wadsworth, Divyen Vanniasegaram, Allifia Abbas. *Epsom and Saint Helier University Hospitals NHS Trust, Carshalton, United Kingdom.*

Background: For many chronic diseases there is a clear relationship between social deprivation, health literacy, healthcare access and delayed presentation with disease progression. Outcomes of renal replacement therapy (RRT) may be affected by patient deprivation influencing delays in diagnosis, provision of pre-dialysis education and optimal dialysis access, resulting in line sepsis, central venous occlusion and inferior dialysis clearance. This study explores the influence of patient deprivation on the provision of dialysis access in a cohort of patients, using a 7-point deprivation index linked to patient postcode (IMD2019).

Methods: Data on 1600 haemodialysis patients aged 18+ was gathered from 2015 to present day, from an urban and peri-urban catchment area. Demographic data, initiation date on RRT, mode of dialysis access at initiation and 1 year follow up were analysed with respect to the individual patient's IMD2019.

Results: Data from 308 patients was analysed. Mean age was 64 years, 64% (198) male and 50% Caucasian. A tendency towards lower levels of deprivation was noted, 16% of the cohort belonging to the least deprived decile. 207 (67%) patients commenced dialysis via a tunnelled line. At 1 year of dialysis, 88 (29%) of patients remained using a dialysis line. There was no statistically significant difference between IMD2019 for mode of access at initiation or the probability of having a fistula formed following dialysis initiation ($\chi 2$ 1.6618, p 0.798). The length of time from dialysis initiation to successful fistula formation was 7.5 months for deprivation deciles 1 and 2 (most deprived), 13 months for decile 10 (least deprived). Patients in decile 10 spent on average, 29 months on dialysis, compared to 55 months in decile 2. Deprivation deciles 5 and 6 performed marginally better than deciles 1 and 10 on the rates of access to fistula surgery (relative risk 1.2, p 0.1).

Conclusions: This dataset does not demonstrate a statistically significant impact of deprivation on the first or final mode of vascular access among haemodialysis patients. However, there are significant biases. The study was conducted in a predominantly low deprivation, Caucasian cohort. There is a suggestion that lower decile patients were initiated earlier on dialysis and that middle-decile patients may have better access to fistulas compared to deciles 1 and 10.

FR-PO476

Effectiveness of Custom-Made Under-Table Shield in a Mobile C-Arm Fluoroscopy Unit

Jinha Jang, Ji Hwan Kim, In Soo Kim, Sung Gyun Kim, Jwa-kyung Kim, Jung Nam An, Hyungseok Lee. *Hallym University Sacred Heart Hospital, Anyang, Gyeonggi-do, Republic of Korea.*

Background: It is emphasized that interventionists should adhere to the "As Low As Reasonably Achievable (ALARA)" principle and radioprotection strategies. However, radioprotection is limited when performing interventional vascular access procedures using mobile C-arm fluoroscopy, because the under-table shields are challenging to be mounted on an arm board of the table in a mobile C-arm angiography unit. We modified commercial tools and implemented custom-made under-table shields to overcome these limitations in the radioprotection strategy. This study aimed to quantitatively analyze the protective effect of the shields using real-time dosimeters.

Methods: Commercial shields were tailored and modified to completely cover the angiography table equipped with an arm board (Figure 1A). Custom-made under-table shields completely covered the table and arm board in all directions to protect operators and assistants (Figure 1B). There was no radiopaque material between the table and arm board, so the shields didn't interfere with the fluoroscopy-guided procedures (Figure 1C). To quantitatively measure the dose equivalent of radiation, real-time dosimeters (RaySafe i2) were located one meter and two meters away from the table (Figure 1D).

Results: Digital subtraction angiography was performed five times with eight pulses per second mode using a mobile C-arm fluoroscopy (GE OEC 9900 system), and the mean radiation doses were compared before and after applying the customized under-table shields. After application of them, the dose equivalent (μSv) was reduced by 34% at a 1-meter distance and 82% at a 2-meter distance, respectively (Figure 2).

Conclusions: Optimizing fluoroscopy settings and implementing radioprotective shields are crucial for ensuring safety. Under-table shields play a significant role in radioprotection strategy and should be emphasized. We customized commercial shields to overcome the limitations of radioprotective strategies in mobile C-arm fluoroscopy settings, and the shields proved effective in reducing the radiation dose.

Hemodialysis Catheter Rewiring vs. Removal and Replacement: Post Hoc Analysis of a National Stepped Wedge Cluster Randomized Trial

Ben Lazarus,[1,2] Sradha S. Kotwal,[2,3] Martin P. Gallagher,[2,3] Nicholas A. Gray,[4,5] Sarah E. Coggan,[2] Girish S. Talaulikar,[6,7] Kevan Polkinghorne.[1,8] REDUCCTION Investigators. *[1]Monash University, Clayton, VIC, Australia; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]University of New South Wales, Sydney, NSW, Australia; [4]Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; [5]University of the Sunshine Coast, Sippy Downs, QLD, Australia; [6]Canberra Hospital, Canberra, ACT, Australia; [7]Australian National University, Canberra, ACT, Australia; [8]Monash Health, Clayton, VIC, Australia.*

Background: Tunnelled haemodialysis catheters are widely used but often fail prematurely. The optimal replacement strategy is unknown. Rewiring is less burdensome for patients but may predispose to infection. We aimed to quantify variation in tunnelled

haemodialysis catheter rewiring practices among Australian nephrology services, and to determine whether rewiring was associated with infection.

Methods: In a post-hoc analysis of the national stepped wedge cluster randomized REDUCCTION trial, encompassing 37 nephrology services and 6399 adult patients, we examined variation in the service-wide proportion of tunnelled catheters that were replaced by rewiring, for infectious or non-infectious reasons. Given the findings, we compared the absolute risks of, and time to infectious removal between rewired and non-rewired (new exit site) catheters that replaced failing non-infected catheters. Marginal Cox and competing risk proportional hazard models, including catheter, patient, and service-level covariates were used. Confirmed bloodstream infections were assessed in sensitivity analysis. Competing risks included removal for dysfunction and death before removal.

Results: Services universally avoided rewiring infected catheters but varied widely in rewiring non-infected failing catheters (range = 0 – 90% rewired). Among new catheters that replaced failed non-infected catheters, 36 of 480 rewired (7.5%), and 36 of 372 non-rewired (9.7%) were removed for infection. At three months the cumulative incidence of premature infectious and mechanical removals was 5% and 21% for rewired and 7% and 23% for non-rewired respectively. The hazard of infectious removal did not differ between rewired and non-rewired catheters (adjusted HR 0.81, 95% CI 0.46, 1.42). The incidence of confirmed catheter-related bloodstream infections and catheter dysfunction requiring removal were similar between groups.

Conclusions: The practice of rewiring non-infected failing catheters varied widely between services, was not associated with catheter infection, and did not appear to affect the high rate of subsequent catheter dysfunction in this population.

FR-PO478

Burden of Haemodialysis Catheter-Related Bloodstream Infections in Australia: A National Data-Linkage Study

Ben Lazarus,[1,2] Kevan Polkinghorne,[1,3] Martin P. Gallagher,[2,4] Nicholas A. Gray,[5,6] Sarah E. Coggan,[2] Girish S. Talaulikar,[7,8] Sradha S. Kotwal.[2,4] REDUCCTION Investigators. *[1]Monash University, Clayton, VIC, Australia; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]Monash Health, Clayton, VIC, Australia; [4]University of New South Wales, Sydney, NSW, Australia; [5]Sunshine Coast University Hospital, Sunshine Coast, QLD, Australia; [6]University of the Sunshine Coast, Sippy Downs, QLD, Australia; [7]Canberra Hospital, Canberra, ACT, Australia; [8]Australian National University, Canberra, ACT, Australia.*

Background: Haemodialysis catheters are widely used and prone to infection, but the health impact of these infections is unknown. We aimed to quantify the health burden of haemodialysis catheter-related bloodstream infection (HDCRBSI) among chronic haemodialysis patients in Australia.

Methods: Patients who commenced chronic haemodialysis via a catheter in the REDUCCTION trial (Dec 2016- Mar 2020) were followed from first catheter insertion to the later of final catheter removal or end of the trial. Hospitalizations in all States and Territories (except WA) were probabilistically linked and classified using the principal ICD10-AM diagnostic code. Same-day admissions were excluded. Hospitalizations for vascular access infection (VAI) or bacteraemia, with concurrent HDCRBSI reported at time of admission, were characterized.

Results: In REDUCCTION, 4004 patients commenced chronic haemodialysis via a catheter and were followed for 968,783 days, with baseline characteristics comparable to the Australian haemodialysis population. Infection was coded as the primary reason for admission in 1838 (18.1%) of 10,154 non-same-day hospitalizations and accounted for 18,982 (24.1%) of 78,696 total days in hospital. Mean duration of hospitalization for VAI (3649 total bed days, 377 admissions) and bacteraemia (5981 total bed days, 391 admissions) were longer than for pneumonia (2183 total bed days, 361 admissions) or cellulitis (1535 total bed days, 139 admissions; all $p<0.01$). Concurrent HDCRBSI at time of hospitalization was reported in 148 admissions, 122 (82%) with primary code for VAI or bacteraemia. The median length of stay was 9 days (IQR 5-15), 19 (15.6%) admissions required intensive care (median 64 hours, IQR 27 – 110), 10 (8.2%) were complicated by metastatic infection, and 4 (3.3%) resulted in death.

Conclusions: Catheter-related infections are a major source of infectious hospitalization among Australians receiving chronic haemodialysis via a catheter.

FR-PO479

The Magnetic Snare Endovascular Catheter System for Central Venous Stenosis

Jonathan G. Owen, Alex Bender. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Central venous stenosis (CVS) is a common complication in patients with End Stage Kidney Disease undergoing hemodialysis, and most commonly occurs after exposure to tunneled dialysis catheters. CVS can lead to vascular access failure and can become life threatening. Sharp needle recanalization is an option for revascularization when a lesion can be approached bi-directionally, i.e. from the femoral vein and the internal jugular vein, however this procedure carries a high-risk of mediastinal perforation, which can be rapidly fatal. A novel two catheter system, the Magnetic Snare Endovascular Catheter (patent pending PCT/US23/62960), utilizing magnets to approximate either end of the stenosis has recently been developed to address this problem and improve safety of the revascularization procedure.

Methods: Mechanical engineering students at the University of New Mexico were recruited to develop an initial prototype of the catheter system. After initial success, one of the graduates was retained for further work and development of additional working prototypes.

Results: Three distinct prototype catheter systems have been developed for further testing. The first prototype utilizes a neodymium to neodymium magnetic tip and would traverse a central stenosis using thermal or radiofrequency energy. The second catheter design utilized a broad-based neodymium magnet on one catheter, and a needle fashioned from neodymium on the opposite catheter. The final prototype consists of a powerful electromagnetic tip that would be used to attract conventional steel needles and guidewires from the opposing side.

Conclusions: The Magnetic Snare Endovascular Catheter system is a promising new technology to improve safety of central venous stenosis revascularization. Three working prototypes are now developed for additional testing.

FR-PO480

Initial Testing of a Novel Vascular Access Device in a Rabbit Model

Jonathan G. Owen, Joshua A. Hanson, Gus Pedrotty, Tara G. Konecny, Victoria A. Sugita, Christos Argyropoulos, Sam Pedrotty. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Ideal vascular access for dialysis is the arteriovenous fistula (AVF). However, AVF have delays in maturation or frequently fail to mature. Arteriovenous graft (AVG) mature more quickly but are prone to thrombosis and have higher incidence of infection. Tunneled dialysis catheters (TDC) can be placed rapidly but have the greatest incidence of infection. Recently, a novel vascular access device was created using a titanium needle guide to be inserted around an artery and separately a vein, allowing the placement of a modified removable shunt. The device could be usable for dialysis rapidly and obviate need for AVF or AVG placement. Feasibility of this device was achieved previously in a porcine model. A rabbit model is sought in this study to expand testing and to examine the effects of repeated arterial cannulation.

Methods: A male New Zealand white rabbit was obtained. After a 2-week acclimation, the animal was anesthetized, the right femoral artery dissected, and the vascular access device attached around it. The device was secured with dissolvable sutures, and site closed in three layers. The animal was recovered uneventfully, and after two weeks the site was well healed. The femoral artery was then cannulated via the device twice per week, with 2.5 mL blood withdrawn during each cannulation, for a total of 4 weeks, after which the animal was euthanized and submitted to pathology for examination.

Results: The vascular access device installed easily and without complication. The surgical site healed well with no visible signs of ischemia, trauma, or discomfort. All arterial access cannulations were successful with bright red arterial blood aspirated. After euthanasia, the femoral artery within the device was found to be intact, without neointimal hyperplasia or thrombosis on histologic examination. No visible signs of ischemia in the femoral artery vascular bed were seen. A small amount of neointimal hyperplasia was seen within the adjacent femoral vein, felt most likely secondary to manipulation and dissection from initial surgical implantation.

Conclusions: The novel vascular access device was successfully implantable in a rabbit model. The device allowed for repeated arterial cannulations as intended. No visible damage of the femoral artery was observed after 8 repeated arterial cannulations over four weeks.

FR-PO481

Achromobacter xylosoxidans: A Potentially Serious Occult Dialysis Catheter-Related Infection

Zahoor U. Rehman,[1,2] Ashok P. Chaudhari,[1,2] Donald I. Baumstein,[1,2] Muhammad Khalid Tahir.[1,2] *[1]New York City Health and Hospitals Metropolitan, New York, NY; [2]New York Medical College, Valhalla, NY.*

Introduction: Hemodialysis(HD) catheter-related infection is one of the major causes of morbidity and mortality in HD patients. Achromobacter xylosoxidans (AX) is an aerobic, oxidase, and catalase-positive gram-negative bacillus that lives in various

aqueous environments. There are reported cases of AX endocarditis, bacteremia, and an outbreak of AX bacteremia in a hemodialysis unit; however, after a thorough literature review, no case of isolated AX hemodialysis tunneled catheter infection was found. Therefore, we are reporting a case of an AX tunneled dialysis catheter infection causing sepsis.

Case Description: A 50-year-old African American man with a past medical history of end-stage-kidney-disease on hemodialysis for more than one year, hypertension, and hyperlipidemia, who had recently returned from Africa, presented with a low-grade fever, chills, and lethargy. While in Africa, the patient received hemodialysis via a right internal jugular permcath. He was treated with an unknown antibiotic in Africa for 14 days. However, his fever never resolved. On return to the United States, peripheral and tunneled catheter blood cultures revealed no growth, and no other focus of infection was identified. Chest x-ray and CT scan abdomen were unremarkable for any focus of infection. Respiratory PCRs were negative for viruses and atypical bacteria. As an inpatient, in spite of receiving ceftazidime and vancomycin for more than two weeks, he was still febrile despite repeat negative peripheral blood and central line cultures; therefore, a decision was made to remove the tunneled catheter and send the catheter tip for culture, which showed growth of achromobacter xylosoxidans(too numerous to count). It was resistant to a variety of antibiotics; however, sensitive to meropenem. He was treated with meropenem, and his fever resolved following the removal of the tunneled catheter.

Discussion: Achromobacter xylosoxidans is an aerobic, oxidase, and catalase-positive gram-negative bacillus living in various aqueous environments with low virulence. It can cause occult dialysis catheter-related infections and be challenging to identify and treat. Strains of AX are highly resistant to various antibiotics and should be treated with appropriate antibiotics, usually sensitive to antipseudomonal penicillin, levofloxacin, meropenem, and trimethoprim-sulfamethoxazole.

FR-PO482

Should Alcohol Lock Replace Antibiotic Lock in Catheter-Related Bloodstream Infection (CRBSI) Management?

Prem P. Varma, Mehak Singla. *Primus Super Speciality Hospital, Chanakyapuri, India.*

Background: Catheter related blood stream Infection (CRBSI) is a dreaded complication of Tunneled Cuffed Catheter (TCC), with a reported incidence of 1.1- 5.5 episodes/1000 catheter days. Patients with Staphylococcus aureus, Pseudomonas aeruginosa or fungal growth generally require catheter removal. As per the KDOQI clinical practice guideline for vascular access: 2019, Systemic antibiotics plus antibiotic lock is the current standard of care for CRBSI. This study was done to find the usefulness of 70% alcohol lock (in place of antibiotic lock) in patients with established CRBSI.

Methods: All dialysis patients with TCC as vascular access were the subjects of the study. As per our center's protocol, all patients were given heparin lock after each session of dialysis. CRBSI was diagnosed as per CDC/IDSA criteria. In patients with CRBSI, 70 % alcohol lock (2 ml in each port) was given for 3 consecutive days, in addition to systemic antibiotics. Outcome of these patients was studied and compared with retrospective controls, who were given 'antibiotic lock with systemic antibiotics'.

Results: Over the last two- years 188 TCCs were placed in 181 patients at our center. Our CRBSI rate was 1.38/1000 catheter days. We encountered 31 episodes of CRBSI in 23 patients. There were 16 males and 7 females, with mean age of 57.03 ±11.65 years. Presentation was with fever and chills in 80.6% and hemodynamic compromise in 20%. Relevant investigations showed raised leucocyte count in 23 (74.1%) and procalcitonin in 27 (87%) episodes. The etiological agents were gram positive organisms in 12 (38.7%) and gram negative infections in 19 (61%) episodes ; Staphylococcus aureus was isolated in 11 and albus in 1, Pseudomonas aeruginosa in 6, Klebsiella pneumonie in 8, citrobacter in 3 and E coli in 2 episodes. Only 4 cases required catheter removal. Over a mean follow up period of 145 days after alcohol lock, all catheter have been functioning well. On comparison with our retrospective data of 22 patients with CRBSI who were given antibiotic lock, 15 required catheter removal. The differeence in catheter salvage is statistically significant ($p<0.001$). Our study shows that alcohol lock with systemic antibiotics works as panacea.

Conclusions: Our single center data suggests that alcohol lock works wonder in the management of CRBSI and can be included in the current standard of care.

FR-PO483

Clinical and Demographic Characteristics Associated with Arteriovenous Access-Related Infections in US Patients Initiating Hemodialysis

Sonia J. Pulgar,[1] Mary P. Panaccio,[1] Joanna Willetts,[2] Mohamad A. Hussain,[3] Sheetal Chaudhuri,[2] Len A. Usvyat,[2] Laura E. Niklason.[1] *[1]Humacyte Global Inc, Durham, NC; [2]Fresenius Medical Care Holdings Inc, Waltham, MA; [3]Brigham and Women's Hospital Department of Medicine, Boston, MA.*

Background: End-stage renal disease (ESRD) patients are dependent on successful arteriovenous (AV) access for continual hemodialysis (HD). Infection risk can be elevated due to AV access type and may vary by patient factors and if severe – this can lead to hospitalization and even death. The study objective was to describe demographic and clinical factors associated with access-related infections (AVI) for patients initiating HD.

Methods: Patients aged 18+ years initiating HD at Fresenius Kidney Care (FKC) clinics from 2016 to 2018 were followed for up to 18 months, with censoring due to death or loss to follow-up. Patient characteristics were compared between those who developed an AVI (defined as graft infection or bloodstream infection) to those who did not. Data were stratified by gender, age range, and diabetes status. Univariate models were constructed and odds-ratios (OR) with 95% confidence intervals (CI) were calculated.

Results: Among the 87,707 HD incident patients, 43% were female, 56% were white, with mean age 63 yrs. Incidence of AVI was highest among the youngest age group (18-45), particularly, women (Figure 1). At 18 months, women aged 18-45 (OR: 1.3, CI: 1.2-1.35 vs. aged 45-64) and patients with type 1 diabetes (T1DM) were at high risk for AVI (OR: 1.4, CI: 1.2-1.6 vs. non-DM patients) (Figure 2). AVI risk was highest among younger women with T1DM (OR: 1.65, CI: 1.24 - 2.2 vs similarly aged non-DM patients). Patients with multiple access changes whose initial vascular access was an AV graft were among the highest risk compared to the overall population. Indigenous patients also had elevated AVI risk (23% by month 18) and were more likely to have multiple AV access changes.

Conclusions: Younger women with T1DM had the highest AVI risks compared to those without DM, men, and older patients. Multivariate modeling of this sub-population is required to assess the interplay of other factors mediating the risk of these poorer outcomes.

The Vasa Vasorum Is the Gateway to Vascular Inflammation Determining Arteriovenous Fistula Outcomes

Laisel Martinez,[1] Miguel G. Rojas,[1] Zachary M. Zigmond,[2] Simone Pereira-Simon,[1] Marwan Tabbara,[1] Roberto I. Vazquez-Padron.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Veterans Affairs Medical Center, Miami, FL.*

Background: Postoperative vascular inflammation is believed to contribute to arteriovenous fistula (AVF) maturation failure. However, the cellular mechanisms controlling inflammatory cell recruitment and inflammation resolution after anastomosis remain obscure.

Methods: In this work, we used for the first time a combination of single-cell RNA sequencing (scRNAseq) and histologic validations to reveal the place of entrance of inflammatory cells into the venous wall following AVF creation.

Results: Analyses of vascular tissues collected in the first week after AVF creation demonstrate an extensive infiltration of leukocytes in the media and adventitia and less so in the intima. Interestingly, these AVF showed a notable expansion of vasa vasorum (VV) number and size. Next, we characterized the cellular composition of cells forming the VV of pre-access veins and AVF using scRNAseq and validated our findings by immunofluorescence. Single-cell profiling of endothelial cells (ECs) identified markers for arterioles, capillaries, and venules. Immunofluorescence staining demonstrated an abundance of capillaries throughout the entire wall, venules in the outer media and adventitia, and a comparatively smaller number of arterioles in the outer adventitia. Venular ECs had significant upregulation of adhesion molecules with respect to the other endothelial subsets, indicating that they may act as docking sites for leukocyte infiltration. This work demonstrates a diversity of VV in the walls of veins and constitutes an important foundation for the study of intramural vascularization in vascular access remodeling.

Conclusions: In conclusion, our data strongly support the importance of the VV network, and particularly venules, in postoperative inflammation and AVF outcomes. These results also support the perivascular delivery of drugs targeting neoangiogenesis and microvessel permeability as future treatments to improve vascular access outcomes.

Analysis of the Arteriovenous (AV) Fistula Maturation in Eastern North Carolina and Validation of the Failure to Mature Equation

Akil S. Kavcar,[1] Iskra Myers.[2] *[1]East Carolina University Brody School of Medicine, Greenville, NC; [2]East Carolina University, Greenville, NC.*

Background: AVF is the preferred vascular access for hemodialysis patients but has a high maturation failure rate. Lok et al developed a clinical prediction tool to identify AVFs at risk for Failure to Mature (FTM) and it has achieved good prediction accuracy. We aim to examine the AVF success rate at 6 months and validate the FTM equation in patients with AVF in Eastern North Carolina.

Methods: The retrospective cohort study was done to identify patients who received AVF as their first HD access from 12/01/2009 to 12/01/2020. The primary outcome was AVF failed to mature. The FTM equation risk score was retrospectively applied to our patient cohort and compared with the observed clinical outcomes using Receiver Operating Characteristic (ROC) curve. Univariate and multivariate logistic regression analyses were used to assess the association between the clinical predictors and AVF maturation. A nomogram was developed based on the regression coefficients from the multivariable model, and the weight (point) was given based on the regression coefficient.

Results: A total of 162 patients were found; the mean age was 55 years(SD:13.3), 41% were females, and 89% were African American. The failure to maturation rate at 6 months was 53.5%. Compared to the FTM cohort, there were statistically significant differences in age, ethnicity, BMI, presence of diabetes, CAD, and PVD($p<0.05$).

Univariate logistic regression showed PVD was associated with increased arteriovenous fistula failure (OR = 2.07; 95% CI = 1.05–4.09; p < 0.05). When results were adjusted for confounders on multivariate analysis odds ratio was 1.8 with a p-value of 0.08 (CI 0.91-3.8). The failure to maturation equation failed to predict maturation outcomes with the area under the curve performance of 0.587. We also developed a different scoring system by using coefficiency values of Hypertension, PVD, and CAD, calculated with multivariate analysis but AUC on the ROC was 0.63 with the new scoring system.

Conclusions: The failure to mature equation failed to predict fistula maturation failure in our cohort. The difference in characteristics between cohorts is the likely reason. PVD was shown to be significantly associated with fistula failure in univariate analysis but when adjusted for other variables it was no longer significant. Analysis for the rest of the clinical factors did not show any significance.

FR-PO486

Metabolomic Analysis of Plasma Samples Collected Before Arteriovenous Fistula Creation Reveals Metabolome Clusters that Associate with Maturation Outcomes

Xin Wang,[1] Syed S. Zaidi,[4] Cindy Chan,[5] Yan Yi Cheung,[2] Nadja Grobe,[1] Peter Kotanko,[1,3] Sandip Mitra,[4] Milind Nikam.[2] *[1]Renal Research Institute, New York, NY; [2]Global Medical Office, Fresenius Medical Care, Singapore, Singapore; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Manchester Royal Infirmary, Manchester University NHS Foundation Trust, Manchester, United Kingdom; [5]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong.*

Background: The Manchester Vascular Access study was a prospective observational study intended to investigate the natural history and maturation of arteriovenous fistulas (AVF). We aimed to identify biomarkers that predict maturation success already before AVF creation.

Methods: Plasma samples were obtained before AVF creation. Unassisted maturation was defined either by successful hemodialysis or a combination of ultrasound features (vein size > 4 mm with fistula flow ≥ 500 ml/min) and clinical assessment. Untargeted metabolomic analysis employed liquid chromatography-mass spectrometry. Hierarchical clustering and principal component analyses were performed to cluster patients using 819 metabolite features. We used Chi-square test to explore differences in demographics, comorbidities, and AVF maturation between clusters.

Results: We studied 44 patients. Metabolomic analysis revealed 2 clusters (Cluster 1: 21 patients, Cluster 2: 23 patients) with diverse levels of plasma metabolites (Fig. 1). There was a significant statistical difference in unassisted maturation rates between the two clusters (Cluster 1: 85.7% vs. Cluster 2: 43.5%; p=0.0095). No significant differences between the clusters were found with respect to variables commonly associated with maturation (age, sex, diabetes, and cardiovascular disease).

Conclusions: In this cohort, we observed 2 clusters of metabolomic signatures associated with successful and unsuccessful AVF maturation, respectively. If corroborated in a larger cohort, metabolomic analysis could help identify biomarkers that predict AVF maturation success or failure already prior to AVF creation, thus allowing individualisation of vascular access planning. Future targeted metabolomic analysis may also shed light on biological pathways related to AVF maturation.

Funding: Commercial Support - Fresenius Medical Care

Deficient Endothelial Autophagy Promotes Accelerated Atherosclerosis and Impaired Arteriovenous Fistula (AVF) Remodeling

Paul C. Collie, Kevin A. Ingle, Tatyana Isayeva Waldrop, William A. Gard, Jeonga Kim, Timmy C. Lee. *The University of Alabama at Birmingham Department of Medicine, Birmingham, AL.*

Background: Arteriovenous fistulas (AVFs) are the preferred vascular access for hemodialysis patients. Atherosclerosis is highly prevalent in arteries of patients with Chronic Kidney Disease undergoing hemodialysis. We investigated the role of macroautophagy in the venous region of the AVF in an atherosclerotic mouse model.

Methods: At 8-12 weeks of age endothelial cell autophagy-related 7 gene knockout mice with LDLR gene deletion (ecAtg7$^{-/-}$/LDLR$^{-/-}$) and mice where the LDLR gene was deleted (LDLR$^{-/-}$) were introduced to a high fat diet for 3 months before AVF creation surgery. Subsequently, mice underwent AVF surgery using the carotid artery and jugular vein. At day 7 blood flow in the AVF vessels was measured and mice were sacrificed, and histology and oil red staining were performed.

Results: Intimal hyperplasia was significantly greater in the AVF vein in ecAtg7$^{-/-}$/LDLR$^{-/-}$ mice compared to LDLR$^{-/-}$ mice ($p<0.04$). Collagen deposition was significantly greater in the AVF arteries and veins in the ecAtg7$^{-/-}$/LDLR$^{-/-}$ mice compared to LDLR$^{-/-}$ mice ($p<0.01$). Oil red staining in the AVF was significantly greater in ecAtg7$^{-/-}$/LDLR$^{-/-}$ mice compared to LDLR$^{-/-}$ mice ($p<0.01$). There was a trend towards increased blood flow in AVF vein and arteries in LDLR$^{-/-}$ mice compared to AVF vessels in ecAtg7$^{-/-}$/LDLR$^{-/-}$.

Conclusions: Autophagy may play an important role in AVF maturation by worsening atherosclerosis and arterial remodeling, which subsequently impacts vein remodeling.

Phenotypic Switch Study in Cultured Arterial and Venous SMCs: Messages for the Future Development of Novel Therapies for Vascular Access Dysfunction

Eyla C. Arteaga, Christine Wai, Unimunkh Uriyanghai, Vinay A. Sudarsanam, Prabir Roy-Chaudhury, Gang Xi. *The University of North Carolina at Chapel Hill Kidney Center, Chapel Hill, NC.*

Background: Smooth muscle cell (SMC) dedifferentiation, proliferation, migration, and extracellular matrix protein secretion are key events in the progression of SMC phenotypic switch and the development of intimal hyperplasia (IH) as well as negative vascular remodeling, which is responsible for arteriovenous access (AVF and AVG) failure. Previous studies have demonstrated differences in proliferation between venous (vSMC) and arterial SMCs (aSMC) but have not attempted to characterize specific pathways in this process. We herein aim to characterize the role of IRS-1/KLF-4/p53 pathway and other dedifferentiation related pathways regulating SMC phenotypic switch in pig vSMCs and aSMCs.

Methods: To reach the SMC differentiation stage before applying phenotypic switch stimuli, confluent cells were exposed to differentiation medium (DM, containing 1%FBS, 1% P/S and 30ug/ml heparin) for different time periods. A hyperglycemic milieu was created through the addition of 20 mM glucose 24-48hr before harvesting/treatments. PDGFBB or IGF-1 was applied to create a dedifferentiation milieu for different durations. Cellular expression of proteins of interest were assessed using either immunofluorescence (IF) staining or Western blots.

Results: Hyperglycemia significantly suppressed myocardin expression and enhanced KLF-4 expression in both cell types. IRS-1 suppression in response to hyperglycemia,

however, only occurred in aSMCs. Exposure to DM resulted in a suppression of proliferation and an increase in SMC differentiation marker expression (calponin and myocardin), in both cell types. IF staining demonstrated that Thrombospondin-1 was highly expressed over time in vSMCs under both hyperglycemic and normoglycemic conditions whereas, in aSMCs, this only occurred in the setting of hyperglycemia. Finally, PDGFBB was able to induce dedifferentiation under either normal or hyperglycemic conditions in both cell types while IGF-I was able to induce SMC dedifferentiation only under hyperglycemic conditions.

Conclusions: Arterial and venous SMC appear to have both similarities and differences regarding dedifferentiation/phenotypic switch pathways in response to hyperglycemia or growth factors. Hyperglycemia and PDGFBB are potent stimuli for SMC dedifferentiation.

Comparative Prognostic Accuracy of Vascular Access Flow and Artificial Intelligence (AI)-Based Arteriovenous Fistula (AVF) Failure Risk Score

Francesco Bellocchio,[1] Mario Garbelli,[1] Stefano Stuard,[1] Milind Nikam,[2] Len A. Usvyat,[3] Luca Neri.[1] *[1]Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy; [2]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong; [3]Fresenius Medical Care, Waltham, MA.*

Background: Technical surveillance based on vascular access blood flow (Qa) measurement it is time consuming, requires training, and specific equipment. We developed a risk score which accurately and reproducibly predicts AVF failure within 3 months. The risk score may offer a cheap and automated alternative to Qa measurement. We compared the prognostic accuracy of Qa measurement and AVF failure risk score.

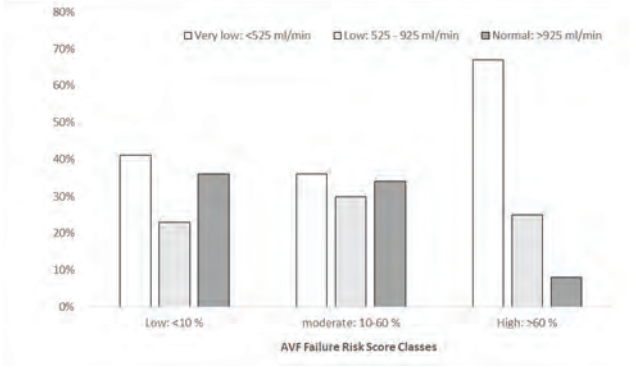
Methods: We included 8,969 AVF Qa measurements from 1,116 dialysis patients in 4 European countries. We used the AVF failure risk score to classify patients into 3 classes (low:<10%, moderate: 10%-60%, high:>60%) representing AVF failure risk within 3 months. Qa was measured with the thermodilution method and classified in very low (<525 ml/min), low (525-925 ml/min), normal (>925 ml/min). We computed the incidence of observed AVF failures by Qa levels and AVF risk classes to assess the overlap between the two metrics.

Results: A large share of patients was classified in the low-risk class by the AVF failure risk model (44%) whereas a tiny proportion were considered high risk (0.5%). We observed 907 AVF failures (10.1 %). There was a weak correlation between Qa and AVF failure risk score ($p>0.05$; Figure 1). The AVF failure risk score showed stronger association with AVF prognosis over a 3-month horizon compared to Qa measurement ($p<0.05$; Table 1).

Conclusions: Our study suggests that AVF failure risk may represents a valuable, cheap, automated alternative to Qa measurement for AVF technical surveillance.

	AVF Failure Risk		
Qa	low: <10 %	High: 10-60 %	Very high: >60 %
very low: <525 ml/min	4% (58)	21% (373)	83% (20)
low: 525 - 925 ml/min	5% (46)	17% (245)	67% (6)
normal: >925 ml/min	2% (31)	8% (127)	33% (1)

Incidence of AVF failures ("number of failures"/"number of Qa measurements" × 100) stratified by Qa and AVF failure risk levels.



Percentage of Qa measures for each AVF failure risk class.

FR-PO490

Impact of Arteriovenous Fistula (AVF) Dysfunctional and Repeated Endovascular Procedures on AVF Intervention-Free Survival

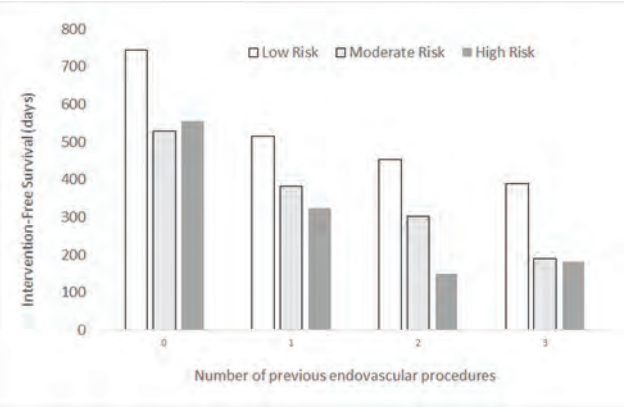
Alessandro Bregoli,[1] Francesco Bellocchio,[2] Mario Garbelli,[2] Stefano Stuard,[2] Milind Nikam,[3] Len A. Usvyat,[4] Luca Neri.[2] *[1]Universita degli Studi di Milano-Bicocca, Milano, Italy; [2]Fresenius Medical Care Italia SpA, Palazzo Pignano, Italy; [3]Fresenius Medical Care Asia Pacific Ltd, Hong Kong, Hong Kong; [4]Fresenius Medical Care, Waltham, MA.*

Background: Endoluminal and surgical procedure effectively re-establish patency of disfunctional Arteriovenous Fistulas (AVF); however, repeated intervention may reduce overall vascular access survival. We previously developed a risk score predicting AVF failure within 3 months that shows high accuracy and reproducibility. To enhance score interpretability we sought to assess its association with AVF intervention-free survival among patients with previous intervention to re-establish vascular access patency.

Methods: We included all patients receiving in-center hemodialysis therapy with an AVF in Nephrocare Portugues network between January 1st, 2015 and December 30th, 2022. We abstracted data from the European Clinical Database (EuCliD). We used generalized linear models to assess the association between the AVF failure risk score and intervention-free survival by the number of previous endoluminal interventions.

Results: We included 4,668 AVFs from 4,355 patients in the analytical dataset. Whereas patients with previous multiple endovascular procedures were common, only a small minority had more than 3 procedures. Both the AVF risk score class ($p<0.01$) and the number of previous endoluminal interventions ($p<0.01$) independently predicted AVF intervention-free survival (Fig. 1).

Conclusions: AVF intervention-free survival was associated with both AVF risk score classes and the number of previous endovascular procedures; both factors should be considered in evaluating the risk-benefit ratio of additional endoluminal procedure against alternative interventions for dysfunctional AVFs.



AVF intervention-free survival (in days) with respect to the number of previous endovascular procedures and AVF failure risk class

FR-PO491

Initial Vascular Access Flow Rate for Early Prediction of Need for Intervention: A Retrospective Cohort Study

Matthias Bergmann,[1,2] Butros Fakhoury,[1,2] Tiago Costa,[1,2] Bertrand L. Jaber,[1,2] Vaidyanathapuram Balakrishnan.[1,2] *[1]St Elizabeth's Medical Center, Brighton, MA; [2]Tufts University School of Medicine, Boston, MA.*

Background: Arterio-venous fistula (AVF) or graft (AVG) are lifelines for most hemodialysis (HD) patients. Low access flow rate (AFR) often requires intervention to prevent access failure. This study examines if AFR, measured at initial AVF/AVG cannulation, predicts need for intervention in the first year.

Methods: From 2012 to 2021, 52 (30.7%) of 169 patients with surgical AVF/AVG creation had AFR measurements. Up to three values were collected per subject. Need for intervention within one year was documented.

Results: Of 52 subjects, 28 (53.8%) required access intervention. After stratification by need for intervention (data not shown), patient characteristics were not significantly different. However, *first* AFR was significantly lower in the group with access intervention (898±495 vs. 1471±777mL/min; P=0.003), as was *average* AFR (841±399 vs. 1506±700mL/min; P<0.001). Receiver-operating characteristic (ROC) curve analyses (Figure1 and Table1) showed that *first* AFR (area-under-the-curve [AUC] 0.743; 95% CI 0.608, 0.877) and *average* AFR (AUC 0.775; 95% CI 0.648, 0.903) predicted need for access intervention within one year.

Conclusions: In HD patients, early AFR measurements can predict access intervention within one year after initial access cannulation. Our results are limited by single center setting and small sample size. Further studies are needed to determine optimal AFR cut-offs that indicate AVF/AVG at higher risk of early stenosis.

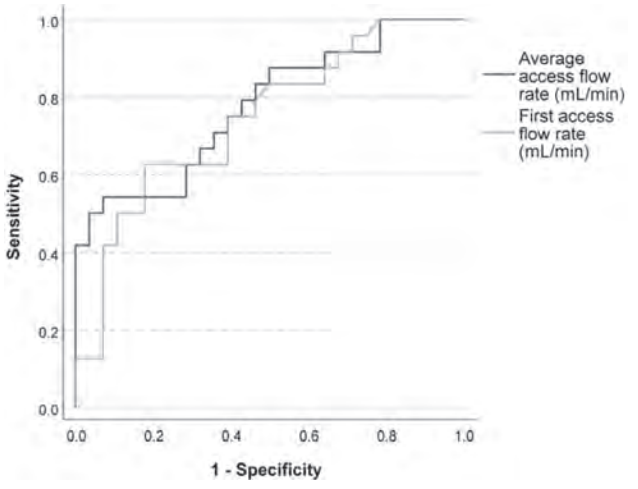


Figure 1. Receiver operating characteristic (ROC) curve showing diagnostic performance of *first* and *average* access flow rates (AFR) in new arterio-venous fistulas (AVF) and grafts (AVG) for predicting need for intervention within one year.

Receiver-operating characteristic (ROC) curve analyses

Vascular access type	Area-under-the-curve	95% confidence interval	P value
AVF and AVG combined (*n* = 52)			
***First* vascular access flow rate**	0.743	0.608, 0.877	< 0.001
Average* vascular access flow rate	0.775	0.648, 0.903	< 0.001
AVF only (*n* = 31)			
***First* vascular access flow rate**	0.696	0.508, 0.884	0.04
Average* vascular access flow rate	0.746	0.574, 0.918	0.005
AVG only (*n* = 21)			
***First* vascular access flow rate**	0.865	0.702, 1.000	< 0.001
Average* vascular access flow rate	0.856	0.695, 1.000	< 0.001

* Average of the first 3 consecutive measurements derived from the Transonic vascular access flow methodology; AVF, arteriovenous fistula; AVG, arteriovenous graft.

Table 1. Area-under-the-curve (AUC) shows good diagnostic performance of access flow rate (AFR) for predicting patency-assisted intervention within one year.

FR-PO492

Be Positive: Breaking the Cycle of Recurrent Vascular Access Thrombosis

Roisin Horgan, Jenny Kinane, Niamh Corcoran, David Lappin. *Galway University Hospitals, Galway, Ireland.*

Introduction: Vascular access failure is a major cause of morbidity in patients on haemodialysis. Thrombosis and stenosis can occur due to shear stress on the vessel wall and formation of a thrombus or fibrin sheath. Recurrent episodes of vascular access failure in the absence of anatomical factors such as a venous stenosis or haemodynamic factors such as hypotension raise the possibility of an underlying hypercoagulable state.

Case Description: A 28-year-old Irish male was commenced on haemodialysis via a tunnelled catheter following presentation with severe renal impairment with advanced chronic tubulointerstitial nephritis on biopsy. One year into diagnosis he began to experience repeated episodes of vascular access failure. Over the course of three months, he had five different malfunctioning catheters, including three right internal jugular tunnelled lines, one right internal jugular non-tunnelled line and one right femoral non-tunnelled line. This was despite use of catheter-locking solutions and heparin with dialysis. His left side was being saved for an arteriovenous fistula. He was screened for antiphospholipid syndrome as a cause of recurrent thromboses. He was found to have significant positivity for IgG anticardiolipin antibodies, IgG antibeta2 glycoprotein1 antibodies and lupus anticoagulant, persistent on two occasions more than twelve weeks apart. Triple antiphospholipid antibody positivity is associated with a high risk for thrombosis. He was commenced on warfarin with an INR target of 2-3. Seven months later he has had no further vascular access complications with a functioning right internal jugular tunnelled catheter and recent formation of a left arteriovenous fistula which is maturing well.

Discussion: In this case a thrombophilia screen critically altered management, halting the cycle of recurrent access failures in a young patient on haemodialysis. It has been reported that there is a higher prevalence of antiphospholipid antibodies in the haemodialysis population and some studies suggest that these are associated with a higher incidence of vascular access thrombosis. Our patient was strongly positive for all three antiphospholipid antibodies, idenitifying him as of particularly high risk. This case highlights the need to consider thrombophilia as a cause of recurrent vascular access failure, particularly in cases without an identifiable stenosis.

FR-PO493

Autosomal Dominant Polycystic Kidney Disease Results in Increased Flow in Murine Arteriovenous Fistulas

Suzanne Laboyrie, Dorien J. Peters, Roel Bijkerk, Margreet R. De vries, Joris I. Rotmans. *Leids Universitair Medisch Centrum, Leiden, Netherlands.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a renotubular disease caused by mutations in the *PKD1*-gene. ADPKD is the most common monogenic kidney disorder, affecting 10% of end-stage kidney disease (ESKD) patients. The arteriovenous fistula (AVF) is the gold standard of hemodialysis vascular access, although non-maturation due to inadequate vascular remodeling is a major limitation of these conduits. Polycystins are expressed in endothelial and vascular smooth muscle cells, and involved in production of extracellular matrix supporting the vessel wall and mechanosensation. In the present study, we investigated whether reduced expression of *Pkd1* impacts vascular remodeling in a murine model of AVF failure.

Methods: Unilateral jugular-carotid AVFs were created in adult B6Ola*Pkd1*$^{nl/nl}$ mice and wild-type litter mates. Blood pressure was measured using a tail cuff, before and six days after AVF-surgery. Flow volume was measured weekly over three weeks post-AVF creation using doppler ultrasound. After three weeks, the mice were sacrificed and AVFs were used for histological analysis and collagen analysis through multiphoton microscopy. Longitudinal flow data was analyzed using Mixed-effects model, histological data using the Mann-Whitney U test.

Results: B6Ola*Pkd1*$^{nl/nl}$ mice show signs of renal failure, with cystic kidneys and elevated blood urea levels throughout the study. *Pkd1*$^{nl/nl}$ mice had elevated mean arterial blood pressure at both timepoints compared to WT mice (1.2 and 1.3 fold increase in ADPKD mice). Whereas arterial flow was comparable in both groups before surgery, AVF flow in *Pkd1*$^{nl/nl}$ mice was consistently higher post-AVF creation (1.9 fold difference, p=0.0002, at all time points). There was no difference in luminal area between the two groups, nor aneurysm formation in the afferent artery. Histological analysis revealed a reduction of collagen deposition in the venous outflow tract in *Pkd1*$^{nl/nl}$ mice at 21 days post-surgery.

Conclusions: AVFs in mice with ADPKD are characterized by a higher flow and reduced collagen deposition in the venous outflow tract, when compared to wild type mice. Clinical studies should reveal if ADPKD patients have better primary patency rates of their AVFs compared to patients with other causes of ESKD.

FR-PO494

Arterio-Venous Shunt and Right Heart Function and Structure

Richard E. Wing, Nikhila S. Rao, Nilesh S. Rao, Eliane S. Grace, Matthew Wang, Thu H. Le. *University of Rochester Medical Center, Rochester, NY.*

Background: Emerging evidence suggests that right ventricular dysfunction (RVD) is a major determinant of adverse health outcomes. Data regarding the effect of AV shunt (AVS) placement on right heart function (RHF) and right heart structure (RHS) are sparse.

Methods: We conducted a cross-sectional study on patients with advanced CKD or ESRD who were followed by URMC nephrology faculty. We identified subjects who underwent an ambulatory echocardiogram within 90 days of AVS creation (Pre) and another ambulatory echocardiogram at least six months after AVS creation (Post). Original echocardiographic images were re-read to focus on RHF and RHS. Measures of RHF included: Tricuspid annular plane systolic excursion (TAPSE) and right ventricular fractional area change (RVFAC). Measures of RHS included length and diameter in systole and diastole. Changes between first and second echocardiograms were assessed. Continuous variables were analyzed by paired T-test. Categorical variables were analyzed by the McNemar test.

Results: Between 1/1/2010 and 12/31/2022, 1319 advanced CKD or ESRD patients under our care underwent at least one echocardiogram and/or underwent AVS construction. Thus far we have identified 39 subjects who met the criteria of having Pre and Post ambulatory echocardiograms that have interpretable measurements for the right heart. Selected subject characteristics are summarized in table 1. Selected echocardiographic changes are summarized in table 2.

Conclusions: Changes consistent with worsening RHF and RHS are observed in patients who underwent AVS construction. The observed population deterioration may have been attenuated due to survival bias as only subjects with two ambulatory echocardiograms at least six months apart were considered for analysis. Future efforts include adding a comparator group of failed AVS creation.

Table 1. Baseline Characteristics of Group (N=39)		Count or Mean (Std)	%
Male Sex		26	66.7%
Black Race		15	38.5%
Hispanic Ethnicity		6	15.4%

Time-Dependent Efficacy of Percutaneous Angioplasty with Drug-Coated Balloon in the Treatment of Stenosis of Artero-Venous Fistulae: A Retrospective Study

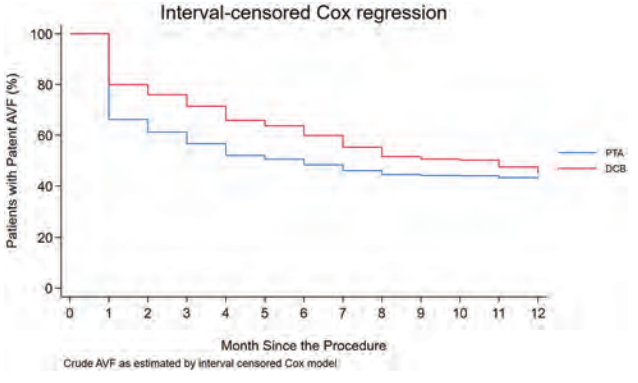
Claudia Morganti, Enrico Fiaccadori, Stella Bedogni, Tommaso Di Motta, Umberto Maggiore. *Universita degli Studi di Parma Dipartimento di Medicina e Chirurgia, Parma, Italy*.

Background: Percutaneous transmural angioplasty (PTA) is the first-line treatment for stenosis of the arteriovenous fistulae (AVF). Even if paclitaxel drug-coated balloon (DCB) has become the standard of care, trials testing efficacy in comparison with standard PTA has provided conflicting results. We tested the hypothesis that conflicting findings from trials may result from the effect of DCB being short-lived.

Methods: We enrolled all patients undergoing angioplasty AVF stenosis with PTA or DCB 01/2011 to 04/2022 at the Parma dialysis centre. The choice of PTA vs. DCB depended on the temporary supply of each device. AVF patency was assessed after the procedure and at monthly intervals until month 12. We compared the hazard of AVF failure using interval-censored Cox-multiple regression model, with the procedure (DCB vs. PTA) being included as a time-varying effect (i.e. interacted with time), and the standard errors adjusted for accounting of multiple procedures within the same patient.

Results: We retrospectively examined 146 procedures (in 143 subjects), 69 with PTA and 77 with DCB. Baseline features were similar between groups, apart from DCB performed most often in patients with multifocal stenosis (22.1 vs. 1.4%; P<0.001) and with previous AVF (76.6 vs. 58%; P=0.021), but less often with cardiovascular disease (46.8 vs. 69.6%; P=0.007). Figure 1 shows crude AVF patency over the follow-up: survival curves diverged shortly after the procedure and eventually converged. Adjusted for different variables, the hazard of AVF failure was halved with DCB compared to PTA after the procedure (adjusted hazard ratio aHR 0.48 [95%CI: 0.26-0.97; P=0.016]); then, benefit vanish over time and aHR increasing (toward the null value of 1) by 1.20 per every month elapsed since the procedure (95%CI: 1.07-1.34; P=0.001).

Conclusions: Compared to PTA, DCB provides significant short-term benefit which vanishes by 12 months after the procedure.



FR-PO496

Differences in Vascular Access Can Influence the Level of Thrombo-Inflammation and Oxidative Stress in Patients with Hemodialysis

Fakiha Siddiqui,[1] Srdjan Nikolovski,[1] Bulent Kantarcioglu,[1] Debra Hoppensteadt,[1] Omer M. Iqbal,[1] Emily G. Krupa,[1] Jawed Fareed,[1] Vinod K. Bansal.[2] *[1]Loyola University Medical Center, Maywood, IL; [2]Loyola University Medical Center Department of Nephrology, Maywood, IL*.

Background: Patients undergoing hemodialysis require vascular access which includes arteriovenous (AV) fistula, AV graft, and tunneled catheter. At these sites changes in the vessel wall result in a positive feedback loop that propagates inflammation and cell proliferation which can progress to stenosis and thrombosis. This study was designed to compare the levels of biomarker of thrombo-inflammation and oxidative stress in patients with ESRD requiring different vascular access sites.

Methods: A prospective cohort of 95 patients undergoing hemodialysis at Loyola University Chicago were compared to 50 normal healthy individuals. The ESRD patients were stratified according to the vascular access sites. All plasma samples were analyzed for D-Dimer, PAI-1 antigen, vWF, CRP, annexin V, MPO, nitotyrosine, eNOs, IL4, IL6, IL10, VEGF, and EGF by using Sandwich ELISA methods and Randox Biochip Array.

Results: The ESRD patient cohort included 48 male and 47 female, with the median age 66-years, weight 77-kg and BMI 27.2-kg/m^2. The levels of thrombo-inflammation and oxidative stress marker were significantly ($p < 0.05$) higher in ESRD patients while MPO, IL4, and IL10 were significantly ($p < 0.05$) lower in ESRD patients compared to normal controls. The biomarker profiles demonstrated that various markers of thrombo-inflammation and oxidative stress were significantly elevated in patients with various vascular access types (table 1).

Conclusions: These studies suggest that ESRD patients with the AV fistula are at high risk of fibrinolytic deficit, inflammation, and oxidative stress they are at low risk of thrombosis. Patients with AV graft and tunneled catheter are at high risk of inflammation, oxidative stress, and thrombosis.

Table 1: Comparison of the level of thrombo-inflammation and oxidative stress in hemodialysis patients with different vascular access.

A. Comparison between AV Fistula and AV Graft			
Biomarkers	**AV Fistula N=49 (median)**	**AV Graft N=32 (median)**	**P Value**

Outcome of Central Venoplasty and AVFistuloplasty in a Tertiary Care Centre in Eastern India

Sourav Sadhukhan, Atanu Pal, Aniruddha Datta. *Institute of Postgraduate Medical Education and Research, Kolkata, India*.

Background: Access crisis is the Achilles heel of dialysis in ESRD patients. Central vein stenosis and stenosis in mature AVfistulas are common and negatively impact the quality of hemodialysis. Here we report the outcome of central venoplasty and fistuloplasty in our centre.

Methods: This was an retrospective observational study. Study period january21 to april22. Minimum follow up was 6 months. Central venoplasty was preceded with venography. Right/left common femoral, internal jugular/venous limb of fistula were used as access, followed by gradual balloon dilatation and stent placement if required. For fistuloplasty, arterial/venous limb was used as access, followed by balloon dilatation.

Results: Total 38 primary and 5 secondary venoplasty performed. 42.1% patients had tunneled catheter, 52.6% had AVF and 5.3% had temporary catheter.73.7%patients had access failure, 26.3%- upper limb swelling.73.7% had CRBSI episodes>3. Mean duration to develop CVS-34.5m(SD-13.6m). 32(84.2%) were successful and 15.8% failed. Restenosis developed in 7(18.4%). Mean duration to develop restenosis-

105.3d(SD-53.6d). 21 patients undergone Fistuloplasty. Mean patency of AVF -1.03Yr. perianastomotic stenosis -71.4% outflow stenosis -19.04%, inflow stenosis-9.52%. Fistuloplasty was successful in 85.7% cases. Mean fistula flow volume-110.47ml/min(SD-79ml/min)(pre) 438ml/min(SD-244.9 ml/min)(post). 4 cases developed restenosis. complications-minor bleeding-6 cases, venous rupture in 2 and brachial artery pseudoaneurysm in 1 case.

Conclusions: This outcome analysis suggests that central venoplasty and fistuloplasty have very good outcome in the management of access issues in ESRD patients, but cost and restenosis are the main limiting factors.

Types of AVF

Safety and Efficacy of a Novel Compression Hemostatic Device for Vascular Access: A Quality Improvement Study

Mohamed Modar Abidian,[1] Rodella Broxton-Key,[2] Forest Rawls,[2] Vandana D. Niyyar.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]Emory Healthcare, Atlanta, GA.*

Background: Arteriovenous fistulas (AVF) and arteriovenous grafts (AVG) are common types of vascular access for chronic hemodialysis (HD) patients that require frequent needle cannulations. Proper cannulation and decannulation techniques are important for achieving hemostasis and preventing complications from bleeding. After decannulation, most protocols require manual pressure at vascular access sites to prevent bleeding. A novel compression device with a simple manual inflation/deflation pump has been developed to achieve post decannulation hemostasis. The purpose of this quality improvement (QI) study was to assess the safety and effectiveness of such a device in our clinical practice.

Methods: Our protocol for using the device is detailed in Figure 1. All patients who had HD with either AVF or AVG and were holding manual pressure for hemostasis were eligible for the study. Efficacy outcome was achieving post decannulation homeostasis within 15 minutes. Safety outcome measures were prolonged bleeding (more than 15 minutes), access thrombosis, and local infection. Patient satisfaction surveys were performed using the Likert scale.

Results: We evaluated 166 HD sessions using the compression device in 28 patients. There were no access infections or thrombosis. Only 1 (0.03%) episode of prolonged bleeding post decannulation in a patient who was on warfarin therapy. Almost all patients preferred the device to manual compressions and the average satisfaction rate was 4.6/5.

Conclusions: This novel device was safe and effective in achieving post-cannulation hemostasis and was preferred to manual compression by patients at our center.

Funding: Commercial Support - No financial payment was received by the manufacturing company Sun-Scientific as the device was donated free of cost

Table 1. Incidence Rate of Complications

No. of patients	Total No. (average per patient) of HD sessions performed using the device	No. of prolonged bleeding >15 min per patient	No. of access thrombosis	No. of local infection	Average patient satisfaction (1-5)
28	166 (5.8 per patient)	1 (0.03%)	0 (0%)	0 (0%)	4.6

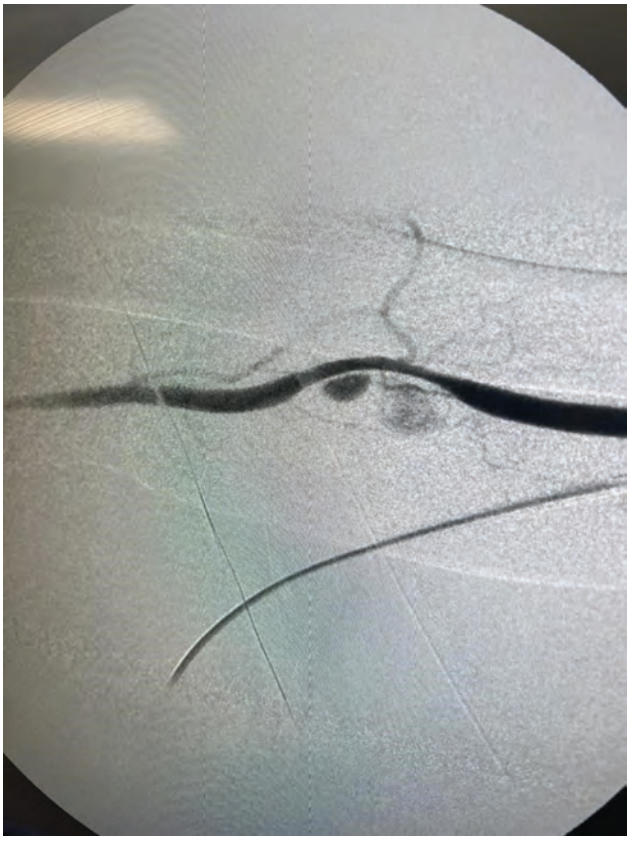
Brachial Artery Pseudoaneurysm (BAP): A Rare Cause of Median Nerve Neuropathy

Huy Truong, Hira H. Al-adroos, Mohamed Z. Ghyaz, Dalia Dawoud. *Riverside Community Hospital, Riverside, CA.*

Introduction: BAP, a complication in long-term hemodialysis (HD) patients, often develops without symptoms but can rarely lead to median nerve neuropathy. Differentiating between causes of the neuropathy is crucial due to distinct treatment approaches, but it is challenging and can result in severe consequences. This case report aims to raise awareness of BAP as a possible diagnosis for HD patients with the neuropathy.

Case Description: A 53-year-old man with end-stage renal disease undergoing HD via a left brachiobasilic arteriovenous fistula (AVF) presents to the hospital with pain and weakness in his left first three fingers for three weeks. Patient had a history of difficulty with AVF cannulations, but his HD sessions were able to be completed fully. During a thrombectomy for AVF thrombosis outpatient, a brachial artery pseudoaneurysm was incidentally discovered through a retrograde arterial angiogram. The patient underwent surgical intervention, which relieved the pain but did not fully restore motor function due to prolonged compression of the median nerve.

Discussion: BAP warrants prompt recognition in patient's presenting with median nerve neuropathy or pain at AVF sites. Symptoms may mimic other etiologies such as distal hypoperfusion ischemic syndrome. However, BAP can develop when there is arterial infiltration, especially in the patient whose AVF body overlaps with the feeding arteries. Therefore, it is crucial to educate dialysis staff not only on proper cannulation techniques but also on the mentioned anatomical variation. Additionally, physicians should consider arteriography to exclude the presence of arterial pseudoaneurysm in patients with progressing neuropathy, particularly those who have a history of difficulty with cannulation, to prevent prolonged nerve ischemia.



BAP in a retrograde arterial angiogram

FR-PO500

Pseudoaneurysms in Arteriovenous (AV) Fistulas: A Common Complication or a Rare Occurrence?

Nicole Wyatt, Naief N. Abudaff, Megha Salani. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Although pseudoaneurysms are primarily a complication seen with arteriovenous grafts (AVGs) with repeated localized cannulation, they can more rarely be seen in arteriovenous fistulas (AVFs). The incidence of AVF pseudoaneurysms remains largely unknown and there is limited quality evidence to guide management. We present a case of pseudoaneurysm in a native AVF that required surgical correction.

Case Description: A 56-year-old male with end stage kidney disease on hemodialysis via right brachiobasilic (BB) AVF presented with two days of shortness of breath and right upper extremity (RUE) swelling. He denied any inciting event or prior difficulty with AVF cannulation. Exam revealed unilateral RUE swelling and a tortuous right BB AVF with palpable thrill and audible bruit. There was no bleeding, ulcerations, or skin breakdown noted. A RUE ultrasound revealed a superficial thrombosis of right basilic vein and a saccular outpouching concerning for a pseudoaneurysm. A fistulagram revealed severe stenosis of right innominate vein requiring venoplasty/stenting, as well as two pseudoaneurysms in the cannulation zone, the largest of which was 2.8 x 2.2 x 1.5cm. Surgery was consulted and recommended against cannulation of AVF given risk of rupture. The pseudoaneurysms were deemed too large for non-invasive treatment, therefore he had a tunneled dialysis catheter placed and underwent prompt AVF revision including pseudoaneurysm resection and conversion to AVG.

Discussion: This case highlights an important complication of AVFs which impacts patient safety. Though many AVF pseudoaneurysms may be asymptomatic, they pose risks such as rupture and infection. Despite this, the incidence of AVF pseudoaneurysms is scarcely reported and ranges from 0.3% to over 15% in available literature. In addition, there is insufficient literature on treatment results with poorly available evidence and no randomized control trials to guide recommendations for management. Treatment decisions are largely based on access type and etiology of underlying problem, with options including ultrasound-guided manual compression, direct thrombin injection, or surgical options such ligation and excision/repair with graft interposition. We present this case to encourage further research to define AVF pseudoaneurysm classifications, natural history, and optimal treatment guidelines.

FR-PO501

mTORC2 Coordinates Renal Gluconeogenesis and Glucose Reabsorption

John E. Demko, Bidisha Saha, Enzo Takagi, David Pearce. *University of California San Francisco, San Francisco, CA.*

Background: The proximal tubule is uniquely responsible for both gluconeogenesis (GNG) and glucose reabsorption from the filtrate. Insulin signaling in the proximal tubule suppresses gluconeogenesis and stimulates glucose transport. However, the coordinated regulation of these processes is poorly understood. The kinase mTORC2 is regulated by insulin signaling in multiple cell types, but its mechanistic role in proximal tubule glucose homeostasis is unknown.

Methods: Rictor is a critical component of the mTORC2 complex. Inducible tubule-specific Rictor knockout (TRKO) mice were made with Pax8-rtTA TetOCre Rictor$^{flox/flox}$. Male and female TRKO mice and wild-type (WT) littermates were fasted for 18 hours then refed 4 hours before sacrifice. Whole kidney relative mRNA was measured via RT-PCR. Kidney plasma membrane and cytosolic proteins were separated using the BioVision Plasma Membrane Protein Extraction Kit, and protein abundance was measured with western blotting.

Results: There were no differences in serum glucose between TRKO and WT mice during refeeding (n=6–10 per group for all experiments). However, the mean ± standard error of the mean urine glucose excretion was 1824.9±768.5 µg in TRKO mice compared to 69.2±15.0 µg in WT animals during refeeding ($p<0.05$). TRKO kidneys compared to WT had significantly higher relative PEPCK protein abundance (0.54±0.05 vs 0.28±0.03 AU; $p<0.001$) and mRNA levels (0.54±0.17 vs 0.17±0.01 AU; $p<0.05$). TRKO kidneys compared to WT had statistically similar G6Pase protein abundance and significantly higher relative mRNA levels (0.58±0.17 vs 0.18±0.05 AU; $p<0.05$). Refed TRKO kidneys showed a decrease in plasma membrane SGLT2 after refeeding (0.64±0.07 vs 1.22±0.24 AU; $p<0.05$) and no significant difference in SGLT2 mRNA levels compared to WT mice. There were no significant differences in plasma membrane protein abundance or mRNA levels for SGLT1 or GLUT2 between TRKO and WT kidneys.

Conclusions: TRKO mice have glycosuria with normal serum glucose. TRKO mice fail to suppress renal GNG and have decreased plasma membrane SGLT2. Coordinated suppression of GNG and stimulation of glucose reabsorption by mTORC2 is critical to conserve energy by preventing excess glucose production and urinary glucose loss. Future studies will examine changes in the insulin and mTORC2 signaling pathways which mediate these findings.

FR-PO502

High Potassium Suppresses Glycosuria in Tubule-Specific mTORC2 Knockout Mice

John E. Demko, Bidisha Saha, Enzo Takagi, David Pearce. *University of California San Francisco, San Francisco, CA.*

Background: Insulin signaling promotes proximal tubule glucose reabsorption and suppresses gluconeogenesis (GNG). mTORC2 is critical to insulin signaling in multiple cell types and there is emerging evidence for its importance in the proximal tubule. Potassium (K) has also been shown to regulate GNG in the kidney. However, the mechanism and overall significance of the relationship between K and glucose homeostasis is poorly understood.

Methods: Rictor is an essential component of the mTORC2 complex. Inducible tubule-specific Rictor knockout (TRKO) mice were made with Pax8-rtTA TetOCre Rictor$^{flox/flox}$. Mice were fasted for 18 hours then refed 4 hours before sacrifice. Mice were adapted to a 0.5% K diet prior to refeeding and then switched to either a 0.5% K or 3% K diet for refeeding. Data were obtained in metabolic cages during refeeding.

Results: Figure 1 shows a significant decrease in urine glucose excretion after refeeding on a 3.0% K diet compared to a 0.5% K diet despite no difference in area under the curve (AUC) of serum glucose (n=6–10 per group for all experiments). TRKO mice refed with a 3.0% K diet compared to 0.5% K diet had higher serum K (mean ± standard error, 7.3±0.4 vs 4.7±0.2mEq/L; $p<0.001$), higher hematocrit (42.0±0.8 vs 35.7±0.6%; $p<0.001$), decreased refeeding weight gain (0.70±0.09 vs 2.25± 0.24g; $p<0.001$), decreased food intake (1.02±0.08 vs 1.92±0.19g; $p<0.001$), and higher urine output (0.87±0.10 vs 0.39±0.05mL; $p<0.001$). There were no differences in baseline weight, refeeding water intake, or BUN between TRKO mice on either diet.

Conclusions: High dietary K rapidly suppressed glycosuria without changing serum glucose in TRKO mice. A change in GFR or filtered load of glucose is less likely to explain the reduction in glycosuria in these short-term experiments. Dietary K appears to act through an mTORC2-independent pathway to regulate renal glucose reabsorption. Future studies will examine the role of dietary K on GNG, glucose transporters, and insulin signaling pathways.

Mechanisms of Renal Potassium Handling Sexual Dimorphism Resolved at Single-Cell Level

Hyun Jun Jung, Rick Grimm, Paul A. Welling, Lama Al-Qusairi. *The Johns Hopkins University School of Medicine, Baltimore, MD.*

Background: A recent study revealed a rising trend of hypokalemia in the US general population, with women being more prone to hypokalemia. Our previous study revealed that the response to potassium (K^+) deficiency in mice phenocopies the human condition, with females being more susceptible to hypokalemia than males upon dietary K^+ deprivation.

Methods: C57BL6J wild-type male and female mice were randomized to a control or K^+-free diet for 8 days. K^+ balance and key transporters involved in renal K^+ secretion were analyzed. The sexual dimorphic transcriptional responses to K^+ deprivation were assessed using single nucleus RNA-Seq (snRNA-Seq) in whole kidneys.

Results: Males exhibited a more robust reduction in renal K^+ excretion in response to K^+ deprivation compared with females. The apical localization of K^+-secretory ROMK channel in the early distal nephron was less abundant in males under basal conditions and decreased to a greater extent than in females in response to K^+ deprivation. snRNA-Seq of whole kidneys from both sexes defined 45 cell-type clusters. Given the key role of the distal nephron in K^+ regulation, we initially analyzed distal tubular cells. Cell type-dependent transcriptome profiling revealed that connecting tubule (CNT) cells exhibited striking sex-dependent changes in response to K^+ deprivation. Pathway enrichment analysis of the CNT differentially expressed genes (DEGs) between control and K^+-deprived animals revealed that cellular processes associated with the cytoskeleton and actin organization were mostly reprogrammed in females, while ion channel regulating pathways exhibited more active reprogramming in males. Among the DEGs, transcript abundance of the *Kl* gene encoding for Klotho protein, a positive regulator of ROMK, was significantly decreased in K^+-deprived males only. Similar to the transcript levels, Klotho protein was significantly decreased in response to K^+ deprivation only in males, consistent with more robust reduction in ROMK, leading to more efficient K^+ conservation in males.

Conclusions: Females are more susceptible to hypokalemia due to urinary K^+ loss. This sexual dimorphism is mediated by sex-dependent gene reprogramming of the CNT. Specifically, ROMK and its regulatory network, including Klotho, are involved in shaping the sexual dimorphism of K^+ regulation.

FR-PO504

Changes in Renal Acid-Base Handling in Megalin-Knockout Mice

Peter A. Klahn, Peder Berg, Mads V. Sorensen, Kathrin Weyer, Samuel L. Svendsen, Jens G. Leipziger, Rikke Nielsen. *Aarhus Universitet Faculty of Health, Aarhus, Denmark.*

Background: Megalin is a ~600 kDa receptor abundantly expressed in the renal proximal tubules. It facilitates reabsorption of a great variety of proteins avoiding their loss in the urine. Lack of megalin therefore leads to insufficient reuptake of its substrates, and thus low-molecular weight proteinuria. In addition, our preliminary data suggest that lack of megalin also causes impaired regulation of renal acid-base excretion.

Methods: Kidney specific mosaic megalin knockout mice Immunofluorescence Western blotting Liquid chromatography/mass spectrometry Biochemistry of mouse blood and urine

Results: Immunofluorescence showed a very marked increase of brush border carbonic anhydrase 4 (CA4) in proximal tubular cells lacking megalin compared to megalin-positive cells (Figure 1). This was confirmed by western blotting of cortex homogenates. To investigate if other proximal tubular proteins involved in acid-base handling were changed, we applied proteomics. We found a significantly decreased abundance of NBCe1A (-20%), V-ATPase and NHE3 (-20%) and confirmed an increased abundance of CA4 (324%) in megalin KO mice. Megalin knockout mice showed mild alkalosis during baseline conditions. Urine analyses showed a very unusually combination of high NH4+ excretion concomitant with reduced titratable acid excretion and increased bicarbonate excretion. Despite high NH4+ excretion net acid excretion was reduced.

Conclusions: Our data suggest that the absence of megalin has major effects on renal acid-base handling. We suggest that megalin KO mice have increased ammoniagenesis in PT-cells and that this causes a compensatory reduction in TA excretion and increase in bicarbonate excretion. Further experiments are necessary to solidify this hypothesis.

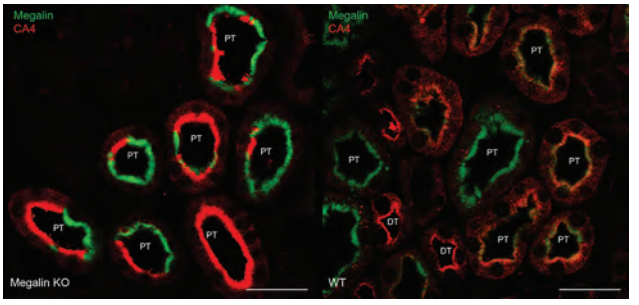

Figure 1. Micrograph showing double labeling of megalin (green) and CA4 (red) in a megalin KO (left) and a WT mouse (right). The megalin KO is mosaic, which means that it still has megalin in a few percentage of cells. Distal tubules (DT). PT=proximal tubule. Scale bar = 50 mm.

LRBA Signalosomes Activate Vasopressin-Induced AQP2 Trafficking at Recycling Endosomes

Yu Hara, Fumiaki Ando, Hideki Yanagawa, Soichiro Suzuki, Tamami Fujiki, Shintaro Mandai, Yutaro Mori, Koichiro Susa, Takayasu Mori, Eisei Sohara, Shinichi Uchida. *Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: In dehydrated states, increased plasma osmolarity stimulates the release of the antidiuretic hormone vasopressin from the posterior pituitary gland. Subsequently, vasopressin binds to vasopressin type 2 receptor in renal collecting ducts and then activates protein kinase A (PKA)/aquaporin-2 (AQP2) water channels signaling, which increases water reabsorption from urine. Lipopolysaccharide-responsive beige-like anchor protein (LRBA) is a protein kinase A (PKA) anchoring protein localized at renal intracellular endosomes that creates compartmentalized PKA signaling responsible for AQP2 phosphorylation. cAMP/PKA signaling phosphorylates AQP2, promoting AQP2 trafficking from intracellular endosomes to the apical plasma membrane; however, the molecular mechanisms by which LRBA mediates vasopressin-induced AQP2 phosphorylation remain unknown.

Methods: To elucidate the *in vivo* role of LRBA in vasopressin-induced AQP2 phosphorylation and endosomal trafficking, a density gradient ultracentrifugation technique was combined with an *in situ* proximity ligation assay (PLA) and superresolution structured illumination microscopy (SIM). *Lrba*$^{-/-}$ mice were used as negative controls for vasopressin-induced AQP2 activation.

Results: Sucrose density gradient and SIM revealed that AQP2 was stored in the recycling endosome under resting conditions. Desmopressin phosphorylated AQP2, translocating it from the recycling endosome to the apical plasma membrane. In contrast, SIM and PLA demonstrated that LRBA was constitutively localized on Rab11-positive recycling endosomes in WT mice regardless of vasopressin stimulation. Therefore, LRBA and AQP2 were well-colocalized in the absence of vasopressin stimulation. The loss of LRBA/PKA signaling by *Lrba* knockout impaired vasopressin-induced AQP2 phosphorylation, resulting in AQP2 retention at the recycling endosome. Defective AQP2 trafficking reduced urinary concentrating ability in *Lrba*$^{-/-}$ mice.

Conclusions: AQP2 was found to be stored on the LRBA-containing recycling endosome, and LRBA-induced compartmentalized PKA signaling efficiently phosphorylated AQP2 in response to vasopressin.

Ghrelin Enhances Tubular Magnesium Absorption in the Kidneys

Matthias T. Wolf, Mingzhu Nie, Jing Zhang, Manjot S. Bal, Michel G. Baum. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: In animal models mimicking bariatric procedures, bone disease, decreased serum levels of Ca^{2+}, Mg^{2+} and the gastric hormone Ghrelin were described. Ghrelin binds to the growth hormone secretagogue-receptor (GHSR) which is expressed in renal tubules. We tested if Ghrelin modifies tubular calcium or magnesium absorption via the ion channels TRPV5 or TRPM6.

Methods: We expressed GHSR1 with TRPV5 or TRPM6 channel in HEK293 cells and treated them with purified Ghrelin. Whole-cell current density was analyzed by patch-clamp recording. Nephron-specific gene expression of Ghrelin, GHSR, and Trpm6, was determined in microdissected tubules. Tubular localization of GHSR was examined by immunofluorescent (IF) imaging of GHSR-GFP mice. As there is more Ghrelin secreted with fasting, we elucidated the effect of Ghrelin in tubular magnesium homeostasis in GHSR-null mice at baseline and after starvation.

Results: After Ghrelin exposure whole-cell current density did not change for TRPV5 but increased for TRPM6 in a dose-dependent fashion. While a Ghrelin-mimetic also increased TRPM6 current density, addition of a GHSR antagonist inhibited the effect. GHSR signals via protein kinase A (PKA) and applying the PKA inhibitor H89 abrogated TRPM6 stimulation by Ghrelin. In microdissected tubules of wild-type (WT) mice there was abundant Ghrelin and GHSR mRNA in the TAL with 50% lower levels

in microdissected DCTs. TRPM6 was highly expressed in the DCT. Unexpectedly, we also detected TRPM6 mRNA in the TAL at 15% expression compared to DCT. IF studies of GHSR-GFP mice confirmed a GFP signal in the TAL but not in the DCT. In 3, 6, and 9 month-old GHSR-null and WT mice, baseline serum magnesium and 24-hour urinary excretion of magnesium was not significantly different. Starved GHSR-null mice, displayed a significantly higher urinary magnesium excretion and lower serum magnesium levels with downregulation of tubular magnesiotropic genes *Hnf1b*, *Cldn-16*, *Cldn-19*, *Fxyd-2b*, and *Parvalbumin*.

Conclusions: Ghrelin stimulates TRPM6 via GHSR and $G\alpha_s$-PKA signaling *in vitro*. The physiological significance of this mechanism is unclear given the higher GHSR mRNA abundance in the TAL compared to DCT. Starved GHSR-null mice had increased urinary magnesium excretion and lower serum magnesium levels. This may be mediated by Ghrelin-upregulation of TRPM6 in the TAL and/or upregulation of other magnesiotropic genes.

Lithium-Associated Tubulointerstitial Nephropathy, Role of Collecting Duct Cell Proliferation

Marie Himbert,[1,2] Mélanie Try,[1,2] Lydie Cheval,[1] Samia Lasaad,[1] Luciana Morla,[1] Emmanuelle Vidal-Petiot,[2] Martin Flamant,[2] Francois Vrtovsnik,[2] Gilles Crambert,[1] Nahid Tabibzadeh.[1,2] *[1]Centre de Recherche des Cordeliers, Paris, France; [2]Assistance Publique - Hopitaux de Paris, Paris, France.*

Background: Lithium salts are the main treatment for bipolar disorder, a common and serious illness. However, their effectiveness is offset by their renal toxicity, especially microcystic tubulointerstitial nephropathy, which can lead to end-stage renal failure. The aim of this project is to determine the mechanisms involved in this nephropathy, and to identify predictive biomarkers of renal outcome, especially GDF15, a growth factor known to be involved in the proliferation of intercalary A cells in an acid environment.

Methods: The project is based on a model of lithium exposure, for 1 month, of mice expressing or not GDF15, followed prospectively in a metabolic cage, allowing the analysis of urine, including the dosage of GDF15, by ELISA test. Cell proliferation was studied by immunofluorescence analysis of mouse kidneys collected at sacrifice. The role of GDF15 was also clarified in humans, from a prospective cohort of lithium treated patients, in whom GDF15 was measured in the urine and correlated with the clinico-biological phenotype.

Results: Plasma levels of GDF15 are increased in lithium treated mice ($p=0.019$). The phenotype of GDF15-/- mice is not different from WT lithium carbonate treated mice, while in lithium chloride treated mice, diuresis and cell proliferation are significantly lower in GDF15-/- mice ($p=0.0159$ and $p=0.0147$ respectively). In patients, GDF15 urinary excretion is positively correlated with diuresis ($p<0.0001$) and natremia ($p<0.0001$), but negatively with eGFR ($p<0.0001$).

Conclusions: GDF15 is both increased in lithium treated mice and patients, suggesting it as a prognostic marker of nephropathy. There is a differential causal relation depending on the associated anion, requiring more investigations. It could be a protective mechanism to limit polyuria by increasing the proliferation of the principal cells.

WNK1 Is a Central Osmolality Sensor for Arginine Vasopressin Release and Acts Through OSR1/SPAK Kinase Cascade

Xin Jin, Jian Xie, Chou-Long Huang. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Terrestrial animals are subject to constant stress of water deprivation. Maintaining internal osmolality constancy is essential for life. The circumventricular organs (CVO's) of brain including the organum vasculosum of the lamina terminalis (OVLT) and subfornical organ (SFO) lack a blood-brain barrier. Neurons in OVLT and SFO detect increases in serum osmolality that stimulates the production of AVP in paraventricular nuclei (PVN) to be released in the posterior pituitary. We have recently reported that WNK1 in sensory neurons in CVOs functions as an osmolality sensor for AVP release (Xin et al., JCI, 2023). WNK1 activates Kv3.1 to increase action potential travelling down to PVN to increase AVP synthesis for release from the posterior pituitary. Here, we further investigated the hypothesis that OSR1/SPAK acts as the downstream kinase for WNK1 in regulating AVP release.

Methods: PVN nuclei from control mice and Spak-null mice with homozygous Osr1-floxed allele ($Spak^{-/-}$;$Osr1^{flox/flox}$) were stereotaxically injected with Cre-recombinase-carrying retrograde AAV virus. Metabolic cage studies were performed in mice. Urine output, water intake, serum, urine osmolality, serum AVP and copeptin levels were measured.

Results: Increased osmolality either by water restriction or mannitol injection activated OSR/SPAK in OVLT as evident by increased serine-373 phospho-SPAK/serine-325 phospho-OSR. Like Wnk1 deletion, double deletion of OSR/SPAK in OVLT caused polyuria with decreased urine osmolality that persisted in water restriction. Circulating levels of AVP and copeptin were increased by water restriction in control mice. In contrast, water restriction failed to increase the levels in OSR/SPAK-deletion mice. Knockdown of Kv3.1b channel in OVLT by shRNA reproduces the phenotypes.

Conclusions: WNK1 in osmosensory neurons in CVOs detects extracellular hypertonicity and mediates the increase in AVP release by activating Kv3.1 and increasing action potential firing from osmosensory neurons. OSR1/SPAK acts downstream of WNK1 to regulate AVP release. Our findings reveal that an intracellular protein acts as a sensor for extracellular tonicity and provide fresh insights into mechanism how body maintains osmolality constancy. Future studies will investigate how OSR1/SPAK regulates Kv3.1 channels.

Replacing the Brattleboro Rat: Generation of an Inducible Avp Knockout Mouse Line Using CRISPR/Cas9 and Cre/LoxP

Shaza Khan,[1,2] Lihe Chen,[1] Syed J. Khundmiri,[2] Mark A. Knepper.[1] *[1]National Institutes of Health, Bethesda, MD; [2]Howard University College of Medicine, Washington, DC.*

Background: Arginine vasopressin (AVP) is a peptide hormone coded by the *Avp* gene, synthesized in the hypothalamus and secreted by the posterior pituitary. Dysregulation of AVP secretion contributes to a variety of human diseases. Previous studies of functional roles of AVP have been largely dependent on the use of Brattleboro rats, which manifest a spontaneous mutation in the *Avp* gene and lack circulating AVP. Despite their utility, Brattleboro rats are difficult to breed owing largely to the fixed nature of the *Avp* mutation, resulting in increased neonatal death and behavioral effects in the adults. Consequently, commercial breeders have ceased production, despite a continued need. To fill this need, we have now created a mouse model with tamoxifen-inducible deletion of AVP.

Methods: We employed CRISPR/Cas9 to flox a portion of exon 2 of the *Avp* gene. Successful insertion of the two loxP sites was confirmed by PCR using primers flanking the targeted regions. Restriction enzymes *Bam*HI or *Eco*RI were used to confirm correct targeting. For additional confirmation, PCR products were cloned into the TA-cloning vector and sequenced. Mice harboring the floxed allele were mated to mice that globally express a tamoxifen-inducible *Cre* recombinase.

Results: The resultant homozygous conditional knockout mice ($Cre^{+}Avp^{flx/flx}$) are viable, fertile and show no signs of polydipsia or polyuria prior to induction, indicating that the conditional alleles retain their wild-type function. Induction of *Cre*-mediated recombination by administration of tamoxifen (2-3 mg q.d., i.p. for 5 days) in 8-week-old mice resulted in a decrease in urine osmolality from 2076±138 to 122±6 mOsm/kgH_2O on day 31 after induction ($P<0.0001$). Sanger sequencing demonstrated the expected 1245 bp deletion at the *Avp* locus. The kidney parenchyma was structurally normal with no evidence of medullary atrophy 6 weeks after induction. Immunoblotting of AQP2 in the inner medulla showed a significant decrease in AQP2 band density in $Cre^{+}Avp^{flx/flx}$ mice to 27±14% of values in Cre^{-} floxed control mice ($P<0.05$).

Conclusions: We developed an inducible AVP knockout mouse line $Cre^{+}Avp^{flx/flx}$ that will be shared with the research community and are likely to be useful for further study of regulation of water balance and polycystic kidney disease, as well as neural, vascular, and metabolic roles of AVP.

Acute and Chronic Modulation of Kidney Proximal Tubule Endocytic Capacity by Fluid Shear Stress

Emily Lackner, Katherine E. Shipman, Isabella Cowan, Kimberly R. Long, Ora A. Weisz. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: The kidney proximal tubule (PT) is uniquely specialized for efficient apical uptake of proteins that escape the glomerular filtration barrier. These proteins bind to the multiligand receptors megalin and cubilin and are internalized into apical early endosomes that rapidly mature into larger apical vacuoles (AVs). Dissociated ligands are delivered from AVs to lysosomes for degradation, while receptors are collected into dense apical tubules for recycling to the cell surface. We have extensively characterized an opossum kidney (OK) PT cell model cultured under continuous fluid shear stress (FSS) that has several-fold higher levels of megalin, cubilin, and endocytic capacity compared with static-grown cells. Additionally, cells cultured in this manner rapidly and reversibly adjust their endocytic capacity in response to acute changes in FSS. We hypothesize that flow-dependent modulation of endocytic capacity enables PT cells *in vivo* to preserve uptake efficiency in response to changes in glomerular filtration, though these mechanisms are unknown.

Methods: We combined biochemical, imaging, and mathematical modeling approaches to compare the effects of chronic vs acute changes in FSS on megalin trafficking. Biochemical measurements of surface expression, endocytic kinetics, and half-life were combined with quantitative imaging to determine subcellular distribution of megalin with markers of endocytic compartments. Data were fit to a previously validated mathematical model.

Results: Cells cultured under continuous FSS have faster megalin endocytic and recycling rates and slower degradation rates compared with static grown cells. These cells also have reduced steady state fraction of surface megalin due to the enhanced endocytic flux. By contrast, surface expression and endocytic kinetics of megalin were not significantly altered when cells were removed from FSS for 1h, despite an overall reduction in endocytic capacity. Our model predicts that this decrease reflects slower endosomal maturation and megalin recycling.

Conclusions: Chronic vs acute changes in FSS mediate alterations in endocytic capacity via distinct mechanisms. Whereas the primary rate affected when cells are cultured under continuous FSS is megalin internalization, acute drops in FSS preferentially alter intracellular trafficking steps to reduce endocytic uptake.

FR-PO511

The Effects of Hypoxia-Inducible Factors on Water Regulation in the Kidneys

Ching-Chun Yang,[1] Kai-Ting Huang,[1] Szu-Yu Pan,[1,2] Shuei-Liong Lin.[1,2]
[1]National Taiwan University College of Medicine, Taipei, Taiwan; [2]National Taiwan University Hospital, Taipei, Taiwan.

Background: Hypoxia-inducible factor (HIF) is one of important cellular responders when facing decreased oxygen tension or under hypoxia. HIF stabilization can improve anemia through erythropoietin production from kidneys; however, its overexpression could be seen in different cancer types, such as clear cell renal cell carcinoma. Previous studies have shown wide-spread HIF-1a-dependent hyperplastic, inflammatory and fibrotic lesions in the kidney of mice with von Hippel-Lindau gene (*Vhlh*) deletion in Hoxb7-expressing renal collecting duct (CD) epithelia. Interestingly, *Vhlh* deletion in Ksp1.3-expressing renal tubular epithelia has also been reported to cause HIF-1a dependent diuresis in mice.

Methods: *Tg(Hoxb7-cre);Vhlh$^{F/F}$* (*Vhlh* KO), *Tg(Hoxb7-Cre);Vhlh$^{F/F}$;Hif1a$^{F/F}$* (*Vhlh*;*Hif1a* DKO), and *Tg(Hoxb7-Cre);Vhlh$^{F/F}$;Hif2a$^{F/F}$* (*Vhlh*;*Hif2a* DKO) mice were bred to study the effect of HIF stabilization in Hoxb7-expressing renal CD epithelia. Littermate without *Hoxb7-cre* transgene was used as the control to compare body weight, blood and urine biochemistry, gene/protein expression and histology in kidney.

Results: Compared to littermate control, *Vhlh* KO mice exhibited higher 24-hour urine volume and lower urine osmolality which could be partially ameliorated by water deprivation. Water deprivation-induced, vasopressin-dependent urine concentration was not different between *Vhlh* KO mice and littermate control. *Vhlh* KO mice exhibited higher food intake and solute diuresis, but decreased body weight. Food restriction led to similar excretion of urine solutes, but *Vhlh* KO mice consistently exhibited higher urine volume and lower urine osmolality than littermate control. *Vhlh*;*Hif2a* DKO mice exhibited higher urine volume and lower urine osmolality, but no more solute diuresis. *Vhlh*;*Hif1a* DKO mice did not exhibit abnormality in urine volume and osmolality. Histologically, *Vhlh* KO mice exhibited substantial tubulointerstitial injury.

Conclusions: *Vhlh* KO and hence HIF-1a/HIF-2a overexpression in renal CD epithelia led to HIF-1a-dependent decrease in renal concentrating ability. However, increase of solute diuresis was HIF-2a-dependent. Water deprivation-induced, vasopressin dependent urine concentration was not impaired in *Vhlh* KO mice. HIF-1a-dependent diuresis might be caused by destructed renal interstitium. But the mechanisms underlying HIF-2a-dependent solute diuresis need further study.

Hyperosmolarity-Induced Cell Shrinkage in Renal Cells: What a Role for RhoB?

Mariangela Centrone,[1] Mariagrazia D'Agostino,[1] Marianna Ranieri,[1] Maria Venneri,[1] Ines Angelini,[1] Annarita Di Mise,[1] Laura Simone,[2] Francesco Pisani,[1] Giovanna Valenti,[1] Grazia Tamma.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Fondazione IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo, Italy.*

Background: The small Rho GTP-binding proteins are important regulators of cell morphology, function, and apoptosis. Unlike other Rho proteins, RhoB can be subjected to either geranylgeranylation (RhoB-GG) or farnesylation (RhoB-F), making that the only target of the farnesyltransferase inhibitors (FTIs). This study evaluated the involvement of RhoB farnesylation in the mechanism that regulates cell volume changes.

Methods: Mouse collecting duct MCD4 cells and human proximal tubule HK-2 cells were used as experimental models. Fluorescence Resonance Energy Transfer (FRET) studies were applied to evaluate the activity of RhoB. Cell volume was detected using an automated cell counter (Luna, Logos Biosystem), a calcein-based assay, and laser-scan confocal microscopy followed by 3D reconstruction and cell-volume analysis (3D-LSCM).

Results: Treatment with FTI-277 significantly reduced the cell volume in MCD4 and HK-2 cells. Compared to untreated cells, FTI-277 treatment altered hyperosmotic-dependent cell shrinkage response. FRET experiments revealed that RhoB was activated by hyperosmolarity regardless of FTI exposure. By contrast, hyposmolarity did not alter the activity of RhoB. To evaluate whether RhoB plays a role in volume reduction, cells were transiently transfected with RhoB-wt-EGFP and RhoB-CLLL-EGFP which cannot undergo farnesylation. Notably, hyperosmolarity caused a significant reduction in cell volume in mock and RhoB-wt-EGFP-expressing cells. By contrast, cells treated with FTI-277 or expressing the RhoB-CLLL-EGFP mutant did not properly respond to hyperosmolarity compared to mock and RhoB-wt-EGFP expressing cells. These findings were further confirmed by 3D-LSCM. Additionally, RhoB-CLLL-EGFP expressing cells showed relevant staining for Annexin-V compared to cells expressing EGFP and RhoB-wt-EGFP.

Conclusions: Together, these data suggest that: i) RhoB is sensitive to hyperosmolarity but not to hyposmolarity; ii) inhibition of RhoB farnesylation associates with an increase in cell apoptosis, likely suggesting that RhoB might be a paramount player controlling apoptosis by interfering with responses to cell volume change.

Tamoxifen Attenuates the Lithium-Induced Decrease in Necroptosis in Renal-Collecting Duct Cells

Mariangela Centrone,[1] Mariagrazia D'Agostino,[1] Ines Angelini,[1] Annarita Di Mise,[1] Marianna Ranieri,[1] Stine Julie Tingskov,[2] Rikke Norregaard,[2] Giovanna Valenti,[1] Grazia Tamma.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Aarhus Universitetshospital, Aarhus, Denmark.*

Background: Lithium is recommended for bipolar disease, but it generally displays adverse effects including chronic kidney disease and acquired nephrogenic diabetes insipidus, a disorder characterized by a defective renal concentrating ability that leads to massive water loss. Several data demonstrated that tamoxifen attenuates the development of lithium-induced NDI by modulating AQP2 and AQP3 expression and function. Recent studies revealed that lithium promotes proliferation and autophagy in renal cells. Here, we identify the heat-shock-protein 90 (HSP90) as a novel player involved in signaling activated by lithium treatment and leading to the inhibition of cell necroptosis. Inhibition of HSP90 may lead to conformational changes and degradation of RIP3 which is a key protein promoting necroptosis via MLKL.

Methods: Renal collecting duct MCD4 cells were used as an experimental model. Western Blotting analysis was applied to evaluate the expression and function of proteins.

Results: Exposure of MCD4 cells to lithium (10mM for 48 hours) significantly reduced the expression of HSP90, RIP3, and MLKL. A relevant decrease in phosphorylated MLKL was also detected. A decrease in the expression of BID and an increase of beclin, selective markers of apoptosis and autophagy respectively, were found as well. The effect of tamoxifen on necroptosis was evaluated considering that tamoxifen enhances the client activity of HSP90. Notably, either tamoxifen or IP6, a known activator of necroptosis, reversed the effect of lithium on HSP90 and RIP3 expression. Importantly, preliminary in vivo data showed that lithium decreased the expression of RIP3. By contrast, tamoxifen reversed the lithium-induced RIP3 reduction.

Conclusions: Together, these findings revealed for the first time that exposure of renal collecting duct cells to lithium resulted in a significant reduction in the expression level of selective markers of necroptosis possibly through HSP90 inhibition. Treatment with tamoxifen counteracts the lithium-induced downregulation of HSP90 and RIP3.

Gut Dysbiosis and Hyperoxaluria in Nephrolithiasis

Thasinas Dissayabutra, Sittiphong Hunthai, Mana Taweevisit, Natthaya Chuaypen, Piyaratana Tosukhowong. Metabolic Diseases in Gastrointestinal and Urologic System Research Unit (MEDGURU). *Chulalongkorn University, Bangkok, Thailand.*

Background: Nephrolithiasis is a urologic disease with high recurrence rate. Hypercalciuria, hypocitraturia and hyperoxaluria are common risk factors. Previously studies reviewed gut dysbiosis in patients with nephrolithiasis, including increased *Bacteroidota*, although no evidence showed that gut dysbiosis is the cause or consequence of nephrolithiasis. We underwent human-to-animal fecal microbiota transplant (FMT) to elucidate this gut-kidney axis.

Methods: Five nephrolithiasis patients and 5 healthy adults with age- and gender-matched were enrolled. Urine was collected for calcium, oxalate, citrate, and magnesium measurement, while feces were analyzed for gut microbiome, and feces were mixed and extracted for microbiota. Rats with intestinal microbial eradication by antibiotics for 1 week were divided into (a) Control, (b) Healthy-FMT (hFMT) and (c) Nephrolithiasis-FMT (nFMT) (n=6 each). The hFMT and nFMT were gavaged with fecal microbiota from Healthy and Nephrolithiasis group, respectively, twice a week for 4 weeks. Blood and urine were collected at Week-0 and Week-4 to measure calcium, oxalate, citrate, and magnesium, and feces for fecal microbiome.

Results: Compared with Healthy control, participants with nephrolithiasis had higher urinary calcium and oxalate excretion rate (p=0.043 and p=0.005) and lower citrate excretion rate (p=0.031). Tiselius supersaturation index is higher in Nephrolithiasis (p=0.027). Fecal microbiota showed increased *Bacteroidota* spp in Nephrolithiasis group. In rats, nFMT had insignificant increases in gut *Bacteroides*, and increased urinary oxalate excretion rate in post-FMT compared to pre-FMT (p=0.020), while hFMT rats had no significant change (p=0.625). Higher Tiselius index in nFMT rats (p=0.032) was detected. Moreover, nFMT rats had higher renal NF-kB expression than hFMT, suggesting renal inflammation. In addition, intestinal expression of oxalate transporter was higher, and zonula occluden-1 was lower in nFMT rats, indicating increased gut permeability to oxalate in nFMT rats.

Conclusions: Our study reviewed hypercalciuria, hyperoxaluria and hypocitraturia and gut dysbiosis in patients with nephrolithiasis. FMT from nephrolithiasis to rats induced hyperoxaluria, renal inflammation and higher risk of stone formation, possibly due to increased intestinal oxalate absorption from gut leakage and oxalate transporter overexpression.

