JASN®

KIDNEY WEEK EDITION

Journal of the American Society of Nephrology

Abstract Supplement

KIDNEY WEEK 2023

Abstract Supplement

Abstract Publication
More than 3,000 abstracts are published in this supplement. Abstracts are arranged by the abstract type**, then by presentation date* for orals and posters, and then by chronological publication number. Abstracts with a "PUB" number will not be presented at the ASN Annual Meeting.

* TH = Thursday, FR = Friday, SA = Saturday
** OR = Oral, PO = Poster, PUB = Publication Only

The presenting author's name is underlined.

Abstract Author Index
The Author Index lists all abstract authors in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB), then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Keyword Index
The Keyword Index lists major keywords from each abstract in alphabetical order. To locate an abstract, first reference the abstract type (OR, PO, or PUB), then the presentation day (TH, FR, or SA), and then the chronological publication number.

Abstract Reference Format
To cite abstracts in this publication, please use the following format: Author Names: Abstract Title [Abstract]. J Am Soc Nephrol 34, 2023: Page(s).

Abstract Disclaimer and Copyright
This abstract issue of JASN® contains proprietary information belonging to the American Society of Nephrology. It is published as a service for the personal, noncommercial, and informational use only of the kidney community. Any commercial use is strictly prohibited. ASN's program materials and publications facilitate scientific discourse for educational purposes. ASN accepts no responsibility for any products, presentations, opinions, statements, or positions expressed, and inclusion of such materials within Kidney Week and other ASN publications or online postings does not constitute endorsement by ASN.

Abstract Experts
Abstract submissions were rigorously reviewed and graded by multiple experts. ASN thanks the abstract category chairs and reviewers for assistance with the abstract process. The ASN website lists all abstract experts.

ASN General Information
Kidney Week Program and Presentations
The Kidney Week program, which can be found on the ASN website, includes:

- Plenary Sessions
- Basic/Clinical Science Sessions
- Clinical Practice Sessions
- Translational Sessions
- Special Sessions
- Educational Symposia
- Oral Abstract Sessions
- Poster Sessions

Disclosure Statement
ASN requires all individuals in a position to control content for Kidney Week to complete a disclosure form. Responses are listed on the ASN website.

TH-OR01

Heart-Specific LIM Protein (CSRP3) as a Novel Cardiorenal Connector in Acute Cardiorenal Syndrome-Related CKD Progression

Yoshio Funahashi,[1] Michael Hutchens.[1,2] *[1]Oregon Health & Science University, Portland, OR; [2]Portland VA Medical Center, Portland, OR.*

Background: Cardiorenal syndrome type 1 (CRS1) is acute kidney injury (AKI) caused by acute cardiovascular disease. Our translational CRS1 model, cardiac arrest and cardiopulmonary resuscitation (CA/CPR) causes AKI-CKD transition characterized by reduced GFR, increased fibrosis, renovascular hypertrophy, and elevated blood pressure--CRS1-induced AKI-CKD (CRACKD). Heart specific LIM protein (CSRP3) is secreted into blood stream by acute cardiac injury, and taken up by renal proximal tubular cells via megalin mediated endocytosis. We hypothesized that cardiac CSRP3 mediates CRACKD.

Methods: We generated inducible cardiac CSRP3 KO mice (iCSRP3KO, csrp3 flfl/myh6 cre-esr1). CA/CPR (8min cardiac arrest) or 8min ischemia reperfusion injury (IRI) was performed to C57BL6 mice, inducible proximal tubules megalin KO mice (iMegKO), or iCSRP3KO mice. IRI mice were injected 5ug CSRP3 or PBS. GFR, αSMA expression, and renovascular wall thickness were analyzed at 49 days. Research-designated human kidney proximal tubular epithelial cell (PTEC) was used in vitro.

Results: iCSRP3KO mice did not express CSRP3 in myocardium. SnRNA sequencing of CA/CPR kidney and bulk RNA sequencing of CSRP3 treated PTEC demonstrated similar alteration of fibrosis and myogenesis related genes. CSRP3-treated IRI mice (CSRP3-IRI) demonstrated reduced GFR (785.0±96.6 vs 933.3±148.6 (μg/min/100g), $p<0.05$), increased fibrosis ($V_{\alpha SMA}/V_{kidney}$: 2.37±0.99 vs 1.43±0.40, $p<0.05$) and renovascular hypertrophy (thickness index: 0.61±0.03 vs 0.50±0.03, $p<0.01$) compared with PBS-treated IRI mice. These CSRP3 induced phenotypic changes were attenuated by pharmacological megalin inhibition in CSRP3-IRI mice or iMegKO-CA/CPR mice. Compared with littermate control, deletion of cardiac CSRP3 ameliorated CA/CPR induced GFR loss (845.4±75.6 vs 723.3±75.5, $p<0.05$) and BP elevation (122.8±13.3 vs 145.1±15.7 (mmHg), $p<0.05$). (Mean+/-SD, Student's t-test)

Conclusions: Cardiac CSRP3 mediates renal fibrosis and myogenesis leading to CRACKD. We report a novel mechanism of CRS1 induced AKI-CKD transition.

TH-OR02

The Epidermal Growth Factor Receptor Is an Essential Mediator of Interstitial Fibrosis Development Following AKI

Shirong Cao,[1] Yu Pan,[1,2] Ming-Zhi Zhang,[1] Raymond C. Harris.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Division of Nephrology, Shanghai Ninth People's Hospital, Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: In the kidney, tubulointerstitial fibrosis can result from incomplete recovery from acute kidney injury (AKI), toxic injury or other inflammatory insults. Activation of the Epidermal Growth Factor Receptor (EGFR) has been implicated as a potential mediator of interstitial fibrosis but underlying mechanisms of EGFR's actions have not been previously addressed.

Methods: To delete EGFR selectively in the fibroblast/pericyte population, we generated PDGFRβ-Cre/ERT2; mCherry (WT) and PDGFRβ-Cre/ERT2; mCherry; $EGFR^{f/f}$ (FibEGFR-/-) mice. Models of acute kidney injury included ischemia/reperfusion, UUO and folate and adenine nephropathy. In vitro studies utilized immortalized mouse fibroblasts.

Results: In all models of acute injury, FibEGFR-/- mice developed less tubulointerstitial fibrosis and isolated fibroblasts had decreased collagen mRNA expression. Fibroblast EGFR expression played an essential role in fibroblast migration and proliferation after injury. In cultured mouse fibroblast cells, EGFR activation induced proliferation but decreased expression of SMAD3 and myofibroblast markers. TGF-ß did not induce proliferation but reversed EGFR's inhibition and stimulated myofibroblast differentiation. SnRNAseq confirmed decreased markers of fibroblast proliferation and cell motility and numbers of myofibroblasts in FibEGFR-/- mice.

Conclusions: These studies provided evidence for a heretofore undescribed and important role for EGFR in kidney fibroblasts and pericytes as a specific initiator of interstitial fibrosis in response to kidney injury by stimulating pericyte/fibroblast migration and proliferation.

TH-OR03

Prevention of Ischemia-Reperfusion Injury (IRI)-Induced AKI by Maintaining Na+/K+ ATPase Activity

Nadezhda N. Zheleznova,[1] Tamara A. Wahbeh,[1] Lei Wang,[1] Jie Zhang,[2] Jin Wei,[2] Nathan Hall,[1] Nohely Hernandez Soto,[1] Bo Chen,[1] Wei Chen,[1] Ruisheng Liu.[1] *[1]University of South Florida, Tampa, FL; [2]Boston University, Boston, MA.*

Background: IRI impairs Na/K ATPase pump function leading to cellular death. We developed a method using a 3rd Generation Synchronization Modulation Electric field (SMEF) to optimize Na/K ATPase activity during ischemia (Sci Trans Med. 2022). Now, advanced to a 4th Generation SMEF, we have incorporated dual-energy transformation functions and power injections for ATP generation, hypothesizing that it will more efficiently combat ischemia-reperfusion-induced acute kidney injury (AKI).

Methods: Male and female C57BL/6J mice were divided into 3 groups: sham control, AKI without 4th-SMEF, and AKI with 4th-SMEF. A right nephrectomy was performed, followed by warm ischemia induction by clamping of the left renal pedicle (20 min in males vs. 25 min in females). In the 4th-SMEF group, an electric field was applied to the left kidney pre-clamping. Plasma creatinine (Day 1,3,7), Glomerular Filtration Rate (day 7), KIM-1, and Na/K pump activity and expression were evaluated. A histological kidney tissue examination was conducted.

Results: The 4th-SMEF reduced plasma creatinine by 92% in males (4th-SMEF:0.21±0.10 mg/dL, untreated AKI:2.56±0.9 mg/dL) and 82% in females (4th-SMEF:0.34±0.3 mg/dL, untreated AKI 1.84±0.4 mg/dL), displaying similitude to sham groups. This outperforms the previous 3rd-SMEF approach, decreasing plasma creatinine by only 40% (Chen, 2022). GFR showed 60% improvement in males (4th-SMEF:255 μl/min, untreated AKI:110 μl/min) and 55% improvement in females (4th-SMEF: 220μl/min, untreated AKI:98μl/min). KIM-1 marker in the AKI-treated group, the sham, and 4th-SMEF-treated groups showed: (271±30 pg/ml, 60±9 pg/ml, and 66±21 pg/ml) respectively. Baseline Na/K expression is higher in females. AKI groups of both genders exhibited reduced activity, and expression, alongside cellular relocation. With 4th-SMEF, both genders reached equalized Na/K pump activity and degradation reduction. Histology conveyed diffuse renal tubular necrosis and casts comprising necrotic cells and debris in AKI groups. In contrast, the 4th-SMEF treatment essentially normalized the histopathologic changes aiding strong similarity to the sham group.

Conclusions: 4th-SMEF prevented AKI by equally normalizing Na/K pump activity in both genders of mice, leading to similar prevention of IRI-induced AKI.

TH-OR04

Analysis of the Immune Cell Landscape Identifies Immunosenescence as a Therapeutic Target in Rhabdomyolysis-Induced AKI

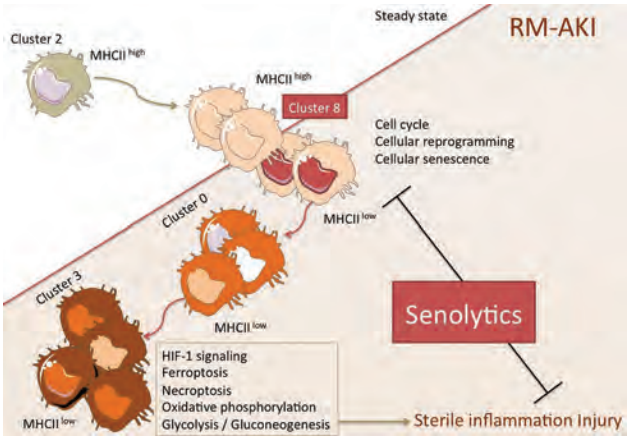
Snigdha N. Rao,[1] Jean Sébastien Saulnier-Blache,[1] Joost Schanstra,[1] Julie Belliere.[1,2] *[1]INSERM U1297, Toulouse, France; [2]Centre Hospitalier Universitaire de Toulouse, Toulouse, France.*

Background: Rhabdomyolysis (RM) accounts for 10% of the acute kidney injury (AKI) cases. The role of macrophages in the development of RM-AKI lesions has been clearly established, but a high resolution understanding of the changes in the immune landscape could help to improve targeted strategies.

Methods: Single-cell RNA sequencing was used in the murine glycerol-induced RM-AKI model to dissect the transcriptomic characteristics of CD45+ live cells sorted from kidneys 2 days after injury. A combination of senolytics (dasatinib and quercetin) was administered to mice exposed or not to RM-AKI.

Results: Unsupervised clustering of nearly 17,000 single-cell transcriptomes identified 7 known immune cell clusters. Sub-clustering of the mononuclear phagocyte cells (MPC), including monocytes, macrophages and dendritic cells, revealed 9 distinct cell sub-populations differently modified with RM. One macrophage cluster was particularly interesting since it behaved as a critical node in a trajectory connecting one MCHIIhigh cluster only present in control to 2 MCHIIlow clusters only present RM-AKI. Because this crucial cluster expressed senescence hallmark genes, the effect of combined dasatinib and quercetin (DQ) senolytics treatment was evaluated. DQ treatment in RM-AKI improved kidney function and blocked the known phenotypic switch from F4/80highCD11blow to F4/80lowCD11bhigh MPC.

Conclusions: scRNASeq identified novel renal myeloid subtypes after RM-AKI and unmasked a transition macrophage population affected by cellular senescence processes. This work provides a proof-of-concept that immunosenescence occurs during AKI and that senolytics deserve attention as potential nephroprotective drugs.



TH-OR05

Novel Anti-Inflammatory Effects of IL-1 Receptor in Kidney Myeloid Cells Following AKI

Yanting Chen,[1] Xiaohan Lu,[2] Jiahui Su,[2] Steven D. Crowley,[2] Jamie Privratsky.[1,3] *[1]Center for Perioperative Organ Protection, Department of Anesthesiology, Duke University Medical Center, Durham, NC; [2]Division of Nephrology, Department of Medicine, Duke University Medical Center, Durham, NC; [3]Division of Critical Care Medicine, Department of Anesthesiology, Duke University Medical Center, Durham, NC.*

Background: Acute kidney injury (AKI) is a leading cause of organ failure in hospitalized and critically ill patients. Following AKI, the canonical pro-inflammatory cytokine interleukin-1β (IL1β) is released predominantly from activated myeloid cells and binds to the interleukin-1 receptor R1 (IL1R1). IL1R1 activation is known to amplify the immune response and exacerbate AKI. However, the specific role of IL-1R1 on myeloid cells during AKI is poorly understood. Our objective was to study the function of myeloid cell IL-1R1 during AKI. As IL1R1 is known to signal through the pro-inflammatory Toll-like receptor (TLR)/MyD88 pathway, we initially hypothesized that myeloid cell IL1R1 activation would exacerbate AKI.

Methods: IL1R1 was selectively depleted in CD11c+ myeloid cells with *CD11cCre(+) / Il1r1$^{fl/fl}$* ($IL1R1^{CD11cKO}$) mice. $IL1R1^{CD11cKO}$ and littermate controls (*CD11cCre(-) / Il1r1$^{fl/fl}$* - $IL1R1^{CD11cWT}$) were subjected to kidney ischemia/reperfusion (I/R) injury. Kidney injury was assessed by serum creatinine and histologic injury scoring. Renal tubular cells (RTC) were co-cultured with CD11c+ bone-marrow derived dendritic cells (BMDC) from $IL1R1^{CD11cKO}$ and $IL1R1^{CD11cWT}$ mice.

Results: Surprisingly, compared to $IL1R1^{CD11cWT}$ mice, $IL1R1^{CD11cKO}$ mice displayed exaggerated I/R-induced kidney injury, as indicated by elevated levels of serum creatinine (mean ± SD: 1.24 ±0.85 vs 2.06 ± 1.17 mg/dl, $p<0.05$), BUN (mean ± SD: 90.91 ± 35.68 vs 134.87 ± 37.92 mg/dl, $p<0.01$), and histologic injury scoring. In support of these findings, *in vitro* co-culture studies showed that RTC co-cultured with $IL1R1^{CD11cKO}$ BMDC (in the presence of IL1β or LPS) exhibited higher mRNA levels of the kidney injury marker neutrophil gelatinase-associated lipocalin (NGAL) than those co-cultured with $IL1R1^{CD11cWT}$ BMDC. Furthermore, we observed that IL1R1 activation on $IL1R1^{CD11cWT}$ BMDC preferentially augmented expression of anti-inflammatory mediators tumor necrosis factor alpha induced protein 3 (A20) and interleukin-1 receptor antagonist (IL1Ra/Il1rn), effects that were abrogated by $IL1R1^{CD11cKO}$ BMDC.

Conclusions: Our findings suggest a novel function of IL1R1 is to serve as a critical negative feedback regulator of IL1 signaling in CD11c+ cells to dampen inflammation and limit AKI. Our results lend further support for cell-specific, as opposed to global, targeting of immunomodulatory agents.

TH-OR06

The Kidney-Gut-Brain Axis in AKI

Jihyun Yang,[1] Young Eun Choi,[2] Sungyeon Kim,[2] Suk Min Chung,[2] Yookyung Jang,[2] Ko Yoon Sook,[2] Lee Hee Young,[2] Tai yeon Koo,[2] Sewon Oh,[2] Myung-Gyu Kim,[2] Sang-Kyung Jo.[2] *[1]Kangbuk Samsung Hospital, Jongno-gu, Seoul, Republic of Korea; [2]Korea University, Seongbuk-gu, Republic of Korea.*

Background: Although epidemiological studies suggest that long-term survivors of dialysis requiring AKI had increased risk of dementia, its underlying mechanisms remain uncertain. Based on recent data showing kidney-gut crosstalk mediated by immune modulation in AKI, we hypothesized that gut dysbiosis and aberrant gut immune response might contribute to the cognitive dysfunction following AKI.

Methods: In mouse long-term AKI survival model (1yr after kidney ischemia/reperfusion injury (IRI)), we determined functional and structural alterations of brain, changes in gut microenvironment including dysbiosis and immune cell phenotypes. For better insight about the causal relationship in kidney-gut-brain axis, we also tested the effect of fecal microbiota transfer (FMT) and cohousing (transfer microbiota by coprophage) on kidney and brain in long-term AKI mouse model.

Results: One year after kidney IRI, mice showed abnormal behaviors in open field test compared to age matched sham control. Transcriptosome of hippocampus demonstrated more than 120 differentially regulated genes including those involved in angiogenesis/immune and inflammatory response. We also found structural brain injury including disruption of BBB, neuroinflammation, oxidative stress as well as accumulation of amyloid-b fibrils and hyperphosphorylated tau proteins, suggesting the development of Alzheimer like dementia long after AKI. Gut microbiota structure 1yr after kidney IRI was also clearly distinguished from that of sham control and was associated with increased ratio of Th17/Tregs balance, showing the persistence of gut dysbiosis and aberrant gut mucosal immune response long after AKI. Both cohousing and FMT partially restored the gut mucosal inflammation and this also led to not only decreased kidney fibrosis but also improved cognitive function as well as neuroinflammation and tauopathy.

Conclusions: This is the first animal study that showed that AKI can lead to Alzheimer like neurodegeneration. Gut dysbiosis and aberrant mucosal immune response is thought to contribute to the development of tauopathy/neuroinflammation and congtivie dysfunction long after AKI. Our data provide new insights into "kidney-gut-brain" axis in the field of AKI and suggest that gut might be a new therapeutic target for the prevention of long-term adverse outcomes in AKI patients.

TH-OR07

Spatial Multi-Omic Atlas of Pyelonephritis

Xin Wang, Israel Cotzomi Ortega, Yuriko I. Sanchez-Zamora, Rishil H. Patel, Macie M. Kercsmar, Ashley R. Jackson, John D. Spencer, Brian Becknell, Juan de Dios Ruiz-Rosado. *Nationwide Children's Hospital, Columbus, OH.*

Background: Pyelonephritis (PN) causes renal injury, inflammation, and scarring. Over 80% of PN episodes are due to uropathogenic *Escherichia coli* (UPEC). The molecular mechanisms of acute kidney injury and renal fibrosis in PN patients are poorly understood, hindering the development of effective therapies.

Methods: We infected female C3H/HeOuJ mice via transurethral inoculation with UPEC. Spatial transcriptomics (ST, Visium 10x genomics) and PIPseq™ single-cell RNA-seq were performed on kidney samples at multiple time points (0, 1, 3, 5, 7, and 28 days post infection). The integrative analysis encompassed pathological evaluation, cell type annotation, spatial deconvolution, differential gene expression, cell-cell communication, pseudotime inference, and signaling pathway exploration, aiming to unravel the dynamic structural and molecular changes during PN.

Results: We characterized 20,831 spatial spots with deconvoluted cell-type compositions at six timepoints. We profiled 40,224 single cells representing 18 major cell types and identified infected proximal tubule cells with distinct cell-cycle and key signaling states. Integration of these multi-modal datasets revealed two distinct clustering structures of tissue abscesses that were specific to the infection and associated with fibrotic injury, repair, and remodeling. These abscess structures exhibited increased levels of colocalization between leukocytes, fibroblasts, and endothelial cells after infection, along with activations in leukocyte migration and proliferation, T cell activation, TNF-α signaling, and cell-cell adhesion. Signaling analyses unveiled unique spatial dependencies in hypoxia, apoptosis, proinflammatory responses, profibrotic and proliferative processes. The marginal regions of the renal abscess displayed dramatically increased activation in NF-κB, TNF-α, EGFR, and P53 signaling pathways, but decreased Stat1 and Wnt pathway activity.

Conclusions: Our study provides an integrative map of the spatial gene expression and gene-regulation networks involved in maintaining kidney homeostasis and immune responses during PN. We believe our findings will contribute to the advancement of mechanistic insights and potential therapeutic strategies to treat PN.

Funding: NIDDK Support

TH-OR08

Differential Roles of Regnase3 in Resident Macrophages vs. Renal Tubular Epithelial Cells in Kidney Injury

Chenyu Li, Hans J. Anders. *Klinikum der Universitat Munchen Medizinische Klinik und Poliklinik IV - Standort Ziemssenstrasse, Munchen, Germany.*

Background: RNA-binding proteins are a class of proteins that regulate RNA and have been implicated in a wide range of diseases. Regnase3 as one of those proteins has been shown to promote inflammation by increasing TNF in macrophages (Mφ). However, the full extent of its functions in kidney disease remains unknown. We hypothesized that Regnase3 plays a role in both kidney resident Mφ and renal tubular epithelial cells (RTEC), influencing inflammation and kidney repair after injury.

Methods: A series of genetically-modified mice were developed, including the Pax8rTtA, TetOCre, receptor activator of nuclear factor kappa-B (Rank, a lineage tracer for kidney resident Mφ)-Cre (RankCre), and Regnase3 floxed (Regnase3fl/fl) mice. Upon these mice, we applied a range of kidney injury models involving unilateral ischemia-reperfusion and nephrocalcinosis. Furthermore, scRNA-seq and RNA-seq were utilized to investigate the underlying mechanisms.

Results: The scRNA-seq showed both Regnase3 is highly expressed in the kidney Mφ and positively correlated with the chemokines, Mφ phagocytosis, and Mφ maturation after kidney injury. In vivo, after the kidney injury, the RankCre-Regnase3fl/fl (Regnase3 conditional KO in kidney resident Mφ) mice suffered from more inflammation, characterized by CCR2 positive pro-inflammatory Mφ accumulation. In vitro, Regnase3 is involved in modulating resident Mφ polarization towards the pro-inflammatory and migration, indicating that it contributes to Mφ-related inflammation. Next, we aimed to examine the role of Regnase3 in RTEC. Through in silico, we found that Regnase3 is highly expressed in healthy RTEC but reduced following injury, and it controls early apoptosis. In vivo and in vitro experiments suggested that the Regnase3 deletion in RTEC (Pax8rTtA-TetOCre-Regnase3fl/fl) against kidney injury and promote the repair

of RTEC. Regnase3 targets pre-RNA and modulates alternative splicing by increasing skipped exon events and decreasing the probability of retained intron events.

Conclusions: Regnase3 contributes to kidney injury but the impact of it is contingent upon the specific cell lineage in question. The RankCre-Regnase3fl/fl leads to an exacerbation of kidney injury by increasing pro-inflammatory Mφ recruitment, whereas the Pax8rTtA-TetOCre-Regnase3fl/fl leads to an improvement after injury through its effects on cell death and RTEC repair.

TH-OR09

Role of YB-1 in the Early Pathogenesis of Acute Respiratory Distress Syndrome (ARDS) and Associated Renal Damage

Anna Leitz,[1] Daniela Hermert,[1] Vera Jankowski,[3] Yingying Gao,[1] Xiyang Liu,[1] Marcus Schultz,[2] Jürgen Floege,[1] Stefan Uhlig,[4] Tammo Ostendorf,[1] Lucy K. Reiss,[4] Ute Raffetseder.[1] *[1]Universitatsklinikum Aachen Klinik fur Nieren- und Hochdruckkrankheiten rheumatologische und immunologische Erkrankungen, Aachen, Germany; [2]Department of Intensive Care, Amsterdam University Medical Centres, Amsterdam, Netherlands; [3]Universitatsklinikum Aachen Institut fur Molekulare Herz Kreislauf Forschung, Aachen, Germany; [4]Institute of Pharmacology and Toxicology, Medical Faculty, RWTH Aachen, Aachen, Germany*.

Background: Acute respiratory distress syndrome (ARDS) is a life-threatening lung impairment that is associated with a mortality of 25% up to 45%. It is caused by acute inflammation and currently patients with ARDS can only be stabilized by mechanical ventilation and intensive care. Acute kidney injury (AKI) is the most common extrapulmonary organ dysfunction associated with ARDS, affecting more than 35% of the patients. Proteins with alarmin function, such as the highly conserved Y-box binding protein (YB-1), are good candidates for early progression of ARDS and the crosstalk between lung and kidney. YB-1 functions as a translation or transcription factor and is also secreted during inflammation.

Methods: Mice were mechanically ventilated in a mouse intensive care unit (MICU). The role of YB-1 in murine ARDS and its effect on the kidneys was evaluated in a two-hit- (intratracheal (i.t.) application of hydrochloric acid & ventilation) and a triple-hit- (hydrochloric acid i.t., lipopolysaccharide (LPS))- i.t. & ventilation) model in heterozygous *Yb1*-deficient (*Yb1*$^{+/-}$)-mice and after i.t.-application of recombinant YB-1 protein. In addition, tracheal secretion, urine and serum from ARDS patients were analyzed for (post-translationally modified) extracellular YB-1 by mass spectrometry.

Results: In both models, *Yb1*$^{+/-}$ mice were protected in terms of pulmonary inflammatory parameters. In the two-hit model, the improved lung function in the *Yb1*$^{+/-}$ mice deteriorated to wild-type (WT) level by additional i.t. application of recombinant YB-1. Interestingly, however, heterozygous YB-1 deficiency in the kidneys led to more intense inflammatory reactions. YB-1 i.t. (instillation in the absence of lung injury) already triggered nephritis. Extracellular YB-1 in murine and human ARDS was post-translational modified, and mass spectrometric analysis of ARDS patient samples showed a correlation of guanidinylated YB-1 levels in tracheal secretion/serum and disease severity.

Conclusions: Taken together, YB-1 expression in ARDS mouse models has opposite effects on the inflammatory process in the primarily damaged lung and the secondarily affected kidney. In addition, the intracellular or extracellular localization of YB-1 also determines its protective or destructive character.

Injured Tubular Epithelia-Derived CCN1 Promotes the Mobilization of Fibroblasts Toward the Injury Sites at the Acute Phase After Kidney Injury

Tomohiro Nakata,[1] Yuhei Kirita,[2] Keiichi Tamagaki,[2] Tetsuro Kusaba.[2] *[1]Department of Nephrology, Graduate School of Medical Science, Kyoto Prefectural University of Medicine, Kyoto, Japan; [2]Kyoto Prefectural University of Medicine, Kyoto, Japan*.

Background: Renal fibrosis is associated with the progression of renal injury. Conversely, the function of fibroblasts is indispensable for the reconstruction of normal tissue structure following injury in various organs. Consequently, the humoral factors that prompt fibroblasts to migrate to the injury site at an appropriate time point are deemed indispensable. However, the precise mechanisms through which these factors influence fibroblasts and promote migration to the tissue-injured site remain unclear.

Methods: To expound on the paracrine effects on fibroblasts (NRK49F), we subjected them to treatment with conditioned medium (CM) derived from either normal or injured tubular epithelial cells (NRK52E). Based on the transcriptomics data, we identified Cellular Communication Network Factor 1 (CCN1) signaling as a candidate and analyzed its impact on kidney injury.

Results: The CM from injured NRK52E expedited NRK49F chemotaxis and proliferation. Based on ligand-receptor analysis of RNA-seq between NRK49F and NRK52E in vitro, as well as proximal tubular-specific transcriptomics utilizing proximal tubular-specific tdTomato-reporter mice, we identified the upregulation of CCN1 signaling during the early phases of various kidney injury models. The enhanced fibroblast chemotaxis induced by CM from injured NRK52E was nullified by CM from injured NRK52E with CRISPR-mediated CCN1 knockout. CCN1 activated FAK-ERK signaling, thereby expediting the migration and proliferation of fibroblasts, which were attenuated by ERK and FAK inhibitors. Lastly, in vivo analyses utilizing proximal tubular-specific CCN1 knockout (SLC34a1GCE/CCN1-floxed) mice demonstrated the accumulation of fibroblasts surrounding injured tubular epithelial cells was scarcely observed during the acute phase following cisplatin-induced kidney injury in tubular CCN1 knockout mice. Furthermore, tubular injury was exacerbated in CCN1 knockout mice, suggesting that mobilized fibroblasts by tubule-derived CCN1 may impede the expansion of tubular injury.

Conclusions: During the acute phase after injury, the interaction between tubular epithelia and fibroblasts hinges upon the pivotal role played by damaged tubule-derived CCN1 in mobilizing fibroblasts toward the injury sites, thereby potentially inhibiting the progression of tubular injury expansion.

TH-OR11

Unified Cross-Species Kidney Single-Cell Atlas: Unraveling Conserved Cellular Features and Species-Specific Adaptations

Konstantin A. Kloetzer,[1,2] Amin Abedini,[1] Michael S. Balzer,[1,3] Xiujie Liang,[1] Jonathan Levinsohn,[1] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Medizinische Universitat Graz, Graz, Austria; [3]Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: The kidney plays a critical role in maintaining systemic homeostasis, yet our current understanding of species differences, health states, and changes in disease states remains limited. Owing to the kidney's complex cellular architecture, single-cell tools can provide pivotal insight into these processes.

Methods: We processed seven large renal single-nucleus RNA sequencing (snRNA-seq) and spatial transcriptomics datasets derived from healthy and disease-affected mouse, rat, and human samples. Following meticulous quality controls, we harmonized gene symbols and integrated data using deep generative modeling (scVI). A variety of computational tools were utilized to comprehend cell type conservations as well as species and disease state-specific changes.

Results: We present the first comprehensive, fully integrated interspecies renal snRNA-seq atlas, comprising more than 140 samples and over 1 million cells - the largest kidney cell atlas to date. Our atlas uncovers over 100 distinct cell states, providing a detailed understanding of conserved biological functions, marker genes, species-specific differences, and cellular adaptations in response to disease. Conserved cell types were anatomically positioned using spatial transcriptomics data. By employing the concept of Differentially Expressed Gene Ontology terms (DEGOs) – which focus on mean expression values for functional gene sets rather than individual genes – we highlighted the conserved renal physiology at the single-cell and spatial level. We observed notably fewer proximal tubule S3 segment cells in the human kidney compared to rodents. We identified a conserved injured proximal tubule subset with its unique markers. Additionally, we discovered novel cell types in the loop of Henle cluster expressing developmental process-related gene signatures.

Conclusions: This comprehensive kidney single-cell atlas serves as a valuable resource, offering a consistent reference across species with standardized cell terminology. It enables a deeper understanding of kidney biology and paves the way for developing novel therapeutic strategies.

Funding: NIDDK Support

TH-OR12

Extracellular miRNAs as Predictors of CKD Progression

Anvesha Srivastava,[1] Richard L. Amdur,[2] Ana Pabalan,[1] Dominic S. Raj.[1] *[1]The George Washington University, Washington, DC; [2]Northwell Health, New Hyde Park, NY*.

Background: Kidney fibrosis is final common pathway downstream of most renal injuries that contributes to progressive chronic kidney disease (CKD). Noncoding RNAs regulate kidney fibrosis through direct repression and/or expression of matrix genes and TGF-β signaling. We hypothesized that specific circulating microRNAs (miRNAs) are indicators of underlying kidney fibrosis and can serve as early biomarkers for CKD progression.

Methods: The study was performed using patient samples/clinical data from the Chronic Renal Insufficiency Cohort (CRIC) cohort (n= 3,471). The slowest and fastest progressors of CKD were defined based on the largest and smallest negative slope of eGFR change over time, using within-subject ordinary least-squares regression of follow-up eGFR readings. Next Generation Sequencing (NGS) was performed to identify miRNAs associated with CKD progression. Circulating RNAs from plasma samples were isolated and sequencing was performed on NovaSeq platform (Illumina, Inc). The raw counts, mapping, and differential expression analysis was done using R Bioconductor packages. Total of 500 genes with highest variance were used for principal component analysis and 35 genes with highest variance across samples were selected for hierarchical clustering. The biological effects, mechanisms and functions of identified miRNAs were analyzed using Ingenuity Pathway analysis.

Results: Global extracellular miRNA expression analysis showed presence of 1,888 miRNAs in plasma. Differential analysis using generalized linear models (GLMs) in edgeR was performed to identify the miRNA associated with rapid progression adjusting for sex, ethnicity, diabetes status, UAC Ratio and EGFR levels. Expression of 8 miRNAs (miR-887-5p, miR-1197, miR-6729-3p, miR-6774-3p, miR-6795-5p, miR-548f-3p, miR-3135a, miR-1469) varied significantly between fast and slow progressor groups. This differential expression of miRNAs between the two groups was significantly modulated by ethnicity and diabetic status of patient. Bioinformatic analysis showed pivotal role of these miRNAs in variety of important cell activities such as apoptosis, organ fibrosis, autophagy, metastasis etc.

Conclusions: This study identifies extracellular miRNAs that can serve as indicator of CKD progression. Identification of specific miRNA pathways for CKD progression will enhance diagnosis, enable risk stratification and lead to targeted interventions.

Alternative Splicing in CKD

Samer Mohandes, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Alternative splicing (AS) is a process that can lead to variable genotype expression. The primary forms are exon skipping, intron inclusion, alternative 5′ and 3′ splice sites. The role of alternative splicing of VEGF has been shown to play an important role in chronic kidney disease (CKD) development, however a comprehensive assessment of AS events in CKD has not been undertaken yet.

Methods: Human kidney tissue (n=410) was collected from nephrectomies of healthy subjects and patients with diabetic or hypertensive CKD. Clinical demographics information was collected via honest broker and histopathology was analyzed in an unbiased manner. RNA was extracted from the tubular compartment and sequenced. RNA-seq reads were aligned to the human genome using STAR v 2.7.3. Outliers identified by Mahalanobis distance. Aligned BAM files were sorted and indexed using Samtools v1.17 and junctions were extracted using Regtools v 1.0. Differential splicing for was analyzed separately using leafcutter v 0.2.7 and adjusted for age, sex, race and RNA quality indices (RNA integrity number, 5'-3'bias, %ribosomal genes, total reads).

Results: When comparing healthy samples to those with eGFR of less than 60 cc/min/1.73m2 (CKD stage 3-5), we identified 31 intron cluster alternative splicing events at an adjusted p-value of 0.05. 26 of these were previously annotated. Pathway analysis using gene ontology (GO) terms showed enrichment for cell death and metabolic pathway. When comparing samples with less than 10% fibrosis to those with greater than 10% fibrosis, we identified 239 alternative differential splicing clusters. 233 of these were previously annotated. Pathway analysis using GO terms demonstrated these genes were enriched in the metabolic and immune pathways.

Conclusions: Large number of differential splicing events were observed in CKD compared to controls with enrichment in the metabolic and immune pathway genes.

Comparison	Samples (CKD vs control)	No. of Significant Differentially Spliced Genes	Top Genes	Top pathway enrichment by GO terms
GFR <60 ml/min/1.73m2	146 vs 264	31	RAB11FIP3 RPS24 AP2S1 FIS1 RPS3A	Regulation of cell death Negative regulation of cell death Generation of precursor metabolites and energy Cell death Homeostatic process
Interstitial Fibrosis >10%	170 vs 240	239	RPS24 RAB11FIP3 RACK1 TPM1 GLS	Small molecule metabolic process Organic acid metabolic process Positive regulation of immune system Positive regulation of leukocyte migration Organonitrogen compound

Adenine Accumulation Induced by Hypoxia in Kidney Organoids

Akihiro Minakawa,[1] Pragya Singh,[2] Celine C. Berthier,[1] Matthew Fischer,[1] Jamal El Saghir,[1] Judy J. Baek,[1] Chenchen He,[1] Rajasree Menon,[1] Subramaniam Pennathur,[1] Kumar Sharma,[2] Matthias Kretzler,[1] Jennifer L. Harder.[1] *[1]University of Michigan Division of Nephrology, Ann Arbor, MI; [2]The University of Texas Health Science Center at San Antonio Division of Nephrology, San Antonio, TX.*

Background: Kidney disease progression is thought to result from a multitude of metabolic and genetic changes, including hypoxia and adenine. Adenine-rich diet has previously shown to be nephrotoxic in rodent models. Recently, a pathway contributing to endogenous adenine production was identified (manuscript in revision). We explored the association between adenine, kidney hypoxia and kidney injury using a human kidney organoid system with multi-omic analysis.

Methods: Kidney organoids generated from human pluripotent stem cells and exposed to 1% O_2 for 24 h were split into 2 treatment groups: group 1 organoids were treated with C13-glucose for the last 3 hours of hypoxic treatment underwent targeted metabolomic analysis (C13 flux study) by LC-MS; group 2 untreated organoids were harvested for IF, qRT-PCR and sc RNA-seq. Organoids of both groups were embedded, sectioned and evaluated by MALDI-mass spectrometry imaging (MSI) using DAN matrix and the METASPACE platform.

Results: IF imaging of hypoxic kidney organoids revealed nuclear accumulation of HIF1α; targeted transcriptional analysis showed that HIF1's target gene expression, including glycolytic pathway genes, was increased. Single cell transcriptional profiling revealed increased expression of MTAP (methylthioadenosine phosphorylase) and reduced expression of APRT (adenine phosphoribosyltransferase) in proximal tubular cells and podocytes; mitochondrial gene expression was increased in kidney cell types of especially podocytes. Metabolomic analysis showed that the percentage of C13-labeled metabolites was increased in late glycolysis but decreased in TCA cycle. MALDI-MSI of hypoxic kidney organoids revealed an increased intensity of adenine metabolite and decreased intensity of TCA metabolites such as malic acid.

Conclusions: Our hypoxic kidney organoid model successfully recapitulates key transcriptional, protein and functional alterations associated with hypoxic conditions. Under these hypoxic conditions, MTAP pathway was perturbed leading to adenine accumulation in kidney organoid cells, suggesting a potential mechanism of endogenous adenine generation contributing to kidney disease.

Induced Senescent Cells Recruit Leukocytes and Permit Their Own Clearance from Healthy Young Kidneys

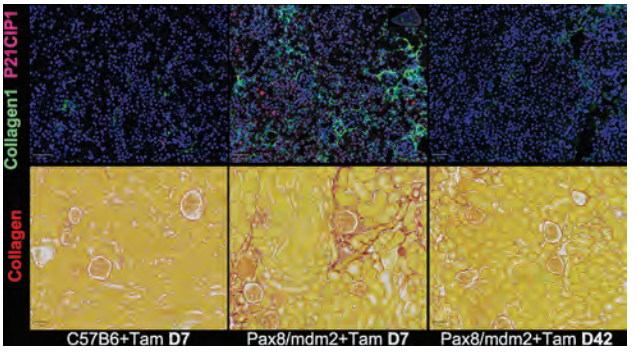
Marie Docherty,[1] Maximilian Reck,[2] Ross A. Campbell,[1] David P. Baird,[1] Laura Denby,[2] Katie J. Mylonas,[1] David A. Ferenbach.[1] *[1]The University of Edinburgh Centre for Inflammation Research, Edinburgh, United Kingdom; [2]The University of Edinburgh Centre for Cardiovascular Science, Edinburgh, United Kingdom.*

Background: Increasing evidence links senescent epithelia to fibrosis and functional loss in experimental and human kidney disease. Whether senescent cells themselves are sufficient to initiate and sustain kidney fibrosis is unknown. We hypothesised that induction of epithelial senescence alone, in absence of other renal injuries, is sufficient to initiate and sustain fibrosis.

Methods: We generated a Pax8creERT2;mdm2 fl/fl mouse ('TG') via a cross of two established stains and treated these and wild type (WT) mice with tamoxifen by oral gavage to induce epithelial restricted senescence via mdm2 deletion. Markers of fibrosis (Collagen I) and growth arrest (p21cip1) were quantified by immunofluorescence (IF), and total collagen by picrosirius red. Full transcriptomic analysis was undertaken using scRNA-seq (10X).

Results: Tamoxifen resulted in p21cip1 induction in renal epithelia in TG but not in wild WT mice by IF (10.45 ± 2.9 *vs* 3.15 ± 0.7, $p<0.05$). On scRNA-seq, TG (but not WT) kidneys contained transcriptionally distinct, cdkn1a+ epithelia, recruited leukocytes and increased activated myofibroblasts. IF confirmed increased renal fibrosis at D7 in TG *vs* WT (Collagen1 1.1 ± 0.3 *vs* 3.1 ± 0.5, $p<0.005$). By D42, scRNAseq analysis demonstrated clearance of cdkn1a+ senescent epithelia, normalisation of leukocyte counts and resolution of myofibroblast activation in TG kidneys, with confirmation by IF; showing no difference in p21cip1 levels between WT and TG mice (2.4 ± 1.4 *vs* 4.1 ± 1.1, $p=0.7$) and no progressive fibrosis.

Conclusions: Our results demonstrate that epithelial senescence is profibrotic in absence of injury to other cell lineages. Of importance, mechanisms in the healthy adult kidney allow detection and physiologic clearance of senescence and prevent ongoing fibrosis. Understanding how these pathways are lost with age and chronic injury may lead to new routes to promote clearance of profibrotic senescent epithelia.



TH-OR16

Identification of Noninvasive Biomarkers Reflecting Cellular Mechanisms of Endothelin A (ETA) Receptor Activity and Atrasentan Response in CKD

N. Eric Olson,[1] Tobias Bohnenpoll,[2] Seamus Ragan,[1] I-Ju Lo,[2] Shawn S. Badal,[1] Jennifer H. Cox,[1] Olivier Radresa,[2] Uwe Andag,[2] Andrew J. King.[1] *[1]Chinook Therapeutics Inc, Seattle, WA; [2]Evotec International GmbH, Gottingen, Germany.*

Background: Endothelin pathway activation contributes to disease progression across multiple CKD etiologies. Atrasentan is a potent and selective endothelin A receptor (ET_A) antagonist that has demonstrated rapid and sustained reductions in proteinuria, preservation of kidney function and improved kidney outcomes in diabetic kidney disease patients. Single cell transcriptomic characterization of a preclinical mouse model of IgA nephropathy revealed specific ET_A activity and atrasentan responses associated with proximal tubular failed repair (FR-PTs). We conducted an analysis of patient-matched kidney biopsies and biofluids from the NURTuRE cohort with the aim to identify non-invasive biomarkers associated with specific cellular responses that will enable precision treatment in CKD.

Methods: Serum (n= 99) and urine samples (n= 22) from the NURTuRE biobank were assayed using Olink and SomaScan proteomics platforms, respectively. Patient-matched kidney biopsies for each sample were analyzed by RNA-Seq and scored for a gene signature reflecting atrasentan responses in the gddY mouse model. Correlation analysis of biofluid protein abundance with kidney mRNA expression and atrasentan response scores suggested candidate non-invasive biomarkers for further validation ($r \geq 0.4$ and $p \leq 0.05$).

Results: Proteomic analysis identified 173 serum and 174 urine proteins significantly correlated with atrasentan response score in CKD patients. Strong positive correlation of 16/173 serum and 12/174 urine proteins with kidney mRNA expression suggests these proteins could originate from the kidney. Importantly, the majority of the respective genes were expressed by FR-PTs or immune cells, likely reflecting

mechanisms of ET_A activation and atrasentan response in the kidney inflammatory and fibrotic microenvironment.

Conclusions: This study identified potential biomarkers reflecting cellular mechanisms of ET_A activation and atrasentan response in the NURTuRE CKD cohort. These biomarkers may be useful in assessing and differentiating cellular responses in atrasentan-treated CKD patients. To validate these initial findings, serum and urine collected at baseline and following treatment in the AFFINITY IgAN cohort are currently being analyzed.

TH-OR17

LACTB Is a Kidney C Mitochondrial Metabolism

Shen Li, Hailong Hu, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Genome-wide association studies (GWAS) have identified hundreds of loci where genetic variants are associated with kidney function. However, the causal variants, genes, cell types, and disease mechanisms remain mostly unknown.

Methods: We integrated GWAS, human kidney expression of quantitative trait analysis using Bayesian colocations, transcriptome-wide association studies, and summary-based Mendelian randomization studies to identify likely causal genes for kidney function. We used single-cell RNA and ATACseq data to identify causal cell types. Finally, we generated mice with genetic deletion to study kidney disease mechanisms.

Results: We identified serine beta lactamase-like protein (LACTB) as a kidney disease risk gene. LACTB is expressed in kidney tubule cells. LACTB knockout mice were more susceptible to acute and chronic kidney injury induced by cisplatin and folic acid. LACTB knockout mice had lower cardiolipin levels and abnormal mitochondria morphology, causing elevated mitochondrial injury and activation of the cytosolic nucleotide sensing pathways (cGAS-STING) with an increment of inflammation. Cardiolipin is a crucial lipid for maintaining mitochondrial morphology and function. Additionally, we discovered that as a protease, LACTB cleaves PLA2G6, an enzyme involved in cardiolipin biosynthesis, generating a more active fragment that promotes cardiolipin production.

Conclusions: In summary, the integration of GWAS, epigenome analysis, mouse models, and cultured cell systems has identified LACTB as a causal gene for kidney disease. LACTB plays a crucial role in regulating cardiolipin metabolism, mitochondrial function, and inflammation.

Glutathione-Specific γ-Glutamylcyclotransferase 1 (CHAC1) Is a Kidney Disease Risk Gene by Controlling Ferroptosis

Kolligundla L. Prasanna, Katalin Susztak. *University of Pennsylvania, Philadelphia, PA.*

Background: Despite GWAS identified over 800 loci associated with kidney function, the specific genes, cell types, and mechanisms influenced by these genetic variants largely remain unexplored. In our research, we leveraged human kidney gene expression and methylation quantitative trait data, as well as human kidney single nuclear gene expression and open chromatin analysis, to prioritize CHAC1 on chromosome 15 as a likely causal gene. CHAC1 is essential for maintaining cellular glutathione levels but the role of CHAC1 remains unknown in kidney disease development.

Methods: Using CRISPR technology, we generated CHAC1 heterozygous mice (CHAC1+/-). To study the role of CHAC1 in kidney disease, we induce kidney disease by streptozotocin or folic acid injections or by feeding adenine diet. To uncover the mechanistic role of CHAC1, we used cultured tubule cells and performed biochemical assays.

Results: CHAC1 heterozygous mice (CHAC1+/-) showed no basal differences in kidney function, birth, and growth defects. On induction of kidney disease using streptozotocin or folic acid injection, the CHAC1+/- mice demonstrated improved kidney function (measured by BUN, creatinine, and cystatin C), diabetic kidney injury, and less fibrosis compared to WT counterparts. On chronic adenine feeding by *ad libitum* chow, the CHAC1+/- mice showed lower chronic kidney disease. The single nuclear ATAC-seq, RNA in situ hybridization, and immunostaining analyses indicated CHAC1 expression in the Loop of Henle (LOH). Cultured primary tubule cells from CHAC1+/- mice showed lower ferroptosis (an iron-dependent form of cell death), preserved cell viability, reduced lipid peroxidation and reactive oxygen species. Derepressed levels of ferroptosis inhibitor, Glutathione peroxidase 4 (GPX4) and the system xCT, and available glutathione levels in CHAC1+/- primary tubule cells likely mediating the resistance to ferroptosis in the conditions of cysteine methionine deprivation or transforming growth factor beta. The lower ferroptosis in CHAC1+/- mice is likely the mechanism for lower fibrosis and better kidney function in disease states (as CHAC1 degrades glutathione).

Conclusions: Our research identified CHAC1 as a novel kidney disease risk gene with a significant role in modulating ferroptosis and cellular glutathione levels in kidney tubule cells.

Calprotectin Is Associated with Vascular Calcification and Cardiovascular Complications During CKD

Julie Klein,[1] Ana Amaya-Garrido,[1] Manon Brunet,[1] Benedicte Buffin-Meyer,[1] Arnaud Del Bello,[4] Serban Ardeleanu,[5] Jakob Voelkl,[6] Griet L. Glorieux,[7] Karolina Kublickiene,[2] Peter Stenvinkel,[2] Stanislas Faguer,[4] Jose M. Valdivielso,[3] Joost Schanstra.[1] *[1]Inserm U1297, Toulouse, France; [2]Karolinska Institutet, Stockholm, Sweden; [3]Institut de Recerca Biomedica de Lleida Fundacio Dr Pifarre, Lleida, Spain; [4]Centre Hospitalier Universitaire de Toulouse, Toulouse, France; [5]Association pour l'Utilisation du Rein Artificiel a la Reunion, Saint-Gilles-les-Bains, Réunion; [6]Johannes Kepler Universitat Linz, Linz, Austria; [7]Universiteit Gent, Gent, Belgium.*

Background: In patients with chronic kidney disease (CKD), vascular calcification is considered a major risk factor of cardiovascular (CV) mortality. The mechanisms of vascular calcification are complex and treatment options remain limited. Serum proteome analysis could help identify novel actors and potential therapeutic targets.

Methods: In this observational, European, multicenter study, we included 112 CKD3-4 patients from Spain, 171 dialysis patients from Toulouse and La Reunion (France), and 170 CKD5 patients from Sweden. Serum proteome analysis was performed using LC-MS/MS on a subset of 66 CKD3-4 patients. Circulating calprotectin concentration was validated in the serum or plasma from the full cohorts by ELISA. Calprotectin was associated with CV outcome (2-4 years of follow-up) or with vascular calcification score assessed by Von Kossa staining on a piece of epigastric artery collected during renal transplantation surgery. The effect of calprotectin on calcification was measured in primary human vascular smooth muscle cells (VSMCs) and mouse aortic rings. The anticalcific potential of calprotectin inhibitor paquinimod was studied in a 5/6 subtotal nephrectomy mouse model.

Results: We identified using serum proteome analysis and further validation by ELISA that calprotectin, a circulating damage-associated molecular pattern protein, was associated with vascular calcification, CV outcome and mortality in CKD and dialysis patients. In primary human VSMCs and mouse aortic rings, calprotectin exacerbated calcification. Treatment with paquinimod inhibited the pro-calcifying effect of calprotectin. Paquinimod also ameliorated calcification induced by serum of uremic patients in primary human VSMCs. Finally, treatment with paquinimod blocked vascular calcification in mice with chronic renal failure induced by 5/6 subtotal nephrectomy.

Conclusions: We identified calprotectin as a key factor associated with vascular calcification, CV outcome and mortality in CKD patients. Blockade of calprotectin by paquinimod might be a promising strategy to reduce the burden of vascular calcification in CKD.

PCSK9 Targets Megalin in the Kidney Proximal Tubule and Aggravates Proteinuria in Nephrotic Syndrome

Sandra Hummelgaard,[1] Cecilie K. Skeby,[1] Camilla Gustafsen,[1] Federica Petrillo,[1] Kathrine P. Frederiksen,[1] Ditte Olsen,[1] Tilde Kristensen,[2] Per Ramlov Ivarsen,[2] Peder Madsen,[1] Erik I. Christensen,[1] Rikke Nielsen,[1] Henrik Birn,[2,1] Simon Glerup,[1] Kathrin Weyer.[1] *[1]Aarhus Universitet, Aarhus, Denmark; [2]Aarhus Universitets-hospital, Aarhus, Denmark.*

Background: Proteinuria is a prominent feature of chronic kidney disease (CKD). Interventions that reduce proteinuria slow CKD progression and the associated risk of cardiovascular disease (CVD). We here propose a mechanistic coupling between proteinuria and the CVD-risk protein PCSK9 involving the receptor megalin.

Methods: Urinary PCSK9 excretion was determined in megalin knockout (KO) mice and patients carrying megalin pathogenic variants as well as minimal change disease patients at baseline and remission after standard prednisolone treatment (1 mg/kg/day). Mechanistical studies were performed in proximal tubular cell cultures (LLC-PK1 cells). PCSK9-mediated megalin regulation and proteinuria were investigated in PCSK9 KO mice, PCSK9 overexpressing mice as well as wildtype and nephrotic podocin KO mice treated with the PCSK9 inhibitor alirocumab (30 mg/kg/day and 50 mg/kg/day, respectively). Kidney injury was evaluated in podocin KO mice treated with alirocumab for 14 days.

Results: We find that PCSK9 undergoes glomerular filtration and is captured by megalin, the receptor responsible for driving protein reabsorption in the proximal tubule. Accordingly, megalin-deficient mice and patients carrying megalin pathogenic variants are characterized by elevated urinary PCSK9 excretion. Interestingly, PCSK9 knockout mice displayed increased renal megalin while PCSK9 overexpression resulted in its reduction. Furthermore, PCSK9 promoted trafficking of megalin to lysosomes in cultured proximal tubule cells, suggesting that PCSK9 is a negative regulator of megalin. This effect is potentially accelerated under disease conditions as genetic destruction of the glomerular filtration barrier in mice, and minimal change nephropathy in humans, resulted in markedly increased tubular PCSK9 uptake and urinary PCSK9 excretion. Pharmacological PCSK9 inhibition increased renal megalin, while reducing urinary albumin excretion and kidney injury markers in nephrotic mice.

Conclusions: In conclusion, glomerular damage increases filtration of PCSK9 and concomitantly megalin degradation, resulting in escalated proteinuria. Targeting PCSK9 may be beneficial to attenuate proteinuria-induced kidney injury in CKD.

Prediction of Kidney Failure Using Multiple Data Domains in Glomerulonephropathy: A CureGN Study

Laura H. Mariani,[2] Sarah Mansfield,[1] Abigail R. Smith,[1] Katherine R. Tuttle.[3] CureGN Machine Learning Writing Group. *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]University of Michigan, Ann Arbor, MI; [3]University of Washington, Seattle, WA.*

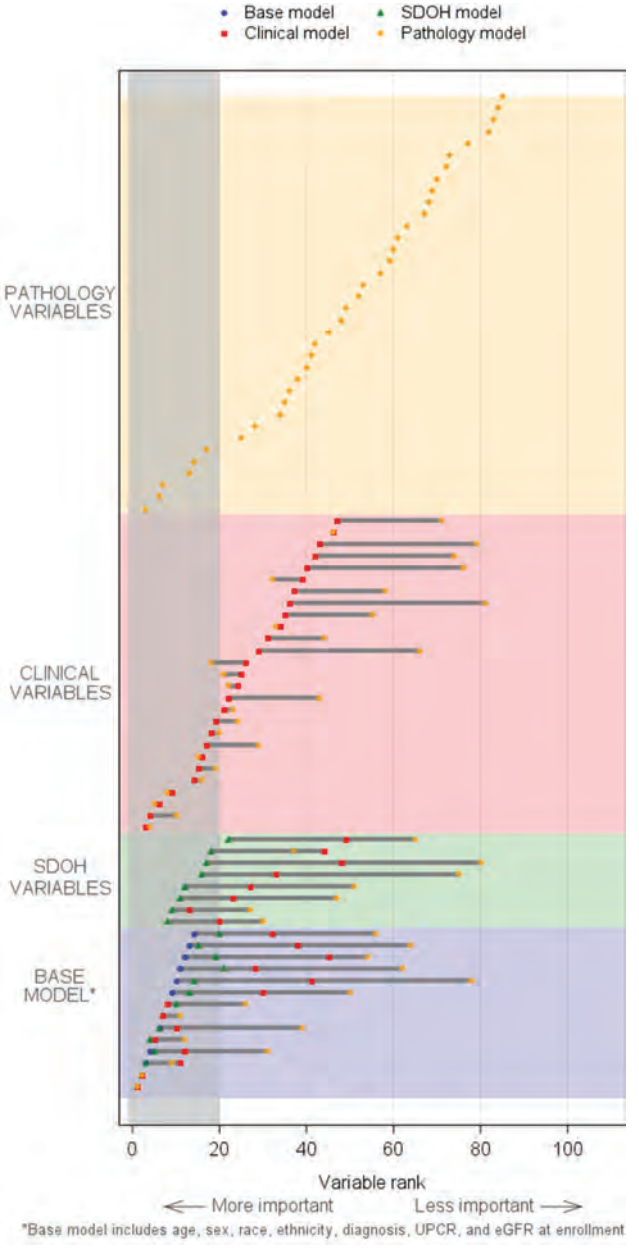
Background: Clinical risk factors do not fully predict kidney failure in patients with glomerular diseases. Using data from multiple domains in CureGN we applied machine learning to improve risk prediction and identify novel predictors of kidney failure.

Methods: Sequential ridge regression models using demographics (I), social determinants of health (SDOH; II), clinical (III), and pathology features (IV) were fitted to predict time to kidney failure (estimated glomerular filtration rate (eGFR) <15 mL/min/1.73m^2 or treatment by dialysis or transplant). Discrimination was assessed by integrated area under the curve (iAUC); variables were ranked by absolute value of standardized coefficients.

Results: The kidney failure rate was 2.9 per 100 person years in 2,544 CureGN participants. 36 predictors were included (7 base, 2 socioeconomic, 27 clinical). Discrimination was similar between models I and II (iAUC=0.89) and higher for model III (iAUC=0.91). eGFR, urine protein to creatinine ratio, age, Black race, and FSGS were highly ranked across models I-III; the ranking of Black race was lower in model III (Figure). Medicaid as primary insurance, hypertension, renin angiotensin system inhibitor use, and serum albumin and urea nitrogen levels were highly ranked in model III. In model IV (n=670), interstitial fibrosis/tubular atrophy (IFTA), presence of tubular microcysts, and sclerotic glomeruli ranked as top predictors, displacing Black race, and reducing ranking of age and FSGS.

Conclusions: Machine learning improves prediction of kidney failure through incorporation of novel data domains. In CureGN, addition of these data improved prediction for kidney failure across conventional diagnostic categories and detected novel predictors that displaced traditional risk factors.

Funding: NIDDK Support



Varible rankings from models I-IV.

Plasma Metabolic Profiles and Clinical Outcomes in Focal Segmental Sclerosis (FSGS) and Minimal Change Disease (MCD)

Takaya Ozeki, Fadhl Alakwaa, Anna V. Mathew, Matthias Kretzler, Laura H. Mariani. *University of Michigan, Ann Arbor, MI.*

Background: Metabolomics is a powerful approach to investigate the relationship between disease mechanisms and patients' phenotype. However, the association between plasma metabolic profiles and clinical outcomes of focal segmental glomerulosclerosis (FSGS) and minimal change disease (MCD) has not been studied well.

Methods: Plasma samples from 135 FSGS/MCD participants in the Nephrotic Syndrome Study Network (NEPTUNE) were studied. Samples were collected within 45 days from kidney biopsy. Untargeted metabolomics data were obtained using liquid chromatography mass spectrometry (LC-MS). We performed rigorous preprocessing to identify metabolites, remove outliers, and impute missing values. Outcomes with our interest were time to complete remission of proteinuria (UPCR<0.3) and, time to composite renal outcome (40% decline of eGFR or ESKD). Metabolites associated with clinical outcomes were selected by Cox-Elastic Net algorithm. Among the selected metabolites, a hypergeometric test was performed to identify the enriched metabolite categories.

Results: Among the 135 participants, 85 (63.0%) were male, 49 (36.3%) were pediatrics and 81 (60.0%) were FSGS. Median UPCR level was 1.65, and 42 (31.1%) demonstrated nephrotic range proteinuria (UPCR>3.5). Median eGFR levels was 84.2

at the time of sample collection. During the follow-up period (median: 51 months), 47 attained complete remission and 33 reached to composite renal outcome. From the metabolomics data, 371 high-quality named metabolites were analyzed. Cox-Elastic Net models selected 21 and 47 endogenous metabolites that associated with time to complete remission and eGFR decline or ESKD, respectively. Among 87 metabolite categories, hypergeometric tests revealed that Fatty esters and were associated with complete remission while Bile acids were associated with eGFR decline or ESKD.

Conclusions: Specific combinations of plasma metabolites, particularly included as lipids and lipid derivatives, were associated with clinical outcomes in FSGS/MCD, which could help to understand disease mechanisms and can be potential biomarkers to improve treatment strategies.

TH-OR23

Idiopathic Collapsing Glomerulopathy Is Associated with APOL1 High-Risk Genotypes or Mendelian Variants in Most Affected Individuals in a Highly Admixed Population

Precil D. Neves,[1,2] Andreia Watanabe,[1] Elieser H. Watanabe,[1] Amanda M. Narcizo,[1] Kelly Nunes,[1] Frederico M. Ferreira,[1] Janewit Wongboonsin,[3] Livia B. Cavalcante,[1] Denise M. Malheiros,[1] Lectícia Jorge,[1] Matt G. Sampson,[3] Irene L. Noronha,[1] Luiz F. Onuchic.[1] *[1]Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil; [2]Hospital Alemao Oswaldo Cruz, Sao Paulo, Brazil; [3]Boston Children's Hospital, Boston, MA.*

Background: Collapsing glomerulopathy (CG) is most often associated with fast progression to chronic kidney disease requiring renal replacement therapy (CKD-RRT). Its incidence is apparently higher in Brazil than in other countries, however the reason for this occurrence is unknown.

Methods: We performed an integrated analysis of clinical, histological, therapeutic, causative genetic and genetic ancestry data in a highly genetically-admixed cohort with 70 idiopathic CG (ICG) patients, including children and adults. Genetic analyses included targeted-gene panel or whole exome sequencing and a high-density SNP array for ancestry assessment.

Results: The disease onset occurred at 23 (17-31) years and 51.4% of patients progressed to CKD-RRT 36 months after diagnosis. Causative genetic bases were identified in 58.6% of patients. Among these cases, 80.5% harbored *APOL1* high-risk genotypes (HRG) and 19.5% causative Mendelian variants (MV). Self-reported non-White patients presented more frequently HRG. MV was an independent risk factor for progression to CKD-RRT at 36 months (HR: 2.583, 95%CI 1.151-7.076, p=0.024) and the end of follow-up (HR: 2.355, 95%CI 1.018-5.447, p=0.045). Older age at kidney biopsy and remission were independent protective factors against progression to CKD-RRT at 36 months (HR: 0.961, 95%CI 0.927-0.996, p=0.029; and HR: 0.230, 95%CI 0.085-0.623, p=0.004, respectively), and remission also at the end of follow-up (HR: 0.155, 95%CI 0.069-0.351, p<0.001). All HRG patients manifested CG at 9-44 years of age whereas in those with *APOL1* low-risk genotype the disease arose throughout life. HRG associated with higher proportion of African genetic ancestry. Novel causative MVs were identified in *COL4A5, COQ2,* and *PLCE1* and previously described causative MVs in *MYH9, TRPC6, COQ2, COL4A3,* and *TTC21B.* Three patients displayed HRG combined with a VUS (*ITGB4, LAMA5* or *PTPRO*). MVs was associated with worse kidney prognosis.

Conclusions: Our data revealed that the genetic status plays a major role in ICG pathogenesis, accounting for more than half of cases in a highly-admixed Brazilian population.

TH-OR24

Anti-Nephrin Antibody as a Potential Etiology in Primary Focal Segmental Sclerosis (FSGS)

Claire Avillach,[1] Qiyu Wang,[2,3] Andrew J. Watts,[2] Astrid Weins.[2] *[1]Boston Medical Center, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA; [3]Massachusetts General Hospital, Boston, MA.*

Background: Minimal change disease (MCD) and primary FSGS have long been pondered to have shared pathogenesis representing a spectrum of different stages of podocyte injury and repair. Recent discovery of anti-nephrin antibodies (Ab) in MCD led us to hypothesize that anti-nephrin Ab may also be present in primary FSGS.

Methods: We retrospectively reviewed all native kidney biopsies performed at BWH from 1/2018-4/2022. We identified 52 cases of primary FSGS (diffuse podocytopathy+segmental sclerosis). We compared the pathological and clinical features between patients (pts) who have punctate IgG deposition on biopsies (+IgG) and those without (-IgG). Anti-nephrin Ab was tested in select pts with +IgG.

Results: Among the 52 cases, 14 had +IgG on IF (27%). There was no difference in the presence of collapsing lesion (36% vs. 45%, P=0.6), percentage of segmental sclerosis (7% vs. 8%, P=0.6) and IFTA (18% vs. 20%, P=0.7) between +IgG and -IgG groups. There was a trend towards enrichment of tip lesions in the +IgG group (21% vs. 11%, P=0.3). Among the 40 pts with available clinical data at biopsy, median proteinuria was significantly higher in the +IgG compared to -IgG group (13 vs 8 g/g, P=0.01). Five pts with +IgG had anti-nephrin Ab tested during active disease and all were positive (Table 1); all 5 biopsies showed colocalization of the punctate IgG with nephrin (Figure 1).

Conclusions: Punctate IgG deposition that colocalizes with nephrin is also observed in patients with primary FSGS and correlates with circulating anti-nephrin Ab. This suggests that anti-nephrin Ab-mediated podocyte dysfunction may be a shared disease mechanism between MCD and primary FSGS.

Table 1

Pt ID	Age/Race /Sex	FSGS subclass	IgG dusting	Serum anti-nephrin antibody	Disease activity when antibody tested	Time between biopsy and antibody testing (months)	Treatment after biopsy	Last known disease status (months from biopsy)
1	64 WM	tip	+	+	Active, initial presentation	0	steroid, rituximab	CR (3)

Exploring Epitope Spreading of PLA2R and Its Clinical Relevance in Idiopathic Membranous Nephropathy (IMN) Based on Yeast Surface Display System

Yanan Liu,[1] Peng Chen,[2] Junxian Hong,[2] Yan Qin.[1] *[1]Peking Union Medical College Hospital, Dongcheng-qu, China; [2]Department of Basic Medical Sciences, School of Medicine, Tsinghua University, Beijing, China.*

Background: PLA2R is the main target antigen of idiopathic membranous nephropathy (IMN). The PLA2R extracellular segment consists of Ricin, FNII and 8 CTLDs. The major epitope is located in Ricin, and CTLD1, CTLD7 and CTLD8 have also been found as epitopes. The presence of epitope spreading and its clinical significance are controversial.

Methods: A random library of PLA2R was constructed by yeast surface display technique and screened by serum from 18 patients with PLA2R-associated IMN. Serum was prospectively collected from 389 patients. A batch flow analysis was carried out with the monoclonal yeast of each epitope. The clinical value of epitope was explored. The dynamic changes of epitope profiles during follow-up were observed.

Results: 1. The first PLA2R yeast surface display system was constructed. 2. In addition to Ricin, CTLD1, CTLD7, and CTLD8, 3 new epitopes (CTLD4, CTLD5, and CTLD6) were found (Figure 1). 3. The positive rates of CTLD1 and CTLD7 were about 50%. CTLD6, CTLD8 and CTLD4 were weak epitopes with a positive rate of less than 10%. 69 (17.7%) patients had epitope limited to Ricin. 4. 24hUP increased with the number of epitopes. The relationship between epitope spreading and 24hUP in subgroup divided by anti-PLA2R titer was consistent with the whole cohort. 5. By multivariate COX regression, gender, age, baseline 24hUP, anti-PLA2R titer were adjusted. Patients with epitope number ≥4 had lower response rates than patients with only 1 epitope (HR 0.571, 95%CI 0.363-0.899, p=0.015). 6. Reversal of epitope spreading was observed in responders. Further epitope spreading was observed in non-responders.

Conclusions: We identified 3 new epitopes through PLA2R yeast surface display system. Epitope spreading in PLA2R was confirmed. The epitope number was correlated with 24hUP. Baseline epitope spreading had a prognostic value for remission independent of anti-PLA2R Ab titer and 24hUP. Clinical remission was accompanied with epitope reversal.

eGFR Decline in Patients with IgA Nephropathy Treated with Nefecon or Placebo: Results from the 2-Year NefIgArd Phase 3 Trial

Richard A. Lafayette,[1] Jens Kristensen,[2] Andrew M. Stone,[3] Jürgen Floege,[4] Vladimir Tesar,[5] Hernan Trimarchi,[6] Hong Zhang,[7] Necmi Eren,[8] Alexander Paliege,[9] Heather N. Reich,[10] Brad H. Rovin,[11] Jonathan Barratt.[12]
[1]Division of Nephrology, Department of Medicine, Stanford University, Stanford, CA; [2]Calliditas Therapeutics AB, Stockholm, Sweden; [3]Stone Biostatistics Ltd., Crewe, United Kingdom; [4]Department of Nephrology and Clinical Immunology, Rheinisch Westfälische Technische Hochschule Aachen University Hospital, Aachen, Germany; [5]Department of Nephrology, First Faculty of Medicine and General University Hospital, Charles University, Prague, Czechia; [6]Nephrology Service, Hospital Británico de Buenos Aires, Buenos Aires, Argentina; [7]Renal Division, Peking University First Hospital, Peking University Institute of Nephrology, Beijing, China; [8]Department of Nephrology, Kocaeli University, Kocaeli, Turkey; [9]Division of Nephrology, Department of Internal Medicine III, University Hospital Carl Gustav Carus, Technische Universität Dresden, Dresden, Germany; [10]Division of Nephrology, University Health Network, Department of Medicine, University of Toronto, Toronto, ON, Canada; [11]Division of Nephrology, The Ohio State University Wexner Medical Center, Columbus, OH; [12]College of Medicine Biological Sciences and Psychology, University of Leicester, Leicester, United Kingdom.

Background: The novel targeted-release budesonide formulation Nefecon is designed to treat immunoglobulin A (IgA) nephropathy (IgAN) by downregulating IgA1 antibody production in the distal ileum. 9-month data from the first 199 patients (pts) in the Phase 3 NefIgArd trial demonstrated significant urine protein–creatinine ratio (UPCR) reduction and estimated glomerular filtration rate (eGFR) preservation with Nefecon vs placebo in pts with IgAN, as reported previously (Barratt J et al. Kidney Int 2023;103:391–402). Here, we present data for the complete study population from the full 2-year trial (9 months of treatment and 15 months of follow-up) comparing eGFR decline (measured as a confirmed 30% reduction in eGFR from baseline) in pts treated with Nefecon 16 mg/day vs placebo.

Methods: Pts (≥18 years) with primary IgAN, eGFR 35–90 mL/min/1.73 m^2, proteinuria ≥1 g/24 h despite renin–angiotensin system blockade, and blood pressure <140/90 mmHg, were eligible. A 30% reduction from baseline in eGFR (Chronic Kidney Disease Epidemiology Collaboration formula) was confirmed by 2 values.

Results: 364 pts were included in the full analysis set. The proportion of pts with a confirmed 30% eGFR reduction was lower in the Nefecon vs placebo arm (Figure). The time to a confirmed 30% reduction was significantly delayed with Nefecon vs placebo (hazard ratio [HR] 0.45 [95% confidence interval 0.26–0.75]; p=0.0014 [1-sided]). A pre-defined supplementary analysis with rescue medication use included as an event yielded a similar result (HR 0.51). Baseline UPCR (<1.5 and ≥1.5 g/g) did not affect outcome (HR 0.51 and 0.42, respectively).

Conclusions: The significantly longer time to a confirmed 30% reduction in eGFR with Nefecon vs placebo strongly indicates preserved kidney function and supports the role of Nefecon as a disease-modifying therapy.

Funding: Commercial Support - Calliditas Therapeutics

Safety and Efficacy of Felzartamab in Primary Membranous Nephropathy (PMN): Final Analysis of the M-PLACE Study

Brad H. Rovin,[1] Pierre M. Ronco,[2] Jack F. Wetzels,[3] Sharon G. Adler,[4] Isabelle Ayoub,[1] Seung Hyeok Han,[5] Jaideep Dudani,[6] Houston N. Gilbert,[6] Uptal D. Patel,[6] Julia Jauch-Lembach,[7] Nicola Faulhaber,[7] Rainer Boxhammer,[7] Stefan Haertle,[7] Ben Sprangers.[8]
[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Sorbonne Universite, Paris, France; [3]Radboud Universiteit, Nijmegen, Netherlands; [4]Harbor-UCLA Medical Center, Los Angeles, CA; [5]Yonsei University, Seoul, Seoul, Republic of Korea; [6]Human Immunology Biosciences Inc, South San Francisco, CA; [7]MorphoSys AG, Planegg, Germany; [8]Katholieke Universiteit Leuven Universitaire Ziekenhuizen Leuven Campus Gasthuisberg, Leuven, Belgium.

Background: PMN, a common cause of nephrotic syndrome with serious sequelae, is characterized by deposition of pathogenic autoantibodies forming immune complexes between podocytes and the basement membrane. Felzartamab (Felza), a fully human IgG1 anti-CD38 mAb, binds to CD38 antigen and depletes plasmablasts and plasma cells, the source of pathogenic aPLA2Rab.

Methods: M-PLACE (NCT04145440), a P1b/2a multi-national study, assessed safety and efficacy of felza in 2 adult cohorts with aPLA2R+ PMN requiring immunosuppressive therapy (IST). Cohort 1 (C1) enrolled newly diagnosed or relapsed patients and Cohort 2 (C2) enrolled IST-refractory patients. Nine infusions (16 mg/kg) were given over 5 months with a total observation period of 12 months.

Results: Among 31 patients (C1, n=18; C2, n=13) baseline characteristics include (Mean (SD)): Age 57.5 (11.8) yrs, serum aPLA2R titer 247.1 (259.3) U/mL, UPCR 6.4 (2.2) g/g, and serum albumin 26.8 (4.96) g/L. Most frequently reported TEAEs were infusion reactions in 9 patients (29.0%); 5 patients (16.1%) had serious TEAEs. Twenty-three patients (74%) achieved immunological response of > 50% aPLA2R reduction, with 8 (26%) achieving complete immunological response (aPLA2R changes shown in Fig. 1). Of the patients who received >5 Felza doses and no other IST, 7/15 (47%) patients in C1 and 2/11 (18%) patients in C2 achieved partial remission (UPCR reduction > 50%, UPCR < 3.0 g/g, and stable GFR) within the 12 month period. Consistent with the short period of follow-up, no patients achieved CR. Serum albumin increased in 11/15 (73%) patients in C1 and 7/10 (70%) patients in C2.

Conclusions: In high-risk patients with high unmet need (previously relapsing or refractory to IST, among the highest aPLA2R titer in a therapeutic clinical study to date), felza resulted in rapid, deep, and durable aPLA2R responses with associated improvements in proteinuria and serum albumin. Depleting CD20–/CD38+ plasma cells is a promising therapeutic strategy for treatment of PMN, including patients with high aPLA2R titers.

Remission, Glucocorticoid Toxicity, Health-Related Quality of Life, and Safety Outcomes in Patients with Renal Involvement in the ADVOCATE Trial

Duvuru Geetha,[1] Frank B. Cortazar,[2] Annette Bruchfeld,[3,4] Alexandre Karras,[5] Peter A. Merkel,[6] David R. Jayne.[7] ADVOCATE Study Group. *[1]Johns Hopkins University, Baltimore, MD; [2]St Peter's Hospital, Albany, NY; [3]Karolinska Institutet, Stockholm, Sweden; [4]Linkopings universitet, Linkoping, Sweden; [5]Universite Paris Cite, Paris, France; [6]University of Pennsylvania, Philadelphia, PA; [7]University of Cambridge, Cambridge, United Kingdom.*

Background: In the Phase 3 ADVOCATE trial comparing avacopan to a prednisone taper, 81% of patients with ANCA-associated vasculitis (AAV) had renal involvement based on the Birmingham Vasculitis Activity Score. This renal subgroup had a baseline mean estimated glomerular filtration rate of 45.1 mL/min/1.73 m^2.

Methods: This post hoc analysis evaluated remission, glucocorticoid (GC) use, GC toxicity index (GTI), health-related quality of life (HRQoL by SF-36), and safety in patients with baseline renal involvement for those treated with avacopan (N=134) versus a prednisone taper (N=134).

Results: Compared to the overall study population, for this subgroup the mean age was similar (62 vs 61 years), but there was a slightly higher proportion of patients with newly diagnosed AAV (74% vs 69%), myeloperoxidase+ ANCA (63% vs 57%), microscopic polyangiitis (52% vs 45%), and use of cyclophosphamide (39% vs 35%). The avacopan group achieved a higher sustained remission rate at week 52 (67.9% vs 56.7%) while receiving a (mean/median) 2.4-/5.3-fold less total GC dose than the prednisone taper group (**Table 1**). The GTI cumulative worsening and aggregate improvement scores were lower at weeks 13 and 26 in the avacopan group compared to the prednisone group. At weeks 26 and 52 the avacopan group reported a greater improvement in SF-36 physical and mental component summary scores. Serious adverse events occurred in 46% (2 deaths) and 49% (3 deaths) of patients in the avacopan and prednisone groups, respectively.

Conclusions: In the ADVOCATE trial, patients with AAV with baseline renal involvement treated with avacopan achieved higher sustained remission rates while receiving less GCs, experiencing less GC-related toxicity, and reporting greater improvements in HRQoL versus those treated with a prednisone taper.

Repeat Kidney Biopsies from the AURORA 2 Study of Voclosporin in Active Lupus Nephritis

Samir V. Parikh,[1] Clint Abner,[2] Ernie Yap,[2] Krista Piper,[2] Robert B. Huizinga,[3] Henry Leher.[2] *[1]The Ohio State University Wexner Medical Center, Columbus, OH; [2]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada; [3]Reformation Consulting Services, North Saanich, BC, Canada.*

Background: Voclosporin is approved for the treatment of adults with active lupus nephritis (LN). Addition of voclosporin to MMF and low-dose glucocorticoids in the Phase 3 global AURORA studies led to significantly earlier and greater reductions in proteinuria while maintaining stable renal function. To characterize the long-term renal impact of voclosporin at the histologic level, we analyzed repeat kidney biopsies from a subset of patients in these studies.

Methods: Patients in AURORA 1 had biopsy-proven LN, UPCR ≥1.5 g/g (≥2 g/g for Class V), and eGFR >45 mL/min/m². Patients were randomized to voclosporin or control for 1 year in AURORA 1 and continued the same blinded therapy for 2 additional years in AURORA 2; all patients received MMF and low-dose glucocorticoids. A subset of patients had a kidney biopsy prior to screening and a repeat biopsy after approximately 18 months of therapy. Histopathologic grading according to NIH indices for LN activity and chronicity was conducted by Arkana Laboratories. Efficacy outcomes and mean eGFR over time were assessed.

Results: Repeat biopsy samples were collected from 16 patients in the voclosporin arm and 10 patients in the control arm. Baseline mean activity scores were similar between arms, with scores improving with treatment in both arms. Mean chronicity scores were also similar between arms at baseline and remained stable over time in most patients. Measures of renal function remained stable in both arms over the 3-year follow-up. Voclosporin-treated patients had numerically greater mean reductions from baseline in UPCR year-on-year compared to patients in the control arm.

Conclusions: As expected, mean activity scores improved in both treatment arms. Importantly, exposure to voclosporin was not associated with chronic injury, with the mean index remaining stable at follow-up. Similar to the overall population, patients treated with voclosporin saw greater reductions in UPCR over 3 years of treatment; safety outcomes from this small subgroup were also consistent with outcomes in AURORA 1.

Funding: Commercial Support - Aurinia Pharmaceuticals Inc.

Kidney-Related Outcomes in Patients with Active Lupus Nephritis Treated with Obinutuzumab: A Post Hoc Analysis of the Phase 2 NOBILITY Trial

Brad H. Rovin,[1] Jorge Alfonso Ross Terres,[2] Sophia Giang,[2] Thomas Schindler,[3] Armando Turchetta,[3] Jay P. Garg,[2] Richard Furie,[4] William F. Pendergraft,[2] Ana Malvar.[5] *[1]Department of Internal Medicine, The Ohio State University College of Medicine, Columbus, OH; [2]Genentech Inc, South San Francisco, CA; [3]F. Hoffman-La Roche Ltd, Basel, Switzerland; [4]Northwell Health, Great Neck, NY; [5]Nephrology Unit, Hospital Fernandez, Buenos Aires, Argentina.*

Background: Preservation of long-term kidney function is a major therapeutic goal in lupus nephritis (LN). In the randomized, double-blind, placebo-controlled, Phase 2 NOBILITY trial (NCT02550652; PMID: 34615636), patients with proliferative LN receiving obinutuzumab with standard-of-care therapy showed clinically meaningful improvement in complete and overall renal responses at Weeks 52, 76 and 104 compared with those receiving placebo and standard-of-care therapy. We conducted a post hoc analysis of NOBILITY to assess kidney-related outcomes.

Methods: Cox regression analysis was conducted for the time to first kidney-related event (death, doubling of serum creatinine or treatment failure), LN flare and first 30% and 40% eGFR decline from baseline. The eGFR slope was assessed in a linear mixed-effects model.

Results: Obinutuzumab significantly reduced the risk of kidney-related events or death (HR, 0.40; 95% CI, 0.20 to 0.80), LN flare (HR, 0.43; 95% CI, 0.20 to 0.95) and first eGFR decline of 30% (HR, 0.20; 95% CI, 0.06 to 0.61) and 40% (HR, 0.09; 95% CI, 0.01 to 0.73) (**Figure**). Risk of sustained eGFR decline of 30% and 40% was numerically lower, and a significant difference in attenuation of eGFR slope decline was observed between patients receiving obinutuzumab and standard-of-care therapy and those receiving placebo and standard-of-care therapy (annual slope difference, 4.10 mL/min/year; 95% CI, 0.14 to 8.08).

Conclusions: Obinutuzumab, in addition to increasing the possibility of achieving a complete renal response, significantly reduced the risk of kidney-related events, eGFR decline, time to LN flare and eGFR slope decline in a post hoc analysis, suggesting that obinutuzumab in combination with standard-of-care therapy may positively impact kidney-related outcomes. Obinutuzumab is being evaluated in patients with active proliferative LN in the global registrational Phase 3 REGENCY trial (NCT04221477).

Funding: Commercial Support - This study was funded by Genentech, Inc., a member of the Roche Group. Editorial assistance was provided by Health Interactions, Inc., and funded by F. Hoffmann-La Roche Ltd.

TH-OR31

PI3K/AKT/mTOR Pathway Regulates Renal Expression of Klotho

Aurora Perez-Gomez, Juan M. Diaz Tocados, Juan Diego Domínguez Coral, Alicia G. Carrasco, Jose M. Valdivielso. *Institut de Recerca Biomedica de Lleida Fundacio Dr Pifarre, Lleida, Spain.*

Background: Renal Klotho expression decreases early in chronic kidney disease (CKD), increasing circulating FGF23 and phosphate levels. This negatively affects renal disease progression and cardiovascular complications. Preserving renal Klotho expression is of interest, but the underlying mechanisms are unclear. During early stages of CKD, kidneys activate mechanisms of hypertrophy, in which the PI3K/Akt/mTOR pathway plays a role. This pathway is activated by growth factors such as insulin-like growth factor-1 (IGF-1). The main negative regulator of this pathway is PTEN, which reduces the activation of canonical insulin signaling. We aimed to investigate the role of PTEN and the PI3K/AKT/mTOR pathway in kidney Klotho levels and their possible implication in CKD.

Methods: We measured renal Klotho levels, circulating FGF23, and phosphate in mice lacking PTEN in renal proximal tubular cells (PTEC) and in HK2 cells in vitro. We also examined normal mice with models of decreased renal mass caused by uninephrectomy (UNX) and 5/6 nephrectomy (SNX). Additionally, we tested the effect of mTOR inhibition. Furthermore, we analyzed PTEN and Klotho expression in kidney samples from CKD patients.

Results: We found that PTEC with downregulated PTEN exhibited decreased Klotho expression both in vitro and in vivo, accompanied by increased mTOR activity. Animals with PTEN elimination in PTEC also showed increased circulating phosphate and FGF23

levels, as well as a decrease in the fractional excretion of phosphate. These alterations were normalized by treatment with rapamycin. Normal mice with UNX or SNX exhibited increased renal IGF-1 expression and activation of the PI3K/AKT/mTOR pathway. Furthermore, these mice showed a reduction in renal Klotho expression and an increase in circulating FGF23 and phosphate. Both of these alterations were restored with rapamycin administration. In renal samples from CKD patients, we observed a positive correlation between the expression of PTEN, KLOTHO, and glomerular filtration rate (GFR).

Conclusions: The overactivation of the PI3K/AKT/mTOR pathway in PTEC modulates Klotho levels in the kidney. Our findings represent a significant advancement in the search for new therapeutic targets to maintain and prevent reductions in renal Klotho levels, potentially benefiting kidney disease patients.

TH-OR32

Spatial Genomics Localized Nephron Segment-Specific FGF23 and CKD Klotho-Dependent and -Independent Transcriptional Reprogramming

Lainey M. Hibbard, Sheng Liu, Rafiou Agoro, Yamil Marambio, Kayleigh N. Jennings, Steven S. Welc, Jun Wan, Kenneth E. White. *Indiana University School of Medicine, Indianapolis, IN*.

Background: FGF23 acts in the kidney via Klotho (KL) to control phosphate metabolism. However, in CKD, KL is lost and FGF23 is pathologically increased, disrupting mineral homeostasis. KL is expressed in multiple nephron segments, thus localization of FGF23 actions in the nephron remain unclear. Herein, we tested for novel FGF23 bioactivity localized with KL, as well as hypothesized that CKD alters FGF23/KL signaling and causes spatially unique transcriptional reprogramming.

Methods: Visium spatial transcriptomics (ST) was performed on kidney sections from normal mice injected with FGF23 (250 ng/kg) for 1 or 4 h, and male mice with adenine diet induced CKD (0.2% for 4 weeks).

Results: The FGF23-injected and CKD kidney sections had >6900 genes/sequencing spot and formed 12 and 10 UMAP cell clusters, respectively. Mapping nephron segment markers showed clear demarcation of cortical and medullary gene expression. PT S1/S2 marker Slc5a2 was highly expressed in the cortex and S3 marker Eci3 localized to the outer stripe of the medulla (OSOM). FGF23 increased MAPK-dependent transcription factor Egr1 more at 1 h than 4 h. The vitamin D metabolic enzymes Cyp24a1 and Cyp27b1 mRNAs were increased or decreased, respectively, at 4 h and overlapped with KL. ST data was validated by qPCR and independent scRNAseq data from FGF23-injected mice. We also identified novel changes in response to FGF23, including increased cortical Cyp4b1 at 4 h, which CKD decreased. Mice with CKD had reduced KL mRNA and increased Cyp27b1. Consistent with CKD fibrosis, Col1a1, -1a2, -3a1, and -4a1 were ubiquitously increased, although Col3a1 was more focused to the inner stripe of the medulla (ISOM). Further, pro-fibrotic Tgfb1 broadly increased, whereas its target Mmp7 increased in the ISOM. In contrast, damage and injury markers C3 and Havcr1 were restricted to the cortex and OSOM, respectively. Finally, evidence of wider immune infiltration was present in CKD with elevated neutrophil marker Lcn2, and macrophage markers Cd68 and Ptprc.

Conclusions: Using ST, we identified unbiased, spatially identifiable effects of FGF23 bioactivity in kidney, including new potential FGF23 targets. We also localized pathologic KL-dependent and -independent CKD gene alterations that differentially occur in distinct cell populations.

TH-OR33

Role of miR-122 on FGF23 Cleavage

Jane J. Thomas, John C. Von Drasek, Guillaume Courbon, Jadeah J. Spindler, Aline Martin, Valentin David. *Northwestern University Feinberg School of Medicine, Chicago, IL*.

Background: In chronic kidney disease (CKD), iron deficiency and inflammation contribute to elevated levels of intact fibroblast growth factor 23 (iFGF23) by increasing FGF23 production. Proteolytic cleavage of intact fibroblast growth factor 23 (iFGF23) yields C-terminal FGF23 peptides (Cter-FGF23) that play a protective role in iron deficiency anemia (IDA) and inflammation. O-glycosylation of iFGF23 cleavage site by GALNT3 protects iFGF23 from cleavage, but the regulation of GALNT3 is unknown. We found that IDA increases the expression of miR-122-5p (miR122), which is a predicted inhibitor of *Galnt3* expression. We hypothesized that inhibition of GALNT3 by miR122 results in increased iFGF23 cleavage in IDA.

Methods: Since miR122 is mainly produced by the liver, we generated mice harboring a conditional deletion of miR122 in hepatocytes (miR122cKO) by crossing miR122 floxed mice with mice expressing a Cre recombinase driven by the Albumin promoter. We induced IDA by feeding 3-week-old wild-type (WT) and miR122cKO mice either a control diet (Ctr) or a low iron diet (IDA) for 3 weeks. At 6 weeks of age, we analyzed serum biochemical and hematological parameters as well as bone Galnt3 expression in all mice.

Results: Compared to WT-Ctr, miR122cKO-Ctr mice exhibited reduced miR-122 levels, increased bone Galnt3 expression and iFGF23 levels, despite normal total cFGF23. These mice also showed reduced iron levels and transferrin saturation, but normal hemoglobin levels and red blood cells counts. As expected, WT-IDA mice were anemic and showed higher levels of miR122, reduced Galnt3 expression along with a 3.6-fold increase in total cFGF23 compared to WT-Ctr, and a slight but significant increase in iFGF23. Compared to WT-IDA, miR122cKO-IDA mice showed increased Galnt3 expression, total cFGF23 and iFGF23 levels, resulting in an increased i/cFGF23 ratio, a surrogate marker of FGF23 cleavage. miR122cKO-IDA mice also exhibited further reduced levels of iron and transferrin saturation, but this did not aggravate the severity of anemia in these mice.

Conclusions: Our results demonstrate that iron deficiency increases miR122, which inhibits osseous Galnt3 expression and results in increased FGF23 cleavage, elevated Cter-FGF23 but reduced iFGF23. miR122 could be a potential therapeutic target to reduce iFGF23 and thus improve adverse outcomes in early stages of CKD.

Direct Effects of FGF23 on Osteoblasts Contribute to Bone Defects in Dmp1KO Mice Independently of Phosphate

Dominik Kentrup, Guillaume Courbon, Hao-Hsuan Tsai, Xueyan Wang, John C. Von Drasek, Jadeah J. Spindler, Lauriane Hivert, Valentin David, Aline Martin. *Northwestern University Feinberg School of Medicine, Chicago, IL*.

Background: Fibroblast growth factor 23 (FGF23) is a phosphate (Pi)-regulating hormone produced in bone. Hereditary hypophosphatemic disorders are associated with FGF23 excess that leads to hypophosphatemia, impaired skeletal growth, rickets and osteomalacia. The blockade of FGF23 signaling to correct serum Pi levels has become a superior therapeutic strategy to Pi supplementation in X-linked hypophosphatemia, but remains untested in autosomal recessive hypophosphatemic rickets (ARHR). In this study, we compared the effects of reducing circulating FGF23 levels using osteocyte-specific deletion of *Fgf23* ($Fgf23^{cKO}$) to the effects of dietary Pi supplementation in the *Dmp1* knockout ($Dmp1^{KO}$) mouse model of ARHR.

Methods: We deleted *Fgf23* specifically in osteocytes ($Fgf23^{cKO}$) using a Dmp1-cre recombinase, in wild-type (WT) and $Dmp1^{KO}$ mice. In addition, we fed WT and $Dmp1^{KO}$ mice a diet containing either 0.5% (NP) or 2% Pi (HP). In parallel, we cultured primary osteoblasts isolated from WT, $Fgf23^{cKO}$, $Dmp1^{KO}$ and $Dmp1^{KO}$/$Fgf23^{cKO}$ mice to understand the direct impact of FGF23 and DMP1 on osteoblast differentiation and activity.

Results: Compared with WT mice and concurrent with successful *Fgf23* deletion, $Fgf23^{cKO}$ mice showed reduced serum FGF23 levels and increased serum Pi levels, whereas $Dmp1^{KO}$ mice displayed highly increased serum FGF23 levels, hypophosphatemia, impaired growth, rickets and osteomalacia. In contrast, $Dmp1^{KO}$/$Fgf23^{cKO}$ mice showed a near complete correction of FGF23 excess, which fully restored serum Pi levels, but only partially corrected the bone phenotype. Compared to NP diet, HP diet increased circulating FGF23 levels, PTH levels, and phosphaturia in WT mice. HP-$Dmp1^{KO}$ mice remained hypophosphatemic and showed exacerbated FGF23 production, hyperparathyroidism, and phosphaturia, resulting in a worsened bone phenotype. In vitro, we found that FGF23 directly impairs osteoblast differentiation and that DMP1 deficiency contributes to impaired mineralization independently of FGF23 or Pi levels.

Conclusions: To conclude, our data suggest that the direct effects of FGF23 and DMP1 on osteoblasts need to be considered to effectively correct ARHR-associated mineral and bone disorders, independently of hypophosphatemia.

The Essential Roles of miRNA and mTORC1 in Parathyroid Function and in Maintaining Parathyroid Glands in the Adult

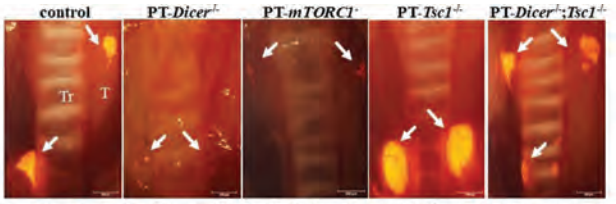
Alia Hassan,[1] Nareman Khalaily,[1] Rachel Levin,[2,1] Oded Volovelsky,[1] Morris Nechama,[1] Iddo Z. Ben-Dov,[1] Tally Naveh-Many.[1] *[1]Hadassah Hebrew University Medical Center, Jerusalem, Israel; [2]Jerusalem Collage of Technology Lev Institute, Jerusalem, Israel*.

Background: Secondary hyperparathyroidism (SHP) of CKD is a leading cause of morbidity and mortality. The molecular mechanisms governing basal PTH levels and SHP are undefined. We have shown that the parathyroid mTORC1 pathway is activated in CKD-SHP and that ablation of the miRNA processing enzyme *Dicer* and hence miRNA prevents CKD-SHP with no effect on basal serum PTH.

Methods: We generated mice with parathyroid (PT) specific KO of *Dicer*, *mtorc1*, tuberous sclerosis complex 1 (*Tsc1*) or double $Dicer^{-/-}$;$Tsc1^{-/-}$ KO and tdTomato expression to identify the glands by fluorescent microscopy. Parathyroid sections were IF stained.

Results: Despite normal serum PTH, adult PT-$Dicer^{-/-}$ mice had no intact parathyroid glands, unlike controls. The glands were present at birth but soon after only clumps of parathyroid cells remained, indicating that Dicer and miRNA are not essential for parathyroid embryogenesis but rather for maintaining intact glands later in life. To characterize a miRNA-mTORC1 link in the parathyroid, we generated PT-$mTORC1^{-/-}$ mice that had parathyroid cell clumps from early after birth but normal serum PTH, resembling PT-$Dicer^{-/-}$ mice. In contrast, PT-$Tsc1^{-/-}$ mice with mTORC1 hyper-activation due to deletion of its inhibitor, had vastly larger (x10) glands and increased serum PTH and calcium levels. IF staining for parathyroid specific and proliferation markers supported the KO phenotypes. Importantly, a double PT-$Dicer^{-/-}$;$Tsc1^{-/-}$ mouse had intact parathyroid glands similar to controls, indicating that *Tsc1* ablation over-rides the aparathyoridism of *Dicer* KO.

Conclusions: miRNAs are essential for PTH stimulation in CKD induced SHP. Both miRNA and mTORC1 maintain intact glands in the adult.



Parathyroid specific *Dicer* and *Tsc1* double knock-out (PT-*Dicer*$^{-/-}$; *Tsc1*$^{-/-}$) reverses the aparathyroidism of PT-*Dicer*$^{-/-}$ mice. tdTomato parathyroid glands visualized by fluorescent microscopy in control (PT-*Dicer*$^{+/+}$;*Tsc1*$^{+/+}$) and parathyroid specific *Dicer*; *mTORC1*, *Tsc1*, or double *Tsc1* and *Dicer* ablation. Representative fluorescent microscope images overlaid over visible light images of the exposed neck area of 2 month old mice are shown. The arrows point to the parathyroid glands or cell clumps, T, thyroid, Tr, trachea.

TH-OR36

The Role of Osteopontin and Osteocyte-Derived Factors in Secondary Hyperparathyroidism-Induced Muscle Dystrophy

Eduardo J. Duque,[1] Shirley F. Crispilho,[2] Andre Kakinoki Teng,[1] Ivone B. Oliveira,[1] Luzia N. Furukawa,[1] Rosilene M. Elias,[1,2] Vanda Jorgetti,[1] Rosa M. Moyses.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Nove de Julho, Sao Paulo, Brazil.*

Background: Secondary hyperparathyroidism (SHPT) leads to harmful effects, including muscle dystrophy. We have previously shown that parathyroidectomy (PTX) improves muscle function, but not muscle mass. We hypothesized that this improvement is related to muscle inflammatory modulation. Osteopontin (OPN), a bone matrix protein, is stimulated by PTH and phosphate, and regulates the immune system at different levels. In this study, we sought to investigate the relationship between changes in mineral and bone metabolism (MBD) in patients with SHPT pre- and post-PTX, muscle expression of osteocyte-derived factors and inflammatory markers.

Methods: We prospectively enrolled 30 patients on dialysis (39 ys, 62% female) referred for PTX. Muscle phenotyping involved tissue analysis by immunohistochemistry, multiplex protein quantification, and gene expression; DXA for body composition; physical evaluation by accelerometer. Muscle biopsies were obtained from the vastus lateralis at baseline and 6 months after PTX, and from healthy controls. Biochemical parameters were also collected.

Results: MBD, DXA, physical evaluation, and tissue analysis are shown in Table1. We found a significant decrease in systemic and muscle OPN concentrations. Higher muscle OPN expression was noted at baseline compared to controls (11vs 2.9%*) and PTX led to a marked reduction (11vs 3%*). Systemic and muscle cytokines concentrations also decreased. Muscle, but not systemic, RANKL and sclerostin concentrations decreased after PTX. *p<0.01.

Conclusions: Our findings suggest that muscle OPN and osteocyte-derived factors might play a role in CKD-associated sarcopenia. In addition to its role in mineralization, OPN may foster muscle tissue inflammation, which is blunted after PTX. Based on these results, new pathways are revealed as therapeutic targets for uremic sarcopenia.

Bone Quality in Uremic Patients: Interactions Between Parathyroid Hormone (PTH) and Propionic Acid

Elizabeth M. Kermgard,[1] Katherine Wesseling-Perry,[2] Thomas Nickolas.[3] *[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]Phoenix Children's Hospital, Phoenix, AZ; [3]Columbia University Irving Medical Center, New York, NY.*

Background: Chronic kidney disease (CKD) associated hyperparathyroidism (HPT) results in impaired bone quality and strength. While calcitriol deficiency partially drives elevations in parathyroid hormone (PTH), skeletal resistance to PTH also contributes to progressive HPT. In mice with normal kidney function, short-chain fatty acids (SCFAs) produced by the gut microbiome, were shown to moderate PTH effects on bone. Interactions between SCFAs and PTH on bone quality in humans with CKD are unknown. We hypothesized that SCFAs moderate the skeletal effects of PTH in CKD.

Methods: In a cross-sectional study of 60 CKD patients with double label transiliac crest bone biopsies, we measured parameters of dynamic histomorphometry, PTH and 24 SCFA metabolites (Metabolon, Inc). Ages were 29-88 yrs, 13% were on dialysis and 40% were male. High resolution peripheral quantitative computed tomography (HRpQCT; resolution 60 μm3) imaging of the radius and tibia for cortical (Ct) and trabecular (Tb) geometry, density and microarchitecture was performed in a subset of 45 patients. SCFAs were dichotomized at the median. Generalized linear regression models were used to evaluate relationships between bone outcomes, PTH, SCFA, SCFA-PTH and SCFA-sex interactions.

Results: We found that the SCFA, propionic acid (PA), modified relationships between PTH and bone outcomes. In contrast to low levels of PA, high levels of PA and PTH were associated with thicker osteoid (β=3.32, SE 1.58, p=0.041) on histomorphometry, thicker cortices at the radius (β=12.50, SE 3.43, p=0.001) and tibia (β=24.46, SE 8.34, p=0.006) and greater Tb volumetric density (β=26.59, SE 11.28, p=0.024) at the radius by HRpQCT.

Conclusions: In conclusion, in a cohort of CKD patients with bone biopsy and HRpQCT imaging, we observed that PA modified the skeletal response to PTH. When PA levels were elevated, higher PTH was associated with better bone quality. In contrast, when PA levels were low, higher PTH levels were associated with catabolic effects on bone quality. Prospective studies are needed to investigate whether PA has a therapeutic role in the management of renal osteodystrophy.

Calcium Isotope Ratios in Serum: A Novel Biomarker of Bone and Vessel Calcium Balance in Patients on Dialysis

Rukshana Shroff,[1] Anton Eisenhauer,[2] Alexander Heuser,[2] Ana Kolevica,[2] Michael Mueller,[4] Patrick D'Haese,[3] Pieter Evenepoel.[5] *[1]UCL Great Ormond Street Hospital and Institute of Child Health, London, United Kingdom; [2]Geomar Helmholtz Centre for Ocean Research, Kiel, Kiel, Germany; [3]Universiteit Antwerpen, Antwerpen, Belgium; [4]University Medical Center Schleswig-Holstein (UKSH), Kiel, Germany; [5]KU Leuven, Department of Immunology and Microbiology, Laboratory of Nephrology, Leuven, Belgium.*

Background: Dysregulated mineral homeostasis in CKD can cause bone demineralization and vascular calcification. We have shown that non-radioactive calcium (Ca) isotopes, ^{42}Ca and ^{44}Ca, that are naturally present in our diet can be measured in serum, and their ratio ($\delta^{44/42}Ca_{serum}$) quantitatively determines changes in bone Ca balance (BCaB). Isotopically light ^{42}Ca is preferentially incorporated into bone, so $\delta^{44/42}Ca_{serum}$ increases when bone formation exceeds resorption and vice versa. We studied bone and arterial biopsies to determine the sensitivity of $\delta^{44/42}Ca_{serum}$ in estimating BCaB and vascular calcification.

Methods: ^{44}Ca and ^{42}Ca were measured by inductively coupled plasma mass-spectrometry in the serum, bone and arterial biopsies of 19 chronic dialysis patients. Data were compared with adults with osteoporosis.

Results: $\delta^{44/42}Ca_{serum}$ and $\delta^{44/42}Ca_{bone}$ were significantly lower in dialysis patients (median age 59.8 years, time on dialysis 3.3 years) compared to adults with osteoporosis, implying lower BCaB in dialysis patients.(Fig 1). $\delta^{44/42}Ca_{serum}$ showed a strong positive correlation with $\delta^{44/42}Ca_{bone}$ and $\delta^{44/42}Ca_{vessel}$. $\delta^{44/42}$Ca serum and bone correlated positively with the BAP/TRAP5-b ratio and osteoblastic markers P1NP and inversely with osteoclastic markers PTH and RANKL. Although $\delta^{44/42}Ca_{serum}$ indicated low BCaB in 89%, only 31% manifested DXA confirmed osteoporosis (T-scores <-2.5). On histology $\delta^{44/42}Ca_{bone}$ inversely correlated with osteoid area and positively with absolute mineralized area and trabecular thickness. Significant and independent predictors of $\delta^{44/42}Ca_{serum}$ were

$\delta^{44/42}Ca_{bone}$ (p=0.01, 95%CI -1.35 to -0.26), BAP/TRAP5-b ratio (p=0.04, 95%CI 0.04 to 0.26) and osteoid area (p=0.03, 95%CI -1.11 to – 0.09), together predicting 79% of the variability in $\delta^{44/42}Ca_{serum}$.

Conclusions: $\delta^{44/42}Ca_{serum}$ is a significant and independent maker of BCaB, correlating with bone histology, and may provide a more sensitive and non-invasive measure of BCaB than bone biomarkers or DXA.

Role of Plasma Inorganic Pyrophosphate in Calciphylaxis: A Prospective Study

Api Chewcharat,[1] Houda Bouchouari,[1] Scott Krinsky,[1] Jennifer Howe,[2] Jeanfranco Torcatti,[2] Borut Cizman,[2] Yves Sabbagh,[2] Sagar U. Nigwekar.[1]
[1]Massachusetts General Hospital, Boston, MA; [2]Inozyme Pharma, Boston, MA.

Background: Calciphylaxis is a devastating disorder characterized by painful skin lesions caused by calcific microvascular occlusion and no approved treatment. In experimental models and genetic disorders, deficiency of pyrophosphate (PPi) is linked with vascular calcification and neointimal proliferation. This study was conducted to investigate the influence of plasma PPi on severity and outcomes in calciphylaxis.

Methods: In this prospective study, we enrolled 70 patients with calciphylaxis. Plasma PPi levels were measured using an ATP Sulfurylase/Luminescence-based method at enrollment (n=70) and at 6-week follow up (n=30). We examined the associations of 1) PPi levels at enrollment with skin lesion count, pain severity (assessed by Brief Pain Inventory), and 6-week mortality, and 2) change in PPi levels over 6-week period after enrollment with 12-week mortality.

Results: Median age of our cohort was 60 years and 67% of patients had end-stage kidney disease. Median skin lesion count was 3 [IQR: 2-4] and median pain severity score was 5 [IQR: 4-7]. Median PPi levels were 568 nM [IQR: 253-1205] at enrollment and 1155 nM [IQR: 835-1456] at 6-week follow up. At enrollment, there were modest negative associations of PPi with skin lesion count (r=-0.26) and pain severity (r=-0.28). Mortality at 6 weeks was 21%. Among patients who died by 6-week follow up, PPi levels at enrollment were 66% lower compared to patients who were alive (p=0.002) **(Fig)**. In adjusted models, for every 100 nM decrease in PPi at enrollment, there was 25% increased risk of 6-week mortality. Decrease in PPi levels over 6-week period since enrollment was associated with increased 12-week mortality (p=0.04).

Conclusions: Our novel findings demonstrate the potential of PPi as a target for therapies aimed at improving patient-oriented and clinical outcomes in calciphylaxis.

Loss of Renal Tubular Claudin-2 Increases Renal Calcification and Urinary Stone Disease

Muthuvel Jayachandran, Heather L. Holmes, Zejfa Haskic, Andrew D. Rule, Michael F. Romero, Kevin Koo, John C. Lieske. *Mayo Clinic College of Medicine and Science, Rochester, MN.*

Background: Mechanisms of hypercalciuria-associated renal calcification and urinary stone disease (USD) are not completely understood. Global *Claudin-2* knockout (Cldn2KO) male mice share many key features of human hypercalciuric idiopathic calcium stone formers (ICSFs). Here we characterized urine biochemistry, urinary extracellular vesicles (uEVs), and renal pathophysiology to determine if uEVs could serve as a biomarker for human idiopathic, hypercalciuric, first time stone formers (SFs) with potential pathologic changes in renal claudin-2 (Clnd2) expression.

Methods: Twenty-hour (24-h) urine samples were collected from male mice (Cldn2KO (n=12) and age-matched wild type (WT; n=8)) and human SFs (n=20; hypercalciuric SFs and age-/sex-matched non-SFs (NSFs). *In vivo* renal calcification in mice were measured by Bruker high-resolution *in vivo* 3D X-ray microtomography. Data are presented as median (25^{th}, 75^{th} percentile) and analyzed by Wilcoxon rank-sum test to identify statistically significant (P<0.05) differences between groups.

Results: Age, body weight, total 24-h urine volume, milliosmole, excretion of 24-h urine albumin, Cl^-, phosphorous, K^+, protein, and Na^+ were not different between Cldn2KO and WT mice. However, 24-h excretion of urinary Ca^{2+} was greater (P<0.002; Fig.) in Cldn2KO compared to WT mice. Spontaneous renal papillary calcifications were identified in Cldn2KO (Fig.) but not WT mice. Cldn2 protein expression on uEVs was increased in SFs compared NSFs (P=0.004; Fig.).

Conclusions: Loss of renal tubular Clnd2 protein increased urinary Ca^{2+} excretion and papillary calcification in mice. Our nephrectomy patients study showed a significant decrease in Clnd2 expression in SFs compared NSFs. Thus, increased excretion of Cldn2 protein carrying uEVs in hypercalciuric SFs may reflect decreased tubular Cldn2 protein expression that results in reduced renal Ca^{2+} reabsorption and increased USD, and quantification of Clnd2 content of uEVs could serve as a useful biomarker for further studies.

The Relationship Between Patient Activation and Clinical Outcomes: A Longitudinal, Retrospective, Observational Study

Wael F. Hussein,[1,2] Tejas Gopal,[2,1] Shijie Chen,[1] Eric D. Weinhandl.[1,3]
[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Palo Alto, CA; [3]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN.

Background: Patient activation, defined as an individual's readiness, willingness, and ability to manage their own health and health care, is associated with healthy behaviors and improved outcomes. Patients undergoing in-center hemodialysis (HD) have low activation, but the association of patient activation with clinical outcomes among dialysis patients is unclear. We investigated the association between patient activation and outcomes in HD patients.

Methods: This cohort included 925 prevalent, in-center HD patients among 10 facilities in a mid-sized dialysis provider. Patients had completed a PAM-13 survey—a measure of patient activation—during a previous study. Patients were followed for 180 days after completion of the survey for the co-primary outcomes of (1) death and (2) the composite of death or hospitalization. Markers of non-adherence were examined as secondary outcomes, including (1) serum potassium >5.0 mEq/L; (2) serum phosphorus >5.5 mg/dL; (3) missed dialysis treatment due to absence (not hospitalization); and (4) interdialytic weight gain >4.0%. Univariate and adjusted regression models were fit to estimate associations of a 3-point increment in PAM-13 score with the outcomes of interest; adjustment factors comprised age, sex, dialysis vintage, serum albumin, and hospitalization history.

Results: A 3-point increment in PAM score was associated with lower hazard of death (univariate HR=0.89, 95% CI: 0.84 – 0.94; adjusted HR=0.91, 95% CI: 0.86-0.96), but not with the composite outcome of death or hospitalization (univariate HR=0.98, 95% CI: 0.96 – 1.00; adjusted HR=0.99, 95% CI: 0.96–1.00). There were no significant relationships between a 3-point increment in PAM score and any of the secondary outcomes in univariate and adjusted analyses.

Conclusions: In a cohort of prevalent, in-center HD patients, low activation was associated with mortality but not with hospitalization or measures of non-adherence.

Self-Efficacy and Social Support Determine Self-Reported Health in Hemodialysis Patients

Krister Cromm,[1,2] Le Hong Ngoc Pham,[2] Hanna Jaha,[1] Anna Schappert,[1] Gregor Liegl,[1] Kathrin I. Fischer,[1] Felix Fischer,[1] Matthias Rose.[1]
CONVINCE Scientific Committee and CONVINCE Investigators. *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Fresenius Medical Care Deutschland GmbH, Bad Homburg, Germany.*

Background: Patients with kidney disease receiving dialysis are a highly vulnerable population. There is some evidence from small studies that Health-Related Quality of Life (HRQL) in these patients is influenced by psychosocial determinants, but their relevance for clinical outcomes is debated. We investigated whether Self-Efficacy (SE) and Social Support (SS) can explain differences in HRQL outcome domains over time in hemodialysis patients.

Methods: HRQL in 1264 participants from the CONVINCE randomized, controlled trial investigating hemodiafiltration versus hemodialysis were assessed, using screening and quarterly follow-up data up to 24 months. Measures included the MOS Social Support Scale, General Self-Efficacy Scale, Perceived Stress Questionnaire and PROMIS short forms for fatigue, physical function, pain interference and intensity, sleep disturbance, anxiety, cognitive function, depression, and ability to participate in social roles. SE and SS were included as independent variables and HRQL domains as dependent variables in a linear mixed effects model with random intercept and slope for SE and SS.

Results: Participants were 20-92 (M=62.33, SD=13.50) years old, 62.9% were male. Linear mixed effect regression models showed significant main effects for self-efficacy (β=.85-4.84, p<.001) on all HRQL domains. Main effects for social support were found for Cognition, Depression, Pain Intensity and Sleep (β=.27-2.17, p<.01). For time, significant main effects were found for Anxiety and Sleep (β=.56 & .50, p<.01). Significant SE x Time interactions were found for Anxiety, Depression and Sleep (β=.11-.19, p<.05). Significant SS x Time interactions were found for Cognition and Sleep (β=.17 & .18, p<.01).

Conclusions: Our results indicate that higher SE is associated with higher HRQL of dialysis patients over time. Effects of SE are larger than those of SS and larger than previously reported. This bears the chance to develop targeted psychosocial interventions to improve health outcomes when undergoing dialysis.

Impact of Conservative Management vs. Dialysis on the Survival of US Veterans with Advanced CKD

Connie Rhee,[1] Yoko Narasaki,[1] Susan T. Crowley,[2] Csaba P. Kovesdy,[3] Dana B. Mukamel,[1] Seungsook You,[1] Alejandra Novoa-Vargas,[1] Ji Hoon Yoon,[1] Danh V. Nguyen,[1] Kamyar Kalantar-Zadeh.[4] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Yale University, New Haven, CT; [3]The University of Tennessee Health Science Center, Memphis, TN; [4]Harbor-UCLA Medical Center, Torrance, CA.*

Background: Given that dialysis patients may experience high early mortality rates, healthcare utilization, and withdrawal, particularly in those of older age and multimorbidity, there has been interest in conservative management (CM) as an alternative treatment strategy for advanced CKD patients. Among a national cohort of US Veterans, we compared the impact of CM vs. dialysis on survival.

Methods: Using linked national VA, USRDS, and Medicare data, we examined Veterans with advanced CKD (≥2 eGFRs <25 separated by ≥90 days) categorized according to receipt of CM vs. dialysis (non-receipt vs. receipt of dialysis within 2-yrs of the 1st eGFR <25), with the latter group parsed into later dialysis (LD) vs. earlier dialysis (ED) (eGFRs <15 vs. ≥15 at dialysis transition, respectively). We compared survival in CM vs. dialysis patients matched by propensity score (PS) in a 1:1 ratio to address confounding by indication using Cox models.

Results: Among 91,598 patients who met eligibility criteria, 3628 CM patients were PS-matched to 3628 ED patients, while 9833 CM patients were PS-matched to 9833 LD patients. In PS-matched models, both ED and LD were each associated with higher mortality vs. CM: HRs (95%CIs) 1.25 (1.19-1.32) and 1.08 (1.05-1.12), respectively. Similar findings were observed in sensitivity analyses doubly-adjusted for PS covariates. When examining survival trajectories after the index eGFR date, ED and LD demonstrated worse survival vs. CM after 2-years and 4-years, respectively.

Conclusions: In a national cohort of US Veterans, earlier transition to dialysis was associated with worse survival compared to CM. Later transition to dialysis was also associated with worse survival vs. CM, albeit to a lesser degree. Further studies are needed to examine the impact of CM vs. dialysis transition on other hard endpoints and patient-centered outcomes.

Encouraging a Standardized ESKD Transition Approach in a Comprehensive Kidney Care Contracting (CKCC) Program Is Associated with Increased Optimal Dialysis Starts

Roy G. Marcus,[1] Dave M. Miller,[3] Brian H. Nathanson,[2] Steven Henry,[3] Nirav Vakharia.[3] *[1]Clinical Renal Associates Ltd, Exton, PA; [2]OptiStatim, Longmeadow, MA; [3]Panoramic Health, Tempe, AZ.*

Background: The standard care for chronic kidney disease (CKD) is shifting from a "fee-for-service" model that focuses on volume of care and profitability of services to a Value Based Care (VBC) model that rewards better outcomes. It is well-established that starting ESKD care with peritoneal dialysis (PD) or hemodialysis (HD) with either an arteriovenous (AV) fistula or AV graft, instead of HD with a central venous catheter (CVC), produces better mortality, morbidity, and cost outcomes. The purpose of this study was to determine if a standardized ESKD transition pathway could improve the number of optimal starts within Kidney Care Entities (KCEs).

Methods: All patients were in the Comprehensive Kidney Care Contracting (CKCC) program. The CKCC program defines an optimal start to be the initiation of dialysis without a CVC. We recorded the proportion of optimal starts and the initial modality type (HD vs PD) in adult Medicare patients at 4 geographically diverse KCEs within a single physician-led nephrology organization. Data were recorded quarterly (Q) during 2022. During Q1-Q2, patients and clinicians were formally instructed on the benefits of optimal starts only. Starting in Q3, a standardized care pathway was deployed for patients at high risk for transition to ESKD across all 4 KCEs, inclusive of electronic health record and analytics tools, and treatment teams were provided lists of patients who met the high risk criteria. The proportion of optimal starts and the proportional of initial PD from Q1-Q2 versus Q3-Q4 were compared with Student's t-test for proportions.

Results: In 2022, the 4 KCEs treated 9,099 patients with 5,457 (60.0%) having CKD. 371 patients initiated dialysis during the study period with 164 (44.2%) in Q1-Q2. The proportion of optimal starts increased from 37.2% (61/164) in Q1-Q2 to 53.1% (110/207) in Q3-Q4, p = 0.002. The proportion of PD starts increased from 11.0% (18/164) in Q1-Q2 to 26.1% (54/207) in Q3-Q4, p <0.001.

Conclusions: The deployment of a standardized ESKD transition pathway as part of an intensive VBC educational program is associated with a significant increase in both optimal starts and the number of patients starting on PD.

Higher Patient-to-Patient Care Technician Ratios Associated with Worse Outcomes Among US In-Center Hemodialysis Patients

Laura Plantinga,[1] Alexis A. Bender,[1] Megan Urbanski,[1] Courtney E. Hoge,[1] Jennifer C. Morgan,[2] Bernard G. Jaar.[3] *[1]Emory University, Atlanta, GA; [2]Georgia State University, Atlanta, GA; [3]Johns Hopkins University, Baltimore, MD.*

Background: It is increasingly difficult to maintain adequate dialysis patient care technician (PCT) staffing at U.S. in-center hemodialysis (ICHD) facilities. We aimed to explore the associations of ICHD patient outcomes with facility-level PCT staffing.

Methods: U.S. patients (ages 18-100) initiating ICHD between 1/1/16 and 12/31/18 were included if they remained on ICHD for ≥90 days and had data on PCT staffing at their ICHD facility (*N*=236,126; mean age, 63.1; 57.6% male; 27.9% Black; 61.8% with diabetes; 60.2% starting ICHD with a catheter only). We estimated the association of time to 1-year patient outcomes with facility-level PCT staffing (=quartiles of patient:PCT ratios) using mixed-effects Poisson regression, with censoring as appropriate and adjustment for age, sex, race, pre-end-stage kidney disease nephrology care, diabetes, and first vascular access type.

Results: After adjustment, highest vs. lowest quartile of facility-level patient:PCT ratio was associated with 11%, 10%, and 10% higher rates of patient mortality, hospitalization, and readmission, respectively; associations with rates of waitlisting and transplant were not significant (**Figure 1**). Highest vs. lowest quartile of patient:PCT ratio was associated with 10%, 13%, and 22% higher rates of fluid overload-, sepsis-, and vascular access-related hospitalizations, respectively (**Figure 2**).

Conclusions: Patients initiating treatment in facilities with the least adequate PCT staffing may have worse early outcomes. While effects are modest and causal inference is limited, our results support further investigation of the effects of U.S. PCT staffing on patient safety and quality of U.S. ICHD care.

Funding: Other U.S. Government Support

The Impact of Affordable Care Act Medicaid Expansions on Dialysis Facility Medicaid Enrollment and Quality Measures

Allison C. Reaves,[1] Hocine Tighiouart,[1] Cindy P. Thomas,[2] Daniel E. Weiner.[1] *[1]Tufts Medical Center, Boston, MA; [2]Brandeis University Heller School for Social Policy and Management, Waltham, MA.*

Background: The Centers for Medicaid and Medicare Services proposed using Medicare Medicaid dual eligible enrollment (DEE) to adjust for social risk in dialysis facility quality scores. Because Medicaid eligibility varies by state, in part due to variable uptake of Affordable Care Act (ACA) Medicaid expansions, we examined the extent to which dialysis facility location in an expansion state was associated with increased DEE and improved dialysis facility quality scores.

Methods: Using data from the ESRD Quality Improvement Program (QIP) and US Renal Data System, we identified a longitudinal cohort of US hemodialysis dialysis facilities with ESRD QIP data from 2012-2018. We tested whether location in an expansion state was associated with increases in the proportion of Medicaid-enrolled incident and dual-eligible enrolled prevalent dialysis patients as well as improved ESRD QIP total performance scores (TPS) and vascular access scores (VAS). We compared pre-expansion data (2012-2013) with early and late post-expansion times points (2015 and 2018, respectively). We used a difference-in-differences approach and adjusted for facility patient characteristics and area-level social vulnerabilities.

Results: Expansions were associated with increases in incident patient Medicaid enrollment in the early and late expansion periods (5.5 percentage points, 95% CI (4.6, 6.5) and 7.4 percentage points, 95% CI (6.4, 8.4), respectively) and increases in dialysis facility DEE in the late expansion period (1.3 percentage points, 95% CI (0.7, 1.9)). Facility location in an expansion state was also associated with an increase of 2.2 points (95% CI (1.3, 3.1)) in TPS in the late expansion period. Catheter measure scores were lower and fistula measure scores higher in facilities located in expansion states. There was not a clear pattern of improvement in VAS associated with expansions.

Conclusions: Dialysis facilities in states that have not implemented Medicaid expansions may experience lower growth of Medicaid enrollment due to limited Medicaid coverage available to their patients and may also have a greater decline in quality scores. Accordingly, adjustments to quality performance metrics based on DEE may favor facilities located in expansion states and further exacerbate health disparities among patients receiving dialysis.

Roles of Matrix Metalloproteinase-2 and ETS Proto-Oncogene 1 in Rodent Arteriovenous Fistula Development

Hannah M. Northrup,[1] Yan-Ting E. Shiu,[1,2] CS Jason Tey,[1] Yuxia He,[1] Edgar A. Jaimes.[3] *[1]University of Utah Health, Salt Lake City, UT; [2]VA Salt Lake City Health Care System, Salt Lake City, UT; [3]Memorial Sloan Kettering Cancer Center, New York, NY.*

Background: Arteriovenous fistulas (AVFs) have high rates of maturation failure with no proven effective treatments. A few clinical studies have reported that stenotic AVFs had increased expression of matrix metalloproteinases (MMPs) when compared to native veins, and post-surgery fibrosis in newly created AVFs was positively associated with maturation failure. This study therefore examined the roles of MMP-2, which is a critical MMP in vascular remodeling, and the transcription factor ETS proto-oncogene 1 (ETS-1), which is a potent pro-fibrotic factor, in AVF maturation development.

Methods: Carotid-jugular AVFs were created in global MMP-2 homozygous knockout (MMP-2 KO) mice on C57BL/6 background, with C57BL/6 mice serving as wild-type (WT) controls. Femoral AVFs were created in global ETS-1 heterozygous knockout (ETS-1 KO) rats on Sprague-Dawley (SD) background, with SD rats serving as WT controls. AVFs and contralateral non-surgical veins were harvested at 1 and 4 weeks after AVF creation for RNA sequencing (RNA-seq), histology, and morphometry.

Results: In our mouse studies, RNA-seq data indicated drastically different transcriptional profiles between non-surgical veins and AVFs at 1 week after AVF creation. Genes regulated by MMP-2 and ETS-1 were significantly enriched in AVFs. Both MMP-2 KO and ETS-1 KO had significantly increased open lumen area of the AVF veins when compapred to WT controls. In mouse studies, the percent open lumen area of

the AVF veins was significantly larger in MMP KO (39% ± 6%) vs. WT (11% ± 2%) at 1 week, as well as at 4 weeks (MMP-2 KO: 20% ± 4%, WT: 6% ± 3%) (p<0.05 for both time points). ETS-1 expression was decreased in MMP-2 KO when compapred to WT. In rat studies, the percent open lumen area of the AVF veins was significantly larger in ETS-1 KO (70% ± 9%) vs. WT (39% ± 15%) at 1 week (p=0.04) and trending larger in ETS-1 KO (52% ± 26%) vs. WT (22% ± 7%) at 4 weeks (p=0.13).

Conclusions: Our animal studies showed that inhibition of MMP-2 and ETS-1 by genetic knockout improved AVF development. Therapeutic approaches of inhibiting these molecules may enhance AVF maturation in hemodialysis patients.

Long-Term Intervention Rate with Drug-Coated Balloons for Dysfunctional Arteriovenous (AV) Fistulas: Meeting KDOQI Targets in the IN.PACT AV Access Trial

Anjana Gopal, Charmaine E. Lok. *University of Toronto, Toronto, ON, Canada.*

Background: A key KDOQI Guidelines target is to have ≤3 percutaneous or surgical interventions per year to maintain AV fistula (AVF) patency. We aimed to define the intervention and thrombosis rates per AVF-years through 36 months from the IN.PACT AV Access trial.

Methods: This global, 29-center, single-blinded pivotal study randomized participants with de novo or non-stented restenotic obstructive lesion(s) of upper extremity AVF 1:1 to treatment with an IN.PACT AV paclitaxel drug-coated balloon (DCB; n=170) or standard percutaneous transluminal angioplasty (PTA; n=160). Participants were followed for 36 months; intervention rates and fistula-years of use were captured and compared to KDOQI guidelines target. 36 month thrombosis rates were compared between DCB and PTA groups.

Results: Of the 330 participants randomized, 133 completed their 3-year visit. Including the index procedure, the rates of intervention ranged 1.24-2.55 per AVF-year for DCB group and 1.48-3.06 per AVF-year for PTA group (Table). The cumulative incidence rate of access circuit thrombosis at 36 months was 8.2% (10) in DCB group and 18.3% (19) in PTA group with a hazard ratio of 0.457 (95% confidence interval: 0.212- 0.983; P = 0.04).

Conclusions: The need for interventions to maintain patency and thrombosis rate was reduced with use of DCB compared with PTA at the 1-, 2-, and 3-year timepoints post index procedure for the treatment of dysfunctional AVF. At the 3-year timepoint, both DCB and PTA groups met the KDOQI targets for AVF interventions per year to maintain patency.

Extreme Heat Exposure and Mortality Among Patients Receiving Dialysis

Matthew F. Blum,[1] Yijing Feng,[4] Cascade Tuholske,[5] Byoungjun Kim,[2] Mara McAdams-DeMarco,[2] Brad C. Astor,[3] Morgan Grams.[2] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]New York University Grossman School of Medicine, New York, NY; [3]University of Wisconsin-Madison, Madison, WI; [4]Harvard University T H Chan School of Public Health, Boston, MA; [5]Montana State University, Bozeman, MT.*

Background: Patients receiving maintenance dialysis represent a population vulnerable to extreme weather events such as wildfires and hurricanes, but the dangers posed by extreme heat exposure remain to be determined.

Methods: In the United States Renal Data System, we identified adults living in US cities prone to extreme heat who initiated maintenance dialysis from 1997 to 2016. We defined an extreme heat event as a heat index of >40.6°C for ≥2 days or >46.1°C for ≥1 day. We estimated the risk of death during a heat event using adjusted Cox proportional hazards regression and tested for effect modification by age, sex, race and ethnicity, year of dialysis initiation, dialysis modality, poverty level, and climate region.

Results: Among 945,437 adults in 246 cities, the median age was 64 years and 44% were female. During a median follow-up of 3.7 years, 519,748 adults were exposed to at least one of 7,152 extreme heat events, and 530,616 deaths occurred. In adjusted models, there was an increased risk of death (HR, 1.18; 95% CI, 1.15 to 1.20) during exposure to extreme heat (Table). Relative mortality risk was higher among patients who were ≥65 years-old (P=0.003), male (P=0.04), and living in the Northern Rockies and Plains (P=0.03), Ohio Valley (P=0.02), Northeast (P=0.01), and Southeast (P<0.001). Relative mortality risk was lower among Hispanic patients (P=0.02) compared to non-Hispanic White patients (Figure).

Conclusions: Patients receiving maintenance dialysis face an increased risk of death during extreme heat.

Funding: Other NIH Support - NHLBI

Risk of death with extreme heat exposure

Exposure to Wildfire-Related Particulate Matter and Risk of Hospitalization and Mortality Among Hemodialysis Patients

Hyeonjin Song,[1] Nicole E. Sieck,[1] Jochen G. Raimann,[2] Peter Kotanko,[2,3] Franklin W. Maddux,[4] Evan A. Ellicott,[1] Amir Sapkota.[1] *[1]The University of Maryland, College Park, MD; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Ongoing climate change is contributing to increases in frequency and severity of wildfires and the length of wildfire season. Wildfires are major sources of air pollution including fine particulate matter (aerodynamic diameter < 2.5 microns; $PM_{2.5}$) that may disproportionately impact vulnerable populations such as hemodialysis patients. We investigated the effect of wildfire-related $PM_{2.5}$ on hospitalization and mortality risk among hemodialysis patients.

Methods: We analyzed health records of 79,963 hemodialysis patients who received in-center hemodialysis treatment at 191 Fresenius Kidney Care clinics in Washington, Oregon, and California during 2005-2018. We estimated wildfire-related $PM_{2.5}$ for each of the clinics using satellite-derived smoke polygons (Hazard Mapping System) and ground-based $PM_{2.5}$ monitors (Air Quality System operated by Environmental Protection Agency). We conducted a time-stratified case-crossover analysis with a conditional Poisson model to investigate the association between exposure to wildfire-related $PM_{2.5}$ and risk of hospitalization and mortality among hemodialysis patients.

Results: The daily wildfire-related $PM_{2.5}$ concentration during the study period ranged from 0 to 551.3μg/m³ with the average of 0.7μg/m³ (SD=5.7μg/m³). A 10μg/m³ increase in wildfire-related $PM_{2.5}$ was associated with 1% higher risk of all-cause hospitalization (RR: 1.01, 95% CI: 0.99, 1.02), and 4% higher risk of all-cause mortality (RR: 1.04, 95% CI: 1.02, 1.06).

Conclusions: We observed positive associations between increases in wildfire-related $PM_{2.5}$ concentration and risk of all-cause hospitalization and mortality. Our findings highlight the need for targeted intervention, including early warnings, timely relocation of patients during wildfire events or improved air filtration systems to mitigate the adverse health effects of wildfire-related air pollution.

TH-OR51

Glycated Albumin and Adverse Clinical Outcomes in Patients with CKD

Mengyao Tang,[1] Anders H. Berg,[2] Eugene P. Rhee,[1] Andrew S. Allegretti,[1] Sagar U. Nigwekar,[1] S. Ananth Karumanchi,[2] James P. Lash,[3] Sahir Kalim.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Cedars-Sinai Medical Center, Los Angeles, CA; [3]University of Illinois Chicago, Chicago, IL.*

Background: HbA_{1c} is widely used to estimate glycemia, yet it is less reliable in patients with CKD. There is growing interest in complementary use of glycated albumin (GA) to improve glycemic monitoring and risk stratification in this population. However, whether GA associates with long-term clinical outcomes in a non-dialysis dependent CKD population has not been investigated.

Methods: To determine the prognostic value of GA, we measured baseline serum GA levels in 3110 patients with CKD stages 2–4 enrolled in the prospective Chronic Renal Insufficiency Cohort study. Outcomes include 1) incident ESKD (requiring chronic dialysis or kidney transplant); 2) CVD events (a composite of myocardial infarction, congestive heart failure or stroke); and 3) all-cause mortality.

Results: Participant characteristics included mean age 59 (SD 10.8) years; 1357 (43.6%) female; 1550 (49.8%) with diabetes. The median GA was 18.7 (interquartile range, 15.8-23.3)%. During an average 7.9-year follow-up, there were 980 ESKD events, 968 CVD events, and 1084 deaths. In multivariable adjusted Cox models, higher GA levels were associated with greater risks of all outcomes in patients with CKD, regardless of diabetes status (Fig 1): hazard ratios for ESKD, CVD, and death among participants with the highest quartile compared with quartile 2 (reference) were 1.42 (95% CI, 1.19-1.69), 1.67 (CI, 1.39-2.01), and 1.63 (CI, 1.37-1.94), respectively. The associations with CVD and death appeared J-shaped, with increased risk also seen at the lowest GA levels (quartile 1 vs. reference). Among patients with coexisting CKD and diabetes, the associations of GA with outcomes remained statistically significant even after adjustment for HbA_{1c}. For each outcome, we observed a significant fraction of new prognostic information when both GA and HbA_{1c} were added to models.

Conclusions: Among patients with CKD, GA levels were independently associated with risks of ESKD, CVD, and mortality, regardless of diabetes status. GA added prognostic value to HbA_{1c} among patients with coexisting CKD and diabetes.

Harnessing Kidney Transcriptome Profiles to Predict Rapid Progression of Diabetic Kidney Disease

Dianne Acoba,[1,2] Anna Levin,[3] Anna Witasp,[3] Johan C. Mölne,[4] Peter J. Greasley,[1] Jenny C. Nystrom,[5] Annika Wernerson,[3] Anna Reznichenko.[1] *[1]Research and Early Development, Cardiovascular, Renal and Metabolism, BioPharmaceuticals R&D, AstraZeneca, Gothenburg, Sweden; [2]Université Paris Cité, INSERM U1151, Institut Necker Enfants Malades (INEM), Paris, France; [3]Department of Clinical Science, Intervention and Technology, Division of Renal Medicine, Karolinska Institutet, Stockholm, Sweden; [4]Department of Laboratory Medicine, Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [5]Department of Physiology, Institute of Neuroscience and Physiology, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden.*

Background: Kidney gene expression has been shown to be associated with kidney function in diabetic kidney disease (DKD) patients by cross-sectional transcriptomics studies. However, how the renal transcriptome correlates to disease progression has not been established due to the paucity of longitudinal studies. We hypothesized that certain intra-kidney transcriptomic patterns associated with progressive DKD may elucidate disease drivers and predictive factors.

Methods: RNA-seq data from micro-dissected kidney biopsies and post-biopsy clinical data were available for 19 DKD patients. Patients were stratified into rapid and non-rapid progressors based on the following: eGFR decline more than ≤ -5 ml/min/year, CKD stage advancement, ≥30% UACR increase, nephrotic range albuminuria, and a composite outcome of kidney failure/≥40% eGFR loss. Gene signatures associated with rapid DKD progression were identified by differential expression (DEA), weighted gene co-expression network (WGCNA) and pathway enrichment analyses.

Results: We identified 265 statistically significant (*Padj* < 0.05) rapid progression-associated genes in the glomerular and tubulointerstitial compartments across all disease progression definitions through DEA. With WGCNA, 1 module in the glomeruli and 7 in the tubulointerstitium were found to be significantly correlated to eGFR slope ($P < 0.05$). The rapid progression-associated genes in the glomeruli were enriched for pathways linked to cell adhesion by integrins and syndecans, and signaling by NOTCH, MET and PTK2. Pathways involved in cellular response to starvation mediated by GCN2 and mTORC, SLIT signaling through ROBO receptors, and cytoskeletal reorganization were enriched in the tubulointerstitium. These pathways are less studied in the context of DKD progression and could elucidate novel disease understanding.

Conclusions: To the best of our knowledge, this study is the first to link baseline kidney compartment-specific gene expression to prospective DKD progression. We have identified transcriptomic profiles prognostic of rapid DKD progression that were distinct from those previously reported as associated with cross-sectional kidney function. Potentially, our findings can advance the understanding of DKD biology and steer towards discovery of prognostic biomarkers and therapeutic targets.

FIGARO-BM, a Biomarker Study of FIGARO-DKD, Reveals New Insights into the Mode of Action of Finerenone

Mario Berger,[1] Lydia J. Christopher,[2] Laura Goea,[1] Peter Kolkhof,[1] Aidan Macnamara,[1] Richard Nkulikiyinka,[1] Andrea Scalise,[3] Adam Skubala,[1] Sebastian Voss,[4] Katja Rohwedder,[5] Joachim H. Ix,[6] Faiez Zannad,[7] Peter Rossing,[8] Hiddo J. Heerspink.[9] *[1]Bayer AG, Pharmaceuticals, R&D, Wuppertal/Berlin, Germany; [2]Bayer UK, Cardiology, Reading, United Kingdom; [3]Bayer Hispania SL, Pharmaceutical Development, Barcelona, Spain; [4]CHRESTOS Concept GmbH & Co. KG, Essen, Germany; [5]Bayer AG, Pharmaceuticals, Medical Affairs, Berlin, Germany; [6]UCSD, Department of Medicine, San Diego, CA; [7]Université de Lorraine, Nancy, France; [8]Steno Diabetes Center Copenhagen, Herlev, and University of Copenhagen, Copenhagen, Denmark; [9]University Medical Center Groningen, Department of Clinical Pharmacy and Pharmacology, Groningen, Netherlands.*

Background: Mineralocorticoid receptor (MR) overactivation contributes to tissue fibrosis and organ damage found in cardiorenal disease. FIGARO-BM is an exploratory biomarker study aimed at advancing the understanding of the longitudinal pharmacodynamic response to finerenone, a non-steroidal, selective MR antagonist.

Methods: Samples were derived from the phase III parent trial FIGARO-DKD, which investigated finerenone's efficacy on cardiorenal outcomes and safety in CKD patients with type 2 diabetes (T2D). This biomarker substudy included 945 subjects from 21 countries, overall comparable to the total population, and analyzed 2941 biomarkers in more than 4000 longitudinal post-randomization plasma samples using Olink EXPLORE proteomics. Subjects on treatment with either placebo or finerenone for at least 36 months, and alive to consent, were eligible to participate in FIGARO-BM. Biomarkers with a significant difference ($p \leq 0.05$) between treatment arms at more than one study visit (month 4, 12, 24, 36 and 48, based on a linear mixed model adjusted for gender) and with effect estimates above threshold were used for gene enrichment analysis using Metascape. Enriched terms were grouped into clusters based on membership similarities.

Results: 373 plasma protein biomarkers were modulated by finerenone treatment. Gene enrichment of the biomarker profile identified two clusters of extracellular matrix (ECM)-related pathways, involving several well-established markers of inflammation and fibrosis such as fibronectin, osteopontin, and members of the interleukin-17 family, along with novel markers of ECM remodeling. Other clusters linked directly to mineralocorticoid/aldosterone biology and diuresis reflecting target modulation.

Conclusions: For the first time, FIGARO-BM provides human biomarker evidence that finerenone acts on inflammation and fibrosis pathways, one key driver of cardiorenal disease progression in T2D. The study supports preclinical findings from animal models and provides insights to mechanisms leading to clinical benefits in a broad cardiorenal patient population. Future studies are needed to validate these findings.

Funding: Commercial Support - The study and this analysis were funded by Bayer AG, Wuppertal, Germany.

Renal Effects of Empagliflozin Alone or in Combination with Semaglutide in Albuminuric Type 2 Diabetes: A Randomized, Placebo-Controlled Trial

Frederik Persson,[1] Suvanjaa Sivalingam,[1] Victor Wasehuus,[1] Viktor Rotbain Curovic,[1] Tine Hansen,[1] Peter Rossing.[1,2] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Kobenhavns Universitet, Kobenhavn, Denmark.*

Background: Different mechanisms of sodium-glucose cotransporter-2 (SGLT2) inhibitors and glucagon-like peptide-1 receptor (GLP-1) agonists indicate that combination therapy may have additive or synergistic effects. We investigated if combined treatment with empagliflozin (SGLT2) and semaglutide (GLP-1RA) can reduce urinary albumin creatinine ratio (UACR) compared to treatment with empagliflozin alone in individuals with type 2 diabetes and albuminuria.

Methods: Randomized, placebo-controlled, double-blind, parallel study including individuals with type 2 diabetes and albuminuria. All initiated open label empagliflozin in a run-in period of 26 weeks. Subsequently, they were randomized to subcutaneous injections of semaglutide or placebo for 26 weeks. Primary endpoint was change in UACR. Secondary endpoints were change in (1) HbA_{1c}; (2) body weight; (3) measured glomerular filtration rate (GFR); and (4) 24-hour systolic blood pressure.

Results: A total of 60 participants on empagliflozin were randomly assigned to additional semaglutide (n=30) or placebo (n=30). Mean age was 70.1 (SD 8.0) years, 22 % were female and median UACR was 128.2 [IQR 78.5-285.3] mg/g. Mean UACR change from randomization to week 52 was -15.5 ((95 % CI -34.0 to 8.0) %, p=0.17) in the semaglutide group and 14.8 ((-11.8 to 49.4) %, p=0.29) in the placebo group with a mean difference of -26.4 ((-48.2 to 4.6) %; p=0.086). The mean change in HbA_{1c} was -9.4 ((-13.5 to -5.2) mmol/mol, p<0.001) in the semaglutide group and -0.6 (-4.4 to 3.3) mmol/mol, p=0.77) in the placebo group with a significant difference between groups (mean difference: -8.8 (-14.3 to -3.3) mmol/mol, p=0.002). No difference between treatment groups in body weight (p=0.28), measured GFR (p=0.33) or 24-hour systolic blood pressure (p=0.26) was observed.

Conclusions: This randomized clinical trial could not demonstrate a significant effect of combined treatment with empagliflozin and semaglutide compared to empagliflozin alone on UACR, measured GFR, 24-hour systolic blood pressure or body weight in participants with type 2 diabetes and albuminuria. The combined treatment significantly improved glycemic control compared to treatment with empagliflozin alone.

Effects of Canagliflozin on Renal Oxygenation Evaluated Using Blood Oxygenation Level-Dependent MRI in Patients with Type 2 Diabetes

Katsuhito Mori,[1] Tsutomu Inoue,[2] Yuri Machiba,[1] Shinya Nakatani,[1] Hideki Uedono,[1] Masahiro Ishikawa,[2] Satsuki Taniuchi,[1] Akira Yamamoto,[1] Naoki Kobayashi,[2] Eito Kozawa,[2] Taro Shimono,[1] Yukio Miki,[1] Hirokazu Okada,[2] Masanori Emoto.[1] *[1]Osaka Metropolitan University Graduate School of Medicine, Osaka, Japan; [2]Saitama Medical University, Saitama, Japan.*

Background: Results obtained in recent clinical trials suggest that SGLT2 inhibitors have protective effects against diabetic and chronic kidney disease, though the precise mechanisms remain largely unknown. Since the kidneys are susceptible to hypoxic damage, we hypothesized that use of an SGLT2 inhibitor improves renal oxygenation.

Methods: The effects of canagliflozin on renal oxygenation in patients with type 2 diabetes (T2D) were examined using blood oxygenation level-dependent (BOLD) MRI. Based on a method previously reported, T2* maps were generated, then primary analysis of cortical T2* values was performed using the 12-layer concentric objects (TLCO) method, while cortical oxygenation was also evaluated based on region of interest (ROI) method. The primary endpoints were change in T2* value from before (Day 0) to after the initial treatment (Day 1, about two hours after initial single dose) and also after five consecutive canagliflozin treatments (Day 5).

Results: Fourteen patients with T2D were enrolled, with median age 65.5 (interquartile range 59.0-72.0) years, body mass index 24.2 (22.3-26.7) kg/m^2, HbA1c 7.1% (6.9-7.7%), estimated glomerular filtration rate 59.2 (46.9-76.8) mL/min/1.73 m^2, and urinary albumin creatine ratio 20.5 (5.7-468.7) mg/gCr. Results with the TLCO method showed that canagliflozin treatment did not cause a significant change in T2* (mean and 95% confidential interval) from Day 0 [54.1 (51.4-56.9)] to Day 1 [55.2 (52.5-58.0)] (p=0.336) and also to Day 5 [53.4 (50.7-56.2)] (p=0.519). On the other hand, the T2* value was significantly increased from 52.8 (50.6-55.0) to 54.5 (52.3-56.9) (p=0.031) on Day 1, while no significant change from Day 0 to Day 5 [53.7 (51.5-56.0) (p=0.241)] was found with use of the ROI method.

Conclusions: The present findings indicate that canagliflozin administration may improve renal cortical oxygenation in patients with T2D.

Insulin Resistance, Kidney Outcomes, and Effects of the Endothelin Receptor Antagonist Atrasentan in Patients with Type 2 Diabetes and CKD

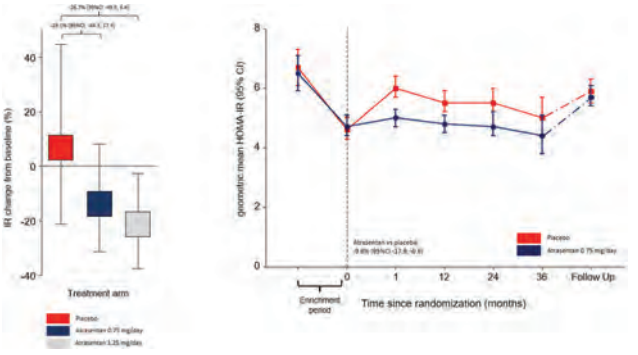
Johannes D. Smeijer,[1] Donald E. Kohan,[2] Peter Rossing,[3] Ricardo Correa-Rotter,[4] Adrian Liew,[5,6] Sydney C. Tang,[7] Dick de Zeeuw,[1] Ron T. Gansevoort,[1] Wenjun Ju,[8] Hiddo J. Heerspink.[1,6] *[1]Universitair Medisch Centrum Groningen, Groningen, Netherlands; [2]University of Utah Health, Salt Lake City, UT; [3]Steno Diabetes Center Copenhagen, Herlev, Denmark; [4]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [5]Mount Elizabeth Hospital, Singapore, Singapore; [6]The George Institute for Global Health, Newtown, NSW, Australia; [7]The University of Hong Kong Li Ka Shing Faculty of Medicine, Hong Kong, Hong Kong; [8]University of Michigan, Ann Arbor, MI.*

Background: Insulin resistance (IR) is a pathophysiologic hallmark of type 2 diabetes mellitus (T2DM) and associated with chronic kidney disease (CKD). Experimental studies suggest that endothelin-1 increases IR. We assessed the association between IR and cardio-renal outcomes and the effect of the selective endothelin receptor antagonist atrasentan on IR in patients with T2DM and CKD.

Methods: We used data from the RADAR and SONAR trials that recruited participants with T2DM and CKD [eGFR 25–75 mL/min/1.73 m2, urine albumin-to-creatinine ratio of 300–5000 mg/g]. IR was calculated using the homeostatic model assessment (HOMA-IR). The association between HOMA-IR and the pre-specified cardio-renal outcomes was assessed using multivariable Cox proportional hazards regression, and effects of atrasentan on HOMA-IR by a linear mixed effect model.

Results: In the SONAR trial, each log-unit increase in HOMA-IR was associated with an increased risk of the composite cardio-renal outcome [hazard ratio 1.32 (95%CI 1.09,1.60; p=0.004)], kidney outcome [hazard ratio 1.30 (95%CI 1.00,1.68; p-value = 0.048)], and the kidney or all-cause mortality outcome [hazard ratio 1.25 (95%CI 1.01,1.55; p-value = 0.037)]. After 12 weeks' treatment in the RADAR trial (N=123), atrasentan reduced HOMA-IR compared to placebo [0.75 mg/d 19.1% (95%CI -17.4, 44.3) and 1.25 mg/d 26.7% (95%CI -6.4, 49.5)]. In the SONAR trial (N=1914), long-term treatment with atrasentan 0.75 mg/day compared to placebo reduced HOMA-IR by 9.6% (95%CI 0.6, 17.9).

Conclusions: More severe IR is associated with increased risk of cardio-renal and mortality outcomes. The endothelin receptor antagonist atrasentan reduced IR, which may translate into clinical kidney benefits.



Atrasentan reduces insulin resistance. *Panel A*: Change from baseline in HOMA-IR in the RADAR trial. *Panel B*: Geometric mean HOMA-IR values per study visit in the SONAR trial.

Single-Nephron Dynamics in Patients with Overt Diabetic Nephropathy

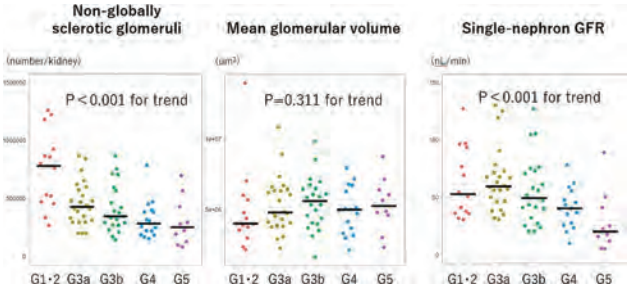
Akane Miura, Masahiro Okabe, Takaya Sasaki, Yusuke Okabayashi, Kotaro Haruhara, Nobuo Tsuboi, Takashi Yokoo. *Division of Nephrology and Hypertension, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo, Japan.*

Background: In diabetic nephropathy (DN), total glomerular hyperfiltration is observed from early stage of the disease, and glomerular filtration rate (GFR) decreases with a marked increase in albuminuria, leading to renal failure. In the clinical course of such overt DN, the single-nephron GFR (SNGFR) is thought to be dysregulated with a decrease in the number of functioning nephrons. However, the single-nephron dynamics has not been studied in human DN due to technical difficulties. We applied novel methodology to explore single-nephron dynamics in DN.

Methods: The number of non-globally sclerotic glomeruli (N_{NSG}) per kidney was estimated using cortical volume assessment via unenhanced computed tomography and biopsy-based stereology. Mean glomerular volume (MGV) was calculated from the measured area of glomerular tufts. SNGFR and single-nephron urinary protein excretion (SNUPE) was calculated by dividing estimated GFR and UPE by the total number of N_{NSG} per body (per kidney x 2). Single-nephron parameters (MGV, SNGFR and SNUPE) were compared among CKD stages.

Results: This study included 86 patients with DN evaluated at kidney biopsy (median age 55 [quartile 46-67] years, 84% male, HbA1c 6.6 [5.9-7.3] %, 53% with nephrotic syndrome, and 64% on renin-angiotensin-system inhibitors prebiopsy). CKD stage were 16% CKD1+2, 28% CKD3a, 25% CKD3b, 19% CKD4, and 12% CKD5. With advancing CKD stage, sclerotic glomerular lesions increased, whereas N_{NSG} decreased from median 780,900 to 251,200 per kidney. In contrast to the higher MGV and elevated SNUPE, SNGFR was markedly decreased in patients with advanced CKD (**Figure 1**).

Conclusions: Despite residual glomerular hypertrophy, the progressive decrease in SNGFR with decreased number of functioning nephrons in advanced stage DN suggests glomerular filtration failure due to progressive glomerulosclerotic lesions and reduced filtration surface.



TH-OR58

Implementation of a Kidney Screening Intervention to Improve Early CKD Detection in Type 2 Diabetes (T2D)

Margaret Spolnik,[1] Binu Sharma,[2] Michael R. Ellwood,[2] Jennie Z. Ma,[2] Jason A. Lyman,[2] Julia J. Scialla.[2] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]UVA Health, Charlottesville, VA.*

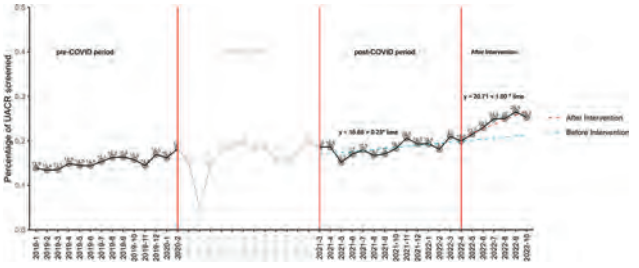
Background: American Diabetes Association and KDIGO guidelines recommend annual screening with UACR and eGFR in patients with T2D. To improve screening, we implemented clinical decision support (CDS) in April 2022 at University of Virginia Health System (UVA), including: (1) auto-enrollment of primary care patients with T2D in the EPIC health maintenance plan; and (2) prompting one-click ordering of the Kidney Profile (KP; panel including UACR and eGFR) or UACR alone, as needed, to satisfy screening.

Methods: We assessed effectiveness of the CDS by comparing screening across 3 periods (pre-COVID control: Jan 2019-Feb 2020; post-COVID control: Mar 2021- Apr 2022; post-CDS: May 2022 - Oct 2022) for all non-acute office, nursing and telehealth encounters in UVA primary care for T2D patients aged ≥22 years. Encounters with a coded diagnosis of CKD in the prior 4 yrs or fully screened for CKD in past 365 days were excluded. Orders for UACR testing within 30 days constituted screening. Rates were aggregated by calendar months and compared via interrupted time series. Sensitivity analyses included all primary care encounters during this period.

Results: There were 59,147 encounters (24,242 pre-COVID control; 23,413 post-COVID control; 11,492 post-CDS). The screening trend in both control periods was similar, therefore only the post-COVID control was considered further. Demographics, encounter types, and clinic distribution were similar in the control and post-CDS periods. There was no immediate impact on screening (p=0.4), but screening accelerated post-intervention (p=0.003, Figure). Results were similar if all primary care encounters were included (e.g., inclusive of acute visits).

Conclusions: Roll out of CDS coincided with acceleration of the screening rate for CKD among adult patients with T2D. These results suggest that simple CDS may be an effective intervention to promote annual CKD screening.

Funding: Other U.S. Government Support



Screening rates by month pre/post intervention. Blue line depicts the control rate of screening. Red line depicts observed screening after the intervention.

Effects of GLP-1 Receptor Agonist Dulaglutide on Profile of Circulating miRNAs Associated with ESKD in Type 2 Diabetes

Eiichiro Satake,[1] Brandon E. McFarlin,[2] Sok Cin Tye,[1] Joseph Ricca,[1] Kevin L. Duffin,[2] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]Eli Lilly and Company, Indianapolis, IN.*

Background: Glucagon-like peptide-1 (GLP-1) receptor agonists have been shown to slow kidney function decline in patients with type 2 diabetes (T2D), but the underlying mechanism remains unclear. Circulating microRNAs (miRNAs) are short non-coding RNA molecules known to regulate proteins. Previously, we identified 17 plasma miRNAs (8 risk and 9 protective) that were predictive of end-stage kidney disease (ESKD) in T2D patients (Satake et al. JASN 2022). In this study, we investigated the treatment effect of the GLP-1 receptor agonist, Dulaglutide on longitudinal changes in plasma concentrations of these miRNAs in patients enrolled in the AWARD-7 trial.

Methods: Plasma samples were obtained from T2D patients with chronic kidney disease (CKD) stages 3-4 who received Dulaglutide 1.5 mg (n=29) or insulin Glargine (n=31) for 52 weeks. Using the HTG edgeSeq platform, we measured 17 ESKD-associated miRNAs at baseline and 52 weeks. Fold change (FC) values were calculated for each patient and each miRNA by dividing the concentration of miRNA at 52 weeks by its concentration at baseline.

Results: Comparing the FC values between Dulaglutide and Glargine groups, we observed that the plasma concentration of protective miRNAs (in blue) increased during Dulaglutide treatment, and 5 of them (miR-378d, -324-3p, -22-3p, -378a-3p and -339-5p) showed statistically significant increases (P<0.05). The plasma concentrations of all risk miRNAs (in red) were reduced with Dulaglutide treatment, but only the reduction of miR-6722-3p reached statistical significance (Figure).

Conclusions: Treatment of T2D patients with stage 3-4 CKD with Dulaglutide altered the profile of circulating miRNAs associated with ESKD, resulting in increased concentrations of protective miRNAs and decreased concentrations of risk miRNA in circulation.

Earlier Intervention in Diabetic Kidney Disease Management Using the In Vitro Diagnostic Test PromarkerD Shows Economic Health Benefits over Current Standard of Care

Kirsten E. Peters, Gareth C. Fernandez, Lianzhi Chen, Li Ying Kam, Pearl Tan, Richard Lipscombe. *Proteomics International, Perth, WA, Australia.*

Background: Diabetic kidney disease (DKD) is present in 1 in 3 people with type 2 diabetes (T2D) and is the leading cause of end-stage renal disease (ESRD). PromarkerD is a newly developed biomarker-based blood test that predicts risk of DKD in people with T2D. Recent studies have shown the clinical benefit of early intervention with sodium glucose cotransporter-2 inhibitors (SGLT2s) in DKD management for patients with no or early-stage kidney disease. This study aimed to assess the consequent economic health benefit of earlier introduction of SGLT2s resulting from a proactive testing regime using the PromarkerD test versus current standard of care (SoC).

Methods: A ten-year model was developed according to the International Society of Pharmacoeconomics and Outcomes Research (ISPOR) guidelines to evaluate potential net savings from introducing PromarkerD testing versus SoC in a hypothetical cohort of 1 million people with T2D. Model inputs included costs and frequency of testing, costs associated with initiation of SGLT2s, and cost-savings from slowed DKD progression and averted renal replacement therapy for ESRD (dialysis and kidney transplants).

Results: PromarkerD testing could produce net savings for US payers exceeding $10 billion USD per one million people with T2D over the ten-year time horizon. In the baseline case, the total annual savings equal the costs after four years. Savings increase exponentially in subsequent years, significantly outweighing the associated costs compared to the current SoC without PromarkerD testing. The breakeven point occurs after six years, after which the total savings are greater than the total costs. Significant savings arise from slowing the progression of DKD, against costs from the use of SGLT2s and cost of PromarkerD testing over 10 years.

Conclusions: Earlier intervention with SGLT2s following implementation of the PromarkerD test could result in substantial savings to US payers in the management of DKD. PromarkerD testing would enable earlier intervention for those at high risk of DKD, before progression to more costly later stage disease requiring renal replacement therapy, as well as reduce unnecessary treatment in those at low risk.

ApoA4 Mutations Cause Autosomal Dominant Tubulointerstitial Kidney Disease with Medullary Amyloidosis

Anthony J. Bleyer,[1,2] Tereza Kmochova,[2] Martina Zivna,[2] Kendrah O. Kidd,[1] Varun Agrawal,[7] Michael L. West,[3] Andrew Orr,[3] Nelson Leung,[4] Astrid Weins,[5] Helmut G. Rennke,[5] Adam P. Levine,[6] Ellen D. Mcphail,[4] Surendra Dasari,[4] Jakub Sikora,[2] Stanislav Kmoch.[2,1] *[1]Wake Forest University School of Medicine, Winston-Salem, NC; [2]Univerzita Karlova 1 lekarska fakulta, Praha, Czechia; [3]Dalhousie University Faculty of Medicine, Halifax, NS, Canada; [4]Mayo Clinic Minnesota, Rochester, MN; [5]Harvard Medical School, Boston, MA; [6]University College London, London, United Kingdom; [7]University of Vermont Medical Center, Burlington, VT.*

Background: We describe for the first time mutations in the *APOA4* gene as a cause of inherited kidney disease.

Methods: Whole genome sequencing was performed in 5 members of a large family with autosomal dominant tubulointerstitial kidney disease(ADTKD), and we then screened other ADTKD families in our registry for mutations in the identified gene.

Results: There was an ~15 megabase shared genomic region on chromosome 11 (chr11: 110012896- 124998347) with only one relevant candidate variant chr11:116692578 G>C (hg19) encoding for a missense mutation in *APOA4* (NM_000482.4): c.196C>G (p.L66V). Using Sanger sequencing and segregation analysis, we genotyped 19 individuals from the family. Of 12 genetically affected individuals (10 genotyped and two obligate heterozygotes), 10 had CKD, with two females being as yet clinically unaffected. Of nine genetically unaffected, the lowest eGFR was 59 ml/min/1.73m^2 at age 69. Screening families from our ADTKD registry, we identified two other distantly related families with the same variant and two distantly related families with a chr11:116693454 C>T (hg19) variant encoding the missense mutation p.D33N. All 31 clinically affected individuals suffered from CKD without proteinuria and a bland sediment and carried their familial pathogenic *APOA4* mutation. The mean age of end-stage kidney disease was 72.7±10.2 for the p.L66V mutation and 58.2±11.1 for the p.D33N mutation (p=0.009). In an individual with the p.L66V mutation, pathologic examination of a nephrectomy specimen revealed marked medullary amyloid deposition, with mass-spectrometric analysis revealing the p.L66V ApoA4 protein as the predominant constituent. Four kidney biopsies containing only cortical tissue revealed no cortical amyloid deposition, while another biopsy containing cortex and medulla showed medullary amyloid deposits but no cortical amyloid deposits. In summary, ApoA4 mutations may lead to marked medullary amyloid deposition and ADTKD.

Conclusions: For the first time, we identified mutations in the *APOA4* gene as a cause of ADTKD. *APOA4* mutations result in medullary ApoA4 deposition, which can be missed on routine kidney biopsies that only sample the renal cortex.

Mesencephalic Astrocyte-Derived Neurotrophic Factor (MANF) Stimulates Autophagy and Restores Mitochondrial Homeostasis to Treat Uromodulin-Associated Nephropathy

Chuang Li,[1] Yeawon Kim,[1] Chenjian Gu,[1] Yili Fang,[1] Eric Tycksen,[1] Anuradhika Puri,[5] Terri A. Pietka,[1] Jothilingam Sivapackiam,[1] Kendrah O. Kidd,[2] Sun-Ji Park,[1] Bryce G. Johnson,[3] Stanislav Kmoch,[4] Jeremy S. Duffield,[7] Anthony J. Bleyer,[2] Meredith Jackrel,[5] Fumihiko Urano,[1] Vijay Sharma,[1] Maria Lindahl,[6] Ying M. Chen.[1] *[1]Washington University in St Louis School of Medicine, St Louis, MO; [2]Wake Forest University School of Medicine, Winston-Salem, NC; [3]Pfizer Inc, New York, NY; [4]Univerzita Karlova, Praha, Czechia; [5]Washington University in St Louis, St Louis, MO; [6]Helsingin yliopisto, Helsinki, Finland; [7]Prime Medicine, Cambridge, MA.*

Background: Autosomal dominant tubulointerstitial kidney disease due to uromodulin mutations (ADTKD-*UMOD*), a leading hereditary kidney disease, has no targeted therapies. UMOD is expressed in the thick ascending limb (TAL) tubules, and p.H177_R185del in-frame deletion is the most prevalent human mutation.

Methods: CRISPR/Cas9 was utilized to generate an ADTKD-*UMOD* mouse model carrying *Umod* p.Y178_R186del, analogous to human H177_R185del. To assess the functional role of mesencephalic astrocyte-derived neurotrophic factor (MANF) in ADTKD, inducible tubular cell-specific MANF transgenic and TAL-specific MANF knockout mice were generated. Meanwhile, stable HEK cell line harboring WT or H177_R185del was established. RNA sequencing was performed on isolated TAL cells. Immunoblot, q-PCR, immunofluorescence staining and electron microscopy were employed. Mitochondria function was assessed by Oroboros high resolution respirometry and mitochondrial ROS was monitored by ^{68}Ga-Galuminox PET/CT in live animals for the first time.

Results: Mutant TALs exhibit impaired autophagy/mitophagy and mitochondrial dysfunction. Subsequently, mitochondrial DNA leaking to cytosol leads to activation of stimulator of interferon genes (STING) signaling, inflammation and renal fibrosis in *Umod* Y178-R186del mice. MANF, a novel endoplasmic reticulum stress-regulated secreted protein, is induced in the mutant TALs. Genetic ablation of MANF in the mutant TALs worsens autophagy and mitochondrial failure and exacerbates kidney fibrosis. Most importantly, inducible tubular overexpression of MANF after the onset of disease stimulates autophagy/mitophagy and kidney clearance of mutant UMOD, as well as promotes mitochondrial biogenesis and oxidative phosphorylation through p-AMPK and downstream FOXO3 and PGC1a enhancement. Consequently, tubular MANF overexpression suppresses STING-mediated inflammation and fibrosis, thereby improving kidney function.

Conclusions: For the first time, we discover that MANF, as a novel biotherapeutic protein, can regulate organelle homeostasis and treat ADTKD, which may have broad therapeutic applications to treat various protein misfolding diseases.

TH-OR63

Inactivation of Ire1alpha Endoribonuclease Domain Slows Down ADPKD in Orthologous Mouse Models

Rishi Bhardwaj,[1] Isabel Volpe,[1] Duygu Elif Yilmaz,[2] Carlotta Pioppini,[2] Kasturi Roy,[1] Michael Rehman,[1] Yiqiang Cai,[1] Matteus Krappitz,[2] Stefan Somlo,[1] Sorin V. Fedeles.[1] *[1]Yale School of Medicine, New Haven, CT; [2]Charite Universitatsmedizin Berlin, Berlin, Germany*.

Background: The Ire1alpha-XBP1 pathway is the most conserved UPR branch from yeast to mammals. Our previous studies (abstract WCN23-2042) showed that genetic inactivation of XBP1 leads to significant improvement in disease severity in neonatal and adult Pkd1-dependent ADPKD mouse models through specific apoptosis of cystic cells. The endoribonuclease domain of Ire1α splices an intron from the XBP1 mRNA leading to the formation of active XBP1 which acts as a transcription factor to mitigate ER stress. Here we investigated whether a point mutation in the endoribonuclease domain of Ire1alpha can recapitulate the genetic XBP1 inactivation rescue in the context of orthologous ADPKD mouse models.

Methods: We generated an in vivo Ire1alpha endoribonuclease dead point mutation (K907A) via CRISPR/Cas9. We crossed the Ire1alpha mutant with Pkd1 deficient early and adult models and assessed the impact on disease severity via morphological and functional parameters. Finally, we examined the effect of XBP1 inactivation in bile ducts in polycystic liver disease models due to polycystin-1 deletion.

Results: We confirmed that the K907A mutation in the endoribonuclease domain of Ire1alpha leads to impaired XBP1 splicing activity as seen via western blotting. We generated Ire1alpha ^{K907A} animals and confirmed homozygous embryonic lethality. We then used Ire1alpha $^{K907A/flox}$ animals and crossed them with either Pkd1$^{flox/flox}$;Pkhd1-Cre (early model) or Pkd1$^{flox/flox}$;Pax8^{rtTA};Tet-OCre (adult model) mice to generate experimental Ire1alpha$^{K907A/flox}$;Pkd1$^{flox/flox}$;Pkhd1-Cre or Ire1$^{K907A/flox}$;Pkd1$^{flox/flox}$;Pax8^{rtTA};Tet-OCre mice. The mice showed significantly improved kidney to body weight ratio (KW/BW) compared with the Pkd1-SKO mice (0.095±0.011 vs 0.136±0.022, **p=0.008, early model; 0.088±0.031 vs 0.149±0.043, *p=0.027, adult model). Finally, when XBP1 was inactivated concomitantly with Pkd1 in bile ducts using Ubc-Cre, a dramatic impact on cystic disease severity was observed compared with the single Pkd1 KO animals.

Conclusions: Our results demonstrate that specific inactivation of the Ire1alpha endoribonuclease domain upstream of XBP1 is beneficial in slowing down ADPKD progression. Ire1alpha endoribonuclease inhibitors may serve as potential starting points for development of ADPKD therapeutics.

TH-OR64

Role of ER-Mitochondria Connection in the Pathogenesis of ADPKD

Biswajit Padhy, Jian Xie, Chou-Long Huang. Huang Lab. *University of Iowa Carver College of Medicine, Iowa City, IA.*

Background: Mutations in PKD1 and PKD2 gene cause ADPKD. One hypothesis states that ADPKD is a ciliopathy. We have recently demonstrated that ER-localized PC2 is also important in anti-cystogenesis via K^+-Ca^{2+} exchange for ER Ca^{2+} release. Metabolic reprogramming and mitochondrial dysfunction are important in pathogenesis of ADPKD. Mitochondrial (Mito) translocation of the C-terminal tail of PC1 (CTT) is believed important. How PC2 regulates Mito function is unknown. 3 potential mechanisms underlie regulation of Mito by PC2-mediated ER Ca^{2+} release: direct ER-Mito Ca^{2+} transfer at mitochondria-associated ER membranes (MAMs) to regulate TCA enzyme, and cytosolic Ca^{2+} regulation of PGC1α (via CaMKII) and PPARα (via myc and miR17), two master regulators of Mito biogenesis.

Methods: TricB, an ER-restricted K^+ channel mediates K^+-Ca^{2+} exchange for Ca^{2+} release as an experimental tool for role of ER-localized PC2. Oxygen consumption rate (OCR) for Mito function and transmission EM (TEM) for Mito morphology.

Results: Mito DNA mass, PPARα, PGC1α, mitofusin-2 were downregulated while myc and miR-17 were upregulated in both Pkd1- and Pkd2-cKO kidneys. OCR decreased in proximal tubules isolated from both Pkd1- and Pkd2-cKO kidneys. TEM revealed ER in close contact with Mito forming MAMs. About 25% ER membrane and 60% Mito membrane form MAMs. Mito morphology (area, cristae density, roundness, etc) were altered in Pkd2-cKO kidneys. MAM distance was increased in Pkd2-cKO, indicating reduced ER-Mito contact. In many parameters measured, changes occurred in pre-cystic as well cystic stage. In all above, the changes by cKO were reversed at least partially by transgenic expression of TricB, indicating PC2-dependent ER Ca^{2+} release is important. To further demonstrate convergence of PC1 and PC2 function in ER, transgenic TricB expression reversed cystogenesis in Pkd1-cKO mice. Interestingly, PC1-CTT translocation to Mito decreased in Pkd2-cKO, which was reversed by TricB expression.

Conclusions: Both PC1 and PC2 deficiency result in mitochondrial dysfunction. TricB is not in cilia nor Mito; complementation of the deficiency by TricB supports an important role for ER Ca^{2+} homeostasis. ER-mitochondria connection is a downstream effector for PC1 and PC2 convergence and plays an important role in anti-cystogenesis of PCs.

Organoid Xenograft Model of Polycystic Kidney Disease Reveals Context-Dependent Cross-Talk Between Primary Cilium and Autophagy in Cystogenesis

Yun Xia, Meng Liu, Angelysia Cardilla, Tian Zhang, Mihir Y. Naik. *Nanyang Technological University, Singapore, Singapore*.

Background: In the past few years, organoid models have been developed to study polycystic kidney disease (PKD), including those derived from human pluripotent stem cells (PSC) and adult kidney tissue. Despite successful recapitulation of tubular cyst formation *in vitro*, most organoid models of PKD rely on stress stimulation to demonstrate disease phenotypes, possibly due to the lack of native tissue microenvironment. Novel organoid models of PKD need to be developed to reveal the pathogenetic underpinnings for human PKD.

Methods: We generated kidney organoids from PKD patient induced PSCs (iPSC) and gene-corrected iPSCs, followed by engrafting these kidney organoids into the sub-renal capsule space of immunocompromised mice. Genetic editing was performed in

PKD patient iPSCs to modulate primary cilium-autophagy signaling axis, followed by organoid generation and xenotransplantation. The organoid xenografts were recovered four weeks post engraftment for phenotypic assessment and single cell transcriptomic analysis.

Results: PKD patient iPSCs-derived kidney organoids spontaneously developed tubular cysts *in vivo*, whereas gene-corrected organoid xenografts showed an absence of cystogenesis. PKD organoid xenografts showed a myriad of structural and functional abnormalities reminiscent of human PKD. In particular, cellular autophagy was significantly compromised in PKD organoid xenografts. Primary cilium ablation in PKD organoid xenografts inhibited cystogenesis, alongside an upregulation of autophagy. On the contrary, primary cilium ablation in the gene-corrected organoid xenografts induced cystogenesis, in parallel with a significant downregulation of autophagy. Employing the organoid xenograft model of PKD, we evaluated the effect of an FDA-approved drug on cystogenesis *in vivo*.

Conclusions: The organoid xenograft model of PKD recapitulates spontaneous cyst formation *in vivo*, representing a more sophisticated system for revealing novel therapeutic targets and for evaluating the clinical potential of candidate drugs.

Downregulation of O-GlcNAcylation, a Metabolic Regulator, Attenuates PKD Progression

Matthew A. Kavanaugh, Dona G. Isai, Henry Wang, Antonio Artigues, Maria T. Villar, Stephen C. Parnell, Chad Slawson, Darren P. Wallace, Pamela V. Tran. *University of Kansas School of Medicine, Kansas City, KS.*

Background: Altered cell metabolism is an important component of autosomal dominant polycystic kidney disease (ADPKD) pathogenesis, but drivers of these alterations are not understood. The addition of O-linked b-N-acetylglucosamine (O-GlcNAc) onto protein substrates by O-GlcNAc transferase (OGT) is a nutrient-sensitive post-translational modification that integrates multiple metabolic signals. We have reported that protein O-GlcNAcylation is increased in kidneys of ADPKD patients and PKD mouse models. Thus, we hypothesize that increased O-GlcNAcylation is pathogenic in ADPKD.

Methods: We generated juvenile and adult *Pkd1* conditional knockout (cko) and *Pkd1;Ogt* double knockout (dko) mice using the HoxB7-Cre and the doxycycline-inducible Pax8rtTA;LC1-Cre recombinases (induced from 4-6 weeks of age). Juvenile and adult mouse kidneys were analyzed on postnatal day (P)14 and at 4 months of age, respectively. To identify hyper-O-GlcNAcylated proteins in PKD, immunoprecipitation and Western blot were performed on mouse renal tissue extracts. Mass spectrometry is underway to map O-GlcNAcylation sites on identified proteins. To examine mechanisms in human ADPKD, cyst-lining epithelial cells were cultured in a 3D collagen matrix and an OGT inhibitor was tested on *in vitro* cyst formation.

Results: In juvenile mice, *Ogt* deletion in *Pkd1* cko mice reduced renal cystogenesis and kidney weight:body weight ratios (KW/BW); restrained renal cilia lengths; reduced inflammation and fibrosis; increased activation of the energy sensor AMPK; and improved kidney function. Further, while *Pkd1* cko mice die between P14-P20, *Pkd1;Ogt* dko mice continue to thrive beyond 14 weeks of age. Additionally, AMPK was found to be hyper-O-GlcNAcylated at P14 in *Pkd1* cko kidneys. Similarly, in adult mice, deletion of *Ogt* in *Pkd1* cko mice reduced renal cystogenesis and KW/BW. Finally, OGT inhibition reduced *in vitro* cyst formation by cultured human ADPKD cells.

Conclusions: In PKD, protein O-GlcNAcylation, including of AMPK, is increased, and deletion or inhibition of OGT reduces cyst growth and disease severity, demonstrating that O-GlcNAcylation is an important driver of PKD progression. We propose that targeting O-GlcNAcylation may have therapeutic potential in ADPKD.

TH-OR67

Ciliary Exclusion of ARL13B or Loss of Its GEF Activity for ARL3 Suppresses Polycystic Kidney Disease in Mice

Robert E. Van Sciver, Tamara Caspary. *Emory University School of Medicine, Atlanta, GA.*

Background: Polycystic kidney disease (PKD) and primary cilia are intricately linked. Mutations in *PKD1* and *PKD2*, which encode for ciliary polycystin proteins, are the most common genetic causes of PKD. Mouse models predict the presence of a cilia-dependent cyst activating (CDCA) pathway that functions in cilia to drive cystogenesis in mouse models of PKD. This CDCA pathway is normally inhibited by the polycystin proteins, yet the ciliary driver(s) of cyst pathogenesis remain unknown. ARL13B is an atypical ciliary GTPase which also possesses guanine nucleotide exchange factor (GEF) activity for another ARL family GTPase, ARL3. Recent work revealed a central role of ARL13B's cilia localization in cystogenesis, yet its role in the CDCA pathway is unknown.

Methods: To directly test ARL13B's role in the CDCA pathway, we engineered two distinct *Arl13b* mutant alleles at the endogenous locus in mice: (1) *Arl13b*^{V358A}, which mutates a single amino acid in ARL13B's cilia-localization motif; and (2) *Arl13b*^{R79Q}, which prevents ARL13B's GEF activity for ARL3. ARL13B^{V358A} retains all known ARL13B biochemical functions, is stably expressed, yet is undetectable in cilia. ARL13B^{R79Q} localizes to cilia, retains its GTPase activity, yet cannot activate ARL3. Using the *Pax8*^{rtTA}*; TetO-Cre* system, we induced kidney-specific loss of *Pkd1* alone (*Pkd1*$^{fl/fl}$) or in combination with either of these alleles (*Pkd1*$^{fl/fl}$; *Arl13b*$^{V358A/fl}$ or *Pkd1*$^{fl/fl}$; *Arl13b*$^{R79Q/fl}$) in adult mice. This adult induction model allowed us to directly test ARL13B's ciliary and enzymatic roles in kidney cystogenesis *in vivo*.

Results: At 18-weeks, control mouse kidneys had a kidney weight to body weight ratio (KW:BW) of 1.39±0.04. In adult induction models, loss of *Pkd1* alone led to severe cystic kidneys with KW:BW of 9.71±1.21, while concomitant loss of *Pkd1* and ciliary exclusion of ARL13B (V358A) or loss of GEF activity for ARL3 (R79Q) suppressed the cystic phenotype caused by loss of *Pkd1* alone with KW:BW of 2.69±0.47 and 2.44±0.43, respectively.

Conclusions: In mouse models, loss of ciliary ARL13B or loss of GEF activity for ARL3 suppressed the severe cystic kidney phenotype caused by loss of *Pkd1* alone. These results reveal that ARL13B regulates the CDCA through its GEF activity. Our findings indicate that ARL13B activates a pro-cystogenic pathway, providing a mechanism that could be targeted therapeutically.

Deletion of the Circadian Clock Gene Bmal1 in Renal Collecting Ducts Leads to Rapid Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Abeda Jamadar,[1] Meekha M. Varghese,[1] Michelle L. Gumz,[2] Reena Rao.[1] *[1]University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS; [2]University of Florida, Gainesville, FL.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is an inherited kidney disease characterized by progressive cyst growth from the nephrons that can lead to loss of renal function and end stage renal disease. Here we examined if disruption of the circadian clock can alter ADPKD progression. Circadian rhythms are intrinsic, cyclical ~24-hour oscillations in behavior and physiology that coordinate biological processes with the time of day. In mammals, circadian rhythms are regulated by cell-autonomous circadian clocks. BMAL1 is a transcription activator, and a core component of the circadian clock, which plays an important role in physiological rhythms including the cell cycle, metabolism, and inflammation.

Methods: To determine the effect of Bmal1 gene deletion in ADPKD kidneys, we used the Pkd1$^{RC/RC}$ mouse, a Pkd1 gene hypomorph mouse model of ADPKD. Pkd1$^{RC/RC}$;Bmal1$^{f/f}$;Pkhd1^{cre} mice (RC/RC-Bmal1KO) in which Bmal1 (*Arntl1* gene) was specifically deleted in the renal collecting ducts and connecting tubules was generated on pure C57BL6/J background and compared with wild type (WT) and Bmal1$^{f/f}$;Pkhd1^{cre} mice (RC/RC-Bmal1KO). All the mice were sacrificed at 8 months of age at noon time and kidneys were analyzed

Results: We found that the disease progressed rapidly in RC/RC-Bmal1KO mouse kidneys. At 8 months, RC/RC-Bmal1KO littermates showed significantly larger kidneys with significantly higher kidney/body weight ratio and cyst area as compared to RC/RC kidneys. In addition, we found that RC/RC-Bmal1KO kidneys had increased cell proliferation and apoptosis as indicated by higher KI-67 and TUNEL staining, respectively. Immunoblot analysis showed significantly increased expression of pro-proliferative factors in RC/RC-Bmal1KO kidneys compared to RC/RC kidneys. Bulk RNA seq analysis indicated significantly reduced fatty acid metabolism in RC/RC mice as compared to WT mice, which was further reduced in RC/RC-Bmal1KO mice.

Conclusions: These results show for the first time that disruption of the renal circadian clock is a trigger for early and accelerated disease progression in ADPKD.

Ablation of Long Noncoding RNA Hoxb3os Exacerbates Cystogenesis in Mouse Polycystic Kidney Disease

Karam S. Aboudehen,[1] Ivan D. Weisser,[2] Kara Eckberg,[2] Stephen D'Amico,[1] Daniel J. Buttram.[2] *[1]Stony Brook University, Stony Brook, NY; [2]Regents of the University of Minnesota, Minneapolis, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is a monogenic disorder characterized by the formation of cysts in the kidney, and is primarily caused by mutations in two genes, *PKD1* and *PKD2*. Long non-coding RNA (lncRNA) are >200 bp in length, lack an open reading frame, and have recently emerged as epigenetic regulators of development and disease. The involvement of lncRNAs in ADPKD is not known.

Methods: In this study, we investigated the role of lncRNA *Hoxb3os* in ADPKD by ablating its expression in the mouse.

Results: Phenotypic analysis revealed that *Hoxb3os*-null mice were viable and had grossly normal kidney morphology. At the molecular level, *Hoxb3os*-null kidneys showed activation of mTOR/AKT signaling and subsequent increase in cell proliferation. To determine whether downregulation of *Hoxb3os* affects cystogenesis, we crossed the *Hoxb3os*-null mouse to two orthologues Pkd1 mouse models: *Pkhd1*/Cre;*Pkd1*$^{F/F}$ (rapid cyst progression) and *Pkd1*$^{RC/RC}$ (slow cyst progression). Ablation of *Hoxb3os* exacerbated cyst growth in both mouse models. To gain insight into the mechanism(s) whereby *Hoxb3os* inhibition promotes cystogenesis, we performed proteomic analysis of mTOR/AKT pathway between single knockout (*Pkd1*$^{-/-}$, SKO) and double knockout (*Pkd1*$^{-/-}$ and *Hoxb3os*$^{-/-}$, DKO) mice. Compared to SKO, DKO mice displayed increased levels of total and phosphorylated RICTOR, a protein component specific to mTORC2. This was accompanied by enhanced phosphorylation of AKT at Ser473, a known mTORC2 phosphorylation site. Physiologically, kidneys from DKO mice displayed between 40-50% increase in cell proliferation.

Conclusions: Results from this study indicate that ablation of *Hoxb3os* in mouse ADPKD dysregulated mTORC2 and exacerbated cystogenesis.

Aberrant Renal Microvascular Remodelling and Impaired Blood Perfusion Occur in the Early Stages of Autosomal Dominant Polycystic Kidney Disease

Daniyal J. Jafree,[1] Charith Perera,[1] Gideon Pomeranz,[1] Laura Wilson,[1] William J. Mason,[1] Maria K. Joannou,[1] Yoshiharu Muto,[2] Benjamin D. Humphreys,[2] Mark Lythgoe,[1] Simon Walker-Samuel,[1] David A. Long.[1]
[1]University College London, London, United Kingdom; [2]Washington University in St Louis School of Medicine, St Louis, MO.

Background: The renal microvasculature is altered in autosomal dominant polycystic kidney disease (ADPKD); assumed to be a secondary consequence of expanding fluid-filled cysts. However, the vascular phenotype may be an important contributor from the initiation of PKD. Therefore, we assessed the molecular profile, structure, and function of the renal microvasculature in the early stages of ADPKD.

Methods: We amassed single nucleus RNA-seq (snRNA-seq) data of microvasculature from human ADPKD explants, validating findings using 3D confocal microscopy. A time-course of murine PKD carrying an orthologous mutation (p.R3269C) in *Pkd1* (*Pkd1*$^{RC/RC}$) was generated by assessing kidney:body weight ratio and blood urea nitrogen. Arterial spin labelling (ASL) and 3D confocal microscopy were leveraged to examine renal blood flow and microvascular structure at early (3 months) and late (9 months) timepoints in the *Pkd1*$^{RC/RC}$ murine model.

Results: A population of osteopontin (SPP1)$^{+}$ vessels was identified in pericystic regions of human ADPKD, but not in human kidney disease of other etiologies. Endothelial SPP1 was upregulated in mice at 3 months of age; long before kidney function declined in the mouse model. This was associated with reduction in renal blood flow in non-cystic regions of cortex of *Pkd1*$^{RC/RC}$ mice compared to controls at both 3 months (p = 0.005) and 9 months (p = 0.004) of age. In 3-month-old *Pkd1*$^{RC/RC}$ mice, abnormal microvascular patterning was found, including decrease in mean vessel length (p = 0.04) and increased vascular density (p = 0.01).

Conclusions: Multiple modalities applied to mouse and human tissues suggest that microvascular molecular profile, structure and function are altered in ADPKD prior to irreversible loss of renal function. Our findings advocate the renal microvasculature in ADPKD as a therapeutic target, with the potential to modulate or preserve organ function from early stages of the disease.

Live Imaging Coupled with Image-Based Machine Learning Uncovers Potential Drivers and Therapeutic Targets in a Human Model of Ischaemic Reperfusion Injury

Carmen M. Cusack, Harry Horsley, Alan D. Salama, Enriko Klootwijk.
University College London, London, United Kingdom.

Background: During renal transplantation, kidneys are subjected to periods of hypoxia accompanied with nutrient deprivation, followed by reperfusion, stimulating the infiltration of immune cells into the kidney. There is growing interest in novel preservation methods to improve graft outcomes.

Methods: Primary proximal tubular epithelial cells (PTCs) were exposed to hypoxia (1% O_2) for 72 hours in Hanks Balanced Salt Solution (HBSS) to mimic nutrient deprivation, with or without foetal bovine serum (FBS). PTCs were re-oxygenated (21% O_2) in complete Dulbecco's Modified Eagle Medium (DMEM). PTCs were imaged live using deconvolution laser-scanning confocal microscopy. A supervised machine learning (ML) random forest pixel classifier was trained to extract cellular morphometrics and injury data.

Results: Nutrient deprivation was associated with greater cell death and injury independent of hypoxia and is partially ameliorated by FBS supplementation (P≤.001). Furthermore, distinct cellular morphological differences were observed between conditions, indicating specific patterns of cellular injury and death.

Conclusions: Nutrient Deprivation is associated with the greatest degree of renal tubular injury, regardless of oxygen concentration. FBS may help to reduce tubular injury in transplanted organs. Further work is required to define the protective properties exhibited by FBS. Live imaging and ML are promising modalities for exploring cell death and potential therapeutics in ischemic reperfusion injury.

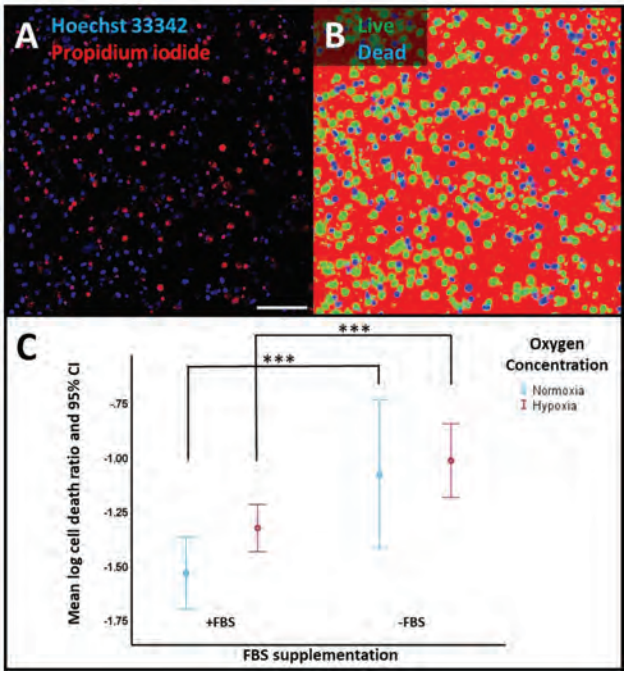

Figure 1: A) Nutrient deprived PTCs exposed to normoxia with no FBS (72h) and reoxygenated with complete DMEM (24h) B) ML mask generated from (A), C) Cell death ratios of PTCs +/- FBS generated from ML pipeline.

PPARα, as a Key Determinant of Kidney Size, Revealed by Multi-Omics

Hiroaki Kikuchi,[1,2] Mark A. Knepper.[1] *[1]National Institutes of Health, Bethesda, MD; [2]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: Mechanisms involved in compensatory hypertrophy of the kidney remain incompletely understood. New '-omic' methodologies have been recently introduced that have the potential of identifying complex mechanisms. Here we seek to identify the earliest signaling changes in the contralateral kidney after unilateral nephrectomy (UNx) in mice using next-generation sequencing and proteomics techniques combined with lipid analysis.

Methods: Experiments were done in mice undergoing UNx and sham nephrectomy. At specific time points (24 hours and 72 hours) after surgery, the earliest portion of the kidney proximal tubule (PT-S1) was manually micro-dissected and utilized for transcriptomic analysis by single-tubule small sample RNA-Seq and single-tubule ATAC seq. Furthermore, quantitative proteomic analysis and lipid anlaysis were carried out using whole kidney.

Results: Kidney volume was already increased 24 hours after UNx, reaching a plateau at 72 hours. Quantitative morphometry in microdissected proximal tubules showed significant increases in outer diameter and mean cell volume, but no clear increase in the cell count per unit length. Measurements of DNA accessibility (ATAC-seq), transcriptome (RNA-seq) and proteome (quantitative protein mass spectrometry) independently identify patterns of change that are indicative of activation of the lipid-regulated transcription factor, PPARα. Among genes/proteins included as "Lipid Transport", Cd36, Fabp5, Atp8a1, Atp11c, Gm2a, Gramd1b, Npc2, Apoa2, Apoa4, Atg9a, Cert1, Osbpl9, Slc10a2 and Tex2 were identified as changed in our data integration analysis. Lipid analysis using gas chromatography shows an increased abundance of PPARα ligands in the hypertrophied kidney. Activation of PPARα by fenofibrate administration increases proximal tubule cell size, while genetic deletion of PPARα decreases it.

Conclusions: Compensatory growth of the kidney is associated with increased proximal tubule cell size, but not cell number. PPARα is an important determinant of proximal tubule cell size and is a likely mediator of compensatory proximal tubule hypertrophy. Early stages of compensatory hypertrophy are associated with altered fatty acid and cholesterol metabolism including anabolic pathways required for synthesis of new membranes needed for cell growth.

Spatiotemporal Immune Atlases of Two Gene-Edited, Pig-to-Human Kidney Xenotransplants

Matthew D. Cheung, Rebecca Asiimwe, James F. George, Jayme E. Locke, Paige M. Porrett. *The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL.*

Background: Xenotransplantation is a promising solution for the organ shortage, but enthusiasm to proceed to clinical trials is tempered by persistent knowledge gaps about the human immune response to porcine kidney xenografts and how best to control it. Preliminary data from our group and others have suggested a role for complement immune-mediated injury of the xenograft. We used state-of-the-art single-cell technologies to characterize the human immune response to porcine kidney xenografts in two brain-dead human recipients, one of whom received the C5a inhibitor eculizumab.

Methods: Kidneys from 10-gene modified pigs were transplanted into two nephrectomized brain-dead human recipients in the setting of standard immunosuppression (induction: anti-thymocyte globulin and rituximab; maintenance: tacrolimus, mycophenolate mofetil, prednisone). Decedent 2 also received eculizumab. Xenograft core biopsies were taken pre- and post-transplant (days 1, 2, and at termination on day 3) and assessed by spatial transcriptomics. Porcine and human CD45+ cells were sorted from the explanted xenograft and analyzed using single-cell RNA seq. Data were aligned to a custom porcine-human reference genome to distinguish porcine and human transcripts and analyzed using Seurat and cell2location.

Results: Human immune cells were uncommon in the xenograft biopsies; few human neutrophils and macrophages were detected 3 days after transplant. Human neutrophils were reduced by 7-fold in decedent 2. Myeloid cells were the predominant lineage in the porcine and human compartments, and both human and porcine macrophages expressed an anti-inflammatory gene signature. Notably, human B and T cells were absent in the xenograft cortex at all time points assessed in both decedents.

Conclusions: Limited human immune cells infiltrate the porcine kidney early after xenotransplantation. Eculizumab administration was associated with a decrease in neutrophils in the xenograft. These data suggest that the addition of a complement inhibitor to conventional immunosuppression may limit further innate immune cell graft infiltration in a preclinical human model of xenotransplantation. These data may help inform the immunosuppression design for upcoming clinical trials.

Subpopulations of Injured Proximal Tubular Cells in Allograft Kidneys: Computational Analysis of Available scRNAseq Datasets

Sylvina da Silva Fernandes,[1,2] Peter Boor,[2] Benjamin A. Vervaet.[2,1] Laboratory of Pathophysiology and Laboratory of Nephropathology. *[1]Universiteit Antwerpen, Antwerpen, Belgium; [2]Universitatsklinikum Aachen, Aachen, Germany.*

Background: Single-cell RNAseq has been used to investigate the cellular phenotypical landscape of allograft kidneys undergoing ischemia/reperfusion injury. Rather less attention has been paid to the proximal tubular cell (PTC) population. Here, we re-analyzed human single-cell (sc)RNAseq datasets of histologically normal and injured allograft kidneys to characterize PTC phenotypes.

Methods: We analyzed five publicly available human scRNAseq datasets, including data on histologically normal appearing kidney allografts (two datasets) and allografts with acute tubular injury (three datasets). Using R software (Seurat, DESeq2, clusterProfiler), we identified "injured" and "healthy" PTC populations, and determined their differentially expressed genes (DEGs) and enriched pathways. We compared the DEGs and pathways of "injured PTC populations" from histologically normal allografts with those of adverse allografts.

Results: In all datasets, we identified at least one healthy and one injured PTC population. The injured PTCs were characterized by the expression of established PTC injury markers (CDH6, SPP1, IL32). Most of the commonly dysregulated pathways in the injured PTCs were related to energy metabolism: fatty acid/amino acid metabolism, oxidative phosphorylation, glycolysis/gluconeogenesis. The injured PTCs in one of the two histologically normal allograft datasets presented markers of failed repair (upregulated DCDC, downregulated SLC5A12/SLC7A13). These PTCs also showed enrichment of Wnt- and Hippo-signaling pathways, previously identified in a mouse model of AKI-to-CKD progression. Although the average relative proportion of injured PTCs was lower in the histologically normal allografts (4,6% +/- 4,6%) compared to the injured allografts (15,1% +/- 9,9%), inherent inter-dataset heterogeneity did not reveal statistical significance.

Conclusions: We identified and characterized common PTC subpopulations across five allograft scRNAseq datasets. We found that histologically normal appearing allograft kidneys contain an injured PTC population, which is shared with allografts with acute tubular injury.

TH-OR75

Cold Storage-Mediated p38MAPK Activation: A Potential Contributor of Proteasome Dysfunction and Kidney Damage After Transplantation

Dinesh Bhattarai, Seongok Lee, Nirmala Parajuli. *University of Arkansas for Medical Sciences, Little Rock, AR.*

Background: The majority of donor kidneys require cold storage (CS) prior to transplantation, but this process usually leads to suboptimal outcomes, due to CS activating cellular pathways that damage kidney tissue. Previously, we demonstrated that the CS followed by transplantation decreases proteasome function in rat renal grafts; however, the mechanism of this dysfunction is not known.

Methods: Established in vivo (CS+Tx) and in vitro (CS+RW) models of rat kidney cold storage followed by transplantation. The proteasome function was performed using rat kidney homogenates and fluorescent-based peptide substrates. The subunit level of the proteasome subunit was characterized using renal extracts and western blotting.

Results: Western blots showed an unprecedented higher-molecular-weight band of Rpt6 subunit of the proteasome after CS+Tx, suggesting a post-translational modification (PTM) of the Rpt6 subunit. Non-denatured western blots for Rpt6 revealed aggregated proteasome levels after CS+Tx. Phosphatase treatment of renal extracts depleted the higher-molecular-weight band of the Rpt6 subunit in the CS+Tx, suggesting that the aggregation of Rpt6 was associated with phosphorylation. Renal (NRK) cells exposed to CS+RW showed a time-dependent increase p38MAPK activation. Treatment of NRK cells with p38MAPK inhibitor (SB202190 or VX-745) during CS followed by rewarming increased the cell viability and proteasome activity when compared to the CS+RW condition, suggesting p38 MAPK negatively regulates tubular cell viability during CS+Tx/RW. Finally, ex vivo treatment of the donor kidney with Bortezomib prior to transplantation (no CS) increased renal dysfunction after transplantation, suggesting normal proteasome function is needed to prevent renal injury in the transplants.

Conclusions: Together, our results suggest that CS-mediated activation of the p38MAPK may contribute to Rpt6 phosphorylation/aggregation, which then leads to decreased proteasome function and renal injury following CS+Tx. Therefore, p38MAPK could be a novel therapeutic target during CS to reduce CS+Tx-mediated graft failure.

TH-OR76

Mechanism of Cold Storage-Mediated Regulation of Heat Shock Proteins in Renal Grafts After Transplantation

Seongok Lee, Nirmala Parajuli. *University of Arkansas for Medical Sciences College of Medicine, Little Rock, AR.*

Background: Ischemia-reperfusion injury associated with cold storage (CS) followed by transplantation contributes to impaired protein homeostasis leading to kidney graft injury. However, the mechanisms of impaired protein homeostasis remain elusive.

Methods: Isolated donor rat kidneys were stored in University of Wisconsin (UW) solution at 4°C for 0- or 18-hr followed by transplantation to recipient rats (CS+Tx). To simulate in vitro model of CS+Tx, rat or human proximal tubular cells (PTCs) were exposed to UW solution at 4°C followed by rewarming (RW) at 37°C (CS+RW). RNA interference, overexpression studies, and western blotting were the key assays.

Results: Using *in vivo* and *in vitro* models of transplantation, we found that the two members of 70-KDa heat shock proteins (HSPs) were dysregulated—a robust increase of Hsp72 and a decrease of Hsc70—in kidney grafts after CS+Tx. HSF1 is a stress-activated transcription factor that induces HSPs during stress. Our data show that the HSF1 was significantly increased and modified during CS in both *in vitro* and *in vivo* transplant models, but decreases after reperfusion/rewarming episodes in kidney/renal cells. To investigate the mechanisms of excessive induction of Hsp72 after CS+Tx, the protein level of Hsc70 and/or HSF1 was modulated in PTCs, followed by CS+RW. Interestingly, Hsc70 knockdown in PTCs increased Hsp72 protein but decreased HSF1 protein. Whereas HSF1 depletion increased Hsc70 protein and did not change the Hsp72 protein level in PTCs, the double knockdown of HSF1 and Hsc70 significantly increased the Hsp72 protein levels. Finally, the HSF1 knockdown in PTCs followed by CS+RW decreased Hsc70 levels but increased the Hsp72 protein.

Conclusions: These data show a reciprocal relationship between Hsc70 and Hsp72 in PTCs and that the Hsc70 negatively regulates Hsp72 protein levels. Our data also indicated that the excessive increase of Hsp72 is not regulated by the classical HSF1 pathway, and the elevated Hsp72 protein negatively regulates kidney function after CS+Tx. Together, the results suggest Hsp72 as a potential therapeutic target during CS to improve outcomes after kidney transplantation.

TH-OR77

Evaluation of Porcine Cell Chimerism and Viral Transmission Using a Preclinical Human Brain-Dead Decedent Model

Matthew D. Cheung, Christopher Fucile, Rebecca Asiimwe, James F. George, Jayme E. Locke, Paige M. Porrett. *The University of Alabama at Birmingham Heersink School of Medicine, Birmingham, AL.*

Background: Xenotransplantation is a potential solution to the organ shortage crisis, but questions around the potential for zoonotic disease transmission need to be addressed before clinical trials can be safely undertaken. Because zoonotic transmission cannot be assessed in vitro or in preclinical animal models, we used a preclinical brain-dead

human decedent model to evaluate porcine cell chimerism in human tissues as well as the transmission of porcine endogenous retroviruses (PERVs) and porcine cytomegalovirus (PCMV) after porcine kidney xenotransplantation.

Methods: Kidneys were procured from a 10-gene modified pig, transplanted into two nephrectomized brain-dead human decedents, and followed for 3 days. Single-cell RNA seq (scRNAseq) was performed on peripheral blood mononuclear cells (PBMCs) sorted from the xenograft recipients before and after transplantation on post-operative (POD) days 1, 2, and 3. Single-nucleus RNA seq (snRNAseq) was performed on kidney biopsies collected pre-transplant and on POD 1 and 3, as well as distant tissues such as heart, lung, liver, spleen, lymph node, small bowel, and omentum upon termination of the experiment. Sequencing data were aligned to a novel PERV-PCMV-porcine-human merged reference genome to differentiate porcine and human cell types and assess for viral transcript expression. Data were analyzed using the package Seurat 4.0.

Results: ScRNAseq analysis of over 500,000 PBMCs revealed a small number of porcine cells (0.04% and 0.008%) in decedent 1 and 2, respectively, while there was no detection of porcine cells in any of the 150,000 sequenced cells from human organs. PERV-A and PERV-B (expression level range: 0.5-4) transcripts were detected in a small number of porcine kidney cells (0.79%) and within the porcine cells detectable in the human PBMCs; however, there was no detection of PERV-C. There was no detection of PERV in any of the human organs. No PCMV was detectable in any porcine or human compartment.

Conclusions: Sc- and snRNAseq can detect viral transcript expression and cell chimerism from mixed porcine-human samples. There was no detectable PERV or PCMV transmission early after xenotransplantation, but limited by the short duration of the study. Additional studies will be needed to address long-term safety profiles after xenotransplantation.

TH-OR78

The Alteration of Monocyte Subsets and the Early Acute Rejection After Kidney Transplantation

Jeongin Song, Jeongmin Cho, Yong Chul Kim, Hajeong Lee. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Despite the use of recent immunosuppressive agents that mainly modulate adaptive immunity, early acute rejection (EAR) remains an unresolved problem in kidney transplantation (KT). Innate immune cells including monocyte/macrophage-lineage cells may contribute to the EAR occurrence, so we explored the population and phenotypic changes of circulating monocytes in KT recipients.

Methods: Pre- and post-KT peripheral blood mononuclear cells (PBMCs) from 60 KT recipients and 20 live donor samples were collected and analyzed by flow cytometry. Monocytes were classified into three types: classical ($CD14^{++}CD16^{-}$), intermediate ($CD14^{++}CD16^{+}$), and non-classical ($CD14^{+}CD16^{++}$) monocytes. Post-KT samples were collected at the same time as the protocol biopsy within post-operative days 14. The outcome was biopsy-proven acute rejection (BPAR) events excluding borderline T-cell mediated rejection.

Results: A total of 60 study population, BPAR was diagnosed in 10 of the KT recipients, and 7 of them received living donor KT. In recipients without EAR, the proportions of classical monocytes among $CD45^{+}$ cells were significantly increased (Fig. 1A, 8.90±5.40% vs 14.60±7.97%, p<0.001) after KT, and the proportions of non-classical monocytes were distinctly decreased(Fig. 1C, 1.45±1.70% vs 0.40±0.47%, p<0.001) after KT. In contrast, in BPAR patients, there were no significant differences in the proportions of all monocyte subsets after KT. Interestingly, the proportion of non-classical monocytes was the lowest in BPAR patients than KT recipients without rejection or kidney donors in both the pre-and post-KT periods(Fig. 1F. 0.72±0.42% vs 1.45±1.67% and 1.09±0.56% at pre-KT (p=0.150 and 0.652), 0.72±0.42% vs 0.37±0.37% and 1.09±0.56% at post-KT (p=0.035 and 0.204)).

Conclusions: Our findings suggest that changes in monocyte subsets before and after KT are associated with EAR occurrence in KT recipients. Non-classical monocytes, in particular, may play an important role in the development of EAR.

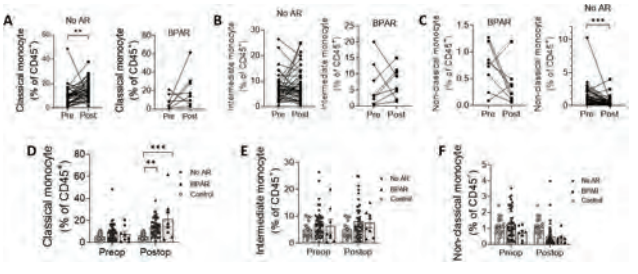

Figure 1. Changes in each monocyte subset before and after KT. (No AR; No acute rejection, BPAR; biopsy-proven acute rejection)

MIF-CD74: A Novel Inflammatory Pathway that Suppresses Allograft-Infiltrating Tregs During Rejection

Nour K. Younis,[1] Zhabiz Solhjou,[2] Hengcheng Zhang,[1] Abdullah B. El Kurdi,[3] Ahmad Halawi,[1] Richard Bucala,[4] Dongliang Zhang,[1] Jamil R. Azzi.[1] *[1]Brigham and Women's Hospital, Boston, MA; [2]Scripps Green Hospital, La Jolla, CA; [3]American University of Beirut, Beirut, Lebanon; [4]Yale School of Medicine, New Haven, CT.*

Background: We previously showed that CD74, a key receptor of MIF, a pro-inflammatory cytokine, is upregulated in the urinary exosomal mRNAs of kidney transplant recipients during rejection. We investigated this pathway in allo-immunity and discovered a previously unknown critical role in suppressing immune regulation.

Methods: CD74KO (KO), and CD74fl/fl-Foxp3-GFP-Cre C57BL/6J mice were generated using CRISPR-Cas9 technology and used as recipients for fully mismatched BALB/c heart transplants. We performed single-cell and bulk RNA sequencing, CHIP-seq, immunophenotyping using flow cytometry, and various ex-vivo studies to assess the impact of the MIF-CD74 pathway on Tregs Homeostasis.

Results: CD74KO recipients of fully mismatched heart allograft displayed indefinite allograft survival with a 3-fold increase in allograft-infiltrating Tregs, compared to WT. While naïve Tregs and Tregs in the spleen of WT recipients did not express CD74, Tregs infiltrating the heart allograft and dLN and Tregs stimulated in vitro upregulated CD74 up to 5-fold. Furthermore, conditional deletion of CD74 in Tregs doubled allograft survival while resulting in a 2-fold increase in allograft-infiltrating Tregs. Moreover, compared to WT, KO Tregs displayed enhanced proliferative capacity, increased FoxP3 stability, and improved suppressive function in vitro and in vivo. Furthermore, MIF was predominantly produced by CD4 and CD8 effector cells upon antigen stimulation in vitro and in vivo. Congruently, our single-cell genomic analysis performed on allograft-infiltrating T cells endorsed the superior suppressive phenotype of CD74 deficient Tregs. While allograft-infiltrating WT Tregs had an interferon-responsive phenotype, KO Tregs had a KLRG1+Areg+ phenotype with higher Helios and PD1 expression. Our TCR clonal analysis also suggested that allograft-infiltrating KO Tregs are more antigen-specific. Furthermore, our genomic analysis revealed that Interferon Regulatory Factor 1 (IRF1), a transcriptional repressor of FoxP3, is downregulated in allograft-infiltrating KO Tregs. In vitro, MIF activates IRF1 in WT but not KO Tregs.

Conclusions: MIF produced by effector T cells in response to alloantigens negatively affects Tregs function and homeostasis via CD74 signaling. The MIF-CD74 pathway exerts this effect through IRF1.

CER-001, a Recombinant HDL, Modulates Ischemia/Reperfusion Injury (IRI) in Hypothermic (HMP) and Normothermic Perfusion (NMP) Solutions Through pAKT/eNOS Activation

Rossana Franzin, Alessandra Stasi, Marco Fiorentino, Irene Scalera, Monica Campioni, Maria Teresa Cimmarusti, Giuseppe Castellano, Fabio Sallustio, Paola Pontrelli, Simona Simone, Loreto Gesualdo. *Universita degli Studi di Bari Aldo Moro, Bari, Italy.*

Background: The growing use of expanded criteria donor leads to urgent need for efficient organ reconditioning strategies. CER-001 (Abionyx), a HDL lipoprotein particle, has shown clinical anti-inflammatory and protective vascular efficacy. This study aims to evaluate to role of CER-001 supplementation in perfusion solution to modulate IRI.

Methods: In an experimental model of donation in cardiac death (DCD), after 60 minutes of warm ischemia, pig kidneys were subjected to standard cold storage(12h). Oxygenated hypothermic and normothermic renal perfusion were carried out by PerKidney system(Aferetica) for 4h. Perfused organs were divided into the CTRL and CER-001 groups (CER-001 0.4 mg/ml) and compared to organs stored on ice (SCS). Endothelial cells exposed to H_2O_2, C5a and CER-001 (50-100 ug/ml) were analyzed by cell proliferation assay, qPCR, Western blot and FACS.

Results: During HMP and NMP treatments, resistances (mmHg/ml/min TEND CER-001 0.404 vs CTRL 0.766, change from T0, p=0.24) and flows significantly improved in CER-001 perfused group. ELISA data on perfusates showed a reduction in MCP-1, TNFα (CER-001 vs CTRL, p<0.05). In the SCS group, the tubules appeared dilated, interstitium with infiltrate, the floccule detached from the Bowman capsule. The use of CER-001 induced a reduction in the gene expression of *IL-6* and *Endothelin-1* in the CER-001 vs CTRL group. Urinary proteinuria measured during NMP was significantly decreased in CER-001 group. WB analysis revealed that CER-001 promoted the SR-BI-pAkt-eNOS pathway, the signaling pathway that through the phosphorylation of eNOS Serine 1177 lead to release of protective nitric oxide (NO). In vitro, CER-001 prevents apoptosis, endothelial dysfunction as observed by MTT and CD31/eNOS expression and reduced the levels of marker of endothelial activation (ICAM and VCAM).

Conclusions: The use of CER-001 in the perfusion liquid counteracted vasocostriction and inflammation and improved renal resistance during kidney perfusion, thereby increasing pool of organ for transplant.

Chemogenetic Activation of Pericytes Alters Systemic and Renal Hemodynamics

Jonathan W. Nelson, Matthew W. Hagen, Susan B. Gurley. *Oregon Health & Science University, Portland, OR.*

Background: Pericytes are specialized cells that wrap around capillaries to provide structural and metabolic support. Pericytes have also been shown to respond to vasoactive compounds, such as angiotensin II, to constrict capillaries. However, the full functional consequence of pericyte activation on systemic and renal hemodynamics are poorly understood. To determine whether pericytes regulate systemic or renal hemodynamics we coupled a pericyte expressing cre line (Pdgfrb-creERT2) with the Gq-DREADD (Designer Receptor Exclusively Activated by Designer Drug) mouse to create Peri-DREADD mice which have pericyte-specific activation in the presence of a DREADD agonist.

Methods: Chemogenetic activation of pericytes was induced with intraperitoneal injection of the DREADD-specific agonist deschloroclozapine (DCZ) in Peri-DREADD mice and control littermates. Activation of pericytes was determined by measurement of cFos accumulation in pericyte nuclei by immunohistochemistry. Acute blood pressures were measured with a Millar catheter. Cortical and medullary perfusion was measured by contrast enhanced ultrasound. Sodium excretion was measured from urine collected in metabolic cages followed by electrolyte quantification with flame photometry.

Results: We find that Peri-DREADD mice express DREADD protein within pericytes which accumulate nuclear cFos after activation with DCZ. DCZ treatment of peri-DREADD mice acutely increases arterial pressure and decreases medullary and cortical perfusion. Sodium excretion increases following pericyte activation by DCZ.

Conclusions: Pericytes are capable of altering hemodynamics, particularly within the kidney where we observed decreases in cortical and medullary perfusion after chemogenetic activation concurrent with an increased natriuresis that correlates with an increase in systemic blood pressure.

Piezo1 Participates the Mechanosensation of Juxtaglomerular Cells and Regulates Renin Production In Vitro and In Vivo

Yiming Zhou, Xiaoqiang Yang, Le Wang, Siweier Luo. *Medical Research Center, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China.*

Background: Renin is a key rate-limiting enzyme in RAS system, which is closely related to water and salt metabolism and the development of cardiovascular diseases such as hypertension. The synthesis and secretion of renin in juxtaglomerular (JG) cells are closely regulated by the blood pressure. To date, however, the molecular identity through which JG cells respond to the blood pressure remains unclear. Recent studies identified the nonselective cation channels Piezo1 as a novel mechanosensitive ion channel which plays an important role in various physiological functions. However, whether Piezo1 channels regulates renin expression remains undetermined.

Methods: In this study, we determined the expression and subcellular localization of Piezo1 in JG cells by qPCR, Western blot, Immunohistochemistry. Then, a Fluo-4 AM-based calcium-imaging system was used to detect the dynamic changes of intracellular calcium in response to Piezo1 specific agonist Yoda1 and mechanical stress (MS)-induced by perfusion. Piezo1 knockout JG cells abolished Yoda1-induced effect. Then, we used RNA-seq experiment to investigate the downstream signaling of Piezo1 in JG cells. Finally, we generated adeno-associated virus (AAV)-mediated kidney-specific Piezo1 knockdown mice to investigate the in vivo effect of Piezo1.

Results: We found that the calcium permeable ion channel Piezo1 was expressed in JG cells in mouse kidney slides as well as mouse JG cells. Activation of Piezo1 by its agonist Yoda1 and MS induced an intracellular calcium increase and reduced the expression of renin in these cells, while knockout of Piezo1 in JG cells abolished the effect of Yoda1. Mechanistically, RNAseq assay demonstrated that activation of Piezo1 upregulated the PTGS2 expression via the calcineurin-NFAT pathway and increased the production of PTGS2 (COX-2) and PGE2 in JG cells, which inhibited cAMP production and reduced renin expression in JG cells. In animal models, we demonstrated that activation of Piezo1 significantly downregulated the blood pressure in wildtype but not kidney-specific Piezo1 knockdown mice.

Conclusions: In summary, these results revealed that activation of Piezo1 could regulate the renin expression *in vitro* and *in vivo*, subsequently reduction of blood pressure, highlighting its therapeutic potential as a drug target of the renin-angiotensin system.

TH-OR83

Cellular-Level Transcriptomics and Three-Dimensional Imaging for Recruited Renin Cells

Hiroki Yamaguchi,[1] Manako Yamaguchi,[1] Hirofumi Watanabe,[2] Silvia Medrano,[1] Maria Luisa S. Sequeira Lopez,[1] Roberto Ariel Gomez.[1] *[1]University of Virginia School of Medicine, Charlottesville, VA; [2]Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan.*

Background: Renin synthesis is tightly regulated by the ability of juxtaglomerular cells (JG) to sense arterial pressure signals. Once severe hypotension occurs in adult animals, JGs promote renin synthesis first. Subsequently, a subset of vascular smooth muscle cells (VSMC) derived from renin progenitors turn on renin expression to restore homeostasis: this phenomenon is termed recruitment. However, identifying the mechanisms of the recruitment of renin lineage cells has been challenging due to their rarity and structural complexity. In this study, we investigated the transcriptome profiles and expression patterns of individual recruited renin cells by single-cell RNA-seq and three-dimensional (3D) imaging.

Methods: Since forkhead box protein D1 (FoxD1) expressing stromal cells are the progenitors for JGs and VSMCs of the renal arteriole, we generated *FoxD1-GC; R26R*^{TdTomato} mice, where all *FoxD1*$^{+}$ descendants express tdTomato reporter. We applied a surgical model of aortic coarctation (AoCo) between the base at the renal arteries of the left kidney (LK) and right kidneys (RK) that received low and high perfusion pressure, respectively. We FACS sorted tdTomato^{+} cells from the LK and RK cortices and performed single-cell RNA-seq to analyze the differentially expressed genes (DEG) and the gene ontologies between LK and RK. To visualize renin-expressing cells in 3D, we applied the clear, unobstructed brain/body imaging cocktails (CUBIC) protocol for clearing kidneys of the *Ren1*^{c}*-tdTomato* mice that underwent AoCo surgery. We used Zeiss Lightsheet7 for 3D imaging.

Results: By single-cell RNA-seq, FoxD1^{+} cells were clustered into JG, VSMC, and other cell types. DEG analysis in LK compared to RK showed that *Ren1* was the upregulated DEG in JG and VSMC. In VSMC, gene ontology analysis showed the upregulation of the cellular response to laminar fluid shear stress pathway in LK, suggesting that extracellular force changes affect the gene expression. By CUBIC protocol, renin-expressing cells in the *Ren1*^{c}*-tdTomato* mouse kidneys could be visualized in 3D. In LK, we could identify recruited VSMCs forming a stripped and ring pattern along with afferent arterioles, some extending close to or beyond the bifurcation point.

Conclusions: Severe hypotension causes the widespread recruitment of renin lineage VSMCs in the renal arteriole.

Identification and Characterization of a Vascular Calcification Mediator Originating in the Adrenal Glands

Shruti Bhargava,[1] Zhuojun Wu,[1] Vera Jankowski,[1] Joachim Jankowski.[1,2] *[1]Universitatsklinikum Aachen, Aachen, Germany; [2]Experimental Vascular Pathology, Cardiovascular Research Institute Maastricht (CARIM), University of Maastricht, Maastricht, Netherlands.*

Background: Patients undergoing dialysis for chronic kidney disease (CKD) often suffer from vascular calcification, leading to diverse cardiovascular complications. In this study, we conducted a comprehensive investigation to identify and characterize a newly discovered endogenous peptide that plays a regulatory role in vascular calcification processes. Our findings shed light on an unexplored cardioprotective function of the adrenal glands in the context of CKD-associated vascular calcification.

Methods: Chromatographic fractions derived from bovine adrenal glands were tested for their effect on vascular calcification processes using in vitro, ex vivo, and in vivo rat model of elastocalcinosis. To identify potential mediators, mass spectrometric analysis was conducted, and the results were compared with relevant databases.

Results: A 19-aa peptide was discovered and its levels were quantified in the serum of end-stage renal disease patients undergoing dialysis, as well as in matched controls. This newly identified peptide, named Calcification Blocking Factor(CBF), demonstrated significant protective effects against vascular calcification. Treatment with CBF effectively reduced the calcium content in cells, thoracic aortic rings cultured under calcifying conditions, and aortas from elastocalcinosis animal models. CBF exerts its protective effects by inhibiting the transdifferentiation of aortic smooth muscle cells into osteoblast-like cells, which are responsible for driving the progression of vascular calcification. CBF interacts with the sodium-dependent phosphate transporter PIT-1, and hinders NF-κB activation and the BMP2/p-SMAD pathway, all implicated in vascular calcification. CBF treatment reduced arterial stiffness in elastocalcinosis animals. CKD patients, susceptible to vascular calcification, showed decreased CBF concentration in serum. The 19-amino acid peptide is derived from the enzymatic cleavage of the adrenal protein chromograninA by calpain1 and kallikrein. Further analysis revealed that a specific 6-8 amino acid sequence within the 19-amino acid peptide serves as the active site responsible for the calcification-blocking properties of CBF.

Conclusions: Our findings suggest that CBF, a novel inhibitor of vascular calcification derived from the adrenal glands, plays a crucial role in reducing the risk of vascular calcification.

Mechanisms of Vascular Pathology Following Peritonitis in Peritoneal Dialysis Patients and Therapeutic Intervention

Esra Cetin,[1] Morgane Mazzarino,[1] Guadalupe T. Gonzalez- Mateo,[2] Valeria Kopytina,[2] Maria Bartosova,[3] Iva Marinovic,[3] Soma Meran,[1] Donald Fraser,[1] Claus Peter Schmitt,[3] Manuel Lopez-Cabrera,[2] Mario O. Labeta,[1] Anne-Catherine Raby.[1] *[1]Cardiff University, Cardiff, United Kingdom; [2]Universidad Autonoma de Madrid Centro de Biologia Molecular Severo Ochoa, Madrid, Spain; [3]UniversitatsKlinikum Heidelberg, Heidelberg, Germany.*

Background: In PD patients, CV death is 10 times more likely than in the general population and this risk further increases following each peritonitis episode. Damage-Associated Molecular Patterns (DAMPs) play a critical role in inflammatory pathologies, notably via their activation of Toll-like receptors (TLRs), but their specific role in mediating long-term vascular pathology following an infection remains undescribed.

Methods: We investigated a potential role for DAMPs in mediating long-term CV risk following peritonitis by i) characterising the long-term vascular inflammatory changes induced by peritonitis in mice, ii) identifying potential target DAMPs following peritonitis by analysis of *in vivo* and PD patients' plasma samples, iii) mechanistically characterising the potential of our selected DAMP to promote key vascular inflammatory responses by critical cell types *in vitro*, iv) demonstrating, by pharmacologic inhibition, the critical contribution of a DAMP candidate to the maintenance of vascular pro-atherogenic responses following peritonitis in mice.

Results: Bacterial peritonitis in mice was resolved in 24h but led to vascular inflammatory responses, expected to promote CVD, that were maintained up to 28 days. These included higher proportions of inflammatory leukocytes, increased cytokine levels, higher adhesion molecules, and increased blood and aortic inflammatory and atherosclerosis-associated gene expression. These findings were maintained in nephropathic animals and exacerbated in animals routinely exposed to PD fluids. In parallel to these changes, a peritonitis episode led to elevated plasma levels of a specific TLR DAMP, Calprotectin, both in animals and PD patients. *In vitro*, Calprotectin could promote typical vascular inflammatory and pro-atherosclerotic responses: monocyte chemotaxis, foam cell formation, via a reduction of cholesterol efflux by macrophages and loss of endothelial resistance. *In vivo,* Calprotectin blockade robustly inhibited the short and long-term vascular inflammatory consequences of peritonitis.

Conclusions: This study demonstrates the major role that the Calprotectin-TLR pathway plays in driving long-term vascular pathology following a peritonitis episode.

Single-Cell Pathological Landscape Analysis of Vascular Calcification in CKD by Imaging Mass Cytometry

Yuyao Wang, Anying Cheng, Qing Li, Yongman Lv, Fan He. *Tongji Hospital of Tongji Medical College of Huazhong University of Science and Technology, Wuhan, China.*

Background: Vascular calcification (VC) is regarded as an important pathological change which associated with high mortality in patient with chronic kidney disease (CKD). It is necessary to study changes of cell communication and their PTMs in situ.

Methods: A highly multiplexed imaging mass cytometry (IMC) panel was designed to simultaneously quantify 34 biomarkers of tissues from 38 patients with CKD and 2 donors to generate 64 highly multiplexed images at single-cell resolution. All cells were divided into different cell types according to the expression of markers. Neighboring cells were defined as the top 15th nearest cells to a cell. K-means clustering algorithm was then applied to cluster cell neighborhoods into numerous community clusters (CCs). Relevant to the stage of vascular calcification by Von Kossa staining was identified as a specific target for preventing vascular calcification.

Results: 8 cell types and 16 community clusters were defined. We found that contractile VSMCs and progenitor cells decrease with progression of vascular calcification. The osteochondrogenic VSMCs showed a trend of decreasing first and then increasing, which may be caused by the proliferation of synthetic VSMCs in the early stage of calcification. At the same time, community clusters changed with progression of vascular calcification. Contractile VSMCs and osteochondrogenic VSMCs mixed community clusters decreased with the progression of vascular calcification. On the contrary, osteochondrogenic VSMCs dominant community clusters osteochondrogenic VSMCs elevated in severely calcified vessels. In addition, expression of H3K27me3 of community cluster 10 that mainly composed of osteochondrogenic VSMCs and fibroblasts decreased with the progression of vascular calcification.

Conclusions: Our findings reveal for the first time the various topological function units of VC in CKD, which also presents the single-cell pathological landscape for VC in CKD. This work highlights the potential of a community cluster with a mixture of osteogenic VSMC and fibroblasts in driving vascular calcification, which may cause by the decreasing of H3K27me3.

CKD Causes Cardiac Metabolic Remodeling via FGF23 and FGFR4

Michaela A. Fuchs,[1] Emily Burke,[1] Myles Wolf,[1] Alexander Grabner.[1,2] *[1]Duke University School of Medicine, Durham, NC; [2]University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: In chronic kidney disease (CKD), serum levels of fibroblast growth factor (FGF) 23 are associated with increased risks of left ventricular hypertrophy (LVH), heart failure and death. We reported that FGF23 directly induces hypertrophic growth of cultured cardiomyocytes and structural cardiac remodeling in rodents via cardiac FGF receptor (FGFR) 4. Mitochondrial dysfunction and cardiac metabolic remodeling contribute to the development and progression of LVH and heart failure. We tested the hypothesis that FGF23-FGFR4 promote cardiac metabolic remodeling in CKD.

Methods: We induced CKD in FGFR4 global knock out mice, mice with inducible cardiomyocyte-specific deletion of FGFR4 and wildtype littermates using a 0.2% adenine diet for 16 weeks. At study end, cardiac structure, function, metabolism and mitochondrial composition and function was analyzed. In neonatal rat ventricular myocytes and bioengineered cardio-bundles we studied mitochondrial respiration, substrate utilization and cellular hypertrophy in response to FGF23 and inhibition of FGFR4.

Results: CKD induced robust changes to the cardiac mitoproteome (118 of 781 proteins significantly regulated) and impairs cardiac metabolism with significant alterations in cardiac organic acids, amino acids and acylcarnitines as well as mitochondrial respiration through complex I and II. Alterations in the cardiac metabolome preceded overt signs of structural cardiac remodeling and heart failure. In mice, deletion of FGFR4 prevented cardiac metabolic remodeling, mitochondrial dysfunction and heart failure in CKD. In cardio-bundles, FGF23 transcriptionally regulated metabolism. In cultured cardiomyocytes, FGF23 impaired mitochondrial respiration and substrate utilization via FGFR4, characterized by increased proton leak (fold change ctrl vs. FGF23: 1 ± 0.48 vs 1.43 ± 0.56*) and elevated glycolysis (fold change ctrl vs. FGF23: 1 ± 0.46 vs. 1.52 ± 0.66*; *=$p<0.05$).

Conclusions: Cardiac metabolic remodeling is an early complication of CKD that contributes to LVH. Mechanistically, FGF23-mediated activation of FGFR4 causes mitochondrial dysfunction including impaired respiration and increased glycolysis. We postulate that early pharmacologic inhibition of FGFR4 might serve as novel therapeutic intervention to attenuate heart failure in patients with CKD.

TH-OR88

Left Ventricular Systolic Dysfunction in the NBCe1-B/C Knockout Mouse: A Possible Unappreciated Phenotype of Congenital Proximal Renal Tubular Acidosis (pRTA)

Clayton Brady,[1] Aniko Marshall,[1] Lisa A. Eagler,[2] Thomas M. Pon,[2] Brian R. Weil,[1] Jennifer K. Lang,[2] Mark Parker.[1] *[1]University at Buffalo Jacobs School of Medicine and Biomedical Sciences, Buffalo, NY; [2]University at Buffalo, Buffalo, NY.*

Background: Congenital proximal renal tubular acidosis (pRTA) is caused by autosomal recessive mutations in the *SLC4A4* gene that encodes the electrogenic $Na^+/2HCO_3^-$ cotransporter NBCe1. Congenital pRTA is characterized by severe acidemia due to the loss of the kidney-specific NBCe1-A variant, which consequently impairs proximal tubule HCO_3^- transport. However, congenital pRTA also presents with growth retardation, intellectual disability, and ocular and dental abnormalities. Intriguingly, a mouse model lacking NBCe1-B and NBCe1-C (variants which have predominantly extra-renal expression) but with intact NBCe1-A, recapitulates the spectrum of ailments of congenital pRTA without the acidemia. No cardiac phenotype has been reported in congenital pRTA patients, however recent evidence from a virally-induced partial knockdown of cardiac NBCe1 in rats suggests that NBCe1-B is cardioprotective. Therefore, we assessed NBCe1-B/C knockout mice ($KO_{b/c}$) for signs of cardiac impairment.

Methods: Echocardiography, intraventricular pressure-volume (PV), and electrocardiogram measurements were used to assess cardiac function in vivo. Heart-weight to body-weight ratio and cardiomyocyte area were used to assess for signs of cardiac hypertrophy. The Ca^{2+}-sensitive dye Fura-2 AM and an IonOptix imaging system was used to assess Ca^{2+}-transients in isolated cardiomyocytes. Lastly, RNA-seq was used to investigate transcriptional changes in $KO_{b/c}$ hearts.

Results: We observed elevated end-diastolic and end-systolic volumes as well as a reduced left ventricular ejection fraction in $KO_{b/c}$ mice. PV loop analysis revealed reductions in load-independent contractility but not relaxation. Cardiac hypertrophy was not present in $KO_{b/c}$ mice. The QT interval was not different between genotypes, however we observed increased QT variability in $KO_{b/c}$ mice. We further found a reduction in the amplitude of Ca^{2+}-transients in cardiomyocytes isolated from $KO_{b/c}$ mice, providing an explanation for the reduction in contractility. Lastly, RNA-seq analysis revealed upregulation of gene-sets associated with membrane excitability and calcium handling.

Conclusions: We conclude that congenital absence of cardiac NBCe1-B leads to mechanical and electrical cardiac dysfunction in $KO_{b/c}$ mice that is likely driven by dysregulated cardiomyocyte Ca^{2+}-handling.

TH-OR89

Dopamine D4 Receptor Regulates Sodium Chloride Cotransporter in Renal Distal Convoluted Tubules

Mingzhuo Zhang, Mingda Liu, Weiwan Wang, Zhiyun Ren, Xiaoyan Wang. *Nanjing BenQ Medical Center, Nanjing, China.*

Background: Dopamine D4 receptor (D4R) is expressed in the distal convoluted tubule (DCT) and the mice lacking D4R have kidney-related hypertension.

Methods: The regulation and mechanisms of D4R on NCC were determined in D4R null mice (20 weeks-old, mixed sex) and cultured mouse distal convoluted tubule (mDCT) cells.

Results: NCC activities, measured by response to NCC inhibitor hydrothiazide (30mg/kg/day, IP, 7d), were greater in *Drd4*$^{-/-}$ mice than *Drd4*$^{+/+}$ littermates in initial 6-hrs (UNa: 513±121 vs 635±87μmol/mg of Cr, n=8) with SBP (118±5 vs 104±6 mmHg, n=8, tail-cuff) normalized on days 4-7. The renal NCC protein abundance by immunoblotting (230±51, % of control, n=4-5, same as below) and immunofluorescence was greater but ubiquitinated-NCC levels (66±13) were lower in KO than in WT mice. mRNA levels of NCC by Q-PCR and phosphorylation-NCC were not altered. NCC abundance (121±9) in KO mice remained higher than WT under the infusion of dopamine via osmotic mini-pump (1μg/kg/min, 1wk). In the mDCT cells, the immunoprecipitation of D4R with NCC was increased by PD168077. Colocalization and interaction of them was seen with confocal microscopy and confirmed by Fret.D4R-siRNA (1.5nM, 48 hrs) increased the protein expression of NCC (152±34, n=4); D4R agonist PD168077 (0-10μM, 24 hrs) decreased NCC protein abundance concentration-dependently; D4R antagonist L-745,870 (10μM, 24 hrs) had no effect but blocked the D4R agonist-mediated inhibition of NCC abundance. Total NCC (72±18) was decreased but ubiquitinated-NCC was increased remarkably (266±114) by PD168077 (10μM). PD168077 internalized NCC by membrane-biotinlaytion-method and increased the NCC colocalization with lysosomal-associated membrane protein 1. The PD168077-induced NCC decrease was reversed by lysosomal inhibitor chloroquine (20μM). 1 hr PD168077 also decreased NCC-dependent-intracellular sodium transport (74±1, n=7), which was blocked by D4R antagonist L-745,870. AT1R protein abundances (96±8, n=4), *Ncc* mRNA levels (116±13, n=9) of were not altered in D4 agonist treated cells at 24 hrs.

Conclusions: D4R inhibits NaCl transport in renal DCT by reducing NCC activity and protein abundance with promoting its internalization, ubiquitination and consequent lysosomal degradation.

TH-OR90

Targeted Antibiotic Modulation of the Gut Microbiome Ameliorates Hypertensive Organ Damage

Moritz I. Wimmer,[1,2] Valentin Vecera,[1,2] Harithaa Anandakumar,[1,2] Ulrike Löber,[3,1] Sofia K. Forslund,[3,1] Dominik N. Müller,[1,3] Hendrik Bartolomaeus,[1,2] Nicola Wilck.[2,1] *[1]Max Delbruck Centrum fur Molekulare Medizin Experimental and Clinical Research Center, Berlin, Germany; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Max-Delbruck-Centrum fur Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.*

Background: Gut microbiota play an important role in the development of hypertension. To better understand the role of the gut microbiota in modulating hypertensive organ damage, we used narrow-spectrum antibiotics without enteral absorption to specifically deplete gram-negative or -positive bacteria in double transgenic rats (dTGR).

Methods: Four-week-old dTGR (transgenic for human renin and angiotensinogen) were treated with oral Vancomycin (Vanco), Polymyxin B (Poly) or Vehicle (Veh) for 3 weeks. Seven-week-old SD rats were included as healthy controls. Flow cytometry, echocardiography, telemetric blood pressure (BP) measurement, shotgun metagenomic sequencing, clinical chemistry, and gene expression analyses (qPCR & bulk RNAseq) were employed to analyze the microbiome, clinical and immune phenotype.

Results: Hypertensive kidney damage was ameliorated in Vanco treated dTGR, as assessed by renal *Lcn2* expression, blood urea nitrogen and albuminuria. Vanco treated dTGR had significantly decreased cardiac hypertrophy. Poly treatment showed no effect. BP levels for both antibiotic treatments were not significantly different from Veh, despite a significantly improved endothelium-dependent and –independent vasorelaxation in isolated mesenteric arteries in both treated groups. Surprisingly, Vanco treatment led to a massive increase of gram-positive *Lactobacilli*. As the microbiome and immune system are closely connected, we performed in-depth flow cytometry of immune cells isolated from the heart, kidney, blood, spleen, and intestine. We observed a broad shift to pro-inflammatory immune cell subsets in dTGR. Vanco treatment could partially rescue the kidney inflammation as observed by a reduction in Th17 cells, classical dendritic cells and tissue infiltrating monocytes. Poly treatment did not alter the inflammatory signature.

Conclusions: Modulation of the intestinal microbiome by narrow-spectrum antibiotics affects hypertensive organ damage. Depletion of gram-positive intestinal bacteria by oral Vanco ameliorates organ damage independent of BP. Our data underscores the importance of the gut microbiome in modulating hypertensive organ damage and helps to identify potential therapeutic strategies in the microbiome (e.g. *Lactobacilli*).

TH-OR91

Performance of eGFR Equations for Drug Dosing in Kidney Transplant Recipients

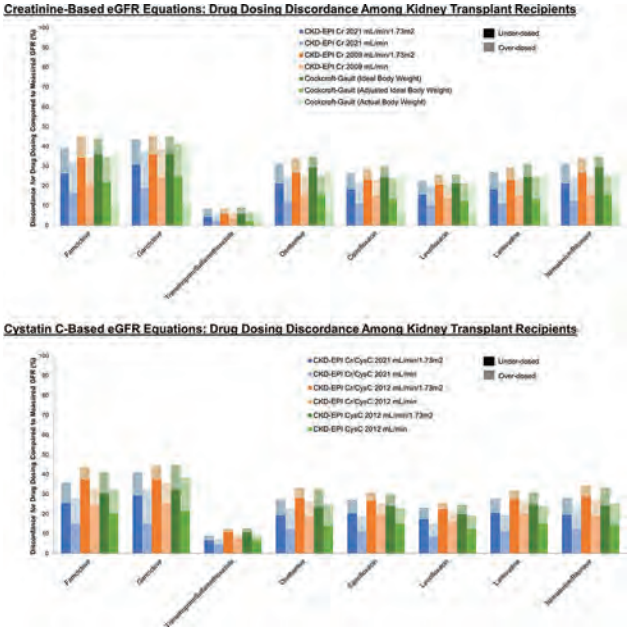
Gregory L. Hundemer, Manish M. Sood, Ayub Akbari. *Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: For kidney transplant recipients (KTRs), drug dosing is most commonly determined by using eGFR as a surrogate for graft function. Which eGFR equation performs best for drug dosing in KTRs remains unknown.

Methods: Cross-sectional study of 415 stable KTRs from Canada and New Zealand with same-day values of serum creatinine and cystatin C along with measured GFR (^{99m}Tc-DTPA). We assessed the performance for drug dosing of CKD-EPI (both indexed to a standardized body surface area [BSA] of 1.73m^2 [mL/min/1.73m^2] and non-indexed to account for actual BSA [mL/min]) and Cockcroft-Gault (via 3 different weights: ideal, adjusted ideal, and actual body weight) eGFR equations relative to measured GFR based upon recommended renal dosing of 8 medications commonly prescribed to KTRs: famciclovir, ganciclovir, trimethoprim/sulfamethoxazole, oseltamivir, ciprofloxacin, levofloxacin, lamivudine, and nimatrelvir/ritonavir. The primary outcome was proportion of drug dosing discordance (under- or over-dosing) overall and stratified by obesity status (BMI < or ≥30kg/m^2).

Results: The non-indexed CKD-EPI equations led to a lower proportion of drug dosing discordance compared to the indexed CKD-EPI equations across all study drugs (**Figure**). The Cockcroft-Gault equations based upon adjusted ideal and actual body weight led to a lower proportion of drug dosing discordance compared to ideal body weight. These findings were most pronounced among obese KTRs. Overall, the non-indexed 2021 CKD-EPI eGFR equations showed the lowest proportion of drug dosing discordance across all study drugs.

Conclusions: When employing eGFR-based drug dosing for KTRs, actual BSA should be accounted for to mitigate the risks of under- or over-dosing. The non-indexed 2021 CKD-EPI equations provide the most accurate eGFR-based guidance for appropriate drug dosing among KTRs.



TH-OR92

Performance of Creatinine and Cystatin C-Based Equations Among Patients with Hematological or Solid Cancers: Real-World Data from a Clinical Cohort

Silvia Titan, John C. Lieske, Jeff W. Meeusen, Andrew D. Rule, Sandra Herrmann. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Performance of creatinine-based eGFR equations in patients with malignancy may be worse than in the general population with implications for management including drug dosing.

Methods: We retrospectively studied all cases who had mGFR (urinary iothalamate clearance) performed at Mayo Clinic 2017-2023 and ICD codes for neoplasia (excluding in situ and benign lesions) up to one year prior to the mGFR date. Serum creatinine and cystatin C within 2 days of the mGFR were used to compute CKD-EPI 2021 eGFRcr and eGFRcrcys, and 2012 eGFRCys. Bias (absolute and % mGFR - eGFR) and P30 (% with eGFR >=30% different from mGFR) and confidence intervals (bootstrap) were computed. Analyses were stratified for cancer type.

Results: Results by cancer type are in the Table. Among 3719 patients with eGFRcr, the median bias was similar to that in the literature. Among the 522 patients with available creatinine plus cystatin C, eGFRcr had less bias but eGFRcrcys (15.5% [12.6 – 18.9]) was more accurate compared to eGFRcr (26.7% [23.1 – 30.8]) or eGFRcys (25.5% [12.6 – 18.9]). Results were similar by cancer type.

Conclusions: Our study suggests that among patients with either solid or hematological malignancies, the CKDEPI eGFRcrcys better reflects mGFR than either eGFRcr or eGFRcys. When possible, mGFR may be optimal for clinical decision making in these populations.

Table 1.

	Median Bias / CI (mL/min/1.73m2	P30 / CI (%)
Creatinine and Cystatin C available		
All patients (n=522)		
eGFRcr	-0.81 (-1.57, 0.44)	26.7 (23.08, 30.77)
eGFRcys	6.29 (4.65, 7.88)	25.5 (22.07, 29.07)
eGFRcrcys	3.06 (2.00, 4.27)	15.5 (12.60, 18.85)
Solid tumors (n=337)

MTX652, a Novel Selective USP30 Inhibitor for the Treatment of AKI: Phase 1 Results in Healthy Subjects and Model-Driven Human Efficacious Dose Projections

Pau Aceves, Paul W. Thompson, Natalie Jones, Suhail Nurbhai. *Mission Therapeutics Ltd, Cambridge, United Kingdom.*

Background: New treatments are needed for AKI. Dysfunctional mitochondria in kidney tubule epithelia are key drivers of kidney injury, therefore approaches to improving mitochondrial quality may be beneficial in kidney disease. Here we describe the clinical stage molecule MTX652 (also known as MTX115652), a novel, potent and specific inhibitor of USP30, a mitochondrial deubiquitylating enzyme which naturally antagonizes ubiquitin-dependent mitochondrial quality control mechanisms. In preclinical studies MTX652 protected against tubular atrophy and fibrosis in models of ischemia-reperfusion injury and unilateral ureter obstruction at doses from 0.5 to 5 mg/kg.

Methods: We report data from a randomized, double-blind, placebo-controlled first-in human study of MTX652 with cohorts evaluating SAD/MAD, elderly subjects, relative bioavailability (capsule vs. suspension), food effect and the DDI potential with a CYP3A4 inhibitor. MTX652 was administered as a solution/suspension in seven single dose cohorts between 0.25 to 200mg and four multiple dose cohorts between 3.5 to 100mg QD for 14 days. Safety was evaluated through the review of adverse events, physical examinations, clinical laboratory tests, vital signs and electrocardiograms. A PK/PD model was constructed to predict human target engagement (TE) at exposures which were effective in preclinical models.

Results: There were no Serious Adverse Events or safety or tolerability concerns in healthy subjects. MTX652 was rapidly absorbed with a plasma half-life of 8 hours. C_{max} and AUC were dose proportional and there were no meaningful time-dependent effects on PK. Formulation (capsule) or food had no clinically relevant impact. Plasma exposures in elderly and younger adults were comparable. Simulations identified a once daily dosing regimen within the range tested in the clinic able to attain TE levels similar to those associated with maximal renal protective effects in preclinical models.

Conclusions: This is the first report of clinical data with a USP30 inhibitor. MTX652 presented an acceptable safety/PK profile in healthy subjects. PK/PD modelling enabled the selection of a safe and well tolerated dose predicted to have renal protective effects in humans. These results support further development of MTX652 as a potential therapy for AKI.

Treatment of Diuretic Resistance with a Kappa Opioid Agonist, an Inhibitor of Central Vasopressin Secretion

Ashlyn Y. Anderson, Juan Gao, Kara Johnson, Ian B. Denys, Luke E. Beckendorf, Jacob K. Meariman, Daniel R. Kapusta. *LSU Health New Orleans, New Orleans, LA.*

Background: Prolonged use of furosemide for treatment of congestive heart failure can produce adverse effects including hypokalemia, hyponatremia, and diuretic resistance. We hypothesized that due to diuretic-induced excretion of water, increased vasopressin (AVP) secretion may be a key compensatory mechanism contributing to diuretic resistance. Since kappa opioid receptor (KOR) agonists act centrally to inhibit AVP secretion and produce water diuresis, we predicted that administration of difelikefalin, a KOR agonist, will reverse diuretic resistance to furosemide without enhancing urinary sodium/potassium excretion.

Methods: To test this, changes in 5-hr urine output (metabolic cages; no water) were measured daily in Sprague-Dawley rats following injection (9:00am) of saline (day 0) and furosemide (10 mg/kg, i.p.; days 1-5). Over days 6-10 rats were administered either, furosemide, furosemide + difelikefalin (F+D, 20 μg/kg, i.p.; days 6-10), or furosemide + tolvaptan (F+T, 1 mg/kg, i.p.) an AVP V2 receptor antagonist. After urine collection, rats received a 2nd drug treatment (2:00 pm) and were placed in home cages.

Results: Initial treatment (day 1) of rats with furosemide evoked a marked increase in urine output (V), urinary sodium excretion (UNaV), and urinary potassium excretion (UKV), with the magnitude of each greatly reduced by day 5 (day1:day5; V, 10.5±0.6 vs 5.6±0.4 ml/5hrs; UNaV, 971±55 vs 396±23 μEq/5hrs; UKV, 250±14 vs 193±20 μEq/5hrs). Over days 6-10, 5-hr urine output remained reduced throughout furosemide treatment (diuretic resistance). Combination treatment with either difelikefalin or tolvaptan over days 6-10 reversed diuretic resistance as noted by a sustained increase in V without increasing UNaV compared to furosemide alone (day 10, V; F, 5.6±0.2 ml/5hrs; F+D, 10.1±0.77 ml/5hrs; F+T, 11.1±0.9 ml/5hrs). Further, tolvaptan but not difelikefalin increased UKV over days 6-10.

Conclusions: These findings demonstrate that AVP plays a major role in mediating diuretic resistance to furosemide. Further, we show that combination therapy with a KOR agonist (difelikefalin) can reverse and potentially prevent diuretic resistance while improving loop diuretic induced hypokalemia and hyponatremia. Cystatin C-Defined AKI in Children Treated with Cisplatin

Erin Hessey,[1] Kelly McMahon,[2] Tom D. Blydt-Hansen,[3] Cherry Mammen,[3] Michael Zappitelli.[1] *[1]University of Toronto, Toronto, ON, Canada; [2]McGill University Health Centre, Montreal, QC, Canada; [3]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada.*

Background: Cisplatin chemotherapy causes acute kidney injury (AKI). Early AKI detection and mitigation may prevent long-term sequelae. Serum Cystatin C (CysC) may be an early AKI biomarker compared to SCr and is not impacted by muscle mass. We: 1) compared AKI defined by acute CysC change (CysC-AKI) to SCr-defined AKI (SCr-AKI) in children treated with cisplatin; 2) evaluated the relation of a) urine neutrophil gelatinase-associated lipocalin [NGAL] and kidney injury molecule-1 [KIM-1] with CysC-AKI and SCr-AKI and b) of CysC with SCr-AKI.

Methods: 12-centre prospective study of 159 children receiving cisplatin. Exclusions: CKD, missing CysC or baseline SCr. At early cisplatin infusions (1st or 2nd cisplatin cycle), SCr, CysC, urine NGAL and KIM-1 were measured pre-/post-infusion and at discharge. Outcomes: KDIGO SCr-AKI (yes/no). CysC-AKI was ≥1.5x rise from baseline or CysC-GFR<35ml/min/1.73m^2. We calculated kappa statistic for agreement of AKI definitions, Mann-Whitney U test to compare biomarker levels by AKI, and area under the curve (AUC) for a) NGAL/KIM-1 to predict CysC-AKI and SCr-AKI and b) for CysC to predict SCr-AKI.

Results: 154 children included (51% male, median age [IQR] 5.6 [2.4-11.7] years). SCr-AKI 7/154 (5%), CysC-AKI 25/154 (16%), 83% agreement (kappa=0.13, p=0.025). There was no significant difference in NGAL or KIM-1 concentrations by SCr-AKI or CysC-AKI at all time points (Figure1). Pre- and post-infusion NGAL performed similarly to predict SCr-AKI and CysC-AKI (Figure1). KIM-1 poorly predicted SCr-AKI and CysC-AKI (Figure1). Pre-infusion CysC had the highest AUC for predicting SCr-AKI (AUC 0.56).

Conclusions: CysC-AKI had a low level of agreement with SCr-AKI in children treated with cisplatin. CysC was not a strong predictor of SCr-AKI in this population. Future studies with more measurement time points are needed to determine if this is possibly due to earlier rise of CysC compared to SCr. NGAL and KIM-1 did not strongly predict AKI by either definition.

Figure1: Comparison of urinary biomarkers (NGAL/KIM-1) by SCr-AKI and CysC-AKI in children treated with cisplatin.

SGLT2 Inhibitor Protects from Repeated Low-Dose Cisplatin-Induced Chronic Kidney Damage

Dianet Sanchez Vega,[1] Leah J. Siskind,[1] Andrew Orwick,[1] Pranav S. Garimella,[2] Volker Vallon,[2] Theresa A. Weis,[1] Dana Hammouri.[1] *[1]University of Louisville School of Medicine, Louisville, KY; [2]University of California San Diego, La Jolla, CA.*

Background: Cisplatin is Cognitive dysfunction is a well-known complication agent that causes a dose dependent acute kidney injury (AKI) in nearly a third of treated patients, which subsequently leads to chronic kidney disease (CKD). There are no current FDA approved medications to prevent cisplatin induced kidney damage. Sodium-glucose cotransporter 2 inhibitors (SGLT2i) reduce risk of AKI and CKD in humans, and have shown renoprotection in a single high dose experimental model of cisplatin-induced AKI. We hypothesized that SGLT2i could protect the kidney in a mouse model of repeated low dose cisplatin and cancer to better mimic the clinical scenario.

Methods: B6:129 mice with and without lung adenocarcinoma were treated with daily SGLT2i (empagliflozin or dapagliflozin) or vehicle control for 28 days beginning 1 week prior to the first dose of weekly cisplatin (7mg/kg) or vehicle control. Following the third cisplatin injection, biomarkers for kidney function, injury, fibrosis, inflammation, kidney histology and tumor growth were assessed and compared between SGLT2i and vehicle control.

Results: SGLT2i treatment attenuated cisplatin-induced alterations in kidney function and injury. Markers of kidney fibrosis including TGF-b, a-SMA, fibronectin and collagen were lower in mice co-administered SGLT2i and cisplatin as compared to mice given vehicle control and cisplatin. SGLTi did not alter tumor growth or response to cisplatin.

Conclusions: SGLTi demonstrate a beneficial effect against kidney damage in a model of repeated low dose cisplatin and lung cancer. Future studies are needed to determine if they can be used post cisplatin treatment to improve and/or prevent progression of kidney injury to fibrosis and CKD.

Pharmacokinetics of Henagliflozin in Dialysis Patients with Diabetes

Leyi Gu. PHD Group. *Molecular Cell Lab for Kidney Disease, Shanghai Peritoneal Dialysis Research Center, Renji Hospital, Uremia Diagnosis and Treatment Center, Shanghai Jiao Tong University School of Medicine, Shanghai, China.*

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) are recommended to treat heart failure, irrespective of the presence of type 2 diabetes. Heart failure is one of the most common complications in dialysis patients. Not all SGLT2i are recommended for use in dialysis patients because less glucose enters the proximal tubule and the effects of inhibiting glucose and sodium reabsorption are reduced, as well as due to a lack of efficacy and safety data. However, emerging evidence has suggested that SGLT2i improve heart failure outcome through the off-target effect. Therefore, patients on dialysis with heart failure may benefit from SGLT2i. We conducted this study to evaluate the pharmacokinetics and safety of Henagliflozin doses of 5 mg and 10 mg in dialysis patients with diabetes.

Methods: In this prospective, randomized, open-label study, 10 hemodialysis and 10 peritoneal dialysis patients with diabetes were randomized in a 1:1:1:1 ratio to oral administration of Henagliflozin in doses of 5 and 10 mg/day. The pharmacokinetics of a single dose of Henagliflozin on days 1 and 2, the minimum plasma concentration (*C*min) of the steady state on day 10, and single hemodialysis clearance of Henagliflozin were measured. Plasma concentrations of Henagliflozin were analyzed by using validated liquid chromatography-tandem mass spectrometry method.

Results: The mean values of *C*max were 70.2–77.0 ng/mL and 105–143 ng/mL in the 5 mg and 10 mg Henagliflozin groups, respectively; the mean values of AUCinf were 777–811 h*ng/mL and 1290–1730 h*ng/mL in the 5 mg and 10 mg Henagliflozin groups, respectively. The median *T*max values ranged from 1 to 3 h across the dose range. The mean values of *T*1/2 of Henagliflozin were 14.1–14.5 and 16.2–21.0 h in the 5 mg and 10 mg groups, respectively. The *C*min values of the steady state in dialysis patients taking 5 mg and 10 mg of Henagliflozin were 15.0 ± 4.4 ng/ml and 26.8 ± 16.3 ng/ml, respectively, which were 123.8% and 131.0% higher than those in diabetic patients with normal renal function, respectively. Henagliflozin concentration was decreased by 1.1% after hemodialysis treatment. No treatment-related serious adverse events or discontinuations occurred.

Conclusions: Henagliflozin at the current recommended dosage may be safe although it accumulates in patients on dialysis. Clinical trials should be conducted to examine the cardioprotective effects of Henagliflozin in dialysis patients.

Canagliflozin Pharmacokinetics at Steady State in Patients on Maintenance Hemodialysis

Thomas Mavrakanas, Ari Gritsas, Efrosyne Tsirella, Norka Rios, Abhinav Sharma, Rita Suri. *McGill University Health Centre, Montreal, QC, Canada.*

Background: Sodium glucose co-transporter 2 (SGLT-2) inhibitors improve cardiovascular and kidney outcomes in patients with preserved renal function or with mild and moderate chronic kidney disease. However, they have not been studied in patients on maintenance hemodialysis (HD). Detailed study of SGLT-2 inhibitor pharmacokinetics in patients receiving HD is the first step to establishing their safety in this population.

Methods: Patients with kidney failure on maintenance HD for at least 3 months were invited to participate. Those with type 1 diabetes mellitus, euglycemic ketoacidosis, or liver disease were excluded. All participants received 100 mg of canagliflozin once daily for nine days. Venous blood samples were collected immediately before (0) and 1, 1.5, 2, 3, 4, 6, 9, 12, and 24 hours after canagliflozin administration for pharmacokinetic analyses on day 8 (a mid-week non-dialysis day) and hourly during hemodialysis on day 9. Canagliflozin plasma levels were measured with liquid chromatography- mass spectrometry and compared to published estimates in healthy controls.

Results: We enrolled 10 patients (59 ± 14 years old, 30% female, median dialysis duration 26 months). Canagliflozin levels reached steady state on day 4, based on a calculated half-life of 7.3 hours. Pharmacokinetic results on day 8 are shown in the **Table**. There were no significant differences in drug exposure, peak plasma levels, nor time to peak plasma levels between our patients and patients with preserved renal function. Canagliflozin levels were not modified by hemodialysis (p=0.39).

Conclusions: Drug exposure with canagliflozin 100 mg daily is similar between patients receiving HD and individuals with preserved kidney function, and levels were not affected by HD. These results suggest canagliflozin does not accumulate in HD patients and trials of canagliflozin may be safely conducted in patients on HD to test its efficacy.

Ondansetron and the Risk of Sudden Cardiac Death Among Patients Receiving Hemodialysis

Sherin Ismail,[1] Michele Jonsson Funk,[1] Jennifer E. Flythe.[2,3] *[1]The University of North Carolina at Chapel Hill Gillings School of Global Public Health, Chapel Hill, NC; [2]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [3]Cecil G.Sheps Center for Health Services Research, Chapel Hill, NC.*

Background: Sudden cardiac death (SCD) is common among hemodialysis (HD) patients. Ondansetron, an antiemetic with known QT prolonging potential, has a Food and Drug Administration warning about its association with fatal arrythmias in the general population. The cardiac safety of ondansetron in the HD population is unknown.