FR-PO515

RNAseq of Microdissected Collecting Ducts Revealing the Early Signaling Mediating the Loss of Aquaporin 2 After K+ Deprivation

Chih-Chien Sung, Min-Hsiu Chen, Yu-Juei Hsu, Shih-Hua P. Lin. *Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Potassium (K^+) deficiency could cause a reduction in urinary concentrating ability, resulting in nephrogenic diabetes insipidus (NDI), but the detailed mechanism remains unclear. Recently, transcriptomic and proteomic data from acquired NDI models reveals that oxidative stress, apoptosis, and inflammatory signaling are associated with AQP2 loss. We aim to explore the early signaling after K^+ deprivation in cortical collecting ducts (CCDs).

Methods: Immunoblotting and bulk kidney RNAseq were performed at 0, 12, 24, and 48 hours after K^+ deprivation in rats. Serum and urine biochemistry were also recorded. Based on immunoblotting and bulk kidney RNAseq, CCDs were microdissected from rats at 6 hrs after K^+ deprivation versus time controls. Single-tubule RNA-Seq was carried out independently in K^+ deprivation rats versus controls (n=4).

Results: Immunoblotting of bulk kidney showed a decrease in AQP2 protein abundance at 12 hours of K^+ deprivation diet, and urine osmolality was significantly decreased at 24 hours, confirming the animal model of K^+ deprivation-induced NDI. Preliminary bulk kidney RNA-Seq time course experiments also revealed that *Aqp2* and other collecting ducts markers such as *Aqp3, Aqp4,* and *Fxyd4* mRNA started to decrease at 12 hrs. Single-tubule RNA-Seq data of CCDs at 6 hrs after K^+ deprivation showed *Aqp2, Aqp3,* and *Atp1a1* were significantly downregulated. It also revealed that chemokine transcripts (*Ccl20* and *Ccl28*) were increased significantly. We also carried out analysis of *Gene Ontology Biological Process* terms that are statistically over-represented in the list of 88 "Increased Transcripts"at 6 hrs of K^+ deprivation in CCDs, and many of the terms are related to glutathione metabolic process (*Gstm1, Gsta1, Gstt3, Txnrd3*), positive regulation of ERK1 and ERK2 cascade (Nrp1, *Ccl20, Ripk2, Fgfr4, Fgfr3*), cell chemotaxis (*Ccl20, Ccl28, Hbegf*), cellular response to lipopolysaccharide (*Ccl20, Ripk2, Cd14, Tfpi*), consistent with an inflammatory response.

Conclusions: Our small samples RNA-Seq from microdissected CCDs in rats showed early cellular signaling changes in activation of oxidative stress and inflammatory signaling causing loss of aquaporin-2 in K^+ deficiency induced NDI.

FR-PO516

Role of Paraoxonase 3 (PON3) in Regulating Epithelial Sodium Channel (ENaC)-Mediated Na+ Transport in Distal Nephron

Shujie Shi, Stephanie Mutchler, Sarah Christine Whelan, Allison L. Marciszyn, Thomas R. Kleyman. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: PON3 is expressed in the aldosterone-sensitive distal nephron, where ENaC plays an essential role in maintaining Na^+/ K^+ homeostasis in the kidney. The aims of our study were to determine the physiological roles of PON3 in renal Na^+ and K^+ handling. We hypothesize that PON3 functions as a molecular chaperone to regulate ENaC expressionand Na^+ reabsorption in the kidney.

Methods: We have obtained a *Pon3* global knockout mouse model and examined the effect of PON3 on ENaC functional expression using several approaches, including biochemistry, immunohistochemistry, electrophysiology, and whole animal metabolic cage studies.

Results: *Pon3* KO mice have normal kidney histology without evidence of inflammation or injury. At baseline, *Pon3* KO mice have a significantly lower blood [K^+] and higher blood [Na^+] when compared to WT littermates. Amiloride-induced natriuresis was significantly greater in the KO mice, reflecting, in part, an upregulation in ENaC-dependent Na^+ reabsorption in the absence of the PON3. Immunoblotting of whole kidney lysates indicated that the total abundance of ENaC subunits was not altered in KO mice. However, γENaC was more apically distributed within the cortical collecting ducts (CCD) of the KO kidneys. Single channel recordings of ENaC in split-open tubules freshly isolated from WT or *Pon3* KO mice kidneys demonstrated that open probability (P_O) was similar between the two groups of animals. However, the number of active channels per patch (*N*) was significantly higher in the KO kidneys, resulting in a higher ENaC activity (NP_O) in the distal nephron segments of *Pon3* KO mice. Consistent this notion, we found that γENaC surface abundance was increased in mCCD cells when PON3 expression was knocked down by siRNA.

Conclusions: Together, our data suggest that *Pon3* KO mice have upregulated Na^+ reabsorption and K^+ secretion, likely a result of increased ENaC functional expression in the absence of PON3.

Circadian Rhythm Misalignment Induced Differential Expression of Mineralocorticoid Receptor Type I and Aldosterone in Kidneys and Urine of Male Rats

Tyler Cholankeril, Margaret Roccato, Diana Martinez, Michael E. Disanto. *Rowan University Cooper Medical School, Camden, NJ.*

Background: Circadian rhythm misalignment (CRM) adversely impacts health and increases blood pressure (BP), especially in shift workers. Aldosterone (ALD) acting through mineralocorticoid receptor-1 (MCR1) causes sodium retention and water reabsorption to increase BP. The aim of this study was to determine if CRM alters the expression of MCR1 in the kidneys and aldosterone levels in the urine of rats.

Methods: 32 young male rats were divided into control (CTL) and CRM groups. CTLs experienced normal light/dark cycles but CRMs were phase-advanced every 2 days for 22 days after which BPs were measured at 6-hour intervals. Rats were sacrificed and kidney tissue and urine stored at 80°C. RNA was extracted and Real-Time PCR conducted. ELISA was utilized to quantitate urine ALD. The MCR1 expression was normalized to 18s ribosomal RNA. An independent sample two-tailed t-test was used to determine effects of variance in both directions for both ELISA and RT-PCR data.

Results: Overall MCR1 expression was ~7.5-fold higher in combined CRM groups compared to CTL ($p = 0.00019$). Subgroup analyses revealed significance in the 9AM CRM group with an ~18-fold higher MCR1 expression ($p = 0.20$). The 3PM, 9PM and 3AM CRM groups also exhibited higher expression but did not reach statistical significance (Fig. 1). ALD was ~1.8-fold higher in combined CRM compared to CTL groups ($p < 0.0035$). Subgroup analyses revealed the 9AM, & 3PM CRM groups with significantly higher ALD expression (~2.96-fold ($p = 0.005$) and ~ 2.87-fold ($p = 0.011$), respectively). 3AM also showed higher expression but the 9PM CRM subgroup did not differ from CTL.

Conclusions: MCR1 expression and ALD are upregulated in kidneys and urine of rats after CRM and may be a potential mechanism for CRM-induced renal and cardiovascular dysfunction (CVD). Additionally, MCR1 expression and ALD levels appear to vary over a daily 24-hour cycle. Shift workers, have an increased risk of impaired sodium excretion and water retention. We hypothesized that this impaired cycle is due to the improper activation of the renin-aldosterone-angiotensin system thus resulting in hypertension, renal dysfunction, and CVD.

FR-PO518

Proximal Tubule Regulates the Collecting Duct Response to Hypokalemia

Hyun-Wook Lee,[1] Autumn N. Harris,[2] I. D. Weiner.[1,3] *[1]University of Florida College of Medicine, Gainesville, FL; [2]University of Florida College of Veterinary Medicine, Gainesville, FL; [3]Gainesville VA Medical Center, Gainesville, FL.*

Background: Hypokalemia induces phenotypic and remodeling responses in the collecting duct that increase net acid excretion. We showed recently that the proximal tubule, through an NBCe1-A-dependent signaling pathway likely involving ammonia, regulates the collecting duct response to metabolic acidosis. Because hypokalemia stimulates proximal tubule NBCe1-A-dependent ammoniagenesis, we postulated that a similar mechanism would control the collecting duct response to hypokalemia.

Methods: Male and female NBCe1-A knock-out (KO) and wild-type (WT) mice were studied either on a K-control diet or a nominally K-free diet (KFD). Immunoblot analysis, immunohistochemistry, and cell counting evaluated phenotypic and remodeling responses.

Results: KO mice tolerated only four days of KFD before developing life-threatening hypokalemia. After four days, KFD increased the number of Type A intercalated cells (A-cell) in the inner stripe of the outer medullary collecting duct (OMCDis) and decreased the number of Type B intercalated cells (B-Cell) in the cortical collecting duct (CCD), and KO significantly blocked these remodeling responses. KFD increased the number of A-cells in the CCD, and KO did not alter this response. Immunoblot analysis showed KFD decreased cortical pendrin expression, and KO did not alter this response. In the inner stripe of the outer medulla (ISOM), KFD did not significantly alter either AE1 or Rh B Glycoprotein (Rhbg) expression, and NBCe1-A deletion did not alter the response to KFD. ANOVA analysis showed no significant effect of sex on these immunoblot responses.

Conclusions: We conclude: (1) the CCD B-Cell and OMCDis A-cell remodeling responses to hypokalemia are present at four days and involves a proximal tubule NBCe1-A-dependent response likely involving ammonia; (2) the ISOM collecting duct phenotypic response to hypokalemia that involves AE1 and Rhbg requires more than four days to develop; and, (3) the CCD pendrin response to hypokalemia occurs more rapidly than ISOM responses, and is independent of proximal tubule NBCe1-A expression.

FR-PO519

Distal Convoluted Tubule-Specific Disruption of the COP9 Signalosome and CUL3 Activates the WNK4-SPAK-NCC Pathway

Ryan J. Cornelius, Yujiro Maeoka, Tanner Bradford, Xiao-Tong Su, Chao-Ling Yang, David H. Ellison, James A. McCormick. *Oregon Health & Science University, Portland, OR.*

Background: The disease Familial Hyperkalemic Hypertension (FHHt; also known as Gordon Syndrome) is caused by aberrant accumulation of WNK4 activating the NaCl cotransporter (NCC) in the distal convoluted tubule (DCT) of the kidney. Mutations in cullin 3 (CUL3) cause FHHt by disrupting interaction with its regulator, the COP9 signalosome (CSN). Deletion of *Cul3* and *Jab1* (the catalytically active CSN subunit) along the entire nephron causes an FHHt phenotype with activation of the WNK4-SPAK-NCC pathway.

However, only a partial FHHt phenotype develops due to kidney injury. We hypothesized that DCT-specific deletion would more accurately model the disease.

Methods: We utilized NCC-Cre-ERT2 mice to delete *Cul3* (DCT-*Cul3*$^{-/-}$) and *Jab1* (DCT-*Jab1*$^{-/-}$) only in the DCT. Blood was collected for plasma electrolyte analysis, and kidneys were collected for Western blotting and immunofluorescent staining.

Results: Both DCT-*Cul3*$^{-/-}$ and DCT-*Jab1*$^{-/-}$ mice showed an FHHt-like phenotype, with increased WNK4, SPAK, and pNCC abundance. CUL3 inactivation in the DCT-*Cul3*$^{-/-}$ mice caused an increase in both KLHL3 (the CUL3 substrate adaptor for WNK4) and WNK4 abundance. WNK4 accumulated in DCT-*Jab1*$^{-/-}$ mice due to hyperactivation of CUL3, which caused decreased CUL3 and KLHL3 abundance. Both genotypes showed formation of pSPAK and WNK4 puncta, however, the number of WNK4 puncta was higher in DCT-*Cul3*$^{-/-}$ mice. Contrasting the disease, both genotypes showed no change in plasma K^+, Cl^-, or HCO_3^- at baseline, but the DCT-*Jab1*$^{-/-}$ mice became hyperkalemic when challenged with a high K^+ diet. Additionally, over time DCT-*Jab1*$^{-/-}$ mice showed a large decrease in NCC abundance, which was not observed in the DCT-*Cul3*$^{-/-}$ mice. Interestingly, although *Jab1* was deleted only in the DCT, the mice had increased abundance of KIM-1, a marker of proximal tubule injury.

Conclusions: DCT-specific knockout of both CUL3 and the cullin-RING-ligase regulator JAB1 led to an FHHt-like phenotype. Chronically, only DCT-*Jab1*$^{-/-}$ mice developed a large reduction in NCC abundance, suggesting the decrease is due to a direct JAB1 effect, or effects of JAB1 on other cullins.

Regulation of NKCC1, NKCC2, and NCC69 by TSC1/TSC2 Complex

Aylin R. Rodan,[1] Sylvie Demaretz,[2,3] Nadia Frachon,[2,3] Kamel Laghmani.[2,3] *[1]University of Utah Health, Salt Lake City, UT; [2]Centre de Recherche des Cordeliers, Paris, France; [3]Sorbonne Université, INSERM U1138, CNRS ERL 8228, Paris, France.*

Background: Na-K-2Cl cotransporters NKCC1 and NKCC2 play important roles in numerous physiological processes and several human diseases such as salt losing tubulopathies, hypertension and cancer. In the kidney, NKCC1 plays a pivotal role in K+ secretion in the collecting duct while NKCC2 is the pacemaker of NaCl reabsorption in the thick ascending limb. Using the two-hybrid system, we identified tuberin (TSC2) as a binding partner of NKCC2. We therefore sought to characterize the mechanism by which TSC2, with or without hamartin (TSC1), could regulate NKCC2 and / or NKCC1.

Methods: NKCC1 and NKCC2 protein expression was monitored in HEK cells transiently or stably transfected with the cotransporters using immunoblot and confocal imaging. The stability of the cotransporters was assessed by cycloheximide chase assay. NCC69 function was evaluated in *Drosophila* Malpighian tubules overexpressing TSC1 and/or TSC2 in a control of *Ncc69* mutant background.

Results: Co-immunoprecipitation experiments showed robust interaction between TSC2 and the complex-glycosalyed form of NKCC2 suggesting that the interaction takes a place at the post-Golgi level. TSC2 and/or TSC1 knock-down (KD) similarly increased total NKCC2 protein. Cycloheximide assays and leupeptin treatment (lysosome inhibitor) revealed that TSC1/2 KD upregulate NKCC2 by increasing its stability and maturation. Interestingly, similar to NKCC2, the KD of TSC1/TSC2 reproduced the same effects on NKCC1. To elucidate *in vivo* the role of TSC1/TSC2 in the regulation of NKCC, we took advantage of the expression of NCC69, the fly NKCC **in** the Drosophila melanogaster renal tubule. Importantly, while overexpression of either TSC1 or TSC2 alone had no effect, overexpression of TSC1 and TSC2 together resulted in decreased tubule K^+ secretion in control tubules, but not in tubules lacking NCC69, strongly indicating that the two TSC function together to regulate NCC69 function.

Conclusions: We identified TSC1/TSC2 complex as a novel key player in the post-Golgi regulation of NKCCs. Our results are consistent with a model whereby TSC1 and TSC2 function together to decrease the expression of the cotransporters via the lysosome pathway. A better understanding of the regulatory pathways acting on NKCC1 and NKCC2 will ultimately help to identify new "druggable" targets to prevent and/or treat several disorders in which these two cotransporters are involved.

Chloride-Induced Monomer to Dimer Transition Controls WNK1 Scaffold Activity

Bidisha Saha, Enzo Takagi, John E. Demko, David Pearce. *University of California San Francisco, San Francisco, CA.*

Background: Although it is well established that WNK kinase activity is involved in controlling cation-chloride co-transporters, such as NCC and NKCC, recent findings demonstrate that WNK1 can also act as a scaffold, independent of its kinase function. It facilitates the interaction between mTORC2 and SGK1 and stimulates SGK1 phosphorylation thereby enhancing ENaC activity. Extracellular K^+ stimulates this non-kinase scaffolding activity at the same time that it inhibits WNK kinase activity. Both of these effects are mediated by intracellular Cl^-, which directly binds to WNKs. Previous studies have identified two conformational states of WNK kinases: a kinase inactive, unphosphorylated chloride-bound dimer and a kinase active monomer, which is not chloride-bound. The dimer conformation is maintained by salt bridges between the monomers, which dissociate in low chloride conditions. This study explores the conformational changes in WNK1 that contribute to its catalytic and non-catalytic functions.

Methods: Salt bridge mutations were generated using site-directed mutagenesis. WNK1 knockout (WNK1 KO) HEK293 cells were transfected with either wild-type (WT) WNK1 or the salt bridge mutants of WNK1. Subsequently, the cells were adapted to 1 mM [K^+] and then subjected to an increase in [K^+] to 5 mM. Following this, the cells were processed for co-immunoprecipitation (co-IP) and immunoblot analysis. Whole cell lysates were also assayed for OSR1/SPAK and SGK1 phosphorylation.

Results: In cells transfected with wild-type (WT) WNK1, extracellular K^+ stimulated mTORC2-dependent SGK1 phosphorylation, while inhibiting WNK kinase activity-dependent SPAK phosphorylation. In contrast, mutations disrupting the salt-bridge interface of WNK1 blocked the effect of K^+ on mTORC2-dependent SGK1 phosphorylation but not SPAK phosphorylation, which became insensitive to changes in extracellular [K^+]. Additionally, extracellular [K^+] stimulated dimer formation in the WT WNK1, but it was significantly reduced or absent in mutant forms of WNK1.

Conclusions: Our data suggest that the Cl^- induced shift of WNK1 from monomer to dimer conformations both inhibits WNK kinase activity and enhances scaffolding activity, providing a parsimonious mechanism for its opposite regulation of cation-chloride cotransporters and ENaC.

Sexual Dimorphism in Vasopressin Signaling

Rick Grimm, Hyun Jun Jung, Lama Al-Qusairi. *Johns Hopkins Medicine, Baltimore, MD.*

Background: Hyponatremia is a life-threatening condition characterized by decreased body natrium (sodium) concentration due to water retention. For reasons not yet understood, women are more prone to hyponatremic conditions, including exercise-associated hyponatremia, post-operative hyponatremia, and ecstasy-associated hyponatremia. Recent reports suggest that compared to males, female mice concentrate their urine more effectively due to enhanced AQP2 apical membrane localization. It has been suggested that sex hormones affect water balance; however, it is unknown if vasopressin signaling itself exhibits sex-dependent differences.

Methods: The sexual dimorphism in water balance was analyzed in C57BL6J wild-type males and females at basal conditions and after 12 hours of water deprivation. The *in-vivo* activation of vasopressin signaling was assessed using western blot (WB) and confocal imaging. Plasma copeptin, a surrogate marker of vasopressin secretion, was analyzed using ELISA.

Results: Our data revealed that females exhibit higher urine osmolality at baseline and have an enhanced ability to further concentrate their urine following 12 hours of water deprivation. Plasma copeptin was higher in females compared to males under basal conditions. WB analysis of the renal cortex and medulla in both sexes under basal conditions revealed AQP2 total protein levels were similar between males and females. However, AQP2 phosphorylation at Ser256, in a protein kinase A (PKA) consensus site, was more enhanced in the renal cortex and medulla of females. This is consistent with higher AQP2 apical localization in females as revealed by confocal imaging. To assess a potential sex-dependent activation of vasopressin signaling in the principal cells, we analyzed phospho-PKA substrates in the AQP2-positive cells using phospho-PKA substrate (RRXS/T) antibody. Quantitative analysis of confocal images revealed PKA-substrates were more phosphorylated in the principal cells of females compare to males, indicating more enhanced vasopressin signaling in females.

Conclusions: The sexual dimorphism in water balance is mediated, at least in part, by higher circulating vasopressin levels in females. Subsequently, vasopressin signaling in the collecting duct was more enhanced in females resulting in more robust AQP2 apical translocation.

α-Epithelial Sodium Channel (ENaC) Proteolysis Regulates Channel Function In Vivo in a Sex- and Tissue-Specific Manner

Andrew Nickerson,[1] Shaohu Sheng,[1] Evan C. Ray,[2,1] Marcelo D. Carattino,[1] Allison L. Marciszyn,[1] Tracey Lam,[1] Thomas R. Kleyman.[2,1] *[1]University of Pittsburgh Department of Medicine, Pittsburgh, PA; [2]UPMC, Pittsburgh, PA.*

Background: Epithelial Na^+ channels (ENaCs) facilitate Na^+ and water reabsorption in the distal nephron and distal colon, while also controlling K^+ secretion in the distal nephron. ENaC activity is regulated, in part, by proteolysis of the channel's α and γ subunits. *In vitro*, α-ENaC is typically cleaved twice by furin proteases during synthesis. As a result, an autoinhibitory peptide sequence is excised, thereby increasing the channel's open probability (P_O). However, the importance of α-ENaC cleavage with respect to Na^+ and fluid handling *in vivo* is unknown.

Methods: We tested the hypothesis that α-ENaC cleavage is necessary for channel function *in vivo* by generating mice that lack a key furin cleavage site (^{229}RSAR^{232} > ^{229}QSAQ^{232}; α^{Fm} = α furin site mutant). We assessed ENaC function in α^{Fm} versus wild-type (WT) littermates via electrophysiological and systemic analyses under normal and Na^+-restricted dietary conditions.

Results: At baseline, male α^{Fm} mice had elevated blood K^+ versus WT littermates (α^{Fm} vs. WT: 4.7 ± 0.1 vs. 4.3 ± 0.1 mM; p=0.03), but this was not observed in females (α^{Fm} vs. WT: 4.8 ± 0.1 vs. 5.0 ± 0.2 mM; p=0.8). Otherwise, α^{Fm} mice of either sex exhibited no baseline phenotype regarding blood electrolyte or metabolic parameters. Western blot analysis showed no differences in ENaC subunit expression in the kidney or distal colon. Patch clamp experiments revealed no differences in ENaC activity (P_O) in isolated kidney tubules. However, short-circuit current (I_{SC}) measurements revealed that male α^{FM} mice had diminished ENaC activity in the distal colon (α^{Fm} vs. WT ΔI_{SC}(amiloride): -0.2 ± 2.3 vs. -17.7 ± 4.4 μA/cm^2; p<0.01). Colonic ENaC activity in both genotypes was stimulated by dietary Na^+ restriction (α^{Fm} vs. WT ΔI_{SC}(amiloride): -104 ± 38 vs. 64 ± 19 μA/cm^2;

p=0.4) and plasma aldosterone levels were also similar following treatment (α^{Fm} vs. WT: 2,910 ± 323 vs. 2,275 ± 584 pg/mL). Body composition analysis showed that during Na^+-restriction, α^{FM} mice maintained body water content, but lost total body weight more rapidly than WT littermates.

Conclusions: α subunit cleavage is required for full ENaC function in male mice. However, loss of α-ENaC cleavage can be compensated by elevated aldosterone under Na^+-restricted conditions to maitain salt and fluid balance.

Inhibition of Calcium-Sensing Receptor in Mice Proximal Tubule Leads to Calcium Phosphate Crystalluria

Samuel Shin,[1] Laureano D. Asico,[2] Pedro A. Jose,[2] Bidhan C. Bandyopadhyay.[1,2] *[1]Washington DC VA Medical Center, Washington, DC; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC.*

Background: The proximal tubular (PT) Ca^{2+} transport is crucial for maintaining tubular Ca^{2+} levels to prevent downstream calcium phosphate (CaP) crystal formation. While PT Ca^{2+} transport is often described as paracellular, we found a transcellular Ca^{2+} transport pathway in the PT that is mediated by the interaction of calcium-sensing receptor (CaSR) and transient receptor potential canonical type 3 (TRPC3) channel. TRPC3 knockout mice exhibited hypercalciuria and microcalcifications arguing for a protective role of TRPC3 in preventing nephrocalcinosis. However, the role of CaSR in CaP crystal formation is unclear. Thus, we used a renal-selective knockdown of CaSR by the renal subcapsular infusion of CaSR siRNA to sort out the CaSR-mediated Ca^{2+} transport in the PT and its contribution to urinary CaP formation.

Methods: Adult male C57BL/6J mice were uninephrectomized 1 week before the renal implantation of osmotic minipumps. Osmotic minipumps (100 μL; flow rate 0.5 μL/h for 7 days) were filled with previously validated CaSR or non-silencing siRNA as control. siRNAs were dissolved in an *in vivo* transfection reagent under sterile conditions and was delivered via the osmotic minipumps into the renal cortex of each mouse. 24h urine collection and ion measurements were performed and collected urine were stained with AR pH 4.3 to detect CaP. Real time intracellular Ca^{2+} was measured in siRNA- or scramble-transfected isolated mice PT cells.

Results: In mice that underwent renal subcapsular infusion with siRNA for two weeks, 24h urine showed notable CaP crystal formations compared with that of control and scramble siRNA- infused mice. Renal cortical knockdown of CaSR did not significantly affect Na^+, Cl^-, and K^+ excretion (normalized by creatinine) except for Ca^{2+}. Fura-2 intracellular Ca^{2+} measurements in CaSR siRNA-transfected PT cells revealed decreased or nearly complete absence of Ca^{2+} entry after application with L-phenylalanine (CaSR agonist), confirming the effects of the siRNA.

Conclusions: The decreased Ca^{2+} influx due to CaSR inhibition suggest diminished tubular Ca^{2+} reabsorption confirming CaSR's involvement in PT Ca^{2+} regulation. This study thus enhances our understanding about transcellular regulation of PT Ca^{2+} and its role in regulating urinary Ca^{2+} levels and subsequently CaP stone formation.

Mice Lacking P300/CBP-Associated Factor Have a Resistance to Salt-Induced Hypertension Probably Through Dysregulation of NKCC2 and Aquaporin 2

So Young Lee, Eun Sil Koh, Sungjin Chung. *Catholic University of Korea Yeouido Saint Mary's Hospital, Yeongdeungpo-gu, Seoul, Republic of Korea.*

Background: P300/CBP-associated factor (PCAF), a member of the GNAT acetyltransferase family, is involved in the modulation of differentiation and cell cycle progression. Several neurodegenerative conditions have been thought to be associated with an alteration of PCAF activity and subsequent histone acetylation, and patients with neurodegenerative diseases often experience hypotension although the consequence of dysfunctional PCAF on blood pressure remains unknown. This study investigated a potential role of PCAF in the relationship between blood pressure and urinary sodium and water excretion in the kidney.

Methods: PCAF knockout (KO) mice and wild-type (WT) mice received 8% or normal NaCl salt diet for 2 weeks.

Results: WT mice had higher blood pressure on a high-salt diet than on a normal salt diet, but changes of dietary salt did not affect the blood pressure of PCAF KO mice. Free water clearance (FWC) and electrolyte free water clearance (EFWC) in PCAF KO mice on a high-salt diet were higher than those of WT mice on a high-salt diet. Both PCAF KO and WT mice on a high-salt diet had higher expression of Na^+/H^+ exchanger isoform 3 (NHE3) compared with normal salt-fed groups. In PCAF KO mice fed a high-salt diet, there was an increase in renal expression of Na^+-Cl^- cotransporter (NCC) and a decrease in renal expression of Na^+-K^+-$2Cl^-$ cotransporter (NKCC2) compared with WT mice fed a high-salt diet. Although renal mRNA expression of aquaporin 2 (AQP2) was upregulated in all groups on a high-salt diet, the phosphorylated protein level of AQP2 at serine 261 was significantly increased only in PCAF KO mice on a high-salt diet.

Conclusions: A deletion in PCAF expression makes blood pressure less sensitive to salt probably via inappropriate downregulation of NKCC2 and AQP2 in kidneys, indicating that genetically impaired PCAF activity is likely to affect how blood pressure responds to changes in dietary salt.

FR-PO526

TGR5 Activation Ameliorated Hypertension Through Inhibiting Epithelial Sodium Channel (ENaC) Expression in the Kidney of Deoxycorticosterone Acetate (DOCA) Salt-Treated Mice

Long Xu,[1,2] Xinyan Wu,[1,3] Suchun Li,[1,4] Wei Chen,[4,6] Lei Wang,[5] Chunling Li,[1,2] Weidong Wang.[1,3] *[1]Institute of Hypertension, Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, China; [2]Department of Physiology, Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, China; [3]Department of Pathophysiology, Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, China; [4]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [5]School of Pharmaceutical Sciences, Guangzhou University of Chinese Medicine, Guangzhou, China; [6]NHC Key Laboratory of Clinical Nephrology (Sun Yat-Sen University) and Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, China.*

Background: Epithelial sodium channel (ENaC), located in the collecting duct principal cells of the kidney, plays a critical role in regulating sodium balance and blood pressure in the body. The G protein-coupled bile acid receptor (TGR5) is a cell-surface receptor mediating bile acid effects and is implicated in several kidney diseases. The current study aims to investigate whether activation of TGR5 by lithocholic acid (LCA) regulated renal ENaC expression and blood pressure in deoxycorticosterone acetate (DOCA)-salt induced hypertensive mice.

Methods: Hypertension was induced in mice by subcutaneous implantation of DOCA pellets with 1% NaCl in drinking water. LCA was given by gavage.

Results: LCA markedly decreased blood pressure induced by DOCA-salt in mice, which was associated with decreased expression levels of ENaC mRNA and protein in the kidney. Compared with wild type group, TGR5 knockout mice developed increased blood pressure and ENaC protein expression in the kidney after DOCA-salt treatment. Bioinformatic indicates H3K4me1, 2, 3 enrichment in the promotor of ENaC. DOCA-salt treatment was associated with increased H3K4me3 expression in the kidney cortex which was markedly inhibited by LCA, while TGR5 knockout caused further increased H3K4me3 expression mice with DOCA-salt. Interestingly the mRNA and protein expression of KDM5A, a lysine demethylase, was significantly decreased in the kidney of mice with DOCA-salt, which was also significantly prevented by LCA. These data likely suggests that TGR5 activation decreased H3K4me3 enrichment of ENaC thus downregulated ENaC mRNA and protein expression. In immortalized mouse cortical collecting duct cells (mpkCCD) cells treated with either Ang II or aldosterone, the protein and mRNA expression levels of ENaC subunits were dramatically increased in association with increased protein expression of H3K4me3 and decreased mRNA and protein abundance of KDM5A, which were all inhibited by LCA treatment. Inhibition of KDM5 or KDM5A knockdown in mpkCCD cells treated with Ang II or aldosterone prevented the downregulation of ENaC expression induced by LCA.

Conclusions: In conclusion, LCA decreased blood pressure and ENaC protein expression in the kidney of mice with DOCA-salt, likely through increased KDM5A-mediated H3K4me3.

Metabolic Reprogramming of Renal Epithelial Cells Contributes to Lithium-Induced Nephrogenic Diabetes Insipidus

Mi Liu,[1] Xiulin Li,[1] Mokan Deng,[2] Qimei Luo,[1] Xianrui Dou.[1] *[1]Shunde Hospital of Southern Medical University, Foshan, China; [2]University of Macau Faculty of Health Sciences, Taipa, Macao.*

Background: Lithium, mainstay treatment for bipolar disorder, frequently causes nephrogenic diabetes insipidus (NDI). However, the detailed mechanism remains unclear. Metabolic reprogramming is not only a hallmark of disease progression, but also an important pathogenic cause and therapeutic target in diseases. But its role in Li-NDI is unknown. Rotenone (ROT), an inhibitor of electron transport complex I, has a strong protective effect in various renal diseases. Whereas, the effect of ROT on metabolic status of kidney during Li-NDI remains unknown.

Methods: Mice were treated with lithium chloride (40 mmol/kg chow) and ROT (100 ppm) in diet for 28 days. Transmission electron microscopy was performed to evaluate structural changes of nephron. Metabolomics and transcriptomics were applied to examine metabolic status during Li-NDI.

Results: ROT treatment markedly ameliorated lithium-induced NDI and mitochondrial structural abnormalities. Metabolomics and transcriptomics data demonstrated that lithium resulted in metabolic over-activation in the kidney, which were significantly ameliorated by ROT intervention.

Conclusions: Mitochondrial abnormalities and metabolic reprogramming play a key role in Li-NDI, thereby serving as a novel therapeutic target.

Funding: Government Support - Non-U.S.

FR-PO528

Deletion of Kcnj16 Disturbs Acid-Base Homeostasis in Dahl Salt-Sensitive Rats

Biyang Xu,[1] Adrian P. Zietara,[1,3] Lashodya V. Dissanayake,[1] Olha Kravtsova,[1] Alexander Staruschenko.[1,2] *[1]University of South Florida, Tampa, FL; [2]VA James A Haley Hospital, Tampa, FL; [3]Medical College of Wisconsin, Milwaukee, WI.*

Background: The role of renal inwardly-rectifying potassium (K_{ir}) channels in regulating acid-base homeostasis has been suggested by various studies. Previous studies demonstrated that patients with loss-of-function variants of *Kcnj16* (the gene encoding $K_{ir}5.1$) presented with disturbed acid-base homeostasis. However, the underlying mechanisms are still not fully understood. Here, we aim to investigate the renal handling of acid-base balance under the deletion of $K_{ir}5.1$ in Dahl salt-sensitive rats ($SS^{Kcnj16-/-}$).

Methods: To evaluate the baseline acid-base status of $SS^{Kcnj16-/-}$ rats, 12-week-old male SS^{WT} and $SS^{Kcnj16-/-}$ rats were used (N=5 per group). 24 hrs urine and blood were collected for measurement of blood pH, $HCO3^-$ and urinary pH, $NH4^+$, titratable acid, and net acid excretion (NAE). At the end of the experiments, RNA-Seq and Western blot analysis were performed on extracted kidneys to evaluate the expression of key transporters related to renal $HCO3^-$, H^+, and $NH4^+$ handling.

Results: At baseline, $SS^{Kcnj16-/-}$ rats showed significantly lower blood pH and $HCO3^-$, but higher urinary $NH4^+$, titratable acid and NAE than SS^{WT} rats. RNA-Seq and Western blot analysis revealed altered expression of several transporters essential for renal handling of $HCO3^-$, H^+ and $NH4^+$. For example, for $HCO3^-$ transport, both RNA-seq and Western blot analysis demonstrated increased expression of NBCe1 while decreased expression of pendrin, which may suggest enhanced $HCO3^-$ reabsorption in the proximal tubule while inhibited $HCO3^-$ excretion in the collecting duct of $SS^{Kcnj16-/-}$ rats. For $NH4^+$ transport, increased mRNA expression of *Rhbg* and *Rhcg* may indicate enhanced $NH4^+$ excretion in the kidney of $SS^{Kcnj16-/-}$ rats. For H^+ transport, elevated mRNA and protein expression of NHE3 may suggest enhanced H^+ secretion in the proximal tubule. Additionally, although the RNA-Seq suggested increased expression of various subunits of V-ATPase, we didn't observe any differences at protein levels.

Conclusions: Our data suggested that at baseline, loss of $K_{ir}5.1$ initiated metabolic acidosis and altered the renal transport of $HCO3^-$, $NH4^+$, and H^+ in Dahl SS Rats. The following analysis will further investigate the phenotype after the NH_4Cl challenge test in both genders.

FR-PO529

Physiologic Importance of Proteolytic Cleavage of Epithelial Sodium Channel (ENaC)'s γ Subunit in Na+ and K+ Handling

Evan C. Ray,[1] Andrew Nickerson,[1] Rolando Carrisoza-Gaytan,[2] Tracey Lam,[1] Aaliyah Winfrey,[1] Allison L. Marciszyn,[1] Lisa M. Satlin,[2] Shaohu Sheng,[1] Thomas R. Kleyman.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Proteolytic removal of a peptide inhibitory tract (IT) from the epithelial Na^+ channel (ENaC) γ subunit's extracellular domain increases channel open probability (P_O) *in vitro*. IT removal requires cleavage at a furin recognition sequence (^{140}RKRR^{143}) proximal to the inhibitory tract *and* a site distal to the IT. We hypothesized that mice with impaired IT removal would exhibit diminished distal nephron ENaC P_O, decreased Na^+ transport, and increased susceptibility to hyperkalemia and body fluid volume depletion.

Methods: We disrupted the γ subunit furin cleavage site in mice (^{140}QQQQ^{143}, or "Q4"), reducing furin cleaved / full length γ subunit in Q4 mouse kidneys compared to wild-type (WT) littermates.

Results: Q4 mice exhibited no significant difference in blood Na^+, K^+, tCO_2, BUN, Hb, and Ca^{2+} on a standard, low Na^+, or high K^+ diet and no difference in plasma aldosterone on a low Na^+ diet. Collecting duct patch clamp experiments revealed an 8 pS channel, consistent with canonical heterotrimeric ENaC, that exhibited no difference in P_O or NP_O. A 17pS ion channel also showed no change in P_O or NP_O. In isolated, perfused collecting ducts from low Na^+-diet fed mice, Na^+ flux (J_{Na}) was not different between Q4 and WT animals at low or high luminal fluid flow rates (1 or 5 nl min^{-1} mm^{-1}). K flux (J_K) was also not different at a low flow rate. At a high flow rate, the J_K magnitude was greater in WT than Q4 collecting ducts (6.0 ± 1.1 vs 3.8 ± 0.6 pmol min^{-1} mm^{-1}, $p \leq 0.01$). In colonic epithelium, we observed no difference in amiloride-sensitive short-circuit currents (I_{SC}) in Q4 vs. WT. Total body water (TBW), measured via quantitative magnetic resonance and normalized to starting TBW, declined more in Q4 than WT males. TBW change was not different in female Q4 mice compared with WT mice.

Conclusions: Impaired furin site cleavage in ENaC's γ subunit did not influence blood electrolytes, colonic I_{SC}, or collecting duct channel P_O or J_{Na}, but diminished flow-induced stimulation of J_K in the collecting duct, and impaired body fluid conservation in males. Differences, where observed, were relatively subtle, indicating that additional factors influence ENaC activity and Na^+ and K^+ balance in live animals.

FXR Modulates the Epithelial Sodium Channel Expression Through WNK1/SGK1/NEDD4-2 Signaling in the Kidney

Suchun Li,[1,2] Siyang Ye,[1,2] Yuting Fan,[1,2] Bin Li,[1,2] Chunling Li,[3] Weidong Wang,[3] Wei Chen.[1,2] *[1]Department of Nephrology, The First Affiliated Hospital, Sun Yat-sen University, Guangzhou, China; [2]NHC Key Laboratory of Clinical Nephrology, Sun Yat-Sen University, Guangzhou, China; [3]Sun Yat-sen University Zhongshan School of Medicine, Guangzhou, China.*

Background: Epithelial sodium channel (ENaC), located in the aldosterone sensitive nephron, is essential for renal salt handling and blood-pressure homeostasis. The farnesoid X receptor (FXR) signaling is involved in various important physiological and pathophysiological processes in the kidney such as energy metabolism, immune responses and fluid homeostasis. Here, we aimed to investigate whether FXR is involved in regulating renal ENaC expression and the potential roles in angiotensin II-induced hypertension.

Methods: Immortalized mouse cortical collecting duct ($mpkCCD_{c14}$) cells and mice were treated with FXR agonists or antagonists. To induce hypertension, mice were infused with angiotensin II (300 ng/kg/min) for 2 weeks by osmotic minipump.

Results: We found that FXR activation by CDCA and INT-747 markedly decreased, whereas FXR antagonist guggulsterone increased the protein and mRNA expression levels of ENaC in the $mpkCCD_{c14}$ cells. CDCA reduced the amount of ENaC at the plasma membrane of $mpkCCD_{c14}$ cells, which indicated FXR activation inhibits the trafficking of ENaC to the cytomembrane. Interestingly, CDCA significantly reduced With-No-Lysine 1 (WNK1) and SGK1 expressions, whereas induced the E3 ubiquitin ligase NEDD4-2 expression. Additionally, immunofluorescence and immunoprecipitation revealed that the level of ubiquitin binding to ENaC was increased as a result of FXR activation. Consistent to the in vitro study, CDCA downregulated the expressions of ENaC in the kidney of mice, which was associated with increased abundance of WNK1 and SGK1 and decreased abundance of NEDD4-2. In angiotensin II-induced hypertension, CDCA treatment lowered the systolic and diastolic blood pressure in mice. The increased expressions of ENaC in the kidney induced by angiotensin II were prevented by CDCA through activation of NEDD4-2 signaling.

Conclusions: Our findings demonstrated FXR activation decreased renal ENaC expression likely through WNK1/SGK1/NEDD4-2 signaling and thus reduced blood-pressure in angiotensin II-induced hypertensive mice. FXR represents a promising target for the treatment of hypertension.

Extracellular Flux Analysis Reveals that Transport Activity Regulates Mitochondrial Bioenergetics in Thick Ascending Limbs and Distal Convoluted Tubules

Meng-Hsuan Lin, Jen-Chi Chen, Chou-Long Huang, Chih-Jen Cheng. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Alterations of mitochondrial functions and substrate oxidation have been proven pathogenic in many renal tubulopathies. Traditional assays using kidney slices or cultured cells do not provide tubule-specific resolution because of cell heterogeneity and rapid dedifferentiation in vitro. Understanding mitochondrial respiration and energy metabolism in renal tubules offers deeper insights into the metabolic adaptations of renal tubules to stimuli.

Methods: We applied extracellular flux analysis (EFA) to investigate mitochondrial respiration and energy metabolism in isolated renal tubules. Briefly, after mice were sacrificed and perfused, renal tubules were microdissected and incubated at 37°C for 1 hour. The dynamic oxygen consumption and extracellular acidification rates (OCR/ECAR) following the sequential injection of mitochondrial/metabolic inhibitors were measured by Seahorse XFp analyzer.

Results: Isolated renal tubules remained metabolically active and energetically dependent on mitochondrial oxidative phosphorylation (OXPHOS) during the assay. EFA detected significant OCRs/ECARs linearly correlated with sample sizes in millimeter-length renal tubules. Mitochondrial electron transport chain inhibitors suppressed OCRs and induced a simultaneous increase of ECARs in thick ascending limbs (TALs) and distal convoluted tubules (DCTs), indicating compensatory glycolysis. However, the proximal tubules (PTs) lacked noticeable compensatory glycolysis when OXPHOS was shut off. TALs and DCTs relied on glucose/pyruvate oxidation for ATP production in the basal state, and stimulation of oxygen consumption by mitochondrial uncoupler did not provoke the utilization of glutamine or long-chain fatty acids. Two-hour ouabain treatment reduced basal and ATP-linked mitochondrial respiration in isolated TALs. Besides, two-week furosemide treatment or deletion of with-no-lysine (WNK) kinase 4 further decreased the maximal and spare capacity of mitochondrial respiration in TALs via downregulating mitochondrial biogenesis.

Conclusions: EFA successfully provides tubule-specific metabolic features, showing differential glycolysis capacity and substrate utilization in PTs, TALs and DCTs. The transport activity can acutely regulate ATP turnover rate and chronically modulate mitochondrial biogenesis in TALs and DCTs.

CREB and ATF1 Transcription Factors Are Not Required for the Vasopressin-Mediated Increase in AQP2 Abundance in Collecting Duct Cells

Adrian R. Murillo-de-Ozores, Lihe Chen, Mark A. Knepper. *National Heart, Lung and Blood Institute, Bethesda, MD.*

Background: Aquaporin-2 (AQP2) abundance is regulated by arginine vasopressin (AVP), largely by increasing *Aqp2* gene transcription. In both native collecting duct and cultured mpkCCD cells, long-term exposure to AVP increases AQP2 abundance by 10-fold or more. Most review articles and textbook chapters on AQP2 regulation attribute the increase to PKA-mediated activation of the transcription factor CREB, by phosphorylation of S133 at the Kinase Inducible Domain (KID). Two KID-containing transcription factors are strongly expressed in collecting duct principal cells, namely ATF1 and CREB. Here, we investigated their potential roles in the AVP-mediated increase in AQP2 abundance.

Methods: PKA knockout (PKA-KO) and WT mpkCCD cells were utilized. CREB and ATF1 phosphorylation was analyzed by immunoblotting. *Atf1* and *Creb1* genes were deleted by CRISPR/Cas9 in WT mpkCCD cells and verified by immunoblotting (using a custom mouse ATF1 specific antibody and a commercial CREB antibody) and Sanger sequencing. RNA-seq was performed in *Atf1*-KO cells and AQP2 protein levels were analyzed by immunoblotting in *Atf1*-KO cells as well as *Atf1/Creb1*-KO cells, with or without desmopressin (dDAVP), an AVP analogue.

Results: Basal phosphorylation levels of CREB-S133 and ATF1-S63 were similar between WT and PKA-KO cells, however the dDAVP-mediated increase was blunted in PKA-KO cells. In WT cells, dDAVP (0.1nM for 72 hours) produced a 15-fold increase in AQP2 band density ($P < 0.005$), whereas it increased AQP2 17-fold in *Atf1*-KO cells ($P < 0.0005$) and 14-fold in *Atf1/Creb1* double KO cells ($P < 0.01$). RNA-seq analysis found only 11 differentially expressed genes comparing WT and *Atf1*-KO cells in the presence of dDAVP ($P_{adj} < 0.05$ and $|\log_2 KO/WT| > 1$), and *Aqp2* mRNA was not affected.

Conclusions: We conclude that CREB and ATF1 are not necessary for the action of dDAVP to increase *Aqp2* gene expression, contrary to the conventional belief in the literature. Future studies will assess whether other dDAVP-responsive genes are regulated by KID transcription factors, and what other transcription factors might be modulated by vasopressin-mediated signaling to explain the upregulation of AQP2.

MEF2A Is a Novel Osmoregulatory Transcription Factor

Jason A. Watts,[1] Ma Wan,[1] Don Delker,[1] Juan Pablo Arroyo Ornelas,[2] Winny Soerianto.[1] *[1]National Institute of Environmental Health Sciences, Research Triangle Park, NC; [2]Vanderbilt University Medical Center, Nashville, TN.*

Background: Osmoregulation is a complex component of cell physiology, yet the initial transcriptional regulators of the osmotic stress response remain to be fully characterized. Here we studied the regulation of promoter-proximal RNA polymerase pausing after osmotic stress and uncovered MEF2A as a tonicity-responsive transcription factor.

Methods: We identified tonicity responsive genes by expression profiling in skin fibroblasts and inner medulla collecting ducts cells following osmotic stress. To identify genes with paused RNA polymerase we used the Precision nuclear Run-On and Sequencing assay (PRO-seq) to determine the locations of actively transcribing RNA polymerases.

Results: Aldose reductase (*AKR1B1*) and sodium myoinositol transporter (*SLC5A3*) are tonicity-responsive genes marked by abundant paused RNA Pol II at baseline. Both genes are induced by hypertonic stress, but induction is abrogated in the presence of a small molecule that stabilizes paused RNA Pol II. While *AKR1B1* and *SLC5A3* require pause-release for gene induction, not all genes with paused polymerase are induced by hypertonic stress, indicating specificity to pause-release. To identify other pause-dependent tonicity-responsive genes, we performed RNA sequencing and Precision Nuclear Run-On sequencing (PRO-seq) to measure gene expression and nascent transcription. We observed pause-dependent induction of 335 tonicity-responsive genes. To ask how pausing at these genes is regulated, we searched for transcription factor binding sites and identified motifs for MEF2A at 48% of the induced genes. We then performed CUT&Tag in fibroblasts and found tonicity-dependent binding of MEF2A at 1230 sites, including the *SLC5A3* promoter. Next, we knocked down MEF2A using siRNA and found *SLC5A3* and *AKR1B1* expression is significantly reduced following hypertonic stress. Finally, we water restricted mice to test if MEF2A responds to physiologic hypertonic stress. We observed increased MEF2A staining in the nuclei of renal collecting duct cells of water restricted mice compared to controls.

Conclusions: Together, we show MEF2A exhibits osmotic stress-dependent nuclear localization and chromatin binding, and that it regulates expression of *SLC5A3* and *AKR1B1*. We suggest MEF2A mediates RNA Pol II pause release to induce transcription of tonicity-responsive genes.

FR-PO534

Activation of BKα Channel Prevented the High Glucose-Induced Oxidative Stress in Human Proximal Tubular Cells

Xiaomao Luo,[1,3] Shuyang Bian,[1] Yijin Huang,[1] Faten Hassounah,[1] Qiang Yue,[1] Xiaonan H. Wang,[1] Hui Cai.[1,2] *[1]Emory University School of Medicine, Atlanta, GA; [2]Joseph Maxwell Cleland Atlanta VA Medical Center, Decatur, GA; [3]Shanxi Agricultural University, College of Veterinary Medicine, Jinzhong, China.*

Background: Hyperglycemia stimulates the production of reactive oxygen species (ROS) leading to oxidative stress. Oxidative stress could cause inflammation or fibrosis. Our previous study found that activation of the large conductance, calcium-activated potassium channels (BK channels) attenuated renal fibrosis in mice. We hypothesized that upregulation BK channel activity would suppress the high glucose (HG)-induced oxidative stress.

Methods: Human proximal tubular epithelial cell (HK-2) was cultured in DMEM/F12 medium. HEK-BKα cells (HEK293 stably expressing BKα) were maintained in DMEM with G418. Cells were cultured in the low glucose DMED (5.5mM glucose) for 24 hours before treatments. NS1916 (Sigma) was used to activate BKα channel. Two ROS products were measured: 1-hydrogen peroxide (H2O2) was tested by Amplex Red Hydrogen Peroxide Kit (cat # A22188, Molecular Probes): 2- DHE (Dihydroethidium) Assay (Abcam ab236206) was used to detect superoxide. Superoxide Dismutase (SOD), a defense of oxidative enzyme, was measured using colorimetric activity kit (Invitrogen EIASODC). Single channel recordings were used to analyze the activity of BKα channel.

Results: Using single channel recordings we showed that high glucose (HS, 25 mM D-glucose) inhibited BKα channel activity in HEK-BKα cells. As an osmolarity control, 25 mM mannitol does not change the BKα activity. To determine the effect of BKα activation on HG-induced ROS production HK2 cells was treated with HS (25mM) with or without NS1916 (BKα channel opener). H2O2 and superoxide productions were significantly increased with high glucose treatment, whereas NS1916 (20mM) prevented the HG-induced upregulation of H2O2 and ROS. In addition, HS treatment (25 mM) significantly decreased SOD activity in HK2 cells, whereas activation of BKα activity with NS1916 reversed the decreased SOD activity induced by HS.

Conclusions: High glucose inhibited BKα activity while increasing H2O2 and superoxide productions in HK2 cells. Activation of BKα channel activity attenuated HS-induced the ROS production. In addition, BKα reversed HS-induced down-regulation of SOD. These results suggest that activation of BKα channel has novel roles in preventing oxidative stress.

Neuropeptide FF Increases Na+/K+-ATPase Activity in Live Renal Proximal Tubule Cells

Hewang Lee,[1] Jacob Q. Polzin,[1] Bibhas Amatya,[1] Laureano D. Asico,[1] Ines Armando,[1] Robin A. Felder,[2] Pedro A. Jose.[1] *[1]The George Washington University School of Medicine and Health Sciences, Washington, DC; [2]UVA Health, Charlottesville, VA.*

Background: Neuropeptide FF (NPFF), an amidated peptide, acts as a pain-modulator. However, the effects of NPFF on renal Na^+ transport and blood pressure are unknown.

Methods: Intracellular Na^+ concentration in renal proximal tubule cells (RPTCs) was measured using the lifetime Na^+-binding of NaTRIUM Green-2 (Green-2), monitored by fluorescence lifetime imaging (FLIM) and Na^+ green tetraacetate, monitored by spectrometry. Blood pressure and sodium excretion were also studied in mice.

Results: In glass bottom-cultured RPTCs, Green-2 (5 μM/1 hr) had a biexponential decay in time-resolved fluorescence measurements in randomly selected regions of interest (ROI) in the cytoplasm of these RPTCs. In the basal state, the lifetime t_2 (Na^+-binding decay time component, nanoseconds) was 3.44±0.05 (n=8). NPFF (100 nM) sequentially decreased the lifetime t_2: 3.44±0.04 (5 min), 3.35±0.07 (10 min), 3.31±0.07 (15 min), and 3.25±0.06 (20 min), analyzed from the ROIs (n=8-20). The decrease in t_2, Na^+-binding decay time component, due to NPFF was associated with a decrease in intracellular Na^+ concentration (NPFF: 79.0±4.7%, n=4 vs vehicle: 100.0±9.4%, n=4). The NPFF-mediated decrease in intracellular Na^+ was due to an increase in Na^+/K^+-ATPase activity, because ouabain (50 μM) which inhibits Na^+/K^+-ATPase activity increased intracellular Na^+ (125.9±6.1%, n=4) and prevented the NPFF-mediated decrease in intracellular Na^+ concentration (124.3±4.9%, n=4). The effect of NPFF on other sodium transporters and exchangers was not determined. The stimulatory effect of NPFF on Na^+ transport has physiological significance because in anesthetized C57Bl/6 mice (n=4), the acute bilateral renal subcapsular injection of NPFF (10 μg/100 μL) increased systolic blood pressure (SBP, mm Hg), 15 min post injection (138.5±12.8 vs basal, 99.5±1.3, $P < 0.05$), peaked at 25 min (148.3±8.3), and gradually returned to baseline at 60 min. The chronic bilateral renal subcapsular infusion of NPFF (9.25 mM, 0.5 mL/hr, n=4) for 7 days also increased SBP and decreased urinary sodium excretion that were prevented by RF9, an NPFF antagonist.

Conclusions: NPFF decreased intracellular Na^+ concentration in RPTCs by stimulating Na^+/K^+-ATPase activity, decreased Na^+ excretion, and increased blood pressure in C57Bl/6 mice.

Cell Volume-Sensitive Transcription Factor(s) Regulate Claudin-2 Expression in Epithelial Cells

Rainelli Koumangoye, Eric J. Delpire. *Vanderbilt University Medical Center, Nashville, TN.*

Background: The basolateral Na^+-K^+-$2Cl^-$ cotransporter (NKCC1) plays a critical role in maintaining the intracellular concentrations of Na^+, K^+, and Cl^- ions, and cell volume. While it is well recognized that NKCC1 is critically important for vectorial transport of Na^+, K^+, and Cl^- across epithelia, its role in transcellular ions transport and epithelial barrier function is not well understood. Here we ask whether loss of NKCC1 function affect kidney and intestinal epithelial tight junction permeability.

Methods: Wild-type MDCK I and NKCCC1-deficient clones LKA3 and LKC1 were plated and polarized on transwell filters, and their TER was measured. Tight junction protein expression and localization was assessed by western blotting and immunofluorescence.

Results: The TER values of NKCC1-deficient MDCK I cells decreased by more than 20-fold, from 8000 Ω.cm² in parental MDCK I to 300-500 Ω.cm² in LKA3 and LKC1 clones. Western blot analysis showed that genetic ablation or pharmacologic of NKCC1 function increases the expression of the cation selective claudin-2. This is consistent with the observed decreased TER. In addition, growing MDCK I cells in Cl^--free, Na^+-free or both Cl^- and Na^+-free media upregulates claudin-2 expression.

Conclusions: Our data indicate that loss of NKCC1 function affects tight junction protein expression without affecting their localization. Particularly, claudin-2 was significantly upregulated. This led to an increase in paracellular flux of positively charged ions across the MDCK epithelial cell monolayers. Notably, this phenomenon is not unique to kidney epithelial cells cells, as loss of NKCC1 function in intestinal HT29 cells also led to significant decrease in TER and upregulation of claudin-2 expression.

Resveratrol Inhibits Proximal Tubular Sodium Reabsorption and Suppresses the Progression of Renal Injury

Motonobu Nakamura, Nobuhiko Satoh, Mayuko Takagi, Masaomi Nangaku. *Division of Nephrology and Endocrinology, The University of Tokyo, Bunkyo, Japan.*

Background: Resveratrol(RSV), a natural polyphenol compound, has demonstrated anti-inflammatory, anti-cancer, anti-oxidant, and anti-aging effects in vitro and in vivo studies. However, its effects on the proximal tubules (PTs) and kidney disease remains unknown. In this study, we evaluated the effect of RSV on Na transport in isolated PTs and its potential to inhibit the progression of chronic renal injury in rat models.

Methods: By using a pH-sensitive dye BCECF we measured the basolateral Na^+-HCO_3^- Cotransporter (NBCe) 1 activity and apical Na^+-H^+ Exchanger (NHE) activity in freshly-isolated rat PTs. To evaluate the effect of RSV on the progression of kidney disease, 6-week-old OLETF rats that had undergone unilateral nephrectomy were fed a high-salt diet, administered aldosterone (Ald) continuously by osmotic pump, and compared to a group receiving 50 mg/kg BW RSV orally daily for four weeks. Comparisons were made by serum biochemical, histological tests and protein expression. Protein expression was determined by Western blot.

Results: In a concentration-dependent manner, RSV significantly inhibited the stimulatory effects of insulin on Na reabsorption on PTs, and inhibited insulin-induced phosphorylation of Akt. Moreover, continuous Ald administration resulted in severe albuminuria and renal dysfunction, whereas those treated with RSV exhibited a significant reduction in both albuminuria ($p < 0.05$) and renal dysfunction ($p < 0.05$). In the renal cortex, phosphorylation of Akt and expression of Rictor and Raptor were significantly decreased ($p < 0.05$).

Conclusions: RSV inhibits insulin-induced sodium reabsorption in PTs, and it could have a renoprotective effect.

Exposure of Junctional Claudin-3 Epitopes in the Thick Ascending Limb of Cldn19-Deficient Mice

Henrik Dimke,[1,2] Pascal Houillier,[3,4] Caroline Prot-Bertoye.[3,4] *[1]Syddansk Universitet, Odense, Denmark; [2]Odense Universitetshospital, Odense, Denmark; [3]Centre de Recherche des Cordeliers, INSERM, Sorbonne Université, Université Paris Cité, Paris, France; [4]CNRS EMR 8228 - Laboratoire de Physiologie Rénale et Tubulopathies, Paris, France.*

Background: The kidney plays a vital role in maintaining mineral balance. The reabsorption of calcium and magnesium in the renal thick ascending limb (TAL) is facilitated by CLDN16 and CLDN19 and mutations in either gene results in severe calcium and magnesium loss. *Cldn3* is also expressed in TAL RNAseq databases, however some but not all studies localize the CLDN3 protein to the TAL. In our hands, using 3 distinct antibodies, we have been unable to detect CLDN3 expression in the TAL.

Methods: The pattern of expression of CLDN3 was evaluated using 3 distinct CLDN3 antibodies: 1. Anti-CLDN3 antibody (HPA014361 Sigma-Aldrich), 2. Anti-CLDN3 antibody (STJ23159, St John's Laboratory), and 3. Anti-CLDN3 Antibody (34-1700, Invitrogen), all produced in rabbit. Using these antibodies, we investigated the localization of CLDN3 in the kidneys of both wild-type and Cldn19 deficient mice on 2 um paraffin sections.

Results: All antibodies showed immunoreactivity towards epitopes situated in the tight junctions of the renal tubular cells. In addition, the Sigma antibody labeled epitopes in the intercalated cells and the Invitrogen labelled epitopes in the perinuclear region of epithelial cells. With respect to the tight junction, CLDN3 was expressed in portions of the proximal tubule as well as distal nephron cells but was absent from the TAL in wild-type animals using all three antibodies. In contrast, in *Cldn19* deficient animals, immunoreactivity was also found in the TAL in a mosaic pattern.

Conclusions: These findings suggest that CLDN3 localizes to the TAL where it may play a direct role in determining the permeability. Why immunoreactivity in the TAL is only seen in Cldn19 deficient animals remains to be elucidated. The findings could suggest that CLDN19 shields the epitope towards which CLDN3 binds in fixed tissue.

A Novel R881S Mutant of Transporter NBCe1 Has Cytosolic Retention and Lacks Dominant Negative Effect

Osamu Yamazaki, Wataru Fujii, Yoshihide Fujigaki, Shigeru Shibata. *Division of Nephrology, Department of Internal Medicine, Teikyo University School of Medicine, Tokyo, Japan.*

Background: The electrogenic Na^+/HCO_3^- cotransporter NBCe1 is expressed in many organs including the brain, eye, and the kidney, where it controls sodium and bicarbonate reabsorption. NBCe1 homozygous mutation causes not only severe hypotension but also proximal renal tubular acidosis (RTA) in human and rodents. Here we characterized the functional significance of SNVs reported from NCBI database.

Methods: We identified the missense mutation R881S in NBCe1 variant A (kidney type) from the database. Given the report of R881C mutation in patients with RTA (JASN 2005), we conducted a comparative analysis of cellular localization and cell protein expression between R881S and R881C using confocal microscopy and Western blotting.

Results: Immunofluorescence analysis with confocal microscopy revealed that the R881S variant was present exclusively in the cytoplasm in both HEK293 cells and MDCK cells. Biotinylated western blotting in HEK293 cells confirmed that the cell-surface expression was completely abolished in R881S mutant. In total cell lysates, R881S-NBCe1 showed a lower molecular weight compared with wild-type, and deglycosylation study confirmed that R881S substitution impaired N-glycosylation. Moreover, co-immunoprecipitation study revealed that the interaction with wild-type NBCe1 was severely impaired in R881S compared with R881C.

Conclusions: R881S mutation inactivates the NBCe1 function without lack of dominant-negative effect. These data illustrate the diverse physiological consequences of distinct SNVs and underscore the importance of functional characterization in membrane transport proteins.

Funding: Government Support - Non-U.S.

FR-PO540

Estimation of Plasma Vasopressin Activity by AQP2 in Urinary Extracellular Vesicles

Tamami Kawaguchi, Hiroko Sonoda, Masahiro Ikeda. *Laboratory of Veterinary Pharmacology, Faculty of Agriculture, University of Miyazaki, Miyazaki, Japan.*

Background: The antidiuretic hormone, vasopressin (AVP), activates protein kinase A (PKA) in the principal cells of the collecting duct via the V2 receptor. Activated PKA is known to phosphorylate the amino acid residues (S256 and S269) on the water channel, aquaporin 2 (AQP2). These phosphorylations are considered to promote water reabsorption by increasing the trafficking of AQP2 into the apical membrane. The measurement of the blood AVP concentration is difficult because of its instability and binding to the platelets. It has been shown that urinary extracellular vesicles (uEVs) contain AQP2 protein. Therefore, in this study, we investigated whether AVP activity could be inferred by measuring the total or phosphorylated form of AQP2 in uEVs.

Methods: In experiment I, male SD rats were divided into three groups: a control group (free-drinking tap water), a dehydration group (water deprivation; DH group), and a hydration group (free-drinking 20% sucrose; HY group). In experiment II, male SD rats were divided into two groups: a vehicle group (50% of 5% glucose, 50% of saline, s.c.) and a dDAVP group (300 ng/kg desmopressin, V2 agonist, s.c.). Urine samples were collected for 12-24 hrs, and blood and kidney samples were collected at 24 hrs after the treatment. Total and phosphorylated (pS256, pS269) AQP2 protein levels in uEVs were evaluated by immunoblot analysis.

Results: In experiment I, urine volume was decreased in the DH group and was increased in the HY group. Moreover, urine osmolality was elevated in the DH group and reduced in the HY group. Total and phosphorylated AQP2 levels in uEVs were increased in the DH group, and only the pS269-AQP2 level was decreased in the HY group. In experiment II, urine osmolality in the dDAVP group significantly increased in comparison with the control group. The total AQP2 level showed an increasing tendency, and the pS269-AQP2 level was significantly increased in the dDAVP group. On the other hand, the pS256-AQP2 level was not altered.

Conclusions: These results indicate that the pS269-AQP2 level in uEVs responded well to the physiological and pharmacological changes in V2 receptor activation. Therefore, pS269-AQP2 in uEVs may be a potential non-invasive biomarker to estimate plasma AVP activity.

FR-PO541

Elucidating the Diuretic Effect of Corticosteroids in Rats

Keito Uema,[1] Hiroko Sonoda,[1] Akane Oguchi,[1] Yoshiki Higashijima,[2] Masahiro Ikeda.[1] *[1]Laboratory of Veterinary Pharmacology, Faculty of Agriculture, University of Miyazaki, Miyazaki, Japan; [2]Institute for Promotion of Tenure Track, University of Miyazaki, Miyazaki, Japan.*

Background: Corticosteroids are widely used to treat kidney diseases such as nephrotic syndrome. A few cases of polyuria following corticosteroid treatment have been reported in human patients with heart failure or hypopituitarism. In dogs, corticosteroids frequently cause polyuria and polydipsia (Elkholly DA et al., *Front Vet Sci.* 2020). In experimental rat models, acute corticosteroid treatment is known to cause a potent diuretic effect (Tunhorst RL et al., *Am J Physiol Regul Integr Comp Physiol* 2007). However, the mechanisms by which corticosteroids cause polyuria is largely unknown. Here, we investigated the mechanism of corticosteroid-induced polyuria in rats treated with prednisolone (PSL).

Methods: Male SD rats aged 10 weeks were treated with PSL (0.3 or 1.0 mg/kg, s. c.) or vehicle (25% DMSO/75% Corn Oil, s. c.). Urine was collected for 6 hours after the treatment. Blood and kidneys were isolated at 6 hours post-treatment. The levels of electrolyte and osmolality in urine and blood were measured. Free water clearance was also calculated. The gene expression levels of sodium-dependent transporters and water channels were investigated by real-time PCR.

Results: The urine volume was significantly increased and the urinary osmolality was significantly decreased after the treatment of PSL, in a dose-dependent manner. The total excretion of Na^+, K^+, Cl^- and inorganic phosphorus was significantly higher in rats treated with PSL than in without it. The free water clearance value was negative in the PSL-treated rats. Real-time PCR revealed that mRNA levels of sodium/chloride cotransporters (NKCC2/Slc12a1 and NCC/Slc12a3), sodium/phosphate cotransporters (Slc34a1 and Slc34a3) and a water channel (AQP2) were decreased in the PSL group. In addition, significant negative correlations were observed between urinary sodium excretion and the gene expression of NKCC2 and NCC.

Conclusions: These results indicate that reduced renal expression of sodium-dependent transporters in response to PSL may contribute to the suppression of electrolyte reabsorption, leading to the diuretic and natriuretic effects in rats. Since the free water clearance value was negative, the contribution of AQP2 was considered modest in the diuretic effect of PSL.

FR-PO542

Colistin-Induced Acute Tubular Dysfunction: Toxicity Beyond Creatinine

Martin B. Yama Estrella, Mario Alamilla-Sanchez, Jose H. Cano Cervantes, Mayra M. Matias Carmona, Enrique F. Morales Lopez, Jose L. Torres Cuevas. *Centro Medico Nacional 20 de Noviembre, Mexico City, Mexico.*

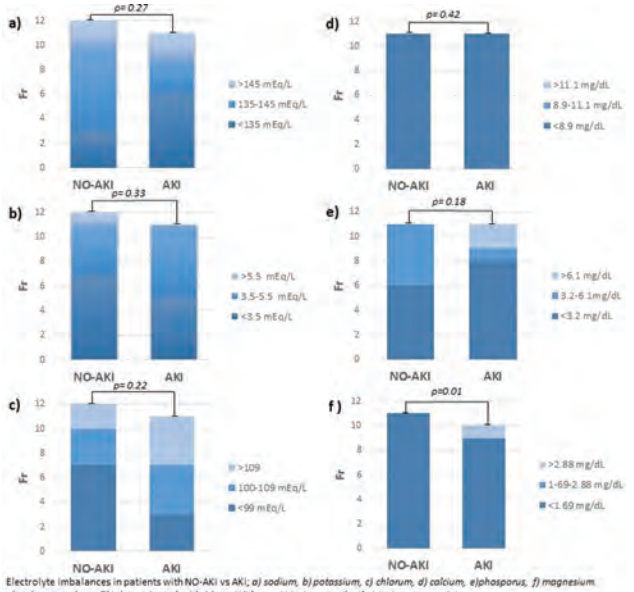
Background: Colistin is a relevant antibiotic for infections by multiresistant microorganisms. However, it is not exempt from serious renal adverse events, e.g.: acute kidney injury (AKI). The present study describes the hydroelectrolytic disorders associated with the prescription of colistin.

Methods: Retrospective cohort design. Data were obtained from January 2021 to December 2022. Patients who received colistin for at least 48 hours were included. Patients with chronic renal support therapy or acute kidney injury prior to starting colistin were excluded.

Results: 23 patients were evaluated, with an average age of 55.96 years, men 60.86%. The most frequently isolated microorganism was *P. aeruginosa* (56.52%). The reported findings were: euvolemic hyponatremia (39.13%), hypochloremia (43.47%), hypokalemia (52.17%), hypocalcemia (100%), hypophosphatemia (63.63%), and hypomagnesemia

(95.23%). 11 patients (47.82%) developed AKI. When comparing the development of electrolyte disturbances between patients with and without AKI, hypomagnesemia was more frequent in the AKI group. There was a constant increase in the renal elimination of potassium, phosphate, and magnesium.

Conclusions: A high incidence of hydroelectrolytic imbalance associated with colistin was found. Interestingly, 100% of patients developed hypocalcemia and the majority had hypomagnesemia and hypophosphatemia. Urinary biochemical evaluation for potassium, phosphate and magnesium provides data highly suggestive of acute tubular dysfunction, an event rarely reported in the literature, which causes high comorbidity if the imbalance is not treated.



Electrolyte imbalances in patients with NO-AKI vs AKI; *a) sodium, b) potassium, c) chlorum, d) calcium, e)phosporus, f) magnesium.* α level accepted was 5% determinated with *Mann-Withneyy U test or student's t test as appropriate .*

Mechanisms of Thiazide-Induced Magnesium Wasting and Calcium Retention at Single-Cell Resolution

Jeremiah V. Reyes,[1,2] Xiao-Tong Su,[2] Paul Mark B. Medina,[1] Chao-Ling Yang,[2] Hasan Demirci,[3] Sebastian Bachmann,[3] James A. McCormick,[2] Jonathan W. Nelson,[2] David H. Ellison.[2] *[1]University of the Philippines Manila College of Medicine, Manila, Philippines; [2]Oregon Health & Science University, Portland, OR; [3]Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: States of NCC inhibition, as in Gitelman syndrome and chronic thiazide treatment, present with hypokalemia, alkalosis, hypomagnesemia, and hypocalciuria. The mechanism by which loss of NCC function affects Mg and Ca handling remains very unclear. Here we combined single nucleus RNA sequencing with physiologic and morphometric analysis to unravel the causes of hypomagnesemia and hypocalciuria secondary to NCC inhibition.

Methods: 8 to 10-week-old male NCC-Cre-INTACT mice received 50 mg/kg/day metolazone (MTZ) orally for 4 days. Fluorescence-activated nuclei sorting was performed to select for DCT nuclei. Sequencing was done using 10X Chromium. Reads were analyzed using a transcriptomic bioinformatics pipeline with Seurat. We also performed tubule morphometrics.

Results: MTZ-treated mice had lower plasma Mg and lower urinary Ca excretion compared to controls, consistent with NCC inhibition. Our snRNA-seq dataset showed 2 clusters, DCT1 and DCT2, based on canonical markers consistent with published transcriptomic atlases. We curated Mg and Ca cassettes from known magnesiotropic and calciotropic genes and defined Mg and Ca scores from the pooled expressions of the genes and used them to indicate Mg and Ca handling capacity. The analyses showed that Mg handling is primarily a DCT1 process and Mg score was lower in the MTZ group. We also found that the DCT1 undergoes dedifferentiation leading to reduction in magnesiotropic gene expression. Additionally, 3D morphometrics showed that DCT1 was shorter in the MTZ group. Ca handling is primarily a DCT2 process and Ca score was lower in the MTZ group consistent with low distal delivery due to enhanced proximal Ca reabsorption. Yet, DCT2 cells maintained their cell state and were less vulnerable to NCC inhibition compared to DCT1 cells. Lastly, MTZ-treatment caused hypertrophy of the Ca-transporting connecting tubule (CNT).

Conclusions: The results indicate that hypomagnesemia secondary to NCC inhibition results both from a disruption of genes involved in Mg handling and from DCT1 dedifferentiation and atrophy. While increased proximal tubule Ca reabsorption is required for hypocalciuria, our results also indicate that aldosterone-induced hypertrophy of the CNT and relative preservation of DCT2 contribute to calcium retention.

FR-PO544

WNT Ligands Drive PKD1-Mediated G Protein Signaling and Receptor Internalization and Downregulation

Emily P. Hardy, Leonidas Tsiokas. *The University of Oklahoma Health Sciences Center, Oklahoma City, OK*.

Background: Autosomal Dominant Polycystic Kidney Disease is a genetic disorder caused by mutations in *PKD1* or *PKD2*, which encode PKD1 and PKD2, respectively. PKD2 is a nonselective cation channel and forms a complex with PKD1 in which the channel is activated upon WNT binding to PKD1. Independently, PKD1 is proposed to act as an atypical G protein-coupled receptor (GPCR) for which the activating ligand is unknown. Here, we investigated the role of WNTs in PKD1-mediated G protein signaling and receptor internalization and downregulation.

Methods: An interaction between PKD1 and G_q has been previously established and was used to investigate PKD1-mediated signaling in response to WNTs. Using wild type and PKD1 knockout IMCD3 cells, single-cell calcium imaging was employed to test whether PKD1-G_q coupling is functional and occurs in response to WNTs. To determine if WNTs induce downstream PKD1 internalization and downregulation, pull down assays in combination with BRET (Bioluminescence Resonance Energy Transfer) were used. HEK293T cells were either singly- or co-transfected with PKD1 and WNT/empty vector, and assayed following co-expression or co-culture. Co-immunoprecipitation and western blot techniques coupled with a BRET titration approach were used to assess GPCR kinase (GRK) and β-arrestin recruitment to PKD1.

Results: Compared to wild type cells, PKD1 knockout IMCD3 cells showed a significant reduction in the rise of intracellular Ca^{2+} following WNT5A stimulation, suggesting a role for WNT5A in PKD1-dependent downstream Ca^{2+} transients. Following co-expression/co-culture, our western blot and BRET analysis revealed a significant decrease in whole cell and cell surface levels of PKD1 in cells transfected with WNT5A/9B, but not empty vector. This data suggests requirement for WNT in PKD1 internalization and downregulation. Supporting the notion that this process occurs as GPCR desensitization, GRK2/6 and β-arrestin1/2 were found to interact specifically with PKD1.

Conclusions: Our findings highlight an important role for WNTs in the GPCR-function of PKD1 for both receptor activation and desensitization. WNTs have been shown to interact with PKD1 to activate PKD2 channel activity, andtogether with our findings suggest a model whereby WNT-induced activation of PKD1 leads to intermediary G protein signaling and downstream activation of PKD2 channel activity.

Addition of an N-Terminal SNAP-Tag Induces a Novel Hypomorphic Pkd1 Allele

Stephen C. Parnell,[1] Pamela V. Tran,[1] Gauri Prasad,[1] Jordan A. Unger,[1] Courtney J. Haycraft,[2] Patricia Outeda,[3] Bradley K. Yoder,[2] Terry J. Watnick,[3] Darren P. Wallace.[1] On Behalf of the Polycystic Kidney Disease Research Resource Consortium (PKD-RRC). *[1]University of Kansas Medical Center, Kansas City, KS; [2]University of Alabama, Birmingham, AL; [3]University of Maryland School of Medicine, Baltimore, MD.*

Background: We engineered mice that express endogenous polycystin-1 (PC1) with an N-terminal, self-labeling SNAP-tag to facilitate the *in vivo* visualization of PC1 trafficking and co-immunoprecipitation of multiprotein complexes. While initial reports indicated that the allele is normal, follow-on work has demonstrated that addition of SNAP results in a hypomorphic cystic phenotype that is variable depending on the nature of the second *Pkd1* allele.

Methods: A repair construct encoding SNAP fused in-frame with the first exon of *Pkd1* was injected into C57 pronuclei for homology-driven repair using CRISPR. Resulting $Pkd1^{N\text{-}SNAP}$ mice were crossed to homozygosity and also crossed with non-functional $Pkd1^{NdL}$ (truncation) mice, and hypomorphic $Pkd1^{V}$ and $Pkd1^{RC}$ mice, to generate compound heterozygotes. Mice were maintained up to 26-weeks of age, then sacrificed for analysis.

Results: Compound heterozygous $Pkd1^{N\text{-}SNAP/NdL}$ pups had severely cystic kidneys at 2 weeks of age, with an average percent kidney weight to body weight (%KW/BW) of 9.4%. Homozygous $Pkd1^{N\text{-}SNAP/N\text{-}SNAP}$ mice had moderately cystic kidneys with a %KW/BW of 2.6% at 8 weeks, progressing to 5.2% at 23-26 weeks. In contrast to compound heterozygous $Pkd1^{V/RC}$ mice, which are severely cystic by 3 weeks, compound heterozygous $Pkd1^{N\text{-}SNAP/V}$ and $Pkd1^{N\text{-}SNAP/RC}$ mice had kidneys with only a few very small cysts with a %KW/BW of 1.4% at 23-26 weeks. Interestingly, a female $Pkd1^{N\text{-}SNAP/V}$ mouse and a female $Pkd1^{N\text{-}SNAP/RC}$ mouse used as breeders had a few large cysts at 23-26 weeks.

Conclusions: Addition of SNAP to the N-terminus of PC1 generates a hypomorphic $Pkd1^{N\text{-}SNAP}$ allele. The cystic phenotypes in $Pkd1^{N\text{-}SNAP/NdL}$ and $Pkd1^{N\text{-}SNAP/N\text{-}SNAP}$ mice suggest that the tag affects PC1 trafficking, stability, and/or a critical function of the polycystin complex. However, the very mild phenotype in $Pkd1^{N\text{-}SNAP/V}$ and $Pkd1^{N\text{-}SNAP/RC}$ mice suggests complementation between the SNAP allele and the V or RC alleles. This suggests the PC1-SNAP defect is functionally distinct from that of the defects caused by

the V and RC mutations, allowing partial preservation of PC1 function when present *in trans* within the same animal. Future experiments will determine the functionality of the SNAP-tag, the localization of the $PC1^{N\text{-}SNAP}$ protein, and the nature of the defect caused by the SNAP-tag.

Cleavage of PC1 Is Not Required for Embryonic Vasculature Development

Denis Basquin, Patricia Outeda, Terry J. Watnick, Feng Qian. *University of Maryland School of Medicine, Baltimore, MD.*

Background: Polycystin 1 (PC1) is a large membrane protein that undergoes an autoproteolytic cleavage at a G protein coupled receptor (GPS) site. PC1 cleavage at the GPS is essential for trafficking of the PC1/PC2 complex to the primary cilium. While homozygous *Pkd1* or *Pkd2* knock-out mice die at mid-gestation due to vascular and lymphatic abnormalities homozygous $Pkd1^{V/V}$ mutant embryos, harboring a mutation that abolishes PC1 cleavage, survive embryogenesis, suggesting that uncleaved PC1 ($PC1^{V}$) might play a role in embryonic vascular development.

Methods: We analyzed the vascular phenotype of $Pkd1^{V/V}$, $Pkd1^{-/-}$ and control E14.5 embryos including placenta branching morphogenesis and epidermal lymphatic vessel development. Rescue experiments were performed using a transgenic BAC expressing HA-tagged-$PC1^{V}$ ($PC1^{V\text{-}F/H}$). We evaluated the impact of PC1 cleavage on cell migration/polarity via wound healing assay. Trafficking of $PC1^{V}$ and the PC2/$PC1^{V}$ complex was assessed by N-glycosylation studies and biotinylation assays. Localization of PC1 and $PC1^{V}$ in the cilia was performed using immunofluorescence in endothelial cells (EC).

Results: $Pkd1^{V/V}$ embryos lacked the vascular abnormalities observed in $Pkd1^{-/-}$ embryos including hemorrhage, edema and polyhydramnios. The complexity of the placental labyrinth vasculature and the lymphatic vasculature were similar between $Pkd1^{V/V}$ and controls but reduced in $Pkd1^{-/-}$ embryos. Transgenic expression of $PC1^{V\text{-}F/H}$ was sufficient to rescue the vascular phenotype observed in $Pkd1^{-/-}$ mutants. Using wound-healing assays we observed that $Pkd1^{V/V}$ cells migrated properly and that front-rear polarity was similar to controls. We confirmed that PC1 and PC2 colocalized in the primary cilia of cultured ECs. In contrast, PC2 was undetectable in cilia from $Pkd1^{V/V}$ cells. In addition, we showed that the pool of PC2 protein that co-immunoprecipitated with $PC1^{V}$ was Endo H sensitive, indicating that PC1 cleavage is a pre-requisite for the protein complex to traffic beyond the Golgi in ECs. $PC1^{V}$ was partially resistant to Endo H and able to reach the cell surface.

Conclusions: Our data suggests that expression and localization of PC1 and/or PC2 in the primary cilia of ECs is not required for a proper vascular/lymphatic vessel development. This is the first time that an extraciliary role for full length PC1 has been identified.

Involvement of Glycolipids in Cyst Formation in Cystic Kidney Disease

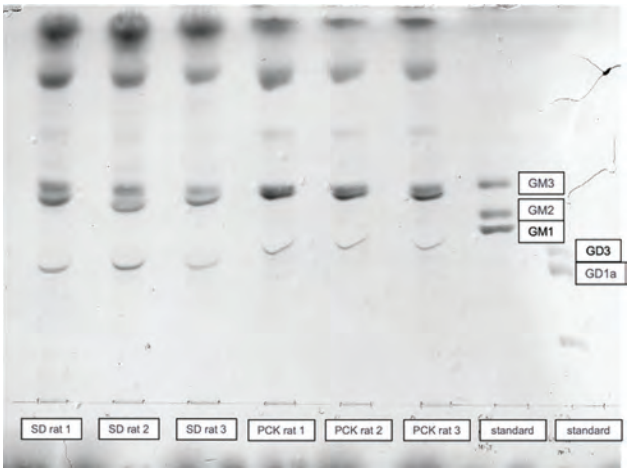
Yuhei Noda, Noritoshi Kato, Yuka Sato, Kayaho Maeda, Tomoki Kosugi, Shoichi Maruyama. *Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan.*

Background: ADPKD is an important disease that can lead to end-stage renal failure, yet many aspects of the mechanism of cyst enlargement remain unclear. In this study focusing on cystic kidney diseases, we examined the differences in glycolipids, a post-translational modification of proteins. Previous studies have demonstrated the accumulation of sphingolipids, such as GlcCer, LacCer, and GM3, in cystic kidney diseases. However, their direct involvement in cyst formation has not been established.

Methods: Glycolipids were extracted from the kidneys of PCK rats, a model of ARPKD, and developed by thin layer chromatography. Total RNA was extracted from the kidney tissue of the model animals and expression of glycosyltransferase was confirmed by qPCR. The same was also confirmed by WB.

Results: Thin layer chromatography of glycolipids extracted from renal tissue revealed changes in gangliosides including GM3, an acidic glycolipid. In cystic kidney tissue, GD3 with malignant phenotype was detected. qPCR and WB showed decreased expression of B4galnt1, a glycosyltransferase, in the medullary tubules of cystic kidney tissue. Primary culture of kidney cells from ADPKD patients also showed decreased expression of *B4GALNAT1*.

Conclusions: In the kidneys of mouse models of cystic kidney disease, disturbance in the composition of glycolipids was observed. Accumulation of GD3 is said to be involved in signaling of cell proliferation and may contribute to cyst enlargement. Decreased expression of B4galnt1 could explain these disturbed glycolipids change.



FR-PO548

Role of FBW7 in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Maulin M. Patel, Leonidas Tsiokas. *The University of Oklahoma, Oklahoma City, OK.*

Background: ADPKD, caused by mutations mostly in *PKD1* or *PKD2* genes, is a leading cause of end-stage renal disease. Deleting structural components/proteins of cilia in mouse models of *Pkd1* inactivation ameliorates ADPKD progression, highlighting the importance of cilia regulation in ADPKD. Our lab has shown that FBW7, a substrate recognition receptor of the SCF^{FBW7} Ubiquitin E3 ligase, can regulate ciliogenesis. It recognizes proteins with a specific phosphorylated sequence called "phospho-degrons" and targets them for degradation via the ubiquitin-proteasome system. In this study, we sought to investigate the role of FBW7 in ADPKD.

Methods: We adopted an early-onset ADPKD mouse model where we induced *Pkd1* and/or *Fbxw7* deletion in postnatal mice using a global tamoxifen-inducible *Ubc-*Cre^{ERT2}.

Results: We found that *UbcCre*^{ERT2}*; Pkd1*$^{f/f}$ P16 pups develop cysts and significantly increased the Two kidney weight/body weight (2KW/BW) and cystic index, along with the loss of kidney function measured by levels of three different markers, BUN, Creatinine, and cystatin C in the blood serum compared to the WT pups. Furthermore, *UbcCre; Pkd1*$^{f/f}$*; Fbxw7*$^{f/+\ \&\ f/f}$ p16 pups also developed cysts and increased 2KW/BW and cystic index similar to *UbcCre*^{ERT2}*; Pkd1*$^{f/f}$ P16 pups. However, surprisingly, *UbcCre; Pkd1*$^{f/f}$*; Fbxw7*$^{f/+\ \&\ f/f}$ p16 pups showed significant rescue in the kidney function based on BUN, Cystatin C, and Creatinine levels in the serum compared to *UbcCre*^{ERT2}*; Pkd1*$^{f/f}$ P16 pups. Although the kidney function parameters in *UbcCre; Pkd1*$^{f/f}$*; Fbxw7*$^{f/+\ \&\ f/f}$ p16 pups were still significantly higher compared to the WT pups, the fact that the *UbcCre; Pkd1*$^{f/f}$*; Fbxw7*$^{f/f}$ p16 pups displayed improved kidney function despite having no significant changes in 2KW/BW, and cystic index compared to *UbcCre*^{ERT2}*; Pkd1*$^{f/f}$ P16 pups was exciting. This protective effect on kidney function upon loss of FBW7 was persistent when we analyzed P21 pups. *Ubc-*Cre^{ERT2}*; Fbxw7*$^{f/f}$ pups do not show any apparent kidney phenotype.

Conclusions: Loss of FBW7 ameliorates ADPKD progression via proteomic reprogramming that perhaps partially uncouples the kidney function and cystogenesis, challenging the prevailing dogma that kidney function is secondary to defects/cysts in kidney architecture.

FR-PO549

Anoctamin 3 Enhances Cystogenesis and Ciliary Dosage of Polycystins by cAMP Signaling in Renal Cilia

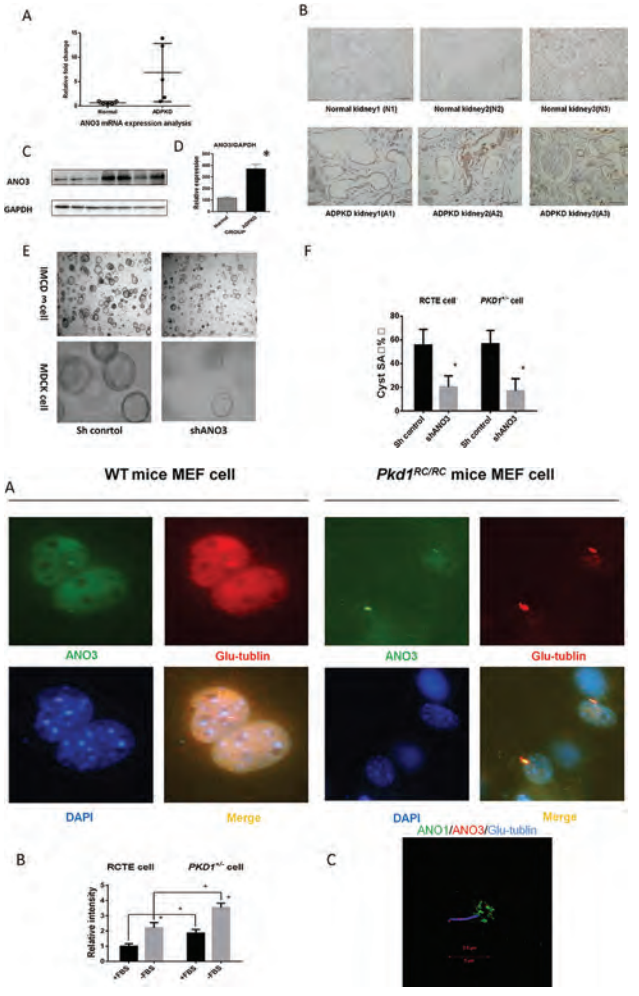
Tao Xu. *Shanghai Jiaotong University School of Medicine Affiliated Shanghai Sixth People's Hospital, Shanghai, China.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a ciliopathy which is characterized by abnormal tubular epithelial proliferation and fluid secretion. We reported Anoctamin1(ANO1), one of chlorine channels family could accelerate both cilia formation and cilia trafficking of polycystins. Anoctamin3(ANO3) was recently shown to be involved in ADPKD progression in our research.

Methods: 1.Real-time RCR, IHC and Western blot to detect expression of ANO3 in kidney tissue of ADPKD patients and normal kidndy. 2.3D culture to vertify the function of ANO3 in cysts formation with siANO3. 3.Super-resolution 3D structured illumination microscopy and co-IF to investigate ANO3 location and the impact of ANO3 on PC2 by siRNA in cilia. 4.MQAE to detect chloride ion flow by shANO3 and ad-ANO3 treating in ADPKD cells. 5.MRI to calculate the separates normal tubule space from cystic fluid area (Cyst fluid SA) in *PKD1* $^{flox/flox}$*CAG-creER*$^{+}$ mice.

Results: 1.ANO3 located in renal tubules and cyst and upregulated in human and mouse ADPKD kidneys. 2.siANO3 could inhibited cysts formation. 3.ANO3 was puncta-like localization on cilia membrane and siANO3 increased the cilia length and the expression of PC2. 4.Chloride ion flow was lower by shANO3 treating than ad-ANO3 in ADPKD cells. 5.Cyst fluid SA in *PKD1* $^{flox/flox}$*CAG-creER*$^{+}$ mice was significantly decrease than which in $PKD1^{RC/RC}$ mice.

Conclusions: ANO3 may aggravate ADPKD by regulating the renal cilia length and PC2 expression through cAMP signaling and provide mechanistic insights regarding the therapeutic potential of ANO3 pathway.



FR-PO550

The Cilia-Enriched Oxysterol 7β,27-DHC Is Required for Polycystin Activation

Kotdaji Ha, Nadine Mundt, Aide Pinedo, Gabriel Loeb, Jeremy Reiter, Markus Delling. *University of California San Francisco, San Francisco, CA.*

Background: The polycystin complex (PC-1 and PC-2) forms a non-selective cation channel and mutations within the polycystin complex cause Autosomal Dominant Polycystic Kidney Disease (ADPKD). The spatial and temporal regulation of the polycystin complex within the ciliary membrane is poorly understood, partially due to technical limitations studying the electrical properties of this tiny cellular compartment.

Methods: In this study, we used both whole-cell and ciliary patch-clamp recordings to measure the polycystin activity in the plasma or ciliary membrane. For carbenoxolone (CNX) injection study, we used intravenous and intraperitoneal injections to C57BL/6 strain mice from postnatal day 0.5 to 17.

Results: We identified a novel oxysterol binding pocket within PC-2 to modulate channel activation and showed that mutations within the oxysterol binding pocket disrupt 7β,27-DHC dependent polycystin activation. Pharmacologic and genetic inhibition of 11B-HSD enzyme that synthesizes oxysterol deplete channel activity in primary cilia and result in renal tubular dilation *in vivo*.

Conclusions: Our results identify the oxysterol binding pocket in PC-2 as an allosteric regulatory site in the polycystin complex, which may provide a specific target for novel ADPKD therapeutics.

Funding: NIDDK Support

FR-PO551

Ouabain Enhances Renal Cyst Growth in a Slowly Progressive Mouse Model of Autosomal Dominant Polycystic Kidney Disease

Jordan Trant, Gladis S. De Blanco, Jeff P. Mcdermott, Gustavo Blanco. *University of Kansas Medical Center Department of Cell Biology and Physiology, Kansas City, KS.*

Background: Renal cyst progression in autosomal dominant polycystic kidney disease (ADPKD) is highly dependent on agents circulating in blood. We have previously shown, using different *in vitro* models, that one of these agents is the hormone ouabain. By binding to Na,K-ATPase (NKA), ouabain triggers a cascade of signal transduction events which enhance ADPKD cyst progression by stimulating cell proliferation, fluid secretion, and dedifferentiation of the renal tubular epithelial cells, all effects not seen in normal human kidney cells. The potential mechanism behind these effects is the abnormally high affinity that ~25% of the NKA of ADPKD cells have for ouabain. Here, we validate ouabain's effects *in vivo* and show that NKA ouabain affinity is critical for these effects.

Methods: Low dose ouabain (0.01 or 0.03 mg/g) or saline was injected intraperitoneally to mice daily, starting at postnatal day 9 and continuing for 1-5 months. The mouse models used include wildtype (WT), a slowly progressive ADPKD model ($Pkd1^{RC/RC}$), and an ADPKD mouse model in which all NKA has a high ouabain affinity ($Pkd1^{RC/RC}NKA\alpha1^{OS/OS}$). Kidney weight to body weight ratio (%KW/BW), blood urea nitrogen (BUN), renal percent cystic area (% cyst area), cyst number, and percent fibrosis were measured.

Results: Ouabain augmented % cyst area, cyst number, and renal fibrosis in $Pkd1^{RC/RC}$ mice when compared to saline-administered controls. By contrast, ouabain had no significant effect on WT mice. $Pkd1^{RC/RC}NKA\alpha1^{OS/OS}$ mice receiving saline had significantly increased % cyst area, cyst number, %KW/BW, and % fibrosis than $Pkd1^{RC/RC}$ mice receiving saline. Ouabain administration to $Pkd1^{RC/RC}NKA\alpha1^{OS/OS}$ mice did not alter any of the cystic parameters studied when compared to the saline-administered controls, and when compared to $Pkd1^{RC/RC}$ mice receiving ouabain, only % cyst area and renal fibrosis were increased over the study period.

Conclusions: These findings demonstrate that ouabain at levels similar to those circulating in plasma stimulates kidney cyst progression in ADPKD *in vivo* as well as *in vitro*. Additionally, the ouabain affinity of NKA plays a key role in the hormone's cystogenic effects.

Cytoplasmic Domain of Fibrocystin/Polyductin Suppresses cAMP-Induced Cyst Formation of Pkhd1 Knockout (KO) Cells

Wolfgang H. Ziegler, Fatima Hassan, Susanne Hahnenstein, Dieter Haffner. *Medizinische Hochschule Hannover Zentrum fur Kinderheilkunde und Jugendmedizin, Hannover, Germany*.

Background: Loss of ciliary protein function leads to defective control of epithelial homeostasis in hereditary polycystic kidney diseases. To address molecular aspects of epithelial function, monolayered epithelial spheroids can be used to analyze consequences of protein expression and pharmacological intervention. Here, we employed epithelial cell clones deficient for the protein fibrocystin/polyductin (FPC), the cause of ARPKD, to study the impact of FPC cytoplasmic domain expression on cAMP/Src-induced cyst formation.

Methods: We used pl-MDCK, sub-cloned principal-like cell lines, with CRISPR/Cas9-based genetic knockout (KO) of *Pkhd1* / FPC, and corresponding controls. Cells were grown in matrigel to allow formation of epithelial spheroids within 3 days. Forskolin (Fsk) treatment was employed to induce cAMP-mediated cyst growth mimicking disease conditions. Proportional lumen, i.e. the ratio of lumen to spheroid area, provided the measure to detect the enhanced water / ion transport across the barrier that is characteristic for cystic epithelia. Cellular signals known to stimulate cyst formation were modulated by viral expression of the FPC C-terminal domain and/or interventional treatment.

Results: In *Pkhd1*-KO cell lines, enhanced cAMP levels resulted in massive lumen expansion of epithelial spheroids with no increase in cell number. Cyst induction was sensitive to inhibition of Src kinase and led to activation and increased Y705 phosphorylation of STAT3. To address the contribution of FPC to cyst signaling, expression of a membrane-bound FPC C-terminal protein domain was studied, and its processing and intracellular localization determined. Controlled expression of the FPC cytoplasmic domain in *Pkhd1*-KO cell lines suppressed the Fsk-induced increase of proportional lumen / cyst formation, and furthermore, reduced activation of Src and STAT3 as well as STAT3-dependent transcription.

Conclusions: In FPC-deficient pl-MDCK cells, cyst formation stimulated by high cAMP levels is associated with enhanced Src/STAT3 signaling. Expression of the FPC cytoplasmic domain can correct control of the epithelial barrier in *Pkhd1*-KO and inhibit cyst growth *in vitro*. Therefore, expression of FPC domain constructs can lead to a gain-of-function and limit cyst promoting signals, a proposed cellular function of FPC protein.

Transcriptomics Analysis of ADPKD Cysts Shows Remodeling of Purinergic Receptors in Pkd1RC/RC Mice

Tengis S. Pavlov,[1,2] Sergey N. Arkhipov,[1,2] Andrew Wu,[1] Ze Meng,[1] Indra Adrianto,[1] Pablo A. Ortiz.[1,2] *[1]Henry Ford Hospital, Detroit, MI; [2]Wayne State University, Detroit, MI*.

Background: Polycystic kidney diseases (PKD) are characterized by development of multiple cysts, dilations of nephron segments, which replace normal tissues and lead to kidney insufficiency.

Methods: To identify new gene pathways affected by cyst development in collecting ducts, we used a bulk RNAseq approach comparing gene expression of normal microdissected cortical collecting ducts (n=3) vs cysts (n=4) microdissected from the same *Pkd1*$^{RC/RC}$ mice.