Methods: We conducted a new-user, active-comparator, cohort study using US Renal Data System data (2012-2019) to assess the comparative 10-day risk of SCD between HD patients initiating ondansetron vs. non-QT-prolonging antiemetics (metoclopramide/ prochlorperazine/ promethazine). We used inverse probability of treatment weighting and Fine and Gray proportional subdistribution hazard models to estimate adjusted hazard ratios (aHRs) and 95% confidence intervals (CIs). We used an intention-to-treat approach and treated non-SCD as a competing event. In secondary analyses, we considered broader cardiac outcomes.

Results: Of 119,254 study patients, 64,978 (54.5%) initiated ondansetron and 54,276 (45.5%) initiated a comparator antiemetic. The mean age ± SD was 60 ±15 years, median (IQR) years on HD was 2.2 (0.9, 4.6), and 55% were female. Ondansetron vs. comparator antiemetic initiation was associated with higher relative and absolute 10-day risks of SCD, aHR (95% CI) = 1.45 (1.08, 1.93); weighted risk difference (95% CI) = 0.06% (0.01,0.11). The number needed to harm was 1,672 ondansetron initiations. Analyses of other cardiac outcomes yielded similar findings.

Conclusions: Ondansetron (vs. comparator antiemetic) treatment was associated with higher absolute and relative 10-day risks of SCD among HD patients. Our findings may inform prescriber decisions about antiemetic selection in the HD population.

Funding: Other NIH Support - NIH/NHLBI

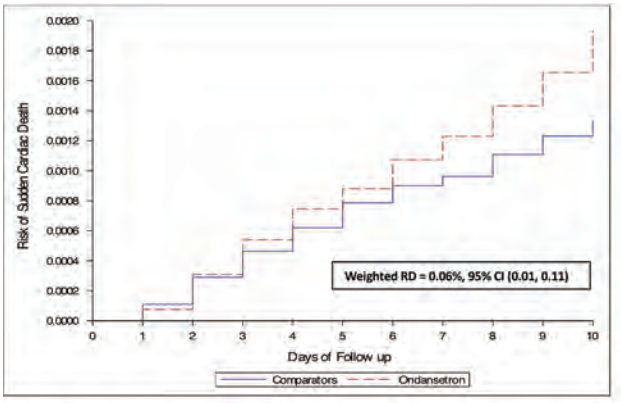

Figure 1. The 10-day SCD risk among hemodialysis patients initiating ondansetron vs. a non-QT-prolonging antiemetic.

Safety Outcomes of Sodium-Glucose Cotransporter-2 Inhibitors in Patients with Diabetes Mellitus and Cancer

Aisha Shaikh,[1,2] James H. Flory,[1,2] Andrea Knezevic,[1] Edgar A. Jaimes.[1,2]
[1]Memorial Sloan Kettering Cancer Center, New York, NY; [2]Weill Cornell Medicine, New York, NY.

Background: Sodium-glucose co-transporter-2 (SGLT2) inhibitors are glucose-lowering agents that reduce the risk of hospitalization for heart failure and chronic kidney disease progression. The risk of serious adverse events with SGLT2i use was low in large clinical trials, but patients with cancer were excluded from these trials. Therefore, the safety of SGLT2 inhibitors in patients with cancer is unknown.

Methods: Using our institute's electronic medical record system, we identified 5,478 patients with a history of diabetes mellitus and cancer who were prescribed an SGLT2 inhibitor, i.e., empagliflozin, dapagliflozin, canagliflozin or ertugliflozin, between 2013 and 2022. Data on adverse events, including urinary tract infections (UTIs), diabetic ketoacidosis (DKA), genital infections, and non-vertebral fractures, were collected using the ICD-9/10 diagnostic codes.

Results: The medical record query identified 5,478 patients who were prescribed an SGLT2 inhibitor. Each patient had a start and an end date for the SGLT2 inhibitor prescription, which added up to a total of 11,175 patient-years on SGLT2 inhibitors. The ICD diagnosis query revealed 424 instances of adverse events coinciding with the SGLT2 inhibitor prescription. The incidence rate of adverse events is shown in Table 1.

Conclusions: In this cohort of diabetic patients with cancer, the incidence rate of DKA in patients taking an SGLT2 inhibitor was higher (5.1 per 1000 patient-years) as compared to the incidence rate of DKA reported in a recent meta-analysis[1] of SGLT2 inhibitor trials (0.0-2.2 per 1000 patient-years) and a large observational study[2] (2.37 per 1000 patient-years). We also observed a high incidence rate of UTIs, genital mycotic infections, and non-vertebral fractures. To our knowledge, this is the first study to report the safety outcomes of SGLT2 inhibitors in diabetic patients with cancer. *[1]Impact of diabetes on the effects of SGLT2 inhibitors on kidney outcomes. Lancet. 2022 [2]Comparative Effectiveness and Safety of SGLT2 Inhibitors Versus GLP1-RA in Older Adults. Diabetes Care. 2021*

AKI Is Associated with Long-Term Decline in Cognitive Function at 3 Years: ASSESS-AKI Study

Pavan K. Bhatraju,[1] Leila R. Zelnick,[1] Edward D. Siew,[2] Steven Menez,[3] Vernon M. Chinchilli,[4] Steven G. Coca,[5] James S. Kaufman,[8] Paul L. Kimmel,[6] Chirag R. Parikh,[3] Alan S. Go,[7] Talat Alp Ikizler,[2] Jonathan Himmelfarb,[1] Mark M. Wurfel.[1] *[1]University of Washington, Seattle, WA; [2]Vanderbilt University, Nashville, TN; [3]Johns Hopkins University, Baltimore, MD; [4]The Pennsylvania State University, University Park, PA; [5]Mount Sinai Health System, New York, NY; [6]National Institutes of Health, Bethesda, MD; [7]Kaiser Permanente, Oakland, CA; [8]New York University, New York, NY.*

Background: Cognitive dysfunction is a well-known complication of chronic kidney disease but it is less known whether these long-term adverse events are present in survivors of AKI. We hypothesized that an episode of AKI is associated with poorer cognitive function, mediated, at least in part, by persistent systemic inflammation.

Methods: ASSESS-AKI was a multicenter prospective cohort study that enrolled patients surviving three months after hospitalization with and without AKI who were matched based on demographics, comorbidities and baseline kidney function. A subset of patients underwent cognitive testing using the modified mini-mental test (3MS) at 3, 12 and 36 months. The 3MS is scored on a scale of 0-100. We examined the association of AKI with long-term cognitive testing using mixed linear models accounting for matching and loss to follow-up and assessed the proportion in risk mediated by 3-month systemic inflammatory biomarkers (sTNFR-1, IL-6 and IL-8).

Results: Among 1538 patients enrolled in the parent study (769 with AKI and 769 without), 1465 (95%) completed the 3MS at 3 months. Patients with AKI had lower 3MS scores at 3 months (difference -1.1 (95% CI: -2.0, -0.3) $p=0.01$) and at 3 years (-1.5 (95% CI: -2.4, -0.7) $p<0.01$) compared to matched patients without AKI. We also found that a higher proportion of patients with AKI had a clinically meaningful (>5 point) reduction in 3MS scores at 3 years compared to patients without AKI (10% and 5%, $p<0.01$). In mediation analyses, serum sTNFR-1 mediated 34% ($p=0.01$) of the AKI related risk for 3MS scores at 3 years, while IL-6 and IL-8 had non-significant proportion mediated.

Conclusions: We found that patients with AKI had significantly worse cognitive function at 3 years after hospitalization. We also found that sTNFR-1 levels appear to mediate a significant proportion of the risk of long-term cognitive impairment.

Funding: NIDDK Support

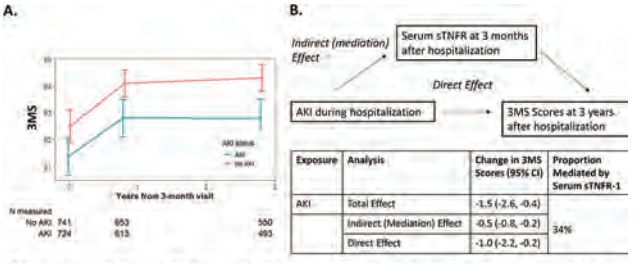

Figure Legend: (A) Displays the trajectory of 3MS scores in patients with AKI (blue line) and patients without AKI (red line) over 3 years of follow-up after hospitalization. Patients with AKI have significantly lower 3MS scores at 3 months and 3 years after hospitalization. (B) Mediation analysis testing the direct and indirect (mediation) effect of AKI on 3MS scores at 3 years. sTNFR-1 levels mediate 35% of the decreased 3MS scores in patients with AKI compared to no AKI.

FR-OR02

AKI, Glomerulonephritis, and Tubulointerstitial Nephritis Following Vaccination: VigiBase Analysis

Soo-Young Yoon,[1] Hyo Jin Lee,[1] Dae Kyu Kim,[1] Jin sug Kim,[1] Yang Gyun Kim,[2] Ju young Moon,[2] Kyunghwan Jeong,[1] Hyeon Seok Hwang.[1] *[1]Kyung Hee University Hospital, Dongdaemun-gu, Seoul, Republic of Korea; [2]Kyung Hee University Hospital at Gangdong, Gangdong-gu, Seoul, Republic of Korea.*

Background: Vaccination is the long-term established measure for disease prevention and worldwide outbreak of COVID-19 necessitates mass scale vaccination. However, there is a public concern on the risk of renal adverse reactions from several types of vaccination.

Methods: We analyzed VigiBase (n = 120,715,116 reports), the World Health Organization pharmacovigilance database from Dec 1967 to Jul 2022 using disproportionate Bayesian reporting. Information component (IC) compares observed and expected values to find the associations of vaccines with acute kidney injury (AKI), glomerulonephritis (GN) and tubulointerstitial nephritis (TIN).

Results: We found 5,484 AKI (13.8% fatal), 2,846 GN (29.4% fatal) and 289 TIN reports (23.2% fatal) as vaccine-associated adverse reactions. Almost reports indicated single drug suspected cases. Cumulative number of reports on AKI, GN and TIN gradually increased and Americas was most prevalent regions of reporting. Examining the different vaccines separately, reporting count of COVID-19 mRNA vaccines sharply increased and it solely was associated with significantly higher reporting of AKI (IC_{025} 1.09) and TIN (IC_{025} 0.48). Patients aged 12-17 years had the highest IC values for COVID-19 mRNA vaccine-associated AKI and TIN. Hepatitis B, encephalitis and COVID-19 mRNA vaccine were prominently over-reported among ten types of vaccines with significant signals of GN.

Conclusions: AKI, GN and TIN substantially occurred following vaccination and it was most noticeable in patients exposed to COVID-19 mRNA vaccines. Clinicians should consider the increased risk of renal adverse reactions after vaccination.

FR-OR03

Use of a Recurrent Neural Network to Predict Development of Nephrotoxic AKI in Adults

Benjamin R. Griffin,[1] Mary V. Sarrazin,[1] Diana I. Jalal,[1] Jason Misurac.[2]
[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]The University of Iowa Stead Family Children's Hospital, Iowa City, IA.

Background: The Nephrotoxic Injury Negated by Just-in Time Action (NINJA) program identifies children with high exposure to nephrotoxic medications and has been shown to reduce rates of acute kidney injury (AKI) by 25% through preemptive medication adjustments. However, attempts to translate NINJA to the adult population have been hampered by the much larger patient volume at adult hospitals combined with NINJA's relatively low positive predictive value (PPV), which generates a high number of false alerts. We used a recurrent neural network (RNN) machine learning algorithm to improve nephrotoxic AKI prediction in patients with high nephrotoxin exposure.

Methods: We collected over 100 variables including demographics, laboratory data, vital signs, and medication usage on adult patients admitted to the University of Iowa Hospital from 2017-2022. Patients admitted for >48 hours who met the NINJA definition for high nephrotoxin exposure (≥ 3 nephrotoxins on 1 day or intravenous aminoglycoside or vancomycin for ≥ 3 days) were included in the final dataset. A gated recurrent unit (GRU)-based RNN was trained on 85% of the data, and then tested on the remaining 15%, with the goal of predicting AKI development (defined as a creatinine increase of ≥0.3 mg/dL or ≥1.5x baseline) within 48 hours. We then used an artificial neural network (ANN) to determine feature importance.

Results: There were 37,300 patient-days meeting criteria for NINJA high nephrotoxin exposure. In the testing cohort, 29% of exposures developed AKI within 48 hours (2.4 false alerts per true AKI). The RNN model predicted 48-hour AKI with a PPV of 0.58 (0.7 false alerts per true AKI) and a NPV of 0.87. Hospital day, lowest hemoglobin, lowest platelet count, lowest blood pressure, and highest white blood cell count were the 5 most important variables in the ANN model. Vancomycin, piperacillin-tazobactam, iopamidol, and lisinopril were the most important medication variables.

Conclusions: Our RNN machine learning model was able to dramatically reduce the number of false alerts for nephrotoxic AKI in adults, which may facilitate NINJA translation to adult hospitals by providing more targeted intervention with less resource utilization.

Genome-Wide Association Study of Hospitalized AKI

Edward D. Siew,[1,2] Jacklyn N. Hellwege,[2,1] Adriana Hung,[1,2] Bethany Birkelo,[2] Sharidan Parr,[5] Cassianne Robinson-Cohen,[2,1] Katalin Susztak,[3,4] Robert Greevy,[2,1] Andrew J. Vincz,[2,1] Michael E. Matheny,[1,2] Digna R. Velez edwards.[2,1] *[1]VA Tennessee Valley Healthcare System, Nashville, TN; [2]Vanderbilt University Medical Center, Nashville, TN; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Corporal Michael J Crescenz VA Medical Center, Philadelphia, PA; [5]Nebraska Western Iowa Veterans Affairs, Omaha, NE.*

Background: AKI commonly complicates hospitalization and has a potential genetic basis for susceptibility.

Methods: We conducted a genome-wide association study of AKI in the Million Veteran Program(MVP) and Vanderbilt University's DNA biobank(BioVU). Among patients hospitalized during 2002-2019, AKI cases were defined as KDIGO Stage ≥2, or Stage 1 AKI for ≥2 days. Non-AKI controls were identified among hospitalized patients without historical evidence of AKI. Single variant logistic regression analyses were performed on imputed genetic variants, adjusting for sex, age, and the top 10 principal components of ancestry. Results were meta-analyzed using fixed effects analyses. A second meta-analysis was performed with summary statistics from UK Biobank, FinnGen, and BioBank Japan. Bioinformatic analyses were performed to provide functional information for significant variants.

Results: There were 58,891 patients with AKI(53,079 MVP,5,812 BioVU) and 139,098 non-AKI controls(127,627 in MVP, 11,471 BioVU). Three novel loci reached genome-wide significance (Fig): rs11642015 near *FTO*(odds ratio[OR] 1.07(95% confidence interval [CI], 1.05-1.09), p=8.2x10-17, EAF[effect allele frequency]=0.36); rs20654180 near *MPPED2*(OR 1.05(95% CI 1.03-1.06), p=2.9x10-8, EAF=0.68]); and rs8042910 near *INTS14*(OR 1.06(95%CI:1.04-1.08), p=3.9x10-8, EAF=0.20). Effects were consistent across groups and replicated in diagnosis code-based datasets. Within MVP, FTO remained significant after adjusting for BMI. Genome-wide meta-analysis of Biobank Japan, FinnGen, and UK Biobank (N=67,051 cases, 788,014 controls) identified one additional significant locus: rs76704066 in *NALCN* [EAF = 1.9%; OR 0.82 (95%CI:0.77-0.88)]. *FTO* and *MPPED2* remained significant (p= 1.0x10-17 and 9.6x10-9, respectively), while *INTS14* did not (p= 8.1x10-8).

Conclusions: Three loci were associated with AKI including one (*MPPED2*) previously associated with CKD. *FTO* may contribute to the risk of AKI independently of BMI. Further work to determine how these genes may contribute to AKI is ongoing.

Machine Learning-Guided Novel Subphenotypes of Sepsis-Associated Persistent AKI

Wonsuk Oh,[1] Hannah Kittrell,[1] Roopa D. Kohli-Seth,[1] Girish N. Nadkarni,[1] Ankit Sakhuja.[2] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]West Virginia University, Morgantown, WV.*

Background: Sepsis associated acute kidney injury (SA-AKI) is common and is associated with high mortality. AKI lasting 48 hours or longer, known as persistent AKI (pAKI), has much worse outcomes. SA-AKI is a heterogenous disease, however, it is unknown whether such heterogeneity exists in SA-pAKI. We aimed to identify subphenotypes (SP) of SA-pAKI using routinely collected data in electronic medical records.

Methods: We conducted a retrospective study using MIMIC IV database. We defined AKI and pAKI using both creatinine and urine output based KDIGO criteria. We identified adult patients (≥18y) with sepsis who developed SA-AKI within 48h and SA-pAKI within 96h of ICU admission. We used available features for demographics, comorbidities, SOFA score, vital signs, labs, fluid balance & vasopressors to identify SPs. We used factor analysis of mixed data for dimensionality reduction followed by k-means clustering to identify SPs. Outcomes were 30-day in-hospital mortality and 30-day AKI recovery while adjusting for competing risk of mortality.

Results: Among 6,681 patients with SA-pAKI, we identified 4 distinct SPs. Each SP demonstrated distinct characteristics and outcomes (Fig 1a & b). SP1 (n=1,137) included patients with severe AKI, low systolic BP, high INR, and WBC counts. It had highest mortality(47%) and low AKI recovery(37%). SP 2 (n=1,231) had moderate to severe AKI but low vasopressor requirements. It had low mortality (19%) but also low rates of AKI recovery (32%). SP3 (n=1315) included patients with high comorbidity burden but low disease acuity. Their mortality was between that of first two SPs and had high rates of AKI recovery (54%). SP4 (n=1,678) included patients with mild to moderate AKI and low disease acuity. They had highest rates of AKI recovery (56%) and lowest mortality (13%).

Conclusions: We identified 4 distinct SPs of SA-pAKI with differing patient characteristics and outcomes. Early recognition of these SPs will allow for personalized management strategies.

Arterial Stiffness and AKI in the Atherosclerosis Risk in Communities (ARIC) Study

Ester Oh,[1] Aditya L. Surapaneni,[2] Jessica B. Kendrick,[1] Josef Coresh,[4] Kunihiro Matsushita,[4] Morgan Grams,[2] Kristen L. Nowak,[1] Anna Jovanovich.[1,3] *[1]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [2]New York University Grossman School of Medicine, New York, NY; [3]VA Eastern Colorado Health Care System, Aurora, CO; [4]Johns Hopkins University, Baltimore, MD.*

Background: Acute kidney injury (AKI) is associated with prolonged hospitalization and increased in-hospital mortality risk. However, the prediction of incident AKI is inaccurate and additional predictors of AKI are strongly needed. Arterial stiffness, as measured by carotid-femoral pulse wave velocity (cfPWV), is associated with kidney

function decline and may serve as a plausible predictor of AKI. We hypothesized a higher cfPWV at baseline would be independently associated with AKI risk in community-dwelling older adults who participated in the Atherosclerosis Risk in Communities (ARIC) study.

Methods: We included adults with available PWV measures (i.e., cfPWV [primary predictor], heart-femoral PWV [hfPWV], heart-carotid PWV [hcPWV], heart-ankle PWV [haPWV], and brachial-ankle PWV [baPWV], femoral-ankle PWV [faPWV]). Cox proportional hazard models were used to examine the association between PWV measures and time to AKI. Given its J-shaped relation with AKI, PWV was modeled as a categorical variable in quartiles (Q), with Q2 serving as the reference category.

Results: A total of 4,245 participants (44% male; 77% white; mean±SD age 75±5 years; cfPWV 11.9±3.9 m/s) were included. There appeared to be a J-shaped association between cfPWV and AKI risk (Q1, hazard ratio 1.15 [95% confidence interval 0.90-1.46]; Q4, 1.38 [1.08-1.77] vs. Q2) after fully adjusting for demographics, CVD risk factors, and markers for kidney function and peripheral artery disease (Figure).

Conclusions: A higher arterial stiffness, measured by cfPWV, is an independent predictor of AKI in community-dwelling older adults.

Noninvasive Identification of Acute Tubular Injury Using Plasma Proteomics

Insa M. Schmidt,[1] Aditya L. Surapaneni,[2] Dhairya A. Upadhyay,[2] Runqi Zhao,[1] Wan-Jin Yeo,[2] Pascal Schlosser,[3] Anand Srivastava,[4] Isaac E. Stillman,[5] Eugene P. Rhee,[6] Morgan Grams,[2] Sushrut S. Waikar.[1]
[1]Boston University, Boston, MA; [2]NYU Langone Health, New York, NY; [3]Johns Hopkins University Center for Health Security, Baltimore, MD; [4]University of Illinois Chicago, Chicago, IL; [5]Icahn School of Medicine at Mount Sinai, New York, NY; [6]Massachusetts General Hospital, Boston, MA.

Background: Biomarkers for the non-invasive assessment of acute tubular injury (ATI) are needed in patients with kidney disease.

Methods: Using the SomaScan proteomics platform, we measured 6592 circulating plasma proteins in 434 individuals with biopsy-confirmed kidney diseases and pathologist-adjudicated semi-quantitative assessments of histopathologic ATI. We identified proteomic correlates of ATI severity. For the proteins with the strongest associations with ATI, we evaluated cell-specific gene expression in patients with AKI in the Kidney Precision Medicine Project (KPMP).

Results: Fifty-three % of individuals had no ATI, 30% had mild ATI, 13% had moderate, and 3% had severe ATI. After multivariable adjustment and correction for multiple testing, 170 proteins were associated with ATI. The proteins with the strongest associations with greater ATI severity were osteopontin (p=9.8E-18), macrophage mannose receptor 1 (p=2.2E-16), and tenascin (p=1.4E-14) (Figure 1). Previously identified proteins such as kidney-injury molecule-1 and tumor necrosis factor receptor superfamily member 1 were also associated with ATI (p=9.9E-10 and 5.7E-06, respectively). The top proteins with inverse associations with ATI were plasma serine protease inhibitor (p= 6.1E-11), cholinesterase (p= 1.3E-10), and neuropeptide S (p=1.4E-10). In KPMP snRNA sequencing data, *SPP1* (the gene encoding osteopontin) was primarily expressed in thick ascending limb (TAL) and proximal tubular (PT) cell clusters (p=4.2E-141 and 5.2E-108, comparing the expression in TAL and PT with all other cell clusters, respectively).

Conclusions: Plasma proteomic approaches may identify novel biomarkers to non-invasively identify biopsy-proven ATI.

AKI Diagnostic Accuracy and Implications of AKI Baseline Creatinine (ABC) vs. Other Baseline Creatinine Estimating Equations

Erica C. Bjornstad,[1] Mithun K. Acharjee,[2] Akm F. Rahman,[2] Michael Zappitelli,[3] Rajit K. Basu,[4] George J. Schwartz,[5] Stuart Goldstein,[6] Chloe G. Braun,[1] David J. Askenazi.[1] *[1]The University of Alabama at Birmingham Department of Pediatrics, Birmingham, AL; [2]The University of Alabama at Birmingham Department of Biostatistics, Birmingham, AL; [3]Toronto Hospital for Sick Children, Toronto, ON, Canada; [4]Ann and Robert H Lurie Children's Hospital of Chicago, Chicago, IL; [5]University of Rochester, Rochester, NY; [6]Cincinnati Children's Hospital Medical Center, Cincinnati, OH.*

Background: Acute kidney injury (AKI) definitions rely on a known baseline creatinine (Cr_b), which is missing in up to 75% of hospitalized children. A new method (ABC equation) for estimating Cr_b was derived from children without kidney disease. We aim to externally validate the ABC method in an international cohort and assess how different Cr_b estimating equations alter AKI epidemiology.

Methods: AWARE is a prospective international study of 4984 critically ill children (age 0-25 years) from 32 PICUs. The validation of the ABC equations uses a subset of this cohort (n=2451) with a known Cr_b which serves as the gold standard, using statistical measures of accuracy and precision. The entire cohort is used for assessing changes in AKI epidemiology for different Cr_b estimating equations (3 ABC equations and 4 common eGFR equations). Univariate statistics determine how different Cr_b equations impact the incidence of AKI and its association with key clinical outcomes including 28-day mortality.

Results: The simplified ABC equation (requiring only age) performed similarly to existing Cr_b equations (e.g., new Schwartz). When an admission hospital creatinine value was available, the ABC equations outperformed all existing equations up to 19% in accuracy and 32% in precision. AKI incidence varied from 2-10% depending on Cr_b definition. Adverse clinical outcomes were rare: 28-day mortality (n=169) was 3.4% and ICU length of stay>=14 days (n=147) was 2.9%. Compared to previous Cr_b equations, ABC equations consistently perform better (or similar) to predict poor clinical outcomes. For example, relative risk (RR) of AKI using the ABC equation for 28-day mortality was 4.5 (95% CI 2.8-7.2); this was 5-29% higher RR than AKI defined by other Cr_b equations.

Conclusions: ABC equations outperform existing Cr_b estimating equations. This international cohort confirms earlier findings that ABC equations are improved methods for estimating Cr_b values. The data suggest ABC equations performed similarly, or perhaps better, in predicting select poor clinical outcomes.

FR-OR09

Vancomycin-Tacrolimus Combination Increases AKI Risk in Post-Hematopoietic Stem Cell Transplantation (HSCT) Patients

Tuisha Gupta,[1] Yuan Liu,[2] Kevin Hall,[2] Minal J. Surati,[2] Edmund K. Waller.[2]
[1]Tbilisi State Medical University, Tbilisi, Georgia; [2]Emory University, Atlanta, GA.

Background: Acute kidney injury (AKI) is a common complication in hematopoietic stem cell transplant (HSCT) recipients, leading to prolonged hospital stays, increased healthcare costs and mortality rates. Drug-related effects are major contributors of AKI in this patient population. Immunosuppressive and antibacterial drugs, such as vancomycin and tacrolimus, have well-documented nephrotoxic effects. Combinations of tacrolimus and vancomycin with other drugs are known to induce AKI. However, the combined nephrotoxic effect of vancomycin and tacrolimus warrants further investigation. This study aims to evaluate their simultaneous nephrotoxic effects in HSCT patients.

Methods: Institutional Review Board approval was obtained for retrospective analysis of transplant outcomes. This retrospective cohort study includes 1444 HSCT patients (age>18) from 2018-2021 at Emory University Hospital. Patients with end-stage renal disease were excluded from the study. The KDIGO guidelines: increase in serum creatinine levels ≥0.3 mg/dL within 48 hours or ≥50% within 7 days, were used

to define AKI in the study population. Data was collected from day 0 to day +30 post-HSCT by reviewing in and out-patient medical records. Univariate and multivariable logistic regression was used to estimate the interaction effect between vancomycin and tacrolimus.

Results: The median patient age was 61, with 55% males, 58% white/35% black. Of the total patients, 51% had hypertension, 14% diabetes mellitus, 15% CKD, 8% congestive heart failure (CHF). The overall AKI incidence was 9.94%, with 19.81% among allogeneic transplant recipients and 7.24% among autologous transplant recipients (OR 3.28 p<0.001). Other AKI associated covariates were male gender (OR 1.59 p 0.022), CHF history (OR 2.26, p 0.006), high BMI (OR 1.06, p<0.001) and low creatinine clearance (OR 0.96 p<0.001). Using multivariate logistic regression, the primary outcome measure, the incidence of AKI was significantly higher in patients receiving a combination of vancomycin and tacrolimus (OR 5.50 p<0.001) than patients receiving tacrolimus alone without vancomycin (OR 4.04 p<0.001).

Conclusions: Concurrent administration of vancomycin and tacrolimus greatly increases the risk of AKI compared to the individual drugs alone. Thus, the simultaneous use of these medications should be avoided or minimized with close monitoring in allo-HSCT recipients.

FR-OR10

Heart Failure with Preserved Ejection Fraction (HFpEF) vs. Heart Failure with Reduced Ejection Fraction (HFrEF) After AKI

Bethany Birkelo,[1,2] Robert Greevy,[1,2] Andrew Guide,[1,2] Michael E. Matheny,[1,2] Trey H. Richardson,[1] Evan Brittain,[1] Edward D. Siew.[1,2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN.*

Background: There is an increased risk of incident heart failure (HF) after acute kidney injury (AKI). Preclinical studies have shown AKI causes structural changes and diastolic dysfunction. The nature and phenotype of HF experienced by AKI survivors is unknown.

Methods: We conducted a case control study of adults at Vanderbilt University Medical Center. To ensure patients had established care at VUMC, we required at least one outpatient serum creatinine at least two years prior to the code for HF. Eligible patients were also required to have an echocardiogram within 30 days before or 1 year after HF diagnosis to determine HF subtype. Patients with a history of ESRD were excluded. The primary exposure was hospitalized AKI defined using creatinine-based KDIGO definitions during the exposure ascertainment period. The primary outcome was determined as HF, defined by either 1 inpatient or 2 outpatient diagnosis codes and classified using the echocardiogram closest to the HF diagnosis date (HFpEF if EF ≥45%, HFrEF if EF <45%). Baseline vitals, conditions, and medications were ascertained prior to AKI. Multivariable logistic regression was used to estimate the odds of AKI prior to HFpEF versus HFrEF.

Results: We identified 7,509 adults with incident HF (5,544 HFpEF, 1,965 HFrEF). AKI (stages 1-3) was associated with a 20% higher odds of HFpEF which was not statistically significant (OR 0.80, 95% CI 0.62 – 1.03). Stage 1 AKI was associated with a 40% higher odds of HFpEF (OR for HFrEF 0.60, 95% CI 0.42 – 0.85) whereas Stage 2-3 AKI was associated with a 17% higher odds of HFrEF, though this finding was not statistically significant (OR 1.17, 95% CI 0.81 – 1.68).

Conclusions: Stage 1 AKI was preferential towards incident HFpEF compared to HFrEF, with an association on par with other HFpEF risk factors such as female sex, obesity, atrial fibrillation, and hypertension. More severe AKI trended towards favoring HFrEF. Multimorbidity increases risk of HFpEF and may render patients susceptible to small fluctuations in serum creatinine when hospitalized. Further work is needed to elucidate mechanisms of this relationship.

FR-OR11

Role of Biomechanics in the Regulation of Ureteric Bud Branching Morphogenesis

Satu Kuure, Vladislav Iaroshenko, Kristen Kurtzeborn. Kuure Lab. *Helsingin yliopisto Laaketieteellinen tiedekunta, Helsinki, Finland.*

Background: Branching morphogenesis is a fundamental developmental process driving the formation of several organs. Branching pattern in the developing kidney is stereotyped and involves geometrically distinct modes: tip bifurcation and trifurcation, and only very rarely lateral branching. The branching epithelium, known as ureteric bud (UB), undergoes a series of complex changes which first transform a single layered epithelial bud to an ampulla where then the terminal bifurcations take place. While the molecular mediators of tissue crosstalk during renal branching are rather well characterized, the mechanisms controlling exact branch-initiating cell identity in UB tips remain unknown. Moreover, the roles of cellular niche, extracellular matrix and biomechanics in branch point determination are poorly understood.

Methods: We utilize a combination of mouse genetics and a custom machine-learning based segmentation pipeline in MATLAB to quantify 3D UB epithelial cell shapes and sizes in wholemount kidneys to determine how cell shapes change and drive complex branching patterns. Live imaging of fluorescently labelled UB cells, traction force microscopy and primary UB cell cultures on matrices with varying stiffness are utilized to study how basic cellular features drive arborization of ureteric bud epithelium in normal and growth factor deficient kidneys.

Results: Cell shape characterization of 3D epithelium shows that individual cells in the bud stage are mostly elliptical but become significantly rounder as ureteric branching proceeds to the ampulla stage. In the next branch phase, the cells convert into elongated shape suggesting that the ampulla remodeling to bifurcated tips involves spatial constraints squeezing bud epithelial cells into tube-like organization. Accordingly, our results demonstrate not only remarkable differences in cell shapes in the MAPK/ERK-deficient UB epithelium incapable of complex branch formation but also clear fluctuations in adhesive forces exerted between epithelial cells themselves and towards their niche composed of nephron progenitors.

Conclusions: Our work describes the basic characteristics of ureteric bud epithelial cells during different branch formation phases. Together with our biomechanical studies, this provides a new cellular mechanism through which novel branch points are determined and how growth is regulated in developing kidney.

Multi-Omic Profiling of Human Renal Organoids Reveals PAX8 as a Critical Regulator of Human Renal Mesenchymal-to-Epithelial Transition

Julie Williams,[1] John-Poul Ng-Blichfeldt,[2] Katja Röper.[2] *[1]AstraZeneca PLC, Gothenburg, Sweden; [2]MRC-LMB, Cambridge, United Kingdom.*

Background: The nephron, the functional unit of the kidney that filters blood, is a tubular epithelial structure that arises from metanephric mesenchyme through a mesenchymal-to-epithelial transition (MET) during kidney development. Wnt signalling specifies nephron fate, however, the relationship between Wnt signalling and establishment of epithelial junctions and apical-basal polarity during renal MET is unclear, and in general, developmental MET processes *in vivo* are poorly understood.

Methods: To investigate transcriptional control of MET, we used human induced pluripotent stem cell-derived renal organoids, which recapitulate nephrogenesis and generate epithelial tubes that express molecular markers of nephron cell types. Organoids were harvested for single nucleus multi-omic (paired RNA-seq and ATAC-seq) profiling to investigate transcription factors driving MET. CRISPR-interference was used to perturb candidate transcription factors.

Results: Human renal organoids recapitulate MET with upregulation of epithelial genes including CDH1 (E-cadherin), establishment of apical-basal polarity and epithelial junctions. Organoids exhibit dynamic gene expression and chromatin accessibility signatures throughout MET driven by transcriptional activators and repressors. PAX8 is a critical upstream regulator of human renal MET. Previous studies found PAX8 was dispensable for mouse renal MET. We show using CRISPR-interference that PAX8 is essential for initiation of MET in human kidney organoids. Moreover, Wnt signalling must be deactivated for completion of MET; persistent Wnt activation prevented completion of epithelial polarisation.

Conclusions: These results reveal how the developing kidney balances fate-commitment and morphogenesis with implications for understanding both developmental kidney diseases and aberrant epithelial plasticity following adult renal tubular injury.

FR-OR13

Interpreting Geometric Rules of Early Kidney Formation for Synthetic Morphogenesis

Alex Hughes.[1,2] Hughes Lab, Penn Bioengineering. *[1]University of Pennsylvania, Philadelphia, PA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: The kidney develops through coordinated growth of ureteric epithelial tubules (the future urinary collecting ducts), stroma, and nephron progenitors in the cap mesenchyme that surrounds each ureteric tip as they branch. Dynamic interactions between these tissues set nephron numbers for life, impacting the probability of adult disease. How then are the rates of nephron formation and ureteric tubule duplication balanced?

Methods: Here we study the geometric and mechanical consequences of tubule tip packing at the embryonic kidney surface for tip organization and nephron formation. We study whole-mount mouse embryonic kidneys and human iPSC-derived nephron progenitor organoids using confocal immunofluorescence, mechanical microindentation, Brillouin microscopy, laser microdissection, and spatial RNA sequencing.

Results: We find that over developmental time, kidney curvature reduces and 'tip domains' pack more closely, which together create a semi-crystalline tip geometry at the kidney surface. We apply a geometric parameter of tip domains called the shape index to predict a rigidity transition to more solid-like tissue properties at later developmental stages and confirm by micromechanical measurements. At the level of individual tips we use the shape index to define a tip 'life-cycle' between branching events, and find that nephrogenesis rate varies over this life-cycle. Applying force inference techniques

adapted from a cell vertex model and validating with laser ablation shows that tip domains experience a cyclical mechanical transient over each life-cycle. We then hypothesized that tip duplication periodically creates a mechanical microenvironment permissive to nephrogenesis. Indeed, mimicking a mechanical transient in human iPSC-derived nephron progenitor organoids increased Wnt-driven commitment to early nephron cell aggregates.

Conclusions: The data suggest that temporal waves of mechanical stress within nephron progenitor populations could constitute a clock that synchronizes nephron formation and ureteric tubule duplication. Ongoing work to understand the spatial and temporal regulation of nephron induction will clarify variation in nephron endowment between kidneys and advance engineered replacement kidney tissues for regenerative medicine.

FR-OR14

ZEB2 Signaling Is Essential for Ureteral Smooth Muscle Cell Differentiation and Maintenance

Sudhir Kumar, Xueping Fan, Emily Zaltz, Paul Song, Yuqiao Jiang, Weining Lu. *Boston University, Boston, MA.*

Background: Mowat-Wilson Syndrome (MWS) is an autosomal dominant complex disorder caused by mutations in the *ZEB2 that* plays a critical role in cell fate determination and differentiation during development. Congenital anomalies of the kidney and urinary tract (CAKUT), such as hydroureter and hydronephrosis, have been reported in MWS patients. However, the role of ZEB2 in urinary tract development and the cellular and molecular mechanism underlining the CAKUT phenotype in MWS remains unknown.

Methods: We performed ZEB2 protein expression analysis in the developing mouse ureter. We generated *Zeb2* ureteral mesenchyme-specific conditional knockout mice by crossing *Zeb2* floxed mice with Tbx18Cre mice (*Zeb2* cKO) and analyzed the urinary tract phenotypes in *Zeb2* cKO mice and their wild-type littermate controls by gross and histological examination. Ureteral cellular and molecular phenotypes were studied using cell-specific markers such as TAGLN, ACTA2, FOXD1, POSTN, CDH1, TBX18, and SOX9.

Results: We found that ZEB2 is expressed in TBX18$^+$ ureteral mesenchymal cells at E14.5 and E15.5 during mouse fetal development. Deletion of *Zeb2* in developing ureteral mesenchymal cells causes hydroureter and hydronephrosis phenotypes, leading to obstructive uropathy, kidney failure, and early mortality. Cellular and molecular marker analyses showed that the TAGLN$^+$ and ACTA2$^+$ ureteral smooth muscle cells (SMCs) layer is not formed in *Zeb2* cKO mice at E15.5, but the FOXD1$^+$ and POSTN$^+$ tunica adventitia cells layer is significantly expanded compared to wild-type littermate controls. CDH1$^+$ urothelium cells are reduced considerably in the *Zeb2* cKO ureters at E15.5. Mechanistically, we found that *Zeb2* cKO mice have significantly decreased TBX18 expression but an increased SOX9 expression in the developing ureter at E14.5 and E15.5 compared to wild-type littermate controls.

Conclusions: Our results show that ZEB2 is essential for mouse ureter development by maintaining ureteral mesenchymal cell differentiation into normal ureteral SMCs. Our study also shed new light on the pathological mechanism underlying the developmental abnormalities of the urinary tract and CAKUT phenotype in MWS patients.

FR-OR15

The Multimodal Role of TBX6 in Kidney and Urinary Tract Development and Disease

Gregory B. Whittemore,[1,2] Jeremiah Martino,[1] Yask Gupta,[1] Tze Yin Lim,[1] Ekatherina Batourina,[2] Qingxue Liu,[1] Juntao Ke,[1] Rosemary V. Sampogna,[1] Virginia E. Papaioannou,[3] Cathy L. Mendelsohn,[2] Simone Sanna-Cherchi.[1] *[1]Columbia University Division of Nephrology, New York, NY; [2]Columbia University Department of Urology, New York, NY; [3]Columbia University Department of Genetics and Development, New York, NY.*

Background: TBX6 is a transcription factor involved in fate-determination of neuromesoderm precursors (NMP). We recently implicated haploinsufficiency of TBX6 as a driver of the congenital anomalies of the kidney and urinary tract (CAKUT) observed in the chromosome 16p11.2 microdeletion syndrome. Although deletion in mice results in loss of posterior somites and formation of ectopic neural tubes (eNTBs), Tbx6-dependent mechanisms of genitourinary development remain elusive.

Methods: We generated an allelic series from independent null and hypomorphic *Tbx6* alleles. We then integrated bulk and single-cell transcriptomics, epigenetics, and transcription factor binding site analysis at E9.5 to identify target tissues and genes. Selected targets were validated by electrophoretic mobility shift assay and *in situ* hybridization.

Results: We found that severe inactivation of *Tbx6* at E9.5 results in a loss of inhibitory control of the *Kdm7a* promotor, leading to overexpression, driving NMPs to preferentially differentiate into posterior NTB cells and form eNTBs at the expense of intermediate mesoderm (IM). Furthermore, eNTBs likely secrete trophic factors that induce mal-patterning and ectopic positioning of the metanephric mesenchyme (MM). This therefore disrupts the normal interaction of the MM and ureteric bud (UB) required for kidney development resulting in renal agenesis and duplications of the collecting system. Interestingly, less severe Tbx6 inactivation does not yield eNTBs, but still causes renal hypodysplasia and ureteric obstruction. We found this to be due to a loss of Tbx6-dependent activation of the *Fgf9* promoter in the IM, leading to a mild depletion of this population.

Conclusions: Here we show spatially and temporally distinct mechanisms whereby Tbx6 influences urinary tract development. Severe inactivation exerts its effect through a *Kdm7a*-dependent pathway in NMPs, while less severe defects unmask a *Kdm7a*-independent, *Fgf9*-dependent effect on the IM. These findings illustrate the importance of spatially and temporally linked gene-dosage on multiorgan development and may also contribute to our understanding of regenerative medicine.

FR-OR16

TGFβ Signaling Regulates Renal Patterning via Cadm1 During Nephrogenesis

Sara Qubisi, Norman D. Rosenblum. *The Hospital for Sick Children, Toronto, ON, Canada.*

Background: Impaired nephrogenesis affects kidney health, causing childhood CKD and increasing CKD risk in adults. *Foxd1$^+$ kidney* stromal cells regulate nephron development by interacting with *Six2$^+$* nephrogenic precursors. Previously, we (Rowan CJ et al, *Development*, 2018) demonstrated that Hedgehog-GLI signaling in *Foxd1$^+$* stromal cells is required to promote murine nephrogenesis through TGFβ signaling, specifically via promoting the transformation of mesenchymal cells into epithelial cells (MET) in the *Six2$^+$* nephrogenic zone. However, the underlying molecular mechanisms that guide MET are incompletely defined. Here we aim to define molecular mechanisms by which TGFβ signaling regulates nephrogenesis.

Methods: Whole-kidney RNA seq and single-cell RNA seq to examine *Tgfβr2* deficiency in *Foxd1$^+$* stromal and *Six2$^+$* nephrogenic kidneys. We validated the bioinfrmatics data through immuno-staining and Western blot. Compound mutant mice were generated to investigate the deficiency of Cadm1 alone or both Tgfβr2 and Cadm1, followed by histological analysis, immunostaining, and nephron quantitation.

Results: Whole-kidney RNA seq (n=4) and scRNA seq (n=169 cell, P<0.001) in *Foxd1$^+$* stromal and *Six2$^+$* nephrogenic Tgfβr2-deficient kidneys identified Cadm1 (P<0.00003,P<0.0013) in *Foxd1$^+$*stromal cells as a TGFβ signaling downstream target. Western blot analysis in HEK-T293 cells (n=2) demonstrated that treatment with TGFβ1 induced CADM1 expression in a dose-dependent manner. Kidney tissue with Stromal and/or nephrogenic cell deficiency of Cadm1 exhibited normal nephrogenesis (n=2-3,P<0.01). Kidney tissue with deficiency of both *Tgfβr2* and *Cadm1* in *Foxd1$^+$* stroma exhibited renal hypodysplasia characterized by 32% reduction in kidney:body weight (n=6,P<0.0001), a 35% reduction in nephron number (n=3,P<0.05), expansion of *Six2$^+$* cells/UB tip (n=2,P<0.05), and loosely packed cortex and irregular stromal pattern (n=3). Similarly, kidney tissue with deficiency of both *Tgfβr2* and *Cadm1* in *Six2$^+$* nephrogenic cells exhibited renal hypodysplasia characterized by a 27% reduction in kidney:body weight (n=3,P<0.01), a 48% reduction in nephron number (n=2,P<0.05) and expansion of *Six2$^+$* cells/UB tip (n=3, P<0.01).

Conclusions: We conclude that Cadm1 is required for normal nephrogenesis in mice. Further, our data suggest that CADM1 may play a role in regulating the epithelialization of nephrogenic precursors under the influence of TGFβ signaling

ATP-Citrate Lyase (ACLY) Is a Key Modulator of Nephron Progenitor Cell Fate Decisions In Vivo

Giovane G. Tortelote, Fabiola Diniz, Sylvia Hilliard, Samir S. El-Dahr. Tortelote Lab. *Tulane University School of Medicine, New Orleans, LA.*

Background: Nephron endowment at birth impacts long-term renal and cardiovascular health and is contingent on the nephron progenitor cells (NPC) pool. NPC fate decisions are influenced by the cell's metabolome. Acetyl-CoA is a key molecule involved in cellular metabolism. Acetyl-CoA provides energy and serves as a metabolic intermediate necessary for cellular growth and differentiation. However, the *in vivo* requirement of Acetyl-CoA for kidney development is still unknown.

Methods: Six2^{GFPCRE};Acly$^{f/+}$ males were bred to floxed Acly homozygous female mice to generate embryos lacking Acly expression in the NPC and nephrogenic lineage. Immunofluorescence (E14.5, E16.5, and P0) and organ culture (E12.5+24h) were used to characterize the mutant phenotype. NPC and fluorescence intensity quantifications were performed with ImageJ. H&E staining was used for morphological analysis and glomeruli counts.

Results: Removal of *Acly* (a gene that regulates cytosolic availability of acetyl-CoA) from the NPC pool during embryonic development led to a reduction in glomeruli counts (≈ 30%), depletion of cap-mesenchyme (WT = 44 vs MUT = 32 NPC/niche), and increased *Wnt4* expression at birth. Cap depletion and UB abnormalities were evident at E14.5 and E16.5. Sodium-acetate supplementation to cultured E13.5 mutant kidneys rescued cap mesenchyme depletion without hindering differentiation. Furthermore, *Six2Cre*-mediated removal of *Acly* led to the upregulation of Acyl-CoA Synthetase Short Chain Family Member 2 (Acss2) in nascent proximal tubules (PT) exclusively. Upregulation of *Acss2* suggested a compensatory route for acetyl-CoA production during PT nephrogenesis. The upregulation of *Acss2* was accompanied by an increased abundance of *Hnf4a*, a key regulator of proximal tubule maturation.

Conclusions: In conclusion, our findings revealed a crucial role of acetyl-CoA metabolism during kidney development and provided insights into the molecular mechanisms underlying early nephrogenesis. In addition, we identified a new molecular target with therapeutic potential to offset the programming process during early life to prevent the development of adult kidney disease.

A Single-Cell Atlas of Human Fetal Kidneys Identifies Cell States Associated with Rare and Common Human Disease

Jonathan Levinsohn,[1] Amin Abedini,[2] Konstantin A. Kloetzer,[2] Kotaro Sasaki,[2] Katalin Susztak.[2,1] *[1]The Children's Hospital of Philadelphia, Philadelphia, PA; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Abnormal kidney development can present as congenital anomalies which can severely impact renal function. It is further thought that development may also influence more subtle phenotypes that can present later in life. Low birth weight is a risk factor for hypertension and prematurity is a risk factor for CKD.

Methods: We performed single cell RNA sequencing of 5 human fetal kidneys. We mapped developmental trajectories using RNA velocity and CellRank, creating a probabilistic model for cell differentiation in nephron development.

Results: We created an atlas of cells of human fetal kidney with a total of 65,348 cells, the largest, most comprehensive atlas of this tissue to date. This atlas demonstrates contiguous trajectories of cell states starting from a putative progenitor population to mature cell types. By examining diffusive properties within this map, we were able to identify and map previously hypothesized transitions between PTs, PECs and podocytes. We also applied this model to identify the cell states and transitions during fetal development to both common and rare human genetic disease, finding cell states that appear to be important in CAKUT, as well as cell states that influence adult eGFR.

Conclusions: We present the most complete atlas of the human fetal kidney to date. Using this atlas, we identify cell states are associated with human genetic disease and that these states are correlated by phenotype, leading to novel insights into developmental mechanisms of human disease.

Identification of Genes and Regulatory Elements Affecting Human Kidney Function

Gabriel Loeb,[1] Pooja Kathail,[2] Richard W. Shuai,[2] Ryan K. Chung,[2] Reinier J. Grona,[1] Sailaja Peddada,[3] Volkan Sevim,[4] Scot M. Federman,[3] Karl A. Mader,[3] Audrey Y. Chu,[4] Jonathan M. Davitte,[4] Shawn L. Shafer,[4] Laralynne Przybyla,[3] Nilah Ioannidis,[2,5] Jeremy Reiter.[1,5] *[1]University of California San Francisco, San Francisco, CA; [2]University of California Berkeley, Berkeley, CA; [3]Laboratory of Genomics Research/UCSF, San Francisco, CA; [4]GSK plc, San Francisco, CA; [5]Chan Zuckerberg Biohub, San Francisco, CA.*

Background: The molecular mechanisms underlying human kidney disease remain largely unknown. Genome-wide association studies (GWAS) have identified hundreds of genomic loci associated with kidney function and disease. However, the genetic variants and genes mediating the effect of most of these loci remain unclear.

Methods: We performed a genome-wide association study (GWAS) of kidney function estimated using both creatinine and cystatin C in the UK Biobank and used functionally informed fine-mapping to identify putative causal kidney function variants. To determine the effect of genetic variants implicated in kidney function, we used scATAC-seq in human kidneys, genome-wide measurements of H3K27 acetylation (CUT&RUN), and measured the effect of CRISPR-mediated perturbation of regulatory elements on gene expression.

Results: We found that 58% of kidney function SNP-heritability localized to candidate regulatory elements of kidney tubule epithelial cells, an additional 6.5% localized to podocyte candidate regulatory elements, and <1% localized within endothelial, stromal, or immune cell-specific regulatory elements. We identified putative causal kidney function variants using functionally-informed fine-mapping and used these variants to identify regulatory elements and genes involved in kidney function. In human kidneys and primary tubule epithelial cells, we assessed how kidney function variants affect chromatin accessibility and enhancer function. We found that kidney function variants alter chromatin accessibility and enhancer function within tubule epithelial regulatory elements. A pooled screen targeting kidney function noncoding regulatory elements with CRISPR interference (CRISPRi) identified novel genes involved in human kidney function.

Conclusions: By integrating human genetics and studies of enhancer function, this work provides a framework for identifying variants, regulatory elements, and genes involved in human kidney disease. The combination of fine-mapping of GWAS-nominated variants, regulatory element identification, and mapping enhancers to regulated genes provides a framework for moving from GWAS to molecular mechanisms of disease.

Genome-Wide Association Study Across Biobanks Identifies New Susceptibility Loci for Urinary Tract Infections

Katherine Xu, Atlas Khan, Ning Shang, Cecilia C. Berrouet, Tian Shen, Jonathan M. Barasch, Peter A. Sims, Krzysztof Kiryluk. *Columbia University Irving Medical Center, New York, NY.*

Background: Urinary tract infections (UTIs) represent the most common bacterial infections worldwide and if untreated, can lead to pyelonephritis, urosepsis, and severe complications. Urologic abnormalities, immunosuppression, sexual activity, and other known risk factors do not completely explain why some individuals are more susceptible to severe or recurrent UTIs. Genetic predisposition to UTIs has not been well studied.

Methods: We designed an electronic phenotype for UTIs and defined 75,485 cases and 634,538 controls across several biobanks, including eMERGE, UKBB, BioVU, and All of Us. Cases were defined by ICD9/10 codes by ≥2 events ±1 week apart in the absence of known clinical risk factors. We performed a GWAS for UTI across diverse ancestries using REGENIE, controlling for age, sex, and genetic ancestry, followed by a fixed effects meta-analysis across individual biobanks. We also performed single cell RNA-seq (scRNAseq, 10x Genomics) of kidneys from mice ±UTI (n=10). We used UPEC isolate UTI89 in bacterial growth rate and recombinant protein binding assays.

Results: Our UTI GWAS meta-analysis defined several genome-wide significant loci, including the *PSCA* locus (P=2.9E-11). This gene is specifically expressed in urothelium and kidney papilla. Based on the latest kidney eQTL datasets, the risk allele at this locus was associated with lower *PSCA* expression in the tubulointerstitial compartment (P=8.8E-39). Our scRNAseq data demonstrated its expression in the kidney pelvic epithelial cells in both infected and noninfected mice, and RNA in situ localized kidney *PSCA* exclusively to the ascending thin limbs. In binding assays, we found *E. coli* bound to human PSCA, a heavily N-glycosylated protein (initial calculations show >1000 PSCA molecules/bacterium). Co-incubation with PSCA in vitro limited bacterial growth in a dose-dependent manner (0.35μM PSCA + 1E7 CFUs: 21% reduction at 8 hours (OD600 0.71±0.01 vs 0.56±0.02, p=0.004)).

Conclusions: Our large-scale multi-biobank-based GWAS combined with kidney scRNAseq data and bacteria binding assays identified *PSCA* as a candidate causal gene in human UTIs. *PSCA* is expressed in various urinary tract epithelia and inhibits bacterial growth in vitro. Our findings suggest that PSCA plays an important role in human innate immunity against bacterial UTIs.

Empagliflozin Blunts Renal Mg2+ Wasting and Restores Distal Tubule Sodium Chloride Cotransporter (NCC) and TRPM6 Expression in Rats with Cisplatin-Induced Hypomagnesemia

James A. McCormick,[1] Erika F. Jesus,[2] Marcos V. Caetano,[2] Weverton M. Luchi,[3] Adriana C. Girardi.[2] *[1]Oregon Health & Science University School of Medicine, Portland, OR; [2]Universidade de Sao Paulo, Sao Paulo, Brazil; [3]Universidade Federal do Espirito Santo, Vitoria, Brazil.*

Background: The chemotherapeutic agent cisplatin is known to cause hypomagnesemia and renal Mg^{2+} wasting. Damage to the distal convoluted tubule (DCT), a key site of regulated Mg^{2+} reabsorption, may contribute. Recent clinical studies suggest that SGLT2 inhibitors increase serum Mg^{2+} concentration in patients with diabetes. However, the potential therapeutic use of SGLT2 inhibitors in a scenario of cisplatin-induced hypomagnesemia has not been investigated. This study tested the hypothesis that the SGLT2 inhibitor empagliflozin (EMPA) attenuates cisplatin-induced hypomagnesemia in rats through effects on the DCT.

Methods: Male Wistar rats (10 weeks of age) were treated weekly with cisplatin (2.5 mg/kg/or vehicle, i.p.) for five weeks. After three weeks of treatment, cisplatin (Cis) and vehicle-treated (Ctrl) rats were randomized and orally treated or not with EMPA (10 mg/kg/day) for two weeks.

Results: Cis-treated rats developed significant hypomagnesemia (1.42 ± 0.05 vs. 2.19 ± 0.03 mg/dl in Ctrl and 2.23 ± 0.03 mg/dl in Ctrl + EMPA, $P < 0.0001$) and increased fractional excretion (FE) of Mg^{2+} compared to control groups (14.3 ± 1.3 vs. 0.48 ± 0.10% in Ctrl and 0.65 ± 0.10% in Ctrl + EMPA, $P < 0.0001$). EMPA reduced FE Mg (2.2 ± 0.2 vs. 14.3 ± 1.3% vs. $P < 0.0001$) and restored Mg^{2+} serum levels in Cis-treated rats (2.21 ± 0.05 mg/dl). The mRNA and protein abundance of NCC and TRPM6 and NCC phosphorylation were reduced in Cis-treated rats and rescued by EMPA. EMPA-treated Ctrl rats displayed higher NCC and TRPM6 mRNA and protein expression and NCC phosphorylation levels than untreated Ctrl. The effects of cisplatin and EMPA on NCC were confirmed using a hydrochlorothiazide (HCTZ) challenge. The natriuretic response to HCTZ in Cis-treated rats was lower and in Ctrl + EMPA higher than the other groups of rats. No difference was found in the natriuretic response to HCTZ between controls and EMPA-treated Cis-rats. Remarkably, immunohistochemistry suggested that EMPA reversed Cis-induced DCT injury.

Conclusions: Empagliflozin blunts renal Mg^{2+} wasting and restores serum Mg^{2+} concentration in cisplatin-treated rats. The effects of the SGLT2 inhibitor were associated with reversal of DCT injury, rescue of expression of TRPM6, NCC, and phosphorylated NCC, and normalization of NCC activity.

Critical Role of mTORC2 in Maintaining Sodium and Potassium Balance: Implications for Aldosterone-Independent Regulation of Epithelial Sodium Channel (ENaC) in the Distal Nephron

Bidisha Saha, John E. Demko, Enzo Takagi, David Pearce. *University of California San Francisco, San Francisco, CA.*

Background: mTOR complex-2 (mTORC2) is crucial for maintaining sodium and potassium balance in the kidneys and responding to high K^+ ingestion. Recent evidence supports the idea that, in contrast to the late connecting tubule (CNT) and cortical collecting duct (CCD), ENaC activity in the late distal convoluted tubule (DCT2) and early CNT is not aldosterone-dependent. Here, we examined the role of mTORC2 in distal nephron K^+ secretion by disrupting mTORC2 expression in various distal segments and examining its effects on potassium secretion during high dietary potassium conditions.

Methods: Rictor, a core component of mTORC2, was selectively knocked out (KO'd) in specific segments of the distal nephron or throughout the entire nephron using segment-specific Cre-Lox- KO techniques. Both WT and KO mice were fed a high K^+ diet for short-term (4 h) or medium-term (48 h). Various parameters, including urinary and blood electrolytes, renal transporter expression and activity, and phosphorylation status of mTORC2 targets were assessed.

Results: Mice lacking mTORC2 in the DCT2 and CNT (using Calbindin as Cre-driver) responded to high K^+ intake in a manner resembling mice in which Rictor was KO'd throughout the nephron (using Pax8/LC1): they developed hyperkalemia, increased urine output, elevated BUN levels, lower serum sodium, and elevated plasma aldosterone levels under both short (4 h) and medium (48 h)-term high K^+ diet conditions. After 48 h under HK diet, these mice showed severe pathophysiological changes including weight loss, reduced food intake, markedly reduced GFR and listlessness. Phosphorylation of mTORC2 targets, involved in ENaC regulation (SGK1 and Nedd4-2) was also reduced in KO mice. Mice lacking mTORC2 specifically in the AQP2-expressing distal part of the CNT and CCD displayed a milder phenotype with elevated aldosterone but normal plasma [K^+].

Conclusions: The data suggest that mTORC2 activity is crucial for maintaining aldosterone-independent ENaC activity in the late DCT and preserving potassium balance during high dietary potassium intake.

FR-OR23

Role of KLHL3-S433 Phosphorylation in Potassium Homeostasis in Mice

Kenichi Ishizawa,[1,2] Ken Kaseda,[1] Osamu Yamazaki,[1] Shigeru Shibata.[1]
[1]Teikyo University School of Medicine, Itabashi-ku, Japan; [2]Shinsen Ikebukuro Clinic, Toshima-ku, Japan.

Background: Kelch-like 3 (KLHL3) is a component of an E3 ubiquitin ligase complex that binds and degrades with-no-lysine kinases (WNKs) in the kidney. Previously, we reported that volume depletion and potassium(K) changes regulate KLHL3 function by altering phosphorylation at S433, thereby regulating fluid homeostasis. The current study was designed to demonstrate the physiological importance of S433 in KLHL3 function in vivo in mice.

Methods: S433 of KLHL3 was substituted to non-phosphorylatable Ala by CRISPR/Cas9 (KLHL3-S433A knock-in mice: KI). Baseline characteristics, as well as the response to K loading and to salt restriction, were compared between wild-type (WT) and KI. Efects of intestinal K binding by sodium zirconium cyclosilicate (SZC) was also tested.

Results: KI showed a significant increase in plasma K levels that were attributable to the decreased renal excretion. KI also showed a decrease in plasma bicarbonate and an increase in blood pressure compared with WT. In KI, KLHL3 protein abundance (but not mRNA levels) was significantly reduced, which was accompanied by the increase in KS-WNK1, WNK4, and NCC, suggesting that S433 is important for the protein stability of KLHL3. In immunofluorescence, WNK1 puncta was observed not only in distal convoluted tubule but also in AQP2-positive collecting duct. In the renal cortex, K channel ROMK was decreased, not increased, in KI compared with WT. Given that $KLHL3^{S433A}$ can target WNK4 for degradation in vitro, we evaluated the response to K loading and to salt restriction. K challenge via 1% KCl did not alter plasma K in WT, while KI Plasma K increased to 1.7 mmol/L. In the kidney, NCC was significantly decreased by K in WT, whereas it remained unchanged in KI. Furthermore, although plasma K levels were significantly reduced by SZC in KI, NCC remained unaltered. Finally, increased aldosterone by a low-salt diet not alter plasma K in WT, whereas KI showed a significant reduction in plasma K in response to the same diet.

Conclusions: KLHL3-S433 regulates K homeostasis by controlling NCC and likely ROMK. The significant changes in plasma K levels in response to K loading and to volume depletion in KI indicate that the context-dependent regulation of renal K handling in high aldosterone states is compromised in this model, demonstrating the critical role of $KLHL3^{S433}$ phosphorylation in the molecular basis of aldosterone paradox.

FR-OR24

PIEZO1 Channels Are Necessary for BK Channel-Mediated Flow-Induced K+ Secretion (FIKS) in the Cortical Collecting Duct (CCD)

Rolando Carrisoza-Gaytan,[1] Stephanie Mutchler,[2] Marianela G. Dalghi,[2] Francisco Carattino,[1] Gerard Apodaca,[2] Thomas R. Kleyman,[2] Lisa M. Satlin.[1] *[1]Icahn School of Medicine at Mount Sinai Department of Pediatrics, New York, NY; [2]University of Pittsburgh Department of Medicine, Pittsburgh, PA.*

Background: BK channel-mediated FIKS in intercalated cells (IC) of the CCD requires an elevation in intracellular calcium concentration $[Ca^{2+}]_i$ triggered by hydrodynamic forces associated with an increase in tubular fluid flow rate (TFFR). This increase in $[Ca^{2+}]_i$ is proposed to be due to influx of extracellular Ca^{2+} through apical and basolateral mechanosensitive Ca^{2+} channels and release of Ca^{2+} from internal stores. We previously identified functional expression of the mechanosensitive Ca^{2+} channel PIEZO1 at the basolateral membranes of CCD principal (PC) and ICs (ASN Kidney Week, 2021). We hypothesize that PIEZO1 contributes to the flow-induced increase in $[Ca^{2+}]_i$ necessary for BK channel-mediated FIKS.

Methods: To test this hypothesis, control and conditional IC-cell *Piezo1* KO mice were fed a high K^+ diet (HK, 5% K^+) for 10 d. Isolated CCDs were microperfused *in vitro* to measure flow-induced increases in $[Ca^{2+}]_i$ and net transepithelial transport (J_X) of Na^+ and K^+ at slow and fast tubular fluid flow rates (0.9 and 5.5 nl/min·mm).

Results: Both PCs and ICs from control mice exhibited typical biphasic increases in $[Ca^{2+}]_i$ in response to an acute increase in TFFR. However, flow-induced $[Ca^{2+}]_i$ transients were significantly dampened in ICs from conditional IC-cell *Piezo1* KO mice ($p \leq 0.001$, n=4/group). Similar rates (in pmol/min.mm) of flow-stimulated J_{Na} were observed in CCDs from control (49.9±5.5) and KO (51.2±5.2, p=0.7; n=6, including 3 male and 3 female/group) mice with no significant differences between sex. FIKS, present in control CCDs (5.3±1.2), was absent in tubules from conditional KO mice (1.0±1.2; $p<0.005$). IC-cell *Piezo1* KO male mice exhibited higher blood [K^+] vs controls, 30 and 60 mins after gavage administration of 5% KCl solution (7.8±0.91 and 6.4±0.89 vs 6.5±0.35 and 5.1±0.17 mmol/L, n=6/group; p=0.01 and 0.02 respectively).

Conclusions: We conclude that mechanoactivated PIEZO1 channels mediate basolateral influx of Ca^{2+} in CCD ICs, and are indispensable for BK channel-mediated FIKS. We further speculate that basolateral PIEZO1 channels are activated by increases in membrane tension associated with an increase in TFFR.

The Role of Renal Mechanotransduction in Blood Volume Sensing

Rose Z. Hill,[1,2] Sebastian Burquez,[1,2] Sepenta Shirvan,[1,2] Jeffrey H. Miner,[3] Ardem Patapoutian.[1,2] *[1]Scripps Research Institute Department of Molecular and Cellular Neuroscience, La Jolla, CA; [2]Howard Hughes Medical Institute - Scripps Research, La Jolla, CA; [3]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: The kidneys tightly control the composition of our internal environment to maintain homeostasis in the face of external variability. For example, the regulation of blood volume begins in the kidneys and is essential for vertebrate life in terrestrial environments where salt and water availability are unpredictable. Renin release by specialized juxtaglomerular cells of the kidney is the rate-limiting step in an essential hormonal cascade that modulates blood volume, filtration, and salt balance. For several decades, it was known that renin is released in response to a loss of mechanical cues triggered by relaxation of the afferent arteriole. However, the identity and physiological significance of the mechanosensor in these cells was unknown. Here we examine the expression, function, and requirement of force-gated ion channels in renal juxtaglomerular cells.

Methods: We use in situ hybridization and immunohistochemistry to characterize the localization of force-gated ion channels in the juxtaglomerular apparatus (JGA). We generated conditional knockout mouse lines targeting stromal progenitors, cells of renin lineage, and adult-inducible pericyte-like cells, encompassing both the mesangium and the renin-expressing JG cells. We then subjected male and female mice to measurements of RAAS pathways hormones, glomerular filtration rate, and systemic blood pressure. Additionally, we isolated glomeruli from the kidneys of transgenic mice and cultured primary renin-expressing and mesangial cells for whole cell voltage clamp electrophysiology in order to measure mechanically activated currents due to force-gated ion channels.

Results: We find that loss of mechanotransduction in renin-expressing JG cells perturbs renal function and RAAS under normal conditions and subcutaneous polyethylene glycol-evoked hypovolemia. Specifically, we observe that genetic loss of mechanotransduction

enhances renin release and RAAS function and promotes glomerular hyperfiltration. Furthermore, we find that primary cultured renin-expressing and mesangial cells are mechanosensitive and express functional force-gated ion channels.

Conclusions: Our findings highlight the importance of mechanotransduction within the JGA to renal blood volume sensing and represent the first molecular and cellular characterization of JGA mechanosensitivity and the consequences of its loss *in vivo*.

FR-OR26

Kidney Tubular YAP Controls the Expression of Collecting Duct Aquaporins and Water Homeostasis

Yin Xia. *The Chinese University of Hong Kong Faculty of Medicine, Hong Kong, China*.

Background: Final urine volume and concentration are defined by water reabsorption through the water channel proteins aquaporin (AQP)-2, -3 and -4 in the collecting duct. However, the transcriptional regulation of these AQPs is not well understood. The Hippo/YAP pathway plays an important role in organ size control and tissue homeostasis. When the Hippo pathway including the Mst1/Mst2 kinases is inhibited, YAP is activated and functions as a transcription co-activator. Our previous work revealed a pathological role of tubular YAP activation in chronic kidney disease, but the physiological role of YAP in the kidney remains to be established.

Methods: Tubule-specific Yap knockout (Yap cKO) mice were generated by crossing *Yap$^{f/f}$* mice with *Ksp-Cre* mice. Tubule-specific Mst1/Mst2 double (dKO) and Mst1/Mst2/Yap triple (tKO) mice were generated by crossing *Mst1$^{f/f}$;Mst2$^{f/f}$* or *Mst1$^{f/f}$;Mst2$^{f/f}$;Yap$^{f/f}$* mice with *Ksp-Cre* mice respectively. Primary mouse medullary collecting duct cells were isolated from control and Yap cKO mice. RNA sequencing was performed on the medullae of control and Yap cKO mice at 6 weeks of age. ChIP-qPCR was performed using an YAP antiboty to determine whether YAP binds to the promotors of the Aqp2 and Aqp4 genes. Immunoprecipitation experiments were carried out to examine the interactions of YAP and GATA2, GATA3 or NFATc1.

Results: Tubule-specific Yap knockout mice showed increased urine output and decreased urinary osmolality. Decreases in Aqp2, -3 and -4 mRNA and protein abundance in the kidney were evident in Yap knockout mice. Analysis of Mst1/Mst2 double knockout and Mst1/Mst2/Yap triple knockout mice showed that expression of Aqp2 and Aqp4 but not Aqp3 was dependent on YAP. Furthermore, YAP was recruited to the promoters of the Aqp2 and Aqp4 genes and stimulated their transcription. Interestingly, YAP was found to interact with transcription factors GATA2, GATA3 and NFATc1. These three factors promoted Aqp2 transcription in a YAP dependent manner in collecting duct cells. These three factors also promoted Aqp4 transcription whereas only GATA2 and GATA3 enhanced Aqp3 transcription.

Conclusions: Our results suggest that YAP promotes Aqp2 and Aqp4 transcription, interacts with GATA2, GATA3 and NFATc1 to control Aqp2 expression, while Aqp-2, -3 and -4 exploit overlapping mechanisms for their baseline transcriptional regulation.

Calcium-Binding Protein 39 (Cab39) Is Required for Na+-Cl- Cotransporter (NCC) Phosphorylation in Mice

Mohammed Z. Ferdaus,[1] Paul A. Welling,[2] Eric J. Delpire.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Johns Hopkins Medicine, Baltimore, MD*.

Background: The Na^+-Cl^- cotransporter (NCC), expressed along the distal convoluted tubule (DCT) in the kidney, is essential for sodium and potassium homeostasis and blood pressure (BP) regulation. We showed previously that WNK4 (with-no-lysine kinase 4) phosphorylates and activates SPAK (STE20/SPS1-related proline/alanine-rich kinase), which in turn phosphorylates and activates NCC. According to *in vitro* studies, calcium-binding protein 39 (Cab39) is a scaffold that facilitates SPAK activation by stabilizing a fully active kinase conformation. Cab39 and its homolog, Cab39-like (Cab39l), are both are expressed in the DCT. A previous study published in abstract form showed that Cab39l-knockout (Cab39l-KO) mice did not exhibit differences in electrolyte homeostasis or BP compared with wild-type mice. Here we created a Cab39/Cab39l double knockout mouse to test if the adaptor proteins are necessary for WNK-SPAK-NCC signaling *in vivo*.

Methods: Inducible NCC-Cre was used to remove Cab39 along the DCT, creating DCT-specific double knockout (DKO) mice against a background of global Cab39l-KO mice. With blood electrolyte analysis, protein quantification and localization analyses were carried out using Western blotting and immunofluorescence, respectively in wild-type or single Cab39l-KO and Cab39/Cab39l double knockout (DKO) mice.

Results: We showed that phosphorylated NCC abundance, a proxy for NCC function, and total NCC abundance were significantly lower in DKO mice. Despite having higher levels of WNK4 and equal levels of total and phosphorylated (active) SPAK, DKO mice on a low K^+ diet, a known activator of NCC function, had lower blood [K^+] and significantly less phosphorylated and total NCC abundance. Importantly, SPAK was distributed in puncta in the DKO mice, compared to the apical membrane of wild-type mice.

Conclusions: Our study demonstrates that Cab39 is critical for SPAK phosphorylation and localization and NCC function. Deletion of Cab39/Cab39l along the DCT prevents SPAK activation and causes SPAK to be confined to cytosolic puncta. Mice lacking Cab39 have compromised NCC function, reminiscent of Gitelman syndrome.

Extracellular Calcium-Sensing Receptor (CaSR) and Vasopressin Type 2 Receptor (V2R) Interaction: An Emerging Mechanism to Fine-Tune Water Permeability in Renal Cells

Marianna Ranieri,[1] Yanhua Wang,[2] Ciro Leonardo Pierri,[1] Ines Angelini,[1] Annarita Di Mise,[1] Jeff M. Sands,[2] Grazia Tamma,[1] Giovanna Valenti.[1] *[1]Universita degli Studi di Bari Aldo Moro, Bari, Italy; [2]Emory University, Atlanta, GA.*

Background: We have previously shown that Extracellular Calcium-Sensing Receptor (CaSR) signaling counteracts Vasopressin type 2 Receptor (V2R) signaling in renal collecting duct cells. In collecting duct principal cells, the V2R is expressed in both the basolateral and apical membranes.

Methods: Biochemical, computational, and functional methods were used to provide evidence that CaSR and V2R interact as multimeric complex. AQP2-mediated osmotic water permeability measurements were performed to evaluate the functional CaSR/V2R interaction.

Results: In collecting duct MDC4 cells and mouse kidney, immunolocalization and confocal xz reconstruction confirmed that both the CaSR and V2R are co-expressed in the apical membrane with a significant degree of co-localization. Moreover, the CaSR co-immunoprecipitated with the V2R, and stimulation with vasopressin increased the amount of immunoprecipitated CaSR. Proximity ligation experiments confirmed CaSR/V2R interaction and their sensitivity to vasopressin stimulation. In silico comparative modeling analysis allowed us to predict a possible structure of the CaSR/V2R protein complex. Functional data obtained in isolated perfused rat inner medullary collecting duct indicated that luminal vasopressin acts as a negative feedback system to the basolateral action of vasopressin on osmotic water permeability (Pf), and luminal CaSR activation further inhibited the Pf providing a functional significance to the described receptor-receptor interaction.

Conclusions: This study opens new perspectives on the regulation of AQP2 trafficking and function not considered when the two GPCRs are viewed individually.

Inhibition of Urate Transporters and Insulin-Activated Urate Transport by SGLT2 Inhibitors

David B. Mount,[1,2] Asim Mandal.[1] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]VA Boston Healthcare System, West Roxbury, MA.*

Background: Sodium-glucose cotransporter 2 inhibitors (SGLT2i) have well-established uricosuric and urate-lowering effects, with protective effects on gout. The mechanisms of these uricosuric effects are not clear, however, and direct effects on urate transporters have not been fully investigated. We report the effects of empagliflozin, canagliflozin, and dapagliflozin on urate transport in a human proximal tubular cell line and in *Xenopus* oocytes expressing individual urate transporters.

Methods: Western blotting, *in vitro* transcription of cRNA from cloned cDNA and urate transport assays in human renal proximal tubule epithelial cells (PTC-05) and *Xenopus laevis* oocytes expressing individual human urate transporters.

Results: SGLT2 inhibitors significantly inhibited net urate uptake in a dose-dependent manner in human PTC-05 cells, which express endogenous SGLT2 and the urate transporters GLUT9a, GLUT9b, OAT10, OAT1, NPT1, ABCG2 and ABCC4. In the *Xenopus laevis* oocyte expression system, these inhibitors inhibited the basal urate transport activities of URAT1, OAT10, OAT3 and ABCC4 but not GLUT9, OAT1, and ABCG2. OAT10 was only modestly sensitive to empagliflozin and canagliflozin (~38% and 28% inhibition with 500 μM empagliflozin and canagliflozin respectively). For URAT1, the IC50s for empagliflozin, canagliflozin, and dapagliflozin were 460, 230, and 487 μM, respectively; for OAT3 the IC50s were 42, 29, and 21 μM, respectively. In addition, SGLT2i inhibited insulin-induced stimulation of urate transport in PTC-05 cells, with dose-dependent inhibitory effects on insulin-induced phosphorylation of the downstream Akt and ERK kinases.

Conclusions: These results indicate that the uricosuric action of SGLT2 inhibitors is at least partially due to direct inhibition of the apical urate reabsorptive transporters URAT1 and OAT10. Additionally, SGLT2 inhibitors inhibited insulin-activated transport in a human proximal tubular cell line, with attenuated phosphorylation of Akt and ERK; given the key role for insulin-activated urate transport in the genesis of hyperuricemia this indicates another potential mechanism for SGLT2i-associated uricosuria.

FR-OR30

ENaC Inhibition with Trimethoprim Occurs Without Changing Urinary H+ Excretion

Niklas Ayasse,[1,2] Peder Berg,[2] Samuel L. Svendsen,[2] Amalie Q. Rousing,[2] Mads V. Sorensen,[2] Natalya U. Fedosova,[2] Jens G. Leipziger.[2] *[1]Universitatsklinikum Mannheim, Mannheim, Germany; [2]Aarhus Universitet, Aarhus, Denmark.*

Background: There is growing consensus that collecting duct H^+ secretion occurs independent of changes in the transepithelial voltage (V_{te}). We recently identified a new mechanism how benzamil stimulates acute urinary alkalization. In addition to its

direct inhibition of the epithelial sodium channel (ENaC), benzamil acutely impairs H^+ excretion by blocking the H^+/K^+ ATPase. The latter effect explains benzamil's acute and marked effect on urine alkalization. However, the question remained whether inhibition of ENaC activity causes alterations in renal H^+ excretion. To revisit this question, we studied the effect of a direct ENaC inhibitor which is structurally different from benzamil. Here, we chose the antibiotic molecule trimethoprim, well-known to cause K^+ retention by direct ENaC inhibition.

Methods: *In vivo* experiments were performed in bladder-catheterized C57BL/6J mice, allowing real-time measurement of urinary pH, electrolyte, and acid excretion. Trimethoprim was administered as an intraperitoneal bolus injection (5 µg/g bw). Additionally, the effect of trimethoprim on H^+/K^+-ATPase activity was assessed *in vitro* in pig gastric H^+/K^+ ATPase enriched membrane vesicles under different pH and extracellular K^+ concentrations.

Results: We find that trimethoprim inhibits ENaC, acutely increasing natriuresis and decreasing kaliuresis, thus confirming earlier studies. However, trimethoprim had no effect on urinary pH or net acid excretion, contrasting the effects of benzamil that acutely alkalizes the urine and reduces net acid excretion. Moreover, *in vitro* experiments on isolated pig gastric H^+/K^+-ATPase proteins showed near to no effect of trimethoprim on the pump's activity, again contrasting the action of benzamil.

Conclusions: In comparison to benzamil, that inhibits both ENaC and the H^+/K^+-ATPase proteins, the renal action of trimethoprim appears to be confined to ENaC inhibition. These findings further support the hypothesis that inhibition of ENaC does not cause inhibition of H^+ secretion in the collecting duct. Thus, these results add an additional argument refuting the hypothesis of voltage-dependent H^+ secretion in collecting duct.

FR-OR31

Decoding the Spatial Transcriptomic Landscape of Diabetic Nephropathy

Qiwen Deng, Yu Liu, Nathan Bracey, Vivek Charu, Gerlinde Wernig.
Stanford University School of Medicine, Stanford, CA.

Background: Diabetic nephropathy (DN) is a major cause of chronic kidney disease globally. However, the lack of targeted treatments for renal fibrosis in DN is due to an incomplete understanding of disease progression. We generated a detailed map of human diabetic nephropathy by employing single-cell gene expression and spatial transcriptomic profiling of DN patients and controls.

Methods: We characterized the signature of diabetic nephropathy through spatial transcriptomics, analyzing eight patient biopsies using the 10x VISIUM-FFPE platform. Integrating spatially resolved transcriptomics with single-cell gene expression, we mapped cell types in space, revealing the spatial organization and structure of DN tissue. Our analysis included trajectory analysis for cell transition directions, spatial dependencies between signaling pathways and cell types, and gene-regulatory networks distinguishing DN from normal kidney tissue. Furthermore, subcellular characterization of 100 genes of interest was performed using Molecular Cartography on frozen tissues from the same patients.

Results: Deconvoluting spatial transcriptomic spots into cell-type abundances unveiled the spatial organization of kidney tissue, identifying major cell-type niches as structural building blocks. Within the glomerulus niche, we inferred a pseudotime trajectory from endothelial cells to pathogenic fibroblasts (*IGKC*+), supported by significant upregulation of *POSTN* in DN endothelial cells. We linked spatial cell composition information to cellular functions, detecting increased TGFß signaling activity in areas abundant in mesangial cells and fibroblasts. In the fibrotic niche, we observed strong dependencies between mesenchymal cells and leukocytes, highlighting the key role of macrophages in fibroblast activation. Subclustering fibroblasts and mesangial cells identified pathogenic fibroblasts (Fib 6) marked by *IGKC* and pathogenic mesangial cells (MES 2 & 3) marked by *TMSB4X*, *MYL9*, and *ACTA2*. Additionally, we discovered a novel innate immune checkpoint, *CD63*, highly expressed in DN samples and specifically overexpressed in Fib 6 and MES 2 & 3, supporting its crucial role in DN fibrogenesis.

Conclusions: Our study provides an integrative molecular map of diabetic nephropathy, serving as a vital reference for the field and facilitating advanced mechanistic and therapeutic investigations of diabetic kidney disease.

FR-OR32

Spatially Localized Mesangial Cell Communication in Diabetic Kidney Disease

Ricardo Melo Ferreira,[1] Carrie L. Phillips,[1] Mahla Asghari,[1] Debora L. Gisch,[1] Daria Barwinska,[1] Michael J. Ferkowicz,[1] Angela R. Sabo,[1] Blue Lake,[3] Timothy A. Sutton,[1] Shunhua Guo,[1] Ying-Hua Cheng,[1] Charles E. Alpers,[2] Sanjay Jain,[4] Tarek M. El-Achkar,[1] Pierre C. Dagher,[1] Katherine J. Kelly,[1] Michael T. Eadon.[1] KPMP. *[1]Indiana University School of Medicine, Indianapolis, IN; [2]University of Washington, Seattle, WA; [3]San Diego Institute of Science, Altos Labs, San Diego, CA; [4]Washington University in St Louis School of Medicine, St Louis, MO.*

Background: Substantial knowledge has been gained regarding podocyte injury in diabetic kidney disease (DKD) but less is known about the mechanisms of mesangial expansion, nodule formation, and its relationship with neovascularization. Changes in communication between injured cells serve as both a marker of disease progression and a mediator, promoting injury responses through positive feedback in surrounding cells. In this study, we aim to spatially localize changes in intra-glomerular communication between mesangial, endothelial, and epithelial cells.

Methods: We subsetted the KPMP / HuBMAP snRNAseq atlas into reference (N=11) and diabetic (N=7) samples. Using the CellChat database, we modelled cell-cell communication in glomerular cell types. The snRNAseq atlas was used as reference to deconvolute 23 kidney spatial transcriptomics samples, including reference (N=6) and diabetic (N=10). The modelled cell-cell communication and associated pathway vectors were then localized onto glomeruli with COMMOT.

Results: The cellular communication decreases in diabetic glomeruli (442) when compared to reference (1092). The overall loss of receptor-ligand interaction is more pronounced in diabetic mesangial cells, from 309 to 55 (p value < 10^{-9}, Fisher's Exact). Some of the communication absent in diabetic mesangial cells include the JAG1 - NOTCH interaction with glomerular capillaries and podocytes and the Gas6 – TAM, cell proliferation, angiogenesis and immune activation. Associated pathways were differentially represented in healthy control and DKD spatial transcriptomic samples.

Conclusions: These studies indicate a change in the intercellular communication in diabetic glomeruli. Identified pathways are potentially implicated in the process of neovascularization, mesangial expansion and glomerulosclerosis.

Interferon-γ (IFN-g) Signaling in Diabetic Kidney Disease (DKD) Associated with ESKD

Viji Nair,[1] Jennifer L. Harder,[1] Jamal El Saghir,[1] Felix H. Eichinger,[1] Shannon M. Harlan,[2] Hana Baker,[2] Frank C. Brosius,[3] Kevin L. Duffin,[2] Robert G. Nelson,[4] Matthias Kretzler,[1] Wenjun Ju.[1] *[1]University of Michigan, Ann Arbor, MI; [2]Eli Lilly and Company, Indianapolis, IN; [3]University of Arizona, Tucson, AZ; [4]National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ.*

Background: The mechanisms by which circulating pro-inflammatory factors modulate kidney signaling and disease progression in DKD remain poorly defined.

Methods: SOMASCAN plasma proteomics (n=162) and RNA profiles (n=74) from kidney biopsies of Southwest Native Americans with type 2 diabetes were used to identify differentially expressed genes (DEGs) and proteins and upstream regulators (URs) associated with progression to ESKD. Based on quantitative transcriptomic analysis, activation scores for IFN-g signaling were computed and associated with structural lesions and outcomes in DKD patients. These findings were validated in cultured human kidney cell lines, kidney tissue from 2 DKD mouse models (DBA/2 podocyte-JAK2 transgenic and uninephrectomized BKS ReninAAV db/db mice) and human kidney organoid cultures.

Results: Plasma IFN-g was upregulated in ESKD patients and identified as the top predicted UR for ESKD-associated kidney DEGs. Higher IFN-g activation scores, in both glomeruli and tubulo-interstitium correlated (r=0.40 and 0.35, respectively, p<0.05) with faster GFR decline. Participants with higher scores were more likely to reach ESKD (p<0.05). IFN-g significantly increased activation scores in cultured human kidney podocytes and proximal tubular cells (p<0.0001). Inhibition of the IFN-g pathway by a JAK1/2 inhibitor baricitinib reduced the activation scores and ameliorated albuminuria and mesangial expansion in podocyte JAK2 transgenic DBA/2 mice. Similar phenotypic improvements were observed in ReninAAV db/db uNx mice after treatment with the JAK1/2 inhibitor, ruxolitinib. Single cell profiling of IFN-g-treated organoids demonstrated the presence of IFN-g receptors and downstream target gene *CXCL10* in kidney cell types. Higher kidney organoid IFN-g scores following stimulation with IFNG were suppressed with baricitinib. Secreted CXCL10 protein strongly associated with the IFN-g activation score in organoids.

Conclusions: Circulating IFN-g levels were directly associated with alterations in kidney transcriptomic programs and the progression to ESKD in human DKD and multiple models. A clinically available drug (baricitinib) reversed IFN-g activation and albuminuria in murine models identifying IFN-g as a target for treatment in DKD.

Metabolomic and Transcriptomic Reveal Signature of Citrate Homeostasis in Diabetic Kidney Disease

Soumya Maity,[1] Christine P. Limonte,[2] Erkka A. Valo,[5] Guanshi Zhang,[1] Hak Joo Lee,[1] Subramaniam Pennathur,[7] Janet Snell-Bergeon,[6] Tina Costacou,[8] Peter Rossing,[4] Per-Henrik Groop,[9] Sourav Roy,[3] Kumar Sharma.[1] KPMP Consortium. *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]University of Washington, Seattle, WA; [3]The University of Texas at El Paso, El Paso, TX; [4]Steno Diabetes Center Copenhagen, Herlev, Denmark; [5]Folkhalsanin tutkimuskeskus, Helsinki, Finland; [6]University of Colorado Anschutz Medical Campus, Aurora, CO; [7]University of Michigan, Ann Arbor, MI; [8]University of Pittsburgh, Pittsburgh, PA; [9]Helsingin yliopisto, Helsinki, Finland.*

Background: Kidneys are highly metabolic organs, and the TCA cycle primarily fulfills the enormous energy required to maintain their normal function. In our previous cross-sectional study, low urinary citrate was associated with chronic kidney disease progression in Type 2 Diabetic patients. In this study, we performed a longitudinal targeted urinary metabolomic screening in 4 cohorts of Type 1 Diabetic (T1D) patients and single-cell RNAseq analysis of separate kidney biopsies to explore potential metabolic reprogramming in diabetic kidney disease (DKD).

Methods: Metabolomic markers for DKD progression were investigated in a case-control study of four geographically and ethnically distinct cohorts (EDC, CACTI, STENO, and FinDiane) of type 1 diabetic patients. Cases were identified among patients with yearly eGFR decline ≥3 ml/min/1.73m2, while controls had yearly eGFR decline <1 ml/min/1.73m2. 42 urinary metabolites were measured using ZipChip mass spectrometry over 1750 participants. Comparative transcriptomics analysis was conducted in 11 kidney resident cells using Kidney Precision Medicine Project (KPMP) single-cell RNAseq data sets. Spatial metabolomic analysis in kidney biopsies was performed using MALDI-MSI.

Results: Glycolic acid and three TCA cycle metabolites, citrate, succinate, and fumarate, were significantly decreased in the cases compared to the control. Among them, citrate and glycolic acid were significantly associated with rapid eGFR decline and albuminuria. Single-cell RNAseq analysis demonstrates increased fatty acid uptake, impaired β-oxidation, improved glycolysis, partially maintained TCA cycle, and mitochondrial citrate accumulation in proximal tubules of DKD patients. Spatial metabolomic analysis reveals citrate accumulation in kidney biopsies of T1D patients compared to healthy control. Proximal tubule-specific upregulation of ACLY indicates the entry of accumulated citrate in *de novo* lipogenesis. The downregulation of both apical and basolateral membrane citrate transporters SLC13A2 and SLC13A3 implies dysregulation of tubular citrate flux in DKD.

Conclusions: Low urinary citrate could be a potential marker for CKD progression in T1D patients, and intracellular citrate homeostasis could be associated with DKD progression.

Whole Blood DNA Methylation Signature, Circulating Proteins, and Risk of Progression to ESKD in Type 1 Diabetes (T1D)

Zhuo Chen,[1] Eiichiro Satake,[2,3] Marcus G. Pezzolesi,[4] Zaipul Md Dom,[2,3] Devorah O. Stucki,[4] Xiwei Wu,[5,6] Andrzej S. Krolewski,[2,3] Rama Natarajan.[1] *[1]City of HopeDepartment of Diabetes Complications and Metabolism, Arthur Riggs Diabetes & Metabolism Research Institute and Beckman Research Institute, Duarte, CA; [2]Section on Genetics and Epidemiology, Research Division, Joslin Diabetes Center, Boston, MA; [3]Department of Medicine, Harvard Medical School, Boston, MA; [4]Department of Internal Medicine, Division of Nephrology and Hypertension, University of Utah School of Medicine, Salt Lake City, UT; [5]Department of Computational and Quantitative Medicine, Beckman Research Institute of City of Hope, Duarte, CA; [6]Integrative Genomics Core, Beckman Research Institute of City of Hope, Duarte, CA.*

Background: Diabetic Kidney Disease (DKD) can progress to end stage kidney disease (ESKD) which increases morbidity and mortality. Since commonly utilized clinical variables do not adequately predict ESKD onset, there is an unmet need to update the current ESKD risk prediction model with more sensitive biomarkers. We examined whether DNA methylation (DNAme) can fulfil this need.

Methods: Using human EPIC DNAme arrays, we profiled DNAme in whole blood DNAs of 277 well characterized T1D participants with DKD (median eGFR 52.2mL/min/1.73m^2 and ACR 728.9mg/g) from the Joslin Kidney Study; 51% of our cohort developed ESKD during follow-up (7-20 years). We then performed epigenome-wide analysis followed by integration with genetics and circulating proteins data (Olink) from the same cohort, and developed statistical models including DNAme for ESKD-risk prediction.

Results: We identified DNAme at 17 CpGs associated with ESKD risk (ESKD-associated CpGs) independent of major demographic/clinical risk factors. These CpGs were located in/near genes related to pathogenesis of DKD and/or ESKD, including inflammation. Notably, 7 of these ESKD-associated CpGs had methylation quantitative trait loci SNPs. Some of these SNPs could affect binding sites for key transcription factors with functions related to DKD, suggesting novel links between genetic variants and ESKD via DNAme. Moreover, the impact of 5 of these CpGs on ESKD-risk were partially mediated by several circulating proteins previously reported to be associated with ESKD e.g. TNF-R27 and KIM1, suggesting downstream functions of these CpGs on target cells/tissues related to inflammation and renal injury. Notably, using our ESKD-associated CpGs, we developed two updated ESKD prediction models by adding DNAme at selected CpGs, or a DNAme score (imputed using selected CpGs) to the Clinical Model (using only clinical predictors). Both updated models markedly improved ESKD prediction (by 20%) compared to the Clinical Model alone.

Conclusions: Our results identified novel putative epigenetic DNAme prognostic biomarkers to significantly improve ESKD risk prediction in T1D, and uncovered molecular mechanisms of DNAme involvement in ESKD, both important for early detection and prevention.

Single-Cell Resolution Drug Effects on RAAS Blockade in ZSF1 Rat Diabetic Kidney Disease

Michael S. Balzer,[1,2] Jianfu Zhou,[1] Amin Abedini,[1] Ziyuan Ma,[1] Manuel Grundmann,[3] Mira Pavkovic,[3] Katalin Susztak.[1] *[1]University of Pennsylvania, Philadelphia, PA; [2]Charite Universitatsmedizin Berlin, Berlin, Germany; [3]Bayer AG, Leverkusen, Germany.*

Background: Diabetic kidney disease (DKD) is the leading cause of renal failure worldwide. Overactivation of the renin-angiotensin-aldosterone system (RAAS) is associated with detrimental outcomes in DKD patients. RAAS inhibitors such as enalapril have been used for decades as antiproteinuric, antihypertensive, and kidney protective agents. Still, the exact cell type of action and the main drivers of drug action remain elusive.

Methods: To this end, in addition to detailed biochemical, histological, and tissue proteomics analysis of the ZSF1 obese rat with or without enalapril treatment, we leveraged single-cell transcriptomics (scRNA-seq). We exploited state-of-the-art analyses of unbiased tensor decomposition, differential gene expression, pathway enrichment, cell trajectories, RNA velocity, weighted gene correlation networks, integration with CITE-seq imputed antibody-derived tags, and cell-cell communication. Results from the ZSF1 model were validated in human kidney samples and datasets.

Results: RAAS inhibition via enalapril ameliorated hypertension, proteinuria, kidney tissue levels of progression markers, and fibrosis in the ZSF1 rat model of DKD. ScRNA-seq highlighted immune cell enrichment, endothelial and tubular cell depletion. Unbiased tensor decomposition analysis showed distal nephron tubule cells were associated with treatment status. Enalapril downregulated cathepsin D (*Ctsd*) in diabetic distal nephron and myeloid cells. *Ctsd*+ injured tubule cells of the distal nephron were enriched in DKD and depleted upon enalapril treatment. *Ctsd* was also a marker for *Trem2*+ residential macrophages, which demonstrated an inflammatory phenotype and interacted strongly with distal nephron tubule cells. *CTSD* was particularly enriched in kidneys from DKD patients and correlated with outcome-relevant parameters such as fibrosis and glomerular filtration rate.

Conclusions: We report previously unknown injury cell states of the distal nephron, describe CTSD as an important regulator of enalapril effects, and reveal *Trem2*+ residential macrophages as top receivers of distal nephron cell-cell communication. Finally, we show that our findings translate to humans and demonstrate that enalapril-associated gene signatures allow stratification of human kidney samples by disease-relevant outcome measures such as kidney function and fibrosis.

FR-OR37

Long Noncoding RNA (lncRNA) PVT1 Induces Mitochondrial Damage and Inflammation via TRIM56 in Diabetic Kidney Disease

Zhimei Lv, Ziyang Wang, Rong Wang. *Shandong Provincial Hospital, Jinan, China.*

Background: Diabetic kidney disease (DKD), one of the chronic microvascular complications of diabetes mellitus (DM), is the leading inducement of end stage renal disease (ESRD) globally, and increasing number of studies have demonstrated that immunity and inflammation are key pathogenic mechanisms in DKD. Notably, hyperglycemia-induced mitochondrial dysfunction played a pivotal role in activating innate immunity. However, the concrete mechanisms responsible for mitochondrial damage and inflammation of podocytes during DKD remain poorly understood.

Methods: The role of *PVT1* was investigated by resorting to cultured podocytes, podocyte-specific deletion of *Pvt1* (*Nphs2-Cre/Pvt1$^{flox/flox}$*) mice and human samples. RT-qPCR, western blotting, RNA-FISH, TEM, histology staining, immunofluorescence, RIP, MeRIP, RNA pull-down, luciferase reporter assays, and Seahorse XF Cell Mito Stress Test were utilized for mechanistic study of the interaction between *PVT1*, TRIM56 and AMPKα further.

Results: We observed a significant upregulation of long non-coding RNA (lncRNA) *PVT1* in plasma of patients with DKD. And we generated mice with podocyte-specific deletion of *Pvt1* (*Nphs2-Cre/Pvt1$^{flox/flox}$*) and confirmed that *PVT1* deletion ameliorated diabetes-induced podocyte injury, glomerular pathology and proteinuria. We further demonstrated a novel role of *PVT1* in regulating podocyte mitochondrial dysfunction and inflammation through TRIM56-mediated cGAS-STING signaling pathway. Similar results were validated in podocyte-specific deletion of *Trim56* (*Nphs2-Cre/Trim56$^{flox/flox}$*) in DKD mice models. Mechanistically, *PVT1* was upregulated due to m6A demethylation under hyperglycemia conditions, and the stabilized *PVT1* involved in mitochondrial dysfunction by interacting with TRIM56 post-transcriptionally to manipulate the ubiquitination of AMPKα, which subsequently induced mitochondrial injury. Meanwhile, the cytosolic mtDNA, released from damaged mitochondria, was recognized by the cGAS-STING pathway, linking mitochondrial homeostasis disruption to inflammatory responses in podocytes. Moreover, TRIM56 could catalyze STING in a ubiquitous manner to mediate inflammation directly in podocytes under high glucose environment.

Conclusions: Our study proposes the important role of *PVT1* and TRIM56 in mitochondrial damage and inflammation, providing a potential therapeutic target against DKD.

NDUFS4 Regulates Cristae Remodeling in Diabetic Kidney Disease

Koki Mise,[1,2] Jianyin Long,[1] Jun Wada,[2] Benny B. Chang,[1] Farhad R. Danesh.[1]
[1]The University of Houston MD Anderson Cancer Center, Houston, TX; [2]Okayama University Graduate School of Medicine, Dentistry & Pharmaceutical Sciences, Okayama, Japan.

Background: Despite considerable progress in understanding the role of mitochondrial remodeling in kidney cells, the exact role and nature of mitochondrial electron transport chain (ETC) in the diabetic environment remains elusive.

Methods: We examined ETC remodeling in podocytes of established mouse models of diabetic kidney disease (DKD), and generated diabetic mice with podocyte-specific overexpression of Ndufs4 (NADH: ubiquinone oxidoreductase iron-sulfur protein 4, $Ins2^{Akita/+}$;$Ndufs4^{podTg}$), an accessory subunit of mitochondrial complex I, as a model to investigate the role of ETC integrity in DKD. APEX2 proximity labeling and complexsome profiling were performed to seek the Ndufs4 interactome in the context of mitochondrial respiratory supercomplexes (RSCs).

Results: We found that diabetic mice with conditional overexpression of Ndufs4 in podocytes ($Ins2^{Akita/+}$;$Ndufs4^{podTg}$) showed reduced albuminuria coupled with marked improvement in cristae morphology and mitochondrial dynamics. Importantly, primary podocytes from these mice exhibited increased ATP production, oxygen consumption rates, and complex I activity along with significantly reduced mitochondrial ROS and mitochondrial fission as compared to diabetic $Ins2^{Akita/+}$ mice. Using cryo-electron tomography, we found that diabetes-induced cristae remodeling was significantly improved with the forced expression of NDUFS4. By coupling proximity labeling, streptavidin pulldown assays, complexsome profiling and super-resolution imaging approaches, we identified a possible interaction between STOML2, a 39 kDa cristae shaping protein, and NDUFS4 in the context of improved supercomplexes assembly as the main explanation for the NDUFS4-mediated improvement in the cristae morphology. We further validated this interaction and found that two regions of the β-pleated sheet structures in STOM domain of STOML2 were crucial for its binding to NDUFS4.

Conclusions: Our findings uncover an unexpected role of Ndufs4 as a powerful regulator of cristae remodeling and mitochondrial dynamics. We propose that impaired mitochondrial respiration is a key defining feature of mitochondrial dysfunction in the diabetic environment, and targeting Ndufs4 could be a promising approach for developing therapies to slow the progression of DKD.

The Transcription Factor ChREBP Links Mitochondrial Lipidomes to Mitochondrial Morphology and Progression of Diabetic Kidney Disease

Jianyin Long,[1] Li Li,[1,2] Koki Mise,[1] Benny B. Chang,[1] Farhad R. Danesh.[1]
[1]The University of Texas MD Anderson Cancer Center, Houston, TX; [2]The Second Xiangya Hospital of Central South University, Changsha, China.

Background: Recent studies have suggested that both mitochondrial dynamics and lipid metabolism contribute to the pathogenesis of diabetic kidney disease (DKD). However, the precise interplay between these two key metabolic regulators is not fully understood. We recently showed that the expression of carbohydrate-response element-binding protein (ChREBP), a glucose-responsive transcription factor and a master regulator of lipogenesis, is induced by high glucose in podocytes (*J Long, et al, JBC 2020*). Here we examine the role of ChREBP on progression of DKD *in vivo* and its role as a link between mitochondrial dynamics and lipid metabolism

Methods: An inducible podocyte-specific ChREBP knockout mouse model was generated by crossing floxed ChREBP mice with tamoxifen-inducible Cre transgenic mice controlled by human podocin promoter. These mice subsequently rendered diabetic by crossing with *db/db* mice. The triple transgenic mice were assessed for kidney function, morphometric analyses and mitochondrial morphology. To explore whether ChREBP-mediated lipidomes plays a role in mitochondrial remodeling, we generated a stable ChREBP-knockdown cell line in podocytes and carried out an untargeted mitochondrial lipidomic profiling. ChIP-qPCR, site-directed mutagenesis and luciferase assay were used to validate whether glyceronephosphate O-acyltransferase (GNPAT), an enzyme involved in the *de novo* biosynthesis of plasmalogens phospholipids, serve as a direct transcriptional target of ChREBP.

Results: We find that ChREBP deficiency in podocytes of diabetic mice improves key biochemical and histological features of DKD in addition to significantly reducing mitochondrial fission. Using mitochondrial lipidomic analysis, we find that the abundance of plasmalogen, but not that of diacyl or alkyl subclasses of PC or PE, is increased by high glucose and reversed with ChREBP knockdown, suggesting a modulatory role of ChREBP on plasmalogen phospholipids biosynthesis. Importantly, overexpression of GNPAT reverses the protective phenotype of ChREBP deficiency on mitochondrial fragmentation. Finally, our findings suggest that ChREBP bind to *Gnpat* promoter to activates its transcription.

Conclusions: Our results uncover a distinct plasmalogen phospholipids as the mechanistic link between ChREBP-mediated lipid metabolism and mitochondrial remodeling.

Transcriptomics of SGLT2-Positive Proximal Tubule S1 Segments in Mice: Response to Diabetes, SGLT1/2 Inhibition, or GLP1 Receptor Agonist

Young Chul Kim,[1,2] Vivek Das,[3] Sadhana Kanoo,[2] Stephanie Stanford,[1] Nunzio Bottini,[1] Anil K. Karihaloo,[3] Volker Vallon.[1,2] *[1]University of California San Diego, La Jolla, CA; [2]VA San Diego Healthcare System, San Diego, CA; [3]Novo Nordisk Research Center, Seattle, WA.*

Background: SGLT2 inhibitors (SGLT2i) and GLP1 receptor (GLP1R) agonists have kidney protective effects. However, their molecular effects on SGLT2-expressing early proximal tubule S1 segments, which have negligible SGLT1 expression, have not been fully understood.

Methods: Fourteen week-old male wildtype (DBA) and diabetic (DBA-Akita) mice ± systemic Sglt1 knockout (ko) were given vehicle or SGLT2i dapagliflozin (Dapa; 10mg/kg diet) for 2 weeks, while other DBA-Akita received GLP1R agonist semaglutide (Sema; 3nmol/[kg body weight*day], s.c.). RNA sequencing was performed in SGLT2-positive proximal tubule segments isolated by immunostaining-guided laser capture microdissection (IS-LCM) using a Sglt2 ko-validated antibody (n=6 mice/group).

Results: Blood glucose in DBA-Akita was significantly reduced by Dapa (254±11mg/dL) and Sglt1 ko (367±11mg/dL) but not by Sema (407±44mg/dL) vs. vehicle (480±33mg/dL). A total of 20,748 annotated protein-coding genes was detected by RNA sequencing, and robust enrichment of S1 segment genes was confirmed by ranking marker genes based on the number of transcripts. DBA-Akita showed 116 differentially expressed genes vs. DBA (DEGs; adjusted $p<0.1$, log2FC +/-0.6) suggesting downregulation of metabolic pathways like unsaturated fatty acid and carboxylic acid metabolism. Dapa restored 40/116 genes and increased genes in lipid metabolic pathway, carboxylic acid metabolism and organic anion transport. Meanwhile, Dapa changed only 2 genes in DBA. Moreover, Sema and Sglt1 ko restored only 11 and 0 of the DEGs in DBA-Akita. Sglt1 ko enhanced the Dapa effect in DBA-Akita (207 DEGs and 64 restored genes) possibly due to additive effects on blood glucose (193±15mg/dl).

Conclusions: Transcriptomic profiling of SGLT2-positive S1 segments was established by IS-LCM. Despite SGLT2 expression in these segments, SGLT2i had little effect on transcriptomics in non-diabetic conditions. In diabetic mice, however, it restored transcription for multiple metabolic pathways, while targeting GLP1R or SGLT1 showed little effect. The approach warrants further studies in SGLT1-expressing S3 segments, which compensate during SGLT2i, and in glomeruli.

Effect of Dietary Acid Reduction on Acid-Base Status of Patients with CKD but with Normal eGFR: A 5-Year Randomized Trial

Nimrit Goraya,[1] Jan Simoni,[2] Maninder Kahlon,[3] Nazan Aksan,[3] Donald E. Wesson.[3] *[1]Baylor Scott and White Central Texas, Temple, TX; [2]Texas Tech University System, Lubbock, TX; [3]The University of Texas at Austin Dell Medical School, Austin, TX.*

Background: Previous studies show that high acid-producing diets contribute to metabolic acidosis in subjects with chronic kidney disease (CKD) stage G3 and to eubicarbonatemic acidosis in those with stage G2, conditions of acid accumulation that have been associated with adverse outcomes. We tested the hypothesis that high acid-producing diets have discernible effects on acid-base status of those with CKD but with normal baseline eGFR.

Methods: One hundred fifty-three macroalbuminuric, non-diabetic G1 participants with eGFR (>90 ml/min/1.73 m2) and baseline high acid-producing diets (potential renal acid load [PRAL, mean (SE)] = 61.7 (0.83) mmol/day) were randomized to Usual Care (UC, n=51) or to base-producing fruits and vegetables (F+V, n=51) in amounts to reduce dietary PRAL by half, or oral NaHCO3 (HCO3, n=51) 0.4 mmol/kg bw/day. They were followed for 5 years, measuring eGFR (CKD-EPI equation) and plasma total CO2 (PTCO2) annually and the following at baseline and 5 years: plasma citrate (Pcit), 8-hour urine citrate excretion (UcitV), and acid retention by comparing observed to expected increase in PTCO2 in response to retained HCO3 (dose minus UHCO3V) 2 hours after oral NaHCO3 bolus (0.5 mmol/kg bw), assuming 50% body weight HCO3 apparent space of distribution.

Results: Baseline values were similar among groups. For both F+V and HCO3 relative to UC, 5-year eGFR was higher ([mean (SE)], F+V [96.5(0.79)], HCO3 [95.9 (0.96)] vs. UC [92.1 (1.23), ml/min/1.73 m2, ps<0.001]). For both F+V and HCO3 relative to UC, 5-year PTCO2 was higher (PTCO2, F+V [26.7(0.08)], HCO3 [26.7 (0.08)] vs. UC [26.2 (0.09), mM, p<0.001]). For both F+V and HCO3 relative to UC, 5-year Pcit and UcitV, were higher (Pcit, F+V [0.159 (0.001)], HCO3 [0.158 (0.002)] vs. UC [0.157 (0.001), mmol/ml, p<0.02]; UcitV, F+V [1.163 (0.011)], HCO3 [1.141 (0.002)] vs. UC [1.124 (0.006), mmoles/8 hours, ps<0.05]). For both F+V and HCO3 relative to UC, 5-year acid retention was lower (acid retention, F+V [-1.19(1.61)], HCO3 [-1.72 (1.58)] vs. UC [5.23 (1.55), mmol, ps<0.003]).

Conclusions: In participants with CKD and normal eGFR eating high acid-producing diets at baseline, dietary acid reduction over 5 years with either F+V or NaHCO3 yielded small but discernible improvements in acid-base status that might mediate slower CKD progression.

FR-OR42

Supporting Self-Management of Healthy Behaviors (SMART-HABITS) in CKD and Hypertension: A Pilot Trial

Sarah J. Schrauben,[1] Adriana Purcell,[3] Andrea Bilger,[1] Sandra Amaral,[1,2] Harold I. Feldman,[1,4] Laura M. Dember.[1] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]Yale School of Medicine, New Haven, CT; [4]Patient-Centered Outcomes Research Institute, Washington, DC.*

Background: Home blood pressure monitoring (HBPM) and physical activity monitoring may have health benefits, but the feasibility and acceptability among individuals with chronic kidney disease (CKD) and hypertension (HTN) are not known.

Methods: In a 12-week study among individuals with stage 3-4 CKD and HTN, we evaluated the acceptance and feasibility of SMART-HABITS, a smartphone-based intervention to support physical activity and HBPM. Participants were asked to perform HBPM and share results at least 3x/wk and share step counts daily. For 6 weeks, two approaches to communicate HBPM were: 1) text message and 2) a smartphone application (app) connected to a Bluetooth-enabled BP machine, with the sequence determined via randomization. Step counts were monitored with a wearable device (Fitbit) and communicated via the Fitbit app for 12 weeks. Primary outcomes were 1) acceptance- assessed through surveys and interviews, and 2) feasibility- assessed with measures of adoption, adherence, and usability with the System Usability Survey (SUS). Secondary outcomes were maintenance (a HBPM or step count transmission ≥1x/wk), change in survey scores related to CKD knowledge, electronic health (eHealth) literacy, self-efficacy, self-management, QOL, BP, and daily step counts.

Results: Forty-seven participants were randomized. Mean age was 63 years, 49% women, and 48% were Black. For HBPM, 44 participants (94%) completed the text phase and 43 (92%) completed the Bluetooth phase. Adoption was reflected in a 92% retention rate, HBPM adherence was 81% in the text phase and 69% in the Bluetooth phase, and step count adherence was >83% over 12 weeks. Usability was adequate (SUS score ≥68), and participants rated SMART-HABITS as acceptable. CKD knowledge scores significantly increased (63 vs 66.7), but scores of self-management, self-efficacy, and QOL did not increase. eHealth literacy scores were inadequate at baseline (adequate score <32) and did not change. Forty-three (91.5%) participants communicated HBPM and/or step count data ≥1x/wk. Mean daily step counts significantly increased by 3414 steps, but BP did not change.

Conclusions: In this study of individuals with CKD and HTN, implementing a smartphone-based tool to support physical activity and HBPM is feasible and acceptable despite low eHealth literacy levels.

Association of Leukotriene Antagonist Use with the Incidence of ESKD

Jessica B. Kendrick,[1] Prabin Shrestha,[2] Keiichi Sumida,[2] Fridtjof Thomas,[2] Jun Ling Lu,[2] Seth B. Furgeson,[1] Kamyar Kalantar-Zadeh,[3] Csaba P. Kovesdy.[2,4] *[1]University of Colorado, Denver, CO; [2]The University of Tennessee Health Science Center, Memphis, TN; [3]University of California Los Angeles, Los Angeles, CA; [4]VA Memphis Medical Center, Memphis, TN.*

Background: Pro-inflammatory lipid mediators known as leukotrienes (LTR) have been implicated in the etiology of chronic kidney disease (CKD). We have found that short-term inhibition of cysteinyl LTRs in mice with montelukast inhibits CKD progression after acute kidney injury. Whether LTR inhibitor use is associated with a reduction in kidney disease in humans is not known. We examined the association of LTR inhibitor (LTRi) therapies with the risk of developing end stage kidney disease (ESKD).

Methods: In a national cohort of 651,509 US Veterans with a diagnosis of asthma or allergic rhinitis, we identified 50,895 incident users of LTRi (montelukast or zafirlukast) and 600,614 patients who did not receive LTRi. We examined the association of LTRi with ESKD in competing risk regressions and cause-specific Cox models. We used propensity score (PS) weighing to account for differences in demographics, comorbidities, relevant medication use and laboratory values between the two groups. ESKD was determined using USRDS data.

Results: The overall mean (SD) age was 61±13 years, 91% were male and 79% were white. The mean (SD) baseline eGFR and BMI were 73±21 ml/min/1.73m^2 and 29±6.4 kg/m^2, respectively. UACR of 30-300 and >300 mg/gm was present in 10% and 3.6% of patients at baseline, respectively. There were 4,055 cases of incident ESKD over a median follow-up of 9.8 years, with 160 events in LTRi treated patients (event rate and 95%CI: 5.0/1000PY, 4.2-5.7) and 3,895 events in untreated patients (7.1/1000PY, 6.9-7.4). LTRi use was associated with a significantly lower risk of incident ESKD in both PS-weighed competing risk regression and in a PS-weighed cause-specific Cox model (Table).

Conclusions: In this large cohort of patients with a diagnosis of asthma and allergic rhinitis, use of LTRi was associated with a lower risk of incident ESKD.

Initiation of ACE Inhibitor and ARBs in Patients with Advanced CKD

Elaine Ku,[1] Lesley A. Inker,[3] Hocine Tighiouart,[3] Charles E. Mcculloch,[1] Ogechi M. Adingwupu,[3] Tom Greene,[2] Mark J. Sarnak.[3] *[1]UCSF Medical Center, San Francisco, CA; [2]University of Utah Health, Salt Lake City, UT; [3]Tufts Medical Center, Boston, MA.*

Background: The treatment benefit of ACEi/ARB initiation on the risk of kidney failure with replacement therapy (KFRT) and mortality remains unclear in patients with CKD stage 4-5 who were not well-represented in individual trials evaluating the use of these agents.

Methods: We pooled individual-level data from 15 trials that included patients with eGFR<30 mL/min/1.73 m^2 to examine the effect of ACEi/ARB use on the risk of the onset of KFRT, or secondarily, death using Cox models. We performed pre-specified subgroup analyses and tested for interaction to evaluate the effect of ACEi/ARB inhibitor use by baseline albuminuria (<300 mg/g versus ≥300 mg/g), eGFR (≤20 versus >20 mL/min/1.73 m^2), age (<65 versus ≥65 years), race, and history of diabetes. All analyses were conducted in an intention-to-treat approach.

Results: We included 1752 participants from 15 trials, of whom 611 (35%) required KFRT and 215 (12%) died. Overall, ACEi/ARB use was associated with lower risk of KFRT (HR 0.71 [95% CI 0.60-0.83]) but not death (HR 0.95 [95% CI 0.72-1.24]). However, there was heterogeneity in the effect of the intervention on KFRT by baseline severity of albuminuria ($p_{interaction}$=0.08). ACEi/ARB initiation was associated with lower risk of KFRT in those with severe albuminuria (HR 0.68 [95% CI 0.57-0.80]), but not in those without severe albuminuria (HR 1.05; 95% CI 0.60-1.86). There was no interaction between ACEi/ARB use and baseline eGFR, diabetes, race, or age for KFRT (all $p_{interaction}$>0.10). For example, the risk of KFRT in those who started ACEi/ARBs was 0.73 (95% CI 0.57-0.94) in those with baseline eGFR ≤20 mL/min/1.73 m^2 and 0.69 (95% CI 0.56-0.85) in those with eGFR >20 mL/min/1.73 m^2.

Conclusions: Data from this pooled individual-level analysis demonstrated a benefit of ACEi/ARB use in delaying onset of KFRT, but not death in patients with stages 4-5, regardless of the baseline eGFR.

FR-OR45

Sotagliflozin and Kidney and Cardiorenal Outcomes in SCORED

David Cherney,[1] Deepak L. Bhatt,[2,3] Michael Szarek,[4] Michael J. Davies,[5] Phillip Banks,[5] Bertram Pitt,[6] Philippe Gabriel Steg.[7,8] *[1]University of Toronto, Toronto, ON, Canada; [2]Mount Sinai Heart, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]University of Colorado Anschutz Medical Campus, Aurora, CO; [5]Lexicon Pharmaceuticals Inc, The Woodlands, TX; [6]University of Michigan, Ann Arbor, MI; [7]Universite Paris Cite, Paris, France; [8]Hopital Bichat - Claude-Bernard, Paris, France.*

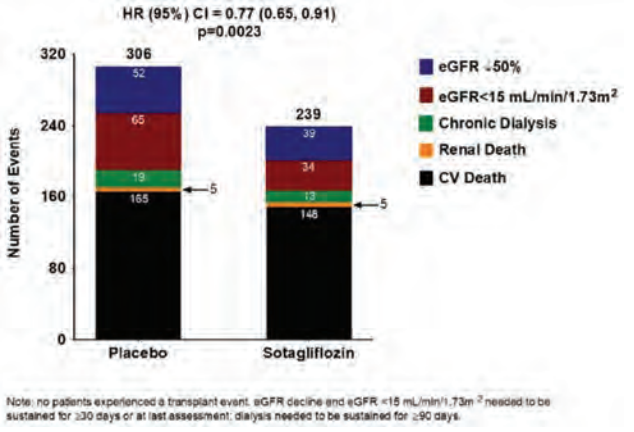
Background: SGLT2 inhibitors reduce kidney and cardiovascular (CV) outcomes in patients with and without type 2 diabetes (T2D). The aim of this exploratory analysis was to evaluate the effect of sotagliflozin (SOTA), a dual SGLT1 and 2 inhibitor, on kidney and cardiorenal outcomes in patients with T2D and chronic kidney disease (CKD).

Methods: SCORED, a Phase 3, double-blind, placebo-controlled study, randomized 10,584 patients with T2D, CKD, and CV risk factors to SOTA or placebo (1:1). Kidney criteria for inclusion were an eGFR 25 to 60 mL/min/1.73m^2 regardless of UACR. The outcomes in this analysis included kidney and cardiorenal composites derived using laboratory values, with treatment comparisons by proportional hazards models.

Results: At baseline, median eGFR was 45 mL/min/1.73m^2 and 35, 34, and 31% of patients were categorized as having normo-, micro-, and macroalbuminuria, respectively. Over a median follow up of 16 months, SOTA reduced the primary CV endpoint by 26% (p<0.001). SOTA reduced the risk of the composite of first event of 50% decline in eGFR, eGFR<15 mL/min/1.73m^2, chronic dialysis, renal transplant, or renal or CV death (p=0.0023, Figure 1). Results were generally consistent when using different eGFR decline thresholds and/or only renal death (all p<0.01, Figure 2).

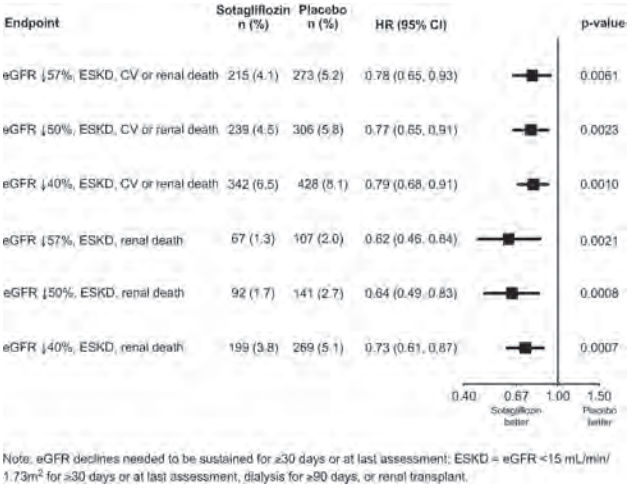
Conclusions: SOTA reduced the risk of kidney and cardiorenal endpoints in patients with T2D and CKD.

Funding: Commercial Support - Lexicon Pharmaceuticals, Inc.



Note: no patients experienced a transplant event. eGFR decline and eGFR <15 mL/min/1.73m $^{-2}$ needed to be sustained for ≥30 days or at last assessment; dialysis needed to be sustained for ≥90 days.

Figure 1. First event within cardiorenal composite



Note: eGFR declines needed to be sustained for ≥30 days or at last assessment; ESKD = eGFR <15 mL/min/1.73m² for ≥30 days or at last assessment, dialysis for ≥90 days, or renal transplant.

FR-OR46

Impact of Primary Kidney Disease on the Effects of Empagliflozin in Patients with CKD

Parminder K. Judge, William G. Herrington. On Behalf of the EMPA-KIDNEY Collaborative Group. *University of Oxford, Oxford, United Kingdom*.

Background: The EMPA-KIDNEY trial reported that empagliflozin reduced the risk of its primary composite outcome of kidney disease progression or cardiovascular death in a broad range of patients with CKD at risk of progression. We now compare effects on kidney outcomes among the different types of kidney diseases studied.

Methods: Eligible patients with eGFRs ≥20-45, or ≥45-90 ml/min/1.73m² with a urinary albumin-to-creatinine ratio of ≥200 mg/g, and receiving renin angiotensin system inhibitor, where indicated and tolerated were randomised to empagliflozin 10mg once daily vs matching placebo. Kidney disease progression was defined as a sustained ≥40% eGFR decline from randomisation or to <10 mL/min/1.73m², start of maintenance dialysis or receipt of a kidney transplant, or renal death, and the effects of empagliflozin were analysed using a pre-specified Cox model. Testing for heterogeneity of effect between pre-specified kidney disease subgroups was performed, including exploratory analyses by specific glomerular disease aetiologies.

Results: 6609 participants were followed for a median of 2.0 years. 2057 (31%) had diabetic kidney disease, 1669 (25%) had glomerular disease, 1442 (22%) had hypertensive or renovascular disease, and 1441 (22%) had other or unknown causes. Overall, empagliflozin reduced the risk of kidney disease progression by 29% (empagliflozin 384/3304 *vs* placebo 504/3305; hazard ratio 0.71, 95%CI 0.62-0.81). This relative risk reduction appeared broadly similar in subgroup analyses by primary cause of kidney disease and by different types of glomerular disease, with limited data in participants with focal segmental glomerulosclerosis (Fig. 1).

Conclusions: EMPA-KIDNEY studied a large number of patients with diabetic and non-diabetic causes of CKD and showed that empagliflozin reduced risk of kidney disease progression with relative risk reductions that were broadly similar across the different CKD aetiologies.

Funding: Commercial Support - Boehringer Ingelheim & Eli Lilly (Clinicaltrials.gov: NCT03594110).

Effect of Tirzepatide on Kidney Function in People with Excess Body Weight: A Post Hoc Analysis of the SURMOUNT-1 Trial

Hiddo J. Heerspink,[1] Allon N. Friedman,[2] Petter Bjornstad,[3] Daniël H. van Raalte,[4] Zhengyu Yang,[5] Adam Stefanski,[5] Farai B. Chigutsa,[5] Ibrahim Turfanda,[5] Mathijs Bunck,[5] Carolina Piras de Oliveira.[5] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO; [4]Amsterdam Universitair Medische Centra, Duivendrecht, Netherlands; [5]Eli Lilly and Company, Indianapolis, IN*.

Background: The prevalence of chronic kidney disease due to obesity is rapidly increasing, but few proven effective therapies are available. Tirzepatide, a glucose-dependent insulinotropic polypeptide and glucagon-like peptide-1 receptor agonist, has shown potential in attenuating the decline in estimated glomerular filtration rate (eGFR) in people with type 2 diabetes (T2D) at high risk for cardiovascular disease. In the SURMOUNT-1 trial in people with obesity or overweight without T2D, tirzepatide significantly reduced body weight and blood pressure by week 72 (the primary endpoint) compared with placebo. This post-hoc analysis assessed the potential impact of tirzepatide compared with placebo on kidney function in SURMOUNT-1 trial participants.

Methods: Data from all participants randomly assigned to treatment were included (pooled tirzepatide [5, 10, and 15 mg], N = 1896; placebo, N = 643). Assessments included CKD-EPI creatinine- and cystatin-C-based eGFR (Cr-eGFR and CysC-eGFR, respectively), and urine albumin-to-creatinine ratio (UACR). The change from baseline to week 72 was analyzed using a mixed model for repeated measures with on-treatment data.

Results: Baseline mean Cr-eGFR was 98.1±18.0 mL/min/1.73m² and CysC-eGFR was 95.5±19.1 mL/min/1.73m²; 27%-36% of participants had mean eGFR <90 mL/min/1.73m². Baseline median UACR was 6.0 mg/g (interquartile range 4.0-11.0 mg/g); 8.6% of participants had UACR ≥30 mg/g. The estimated treatment difference (ETD) between pooled tirzepatide groups and placebo on the change from baseline Cr-eGFR was -0.2 mL/min/1.73m² (95% confidence interval [CI] -1.2, 0.9; p=0.780). For CysC-eGFR the ETD was 3.2 mL/min/1.73m² (95% CI 2.1, 4.3; p<0.001). The ETD on the percent change in UACR was -8.4% (95% CI -14.7, -1.6; p=0.017). In participants with baseline UACR ≥30 mg/g, the ETD was -42.3% (95% CI -60.8, -15.0; p=0.006).

Conclusions: Tirzepatide demonstrated an increase in CysC-eGFR and reductions in UACR compared with placebo, suggesting renoprotective effects. These results warrant a long-term, prospective kidney outcome trial for people with obesity or overweight.

Practice Patterns for Patient Pain Control and Outcomes Among CKD Patients: A CKDopps Analysis

Nikhil Nair,[1] Murilo H. Guedes,[2] Natalia Alencar de Pinho,[5] Charlotte Tu,[2] Brian Bieber,[2] Helmut Reichel,[6] Christos Argyropoulos,[7] Roberto Pecoits-Filho,[2] Rupesh Raina.[3,4] *[1]Case Western Reserve University School of Medicine, Cleveland, OH; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Akron Children's Hospital, Akron, OH; [4]Cleveland Clinic Akron General, Akron, OH; [5]Centre de Recherche en Epidemiologie et Sante des Populations, Villejuif, France; [6]Scientific Institute for Nephrology, Dusseldorf, Germany; [7]University of New Mexico School of Medicine, Albuquerque, NM*.

Background: Chronic kidney disease (CKD) patients often suffer from poorly managed pain. Opioid and analgesic abuse is of concern. This study examines international pain management practices for non-dialysis-dependent CKD patients and the association between pain and patient-reported outcomes.

Methods: Data from the CKD Outcomes and Practice Patterns Study, a cohort of Stage 3-5 CKD patients from Brazil, France, Germany, and the US, were analyzed. Self-reported pain was assessed using the Kidney Disease Quality of Life Short Form, and analgesic prescriptions were categorized. Outcomes included depression, functional status, health-related quality of life and prescription practices.

Results: The study included 4,160 patients. A majority reported some degree of pain interference, with levels varying with CKD stage and country. Extreme pain was associated with eGFR and higher BMI. Analgesic prescriptions, notably NSAIDs and

opioids, were most frequent in the US followed by Germany, Brazil and France. Pain levels were directly associated with poorer health-related quality of life, with patients reporting lower general health, physical function, and emotional well-being. Patients who were prescribed analgesics reported similar levels of health-related quality of life to those not prescribed. Patients prescribed analgesics were more often females, had lower eGFR, slightly higher BMI, and were more commonly diagnosed with cardiovascular and psychiatric disorders.

Conclusions: The results highlight a significant pain burden in CKD patients and variations in international pain management practices. The findings emphasize the importance of improved pain management strategies in CKD care, necessitating comprehensive pain assessment, patient education, and consideration of pharmacokinetic alterations due to CKD. Consensous pain management guidlines and discussions are imperative.

Implications of Follow-Up Time on the Optimal Weighting of the Acute and Chronic Slopes to Predict Treatment Effects on Clinical End Points

Tom Greene,[1] Lesley A. Inker,[2] Hiddo J. Heerspink.[3] CKD-EPI(CT).
[1]University of Utah Health, Salt Lake City, UT; [2]Tufts Medical Center, Boston, MA; [3]Universiteit Groningen Afdeling Gezondheidswetenschappen, Groningen, Netherlands.

Background: We have shown in a meta-analysis of 66 randomized treatment comparisons (RTCs) that treatment effects on the established clinical endpoint (CE) based on doubling of serum creatinine (SCR), GFR ≤ 15 ml/min/1.73m^2 or kidney failure are in aggregate predicted accurately by the mean GFR slope over 3 years. We evaluate implications of follow-up time for the optimal weighting of the acute and chronic GFR slopes to predict treatment effects on the CE.

Methods: For each RTC, we used a mixed effects model to estimate treatment effects on the acute (evaluated from baseline to 3 months) and chronic (evaluated after 3 months) GFR slopes, and Cox regression to estimate treatment effects on the CE. We used an extended multivariable Bayesian meta-regression model to relate the treatment effects on the CE jointly to those on the acute and chronic slopes. The extended model expresses the optimal weighted average of the acute and chronic slopes as $\alpha\times$[*Acute Slope*]+(1-α)$\times$[*Chronic Slope*], and allows α to depend on the median follow-up time of each RTC.

Results: The multivariable model accurately predicted the treatment effect on the CE (median R^2 = 0.97 for a RTC with 3 years follow-up). The optimal weight α for the acute slope relative to the chronic slope had a strong inverse relationship with the median follow-up time, decreasing from a median (95% Bayesian credible interval) of 0.105 (0.065, 0.154) at 2 years by 34% to 0.069 (0.049,0.091) at 3 years and by 65% to 0.037 (0.013,0.075) at 4.5 years.

Conclusions: The optimal weighting of the acute and chronic slopes for predicting the treatment effect on the CE assigns a major role to the acute effect when the CE is evaluated over a relatively short follow-up time typical of some CKD trials, but deemphasizes the acute effect and more closely approximates the chronic slope when the CE is evaluated over longer follow-up times which are relevant to patients.

Funding: Private Foundation Support

Effect of Follow-up Time on Optimal Weighted Average of Acute and Chronic Slopes

Term	Median	95% Bayesian CI
Intercept	-0.02	(-0.08, 0.04)
% hazard reduction in the CE per 0.75 ml/min/1.73m2/year greater effect on optimal weighted average of the acute and chronic GFR slopes	33%	(27%,38%)
Optimal α when evaluating CE over 2 years	0.105	(0.065,0.154)
Optimal α when evaluating CE over 3 years	0.069	(0.049, 0.091)
Optimal α when evaluating CE over 4.5 years	0.037	(0.013,0.075)
Trial level R2 with follow-up standardized to 3 years	0.97	(0.82, 1.00)

Improvement in Anemia by SGLT2 Inhibitors Were More Prominent Among Those with Inflammation

Miho Murashima, Takahisa Kasugai, Tatsuya Tomonari, Minamo Ono, Masashi Mizuno, Takayuki Hamano. *Nagoya Shiritsu Daigaku, Nagoya, Japan.*

Background: SGLT2 inhibitors (SGLT2i) were reported to increase hemoglobin (Hb) by suppressing hepcidin and increasing erythropoietin, similar to hypoxia-inducible factor prolyl hydroxylase (HIF-PH) inhibitors. We hypothesized that an increase in Hb by SGLT2i might be more prominent among patients with inflammation similar to HIF-PH inhibitors.

Methods: In this retrospective cohort study, diabetic outpatients from 2019 to 2020 at our hospital were enrolled. Exposure was the use of SGLT2i. The Hb slope within 6 months after initiation of SGLT2i (the first 6 months of the observation period for non-users) was analyzed using a mixed-effects model. Non-linear regression models were fitted with restricted cubic splines to investigate Hb levels at the last visit across different eGFR levels. Analyses were performed separately for those with higher and lower than the median baseline C-reactive protein (CRP) levels. The data were adjusted for potential confounders.

Results: Among 1,246 patients, 306 were on SGLT2i. During the first 6 months, CRP and eGFR trajectories were not significantly different between users and non-users of SGLT2i. Differences in Hb slope between users and non-users of SGLT2i were 0.14 (0.05–0.24) and 0.05 (-0.05–0.15) g/dL/month for those with higher and lower baseline CRP, respectively, after adjustment for confounders including time-dependent eGFR. Hb levels at the last visit were significantly higher among SGLT2i users across the range of eGFR levels, and it was more prominent among those with higher CRP (p for interaction<0.1).

Conclusions: SGLT2i use was associated with higher Hb levels, especially among those with inflammation across the range of eGFR levels. The results suggest that SGLT2i could improve anemia among patients with anemia of chronic kidney disease and inflammation which are refractory to treatment with erythropoiesis-stimulating agents.

Membranous-Like Glomerulopathy with Masked Immunoglobulin G (IgG) Kappa Deposits: A Clinicopathologic Analysis of 247 Patients

Tiffany Caza,[1] Samar Hassen,[1] Meryl Waldman,[3] Nicole K. Andeen,[2] Christopher P. Larsen.[1] *[1]Arkana Laboratories, Little Rock, AR; [2]Oregon Health & Science University, Portland, OR; [3]National Institutes of Health, Bethesda, MD.*

Background: Membranous-like glomerulopathy with masked IgG kappa deposits (MGMID) is a rare autoimmune kidney disease that disproportionately affects young women and causes proteinuria and progressive chronic kidney disease. Since discovery of serum amyloid P (SAP) as a specific biomarker, there is increased recognition and the pathologic spectrum has broadened. Here, we examine 247 patients with MGMID to characterize histopathology and outcomes.

Methods: Patients with a diagnosis of MGMID were identified from 3 institutions. Clinical and laboratory data at the time of biopsy and at follow-up were obtained. Histopathology was reviewed, including light microscopy (LM), routine and paraffin immunofluorescence (IF), electron microscopy (EM), and immunostaining for SAP.

Results: 286 kidney biopsies corresponding to 247 patients with MGMID were identified, including 278 native and 8 allografts. LM demonstrated mesangial hypercellularity in 42%, segmental sclerosis in 68%, endocapillary hypercellularity in 8%, and fibrinoid necrosis and/or crescents in 9%. Over one-third had significant tubulointerstitial fibrosis. On IF, the majority of cases had 'masked' immune deposits without IgG staining on frozen sections (76%). SAP immunostaining was positive in all cases tested. EM showed subepithelial deposits and mesangial deposits in 86%. Of patients with follow-up (n=166), 58% achieved complete or partial remission, 42% had no remission or disease progression of which 9% developed ESKD. Disease flares occurred in 16%. The majority of patients received RAAS blockade and immunosuppression varied (see table).

Conclusions: MGMID has multiple histopathologic patterns and variable outcomes. Further follow-up is ongoing to identify the clinical impact of different treatments on disease progression.

Clinical data		Histopathology	
Demographics		Light microscopy

Clinicopathologic features of MGMID

FR-OR52

The Characteristics of Concurrent Anti-Glomerular Basement Membrane Nephritis and Membranous Nephropathy

Lihong Bu,[1] Samar M. Said,[2] Loren P. Herrera Hernandez,[1] Benjamin J. Madden,[1] Christopher P. Larsen,[3] Youngki Kim,[4] Sanjeev Sethi,[1] Samih H. Nasr.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Olmsted County Medical Center, Rochester, MN; [3]Arkana Laboratories, Little Rock, AR; [4]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Concurrent anti-glomerular basement membrane (GBM) nephritis and membranous nephropathy (MN) is rare and has been previously addressed only in case reports and small series (≤12 patients). Its target antigen is unknown.

Methods: We studied the clinicopathologic characteristics and outcome of 28 patients with anti-GBM nephritis and MN diagnosed at a large nephropathology laboratory over a 23-year period. A pathologic diagnosis of anti-GBM nephritis was defined by the immunofluorescence finding of intense linear GBM staining for IgG, in the absence of (or much weaker) staining for albumin, and concurrent MN was defined by the presence of segmental or global subepithelial deposits by electron microscopy.

Results: These cases are among 449 (6.2%) anti-GBM nephritis and 5183 (0.5%) non-lupus MN. The patients were 57% male and a median age of 54 years (range 15-82) at diagnosis. Most (96%) patients presented with acute kidney injury with a median serum creatinine at biopsy of 7.8 mg/dL (range 1.2-24.0), proteinuria (median 3.5 g/day, range 0.4-11) and hematuria. Kidney biopsy showed classic (n=26) or atypical (n=2) anti-GBM nephritis. Most patients received immunosuppressive therapy. After a median follow up of 17 months, 11% had complete remission (including the 2 with atypical anti-GBM nephritis), 27% had persistent kidney dysfunction, 62% progressed to ESKD. The rate of progression to ESKD was 93% in those on dialysis at presentation. The dominant IgG subclass of granular staining was different from that of linear staining, a feature facilitating the recognition of granular staining and thus the diagnosis of concurrent MN, particularly when EM unavailable. Immunostains for PLA2R, THSD7A, NELL-1 and EXT2 was negative in all cases tested. Proteomic analysis (n=8) of glomeruli did not detect any of the known or novel target antigens.

Conclusions: Concurrent classic anti-GBM nephritis and MN has poor prognosis, particularly in patients requiring dialysis at presentation, while atypical anti-GBM nephritis and MN has a favorable outcome. It is not associated with any of the known MN antigens and no novel target antigen(s) detected by mass spectrometry, favoring that the MN target antigen is likely an exposed structural GBM antigen.

FR-OR53

Clinicopathologic Features of Anti-Brush Border Antibody Disease: A Series of 66 Patients

Joel D. Murphy,[1] Tiffany Caza,[1] Clarissa A. Cassol,[1] Patrick D. Walker,[1] Shree G. Sharma,[1] Josephine M. Ambruzs,[1] Christie L. Boils,[1] Nicole K. Andeen,[2] Matthew Palmer,[3] Anatoly Urisman,[4] Christopher P. Larsen.[1] *[1]Arkana Laboratories, Little Rock, AR; [2]Oregon Health & Science University, Portland, OR; [3]Penn Medicine, Philadelphia, PA; [4]University of California San Francisco, San Francisco, CA.*

Background: Anti-brush border antibody disease (ABBA) is an autoimmune tubulointerstitial kidney disease that primarily affects older individuals and results in progressive kidney failure. It is a rare entity with only 20 cases reported to state. Therefore, the histopathologic spectrum, clinical associations, prognosis, and response to therapy are poorly understood.

Methods: We performed a retrospective clinicopathologic analysis of kidney biopsies and identified 66 cases with ABBA including 63 native and 3 recurrence in an allograft identified from 4 institutions. Demographics, clinical findings, and laboratory data were obtained. Histopathologic data included light, immunofluorescence, electron microscopy, and immunostaining for LRP2, CUBN, and AMN. Follow-up data was available from 49 patients, examining treatment(s), laboratory values, and outcome measures.

Results: Patients with ABBA were predominantly male (74%) with a mean age of 70.0 ± 12.3 years. Progressive chronic kidney disease was the most common biopsy indication. The mean serum creatinine was 3.5 ± 2.6 mg/dL, proteinuria 2.7 ± 2.9 g/day, and 66% had hematuria. Acute tubular injury with LRP2-positive tubular basement membrane deposits were seen in 94% patients, with one case demonstrating CUBN and AMN positivity in addition to LRP2. Thirty-eight patients (57.6%) had secondary diagnoses, most commonly glomerular diseases with high proteinuric states. These included podocytopathies, membranous nephropathy, IgA nephropathy, lupus nephritis, crescentic glomerulonephritis, acute or chronic tubulointerstitial nephritis, and renal involvement by B-cell lymphoma. The majority of patients with available follow-up data were treated with immunosuppression (73.5%). Complete or partial remission was achieved for 32.7%, 67.3% had no remission, and 22.5% required dialysis or were deceased at follow-up. Patients not treated with immunosuppression were at the highest risk of kidney failure.

Conclusions: ABBA is frequently concurrent with other kidney diseases, which may lead to under-diagnosis of this important cause of kidney failure.

FR-OR54

Clinicopathologic Characteristics, Etiologies, and Outcomes of Secondary Oxalate Nephropathy

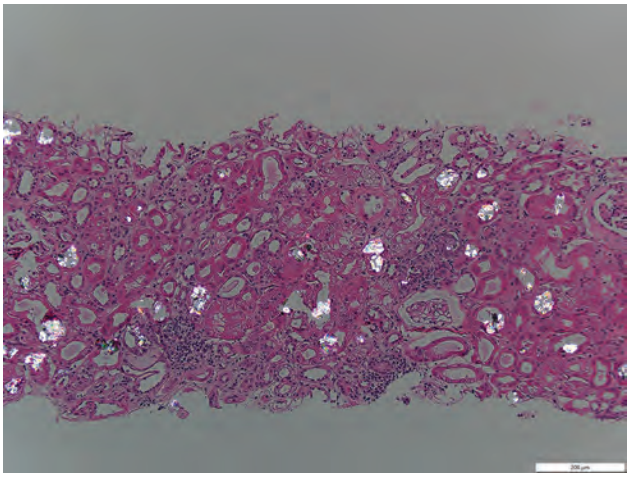
Samih H. Nasr,[1] Anthony M. Valeri,[3] Samar M. Said,[2] Sanjeev Sethi,[1] Karl A. Nath,[1] John C. Lieske,[1] Lihong Bu.[1] *[1]Mayo Foundation for Medical Education and Research, Rochester, MN; [2]Olmsted County Medical Center, Rochester, MN; [3]Columbia University, New York, NY.*

Background: The characteristics of secondary oxalate nephropathy (ON) are not well define, and the rate of recurrence after kidney transplant (Tx) and Tx outcome are unknown. We report the largest series on secondary ON to date

Methods: Retrospective analysis of clinicopathologic and outcome characteristics of 113 patients with secondary ON in the native kidney diagnosed at a large tertiary care academic center.

Results: Biopsy incidence was 0.97%. ON was attributed to enteric hyperoxaluria in 60% (most commonly RYGB), excessive ingestion of foods high in oxalate or oxalate precursors in 23% (most commonly vitamin C), and was idiopathic in 17%. Most patients presented with AKI (particularly in the ingestion group) or AKI on CKD, and 63% were diabetic. Calcium oxalate (CaOx) crystals were more abundant in the ingestion than enteric group, and were accompanied by acute tubular injury, inflammation, and interstitial fibrosis and tubular atrophy (IFTA). Concurrent pathologic conditions were present in 53%, most commonly diabetic nephropathy. After a median follow up of 36 months, 27% had kidney recovery, 19% had persistent kidney dysfunction, 54% developed kidney failure, and 29% died. The mean kidney survival was worse for patients with a concurrent pathologic lesion (30 vs. 96 months for those without, $p<0.001$). Independent predictors of kidney failure were degree of IFTA and nadir eGFR but not degree of crystal deposition. After a median follow up of 58 months in 23 patients who received kidney TX, 4 had graft loss (due to ON in 3). The 2-, 5-, and 10-year graft survivals were 90%, 79%, and 50%.

Conclusions: ON is a rare cause of AKI or AKI on CKD. Most patients have co-morbid pathologic conditions, particularly diabetic nephropathy, which worsen the prognosis. Recurrence in the renal allograft and graft loss may occur if hyperoxaluria is not controlled.



Abundant calcium oxalate crystals are seen under polarized light

Computationally Derived Tubular Features Are Prognostic of Clinical Outcomes in Glomerular Kidney Diseases

Fan Fan,[1] Qian Liu,[2] Jarcy Zee,[2,3] Takaya Ozeki,[4] Dawit S. Demeke,[5] Bangchen Wang,[6] Laura H. Mariani,[4] Kyle J. Lafata,[7] Yijiang Chen,[1] Lawrence B. Holzman,[8] Jeffrey B. Hodgin,[5] Anant Madabhushi,[9,10] Laura Barisoni,[6,11] Andrew Janowczyk.[9,12] *[1]Department of Biomedical Engineering, Case Western Reserve University, Cleveland, OH; [2]The Children's Hospital of Philadelphia Research Institute, Philadelphia, PA; [3]Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]Department of of Internal Medicine, University of Michigan, Ann Arbor, MI; [5]Department of Pathology, University of Michigan, Ann Arbor, MI; [6]Department of Pathology, Duke University, Durham, NC; [7]Department of Radiation Oncology, Duke University, Durham, NC; [8]Department of Medicine, Division of Nephrology and Hypertension, University of Pennsylvania, Philadelphia, PA; [9]Department of Biomedical Engineering, Emory University and Georgia Institute of Technology, Atlanta, GA; [10]Atlanta Veterans Administration Medical Center, Atlanta, GA; [11]Department of Medicine, Division of Nephrology, Duke University, Durham, NC; [12]Department of Oncology, Division of Precision Oncology & Department of Clinical Pathology, Division of Clinical Pathology, University Hospital of Geneva, Geneva, Switzerland.*

Background: The visual semiquantitative assessment of chronic and acute tubular damage has limited reproducibility and prognosticating/predictive power. We hypothesize that sophisticated, computationally assessed, domain-inspired tubular pathomic features can enhance prognostication of proteinuria diseases.

Methods: We developed and applied tubular segmentation algorithms for tubular lumen (TL), epithelium (TE), nuclei, and basement membranes (TBM), to 235 PAS NEPTUNE/CureGN PAS-stained whole slide images (124 FSGS,111 MCD/MCD-like). From these segmentations, 56 features were extracted and summarized at the patient level. We used MRMR to select 10 features most prognostic for time from biopsy to 40% eGFR decline/kidney failure, and proteinuria remission, and Ridge regression models to estimate prognostic accuracy.

Results: Features (Fig.2-A), reflecting TE simplification and TBM thickening/smoothing, were most prognostic of disease progression; when added to other parameters, they increased prognostic accuracy for both outcomes (Fig.2-B).

Conclusions: Computational quantification of tubular pathomic features provides prognostic information above routine measures in glomerular diseases.

Quantitative Characterization of Nonsclerotic Glomeruli Is Prognostic of Clinical Outcomes in Proteinuric Diseases

Akhil Ambekar,[1,2] Qian Liu,[3] Jarcy Zee,[3,4] Bangchen Wang,[1] Clarissa A. Cassol,[5] Laura H. Mariani,[6] Lawrence B. Holzman,[7] Jeffrey B. Hodgin,[8] Anant Madabhushi,[9,10] Kyle J. Lafata,[11] Laura Barisoni,[1,12] Andrew Janowczyk.[9,13] *[1]Department of Pathology, Division of AI & Computational Pathology, Duke University, Durham, NC; [2]AI Health, Duke University, Durham, NC; [3]Children's Hospital of Philadelphia Research Institute, Philadelphia, PA; [4]Department of Biostatistics, Epidemiology, and Informatics, University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [5]Arkana Laboratories, Little Rock, AR; [6]Department of Internal Medicine, University of Michigan, Ann Arbor, MI; [7]Department of Medicine, Division of Nephrology and Hypertension, University of Pennsylvania, Philadelphia, PA; [8]Department of Pathology, University of Michigan, Ann Arbor, MI; [9]Department of Biomedical Engineering, Emory University and Georgia Institute of Technology, Atlanta, GA; [10]Atlanta Veterans Administration Medical Center, Atlanta, GA; [11]Department of Radiation Oncology, Duke University, Durham, NC; [12]Department of Medicine, Division of Nephrology, Duke University, Durham, NC; [13]Department of Oncology, Division of Precision Oncology and Department of Clinical Pathology, Division of Clinical Pathology, University Hospital of Geneva, Geneva, Switzerland.*

Background: Visual assessment of segmentally (SS), globally (GS) and non-GS/SS glomeruli is used clinically for the diagnosis and prognostication of glomerular diseases. We hypothesized that encoded in non-GS/SS glomeruli are computationally derivable subvisual features prognostic of outcome.

Methods: N=186 (99 MCD/MCD-like, 87 FSGS) patients from the NEPTUNE/CureGN cohorts with at least one PAS whole slide image (WSI) containing ≥4 non-GS/SS glomeruli were included. A previously validated pipeline for glomerular segmentation and classification was applied to WSIs, yielding 272 GS, 113 SS, and 2661 non-GS/SS glomeruli. Percent of SS and GS was calculated. From non-GS/SS glomeruli, 108 intensity, shape, and texture features were computed. Patient-level summary statistics were produced using mean, standard deviation, kurtosis, minimum, maximum, and median. Maximum Relevance Minimum Redundancy (MRMR) selected the 10 most prognostic features for time from biopsy to disease progression (≥40% eGFR decline with last eGFR<90 or kidney failure), and to first complete proteinuria remission (UPCR<0.3). Ridge regression models estimated prognostic accuracy of non-GS/SS glomerular features.

Results: Prognostic features (Table 1) reflect the heterogeneity of intra-glomerular organization. These features were the most prognostic of disease progression compared to other models and increased the prognostic accuracy of both clinical outcomes when added to conventional parameters (Table 2).

Conclusions: Computational methods allow for extraction from non-GS/SS glomeruli of information prognostic of clinical outcomes above and beyond conventional

methods. This novel approach may enable early diagnosis and facilitate risk-stratification independently from the presence of conventional diagnostic lesions of sclerosis.

A Spatial Atlas of the Human Kidneys of Cell Types and Functional Tissue Units Identified in Highly Multiplexed Immunofluorescence Images

Seth Winfree,[1] Angela R. Sabo,[2] Daria Barwinska,[2] Ying-Hua Cheng,[2] William S. Bowen,[2] Michael J. Ferkowicz,[2] Ricardo Melo Ferreira,[2] Madhurima Kaushal,[3] Joseph Gaut,[3] Michael T. Eadon,[2] Tarek M. El-Achkar,[2] Sanjay Jain.[3] *[1]University of Nebraska Medical Center, Omaha, NE; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Washington University in St Louis, St Louis, MO.*

Background: Kidney tissue can be defined at the cell level and at the level of unique functional tissue units (FTUs, e.g. glomeruli and tubules). FTUs are tightly linked to the spatial organization of the kidney. Several single cell transcriptomic atlases have been developed for the kidney, but a spatially anchored comprehensive atlas for cell types and FTUs based on protein expression has yet to be described.

Methods: Mesoscale sequential sections from reference kidney tissue spanning from cortex to papilla were imaged using Fusion-Phenocycler, a mesoscale highly multiplexed fluorescence imaging platform. 40 markers were used to identify major cell types (epithelial, immune, endothelial), states (stress, repair, cycling) and FTUs. An analytical pipeline was developed to perform image registration, followed by cell and FTU segmentation, labeling, mapping, and neighborhood definition.

Results: Over 4 million cells from 5 donors and 18 tissue sections were incorporated in the analytical pipeline, which resulted in the identification of over 30 cell types distributed across the kidney and localized in structures that align with FTU ontologies. A cell-based neighborhood analysis captured tubular niches unique to the renal cortex and outer or inner stripe of the medulla. This spatial segregation was complemented with interstitial niches unique to the cortex or medulla. FTU segmentations mapped the major FTUs of the kidney, including vasculature, glomeruli, several tubules and interstitium. Using sequential sections interrogated with Fusion-Phenocycler, FTU segmentation were used to generate 3D models of renal FTUs highlighting the 3D arrangement of kidney FTUs.

Conclusions: We establish a reference mesoscale spatial atlas to define anatomically and functionally distinct compartments of the kidney with single cells and FTUs. This work begins to define: 1) the 3D relationship of FTUs, including the relationship between vasculature and tubules, 2) a comprehensive map of cell-types in the human kidney and their organization into FTUs and the how cellular niches vary across the kidney. This atlas provides a cellularly resolved and spatially anchored reference to understand kidney function in health and disease.

Multiplexed Single-Nucleus RNA and ATAC Sequencing in the Renal Biopsy Specimen

Lubin Xu,[1] Yun Li,[2] Zheng Huang,[2] Minxian Wang,[2] Lan Jiang,[2] Limeng Chen.[1] *[1]Peking Union Medical College Hospital, Dongcheng-qu, China; [2]Beijing Institute of Genomics Chinese Academy of Sciences, Beijing, China.*

Background: Multi-omic technology allows simultaneous transcriptomic and epigenomic profiling in various kidney cell types, bringing about opportunities to identify crucial pathways, novel biomarkers, and physiology-relevant disease subtypes, while limited by cost and the amount of tissue required.

Methods: We developed a novel multiplexed droplet-based single-cell/nucleus sequencing technique to achieve higher throughput and lower cost with less tissue. We applied this method to simultaneously profile transcriptomic (RNAseq) and chromosomic access (ATACseq) data in 27 patients who underwent renal biopsy due to various kidney diseases, ten time-zero transplant biopsy samples, and seven paracancerous kidney samples.

Results: After quality control, we yielded about 120,000 nuclei (mean nuclei number 2727 per sample) with both transcriptomic and epigenomic profiling data. For snRNAseq, the median gene number per cell is more than 1100. For snATAC-seq, the median fragments number per cell is about 6000, and the TSS enrichment score is 8.83. Major renal cells types including proximal tubule cells, descending thin limb cells, thick ascending limb cells, distal convoluted tubule cells, connecting tubule cells, principal cells, intercalated cells, podocytes, endothelial cells, vascular smooth muscle cells, as well as infiltrating B cells, T cells, and fibroblasts can be robustly identified from the snRNAseq dataset.

Conclusions: We developed a novel single-nucleus multi-omic approach that offers rich transcriptomic and epigenomic data, showing promise as a molecular renal pathology technique.

T Cell-Receptor (TCR)-Independent Activation of CD8 Effector T Cells by IL-15 and IFNβ Drives Kidney Damage in Lupus Nephritis

Christopher Skopnik,[1] Diana Metzke,[1] Paul Freund,[1] Luka Prskalo,[1] Emil Grothgar,[1] Leonie F. Wagner,[1] Nina Goerlich,[1] Mario Bunse,[2] Falk Hiepe,[1] Jan Klocke,[1] Philipp Enghard.[1] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Max-Delbruck-Centrum fur Molekulare Medizin in der Helmholtz-Gemeinschaft, Buch, Germany.*

Background: Lupus nephritis (LN) implies morbidity in Systemic Lupus Erythematosus (SLE). A T cell-rich infiltrate parallels deposition of antibodies. How infiltrating T cells contribute to kidney damage is unclear. They can also be observed in urine, which thus can be used as a "window into the kidney" to investigate the cellular pathogenesis of LN. We report analysis of kidney infiltrating T cells found in urine to test if a renal autoimmune reaction contributes to tubulointerstitial inflammation (TII).

Methods: Urinary T and tubular epithelial cells (TEC) were quantified by flow cytometry (FC) in LN patients. T cells were subjected to single cell RNA sequencing after FC sort from urine and blood of five LN patients at flare. Comparison of gene transcription revealed putatively pathogenic cells. 67 T cell receptors (TCR) from expanded clonotypes were cloned to test specificity; T cell subsets from blood were subjected to in-vitro experiments. T cell stimulating cytokines were determined in urine from LN and healthy donors, reflecting the renal milieu.

Results: Majority of urinary T cells in LN are of CD8 lineage, the amount of which correlates with urinary TEC, a proxy for kidney damage. Mainly being of effector memory phenotype they are recruited partially from a CX3CR1 positive subset in blood which has a of type I interferon (IFN) signature. TCR analysis revealed expanded CD8 clones, none of which reacted with autologous TEC (0/18). Reactivity to viral CMV and EBV epitopes was shown for 15/67 clones. CMV or EBV was not detectable in respective kidney biopsies. In kidney tissue and/or urine we detected elevated levels of T cell stimulating cytokines, like IL-15. In-vitro, stimulation of CD8 T cells with IL-15 and IFNβ caused TCR-independent activation, degranulation and secretion cytokines TNF and IFNγ, almost exclusively by CX3CR1 positive CD8 effector T cells.

Conclusions: Contribution of CD8 T cells to TII and TEC damage in LN is antigen and TCR independent. In-vivo stimulation with IL-15 and type I IFN may be sufficient to trigger effector functions of a CX3CR1 positive subset. Targeting these cells in the blood, their migration, their response to cytokines or reducing renal cytokine levels may prevent LN flares and represent a tailored treatment.

Adoptive Cellular Immunotherapy for the Control of Primary Membranous Nephropathy

Ainhoa Garcia Busquets,[1] Marina Matilla,[1] Carolt Arana,[2,1] Sergi Betriu Méndez,[3] Maria Jose Ramirez-Bajo,[1] Elisenda Bañón-Maneus,[1] Marc Xipell Font,[2,1] Josep Maria Campistol Plana,[2,1] Manel Juan,[3] Luis F. Quintana,[2,1] Eduard Palou,[3] Fritz Diekmann,[2,1] Jordi Rovira.[1] *[1]FRCB-IDIBAPS, Laboratori Experimental de Nefrologia i Trasplantament (LENIT), Barcelona, Spain; [2]Clinic Barcelona, Department of Nephrology and Kidney Transplantation, Barcelona, Spain; [3]Clinic Barcelona, Department of Immunology, Barcelona, Spain.*

Background: Primary membranous nephropathy (PMN) is an autoimmune podocytopathy caused by subepithelial immune deposits that thicken the glomerular basal membrane and fusion of podocyte processes, causing proteinuria. It is the most common cause of non-diabetic nephrotic syndrome in adults. It is caused in 80% of cases

by antibodies targeting podocytes' M-type receptor of phospholipase A2 (PLA2R), in 5% against thrombospondin 7A type-1 (THSD7A), or other recently described antigens. A third of affected patients evolve into terminal kidney disease. Immunotherapy based on chimeric antigen receptors (CAR)-T cells has been an extraordinary advance in the fight against cancer. The current proposal aims to generate a chimeric anti-PLA2R autoantibody receptor (PLA2R-CAAR) and anti-THSD7A autoantibody receptor (THSD7A-CAAR) to target antibody-producing B cells.

Methods: In this pre-clinical study, human T lymphocytes were obtained from healthy volunteers. The design, generation, and production of PLA2R-CAAR and THSD7A-CAAR will be carried out, with subsequent evaluation of their cytotoxic properties and cytokine production, through an *in vitro* model.

Results: We have identified and cloned the genetic sequence corresponding to PLA2R and THSD7A. The PLA2R-CAAR construct has been generated from domain binding, leader peptide, extracellular domain (either PLA2R or THSD7A), and intracellular domains from A2-CHAR (developed in our laboratory). We produced lentiviral particles with the construct in HEK-293T cells. After the isolation of CD3+ cells from healthy volunteers, transduction and production of PLA2R-CAAR and THSD7A-CAARs is performed. CAAR-T cell's cytotoxic properties were assessed using serum samples containing anti-PLA2R or anti-THSD7A antibodies from patients with membranous nephropathy.

Conclusions: This strategy may be the prelude to a new immunotherapy for patients with membranous nephropathy who have anti-PLA2R or anti-THSD7A antibodies in circulation.

FR-OR61

Correlation of HLA Matchmaker and PIRCHE Reveals T Cell Epitope Mismatches High Risk for Donor Specific Antibodies (DSA) and Antibody-Mediated Rejection (AMR)

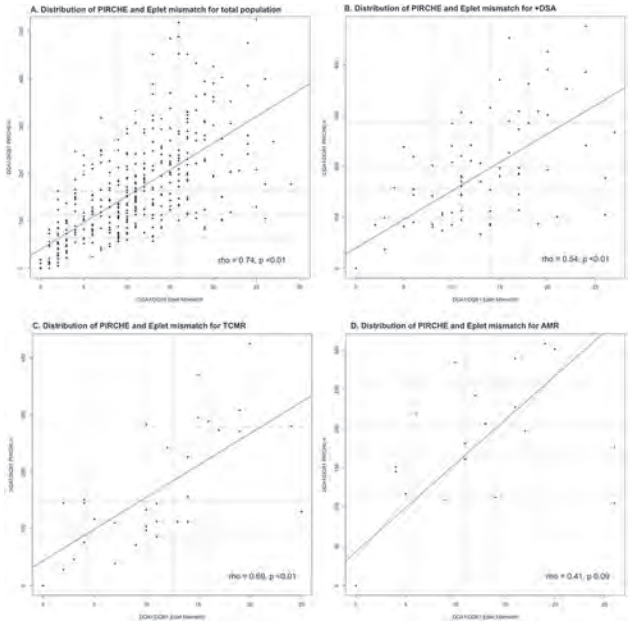
Clarkson Crane, Elizabeth G. Ingulli, Gerald P. Morris. *University of California San Diego School of Medicine, La Jolla, CA.*

Background: Both HLA Matchmaker and PIRCHE algorithms associate with de novo donor specific antibody (DSA) in kidney transplant recipients (KTR), but each predicts a different mechanism of the alloimmune response. Activation of CD4 T helper cells via indirect allorecognition (PIRCHE) occurs upstream of T-B cooperation resulting in antibody production (HLA Matchmaker). Given this, we aim to describe their correlation and hypothesize PIRCHE can provide insight as to the molecular mismatches highest risk for DSA and subsequent rejection.

Methods: KTR between 2017 to 2022 with high-resolution HLA typing were identified. Eplet mismatches were calculated with HLA Matchmaker and PIRCHE score determined. Spearman correlation was preformed and results plotted with quintile cutoffs.

Results: We identified 420 adult (n= 377) and pediatric (n= 43) KTR. Median age 52 years old, 68% male, 68% deceased donor and median time 20 months from transplant. DQA1/DQB1 had the strongest association with DSA when assessed with each algorithm. Distribution and correlation of PIRCHE and eplet mismatches for the entire cohort, +DSA, TCMR and AMR are shown in Figure 1, panels A-D. There was moderate correlation between the algorithms but more discordance of high PIRCHE/low eplet mismatch in DSA and AMR.

Conclusions: Our results demonstrate moderate strength correlation of PIRCHE and HLA matchmaker with transplant outcomes. High PIRCHE in setting of lower eplet mismatch in those with DSA and AMR suggests PIRCHE is predicting mismatched T cell epitopes that may be relevant for antibody formation and rejection. This cohort is limited by its retrospective nature and small sample size, but our next phase aims to test this hypothesis by quantifying *ex vivo* alloreactivity in donor/recipient pairs with high predicted T-cell epitope mismatches.



FR-OR62

Validation of Diagnostic, Prognostic, and Predictive Performances of a Novel Urinary Exosomal mRNA Clinical Test

Rania El Fekih,[1] Brian C. Haynes,[2] Tamara Merhej,[3] Ahmad Halawi,[3] Nour K. Younis,[3] Anil K. Chandraker,[1] Leonardo V. Riella,[4] Johan Skog,[2] Jamil R. Azzi.[1] Transplant Research Center, Brigham and Women's Hospital. *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Exosome Diagnostics, a Bio-Techne brand, Waltham, MA; [3]Transplant Research Center, Boston, MA; [4]Mass General Brigham Inc, Boston, MA.*

Background: Urinary Exosomes contain a biological payload of proteins and nucleic acids that reflect the physiology of the parent cells (kidney cells and immune infiltrates). Here we further characterize diagnostic performances of a novel urinary exosomal mRNA multigene signature for the diagnosis of any-cause rejection in kidney transplant, and describe its prognostic and predictive performances.

Methods: A total of 411 urine samples -from 366 patients- were collected at time of clinically indicated or protocol kidney biopsy. The transcript of 17 gene targets were pre-amplified and evaluated by RT-qPCR. Cross validation was applied to estimate the performance of the gene signatures. A composite endpoint of subsequent events were determined using the electronic medical records, and outcomes in subjects with positive and negative exosome signature were compared.

Results: The multi-gene classifier accurately distinguished any-cause rejection from no rejection, in the for-cause cohort (AUC 0.731) and the protocol biopsies cohort (AUC 0.781). We further identified a 5-gene signature (*IL18BP, CXCL11, CD74, CD44, C3*) that accurately distinguishes TCMR from ABMR with an AUC of 0.756. Majority of rejection negative by biopsy classified as positive by our model (false positive) showed significant underlying inflammation on biopsy such as lymphoproliferative infiltrate, moderate to significant lymphocytic infiltration, interstitial nephritis (BKV nephritis or acute interstitial nephritis), glomerulopathy or immune complex deposition. Furthermore, the remaining inflammation negative but positive urinary exosome scores were associated with three-fold increase in risk development of composite outcomes of subsequent rejection, decrease eGFR and loss of allograft at 3 years. The exosomal score showed a mean decrease of -0.05666 (p 0.0431) in responders to rejection treatment.

Conclusions: Urinary exosomal mRNA is a non-invasive clinical test that offers an insight into the status of the immune activation in the kidney allograft, and complement other laboratory surveillance strategies as a diagnostic, prognostic and predictive marker and risk-stratification tool in kidney transplant recipients. This assay is now ready for clinical use.

Differential cfDNA Methylation in Kidney Allograft Rejection

Benjamin L. Spector,[1,2] Drinnan Sante,[3] Warren A. Cheung,[2,4] Boryana S. Koseva,[2,4] Alexander Kats,[4] Gerald J. Wyckoff,[3] Laurel K. Willig.[4] *[1]University of Wisconsin School of Medicine and Public Health, Madison, WI; [2]Children's Mercy Research Institute, Kansas City, MO; [3]University of Missouri Kansas City, Kansas City, MO; [4]Children's Mercy Kansas City, Kansas City, MO.*

Background: Acute allograft rejection (AAR) is a risk for kidney allograft failure, however, knowledge of the molecular pathophysiology of rejection is lacking. Allograft life is limited and organ availability is scarce, emphasizing the need to understand rejection pathophysiology to preserve the primary allograft. Cell-free DNA (cfDNA) serves as a real-time marker of organ injury and immune response. DNA methylation patterns dictate gene expression. Generally, hypermethylation silences gene expression and hypomethylation indicates active transcription. We propose methylation changes in cfDNA during AAR inform the biologic pathways involved in its development and sequelae.

Methods: Methylation status of total plasma cfDNA samples from 20 pediatric kidney transplant recipients at the time of allograft biopsy was assessed using whole genome bisulfite sequencing. 7,789 differentially methylated CpG sites (DMCs) between individuals with *vs* without AAR were determined through logistic regression analysis (≥20% difference in methylation rate, q-value <0.05) and were assessed for gene associations and pathway/functional enrichments.

Results: AAR was present in 7 patients. 3,390 DMCs were relatively hypermethylated in the setting of AAR and 4,399 were relatively hypomethylated; these DMCs were associated with 114 and 138 genes, respectively. On enrichment analysis, "Relationship between inflammation, COX-2 and EGFR", "Negative regulation of mononuclear cell proliferation", "Regulation of cysteine-type endopeptidase activity in apoptotic process", "Regulation of interleukin-8 production", and "PID CD8 TCR Pathway" were among the most significant WikiPathways, canonical pathways, and Gene Ontology (GO) Terms in hypermethylated genes ($P < 0.005$). "Response to oxidative stress" and "Regulation of leukocyte mediated cytotoxicity" were among top GO Terms in hypomethylated genes ($P \leq 0.01$).

Conclusions: Our data implicate differential immune responses in acute rejection compared to non-rejection in kidney transplant recipients. These differences include the innate and adaptive immune responses and involve the differential regulation of leukocytes and mediation of cytokines. These results provide evidence that methylation differences of cfDNA inform the mechanisms of AAR.

Urinary Endotrophin Excretion Is Associated with Graft Failure and Mortality in Kidney Transplant Recipients

Firas F. Alkaff,[1,2] Daan Kremer,[1] Olivier Thaunat,[3] Stefan P. Berger,[1] Jacob Van Den Born,[1] Federica Genovese,[4] Morten A. Karsdal,[4] Stephan J. Bakker,[1] Daniel Guldager Kring Rasmussen,[4] Martin Tepel.[5,6] *[1]University of Groningen, University Medical Center Groningen, Groningen, Netherlands; [2]Faculty of Medicine, Universitas Airlangga, Surabaya, Indonesia; [3]Hospices Civils de Lyon, Hôpital Edouard Herriot, Service de Transplantation, Néphrologie et Immunologie Clinique, Lyon, France; [4]Nordic Bioscience, Herlev, Denmark; [5]Odense University Hospital, Department of Nephrology, Odense, Denmark; [6]University of Southern Denmark, Institute of Molecular Medicine, Cardiovascular and Renal Research, Odense, Denmark.*

Background: Kidney fibrosis is a suggested cause of kidney failure and premature mortality, regardless of the underlying cause. Since collagen type VI is closely linked to kidney fibrosis, we aimed to evaluate whether endotrophin, a profibrotic signaling molecule that reflects collagen type VI formation, in the urine was independently associated with graft failure and mortality among kidney transplant recipients (KTR).

Methods: We used data of KTR with a functioning graft ≥ one year that were enrolled in the TransplantLines Biobank and Cohort Study. Endotrophin was measured by the PRO-C6 enzyme-linked immunosorbent assay in the 24h urine.

Results: There were 621 KTR (age 53 ± 13 years old, 43% female, 5.2 [2.0-12.0] years after transplantation, eGFR 45 ± 19 mL/min/1.73 m²) included in the analyses. The 24h urinary endotrophin excretion at baseline was 5.6 [3.1-13.5] µg/24h. During median follow-up of 5.3 years, 70 KTR (11.3%) developed graft failure and 134 KTR (21.6%) died. 24h urinary endotrophin excretion was prospectively associated with both increased risk of graft failure and mortality, independent of potential confounders **(Table)**.

Conclusions: Urinary endotrophin excretion is independently associated with an increased risk of graft failure and mortality in KTR. Further studies with different KTR populations are needed to confirm these findings.

Funding: Commercial Support - Astellas BV and Chiesi Pharmaceuticals BV, Government Support - Non-U.S.

Cox proportional-hazards analyses for the association of 24h urinary endotrophin excretion with graft failure and mortality.

	Graft Failure		Mortality	
Model	HR per doubling (95% CI)	p-value	HR per doubling (95% CI)	p-value
Crude	1.59 (1.44-1.75)	<0.001	1.26 (1.15-1.37)	<0.001
Model 1	1.63 (1.47-1.80)	<0.001	1.31 (1.20-1.42)	<0.001
Model 2	1.16 (1.02-1.33)	0.027	1.19 (1.07-1.33)	0.001
Model 3	1.19 (1.03-1.38)	0.018	1.17 (1.05-1.30)	0.005
Model 4	1.22 (1.05-1.42)	0.009	1.16 (1.04-1.29)	0.009

Model 1 was adjusted for age, sex, and time after transplantation at inclusion. Model 2 was further adjusted for estimated glomerular filtration rate and log2 24h urinary protein excretion. Model 3 was further adjusted for body mass index and diabetic nephropathy as primary kidney disease. Model 4 was further adjusted for donor age and history of delayed graft function.

FR-OR65

Elevated Glycolytic Markers in Urinary Extracellular Vesicles in Kidney Transplant T Cell-Mediated Rejection

Po Yee Mia Leung,[1,2] Alison S. Graver,[1,2] Marina Katerelos,[2,3] John B. Whitlam,[1,4] David A. Power,[1,2] Peter F. Mount.[1,2] *[1]Faculty of Medicine, Denistry and Health Sciences, University of Melbourne, Melbourne, VIC, Australia; [2]Department of Nephrology, Austin Health, Melbourne, VIC, Australia; [3]Kidney Laboratory, Institute for Breathing and Sleep, Heidelberg, VIC, Australia; [4]Victorian Clinical Genetics Services, Murdoch's Children's Research Institute, Parkville, VIC, Australia.*

Background: Urinary extracellular vesicles (UEV), containing components of their parent cells, are released from cells lining the kidney and urinary tract. Changes in kidney protein expression are reflected in the proteome of UEV and its use as a non-invasive marker of allograft function is of particular interest in kidney transplantation. Under stress, renal energy metabolism switches from fatty acid oxidation to glycolysis. We evaluated changes in glycolytic control proteins in UEV at the time of clinically-indicated kidney transplant biopsies and correlated this with histological lesions described in the Banff classification.

Methods: This prospective observational study involved collection of pre-biopsy urine samples from kidney transplant recipients at the time of indication biopsy. UEV were isolated by differential ultracentrifugation. Western blots were performed to confirm vesicle markers (CD9, TSG101 and Tamm-Horsfall protein) and then probed for glycolytic markers.

Results: The cohort of 25 subjects (mean age 50.6 years, 60% male) included 5 cases of T-cell mediated rejection (TCMR), 4 cases of borderline TCMR and 16 normal biopsies. TCMR and borderline TCMR were analysed as one group (n = 9) and the following glycolytic markers were detected in this group: phosphofructokinase-liver, isoenzymes of 6-phosphofructo-2-kinase/fructose-2,6-bisphosphatase (PFKFB2, phosphorylated ser461 PFKFB2, phosphorylated ser483 PFKFB2, PFKFB3, PFKFB4) and pyruvate kinase (PK-M2, PK-LR). There was significantly increased expression of PFKFB3+ UEV in 3/9 (33%) of TCMR samples compared to 0/16 of normal biopsy samples (p=0.04). PFKFB4+ UEV was expressed in 6/9 (66%) of TCMR samples compared to 1/16 of normal biopsy samples (p=0.003).

Conclusions: This study demonstrates elevated expression of PFKFB3 and PFKFB4 in UEV in kidney transplant recipients with biopsy-proven TCMR. This may represent altered energy metabolism in the form of increased renal glycolysis in association with cell mediated rejection.

FR-OR66

Proenkephalin A 119-159 as a Novel Biomarker for Early Detection of Delayed Graft Function After Kidney Transplantation

Christian Nusshag,[1] Louise Benning,[1] Daniel Göth,[1] Christoph F. Mahler,[1] Florian Kälble,[1] Claudius Speer,[1] Marvin Reineke,[1] Felix C.F. Schmitt,[2] Markus Mieth,[3] Martin G. Zeier,[1] Arianeb Mehrabi,[3] Markus A. Weigand,[2] Christian Morath.[1] Group Nusshag. *[1]Heidelberg University Hospital Department of Nephrology, Heidelberg, Germany; [2]Heidelberg University Hospital Department of Anesthesiology, Heidelberg, Germany; [3]Heidelberg University Hospital Department of General, Visceral and Transplantation Surgery, Heidelberg, Germany.*

Background: Delayed graft function (DGF) frequently occurs following kidney transplantation and adversely affects patient outcomes such as length of hospital stay, impaired long-term graft function and ultimately quality of life. Though a universal definition of DGF is lacking, a common classification is the need for dialysis in the first postoperative week excluding the first 24 hours. The aim of this study was to evaluate the capabilities of the novel kidney function biomarker proenkephalin A 119-159 (penKid) to predict DGF compared to serum creatinine (SCr).

Methods: In the currently ongoing study, penKid has been quantified from plasma using a chemiluminescence immunoassay in our daily routine in all freshly transplanted patients since November 2022. PenKid is quantified the day of transplantation and every weekday following transplantation. For this preliminary analysis, penKid levels were compared to SCr. The end of data collection is June 30, 2023.

Results: In a preliminary analysis including 70 kidney transplant recipients (70% cadavric transplants), results suggest, that penKid may discriminate patients with delayed graft function from patients with primary graft uptake earlier than SCr. In contrast to SCr, penKid was able to distinguish between DGF and no DGF as early as 24 hours after transplantation (Figure 1). In addition, other than SCr, penKid levels do not seem to be affected by dialysis.

Conclusions: PenKid is a promising new biomarker for the early prediction of DGF after kidney transplantation and may enable clinicians to adjust their treatment in high-risk patients accordingly. However, more clinical data is needed to validate our findings and to establish the clinical utility of penKid in the management of kidney transplant patients.

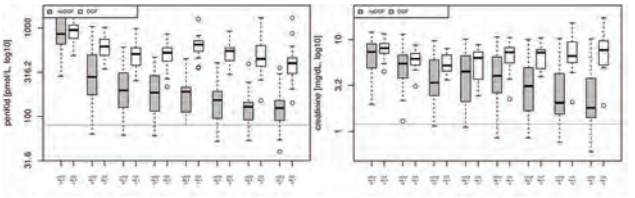

Figure 1: Proenkephalin A 119-159 (penKid) is an early indicator for predicting delayed graft function, (penKid DGF vs. no DGF: day 0: p>0.05; day 1-7: p<0.001), whereas serum creatinine levels provide a much later signal for distinguishing DGF from no DGF (SCr DGF vs. no DGF: day 0-3: p>0.05; day 4: p=0.02; day5-7 p<0.001). DGF: delayed graft function, defined as need for dialysis within 7 days after transplant, excluding the first 24h. Biomarker measurement at day 0 was performed before transplantation.

FR-OR67

Uncontrolled Hypertension Is Associated with Increased Risk of Graft Failure in Kidney Transplant Recipients: A Nationwide Population-Based Study

Chang Seong Kim,[1,2] Minah Kim,[3] Sang Heon Suh,[1,2] Hong Sang Choi,[1,2] Eun Hui Bae,[1,2] Seong Kwon Ma,[1,2] Soo Wan Kim.[1,2] *[1]Chonnam National University Medical School, Gwangju, Gwangju, Republic of Korea; [2]Chonnam National University Hospital, Gwangju, Gwangju, Republic of Korea; [3]Chonnam National University Hwasun Hospital, Hwasun-gun, Jeollanam-do, Republic of Korea.*

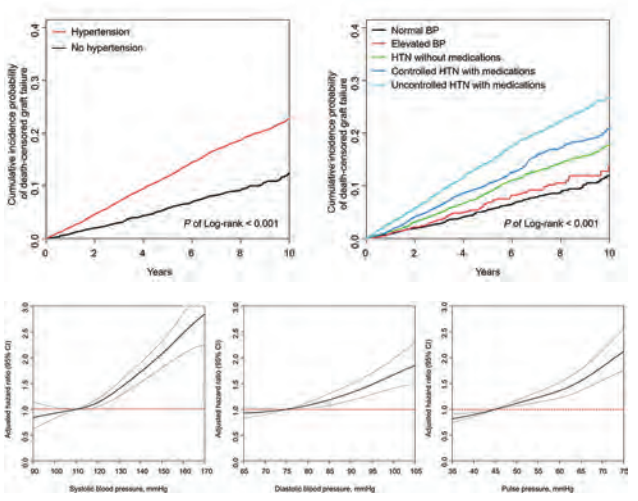
Background: Hypertension is highly prevalent in patients with kidney transplantation caused by transplantation-related immunologic or non-immunologic risk factors. However, whether a strict definition of hypertension (≥130/80 mmHg) and subdivided blood pressure (BP) groups are associated with an increased risk of graft failure after kidney transplantation using a nationwide large cohort study are still unknown.

Methods: Using Korena National Health Insurance Service data, we included 14,249 patients who underwent kidney transplantation from 2002 to 2016. Patients were categorized into five BP groups according to the 2021 Kidney Disease: Improving Global Outcomes practice guidelines for BP management: normal BP (<120/80 mmHg), elevated BP (120–129/<80 mmHg), incident hypertension (≥130/80 mmHg), and controlled or uncontrolled hypertension with anti-hypertensive medications.

Results: The primary outcome was graft failure, which occurred in 1,934 (13.6%) participants during the 6-year follow-up. After adjusting for covariates, hypertension was associated with a higher risk of graft failure [Adjusted hazard ratio (AHR), 1.70; 95%

confidence interval (CI), 1.48–1.96)] than no-hypertension. The AHR for graft failure was the highest in patients with uncontrolled hypertension (AHR, 2.13; 95% CI, 1.80–2.52). The risk of graft failure had a linear relationship with systolic and diastolic BP, and pulse pressure.

Conclusions: In this nationwide population-based study, hypertension ≥ 130/80 mmHg based on the 2021 KDIGO BP guidelines in kidney transplantion recipients, and elevated systolic and diastolic BP, and pulse pressure were associated with the risk of developing graft failure in kidney transplant recipients.



FR-OR68

The Molecular Microscope Diagnostics System (MMDx) Does Not Identify Molecular T Cell-Mediated Rejection (TCMR) in Cases with Borderline Changes or Isolated Intimal Arteritis in the Absence of Microvascular Inflammation

Thomas Schachtner, Lukas Weidmann, Dusan Harmacek, Nicola Bortel, Kai C. López, Raphael Korach, Thomas F. Mueller. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: Borderline changes suspicious for T-cell mediated rejection (TCMR) and isolated intimal arteritis (v-lesion) represent a particular challenge. Even though the Molecular Microscope Diagnostics System (MMDx) has not been trained on borderline changes and v-lesions, it has been suggested that MMDx may reclassify a subgroup of cases to molecular TCMR.

Methods: In this single-center cohort of 326 kidney allograft biopsies assessed by histology and MMDx at the University Hospital Zurich, we analyzed 153 cases with isolated tubulitis (i0, t1-3; n=114), borderline changes (n=10), and isolated intimal arteritis (i0, t0-2, v1; n=39) in the presence (n=81) and absence (n=72) of microvascular inflammation (MVI). 83 cases without histologic lesions suspicious for TCMR (i0, t0, v0) were used for comparison of rejection phenotype scores. Any cases with overlapping pathologies were excluded from the analysis.

Results: 41 of 81 cases (51%) with suspicion for TCMR and MVI showed molecular rejection (30 cases with molecular ABMR, 4 cases with molecular ABMR/TCMR (2 cases with isolated tubulitis, 1 case with borderline changes, 1 case with isolated intimal arteritis), and 7 cases with minor ABMR) compared to 6 of 32 cases (19%) without suspicion for TCMR but MVI (5 cases with molecular ABMR, 1 case with molecular ABMR/TCMR; p=0.003). However, 1 of 72 cases (1%) only with suspicion for TCMR, but no MVI showed molecular rejection (1 case with minor ABMR). No pure molecular TCMR was identified in any group. 11 of 153 cases (7%) with suspicion for TCMR showed a TCMR phenotype score (R2) ≥0.10 (7 cases with isolated tubulitis and 4 cases with isolated intimal arteritis) compared to 5 of 83 cases (6%) without suspicion for TCMR (p=1).

Conclusions: MMDx may identify molecular TCMR among cases with MVI irrespective of histologic suspicion for TCMR. MMDx does not identify molecular TCMR in cases with isolated tubulitis, borderline changes, or intimal arteritis without MVI. TCMR phenotype scores do not differentiate between isolated tubulitis, borderline changes, isolated intimal arteritis, or no histologic lesions suspicious for TCMR.

Donor-Derived Cell-Free DNA (dd-cfDNA) in Kidney Transplant Recipients with Indication Biopsy: Results of a Prospective German Single-Center Trial

Louise Benning,[1] Christian Morath,[1] Annette Fink,[2] Markus A. Rudek,[1] Claudius Speer,[1] Christian Nusshag,[1] Florian Kälble,[1] Christoph F. Mahler,[1] Constantin Schwab,[3] Martin G. Zeier,[1] Caner Süsal,[2,4] Thuong H. Tran.[2] *[1]Department of Nephrology, University Hospital Heidelberg, Heidelberg, Germany; [2]Transplantation Immunology, Heidelberg Institute of Immunology, University Hospital Heidelberg, Heidelberg, Germany; [3]Institute of Pathology, University Hospital Heidelberg, Heidelberg, Germany; [4]Transplant Immunology Research Center of Excellence, Koç University Hospital, Istanbul, Turkey.*

Background: Donor-derived cell-free DNA (dd-cfDNA) identifies allograft injury and discriminates active rejection from no rejection. With a number of studies investigating the benefit of dd-cfDNA in US American transplant cohorts, we aimed at evaluating the performance of dd-cfDNA in a cohort of German kidney transplant recipients.

Methods: We enrolled 106 kidney transplant recipients with clinically indicated biopsy between November 2020 and March 2023 at the Department of Nephrology at Heidelberg University Hospital. dd-cfDNA was quantified using the AlloSeq cfDNA assay (CareDx) at time of biopsy to correlate dd-cfDNA levels with histopathological reporting and on days 7, 30 and 90 following biopsy to assess the utility of dd-cfDNA in monitoring treatment response.

Results: Of the 108 allograft biopsies, 36 (33%) were classified as different types of rejection. Patients with ABMR or TCMR (N=13) showed significantly higher dd-cfDNA levels with a median (IQR) of 1.60% (0.38–3.35) compared to the 0.44% (0.20–1.10) in patients with borderline changes (N=23) and the 0.2% (0.11–0.53) in patients with no signs of rejection (N=72) (P<0.05 and P<0.001, respectively). The AUC for dd-cfDNA to differentiate any type of rejection including Borderline changes from no rejection was at 0.72 (95% CI 0.62–0.83). The optimal cut point for dd-cfDNA to discriminate active rejection was at a threshold of 0.57%, yielding a sensitivity of 53% (95% CI 37–68%), a specificity of 81% (95% CI 70–88%), a PPV of 58% (95% CI 41–73%), and a NPV of 77% (95% CI 67–85%). In patients receiving anti-rejection treatment, dd-cfDNA levels decreased significantly during the 7-, 30-, and 90-day follow-up compared to levels at the time of biopsy (P=0.006, P=0.002, and P<0.001, respectively).

Conclusions: Our data verify the good performance of dd-cfDNA to correctly identify kidney transplant recipients with active rejection at a German transplant center. We show that dd-cfDNA may aid the clinician in recognizing patients at risk and in decision-making regarding the need for a graft biopsy. The potential benefit of dd-cfDNA to assess response to therapy needs further validation.

Pretransplant HbA1C as a Predictor of Kidney and Pancreas Allograft Survival in Simultaneous Pancreas-Kidney Transplantation: A Retrospective Nationwide Study

Jathurong Kittrakulrat,[1,2] Ekamol Tantisattamo.[3] *[1]Prapokklao Hospital, Chanthaburi, Thailand; [2]King Chulalongkorn Memorial Hospital, Bangkok, Thailand; [3]University of California Irvine, Irvine, CA.*

Background: Simultaneous pancreas-kidney transplant (SPKT) is a therapeutic option for patients with end-stage kidney disease (ESKD) and diabetes mellitus (DM). Hemoglobin A1C (HbA1C) is a widely used biomarker for glycemic control in DM patients. However, its role in predicting SPKT outcomes remains unclear. This study aimed to investigate the association of pre-transplant HbA1C levels with kidney and pancreas allograft survival in patients with SPKT.

Methods: Using data from the United Network for Organ Sharing (UNOS) database, a total of 3,351 SPKT recipients were included in the analysis. Cox proportional hazards regression models with time varying covariates were used to evaluate the association between HbA1C and allograft survival.

Results: Our results showed that higher pre-transplant HbA1C levels were significantly associated with lower kidney and pancreas allograft survival rates. Compared to patients with HbA1C levels ≤7%, patients with HbA1C levels >7% had a hazard ratio of 3.38 (95%CI: 2.40-4.75, P< 0.01) and 7.99 (95%CI: 6.02-10.60, P< 0.01) for kidney and pancreas allograft failure, respectively (Figure 1A and 1B). Moreover, this association remained significant after adjusting for relevant potential confounders, including age, gender, body mass index, and donor types.

Conclusions: Pre-transplant HbA1C is a strong predictor of both kidney and pancreas allograft outcomes in SPKT recipients. Our findings highlight the importance of glycemic control in uremic diabetic patients as one of the pre-transplant preparation strategies to improve allograft survival after successful SPKT.

The Standardized Discontinuation Ratio: A Novel Measure for Real-Time Monitoring of Home Dialysis Discontinuation

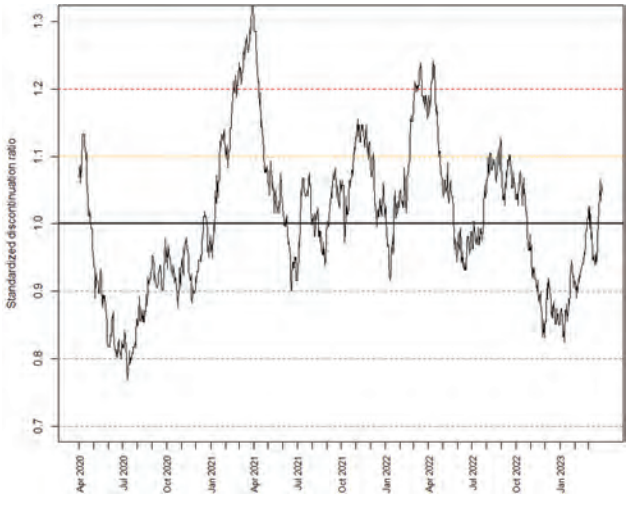
Eric D. Weinhandl,[1,2] Wael F. Hussein,[1,3] Graham E. Abra.[1,3] *[1]Satellite Healthcare, San Jose, CA; [2]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [3]Stanford University School of Medicine, Stanford, CA.*

Background: Home dialysis attrition is a significant challenge. Attrition slows growth, and discourages both nurses and patients who devote great effort to training. Many measures, including the "churn rate" and the cumulative incidence of all-cause attrition, are not ideal for real-time quality monitoring, due to slow evolution and the inclusion of kidney transplantation, a positive outcome. We developed a novel measure, the standardized discontinuation ratio (SDR), that facilitates ongoing assessment of whether the composite event of conversion to in-center hemodialysis or death is occurring more or less frequently than is expected.

Methods: We analyzed the electronic health records of Satellite Healthcare, a mid-sized, not-for-profit dialysis provider. On any given day, we defined the SDR as the ratio of actual versus expected discontinuations from home dialysis during the past 13 weeks. Discontinuation was defined by either conversion from home dialysis to in-center hemodialysis or death. The expected number of discontinuations was summed from patient-day probabilities of discontinuation, estimated as a function of age, modality, and time since home dialysis initiation.

Results: During the 4-year period ending on May 15, 2023, there were 288 discontinuations among 1011 home hemodialysis (HHD) patient-years and 1557 discontinuations among 5430 peritoneal dialysis (PD) patient-years. C-statistics for modality-specific models of discontinuation were 0.61 for HHD and 0.58 for PD. As displayed, the organization-wide SDR from April 2020 to March 2023 varied widely, ranging from 0.77 on July 11, 2020, to 1.34 on March 30, 2021. The SDR was between 1.1 and 1.2 on 12.2% of days during the 3-year period ending in March 2023, and greater than 1.2 on 6.5% of days.

Conclusions: The SDR can be used in real-time to monitor trends in home dialysis discontinuation for the purpose of organizational quality improvement.



FR-OR72

Breaking Through Barriers with Home Hemodialysis (HHD) Group Training, Enhancing Access and Improving Patient Experience: A Single-Center Experience

Maria Bermudez, Waleed Zafar. *Geisinger Medical Center, Danville, PA.*

Background: Despite emerging evidence supporting greater quality of life (1) and improved cardiovascular outcomes (2, 3), HHD remains underutilized in the U.S. (4) Two barriers to widespread adoption are delayed access to HHD due to a shortage of HHD units and staff; and patient apprehension about taking dialysis in their own hands. Group training for HHD remains underutilized in the US with less than 5% of units implementing this training strategy. Given lack of experience, little is known about group training in HHD. We describe a single center experience of instituting group training for HHD.

Methods: All patients and their care-partners currently enrolled in HHD program who underwent group training were surveyed. We evaluated the impact of group training on duration of training, unit census growth, need for retraining, incidence of complications and patient experience.

Results: A total 6 consecutive groups of 2 and 3 patients at a time for a total of 16 patients were trained in HHD over a period of 7 months. Training time averaged 30-40 days and was similar for all groups and comparable to solo training. Unit census tripled during this period going from 7 patients to 23. Demographic characteristics are described in table 1. 14 (87.5%) patients had no missed treatments over a 3 month period and no patient needed retraining over the follow up period. 1 patient transitioned to in-center dialysis and 1 died. All patients who were surveryed agreed that group training was an enjoyable experience and strongly recommended to others.

Conclusions: In our experience, group training has proven to be an effective strategy for scaling HHD training. It has helped overcome two major barriers to HHD: prompt access to training and patients' need for strong support in the early training phase. Ongoing longitudinal data collection will help us evaluate association of group HHD training with outcomes including missed treatments, need for retraining and respite care, and patient quality of life scores. Group training has the potential to be an empowering tool for our patients and to enhance our ability to cross train nurses in HHD thus potentially helping with nursing attrition.

Hospitalisation Risk in the Integrated Home Dialysis Model: Analysis of the Canadian Organ Replacement Register

Louis-Charles Desbiens,[1] Karthik K. Tennankore,[2] Remi Goupil,[3,1] Jeffrey Perl,[4] Emilie Trinh,[5] Christopher T. Chan,[6] Annie-Claire Nadeau-Fredette.[7,1] *[1]Universite de Montreal Faculte de Medecine, Montreal, QC, Canada; [2]Dalhousie University, Halifax, NS, Canada; [3]Hopital du Sacre-Coeur de Montreal, Montreal, QC, Canada; [4]St Michael's Hospital, Toronto, ON, Canada; [5]McGill University Faculty of Medicine and Health Sciences, Montreal, QC, Canada; [6]Toronto General Hospital, Toronto, ON, Canada; [7]Hopital Maisonneuve-Rosemont, Montreal, QC, Canada.*

Background: The integrated home dialysis model proposes the initiation of dialysis with peritoneal dialysis (PD) followed by transition to home hemodialysis (HHD) after PD ends. Outcomes of integrated home dialysis versus a "direct to HHD approach" are poorly known. We aimed to compare the hospitalization risk of patients in integrated home dialysis (before, during and after transfer to HHD) with patients directly initiating HHD.

Methods: We studied patients in the Canadian Organ Replacement Register who initiated PD or HHD between 2005 and 2018. A 1:1 propensity score was used to match patients transitioning from PD to HHD in less than 90 days after PD ("PD+HHD" group) to patients with HHD as the first home-dialysis modality ("HHD" group). Our outcome was all-cause hospitalization, assessed from the beginning of home dialysis (PD or HHD) until transfer to facility HD, death, end of follow-up (December 31st 2019) or kidney transplant. Hospitalizations were compared between groups with shared frailty models in three periods: before PD-HHD transition, during transition, and after transition (Fig 1).

Results: From 63,327 patients, 13,726 initiated PD and 745 initiated HHD. 4,420 patients transferred from PD to facility HD and 163 transferred to HHD (3.6% of transfers; median time on PD 1.9 years). Hospitalization risk was similar between groups in the period before and after the PD-HHD transition but was significantly increased during the transition period (Table). Similar trends were observed when these periods were sub-divided by year (Fig 2).

Conclusions: Patients transitioning from PD to HHD do not have an increased hospitalization risk outside their transfer period when compared with patients who start dialysis directly in HHD.

Funding: Government Support - Non-U.S.

Figure 1:

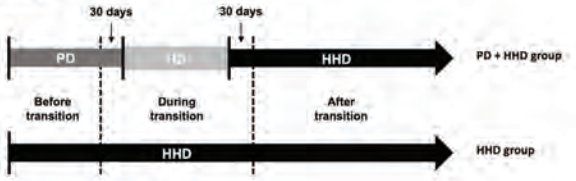

Table:

Time period	Hospitalization rate (PD-HHD; events/pt-year)	Hospitalization rate (HHD; events/pt-year)	Hazard ratio (95% CI)
Before transition	0.44	0.52	0.91 (0.61-1.37)
During transition	1.88	0.73	2.69 (1.25-5.82)
After transition	0.73	0.79	0.83 (0.56-1.24)

Physical Activity Perceptions and Practices of People Receiving Peritoneal Dialysis: An International Cross-Sectional Survey

Jennifer M. MacRae,[1] Trinity A. Tam,[1] Clara Bohm,[3] Tyrone Harrison,[1] Paul N. Bennett,[2] Nancy Verdin,[5] Nicole J. Scholes-Robertson,[6] Madeleine Warren,[7] Stephanie E. Thompson.[4] *[1]University of Calgary Cumming School of Medicine, Calgary, AB, Canada; [2]Griffith University, Nathan, QLD, Australia; [3]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [4]University of Alberta Faculty of Medicine & Dentistry, Edmonton, AB, Canada; [5]GREX, Red Deer, AB, Canada; [6]Flinders University, Adelaide, SA, Australia; [7]Warren-Charnock Associates, Coventry, United Kingdom.*

Background: Life participation is a core patient-reported outcome for people receiving peritoneal dialysis (PD) that is dependent on physical activity engagement and adequate physical function. Little is known about exercise practice patterns or perceptions of people receiving PD. The aim was to describe the physical activity and exercise practices and perceptions of people receiving PD to inform patient education, future areas of research, and clinical recommendations.

Methods: A cross-sectional, descriptive, web-based 25 item survey (16 perception and practice questions, 9 demographic questions) was co-developed and pilot tested by persons living with kidney disease, PD clinicians and exercise specialists. Adults who currently or previously received PD were invited to participate in the survey. Recruitment was completed through national and international kidney organization websites and social media platforms. All variables were reported descriptively, and free text responses were collated and summarized.

Results: There were 114 respondents, 6 excluded due to duplication or incompletion, the majority were from Canada (68%), United Kingdom (25%) and 7% other. Women represented 55% of respondents, with most 50-64 years old (43.5%). Forty-one percent received PD for 1-3 years and 72.9% had post secondary education. Physical activity was felt to be beneficial by 91.8% of respondents and 40% reported they had good physical function (could walk an unlimited distance without stopping). Variable medical advice regarding swimming and weightlifting emerged: 44% were told they could or could not swim, and respondents were told to limit weight lifting from 2 to 45 kg. A minority of respondents reported receiving instructions on draining PD fluid prior to physical activity (28% yes, 53% no, 19% unsure).

Conclusions: Survey respondents were knowledgeable regarding benefits of exercise and physical activity on physical and mental health for people receiving PD. Knowledge gaps emerged including maximum weightlifting, whether exercise was safe with or without intrabdominal PD fluid in situ, and whether swimming is allowed. Education for both health care providers and patients is needed regarding the practice of exercise for people receiving PD.

Decreasing the Burden: A Single-Centre Experience of Decremental Peritoneal Dialysis (PD) in Toronto, Canada

Shabnam Hamidi,[1,2] M Azfar Qureshi,[1,2] Bourne L. Auguste.[1,2] *[1]Sunnybrook Health Sciences Centre, Toronto, ON, Canada; [2]University of Toronto, Toronto, ON, Canada.*

Background: The 2020 International Society of Peritoneal Dialysis (ISPD) recommendations on providing high-quality peritoneal dialysis (PD) prescriptions highlight shared-decision making principles that deemphasize the focus on Kt/V clearance targets. As a result, incremental PD has gained popularity amongst care providers in recent history. However, "decremental PD", a practice in which PD dose is reduced after patients are started on high dose PD (>10L/day), has not been well described in the literature. Decremental PD utilizes the principles of goal-directed therapy as outlined by the ISPD to reduce prescriptions where possible; particularly when treatment is burdensome for patients. We describe our experience with this approach and potential benefits to both patients and the healthcare system.

Methods: Nine prevalent patients on high-dose automated PD prescriptions seen between August 1-December 31, 2019, were included in this analysis. All patients reported prescriptions were burdensome. Patients were offered a reduced dose in their prescription after clinical assessment and laboratory investigations were reviewed. Patients were compared 6 months before and after the change in prescription for any significant differences in hospitalization, peritonitis rates and technique failure. Small solute clearance using Kt/V and creatinine clearance along with residual urine output were also compared.

Results: Total dialysis volume and time on cycler were significantly reduced from a mean of 12.6 L to 9.2L ($p < 0.001$) and from 8.7 to 8.2 hours ($p < 0.035$). No statistically significant differences in Kt/V and CrCl values 6 months after the change in prescription were observed. There were no observed peritonitis episodes or hospitalizations six months after prescription change. All patients remained on PD 12 months after the intervention with no further prescription changes. The reduced prescription resulted in a 19.2% cost reduction per patient at six months compared to high-dose prescription.

Conclusions: We demonstrate that decremental PD prescriptions align with ISPD recommendations in maintaining patient-centered care while reducing cost.

	Mean prior to prescription change	Mean after prescription change	P value (95%)
PD Volume (mL)	12688.89 ± 3835.18	9244.44 ± 3280.67	*P <0.001*
Time on cycler	8.67 ± 0.71	8.22 ± 0.67	*P = 0.035*
Total Kt/V_{urea}	2.79 ± 0.87	2.51 ± 0.51	P = 0.48
Total CrCl (L/week)	83.33 ± 29.28	77.50 ± 18.67	P = 0.50
Residual urine output (mL/day)	946.13 ± 786.19	1071.33 ± 801.14	*P = 0.035*

CrCl – Creatinine clearance

	Prior to change	After change	Cost Difference	% Change
Cost of solutions for 6 months*	$49,883.40	$40,312.80	$9,570.60	⇓19.2%

**Total cost of solutions for all patients 6 months before and 6 months after prescription change.*
These costs reflect solutions only and not supplies nor other materials related to routine daily care.

FR-OR76

CKD-Associated Pruritus: Prevalence and Association with Quality of Life for Peritoneal Dialysis Patients, International Results from PDOPPS

Karthik K. Tennankore,[1] Jeffrey Perl,[2] Ronald L. Pisoni,[3] David W. Johnson,[4] Talerngsak Kanjanabuch,[5] Hideki Kawanishi,[6] Yong-Lim Kim,[7] Mark Lambie,[8] Jenny I. Shen,[9] Yeoung Jee Cho,[4] Claudio Rigatto,[10] Keith McCullough.[3] *[1]Dalhousie University Faculty of Medicine, Halifax, NS, Canada; [2]St Michael's Hospital, Toronto, ON, Canada; [3]Arbor Research Collaborative for Health, Ann Arbor, MI; [4]The University of Queensland, Brisbane, QLD, Australia; [5]Division of Nephrology and Center of Excellence in Kidney Metabolic Disorders, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand; [6]Tsuchiya General Hospital, Hiroshima, Japan; [7]Kyungpook National University, Daegu, Republic of Korea; [8]Keele University, Keele, United Kingdom; [9]The Lundquist Institute, Torrance, CA; [10]Chronic Disease Innovation Centre, Winnipeg, MB, Canada.*

Background: Chronic kidney disease associated pruritus (CKD-aP) is associated with morbidity. The prevalence and burden of CKD-aP in peritoneal dialysis (PD) is not well-known. We sought to determine the CKD-aP prevalence, identify factors associated with a high severity of CKD-aP and the impact of CKD-aP on quality of life (QOL) among patients in the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS).

Methods: We analyzed cross-sectional data on QOL and CKD-aP from PDOPPS patients from Australia, Canada, Japan, New Zealand, Republic of South Korea, Thailand, the UK, and US between 2014-22. CKD-aP severity in the preceding 4 weeks was self-rated by patients using a 5-point Likert scale from 1: "Not at all bothered by itch" to 5: "Extremely bothered by itch". Factors associated with CKD-aP 3-5 (moderate to extreme) v. 1-2 were analyzed using logistic regression. Adjusted linear regressions were used to compare CKD-aP and QOL, assessed using the physical and mental component summary scores (PCS and MCS) of the 12-item Short-Form (SF-12) on the same questionnaire.

Results: 43% of the 5534 patients reported moderate to extreme itch; ranging from 50% and 49% (Thailand and the UK, respectively), to 32% (the US). Adjusted logistic regression revealed several parameters associated with CKD-aP (Figure 1). MCS and PCS were negatively associated with increasing CKD-aP severity ($p < 0.0001$).

Conclusions: Worldwide, CKD-aP is highly prevalent among PD patients and associated with poor quality of life. Efforts to better identify and manage CKD-aP for PD patients are urgently needed.

Outcomes of an Assisted Peritoneal Dialysis Program in the United States

Wael F. Hussein,[1,2] Shijie Chen,[2] Jugjeet Atwal,[2] Sijie Zheng,[3] Graham E. Abra.[1,2] *[1]Stanford University School of Medicine, Stanford, CA; [2]Satellite Healthcare, San Jose, CA; [3]Kaiser Permanente, Oakland, CA.*

Background: Staff-assisted peritoneal dialysis (PD) can support patients to initiate or remain on PD following challenges to self-care. These programs are not currently supported by Medicare in the Unites States (US) despite the intentions put forward in the Advancing American Kidney Health initiative to increase home dialysis utilization.

Methods: Assistance was provided by trained non-nurse healthcare personnel to patients with short-term limitations to self-care who lacked adequate support by family or friends. Descriptive statistics are provided on indications, services, and outcomes.

Results: A total of 121 referrals were received. Mean patient age was 71 (SD 14) years, and 45% were female. Forty five percent of the referrals were before completion of PD training, while the remaining 55% were for prevalent patients. The main indications for referral were physical function limitations (57%), cognition (47%), and psychosocial reasons such as anxiety (46%). A total of 48 referrals were cancelled due to resolved needs or inability to continue PD. A total of 604 visits (12% virtual) were provided for 73 patients, with a median of 5 (interquartile range [IQR]: 3 to 10) visits per patient over a median of 8 (IQR 2 to 21) days. Services provided included setting up and observing PD treatments (81%), exit site care (36%), checking the blood pressure (36%), and checking the weight of the patient (28%). A total of 68 (93%) patients were discharged on PD, with no further need for staff assistance. Three patients died during the course of the program and two transferred to in-center hemodialysis. No peritonitis or exit site infections were reported. During post-discharge follow up, 74% and 62% of patients continued on PD at six and 12 months.

Conclusions: Staff-assisted PD programs in the US delivered by non-nursing staff are feasible and effective. With a brief period of assistance, patients were able to successfully initiate or continue PD, leading to positive outcomes.

FR-OR78

QuickCheck: A Point-of-Care Method for Rapid Cell Counting in Peritoneal Dialysis-Associated Peritonitis

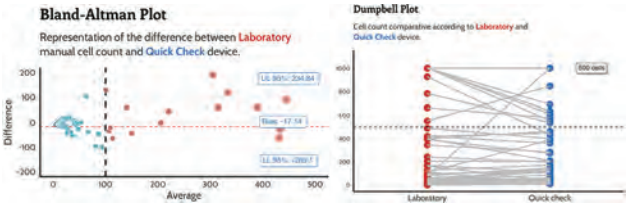
Junaid Z. Qazi,[1] Jyoti B. Baharani,[2] Amna Kununa,[3] Hannah M. O'Keeffe,[3] Annamma John,[3] Jen Young,[3] Conor O. Seery,[3] Helen M. Gannon,[3] Anand Vardhan,[1] Julio L. Chevarria.[3] *[1]Manchester Royal Infirmary, Manchester, United Kingdom; [2]Birmingham Heartlands Hospital, Birmingham, United Kingdom; [3]Tallaght University Hospital, Dublin, Ireland.*

Background: Peritoneal dialysis (PD) associated peritonitis is a severe complication, often requiring hospitalization and transfer to hemodialysis. Diagnostic criteria include clinical features, effluent white cell count, and culture. The standard method of cell counting is manual microscopy, which is expensive and time-consuming. QuickCheck is CE marked, point-of-care device that utilizes laser light to instantly determine the cell count. We assess the comparability in detecting the number of cells in PD effluent samples and evaluate accuracy and precision in diagnosis of peritonitis.

Methods: A non-interventional study for method comparison was conducted in PD unit of Tallaght University Hospital, Manchester Royal Infirmary, and Birmingham Heartlands Hospital. From June 2022 to April 2023, effluent samples from patients with suspected peritonitis were analyzed with QuickCheck and manual microscopy. We included patients >18 y old, on PD, suspected peritonitis, and PD effluent culture. Reproducibility was assessed using intra-class correlation coefficients (ICC), validity by sensitivity, specificity, predictive values, and likelihood ratios. Bland-Altman graphs estimate bias and limits of agreement.

Results: 89 patients were included. The median cell count was 48 (IQR 18-662) for manual microscopy and 86 (IQR 18.5-595) for QuickCheck. The ICC agreement was 0.93 (95%CI 0.89-0.95), and consistency 0.93 (CI95% 0.89-0.95). Blant-Altman graphic is detailed. Sensitivity was 71% and 75%, specificity 78% and 69%, PPV 83% and 78%, NPV 65% and 66%, LR+ 3.2 and 2.47, LR- 0.36 and 0.35, accuracy 74% (CI95% 64-83) and 73% (CI95% 63-82) for QuickCheck and manual microscopy, respectively.

Conclusions: QuickCheck is comparable to manual microscopy in accuracy and reproducibility in cell counting. The high specificity with a cell count >100 cells suggests that QuickCheck is a reliable point-of-care method for rapid diagnosis and treatment of PD-associated peritonitis. Its speed, simplicity, and portability make it an attractive option for use at the point-of-care.



FR-OR79

A Cutting-Edge Multiphoton Microscopy-Based Approach to Test the Structure of the Peritoneal Membrane Reveals the Protective Effects of Glucose-Sparing Solution

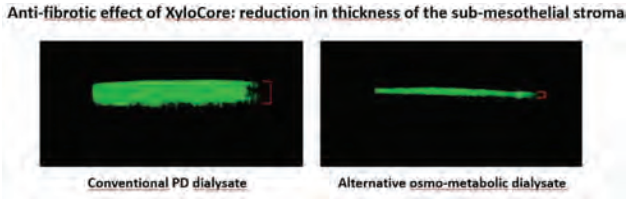
Luciano D'Apolito,[1,2] Valentina Masola,[3] Abbas Shams,[2,1] Angelo D'Alessandro,[4] Mario Bonomini,[5] Jose C. Divino-Filho,[7] Arduino Arduini,[6] Giovambattista Capasso,[1,2] Francesco Trepiccione.[1,2] Translational Nephrology Laboratory. *[1]Biogem, Institute of Molecular Biology and Genetics, Ariano Irpino, Italy; [2]Universita degli Studi della Campania Luigi Vanvitelli, Caserta, Italy; [3]Universita degli Studi di Padova, Padova, Italy; [4]University of Colorado, Denver, CO; [5]Universita degli Studi Gabriele d'Annunzio Chieti Pescara, Chieti, Italy; [6]Iperboreal Pharma Srl, Pescara, Italy; [7]CLINTEC, Karolinska Institutet, Stockholm, Sweden.*

Background: Peritoneal dialysis (PD) is a renal replacement therapy that enables metabolic waste products and excess fluids to be eliminated through the peritoneal membrane. Exposure to conventional dialysates at high glucose content is considered critical for the pathogenesis of peritoneal fibrosis, angiogenesis, and epithelial-mesenchymal transition and leads to technique failure. Pre-clinical research in this field suffers from limited *in vivo* models. Here, we propose a method, based on multi-photon microscopy (MPM), that aims to study the physiology of the peritoneal membrane during dialysis exchange and to validate the effects of biocompatible dialysates in animal models.

Methods: By imaging the parietal peritoneum by MPM we are able to quantify blood flow, degree of fibrosis and vessels distribution. *In vivo* microscopy evaluation of peritoneal membrane was conducted in rats receiving for 15 days a daily i.p. injection of conventional glucose containing dialysate or a new glucose-sparing dialysate that keep iso-osmolality by substituting glucose with carnitine and xylitol (XyloCore).

Results: Treatment with XyloCore was associated with a lower thickness of the sub-mesothelial collagen deposition compared to glucose containing solution (p=0.013). In addition, the density of collagen fibers (p=0.012) and the vascular composition (p=0.006), as well as the number of branch points (p=0.0335), when compared to rats treated with a conventional PD solution was significantly lower. All these parameters were associated with a better functional performance at the PET test in the glucose-sparing group. Finally, metabolomic analysis of membrane extract and dialysate showed a marked difference in metabolic pathways.

Conclusions: Previous *in vitro* studies have shown that XyloCore is able to counteract the glucotoxic effects on the peritoneal membrane induced by conventional dialysates. Our *in vivo* approach confirms these findings and suggests that long-term protective effects may be achieved with XyloCore.



FR-OR80

Pregnancies in Women with Kidney Failure on Home Dialysis

Silvi Shah,[1] Eric D. Weinhandl,[3] Anthony C. Leonard,[1] Jeffrey Perl,[2] Annette Christianson.[1] *[1]University of Cincinnati, Cincinnati, OH; [2]St Michael's Hospital, Toronto, ON, Canada; [3]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Women with kidney failure have impaired fertility and are at a higher risk of maternal and fetal morbidity and mortality. Little is known about pregnancies in women receiving maintenance home dialysis in the United States.

Methods: Using data from the United States Renal Data System, a cohort of 26,387 women aged 15-49 years with kidney failure receiving maintenance home dialysis in 2005-2018 was examined. We calculated pregnancy rates and identified factors including the modality associated with pregnancy on home dialysis.

Results: Overall, 437 pregnancies were identified in 26,837 women on home dialysis. Unadjusted pregnancy rate was 8.6 per 1000 person-years (PTPY). The unadjusted pregnancy rate was higher on home hemodialysis (16.0 vs. 7.5 PTPY) than on peritoneal dialysis. Women on home hemodialysis had a higher adjusted likelihood of pregnancy than women on peritoneal dialysis (HR, 2.34; 95% CI, 1.79-3.05). Compared with women aged 20–24 years, the likelihood of pregnancy was lower in women 30-34 years (HR, 0.64; 95% CI, 0.43-0.96), 35–39 years (HR, 0.53; 95% CI, 0.35-0.79), 40–44 years (HR, 0.32; 95% CI, 0.21-0.49), and 45-49 years (HR, 0.21; 95% CI, 0.13-0.33). While Black women had a higher likelihood of pregnancy (HR, 1.40; 95% CI, 1.07-1.83), there was no difference in likelihood of pregnancy in Asian, Hispanic, and Native Americans as compared to Whites. Body mass index, cause of kidney failure, socioeconomic status, rurality, pre-dialysis nephrology care, or dialysis vintage were not significantly associated with pregnancy on home dialysis.

Conclusions: The pregnancy rate in women with kidney failure undergoing home dialysis is higher with home hemodialysis than with peritoneal dialysis. Younger age and Black race/ethnicity are associated with a higher likelihood of pregnancy among women on home dialysis. This information can guide clinicians in preconception counseling and making informed treatment decisions for pregnant women on home dialysis.

FR-OR81

Representativeness of Randomized Control Trials in Kidney Transplantation

Oshorenua Aiyegbusi,[1] Sara Fakhredine,[1] Ulrike Mayer,[2] John S. Gill.[1] *[1]The University of British Columbia, Vancouver, BC, Canada; [2]Providence Health Research Institute, Vancouver, BC, Canada.*

Background: Differences between participants in randomized controlled trials (RCTs) and the target patient population may impact the intervention effect of trial findings in clinical practice. The purpose of this study was to determine the extent to which participants in clinical trials were similar to transplant recipients who underwent transplantation in the U.S. at the time of clinical trial enrolment.

Methods: We undertook a systematic search of PubMed, Embase and ClinicalTrials.gov for RCTs completed between 1990 to 2020 that included adults ≥ 18 years of age in kidney transplant recipients. Trials were included if at least one U.S. center participated and ≥ 100 participants were randomized. For each trial, the inclusion and exclusion criteria were extracted and applied to the scientific registry of transplant recipients (SRTR) to identify patients undergoing transplantation during the trial enrollment period. Demographics of interest included participant age, the proportion of women, and the proportion of patients from race and ethnic minority groups.

Results: Our search identified 5206 records, 43 trials met the study inclusion criteria. Participants characteristics included age, sex, race/ethnicity, cause of kidney failure, donor source, and comorbid conditions. From the trials, a total of 13591 participants enrolled. 74% enrolled patients only in the U.S., and 52% were multicenter studies. After searching each trial's inclusion and exclusion criteria during the trial enrollment period, 1,011,861 transplant recipients were identified in the SRTR who were potentially eligible for trial participation. Trial participants were younger, more likely to be White, and less likely to be Black or Asian (table 1). Demographic differences between trial participants and transplant eligible transplant recipients in the U.S. persisted in more recent trials.

Conclusions: We conclude that women and non-White patients are under-represented in kidney transplant trials. These differences may limit the applicability of trial findings to the real-world setting. Efforts to improve the representativeness of transplant trials are needed.

	Trial participants Mean (SD)	Contemporary trial Mean (SD)	P value
Age (years)	47.7 (± 3.0)	49.1 (±1.8)	0.02
Women (%)	35.7 (± 6.3)	39.0 (± 1.8)	<0.01
Race (%)			
White	66.7 (± 18.5)	53.6 (± 3.4)	<0.01
Black	20.7 (± 12.9)	26.0 (± 1.0)	<0.01
Asian	5.0 (± 4.2)	5.1 (± 1.1)	0.06
Hispanic ethnicity (%)	15.0 (± 11.9)	13.6 (± 2.0)	0.6

FR-OR82

Primary Care Clinician Perspectives on APOL1 Testing for Kidney Diseases

Dinushika Mohottige, Rennie Negron, Michelle Ramos, Tatiana Sabin, Miguel Gomez, Carol R. Horowitz. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Black and Hispanic individuals experience a disproportionate burden of ESKD and CKD progression compared to White counterparts. These disparities are multifactorial and related to health-harming socio-contextual factors and partly explained by high-risk genetic alleles including APOL1, and gene-environment interactions. Despite the growing importance of high-quality patient-centered communication around genetic risk, little is known about the perspectives of front-line primary care physicians regarding APOL1 testing for kidney disease risk.

Methods: We conducted, recorded, and transcribed 15 semi-structured interviews in 2014-2016 with general internists and family physicians in New York, NY. Two independent trained researchers coded transcripts, modified discrepancies through consensus, and used modified grounded theory to identify themes.

Results: Interviewed clinicians had a mean age of 38 years, 10 (67%) were female, 8 (52%) self-identified their race as White, 3 (20%) as Asian, 2 (13%) as Black, and 1 (7%) self-identified as Hispanic. Participants mentioned environmental and behavioral factors as contributors to kidney risk and patients' fear of dialysis as a primary driver of HTN-related behavioral change. Additional emergent themes included 1) desires for additional training opportunities to effectively communicate testing considerations and implications of genetic testing, including potential stigma, 2) challenges identifying individuals appropriate for testing based on race/ethnicity and other sociodemographic characteristics 3) the need for low literacy, culturally-tailored, action-oriented post-testing instructions and guidance for patients, 4) fears that *APOL1* disclosure would result in fatalism and decreased engagement in health promoting behaviors, and 5) the importance of ensuring *APOL1* testing discussions are attentive to patient-level barriers including racial discrimination and medical mistrust.

Conclusions: Primary care physicians describe a broad interest in clinical decision-support for *APOL1* genetic testing and return of results, as well as clear guidance regarding effective communication about risk and modifiable actions to reduce risk.

Funding: Other NIH Support - National Human Genome Research Institute (NHGRI) (Grant Nos. 5U01HG007278 and U01HG006380) and the National Center for Advancing Translational Sciences (NCATS) (Grant No. UL1TR000067). Neither the NHGRI nor the NCATS was involved in the study design, collection, analysis or interpretation of data, writing of this article, or decision to submit it for publication. The authors thank the genomics board; the Genetic Testing to Understand Renal Disease Disparities team of academic, community, and clinical partners as well as the study coordinators and staff members at the study sites; and their partners in the Implementing Genomics in Practice (IGNITE) Network for their valuable contributions to this project.

Association of Unmet Social Needs with Blood Pressure Severity and Target Organ Injury: Interim Analysis of the SUPERHERO Study

Elizabeth A. Onugha,[1] Fallon Campbell,[1] Andrew M. South.[2] SUPERHERO Registry. *[1]Baylor College of Medicine, Houston, TX; [2]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Hypertension (HTN) is a leading cause of cardiovascular disease and when uncontrolled is associated with increased risk for target organ injury (TOI). The burden of HTN disproportionately falls on individuals of low socioeconomic status (SES) and racial and ethnic minorities. Studies in adults have shown that low, including education, income, and neighborhood characteristics are linked to poor blood pressure (BP) control. Data in youth relating to the influence of SES factors on HTN epidemiology are sparse.

Methods: Cross-sectional analysis of baseline electronic health record data from the SUPERHERO Registry in youth referred to subspecialists for ICD-10 code-defined HTN disorders from 1/1/2015 – 12/31/2022. We excluded those with pregnancy, kidney transplantation, or dialysis. We examined the association of individual-level social drivers (transportation, financial, food access, housing, education, employment, occupational exposures, physical environment, social environment, family, and crime) by ICD-10 codes with BP severity and risk of TOI in youth using unadjusted generalized linear models.

Results: Of our cohort of 11,580 participants, 56% (6,508 of 11,580) were Caucasian and 27% (3,114 of 11,580) African American. Of the 47 with documented unmet social needs, 57% (n = 27) were African American vs 26% (n = 12) were Caucasian. Stage 2

HTN was noted in 23% (2,663 of 8,859), 35% (4,092 of 8,859) had stage 1 HTN and 18% (2,104 of (8,859) had BP. TOI was present in 8% (n = 903) of those with no unmet social needs and 6% (n = 3) of those with unmet needs.

Conclusions: In our large cohort of youth referred for HTN disorders, we found that unmet social needs were not associated with worse BP severity and greater risk of TOI at baseline. These findings are likely due to lack of inquiry into social needs by providers.

FR-OR84

Association of Unmet Social Determinants of Health (SDOH) with Quality of Life (QoL) in Patients on Hemodialysis (HD)

Huei Hsun Wen, Yang Dai, Girish N. Nadkarni, Lili Chan. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Patients on hemodialysis (HD) have low quality of life (QoL). Social determinants of health (SDOH) are the non-medical aspects of a patient's life that affect their health. Whether unmet SDOH are associated with QoL in patients on HD has not previously been studied.

Methods: We prospectively surveyed patients on their living situation, food security, transportation, utilities, and safety using the AHC-HRSN and their QoL using the KDQOL-36. From the KDQOL-36, we calculated the physical component score (PCS), mental component score (MCS), and scores for effect, burden, and symptoms of kidney disease. Patients were included if they were over the age of 18, had been on HD for more than 30 days, and was able to complete the surveys with minimal assistance. Patients completed the surveys during their HD treatments. Laboratory values of hemoglobin, albumin, calcium, phosphorus, intact parathyroid hormone, and Kt/V were obtained from the monthly blood work closest to the survey administration. QoL scores were compared using Student's T-test. We used linear regression to evaluate the association between SDOH and QoL while adjusting for age and gender.

Results: A total of 138 patients participated in the study, 53% were female, 50% were Black, and 43% were Hispanic. Unmet SDOH were common in our patients, with 40% of patients reporting food insecurity and 23% of patients reporting housing insecurity (Figure 1A). Patients with unmet SDOH had lower scores for PCS and MCS, and higher scores for effect, burden, and symptoms of kidney disease, although these were not statistically significant (Figure 1B&C). There was no clinically or statistically significant difference in laboratory values between patients with and without unmet SDOH. There was no significant association between SDOH measures and the PCS or MCS of the KDQOL-36.

Conclusions: Unmet SDOH are common in patients on HD, particularly food and housing insecurity. Patients with unmet SDOH report lower QoL and higher effect, burden, and symptoms of kidney disease. While not statistically significant, this may be related to a small sample size.

Exploring Unconscious Bias in Peer-to-Peer Interactions in Medical Conferences: A Retrospective Analysis

Joseph Wahba,[1] Chaitanya S. Vankireddy,[1] Sandeep Aggarwal.[2] *[1]University of Pennsylvania, Philadelphia, PA; [2]Penn Medicine, Philadelphia, PA.*

Background: Unconscious bias in academic interactions has garnered increasing attention across several disciplines, including the field of medicine. We explored the presence of these biases using speakers' introductions at ASN (American Society of Nephrology) Kidney Week.

Methods: We screened 535 archived sessions from ASN Kidney Week 2019 and 2021 to conduct this study. The moderators' gender and academic title were documented, along with the presence of the speaker's academic title, first name, and last name in each announcement. R.4.2.2 was used for inferential and descriptive statistics.

Results: The professional title announcement frequency from highest to lowest were female moderators introducing female speakers (85%), female moderators introducing male speakers (77%), and male moderators introducing male (73%) or female speakers (72%). A multivariate logistic regression using variables "speaker rank," "moderator rank," "speaker gender," "moderator gender," "first name announcement," and "last name announcement" found female moderators had the highest odds ratio of title announcement (OR = 1.76 (Female vs Male), p = 0.01) and high academic rank had the lowest odds ratio of title announcement (OR = 0.66 (higher rank), p = 0.01). Another multivariate analysis combining variables of "moderator gender" with "speaker gender" and "moderator rank" with "speaker rank" found that males (moderators) introducing females (speakers) had the lowest (OR = 0.48, p = 0.05), whereas associate professors introducing professors had the highest title announcement odds (OR = 4, p = 0.001).

Conclusions: Our findings suggest the possibility that unconscious bias exists in peer to peer interactions in renal academic circles, though larger studies are necessary to understand the extent of this issue and the interplay of additional variables.

Title Announcement Odds Predictors (Only Statistically Significant Results Included)

Predictor Variable	OR (Odds Ratio)	Standard Error	p-value
Moderator Gender	1.762	.2482	.01
Moderator Rank	.6594	.1909	.01
Male Moderator/Female Speaker Introductions	.4885	.4271	.05
Associate Professor Moderator/Professor Speaker Introductions	4.141	.4617	.001

County-Level Structural Racism Predicts Black-White ESKD Patient Mortality Disparities

Jonathan Daw,[1] Avrum Gillespie,[2] Tanjala S. Purnell.[3] *[1]The Pennsylvania State University - University Park Campus, University Park, PA; [2]Temple University Health System Inc, Philadelphia, PA; [3]Johns Hopkins Medicine, Baltimore, MD.*

Background: Despite numerous call for structural racism (SR) research in nephrology, no prior research has employed multidimensional, empirical measures of SR to racial disparities in ESKD mortality. We estimate the first-ever analysis of the role of SR in racial disparities in ESKD patient mortality.

Methods: We analyze data from United States Renal Data System (USRDS), American Community Survey 2006-10 (ACS), and Vera Institute (VI), linked by county. USRDS ESKD who were alive on Jan. 1, 2011 and lived in a county with ≥1,000 White and Black residents were included. SR was constructed from ACS and VI county Black-White disparities in imprisonment, homeownership, college graduation, median income, unemployment, poverty, and segregation. Black-White disparities in each measure were converted to county z-scores and summed. Patient person-months through Dec. 2019 were analyzed using complementary log-log discrete time survival models. Monthly ESKD treatment was assigned based on treatment received on 1st day of each month (hemodialysis, peritoneal dialysis, deceased donor kidney transplant, living donor kidney transplant). Models controlled for region, county racial composition, and patient gender and birth cohort.

Results: Black race statistically significantly interacted with SR to predict monthly mortality risk among ESKD patients. Black patients experienced survival advantages compared to Whites at lower levels of SR, but experienced survival disadvantages compared to Whites at higher levels of SR. When stratified by monthly treatment, the core finding that Black survival advantages are eroded or erased at higher SR levels was replicated within each treatment group.

Conclusions: County-level SR is a significant determinant of ESKD patient mortality. Future research should prioritize including area-level measures of SR in ESKD disparities research.

Significant Variation in Kidney Disease Indicators Within Cook County, IL: Findings from Geospatial Analysis of 2022 National Laboratory Data

Jennifer L. Bragg-Gresham,[1] Linda Fraunhofer,[3] Ana Laura Licon,[1] Tiffany C. Veinot,[2] Jennifer L. Ennis,[3] Rajiv Saran.[1] *[1]University of Michigan Medical School, Ann Arbor, MI; [2]University of Michigan School of Information, Ann Arbor, MI; [3]Laboratory Corporation of America Holdings, Burlington, NC.*

Background: Chronic Kidney Disease (CKD) is frequently diagnosed through routine laboratory tests. There is not currently a source for population-level data on kidney disease and it is therefore difficult to assess prevalence at the local level. We sought to assess the feasibility of analyzing data from one of the largest clinical laboratory networks in the US to measure the extent of variation in kidney disease indicators found within a single county by ZIP code.

Methods: Data from approximately 600,000 Labcorp tests, resulted in 2022, for estimated glomerular filtration rate (eGFR) and urine albumin:creatinine ratio (UACR) in the greater-Chicago area of Cook County, IL were utilized. The presence of a kidney disease indicator was defined as an eGFR < 60 ml/min/1.73m^2 or a UACR > 30 mg/g. The overall ZIP code percentage of lab results with kidney disease indicators were visualized with ArcGIS, stratified by Jenks Natural Breaks (5 classes). ZIP codes with less than 10 results were suppressed. Optimized hotspot analyses were conducted with the Getis-Ord Gi* statistic and Moran's I statistic was applied for the outlier analysis. The interstate system was included to aid visualization.

Results: Kidney disease indicators varied markedly at the ZIP code level across Cook County, IL. The ZIP code percentage of lab results with kidney disease indicators ranged from a low of 0% to a high of 67%. Hotspot analysis indicated a clear high-high cluster in south and southeastern sections of the county. The northeastern section of the county appeared to be a low-low cluster, or cold spot. Both high-low and low-high outliers were found.

Conclusions: We demonstrate the feasibility of utilizing a large national laboratory database for mapping kidney disease indicators and identification of hotspots of kidney disease within a county. This work has the potential to support CKD surveillance systems to guide area-level CKD prevention and population health improvement initiatives.

Barriers and Opportunities to Increase Home Dialysis Among African American Patients

Unini Odama,[1] Karen-Marie Eaton,[2] Steven M. Brunelli,[2] Danelle Radney,[1] Francesca Tentori.[2] *[1]DaVita Inc, Denver, CO; [2]Davita Clinical Research, Minneapolis, MN.*

Background: Home dialysis offers patients another treatment option for kidney failure. Home dialysis use is lower in African American patients. In this study we sought to understand the experiences that patients and care partners face and uncover influencing factors and barriers to home dialysis use.

Methods: A total of 29 participants (African American patients at a dialysis provider, both in-center and home, and their care partners) were recruited to join in-person focus groups held in December 2022 and February 2023. Focus groups were audio and video recorded and transcribed verbatim. Responses were analyzed using inductive thematic analysis.

Results: Patients reported that physicians did not make a clear connection between poor management of underlying health conditions and kidney failure; irrespective of a patient's access to primary care. Patients and care partners want improved/additional education, especially regarding modality selection as some information was lost or forgotten. African American patients and care partners primarily rely on healthcare professionals (HCP) for information. However, if the patient or care partner feels the HCP is less than forthcoming or insensitive when providing information, their trust is quickly eroded. Unsurprisingly, care partners are a critical part of the decision to choose and remain on home dialysis. Faith plays a significant role for many respondents in terms of disease experience (i.e., "God is in control") and emotional support. Physician guidance was cited as the most important factor in the initial modality decision for African American patients and care partners. While most patients and care partners acknowledge the benefits of home dialysis, significant barriers included the fear of being solely responsible for a complex procedure, risk of infection, and loss of social interaction and/or support from other dialysis patients and center staff.

Conclusions: Opportunities exist for early and direct linkage of co-morbidities with kidney disease and consideration of patient concerns in home dialysis modality education.

FR-OR89

Experiencing Discrimination Reduced the Effectiveness of the TALK Intervention on Kidney Failure Patients

Larissa Myaskovsky,[1] Jamie M. Loor,[1] Yuridia Leyva,[1] Emilee J. Croswell,[2] Mary Amanda Dew,[2] L. Ebony Boulware.[3] *[1]University of New Mexico Health Sciences Center, Albuquerque, NM; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA; [3]Wake Forest University School of Medicine, Winston-Salem, NC.*

Background: Although kidney transplantation (KT) is the optimal treatment for patients with kidney failure, few patients receive it. Our study tested the effect of an empirically-developed culturally-concordant education intervention on increasing KT evaluation completion rates for patients starting the evaluation process. We also examined the impact of novel social determinants of health (e.g., experience of discrimination) on outcomes.

Methods: We recruited patients for a baseline interview before their first KT evaluation appointment. We randomly assigned patients to receive the Talking About Live Kidney Donation (TALK) intervention or no intervention at their evaluation appointment. The TALK group received an educational booklet and video encouraging shared decision making and informed consideration of kidney failure treatment options. We called patients after two weeks to address questions and encourage review of materials. We conducted a second interview to assess intervention engagement and other outcomes after patients completed or discontinued evaluation.

Results: Our study sample included 1028 participants (63% male; mean age=56.7 yrs; 45% ≤ high school graduates; 71% non-Hispanic White; 21% Black). Using a Fine-Gray proportional subdistribution hazards model for time to evaluation completion, and controlling for demographic, medical, cultural, psychosocial, and transplant knowledge covariates, we found no significant difference in the likelihood of evaluation completion between TALK and no-TALK (SHR = 1.13, 95% CI = 0.96-1.34, p=0.153). Interaction analyses showed that the TALK intervention increased the rate of evaluation completion among people who reported *never* experiencing discrimination in healthcare (SHR=1.26, 95%CI=1.04-1.52, p=0.019), but not among those who reported *ever* experiencing discrimination.

Conclusions: Our findings suggest that TALK education materials alone did not promote higher KT evaluation completion rates and that the impact of experiencing discrimination in healthcare may be particularly relevant. Patients, especially those who have experienced discrimination, may need additional or different support to encourage their completion of KT evaluation, such as a social worker, peer mentor, or community health worker.

FR-OR90

Regional Variation in the Use of Percutaneous Kidney Biopsy in Japan

Yasuhiro Oda, Hiroshi Nishi, Masaomi Nangaku. *The University of Tokyo Graduate School of Medicine, Bunkyo, Japan.*

Background: Several studies have conducted questionnaires on kidney biopsies performed in Japan, but there is no exhaustive survey of all kidney biopsies in Japan. Moreover, it is unknown whether there is a regional variation in the use of percutaneous kidney biopsies in Japan.

Methods: The number of percutaneous kidney biopsies stratified by the demographic data of the patients was obtained from the National Database of Health Insurance Claims and Specific Health Checkups of Japan. Data from other nationwide surveys, including the population census, kidney transplant registry, dialysis registry and statistics of physicians, were also used. Pearson's product-moment correlation coefficient was calculated using the R system for statistical computing.

Results: A total of 22,419 health insurance claims for percutaneous kidney biopsy in the fiscal year 2020 was registered in the database. The majority (99.9%) was inpatient percutaneous kidney biopsy. There was a large difference in the number of inpatient percutaneous kidney biopsies per population among prefectures, which could be up to 4.8 times as large in one prefecture than in another, even after adjusting for age. The number of inpatient percutaneous kidney biopsies per population positively correlated with the number of annual kidney transplants per population ($R = 0.39$, $p = 0.006$) and the number of patients on peritoneal dialysis per population ($R = 0.47$, $p < 0.001$). There was a weak negative correlation between the number of inpatient percutaneous kidney biopsies per population and the prevalence of reduced kidney function in the population aged 40–74 years ($R = -0.36$, $p = 0.013$). The frequency of kidney biopsy had no correlation with the number of patients on hemodialysis or the number of nephrologists or urologists per population.

Conclusions: The National Database of Health Insurance Claims and Specific Health Checkups of Japan revealed for the first time that more than 20,000 kidney biopsies were performed per year in Japan, as of 2020. Peritoneal dialysis and kidney transplant are offered more frequently in prefectures with a higher frequency of kidney biopsy. Further research is warranted to understand the reason for the wide regional variation in the frequency of kidney biopsy.

FR-OR91

One-Month Treatment with Dapagliflozin Triggers Renal Water Conservation and Thus Prevents Osmotic Diuresis in Patients with Chronic Heart Failure

Adriana Marton,[1,2] Seyed Ehsan Saffari,[3] Ruo-Ning Sun,[4] Armin M. Nagel,[5] Peter Linz,[5] Tzy Tiing Lim,[1] Kaoru Minegishi,[1] Norihiko Morisawa,[1] Wan Keat Yam,[1] Shintaro Minegishi,[1] John J. Totman,[4] Kento Kitada,[6] Johannes Wild,[7] Jean-Paul Kovalik,[1] Friedrich Luft,[8] Peter J. Greasley,[9] David Sim,[10] Jens Titze.[1,11] *[1]Duke-NUS Medical School Cardiovascular & Metabolic Disorders Programme, Singapore, Singapore; [2]Klinikum Nurnberg, Nurnberg, Germany; [3]Duke-NUS Medical School, Singapore, Singapore; [4]Clinical Imaging Research Centre, Singapore, Singapore, Singapore; [5]Universitatsklinikum Erlangen, Erlangen, Germany; [6]Kagawa Daigaku, Takamatsu, Japan; [7]Universitatsmedizin der Johannes Gutenberg-Universitat Mainz Zentrum fur Kardiologie, Mainz, Germany; [8]Max Delbruck Centrum fur Molekulare Medizin Experimental and Clinical Research Center, Berlin, Germany; [9]AstraZeneca, Gothenburg, Sweden; [10]National Heart Centre Singapore, Singapore, Singapore; [11]Duke Medicine, Durham, NC.*

Background: It is unclear whether SGLT2 inhibitors improve cardiac outcomes due to their osmotic-diuretic potential. We tested the hypothesis that SGLT2 inhibition with dapagliflozin does not promote renal water excretion in patients with chronic heart failure.

Methods: DAPA-Shuttle1 was a mechanistic, double-blind, randomized trial which investigated the early (48h) and late (4 weeks) effects of dapagliflozin on urine volume generation and body solute handling. Participants with chronic heart failure NYHA classes I/II were randomly assigned to receive dapagliflozin 10mg daily or placebo for 4 weeks. The primary endpoint was change from baseline in urine osmolyte concentration. ClinicalTrials.gov registration NCT04080518.

Results: 29 participants (placebo n=14; dapagliflozin n=15) completed the study (age 59±14 years). Dapagliflozin increased glucosuria by 3.3±0.4 mmol/kg/d ($p<0.0001$) within 48h; this effect persisted after 4 weeks (2.7±0.4 mmol/kg/d, $p<0.0001$). Dapagliflozin did not increase natriuresis (early: p=0.68; late: p=0.64), and did not change MRI-determined tissue Na^+ content (early: p=0.62; late: p=0.90). Despite sustained glucosuria, urine volume remained stable in the dapagliflozin group after one month (+0.9±2.4 ml/kg/d, p=0.70). Dapagliflozin increased plasma copeptin (early: +5.5±2.5 pmol/L, $p<0.05$; late: +7.8±2.5 pmol/L, $p<0.01$), leading to proportional reductions in free water clearance (early: -9.1±2.5 ml/kg/d, $p<0.001$; late: -11.0±2.5 ml/kg/d, $p<0.0001$) and increases in urine concentration (late: +134±47 mmol/L; $p<0.01$).

Conclusions: SGLT2 inhibition with dapagliflozin triggered a vasopressin-driven water conservation response in patients with chronic heart failure, and thereby prevented a 800-1000 ml/d glucose-driven increase in urine volume. In contrast to saluretic diuretics, which promote solute excretion to increase free water excretion in the urine, SGLT2 inhibitors reduce solute-free water excretion, abolishing the osmotic-diuretic effect of glucosuria.

Association of Polygenic Risk Scores for Blood Pressure with Incidence of Hypertension and CKD

Soyeon Kim,[1] Soon hyo Kwon,[1,2] Hyunjin Noh,[1,2] Hyoungnae Kim,[1,2] Haekyung Lee.[1,2] *[1]Soonchunhyang University Hospital, Seoul, Republic of Korea; [2]Soonchunhyang University Hospital Kidney Center, Seoul, Republic of Korea.*

Background: Genetic risk for elevated blood pressure (BP) has been associated with a higher risk of hypertension and cardiovascular disease. However, the generalizability of previous findings has been limited due to a lack of studies among Asian populations. This study aimed to investigate whether genetic risk for BP predicts the incidence of hypertension and chronic kidney disease (CKD).

Methods: We constructed polygenic risk scores (PRSs) for systolic and diastolic BP (SBP and DBP, respectively) using genome-wide association data from the Biobank Japan. We then examined the association between BP PRSs and incident hypertension or CKD in the Korean Genome and Epidemiology Stduy. The study included participants without hypertension, cardiovascular disease, or CKD at baseline (n = 4351, median age 48 years, 48.8% men). Participants were categorized into four groups based on their PRS percentile (<5%, 5-50%, 50-95%, >95%).

Results: The PRS for SBP and DBP showed independent associations with SBP and DBP, respectively (both P <0.001). Compared to individuals with the lowest 5% SBP PRS, those with SBP PRS in the 50 to 95 percentile range and the highest 5% had a 1.62-fold (95% confidence interval [CI], 1.24–2.11; P <0.001) and 1.75-fold (95% CI, 1.23–2.49, P = 0.002) higher risk of hypertension, respectively. Elevated DBP PRS was associated with 1.47-fold (95% CI, 1.11–1.94, P = 0.006), 1.79-fold (95% CI, 1.35–2.35, P <0.001), and 2.03-fold (95% CI, 1.41–2.91, P <0.001) higher risk of hypertension in the 5 to 50 percentile, 50 to 95 percentile, and the highest 5%, respectively. The highest PRS percentile for SBP and DBP was associated with earlier onsets of hypertension by 5.9 years (95% CI, 2.9–8.9) and 6.7 years (95% CI, 3.9–9.4), respectively, compared to the lowest PRS percentile for SBP and DBP. However, both SBP and DBP RPSs were not associated with incident CKD.

Conclusions: Genetic risk for elevated BP was associated with a higher risk of incident hypertension and earlier onset of hypertension in the general population. However, there was no association between PRS for elevated BP and the incidence of CKD.

FR-OR93

Polygenic Scores for Incident Myocardial Infarction in CKD

Amarnath Marthi,[1] Jiang He,[2] Panduranga S. Rao,[3] Mahboob Rahman,[4] Alan S. Go,[5] Ana C. Ricardo,[6] Yun Li,[1] Nora Franceschini.[1] *[1]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [2]Tulane University School of Public Health and Tropical Medicine, New Orleans, LA; [3]University of Michigan Health System, Ann Arbor, MI; [4]University Hospitals, Cleveland, OH; [5]Kaiser Permanente Division of Research, Oakland, CA; [6]University of Illinois Chicago College of Medicine, Chicago, IL.*

Background: Improving prediction of cardiovascular events in CKD has focussed on integrating kidney biomarkers to existing models. In the general population, genetic data may provide orthogonal information to clinical variables, identifying individuals at high risk of coronary artery disease (CAD) even in the absence of classical risk factors. In CKD, where cardiovascular risk is elevated and underlying aetiology may differ, the utility of CAD polygenic scores (PGS) has not been assessed.

Methods: Individuals with genetic data at risk of incident myocardial infarction (MI) in the Chronic Renal Insufficiency Cohort (CRIC) were included. Following relevant quality control and imputation of array-derived genotypes, variants with an imputation quality RSQ ≥ 0.3 or RSQ ≥ 0.8 with minor allele frequency <0.01 were retained. Individuals were stratified as European [EUR] or African [AFR] ancestry (based on self-report and genotype). We applied PGS derived in European and multi-ancestry populations (pgscatalog.org), for CAD and for estimated glomerular filtration rate (eGFR), to Cox-proportional hazard models sequentially adjusted for: first 10 PCs, age, sex, baseline eGFR and statin use. The primary outcome was incident MI; over the follow-up period and after censoring at dialysis initiation.

Results: 1175 AFR and 1607 EUR individuals in CRIC included, had 142 (12.1%) and 156 (9.7%) MI events, respectively, including 79 (6.7%) and 113 (7.0%) events occurring before dialysis initiation. Variant availability limited application of some PGS (Tcheandjieu 2022). Among EUR individuals, one standard deviation increase in European-derived CAD PGS was associated with 31% increased hazard of MI (95% confidence interval [CI] 1.1 – 1.56). This result was similar when events were censored at dialysis (1.35, 95% CI 1.1 – 1.66). However, the CAD-PGS association was not significant in CRIC AFR individuals or when using PGS for eGFR in both AFR or EUR individuals.

Conclusions: Current PGS for CAD predicts incident MI in European ancestry individuals with CKD but no significant effect was revealed in African ancestry individuals. As PGS is being considered as a potential tool for prediction in clinical practice, there is a pressing need to understand the genetic architecture of CAD in the milieu of CKD and how PGS perform in the context of diverse ancestry.

FR-OR94

Kidney Function Trajectories, Risk Factors, and Outcomes in Left Ventricular Assist Device (LVAD) Recipients

Carl P. Walther, Nandan Mondal, Sankar D. Navaneethan. *Baylor College of Medicine, Houston, TX.*

Background: LVAD (Left ventricular assist device) implantation can improve or worsen kidney function due to several known and hypothesized causes. However, competing risks of death and transplantation, patterns of missing data, and inaccuracy of estimating equations complicate kidney outcome assessment. To enable additional insight into the effects of LVAD implantation on kidney health, we investigate use of a continuous metric (trajectory of log eGFR) to summarize long-term post-LVAD kidney health.

Methods: We identified adults who received isolated primary continuous-flow LVADs from 2012 to 2017 in a US national database of LVAD recipients (INTERMACS). We assessed eGFR-Cr (CKD-EPI 2021) from pre-LVAD implantation to 12 months, fitting linear mixed models with random slopes and intercepts to natural log-transformed eGFR values (so that slopes would approximate proportional changes), adjusted for baseline eGFR. We then investigated how baseline factors related to worse than average kidney function trajectory and how kidney function trajectory related to mortality risk.

Results: We identified 15,052 LVAD recipients (median age 59 years, 21.2% female, median pre-LVAD eGFR 62 ml/min/1.73m^2). The median eGFR trajectory slope was approximately -5.6% over one year; only 23.3% had a positive trajectory slope. The ten baseline factors most associated with worse than average kidney function trajectory are shown in Figure 1A: ‘older age’ was the most significant risk factor; ‘no prior cardiac operation’ was the most significant protective factor. In addition, mortality was progressively higher with worse kidney function trajectory (Figure 1B).

Conclusions: A log eGFR trajectory measure over one year may be a useful summary outcome metric in investigating the effects of LVADs on kidney health/function. As a continuous summary metric, this may provide improved power to study determinants of kidney outcomes in LVAD recipients. In addition, as a log trajectory measure, it may be less susceptible to the imprecision and non-kidney-related confounding inherent in estimating GFR.

Associations Between Clonal Hematopoiesis of Indeterminate Potential and Cardiovascular Disease in Three Prospective CKD Patient Cohorts

Yang Pan,[1] Caitlyn Vlasschaert,[2] Varun S. Rao,[1] James E. Hixson,[3] Md Mesbah Uddin,[4] Zhi Yu,[4] Do-Kyun Kim,[3] Alexander Bick,[5] Bryan R. Kestenbaum,[10] Michael J. Rauh,[2] Adeera Levin,[6] James P. Lash,[1] Manjula Tamura,[7] Debbie L. Cohen,[11] Jiang He,[8] L. Lee Hamm,[8] Rajat Deo,[11] Zeenat Y. Bhat,[9] Panduranga S. Rao,[11] Pradeep Natarajan,[4] Tanika Kelly,[1] Cassianne Robinson-Cohen,[5] Matthew B. Lanktree.[12] *[1]University of Illinois Chicago, Chicago, IL; [2]Queen's University, Kingston, ON, Canada; [3]The University of Texas Health Science Center at Houston, Houston, TX; [4]Broad Institute, Cambridge, MA; [5]Vanderbilt University Medical Center, Nashville, TN; [6]The University of British Columbia Faculty of Medicine, Vancouver, BC, Canada; [7]Stanford University, Stanford, CA; [8]Tulane University, New Orleans, LA; [9]University of Michigan Michigan Medicine, Ann Arbor, MI; [10]University of Washington, Seattle, WA; [11]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [12]McMaster University, Hamilton, ON, Canada.*

Background: Clonal hematopoiesis of indeterminate potential (CHIP) is an age-related condition characterized by the clonal expansion of blood cells carrying somatic mutations to specific driver genes. Although CHIP has been established as an important contributor to cardiovascular diseases (CVD) in the general population, its association with CVD in a pro-inflammatory chronic kidney disease (CKD) setting has not been examined.

Methods: We examined prospective associations between CHIP status and CVD events in three cohorts that included a total of 3,414 CKD patients: the Chronic Renal Insufficiency Cohort (CRIC), the African American Study of Kidney Disease (AASK), and the Canadian study of prediction of death, dialysis and interim cardiovascular events (CanPREDDICT). Primary analyses tested associations between CHIP status and a composite CVD endpoint of myocardial infarction (MI), stroke, congestive heart failure (CHF), or peripheral artery disease (PAD). Cox proportional hazards regression models were used, adjusting for demographic, lifestyle, and clinical covariables, including cardiovascular risk factors. Secondary analyses investigated individual CVD endpoints. Random-effect meta-analyses were employed to combine effects across studies.

Results: Study participants had an average age of 68.8 years and a mean eGFR of 40.2 ml/min/1.73m^2. As expected, participants had a high frequency of hypertension (95%) and diabetes (49%), with CHIP identified in 25% of participants. Those with large CHIP clone size (VAF≥10%) and a non-*DNMT3A* CHIP gene mutation exhibited 38% (95% CI:2%-85%) and 42% (95% CI: 6%-90%) higher risks of the composite CVD endpoint, respectively, compared to noncarriers. Compared to non-CHIP status, large clone size was further associated with incident CHF (HR: 1.53, 95% CI: 1.13-2.00).

Conclusions: CHIP carrier status may be an important risk factor for CVD among CKD patients, with associations mirroring those observed in the general population.

Effects of Aprocitentan for Blood Pressure Lowering and Proteinuria in Patients with CKD and Resistant Hypertension

George L. Bakris,[1] John M. Flack,[2] Krzysztof Narkiewicz,[3] Markus P. Schlaich,[4] Jiguang Wang,[5] Michael A. Weber,[6] Mouna Sassi-Sayadi,[7] Lloyd P. Haskell,[8] Bruno Flamion.[7] *[1]University of Chicago Medicine, Chicago, IL; [2]Southern Illinois University School of Medicine, Springfield, IL; [3]Medical University of Gdansk, Gdansk, Poland; [4]University of Western Australia, Perth, NSW, Australia; [5]Jiaotong University School of Medicine, Shanghai, China; [6]State University of New York, Brooklyn, NY; [7]Idorsia Pharmaceuticals, Ltd, Allschwil, Switzerland; [8]Janssen Research & Development, LLC, Raritan, NJ.*

Background: Hypertension is often difficult to control in patients with CKD. In the phase 3 PRECISION trial, the dual endothelin receptor antagonist aprocitentan (APRO) at 12.5 and 25mg once-daily demonstrated significant BP reductions vs placebo (PBO) in patients with resistant hypertension. We evaluated APRO in patients with CKD enrolled in PRECISION.

Methods: Participants had unattended automated office systolic BP (SBP) ≥140mmHg despite use of ≥3 antihypertensive drugs. This subgroup analysis included patients with an eGFR of 15 to <60mL/min/1.73m^2. Reductions in office SBP, ambulatory BP monitoring (ABPM), and urinary albumin-to-creatinine ratio (UACR) were assessed following the double-blind treatment phase (Week 4), after 32-week single-blind APRO 25mg treatment (Week 36), and after 4 weeks of randomized withdrawal (Week 40).

Results: Changes in office BP and UACR in 162 CKD patients included in this analysis are summarized in the table below. Both doses of APRO resulted in a more pronounced BP reduction from baseline to week 4 compared to PBO. This was confirmed by ABPM. At Week 4, edema or fluid retention occurred in 18% and 24% of patients receiving APRO 12.5mg and 25mg, respectively, vs 2% with PBO; this rate was 34% in subjects exposed to APRO 25 mg during the trial. 55% of them were treated with diuretics (90% loop); 2 discontinued treatment due to this event. Five patients receiving APRO 25mg and 1 receiving placebo had heart failure leading to hospitalization; all but one had a history of heart disease.

Conclusions: In patients with CKD stage 3 or 4 and resistant hypertension, APRO 12.5 and 25mg added to ≥3 antihypertensive drugs resulted in a substantial reduction of both office and ambulatory BP and UACR. Edema and fluid retention were manageable with additional diuretics.

Funding: Commercial Support - Janssen Pharmaceuticals and Idorsia Pharmaceuticals, Ltd

(mean values)	APRO 12.5mg	APRO 25mg	PBO
Baseline Office SBP (mmHg)	154.1	153.5	154.7
Week 4 Office SBP (mmHg)	140.6	134.6	148.0
Week 36 Office SBP (mmHg)	Not applicable	134.8	Not applicable
Week 40 Office SBP (mmHg)	Not applicable	136.1	143.5
Baseline UACR (mg/g)	109.2	63.4	114.9
Week 4 UACR (ratio from baseline)	0.72	0.56	0.96
Week 36 UACR (ratio from baseline)	Not applicable	0.50	Not applicable

FR-OR97

Increased Coronary Artery Pathology in Type 2 Diabetes Without Cardiovascular Disease but with Albuminuria

Tine Hansen,[1] Ida Rasmussen,[1] Anne-Cathrine Skriver-Møller,[1] Rasmus S. Ripa,[3] Philip Hasbak,[3] Victor Wasehuus,[1] Katra Hadji-Turdeghal,[4] Emilie Zobel,[1] Martin Lyngby Lassen,[3] Piotr Slomka,[5] Peter Rossing,[1,2] Andreas Kjaer.[3,2] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Copenhagen University, Copenhagen, Denmark; [3]Department of Clinical Physiology & Nuclear Medicine, Copenhagen, Denmark; [4]Rigshospitalet, Kobenhavn, Denmark; [5]Departments of Medicine and Biomedical Sciences, Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Advances in non-invasive imaging enables combined structural and functional assessment of coronary artery pathophysiology. We evaluated sub-clinical coronary artery pathology using multimodal imaging in persons with type 2 diabetes.

Methods: Cross-sectional study including persons with type 2 diabetes, without known cardiovascular disease or symptoms. Coronary microcalcification activity was measured using ^{18}F-sodium fluoride positron emission tomography/computed tomography (PET/CT). Plaque inflammation was measured using ^{64}Cu-DOTATATE PET/CT and estimated as coronary inflammation activity. Myocardial flow reserve was calculated using ^{82}Rubidium PET/CT, and the coronary artery calcium score was quantified using CT.