Results: Bulk-RNA analysis identified 18,000 genes and allowed statistical comparison of over 15,000 genes. Our data reveals that although cysts originate from normal collecting ducts, cystic epithelium show 2692 down-regulated and 2278 up-regulated genes ($p<0.05$ pAdj. FDR). Ingenuity Pathways Analysis identifies the following intracellular mechanisms mostly affected by transition: Rac and Rho signaling, fibrosis signaling, epithelial-to-mesenchymal transition, cytoskeleton rearrangement and ERK/MAPK signaling. Our previous publication reported that development of cysts in an autosomal recessive model of PKD is associated with a shift of P2Y to P2X receptor abundance. In the current study we found that in the autosomal dominant *Pkd1*$^{RC/RC}$ mice model purinergic signaling undergoes similar remodeling. The most abundant ionotropic receptors with reduced expression were *P2ry2* and *P2ry4*, whereas ionotropic receptors *P2rx5* and *P2rx7* increased expression (2.88 and 1.53, log2). Additionally, analysis detected elevated abundance of *P2ry6*, *P2ry12* and *P2ry13* RNA level. We hypothesize that the physiological significance of the predominant P2X signaling in the cysts include their role in regulation of ATP release via pannexin-1 channels. Abnormal ATP accumulation in the cyst space was shown earlier to contribute in cystogenesis and we previously showed that pannexin-1 mediates ATP release to the cyst lumen. In the presented study, RNAscope confirms hyperexpression of *P2rx7* mRNA in cysts. In a heterologous CHO cells system, interaction of P2X7 with pannexin-1 upregulates channel activity and both proteins co-immuno precipitate.

Conclusions: Development and establishment of ADPKD cysts involves massive transcriptome remodeling of collecting ducts which include a shift in purinergic signaling that facilitates pathogenic pannexin-1 hyperactivity.

FR-PO554

Early Transcriptional Changes in Distal Convoluted Tubule Cells Are Evident in PKD1 (Polycystin 1) Mutant Mice Prior to Cyst Development

Elizabeth D. Nguyen,[1,2] Amrei M. Mandel,[3,4] Scott R. Houghtaling,[2] Sean Gombart,[2] David R. Beier.[1,2] *[1]University of Washington, Seattle, WA; [2]Seattle Children's Research Institute, Seattle, WA; [3]Universitat zu Koln, Koln, Germany; [4]Universitatsklinikum Koln, Koln, Germany*.

Background: Autosomal dominant polycystic kidney disease (ADPKD) is due to mutations in PKD1 and PKD2 and is not diagnosed in patients until cyst formation has already occurred. Cysts arise mainly from distal portions of renal tubular segments but the mechanism of cyst formation is still unclear, and there are no treatment strategies to prevent formation of cysts. The PKD1 p.R3277C *Pkd1*$^{tm1.1Pcha}$ knockin mouse (RC/RC) develops gradual cystogenesis mimicking the features of ADPKD (Hopp K et al., JCI 2012). Here, we use this model to identify transcriptional changes at early timepoints; post-natal day 10 (p10), before gross cyst formation and p20, after cystic changes occur in the kidney.

Methods: Single nuclei RNA-seq was performed on kidneys from RC/RC and age matched control mice at p10 (n=3) and p20 (n=3). Sequencing data within the same condition were aggregated. Cluster identities were assigned using expression of known cell markers. Differentially expressed genes between p10 and p20 with correlating controls was performed on distal convoluted tubule (DCT) cell clusters using regression analysis with a cutoff of log2 fold change.

Results: Cells with unique molecular identifiers (UMI) > 1000 ranged between 7000 to 10,000 for controls and 25,000 to 31,000 for kidneys from RC/RC mice. There were 20-26 clusters for each condition covering 12 kidney cell types, including >1500 DCT cells per condition. Genes with significant differential expression in the RC/RC mouse at p10 included genes associated with cystic disease (*Nek1* and *Pde1a*) in addition to 34 other genes. Genes with differential expression within DCT cells at p20 include *Hsf2bp* in addition to 5 other genes.

Conclusions: This work identifies genes within distal convoluted tubule cells implicated in cyst formation in polycystic kidney disease caused by mutations in PKD1. The transcriptional landscape of the pre-cystic kidney is significantly different than control, indicating that molecular pathways are activated at early timepoints before structural changes in the tissue. Further characterization of differentially expressed genes at early timepoints will address an important gap in field of ADPKD by identifying pathways leading to cyst formation and potential targets for therapeutics before cysts occur.

Dynamics of the Renal Transcriptomic Profile Through the Course of the Disease in Experimental ADPKD

Yahya Alsawaf, Cassandra Trask, Sara Kazeminia, Alfonso Eirin, Maria V. Irazabal. *Mayo Clinic Department of Internal Medicine, Rochester, MN*.

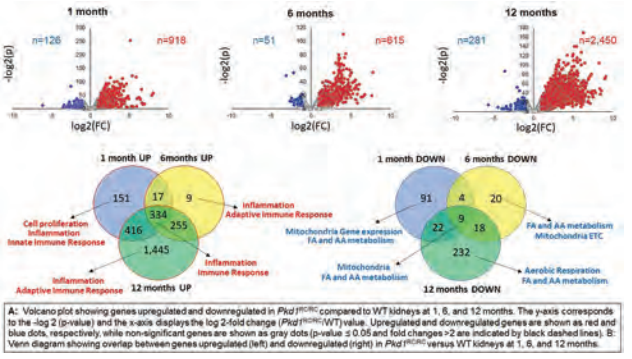
Background: Autosomal dominant polycystic kidney disease (ADPKD) is a chronic disease spanning an affected individual's life where earlier stages are marked by cyst development and kidney enlargement with preservation of renal function and later stages by increased kidney fibrosis and renal function decline. To understand the underlying molecular processes accompanying the dynamics of the disease phenotype, we comprehensively characterized the kidney transcriptomic profile in the slowly progressive hypomorphic *Pkd1* mutant mouse (p.Arg3277Cys, *Pkd1*$^{RC/RC}$) across the course of the disease.

Methods: *Pkd1*$^{RC/RC}$ and wild type (WT) mice (n=10, 5 males and 5 females each) were studied longitudinally, and their renal mRNA profiles were analyzed using high-throughput mRNA-sequencing (seq) at 1, 6, and 12m (n=5 each). Disease severity and progression were evaluated by kidney weight/body weight (KW/BW), cystic index (CI), fibrotic index (FI), and BUN. Renal tubular cell proliferation, inflammation, mitochondrial morphology, and metabolic function were assessed by immunostaining, western blot, electron microscopy, and metabolomics at all time points.

Results: KW/BW and CI were higher in *Pkd1*$^{RC/RC}$ from 1m and FI from 6m, but BUN was similar until 12m. mRNA-seq identified an important number of differentially expressed (DE) genes [fold-change ≥ 2, and false discovery rate (FDR) ≤ 0.05] in *Pkd1*$^{RC/RC}$ versus WT kidneys, which was higher at 1- compared to 6-, but further increased at 12m (Figure). Functional analysis showed that while DE genes were primarily implicated in inflammation, immune response, and mitochondrial functions, different signatures characterize each timepoint. Confirmatory studies on cell proliferation, inflammation, mitochondria, and kidney metabolism agreed.

Conclusions: Our findings that the renal phenotype and transcriptomic landscape varied across the course of ADPKD may have significant clinical implications and suggest that different therapeutic strategies might be beneficial throughout the disease.

Funding: NIDDK Support



A: Volcano plot showing genes upregulated and downregulated in *Pkd1*^{RCRC} compared to WT kidneys at 1, 6, and 12 months. The y-axis corresponds to the -log 2 (p-value) and the x-axis displays the log 2-fold change (*Pkd1*^{RCRC}/WT) value. Upregulated and downregulated genes are shown as red and blue dots, respectively, while non-significant genes are shown as gray dots (p-value ≥ 0.05 and fold changes >2 are indicated by black dashed lines). B: Venn diagram showing overlap between genes upregulated (left) and downregulated (right) in *Pkd1*^{RCRC} versus WT kidneys at 1, 6, and 12 months.

FR-PO556

CRISPR Activation of PKD1 in Immortalized Cell Lines Is Limited by Its Heterochromatinized Proximal Promoter

Anubhav Chakraborty, Christopher J. Ward, Alan S. Yu. *University of Kansas Medical Center, Kansas City, KS.*

Background: Loss of function mutations in *PKD1* are the predominant causes of autosomal dominant polycystic kidney disease (ADPKD). ADPKD is characterized by the progressive enlargement of renal cysts which leads to a decline in renal function. Cysts form when the functional levels of polycystin 1 (PC1), the protein product of *PKD1*, decrease below a critical threshold. We hypothesize that increasing the expression of *PKD1* could potentially restore functional levels of PC1 and rescue the disease.

Methods: To increase the expression of *PKD1* using CRISPR activation (CRISPRa), we designed and screened several guide RNAs (gRNA) targeting the proximal promoter of the gene in mouse renal cortical collecting duct (M1) and HEK293T cell lines. We measured the abundance of *PKD1* transcripts in these cell lines using qRTPCR and assessed the chromatin accessibility of the *PKD1* proximal promoter.

Results: CRISPRa-mediated *PKD1* upregulation in M1 or HEK293T cells reached a maximum of 2-2.5-fold ($p<0.001$) using pooled gRNAs targeting the 100 bp region upstream of the transcriptional start site. In contrast, positive control genes (*Klf1*, *Nkx2*, *Oct4*, *INS*, and *TTN1*) displayed substantially greater increases in expression (5-6000-fold). Both cell lines exhibited low *PKD1* mRNA abundance (~10 copies/cell). PCR-based chromatin accessibility assay showed less than a 4-fold enrichment in the *PKD1* proximal promoter (in both cell lines), indicating a heterochromatinized region. Additionally, H3K27 acetylation and DNase hypersensitivity data from ENCODE showed that heterochromatization of the mouse or human *PKD1* proximal promoter is common to most immortalized cell lines.

Conclusions: Our findings suggest that the heterochromatinized *PKD1* proximal promoter poses a limitation on the extent to which the gene can be effectively upregulated by CRISPRa. Understanding these constraints is crucial for developing strategies to overcome heterochromatinization and enhance *PKD1* expression, potentially enabling therapeutic interventions for ADPKD.

FR-PO557

Identification of Paracrine Factors in the Early Cyst Microenvironment in Polycystic Kidney Disease

Sevtap A. Yasinoglu,[1] Thomas B. Kuipers,[1] Hester Bange,[2] Michael Eikmans,[1] Hailiang Mei,[1] Hans J. Baelde,[1] Dorien J. Peters.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Crown Bioscience Netherlands B.V., Leiden, Netherlands.*

Background: Initial cysts that are formed upon *Pkd1* loss in mice impose persistent stress on surrounding tissue and trigger a cystic snowball effect, leading to the activation of PKD-related signaling which increases the likelihood of new cyst formation and disease progression. In the present study, we profiled transcriptomic changes that occur in the cyst microenvironment in PKD mice and identified paracrine factors with increased activity in PKD mice and in human ADPKD cyst cultures.

Methods: To perform an unbiased analysis of transcriptomic alterations that occur in the cyst microenvironment, microdomains were collected from *iKsp-Pkd1*^{del} mice with scattered *Pkd1*-deletion using Laser Capture Microdissection. Based on F4/80 staining, collected microdomains were defined as either macrophage (MΦ)-low cystic, representing early alterations in the cyst microenvironment, MΦ-high cystic, with more advanced alterations, or non-cystic. Pathway and upstream regulator analyses were applied to identify dysregulated pathways and secreted factors that may play a key role in altered signaling. Finally, supernatants from 3D cultures of primary ADPKD cells were harvested to analyze secreted paracrine factors using a Bio-Plex assay.

Results: When compared to the non-cystic microdomains, 953 and 8088 genes were dysregulated in MΦ-low and MΦ-high regions, respectively. Several injury-repair, growth, and tissue remodeling-related pathways were activated in MΦ-low microdomains, accompanied by mild metabolic alterations. In the more advanced MΦ-high microdomains, these pathways were strongly potentiated and the metabolism was more dysregulated. Using upstream regulator analysis, paracrine factors were identified with increased activity in the early cyst microenvironment, including IFNG, TNF, IL1B, TGFB1, AGT, and PDGFB. In addition, we identified TNF-α, PDGF-β, and several other factors that were secreted by primary ADPKD cells in the culture medium.

Conclusions: Collectively, our data provide an overview of molecular alterations that occur specifically in the MΦ-low and MΦ-high cyst microenvironment. Also, paracrine factors were identified that may drive early epithelial cell-induced alterations and tissue remodeling, which potentially give rise to the formation of more cysts.

Identification of Early Transcriptional Markers of ADPKD Cystic Epithelial Cells

Victoria Rai, Laura Onuchic, Marcela A. Reyna-Neyra, Giorgia Schena, Joseph E. Craft, Michael J. Caplan. *Yale University, New Haven, CT.*

Background: Mechanisms driving ADPKD cystogenesis are not well understood, and reliable biomarkers are scarce. To explore molecular changes in cystogenesis, we performed single cell RNA sequencing on kidneys from an ADPKD mouse model at an early stage of cyst formation and from a model in which cystic disease was suppressed by expression of the polycystin-1 C-terminal tail (PC1-CTT).

Methods: Doxycycline inducible *Pkd1*$^{fl/fl}$*;Pax8*^{rtTA}*;Teto-Cre* ADPKD C57BL/6N mice expressing CTT (*Pkd1*-KO+CTT) or not (*Pkd1*-KO) were induced between 4-6 weeks and aged to 10 weeks. Single cell kidney suspensions from biological replicates were pooled and processed for cDNA synthesis and library preparation with 10X Chromium technology. Reads were aligned using the 10X Genomics CellRanger pipeline and further processed using Seurat v4.3.

Results: Clusters corresponding to tubule segments were identified using established annotations. Several novel clusters defined by expression of multiple markers, including *Jarid2*, *Tmtc2*, and *Filip1l*, were identified in the *Pkd1*-KO model. These clusters were sparsely populated in *Pkd1*-KO+CTT samples, suggesting that they may correspond to cyst epithelial cells that are suppressed by PC1-CTT expression. Each of these novel clusters included cells whose markers identified them from distinct tubule segments (e.g. *Sglt2*, *Umod*, *S100g*), suggesting that cells of different segments are clustered together by virtue of sharing the putative cyst cell transcriptional signature. The single cluster observed in *Pkd1*-KO+CTT model and not in the *Pkd1*-KO model is enriched in markers associated with metabolic processes including *Ugt1a2*, *Cbr1*, and *Pck1*. Importantly, at 10 weeks, there are no significant differences in %KW/BW or kidney morphology between the *Pkd1*-KO+CTT and *Pkd1*-KO models, suggesting that the cells belonging to the cystic epithelial cell clusters exhibit early identifiable differences in transcriptional programming.

Conclusions: scRNA-seq at an early timepoint reveals novel transcriptional makers of putative cystic epithelial cells. The protein expression levels of individual markers are being assessed. These results suggest that there are epithelial cells early in disease progression exhibiting a unique transcriptional signature that may elucidate the mechanisms of cyst formation and that may provide new candidate biomarkers.

Repression of Foxo3-Gatm Accelerates Cystogenesis by Increasing Reactive Oxygen Species (ROS) in ADPKD

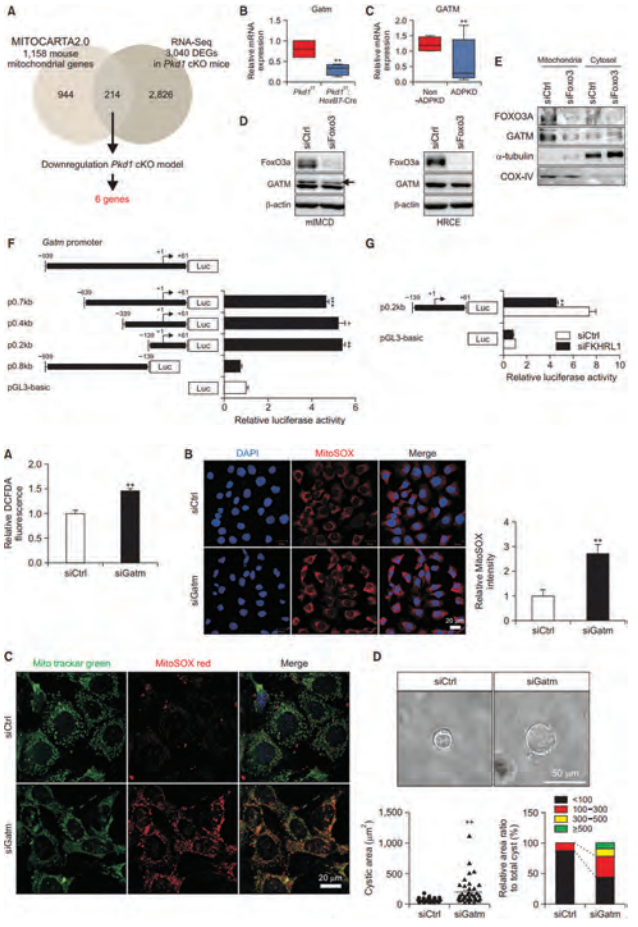
Jaehee Jun, Jong Hoon Park, Je Yeong Ko, Yejin Ahn, Oh Chaewon, Jinui Min. Sookmyung Women's University. *Sookmyung Women's University, Yongsan-gu, Seoul, Republic of Korea.*

Background: The most common inherited renal disorder and leading cause of genetic end-stage renal disease is ADPKD. The relationship between ADPKD and oxidative stress have reported in in the early stage with disease progression, however the mechanism of correlation remains unclear.

Methods: We generate *Pkd1*^{flox}:HoxB7-Cre and performed integrative analysis. 3D cell culture produced *in vitro* cyst formation, and we observed differences in cyst formation.

Results: We explored the mechanisms associated with FOXO3 in ADPKD through screening by integrative analysis since FOXO3 regulates mitochondrial gene expression. And notably, GATM were significantly reduced in ADPKD patients. Furthermore, GATM was decreased by FOXO3 knockdown. Additionally, Inhibition of FOXO3 decreased GATM in the mitochondria. Therefore GATM is regulated by FOXO3 in the mitochondria. To verify the effect of Gatm on oxidative stress in ADPKD, we measured cellular ROS, DCFDA fluorescence intensity is elevated in Gatm knockdown. More specifically, Gatm silencing increased mitochondrial superoxide levels. This Gatm-mediated increase in superoxide levels was confirmed by co-staining with MitoSOX Red. To investigate the effect of Gatm on cyst formation in ADPKD, we experimented 3D cell culture and observed significantly promoted cyst progression with Gatm silencing.

Conclusions: We suggest a novel insight of cystogenesis, in which inhibited Foxo3 reduces Gatm expression, thereby increasing ROS and oxidative stress, consequently progressing cyst enlargement in ADPKD.



FR-PO560

Enhancing Intracellular Cholesterol Biosynthesis Slows PKD Progression

Ronak Lakhia, Laurence M. Biggers, Maggie Zumwalt, Goncalo Vale, Jeff McDonald. *The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Metabolic reprogramming is a hallmark of ADPKD but remains incompletely understood. Cholesterol is a building block for cell membranes and functions in signaling pathways. Abnormal activation of cholesterol biosynthesis has been implicated in the pathogenesis of proliferative diseases such as cancer. However, the role of cholesterol biosynthesis in ADPKD is unknown.

Methods: We used transgenic mouse models to manipulate the activity of the transcriptional regulators of cholesterol/lipid synthesis: sterol regulatory element binding proteins (*Srebp1/2*). We inhibited cholesterol biosynthesis by deleting *Scap* in *Ksp*rtTA;TetOCre;*Pkd1*$^{F/F}$; *Pkhd1*Cre;*Pkd1*$^{F/F}$ and *Pkd1*$^{RC/RC}$ mouse models. To enhance cholesterol biosynthesis we inactivated *Insig1/2* in *Ksp*rtTA;TetOCre;*Pkd1*$^{F/F}$; *Ksp*Cre;*Pkd1*$^{F/F}$ and *Ksp*Cre;*Pkd1*$^{F/RC}$ mouse models. Mice were sacrificed at pre-determined timepoints for histological and molecular analysis or monitored for survival. 3D cyst assay was performed on human ADPKD kidney cell lines treated with scramble or *Insig1/2* siRNA. Western blot and sterolomics was completed on 10 and 18 day old *Ksp*Cre;*Pkd1*$^{F/RC}$ and control mice kidneys to assess baseline Srebp1/2 activity and cholesterol levels.

Results: Total cholesterol was reduced in *Ksp*Cre;*Pkd1*$^{F/RC}$ kidneys compared to controls. Western blot showed reduced nuclear Srebp2, the primary transcriptional driver of cholesterol synthesis, in early cystic *Ksp*Cre;*Pkd1*$^{F/RC}$ kidneys. Inhibition of cholesterol synthesis (*Scap* deletion) increased kidney-weight/body-weight ratio and reduced kidney function in 3 mouse models of PKD. Conversely, augmentation of cholesterol synthesis pathway (knockout of *Insig1/2*) reduced kidney weight/body weight ratio reduced serum creatinine and prolonged survival in multiple mouse models of PKD. RNA-seq confirmed appropriate inhibition or activation of cholesterol biosynthesis pathway. Finally, *Insig1/2* siRNA reduced cyst growth in 2 human ADPKD cell lines.

Conclusions: Srebp2 and cholesterol are reduced in *Pkd1* mutant mice. Inhibition of cholesterol biosynthesis markedly aggravates cyst growth. Surprisingly, activation of cholesterol biosynthesis slows cyst growth in 3 mouse models of PKD and in human ADPKD cell lines. Further studies are needed to understand how enhancing intracellular cholesterol reduces PKD progression and determine if this pathway can be targeted therapeutically.

Progressive Cellular Senescence Promotes and Senolytic Therapy Delays Cyst Growth in ADPKD

Xinyue Mao,[1,2] Lu Li,[1,2] Xia Zhou,[1,2] Peter C. Harris,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is one of the most common, life-threatening inherited kidney disease. Cellular senescence is permanent proliferative arrest, which accumulates with the progression of a variety of chronic diseases and age in response to endogenous and exogenous stresses. However, the roles and mechanisms of cellular senescence in ADPKD remains elusive.

Methods: To investigate the roles of senescence in ADPKD and evaluate the senescence removal therapy on cyst growth, we treated two *Pkd1* mutant mouse models with senescent inducer D-galactose (D-gal) or senolytics. To understand senescence-associated mechanisms in promoting cyst growth, we performed H&E staining, Western blot, qRT-PCR and TUNEL analysis *in vitro* and *in vivo*. We also identify SASP produced by *Pkd1* mutant cells by mass spectrometry.

Results: Cellular senescence was increased in *Pkd1* mutant mouse and human ADPKD kidneys characterized by the increase of the expression of SA-β-Gal and p16. Treatment with senolytics, including dasatinib (D) (7.5mg/kg), quercetin (Q) (75 mg/kg) and D plus Q, delayed cyst growth in kidneys of two *Pkd1* mutant mouse models as seen by decrease of cyst index, KW/BW ratios, BUN levels as well as cyst lining epithelial cell proliferation and the release of senescence-associated secretory phenotype (SASP), but increase cystic renal epithelial cell apoptosis. Co-treatment with D plus Q had synergized effect on cyst growth compared to that in kidneys treated with either D or Q alone. The release of SASP from *Pkd1* mutant renal epithelial cells stimulated the proliferation of nearby renal epithelial cells and activated renal fibroblasts characterized by the increased the phosphorylation of Akt, S6 and Stat3 and the expression of fibrotic markers (Fibronectin, α-SMA and Col-1). In addition, treatment with senescent inducer, D-gal, promotes cyst growth in *Pkd1* mutant kidneys. The clearance of senescence-associated P16^{INK4a}-positive cells by treating *Pkd1*$^{RC/RC}$*:INK-ATTAC* and *Pkd1*$^{fl/fl}$*:Pkhd1-Cre:INK-ATTAC* mice with AP20187 delays the cyst growth in ADPKD.

Conclusions: Senescence was increased in *Pkd1* mutant mouse and ADPKD kidneys, which is mediated by p16 associated signaling pathways, and the senescence removal therapy with senolytics is a novel therapeutic strategy for ADPKD treatment.

FR-PO562

Total and Phosphoproteomic Analyses in Kidneys from an Authentic Mouse Model of Human Autosomal Dominant Polycystic Kidney Disease

Davoud Ghazanfari,[1,2] Ario Mohammadi,[1] Jing Zhou.[1,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: ADPKD (Autosomal Dominant Polycystic Kidney Disease) is a genetic disorder characterized by the development of multiple cysts in the kidneys. The disease is caused by mutations in PKD1 and PKD2, encoding PC1 and PC2 respectively. To date, PC1 and PC2 have been implicated in modulating a number of cellular events such as Ca^{2+} signaling, mTOR, cyclic AMP, Wnt, PCP, and STAT3 pathways. How the polycystins modulate these pathways remains elusive, however. While transcriptome studies provide essential insights into gene expression patterns, proteomic studies offer a more comprehensive understanding of the functional proteome, including protein abundance, alternative splicing and posttranslational modifications. Integrating both transcriptome and proteome data can provide a more holistic view of biological systems and diseases, complementing each other's strengths and limitations.

Methods: Mice homozygous with an inducible mutation in *Pkd1* gene were generated by intraperitoneal injection of tamoxifen. Kidneys from *Pkd1* knockout mice and controls were isolated at different stages and subjected to multiplexed proteomics and phosphoproteomics. Various bioinformatic techniques, RT-PCR, immunostaining, and western blotting were used for analysis and validation.

Results: To determine the cystogenic total and phosphoproteome, we performed multiplexed quantitative mass spectrometry analysis in Pkd1 knockout mouse kidneys at pre-/early disease and disease stages. Several thousands of proteins were quantified and hundreds of phosphorylation events were measured. MS/MS data were searched against a Uniprot mouse database with both the forward and reverse sequences using the SEQUEST algorithm, MS3 data was used for quantification. Phosphopeptides were processed separately but taken through a similar software pipeline with an additional phosphorylation site localization step using the Ascore algorithm. Several significant pathways were identified. A specific selection of proteins identified in the total and phosphoproteomic studies are being validated and further analyzed.

Conclusions: We have identified several pathways that are changed in an authentic mouse model of human ADPKD and determined the sequence of change of specific pathways in relation to disease development.

Tubular Obstruction-Induced Polycystin Upregulation is Profibrotic and Induced a Severe Cystic Phenotype in Adult Mice with ADPKD

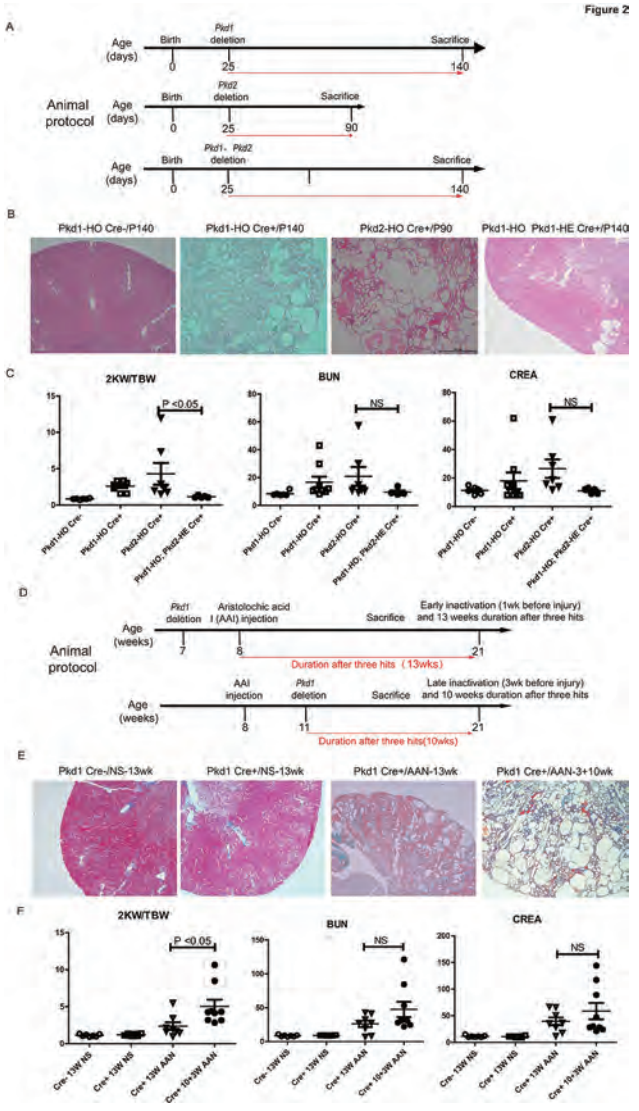
Ming Wu. *Shuguang Hospital, Shanghai, China.*

Background: Mutations in *PKD1* or *PKD2* gene cause ADPKD, however high levels of polycystins are detected in renal tissues of ADPKD patients. Animal studies showed that loss and gain of function of polycystins are both pathogenic and can induce cystic phenotype in the kidney, which are associated with enhanced renal fibrosis.

Methods: UUO or aristolochic acid I (AAI) induced mouse nepropathy was established for renal fibrosis study. Pkd1 or Pkd2 gene was inactivated in mice.

Results: We demonstrated that polycystin-1 or polycystin-2 was highly expressed in fibrotic mouse kidneys and positively correlated with expression of collagen-I. Inhibition or deletion of polycystin-2 reduced the deposition of extracellular matrix proteins in fibrotic kidneys. Similarly, knockout of *Pkd1* gene attenuated renal fibrosis in fibrotic mouse models. We further hypothesized that inhibition of polycystins delays cyst growth by mitigating renal fibrosis. Here, we showed that polycystin-1 or polycystin-2 was up-regulated in *Pkd2* or *Pkd1* mice respectively and tightly correlated with the growth of renal cysts and fibrosis development. Genetic deletion of both polycystin-1 and polycystin-2 retarded cyst growth in adult ADPKD mice. Finally, we inactivated Pkd1 gene in a fibrosis triggered adult ADPKD mouse model at different time point before or after the fibrotic injury. We showed that early and long-term inactivation of *Pkd1* delayed fibrosis triggered renal cyst growth in adult *Pkd1* mice as compared with mice with late and short-term inactivation of *Pkd1* gene.

Conclusions: We conclude that tubular obstruction induced polycystin up-regulation is pro-fibrotic and accelerates cyst growth through enhancing renal interstitial fibrosis in ADPKD mice. Our study indicates that ADPKD is caused by the coexistence of loss and gain function of polycystins.



FR-PO564

CDK6 Suppresses Tubulin Polyglutamylation in Primary Cilia and Promotes Renal Cystogenesis in ADKPD

Kai He, Xiaobo Sun, Chuan Chen, Yan Huang, Jinghua Hu. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Polycystin-1 (PC1) and Polycystin-2 (PC2) hypothetically forming an ion channel complexes localize on primary cilium to inhibit renal cyst growth. Polyglutamylation (PG) is one of the tubulin posttranslational modifications (PTMs) predominantly occurs on cilia axoneme which controls the ciliary localization of PC1/2. Defective axoneme PG has been correlated with ciliopathies that usually manifest syndromic forms of PKD. We recently discovered an uncanonical CDK6-mediated pathway that specifically inhibits axoneme PG by engaging the ciliary import of tubulin glutamylases. Intriguingly, CDK6 is strongly upregulated in the renal tubules of ADPKD mice and human patients. In agreement with the inhibitory role of CDK6 in ciliary import of tubulin glutamylases, defective axoneme PG was observed in ADPKD cells. Remarkably, pharmacologic inhibition of CDK6 restores defective axoneme PG, increase ciliary dosage of PC2 in ADPKD cells, and significantly suppressed the cyst growth in the *ex vivo* model of ADPKD. These data suggest that targeting axoneme PG could be a novel therapeutic approach for ADPKD. To identify novel small molecules/drugs to specifically target axoneme PG, we established high-content image-based strategy to screen drug-repurposing compound library and kinase inhibitor library. We will further access the therapeutic potential of drug hits in ADPKD, using *in vitro, ex vivo* and *in vivo* ADPKD models.

Methods: Cell-imaging Drug screening Biochemstry and Molecular Biology Ex vivo renal cystogenesis

Results: 1. CDK6 suppresses tubulin polyglutamylation by inhibiting ciliary import of tubulin glutamylases. 2. CDK6 is strongly upregulated in renal tubules of ADPKD mice and human patients. 3. ADPDK cells exhibit defective tubulin polyglutamylation in primary cilia. 4. Inhibition of CDK6 suppresses cyst growth in ex vivo ADPKD model.

Conclusions: Targeting axoneme PG could be a novel therapeutic approach for ADPKD.

Eliosin, A Protein Encoded by a Transcript from the HmPKD Locus, Is a Component of Mitochondria-ER Contact Sites/Mitochondria-Associated Membranes (MAMs)

Robert L. Bacallao,[1,2] Virginie Lazar,[2] Weimin Xu.[2] [1]*Richard L Roudebush VA Medical Center, Indianapolis, IN;* [2]*Indiana University School of Medicine, Indianapolis, IN.*

Background: The HmPKD1 gene locus is predicted to produce multiple transcripts whose functions are largely unknown. We studied one alternative transcript that starts at intron 40 but has a protein start site in exon 41. This transcript has a splice from the 3' end of exon 41 to the 5' end of exon 43 of the HmPKD1 gene. Subsequent splices follow the same splicing pattern found in the full-length polycystin-1 mRNA. The subcellular localization and function of this alternative transcript is not known.

Methods: PCR primers are designed to detect the transcript's unique splice features that are not found in full-length HmPKD1 transcripts. RT-PCR studies were conducted to identify the alternative transcript. cDNA encoding the alternative transcript and its product (Eliosin) were expressed in COS-1, 293, and NIH 3T3 cells for immune-blot and light microscopy analysis. Co-localization studies were performed with mCherry-Eliosin fusion protein and dynamin-related protein (DRP-1) or mitofusin-1 (MFN-1). Analysis of mitochondria morphology in co-transfection studies was performed in 293 and PKD 9-7 cells.

Results: RT-PCR reactions performed using human kidney RNA confirmed that a shortened PCR fragment from the PKD1 gene's exons 41/43 splice is expressed. Immune blot analysis revealed that the protein, we name Eliosin is a 48 kDa protein and it is expressed by a cDNA isolated from human testes. Fluorescence microscopy studies show co-localization between Eliosin and Inositol-3-phosphate receptor or MFN-1, known components of MAMs. However, when Eliosin and DRP-1 are co-expressed, DRP-1 is found in the cytosol. Since DRP-1 mediates mitochondria scission, we reasoned that the mutation in Eliosin leads to unopposed mitochondria scission in PKD 9-7 cells. We find that untransfected PKD 9-7 cells have fragmented mitochondria while Eliosin-transfected PKD 9-7 cells have normal-appearing mitochondria.

Conclusions: Eliosin is a 48 kDa protein that is a component of mitochondria-ER membrane contact sites, and it acts to displace dynamin-related protein-1 from MAMs. We conclude that Eliosin plays a role in altering the balance between mitochondria fusion and scission. This finding extends the HmPKD1 locus' role in mitochondria metabolic physiology.

Manipulation of Autophagy in PKD Mice

Daniel Atwood, Anjana Chaudhary, Zhibin He, Ozgur A. Oto, Charles L. Edelstein. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: 2-Deoxyglucose (2DG) and Chloroquine (CHLQ) are known to potentially induce or inhibit autophagy, respectively. Aim of the study was to determine the effect of pharmacological and genetic manipulations of autophagy on tubular cell proliferation and cyst growth.

Methods: Pkd1$^{RC/RC}$ (RC) male mice. 2DG (100 mg/kg) or CHLQ (60 mg/kg) from 50 - 120d of age. Kidney specific *Pkd1, Atg7* double knockout mice generated by Ksp 1.3 Cre-lox recombination. Autophagic flux measured by increase in LC3-II (autophagosomes) with the lysosomal inhibitor, bafilomycin. Autophagy proteins measured by immunoblot. Cyst index (%) number and area determined on kidney cross sections by a computerized algorithm.

Results: See table. 2DG significantly reduced two kidney/body weight ratio (2K/BW), cyst index, cyst count, cyst area, BUN. 2DG significantly (P<0.05) reduced PCNA + cells lining cysts. 2DG decreased autophagy-related proteins (ATG12-5 complex, ATG3) and suppressed autophagic flux in RC kidneys. p-ERK and p-AMPK known to activate autophagy were decreased by 2DG. 2DG from 150-350d of age (later stage of PKD) had no effect on cyst growth. CHLQ had no effect on PKD or proliferation in the cells lining the cysts. CHLQ resulted in decreased expression of pBeclin (critical regulator of autophagy) and suppressed autophagic flux in RC kidneys. Next autophagy (ATG7) was knocked out in PKD mice. In a rapid PKD model, 2K/BW and BUN at 28 d old was the same in Pkd-/- vs Pkd1-/- ATG+/- vs Pkd1-/- ATG7-/- mice. In a slow PKD model, at 120 d, double knockout RC ATG7 mice had higher cyst indices than RC mice.

Conclusions: 2DG suppressed autophagy, decreased proliferation, slowed PKD and improved kidney function. CHLQ suppressed autophagy but had no effect on PKD. Knockout of autophagy (ATG7) had no effect on PKD in a rapid severe model and worsened PKD in a slowly progressive model. Pharmacological suppression of autophagy had variable effects on proliferation and cyst growth and genetic knockout of autophagy worsened PKD in a slowly progressive PKD model.

Funding: Veterans Affairs Support

FR-PO567

Pkd1 Mutation Causes Memory Impairment Driving by Cellular Senescence in ADPKD

Zeba Firdaus,[1,2] Xinyue Mao,[1,2] Lu Li,[1,2] Xiaoyan Li,[1,2] Xia Zhou,[1,2] Peter C. Harris,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN.*

Background: Cellular senescence is a hallmark of aging. It plays a crucial role in a wide variety of age-related diseases and neuronal disorders. Accumulation of senescent cells in the brain leads to structural and functional changes and result in memory impairment. It is not clear whether *Pkd1* mutation results in memory impairment in ADPKD patients. We hypothesize that *Pkd1* mutation impairs memory in mice through cellular senescence signaling.

Methods: To test our hypothesis, we performed behavioral experiments (Y-maze and novel object recognition test) to evaluate the memory deficit in wild type and *Pkd1$^{RC/RC}$* mice. To understand the underlying molecular mechanisms, we isolated cerebral cortex and hippocampus from wild type and *Pkd1$^{RC/RC}$* brain and then performed Western blot, qRT-PCR, and immunostaining analysis.

Results: We observed an impairment of hippocampal and cortical dependent memory with novel object recognition and Y-maze test in *Pkd1$^{RC/RC}$* mice. To understand the underlying molecular mechanisms, we found that the expression of PSD-95, a synaptic marker, and neural growth factor BDNF was decreased in *Pkd1* mutant brains compared to wild type controls, and thus resulting in synaptic dysfunction and memory impairment. The downregulation of PSD-95 and BDNF was regulated by the RE-1 silencing transcription factor (REST), which was downregulated in *Pkd1* mutant mouse brain. Mutation of *Pkd1* also resulted in the accumulation of macrophages in mouse brain as examined with F4/80 staining. We further found that cellular senescence was increased in *Pkd1* mutant mouse brain as seen by the increase of p16. The mRNA levels of senescence associated secretory proteins (SASP), including CCL2, IL1-β, IL6, and TNF-α, were upregulated, which contribute to neuroinflammation as seen by the increase of the accumulation of activated microglial cells in *Pkd1* mutant mouse brain. The increased SASP level was regulated by the activation of JAK/STAT signaling in *Pkd1* mutant mouse brain.

Conclusions: This is the first study to show that *Pkd1* mutation causes memory loss and cognitive impairment in mouse brain via the accumulation of senescent cells to increase SASP production, which causes activation of microglial cells and downregulation of REST, resulting in synaptic dysfunction.

Dephosphorylation Facilitates Trafficking of Mutant Polycystin-2 to Cilia

Yiqiang Cai,[1] Ke Dong,[1] Max Spitzer,[1] Linda Geiges,[1] Xin Tian,[1] Matteus Krappitz,[1] Lonnette Diggs,[1] Zemeng Wei,[1] Adrian Cordido,[1] Steven Lim Cho Pei,[1] Sorin V. Fedeles,[1] Stefan Somlo.[1,2] *[1]Yale University Department of Internal Medicine, New Haven, CT; [2]Yale University Department of Genetics, New Haven, CT.*

Background: ADPKD is characterized by mutations in polycystin-1 (PC1) and polycystin-2 (PC2) that result in progressive cyst formation in the kidneys and liver. The steady state expression and ciliary trafficking of PC1 requires the presence of PC2. Missense mutations resulting in alterations in trafficking properties of PC1 and PC2 underlie a subset of cases of ADPKD. Here, we investigate the role of phosphorylation of PC2 in its localization to cilia.

Methods: Unbiased phosphoproteomic analysis of mouse kidney lysates was performed to identify the phosphorylation sites of native PC2. mNeonGreen-tagged PC2 (PC2NG) constructs of wild type or dephosphorylated forms were generated and expressed in IMCD3 cells lacking endogenous *Pkd1* or *Pkd2* or both. Ciliary expression of PC2 was analyzed via live-cell imaging and by immunofluorescent cell staining. Knock-in mice carrying dephosphorylated *Pkd2^{S829A}* and a novel anti-phospho-specific PC2 antibody were generated and utilized as part of this study.

Results: Two phosphorylation sites in native PC2 were identified from native protein in mouse kidneys: Ser812 and Ser829. We investigated the functional effects of Ser829 phosphorylation. We found that expression of PC2 in cilia was regulated by phosphorylation at Ser829. While dephosphorylation at the Ser829 was not a prerequisite for PC2 ciliary expression, the phosphorylation deficient Ser829Ala (S829A) form of PC2 showed quantitatively enhanced expression in cilia that did not require the presence of PC1. Mice carrying a homozygous knockin phosphorylation deficient *Pkd2^{S829A}* allele have no phenotype indicating that the absence of phosphorylation at Ser829 does not result in reduced PC2 function. Introduction of S829A into a PC2 construct containing a human pathogenic mutant that otherwise does not appear cilia resulted in expression in cilia, indicated that dephosphorylation rescued the trafficking defect of the human mutation.

Conclusions: Dephosphorylation of PC2 at Ser829 retains normal function in vivo. Dephosphorylation at Ser829 enhances the steady state expression of PC2 in cilia and it overcomes cilia trafficking defect of a human pathogenic missense mutant of PC2. The phosphorylation state of PC2 has a functional role in expression of the polycystin complex in cilia.

Pkd2 Deficiency in Embryonic Aqp2+ Progenitor Cells Is Sufficient to Cause Severe Polycystic Kidney Disease

Akaki Tsilosani,[1] Chao Gao,[1] Sana A. Shehzad,[1] Enuo Chen,[1] Madhulika Sharma,[2] Pamela V. Tran,[3] Carlton M. Bates,[4] Darren P. Wallace,[2] Wenzheng Zhang.[1] *[1]Albany Medical Center, Albany, NY; [2]University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; [3]University of Kansas Medical Center, Kansas City, KS; [4]UPMC Children's Hospital of Pittsburgh Child Development Unit, Pittsburgh, PA.*

Background: Most cases of autosomal dominant polycystic kidney disease (ADPKD) are caused by mutations in *PKD1* or *PKD2*, which encode polycystin-1 and polycystin-2, respectively. The mechanism for renal cyst formation remains unclear. We showed that embryonic Aqp2$^+$ progenitor cells (AP) give rise to principal cells (PC) and intercalated cells (IC) to generate the distal renal segments consisting of the late distal convoluted tubules (DCT2), connecting tubules (CNTs), and collecting ducts (CDs). Adult AP also contribute to the renal tissue maintenance and injury repair by regenerating DCT2/CNT/CD cells. Here, we tested the hypothesis that ablation of *Pkd2* in embryonic AP is sufficient to induce PKD.

Methods: *Aqp2Cre Pkd2$^{f/f}$* mice were generated to disrupt *Pkd2* in embryonic AP. *Aqp2$^{ECE/+}$ Pkd2$^{f/f}$* mice were tamoxifen-inducted at P1 or P60 to disrupt *Pkd2* in neonate or adult AP and PC, respectively, and sacrificed 7 months after Cre induction. Immunofluorescence was done to assess cell types that lined the cysts. Cells were categorized and quantified. We also analyzed cyst-lining cells in four other PKD mouse models (cpk, *Six2creFrs2αKO, Pkd1$^{RC/RC}$* and *Thm1CKO),* and compared staining between ADPKD patients and normal controls.

Results: *Pkd2* is expressed in all segments from proximal tubule to CD, and in all CNT/CD cell types. *Pkd2$^{f/f}$ Aqp2Cre* mice developed severe PKD and died ~P17. The kidneys showed a reduced IC to PC ratio and a complete lost of α-IC by P12. Cysts extended from the CD to DCT1 and possibly to the loop of Henle, but not to the proximal tubules. *Pkd2$^{f/f}$ Aqp2Cre* mice had obvious cysts by P6 with rare α-IC. IC were more apoptotic than PC. Ablation of *Pkd2* in neonate or adult AP and PC in *Aqp2$^{ECE/+}$ Pkd2$^{f/f}$* mice did not cause PKD. Cyst-lining α-IC were found in the other PKD models. AQP2$^+$ cells were found in the cysts of only 13 out of 27 ADPKD samples, which had a diminished IC to PC ratio. None of the ADPKD kidneys had α-IC within the AQP2$^+$ cysts.

Conclusions: *Pkd2* deletion in embryonic AP, but not in neonate or adult Aqp2$^+$ cells (PC and AP), was sufficient for PKD development. IC, particularly α-IC, were selectively depleted in *Pkd2$^{f/f}$ Aqp2Cre* mice and ADPKD patients. We proposed that *Pkd2* is critical for maintenance of cystic α-IC.

The Direct Physical Interaction Between Calcium-Sensing Receptor and Polycystin-2: Implication in Autosomal Dominant Polycystic Kidney Disease (ADPKD)

Annarita Di Mise,[1] Maria Venneri,[2] Angela Ferrulli,[1] Marianna Ranieri,[1] Mariangela Centrone,[1] Rosa Caroppo,[1] Grazia Tamma,[1] Giovanna Valenti.[1]
[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Istituti Clinici Scientifici Maugeri SpA SB IRCCS, Pavia, Italy.

Background: ADPKD is a ciliopathy caused by mutations in *PKD1* or *PKD2* genes, encoding polycystin-1 (PC1) and polycystin-2 (PC2), respectively, which form a complex localized to the primary cilium. PC2 is a member of the transient receptor potential polycystic (TRPP) family of cation channels acting as a non-selective cation channel which, in the primary cilium of renal epithelial cells, preferentially conducts K^+ and Na^+ over Ca^{2+} ions. In this study, we explored the possibility that the Calcium Sensing Receptor (CaSR) is involved in PC2 functional regulation.

Methods: Human conditionally immortalized Proximal Tubular Epithelial cells isolated from urine sediments (ciPTECwt) and with stably down-regulated *PKD2* (ciPTEC-PC2KD), expressing endogenous CaSR, were used as experimental tools.

Results: Immunofluorescence experiments showed the expression of both CaSR and PC2 on the primary cilium. CaSR and PC2 co-immunoprecipitated both in ciPTEC and mouse kidney. Worthy of note, Proximity Ligation Assay demonstrated the direct interaction between CaSR and PC2 in both ciPTEC and mouse kidney slices. Preliminary electrophysiological measurements demonstrated that, in ciPTEC, CaSR activation caused plasma membrane hyperpolarization, consistent with modulation of cation channels. Interestingly, the membrane hyperpolarization induced by the activation of CaSR in ciPTEC-PC2KD was significantly lower with respect to ciPTECwt.

Conclusions: These studies underline the functional coupling of CaSR with PC2, providing a rationale for the amelioration of the principal cellular ADPKD dysregulations observed in our previous studies in ciPTEC-PC1KD exposed to calcimimetics (CaSR allosteric modulators) as well as in animal models of ADPKD.

Molecular Basis of the Regulation of a Gain-of-Function Polycystin-2 Channel by Small Molecule Ligands

Zhifei Wang, Yong Yu. *St. John's University, Queens, NY.*

Background: Mutations in PKD2 gene lead to autorsomal dominant polycystic kidney disesae (ADPKD). PKD2 encodes polycystin-2 (PC2) protein. As a member of the transient receptor potential (TRP) channel superfamily, PC2 functions as a non-selective cation channel. The activation and regulation of PC2 channel is largely unknown and no small molecule ligand of PC2 has been reported.

Methods: We expersssed human PC2 channel in *Xenopus oocytes*, and used two-electrode voltage clamp (TEVC) method to record the ion channel function.

Results: In this work, we tested the effect of a group of know TRP channel small molecule agonists on PC2 channel funciton, and found that while most of them inhibit the activity of PC2_F604P, a gain-of-function PC2 mutant PC2 channel, some others have a dual regulating effect with low concentration further activates PC2_F604P, and high concentration leads to inactivation of the channel. We identified two distinct binding sites of the ligand in PC2_F604P that are responsible for activation and inactivation respectively. Our results also suggest that Ca^{2+} binding at the outer pore region is essential for ligand-induced inactivation.

Conclusions: These results provide structural and functional views of the interaction between PC2 and small molecule ligands and showcase how ligands can regulate channel function in unusual mechanisms.

Transcriptomic Analysis of Pkd2-Deficient Kidneys Shows Altered Metabolic and Cytoskeleton Pathways Similar to Pkd1 Models and Evidence of an Increased Inflammatory Response

Patricia Outeda,[1] Luis F. Menezes,[2] Denis Basquin,[1] Terry J. Watnick.[1]
[1]Division of Nephrology, Department of Medicine, University of Maryland School of Medicine, Baltimore, MD; [2]National Institutes of Health, Kidney Disease Branch/National Institute of Diabetes and Digestive and Kidney Disease, Bethesda, MD.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is characterized by fluid-filled cysts and progressive enlargement of the kidney. Mutations in either *PKD1* or *PKD2* genes, encoding polycystins 1 and 2, are responsible for the disease. Despite advances in understanding polycystins structure and function, how mutations in PKD genes lead to cystogenesis is still unknown. While dozens of studies have investigated the transcriptome of human and mouse *PKD1* mutant kidneys, none focused on *PKD2* deficient kidneys. Here we report RNAseq from *Pkd2* cystic kidneys from a slow progression model.

Methods: We induced *Pkd2* deletion at P27 (postnatal day 27) in a strain that inactivates *Pkd2* in the renal epithelium. We isolated RNA from kidneys at P125 from 10 males and 10 females (5 *Pkd2$^{fl/fl}$; Pax8rtTA-Cre* (+) and 5 littermate *Pkd2$^{fl/fl}$; Pax8rtTA-Cre* (-) per set) and sequenced using and Illumina NovaSeq 6000 S4 system. Sequence reads were mapped to mm10 mouse genome and counted using STAR. Differential gene expression and pathway analyses were done in R using DESeq2, clusterProfiler and fgsea.

Results: Transcriptomic analysis identified ~1976 significantly differentially expressed (DE) genes (adjusted $p < 0.05$), of which 622 were only DE in males and 229 in females. In both sexes, injury markers were up-regulated and pathway analyses suggested increased chemokine activity. Gene set enrichment analysis suggested enrichment of up-regulated genes in inflammatory pathways and down-regulated genes in oxidative phosphorylation and fatty acid metabolism, similar to what is observed in *Pkd1* knockout kidneys. Approximately 700 DE genes in *Pkd2* knockout kidneys were also DE in *Pkd1* knockout kidneys. Pathway analysis of DE genes in both *Pkd1* and *Pkd2* models showed enrichment of genes involved in cytoskeleton, actin biding and encoding proteins in the kinetochore.

Conclusions: The data suggest an increased inflammatory response in *Pkd2* knockout kidneys and some of the transcriptional changes previously reported in *Pkd1*. The presence of injury markers suggests that some of these differences could be secondary to kidney injury. Meta-analysis of *Pkd1* and *Pkd2* knockout kidneys implicate changes in cytoskeleton and actin signaling as common pathways.

FR-PO573

Generation of a New Mouse Model Harboring the Polycystin-2 Loss-of-Function D511V Patient Variant

Patricia Outeda,[1] Courtney J. Haycraft,[2] Denis Basquin,[1] Pamela V. Tran,[3] Stephen C. Parnell,[3] Paul G. DeCaen,[4] Darren P. Wallace,[3] Bradley K. Yoder,[2] Terry J. Watnick.[1] On Behalf of the Polycystic Kidney Disease Research Resource Consortium (PKD-RRC).
[1]Deparment of Medicine/Division of Nephrology, University of Maryland, School of Medicine, Baltimore, MD; [2]Department of Cell, Developmental and Integrative Biology, Heersink School of Medicine, Birmingham, AL; [3]The Jared Grantham Kidney Institute, University of Kansas Medical Center, Kansas City, KS; [4]Department of Pharmacology, Feinberg School of Medicine, Northwestern University, Chicago, IL.

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is one of the most frequent renal genetic disorders caused by genetic mutations in either *PKD1* or *PKD2* genes, which encodes for protein products polycystin-1 (PC1) and polycystin-2 (PC2), respectively. The molecular pathogenesis of ADPKD and the function of polycystins is an area of active research. PC2 subunits can form ion channels within organelle membranes such as the ER and primary cilia, or it can form channel complexes with PC1. There remains a need to develop novel animal models to mimic mutations observed in humans to study the allelic contributions of PKD genes, and to understand the impact of ADPKD-causing variants. To date there are no mouse models with *Pkd2* missense variants.

Methods: We used CRISPR/Cas9 gene editing to engineer a new *Pkd2* mouse model with the human pathogenic variant D511V (D509V in the mouse, *Pkd2^{D509V}*). This *Pkd2* variant affects a highly conserved region in the voltage-sensor domain (VSD). Prior studies in cell models showed that PKD2^{D511V} encodes a temperature sensitive mutant protein that is more stable at 27°C versus 37°C, interacts with PC1 and can traffic to cilia. Nonetheless this protein is "channel-dead" in ER vesicles.

Results: We found that heterozygous *Pkd2^{D509V}* mice are viable and fertile but initial studies suggest that homozygous carriers are embryonically lethal, as no homozygotes were alive at P0 (postnatal day 0). We are in the process of determining the cause of embryonic lethality and of measuring PC2^{D509V} protein abundance and ciliary localization *"in vivo"* and *"in vitro"*. We will examine the functional role of the PC2^{D509V} variant in maintaining kidney homeostasis in adult and postnatal kidneys by crossing it to a renal tubule specific inducible *Pkd2* mouse model.

Conclusions: The generation of this new *Pkd2^{D509V}* model provides a relatively rapid system to: 1) study the roles of PC2 *"in vivo";* 2) decipher the pathogenic mechanisms leading to cyst formation after inactivating the channel activity of PC2 and 3) may be useful for precision medicine applications using patient-derived variants.

FR-PO574

Epigenetic Age Is Accelerated in ADPKD Kidneys and Is Regulated by Autophagy-Mediated DNA Methyltransferase

Lu Li,[1,2] Xiaoyan Li,[1,2] Peter C. Harris,[1,2] James P. Calvet,[3] Xiaogang Li.[1,2]
[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN; [3]University of Kansas Medical Center Department of Biochemistry and Molecular Biology, Kansas City, KS.

Background: The epigenetic clock (DNA methylation age) is characterized by changes in DNA methylation (DNAm) levels across specific CpG sites that are associated with chronological age, diseases and mortality. Epigenetic age acceleration (EAA), the residual variation in DNAm age, indicates whether individuals and specific organs are aging faster or slower than their chronological age in response to endogenous and exogenous factors. Whether epigenetic age is regulated by autophagy and accelerated in ADPKD kidneys remains unknown.

Methods: To investigate an association between epigenetic clock/EAA and autophagy in ADPKD, we performed single cell RNA sequencing (scRNA-seq), whole-genome bisulfite sequencing (WGBS), Western blot and qRT-PCR analysis.

Results: We found that 353 human and 329 mouse CpG dinucleotide DNA methylation markers correspond to 309 human genes and 224 mouse genes. Our scRNA-seq analysis

indicated that the numbers of dysregulated epigenetic clock associated genes were 48, 33 and 70 in collecting duct cells; 8, 14 and 44 in macrophages; and 2, 14 and 57 in fibroblasts in day 7, 14 and 21 *Pkd1* homozygous kidneys compared to the same cell types in age matched *Pkd1* heterozygous kidneys. The differential methylation status of these epigenetic genes and the specific methylation sites on these genes were identified in ADPKD kidneys compared to normal individuals as examined by WGBS. The dysregulation of epigenetic clock genes is associated with a gradual upregulation of DNA methyltransferase1 (DNMT1), the only DNMT responsible for maintaining DNA methylation, in day 7, 14 and 21 *Pkd1* homozygous kidneys. DNMT1 interacted with ATG7, a key player of autophagy. Treatment with the autophagy inhibitor, Lys05, increased DNMT1 protein, whereas treatment with autophagy inducer decreased DNMT1 protein in kidneys, supporting that autophagy is involved in DNMT1 mediated epigenetic age acceleration in ADPKD. We also found that the methylation status of four epigenetic clock genes, including *Apoe, Cldn4, Mgp* and *Slc38a2,* are potential biomarkers that indicate epigenetic age acceleration in ADPKD kidneys.

Conclusions: Autophagy is a key player of DNMT1 mediated epigenetic age and cyst growth in ADPKD kidneys. Targeting DNMT1 and inducing autophagy should have a synergistic effect on decreasing cyst growth and epigenetic age acceleration.

FR-PO575

Tumor-Associated Calcium Signal Transducer 2 (Tacstd2) Expression Is Increased in Early Polycystic Kidney Disease

Abigail O. Smith,[1,2] William T. Frantz,[1,3] Kenley M. Preval,[1] Yvonne J. Edwards,[4] Julie A. Jonassen,[1] Gregory J. Pazour.[1] *[1]University of Massachusetts Chan Medical School, Worcester, MA; [2]Boston Children's Hospital, Boston, MA; [3]Yale New Haven Hospital, New Haven, CT; [4]The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL.*

Background: Autosomal Dominant Polycystic Kidney Disease (ADPKD) is caused by polycystin gene mutations, leading to kidney cysts. Cysts grow via abnormal epithelial proliferation and secretion. Despite known mutations and pro-cystic pathways, the initiating transcriptional events in cyst formation are unclear. By studying pre-cystic ADPKD mice, we found new candidate genes for cyst initiation.

Methods: *Pkd2^{fl}; CAG-Cre^{ERT2}* pups received tamoxifen via IP injection on postnatal day 2 (P2). RNA was isolated on P6 and P10, followed by library preparation and analysis. Results were compared to published data and mouse and human kidney tissues were stained to confirm epithelial candidate localization.

Results: We found 91 differentially expressed genes (DEGs) in pre-cystic kidneys (P6) and 5,309 DEGs at the early cystic timepoint (P10) (FDR<0.05). P6 and P10 overlapping DEGs include 74 genes, defined as cyst initiation candidates (CICs). We characterized CICs using published datasets (bulk RNAseq from alternative early ADPKD models, single-cell RNAseq from healthy mouse kidney and human ADPKD patients). Tacstd2 emerged as a promising candidate due to its epithelial specificity. Experiments showed high Tacstd2 expression in cystic-lining epithelium in mouse and human tissue.

Conclusions: 74 candidate cyst initiation genes warrant further investigation. Tacstd2 selectively labels cystic epithelium in *Pkd2* mice and humans with ADPKD. Antibody drug conjugates targeting Tacstd2 in human epithelial tumors have been approved by the FDA for treatment of metastatic triple-negative breast cancer and urothelial cancer. Adapting this technology may prove efficacious in ADPKD.

Heterozygous PKD Organoids Show Increased Sensitivity to Forskolin-Stimulated Cystogenesis

Chardai J. Thomas, Benjamin S. Freedman, Courtney E. Vishy. *University of Washington School of Medicine, Seattle, WA.*

Background: Polycystic kidney disease (PKD) is inherited as a single heterozygous loss-of-function mutation, but theorized to require additional loss-of-function to cause cystogenesis. Activation of cAMP can stimulate cystogenesis, but whether this happens in heterozygotes is not well understood. We set out to test this in human kidney organoids.

Methods: We established human pluripotent stem cells in allelic series using CRISPR base editing to introduce nonsense mutations previously documented in ADPKD patients – *PKD1* R2430X and Q3838X and *PKD2* R186X and R872X. Mutations were confirmed by sequencing and protein changes by immunoblot. Homozygous mutant, heterozygous mutant, and isogenic control stem cells were differentiated into kidney organoids to determine if nonsense mutations conferred a cystic phenotype. Each genotype was treated with 0 uM or 30 uM forskolin, a stimulant of the cAMP pathway.

Results: Heterozygous cells expressed ~50% of PC1 or PC2 protein compared to controls. When differentiated into human kidney organoids, homozygous mutants spontaneously formed cysts whereas heterozygous mutants expressed no detectable phenotype, similar to non-mutant controls. Following forskolin treatment, heterozygous organoids showed a significant increase in the number of cysts formed which was not observed in homozygous mutant or non-mutant organoids (Figure 1).

Conclusions: Heterozygosity alone is insufficient to cause expression of PKD phenotypes in human kidney organoids. However, when treated with forskolin, heterozygosity sensitizes tubules to become cystic. Thus, even partial loss of function may enhance the PKD phenotype in the context of high levels of cAMP.

Funding: NIDDK Support

Organoid Model of Polycystic Kidney Disease Recapitulates Clinically Relevant Symptoms and Identifies Candidate Drugs

Meng Liu, Chao Zhang, Tian Zhang, Angelysia Cardilla, Yun Xia. *Nanyang Technological University, Singapore, Singapore.*

Background: Polycystic kidney disease (PKD) is one of the most common genetic kidney diseases, characterized by the progressive expansion of fluid-filled cysts in the kidney. Currently, there are limited treatment approaches for PKD. Advances in generating kidney organoids from human pluripotent stem cells (hPSCs) have helped overcome many of the drawbacks of the traditional mouse and 2D cell culture models. Alongside genetic editing, these organoids have been used to investigate the pathogenic mechanisms of PKD and to screen for potential drugs.

Methods: Herein, we have generated a collection of kidney organoids from both ARPKD and ADPKD patient-derived iPSCs, as well as genetically engineered hPSCs. Subsequently, we employed stress paradigms to modulate intracellular levels of cAMP or Ca^{2+} for inducing cystogenesis. We further characterized the structural and functional abnormalities in PKD kidney organoids using a multitude of analyses, including cell biology, molecular biology, biochemistry, and single nuclei RNA-sequencing. Finally, we performed a small-scale drug screening to identify candidate drugs.

Results: PKD kidney organoids developed tubular cysts in response to upregulation of intracellular cAMP or downregulation of Ca^{2+} homeostasis. Multiple structural and functional abnormalities were observed in PKD organoids, including hyper-proliferation of cystic epithelial cells, increased fluid secretion, tubular injury and dedifferentiation, as well as aberrant renin release which are commonly observed in PKD patients. Employing cystic index as the readout, we identified two candidate drugs that can effectively attenuate cyst formation in PKD organoids.

Conclusions: hPSCs derived organoid model of PKD can faithfully recapitulate critical structural and functional characteristics of PKD which would serve as an invaluable tool to investigate PKD pathogenesis and to discover potential therapeutics.

Epithelial-Mesenchymal Cross-Talks in Murine Models of Renal Ciliopathy

Zhaoxia Sun,[1] Chia-Ling Hsieh,[1] Yuanyuan Li,[1] Wenyan Xu,[1] Svetlana Z. Makova,[2] Martina Brueckner.[2] *[1]Yale University School of Medicine Department of Genetics, New Haven, CT; [2]Yale University School of Medicine Department of Pediatrics, New Haven, CT.*

Background: Ciliary defects underpin a variety of renal ciliopathies, including polycystic kidney disease and Nephronophthisis (NPHP). Both epithelial and stromal abnormalities are manifested in these diseases. Previously, to clarify the role of different cell types in disease progression, we utilized tissue specific mouse models of *Arl13b*, a cilia biogenesis gene, and *Invs/Nphp2*, a NPHP gene that encodes a protein localized to the proximal part of the cilium. Our results showed that epithelial specific knockout of *Arl13b* or *Invs/Nphp2* was sufficient to cause both epithelial cyst and interstitial fibrosis. By contrast, stromal specific knockout of *Invs/Nphp2* showed no obvious renal phenotypes up to the young adult stage, suggesting that epithelial cells are the main driver of the phenotypes and abnormal signaling from epithelial cells triggers interstitial fibrosis. Moreover, when *Arl13b* was specifically deleted in epithelial cells, Hedgehog signaling (HH) was activated non-cell autonomously in stromal cells and global pharmacological inhibition of HH signaling ameliorated fibrosis, kidney function decline and cyst progression, revealing a critical role of epithelial-mesenchymal crosstalk in disease progression. Combined, these results highlighted not only the importance of epithelial cells, but also epithelial-mesenchymal communications that include HH signaling in the molecular etiology of renal ciliopathy. However, the role of cilia in stromal response to epithelial signaling remains unclear.

Methods: In this study, we generated genetic mutants with *Invs/Nphp2* and cilia biogenesis genes deleted in both epithelial and stromal cells and will investigate the renal phenotypes of the mutant mice. We further investigated cilia distribution in stromal cells.

Results: Our results suggest that cilia are present on stromal cells. Further phenotypic analysis will reveal whether cilia and *Invs/Nphp2* in stromal cells modify the phenotypes triggered by defective epithelial cells.

Conclusions: Tissue specific function of cilia and ciliary genes plays a role in epithelial-mesenchymal crosstalks in renal ciliopathy.

FR-PO579

Lyve1+ Macrophages Play No Role in Initiating Polycystic Kidney Disease

Laura Wilson,[1] Adrian S. Woolf,[2] David A. Long.[1] *[1]University College London, London, United Kingdom; [2]The University of Manchester, Manchester, United Kingdom.*

Background: Recent studies show macrophages modulate progression of polycystic kidney disease (PKD). As examples, depletion of macrophages chemically with clodronate or genetically by deleting macrophage chemoattractant protein 1 (MCP1) reduces PKD severity. We hypothesised that a specific population of macrophages may be needed to initiate kidney cystogenesis.

Methods: We characterised macrophage subpopulations in cystic *Cpk* and *Pkd1*^{RC} mouse kidneys from the embryonic period. Additionally, we specifically depleted Lyve1^{+} macrophages by crossing *Lyve1-Cre* with *Csf1r-floxed* mice in the context of wild type and *Cpk* mice.

Results: Using macrophage-specific markers F4/80 and CD11b, we identified two populations of macrophages (F4/80^{hi}CD11b^{lo} and F4/80^{lo}CD11b^{hi}) by flow cytometry. CD206, Lyve1, TIMD4 and CCR2 markers were used to further characterise the subpopulations. Renal F4/80^{hi}CD11b^{lo} macrophages were CD206^{+}, some expressed Lyve1 and some were TIMD4^{+}. F4/80^{lo}CD11b^{hi} macrophages were CCR2^{+} and negative for the other markers. At embryonic day 18.5, when homozygous *Cpk* and *Pkd1*^{RC} mutant mice have dilated tubules, there was a significant increase in the proportion of Lyve1^{+} macrophages in mutant compared with wild-type kidneys, with no changes in other populations. By studying a detailed time course of *Cpk* disease progression, we observed the initial accumulation of Lyve1^{+} macrophages was followed by an increase in F4/80^{hi}CD11b^{lo} macrophages in kidneys as cysts initiate. All macrophage populations were significantly increased in severely cystic kidneys. Depleting Lyve1^{+} macrophages did not compromise kidney development in non-PKD-mutant mice, with no significant change in glomerular numbers in *Lyve1-Cre Csf1r*$^{fl/fl}$ embryos. There were no differences in PKD severity between *Cpk*$^{-/-}$ and Lyve1^{+} macrophage-depleted *Cpk*$^{-/-}$ mice based on kidney/body weight, renal cystic index and blood urea nitrogen two weeks after birth.

Conclusions: Lyve1^{+} macrophages accumulate before PKD cysts initiate during embryonic development. Genetic depletion of Lyve1^{+} macrophages from this period, however, does not affect the severity of PKD.

FR-PO580

The Immune Checkpoint Protein PD-L1 Interacts with BBS5 to Regulate Ciliogenesis and Hedgehog Signaling

Ewud Agborbesong,[1,2] Xiaoyan Li,[1,2] Xia Zhou,[1,2] James P. Calvet,[3] Peter C. Harris,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN; [3]University of Kansas Medical Center Department of Biochemistry and Molecular Biology, Kansas City, KS.*

Background: Programmed cell death 1 ligand 1 (PD-L1) is an immune checkpoint protein regulates the immune synapse, a structure formed between immune cells and share structural and functional homology to primary cilium. However, whether and how PD-L1 regulates ciliogenesis remains elusive.

Methods: To investigate the role of PD-L1 on ciliogenesis, we performed immunostaining, Western blot, and qRT-PCR analysis in mouse NIH3T3 fibroblasts and human retinal pigment epithelium (RPE) cells. We also performed co-immunoprecipitation analysis to examine the interaction between PD-L1 and cilia associated proteins.

Results: We found that PD-L1 is located at the basal body and the Golgi apparatus as seen by its co-localization with centrosome marker γ-tubulin, Golgi associated protein Ift20, and Golgi marker Giantin. Knockdown of PD-L1 resulted in an increase in percentage of ciliated cells and average cilia length in 3T3 and RPE cells, whereas that overexpression of GFP-PD-L1 inhibited ciliogenesis in those cells. Consistent with this result, we found that serum starvation, which induces ciliogenesis, resulted in the downregulation of PD-L1 levels. Knockdown of PD-L1 increased the accumulation of Rab8a, BBS5 and polycystin 2 along the cilia axoneme in 3T3 cells but decreased the accumulation of Ift140 along the cilia in 3T3 cells and RPE cells. In addition, we found that the protein levels of BBS5, IFT20 and Rab8a were upregulated in PD-L1 knockdown 3T3 and RPE cells. We also found that PD-L1 formed a complex with BBS5 by co-immunoprecipitation analysis, and that knockout of BBS5 in PD-L1 knockdown 3T3 cells decreased the accumulation of polycystin 2 along the cilia. However, knockdown of BBS5 did not affect the localization, or protein level of PD-L1. We further found that knockdown of PD-L1 resulted in 1) the accumulation of the components of the hedgehog signaling pathway, including Smoothened (Smo) and Gli3, on cilia axoneme in 3T3 cells, 2) the upregulation of mRNA and protein levels of Gli1 and Gli3, and 3) the downregulation of Smo, Gli2 and Ptch1 proteins but not their mRNAs.

Conclusions: This study shows that PD-L1 is a novel basal body/Golgi component to regulate ciliogenesis and polycystin 2 ciliary trafficking through BBS5 and connects for the first time an immune checkpoint protein with ciliopathies, and possibly immune response.

FR-PO581

Role of Interferon-Gamma in Cyst Formation After AKI

Morgan E. Smith,[1] Ummey Khalecha Bintha Ahmed,[1] Katharina Hopp,[2] Kurt Zimmerman.[1] *[1]The University of Oklahoma Health Sciences Center, Oklahoma City, OK; [2]University of Colorado Anschutz Medical Campus Department of Medicine, Aurora, CO.*

Background: Acute kidney injury (AKI) is known to accelerate cystogenesis in conditional ciliopathy (*Ift88*) mice. Our lab previously showed that genetic deletion of adaptive immune cells significantly reduced cystic disease in *Ift88* mice after AKI. Additionally, using single-cell RNA sequencing, we found that T cells isolated from conditional *Ift88* mice after AKI had enriched expression of the cytokine interferon-gamma (IFN-γ). Based on these data, we hypothesize that T-cell-derived IFN-γ is a significant contributor to the accelerated cystogenesis that is seen following AKI in ciliopathy mice.

Methods: To test this hypothesis, we crossed conditional *Ift88* mice to mice lacking IFN-γ. At 8 weeks of age, we induced loss of *Ift88* and primary cilia through tamoxifen injection followed by administration of folic acid to induce AKI at 11-12 weeks of age; sodium bicarbonate solution was used as a vehicle-only control. Kidneys were harvested 56 days post-injury and cystic severity was measured by quantifying cystic index. We also analyzed changes in immune cell populations at the same time point using flow cytometry.

Results: Analyses of cyst severity 56 days post AKI indicate that conditional *Ift88* IFN-γ knockout mice had a significant reduction in the severity and number of renal cysts compared to conditional *Ift88* IFN-γ control mice. Analysis of flow cytometry data indicates a correlative reduction in the number of kidney resident macrophages and neutrophils in the conditional *Ift88* IFN-γ knockout AKI mice compared to conditional *Ift88* IFN-γ control AKI mice.

Conclusions: Collectively, our data indicate that T-cell-derived IFN-γ is a major contributor to accelerated cystic disease that is observed in conditional *Ift88* mice post AKI. Ongoing studies are addressing the specific T cell subset involved in injury-accelerated disease and the potential mechanism through which IFN-γ accelerates cystic disease in conditional *Ift88* mice following AKI.

FR-PO582

The CPLANE Protein Fuzzy Regulates Primary Ciliogenesis Through Actin Remodeling

Rita K. Kalot,[1,2] Sima Babayeva,[1] Elena Torban.[1,2] *[1]McGill University Health Centre, Montreal, QC, Canada; [2]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada.*

Background: Defects in primary cilia cause a set of diseases termed ciliopathies manifesting in developmental defects including cystic/dysplastic kidneys. Mutations in ciliogenesis and planar cell polarity (CPLANE) genes *FUZZY*, *INTURNED*, and *WDPCP* lead to a ciliopathy spectrum with abnormal kidney phenotypes. Although Fuzzy ortholog in *D.Melanogaster* was identified as a part of the planar cell polarity and actin regulatory pathway, its functions in primary cilia assembly and ciliopathies remain largely unknown. We hypothesize that Fuzzy modulates actin-assembly involved in primary cilia formation.

Methods: The interactions between Fuzzy-Flag, p190A RhoGAP and IQGAP1-GFP were assessed by co-Immunoprecipitation. Rhotekin G protein-binding domain-eGFP biosensor in mutant and control mouse embryonic fibroblast (MEF) cells was used to measure RhoA activity. IQGAP1 was knocked down by siRNA in Retinal Pigmented Epithelial cells (RPE-1). Overexpression of Fuzzy-GFP was done by stable transfection in MDCK cells. Immunofluorescence with gamma-tubulin, Arl13b and phalloidin was used for cilia assessment.

Results: We established that Fuzzy interacts with p190A RhoGAP and controls its localization to the basal body. Normally, p190ARhoAGAP localizes to the primary cilia base and inactivates the actin-regulating protein RhoA. However, in Fuzzy mutant cells, RhoA is excessively activated. We also demonstrate that Fuzzy interacts with IQGAP1 – a protein that facilitates the interaction between p190ARhoGAP and RhoA. siRNA-mediated knockdown of IQGAP1 negatively affected ciliogenesis in RPE-1 cells. On the other hand, we show that Fuzzy is involved in regulation of the early stages of ciliogenesis: the overexpression of Fuzzy in MDCK cells triggered earlier cortical actin clearing at the apical membrane and earlier ciliogenesis.

Conclusions: We conclude that Fuzzy regulates the actin cytoskeleton at the primary cilium during the early and later stages of ciliogenesis. Fuzzy recruits p190A RhoGAP to the ciliary base and interacts with IQGAP1 resulting in the inhibition of RhoA and the suppression of excessive actin polymerization at the base of the cilium. Fuzzy is also involved in the process of actin clearing during the early stages of ciliogenesis, but the exact mechanism is yet to be elucidated.

Identification of Novel Targets for Autosomal Dominant Polycystic Kidney Disease Using a Patient Cell-Derived Cyst Model

Ryan E. Feaver, Banumathi K. Cole, Taylor Pourtaheri, Steve A. Hoang, Mark J. Lawson, Emile Velthuisen, Brian Johns, Robert A. Figler.
HemoShear Therapeutics, Inc. *HemoShear Therapeutics, Charlottesville, VA.*

Background: Autosomal dominant polycystic disease (ADPKD) is the most common potentially lethal monogenic disorder and the most inherited kidney disease. Therapeutic development in ADPKD has been hampered by the lack of understanding of how mutations in polycystin 1 or 2 lead to uncontrolled cyst growth and ultimately end-stage renal disease.

Methods: We developed a 3-dimensional *in vitro* cyst model consisting of primary human epithelial cells derived from the cyst walls of ADPKD patients. The cells progressively form fluid-filled cysts within a collagen-rich gel in the span of 5-10 days and can be quantified through high-content imaging. To validate this model, a transcriptomic time course was obtained during cyst development and compared to transcriptomic signatures obtained from normal versus ADPKD biopsy tissue and secreted protein analysis of patient cyst fluid. Using data from these analyses, novel targets were assessed alongside established industry targets for their ability to inhibit cyst formation in the *in vitro* model.

Results: Comparing the transcriptomic signatures from the human *in vitro* model to patient tissue showed a high degree in overlapping responses and pathways that were consistent with the growth factors and chemokines confirmed to be present in patient cyst fluid. Clinical targets such as V2R, CFTR, and NRF2 showed varying effects in their ability to inhibit cyst formation. From our analysis, we hypothesized new targets based on the unbiased bioanalyses of the transcriptomic signatures, which showed equal or better inhibition of cyst formation in the model.

Conclusions: Mapping the response profile of over 50 therapeutic targets spanning diverse mechanisms of actions in the validated ADPKD patient-derived cyst model has enabled prioritization of key signaling hubs that may represent promising new therapeutic targets for ADPKD.

FR-PO584

Primary Cilia Change Protein Composition in Response to Glutamine Deprivation

Anne K. Nielsen,[1,2] Maria Elena Steidl,[1] Mariam Aslanyan,[3] Sylvia E. van Beersum,[3] Daniel Spies,[1] Lotte B. Pedersen,[5] Karsten Boldt,[4] Ronald Roepman,[3] Alessandra Boletta.[1] *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy; [3]Radboud Universiteit, Nijmegen, Netherlands; [4]Universitatsklinikum Tubingen, Tubingen, Germany; [5]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: ADPKD is a genetic disorder in majority of cases caused by mutations in PKD1 and PKD21. Genes encode for Polycystin 1 and 2 which form a receptor-complex located to primary cilia. Primary cilia are sensory organelles that protrude from the cell membrane. From this extroverted position it responds to changes in the cellular environment and convey various signaling pathways to control cell function, such as cell maintenance. Our lab previously published that loss-of-function of Pkd1 leads to metabolic reprogramming. Recently we published the importance of glutamine availability during nutrients-stress conditions on cilia length. Demonstrating that primary cilia respond to nutrients availability and particularly to glutamine. We also showed that the glutamine response of cilia requires the presence of Asparagine Synthetase (ASNS), which localizes to the cilia-centrosome complex.

Methods: To follow up on these findings we set up a large-scale proteomics study using mIMCD3 cells expressing a ciliary target fused to the proximity labelling tag, BioID. We affinity purified biotinylated proteins specific to the cilium by taking advantage of the high affinity of streptavidin coupled to beads. IP samples were analyzed with LC-MS. We generated an expression vector with ASNS fused to mNeonGreen fluorescent-tag and generated stable transfectants in IMCD3s.

Results: A first LC-MS analysis of proteins exclusively observed in cilia of cells grown in medium with or without glutamine revealed a total of 22 proteins significantly changing with removal of glutamine. A few proteins were found to change both in expression levels and in ciliary abundance. Among these, ASNS was upregulated with removal of glutamine in both the cytoplasm, and in the cilium. In line with these findings live imaging and IF performed with mNG-ASNS IMCD3s showed ASNS localizing not only at the base of the cilium, as we reported, but also within the axoneme. To accumulate ASNS in the cilium we treated mNG-ASNS cells with CilioBrevin D which inhibits dynein proteins and found that ASNS accumulates at the tip of the cilium.

Conclusions: Our data demonstrate that primary cilia respond to glutamine removal by changing their protein composition. And that the enzyme ASNS is among the proteins responding to glutamine availability.

FR-PO585

Dissecting Heterogeneity and Common Pathogenetic Pathways in Autosomal Dominant Tubulointerstitial Kidney Disease due to Mutations in REN

Celine Schaeffer,[1,2] Maurizio De Fusco,[1] Elena Pasqualetto,[1] Caterina Scolari,[1] Claudia Izzi,[3,4] Francesco Scolari,[3,4] Luca Rampoldi.[1,2] Molecular Genetics of Renal Disorders. *[1]IRCCS Ospedale San Raffaele, Milano, Italy; [2]Universita Vita Salute San Raffaele, Milano, Italy; [3]Universita degli Studi di Brescia, Brescia, Italy; [4]Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy.*

Background: Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD) is a rare genetic disorder characterised by renal tubulointerstitial fibrosis and progressive chronic kidney disease. ADTKD is caused by mutations in different genes including *REN* encoding renin, a key player in the regulation of salt and blood pressure homeostasis. Renin is a secreted protein composed of 3 domains: the leader peptide allowing its insertion in the endoplasmic reticulum (ER), a pro-segment regulating its aspartyl protease activity, and the mature part. Mutations in mature renin lead to ER retention of mutant protein and to a late onset disease, while mutations in the leader peptide, associated with defective ER translocation, and mutations in the pro-segment, accumulating in the ER-to-Golgi compartment, lead to early onset disease.

Methods: We used transiently and stably transfected cells as well as an inducible system of renin expression to investigate the effect of mutations on renin trafficking.

Results: We demonstrated an unprecedented effect of mutations in the leader peptide and pro-segment leading to full or partial mistargeting of mutated protein to mitochondria. By studying GFP-fusion constructs we observed that the pre-pro sequence of renin, carrying mutation in either the leader peptide or the pro-segment, is necessary and sufficient to drive mitochondrial rerouting. In turn, this leads to mitochondrial import defect and mitochondria fragmentation. Induction of the 3 branches of the Unfolded Protein Response is observed in cells expressing renin mutated in the mature part, while induction of the IRE1 branch only is observed for the other mutants. Interestingly, the chronic expression of all mutants leads to toxicity and cell death.

Conclusions: Our results unravel a common cellular phenotype for mutants in the leader peptide and pro-segment (i.e. mitochondrial mistargeting) associated with an early-onset disease that differs from the one associated with mutants in the mature part (i.e. ER retention) that lead to a late onset disease. We currently aim at understanding how expression of these different mutants eventually converges to kidney inflammation and fibrosis by characterising stress signals emerging from the ER and mitochondria.

Antisense Oligonucleotide Knock Down of Uromodulin: A Potential Treatment Autosomal Dominant Tubulointerstitial Kidney Disease (ADTKD)

Kathy Y. Morgan, Nino Jungels, Tushare Jinadasa, Christopher Greer, Stephanie Garcia, Xuyu Tan, Kailash Adhikari, Vincent Guerlavais, Kevin Kim, Ryan A. Oliver, Annika Malmberg. *Sarepta Therapeutics Inc, Cambridge, MA.*

Background: Autosomal Dominant Tubulointerstitial Kidney Disease-Uromodulin (ADTKD-UMOD) is a genetic disease caused by destabilizing mutations in the uromodulin (UMOD) or Tamm-Horsfall protein. Misfolded UMOD protein aggregates and accumulates inside the loop of Henle and the distal convoluted tubule, leading to progressive and irreversible chronic kidney disease. We hypothesized that peptide-conjugated phosphorodiamidate morpholino oligomers (PPMOs) could knock down *UMOD* expression and potentially reduce the disease-causing UMOD aggregation inside the cells.

Methods: A library of PPMOs was designed to bind to the complementary sequences of the mouse *Umod* gene and induce nonsense-mediated decay. These PPMOs were screened in mIMCD-3 cells, which express endogenous transcript to identify the most active compounds. The most efficacious PPMO compound was tested in both wildtype and UMOD C93F mice, a well characterized disease model of ATDKD, to determine the ability of the PPMO to reduce UMOD expression at the transcript and protein levels.

Results: A single dose of lead PPMO resulted in a 70% knockdown of *Umod* transcript that led to protein reduction that was sustained for at least 28 days. Furthermore, UMOD protein expression was reduced in the UMOD C93F animals after a single dose of PPMO.

Conclusions: This study shows the ability of PPMO technology to reduce UMOD transcript and protein levels *in vitro* and *in vivo.*

FR-PO587

Retinal Oxalosis: An Unusual Presentation of Hyperoxaluria

Tyler Maggio, Meenakshi Sambharia. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Introduction: Hyperoxaluria can be primary due to inherited disorders of enzymatic defects in the glyoxylate pathway causing decreased oxalate metabolism, or secondary from increased intestinal absorption. Type 1 primary hyperoxaluria (PH) is typically diagnosed in infancy/childhood, leading to kidney failure by the fourth decade of life with more mild presentation in types 2 and 3. Retinal oxalosis is a rare finding, especially in adults. Herein we describe a case of suspected primary hyperoxaluria diagnosed late in life causing rapid decline in kidney function and vision loss.

Case Description: An 81-year-old woman with history of coronary artery disease, melanoma, hypertension, CKD stage 2 was referred to kidney clinic for rapid worsening of kidney function. History was pertinent for left nephrectomy at age 15 presumably from kidney stones/pyelonephritis. Kidney function began rapidly deteriorating 6-8 months prior to the referral with minimal proteinuria (random urine protein creatinine ratio of 0.22) and no hematuria. Kidney biopsy was performed which showed calcium oxalate crystal deposition. Except for 4-6 glasses of iced tea daily, no other risk factors could be identified. Despite dietary restriction of oxalate, her kidney function decline continued, warranting peritoneal dialysis (PD) initiation. Four months post PD initiation she developed sudden worsening of vision and was found to have oxalate retinopathy after extensive evaluation ruling out other causes. Primary hyperoxaluria was suspected and she was referred for genetic testing at the kidney genetics clinic at our institution.

Discussion: Dialysis patients are at high risk of systemic oxalosis due to poor oxalate removal by dialysis. Treatment for PH Type 1 includes combined liver and kidney transplant in those with kidney involvement. Other treatment options include high dose pyridoxine, oral citrate and hydration. Lumasiran -an RNA interference agent- has been approved for PH Type 1. In those with ESKD, daily dialysis/dialysis with high flux dialyzers has been attempted with limited benefit. Our patient refused to switch to hemodialysis. Genetic testing was performed, and results are pending. Despite aggressive treatment oxalate retinopathy is known to be irreversible. Hyperoxaluria is a rare cause of nephrolithiasis and kidney failure yet should remain on the differential in the setting of rapid decline of kidney function with no clear cause.

FR-PO588

Better Oxalate than Never: A Diagnosis of Primary Hyperoxaluria Made After Renal Transplantation

Justin J. Panthappattu, Zalman L. Suldan. *Hackensack Meridian Hackensack University Medical Center, Hackensack, NJ.*

Introduction: Primary hyperoxaluria (PH), a genetic impairment of glycoxylate metabolism, causes kidney injury and end-stage renal disease (ESRD) when left untreated. We present a case of PH diagnosed following deceased donor renal transplantation (DDRT).

Case Description: A 60 year old woman with ESRD on hemodialysis (HD) thought to be from hypertension with no prior kidney stones underwent DDRT. Post-reperfusion biopsy of the transplant showed mild tubular atrophy and interstitial fibrosis occupying 10-15% of the sampled cortex. Immunosuppression was induced with thymoglobulin and methylprednisolone and has been maintained on prednisone, belatacept and mycophenolic acid. Four years later, kidney stones were identified in the transplant. Cystoscopy and lithotripsy were performed with retrieval of a 100% calcium oxalate stone by analysis, prompting initiation of potassium citrate and pyridoxine. A 24-hour urinary oxalate collection revealed markedly elevated oxalate levels. Genetic testing revealed heterozygosity of the GRHPR alleles. One allele contained a known mutation for PH2. The other allele contained a mutation that likely rendered it nonfunctional. Pyridoxine has since been held and potassium citrate dose increased. The patient was counseled on adequate hydration and low oxalate intake. Nedosiran is being considered for this patient.

Discussion: PH is characterized by deranged metabolism of glycoxylate, causing accumulation of oxalate. Calcium oxalate then precipitates in the urine and deposits in the kidneys, causing inflammation and cortical scarring. While PH1 is more prevalent and classically thought to cause more rapidly-progressive disease, PH2 can also cause significant kidney injury despite its relative indolence. The condition is diagnosed by detection of increased urinary oxalate followed by confirmatory genetic testing. In the post-transplantation phase, kidney dysfunction secondary to hyperoxaluria can be confused for delayed graft function, defined as the use of HD in the seven days post-transplantation. In the absence of a clear etiology for the underlying native renal function, and with genetic testing becoming affordable, it may be worthwhile to consider genetic testing for underlying renal diseases that could affect a transplanted kidney with the intention of increasing the longevity of transplanted kidneys in the post-transplantation phase.

FR-PO589

Heart Failure Recovery After Lumasiran and Isolated Kidney Transplantation in Primary Hyperoxaluria Type 1

Gerlineke M. Hawkins-van der Cingel, Mira Choi, Andreas Kahl, Felix Schoenrath, Gregor Rehse, Kai-Uwe Eckardt, Felix Knauf, Fabian Halleck. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Introduction: Primary hyperoxaluria type 1 (PH1) is characterized by oxalate stones leading to kidney failure. In advanced PH1, systemic oxalate deposition may lead to heart failure. Lumasiran, a small interfering RNA, reduces oxalate load and may improve organ dysfunction in systemic oxalosis.

Case Description: A kidney biopsy revealed diffuse interstitial nephritis with massive oxalate deposition. Genetic testing confirmed two compound heterozygous Alanine-Glyoxylate Aminotransferase (AGXT) gene mutations. Our patient had peritoneal dialysis (PD) for 6 months. In addition, he suffered from severe heart failure (NYHAIII) with a left ventricular ejection fraction (LVEF) of 25%, marked left ventricular hypertrophy and a NTproBNP of >50,000pg/mL. A cardiac biopsy revealed severe oxalate deposition. Hemodialysis (HD) therapy was commenced to optimize volume overload and lower plasma oxalate (POx) levels. The initial POx level of 141.3µmol/L decreased to less than half after combined PD and HD. After starting lumasiran and high dose pyridoxine, POx levels further decreased to 29.2µmol/L. Subsequently, cardiac output improved to an LVEF of 35-40%. He received a living kidney donation from his father using standard immunosuppression and intensive hydration post transplantation. Daily oral pyridoxine and 3 monthly subcutaneous lumasiran was continued. At 3 months follow up, allograft function stabilized at a creatinine of 2.0 mg/dL. An allograft biopsy showed no oxalate deposition. His cardiac function improved further (NYHAI, LVEF 55%, NTproBNP of 449pg/mL) with a recent POx level of 11µmol/L.

Discussion: To our knowledge, this is the first case demonstrating complete remission of heart failure in a patient with PH1 following lumasiran therapy and isolated kidney transplantation. This underscores the utility of lumasiran and the conclusion that cardiac dysfunction related to PH1 is potentially reversible.

FR-PO590

Genetic Prevalence Estimates for All Types of Primary Hyperoxaluria

Giorgia Mandrile,[1] Gill Rumsby,[2] Veronica Sciannameo,[3] Peter C. Harris,[4] John C. Lieske,[4] Michelle Glover.[5] *[1]Azienda Ospedaliero Universitaria San Luigi Gonzaga, Orbassano, Italy; [2]UCL Hospitals, Kintbury, United Kingdom; [3]Universita degli Studi di Torino Scuola di Medicina, Torino, Italy; [4]Mayo Clinic Minnesota, Rochester, MN; [5]Novo Nordisk Inc, Plainsboro, NJ.*

Background: Primary hyperoxaluria is a rare disorder caused by biallelic pathogenic changes in 3 known genes (*AGXT* (PH1), *GRHPR* (PH2), *HOGA1* (PH3)). Affected patients have marked hyperoxaluria, frequent kidney stones, and are at high risk for kidney failure. Patients are often diagnosed late after they have developed severe disease complications, including systemic oxalosis. Given approved and emerging therapies for these diseases, it is important to understand the genetic prevalence of PH to determine the magnitude of missed diagnoses/reduced penetrance and develop strategies to improve patient outcomes.

Methods: Variants from all 3 genes were curated from OxalEurope, Rare Kidney Stone Consortium, ClinVar, and GnomAD registries in addition to an extensive literature review. Variants were scored as Pathogenic or Likely Pathogenic according to the 2015 ACMG guidelines using Intervar. Allelic frequencies were determined from GnomADv.2.1.1 after all identified variants were curated/reclassified and used to calculate the lifetime genetic prevalence of disease.

Results: The number of Pathogenic or Likely Pathogenic variants studied following comprehensive curation or reclassification of variants were 89 *AGXT*, 45 *GRHPR*, and 74 *HOGA1*. The following overall estimated genetic prevalence was determined: PH1 (1:209,357), PH2 (1:863,028), and PH3 (1:90,834) resulting in an estimated 17 per 1M individuals (136,000 individuals worldwide) with a lifetime possibility of developing PH regardless of ethnicity. The estimated carrier frequency is the following: PH1 (1:229), PH2 (1:465), and PH3 (1:151). Furthermore, ethnic groups were examined using post-curated variants showing the genetic prevalence is most predominant for PH1, PH2, and PH3 in the following populations respectively: East Asian (1:84,574), South Asian (1:390,788), and Ashkenazi Jewish (1:5,633).

Conclusions: Based on analysis of available genetic data, the estimated lifetime prevalence of PH is approximately 1:58,823 individuals globally. This is more common than currently diagnosed by at least an order of magnitude. The extent to which this is due to reduced disease penetrance or underdiagnosis is to be determined. Increasing access to diagnostic testing and continued curation of variants to the ClinVar registry is important to improve outcomes for all patients.

FR-PO591

Unlocking the Potential of Genetic Testing: Insights into Primary Hyperoxaluria and Monogenic Kidney Stone Disease

Michelle Glover. *Novo Nordisk Inc, Plainsboro, NJ.*

Background: Primary Hyperoxaluria (PH) is an autosomal recessive disorder that results in kidney stone disease and/or nephrocalcinosis affecting both pediatric and adult patients. Over time, the chronic disease progresses to end stage kidney disease (ESKD) necessitating a kidney and liver transplant. PH is divided into three types: PH1, PH2, and PH3, caused by mutations in *AGXT*, *GRHPR*, and *HOGA1* genes resulting in reduced enzyme activity and excess oxalate production. Nedosiran is an investigational RNA interference therapy holding the promise of mitigating excessive oxalate production and offering potential therapeutic benefits to patients suffering from this debilitating condition.

Methods: Novo Nordisk and PerkinElmer Genomics have partnered to provide sponsored genetic testing for patients with high-risk clinical symptoms for monogenic kidney stone diseases (MKSD) including PH. Two panels were offered: a 3-gene panel for PH and a 35-gene panel for MKSD. Results were categorized as the following: 1) Positive Genetic Diagnosis (Pathogenic or Likely Pathogenic variants in autosomal dominant (AD)/autosomal recessive (AR) genes), or 2) Possible Genetic Diagnosis (Pathogenic, Likely Pathogenic, or Variant of Uncertain Significance) in AD/AR genes.

Results: Out of 209 patients tested globally, 27 had PH1, 1 had PH2, and 2 had PH3, resulting in a 14% diagnostic yield for PH. An additional 15 patients received a positive diagnosis for MKSD, leading to a 22% overall diagnostic yield. Furthermore, 2 patients had a possible genetic diagnosis of PH2, 1 patient had a possible genetic diagnosis of PH3, and 27 patients received possible genetic diagnoses for MKSDs in addition to PH.

Conclusions: Genetic testing is vital for accurate diagnosis and treatment of patients who are at high risk for underlying MKSD including PH. In this study, genetic testing in pediatric and adult patients with high-risk clinical symptoms resulted in a positive genetic diagnosis in 45 of 209 patients. It is worth noting that genetic testing also yields valuable information beyond definitive diagnoses. An additional 30 patients obtained a possible genetic diagnosis, indicating the need for further metabolic and/or familial genetic testing.

Background: Primary hyperoxaluria type 1 (PH1) is a rare genetic disorder in which hepatic oxalate overproduction can lead to chronic kidney disease (CKD). Plasma oxalate (POx) increases with declining kidney function, leading to systemic oxalosis. Lumasiran, an RNA interference therapeutic that reduces hepatic oxalate production, administered to patients with PH1 and CKD 3b–5 in the ILLUMINATE-C trial (NCT04152200), resulted in decreased POx at month (M) 6 and 12 with acceptable safety. Here we present M24 results.

Methods: ILLUMINATE-C is an ongoing, single-arm study evaluating lumasiran in patients of all ages with PH1, eGFR ≤45 mL/min/1.73m^2 including hemodialysis (HD), and POx ≥20 μmol/L. The 6M primary analysis period is followed by a 54M extension period.

Results: Of 21 patients who entered the study, 5 of 6 (83%) assigned at study start to Cohort A (no HD) and 12 of 15 (80%) assigned to Cohort B (on HD) completed the M24 visit. Mean reduction from baseline in POx at M24 was 60.5% (Cohort A) and 30.6% (Cohort B). Two Cohort A patients with low baseline eGFR (8.6, 16 mL/min/1.73m^2) initiated HD. Two Cohort B patients who underwent kidney-only transplantation remained in the study with a functional graft after 16 and 21 months and comparable POx levels to 2 patients who underwent combined liver-kidney transplant. In patients with an ejection fraction (EF) <55% at baseline, 2 of 3 had improvement of ≥5% at M24; none met criteria for EF worsening. Mild injection site reactions were the most common lumasiran-related AEs, occurring in 5 of 21 (24%) patients overall. No deaths or lumasiran-related serious/severe AEs, discontinuations, or withdrawals occurred.