Results: We included 90 participants, 30 had normoalbuminuria (urine albumin creatinine ratio (UACR) <30 mg/g) and 60 had current albuminuria or a history of albuminuria (UACR ≥ 30 mg/g). Mean age was 65 (SD 7.5) years, 19 % were females. Participants with albuminuria had increased microcalcification activity (median 0.75 [IQR: 0.30 -1.85]) compared to normoalbuminuria (0.43 [0.24 - 0.87]; p=0.04), but not after adjustment for clinical risk factors for cardiovascular disease (p=0.09). Microcalcification activity was positively associated with the current level of UACR (standardized β=0.53, p=0.008), and a trend remained after adjustment (β=0.44, p=0.05). Mean myocardial flow reserve was lower in participants with albuminuria (2.5 (SD 0.7)) compared to normoalbuminuria (2.9 (0.7); p=0.02), but not after adjustment (p=0.07). Coronary inflammation activity and coronary artery calcium score were similar between albuminuria groups (p≥0.40). Higher current level of UACR was associated with lower myocardial flow reserve (β=-0.42, p=0.03) and higher coronary artery calcium score (β=0.40, p=0.03) in unadjusted analysis. Current level of UACR was not associated with coronary inflammation activity (p=0.74).

Conclusions: In persons with type 2 diabetes, without cardiovascular disease, the presence of albuminuria was associated with sub-clinical coronary artery pathology and microcalcifications when compared to normoalbuminuria.

Podocyte-Specific Knockout (KO) of the Natriuretic Peptide Clearance Receptor (NPRC) Ameliorates Glomerular Injury in a Mouse Model of Focal Segmental Glomerulosclerosis (FSGS)

Liming Wang,[1] Yuping Tang,[1] Anne Buckley,[1] Robert F. Spurney.[1,2] *[1]Duke University, Durham, NC; [2]Durham VA Health Care System, Durham, NC.*

Background: Natriuretic peptides (NPs) have podocyte protective effects by stimulating cGMP generation (J Am Soc Nephrol 28: 260, 2017). NPs stimulate cGMP production by binding to NP receptors (NPRs). Atrial NP (ANP) and the C-type NP (CNP) stimulate cGMP generation by binding to NPRA and NPRB, respectively.

In contrast, the NP clearance receptor (NPRC) binds and degrades NPs and, in turn, negatively regulates the beneficial effects of NPs. Podocytes express all three NPRs (NPRA, NPRB, and NPRC). We previously found that pharmacologic blockade of NPRC reduced proteinuria in a mouse model of FSGS (Physiological Reports. 2021;9:e15095). In this study, we investigated the effects of podocyte specific KO of NPRC in FSGS using the same mouse model.

Methods: NPRC was deleted specifically in podocytes in a transgenic (TG) mouse model of FSGS created in our laboratory (J Clin Invest 125:1913, 2015). These TG mice express a constitutively active Gq α-subunit specifically in podocytes (Gq mice). In these animals (Gq mice), treatment with a single dose of the podocyte toxin puromycin aminonucleoside (PAN) causes robust albuminuria, but only mild disease in wild type (WT) mice.

Results: Podocyte specific KO of NPRC significantly reduced albuminuria in Gq mice 10 days after PAN injection (6094 ± 1130 [NPRC+/+] vs. 2740 ± 627 [NPRC-/-] ug/mg creatinine; P = 0.007). KO of NPRC also significantly reduced the number of Gq mice with glomerular sclerosis (GS) (85% [NPRC+/+; N = 20] vs 46% [NPRC-/-; N = 13]; P = 0.026). Consistent with the GS results, there was a significant increase in mRNA and protein levels of the myofibroblast marker alpha-smooth muscle actin (alpha-SMA) in NPRC+/+ Gq mice, and this increase in alpha-SMA expression was significantly reduced in NPRC-/- Gq mice. Treatment with PAN also decreased expression of both nephrin and podocin in NPRC+/+ Gq mice, which was prevented by podocyte specific KO of NPRC.

Conclusions: Podocyte specific KO of NPRC significantly decreased albuminuria, reduced GS, decreased myofibroblast activation and preserved expression of the podocyte proteins nephrin and podocin in a mouse model of FSGS. These data suggest that strategies to augment the effects of NPs might be a useful therapeutic approach for treating FSGS.

Hemizygous Loss of Vegfa in Cap Mesenchyme Is Associated with Thrombotic Microangiopathy and Metabolic Reprogramming of the Thick Ascending Limb (TAL) Epithelium

Dorian Kaminski,[1,2] Dilip K. Deb,[1] Yalu Zhou,[1] Susan E. Quaggin.[1,3]
[1]Northwestern University Feinberg School of Medicine, Chicago, IL; [2]Yale New Haven Hospital, New Haven, CT; [3]Northwestern Memorial Hospital, Chicago, IL.

Background: Tonic secretion of VEGFA from nephron progenitors and their epithelial derivatives plays a key role in both development and homeostatic maintenance of kidney microvascular beds. Reduction of Vegfa production by podocytes or tubular epithelial cells results in glomerular endotheliosis and loss of peritubular capillaries, respectively. Here, we report a kidney epithelial-specific, hemizygous *Vegfa* knockout mouse model. Fifty per cent reduction of Vegfa in Six2-progenitor cells results in a thrombotic microangiopathy phenotype, with progressive loss of glomerular function after 4 weeks of age.

Methods: *Vegfa* floxed mice were generated using the CRISPR-Cas9 system and were crossed with transgenic *Six2-eGFPCre* mice to generate *VegfA*$^{\Delta/+}$*;Six2-Cre* mice, leading to excision of *Vegfa* from nephron progenitor cells of cap mesenchyme. Kidneys from 1, 2, and 4 week old mice were examined histologically using light and electron microscopy and single-cell RNAseq libraries were generated from knockout and control kidneys at 2 and 4 weeks which were analyzed in R using Seurat.

Results: *VegfA*$^{\Delta/+}$*;Six2-Cre* mice began to develop albuminuria at 2 weeks. On light microscopy, kidneys from *VegfA*$^{\Delta/+}$*;Six2-Cre* mice were indistinguishable from those of their control littermates at 1 week. Electron microscopy at 2 weeks showed evidence of glomerular injury, with subendothelial expansion and podocyte foot process effacement. At 4 weeks, *VegfA*$^{\Delta/+}$*;Six2-Cre* glomeruli exhibited florid thrombotic microangiopathy. In scRNAseq data, glomerular endothelial cell clusters from *VegfA*$^{\Delta/+}$*;Six2-Cre* mice exhibited decreased expression of transcripts encoding markers of glomerular identity. Analysis also identified a new population of thick ascending limb (newTAL) cells that were found only in knockout kidneys at both time points. Compared to other TAL clusters, newTAL cells expressed cytokeratin 19 as well as classic genes such as *UMOD*. Pathway analysis of differentially expressed genes in the newTAL showed downregulation several metabolic pathways with enrichment of growth factor signaling.

Conclusions: *Vegfa* gene dosage in renal epithelium is important for the maintenance of the glomerular endothelium and plays a role in the metabolic programming of the TAL.

FR-OR100

SMPDL3b Modulates Podocyte Innate Immunity via Stimulator of Interferon Genes (STING) Activation in CKD

Antonio M. Fontanella, Veronika Semenova, Judith T. Molina David, Shamroop Kumar Mallela, George W. Burke, Sandra M. Merscher, Alessia Fornoni, Alla Mitrofanova. *University of Miami School of Medicine, Miami, FL.*

Background: Chronic kidney disease (CKD) is a global problem with rising incidence, prevalence and poor understood pathogenesis. Our prior studies support the hypothesis that sphingolipids are major determinants of podocyte function and survival, where sphingomyelin phosphodiesterase acid like 3b (SMPDL3b) plays an important role. Sphingolipids are known regulators of inflammation, also a major contributor to CKD progression. We reported that activation of the stimulator of interferon genes (STING), an important innate immune signaling protein, contributes to alterations in podocyte foot processes, proteinuria, and CKD progression. Here we test the hypothesis that increased SMPDL3b expression leads to podocyte injury through activation of STING.

Methods: Immortalized control or overexpression (SMP OE) human podocytes were used. Illumina sequencing RNA data analysis, qRT-PCR and Western blot analysis were used to characterize the cells. c-diAMP, a STING specific agonist, treatment (10μM) was performed for 24h. Glomeruli isolated from 8-week-old mice with podocyte specific Smpdl3b deficiency (pSMP$^{fl/fl}$) or overexpression (pSMP^{Tg}) were used to evaluate STING activation. pSMP$^{fl/fl}$ and pSMP^{Tg} mice were intraperitoneally injected with a single dose of c-diAMP, 50mg/kg or 5% DMSO and sacrificed 72h after, followed by urinary albumin-to-creatinine ratio (ACR), histological and serum analyses. Two-tailed t-test or One-Way ANOVA followed by Tukey's post-test were used to detect statistical changes.

Results: Genes involved in the cytosolic DNA sensing pathways in SMP OE podocytes are significantly regulated. *In vitro* and *in vivo* studies demonstrated that SMP OE podocytes and glomeruli isolated from pSMP^{Tg} mice have increased levels of STING phosphorylation (pSTING). Treatment with c-diAMP resulted in increased pSTING in control, but not in SMP OE podocytes. While both pSMP$^{fl/fl}$ and pSMP^{Tg} mice did not develop proteinuria at the baseline, treatment with c-diAMP resulted in significantly increased ACR in pSMP^{Tg}, but not in pSMP$^{fl/fl}$ mice. No changes in serum BUN and creatinine levels were observed in pSMP$^{fl/fl}$ and pSMP^{Tg} mice treated with c-diAMP.

Conclusions: Our data indicate that SMPDL3b overexpression is associated with STING activation in podocytes *in vitro* and STING-dependent proteinuria *in vivo*.

FR-OR101

Podocyte-Derived Endothelin-1 and Cross-Talk with Endothelial Cells Through EdnrA Is Essential for Glomerular Injury

Ilse S. Daehn, Liping Yu, Zhengzi Yi, Weijia Zhang. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Crosstalk between activated podocytes and glomerular endothelial cells (GECs) has been demonstrated in mouse models of focal segmental glomerulosclerosis (FSGS). We have previously demonstrated that podocytes activation can result in GEC stress and dysfunction and concomitant albuminuria via increased endothelin-1 and endothelin receptor A (Edn1/Ednra) signaling. However, the mechanistic link between podocyte activation and Edn1 production, GEC injury, and reciprocal crosstalk that results in podocyte loss and albuminuria remains unclear.

Methods: Transforming growth factor-β (TGFβ) is a cytokine that is implicated in glomerular diseases and podocyte depletion. We examined the effects of TGFβ on podocyte activation in culture on *Edn1* expression on podocytes in culture, as well as in podocytes with inducible TGFβR1 expression; PodTgfbR1, treated with doxycycline (Dox). We performed RNAseq analysis on GECs treated with Edn1 and isolated from Dox treated PodTgfbR1 mice. We generated a mouse model through targeted gene deletion of *Edn1* in podocytes using the Cre-loxP system (*Npsh2:Cre-ET1*$^{fl/fl}$) and a quadruple transgenic mice line with podocyte specific Edn1 knockout, and inducible, podocytes specific TGFβR1 signaling (*Nphs2:Cre-ET1-Nephs1TgfbrI*). Mice were treated with adriamycin (i.p.) or with Dox (food) to induce nephropathy.

Results: TGFβ signaling resulted in a significant increase in *Edn1* expression and Edn1 release by podocytes in culture, which was prevented by a TGFβR1/Smad inhibitor or by knockout (ko) Smad2 or double ko Smad2/3, suggesting canonical TGFβ signaling dependent pathway is required for Edn1 production. RNAseq from Edn1 treated GECs showed upregulation of cellular responses to stress and endothelial dysfunction. Compared to adriamycin treated control *Npsh2:Cre-ET1*$^{+/+}$, adriamycin treated *Npsh2:Cre-ET1*$^{fl/fl}$ mice had reduced glomerular injury, albuminuria and podocyte depletion. Compared to *Nephs1TgfbrI*, *Nphs2:Cre-ET1-Nephs1TgfbrI* mice treated with Dox had no glomerular injury, albuminuria and podocyte depletion was completely prevented, and there was no increase in GEC associated Ednra expression.

Conclusions: Our studies provide evidence for the essential role of podocyte derived Edn1 upon activation and crosstalk with GECs via Ednra that results in GEC injury, podocyte depletion and albuminuria in experimental FSGS.

FR-OR102

Conditional Knockout of YAP Decreases Podocyte Adhesion and Exacerbates FSGS Progression Through α3β1 Integrin

Guangze Shao, Jitu Xu, Yanyong Xu, Huijuan Wu. *Fudan University School of Basic Medical Sciences, Shanghai, China.*

Background: The occurrence of proteinuria in FSGS patients is closely related to the decreased adhesion and further loss of podocytes. Previous studies showed YAP nuclear exclusion contributes to podocyte apoptosis and FSGS progression, but its role in the podocyte adhesion remains unclear.

Methods: We generated podocyte-specific *Yap* gene knockout mice (*Yap*^{podoKO}) by crossing *Yap*$^{flox/flox}$ mice with NPHS2-Cre mice. We then constructed Adriamycin induced FSGS model by using *Yap*^{podoKO} mice and control mice. Furthermore, we treated the above mice with pyrintegrin, an agonist of α3β1 integrin.

Results: By 16 weeks of age, compared to *Yap*$^{flox/flox}$ mice, *Yap*^{podoKO} mice developed decreased podocyte adhesion including reduced α3β1 integrin and focal adhesion (examined by double immunofluorescence staining of vinculin and F-actin), with effacement of a few of foot process under the electron microscopy, although showed no significant difference in morphology by light microscopy, proteinuria, serum creatinine and BUN. Compared to Adriamycin treated *Yap*$^{flox/flox}$ mice, *Yap*^{podoKO} mice aberrantly aggravated decrease in α3β1 integrin, focal adhesion and podocyte number induced

by Adriamycin, with markedly increased segmental or global glomerulosclerosis, foot process effacement and proteinuria. Of note, pyrintegrin treatment largely improved the podocyte adhesion and ameliorated the disease progression of FSGS caused by Adriamycin treatment with or without podocyte-specific *Yap* knockout.

Conclusions: This study, for the first time, demonstrated that podocyte-specific *Yap* gene knockout can reduce podocyte adhesion thus aggravating the process of FSGS via α3β1 integrin. This is important to report because, so far, there is no clinical strategy to treat FSGS by targeting α3β1 integrin and its regulatory factors.

FR-OR103

Paracrine Effects of Injured Podocytes on the Transcriptome of Neighboring Cells

Yuting Zeng,[1] Robert A. Schweickart,[2] Jeffrey W. Pippin,[1] Oliver Wessely,[2] Ashleigh B. Theberge,[1] Stuart J. Shankland.[1] *[1]University of Washington, Seattle, WA; [2]Cleveland Clinic, Cleveland, OH.*

Background: Knowledge gaps in glomerular diseases include how podocytes respond to different forms of injury and the crosstalk between injured podocytes and neighboring cells (healthy podocytes or parietal epithelial cells (PECs)). The goal of this study was to establish an *in vitro* microfluidic coculture model to distinguish podocyte's responses to different injuries, and to determine what mediators from injured podocytes cause paracrine damage to neighboring cells in the glomeruli.

Methods: We engineered an open microfluidic coculture device consisting of two separate but interconnectible chambers. The outer chamber was seeded with primary human podocytes and the inner chamber was seeded with human podocytes or PECs in different series of experiments. Following the induction of podocyte injury in the outer chamber by cytotoxic sheep anti-podocyte IgG (IgG), puromycin (PAN), Adriamycin (ADR), chambers were connected to study the paracrine effects between injured podocytes and naïve podocytes or PECs. Imaging, cell viability and RNA-sequencing were temporally measured in cells of both chambers.

Results: Injured human podocytes displayed foot process effacement, cell body shrinkage, and decreased cell viability. In the podocyte-podocyte coculture, gene set enrichment analysis showed several common pathways for injury by IgG, PAN, and ADR, including apoptosis, complement, p53, TNFα, IFN, Wnt/β-catenin, and reactive oxygen species (ROS). IgG and ADR but not PAN increased TGFβ or inflammatory response (IL2, IL6, KRAS). ADR and PAN but not IgG increased DNA repair. The naïve podocytes cocultured with injured ones showed similar enrichments. Among the 65 ligand-receptor pairs shared by all three injuries were CSF1 & CSF1 receptor, BMP2 & BMP type I receptors, IL1A & IL1 receptor, and GDNF & RET receptor. The transcriptomic results from podocyte-PEC experiments are pending.

Conclusions: The *in vitro* open microfluidic coculture device represents a new model for studying autocrine and paracrine signaling between injured podocytes and healthy neighboring cells. The paracrine injury response of podocytes is similar to the direct injury response. Mechanistic studies are currently ongoing to identify which ligands from the injured podocytes and which receptors on naïve podocytes mediate these paracrine effects.

FR-OR104

A Novel Small Therapeutic Peptide with Potential for Treating αvβ3-Mediated Glomerular Damage

Yan Xu,[1] Ryan Spear,[1] Yanxia Cao,[1] Kwi Hye Koh,[2] Steve Mangos,[1] Alexis P. Jimenez Uribe,[1] Jochen Reiser,[1] Eunsil Hahm.[1] Dr. Eunsil Hahm's Lab. *[1]Rush University Medical Center, Chicago, IL; [2]Morphic Therapeutic, Boston, MA.*

Background: αvβ3-mediated podocyte injury represents an initial pathological event observed in several glomerular diseases. However, effective clinical strategies targeting αvβ3 integrin remains elusive. Our recent research has unveiled a new function of inducible costimulatory ligand (ICOSL), which acts as an endogenous antagonist of αvβ3 integrin through its RGD motif. In this study, we identified a novel 19-mer peptide derived from ICOSL and evaluated its therapeutic potential for mitigating αvβ3-mediated podocyte injury.

Methods: The binding affinity of human ICOSL and its small linear peptide (hICOSL-peptide) to αvβ3 Integrin was assessed using surface plasmon resonance (SPR) at the molecular level, along with podocyte adhesion assays at the cellular level. Subsequently, we evaluated the therapeutic potential of hICOSL-peptide in proteinuric mice challenged with LPS by measuring ACR and BUN. To improve the pharmacokinetics (PK), a PEG12 molecule was introduced to the N terminal of hICOSL-peptide and the resulting PEG12-hICOSL-peptide was analyzed for its PK profile using ELISA.

Results: Our study showed that ICOSL binding favored the active αvβ3 integrin rather than the inactive form and showed no or weak affinity for other integrins. Through the analysis of ICOSL's crystal structure, we have successfully identified a 19-mer peptide possessing an RGD sequence. This peptide exhibited robust binding to the active form of αvβ3 integrin and exerted a strong influence on integrin-dependent podocyte adhesion. Moreover, administration of hICOSL-peptide effectively mitigated albuminuria in LPS-challenged ICOSL knockout (KO) mice, highlighting the therapeutic potential of hICOSL-peptide. Importantly, PEGylation process did not compromise the functional interaction of these peptides with αvβ3 integrin, but significantly enhanced the pharmacokinetic profile of hICOSL-peptide by a five-fold increment, further emphasizing its augmented therapeutic promise.

Conclusions: We identified a novel 19-mer linear peptide derived from ICOSL. This peptide exhibited the ability to specifically target αvβ3 integrin in podocytes and effectively reverse proteinuria in mice. These finding suggests that ICOSL and ICOSL-based small peptides hold significant promise as novel and safe therapeutic options for treating αvβ3-mediated glomerular diseases.

Prevention of Proteinuria by a Novel, Subnanomolar ApoL1 Inhibitor

Brett M. Antonio,[1] Nathan Zahler,[1] Ingrid Mechin,[1] Jonathan W. Theile,[1] Robert L. Dow,[2] Robert A. Volkmann,[2] Shannon G. Zellmer,[1] Lhoucine Chdid,[1] Anil Nair,[1] Douglas Krafte.[1] *[1]OmniAb, Durham, NC; [2]BioPharmaWorks, Groton, CT.*

Background: Genetic variants of human ApoL1, which have arisen under evolutionary pressure to target mutant trypanosomes, have also been associated with an increased risk of developing chronic kidney diseases (CKD) in people of African ancestry[1]. Recently reported clinical results suggest inhibition of ApoL1 ion channel function may produce clinical benefit in patients with ApoL1-induced nephropathies[2]. 1. doi: 10.2215/CJN.15161219 2. doi: 10.1056/NEJMoa2202396

Methods: We established stable HEK-TREx cell lines in the EIK haplotype expressing human G1 and G2 variants under control of an inducible promoter and identified compounds for evaluation via high throughput screening, in silico profiling and medicinal chemistry design. Tl^+ flux and electrophysiology assays were used to assess *in vitro* efficacy of compounds against ApoL1 function. A human transgenic mouse model expressing ApoL1-G1 EIK and exhibiting a significantly elevated urinary albumin/creatine ratio (uACR) following IFNγ challenge was used to assess *in vivo* efficacy. Compound efficacy was determined by assessing inhibition of proteinuria.

Results: Our lead compound, ICA-264 demonstrated concentration-dependent inhibition of ApoL1-G1 mediated Tl^+ flux with an IC_{50} value of 4 nM (95% CI 3.5-4.4 nM, n=196). The potency was similar against ApoL1-G2 (IC_{50} = 5 nM, 95% CI 4.4-6.0 nM, n=77). Directly measuring ApoL1 current in electrophysiological experiments demonstrated potent inhibition with IC_{50} values at -80 mV and +60 mV of 0.6 nM and 0.4 nM (95% CI 0.35-0.47 and 0.49-0.65, respectively). Analogs of ICA-264 were identified with IC_{50} values as low as 0.26 nM in electrophysiological assays. In our *in vivo* model oral dosing of ICA-264 (BID) at 3, 10, and 30 mg/kg decreased the IFNγ-induced rise in uACR by 73%, 92%, and 91%, respectively (n=6) on day 2.

Conclusions: ICA-264 is a novel ApoL1 inhibitor with excellent drug-like properties and *in vivo* efficacy. This merits further consideration as a potential novel therapeutic for the treatment of ApoL1-induced nephropathies.

Dynll1-PI31 Facilitated Proteasome-Mediated Degradation as a New Therapeutic Target for Interferon 2 (INF2)-Related FSGS

Jillian Williquett, Hua Sun. *University of Iowa Hospitals and Clinics, Iowa City, IA.*

Background: Mutations in Inverted formin 2 (INF2) gene leads to treatment lacking, autosomal dominant Focal Segmental Glomerulosclerosis (FSGS). We found the R218Q mutation in INF2 disrupts the INF2-Dynll1 interaction, leading to dysregulation of dynein-mediated trafficking and degradation of nephrin in *in vitro* and *in vivo* models of INF2-mediated podocytopathy. Our previous study found Dynll1 facilitates lysosomal degradation of nephrin via adaptor Histone deacetylase 6 (HDAC6). Here, we identified Proteasomal Inhibitor of 31kD (PI31) as a new adaptor protein which mediates dynein-driven proteosome-mediated degradation. We hypothesized that the INF2-R218Q disinhibits dynein-mediated trafficking of nephrin to the proteasome for degradation via enhanced Dynll1-Pi31 interaction and treatment with Bortezomib (a proteasome protease inhibitor), could become a therapeutic target for INF2-related FSGS.

Methods: Proteasome-mediated degradation of nephrin was studied in immortalized podocytes harboring INF2 R218Q mutation, with or without siRNA silencing of *Dynll1* or *PI31*. Puromycin aminonucleoside nephropathy (PAN) was established in *INF2 R218Q* knockin (KI) mice and effects of Bortezomib versus normal saline control among the different genotypes were evaluated by quantifying severity of proteinuria and podocytopathy.

Results: Increased Dynll1-PI31 interaction was shown in R218Q KI podocytes, correlated with the R218Q disrupted Dynll1-INF2 interaction. The nephrin protein in R218Q KI cells could be stabilized by 1) dynein inhibitor Ciliobrevin D and by

Bortezomib, suggesting an enhanced dynein-mediated degradation of nephrin via proteasome; or by 2) siRNA mediated knockdown of either Dynll1 or PI31, suggesting a critical role for Dynll1-PI31 interaction in nephrin depletion caused by INF2-R218Q. The Bortezomib treatment rescued the PAN of the INF2-R218Q KI mice by attenuating the dynein-facilitated degradation of nephrin via proteasome and preserving the surface trafficking of nephrin that is needed to maintain the slit diaphragm.

Conclusions: The R218Q mutation disrupts the Dynll1-INF2 interaction and facilitates dynein-mediated trafficking of nephrin to the proteasome via an increased Dynll1-PI31 interaction. Enhanced dynein facilitated proteasome-mediated degradation of nephrin represents new therapeutic target for INF2-related FSGS.

Fasting-Mimicking Diet and Podocyte Protection

Laura Perin,[1] Valentina Villani,[1] Camille H. Nicolas Frank,[3] Xiaogang Hou,[1] Stefano Da Sacco,[1] Kevin V. Lemley,[1] Silvia Lai,[2] Alessandro Laviano.[2]
[1]Children's Hospital Los Angeles, Los Angeles, CA; [2]Universita degli Studi di Roma La Sapienza, Rome, Italy; [3]Harvard Medical School, Boston, MA.

Background: Dietary management is of particular importance in the context of kidney disease. Our data indicate that periodic cycles of a fasting-mimicking diet (FDM) can ameliorate kidney damage by preventing podocyte loss. Using different tools and animal models, we showed the renoprotection of the FDM in the contest of glomerulopathies. We also showed, in a small pilot clinical trial that FMD is safe, feasible, and potentially beneficial to patients with CKD.

Methods: Damage in rats was established by puromycin (PAN). Rats were fed with six cycles of FMD or ad-lib. Morphological, physiological, and spatial transcriptomics (ST) data were collected at long term. Early molecular changes induced by the FMD were studied by snRNA-seq after one cycle. We used our Alport-podocyte-FUCCI (Fluorescence Ubiquitin Cell Cycle Indicator) mice to study the podocyte cell cycle. We administered 3 cycles of FMD to a small cohort of 13 patients (9 men and 5 women, 38-63 years) with stage III CKD.

Results: FMD downregulated proteinuria, ameliorated glomerular sclerosis, and protected podocyte number. ST showed that ctrl and FMD-rats present very similar spatial gene maps vs the PAN-rats. snRNA-seq showed that in PAN-rat, the FMD activated podocyte-specification genes, revealing the important role of fasting followed by refeeding in inducing transcriptional changes in podocytes after damage. In the Alport-podocyte-FUCCI mice, FMD lowered the podocyte number in G1 and increased the podocyte number in G0. In CKD patients, FMD downregulated IGF1, protein C, proteinuria, epicardial fat, and upregulated flow-mediated dilation value (indicating amelioration of endothelial function).

Conclusions: These results indicate that FMD promotes the maintenance of glomerular structure and function by inducing podocyte repair and by preserving the G0 state in these cells. FMD cycles could represent a potential treatment for patients affected by progressive kidney disease.

IMPROVE AKI: Sustainability of Team-Based Coaching Interventions to Improve AKI in a Cluster-Randomized Trial

Michael E. Matheny,[1,2] Richard J. Solomon,[3] Sharon E. Davis,[1] Kevin C. Cox,[4] Meagan E. Stabler,[4] Dax Westerman,[1] Chad A. Dorn,[1] James O'Malley,[4] Jeremiah R. Brown.[4] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]VA Tennessee Valley Healthcare System, Nashville, TN; [3]University of Vermont Medical Center, Burlington, VT; [4]Dartmouth College Geisel School of Medicine, Hanover, NH.*

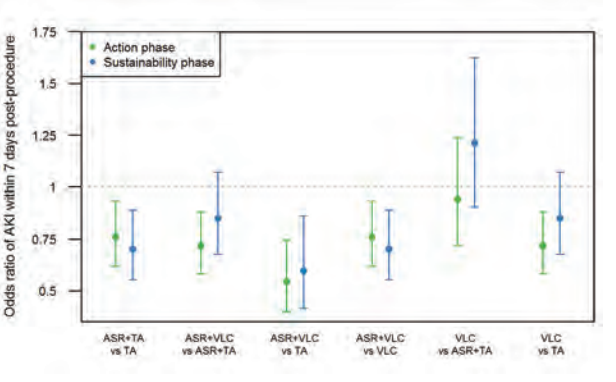
Background: Up to 14% who undergo cardiac catheterization procedures in the U.S. each year may experience acute kidney injury (AKI). An absence of standards for implementing known interventions hinders efforts to prevent AKI. In a 2x2 factorial cluster-randomized trial, we found the combination of team-based coaching and a data-driven surveillance dashboard reduced the odds of AKI by 46%. We hypothesized these improvements would persist in the period following the active intervention phase of the trial.

Methods: A 2x2 factorial cluster-randomized trial was conducted that randomized 20 Veteran Affairs hospitals to receive team-based coaching in a Virtual Learning Collaborative (VLC) compared to Technical Assistance with an AKI Prevention Toolkit (TA), both with and without Automated Surveillance Reporting (VLC+ASR and TA+ASR). Patient outcomes were collected over 18 months following the active intervention phase. Multilevel logistic models for AKI were fit with site-level random effects to account for the clustered design.

Results: Across 20 randomized sites, 440 of 4,160 patients experienced AKI during 18-months following the active intervention phase, including 216 of 1,260 patients with pre-existing chronic kidney disease (CKD). We observed a substantial reduction in AKI within the VLC+ASR cluster compared to the TA cluster (aOR=0.60; 0.42-0.86) consistent with the effect previously reported for the active intervention phase (aOR=0.54; 0.40-0.74).

Conclusions: Team-based coaching along with a data-driven surveillance dashboard can sustainably reduce AKI by 40%, even after active participation in the trial is complete. These combined interventions are an effective, scalable framework to establish aggressive AKI prevention protocols.

Funding: NIDDK Support



The following patient features were included for adjustment: age, race, tobacco use, anemia, heart failure, CKD, diabetes, hypertension, and prior percutaneous coronary intervention.

SA-OR02

Effects of Avasopasem Manganese on Cisplatin-Induced AKI and CKD

Benjamin R. Griffin,[1] Chou-Long Huang,[1] Masaaki Yamada,[1] Melissa L. Swee,[1] Carryn Anderson,[1] Douglas R. Spitz,[1] Kranti A. Mapuskar,[1] Diana Zepeda-Orozco,[3] Eugene P. Kennedy,[2] Robert A. Beardsley,[2] Bryan Allen,[1] Diana I. Jalal.[1] *[1]University of Iowa Hospitals and Clinics, Iowa City, IA; [2]Galera Therapeutics Inc, Malvern, PA; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: Nephrotoxicity is a major complication of cisplatin treatment in cancer patients. Rates of acute kidney injury (AKI) range from 31-68%, and about 30% of cancer survivors receiving cisplatin develop chronic kidney disease (CKD) within 1 year. Superoxide production plays a crucial role in cisplatin-induced AKI and CKD. Avasopasem (AVA) is a selective superoxide dismutase mimetic shown in phase 3 to reduce severe oral mucositis in head and neck cancer (HNC) patients receiving radiation plus high-dose cisplatin.

Methods: We analyzed renal function data from a phase 3, double-blinded, randomized trial that compared 90 mg AVA vs placebo (PBO) during cisplatin (weekly or every 3 weeks) and radiation therapy (CRT). Renal adverse events (AEs) were AKI, creatinine increase, or hypomagnesemia meeting grade 3+ criteria of the Common Terminology Criteria for Adverse Events for patients receiving cancer therapy. Creatinine was measured pretreatment, weekly during CRT, and then every 3 months for 1 year. CKD was staged at 1 year based on eGFR calculated using the CKD-EPI formula.

Results: 241 patients were randomized to AVA and 166 to PBO. Grade 3+ AKI was reported in 0.8% of AVA group vs 3.8% of PBO, grade 3+ creatinine increase in 1.2% vs 2.4%, and grade 3+ hypomagnesemia in 3.3% vs 5.4%. 202 AVA and 149 PBO patients were available to assess at 1 year with 10.4% CKD incidence in AVA group compared to 20.1% in PBO (p=0.004), primarily due to a reduction in stage 3b or greater disease (Figure).

Conclusions: In patients with HNC receiving radiation plus high-dose cisplatin, AVA, a superoxide dismutase mimetic, was significantly associated with decreased incidence and severity of CKD, with a trend towards decreased incidence of grade 3+ acute renal AEs. AE profile was otherwise consistent with expectations for CRT.

Effect of Terlipressin Treatment on the Incidence of Renal Replacement Therapy in Patients with Hepatorenal Syndrome and Fluid Overload: A Post Hoc Analysis of the Phase 3 CONFIRM Study

Hani Wadei,[1] Muhammad A. Mujtaba,[2] Khurram Jamil.[3] [1]*Mayo Clinic, Jacksonville, FL;* [2]*University of Texas Medical Branch, Galveston, TX;* [3]*Mallinckrodt Pharmaceuticals, Bridgewater, NJ.*

Background: Terlipressin (terli) is an FDA-approved vasopressin analogue for the treatment of patients with hepatorenal syndrome (HRS). However, in the Phase III CONFIRM study, terli use was associated with respiratory failure in 10% of terli-treated patients; this could have been due to increased intravascular volume, which is often managed with renal replacement therapy (RRT). In this analysis, we retrospectively examined the subgroup of patients in CONFIRM with fluid overload to determine the incidence, indications, and modality of RRT.

Methods: This post hoc analysis of the Phase III, randomized, placebo (pbo)-controlled CONFIRM study (NCT02770716) evaluated the incidence of RRT, indications, and modes of RRT used, in the subgroup of patients with fluid overload (pooled term for: hemodynamic edema, effusions, and fluid overload), as determined by investigator assessment. Incidence of RRT was determined on Days 14, 30, 60, and 90 in patients treated with terli or pbo; RRT was initiated after treatment discontinuation. Indications and mode of RRT were determined up to Day 14. Statistical analysis was determined using a Chi-square or Fisher Exact test.

Results: The CONFIRM study enrolled 300 patients (terli, n=199; pbo, n=101), of which 88 patients had fluid overload (terli: n=69; pbo, n=19). RRT incidence was significantly lower in the terli versus pbo group by Day 14 (23.2% [16/69] vs 47.4% [9/19], *P*=.039), and similar results were observed by Days 30, 60, and 90 (*P*≤.05). The indications for RRT up to Day 14 did not differ significantly between treatment groups, and the most common indications for both terli and pbo were fluid overload (14.5% [10/69] vs 15.8% [3/19]; *P*=1.000) and pulmonary edema (5.8% [4/69] vs 10.5% [2/19]; *P*=.606). Hemodialysis (terli vs pbo: 10.1% [7/69] vs 36.8% [7/19], *P*=.005) was the only mode of RRT with a significant difference between treatment groups.

Conclusions: This analysis from the CONFIRM study demonstrated that the incidence of RRT in patients with HRS and fluid overload was lower in terli-treated patients compared with pbo-treated patients. Improved renal function with terli may lead to reduced RRT requirements in patients with HRS and fluid overload.

SA-OR04

Niacinamide and Renal Recovery After AKI: A Randomized, Controlled Trial

Harbir S. Kohli, Sahil Garg, Jaskiran Kaur, Ashok K. Yadav, Vivek Kumar. *Post Graduate Institute of Medical Education and Research, Chandigarh, India.*

Background: Incomplete recovery following community acquired acute kidney injury CA-AKI may be seen in 15-20% of patients. Strategies to improve recovery rates and follow-up of such patients are required. The impaired NAD+ biosynthesis pathway has been recently implicated in AKI. Niacinamide, which bypasses the salvage denovo pathway and produces NAD, could be protective. Its role in recovery following AKI has been postulated. In this pilot phase of clinical trial, role of niacinamide supplementation in recovery after CA-AK was investigated.

Methods: The study was an open label, randomized, controlled trial. Patients of CA-AK aged 18-70 years were enrolled. Underlying CKD, urinary tract obstruction, malignancy, heart failure, pregnancy, lactating women or poor performance status were excluded. Participants were randomized to receive either niacinamide (500 mg BD for 14 days) or no intervention. Follow-up visits were at 1and 4 months after hospital discharge. The primary outcome was difference in renal recovery at 4 months after discharge. Renal recovery was defined as eGFR ≥60 ml/min/1.73m^2 at 4 months after hospital discharge. Secondary outcome measures were differences in eGFR between groups at 1 and 4 months after hospital discharge. Trial was prospectively registered (CTRI/2022/03/040892).

Results: Over a period of 6 months starting June 2022, 89 patients were screened. 50 patients were enrolled and randomized. Infections (70%), toxic envenomations (8%), rhabdomyolysis (8%) and drug induced AKI (6%) were leading causes. Majority (49 of 50) had stage 3 AKI with 32 (64%) requiring kidney replacement therapy. 6 patients expired and one patient did not report for follow up. Finally 43 patients were analyzed for outcome measures. The clinical characteristics: age, sex, DM, HT, AKI stage, were similar between groups at baseline. Renal recovery at 4 months was significantly higher in the niacinamide group (20/21, **95.2%)** as compared to the controls (15/22, **68.18%** p0.023). eGFR (ml/my/1.73m^2) at 1 month (99.9±27.9 *vs* 71.9±33.3 p0.040) and 4 months (108.2±26.2 vs 77.7±31.3 p0.001) after hospital discharge were also significantly higher in the intervention group as compared to control group. No major drug-related adverse events were recorded.

Conclusions: Niacinamide supplementation improved renal recovery at 4 months after hospital discharge in patients with severe AKI.

Impact of Using Blood Warmer During Continuous Kidney Replacement Therapy on Adverse Kidney Events and Mortality

Aisha Abbasi, Akshith Doddi, Ambika Ramesh, Ankit Sakhuja, Khaled Shawwa. *West Virginia University Health Sciences Center, Morgantown, WV.*

Background: Hypothermia is a complication of continuous kidney replacement therapy (CKRT). Blood rewarming is often used to prevent hypothermia; however, its impact on adverse kidney outcomes is unknown.

Methods: Patients with acute kidney injury (AKI) who required CKRT between 1/1/2012 and 1/1/2021 and admitted at a tertiary academic hospital were included. Major adverse kidney events (MAKE) is a composite outcome of need of kidney replacement therapy, doubling of the serum creatinine from baseline or death. We assessed MAKE at 30 and 90 days after CKRT initiation.

Results: There were 669 patients with AKI that required CKRT during the study period. There were 324 (48%) patients in whom a blood warmer was used on first day of CKRT. Patients where a blood warmer was used were more likely to be diagnosed with sepsis/septic shock (81% vs 74%, p=0.04), and were in a less positive fluid balance at the time of CKRT initiation (1.0 vs 1.3 L, p=0.03) compared to patients where a blood warmer was not used. There was no difference in hypotensive episodes during first day of CKRT between the two groups. MAKE-30 and MAKE-90 occurred in 376 (56%) and 422 (63%) of the patients, respectively. Patients who developed MAKE-30 were older (62 vs 56) and had higher SOFA score (10.5 vs 9), higher norepinephrine equivalent (NEE) requirement (0.15 vs 0.07 mcg/kg/min), higher lactate (5.5 vs 3.3 mmol/L), higher Charlson comorbidity index (CCI) (8 vs 7), lower mean arterial pressure (MAP) (74 vs 80 mmHg) and were more likely to be requiring mechanical ventilation (75% vs 63%) at CKRT initiation compared to patients who did not develop MAKE-30, p<0.001. Baseline creatinine was not different between the two groups (1.2 mg/dl). After adjusting for age, CCI, baseline serum creatinine and SOFA score, lactate, MAP, mechanical ventilation and NEE at CKRT initiation, the use of a blood warmer was independently associated with MAKE-30 (OR: 1.6, 95% C): 1.1-2.2, p=0.009) but not MAKE-90 (OR: 1.3, 95% CI 0.9-1.98, p-value=0.1). In adjusted Cox proportional hazard model, use of blood warmer was independently associated with mortality: hazard ratio 1.33 (95% CI: 1.1-1.6, p=0.002).

Conclusions: Blood warming techniques were associated with worse outcomes in patients with AKI on CKRT. More studies are required to explain this relationship.

Machine Learning-Guided Personalized Diuretic Strategy in Patients with Sepsis-Associated AKI

Wonsuk Oh,[1] Hannah Kittrell,[1] Roopa D. Kohli-Seth,[1] Girish N. Nadkarni,[1] Ankit Sakhuja.[2] [1]*Icahn School of Medicine at Mount Sinai, New York, NY;* [2]*West Virginia University, Morgantown, WV.*

Background: Fluid overload is common in patients with sepsis associated acute kidney injury (SA-AKI) and is associated with worse outcomes. Loop diuretics are commonly used to manage fluid overload, but their role in patients with SA-AKI is unclear. In this study we aimed to develop a personalized strategy for use of loop diuretics in patients with SA-AKI using machine learning.

Methods: This was a retrospective study using MIMIC IV database. We defined AKI using both creatinine and urine output based KDIGO criteria. We identified patients with sepsis who developed AKI within 48 hours of ICU admission. The primary outcome was AKI recovery within 48 hours of AKI onset. We used available features for demographics, comorbidities, SOFA score, vital signs, laboratory measurements, fluid balance, vasopressors and mechanical ventilation to estimate time varying individual treatment effects (ITE) using a two-model approach employing gradient boosting. The policy tree algorithm with pruning was then employed to identify subpopulations with the highest average treatment effects (ATE) for loop diuretic therapy, enabling a personalized diuresis strategy.

Results: Of 10,739 patients with SA-AKI, 37.8% had AKI recovery within 48 hours. Loop diuretics were used in 3,661 patients within 48 hours after onset of SA-AKI. ATE of loop diuretics was HR 0.935 (95% CI: 0.934, 0.937). Further policy tree analysis identified a personalized strategy for use of loop diuretics with goal to increase AKI recovery within 48 hours (Fig 1a). Specifically, patients with SA-AKI with Blood Urea Nitrogen (BUN)<=18 and red cell distribution width (RDW)<=14.2 benefited from loop diuretic therapy with an ATE of HR 1.086 (CI: 1.080, 1.091) (Fig 1b).

Conclusions: In this study we identified subgroups of patients with SA- AKI who may benefit from loop diuretic therapy to improve the likelihood of recovery of AKI within next 48 hours. This study shows the potential of machine learning to help personalize therapies for patients with AKI.

Association of Post-Hospitalization Vascular Biomarker Clusters with Future Heart Failure

Audrey Shi,[1] Anna Simone Andrawis,[1] Wassim Obeid,[2] Alan S. Go,[3] Kathleen D. Liu,[3] Mark M. Wurfel,[4] Jonathan Himmelfarb,[4] Chirag R. Parikh,[2] Pavan K. Bhatraju,[4] Vernon M. Chinchilli,[8] Paul L. Kimmel,[7] James S. Kaufman,[5] Steven G. Coca,[9] William B. Reeves,[10] Amit X. Garg,[11] Edward D. Siew,[6] Talat Alp Ikizler,[6] Heather Thiessen Philbrook,[2] Chi-yuan Hsu,[3] David K. Prince,[4] Francis P. Wilson,[1] Sherry Mansour.[1] *[1]Yale School of Medicine, New Haven, CT; [2]Johns Hopkins University, Baltimore, MD; [3]University of California San Francisco, San Francisco, CA; [4]University of Washington, Seattle, WA; [5]VA New York Harbor Healthcare System, New York, NY; [6]Vanderbilt University, Nashville, TN; [7]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [8]The Pennsylvania State University, University Park, PA; [9]Icahn School of Medicine at Mount Sinai, New York, NY; [10]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [11]Western University, London, ON, Canada.*

Background: Individual vascular biomarkers helped elucidate the connections between acute kidney injury (AKI) and future heart failure (HF). The role of combined vascular biomarkers in recently discharged patients with risk of future hospitalizations with HF is unknown.

Methods: Using the ASSESS-AKI cohort, we performed an unsupervised spectral cluster analysis with 9 plasma biomarkers measured at 3 months post-hospitalization *[Angiopoietin (angpt)-1, angpt-2, vascular endothelial growth factor (VEGF)-A, VEGF-C, VEGF-d, VEGF receptor 1 (R1), solubleTie-2 (sTie-2), placental growth factor (PlGF), and basic fibroblast growth factor (bFGF)]* in 1,497 patients, half of whom had AKI. We used a Cox regression analysis to evaluate the associations between clusters and future hospitalizations with HF. Models were adjusted for demographics, cardiovascular disease risk factors, medications, ICU status, lung disease, sepsis, serum creatinine, proteinuria, and admission center.

Results: 3 biomarker-derived clusters were identified: Cluster 1 [n=302, Vascular Injury (VI) phenotype] had higher levels of vessel injury markers, whereas Cluster 2 [n=728, Vascular Repair (VR) phenotype] had higher levels of vessel repair markers. Cluster 3 (n=467) had lower levels of both repair and injury markers (dormant phenotype). The median time to HF was 4.7 years (IQR: 2.93-5.93). Participants with the VI phenotype were twice as likely to have a HF event [aHR 2.23 (1.56, 3.18)] compared to the VR phenotype. The dormant phenotype was also significantly associated with HF [1.98 (1.22, 3.21)] compared to the VR phenotype. AKI was a significant effect modifier for the relationship between clusters and HF with an interaction *P*-value of <0.01. Among those with AKI, the relationship between the VI phenotype and HF was significant [aHR 2.13 (95%CI: 1.36-3.36)].

Conclusions: Vascular biomarkers can be used to derive clusters to risk-stratify patients for future HF events. Vascular panels may be used to tailor post-AKI follow-up to minimize risk of future HF.

SA-OR08

The Association of Female Sex Hormones and AKI

Ladan Golestaneh,[1] Nahian Ehtesham,[1] Abby M. Basalely,[2] Kimberly J. Reidy,[1] Joel Neugarten.[1] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Northwell Health, New Hyde Park, NY.*

Background: Women have a lower risk of chronic kidney disease progression; however, controversy exists as to the relative roles of comorbid, biological, and socioeconomic factors. Whether the reno-protective effects of female gender extend to AKI remains to be established.

Methods: Our cohort consisted of hospitalized patients without kidney failure in the Montefiore Health System, Bronx, NY, from October 1, 2015, to December 31, 2018. We defined community-acquired AKI(CAAKI) as meeting criteria defined by KDIGO within the first 48 hours of admission and hospital-acquired AKI(HAAKI) as to a within 48-hour window rise in creatinine occurring after 48 hours of admission and before discharge. We categorized age into prepubertal (<16 years), adult (16-55years), and post-menopausal (>55 years). We used logistic regression and stratified models by age category to examine the association of sex with AKI in progressive models adjusting for:1-age and race/ethnicity only, 2-addition of previous comorbidity, 3-addition of census tract level socioeconomic status (SES) normalized to the NY state mean SES.

Results: Of the 286,383 hospitalizations, 120,711(42.1%) were men, 30,576 (10.7%) were White, and 82,505(28.8%) were Black, 44,172 (15.4%) were prepubertal, 100,115(35.0%) were adult and 142,101(49.6%) were older than 55 years. Of the 56,731 (19.8%) who developed AKI, 33,207(58.5%) had HAAKI and 23, 524(41.5%) had CAAKI. Males had a higher odds of developing both types of AKI (1.46 (1.43-1.49) in HAAKI and 1.31(1.27-1.34) in CAAKI). The odds of AKI were higher in males in all 3 age categories but was strongest in adults (Table 1). Adjustment for comorbidity attenuated the male risk in adults only, adjustment for socio-economic status did not change the strength of the association meaningfully.

Conclusions: Men are more likely than women to develop AKI. The attenuation of sexual dimorphism in AKI incidence before puberty and after menopause suggests that female sex hormones are protective in AKI.

Table 1: Logistic regression models stratified by age categories, of the association between sex and AKI incidence in progressively adjusted models.

	Model 1: adjusting for age and race	Model 2=Model 1+adjustment for comorbidity*	Model 3=Model 2 +adjustment for SES
Odds of AKI in age<16; n=44,170 Female Male	1 1.12(1.03-1.22)	1 1.14(1.03-1.25)	1 1.15(1.04-1.26)
Odds of AKI in those aged 16-55; n=100,114 Female Male	1 2.04(1.96-2.11)	1 1.71(1.65-1.79)	1 1.73(1.66-1.81)
Odds of AKI in those aged >55 years; n=142,099 Female Male	1 1.28(1.24-1.31)	1 1.21(1.18-1.24)	1 1.22(1.19-1.25)

Dialysis Weaning Is Uncommon in the Treatment of Outpatient AKI Requiring Dialysis (AKI-D)

Ian E. McCoy,[1] Eric D. Weinhandl,[2] Wael F. Hussein,[2] Chi-yuan Hsu.[1] *[1]University of California San Francisco, San Francisco, CA; [2]Satellite Healthcare, San Jose, CA.*

Background: Recovery from dialysis-requiring acute kidney injury (AKI-D) often occurs after discharge from the hospital, following treatment in outpatient hemodialysis units. The dialysis weaning strategies employed during outpatient recovery (weaning dialysis frequency, weaning dialysis session duration, or proceeding directly to a trial of complete dialysis cessation) have not been described.

Methods: We examined outpatient dialysis orders for a cohort of 1,754 AKI-D patients initiating in-center hemodialysis between 7/1/2017 and 6/30/2022 across 67 different dialysis units operated by a medium-sized, not-for-profit dialysis provider. We followed patients for 3 months after first outpatient hemodialysis treatment (or until recovery defined as discharge from dialysis with no readmission or death within the next two weeks). During follow-up, we assessed changes in prescribed hemodialysis frequency and session duration.

Results: 95% of AKI-D patients were initially ordered for ≥3x/week dialysis frequency. At 3 months after first outpatient hemodialysis treatment, 41% had recovered, 49% continued to receive dialysis, and 10% had died. During follow-up, 70% had no changes to either prescribed dialysis frequency or session duration. Among those who recovered, dialysis frequency was weaned in 18% and dialysis session duration was weaned in 9%; all others discontinued dialysis without a change from their initial prescription. Among those who remained on dialysis or died, frequency was weaned in 11%.

Conclusions: In this contemporary cohort of patients with AKI-D in outpatient hemodialysis centers, dialysis weaning was uncommon. That many patients were able to transition directly from thrice-weekly treatment to no hemodialysis suggests there may be substantial opportunity to wean dialysis more often (e.g., to twice weekly treatment), likely resulting in cost savings and quality of life improvement.

Funding: NIDDK Support, Commercial Support - Satellite Healthcare Inc., not-for-profit dialysis provider

Outpatient dialysis prescriptions for AKI-D patients, stratified by outcomes 3 months after first outpatient dialysis

	Recovered	Continued receiving dialysis	Died without recovery
Sample size (N)	725	862	167
No prescription change during follow-up	522 (72%)	569 (66%)	133 (80%)
Decrease in dialysis frequency (sessions/week) during follow-up	132 (18%)	95 (11%)	14 (8%)
Decrease in dialysis session duration (minutes/session) during follow-up	62 (9%)	77 (9%)	8 (5%)

Prediction of Postdischarge Kidney Disease Progression Among Patients with Hospitalized AKI: The ASSESS-AKI Study

Steven Menez,[1] Kathleen F. Kerr,[2] Si Cheng,[2] David Hu,[1] Heather Thiessen Philbrook,[1] Dennis G. Moledina,[3] Sherry Mansour,[3] Alan S. Go,[4,5] Talat Alp Ikizler,[6] James S. Kaufman,[7] Paul L. Kimmel,[8] Jonathan Himmelfarb,[2] Steven G. Coca,[9] Chirag R. Parikh.[1] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]University of Washington School of Medicine, Seattle, WA; [3]Yale School of Medicine, New Haven, CT; [4]University of California San Francisco, San Francisco, CA; [5]Kaiser Permanente, Oakland, CA; [6]Vanderbilt University School of Medicine, Nashville, TN; [7]New York University Grossman School of Medicine, New York, NY; [8]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [9]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Acute kidney injury (AKI) occurs frequently during hospitalization, but only a fraction of patients progress to chronic kidney disease (CKD) after discharge. Biomarkers of kidney injury, inflammation, and repair have been shown to be informative of long-term kidney disease risk.

Methods: We evaluated data from 723 hospitalized patients with AKI and post-discharge follow-up in the prospective Assessment, Serial Evaluation, and Subsequent Sequelae of AKI (ASSESS-AKI) Study. We investigated 75 candidate predictors, including 11 urinary and 28 plasma biomarkers measured at 3-month post-discharge follow-up. We employed both random forests and least absolute shrinkage and selection operator (LASSO) regression to predict major adverse kidney events (MAKE): CKD incidence, CKD progression, or development of end-stage kidney disease. The data was split into training (80%) and test (20%) datasets. We used multiple imputation to handle missing data and independent test data for unbiased estimates of model performance.

Results: A total of 235 patients developed MAKE over 3 years of follow-up. While a prediction model containing 9 key clinical variables yielded an area under the receiver-operating characteristic curve (AUC) of 0.75 (0.63-0.87), random forest and LASSO models using all 75 variables yielded AUC values of 0.81 (0.71-0.92) and 0.80 (0.70-0.91), respectively (**Table 1**). The top 5 predictive biomarkers based on random forest modeling were sTNFR1, sTNFR2, NT-proBNP, FGF-23, and Ang2, all measured in the plasma and yielded an AUC of 0.75 (0.63-0.88). A combination model leveraging both clinical variables and the top 5 biomarkers demonstrated an AUC of 0.77 (0.65-0.89).

Conclusions: A parsimonious prediction model using a combination of key clinical variables and top biomarkers offers moderately strong discrimination in identifying patients with hospitalized AKI at highest risk of progression of kidney disease long-term.

Funding: NIDDK Support

Table 1. Model discrimination

Model	Variables	Number of predictors	AUC [95% CI]
Random forest	9 key clinical variables + 28 plasma biomarkers + 11 urine biomarkers + 10 drug classes + 17 other patient and hospitalization-related variables	75	0.81 (0.71-0.92)
LASSO	9 key clinical variables + 28 plasma biomarkers + 11 urine biomarkers + 10 drug classes + 17 other patient and hospitalization-related variables	75	0.80 (0.70-0.91)
Key clinical variables	Age, sex, race, BMI, diabetes mellitus, systolic blood pressure, AKI stage, Urine Alb/Cr, and 3-month eGFR	9	0.75 (0.63-0.87)
Top 5 biomarkers	plasma sTNFR1, NT-proBNP, sTNFR2, FGF-23, Ang2	5	0.75 (0.63-0.88)
Clinical variables + top 5 biomarkers	Age, sex, race, BMI, diabetes mellitus, systolic blood pressure, AKI stage, Urine Alb/Cr, and 3-month eGFR + plasma sTNFR1, NT-proBNP, sTNFR2, FGF-23, Ang2	14	0.77 (0.65-0.89)

Confidence intervals calculated with Rubin's rules for multiple imputation models
Ang2 = angiopoietin-2, FGF-23 = fibroblast growth factor-23, NT-proBNP = N-terminal pro-brain natriuretic peptide, sTNFR1 = soluble tumor necrosis factor receptor-1, sTNFR2 = soluble tumor necrosis factor receptor-2

Development of Physiologically Relevant In Vitro Model of Human Kidney Collecting Duct System Toward a Functional Kidney Replacement

Shayan Gholizadeh,[1,2] Cody C. Gifford,[1,2] Ling Cai,[1,2] Ana K. Michel Farías,[1,2] Yi Li,[1,2] Y. Shrike Zhang,[1,2] Joseph V. Bonventre.[1,2] Bonventre Lab. *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: A significant number of patients with end-stage kidney disease face a restricted supply of kidney donors. Urgently needed alternatives are necessary due to the shortcomings of dialysis. Engineered kidney models have mainly focused on the proximal nephron, with little attention given to recapitulating the kidney collecting duct (CD) system. The collecting system refines formative urine and is vital for regulating acid-base balance, Na+ and K+ handling, and body water homeostasis. Applying microfluidic and 3D bioprinting methods to the development of kidney CD systems can potentially lead to a mature understanding of CD function in health and disease, as well as serve as an important component of functional kidney replacement.

Methods: PDMS soft lithography was employed to create a three-compartment cell culture device in which channels are separated by phase guides. These phase guides allow for in situ hydrogel formation while enabling subsequent fluidic exchange. These devices were designed to support both 2D cell culture for preliminary tests and as an enclosed system for fitting 3D-bioprinted tubes. Each channel is connected to a peristaltic pump channel, enabling shear stress in 2D or 3D culture. Ureteric bud-derived CD cells were seeded in the central channel, while the surrounding channels can be potentially used to culture stromal cells and endothelial cells to resemble the in vivo setting.

Results: Preliminary testing of the fabricated devices exhibited high cytocompatibility and the ability to withstand shear stress values up to 10 dynes/cm^2 in the channels without mechanical failure or cell detachment. In situ hydrogel formation demonstrated the effectiveness of the phase guides in preventing mixture before crosslinking, while allowing fluidic transfer between the channels. The hydrogel structures within the devices showed sustained resistance to flow flows with no structural defects.

Conclusions: Our human kidney CD system can be used to model the CD in health and disease, as well as serve as a potential component for kidney functional replacement. Our initial studies involve demonstrating the functionality of this system to study human CD system physiological function in health and in models of genetic disease.

Induced Pluripotent Stem Cell (iPSc)-Derived and Primary Podocyte-Like Cells Are Capable of Macromolecular Sieving After Culture in Scalable Scaffolds

Thomas F. Gallegos, Aneta J. Przepiorski, Mohsen Sarikhani. *Iviva Medical, Woburn, MA.*

Background: With the growing demand for donor kidneys and insufficient donor organs, there is an urgent need for alternatives to dialysis and kidney transplantation. Our team has developed a biocompatible engineered glomerular tissue construct comprising hollow vascular and epithelial networks separated by a porous biomimetic membrane. The scaffolds are seeded with endothelial cells and podocytes that when perfused under vascular pressure, recapitulate glomerular function to produce a primary filtrate. The glomerular units are seeded with primary cells isolated from non-transplantable human donor kidneys of by isolation of cells from human induced pluripotent stem cells (iPSCs), that have been differentiated into endothelial cells and podocyte-like cells. We evaluated filtration dynamics and cell characteristics.

Methods: Human primary podocytes and endothelial cells are isolated by enzymatic digestion and glomerular isolation by sieving. Podocytes and endothelial cells were isolated by subsequent glomerular digestion and FACS sorting. Isolates were perfusion seeded. Human iPSCs were differentiated into endothelium using an established protocol. Human kidney organoids were generated using published methods with modifications. MAFB positive podocyte clusters were isolated using enzyme digestion and size filtration and expanded to form a monolayer. Cell seeded scaffolds were cultured using custom bioreactors and perfusion control units. Physiology was assayed by vascular perfusion under defined backpressure to generate primary filtrate through the epithelial channel.

Results: Acellular control scaffolds are highly permissive to transmembrane fluid flux and produce filtrates which contain micro- and macromolecules. Histological analysis of fixed primary and iPSC scaffolds shows cellular coverage within the endothelial and podocyte channels, indicating good cellular attachment and survival under perfusion for a minimum of 7 days. Pressurized perfusion of cellularized scaffolds with a blood-like buffer containing physiologic albumin and hematocrit through the vascular channel, produced RBC-free filtrate which resists macromolecule loss from the vasculature.

Conclusions: Our results demonstrate that both primary and iPSc derived endothelial and podocyte-like cells are a viable option for physiologically relevant engineered renal tissues.

SA-OR13

A Novel Vascularized Human Kidney Organoid to Study Podocyte and Endothelial Health and Disease

Joseph C. Maggiore, Mo R. Ebrahimkhani, Neil A. Hukriede. *University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Background: Recapitulating vasculature in *in vitro* kidney systems is critical for mechanistic studies due to its important role in health and disease. Many methods for vascularizing have been taken, however, few have been robust, reliable, high-throughput, and can be used to study podocyte/endothelial morphology and morphological changes in injury settings.

Methods: Here, we generate vascularized human kidney organoids by mixing an inducible *ETS translocation variant 2* (*ETV2*) human induced pluripotent stem cell line (iETV2-hiPSC), which directs endothelial fate, with a non-transgenic iPSC line in suspension organoid culture.

Results: We demonstrate that the addition of iETV2-hiPSCs to an established kidney organoid protocol generates a vascularized human kidney organoid with a ~10-fold increase in endothelial cells and a 60% increase in organoid diameter. Podocyte clusters were consistently encased in a network of endothelial cells with invagination. On snRNAseq we found vascularized podocytes exhibit enhanced VEGF signaling, basement membrane maturation, and endothelial differentiation markers. Additionally, we demonstrate that vascularization of human kidney organoids enables the formation of a functional interstitium with drug responsive renin+ cells. These renin cells existed within podocyte clusters of vascularized organoids only. Finally, we show that iETV2-hiPSCs undergo co-development with kidney organoid parenchymal tissue, thus generating mature fenestrated kidney-specific endothelial networks.

Conclusions: We generated a vascularized human kidney organoid with increased maturation of nephron structures including more mature podocytes with improved foot process interdigitation, a fenestrated endothelium, and the presence of renin+ cells. This represents the first demonstration of renin+ cells in a kidney organoid without the use of exogenous stimulation. The creation of an engineered vascular niche capable of improving kidney organoid maturation and cell type complexity is a significant step forward in the path to clinical translation.

SA-OR14

A Mouse Glomerular Nanoscale Spatial Atlas

Adilijiang Ali, Zixuan Liu, Kenan Ye, Tingxuan Liu, Chetan Poudel, Madeline K. Wong, Joshua C. Vaughan. Vaughan Group. *University of Washington, Seattle, WA.*

Background: Glomeruli are anatomically complex structures essential to kidney function. Much of our current understanding of glomeruli comes from optical microscopy, for general physiology and molecular distributions, and electron microscopy, for ultrastructure. While powerful, these methods yield uncorrelated results obtained on different pieces of tissue and typically for thin sections at random angles. Researchers therefore generally study small regions of glomeruli, rather than viewing them as distinct, functioning units. We are creating a Glomerular Nanoscale Spatial Atlas (GNSA) that will provide a detailed, annotated collection of high-resolution 3D reconstructions of whole mouse glomeruli. Our goals are to identify previously unknown glomerular phenotypes and to create a rich, downloadable resource.

Methods: We used optical super-resolution microscopy methods at 50-100nm resolution together with advanced tissue labeling techniques and a mix of manual and deep-learning-based data analysis techniques to image and segment major structures in whole mouse glomeruli.

Results: We have reconstructed and analyzed 7 glomeruli (3F, 4M) from healthy adult mice (3-6mo), whose models reveal Bowman's capsule, Bowman's space, blood space, all cell types and locations, glomerular basement membrane and mesangial matrix.

Conclusions: We have established a pipeline for creating detailed 3D models of whole renal glomeruli. We are performing a detailed spatial analysis of the models and acquiring new results for aged and model diseased mice with a focus on identifying spatial correlations between components of glomeruli. Once published, the unique data sets of the GNSA may be mined for diverse purposes by the nephrology community.

A Novel Glomerular Endothelium-Targeting Adeno-Associated Virus (AAV) Delivers Bacterial Proteinase to Treat Glomerulonephritis

Shuya Liu,[1,2] Guochao Wu,[1,2] Jakob Körbelin,[3] Shun Lu,[1,2] Tobias B. Huber.[1,2] *[1]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Hamburg Center for Kidney Health (HCKH), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Department of Oncology, Hematology and Bone Marrow Transplantation with Section Pneumology, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: The breakdown of glomerular filtration barrier (GFB) is relevant to the pathogenesis of most kidney diseases. Targeting the GFB by conventional drugs is challenging due to the lack of cell-targeting specificity, which consequently compromises the therapy efficacy. Adeno-associated virus (AAV) as a promising *in vivo* gene delivery platform shows the advantage in delivering therapeutic molecules to those difficult or non-druggable cells. However, natural AAV serotypes have insufficient targeting specificity and transduction efficiency in kidney cells, thus approaches to broaden the tropism of AAV and screenings for kidney-specific AAV vectors are particularly needed. In this study, we aimed to discover new AAV vectors targeting the renal glomerulus.

Methods: We developed a selection protocol specifically for kidneys and screened a random AAV2 display peptide library *in vivo*. Integrative experimental and bioinformatics workflows were conducted to identify the most promising AAV vectors enriched in renal glomeruli. The targeting specificity and transduction efficiency of the selected AAV were evaluated *in vivo* under both physiological and pathological conditions.

Results: We identified a new AAV vector termed AAV2-GEC, which specifically and efficiently targeted the glomerular endothelial cells (GEC) after systemic administration. AAV2-GEC exhibited robust GEC tropism in C57BL/6J, Balb/c mice and Sprague Dawley rats, as well as in disease models causing GEC damage. The potential of AAV2-GEC for kidney-targeting therapy was evaluated by delivering a bacterial cysteine proteinase originally purified from Streptococcus pyogenes (IdeS) to the GEC. IdeS, also known as imlifidase, is an antibody-cleaving enzyme used in the clinic to eliminate pathogenic IgG. We showed that AAV2-GEC-IdeS transduction efficiently produced IdeS in GEC, which provided sustained clearance of kidney-bound IgG and successfully prevented the progression of anti-glomerular basement membrane glomerulonephritis.

Conclusions: This study establishes an AAV *in vivo* screening approach for renal glomeruli. It identifies a novel GEC-targeting AAV vector with robust tropism maintained cross species in both physiological and pathological settings. The identification of AAV-GEC demonstrates the feasibility of future GFB-targeting strategies for novel kidney therapies.

Comprehensive Single-Cell Transcriptomic, Epigenomic, and Metabolomic Profiling Reveals Anatomical and Metabolic Heterogeneity in Human Kidneys

Haikuo Li, Dian Li, Qiao Xuanyuan, Nicolas Ledru, Haojia Wu, Benjamin D. Humphreys. *Washington University in St Louis, St Louis, MO.*

Background: The human kidney has a distinct spatial organization, with multiple anatomic structures constituted by diverse cell types and performing unique metabolic functions. We lack a large-scale spatially-resolved multimodal (transcriptome, epigenome, metabolome) single-cell atlas for the human kidney.

Methods: We developed an optimized, split-pool barcoding-based multimodal profiling method based upon SHARE-seq (concurrent scATAC/RNA-seq). We profiled 50 human kidney samples from cortex, medulla, papilla, ureter and renal artery. Computational analysis (e.g. gene regulatory network, module enrichment analysis) identified molecular signature of different anatomic regions. Mass spectrometry spatial metabolomics was used to identify region-specific metabolites at single-cell resolution. Clinical data were used to identify novel genes in kidney disease progression.

Results: We generated transcriptomes of 446,000 cells, chromatin accessibility profiles of 401,000 cells & spatially resolved metabolomes of 408,000 cells. Multiomic analysis revealed cell types in different anatomic regions are characterized by markedly different transcriptome & chromatin accessibility profiles depending on the region (e.g. cortical vs. medullary vs. papillary TAL cells). Healthy PT (proximal tubule)-to-maladaptive PT transition is accompanied by acquisition of a distinct metabolic signature (e.g. reduced fatty acid oxidation, elevated lipid accumulation). Tubular cell types had non-overlapping metabolomic profiles. We developed MALDIpy, a package for single-cell analysis of imaging mass spectrometry data.

Conclusions: Our optimized SHARE-seq achieved single-cell multiome profiling at 20-fold lower cost compared to 10X Genomics. We developed a comprehensive single-cell multiomics atlas of human kidneys covering diverse anatomic structures. Distinct signatures of cells in different regions suggest cellular plasticity and metabolic heterogeneity. Genes (e.g. PPFIBP1) correlated with disease severity were identified as potential therapeutic targets.

Improving Patient Activation via a Novel Digital Health Intervention: My Kidneys and Me, a Multicenter Randomized Controlled Trial

Courtney J. Lightfoot, Thomas J. Wilkinson, Matthew Graham-Brown, Alice C. Smith. *University of Leicester, Leicester, United Kingdom.*

Background: Self-management is an important component of chronic kidney disease (CKD) healthcare which requires knowledge, skills and confidence (patient activation). Evidence-based and theory-driven resources to support self-management are lacking but digital health interventions (DHIs) may offer cost-effective and equitable education delivery. We co-produced My Kidneys & Me (MK&M), an educational DHI, and tested its effect on patient activation in a multicenter randomized control trial.

Methods: Patients from 26 sites in England were randomized 2:1 to intervention (MK&M) or control groups. MK&M provided theory-based education sessions and trackers for goals, symptoms, physical activity and clinical measures. The Patient Activation Measure (PAM-13) was collected at baseline, 10 and 20 weeks. A 4-point increase in PAM-13 was deemed a meaningful important difference. Intention-to-treat (ITT) and per-protocol (PP) analyses (including patients who used MK&M at least once) were conducted.

Results: 421 patients (mean age 59.9±13.4 years, 60% males, eGFR 39.5±24.6 ml/min/1.73m^2) were recruited: 281 randomized to receive MK&M, 140 to control. 205 (73%) participants used MK&M at least once. Changes in PAM-13 are shown in Figure 1. Significant between group differences in PAM-13 were observed at 20 weeks in PP analysis. In those with low PAM-13 at baseline, MK&M significantly improved PAM-13 by 9.3-11.4 points. No changes were seen in those with high baseline PAM-13 scores.

Conclusions: Use of the MK&M DHI increased patient activation (measure of self-management). Greater benefit was seen with frequent and sustained usage, and in those with low PAM-13. As higher patient activation is associated with better outcomes, MK&M may improve CKD healthcare management.

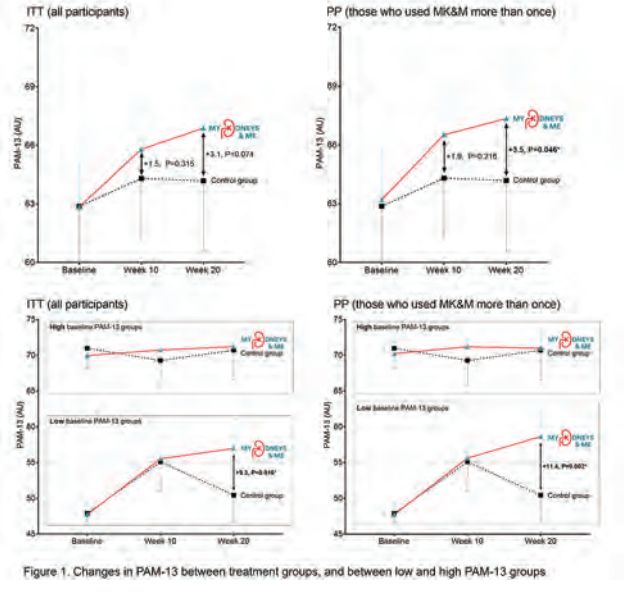

Figure 1. Changes in PAM-13 between treatment groups, and between low and high PAM-13 groups

The Effect of a Novel Digital Physical Activity Intervention on Health-Related Quality of Life in People with CKD: A Multicenter Randomized Controlled Trial (Kidney BEAM)

Sharlene A. Greenwood,[1,2] Hannah M. Young,[3] Ellen M. Castle,[4] Christy G. Walklin,[2] Juliet Briggs,[2] Roseanne Billany,[3] Kate Bramham,[1] Sunil Bhandari,[5] David C. Wheeler,[6] Thomas J. Wilkinson,[3] Elham Asgari,[7] Philip A. Kalra,[8] James Tollitt,[8] Maarten W. Taal,[9] Zoe L. Saynor,[10] James Burton,[3] Matthew Graham-Brown,[3] Andrew C. Nixon,[11] Helen R. Noble,[12] Nicolette C. Bishop,[13] Kieran Mccafferty,[14] Alexander J. Hamilton,[15] Jackie Campbell,[16] Nicola Cooper,[3] Jamie H. Macdonald.[17] Kidney Beam. *[1]King's College London Faculty of Life Sciences & Medicine, London, United Kingdom; [2]King's College Hospital NHS Foundation Trust, London, United Kingdom; [3]University of Leicester, Leicester, United Kingdom; [4]Brunel University London, London, United Kingdom; [5]Hull University Teaching Hospitals NHS Trust, Hull, United Kingdom; [6]University College London, London, United Kingdom; [7]Guy's and St Thomas' NHS Foundation Trust, London, United Kingdom; [8]Northern Care Alliance NHS Foundation Trust Salford Care Organisation, Salford, United Kingdom; [9]Royal Derby Hospital, Derby, United Kingdom; [10]University of Portsmouth, Portsmouth, United Kingdom; [11]Lancashire Teaching Hospitals NHS Foundation Trust, Preston, United Kingdom; [12]Queen's University Belfast, Belfast, United Kingdom; [13]Loughborough University, Loughborough, United Kingdom; [14]Barts Health NHS Trust, London, United Kingdom; [15]Royal Devon University Healthcare NHS Foundation Trust, Exeter, United Kingdom; [16]University of Northampton, Northampton, United Kingdom; [17]Bangor University, Bangor, United Kingdom.*

Background: Remote digital health interventions (DHI) to enhance PA (PA) provide a potential solution to improve health related quality of life (HRQoL) for people with chronic kidney disease (CKD). The Kidney BEAM trial evaluated the effect of a 12-week PA DHI on HRQoL.

Methods: 340 participants with CKD from 11 UK Kidney units were recruited and randomized (1:1) to Kidney BEAM PA DHI (www.beamfeelgood.com) or a waitlist control. The primary outcome was a powered 3-point difference in the Kidney Disease Quality of Life SF 1.3 Mental Component Summary (KDQoL-SF1.3 MCS) between baseline and 12-weeks. Secondary outcomes included KDQoL-SF1.3 Physical Component Summary and sub-scales; physical function (sit-to-stand 60, STS60); patient activation (Patient Activation Measure 13, PAM13); anxiety/depression (Patient Health Questionnaire, PHQ4); and fatigue (Chalder Fatigue Scale, CFS). Outcomes were analysed by intention-to-treat approach utilising an analysis of covariance model.

Results: 340 participants were included in the intention-to treat analyses. At 12-weeks there was a significant mean difference between Kidney BEAM and waitlist control in KDQoL MCS score of 3.1 {95% confidence interval (CI): 1.8 to 4.4} arbitrary units ($p<0.001$). KDQoL burden of kidney disease, energy/fatigue, and social function sub-scales ($p=0.049$, $p=<0.001$, and $p=0.013$, respectively) all improved in favour of the intervention. Physical function also improved (STS60 mean between-group difference: 4 {95% CI: 3 to 5} repetitions ($p<0.001$) and patient activation was enhanced (PAM13 mean between-group difference: 6.9 {95% CI: 4.9 to 8.8} points ($p<0.001$)). Fatigue and anxiety/depression were unchanged ($p=0.33$ and $p=0.08$, respectively).

Conclusions: These results demonstrate that the Kidney BEAM DHI is an effective innovation to improve mental HRQoL in people with CKD. This is the first large randomised controlled trial of an effective, and deliverable, PA DHI for people with CKD.

SA-OR19

Hemodialysis Patient App Promotes Patient Engagement and May Improve Patient Outcomes Such as Hospitalisation and Phosphate Control

Milind Nikam,[1] Cindy Chan,[1] Yan Yi Cheung,[1] Nandakumar Mooppil,[2] Margaret Li,[1] Jeffrey L. Hymes.[3] *[1]Fresenius Medical Care Asia Pacific Ltd, Singapore, Singapore; [2]Fresenius Medical Care Singapore Pte Ltd, Singapore, Singapore; [3]Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Mobile applications (apps) have been shown to improve engagement in patients with chronic diseases. The aim of this study was to investigate patient engagement with our patient app (MyCompanion) and assess the impact of app usage on the outcomes of our hemodialysis (HD) patients.

Methods: We conducted a retrospective review of 2,970 chronic HD patients from 33 dialysis clinics in Singapore over a 2-year period (July 2020 - June 2022). An online survey was disseminated to gather user feedback. We compared the demographics, clinical, laboratory and outcome variables between app users and non-users using linear regression, and changes to the variables before and after app usage (1-year period) using paired t-test.

Results: As of June 2022, 13.5% (194 out of 1594 total active in-centre HD patients) of the patients logged in to the app at least once monthly. From the online survey with 64 respondents, a vast majority (87.5%) reported that the app empowered them for self-care. Out of the 5 core features within the app, patients ranked treatment data (39.1%) followed by laboratory results (32.8%) as the most favoured. For the analysis of outcome variables, 822 app users and 2,148 non-users were identified. App users were statistically significantly younger (60.1 vs 66.0 years), had longer dialysis vintage (3.9 vs 2.0 years), higher dry body weight (70.7 kg vs 65.6 kg in males and 59.3 kg vs 56.7 kg in females)

and lower adjusted Charlson Comorbidity Index (5.0 vs 5.5) (p<0.001). The percentage of patients achieving the phosphate target (≥2.5 and <5.5 mg/dL) was higher in app users (68.9%) compared to non-users (66.4%) (p<0.001). Phosphate control improved after 1 year of app usage from 62.2% to 69.4% (p=0.001). Hospitalisation rate (events per patient year) was 1.55 for app users and 1.97 for non-users (p<0.001). The number of hospitalization days per patient year for users and non-users were 10.2 and 10.9 days, respectively (p<0.001). The impact of app usage on patients' interdialytic weight gain was not statistically significant.

Conclusions: HD patient app promotes patient empowerment and self-care. Additionally, app usage may improve medical outcomes such as phosphate and hospitalisation.

Integrated Proteomic and Metabolomic Modules Associated with Risk of Kidney Function Decline

Pascal Schlosser,[1] Aditya L. Surapaneni,[2] Eugene P. Rhee,[3] Josef Coresh,[1] Morgan Grams.[2] On Behalf of the CRIC and CKD BioCOn Writing Group. *[1]Johns Hopkins University Department of Epidemiology, Baltimore, MD; [2]Division of Precision Medicine, New York University School of Medicine, New York, NY; [3]Massachusetts General Hospital, Boston, MA.*

Background: Proteins and metabolites play crucial roles in various biological functions and are frequently interconnected through enzymatic or transport processes. Many molecules have been linked to kidney disease, and several of them are potentially representing pathways or endophenotypes.

Methods: We present an integrated analysis of proteomics (4,091 proteins) and metabolomics (634 metabolites) via a dimensionality reduction clustering method in the Chronic Renal Insufficiency Cohort (CRIC) Study. We split the 1,708 participants (mean age 59; mean eGFR=42.8 mL/min/1.73m^2) with a random split in discovery (2/3) and replication (1/3). Linear regressions (eGFR decline) and Cox proportional hazards models (CKD progression, ESKD) were comprehensively adjusted for demographics and risk factors including eGFR and PCR. Multiple testing in discovery and replication was accounted for by Bonferroni adjustment. Identified modules were characterized through pathway enrichment analyses.

Results: We identified 139 modules of correlated proteins and metabolites in the discovery data. The mean module size was 34 proteins / metabolites. There were 286 principal components (PCs) used to represent the 139 modules. Module membership and PC directions were projected onto the replication dataset. The average follow-up period was 9.5 and 7.4 years for ESKD and CKD progression respectively (537 and 685 events). Eight module PC to endpoint associations originating from four different modules were identified and replicated (1 eGFR decline; 3 CKD progression; 4 ESKD). One module showed associations with all three traits and ESKD concordance in the replication dataset was improved (87% to 88%, p=0.03) by the addition of this module to the full model of ten covariables. All five protective protein components of this module (ATF6, CLSTN1, EGFR, GHR, C1GALT1C1) were transmembrane proteins and several transmembrane related terms were significantly enriched among the 298 module components. Transmembrane-ephrin receptor activity displayed the largest odds ratio among these (OR = 13.2, P-value = 5.5e-5).

Conclusions: In summary, this study demonstrates that the integration of the proteome and metabolome can identify functions of (patho-) physiologic importance in human health and disease. Specifically, the ephrin receptor activity pathway might play a role on a systemic level.

A Soluble ACE2 Protein Improves Survival and Lowers Viral Titers in a Lethal Mouse Model of SARS-CoV-2 Infection with the Delta Variant

Cosimo L. Cianfarini, Jan Wysocki, Ahmed K. Ismail, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Severe Acute Respiratory Syndrome Coronavirus Type 2 (SARS-CoV-2) utilizes Angiotensin Converting Enzyme 2 (ACE2) as its main receptor for cell entry. We have previously shown that a bioengineered soluble ACE2 protein designed to have increased binding to the SARS-CoV-2 spike protein and with extended duration of action can neutralize SARS-CoV-2 in the k18hACE2 mouse model infected with the ancestral SARS-CoV-2 strain (Washington isolate). Here we investigated the preventative/therapeutic potential of intranasally administering this soluble ACE2 protein in the same lethal mouse model infected with the SARS-CoV-2 delta variant which causes severe disease in humans.

Methods: k18hACE2 mice were inoculated with SARS-CoV-2 delta variant (2x10^4 PFU) and followed for up to 14 days in a BSL-3 facility. ACE2-618-ABD-DDC or PBS as vehicle control (n=10 per group) were administered intranasally 6h prior as well as 24 and 48hrs after viral inoculation. Infected animals were observed for weight loss, a clinical score, and mortality. Viral load was assessed by plaque assay in brain, lung, and kidney tissue.

Results: All untreated animals had succumbed to the disease at day 6, whereas survival at day 14 was 90% in mice receiving ACE2-618-ABD-DDC (Fig, left panel). Brain and lung viral titers were markedly reduced in mice receiving ACE2-618-ABD-DDC (Fig, middle panels). Despite uniform lethality of the disease in untreated animals, infected mice showed absence of kidney viral titers in all groups (Fig, right panel).

Conclusions: This study demonstrates the protective effect of ACE2-618-ABD-DDC in a lethal mouse model of SARS-CoV-2 infection with the delta variant. This soluble ACE2 protein markedly improved survival in the otherwise lethal model and reduced viral titers in lungs and brains to almost undetectable levels. It also shows a consistent lack of replicating virus in the kidney of animals infected with the delta variant. Taken together with our previously published experiments, the data supports a universal protective effect of our soluble ACE2 protein against infections with different SARS-CoV-2 variants.

University of California Health Systems Kidney COVID Study Inpatient Cohort

Hiba Hamdan, Brian M. Paciotti, Blythe Durbin-Johnson, Brian Y. Young, Juan P. Moreno-Ortiz, Baback Roshanravan. *UC Davis Health, Sacramento, CA.*

Background: Understanding long term changes in kidney function following moderate to severe COVID-19 is important. The aim of our study was to compare changes in eGFR between people hospitalized with and without COVID-19 to better understand its longer-term kidney sequelae.

Methods: We conducted a retrospective cohort study of adults receiving care within the five major University of California (UC) Health Systems, who underwent PCR testing for SARS-CoV-2 between March 1, 2020, and December 31, 2021, and were hospitalized within 10 days of testing. The cohort was restricted to those without ESKD, with a serum creatinine (sCr) within 12 months prior to SARS-CoV-2 testing or normal kidney function on admission, length of stay ≥1 day, no pregnancy throughout the study period, and at least one outpatient sCr 30 days after initial PCR test. Individuals were classified as COVID/non-COVID based on the index SARS-CoV-2 PCR result and those classified as non- COVID were required to remain negative. The outcome was the difference in the rate of eGFR change among those who survived hospitalization. The cohort was followed until December 31, 2022. Descriptive statistics were used to compare patient characteristics. Trajectories of eGFR were compared between those with and without COVID using linear mixed models with inverse probability weighting to account for missingness of baseline and follow-up eGFR measurements. Three linear mixed models were fitted as detailed in attached figure.

Results: The cohort included 2,356 and 26894 patients hospitalized with and without COVID, respectively. Patients hospitalized with COVID-19 were more likely to be male, Hispanic, reside in areas with higher Area deprivation index (ADI), and have pre-existing chronic diseases, including DM, HTN and CKD. The results of the three fitted models are shown in attached figure.

Conclusions: In a large cohort from one of the largest health care systems in California, we did not observe a significant difference in eGFR decline over almost 2 years of follow up. This study has the longest reported follow up of kidney function post SARS COV 2 infection.

Funding: Other NIH Support - UC Davis School of Medicine

Estimates of Annual eGFR Change in Inpatients from Linear Mixed Effects Models

Machine Learning-Based Multi-Omics Analyses Predict Disease Severity and Identify Molecular Mechanisms of COVID-Associated Kidney Injury

Nanditha Anandakrishnan,[1] Zhengzi Yi,[1] Tong Liu,[3] Zeguo Sun,[1] Jonathan C. Haydak,[1] Matthias Kretzler,[2] Hong Li,[3] Girish N. Nadkarni,[1] Lili Chan,[1] Weijia Zhang,[1] Evren U. Azeloglu.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]University of Michigan, Ann Arbor, MI; [3]Rutgers The State University of New Jersey, New Brunswick, NJ.*

Background: Studies show a higher prevalence of acute kidney injury (AKI) in COVID-19 patients, however mechanisms leading to severe kidney outcomes are unclear. Identifying these mechanisms may help develop therapies for the management of COVID-associated nephropathy (COVAN). In this multicenter study, we combine urinary proteomics and machine learning (ML) to predict severe kidney outcomes in COVID-19 patients and further combine multiomic datasets to identify gene networks driving disease (Fig 1A).

Methods: Quantitative LC-MS/MS analysis of urine samples from hospitalized participants was performed. For ML algorithm construction, samples were stratified into

severe and mild outcomes and randomized into discovery and validation set at a 2:1 ratio. Limma test was used to identify differentially abundant proteins (DAPs) and the Boruta feature selection method was used to select features to construct the ML algorithm.

Results: Limma test on the discovery set identified DAPs in severe vs mild outcome cohort (Fig 1B). The top features identified using Boruta feature selection method used for random forest model construction demonstrated good predictive power of greater than 76% accuracy for both discovery and validation set (Fig 1C, D). Enrichment analysis showed significant upregulation of exocytosis and immune related processes and downregulation of cell adhesion and extracellular matrix organization related processes in severe COVID-19 (Fig 1E, F). The top features showed expression in multiple nephron segments based on the public KPMP data (Fig 1G).

Conclusions: The novel biomarkers identified here can be used for assessment of kidney function in patients with COVAN.

Funding: NIDDK Support

SA-OR24

Longitudinal Kidney Outcomes of COVID-19-Associated AKI

Abinet M. Aklilu, Sanchit Kumar, James Nugent, Francis P. Wilson. Clinical and Translational Research Accelerator. *Yale School of Medicine, New Haven, CT.*

Background: COVID-19 infection is associated with a high incidence of acute kidney injury(AKI). The long-term impact of COVID-associated AKI on kidney function trajectory remains unknown.

Methods: This was a longitudinal health record cohort study that included 9624 adults hospitalized with AKI within a large New England health system assessing the association of COVID-19-associated AKI with the slope of estimated glomerular function rate (eGFR) for up to 2-yrs after discharge using multivariable linear mixed effects models. Three groups were compared: 1) patients hospitalized with COVID-19-associated AKI; 2) patients hospitalized during the COVID pandemic who tested negative for SARS CoV-2 and had AKI due to other causes (Other-AKI); and 3) patients hospitalized with influenza-associated AKI in the 5yrs before the COVID pandemic (Flu-AKI). A key secondary outcome included 2-yr major adverse kidney events (MAKE-a composite of mortality, ≥25% eGFR decline from discharge or end-stage kidney disease diagnosis) assessed using multivariable time-to-event analyses.

Results: The adjusted eGFR slope was -6.79ml/min/1.73m^2 per year (95%CI -7.93,-5.64) following COVID-AKI, -5.55 (95%CI -7.45,-3.65) following Flu-AKI, and -2.60 (95%CI -3.01,-2.20) following Other-AKI. COVID-AKI was associated with lower 2-yr MAKE (adjHR: 0.67, 95%CI: 0.59-0.75), with lower 2-yr mortality (adjHR: 0.31, 95%CI: 0.24–0.39, p<0.001) and lower 2-yr renal progression (adjHR 0.78, 95%CI: 0.69–0.88, p<0.001) compared to Other-AKI.

Conclusions: While survivors of COVID-AKI experience an initial faster eGFR decline compared to AKI due to other causes, they have higher eGFR on discharge and exhibit lower rates of longitudinal renal progression and mortality.

Funding: Other U.S. Government Support

Annualized rate of eGFR decline over 2yrs of follow up

Group Name	Unadjusted eGFR Slope (ml/min/1.73m^2 per year)	p-interaction	Adjusted eGFR Slope (ml/min/1.73m^2 per year)	p-interaction
COVID-AKI	-6.86 (-8.00, -5.73)	<0.001	-6.79 (-7.93, -5.64)	<0.001

Monovalent and Bivalent mRNA Vaccine Effectiveness Against Severe COVID-19 Associated with Omicron Variant in Maintenance Dialysis Patients

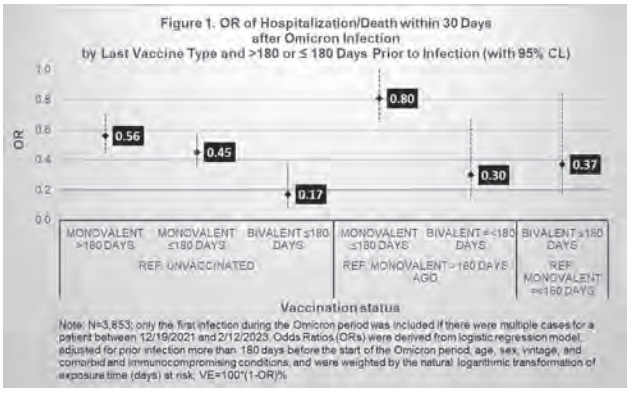
Nien Chen Li,[1] Harold Manley,[1] Antonia Harford,[1] Monica Shieu,[1] Caroline M. Hsu,[2] Dana Miskulin,[2] Daniel E. Weiner,[2] Doug Johnson,[1] Eduardo K. Lacson.[1] *[1]Dialysis Clinic Inc, Nashville, TN; [2]Tufts Medical Center, Boston, MA.*

Background: Recent data suggest that SARS-CoV-2 bivalent (BV) booster is more effective than monovalent (MV) booster against severe Omicron infection. We compared the effectiveness (VE) of BV and MV booster regimens in a national population of maintenance dialysis patients.

Methods: All adult patients receiving maintenance dialysis during the Omicron era (12/19/21-2/12/23) at Dialysis Clinic, Inc. (DCI) facilities who had COVID-19 during this time were included. Vaccination status was categorized as unvaccinated or received MV or BV booster <180 or ≥180 days prior to COVID. A logistic model was used to determine odds ratio (OR) of hospitalization/death within 30 days of infection by vaccination status. The model was adjusted for COVID prior to the Omicron period, age, sex, dialysis vintage, COPD, thyroid disease, PVD, diabetes, and immunocompromising conditions, and weighted by the natural log transformation of exposure time at risk.

Results: Among 3,853 eligible patients, mean age was 63 (±15) years; 55% were male and 31% Black. Figure 1 shows ORs of hospitalization or death within 30 days of infection by vaccination status. Relative to unvaccinated, the VE, defined as 100*(1-OR)%, was 44% (95% CI 30-56%) for MV booster doses received more than 180 days before Omicron infection; was 55% (42-65%) for MV received within 180 days; and was 83% (62-93%) for BV received within 180 days of infection. Relative to MV received more than 180 days before infection, the VE for MV and BV received within 180 days of infection were 20% (0.2-35%) and 70% (33-87%), respectively. The VE was 63% (16-84%) for BV relative to MV when both were received within 180 days of infection.

Conclusions: Bivalent SARS-CoV-2 vaccine is more effective than monovalent vaccine against severe Omicron infection in maintenance dialysis patients. Vaccine effectiveness declines after 180 days in this population suggesting a need for revaccination.



SA-OR26

Excess Mortality During the COVID-19 Pandemic in a Mid-Sized Dialysis Provider

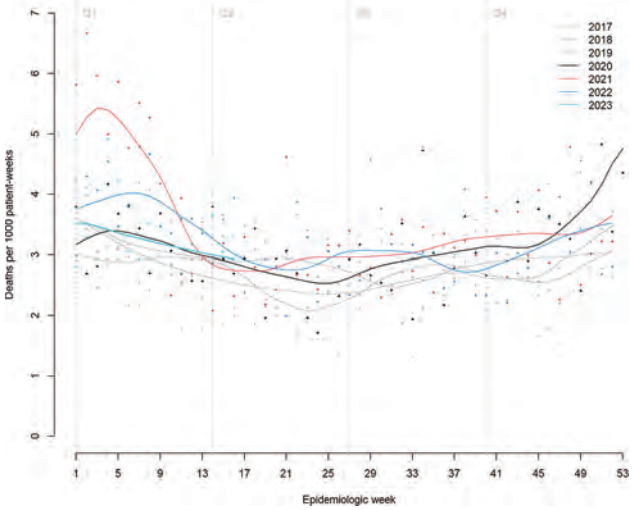
Eric D. Weinhandl,[1,2] Wael F. Hussein,[1,3] Gopa B. Green,[1] Graham E. Abra.[1,3]
[1]Satellite Healthcare, San Jose, CA; [2]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [3]Stanford University School of Medicine, Stanford, CA.

Background: Before widespread availability of vaccination, the coronavirus disease 2019 (COVID-19) pandemic incited a sharp increase in the all-cause death rate among chronic dialysis patients. Whether excess mortality has persisted during 2022 and early 2023 remains uncertain.

Methods: We analyzed the electronic health records of Satellite Healthcare, a mid-sized, not-for-profit dialysis provider. During each epidemiologic week from week 1 of 2017 to week 16 of 2023, we identified all chronic dialysis patients in centers in California, Hawaii, Tennessee, and Texas. For each patient-day, we collected age, sex, and duration of end stage kidney disease (ESKD). We fit a logistic regression of death with generalized estimation equations, adjusted for age, sex, duration of ESKD, state, and seasonality; and estimated excess mortality in 9 pandemic intervals, relative to the interval from week 1 of 2017 to week 11 of 2020, overall and by setting (in-center, home).

Results: During the pandemic era, there were 4175 deaths, or 16.5 deaths per 100 patient-years; in contrast, there were 14.5 deaths per 100 patient-years during the pre-pandemic era. As displayed, the rate of death was initially elevated between September 2020 and March 2021 (excess mortality factor, 1.34; 95% CI, 1.24-1.45), and remained elevated from July 2021 to October 2022, with excess mortality factors ranging from 1.11 to 1.18. From November 2021 to February 2023, excess mortality was more pronounced among home dialysis patients (range of excess mortality factors, 1.20-1.35 among home patients versus 1.07-1.14 among in-center patients). Since March 2023, the rate of death has been in line with the pre-pandemic norm (excess mortality factor, 0.96; 95% CI, 0.81-1.14).

Conclusions: Excess mortality during the pandemic has gradually decreased since Winter 2020-2021, although it dissipated more slowly among home dialysis patients. In Spring 2023, excess mortality is absent.



SA-OR27

Kidney Transplant Graft Loss During 2020

Kirsten L. Johansen,[1] David T. Gilbertson,[1] Jiannong Liu,[1] Kayla L. Horak,[1] Elaine Ku.[2] *[1]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN; [2]University of California San Francisco, San Francisco, CA.*

Background: We hypothesized that disruption of clinical care during the COVID-19 pandemic in 2020 led to an increase in kidney transplant graft loss compared with rates in 2018 and 2019.

Methods: We examined point prevalent cohorts of adult kidney transplant (KT) recipients with functioning allografts on January 1 of 2018, 2019, and 2020. We calculated rates of all-cause graft loss and death-censored graft loss during each quarter. We used Poisson regression to estimate incidence rate ratios (IRR) for each quarter, comparing rates in 2020 to those in 2018-2019, adjusting for age, sex, race/ethnicity, type of donor, and duration of transplant (<1 year, ≥1 year).

Results: There were 220,079, 228,549, and 238,578 individuals in the 2018, 2019, and 2020 cohorts. In 2020, mean age was 55.3 years, 62.4% were deceased donor KT recipients, and 9.8% were within one year of KT. 51.9% were White, 20.5% Black, 16.1% Hispanic, and 11.4% other. All-cause graft failure rates ranged from 5.6 to 6.8 per 100 person years and death-censored rates from 2.6 to 3.2 per 100 person years. Compared with earlier years, rates of all-cause graft loss were higher in quarters 2-4 of 2020 (**Table**). There was a statistically significant interaction between race/ethnicity and year (2018-2019 vs 2020) across quarters; during 2020, there was a greater increase in all-cause graft loss among Black and Hispanic than among White individuals. Contrary to our hypothesis, there was no statistically significant increase in death-censored graft loss in 2020 compared with 2018-2019 overall or for any race/ethnicity group. The increase in overall graft loss in 2020 and the stable or lower rates of death-censored graft loss were consistent among recipients with shorter (<1 year) versus longer graft vintage (p-values for interaction >0.3).

Conclusions: All-cause graft loss increased in 2020 compared with 2018-2019, but death-censored graft loss did not. COVID-19 related mortality likely dominated all-cause graft loss, but surviving patients did not experience higher rates of graft loss.

Funding: NIDDK Support

IRR for all-cause and death-censored graft loss in 2020 compared with 2018-2019

Quarter	All-cause graft failure, IRR (95% CI)	Death-censored graft failure, IRR (95% CI)
Quarter 1 (Jan-Mar)	0.94 (0.90, 0.98)	0.93 (0.88, 0.98)
Quarter 2 (Apr-Jun)	1.10 (1.05, 1.14)	0.87 (0.82, 0.93)
Quarter 3 (Jul-Sept)	1.14 (1.10, 1.19)	0.97 (0.92, 1.04)
Quarter 4 (Oct-Dec)	1.24 (1.19, 1.29)	0.90 (0.85, 0.96)

SA-OR28

Abrupt Estimated Glomerular Filtration Rate Decline After Initiating Sodium-Glucose Cotransporter-2 Inhibitors Predicts Clinical Outcomes: A Systematic Review

Yu-Shuo Tang,[1,2] Min-Hsiang Chuang,[3] Jui-Yi Chen,[3,4] Heng-chih Pan,[5] Hung-Wei Liao,[1] Wen-Kai Chu,[6] Chung-Yi Cheng,[1] Vincent Wu,[6] Michael Heung.[7] *[1]Division of Nephrology, Department of Internal Medicine, Wan Fang Hospital, Taipei Medical University, Taipei, Taiwan; [2]Taipei Medical University Research Center of Urology and Kidney, Taipei, Taiwan; [3]Chi Mei Medical Center, Tainan, Taiwan; [4]Chia Nan University of Pharmacy and Science, Rende, Taiwan; [5]Chang Gung Memorial Hospital Keelung Branch Library, Keelung, Taiwan; [6]National Taiwan University Hospital, Taipei, Taiwan; [7]University of Michigan, Ann Arbor, MI.*

Background: The initiation of sodium-glucose cotransporter-2 inhibitors (SGLT2i) typically leads to a reversible initial decline or "dip" in estimated glomerular filtration rate (eGFR). However, the implications of this phenomenon on clinical outcomes are not well-defined.

Methods: We searched MEDLINE, Embase, and Cochrane Library from inception to March 23, 2023 to identify randomized controlled trials and cohort studies comparing kidney and cardiovascular outcomes in patients with and without initial eGFR dip after initiating SGLT2i. Pooled estimates were calculated using random-effect meta-analysis.

Results: We included seven studies in our analysis, which revealed that an initial dip in eGFR following the initiation of SGLT2i was associated with less annual eGFR decline (mean difference: 0.64, 95% confidence interval [CI]: 0.437-0.843 mL/min/1.73m^2). The risk of major adverse kidney events was similar between non-dipping and dipping groups but reduced in patients with a 0-10% eGFR dip (hazard ratio [HR]: 0.915, 95% CI: 0.865-0.967). No significant differences were observed in the composite of hospitalized heart failure and cardiovascular death (HR: 0.824, 95% CI: 0.633-1.074), hospitalized heart failure (HR: 1.059, 95% CI: 0.574-1.952), or all-cause mortality (HR: 0.83, 95% CI: 0.589-1.170). However, trial sequential analysis indicated that the required sample size had not been reached to make conclusive claims about cardiovascular and mortality outcomes. The risk of serious adverse events (AEs), discontinuation of SGLT2i due to AEs, kidney-related AEs, acute kidney injury, and volume depletion were similar between the two groups. However, patients with >10% eGFR dip had a higher risk of hyperkalemia compared to the non-dipping group.

Conclusions: The findings of this study suggested that the initial dip in eGFR following the initiation of SGLT2i might be associated with less annual eGFR decline. Additionally, there were no significant differences in the risks of adverse kidney and cardiovascular outcomes between the dipping and non-dipping groups.

Global Burden of CKD and Attributable Risk Factors in 38 Organization for Economic Cooperation and Development (OECD) Countries: Results from GBD 2019

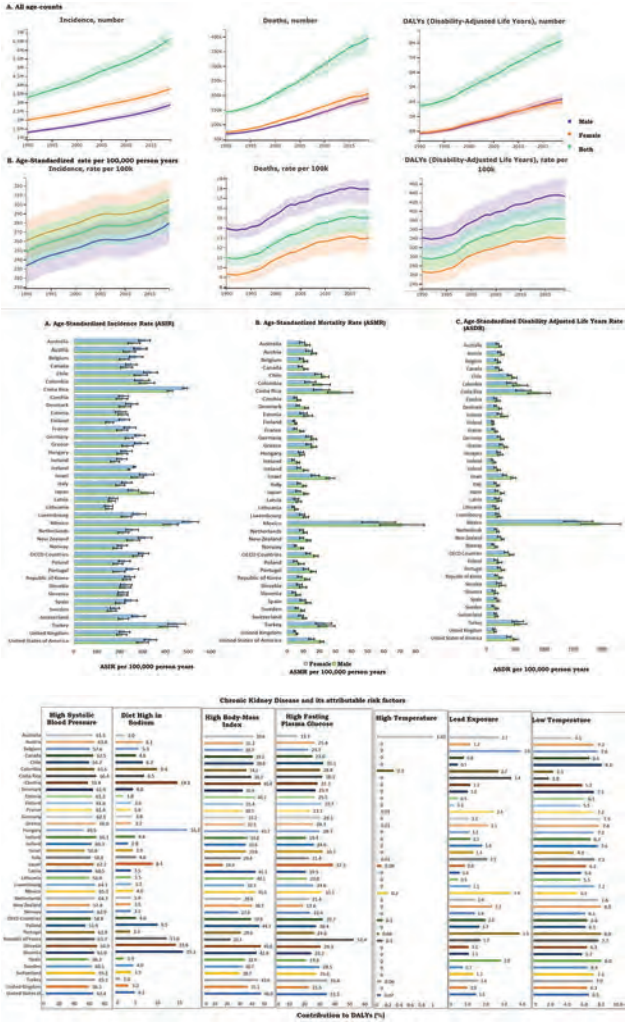
Hardik Desai,[1] Joseph Lieber,[2] Bijin Thajudeen,[3] Vishrant Amin,[4] Mohammed Dheyaa Marsool Marsool,[5] Juhi Patel,[4] Sumit Kyada,[4] Mohit Lakkimsetti,[6] Arushi Dhawan.[7] *[1]Gujarat Adani Institute of Medical Science, Bhuj, India; [2]Mount Sinai Health System, New York, NY; [3]Banner University Medical Center South, Tucson, AZ; [4]Gujarat Medical Education and Research Society Medical College & Hospital Valsad, Valsad, India; [5]University of Baghdad, Baghdad, Iraq; [6]Mamata Medical College, Khammam, India; [7]Punjab Institute of Medical Sciences, Jalandhar, India.*

Background: CKD was the 8th leading cause of death in Organization for Economic Cooperation and Development(OECD) nations in 2019, accounting for 3.5% of all fatalities.

Methods: This study utilized the Global Burden of Disease methodology to analyze CKD incidence, mortality, disability-adjusted life years(DALYs), and associated risk factors in OECD countries.

Results: In 2019, OECD countries accounted for 35.06% of total global incident cases, 27.7% of deaths, and 19.6% of DALYs attributed to CKD. Within the combined OECD countries, CKD incident cases increased by 103%, deaths by 179%, and DALYs by 120% from 1990-2019. Age-standardized incidence rates(ASIR) increased by 18%, ASDR by 29%, and ASMR by 37% between 1990-2019. In absolute counts, the United States(US) had the highest numbers with 1.7million incident cases (95%UI:1.5-1.8million),106,954 deaths(95,861–114,383), and 2.2million DALYs(2.1-2.4million) in 2019. Japan, Mexico, Germany, and Turkey followed suit. When comparing ASR, the US had a relatively lower ASIR(318) compared to countries such as Mexico(469) and Turkey(432) in 2019, but higher than Chile(316), Israel(299), and Japan(292).

Conclusions: CKD represents a significant burden in the 38 OECD countries. The high prevalence rates, association with cardiovascular disease, economic costs, health disparities, and impact on quality of life emphasize the need for comprehensive strategies to address CKD.



SA-OR30

The Risk of CKD in Lithium-Treated Individuals

Gisli Gislason,[1,2] Olafur S. Indridason,[2] Engilbert Sigurdsson,[1,2] Runolfur Palsson.[1,2] *[1]Heilbrigdisvisindasvid - Haskoli Island, Reykjavik, Iceland; [2]Landspitali, Reykjavik, Iceland.*

Background: The use of lithium may contribute to chronic kidney disease (CKD) but studies have yielded conflicting results. The aim of this study was to examine the risk of developing CKD stage 3 and above among persons treated with lithium.

Methods: This was a retrospective cohort study of all persons in Iceland using lithium in the years 2008-2018. Patients with affective disorders (ICD-10 codes F30-F39) attending the outpatient clinics of the Landspitali–The National University Hospital Mental Health Services in 2014-2016 who had not been prescribed lithium served as controls. CKD stages 3-5 was defined as eGFR <60 ml/min/1.73 m^2, eGFR was calculated using the serum creatinine (SCr) based CKD-EPI equation. Individuals with fewer than 2 SCr measurements during the study period and those with CKD stages 3-5 prior to 2008 were excluded. Cox regression was performed to assess the risk of CKD associated with lithium treatment in a time dependent manner, adjusting for important confounding factors where acute kidney injury (AKI), hypertension, diabetes mellitus (DM) and cardiovascular diseases were treated as time-dependent covariates.

Results: A total of 2760 persons received lithium treatment during the study period, of whom 2046 (74.1%) were included in the study. Of those, 221 (10.9%) developed CKD stages 3-5. Of the 1615 persons in the control group, 1220 (75.6%) were included, of whom 39 (3.2%) developed CKD 3-5. Lithium use was associated with incident CKD (hazard ratio [HR] 1.93, 95% confidence interval [CI] 1.37–2.74) in the adjusted model. Age per year (HR 1.03, 95% CI 1.02–1.04), initial eGFR per mL/min/1.73 m^2 (HR 0.92-0.96, 95% CI 0.92–0.99), DM (HR 1.73, 95% CI 1.15–2.48) and AKI (HR 1.89, 95% CI 1.32–2.74) were other significant CKD risk factors. When compared to individuals not exposed to lithium the HR for CKD in adjusted analysis was 1.24 (95% CI 0.81–1.89) for those with mean lithium concentration of 0.3-0.59 mmol/L, 2.88 (95% CI 1.97–4.20) for those with mean lithium concentration of 0.6-0.79 mmol/L, and 5.23 (95% CI 3.31-8.26) for those with mean lithium concentration of 0.8-0.99 mmol/L.

Conclusions: Long-term lithium use is associated with risk of CKD in a concentration-dependent manner among patients with bipolar and unipolar mood disorders. Therefore, the mean blood concentration of lithium should be kept as low as possible for adequate mood stabilization and treatment.

CKD Among Childbearing Age Women in the United States: NHANES 1999-2018

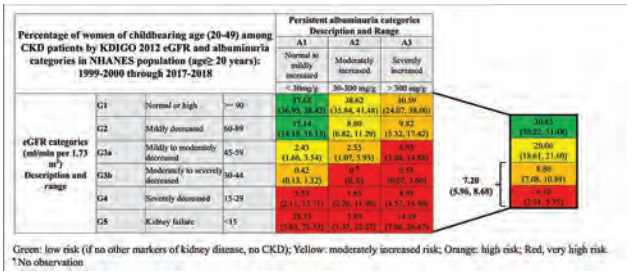
Zihe Zheng,[1] Ajay K. Singh,[1,2] Youssef M. Farag.[3,2] *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD.*

Background: Previous studies reported 3% and up to 6% prevalence of CKD among pregnant women and women of childbearing age in high income countries, respectively. However, the prevalence and severity of CKD among women of childbearing age (20-49) in the US has not been well characterized. We aimed to examine this epidemiology evidence gap in a representative sample of the US adult population.

Methods: We analyzed data from the National Health and Nutrition Examination Survey (NHANES), 1999-2018. The definition of childbearing age for women was derived from the CDC vital and health statistics report. We used KDIGO guidelines to define CKD and the prognosis risk categories. We examined common kidney risk factors in the age group between 20 to 49, including eGFR, albuminuria, blood pressure, HbA1c, glucose, hemoglobin, BMI, and lipids. We used Poisson regression to estimate the CKD prevalence ratio comparing women to men in this age group.

Results: The weighted period prevalence of CKD among childbearing age women in the US was 7.51%, while the prevalence of CKD among men in the same age group was 5.08%. Non-Hispanic black and Hispanic women of childbearing age had higher prevalence of CKD (9-10%). Fig 1 shows that more than 1 in 5 CKD patients with moderately increased KDIGO risk and more than 1 in 14 CKD patients with high/very high KDIGO risk were women of childbearing age. The percentage of Hispanics was higher among childbearing age females (20.2%) compared to females≥ age 50 (8.4%) in CKD patients. After adjusting for race/ethnicity and age, female gender was independently associated with 47% increased prevalence for CKD in the childbearing age group (PR=1.47, 95% CI 1.32, 1.63), yet female CKD patients showed largely more favorable profiles of common kidney risk factors compared to their male counterparts.

Conclusions: Our study highlighted that women of childbearing age had disproportionally higher prevalence of CKD in the US, especially among Hispanic women, than previously reported. Our findings quantify disparities and highlight the need and gaps in kidney/reproductive health among one of the most vulnerable populations in CKD patients.



Green: low risk (if no other markers of kidney disease, no CKD); Yellow: moderately increased risk; Orange: high risk; Red, very high risk.
*No observation

Mortality and Transplant After Delivering on Hemodialysis: A Matched Cohort Study

Andrea L. Oliverio, Mia Wang, Jennifer L. Bragg-Gresham, Rajiv Saran, Michael Heung. *University of Michigan Medical School, Ann Arbor, MI.*

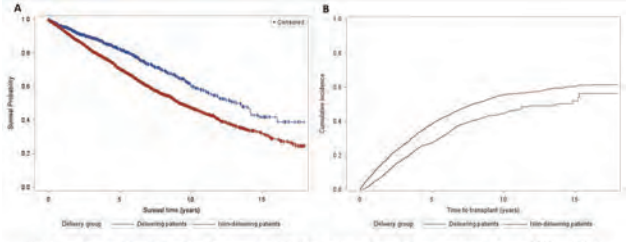
Background: Rates of successful pregnancies among women with ESKD on hemodialysis (HD) are increasing, however risk of preeclampsia and cesarean delivery remain high. Subsequent mortality and transplantation after delivery on HD are unknown.

Methods: Using USRDS data, women treated with HD who delivered an infant between 2002 and 2019 were identified from ICD-9/10-CM codes and matched up to 1:4 by age, vintage, race and ethnicity, and diabetes as primary cause of ESKD to contemporary women on HD who did not deliver. We assessed mortality and transplantation rates over time. A Cox proportional hazards model was fit to compare mortality and transplantation rates between delivering and non-delivering women. Logistic regression was used to evaluate 1 and 5 year transplant rates for delivering vs. non-delivering female patients. All models were adjusted for age, vintage, BMI, race, Hispanic ethnicity, incident comorbidities, area deprivation index, rural-urbanicity, nephrology care pre-ESKD, Medicare insurance, and prior transplant history; patient waitlist status and PRA values were also adjusted in the transplant models.

Results: 1,109 delivering women were matched to 4,404 non-delivering women. Unadjusted mortality and transplantation rates for delivering vs non-delivering women were 4.5 vs 7.2 and 6.0 vs. 8.6 per 100 patient-years, respectively (**Figure**). In adjusted models, the HR (95% CI) for mortality and transplant are 0.69 (0.64, 0.74; p<.0001) and 0.76 (0.71, 0.81; p<0.0001), respectively, in delivering compared to non-delivering women. 1 and 5 year transplantation rates were lower in delivering women compared to non-delivering women.

Conclusions: While pregnancy on hemodialysis is associated with significant risk of preeclampsia and preterm delivery, delivery on hemodialysis was associated with a lower risk of subsequent mortality. Residual confounding may explain superior survival of delivering women vs. non-delivering women, however persistently lower transplant rates in delivering women warrant further research.

Funding: NIDDK Support



Unadjusted survival time (A) and time to transplant (B) of delivering and non-delivering women between 2002 and 2019.

Performance of Creatinine-Based GFR Estimating Equations in Young Adults

Lesley A. Inker. CKD-EPI and CKiD. *Tufts Medical Center, Boston, MA.*

Background: In the United States, GFR is estimated using serum creatinine and the 2021 CKD-EPI equation for individuals ≥ 18 years or the 2021 CKiD-U25 equation for those 1-25 years with CKD. These equations may result in different eGFR values at 18 years and older, leading to uncertainty in level of GFR.

Methods: We compared the CKD-EPI, CKiD-U25, and European Kidney Function Consortium (EKFC) equations in young adults (aged 18 to 40 years) in an independent dataset from which all three equations were developed (1491 participants from 21 studies). Performance compared to measured GFR was assessed as bias (median difference between mGFR and eGFR) and percentage of eGFR within 30% of mGFR (P_{30}).

Results: Mean (SD) age was 31.7 (6.0) years and mGFR was 92.7 (32.7) mL/min/1.73m². The equations provided similar estimates for participants with eGFR less than 60 mL/min/1.73 m². At eGFR ≥ 60, CKD-EPI yielded higher eGFR (Figure). For the CKD-EPI equation, there was minimal bias between mGFR and eGFR overall ([-0.5 (95%CI -1.5 to 0.7) mL/min/1.73m²], with small variation by GFR. In contrast, the CKiD-U25 equation moderately underestimated mGFR overall [7.2 (6.1, 8.3) mL/min/1.73m²], with larger bias at higher levels of eGFR. There was greater variation by age groups with CKiD-U25 than CKD-EPI, with larger bias at younger adult ages for CKiD (e.g. age 18-25 year, 12.0 (7.7, 15.5) for CKiD vs -3.3 (-5.0, 0.0) for CKD-EPI) vs older age (e.g. age 35-40, 4.8 (2.8, 6.7) for CKiD vs 1.0 (-0.3, 2.2) for CKD-EPI. Results for EKFC were similar to that of CKiD, with underestimation at higher levels of GFR and in the younger age group.

Conclusions: The results support use of the 2021 CKD-EPI equation for reporting of eGFR by clinical laboratories in individuals older than 18 years of age. For young adults with childhood CKD, our results support continuing use of the CKiD-U25 equation, during the transition to adult services, to maintain consistency of eGFR. Additional research in young adults to resolve differences observed at high levels of GFR and refine recommendations for use of eGFR equations is needed.

Funding: NIDDK Support

Discrepancy Between eGFR Cystatin C and eGFR Creatinine in Recently Hospitalized Adults

Yumeng Wen,[1] Danielle K. Farrington,[1] Heather Thiessen Philbrook,[1] Steven Menez,[1] Dennis G. Moledina,[2] Steven G. Coca,[3] Talat Alp Ikizler,[4] Alan S. Go,[5] Chi-yuan Hsu,[6] Jonathan Himmelfarb,[7] Vernon M. Chinchilli,[8] James S. Kaufman,[11] Paul L. Kimmel,[9] Amit X. Garg,[10] Morgan Grams,[11] Chirag R. Parikh.[1] *[1]Johns Hopkins Medicine, Baltimore, MD; [2]Yale School of Medicine, New Haven, CT; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Vanderbilt University Medical Center, Nashville, TN; [5]The Permanente Medical Group Inc, Oakland, CA; [6]University of California San Francisco, San Francisco, CA; [7]University of Washington, Seattle, WA; [8]Penn State College of Medicine, Hershey, PA; [9]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [10]London Health Sciences Centre, London, ON, Canada; [11]New York University Grossman School of Medicine, New York, NY.*

Background: Having a lower estimated glomerular filtration rate using cystatin C (eGFRcys) than creatinine (eGFRcr) is associated with a higher risk of cardiac disease and death in the outpatient setting. However, the distribution of this discrepancy and its prognostic values in recently hospitalized adults are not well described.

Methods: In 1534 hospitalized adults enrolled in the Assessment, Serial Evaluation, and Subsequent Sequelae of Acute Kidney Injury (ASSESS-AKI) cohort, we characterized the difference between eGFRcys and eGFRcr at 3 months after discharge. We used survival analysis to determine the associations between differences in eGFRcys and eGFRcr and risk of end-stage kidney disease (ESKD), major adverse cardiac events (MACE), first heart failure hospitalization, and death after a median follow up of 4.7 years.

Results: The mean age of study participants was 64.5 years, 37.3% are female, and 50% had AKI during hospitalization. At 3 months after hospitalization, eGFRcys was lower than eGFRcr by a large margin (Table). The difference between eGFRcys and eGFRcr at 3 months was 4.4% (2.4%- 6.5%) and 7.1% (3.8%- 10.5%) larger in those with AKI and sepsis during hospitalization, respectively. Having a lower in eGFRcys than eGFRcr was further associated with a higher risk of MACE, heart failure, ESKD, and death (Table), and these associations are consistent in participants with and without AKI (p for interaction with AKI all > 0.1).

Conclusions: By systematically measuring eGFRcys and eGFRcr in a cohort of recently hospitalized adults, we found that having lower eGFRcys than eGFRcr is commonly observed and provides additional prognostication for adverse clinical events.

SA-OR35

Comprehensive Evaluation of CKD Heat Map

Morgan Grams, Ron T. Gansevoort. CKD Prognosis Consortium. *CKD Prognosis Consortium, Baltimore, MD.*

Background: The 2012 KDIGO heat map framework for CKD analyzed five outcomes in 1.2 million participants. We comprehensively evaluated this framework using new equations for eGFR using creatinine alone and in combination with cystatin C (eGFRcr and eGFRcr-cys; CKD-EPI 2021 and EKFC) and more categories of albuminuria, assessing their individual and combined associations with ten adverse outcomes, overall and by age, sex, diabetes, and cardiovascular disease.

Methods: Individual-level data analysis: 27,503,140 participants from 114 global cohorts (eGFRcr); 720,736 participants from 20 cohorts (eGFRcr-cys). Outcomes: kidney failure with replacement therapy, all-cause mortality, cardiovascular mortality, acute kidney injury, hospitalization, coronary heart disease, stroke, heart failure, atrial fibrillation, and peripheral artery disease.

Results: Mean participant eGFRcr was 90 ml/min/1.73 m² (SD, 22) and median ACR was 11 mg/g (interquartile range 8-16 mg/g). Lower eGFRcr and higher ACR were associated with higher risk of all ten adverse outcomes, including in the mildest categories of CKD (eGFR 45-59 ml/min/1.73 m² and ACR <30 mg/g, or ACR 30-299 mg/g) and within subgroups. Associations were generally stronger and with less U-shape in the higher range of eGFR for eGFRcr-cys compared with eGFRcr.

Conclusions: This comprehensive evaluation of the heatmap framework in >27 million people demonstrated that the framework holds for associations with previous endpoints as well as novel kidney and cardiovascular endpoints; across subgroups of age, sex, diabetes, and cardiovascular disease; and for different GFR equations, including those incorporating cystatin C.

Hospital Health Care Costs Following Incident CKD in Japan, Sweden, and the United States

Navdeep Tangri,[1] Maria K. Svensson,[2] Tadashi Sofue,[3] Johan Bodegard,[4] Samuel Adamsson Eryd,[4] Marcus Thuresson,[5] Stefan Gustafsson.[6] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Uppsala Universitet, Uppsala, Sweden; [3]Kagawa Daigaku, Takamatsu, Japan; [4]AstraZeneca, Gothenburg, Sweden; [5]Statisticon AB, Uppsala, Sweden; [6]Sence Research AB, Uppsala, Sweden.*

Background: Chronic kidney disease (CKD) affects an estimated 10% of the global population. It is associated with cardiorenal complications (e.g. end stage kidney disease and heart failure [HF]), premature mortality, and high healthcare burden and costs. Here we assess hospital healthcare costs following incident CKD.

Methods: This study uses secondary data from electronic health records or claims data sources from Japan, Sweden and the US. Adult patients with incident CKD (defined as having either: two estimated glomerular filtration rate [eGFR] measurements ≥ 90 days apart of ≤ 60 mL/min/1.73 m² or an eGFR measurement ≤ 60 mL/min/1.73 m² followed by a CKD diagnosis) were identified during 2016–2023. Cumulative costs per patient for hospitalizations associated with a main diagnosis of HF, CKD, myocardial infarction (MI), stroke or peripheral artery disease (PAD) were summarized for up to 5 years after index (date of second eGFR measurement or CKD diagnosis).

Results: Overall, 549 884 patients were included (Japan, 74 285; Sweden, 76 133; US, 399 466). In Japan, Sweden and the US, respectively: median ages were 81, 78 and 74 years; 54%, 48% and 37% were males; and across countries the majority (68%) of patients did not have type 2 diabetes. Median eGFR measurements were similar across countries. Hospital healthcare costs associated with cardiorenal events (CKD and HF) were high (Figure). Atherosclerotic cardiovascular disease (MI, stroke and PAD) contributed less to hospital healthcare costs.

Conclusions: Hospital healthcare costs were high and largely driven by cardiorenal events (CKD and HF) among patients with incident CKD. This was consistent across all three countries, despite differences in healthcare systems.

Funding: Commercial Support - AstraZeneca

External Validation of the Klinrisk Model in US Commercial, Medicare Advantage, and Medicaid Populations

Navdeep Tangri,[1] Thomas W. Ferguson,[1] Ryan J. Bamforth,[1] Chia-Chen Teng,[2] Joseph L. Smith,[2] Maria Guzman,[2] Ashley Goss.[3] *[1]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [2]Carelon, Indianapolis, IN; [3]Boehringer Ingelheim International GmbH, Ingelheim, Germany*.

Background: Chronic kidney disease (CKD) is typically undiagnosed till the majority of kidney function (eGFR) is lost. Accurate risk prediction tools for progressive CKD can enable early intervention for high risk individuals. The Klinrisk machine learning model accurately predicts progressive CKD using routinely collected laboratory data. We aimed to validate this model in US commercial, Medicare Advantage, and Medicaid populations.

Methods: The Klinrisk random survival forest model predicts progressive CKD (40% decline in eGFR or kidney failure) using the values of age, sex, and 20 laboratory variables, including results from complete blood cell counts, chemistry panels, comprehensive metabolic panels, and urinalysis. We assessed model performance at 2- and 5- years post-index (first available serum creatinine result) in patients with/without urinalysis results (albumin-to-creatinine ratio, protein-to-creatinine-ratio, and semi-quantitative dipstick) in a large representative US population. Performance was assessed with discrimination (area under the receiver operating characteristic curve), Brier scores, and calibration plots.

Results: A total of 4,410,131 patients were evaluated with commercial insurance, 341,666 with Medicare Advantage, and 93,056 patients with Medicaid coverage. Discrimination was excellent across all forms of payor and with or without the results of urinalysis. In all cohorts, for prediction of the progression, AUCs ranged between 0.80 to 0.83 at 2 years, and 0.78-0.83 at 5 years. When urinalysis data were available, AUCs ranged between 0.81 to 0.87 at 2 years, and 0.80 to 0.87 at 5 years (Table). Brier scores were below 0.071 (0.068 to 0.075) for each combination of urinalysis availability and insurer type.

Conclusions: A machine model trained on routine laboratory data can predict progression of CKD in a large representative US population of adults with or at risk for kidney disease. Implementation of the Klinrisk model can help identify patients who benefit from early intervention to delay CKD progression and reduce health care costs.

The Effect of Thiazide Diuretics on Urinary Prostaglandin E2 Excretion and Serum Sodium in the General Population

Crissy F. Rudolphi, Frank Geurts, Anissa Pelouto, Anna C. van der Burgh, Pedro Henrique Imenez Silva, Mahdi Salih, Layal Chaker, Ewout J. Hoorn. Rotterdam Kidney Lab. *Erasmus MC, Rotterdam, Netherlands*.

Background: Recent data suggest that thiazide-induced hyponatremia (TIH) is induced by prostaglandin E2 (PGE2)-mediated water reabsorption and that people with a single nucleotide polymorphism (SNP) in SLCO2A1 are more susceptible for TIH. Here, we hypothesize that higher urinary PGE2 excretion is also associated with lower serum sodium in the general population and that this association is stronger in thiazide users.

Methods: PGE2 and its metabolite PGEM were measured in spot urines from the population-based Rotterdam Study cohort and expressed as ratio with creatinine. The association between PGE2 and serum sodium and its interaction with thiazide use was analyzed using regression analysis with adjustments for potential confounders (sex, age, BMI, baseline eGFR, smoking status, systolic blood pressure, ACE-inhibitor use). A propensity score-matched cohort was generated by matching on the same confounders in addition to serum potassium and diabetes status. The contribution of SNPs was analyzed using genome wide association studies (GWAS).

Results: 2178 patients were included in the analysis (65% female, age 64 ± 8 years). Thiazide users (n=190) had a significantly lower serum sodium compared to non-thiazide users (140.9 vs. 141.3 mmol/l, p=0.007) but had similar urinary PGE2 (101.7 vs. 101.5 pg/mmol, p=0.7) and PGEM (55.6 vs. 56.3 pg/mmol, p=0.6) excretions. Urinary PGE2 and PGEM excretions were negatively associated with serum sodium in the multivariable analysis (PGE2: p=0.002, PGEM: p<0.001) and this association was stronger in thiazide users (Figure 1). Similar findings were observed in the propensity score matched cohort. The GWAS data is currently being analyzed.

Conclusions: Urinary PGE2 and PGEM excretions are higher in people with lower serum sodium, and this association is stronger in thiazide users. Our findings provide further evidence for the role of PGE2 in renal water handling, even within the normal range of serum sodium, and its potential contribution to hyponatremia and TIH.

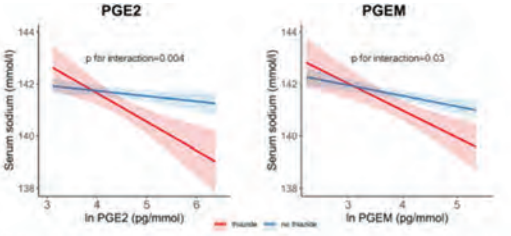

Figure 1. Multivariable analyses for the associations between urinary PGE2 / PGEM excretion and serum sodium. The association is stronger in thiazide users.

The Plasma Metabolome and Risk of Incident Kidney Stones

Pietro Manuel Ferraro,[1] Yukun Li,[3] Gary C. Curhan,[2] Eric N. Taylor.[2] *[1]Universita Cattolica del Sacro Cuore Facolta di Medicina e Chirurgia, Roma, Italy; [2]Brigham and Women's Hospital Channing Division of Network Medicine, Boston, MA; [3]University of Massachusetts Amherst, Amherst, MA.*

Background: The pathogenesis of kidney stone disease is not completely understood. Information on metabolomic profiles in kidney stone formers is limited, with most studies focusing on urine metabolomics or on pediatric populations using cross-sectional designs. To examine independent associations between plasma metabolomic profiles and the risk of incident, symptomatic kidney stones in adults, we conducted prospective nested case-control studies in two large cohorts.

Methods: We performed plasma metabolomics on 1,758 participants, including 879 stone formers (346 from the Health Professionals Follow-up [HPFS] cohort, 533 from the Nurses' Health Study [NHS] II cohort) and 879 non-stone formers (346 from HPFS, 533 from NHS II) matched for age, race, time of blood collection, fasting status and (for NHS II) menopausal status and luteal day of menstrual cycle for premenopausal participants. Conditional logistic regression models were used to estimate the odds ratio of kidney stones corresponding to a one standard deviation increase in metabolite levels, adjusted for confounders. A plasma metabolite based score reflecting risk of incident kidney stones was developed in each cohort in a conditional logistic regression model with a lasso penalty. The scores derived in the HPFS ('KMS_HPFS') and the NHS II ('KMS_NHS') were each tested for its association with kidney stone risk in the other cohort.

Results: In each cohort, a variety of individual metabolites were associated with incident kidney stone formation at prespecified levels of metabolome-wide statistical significance. We identified three novel metabolites associated with kidney stones in both HPFS and NHS II, all with inverse associations with kidney stones risk: beta-cryptoxanthin, sphingomyelin (d18:2/24:1, d18:1/24:2), and sphingomyelin (d18:2/24:2). The standardized KMS_HPFS yielded an OR for stones in the NHS II cohort of 1.23 (95% CI 1.05, 1.44; p-value = 0.008). The standardized KMS_NHS was in the expected direction but did not reach statistical significance in HPFS (OR 1.16, 95% CI 0.97, 1.39; p-value = 0.10).

Conclusions: The findings of specific metabolites associated with kidney stone status in two cohorts as well as a plasma metabolomic signature in stone formers offers a novel approach to characterize stone formers and to elucidate the pathogenesis of stone formation with the future potential to personalize therapeutic approaches.

Dietary Potassium and Potassium Supplementation Differentially Affect Plasma Potassium in Patients with CKD

Martin Gritter, Wesley Visser. *Erasmus MC, Rotterdam, Netherlands.*

Background: Guidelines advise increased potassium (K^+) intake to prevent hypertension and cardiovascular disease, but whether patients with chronic kidney disease (CKD) can safely increase K^+ intake is unknown.

Methods: We performed a systematic review and meta-analyses of intervention studies that assessed the acute or short- to long-term effects of increased K^+ intake on plasma K^+ in patients with CKD. Studies were eligible if they studied the effects of specified amounts of dietary K^+, K^+ supplementation, or K^+-enriched salt substitution in patients with CKD and provided plasma K^+ at baseline and end of study (for pre-post intervention studies) or at end of study in control and intervention groups (for randomized trials).

Results: Fourteen eligible studies were identified (2 randomized, 12 pre-post intervention studies). K^+ supplementation for five days to two years increased plasma K^+ by on average 0.7 (95% confidence interval, 0.2-1.1) mmol/L and caused hyperkalemia in 4-33% (3 studies, 370 participants). In contrast, increased dietary K^+ intake for two weeks to three years did not significantly increase plasma K^+ (7 studies, 275 participants). One study reported two hyperkalemia occurrences on the high K^+ diet, another study reported lower hyperkalemia incidence on the high K^+ than on the low K^+ diet, and five studies reported that no hyperkalemia occurred. These results suggest that increased dietary K^+ intake may be safer than K^+ supplementation (**Table**). However, they do not rule-out the risk of postprandial hyperkalemia, i.e. hyperkalemia occurring after a K^+-rich meal. Unfortunately, no studies assessed the acute effects of a K^+-rich meal on plasma K^+ in CKD. Acute K^+ supplementation increased plasma K^+ by 1.2 (95% confidence interval, 0.9-1.6) mmol/L (4 studies, 35 participants). We found no studies that assessed the safety of K^+-enriched salt substitution in CKD.

Conclusions: In the short- to long-term, K^+ supplementation increases plasma K^+ and the risk of hyperkalemia, although the majority maintains normokalemia. Conversely, increased dietary K^+ intake does not increase plasma K^+ in the short- to long-term. Whether a K^+-rich meal causes postprandial hyperkalemia is unknown.

	K^+ supplementation	Dietary K^+	K^+-enriched salt
Short- to long-term effects on plasma K^+	+ 0.7 mmol/L	No change	?
Acute effects on plasma K^+	+ 1.2 mmol/L	?	?

HARMONIZE ASIA: A Phase 3 Study to Investigate the Safety and Efficacy of Sodium Zirconium Cyclosilicate in Patients with Hyperkalemia in China

June Zhao,[1] Xueqing Yu,[2] Xinling Liang,[2] Wanhong Lu,[3] Hong Cheng,[4] Qiang He,[5] Qingfeng Peng,[6] Zhaohui Ni,[7] Gang Long,[8] Lihua Wang,[9] Gang Xu,[10] Wei Chen,[11] Yong Zhang,[12] Vera Lisovskaja,[13] Zhiji Tang.[12] HARMONIZE ASIA Study Group. *[1]BioPharmaceuticals Medical, AstraZeneca, Gaithersburg, MD; [2]Department of Nephrology, Guangdong Provincial People's Hospital (Guangdong Academy of Medical Sciences), Southern Medical University, Guangzhou, China; [3]The First Affiliated Hospital of Xi'an Jiaotong University, Xian, China; [4]Anzhen Hospital, Capital University of Medical Science, Beijing, China; [5]Sichuan Provincial People's Hospital, Chengdu, China; [6]Zhuzhou Central Hospital, Zhuzhou, China; [7]Renji Hospital Affiliated to Shanghai Jiaotong University, Shanghai, China; [8]Tianjin People's Hospital, Tianjin, China; [9]The Second Hospital of Shanxi Medical University, Taiyuan, China; [10]Tongji Hospital Affiliated to Hua Zhong Technology University, Wuhan, China; [11]The First Affiliated Hospital Of Sun Yat-Sen University, Guangdong, China; [12]AstraZeneca R&D, Shanghai, China; [13]Department of Biostatistics, Research and Development, AstraZeneca, Gothenburg, Sweden.*

Background: Sodium zirconium cyclosilicate (SZC) is an oral potassium (K^+)-lowering therapy for adults with hyperkalemia (HK). HARMONIZE Asia (NCT03528681) evaluated SZC safety and efficacy in patients (pts) with HK in China.

Methods: This Phase 3, randomized, double-blind, placebo (PBO)-controlled study recruited pts with serum K^+ (sK^+) ≥5.1 mmol/L at 35 sites in China. Pts received SZC 10 g three times daily for 24 or 48 hours in an open-label phase (OLP). Those achieving normokalemia (sK^+ 3.5–5.0 mmol/L) entered a 28-day randomized treatment phase (RTP), randomized 2:2:1 to receive SZC 5 g, SZC 10 g, or PBO once daily. The primary endpoint measured mean sK^+ level during RTP days 8–29. Secondary endpoints included mean change in sK^+ level during the OLP, proportion of pts achieving/maintaining normokalemia during the RTP, and time to recurrence of HK.

Results: In total, 270 pts received SZC during the OLP and 256 (94.8%) completed the OLP. The mean eGFR was 17.9 mL/min/1.73m^2. During the OLP, mean sK^+ decreased by 1.11 mmol/L from baseline (5.85 mmol/L; P<0.001) and 87.4% of pts achieved normokalemia. During the RTP, SZC 5 g and 10 g (both P<0.001) reduced mean sK^+ vs. PBO in a dose-dependent manner; least-squares means (95% confidence interval [CI]) sK^+ were 4.86 mmol/L (4.71, 5.01), 4.44 mmol/L (4.30, 4.58), and 5.23 mmol/L (5.06, 5.40), for SZC 5 g, 10 g, and PBO, respectively. At RTP end, 58.8%, 76.5%, and 36.8% of pts maintained normokalemia with SZC 5 g, 10 g, and PBO, respectively. Pts were more likely to maintain normokalemia with SZC 5 g and 10 g vs. PBO (odds ratios: 2.54, 95% CI 1.07, 6.05; P=0.035 and 6.25, 95% CI 2.56, 15.27; P<0.001). Risk of recurrent HK was reduced by 61.0% and 84.0% with SZC 5 g and 10 g (both P<0.001), vs. PBO, respectively. AE incidence during the RTP was higher with SZC 5 g (50.0% of pts) and 10 g (44.0%) vs. PBO (36.0%). The incidence of constipation was higher in the SZC 5 g (7.0%) and 10 g (5.0%) groups compared to the placebo group (0).

Conclusions: Both SZC doses were statistically significant to PBO for all confirmatory sK^+ analyses, with dose-dependency observed during the RTP. The safety profile of SZC was generally consistent with previous studies.

Effect of Protein Supplementation on Plasma Sodium Levels and Urinary Urea Excretion in Patients with Chronic Syndrome of Inappropriate Antidiuresis (SIAD): A Monocentric Open-Label Proof-of-Concept Study

Sophie Monnerat,[1,2] Cihan Atila,[1,2] Fabienne Baur,[1,2] Joyce Santos de Jesus,[1] Julie Refardt,[1] Michael Dickenmann,[3] Mirjam Christ-Crain.[1,2] Clinical Neuroendocrinology. *[1]Department of Endocrinology, Diabetology and Metabolism, University Hospital Basel, Basel, Switzerland; [2]Department of Clinical Research, University of Basel, Basel, Switzerland; [3]Clinic for Transplantation Immunology and Nephrology, University Hospital Basel, Basel, Switzerland.*

Background: The syndrome of inappropriate antidiuresis (SIAD) can be treated with oral urea. We hypothesized that dietary proteins could increase free-water clearance through urea-induced osmotic diuresis and aimed to investigate the effect of a high-protein supplementation on plasma sodium levels in chronic SIAD.

Methods: This is a monocentric open-label proof-of-concept trial conducted at the University Hospital of Basel, Switzerland, between 10/2021 and 02/2023. Adult outpatients with chronic SIAD received 90 g protein daily for 7 days in the form of protein powder. After a wash-out period of at least a week, patients received 30 g of oral urea daily for 7 days. The primary endpoint was the increase in sodium levels from baseline to the end of the 7-day protein supplementation.

Results: Seventeen patients were included (14 females, median age 68 [61, 79]). After 7 days of 90 g daily protein supplementation (n = 17), plasma sodium levels increased by a median of 3 mmol/l [0, 5], plasma urea by 3 mmol/l [1.7, 4.9] and urinary urea corrected for urine creatinine by 21.2 mmol/mmol [6.2, 29.1]. After 7 days of oral urea (n = 10), sodium levels increased by a median of 2 mmol/l [1, 3], plasma urea by 5.8 mmol/l [2.7, 9.2] and urinary urea corrected for urine creatinine by 31.0 mmol/mmol [18.7, 45.1].

Conclusions: Our findings suggest that a high-protein supplementation with protein powder increases plasma sodium levels in patients with chronic SIAD through protein-induced ureagenesis and osmotic diuresis. The effects are comparable to oral urea intake.

Safety and Efficacy of Proactive vs. Reactive Administration of DDAVP in Severe Symptomatic Hyponatremia: A Randomized Controlled Trial

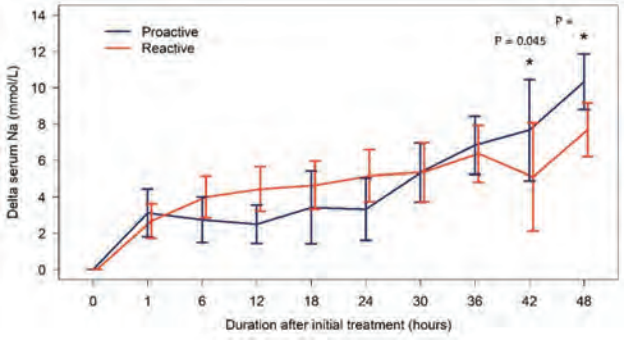
Nichanone Kanjanasuphak, Anan Chuasuwan, Pongsathorn Gojaseni, Anutra Chittinandana, Kamolwan Pakchotanon. *Division of Nephrology, Department of Medicine, Bhumibol Adulyadej Hospital, Royal Thai Air Force, Sai Mai, Thailand.*

Background: DDAVP is effective in preventing and reversing overcorrection of hyponatremia. However, the recommended strategy for its use remains unclear and is based on retrospective data. This study aims to compare the safety and efficacy of proactive and reactive DDAVP strategies in severe symptomatic hyponatremia.

Methods: This randomized controlled trial included patients with severe symptomatic hyponatremia (serum sodium < 125 mmol/L) from June 20, 2022, to February 20, 2023. Patients were assigned to either the proactive group, which received DDAVP immediately after diagnosis, or the reactive group, which received DDAVP only if the serum sodium level tended to overcorrect. The primary outcome was the incidence of overcorrection between the two groups.

Results: The study enrolled 49 patients, with 24 in the proactive group and 25 in the reactive group. There was no significant difference in the incidence of overcorrection between the two groups (16.7% vs. 28%, P = 0.54), nor in the change of serum sodium levels at 1, 6, 12, and 24 hours. However, at 48 hours, the proactive group had a higher change in serum sodium levels than the reactive group (10.3 ± 3.6 vs. 7.7 ± 3.6, P = 0.013), but it remained within the safety range. The time to symptom improvement, total amount of intravenous fluid administered, dose of DDAVP, urine volume, length of hospital stay, incidence of ODS, and 28-day mortality did not differ significantly between the two groups.

Conclusions: This study found no significant difference in the incidence of overcorrection between the proactive and reactive strategies for treating severe symptomatic hyponatremia. However, future large studies are needed.



Primary outcome.

Variables	Proactive strategy (n=24)	Reactive strategy (n=25)	P – value
Overcorrection	4 (16.7)	7 (28)	0.543

Monitoring Serum Potassium Concentration in Patients with Severe Hyperkalemia: The Role of Bloodless Artificial Intelligence (AI)-Assisted Electrocardiography

Chien-Chou Chen, Chih-Chien Sung, Yu-Juei Hsu, Shih-Hua P. Lin. *Tri-Service General Hospital Department of Internal Medicine, Taipei, Taiwan.*

Background: Severe hyperkalemia is a potentially life-threatening emergency requiring prompt recognition with rapid management and surveillance. Although bloodless artificial intelligence (AI)-enabled electrocardiography (ECG) provides real-time detection of severe hyperkalemia, its application to monitor blood potassium (K^+) levels during management has not been evaluated. This study aimed to determine the value of AI-enabled ECG (AI-ECG) for blood K^+ monitoring in patients with severe hyperkalemia.

Methods: This retrospective cohort study was performed at an emergency department (ED) of a single academic medical center over 2.5 years. Patients with true severe hyperkalemia defined as Lab-K^+ ≥ 6.5 mmol/L with matched AI-ECG K^+ ≥ 5.1 mmol/L were included. AI-ECG K^+ was quantified by ECG12Net as developed previously. The following ECG K^+ and Lab-K^+ were measured almost simultaneously during or after K^+-lowering therapy at least 2 times. Clinical characteristics, therapeutic intervention, and pertinent laboratory data were analyzed.

Results: Seventy-eight patients fulfilled the enrolled criteria. Most of them had acute on chronic kidney injury, advanced CKD not yet on dialysis, and dialysis-dependent renal failure. Their initial Lab-K^+ and AI-ECG K^+ were 7.2 ± 0.7 and 6.6 ± 0.5 mmol/L, respectively. During and after K^+-lowering therapy, both Lab-K^+ and ECG-K^+ were significantly declined in parallel in the patients both treated medically (n=37) and with hemodialysis group (n=41). Of note, six patients showing persistent ECG-K^+ hyperkalemia despite the normalized Lab-K^+ levels.

Conclusions: Point-of-care AI-ECG K^+ may provide an effective monitoring of blood K^+ changes for severe hyperkalemia and also reveal the pseudo-positive patients with the underlying cardiac structure changes or disorders.

The ΔAG/ΔHCO3 Ratio in Lactic Acidosis: Time for a New Baseline?

Deborah D. Lu,[1] Richard M. Treger,[1,2] Hubert Song.[3] *[1]Department of Nephrology and Hypertension, Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [2]Kaiser Permanente Bernard J. Tyson School of Medicine, Pasadena, CA; [3]Kaiser Permanente Department of Research and Evaluation, Pasadena, CA.*

Background: The ratio of Δanion gap and Δbicarbonate ($\Delta AG/\Delta HCO_3$) is used to detect co-existing acid-base disorders in patients with high anion gap (AG) metabolic acidosis. Prior studies demonstrating that in lactic acidosis (LA) the $\Delta AG/\Delta HCO_3$ is approximately 1.6-1.8:1 used mean normal values for anion gap and serum HCO_3. This study is the first to examine the $\Delta AG/\Delta HCO_3$ using each patient's individual baseline AG and serum HCO_3.

Methods: This was a retrospective cohort study of adult Kaiser Permanente Southern California (KPSC) health system members admitted to the ICU with sepsis. Baseline AG and albumin measurements were obtained 1-24 months prior to ICU admission. An albumin-corrected $\Delta AG/\Delta HCO_3$ ratio was calculated using each patient's individual baseline AG and serum HCO_3. The association between ΔHCO3 and ΔAG was examined using Pearson correlation, a linear regression model was constructed, and 95% prediction limits were computed.

Results: 293 patients were included. $\Delta AG/\Delta HCO_3$ was calculated for 177 patients who had elevated serum lactate levels (≥1.9 mM). The mean $\Delta AG/\Delta HCO_3$ for all patients with elevated serum lactate levels was 1.44 (SD 1.89). The correlation between ΔHCO_3 and ΔAG with 95% prediction limits is shown in Figure 1.

Conclusions: The mean $\Delta AG/\Delta HCO_3$ was 1.44. To our knowledge, this is the first study to determine the $\Delta AG/\Delta HCO_3$ using each patient's individual baseline AG and serum HCO_3. This has important clinical implications given the wide interindividual variability in AG and HCO_3. Regardless, even using the baseline AG and serum HCO_3 to calculate the $\Delta AG/\Delta HCO_3$, the wide 95% prediction limits (Figure 1) suggest that $\Delta AG/\Delta HCO_3$ should be used cautiously in the diagnosis of mixed acid-base disorders.

Funding: Commercial Support - The research is supported by a grant from the Regional Research Committee of Kaiser Permanente. Grant No. KP-RRC-20210504.

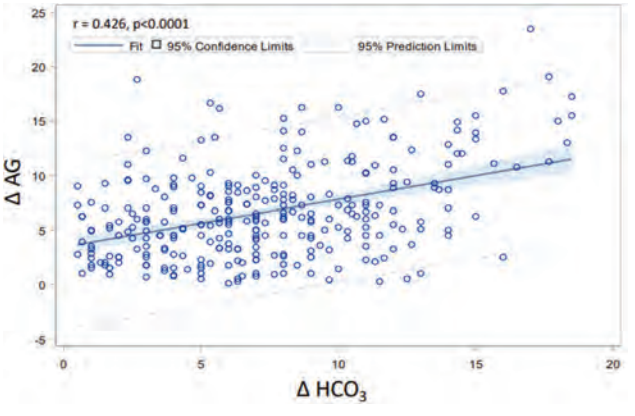

Figure 1: Correlation between ΔHCO_3 and ΔAG

Arterial pCO2 and Arterial pH from Venous Blood Gas Concurrent Measurements from 7470 Samples: An Easy Conversion of Venous to Arterial Blood by Formula

Gabriela P. Araujo, Mohammed Z. Rehman, Carlos A. Rueda Mantilla, Robert M. Rosa, Daniel Batlle. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Venous blood gas sampling to estimate blood pH and pCO2 has become standard medical practice with limited scientific data to avoid the cumbersome performance of arterial sampling. Efforts to estimate arterial pCO2 from venous blood and, in particular, blood pH from venous pH suffer from the limitation of observations made in relatively small databases (at the most hundreds of patients) and it is not always clear that the measurements were done simultaneously. We reasoned that existing estimations of arterial pH and pCO2 from venous blood could be improved using contemporary data extracted from a large database available from the electronic medical record.

Methods: We used de-identified data on venous and arterial blood gas measurements from Northwestern Medicine over 7 years (2016-2023). We extracted data from de-identified subjects with a total of 7470 samples where it was verified that the sampling for venous and arterial blood gas performed at the same time and by the same blood gas

laboratory. The data was provided by an independent observer and verified that the times of sampling coincided with each other.

Results: From the 7470 samples, the relationship between arterial and venous pCO2 was strong (r= 0.845) and as expected, the venous pCO2 was higher than arterial pCO2 (see dotted line vs. line of identity in red, Fig. left panel). The correlation between the venous pH and arterial pH in the same 7470 samples was also very strong (r = 0.9) and as anticipated the venous pH was lower than the corresponding arterial pH and therefore most of the pH points are below the line of identity (Fig. right panel).

Conclusions: The correlations between venous and arterial pH and pCO2 in a database unique because of the large sample size and concurrent measurements in venous and arterial blood show that estimations of each one of the two acid-base parameters can be reasonably made with formulas derived from the correlations here reported that will be incorporated in an App that should be available at the time of the ASN 2023 meeting.

Minimizing Hypoglycemia After Intravenous Insulin Regular Therapy for Hyperkalemia

Daniel L. Landry, Emily Duff, Erin Naglack. *Baystate Medical Center, Springfield, MA*.

Background: Intravenous (IV) insulin regular is utilized for the management of hyperkalemia. There is data demonstrating that weight-based (0.1 unit/kg) insulin results in less hypoglycemia while maintaining equivalent efficacy. The objective of this project was to evaluate if weight-based IV insulin regular dosing would minimize rates of hypoglycemia at our institution.

Methods: This single-center, pre-post design project included adult patients with hyperkalemia (potassium > 5 mEq/L) treated with IV insulin regular in the emergency department at a large tertiary care medical center. Historical management utilized fixed-dose 10 units of insulin regular (pre-intervention group). Exclusion criteria were patients who received insulin products for indications other than hyperkalemia, treated with hemodialysis, or received continuous dextrose fluids. The hyperkalemia order set was updated to 0.1 unit/kg IV insulin regular (maximum 10 units) and expanded point-of-care (POC) glucose monitoring from one hour to a total of four hours (post-intervention group). The primary outcomes were rates of hypoglycemia (blood glucose < 70 mg/dL) and severe hypoglycemia (blood glucose < 50 mg/dL). Secondary outcomes were reduction in potassium levels, administration of additional potassium lowering agents, and compliance to weight-based dosing and expanded POC monitoring.

Results: A total of 68 patients were included in the pre-intervention group and 58 patients in the post-intervention group. Hypoglycemia was more frequent in the pre-intervention group compared to the post-intervention group (26.5% versus 17.2%). Similar results were seen with severe hypoglycemia (7.3% versus 1.7%). The median reduction in potassium levels in the pre-intervention group was 0.95 mEq/L and 0.85 mEq/L in the post-intervention group. For patients who received insulin regular only and with no concomitant potassium lowering agent, the median reduction in potassium in the pre-intervention group was 0.7 mEq/L (IQR 0.5-1.55) compared to 0.85 mEq/L (0.35-1.33). There was 36.2% compliance with weight-based insulin regular dosing and 0% compliance with the extended POC monitoring schedule in the post-intervention group.

Conclusions: This project found that using weight-based insulin regular dosing may lead to a reduction in hypoglycemia, especially severe hypoglycemia, without needing additional potassium lowering agents.

Role of Midodrine in Prevention of Intradialytic Hypotension: A Randomized Cross-Over Controlled Trial

Pajaree Krisanapan,[1] Rattiporn Techakajornkeart,[1,2] Sithichai Kunawathanakul,[1,2] Pichaya Tantiyavarong,[2] Thanee Eiamsitrakoon,[3,4] Opas Traitanon,[2] Pattharawin Pattharanitima.[2] *[1]Thammasat University Hospital, Khlong Nueng, Thailand; [2]Thammasat University Faculty of Medicine, Khlong Nueng, Thailand; [3]Thammasat University, Bangkok, Thailand; [4]Chulabhorn International College of Medicine, Khlong Luang, Thailand.*

Background: Intradialytic hypotension (IDH) is one of the most common complications in hemodialysis (HD) patients. It is associated with reduced quality of life as well as an increased risk of myocardial infarction and mortality. Although midodrine, an α-1 adrenergic receptor agonist, has been proposed as a potential benefit in the prevention of IDH and has demonstrated efficacy in some studies, its long-term use with normal dialysate calcium has not yet been established.

Methods: This cross-over, placebo-controlled trial recruited adult patients who received thrice-weekly HD and had frequent IDH during the past 3 months. Participants were randomized to receive either oral 10-mg midodrine or placebo pills. The administration of the drugs took place 30 minutes prior to each dialysis session over a duration of 2 months (24 sessions) in each phase, with a one-week washout period between phases. All patients were prescribed a dialysate calcium concentration of 2.5 mEq/L. The trial protocol for this study was registered at thaiclinicaltrials.org (TCTR20211007003).

Results: In the midodrine treatment group, the incidence rate of IDH was significantly lower compared to the placebo group (8.5 vs. 16.0 events per 100 HD sessions, p = 0.004). Furthermore, the midodrine group demonstrated significantly reduced incidence rates of dizziness (7.7 vs 16.2 events per 100 HD sessions, p < 0.001) and headache (0 vs 1.3 events per 100 HD sessions, p = 0.04). However, there were no significant differences observed between the midodrine and placebo groups in terms of nadir systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), and heart rate (HR). Regarding safety, there were no significant differences in the incidence of adverse events between the two treatment groups.

Conclusions: Midodrine demonstrates safety and efficacy as a prophylactic intervention for IDH while also effectively mitigating symptoms of dizziness and headache in patients undergoing hemodialysis with a normal dialysate calcium concentration.

SA-OR49

Association of Calcium Channel Blocker Use with Intradialytic Hypotension

Armida lefranc Torres, Finnian R. McCausland. McCausland Lab. *Brigham and Women's Hospital, Boston, MA.*

Background: Calcium channel blockers (CCBs) are commonly used as anti-hypertensive agents among patients receiving maintenance hemodialysis (HD). Despite this, little is known regarding the association of CCBs with intra-dialytic hypotension (IDH), an important adverse outcome that is associated with cardiovascular morbidity and mortality.

Methods: Using detailed data from kinetic modeling sessions of the Hemodialysis Study, random-effects regression models were fit to assess the association of CCB use versus not with IDH (defined as systolic blood pressure (SBP) <90 mm Hg if pre-HD SBP <160 mm Hg or <100 mm Hg if pre-HD SBP ≥160mm Hg. Models were adjusted for age, sex, race, Kt/V assignment, flux assignment, heart failure, ischemic heart disease, peripheral vascular disease, diabetes mellitus, BUN, ultrafiltration rate, access type (catheter, fistula, graft), pre-HD SBP, and other anti-hypertensive use.

Results: Data was available for 1,838 patients and 64,538 sessions; at baseline 49% of patients were prescribed CCBs. The overall frequency of IDH was 14% with a mean decline from pre- to nadir-SBP of 33 ±15 mmHg. CCB use was associated with a lower adjusted odds of IDH, compared with no use (OR 0.81; 95%CI 0.75, 0.87). The association was most pronounced for those with (OR 0.77; 95%CI 0.69, 0.86) versus without (OR 0.87; 95%CI 0.78, 0.98) a history of HF at baseline (P-interaction=0.05).

Conclusions: Among patients receiving thrice-weekly HD in the Hemodialysis study, CCB use was associated with a lower risk of developing IDH, independent of pre-HD SBP and other anti-hypertensive use. Mechanistic studies are needed to better understand the effects of CCB and other anti-hypertensives on peri-dialytic blood pressure parameters among patients receiving maintenance HD.

Table 1. Baseline characteristics of participants according to CCB use

Association Between Ultrafiltration Rates and All-Cause Death in Patients Undergoing Extended-Hours Hemodialysis Using Time-Fixed and Time-Dependent Models: The LIBERTY Cohort

Takahiro Imaizumi,[1] Masaki Okazaki,[2] Shoichi Maruyama.[1] *[1]Nagoya Daigaku, Nagoya, Japan; [2]University of California Irvine School of Medicine, Irvine, CA.*

Background: Overhydration or excessive fluid removal during dialysis sessions is a risk for congestive heart failure (CHF) and death for dialysis patients, as evidence shows that the ultrafiltration rate (UFR) was associated with CHF and all-cause death. Studies have shown that extended-hours hemodialysis (EHD, >18 hr/w) improves various dialysis-related parameters such as hemoglobin, phosphate, and left ventricular hypertrophy, as well as survival. Although EHD may prevent congestion, the appropriate range of UFR in patients undergoing EHD is unknown.

Methods: Using data from 636 patients undergoing EHD in the LIBeralized diet Extende-houRs hemodialysis TherapY (LIBERTY) cohort, we examined the association between UFR and all-cause death in time-fixed or time-dependent multivariable Cox models adjusted for dialysis conditions and laboratory data. UFR was calculated by fluid removal (mL) per hour divided by dry weight (kg) and averaged in a week (mL/h/kg). UFR and covariates at baseline (within 6 months from EHD initiation) were used in the time-fixed model, while, the mean values of UFR and covariates every 3 months in a time-updated manner were used in the time-dependent model.

Results: The mean age was 62 years and male participants comprised 65%. Median UFR was 7.0 mL/kg/h. The median time since starting dialysis was 1.8 [IQR, 0.1–5.6] years. During a median of 6.4 [IQR, 3.4–10.3] years, 230 patients died. Overall survival at 5 years from the baseline was 79% (95% CI, 76–83%). Baseline UFR was not associated with all-cause death (Log-rank test P=0.091, Figure A). In the multivariable-adjusted models, baseline UFR was not associated with the outcome, while low or high time-updated UFR was associated with the outcome (Figures B and C).

Conclusions: UFR at the start of EHD was not associated with all-cause mortality, while time-updated UFR <7 mL/kg/h, which may represent reduced dietary intake, was associated with short-term prognosis.

Impact of ESRD on Stroke Risk in Atrial Fibrillation Patients

Abdallah El Bizri, Ahmad Mustafa, John A. Afif, Fasih Sami Siddiqui, Chapman Wei, Shahkar Khan, Taqi A. Rizvi, Radu C. Grovu, Elie El-Charabaty, Mitchell Weinberg, Suzanne E. El Sayegh. *Staten Island University Hospital, Staten Island, NY.*

Background: Patients with end-stage renal disease (ESRD) are at higher risk of atrial fibrillation (Afib) due to multiple underlying factors. However, the impact of concomitant Afib and ESRD on stroke risk is now well established. The purpose of this study is to evaluate the impact of concomitant Afib and ESRD on stroke risk compared to individuals with Afib alone.

Methods: The national inpatient sample (NIS) database 2016-2018 was used to identify individuals with Afib uaing ICD-10 codes. Patients with age less than 18 or those with history of stroke were excluded. 1:1 propensity matching was used to match patients with ESRD to those without ESRD on different comorbidities. Univariate analysis pre- and post-match were performed. Binary logistic regression was performed after matching to assess whether ESRD was independently associated with stroke risk. A p-value of <0.05 was considered statistically significant.

Results: A total of 1,749,172 patients were included in the study with 89,741 being ESRD. ESRD patients were younger and had higher prevalence of baseline comorbidities except for COPD, CAD, and smoking. Oral anticoagulation use and aspirin use was less in ESRD patients. On univariate analysis, ESRD patients had significantly lower ischemic stroke (1.8% vs 2.9%), hemorrhagic stroke (0.3% vs 0.6%), transient ischemic attack (TIA) (0.4% vs 0.7%). However, mortality was higher in ESRD group (8.1% vs 4.8%). Post-match analysis showed that ESRD patients had significantly lower ischemic stroke [OR: 0.59], hemorrhagic stroke [OR: 0.37] and TIA [OR: 0.76] along with higher mortality [OR: 1.95].

Conclusions: Concomitant presence of Afib and ESRD was associated with a lower stoke rates compared to Afib alone. The platelet dysfunction associated with ESRD along with exposure to heparin during dialysis sessions might explain this decrease in stroke risk. Additional large-scale studies are necessary to validate our findings.

Post-match regression analysis of stroke, hemorrhagic stroke, TIA, and Mortality in ESRD vs No-ESRD patients

	OR	CI	P-value
Stroke	0.59	0.55-0.63	<0.001
Hemorrhagic Stroke	0.37	0.31-0.43	<0.001
TIA	0.76	0.65-0.88	<0.001
Mortality	1.95	1.87-2.04	<0.001

Use and Association of Rate Control and Anti-Arrhythmic Medications with Risk of Subsequent Stroke and Mortality Among Hemodialysis Patients with Atrial Fibrillation

Benjamin Lidgard,[1] Leila R. Zelnick,[1] Jaejin An,[2] Teresa N. Harrison,[2] Ming-Sum Lee,[3] Daniel E. Singer,[5] Alan S. Go,[4] Nisha Bansal.[1] *[1]University of Washington, Seattle, WA; [2]Kaiser Permanente Southern California Department of Research & Evaluation, Pasadena, CA; [3]Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [4]Kaiser Permanente Northern California, Oakland, CA; [5]Massachusetts General Hospital, Boston, MA.*

Background: Atrial fibrillation (AF) is highly prevalent amongst patients with kidney failure on maintenance dialysis and is associated with poor clinical outcomes. Treatment of AF in this population is particularly challenging, as associations of the core AF management strategies of antiarrhythmic and rate-control medications with clinical outcomes in dialysis patients are unknown.

Methods: We evaluated patients with kidney failure on maintenance dialysis and incident AF from Kaiser Permanente Northern and Southern California. We evaluated associations between time-updated use of rate-control medications alone, antiarrhythmic medications alone, use of both medications, and use of neither medication (referent group) with the composite outcome of ischemic stroke and all-cause mortality using Cox regression models, with adjustment for multiple covariates.

Results: Among a total of 2,100 patients, 44.0% were newly initiated on rate-control medications alone, 4.6% were on antiarrhythmic medications alone, 8.5% were on both, and 42.9% were on neither medication within 12 months of incident AF diagnosis. Over a median (IQR) follow-up of 1.66 (0.45, 3.39) years, we observed 1,406 composite events. Use of antiarrhythmic medications alone (adjusted HR 0.73, 95% CI 0.57-0.95), or both medications (adjusted HR 0.70, 95% CI 0.56-0.88) was associated with lower risk of ischemic stroke or death compared to neither medication use (**Table**). Use of rate-control medications alone was not associated with decreased risk for the composite outcome.

Conclusions: While the use of antiarrhythmic medications was low in AF patients on maintenance dialysis, antiarrhythmic medication use alone or with rate-control medications was associated with decreased risk of ischemic stroke or all-cause mortality. Future trials are needed to confirm the efficacy and safety of antiarrhythmic medications in dialysis patients.

Funding: NIDDK Support, Other NIH Support - NHLBI: R01 HL142834, Private Foundation Support

Table: Associations of time-updated rate and antiarrhythmic medication use with the composite of stroke and all-cause mortality by Cox regression

Ischemic stroke or all-cause mortality	N of events	Rate per 100 person-years	Unadjusted HR (95% CI)	Adjusted HR 1 (95% CI)	Adjusted HR 2 (95% CI)
Medication use status	1406	13.5 (12.8-14.2)			
Rate control only	621	15.0 (13.9-16.2)	0.93 (0.85-1.01)	0.93 (0.84-1.03)	0.94 (0.85-1.04)
Anti-arrhythmic only	58	6.7 (5.2-8.7)	0.71 (0.57-0.90)	0.70 (0.54-0.91)	0.73 (0.57-0.95)
Both	77	7.0 (5.6-8.7)	0.67 (0.54-0.83)	0.68 (0.54-0.85)	0.70 (0.56-0.88)
Neither	650	15.0 (13.9-16.2)	1.0 (Referent)	1.0 (Referent)	1.0 (Referent)

Model 1: Adjusted for age, gender, race and ethnicity, education, and income
Model 2: Adjusted for the components of Model 1 plus dialysis vintage, chronic liver disease, prior stroke, transient ischemic attack, peripheral vascular disease, heart failure, myocardial infarction, coronary artery bypass graft, percutaneous coronary intervention, valvular disease, hypertension, diabetes, systolic blood pressure, body mass index, and use of warfarin

Hemoglobin Stability in the ASCEND-TD Trial

Anjali Acharya,[1] Anjay Rastogi,[2] Vivekanand Jha,[3] Ajay K. Singh,[4] Amy M. Meadowcroft,[5] Purav R. Bhatt,[5] Angela R. Jones-Leone,[5] Jennifer Shannon.[5] *[1]Jacobi Medical Center, Bronx, NY; [2]University of California Los Angeles, Los Angeles, CA; [3]George Institute for Global Health, New Delhi, India; [4]Brigham and Women's Hospital and Harvard Medical School, Boston, MA; [5]GSK, Collegeville, PA.*

Background: Daprodustat (Dapro), a hypoxia-inducible factor–prolyl hydroxylase inhibitor (HIF-PHI), has been investigated as a treatment for anemia of chronic kidney disease (CKD) in the ASCEND program. Maintaining hemoglobin (Hb) levels in the target range per clinical guidelines for patients (pts) with CKD is complex. Primary efficacy results for dapro administered three times weekly (TIW) are reported (Coyne DW. *CJASN* 2022). Here we examine additional Hb stability data of Dapro dosed TIW.

Methods: ASCEND-TD (NCT03400033) was a randomized, double-blind, double-dummy, active comparator study evaluating the efficacy and safety of Dapro dosed over 52 weeks compared with epoetin alfa (EPO) in pts receiving hemodialysis. Various Hb stability measures were assessed in a pre-specified manner. Responders were defined as pts with mean Hb within the Hb analysis range (10–11.5 g/dL) during the evaluation period (EP, Weeks 28–52).

Results: 322/407 (79%) pts had evaluable Hb during the EP. The difference in response rate (dapro-EPO) was 0.1645 (95% CI [0.06, 0.27]) and demonstrated nominal superiority. Median time Hb was in the analysis range (% [interquartile range]) was higher in pts administered Dapro compared with pts administered EPO (70.83 [50.98; 91.07] and 61.76 [29.69; 85.19], respectively). The Hodges-Lehmann estimate of the median treatment difference (dapro-EPO) of 11.18% met non-inferiority. Dapro TIW was also nominally superior to EPO for percentage of time Hb was within the analysis range according to the van Elteren's test stratified by region (one-sided P=0.0034; **Table**). The proportion of pts with evaluable Hb <7.5 g/dL and ≥12 g/dL during the EP and the proportion of time Hb ≥12 g/dL during the EP was lower in pts administered Dapro compared with pts administered EPO.

Conclusions: In ASCEND-TD, Dapro TIW demonstrated a potential benefit in maintaining stable Hb compared with EPO. Further analysis is required to understand this effect and to provide conclusive evidence of better Hb stability for Dapro compared with EPO.

Funding: Commercial Support - The study and this analysis were funded by GSK.

Table. Analysis of % time Hb within the analysis range during the EP using evaluable Hb values

	Daprodustat (N=270)	EPO (N=137)
n † (%)	215 (80)	107 (78)
Median (%) time in range (10–11.5 g/dL)	70.83	61.76
Hodges–Lehmann estimate of treatment difference (daprodustat–EPO) (%)	11.18	
Hodges–Lehmann two-sided asymptotic 95% CI (%)	(2.83, 19.56)	
One-sided P-value ‡	0.0034	

† Participants who have at least two post-randomization evaluable Hb values on different days, where at least one evaluable Hb value is contained within the EP and another evaluable Hb value occurs within the range of the Week 16 visit through to the Week 52 visit, inclusive. ‡ Treatment group comparisons are based on van Elteren's test stratified by region. Depletion of Plasma Aromatic Amino Acids During Hemodialysis Is Associated with Fatigue

Subrata Debnath, Jose M. Garcia, Niklesh Akula, Kumar Sharma, Carlos Lorenzo. *The University of Texas Health Science Center at San Antonio, San Antonio, TX*.

Background: The etiology of fatigue in hemodialysis (HD) patients remains elusive. Aromatic amino acids (AAA – tryptophan, phenylalanine, and tyrosine), the precursors of neurotransmitters serotonin, dopamine, and norepinephrine, are implicated in the pathogenesis of fatigue. A significant amount of AAA is lost during a dialysis. We examined the association of changes in AAA during a dialysis session with fatigue.

Methods: 114 adult HD patients self-reported fatigue on a dialysis day using validated Brief Fatigue Inventory. Pre- and post-dialysis plasma AAA levels were measured by HPLC-mass spectrometry. Spearman correlation was used to assess the relationship between AAA levels and fatigue.

Results: Post-dialysis plasma levels of phenylalanine and tyrosine decreased significantly compared to the baseline pre-dialysis levels except for tryptophan ($p < 0.0001$, 0.04, and 0.62, respectively). None of the pre-dialysis plasma levels of amino acids were associated with fatigue ($p > 0.05$ for all correlations). Post-dialysis plasma levels of phenylalanine, tryptophan, and AAA correlated inversely with fatigue score ($p < 0.05$ for all correlations). The relative decline (post – pre/pre values) in phenylalanine, tyrosine, and AAA levels during dialysis was positively correlated with fatigue score ($p < 0.05$ for all correlations). Compared to the HD patients in the lowest tertile of fatigue score, those in the highest tertile had greater relative decline in plasma AAA levels between pre- and post-dialysis, p=0.045 (Figure).

Conclusions: Plasma AAA depletion during a dialysis session is associated with fatigue, suggesting possible neurotransmitters imbalance as a contributory factor. Future studies are warranted to explore the role of neurotransmitters to the pathogenesis of HD fatigue using functional MRI.

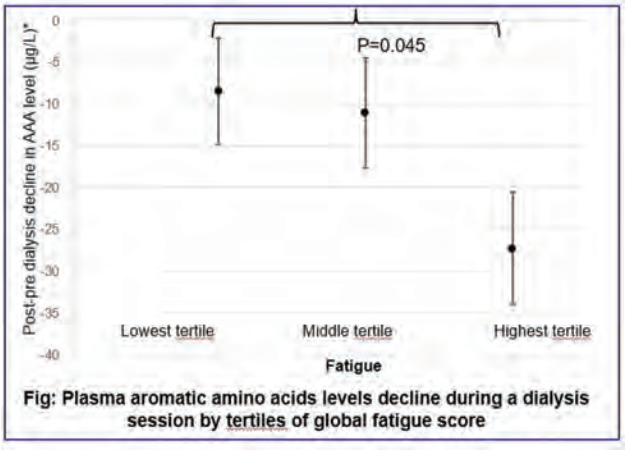

Fig: Plasma aromatic amino acids levels decline during a dialysis session by tertiles of global fatigue score

Association Between Circulating Extracellular Matrix (ECM)-Associated Molecules and Cardiovascular Outcomes in Hemodialysis Patients

Jihyun Baek,[1] Yu ho Lee,[1] So-young Lee,[1] Hyeyun Jeong,[1] Jin sug Kim,[2] Hyeon Seok Hwang.[2] *[1]CHA Bundang Medical Center, Seongnam, Gyeonggi-do, Republic of Korea; [2]Kyung Hee University, Seoul, Republic of Korea*.

Background: The extracellular matrix (ECM) is a complex network of non-cellular components that provide structural support for the tissues. Circulating ECM-associated molecules are increased during cardiovascular (CV) remodeling process and can be potential biomarkers of adverse CV outcomes. However, their clinical significance in hemodialysis patients is unclear.

Methods: A total of 372 hemodialysis patients were enrolled from a prospective multicenter cohort study. We measured four plasma ECM-associated proteins: matrix metalloproteinase (MMP)-2, MMP-9, tenascin-C, and thrombospondin-2. The primary outcome was set as a composite of cardiac and noncardiac vascular events.

Results: Plasma MMP-2 levels were significantly higher in patients with future CV events than in those without ($p = 0.004$), while the others were not. All the measured molecules had significant correlations with NT-proBNP levels, but the correlation coefficient was most strong with plasma MMP-2 (Rho = 0.317, $p < 0.001$). In logistic regression analysis, elevated plasma MMP-2 levels were independently associated with LV diastolic dysfunction (adjusted odds ratio [OR] per standard deviation, 1.48; 95% confidence interval [CI], 1.05 – 2.08; $p = 0.024$). Cox regression analysis showed that plasma MMP-2 levels were associated with a 1.30-fold risk for the composite of CV events (per a standard deviation increase; 95% CI, 1.04 – 1.63; $p = 0.022$) after multivariable adjustments

Conclusions: Plasma MMP-2 levels were independently associated with an increased risk of LV diastolic dysfunction and adverse CV outcomes in hemodialysis patients. Our results suggest that MMP-2 levels can be a useful biomarker in identifying hemodialysis patients at high risk of future CV events.

SA-OR56

Plasma Aβ42/Aβ40 Ratio as a Biomarker for Cognitive Impairment in Patients Undergoing Hemodialysis: A Multicenter Study

Xujiao Chen. *Fudan University Huashan Hospital Department of Nephrology, Shanghai, China*.

Background: Mild cognitive impairment (MCI) and dementia, are more prevalent in patients undergoing hemodialysis. Although the cerebrospinal fluid amyloid beta (Aβ) and tau have proven to be valid biomarkers for the diagnosis of Alzheimer's disease in the general population, the roles of plasma Aβ and tau for the diagnosis of cognitive impairment in patients undergoing hemodialysis remain unknown.

Methods: We conducted a cross-sectional study including patients receiving hemodialysis in three hospitals in Shanghai. All patients completed the Montreal Cognitive Assessment Basic (MoCA-B). To validate the effectiveness of MoCA-B score for screening MCI, a subset group underwent neuropsychological batteries. Serum proteomes were compared in patients with normal cognitive function and dementia undergoing HD. Plasma $A\beta_{42}$, $A\beta_{40}$, and total tau were measured using a single molecule array.

Results: A total of 311 patients undergoing hemodialysis were enrolled (mean age, 63 years; 55% male). The best cut-off score of MoCA-B for differentiating MCI and normal cognition was 24 with an area under the curve of 0.94. Serum proteomics revealed that neurodegenerative pathways related to Alzheimer's disease were enriched in patients with dementia undergoing hemodialysis. The plasma $A\beta_{42}/A\beta_{40}$ ratio was significantly reduced in patients with MCI and dementia. The plasma $A\beta_{42}/A\beta_{40}$ ratio was independently associated with cognitive function after adjusting for age, sex, and educational levels.

Conclusions: We validated the MoCA-B as an optimal cognitive function screening instrument for MCI in patients undergoing hemodialysis. The plasma $A\beta_{42}/A\beta_{40}$ ratio was a potential biomarker in distinguishing normal cognition, MCI, and dementia in populations undergoing hemodialysis.

Using Internal Pilot Data to Create a Dynamic Recruitment Strategy: Experience from the NightLife Trial

Katherine L. Hull,[1,2] Niamh Quann,[3] James Fotheringham,[5,6] Carmel Conefrey,[4] James Burton.[1,2] NightLife Study Investigators. *[1]University of Leicester College of Life Sciences, Leicester, United Kingdom; [2]University Hospitals of Leicester NHS Trust, Leicester, United Kingdom; [3]University of Leicester Clinical Trials Unit, Leicester, United Kingdom; [4]University of Bristol, Bristol, United Kingdom; [5]The University of Sheffield, Sheffield, United Kingdom; [6]Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, United Kingdom*.

Background: The NightLife study is a randomised controlled trial to evaluate the impact of in-centre nocturnal haemodialysis (INHD) compared to conventional haemodialysis on quality of life. At 12-months, an internal pilot review was completed to evaluate trial feasibility.

Methods: Recruitment and retention rates across sites were reviewed. The site set-up processes and associated timelines were mapped out. Findings were utilised to model the recruitment trajectory for the remaining 18-month study period.

Results: Eight dialysis units contributed to the internal pilot, achieving the 12-month site set-up target. Site set-up was completed in ≈14 months. Recruitment was below the 12-month target (30 participants randomised, 12-month target was 96). Participant retention was higher than expected; the crossover rate from intervention to control 3%, much below the anticipated 25%. Participating sites were categorised as *naïve* (require INHD service set-up) or *established* (existing INHD service). 63% of the recruited participants were obtained from a *naïve* site; recruitment occurred rapidly until INHD bed capacity was saturated. Recruitment from the *established* sites relied on natural flow of patients through the service (e.g. change in dialysis modality, transplantation), with a rate of ≈1 participant per month. Fifteen sites had expressed an interest to join the NightLife study; 14 were *naïve*. The recruitment trajectory was remodelled, demonstrating study feasibility (Figure 1).

Conclusions: Remodelling of NightLife study recruitment demonstrated it is non-linear with participants joining in a stepwise manner. This resulted in a shift in focus to assisting *naïve* sites in INHD service development. Understanding and modelling of bed capacity aids service design, alteration to dialysis regimens and research delivery.

Posoleucel Associated with Reduction of BK Viremia and Persistence of BK-Reactive T Cells in a Phase 2 Trial

Anil K. Chandraker,[1] Anil Regmi,[2] Reginald Y. Gohh,[3] Akhil Sharma,[4] E. Steve Woodle,[5] Mohammed Javeed Ansari,[6] Vinay Nair,[7] Ling-Xin Chen,[8] Tarek Alhamad,[9] Silas P. Norman,[10] Francesca Cardarelli,[11] Julie Ma,[11] Sarah Gilmore,[11] Spyridoula Vasileiou,[11,12] David Wojciechowski.[13] *[1]Brigham and Women's Hospital, Boston, MA; [2]Inova Transplant Center, Falls Church, VA; [3]Rhode Island Hospital, Providence, RI; [4]UPMC, Pittsburgh, PA; [5]University of Cincinnati, Cincinnati, OH; [6]Northwestern University, Evanston, IL; [7]Northwell Health, New Hyde Park, NY; [8]University of California Davis, Davis, CA; [9]Washington University in St Louis School of Medicine, St Louis, MO; [10]University of Michigan, Ann Arbor, MI; [11]AlloVir Inc, Waltham, MA; [12]Baylor College of Medicine, Houston, TX; [13]The University of Texas Southwestern Medical Center, Dallas, TX.*

Background: Kidney transplant recipients (KTRs) with BK virus infection are at risk of nephropathy & graft loss. Posoleucel (PSL) is an off-the-shelf allogeneic multivirus-specific T cell therapy targeting BKV.

Methods: In this phase 2 double-blind study (NCT04605484), KTRs with BK viremia were randomized 1:1:1 to receive PSL cells wkly for 3 wks then q14 (PSL1) or q28 d (PSL2), or placebo (PBO) for 12 wks. Patients (pts) were followed for 12 wks after treatment. Primary objective was safety; secondary was plasma BK viral load (VL) reduction.

Results: Baseline (BL) characteristics of 61 dosed pts were similar across groups. No deaths, GVHD, or cytokine release syndrome were seen. 3 pts in PSL groups had graft rejection but none deemed treatment-related: 1 pt had history of rejection, 1 had renal TB, and 1 had rejection 68 d after last PSL dose. eGFR was stable in all groups. Table shows VL changes in 52 pts with stable immunosuppression (IS) in the 30 d before randomization who completed study. Superior antiviral effects were seen in both PSL groups vs PBO. Greatest effect on BK VL was at wk 24 in PSL1 pts with BK VL ≥10,000 cp/mL at screening: 75% (6/8) had a ≥1 $\log_{10}$ cp/mL decrease from BL (median -1.4 log) vs 25% (1/4) of PBO (-0.4 log). At BL most pts with high BK VL had no BK-specific T cell immunity. Over the 6 months after PSL infusion, circulating frequency of BK-reactive T cells increased vs PBO, more so in PSL1 group, coincident with VL reduction. PSL presence & persistence were confirmed by TCRvβ deep sequencing, with higher levels in pts with high VL.

Conclusions: PSL was generally safe & well tolerated. Clinically meaningful BK VL reductions & increases in BK-reactive T cells were seen in PSL pts, particularly those with high VL who are at highest risk for renal impairment.

Results at Wk 24 in Patients with Stable IS* before Randomization

Endpoint	PSL1 N=20	PSL2 N=18†	PBO N=14‡
Pts w/ BK VL decreased by ≥1 log10 BKV DNA cp/mL vs BL, n (%)	10 (50)	5 (28)	2 (14)
BK VL reduction from BL, median log10 BKV DNA cp/mL (min, max)	-0.9 (-2.1, 0.1)	-0.45 (-1.8, 0.5)	-0.15 (-2.1, 0.3)
BK VL ≥50% reduction, n (%)	17 (85)	10 (56)	6 (43)

*<50% IS reduction within 30 (+/-2) d of randomization.

A Phase 1/2a Trial of Autologous Regulatory T Cell Therapy Together with Donor Bone Marrow Infusion in Kidney Transplantation

Rainer Oberbauer, Moritz Muckenhuber, Jasmin Mucha, Roman Reindl-Schwaighofer, Andreas Heinzel, Gabriela Berlakovich, Michael Wolzt, Thomas Lion, Nina Worel, Thomas Wekerle. *Medizinische Universitat Wien, Wien, Austria.*

Background: In preclinical models combining Treg therapy with donor bone marrow transplantation leads to mixed hematopoietic chimerism and tolerance without myelosuppressive recipient conditioning, avoiding the adverse effects of irradiation or cytotoxic drugs.

Methods: A single center, controlled, first-in-human phase I/IIa trial is conducted in HLA-mismatched living donor kidney transplant recipients. In vitro expanded polyclonal recipient Tregs and MNC-separated donor bone marrow cells are administered within 3 days after transplant, tocilizumab is injected s.c. for the first 3 weeks. No irradiation or cytotoxic drugs are given. Immunosuppression (IS) consists of thymoglobulin, belatacept, sirolimus and steroids. Starting at 6 months, sirolimus and steroids are gradually withdrawn in stable study group patients. A parallel control group receives the same IS, but no Tregs, bone marrow or tocilizumab. Total leukocyte donor chimerism and safety are co-primary endpoints. Immune monitoring accompanying the trial includes NGS of the TCR repertoire (of the recipient and Treg cell product), flow cytometric leukocyte subset analysis, scRNAseq and protocol biopsies (at 6, 12, 24, 36 and 60 months) including transcriptomic analysis.

Results: Ten patients have been enrolled and treated so far. One additional patient was enrolled but not treated as Treg manufacturing failed. Treg (1.1-1.5x10^7 cells/kg) and bone marrow cell (0.7-1.9x10^8 nucleated cells/kg) infusions were well tolerated. The study group developed low levels of total leukocyte donor chimerism (<1%) in the first weeks post-transplant, whereas no chimerism was detectable in the control group. The study group shows a favorable clinical course, with GFRs of 50-82 ml/min/1.72m2 at latest follow-up (median follow-up 23 months) and no safety signals were observed. IS reduction has been completed in three patients currently maintained on belatacept monotherapy q8 weeks and is in progress in all other patients. Protocol biopsies at 12 months were clear.

Conclusions: Combined Treg therapy and bone marrow transplantation is safe and feasible in living donor kidney transplantation and induces low-level chimerism.

Reduction of Renal Graft Fibrosis with Valganciclovir Prophylaxis for Cytomegalovirus Prevention Compared to Preemptive Therapy: Long-Term Outcomes of Randomized Controlled Trial (OVERT Study)

Tomas Reischig,[1,2] Tomas Vlas,[1,2] Petr Drenko,[1,2] Lukas Kielberger,[1,2] Pavlina Richtrova.[1,2] *[1]Faculty of Medicine in Pilsen, Charles University, Pilsen, Czechia; [2]Teaching Hospital, Pilsen, Czechia.*

Background: Prevention of cytomegalovirus (CMV) infection including CMV indirect effects is essential in kidney transplantation. The 12-month results of OVERT Study showed less subclinical rejection and a trend toward lower incidence of acute rejection in recipients receiving valganciclovir prophylaxis compared to preemptive therapy. Here we report long-term results of OVERT Study.

Methods: This was an open-label, single-center, randomized clinical trial of valganciclovir prophylaxis vs preemptive therapy in 140 kidney transplant recipients recruited between June 2013 and May 2018. CMV-seronegative recipients with negative donors (D-R-) were excluded. Patients were randomized 1:1 to receive either valganciclovir prophylaxis for 3 months (or 6 months in D+R-) (n=70) or preemptive valganciclovir for significant CMV DNAemia detected in predefined assessments through month 24 (n=70). The primary outcome was the incidence of moderate to severe interstitial fibrosis and tubular atrophy (IFTA) in protocol biopsy at 3 years. Key secondary outcomes included acute rejection, CMV disease and DNAemia, patient and graft survival.

Results: Among the 127 patients who had a protocol biopsy specimen available at 3 years, 5 (8%) of 66 patients in the prophylaxis group and 14 (23%) of 61 patients in the preemptive group had moderate to severe IFTA (P=0.015). At 3 years the incidence of acute rejection was lower with valganciclovir prophylaxis (13% vs 36%, P=0.052). In spite of 5 (7%) additional patients with CMV DNAemia after month 12 in the prophylaxis group in contrast to none in the preemptive group (P=0.025) the cumulative incidence at 2 years remained lower with prophylaxis (51% vs 75%, P<0.001). Both regimens prevented CMV disease (6% vs 4%, P=0.733). While the 4-year graft survival was comparable (96% vs 93%, P=0.460) patient survival was improved in the prophylaxis group (100% vs 94%, P=0.042).

Conclusions: Among kidney transplant recipients, the use of valganciclovir prophylaxis, compared with preemptive therapy, led to less severe IFTA at 3 years after transplantation.

Outcomes Associated with Sodium-Glucose Cotransporter-2 Inhibitors in Kidney Transplant Recipients: A Real-World Analysis Using a Global Federated Database

Nageen Anwar,[1] Elin Davies,[1,2] Mark A. Devonald,[1] Gregory Y. Lip,[2,3] Garry Mcdowell,[4,3] Anirudh Rao.[1,2] *[1]Liverpool University Hospitals NHS Foundation Trust, Liverpool, United Kingdom; [2]University of Liverpool Faculty of Health and Life Sciences, Liverpool, United Kingdom; [3]Liverpool Heart and Chest Hospital NHS Foundation Trust, Liverpool, United Kingdom; [4]Liverpool John Moores University, Liverpool, United Kingdom.*

Background: Several trials have shown the effectiveness of sodium-glucose cotransporter-2 inhibitors (SGLT2i) in cardiovascular events and its nephroprotective effects among patients with native kidney disease, but little is known about the safety and efficacy of SGLT2i in the kidney transplant setting. The study aimed to investigate the benefits of SGLT2i in kidney transplant recipients.

Methods: A retrospective cohort study was performed of adult renal transplant patients (≥ 18 years) using electronic medical records from a TriNetX database searched on 19th May 2023. Cohorts were grouped by receipt of SGLT2i and 1:1 propensity-score matched for demography (age, gender, & ethnicity), baseline co-morbidities (cardiovascular disease, diabetes mellitus & smoking status), laboratory data (estimated glomerular filtration rate & proteinuria) and immunosuppression. Logistical regression produced odds ratios with 95%CI for incident 3-year graft failure, rejection, major adverse cardiac events (MACE), all-cause mortality, and genitourinary infections. All statistical analyses were performed on the TriNetX online platform.

Results: The propensity score matching identified 3,450 patients (Mean age 59.4 SD± 11.9, 65% Male), each in the SGLT2i and non-SGLT2i treated renal transplant cohorts. The table shows the outcomes, odds ratio (OR), and 95% confidence interval (CI) for the SGLT2i and non-SGLT2i treated renal transplant patients 3 years post-index event.

Conclusions: Kidney transplant patients treated with SGLT2i demonstrated a significant reduction in graft failure, rejection, MACE, all-cause mortality, and genitourinary infections. These data call for a Randomized Control Trial to evaluate the long-term kidney and cardiovascular outcomes of SGLT2i therapy in the renal transplant setting.

Outcome	Cohorts	Number with outcome	Odds Ratio (OR)	95% CI	P-value
Kidney Transplant Failure	non- SGLT2i	346	-	-	-
	SGLT2i	82	0.25	0.20-0.32	< 0.0001
Kidney Transplant Rejection	non- SGLT2i	695	-	-	-
	SGLT2i	186	0.28	0.23-0.33	< 0.0001

Deceased Donor Kidney Function Is Determined by Branch Chained Amino Acid Metabolism During Ex Vivo Normothermic Perfusion

Armin Ahmadi, Jacquelyn M. Yu, Jennifer Loza, Brian C. Howard, Peter Than, Naeem Goussous, Junichiro Sageshima, Baback Roshanravan, Richard V. Perez. *University of California Davis, Davis, CA.*

Background: Current kidney perfusion protocols are not optimized for addressing ex vivo physiological and metabolic needs of the kidney. We studied kidney function parameters and their link with metabolic competence during a 12-hour ex vivo normothermic perfusion (EVNP).

Methods: Eight human kidneys from deceased donors deemed unsuitable for transplantation were preserved using 12 hours of EVNP during which markers of function and injury were monitored. Kidneys were grouped into good and poor performers based on their functional parameters. Metabolic profile from kidney cortex samples were obtained throughout the perfusion.

Results: The mean age of the deceased kidney donors was 43 ± 16 yrs with a mean cold ischemia time of 37 ± 12 hrs. Hemodynamics parameters such as urine output (mean=99.5 ml/hr) and creatinine clearance (mean=32.6 ml/min) progressively increased and peaked at 6 hours post perfusion among good performers (**Figure 1**). Urinary neutrophil gelatinase-associated lipocalin was also significantly different at 6 hours between the two groups (mean difference=85.8 ng/ml, *P*=0.02) (**Figure 1B**). Peak functional differences at 6 hours coincided with tissue accumulation of branch chain amino acids (BCAA) among poor performers compared to good performers (**Figure 2**).

Conclusions: We identified impaired BCAA metabolism at 6 hours of EVNP as the metabolic phenotype distinguishing poor and good performing kidneys. Future studies with larger sample sizes are needed to validate the association of impaired BCAA metabolism with kidney functional decline.

The Association Between V-Set Ig Domain-Containing 4 (VSIG4) Expression and Chronicity in Transplant Kidneys

Sang Youb Han,[1] Heungman Jun,[2] Han Seong Kim.[1] *[1]Inje University Ilsan Paik Hospital, Goyang, Republic of Korea; [2]Korea University Anam Hospital, Seoul, Republic of Korea.*

Background: A Banff-based chronicity index is asociated with graft outcomes in patients with a kidney transplant. Recent studies have highlighted the association of V-set Ig domain-containing 4 (VSIG4) with epithelial-mesenchymal transition in various diseases, including chronic kidney diseases. However, its role in kidney transplantation remains unclear. This study aimed to assess the significance of serum and urinary VSIG4 levels in kidney transplant patients who underwent biopsy.

Methods: A total of 44 patients (24 males, 20 females, average age 50.9 ± 12.8 years) were categorized into three groups based on their chronicity index (1-4, 5-8, and >9) as per the 2019 Banff classification. The chronicity index, with a maximum score of 15, represents the sum of scores for interstitial fibrosis, tubular atrophy, chronic vasculopathy, and chronic glomerulopathy. Serum and urinary VSIG4 levels were measured using ELISA, with urinary levels adjusted for urine creatinine levels.

Results: The mean serum creatinine was 1.92 ± 0.88 mg/dL, and eGFR was 41.2 ± 16.1 ml/min/1.73m^2. The mean number of HLA mismatches was 3.44 ± 1.40. The mean activity index and chronicity index were 2.07 ± 0.87 and 6.27 ± 2.34, respectively. Significant differences in both serum and urinary VSIG4 levels were observed among the three groups using the Kruskal-Wallis test: serum VSIG4 (ng/mL) - lower group median (IQR): 66.5 (59.1, 73.4); middle group: 69.6 (49.9, 133.1); higher group: 125.1 (116.8, 351.6), p = 0.019; urinary VSIG4 (ng/mgCr) - lower group : 3.66 (2.67, 4.29); middle group: 9.46 (4.99, 23.8); higher group: 17.8 (14.3, 26.9), p = 0.039. Spearman's rank test revealed positive correlations between serum VSIG4 levels and the total chronicity index (r = 0.391, p = 0.009), age (r = 0.377, p = 0.013), and BUN (r = 0.439, p = 0.003). Negative correlations were found with eGFR (-0.554, p < 0.001) and albumin (r = -0.469, p = 0.003). Urinary VSIG4 levels showed a negative correlation with eGFR (r = -0.367, p = 0.009). However, both serum and urinary VSIG4 levels did not differ significantly based on the total activity score.

Conclusions: This study concludes that serum and urinary VSIG4 levels are associated with chronic changes in patients with kidney transplantation. Given the relationship between the chronicity index and allograft loss, these levels may serve as markers for graft outcomes.

Overlapping Pathologic Findings in the Kidney Allograft Biopsy: Pitfalls for the Molecular Microscope Diagnostics System (MMDx)

Thomas Schachtner, Lukas Weidmann, Dusan Harmacek, Raphael Korach, Nicola Bortel, Kai C. López, Thomas F. Mueller. *UniversitatsSpital Zurich, Zurich, Switzerland.*

Background: The Molecular Microscope Diagnostic System (MMDx) has been suggested to add diagnostic value in cases suspicious of antibody-mediated (ABMR) and T cell-mediated rejection (TCMR). Other overlapping pathologies, however, have the potential to mimic molecular rejection.

Methods: In this single-center cohort of 326 indication kidney transplant biopsies assessed by histology and MMDx at the University Hospital Zurich, we analyzed 66 cases with overlapping pathologic findings by histology: 15 cases with pyelonephritis, 21 cases with BK nephropathy (BKVN), 5 cases with acute interstitial nephritis (AIN), and 28 cases with recurrent/de novo glomerulonephritis (GN).

Results: Pyelonephritis: 5 of 15 cases (33%) with pyelonephritis showed minor molecular findings (normal rejection score but abnormal ABMR and/or TCMR score or vice versa), which were diagnosed in only 18 of 260 (7%) cases without overlapping pathologies (p=0.004). 8 of 15 cases (53%) with pyelonephritis showed a TCMR phenotype score (R2) ≥0.10. BKVN: 4 of 21 cases (19%) with BKVN showed minor molecular findings, whereas 3 (14%), 3 (14%), and 6 (29%) of 21 cases showed ABMR, TCMR, and ABMR/TCMR, respectively. 11/21 cases (52%) with BKVN showed an all ABMR rejection phenotype score (sum of R4, R5, and R6) ≥0.20, none of which had proven ABMR by histology. AIN: 3 of 5 cases (60%) with AIN showed molecular TCMR, of which 2 cases showed mixed ABMR/TCMR in the absence of any antibody-mediated changes by histology. GN: 21 of 28 cases (75%) with GN showed no molecular ABMR/TCMR, whereas 2 of 28 cases (7%) showed minor molecular findings, and 5 of 28 cases (18%) showed ABMR. Surprisingly, 16 of 28 cases (57%) showed an all ABMR rejection phenotype score ≥0.20, and 8 of 28 cases (29%) showed a late-stage ABMR score ≥0.20.

Conclusions: Minor molecular findings should always suggest the presence of any overlapping pathology. Cases of pyelonephritis, BKVN, and AIN mostly mimic molecular rejection and might be misleading in their interpretation. Although GN does not show molecular rejection in most cases, the elevated ABMR scores suggest a GN-associated phenomenon.

The Impact of Subclinical T Cell-Mediated Rejection on Subsequent Rejections and Allograft Survival in Kidney Transplant Recipients: A Systematic Review and Meta-Analysis

Takayuki Yamada,[1] Shota Obata,[2] Arjun L. Kalaria,[1] Michele Molinari,[1] Rajil B. Mehta.[1] *[1]UPMC, Pittsburgh, PA; [2]Mount Sinai Beth Israel Hospital, New York, NY.*

Background: Subclinical T cell mediated rejection (SC-TCMR) refers to the presence of histological features of acute rejection on renal biopsy without a decline in renal function. Although single centers have reported an adverse impact of SC-TCMR on allograft outcomes, there is a dearth of data on this subject.

Methods: We conducted a comprehensive systematic search on PubMed, EMBASE, and the Cochrane Library from inception to May 16th, 2023. We included studies involving adult patients (>18 years old) who underwent kidney transplants and exhibited SC-TCMR detected through surveillance biopsy. Studies involving non-human subjects or lacking available data were excluded. The primary outcome measure was death-censored allograft loss, while the secondary outcome was subsequent rejection. A random-effects model was used to determine the risk.

Results: A total of nine studies were selected, encompassing a pooled population of 2,423 patients. SC-TCMR was found to be associated with an increased risk of death-censored graft loss (Risk ratio (RR) 1.78, 95% confidence interval (CI) 1.03 to 3.07), although heterogeneity was high (I2 69%). Furthermore, SC-TCMR was also associated with a higher risk of subsequent rejection (RR 2.66, 95% CI 1.96 to 3.61, I2 0%).

Conclusions: SC-TCMR diagnosed through surveillance biopsy was found to be linked with an elevated risk of subsequent rejection and death-censored graft loss.

Cell Subtypes and Cell-Specific Pathways Associated with Acute-to-Chronic Injury Transition in Posttransplant AKI

Enver Akalin,[1] Shafquat Azim,[2] Amol C. Shetty,[2] Thomas Rousselle,[2] Haseeb Zubair,[2] Valeria R. Mas.[2] *[1]Montefiore Medical Center, New York, NY; [2]University of Maryland School of Medicine, Baltimore, MD.*

Background: Kidney transplants (KT) offer a unique opportunity to evaluate molecular pathways involved in development and response to acute kidney injury (AKI). This study of transplanted kidneys with AKI aims to identify cells involved in injury or impaired reparation.

Methods: A total of 14 kidney samples (normal donor kidneys, n=5, normal allografts, n=4, and samples from patients with post-KT AKI, n=4 (<6weeks post-KT)) were evaluated using single nuclei (sn) RNA-seq.

Results: The analyses of 49,787 combined nuclei showed increased fibroblasts in post-KT AKI samples. Fibroblasts in post-KT AKI compared to normal allografts showed increased expression of genes enriched in extracellular matrix (ECM) organization, proteoglycans, ecollagen formation, and response to wounding. The analyses of these fibroblasts in 3 sex-mismatched cases using an XY-gene expression signature showed both donor- and recipient-derived fibroblasts (**Fig 1A**) not observed in normal allografts. Up-regulated genes in recipient fibroblasts were enriched in laminin interactions, ECM organization, and cellular response to TGF-β stimulus. Increased macrophages (MΦ) proportions in AKI samples, and 3 MΦ subsets were identified, including: MΦ1 (*MRC1, LGMN, STAB1*) and MΦ3 (*FCN1, LYN1, KYNU1, RTN11*), and the MΦ2 (*CSF3R, LUCAT1, NCF1, LIMK2*) (**Fig 1B-C**) characterized by markers of myofibroblasts/fibroblast-like (*COL18A1, COL4A3, COL4A4, VCAN, AB3BP, FGL2, GAS6, THSD4*). Resident and infiltrating MΦ present a pro-inflammatory profile and enriched in immunoregulatory response signaling pathways.

Conclusions: These novel data emphasize the critical role of resident MΦ in responding to injury transform into MΦ with fibroblast-like markers and a transcriptomic phenotype leading to impaired repair.

Funding: Other NIH Support - R01DK109581-01 and R01DK122682-01

Suitability to Donate and Attitude Toward Living Kidney Donation in Older Adults: Results from the BIS Study

Cédric Villain,[1,2] John S. Gill,[3] Nina Mielke,[1] Tim Bothe,[1] Muhammad Barghouth,[1] Anna Pöhlmann,[1] Anne-Katrin Fietz,[1] Natalie Ebert,[1] Elke Schaeffner.[1] *[1]Charité – Universitätsmedizin Berlin corporate member of Freie Universität Berlin and Humboldt Universität zu Berlin, Berlin, Germany; [2]Normandie Univ UNICAEN, CHU de Caen, Caen, France; [3]Division of Nephrology, St. Paul's Hospital, University of British Columbia, Vancouver, BC, Canada.*

Background: Guidelines differ regarding thresholds of glomerular filtration rate (GFR) and albuminuria (ACR) to accept living kidney donation (LKD). We aimed to assess the proportion of community-dwelling older adults suitable to LKD according to different GFR and ACR thresholds, and their attitude towards LKD.

Methods: We used data from the BIS-study, a cohort of adults aged ≥70 years. Kidney-related contraindications to LKD were defined using KDIGO (high and low GFR thresholds of 90 and 60ml/min/1.73m2 using the EKFC equation based on creatinine and cystatin C, respectively; LKD can be discussed between these thresholds) and British Transplantation Society (BTS; age- and sex-specific GFR thresholds) guidelines. The ACR thresholds were 30mg/g (low threshold for both guidelines), 100mg/g (high KDIGO threshold), and 300mg/g (high BTS threshold). Participants' attitude towards LKD was asked at the first follow-up visit.

Results: Among the 2069 participants (median age 80 years, 53% women, median estimated GFR 63ml/min/1.73m2), none had an estimated GFR above the high KDIGO GFR threshold at baseline. Considering the combination of other GFR and ACR thresholds, prevalence of renal contraindication to LKD ranged from 38 to 54%. Ninety-three percent of participants presented ≥1 non-kidney-related contraindication to LKD, among which heart failure, coronary artery disease, and cancer were the most frequent. Prevalence of suitability to LKD ranged from 0 to 6%, depending on combinations of thresholds of GFR and ACR. After an 8-year follow-up period, 11 to 16% of participants suitable to LKD at baseline maintained their suitability criteria, 6 to 11% had died, and none of them developed CKD stage 4-5. Overall, 73% of all participants agreed to donate a kidney to a relative, but this percentage rose to 85 to 87% in participants suitable to LKD.

Conclusions: Most older adults were theoretically willing to donate a kidney to a relative. Regardless of the low percentage of participants without any contraindication to LKD, their absolute sample size could be an opportunity to increase the number of kidney donors at the population level. To this purpose, the choice of GFR and ACR thresholds may be crucial.

The Association Between Potassium Intake and Risk of CKD

Hyo Jeong Kim,[1,2] Hee Byung Koh,[3] Tae ik Chang,[4] Connie Rhee,[5] Diana S. Kalantar,[5] Kamyar Kalantar-Zadeh,[5] Seung Hyeok Han.[2] *[1]Gangnam Severance Hospital, Seoul, Republic of Korea; [2]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea; [3]Catholic Kwandong University International Saint Mary's Hospital, Incheon, Republic of Korea; [4]National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea; [5]University of California Irvine School of Medicine, Irvine, CA.*

Background: High dietary potassium intake is associated with lower risk of cardiovascular disease. However, the association between potassium intake and chronic kidney disease (CKD) development in the general population is uncertain.

Methods: From UK biobank cohort, we included 317,162 participants without CKD between 2006-2010. The main predictor was spot urine potassium-to-creatinine ratio (KCR) as a surrogate of potassium intake. The primary outcome was incident CKD, defined by ICD-10 and OPCS-4 codes. In secondary analyses, we examined dietary potassium intake as an additional predictor in 141,180 participants who completed 24-h dietary recall questionnaires.

Results: At baseline, individuals with higher KCR had lower levels of blood pressure, BMI, and inflammation were less likely to have diabetes and hypertension vs. those with lower KCR. During a median follow-up of 11.9 years, the primary outcome occurred in 15,255 (4.8%) participants. In cause-specific models, the adjusted hazard ratio (aHR) per 1-SD increase in KCR for incident CKD was 0.90 (95% confidence interval [CI], 0.89-0.92). In addition, compared with quartile (Q)1 of KCR, the aHRs (95% CIs) for Q2, Q3, and Q4 were 0.98 (0.94–1.02), 0.90 (0.86–0.95), and 0.80 (0.76–0.84), respectively. In secondary analyses, higher potassium consumption was also inversely associated with risk of CKD. Compared with Q1 of dietary potassium intake, the corresponding aHRs (95% CIs) for each Q were 0.85 (0.78–0.92), 0.73 (0.67–0.81), and 0.67 (0.60–0.75), respectively.

Conclusions: In this large-scale population-based cohort study, higher urinary potassium excretion and dietary potassium intake were significantly associated with a lower risk of incident CKD development. Our findings provide new insight into dietary interventions among healthy adults to prevent CKD development.

Estimated Potassium Intake in Patients with CKD Is Associated with CKD Progression: The Fukuoka Kidney Disease Registry (FKR) Study

Tatsuya Suenaga,[1] Shigeru Tanaka,[1] Hiromasa Kitamura,[1] Kazuhiko Tsuruya,[2] Takanari Kitazono,[1] Toshiaki Nakano.[1] *[1]Kyushu Daigaku Igakubu Daigakuin Igakukei Gakufu Daigakuin Igaku Kenkyuin, Fukuoka, Japan; [2]Nara Kenritsu Ika Daigaku, Kashihara, Japan.*

Background: Higher potassium intake is associated with a lower odds ratio of chronic kidney disease (CKD) prevalence among the general population. On the other hand, because of the limited evidence examining the benefits and risks of encouraging potassium intake or restricting potassium in patients with CKD, the Kidney Disease Improving Global Outcomes and Kidney Disease Outcomes Quality Initiative guidelines only recommend potassium restriction in hyperkalemic patients with CKD, without making any recommendations regarding potassium intake.

Methods: A total of 4,092 patients aged 18 years or older in Japan were prospectively followed for 5 years using data from the Fukuoka Kidney Disease Registry (FKR) Study. Patients were divided into quartiles according to estimated potassium intake (EPI) levels assessed by the Tanaka formula from spot urine samples (Q1: <1609.5, Q2: 1609.5–1887.2, Q3: 1887.2–2184.4, Q4: >=2184.4 mg/day). The primary outcome was a progression of CKD defined as a composite of a 1.5-fold increase in creatinine from baseline and/or development of end-stage kidney disease. We estimated the relationship between EPI levels and outcomes using Cox proportional hazards models and Fine–Gray models.

Results: A total of 1,407 patients developed primary outcome during follow-up periods with an incidence rate of 89.0 per 1,000 person-years. Patients in Q1 had a significantly higher hazard ratio (HR) for the progression of CKD than those in Q4 in the multivariable-adjusted Cox proportional hazards models (multivariable-adjusted HR [95% confidence interval {CI}], 1.33 [1.10–1.59]). The HR (95% CI) for each 1-SD decrease in EPI levels was 1.13 (1.06–1.22, p <0.05). Similarly, patients in Q1 had a significantly higher subdistribution HR for the progression of CKD than those in Q4 in the multivariable-adjusted Fine–Gray model with all-cause death as a competing risk (subdistribution HR [95% CI], 1.29 [1.08–1.55], p <0.05).

Conclusions: Lower estimated potassium intake is associated with the progression of CKD among patients with CKD. Future studies are needed to determine whether increasing potassium intake has an impact on preserving kidney function.

SA-OR70

Association of Dietary Potassium and Fiber Intake with Death Risk in a Prospective Hemodialysis Cohort

Yoko Narasaki,[1] Kamyar Kalantar-Zadeh,[2] Seung Hyeok Han,[3] Tae ik Chang,[4] Diana S. Kalantar,[1] Tracy Nakata,[1] Danh V. Nguyen,[1] Connie Rhee.[1] *[1]University of California Irvine School of Medicine, Irvine, CA; [2]Harbor-UCLA Medical Center, Torrance, CA; [3]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [4]National Health Insurance Service, Wonju, Gangwon-do, Republic of Korea.*

Background: In ESKD patients, guidelines recommend dietary potassium (K) restriction given concerns about potential hyperkalemia leading to malignant arrhythmias and mortality. Yet there are sparse data informing recommendations for dietary K intake in this population. We examined the relationship between dietary K intake and death risk in a prospective HD cohort.

Methods: In 687 hemodialysis patients from the multi-center NIH MADRAD cohort recruited from 16 outpatient dialysis clinics, dietary K intake data were obtained using protocolized Food Frequency Questionnaires (FFQs) administered over 10/2011-9/2022. We examined associations of dietary K intake categorized as tertiles with mortality using multivariable Cox regression. Given the high fiber content of plant-based K-rich foods, we also examined different pairings of dietary K and fiber intake across four exposure groups (low K/low fiber, low K/high fiber, high K/low fiber, high K/high fiber) with survival.

Results: In expanded case-mix analyses, the lowest dietary K intake tertile was associated with higher mortality (ref: highest tertile): HR (95%CI) 1.58 (1.07, 2.33) (Fig A). After further adjustment for laboratory+nutritional covariates, associations showed greater magnitude of risk: HR (95%CI) 1.66 (1.11, 2.49). In adjusted analyses of dietary K/fiber pairings, patients with low K/low fiber intake and those with high K/low fiber intake had worse survival vs. those with high K/high fiber intake: HRs (95%CIs) 1.45 (1.04, 2.00) and 1.51 (1.03, 2.28), respectively (Fig B).

Conclusions: In a prospective HD cohort, lower dietary K intake was associated with higher mortality. When examined in combination with fiber intake, both low K/low fiber and high K/low fiber intake were associated with worse survival. These findings suggest excessive dietary K restriction as well as high K intake from foods with lower fiber content (animal-based sources) may be deleterious in HD patients. Further studies are needed to determine the optimal amount and sources of dietary K intake in ESKD.

Effects of a Whole-Food, Plant-Based Nutrition Education Program on Blood Pressure and Potassium Levels in CKD

Scott E. Liebman,[1] Ted D. Barnett,[2] Thomas M. Campbell,[1] Luojing Chen,[1] Susan Friedman,[1] Shamsul Hasan,[1] Thu H. Le,[1] Rebeca D. Monk,[1] Nellie Wixom,[1] Anne Zhang,[1] Erin K. Campbell.[1] *[1]University of Rochester Medical Center, Rochester, NY; [2]Rochester Lifestyle Medicine Institute, Rochester, NY.*

Background: Evidence suggests adoption of a predominately whole food plant based diet (WFPBD) may be beneficial in management of CKD. Concerns over adherence and the potential for hyperkalemia may limit enthusiasm for this approach. This pilot trial tested the hypothesis that individuals with CKD 3 or 4 who attend an education program (known as Jumpstart [JS])- designed to foster lifestyle changes including adoption of a WFPBD via a combination of lectures, support systems and food demonstrations - would achieve lower blood pressure (BP) without an increased risk of hyperkalemia.

Methods: 40 subjects with CKD 3 or 4, with HTN but without proteinuria or hyperkalemia, were randomized to attend the JS education program or not (controls). Participants had vital signs, laboratory studies, and food diaries done before and at the completion of the 15 day JS program (or equivalent times for the controls). At the end of the trial, t-tests were use to compare values between the intervention and control groups.

Results: JS participants (n = 20) saw a greater decrease in systolic BP from baseline to day 15 compared with controls (n = 20) but this did not reach statistical significance (-8 vs 2.8 mm Hg, p=0.12). Potassium changed by -0.01 mEq/L in the JS group and -0.08 mEq/L in the control group (p=0.62). JS subjects had a statistically significant decrease in body mass (3.0 vs. 0.12 kg, p< 0.0001) BMI (1.08 vs. 0.18, p= 0.0002), total cholesterol (39.35 vs. 4.95 mg/dl, p< 0.0001), LDL (28.35 vs. 0.6 mg/dl), HDL (8.15 vs. 0.4 mg/dl, p=0.008) and BUN (7.35 vs. 0.75 mg/dl, p=0.0001) compared with controls. Changes in albumin, phosphorus, PTH, other chemistry values, and measures of urinary 8-isoprostane, a marker of oxidative stress, were not different between the groups.

Conclusions: Subjects with CKD 3 or 4 attending the 15-day JS program emphasizing a WFPBD had non-significant reductions in systolic BP without increased risk of hyperkalemia. JS attendees achieved greater reduction in weight, BMI and most cholesterol values, without adverse effects on albumin and phosphorus. Larger trials are warranted to investigate potential long-term benefits of this approach.

SA-OR72

Effect of Dietary Acid Reduction with Fruits and Vegetables vs. Oral NaHCO3 on Parameters of Cardiovascular Health in Stage 1 CKD: A 5-Year Randomized Trial

Nimrit Goraya,[1] Jan Simoni,[2] Maninder Kahlon,[3] Nazan Aksan,[3] Donald E. Wesson.[3] *[1]Baylor Scott and White Central Texas, Temple, TX; [2]Texas Tech University System, Lubbock, TX; [3]The University of Texas at Austin Dell Medical School, Austin, TX.*

Background: Patients with macroalbuminuric (urine albumin-to-creatinine ratio [ACR] > 200 mg/g cr) chronic kidney disease (CKD) have increased cardiovascular disease (CVD) risk. As high acid-producing diets are associated with increased CVD risk, we compared effects of base-producing fruits and vegetables (F+V) vs. oral NaHCO3 on contributors to cardiovascular health and on indices of CVD risk in participants with normal eGFR (> 90 ml/min/1.73 m2 or stage G1).

Methods: One hundred fifty-three macroalbuminuric, non-diabetic G1 participants on ACE inhibitors were randomized to receive F+V (n=51) in amounts to reduce dietary potential renal acid load 50%, oral NaHCO3 (HCO3, n=51) 0.4 meq/kg bw/day, or no additional intervention (Usual Care, n=51). They were followed annually for 5 years, measuring systolic blood pressure (SBP), eGFR, isoprostane 8-isoprostaglandin F2α (8-iso), BMI, ACR, and Lp(a). Mixed linear regressions with random person intercepts tested differential group trajectories, p-values from the relevant interaction terms are included below.

Results: We highlight group differences at year-5 for brevity and provide p-values from the full model. At 5 years, SBP and BMI were lower in F+V than HCO3 and UC (SBP [mean (SE)], F+V[128.9 (0.70)], HCO3 [135.0 (0.73)], UC [134.6 (0.62)], mm Hg, ps<0.001); BMI, F+V [27.0 (0.25)], HCO3 [28.4 (0.26)], UC [28.0 (0.30)], ps<0.001). For both F+V & HCO3 relative to UC, 5-year eGFR was higher (eGFR, F+V [96.5(0.79)], HCO3 [95.9 (0.96)] vs. UC [92.1 (1.23), ml/min/1.73 m2, ps<0.001]) and 8-iso was lower (8-iso, F+V [1.08 (0.02)], HCO3 [1.06 (0.02)] vs. UC [1.27 (0.03)], μg/g cr, ps<0.001]). Five-year Lp(a) was lower in F+V than HCO3 and UC (Lp(a), F+V [53.3 (1.2)], HCO3 [62.2 (1.4)], UC, [60.8 (1.5), mg/dl, ps<0.001]). Furthermore, 5-year ACR was lower for F+V and HCO3 than UC (F+V [306 (8.5)], HCO3 [308 (8.4)] vs. UC [416 (15), mg/g cr, ps<0.001]).

Conclusions: Dietary acid reduction with either F+V or NaHCO3 over 5 years yielded similar eGFR preservation, systemic oxidative stress reduction, and lower ACR benefits. Dietary acid reduction with F+V compared to NaHCO3 and UC yielded better SBP control, lower BMI and lower Lp(a) and yielded better overall CVD protection in macroalbuminuric patients with initially normal eGFR.

SA-OR73

Food Insecurity, Dietary Intake, and Mortality Among Adults with CKD

Jenna Kiryakos,[1] Ana Laura Licon,[2] Tiffany C. Veinot,[4] Brenda W. Gillespie,[2] Yun Han,[1] Michael Heung,[1] Stephen J. Onufrak,[3] Rajiv Saran,[1] Jennifer L. Bragg-Gresham.[1] *[1]University of Michigan Department of Internal Medicine, Ann Arbor, MI; [2]University of Michigan Department of Biostatistics, Ann Arbor, MI; [3]Centers for Disease Control and Prevention, Atlanta, GA; [4]University of Michigan School of Information, Ann Arbor, MI.*

Background: Food insecurity in adults has been associated with a higher risk of diabetes, hypertension, chronic kidney disease (CKD), and mortality. We sought to examine the role of dietary intake in mortality risk due to food insecurity in adults with CKD.

Methods: We used data from the National Health and Nutrition Examination Survey (1999–2018) to assess differences in demographics, comorbidities, socioeconomic status (SES), and dietary intake in food secure versus food insecure adults with CKD (*N*=8935). Marginal, low, or very low household food security defined food insecure. Using publicly available mortality-linked data, we explored mortality related to food insecurity, food intake, and other risk factors using Cox regression.

Results: Approximately 22% of adults with CKD reported food insecurity. These adults were younger, had lower SES and rates of health insurance, were more likely to be from a racial minority group, and had higher prevalence of obesity and diabetes. Food insecure adults had overall higher calorie intake, but fiber and potassium intake were lower, while carbohydrate and sodium intake were higher. Adjusting for demographics only, food insecure adults had a higher mortality rate (HR=1.46, *P*<0.0001). Risk decreased when comorbidities, income, and education were considered (HR=1.22, *P*=0.006). Dietary intake did not further reduce this association.

Conclusions: Differing nutrient intake was seen in adults with CKD and food insecurity, yet these differences did not attenuate food insecure-related mortality risk; however, the potential role of diet in inducing comorbidities overtime is not excluded. Future work may consider the higher risk of comorbidities in food insecure adults with CKD to improve health outcomes.

Dietary Inflammatory Potential and Kidney Function in the Hispanic Community Health Study/Study of Latinos

Tanya S. Johns,[1,2] Josiemer Mattei,[3] Michelle M. Estrella,[4] Daniela Sotres-Alvarez,[5] Martha L. Daviglus,[6] Yasmin Mossavar-Rahmani,[1] Michal L. Melamed.[1,2] *[1]Albert Einstein College of Medicine, Bronx, NY; [2]Montefiore Health System, Bronx, NY; [3]Harvard University T H Chan School of Public Health, Boston, MA; [4]University of California San Francisco, San Francisco, CA; [5]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [6]University of Illinois Chicago, Chicago, IL.*

Background: Inflammation is implicated in the pathogenesis and progression of CKD. Diet modulates chronic inflammation and possibly kidney health. We evaluated the association of diet-related inflammation and kidney function among US Hispanic/ Latino adults.

Methods: Data were from participants in the Hispanic Community Health Study/ Study of Latinos (HCHS/SOL), a population-based study of Hispanic/Latino adults 18-74 years old from 4 US communities, who were examined at visit 1 (V1) (2008-2011) and visit 2 (V2) (2014-2017) and had data on dietary intake and serum creatinine. Dietary inflammatory potential was assessed using the dietary inflammatory index (DII®). Scores were adjusted for total energy intake (E-DII®) and categorized into tertiles: T1 having the lowest dietary inflammatory potential, and T3 having the highest (most pro-inflammatory). Creatinine-based eGFR was calculated using the 2021 CKD-Epi equation. Primary outcomes were incident CKD (eGFR <60 ml/min/1.73m² at V2 and ≥25% eGFR decline from V1 to V2) and rapid kidney function decline (RKFD) (≥30% decline in eGFR from V1 to V2). We excluded participants with eGFR <15 ml/min/1.73m², and for incident CKD, those with eGFR <60 ml/min/1.73m² at V1. Logistic regression models adjusting for study center and baseline socio-demographics, comorbidities, behavioral factors, medications, anthropometric measures, eGFR and albuminuria were used to compare E-DII® tertiles and determine odds ratio for incident CKD and RKFD.

Results: Of 10,574 participants, median age was 49 years, 22% had diabetes, 46% had hypertension. Median eGFR was 101.7 ml/min/1.73m². Median E-DII® was 0.18 (IQR -1.06 to 1.30). Over a mean follow-up of 6 years, 122 incident CKD and 196 RKFD events occurred. Participants with the most pro-inflammatory dietary patterns compared to the lowest had 2.2-fold higher odds of incident CKD (95% CI: 1.14 – 4.31) after adjusting for covariates. The E-DII® was not significantly associated with RKFD.

Conclusions: A pro-inflammatory dietary pattern is associated with a higher likelihood of incident CKD among US Hispanic/ Latino adults. To prevent kidney disease, US Hispanic/ Latino adults may opt to reduce intake of foods with higher pro-inflammatory potential (e.g., processed or fried foods, red meat, sweetened beverages).

Personalized Patient Education on Lifestyle Modification and Nutrition Management in CKD Using ChatGPT

Prakrati C. Acharya,[1] Chirag Acharya,[1] Pajaree Krisanapan,[2] Supawit Tangpanithandee,[3] Iasmina Craici,[3] Charat Thongprayoon,[3] Wisit Cheungpasitporn.[3] *[1]Texas Tech University Health Sciences Center El Paso, El Paso, TX; [2]Thammasat University Hospital, Khlong Nueng, Thailand; [3]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Lifestyle modifications are critical for managing CKD. Patients struggle to access reliable information on modifying lifestyle. AI-based natural language processing technology, like ChatGPT, has the potential to provide information on lifestyle modification and nutrition. This study aimed to evaluate the effectiveness of ChatGPT in providing education by addressing questions related to lifestyle modification and nutrition in CKD.

Methods: 15 frequently asked questions were generated using the Kidney Disease Improving Global Outcomes (KDIGO) guidelines "CKD evaluation and management 2012", "Diabetes in CKD 2022", and "Lipids in CKD 2013". The questions were categorized into 4 steps to evaluate the versatility of ChatGPT in generating responses. ChatGPT (March 23 Version) provided responses were evaluated by nephrologists and compared to KDIGO guidelines.

Results: Overall the response to addressing patient queries for original questions, paraphrased questions with different interrogative adverbs, paraphrased questions with incomplete sentences, and paraphrased questions with misspelled words were similar. ChatGPT provided accurate responses to 13 out of 15 FAQs across various complexity levels and paraphrasing variations. In 2 questions some statements made by ChatGPT could have been misleading to patients, such as "medications like erythropoietin stimulating agents and phosphate binders may affect the patient's ability to engage in physical activity." Statements such as "high protein intake can result in accumulation of metabolites like ammonia in tubular cells" and "excessive protein intake can activate renin angiotensin aldosterone system" could be confusing to providers when these statements are not proven in human studies. Consultation with nephrologist was encouraged by ChatGPT in all the questions.

Conclusions: This research highlights the potential of ChatGPT as an effective tool for providing patient education. ChatGPT's response in addressing patient queries was comparable to the assessments provided by the KDIGO guidelines. Rare statements though made by ChatGPT could be misleading. Further advancements are necessary to enhance ChatGPT's performance in addressing more intricate aspects of lifestyle modification and nutrition management.

Intradialytic Cycling Exercise Improves Arterial Stiffness in Hemodialysis Patients

Ho-Hsiang Chang,[1] Yu-Hsien Lai,[1,2] Bang-Gee Hsu.[1,2] *[1]Division of Nephrology, Buddhist Tzu Chi General Hospital, Hualien, Taiwan; [2]School of Medicine, Tzu Chi University, Hualien, Taiwan.*

Background: Cardiovascular diseases are the main causes of death and morbidity in hemodialysis patients. Arterial stiffness is an essential predictor of cardiovascular mortality. Exercise has been shown to contribute vascular and physical benefits in healthy populations. Physical function would affect the quality of life in hemodialysis patients. Intradialytic cycling exercises provide regular exercise with good supervision. We conducted this randomized controlled project to examine the vascular and physical effects of intradialytic exercise in hemodialysis patients.

Methods: One hundred and fourteen hemodialysis patients were randomly assigned to either intradialytic cycling exercise group (EX) or to a regular care group (RC) for 12 months. We compared the effect of intradialytic cycling on arterial function (carotid-femoral pulse wave velocity, cfPWV) as primary endpoint and physical performance (gait speed and 5 times sit to stand) as secondary evaluations in these participants.

Results: Among 114 participants, 89 and 82 patients completed the tests at 6 and 12 months, respectively. We observed a significantly decrease in cfPWV in the EX group compared to the RC group (95% confidence interval (CI): (-5.71, -2.90), p <0.001). With further evaluation with GEE analysis, there was a significant difference on group-by-time interaction of cfPWV (p <0.001 both after 6 and 12 months). In the secondary outcomes, we observed a significantly faster gait speed in the EX group compared with RC group (95% confidence interval (CI): (0.03, 0.30), p =0.019). However, the difference in group-by-time interaction of gait speed between the two groups was not observed during further evaluation with GEE analysis (p =0.134 and 0.435, after 6 and 12 months, respectively). There were no significant differences in blood pressure, pulse rate, 5 times sit-to-stand test and body compositions between the two groups throughout the trial.

Conclusions: Our investigation demonstrated that cfPWV improved after intradialytic cycling exercise with significant benefit. In addition, profound benefit was revealed with a longer duration of exercise. Physical performance as gait speed also showed improvement in the exercise group. Therefore, intradialytic cycling is an effective exercise to achieve arterial health and physical performance in the hemodialysis population.

SA-OR77

Oxygen Consumption Recovery Is Delayed After the Long Interdialytic Period

Eliott Arroyo,[1] Drake Dillman,[1] Andrew R. Coggan,[2] Syed J. Sher,[1] Sharon L. Karp,[1] Sharon M. Moe,[1] Kenneth Lim.[1] *[1]Indiana University School of Medicine, Indianapolis, IN; [2]Indiana University Purdue University Indianapolis, Indianapolis, IN.*

Background: Prolonged interdialytic periods leading to accumulation of uremic toxins and volume changes may be associated with alterations in ventilatory response to exercise. O_2 uptake (VO_2) kinetics during the early recovery period on cardiopulmonary exercise testing (CPET) have strong prognostic value in patients with heart failure and have the advantage of being independent of achieving maximal volitional effort. In this study, we sought to examine the effects of the long interdialytic interval on VO_2 kinetics.

Methods: We analyzed data from the ongoing, "Effects of long interdialytic intervals on Cardiovascular Functional Capacity (ECON)" study, a randomized crossover trial of patients on conventional HD. CPET was performed on three study visits: post-HD (baseline; BL), and at the end of a 2-day and the 3-day interdialytic intervals. VO_2 recovery (%) was calculated using the following formula: (VO_2 peak–VO_2 at minute 1 of recovery)/VO_2 peak.

Results: A total of 30 patients (n=19 men, mean [SD] age=54 [11] years, dialysis vintage=71.1 [63] months) were included in this analysis. No differences between visits were observed in VO_2Peak (BL=1.00 [IQR: 0.84-1.14] L/min; 2-day=0.96 [0.83-1.22] L/min; 3-day=0.99 [0.87-1.20] L/min; p=0.71) nor in VO_2 at ventilatory threshold (BL=0.67 [0.15] L/min; 2-day=0.67 [0.15] L/min; 3-day=0.68 [0.14] L/min; p>0.9). However, post-HD fatigue limited the patients' effort during the BL CPET, as reflected by a lower peak respiratory exchange ratio compared to non dialysis day visits (p=0.014). VO_2Recovery was lower during the 3-day interval (20 [9] %) compared to BL (25 [8] %; p=0.013), while no differences were observed between the 2-day interval (22 [11] %) and BL (p=0.11). Additionally, heart rate (p=0.044) and minute ventilation (p=0.025) after 1 minute of recovery were higher during the 3-day interval compared to BL.

Conclusions: The long interdialytic period may be associated with slowed replenishment of energy stores in peripheral muscles as reflected by the delay in VO_2 and ventilation recovery following maximal exercise. VO_2Peak assessment the same day following HD may be confounded by post-HD fatigue, therefore exercise recovery kinetics may provide incremental prognostic data and unveil subclincial pathophysiological alterations occurring during interdialytic intervals.

Liddle Syndrome Caused by Loss-of-Function Mutations in the Ubiquitin Ligase NEDD4L

Daniela Rotin,[1,2] Avinash Persaud,[1] Larry T. Patterson,[3] Joshua Zaritsky,[4] Thomas R. Kleyman,[5] Mathieu J. Lemaire.[1,2] *[1]SickKids Research Institute, Toronto, ON, Canada; [2]University of Toronto Temerty Faculty of Medicine, Toronto, ON, Canada; [3]University of Florida, Gainesville, FL; [4]Phoenix Children's Hospital, Phoenix, AZ; [5]UPMC, Pittsburgh, PA.*

Background: Liddle Syndrome (Pseudohyperaldosteronism) is an autosomal dominant form of hereditary hypertension characterized by early-onset hypertension, hypokalemia, low blood aldosterone and renin levels, and metabolic alkalosis. In most patients it is caused by a pathogenic variant in the PY motifs (PPxY) of the b (*SCNN1B*) or g (*SCNN1G*) subunits of the amiloride-sensitive Epithelial Na^+ Channel, ENaC. Mutant ENaC exhibits increased retention and function at the plasma membrane in the distal nephron, increased reabsorption of luminal Na^+, increased circulatory blood volume and hypertension. These ENaC variants impair its binding to NEDD4L, an E3 ubiquitin ligase comprised of C2-WW(4)-HECT domain architecture. Impaired NEDD4L binding to ENaC leads to reduced cell surface ENaC ubiquitination, impaired channel endocytosis and degradation, thus explaining the increased retention of ENaC at the plasma membrane.

Methods: Targeted exome sequencing was used, which included *SCNN1A, SCNN1B, SCNN1G* and *NEDD4L*. The patient's variants on either allele of NEDD4L were generated by site-directed mutagenesis and tested for self-ubiquitination *in vitro*, substrate ubiquitination against a model substrate and against cell-surface αβγENaC in kidney Hek293T cells. Cell surface ENaC stability was analyzed in parallel.

Results: Unlike most Liddle syndrome patients with pathogenic *ENaC* variants, a subset of patients have normal ENaC. Here we describe the discovery of novel compound heterozygous pathogenic variants in the *NEDD4L* gene in a patient with Liddle syndrome and normal ENaC genes. Both parents are unaffected carriers. The maternal allele is a frameshift variant that yields a truncated NEDD4L protein devoid of the entire catalytic HECT domain. The paternal allele is a missense variant in the HECT domain that exhibits a severe loss of its enzymatic activity. This results in a dramatic reduction in ENaC ubiquitination, thereby increasing the stability of this channel at the plasma membrane.

Conclusions: This is the first demonstration of a novel recessive form of Liddle syndrome caused by loss of function of the ENaC suppressor NEDD4L. On this basis, it will be important to include *NEDD4L* in commercial hypertension gene panels to facilitate the diagnosis of other Liddle syndrome patients with normal *SCNN1* (ENaC) genes.

Recessive Variants in MYO1C as a Potential Novel Cause of Nephrotic Syndrome

Ronen Schneider,[1,2] Shirlee Shril,[1,2] Friedhelm Hildebrandt.[1,2] *[1]Boston Children's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA.*

Background: Steroid resistant nephrotic syndrome (SRNS) is the second leading cause of chronic kidney disease in the first three decades of life. The identification of monogenic causes of SRNS has revealed ~60 single-gene etiologies. While in 12-30% of patients with SRNS a causative variant may be detected, many remain without a molecular diagnosis (Sadowski *JASN* 26:1279, 2015).

Methods: To elucidate novel monogenic causes of NS, we performed whole exome sequencing (WES) in an international cohort of 1,382 NS patients.

Results: We identified homozygous missense variants in *MYO1C* in 2 unrelated children with nephrotic syndrome (c.2273 A>T, p.Lys758Met; c.292C>T, p.Arg98Trp). Myosins including MYO1C are actin-based molecular motors that actively participate in various cellular functions including intracellular trafficking, cell adhesion, motility and maintenance of membrane tension. Podocyte-specific MYO1C knockout shows MYO1C is critical for TGF-β-signaling in podocyte disease pathogenesis (Ehtesham *KI* 96:139, 2019). We evaluated publicly available kidney single-cell RNA sequencing datasets and found *MYO1C* to be predominantly expressed in podocytes (Cebrian *Development* 145:16, 2018). We then performed structural modeling in molecular viewer PyMol using the *super* function aligning shared regions within both partial structures (*4byf* and *4r8g)*. In both structures, calmodulin, a common regulator of myosin activity, is shown to bind to the IQ motif. At both residue sites (K758, R98W), there are ion-ion interactions stabilizing intradomain and ligand interactions: R98W binds to nearby D220 within the Myosin Motor Domain and K758 binds to E14 on a calmodulin molecule. Variants of these charged residues to non-charged amino acids could ablate these ionic interactions, weakening protein structure and function establishing the importance of these variants. Future *in vivo* knockout and mutagenesis models are required to confirm mutation pathogenicity.

Conclusions: We, here, identified recessive mutations in *MYO1C* as a potential novel cause of nephrotic syndrome in children.

SA-OR80

Circulating Nephrin Autoantibodies Are Present in Almost 2/3 of Steroid-Naïve Pediatric Idiopathic Nephrotic Syndrome

Astrid Weins,[1,2] Andrew J. Watts,[1,2] Yu Kamigaki,[3] Nicole Bowman,[1] Julie Dougherty,[3] William E. Smoyer.[3] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]Nationwide Children's Hospital, Columbus, OH.*

Background: Children who present with idiopathic nephrotic syndrome (INS) are initially treated with corticosteroids (CS) and do not routinely require a renal biopsy unless they have atypical features or subsequent resistance to CS. We recently identified circulating nephrin autoantibodies in approximately 30% of children and adults with biopsy proven MCD. As the majority of these patients had already received CS prior to serum sampling we hypothesized that this likely underestimated the true prevalence of pediatric nephrin autoantibody positive INS.

Methods: In this North American, multicenter, prospective study (via the Pediatric Nephrology Research consortium (PNRC)) we evaluated serum samples obtained from children at presentation and following GC monotherapy for nephrin autoantibodies by indirect ELISA. A threshold for positivity was determined from a healthy control cohort without renal disease. Patients received either no GC therapy (steroid naïve) or up to 2 days of GC therapy (minimal steroids) prior to the initial presentation sample. Patients were categorized into steroid sensitive (SSNS) and steroid resistant (SRNS) dependent on whether they achieved complete remission within 7 weeks of GC monotherapy.

Results: The median age was 4 years (IQR 3-11years) and 45% male. Almost two thirds, 63% (n=12/19) of steroid naïve INS patients were positive for nephrin autoantibodies at initial presentation and of those 75% (n=9/12) became negative following CS therapy. Including patients with minimal steroids prior to initial presentation revealed that 59% (n=17/29) were nephrin autoantibody positive. In those children who were steroid naïve at initial presentation, 69% (n=9/13) with SSNS were nephrin autoantibody positive compared with 50% (n=3/6) with SRNS.

Conclusions: We found that just under 2/3 of children with INS who were steroid naïve at initial presentation were serologically positive for nephrin autoantibodies. Furthermore, we identified nephrin autoantibodies in both SSNS and SRNS, and although the mechanism of GC in INS remains to be determined, B-cell targeted therapies are effective in treating some patients with SSNS and SRNS. This raises the possibility that nephrin autoantibodies may serve as an important biomarker to guide B cell targeted therapies in both SSNS and SRNS.

Unveiling the Disproportionate Impact of Rare Kidney Diseases on Kidney Failure: A Longitudinal Analysis Using the UK National Registry of Rare Kidney Diseases (RaDaR)

Daniel P. Gale,[1,2] Katie Wong,[1,2] David Pitcher,[1,2] Dorothea Nitsch,[3,5] Kate Bramham.[1,4] *[1]Rare Renal Disease Registry, Bristol, United Kingdom; [2]University College London Faculty of Medical Sciences, London, United Kingdom; [3]London School of Hygiene & Tropical Medicine Faculty of Epidemiology and Population Health, London, United Kingdom; [4]King's College London, London, United Kingdom; [5]UK Renal Registry, Bristol, United Kingdom.*

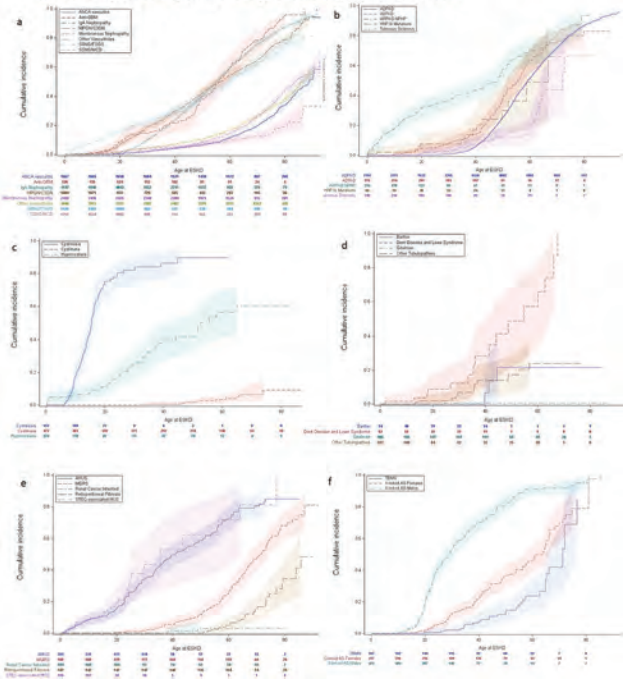
Background: Patients with rare kidney diseases account for <10% of people living with CKD, but make up 25% of prevalent patients on Renal Replacement Therapy (RRT). The natural history of rare kidney diseases are poorly described. Formed in 2010, RaDaR gathers longitudinal data from UK rare kidney disease patients. We used these data to study outcomes of death and RRT initiation for these conditions.

Methods: RaDaR recruited patients from 108 UK renal units. Incidence rates for mortality and ESKD were calculated and compared to those from unselected UK patients using population estimates of CKD and UK Renal Registry RRT incidence data. Cumulative incidence and Kaplan Meier survival estimates were calculated for a)Age at RRT start b) age at death c) time from RRT start to death d) time from diagnosis to eGFR thresholds allowing calculation of time from last eGFR ≥75 to first <30mls/min/1.73m^2 (therapeutic window).

Results: 27,293 patients in 20 Rare Disease Groups (RDGs) were included. RaDaR patients had higher 5 year incidence rates of ESKD compared to 2.81 million patients with all cause CKD (28% vs 1%) and better survival rates (Standardised Mortality Ratio 0.45, 95% CI 0.37-0.54). There was heterogeneity in median age at RRT start between RDGs (Fig 1). Time in therapeutic window varied between 20 years in Retroperitoneal Fibrosis to 1.3 years in Monoclonal Gammopathy of Renal Significance.

Conclusions: Patients with rare kidney diseases differ from the general CKD population: they are more likely to reach ESKD and half as likely to die with CKD stages 3-5, so are disproportionately represented in the RRT population. Successfully addressing unmet need in rare diseases may therefore have a disproportionate effect on RRT demand long term.

Figure 1: Cumulative incidence of End Stage Kidney Disease for a) Glomerular b) Cystic c) Metabolic d) Tubular e) Other kidney conditions f) Alport Syndrome



Characteristics and Outcomes for Neonates Receiving Dialysis

Characteristics	Total n=183	AKI n=105	ESKD n=55	Hyperammonemia n=15	Other/Unknown n=8

Nelson-Taylor,[15] Robin High,[1] Keia Sanderson.[16] *[1]University of Nebraska Medical Center, Omaha, NE; [2]Children's Hospital and Medical Center, Omaha, NE; [3]University of Alabama at Birmingham, Birmingham, AL; [4]Riley Hospital for Children at Indiana University Health, Indianapolis, IN; [5]University of California San Diego, Rady Children's Hospital, San Diego, CA; [6]The University of Iowa Stead Family Children's Hospital, Iowa City, IA; [7]University of Rochester Medical Center, Rochester, NY; [8]Oregon Health & Science University, Portland, OR; [9]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [10]Penn State College of Medicine, Hershey, PA; [11]Arkansas Children's Hospital, Little Rock, AR; [12]University of Arkansas for Medical Sciences College of Medicine, Little Rock, AR; [13]Washington University in St Louis School of Medicine, St Louis, MO; [14]Connecticut Children's Medical Center, Hartford, CT; [15]Children's Hospital of Colorado, Aurora, CO; [16]University of North Carolina Kidney Center, Chapel Hill, NC.*

Background: Neonatal dialysis is technically challenging and rare. Prior neonatal dialysis research is primarily limited to medical claims/coding data. There are critical knowledge gaps specific to neonatal dialysis. Our objective was to describe contemporary neonatal dialysis demographics, access, modalities, complications, and outcomes.

Methods: This is a preliminary report from a multicenter retrospective cohort study of 14 centers in the Pediatric Nephrology Research Consortium. Neonates initiated on dialysis within the first 30 post-natal days between June 2017-May 2022 were enrolled. Neonates with a dialysis catheter placed post-cardiac surgery for fluid management without kidney dysfunction were excluded. Data were collected until initial hospital transfer/discharge.

Results: 183 neonates on dialysis were enrolled. 58% were diagnosed with acute kidney injury (AKI) and 30% with end-stage kidney disease (ESKD). The majority received some form of continuous kidney replacement therapy (CKRT) (71%). 25% experienced a change in dialysis modality, 52% died before hospital discharge, and 19% remained on dialysis at discharge/transfer on dialysis.

Conclusions: In this multicenter, cohort, a larger number of neonates received CKRT, many neonates changed dialysis modalities prior to discharge/transfer, and mortality rates are far greater than previously reported. Future research to inform development of evidence-based guidelines is needed to improve neonatal dialysis management and outcomes.

Risk Factors and Impact of Peritoneal Podoplanin in Children on Chronic Peritoneal Dialysis

Maria Bartosova,[1] Conghui Zhang,[1] Fabian Eibensteiner,[2,5] Rebecca Herzog,[2,5] Iva Marinovic,[1] Betti Schaefer,[1] Karel Vondrak,[3] Bradley A. Warady,[4] Klaus Kratochwill,[2,5] Claus Peter Schmitt.[1] Int. Pediatric PD Biopsy Study Group. *[1]UniversitatsKlinikum Heidelberg, Heidelberg, Germany; [2]Medizinische Universitat Wien, Wien, Austria; [3]University Hospital Motol Prague, Prague, Czechia; [4]Children's Mercy Kansas City, Kansas City, MO; [5]Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Medical University of Vienna, Vienna, Austria.*

Background: Diffuse, peritoneal podoplanin staining (DPS) positivity has been described with encapsulating peritoneal sclerosis (EPS) in patients on peritoneal dialysis (PD). The pathophysiological role in PD is uncertain.

Methods: Peritoneal tissues from 250 children (8.5, IQR 2.5, 13.2 years), with normal renal function (NRF), CKD5, and on chronic PD with fluids that contain low and high glucose degradation product (GDP) concentrations underwent digital histomorphometry and high-dimensional multiplexed imaging mass cytometry followed by deep learning-based segmentation and spatial single-cell and cellular neighbourhood interaction analysis.

Results: Children with NRF and CKD5 exhibited no DPS. 21% of children on low-GDP PD and 46% on high-GDP PD were DPS positive, but without clinical, radiological or histological features of EPS. PD duration and peritonitis incidence were similar in DPS positive and as in non-DPS PD patients. DPS positive patients were younger, had higher dialytic glucose exposure and more arteriolar lumen narrowing. Dialytic glucose exposure, PD duration, lower body surface area (BSA) and epithelial-to-mesenchymal (EMT) transformed cell counts were independently associated with DPS. DPS and lower mesothelial surface coverage independently associated with arteriolopathy. In subgroups matched for age, PD duration and dialytic glucose exposure, DPS positive children had higher submesothelial leucocyte (CD45+) and macrophage (CD68+) counts, and higher lipopolysaccharide and hyaluronan receptor CD44 abundance. DPS intensity was higher with history of peritonitis. Hierarchical clustering demonstrated highest similarity of DPS positive areas with CD68 positive areas, classified as M2 macrophages (CD68+CD163+), followed by fibroblastic cells (αSMA+PROX1-CD31-CD68-CD163-); DPS signals from M1 macrophages (CD68+CD163-) were low.

Conclusions: DPS is prevalent in children on PD devoid of EPS, and is independently associated with peritoneal arteriolopathy. Independent DPS risk factors are high dialytic glucose and GDP exposure, history of peritonitis, BSA, peritoneal inflammatory and EMT cell invasion; M2 macrophages presumably play a key role.

Preliminary Findings from the Phase 2 EPPIK Study of Sparsentan in Pediatric Patients with Selected Proteinuric Glomerular Diseases

Kenneth V. Lieberman,[1] Howard Trachtman,[2] Rosanna Coppo,[3] Ping He,[4] Alex Mercer,[5] Michelle N. Rheault,[6] Moin Saleem,[7] Teresa Shafer,[4] Radko Komers.[4] *[1]Joseph M. Sanzari Children's Hospital of the Hackensack Meridian Health, Hackensack, NJ; [2]University of Michigan, Ann Arbor, MI; [3]Fondazione Ricerca Molinette, Regina Margherita Hospital, Turin, Italy; [4]Travere Therapeutics Inc, San Diego, CA; [5]JAMCO Pharma Consulting, Stockholm, Sweden; [6]University of Minnesota Medical School, Minneapolis, MN; [7]University of Bristol & Bristol Royal Hospital for Children, Bristol, United Kingdom.*

Background: Sparsentan (SPAR) is a novel, non-immunosuppressive, single molecule Dual Endothelin Angiotensin Receptor Antagonist (DEARA) approved by the US FDA for the treatment of adults with IgA nephropathy (IgAN) at risk of rapid disease progression and is being investigated for focal segmental glomerulosclerosis (FSGS).

The ongoing Phase 2 EPPIK study is examining the safety and long-term antiproteinuric and nephroprotective potential of SPAR in pediatric patients with FSGS, minimal change disease (MCD), IgAN, IgA vasculitis (IgAV), and Alport syndrome (AS). Here we report preliminary findings.

Methods: This open-label, single-arm, multicenter trial is evaluating the safety, efficacy, and pharmacokinetics of SPAR in ~30 patients aged 1-<18 years with FSGS and/or MCD (Population 1) and ~27 aged 2-<18 years with IgAN, IgAV, or AS (Population 2) over 108 weeks with a 4-week safety follow-up. SPAR is administered once daily in a liquid formulation with dose adjusted to body weight. Patients receiving RAASi undergo a 2-week washout prior to study medication start (baseline). Primary endpoints include safety and efficacy (change in urine protein/creatinine ratio [UP/C] from baseline over 108 weeks).

Results: At data cutoff (4/5/23) 23 participants had received ≥1 dose of SPAR. Baseline characteristics are shown in **Table**. UP/C decreased over 12 weeks by 26% and 52% in Populations 1 and 2 and 35% overall (**Figure**). SPAR has been safe and generally well-tolerated.

Conclusions: SPAR treatment reduced proteinuria over the initial 12 weeks in pediatric patients with a range of proteinuric glomerular diseases. SPAR was safe and generally well-tolerated, consistent with findings from ongoing FSGS and adult IgAN trials.

Assessing Baseline Cardiovascular Disease for Kids Initiating Kidney Replacement Therapy: ABCD4Kids Study

Priyanka Khandelwal,[1] Jonas Hofstetter,[2] Claus Peter Schmitt,[2] Anette Melk,[3] Uwe Querfeld,[4] Franz S. Schaefer,[2] Rukshana Shroff.[1] 4C Study Consortium. *[1]Great Ormond Street Hospital for Children NHS Foundation Trust, London, United Kingdom; [2]Center for Pediatrics and Adolescent Medicine, University of Heidelberg, Heidelberg, Germany; [3]Department of Pediatric Kidney, Liver and Metabolic Diseases, Hannover Medical School, Hannover, Germany; [4]Charité Children's Hospital, Berlin, Germany.*

Background: Information on cardiovascular (CV) damage in children initiating kidney replacement therapy (KRT) is limited. We evaluated the CVD burden in incident dialysis and preemptive transplant recipients from two multicenter cohorts: Cardiovascular Comorbidity in Childhood CKD (4C) and Haemodiafiltration, Heart and Height (3H) studies.

Methods: The incident KRT cohort was compared with independent cross-sectional cohorts: CKD stage 3b (median eGFR 34 ml/min/1.73m²), 1-year on dialysis, and 1-year after transplantation. Structural (carotid intima-media thickness, cIMT-SDS, left ventricular mass index, LVMI) and functional (pulse wave velocity, PWV-SDS; and distensibility SDS) CVD indices were measured in all.

Results: 248 incident KRT patients, median age 14 yr, eGFR 12.2 ml/min/1.73m², 63% boys were studied. 82 (33%) were pre-emptively transplanted. At KRT initiation, pre-emptively transplanted patients had higher eGFR and lower 24-hr mean arterial BP, PWV-SDS and PTH compared to patients starting dialysis (P<0.01 for all). Incident KRT patients had significantly higher CV burden than the CKD3b cohort: elevated cIMT-SDS and PWV-SDS in 40% and 21% respectively and LV hypertrophy in 41% (**Fig**). Incident KRT patients had uncontrolled ambulatory (23%) and masked (21%) hypertension; whereas systolic BP and 24-hr mean arterial BP were lower following KRT initiation. While PWV-SDS was lower in transplanted patients, there was no difference in cIMT-SDS or LVMI (**Fig**). In incident KRT patients the independent predictors of PWV-SDS were systolic BP SDS (ß=0.36, P<0.001) and higher PTH (ß=0.27; P=<0.001). LVMI independently associated with systolic BP SDS (ß=0.30, P<0.001), higher BMI SDS (ß=0.20; P=0.001), lower hemoglobin (ß=0.17; P=0.008) and lower calcium (ß=0.15; P=0.01).

Conclusions: Incident KRT patients have a high burden of sub-clinical CVD comparable to that seen in chronic dialysis patients. Early intervention to manage modifiable risk factors is essential.

Molecular Pathways Associated with Early Vascular Calcification in Pediatric CKD

Julie Bernardor,[1,2] Maria Bartosova,[2] Conghui Zhang,[2] Iva Marinovic,[2] Rebecca Herzog,[3,4] Klaus Kratochwill,[3,4] Delphine Farlay,[5] Ingrid Dijkgraaf,[6] Armand Jaminon,[6] Leon J. Schurgers,[6] Claus Peter Schmitt.[2] *[1]CHU de Nice, Nice, France; [2]Universitat Heidelberg, Heidelberg, Germany; [3]Christian Doppler Laboratory for Molecular Stress Research in Peritoneal Dialysis, Department of Pediatrics and Adolescent Medicine, Vienna, Austria; [4]Division of Pediatric Nephrology and Gastroenterology, Department of Pediatrics and Adolescent Medicine, Comprehensive Center for Pediatrics, Medical University of Vienna, Vienna, Austria; [5]INSERM UMR 1033, Lyon, France; [6]Universiteit Maastricht, Maastricht, Netherlands.*

Background: Children with advanced stages of chronic kidney disease (CKD) are at high risk of cardiovascular disease (CVD) and vascular calcification (VC) may already occur during childhood. This study comprehensively investigated the molecular pathways underlying early VC in children with CKD stage 5.

Methods: Arterioles from children with normal renal function and CKD5, (median age 8.9 and 8.8 years) were analyzed using digital quantitative histomorphometry, von Kossa staining and ^{18}F-sodium autoradiography (^{18}F-NaF) for calcium deposit quantification. Arteriolar transcriptome and proteome analyses were followed by gene set enrichment (GSEA) and Ingenuity pathway analysis. Based on literature mining, a VC pathway library was established consisting of 442 biological processes and molecular functions and associated genes were extracted from Gene Ontology database. The identified key molecular mechanisms were validated in independent pediatric CKD5 cohorts (n=32) and healthy controls (n=20) using quantitative immunostaining.

Results: Von Kossa staining did not reveal calcium deposits, but ^{18}F-NaF autoradiography demonstrated arteriolar microcalcifications in children with CKD5. Compared to children with normal renal function, the arteriolar lumen/vessel ratio was reduced (p=0.001), due to intima and media thickening (p<0.0001/0.02), together with CD68+ macrophage infiltration in the subendothelial space (p=0.001/0.02). Multi-omics VC pathway analysis identified 30 pathways primarily associated with actin cytoskeleton, Wnt signaling, extracellular matrix (ECM) organization, complement activation, apoptosis, and ossification regulation. In independent age-matched cohorts, two components of the Wnt pathway, DKK3 and Wnt2b, were decreased (p=0.0004/0.009). Fibronectin-1, a major regulator of ECM, was identified as a hub gene in VC and showed reduced abundance in children with CKD5 (p=0.001). Arteriolar osteoglycin, involved in ectopic bone formation, was increased in CKD5 (p<0.001).

Conclusions: Arteriolar microcalcifications are already present in young children with CKD5. We provide a comprehensive analysis of underlying molecular pathways and identified processes involved in vascular remodeling which open new avenues for potential therapeutic targets.

Prospective Validation of the PERSEVERE-II AKI Prediction Model in Pediatric Septic Shock

Natalja L. Stanski,[1,2] Stuart Goldstein.[1,2] *[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [2]University of Cincinnati, Cincinnati, OH.*

Background: Treatment of sepsis-associated AKI (SA-AKI) is supportive, without effective therapies. Identification of patients at risk for severe SA-AKI could facilitate targeted kidney protection and enrich future trials. We derived the multi-biomarker PERSEVERE-II AKI Model that predicts Day (D) 3 severe SA-AKI with strong test characteristics (AUC 0.95, 95%CI 0.92-0.98, sensitivity 92%, specificity 89%). We aimed to prospectively validate this tool.

Methods: Secondary analysis of a prospective study of patients aged 0-25 admitted to 11 PICUs with septic shock from 3/19 to 12/22. D1 PERSEVERE biomarker values (C-C chemokine ligand 3, granzyme B [GZMB], heat shock protein 70 kD 1B [HSPA1B], IL-8 and MMP8) were combined with platelet count to assign a PERSEVERE-II mortality probability (PII MP). D1 KDIGO Stage, PII MP, GZMB, HSPA1B and IL-8 levels were used to assign a D3 severe AKI probability (**Figure 1**). Model performance was assessed and compared to D1 serum creatinine (SCr) elevation.

Results: Seventy-nine of 363 subjects (22%) had D3 severe AKI. The model predicted D3 severe AKI with an AUC 0.89 (95%CI 0.85-0.93), sensitivity 77% (95%CI 66-86) and specificity 88% (95%CI 84-92). Compared to subjects with D1 SCr-based AKI, those predicted to have severe AKI by the model (n=94) had more D3 severe SA-AKI (65% *vs* 45, p=0.003) and kidney replacement therapy use (40% *vs* 26%, p=0.021), and lower rates of renal recovery from early AKI (37% *vs* 53%, p=0.019) (**Figure 2**). Model performance was superior to D1 SCr elevation above baseline (p=0.004).

Conclusions: We have prospectively validated the PERSEVERE-II AKI Model for prediction of D3 severe AKI in pediatric septic shock. The next step to translating this tool to the bedside is timely biomarker availability.

IFNγ-Induced APOL1 Expression and Pyroptotic Angiopathy in Human Kidney Organoids Mirrors a Nephrotic Gene Signature in Patient Biopsies

Benjamin A. Juliar,[1] Ian B. Stanaway,[1] Kelly D. Smith,[1] Jennifer L. Harder,[2] Sean Eddy,[2] Matthias Kretzler,[2] Jonathan Himmelfarb,[1] Benjamin S. Freedman.[1] *[1]University of Washington School of Medicine, Seattle, WA; [2]University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: The cytokine interferon-γ (IFNγ) is an essential mediator of the innate immune response, including induction of apolipoprotein L1 (APOL1). Risk variants of APOL1 can cause glomerular nephropathy in coordination with inflammatory stimuli, but how distinct nephron segments are affected by IFNγ itself during glomerular disease progression remains poorly characterized.