Conclusions: POx reductions with lumasiran were maintained at M24 with an acceptable safety profile in PH1 patients with CKD 3b–5, including those on HD, and in patients with an isolated kidney transplant. Noninvasive indicators of systemic oxalosis including EF appear stable or possibly improving after 2 years of treatment in this study population.

Functional Analysis of AGXT1 Missense Variants of Uncertain Significance in HepG2 Cells: Association with Primary Hyperoxaluria Type I

Barbara Cellini, Leonardo Gatticchi, Ilaria Bellezza. *Universita degli Studi di Perugia Dipartimento di Medicina e Chirurgia, Perugia, Italy.*

Background: Primary Hyperoxaluria Type I (PH1) is caused by functional deficit of alanine:glyoxylate aminotransferase (AGT1), a liver enzyme that detoxifies glyoxylate, thus preventing its conversion into oxalate. The hallmark of PH1 is the progressive deposition of calcium oxalate resulting in kidney stones leading to ESRD and systemic oxalosis. The diagnosis is established on a proband with hyperoxaluria or hyperoxalemia by the presence of biallelic pathogenic or likely pathogenic variations in the *AGXT1* gene encoding AGT1, 67% of which are missense. Although the pathogenicity of some genetic variants has been clearly defined, the clinical assessment of variants of uncertain significance (VUS) represents a big challenge. Our work is aimed at determining pathogenicity of *AGXT1* missense variants in a cellular model of disease.

Methods: We used hepatocarcinoma-derived human HepG2 cell line knocked-out for the *AGXT1* gene utilizing CRISPR/Cas9 technology, since they exhibit conserved glyoxylate/oxalate metabolism. By lentiviral infection we created and analyzed stable clones of *AGXT1*-KO HepG2 cells expressing the two polymorphic forms of AGT1 (AGT1-Ma and AGT1-Mi). Eight VUS were expressed on the AGT1-Ma background and three on the AGT1-Mi background. We validated our experimental setting to mimic the liver expression of AGT1 and investigated the effects of amino acid changes at the protein level.

Results: The p.Pro28Ser, p.Arg118Cys, p.Asp129His, p.Ala248Val, p.Arg317Trp mutations on AGT1-Ma, and the p.Glu274Asp, p.Ile279Thr, p.Arg289Cys mutations on AGT-Mi led to a biologically meaningful reduction in protein levels and activity, denoting the variants are likely pathogenic. On the other hand, the p.Pro314= mutation did not significantly affect AGT1 protein levels and activity, while p.Ala186Val and p.Arg197Gln cause only a partial reduction, thus suggesting that they could be benign or likely-benign.

Conclusions: We developed a platform to predict the pathogenicity of newly identified *AGXT1* variants that could have a significant clinical implication as potential tool to support the diagnosis of PH1 and establish genotype/phenotype correlations.

FR-PO594

An Un-Hex-Pected Cause of Crystalluria

Christina L. Blum, Maura A. Watson, Megha R. Joshi. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Cystinuria, a genetic cause of kidney stones, is present in 1/7000 births, and 75% present in childhood. Cystinuria should be suspected in those with childhood kidney stones, staghorn calculi, or family history of stones. Diagnosis is confirmed by cystine calculi on analysis, hexagonal cystine crystals on microscopic urinalysis, or genetic testing. Patients are at increased risk of developing chronic kidney disease.

Case Description: A 21-year-old man with no significant past medical history presented with acute onset chest pain and dyspnea following a strenuous run. He had a nagging cold and took guaifenesin and half a scoop of workout supplement prior to running. Immediately afterward, he had lightheadedness, paraesthesias, headache, and progressive dyspnea. He had an anion gap of 28, elevated troponin, normal pro-BNP, HCO3 11 meq/L, sCr 1.6 mg/dl (no prior), Ca 10.6 mg/dl, and glucose 277 mg/dl. His symptoms were transient, and although he had acute myocardial injury, cardiac workup was negative. Creatinine peaked at 2.3 mg/dl. Urinalysis was notable for hemoglobinuria and proteinuria; microscopy showed hexagonal crystals. Two 24hr urine collections, 1 month apart, showed elevated cystine and low citrate. He was found to have a heterozygous pathogenic variant in the gene SLC7A9, c.997C>T, p.Arg333Trp consistent with autosomal dominant cystinuria. His father had a stone in his 40s, attributed to diet. While the patient has never had nephrolithiasis, he is at increased risk. He was started on potassium citrate and counseled to increase fluid intake and reduce dietary sodium and animal protein, with a goal urine cystine <250mg/L and urine pH >7.

Discussion: SLC7A9 variants are associated with autosomal dominant and recessive cystinuria, with variable penetrance. Heterozygotes often have increased urine excretion of cysteine and dibasic amino acids, which can lead to nephrolithiasis. Cystinuria was

unexpected in this patient, and upon renal recovery urine cystine crystals were absent. The combination of his mild cold, supplement use, and strenuous exercise predisposed him to acute kidney injury and revealed his otherwise quiescent cystinuria. Continued monitoring and treatment is warranted to prevent nephrolithiasis and chronic kidney disease. *The views expressed in this abstract are those of the author(s) and do not necessarily reflect the official policy of the Department of Defense or the U.S. Government.*

FR-PO595

Clinical Characterization of a Cohort with Suspected Monogenic Stone Disease

Muhammad G. Arnous, Andrea G. Cogal, Barbara M. Seide, David J. Sas, Peter C. Harris, John C. Lieske. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Monogenic stone diseases (MSDs) result from pathogenic variants in ~40 genes, displaying early onset, frequent stone events, chronic kidney failure, and positive family history. Targeted next-generation sequencing (tNGS) is a valuable approach for identifying genetic causes. Here, we share tNGS panel analysis results from a large cohort with suspected MSDs.

Methods: Subjects were recruited by Rare Kidney Stone Consortium (RKSC) collaborators with features suggestive of a possible MSD. Genotyping with a tNGS panel that includes 149 known and candidate causes of MSD. All variants were scored for pathogenicity using ACMG criteria. Clinical features were extracted from the RKSC registries and medical records. Urine parameters and eGFR were adjusted for age and sex. Data are reported as medians for continuous variables and percentages for categorical variables. Non-parametric and proportional tests were used for analysis.

Results: A total of 374 families (540 patients) were enrolled and screened. Of these, 131 families (40%; 216 individuals) were resolved with an identified pathogenic change in a total of 20 different genes, while in 243 families no mutation was detected (NMD) (60%, 324 individuals). Families were categorized based on the reason for recruitment into the following groups: Hyperoxaluria, hypercalciuria, cystinuria, and Stones without urine abnormalities. Table 1- shows a summary of the clinical features of resolved cases. Resolved hypercalciuria cases had a lower eGFR ($p<0.01$). Dent disease patients had a higher urinary calcium excretion than other resolved cases, and primary hyperoxaluria patients manifested hyperoxaluria as expected. Patients with SLC34A1 and SLC34A3 variants required more stone surgeries ($p=0.03$).

Conclusions: Despite a wide range of etiologies, the clinical characteristics of MSD show an overlap, yet kidney stones, nephrocalcinosis, and kidney failure are prevalent. A candidate gene panel is efficient to screen for the many causes of MSD with a high resolving rate improving diagnostics and allowing appropriate management and treatments.

Understanding the Clinical Genetics of Kidney Stone Disease Using a Kidney Disease-Specific Genetic Test Panel

Kevin Labagnara,[1] Rutul D. Patel,[2] Benjamin Green,[1] Michael Zhu,[1] Kavita Gupta,[2] Andrea A. Asencio,[2] Deep Sharma,[2] Wei Chen,[2] Dima Raskolnikov,[2] Jillian Donnelly,[2] Kara Watts,[2] Alexander Small.[2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY.*

Background: The etiology of kidney stone disease (KSD) is multifactorial. Emerging data suggest that genetics may play a larger role than previously thought. 11% to 56% of KSD has heritable stone-related genetic mutations. We aimed to better understand the genetics of KSD using a kidney disease focused genetic test at our diverse, urban academic center.

Methods: A single-center, prospective study was conducted on patients with recurrent stones or a single stone with family history. Those with known causes of urolithiasis, active UTI or acutely passing a stone were excluded. All underwent standard stone analysis, serum metabolic evaluation, 24-hour urine studies and buccal DNA screen for 385 kidney disease-linked genes using the Natera Renasight™ kit. Variants were categorized as "positive" if pathologic, "carrier" if autosomal recessive, or of "uncertain significance" (VUS).

Results: 89 patients were enrolled. 55% were female, 60% were Hispanic, and 30% reported a first-degree family history. Median (IQR) patient age was 49 years (IQR 41-60) with 2 (IQR 1-3) stone episodes in the prior 5 years. 61% formed calcium oxalate stones. 7 (8%) subjects were positive for amyloidosis (*TTR*), Alport syndrome (*COL4A3*), cystinuria (*SLC7A9*), polycystic kidney disease (PKD1), or FSGS (*APOL1*). 39 (44%) were carriers for 30 unique genes and all patients had multiple VUS spanning 247 unique genes. Positive/carrier patients were similar to negative patients in demographics, comorbidities, stone analysis and 24-hour urine studies. They had lower median vitamin D (22.3 vs 29.7 ng/ml; $p=0.041$) and higher potassium (4.4 vs 4.2 mEq/ml; $p=0.090$).

Conclusions: Our study sheds light on potential genetic variants in recurrent stone formers in our diverse patient population. The initial wide range of results support the complex and polygenetic expression of KSD.

A Rare Cause of Proteinuria and Nephrolithiasis: Biallelic SLC26A1 Variants

Elhussein A. Elhassan,[1,2] Eva B. Long,[3] Katherine A. Benson,[1] Gianpiero Cavalleri,[1] Peter J. Conlon.[2,1] *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland; [3]University College Cork, Cork, Ireland.*

Introduction: Up to 2% of adult nephrolithiasis cases are attributable to a monogenic disease, a clinically and genetically heterogeneous group. Although high-throughput sequencing has identified >90 nephrolithiasis-causing genes, some of these genes are understudied.

Case Description: This Irish family consists of 2 affected siblings. The proband (W94_1), a 63-year-old woman, presented with recurrent non-obstructive nephrolithiasis, urinary infections, and proteinuria. Sonography revealed normal-sized kidneys. In addition, she reported bilateral sensorineural deafness since childhood, indicating hearing aids at age 50 years. No further evidence of systemic involvement was identified. At the last follow-up, aged 63 years, she exhibited reduced estimated glomerular filtration rate (eGFR). Despite recurrent nephrolithiasis, the kidney function of her 61-year-old brother (W94_2) is adequate (eGFR = 88 mL/min). At the time of genetic analysis, oxalate and calcium excretion in the urine were normal, with normal serum bicarbonate. Genetic testing revealed both harbor biallelic variants in The Solute Carrier Family 26-Member 1 (*SLC26A1*) gene (NM_022042:c.C1073T; p.S358L and c.C554T; p.T185M) associated with monogenic calcium oxalate nephrolithiasis. The *SLC26A1* gene encodes for an anion transporter critical in oxalate and sulfate hemostasis. These reported *SLC26A1* variants (p.S358L and p.T185M) occurred at conserved resides and reported at a low frequency in population databases, such as the Genome Aggregation Database (gnomAD). It is localized into the basolateral membrane of proximal tubules. Functional studies of similar reported variants demonstrate a dysfunctional process of protein and impaired transporter activity. However, the effect of *SLC26A1* on oxalate homeostasis, which causes hyperoxaluria and urolithiasis, remains controversial. Nevertheless, its role in sulfate homeostasis in humans has only recently been established.

Discussion: Clinical features of kidney stone formers harboring *SLC26A1* variants can vary, indicating the potential expressivity. Awareness of monogenic nephrolithiasis, especially in families with history, should allow early diagnosis, treatment, and personalized counseling.

FR-PO598

Characterization of Monogenic Kidney Disease in Patients over 60 Years of Age

Elhussein A. Elhassan,[1,2] Katherine A. Benson,[1] Gianpiero Cavalleri,[1] Peter J. Conlon.[2,1] *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland.*

Background: Approximately 10% of adults with chronic kidney disease (CKD) have monogenic forms of the disease. However, the prevalence of monogenic kidney diseases in the over-60 population is not well characterized.

Methods: For genetic screening in this cohort with suspected monogenic kidney disease, excluding polycystic kidney disease, we utilized gene-panel and exome sequencing. The purpose of this study was to assess the diagnostic yield of clinically validated disease-causing variants and to compare the clinical characteristics of solved and unsolved cohorts.

Results: Genetic testing was performed for 113 adults (*n*= 93 families) with a median age at recruitment of 69 years (IQR: 64 - 73). 83.3% participants reported a family history of CKD and 52.2% were females. At last follow up, 84 (75.7%) individuals progressed to kidney failure at a median age of 57 years [IQR: 41.5 – 65]. We were able to demonstrate likely-pathogenic/pathogenic variant in 37/113 (32.7%), encompassing 13 distinct monogenic entities. Disease-causing variants in three phenotypes accounted for up to 76% of solved cases. These included *MUC1* (*n*=6), *UMOD* (*n*=3), *HNF1B* (*n*=5) and *DNAJB11* (*n*=1) associated with tubulointerstitial kidney disease; *COL4A5* (*n*=4) and monoallelic *COL4A3* (*n*=4) associated with Alport–related kidney disease; and *INF2* (*n*=5) associated with focal segmental glomerulosclerosis. We identified disease-causing variants in the *CLCN5* gene associated with Dent disease type 1 in an additional 3 (2.6%) individuals. In 32% (*n*=8) of the 25 patients referred with *a priori* diagnosis of CKD of undetermined cause were found to have a known monogenic cause. There was no difference in age at initial presentation [45.4 vs. 46 years; $p = 0.863$] and age at kidney failure [52.8 vs. 52.8 years; $p = 0.747$] between individuals with monogenic disease and those without. A family history of CKD was an independent predictor of a genetic diagnosis [odds ratio: 5; 95% CI: 1.1 - 23.3, $p = 0.040$], with a higher proportion of solved cases than unsolved cases [94.4% vs. 77.7%, $p = 0.02$].

Conclusions: We estimated that about a third of this cohort over 60 years old with suspected inherited CKD would have a monogenic nephropathy. Awareness of monogenic nephropathies, particularly in this population group, should permit family counselling and individualized treatment.

FR-PO599

Comprehensive Genetic Analysis Reveals Novel Variants in Nephrolithiasis and Nephrocalcinosis

Ken Saida, Florian Buerger, Isabel Ottlewski, Daanya Salmanullah, Seyoung Yu, Caroline M. Kolvenbach, Katharina Lemberg, Bshara Mansour, Nils D. Mertens, Selina Hölzel, Izzeldin Elmubarak, Gijs A. Franken, Ronen Schneider, Amar J. Majmundar, Shirlee Shril, Friedhelm Hildebrandt. *Boston Children's Hospital, Boston, MA.*

Background: Renal stones or nephrolithiasis (NL) and nephrocalcinosis (NC) are clinically heterogeneous conditions. The etiology of renal stone disease is multifactorial and influenced by a combination of genetic and environmental factors. 33 monogenic causes of NL/NC have been identified to date; we have shown that a genetic cause of NL/NC can be identified in approximately 11 % of adults and 16-20% of children (Halbritter *JASN* 26:543, 2015; Braun *CJASN* 11: 664, 2016). Several investigations have been conducted using next-generation sequencing (predominantly targeted sequencing). Nonetheless, a comprehensive genetic analysis of NL/NC, particularly in terms of copy number variation (CNV), is yet to be done.

Methods: Individuals with a history of at least one renal stone or NC before the age of 25 years were recruited from international stone clinics between January 2013 and December 2020. Affected individuals with NL/NC from 285 families were enrolled in this study. Exome sequencing (ES) was performed to determine the genetic cause of NL/NC. Detected variants were assessed using a population database, evolutionary conservation, and *in silico* pathogenicity prediction scores, and categorized according to the American College of Medical Genetics (ACMG) guidelines. Furthermore, CNVs were analyzed using sequencing coverage data.

Results: 37 Likely disease-causing variants were detected in 42 families, leading to genetic diagnosis in 14.7% (42/285) of all cases. Of the 37 detected variants, 20 were novel. The *CTNS* gene was the most frequent (n=8), followed by AGXT (n=5), *SLC3A1* (n=4), *ATP6V1B1* (n=3), and *ATP6V0A4* (n=2). The other genes included *CLCN5, CLDN16, CLDN19, MOCOS, SLC4A1, SLC7A9, SLC12A1, SLC34A1,* and *BSND*. CNVs were detected in three cases. Homozygous deletions in *SLC3A1* were detected in two cases: one showed deletion in exon 4-9, and the other showed a deletion involving only exon 7.

Conclusions: Our data represent a comprehensive analysis of the monogenic causes of renal stone disease. In-depth analysis at the single-exon level is beneficial. Simultaneous analysis of CNVs and SNVs based on ES has potential as a first-choice diagnostic approach for renal stone disease.

FR-PO600

Heterozygous Pathogenic Variants in SLC34A3 in Patients with Recurrent Calcium Phosphate Kidney Stones

Mohammad A. Sohail, Xiangling Wang, Juan C. Calle, Laura Ferreira Provenzano. *Cleveland Clinic Glickman Urological and Kidney Institute, Cleveland, OH.*

Introduction: The solute carrier family 34-member 3 (SLC34A3) gene encodes the renal type 2c sodium-phosphate cotransporter and mutations in SLC34A3 cause an autosomal recessive disorder known as hereditary hypophosphatemic rickets with hypercalciuria (HHRH). Disease onset is typically observed in infancy/childhood and is associated with hypophosphatemia, growth retardation, rickets and/or osteomalacia. There is also an adult-onset form recognized in heterozygous carriers of SLC34A3 variants with manifestations of reduced bone density and multiple fractures. Here we describe two adult patients with heterozygous pathogenic variants in SLC34A3, who presented with recurrent calcium phosphate nephrolithiasis without hypophosphatemia or bone disease.

Case Description: Case 1: A 47-year-old female with type 2 diabetes mellitus, migraine headaches on topiramate and a paternal history of nephrolithiasis was evaluated by renal genetics for recurrent kidney stones. As shown in Table 1, she had hypercalciuria, hypocitraturia and urine pH of 6-7. Calculus analysis revealed 90% calcium phosphate composition. Genetic testing showed a heterozygous pathogenic variant in SLC34A3 (c.1304del). **Case 2:** A 46-year-old female with morbid obesity S/P sleeve gastrectomy 4 years ago presented for renal genetics evaluation for recurrent kidney stones since age 18. As shown in Table 1, she had hypercalciuria, hypocitraturia despite potassium citrate, hyperoxaluria and urine pH of ≥7. Multiple calculi analyses revealed 78-90% calcium phosphate composition. Genetic testing showed a heterozygous pathogenic variant in SLC34A3 (c.1046_1047del).

Discussion: Our patients seemed to have a predilection for developing calcium phosphate stones, and to our knowledge, this has not been previously recognized in the literature in patients with heterozygous pathogenic variants in SLC34A3. Both cases presented with hypercalciuria, hypocitraturia and alkaline urine pH. The association of SLC34A3 gene variants with calcium phosphate stone formation deserves further investigation.

Table 1

Laboratory Data	Case 1	Case 2
Urine Calcium / 24 hours (mg) (range)	390 - 450	232 - 315
Urine Citrate / 24 hours (mg) (range)	207 - 454	< 40
Urine Oxalate / 24 hours (mg) (range)	22 - 30	52 - 60
Urine pH (range)	6 - 7	≥ 7
Serum Phosphorus (mg/dL) (range)	3.0 - 3.5	3.2 - 3.4

FR-PO601

A Canine Model Implicates Uromodulin Peptides in Calcium Oxalate Urinary Stone Risk

Eva Furrow,[1] Luca Rampoldi,[2] Luca Jovine,[4] Jeffrey Wesson,[5] Muthuvel Jayachandran,[3] John C. Lieske,[3] Michael F. Romero,[3] Jody P. Lulich.[1] *[1]University of Minnesota Twin Cities College of Veterinary Medicine, Saint Paul, MN; [2]IRCCS Ospedale San Raffaele, Milano, Italy; [3]Mayo Clinic College of Medicine and Science, Rochester, MN; [4]Karolinska Institutet, Stockholm, Sweden; [5]Medical College of Wisconsin, Milwaukee, WI.*

Background: Dogs offer a spontaneous model of calcium oxalate (CaOx) urinary stone formation. Our previous research identified a pathogenic variant (PV) in the canine uromodulin gene (*UMOD*) that is associated with a dramatic risk for CaOx stones. This stone-risk PV resides in the external hydrophobic patch (EHP) of uromodulin, which is cleaved from the mature protein before secretion into tubular fluid. In this study, we characterized urinary excretion of EHP-containing peptides from CaOx stone former (SF) dogs with and without the *UMOD* PV.

Methods: Urinary uromodulin peptides were measured in urine samples from SFs with (n=4) and without (n=4) the *UMOD* PV plus healthy control dogs (n=7) and normalized to urinary creatinine. Dogs with kidney disease were excluded. Uromodulin peptide abundances were summed for comparisons of total excretion. For individual peptides, abundance was calculated relative to the sum of all uromodulin peptides to obtain a percentage. Cleavage patterns were compared between groups.

Results: Total uromodulin peptide abundance was reduced in SF dogs with the *UMOD* PV. Urine from PV SF dogs lacked a peptide cleavage site, resulting in longer peptides compared to healthy controls. Total uromodulin peptide abundance did not differ between non-PV SF and healthy dogs. However, non-PV SF dogs had decreased abundance of specific EHP-containing peptides that was intermediate between healthy and PV SF dogs (**Figure 1**).

Conclusions: Reduced urinary excretion of specific uromodulin peptides in CaOx SF dogs with and without the *UMOD* PV implicates these peptides in stone risk. Previous research has demonstrated bioactivity of uromodulin peptides. The peptides that are decreased in the urine of SF dogs may have a protective effect against stone formation.

Funding: Other NIH Support - ULTR002494

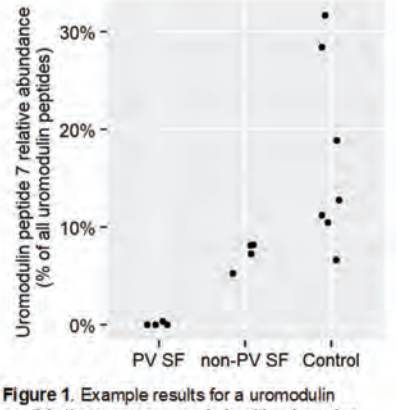

Figure 1. Example results for a uromodulin peptide that was common in healthy dog urine but nearly absent in SF dogs with the *UMOD* PV and decreased in SF dogs without the PV.

FR-PO602

Novel Therapy for Cystinuria Using Genetic Tools

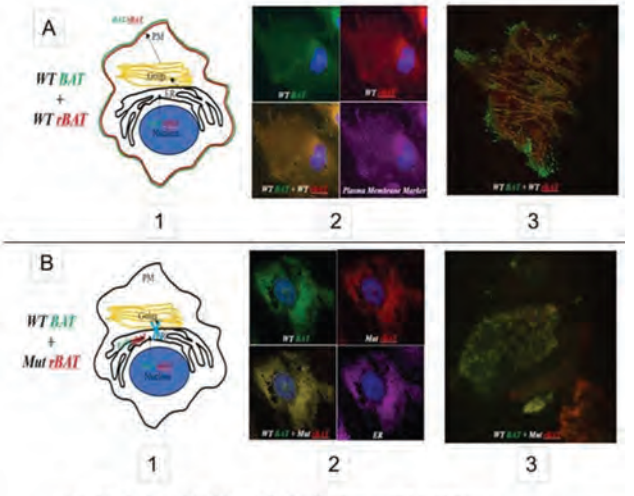
Mohammed Dakhakhini. Bristol Renal Group. *University of Bristol Faculty of Health Sciences, Bristol, United Kingdom.*

Background: Available drug treatment for Cystinuria is still imposes huge disadvantages to patients through harmful side-effects. This fact necessitates the need for other therapeutic approaches without causing major side-effects. Cystinuria is caused by a mutation of $b^{0,+}AT$ *(SLC7A9)* or *rBAT (SLC3A1)* Proteins. Mutations result in the mis-localization of functioning channles at the plasma membrane (PM) leading to a disruption in cystine reabsorption that results in the accumulation of cystine stones. This research hypothesizes that repurposing established drug compounds to re-direct both proteins into the PM is a new and improved therapeutic approach.

Methods: In this study, we utilised constructed transduced human PTEC to investigate the localisation of $b^{0,+}AT$ and *rBAT* in wildtype and four mutated cell lines: *p. Met467Thr, p. Thr216Met, p. Gly458Arg,* and *p. Asn254Thr* using various imaging systems. Primary investigation was done using ICC/IF followed by Widefield Fluorescence Microscopy. Follow-up investigations were done using Confocal Microscopy and co-localisation analysis of obtained data. Findings were confirmed by TIRF Microscopy. Currently, the INCELL analyser is being used to optimise the LOPAC 1280 in these cell lines.

Results: All localisation studies done using different imaging systems showed the same results. Firstly, both proteins were found to be trafficked together. Secondly, in the wild-type cell line, both proteins were located at the PM. Thirdly, in mutated cell lines, both proteins were trapped in the ER. Morphological changes of PTEC were supportive of the co-localisation studies.

Conclusions: Both proteins were trapped in the ER in all four mutants in contrary to wild-type cell line. These findings allow testing of LOPAC 1280 drugs to show their efficacy in re-locating proteins into the PM. Radiation testing will followed to confirm functionality of both proteins.



(The Localization of $b^{0,+}AT$ and *rBAT* in Wildtype and Mutated Genes)

The figure A-1 illustrates the trafficking of $b^{0,+}AT$ and *rBAT* in the Wildtype gene from the nucleus to the plasma membrane (PM) of the cell, while in mutated *rBAT* both proteins are trapped in the Endoplasmic Reticulum (ER) as illustrated in B-1. A-2 displays Widefield microscope images for the colocalization of both protein at the plasma membrane in the Wildtype gene (*BAT* tagged with E-GFP, *rBAT* tagged with mCherry, Far-red is CellMask plasma membrane stain from Invitrogen), while in mutated *rBAT* both proteins colocalize in ER as seen in B-2 (ER marker is Anti-KDEL antibody from abcam). A-3 displays TIRF microscope image which confirms clear localization of both proteins at the plasma membrane in the Wildtype gene, while in the mutated gene of *rBAT* only a slight shadow is observed which suggest a modest degree of localisation for both proteins at the PM.

FR-PO603

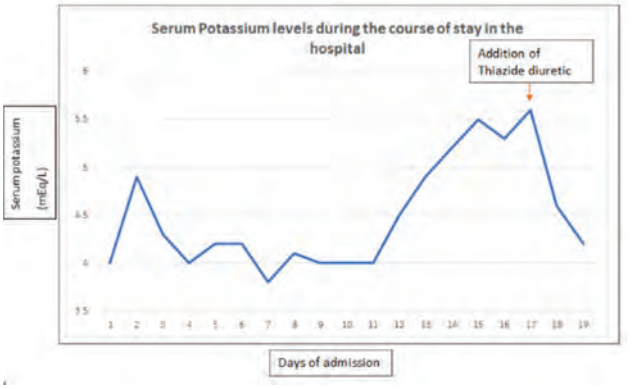
Gordon Syndrome in an Elderly Adult: A Rare Presentation

Iktej S. Jabbal, Sehajpreet Kaur, Gaayathri Krishnan, Fernando M. Abanilla. *AdventHealth Sebring, Sebring, FL.*

Introduction: Gordon syndrome (GS) is a rare autosomal dominant condition with a loss of function mutation of WNK1, WNK4, KLHL3, and CUL3 genes. This affects the thiazide-sensitive sodium-chloride channels (NCC) in the distal convoluted tubule. Being a hereditary disease, it is expected to present at a young age, but may rarely present in adults as well.

Case Description: A 70-year-old male with obstructive uropathy, indwelling Foley catheter and right nephrostomy tube, CKD stage G3B/A3, and persistent atrial fibrillation (AF), presented to the ER with generalized weakness. He developed urosepsis, metabolic acidosis and AKI, for which empiric antibiotics and IV fluids with sodium bicarbonate were started. Development of fluid overload secondary to chronic heart failure prompted the addition of 40mg IV daily of furosemide. He was started on metoprolol tartrate 100 mg PO b.i.d. for AF with rapid ventricular rate. Bicarbonate drip was stopped on day 5 when levels normalized. IV furosemide had to be decreased to 20 mg daily along with addition of IV acetazolamide, due to development of contraction alkalosis on day 12. While alkalemia improved, serum potassium (K) surprisingly rose, with levels not improving even with lowering the metoprolol dosage. This paradoxical trend of K led to clinical suspicion of GS. Lo and behold, administering hydrochlorothiazide after discontinuing the previous diuretics resulted in immediate and sustained decline of K back to normal.

Discussion: Hyperkalemia can be attributed to various factors, with beta-blockers, metabolic acidosis, and insulin deficiency being some of them. True hyperkalemia is rare unless there is a large K load, marked exercise, or a defect in K handling that prevents the excretion of the excess extracellular K. GS, a rare cause of hypertension and hyperkalemia, can be missed, especially in adults, without vigilance for electrolytes and acid-base abnormalities. It should therefore be included in the differential diagnosis of patients presenting with unexplained hyperkalemia.



FR-PO604

Clinical Features and Genotype-Phenotype Correlation of Bartter Syndrome Type 1 and 2

Atsushi Kondo,[1] Yuta Inoki,[1] Yuta Ichikawa,[1] Yu Tanaka,[1] Hideaki Kitakado,[1] Chika Ueda,[1] Shinya Ishiko,[1] Nana Sakakibara,[1] Tomoko Horinouchi,[1] Tomohiko Yamamura,[1] Kazumoto Iijima,[2] Kandai Nozu.[1] *[1]Kobe Daigaku, Kobe, Japan; [2]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan.*

Background: Bartter syndrome type 1 and 2 (T1/T2BS) are autosomal recessive hereditary salt-losing tubulopathy (SLT) caused by loss-of-function variants of *SLC12A1* (NM_000339) and *KCNJ1* (NM_000220) respectively. Although the typical case of both diseases presents severe clinical manifestation at the perinatal period, they are very rare diseases and there are few reports on their clinical course and genotype-phenotype correlations.

Methods: Of 651 patients with suspected SLT who underwent comprehensive genetic testing of 124 genes related to the renal disease by next-generation sequencing at our department, T1BS: 16 and T2BS: 10 cases genetically diagnosed were evaluated retrospectively.

Results: In T1BS, 23 variants (novel:15) were found in the *SLC12A1*, and in T2BS, 11 variants (novel:7) were identified in the *KCNJ1*. The median age at the time of genetic testing was 0 years for both diseases. The mean serum potassium level at diagnosis was 2.9 mEq/L in T1BS, but all T2BS patients showed transient hyperkalemia (mean 7.5 mEq/L) in the early postnatal period, followed by hypokalemia (mean 3.2 mEq/L). All patients with T1BS required continuous treatment with potassium products, potassium-retaining diuretics, and/or NSAIDs as a treatment for hypokalemia, whereas only 5 patients (50%) with T2BS required these treatments. Concerning renal prognosis, 3 patients with T1BS and 5 patients with T2BS had deteriorated renal function at the time of genetic testing. Regarding the genotype-phenotype correlation, some of the missense variants of both T1 and T2BS did not show polyhydramnios and presented an atypical mild clinical manifestation without any symptoms in neonatal age. As for the *KCNJ1* gene, serum potassium levels tended to be high (mean 3.3 mEq/L) in patients with the large deletion variant including the promoter region that has been previously reported, and this variant may present with mild manifestation.

Conclusions: T2BS shows significant hyperkalemia in the early postnatal period, but the severity of hypokalemia after infancy is milder than that of T1BS, and some cases did not require potassium supplementation. The correlation between the genotype-phenotype is not yet clear, but there were some clinically atypical cases, and further research is needed.

FR-PO605

Adrenal Mass in Bartter: Incidentaloma or Adenoma?

Rhoshini Rajasekaran, Deepak Chandramohan, Apoorv Deotare. *The University of Alabama at Birmingham, Birmingham, AL.*

Introduction: Bartter's syndrome is rare, characterized by salt wasting caused by impaired absorption of sodium in the thick ascending limb of the loop of Henle. Young patients present with hypokalemia, metabolic alkalosis, and hyperaldosteronism. Our case presents a patient with Bartter's syndrome with an incidental adrenal mass.

Case Description: A 39 yo F with hx of Bartter's syndrome type III (heterozygous for CLCKNB) and Sjogren's syndrome presents for an office visit for evaluation of incidental right adrenal complex mass 1.5cm X 1.7cm with a question of whether the hyperaldosteronism was because of Bartter's syndrome or a hypersecretory adrenal nodule. She denies any h/o Hypertension. She was diagnosed at the age of 5 months with Bartter's syndrome, hypokalemia, and hypomagnesemia. Vitals - temp 97.3, pulse 80, BP 120/81. The physical exam was unremarkable. Her daily medications include Losartan 50 mg, Amiloride 10 mg BID, and Potassium and Magnesium supplements. Labs: BMP: Na 138, K 4.9, Cl 103, bicarb 23, BUN 10, Cr 0.8, Mg 1.7, Hb 12.6, WBC 9.2, Plt 419. Renin 48ng/mL/h, aldosterone 1100ng/dL.

Discussion: Bartter syndrome presents as hypochloremic, hypokalemic metabolic alkalosis. It is diagnosed in young individuals with an incidence of 1/1000000. Hyperaldosteronism and high rennin levels occur secondary to compensation mechanisms that cause macula densa hypertrophy. An adrenal mass occurring in Bartter syndrome has not been reported in the literature. This patient was normotensive with an elevated renin and aldosterone level. Our case makes us wonder if the elevated aldosterone was compensatory vs hypersecretory. An adrenal adenoma in this case would present with suppressed renin, elevated aldosterone with hypertension. Primary hyperaldosteronism would have suppressed renin levels in addition to elevated aldosterone levels. A salt suppression test could be used to differentiate between the etiology of primary vs secondary hyperaldosteronism if renin levels are suppressed. In conclusion, Bartter syndrome causes compensatory hyperaldosteronism with high renin levels.

FR-PO606

Knocking out the Sweetest Urine

Stepfany Fuentes, Alan Segal. *Maine Medical Center, Portland, ME.*

Introduction: SGLT2 inhibitors—which act on a Na-glucose co-transporter in the apical membrane along the proximal tubule—lead to natriuresis and glycosuria, and have been shown to have an astonishing salutary effect on slowing CKD, perhaps in part by stimulating tubuloglomerular feedback. Here, we present siblings with a naturally occurring loss-of-function mutation of the SGLT2 co-transporter.

Case Description: A 44-year-old male presented to the clinic for glucosuria first discovered at age 10. He reported concurrent polyuria and polydipsia since childhood. He denied history of UTI, dysuria, urinary retention, change in appetite, or change in vision. His biological sister was found to have glucosuria as well. Both have enjoyed perfect health with normal blood pressure, electrolytes, and kidney function; both have normoglycemia and neither have diabetes. A 24-hour urine demonstrated 29 g glucose in 3.1 L (935.5 mg/dL). Genetic testing revealed a mutation in SLC5A2, the gene encoding the SGLT2 co-transporter.

Discussion: In these siblings, an SLC5A2 loss-of-function variant c. 1152_1163del (p.Val385-Ala288del) is the cause of their familial renal glucosuria. While the SGLT2 inhibitor class of medication is growing in popularity for its known benefits at reducing CV disease and progression of CKD, few studies have evaluated the effect of the gene mutation induced glucosuria. One study of 13 family members in Finland with a SLC5A2 genetic mutation was followed over 30 years. While they were at increased risk of urinary tract infections and postprandial hypoglycemia, there has been no effect on glucose tolerance and they maintain normal kidney function. We conclude that, as has been the case with other genetic abnormalities of transporters along the nephron, individuals and families with SLC5A2 mutations should be studied in an effort to elucidate the potential mechanisms that underlie the beneficial effects of SGLT2 inhibitors in patients with kidney disease.

FR-PO607

Clinical and Genetic Characterization of Patients with CUBN Variants

Poemlarp Mekraksakit, Silvia Titan, Cheryl L. Tran, Filippo Vairo, Marie C. Hogan. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Isolated persistent proteinuria caused by *CUBN* variants is rare with only a few cases reported and even fewer have had phenotypic characterization with a kidney biopsy and electron microscopy.

Methods: We retrospectively reviewed all cases undergoing genetic testing in the Mayo Clinic Nephrology Genomics Clinic with *CUBN* variants identified and described their clinical, pathological, and molecular genetic characteristics.

Results: We identified one patient with two *CUBN* variants who developed subnephrotic-range proteinuria after a urinary tract infection at 4 years and 9 months of age (UPCR 1.51 mg/mg; current cystatin eGFR 97 ml/min/1.73 m^2). A kidney biopsy revealed minimal change disease (MCD) and minimal mesangial hypercellularity. A exome-based panel testing detected a variant of uncertain significance (VUS) in *CUBN* (NM_001081.4:c.9079G>A, p.(Gly3027Arg)) which has been reported in the homozygous or compound heterozygous state in at least one affected individual (PMID: 31613795) (PM3_Supporting) and it is predicted to have a deleterious effect to the protein (PP3). Also, this variant has a 0.0402% allele frequency in population databases (PM2_Supporting). Subsequent genome-based panel (432 kidney-related genes) identified a pathogenic deep intronic *CUBN* variant (NM_001081.4:c.3330-439C>G) predicted to impact splicing (PP3) and result in loss of function, a known disease mechanism for CUBN-related diseases (PMID: 10080186, 15024727, 24156255). This variant has been reported in the homozygous or compound heterozygous state in at least 3 affected individuals (PMID: 10080186, 22929189) (PM3_strong), segregated with disease in one family (PMID: 10080186), and it is absent in population databases (PM2_Supporting). Treatment with RAAS blockade, resulted in partial improvement of albuminuria. B12 levels were normal. Additionally, we identified single *CUBN* VUSs in 8 patients with FSGS and 1 patient with MCD. Among those, 3 required renal replacement therapy and one had a pathogenic variant in the *INF2* (NM_022489.4:c.641G>A, p.(Arg214His)) associated with autosomal dominant proteinuric kidney disease.

Conclusions: We confirm the rarity of *CUBN* related kidney disease in our nephrology practice and highlight the utility of genome sequencing to identify non-coding variants, improving genetic diagnostic yield when targeted or exome-based panels are inconclusive.

FR-PO608

SLC5A2 Mutation in a Patient Presenting with Volume Depletion

Maria Fernanda Martinez Lopez,[1] Danielle Janosevic.[2] *[1]Universidad Iberoamericana, Santo Domingo, Dominican Republic; [2]Indiana University School of Medicine, Indianapolis, IN.*

Introduction: We present a patient found to have a heterozygous SLC5A2 mutation in the absence of glucosuria with volume depletion and underlying tubulopathy.

Case Description: 30 year old African American male, no prior medical history with chief complaint of fatigue and persistent alkalemia on bloodwork. Evaluation of fatigue included a sleep study negative for central/obstructive sleep apnea, pulmonary function testing without obstruction/restriction. He stated the fatigue had been worsening over the past year, prior asymptomatic, water intake 4L/day. He denied the use of laxatives, diuretics, antacids, herbals and medications. ROS was positive for orthostasis, palpitations, denied: poor oral intake, nausea, vomiting, diarrhea, polyuria. Family history unknown, and he never had surgery. Exam revealed BP: 89/60 mmHg, HR 88 bpm, RR 16 bpm, small/thin stature, positive orthostatics, moist mucous membranes. Labs remarkable for *Serum*: bicarbonate 34 mmol/L, normal: sodium, potassium, chloride, magnesium, phosphorus, creatinine, glucose, elevated plasma renin 58.9 pg/ml. Fractional excretions of: Sodium 0.3%, Chloride 0.5% Magnesium 5%, Potassium 17%, and *urine* significant for K/Cr 9 and Ca/Cr 0.05, no glucosuria on urinalysis, diuretic screen negative, Uosm 685 mOsmol/kg. Renal US: 1 simple cyst, absence of nephrocalcinosis. Differential included volume depletion on background of salt wasting tubulopathy. Genetic testing performed which revealed SLC5A2 heterozygous mutation (c.1024G>T, p.Glu342*). He was counseled to intake copious fluids and sodium chloride to mitigate the effects of volume depletion and symptoms improved.

Discussion: SLC5A2 encodes the renal sodium/glucose transporter, responsible for renal glucose reabsorption. While homozygous mutations result in glucosuria which may lead to volume depletion, heterozygous mutations are variable with differing phenotypes, and many do not manifest with overt volume depletion in the absence of glucosuria. Here we present a patient with a heterozygous mutation in the SLC5A2 gene without glucosuria, who presented with evidence of volume depletion and electrolyte wasting tubulopathy. This case emphasizes the need for phenotyping various mutations in the SLC5A2 gene, to aid in the differential of metabolic alkalosis and altered tubular handling of electrolytes in the setting of such mutations.

FR-PO609

Juvenile Nephronophthisis Caused by Two New XPNPEP3 Gene Mutations: A Case Report

Xunzi Tang, Ming Xia, Xinyan Fan, Juanyong Zhao, Hong Liu. *Department of Nephrology, The Second Xiangya Hospital, Central South University, Hunan Key Laboratory of Kidney Disease and Blood Purification, Changsha, China.*

Introduction: Nephronophthisis(NPHP) is an autosomal recessive disease that mainly involves the tubulointerstitium. This article reports a case of a juvenile type of Nephronophthisis with a small proportion of urine, an increase in serum creatinine and anemia of uric acid, as the main clinical manifestations, renal pathological features of renal tubule atrophy, renal tubule membrane thickening, fibrosis, and inflammatory cell infiltration. The whole exome of the XPNPEP3 gene showed two mutations: CHR22:41278058,c.466(exon 3) C>T, and Chr22:41253249,c.64(exon 1) G>A, which caused Nephronophthisis. These two mutations are novel mutations of the XPNPEP3 genes.

Case Description: The patient, a 14-year-old male, was admitted to the hospital because of "abnormal renal function for 3 years." Pathological diagnosis: Proliferative sclerosing glomerulonephritis with chronic renal tubulointerstitial nephropathy is initially considered, and genetic screening is recommended. The whole exome of the XPNPEP3 gene showed two mutations: CHR22:41278058,c. 466(exon 3) C>T, and Chr22:41253249,c. 64(exon 1) G>A. Mutations in this gene can lead to Nephronophthisis. The clinical diagnosis was: 1. Nephronophthisis 2. Chronic renal insufficiency 3. Metabolic syndrome, Category 1 high blood pressure, high-risk glucose tolerance, abnormal abdominal obesity 4. Hyperuricemia 5. mild anemia. At present, the patient is still under regular follow-up.

Discussion: Nephronophthisis(NPHP) is an autosomal recessive disease that primarily involves the renal tubulointerstitium. NPHP is characterized by normal or reduced renal size, renal cysts concentrated at the corticomedullary junction, and tubulointerstitial fibrosis. Whole exome sequencing of the XPNPEP3 gene showed two NPHP-causing variants, Whole exome sequencing of the patient's father and mother confirmed the existence of compound heterozygous mutations. The clinical manifestations of the patient were partially consistent with Nephronophthisis type 1. At present, there is no specific drug for the treatment of Nephronophthisis, and the principle of clinical treatment is supportive therapy. Risk factors leading to renal injury and complications should be controlled. Hormones should be avoided in patients with hypertension, worsening renal function, edema, or hyperkalemia.

FR-PO610

In Vivo Disruption of pH Gradients Alters Endo-Lysosomal Dynamics in the Proximal Tubule

Imene B. Sakhi,[1] Monika A. Kaminska,[1] Nevena Jankovic,[1] Andrew Hall.[1,2] Structural and Functional Imaging of the Kidney. *[1]Universitat Zurich, Zurich, Switzerland; [2]Universitatsspital Zurich Klinik fur Nephrologie, Zurich, Switzerland.*

Background: The proximal tubule (PT) displays an apical endo-lysosomal system (ELS) that reabsorbs and degrades filtered plasma proteins. Defects in this process result in proteinuria. Vesicular acidification is integral to endocytotic function and is impaired in some genetic kidney disorders, such as Dent disease; but the nature of pH gradients in the PT ELS and their functional relevance to dynamic processes were not well understood. Data from partially differentiated *in vitro* models suggest that pH decreases progressively through early endosomes (EEs), late endosomes (LEs) and lysosomes, but whether it is also the case in PTs *in vivo* was unclear.

Methods: We have used small molecules as carriers to target pH dependent and independent fluorescent sensors to the PT ELS in living mice and provide ratiometric readouts of intracellular pH. We have applied intravital multiphoton microscopy to track probes through ELS components in real-time, and have mapped changes in pH to specific structures identified by antibody labeling in fixed tissue. The lipophilic weak base hydroxychloroquine (HCQ) was injected intravenously to explore the effects of rapidly de-acidifying ELS vesicles.

Results: The ratiometric technique was shown to provide a readout of pH across the physiological range in a PT cell line. Clear decreases in pH were identified within PTs *in vivo* in both EEs and lysosomes, but surprisingly not in LEs. Abolishing these pH gradients with HCQ disrupts recycling of megalin and reroutes it to the degradative pathway, resulting in a severe defect in protein uptake. However, HCQ treatment did not recreate characteristic defects in endosomal maturation described previously in Dent disease models. Meanwhile, de-acidification of lysosomes inhibits dissociation from LEs and prevents their trafficking into the basal, mitochondrial-rich region of the cell.

Conclusions: By using an innovative intravital imaging approach, we have generated the first functional map of ELS pH changes within working PTs, which differs significantly from the previous textbook paradigm. Moreover, we show that vesicular acidification is critical for endocytotic receptor recycling and lysosomal dynamics. However, our results suggest that endosomal alkalinization alone does not fully explain the pathogenesis of Dent disease, meaning that pH-independent mechanisms still need to be considered.

FR-PO611

Hypokalemia in an Older Adult due to Heterozygosity for a Novel Pathogenic Variant that Causes Gitelman Syndrome

Laith Alzyood,[1,2] Molly Fisher.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Medical Center, New York, NY.*

Introduction: Gitelman Syndrome (GS) is a rare autosomal recessive disorder due to a mutation in the *SLC12A3* gene that encodes thiazide-sensitive sodium-chloride cotransporter (NCCT) in the distal convoluted tubule. GS classically presents as a salt-losing tubulopathy characterized by low-normal blood pressure, hypokalemia, hypomagnesemia, and metabolic alkalosis and is typically diagnosed in childhood or adolescence. We present an unexpected case of isolated hypokalemia in an older adult with HIV due to a heterozygous *SLC12A3* variant mutation.

Case Description: A 63-year-old male with well controlled hypertension, coronary artery disease and HIV with undetectable viral load was referred for hypokalemia. He had intermittent hypokalemia for at least 15 years with potassium as low as 2.7 mEq/L. He had no symptoms of gastrointestinal loss of potassium or family history of hypokalemia. Medications included losartan 50 mg daily, metoprolol 50 mg daily, and amlodipine 10 mg daily, potassium chloride 10 mEq thrice daily, emtricitabine-tenofovir alafenamide 200-25 mg daily, and dolutegravir 50 mg daily. His blood pressure was 110/75 mmHg. Serum magnesium and phosphate were normal and serum bicarbonate ranged from 25-28 mEq/L. Urine spot potassium was 43 mEq/L and fractional excretion of potassium was 11%, indicating renal potassium wasting. Screening for hyperaldosteronism was negative. A prior computed tomography showed a hyperdense appearance to the renal medullary pyramids and several non-obstructing kidney stones. Due to concern for an underlying genetic etiology of his hypokalemia, genetic testing was performed which revealed a heterozygous single amino acid substitution of *Glu* to *Asp* at codon 121 in exon 2 of the *SLC12A3* gene.

Discussion: Our patient was heterozygous for a pathogenic variant in the *SLC12A3* gene that causes GS. Though the inheritance pattern of GS is autosomal recessive, we believe our patient's isolated renal potassium wasting reflects an intermediate disease phenotype that may be seen in heterozygous carriers. A prior study found heterozygosity for the *p.R642G* variant was associated with lower serum potassium but to our knowledge, this is the first report of hypokalemia associated with the *c.363G* variant. This case supports the concept that pathogenic variants, known to cause many recessive disorders, contribute to complex traits.

FR-PO612

Syntaxin 3 Is Essential for Renal Proximal Tubular Reabsorption

Hiroki Okushima, Kazunori Inoue, Atsuhiro Imai, Yusuke Katsuma, Ayumi Matsumoto, Isao Matsui, Yoshitaka Isaka. *Department of Nephrology Osaka University Graduate School of Medicin, Suita, Japan.*

Background: Transporters at the apical membrane of renal proximal tubular epithelial cells (PTEC) are essential for reabsorbing water and electrolytes from primary urine. However, how these transporters are trafficked to the apical membrane remains uncertain. Syntaxin 3 (STX3) is a molecule that belongs to the membrane fusion-associated protein superfamily. The study aims to investigate the role of STX3 in the trafficking of transporters to the apical membrane in PTEC.

Methods: Localization of STX3 in mouse and human kidneys were analyzed by immunohistochemistry. Mice with floxed *Stx3* were crossed with tamoxifen (Tam)-inducible PTEC-specific Cre-expressing mice (*Ndrg1-CreERT2 Stx3$^{fl/fl}$* (*Stx3* cKO)). Samples of the *Stx3* cKO mice were analyzed 1, 2, and 6 months after tamoxifen injection. Urinary electrolytes, urinary glucose, and urinary low molecular weight proteins were quantified to determine the presence of a Fanconi syndrome-like phenotype. The expression levels and localization of various transporters of PTEC were examined by immunohistochemistry. The localization of transport vesicles and brush border in PTEC were analyzed by electron microscopy.

Results: STX3 was localized at the apical membrane of PTEC, both in humans and mice. Increased urinary excretion of phosphate, glucose, and low molecular weight proteins were found in *Stx3* cKO mice compared to control (Ctrl) mice. Urinary calcium excretion and serum creatinine levels in *Stx3* cKO mice were similar to those in Ctrl mice. Immunohistochemical analyses revealed that sodium phosphate transporter 2a was distributed intracellularly and sodium-glucose transporter 2 expression was reduced in the PTECs of *Stx3* cKO mice. Apical brush border membranes were diffusely shortened, and intracellular vesicles were accumulated in the sub-apical areas of the PTECs in *Stx3* cKO mice.

Conclusions: These results suggest that STX3 is critical for the apical trafficking of various transporters that regulate urinary reabsorption in PTEC.

Natural History of Advanced Primary Hyperoxaluria Type 1: A Retrospective Study

John C. Lieske,[1] Jaap Groothoff,[2] Yaacov Frishberg,[3] Sander F. Garrelfs,[2] Dawn S. Milliner,[1] Daniella Magen,[4] Anne-Laure A. Sellier-Leclerc,[5] Hadas Shasha-Lavsky,[6] Sevcan A. Bakkaloglu,[7] Sandrine Lemoine,[8] Daniel G. Fuster,[9] Arnaud Devresse,[10] Ruth Cytter Kuint,[3] Farshad Kajbaf,[11] Richard G. Willey,[11] John M. Gansner.[11] *[1]Mayo Clinic, Rochester, MN; [2]Emma Children's Hospital, Amsterdam, Netherlands; [3]Shaare Zedek Medical Center, Jerusalem, Israel; [4]Rambam Medical Center, Haifa, Israel; [5]CHU Lyon – Hôpital Femme-Mère-Enfant, Bron, France; [6]Galilee Medical Center, Nahariyya, Israel; [7]Gazi University Hospital, Ankara, Turkey; [8]CHU Lyon – Hôpital Edouard Herriot, Lyon, France; [9]Bern University Hospital, Bern, Switzerland; [10]Cliniques Universitaires Saint-Luc, Bruxelles, Belgium; [11]Alnylam Pharmaceuticals, Cambridge, MA.*

Background: Primary hyperoxaluria 1 (PH1) is a genetic disease of oxalate overproduction that can cause progressive kidney damage and systemic oxalosis. We aimed to characterize the natural history of advanced PH1 in the context of standard of care.

Methods: In this retrospective, multinational chart review study, eligible patients had ≥4 healthcare visits related to PH1 spanning ≥6 months (except deceased patients) on or after January 1, 2000, and ≥2 eGFR values ≤45 mL/min/1.73m^2 (or, if age <12 months, 2 serum creatinine values elevated for age [>ULN]). Diagnosis details, laboratory values, clinical events, and imaging data were collected. Patients were assigned to one or both of 2 cohorts, nondialysis (Cohort A) and hemodialysis (Cohort B). Censoring events included participation in a therapeutic clinical trial or initiation of lumasiran. Bone x-ray images were evaluated centrally for evidence of systemic oxalosis and graded using a novel bone oxalosis grading scale.

Results: Fifty-four patients met criteria for Cohort A and 53 for Cohort B; in total, 70 patients were analyzed with up to 21 years of data. Median age at cohort entry was 11.8 years and 12.2 years (Cohorts A and B, respectively); 28 and 13 patients, respectively, met cohort entry criteria prior to PH1 diagnosis. In Cohort A, eGFR slope was –2.8 mL/min/1.73m^2/y (n=25). In Cohort B, patients underwent hemodialysis a median of 6 days/week (range 3–7; n=41) and 3.8 hours/session (range, 2–8; n=31). Overall, 42 patients underwent liver and/or kidney transplantation at least once (median age at first transplant, 15.3 years). Nineteen patients died at a median age of 3.9 years (range, 2.2–34.9); systemic oxalosis was evident in all. Among these, the primary cause of death was transplant-related or occurred within 6 months of transplant in 6 patients. Skeletal oxalosis grade improvement after liver-kidney transplantation generally took more than a year.

Conclusions: Advanced PH1 is associated with high morbidity and mortality; liver and/or kidney transplantation have frequently been pursued. Although liver transplantation corrects the metabolic defect, it also carries significant risk.

The Effect of Slc7a9 Knockout in Dahl SS Rats on Blood Pressure, Metabolism, and Kidney Function

Olha Kravtsova,[1] Yifan Tan,[2] Vladislav Levchenko,[1] Adrian P. Zietara,[1,3] Lashodya V. Dissanayake,[1] Oleg Palygin,[4] Markus M. Rinschen,[2,5] Alexander Staruschenko.[1,6] *[1]University of South Florida Department of Molecular Pharmacology and Physiology, Tampa, FL; [2]Aarhus University Department of Biomedicine, Aarhus, Denmark; [3]Medical College of Wisconsin, Milwaukee, WI; [4]Medical University of South Carolina Department of Medicine, Charleston, SC; [5]University Medical Center Hamburg-Eppendorf Department of Medicine, Hamburg, Denmark; [6]VA James A Haley Hospital, Tampa, FL.*

Background: Amino acid balance plays a crucial role in regulating blood pressure and kidney function, impacting overall cardiovascular health. Mutations in the *Slc7a9* gene, which encodes b(0,+)-type amino acid transporter 1 (b(0,+)AT1) responsible for transporting dibasic amino acids (AA) and cystine, are associated with chronic kidney disease (CKD) and reduced glomerular filtration rate. Patients with cystinuria have a higher risk of developing hypertension due to renal impairment. However, the precise role of AA balance in the development of hypertension and CKD remains incompletely understood. We hypothesized that knockout of *Slc7a9* on the Dahl salt-sensitive background (SS$^{Slc7a9-/-}$) will enhance the excretion of dibasic AAs and disrupt AA homeostasis, thereby affecting blood pressure and kidney function.

Methods: The *Slc7a9*$^{-/-}$ rat model was generated on the Dahl SS background by CRISPR/Cas9. The mutation was confirmed by RT-qPCR and Western blotting. Transcriptomic, proteomic, and targeted metabolomic analyses were performed.

Results: Both male and female knockout rats exhibited reduced body weight, hepatic steatosis, lower diuresis, and both hexagonal and needle crystals in urine sediments. Loss of function of b(0,+)AT1 increased the fractional excretion of several AAs, most notably arginine (0.25 ± 0.1 & 76 ± 18 %, p<0.003), lysine (0.13 ± 0.03 & 39 ± 9 %, p<0.003), 3-methylhistidine (1.3 ± 0.5 & 36 ± 9 %, p<0.003) and ornithine (0.1 ± 0.04 & 21 ± 5 %, p<0.002). Regarding urine metabolites related to the tricarboxylic acid cycle, we observed a decrease in acetoacetic acid and an increase in glutaric and citric acid in *Slc7a9*$^{-/-}$ rats. Following the high salt (4% NaCl) diet for 3 weeks, female Slc7a9$^{-/-}$ rats but not male Slc7a9$^{-/-}$ rats displayed higher mean arterial pressure compared to Slc7a9$^{+/+}$ (184 ± 10 & 144 ± 6 mmHg). The following proteomic and transcriptomic analyses uncovered several pathways that exhibited differential regulation between *Slc7a9*$^{+/+}$ and *Slc7a9*$^{-/-}$. For instance, it was found that "α-amino acid-", "cellular-" and "glutamine family AA" metabolic processes were targeted.

Conclusions: Based on our data, it can be inferred that the knockout of Slc7a9 disrupts AA metabolism, which likely contributes to the effects on blood pressure and metabolic processes.

FR-PO615

Nine New Genetic Associations with Medullary Sponge Kidney (MSK) and Successful Pain Therapy with Rimegepant

Gregory L. Braden, Daniel L. Landry, Spencer Hodgins, Anthony E. Poindexter, Jeffrey Mulhern. *UMass Chan Med School-Baystate, Springfield, MA.*

Background: MSK has been associated with glial derived neurotrophic factor(GDNF) mutations in 15 % of patients(pts). Chronic kidney pain occcurs in 80% of MSK pts (D Goldfarb, J Nephrol 81: 537, 2018).

Methods: We studied 15 consecutive radiologically confirmed MSK pts, 2 male and 13 female. 24 hour urinary metabolic changes were studied & gene mutations using Renasight, (Natera, Austin, TX).were performed. Since the kidney sensory afferent nerve fibers in the tubules, pelvis, & ureters are mediated by calcitonin gene-related peptide(CGRP) we studied the effects of eresumab 70 & 140 mg/month subcut & rimegepant(R) 75 mg po qod (both block CGRP activity) to relieve kidney pain in the 6 pts with migraines & MSK. Eresumab caused GI upset in all 6. Chronic kidney pain was assessed before R & after 3 & 6 months of R utilizing the numeric pain rating scale.

Results: Urine studies revealed hypercalciuria > 250 mg/d in 5/15, hypocitraturia < 200 mg/d in 6/15 pts, hyperuricosuria > 700 mg/d in 4/15 pts and none had hyperoxaluria. 13 pts had at least 1 urine abnormality & 14/15 had normal electrolytes without acidosis. Two pts had no mutations & none had GDNF mutations. 13 pts have new mutations associated with MSK: Two pts have Cystinuria: SLC7A9 & SLC3A1. Two pts have Alport's syndrome : COL4A4. One pt has Ehler Danlos Syndrome: COL5A1 One pt has Noonans's Syndrome: PTPN11 Two pts have Smith Lemli Opitz Syndrome: DHCR7. One pt has Pallister Hall Syndrome: CLI3. Two pts have nephronopthisis: NPHP2 & NPHP3. One pt has a defect in both FGFR-2 & Xanthinuria: MOCOS. One pt has proximal renal tubular acidosis: SLC4A4. Six pts had refractory migraines. The X +SEM pain score before R was 8.9+/- .4 & was reduced to 5.7+/-.3 at three & 6 months of R therapy, respectively, (p<0001) allowing 3 pts to lower their chronic opioids.

Conclusions: We conclude: all nine new gene mutations associated with MSK can cause structural renal changes especially in the interstitium and medulla & no pt had GDNF mutations. If MSK pts have migraines R can be a promising new successful chronic pain therapy confirming that CGRP is an important mediator of kidney pain in MSK.

A New Mouse Model for Dent Disease 1 with Impaired Mitochondrial Metabolism Develops CKD

Elise de Combiens,[1] Nadia Frachon,[1] Imene B. Sakhi,[2] Stéphane Lourdel.[1] Renal Physiology and Tubulopathies. *[1]Sorbonne Universite, Paris, France; [2]Universitat Zurich, Zurich, Switzerland.*

Background: Dent disease 1 is a rare tubular disorder characterized by low-molecular-weight (LMW) proteinuria, hypercalciuria, and progressive renal failure. It is caused by inactivating mutations of the *CLCN5* gene encoding for the 2Cl$^-$/H$^+$ exchanger ClC-5. In the kidney, ClC-5 is mainly expressed in early endosomes of proximal tubules (PT) cells where it is thought to optimize the function of the vacuolar H$^+$-ATPase to ensure the proper endocytosis of LMW proteins. To better understand the cellular mechanisms involved in Dent disease, we have generated a *Knock-In* (KI) mouse model carrying a patient mutation of ClC-5. Preliminary data from the lab show altered PT endo-lysosomal function and consequent impaired autophagy. Whether this altered pathway could impact mitochondrial metabolism was previously unknown. Therefore, we used this novel mouse model to evaluate the contributing factors of the progressive metabolic disorder observed in Dent disease.

Methods: The renal phenotype of WT and KI ageing mice was explored using metabolic cages. Their mitochondrial distribution and function were assessed with immunofluorescence, western blot, transmission electronic microscopy, and targeted urinary metabolomic analysis.

Results: 10-month-old KI showed an impaired general renal function accompanied by increased fractional excretions of calcium, phosphate, magnesium, indicating a PT dysfunction. KI mice expressed more Lipocalin 2, a tissue damage marker, in their kidneys and showed its increased excretion. These changes were associated with renal fibrosis and inflammation. The renal expression of PGC1 alpha, a marker of mitochondrial biogenesis, was increased between 4 to 10 months in KI mice. It was associated to an increased mitochondrial mass at 10 months. The shape of PT mitochondria from KI mice was altered even at young stages. Additionally, the loss of metabolites crucial for mitochondrial metabolism (alpha ketoglutarate, oxaloacetic acid, etc.) was highlighted in KI mice.

Conclusions: In conclusion, our mouse model suggests that altered endocytosis, consequent to ClC-5 mutation, impairs autophagy and leads to the accumulation of defective mitochondria. This would therefore potentiate renal damages of various origins with age, and a subsequent renal failure. This study opens up new perspectives for the development of therapeutic strategies.

Phosphor-Modified KLHL3 Knockin Mice Reveal WNK1/4-Independent SPAK/OSR1-NCC Activation in Pseudohypoaldosteronism Type II (PHAII)

Shih-Hua P. Lin, Chih-Chien Sung, Chih-Jen Cheng. *Tri-Service General Hospital Department of Internal Medicine, Taipei, Taiwan.*

Background: We have successfully created missense *Klhl3*$^{M131V/+}$ knockin (KI) mice (human *M78V* mutation in BTB domain) and nonsense *Klhl3*$^{W523X/+}$ KI mice (human *W470X* mutation in Kelch domain) to decipher the molecular mechanisms of PHAII. However, the phosphorylation site (S433) on *KLHL3* regulated by several stimuli such as angiotensin II, insulin, and calcineurin inhibitors in PHAII have not been examined *in vivo*.

Methods: We generated and analyzed two missense *Klhl3* KI mice with phosphor-modified at *S486* site. The phenotypes of phosphomimetic *Klhl3*$^{S486D/+}$ mice (human *KLHL3* S433D mutation) and phosphodefective *Klhl3*$^{S486G/+}$mice (human *KLHL3* S433G mutation) were examined. The associated protein expression of their kidney tissue was evaluated by western blot and immunofluorescence.

Results: Unlike the Wnks-dependent Spak/Osr1-Ncc activation in *Klhl3*$^{M131V/+}$ and *Klhl3*$^{W523X/+}$ KI mice, both *Klhl3*$^{S486D/+}$ and *Klhl3*$^{S486G/+}$mice recapitulating typical phenotypes of PHAII exhibited an enhanced phosphorylation of Spak/Osr1-Ncc but the "unchanged" Wnk1/4 and Klhl3 expression. Both phosphor-modified *Klhl3* KI mice demonstrated a significantly increased expression of calcium binding protein 39 (Cab39) known to interact and stimulate Spak/Osr1, as compared to those in WT littermates, *Klhl3*$^{M131V/+}$ and *Klhl3*$^{W523X/+}$ mice. *In vitro* study showed that endogenous Cab39 interacted with KLHL3 and Cul3 complex, but not with WNK1/4. The simulation model demonstrated that KLHL3-WT and phosphor-modified KLHL3 mutants had different binding regions with Cab39.

Conclusions: Phosphor-modified *KLHL3* KI mice exhibiting PHAII reveal a novel Wnks-independent Spak/Osr1-Ncc activation. Whether the phosphorylated status of KLHL3 S433 could affect its binding ability with Cab39 as a substrate for ubiquitination needs to be well validated.

Tracking Molecular and Phenotypic Changes in Kidney Cells in 2D and 3D Cultures Following DHA Exposure: An Approach to Understand Cellular Changes in Adenine Phosphoribosyltransferase (APRT) Deficiency

Hildur R. Helgudottir,[1] Runolfur Palsson,[1,2] Vidar O. Edvardsson,[1,2] Thorarinn Gudjonsson.[1,2] *[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [2]Landspitali–The National University Hospital of Iceland, Reykjavik, Iceland.*

Background: Adenine phosphoribosyltransferase (APRT) deficiency is a rare autosomal recessive disorder of adenine metabolism that results in the generation and renal excretion of 2,8-dihydroxyadenine (DHA), leading to kidney stones and crystal nephropathy characterized by inflammation and fibrosis. The aim of this study was to create a cell culture model to investigate DHA crystal-induced kidney injury in order to identify potential targets for clinical intervention.

Methods: Three kidney cell lines, MDCK, HK-2, and HEK293, were used in this study. All cell lines were treated with DHA at concentrations comparable to those found in the urine of untreated humans with APRT deficiency, both in monolayer and 3D assays. Furthermore, siRNA against *APRT* was used to knock down the gene in HEK293 and HK-2 cells. The readout assays included cell viability, RT-PCR, western blotting, and immunostaining.

Results: Following DHA exposure, decreased viability was observed in all cell lines. HEK293 cells exhibited increased expression of IL-8 following DHA treatment, indicating an inflammatory response. MDCK cells showed increased expression of N-cadherin when treated with high concentrations of DHA compared to the control, suggesting an epithelial–mesenchymal transition (EMT) response. Additionally, both HEK293 and MDCK cells showed increased CD44 expression, which is believed to be important for crystal binding to renal epithelial cells, upon exposure to higher DHA concentrations. When cultured in 3D condition with the addition of DHA, MDCK cells were still able to form polarized structures, and DHA accumulated within and around the structures. HEK293 cells form solid colonies and with the addition of DHA, the DHA accumulates inside the colonies. APRT expression was significantly reduced in HEK293 and HK-2 cells after successful knockdown, and HEK293 cells exhibited elongated protrusions.

Conclusions: We have established a cell culture model that captures kidney cell alterations observed in APRT deficiency. Data suggest that DHA treatment of these cell lines *in vitro* induces an inflammatory response, EMT, and reduces cellular viability. This cell culture model provides insights into the inflammatory response and potential disease-specific targets for clinical intervention.

Acyl-CoA Synthetase Short-Chain Family 2 Is a Renal Disease Risk Gene: Controlling De Novo Lipogenesis in Kidney Tubules

Dhanunjay Mukhi, Katalin Susztak. Susztak Lab. *University of Pennsylvania, Philadelphia, PA.*

Background: Worldwide, over 800 million people are affected by kidney disease, yet its pathogenesis remains elusive, hindering the development of novel therapeutics.

Methods: In this study, we employed kidney-specific expression of quantitative traits and single-nuclear open chromatin analysis to show that genetic variants linked to kidney dysfunction on chromosome 20 target the acyl-CoA synthetase short-chain family 2 (ACSS2). By generating ACSS2 knock-out mice, we demonstrated their protection from kidney fibrosis.

Results: Our analysis of primary tubular cells revealed that ACSS2 regulates de novo lipogenesis (DNL), causing NADPH depletion and increasing ROS levels, ultimately leading to NLRP3-dependent pyroptosis. Additionally, we discovered that pharmacological inhibition or genetic ablation of fatty acid synthase safeguarded kidney cells against profibrotic gene expression and prevented kidney disease in mice. Lipid accumulation and the expression of genes related to DNL were elevated in the kidneys of patients with fibrosis.

Conclusions: Our findings pinpoint ACSS2 as a critical kidney disease gene and reveal the role of DNL in kidney disease.

Mitochondrial Reactive Oxygen Species (ROS) Triggers Karyomegalic Interstitial Nephritis (KIN) Pathogenesis in FAN1-Deficient Kidneys

Merlin Airik,[1] Eric S. Goetzman,[1] Stanislav Kmoch,[2] Peter J. Conlon,[3] Anthony J. Bleyer,[4] Rannar Airik.[1,5] *[1]Children's Hospital of Pittsburgh of UPMC, Pittsburgh, PA; [2]Univerzita Karlova, Praha, Czechia; [3]Beaumont Hospital, Dublin, Ireland; [4]Wake Forest Baptist Medical Center, Winston-Salem, NC; [5]University of Pittsburgh, Pittsburgh, PA.*

Background: Karyomegalic interstitial nephritis (KIN) is a genetic adult-onset chronic kidney disease (CKD) characterized by genomic instability and mitotic abnormalities in the tubular epithelial cells. KIN is caused by recessive mutations in the FAN1 DNA repair enzyme. However, the endogenous source of DNA damage in FAN1/KIN kidneys has not been identified.

Methods: KIN was induced in 12-week-old *Fan1* KO mice by employing low dose cisplatin injury models: one mimicking AKI (1 x 2 mg/kg cisplatin), and another CKD (weekly 5 x 2 mg/kg cisplatin). Coincident with cisplatin, mice were administered a novel mitochondrial ROS and electron scavenger JP4-039 at a dose of 10 mg/kg. Histological analysis was performed using PAS and HE. Markers of tubular injury, DNA damage and fibrosis were assessed by IF and IHC. Human kidney proximal tubular cells (PTECs) were used to model FAN1 loss of function *in vitro*. RNA-seq analysis was performed to identify transcriptional changes in KIN. Mitochondrial OXPHOS was measured using the Oroboros Oxygraph-2k System. Metabolite measurements were preformed using YSI 7100 Bioanalyzer.

Results: Transcriptional profiling of kidneys with KIN revealed a significant downregulation of genes involved in mitochondrial energy metabolism - OXPHOS, fatty acid oxidation (FAO) and peroxisomal function. Metabolic analysis of FAN1KO PTECs showed a defect in respiratory chain, increased oxidative stress and a shift to increased lactate secretion. Similarly, *Fan1* KO kidneys revealed marked increase in oxidative DNA damage (8-OHdG), lipid peroxidation (4-HNE) and tubular lipotoxicity (OilRedO) after AKI or CKD. Treatment with mitochondrial ROS scavenger reduced the level of oxidative lesions in *Fan1* KO kidneys, mitigated tubular damage and blocked the formation of KIN.

Conclusions: Loss of *FAN1* causes defective mitochondrial metabolism and increased ROS generation in the kidney which give rise to oxidative DNA lesions and results in KIN. Blocking mitochondrial ROS protects *Fan1* KO kidneys from DNA damage accumulation, mitigates tubular injury and improves kidney function in mice.

A Novel Renal Collecting Duct Model to Study Secondary Nephrogenic Diabetes Insipidus Associated with Cystinosis

Angela Ferrulli,[1,2] Rik Gijsbers,[2] Annarita Di Mise,[1] Sara Cairoli,[3] Lambertus P. Van den heuvel,[2] Elena Levtchenko,[4] Giovanna Valenti.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Katholieke Universiteit Leuven, Leuven, Belgium; [3]Ospedale Pediatrico Bambino Gesu, Roma, Italy; [4]Universiteit van Amsterdam, Amsterdam, Netherlands.*

Background: Cystinosis is a severe lysosomal disorder caused by mutations in the *CTNS* gene, encoding for the lysosomal transporter cystinosin, resulting in the accumulation of cystine throughout the body. It manifests as Renal Fanconi syndrome in the first months of life, and lastly progresses into end stage renal failure. Secondary Nephrogenic Diabetes Insipidus (NDI) has been reported as a secondary complication of cystinosis due to the resistance to vasopressin, a key hormone that, in the collecting duct activates the vasopressin-sensitive water channel Aquaporin-2 (AQP2), regulating water reabsorption. Over the past years, the development of several *in vivo* and *in vitro* models of cystinosis has contributed to understand the pathophysiology of this severe disease. Nevertheless, the molecular mechanisms causing the secondary NDI phenotype have not been investigated due to the lack of collecting duct cellular models.

Methods: A CRISPR/Cas9 *CTNS* knock out model derived from MCD4 cells, a mouse renal collecting duct cell line, stably expressing human AQP2 and vasopressin receptor 2 (V2R), was established and validated by Sanger sequencing, qPCR and mass spectrometry (MS). Osmotic water permeability measurements in presence or absence of Desmopressin (DDAVP), a synthetic vasopressin analog to investigate AQP2 function were carried out.

Results: Sanger sequencing analysis demonstrated that *CTNS* was efficiently CRISPRed. This result was further confirmed by a significant reduction of *CTNS* transcript levels, up to 65%, and a significant accumulation of cystine by MS in CRISPRed *CTNS* KO cells with respect to wt. Preliminary studies on osmotic water permeability indicate that, compared to control, in *CTNS* CRISPR cells, the osmotic water permeability does not significantly increase in response to DDAVP treatment, consistent with an impairment of the vasopressin-AQP2 pathway.

Conclusions: We provide here the first *CTNS* KO collecting duct *in vitro* model useful for the study of secondary NDI in cystinosis.

Sox2/CD63-GFP Transgenic Rat: A Novel Model for Nephrogenic Diabetes Insipidus

Aya Yoshimura,[1] Takahiro Shirozu,[1] Masanori Kugita,[1] Kanako Kumamoto,[1] Tamio Yamaguchi,[2] Shizuko Nagao.[1] *[1]Fujita Health University, Toyoake, Japan; [2]Suzuka University of Medical Science, Suzuka, Japan.*

Background: Tetraspanins are transmembrane proteins with four membrane domains that form complexes with other membrane proteins, playing diverse roles in physiological functions. The tetraspanins CD9, CD63, and CD81 are well-established exosome markers, while CD151 variants have been associated with glomerular disease. Previous studies using transgenic (Tg) rats expressing CD63-GFP under the Sox2 promoter, aimed at visualizing exosomes, revealed prominent symptoms of polydipsia and polyuria (Yoshimura et al., Disease Models & Mechanisms, 2018). This study aims to explore the pathophysiological characteristics of Tg (Sox2/CD63-GFP) rats.

Methods: We assessed body weight, food consumption, water intake, blood pressure, serum urea nitrogen (UN), creatinine (Cre), urine volume, and urine osmolality in Sox2/CD63-GFP rats, along with age- and sex-matched normal littermates. Histological and immunohistochemical analyses of the kidneys were conducted.

Results: Tg rats exhibited lower body weight compared to normal rats, along with approximately 7-8 times higher water intake and urine volume. Serum biochemical analysis indicated elevated UN and Cre levels in Tg rats, suggesting deteriorating renal function. Tg rat kidneys showed significant enlargement and symptoms of hydronephrosis. In normal rat kidneys, AQP3 was distributed laterally, while AQP2 was distributed apically in the collecting ducts. In contrast, Sox2/CD63-GFP rats exhibited reduced AQP2 expression in both the plasma membrane and cytoplasm of the cortical collecting ducts.

Conclusions: Nephrogenic diabetes insipidus, one of the two primary types of diabetes insipidus, primarily results from mutations in the vasopressin receptor or AQP2 in the collecting ducts. The observed symptoms in Sox2/CD63-GFP rats resembled those of diabetes insipidus, characterized by impaired water reabsorption in the kidneys and severe renal manifestations such as polydipsia, polyuria, and hydronephrosis due to excessive urinary output. CD63-GFP expression may disrupt intracellular trafficking of AQP2, given CD63's involvement in intracellular trafficking and protein localization at the plasma membrane.

Renal Failure from Bladder Acontractility in Untreated X-Linked Nephrogenic Diabetes Insipidus

Dureya Syed, Martin Sedlacek. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: A lot is known about about the genetics and molecular pathophysiology of hereditary nephrogenic diabetes insipidus (DI) but there is little information on the long term renal outcome of this condition. Case series show that nephrogenic DI can lead to CKD but the mechanism is unclear. Here we report a patient with untreated x-linked nephrogenic DI who developed renal failure from bladder acontractility.

Case Description: A 45 year old man presented to the emergency room with a distended abdomen and 10lbs weight gain over several weeks. Ultrasound showed a large bladder and bilateral severe hydronephrosis. His serum creatinine was 1.36mg/dl, increased from a 1.2mg/dl previously. Bladder catheterization produced immediate drainage of 7.5L of urine. In the following hours large urine output was noted. The next morning the patient's serum creatinine was 1.5mg/dl, serum sodium 149mEq/L and serum osmolality 307mOsm/L. The urine osmolality was 84mOsm/L, sodium <20 and specific gravity 1.003. An ADH level was elevated at 16.3pg/ml. The patient was diagnosed with nephrogenic DI at birth and lost to follow up since his early teenage years. He has three brothers with DI and an adult son who is not affected. X-linked nephrogenic DI was confirmed by genetic testing showing substitution of guanosine by adenosine at codon 296 of the AVP Receptor 2 gene, introducing an early stop codon. Imaging showed a normal sized prostate, cystoureteroscopy was normal except large bladder capacity and urodynamic studies revealed detrusor acontractility. The patient received fluids and was discharged on HCTZ and with an indwelling Foley catheter. He learned to self-catheterize and four months later his serum creatinine was 1.02mg/dl and his urine output 7 L per day.

Discussion: Patients with nephrogenic DI produce urine volumes in the range of 10-12 L and with a bladder volume of 400ml, they will have to urinate at least 25 times in 24 hours, night and day. Because of Poiseuille's law, increased urine flow leads to increased pressure, causing hydronephrosis and bladder distention which in turn leads to detrusor dysfunction and ultimately bladder acontractility. We suspect this chain of events is a frequent cause of renal failure in DI, preventable by flow reduction via diuretic treatment and reduced osmole diet. Straight catheterization can improve renal function in patients with bladder acontractility.

FR-PO624

A Rare Case of Pseudohypoparathyroidism Type 1B Diagnosed by Methylation-Specific Multiplex Ligation-Dependent Probe Amplification (MS-MLPA)

Hong Sang Choi,[1,2] Minah Kim,[3] Tae ryom Oh,[2] Sang Heon Suh,[1,2] Chang Seong Kim,[1,2] Seong Kwon Ma,[1,2] Soo Wan Kim,[1,2] Eun Hui Bae.[1,2] *[1]Chonnam National University Medical School, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Republic of Korea; [3]Chonnam National University Hwasun Hospital, Hwasun-gun, Jeollanam-do, Republic of Korea.*

Introduction: Pseudohypoparathyroidism (PHP) is a rare disorder characterized by hypocalcemia, hyperphosphatemia, and increased serum parathyroid hormone (PTH). Pseudohypoparathyroidism type 1B (PHP1B) is a subtype of PHP characterized by isolated renal PTH resistance, usually without physical abnormalities such as Albright hereditary osteodystrophy or other endocrine abnormalities. We present a rare case of PHP1B presented as hypocalcemia with elevated PTH.

Case Description: A 33-year-old man visited the nephrology department outpatient clinic with abnormal laboratory finding. His serum calcium level was 5.9 mg/dL in recent health exam. He had a history of dyslipidemia without any medication. He complained of tingling sensation in hands and eyelid twitching. On physical examination, he showed Chvostek's sign. His laboratory findings included a serum calcium level of 7.7 mg/dL, a serum ionized calcium level of 1.74 mEq/L, a serum phosphorus level of 4.7 mg/dL, a serum creatinine level of 0.9 mg/dL and a serum PTH level of 284.2 pg/mL. A serum 25-hydroxyvitamin D level of 27.5 ng/mL and a serum 1,25-dihydroxyvitamin D level of 28.2 pg/mL. Under strong suspicion of PHP, DNA sequence analysis and methylation specific multiplex ligation-dependent probe amplification (MS-MLPA) of the GNAS and STX16 genes was performed. MLPA analysis of GNAS gene revealed methylation abnormality in multiple differentially methylated region (DMR). Finally, he diagnosed as PHP1B. He is on outpatient follow-up with adequate calcium replacement and no specific symptoms.

Discussion: The exact prevalence of PHP is not yet known. PHP1B can be sporadic or familial. The genetic characteristics of most sporadic PHP1B is still not well-known but GNAS imprinting abnormalities, hypomethylation at A/B DMR has been reported. Symptoms of PHP1B usually begin in childhood due to low calcium levels and may include numbness, seizures, tetany, cataracts, and dental problems. However, as in our case, specific symptoms may not occur until adulthood. Therefore, when evaluating the cause of hypocalcemia, it is necessary to differentiate PHP1B even in adults, especially in cases with hyperphosphatemia and high PTH levels.

FR-PO625

Effects of N-Acetylcysteine on Evolution of Kidney Function in Patients with Acadian Variant Fanconi Syndrome

Mohammad Al-Qadi,[1] Caroline Jose,[2] Etienne Hebert-Chatelain,[3] Yves Thibeault.[2] *[1]Universite de Sherbrooke, Sherbrooke, QC, Canada; [2]Reseau de Sante Vitalite, Bathurst, NB, Canada; [3]Universite de Moncton, Moncton, NB, Canada.*

Background: Acadian variant of Fanconi syndrome (AVFS) is an autosomal recessive disease that leads to chronic kidney failure, proximal tubule dysfunction and pulmonary fibrosis, and is present only in the Acadian people. This condition is caused by a mutation in the NDUFAF6 gene which results in mitochondrial dysfunction and oxidative damage to the kidneys. The objective of this study is to evaluate the effect of N-acetylcysteine (NAC), an antioxidant, on the progression of loss of renal function in patients with AVFS.

Methods: A retrospective self-controlled study was conducted with 4 individuals diagnosed with AVFS, comprising 100% of the known active population who were neither transplanted nor on dialysis. Medical records were reviewed to obtain information regarding glomerular filtration rate (eGFR), serum creatinine, blood pressure, and medications. eGFR was calculated using the Schwartz formula for patients under 18 years of age and the MDRD formula for adults. The changes in GFR before and after NAC prescription were analyzed for each patient to assess the effect of NAC on disease progression, and these changes were also compared with past AVFS patients who had never received NAC.

Results: NAC was projected to delay the need for kidney replacement therapy by an average of 135 months in the treated patients who otherwise would have required it by a mean age of 28 years, which is comparable to past patients who underwent kidney replacement therapy at an average age of 30.

Conclusions: This study demonstrated that NAC appears to have a beneficial effect on the progression of GFR in patients with AVFS, delaying the projected need for kidney replacement therapy by over 11 years. Further studies are needed to evaluate the potential benefits of NAC in other chronic kidney conditions.

FR-PO626

ABCC6 and CKD: The Phenotypic Expansion of Pseudoxanthoma Elasticum

Clara Schott,[1,2] Cadence Baker,[2] Samantha Colaiacovo,[2] Dervla M. Connaughton.[1,2] *[1]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada.*

Background: Adenosine triphosphate (ATP) Binding Cassette Subfamily C Member 6 *(ABCC6)* is a transporter nucleotide that mediates cellular efflux of ATP, which is hypothesized to prevent calcification. In chronic kidney disease (CKD) patients, vascular calcification is prevalent but not completely understood. Monogenic cause occurs in 10% of CKD patients, however monogenic causes of vascular calcification in CKD have yet to be identified. Both recessive and dominant variants in *ABCC6* are known to cause Pseudoxanthoma Elasticum (PXE), a heritable disorder characterized by the accumulation calcium deposits and subsequent vascular calcification involving elastic fibers in the skin, eyes, and cardiovascular system. Data suggests PXE is associated with nephrolithiasis and nephrocalcinosis, with reports also suggesting higher prevalence of end-stage kidney disease (ESKD), glomerulonephritis, and renovascular hypertension. This is hypothesized to be secondary to elastic fiber fragmentation and mineralization in renal arteries. In addition, knockout mice models in *ABCC6* developed calcification in the blood vessels, prominently in the renal cortex, in association with papillary calcification.

Methods: To identify monogenic kidney disease associated with vascular calcification phenotype, we performed whole exome sequencing (WES) in 94 families with CKD, looking for pathogenic variants in the gene *ABCC6*.

Results: We identified 2 heterozygous, loss of function variants in *ABCC6* in 2 families with CKD of unknown etiology (c.1999delG p.A667fs and c.C3421T:p.R1141X). No formal diagnosis of PXE was established prior to analysis. Affected individuals were reviewed post exome analysis and were found to exhibit a broad spectrum of extra-renal phenotypes including eye and skin pathology, and severe peripheral vascular disease. Renal phenotype included a history of kidney stones along with CKD of unknown etiology progressing to ESKD in multiple family members.

Conclusions: We identified loss of function variants in *ABCC6* in two families with CKD by reverse phenotyping for PXE. This report suggests the need for phenotype expansion of PXE to include CKD. Further work is required to establish the exact role in disease pathogenesis but preliminary data suggests that heterozygous variants in ABCC6 may lead to multi-system vascular calcification disease, also affecting the kidney.

FR-PO627

Utility of a Renal Genetics Clinic: A Canadian Prospective Cohort

Clara Schott,[1,2] Cadence Baker,[2] Samantha Colaiacovo,[2] Dervla M. Connaughton.[2,1] *[1]Western University Schulich School of Medicine & Dentistry, London, ON, Canada; [2]London Health Sciences Centre, London, ON, Canada.*

Background: Genetic kidney disease (GKD) is more prevalent than previously considered, with 1 in 10 chronic kidney disease (CKD) patients affected. When correct inclusion criteria for GKD is used, 34-67% of patients can have a genetic diagnosis. Genomic testing using gene-panel or exome sequencing (ES) can confirm GKD through detection of mutations in genes known to cause CKD. Unfortunately, widespread integration into clinical practice has been hampered by small studies and highly selective populations predominately performed in research rather than clinical settings. This study aims to prospectively demonstrate the utility of a renal genetics clinic in a Canadian cohort.

Methods: We analyzed data from a cohort of patients (n=174 families, n=209 affected patients) referred to a renal genetic clinic between September 2019 and April 2023. Testing strategy was firstly to perform gene-panel testing, and if negative or unsuitable, ES was performed. Testing was performed for the detection of mutations in genes suspected to cause the specific subtype of CKD. Mutations are classified according to the American College of Medical Genetics guidelines, with pathogenic and likely pathogenic variants being causative.

Results: We identified a causative mutation in a gene known to cause CKD in 38% of patients (n=80/209). Gene panel testing, performed as the first line of investigation, detected the underlying molecular cause of CKD in 31% of patients tested (n=44/142). Primary ES was performed as the first test in patients with CKD of unknown etiology (CKDu) and had a solve rate of 18% (n=8/45). In patients whom gene-panel was negative or not possible (n=82), secondary ES analysis was performed and confirmed the suspected clinical diagnosis in 26% of patients (n=21/82). For solved patients (n=80), there were many clincial outcomes, including change of diagnosis. Of note, 48% of solved patients had a pre-priori diagnosis of CKDu, but all receied a diagnosis after testing. Other important clinical outcomes include, avail of genetic counselling, resolved diagnostic confusion, and correction of diagnosis.

Conclusions: We show that in a Canadian cohort of adults referred to a renal genetic clinic, genomic testing has utility by confirming the cause of genetic kidney disease in 38% of patients. Genetic sequencing also has significant impacts on clinical management and patient outcomes.

FR-PO628

Diagnostic Utility and Clinical Impact of Genomic Testing in Adolescent and Adult Kidney Disease Patients with Suspected Monogenic Etiology by Establishing an Integrated Kidney Genetics Service

Suceena Alexander, Santosh Varughese, Selvin Sundar Raj Mani. GRACE-KGS. *Christian Medical College Vellore, Vellore, India.*

Background: Though studies have shown positive impact of genomic testing in pediatric population, the diagnostic utility and the clinical impact in real world situations faced by nephrologists when managing adolescent and adult patients with suspected monogenic kidney disease is not known.

Methods: It is a prospective observational pragmatic cohort study. Consecutive patients satisfying the inclusion and exclusion criteria was recruited after written informed consent and pre-test genetic counselling. Genetic testing was by exome sequencing and results returned with post- test genetic counselling. The whole exome sequencing was done for all probands and the bio-informatics was performed using in-house and commercial (VarSeq, Golden Helix) pipeline to identify diagnostic variants for patients' renal disease by data scientist and nephrologist trained in genetics. Segregation testing was done on parents of probands to confirm inheritance pattern if required. The diagnostic utility and the clinical impact was assessed at 3 months of patient follow-up following detailed phenotype-genotype correlations.

Results: More than 100 patients were prospectively recruited for this study. Diagnostic utility was 60% and covered the whole spectrum of renal diseases. Phenotypic enrichment prior to recruitment is essential for optimum test usage. There was definite clinical impact and cascade testing could be offered to family members. Cost was significantly decreased with in-house bioinformatics pipeline.

Conclusions: In-house generation of database and bio-informatics performed together nephrologist in the team, helps to correlate the phenotype and genotype tightly and identify disease causing variants by ACMG criteria.

Funding: Government Support - Non-U.S.

Developing Best Practices for Returning Genetic Results to Participants in Nephrology Research: A Study of the CureGN Network

Hila Milo Rasouly,[1] Natalie Vena,[1] Mark Elliott,[1] Kelsie Bogyo,[1] Janneke M. Kuiper,[1] Maddalena Marasa,[1] Victoria Kolupaeva,[1] Zubin J. Modi,[2] Ali G. Gharavi,[1] Maya Sabatello.[1] *[1]Columbia University Irving Medical Center, New York, NY; [2]University of Michigan, Ann Arbor, MI.*

Background: Returning genetic results (RoR) from research is a growing practice aiming to improve patient care and to serve as a trust-building measure by showing reciprocity in health research. No guidelines for RoR in nephrology research currently exist, leading to diverse practices across research sites which limits the ability to understand the impacts of RoR on research participants. We developed a workflow for RoR in the Cure Glomerulonephropathy Network (CureGN) and a study to assess its implementation and the medical and psychosocial impacts of RoR.

Methods: Genome sequencing was performed on 1957 CureGN participants. We identified 3 variants' groups: variants consistent with kidney diseases; APOL1 high risk genotypes; and variants in actionable genes per ACMG/AMP's guidelines. A multidisciplinary team developed a framework for RoR, assessed its acceptability and barriers via a survey with nephrologists, followed by webinars with nephrologists, research participants and parents of pediatric participants, refined and finalized the workflow. We developed pre- and post-RoR surveys for parents, research participants (adults and adolescents), and treating nephrologists to assess satisfaction, medical and psychosocial impacts of the RoR, and barriers for Post-RoR care. With an NIDDK grant, the RoR is free to CureGN participants.

Results: Based on findings from the nephrologists' survey and webinars, we will return the 3 variants' groups. A centralized RoR workflow is implemented by Columbia University (CU) and the CureGN Data Coordinating Center (DCC) at the University of Michigan. Given privacy protections, we instituted a multistep process to inform participants with positive results (n=270): CU will share relevant CureGN IDs with the DCC to inform sites on who to invite for RoR. Interested participants will contact CU's genetic counselors (GCs) to discuss the RoR study, consent and provide a DNA sample for clinical confirmation. GCs will return the results to participants and their nephrologists, add them to the medical records, and send out the surveys.

Conclusions: Findings will inform about the feasibility of, and best practices for, RoR in a large, racially and ethnically diverse Network and will be generalizable to other consortia.

Funding: NIDDK Support

FR-PO630

Pathogenic Genes in the Mesoamerican ESRD Population

Shruti Kore,[1] Mobolaji A. Obayomi,[1] Dinah Clark,[2] Heather Wade,[2] George N. Coritsidis.[1] *[1]Westchester Medical Center, Valhalla, NY; [2]Natera Inc, Austin, TX.*

Background: Dialysis clinics in the New York area treat a large population of immigrants originating from Central and Northern South America. Many do not have an etiology for ESRD, which may result from Mesoamerican (MA) Nephropathy, a pathology not well understood. This study assesses if there are underlying diseases due to genetic variances that predispose these patients to ESRD.

Methods: MA subjects were recruited prospectively from Atlantic Dialysis Management Services units in New York City and Dialysis Clinic Inc. from Westchester Medical Center, along with Non-Mesoamerican subjects (n-MA). Saliva swabs were acquired and processed via Renasight genetic kits. 385 genes were assessed for pathogenic or likely pathogenic variants.

Results: 228 subjects were recruited, of which 123 were MA. 11% of MAs were found to have 23 pathogenic or likely pathogenic variants of positive genes. Of these 23 cases, the most common variants were identified in genes associated with Alport Syndrome (*COL4A3* and *COL4A4*) at a frequency of 26% (6/23). The variants in genes associated with Polycystic Kidney Disease (PKD) (*PKD1* and *PKD2*) also had a frequency of 22% (5/23). Of the 105 n-MA subjects, 20% of them were found to have 39 pathogenic or likely pathogenic variants of positive genes. The frequency of pathogenic variants of genes encoding for Alport Syndrome is 10%, and the frequency of PKD is 8%. The frequency of pathogenic variants of genes encoding for Alport Syndrome is 10% (4/39), and the frequency of PKD is 8% (3/39). The incidence of the APOL1 risk allele in the n-MA population was 28% (11/39), compared to 4% (1/23) in the MA population.

Conclusions: The frequency of genes related to Alport's Syndrome and PKD were increased in MAs. The higher frequency of APOL1 risk alleles in the n-MA contributes to a higher incidence of variants of positive genes, but it is unclear if this led to an underlying genetic cause of kidney disease. Although pathogenic variants were found, their presence does not clearly point to genetic etiologies for MA Nephropathy.

Association Between Sickle Cell Disease and Mortality and Hospitalizations Among In-Center Hemodialysis Patients

Derek M. Blankenship,[1] Adam M. Garrison,[1] Peter Kotanko,[2,3] Jochen G. Raimann,[2] Hao Han,[1] Len A. Usvyat,[1] Murray Epstein,[4] Kabir O. Olaniran,[5] Franklin W. Maddux.[1] *[1]Global Medical Office, Fresenius Medical Care, Waltham, MA; [2]Research Division, Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Division of Nephrology, University of Miami Miller School of Medicine, Miami, FL; [5]Division of Nephrology, Department of Internal Medicine, University of Texas Southwestern, Dallas, TX.*

Background: Sickle cell disease (SCD) is the most common hemoglobinopathy and genetic disorder worldwide, and a significant cause of end stage kidney disease (ESKD). Despite this, our understanding of adverse outcomes in SCD patients undergoing in-center hemodialysis (ICHD) is limited by small sample sizes, non-granular data and significantly different control groups resulting in residual confounding. The purpose of this preliminary study was to assess mortality and hospitalizations within a SCD patient population treated with ICHD for at least 6 months.

Methods: This retrospective study identified SCD and non-SCD patients receiving ICHD treatment from Fresenius Kidney Care (FKC) between 1-1-2017 and 12-31-2021. The baseline period was considered the first 6 months of treatment at FKC. Incident and prevalent ESKD status was defined as less than or more than 4 months since first dialysis date at the start of baseline, respectively. 602 incident and 541 prevalent SCD patients were matched to non-SCD controls using propensity score matching with confounders including incidence/prevalence status (exact match), sex, race, ethnicity, age, and vascular access type. All-cause mortality was analyzed using the Cox proportional hazards model, with the number and duration of hospitalizations being modeled using generalized estimating equations with a Poisson distribution and log link function.

Results: a) Incident Patients: Compared to matched controls, incident SCD patients were 45% more likely to pass away at any given time point ($p<0.001$). SCD patients also had higher rates of hospitalizations per year (2.8 vs 1.6, $p<0.001$) and days hospitalized per year (8.2 vs 4.2, $p< 0.001$) than controls. **b) Prevalent Patients:** Compared to matched controls, prevalent SCD patients were 23% more likely to pass away at any given time point ($p< 0.023$). SCD patients also had higher rates of hospitalizations per year (2.8 vs 1.6, $p<0.001$) and days hospitalized per year (9.6 vs 5.0, $p< 0.001$) than controls.

Conclusions: This preliminary study provided evidence that SCD patients who have received ICHD treatments for at least 6 months remain at an elevated risk for all-cause mortality and hospitalizations compared to similar, non-SCD patients. The all-cause mortality risk was attenuated by prevalent status.