Methods: Cell-type dependent changes in organoid gene expression and morphometrics were quantified with single-cell RNA sequencing and quantitative fluorescence-based assays. RNA-sequencing of kidney biopsies quantified relative differences in gene expression between patient cohorts depending on disease severity.

Results: IFNγ-mediated expression of APOL1 in wild-type kidney organoids was accompanied by endothelial network degradation (**Fig1A**) and upregulation of pyroptosis-associated genes across organoid cell types, especially endothelial cells (ECs) (**Fig1B**). Transcriptional profiling identified a similar pyroptotic gene signature in biopsies from patients with poor clinical outcomes. Pharmacological blockade of IFNγ signaling inhibited APOL1 expression, prevented upregulation of pyroptosis-associated genes, and rescued the endothelial network in organoids.

Conclusions: Our results suggest that simultaneous triggering of endothelial insult and epithelial priming towards pyroptosis by IFNγ may synergistically contribute to APOL1-mediated disease progression (**Fig2**), which can be targeted therapeutically.

Funding: Other NIH Support - NIH Awards: U01DK127553, UG3TR003288, UC2DK126006. Department of Defense Award: W81XWH2110007, Other U.S. Government Support

Plasma Proteome Profiling for Remission Diagnosis in ANCA Vasculitis

Ralph Kettritz,[1,2] Uwe Jerke,[1] Marieluise Kirchner,[3] Theda U. Bartolomaeus,[1] Maximilian Ebert,[1] Lovis Kling,[1] Sofia K. Forslund,[1] Philipp Mertins,[3] Kai-Uwe Eckardt,[2] Adrian Schreiber.[1,2] *[1]Experimental and Clinical Research Center (ECRC) and Max Delbrück Center for Molecular Medicine (MDC) in the Helmholtz Association and Charité, Berlin, Germany; [2]Nephrology and Medical Intensive Care, Charité, Berlin, Germany; [3]Core Unit Proteomics, Berlin Institute of Health (BIH) at Charité and MDC, Berlin, Germany.*

Background: Systemic anti-neutrophil cytoplasmic autoantibody (ANCA)-associated vasculitis (AAV) requires intensive immunosuppressive treatment that is deescalated once patients achieved remission. Thus, reliably diagnosing remission has therapeutic implications but remains challenging. We hypothesized that the plasma proteome harbors objective information that may assist clinicians in diagnosing AAV remission.

Methods: Plasma proteomes from 50 healthy controls (HC), 59 active, and 55 remission AAV patients were analyzed with LC-MS/MS based proteomics. For data analysis, a machine learning pipeline was established, containing confounder analysis, LASSO regression and Likelihood ratio test. After "leave-one-out" validation the final biomarker combination for ANCA disease status assignment was tested on the 20/80 data split.

Results: From 970 identified proteins, 605 passed the quality check for quantification and 325 were differently expressed. The principal component analysis showed excellent separation of active and remission AAV patients. Using machine learning, we identified a 5-protein biomarker combination with the potential to separate active AAV from remission patients, namely leucine-rich alpha-2-glycoprotein 1, beta-2-microglobolin, insulin-like growth factor-binding protein 3, tenascin X, and alpha-2-HS-glycoprotein. Assessing all AAV patients, the 5-protein panel showed an AUC of 0.94 with a negative predictive value (NPV) of 87.5% and performed better than ANCA titer (AUC 0.75, NPV 63.6%) or c-reactive protein (CRP) (AUC 0.91, NPV 73.3%) using a binary logistic regression model of remission diagnosis. In challenging remission patients with positive ANCA, the panel was the better classifier compared to CRP (AUC 0.96, NPV 85.7% versus AUC 0.92, NPV 75.0%), and better than ANCA in challenging remission patients with increased CRP (AUC 0.82, NPV 83.3% versus AUC 0.68 without any value in diagnosing remission).

Conclusions: Using proteomics combined with machine learning, we identified a protein signature that may assist clinicians in diagnosing AAV remission and guiding immunosuppressive treatment.

Development of Novel Selective DDR1 Inhibitors with the Potential to Treat CKD

Nicolas E. Guisot, Daniel J. Wilcock, Inder Bhamra, Kay Eckersley, Gayle E. Douglas, Kelvin Ho, Cliff Jones, Daniel J. Leng, Jack W. Lloyd-Weston, Amy B. Marshall, Helen Mckeever, Caroline Phillips, Shân Preece, James Ryan, Robert J. Street, Richard Armer. *Redx Pharma plc, Macclesfield, United Kingdom.*

Background: Discoidin domain receptors (DDRs) are collagen-activated receptor tyrosine kinases which have been shown to have increased expression in many fibrotic diseases. Inhibition or knockout of DDR1 has previously been shown to decrease fibrosis and protect kidney function in multiple preclinical mouse models of kidney fibrosis. However, to date there are no approved selective inhibitors of DDR1 in the clinic. In this study, the protective role of REDX-DDR1, a novel and selective orally bioavailable small molecule inhibitor of DDR1 was investigated in a mouse unilateral ureteral obstruction (UUO) model.

Methods: For therapeutic intervention, mice were subjected to UUO and subsequently from day 5 to treatment with vehicle, REDX-DDR1 *via* oral gavage. Animals were sacrificed at day 10 and kidneys were collected and processed for histological analysis of collagen deposition and myofibroblast transformation in stained tissue sections.

Results: REDX-DDR1 exhibits nanomolar potency in cells and target engagement in the kidney as measured by suppression of phospho-DDR1. REDX-DDR1 is highly selective when tested against a panel of 468 kinases. REDX-DDR1 has a favourable *in vitro* and *in vivo* ADME profile including good *in vivo* exposure across species and low potential for drug-drug interactions. Early safety pharmacology assessment showed no findings in standard ion channel panels. *In vitro* genetic toxicology showed no genotoxic findings in 5-strain Ames test. The favourable selectivity and pharmacokinetic profiles of REDX-DDR1 allow for selective inhibition of DDR1 in mouse models of chronic kidney disease. Animals treated with REDX-DDR1 had a significant reduction in histological markers of inflammation and fibrosis in the therapeutic mouse UUO model. REDX-DDR1 suppressed inflammation and fibrosis as measured by F4/80, α-SMA and PSR respectively. In addition REDX-DDR1 suppressed a number of pro-fibrotic genes.

Conclusions: These data show that selective inhibition of the DDR1 receptor via REDX-DDR1 results in anti-fibrotic efficacy in the UUO model. Selective inhibition of DDR1 represents an attractive approach for further investigation towards the development of new treatments for CKD.

Spatial Metabolomics Identifies Novel Glomerular Metabolite Signatures of Normal and Diabetic Kidneys

Leila Hejazi,[1,2] Shoba Sharma,[1] Aaron Ruiz,[1] Guanshi Zhang,[2] Fabio C. Tucci,[3] Kumar Sharma.[2] *[1]SygnaMap, San Antonio, TX; [2]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [3]Epigen Biosciences Inc, San Diego, CA.*

Background: The Zucker Diabetic Fatty (ZDF) rat is a model of type 2 diabetes as it develops pathologic changes in the glomerulus similar to human disease. Untargeted matrix-assisted laser desorption/ionization (MALDI) - mass spectrometry imaging (MSI) can be a powerful platform to identify metabolic pathways linked to pathologic features. However, quantification of metabolites from specific regions of interest in an unbiased manner via MALDI-MSI is challenging. MSI-DeepPath is a new computational platform that enables spatial quantitation of metabolites.

Methods: Control and ZDF male rats (age 6 mo, n=3/group) were used for the current study. Spatial metabolomic analysis of glomeruli in Control and ZDF rat kidneys was performed using MALDI-MSI at 20 µm spatial resolution from replicate samples per animal. Metabolites were detected at mass accuracy <2 ppm using Q-Exactive orbitrap MS followed by annotations using METASPACE. SygnaMap's MSI-DeepPath computational platform was used to register each glomerulus in a section to the corresponding MSI pixels and then quantify the annotated metabolites per glomerular pixel.

Results: Of 1600 metabolites annotated at m/z range 70-500 Da the top features were selected by ranking individual metabolite intensity per pixel in the normal and the diabetic groups. The top metabolite in normal glomeruli was L-glutamic acid and in diabetic glomeruli was D-glucose. Based on the top 20 enriched metabolites, the most prominent pathway in the normal glomeruli was Arginine biosynthesis whereas the most prominent pathway in the diabetic glomeruli was Glyoxylate and dicarboxylate metabolism.

Conclusions: For the first time, MSI-DeepPath enables quantification of spatial metabolomics of glomeruli using untargeted MALDI-MSI data. With MSI-DeepPath-based analysis of kidney sections from the ZDF rat, we identified that Glyoxylate-dicarboxylate metabolism was the most prominent pathway in the diabetic glomeruli. As glyoxylate is a highly reactive aldehyde and can be nephrotoxic via conversion to oxalate, further studies on glomerular glyoxylate-dicarboxylate metabolism will shed new light on its potential role in diabetic glomerular disease.

Single-Nucleus Transcriptome Profiling of the Kidney Glomerulus Identifies Cell-Specific Responses in an Autoimmune Mouse Model of Membranous Nephropathy

Ming Huang,[1,2] Annabel Schnarre,[1,2] Saskia-L. Jauch-Speer,[3,4] Shun Lu,[1,2] Shuya Liu,[1,2] Varshi Sivayoganathan,[1,3] Christian F. Krebs,[1,3] Tobias B. Huber,[1,2] Gunther Zahner,[1,2] Nicola M. Tomas.[1,2] *[1]III. Department of Medicine, University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [2]Hamburg Center for Kidney Health (HCKH), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [3]Hamburg Center for Translational Immunology (HCTI), University Medical Center Hamburg-Eppendorf, Hamburg, Germany; [4]Single Cell Core Facility, University Medical Center Hamburg-Eppendorf, Hamburg, Germany.*

Background: Membranous nephropathy (MN) is the most common cause of nephrotic syndrome in adults. However, the pathogenic mechanisms remain poorly understood due to a missing comprehensive characterization of cell-specific changes during disease progression.

Methods: We developed a novel pipeline involving the gentle enrichment of glomeruli followed by single-nucleus RNA-sequencing (snRNA-seq). We applied this technique to mice with experimental autoimmune THSD7A-associated MN at different time points.

Results: We generated a transcriptomic landscape involving 91,114 single-nuclei, with >95% deriving from glomerular cells, i.e. podocytes, mesangial cells and endothelial cells (ECs). This procedure provided a high-quality dataset with only minimal technical perturbations such as stress gene activation during the single cell dissociation process. Distinct changes in gene expression specific to podocytes were identified in MN model mice. A side-by-side comparison with other snRNA-seq datasets revealed both an MN-specific gene expression profile as well as transcriptomic alterations observed also in other glomerular nephropathies. Pathways enriched in MN model mice included regulation of focal adhesion, actin cytoskeleton, cell migration, and changes in kinase activities in podocytes. We further found increased infiltration of immune cells with disease progression and a cluster of proliferating/ repairing cells mainly consisting of mesangial cells and ECs in MN model mice. Interestingly, mesangial cells and ECs were identified to participate in modulation of leukocyte transendothelial migration, cytokine signaling, and cell-cell/cell-matrix interactions, indicating the involvement of various glomerular cell types in the pathogenesis of MN.

Conclusions: Our study identifies cellular pathways underlying podocyte injury in experimental MN and provides important novel molecular insights into the pathogenesis of MN.

SA-OR93

Lymphangiogenesis Regulates the Differentiation and Function of Th1 Cells in Experimental Anti-Glomerular Basement Membrane (GBM) Crescentic Glomerulonephritis (cGN)

Danni Hu, Guangchang Pei, Gang Xu, Rui Zeng. *Division of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Increasing evidence has shown the critical role of Th1 cells in the pathogenesis of anti-GBM cGN, however, the underlying mechanism is unclear. Our previous study has reported lymphangiogenesis regulate the activation and polarization of T cells in chronic kidney diseases. However, whether lymphatic vessel endothelial cells (LECs) controls the differentiation of Th1 cells in anti-GBM cGN remains unknown.

Methods: To address this question, we established the selective proliferating lymphatic vessel knockout mice for experimental anti-GBM cGN. Single-cell RNA sequencing, Bulk RNA sequencing and histological methods were used to investigate the immunopathological features of various renal T cells in anti-GBM cGN. Intra-renal LECs were obtained through multicolor flow cytometry and smart sequencing technology was applied to analyze the transcriptional signature of LECs.

Results: We found lymphangiogenesis is actively involved in anti-GBM cGN. Deletion of proliferated LECs protects against anti-GBM cGN. Most significantly, the proportion of Th1 cells in the LECs knockout mice decreased with a significantly down-regulated interferon response. Smart sequencing analysis on LECs revealed that the expression of IFN-γ which promotes Th1 differentiation increased significantly in anti-GBM cGN group, but decreased in LECs knockout group. At the same time, the function of cDC1, the main effector cell to induce Th1 differentiation, changes from pro-inflammatory activation to regulation of tolerance. In addition, the transcriptional expression profiles of T cells enriching the signal pathways related to Th1, Th2 and Th17 cell differentiation were inhibited after LECs knockout. It is further demonstrated that LECs also produce chemokines CCL5 and XCL1 to recruit cDC1, which was reversed by LECs knockout in anti-GBM cGN.

Conclusions: Our studies reveal functionally crosstalk between LECs and T cells in anti-GBM cGN. LECs directly or indirectly involved in the chemotaxis, differentiation and activation of Th1 cells. In conclusion, the findings uncover a previously unidentified role for lymphangiogenesis in progressive immune-mediated kidney disease, implying that LECs-Th1 cell axis can be a novel and effective immunotherapy target for anti-GBM cGN.

SA-OR94

Bub1 Is a Potential Mediator of TGFβ-Induced Renal Fibrosis

Yasuhiro Onishi, Haruhito A. Uchida, Yoshimasa Sakurabu, Tomohiko Asakawa, Katsuyoshi Katayama, Yoshiko Hada, Hidemi Takeuchi, Keiko Tanaka, Ryoko Umebayashi, Jun Wada. *Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama, Japan.*

Background: Budding Uninhibited by Benzimidazole 1 (Bub1) is a widely conserved eukaryotic kinase and Bub1 gene-deficient mice are embryonic lethal. Bub1 has long been recognized to localise to the centromere in mitosis as a component of the spindle checkpoint complex and to regulate chromosome segregation. Meanwhile, on siRNA screening targeting human kinases against cancer cell lines, it has been suggested that Bub1 may co-activate with TGFβ receptors to regulate SMAD2/3 phosphorylation. Since TGF-β/SMAD pathway is a major pathway in fibrosis, it is assumed that Bub1 may be involved in development of fibrosis as a novel mediator of the TGF-β/SMAD pathway. These findings are limited to cancer cell lines, therefore, it remais unknown whether similar events will be identified in the kidney.

Methods: The expression and localization of Bub1 was confirmed in the kidney of wild type (BL6) mice. To generate conditional Bub1 knockout mice, the $Bub1^{fl/fl}$ mice were crossed with gGT-Cre mice or FSP1-Cre mice. Renal fibrosis was induced in 8-10 week old male conditional Bub1 knockout mice by unilateral ureteral obstruction (UUO) model. In vitro, human renal proximal tubular epithelial cells (HK-2) were cultured, then Bub1 knockdown was performed by siRNA transfection.

Results: In wild-type mice, Bub1 was expressed in renal tubular epithelial cells by immunofluorescence staining with LTA. The Bub1 staining was diminished in conditional Bub1 renal knockout mice. Renal fibrosis and the expression of aSMA induced by UUO were attenuated in the mice with Bub1 proximal tubular cells (PTCs) knockout compared to wild type mice. On the other hand, the renal fibrosis induced by UUO in the mice with Bub1 fibroblasts knockout was not changed compared to wild type mice. Furthermore, knockdown of Bub1 in HK-2 cells attenuated the phosphorylation of SMAD3 by TGF-β stimulation.

Conclusions: These results uncovered that Bub1 deficiency of renal proximal tubular cells plays a protective role in renal fibrosis triggered by UUO via TGF-β/SMAD pathway.

SA-OR95

Protective Role of RBPjk in HIV-Related CKD

Madhulika Sharma, Nicole Sommer, Mackenzie Thornton. *University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS.*

Background: The Notch signaling is activated in HIV-associated Nephropathy. The Notch signaling is initiated when a ligand binds to a Notch receptor and leads to cleavage and translocation of the Notch intracellular domain (NICD) into the nucleus. NICD binds to RBPjk and converts it into a transcriptional activator from a repressor and leads to activation of Notch downstream targets. The HIV-LTR promoter contains two RBPjk binding sites. It is thought that RBPjk is a repressor of HIV-LTR. This would imply counterintuitive roles of Notch and RBPjk in HIV-related diseases. Here we investigate for the first time the *in vivo* roles of RBPjk in regulating the podocyte and myeloid-specific HIV gene expression.

Methods: The Tg26 mice harbor the active HIV-LTR promoter in many cells/tissues. Tg26 mice were bred with floxed RBPjk mice. The resulting mice were further bred with mice harboring *podocin-cre* or *lysM-cre* promoters to drive the RBPjk deletion in podocytes or myeloid precursors, respectively. The resulting mice, Tg26: RBPjkKO-Pod or Tg26:RBPjkKO-LysM were compared with normal or Tg26 mice. Renal disease severity was assessed by histology, renal function and inflammation assessment. *Nef* gene expression served as a measure of HIV-LTR activity.

Results: Deletion of RBPjk alone in podocytes led to disease aggravation and early lethality in Tg26 mice. Compared to Tg26 mice, Tg26:RBPjkKO-Pod mice exhibited increased collapsing glomerular phenotype, focal segmental glomerulosclerosis, blood urea nitrogen, tubular dilations and fibrosis. There was an increase in inflammatory markers IL6 and MMP10. NFkB (p65) was drastically elevated in the glomerular and tubular compartments. RBPjk deletion in podocytes of Tg26 mice did not affect N3ICD expression. Moreover, a significant increase in the *nef* expression was observed. Similarly Tg26:RBPjkKO-LysM mice had increased disease severity compared to Tg26 mice but less than Tg26:RBPjkKO-Pod mice.

Conclusions: RBPjk deletion in podocytes may be sufficient to activate the HIV-LTR promoter which increases expression of HIV genes leading to inflammation and disease aggravation. This indicates a non-canonical Notch signaling activation and Notch-independent roles of RBPjk in HIV-related diseases. Elucidating these mechanisms are important for treatment strategies and add to our understanding of the latency caused by HIV in people treated with antiretroviral therapy.

SA-OR96

Changes in Gene Expression in Fatty Acid Metabolism and De Novo Lipogenesis Are Conserved in Human CKD and Animal Models

Lauren Elizabeth Lee,[1] Tomohito Doke,[1,2] Dhanunjay Mukhi,[1,2] Li Zeng,[1,2] Katalin Susztak.[1,2] *[1]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [2]Department of Genetics, University of Pennsylvania, Perelman School of Medicine, Philadelphia, PA.*

Background: Lipid accumulation has been consistently observed in kidneys of patients and animal models of kidney disease. Altered fatty acid oxidation (FAO) and de novo lipogenesis (DNL) signaling are proposed to drive the fatty kidney's transition to kidney disease. However, changes in lipid composition and mechanisms of lipid accumulation that specifically drive alterations in FAO, DNL, and lipid uptake have not yet been characterized in unbiased manner.

Methods: We collected control (healthy) and diseased (diabetic and hypertensive kidney disease) human kidney samples from surgical nephrectomies. Demographics, clinical information, and estimated Glomerular Filtration Rate (eGFR) were collected, and histological analysis was performed by our renal pathologist. We analyzed gene expression changes in 405 microdissected human kidney tubule samples by RNA sequencing (RNA-seq). Bulk RNA-seq data from 3 mouse induced CKD models–unilateral ureteral obstruction (UUO, n=3), folic-acid induced nephropathy (FAN, n=3), and tubule-specific deletion of mitochondrial transcription factor A (TFAM, Ksp-Cre/$Tfam^{flox/flox}$, n=3)–was generated. Furthermore, an unbiased metabolomics analysis was performed on both human and mouse kidney samples using the Metabolon platform.

Results: Kidney metabolomics data indicated complex changes in lipid levels. We observed accumulation of glycerophospholipids in diseased kidney samples. Transcripts related to FAO (ACOX1, ACOX2, CPT1, CPT2, ESRRA, FABP, HADHA, HADHB, PGC1a, PPARa, SLC25A20) were lower in kidneys of mouse CKD models. Their expression levels positively correlated with kidney fibrosis and negatively correlated with eGFR. Genes associated with DNL genes (ACSS2, ChREBP, SCAP) showed higher expression in mouse kidney disease models; their expression levels negatively correlated with fibrosis and slightly positively correlated with eGFR.

Conclusions: Unbiased metabolomics and gene expression analysis of human and mouse kidneys indicated increased lipid accumulation in diseased kidneys. Decrease in FAO and to some degree an increase in DNL likely contribute to lipid accumulation.

Humanized IGHA1 Mouse Induced by Lactobacillus casei Cell Wall Extract: A Novel Galactose-Deficient Immunoglobulin A1 (IgA1) Elevated Mouse Model of IgA Nephropathy

Run Li,[1] Manliu Wang,[1] Xinfang Xie,[2] Wenmin Tian,[3] Yong Zhang,[4] Jingyi Li,[1] Yaping Dong,[1] Jincan Zan,[1] Jing Jin,[5] Jicheng Lv,[1] Hong Zhang.[1,6] *[1]Peking University First Hospital; Key Laboratory of Renal Disease, Ministry of Health of China; Key Laboratory of CKD Prevention and Treatment (Peking University), Ministry of Education, Beijing, China; [2]Department of Nephrology, The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an, China; [3]Department of Biochemistry and Biophysics, Center for Precision Medicine Multi-Omics Research, School of Basic Medical Sciences, Peking University Health Science Center, Beijing, China; [4]Institutes for Systems Genetics, West China Hospital, Sichuan University, Chengdu, China; [5]Department of Medicine, Division of Nephrology and Hypertension, Feinberg Cardiovascular and Renal Research Institute, Northwestern University Feinberg School of Medicine, Chicago, IL; [6]Research Units of Diagnosis and Treatment of Immune-mediate Kidney Disease, Chinese Academy of Medical Sciences, Beijing, China.*

Background: IgA nephropathy (IgAN) is the most common primary glomerulonephritis in the world. A 'multi-hit' hypothesis has been proposed to explain the pathogenesis of IgAN and galactose-deficient IgA1 (Gd-IgA1) was defined as the first hit. In this study, we constructed a novel Gd-IgA1 elevated mouse model with typical histopathology features of IgAN, by immunizing the immunoglobulin heavy constant alpha 1 knock-in ($IGHA1^{+/+}$) mice with *Lactobacillus casei* Cell Wall Extract (LCWE).

Methods: $IGHA1^{+/+}$ mice were generated by replacing the endogenous mouse *Igha* gene with the human *IGHA1* gene via a CRISPR/Cas9 system. 2-month-old male $IGHA1^{+/+}$ mice were injected i.p. with either 0.5mg/g LCWE plus complete Freund's adjuvant (CFA) or PBS eight times. 8-month-old mice were euthanized for further examination.

Results: $IGHA1^{+/+}$ mice expressed human IgA1 heavy chain instead of mouse IgA. Human IgA, human IgA-mouse IgG complex, and CD89-binding pIgA1 complex levels were significantly increased from 4 months old in the serum of $IGHA1^{+/+}$ mice induced by LCWE plus CFA compared with PBS. Meanwhile, as observations continued, the

serum Gd-IgA1 absolute value and relative proportion to hIgA1 increased 4 times in IGHA1$^{+/+}$-LCWE mice. We quantitatively analyzed the *O*-glycopeptides of human IgA1 hinge region (HR) using LC-MS analysis and found HR from IGHA1$^{+/+}$-LCWE mice showed hypo-galactosylation than IGHA1$^{+/+}$-PBS mice. IGHA1$^{+/+}$-LCWE mice showed a continuous and stable human IgA1 (positive rate: 100%) kidney mesangial deposition with C3 co-deposits (positive rate: 81.25%) until 8 months old. Histology demonstrated a significant rise in mesangial expansion and hypercellularity. Electron microscopy showed typical mesangial electron-dense deposits in IGHA1$^{+/+}$-LCWE mice.

Conclusions: We established a novel serum Gd-IgA1 elevated mouse model presenting typical pathological characteristics of IgAN, which will be used to further explore the mechanisms and new therapeutic strategies.

Revolutionizing Kidney Transplantation Education: Evaluating ChatGPT's Accuracy on Core Questions

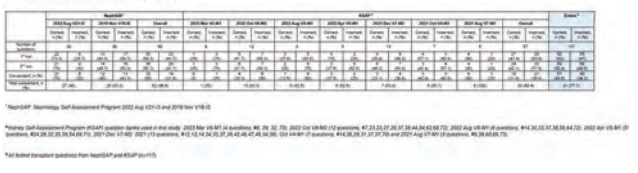
Oscar A. Garcia Valencia, Andrew J. Bentall, Naim S. Issa, Mireille El Ters, Iasmina Craici, Charat Thongprayoon, Paul W. Davis, Wisit Cheungpasitporn. *Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.*

Background: ChatGPT is a state-of-the-art, high-capacity language model that has shown proficiency in various processing tasks, such as generating responses resembling those of human beings. While there is growing speculation about ChatGPT serving as a potential substitute for physicians in a clinical environment, its proficiency in clinical subspecialties remains unclear. The aim of this study is to evaluate the performance of ChatGPT in answering questions related to kidney transplantation.

Methods: We conducted an evaluation of ChatGPT's accuracy in answering questions related to kidney transplantation using the Nephrology Self-Assessment Program and Kidney Self-Assessment Program of the American Society of Nephrology (ASN). Questions containing images were excluded due to current limitations in ChatGPT's image processing capabilities. A total of 117 questions were included in the evaluation, 60 from NephSAP and 57 from KSAP. Each question bank was executed twice using ChatGPT (Mar 14 version, OpenAI), and the level of concordance between the runs, conducted 2 weeks apart, was determined.

Results: On the 60 NephSAP questions, ChatGPT achieved accuracies of 58.3% and 58.3% on the 1st and 2nd runs, respectively, with an overall concordance of 86.7%. Similarly, on the KSAP question banks (57 questions), the accuracy of ChatGPT was 47.4% and 42.1% on the 1st and 2nd runs, respectively, with a concordance of 68.4%. The overall concordance between the two runs was 77.8%. The concordance in correct answers was found to be higher than that of incorrect answers (43.6 vs 34.2%).

Conclusions: Upon evaluating ChatGPT's performance in answering questions related to kidney transplantation, we found that its accuracy was below the passing threshold set by the ASN for both Nephsap and KSAP. Excluding questions with clinical images, the overall accuracy of ChatGPT (Nephsap + KSAP) was found to be 53% on the 1st try and 50.4% on the 2nd one. From this we conlclude that the current version of ChatGPT is not yet a reliable medical education tool for training nephrologists, and requires further development.



TH-PO002

Assessing Drug Interactions with Tacrolimus: Evaluating ChatGPT as a Promising Resource for Drug Interactions with Tacrolimus

Oscar A. Garcia Valencia, Andrew J. Bentall, Naim S. Issa, Mireille El Ters, Iasmina Craici, Charat Thongprayoon, Carrie A. Schinstock, Wisit Cheungpasitporn. *Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.*

Background: Tacrolimus is the most common immunosuppressant in kidney transplant recipients. However, its blood concentration can be affected by other medications and thus, assessing drug interactions is essential to optimize its efficacy and minimize toxicity. ChatGPT is a high-capacity language model proficient in natural language processing tasks. This study aims to evaluate the accuracy of ChatGPT in assessing drug interactions involving tacrolimus.

Methods: We used the Micromedex Drug Interactions and Lexicomp databases to evaluate ChatGPT's ability to correctly assess if a drug interaction with Tacrolimus was present and in what direction should the tacrolimus dose be adjusted. A total of 79 drugs were chosen based on the risk rating of D (consider therapy modification) or X (avoid combination). Each question was executed twice using ChatGPT (03/2023, OpenAI), and we determined the concordance between the 2 runs, conducted 2 weeks apart. An additional assessment was conducted using ChatGPT to draw a conclusion from our study.

Results: The overall accuracy of ChatGPT in assessing the presence of drug interactions with tacrolimus was found to be 96% on the 1st run and 98% on the 2nd run. The direction of adjustment was correct in 87% on both runs. The concordance in correct answers was 96% for the need of adjustment and 86% on the direction. ChatGPT itself acknowledged these results, emphasizing that while it exhibits promising accuracy, it should not be the sole source of information for clinical decision-making. Comprehensive and reliable assessment of drug interactions and dosing adjustments should involve consultation with additional resources and healthcare professionals.

Conclusions: ChatGPT demonstrated an accuracy exceeding 96% regarding the presence of drug interactions involving tacrolimus. However, when asked about the adjustment direction, the accuracy dropped to 87%. The integration of ChatGPT in clinical practice should be accompanied by caution and should not replace consultation with healthcare professionals or the utilization of comprehensive resources. Future steps should focus on refining ChatGPT's capabilities to ensure its safe and effective use in assessing drug interactions involving tacrolimus.

TH-PO003

The Performance of ChatGPT in CKD: An Assessment Using NephSAP and KSAP

Pajaree Krisanapan,[1,2] Supawit Tangpanithandee,[1] Oscar A. Garcia Valencia,[1] Jing Miao,[1] Charat Thongprayoon,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Thammasat University Hospital, Khlong Nueng, Thailand.*

Background: ChatGPT is an AI-powered cutting-edge language model that has demonstrated outstanding capabilities in numerous natural language processing tasks, such as producing responses that closely resemble those generated by humans. While there has been growing discussion about ChatGPT's potential to serve as a replacement for physicians in clinical contexts, its proficiency in nephrology, specifically chronic kidney disease, remains unclear. The objective of this study is to evaluate ChatGPT's accuracy in answering essential questions related to chronic kidney disease, such as diagnosis, treatment, and management.

Methods: We evaluated ChatGPT's performance using the Nephrology Self-Assessment Program (NephSAP from 2011-2019) and Kidney Self-Assessment Program (KSAP from 2020-2023) of the ASN. Questions containing images were excluded. A total of 308 questions were included, with 205 from NephSAP and 103 from KSAP. Each question bank was executed twice using ChatGPT, and agreement between the initial and subsequent runs was determined.

Results: ChatGPT's performance in chronic kidney disease fell below the minimum passing threshold of 75% set by the ASN for nephrologists. On the NephSAP question banks, ChatGPT achieved accuracies of 53.2% and 55.6% on the first and second runs, respectively, with an overall agreement of 78.1%. On the KSAP question banks, ChatGPT's accuracy was 48.5% and 44.7% on the first and second runs, respectively, with an agreement of 66.0%. The overall agreement between the two runs was 74.0%. ChatGPT's level of agreement between initial and subsequent runs was higher for correct answers compared to incorrect ones.

Conclusions: Based on these results, it can be concluded that the current version of ChatGPT is not yet a fully reliable and useful medical education tool for clinical physicians, medical students, and nephrologists, and requires further development.

TH-PO004

Unraveling ChatGPT's Performance in Addressing ESKD: Implications for Artificial Intelligence (AI)-Assisted Healthcare

Paul W. Davis, Oscar A. Garcia Valencia, Iasmina Craici, Andrea G. Kattah, Charat Thongprayoon, James R. Gregoire, John J. Dillon, Wisit Cheungpasitporn. *Mayo Clinic Rochester, Rochester, MN.*

Background: ChatGPT, an artificial intelligence language model, is at the forefront of cutting-edge technology. It has shown abilities in natural language processing tasks, producing responses resembling those crafted by human beings. While there is discourse

about the potential of ChatGPT as a substitute for physicians, its abilities in the field of nephrology, particularly in ESKD including dialysis, remains uncertain. The objective of this study is to assess the performance of ChatGPT in addressing fundamental inquiries pertaining to ESKD.

Methods: We conducted an evaluation of ChatGPT's accuracy in answering questions related to CKD, ESKD, including hemodialysis, and peritoneal dialysis, using the ASN eLEARNING CENTER (nephSAP vol1-No2 and Dialysis Core Curriculum 2021). There were 95 questions included. Each question set was executed twice using ChatGPT (Mar 14 version, OpenAI), and the level of agreement between the initial and subsequent run, conducted two weeks apart, was determined. Also, an assessment was performed using ChatGPT using the query, "Based on these findings, what is ChatGPT's performance, and is ChatGPT ready to provide answers pertaining to ESKD?"

Results: In our study evaluating ChatGPT's performance in answering questions related to CKD and ESKD, we found that on the two different question banks combined, ChatGPT achieved accuracies of 54% and 57% on the first and second runs, respectively. The overall agreement between the two runs was 71%. The study revealed that the level of agreement between the initial and subsequent runs of ChatGPT was higher for correct answers compared to incorrect ones, concordance of 46% vs 24%, respectively. Among the 28 instances where ChatGPT provided different responses, it changed from incorrect to correct in 10 questions (36%), from correct to incorrect 7 times (25%). ChatGPT acknowledged these results, further highlighting its limitations in accurately addressing questions related to ESKD.

Conclusions: The current study demonstrates that ChatGPT's accuracy in answering questions related to ESKD is below the minimum passing threshold of 75% set by the ASN for nephrologists, with an accuracy of 55% (average of the two runs), indicating the need for further development and training to improve its accuracy and consistency.

TH-PO005

ChatGPT vs. a First-Year Nephrology Fellow in Electrolyte and Acid-Base Disorders

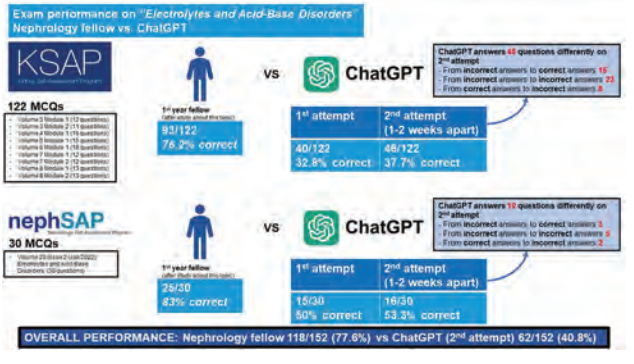
Poemlarp Mekraksakit, Pajaree Krisanapan, Iasmina Craici, Kambiz Kalantari, Charat Thongprayoon, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ChatGPT is a leading natural language processing model known for its impressive ability to generate human-like responses in various tasks. This study aims to assess ChatGPT's proficiency in addressing electrolyte and acid-base disorders in Nephrology.

Methods: In our study, we used nephSAP and KSAP, provided by the American Society of Nephrology (ASN), to assess ChatGPT's accuracy in answering basic questions about electrolyte and acid-base disorders. Questions with images were excluded as ChatGPT cannot process images. We evaluated a total of 152 questions, with 122 from KSAP and 30 from nephSAP. ChatGPT was tested twice, with the initial and subsequent runs conducted 1 to 2 weeks apart. To compare scores, we considered the performance of a first-year Nephrology fellow who extensively studied this topic. The complete set of questions can be found at https://education.asn-online.org/.

Results: In the 122 KSAP question banks, ChatGPT achieved accuracies of 32.8% and 37.7% on the first and second runs, respectively. In comparison, a first-year Nephrology fellow achieved an accuracy of 76.2%. On the nephSAP question banks, consisting of 30 questions, ChatGPT demonstrated an accuracy of 50% on the initial run and 53.3% on subsequent runs. The first-year Nephrology fellow correctly answered 83% of the questions. Notably, ChatGPT changed its answers on the second run for 56 out of 152 questions (36.8%). Out of these 56 questions, ChatGPT corrected its answers from incorrect to correct in 18 cases, but also changed its answers from correct to incorrect in 10 instances.

Conclusions: ChatGPT's proficiency in addressing electrolyte and acid-base disorders in nephrology is limited. It did not achieve the minimum passing threshold of 75% set by the ASN for nephrologists. Its accuracies were lower compared to a dedicated first-year Nephrology fellow. ChatGPT's responses were inconsistent across different runs. Therefore, ChatGPT is not a suitable replacement for human clinicians in this clinical setting.



TH-PO006

Exploring ChatGPT's Aptitude in Essential Concepts of Hypertension

Maria Lourdes Gonzalez Suarez, Gary L. Schwartz, James R. Gregoire, Stephen B. Erickson, Charat Thongprayoon, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: ChatGPT is a state-of-the-art language model with human-like response generation capacity for various tasks. While there are debates about the possibility of ChatGPT replacing clinicians in clinical settings, its competence in nephrology, specifically in hypertension, remains uncertain. This study aims to assess ChatGPT's proficiency in addressing fundamental queries related to the diagnosis, treatment, and management of hypertension.

Methods: Using the Nephrology Self-Assessment Program (NephSAP) issues 2016-2022: V15N1, V17N1, V19N1, V21N4 from the American Society of Nephrology, we conducted a rigorous evaluation of ChatGPT's accuracy in answering questions related to hypertension. We excluded questions containing images due to ChatGPT's current limitations in image processing. The analysis included 95 questions from NephSAP. Each question set was executed 3 times using ChatGPT (version Mar 14, OpenAI), and we determined the level of agreement between the initial and subsequent attempts, conducted 2 weeks apart.

Results: Our analysis revealed that ChatGPT achieved accuracies of 65.5% on first attempt, and 76.4 and 78.1 % on second and on third attempts, respectively, for the NephSAP questions. We noted that ChatGPT had a higher level of correct answers compared to incorrect ones, and it improved its knowledge after every attempt (table 1).

Conclusions: Our findings indicate that ChatGPT's accuracy in addressing core concepts related to hypertension management falls below the minimum passing threshold of 75% established by the ASN for nephrologists, with an initial accuracy rate of 65.5%. This emphasizes the need for further development and training to improve ChatGPT's accuracy and consistency in the area of hypertension. Our study's outcomes have significant implications for ChatGPT's potential use as an educational tool for clinicians, highlighting the importance of ongoing research and development to broaden its proficiency in clinical subspecialties.

Accuracy of ChapGPT on Hypertension Questions

KSAP Issue	First Attempt, (%)	Second Attempt, (%)	Third Attempt, (%)
V15N1	62	75.9	79.3
V17N1	83.3	93.3	93.3
V19N1	53.3	63.3	66.6
V21N4*	63.3	73.3	73.3
Total accuracy	65.48	76.45	78.12

The Accuracy of Artificial Intelligence in Identifying Potentially Harmful Non-Prescription Medications and Dietary Supplements in Patients with Kidney Diseases

M. Salman Sheikh, Erin F. Barreto, Benjamin Dreesman, Fawad Qureshi, James R. Gregoire, Stephen B. Erickson, Charat Thongprayoon, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: Search engines are commonly used to obtain health-related information, including information about drug safety. Non-prescription medications and supplements are generally perceived as safe, however, may be harmful to patients with kidney diseases. ChatGPT is a cutting-edge language model that has gained attention for its potential to improve clinical decision making. Its ability to serve as a drug information resource for patients with kidney disease has not been determined. This study aimed to evaluate ChatGPT's accuracy in discerning the safety of medications in patients with kidney diseases when compared to Micromedex, a widely used tertiary drug information reference.

Methods: One hundred twenty-four commonly used non-prescription medications and supplements were evaluated in ChatGPT using the query "Is X potentially harmful in people with kidney disease?" The resultant output was evaluated and categorized into one of three categories: "generally safe", "potentially harmful", or of "unknown" level of harm. Safety of the non-prescription medications and supplements was also evaluated in Micromedex and categorized similarly. Concordance between the two resources was summarized.

Results: Micromedex identified 68(55%) medications as safe, 52(42%) as potentially harmful, and 4(3%) as unknown. ChatGPT identified 74(60%) medications as safe, 26(21%) as potentially harmful, and 24(19%) as unknown. The overall agreement between Micromedex and ChatGPT was 65% with ChatGPT identifying only 46% of potentially harmful medications. Supplements as a subclass had the lowest concordance between ChatGPT and Micromedex, with a rate of 56%. Among the 24 medications identified as unknown by ChatGPT, 21(87%) were supplements.

Conclusions: ChatGPT's ability to accurately assess the safety of non-prescription medications, particularly supplements, was modest in patients with kidney disease when compared to a contemporary drug information resource. The findings suggest that ChatGPT neither be considered nor recommended as a drug information resource for patients with kidney disease or their healthcare professionals. Further development would be necessary to improve its accuracy and reliability in this domain.

TH-PO008

Application of Large Language Models such as ChatGPT to Support Nutritional Recommendations for Dialysis Patients

Lin-Chun Wang,[1] Hanjie Zhang,[1] Nancy Ginsberg,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Fresenius Kidney Care, Waltham, MA; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The diversity of food preferences has increased over the past years and provides challenges to dietitians working in dialysis clinics. We explored the use of Large Language Models (LLM), such as ChatGPT, to support nutritional advice given to patients.

Methods: We applied a simple LLM syntax that allows us to consider a variety of factors that determine personalized dietary recommendations/menu options. The syntax integrates several domains, such as patient demographics (e.g., age, sex, dialysis vintage) and food preferences (e.g., vegetarian, Indian, Mediterranean, etc.), laboratory data (e.g., levels of phosphate, potassium), and clinical characteristics (e.g., weight, BMI, blood pressure). We deployed these characteristics as queries to ChatGPT (ChatGPT (openai.com)). The resulting dietary recommendations were reviewed by an experienced renal dietitian.

Results: The ChatGPT command line allowed simple input of inquiries. We were able to narrow down and personalize requests in a short dialogue with the bot, for example: "*John is a hemodialysis patient aged 65, with diabetes, CHF and fluid overload, his weight is 95 Kg, BMI is 32, his albumin is 3.5 g/dl, potassium is 4.8 mmol/L, phosphorous is 5.3 mg/dl. John likes Mediterranean food. Could you develop a few recipes for him?*" We created multiple requests for several imagined patients. The review of the bot's dietary recommendations by a renal dietitian was in general satisfactory. However, while the amount of phosphate was in target, phosphate additives were not considered by the LMM. We also explored the use of ChatGPT to create personalized dietary recommendations/menu options in different languages, such as Mandarin. The translations, as judged by native speakers, were reliable.

Conclusions: While we identified some gaps, LLMs such as ChatGPT hold promise to provide personalized nutritional guidance to diverse populations of hemodialysis patients. As a next step, exploring their application in clinical practice will be important.

Artificial Intelligence Language Processing Models in Literature Reviews for Nephrology

Supawadee Suppadungsuk,[1,2] Pajaree Krisanapan,[1,3] Supawit Tangpanithandee,[1,2] Oscar A. Garcia Valencia,[1] Charat Thongprayoon,[1] Kianoush Kashani,[1] Wisit Cheungpasitporn.[1] *[1]Mayo Clinic Minnesota, Rochester, MN; [2]Chakri Naruebodin Medical Institute, Bang Phli, Thailand; [3]Thammasat University, Bangkok, Thailand.*

Background: Literature reviews are a valuable tool for summarizing and evaluating the available evidence in various medical fields, including Nephrology. However, identifying and selecting relevant literature can be time-consuming for clinicians and researchers. ChatGPT is a novel artificial intelligence (AI) language model renowned for its exceptional ability to generate human-like responses across various tasks. However, whether ChatGPT can effectively assist medical professionals in identifying relevant literature is unclear. Therefore, this study aimed to assess the effectiveness of ChatGPT in identifying references to literature reviews in Nephrology.

Methods: We keyed the prompt "What are the references to literature reviews in Nephrology, with subgroup analysis in specific areas?" into ChatGPT (03/23 Version). We selected all provided results by ChatGPT and assessed them for existence, relevance, and author/link correctness. We recorded each resource's citations, references, authors' names, and links. The relevance of each resource was assessed by its citation index on Google Scholar.

Results: Of the total 511 references in Nephrology literature, only 319 (62.43%) of the references provided by ChatGPT existed, while 30.3% did not exist, and in 7.3% of recommendations, they were incomplete. Additionally, 208 (40.7%) of the listed authors were found to be incorrect, and the digital object identifier (DOI) was inaccurate in 357 (69.86%) of the references. Moreover, among those with a link provided, the link was correct in only 108 (21.14%) cases, and 7.4% of the references were irrelevant. Notably, analysis of specific topics in electrolyte, hemodialysis, and kidney stones found that >60% of the references were inaccurate or misleading, with less reliable authors and links provided by ChatGPT.

Conclusions: Based on our findings, the use of ChatGPT as a sole resource for identifying references to literature reviews in Nephrology is not recommended. Future studies could explore ways to improve AI language models' performance in identifying relevant Nephrology literature.

TH-PO010

Identification of Topics from Trainee Posts on Nephrology from Public Forums

Yang Dai,[1] Miriam S. Borvick,[2] Ricki Ehrenfeld,[3] Girish N. Nadkarni,[1] Lili Chan.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]University of Nevada Reno, Reno, NV; [3]Touro University, New York, NY.*

Background: Interest in a career in nephrology has waned. Career perceptions that are freely shared on social media sites may influence a trainee's decision when choosing a subspecialty. Examining topics of discussion on public forums have not previously been done.

Methods: We extracted threads from a popular online forum, the student doctor network (SDN), with titles that contained the keywords Nephrology, Nephrologist, Nephro, Dialysis, Kidney, and Renal. We removed posts with <20 words. We performed topic modeling using BERTopic. BERTopic is a topic modeling technique in the Python library that combines transformer embeddings and clustering model algorithms to identify topics using natural language process. We then manually reviewed three posts per topic to better characterize the topics. Additionally, two authors conducted a manual review of 1000 posts to gauge the underlying sentiments expressed. When disagreement occurred, a third reviewer was asked to rate the post and the most frequent category was used.

Results: We included a total of 1725 posts in our final analysis. BERTopic identified 23 topics (Figure 1A). The topics with the largest number of posts were "Nephrology responsibilities and reimbursements", "Fellowship programs mislead", and "Academic vs private practice nephrology". The top 10 topics are visualized in 2D space in figure 2B, where each point represents a post, and topics are separated by color. With manual review, 46% were classified as negative while only 6% were classified as positive. The remaining posts were unclear or irrelevant.

Conclusions: Discussions regarding nephrology careers are present on social media. Topics vary from workload to financial compensation. Unfortunately, a large proportion of posts are negative. To improve the nephrology workforce, we must address the concerns of trainees identified here.

Funding: NIDDK Support

Figure 1A: Topics and Top Words from Posts within Each Topic

Topic	Top Words
Nephrology responsibilities and reimbursements	patient, hd, dialysis, icu, kfr, use, revenue, does, nephrologists, order
Fellowship programs mislead	fellowship programs, crushed, escape, career, applicants, fourth, despite, hd, rule, post
Academic vs private practice nephrology	am, academic nephrology, penis, future, need, doctor, private practice, apply, overly, resident
Reasons not to go into nephrology	drugs, residency, hospitalist, fellowships, opportunity, body, chances, jobs, want, add
Low nephrology salaries	renal, family, hd, subspecialty, unless, dark, primary care, doctor, academic nephrology, easier
Salary and lifestyle of nephrologists	salary, starting, lighter, jobs, data, area, hospitalists, income, data, sure
Fellowship programs mislead	applicants, private practice, grads, reality, going nephrology, trap, sad, brutal, tad, financially
Fellowship interviews	interviews, applied, didn't, advice, week, grad, resident, haven't, visa, actually
Nephrologists need for household jobs	fellowship programs, applicants, sad, unfilled, telling, reality, bad, private practice, grads, reasons
Nephrology CCM	nephro, candidates, icu, offering, gonna, year, faced, possible, renal, clinical care
Nephrologists leave for household jobs	partner, groups, years, start, trap, reasons, salary, exit, reign, loss
Nephrology reimbursements not appropriate for workload	dialysis, nephrologists, busy, training, major, transplant, things, compensation, absolutely, add
Current trends and impact of Covid-19	data, percentage, am, physicians, issues, online, unfilled, continue, future, positions
Nephrology reimbursements not appropriate for workload	income, jobs, im sure, average, difference, nephrologists, hospitalists, rates, salary, huge
Do not override clinic nephrology	scientific, zoom, cardiology, apply, consultants, visuals, fellowships, year, fraud, residency
Interview tips	fun, medical, 15, joined, im sure, interviews, ago, chances, having, glad
Applicant comments of Fellowship programs	clinical, get, hospitals, university, small, good, 30, interviews, transplant, year
Match day updates	wish, places, fun im, match, outcome, bring, life, perspective, positive, year

Kidney Outcome Comparisons of Clinician Evaluated Electronic AKI Alerts

Abinet M. Aklilu, Kyle D. O'Connor, Francis P. Wilson. *Yale School of Medicine, New Haven, CT.*

Background: The personalized recommendations for hospitalized patients with Acute Kidney Injury (AKI) using a Kidney Action Team (KAT-AKI) trial is an ongoing multicenter randomized clinical trial evaluating early recommendations for AKI. It is unknown whether clinician adjudication of an electronic alert for AKI can improve AKI diagnosis.

Methods: We used data from KAT-AKI trial that utilizes an EHR alert for real-time diagnosis of AKI in hospitalized patients. The alert implements the KDIGO serum creatinine(sCr) based AKI criteria (≥50% ↑ or 0.3mg/dL ↑) in 7day and 48hour windows. A trained team of a physician and pharmacist receives an InBasket EHR alert. The team independently reviews sCr trend to adjudicate the AKI diagnosis then select agree or disagree. Patients with eGFR ≤15ml/min/1.73m^2, end-stage kidney disease or admission sCr ≥4mg/dL were excluded. We compared the distribution of ΔsCr_{72} (a difference between sCr at AKI and the maximum sCr in the subsequent 72hrs), ΔsCr_{any} (difference between AKI sCr and max sCr in the next hospital days), 14-day progression to a higher AKI stage, length of stay(LOS) between alerts flagged as AKI_{yes} and AKI_{no}. We used Wilcoxon-Rank Sum test to compare continuous variables and χ^2 test for categorical variables.

Results: Between November 2021 and April 2023, 2414 alerts were screened. The team disagreed with 431(17.9%) of EHR alerts. Baseline sCr and AKI sCr were lower in the AKI_{no} group(Table1). Median(IQR) ΔsCr_{72} was -0.02[-0.20, 0.21]mg/dL (AKI_{yes}) vs 0.00 [-0.10, 0.12]mg/dL (AKI_{no}), while ΔsCr_{any} was 0.02[0.00,0.35]mg/dL vs 0.10[0.00, 0.34]mg/dL, respectively. 14-day AKI progression was 12.6%(AKI_{yes}) vs 9.7%(AKI_{no}), p~0.099. There was no difference in LOS.

Conclusions: Real-time clinician adjudication of an AKI alert did not improve AKI diagnosis as measured by prediction of AKI persistence or progression.

Noninvasive Artificial Intelligence (AI)-Enhanced Electrocardiographic Detection of Hyperkalemia in the Emergency Department (ED) and ICU

John J. Dillon, Kan Liu, Jennifer Dugan, Jacob Jentzer, Zachi I. Attia, Paul Friedman, David M. Harmon. Nephrology/Cardiology. *Mayo Foundation for Medical Education and Research, Rochester, MN*.

Background: We have previously trained a convolutional neural network using an all-patient cohort to produce an AI algorithm that can detect hyperkalemia from the surface ECG. In this validation study, we assessed the network's performance among ED and ICU patients.

Methods: We included adult patients presenting to the ED at all Mayo Clinic sites between February and August 2021 (ED cohort) and patients admitted to the ICU at Mayo Clinic St. Mary's Hospital, Rochester, MN between August 2017 and February 2018 (ICU cohort) if they provided research authorization, had a standard 12-lead supine ECG and had a blood K value within 4 hours of the ECG. The network analyzed leads I and II of the 12-lead ECG to calculate the probability of hyperkalemia, defined as K>6 mEq/L. The ED and ICU cohorts were analyzed separately. Exploratory subgroup analyses were performed for patients with eGFR<45 ml/min and eGFR<30 ml/min.

Results: 40,128 ED patients and 2636 ICU patients were included. The prevalence of hyperkalemia was 0.9% in the ED cohort and 3.3% in the ICU cohort. The AI-ECG had AUCs of 0.88 in both cohorts with sensitivities and specificities ≥ 80%. Negative predictive values (NPVs) were >99% in both cohorts. Although positive AI-ECGs quadrupled the probability of hyperkalemia, positive predictive values (PPVs) were relatively low: 3.5% in the ED and 14% in the ICU in part due to low hyperkalemia prevalences. Low eGFR subgroups had higher hyperkalemia prevalences and higher PPVs as shown in the Table.

Conclusions: The AI-ECG demonstrated excellent discrimination with AUCs of 0.88 in both cohorts. It was highly effective at ruling out hyperkalemia with NPVs>99% in both cohorts, but with much lower PPVs, suggesting that it is most useful as a screening test to exclude hyperkalemia. One method by which PPVs can be increased is by limiting testing to high-risk populations, such as those with reduced eGFR.

Funding: Clinical Revenue Support

Machine Learning Algorithm in Predicting Non-Diabetic Kidney Disease in Type 2 Diabetes Mellitus: Development and Validation of a Noninvasive Predictor Scoring Model

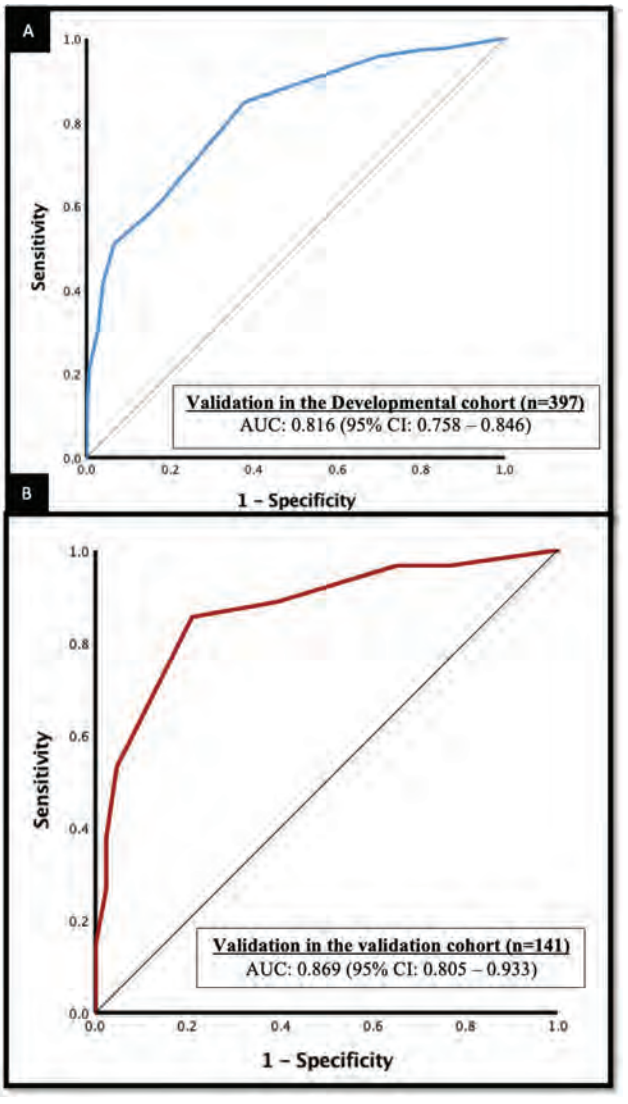
Vamsidhar Veeranki, Narayan Prasad, Jeyakumar Meyyappan. Nephro-SGPGI. *Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*.

Background: Identifying non-diabetic kidney disease (NDKD) is essential in retarding the progression of chronic kidney disease among patients with type-2 diabetes mellitus(T2DM). Renal biopsy, despite being the gold standard in detecting the presence of NDKD, has an inherent risk of life-threatening complications. The current study aims to develop a non-invasive scoring model to predict the presence of NDKD using clinical and laboratory parameters.

Methods: Patients with T2DM who underwent biopsy for various indications were included and were divided into derivational and validation cohorts. Using the variables significantly associated with presence of NDKD on biopsy on univariate analysis, a model was developed using multivariate logistic-regression based machine learning algorithm. The model was then run on the derivational(internal validation) and validation cohort(temporal-validation) and the performance was assessed by receiver operating characteristic(ROC) curve.

Results: A total of 538 patients with T2DM were included in the study analysis; 376 in derivational cohort and 162 in validation cohort. The final model consists- diabetes mellitus duration< 5 years, absence of coronary artery disease, absence of diabetic retinopathy, presence of oliguria, acute rise in creatinine, & low serum complement-C3 level significantly predicted presence of NDKD on renal-biopsy. The model performed robustly with AUC-ROC of 0.869(95%CI:0.805-0.933) in validation cohort.

Conclusions: The clinical and laboratory parameter-based prediction model robustly predicted the NDKD among T2DM patients, and a cut-off total score of ≥ 6 has a high sensitivity & specificity of 86% & 80% in predicting NDKD.



Derivation and validation of the prediction model

TH-PO014

The Renal Prognosis Prediction Model of Diabetes Nephropathy Based on Machine Learning

Chuanpeng Wang,[1] Peng Xia,[1] Ze Zhao,[2] Yubing Wen,[1] Limeng Chen.[1]
[1]*Department of Nephrology, State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing, China;*
[2]*Institute of Computing Technology, Chinese Academy of Sciences, Beijing, China*.

Background: Diabetes nephropathy (DN) has become one of the most common causes of chronic kidney disease (CKD). This study is to establish a prognosis prediction model of DN using machine learning methods.

Methods: This retrospective cohort study enrolled 247 DN patients diagnosed by renal biopsy at Peking Union Medical College Hospital from December 2012 to September 2021 and collected clinical data from the EMR system. The primary endpoint

was all-cause mortality, end-stage renal diseases (ESRD) requiring dialysis and kidney transplantation. We used maximum likelihood estimation to complete the missing data and principal component analysis to standardize the data. K-means, hierarchical, and SOM clustering were compiled in Python to classify the data set. The weight of each variable in the clustering model was measured by several model misjudgments after removing the variable. The weight Analysis was to find the potential risk factors for poor prognosis.

Results: 1. About 57.5% of patients had renal insufficiency, and 62% with massive proteinuria. A total of 100 of them reached the primary endpoint with a median renal survival time of 2 years. Multivariate Cox regression showed that the independent risk factors for renal survival included proteinuria (OR = 1.13, 95%CI (1.07, 1.20), P<0.001), grade 3 hypertension (OR = 2.55,95%CI (1.09, 5.99), P<0.031) and low eGFR (OR = 1.02, 95%CI (1.00, 1.03), P=0.043). 2. By cluster analysis, two groups of patients had significant differences in renal survival at six months (OR=3.06, 95%CI (1.05, 8.92)), 12 months (OR=4.00, 95%CI (1.65, 9.70)), and 24 months (OR=2.46, 95%CI (1.78, 3.40)), as well as 24hUP (p<0.001), urinary red blood cells (p<0.001), hemoglobin (p=0.003), and albumin (p<0.001). 3. The machine learning models using LR, xgboost, and AdaBoost have the highest accuracy of prediction results in the test set, with an accuracy of up to 87.8% and auc = 0.87; The ten characteristics with the highest weight in this model were blood chlorine, hypertension grade, creatinine, EGFR, gender, diabetes retinopathy, age since the onset of diabetes, free triiodothyronine, urinary red cells, and platelet count.

Conclusions: Machine learning models combined with patient history and laboratory examination are a potentially powerful method for predicting the DN prognosis.

TH-PO015

Impact of Retinal Photography-Based Deep Learning System on Risk Stratification for CKD Progression

Young Su Joo,[1,2] Hee Byung Koh,[1,2] Tyler H. Rim,[3] Shin-Wook Kang,[1,2] Jung Tak Park.[1,2] *[1]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea; [2]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [3]Mediwhale, Seoul, Republic of Korea.*

Background: We had previously developed a deep-learning-based risk evaluation system from retinal photographs, Reti-CKD, for stratifying chronic kidney development risk in kidney function preserved people. This study aims to evaluate whether Reti-CKD can improve risk assessment of kidney disease progression in diabetic patients with prevalent CKD.

Methods: Total of 5348 diabetic patients from two tertiary hospitals in Korea were evaluated. Patients with estimated glomerular filtration rate (eGFR) <90 ml/min/1.73m^2 or albuminuria were included. Those with missing data for retinal photograph, serum creatinine, or albuminuria were excluded. Patients were categorized into low-risk, moderate-risk, and high-risk groups according to the KDIGO criteria for prognosis of CKD. The KDIGO groups were additionally dichotomized based on Reti-CKD score (Reti-CKD <20 and ≥20). CKD progression was compared between the categories using Cox regression models. Primary outcome was CKD progression, defined as incremental progression to a higher NKF-KDOQI CKD stage.

Results: The mean age of the patients was 62.4 ± 11.4 years and 60.6% were male. Mean eGFR was 86.6 ± 15.3 mL/min per 1.73 m^2 and albuminuria was present in 46.9%. During a median follow-up of 5.0 (interquartile range, 2.5-7.8) years, primary outcome developed in 1379 (25.8%) patients. The primary outcome incidence rate gradually increased with higher KDIGO and Reti-CKD combined risk categories. The risk for CKD progression progressively increased in KDIG moderate-risk and high-risk groups compared to low-risk. When Reti-CKD was incorporated to the KDIGO category, significant stratification of CKD progression risk was noted in the KDIGO low-risk and moderate-risk groups. Additionally, the combination of KDIGO and Reti-CKD classification showed better discrimination power compared to the KDIGO only classification (delta c-statistics, 0.03; 95% CI 0.02 to 0.040).

Conclusions: Retinal photography-based deep learning system (Reti-CKD) further stratifies the risk of CKD progression and improves predictability in diabetic patients with reduced renal function.

TH-PO016

Computed Tomography Radiomics Analysis for Discrimination and Severity Assessment of Diabetic Kidney: A Retrospective Machine Learning Study

Seung Hye Chu, Soyeon Kim, Hyunjin Noh, Soon hyo Kwon. *Soonchunhyang University Hospital, Seoul, Republic of Korea.*

Background: Kidney radiomics has been evaluated for the development of accurate diagnostics tools for renal tumors. However, there is a scarcity of radiomics studies focused on diabetic kidney disease (DKD). In this study, we aimed to investigate whether computed tomography (CT) radiomics features can differentiate DKD from normal kidneys and assess the severity of DKD.

Methods: We analyzed type 2 diabetes mellitus (T2DM) patients and healthy controls (HCs) who underwent abdominal CT scans between November 2014 and November 2022. CT volumetric data of both kidneys were extracted using a deep-learning model, enabling radiomics feature extraction. T2DM patients were categorized into risk groups based on estimated glomerular filtration rate (eGFR) and degree of albuminuria. Machine learning (ML) models were used to differentiate DKD patients from HCs and classify DKD risk groups. The models were trained and evaluated on separate patient data sets, with performance metrics such as sensitivity, specificity, accuracy, and area under the curve (AUC).

Results: The study included 462 T2DM patients and 90 HCs, who were randomly assigned to a training set (n=386; mean age ± standard deviation, 60.9 years ± 16.2; 239 men) or a test set (n=166; mean age, 60.7 years ± 15.7; 91 men). A total of 1,219 radiomics features were extracted. The random forest model showed excellent performance in differentiating between HCs and patients with low-risk DKD, with an AUC of 1.00 and an accuracy of 100% in the training set and an AUC of 0.84 and an accuracy of 80.6% in the test set. It also showed a good performance in discriminating between DKD groups based on eGFR (AUCs, 0.99-1.00, in the training set; AUCs, 0.70-0.94, in the test set) (Table1).

Conclusions: CT-derived radiomics analysis of the kidneys can effectively differentiate diabetic kidneys from normal kidneys and assess the severity of DKD. These findings suggest that radiomics data capture pathological changes in the kidneys associated with diabetes.

Funding: Government Support - Non-U.S.

Table. Diagnostic performance of the radiomics models in the training and the test set

		AUC	Accuracy (%)	Sensitivity (%)	Specificity (%)
Differentiation of HC and DKD					
Training set		0.99	99.7	99.4	100
Test set		0.85	80.3	94.2	66.5

Machine Learning Classification of Kidney Biopsy Smartphone Images for Adequacy Assessment

Odianosen J. Eigbire-Molen, Clarissa A. Cassol, Shana M. Coley, Daniel J. Kenan, Johnathan O. Napier, Shree G. Sharma. *Arkana Laboratories, Little Rock, AR.*

Background: Kidney biopsy is the gold standard for diagnosis of medical renal diseases. A biopsy that yields predominantly medulla or not enough renal cortex is an unsatisfactory result. There has been a significant increase in the rate of inadequate kidney biopsies. Unfortunately, not all centers have access to trained professionals who can assess biopsy adequacy in real time. Therefore, we aim to create a machine-learning model capable of classifying smartphone images of kidney biopsy tissue as adequate or inadequate.

Methods: 747 kidney biopsy cores and corresponding smartphone macro images were obtained from unused deceased donor kidneys. Each core was imaged, formalin fixed, sectioned and stained with Periodic acid–Schiff (PAS). A photo of the fresh unfixed core was taken using the macro camera on an iPhone 13 Pro. The amount of cortex in each core (percent cortex), was determined by two renal pathologists review of the PAS sections. Biopsies with less than 30% cortex were labelled as inadequate. Biopsies with 30% or more cortex were labeled as adequate. The images were split into a training (n=643), validation (n=30), and test (n=74) sets. The preprocessing steps were converting from HEIC iPhone format to JPEG, normalizing, and detecting the renal tissue; a U-Net deep learning model was trained to segment renal tissue from the background. After preprocessing, a deep learning model was trained on the renal tissue region of interest and corresponding class label. See Figure 1.

Results: The deep learning model had an accuracy of 87% on the training data. On the test dataset, the model had an accuracy of 82%. For inadequate samples in the test dataset, the model had a sensitivity of 71%. The area under the receiver operating curve was 0.79.

Conclusions: We developed and tested a machine learning model to classify smartphone images of kidney biopsy as adequate or inadequate, based on the amount of cortex determined by a renal pathologist. With further work, such models can be deployed as a smartphone application to aid in real time assessment of renal biopsy adequacy.

Machine Learning to Predict Unplanned Dialysis in Advanced CKD

Leslie P. Wong,[1] Chenlee Condie,[1] Mark J. Durst,[1] Kristin F. Mote,[1] Jonathan Sanchez,[2] Michelle Schneider,[2] Peter Calderone.[2] Intermountain Kidney Services. *[1]Intermountain Healthcare, Salt Lake City, UT; [2]MDClone, Beer-Sheva, Israel.*

Background: Unplanned dialysis occurs when dialysis is initiated in the hospital setting and results in increased morbidity, mortality, and healthcare costs. Patients with advanced chronic kidney disease (CKD) are at higher risk for unplanned dialysis, but it is difficult to identify those who might benefit from targeted interventions. Machine learning was used to attempt to predict unplanned dialysis in a large CKD cohort.

Methods: A retrospective analysis of 15,424 patients in a large U.S. health system with stage 4 and 5 CKD between January 2018 to March 2023 was performed using the MDClone ADAMS Platform and a proprietary CKD temporal staging algorithm. Variables included age (71.4 ± 14.9 years), gender (Female, 55%), most recent eGFR (32.4 ± 16.7 ml/min/1.73m^2), count of emergency department visits in two years prior (2.2 ± 3.3), count of all clinical encounters in two years prior (33.3 ± 35), BMI (30.2 ± 9.8), hypertension (77.3%), diabetes (58.6%), obstructive sleep apnea (34.1%), peripheral arterial disease (32.7%), and systolic blood pressure (134.4 ± 24.4 mmHg). XGBoost, a gradient boosting algorithm, was employed to predict unplanned dialysis events.

Results: The model's performance predicting unplanned dialysis was evaluated using accuracy, precision, recall, and F1 score metrics. The model achieved accuracy of 90.5%, precision of 55.2%, and recall of 54.7%, resulting in a F1 score of 0.55. Discrimination was high with an AUC 0.89 (Figure 1).

Conclusions: The model developed using a XGBoost machine learning algorithm demonstrated high accuracy and discriminatory power to identify stage 4 and 5 CKD patients at risk for unplanned dialysis. This predictive model has potential to help guide targeted interventions to prevent these events in the advanced CKD population.

Machine Learning-Based Risk Prediction Model for ICU Survival After Continuous Renal Replacement Therapy Initiation: A WEROCK Study

Shina Menon,[1,2] Sameer Thadani,[5] Katja M. Gist,[3] Danielle E. Soranno,[4] Danny T. Wu.[3] WE-ROCK. *[1]University of Washington, Seattle, WA; [2]Seattle Children's Hospital, Seattle, WA; [3]Cincinnati Children's Hospital Medical Center, Cincinnati, OH; [4]Indiana University School of Medicine, Indianapolis, IN; [5]Baylor College of Medicine, Houston, TX.*

Background: Continuous renal replacement therapy (CRRT) is preferred in critically ill pediatric patients with acute kidney injury (AKI) and/or fluid overload (FO). Prediction of clinical outcomes in patients on CRRT is challenging given heterogeneous clinical practices and study population. Our aim was to predict survival to intensive care unit (ICU) and hospital (HOSP) discharge using machine learning (ML) techniques.

Methods: The Worldwide Exploration of Renal Replacement Outcomes Collaborative in Kidney Disease (WE-ROCK) study is a retrospective international multicenter study (32 centers, 7 nations). Our methods have been published previously. We included 991 patients aged 0-25 years treated with CRRT for AKI and/or FO from 2018-2021. Primary outcomes were survival to ICU and HOSP discharge. Feature selection was done manually through team discussions, resulting in 61 out of 119 demographics variables. The data were split into training(80%) and testing(20%) subsets. The ML process included 5 algorithms (Logistic Regression with L2 regularization, Decision Tree, Random Forest, Gradient Boosting Machine, and Support Vector Machine with linear kernel) and used 5-fold cross validation to train the models. The model performance was determined by the Area Under the Curve of the Receiver Operating Characteristic (AUCROC). The performance of the best trained model on the testing dataset was reported using standard metrics (Table 1).

Results: Random Forest was our highest performing algorithm. Table 1 shows that our models (WE-ROCK) achieved comparable or slightly higher AUROC compared to previous studies in adults.

Conclusions: This is the first ML model to predict survival to ICU and hospital discharge in pediatric patients requiring CRRT. The performance was similar to previously published models in critically ill adults. We will continue refining our models by expanding the input variables, conducting a more sophisticated feature selection, experimenting advanced ML and deep learning algorithms.

Source	Best Model	AUC	Sensitivity	Specificity	Precision	Accuracy	F1-score
Survival to ICU discharge

Early Identification of the Need for CRRT in Children: A Machine Learning Approach

Shina Menon, Qingyang Li, David R. Van De Sompele, Alexander J. Doud, Kin L. Vong, Hillary Bourdrez, Mark W. Wainwright. *Seattle Children's Hospital, Seattle, WA.*

Background: Continuous Renal Replacement Therapy (CRRT) is the preferred modality of renal replacement in critically ill children with acute kidney injury. We sought to develop a machine learning (ML) model to identify patients at least one day before the CRRT initiation.

Methods: We used data from patients admitted to the pediatric ICU with a length of stay >24 hours from 2008-2021. Candidate data elements were selected based on clinical expertise and anticipated United States Core Data for Interoperability requirements. To address the class imbalance problem, we oversampled data from the CRRT patient group and then selected using a random 24-hour window preceding the outcome of interest for each new sample. By including test cases with data collected 1 day before the CRRT decision, this process ensures earlier identification of the need for CRRT. We engineered features by vectorizing the patient state and then selected features using correlation-based feature selection (CFS) and information gain (IG) feature selection in combination with 5 methods of classification: random forest, logistic regression, Naïve Bayes (NB), support vector machine, and extreme gradient boosting. Data curation, analyses and development were conducted using Python (version 3.9).

Results: 19457 PICU encounters (159 received CRRT) were identified and stratified into training(85%) and test(15%) sets after data augmentation. Models constructed using IG contained 436 features versus 42 features using CFS. The top features included blood urea nitrogen, creatinine, platelets, Glasgow coma score, and fluid balance. NB model outperformed the other approaches. NB with IG feature selection achieved area under the ROC curve (AUROC) 0.925, area under the precision-recall curve (AUPRC) 0.813, accuracy 0.88, F1 score 0.88, whereas the NB model with CFS achieved comparable accuracy and F1-score but the performance was slightly better with 0.945 AUROC, 0.890 AUPRC.

Conclusions: We present a model that uses ML and leverages structured, time-series data to identify patients likely to need CRRT in the ICU. The study's limitations include being conducted in a single institution and not considering unstructured data, which may improve the model's performance.

TH-PO021

Machine Learning Models for IgA Nephropathy Diagnosis: A Retrospective Study on Predictive Performance and Influential Variables

Ryunosuke Noda, Daisuke Ichikawa, Yugo Shibagaki. *St. Marianna University School of Medicine, Kawasaki, Japan.*

Background: IgA nephropathy often requires therapeutic modalities associated with potential complications, such as steroids, and so requires definitive diagnosis by invasive renal biopsy rather than non-invasive clinical diagnostic measures. Although the efficacy of machine learning (ML) for diagnostic purposes has been underscored in recent years, its application in the context of nephrology remains unclear. In this study, we investigated the diagnostic performance of ML algorithms for IgA nephropathy.

Methods: We conducted a retrospective cohort study on 1,419 cases that underwent renal biopsy in our hospital from January 2006 to September 2022. Cases with indeterminate diagnoses and overlapping pathologies were excluded. The remaining cases were randomly divided into train and test datasets at an 8:2 ratio. We utilized a total of 44 variables, which included age at the time of renal biopsy, gender, blood tests, and urinalysis, as explanatory variables. Subsequently, multiple machine learning algorithms were evaluated, including K-nearest neighbor, support vector machines, random forest, extreme gradient boosting, and LightGBM, using Python. The model with the highest average Area Under the Curve (AUC) was identified through stratified 5-fold cross-validation in the train set. Thereafter, we compared the AUC of this model in the test

set to that of the logistic regression (LR) model in the test set. To interpret the predictive outcomes, we deployed the SHapley Additive exPlanations (SHAP) methodology.

Results: In the train set, LightGBM outperformed the other ML models, exhibiting the highest AUC of 0.92, which also mirrored its performance in the test set (LightGBM 0.92, LR 0.88). SHAP analysis unveiled that the variables contributing to prediction were, in descending order, urinary red blood cell count, serum albumin, IgA/C3 ratio, urinary protein/creatinine ratio, and age.

Conclusions: Our study indicated that ML, particularly the LightGBM model, could improve IgA nephropathy diagnostic performance beyond conventional logistic regression. The influential variables identified were consistent with those reported in the existing literature. This highlights the potential utility of ML in IgA nephropathy diagnosis, necessitating further validation for clinical use.

Machine Learning Models for the Prediction of Kidney Stone Composition and Recurrence

Matteo Bargagli, Daniel G. Fuster. *Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland.*

Background: Kidney stones are prevalent and cause high patient morbidity and healthcare cost. Kidney stone treatment depends on stone type and recurrence risk. We hypothesized that machine learning (ML) methods provide higher accuracy compared to current approaches for stone type and recurrence risk prediction.

Methods: Data from three comprehensively phenotyped Swiss cohorts comprising 1505 kidney stone formers with demographic, anthropometric and clinical information, stone composition analysis, and 24-h urine measurements were included. Several supervised ML models, including logistic regression, parallel-tree boosting (XGBoost), random forests, and neural networks, were trained independently to predict the stone type and the 5-year recurrence risk.

Results: XGBoost performed with generally high specificity (>90%), except for calcium oxalate stones which demonstrated lower sensitivity. The algorithm achieved an accuracy of 85% when distinguishing between uric acid-containing and calcium phosphate-containing stones. Key features informing the model included age at first stone event, body mass index, 24h urine calcium and pH. The 5-year recurrence risk predicted by the neural network ranged between 48% and 83%, closely aligning with observed recurrence risk ($R^2 = 0.913$).

Conclusions: The developed ML models demonstrated remarkable accuracy in predicting the risk of stone recurrence. These findings have the potential to address an unmet clinical need by assisting healthcare specialists in clinical decision-making, and ultimately enhancing patient outcomes and quality of life for those affected by recurrent kidney stone disease.

Integrating Electronic Health Data Records to Develop and Validate a Predictive Model of Hospital-Acquired AKI in Non-Critically Ill Patients

Alfonso Segarra,[1,2] Jacqueline Del Carpio Salas,[3,1] Natalia Ramos,[4] Jorge González,[1] Jose Bruno Montoro Ronsano,[4] Silvia Pico Fornies,[1] Marina Canales Navarro,[2] María P. Marco,[1] Elias A. Jatem,[1] Pamela J. Chang.[1] *[1]Hospital Universitari Arnau de Vilanova, Lleida, Spain; [2]Institut Catala de la Salut, Lleida, Spain; [3]Universitat Autonoma de Barcelona, Barcelona, Spain; [4]Hospital Universitari Vall d'Hebron, Barcelona, Spain.*

Background: Models developed to predict hospital-acquired acute kidney injury(HA-AKI) in non-critically ill patients have low sensitivity, do not include dynamic changes of risk factors and do not allow the establishment of a time relationship between exposure to risk factors and AKI. We developed and externally validated a predictive model of HA-AKI integrating electronic health databases and recording the exposure to risk factors prior to the detection of AKI.

Methods: The study set 36852 non-critically ill hospitalized patients admitted from January-December 2017. Using stepwise logistic analyses, including demography, chronic comorbidities and exposure to risk factors prior to AKI detection, we developed a multivariate model to predict HA-AKI. Externally validated in 21545 non-critical patients admitted to the validation centre from June 2017-December-2018.

Results: Incidence of AKI in study set was 3.9%. Among chronic comorbidities, the highest ORs chronic kidney disease, urologic disease and liver disease. Among acute complications, the highest ORs acute respiratory failure, anaemia, systemic inflammatory response syndrome, circulatory shock and major surgery. Model showed AUC 0.907, sensitivity 82.7 and specificity 84.2 to predict HA-AKI. In validation set, incidence of AKI 3.2%. Model showed AUC 0.905, sensitivity 81.2 and specificity 82.5 to predict HA-AKI and had an adequate goodness-of-fit.

Conclusions: By using electronic health data records, our study provides a model that can be used in clinical practice to obtain an accurate dynamic and updated assessment of the individual risk of HA-AKI during the hospital admission period in non-critically ill patients.

Classification of Arteriovenous Access Aneurysm in Hemodialysis Patients Using Artificial Intelligence Application

Zijun Dong,[1] Hanjie Zhang,[1] Lin-Chun Wang,[1] Sarah Ren,[1] Lela Tisdale,[1] Maggie Han,[1] Shahzre Mohib,[1] Laura Rosales M.,[1] Sindhuri Prakash-Polet,[2] Denzil Douglas,[2] Piotr Starakiewicz,[2] Dean C. Preddie,[2] Stephan Thijssen,[1] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Azura Vascular Care, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Arteriovenous (AV) access aneurysms in hemodialysis (HD) patients may lead to severe and potentially life-threatening consequences, such as rupture. To address this issue, we developed an artificial intelligence-based app that utilizes images of the AV access to classify AV aneurysms (Zhang, Clin Kidney J, 2022). Our objective

was to assess the correlation between the classification results generated by our aneurysm classification app and the independent clinical examination performed by physicians specializing in access care.

Methods: As described recently (Zhang, Clin Kidney J, 2022), AV accesses were photographed, and the images were transferred to the cloud, where they were classified as "Advanced" or "Not Advanced" by a convolutional neural network algorithm (Fig. 1A). We compared classifications made by physicians who were blinded to the app results (i.e., the ground truth) and those generated by our app.

Results: We studied 28 subjects (Fig. 1B). Twenty out of 22 aneurysms were accurately classified as "Not Advanced" and 5 out of 6 as "Advanced" (Fig. 1C), resulting in an accuracy of 89%, sensitivity of 83%, specificity of 91%.

Conclusions: Our preliminary results show that an AI-powered app can classify AV aneurysms with actionable accuracy in a demographically diverse HD population. If these results are corroborated in a larger patient population, our tool has the potential to support the development of a robust aneurysm monitoring system, enabling timely detection, facilitating referrals, and avoiding emergency interventions associated with aneurysms.

Derivation and Validation of Machine Learning Models for the Prevention of Unplanned Dialysis in Advanced CKD Patients

Martin M. Klamrowski,[1] Ran Klein,[2] James Green,[1] Chris Mccudden,[2] Cedric A. Edwards,[2] Babak Rashidi,[2] Ayub Akbari,[2] Gregory L. Hundemer.[2] *[1]Carleton University, Ottawa, ON, Canada; [2]University of Ottawa, Ottawa, ON, Canada.*

Background: A short timeframe kidney failure risk prediction model may serve to prevent unplanned dialysis starts, a detrimental outcome associated with increased morbidity, mortality, and healthcare costs. To date, no such clinical tool exists.

Methods: We developed and externally validated models for prediction of kidney failure over short timeframes of 6 and 12 months. The models were fit in 2,432 consecutive advanced CKD patients from The Ottawa Hospital. Models were externally validated in two independent advanced CKD cohorts from the Kingston General Hospital (N=724), and the Sunnybrook Health Sciences Center (N=323). All hospitals are in Ontario, Canada. Patients lost to follow-up, under conservative care management, or with <12 months of follow-up were excluded. Random forest classifiers were used to predict the 6- and 12-month probability of kidney failure for each patient at each follow-up visit. Input features included age, sex, and commonly available laboratory measurements and features characterizing their trajectory. The percentage of patients detected within clinically actionable timeframes of 3-15 months were computed for both models.

Results: Internally, upon presentation, patients had a mean±SD age 66±15 years, and eGFR 18±7 mL/min/1.73m^2, and median (IQR) ACR 164 (49, 333). Internal ROC-AUCs (95% CI) of 0.88 (0.87-0.88) and 0.86 (0.86-0.87) were achieved by the 6- and 12-month models, respectively. Models were well-calibrated. Internally, at 70% precision, patients requiring dialysis were correctly identified with at least 6 months advanced notice in 20% and 34% of cases using the 6- and 12-month models. Performance did not significantly differ at either external site.

Conclusions: Machine learning-based short timeframe kidney failure risk prediction models accurately identify advanced CKD patients at high risk for imminent dialysis, including a substantial proportion destined for unplanned (or "crash") dialysis initiation.

TH-PO026

Predictive Model of the Time to Renal Replacement Therapy Using Machine Learning

Jun Okita, Takeshi Nakata, Hiroki Uchida, Akiko Kudo, Akihiro Fukuda, Hirotaka Shibata. *Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan.*

Background: In the treatment of chronic kidney disease, nephrologists are expected to prolong the renal prognosis for those at high risk for end-stage renal disease (ESRD). It is also important to estimate the time to renal replacement therapy (RRT) in patients at high risk of ESRD. In Japan, the "time-series data of estimated glomerular filtration rate (eGFR)" is used to estimate the time to RRT based on the annual decline rate. In this study, we used machine learning to predict the time to RRT from the "data obtained at a single time point."

Methods: Patients who underwent hemodialysis at our hospital from April 2016 to March 2021 were included, and a data set, including 30 laboratory data items (BUN, creatinine [Cr], etc.), six patients' background demographic background, and medications were extracted retrospectively from the electronic medical records. 75% of the data were randomly split for training and 25% for testing, and the predictive models were created with several algorithms: linear regression, ridge regression, least absolute shrinkage selection operator (LASSO) regression, elastic nets, random forests, and gradient boosting decision trees. We also predicted the time to RRT using "time-series data of eGFR" and compared the accuracy by the coefficient of determination (R^2) and mean absolute error (MAE).

Results: A total of 13,323 data were extracted from 147 patients of which 99 were males, resulting in a final total of 1,801 data groups with no missing data. The mean age at dialysis induction was 60.8 years, the most common etiology for ESRD was diabetic nephropathy (44 %), the mean Cr was 7.6 ± 2.0 mg/dL, and the mean eGFR was 6.1 ± 1.7 ml/min/1.73 m^2. The prediction model based on LASSO was moderately accurate with R^2 0.62 and MAE 416, while the prediction based on the "time-series data of eGFR" was highly inaccurate with R^2 of -17.1 and of MAE 2466, indicating that the machine learning is superior in predicting the onset of dialysis.

Conclusions: The machine learning method was used to predict the time to RRT using "data obtained at a single time point," and a moderately accurate prediction model was obtained. The ability to specify the time to RRT, even approximately, is useful not only for medical staff to make treatment decisions, but also for patients to motivate themselves to receive treatment and making long-term plans.

TH-PO027

Prediction of the Presence of Vesicoureteral Reflux Using Kidney Ultrasound Images with Deep Learning

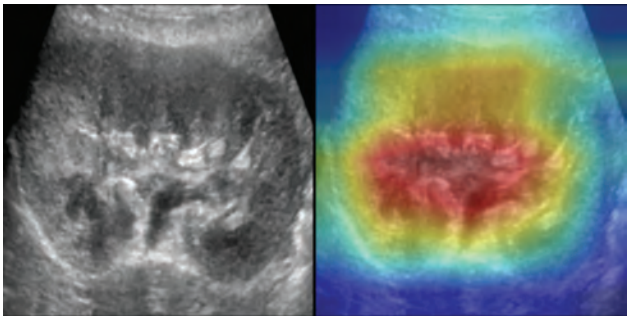
Yuichi Morimoto, Keisuke Sugimoto, Kohei Miyazaki. *Kinki Daigaku, Higashiosaka, Japan.*

Background: In previous studies, detection of vesicoureteral reflux (VUR) and renal scarring by ultrasonography has been attempted, but the results have not yet been satisfactory.

Methods: Patients who underwent ultrasonography and VCUG examinations in the course of a thorough examination for congenital renal urinary tract abnormalities at our hospital from January 1, 2010 to January 1, 2021 were included in the study. We used a deep learning image classification method to create a discriminant model of VUR using kidney echo images as training data and VCUG examination results as teacher data. After creating the model using the training and validation data, the sensitivity and specificity were evaluated using the test data. The model was then evaluated for sensitivity and specificity using the test data. The model was visualized using the Grad-cam to determine the explanatory power of the model.

Results: In this study, 46 VCUG cases (male cases [57%], median age 4.5 years [0 months to 10 years]) were included. 23 of the 46 cases had VUR, 12 were Grade I-III and 11 were Grade IV-V. 230 echo images (115 each) from the groups with and without VUR were used for transition learning For VUR detection, the deep learning model had a sensitivity of 58%, specificity of 87.5%, positive predictive value of 82.4%, negative predictive value of 67.7%, and accuracy of 71.7% (Figure 1).

Conclusions: It was suggested that the presence of VUR could be predicted from renal echographic images and may contribute to the decision of VCUG indication. In addition, it has been reported that thickening of the renal pelvis wall due to reflux has been observed, and in the visualization of features performed with the model created in this study (Figure 1), similar areas may have contributed to the AI's judgment. If the presence and severity of VUR can be determined with a certain degree of accuracy from renal echo images, the pain and radiation exposure caused by VCUG may be avoided.



Features visualized by Gradcam

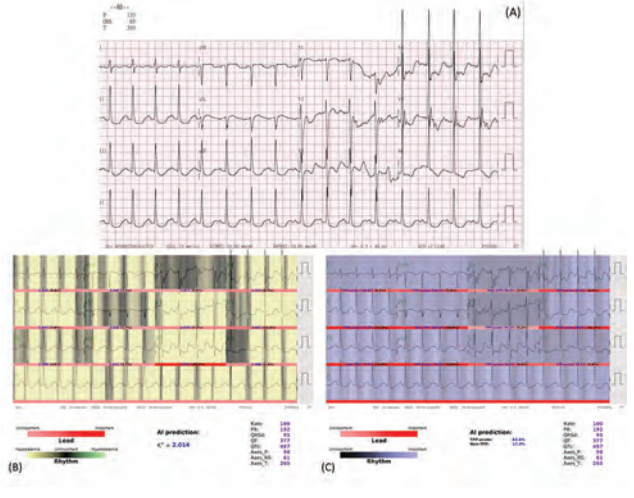
Bloodless Artificial Intelligence Electrocardiography Detecting Thyrotoxic Periodic Paralysis Following SARS-CoV-2 Infection

Ang Lu,[1] Chien-Chou Chen,[1,2] Chin Lin,[3] Tsung-Jui Wu,[4] Shih-Hua P. Lin.[1]
[1]Tri-Service General Hospital Department of Internal Medicine, Taipei, Taiwan; [2]Tri-Service General Hospital Songshan Branch, Taipei, Taiwan; [3]National Defense Medical Center, Taipei, Taiwan; [4]Hualien Armed Forces General Hospital, Xincheng, Taiwan.

Introduction: Hypokalemic paralysis, a metabolic muscle paralysis emergency, is divided into hypokalemic periodic paralysis (HypoPP) due to acute intracellular K^+ shift, and non-HypoPP due to profound K^+ deficiency. Thyrotoxic periodic paralysis (TPP), a form of HypoPP, is characterized by acute muscle paralysis, hypokalemia, and hyperthyroidism and can be triggered by any kind of thyrotoxicosis and occasionally by viral infection. This case highlights a young Chinese male with TPP following SARS-CoV-2 infection, rapidly identified via artificial intelligence electrocardiography (AI-ECG).

Case Description: A 22-year-old man recently infected with SARS-CoV-2 presented with acute paralysis in his lower limbs and palpitations post-exercise. Examination showed symmetrical areflexia and an enlarged thyroid. AI-ECG detected hypokalemia and high TPP likelihood (Figure 1). Intravenous K^+ supplementation began and subsequent test showed hypokalemia (1.6 mmol/L). Treatment with intravenous K^+ normalized muscle strength and serum K^+ while hormone studies confirmed Graves' disease. Hyperthyroidism was managed with antithyroid drug and β-blocker. He had subclinical hyperthyroidism without relapse 3 months later.

Discussion: Despite the incidence of COVID-19-related thyrotoxicosis, TPP following SARS-CoV-2 infection are rare. Rapid diagnosis and appropriate TPP management are vital. The implementation of AI-ECG system, featuring hypokalemia and TPP detection models, allows for rapid identification and treatment initiation. Given the high incidence and swift emergence of COVID-19-related hyperthyroidism, evaluations of thyroid function, electrolytes, and use of AI-ECG are warranted in patient with neuromuscular symptom to ensure early TPP detection and reduces serious complications.



(A) Prolonged QT interval and prominent U wave; (B, C) AI-ECG analysis indicates hypokalemia and high likelihood of TPP

Artificial Intelligence Prediction of Dialysis Access Complications

Adam E. Gaweda,[1] Zygimantas C. Alsauskas,[1,2] Michael E. Brier.[1,2]
[1]University of Louisville Health Sciences Center, Louisville, KY; [2]VA Robley Rex Medical Center, Louisville, KY.

Background: The single most important factor determining quality of dialysis is adequate access. This begins with the placement of an access that is optimized for the individual patient and may include a fistula, graft, or in some cases a catheter. Constant monitoring of the fistula or graft is needed to avoid future complications and with the EMR we can provide this in real time using the dialysis machine / EMR interface. We evaluated an AI approach to prediction venous stenosis at different locations with sufficient warning that an intervention can be performed prior to interruption of dialysis.

Methods: Data were obtained from the University of Louisville dialysis electronic medical record system and the Interventional Nephrology program for the years 2018 to 2020. Routinely collected information at the time of initiation as well as intradialytic data were obtained. Events were determined by direct examination within the interventional facility and segregated into inflow, outflow, central, and other stenosis. Event classification was performed using sequential vector of predictors consisting of target and achieved blood flow rate, arterial pressure, arterial resistance, venous pressure, venous resistance, and mean arterial pressure. Resistance was defined as the ratio of pressure to blood flow rate. Events were predicted 1 week in advance. Classification was performed using tree ensembles (AdaBoost) and Artificial Neural Network.

Results: Data set contained 2369 samples with 27 inflow, 133 outflow, 54 central, and 59 other stenosis events. Classifiers were trained using 10-fold cross-validation. Additionally, 10% of the data were held out for testing. Table 1 shows comparison of the classifier performance on the test data between the two methods.

Conclusions: Sufficient information exists during the dialysis procedure that can be leveraged using advanced mathematical techniques to adequately predict dialysis access complications. The methodology applied also allows for the explanation of the observations seen and can provide predictions through a mathematical model or an expert system in the form of a decision tree.

	Inflow		Outflow		Central		Other

Deep Learning-Based Prediction of Postoperative AKI After Noncardiac Surgery Using Intraoperative Vital Sign Parameters in a Minute Scale

Sehoon Park, Yong Chul Kim, Dong Ki Kim, Hajeong Lee. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea.*

Background: Certain models were used to predict the risk of PO-AKI mainly with preoperative characteristics; however, complex intraoperative vital sign information was difficult to be combined to such strategy although intraoperative hemodynamic alteration is one of the major factor affecting PO-AKI risks. We aimed to construct an externally validated deep learning-based prediction model for PO-AKI, including complex, real-time collected hemodynamic information.

Methods: We collected systolic and diastolic pressure values and heart rate information collected from the real-time intraoperative monitoring in a tertiary university hospital (N = 51,345). The test and the internal validation set was split as 8:2 manner, and additional external validation was performed in two additional tertiary university hospitals (N = 47,093 and 12,259). Total collected measured points of blood pressure values were 17,816,251 (systolic) and 17,793,025 (diastolic) and of heart rate was 17,505,759. Deep-learning model was constructed using the EfficientNet based CNN model. The outcome was PO-AKI and critical AKI events, and the critical AKI was defined as high stage AKI or AKI associated with death or dialysis. We compared the model performances with AUC-ROC values, and the conventional SPARK classification was used as the reference model.

Results: The deep-learning model only including intraoperative variables showed moderate but tolerable discrimination power against PO-AKI [AUC-ROC 0.707 (development), 0.637 and 0.729 (validation)] or critical AKI [AUC-ROC 0.724 (development), 0.729 and 0.716 (validation)] events. When major PO-AKI risk factors were incorporated to the models, the powers outperformed the conventional SPARK model; for PO-AKI [0.765 (development), 0.716 and 0.761 (validation)] and for critical AKI [0.816 (development), 0.741 and 0.794 (validation)]. The model performances even improved in the ensemble model learning both preoperative tabular data and the intraoperative prediction models.

Conclusions: Complex intraoperative vital sign information, including blood pressure and heart rate, can be used to develop tolerable deep-learning based PO-AKI risk stratification model that can be used after non-cardiac surgeries.

Ultrasound-Based Imaging Methods for the Assessment of Kidney Fibrosis on Artificial Intelligence

Dan Zhao. *Shanghai Tongji Hospital, Shanghai, China.*

Background: Renal fibrosis is the common pathway leading to end stage kidney disease, but the assessment of renal fibrosis remains limitations. Artificial intelligence (AI)-based ultrasound imaging has showed high specificity and sensibility in disease diagnosis via image recognition. Hereby, we intend to use artificial intelligence technology to explore a new method for early non-invasive assessment of renal fibrosis through ultrasound images.

Methods: A retrospective cohort of patients receiving kidney biopsy was developped from our hospital between January 2018 and July 2022. All participant underwent kidney ultrasound within one week. The magnitude of renal intersitial fibrosis (RIF) was evaluated by two experienced pathologists according to Banff criteria. All ultrasound images were preprocessed, then randomly divided into training and test sets in a 7 to 3 ratio. Radiomic features extracted from selected regions of interest (ROI), including firstorder, texture, and wavelet-transformed features. Two-sample t-test, LASSO, and Spearman correlation analysis were used to reduce feature dimension. Three machine learning models and one deep learning model were established to distinguish mild and moderate-severe fibrosis. The area under the curve (AUC) of the receiver operating characteristic curve was employed to assess the models' performance.

Results: A total of 193 paients were enrolled in this study, including 100 with mild fibrosis and 93 with moderate-severe fibrosis. 837 radiomic features were extracted from gray scale ultrasound images. After feature dimension reduction, 10 features were retained, of which 9 were wavelet-transformed features. Based on 10 selected radiomic features, three machine learning models were established: LR, SVM and RF. In test sets, the AUCs were 0.75, 0.80, and 0.89, respectively. The accuracy were 60%, 63.7%, and 65% respectively. RF model achieved the best classification performance. For further visualization, LR prediction model were visualized as nomogram. In addition, based on full kidney ultrasound images, VGG16 network model were also establisehed, with AUC of 0.76 (95% CI, 0.63-0.90) and the accuracy of 77%.

Conclusions: AI-assisted imaging analysis endows traditional ultrasound techniques with the promising potential for early diagnosis of renal fibrosis. Our study would provide new insights for the future exploration of noninvasive assessment methods.

TH-PO032

Development of Artificial Intelligence Model for the Prediction of AKI, Acute Kidney Disease, and CKD After General Anesthesia Surgery

Sang Hun Eum,[1,2] Ji Won Min,[3,2] Eun Sil Koh,[4,2] Tae Hyun Ban,[5,2] Suyeon Hong,[6,2] Byung ha Chung,[7,2] Yong Kyun Kim,[8,2] Seok Joon Shin,[1,2] Hye Eun Yoon.[1,2] *[1]Incheon St. Mary's Hospital, Incheon, Republic of Korea; [2]The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea; [3]Bucheon St. Mary's Hospital, Bucheon, Republic of Korea; [4]Yeouido St. Mary's Hospital, Seoul, Republic of Korea; [5]Eunpyeong St. Mary's Hospital, Seoul, Republic of Korea; [6]Uijeongbu St. Mary's Hospital, Uijeongbu, Republic of Korea; [7]Seoul St. Mary's Hospital, Seoul, Republic of Korea; [8]St. Vincent's Hospital, Suwon, Republic of Korea.*

Background: After the occurrence of AKI, ongoing renal pathophysiologic process leads to acute kidney disease (AKD) or chronic kidney disease (CKD). Postoperative AKI is associated with increased mortality and morbidity in patients undergoing surgeries performed under general anesthesia. A machine learning-based prediction model for postoperative AKI, AKD, and CKD is needed.

Methods: In this retrospective cohort analysis, noncardiac surgeries performed between 2009 and 2019 at 7 university hospitals in South Korea were included. According to the creatinine-criteria of KDIGO, postoperative AKI was defined as an increase of serum creatinine at least 1.5 times the baseline value or initiation of renal replacement therapy occurring over 7 days or less after surgery; AKD was defined as persistent AKI over 7 and 90 days; CKD was defined as persistent AKD beyond 90 days. Data imbalance was adjusted using the SMOTE algorithm, and four machine learning prediction models were tested: deep neural networks, decision tree, random forest, and light gradient boosting machine (GBM). Model performance was compared using the area under the curve (AUC) of the receiver-operating characteristic, accuracy, and F1 score.

Results: Among 239,267 surgeries, 2,716 postoperative AKI (1.14%), 97 AKD (0.04%), and 1,203 CKD (0.5%) events occurred. Four machine learning methods were run on 32 independent preoperative predictors. While the model run on random forest exhibited a higher AUC (0.80) than light GBM (0.77), accuracy (0.95), weighted F1 score (0.94), micro-average F1 score (0.95), and macro-average F1 score (0.31) were highest in the model run on light GBM.

Conclusions: In our comprehensive comparison of machine learning approaches, light GBM demonstrated the best performance to predict postoperative AKI, AKD and CKD. The current model may be implemented in clinical practice to predict short- and long-term kidney outcomes after surgery.

TH-PO033

Deep Learning-Based Quantitative Assessment of Renal Chronicity Indices in Lupus Nephritis

Tianqi Tu, Ying Tan. *Peking University First Hospital, Beijing, China.*

Background: Lupus nephritis (LN) is a common condition in patients with SLE. Evaluating kidney chronicity indices (CI) is crucial for diagnosing LN and predicting outcomes. Deep learning (DL) has shown promise in improving the workflow of pathologists. In renal pathology, DL has demonstrated high accuracy in identifying various histopathologic lesions. However, existing studies have not adequately addressed the challenges of assessing CI in LN, such as integrating features at different levels and dealing with class imbalances among tissue compartments.

Methods: This study enrolled 141 patients from two distinct cohorts. Training of the CNN model involved annotating 22,410 images from 30 biopsy slides, which were subsequently tested on 111 slides. The evaluation process encompassed the segmentation of tissue compartments, correlation analysis with pathologists' assessments, and investigating associations with patient outcomes utilizing CoxPH models.

Results: 1) The developed pipeline exhibited an accuracy of over 0.91 in identifying six tissue compartments and histopathologic lesions, surpassing previous segmentation performance benchmarks. 2) Consistent with the evaluations by expert pathologists, our pipeline exhibited an agreement of over 0.85 in assessing CI in both cohorts, highlighting its reliability and consistency. 3) The application of the CoxPH model to predict patients' outcomes achieved a score of 0.82 and 0.78 in the two cohorts.

Conclusions: Our study showcases the state-of-the-art performance of our deep learning pipeline in identifying tissue compartments and histopathologic lesions in lupus nephritis. The pipeline demonstrates strong agreement with pathologists' CI assessments and maintains the correlation between CI and patient outcomes. This automated approach has the potential to enhance pathological assessment and disease stratification in lupus nephritis.

Using Artificial Intelligence (AI) to Predict Mortality in AKI Patients: A Systematic Review and Meta-Analysis

Rupesh Raina,[1,2] Raghav Shah,[3] Sidharth K. Sethi,[4] Jay L. Koyner,[5] Javier A. Neyra.[6] *[1]Cleveland Clinic Akron General, Akron, OH; [2]Akron Children's Hospital, Akron, OH; [3]Northeast Ohio Medical University, Rootstown, OH; [4]Medanta The Medicity Medanta Institute of Kidney and Urology, Gurugram, India; [5]The University of Chicago Medicine, Chicago, IL; [6]Division of Nephrology, University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury (AKI) is associated with increased morbidity and mortality. With the recent advent of artificial intelligence (AI), novel models for mortality prediction in AKI patients have been developed using machine learning (ML). We reviewed the performance of different ML models for evidence generation to support their applicability and implementation in the clinical setting.

Methods: A literature search was conducted through Pubmed, Embase, and Web of Science Databases. Performance metrics of the ML models to predict hospital mortality in adult AKI patients were extracted. The between-study heterogeneity was assessed using the I^2 test and random [for $I^2 \geq 50\%$] and fixed effects model were used. The AUROC of two models were compared using DeLong's test (p-value ≤ 0.05 considered significant). R software version 3.1.0 was used in the analysis.

Results: A total of 8 studies [8 derivation and 6 validation cohorts] with 37,032 adult AKI patients were included. The hospital mortality was 18% in the derivation and 15.8% in the validation cohorts. The pooled AUC (95% CI) was observed to be highest for logistic regression [0.86 (0.80 - 0.93)] and lowest for proposed clinical [0.77 (0.72 - 0.81)] models used as reference. Despite substantial variability, the pooled AUC (95% CI) of logistic regression did not differ significantly from other models except proposed clinical model [Delong's test p=0.022].

Conclusions: Our results show that logistic regression is equally effective as other ML models in predicting in-hospital mortality among AKI patients, with substantial variability across models. Studies evaluating the features influencing mortality and their impact on different models are needed.

Meta-analysis of AUC in assessing in-hospital mortality among AKI patients

AI/ML Model	No. of Mortality / Sample size	No of cohorts; no of studies	Pooled AUC (95% CI)	I2 (95% CI); p values
Logistic regression	1,225/5,690	3 D and 3 V cohort; 3 studies	0.862 (0.795 - 0.928)	96.17% (93.77% - 97.64%); p<0.0001
Broad learning system models*	278/540	2 D and 2 V cohort; 1 study	0.852 (0.820 - 0.883)	44.88% (0.00% - 81.61%); p=0.1421
Elastic Net final model fitted*	544/870	1 D and 1 V cohort; 1 study	0.852 (0.813 - 0.891)	48.05% (8.04% - 75.25%); p=0.1653
Extreme gradient boost	2,525/5,642	3 D and 2 V cohort; 3 studies	0.816 (0.752 - 0.880)	95.09% (91.20% - 97.26%); p<0.0001
Random Forest	5,613/27,467	7 D and 5 V cohort; 6 studies	0.816 (0.782 - 0.851)	90.14% (84.72% - 93.64%); p<0.0001
Support vector machine	4,571/23,816	3 D and 1 V cohort; 3 studies	0.804 (0.760 - 0.849)	93.89% (87.53% - 97.01%); p<0.0001
ANN / MLP	4,571/23,816	3 D and 1 V cohort; 3 studies	0.793 (0.752 - 0.833)	87.22% (69.38% - 94.66%); p<0.0001
Proposed clinical model	1,831/9,587	1 D and 1 V cohort; 1 study	0.765 (0.716 - 0.814)	98.96% (97.92% - 99.48%); p<0.0001

A Systematic Review of Artificial Intelligence Algorithms for Predicting AKI

Marcelo R. Bacci. *Faculdade de Medicina do ABC, Santo Andre, Brazil.*

Background: Acute kidney injury increases mortality and costs in hospitalized patients. New methods for early AKI identification have been developed with targeted biomarkers and electronic health records data analysis. Machine learning use in diagnostics and health data analysis has recently increased. We performed a systematic review to analyze the use of ML for AKI prediction in hospitalized adults.

Methods: Pubmed, EMBASE, Cochrane, and Web of Science databases were searched until 31st March of 2023. English-language studies using ML in adults for AKI prediction were included using predetermined eligibility search terms such as acute kidney injury, machine learning, and artificial intelligence. Two reviewers evaluated the publications' titles, abstracts, and full texts separately and obtained appropriate data. The main outcome was an area under the curve result of at least 0.70.

Results: Ten studies in 102 articles were included involving 242,251 patients. Deep learning (AUC 0.907 in critical care AKI; AUC 0.797 in hospitalized patients AKI was similar to Logistic regression (AUC 0.877 in critical care AKI; AUC 0.789 in hospitalized patients). Decision tree constructions had similar AUC.

Conclusions: AKI is multifactorial;however, ML performed well with different etiologies, such as cardiac-related AKI, drug-related AKI, and critical care patients. Overfitting data and constructing black box models are limitations that might jeopardize the generalization and comprehension of the results. Most studies were single-center, and three manuscripts used the same database with a predominantly Caucasian population resulting in a lack of diversity and reducing external generalization. In conclusion, ML could effectively predict AKI in hospitalized adults. Future directions rely on including a more diverse population and completing prospective and controlled trials.

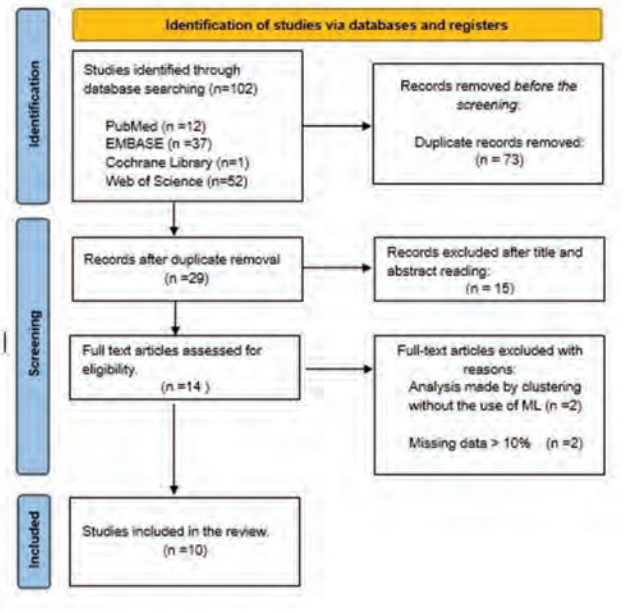

Figure 1. Flow diagram of the identification of relevant studies

Predictive Modeling of Graft Failure Risk in Deceased Donor Kidney Transplants: Leveraging Machine Learning for Improved Outcomes and Data-Driven Insights

Amankeldi Salybekov,[1,2] Ainur Yerkos,[3,2] Aidyn D. Kunikeyev,[2] Zholdas Buribayev,[3,2] Yasuhiro Mochida,[1] Kunihiro Ishioka,[1] Sumi Hidaka,[1] Shuzo Kobayashi.[1] *[1]Shonan Kamakura Sogo Byoin, Kamakura, Japan; [2]Qazaq Institute of Innovative Medicne, Astana, Kazakhstan; [3]Al-Farabi Kazakh National University, Almaty, Kazakhstan.*

Background: Machine learning (ML) has shown its potential to improve patient care over the last decade. The 1-year graft failure rate remains a major concern among ethnic disparities in the deceased donor kidney transplantation (KT). The aim of the study was to evaluate graft failure within a year and determine risk factors associated with these events in ethnic groups.

Methods: The KT data between 2000 to 2020 was obtained from Organ Procurement and Transplantation Network. After data preprocessing n=75000 White, n=35000 Black, and n= 5000 Asian KT were qualified for further data analysis. The random forest (RF) and light gradient-boosting machine (LGBM) models were used to classify the most important variables for further 1-year GF-associated risk factors.

Results: Thus, the number of initial variables was reduced from 490 to 40 in every three groups after significance-test validation. LGBM demonstrated better discrimination of GF-related risk factors among three groups ((AUC=0.78; White), (AUC=0.77; Black), and (AUC=0.73; Asian)) in fivefold cross-validation. Interestingly, the top features for prediction of graft failure were such as donor hepatitis C-virus (HCV) antibody, donor and recipient tattoo, type of perfusion solution, age, arterial blood gas PH level, diabetes, hypertension, etc. Then, LGBM predicted variables were further analyzed in Cox proportional hazard ratio (HR), and the leading risk factor for graft failure was donor HCV antibody level ((HR 1.9; White, HR 2.2; Black, and HR 1.75; Asian, all p values were 0.005). In contrast, donor and recipient tattoos were independent risk factors (HR 1.2; P <0.02) for Asian while arterial blood gas PH (HR 1.2; P <0.01), posttransplant malignancy (HR 1.25-2.2; P <0.005), and organ flushing solution (HR 1.2; P <0.005) associated with 1 -year graft failure for all three groups. Interestingly, Cox proportional HR analysis demonstrated that ML-predicted risk factors such as diabetes, age, BMI, and hypertension were not associated with 1-year graft failure in all three groups.

Conclusions: Taking together, ML algorithms predicted risk factors accuracy almost the same as traditional statistical methods on prediction of 1-year graft failure among ethnic disparities.

TH-PO037

Prospective Study of a Predictive Algorithm of Real-Time Fluid Status in Hemodialysis Patients

Vicki K. Sandys,[1,2] Lavleen Bhat,[1] Anna Ninan,[1] Kevin Doyle,[3] Peter J. Conlon,[2] Donal J. Sexton,[4] Conall M. O'Seaghdha.[1,2] *[1]Royal College of Surgeons in Ireland, Dublin, Ireland; [2]Beaumont Hospital Ireland, Dublin, Ireland; [3]patientMpower, Dublin, Ireland; [4]The University of Dublin Trinity College, Dublin, Ireland.*

Background: An accurate per-session determination of volume status in dialysis patients would have considerable clinical utility.

Methods: We prospectively assessed a predictive algorithm for fluid status in an observational study of hemodialysis (HD) patients. Algorithm performance was compared to clinical volume assessment. Individualised predictions were compared with bioimpedance (BCM) measures at 2-week intervals. Internal validation for linear regression algorithms predicting BCM-based normohydration weight and pre-HD overhydration (OH) has been described (SA-PO351 ASN 2022). MAE, RMSE and Bland-Altman plots were used for continuous outcomes. Precision, recall and F1 score were used for fluid categories: overhydration ≥1.1L, normohydration -1.1L to 1.1L, underhydration ≤-1.1L.

Results: 630 HD sessions were assessed. Root mean squared error (RMSE) for the pre-dialysis overhydration index=2.1kg compared to RMSE=1.6kg in the internal validation set. No significant difference was observed between the BCM normohydration weight versus the predicted value [mean difference 0.22 ± 2.25 kg, t (93) = 0.96, p=0.34]. A histogram showed a close alignment in distribution of predicted noromohydration weight and BCM values (Figure). Nursing staff overestimated fluid overload (Table).

Conclusions: The algorithm showed an ability to discriminate fluid categories compared to nursing staff, but overall accuracy was poor. Additional algorithm training in a larger, heterogeneous dataset would be expected to improve precision of fluid status predictions.

Funding: Commercial Support - Enteprise Ireland Disruptive Technologies Innovation Fund grant DTIF 2019_86, Government Support - Non-U.S.

The Prediction of In-Hospital Mortality in Elderly Patients with Sepsis-Associated AKI Utilizing Machine Learning Models

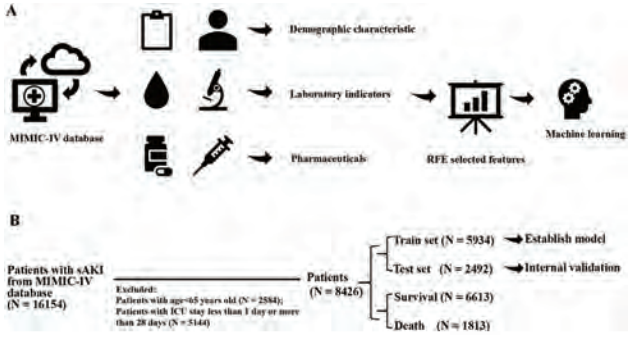
Xin He, Qiongjing Yuan, Zhangzhe Peng. *Xiangya Hospital Central South University, Changsha, China.*

Background: Sepsis-associated acute kidney injury (SA-AKI) is a severe complication associated with poorer prognosis and increased mortality, particularly in elderly patients with sepsis. Currently, there is a lack of accurate mortality risk prediction models for these patients in clinic. This study aimed to develop and validate machine learning models for predicting in-hospital mortality risk in elderly patients with SA-AKI.

Methods: Machine learning models were developed and validated using the public, high-quality Medical Information Mart for Intensive Care (MIMIC)-IV critically ill database. The recursive feature elimination (RFE) algorithm was employed for key feature selection. Eleven predictive models were compared, with the best one selected for further validation. Shapley Additive Explanations (SHAP) values were used for visualization and interpretation, making the machine learning models clinically interpretable.

Results: A total of 8,426 SA-AKI patients were included in this study (median age: 77.0 years; female: 45%). They were randomly divided into a training cohort (5,934, 70%) and a validation cohort (2,492, 30%). Nine key features were selected by the RFE algorithm. The CatBoost model achieved the best performance, with an AUC of 0.844 in the training cohort and 0.804 in the validation cohort. SHAP values revealed that AKI stage, PaO_2, and lactate were the top three most important features contributing to the CatBoost model.

Conclusions: We developed a model capable of predicting the risk of in-hospital mortality in elderly patients with SA-AKI.



Flowchart of this study

TH-PO039

Developing a Risk Index Predicting Kidney Transplant Dropout for African American and Hispanic Patients Using Artificial Intelligence/ Machine Learning

Amy D. Waterman,[1] Enshuo Hsu,[1] David Axelrod,[2] Stephen L. Jones,[1] Shefali A. Patel,[1] Solaf Al Awadhi,[1] Andrea M. Meinders,[1] Catherine Pulicken,[1] Faith Parsons,[1] Victoria Cassell,[1] Ioannis A. Kakadiaris.[3] *[1]Houston Methodist, Houston, TX; [2]University of Iowa Hospitals and Clinics, Iowa City, IA; [3]University of Houston, Houston, TX.*

Background: On average, kidney patients who receive a transplant live longer and have a better quality of life than those who remain on dialysis. Since African American (AA) and Hispanic patients are more likely to drop out before receiving a transplant than White patients, identifying patients at higher risk of dropout can improve care.

Methods: We created a dataset from Houston Methodist sources, including EPIC Clarity, Phoenix, and United Network for Organ Sharing (UNOS), and external databases including Health Resources Services Administration (HRSA), Centers for Disease Control and Prevention (CDC), and the US Census Bureau for community-level characteristics. The final transplant analytical registry included 4,245 kidney patients pursuing transplants from 6/2016 to 5/2022 and contained clinical, demographic, social, and transplant variables. The data was preprocessed to apply AI/ML methods to predict the risk index of patients who began transplant evaluation but were never listed for transplant within 12 months. F1 and AUROC were the evaluation metrics used.

Results: Of the 4,245 individuals who presented for transplant evaluation, 1,999 (47.1%) were waitlisted after 12 months, and 550 (13.0%) were transplanted. AA (7.23%) and Hispanic (12.20%) patients received fewer transplants compared to White patients (19.70%). Our AI/ML-based risk index predicted the probability of not being listed for transplant within 12 months (AUROC=0.732). Patients predicted to be low dropout risk (0-30%) had an 81.3% listing rate, middle risk (30-60%) had a 54.3% listing rate, and high risk (>60%) had a 27% listing rate within 12 months (Figure 1). Compared to low-risk patients, high-risk patients were more likely to be African American (44.2% vs. 19%), Hispanic (31.5% vs. 25.3%), unemployed (91.2% vs. 25%), spent more time on dialysis (488 vs. 131 days), without intended living donors (3% vs. 64.5%), and live in areas with more residents living below the poverty line (28% vs. 17%).

Conclusions: Applying the risk index, we will identify patients at higher risk of dropout and explore health delivery improvements within the transplant care process to slow or eliminate transplant dropout for underserved communities.

Machine Learning-Based Approach to Classifying Risk of Progression of Membranous Nephropathy to ESKD Using Electron Microscopy

Jamie L. Fermin,[1] Samuel Border,[2] Anindya S. Paul,[3] Jurgen Heymann,[4] Avi Z. Rosenberg,[5] Meryl Waldman,[4] Pinaki Sarder.[3] *[1]University of Florida Department of Electrical & Computer Engineering, Gainesville, FL; [2]University of Florida Department of Biomedical Engineering, Gainesville, FL; [3]University of Florida Department of Medicine - Quantitative Health Section, Gainesville, FL; [4]National Institutes of Health Clinical Research Center - NIDDK Kidney Disease Section, Bethesda, MD; [5]Johns Hopkins School of Medicine Department of Pathology, Baltimore, MD.*

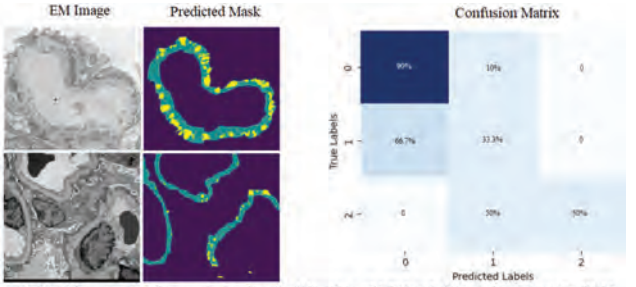
Background: Membranous nephropathy (MN) is an immune complex-mediated process that can result in nephrotic syndrome. Machine learning applications in medicine have emerged as powerful tools that can analyze large volumes of medical data (i.e., imaging, patient records) and extract patterns and relationships with diagnostic and prognostic insights. This work aims to use clinical and classical morphological image features to determine the risk of MN progression to end-stage kidney disease (ESKD).

Methods: Eighty MN cases from multiple institutions, each with available electron micrographs (EMs) of glomerular basement membrane (GBM) and corresponding baseline clinical metrics (albumin, eGFR, creatinine) were collated. An attention U-Net model was trained to perform multiclass segmentation of the GBM, electron-dense deposits, and background. Fifteen morphological features (i.e., total number of deposits, aspect ratio, circularity) were extracted from the predicted mask. Then, an artificial neural network (ANN) was trained to classify cases according to 3 risk tiers: low, intermediate, and high progression to ESKD. The same features were used to train an ANN to predict remission (no remission or complete remission).

Results: The segmentation model achieved a Dice score coefficient of 78%. Moreover, the ANN obtained classification accuracies of 73.3%, 67%, and 73.3% on the test set using clinical metrics alone, morphological features alone, and both clinical and morphological features, respectively. Another ANN trained to predict remission achieved 40% accuracy with both clinical and morphological features.

Conclusions: Clinical and morphological features can predict risk levels with reasonable accuracy. However, the same features are poor predictors of remission. Morphological features combined with clinical features do not improve risk classification accuracy. More meaningful and discriminative morphological features are needed to enhance predictive ability.

Funding: NIDDK Support



Left: Multiclass segmentation result showing the delineation of GBM and electron dense deposits. Right: Confusion matrix illustrating the classification performance of an ANN model for predicting the risk of progression of MN to ESKD (0: low, 1: intermediate, 2: high risk of progression to ESKD).

A Novel Clinical Prioritization Tool Stratifies Nephrology Patients by Acuity and Change over Time

Elizabeth D. Nguyen,[1,2] Michael Mokiao,[2] Ari Pollack.[1,2] *[1]University of Washington, Seattle, WA; [2]Seattle Children's Research Institute, Seattle, WA.*

Background: Finding information to prioritize patient care is a difficult task with the growing amount of data in the electronic health record (EHR). Systems that highlight clinically meaningful patterns in laboratory data can support decision making, particularly

for nephrology patients whose disease severity often correlates with abnormalities in metabolic balance. In this work, we present and evaluate a novel tool which captures a patient's acuity and degree of change based on laboratory data, then places patients in four clinically applicable categories to aid in prioritization.

Methods: An algorithm was developed to use laboratory data to calculate a unique score for patient (1) clinical acuity and (2) degree of change. Data was collected for diverse patient encounters from a tertiary care pediatric hospital. Scores were used to categorize patients as well, chronically sick, acutely sick or improving. To evaluate categorizations, results were compared to physician assessment of eight patient cases using C^2 goodness of fit.

Results: There was agreement in categorization between physicians and the tool ($p<0.001$). Patient categorization by the tool matched what was expected for their encounter and subspeciality type. Patients labeled as "acutely sick" were in the PICU (70% of acutely sick patients). Patients categorized as "chronically sick" were split between inpatient and outpatient encounters. Most chronically sick inpatients were outside of the PICU (89% of chronically sick inpatients) and most chronically sick outpatients were nephrology patients (70% of chronically sick outpatients).

Conclusions: This clinical priority scoring tool supports a physician's recognition of meaningful patterns in the EHR that matches their clinical assessment of patients. The tool also detected subtle trends in the trajectory of patients not otherwise captured by physicians on their first assessment. Specifically, the tool categorized nephrology patients as being chronically sick as compared to other patients which correlates with the electrolyte and acid/base imbalance, anemia and metabolic bone disease often seen in this population. Using the tool to categorize patients, physicians can rapidly identify which patients in the outpatient setting may need further evaluation for admission and which patients in the hospital may need intensive care.

Using an Ensemble Model to Improve ESA Prescription in Hemodialysis (HD)

Yi-Wen Chiu,[1,2] Ming-Yen Lin,[1] Hong-Ren Yen,[3] Chan Hsu,[3] Chan-Tung Ku,[3] Yihuang Kang.[3] *[1]Kaohsiung Medical University Chung Ho Memorial Hospital, Kaohsiung, Taiwan; [2]Kaohsiung Medical University, Kaohsiung, Taiwan; [3]National Sun Yat-sen University, Kaohsiung, Taiwan.*

Background: How the ensemble model trained by new indexes can improve the ESA prescription is unclear.

Methods: We have compiled a dataset from 2013-2020, including bi-monthly ESA prescriptions, Iron doses, Hb, and relevant data of HD patients in our hospital. We divided all records into six categories, status 1 to 6, based on subsequent hemoglobin(sHb), using cut-off values of 10.8 and 11.2 and direction of change (not decreasing: 1-3 vs. decreasing:4-6). Indexes I, II, and III were used to evaluate how the ESA dose deviations of model recommendations theoretically impacted sHb. Index I assesses how model deviations keep sHb near 11 g/dL (positive index), while II and III are away from 11 g/dL (negative index). (Figure 1) Besides the traditional ESA-prescription algorithm (TEA, Figure 2), we have trained various models, including a meta-learning model (MLM).

Results: 25,632 records of 315 ESKD patients were included, with 71.9% of the Hb levels between 10-12mg/dL. Besides TEA, we selected a generalized linear mixed-effect tree model (GLMM) and a weighted random forests model (WRF) for sHb and ESA dose prediction. The overall results are shown in Table 1. Our WRF and MLM can almost preserve the proper prescriptions (Index I), and avoid those improvable or unacceptable recommendations (Index II & III). The MLM can theoretically improve 65.4% and 43.8% of prescriptions with sHb >11.5 and <10.5, respectively. (undetermined)

Conclusions: The ensemble model trained by new indexes can theoretically recommend more proper ESA dosages.

Machine Learning Approach to Predict Hemoglobin Levels for Erythropoietin Dosing in Hemodialysis Patients

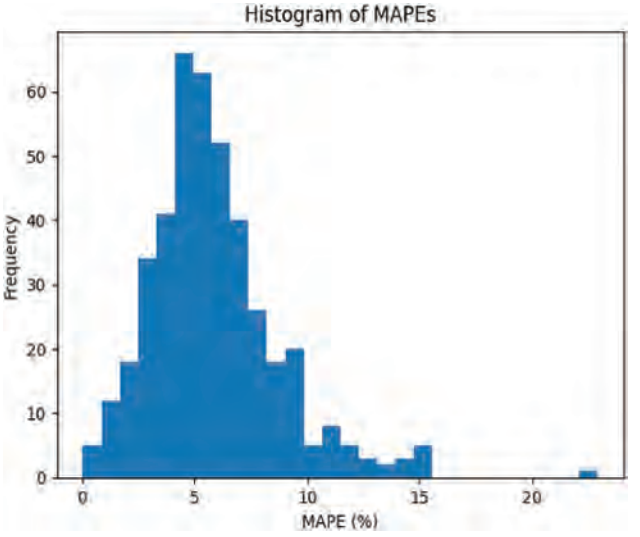
Siwei Zhao,[1] Jason W. Yang,[2] Jingyao Zhang,[2] Pei Lun Lee,[2] Subhasis Dasgupta,[2] Jerome S. Tannenbaum,[1] Joachim H. Ix,[2] Rakesh Malhotra.[2] *[1]Sanderling Renal Services, Nashville, TN; [2]University of California San Diego, La Jolla, CA.*

Background: Erythropoiesis-stimulating agents (ESA) are commonly used to treat anemia in HD patients. However, prediction of patient-specific hemoglobin (Hgb) response to ESA remains challenging. Here we used machine learning techniques to predict Hgb response to ESAs in HD.

Methods: We included patients undergoing HD in Sanderling clinics who were receiving intravenous (IV) ESA (Mircera ®) and IV iron and had ≥5 Hgb measurements. ESA dose, iron dose, demographics and clinical variables were collected. Data was preprocessed to create a patient-specific bi-weekly dataset. We used a range of machine learning models, including long short-term memory networks, random forest, XGBoost and support vector machine. Each model was implemented individually for each patient with K-fold cross-validation. Performance of models to predict future Hgb levels was defined using mean absolute percentage error (MAPE) (average absolute percentage error between the predicted future Hgb and the observed future Hgb).