FR-PO632

Patient Mortality and Graft Failure Risks in Transplant Recipients with Kidney Failure Secondary to Genetic Kidney Disease Compared to People with Other Kidney Diseases

Monica S. Ng,[1,2] Helen Han,[1] Venkat Vangaveti,[3] Matthew D. Jose,[4,5] Andrew J. Mallett.[3,6] *[1]Kidney Health Service, Royal Brisbane and Women's Hospital, Brisbane, QLD, Australia; [2]Faculty of Medicine, University of Queensland, Brisbane, QLD, Australia; [3]James Cook University College of Medicine and Dentistry, Townsville, QLD, Australia; [4]University of Tasmania Hobart Clinical School, Hobart, TAS, Australia; [5]Renal Unit, Royal Hobart Hosptial, Hobart, TAS, Australia; [6]Department of Renal Medicine, Townsville University Hospital, Townsville, QLD, Australia.*

Background: There is limited population-level data on long term outcomes of people with genetic kidney disease (GKD) after kidney transplantation. This study aimed to characterise clinical outcomes in people with GKD after kidney transplantation and compare them to those of people with other kidney diseases.

Methods: Data on first kidney transplants between 1 January, 1989 and 31 December, 2020 were extracted from the Australia and New Zealand Dialysis and Transplant (ANZDATA) registry. GKDs were classified as majority or minority monogenic. People with other primary kidney diseases were included as the comparator group. Outcome measures were mortality and graft failure. Unadjusted and adjusted hazard ratios (AHRs)

were calculated using Cox proportional hazard regression models. Sensitivity analyses were completed to test the effect of major diagnoses (e.g. autosomal polycystic kidney disease and reflux nephropathy) within GKD groups.

Results: 21,860 transplant recipients were included. GKDs were associated with reduced mortality in kidney transplant recipients on univariable analyses. This correlation was not statistically significant on multivariable analyses (majority monogenic AHR 0.92, 95% CI 0.84-1.00; minority monogenic AHR 0.91, 95% 0.82-1.02). Majority monogenic GKDs correlated with reduced graft failure compared to other kidney diseases on univariable (Figure 1) and multivariable analyses (AHR 0.79, 95% CI 0.71-0.87). This result was attributed to reduced graft failure in recipients with polycystic kidney disease which constituted 91.9% of the majority monogenic GKD group.

Conclusions: This binational registry analysis found that people with GKD had similar mortality but reduced graft failure after kidney transplant. This is the first study to provide a broad longitudinal overview of clinical outcomes in kidney transplant recipients with GKD.

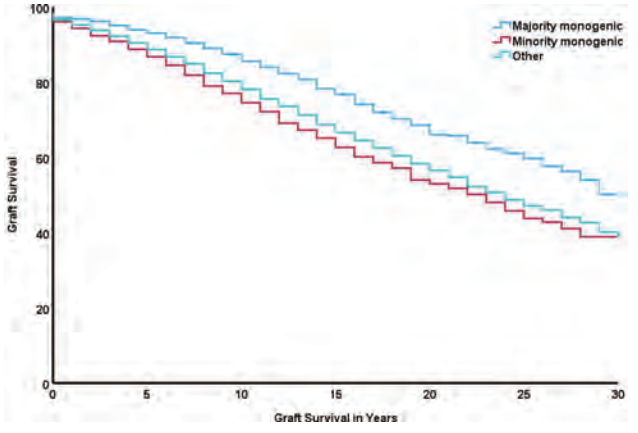

Figure 1 – Kaplan Meier curve for graft failure in kidney transplant recipients

FR-PO633

Evaluating the Association Between Maternal Dietary Vitamin A Status and Fetal Kidney Development

Anum Akbar, Matthew Vanormer, Rebecca Slotkowski, Taija M. Hahka, Melissa Thoene, Corrine Hanson, Ann L. Anderson Berry, Teri Jo Mauch. *University of Nebraska Medical Center, Omaha, NE.*

Background: Vitamin A is a fat-soluble vitamin that plays a crucial role in the development of fetal organs. In vitro, studies have indicated that the number of nephrons, which are functional units in the kidney, is impacted by the presence and quantify of vitamin A. However, the effect of maternal dietary vitamin A status on fetal kidney development remains unknown. As abnormal kidney development can contribute to later renal disease, it is important to identify modifiable factors impacting kidney development, such as dietary intake of vitamin A.

Methods: An IRB-approved study recruited pregnant women who completed a food survey (DHQ III) to evaluate dietary vitamin A intake between 24-28 weeks of gestation. Vitamin A intake was measured in retinol activity equivalents (RAE, mcg/day), with <770 mcg/day being deemed inadequate. Fetal ultrasound between 16-20 weeks gestation measured bilateral fetal kidney size and volume. A post-natal retroperitoneal ultrasound was performed 24-48 hours after birth. Kidney length and volume were compared between maternal vitamin A sufficient and deficient groups using the Mann-Whitney U test. A p-value of <0.05 was considered statistically significant.

Results: A total of 39 women were included in this analysis, with a median age of 32 years. The median RAE was 661.50 RAE (without supplements) and 1200.00 RAE mcg/day (with supplements). There were no significant differences in fetal right kidney measurements, length, and volume ($p = 0.94$ and $p = 0.44$), infant right kidney length and volume ($p = 0.94$ and $p = 0.57$) and change in right kidney length and volume ($p = 0.78$ and $p = 0.62$) across two groups. Similarly, no significant differences were noted in fetal left kidney length and volume ($p = 0.39$ and $p = 0.10$), infant left kidney length and volume ($p = 0.20$ and 0.10) and change in left kidney length and volume ($p = 0.72$ and 0.43) across two groups.

Conclusions: Our study did not find any difference in fetal or infant kidney measurements between maternal vitamin A status and fetal and infant kidney measurements. Furthermore, maternal vitamin A status did not impact kidney growth reported as a change in kidney length or volume. Larger, adequately powered studies should be conducted.

FR-PO634

The Underappreciated Renal Phenotype of EGFR Deficiency: Could It Be that Complex?

Walaa A. Alshammasi, Mathieu J. Lemaire. *The Hospital for Sick Children, Toronto, ON, Canada.*

Introduction: Epidermal Growth Factor Receptor (EGFR) is a cell signaling receptor implicated in cell proliferation, survival, and tissue growth. Neonatal inflammatory skin and bowel disease type 2 is caused by EGFR recessive deficiency (OMIM 616069). Among the 22 known cases, nephromegaly is the only notable renal phenotype. A review of published cases and a new case suggests NISBD2 is frequently associated with tubulopathy.

Case Description: A 10-year-old girl was diagnosed with NISBD2 caused by homozygous pathogenic EGFR variants (NM_005228.3: c.1283G>A; p.G428D). Ultrasound revealed large echogenic kidneys with poor corticomedullary differentiation and many small cysts. We documented hypomagnesemia 0.5 mmol/L and hypokalemia 2.6 mmol/L caused by excessive urinary magnesium wasting FeMg 14%. We also observed mild chronic hypernatremia 155 mmol/L due to a urinary concentration defect UOsm 400 mOsm/kg water. Finally, low-molecular-weight proteinuria and glucosuria without hyperphosphaturia or aminoaciduria suggest partial proximal tubulopathy.

Discussion: In EGFR signaling, there are various downstream pathways, so mutations affect cell proliferation and homeostasis. We will discuss with an in-depth insight into the disease, the potential pathophysiology of the associated tubulopathy and PKD, and its presence in previously reported under-recognized cases. Conclusion: Hypomagnesemia is well-known in EGFR inhibitors but not in EGFR deficiency. Additionally, EGFR deficiency causes enlarged kidneys. The renal phenotype, however, is much more complex, involving hypokalemia, hypernatremia, cystic disorder, and tubulopathy. Electrolytes can be monitored more precisely in cases of EGFR deficiency to determine the significance of this association.

FR-PO635

Müllerian Anomalies in Girls with Solitary Functioning Kidney

Laura E. Walawender,[1] Natasha Santhanam,[2] Benjamin Davies,[2] Yueyang F. Fei,[1] Brian Becknell,[1] Daryl J. Mcleod.[1] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University Wexner Medical Center, Columbus, OH.*

Background: Patients with Müllerian anomalies have a 30-50% increased prevalence of congenital renal anomalies and solitary functioning kidney (SFK) is the most common. However, the prevalence of Müllerian anomalies among patients with SFK is not well defined. A delay in diagnosis of obstructive Müllerian anomalies can increase the risk of poor clinical outcomes. This study describes the prevalence of Müllerian anomalies in patients with congenital SFK.

Methods: A retrospective review was performed of patients within the Nationwide Children's Hospital system with ICD9 or ICD10 diagnostic codes for SFK. Analysis focused on girls with congenital SFK defined as either unilateral renal agenesis (URA) or multicystic dysplastic kidney (MCDK). Patients with complex urogenital pathology, such as, cloaca, urogenital sinus, or bladder exstrophy were excluded. Renal anomaly, Müllerian anomaly, reason for and type of pelvic evaluation, and age of diagnosis of anomalies were evaluated.

Results: Diagnostic codes identified 400 patients; 97 were excluded for complex urogenital anatomy. SFK was confirmed in 204 girls and 169 (82%) were congenital. There were 115 patients with URA and 54 with MCDK. Additional anomalies of the SFK were pelvic/ectopic (4), dysgenesis/hypoplasia (8), cystic (2), and other (19). Of patients with congenital SFK, 85 (50%) had a pelvic evaluation, most frequently in response to abdominal pain/dysmenorrhea (39%). Ultrasound was the most common imaging modality (74%). 49 (29%) patients had a Müllerian anomaly with the majority having combined uterine and vaginal anomalies (28) or isolated uterine anomaly (18). In 59% of patients, the renal anomaly was diagnosed prior to the Müllerian anomaly, at a median age of 6.5 years. In 24 patients, an obstructive Müllerian anomaly was found, including 11 who had a known renal anomaly.

Conclusions: The prevalence of Müllerian anomalies in patients with congenital SFK was 29%. Only half of patients with a congenital SFK had a pelvic evaluation. A Müllerian anomaly was found in about 60% of patients evaluated and it was obstructive in about one third of cases. Over half of the girls with Müllerian anomalies had a prior renal anomaly diagnosis. The high prevalence of Müllerian anomalies in patients with congenital SFK justifies routine screening pelvic ultrasound to improve early diagnosis.

FR-PO636

Pparg Pathway Drives Renal Uroplakin Cell Formation and Parenchymal Preservation During Urinary Tract Obstruction

Mohammad Alharakeh,[1] Kelly Grounds,[1] Felipe Rodriguez,[1] Birong Li,[1] Hanna H. Cortado,[1] Brian Becknell,[1,2] Ashley R. Jackson.[1,2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Urinary Tract Obstruction (UTO) is a leading cause of chronic and end stage kidney disease in children. While no current treatments prevent obstruction-induced kidney disease, future therapies may be identified by understanding how the kidney adapts to obstruction. We previously reported that obstruction triggers the formation of protective uroplakin (Upk) cells which preserve renal parenchyma during congenital and acquired UTO. The molecular program that governs Upk cell formation in the renal urothelium is unknown. In bladder, the *Pparg* signaling pathway drives urothelial differentiation. Thus, we hypothesized that*Pparg* drives renal Upk cell formation during UTO.

Methods: Kidneys from embryonic (E-) and postnatal (P-) female and male mice were collected. We modeled UTO using congenital and surgical models. We conditionally manipulated Pparg in Upk cells using inducible Pparg deletion ($Upk2^{iCre}$;$Pparg^{LOF}$) and gain-of-function ($Upk2^{iCre}$;$Pparg^{GOF}$) mouse lines. Immunofluorescent Analysis (IF-A) and renal ultrasound were used to evaluate the effect of *Pparg* pathway manipulation on UTO-induced Upk cell formation and renal parenchyma, respectively.

Results: Pparg was expressed by renal Upk cells at E17 - P7, but was absent in adult mice ≥P42. Both congenital and surgical UTO triggered Upk cells to re-express Pparg and its targets, Grhl3 and Fabp4. During UTO, $Upk2^{iCre}$;$Pparg^{LOF}$ mice showed a significant reduction in Upk expression (10% Vs 3.1%, P=0.008) accompanied by

significantly thinned renal parenchyma (30.9% Vs 25.9%, P=0.039), compared to Cre(-) mice. However, *Upk2*^{iCre};*Pparg*^{GOF} mice induced a significant upregulation of Upk (10% Vs 17.42%, P=0.006) and exhibited significantly greater parenchymal preservation (30.9% Vs 44.4%, P=0.002), compared to Cre(-) mice.

Conclusions: Our results reveal that UTO-induced *Pparg* signaling is a recapitulation of a renal urothelium developmental program, and that *Pparg* signaling promotes Upk cell formation to preserve renal parenchyma during UTO. Our findings advance our understanding of renal adaptation to UTO and reveal a potential mechanism, such as *Pparg* signaling, with therapeutic utility for mitigating obstructive kidney disease in children. Future studies will investigate the utility of synthetic Pparg agonists during UTO.

FR-PO637

Selected Renal Cells Exhibit Renal Tubule Formation Associated with Transforming Growth Factor B2 Expression

Prakash Narayan, Andrew T. Bruce, Mark A. Rohlfing, Tim A. Bertram, Deepak Jain. *ProKidney, Winston-Salem, NC.*

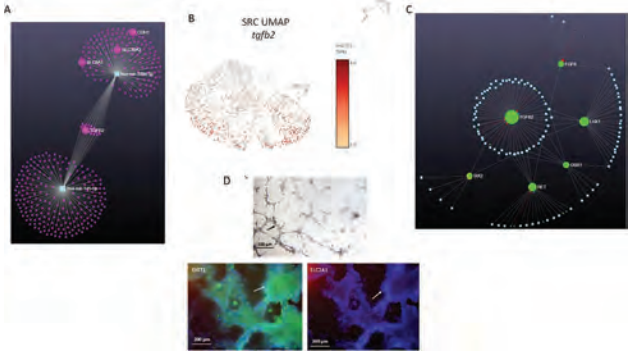
Background: TGFB2 mediates interactions between the ureteric bud and the metanephric mesenchyme resulting in renal tubule formation. Selected renal cells (SRCs) express ureteric bud markers RET and FGF8, and cap mesenchyme markers, LHX1, OSR1 and SIX2, their administration is therapeutic in models of chronic kidney disease. We tested the hypothesis that SRCs express *tgfb2* and assemble into renal tubules.

Methods: Human SRCs (sourced from NDRI kidneys) were submitted to miRNAseq and mRNAseq, differentially expressed nodes identified and seeded into miRNet for interactome visualization. SRCs were submitted to scRNA-seq to map gene expression. SRCs were placed in culture, and secreted TGFB2 measured using ELISA, and evidence of renal tubule formation confirmed by antibody staining for epithelial markers GGT1 and SLC12A1.

Results: Compared to the source biopsy hsa-miR-145-5p (log2FC=-6.9) and hsa-miR-199a-5p (log2FC=-5.7) were downregulated in SRCs (p_{adj}<0.01). Gene ontology revealed that these miRNAs regulate expression of *tgfb2* together with renal epithelial markers (A). SRCs overexpressed *tgfb2* (log2FC=2.5, p_{adj} <0.01). scRNA-seq confirmed *tgfb2* expression (B) and SRC secreted TGFB2 exhibited 12-fold increase vs. control; p<0.01). Gene ontology revealed that *tgfb2* forms an interactome with *ret*, *fgf8*, *lhx1*, *osr1* and *six2*, ureteric bud and cap mesenchyme markers expressed by SRCs (C). Placed in culture, SRCs assembled into GGT1- and SLC12A1-positive renal tubules (D).

Conclusions: These data suggest that therapeutic activity of SRCs may be mediated in part via formation of renal tubules and maintenance of electrolyte balance, fluid homeostasis, reabsorption of essential nutrients, urine concentration and Cystatin C metabolism.

Funding: Commercial Support - ProKidney



(A) hsa-miR-145-and hsa-miR-199a-5p regulate expression of *tgfb2* and renal epithelial markers. SRCs express *tgfb2* (B) which forms an interactome with ureteric bud and cap mesenchyme markers (C). Placed in culture, SRCs assemble into GGT1-and SCL12A1-positive renal tubules (D, arrows).

FR-PO638

Notch Signaling Regulates Renal Urothelium Differentiation

Felipe Rodriguez,[1] Kelly Grounds,[1] Mohammad Alharakeh,[1] Brian Becknell,[1,2] Ashley R. Jackson.[1,2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Children with congenital urinary tract obstruction (UTO) face limited treatment options and experience high rates of ESKD. The renal urothelium undergoes a protective adaptation during UTO by forming differentiated Uroplakin (Upk) cells. However, little is known about signaling pathways that govern Upk expression and urothelial differentiation within the kidney. The Notch signaling pathway regulates bladder urothelial differentiation and single cell RNAseq data suggest a role in renal urothelium development. The objective of this study was to test the hypothesis that Notch signaling regulates Upk expression and urothelial differentiation in the kidney.

Methods: We generated *Hoxb7*^{Cre};RBPJ$^{fl/fl}$ (RBPJ$^{UB\text{-}KO}$) mice and RBPJ$^{fl/fl}$ (controls) to conditionally disrupt Notch signaling. We collected kidneys and bladders from RBPJ$^{UB\text{-}KO}$ and controls at embryonic, neonatal, juvenile, and adult time points. We confirmed tissue-specific depletion of RBPJ and Notch abrogation using immunofluorescent analysis (IF-A) and RNAscope, respectively. We used IF-A to evaluate markers of urothelial differentiation.

Results: IF-A confirmed efficient RBPJ depletion in renal urothelium and collecting ducts, but not bladder urothelium at all time points in RBPJ$^{UB\text{-}KO}$ mice. RNAscope confirmed that Notch targets, *Hes1* and *Hes6*, were significantly decreased in RBPJ$^{UB\text{-}KO}$ renal urothelium compared to controls. IF-A showed that RBPJ$^{UB\text{-}KO}$ kidneys had significant decreases in Upk at each stage. Ppar-γ - a transcription factor that regulates Upk expression - and its targets were also significantly decreased in RBPJ$^{UB\text{-}KO}$ kidneys compared to controls.

Conclusions: We have demonstrated that Notch signaling is key to the formation and maintenance of Upk cells in the renal urothelium. Our data also suggest that Ppar-γ signaling in the renal urothelium may be regulated by Notch. Future studies will investigate whether the Notch signaling directly regulates Upk expression or whether Upk expression is regulated by a Notch-dependent Ppar-γ signaling axis.

FR-PO639

Dot1/H3K79 Pathway Mediates Defective Ureteric Bud (UB) Branching Leading to Renal Hypodysplasia (RHD) in Prorenin Receptor (PRR) PRRUB-/- Mice

Ihor V. Yosypiv, Renfang S. Taylor. *Tulane University School of Medicine, New Orleans, LA.*

Background: Dot1 is histone methyltransferase specific for Histone 3 lysine 79 (H3K79) that is important for differentiation of collecting duct (CD) cells. Targeted deletion of the *Dot1* in the CD principal cells (PCs) in mice represses the acquisition of PC phenotype resulting in polyuria (Wu. JASN, 2013). We tested the hypothesis that RHD and polyuria observed in mice that lack the *PRR* in the UB lineage (*PRR*$^{UB\text{-}/\text{-}}$) (Song. PLoS ONE, 2013) is due to reduced Dot1/H3 dimethyl K79 (H3m2K79) expression.

Methods: Mutant [*Hoxb7*$^{Cre+}$/*PRR*$^{flox/flox}$ (*PRR*$^{UB\text{-}/\text{-}}$), n=3] and control (*PRR*$^{UB+/+}$, n=3) mice were studied on embryonic (E) day E17.5. Dot1 mRNA and protein expression in the kidney was studied by real-time qRT-PCR and immunohistochemistry, respectively. H3m2K79 protein expression was determined by immunohistochemistry and Western blot analysis. The intensity of H3m2K79 and Dot1 immunoreactivity, normalized for surface area of the kidney section, was examined by Slidebook 4.1 software.

Results: Kidney section surface area was smaller in the mutant compared to control mice (220600±20120 vs.533800±72170 pixels, p<0.05). Dot1 mRNA levels were decreased in mutant compared to control mice (0.68±0.06 vs. 1.0±0.01, p<0.01). Dot1 and H3m2K79 immunostaining was reduced in the mutant vs. control kidneys (Dot1: 0.62±0.03 vs. 1.0±0.01, p<0.05; H3m2K79: 0.64±0.04 vs.1.1±0.01. p<0.05.). Western blot analysis revealed decreased H3m2K79 protein levels in mutant compared to control kidneys (1.0±0.06 vs. 1.5±0.02, p<0.05).

Conclusions: We conclude that reduced H3m2K79 methylation by Dot1 in the UB of *PRR*$^{UB\text{-}/\text{-}}$ mice contributes, in part, to RHD and polyuria observed in these mice.

FR-PO640

Roles of microRNA in Development and Maintenance of Urothelium

Macie M. Kercsmar, Hanna H. Cortado, Birong Li, Ashley R. Jackson, Brian Becknell. Kidney and Urinary Tract Center. *Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: MicroRNA (miRNA) serve essential roles in epithelial cell development, maintenance, and response to injury by modulating mRNA and protein expression, but their function in urothelium remains largely unexplored. To address this knowledge gap, we engineered mice with urothelium-specific constitutive and inducible inactivation of *Dicer*, an exonuclease required for miRNA biogenesis.

Methods: We generated urothelial *Dicer* conditional knockout mice by crossing *Dicer*$^{fl/fl}$ and *Upk2*Cre or *Upk2*CreERT$_2$ animals. A tdTomato (tdT) fluorescent protein was expressed in a Cre/LoxP dependent manner from the *Rosa26* locus to identify cells in which *Dicer* inactivation had occurred. Urothelial lineage markers were evaluated by immunofluorescence microscopy, Western blotting and QRT-PCR.

Results: Bladders from control animals displayed the expected urothelial morphology with sequential layers of Krt5+ basal (B) cells, Upk+ intermediate (I) cells, and Upk+; Fabp4+ superficial (S) cells. In contrast, bladders from 3-week-old mice with biallelic inactivation of *Dicer* exhibited rounded S cells appearance with patchy/discontinuous Fabp4 expression and frequent exfoliation into the bladder lumen. This was increasingly evident at 6 and 9 weeks of life and associated with expansion of Krt14+ progenitor cells and thickening of the B and I cell layers. Conditional inactivation of *Dicer* in Upk+ cells of 3-week-old mice recapitulated the phenotype of S cell loss and expansion of the remaining urothelial cell layers.

Conclusions: *Dicer* is dispensable for urothelial formation but serves an essential role in its structural integrity. Ongoing efforts will identify the specific microRNAs responsible for S cell maintenance.

Funding: NIDDK Support

FR-PO641

Defining the Expression and Functions of SLPI, an Antibacterial Peptide Produced by Kidney Intercalated Cells

Aaron A. Simoni, Guillermo Yepes Junquera, Laura Schwartz, John D. Spencer. *Nationwide Children's Hospital, Columbus, OH.*

Background: Mounting evidence suggests intercalated cells (IC) in the kidney collecting duct have antibacterial defenses that prevent pyelonephritis. In part, ICs prevent uropathogenic *E. coli* (UPEC) infections by expressing antimicrobial peptides and secreting them into the urine. The goal of this project is to define the expression, regulation, and antibacterial capacity of secretory leukocyte protease inhibitor (SLPI), a peptide that prevents infections in other organ systems by killing Gram-positive and negative bacteria. SLPI expression in the kidney has not been tested and its antibacterial activity against UPEC is unclear.

Methods: To evaluate SLPI expression, human kidney samples were obtained from people with and without a history of pyelonephritis. Mouse kidney samples were collected before and after mice were transurethrally infected with UPEC. ICs were enriched from mouse kidneys using FACS, cultured to confluency, and challenged with UPEC. SLPI expression was defined using qRT-PCR and Western blot. To test how SLPI is transcriptionally regulated, chromatin immunoprecipitation was performed. The antibacterial activity of SLPI was defined by performing UPEC bactericidal assays.

Results: qRT-PCR and Western blot identify SLPI expression in human and mouse kidneys and show SLPI expression increases with pyelonephritis. Within ICs, *Slpi* transcript expression increases 1.7-fold following UPEC infection. With UPEC infection, we observed increased NF-kB binding to the *SLPI* promoter. Recombinant human and mouse SLPI exhibit dose-dependent killing of UPEC, including multi-drug resistant UPEC.

Conclusions: These findings are the first to demonstrate that SLPI is expressed in human and mouse kidneys and ICs. Its expression is augmented during pyelonephritis, perhaps via NF-kB activation. They also show that SLPI has antibacterial activity against UPEC and multi-drug resistant UPEC. Future studies are needed to assess the utility of SLPI as a pyelonephritis biomarker and define its IC antimicrobial activity in model systems.

FR-PO642

Stat3-Driven Urothelial Programming Prevents Urinary Tract Infection (UTI) Chronicity

Sudipti Gupta,[1] Hanna H. Cortado,[1] Macie M. Kercsmar,[1] Felipe Rodriguez,[1] Ashley R. Jackson,[1,2] Brian Becknell,[1,2] John D. Spencer,[1,2] Christina B. Ching.[1,2] *[1]Nationwide Children's Hospital, Columbus, OH; [2]The Ohio State University, Columbus, OH.*

Background: Uropathogenic E. Coli (UPEC) can evade host immunity resulting in urinary tract infection (UTI) chronicity. We have previously demonstrated that STAT3 limits chronic UTI at 7 days. STAT3 controls several cellular processes by regulating gene transcription. Persistent activation of STAT3 has shown to be oncogenic however not much is known about its impact in UTI. We hypothesize that constitutive STAT3 activation has direct effects on urothelial integrity and epithelial immunity.

Methods: 6-8 weeks old female FVB/N wild type controls (WT) and constitutively active Stat3 (Stat3C) mice underwent experimental UPEC UTI. Serial bladder tissue and urine were collected up to 7 days post infection (dpi). Cytospins were performed on urine. Immunofluorescent staining was performed on bladders for Keratin 5, pStat3, Ly6G, and Iba-1. TUNEL staining was also performed. A Qiagen RT^2 profiler PCR microarray for the IL-6/ STAT3 signaling pathway was also performed on bladders. Results were evaluated by Mann-Whitney U test with $p<0.05$ being significant.

Results: Stat3C and WT urothelium demonstrated induction of pStat3 after infection, with Stat3C urothelium showing persistent activation at 7 dpi. TUNEL staining demonstrated more signs of cellular apoptosis in the WT compared to Stat3C bladders at 24hpi and 7dpi, with cellular shedding on WT cytospins at corresponding time points. There was an earlier infiltration of neutrophils in the urothelium of WT mice with a later infiltration of macrophages in STAT3C mice. RT^2 profile PCR arrays shows altered expression of genes involved in cell cycle regulation, immune cell recruitment, cytokine expression at 24hpi and 7dpi.

Conclusions: Urothelial STAT3 overexpression directly impacts its viability in response to UTI and the recruited inflammatory milieu. Manipulation of this signaling pathway can alter susceptibility to chronic UTI.

Funding: NIDDK Support

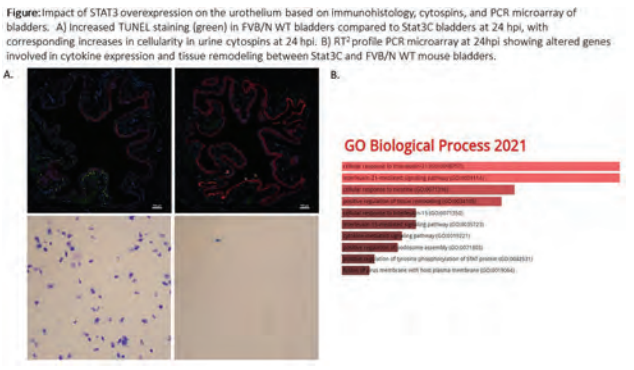

Figure: Impact of STAT3 overexpression on the urothelium based on immunohistology, cytospins, and PCR microarray of bladders. A) Increased TUNEL staining (green) in FVB/N WT bladders compared to Stat3C bladders at 24 hpi, with corresponding increases in cellularity in urine cytospins at 24 hpi. B) RT^2 profile PCR microarray at 24hpi showing altered genes involved in cytokine expression and tissue remodeling between Stat3C and FVB/N WT mouse bladders.

FR-PO643

The Renal Urothelium Serves Essential Roles in Host Defense and Pathogenesis of Pyelonephritis

Birong Li, Rishil H. Patel, Hanna H. Cortado, Sudipti Gupta, Christina B. Ching, Juan de Dios Ruiz-Rosado, Xin Wang, Ashley R. Jackson, Brian Becknell. Kidney and Urinary Tract Center. *Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Uropathogenic *Escherichia coli* (UPEC) causes over 90% of acute pyelonephritis cases in humans. The urothelial lining of the pelvicalyceal system serves a proposed gatekeeper role in limiting renal parenchymal invasion by UPEC, but the exact mechanisms that account for this function are unclear. In this study we utilized spatial transcriptomics to map host-pathogen interactions within renal urothelium during pyelonephritis.

Methods: We established acute pyelonephritis in female C3H/HeOuJ mice by transurethral inoculation of UPEC strain CFT073. We profiled transcriptional changes in renal pelvic urothelium through spatial transcriptomics at baseline and 7 days post infection (dpi). We validated these changes by QRT-PCR and immunofluorescence microscopy. *Upk1b* knockout mice were used to investigate the role of the urothelial plaque in the initiation of pyelonephritis.

Results: Spatial transcriptomics identified induction of transcripts with roles in barrier function, leukocyte recruitment, and bactericidal activity in infected renal urothelium. Conversely, transcripts encoding Uroplakin subunits that comprise the urothelial plaque were decreased following infection. *Upk1b* deletion results in absent urothelial plaque formation. Following transurethral UPEC inoculation, *Upk1b*$^{-/-}$ mice exhibited reduced renal bacterial burden and decreased neutrophil infiltration, when compared to *Upk1b*$^{+/+}$ mice.

Conclusions: The renal pelvis engages multiple antimicrobial mechanisms in response to *E. coli* pyelonephritis – including the downregulation of urothelial plaque formation, which serves to limit parenchymal invasion by UPEC. This study identifies a foundational role for the urothelial plaque in Gram-negative pyelonephritis and further strengthens the rationale for the development of antimicrobial agents that disrupt UPEC-plaque interactions in preventing pyelonephritis.

Gain- and Loss-of-Function Approaches Substantiate Roles for Ribonuclease 6 in Pyelonephritis

Hanna H. Cortado, Macie M. Kercsmar, Birong Li, Ashley R. Jackson, Xin Wang, John D. Spencer, Juan de Dios Ruiz-Rosado, Brian Becknell. Kidney and Urinary Tract Center. *Abigail Wexner Research Institute at Nationwide Children's Hospital, Columbus, OH.*

Background: Acute pyelonephritis (APN) episodes can result in urosepsis, acute kidney injury, and renal scarring. Identifying mechanisms of host defense against APN is a priority to mitigate these sequelae, particularly in an era of mounting antibiotic resistance. Ribonuclease 6 (RNase 6) is a cationic protein with potent bactericidal activity toward uropathogenic *Escherichia coli* (UPEC). We took complementary approaches to examine roles for RNase 6 in experimental APN.

Methods: We utilized a novel *Rnase6*$^{EGFP/+}$ knockin allele to identify the cellular sources of RNase 6 and the impact of its deficiency on APN susceptibility in mice. As a complementary approach we generated human *RNASE6* transgenic mice. Flow cytometry, immunofluorescence microscopy, and scRNAseq identified cellular sources of RNase6 within the kidney. The role of RNase 6 in intracellular UPEC killing was identified in a gentamicin protection assay using bone marrow derived macrophages (BMDM).

Results: Mouse and human RNase 6 are expressed by resident mononuclear phagocytes and circulating monocytes that are recruited to the infected kidney during APN. *Rnase6* deficient mice are more susceptible to APN, whereas *RNASE6* transgenic mice exhibit reduced renal UPEC burden. *Rnase6* deficiency is associated with increased intramacrophage UPEC survival, while human *RNASE6* transgenic macrophages are more adept at killing phagocytosed UPEC.

Conclusions: RNase 6 is an essential antimicrobial protein within the renal mononuclear phagocyte system that promotes UPEC clearance during APN.

Long-Term Complications and Outcomes of Augmentation Cystoplasty in Children with Neurogenic Bladder

Hsin-Lin Tsai,[1,2] Jei-Wen Chang,[1,2] Tzu-Ching Lin.[1,2] *[1]Taipei Veterans General Hospital, Taipei, Taiwan; [2]National Yang Ming Chiao Tung University School of Medicine, Taipei, Taiwan.*

Background: Controversy still exists regarding complications especially malignancy and long-term outcomes of augmentation cystoplasty (AC) in children with neurogenic bladder.

Methods: Pediatric patients <18 years underwent AC between 2000 and 2020 were enrolled. Early postoperative complications, long-term outcomes and histopathologic changes in mucosal biopsies of native bladder and the augmented intestine after AC were reviewed.

Results: Twenty-two patiients with mean age of 7.6±4.4 years were included. The ileum was used in 19 patients and the sigmoid colon in 3 patients. The length of hospital stay was 14.8±6.8 days. Post-operatively, urinary continence rate improved from 22.7% to 86.4% (p<0.001). Vesicoureteral reflux resolved in 16 (64.0 %) of the refluxing ureter units and was downgraded in 8 (32.0%). Hydronephrosis resolved in 17 of 19 patients. Grades of reflux and hydronephrosis significantly improved following AC (p<0.001). The estimated glomerular filtration rate also significantly increased (p=0.012). Formation of urinary tract stones was the most frequent late complication (in 8 patients, 36.4%). After a mean follow-up of 13.4±5.9 years, there were no cases of mortality, new-onset symptomatic metabolic acidosis, or effects on serum electrolytes. No cases of malignancy or metaplastic changes were identified in the native bladder or augmented bowel epithelium.

Conclusions: AC is a safe and effective procedure with low surgical and metabolic complication rates. AC provides a satisfactory continence rate and long-term protection of renal function, increases functional capacity, and regresses reflux and hydronephrosis. Individualized surveillance is recommended for the early identification of urolithiasis and metabolic disturbance.

Funding: Government Support - Non-U.S.

Table 1 The demographic data and clinical characteristics of the children who underwent augmentation cystoplasty

Variables	n (%)
Sex	
Male	6 (27.3%)
Female	16 (72.7%)
Age at surgery (years)	7.6±4.4
Age at the last follow-up (years)	20.9±6.9
Follow-up period (years)	13.4±5.9
Indication for augmentation	
Neurogenic	
Myelomeningocele	19 (86.4%)
Transverse myelitis	1 (4.5%)
Anorectal malformation with vertebral anomalies	1 (4.5%)
Non-neurogenic

Kidney and Urinary Manifestations in Kabuki Syndrome

Hyeonju Lee,[1] Peong Gang Park,[1] Naye Choi,[1] Hyeri Shin,[1] Jung Min Ko,[1,2] Hee Gyung Kang,[1,2] Yo Han Ahn.[1,2] *[1]Seoul National University Children's Hospital, Seoul, Republic of Korea; [2]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Background: Kabuki syndrome (KS) is a rare genetic disorder caused by pathogenic variants in *KMT2D* (formerly *MLL2*) or *KDM6A*. It is characterized by multiple abnormalities including typical facial features, growth delays, varying degrees of intellectual disability, skeletal abnormalities, and short stature. Kidney and urinary manifestations of this syndrome include congenital anomalies of the kidneys and urinary tract (CAKUT), and there were some reports of kidney stone and kidney failure. This study aimed to describe the clinical features and prevalence of renal manifestations in KS patients.

Methods: All genetically confirmed KS patients who visited the Seoul National University Children's Hospital during the period of 2000 to 2023 were included. Medical records were retrospectively reviewed for clinical and laboratory findings.

Results: Sixty-one patients (28 males) were reviewed in this study. Their median age at diagnosis was 32 months (interquartile range (IQR) 9-110). Causative gene of KS were *KMT2D* in 58 cases and *KDM6A* in 3. CAKUT were found in total of 16 (26.2%) patients, including horseshoe kidney (n=6), ectopic kidney (n=5), vesicoureteral reflux (n=2), hypoplastic kidneys (n=2), multicystic dysplastic kidney (n=1), duplex kidney (1), unilateral renal agenesis (n=1), and hydronephrosis (1). In addition, 4 (6.6%) patients had kidney stones or nephrocalcinosis and two had ureter stones. Kidney function at diagnosis was normal in all patients, and one had proteinuria of tubular origin. After median follow-up of 5 years (IQR 2.5-7.5), kidney function did not decrease except for one patient, whose estimated GFR at age of 15 was 59 after partial nephrectomy due to complicated cysts.

Conclusions: More than one third of patients of KS had kidney or urinary involvement, and some of them progress to CKD. Therefore, screening for kidney or urinary problems and regular follow-up would be necessary for KS patients.

FR-PO647

Long-Term Kidney Outcomes in Children with Posterior Urethral Valves: A Population-Based Cohort Study

Cal Robinson,[1] Mandy Rickard,[1] Nivethika Jeyakumar,[2] Graham D. Smith,[2] Joana R. Dos Santos,[1] Rahul Chanchlani,[3] Armando Lorenzo.[1] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]ICES, London, ON, Canada; [3]McMaster Children's Hospital, Hamilton, ON, Canada.*

Background: Posterior urethral valves (PUV) are a common cause of urinary tract obstruction in male infants. However, the long-term kidney outcomes of PUV are uncertain. We aim to determine the risk of major adverse kidney events (MAKE) among PUV patients.

Methods: Retrospective cohort study of all male infants (0-2yr) diagnosed with PUV from 1991-2021 in Ontario, Canada, identified by provincial administrative health databases. We chose two comparator cohorts of males (0-2yr) without PUV: 1) general pediatric population and 2) pyeloplasty patients. Patients were followed until death, provincial emigration, or March 2022 (89%). The primary outcome was modified MAKE (composite of death, chronic kidney replacement therapy (KRT), or *de novo* chronic kidney disease (CKD)).

Results: We included 727 PUV patients, 855 pyeloplasty patients, and 1,013,052 general pediatric comparators. Median age at PUV diagnosis was 40 days (IQR 10-196). Median follow-up was 16.6 years (IQR 8.6-24.5). During follow-up, 32.3% of PUV patients developed MAKE vs. 5.8% of pyeloplasty patients and 0.8% of general comparators. The adjusted HR for MAKE throughout follow-up was 36.6 (95%CI 31.6-42.4, p<0.001) in PUV patients vs. general comparators. The cumulative incidence of CKD, chronic KRT, hypertension, and incident acute kidney injury were also higher among PUV patients.

Conclusions: PUV patients are at a substantially increased risk of long-term kidney sequelae vs. those without PUV. This justifies enhanced kidney function and blood pressure surveillance among those with a history of PUV.

Table. Cumulative incidence of outcomes

Outcome	PUV patients, incidence rate per 1000py (95%CI)	Pyeloplasty patients, incidence rate per 1000py (95%CI)	General pediatric comparators, incidence rate per 1000py (95%CI)
Major adverse kidney event (MAKE)	28.4 (25.0-32.2)	4.5 (3.4-5.9)	0.49 (0.48-0.50)
Kidney replacement therapy (chronic dialysis or kidney transplant)	6.1 (4.7-7.8)	0.5 (0.2-1.1)	0.01 (0.01-0.01)
Chronic kidney disease	26.2 (22.8-30.1)	4.0 (3.0-5.7)	0.24 (0.23-0.25)
Hypertension	14.6 (12.3-17.3)	4.3 (3.2-5.7)	1.79 (1.77-1.81)
Acute kidney injury	15.8 (13.4-18.6)	2.8 (2.0-4.0)	0.27 (0.26-0.28)

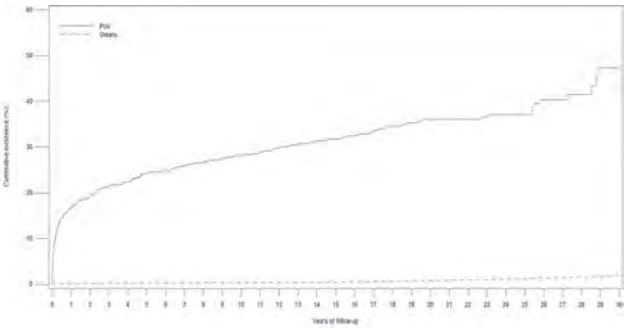

Figure. Cumulative incidence of MAKE among PUV patients vs general pediatric comparators

FR-PO648

Incidence and Risk Factors for Obesity and Short Stature in Childhood Nephrotic Syndrome: A Prospective Cohort Study

Cal Robinson,[1] Nowrin F. Aman,[1] Rahul Chanchlani,[2] Vaneet Dhillon,[1] Christoph Licht,[1] Damien G. Noone,[1] Rachel J. Pearl,[1] Seetha Radhakrishnan,[1] Chia Wei Teoh,[1] Rulan S. Parekh.[1,3] *[1]The Hospital for Sick Children, Toronto, ON, Canada; [2]McMaster Children's Hospital, Hamilton, ON, Canada; [3]Women's College Hospital, Toronto, ON, Canada.*

Background: Children with nephrotic syndrome are at risk of obesity and short stature from repeated steroid treatment. The incidence, timing, and risk factors for these outcomes remain uncertain.

Methods: We evaluated longitudinal growth and obesity in children (1-18yr) enrolled in Insight into Nephrotic Syndrome: Investigating Genes, Health, and Therapeutics (INSIGHT). We included nephrotic syndrome cases diagnosed from 1996-2019 in Greater Toronto. Growth parameters were measured at annual clinic visits. Primary outcomes were *de novo* obesity (body mass index (BMI) Z-score ≥+2) and short stature (height Z-score ≤-2). We calculated hazard ratios (HR) using Cox proportional hazards models.

Results: We included 531 children with nephrotic syndrome (24% frequently relapsing (FRNS) by 1-year). At their initial clinic visit (within 1-year of diagnosis), 23.5% of cases were obese, 51.8% were overweight (BMI Z-score ≥+1), and 4.9% had short stature. At the last clinic visit, the prevalence of obesity had decreased (17.3%) and short stature was unchanged (3.8%). During median 4.2-year follow-up, 69 (17.7%) children developed obesity and 16 (3.3%) developed short stature, among those without obesity or short stature initially. Total relapse count was a significant predictor for *de novo* obesity (adjusted HR 1.03, 95%CI 1.01-1.06, p=0.01) and short stature (unadjusted HR 1.06, 95%CI 1.02-1.10, p=0.01). Children with >6 and >12 total relapses were more likely to develop obesity and short stature, respectively.

Conclusions: Obesity is common among children with nephrotic syndrome early after diagnosis, but prevalence decreases over time. Effective relapse prevention may reduce steroid exposure and the risks of *de novo* obesity or short stature.

Funding: Government Support - Non-U.S.

Obesity and height outcomes, by FRNS classification within 1-year of diagnosis

Outcome	Overall (n=531)	Non FRNS (n=404)	FRNS (n=127)
Prevalent obesity at initial clinic visit, n (%)	125/531 (23.5)	89/404 (22.0)	36/127 (28.4)
De novo obesity during follow-up, n (%)	69/390 (17.7)	46/302 (15.2)	23/88 (26.1)
Prevalent obesity at last clinic visit, n (%)	91/526 (17.3)	65/399 (16.3)	26/127 (20.5)
Prevalent short stature at initial clinic visit, n (%)	26/531 (4.9)	21/404 (5.2)	5/127 (3.9)
De novo short stature during follow-up, n (%)	16/488 (3.3)	8/369 (2.2)	8/119 (6.7)
Prevalent short stature at last clinic visit, n (%)	20/525 (3.8)	13/398 (3.3)	7/127 (5.5)
Change in BMI Z-score during follow-up, mean (SD)	-0.52 (1.23)	-0.48 (1.19)	-0.65 (1.34)
Change in height Z-score during follow-up, mean (SD)	+0.19 (0.84)	+0.22 (0.79)	+0.09 (0.97)

FR-PO649

Associations Between Monogenic Causes of Nephrolithiasis and Initial 24-Hour Urine Studies in Pediatric Patients

Andrew Ticho, Shannon Cannon, Rocio Goodman, Neil J. Paloian. *University of Wisconsin System, Madison, WI.*

Background: In children, testing for monogenic causes of nephrolithiasis offers the potential for early identification of high-risk individuals. The association between positive genetic tests for nephrolithiasis and 24-hour urine (24HU) findings in pediatric patients is unclear. We examined pediatric stone formers at our institution aiming to identify associations between 24HU parameters and the presence of lithogenic genetic variants.

Methods: We performed retrospective review of patients <18 years with nephrolithiasis who underwent genetic testing between 2019-2023 (Invitae Nephrolithiasis Panel, San Francisco, USA). We classified genetic tests as negative, variants of uncertain significance (VUS), and pathogenic (P) variants. Demographic and initial 24HU data were collected. Descriptive and comparative analyses were performed, including Kruskal-Wallis, Mann-Whitney-U and Spearman's tests, with p<.05 considered significant.

Results: We identified 25 patients with nephrolithiasis who underwent both genetic and 24-hour urine testing, with 57% male and 43% female. The median age at the time of genetic test was 10.4 years. There 21 (60%) positive tests, with 19 (54%) VUS and 2 (6%) P variants (Table 1). Mean 24HU results from the cohort are shown (Table 2). On 24HU, all patients had 1 abnormal metabolic parameter. Six had abnormal values >2 standard deviation from mean for age/sex. There were no significant differences in values on 24HU studies between groups.

Conclusions: In this first study of associations between 24HU and nephrolithiasis genetic testing, we found no differences between pediatric stone formers with known variants and those with negative genetic tests. This suggests that genetic testing should not have an immediate impact on preventive care strategies, excluding conditions like primary hyperoxaluria. However, our study did not measure longitudinal outcomes; genetic disposition to stone disease may require more aggressive preventive care and metabolic management over time, so we recommend larger, longitudinal studies of pediatric patients with monogenic causes of nephrolithiasis.

Table 1. Frequency and association of genetic testing results.

Significance Frequency	Gene	Association
6 VUS, 1 Pathogenic	SLC34A3	Hereditary hypophosphatemic rickets with hypercalciuria
1 Likely Benign, 1 VUS	SLC26A1	Autosomal recessive calcium oxalate urolithiasis
1 Pathogenic	SLC7A9	Autosomal recessive cystinuria type B
1 VUS	CYP24A1	Infantile hypercalcemia
1 VUS	XDH	Autosomal recessive xanthinuria type I
1 VUS	UMOD	MCKD2
1 VUS	CLCNKB	BSND
1 VUS	ATP6V0A4	dRTA
1 VUS	SLC3A1	Calcium oxalate urolithiasis
1 VUS	SLC12A1	Bartter syndrome type 1
1 VUS	AQP1	Primary hyperoxaluria, type 1
1 VUS	VDR	VDDR2A
1 VUS	ADCY10	Familial idiopathic hypercalciuria
1 VUS	SLC4A1	dRTA
1 VUS	CASR	Multiple CASR-related conditions
1 VUS	SLC9A3R1	Hypophosphatemic nephrolithiasis and osteoporosis
1 VUS	PREP1	Congenital myasthenic syndrome 22

Clinical and Metabolic Findings in Children with Nephrolithiasis: A Single-Center Experience

Amelia E. Mercado, Jacob P. Scioscia, Leyat Tal, Nicolette Janzen, Mini Michael. *Texas Children's Pediatrics, Houston, TX.*

Background: Prevalence of nephrolithiasis in children has increased in recent decades and is associated with high risk of recurrence. Over 50% of children with nephrolithiasis may have a metabolic, genetic, or anatomic cause, making the epidemiology of the disease notable. The epidemiology of stones, including etiology, may better inform future treatment and prevention in at-risk populations. This study aims to describe clinical and metabolic findings in children with nephrolithiasis followed at a multidisciplinary stone clinic within a tertiary children's hospital.

Methods: This is a retrospective study that included all children (n=330) with nephrolithiasis followed in the stone clinic from 5/2013-5/2023. Demographic, clinical, and metabolic variables were recorded from the patient's first encounter in the clinic. Descriptive statistics were utilized.

Results: A total of 82 patients were reviewed at the time of reporting. Majority of patients were male (59%, n=48). Roughly 37% (n=30) of patients were Hispanic and 48% (n=39) were non-Hispanic White. The median age of presentation with first kidney stone was 11 years (range: 6 months–18 years). Almost half of patients had a family history of stone disease (48%, n=39), with the most common relative being the patient's mother (33%, n=13). For patients who underwent a 24-hour urine collection (73%, n=60), 78% had metabolic abnormalities (n=47). The most common metabolic abnormalities were hypocitraturia (77%, n=36) and hypercalciuria (40%, n=19). A fifth of patients with hypocitraturia (22%, n=8) had bilateral nephrolithiasis. Almost a third of patients had hydronephrosis (30%, n=25) and required surgical stone removal (36%, n=9). Majority of patients had spontaneous passage of a stone (56%, n=46). For patients that completed stone analysis (38%, n=31), 71% (n=22) contained calcium, with the most common composition being calcium phosphate (73%, n=16). Being wheelchair bound (15%, n=12), having cerebral palsy (13%, n=11), or taking Zonisamide (10%, n=8) were frequent risk factors for stone formation.

Conclusions: Almost half of patients had a family history of stone disease, suggesting a genetic aspect to nephrolithiasis and importance of genetic testing in this subset of patients. Metabolic abnormalities were frequent among children with stone disease, with hypocitraturia being the most common.

FR-PO651

Nephritic Factor-Like Autoantibodies Are Present in Unaffected Children

Christopher Culek,[1,2] Carla M. Nester.[1,2] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]University of Iowa Molecular Otolaryngology and Renal Research Laboratories, Iowa City, IA.*

Background: We previously reported that C3-convertase targeted autoantibodies (nephritic factor-like antibodies) were highly prevalent in normal young adults (publication pending). In this study, we explore the prevalence of these convertase-directed antibodies in the pediatric population.

Methods: We measured the binding and stabilization of the C3-convertase and it's proenzyme by normal human IgG purified from plasma samples. We selected samples for three age cohorts: one, five, and ten-year-olds. Binding was determined using surface plasmon resonance with C3b was immobilized as the surface ligand. Each purified antibody was tested in four analyte conditions: IgG alone, IgG with FB (proconvertase), IgG with FD, and IgG with FB and FD (convertase). These conditions were compared to four control conditions: buffer alone, FB alone, FD alone, and FB with FD. Response (in RUs) was recorded at 20 seconds post-injection to measure binding and at 200 seconds post-injection to evaluate stabilization.

Results: Binding and stabilization results were mixed. All three age cohorts (1, 5, 10 years) show a statistically significant increase in binding for IgG+FB (proconvertase) vs FB

alone at 20 seconds post-injection (two-tailed students t-test values of 0.002, 0.004, and 0.007, respectively). However, none of the cohorts show statistical significance at 200 seconds (t-test results of 0.49, 0.13, and 0.41). Significant binding was observed in the IgG+FB+FD samples compared to FB+FD at both 20- and 200-seconds post-injection for all age groups. Review of the data shows strong positive results (increasing reagent response by >20%) in 16 individuals for the convertase and 20 individuals for the proconvertase.

Conclusions: Our data suggests that convertase- and proconvertase-directed antibodies exist in pediatric cohorts. The prevalence is less than what we previously reported in adults (29/30 individuals were positive for both antigens). Whether this indicates the *de novo* emergence of this antibody over time or class switching of an IgM to an IgG over time is currently under investigation. Determining an origin for nephritic factors is an important research goal in complement-mediated kidney disease. Identifying non-pathogenic antibodies that share the convertase antigen may provide an origin for nephritic factors.

FR-PO652

Identification of Patients with Potential Undiagnosed Atypical Hemolytic Uremic Syndrome (aHUS) in the North American Pediatric Renal Trials and Collaborative Studies (NAPRTCS) Registry

Sara A. Boynton,[1] Stuart Goldstein,[3] Tom D. Blydt-Hansen.[2] The NAPRTCS Investigators. *[1]Johns Hopkins Children's Center, Baltimore, MD; [2]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Atypical Hemolytic Uremic Syndrome (aHUS) is a rare disease characterized by thrombocytopenia, microangiopathic hemolytic anemia, and impaired kidney function. Diagnosis of aHUS is complicated by its similarity to other forms of thrombotic microangiopathy (TMA). The recognition of aHUS has become more commonplace in the last 10 years due to advancements in laboratory diagnostics and targeted complement inhibition. Although acute presentation with fulminant TMA are readily diagnosed, more indolent presentations may not be recognized as aHUS but may progress if untreated to end-stage kidney disease.

Methods: Potential participants were identified from the 3 NAPRTCS registry arms through a query of underlying diagnoses that could be associated with TMA or unknown etiology and transplant eligibility (defined as eGFR <30 ml/min/1.73m^2, history of maintenance dialysis or kidney transplant). Identified participants were eligible if they had evidence of TMA (thrombocytopenia, schistocytes, decreased hemoglobin levels, elevated lactate dehydrogenase, and/or decreased haptoglobin levels). Enrollees were evaluated for evidence of thrombocytopenia and severe anemia as a marker of microangiopathic hemolysis. Major organ symptoms and growth factors (height or weight z-score <-2.0), were also reviewed at the time of potential TMA.

Results: Ninety-five participants were identified in the query of diagnosis and transplant eligibility. Thirty-three (35%) participant records from 9 NAPRTCS centers were available for retrospective review and had at least one marker of potential TMA. The most common CKD diagnoses were AKI (27%), Lupus (27%) and unknown (22%). They were 55% biological female and median age at enrollment was 15 years. Thrombocytopenia OR microangiopathic hemolysis were each suspected in 74% of participants, while 42% had evidence of both. Major organ involvement most frequently identified at time of suspected TMA episodes included cardiac (hypertension; 31%) and gastrointestinal (19%), while 44% of participants had evidence of growth failure or were underweight.

Conclusions: This analysis shows that there may be a higher prevalence of aHUS in the NAPRTCS registries than was previously thought.

Shiga Toxin-Producing Escherichia coli (STEC) Infection in a Pediatric Patient with Compound Heterozygous Deletion of CFHR1-3 and CFHR1-4

Gabriele Mortari,[1] Edoardo La Porta,[2] Carolina Bigatti,[2] Giulia Proietti Gaffi,[2] Enrico E. Verrina,[2] Gianluca Caridi,[2] Andrea Angeletti,[2] Gian Marco Ghiggeri,[2] Francesca Lugani.[2] *[1]Azienda Socio Sanitaria Territoriale degli Spedali Civili di Brescia, Brescia, Italy; [2]Istituto Giannina Gaslini, Genova, Italy.*

Introduction: Hemolytic uremic syndrome (HUS) is classified into typical and atypical (aHUS). Typical HUS is secondary to a Shiga-toxin infection as E. Coli (STEC-HUS), whereas aHUS is secondary to complement gene mutation and/or complement factor H (CFH) antibodies. aHUS is diagnosed once ADAMTS13 deficiency and STEC infection have been ruled out. aHUS can be triggered by different conditions also STEC infection. We present a pediatric case firstly diagnosed as STEC-HUS afterward diagnosed as aHUS following a sudden relapse of the thrombotic microangiopathy (TMA) who favorable response to Eculizumab.

Case Description: A 9 years old child developed TMA, acute kidney injury (AKI) and posterior reversible encephalopathy syndrome (PRES). Eculizumab was administered leading to clinical improvement. The patient was initially diagnosed with STEC-HUS based on positive fecal test for STEC O157. After 4 weeks, a severe relapse of TMA occured. Thus, Eculizumab treatment was restarted. Genetic analysis revealed compound heterozygous deletion of CFHR3-CFHR1 and CFHR1-CFHR4, along with high serum titer anti-CFH antibodies (222 U/mL). aHUS diagnosis was made and Eculizumab was continued.

Discussion: STEC infection does not ruled out aHUS diagnosis and early use of Eculizumab might be reasonable in severe HUS cases. Investigations for autoantibodies and genetic factors should be pursued to identify aHUS-related factors and enhance patient outcomes.

Successful Voclosporin Treatment of Lupus Nephritis in an Adolescent

Anil K. Mongia,[1] Basant Hamed,[1] Maria-Anna Vastardi,[1] Hilda E. Fernandez.[2] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]Columbia University Irving Medical Center, New York, NY.*

Introduction: Lupus nephritis (LN) flare is a common cause of kidney injury. Rituximab (RTX) is a widely employed treatment for children with LN flare, though Its use may be limited by severe hypersensitivity reaction. We report here a 17-year-old AA girl with LN flare who had severe hypersensitivity to RTX, who showed significant improvement of proteinuria after introduction of Voclosporin (VCS). We believe this is the first reported case of the use of VCS in an adolescent with LN.

Case Description: 17 yo AA girl diagnosed with LN class V in 2016 after she presented with facial rash, proteinuria, joint stiffness, and weight loss. She was treated with Prednisone and mycophenolate mofetil leading to complete remission. In 2019, she developed increasing proteinuria with flare and required 2 cycles of RTX with remission of LN. Cyclophosphamide (CYC) was not used due to parental refusal. She remained on hydroxychloroquine, prednisone, enalapril and aspirin. In late 2022, she had a symptomatic LN flare with hypoalbuminemia, edema, and serum creatinine of 0.5mg/dL. Repeat RTX infusion led to a severe hypersensitivity reaction characterized by chest pain, SOB and generalized rash which required epinephrine, antihistamine and O_2. Due to severe anaphylaxis, it was decided not to use further RTX. VCS 23.7mg BID was initiated starting Feb 2023. Results: With the use of VCS, patient had rapid improvement in her serum albumin and reduction of proteinuria within 2 weeks, which has been maintained to 12 weeks. At last visit her serum albumin improved to 3.3 gm/dL from 2.1gm/dL and UPCR (mg/mg creatinine) improved to 1.4 from 7.5 at the start of VCS. Her lipid profile (Total cholesterol, LDL, TG) at follow up improved to (157,96,113) from (284,197,162) at start of VCS. No other significant changes in BP, hematologic parameters or eGFR. No adverse events from the use of VCS.

Discussion: Treatment options in children with LN are limited and mostly involve RTX and calcineurin inhibitors. Severe RTX hypersensitivity in our patient precluded its use. We have shown significant improvement of proteinuria with use of VCS in pediatric age group, suggesting it may be a useful option especially if other medications like RTX are not effective or contraindicated. Further controlled trials should be done to evaluate safety and efficacy of VCS in children.

FR-PO655

Clinicopathological Characteristics of the Pediatric IgA Nephropathy with eGFR <90 mL/min/1.73 m2 at Onset

Yuko Shima,[1] Hironobu Mukaiyama,[1] Yu Tanaka,[1] Wataru Shimabukuro,[4] Hiroshi Kaito,[2] Ryojiro Tanaka,[2] Kandai Nozu,[3] Kazumoto Iijima,[3] Daisuke Tokuhara,[1] Norishige Yoshikawa,[5] Koichi Nakanishi.[4] *[1]Wakayama Kenritsu Ika Daigaku, Wakayama, Japan; [2]Hyogo Kenritsu Kodomo Byoin, Kobe, Japan; [3]Kobe Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Kobe, Japan; [4]Ryukyu Daigaku Igakubu Daigakuin Igaku Kenkyuka, Nakagami-gun, Japan; [5]Shakai Iryo Hojin Aijinkai Takatsuki Byoin, Takatsuki, Japan.*

Background: The pediatric IgA nephropathy (IgAN) cases with eGFR<90 ml/min/1.73m^2 (eGFR<90) at onset are regarded as a type of severe case in the Japanese Clinical Practice Guidelines for Pediatric IgA Nephropathy 2020. However, clinicopathological characteristics of those patients are not clarified. So, the purpose of this study is to clarify the clinicopathological features of those with eGFR<90 at onset.

Methods: From July 1976 to December 2018, among 560 children with biopsy-proven IgAN at Kobe University and Wakayama Medical University, Cr-eGFR at onset was available in 555. We investigated clinicopathological differences in 107 (19.3%) patients with eGFR<90 at onset and the other 448 patients.

Results: About 30% of eGFR<90 cases were detected as with gross hematuria. And there were significant differences in the proportion of boys (69.2 vs. 51.8%, p=0.001), onset age (9.6 vs. 11.0 years, p<0.0001), the prevalence of nephrotic syndrome (10.3 vs. 4.9%, p=0.004), proteinuria (1.2 vs. 0.9 g/gCr, p=0.03), and renal biopsy before 1990 vs. after 1990 (73.8 vs. 33.7%, p<0.0001). There was no significant difference in pathological findings. The renal survival rate in the eGFR<90 group was significantly lower (77.9 vs. 93.3% at 15 years; 95%CI: 53.3-91.6 vs. 83.8-97.0%, p=0.006). In patients with eGFR<90 at onset, when irreversible eGFR<60 state is defined as kidney failure, the patients who progressed to kidney failure showed lower eGFR at onset (64.7 vs. 78.2 ml/min/1.73m2, p=0.0001), heavier proteinuria (2.6 vs. 1.0 g/gCr, p=0.008), and no remission of proteinuria after treatment (0.0 vs. 52.6%, p=0.001).

Conclusions: Cases with eGFR<90 at onset are clinically severe cases with various histopathological features, and some of them do not respond to treatment and have poor renal prognoses.

FR-PO656

DNASE1L3-Associated Nephropathy in Two Siblings Presenting C1q Nephropathy and Membranoproliferative Glomerulonephritis

Dae Young Kim, Hee Gyung Kang, Yo Han Ahn. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Introduction: Deoxyribonucleases are in charge of extracellular DNA degradation, limiting inflammatory response. Deoxyribonuclease 1 like 3 (*DNASE1L3*) of DNase I family is known to be essential for the prevention of autoimmune disorders by sustaining plasma extracellular DNA homeostasis. Therefore, DNase1L3 gene mutation might cause autoimmune disorders, although only the cases of systemic lupus erythematous (SLE) had been reported previously. Here we report two siblings, sharing same compound heterozygote pathogenic variants of *DNASE1L3*, who were diagnosed with two different chronic glomerulonephritis.

Case Description: An eight-year-old boy presented hematuria with proteinuria and diagnosed as C1q nephropathy after kidney biopsy. Past medical history and family history were unremarkable. Despite treatment with immunosuppressive agents including steroid and tacrolimus, his kidney function deteriorated and lost at his age of 12. After living-donor kidney transplantation (KT), his allograft function has been well maintained until the last follow-up after 2 years of KT without proteinuria or any other extra-renal symptoms. His brother also presented hematuria and proteinuria at his age of 6 and diagnosed as membranous nephropathy at his first kidney biopsy. Steroid and weekly rituximab treatment led to partial remission, but became resistant to immunosuppressant treatment. Follow-up biopsy revealed membranoproliferative glomerulonephritis type 2 and now he has been managed with medications including tacrolimus and mycophenolate. At his last follow-up on age of 13, his eGFR was 110mL/min/1.73m^2 but nephrotic range proteinuria still persisted. On multiple parallel sequencing, both siblings were found to have same compound heterozygote likely pathogenic variants of *DNASE1L3*, c.401_402dup and c.556A>G, which were inherited from their father and mother, respectively.

Discussion: Here we report sibling cases of *DNASE1L3* associated nephropathy, suggesting that dysfunction of deoxyribonucleases and predisposition to autoimmune diseases can be one of the pathogenic mechanisms of chronic glomerulonephritis. Interestingly, two siblings with same genetic predisposition showed different spectrum of nephropathies with distinct clinical courses, implying that there might be other modifying factors than the genetic predisposition.

FR-PO657

Persistent Proteinuria Associated with CUBN Variants in Korean Children

Yun Young Choi,[1] Naye Choi,[1,5] Jeesu Min,[3,5] Eujin Park,[2] Yo Han Ahn,[1,5] Hee Gyung Kang,[1,5] Hyun Kyung Lee.[4] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Korea University Guro Hospital, Seoul, Republic of Korea; [3]Chungnam National University Sejong Hospital, Sejong, Republic of Korea; [4]Kangwon National University Hospital, Chuncheon, Kangwon, Republic of Korea; [5]Seoul National University College of Medicine, Seoul, Republic of Korea.*

Introduction: Persistent proteinuria is a risk factor of progression for chronic kidney disease (CKD). However, the recent discovery suggests that not all proteinuria is damaging. *CUBN*, encoding the membrane glycoprotein cubilin, forms cubilin-amnionless-megalin complex that is responsible for the receptor-mediated endocytosis of albumin in the proximal tubules. A defect of cubilin decreases albumin reuptake, consequently resulting in proteinuria. Interestingly, variants located at the N-terminal of *CUBN* result in severe proteinuria and megaloblastic anemia, whereas variants at the C-terminal are associated with benign, isolated proteinuria.

Case Description: Here, we report 6 Korean patients (M:F=3:3) presented with persistent proteinuria with homozygous or compound heterozyous C-terminal *CUBN* variants. All patients presented with incidentally found isolated asymptomatic proteinuria, at their median age of 5 years (range 18 months ~ 9years). Their mean urine protein creatinine ratios was 1.13 (range 0.94 ~ 1.5) mg/mg at presentation and laboratory findings were unremarkable at presentation for eGFR, serum albumin, lipid, hemoglobin, urine 2-microglobulin and N-acetyl-beta-D-glucosaminidase. None had hypertension, and kidney ultrasound was normal. Two patients underwent kidney biopsy, which revealed non-specific findings. Their median follow-up duration was 4 years (range 6 months ~ 12 years), median age at the last follow-up was 8.5 years (range 2 years ~21 years) and the amount of proteinuria and the kidney function did not change significantly over time regardless of renin-angiotensin-aldosterone system (RAS) inhibition with mean urine protein creatinine ratio at the last follow up of 0.965 (range 0.75 ~ 1.175).

Discussion: These cases are similar to previously reported cases, indicating that asymptomatic subnephrotic range proteinuria patients should be suspected of C-terminal variants of *CUBN* gene. There are still debates on whether *CUBN* C-terminal mutation is truly benign proteinuria, and whether clinicians should treat these patients with RASi.

Anti-Nephrin Antibodies in Idiopathic Nephrotic Syndrome in Japanese Children

Tomoko Horinouchi,[1] Andrew J. Watts,[2] China Nagano,[1,3] Yuta Ichikawa,[1] Yuta Inoki,[1] Yu Tanaka,[1] Hideaki Kitakado,[1] Chika Ueda,[1] Atsushi Kondo,[1] Nana Sakakibara,[1] Yuko Shima,[4] Kandai Nozu,[1] Matt G. Sampson,[2,3] Astrid Weins,[5] Kazumoto Iijima.[6,7] *[1]Department of Pediatrics, Kobe University Graduate School of Medicine, Kobe, Japan; [2]Department of Medicine/Renal Division, Brigham and Women's Hospital, and Harvard Medical School, Boston, MA; [3]Department of Medicine/Pediatric Nephrology, Boston Children's Hospital, and Harvard Medical School, Boston, MA; [4]Department of Pediatrics, Wakayama Medical University, Wakayama, Japan; [5]Department of Pathology, Brigham and Women's Hospital, and Harvard Medical School, Boston, MA; [6]Hyogo Prefectural Kobe Children's Hospital, Kobe, Japan; [7]Department of Advanced Pediatric Medicine, Kobe University Graduate School of Medicine, Kobe, Japan.*

Background: Many patients with childhood idiopathic nephrotic syndrome are steroid-sensitive, suggesting the involvement of the immune system in the pathogenesis. Several genome-wide association studies have suggested a polygenic contribution, particularly in the *HLA DR/DQ* region and a locus including *NPHS1*, but the etiology remains unclear. Anti-nephrin antibodies have recently been reported in both adults and children with biopsy proven minimal change disease (MCD), but the presence of anti-nephrin antibodies in Japanese childhood idiopathic nephrotic syndrome (INS) has not been investigated.

Methods: Anti-nephrin antibodies were measured by ELISA in paired plasma samples obtained from 14 Japanese pediatric patients with INS (male/female: 8/6), at initial disease onset (active disease) and following steroid monotherapy. Clinical characteristics were compared between the anti-nephrin antibodies positive and negative groups.

Results: The median age at the onset was 75.5 months (interquartile range (IQR): 45-113). Steroid sensitivity resulted in complete remission in 13 patients and almost complete remission in one patient after 4 weeks of glucocorticoid monotherapy. Circulating anti-nephrin antibodies were detected in seven of 14 patients during active disease. In all cases, anti-nephrin antibodies were significantly reduced following treatment concordant with clinical response. There were no differences between the positive and negative groups in pre-treatment parameters. Of the 13 patients who achieved complete remission, nine had at least one relapse during a median follow-up of 851 days (IQR: 808-973). There was also no significant difference in the relapse-free period after the onset between the two groups (P=0.658).

Conclusions: We have identified circulating anti-nephrin antibodies at initial presentation in half of Japanese pediatric INS, which is a higher proportion than previously reported for a North American cohort of adults and children with biopsy proven MCD. Further studies are needed to establish the prognostic implications of anti-nephrin antibodies in childhood INS and the relationship with the *NPHS1* risk variants in this population.

FR-PO659

Metabolic Acidosis in Pediatric Participants with Glomerular Disease in the NEPTUNE and CureGN Cohorts

Stella R. Kilduff,[1,2] Jonathan P. Troost,[3] Sean Eddy,[3] Denver D. Brown,[4] Michal L. Melamed,[2] Matthew K. Abramowitz,[2] Kimberly J. Reidy,[1,2] Rick Kaskel.[1] *[1]The Children's Hospital at Montefiore General Pediatrics, Bronx, NY; [2]Albert Einstein College of Medicine, Bronx, NY; [3]Michigan State University, East Lansing, MI; [4]Children's National Hospital, Washington, DC.*

Background: Metabolic acidosis (MA) has been associated with a more rapid decline of kidney function in cohorts of children with chronic kidney disease (CKD) and children with glomerular (vs. non-glomerular) CKD were more likely to have untreated acidosis. To date, no study has systematically examined MA in children with varying types of glomerular disease.

Methods: Children ages 1-17 y/o, enrolled in the NEPTUNE or CureGN studies with ≥1 serum bicarbonate and eGFR measurement were included. MA was defined as serum bicarbonate <22mEq/L, unresolved acidosis was acidosis at baseline that remained <22 mEq/L whereas resolved acidosis was baseline acidosis that improved to ≥22 mEq/L on repeated measures. The primary outcome of interest was eGFR slope (ml/min/1.73m^2 per year) which was examined using an adjusted linear mixed-effects model.

Results: In the 786 participants eligible for study inclusion, the mean baseline serum bicarbonate was 24.8±3.15 meq/L. 12.2% (n=96) of the cohort were acidotic and only 1.4% (n=11) were receiving alkali therapy. In the adjusted longitudinal analysis, patients with unresolved acidosis had an eGFR slope difference per year of -12.4 ml/min/1.73m^2 compared to those with resolved acidosis (95%CI: -17.5, -7.4) (Table 2).

Conclusions: Untreated MA is common in children with glomerular disease. Patients with unresolved MA had faster eGFR loss when compared to those with resolved acidosis from baseline. Future analyses will examine mechanistic pathways by which MA is proposed to contribute to disease progression through gene expression analysis.

Mitochondrial DNA in Urinary Large Extracellular Vesicles as a Marker of Relapse in Children with Nephrotic Syndrome

Robert L. Myette,[1,2] Fengxia Xiao,[2] Chris R. Kennedy,[2] Dylan Burger.[2] *[1]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada; [2]Kidney Research Center, Ottawa, ON, Canada.*

Background: Nephrotic Syndrome (NS) is one of the most common causes of glomerulopathy in children. There has been an increased focus on reactive oxygen species (ROS) and mitochondrial injury in podocytes as drivers of proteinuric disease. We recently showed that podocyte-specific large extracellular vesicles (LEVs; 0.1-1.0 um) are increased in the urine of children with NS. The aim of this study was to characterize LEV mitochondrial DNA (mtDNA) content from those same children. We investigated this relationship further using cultured podocytes exposed to toxins *in vitro*.

Methods: We analyzed urine samples from a prospective cohort enrolling children 1-18y with NS. Podocyte specific LEVs were quantified using flow cytometry and nanoparticle tracking (NTA). Urinary LEV mtDNA was assessed using qPCR. Human immortalized podocytes (hPod) were used in cell culture experiments. Puromycin aminonucleoside (PAN; 25 ug/mL; 24 hours) and lipopolysaccharide (LPS; 25 ug/mL; 24 hours) were used as podocyte toxins.

Results: We analyzed 28 samples from 14 patients. Podocyte LEVs were significantly lower in remission vs. nephrosis ($p<0.01$). Urine protein to creatinine ratio correlated with elevated LEVs ($p=0.0005$). Patient urinary LEV mtDNA was higher in NS relapse compared to remission ($p=0.04$). In hPod cells, PAN treatment resulted in a 2.5-fold increase in hPod LEVs ($p=0.03$) while LPS caused a 3.5-fold increase ($p=0.0004$). The impact of PAN and LPS treatment on *in vitro* LEV production was abrogated by the antioxidant MITO-Tempol. Following treatment with PAN or LPS *in vitro*, we observed an ~25-fold increase in LEV mtDNA content ($p<0.01$).

Conclusions: In summary, LEVs may serve as a biomarker of podocyte injury in nephrotic syndrome in children and their mtDNA content can differentiate remission from relapse. hPods show similar characteristics when treated with common podocyte toxins, and ongoing studies aim to characterize this further.

FR-PO661

Urine Biomarker Analysis of Pediatric Nephrotic Syndrome

Timothy Cummins,[1] Michael Merchant,[1] Madhavi J. Rane,[1] Laura H. Mariani,[2] Phillip J. McCown,[2] Wenjun Ju,[2] Daniel W. Wilkey,[1] Wimal Pathmasiri,[3] Susan Mcritchie,[3] Julie Dougherty,[4] Saeed A. Jortani,[5] Matthias Kretzler,[2] Susan J. Sumner,[3] William E. Smoyer,[4] Jon B. Klein.[1] *[1]University of Louisville School of Medicine, Louisville, KY; [2]University of Michigan Medical School, Ann Arbor, MI; [3]University of North Carolina at Chapel Hill Nutrition Research Institute, Kannapolis, NC; [4]Nationwide Children's Hospital, Columbus, OH; [5]University of Louisville, Louisville, KY.*

Background: The molecular underpinnings of pediatric nephrotic syndrome remain unclear. Response to immunosuppressive therapy is relatively poor in many patients with Focal Segmental Glomerular Sclerosis (FSGS) as compared to children with Minimal Change Disease (MCD). Elucidation of glomerular disease biomarkers that predict treatment response would be critical towards improved outcomes in pediatric nephrotic syndrome. Identification of subpopulations of nephrotic syndrome by proteomics could indicate differences in patient outcomes. We addressed the hypothesis that comparison of urine proteomes in children with MCD and FSGS could distinguish disease activity and molecular mechanisms of disease progression.

Methods: Proteomic analysis was conducted on urine from children with MCD and FSGS enrolled in the CureGN Consortium to determine differences in disease activity. Urine specimens from 216 patients were analyzed by 2D-LC-MS/MS. MetaboAnalyst 5.0 was employed to perform statistical analyses to identify candidate urine biomarkers of disease activity in pediatric FSGS and MCD. Confirmation ELISA assays were performed for ORM1 and C3. K-means clustering was conducted on nephrotic urine proteome to identify patient clusters.

Results: Proteomic profiles in complete remission urine were dramatically different from nephrotic specimens. ORM1 and C3 levels are significantly higher in nephrotic urine vs complete remission. Unsupervised clustering of nephrotic proteomes showed two distinct clusters suggesting subgroups of patients.

Conclusions: Our findings indicate the potential for ORM1 and C3 to be biomarkers of disease activity. Unsupervised clustering analysis of nephrotic urine proteome indicated a cluster with increased immune response and complement proteins.

FR-PO662

Multi-Omic Serum Profiling in Children and Young Adults Affected by Steroid-Dependent Nephrotic Syndrome

Maurizio Bruschi,[1,2] Andrea Garbarino,[1] Xhuliana Kajana,[1] Sonia Spinelli,[1] Andrea Angeletti,[1] Francesca Lugani,[1] Gianluca Caridi,[1] Edoardo La Porta,[1] Enrico E. Verrina,[1] Gian Marco Ghiggeri.[1] *[1]Istituto Giannina Gaslini, Genova, Italy; [2]Universita degli Studi di Genova, Genova, Italy.*

Background: Idiopathic nephrotic syndrome (INS) is the most common cause of proteinuria in children and young adults. The mainstay of therapy is steroids and based on treatment response, patients can be classified as dependent or resistant. However, there

are no validated biomarkers able to predict treatment response or even to identify the biochemical pathways involved in the pathogenesis of INS.

Methods: We performed a proteomic and lipidomic analysis on serum samples of 82 children and young adults with steroid-dependent INS enrolled in a randomized clinical trial (NCT02394119). With the aim to limit confounding factors due to protein and lipid dysregulation that characterized the acute phases of INS, serum samples were collected during remission. Therefore, all patients had no proteinuria. As control group, we used 26 healthy donors matched for age and sex.

Results: Multi-omics analysis identified a total of 307 and 3.027 unique gene proteins and lipids respectively. Statistical analysis revealed the upregulation of 8 proteins and 38 lipids and the downregulation of 20 proteins and 18 lipids. Moreover, by combining multiple algorithms, including machine learning analysis, we identified a core panel of features able to clearly distinguish between INS patients and healthy donors. In addition, functional analysis of these panel of features revealed the main biological processes associated to steroid-dependent INS patients.

Conclusions: This study confirmed that the multi-omics approach allows to identify a core panel of biomarkers specific for steroid-dependent INS. As a strength point, we emphasize that INS patients had no proteinuria. Therefore, our findings may suggest that INS is characterized by several protein and lipid fingerprints not related to the remission or recurrence phases. Our results may represent the base for further investigation into the still unknown pathogenetic mechanisms of INS.

FR-PO663

Genotype-Phenotype Associations in Patients with Congenital and Infantile Nephrotic Syndrome

Md S. Islam,[1] William E. Smoyer,[2] Tej K. Mattoo,[4] Robert L. Myette,[5] Scott E. Wenderfer,[3] Mahmoud Kallash,[2] Tetyana L. Vasylyeva.[1] Tetyana L. Vasylyeva. *[1]Texas Tech University Health Sciences Center, Amarillo, TX; [2]Nationwide Children's Hospital, Columbus, OH; [3]BC Children's Hospital Department of General Pediatrics, Vancouver, BC, Canada; [4]Wayne State University School of Medicine, Detroit, MI; [5]Children's Hospital of Eastern Ontario, Ottawa, ON, Canada.*

Background: Congenital nephrotic syndrome (CNS) and infantile nephrotic syndrome (INS) are disorders of the slit diaphragm of podocytes in the glomerular basement membrane. CNS manifests during the first three months of life, and INS between 3-12 months. The clinical features of the diseases include nephrotic-range proteinuria, hypoalbuminemia, and edema. The most common causes of CNS and INS are mutations in the *NPHS1* and *NPHS2* genes encoding nephrin and podocin, respectively. This study aimed to establish specific genetic characteristics of CNS and INS and their clinical correlations in the North American population.

Methods: Nine Pediatric Nephrology Research Consortium (PNRC) sites retrospectively reviewed charts of 36 patients born between 1998 and 2019 with CNS or INS and underwent genetic testing. ClinVar, SNP, and Human mutation database confirmed the mutation's pathogenicity.

Results: *NPHS1* mutations were more often seen in CNS patients (27/36; 75%), whereas the INS group had more frequent mutations of *WT1* (3/11;27.2%) and *NPHS2* (4/11;36.3%) genes. Among patients with *NPHS1* mutations, the splice site had more mutations than the gene coding region, irrespective of the group. Among these mutations, IVS17-1 G>A splice mutation was found in 4 subjects that showed aggressive features of CNS. Interestingly, the mutation's pathogenicity was confirmed by ClinVar, SNP, and Human mutation database. In patients with CNS, the frequency (9/18;50%) of multiple mutations of the *NPHS1* gene was higher than in the INS group (2/5;40%) and significantly associated with hyperproteinemia (p=0.021) and hypoalbuminemia (p=0.03). Albumin infusions were much more effective in CNS patients with *NPHS2/WT1* mutations than those with *NPHS1* mutations. In INS patients with *WT1* mutations, albumin infusions were less effective in supporting serum albumin levels.

Conclusions: Variations in splice sites, especially IVS17-1 G>A, and multiple mutations in the *NPHS1* gene were associated with a more aggressive course of CNS in infants.

FR-PO664

Pediatric Nephrotic Syndrome in Brazil: Results from a National Cohort of 772 Cases

Paulo C. Koch Nogueira,[1,2] Luciana S. Feltran,[2] Andreia Watanabe,[4] Vera Maria S. Belangero,[3] Mara S. Guaragna,[3] Patricia Varela-Calais,[6] Joao B. Pesquero,[1] Luiz F. Onuchic.[5] REBRASNI. *[1]Universidade Federal de Sao Paulo Escola Paulista de Medicina, Sao Paulo, Brazil; [2]Hospital Samaritano de Sao Paulo, Sao Paulo, Brazil; [3]Universidade Estadual de Campinas, Campinas, Brazil; [4]Universidade de Sao Paulo Instituto da Crianca, Sao Paulo, Brazil; [5]Universidade de Sao Paulo, Sao Paulo, Brazil; [6]Johns Hopkins University, Baltimore, MD.*

Background: Characterizing pediatric nephrotic syndrome (NS) is crucial to predict long-term outcomes. However, data on this disease condition are yet scarce in developing countries.

Methods: We conducted a retrospective epidemiological study using a nationwide representative sample comprising 16 centers and 772 cases. Cox regression was used to model stage 5 chronic kidney disease (CKD)-free survival, with response to steroid therapy as the explanatory variable, and sex, ethnicity, and family history of nephrotic syndrome as covariates.

Results: There was a slight male predominance in the cohort (436 cases, 56% of the total). The median age at disease onset was 3.3 years (IQR: 2.2 to 5.7), and the follow-up period for the sample was 5.4 years (IQR: 2.8 to 9.1). A family history of NS was reported in 55 cases (9.7% of valid responses to this question). The final classification of the response to steroid treatment revealed 317 (42%) cases of steroid-sensitive NS, 238 (31%) patients with steroid-dependence/frequent relapses, 167 (22%) cases of steroid-resistant NS, and 39 (5%) patients with secondary steroid resistance (initial positive response to steroids followed by subsequent resistance). Considering the whole sample, 317 (41%) underwent a kidney biopsy and only 15 (2%) children had a genetic test, yielding a low molecular genetic diagnostic rate. At the end of the follow-up, 57 children (7.7%) had progressed to stage 5 chronic kidney disease (CKD). CKD stage 5-free survival over a ten-year follow-up period was estimated to be 90% (95% CI: 87% to 94%) and the median time to the event was 5 years. According to the response to steroids, resistance (HR: 63, $p < 0.001$) and secondary resistance (HR: 11, $p = 0.031$) were associated with a worse prognosis. A multivariable model adjusted for sex, ethnicity, and family history of NS did not alter the magnitude or direction of the associations with steroid responses.

Conclusions: Steroid resistance was observed at a higher frequency than typically reported in the literature, and there is low access to molecular diagnosis in the whole country. Moreover, our data reaffirm the negative impact of resistance and secondary resistance to steroids on the prognosis of pediatric nephrotic syndrome.

Nephrotic Syndrome in a Child with R138Q NPHS2 Mutation

Ross A. Tollaksen, Ihor V. Yosypiv. *Tulane University School of Medicine, New Orleans, LA.*

Introduction: Steroid resistant nephrotic syndrome (SRNS) accounts for 30% of all cases of nephrotic syndrome (NS) in children and frequently leads to end stage kidney disease (ESKD). 30% of children with SRNS demonstrate identifiable causative mutations in podocyte-associated genes. Early identification of genetic forms of SRNS is critical to avoid potentially harmful immunosuppressive therapy.

Case Description: A 2-year-old male patient with NS (plasma creatinine of 0.7 mg/dL, serum albumin of 0.6 g/dL, urine protein/creatinine ratio of 18.0 mg/mg) and negative family history of renal disease did not respond to 4-week steroid treatment. Infectious and immune workup for secondary NS was negative. Kidney biopsy showed mesangial proliferative glomerulonephritis, focal membranoproliferative pattern, global glomerulosclerosis (3/50), mild interstitial fibrosis, foot process fusion and basement membrane dysmorphism. Tacrolimus and lisinopril were added to therapy pending results of genetic testing. Genetic panel showed *NPHS2* c.413G>A (p.Arg138Gln) homozygous pathogenic variant. A diagnosis of autosomal-recessive form of nonsyndromic SRNS due to *NPHS2* causative variant was made. Immunosuppressive therapy was stopped, lisinopril dose was increased and weekly infusions of albumin/furosemide were initiated to manage edema.

Discussion: A diagnosis of SRNS due to NPHS2 causative variant was made. Immunosuppressive therapy was stopped, and lisinopril dose was increased. Weekly infusions of albumin/furosemide were initiated to manage edema and prevent complications from hypoalbuminemia. The patient is being managed expectantly until a time when a kidney transplant is necessary. This case demonstrates the importance of early genetic testing in children with SRNS to avoid prolonged potentially harmful immunosuppressive therapy, provide timely genetic family counseling and discuss considerations for future living related donor kidney transplantation.

Improving PPSV23 Vaccination Rates in Children with Nephrotic Syndrome

Emily Frierson,[1,2] Kimmy T. Vuong,[1,2] Brandon M. Fairless,[1,2] Shweta S. Shah,[1,2] Leyat Tal.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Children with nephrotic syndrome (NS) are at high risk for pneumococcal infections and the PPSV23 vaccine is recommended as part of the pneumococcal vaccine series. Barriers such as lack of availability in pediatrician clinics, inability to verify primary series status, and not addressing vaccinations has led to an inadequate rate of PPSV23 vaccination.

Methods: This is a quality improvement (QI) study that aims to increase PPSV23 vaccination rate among eligible NS patients admitted to the renal service to 75% by September 2023. An H&P template was created that includes a smart phrase prompting residents to review eligibility criteria for PPSV23 vaccination and vaccinate if appropriate. Patients older than 2 years of age that have completed primary pneumococcal vaccine series, and had not received Rituximab in the last 6 months were included. Pediatric residents were educated on QI study at the beginning of their renal rotation by fellows and sign placed in workroom to serve as a reminder. Process metrics included resident use of H&P and percent of eligible patients that refused vaccinations.

Results: In 2-month period, 12 patients with NS were admitted to the renal service. 8 patients were up-to-date and 4 were eligible for PPSV23. Of eligible patients, 3 were identified, 2 received PPSV23 prior to discharge and 1 family declined. The H&P template was used for 7/12 (58%) of admissions and at hospital discharge 2/4 (50%) of eligible patients were up-to-date.

Conclusions: Increasing PPSV23 vaccination is important in decreasing serious pneumococcal infections. Our project showed improvement in identifying eligible NS patients with the implementation of the new H&P template. The participation from pediatric residents underscores value of simple interventions woven into work flow and work space.

FR-PO667

Homeostatic Model Assessment (HOMA) in Pediatric Patients with Nephrotic Syndrome Receiving Tacrolimus

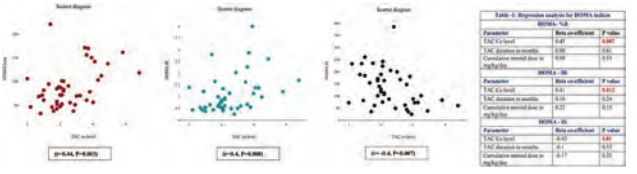
Sukanya Govindan, Saravana Kumar Singaram. *Mehta Multispeciality Hospitals India Pvt Ltd, Chennai, India.*

Background: Children with nephrotic syndrome receive diabetogenic drugs like tacrolimus (TAC) and steroids. TAC is toxic to pancreatic β-cells and suppresses insulin production in a time and dose dependent manner. Post transplant diabetes mellitus due to TAC and or steroids is well documented in renal transplant patients. Although overt diabetes is rare in children receiving TAC with or without steroids for nephrotic syndrome (NS), the subclinical effect on β cell function has not been studied.

Methods: We prospectively followed children with NS who received TAC therapy at least for 1 year. We noted patient demographics, clinical and histologic pattern of NS, cumulative steroid dose (mg/kg/day) received 90 days prior and TAC C_0 levels. Fasting insulin, blood sugar to calculate HOMA indices for IR (insulin resistance), HOMA % β for beta cell function, HOMA-IS (insulin sensitivity), C-peptide and HbA1C were done once at study inclusion and yearly intervals when required. Statistical analysis included Pearson's correlation, paired t test and regression analysis.

Results: We performed HOMA indices in 37 patients between September 2021-February 2023. Six patients had 2 measurements during the study period. The mean TAC duration, TAC Co level and mean cumulative steroid dose were 27 months (95% CI[22;32]), 4.54 ng/ml (95% CI[4.12;4.97]) and 0.36 mg/kg/d (95% CI[0.28;0.44]) respectively. In Pearson's correlation analysis we found positive correlation between TAC Co level, HOMA IR (r=0.4, P=0.008) and TAC Co, HOMA %β (r=0.44, P=0.003) and cumulative steroid dose, fasting blood glucose (r=0.3, P=0.46). There was negative correlation between TAC Co level, HOMA IS (r =-0.4, P=0.007). In regression analysis, only TAC Co level significantly influenced all HOMA indices including insulin resistance, insulin sensitivity and beta cell function. A HbA1C of > 5.7 (pre-diabetes range) was found in 32.4% (12/37) patients which warrants further monitoring. C-peptide levels were significantly higher after 12 months of TAC therapy in 6 patients who had two measurements (p=0.032).

Conclusions: Tacrolimus therapy for nephrotic syndrome in children can affect pancreatic beta cell function as assessed by HOMA indices.



FR-PO668

Using Degree of Foot Process Effacement to Predict Outcome in Paediatric Steroid-Resistant Nephrotic Syndrome: A Multi-Centre Analysis

Moin Saleem,[1] Miranda Rogers,[1] Anna E. Mason,[2] Samantha J. Hayward,[1] Liz Colby,[1] Gavin I. Welsh,[1] Wen Y. Ding.[1] *[1]University of Bristol Medical School, Bristol, United Kingdom; [2]Department of Histopathology, Royal Devon and Exeter Hospitals, Exeter, United Kingdom.*

Background: Steroid resistant nephrotic syndrome (SRNS) is a common cause of paediatric end-stage renal failure requiring transplantation. Recurrence post-transplantation is high in those with no identified pathogenic variant, but those with pathogenic mutations rarely develop recurrence post-transplantation. Previous work suggests that degree of native renal biopsy podocyte foot process effacement (FPE) may distinguish genetic and non-genetic causes of SRNS, but the studies are limited by small samples and single-centre recruitment. This suggests that degree of native biopsy FPE may detect risk of post-transplant recurrence. We hypothesised that diffuse FPE is a marker of circulating factor disease and predicts post-transplant recurrence, while segmental FPE is a marker of non-recurrent disease.

Methods: We analysed a multi-centre nationwide cohort of paediatric SRNS patients (RADAR) to assess if FPE degree can predict disease recurrence. 138 paediatric Nephrotic Syndrome patients had transplantation between 2007-22. 28 with native biopsy electron microscopy (EM) reports available were included. We quantified FPE as diffuse or segmental from report language.

Results: 9/28 patients developed disease recurrence. 27 patients had genetic testing, of which 11 had a causative genetic mutation. No patients with pathogenic genetic variants developed recurrence (recurrence if pathogenic variant 0/11; recurrence if no pathogenic variant 9/17, p=0.0039). 9/11 patients with pathogenic variants show diffuse FPE on EM while 9/17 without identified genetic mutations show diffuse FPE (p=0.2264). All 7 patients with slit diaphragm protein pathogenic mutations had diffuse FPE. Patients with diffuse FPE (recurrence 4/18) trended towards lower recurrence rates than those with segmental FPE (recurrence 5/10, p=0.2096).

Conclusions: In this multi-centre cohort we show trends between genetic causes of SRNS and FPE, and the direction of the association contrasts with literature. We show that slit diaphragm protein mutations are associated with diffuse FPE. We show a not statistically significant trend towards diffuse FPE and lower recurrence post-transplant. This study is limited by small numbers and its retrospective nature, but the trends justify further investigation in larger groups of patients.

FR-PO669

A Pediatric Patient with Proteinuria and Hepatic Steatosis

Kaitlyn Order, Ankana Daga. *Boston Children's Hospital, Boston, MA.*

Introduction: Frasier syndrome is a rare but well described disorder arising from a donor splice site mutation in intron 9 of the Wilms Tumor 1 (*WT1*) gene. It is associated with steroid resistant nephrotic syndrome and progression to ESRD. Patients with Frasier syndrome are characteristically phenotypic females with an XY genotype, streak ovaries and a risk for gonadoblastoma. Here we describe an XX pediatric patient with *WT1* mutation characteristic of Frasier syndrome and an incidental finding of hepatic steatosis.

Case Description: A six year old obese female was referred to nephrology after two years of progressive isolated proteinuria; dipstick of 3+ and UPC of 2.5 mg/mg at time of referral. She had no overt edema. Her serum albumin and creatinine were normal at 4.0 g/dL

and 0.48 mg/dL respectively, and labs were notable for transaminitis with AST 56/ ALT 126. Ultrasound demonstrated normal kidneys but incidentally an echogenic liver. Renal biopsy was consistent with FSGS: 1/24 glomeruli had global sclerosis, EM had diffuse podocyte foot process effacement, and IF was unrevealing. Genetic panel testing was then completed and revealed a pathogenic mutation in *WT1* (IVS9+4C>T) and a separate pathogenic mutation in HNF1A which portends a risk to Mature Onset Diabetes of the Young (MODY) and in some cases hepatic steatosis. Normal uterus and ovaries as well as XX genotype were confirmed on this patient. She was initiated on ACEI therapy with no improvements in proteinuria over two years (recent UPC of 4.7 mg/mg), but renal function has remained stable. She is followed by Hepatology for hepatic steatosis. Parental genetic testing is pending, but father has a history of type 2 diabetes at age 18 years.

Discussion: This case highlights the value of genetic testing in pediatric patients who present with isolated nephrotic range proteinuria without nephrotic syndrome, and whether a renal biopsy can be avoided if genetic results are available. Our patient is unique in that she is an XX female with normal ovarian development thus we question the need for gonadal monitoring as the risk for gonadoblastoma is seen in those XY females with streak ovaries. With regards to proteinuria and progression to ESRD, therapy is mainly limited in pediatrics to ACEI and ARB. In this patient with an HNF1A associated risk of metabolic syndrome, we consider the role of an SGLT-2 inhibitor for its nephroprotective and antiproteinuric effects.

FR-PO670

Improving Polygenic Risk Scores for Steroid-Sensitive Nephrotic Syndrome by Integrating Relevant Traits

China Nagano,[1,2] Michelle Mcnulty,[1,3] Matt G. Sampson,[1,3] Kaylia M. Reynolds.[1,3] *[1]Boston Children's Hospital, Boston, MA; [2]Kobe University Graduate School of Medicine, Kobe, Japan; [3]Broad Institute, Cambridge, MA.*

Background: Polygenic risk scores (PRS) have been widely applied in research studies to identify associations of a person's overall genetic profile with diseases/traits. We are in the early stages of developing PRS for steroid sensitive nephrotic syndrome (SSNS). PRSmix and PRSmix+ have been created to incorporate additional PRS for both the same disease and correlated traits to improve PRS prediction accuracy. Here, we tested the hypothesis that the prediction accuracy of an SSNS PRS would be increased using these strategies.

Methods: Using our previously created SSNS PRS (Barry et al.), we applied PRSmix and PRSmix+ in a European SSNS cohort. Candidate PRSs were obtained from the Polygenic Score Catalog. Individuals in our European SSNS cohort were randomly assigned to a training/testing cohort. Three models were created to assess the additive benefit of combining multiple PRS and correlated traits: the "best PRS" model only includes our SSNS PRS as a predictor, the "PRSmix" model incorporates all SSNS PRS, and the "PRSmix+" model adds high-power PRS from correlated traits to the PRSmix model. The Likelihood-Ratio test (LRT) was used to compare the goodness of when adding a PRS to the model. The Matthews Correlation Coefficient (MCC) was used to evaluate binary classifications; it ranges from –1 to 1, with extreme values 1 reached in case of perfect classification. Comparative predictive accuracy in the testing dataset was assessed using a two-sample z test.

Results: In a 100-fold cross validation study, adding another SSNS PRS (PRSmix) always significantly improved model fit (LRT<0.05) compared to the best PRS. Furthermore, adding high-powered traits (PRSmix+) always significantly improved model fit (LRT<0.05) compared to the PRSmix. The average case prediction accuracy (as measured by MCC) was slightly improved for both the PRSmix (MCC=0.499) over bestPRS (MCC=0.477; p=0.38) and the PRSmix+ (MCC=0.502) over best PRSmix (p=0.36). For PRSmix+, the PRS traits with highest inclusion across 100 models were eosinophil (100%), asthma (79%), and white blood cell counts (72%).

Conclusions: We improved the prediction capability of SSNS PRS using PRSmix and PRS mix+. PRS of other diseases/traits can increase the accuracy of predictive models, may ultimately improve clinical inference, and could provide a better understanding of SSNS disease etiology.

FR-PO671

Trends from 2010 to 2022 in the Utilization of Anti-CD20 Antibodies to Treat Childhood Nephrotic Syndrome

Kathryn Hirabayashi,[1] Amy Goodwin Davies,[1] Hanieh Razzaghi,[1] Vikas R. Dharnidharka,[2,3] Bradley P. Dixon,[4] Joseph T. Flynn,[5,6] Caroline A. Gluck,[7] Mark Mitsnefes,[8,9] William E. Smoyer,[10,11] Susan L. Furth,[12,13] Michelle Denburg.[12,13] *[1]The Children's Hospital of Philadelphia Division of General Pediatrics, Philadelphia, PA; [2]St Louis Children's Hospital, St Louis, MO; [3]Washington University in St Louis Department of Pediatrics, Saint Louis, MO; [4]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [5]University of Washington Department of Pediatrics, Seattle, WA; [6]Seattle Children's Hospital, Seattle, WA; [7]Nemours Children's Hospital Delaware, Wilmington, DE; [8]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [9]University of Cincinnati Department of Pediatrics, Cincinnati, OH; [10]Nationwide Children's Hospital, Columbus, OH; [11]The Ohio State University, Columbus, OH; [12]The Children's Hospital of Philadelphia, Philadelphia, PA; [13]University of Pennsylvania Department of Pediatrics, Philadelphia, PA.*

Background: A growing body of evidence supports the efficacy of the type I anti-CD20 monoclonal antibody, rituximab, in the management of children with frequently relapsing or steroid dependent nephrotic syndrome (NS). We examined trends in the use of anti-CD20 antibodies in a multi-institutional population of children with NS.

Methods: Data came from PEDSnet, a clinical research network that aggregates electronic health record (EHR) data at several children's healthcare organizations (database version 4.8). Patients were aged 2-21.99 years, had ≥2 outpatient visits ≥1 year apart, and met our published EHR-based computable phenotype algorithm for nephrotic conditions between January 2010-November 2022. Children with systemic lupus erythematosus (SLE) or congenital or genetic nephrotic diagnoses were excluded. Treatments were measured from NS diagnosis to kidney transplant or most recent in-person encounter. We stratified the cohort by presence of native kidney biopsy.

Results: Among 6,880,824 patients across 6 centers, 3,021 met criteria for nephrotic conditions. 953 (32%) had at least one kidney biopsy. Rituximab utilization increased over time, with a sustained increase since 2019 from 5.9% to 7.8%. Similar trends were observed for mycophenolate and tacrolimus. Concurrently, use of cyclosporine and cyclophosphamide decreased. Tacrolimus was most frequently used.

Conclusions: Use of rituximab to manage NS has steadily increased. PEDSnet provides the ability to collect real-world data and enhance our understanding of long-term efficacy and trends in steroid-sparing medication use for rare diseases such as NS.

FR-PO672

Efficacy and Safety of Single-Dose Rituximab Biosimilar in the Initial Episode of Paediatric Steroid-Sensitive Nephrotic Syndrome

Liu Jialu, Hong Xu, Qian Shen. *Children's Hospital of Fudan University, National Children's Medical Center, Shanghai, China.*

Background: The 12-month relapse-free survival rate is less than 30% in steroid-sensitive nephrotic syndrome (SSNS) children after the standard corticosteroid therapy. Rituximab is effective in reducing the relapse in children with frequent relapse or steroid dependent NS. Accordingly, we hypothesize rituximab added to guideline-recommended corticosteroid therapy is effective for maintaining remission for the first year of onset.

Methods: An open-label, single-arm, multicentre trial was performed at eight centers in China with a 12-month follow-up (NCT04783675). The first episode of SSNS children treated with standard corticosteroids was eligible for inclusion. Eligible patients received a single dose of 375 mg/m^2 rituximab biosimilar within one week after achieving remission. The primary outcome was the 12-month relapse-free survival rate after rituximab was added to corticosteroid therapy, was compared with historical controls treated without rituximab on NCT03878914.

Results: Totally, 44 children were treated with rituximab and all but one patient completed one year of follow-up. Rituximab therapy was associated with a significantly higher 12-month relapse-free survival rate than the historical control (32 [74.4%] vs 10 [30.3%] children; P <0.001; hazard ratio, 1.89; 95%CI, 1.15-3.11). The median time to first relapse was 123 days (95%CI, 73 to 201 days). The treatment was well tolerated. During infusion, three participants reported throat irritation. Besides two patients with a decreased neutrophil count, all other adverse events were fully resolved.

Conclusions: In children with the initial episode of SSNS, rituximab appears to be an effective and safe treatment for maintaining disease remission. It provides evidence for the initial treatment strategy of SSNS in children to prevent the recurrence.

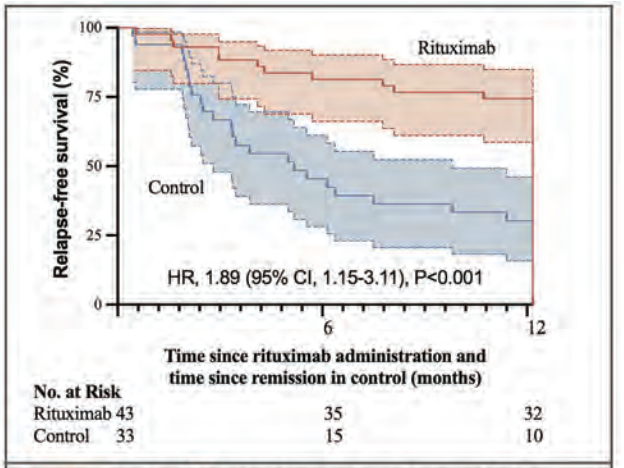

Figure 1. Kaplan-Meier curve of relapse-free survival in patients with rituximab and historical controls
Kaplan–Meier curves indicating the percentage of patients who maintained remission at 6 months and 12 months after rituximab biosimilar (HANLIKANG) infusion and in control. Shading indicates 95% CIs.

FR-PO673

The Genetic Background of Persistent Hypogammaglobulinemia After Rituximab Treatment in Refractory Nephrotic Syndrome

Miyu Sai, Nao Uchida. *Tohoku Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Sendai, Japan.*

Background: Rituximab (RTX) has been proven to be effective for refractory nephrotic syndrome(rNS); however, persistent severe hypogammaglobulinemia (HGG) is occasionally observed and causes health problems in some patients. We suspected the coexistence of common variable immunodeficiency (CVID) in these patients, and we proved that they had either genetic mutations associated with CVID or *FCGR3A* F176V polymorphism, that is, a missense variant, c.526T>G (p.Phe176Val) in *FCGR3A* gene (NM_000569.8).

Methods: We performed whole genome sequence analysis on patients who developed persistent HGG (<400 mg/dL, more than two years) after the last RTX therapy.

Results: Five patients were recruited (table). All of them developed rNS and were treated with repeated RTX <18 years old. Their HGG was persistent for more than five years after the last RTX therapy. Among the five patients, three (No.1-3) showed severe (<200 mg/dL) HGG, pan hypoimmunoglobulinemia, and susceptibility to infection. The other two (No.4 and 5) showed relatively mild HGG, normal to high levels of other types of immunoglobulin, and no clinical symptoms. Genetic analysis revealed that No.1 had a novel heterozygous mutation in *NFKB1*, and No.3 had a heterozygous mutation in *TNFSF12*. Both genes were associated with CVID. *FCGR3A* F176V polymorphisms were found in No.2 and 3. Thus, patients who developed severe and symptomatic pan hypoimmunoglobulinemia had either a genetic mutation associated with CVID or *FCGR3A* F176V polymorphism.

Conclusions: Severe and symptomatic pan hypoimmunoglobulinemia after RTX treatment was accompanied by genetic alterations in CVID-associated genes or in FCGR3A genes. Advanced analysis of these genes before RTX administration could prevent, or at least delay, the development of symptomatic pan hypoimmunoglobulinemia.

No.	gender	IgG level (mg/dL)	other Ig	genetic mutation	FCGR3A F176V	clinical symptoms
1	female	<100	IgA↓, IgM↓	NFKB1	N.A.	otitis media, respiratory infection
2	female	<100	IgA↓, IgM↓	–	+	otitis media, sinusitis
3	male	100-200	IgA↓, IgM↓	TNFSF12	+	rota virus-associated encephalitis

5	female	200-300	IgA↑, IgM↑	–	–	no symptoms

FR-PO674

Genetic Insights into Pediatric Polycystic Kidney Disease

Christian Hanna, Hana Yang, Rachel S. Schauer, David J. Sas, Cheryl L. Tran, Carl H. Cramer, Peter C. Harris. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Pediatric polycystic kidney disease (PKD) exhibits genetic heterogeneity, including autosomal dominant and recessive PKD, as well as ciliopathies with syndromic involvement. Relying solely on gene-specific analyses may lead to missed diagnoses. Our objective was to summarize genetic findings in pediatric patients (pts) with bilateral kidney cysts seen at our clinic, emphasizing unique cases.

Methods: We reviewed resolved cases from Jan 2020 to Apr 2023 involving clinical or research genetic testing. Targeted next-generation sequencing, encompassing known and candidate PKD/ciliopathy genes, was performed at our research lab. Variants were assessed using disease-specific and population databases, along with in silico variant assessment tools. Categorization followed ACMG guidelines.

Results: Genetic screening identified pathogenic changes in 9 genes, accounting for 49 pts (45 families): 40 with monoallelic and 9 with biallelic variants. Monoallelic genes included *PKD1* (n=18), *HNF1B* (n=9), *PKD2* (n=5), *PKHD1* (n=2), *IFT140* (n=2), *NEK8* (n=1), *GANAB* (n=1), *TSC2* (n=1), and *TSC2/PKD1* deletion (n=1). Biallelic genes were *PKHD1* (n=6) and *NPHP1* (n=3). Among PKD1 pts, 83% (15/18) had a positive family history, while 60% (3/5) of PKD2 pts did. Incident discovery or family screening diagnosed 67% (12/18) of PKD1 pts, 28% (5/18) had prenatal presentation, and one case involved an early onset intracranial aneurysm rupture. PKD2 pts were all incidentally diagnosed. Children with monoallelic variants in *IFT140*, *GANAB*, or *PKHD1* exhibited mild PKD phenotypes and were incidentally diagnosed through abdominal imaging. The NEK8 variant pt presented with severe neonatal PKD and kidney failure requiring dialysis at 6 years old, representing a novel manifestation for this gene. Nearly all HNF1B variant/deletion pts (8/9) presented in utero with kidney cysts and/or hyperechoic kidneys.

Conclusions: Comprehensive analysis of clinical and research-related genetic screening reveals the complexity of monogenic causes of PKD. This study reports the first pathogenic variant in *IFT140* found in pediatric pts, an additional case involving *GANAB*, and a new monoallelic NEK8 disorder. Genetic screening in pediatric PKD pts, irrespective of family history, offers a definitive diagnosis, informs prognosis and therapy discussions, and facilitates enrollment in clinical trials.

Kidney Survival in Pediatric Patients with Pathogenic Hepatocyte Nuclear Factor 1β Variants

Joost Schanstra,[1] Benedicte Buffin-Meyer,[1] Juliette Richard,[2] Jens König,[3] Franz S. Schaefer,[4] Laurence Heidet,[5] Stéphane Decramer.[2] HNF1B Study Group. *[1]Inserm U1297, Toulouse, France; [2]CHU de Toulouse, Toulouse, France; [3]University Children's Hospital, Münster, Germany; [4]Universitat Heidelberg, Heidelberg, Germany; [5]Hôpital Necker-Enfants Malades, Paris, France.*

Background: Hepatocyte nuclear factor 1β (*HNF1B*) gene variants represent the most common monogenic cause of developmental kidney disease. Identification of specific genotype-phenotype associations in *HNF1B* disease would inform genetic counselling. The objective of this study was to determine whether the *HNF1B* mutation type is associated with kidney survival.

Methods: This was a retrospective observational study involving 521 patients from 14 European countries using the European ERKNet-ERN network. Mean follow-up time was 7.7 years with 6.2 visits per patient. The primary end point was progression to chronic kidney disease (CKD) stage 3 (eGFR<60 mL/min/1.73m^2). Secondary endpoints were the development of extra renal abnormalities including hypomagnesemia, hyperuricemia and hyperglycemia.

Results: Progression towards CKD-stage 3 was significantly delayed in patients with the 17q12 deletion compared to patients with other pathogenic *HNF1B* variants (HR 0.31 (95%CI: 0.20-0.47), p<0.001). Presence of only one functional kidney due to a contralateral multicystic dysplastic kidney or agenesis was associated with accelerated CKD progression (p=0.028). Interestingly, the 17q12 deletion conferred a significant better kidney function than the other *HNF1B* variants already in the neonatal period. Finally, the 17q12 deletion was associated with hypomagnesemia (HR 2.49, 95%CI:1.57-4.03, p<0.001), but not with hyperuricemia or hyperglycemia.

Conclusions: Pediatric patients with the 17q12 deletion and two functional kidneys display a significantly better kidney survival than patients with other pathogenic *HNF1B* variants. We identified the first clinically relevant *HNF1B* genotype-phenotype correlation that informs genetic counselling of pediatric patients.

Characteristics of Kidney Resident IgA Antibody-Secreting Cells in IgA Nephropathy

Yuko Makita,[1,2] Kei Haniuda,[3] Julia M. Murphy,[1,3] Martin L. Mak,[1,3] Yusuke Suzuki,[2] Sarah Q. Crome,[1,3] Jennifer Gommerman,[3] Heather N. Reich.[1,3] *[1]University Health Network, Toronto, ON, Canada; [2]Juntendo Daigaku, Bunkyo-ku, Japan; [3]University of Toronto, Toronto, ON, Canada.*

Background: The trigger and sources of pathogenic IgA in IgAN are not established. Prevailing theories suggest that circulating polymeric nephritogenic IgA is produced by either antibody secreting cells located within the mucosa-associated lymphoid tissue or the bone marrow. Our recent work demonstrated that in experimental IgAN mice (BAFF-Tg), mucosal pathobiont-directed IgA antibody secreting cells (APC) are identified within the kidney. In the current study we aimed to characterize kidney IgA APC in experimental IgAN, and to elucidate the factors that foster migration to and residence within the kidney and explore cell-cell interactions within the kidney niche.

Methods: Flow cytometry was used to identify IgA APC in the kidneys of the male BAFF-Tg and C57/BL6 (WT). Single-cell mRNA sequencing (scRNA-seq) was performed in 4 BAFF-Tg and 4 WT at 20 weeks of age to characterize immune cells within the kidney.

Results: We identified an age-dependent increase in IgA-producing plasma cells (PC) by flow cytometry (CD45+, B220-, CD98+, IRF4+, IgA+) within the kidneys of BAFF-Tg but not WT mice; these PC were detectable at 6 weeks of age, and numbers continued to rise by 20 weeks of age. scRNA-seq confirmed a population of IgA APC in the BAFF-Tg kidneys. Analysis of differential gene expression supported phenotypically different subpopulations of IgA APC in kidneys of BAFF-Tg. Ligand-receptor pair analysis suggests

cell-cell interaction patterns between IgA APC, macrophages and endothelial cells that may support migration of IgA APC and proliferation of these cells within the kidney.

Conclusions: Our mouse data support the concept that pathogenic IgA production in experimental IgAN can occur within the kidney. We have confirmed the age-dependent presence of IgA-producing PC within the kidneys of the BAFF-Tg by flow cytometry and these cells may be initially proliferating within the kidney. We have further characterized the immune cell populations within the kidney in experimental IgAN using scRNA-seq, and identified possible cell-cell interactions that may foster the migration and support of mucosal derived IgA APC within the kidney, potentially resulting in kidney pathology. Elucidation of the ligands and receptors involved in kidney IgA APC migration and residence will inform therapeutic interventions for the treatment of IgAN.

FR-PO677

Gut Microbial Variation and Disease Status in IgA Nephropathy

Manish K. Saha, Mary M. Collie, Vimal K. Derebail, Amy K. Mottl, Jeffrey Roach, Donna O. Bunch, Susan L. Hogan, Tessa Andermann, Ronald Falk. *The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: The pathogenesis of IgA nephropathy (IgAN) is ill-defined. Recent evidence suggests involvement of the gastrointestinal lymphoid tissue in association with the gut microbiome. We hypothesized that patients with IgAN have alterations in gut microbial composition compared to healthy controls (HC), especially during disease activity.

Methods: We performed a case-control study of adult patients with primary IgAN, and age-sex-gender-BMI matched healthy controls (HC). Patients with IgAN were sub-divided based on disease activity (active - UPCR > 1.5 g/g ; remission - UPCR < 1 g/g) and immunosuppressive therapy status (IS, on/off). DNA isolated from stool sample underwent 16S rRNA amplicon sequencing of the V4 variable region. The QIIME2 pipeline was used for analysis. Kruskal-Wallis and PERMANOVA tests were used to compare alpha- and beta-diversity between groups, respectively. ANCOM-II was used to assess taxonomic abundance between groups, and accounted for multiple testing.

Results: The gut microbiome composition of patients with IgAN in remission, off IS, showed significant differences from HC as measured by alpha-diversity index: a decrease in both Chao1 index (p=0.03) and observed features (p=0.02). No significant difference in beta diversity metric found. The genus Muribaculaceae was estimated to occur only in HC whereas Bacteroidales was estimated to occur only in patients in remission, off IS. Although the gut microbiome composition of patients with active IgAN, off IS, showed no significant differences from HC as measured by diversity indices, there were significant alterations in the differential abundance of taxa among the different groups (Table1).

Conclusions: IgAN is associated with changes in the gut microbial composition. Megasphaera, a commensal of healthy gut, was present in HC and patients with IgAN in remission, off IS. Bacteriodales was present only in patients in remission status, off IS. Higher abundance of Enterobacteriaceae genus may reflect bacterial overgrowth due to IS.

Table 1	Healthy Control (N= 23)	Active off IS (N = 14)	Remission off IS (N = 19)	Remission on IS (N = 15)
UPCR, g/g Median(Q1, Q3)		2.2 (1.5,3.3)	0.6 (0.2,0.8)	0.7 (0.4,1.4)
eGFR, ml/min/1.73m2 Median(Q1 , Q3)		72 (36,108)	67 (46,78)	58 (41, 87)
Differential abundance of gut microbial taxa				
Megasphaera (genus)				
Enterobacteriaceae (genus)				
Rhodospirillales (order)

Dihydroartemisinin Inhibits Mesangial Cell Proliferation in IgA Nephropathy by Regulating PGC1α-Mediated Glycometabolism

Ming Xia, Juanyong Zhao, Xinyan Fan, Xunzi Tang, Hong Liu. *Department of Nephrology, The Second Xiangya Hospital, Central South University, Hunan Key Laboratory of Kidney Disease and Blood Purification, Changsha, China.*

Background: Mesangial cell proliferation is the basic pathological feature of IgA nephropathy (IgAN), but the mechanism of glucose metabolism in mesangial cell proliferation has not been studied. It has been reported that artemisinin analogues can effectively regulate cellular glucometabolic enzymes and improve autoimmune diseases, but their efficacy on IgAN remains unclear. The aim of this study was to clarify the changes of glucose metabolism in IgAN, and to explore the therapeutic effect of dihydroartemisinin (DHA) on IgAN.

Methods: The expression of glucometabolic enzymes, and the relationship between enzymes and clinicopathology in IgAN patients were analyzed using GEO datasets and renal biopsy specimens. The expression of glucometabolic enzymes, energy metabolic pathway, cell proliferation, apoptosis were evaluated in mesangial cells after PGC1α agonist/ inhibitor/DHA intervention. Enrichment pathways was analyzed and the metabolites of glucose metabolism were detected after DHA intervention. The IgAN mouse model was administrated with DHA, renal function and pathology, as well as the expression level of glucometabolic enzymes in glomeruli were detected.

Results: The expression of glycolytic enzyme HK1 was increased, and the expression of gluconeogenic enzyme (PCK1, FBP1) were decreased in IgAN glomeruli. The expression of glycometabolic enzymes were significantly correlated with renal clinical indicators. PGC1α was significantly correlated with differentially expressed glucometabolic enzymes, and its expression was lower in IgAN patients with heavy mesangial cell proliferation. DHA upregulated PGC1α expression, inhibited glycolysis and suppressed mesangial cell proliferation. In vivo, DHA reversed the expression of glucometabolic enzymes and alleviated kidney injury in IgAN mice.

Conclusions: This study demonstrated the alteration of glucose metabolism in glomeruli, and the therapeutic effects of DHA in regulation of PGC1α and glucose metabolism in IgAN. These results provide new strategies for renal protection, as well as theoretical basis and intervention targets for DHA therapy of IgAN.

Spatially Resolved Transcriptomics Reveals Golgi-Endoplasmic Reticulum (ER) Network-Associated Differentially Expressed Genes in Membranous Lupus Nephritis

Jeongmin Cho,[1] Sehoon Park,[1] Jung Hun Koh,[1] Yaerim Kim,[2] Seung Seok Han,[1] Hajeong Lee,[1] Dong Ki Kim.[1] *[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Keimyung University School of Medicine, Daegu, Republic of Korea.*

Background: Class V lupus nephritis (LN) shares histological similarities with membranous nephropathy (MN) characterized by subendothelial immune complex deposits. However, the differences in pathogenesis between class V LN and other LN classes or anti-PLA2R-associated MN are largely unknown.

Methods: Spatial transcriptomic profiling was conducted using GeoMx Digital Spatial Profiler on formalin-fixed paraffin-embedded kidney biopsy specimens obtained from control (n = 7), LN class I to V (n = 24), and anti-PLA2R-associated MN (n = 16). LN and MN specimens were collected at proteinuric status. Differentially expressed genes (DEGs) between (1) each class of LN (I-V) vs. control and (2) class V LN vs. MN were identified. Gene Ontology (GO) terms for DEGs were annotated using the ToppGene suite.

Results: A total of 128 DEGs were downregulated in class V LN compared to MN. These genes were also downregulated in class V LN when compared to control samples, while no significant expression differences were observed in other LN classes compared to controls. Eleven of 128 downregulated DEGs were annotated with biological process GO terms related to Golgi vesicle transport. Regarding cellular component GO terms, Golgi apparatus (30/128 DEGs), endoplasmic reticulum (ER) membrane (19/128 DEGs), and ER-Golgi intermediate compartment (6/128 DEGs) were among the annotated GO terms associated with the DEGs. DEGs in annotation included GOLGA3, TMED7, BET1L, and RAB10.

Conclusions: The ER-Golgi network and related molecular pathway may be involved in the distinct pathogenesis and clinical features of class V LN.

Spatially Resolved Transcriptomic Profiling for Glomerular and Tubulointerstitial Gene Expression in C3 Glomerulonephritis

Jung Hun Koh,[1] Sehoon Park,[1] Jeongmin Cho,[1] Yaerim Kim,[2] Dong Ki Kim.[1]
[1]Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Keimyung University Dongsan Medical Center, Daegu, Republic of Korea.

Background: C3 glomerulonephritis (C3GN) is a rare but clinically significant primary glomerulopathy. However, little is known about its transcriptomic profile. We aimed to investigate the substructure-specific gene expression profile of C3GN using the recently introduced spatial transcriptomics technology.

Methods: We performed spatial transcriptomic profiling using GeoMx Digital Spatial Profiler with formalin-fixed paraffin-embedded kidney biopsy specimens of three C3GN cases and eight donor kidney controls. Profiles from other glomerular diseases, including focal segmental glomerulosclerosis, membranous nephropathy, and minimal change disease, were included as disease controls. Gene expression levels between C3GN and the controls were compared by DESeq2 method, and differentially expressed genes (DEGs) were identified with a false discovery rate threshold of 0.05. We performed gene ontology (GO) annotation by the ToppGene Suite and mapped interaction networks among the DEGs using the STRING database.

Results: We identified 229 and 157 highly expressed DEGs in the glomeruli of C3GN compared to those of donor and disease controls, respectively, with consistently highest fold changes seen in POSTN, COL1A2, IFI44L, and TAGLN. Protease binding, structural molecule activity, and extracellular matrix constituent were the top enriched GO terms in the glomeruli of C3GNs, with consistent features seen in the network analysis. In contrast, no significant GO enrichment was found among the 563 and 347 lowly expressed DEGs in the glomeruli of C3GN compared to donor and disease controls. The tubular transcriptome profiles of C3GN were similar to those of the controls.

Conclusions: This is the first report of kidney substructure-specific transcriptomic profile of C3GN to date. Significant disease-specific transcriptomic alterations occur in the glomerulus of C3GN, providing potential insights into the pathophysiology.

Toll-Like Receptors (TLRs) Regulate the Production of Galactose-Deficient IgA1 in Human Renal Mesangial Cells

Zhenling Deng, Yue Wang. *Peking University Third Hospital, Beijing, China.*

Background: Galactose-deficient IgA1 (Gd-IgA1) is the core factor in the pathogenesis of IgA nephropathy (IgAN). Our group found that glomerular mesangial cells (GMC) could express and secrete IgA1. The aim of this study is to investigate whether Gd-IgA1 can be expressed in normal cultured GMC, upregulated by pathogenic factors, and to explore the regulatory mechanisms between Gd-IgA1 production and pathogen infection.

Methods: Immunofluorescence and western blot were used to confirm Gd-IgA1 expression under normal or stimulated condition. RT-PCR was used to verify the TLRs transcripts.

Results: In this study, we confirmed that Gd-IgA1 can be produced and secreted by mesangial cell lines under normal culture condition, and significantly increased by staphylococcus aureus (SAC), staphylococcal enterotoxin B (SEB), lipopolysaccharide (LPS) and angiotensin II (Ang II). Evidently, SAC and SEB promoted secretion and extracellular granular deposition of Gd-IgA1 in mesangial cells, consistent with renal pathology. Interestingly, mesangial cells constitutively expressed multiple TLRs, and that engagement of mesangial cell TLRs led to produce of Gd-IgA1 and release of proinflammatory cytokines, which can be inhibited by specific repressor of TLRs.

Conclusions: In short, we reported, for the first time, that mesangial cells can produce Gd-IgA1 and regulated by TLRs. This discovery subverted our current understanding for the pathogenesis mechanism of IgAN and hopefully change the current lack of effective treatment for IgAN.

Single-Cell Spatial Profiling of Glomerular Structures in Alport Syndrome

Laura Perin,[1] Kristina Sorg,[3] Jonathan E. Zuckerman,[2] Sargis Sedrakyan.[1]
[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]University of California Los Angeles David Geffen School of Medicine, Los Angeles, CA; [3]NanoString Technologies Inc, Seattle, WA.

Background: Many transcriptomics studies have described the molecular mechanisms underlying the progression of glomerular diseases, but very little is known about the gene spatial map of the different cell types, the heterogenous tissue niche composition, and how each glomerulus is affected during progressive CKD. Here we report the spatial characterization of gene expression at the single-cell level in renal biopsies of Alport Syndrome (AS) patients and from healthy subjects.

Methods: Using the Nanostring CosMX Spatial Molecular Imager (SMI) platform, and the human 1000-plex RNA panel we generated spatial maps of gene expression of kidney biopsies from AS patients (n=3) vs healthy subjects. Using H&E images we selected 29 fields of view (FOV) with dimensions of 0.9mm x 0.7mm for analysis. After data QC and normalization steps, we supervised cell typing. Spatial data analysis was achieved using different software and integrated with histopathology.

Results: We identified 36 clusters corresponding to different renal cells including glomerular, tubular, interstitial, and immune cell types. A spatial map of cell types in each FOV was reconstructed. Localization of podocytes, glomerular endothelial cells, and mesangial cells could be visualized. Color-coded gene expression maps of each cell type could be visualized at a single-cell resolution. Our analysis indicated the cellular composition varied between the different AS biopsies, revealing the presence of different cell types in the AS glomerulus not previously described including 3 different types of fibroblasts. We could also identify specific "glomerular immune niches."

Conclusions: CosMx SMI analysis revealed significant differences in gene expression between AS and healthy biopsies at a single-cell level. These preliminary data using this technology may allow the discovery of potential new therapeutic targets for patients with AS, and other CKDs.

FR-PO683

Transplanted Immune Competent Bone Marrow or Spleen Stem Cells Prevent Myeloperoxidase (MPO)-ANCA Glomerulonephritis in Immune-Deficient Mice

Peiqi Hu,[1] Hong Xiao,[1] Yanglin Hu,[1,2] Shen-Ju Gou,[1,3] Meghan E. Free,[1] Ronald Falk,[1] J. Charles Jennette.[1] UNC Kidney Center. *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Wuhan No 1 Hospital, Wuhan, China; [3]West China Hospital of Sichuan University, Chengdu, China.*

Background: ANCA disease patients cannot suppress the ANCA autoimmune response. Immune deficient *Rag2* knock out (KO) mice also cannot suppress ANCA. We hypothesized that transplantation (Tx) of wild type (WT) bone marrow (BM) or spleen cells would provide Rag-2 KO mice with stem cells capable of defending against Tx of

syngeneic MPO-ANCA B cells. This model could be used to identify specific stem cells for targeted therapy of autoimmune disease.

Methods: As previously described (Xiao H, et al. J Clin Invest 2002; 110:955-963), B6 *Mpo* knockout (KO) mice were immunized with mouse MPO and used as donors of splenocytes (SC) containing B-cells producing pathogenic MPO-ANCA. All B6 WT or B6 *Rag2* KO mice received anti-MPO SC on day 0 (Table G1-8). G3, 7 and 8 *Rag2* KO mice also received normal WT B6 BM or SC Tx on day 0 (G6) or 2-6 weeks before anti-MPO SC Tx. Serum MPO-ANCA was measured on days 0, 4, 7, 11 and 14; and mice were euthanized on day 14 for pathology evaluation.

Results: No male (G1) or female (G4) WT mice developed MPO-ANCA or GN 14 d after injection of MPO-ANCA SC. All male (G2) and female (G5) Rag2 KO mice developed MPO-ANCA and GN by day 14. WT BM Tx into *Rag2* KO mice 6 wks prior to anti-MPO SC (G3) prevented MPO-ANCA and GN. Similarly, Tx of WT SC 2 or 4 wks prior to MPO-ANCA SC (G7,G8) prevented MPO-ANCA and GN. However, Tx of WT SC on 0d (G6) did not prevent MPO-ANCA and GN.

Conclusions: Transplanted immune-competent stem cells from B6 WT BM or spleen prevent MPO-ANCA GN in *Rag2* KO B6 syngeneic mice. Delay in developing autoimmune defense indicates that Tx stem cells require time to proliferate and differentiate to establish autoimmune defense (G6 vs G7 & G8). This model system will be used to identify specific stem cells that are effective in suppressing autoimmunity and effective for targeted immunotherapy.

Funding: NIDDK Support

Table: All mice received anti-MPO SC on day 0. G3,6,7, and 8 also received WT SC or BM cells.

Group	B6 Strain	Sex	n	WT SC or BM Tx	D14 MPO-ANCA (OD)	P vs WT	Crescents %	P vs WT

Regulatory Function of FcγRIIB Involving the NLRP3 Inflammasome in a Mouse Model of IgA Nephropathy

Ann Chen,[1] Yu-Ling Chou,[2] Shuk-Man Ka.[2] *[1]Hualien Tzu Chi Hospital Buddhist Tzu Chi Medical Foundation, Hualien, Taiwan; [2]National Defense Medical Center, Taipei, Taiwan.*

Background: IgA nephropathy (IgAN) is the most common form of glomerulonephritis and represents a leading cause of end-stage renal disease. Ample evidence confirms the deposition of IgA and IgG and filtration of mononuclear leukocytes in IgAN patients. Previously, we established an experimental IgAN model in B cell-deficient mice, which implicated interactions between Fcγ receptors (FcγRs) in the pathogenesis of IgAN. Although it is generally accepted that FcγRIIB plays a regulatory role in humoral responses, it remains unknown whether this function and the cell type-specificity of FcγRIIB are reno-protective in IgAN.

Methods: We observed a dramatic increase in albuminuria, renal function impairment, and renal injury in FcγRIIB knockout mice with induced IgAN. Utilizing a mouse model of IgAN and three different types of FcγRIIB-deficient mice, including CEBP/α Cre (myeloid cells), CD11c Cre (dendritic cells) and CD19 Cre (B cells) in floxed FcγRIIB mice, as well as several specific cell models.

Results: We demonstrated that macrophage- and dendritic cell-specific FcγRIIB deficiency blunted the activation of the NLRP3 inflammasome and inhibited the development of IgAN. Moreover, activation of the inflammasome was induced by IgA immune complexes dependent on TLR4/MyD88 signaling, associated with crosstalk between TLR4 and Dectin-2.

Conclusions: These results suggest that activation of FcγRIIB and its downstream signaling pathways could moderate progression of IgAN involving the suppression of the NLRP3 inflammasome. A cell type-specific targeting of FcγRIIB may help the establishment of therapeutic strategy for the renal disease.

FR-PO685

Group 3 Innate Lymphoid Cells (ILC3s) Accelerate Lupus Nephritis Development by Promoting B Cell Activation in Kidney Ectopic Lymphoid Structures

Feng Li,[1,2] Yi Zhou.[1,2] *[1]The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; [2]NHC Key Laboratory of Clinical Nephrology (Sun Yat-Sen University) and Guangdong Provincial Key Laboratory of Nephrology, Guangzhou, China.*

Background: Group 3 innate lymphoid cells (ILC3s), a novel subset of immune cells with the features of both innate and adaptive immunity, have emerged as important players in autoimmune diseases. However, whether they participate in lupus nephritis (LN) remains elusive. Here, we investigated the role of ILC3s in the pathogenesis of LN.

Methods: Systemic and renal ILC3s were detected by flow cytometry or confocal microscopy in LN patients and spontaneous lupus model MRL/*lpr* mice. The distribution of ILC3s in human and murine kidneys were characterized by immunofluorescence, and the characteristics of ILC3s in different organs of MRL/*lpr* mice were revealed by transcriptome sequencing. Furthermore, ILC3s were adoptively transferred into LN mice to explore their roles in disease. *In vitro*, ILC3s were co-cultured with or without B cells to clarify their function in antibody formation.

Results: The frequencies of ILC3s in blood and kidneys of LN patients were found significantly higher than normal control, and positively associated with serum anti-dsDNA, ANA and total IgG. The elevation of ILC3s and their correlations with autoantibodies were also observed in MRL/*lpr* mice. In the kidney, ILC3s were mainly localized within perivascular ectopic lymphoid structures, showing low expression of resident and proliferative markers. Interestingly, renal ILC3s shared high transcriptomic similarity with gut-derived ILC3s, implying that the small intestine may be a potential source of renal ILC3s. After adoptive transfer of ILC3s into LN mice, both systemic autoimmune manifestations and renal damage were significantly exacerbated. Meanwhile, there were remarkable increases in the proportion of plasma cells and IgG^+ B cells in the kidney after ILC3s transfer. Mechanistically, *in vitro* studies showed that ILC3s promoted the differentiation of B cells into plasma cells and antibody formation.

Conclusions: Our results showed that ILC3s were increased in LN, and accelerated the progression of LN by promoting B cell activation in the kidney.

FR-PO686

A Kidney Organoid-Derived Hypoxic Transcriptional Signature Correlates with Tubular Injury and Disease Progression in Focal Segmental Glomerulosclerosis (FSGS)/Minimal Change Disease (MCD)

Akihiro Minakawa, Celine C. Berthier, Matthew Fischer, Jamal El Saghir, V. Vega-Warner, Rajasree Menon, John R. Hartman, Felix H. Eichinger, Jennifer A. Schaub, Matthias Kretzler, Jennifer L. Harder. *University of Michigan Division of Nephrology, Ann Arbor, MI.*

Background: Alterations in kidney tissue hypoxia are thought to contribute to kidney disease but the pathomechanism is unclear. The aim of our study was to investigate the relevance of a hypoxia molecular signature derived from a kidney organoid model to human kidney disease.

Methods: Kidney organoids (K-Orgs) were treated with 1% O_2 for 24 h, and assessed by qPCR, bulk and single cell (sc) RNA-seq, IF and ELISA. A hypoxia signature was extracted from the differentially expressed genes in hypoxic vs. control K-Orgs. This signature was evaluated in bulk RNA-seq the kidney tissue expression profiles in the molecularly characterized FSGS/MCD NEPTUNE cohort (PMID: 36442540) and accompanied with morphometric scores of tubular injuries and the 3 previously computationally derived disease subclusters (C1~C3) and Living donors (LD).

Results: In hypoxic K-Orgs, IF confirmed HIF-1α nuclear accumulation, along with GLUT1 (IF) and secreted VEGFA (ELISA), and genes related to glycolysis and lactate synthesis (qPCR). sc RNA-seq confirmed HIF-1's target gene expression in kidney cell types (e.g. podocytes), and bulk RNA-seq revealed a total of 380 genes identified a hypoxia signature in hypoxic organoids. As shown in the figure, this signature was significantly higher in C3 that was identified with the poorest outcome. Tubular injury scores also correlated with hypoxic gene signature scores.

Conclusions: A transcriptional signature of hypoxic cell stress generated from a hypoxic K-Orgs was higher in the tubulointerstitial compartment of FSGS/MCD patients with poor outcome and correlated with morphometric evidence of tubular injury. These results suggest that kidney cell hypoxia is contributing to FSGS/MCD disease activity and progression.

Mechanistic Study of Celastrol-Mediated Inhibition of Macrophage M1 Polarization in IgA Nephropathy via Downregulating ECM1

Juanyong Zhao, Ming Xia, Xunzi Tang, Xinyan Fan, Hong Liu. *Department of Nephrology, The Second Xiangya Hospital, Central South University, Hunan Key Laboratory of Kidney Disease and Blood Purification, Changsha, China.*

Background: Macrophages play a vital part in amplifying the inflammatory cascade in IgA nephropathy (IgAN), but the potential mechanism and targeted treatment strategies still need to be explored. The aim of this study is to investigate the therapeutic effect of celastrol (CLT) on IgAN, as well as the mechanism of celastrol-mediated inhibition of macrophage M1 polarization in IgA Nephropathy via down-regulating ECM1.

Methods: We established an IgAN mouse model treated with CLT and an M1 macrophage model induced by LPS in Raw 264.7 in vitro. The proteinuria, serum creatinine levels, renal lesions, and infiltration of M1 macrophages in mice were detected. The macrophage markers such as M1 (iNOS) and M2 (Arg-1) expression levels in vitro were checked, as well as expression situation of inflammatory factors such as IL-6 and TNF- α. The expression of ECM1 in renal biopsy of patients was observed and its clinical significance was analyzed. We detected the activation of the ECM1/STAT5 pathway in IgAN mice and M1 macrophage models. And we constructed stable transfected cells with ECM1 overexpression to detect the changes in macrophage M1 polarization after CLT treatment, as well as the expression of ECM1 and STAT5/p-STAT5.

Results: CLT effectively alleviated renal lesions and macrophage infiltration in IgAN mice, and improved renal function. In addition, after CLT intervention, the expression of iNOS, IL-6, TNF- α was decreased and the expression of Arg-1 was increased. ECM1 was obviously expressed in IgAN patient's renal tissue and it was negatively correlated with eGFR, while positively correlated with 24-hour proteinuria. ECM1 was also highly expressed in IgAN mice and in M1 macrophage models. In the M1 macrophage model with overexpression of ECM1, CLT inhibits macrophage M1 polarization and the production of inflammatory factors by downregulating the ECM1/STAT5 pathway.

Conclusions: CLT can effectively alleviate IgAN renal inflammatory damage, inhibit macrophage M1 polarization, and reduce the production of inflammatory factors. ECM1 was obviously expressed in IgAN renal macrophages, and the increase in ECM1 expression is related to the severity of clinical indicators in IgAN patients. The therapeutic effect of CLT on IgAN may be related to its inhibition of macrophage ECM1/STAT5 pathway.

Spatialomic Profiling of Human Kidney Tissues Stratifies Disease Pathology

Ishwarya Venkatesh, Ameera M. Shaw, Vineet Gupta, David J. Cimbaluk. *Rush University Medical Center, Chicago, IL.*

Background: To make any scientific advancements, there should be an in-depth understanding of pathophysiology of tissue microenvironment. Newer multiplex imaging-based methods are providing important insights into cytoarchitecture of tissue. We recently developed a novel tissue imaging method, termed SeqStain, that allows rapid and easy immunofluorescence based multiplexed tissue imaging and analyses. Here, we utilize this approach to understand the complex assemblage of cells and their correlations with each other in both healthy subjects and patients with various glomerular diseases.

Methods: We synthesized fluorescently-DNA-tagged antibodies for analyzing multiple kidney-specific antigens using cycles of staining and de-staining on a single tissue section. We probed different histological regions relevant to the kidney and used conventional fluorescence microscopy for imaging the tissues and HALO software for image analyses.

Results: We analyzed both paraffin-fixed and frozen tissue sections using off-the-shelf reagents and a confocal microscope. We were able to accurately image tens of antigens on single tissue specimens for healthy subjects, and from patients with lupus nephritis (LN) and diabetic nephropathy (DN). Analysis of various cellular biomarkers indicated enrichment of specific cellular clusters into distinct neighborhoods.

Conclusions: SeqStain proved to be a versatile, gentle, and easily adaptable method for multiplex imaging that can be highly effective in obtaining a spatial map of kidney. Generated spatial maps will provide important new insights about the disease pathobiology and improve future diagnostics and therapeutics for LN and DN.

FR-PO689

Lisinopril-Mediated ACE Inhibition Reduces Proteinuria and Sclerosis in the G1/G1 but not the G2/G2 APOL1 Mouse Model of FSGS

Esilida Sula Karreci, Zsuzsanna K. Zsengeller, David Friedman, Seth L. Alper, Martin Pollak. *Beth Israel Deaconess Medical Center, Boston, MA.*

Background: APOL1 gene variants G1 and G2 account for the 3 to 4-fold elevated risk of kidney disease in individuals of recent African ancestry. These variants confer protection against Trypanosomal disease, but individuals with two high-risk alleles are at higher risk of developing FSGS and renal failure. Molecular disease mechanisms remain controversial and targeted treatments for APOL1 kidney disease remain an unmet need.

Methods: Our lab has created APOL1 BAC transgenic mice that develop proteinuria and glomerulosclerosis upon injection of pCpG-free plasmid DNA encoding murine IFNg. After injection of G1/G1 and G2/G2 mouse groups with IFNg plasmid, mice were randomized on post-injection day 7 (after confirming proteinuria) to treatment with Lisinopril in the drinking water at 75 mg/L or to a no drug control group. Urinary albumin/creatinine ratio was measured biweekly. At time of sacrifice, kidney tissue was harvested, paraffin-embedded, and 4μm sections were stained with periodic acid-Schiff (PAS) stain. An FSGS score was computed from 30 glomeruli per mouse, each scored in a blind manner as normal or displaying segmental or global sclerosis.

Results: Treatment with the ACE inhibitor lisinopril reduced proteinuria by ~100-fold in APOL1 G1/G1 BAC-transgenic mice and greatly reduced severity of FSGS by histological criteria. In contrast, lisinopril treatment of G2/G2 mice produced improvement neither in proteinuria nor in the likelihood of developing severe FSGS in G2/G2 mice.

Conclusions: Lisinopril-mediated inhibition of ACE modified disease phenotype in the BAC-transgenic APOL1 G1/G1 mouse model of FSGS, but not in the G2/G2 model. These findings add to our understanding of APOL1 disease mechanisms in mouse models of FSGS and may provide insight into APOL1-associated human kidney disease. Early genotyping should in future allow trials of inhibition of the renin-angiotensin-aldosterone system starting before clinical onset of glomerular disease in patients with high-risk APOL1 alleles.

Funding: Other U.S. Government Support, Private Foundation Support

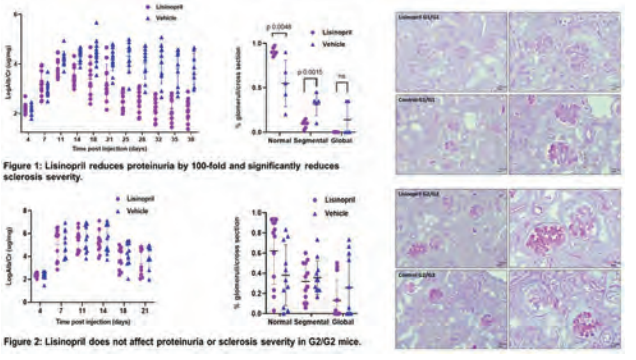

Figure 1: Lisinopril reduces proteinuria by 100-fold and significantly reduces sclerosis severity.

Figure 2: Lisinopril does not affect proteinuria or sclerosis severity in G2/G2 mice.

YBX1 Alleviated Kidney Injury as a "Reader" of m5C Methylation in Adriamycin-Induced FSGS Mice

Hua Zhou,[1] Jeffrey B. Kopp,[2] Zixuan Feng,[1] Feifei Miao,[1] Congcong Jiao,[1] Cong Ma,[1] Yonghe Zhang,[1] Junjun Luan.[1] *[1]Shengjing Hospital of China Medical University, Shenyang, China; [2]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD.*

Background: Focal segmental glomerulosclerosis (FSGS) is a common cause of adult nephrotic syndrome. Currently, effective treatments lack due to unclear understanding of its pathogenesis. Recently, Y-box binding protein 1 (YBX1) has been found as a 5 methylcytosine (m5C) 'reader' to stabilize mRNA and promote protein translation. However, the role of YBX1 in FSGS remains unknown.

Methods: FSGS was induced by adriamycin (ADR) in BALB/c mice. Adeno-associated virus 9 (AAV9) containing YBX1 was delivered to FSGS mice for overexpressing YBX1. Mice (n=24) were randomly divided into four groups: normal control (NC), ADR, ADR + AAV9-control, and ADR + AAV9-YBX1. Urine protein creatinine ratio (UPCR), serum creatinine (Scr), and blood urea nitrogen (BUN) were examined by biochemistry. Histological damages were evaluated by PAS and Masson staining and transmission electron microscopy (TEM). YBX1; podocyte biomarkers WT1, synaptopodin, and podocin; profibrotic proteins α-smooth muscle actin (α-SMA), vimentin, and fibronectin (FN) were analyzed by Western blotting and immunofluorescence (IF) staining. The *synaptopodin* and YBX1 were double stained by fluorescence in situ hybridization and IF. Finally, these proteins were stained in renal biopsies from FSGS patients and NC kidneys.

Results: In FSGS mice, UPCR, BUN, and Scr were increased; WT1, synaptopodin, podocin were decreased; α-SMA, vimentin, and FN were overproduced. Importantly, renal YBX1 was decreased. In YBX1 overexpressed FSGS mice, UPCR, Scr, and BUN levels were improved. Meanwhile, the percentage of sclerotic glomeruli was decreased on PAS and Masson. The degree of foot processes fusion was alleviated under TEM. The levels of podocytic WT1, synaptopodin, and podocin as well as profibrotic α-SMA, vimentin, and FN were reverted by delivering YBX1. The co-localization of *synaptopodin* mRNA and YBX1 protein was shown in the cytoplasm of podocytes. The same change directions of podocytotic and profibrotic proteins were seen in renal biopsies from FSGS patients compared to NC kidneys.

Conclusions: YBX1 may play an important role in pathogenesis of FSGS by regulating synaptopodin mRNA and further alleviating glomerulosclerosis through serving as a m^5C 'reader'. YBX1 might be a novel therapeutic target for FSGS.

CD4+ T Cell Egress in Crescentic Glomerulonephritis Is Regulated by a Converse Expression of S1PR1 and CXCR6

Jonas Engeßer,[1] Hans-Joachim Paust,[1] Yu Zhao,[2] Catherine Meyer-Schwesinger,[1] Thorsten Wiech,[1] Stefan Bonn,[2] Christian F. Krebs,[1] Ulf Panzer.[1] Panzer Lab. *[1]Universitatsklinikum Hamburg-Eppendorf, Hamburg, Germany; [2]Universitatsklinikum Hamburg-Eppendorf Zentrum fur Molekulare Neurobiologie Hamburg, Hamburg, Germany.*

Background: Autoimmune diseases such as crescentic glomerulonephritis (cGN) are characterized by a dramatically increased migration of leukocytes to the inflamed tissue. Infiltration of CD4$^+$ T cells play a key role in orchestrating the immune response during inflammation. However, little is known about the function and mechanisms of T cell exit out of the kidney. The aim of this study is to characterize the CD4$^+$ T cell retention and emigration receptors and their implication on tissue injury, especially in the context of restitutio vs chronification of tissue inflammation.

Methods: Lymph vessel staining of renal biopsy cores was performed by immunohistochemistry (IHC). For leukocyte trafficking analysis cGN was induced in *Kaede*-mice, ubiquitously expressing the photoconvertible *Kaede* protein. Photoconversion of intrarenal leukocytes was performed by UV-A light (385 nm) exposure of the left kidney. Leukocytes from kidneys, blood and dLN were analyzed by scRNAseq, flow-cytometry and IHC. For analysis of the chemokine receptor *CCR7* a *CCR7*$^{-/-}$ deficient mouse model was used, for analysis of *CXCR6* a depleting antibody of its sole ligand *CXCL16* was used. *S1PR1* signaling was blocked using FTY720.

Results: In human biopsy cores an exit of CD4$^+$ T cells but not CD68$^+$ macrophages via the lymphatics could be shown. Murine analysis of emigrated CD4$^+$ T cells revealed a set of differentially expressed genes compared to resident CD4$^+$ T cells, mainly a downregulation of the chemokine receptor *CXCR6* and an upregulation of *S1PR1*. *CCR7*, although upregulated on CD4$^+$ T cells showed to be dispensable for T cell egress. Depleting *CXCL16* resulted in an increased migration of CD4$^+$ T cells to dLN, while blocking *S1PR1* signaling led to an increased retention of CD4$^+$ T cells in the kidney and a marked increase in tissue damage.

Conclusions: CD4$^+$ T cells egress via the lymphatics out of the inflamed kidney is tuned by the downregulation of *CXCR6* and upregulation of *S1PR1*. Blocking T cells egress leads to an increase in tissue damage, thus promoting the idea that T cell egress to the dLN alters organ-specific immunity.

The Serine Protease HTRA1 Mouse Model: A Gateway to Identify the Cellular Origin of New Antigens

Laith Al-Rabadi,[1] Jeff Campsen,[1] Tiffany Caza,[2] Nicole Endlich,[4] Yufeng Huang,[1] Chio Oka,[5] Hans Haecker,[1] Laurence H. Beck.[3] *[1]University of Utah Health, Salt Lake City, UT; [2]Arkana Laboratories, Little Rock, AR; [3]Boston Medical Center, Boston, MA; [4]Nipoka, Greifswald, Germany; [5]Nara Sentan Kagaku Gijutsu Daigakuin Daigaku, Ikoma, Japan.*

Background: While initial membranous nephropathy (MN) autoantigens like PLA2R were found to be transmembrane podocyte proteins, more recently identified antigens are secreted proteins or not clearly derived from podocytes. Whether immune complexes in these cases assemble *in situ* or are deposited after forming in the circulation remains unclear.

Methods: WT and HTRA1 KO mice were immunized with full-length human HTRA1. Immunofluorescence, confocal microscopy and RNAscope were used to identify the origin of autoantigen in HTRA1-associated MN.

Results: As shown in **Figure 1**, MN pathology with mouse HTRA1-mouse IgG immune complexes in a membranous loop pattern and more significant proteinuria was observed in WT, but not HTRA1 KO, mice that were previously immunized with recombinant human HTRA1, despite the presence of circulating anti-human HTRA1 in both animals. This finding suggested that mouse HTRA1 autoantibodies were formed against a shared epitope between human and mouse proteins, leading to *in situ* immune complex formation at the GBM. Furthermore, RNAscope (**Figure 2**) demonstrated podocytes to be the cellular source of HTRA1.

Conclusions: The presence of HTRA1-mIgG deposits in actively immunized WT but not KO mice, along with increased podocyte expression of HTRA1 by podocytes, argues against deposition of circulating immune complexes and instead argues for a podocyte origin of this secreted autoantigen and formation of *in situ* immune deposits. We will further confirm this hypothesis using a podocyte-specific HTRA1 KO.

The Impact of Exposure to Air Pollution on the Progression of Primary Glomerular Disease

Howard Trachtman,[1] Jonathan P. Troost,[1] Jennifer D'Souza,[1] Sara Adar,[1] Miatta Buxton,[1] Abhijit V. Kshirsagar,[2] Lawrence S. Engel,[2] Cassandra R. O'Lenick,[2] William E. Smoyer,[3] Jon B. Klein,[4] Wenjun Ju,[1] Laura H. Mariani,[1] Matthias Kretzler.[1] *[1]University of Michigan, Ann Arbor, MI; [2]University of North Carolina Research Opportunities Initiative, Chapel Hill, NC; [3]Nationwide Children's Hospital, Columbus, OH; [4]University of Louisville, Louisville, KY.*

Background: Exposure to air pollution is linked to chronic disease. Air pollution stimulates injury pathways that contribute to organ damage. However, there is limited information about its impact on the course of kidney disease or the molecular pathways involved.

Methods: Patients enrolled in the Nephrotic Syndrome Study Network (n=228) and Cure Glomerulonephropathy (n=697) studies with residential census tract data and ≥2 yr of follow-up were included. Three indices of air pollution exposure were assessed: (1) $PM_{2.5}$; (2) Black carbon; and (3) Sulfates. The primary outcome was the hazard ratio for >40% decline in eGFR or end-stage kidney disease (eGFR<15 ml/min/1.73 m^2, initiation of dialysis, or kidney transplantation). Air quality was categorized by census tract and assessed using modeled concentrations.

Results: $PM_{2.5}$, black carbon, and sulfate exposure were comparable in the two cohorts but higher in Black participants (p<0.005). Baseline eGFR was lower and proteinuria higher in those with exposure above the median for all three pollutants. Among patients with disease duration ≥1 year, in an adjusted analysis, $PM_{2.5}$, HR 1.23 [95% CI:1.02, 1.49], p=0.029, and black carbon, HR 1.42 [95% CI:1.18, 1.71], p=0.0002, were associated with increased likelihood of worsening kidney disease. Sulfate exposure was associated with increased urinary MCP-1 excretion (p=0.018) and increased serum TNF levels (p=0.003), while $PM_{2.5}$ exposure was associated with increased serum IL-1β levels (p=0.025) (Figure 1).

Conclusions: In patients with primary glomerulopathies, exposure to air pollution is associated with an elevated risk for disease progression and increases in systemic biomarkers of inflammation.

Determining Individual Glomerular Proteinuria and Periglomerular Infiltration in a Cleared Murine Kidney by 3D Fast-Marching Algorithm

Christian Kurts,[1] Alexander M. Böhner,[1] Karin A. Böhner,[1] Sebastian Braehler,[2] Ulrike Attenberger,[1] Martin Rumpf,[3] Alexander Effland.[3] *[1]University Clinic of Bonn, Bon, Germany; [2]Universitat zu Koln, Koln, Germany; [3]Rheinische Friedrich-Wilhelms-Universitat Mathematisch-Naturwissenschaftliche Fakultat, Bonn, Germany.*

Background: Research in organs with a complex architecture like the kidney benefits from 3D image analysis. However, limited resolution and imperfections of real-world 3D image material often preclude algorithmic image analysis. We here present a methodical framework to overcome these obstacles.

Methods: We optimized our optical tissue clearing protocol to preserve fluorescence signals for light-sheet-fluorescence-microscopy and compensated attenuation effects using adjustable 3D correction fields. Next, we adapted the Fast-Marching algorithm (FMA) to conduct backtracking in 3D environments. Furthermore, we designed a local concentration measure termed Volumetric impact factor (VIF) to quantify extractable objects in 3D microenvironments.

Results: We applied this framework to cleared kidneys of mice with nephrotoxic nephritis, a model for human crescentic glomerulonephritis. Our framework generated a list of anatomical and functional parameters of each individual glomerulus of a murine kidney. Using FMA, we determined and visualized the individual proteinuria (Figure 1). Using VIF, we quantified the individual periglomerular dendritic cell infiltration in nephritic kidneys. By correlating these parameters, we disprove the intuitional assumption that the most infiltrated glomeruli are the most proteinuric. Instead, the glomerular density predicted proteinuria.

Conclusions: Our framework allows multiparameter image analysis and advanced 3D analysis of all nephrons of a murine kidney and facilitates understanding of renal immunopathology.

Funding: Government Support - Non-U.S.

Dense Deposit Disease: What Makes the Deposits Dense

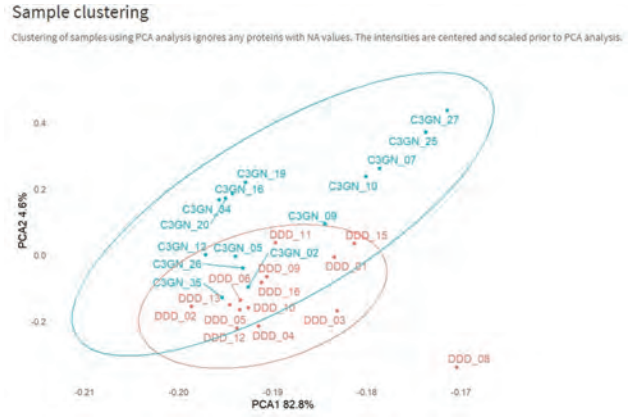
Lilian M. Palma,[1] Benjamin J. Madden,[2] Sanjeev Sethi.[2] *[1]Universidade Estadual de Campinas, Campinas, Brazil; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: C3 glomerulopathy (C3G) is a disease resulting from dysregulation of the alternative pathway (AP) of complement. C3G includes C3GN and DDD; both are characterized by bright glomerular C3 staining. However, on EM, DDD is characterized by dense osmiophilic mesangial and intramembranous deposits, while the deposits of C3GN are not dense.

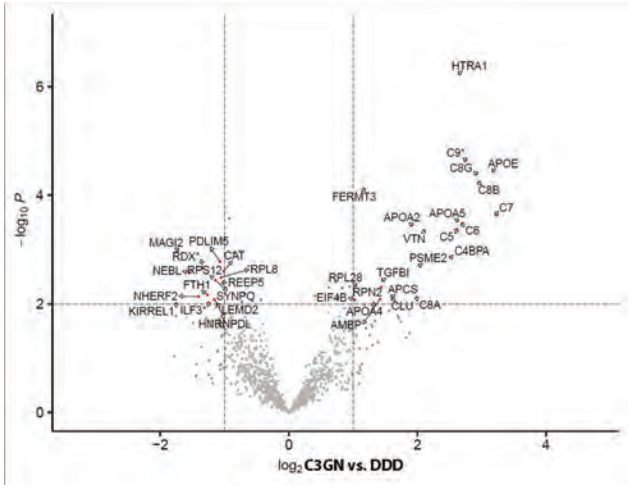
Methods: We performed laser microdissection of glomeruli followed by mass spectrometry in 15 cases of DDD and 29 cases of C3GN to determine the proteomic profile and differences between C3GN and DDD.

Results: As expected, there was overlap in the proteomic profile of C3GN and DDD (figure 1). Both diseases showed high total spectral counts (TSC) of C3, CFHR5, CFHR1, CFHR2 and CFH. Although high TSC of terminal complement proteins (C5-C9) were present in C3GN and DDD, there was a 6-9-fold increase of C5-9 in DDD compared to C3GN. An unexpected finding was the 7-9-fold increase of apoliproteins (APO): APOE, APOA5, APOA2 and APOA4, in DDD compared to C3GN (figure 2). Controls cases showed no accumulation of APO. We also detected increased accumulation of HTRA1, C4b binding protein and SAP proteins in DDD. Immunohistochemistry is being performed to confirm and localize APO in the dense deposits of DDD and compare them with deposits in C3GN.

Conclusions: There is a higher burden of terminal complement pathway proteins in DDD compared to C3GN. In addition, extensive deposition of APOE and APOA5 likely cause the deposits to appear dense in DDD.



Overlap in the proteomic profile of C3GN and DDD.



Differences in protein expresion in DDD compared to C3GN.

Glomerular Spatial Transcriptomics and Integrated Gut Microbiome Analysis Reveals Pathogenetic Importance of Short-Chain Fatty Acid in IgA Nephropathy

Sehoon Park, Jeongmin Cho, Jung Hun Koh, Dong Ki Kim, Hajeong Lee. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis, and the pathogenesis has been reported to be related to the gut microbiome. Additional studies focusing on the linkage between intra-glomerular transcriptomic alterations and associated microbial signals are warranted.

Methods: We performed glomerular spatial transcriptomic profiling of various glomerulopathies without a profound eGFR decrease and healthy controls using the GeoMx Digital Spatial Profiler. This included 8 IgAN, 10 donor kidney biopsy, 6 diabetic nephropathy, 7 focal segmental glomerulosclerosis, 13 minimal change disease, and 16 membranous nephropathy cases. The glomerular transcriptome was compared between the IgAN and each control group using the DeSeq2 method, and gene ontology annotation was performed. For microbial profiling, fecal samples were collected from 247 IgAN, 52 diabetic nephropathy, 27 lupus nephritis, 42 minimal change disease, 72 membranous nephropathy, and 51 healthy control cases and underwent 16S-sequencing. PICRUSt2 analysis was used to predict metagenome functions, which were compared by ALDEx2 between the groups.

Results: We identified 1209 consistently highly expressed genes in the IgAN glomerulus, mainly annotated in major histocompatibility protein binding, immune cell adhesion, and extracellular matrix formation gene ontologies. On the other hand, 1050 genes were consistently lowly expressed in the IgAN glomerulus. Notably, the annotated gene ontologies included beta 1, 3 galactosyltransferase and short-chain fatty acid transporters or G protein-coupled receptor signaling pathways. Although there was an absence of a single taxa consistently showing a significant difference in the IgAN microbial community, the pathway analysis indicated that the methanogenesis from acetate pathway was significantly abundant in the IgAN gut microbiome.

Conclusions: We identified that short-chain fatty acid and related signal receptors, G-protein-coupled receptors, were significantly lowly expressed in the IgAN glom, linked to the alteration of acetate, a representative short-chain fatty acid, metabolism pathway in the IgAN microbiome. Further experimental validation studies are ongoing to investigate the pathogenetic significance of the current findings.

FR-PO697

Development and Application of Multiplexed Proteomics to Investigate Protein Complexes in Kidney Aging and Disease

Thao Nguyen,[1] Phillip Seitzer,[1] Daigoro Hirohama,[2] Niclas Olsson,[1] Leanne Chan,[1] Amin Abedini,[2] Katalin Susztak,[2] Fiona E. Mcallister.[1] *[1]Calico Life Sciences LLC, South San Francisco, CA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Kidney aging is a complex process associated with a decline in renal function. This decline is due to several factors, including changes in cellular states driven by protein expression and their composition in complexes. Proteins rarely function alone, and their activity is often determined by their interactions with others. However, owing to the technical challenges, no attempt has been made to profile the global changes in protein complexes composition and abundance in the kidney as a function of age or disease.

Methods: Co-fractionation mass spectrometry (CF-MS) is an emerging unbiased method that identifies protein complexes in cell or tissue lysate. CF-MS first separates the proteins in a sample by chemical properties such as size and charge using native chromatography, and thereby proteins from the same complexes will co-elute into the same fractions. All the proteins in each fraction are then identified and quantified by MS and the complexes can be inferred using downstream bioinformatics analysis. In a classical CF-MS set-up, one fraction per sample is processed and analyzed by the MS at a time. As samples are fractionated into tens or hundreds of fractions, with each fraction requiring analysis, the large number of samples results in a highly time-consuming process both in sample preparation as well as data acquisition time. To address this bottleneck, we have explored using a multiplexed isobaric labeling strategy (Tandem Mass Tags, TMT) that can significantly reduce the acquisition time. We have applied this approach to analyze young and old human kidneys as well as kidneys from chronic kidney disease patients.

Results: We present the first comparison of profiling global changes in protein complexes in young vs old vs CKD human kidneys. We validate our novel TMT proteomics approach using known complexes before applying the technique to profile complexes in precious human kidneys. Our preliminary results suggest that the method is a promising high throughput tool for comprehensively studying protein complexes in kidney aging and disease.

Conclusions: Our approach of using CF-MS combined with TMT-MS offers a novel direction to explore changes in protein complexes with a great potential to identify new drug targets and therapies for kidney aging and diseases.

FR-PO698

Involvement of Kynurenine Metabolizing Enzymes and Its Metabolites in Antibody-Mediated Glomerulonephritis

Ryosuke Umeda, Midori Hasegawa, Naotake Tsuboi. *Fujita Ika Daigaku, Toyoake, Japan.*

Background: Tryptophan (TRP) is eventually metabolized to NAD in kynurenine pathway (KP), and its metabolites (Figure) potentially exert many biological activities in immune system. The objective of the current study is to elucidate the role of TRP metabolism in the progression of glomerulonephritis.

Methods: We introduced antibody mediated glomerulonephritis by administration of rabbit anti-mouse nephrotoxic serum (NTS-GN) in mouse strains deficient in KP-related enzymes including indoleamine 2,3-dioxygenase 1, 2 (IDO1$^{-/-}$, IDO2$^{-/-}$), and kynurenine 3-monooxygenase (KMO$^{-/-}$) and performed functional and histological analyses in diseased kidneys. For the therapeutic intervention, we administrated kynurenic acid (KYNA) into IDO1$^{-/-}$ with NTS-GN. In vitro, we analyzed morphology of bone marrow derived neutrophils on immune complexes (ICs).

Results: IDO1$^{-/-}$ demonstrated severe renal dysfunction and histological glomerular damage than WT, while those in IDO2$^{-/-}$ were comparable with WT. Conversely, crescent formation was significantly less in KMO$^{-/-}$ mice. Glomerular accumulation of neutrophils was significantly more in IDO1$^{-/-}$ mice, but less in KMO$^{-/-}$ mice. Neutrophils presenting "spread" morphology among attaching cells on ICs was significantly increased in IDO1$^{-/-}$, whereas it was reduced in KMO$^{-/-}$. Administration of KYNA into the diseased IDO1$^{-/-}$ significantly diminished glomerular crescent formation, which associated with the amelioration of renal dysfunction. Moreover, KYNA treated IDO1$^{-/-}$ neutrophils demonstrated less percentage of "spread" cells on IC-coated dishes than non-treated cells.

Conclusions: IDO1/KMO-mediated alterations of TRP metabolism involve in the disease activity of NTS-GN. Of note, KYNA negatively regulates to the disease pathogenesis by the alteration of IC-mediated neutrophil activity.

Quantitative Ultrasound for Glomerulosclerosis in Ex Vivo Murine Kidneys

Rohit Singla, Yasmine Y. Lau, Michael R. Hughes, Ricky Hu, Yicong Li, Maziar Riazy, Mei Lin Bissonnette, Kelly M. Mcnagny, Robert N. Rohling, Christopher Nguan. *The University of British Columbia, Vancouver, BC, Canada*.

Background: Focal segmental glomerulosclerosis (FSGS) is a condition that can lead to kidney function loss over time, making early detection and diagnosis essential for effective treatment and management. The glomeruli are the main source of ultrasound scattering in the kidney. This study proposes a novel approach to detecting FSGS using a multi-parametric quantitative ultrasound (QUS) approach in ex-vivo murine kidney models. QUS analyzes the spectral content of radiofrequency data in ultrasound to provide user- and system-independent quantifiable measurements, such as backscatter. We hypothesize that as FSGS progresses, there is a measurable increase in backscatter.

Methods: Five mice were recruited to each cohort of a podocalyxin knockout (PKO) model, a puromycin aminonucleoside (PAN) model and healthy controls. QUS was performed using a 128-element linear transducer at 15.625 MHz. From radiofrequency data, we extracted 16 parameters. To avoid overfitting, principal component analysis was used to create a reduced set of three parameters. These were inputs to a support vector machine for multi-class classification using a 5-fold cross validation scheme. Histopathologic analysis, performed by two expert pathologists, was used to determine the burden of FSGS as the ground truth.

Results: The average PKO case had 7% global segmental glomerulosclerosis and 19% FSGS, while the average PAN case had 20% global segmental glomerulosclerosis, 17% FSGS, and 7% total inflammation. Across all spatial locations or views, no significant differences in QUS parameters were found within a cohort. The mean classification accuracy was 80% across the three groups, with the mean precision, recall, and F1 scores being 0.86, 0.80, and 0.78, respectively. Misclassification only occurred in three PKO cases that were considered normal by the algorithm. The Nakagami scale parameter showed significant differences between the PAN model and the others, while the shape parameter showed significant differences between the PKO model and the others.

Conclusions: This study demonstrates that ultrasound measurements alone can effectively discriminate between healthy and diseased models of FSGS in mice. The results provide a foundation for further research into the quantification of kidney disease burden and its eventual use in humans.

Analysis of CD169 (Sialoadhesin)-Positive Activated Macrophages in Kidney Damage in Lupus Nephritis

Yohei Ikezumi,[1] Tomomi Kondo,[1] Yuji Matsumoto,[1] Naonori Kumagai,[1] David J. Nikolic-Paterson.[2] [1]*Department of Pediatrics, Fujita Health University School of Medicine, Toyoake, Japan;* [2]*Monash University Department of Medicine, Clayton, VIC, Australia*.

Background: CD169 (sialoadhesin; Sn)$^+$ activated macrophages (MQ) are associated with renal lesions in lupus nephritis (LN). However, the function of Sn$^+$ MQ is unclear as Sn does not fit into the M1/M2 paradigm of MQ activation, and little is known of how steroid therapy affects Sn expression. This study examined the activation status of Sn$^+$ MQ in biopsies of LN and in cultured MQ.

Methods: Biopsies from 32 patients diagnosed as LN with ISN/RPS classification III or IV were examined for accumulation of Sn$^+$ MQ by immunofluorescence staining, and correlated with clinico-pathological findings. For in vitro studies, normal human monocyte-derived MQs were incubated with IFNγ+LPS, with or without dexamethasone (DEX), and transcriptomic changes analysed by DNA microarray.

Results: In vitro, IFNγ+LPS induced an M1 pro-inflammatory MQ response with significant up-regulation of Sn mRNA levels. Dex suppressed the IFNγ+LPS induced M1-type response, but did not affect the increased Sn expression. In addition, Dex drove an M2-type response with up-regulation of the M2 marker CD163. Biopsies showed marked glomerular and interstitial infiltration of Sn$^+$ MQ in all cases, which correlated with glomerular active lesions such as endocapillary proliferation and cellular or fibro-cellular crescents ($p<0.0001$) or interstitial fibrosis ($p<0.05$), respectively. Separating patients into those who did (n=15), or did not (n=17) have steroid therapy before biopsy; there was no difference in the number of glomerular or interstitial Sn$^+$ MQ. However, the number of glomerular (but not interstitial) CD163$^+$ M2-type activated MQ was significantly higher in steroid treated patients ($p<0.0001$). Furthermore, Sn$^+$ MQ co-localized with T lymphocytes in glomerular, periglomerular and interstitial areas.

Conclusions: Sn may be a common activation marker for both M1 and M2 MQ in LN. Sn$^+$ MQ infiltration correlates with disease activity and may play a role in regulating T lymphocytes in LN. The lack of impact of steroids on the Sn$^+$ MQ subset indicates that alternative strategies are needed to target this mechanism of kidney injury.

FR-PO701

Cytokine Profiling in ANCA-Associated Vasculitis

Salem Almaani,[1] Huijuan Song,[1] Stacy Ardoin,[2] Lynn A. Fussner,[1] Brad H. Rovin.[1] [1]*The Ohio State University Wexner Medical Center, Columbus, OH;* [2]*Nationwide Children's Hospital, Columbus, OH*.

Background: ANCA-associated vasculitis (AAV) is a multisystem autoimmune disease that often affects the kidneys. It is unclear why some patients with AAV have kidney involvement while others do not. To investigate the mechanisms underlying these phenotypes, this study examined plasma and urine cytokine profiles in patients with active renal and non-renal AAV (AAGN and NR-AAV, respectively), and healthy controls (HC).

Methods: Levels of 200 cytokines were measured in the plasma and urine of 6 patients with active AAGN, 9 patients with NR-AAV, and 3 HC using a human cytokine array. Urine cytokine levels were corrected to urine creatinine and an analyte-to-creatinine ratio was utilized for analysis. Levels in the three groups were compared using ANOVA. Analytes with false discovery rate (FDR)-corrected p-values <0.05 were further compared using Tukey HSD post-hoc test.

Results: Patient Characteristics are depicted in Table 1. Most cytokines measured were similar between HC and NR-AAV patients. Compared to patients with NR-AAV, patients with AAGN had higher levels of plasma and urine cytokines that are involved in involved in Th17 signaling (IL-17A, IL-17F, IL-17R, IL-23, IL-6), Th1 response (IL-12, GM-CSF, IFNg, TNFa), chemotaxis (especially for T-cells, monocytes, and dendritic cells - eotaxin-2, I-TAC, Lymphotactin, MCP-3, MIP-3a, CCL23), B and T-cell crosstalk (B7-1, CD40, CD40L), and angiogenesis (VEGFR1, FLT4, VEGF-C, VEGF-D, SDF1a) (Figure 1).

Conclusions: Compared to NR-AAV, AAGN is associated with an increase in plasma and urine levels of many pro-inflammatory cytokines. T-cell differentiation, signaling, and crosstalk seem to be the most prominent molecular processes that are active in patients with AAGN. These data suggest a prominent role of T-cells in AAGN which have the potential of being leveraged therapeutically.

Proteinuria Induces Tubular Cell Proliferation in Nephrotic Syndrome Model Mice Without Causing Tubular Injury

Yuya Suzuki, Ryohei Kaseda, Yusuke Nakagawa, Ichiei Narita. *Niigata Daigaku, Niigata, Japan.*

Background: Proteinuria exhibits a robust association with the progression of kidney diseases and causes pathological effects on tubular cells. Nevertheless, the precise molecular mechanisms underlying tubular injury induced by proteinuria remain largely unknown. To elucidate the transcriptome alterations in the kidney resulting from proteinuria, we conducted an RNA sequencing (RNA-seq) analysis on a mouse model of nephrotic syndrome.

Methods: We used NEP25 mice, which express the human CD25 receptor on podocytes. Proteinuria was induced in these mice through the administration of an immunotoxin targeting the human CD25 receptor, LMB2 (0.625 ng/g body weight). After a period of seven days following LMB2 injection, the mice were euthanized, and RNA was extracted from the whole kidney. RNA-seq was performed using Illumina NovaSeq, and differential expression genes (DEGs) were identified using the DESeq2 package in R. Subsequently, we conducted multiple immunostaining and in situ hybridization (ISH) of the DEGs to determine their cellular localization and specific cell types.

Results: Following the administration of LMB2, Nep25 mice exhibited significant proteinuria without exhibiting kidney disfunction or histological damage. Through our kidney RNA-seq analysis of Nep25 mice, we identified 562 up-regulated and 430 down-regulated genes. Enrichment analysis revealed a notable up-regulation of genes associated with cell proliferation, such as Mki67. Notably, we observed a significant up-regulation of the transcription factor Foxm1, known to be involved in cell proliferation. Immunostaining and ISH confirmed the co-expression of Ki67 and Foxm1 in various tubular cells, including the proximal tubule, loop of Henle, distal tubule, and collecting duct.

Conclusions: The RNA-seq analysis of nephrotic syndrome model mice revealed that tubular cell proliferation was triggered by extensive proteinuria without causing kidney dysfunction or histological damage. The up-regulated genes, including Foxm1, have been previously associated not only with cell proliferation but also with tissue fibrosis. Consequently, the modulation of these gene functions is possible to serve as novel targets for chronic kidney disease treatment.

FR-PO703

Gnaq Deficiency Enhances Ifi202b/IFI16 and NF-kappaB Pathway in Kidney Endothelial Cell and Lupus Nephritis Pathology

Lu Zhang,[1] Jianxing Shen,[1] Xing Chen,[1] Guixiu Shi.[2] *[1]Department of Nephrology (Fujian Provincial Clinical Research Center for Glomerular Nephritis), The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, China; [2]Department of Rheumatology and Clinical Immunology, The First Affiliated Hospital of Xiamen University, School of Medicine, Xiamen University, Xiamen, China.*

Background: Lupus nephritis (LN) is a serious complication of systemic lupus erythematosus (SLE), the heterogeneity is still a great major challenge to study. Our previous study revealed a negative correlation between Gnaq (G protein subunit alpha q) and autoimmune diseases. As Gnaq was also relatively enriched in the kidney glomerular endothelium, in addition, Gnaq heterozygous knockout mice exhibited an aberrant glomerular endothelial phenotype. Hereon we found the role of GNAQ in LN remains unclear.

Methods: LN was induced by pristane administration in female appropriate age C57BL/6 *Gnaq*$^{+/-}$ and littermate *Gnaq*$^{+/+}$ mice. Renal disease was assessed by the quantification of proteinuria and histologic analyses. Transcriptomic analysis was conducted on leukocytes and glomeruli obtained from *Gnaq*$^{+/+}$ and *Gnaq*$^{+/-}$ mice for differentially expressed genes.

Results: Treatment with pristane induced diffuse proliferative LN characterized by kidney morphology and persistent albuminuria at 16 weeks follow-up in *Gnaq*$^{+/-}$ mice. Mechanistically, levels of the Interferon activation protein 202b (Ifi202b) were significantly elevated in the glomeruli when Gnaq was deficient and followed lupus. Moreover, GNAQ knockdown endothelial cell increased the expression of IFI16 (Ifi202b human ortholog) and activation of the NF-kappaB pathway, which was associated with enhanced endothelial cell adhesion. Furthermore, by transferring bone marrow from WT-Gnaq$^{+/-}$, mice (WT-Gnaq$^{+/-}$) developed macroproteinuria and diffuse proliferative nephritis induced by pristane when compared with other groups. Last but not the least, increased expression of IFI16 was shown to be associated with proliferative LN on human biopsy among CKDs.

Conclusions: The findings of this study reveal that Gnaq heterozygous loss mice were prone to develop proliferative nephritis by pristane induction. GNAQ acts as an inflammatory regulator in kidney endothelial cells through IFI16-NF-kappaB. The endothelial IFI16 expression level is correlated with human LN among CKDs. These findings offer valuable insights for diagnosing against LN and potential mechanisms behind GNAQ and autoimmune diseases.

The Correlation Between Urinary microRNA-5195 and Renal Parameters in Patients with IgA Nephropathy

Keita Kamei, Natsuko Suzuki, Kazunobu Ichikawa, Masafumi Watanabe, Tsuneo Konta. *Yamagata Daigaku, Yamagata, Japan.*

Background: The microRNA-5195 (miR-5195) modulates cell proliferation by targeting *the Cyclin L1* gene that regulates the cell cycle. In this study, we examined whether the urinary concentration of miR-5195 is related to clinicopathological parameters and short-term changes in renal function in patients with IgA nephropathy.

Methods: We extracted and quantified microRNAs in morning spot urine in 80 patients with IgA nephropathy at biopsy and four control subjects. Then we examined the relationship between clinical and histological parameters, one-year changes in eGFR, and urinary miR-5195. The concentrations of microRNAs and proteins were corrected to the concentration of urinary creatinine and were log-transformed for simple correlation analysis.

Results: The urinary excretion of miR-5195 was detected in all subjects, and the urinary concentration of miR-5195 in patients with IgA nephropathy was significantly higher than in controls. Among 80 patients with IgA nephropathy, urinary miR-5195 levels showed a significantly positive correlation with the urinary concentration of total microRNA (r=0.57), total protein (r=0.46), beta2-microglobulin (r=0.46), and N-*acetyl*-beta-D-glucosaminidase (NAG) (r=0.39), but not with baseline GFR, and urinary red blood cells. Concerning the histological parameters, the urinary miR-5195 levels showed a significant positive correlation with glomerular proliferation (r=0.24) but not with glomerular sclerosis and tubulointerstitial fibrosis. The one-year changes in eGFR after biopsy showed a significant inverse correlation with the urinary concentration of miR-5195 (r= -0.39) and total protein (r=-0.37) but not total microRNA, beta2-microglobulin, and NAG. The correlation between urinary miR-5195 and one-year eGFR change was stronger in the subjects without steroid treatment (r=0.47) than those with steroid treatment (r=0.38).

Conclusions: In this study, the urinary excretion of miR-5195 was correlated with clinical and histological parameters and one-year changes in renal function in patients with IgA nephropathy, suggesting that urinary miR-5195 might be a useful biomarker of IgA nephropathy.

Unprecedented Rise in ANCA Vasculitis: Unveiling Patterns, Phenotypes, and Etiological Factors

Grace Lavery,[1] Lauren Floyd,[1] Joshua Storrar,[2] Ajay P. Dhaygude.[1]
[1]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [2]Northern Care Alliance NHS Foundation Trust, Salford, United Kingdom.

Background: There has been a perceived increase in the incidence of patients presenting with ANCA associated vasculitis (AAV). We aim to quantify the extent of this increase and identify trends and associations.

Methods: The incidence of newly diagnosed AAV was observed from two renal centres in the North West of England from 1st January to 30th April 2023. Retrospective data collection included demographics, serology, AAV phenotype and COVID-19 vaccination status. This data was compared to previous annual incidence rates of AAV diagnosis.

Results: A total of 25 new AAV patients were diagnosed across the two centres. The mean age was 56 and there was a slight male predominance (Fig. 1). Nineteen new cases from centre one suggests a greater than four-fold increase in the incidence of AAV, as compared to data averages from the same centre for the previous decade (Fig. 2). 62.5% of centre one patients had received ≥2 viral vector vaccines for COVID-19, whereas 83.3% of the centre two cohort received mRNA vaccines.

Conclusions: Our data shows a significant increase in AAV this year at one centre. More diagnoses were of the MPA phenotype, contradicting previous studies suggesting a higher prevalence of GPA in northern Europe. Possible explanations for the increase include autoimmune responses triggered by viral illnesses and COVID-19 vaccinations. Although not statistically significant, our data suggests a link between viral vector vaccines for COVID-19 and increased AAV incidence. Environmental factors such as air pollution have also been associated with higher autoimmune risk. The rising incidence necessitates further research into the cause and raises questions about service provision, health promotion and management.

	Total *(n=25)*	Centre 1 *(n=19)*	Centre 2 *(n=6)*
Mean age, years *(IQR)*	58 (42-76)	59 (43-76)	56 (32-72)

Further Insights into Iptacopan Mode of Action in IgA Nephropathy Through Protein Profiling

Andrea Grioni,[1] Mykola Lysetskiy,[2] Anna Kostikova,[1] Anastasiia Zub,[3] Oksana V. Ikkert,[3] Oleksandr I. Karmash,[3] Yaryna Shalai,[1] Anna S. Schubart Wellensiek,[1] Claire L. Harris,[1] Matthias Meier,[1] Marie-Anne Valentin,[1] Dmitrij Kollins.[1] *[1]Novartis Institutes for BioMedical Research Basel, Basel, Switzerland; [2]Novartis Institutes for BioMedical Research Inc, Cambridge, MA; [3]L'vivs'kij nacional'nij universitet imeni Ivana Franka, L'viv, Ukraine.*

Background: IgA nephropathy (IgAN) can lead to progressive loss of kidney function, with ~30% of patients with proteinuria 1-2 g/day progressing to kidney failure within 10 years. Iptacopan is a proximal complement inhibitor that specifically binds factor B and inhibits the alternative complement pathway (AP). In a Phase 2 study (NCT03373461), iptacopan treatment led to a dose-dependent reduction in proteinuria and inhibition of the AP in patients with IgAN (1, 2).

Methods: SomaScan, a large proteomics platform, and statistical analysis were used to examine iptacopan's impact on plasma proteins. Statistical threshold for biomarker definition was set to adjusted p-value < 0.05 and absolute log Fold Change > 0.1.

Results: Iptacopan resulted in a significant modulation of 81 distinct plasma proteins in IgAN patients after 90-days treatment, persisting at the 180-day timepoint. Except for four, proteins were downregulated. Approximately two-thirds of the proteins are likely originated from the kidney (Fig.1), amongst which 4 proteins were reported to have increased expression in kidney from IgAN patients (BCL2L1, HES1, LTbR, C8). These proteins are thought to be released by cellular mechanisms like necrosis, apoptotic vesicles, proteolysis, and cell activation (Fig.1). From scientific literature, the findings are implicating changes in key biological pathways like inflammation, hypercellularity, fibrosis and atrophy. This underscores the potential of iptacopan to modulate protein expression across these pivotal biological processes in the context of IgAN patients.

Conclusions: This data suggests that iptacopan may contribute to reduction of renal inflammation, hypercellularity, fibrosis and atrophy in patients with IgAN. The relevance of these encouraging early findings will necessitate confirmation in a larger data set and at tissue level.

Anti-Glomerular Basement Membrane (GBM) Serum Effects on Kidney Function and Glomerulosclerosis in Mice

Alex Frias Hernandez,[1] Thomas Secher,[2,1] Adam B. Marstrand-Jørgensen,[1] Frederikke E. Sembach,[1] Maria K. Ougaard,[1] Henrik H. Hansen,[1] Michael Christensen.[1] *[1]Gubra, Horsholm, Denmark; [2]Novo Nordisk A/S, Bagsvaerd, Denmark.*

Background: Antibody-induced glomerulonephritis (GN) is a condition characterized by caused by an inappropriate autoimmune response to renal antigens, such as the glomerular basement membrane (GBM), leading to progressive glomerulosclerosis and rapidly declining renal dysfunction for which there exist only few treatment options. Understanding the underlying mechanisms of GN is crucial for developing effective therapeutic strategies. In this study, we aimed to investigate the induction of antibody-induced GN by anti-GBM serum on kidney biomarkers, histology and transcriptome signatures.

Methods: Male C57BL/6J mice (n=15) were randomized into three groups (n=5 per group) and received either vehicle injection, 100, or 200 µl of anti-GBM serum. We measured urine albumin-to-creatinine ratio (ACR) as an indicator of renal function. Renal endpoints included urine albumin-to-creatinine ratio (ACR), AI-assisted glomerulosclerosis scoring, histomorphometric analysis of fibrosis (Col3a1), and RNA sequencing (RNA-seq) analysis.

Results: Compared to vehicle controls, both doses of anti-GBM serum significantly increased urine ACR, indicating renal dysfunction and glomerular injury. AI-assisted based histopathological scoring confirmed significant glomerulosclerosis in anti-GBM serum-treated groups. Additionally, IHC image analysis indicated renal fibrotic injury. Correspondingly, RNA-seq analysis revealed upregulated gene expression programs signifying renal extracellular matrix remodelling (e.g., *Col1a1, Col3a1, Col4a1)* inflammation (e.g., *CD68, Ccl2, Il1b).*

Conclusions: Anti-GBM serum induces fast onset of renal dysfunction, glomerulosclerosis, and fibrosis in the mouse model of antibody-induced GN. The antibody-induced GN model in mice is highly applicable for probing test compounds with potential nephroprotective effects autoimmune GN.

FR-PO708

Successful Use of Intravenous Immunoglobulin (IVIG) in Severe Life-Threatening Hypoalbuminemia in a Young African American (AA) Male with FSGS

Basant Hamed,[1,2] Sandeep R. Sasidharan,[1] Moro O. Salifu,[1] Oluwatoyin F. Bamgbola,[1] Anil K. Mongia.[1] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]SUNY Downstate Health Sciences University, Brooklyn, NY.*

Introduction: Nephrotic syndrome (NS) relapses are common and are mostly managed by intensified doses of steroids with or without IV albumin infusion. In some instances, the relapses may be steroid resistant thereby warranting alternative immunosuppressive modalities. IVIG therapy has shown beneficial effects in patients with certain forms of glomerulonephritis but has been rarely used in steroid resistant NS patients. We hereby report an AA male adolescent with long standing FSGS who presented with NS relapses that are characterized by unusual severe life-threatening hypotensive crisis that was successfully treated with IVIG therapy.

Case Description: A 21-year-old AA male with known history of infrequent relapses of steroid resistant NS since the age of 3 yrs. At the age 18 years, he started having frequent relapses (9 events per year) and a repeat renal biopsy showed FSGS with 40% tubular atrophy and scarring. Relapses were characterized by precipitous events of heavy proteinuria (10-20 gm/day), severe hypoalbuminemia (< 1 gm /dL), and a peripheral circulatory failure. The latter was complicated by cerebral hypoperfusion with a syncope and atrial fibrillation. He was not responsive to Mycophenolate Mofetil and Rituximab. There was an interval event of COVID-19 infection that warranted monoclonal antibody. Patient was reluctant to undergo a proposed medical and surgical nephrectomy. Given a concurrent severe hypoalbuminemia and hypogammaglobinemia, an empirical treatment with a sequential IVIG was commenced. Consequently, frequency and severity of relapses had reduced for the past 10 months with no subsequent ICU admissions. His serum creatinine has always been normal (0.4-0.7 mg/dl). Genetic studies showed heterozygous APOL1 haplotypes of G1 and G2 variants.

Discussion: We present a rare case of life-threatening episodes of severe NS relapses in a patient with FSGS and G1/G2 APOL1 gene mutation who had a superimposed COVID-19 infection that responded to serial doses of IVIG therapy. We believe the beneficial effect of IVIG might be related to an increase in intravascular oncotic pressure and immunologic effects. IVIG therapy may be considered in patients with staroid resistant NS that failed to respond to conventional immunosuppressive modalities.

FR-PO709

Membranoproliferative Glomerulonephritis Associated with Coeliac Disease and Autoimmune Thyroiditis

Ashveer Randhay, Shu Yin Sit, Mei Y. Tan, Hari Dukka. *University Hospitals of Derby and Burton NHS Foundation Trust, Derby, United Kingdom.*

Introduction: Membranoproliferative glomerulonephritis (MPGN) is a pattern of glomerular injury which can be related to immune complex deposition from infections, paraproteinemia and autoimmune diseases. Rarely, there has been associations between MPGN and coeliac disease and MPGN and autoimmune thyroiditis described in literature.

We present a case of a patient who had all three diagnoses and treated with a Sodium/glucose cotransporter-2 inhibitor (SGLT2i).

Case Description: A 21 year old female presented with four month history of leg oedema, and subsequently confirmed nephrotic syndrome. She had recent diagnosis of hypothyroidism and coeliac disease prior to this presentation, and was established on gluten free diet and levothyroxine. At presentation, urine protein creatine ratio was 403.4mg/mmol with serum albumin of 2.9 g/dL. Complements C3 and C4 were normal, with no detected paraprotein and negative immunology (ANA, cryoglobulins, ANCA) and virology screen. Thyroglobulin and TSH receptor antibody levels were raised. Percutaneous kidney biopsy was performed which showed immune complex glomerulonephritis with MPGN pattern. She was commenced on maximally tolerated Angiotensin-converting enzyme inhibitor (ACEi) and SGLT2i. After 8 months, there was resolution of oedema, and marked improvement of proteinuria (123.5 mg/mmol) without need for immunosuppressive therapy.

Discussion: There have been five case reports of MPGN with nephrotic syndrome, associated with autoimmune thyroiditis. There have been biopsy studies showing thyroid antibody deposition in glomeruli, supporting this association. There have been four case reports of MPGN associated with coeliac disease. In these cases, a mix of pediatric and adult patients, hypocomplementemia was observed. In all the cases, gluten-free diet was sufficient to improve gastrointestinal symptoms, resolution of oedema and reduction in proteinuria. As we did in this case, we believe supportive therapy for MPGN associated with coeliac disease and/or autoimmune thyroiditis should include management of the associated conditions with gluten-free diet and maintaining euthyroid state. In addition, ACEi and SGLT2i have a role in managing MPGN, and may help avoid need for immunosuppression in such cases.

FR-PO710

Atypical Presentation of Atypical Anti-Glomerular Basement Membrane Disease

Faten Y. Andrawes Barbara,[1] Teuta Zeitun,[1,2] George Jiries,[1] Etty Kruzel Davila.[1,2] *[1]Galilee Medical Center, Nahariya, Israel; [2]Bar-Ilan University The Azrieli Faculty of Medicine, Ramat Gan, Israel.*

Introduction: Anti-glomerular basement membrane (anti-GBM) disease is a rare aggressive autoimmune disorder characterized by circulating anti-GBM Antibodies (Ab) leading to crescentic necrotizing glomerulonephritis with linear deposits of immunoglobulin G (IgG) along the GBM. As opposed to the classic anti-GBM disease, atypical anti-GBM glomerulonephritis is characterized by an indolent clinical course, undetectable circulating anti-GBM Ab, endocapillary proliferation with only few crescents and linear IgG staining of the GBM. Herein, we present a case of atypical manifestation of atypical anti-GBM disease and emphasize the therapeutic dilemmas and challenges.

Case Description: 24-year-old male with a 3 weeks history of vomiting, was admitted to the hospital with severely impaired kidney function (creatinine 17 mg/dl), massive proteinuria without pulmonary involvement. Anti-nuclear, anti-neutrophilic cytoplasmic, and anti-GBM Ab were negative (anti-GBM was examined by indirect immunofluorescence (IF) assay, and enzyme-linked immunosorbent assay (ELISA)). Kidney biopsy demonstrated 100% cellular crescents with linear polytypic IgG staining of the GBM and C3 on IF. Hemodialysis was started. The patient was treated with high-dose steroids, cyclophosphamide and plasma exchange, as for classic anti-GBM disease. As opposed to classic anti-GBM disease, duration of plasmapheresis could not be dictated in the absence of detectable anti-GBM antibodies. The clinical course was ominous without improvement of his kidney function.

Discussion: The patient's clinical course and pathological findings were consistent of classic anti-GBM disease. Therefore, the absence of circulating anti-GBM Ab was surprising and did not suit the aggressive course of his kidney disease and pathological findings. Several theories had been proposed to explain the undetectable anti-GBM Ab including autoantibodies directed against GBM epitopes other than a3NC1, quaternary epitopes of native a345NC1 hexamers or high avidity for anti GBM ab along the glomeruli leading to undetectable circulating ab. Modified assays to detect a wide range of antigens or epitopes, using more sensitive techniques like biosensors, can unmask circulating anti-GBM antibodies and help in making therapeutic decisions regarding duration of plasmapheresis and immunosuppression therapy well as timing of kidney transplantation.

FR-PO711

Anti-Glomerular Basement Membrane Disease Overlap with Pauci-Immune Glomerulonephritis: Temporal Concurrence at a Single Center

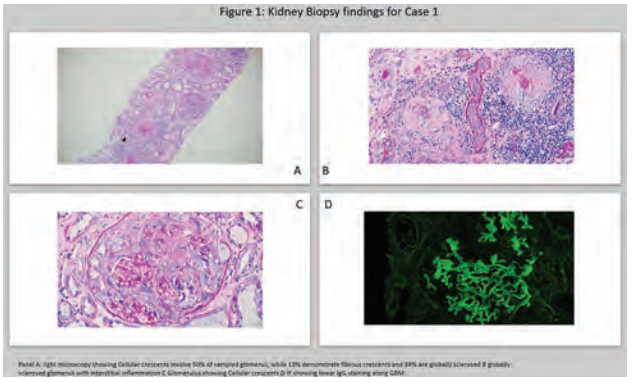
Buckley Fechter, Aisha Batool, Alexander J. Gallan, Shahzad Chaudhry, Christina Mariyam Joy. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Anti-GBM and pauci-immune vasculitis are small vessel vasculitis and cause RPGN with diffuse alveolar hemorrhage (DAH). Overlap between these entities is rare. Upto 38% of the individuals with anti-GBM disease demonstrate double-positivity and approximately 10% of patients with ANCA vasculitis have positive titers of anti-GBM antibodies. We present two double-positive cases diagnosed within 6 weeks at our institution.

Case Description: Case 1:A 74-years-old white male with h.o SARS-COV19 two months ago presented with cough and metallic taste, BUN 60 with S/Cr 5.05 mg/dl, p-ANCA 1:640 and anti-GBM+. Kidney biopsy showing Diffuse crescentic GN with cellular crescents involve 50% of the glomeruli, IF linear IgG staining. Patient was started on PLEX, IV Methylprednisolone and Cyclophosphamide. Patient remains HD dependent. Case 2:A 71-years-old white male with recently diagnosed lung biopsy proven GPA 4 months ago. Patient was admitted with SARS-COV-19 infection, serum creatinine 6.42mg/dl (baseline 0.9mg/dl few months ago). Kidney biopsy showing Crescentic glomerulonephritis with overlapping anti-glomerular basement membrane disease and pauci-immune glomerulonephritis. Patient was started on iv methylprednisolone, PLEX and cyclophosphamide. Patient needed hemodialysis for 2.5 months and has come off with most recent s/cr 3.54 mg/dl.

Discussion: In anti-GBM disease DAH can be the predominant presenting feature and will prompt early diagnosis necessitating early intervention. Hallmark for diagnosis is linear IgG staining of GBM on immunofluorescence. ANCA-associated vasculitis, in contrast, is pauci-immune with few or no immune deposits on IF. Given rarity of the overlap disease and paucity of literature standard treatment strategy is not established. Approach remains similar to treatment of anti GBM disease with PLEX and induction immunosuppression with cyclophosphamide. However longer and closer follow-up is required for double-positive disease due to more frequent relapses.

Figure 1: Kidney Biopsy findings for Case 1



Panel A: light microscopy showing Cellular crescents involve 50% of sampled glomeruli, while 13% demonstrate fibrous crescents and 34% are globally sclerosed & globally sclerosed glomeruli with interstitial inflammation C: Glomerulus showing Cellular crescents @ IF showing linear IgG staining along GBM

FR-PO712

Hydralazine-Induced ANCA Vasculitis Presenting with Pulmonary-Renal Syndrome

Madeline Kirby,[1] Marwa Abdalla,[1] Negiin Pourafshar,[1] Donghyang Kwon.[2] *[1]MedStar Georgetown University Hospital Nephrology Services, Washington, DC; [2]MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Hydralazine, an arterial vasodilator, is a frequently used medication for the management of hypertension and heart failure. It is generally well-tolerated and has a safe profile; however, hydralazine can induce immune-mediated complications. There are rare reports of hydralazine-induced ANCA associated vasculitis (AAV) with pulmonary manifestations, also known as hydralazine-induced pulmonary-renal syndrome (PRS). Here we report a case of hydralazine-induced alveolar hemorrhage and anti-neutrophil cytoplasmic antibody (ANCA)-positive pauci-immune glomerulonephritis.

Case Description: A 75-year-old female with history of hypertension treated with hydralazine 75 mg TID for seven years, presented with five months of dyspnea on exertion, blood tinged sputum and unintentional weight loss. CT scan showed a cluster of pulmonary nodules with mediastinal lymphadenopathy. Transbronchial lung biopsy revealed alveolar hemorrhage. Serum creatinine was 2.8 mg/dL from baseline 1.0 mg/dL and urinalysis showed 2+ blood, 30-50 RBC/hpf and red blood cell casts. Urine protein to creatinine ratio was 0.7 gr/day. Given the complaint of hemoptysis, a vasculitis work-up was pursued. Work-up revealed p-ANCA > 1: 1280, elevated MPO antibodies, elevated PR-3 antibodies, and elevated inflammatory markers. Anti-histone antibodies were present. Additional immunologic and serologic work up was unremarkable. Renal biopsy was consistent with pauci-immune ANCA associated vasculitis with crescents. Given concern for drug induced vasculitis, hydralazine was discontinued. She received 1 gm methylprednisolone for three days and received two doses of Rituximab followed by prednisone taper per the PEXIVAS trial. Hemoptysis resolved after treatment. She has remained off prednisone with stable renal function and minimal proteinuria.

Discussion: This case demonstrates a case of hydralazine-induced small vessel vasculitis. While immune-mediated complications have been frequently reported with the use of hydralazine, drug-induced ANCA vasculitis is rarely reported. This diagnosis should be considered in patients on hydralazine who develop pulmonary-renal syndrome. Diagnosis relies on serologic work-up and renal histopathology. Discontinuing hydralazine is the first step in treatment and this alone might be sufficient; however, more aggressive management including immunosuppression is frequently needed.

FR-PO713

Wrist Drop: An Unusual Initial Presentation of ANCA-Negative Pauci-Immune Glomerulonephritis

Sameen Aamer, Sheahahn V. Soundranayagam, Brandon T. Dunmyre. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: Pauci-immune glomerulonephritis (PING) is often associated with the presence of antineutrophil cytoplasmic antibodies (ANCA). ANCA-negative PING is a rare variant, which primarily affects the kidneys, with fewer extrarenal manifestations as compared to ANCA-positive PING. Our case highlights the initial presentation of progressive neurological weakness in ANCA negative PING.

Case Description: A 77-year-old male with medical history of hypertension and monoclonal gammopathy of undetermined significance (MGUS) presented with acute left wrist drop and progressive muscle weakness for six months. The weakness started in

the lower extremities, and gradually involved the upper extremities. He denied numbness, tingling, rash, fever and gastrointestinal symptoms. Vital signs were stable. Neurological exam was positive for bilateral foot drop, left wrist drop, decreased sensation in all extremities, decreased deep tendon reflexes, and an unsteady steppage gait. Laboratory tests showed elevated creatinine 1.82 mg/dL (baseline 0.7-0.9), low albumin 1.9 g/dL, and elevated CRP 7.5 mg/dL. Lumbar puncture and MRI spine was normal. Electromyography showed moderate acute-on-chronic symmetrical sensory motor polyneuropathy and left radial mononeuropathy. Subsequent sural nerve biopsy revealed marked axonal neuropathy. Patient's kidney function continued to worsen with creatinine peaking at 2 g/dL. 24 hour urine collection revealed 2.5 g proteinuria, with an elevated urine albumin-creatinine ratio of 1300. Therefore, a renal biopsy was performed revealing pauci-immune proliferative and necrotizing glomerulonephritis with crescent formation, negative immunofluorescence with no amyloid and immune deposits. Treatment with intravenous steroids followed by rituximab was initiated, resulting in improved renal function with creatinine of 1.77 at discharge. He demonstrated further renal recovery on outpatient follow up with serum creatinine down to 1.32.

Discussion: ANCA-negative PING is a severe vasculitis with high morbidity and mortality. This is the first case to report severe neurological weakness as the initial presentation of ANCA-negative PING. It highlights the importance of considering PING in the differential diagnosis for patients presenting with neurological weakness and elevated creatinine, as prompt diagnosis and treatment can prevent adverse patient outcomes.

FR-PO714

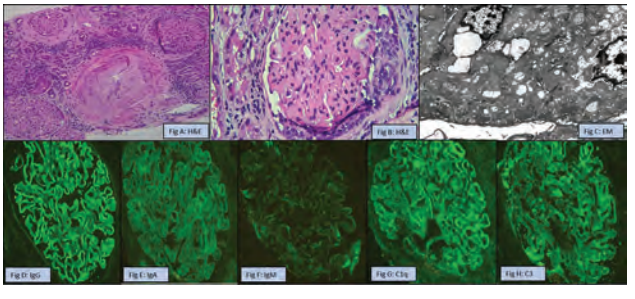
A Case of Lupus-Like Nephritis in a Patient with a Negative Antinuclear Antibody (ANA)

Osama Elhilali, Tasnuva Rashid, Shiguang Liu, Irtiza Hasan. *University of Florida College of Medicine - Jacksonville, Jacksonville, FL.*

Introduction: Diagnosis of SLE cannot be made based only on kidney biopsy, however the histopathologic findings is one of the important cornerstone for the diagnosis of lupus nephritis.

Case Description: A 60-year-old male with PMH of HTN presented with worsening bilateral lower extremity edema with hematuria & heavy proteinuria for 4 months. Other symptoms significant of dyspnea on exertion & a strong family history of kidney disease. Labs showed S. Cr 1.80 mg/dL (previous 0.86) & urine protein/creatinine >7.96 g/g. Workups including ANA, ANCA, C3 (160), C4 (36), and ds-DNA (<1) were negative. Serum protein electrophoresis revealed two small oligoclonal bands without monoclonal paraprotein. CXR, TTE & renal ultrasound were within normal limit. HBsAg, anti-HCV, RPR & HIV were also negtive. A kidney biopsy revealed marked (>50%) endocapillary proliferation, mesangial sclerosis, GBM thickening with two cellular crescents. Immunofluorescence (IF) studies showed full house positivity on immunoglobulins (Ig A, Ig G and Ig M) & complement deposit. Electron microscopy (EM) showed subendothelial & mesangial electron dense depositions with no tubuloreticular inclusion identified. Patient was initially treated with IV methylprednisolone followed by prednisone with improvement in renal function. Patient was discharged on mycophenolate for outpatient follow up and monitoring.

Discussion: Here we presented a case of renal-limited, lupus-like nephritis in a patient with absent extrarenal manifestations & negative lupus serology. As per American Rheumatism Association (ARA) criteria, our patient did not fit into the diagnosis of SLE. However, the presence of immune-complex mediated glomerulonephritis and "full house" IF staining and EM showing subendothelial and mesangial electron dense deposits on kidney biopsy are highly suggestive of the lupus nephritis. There is a need for proper characterization of this disease pathogenesis, precise diagnostic criteria, standardization of treatment protocols & long term follow up studies to identify the true prognosis of this challenging clinical entity.



Histopathologic images of a kidney biopsy

FR-PO715

Mixed Cryoglobulinemic Glomerulonephritis Triggered by Influenza Vaccination

Stephanie Wirtshafter, Gamil Hanna, Marissa Blum, Abdallah Sassine Geara. *University of Pennsylvania, Philadephia, PA.*

Introduction: Mixed cryoglobulinemia is associated with viral infections such as hepatitis B or C virus, lymphoproliferative and autoimmune disorders. Influenza vaccine-induced cryoglobulinemia has been rarely reported. We present a rare case of cryoglobulinemic vasculitis following influenza vaccination with new onset renal involvement.

Case Description: A 68-year-old male with history of atrial fibrillation and chorioretinopathy presented in fall 2022 for a rash and edema of the lower extremities and thrombocytopenia after influenza vaccination. Prior, in both 2020 and 2021, he had similar presentation of rash and edema following annual influenza vaccine. His illness was self-limited, but evaluation had shown mixed cryoglobulins. A bone marrow biopsy was unremarkable and viral etiologies were negative. He was diagnosed with idiopathic mixed cryoglobulinemic vasculitis. For recent presentation, in addition to the edema and rash, he had thrombocytopenia and a positive rheumatoid factor (RF). Patient received intravenous immunoglobulin (IVIG) with improvement of rash and platelet count, but his edema persisted. Soon after, he was readmitted and found to have acute kidney injury (AKI) (creatinine of 2.89 mg/dL; baseline 1.2 mg/dL), hematuria, proteinuria, and labs showing RF elevation and low complements. An evaluation for paraprotein revealed IgM kappa and IgA lambda paraproteins, with cryoglobulin elevation in polyclonal fashion including IgG, IgA, but predominately IgM. He received IVIG and creatinine improved. A kidney biopsy showed endocapillary proliferative glomerulonephritis with organized deposits, consistent with mixed-type cryoglobulinemic glomerulonephritis treated with rituximab infusions, resulting in improvement in cryoglobulins and complement levels and renal function, with creatinine at 1.46 mg/dL in May 2023. Of note, plasmapheresis was given for rash from IVIG.

Discussion: Our patient had a favorable outcome after rituximab, IVIG, and plasmapheresis for diagnosis of mixed cryoglobulinema triggered by the influenza vaccine, noting a reduction of cryoglobulins, improved renal function, and resolution of rash. Cryoglobulins can form as an immune response to infections though it is unclear why cryoglobulins are produced as a response to a vaccination. Understanding this novel association and interaction is important for prompt diagnosis and management.

FR-PO716

Polycythemia and IgA Nephropathy: An Interesting Association

Asheen Zariat, Abdallah Sassine Geara. *University of Pennsylvania, Philadelphia, PA.*

Introduction: IgA nephropathy (IgAN) is often associated with chronic kidney disease (CKD) which usually presents with anemia. We present a case IgAN-associated polycythemia.

Case Description: A 46-year-old patient with known hypertension (HTN) was evaluated for progressive CKD. Serum creatinine (sCr) increased from 1.2 to 1.7 mg/dL over 5-6 years. Urinalysis showed microscopic hematuria and proteinuria of 1g/g of creatinine. A kidney biopsy showed IgAN with an Oxford classification score of M1E0S1T1-C0. He was treated with RAAS blockade and a 6 months course of steroid followed by dapagliflozin and currently with stable sCr and proteinuria of 0.13 g/g. In conjunction to IgAN, polycythemia was noted for several years with Hematocrit (Ht) levels between 50-60%. The most recent Hemoglobin was 18.6 g/dL with normal platelets and white blood cell counts. Abdominal imaging showed normal sized kidneys and no splenomegaly or hepatomegaly. Polycythemia evaluation was unrevealing. The patient had no smoking history, and sleep study was negative. Genetic testing for Janus kinase 2 (JAK2) mutation as well as other polycythemia-associated mutations was negative, excluding Polycythemia Vera. The final diagnosis from hematology was polycythemia associated with IgAN with a recommendation for observation.

Discussion: The 4-hit hypothesis for IgAN pathogenesis involves galactose-deficient IgA1 targeting the hinge region, being recognized by IgG autoantibodies, leading to immune complexes which deposit in kidney mesangium. High polymeric IgA (pIgA1) and IgA1 complexes can stimulate red blood cell formation in some patients. In vitro study showed that the serum of patients with IgAN and unexplained polycythemia increased the number of erythroid burst forming unit (BFU-E)-derived colonies from human progenitor CD34+ cells. Removal of IgA1 from IgAN-Polycythemia patients normalized the number of colonies. Mice studies have shown that increased expression of Polymeric IgA (pIgA1) was associated with increased hemoglobin levels without raising EPO levels likely by sensitizing cells to Epo through activating the transferrin receptor 1 (TfR1). We report an interesting association of IgAN and polycythemia that is supported by in vitro findings of polygenic IgA1 stimulating RBC formation. Evaluation for other etiologies of polycythemia needs to be done before considering the IgAN as the plausible etiology of polycythemia.

FR-PO717

Outcomes from Acute Co-Infection of HIV and Hepatitis B Infection Nephritic Syndrome

Sandeep R. Sasidharan,[1] Tahir A. Jatoi,[1] Mohammad W. Abushawer,[1] Isha Puri,[1] Surya V. Seshan,[2] Subodh J. Saggi.[1] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]Weill Cornell Medicine, New York, NY.*

Introduction: We present a unique case of a previously untreated combined HIV and HBV coinfection presenting as HD requiring AKI with Nephritic syndrome and significant lymphoplasmacytic interstitial inflammation with dominant for CD8 T lymphocyte.

Case Description: 40-year-old AA male with no past history who presented with anasarca, 3+ proteinuria and uremic symptoms of nausea/vomiting for 1-2 weeks. Labs significant for BUN/Cr 56/5.1, Alb <1.5, Urine Prot >500, Hgb 5.8, C3 64, C4 122, CD4 141. SPEP and UPEP negative. Hep B and HIV viral quantitative PCR were 7.7million virions and 280,000. Negative for other serologies. Biopsy showed HIVAN with FSGS and microcystic tubular changes, MPGN, diffuse interstitial lymphocytosis syndrome (DILS) with dominant CD8 cells along with lymphoplasmacytic infiltration. He needed emergent HD for AKIN Stage 3 and anasarca unresponsive to diuretics, on retrovirals without renal response until he was started on a course of steroids, serendipitously for high intracranial pressures from Acute Toxoplasmosis on his second admission.

Discussion: DILS is a rare multisystemic syndrome characterized by CD8+ lymphocytosis associated with a CD8+ T-cell infiltration of multiple organs, usually seen in uncontrolled or untreated viral infections but can also manifest itself independently of CD4+ T-cell counts. The rarity of DILS cases explains the lack of studies describing treatment options but the consensus is that the primary treatment line should be HAART. Specifically, for the renal condition, several case reports suggest the use of corticosteroid therapy. This is congruent with other studies showing initial response may be dramatic with corticosteroids adjunct to ART +/- ACEi/ARB, even reversing dialysis dependence, but transient. Comorbid kidney disease in the setting of HIV/HBV is challenging to manage clinically because the preferred antiretroviral agent in coinfection, tenofovir disoproxil fumarate (TDF), is potentially nephrotoxic. However, in immune-tolerant HBV, steroids could reactivate severe infection. In the current era of retroviral availability, it is extremely rare to see a case of classical HIVAN and DILS. Our case is unique as the patient had 2 viral infections and lymphocyte pattern of CD8 lineage that coincidentally responded to high-dose steroids which were given for other reasons.

FR-PO718

Lactobacillus Endocarditis-Associated Crescentic Glomerulonephritis

Christopher El Mouhayyar,[1,2] Ayman Al Jurdi,[1,3] Harish Shanthanu Seethapathy,[1,3] Pitchaphon Nissaisorakarn,[1,3] Anushya Jeyabalan.[1,3] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Mass General Brigham Inc, Boston, MA.*

Introduction: Infection-related glomerulonephritis (IRGN) encompasses a wide range of clinical and pathologic manifestations. Up to 50% of patients can develop persistent kidney impairment and 1/3 can progress to kidney failure. (Medjeral-Thomas et al. Clin J Am Soc Nephrol. 2014.) Staphylococcus and Streptococcus are the most common pathogens isolated however IRGN in the setting of lactobacillus is considered rare.

Case Description: A 79-year-old male with history significant for heart failure with preserved ejection fraction, bioprosthetic AVR, and chronic kidney disease (CKD) IIIb thought to be secondary to uncontrolled hypertension and recurrent AKI presented with dyspnea on exertion. Physical exam revealed signs of volume overload and a new systolic murmur. Echocardiogram showed vegetation consistent with bioprosthetic valve endocarditis. Blood cultures grew Lactobacillus species and upon reviewing his medication list probiotics was noted. His course was complicated by acute on chronic kidney injury requiring dialysis. Workup included a 24-hour urine collection showing 2.4g of protein and 1.3g of albumin, normal serum free light chain ratio, normal serum protein electrophoresis, and normal C3 and C4 levels. Kidney biopsy performed revealed necrotizing and crescentic glomerulonephritis with immunofluorescence positive for IgG, IgM and C3; consistent with IRGN. Patient was started on ampicillin and a steroid course was proposed. However, the patient and his family declined given risk of exacerbation of infection and decision was made to pursue conservative management with antibiotics and dialysis which the patient is still on.

Discussion: The pathogenesis of IRGN involves glomerular immune complex deposition along with classical complement pathway activation. This is frequently associated with a reduction in serum C3 and normal C4 levels, but as illustrated in our case C3 levels can be normal. The mainstay of treatment is withdrawal of enticing agent (probiotics), treatment of the underlying infection and supportive care. The utilization of systemic steroids in these patients is highly controversial given no evidence of efficacy in IRGN patients at low risk for progression (Arivazhagan et al. Kidney Int Reports. 2022). They can be considered in specific cases, such as patients with diffuse crescentic and rapidly progressive GN.

FR-PO719

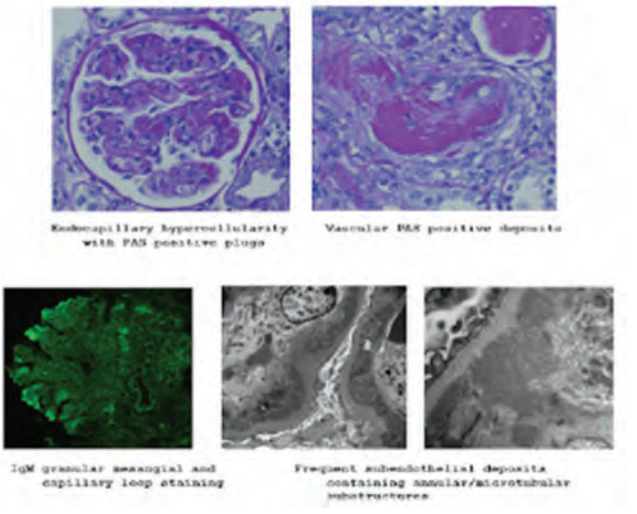
Hepatitis C Negative Type II Cryoglobulinemic Glomerulonephritis

Cameron T. Lawson, Adham Mohsen, Iskra Myers. *East Carolina University, Greenville, NC.*

Introduction: Mixed cryoglobulinemia typically follows a chronic, smoldering course. Here we present a case of rapidly progressive mixed cryoglobulinemic glomerulonephritis (GN) in a hepatitis C negative patient.

Case Description: A 67-year-old female with a history of chronic kidney disease stage III and ophthalmologic Sjogren's syndrome presented to the emergency department for labile blood pressures. Labs were notable for serum creatinine 1.49 mg/dL, positive anti SS-A, anti-B. C3 28 (low), C4 < 3, and negative hepatitis panel. Urine protein: creatinine ratio was 2.2 g/day. Additional labs showed cryoglobulin level < 10% and was identified as Type II cryoglobulinemia monoclonal IgM kappa and polyclonal IgG. A kidney biopsy showed diffuse proliferative GN consistent with cryoglobulinemic GN. The patient's condition continued to decline with worsening creatinine and raising concern for rapidly progressive GN secondary to cryoglobulinemic GN. Patient was initiated on high-dose steroids and plasmapheresis (PLEX). Subsequently, she received Rituximab. Despite these aggressive measures, oliguria and uremia persisted requiring dialysis.

Discussion: Mixed cryoglobulinemic GN is a rare cause of rapidly progressive GN that is commonly associated with hepatitis C viral infections. Sjogren disease is responsible for <10% of HCV-negative mixed cryoglobulinemias. Prompt treatment with steroids, PLEX, cyclophosphamide, or rituximab is essential due to the significant morbidity and mortality associated with this condition.



FR-PO720

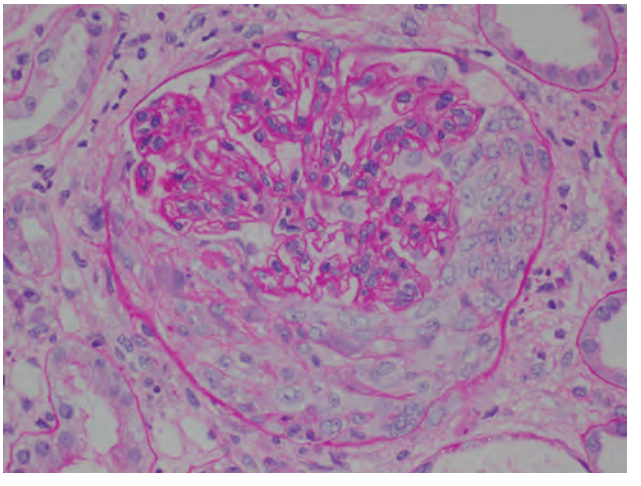
Infection-Related Rapidly Progressive Crescentic Glomerulonephritis

Jacob R. Henderson, Karl B. Pembaur. *The Christ Hospital, Cincinnati, OH.*

Introduction: Rapidly progressive crescentic glomerulonephritis (RPGN) is characterized by progressive loss of renal function. Most cases are diagnosed with a renal biopsy. Here we examine a subtype of RPGN in the setting of IV drug abuse, hepatitis C, and tricuspid valve (TV) MRSA endocarditis.

Case Description: A 32 year-old male with a PMHx significant for IVDU presented with fever, chills, lower extremity edema, and a dark discoloration to his urine. The patient had a new acute kidney injury (AKI) (Cr 1.66, BUN 35), anemia (Hgb 11.2), and leukocytosis (WBC 16.8k). Total protein and albumin were low. Urinalysis revealed hematuria (30 RBC's and RBC casts), proteinuria (300mg/dL), small leukocyte esterase, 41 WBC's and a urine protein to creatine ratio of 4.4mg/g. Blood cultures were positive for MRSA, and TEE revealed TV endocarditis. Hepatitis testing revealed a chronic, active hepatitis C infection and a cleared hepatitis B infection, HIV testing was negative. He underwent TV thrombectomy for vegetation removal and was initiated on antibiotics. Renal function worsened and an ANA, dsDNA, Anti-GBM, SPEP, and cryoglobulin were negative. An atypical P-ANCA was positive with a 1:40 titer, complements C3 and C4 were low. Renal biopsy was performed, and light microscopy revealed 61% crescents with focal segmental necrosis, and mesangial expansion. IF microscopy revealed mesangial staining of 1+ IgG/IgA/IgM/C1q, 3+ C3, and 3+ kappa & lambda.

Discussion: The biopsy was consistent with a necrotizing, crescentic glomerulonephritis with mild interstitial fibrosis. The atypical P-ANCA seropositivity was thought to be due active hepatitis C infection. In the context of MRSA bacteremia, active hepatitis C infection, and chronically inactive hepatitis B infection with rapid progression of renal impairment, the patient was diagnosed with an infection related RPGN. Treatment was directed at the underlying cause of infection, however due to rapid progression of renal injury, and degree of proteinuria, he was started on a steroid taper. This patient will be treated for hepatitis C in the outpatient setting. In the context of an active infection and clinical evidence of RPGN, a renal biopsy should be performed for a definitive diagnosis. While treating the underlying infection is appropriate, immunosuppression should be considered in the right clinical context, in this case, rapidly progressive renal failure.



FR-PO721

Looks Can Be Deceiving: A Case of C3 Glomerulopathy

Kevin Dao, Robin Edwin, Mohid Mirza, Richard G. Macneil, Alexei V. Mikhailov, Pirouz Daeihagh. *Atrium Health Wake Forest Baptist, Winston-Salem, NC.*

Introduction: Complement 3 glomerulopathy (C3G) is caused by an acquired or genetic dysregulation of the complement alternative pathway. It can be further classified into dense deposit disease (DDD) or C3 glomerulonephritis (C3GN). We present a case of a middle age male who presented with suspected infection-related glomerulonephritis (IRGN). However, his renal functions did not significantly improve with antibiotics. Renal biopsy was performed and he was diagnosed with C3GN.

Case Description: 55-year-old male with past medical history of untreated hepatitis C and former intravenous drug use presented for evaluation of oliguric acute kidney injury, hematuria, and rash in the setting of MSSA empyema and chest wall osteomyelitis. He was septic and had acute renal failure requiring broad spectrum antibiotics and renal replacement therapy. Further GN work up was significant for proteinuria 11g/g, elevated Anti-DNASE, cryoglobulins 1.0%, undetectable C3, low C4 and M spike on SPEP. Patient was treated with prolonged course of antibiotics for presumed endocarditis. Differential included IRGN but due to multiple abnormal serological markers a renal biopsy was performed which revealed C3GN. He was started on steroid taper and mycophenolate mofetil with rapid improvement in edema and renal functions. Dialysis was discontinued and patient was discharged on immunosuppressive therapy.

Discussion: C3G is a difficult diagnosis and may often require immunosuppression (IS). Our patient above was requiring routine dialysis until the initation of IS and was able to stop dialysis shortly after. Patients who are suspected to have IRGN that are not improving with antibiotics should have C3GN included in the differential. Biopsy is warranted in these patients and IS may help with improving outcomes.

Mesangial Proliferative Glomerulonephritis and Neurocysticercosis: A Novel Association

Jinlan Liao,[1,4] Brendan Smyth.[2,3] *[1]Peking University Shenzhen Hospital, Shenzhen, China; [2]The George Institute for Global Health, Newtown, NSW, Australia; [3]St George Hospital, Kogarah, NSW, Australia; [4]The First Affiliated Hospital of Anhui Medical University, Hefei, China.*

Introduction: The etiology of nephrotic syndrome is diverse, and parasitic infections typically do not cause this condition. Here, we present a case of nephrotic syndrome associated with parasitic infections.

Case Description: A 21-year-old man with a habit of eating raw fish presented with a 6-week history of bilateral limb edema, back pain and nausea. Nephrotic syndrome with acute kidney injury was diagnosed after finding a creatinine of 163 umol/L, albumin of 19.7 g/L, and proteinuria (9.4 g/day). Peripheral blood eosinophilia was noted (5.78 x10^9 cells/L). A renal biopsy revealed mesangial-proliferative glomerulonephritis and eosinophils within the renal interstitium. Serum was strongly positive for anti-*Taenia solium* antibodies (by enzyme linked immunosorbent assay). Cranial magnetic resonance imaging revealed a 9.8 x 12.8mm mass in the fourth ventricle. A specimen of cerebrospinal fluid was also weakly positive for anti-*Taenia solium* antibodies. On the basis of these findings, a diagnosis of neurocysticercosis was made. The patient did not consent to surgical exploration and removal of cyst in the fourth ventricle. Medical therapy was commenced with albendazole and glucocorticoids. Two months later, 24-hour urinary protein excretion had reduced to 0.8 g/day, and the blood eosinophil level was normal. At a follow-up visit 1 year later, the patient's renal recovery was found to be complete. MRI of the brain revealed no change in the fourth ventricular cyst and he remained asymptomatic.

Discussion: This is the first reported case of mesangial-proliferative glomerulonephritis with eosinophilic infiltrate associated with cysticercosis. We hypothesize that this patient's infection resulted from cross-contamination in the preparation of raw seafood. Cysticercosis should be considered in the differential diagnosis of nephrotic syndrome in areas where *Taenia solium* is endemic.

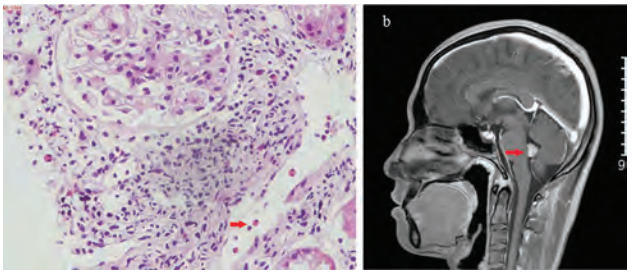

Figure 1: Image a is from a renal biopsy, the arrow indicates eosinophils. Image b is from cranial MRI revealed a mass in the fourth ventricle.

FR-PO723

Anti-Tumor Necrosis Factor Antibody-Induced Lupus-Like Glomerulonephritis

Luis B. Caraballo, Hima B. Doppalapudi, Amar Pandit, Vijay K. Vanguri. *University of Massachusetts Chan Medical School, Worcester, MA.*

Introduction: Anti-TNF agents can lead to expression of autoantibodies resulting in symptoms similar to systemic lupus erythematosus (SLE). This autoantibody expansion can be reversible with the discontinuation of the offending agent. We present a case of a 35-year-old female patient with drug-induced lupus nephritis caused by adalimumab.

Case Description: A 35-year-old female was evaluated for worsening renal function and microscopic hematuria. Her medical history was significant for RA on weekly adalimumab since 2011. Her serum creatinine increased from 0.8-1.7 mg/dL over a period of 2 years. Urine sediment demonstrated dysmorphic RBC's. Urine protein to creatinine ratio (UPCR) was 3.7 g/g. Elevated proteinase 3 antibody, and anti-double stranded DNA antibody. She underwent a renal biopsy to determine the etiology of her worsening renal function. The biopsy revealed immune complex-mediated glomerulonephritis with a focal proliferative and membranoproliferative patterns of injury, as well as a background of 40-50% chronicity. Her findings were compatible with a lupus-like immune complex-mediated glomerulopathy, and were believed to be secondary to adalimumab. Adalimumab was discontinued and she was started on prednisone 1 mg/kg. Her most recent creatinine downtrended to 1.5 mg/dL, with UPCR 1.5 g/g.

Discussion: Anti-TNF drug induced lupus nephritis mechanism is unknown, is believed that this agents promotes anti-dsDNA antibody by inducing cellular apoptosis. Adalimumab has been associated with focal and diffuse membranoproliferative glomerulonephritis similar to our biopsy findings. In our case, the patient had significant renal function improvement after completing four weeks of prednisone therapy.

FR-PO724

Double Insult: Secondary IgA and Anticoagulant-Related Nephropathy

Elizabeth Pabon-Vazquez, George N. Thomas, Bogdan Anea, Vatsalya Kosuru. *Augusta University Medical College of Georgia, Augusta, GA.*

Introduction: Acute kidney injury represents the most frequent nephrology consultation. In select cases, AKI is the result of series of cumulating insults overlapping previously undiagnosed conditions. These usually carry a significant negative impact towards renal recovery.

Case Description: This is the case of a 62-year-old male with a past medical history of peripheral artery disease, s/p right below the knee amputation, severe ischemic cardiomyopathy s/p intra-cardiac device, atrial fibrillation on apixaban, diabetes mellitus and hypertension, who was admitted for cellulitis in the amputated stump. In addition to cellulitis, the patient reported a non-blanching petechial rash on the left arm which was present for several months. Hospitalization was complicated by AKI;and initial workup revealed a history of daily NSAID use and elevated vancomycin levels with granular casts noted on urine microscopy. An initial diagnosis on acute tubular necrosis due to intrinsic etiology was suspected. However, renal function continued to worsen, and given the patient's rash, we suspected for acute interstitial nephritis or vasculitis. Skin biopsy revealed leukocytoclastic vasculitis that was negative for IgA deposition. Further immunologic workup was negative. No peripheral eosinophilia was observed, and blood cultures were positive for Staphylococcus Aureus. A renal biopsy was performed, which showed IgA-dominant immune complex deposition, likely secondary to infection, and numerous cortical and medullary RBC casts out of proportion to the degree of glomerular injury, concern for anticoagulant associated nephropathy. Moderate interstitial fibrosis and tubular atrophy with no crescents was described. Due to active infection, steroids were not recommended, and the patient's anticoagulation was placed on hold. Unfortunately, due to significant renal injury the patient was initiated on hemodialysis and subsequently, did not show signs of renal recovery.

Discussion: Our patient has dialysis-dependent AKI complicated by secondary IgA nephropathy associated with infection along with anticoagulant-associated nephropathy, related to eliquis. Comorbidities such as diabetes, hypertension, and advanced age can negatively impact the response to therapy. In our case, the patient was also diagnosed with anticoagulant-associated nephropathy which further decreased his chances of recovery.

FR-PO725

A Case of Cronkhite-Canada Syndrome-Associated Membranous Glomerulonephritis: Can Lightning Strike Thrice?

Benjamin J. Strimaitis, Shaun P. Chandler, Leo Francis, Rachna V. Pagnis, Dwarakanathan Ranganathan, Eoin D. O Sullivan. *Royal Brisbane and Women's Hospital, Herston, QLD, Australia.*

Introduction: Cronkhite-Canada Syndrome (CSS) is a rare disorder with less than 500 reported cases, characterized by extensive gastrointestinal polyposis and ectodermal abnormalities. It has been rarely associated with membranous nephropathy (MN). Of the 5 cases of MN associated with CSS in the literature, 3 have been in the context of malignancy, and none have tested PLA2R or thsd7a antibodies.

Case Description: A 60-year-old female of Aboriginal heritage presented for evaluation of proteinuria with an Albumin Creatinine ratio (ACR) of 123 mg/mmol and Protein Creatinine ratio (PCR) of 108 mg/mmol on the background of CCS. Her renal function was reduced with a creatinine-based eGFR of 58mL/min/1.73m2 and a blood pressure of 128/78mmHg. She had a history of bilateral hearing loss since her teens requiring hearing aids but no visual impairment. Her brother had been diagnosed with thin basement membrane disease (TBM) and a maternal aunt with a similar presentation. Serological tests and ultrasonography were unremarkable, and a kidney biopsy demonstrated a classical appearance of MN – which was confirmed to be PLA2R and Thsd7a negative. Electron microscopy confirmed TBM with a mean basement thickness of 180nm. No malignancy suggested by history or examination, nor full body CT imaging or colonoscopy. She was treated with ACE inhibition and proteinuria improved to an ACR of 58 mg/mmoL and PCR of 73 mg/mmoL by six months.

Discussion: This case is the first time that contemporary MN associated antibodies have been tested for in CCS, and suggests MN associated with CCS is not caused by PLA2R and thsd7a antibodies as previously suggested. Hiccum's Dictum is the counter to Occam's Razor, which argues a patient may have as many rare diagnoses as they please. This patient was one of 500 reported cases of CCS, one of 5 reported cases of associated MN and is the only reported case with concurrent active TBM disease. This case highlights the careful consideration which should be give to pre-test probabilities when deciding whether to pursue kidney biopsy (isolated TBM was more likely the diagnosis at initial presentation given the confirmed family history) while acknowledging that lightning can indeed strike thrice.

FR-PO726

Molecular Similarity Between Chronic Active Antibody-Mediated Rejection (CA-ABMR) and Acute T Cell-Mediated Rejection (TCMR) of Human Kidney Allografts

Yajas Shah, Carol Y. Li, Sheavonnie Wright, Alex Devito, Thalia Salinas, Steven Salvatore, Deirdre L. Sawinski, Darshana M. Dadhania, Surya V. Seshan, Manikkam Suthanthiran, Thangamani Muthukumar. *Weill Cornell Medicine, New York, NY.*

Background: CA-ABMR, even without concomitant histological TCMR, is characterized by an increased abundance of NK Cells and T cells. We RNA-sequenced kidney allograft biopsies to test the hypothesis that CA-ABMR, but not active-ABMR, is exemplified by the overexpression of key gene sets that are similar to TCMR.

Methods: We did RNA-seq of 57 biopsies from 57 kidney transplant recipients; 39 for-cause biopsies (15 CA-ABMR, 17 TCMR, & 7 active-ABMR), and 18 surveillance biopsies (no rejection [NR]). All biopsies were evaluated independently by two transplant pathologists. We isolated total RNA from stored biopsy samples, prepared cDNA libraries, and sequenced pooled libraries on an Illumina sequencer. After appropriate quality checks, we used standard bioinformatic tools for data analysis.

Results: There were 1425 genes increased and 29 reduced between CA-ABMR and NR biopsies (FC≥2 & P-FDR<0.05); 1829 were increased and 164 were reduced between TCMR and NR biopsies. T and NK cells were the top cell types and pathways in CA-ABMR and TCMR (Fig.1). Differential gene expression analysis between CA-ABMR and TCMR biopsies yielded only one gene, *MARCHF4*, that was significantly different. Cellular deconvolution revealed a similar proportion of immune cells in the three rejection categories; principal component analysis of deconvolved immune cell transcriptomes separated CA-ABMR and TCMR from active-ABMR and NR biopsies (Fig.2).

Conclusions: CA-ABMR exhibits an immune transcriptome profile that resembles TCMR biopsies. Our findings, besides advancing our knowledge of the pathogenesis of CA-ABMR, provide a compelling argument for the pharmacological targeting of T cells and NK cells in CA-ABMR.

Funding: Other NIH Support - NIAID

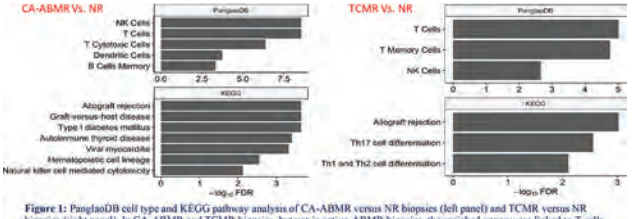

Figure 1: PanglaoDB cell type and KEGG pathway analysis of CA-ABMR versus NR biopsies (left panel) and TCMR versus NR biopsies (right panel). In CA-ABMR and TCMR biopsies, but not in active-ABMR biopsies, the enriched genes were linked to T cells and NK cells, as well as with the allograft rejection pathway.

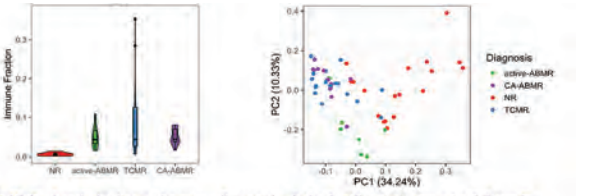

Figure 2: Violin plots depict the total immune cell proportion in the four diagnostic categories (left panel). The proportion of total immune cells in the allograft was not significanly different among the three rejection categories. The total immune cell proportion in each of the three rejection categories was significanlt different when compared to NR. Principal component analysis of the deconvolved immune cell transcriptomes (right panel). Each colored dot represents a biopsy sample. The two principal components, based on deconvolved immune cell transcriptomes, separated CA-ABMR and TCMR from ABMR and NR biopsies.

Unbiased Proteomics Analysis Shows Distinct Graft Protein Expression in Donor-Specific Antibodies (DSA+) Kidney Transplant Recipients with Antibody-Mediated Rejection

Kieran Manion, Maya A. Allen, Sergi Clotet Freixas, Rohan John, Ana Konvalinka. *University Health Network, Toronto, ON, Canada.*

Background: Nearly 1,000,000 North Americans have end-stage renal disease (ESRD), where the kidneys no longer function. Transplantation is the best treatment for ESRD; however, 50% of grafts fail by 10 years, due mainly to antibody-mediated rejection (ABMR), where recipient donor-specific antibodies (DSA) are thought to drive tissue injury. Unfortunately, predicting ABMR onset is challenging, as 30-60% of DSA$^+$ transplant patients do not develop ABMR. We aim to identify factors that regulate kidney protein expression in DSA$^+$ kidney transplant recipients with and without ABMR.

Methods: Glomeruli and tubulointerstitium isolated from DSA$^+$ABMR (n=24) and DSA$^+$ no ABMR (NA; n=21) kidney biopsies using laser capture microdissection were digested to peptides and analyzed by liquid chromatography mass spectrometry. MaxQuant and Perseus software were used to assess protein identification and differential expression. Significantly differentially expressed proteins (t-test, $p<0.05$) were then mapped to signaling pathways using the pathDIP database (FDR with Benjamini Hochberg adjustment, $q<0.05$).

Results: 120 glomerular and 246 tubulointerstitial proteins were significantly differentially expressed between DSA$^+$ABMR and DSA$^+$NA patients, with 55% of these

proteins upregulated in ABMR (Figure 1). pathDIP analysis showed that upregulated proteins mapped significantly to pathways involving the immune system (glomeruli, q=7.6e-8; tubulointerstitium, q=3.8e-11), antigen processing (glomeruli, q=5.6e-11) and integrin activity (tubulointerstitium, q=1.0e-8), while downregulated proteins mapped to tight junction regulation (glomeruli, q= 1.0e-3) and cellular metabolism (tubulointerstitium, q=1.8e-9).

Conclusions: Our preliminary results suggest that ABMR in DSA$^+$ patients is strongly linked to dysregulated immune and cellular responses in multiple kidney tissues. These findings will ultimately help us identify novel targets for the development of therapeutics for kidney transplant recipients.

Funding: Government Support - Non-U.S.

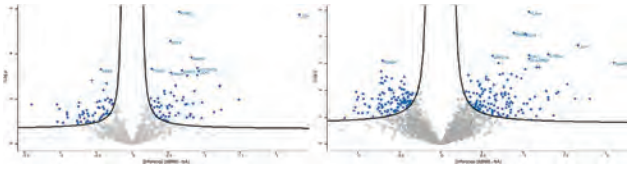

Fig1. Differentially expressed ($p<0.05$) proteins in the glomeruli (*left*) and tubulointerstitium (*right*) of DSA$^+$ kidney transplant recipients with vs without ABMR.

FR-PO728

Role of Urine Exosomal Proteome for Identifying Potential Biomarkers to Predict Renal Allograft Survival

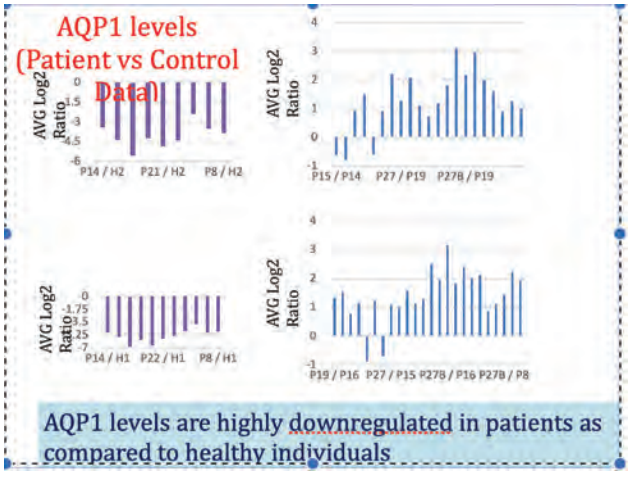
Vinant Bhargava, Anil Bhalla, Ashwani Gupta, Manish Malik, Anurag Gupta, Vaibhav Tiwari, Shiv Chadha. *Sir Gangaram Hospital, New Delhi, India.*

Background: Urine contains proteins bound to extracellular vesicles (exosomes) which are secreted by the cells into the urine as a result of renal insult. We propose to identify exosomal protein markers in urine to predict allograft survival. Molecule-bearing urinary exosome is altered in various kidney diseases. Exosomal molecules such as Aquaporins (AQPs) can be used as potential biomarkers.

Methods: Post renal transplant patient urine samples at 6/7th day were collected using standard protocol. Isolation of exosomes from urine samples was done using standardized protocol. Urine samples were collected at 3, 6, 12 months or/and at the time of graft dysfunction. Further, characterization of exosomal proteins was done through Flow cytometry, Western blotting and NTA (Nano-particle tracking analysis). Exosomal proteome was analysed through LC-MS.

Results: Samples were collected from13 renal allograft patients and 14 healthy controls. There was decreased abundance of urinary exosomal aquaporin-1 observed in allograft renal transplant recipients in the immidiate post transplant and in those with allograft dysfunction (6/13 patients) as compared to healthy individuals. All the 6 patients underwent biopsy and demonstrated rejection (ABMR :2, Tcellrejection: 1), CNI toxicity (n= 2), BKVN (n=1). 24 months followup is underway.

Conclusions: The preliminary analysis of Mass Spectrometry data shows that AQP1 levels are highly downregulated in allograft patients in the immidiate post transplant period and those with allograft dysfunction. This suggests that the excretion of Urinary exosomes UE-AQP1 is altered under the conditions of renal insult. Segregating and co-relating the differential proteome data with clinical parameters and demographic features will help us to define biomarkers specific to a particular cause of allograft dysfunction in our ongoing analysis



Preliminary analysis of mass spectrometry data

FR-PO729

GADD45A and GADD45B as Novel Biomarkers Associated with Chromatin Regulators in Renal Ischemia-Reperfusion Injury and Their Correlation with Immune Cells

Ming Xie,[1] Ruiyan Xie,[2] Yat Hin Desmond Yap,[2] Peng Wu.[1] *[1]Southern Medical University Nanfang Hospital, Guangzhou, China; [2]Queen Mary Hospital, Hong Kong, Hong Kong.*

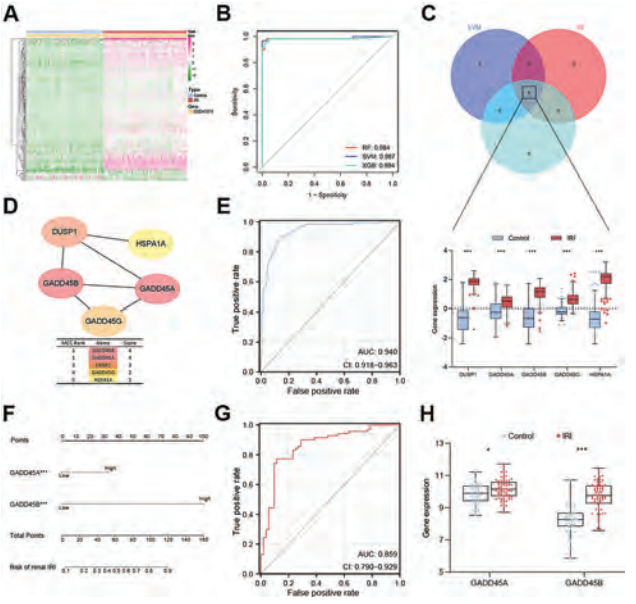
Background: The role of chromatin regulators (CRs) in the pathogenesis of renal ischemia-reperfusion injury (IRI) remains unclear.

Methods: We performed a bioinformatic analysis on the differentially expressed genes of CRs in renal IRI patients using machine learning methods. The hub CRs identified were used to develop a risk prediction model for renal IRI, and their expressions were validated using a murine renal IRI model. We also examined the relationships between hub CRs and infiltrating immune cells in renal IRI.

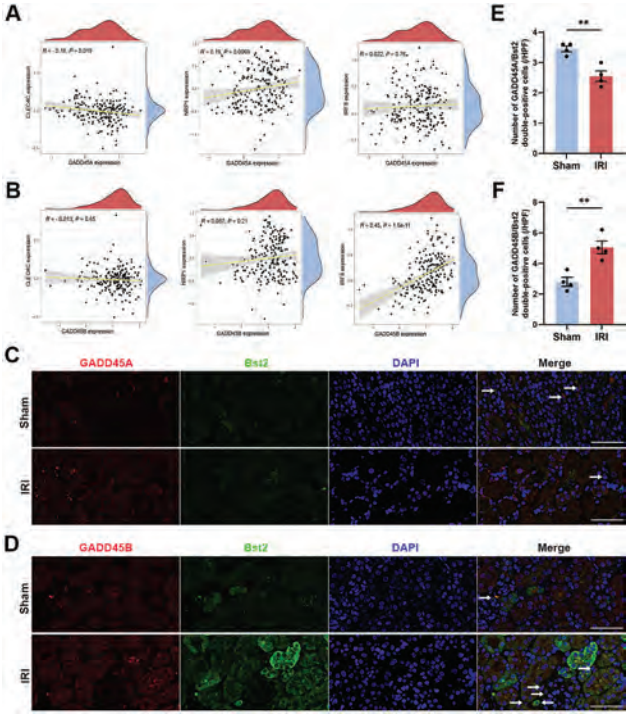
Results: GADD45A and GADD45B were upregulated in renal IRI. GADD45A and GADD45B were chosen to develop a renal IRI risk prediction model and showed good performance. GADD45A and GADD45B showed correlations with plasmacytoid dendritic cells (pDCs) in infiltrating immune cells analysis.

Conclusions: Dysregulation of GADD45A and GADD45B is related to renal IRI and the infiltration of pDCs.

Funding: Government Support - Non-U.S.



Identification of CRs-associated differentially expressed genes in renal ischemia-reperfusion injury using machine learning models, construction and validation of a CRs-associated predictive nomogram.



Correlation analysis of GADD45A and GADD45B expression with cell surface markers of pDCs in renal IRI.

FR-PO730

Renal Denervation Is Protective Against the Development of CKD in a Rat Model of Tacrolimus Nephrotoxicity

Alexander R. Dayton, Mariana Ruiz Lauar, Jaryd Ross, Louise C. Evans, John Osborn. *University of Minnesota Twin Cities, Minneapolis, MN.*

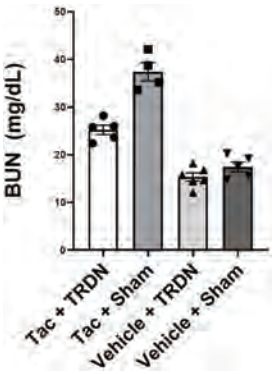
Background: Tacrolimus is the most widely used immune suppressant medication after solid-organ transplant, however it is associated with significant morbidity due to nephrotoxicity and the development of chronic kidney disease. It has recently been appreciated that recipients of transplanted kidneys, which lack intact renal nerves, have a lower incidence of tacrolimus-induced nephrotoxicity. Here we present data demonstrating that denervated kidneys are protected from the development of tacrolimus nephrotoxicity in rats.

Methods: Male and female Sprague-Dawley rats (n=6) underwent either total renal denervation (TRDN) or sham denervation and were subsequently treated with either 2 mg/kg tacrolimus for 14 days or the equivalent dose of vehicle. At the end of treatment BUN was assessed as a marker of renal function. Histology was performed to assess renal fibrosis and glomerulosclerosis. RNA was extracted from the cortex and medulla, and then transcriptome was assessed.

Results: BUN was significantly lower in TRDN animals compared to sham(26 vs 38 mg/dl, $p < 0.01$). Additionally, medullary fibrosis was decreased in denervated rats. RNA-sequencing studies to further investigate the mechanism behind this protection are ongoing.

Conclusions: These findings present an exciting new avenue for the use of renal denervation – if confirmed these would provide the foundation for prophylactic renal denervation in non-renal transplant patients requiring tacrolimus.

Funding: Other NIH Support - R01 HL 116476, T32 HL 144472



Tacrolimus treatment for 14 days induces substantial renal dysfunction. Total renal denervation (TRDN) decreases BUN significantly compared to sham denervation.

FR-PO731

Angiotensin-Converting Enzyme 2 in Delayed Graft Function After Kidney Transplantation

Cosimo L. Cianfarini, Jan Wysocki, Jiao-Jing Wang, Minghao Ye, Zheng J. Zhang, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Delayed graft function (DGF) is a severe form of acute kidney injury occurring post kidney transplantation. There is clinical evidence that the renin angiotensin system (RAS) is overactive in DGF. Angiotensin converting enzyme 2 (ACE2) is a RAS enzyme abundantly present in the kidney and localized in the apical brush border of the proximal tubule where it metabolizes Angiotensin II (Ang II) to form Angiotensin 1-7 thereby protecting from undesirable Ang II accumulation. Here we studied the expression and distribution of ACE2 in a mouse model of DGF.

Methods: Syngeneic kidney transplantation was performed between male C57BL/6 mice using donor kidneys exposed to 3hrs of cold ischemia. The transplanted kidneys (n=9) were harvested 48hrs after surgery and stained for ACE2 by immunohistochemistry (IHC). ACE2 protein was assessed by Western Blot and enzymatic activity using a fluorogenic substrate. Molecular markers for kidney damage and inflammation were assessed by Real-Time PCR. Kidney Angiotensin II levels were measured by ELISA.

Results: In mice with DGF, BUN was increased above 100mg/dl and NGAL and KIM-1 were increased in the kidney cortex. Markers of inflammation and immune cell invasion (IL-6, MCP-1, CD68, CD11b) were increased as well. Kidney Ang II levels were increased 2-fold (1.6±0.2 vs 0.7±0.06 pg/mg total protein, p=0.001) and ACE2 staining by IHC revealed profound alterations in the distribution of apical tubular ACE2 as compared to the healthy contralateral kidney. Tubules were widened and filled with ACE2 positive material, particularly in the corticomedullary region. The medulla showed luminal deposition of ACE2 positive material whereas staining was totally absent in the healthy contralateral kidney. These alterations were associated with decreased kidney ACE2 protein (57±13 vs 100±13 ACE2/GAPDH, p=0.03) and decreased ACE2 enzymatic activity (7.4±0.5 vs 9.3±0.6 RFU/µg total protein/h, p=0.03).

Conclusions: In mice with DGF post kidney transplantation there is a striking maldistribution of tubular ACE2 with loss of apical membrane bound full-length ACE2 into the tubular lumen. This loss results in decreased kidney ACE2 protein, enzymatic activity and increased kidney Ang II. The deficiency of this protective enzyme suggests that its replenishment could have an important therapeutic implication for DGF.

Cellular Responses to BK Polyomavirus Infection in Transplanted Kidneys

Phillip J. McCown,[1] Tess A. Marvin,[2] Rachel S. Sealfon,[3] Fadhl Alakwaa,[1] Evan A. Farkash,[1] Edgar A. Otto,[1] Felix H. Eichinger,[1] Rajasree Menon,[1] Celine C. Berthier,[1] Tavis J. Reed,[2] Paula A. Arrowsmith,[1] Kelly Shaffer,[1] Michael Imperiale,[1] James M. Pipas,[4] Olga Troyanskaya,[2,3] Matthias Kretzler,[1] Chandra L. Theesfeld,[2] Abhijit S. Naik.[1] *[1]University of Michigan Michigan Medicine, Ann Arbor, MI; [2]Princeton University, Princeton, NJ; [3]Flatiron Institute, New York, NY; [4]University of Pittsburgh, Pittsburgh, PA.*

Background: BK virus (BKV) infection remains problematic following kidney transplantation. Despite delineation of tubular responses in cell culture, the effect of an immune system on the cell-specific response *in vivo* to BKV is less well-understood.

Methods: Single-cell RNA sequencing of kidney biopsies (12 surveillance, 5 peak viremia, and 9 resolving viremia) from the Michigan Human Kidney Transplant Transcriptomic Atlas study were analyzed for cell type-specific transcriptomic responses to viremia and viral nephropathy and compared with healthy surveillance biopsies and BKV infected cells in culture.

Results: BKV transcripts were found in tubular cells and immune cells, confirmed in lymphoid clusters by VP1 immunohistochemistry. Cytokine signaling, cell-cycle regulation, translation, and wound healing were activated in BKV-infected tubular cells but not in tubules of viremic patients without nephropathy where stress-signaling and immune response predominated. During peak viremia there was an expansion of adaptive but not innate immune response. BKV-infected tubules showed increased cytokine, interferon γ, and tumor necrosis factor (TNF) signaling in humans. In contrast, TNF signaling was reduced in cell cultures.

Conclusions: Differential transcriptional responses to BKV infection *in vivo* and *in vitro* highlight the complex cellular and immune crosstalk not captured in 2D models. These findings also point towards exploration of anti-TNF therapies for BKV.

FR-PO733

Cyclosporine Distinctly Damages Proximal Tubules, Tacrolimus the Filtration Barrier in Calcineurin Inhibitor Nephrotoxicity

Hasan Demirci, Suncica Popovic, Duygu Elif Yilmaz, Kerim Mutig, Sebastian Bachmann. *Charite Universitatsmedizin Berlin, Berlin, Germany.*

Background: Calcineurin inhibitors (CNI) are the backbone for immunosuppression after solid organ transplantation. Although succesful in preventing kidney transplant rejection, their nephrotoxic side affects notoriously contribute to allograft injury despite attempts to optimize their application, often with additional medications. Complex renal parenchymal damage occurs for cyclosporine A (CsA) as well as for the currently favoured tacrolimus (Tac). We asked whether CsA and Tac exert distinct damage patterns during onset stages CNI nephropathy. We combined mulitomics analysis with histopatholgy from rat kidney exposed to continuous CNI delivery.

Methods: CsA and Tac were administered chronically in wild type Wistar rats using osmotic minipumps (total n=112) over 4 weeks. Physiological parameters were controlled. Animals were prepared for high-end morphological analysis, elective immunostaining, and multiomics analysis. Large scale electron microscopy, confocal stimulated emission-depletion (STED) and 3D-structured illumination microscopy were used for pathology. Standart biochemistry, RNAseq, proteomic, and phosphoproteomic technology was performed to identify molecular alterations.

Results: Damage forms varied strikingly. Both drugs caused significant albeit differential damage in vasculature and nephron. The glomerular filtration barrier was more affected by Tac than CsA, showing prominent deteriorations in pore endothelium and podocytes along with impaired VEGF/VEGFR2 signalling and podocyte-specific gene expression. By contrast, proximal tubule epithelia were more severely affected by CsA than by Tac, revealing lysosomal dysfuction and enhanced apoptosis and necrosis along with impaired proteostais and oxidative stress.

Conclusions: We conclude that pathogenic alterations in renal microenvironments are specific for either treatment. Should this translate to the clinical setting, CNI choice should reflect individual risk factor for renal vasculature and tubular epithelia. As a step in this direction, we share products identified from multiomics for differential pathonomonic biomarkers.

Human Kidneys House Tissue-Resident B Cells with a Distinct Anatomical Location and Phenotype that Changes with Age

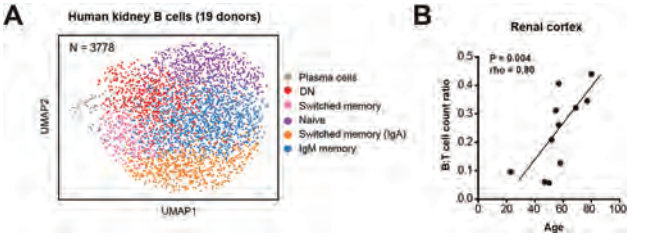
Ondrej Suchanek,[1,2] Benjamin J. Stewart,[1,2] Menna R. Clatworthy.[1,2] *[1]University of Cambridge, Cambridge, United Kingdom; [2]Cambridge University Hospitals NHS Foundation Trust, Cambridge, United Kingdom.*

Background: B cells play a central role in humoral immunity but have also antibody-independent functions, important for generating local immune responses and tolerance. Kidneys are the most commonly transplanted solid organ worldwide but whether they harbor B cells in homeostasis and how they change with donor age has received little attention.

Methods: We examined the number, phenotype and clonality of B cells in human kidneys that were perfused to remove circulating cells, and in matched splenic tissue obtained from the same transplant donor (N=19, median age 56 years (range: 18–80). Suspensions from homogenized organs were analyzed using a 35-marker mass cytometry panel and single-cell RNA sequencing (Figure A). B cells were also sorted for bulk BCR-sequencing.

Results: The frequency of B cells within kidney CD45$^+$ cells was lower than in spleen (8.8% vs. 26%, P<0.005). The renal cortex harbored ten times more B cells per gram of tissue than medulla. In contrast to spleen, B cell count and B:T cell ratio in renal cortex significantly increased with age (Figure B). Kidney B cells were enriched for non-naïve (CD27$^+$IgD$^-$ and double-negative) subsets with innate-like characteristics when compared to spleen or younger donors. BCR analysis showed CDR3 repertoire differences between kidney and spleen, suggesting a specific antigenic exposure, but also clonotypes sharing between matched organs and across donors.

Conclusions: Our study shows that under homeostatic conditions, human kidneys harbor both antigen-experienced and innate-like B cells, mirroring studies of murine tissue-resident T cells. These cells expanded with age and showed a specific anatomical location to the outer part of the kidney, an area specialized for filtration of blood. These kidney B cells may play a role in local immune defense or contribute to immunopathology (autoimmunity, organ rejection), and further studies on diseased tissues and murine models are underway.



FR-PO735

Cell-Specific Expression of Class II HLA Genes in Rejecting Kidney Transplant Biopsies by Single-Cell RNAseq

Andrew F. Malone, Aidan Leckie-Harre, Venkatrao Nunna, Benjamin D. Humphreys, Chang Liu. *Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Antibody-mediated rejection (AMR) remains one of the major causes of allograft failure. Anti-HLA antibody binding to endothelial cells is thought to be a central event driving AMR. Expression of both alpha and beta chains encoded by class II HLA genes is required for complete HLA class II protein expression on the cell surface.

Methods: We determined the expression of HLA-DR and HLA-DQ genes from single cells from two datasets of human kidney transplant biopsies. The proportion of cells expressing both alpha and beta chains for HLA-DR (DRA/DRB1, or DRab hereafter) and for HLA-DQ (DQA1/DQB1 or DQab hereafter) was determined across all rejection phenotypes. The gene expression pattern in endothelial cells with DRab or DQab was compared to that of endothelial cells not expressing DRab or DQab.

Results: We analyzed two datasets for this study: A) 81139 cells from 5 biopsies (AMR or no-rejection) published previously, and B) new data of 31,203 cells from 11 biopsies (no-rejection, AMR, TCMR or mixed). In dataset A, DQab expression was restricted to endothelial cells (EC) and immune cells with little expression in other cells of the kidney. DRab was widely expressed in all cell types. Similar profiles were found in dataset B (fig1a+b). In EC, *PLA1A*, a molecular marker for AMR, showed a significantly increased expression in EC positive for DQab or DRab when compared to EC negative for DQab/DRab (fig1c+d).

Conclusions: Cell specific class II HLA gene expression can be determined from single-cell RNAseq data. Expression of DQab/DRab in ECs is associated with molecular markers for AMR, which may provide diagnostic and mechanistic insight for AMR.

FR-PO736

Kidney Storage at Subzero Temperature Is Safe for Porcine Auto-Transplantation: A World First In Vivo Study

Francisco M. Calderon Novoa,[1,2] Tunpang Chu,[1] Masataka Kawamura,[1] Kaitlin Lees,[2] Sujani Ganesh,[1] Christian Hobeika,[1] Samrat Ray,[1] Catherine Parmentier,[1] Emmanuel Nogueira,[1] Laura Martínez-Arenas,[1] Rachael K. Conliffe,[1] Lisa Robinson,[2,1] Markus Selzner.[3,1] Toronto Organ Preservation Lab. *[1]University Health Network, Toronto, ON, Canada; [2]Sick Kids Foundation, Toronto, ON, Canada; [3]Toronto General Hospital, Toronto, ON, Canada.*

Background: Static cold storage (SCS) at 4°C remains the method of choice for kidney preservation prior to transplantation, but the rapid decline of graft quality at 4°C limits prolonged SCS and graft exchange over larger distances. Kidney storage below 0°C could prolong graft viability and offer new opportunities for kidney graft exchange over larger distances, or controlled scheduling of kidney transplant. The aim of this study was to determine the feasibility of sub-zero storage followed by auto-transplantation of porcine kidneys.

Methods: Kidneys were retrieved from Yorkshire pigs and either stored at 4°C for five hours (n=4) or flushed and stored using a novel preservation solution (CrS SC 0.3 EQ, Cryostasis Inc®) at –2°C (n=4). After storage, kidneys were auto-transplanted.

Results: All kidneys were successfully transplanted and immediately produced urine. Results were compared between the two groups, and assesed using T-test or ANOVA. Creatinine values at days 1, 3 and 7 for the -2°C and 4°C groups were 3.07 vs. 3.05 mg/dL, 3.28 vs. 2.84 mg/dL, and 1.4 vs.1.54 mg/dL, respectively (p>0.05). 24-hour urine output was 1700 ml (562.5 - 3250 ml) vs. 1700 ml (1450- 2650 ml) for -2°C and 4°C groups. Lactate values at 1, 3 and 7 days were 0.9 vs. 1.1, 0.75 vs. 0.56, and 0.95 vs. 0.88 mmol/L (p= 0.34). AST levels at 1, 3 and 7 days were: 152.3 vs.101.6, 33.3 vs. 27.8 and 25 vs. 22.8 U/L (p>0.05). Potassium levels were 4.8 vs. 4.2, 4.3 vs. 3.8 and 4.2 vs. 4.4 mmol/L at days 1, 3 and 7 (p=0.05).

Conclusions: Sub-zero short storage of porcine kidneys is feasible and results are comparable to ideal heartbeating-donor kidneys briefly stored at 4 °C. Histological, celular and molecular analyses are underway to better understand sub-zero protective mechanisms, and its extents will be further studied by prolonging storage times.

Sirolimus Toxicity Manifested with Fanconi Syndrome in a Kidney Transplant Patient

Christopher F. Middleman, Megha R. Joshi. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Sirolimus, a mechanistic target of rapamycin (mTOR) inhibitor, decreases antigen and cytokine stimulated T-lymphocyte activation and proliferation, and inhibits antibody production. It has been shown to prolong kidney allograft survival, and reverse acute rejection. In transplant patients with recurrent basal and squamous cell carcinomas, sirolimus is frequently used to prevent or reduce recurrence of these malignancies. This case highlights a rare but important to recognize side effect of the drug and how it can be managed.

Case Description: A 75-year-old female, with end stage kidney disease due to hypertension, received a living related kidney transplant in 2017. Over the next 5 years her course was complicated by recurrent non-melanomatous skin cancers requiring multiple Mohs surgeries. Immunosuppressive therapy was changed from tacrolimus to sirolimus to reduce skin cancer recurrence while preventing rejection. The sirolimus trough goal was 4-6 ng/mL. Her baseline serum creatinine (sCr) was 0.8-0.9 mg/dL without proteinuria. Within two months of transitioning to sirolimus, she developed lower extremity edema, loss of appetite and generalized fatigue. She was found to have proteinuric acute kidney injury with 1.6 gm protein/gm Cr, sCr 1.1mg/dL, hypokalemia (2.8 mmol/L) and hypophosphatemia (2.3 mg/dL). Sirolimus trough level was 12.9 ng/mL. Further urine testing revealed elevated fractional excretions of potassium, phosphorus, and uric acid. The sirolimus dose was reduced, with subsequent normalization of serum creatinine, electrolytes, and complete resolution of proteinuria. The patient's symptoms also resolved.

Discussion: Long-term use of sirolimus may be associated with proteinuria and sCr increases in kidney transplant patients, however this is the first case to our knowledge where a supratherapeutic level of sirolimus induced a generalized proximal tubular dysfunction (i.e., Fanconi's syndrome), which completely resolved with dose reduction to therapeutic range. As sirolimus is increasingly used in the setting of non-melanomatous skin cancers after kidney transplant, improving awareness and early diagnosis and treatment of associated Fanconi syndrome is critical for allograft survival. *Disclaimer: The views expressed in this abstract are those of the authors and do not reflect the official policy of the Department of Defense, or the United States government.*

FR-PO738

Transplant Renal Artery Embolization: An Alternative to Transplant Nephrectomy in Patients with Graft Intolerance Syndrome

Imran Chaudhri, Martha Pavlakis. *Beth Israel Deaconess Medical Center, Boston, MA.*

Introduction: A subset of patients with failing renal allografts can develop what is known as graft intolerance syndrome (GIS); characterized by fever, malaise, hematuria, and graft tenderness. Traditionally, this was treated by surgical removal of the allograft, but embolization of the transplant renal artery is a potential alternative. Here, we describe a case of GIS with rapid resolution using non-surgical management.

Case Description: A 61-year-old man with history of type 2 diabetes, hypertension, hyperlipidemia, and end stage kidney disease (ESKD) presented in August 2022 with acute onset right lower quadrant (RLQ) abdominal pain. He had a deceased donor kidney transplant in December 2018 and his post-transplant course had been complicated by multiple episodes of acute antibody- and cell-mediated rejection. During this time, his immunosuppression was adjusted multiple times and in June 2022, he was admitted for volume overload and hyperkalemia and was initiated on hemodialysis. On that discharge, he was instructed to continue on a prednisone taper and mycophenolate. Despite these instructions, the patient stopped taking his immunosuppression on his own and subsequently presented with abdominal pain in August 2022. On exam, he was hypertensive to 190/76 and had tenderness to palpation over his allograft. Computerized tomography (CT) of his abdomen showed that his allograft kidney was enlarged at 14 cm by length. A diagnosis of GIS was made. A multidisciplinary discussion between transplant surgery, transplant nephrology, and interventional radiology (IR) occurred and in the end, percutaneous renal artery embolization was pursued by IR. His symptoms resolved, and he was discharged 2 days after the procedure.

Discussion: Traditionally, when GIS is treated with transplant nephrectomy, reported complications include infection, bleeding, human leukocyte antigen sensitization, and death. Transplant renal artery embolization is less invasive, associated with shorter length of stay and, in some studies, with reduced mortality and morbidity. Our patient obtained almost immediate relief with a much less invasive approach and continues to be symptom free. In summary, this case illustrates that renal artery embolization of the allograft can be an effective and safe alternative to transplant nephrectomy in patients with GIS.

FR-PO739

Rare Case of Renal Vein Thrombosis in a Transplanted Kidney with Successful Endovascular Thrombectomy

Hywel Soney, Victor E. Serrano-Santiago, Kosunarty Fa, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Transplant-associated renal vein thrombosis (RVT) is a rare complication in kidney transplant recipients, with high risk of allograft loss and further complications. Here, we present a case of RVT managed by endovascular thrombectomy.

Case Description: A 75-year-old African American female with a history of ESRD due to T2DM, underwent deceased donor renal allograft implantation with Thymoglobulin induction, maintenance with mycophenolate, tacrolimus, and prednisone, and was discharged without complications and stable Creatinine (Cr) 1.0 mg/dL. She was readmitted 4 weeks after transplant for diminished urine output, hypotension, and elevated Cr (2.8 mg/dL). Urinalysis on admission demonstrated >100 red blood cells along with 5-10 white blood cells. Doppler ultrasound demonstrated elevated intrarenal resistive indices, reversed diastolic flow in the renal artery, deep vein thrombosis from the right common femoral vein through the popliteal vein, and with a nonocclusive thrombus in the iliac vein straddling the anastomosis. With high suspicion for RVT, the patient underwent a successful endovascular thrombectomy. Follow-up renal ultrasound demonstrated normalized transplant renal flow dynamics and correction of the reversed diastolic flow in the iliac arteries. Allograft biopsy was performed with findings of acute tubular necrosis and no evidence of rejection. During this time, the patient's Cr peaked at 6.9 mg/dL with intermittent need for vasopressors and continuous renal replacement

therapy. Within the following two weeks, the patient's urine output and Cr recovered to baseline status and she was continued on anticoagulation thereafter.

Discussion: RVT in new transplants has a high risk of poor outcomes. Events usually occur within the first two weeks and can present with worsening renal function, oliguria, hematuria, and/or abdominal pain. Early detection with Doppler ultrasound is key to evaluating for potential RVT and initiating further diagnostic actions or interventions to prevent complications. Interventions may include direct surgical thrombectomy, endovascular thrombectomy or thrombolytic therapy, although studies are lacking in identifying an optimal first-line intervention. Having a high suspicion for RVT and acting quickly is vital in avoiding critical complications in new allografts.

FR-PO740

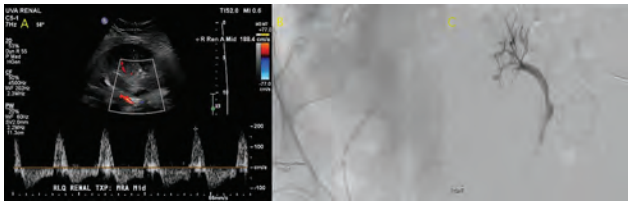
Transplant Renal Vein Thrombosis

Monarch Shah, Swati Rao, Angie G. Nishio Lucar. *University of Virginia, Charlottesville, VA.*

Introduction: Transplant renal vein thrombosis (TRVT) is a dire complication of kidney transplantation and can lead to graft failure. This case highlights the importance of awareness of this infrequent complication and the importance of reviewing donor anatomy to assist in timely diagnosis.

Case Description: A 40-year-old male with ESKD due to IgAN diagnosed at 17 was on peritoneal dialysis since age 36 and underwent a deceased donor kidney transplant (KT). The KDPI was 12%, calculated PRA were 0%, and EPTS was 13%. The donor renal artery was anastomosed to the recipient's external iliac artery. As the right renal vein (RV) is shorter an IVC extension graft is utilized for anastomosis. Despite the atypical incision on the donor IVC, the surgeon achieved a good extension for anastomosis to the recipient's external iliac vein. The kidney perfused well with immediate graft function. Immunosuppression induction was with anti-thymocyte globulin and steroids and maintenance with MMF and tacrolimus. Creatinine improved to 1.8 mg/dl by POD4 (9.4 mg/dl preoperatively). He was re-admitted on POD 8 with hematuria, abdominal pain & reduced urine output. Creatinine was 2.4 mg/dl. CT scan showed a hypoattenuating KT. Ultrasound (fig A) showed diastolic reversal of arterial flow and absence of RV doppler signal. Venography showed thrombosis of the transplant RV up to the anastomosis. Rheolytic thrombectomy of the transplanted RV, balloon angioplasty (Fig B), and stent placement of the juxta-anastomotic stenosis was done with fast outflow (Fig C) seen from the allograft. The allograft was salvaged & urine output is > 1L/day, but he is dialysis dependent. The venous stent thrombosed 2 months post-transplant requiring thrombectomy and balloon angioplasty. Currently, the allograft outcome remains guarded.

Discussion: AKI in transplant patients has a broad differential, and there should be a high suspicion index for TRVT. Knowing donor anatomy and the operative course aids in rapid diagnosis. Despite prompt therapy, TRVT causes profound ischemic damage leading to allograft loss and nephrectomy.



A: Diastolic reversal of arterial flow, B: Balloon angioplasty of the juxta-anastomotic segmental stenosis, C: Fast outflow from the allograft

FR-PO741

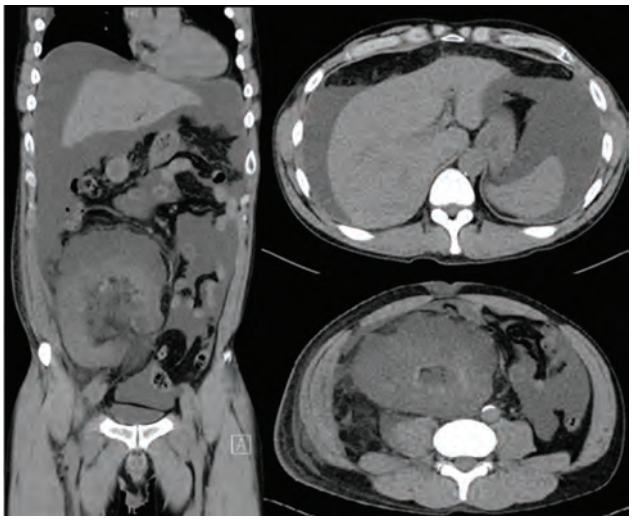
Renal Allograft Lymphangiectasia After Kidney Transplantation

Eun jeong Ko, Byung ha Chung, Chul Woo Yang. *The Catholic University of Korea, Seoul, Republic of Korea.*

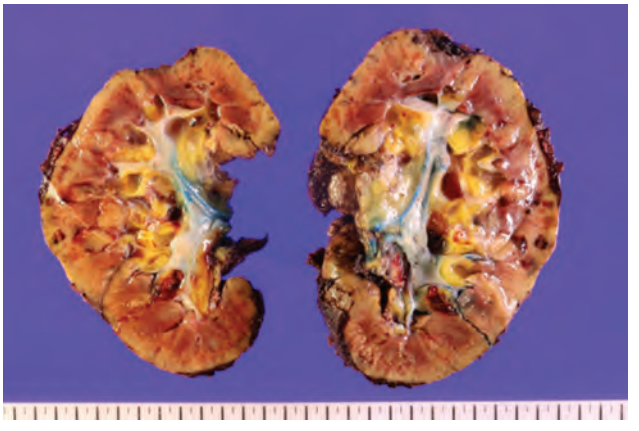
Introduction: Renal lymphangiectasia is a rarein the setting of transplant kidney. We report a case of renal lymphangiectasia after kidney transplantation

Case Description: A 43-year-old man received living donor kidney transplantation due to IgA nephropathy. 14 years after transplantation, he presented with abdominal distension, and dyspnea. Serum creatinine level was elevated to 1.6mg/dL from 1.1mg/dL. Computed tomography (CT) showed multi-septated cystic lesions around the graft kidney with a large amount of ascites. Ascites profile showed transudative, non-chylous, suggesting lymphatic fluid. There was no evidence for infectious or malignant disease. At first, tacrolimus was switched to sirolimus for anti-lymphangiogenic effect, consequently the amount of ascites was significantly reduced. However, 3 weeks after, large amount of ascites were recurred. Surgical approach with explore laparotomy, argon coagulation and helixor injection through Hemo-vac drain were performed. Also, lymphatics embolization was performed using lipiodol. Nevertheless, massive ascites recurred just after 1 week from procedures, therefore, allograft nephrectomy was inevitable

Discussion: Post-transplant renal lymphangiectasia is a rare but critical complication of allografts, still poorly understood. However, once it happens, active treatment is required.



Abominal computed Tomography



Gross pathology of transplant nephrectomy

FR-PO742

Unrecognized Ureteral Injury After Attempted Hysterectomy in Transplant Patients

Amber Anwar, Saed Shawar, Kareem Eid. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Although frequently overlooked, ureteral injuries are well-documented complications following gynecologic surgeries, potentially causing acute kidney injury and failure. To mitigate these undesirable outcomes, involvement of a multidisciplinary team, including transplant surgeons, is highly recommended in complex patients. We present a unique case of a simultaneous pancreas-kidney transplant patient with an unrecognized ureteral during an attempted hysterectomy.

Case Description: A 42-year-old woman with End-Stage Renal Disease due to Type 1 Diabetes Mellitus and status post simultaneous kidney and pancreas transplant in 05/2021. Induced with Alemtuzumab and Solumedrol and maintained on Tacrolimus, Mycophenolate Mofetil, and Prednisone, with creatinine range 0.8-1mg/dl, alongside normal amylase and lipase levels. In 07/2022, the patient attempted a laparoscopic hysterectomy at a local hospital for unresolved menorrhagia. However, the surgery was abandoned due to extensive intraabdominal adhesions, with partial adhesiolysis performed before closure. Following discharge on the same day, she presented with acute abdominal pain, anuria and rise in creatinine 11mg/dl from 0.93mg/dl. CT scan revealed an edematous transplant kidney with hydroureteronephrosis and intra-abdominal and pelvic ascites. The Transferred to Vanderbilt University Medical Center, where ultrasound confirmed hydroureteronephrosis and a discontinuity of the ureter with the bladder. In addition, CT cystogram showed lack of opacification of the reimplanted ureter, concerning for ureteral injury. An urgent laparotomy was performed by a multidisciplinary team of urologists and renal transplant surgeons, resulting in drainage of three liters of urine from the abdominal cavity and the identification of a transected ureter above the urinary bladder. Assisted cystourethroscopy was utilized to repair and reimplant the ureter to the urinary bladder, resulting in the resumption of urine output and a rapid decrease in creatinine levels to baseline.

Discussion: For complex intra-abdominal or pelvic surgeries, involvement of transplant surgeons is paramount. Negligence can lead to significant postoperative complications, such as acute kidney injury, increasing morbidity and mortality. Prompt interventions, like ureteral repair and reimplantation conducted in this case, can lead to a remarkable recovery from severe complications.

FR-PO743

Infection: A Potential Trigger of Recurrent C3 Glomerulonephritis in a Kidney Transplant Recipient

Amber Anwar, Sarah Abu Kar, Laura Binari, Yihan Wang, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: C3 Glomerulonephritis (C3GN) is a rare kidney disease caused by dysregulation of the alternative complement pathway through genetic or acquired alteration in regulatory protein. 67- 84% of kidney transplant recipients have recurrence within median time of 14-28 months and graft loss at 18 months after diagnosis. Therapy for recurrent C3GN can include immunosuppression, plasmapheresis, and complement targeting agents like Eculizumab. We present a case of recurrent C3GN in a kidney transplant recipient.

Case Description: A 57-year-old male with end-stage kidney disease secondary to C3GN on monthly Eculizumab underwent a living unrelated kidney transplant with Alemtuzumab and Solumedrol for induction. He had immediate graft function with nadir creatinine (Cr) of 1.05 mg/dL and urine protein of 0.1g/g, and maintenance immunosuppression was Tacrolimus, Mycophenolate Mofetil (MMF) and Prednisone. Two months post-transplant, he was admitted with periodontitis treated with Augmentin. Also had neutropenia which improved with 3 doses of filgrastim and transient discontinuation of MMF, Bactrim and Valcyte. He was maintained on Tacrolimus and Prednisone 10mg. At 1 week follow up, Cr was 1.9 mg/dl attributed to CNI toxicity and Tacrolimus dose was adjusted. However, he soon after developed hypertension, hematuria, proteinuria (0.75g/g), thrombocytopenia and AKI with Cr 2.7 mg/dl. An allograft biopsy was performed, showed C3GN recurrence with mesangial proliferative GN with C3-dominant and monotypic IgG4 dominant deposits. Functional complement panel showed high C3 nephritic factor (34unit/ml). He was treated with 7 plasmapheresis sessions and reinduction with Eculizumab 900mg IV weekly for 4 weeks and then 1200mg every 2 weeks. A repeat C3 nephritic factor level was undetectable. At 3 months, the Cr stabilized at 2mg/dl and proteinuria resolved.

Discussion: We speculate that C3GN recurrence was triggered by infection and reduction in immunosuppression. Prompt control of disease activity can be achieved with removal of offending proteins via plasmapheresis and stabilization of complement activity with Eculizumab. Close surveillance is deemed necessary for control of disease progression.

FR-PO744

Hypercholesterolemia Is Associated with Cardiovascular Morbidity and Mortality Among Kidney Transplant Recipients

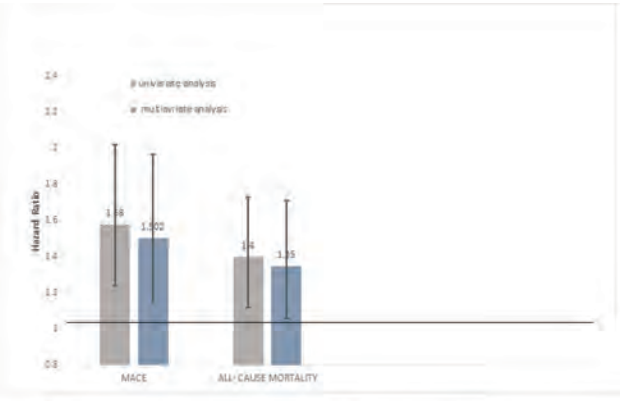
Timna Agur,[1,2] Noam Nagel,[2] Dana Bielopolski,[1,2] Tali Steinmetz,[1,2] Boris Zingerman,[1,2] Ruth Rahamimov,[1,2] Benaya Rozen-zvi.[1,2] *[1]Rabin Medical Center, Petah Tikva, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: Hypercholesterolemia is highly prevalent among kidney transplant recipients (KTR). Unlike the general population, the correlation between hypercholesterolemia and cardiovascular disease in KTR has not been well established. Therefore, we investigated the association between abnormal cholesterol profiles and cardiovascular morbidity and mortality in this unique population

Methods: We conducted a single-center retrospective cohort study that included all adult KTR who had a functioning graft for at least 12 months after transplantation, between January 2005 and April 2014. The primary outcome was a Major Adverse Cardiovascular Event (MACE) defined as non-fatal myocardial infarction, non-fatal CVA, coronary revascularization, hospitalization for acute coronary syndrome and cardiovascular mortality. The secondary outcome was all-cause mortality. To calculate exposure to abnormal cholesterol levels, we used a time-weighted average (TWA) calculation, for LDL-C and HDL-C. MACE risk was analyzed using a multivariate and univariate time-varying Cox model.

Results: The study included 737 KTR, with a median follow-up of 2920 days. The TWA level of LDL-C decreased from 91.6±22.8 mg/dL during the first year to 89.5±20.7 during the 7th year (p=0.021). The TWA level of HDL-C increased from 49.2±12.7 mg/dl to 50.5±13 (p=0.012). A total of 126 patients (17.6%) experienced a MACE event. A correlation was found between high LDL-C levels and MACE risk by multivariate analysis (HR 1.008 per mg/dL, 95%CI 1.001 – 1.016), while low HDL-C levels were not significantly associated with MACE (HR 0.992 per mg/dl, 95%CI 0.976 – 1.009). Higher LDL-C/HDL-C ratios were significantly associated with an increased risk of MACE in both univariate and multivariate analyses (HR 1.502, per unit, 95%CI 1.147-1.968), as well as all-cause mortality (HR 1.35 per unit, 95%CI 1.06 – 1.71).

Conclusions: Exposure to high LDL-C /HDL-C ratio among KTR is associated with an increased risk of cardiovascular morbidity and mortality



LDL/HDL ratio is associated with MACE and all-cause mortality by multivariate analysis.

FR-PO745

Hemophagocytic Lymphohistiocytosis in Adult Renal Transplant Patients: A Case Series of Three Patients

Swati Jain, Cindy T. Pynadath, Maria Ajaimy, Yang Shi, Yorg Al Azzi, Jay A. Graham, Enver Akalin, Luz E. Liriano-Ward. *Montefiore Health System, Bronx, NY.*

Introduction: Hemophagocytic lymphohistiocytosis (HLH) is a rare, life-threatening disease that presents with non-specific symptoms, leading to a delay in diagnosis and early initiation of treatment. We present 3 cases of HLH in renal transplant patients at our institution.

Case Description: 1) 40-year-old female with end stage renal disease (ESRD) on hemodialysis (HD), diabetes mellitus (DM), and hypertension (HTN) who underwent simultaneous kidney-pancreas transplant (SPK) with Thymoglobulin induction on 9/2021, admitted with neutropenia 2 months later. She developed fever, mental status changes, and cholestatic jaundice. CT abdomen showed mild hepatosplenomegaly. Labs showed WBC 0, plt 32, Hgb 6.6, ferritin 11k, CMV 1852, EBV 346, elevated soluble interleukin-2 (sIL-2). Bone marrow biopsy (BMB) revealed hemophagocytic cells. The probability of HLH was 54%-70% based on H score. She was treated with dexamethasone and Etoposide without response. She expired 2 months post presentation. 2) 34-year-old male with chronic kidney disease stage 5, DM, HTN who underwent SPK with thymo induction on 1/2022 admitted with fever and fatigue one month post-transplant. Labs showed WBC 0, plt 27, hgb5.4, ferritin 68k, CMV 1741, EBV 28600, transaminitis, and elevated sIL-2. The probability of HLH was 54-70% based on H score. BMB showed hypocellular marrow (5-10%) with many histiocytes and markedly decreased trilineage hematopoiesis. He received dexamethasone, eltrombopag and cyclosporine without response and expired 6 weeks post presentation. 3) 62-year-old male with DM, HTN, ESRD on HD, who underwent deceased donor kidney transplant with thymo induction on 9/2022, admitted with fever, malaise, and vomiting 4 months post-transplant. Labs showed hgb 6.7, ferritin >100k, elevated triglyceride and sIL-2. CT scan revealed splenomegaly, and BMB showed HLH secondary to histoplasmosis. He received Amphotericin with good response and was discharged 3 weeks after presentation.

Discussion: Idiopathic HLH carries a poor prognosis with high mortality, but HLH secondary to infection has better prognosis if the infection is treated successfully. Early identification and treatment are crucial to optimize outcomes.

FR-PO746

Hemophagocytic Lymphohistiocytosis After Kidney Transplantation

Lina Frauenfeld, Amer A. Belal, Alejandro J. Ruiz Toledo, Gianna M. Mercogliano, Shawna Lord, Rohan V. Mehta, Georgios Vrakas, Ashraf El-hinnawi, Alfonso Santos. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: Hemophagocytic Lymphohistiocytosis (HLH) is an immunological disorder resulting in blood cell phagocytosis. In kidney transplant (KT) recipients (KTR), HLH is usually secondary to infectious or neoplastic processes. Typical findings of HLH are fever, hepatosplenomegaly, cytopenia, hypertriglyceridemia, coagulopathy-related hypofibrinogenemia, liver dysfunction, and elevated ferritin. Early diagnosis with appropriate treatment is recommended.

Case Description: An 18-year-old man with ESRD due to Focal Segmental Glomerulosclerosis (FSGS) received a deceased donor kidney transplant (DDKT). Immunosuppression regimens were anti-thymocyte globulin for induction, and tacrolimus, mycophenolate, and prednisone for maintenance. On postoperative day (POD) 4, he developed a high-grade fever and acute kidney dysfunction with increased serum creatinine, proteinuria (507 mg/gm), and edema. Allograft biopsy showed isolated glomerulitis. Pertinent laboratory data included 6.8 103 /uL WBC, 1367/947 iu/L AST/ALT, and 2,329 iu/L LDH. Workup for infection revealed positive serum HSV PCR treated with IV acyclovir. Hemodialysis was initiated on POD 10 for anuria and hyperammonemia. The patient eventually met 5 out of 8 required HLH-1994 diagnostic

criteria including high SIL-2R level (3171.5 pg/mL), low NK cell (25 cells/uL), and hyperferritinemia (14,397 ng/mL). Etoposide was administered on POD 17 per the HLH-94 protocol along with cyclosporine and dexamethasone. The patient attained renal recovery around POD 50 after completing 9 doses of Etoposide. His hematologic and serum inflammatory markers have since normalized.

Discussion: HLH is a rare syndrome, with extremely high mortality due to an excessive immune activation triggered by events such as infections and immunosuppression that disrupt immune homeostasis. Rapid diagnosis and prompt treatment post-transplant are key to favorable outcomes. In this case, the most likely cause of secondary HLH was HSV infection aggravated by immunosuppressive medications. Current therapy protocols are almost exclusively validated in pediatric patients and for primary HLH. Our case demonstrates the safe and successful application of this treatment protocol in a young adult patient presenting with HLH after a KT.

FR-PO747

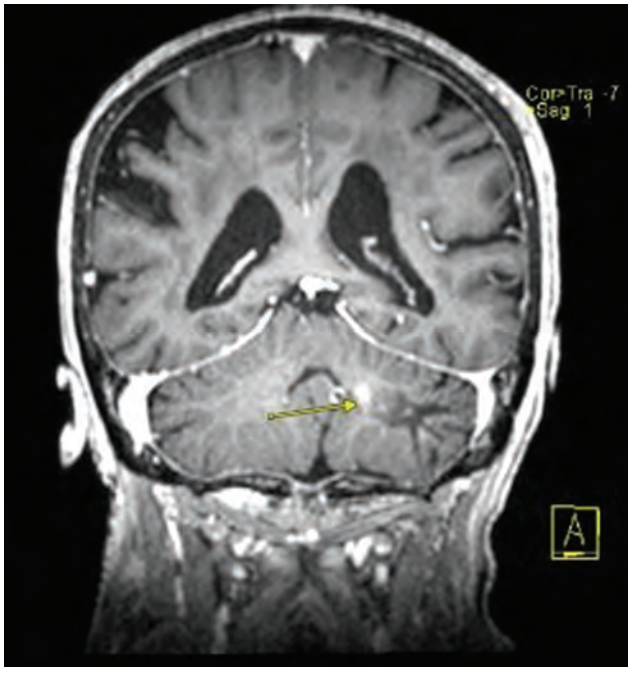
Progressive Multifocal Leukoencephalopathy (PML): A Dreaded Complication of Immunosuppression

Nora H. Hernandez Garcilazo, Sarthak Virmani, William S. Asch. *Yale School of Medicine, New Haven, CT.*

Introduction: JC virus (JCV) can cause progressive multifocal leukoencephalopathy (PML), a demyelinating disorder, in immunosuppressed patients. This infection may present with a variety of neurologic symptoms, ranging in severity and duration, usually identified by the area of white matter lesion. We share a case of a patient who presented with neurological weakness & was found to have PML in the cerebellar region yet no signs of cerebellar dysfunction.

Case Description: A 77-year-old lady, PMH of ESKD due to RPGN received a live donor KT in 2021, on MMF, prednisone & belatacept, presented with lower extremity motor weakness for 2 months without sensory deficits. No cause was identified on clinical exam & lab work. Allograft function was intact. A brain MRI showed a left cerebellar peduncle lesion and surrounding enhancement which did not explain her weakness. This prompted a biopsy that showed features of PML. CSF later resulted positive for JCV by PCR. To reduce her immunosuppression(IS) and belatacept effect, a plasmapheresis session was performed followed by administration of one dose of IVIG 25g. Unfortunately, the next day she had worsening headaches prompting a CT which revealed a large bleed in posterior fossa originating from the biopsy site. Given poor neurological prognosis, decision was made to transition to hospice care, and she died shortly after.

Discussion: PML is catastrophic in patients on chronic IS. It's insidious presentation makes it challenging for an accurate & timely diagnosis. While the site of white matter involvement is associated with signs & symptoms, one must be mindful that lack of classical findings should not rule out a diagnosis of PML. Lack of targeted treatment for JCV infection leaves (IS) withdrawal as the only option which becomes challenging in patients on novel agents with more prolonged half-lives.



FR-PO748

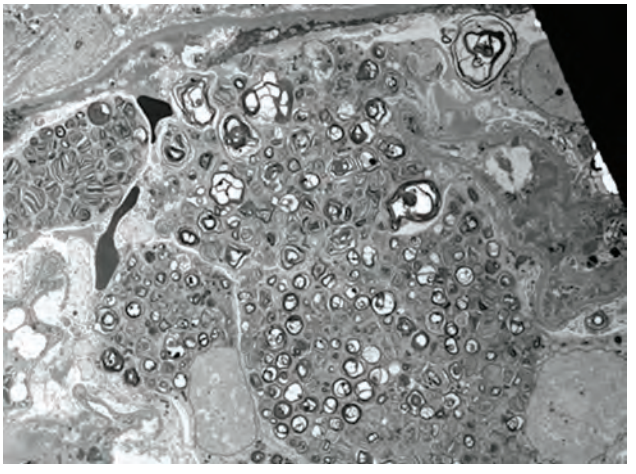
The Importance of Enzyme Replacement Therapy After Kidney Transplantation in Fabry Disease

Manal Alotaibi, Mohamed G. Atta, Daniel C. Brennan, Sam Kant. *Johns Hopkins University, Baltimore, MD.*

Introduction: Fabry disease(FD) is an X-linked disease caused by an enzyme alpha-galactosidase defect due to GLA gene mutations. It can lead to multi-organ involvement including kidneys, heart and nervous system. We present a case of Fabry disease in a patient who received a kidney transplant was initially unable to afford and continue enzyme replacement therapy(ERT) and developed extra-renal complications of FD

Case Description: A 51-year-old woman with a history of Fabry disease was referred to us with progressive kidney disease. The patient was diagnosed with Fabry disease at the age of 32 and subsequently received ERT. However, her therapy ceased due to medical insurance issues. She had progressive kidney disease and development of dilated cardiomyopathy. Genetic testing revealed a novel heterozygous mutation variant c.820G>C (p.Gly274Arg) in the GLA gene that was deemed of unknown significance. A native kidney biopsy revealed glomerular inclusions with diffuse renal parenchymal scarring, Figure 1. The patient was eventually prescribed agalsidase beta due to non-amenability to chaperone therapy with migalastat. However, she progressed to ESRD and subsequently received a kidney transplant with excellent function. She was prescribed agalisidase maintenance therapy. She was admitted 3 months posttransplant with chest pain and found to have increased septal hypertrophy and progression of aortic stenosis. The patient reported that she had been off agalsidase for over 9 months due to a recurrence of medical insurance issues.

Discussion: ERT and migalastat are currently the only approved specific therapies for Fabry disease. In patients with ESRD due to Fabry nephropathy, kidney transplantation is recommended. ERT is safe after kidney transplantation and recommended to be continued posttransplant for extrarenal manifestations, with observational studies demonstrating a slower increase in left ventricular mass index in transplanted patients who continued ERT.



FR-PO749

Combined Liver and Kidney Transplantation from Living Donors in a Young Patient with Primary Hyperoxaluria Type 1: A Case Report

Mohamed M. Ahmed, Magdy ElSharkawy, Hala Talkhan, Ahmed Emara. *Ain Shams University Faculty of Medicine, Cairo, Egypt.*

Introduction: Primary hyperoxaluria type 1 (PH1) is a rare autosomal recessive inherited disease, caused by mutations in AGXT gene. Combined liver kidney transplant (CLKT) is the preferred transplant option for most patients with PH1 since orthotopic liver transplantation replaces the deficient enzyme, thus restoring normal metabolic oxalate production.

Case Description: We present a case of a 27-year-old male with end-stage kidney disease (ESKD). The patient had a right nephrectomy due to recurrent renal stones and chronic pyelonephritis. Histological analysis of the right kidney revealed calcium oxalate deposition within tubules, and genetic testing confirmed the diagnosis of PH1 with a mutation in the AGXT gene. He was maintained on hemodialysis since 2020. Preoperatively, he patient received daily high flux hemodiafiltration (HDF) sessions for ten days. The CLKT was performed using living donors, with his mother donating a kidney and an unrelated person as a liver donor. Perioperative period was uneventful, with both grafts functioning well. His serum creatinine level returned to normal after three days, and his plasma oxalate level decreased from 65 to 22 μmol/L (normal ≤ 30 μmol/L) after 20 days postoperatively. The patient was maintained on immunosuppressive therapy consisting of prednisolone, mycophenolate mofetil, and tacrolimus after the surgery. The patient maintained stable graft function with no complications during the follow-up period. However, his 24-hour urinary oxalate level remained persistently high despite the normalization of his plasma oxalate level, necessitating the addition of pyridoxine and magnesium citrate to his medication regimen in addition to hyperhydration.

Discussion: This case report highlights the successful role of CLKT from living donors in a patient with PH1 with good outcome. Also, preoperative HDF dialysis intensification reduced the oxalate burden, and may reduce incidence of oxalate deposition postoperatively. Crystallization inhibitors may be used postoperatively for a long time to prevent urinary oxalate deposition.

FR-PO750

Primary Hyperoxaluria Type 3 Diagnosed After Kidney Transplant

Kirsten Martin, Marwa Abdalla, Chanigan Nilubol. *MedStar Georgetown University Hospital, Washington, DC.*

Introduction: Primary hyperoxaluria (PH) is a group of genetic disorders that lead to increased hepatic production of oxalate. PH type 3 (PH3), the most recently identified subtype results from mutations in the mitochondrial 4-hydroxy-2-oxoglutarate aldolase gene (HOGA1). To date, there have been 3 cases of kidney failure reported in PH3 patients. Here we report a case of a man with recurrent kidney stones in his childhood who was diagnosed with PH3 late in life after receiving a kidney transplant.

Case Description: A 74-year-old Norwegian man with a history of recurrent kidney stones since infancy leading to left nephrectomy at the age of 12 presented with proteinuric chronic kidney disease (CKD). His eGFR based on serum Cr of 2.6 mg/dL was 23 ml/min/1.73m^2. His urine protein-creatinine ratio was around 2 gm/gm. An ultrasound showed a 13.8 cm right kidney with 2 non-obstructing stones. His CKD was presumably due to secondary focal segmental glomerulosclerosis from adaptive hyperfiltration. Fifteen months later, he received a pre-emptive deceased donor kidney transplant out-of-state with an excellent allograft function. Due to the unclear diagnosis of his kidney disease, he completed a genetic testing panel which was positive for homozygous HOGA1 mutation. His 24-hr urine collection showed a mildly elevated oxalate level at 40 mg/day. This may have reflected his habitual dietary oxalate restriction since childhood. The differential diagnosis may have included oxalate nephropathy in his native kidney.

Discussion: Our case signifies the necessity of metabolic workup and genetic testing in patients with kidney stones, particularly in recurrent cases. PH3 was described as a less severe form of PH. Our case is unique in that despite his severe disease early in life, he did not progress into end-stage renal disease until 5 decades after his nephrectomy. Not until the recently FDA-approved Oxlumo (lumasiran), an RNA interference agent, as a medical therapy for PH type 1, the only curative treatment for PH had been a liver transplant or a combined liver/kidney transplant. While our patient may have missed the opportunity to receive a combined liver/kidney transplant, the impact of PH3 on his metabolic profile is mild and medically manageable. The RNA interference agents for PH type 2 and type 3 are being investigated but are not yet FDA-approved. Our patient may be a candidate for such therapy in the future.

FR-PO751

Opening New Frontiers: Nedosiran Enables Kidney-Only Transplantation for Primary Hyperoxaluria Type 1: A Case Report

Asma Nasir,[1] Elizabeth A. Harvey,[2] John C. Lieske,[3] Carmen Avila-Casado,[4] Christopher T. Chan,[5] Istvan Mucsi,[1] Mathieu J. Lemaire.[2] Ajmera Transplant Centre and Division of Nephrology, University Health Network, University of Toronto, Canada. *[1]Ajmera Transplant Centre and Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada; [2]Division of Nephrology, The Hospital for Sick Children, Toronto, ON, Canada; [3]Division of Nephrology and Hypertension, Mayo Clinic, Rochester, MN; [4]Department of Pathology, University Health Network, University of Toronto, Toronto, ON, Canada; [5]Department of Medicine, Division of Nephrology, University Health Network, University of Toronto, Toronto, ON, Canada.*

Introduction: Primary hyperoxaluria type 1 (PH1) is a genetic disorder caused by deficient activity of the liver enzyme alanine-glyoxylate aminotransferase (AGT) encoded by AGXT. PH1 is associated with overproduction of oxalate that is excreted into the urine, increasing the risk for formation of calcium oxalate crystals, nephrocalcinosis, urinary stones, and kidney failure. Recent short-term placebo-controlled trials have shown the efficacy of two new siRNA-based therapies, lumasiran and nedosiran, in reducing plasma oxalate concentrations and hyperoxaluria. While combined liver-kidney transplantation has been the preferred approach for PH1 patients with kidney failure, kidney-only transplantation may be a safe alternative for those who have responded well to siRNA-based therapy. Here we describe a successful kidney-only transplant in a PH1 patient treated with nedosiran.

Case Description: This adult male had recurrent (calcium oxalate) kidney stones from 2 years of age and was diagnosed with PH1 based on reduced AGT enzyme on liver biopsy; subsequently, AGXT mutations (c.508G>A, p.G170R, and C.744_delC) were confirmed. Although partially responsive to pyridoxine, he progressed to CKD. In early 2021, he was enrolled in a phase III study to receive nedosiran monthly. Due to an acute on chronic kidney injury, he began hemodialysis in July 2021. He received a living donor kidney transplant at age 29 in early 2023 while remaining on nedosiran. Immediately post-transplant, serum creatinine level plateaued at ~150 µmol/L. A transplant biopsy revealed minimal oxalate crystal deposition. Thus, daily hemodialysis was resumed on post-transplant day 6 for two weeks. Serum creatinine remained stable, and plasma oxalate remained low at 4-8 µmol/L, as did the urine oxalate/creatinine ratio <80µmol/mmol at three months post-transplant.

Discussion: We present a patient with PH1 who underwent a successful kidney-only transplant while receiving nedosiran to reduce hepatic oxalate production. To our knowledge, this is the first reported case of kidney-only transplant after initiating this agent. If long-term safety and efficacy are confirmed, a siRNA-based approach will change the care of PH1 patients with kidney failure since kidney-only transplantation is safer than combined liver-kidney transplantation.

FR-PO752

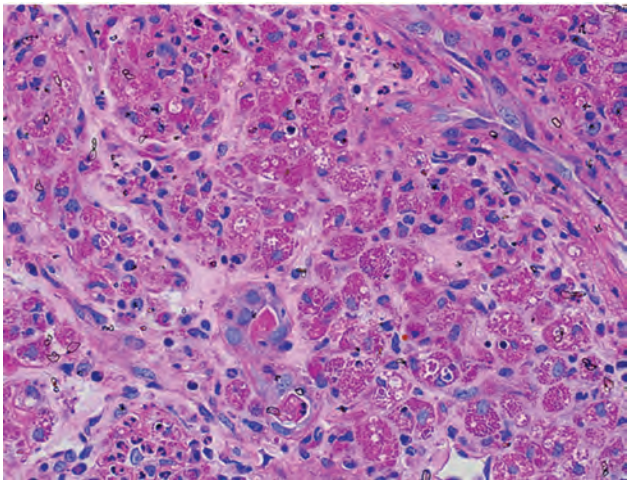
Megalocytic Interstitial Nephritis in a Renal Transplant Patient

Shilpa Sannapaneni, Elissa Foster, Akinwande A. Akinfolarin, Kim Rice. *Baylor Scott & White Health, Dallas, TX.*

Introduction: Megalocytic interstitial nephritis is a rare form of interstitial nephritis first describe by Zollinger in 1945. The exact mechanism of the pathology is unknown but is presumed to be secondary to impairment of bacterial clearance by neutrophils and macrophages, especially in immune-deficient patients. It is clinically identical to the ineffective inflammatory process called malakoplakia. Here we present a unique case of megalocytic interstitial nephritis in a renal transplant patient.

Case Description: A 68-year-old male with medical history of end stage renal disease who underwent a transplant allograft biopsy, 15 months prior, presented with volume overload and acute kidney injury. He was diagnosed with cirrhosis after his transplant and clinical course was complicated by recurrent ascites requiring paracentesis, upper gastrointestinal bleeding requiring variceal banding. His exam was significant for bilateral leg swelling, tense abdomen. Labs on presentation were significant for creatinine of 4.26 mg/dL which was up from his baseline of 1 mg/dL. He underwent paracentesis on admission and the peritoneal fluid analysis was consistent with spontaneous bacterial peritonitis. He was started on antibiotics. His kidney function did not improve and biopsy was performed which showed megalocytic infiltration. He remained dialysis dependent despite antibiotics.

Discussion: Our patient developed megalocytic interstitial nephritis in the setting of spontaneous bacterial peritonitis, likely as a consequence of seeding to the graft, in the setting of kidney transplant immunosuppression. It is a rare disorder and can only be diagnosed by histological examination. A high index of suspicion is required in immunosuppressed patients with slow renal recovery in setting of infection. Treatment of this disease includes antibiotics to control the infection and high dose steroids.



FR-PO753

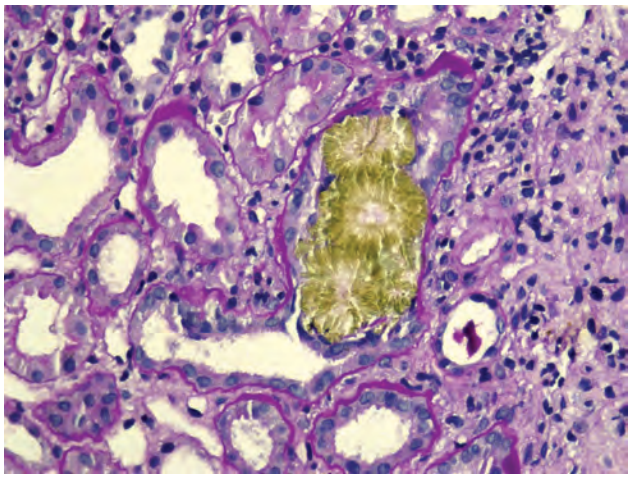
Adenine Phosphoribosyl Transferase (APRT) Deficiency as an Under-recognized Cause of Kidney Graft Failure: A Case Report

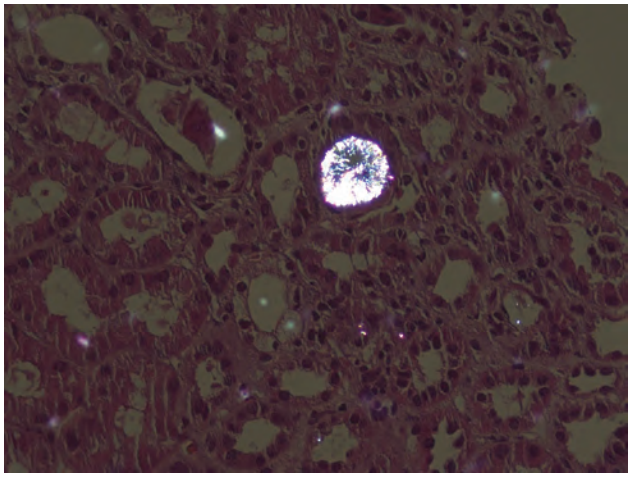
Priscila Dias Goncalves,[1] Geraldo R. Freitas,[2,3] Brenda C. Marques,[2,3] Giuseppe C. Gatto,[2,3] Gustavo G. Arimatea,[2,3] Diego Fernando F. Santos,[2,3] Stanley A. Araujo,[5] Helmut G. Rennke.[4] *[1]Mass General Brigham Inc, Boston, MA; [2]Hospital Universitario de Brasilia, Brasilia, Brazil; [3]EBSERH, Brasilia, Brazil; [4]Brigham and Women's Hospital, Boston, MA; [5]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.*

Introduction: APRT deficiency is a rare and treatable cause of End-stage Kidney Disease (ESKD) that often goes unrecognized. The recurrence of the disease in the allograft may have dire repercussions. Diagnosis and treatment may prevent graft failure.

Case Description: A 32-year-old male with ESKD previously diagnosed as secondary to chronic interstitial nephritis was referred for a pre-transplant evaluation. Due to a history of kidney stones, he and his family were screened for hyperoxaluria, and the results were negative. He underwent a deceased donor transplant in January 2023 and presented with delayed graft function. A graft biopsy was performed and showed a prominent crystalline nephropathy. The biopsy did not distinguish oxalate from 2,8-dihydroxyadenine (2,8-DHA) crystals. Therefore, a genetic test was ordered, and it was positive for a recessive mutation in the APTR gene. Treatment with allopurinol was started, and kidney function remained stable.

Discussion: APRT is the enzyme responsible for adenosine metabolism. APRT deficiency leads to the conversion of adenine into 2,8-DHA by xanthine dehydrogenase. This insoluble compound precipitates in the urine, resulting in the formation of kidney stones and crystal nephropathy. Diagnosis is often challenging and usually made after allograft failure. Genetic testing should be widely available as Allopurinol is an effective treatment.





FR-PO754

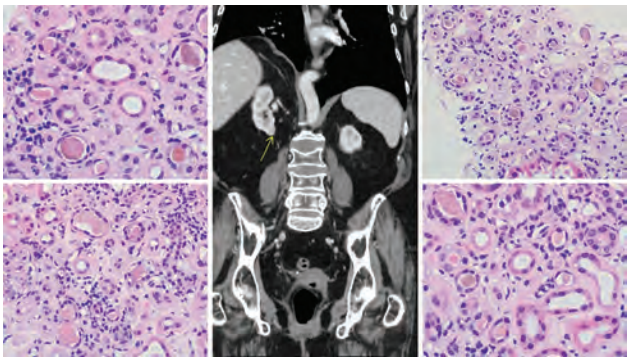
A Unique Case of Prolonged Bile Cast Nephropathy (BCN) Status After Orthoptic Liver Transplant

Sarah D. Savu, Aisha Batool, Alexander J. Gallan, Ahmed Taleb Abdellah, Emily Joachim. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: BCN or Cholemic Nephropathy refers to AKI in the setting of Decompensated liver injury with elevated bilirubin levels. Even though it was first described in 1899 by Quicke while studying cadaveric kidneys, it is still not well investigated, contributing to its limited appearance in current medical literature. It is a multidimensional entity resulting in tubular and interstitial inflammation, tubular obstruction, direct bile salt-induced tubular toxicity, and altered renal hemodynamics.

Case Description: Our patient is a 56-year-old female with history of ESLD due to EtOH s/p Orthoptic liver transplant 3 years ago and ESRD due to ESLD s/p DDKT 1.5years ago. Post transplant course significant for biopsy proven TCMR with suspicion for AMR, treated with IV steroids, PLEX x4 rounds and IVIG. She was also started on everolimus during this admission and was on quadruple therapy. The patient had MRI Abdomen done for abdominal pain with incidental finding of Exophytic enhancing mass off the lower pole of Native right kidney measuring up to 1.5 cm. Ct guided biopsy was performed, which missed the mass however sampled the native kidney. Pathology of native kidney revealed Many bile casts. At this point of time the patient was more than 2.5 Years post liver transplant and had normal LFTs with a normal bilirubin level.

Discussion: In patients with decompensated liver cirrhosis, renal biopsy is usually not performed due to abnormal coagulation profile, hence BCN is underdiagnosed. There is paucity of literature to demonstrate relationship between Total Bilirubin levels and degree or the timing of renal dysfunction. Biliary salt is known to have low solubility in water, and it is not well known the duration that biliary casts persist or the clinical significance of such casts. Our patient is unique with persistence of Biliary casts more than 2.5 years post Liver transplant, thereby pointing to the unknown mechanism as well as much lesser-known chronology of BCN.



Native kidney Biopsy Light Microscopy showing Many Bile casts.

FR-PO755

A Case of Self-Limited Thrombotic Microangiopathy (TMA) After an ABO Incompatible (ABOi) Kidney Transplant (KT)

Varsha Reddy Pothula Venkata, Karen M. Warburton, Jeanne Kamal, William F. Glass, Alden M. Doyle. *University of Virginia, Charlottesville, VA.*

Introduction: TMA is a potentially fatal complication that occurs after solid organ transplant. Post transplant TMA development most commonly triggered with antibody mediated rejection (AMR) and calcineurin inhibitors (CNI).

Case Description: A 44 year old male with CKD secondary to congenital anomalies of kidney and urinary tract who underwent a preemptive living donor ABOi KT (blood type A to O). Anti-A titers prior to transplant were 1:4, and had no donor specific antibodies. Was started on mycophenolate prior to transplant, did not need any further desensitization therapies. Intraop course was uncomplicated with immediate graft function. Induction regimen included thymoglobulin 6 mg/kg, received rituximab and was started on tacrolimus on POD 1. He had worsening anemia and thrombocytopenia on POD 2 with high LDH level and low haptoglobin concerning for TMA. He underwent one session of plasmapheresis on POD 4. His kidney function continued to improve since transplant. Hemolysis improved on POD 5, so further pheresis sessions were held. An allograft biopsy on POD 7 showed acute endothelial injury, diffusely enlarged endothelial cell with mitotic figures and entrapped RBC fragments but no fibrin thrombi. There was no concern for AMR with absence of glomerulitis and peritubular capillaritis. C4d was positive as excepted in ABOi KT.

Discussion: TMA is encountered twice as much in ABOi KT compared to other KT. The rapid clinical improvement with minimal therapy and while remaining on tacrolimus, and the absence of pathological evidence makes AMR and CNI use as less likely triggers of TMA. Evidence of early onset TMA, with injury isolated to endothelial cell, likely from an immune mediated injury triggered by isohemaglutinins against endothelial cells bearing blood group A antigens. The self-limited nature of this insult is possibly similar to the accommodation phenomena which is seen in ABOi KT.

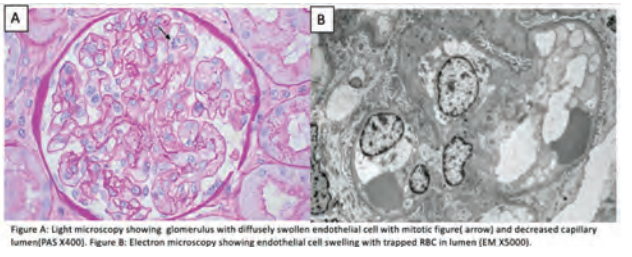


Figure A: Light microscopy showing glomerulus with diffusely swollen endothelial cell with mitotic figure(arrow) and decreased capillary lumen(PAS X400). Figure B: Electron microscopy showing endothelial cell swelling with trapped RBC in lumen (EM X5000).

FR-PO756

Non-ADAMTS13-Mediated Hemolytic Uremic Syndrome (HUS) in a Kidney Transplant Recipient due to SARS-CoV-2 Infection and Its Response to PLEX: A Case Report

David A. Momand, Surakshya Regmi, Lakshmi Ganesan, Rafael Villicana, Aamir Raza, Sami M. Akram. *Loma Linda University Medical Center, Loma Linda, CA.*

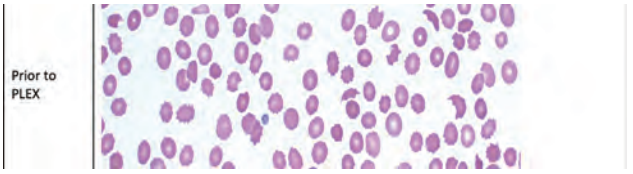
Introduction: During the COVID-19 pandemic many new complications in kidney transplant recipients have arisen. One such entity is Hemolytic Uremic Syndrome characterized by Thrombotic Microangiopathy. Here, we report a rare case of non-ADAMTS-13 and non-complement mediated TMA in a kidney transplant recipient with mild COVID-19 disease.

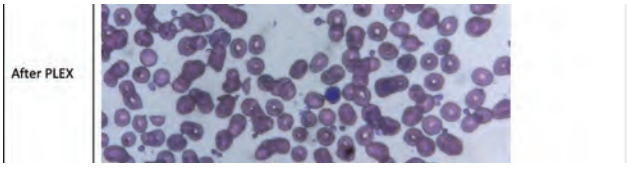
Case Description: 27 y/o F with a history of GN-mediated ESRD, status post DDKTx in April 2016, thymo induction, on tacrolimus, mycophenolate mofetil and prednisone, presented with a two-day history of fevers and diffuse myalgias. Lab work-up positive for COVID19 and AKI with Cr 4.6 mg/dL and oliguria (baseline Cr 0.8 mg/dL). On day 3, platelets decreased to 68K cells/mm^3. Peripheral smear performed showing many schistocytes with low haptoglobin and elevated LDH. C3 and C4 were normal. Alternate

complement pathway function (Mayo laboratory) was normal. Negative for Shiga toxin in stool and the ADAMTS13 activity 73%. Von Willebrand Factor distribution normal. PLEX initiated with high dose steroids with resolution of schistocyte index and AKI.

Discussion: HUS after COVID19 has been reported. The virus can cause HUS directly or indirectly by reducing ADAMTS13. The distribution of vWF multimers can be altered by the virus. A case of Dengue virus causing non-ADAMTS13 HUS has been reported before. Another mechanism of HUS/TMA is dysfunction of alternative complement pathway (inherited or acquired). Also, complement inhibitors such as Eculizumab may not be helpful. Empiric therapy with PLEX was helpful as illustrated by schistocyte response. To the best of our knowledge this is the first case report showing a schistocyte response with two sessions of PLEX in a SARS-CoV-2 mediated HUS.

Differential Diagnosis	Typical HUS	Complement-mediated atypical HUS	Atypical HUS due to COVID19	TTP
Background	No gastroenteritis	No prior C3GN/aHUS	Recent SARS-CoV-2 infection	No history
Testing/Diagnosis	Shiga toxin negative	Complements normal. Alternate complement function S test normal.	UNKNOWN MECHANISM	ADAMTS13 is 73% (normal). vWF distribution normal
Pathophysiology	Shiga toxin mediated endothelial injury	Alternate complement pathway dysregulation (congenital or acquired)	Non-complement mediated endothelial injury	ADAMTS13 deficiency
Therapy	Supportive care	PLEX + Eculizumab	PLEX + Steroids	PLEX + Steroids





FR-PO757

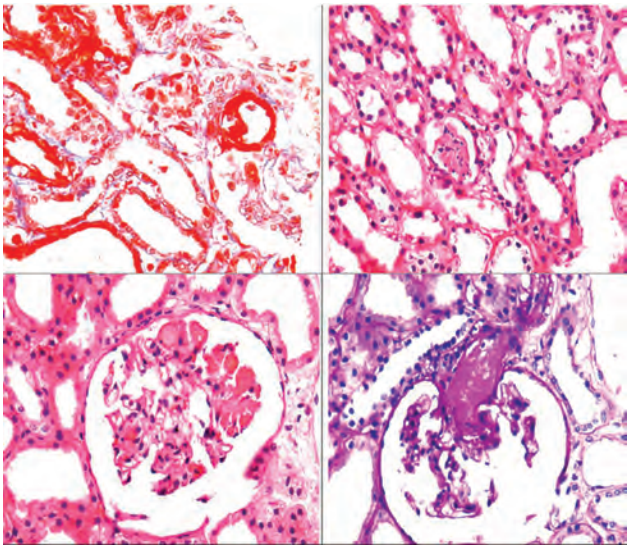
Post-Transplant Thrombotic Microangiopathy as a Manifestation of Atypical Haemolytic Uraemic Syndrome of Primary Origin

Rita B. Aguilar, Allina P. Flores Mendoza, Elisa M. Guerrero Gonzalez, Mara C. Olivo Gutierrez, Juan P. Gomez Villarreal, Lilia M. Rizo Topete. *Hospital Universitario Dr Jose Eleuterio Gonzalez, Monterrey, Mexico.*

Introduction: Several conditions could trigger endothelial injury that leads to Thrombotic Microangiopathy (MAT) which can have primary and secondary etiology. If transplant associated, early diagnosis and aggressive treatment should be done in order to preserve allograft function.

Case Description: 42 year old woman with history of CKD and kidney allograft rejection eighteen years ago. She underwent second kidney transplant from deceased donor, induction immunosuppression included methylprednisolone and thymoglobulin. On day five post-op she developed abrupt onset anuria, delayed graft function and laboratory showed anemia, thrombocytopenia elevated LDH, schistocytes on peripheral smear and normal ADAMST-13 activity, autoimmune screen and coagulation parameters. She also developed surgery associated complications that derived in surgical reintervention. Kidney allograft biopsy was performed and it showed swollen endothelial cells, fibrin-platelet thrombi within glomerular capillaries and negative C4d stain (Fig 1), genetic testing revealed a variant on DGKe gene. Therapeutic plasma exchange was done, soon after patient kidney function improved and started treatment with anti-C5 monoclonal antibody, renal function is successful and stable.

Discussion: In this case we faced a patient who developed what it appears to be an Atypical Haemolytic Uraemic Syndrome (aHUS). Ischemia-reperfusion injury and antibody mediated rejection, secondary causes as well as infections were ruled out. Based on genetic testing aHUS is presumed to be of primary origin.



FR-PO758

Tacrolimus-Induced Thrombotic Microangiopathy After Kidney Transplant

Amer A. Belal, Andrew Slater, William L. Clapp, Hisham Ibrahim, Alfonso Santos, Rohan V. Mehta. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: Thrombotic microangiopathy (TMA) can present with hemolytic anemia, thrombocytopenia, and organ damage. Risks associated with post-transplant TMA include immunosuppressive drugs, viral infections, antibody-mediated rejection, and ischemia-reperfusion injury. We report a case of tacrolimus (TAC) induced TMA early after a kidney transplant (KT).

Case Description: A 73-year-old white woman with ESRD due to acute kidney injury (AKI) from high output ostomy, ulcerative colitis, proctocolectomy and ileostomy, and Hepatitis C was admitted for a deceased donor KT. Induction immunosuppression was with Basiliximab and maintenance was with Prednisone, Cellcept, and TAC, initiated within 24 hours post-KT. On postoperative day (POD) 4, hemoglobin (Hb) and platelets (PLT) dropped to 8.2 g/dL and 37,000/μL respectively. Haptoglobin was <30 mg/dL, lactate dehydrogenase was 1640 IU/L, and peripheral smear revealed schistocytes. Hematology was consulted for concern for TAC-induced TMA. ADAMTS13 activity was 72%, and the Coombs test was negative. She developed AKI requiring hemodialysis (HD) on POD 5. Allograft biopsy revealed severe TMA with coagulative necrosis (Figure 1). TAC was held, and Belatacept was initiated on POD 6. Hematology started Eculizumab on POD 7. PLT improved to 145,000/μL and the patient was discharged on dialysis on POD 12. Genetic susceptibility testing for atypical hemolytic uremic syndrome (aHUS) came back negative. She achieved renal recovery with the last HD on POD 31 and maintained a baseline creatinine of 2.2. Eculizumab was discontinued on POD 48 after 4 doses.

Discussion: Drug-induced TMA (DITMA) due to TAC can present early after KT. DITMA could be idiosyncratic or dose-related. Timely diagnosis and discontinuation of the offending agent are key to management. Eculizumab can be used as rescue therapy in severe cases.

FR-PO759

Ocular Toxoplasmosis After Kidney Transplant

Amer A. Belal, Andrew Slater, Jinghua Chen, Alfonso Santos, Muhannad Leghrouz. *University of Florida College of Medicine, Gainesville, FL.*

Introduction: Toxoplasmosis (TOXO) is a zoonotic infection where the parasite persists dormant within tissue cysts and can result in a life-threatening infection in immunocompromised patients. Acute retinal necrosis (ARN) is a vision-threatening necrotizing retinitis with the most common cause being due to the herpes virus family. We describe a case of ocular TOXO after a kidney transplant (KT).

Case Description: A 58-year-old woman with a history of ESRD due to diabetes and hypertension received a deceased donor KT and was directed to the ER by ophthalmology for severe vision loss (counting finger vision) 2 months post-transplant (PT). At transplant, both recipient and donor were positive for Toxoplasma, CMV, and EBV IgG antibodies and induction was with alemtuzumab followed by triple tacrolimus-mycophenolate-prednisone regimen. Her PT course was complicated by slow graft function, persistent hyperkalemia and neutropenia necessitating switching of TMP/SMZ to pentamidine and BK viremia requiring immunosuppression reduction at the 1st and 2nd months PT, respectively. Based on a funduscopic exam, the ophthalmologist diagnosed her with ARN (Figure 1). She was empirically started on intravitreal ganciclovir and IV followed by PO acyclovir, which was changed to Valtrex. Subsequently, her aqueous sample, which was negative for CMV, VZV, and HSV, tested positive for TOXO PCR. She was started on induction dose Bactrim DS PO BID for 6 weeks followed by lifelong Bactrim prophylaxis. Her steroids were increased to reduce ocular inflammation and tissue damage. On follow-up, her ocular pain improved but significant vision impairment in the left eye (20/200) remains.

Discussion: A high index of suspicion for toxoplasma disease should be maintained when prophylaxis without coverage for toxoplasma is used in kidney transplants where donor and/or recipient has positive toxoplasma serology.

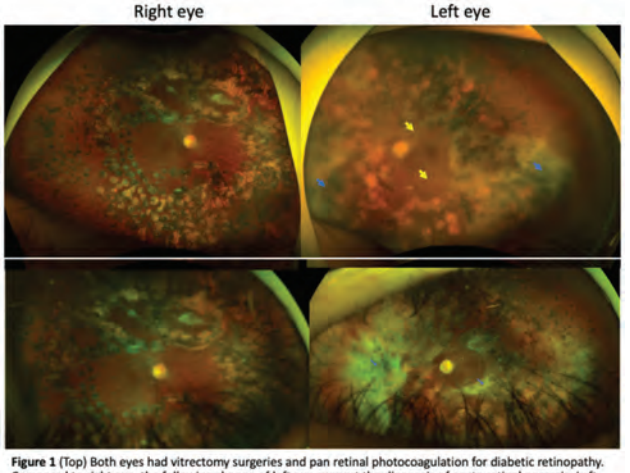

Figure 1 (Top) Both eyes had vitrectomy surgeries and pan retinal photocoagulation for diabetic retinopathy. Compared to right eye, the following change of left eye support the diagnosis of acute retinal necrosis: Left eye has blurred view due to vitritis and Left eye has tortuous and sclerosed blood vessels (yellow arrow) and whitening of periphery retina (blue arrow)

(Bottom) After treatment left eye vitritis resolved. There is fibrotic membrane at nasal retina and at posterior retina around optic nerve and macula (blue arrows)

FR-PO760

Post-Transplant Thrombotic Microangiopathy: A Miraculous Outcome with Eculizumab and Belatacept

Maria Christina Victoria M. Capistrano, Krishna A. Agarwal. *Tufts Medical Center, Boston, MA.*

Introduction: Post-transplant TMA is a rare but devastating complication, often resulting in graft loss. Calcineurin-inhibitors, antibody-mediated rejection and complement pathway mutations are commonly implicated but the diagnosis is often challenging. We present a case of TMA highlighting these diagnostic challenges.

Case Description: A 57-year-old woman with ESKD from reflux nephropathy underwent her 3rd deceased donor kidney transplant (prior grafts failed from chronic AMR, cPRA 100%, KDPI 1%, rATG for induction and tacro/MMF/pred maintenance), complicated by delayed graft function. On post-op day 6, she developed microangiopathic hemolytic anemia, thrombocytopenia, and a kidney biopsy with focal TMA, 10% cortical necrosis, and negative C4d. HLA testing revealed persistent preformed low-level B44 and new Bw4 DSAs (MFI 3537). Plasmapheresis x 5, IVIG and rituximab were employed for AMR and tacrolimus was switched to cyclosporine. A repeat biopsy on day 14 for persistent DGF revealed diffuse TMA with 50% cortical necrosis and negative C4d/SV40. DSAs were at lower levels. Eculizumab was started and cyclosporine switched to sirolimus. MMF was switched to azathioprine for severe diarrhea, but this caused severe pancytopenia. Antimetabolites were stopped and she started belatacept 5 weeks post-transplant. She made urine shortly thereafter and came off dialysis by week 6. An aHUS panel returned with CFH mutation. She continues belatacept, eculizumab and prednisone (5mg daily) with creatinine 1.2 (eGFR 50), now 100 days post-transplant.

Discussion: We present a challenging case with multiple causes of TMA acting in combination on a background of CFH gene mutation. While eculizumab is commonly used for complement-related TMA, experience with belatacept is limited. The treatment of calcineurin-inhibitor induced TMA is withdrawal of the offending agent but there may be refractory cases like ours. A regimen of belatacept and the mTOR inhibitor, sirolimus, resulted in rapid improvement in graft function in our patient. While AMR was probably contributing to the TMA, treatment with lowering of DSA levels did not immediately improve graft function. Testing for complement pathway mutation is not readily available and has a long turnaround time. But this should not deter physicians from sending this as it is a valuable guide for continued use of eculizumab.

FR-PO761

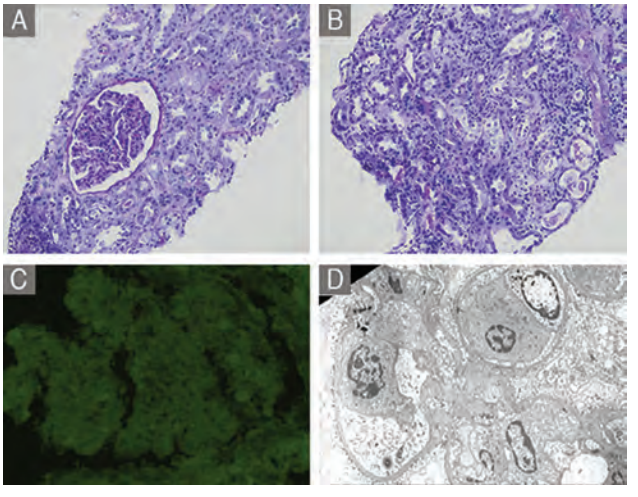
Successful Kidney Transplant in a Patient with Overlap C3 Glomerulonephritis and Thrombotic Microangiopathy Treated with Ravulizumab

Juan P. Huidobro,[1] Rodrigo Sepúlveda,[1] Daniel Carpio,[2] Alejandro Majerson Grinberg,[1] Aquiles Jara.[1] [1]*Pontificia Universidad Catolica de Chile, Santiago, Chile;* [2]*Universidad Austral de Chile, Valdivia, Chile.*

Introduction: Overlap of C3 glomerulopathy (C3G) and thrombotic microangiopathy (TMA) has recently been acknowledged as one of the possible manifestations of a dysregulation of the alternative complement pathway. C3G of genetic cause has high risk of recurrence after kidney transplant (KT). Data of KT in patients with overlap C3G and TMA is scarce.

Case Description: A 30-y/o woman with kidney failure secondary to overlap C3G/TMA received a deceased-donor KT 6 years ago with primary graft failure secondary to early recurrence of C3G and TMA. Genetic study showed two pathogenic variants in complement-factor H. Post-KT PRA was 100%. While on dialysis she received immunoglobulin for desensitization. She then received a second deceased-donor KT. Flow cytometry (FC) crossmatch (XM) was negative. Ravulizumab, thymoglobulin and steroids were used for induction and five sessions of plasma exchange were performed (one pre-KT). She developed DGF requiring dialysis for 3-4 weeks after KT. Graft biopsy one-week post-KT revealed signs of ATN without signs of TMA or antibody-mediated rejection (Fig. 1), with negative C4d. DSA anti-HLA antibodies class I and II were positive and FC XM was positive (T and B). She was discharged on dialysis with tacrolimus, mycophenolate and prednisone. Four weeks after KT creatinine dropped to 2.9 mg/dL, leading to interruption of dialysis. Since then, allograft function has improved to creatinine of 1 mg/dL at month 3 post-KT.

Discussion: Overlap C3G and TMA is an infrequent condition with a high risk of recurrence. While C3G component secondary to a genetic cause has no treatment available, TMA can be successfully treated with complement inhibitors. This case shows a successful KT in a patient with overlap of C3G and TMA secondary to genetic cause and could therefore serve as guidance to the management of KT in these patients.



FR-PO762

A Case of Collapsing Focal Segmental Glomerulonephritis (cFSGS) After Kidney Transplant (KT): Association with SARS-CoV-2 Infection

Lalida Kunaprayoon, William F. Glass, Joseph T. Leeds, Swati Rao, Jeanne Kamal. *University of Virginia, Charlottesville, VA.*

Introduction: cFSGS is manifested by high grade proteinuria and rapid decline in kidney function leading to end stage kidney disease (ESKD). Viral infections including HIV, cytomegalovirus, BK and SARS-CoV-2 can trigger cFSGS in KT. High-risk APOL1 genotype in donors is linked with higher risk of cFSGS and poor allograft outcomes.

Case Description: This is the case of a 70-year-old white man with history of renal cell carcinoma requiring unilateral nephrectomy and eventually ESKD. He received a successful deceased donor KT. After 1.5 years from KT, he developed nephrotic syndrome (creatinine (Cr) 2.2 from 1.1, proteinuria 18-23 g/24h). He had mild COVID infection 2 months prior. On biopsy, glomeruli showed podocyte hyperplasia and hypertrophy consistent with cFSGS. He had diffuse glomerulitis and peritubular capillaritis (ptc)

suspicious of antibody mediated rejection. C4d ptc stain was negative with no evidence of donor specific antibodies. In addition to proteinuria management with RASS blockage, SGLT2i and spironolactone, he completed 13 sessions of plasmapheresis, 2g/kg of IVIG and 2 doses of rituximab. Follow-up biopsy (5 months later) showed progressive glomerular injury (cg2), but improvement of cFSGS. Follow-up Cr is 1.5 and proteinuria is 5 g/g. The donor reported race is white, and APOL1 genotype was negative for high-risk alleles.

Discussion: This is a case of COVID-related de novo cFSGS after KT in APOL1-negative donor and recipient. It is unique as cFSGS manifested 2 months after COVID resolution. Though, case series have shown a link of APOL1 high-risk genotype with COVID19-related cFSGS, cFSGS in KT recipient from APOL1-negative donors has been reported. It is important to rule out a concomitant or recent history of rejection or viral infection in KT recipients with cFSGS. Aggressive treatment is warranted to salvage the kidney allograft.

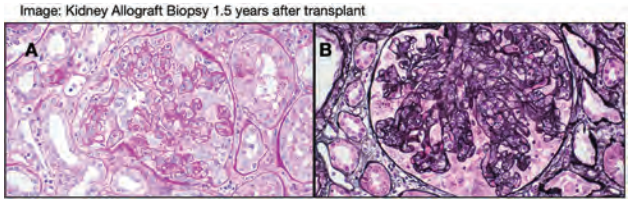


Figure A: Light microscopy (LM)-glomerulus with variably collapsed capillaries, extracapillary hypercellularity with prominent podocyte protein reabsorption droplets & segmental glomerulitis (PASx200) **Figure B:** LM-glomerular capillary collapse & extracapillary hypercellularity (Silverx200)

FR-PO763

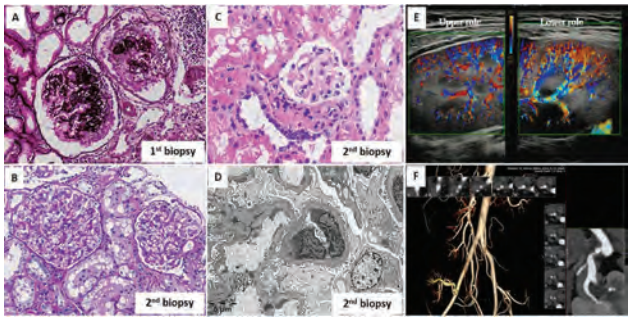
An Unusual Regional Cellular FSGS Secondary to Artery Stenosis in a Renal Allograft

Qihua Wang, Zhengyuan Xu, Shicong Yang, Wenfang Chen. *Sun Yat-sen University First Affiliated Hospital, Guangzhou, China*.

Introduction: Focal segmental glomerulosclerosis (FSGS) in renal allograft derived from various etiology shares similar morphology regardless of recurrent or de novo onset. Here, we reported a recipient presented with moderated proteinuria whose consecutive renal biopsies showed drastic discrepancy due to different regional hemodynamics.

Case Description: A 20-year-old female with end stage IgA nephropathy received a successful renal transplantation 3 years ago. Two years later she developed hypertension and serum creatinine (Scr) increased from 60 to 177 umol/L. Computer tomography angiography (CTA) showed renal artery stenosis. After a percutaneous transluminal angioplasty, her Scr recovered and urine protein remained negative. Six months later she developed moderate proteinuria (2.5g/d) for unknown reason. Renal biopsy showed diffuse (10 out of 16 glomeruli) cellular FSGS lesion without IgA deposition. Ultrastructure change of podocytes was not available due to absence of glomeruli in EM. De novo FSGS was diagnosed with uncertain etiology. Corticosteroid impulse therapy was applied and meanwhile a second biopsy was performed because of unmatched pathology and symptoms. No FSGS among 37 glomeruli but mild ischemic change and remarkable enlarged juxtaglomerular apparatus (JGA) was found. CTA and ultrasound revealed two different hemodynamic areas, which the hypo-infused upper role was fed by the stenotic main artery and the hyper-infused lower pole by an accessary artery. The two biopsies happened to be sampled from opposite poles. Therefore the cellular FSGS was speculated as secondary to hyperperfusion. Corticosteroid impulse therapy was stopped. Her urinary protein turned negative and Scr decreased to 80umol/L 3 days after an endovascular stent angioplasty.

Discussion: Adaptive FSGS caused by hyperperfusion usually shows perihilar pattern. This allograft kidney perfectly simulated unilateral renal artery stenosis of native kidneys, i.e. the hypoperfused area underwent ischemia and proliferation of JGA, while the hyperperfused developed secondary FSGS which could be reversed by improved hemodynamics.



FR-PO764

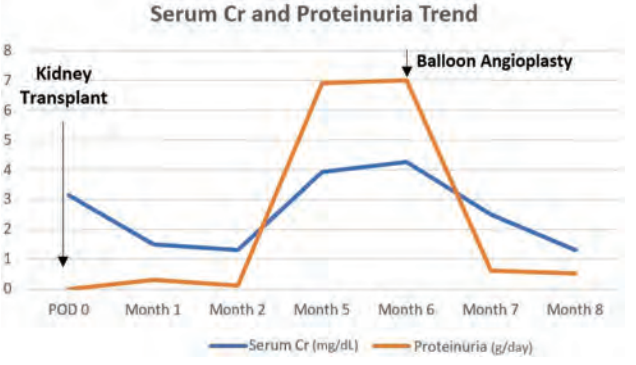
An Unusual Cause of Reversible Nephrotic Syndrome in a Kidney Transplant Recipient

David M. Brooker, Sheahahn V. Soundranayagam, Kalathil K. Sureshkumar, Reem Daloul. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: New onset proteinuria in kidney transplant recipients (KTRs) could be related to recurrent/de novo glomerular diseases or more commonly to chronic antibody mediated rejection. We present a KTR who had a very uncommon cause of nephrotic syndrome.

Case Description: A 73-year old female with diabetic nephropathy underwent deceased donor kidney transplantation using Thymoglobulin induction and tacrolimus/mycophenolate mofetil maintenance along with infection prophylaxis using valgancyclovir and trimethoprim-sulfamethoxzole. There was prompt allograft function with a nadir serum creatinine of 1.3 mg/dl. Serum creatinine started increasing 4 months post-transplant and patient developed significant edema along with worsening hypertension. Further evaluation revealed new nephrotic range proteinuria, hypoalbuminemia, no DSA, along with negative infectious and monoclonal gammopathy work up. Kidney allograft biopsy showed no rejection, negative immunofluorescence, with segmental foot process effacement without transplant glomerulopathy or immune deposits on electron microscopy. Repeat allograft biopsy 2 weeks later showed similar findings. Allograft Doppler ultrasound revealed increased peak systolic velocity of 240 cm/sec in the renal artery which increased to 289 cm/sec on repeat Doppler study 2 weeks later. Based on the Doppler finding, persistent allograft dysfunction and hypertension, patient underwent CO2 angiogram that revealed severe stenosis of the transplant renal artery near the anastomosis with external iliac artery. Stenosis was successfully treated with balloon angioplasty. Within next several weeks, there was improvement in serum creatinine to 1.29 mg/dl and proteinuria to 0.5 g/d.

Discussion: Nephrotic range proteinuria is an uncommon presentation of renal artery stenosis (RAS) that has previously been reported in native kidneys. Our case shows that similar presentation can occur in allograft kidneys. Transplant RAS should be considered as a potential cause for nephrotic syndrome in KTRs.



FR-PO765

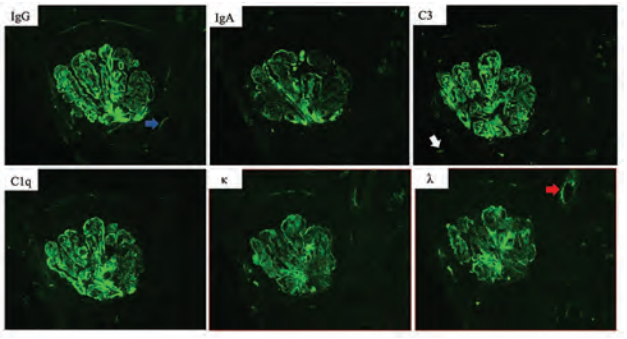
Diffuse Proliferative Glomerulonephritis After Allogenic Hematopoietic Stem Cell Transplantation: A Rare Manifestation of Chronic Graft vs. Host Disease

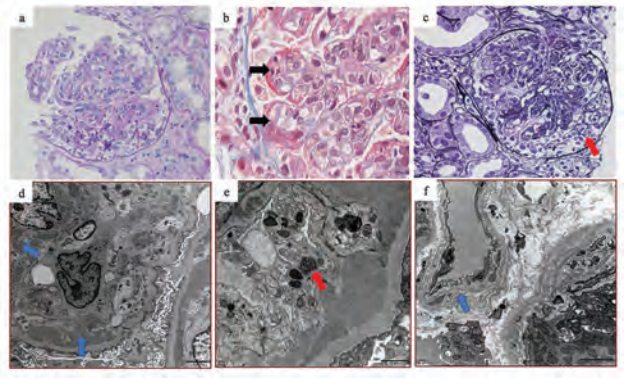
Lei Shen,[1] Jing Yang,[1] Shaojun Liu.[2] [1]*The First Affiliated Hospital of Soochow University, Suzhou, China;* [2]*Huashan Hospital Fudan University, Shanghai, China*.

Introduction: Renal involvement is rare in chronic graft-versus-host disease (GVHD), of which membranous nephropathy (MN) and minimal change disease (MCD) were the most common renal pathological manifestations. In addition to glomerular diseases, thrombotic microangiopathy and tubulointerstitial diseases had also been detected in this entity.

Case Description: This paper presents a case report of a rare manifestation of chronic graft-versus-host disease (GVHD) in an 18-year-old male patient who underwent hematopoietic stem cell transplantation 3 years ago. This patient was clinically manifested as rapidly progressive glomerulonephritis with various autoantibodies detected in the serum and kidney, which was lupus-like manifestations. The renal pathology of this patient was immune complex-mediated diffuse proliferative glomerulonephritis with partial crescent formation, which was a rare manifestation of chronic GVHD. The patient initially received intensive immunosuppressive therapy and achieved partial remission.

Discussion: Immune-complex mediated diffuse proliferative glomerulonephritis was a rare manifestation of chronic GVHD after HSCT, which response well to immunosuppressive therapy. Our findings suggest that a combination of methylprednisolone pulse and cyclophosphamide followed by mycophenolate mofetil and prednisone was effective in managing the condition. We emphasize the need to consider the possibility of different renal manifestations in GVHD and to give it adequate attention.





FR-PO766

ANCA-Associated Vasculitis Recurrence After Kidney Transplantation

Wadhah M. Bin Homam, Fatima Ayub, Ahmed Elkalashy, Venkata R. Manchala. UAMS Internal Medicine/Nephrology. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Introduction: ANCA-associated vasculitis (AAV) is a well-recognized cause of End Stage Kidney Disease (ESKD). It is a necrotizing vasculitis that affects small vessels without immune complex deposition. About 20-25% of patients will progress to ESKD in a few years after diagnosis. AAV may recur in about 5-10% of cases after kidney transplantation despite standard immunosuppression. Here we present a case of AAV recurrence in a kidney transplant recipient.

Case Description: A 49-year-old white female with a past medical history of HTN and ESKD secondary to p-ANCA positive, pauci-immune glomerulonephritis received DDKT 3 years ago with post-transplant course complicated by cryptococcus meningitis and mycobacterium avium infection. She was maintained on cyclosporine and prednisone. Her creatinine rose from baseline of 0.9 to 2.3 along with new onset of microscopic hematuria and proteinuria and UPCR of 2.6 g/g. Her p-ANCA titer is 1:640. Cyclosporine levels ranged from 100-144 ng/ml. Kidney biopsy showed focal crescentic and necrotizing glomerulonephritis, borderline acute TCMR, and diffuse acute tubular injury. Of 22 glomeruli, 3 glomeruli contain cellular, 3 glomeruli contain fibrocellular, 2 glomeruli contain fibrous crescents and 2 glomeruli with cellular crescents also have fibrinoid necrosis. A focal segmental granular mesangial and loop staining is seen with IGG (trace), IGM (1+), C3 (1+), C1q (1+), kappa (trace), and lambda (trace). There is 1+ arteriolar and 2+ focal segmental tubular basement membrane staining with C3. Tubular casts are equally positive with IGA, kappa, and lambda. Electron microscopy with no deposits in any locations. The patient received a 3-days of pulse methylprednisolone, one dose of rituximab and is scheduled to receive a second dose of rituximab in two weeks. The patient was discharged on prednisone with plans for gradual taper over 4-6 months.

Discussion: The diagnosis of AAV flare post transplantation is difficult as relapses may mimic infections and other complications of immunosuppression. Disease recurrence of AAV should be considered in the differential diagnosis of sudden worsening of kidney function and must be confirmed by biopsy. Rituximab is the therapy of choice both in ESKD and kidney transplant patients. It is recommended to maintain continuous vigilance in all AAV transplant recipients for early detection of relapses.

FR-PO767

When Rare Things Return: A Case of Late, Indolent, Post-Transplant Recurrent Collagenofibrotic Glomerulopathy

Divya Sood, Kirk W. Foster, Scott G. Westphal. *University of Nebraska Medical Center, Omaha, NE.*

Introduction: Collagenofibrotic glomerulopathy (CG), also known as Collagen Type III glomerulopathy, is an extremely rare disorder caused by abnormal glomerular deposition of type III collagen. Etiology and prognosis are poorly understood, and its implication in kidney transplantation is unclear.

Case Description: A 44-year-old female with a history of diabetes mellitus developed kidney dysfunction and nephrotic range proteinuria. A biopsy revealed mesangial expansion and nodularity suggestive of diabetic glomerulopathy, however, electron microscopy revealed extensive subendothelial deposition of type III collagen fibrils, consistent with CG. She progressed to ESKD and received a living donor kidney transplant. She experienced a straightforward transplant course with excellent graft function for more than a decade. 12 years post-transplant, she developed sub-nephrotic range proteinuria (UPCR 1.0) with otherwise stable graft function (serum creatinine 1.2 mg/dl). Biopsy revealed features of recurrent CG with notable curved, banded subendothelial aggregates (Figure 1). Diagnosis of recurrent collagenofibrotic glomerulopathy was made and supported by tandem mass spectrometry which confirmed composition of the aggregates as type III collagen.

Discussion: CG is a rare disorder characterized by abnormal glomerular deposition of type III collagen. Its cause and pathogenesis are unclear and lack definitive treatment. There is a paucity of cases describing recurrence post-transplant and its implication on long-term graft outcomes is unknown. Here, we describe a case of late recurrent CG, presenting with sub-nephrotic proteinuria and stable allograft function.

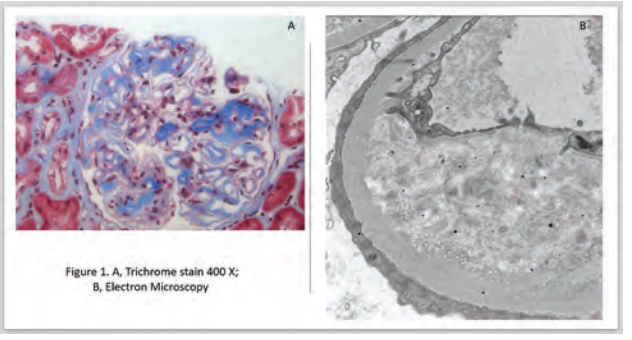


Figure 1. A, Trichrome stain 400 X; B, Electron Microscopy

FR-PO768

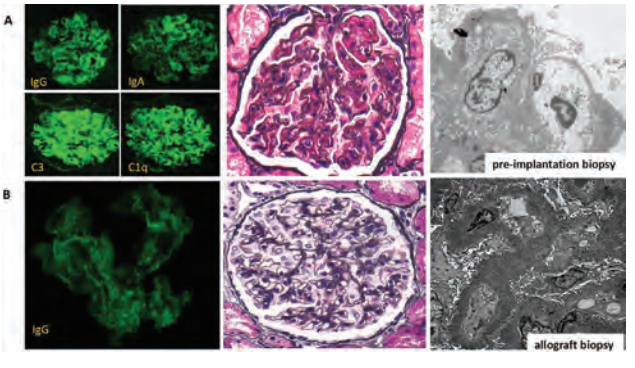
Outcome of Renal Allograft with Preexisting Lupus Nephritis

Zhengyuan Xu, Qihua Wang, Wenfang Chen, Shicong Yang. *Sun Yat-sen University First Affiliated Hospital, Guangzhou, China.*

Introduction: Preexsisting gomelular nephritis(GN) was not a contraindication for kidney donation. The outcome of renal allograft with pre-exsisting GN was not clearly demonstrated. Here, we presented a case of renal allograft with pre-exsisting proliferative lupus nephritis(LN).

Case Description: A 31-year-old female with diffuse sclerotic GN accepted deceased donor kidney transplantation(KT) at 2020. The 32-year-old female donor died of frontal lobe encephalorrhagia, with a medical history of systemic lupus erythematosus. At the time of death, the donor had proteinuria(urine ALB: 3.72g/L), increased serum creatinine(Scr)(180 umol/L), positive ANA(18.4U/ml) and dsDNA(>300.00IU/ml). Pre-implantation histological examination of the kidneys showed "full-house" deposition in immunofluoroscence(IF), diffuse mesangial and endothlial proliferation with immune complex(IC)deposition under light microscope(LM), suggestive of RPS IV(A)+V,Remuzzi scoring=1. After KT, the recipient's Scr decreased while nephrotic range urine protein was notified. At 10th day post-KT, her Scr dropped to 100 umol/L and remained stable afterward, while her urine ALB was 4.34g/L and descended slowly. 3 months later, she undertook allograft renal biopsy with persistent proteinuria(urine ALB:111.5mg/L). The IC deposition persisted in glomerular base membrane with decreased intensity in IF, resembling membranous nephropathy(MN) in LM and electronic microscope. No hypercellularity or rejection was identified. Her urine protein turned negative 4 months after KT. Only slight transient ANA elevation was noted within the first 2 weeks (15-22 U/L), while dsDNA remained negative all throughout.

Discussion: Glomerular IC deposition is common in donor kidney biopsies, which would eventually "wash-out" over time. In our case, the allograft still presented with proteinuria and MN-like change 3 months after KT, indicating that IC clearance was slower than disappearance of hypercellularity. Hence allograft with pre-exsisting GN should undergo careful surveillance before radical clearance of IC to avoid possible complication caused by GN.



FR-PO769

Curious Case of De Novo Lupus Nephritis in Geriatric Patient After Kidney Transplant

Sheikan Elnigomy, Muralidharan Jagadeesan, Divya Shankaranarayanan. *The George Washington University Hospital, Washington, DC.*

Introduction: Glomerular nephritis after transplant can develop De novo or as a recurrence of primary GN. Glomerulonephritis (GN) after a kidney transplant significantly contributes to long-term graft loss. We present a rare de novo lupus nephritis (Membranous GN) case after a kidney transplant.

Case Description: A 73 -year-old African American Male with a history of ESRD presumed secondary to long-standing HTN and DM. He had a Diseased Donor Kidney Transplant (DDKTx) 10 years ago, complicated by graft failure after five years of the transplant secondary to chronic allograft nephropathy diagnosed on kidney biopsy. He was restarted on hemodialysis and subsequently underwent a second DDKTx, Donor 38 AAF, KPDI 61%, CPRA 98%, CMV +/+, EBV +/+, Cold time 13 hours, induction therapy with Anti Thymoglobulin, bortezomib and Solumedrol and maintenance with Tacrolimus, Mycophenolate Mofetil, and prednisone. The post-transplant course is complicated by delayed Graft Function (DGF), 2nd-degree AV block type 1 Wenckebach, and paroxysmal atrial fibrillation. He has maintained the patient on dialysis for DGF. Laboratory studies revealed hemoglobin of 9.5 g/dL, platelets 200 x100 /µL, Leukopenia of 3.200, Creatinine 8 mg/dL, Urine with >500 protein, and 24 protein excretion is 4 grams. Urine Microscopy was bland. Work up for proteinuria; HIV, Hepatitis B, and C are negative, Low C3, and normal C4, Normal PT/INR and APTT. A kidney Biopsy was done in the second week of the transplant and showed Membranous GN, focal glomerulonephritis, and extraglomerular immune complex deposit, EXT2 positive favor autoimmune etiology. Then subsequently, Lupus work up positive for dsDNA. The patient continued on the immunosuppression with Tacrolimus dose adjusted to achieve a level of 8-10, Mycophenolate Mofetil 360 twice a day, and 40 mg of prednisone slowly tapered. In 4 weeks after discharge, the patient off dialysis Kidney functions improved Cr 1.7. Proteinuria resolved, and his three-month protocol kidney biopsy showed similar changes to the previous biopsy result.

Discussion: .De Novo GN after transplant are underdiagnosed because of chronic immune suppression state. Lupus nephritis can occur at any age and may reflect alloimmunization from a previous kidney transplant or an underlying autoimmune condition gets triggered during the transplant.

FR-PO770

Late-Onset Recurrent Lupus Nephritis (rLN) in a Kidney Transplant Recipient

Prashamsa Shenoy,[1] Nora Hajnoczky,[2] Anju Yadav,[1] Rakesh Gulati.[1] *[1]Thomas Jefferson University Sidney Kimmel Medical College, Philadelphia, PA; [2]Albert Einstein Medical Center, Philadelphia, PA.*

Introduction: Despite advances in early allograft survival, long-term graft survival has continued to be a challenge. Recurrence of glomerular disease along with acute/chronic rejection is the most common cause of allograft failure. We present a treatable case of graft failure 27 years post-transplant.

Case Description: A 53-year-old Latino male with history of Class IV Lupus nephritis (LN) 27 years post living related kidney transplantation, maintained on azathioprine and prednisone with good medical adherence presented for a follow-up. He was noted to have a rise in creatinine of 1.51mg/dL (baseline of 1.1-1.3mg/dL) and a urine protein creatinine ratio of 500mg/g. Work-up was significant for suppressed complements, an elevated Anti-DS DNA (16IU/ml), with positive Anti-cardiolipin and Anti-B2 Glycoprotein antibodies. Renal allograft biopsy showed 1/14 glomeruli sclerosed and 2 glomeruli showing endocapillary hypercellularity with hyaline deposits and vascular intimal thickening. There was an old chronic anti-allograft lesion and C4D staining of peritubular capillaries, which is deceivingly noted in LN. There was full house immunofluorescence staining of the glomerular capillary walls and mesangium in 5 glomeruli. Electron microscopy revealed prominent electron-dense deposits in the subendothelium, mesangium, peritubular capillaries and basement membranes. Overall suggestive of rLN Class IV with mild activity and chronicity. The patient was switched to Mycophenolic acid and prednisone 10 mg daily which resulted in complete remission in the next six months that persists three years post-biopsy.

Discussion: rLN is common cause of transplant failure describing upto 93% incidence of graft failure and 43% allograft rejections in the first 10 years of transplant. We demonstrate rLN 27 years post-transplant. Although rLN is reported upto 15 years, it is uncommon, underdiagnosed and adds a potentially treatable cause of graft failure to the evergrowing kidney waitlist. Also, our patient is a perfect outlier for traditional risk factors for rLN such as African ancestry, female gender, age 30-40 yrs, pre-transplant dialysis, and receiving a deceased donor transplant. Therefore, this report conveys the importance of keeping high suspicion for prompt diagnosis and management of rLN to improve the long-term survival of the allograft.

FR-PO771

IgG4-Related Disease Tubulointerstitial Nephritis: Successful Treatment of Post-Transplant Relapse

Wesley J. Earl, Geoffrey K. Dube, Ibrahim Batal. *Columbia University Irving Medical Center, New York, NY.*

Introduction: IgG4-related disease (RD) is a heterogenous condition with renal manifestations. We report a case of IgG4-RD tubulointerstitial nephritis (TIN) with relapse post-transplant.

Case Description: A 66 yo male with a history of chronic kidney disease (CKD) 3b presents with acute renal failure. He underwent a renal biopsy demonstrating interstitial infiltrate with IgG4+ plasma cells consistent with TIN and was diagnosed with IgG4-RD. He underwent preemptive live donor kidney transplant without complication and was started on tacrolimus and mycophenolate (MMF). Two years post-transplant creatinine increased from 1.0 to 1.5. Allograft biopsy showed IgG4+ plasma cells consistent with TIN from recurrence of IgG4-RD. He started on prednisone and rituximab with improvement of his creatinine to 1.2. Steroids were tapered over months. Creatinine returned to 1.1. Ten months after rituximab repeat allograft biopsy showed improvement of TIN. He required no further doses of rituximab and remains on prednisone, tacrolimus and MMF. 11-years after transplantation his creatinine remains 1.1.

Discussion: IgG4-RD is characterized by autoimmune dysregulation of IgG4+ plasmacytes impacting many organs in an inflammatory to fibrotic process. T_h cells stimulate B cells to produce IgG4 and collectively release inflammatory cytokines. Fibroblasts replace the inflammatory milieu with stromal tissue. IgG4 antibodies play an unknown role. Renal involvement can be intrinsic or secondary to retroperitoneal fibrosis. Intrinsic disease typically manifests as TIN. Laboratory findings of TIN include pyuria, variable proteinuria, hypocomplementemia and elevated IgG4 subclass. Histologic evaluation demonstrates IgG4+ plasmacyte infiltrate, storiform fibrosis, and obliterative phlebitis. Progression to renal failure is uncommon and kidney transplant occurs rarely. Treatment of IgG4-RD includes glucocorticoids tapered over 6 months. Rituximab is used with 90-100% remission rate even if refractory to treatment and relapse. Recurrent IgG4-RD TIN post-transplant has only been reported once prior in literature. This is the first reported case without concurrent rejection and the first case demonstrating successful treatment of recurrent IgG4-RD post-transplant. Our case suggests effective use of rituximab, glucocorticoids, and MMF for recurrent IgG4-RD TIN in a post-transplant patient.

FR-PO772

Revealing the Invisible: Invasive Mucormycosis in a Kidney Transplant Recipient

Natasha C. Hughes, John P. Mitchell, Maryn Gardner, Anthony J. Langone, Saed Shawar. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: Mucormycosis is a rare, life-threatening fungal infection; prompt diagnosis and intervention are critical for survival. We present a case where initial sinus CT imaging demonstrated minimal changes despite a severe invasive fungal infection. Further investigation underlined the necessity of nasal endoscopic biopsy to diagnose high-risk patients exhibiting progressive sinus symptoms.

Case Description: A 38-year-old male with ESRD secondary to Alport Syndrome had two kidney transplants, the most recent being a deceased-donor kidney transplant in 2/2022. He was induced with alemtuzumab and maintained on tacrolimus, mycophenolate mofetil, and prednisone. His post-transplant course was complicated by antibody-mediated and cellular rejection in 12/2022, which were treated with PLEX, IVIG, rituximab, and thymoglobulin. His condition was stable until 3/2023 when he started having left-sided facial pain and congestion. A sinus CT scan showed mild mucosal thickening of the left maxillary sinus ethmoid cells. Levofloxacin was given for presumed bacterial sinusitis and a same-day ENT appointment was scheduled, but he was lost to follow-up. Three weeks later, he presented with aggravated facial pain and left-sided numbness, with no other neurological or pulmonary symptoms. A follow-up sinus CT scan suggested progressive chronic sinusitis without aggressive features. However, given the concern for fungal infection, ENT was consulted and did a nasal endoscopy which revealed black and necrotic inferior and middle left turbinates, suggesting invasive fungal sinusitis. The patient underwent surgical debridement and pathological examination confirmed invasive mucormycosis. Amphotericin therapy was initiated. A chest CT revealed a mass-like consolidation in the right middle lobe indicative of fungal pulmonary involvement. Following weekly debridements and amphotericin therapy, the patient improved and transitioned to isavuconazole therapy, further alleviating his symptoms.

Discussion: Invasive mucormycosis can manifest subtly in kidney transplant patients, with early CT scans often minimally indicative despite severe tissue damage. This emphasizes the importance of a high index of suspicion for invasive fungal sinusitis in patients presenting with severe progressive sinusitis and of prompt endoscopic evaluation and early treatment to enhance patient survival.

FR-PO773

Symptomatic Cytomegalovirus (CMV) Infection and Antibody-Mediated Rejection (ABMR) of Kidney Allograft

Lucas Schmitz,[1] Manal Alotaibi,[2] Sam Kant.[2] *[1]Ascension Health, St Agnes, Baltimore, MD; [2]Johns Hopkins University, Baltimore, MD.*

Introduction: CMV infection is a common complication after transplantation, occurring in up to 30% of kidney transplant recipients. The main risk factor for CMV viremia is serological mismatch between the donor and the recipient. Infection can lead to direct virus-induced cytopathic effect on host cells in various systems, such as pneumonia,

gastrointestinal disease, hepatitis, and even invasion of the transplanted organ. However, mechanisms of allograft injury are not limited to direct viral cytotoxicity only, as CMV infection has been shown to promote immune-mediated transplant rejection. We present a patient with symptomatic CMV infection leading to antibody-mediated allograft rejection requiring dialysis, with complete renal recovery after antiviral treatment.

Case Description: A 59 year-old male CMV D+/R- kidney transplant recipient presented seven months after transplantation with fever, chills, fatigue and acute kidney injury. Within four days, creatinine worsened to 4.6 from a baseline of 1.3. He was found to have CMV viremia with a peak of 8350 copies/mL and was started on intravenous ganciclovir. He had previously been on valganciclovir as prophylaxis. Kidney allograft biopsy demonstrated features of antibody mediated rejection, albeit with anti HLA antibodies only against third party antigens. Despite intravenous methylprednisolone and five sessions of plasmapheresis, renal function continued to deteriorate to a creatinine of 11.3, along with signs and symptoms of uremia and volume overload prompting initiation of dialysis two weeks after the initial presentation The patient continued to receive intravenous ganciclovir throughout hospitalization and CMV viral load decreased to 104 copies/mL by the time of dialysis initiation. After 1 week of dialysis, kidney recovery ensued and CMV viral load was undetectable. Repeat allograft biopsy three weeks after initiation of antiviral treatment showed signs of resolving ABMR. Patient has been off dialysis and showed complete recovery of function, with creatinine levels back at baseline two months after initial presentation

Discussion: The immune nature of antibody-mediated allograft rejection may mislead clinicians into overlooking viral infections as a potential underlying etiology. This case highlights the importance of identifying CMV viremia as a trigger of ABMR in kidney transplant recipients, as adequate treatment can lead to complete allograft recovery

FR-PO774

Donor-Derived Disseminated Bartonella Infection After Renal Transplant

Laura Bywater,[1,2] Sara M. Belga,[1,2] James H. Lan.[1,2] *[1]Vancouver Coastal Health Authority, Vancouver, BC, Canada; [2]The University of British Columbia, Vancouver, BC, Canada.*

Introduction: Bacillary angiomatosis is a manifestation of the rare infection caused by *Bartonella quintana*, with disseminated or chronic relapsing infection occurring most often in the immunocompromised. This organism is usually transmitted between hosts via the human body louse. Donor related infection is rare and screening is not routine. Those infected commonly complain of fever, headache, joint pain or weakness. Diagnosis is challenging as typical serologic testing may be negative in the immunocompromised.

Case Description: A 59 year-old male with CKD secondary to biopsy proven lambda light chain AL amyloidosis underwent a deceased donor renal transplant. He received induction immunosuppression with Basiliximab and continued on standard immunosuppression, achieving good graft function, with creatinine 1800mg/dL. The patient did not encounter clinical rejection. His background medical history was significant for amyloidosis, with disease quiescence confirmed on bone marrow aspirate and trephine biopsy pre-transplant. He had travelled extensively, had secure housing and owned a dog and chickens with no other animal exposures. Over the next several months, the patient presented with recurrent episodes of profound fatigue, weakness, headaches and occasional fever with a septic appearance on clinical examination and associated leukocytosis. Broad microbiological work-up was negative. This included serology for Bartonella species. Six months after his original presentation, the patient described small cherry red lesions on his thigh, arm and buccal mucosa. Biopsy identified bacillary angiomatosis. Warthin-Starry stains were negative, but *B. quintana* was confirmed on PCR. Serology later returned a positive result. He was treated for disseminated infection with doxycycline 100mg BID. Rifampicin was not used due to interaction with immunosuppressants. Subsequent testing of donor serum confirmed the presence of *B. quintana* antibodies. On follow-up, the patient demonstrated improvement with resolving symptoms and lesions.

Discussion: This case highlights the challenges inherent in atypical donor derived infections. Patient serology was uninformative, being initially negative after several months of symptoms and became positive much later. Given the prolonged period of infection and the inherent difficulties in diagnosis, reviewing risk factors for infection in the donor may have been useful.

FR-PO775

Concern for Donor-Derived Candidiasis Causing a Mycotic Aneurysm in the Transplanted Renal Artery

Sapna Shah, Santhi Voora, Thin Thin Maw. *University of California System, Oakland, CA.*

Introduction: Donor-derived infections can be associated with dire consequences in transplant recipients. Although extremely rare, fungal infections in renal allografts can result in renal arteritis, urinoma, graft site abscess, and surgical site infection. We present a clinical case of a mycotic aneurysm secondary to Candida krusei infection in a kidney transplant recipient.

Case Description: A 75 year old male with end stage kidney disease secondary to presumed diabetic nephropathy underwent a deceased donor kidney transplantation. At the time of transplantation the donor was noted to have untreated candida species isolated from both urine and sputum. His post-operative course was complicated by delayed graft function and post-operative myopathy. On POD 11 he was found unresponsive and pulseless in his hospital bed. Chest compressions were emergently initiated with return of spontaneous circulation. Labs were notable for new lactic acidosis, acute anemia, and hyperkalemia. CT scans of his abdomen and pelvis were obtained and notable for a large pelvic hematoma with active extravasation. He underwent emergent re-exploration of his kidney transplant and was found to have a 23 cm hematoma, and a necrotic posterior wall of his main renal artery with concern for a ruptured mycotic aneurysm (Figure 1). Both fungal and surgical cultures were positive for Candida krusei. He was initiated on Micafungin and then transitioned to Voriconazole with subsequent clearance of his fungemia after 6 weeks of therapy. Following this event he has had prolonged delayed graft function.

Discussion: Allograft artery mycotic aneurysm is an extremely rare and life-threatening complication that can develop following kidney transplantation. A high index of suspicion is needed to make the correct diagnosis of Candida associated mycotic aneurysms due to its insiduous presentation.

Figure 1: CT Abdomen with extravasation from transplanted renal artery

FR-PO776

A Rare Cause of Early Graft Failure: Mycotic Aneurysm

Adnan Faruqui, Asif A. Sharfuddin, Oluwafisayo O. Adebiyi, Muhammad S. Yaqub, Muhammad Y. Jan. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: Pseudoaneurysm of the kidney artery is a rare complication, seen in <1% of transplant recipients, generally secondary to infectious causes and at the anastomotic site(1). Kidney allograft artery thrombosis is also a rare complication similarly seen in <1% of transplant recipients. Mycotic pseudoaneurysms can present variably from being asymptomatic to fever, abdominal pain, pulsatile expansile mass, and hemorrhagic shock from rupture (2, 3). We present a case of acute allograft dysfunction in a kidney transplant patient caused by mycotic pseudo-aneurysm of the transplanted renal artery(TRA) complicated by thrombosis leading to allograft nephrectomy.

Case Description: A 40-year-old male with a history of ESKD status post deceased donor kidney transplant presented for allograft biopsy for AKI and worsening proteinuria (2.27 g/g from 0.67 g/g). Pre-Biopsy kidney ultrasound showed a new pseudoaneurysm of TRA. He underwent urgent surgical exploration and a cadaveric iliac bypass to the renal artery was done. Subsequently, to reduce the chances of pseudoaneurysm rupture given its friability, interventional radiology was consulted for a covered stent in the aneurysm. Pre-procedure angiogram showed thrombosed transplant renal artery graft, occlusion of the right external iliac and bypass, and transplant nephrectomy was performed. The infected pseudoaneurysm led to disruption of flow to the TRA leading to thrombosis Surgical pathology of the allograft kidney showed organizing thrombi in the main renal artery and segmental branch, acute tubular damage. Clinically the patient remained afebrile, infectious disease workup including blood and urine cultures were negative, Culture of the thrombosed pseudoaneurysm grew Staphylococcus hominis which was treated with IV antibiotics.

Discussion: Renal artery thrombosis and renal artery pseudoaneurysm are themselves rare complications seen in kidney transplant recipients, here we highlight a rare case of pseudoaneurysm contributing to thrombosis, which may further demonstrate urgency in the treatment of pseudoaneurysm.

FR-PO777

Cardiac Tamponade Secondary to Campylobacter Fetus Infection in a Kidney Transplant Recipient

Shota Obata,[1,2] Yasuhiro Mochida,[1] Sumi Hidaka,[3] Shuzo Kobayashi.[1] *[1]Shonan Kamakura Sogo Byoin, Kamakura, Japan; [2]Mount Sinai Beth Israel Hospital, New York, NY; [3]Shonan Kamakura Sogo Byoin, Kamakura, Japan.*

Introduction: Campylobacter fetus (C.fetus) is known to cause diarrhea as well as bacteremia, meningitis, osteomyelitis, mycotic aneurysms, and pericarditis. Immunocompromised patients are at high risk of developing systemic symptoms. We present the first case of cardiac tamponade secondary to C.fetus in a kidney transplant patient and review the outcome of C. fetus infection in organ-transplanted patients.

Case Description: A 61-year-old man with a history of ABO-compatible living-donor kidney transplantation presented to the Emergency Department with altered mental status and fever. Four months before the presentation, he complained of fatigue with mildly

elevated C-reactive protein. Although CT chest with contrast showed a small amount of pericardial effusion, he was carefully monitored without further workup. A week ago, he gradually felt weak and developed a fever. On the presentation day, he was unable to move and call an ambulance. On arrival, he was confused and hypotensive. A physical exam showed elevated jugular venous distension with a muffled heart sound. Transthoracic ultrasound demonstrated pericardial effusion with the diastolic collapse of the right ventricular. Pericardiocentesis was performed, draining 200 mL of purulent fluid. He was diagnosed with bacterial pericarditis and started on meropenem and teicoplanin. The culture returned positive for C.fetus. Then antibiotics were switched to ampicillin according to the susceptibility. He was discharged on 31 hospital-day to a nursing home for rehabilitation.

Discussion: We experienced the first case of cardiac tamponade due to C.fetus infection in a patient with a kidney transplant. C.fetus is known to colonize cattle and sheep and can be transmitted to humans via undercooked meat. Of note, this patient stated that he ate raw cattle liver and meat at a restaurant several months before the presentation. We also reviewed the five cases of C.fetus infection in patients with organ transplants. Four out of five cases responded to antibiotics, whereas one died due to sepsis. The presentations varied from bacteremia, meningitis to splenic abscesses. Interestingly, none of the five cases reported any history of exposure to cattle or sheep or raw meat intake. Nevertheless, this case reminds us of the need for guidance regarding raw meat consumption in patients who take immunosuppressive medications.

FR-PO778

Trichodysplasia Spinulosa: A Rare, Widespread Eruption in a Kidney Transplant Patient

Mariana E. Perez, Noreen Mohsin, Franco H. Cabeza Rivera. *University of Miami School of Medicine, Miami, FL.*

Introduction: Trichodysplasia Spinulosa (TS) is a rare dermatologic condition that occurs primarily in immunocompromised populations carrying the trichodysplasia spinulosa-associated polyomavirus (TSPyV), though its pathophysiology remains incompletely understood. Lesions are commonly described as flesh-colored or erythematous folliculocentric papules with protruding keratin spines and may be pruritic as well as cosmetically disfiguring if left untreated.

Case Description: A 37-year-old female with a history of deceased-donor kidney transplantation 7 months prior was referred to the dermatology clinic for a 1-month history of a pruritic, follicular rash on the face, arms, and back following the discontinuation of prophylactic valganciclovir. She was initially prescribed azelaic acid for suspected acneiform eruption on the face and triamcinolone for pruritic papules on the body. She returned 9 months later with progression of the rash and spread to her lower extremities. A punch biopsy of the patient's cheek eventually confirmed the diagnosis of TS after 13 months. The patient was prescribed cidofovir cream and tretinoin and referred to the Transplant Infectious Disease clinic.

Discussion: Due to its scarcity in medical literature, patients with TS are often misdiagnosed, leading to treatment delays and disease progression. With no standardized treatment guidelines for TS, patients can undergo several ineffective treatment trials. While the condition typically regresses after resolution of the immunosuppressive state, this can prove to be challenging in some transplant recipients, particularly those who are highly sensitized or had prior transplant rejection. Several other treatment options have been trialed with varying levels of success, the most efficacious reportedly being topical cidofovir and oral valganciclovir. Increased awareness of this condition along with close, multi-specialty interprofessional collaboration is required to expedite diagnosis, solidify a treatment plan, and ultimately improve the quality of life of solid-organ transplant patients.

FR-PO779

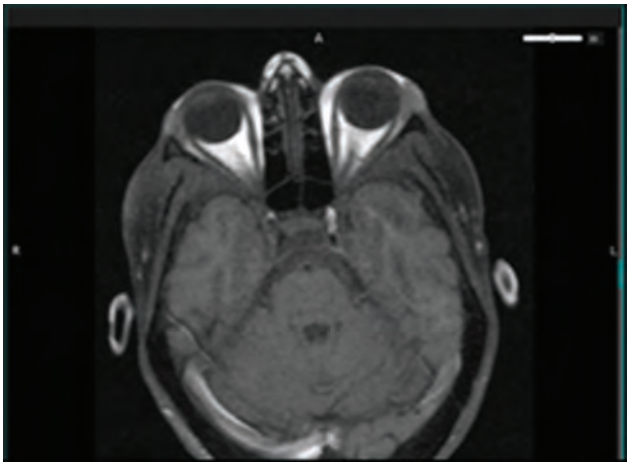
Neuro-Ophthalmic Manifestation of Cryptococcus Meningitis in a Kidney Transplant Patient

Karla G. Carias Martinez, Olwen C. Murphy, Sam Kant. *Johns Hopkins University, Baltimore, MD.*

Introduction: Cryptococcosis is the third most common cause of invasive fungal infection in solid organ transplant recipients- cryptococcal meningitis is the main clinical presentation. Vision loss in cryptococcal meningitis can be due to papilledema or optic nerve sheath infiltration

Case Description: 37-year-old female with atypical HUS (aHUS) on chronic ravulizumab, LRKT in 2019 and 3 prioe failed kidney transplants, maintained on tacrolimus and prednisone for immunosuppression regimen was admitted with progressive left vision loss consistent with optic neuritis. She was initially given pulse steroids followed with a taper with no improvement in symptoms. Subsequent work-up showed cryptococcus fungemia and meningitis with high fungal load on CSF. MRI orbit with contrast (Figure 1) showed marked perineural enhancement of the left optic nerve. There was no history of recent travel or constitutional symptoms. Mycophenolate was held and prompt treatment was started with Amphotericin and flucytosine induction for 2 weeks and then transitioned to maintenance fluconazole.

Discussion: Based on the clinical presentation and orbit MRI results that showed marked perineural enhancement of the optic nerve (a surrogate of meningeal inflammation) and the temporal association with her diagnosis of cryptococcal meningitis, this was deemed to be the most likely etiology of her vision loss. This is an unusual and rare presentation of cryptococcal meningitis but has been described in the literature. With her long-term use of CNIs, tacrolimus induced optic neuropathy was considered. This rare side effect, however, usually affects both optic nerves and orbital MRI reveal optic disc or nerve inflammation in the form of contrast enhancement. The common clinical practice is to switch tacrolimus to another immunosuppressive agent but as her clinical presentation was not consistent with this and her immunosuppression regimen was not altered.



FR-PO780

A Case of Hemorrhagic Cystitis Leading to Disseminated Disease from Adenovirus in a Renal Transplant Patient

Neetha Mathew, Sonalis Fernandez, Zahidul H. Mondal, Sonika Puri, Amar M. Bhagat, Chioma Madu. Rutgers Robert Wood Johnson University Hospital Dept of Nephrology. *Robert Wood Johnson University Hospital, New Brunswick, NJ.*

Introduction: Adenovirus can cause many infections in immunocompromised hosts including nephritis and hemorrhagic cystitis. It commonly occurs in immunocompromised patients from reactivation of latent infection or primary infection. It is especially concerning in patients with renal transplants. The diagnosis requires the use of multiple diagnostic specimens to detect viral shedding. Diagnosis is also made in the context of clinical manifestations, as in our patient who developed adenovirus infection with hemorrhagic cystitis.

Case Description: This is a 63-year-old woman with a history of ESRD secondary to hypertensive nephrosclerosis status-post DDRT on 9/13/2016. Her post-transplant course was uneventful and she was discharged with a creatinine of 0.7 mg/dl. She presented to the hospital six years post-transplant with dysuria, urinary urgency, urinary frequency and lower abdominal pain with urination. Her creatinine at this time was 0.6 mg/dL. Her urinalysis showed 37 white blood cells and > 182 red blood cells. She was started on Zosyn for possible pyelonephritis. Her urine culture had no growth and she was discharged on levofloxacin. She was readmitted about one week later with recurrence of urinary symptoms and hematuria. Her urinalysis showed > 182 red blood cells and her creatinine was 1.6 mg/dL. A CT urogram was done and was unremarkable. Due to her AKI, a renal biopsy was performed which was unable to be analyzed due to an inefficient tissue sample. She was found to be positive for adenovirus PCR DNA and was started on cidofovir and probenecid. Her creatinine normalized to her baseline. She was continued on her immunosuppression regimen of Myfortic, Envarsus and prednisone. She completed treatment for her adenovirus infection after two months with resolution of her symptoms and notable clearance of adenovirus DNA in the serum.

Discussion: Most adenovirus infections are self-limited and treatment is usually supportive. However, adenovirus can be fatal in immunocompromised hosts with high morbidity and mortality. Disseminated adenovirus disease may be preceded by a period of asymptomatic viremia. Thus, the diagnosis can be missed leading to poor outcomes. The early identification of the disease by monitoring viremia has been shown to be beneficial, as we see for CMV infections in immunocompromised patients.

FR-PO781

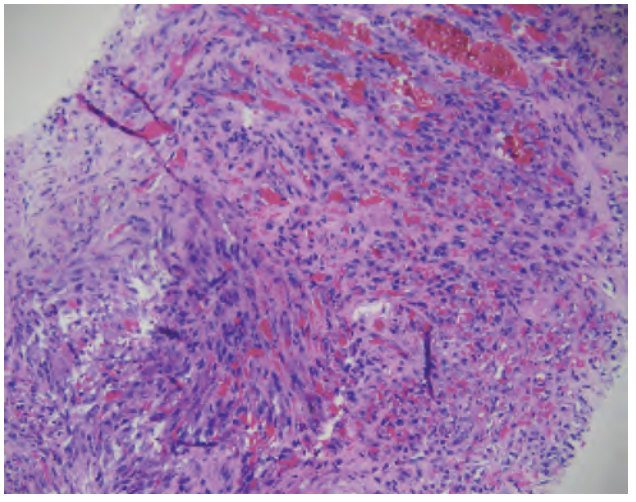
Donor-Derived Human Herpes Virus-8 (HHV8)-Related Kaposi Sarcoma (KS) in Renal Allograft Following a Hepatitis C Virus (HCV)-Positive Kidney Transplantation

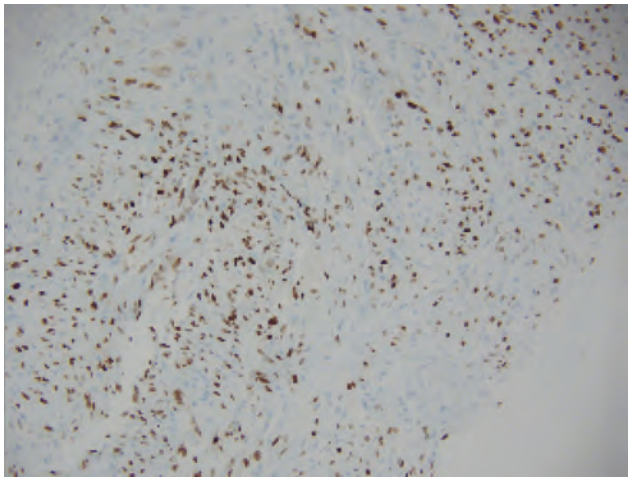
Shikha Jaiswal, Amit Govil, Niralee Patel, Nives Zimmermann, Madison Cuffy, Manish Anand. *University of Cincinnati, Cincinnati, OH.*

Introduction: KS post Kidney transplantation can develop due to reactivation of recipient latent HHV8 infection, or donor acquired HHV8 infection. We describe a rare case of Donor derived HHV8 related KS involving the allograft, presenting as Acute kidney Injury.

Case Description: 54-year-old female underwent kidney transplant from HCV positive deceased donor. Immunosuppression(IS) included Thymoglobulin followed by tacrolimus and mycophenolate (MMF). She was successfully treated for Donor-derived HCV infection with Sofosbuvir/Velpatasvir. Baseline serum creatinine was 1.4 mg/dl. She developed CMV Viremia that responded well to reduced IS and valganciclovir. However, creatinine increased to 2.3mg/dl, and transplant biopsy was done to rule out rejection. It showed foci of vascular proliferation, prominent mitoses, atypical cells with enlarged nuclei (Fig 1) and positive Immunostain for HHV8 (Fig2) indicating KS. Her MMF was switched to Everolimus. She had no cutaneous lesions on exam and has been referred to Oncology.

Discussion: Increasing proportion of PHS high risk organ recipients are at risk for HHV8 infection and KS. To our knowledge only 8 cases of KS involving renal allograft have been described, with only 2 derived from HCV positive donors. With limited pre transplant testing of donors for HHV 8 infection, close monitoring of recipients with PHS high risk organs for KS is suggested.





FR-PO782

Kaposi Sarcoma Involving the Renal Allograft: Report of Two Cases

Khaled Murshed, Mostafa Elshirbeny, Mohamad M. Alkadi, Awais Nauman. *Hamad Medical Corporation, Doha, Qatar.*

Introduction: The use of immunosuppressive agents for prevention of allograft rejection increases the risk of malignancy. The magnitude of the higher risk is dependent on cancer types, with the greatest risk in viral-related and immune driven cancers such as post-transplant lymphoproliferative disease (PTLD) and Kaposi sarcoma (KS). Involvement of the renal allograft by KS is extremely rare. Here, we present two cases of KS involving the renal allograft

Case Description: Case 1: Sudanese gentleman who was diagnosed to have ESRD. He had live unrelated kidney transplant in June 2014. His course was unremarkable till 7/2015 when he presented with acute graft dysfunction and MRI abdomen revealed: bulky transplanted kidney with multiple liver, splenic and vertebral lesions. Anti-human herpes virus 8 (HHV-8) antibody was positive and transplanted kidney and liver biopsies revealed KS. Immunosuppression was reduced and patient experienced improving general condition later. Case 2: 46 years old Mozambican gentleman, known case of ESRD. Underwent living unrelated renal transplant then 10 months after transplant, patient was admitted with rising serum creatinine and pancytopenia. Transplanted kidney biopsy revealed: extensive infiltration by Kaposi sarcoma with negative C4d and SV-40. HHV8 was positive in the nuclei of most of the tumor cells. Then patient decided to return back to his home country.

Discussion: Kaposi sarcoma (KS) was first reported in 1872 by Moritz Kaposi, a Hungarian physician. Several reports have documented an endemic form of KS mostly encountered in Africa**.** Indeed, the incidence of KS is now known to reflect differences in the prevalence of Kaposi Sarcoma Virus (KSHV). This virus is also called Human Herpes Virus8 (HHV8). Patient 1 was from Sudan which generally not considered a Sub-Saharan country but it nevertheless has high incidence of KS. Patient 2 was from Mozambique, a country in Sub Saharan known to have high incidence of KS. Involvement of the renal allograft by KS however is extremely rare with only eight cases reported in the literature. The patient's age ranged from 28 to 71 year and in all cases, KS was diagnosed within 12 months after transplantation. Reduction of immunosuppression resulted in regression of the tumor in most cases. In conclusion we present 2 cases of KS in the renal allograft which brings the number of cases to 10.

FR-PO783

"Goose Bumps" Trichodysplasia spinulosa Viremia in a Patient with Kidney Allograft

Tariq A. Shaheed, Hardeep Aulakh, Cynthia Davila, Rana Sandhu. Kaiser Family Foundation, The Permanente Medical Group, Kaiser San Francisco Hospital, Kidney Transplant Clinics. *The Permanente Medical Group, Berkeley, CA.*

Introduction: Trichodysplasia Spinulosa (TSPyV) is a DNA virus in the polyomavirdae family first identified 1995 and genotyped 2010. This virus is ubiquitous in immune competent humans and immunosuppressed patients rarely have clinical manifestations of viremia.

Case Description: 35-year-old man with h/o ESKD due to an unknown etiology s/p (DDKT) in June of 2021, HTN, Crohn's, asthma, and anaphylaxis to peanuts was seen in transplant clinic for maintenance of immune suppression on tacrolimus (Tac), mycophenolate (MMF), and prednisone. The patient developed a rash involving his gluteus, face, nose, and extremities 7 months post-transplant. (See image) He described it as "bumps with feathers growing out of them." A shave biopsy revealed hyperkeratotic and parakeratotic debris in the hair shaft consistent with TSPyV. Treatment advised was a reduced Tac goal and reduced MMF dose as well as initiation of topical cidofovir. The patient went on a 6-month trekking trip where lesions worsened and was not available for follow up. At this time, he self-discontinued prednisone due to GI upset and stopped cidofovir after 1-2 weeks of use due to skin breakdown. He was switched from MMF to everolimus, but he stopped this due to cystic acne which he attributed to everolimus. After 13 months of adjustments the patient showed improvement of skin lesions and continues Tac with goal of (4-5) and MMF 500mg BID off prednisone Cidofovir and everolimus.

Discussion: TSPyV viremia may have significant dermatologic manifestations and there are allograft threatening implications in the management which typically includes topical antivirals, clinical monitoring, and reduction of immune suppression with lower Tac goals in the 4-5 range. It is important for clinicians to counsel patients on the importance of medication adherence and follow up regarding complications of immune suppression. **Viremia not confirmed. Diagnosis made by clinical presentation and histopathological appearance.*

Before and after TSPyV viremia lesions on patient's arm.

FR-PO784

Donor-Derived West Nile Virus Infection After Renal Transplant Treated with Plasmapheresis

Syeda S. Bukhari,[1] Adrianne F. Basa,[2] Omar N. Elhawary,[1] Sandeep R. Sasidharan,[1] Moro O. Salifu,[1] Subodh J. Saggi.[1] *[1]SUNY Downstate Health Sciences University, New York City, NY; [2]NYU Langone Health, New York, NY.*

Introduction: West Nile Virus is a single-stranded RNA Flavivirus usually transmitted through mosquito bites. The clinical presentation usually varies from asymptomatic, mild gastrointestinal symptoms and fever to <1% developing Neuroinvasive disease. The literature showed that organ derived WNV infection is associated with 70% of neurological sequelae and 30% of severe morbidity and mortality. The onset of symptomatic WNV infection post-organ transplant is usually around 13 days however the range varies from 5-37 days.

Case Description: A 50 Y/O male who presented for a Deceased Donor kidney transplant. His previous history included ESRD on Peritoneal dialysis, Focal segmental Glomerulosclerosis, and Hypertension. He denies any sick contacts and recent travel. His review of systems and physical examination were normal. He developed fever, altered sensorium and seizures almost 16 days post-transplant. On neurological examination, he was found to be minimally responsive. Initial work including CSF fluid analysis and a CT scan of the Brain was inconclusive. His MRI showed linear symmetric restricted diffusion in both cerebellar hemispheres and his post-transplant Ct scan showed a colonic mass. The patient was given two sessions of plasmapheresis based on the pertinent MRI findings and suspicion of paraneoplastic syndrome. His lab reported later showed negative paraneoplastic panel. The primary team sent the WNV panel to the Department of Health and it came back positive for WNV IgM. His serum and urine PCR also came back positive for WNV antigen. Plasmapheresis was stopped and IVIG was started based on some previous case reports. Additional two sessions of plasmapheresis were given post-IVIG, and his blood and urine turned negative for WNV IgM after 14 days of treatment. Repeated MRI also showed stable restriction diffusion defects.

Discussion: The treatment for WNV is usually supportive, reduction of immunosuppressants and IVIG. Some case reports show additional benefits of plasmapheresis especially in neuroinvasive disease. So far only IVIG has been used and showed benefits in West Nile Virus Infection after solid organ transplant. This was the first-time plasmapheresis was done and showed a significant response. WNV screening should be considered a routine workup for potential organ donors living in endemic areas.

FR-PO785

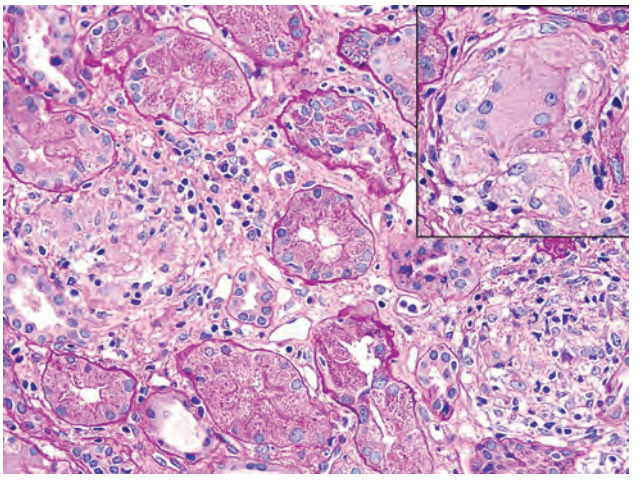
Concurrent Epstein-Barr Virus (EBV) Viremia, Non-Tuberculosis (TB) Mycobacterial Infection, and Acute T Cell-Mediated Rejection (TCMR) in Kidney Transplant (KT) Recipient

Justin S. Love, Satoru Kudose, Meaghan Phipps, Syed A. Husain, Justin G. Aaron. *Columbia University Irving Medical Center, New York, NY.*

Introduction: Managing concurrent rejection and infection after KT is a therapeutic challenge. M. genavense is a rare, difficult-to-identify mycobacterial infection. We present a case of simultaneous EBV viremia, disseminated M. genavense infection, TCMR.

Case Description: A 54yo man with ESKD due to HTN underwent deceased donor KT with thymoglobulin induction followed by tacrolimus dosed for goal trough 9-12 and mycophenolate mofetil (MMF) 1g BID. EBV IgG detectable in donor but not recipient. Initial post-KT course was uncomplicated (nadir Cr 1.19) until developing EBV viremia (1,992 cop/ml) and night sweats 6 months post-KT. MMF was stopped. PET-CT revealed 1.8cm FDG-avid posterior mediastinal node, diffuse increased marrow activity, and possible old granulomatous lung disease. Lymph node biopsy showed non-necrotizing granulomas with AFB. Quantiferon gold was negative. Low-grade EBV viremia, night sweats, chills, and fever continued with labs at 9 months post-KT showing elevated LFTs (Alk Phos 544, TB 3.9, AST 69, ALT 46). Empiric treatment initiated with azithromycin, rifabutin, moxifloxacin, and ethambutol. Liver biopsy revealed non-caseating granulomas consistent with disseminated mycobacterial infection, finally speciated 4 months later as M. genavense. 14 months post-KT, Cr rose from 1.29 to 2.34 with Banff grade 1B TCMR and interstitial non-caseating granulomas on allograft biopsy (Figure). IVIG 2g/kg every other month was initiated and Cr decreased to 1.34. 8 months later, he was asymptomatic and repeat renal biopsy showed no rejection. Antibiotics were discontinued after 12 months of treatment. On follow up 2 years post-KT, remains asymptomatic with Cr 1.34, undetectable EBV, and normalized LFTs.

Discussion: Combination antibiotic treatment for 1 year, high-dose IVIG, and immunosuppression reduction effectively treated concurrent EBV viremia, disseminated M. genavense infection, and TCMR.



FR-PO786

Phlegmonous Gastritis After Renal Transplantation First Case Reported in the Literature

Alejandro R. Montaño, Axel Corona-Deschamps, Lucero Salgado-Ambrosio, Cesar Adolfo Nieves Perez. Equipo Nefrología-Trasplante Ángeles Pedregal. *Hospital Angeles del Pedregal, Mexico City, Mexico.*

Introduction: Phlegmonous gastritis (PG) is a rare condition. Approximately one case per year has been reported in the literature, with a total of around 500 reported cases. We present the first case of phlegmonous gastritis following kidney transplantation, to the best of our knowledge based on the literature available.