Results: Among 427 HD patients, the mean age was 65 ± 14 yrs and 44% were female. Patients received, on average, 93 ± 77 mg per week IV iron, and mean Mircera dose of 103 ± 183 mcg per month. The mean Hgb was 10.1 ± 1.4 mg/dl, and transferrin saturation 32 ± 15 %. The average MAPE for the model over the study cohort was 5.9% vs. Hgb variation of 13.9%. Figure 1 provides distribution of the MAPE for patients included in the analysis.

Conclusions: Our results showed the promising performance of machine learning models in predicting future Hgb levels within 6% of observed levels in HD patients. Future studies should focus on refining these models with the goal of personalized ESA dosing to maximize on-target Hgb levels.



Histogram of MAPE for Hgb prediction.

TH-PO044

Machine Learning Approach for Hemodialysis Prescription: Model Development and Validation Study

Xueqin Bian, Hong Ye, Yang Zhou, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: The prediction model of hemodialysis prescription is established based on machine learning to achieve precise hemodialysis treatment.

Methods: We obtained 108,638 hemodialysis sessions in 965 independent maintenance hemodialysis(MHD)patients in our hospital from October 1, 2020 to June 31, 2021 using random sampling. The sessions were randomly divided into training (70%), calibration (10%), and testing (20%) sets. Apply XGBoost to analyze and extract effective feature data. XGBoost, RF, KNN, SVR, LR, MLP were used to develop the prescription model and model fusion. Training and update the model using reinforcement learning. The area under the receiver operating characteristic curves, the area under the precision-recall curves, F1 scores and MSE obtained to assess model stability and accuracy.

Results: There were 108,638 dialysis records in 965 patients, of whom 62.2 were male, the average age was 59.3±13.2 years, the median dialysis age was 102.3 months, BMI was 23.8±3.9, and the primary disease was diabetic nephropathy (38.6%). There are 13 labels in the hemodialysis program, of which 6 labels are continuous variables and the regression model is used, and 7 labels are discontinuous variables. The average accuracy is greater than 0.88, and the mean square error is less than 0.067.

Conclusions: The artificial intelligence dialysis prescription established based on machine learning has better stability and accuracy.

TH-PO045

Using an Artificial Intelligence Tool Incorporating Natural Language Processing to Identify Low-Prevalence Cases of ANCA-Associated Vasculitis in Electronic Health Records

Jolijn R. van Leeuwen,[1] Erik L. Penne,[2] Ton J. Rabelink,[1] Rachel Knevel,[1] Yoe Kie Onno Teng.[1] *[1]Leids Universitair Medisch Centrum, Leiden, Netherlands; [2]Noordwest Ziekenhuisgroep, Alkmaar, Netherlands.*

Background: Anti-neutrophil cytoplasmatic antibody (ANCA)-associated vasculitis (AAV) is a rare, life-threatening, systemic auto-immune disease. Due to the low prevalence and heterogenous registration, there is an urgent need to improve identification of AAV patients within the electronic health record (EHR)-system of health organizations to facilitate clinical research.

Methods: Our aim was to identify, with a high sensitivity, low-prevalence AAV patients within large EHR-systems (>2.000.000 records) using an artificial intelligence (AI)-search tool. We combined a search on structured and unstructured data with natural language processing (NLP)-based exclusion. We developed the method in an academic center with an established AAV training set (n=203) and validated the method in a non-academic center with a validation set (n=84). We anonymously reviewed all identified patient records for AAV diagnosis.

Results: The final search strategy combined four queries on disease description, laboratory measurements, medication and specialisms. In the training center, this search identified 608 patients, of which 346 were AAV patients upon manual review. 197/203 patients of the training set were retrieved, indicating a sensitivity of 97%. Employing NLP-based exclusion resulted in 444 patients with 339 AAV patients, resulting in an increase of positive predictive value (PPV) from 57% to 78% and a sensitivity of 96%. In the validation center the search strategy identified 333 patients, of which 194 were AAV patients, including 82/84 (98%) patients of the validation set. After NLP-based exclusion 223 patients remained, including 196 AAV patients, improving PPV from 58 to 86% with a sensitivity of 98%. Our identification method outperformed ICD-10 coding predominantly in identifying myeloperoxidase (MPO)-positive AAV patients and patients with few specialisms involved.

Conclusions: We demonstrated excellent performance of an AI-based identification method, incorporating NLP, to identify AAV patients in EHRs and we validated the applicability and transportability. This method can accelerate research efforts, while avoiding the limitations of ICD-10-based registration.

Impact of Nationwide Utilization of a Machine Learning Model to Identify Home Therapy Candidates

Caitlin Monaghan, Maria Hanson, Hao Han, Joanna Willetts, Len A. Usvyat. *Fresenius Medical Care Holdings Inc, Waltham, MA.*

Background: Home therapy (HT) modalities offer excellent treatment options for dialysis patients but are underutilized. As part of a larger effort to provide support to patients, there is a team of Kidney Care Advocates (KCAs) who provide education on treatment modality options with a goal of empowering patients to choose a home modality when appropriate. Towards this, a machine learning (ML) predictive model was built to identify which in center hemodialysis (ICHD) patients would be good candidates to target for HT.

Methods: Patient (n=298552) data collected from 2016-2019 were used to develop an XGBoost ML model to predict the likelihood of an ICHD patient switching to peritoneal dialysis or home hemodialysis in the next 90 days and staying on that HT for at least 90 days. The data were split into training (70%) and validation (30%) datasets, maintaining the 2.5% positive prevalence in both. Data sources included ICHD treatments, labs, hospitalizations, missed treatments, demographics (age, marital status, and vintage), comorbidities, clinical assessments, clinic home program information, and Zillow housing data based on zip code, resulting in 2475 variables. KCAs contacted ICHD patients identified by the model to offer education and services. From January-November 2020, KCAs completed an assessment when a patient was contacted (n=26055), which included questions on if the patient was interested in HT and how the patient was referred to the KCA.

Results: The model achieved good performance with an area under the curve of 0.87 for the validation dataset. Using a threshold set to the positive class prevalence (0.025), recall was 0.77 and precision was 0.09. The top predictors used by the model were dialysis vintage, previously expressing interest in or being referred to HT, age, and dining with one's spouse. During the time examined, KCAs reported contacting 20734 patients. Of those, the model was the sole referral source for 5382 patients and 1219 of them expressed interest in HT. In 2020-2021, 487 ICHD patients referred to KCAs by only the ML model switched to HT.

Conclusions: Through close collaboration with KCAs, an ML model was successfully used to identify ICHD patients who were good candidates for HT. Use of this model had measurable impact with hundreds of ICHD patients switching to HT who otherwise might not have been referred to a KCA.

A Risk-Based Reinforcement Learning Algorithm to Predict Intradialytic Hypotension During Kidney Replacement Therapy

Annabelle H. Lint,[1] Brian P. McLaverty,[1] Robert S. Parker,[1] Raghavan Murugan,[1] Kianoush Kashani,[2] Gilles Clermont.[1] *[1]University of Pittsburgh, Pittsburgh, PA; [2]Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Kidney replacement therapy (KRT) after acute kidney injury is associated with intradialytic hypotension (IDH) in up to 30% of sessions. IDH is associated with premature termination of therapy and is an independent predictor of mortality. Thus, there is a critical need to develop a clinical decision support tool that predicts IDH and preemptively suggests optimal therapy.

Methods: We constructed a reinforcement learning (RL) algorithm that generates personalized, dynamic treatment plans for IDH during intermittent KRT. The RL model was trained and validated using clinical data from a cohort of 277 patients undergoing 1,595 hemodialysis treatments in a tertiary care center. A random forest classifier was used to generate individualized risk trajectories for IDH, which were incorporated with patients' physiological features to define a discrete state space. The RL was trained for an optimal action every 15 minutes. To ensure that selected actions aligned with clinical intuition, a bias term prevented the RL from over-recommending clinically rare actions. Finally, a Q-learning algorithm used risk rewards as intermittent feedback to learn a personalized sequence of optimal actions.

Results: The RL agent tended to recommend interventions more frequently than clinicians, with an RL intervention frequency of 41.7% compared to a clinician intervention frequency of 18.4%. The most frequently recommended clinical intervention by both clinicians and the RL agent was a change in ultrafiltration rate (clinician, 17.8%, RL, 40.8%), followed by administering mannitol or vasopressors (clinician, 0.6%, RL, 0.8%). Implementing the learned policy decreased the occurrence of IDH and increased fluid goal achievment *in silico*, as seen in Table 1 below.

Conclusions: Dynamic risk forecasting and RL generated risk prediction of IDH and personalized treatment plans for IDH during intermittent KRT. These dynamic policies recommend more than twice as many interventions as clinicians. We showed RL agents could decrease the frequency of IDH while meeting therapeutic goals and improving clinical outcomes.

Funding: NIDDK Support

Table 1.

	IDH [count (%)]	Fluid Goals Achieved [count (%)]
RL Treatment Policy	1817 (7.3)	23265 (93.1)
Clinician Treatment Policy	253 (15.0)	1082 (64.2)

TH-PO048

Polygenic Prediction of Estimated Glomerular Filtration Rate in Individuals of African Descent and from the Americas

Holly J. Kramer,[1] Amy Bentley,[2] Odessica N. Hughes,[3] Girish N. Nadkarni,[4] Josyf Mychaleckyj,[5] Andrew Morris,[3] Nora Franceschini.[6] COGENT-Kidney Consortium. *[1]Division of Nephrology and Hypertension, Loyola University Chicago, Maywood, IL; [2]Center for Research on Genomics and Global Health, National Human Genome Research Institute, Bethesda, MD; [3]The University of Manchester, Manchester, United Kingdom; [4]Mount Sinai Health System, New York, NY; [5]University of Virginia, Charlottesville, VA; [6]The University of North Carolina at Chapel Hill, Chapel Hill, NC.*

Background: Chronic kidney disease more often impacts individuals of African descent (AFR) or those from origin from the Americas (AMS), who are under-represented in genome-wide association studies (GWAS). Polygenic scores have been proposed for disease risk prediction. However, polygenic scores developed from GWAS of individuals of European ancestry have limited transferability into other populations, reflecting differences in allele frequencies and linkage disequilibrium across populations. Previous

studies have demonstrated their performance is poor for estimated glomerular filtration rate (eGFR) in AFR and AMS populations. Here, we investigate the predictive power of polygenic scores for eGFR developed in AFR and AMS for African American and Hispanic/Latino individuals.

Methods: We used summary data from eGFR GWAS meta-analyses and the Bayesian Regression and Continuous Shrinkage Priors (PRS-CS) approach to train polygenic scores in: (i) AFR + AMS (66,825 individuals); (ii) AFR-specific (40,001 individuals); and (iii) AMS-specific (26,824 individuals). We compared the performance of the AFR + AMS, and AFR- or AMS-specific polygenic scores in two additional test samples with GWAS data of 8,270 African Americans from the Women's Health Initiative (WHI-AA) and 8,291 Hispanics/Latinos from the BioMe Biobank (BIOME-HA). We assessed the strength of the association and the variance explained of the three polygenic scores in each validation studies.

Results: When applied to WHI-AA, the AFR polygenic score outperformed the AMS score and explained 12.5% of the eGFR variance, while the AFR + AMS polygenic score had the best performance, explaining 13.5% of the eGFR variance. For scores applied to BIOME-HA, the best performance was for the AFR + AMS score, which explained 5.2% of the eGFR variance, compared to the AMS score that explained 2.4%. All polygenic scores were significantly associated with eGFR in the validation datasets.

Conclusions: In this largest aggregated GWAS of AFR and AMS individuals, we showed increased predictive power offered by a multi-population polygenic score for eGFR in both African Americans and Hispanics/Latinos. This study has shown the largest variance explained by a polygenic score in AFR, enhancing resources for disease prediction in this population.

TH-PO049

Empowering Dialysis Patients to Self-Manage Hyperphosphatemia with Mobile Health Technology: Insights from the FOSFO-OK Study

Miguel Hueso,[1,2] Ronny I. Rodriguez Urquia,[1] Rafael Alvarez Esteban,[1] Maria Quero,[1] Gustavo E. Villalobos,[4] Claudia Galofre,[2] Roser Peiró-Jordán,[6] David M. Martínez,[5] Alfredo Vellido.[3] FOSFO-OK. *[1]Hospital Universitari de Bellvitge Servei de Nefrologia, L'Hospitalet de Llobregat, Spain; [2]Institut d'Investigacio Biomedica de Bellvitge, Barcelona, Spain; [3]Universitat Politecnica de Catalunya, Barcelona, Spain; [4]Diaverum Espana, Coslada, Spain; [5]Technology Centre of Catalonia Eurecat, Barcelona, Spain; [6]CSL-VIFOR, Barcelona, Spain.*

Background: mHealth apps are cost-effective technologies that can assist dialysis patients in achieving their therapeutic goals. Since many patients fail to control their phosphate levels, the main objective of this project is to develop a mHealth environment that empowers CKD patients to self-management their hyperphosphatemia under medical supervision. Such an environment will allow nephrologists to provide patients with information beyond their traditional point of care and enable patients to receive timely feedback on their condition.

Methods: We developed a web-based management system that delivers patient's phosphate levels results and medical recommendations through a cloud-based IT environment. Patients with phosphate levels > 6 mg/dL and PTH <88 pmoL/L were included in the study. Patients were randomly assigned to receive the app or continue with the usual educational program. Changes in phosphate binders or vitamin D were allowed and analytical results were collected monthly. The degree of satisfaction of patients and nephrologists was evaluated.

Results: The study included 42 patients (21 in each group). The baseline phosphate levels were 6.94±1.43 mg/dL in the group that received the app vs 6.61±0.99 in the control group (p=ns). At the 3-month follow-up, the group that use the app had a phosphate of 5.64±1.73 mg/dL (81% of the patients reduced phosphate levels), while only 57% of the patients in the control group managed to reduce their phosphate level, with mean levels of 6.06±1.44 mg/dL (p=0.018). These results were maintained at 6 months, and 82% of the patients with the app had improved their phosphate levels, compared to only 56% of the patients who did not use the app. Patients who used the app found it to be useful, and nephrologists were also satisfied with the app.

Conclusions: Patient benefits from a virtual assistant via their smartphone, through an integrated system of participatory, personalized, predictive, and preventive medicine. This study demonstrates that virtual tools through a participatory and personalized medicine system help CKD patients to control hyperphosphatemia.

TH-PO050

Terlipressin Therapy in Patients with HRS and Comorbidities: The North American Experience

Hani Wadei,[1] Zhiwei Zhang,[1] Mo Alzubaidi,[2] Khurram Jamil.[3] *[1]Mayo Clinic, Jacksonville, FL; [2]Columbia Nephrology Associates, Columbia, SC; [3]Mallinckrodt Pharmaceuticals, Bridgewater, NJ.*

Background: Hepatorenal syndrome (HRS)—a rapid kidney failure—occurs in patients (pts) with decompensated cirrhosis and ascites. Terlipressin (Terli) is FDA-approved to treat pts with HRS. Certain pts with HRS and alcoholic hepatitis (AH), systemic inflammatory response syndrome (SIRS), or low mean arterial pressure (MAP) may suffer from a portal hypertension/splanchnic vasodilation-related inflammatory response, which may be attenuated by Terli.

Methods: Data from the 3 largest prospective, randomized, placebo (Pbo)-controlled, clinical studies in pts with HRS (OT-0401, REVERSE, and CONFIRM) were pooled to assess the role of Terli vs Pbo (both plus albumin) on HRS reversal in the subpopulation of pts with AH, MAP <70 mm Hg, or SIRS. HRS reversal was defined as at least 1 serum creatinine (SCr) value of ≤1.5 mg/dL while on treatment.

Results: In the pooled population, 394/608 pts had AH, SIRS, or low MAP, and 214/608 pts did not. At baseline, SCr and MELD score were comparable between treatment groups (gps). Among pts with AH, SIRS, or low MAP, HRS reversal was achieved by 81/233 (35%) pts in the Terli gp vs 21/161 (13%) pts in the Pbo gp (*P*<.001). Among pts with AH, SIRS, or low MAP, fewer pts in the Terli gp (vs Pbo gp) needed renal replacement therapy (RRT) by Day 30 (26% vs 35%, *P*=.049), Day 60 (28% vs 38%, *P*=.046), and Day 90 (30% vs 38%, *P*=.104). Overall survival (OS) up to 90 days demonstrated a positive trend in pts in the Terli gp vs the Pbo gp (*P*=.077; **Figure**).

Conclusions: Pts with HRS who had AH, SIRS, or low MAP had a significantly higher HRS reversal rate and lower RRT rate at Days 30 and 60, and a trend for better OS when randomized to Terli vs Pbo.

Funding: Commercial Support - Mallinckrodt Pharmaceuticals

Association of AKI-Hepatorenal Syndrome (HRS) with Mortality in Hospitalized Cirrhotic Patients Requiring Renal Replacement Therapy: Results from the HRS-HARMONY Consortium

Augusto Cama-Olivares,[1] Tianqi Ouyang,[2] Tomonori Takeuchi,[1,3] Shelsea A. St. Hillien,[2] Jevon E. Robinson,[2] Kavish R. Patidar,[4] Giuseppe Cullaro,[5] Raymond T. Chung,[6] Kevin R. Regner,[7] Juan Carlos Q. Velez,[8] Nabeel Wahid,[9] Pratima Sharma,[10] Andrew S. Allegretti,[2] Javier A. Neyra,[1] Justin M. Belcher.[11,12] HRS-HARMONY Consortium. *[1]The University of Alabama at Birmingham Division of Nephrology, Birmingham, AL; [2]Massachusetts General Hospital Division of Nephrology, Boston, MA; [3]Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan; [4]Indiana University School of Medicine Division of Gastroenterology and Hepatology, Indianapolis, IN; [5]University of California San Francisco Division of Gastroenterology, San Francisco, CA; [6]Massachusetts General Hospital Division of Gastroenterology, Boston, MA; [7]Medical College of Wisconsin Division of Nephrology, Milwaukee, WI; [8]Ochsner Medical Center Department of Nephrology, New Orleans, LA; [9]Northwestern University Feinberg School of Medicine Division of Gastroenterology and Hepatology, Chicago, IL; [10]University of Michigan Health System Department of Gastroenterology and Transplant Hepatology, Ann Arbor, MI; [11]Yale University Department of Internal Medicine, New Haven, CT; [12]VA Connecticut Healthcare System, West Haven, CT.*

Background: While AKI-RRT is associated with mortality in heterogeneous inpatient populations, the epidemiology of AKI-RRT in hospitalized cirrhotic patients is not fully known. Herein, we evaluated the association of etiology of AKI with mortality in hospitalized cirrhotic patients with AKI-RRT.

Methods: This is a multicenter retrospective cohort study using data from the HRS-HARMONY consortium which included 15 hospitals in the U.S. (01/2019-12/2019). Consecutive hospitalized adult (≥18 years) cirrhotic patients with AKI-RRT were included in this study. The primary outcome was 90-day mortality and the main independent variable was AKI etiology, classified as hepatorenal syndrome (HRS-AKI) vs. other. AKI etiology was adjudicated by at least 2 independent adjudicators. We performed multivariate Cox regression analysis adjusting for age, gender, race, transplant listing status, MELD-Na score, requirement of CRRT, pressor use, and study site.

Results: Of 2063 hospitalized cirrhotic patients with AKI, 374 (18.1%) had AKI-RRT. Among these, 65 (17.4%) had HRS-AKI and 309 (82.6%) had other etiologies of AKI which included ATN in the majority of cases (62.6%). The HRS-AKI (vs. other AKI etiology) group required less CRRT than hemodialysis as the initial RRT modality (56.9% vs. 73.9%, p=0.006), more HRS vasoconstrictor use (81.5% vs. 67.9%, p=0.03), and less mechanical ventilation use (50.8% vs. 64.3%, p=0.04). In a fully adjusted model, HRS-AKI (vs. other AKI etiology) was not associated with 90-day mortality (aHR=1.16, 95% CI: 0.75-1.79, p=0.51). Clinical parameters independently associated with 90-day

mortality included liver transplant listing (aHR=0.22, 95% CI: 0.14-0.35), MELD-Na score (aHR=1.04, 95% CI: 1.02-1.05), and the need of CRRT (aHR=2.64, 95% CI: 1.68-4.13).

Conclusions: Among hospitalized adult cirrhotic patients with AKI-RRT, HRS-AKI was diagnosed in about one-fifth of patients, but did not confer an independent increased risk of 90-day mortality when compared to other AKI etiologies. Higher MELD-Na score and the need of CRRT were independently associated with increased 90-day mortality in this susceptible population.

TH-PO052

Improvement in Serum Creatinine Was Associated with Favorable Clinical Outcomes in Patients with Hepatorenal Syndrome: A Post Hoc Analysis of the CONFIRM Study

Juan Carlos Q. Velez,[1,2] Muhammad A. Mujtaba,[3] Hussien A. Elsiesy,[4] Khurram Jamil.[5] *[1]Ochsner Health, New Orleans, LA; [2]The University of Queensland, Saint Lucia, QLD, Australia; [3]The University of Texas Medical Branch at Galveston, Galveston, TX; [4]Baylor Scott & White Health, Plano, TX; [5]Mallinckrodt plc, Dublin, Ireland.*

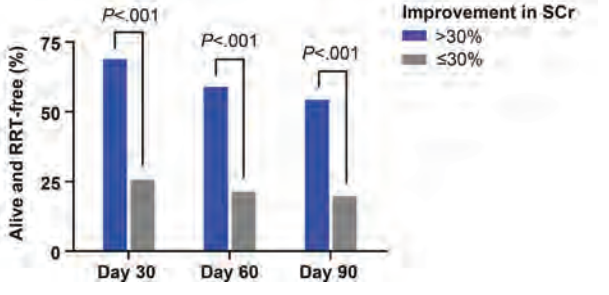
Background: Hepatorenal syndrome (HRS) is a life-threatening but potentially reversible form of acute kidney injury. More patients (pts) with HRS who were treated with terlipressin (terli), achieved verified HRS reversal than placebo (pbo) in the Phase III CONFIRM study (terli 29.1%; pbo 15.8%; *P*=.012). This post hoc analysis assessed pt data from CONFIRM to determine if an improvement in serum creatine (SCr) of >30% was associated with improved clinical outcomes.

Methods: CONFIRM enrolled adult pts with cirrhosis, ascites, HRS, and a SCr ≥2.25 mg/dL with a projected doubling in SCr within 2 weeks. Pts were treated intravenously with terli 1 mg every 6 hours or matched pbo; plus albumin, recommended. Pts from the CONFIRM intent-to-treat (ITT) population were analyzed by their improvement (>30% vs ≤30%) in SCr level from baseline (Day 0; or a prestudy value, if Day 0 value was missing) to the end of treatment (EOT) for the following: length of intensive care unit (ICU) stay; incidence of renal replacement therapy (RRT) and RRT-free survival at Days 30, 60 and 90; as well as survival at Day 90.

Results: More pts in the terli vs pbo group had a >30% improvement in SCr from baseline to EOT (43.7% vs 21.8%; *P*<.001). Among pts admitted to the ICU, the mean (SD) length of stay was numerically shorter (5.8d [3.25] vs 9.4d [11.62]; *P*=.673) among those who had a >30% vs ≤30% improvement in SCr. Fewer pts in the >30% (vs ≤30%) improvement in SCr subgroup required RRT (Day 90: 18.3% vs 40.3%; *P*<.001). Overall, a higher proportion of pts (N=300; terli + pbo combined) who achieved >30% improvement in SCr were alive (67.0% vs 42.9%, *P*<.0001); and alive and RRT-free by Day 90 (55.0% vs 20.4%, *P*<.001) (**Figure**).

Conclusions: Significantly more pts in the terli group achieved a >30% improvement in SCr versus pbo. Pts with a >30% improvement in SCr had significant improvements in clinical outcomes through Day 90.

Figure. Proportion of patients alive and renal replacement therapy (RRT)-free by improvement in serum creatinine (SCr) from baseline to end of treatment



TH-PO053

Outcomes of AKI on CKD in Hospitalized Cirrhotic Patients: Data from the HRS-HARMONY Consortium

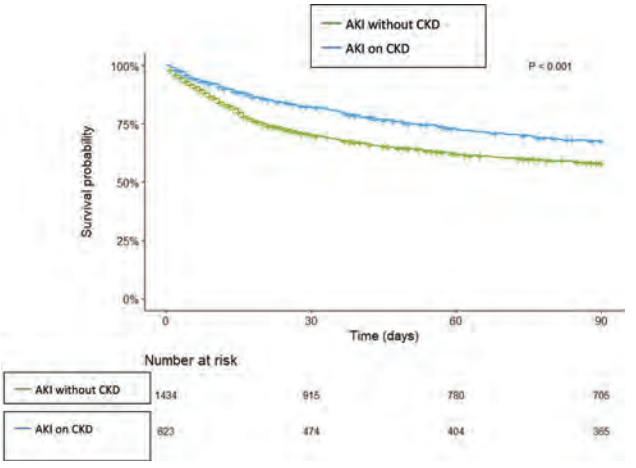
Shelsea A. St. Hillien,[1] Justin M. Belcher,[2] Tianqi Ouyang,[1] Jevon E. Robinson,[1] Kevin R. Regner,[3] Juan Carlos Q. Velez,[4] Kavish R. Patidar,[5] Giuseppe Cullaro,[6] Raymond T. Chung,[1] Andrew S. Allegretti.[1] HRS-HARMONY Consortium. *[1]Mass General Brigham Inc, Boston, MA; [2]Yale School of Medicine, New Haven, CT; [3]Medical College of Wisconsin, Milwaukee, WI; [4]Ochsner Health, New Orleans, LA; [5]Baylor College of Medicine, Houston, TX; [6]University of California San Francisco School of Medicine, San Francisco, CA.*

Background: The frequency of chronic kidney disease (CKD) is increasing in cirrhosis and these patients frequently suffer acute kidney injury (AKI). Direct comparisons of outcomes between AKI vs AKI on CKD are not well described in cirrhosis.

Methods: 2,057 cirrhotic patients with AKI across 11 hospital networks from the HRS-HARMONY consortium were analyzed (70% AKI without CKD and 30% AKI on CKD). Primary outcome was unadjusted and adjusted 90-day mortality, with transplant as a competing risk.

Results: Compared to patients without CKD, patients with AKI on CKD had higher admission creatinine (2.24 [IQR 1.7, 3.18] vs 1.83 [1.38, 2.58] mg/dL) and peak creatinine (2.79 [2.12, 4] vs 2.42 [1.85, 3.50] mg/dL) but better synthetic liver function (total bilirubin 1.5 [IQR 0.7, 3.1] vs 3.4 [1.5, 9.3] mg/dL; and INR 1.4 [IQR 1.2, 1.8] vs 1.7 [1.39, 2.2]; p<0.001 for all). Patients with AKI on CKD were more likely to have NASH cirrhosis (31% vs 17%) and less likely to have alcohol-associated liver disease (26% vs 45%; p<0.001 for all). Patients without CKD had higher unadjusted mortality (39% vs 30%), intensive care unit admission (52% vs 35%), and use of renal replacement therapy (29% vs 15%; p<0.001 for all). After adjusting for age, race, sex, transplant listing status and MELD-Na score; AKI on CKD was associated with a lower 90-day mortality compared to AKI without CKD (sub-HR 0.73 [95% CI 0.61, 0.88]).

Conclusions: In cirrhotic hospitalized patients, AKI on CKD is associated with lower 90-day mortality compared to AKI without CKD. This surprising finding may be due to worse synthetic liver function in the AKI without CKD group as underlying liver function is a strong driver of short-term outcomes in this population. Further study of the complicated interplay between acute and chronic kidney disease in cirrhosis is needed.



TH-PO054

Pre-Liver Transplant Acute Kidney Disease Highlights Impaired Renal Function Recovery Phase

Jacqueline Lee, Edmund Huang, Sanjeev Kumar. *Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: Acute kidney disease (AKD), the phase between acute kidney injury (AKI) and chronic kidney disease (CKD), represents a crucial time window for initiation of therapies that may significantly augment renal function recovery. Herein, we aim to study the impact of duration of AKI in patients with decompensated cirrhosis on subsequent renal function recovery post-liver transplantation.

Methods: This is a single-center, retrospective study of adults who underwent single-organ, orthotopic liver transplant (OLT) from Jan 2015 to Dec 2021. AKD was defined as persistence of AKI for greater than a week but up to 90 days. The study cohort was classified by pre-transplant AKI duration and renal replacement therapy (RRT) status into four groups: normal kidney function, AKI requiring RRT within 7 days of onset (AKI_RRT), AKD without RRT (AKD_noRRT), and AKD with RRT (AKD_RRT). Renal function was compared with serial measurements of eGFR before and after OLT.

Results: Approximately half of the patients required RRT prior to OLT (81/170, 47.6%): 24% (41/170) required RRT within 7 days of AKI and other 23.7% (40/170) during the AKD phase. Only 6.5% (11/170) underwent OLT with AKD but without RRT. The remaining cohort had normal renal function (78/170, 45.8%). Patients who were commenced on RRT during the AKD phase had significantly lower eGFRs at 3 months and 1 year compared to AKI_RRT group [AKD_RRT vs. AKI_RRT; 41.6 ml/min vs. 56.6 ml/min, p < 0.05 (3 months); and 49.7 ml/min vs. 59.2 ml/min, p < 0.05 (1 year)]. No significant deterioration of eGFR was found in the normal function group.

Conclusions: Our study findings suggest AKD is associated with significantly reduced renal function recovery at 1-year post-liver transplantation. Our study demarcates the critical phase of AKI associated with maximal renal function recovery in cirrhotic patients for OLT and inform when best to initiate therapies that are linked with renal function recovery.

Post-liver transplant eGFR Trajectories

Variable	Normal Creatinine Function	AKI_RRT	AKD_noRRT	AKD_RRT	p-value
Participants - n	78	41	11	40	
eGFR at transplant	86.8 ± 46.9	15.7 ± 17.7	51.2 ± 27.8	15.6 ± 15.2	<0.05
At 3 months*	77.3 ± 42.7	56.6 ± 27.3	52.3 ± 15.7	41.6 ± 25.9	<0.05
At 1 year**	77.2 ± 41.5	59.2 ± 29.6	55.3 ± 22.6	49.7 ± 29.2	<0.05

Cholemic Tubulopathy as a Cause of AKI: A Cohort Study

Vipin Varghese, Dustin R. Chalmers, Lauren Cohen, Akanksh Ramanand, Juan Carlos Q. Velez. *Ochsner Health, New Orleans, LA.*

Background: Cholemic tubulopathy (i.e., bile cast nephropathy) is a type of acute kidney injury (AKI) described in individuals with acute cholestasis (obstructive, drug-induced, infectious, acute alcoholic). However, most of the available evidence comes from isolated case reports. We aimed to describe the clinical characteristics of patients diagnosed with cholemic tubulopathy within a single-center prospective AKI cohort.

Methods: We established prospective data collection in patients with AKI stage ≥ 2 (AKIN) over 5-years. Each patient completed microscopic examination of the urinary sediment (MicroExUrSed). The presence of hyaline casts (HC), waxy casts (WxC), renal tubular epithelial cell casts (RTECC), granular casts (GC), and muddy brown granular casts (MBGC) were recorded. We identified patients with documented cholestasis without cirrhosis. Demographic and clinical characteristics were extracted. Cases of shock liver were excluded.

Results: Among 483 patients with AKI without cirrhosis, 22 (4.6%) patients were found to have cholemic tubulopathy as the primary cause of AKI [32% women, 46% white, 27% black, median age 57 (20-84)]. Causes of cholestasis included biliary obstruction due to primary or metastatic cancer (5), biliary stricture (1), drug-induced cholestasis (1), cholelithiasis (6), acute viral hepatitis (3), alcoholic hepatitis (4), and acute liver failure of unknown etiology (2). One case was biopsy-proven bile cast associated acute tubular injury (acute hepatitis A). Median serum bilirubin was 22.8 (5.3-57.7) mg/dL and serum creatinine at presentation was 3.1 (1.4-8.6) mg/dL. By MicrExUrSed, HC, RTECC, GC, MBGC, and WxC were identified 13%, 41%, 64%, 55%, and 28% of patients, respectively. Among patients which had crystals reported, leucine crystals were seen in 5/17 (29%) and bilirubin crystals were seen in 4/17 (24%). Among patients with cholemic tubulopathy, 11 (50%) patients required dialysis, 6 (27%) died, and 6 (27%) recovered kidney function.

Conclusions: Cholemic tubulopathy should be suspected as a cause of AKI in patients with cholestasis with severe hyperbilirrubinemia without an alternative etiology of AKI. Overt evidence of tubular injury is often found by MicrExUrSed.

TH-PO056

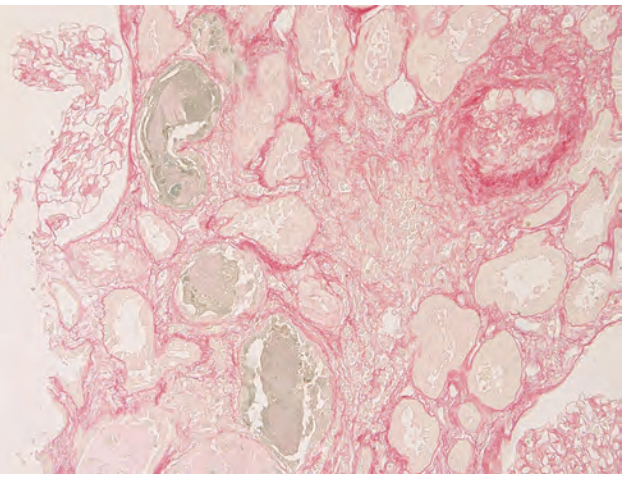
A Case of Bile Cast Nephropathy Treated with Plasma Exchange Therapy for AKI Associated with Acute Hepatitis A

Masahiro Arai, Takahito Moriyama, Fumika Iemura, Rie Suzuki, Yoshitaka Miyaoka, Yoshihiko Kanno. Tokyo Medical University Hospital. *Tokyo Ika Daigaku, Shinjuku-ku, Japan.*

Introduction: Bilirubin-induced renal injury has been reported as bile cast nephropathy (BCN) or cholemic nephropathy (CN) which was a rare form of acute kidney injury (AKI) in Japanese. Although the improvement of hyperbilirubinemia is effective for renal dysfunction, the treatment strategies of blood purification therapy has not been established. Here, we report a case of bile cast nephropathy associated with acute hepatitis A in which hyperbilirubinemia was treated by plasma exchange therapy and AKI was improved.

Case Description: The patient, a 45-year-old man, was admitted to the hospital with acute hepatitis A. His transaminase and serum direct bilirubin (D-Bil) was severely increased (AST: 197 1U/L, AST: 2652 U/L, and D-BIl: 8.31 mg/dL), but serum creatinine (Cr) was normal (0.81 mg/dL). While his transaminase tended to improve with the best supportive care his D-Bil was elevated to 37.6 mg/dL, and Cr was also elevated to 4.5 mg/dL on day 30. Based on the course of the disease, the possibility of BCN was suspected, and plasma exchange therapy was administered 5 times on alternative days from day 30. On day 42, we performed a percutaneous renal biopsy, and we observed bilirubin columns in the renal tubules, and we made diagnosis as BCN. After plasma exchange therapy, his D-Bil was dramatically decreased and the renal dysfunction was recovered as serum Cr level of 1.2 mg/dL.

Discussion: Despite the improvement of transaminase, the elevated D-Bil induced the renal dysfunction, and we suspected BCN as the cause of AKI and successfully treated AKI due to BCN by plasma exchange therapy. BCN is rare in Japanese, and moreover, there have been few reports of renal biopsy in surviving patients. The treatment strategies of blood purification therapy to remove bilirubin have not been established, and further study is needed.



TH-PO057

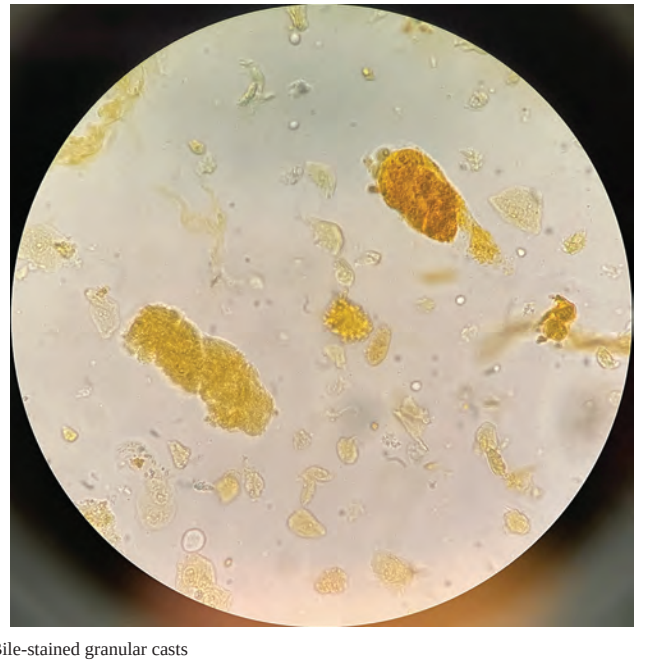
Bile Cast Nephropathy: A Diagnostic Odyssey Beyond Hepatorenal Syndrome

Samira M. Samant, Camilo Cortesi. *The Permanente Medical Group Inc, Santa Clara, CA.*

Introduction: Bile cast nephropathy (BCN) is a rarely recognized and often overlooked complication of hyperbilirubinemia leading to acute kidney injury (AKI). We present a case of BCN in a patient with alcohol hepatitis initially managed as hepatorenal syndrome (HRS).

Case Description: A 66-year-old male with severe alcohol abuse and baseline creatinine of 1.5 mg/dL presented with altered mental status and acute alcohol intoxication, requiring ICU admission. Laboratory tests showed AST 751 U/L, ALT 238 U/L, ALKP 768 U/L, total bilirubin 22.9 mg/dL, direct bilirubin 12.4 mg/dL, INR 2.4, ammonia 181 umol/L, and creatinine 2.6 mg/dL with FENa 0.1%. Ultrasound revealed diffusely hyperechoic liver, diagnosing alcoholic hepatitis with impending liver failure. Glucocorticoids were initiated, with octreotide, albumin, and midodrine for HRS. However, renal function worsened as total bilirubin peaked at 54 mg/dL. Urine microscopy identified bile-stained granular casts, prompting reassessment of the initial HRS diagnosis.

Discussion: HRS is often considered in AKI with liver dysfunction, but urine microscopy should not be overlooked. In AKI, urine microscopy to rule out BCN is crucial, especially when total bilirubin exceeds 20 mg/dL. Bilirubin's nephrotoxic effects involve oxidative damage to renal tubules, bile cast obstruction, and toxicity of sulfated bile salts. Renal biopsy for definitive diagnosis is unsafe in liver disease due to coagulopathy. Treatment focuses on improving hepatic function and relieving biliary obstruction if present. Timely diagnosis and intervention can reverse renal injury; refractory cases may require plasmapheresis or dialysis. Steroids, ursodeoxycholic acid, and lactulose provide minimal benefit. This case highlights the challenges of differentiating BCN from HRS, emphasizing the importance of urine microscopy.



Bile-stained granular casts

Prevent Cardiac Surgery-Associated AKI by Perioperative Implementation of Care Bundles

Youjun Xu, Shuzhen Zhang, Fangfang Zhou, Xingyue Zheng, Qun Luo. *Ningbo No.2 Hospital, Ningbo, China.*

Background: Cardiac surgery-associated acute kidney injury (CSA-AKI) is a serious complication after cardiac surgery. Perioperative implementation of care bundles was recommended for high-risk patients. The study evaluated the impact of care bundles on the incidence and severity of CSA-AKI.

Methods: Patients underwent cardiac surgery with cardiopulmonary bypass in Ningbo No.2 Hospital from 1st October 2020 to 30th September 2021 were retrospectively collected as the control group, and patients from 1st October 2021 to 30th September 2022 were prospectively collected as the intervention group. In the intervention group, patients were treated by care bundles from nephrologists in addition to the standard care perioperatively. The clinical data, the incidence and severity of CSA-AKI were compared between two groups.

Results: A total of 135 patients were included in this study, including 80 cases in the control group and 55 cases in the intervention group. There were 24 patients (43.6%) in the intervention group developed CSA-AKI versus 41 patients (51.2%) in the control group. In the intervention group 7 patients (12.7%) had stage 2-3 AKI, and in the control group 15 patients (18.8%). Both the incidence and severity of AKI showed a decreasing trend in the intervention group. Patients who used febuxostat and statins in the intervention group were significantly higher than the control group (20.0% vs. 1.3%, P=0.001; 40.0% vs. 21.3%, P=0.018). The intervention group had a higher proportion of completing urine examination and urinary albumin-to-creatinine ratio test than the control group (100.0% vs. 58.8%, P<0.001; 100.0% vs. 1.3%, P<0.001). Patients who used contrast agents within 48 hours prior to surgery was significantly less in the intervention group (3.6% vs. 15.0%, P=0.033). Compared with the control group, the intervention group had a higher proportion of use of albumin (83.6% vs. 53.8%, P<0.001), epinephrine (70.9% vs. 50.0%, P=0.015), norepinephrine (60.0% vs. 41.3%, P=0.032), and insulin (45.5% vs. 21.3%, P=0.003). Patients in the intervention group also had a higher mean arterial pressure than the control group (63.4±12.6mmHg vs. 40.5±16.6mmHg, P<0.001).

Conclusions: Perioperative implementation of care bundles may reduce the occurrence of CSA-AKI and prevent progression of CSA-AKI, larger sample size is needed for further verification.

TH-PO059

SGLT2 Inhibitor Dapagliflozin Reduces Biomarkers of Tubular Injury in Patients with Acute Heart Failure

Jananya Wattanakul, Pongsathorn Gojaseni, Anutra Chittinandana. *Bhumibol Adulyadej Hospital, Bangkok, Thailand.*

Background: Sodium-glucose co-transporter 2 (SGLT2) inhibitors improve renal and cardiovascular outcomes in heart failure patients, and there is growing evidence that it would decrease the risk of acute kidney injury (AKI). The aim of this study was to assess the effect of SGLT2 inhibitor on biomarkers of tubular injury in patients with acute heart failure (AHF).

Methods: Patients who hospitalized for AHF were randomized to dapagliflozin added to standard therapy or control group for 28 days. The primary outcome was the change of urinary [TIMP-2] x [IGFBP7] by NephroCheck® from baseline. The secondary outcome was incidence of AKI, the change of serum creatinine from baseline, adverse events and 28-day mortality.

Results: A total of 32 patients underwent randomization. Compared with control group, dapagliflozin group significantly reduced urinary [TIMP-2] x [IGFBP7] after 7 days [dapagliflozin: -0.03 ± 0.37 $(ng/mL)^2/1000$; control: +0.4 ± 0.50 $(ng/mL)^2/1000$; P = 0.022] and continue this trend until the end of the study [dapagliflozin: -0.09 ± 0.79 $(ng/mL)^2/1000$; control: +0.67 ± 0.91 $(ng/mL)^2/1000$; P = 0.096] (Figure 1). In terms of clinical outcomes, dapagliflozin has demonstrated a trend towards decrease in AKI events compared with control (33.3% vs 46.2%; P = 0.513). The change of serum creatinine, adverse events and 28-day mortality showed no differences in both groups.

Conclusions: Initiation of SGLT2 inhibitors in patients with AHF significantly decrease the urinary AKI risk markers TIMP-2 and IGFBP7, that supported protective effect of SGLT2 inhibitor on renal tubular injury.

Funding: Government Support - Non-U.S.

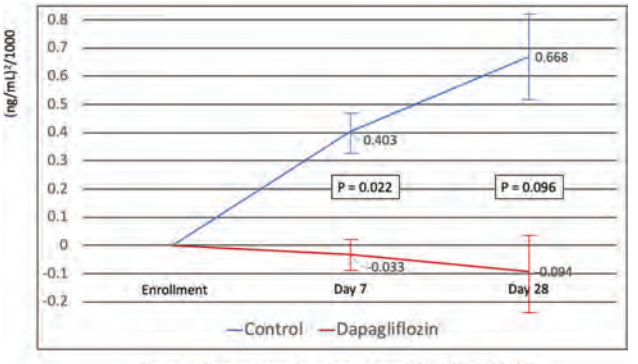

Figure 1: Changes from baseline Urinary [TIMP-2] x [IGFBP7]
Notes: p-value compared changes from baseline between both groups

Probiotics in Septic AKI: A Double-Blind, Randomized Control Trial

Jonathan Chavez,[1] Jose S. Cabrera Aguilar,[1] Guillermo Garcia-Garcia,[1] Maria de la Luz Alcantar Vallin,[1] Francisco Gonzalo Rodríguez García,[1,2] Miguel Ángel P. Venegas,[1] Alexa N. Oseguera Gonzalez,[1] José David G. Barajas,[1] Karina Renoirte,[1] Karla Hernandez Morales,[1] Eduardo M. Hernández.[1,2] *[1]Universidad de Guadalajara, Guadalajara, Mexico; [2]Hospital Civil de Guadalajara, Guadalajara, Mexico.*

Background: During sepsis-induced acute kidney injury (AKI), the intestinal microbiota has profound negative changes, this dysbiosis could aggravates AKI. It is possible that modulating the intestinal dysbiosis with probiotics will favor kidney function recovery (KFR) and clinical outcomes.

Methods: In this double-blind clinical trial, patients with sepsis-induced AKI were randomized to receive probiotics or placebo for 7 days. The primary outcome was the rate of KFR by day 7. Secondary outcomes were mortality, kidney replacement therapy (KRT) requirements, urea reduction, modifications in urine volume, electrolyte abnormalities and treatment related adverse events.

Results: A total of 92 patients from February 2019 to March 2022 were randomized, 48 to probiotics and 44 to placebo. Compared to placebo, probiotics did not improve KFR by day 7(HR 0.93, 0.52-1.68, p = 0.81), mortality hazard ratio at 6 months was 0.57 (95%CI 0.32-1.04, p = 0.06). Urea (mg/dL) decreased significantly in the probiotic group from 154 to 80 mg/dl (p = 0.04) as compared to the placebo group (130 to 109 mg/dl (p=0.09). No significant differences were observed with respect to urinary volume, KRT requirement and electrolytes abnormalities. Adverse events were frequent and similar in both groups. (ClinicalTrial.gov NCT03877081) (registered 03/15/2019)

Conclusions: In septic-induced AKI, administration of probiotics for 7 days was safe; however, they did not improve KFR or reduce mortality.

TH-PO061

The Impact of Statin Use Before Intensive Care Unit Admission on Patients with AKI After Cardiac Surgery

Fanna Liu. *Department of Nephrology, The First Affiliated Hospital of Jinan University, Jinan University, Guangzhou, China.*

Background: Cardiac surgery-associated acute kidney injury (CSA-AKI) is a common and serious complication after cardiac surgery. The influence of statin use before surgery on the renal outcome of patients undergoing cardiac surgery is controversial. The purpose of this study was to evaluate the effect of statins on postoperative renal outcomes in patients undergoing cardiac surgery.

Methods: This is a retrospective observational study. We included CSA-AKI patients in the Medical Information Mart for Intensive Care- IV database, and were divided into statin group and non-statin group according to whether they used statins before entering ICU. The main outcome was inpatient mortality and 30-day mortality, and the secondary outcomes were 60-day mortality and 90-day mortality. We used PSM to adjust for confounding factors. The 95% CI and risk ratio were calculated by COX proportional regression model, and the two groups of ICU LOS were compared by multiple linear regression. At the same time, stratified analysis was used to explore whether the relationship between the statins use before ICU and mortality was different in each subgroup, and whether the relationship between different doses of statins and mortality was different. Finally, CSA-AKI patients in the ICU of the First Affiliated Hospital of Jinan University were used as external validation data.

Results: 675 pre-ICU statin and 2095 non-statin user were identified. In the COX proportional regression model, pre-ICU statin use was associated with the decreased in-hospital mortality (HR=0.407, 95%CI 0.278-0.595, P<0.001) and 30-day mortality (HR=0.407, 95%CI 0.279-0.595, P<0.001). The survival rate of patients who took statins before entering ICU was significantly higher than that of those who did not use statins at 30 days, 60 days and 90 days. In subgroups of patients with age>65 years (HR=0.373, 95%CI 0.240-0.581, P<0.001), AKI grade I (HR=0.244, 95%CI 0.118-0.428, P<0.001), and without post-myocardial infarction syndrome (HR=0.344, 95%CI 0.218-0.542, P<0.001), statin use can reduce the risk of 30-day mortality in CSA-AKI patients. The in-hospital mortality of CSA-AKI patients treated with atorvastatin≥80mg was significantly reduced (P=0.030).

Conclusions: The pre-ICU statin use was significantly associated with decreased risk in-hospital and 30-day mortality, especially the loading dose of atorvastatin (≥80mg).

Association of Inpatient Metformin Use After Recovery from AKI with Lactic Acidosis and Mortality in Type 2 Diabetes Mellitus (DM)

Huiwen Chen,[1] Hsin-Hsiung Chang.[2] *[1]University of Pennsylvania, Philadelphia, PA; [2]Antai Medical Care Corporation Antai Tian-Sheng Memorial Hospital, Pingtung, Taiwan.*

Background: Acute kidney injury (AKI) in the hospitalized setting is an independent risk factor for mortality. The higher the degree of AKI, the higher the rate of mortality. Metformin is a baseline antiglycemic therapy for patients with type

2 diabetes melitus (T2DM) without other comorbidy. Recent studies have shown that metfomin has pleiotropic effect and has been linked with lower cardiovascular mortality. The use of metfomin in the inpatient setting is controversial. We are exploring if metformin use after AKI recovery is associated lower mortality and higher degree of lactic acidosis.

Methods: This is a retroscpective cohort study employed the Medical Information MART for Intensive Care IV (MIMIC-IV) databse, which was released by the Massachusetts Institute of Technology Laboratory for Computational Physiology The database contained intensive care unit data from a single teriary care hospital from 2008-2019. The propensity-score matching study was conducted to analyze the outcomes for the sensivity analyses.

Results: Only 37 of 922 metformin users and 3747 of 5175 metformin nonusers had lactate level evaluated. The median level (IQR) WAS 1.4 (1.0-1.7) in the metformin user versus 1.4 (1.1-1.8) in non-users with P 0.902. There was no statistical difference in the degree of lactic acidossi s developed between two groups.

Conclusions: Metformin therapy during hospitalization after AKI recovery in patients with T2DM is not associated with increased risk of lactic acidosis. In addition, metformin user after recovery from AKI stage 2 and stage 3 is associated with lower 1- year mortality than the metfomin non-users.

TH-PO063

Associations of RAASi Discontinuation with Mortality Among Hospitalized Patients with Cardiovascular Disease in Brazil

Ana Carolina N. Tome,[1] Marcelo Lopes,[2] Paola B. Ferrés,[1] Karise F. Dos santos,[1] Ludmila B. Santos,[2] Isadora G. Dultra,[2] Rodrigo J. Ramalho,[1] Emerson Q. Lima.[1] *[1]Hospital de Base, Sao Jose do Rio Preto, Brazil; [2]Hospital Sao Rafael, Salvador, Brazil.*

Background: It is consensus that renin-angiotensin-aldosterone system inhibitors (RAASi) are a pillar of drugs used for cardiovascular and renal protection, however their effects during an AKI episode are still controversial and most guidelines suggest their discontinuation. The aim of the study is to compare the mortality of hospitalized patients with cardiovascular diseases who developed AKI and discontinued the inhibitors with those who maintained their use.

Methods: We analyzed data from a cohort of hospitalized patients in Hospital de Base - São José do Rio Preto with cardiovascular disease (coronary artery disease and heart failure) identified by an AKI alert, in 2018 and 2020, based on the KDIGO creatinine criteria, who were using RAASi. Discontinuation of RAASi was defined as the suspension of their prescription for up to 3 days after the AKI alert. We used a Poisson model to estimate the adjusted risk of death predicted by the RAASi discontinuation. Race, sex and age were used as possible confounders.

Results: Our cohort consisted of 1683 patients, with a mean age of 63 years of age with 56% male. Of the patients there were using RAASi within 24 hours of the AKI alert, 729 remained off the medications 72 hours later. The patients that discontinued RAASi had a greater risk of death (31% vs 19%) when compared to the patients who remained using them. When accounting for possible confounders, the risk of death for the RAASi discontinuation group was 54% higher (RR=1.54 (1.30, 1.83)) than for those that remained using the drugs.

Conclusions: In patients with cardiovascular disease, that developed AKI during the hospital stay, the strategy of RAASi discontinuation may be associated with higher mortality. Although there are limitations, due to the observational nature of this analysis, this data supports that this class of drugs should not be withdrawn routinely in the inpatient setting.

TH-PO064

Using Kinetic eGFR for Vancomycin Dosing When Renal Clearance Is Acutely Changing: A Simulation Study

Manohar Bairy, Benjamin Z. Khoo, Sock Hoon Tan, Leticia X. Peh, Siow Yu Lim, Chuang Shen Hui. *Tan Tock Seng Hospital, Singapore, Singapore.*

Background: Achieving target vancomycin trough (VT) levels in acutely ill patients is a challenge. Using Cockcroft Gault estimated creatinine clearance (CGeCrCl) for drug dosing lacks validation when the creatinine level is unsteady. In this cohort of hospitalised patients treated with CGeCrCl based vancomycin dosing, we used Kinetic estimated GFR (KeGFR) and MDRD eGFR to predict VT levels and to simulate vancomycin dosing frequencies and explored the likelihood of achieving target VT levels.

Methods: Among 111 methicillin-resistant *Staphylococcus aureus* bacteremic patients treated with intravenous vancomycin who had creatinine levels varying by > 5% during treatment, a study subgroup (SSG) consisted of 38 patients who had VT levels checked after the first (loading) dose and before the second dose. Predicted VT using CGeCrCl, KeGFR and MDRD eGFR calculated using population pharmacokinetic equations and compared to the true (observed) VT using Bland Altman (BA) plots for agreement in the SSG. The dosing frequency was simulated using KeGFR and MDRD eGFRs based on the hospital vancomycin dosing protocol and the likelihood of achieving the target VT (10-20mg/L) was estimated for each method.

Results: VT levels of 41 patients (37%) were <10mg/L. In the SSG, CGeCrCl was 23.3ml/min (IQR 14.3,30.3), 34% had acute kidney injury (AKI) or were recovering from AKI and 79% had at least 5% variation in 2 consecutive creatinine levels including the level used to determine the vancomycin dosing frequency. 17 (45%) patients had subtherapeutic VT levels in the SSG. KeGFR-predicted VT showed the best agreement with true VT with a mean difference of -0.128 using the BA method. The mean difference was +3.81 for CGeCrCl predicted VT and +0.78 for MDRD predicted VT. In the dose frequency simulation model, 11 of the 17 patients with VT <10mg/L were likely to achieve the target VT when KeGFR is used, compared to 10 patients when MDRD eGFR is used and 2 patients with target VT levels were likely to attain subtherapeutic levels when MDRDeGFR is used.

Conclusions: KeGFR based vancomycin dosing is more likely to achieve target VT levels in comparison to CGeCrCl and MDRD eGFR based dosing in patients with fluctuating creatinine levels. KeGFR based vancomycin dosing will need to be further validated prospectively in a randomised clinical trial.

Ciprofloxacin Crystal-Induced Acute Tubular Injury: A Case Series

Dustin R. Chalmers,[1,2] Sakshi Sharma,[2] Akanksh Ramanand,[2] Swetha Rani Kanduri,[2,3] Juan Carlos Q. Velez.[2,3] *[1]LSU Internal Medicine Residency Baton Rouge, Baton Rouge, LA; [2]Ochsner Medical Center, New Orleans, LA; [3]Ochsner Clinical School, The University of Queensland, Brisbane, QLD, Australia.*

Background: Ciprofloxacin crystal-induced acute tubular injury (ATI) is a rare etiology of acute kidney injury (AKI) characterized by precipitation of ciprofloxacin crystals in the kidney tubules causing obstruction and tubular damage. Ciprofloxacin crystalluria is often seen in these cases. However, most of the available evidence comes from isolated case reports. We aimed to compile a series of cases in which ciprofloxacin crystal-induced ATI was the presumed cause of ATI.

Methods: We prospectively collected demographic and clinical data of patients seen in inpatient nephrology consultation who had a urine specimen subjected to microscopic examination of the urinary sediment (MicrExUrSed) as part of the clinical evaluation over 5 years. We identified cases in which ciprofloxacin crystalluria was identified by MicrExUrSed, recent exposure to ciprofloxacin was confirmed, and ciprofloxacin crystal-induced ATI was considered the likely cause of AKI without a possible alternative diagnosis. Urinary ciprofloxacin crystals were identified based on morphology under direct bright field light microscopy and polarized light.

Results: Of 747 AKI cases who underwent MicrExUrSed, we identified 6 cases in which ciprofloxacin crystal-induced ATI was the most likely cause of AKI. The morphology of the identified crystals was consistent across all cases. Median age was 63 (41-79), 4 were women, all 6 were white. None had preexisting CKD, 2 had cirrhosis. Mean number of days from initiation of ciprofloxacin to onset of AKI was 4 (1-12). The route of ciprofloxacin was 3 oral, and 3 IV. Urinary pH averaged 5.3. Mean serum creatinine at presentation was 2.6 (1.2-4.7) mg/dL. One patient developed concomitant shock which could have contributed to the AKI. Four patients needed dialysis. One patient returned to baseline renal function upon discharge and 3 patients died or were discharged to hospice.

Conclusions: Ciprofloxacin crystal-induced ATI should be suspected in individuals who present with AKI shortly after initiation of ciprofloxacin. This case series demonstrates the utility of MicrExUrSed under direct bright field light microscopy and polarized light as a diagnostic tool to aid in the diagnosis of AKI. Further studies are needed to correlate ciprofloxacin crystalluria with pathological evidence of crystal-induced ATI.

TH-PO066

AKI in a Kidney Transplant Patient Started on Ranolazine

Andrew J. Howard, Amy J. Frankston. *Walter Reed National Military Medical Center, Bethesda, MD.*

Introduction: Ranolazine is an antianginal agent only rarely associated with kidney failure (< 1%). We present a case of a kidney transplant recipient who experienced acute kidney injury (AKI) and hyperkalemia after starting ranolazine, and subsequently improved after it was stopped.

Case Description: A 74-year-old man with end-stage kidney disease (ESKD), presumed secondary to diabetic nephropathy, received a deceased-donor kidney transplant in 2014. Post-transplant course was complicated by BK nephropathy with persistent low-grade viremia and atypical hemolytic uremic syndrome treated with ravulizumab. He presented to the Emergency Department at the request of his hematologist for hyperkalemia and acute kidney injury discovered on routine labs. Baseline serum creatinine was 1.3-1.6 mg/dL. At presentation, serum creatinine was 3.23 mg/dL and potassium 7.3 meq/L. After a standard evaluation, there was no obvious etiology for AKI, and an urgent transplant kidney biopsy was performed. Biopsy showed severe tubular injury with interstitial inflammation and focal tubulitis, mild interstitial fibrosis and tubular atrophy (30%). There was no evidence of T-cell or antibody mediated rejection, transplant glomerulopathy, de-novo glomerulonephritis, or recurrent atypical hemolytic uremic syndrome. On review, the only new medication prescribed was ranolazine. This was held and he was treated medically for his hyperkalemia. Renal function subsequently improved, with a new baseline creatinine of 1.8-2.3 mg/dL. Hyperkalemia resolved. He is asymptomatic off ranolazine.

Discussion: This patient developed AKI and hyperkalemia approximately 6 months after starting ranolazine. This is a rare adverse effect with only a few reported cases in the literature. A previous report implicated ranolazine as a cause of AKI due to drug-induced phospholipidosis, with the finding of zebra bodies on electron microscopy. Our patient's biopsy did not have zebra bodies present, making drug-induced phospholipidosis less likely. The mechanism is unclear. This case demonstrates that a thorough medication review and cessation of any possibly offending agents is vital in assessing AKI of unclear etiology. *Disclaimer: The views expressed in this Abstract are those of the authors and do not necessarily reflect the official policy of the Department of Defense or the United States Government.*

TH-PO067

A Case of Rhabdomyolysis and Acute Tubular Necrosis with Lower than Expected Creatinine Kinase Level in a Patient with Cocaine Abuse

Pabitra Adhikari, Armen Kishmiryan, Akshaya Ramachandran, Mustafa Ali. *Ascension Saint Francis, Evanston, IL.*

Introduction: Clinicians rely on serum creatinine kinase (CK) levels to assess the severity of rhabdomyolysis (RM) and predict the development of acute kidney injury (AKI). It is widely accepted that rhabdomyolysis with CK levels less than 5000 U/L is unlikely to cause AKI. We report a case of cocaine induced rhabdomyolysis and subsequent development of myoglobinuric acute tubular necrosis (ATN) in a young healthy male with CK levels of 928 U/L at presentation.

Case Description: A 33-year-old male with a past medical history of poly-substance abuse presented with headache following intake of crack cocaine three days prior to the presentation. Examination were remarkable for blood pressure of 171/108 mmHg and dry mucous membranes. Laboratory studies were significant for serum creatinine (Cr) of 21 mg/dl, Blood Urea Nitrogen (BUN) of 113 mg/dl and CK of 928 U/L. Urine sample obtained after bladder catheterization revealed gross blood with 3-5 red blood cells (RBCs)/hpf, proteinuria of 100 mg/dl and the urine toxicology was positive for cocaine. Renal ultrasound was non-contributory. Patient did not meet the criteria for urgent dialysis and the patient was started on intravenous (IV) fluids. The patient remained anuric. All the work ups done for etiologies of AKI were negative. Renal biopsy was consistent with diffuse ATN with myoglobin casts. Outpatient follow-up and continued supportive treatment resulted in resolution of ATN and normal kidney function.

Discussion: Cocaine induced RM can be traumatic due to seizure and/or hyperpyrexia and non-traumatic due to direct toxic effects of cocaine on skeletal muscle. CK and myoglobin levels change in parallel and CK levels correlate well with the severity of RM but its correlation and property to predict development of AKI is less reliable compared to serum myoglobin levels.

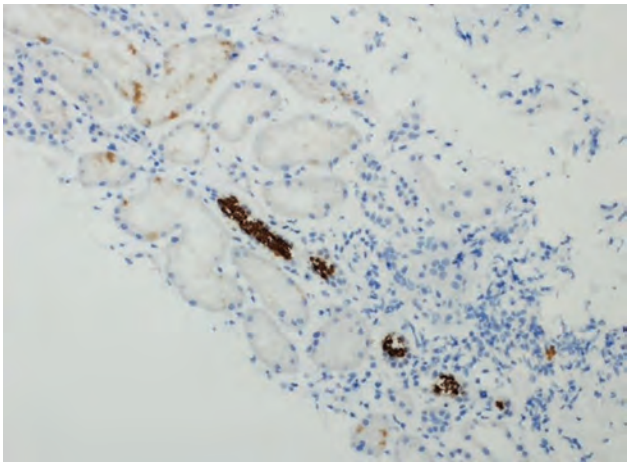

Figure showing Myoglobin Casts

TH-PO068

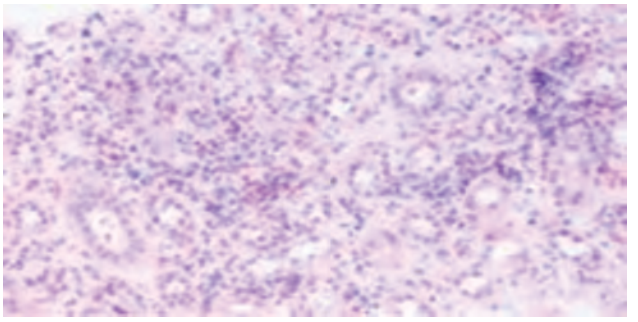
Cocaine-Associated Acute Tubular Injury and Acute Interstitial Nephritis

Akhila Arya P V, Jia Wei Tan. *Bridgeport Hospital Internal Medicine, Bridgeport, CT.*

Introduction: Cocaine can affect various compartments of the nephron, leading to conditions such as rhabdomyolysis-induced acute kidney injury (AKI) and rarely, cocaine-associated acute interstitial nephritis (AIN). In our case, the patient presented with AIN and acute tubular injury (ATI) without rhabdomyolysis.

Case Description: A previously healthy 37-year-old male presented with left flank and epigastric pain for three days. He denied taking any medication or recreational drugs. On admission, his blood pressure was 147/84 mmHg. He appeared euvolemic and had no rashes, purpuras, or arthralgias. Labs showed serum creatinine of 10.7 mg/dL without a prior baseline, blood urea nitrogen of 58 mg/dL, bicarbonate of 19 mmol/L, anion gap of 23, phosphorous of 9.6 mg/dL and creatinine kinase of 66 international units. Urinalysis showed 1+ proteinuria, 1 RBC/hpf, and 1 WBC/hpf. His protein/creatinine ratio was 0.57 mg/mg Cr. C3 and C4 were normal. Hepatitis B, C, and HIV were negative. ANA was negative, and the ANA was 1:40 in a perinuclear pattern. Renal ultrasound showed normal-sized kidneys and CT abdomen did not reveal any pathological findings. A renal biopsy confirmed the presence of diffuse AIN and ATI (Image 1, H & E, 40x). The patient's kidney function gradually improved without steroid treatment and a follow-up outpatient visit showed serum creatinine of 1.67 mg/dL.

Discussion: We highlight the importance of considering cocaine-associated renal complications, even in the absence of rhabdomyolysis, and highlight the rare presentation of concomitant ATI and AIN. The clinical, biochemical and urinalysis of AIN can be subtle and non-specific, making it challenging to diagnose. However, if there is a strong clinical suspicion of AIN, renal biopsy should be pursued to allow early recognition and potential treatment. Our patient's renal function recovered with supportive management alone, but further data are needed to fully understand the clinical course and treatment strategies for cocaine-associated AIN and ATI.



Light microscopy showing patchy diffuse acute interstitial nephritis and focal acute tubular injury

TH-PO069

Mimicking Ulcerative Colitis Flare-Ups Induced by Azathioprine Causes AKI

Mitsuru Yanai, Makoto Araki. *Sapporo Tokushukai Hospital, Sapporo, Japan.*

Introduction: Inflammatory bowel disease (IBD) is correlated with various renal ailments, including renal lithiasis, glomerulonephritis, renal amyloidosis, and drug-induced nephropathy. But no prior reports have documented drug-induced renal dysfunction with azathioprine (AZA) in IBD.

Case Description: A 61-year-old male was referred to our facility for ulcerative colitis flare-up. He had previously tried various medications, including 5-aminosalicylic acid (5ASA), AZA, and anti-TNFα antibody. Achieving remission with 30 mg prednisolone (PSL), he began novel anti-IL12/23 antibody treatment. Over 8 weeks, the PSL dose was gradually reduced without relapse. During the second dose of the anti-IL12/23 antibody, AZA at 25 mg/day replaced PSL. The next morning, the patient experienced chills, fatigue, and worsening diarrhea (over 10 times per day) shortly after the morning dose. Diarrhea persisted, the patient lost appetite, and became anuric. Subsequently, on the fourth day after anti-IL12/23 antibody administration, the patient was ambulance-transported to our hospital. Compared to values from four days prior, white blood cell count increased from 7500 to 9130/μL, C-reactive protein level rose from 0.32 to 41.37 mg/dL, and creatinine level escalated from 1.01 to 8.29 mg/dL. Considering possible infectious enteritis or worsening ulcerative colitis, the patient promptly received intravenous fluids, antibiotics, and 30 mg PSL. Hemodialysis was initiated. On the fourth day of hospitalization, a renal biopsy revealed massive cellular infiltration of the interstitium, leading to the diagnosis of acute interstitial nephritis due to azathioprine hypersensitivity syndrome. The PSL dose was quickly increased to 60 mg. Renal function gradually improved, and dialysis was completed in three sessions. After one month, creatinine levels returned to baseline, and steroid treatment ceased. Subsequently, the patient received a third dose of the anti-IL12/23 antibody without any adverse events.

Discussion: Azathioprine hypersensitivity syndrome is a systemic allergic reaction to immunosuppressive drugs, resulting in acute interstitial nephritis in the kidneys. Severe inflammatory reactions of heightened intensity mimic an exacerbation of the underlying disease or sepsis, frequently leading to delayed treatment. Timely diagnosis and prompt administration of steroids can influence the renal prognosis.

TH-PO070

Ashwagandha Overdose-Induced AKI: A Novel Case Report

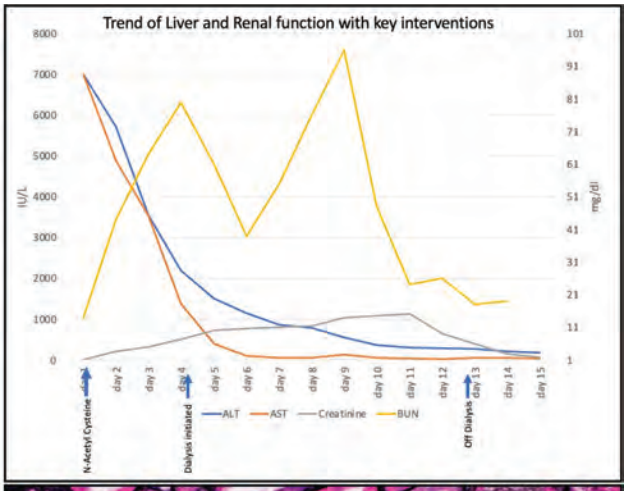
Hariharasudan Natarajan, Bibi Maryam, Zahid B. Ahmad. *OU Health, Oklahoma City, OK.*

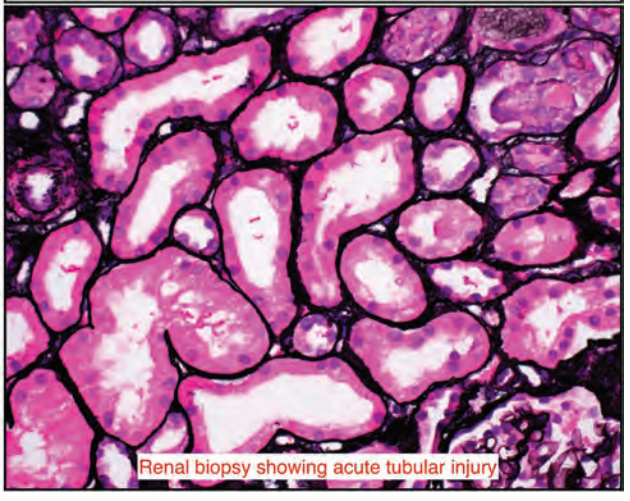
Introduction: Ashwagandha (Withania somnifera) is an Ayurvedic herb with various therapeutic properties, such as anti-inflammatory, antitumor, immunomodulatory, and adaptogenic effects. However, its safety profile is not well established. This abstract highlights the first case of kidney toxicity associated with ashwagandha overdose.

Case Description: A 26-year-old female presented with a 2-day history of progressive abdominal pain, nausea, and vomiting after taking high doses of ashwagandha (6000mg per meal) for a week to treat anxiety. Vital signs were normal, and the physical exam revealed right upper quadrant tenderness. Blood tests showed severe drug-induced liver injury with elevated ALT/AST (>7000 U/L), total bilirubin 2.1 mg/dl, and alkaline phosphatase 82 U/L. Treatment with N-acetyl cysteine improved liver function, but renal function rapidly declined on the second day. Urinalysis showed no hematuria but identified 2+ proteinuria, and a subsequent renal biopsy revealed acute tubular injury. Temporary hemodialysis was required, and the patient eventually recovered with normal kidney function in 2 weeks.

Discussion: Ashwagandha is known for its potential therapeutic benefits in stress, anxiety, and inflammation. However, the optimal daily dosage remains to be determined. Clinical trials used 300-1000mg/day, while commercial preparations may have higher amounts. A recent in-vitro study suggested that an overdose of the herb's primary metabolite, Withanone, may overwhelm the glutathione detoxifying system and cause DNA damage. Acute tubular injury observed may result from impaired renal tubule protection against oxidative stress. Kidney function returned to normal after discontinuing

the medication. Healthcare providers should be vigilant for ashwagandha-related renal toxicities and manage them promptly.





TH-PO071

An Unusual Cause of Cloudy Urine in a Patient with Sepsis

Michael Chang, Martin Sedlacek. *Icahn School of Medicine at Mount Sinai, New York, NY.*

Introduction: Cloudy urine is usually caused by pyuria. Here, we present the case of a patient whose viscous, cloudy urine was caused not by pyuria but by acyclovir crystalluria.

Case Description: A 71-year-old woman with HFpEF and history of diverticulitis was admitted for colostomy trauma. Her hospital stay was complicated by rapid atrial fibrillation, fluid overload and enterococcal urinary tract infection. In her sixth week of hospitalization she developed sepsis secondary to a hepatic abscess, requiring intensive care and treatment with Meropenem and Vancomycin. She also was treated empirically with Acyclovir 600mg IV q 8hrs for suspected HSV encephalitis. Nephrology was consulted for oliguric AKI with a creatinine increase from 0.8mg/dl to 1.57mg/dl and elevated vancomycin trough level. The urine was viscous and cloudy. On microscopy the urine was loaded with needle shaped birefringent crystals, typical of acyclovir crystalopathy. With medication dose adjustments the oliguria resolved and the urine showed no more crystals and rare granular casts. Four days later the patients serum creatinine had decreased to 0.84mg/dl. The patient completed two weeks of acyclovir treatment, eventually recovered and was discharged to rehablitation 6 weeks later.

Discussion: Intravenous Acyclovir can cause transient oliguric AKI with crystalluria so heavy that it resembles pyuria. Despite the dramatic presentation, renal recovery can occurr swiftly wth dose adjustment. There may be additional causes of AKI precipitating the event.

Figure1: cloudy urine

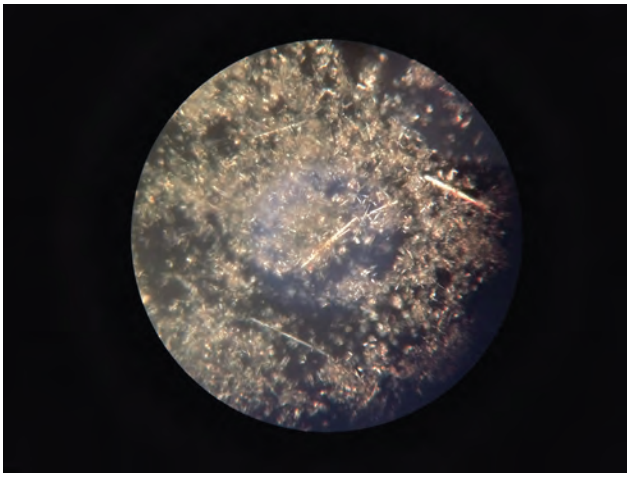


Figure 2: birefringent needle shaped acyclovir crystals

TH-PO072

Anticoagulant-Related Nephropathy in Patients with Mechanical Valves: A Challenging Case and a Possible Solution

Rui Song, Hussam Al Hennawi, Muhammad Shan Ul Abedin, Majid A. Khan. *Abington Memorial Hospital, Abington, PA.*

Introduction: Anticoagulant-related nephropathy (ARN) is a novel form of acute kidney injury (AKI) associated with anticoagulant (AC) use. Management is challenging for patients on long-term AC who develop ARN.

Case Description: A 62-year-old Male with a history of chronic kidney disease [CKD, baseline serum creatinine (sCr) of 1.7 mg/dL], atrial fibrillation (Afib), mechanical aortic valve replacement on warfarin, and non-ischemic cardiomyopathy status post ICD insertion who presented with epistaxis. His medications include aspirin, carvedilol, furosemide, pantoprazole, simvastatin, and warfarin. He had a recent admission for AKI with microscopic hematuria needing workup for glomerulonephritis. The complements, ANA, ANCA, anti-GBM antibody, serum protein electrophoresis, and serum light chains were within normal range. Ultrasonography showed no evidence of kidney stones or hydronephrosis. The cause of AKI was unclear but his sCr improved to 1.96mg/dL from 2.5mg/dL after briefly holding warfarin for an INR of 3.9. Warfarin was continued on discharge. During this admission, labs showed a sCr level of 4.3 mg/dL and an INR of 5.8 on day 0. Warfarin was held and intravenous heparin drip was started. Patient had hematuria with a urine protein/creatinine ratio of 0.92 mg/g and a kidney biopsy was obtained for AKI on CKD. Pathology showed RBC casts and tubular injury consistent with ARN and underlying IgA nephropathy. His sCr improved to 1.7mg/dL and warfarin was restarted

again on discharge. Five months later, he developed AKI on CKD requiring intermittent hemodialysis (HD). AC was held per the patient's request. After holding warfarin, renal function recovered with no further HD needs. His sCr ranged between 1.7 to 2 mg/dL for the next six months. Due to the high risk of stroke given mechanical valve and Afib without AC, Cardiology, Hematology and Nephrology coordinated the care and a trial of apixaban 2.5 mg twice daily was started. His sCr has been followed closely and is stable to date.

Discussion: ARN is often caused by high intensity warfarin usage but has been reported in patients on direct-acting oral AC. For patients with ARN needing lifelong AC, risks and benefits discussion is warranted. Multidisciplinary team effort is required. Trial of alternative low dose AC with close monitoring of sCr could be a possible solution.

TH-PO073

Karyomegalic Interstitial Nephritis in a Patient Treated with Ifosfamide

Sirisha Gudlawar. *Medical College of Wisconsin, Milwaukee, WI.*

Introduction: Ifosfamide is an alkylating used in treating wide variety of cancers including germ line tumors of testes, soft tissue sarcomas, bladder cancer and cervical cancer. It can lead to reversible Fanconi syndrome, acute kidney injury (AKI). Here in, we present a case of karyomegalic interstitial nephritis (KIN) in a patient treated with ifosfamide.

Case Description: 47-year-old female with history significant for high grade extra skeletal osteosarcoma underwent tumor resection with flap reconstruction. She was started on chemotherapy with Adriamycin, Ifosfamide, Mesna and received a total of three cycles of chemotherapy. She developed AKI with creatinine of 1.5 mg/dl (baseline creatinine of 0.8 mg/dl) along with hypokalemia, hypophosphatemia and metabolic acidosis, due to which Nephrology consultation was sought. Her blood pressure was 143/78 mmHg, Heart rate of 79 beats per minute. Urine analysis was performed which showed glucosuria and microscopy was bland. Initial sodium was 141 mmol/L, potassium 2.8 mmol/L, chloride of 116 mmol/L, bicarbonate 16 mmol/L, blood urea nitrogen 12 mg/dL, Serum creatinine (SCr) of 1.59 mg/dL, phosphorus 1.5 mg/dL. She was treated conservatively with electrolyte supplementation and intravenous fluids, discharged home with outpatient follow up. Due to progressive decline in renal function (SCr 2.2 mg/dL) she underwent biopsy which showed chronic interstitial nephritis with karyomegalic features, and severe interstitial fibrosis and tubular atrophy (IFTA 70%). She was started on steroids and creatinine improved to 1.7 mg/dL. Thereafter, her creatinine remained steady at 2 mg/dL. There was no recurrence of cancer and is currently in remission.

Discussion: KIN is a rare form of familial interstitial nephritis, As per previous case reports, AKI occurs between 12 months to 5 years after exposure to the drug. In our case, it was 3 months after the initiation of chemotherapy. About 40% of these patients respond favorably to corticosteroids where as those with chronic tubulointerstitial nephritis responded poorly. This case report illustrates the importance of performing early kidney biopsy with persistent renal dysfunction following chemotherapy. Early diagnosis and initiation of steroids could potentially recover kidney function or prevent the progression of the disease.

TH-PO074

A Rare and Serious Reaction to Frequently Used Rituximab

Gabriel J. Torres-Rivera, Carlos Cortes, Carlos S. Rosado-Rodriguez, Nicole Rivera-Bobe. *VA Caribbean Healthcare System, San Juan, Puerto Rico.*

Introduction: Rituximab is an anti-CD20 monoclonal antibody used in malignancies, and rheumatologic and kidney diseases. Rituximab is seldom associated with life threatening complications. Cytokine Release Syndrome (CRS) is a systemic response following an extensive release of inflammatory cytokines due to activation of myeloid cells and lymphocytes. Depending on its severity, it can present with rash, fever, abdominal pain, mental status changes, and respiratory failure. Few cases are reported in the literature, most leading to a catastrophic cascade of events. We herein present a man with B-Cell lymphoma who became critically ill with severe lactic acidosis, altered mental status, and renal failure within minutes of receiving his first rituximab dose.

Case Description: A 68 y/o man with hypertension went to the ER complaining of chills at night and weight loss. Normal vital signs but found with bilateral cervical and axillary lymphadenopathy. Labs with increased creatinine: 0.9>1.31mg/dL and Ca+: 11mg/dL. He was admitted to Oncology due to symptomatic hypercalcemia, AKI, and lymphadenopathy with suspected malignancy. Lymph node biopsy yielded B-cell lymphoma diagnosis and he was started on rituximab. Minutes after starting the infusion, he presented with chills, tachypnea, tachycardia, hypertension, and altered mental status. No edema or skin rash but presented abdominal discomfort. Infusion was stopped and he was given IV diphenhydramine and solumedrol. Lactic acid: 21.2mmol/L, blood pH: 7.2, Anion Gap: 34, K+: 5.0mEq/L, and PO4-: 5.9mg/dL, LDH 2212 U/L, CPK 55 U/L. Elevated lactic acid without evidence of hypoperfusion and his electrolytic disturbances suggest rapid destruction of tumor cells by rituximab leading to CRS. Initially provided with supportive therapy, but became anuric 2 days later for which a trial of hemodialysis was started. There was no improvement with worsening pancytopenia, the family opted for comfort measures and the patient was discharged home under hospice care.

Discussion: Because of its efficacy, Rituximab is widely and frequently used. Rituximab-associated CRS is very rare but carries a high morbidity and mortality risk. This case is important for the community since it highlights a very rare and overlooked reaction of rituximab which is being used more frequently.

TH-PO075

Plasmapheresis as Adjunctive Treatment for Life-Threatening Rituximab-Induced Acute Respiratory Distress Syndrome

Christopher Yang, Anip Bansal. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Introduction: Rituximab is a monoclonal antibody targeted against the B-cell surface antigen CD20. It is used as therapy for a variety of conditions including hematologic malignancies and autoimmune diseases. Use of rituximab has been associated with hypersensitivity reactions (HSR) which can be classified as infusion-related, cytokine-release, type I (IgE/non-IgE), mixed, type III, and type IV reactions. While rituximab is typically associated with largely benign infusion reactions, it occasionally leads to serious type I reactions, which can cause life-threatening anaphylaxis. Rituximab can cause lung toxicity due to immediate hypersensitivity, via cytokine release and by a delayed HSR. We report the management of a patient with severe shock and ARDS attributed to a mixed HSR to rituximab infusion, which improved with plasmapheresis.

Case Description: A thirty-year old woman with myasthenia gravis (MG) was admitted with an acute exacerbation of MG after missing her maintenance dose of rituximab. She was initially treated with five sessions of plasmapheresis without any complications. Subsequently, she was treated with rituximab, per the standard protocol. Several hours after her rituximab infusion, she developed refractory shock, hypoxia, and hemoconcentration (Hgb 12 to 17 g/dl). Despite treatment with high dose steroids and broad-spectrum antibiotics, she rapidly developed ARDS requiring mechanical ventilation, oliguric acute kidney injury, and severe lactic acidosis. Her echocardiogram showed normal cardiac function and infectious work-up was ultimately negative. She was treated with one additional session of plasmapheresis to facilitate elimination of rituximab based on prior case reports. She subsequently had rapid improvement in clinical parameters with resolution of shock in three days, resolution of AKI soon after and extubation after six days.

Discussion: Severe HSR, while rare, can be a potentially fatal adverse effect of rituximab. There is no well-described treatment of this reaction. We describe a case with rapid improvement after one treatment of adjunctive plasmapheresis. With the widespread use of rituximab for a variety of conditions, clinicians need to be aware regarding the diagnosis and management of the spectrum of HSRs associated with this drug.

TH-PO076

Oxalate Nephropathy in a Diabetic with Intentional Weight Loss

Kartikeya Srivastava,[1] Charles Russell,[2] Naveen Punchayil Narayanankutty.[2] *[1]Srivastava Fracture & Orthopaedic Care Centre, Agra, India; [2]Tampa General Hospital, Tampa, FL.*

Introduction: Oxalate induced nephropathy is a rare cause of acute kidney injury and has the potential to progress to end stage kidney disease.

Case Description: We saw a 60 years old diabetic female with an acute increase in serum creatinine and was admitted for acute renal failure, unspecified renal failure type. She has a history of hypertension, CKD 3b, reported retinopathy and a 50lbs intentional weight loss during the summer. She particularly resorted to foods like nuts and spinach with the avoidance of dairy. Routine evaluation revealed mild hyponatremia (which was attributed to the use of HCTZ). There was also microscopic hematuria. FeNa was 53% which was consistent with intrinsic renal pathology and Renal USG was ordered which revealed a slightly elevated bladder with non- obstructive nephrolithiasis. Testing for antibodies revealed negative ANCA, Anti GBM and ANA. HCTZ and metformin were held as part of initial management with regular monitoriing. Her clinical presentation pointed towards a list of suspected differentials like Acute tubular necrosis secondary to hypotension, RPGN or a possible CKD secondary to T2DM. A lack of improvement in the creatinine levels despite the initial management prompted towards the need of a kidney biopsy. The biopsy revealed mild to moderate tubular injury with frequent oxalate crystals along-with features suggestive of diabetic nephropathy (renal pathology class 2b) Her acute rise in creatinine was attributed to the oxalate deposition (and not diabetes) and she was advised to avoid vitamin C and oxalate containing foods. A regular out patient follow-up had been scheduled and a discussion regarding genetic predisposition to oxalate deposition was initiated.

Discussion: There were a few challenges to the diagnosis. Retinopathy is a predictor of nephropathy in diabetic patients which posed the first obstacle towards diagnosis. The absence of proteinuria is another interesting finding, although it is now commonly accepted that a proportion of patients either with type 1 diabetes or type 2 diabetes have renal function loss without proteinuria, referred to as nonproteinuric diabetic kidney disease. The biopsy finding of oxalate crystals was in line with her history of rapid intentional weight loss where she resorted to foods like nuts and green leafy vegetables.

TH-PO077

Interesting Biopsy of a Patient with AKI on a Background of Systemic Mastocytosis

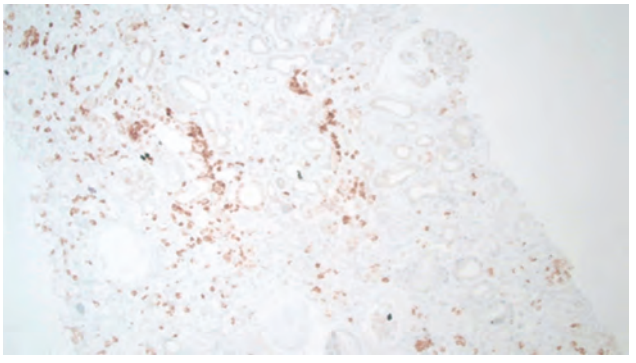
Sorcha O'Brien,[1] Brenda Griffin,[1] Anthony M. Dorman.[2] *[1]St James's Hospital, Dublin, Ireland; [2]Beaumont Hospital, Dublin, Ireland.*

Introduction: Systemic mastocytosis (SM) is a rare disorder characterised by infiltration of clonally derived mast cells in bone marrow and other extracutaneous organs. The most common genetic mutation in SM is *KIT* D816 V and is resistant to

Imatinib, other *KIT* mutations have been identified. F522C accounts for 1% of all SM-associated *KIT* mutations and has been reported to be sensitive to Imatinib.

Case Description: A 72-year-old woman was diagnosed with systemic mastocytosis (*KIT* F522C mutation) following bone marrow biopsy showing mast cell infiltrate and stained positive for CD117. She was commenced on antihistamines and Montelukast. Following the results of the bone marrow sample showing F522C mutation, she was commenced on Imatinib. She initially had a good response to treatment, however she subsequently lost response to Imatinib and required frequent courses of tapering steroids. Two years after diagnosis, she presented to emergency department (ED) with an acute history of facial flushing and oliguria. Her bloods on presentation to ED showed elevated creatinine and tryptase levels. She initially required renal replacement therapy for several days, renal function then recovered. A renal biopsy was arranged. The biopsy showed acute tubular necrosis (ATN) and inflammatory cell infiltration of the interstitium. Immunohistochemical staining showed focal aggregates of CD117 positive cells indicating an infiltrate of mast cells (~10%). Following discussion with the patient, she opted not for further management. She became oliguric and developed disseminated intervascular coagulation without evidence of bleeding. She was transferred to a hospice for where she passed away.

Discussion: Renal involvement in SM is rare and has not been described much in the literature. Consideration needs to be given to other causes of AKI in SM, eg. ATN or acute interstitial nephritis secondary to Imatinib. Renal mastocytosis is typically progressive and leads to chronic kidney disease/end stage kidney disease despite treatment.



Renal cortex with CD117 positive mast cells

TH-PO078

A Case of IgG4-Related Kidney Disease with a Rare Renal Cyst

Hiroki Uchida,[1] Jun Okita,[1] Akiko Kudo,[1] Takeshi Nakata,[1] Akihiro Fukuda,[1] Noriko Uesugi,[2] Hirotaka Shibata.[1] *[1]Department of Endocrinology, Metabolism, Rheumatology and Nephrology, Faculty of Medicine, Oita University, Yufu, Japan; [2]Department of Pathology, Fukuoka University School of Medicine, Fukuoka, Japan.*

Introduction: IgG4-related kidney disease (IgG4-RKD) is characterized by tubulointerstitial nephritis with elevated IgG4-positive plasma cells. Characteristic imaging findings of IgG4-RKD include diffuse kidney enlargement, multiple low-density lesions, solitary masses, and diffuse thickening of the renal pelvis wall. Here, we report a case of IgG4-RKD with a rare renal cystic formation that shrank after steroid treatment.

Case Description: A 73-year-old man was admitted to our hospital with acute kidney injury and tubulointerstitial disorder. Blood tests showed elevated IgG and IgG4 (IgG 3941 mg/dL,IgG4 425 mg/dL). CT imaging showed enlargement of both kidneys, and a solitary mass in the left kidney. Renal biopsy of the right kidney showed tubulointerstitial nephritis with storiform fibrosis and increased IgG4-positive plasma cells, which led to a diagnosis of IgG4-RKD. Ultrasonography showed no substantial component or blood flow within the kidney mass, and MRI showed diffusion-weighted images with heterogeneous diffusion restriction inside the kidney mass, and no clinical findings to suggest infection, suggesting a simple cystic lesion. Steroid treatment for IgG4-RKD improved kidney function and IgG4 levels, in addition, CT imaging showed a markedly reduction of cystic renal mass (Fig 1).

Discussion: In one case, a benign renal lesion due to IgG4-RKD was found after nephrectomy, while in another case, a renal mass thought to be a benign renal lesion was found to be renal cancer after steroid treatment. In this case, the mass lesion shrank following steroid treatment, and CT and MRI imaging findings suggested a cystic renal mass caused by IgG4-RKD. Careful judgment is required when deciding if renal masses may be benign or malignant in patients with IgG4-RKD. Here, we report a rare case of a solitary renal cystic mass associated with IgG4-RKD.

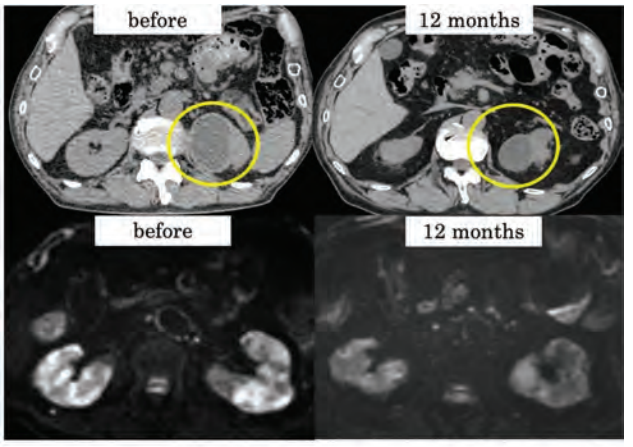


Fig 1. Changes in the solitary mass in the kidney as revealed by CT and MRI findings; before and 12 months after steroid therapy.

Single-Cell Dissection of Cellular and Molecular Features Underlying Mesenchymal Stem Cell Therapy in Ischemic AKI

Wenjuan Wang,[1,2] Min Zhang,[2] Xiangmei Chen,[2,1] Guangyan Cai.[2,1] *[1]Nankai University School of Medicine, Tianjin, China; [2]First Medical Center of Chinese PLA General Hospital Nephrology Institute of the Chinese People's Liberation Army, Beijing, China.*

Background: Mesenchymal stem cells (MSCs) exert beneficial therapeutic effects in acute kidney injury (AKI), while the detailed repair mechanism remains unclear.

Methods: Single cell sequencing was used for the first time to delineate the mechanism of MSC treatment for AKI induced by bilateral ischemia reperfusion injury in C57 mice. Receptor-ligand interaction analysis focused on the elucidation of intercellular communication. Extracellular vesicles (EVs) derived from MSCs were extracted by ultracentrifugation combined with size exclusion chromatography. Transmission electron microscopy, nanoparticle tracking analysis, cell transfection, flow cytometry, RT-qPCR, Western blot, and immunohistochemistry were used to evaluate cellular function.

Results: Our analyses uncovered renal tubular epithelial cells (TECs) and immune cells transcriptomic diversity and highlighted a repair trajectory involving renal stem/progenitor cell differentiation. Our findings also suggested pro-fibrotic factors such as ZEB2 and PDGFβ expressed by TECs promoted the recruitment of inflammatory monocytes and Th17 cells to injured kidney tissue, inducing TGF-β1 secretion and renal fibrosis. Finally, in addition to activating the repair properties of renal progenitor/stem cells, we uncovered a role for MSC-derived miR-26a in mediating the therapeutic effects of MSCs by inhibiting Zeb2 expression and suppressing pro-fibrotic TECs and its subsequent recruitment of immune cell subpopulations.

Conclusions: Exogenous MSCs promote the potential repair trajectories involving renal stem/progenitor epithelial differentiation and the inhibition of the miR-26a/Zeb2 pathway on immune cells infiltration and fibrosis in response to MSC therapy during AKI-CKD progression, which helps to optimize future AKI treatment.

Cannabigerolic Acid (CBGA) Ameliorates Renal Inflammation and Fibrosis in Mouse Nephropathic Models

Sayuri Suzuki,[1] Andrea Fleig,[1,2] Reinhold Penner.[1,2] Queen's Center for Biomedical Research. *[1]The Queen's Medical Center, Honolulu, HI; [2]Unversity of Hawaii Cancer Center, Honolulu, HI.*

Background: Cannabinoids are a major class of compounds in cannabis, comprising some ~100 structurally related but diverse molecules, where cannabidiolic acid (CBDA) and tetrahydrocannabinolic acid (THCA) being the major components in most plant varieties. In some plant varieties, cannabigerolic acid (CBGA) has been reported the dominant molecular species. CBD, the decarboxylated version of CBDA, is thought have multiple biological effects, including the ability to attenuate inflammatory processes. Cannabigerols (CBGA and its decarboxylated CBG molecule) have pharmacological profiles similar to CBD. The endocannabinoid system has recently emerged to contribute to kidney disease, however, the therapeutic property of cannabinoids in kidney disease remains largely unknown. In this study, we determined whether CBD and CBGA can attenuate kidney damage in cisplatin-induced acute kidney injury model. In addition, we evaluated the anti-fibrosis effect of these cannabinoids in Unilateral Ureteral Obstruction (UUO) mice as a chronic kidney disease model.

Methods: CBD or CBGA (10 mg/kg) were injected daily in cisplatin administered mice and UUO mice. Kidneys were collected at day 3 from cisplatin administered mice and used for qRT-PCR, western blotting and TUNEL assay. UUO Kidneys were collected at day 7 and used for immunostaining of Ki-67 and extracellular matrix. We also assessed the effect of CBGA and CBD to ion channel by patch-clamp technique.

Results: We find that CBGA protects the kidney from cisplatin-induced nephrotoxicity. CBGA also strongly suppressed mRNA of inflammatory cytokines and apoptosis through inhibition of caspase-3 activity in cisplatin-induced acute kidney injury, whereas CBD treatment was only partially effective. In UUO kidneys, both CBGA and CBD prevented kidney atrophy, tubule loss, proliferation and maintained overall morphology. Both cannabinoids also strongly reduced renal fibrosis in UUO kidneys. Finally, we find that in contrast to CBD, CBGA has a potent inhibitory effect on the channel-kinase TRPM7 and the TRPM7 protein expression was significantly suppressed in cisplatin-induced acute kidney injury.

Conclusions: We conclude that CBGA and CBD have a reno-protective efficacy in kidney damage, with CBGA especially having a stronger inhibitory effect to prevent inflammation in acute kidney injury by TRPM7 blockage.

AKI-Induced Circulating TNFR1/2 Elevations Correlate with Persistent Kidney Injury and Progression to Fibrosis

Akshayakeerthi Arthanarisami,[1,2] Yohei Komaru,[1] Charikleia Katsouridi,[1] Julian Schumacher,[1] Liang Ning,[1] Mai Abdelmageed,[1] Andreas Herrlich,[1] Eirini Kefalogianni.[1] *[1]Washington University in St Louis, St Louis, MO; [2]Cornell University, Ithaca, NY.*

Background: Elevated levels of circulating Tumor-Necrosis-Factor-Receptors 1 and 2 (cTNFR1/2) predict CKD progression. Whether acute kidney injury drives cTNFR1/2 elevations and whether they predict disease outcomes after AKI remains unknown.

Methods: We used AKI patient serum and urine samples, mouse models of kidney injury (ischemic, obstructive, toxic) and progression to fibrosis, nephrectomy, and related single cell RNA-sequencing datasets.

Results: We show that TNFR1/2 serum and urine levels are highly elevated in all mouse models of kidney injury tested, beginning within one-hour post-injury, and correlate with its severity. Consistent with this, serum and urine TNFR1/2 levels are increased in AKI patients and correlate with severity of kidney failure. Interestingly, the extracellular particle (EP)-bound forms of cTNFR1/2 correlate with renal function better than their soluble forms. TNF neutralization does not affect early cTNFR1/2 elevations, suggesting that cTNFR1/2 levels do not reflect injury-induced TNF activity. Kidney tissue expression of TNFR1/2 after AKI is only mildly increased and bilateral nephrectomies lead to strong cTNFR1/2 elevations, suggesting release of these receptors by extrarenal sources. cTNFR1/2 remain elevated for weeks after severe kidney injury and at these later timepoints cTNFR1/2 correlate to remaining kidney injury. During AKI-to-CKD transition, kidney expression of TNFR1/2 and cTNFR2 levels, correlate with development of fibrosis.

Conclusions: Our data demonstrate that AKI drives acute increases in cTNFR1/2 serum levels which negatively correlate with kidney function, in particular their EP-bound forms. Sustained TNFR1/2 elevations after kidney injury during AKI-to-CKD transition correlate with persistent tissue injury and progression to kidney fibrosis.

COPT Nanoparticles Ameliorate the AKI-to-CKD Transition via Inducing BNIP3-Mediated Mitophagy

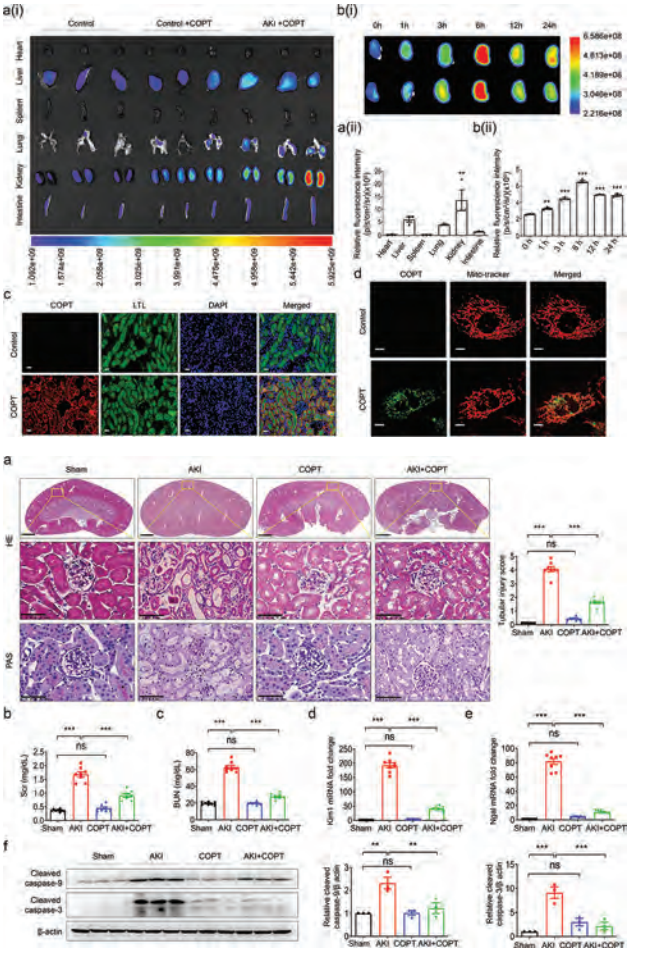
Yinghui Huang, Jinghong Zhao. Dept of Nephrology, Key Laboratory for the Prevention and Treatment of Chronic Kidney Disease of Chongqing, Chongqing Clinical Research Center of Kidney and Urology Diseases, Xinqiao Hospital, Army Medical University. *Army Medical University, Chongqing, China.*

Background: Accumulating evidence highlights mitochondrial dysfunction as a crucial factor in the pathogenesis of acute kidney injury (AKI), thus novel therapeutic strategies maintaining mitochondrial homeostasis are highly anticipated. Recent studies have shown that cobaltosic oxide has peroxidase-like catalytic activities, although its role and mechanism remain elusive in AKI.

Methods: Cobaltosic oxide-polyethylene glycol-triphenylphosphine (COPT) nanoparticles were synthesized by conjugating cobaltosic oxide with polyethylene glycol and triphenylphosphine. Its theranostic effect was evaluated by using AKI mice, zebrafishes and cells.

Results: COPT preferentially accumulated in the renal proximal tubule cells, and significantly alleviated ischemic AKI in mouse and zebrafish models. COPT also inhibited the transition from AKI to chronic kidney disease (CKD), with few side effects. Further, COPT localized in the mitochondria, and ameliorated hypoxia-reoxygenation (HR)-mediated mitochondrial damage through enhancing mitophagy. Mechanistically, COPT dose-dependently induced the expression of Bcl-2/adenovirus E1B 19-kDa interacting protein (BNIP3), while knockdown of BNIP3 attenuated COPT-induced mitophagic flux and mitochondrial protection.

Conclusions: COPT nanoparticles ameliorate AKI and its progression to CKD through inducing BNIP3-mediated mitophagy, indicating that COPT may serve as a promising mitochondria-targeting therapeutic agent against AKI.



TH-PO083

The Role of C5aR vs. C3 in Thrombotic Microangiopathy, Ischemic Kidney Necrosis, and AKI Induced by Cholesterol Crystal Embolism

Danyang Zhao, Hans J. Anders, Elmina Mammadova-Bach. *Ludwig-Maximilians-Universitat Munchen, Munchen, Germany.*

Background: Certain thrombotic microangiopathies (TMA) respond to inhibition of complement factor C5, which abrogates formation of the membrane attack complex and hence impairs host defense. Inhibition of C5a receptor (C5aR) avoids this safety problem and still controls autoimmune systemic vasculitis. We speculated that targeting C5aR could be sufficient also in TMA, e.g., related to cholesterol crystal embolism (CCE).

Methods: We induced experimental TMA in C3-/-, C5aR-/- or wildtype mice by injecting CC into the left kidney artery of mice and analyzed thrombotic angiopathy, drop in measured glomerular filtration rate (GFR), and ischemic necrosis 24 hours after CCE.

Results: In wildtype mice, CC injection caused diffuse TMA followed by a consistent drop of GFR compared to baseline and ischemic kidney necrosis. Genetic deficiency in C3 convertase profoundly attenuated TMA and hence GFR drop and ischemic kidney necrosis indicating a key role of the complement system in CCE-related TMA. Genetic deficiency of C5aR attenuated TMA, GFR drop and ischemic necrosis to the same extent indicating that C5aR provides the main contribution of the complement system to the pathogenesis of TMA.

Conclusions: We conclude that targeting the C5a/C5aR axis could be sufficient to attenuate also TMA for which a better safety profile would be expected as compared to C5 inhibition.

Induction of Cell Cycle Inhibitor p16Ink4a and Cellular Senescence in Heme Protein-Mediated AKI

Raman D. Singh, Anthony J. Croatt, Allan W. Ackerman, Joseph P. Grande, Karl A. Nath. *Mayo Clinic Division of Nephrology and Hypertension, Rochester, MN.*

Background: Senescent cells (SCs) exhibit cellular arrest due to upregulation of cell cycle inhibitors such as $p16^{Ink4a}$. In this study, we demonstrate senescence in heme protein-mediated acute kidney injury (HP-AKI) with the upregulation of $p16^{Ink4a}$ gene along with a senescent phenotype exhibited by murine kidneys.

Methods: $p16^{Ink4a}$ mRNA expression was assessed by RT-PCR and RNAish in the murine glycerol model of HP-AKI, and in murine kidneys after administration of hemoglobin, myoglobin, and hemin. A senescent phenotype was assessed by β-galactosidase staining and lamin B1 protein expression using immunofluorescence and western blotting.

Results: Renal $p16^{Ink4a}$ mRNA was significantly increased at 8, 24, and 48 hours in the glycerol model of HP-AKI. Localization of mRNA using RNAish revealed significantly increased $p16^{Ink4a}$ mRNA expression in the proximal tubules. Similarly, administration of hemoglobin, myoglobin, or hemin to mice with intact kidneys significantly increased $p16^{Ink4a}$ mRNA expression in the kidney. RNAseq analysis of the HP-AKI model showed telomere erosion as reflected by reduced expression of genes in the 1MB telomeric region in HP-AKI model. A senescent phenotype within HP-AKI kidneys was additionally demonstrated by increased β-galactosidase activity and decreased lamin B1 protein expression.

Conclusions: Glycerol-induced HP-AKI resulted in upregulation of the cell cycle inhibitor, $p16^{Ink4A}$, the latter mainly induced in proximal tubules. HP-AKI also resulted in telomere erosion as revealed by reduced expression of genes in the 1MB telomeric region. Confirmation of a senescent phenotype in HP-AKI was provided by increased β-galactosidase activity and decreased lamin B1 protein expression. The kidney subjected to HP-AKI thus exhibits a senescent phenotype which we suggest is driven by upregulation of $p16^{Ink4a}$ mRNA expression within the injured kidney.

The Class B Scavenger Receptors BI and BII Exacerbate Acute Kidney and Liver Injury in Murine Abdominal Sepsis Model

Naoki Hayase,[1] Irina Baranova,[2] Tatyana Vishnyakova,[2] Alexander V. Bocharov,[2] Rohit R. Chari,[1] Alef Aragao Carneiro dos Santos,[1] Xuzhen Hu,[1] Peter S. Yuen,[1] Robert A. Star.[1] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD; [2]National Institutes of Health, Bethesda, MD.*

Background: The class B scavenger receptors BI (SR-BI) and BII (SR-BII) are expressed in multiple tissues and known to recognize various pathogen-associated molecular patterns. Recently, we found that both receptors bind and internalize bacteria and boost proinflammatory cytokine production in HeLa cells transfected with SR-Bs. Moreover, we developed human SR-BI and BII transgenic mice (driven by pLiv-11) that overexpress hSR-BI and BII transgenes in the liver (to a lesser extent in the kidney). LPS I.P. injection markedly increases expression of proinflammatory cytokines in the liver and kidney of both transgenic mice. However, their roles in a clinically relevant sepsis model are unknown.

Methods: We performed cecum ligation and puncture (CLP) surgery in hSR-BI and BII transgenic and wild-type (WT) mice and treated them with antibiotics and fluids. A seven-day survival study was conducted. In a separate experiment at 24 h after CLP surgery, we collected blood, peritoneal lavage fluid, kidney, liver, and lungs for bacterial count, histological and biochemical examination.

Results: First, hSR-BI and BII transgenic mice had significantly worsened survival compared to WT mice (SR-BI vs. WT, 0.0% vs. 28.6% on Day 7, n = 5-7 per group, p = 0.002; SR-BII vs. WT, 0.0% vs. 28.6% on Day 7, n = 5-7 per group, p = 0.003). Second, the blood bacterial count was lower in both hSR-B transgenic mice than WT, while there was the similar trend in the number of bacteria in the peritoneal fluid. Alanine aminotransferase levels of hSR-BI and BII transgenic mice were significantly higher than WT. The kidneys of hSR-BI transgenic mice had abundant vacuole degeneration and the highest tubular injury score among the experimental groups.

Conclusions: In summary, our findings suggest that hSR-BI and BII overexpression contributes to higher mortality in the CLP sepsis by exacerbating liver and/or kidney injury. Future studies are planned (especially endocytosis of bacteria via the receptors, and production of proinflammatory cytokines) to further elucidate the pathogenetic roles of SR-BI/BII in a clinically translatable abdominal sepsis model.

Aging and Immune Response to the Late Recovery Phase of Ischemic AKI

Hojin Jeon, Kyungho Lee, Junseok Jeon, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Hye Ryoun Jang. *Samsung Medical Center, Cell and Gene Therapy Institute, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Kidney immune cells play important roles in acute kidney injury (AKI) and the repair process. Considering that aging affects immune cell compositions and their function in multiple organs, the effect of aging on kidney and extrarenal immune responses in the recovery phase after ischemic AKI was evaluated.

Methods: C57Bl/6 mice with three different age groups, including 7-week, 6- and 12-month-old, underwent unilateral ischemia-reperfusion injury (UIRI) for 45 min. Mice were followed up until 4 weeks, and kidneys and spleens were collected. Serum creatinine and cystatin-C levels were measured. Kidney and splenic lymphocytes were analyzed by flow cytometry.

Results: Serum creatinine (7-week-old, 0.25±0.05; 6-month-old, 0.41±0.04, P=0.01; 12-month-old, 0.39±0.02mg/dL, P<0.01) and cystatin-C (548.67±30.35; 545.00±30.25, P=0.99; 914.60±96.40ng/ml, P=0.01) levels were higher in older mice at 4 weeks after UIRI, although both were comparable between groups at baseline. NK T cells (6.27±0.47 vs 2.51±0.30%, P<0.01) and Tregs (13.42±1.11 vs 7.87±0.53%, P<0.01) were lower in post-ischemic kidneys of 12-month-old mice than 7-week-old mice, whereas they were comparable in contralateral kidneys (NK T cells, 10.83±1.10 vs 9.56±0.65%, P=0.82; Tregs, 2.13±0.15 vs 2.13± 0.62%, P=0.99). There were no differences in the proportion of CD4 T cells and CD8 T cells among total T cells in both post-ischemic and contralateral kidneys. Activated B cells from older mice were higher in post-ischemic kidneys (10.00±1.06; 16.37±2.01, P=0.04; 19.77±1.74%, P<0.01) as well as in contralateral kidneys (2.78±0.19; 6.52±1.07, P<0.01; 7.81±0.42%, P<0.01). Splenic CD4 T cells (60.13±1.68 vs 91.32±2.35% of total T cells, P<0.01) were higher, and splenic Tregs (8.30±0.33 vs 5.34±1.22% of CD4 T cells, P=0.03) were lower in 12-month-old mice compared to 6-month-old mice. Splenic T cells from older mice had higher expression of CD69 (7.83±0.30; 15.95±2.05, P=0.097; 19.62±3.93% of total T cells, P=0.01).

Conclusions: Aging affects long-term intrarenal and systemic immune responses to ischemic AKI during the recovery phase. Older hosts showed an accelerated proinflammatory and diminished anti-inflammatory responses. Future studies are needed to evaluate senescent immune reaction in ischemic AKI.

TH-PO087

Kidney Injury Released HMGB1 Is a Pathogenic Agent to the Development of Acute Lung Injury

Yu Hong, Ying Yao, Rui Zeng. *Division of Nephrology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China.*

Background: Acute kidney injury (AKI) could induce respiratory complications, resulting in a high mortality rate, but molecular mechanisms and mediators of AKI to acute lung injury (ALI) are not yet well understood.

Methods: Male C57BL/6 mice were used to establish bilateral renal ischemia-reperfusion injury (I/R) model. Single-cell RNA sequencing analysis was used to explore which molecule play a crucial role in AKI-ALI. The role of high mobility group box 1 (HMGB1) was verified by constructing renal tubular epithelial cell-specific HMGB1 knockout mice and injecting HMGB1 neutralizing antibodies. The post-translational modification of HMGB1 and its influence on other proteins in injured kidney was detected by the proteomic analysis. Immunoprecipitation, and immunofluorescence co-staining were used to identify the HMGB1 receptor in ALI.

Results: We found renal I/R induced ALI, especially at day one after surgery. The expression of HMGB1 in renal tubular cells increased rapidly after I/R, with the cytoplasmic migration of HMGB1. Specific knockout of HMGB1 in renal tubular cells or injection of HMGB1 neutralizing antibody alleviated AKI-induced ALI. The acetylation of HMGB1 in the kidney increased after I/R, which accelerates the release of HMGB1 into the peripheral circulation. In addition, we found 2469 sites of 1050 proteins were increased in acetylation compared to that in sham mice. Knockout of HMGB1 in renal tubular epithelial cells decreased acetylation of 1093 sites of 698 proteins, which are key proteins involved in several energy metabolism pathways. We further found that the binding receptor for HMGB1 on the membrane of lung tissue cells is depend on the advanced glycation end products (RAGE). After antagonizing RAGE, kidney I/R-induced ALI was alleviated, but kidney damage was not affected. It was further found that the HMGB1-RAGE axis participated in the progression of ALI via impairment of oxidative phosphorylation and the subsequent mitochondrial dysfunction.

Conclusions: Our work identifies HMGB1 released by the injured kidney as a causal key mediator of ALI, which provides a potential therapeutic target for this specific interorgan crosstalk of AKI to ALI.

TH-PO088

IL-22 Secreted from Proximal Tubule Cells Regulates Cell Fate During AKI

Sho Sugahara,[1] Kensei Taguchi,[2] Bertha C. Elias,[1] Guillaume Canaud,[3] Craig R. Brooks.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Kurume Daigaku Igakubu Daigakuin Igaku Kenkyuka, Kurume, Japan; [3]Universite Paris Cite UFR de Medecine, Paris, France.*

Background: Acute kidney injury (AKI) occurs in ~13% of hospitalized patients and is associated with a fourfold increase in mortality. Proximal tubule cells (PTCs) are key to the outcome of AKI as they are the most sensitive cells to AKI and respond by secreting a number of inflammatory and/or pro-reparative cytokines. Interleukin-22 (IL-22) is an IL-10 family cytokine produced after tissue injury. IL-22 is secreted exclusively by immune cells subsets, mainly T cells, while its receptor is expressed on epithelial cells, such as PTCs. Functionally, IL-22 acts as a double-edged sword, with both protective and pathological functions in kidney injury. Here we elucidated the source of IL-22 in the kidney and its physiological function in nephrotoxic injury.

Methods: Patient biopsies were obtained as part of standard clinical practice. IL-22 RNA was detected by RNAScope in situ hybridization staining. IL-22 protein was detected by injecting mice with the secretion inhibitor brefeldin A and immunofluorescence staining. Nephrotoxic AKI was induced by administration of aristolochic acid (AA) or cisplatin in 8 to 12-week-old male wild-type (WT); IL-22 globally knockout mice (IL-22KO), and kidney specific IL-22 receptor knockout (Six2:IL-22RA1fl/fl, IL-22DPT). Rag1 knockout mice were used as an immune deficient model.

Results: RNAScope staining revealed that injured PTCs were a source of IL-22 in both human and mouse AKI. Under basal conditions, no RNA or protein expression of IL-22 was observed in the kidneys. In patient biopsies and all kidney injury models, PTCs stained positive for IL-22 RNA and protein. Urinary IL-22 was 10x higher than serum levels following AKI. Immune deficient Rag1KO mice, lacking mature T and B cells, produced similar urinary IL-22 concentration compared to WT mice. Next, we analyzed the role of IL-22 in nephrotoxic kidney injury by injuring IL-22KO and IL-22DPT mice with cisplatin or AA. Both IL-22KO and IL-22DPT mice had reduced markers of DNA damage and cell death following injury, as well as increased survival and improved kidney function compared to WT.

Conclusions: PTCs represent the first epithelial cells found to express IL-22 and are the main contributors to urinary IL-22. Blocking IL-22 or deletion of the IL-22 receptor prevents PTC cell death and restores kidney function.

TH-PO089

Shiga Toxin Downregulates ERG Protein in Endothelial Cells and Impairs Angiogenesis

Celestina Mazzotta,[1] Julie R. Ingelfinger,[2] Eric F. Grabowski.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Massachusetts Medical Society, Waltham, MA.*

Background: Shiga toxin (Stx) activates inflammatory signaling, leading to vascular dysfunction and pro-thrombotic tissue microenvironment. Stx can trigger enterohemorrhagic hemolytic uremic syndrome (HUS)--thrombocytopenia, hemolytic anemia, and AKI, most often in children, and may require dialysis. Damage may occur in GI tract, pancreas, brain and cardiovascular system, with death in 2-5%. Typical HUS is a thrombotic microangiopathy with endothelial cell (EC) injury and platelet fibrin thrombus formation in glomerular arterioles and arterioles of other affected organs. To elucidate microangiopathy mechanisms, we examined in human ECs the regulation of the platelet adhesion proteins P-selectin and von Willebrand factor, along with the downregulation of erythroblast transformation-specific transcription factor (ERG), a key regulator of angiogenesis and megakaryocyte development.

Methods: von Willebrand Factor (VWF), P-selectin, and ERG levels were determined using immunofluorescence and western blot (WB) in human umbilical endothelial cells (HUVECs). HUVECs treated with tumor necrosis factor-alpha (TNF), Stx-1 or both, compared to normal controls. Capillary morphogenesis on Matrigel was performed in HUVECs treated, for 22 hours with TNF, Stx-1, or both, or treated 4 hours with Stx-1 alone or in combination with TNF for 22 hours.

Results: Stx-1 significantly reduced ETS transcription factor (ERG) and VWF expression on HUVECs, but upregulated P-selectin expression. ERG level decreased with Stx-1 alone or in combination with TNF, in the nuclear, perinuclear and cytoplasmatic regions. Stx-1 reduced capillary morphogenesis, while Stx-1-TNF combined treatment reduced capillary morphogenesis still further.

Conclusions: In the presence of Stx-1 or TNF or both treatments, ECs were activated, expressing higher levels of P-selectin and lower levels of VWF. Our findings, further, provide evidence that Stx-1 downregulates ERG, repressing angiogenesis *in vitro*.

Funding: NIDDK Support

Altered Signaling Pathways in ZSF1 Rats with AKI and Metabolic Disease

Li-Jun Ma,[1] Fuyong Du,[1] Shanker Kalyana-Sundaram,[1] Rong Meng,[1] Jialin Xu,[2] Alessandro Pocai,[1] Andrea R. Nawrocki.[1] *[1]CVMR-PH, Janssen, Johnson & Johnson, Spring House, PA; [2]Discovery Statistics, TMEDS, SDS, Janssen, Johnson & Johnson, Spring House, PA.*

Background: Acute kidney injury (AKI) is a common cause of kidney failure and mortality. No treatments are approved for AKI. We reported at ASN in 2022 (TH-PO088) that obese and diabetic ZSF1 rats subjected to ischemia-reperfusion injury (IRI) exhibit more severe renal function decline and slower renal function recovery relative to lean non-diabetic rats. To further understand the molecular mechanisms underlying the observed phenotypes, RNA-Seq and pathway analysis were performed.

Methods: RNA-Seq was conducted in obese and lean rat kidneys (n=4-6 each) collected at 24 hours (acute phase of AKI) or 7 days post IRI (repairing phase of AKI). Control group included rats without surgery and sham surgery. Pathway enrichment analysis for the differentially regulated genes was carried out using KEGG and Ingenuity Pathway Analysis (IPA). Enrichment *p*-values were adjusted for multiple hypothesis testing using the Benjamini-Hochberg method (p values < 0.05). Further, the correlation analysis was performed to study the potential association between the plasma creatine levels and the expression level of differentially expressed genes.

Results: Principal component analysis showed that the transcriptomic profiling data from RNA-seq was clustered into three distinct groupings: (1) Obese/IRI 24 h, (2) Lean/IRI 24 h and (3) rest of the groups (Lean/IRI/7d, or Obese IRI/7d or control groups). We observed that 509 and 180 genes were significantly dysregulated in obese vs lean rats at 24 hours and 7 days post IRI, respectively. Pathway analysis revealed profound downregulation of the *de novo* NAD synthesis related tryptophan metabolism pathway and activation of proinflammatory interleukin-17 (IL-17) signaling pathway at 24 hours post IRI. Interestingly, IL-17 signaling pathway remained significantly activated even at 7 days post IRI. The expression of genes in the IL-17 pathway correlated with plasma creatinine levels.

Conclusions: Our study suggests *de novo* NAD synthesis and IL-17 as potential pathways involved in AKI progression and highlights novel therapeutic approaches for AKI.

TH-PO091

Renoprotective Effect of Tamm-Horsfall Protein in Crystalline Nephropathy

Larissa de Araujo,[1,2] Maria Oliveira-Souza.[1] Laboratory of Renal Pathophysiology. *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Indiana University School of Medicine, Indianapolis, IN.*

Background: Tamm-Horsfall protein (THP) has an immunomodulatory role in the kidney. Our hypothesis is that the immunomodulatory function of THP is impaired in acute kidney injury (AKI) induced by crystalline nephropathy, and the exogenous administration of THP can play a renoprotective role in the disease.

Methods: Eight weeks old C57BL/6J mice were randomly allocated into four groups: 1. Control (saline 0.9%,i.p); 2. THP (exogenous THP–5µg/animal, single injection i.p); 3. NaOx (sodium oxalate–9mg/100g of body weight, single injection i.p); 4. NaOx administration and THP treatment. The animals were placed in metabolic cages for 24 hours before euthanasia and organ harvest. The results presented as mean ± S.D. were analyzed by two-way ANOVA and a Bonferroni post hoc test using GraphPad Prism software. $p<0.05$ was considered statistically significant.

Results: Treatment with exogenous THP alone did not change any parameter analyzed. Urinary THP excretion was decreased in the NaOx group [(arbitrary units) NaOx:100.1±20.2 vs. Control:195.2±7.9, p=<0.0001] and the co-treatment with exogenous THP prevented that change [(arbitrary units) NaOx+THP:169.3±31.8 vs. NaOx:100.1±20.2, p=0.0002. Interaction: p=0.0012]. Using immunofluorescence imaging, we observed that the treatment with NaOx induced THP clusters formation in the tubular lumen, which was prevented by concomitant with exogenous THP. Treatment with NaOx significantly increased mRNA expression for KIM-1, Ki67, MCP-1, TNFα, IL-1β, and IL-6, consistent with kidney injury. Co-treatment with exogenous THP prevented these changes (Fold change from control for NaOx+THP vs. NaOX, respectively): KIM-1 [95.2±121.7 vs. 730.0±182.5, p=<0.0001. Interaction p=0.0001], Ki67 [2.0±1.0 vs. 5.7±1.7, p=0.0001. Interaction p=0.0006], MCP-1 [1.9±1.8 vs. 8.2±3.8, p=0.0008. Interaction p=0.0030], TNFα [1.3±0.7 vs. 4.0±2.2, p=0.0087. Interaction p=0.0216], and IL-6 [5.4±7.5 vs. 84.4±46.2, p=0.0002. Interaction p=0.0010].

Conclusions: Our results indicate that exogenous THP may have a renoprotective effect on nephropathy crystalline-induced AKI.

Ischemia-Reperfusion-Mediated Kidney Injury Is Attenuated in a New Complement 5 Knockout Model

Madison K. Mcgraw, Dinesh Bhattarai, Seongok Lee, Nirmala Parajuli. *University of Arkansas for Medical Sciences College of Medicine, Little Rock, AR.*

Background: Acute kidney injury (AKI) affects over 13 million people each year around the world due to renal injury caused by ischemia. Additionally, 70% of transplanted kidneys are sourced from deceased donors, and organs are transported in static cold storage (CS) to maintain tissue viability, with the consequence of subjecting the kidney to ischemic conditions. Renal ischemia has been previously attributed to the aberrant activation of the complement system during AKI and transplant. The terminal cascade begins with the cleavage of complement 5 (C5) and drives downstream membrane attack complex (C5b-9) formation, but the role of this terminal pathway during renal ischemia is not fully understood.

Methods: In this preliminary study, we developed a novel C5 knockout (C5KO) rat model via CRISPR/Cas9 deletion of C5 exon 3. Furthermore, C5KO Lewis rats were introduced in a model of renal ischemia-reperfusion (I/R) via 40-minute bilateral clamping of the renal vessels and right nephrectomy. Animals were sacrificed day 1 post-procedure and characterized in terms of arterial blood gases/chemistry, mitochondrial respiration, and fluorescence activated cell sorting (FACS).

Results: We have observed a fertile animal with normal mitochondrial function and no health concerns. I/R resulted in significant elevation of serum creatinine (SCr) and blood urea nitrogen (BUN) in C5+/+ rats compared to sham (n=4 per group; p=0.0004 and 0.0019, respectively). This effect was attenuated by C5-/- for SCr (n=4; p=0.005) and BUN (n=4; p=0.0223). C5+/- also significantly decreased SCr (n=4; p=0.0165) after I/R when compared to C5+/+, but not BUN.

Conclusions: Knockout (or partial knockout) of complement component C5 results in a reduction in SCr and BUN during I/R compared to wild-type, suggesting that targeting C5 during kidney injury may confer a protective effect. This model may be useful in future studies focused on the role of C5 during AKI or CS+Tx.

Caveolin-1 Protects Against AKI via Regulating Endoplasmic Reticulum Stress

Yan Zhang, Zhangzhe Peng. *Xiangya Hospital Central South University, Changsha, China.*

Background: Acute renal injury (AKI) is a serious medical condition characterized by a rapid loss of renal function. Recent evidence has suggested that endoplasmic reticulum (ER) function is important for protein homeostasis (‘proteostasis’) in the kidney, and that ER stress is a component of acute kidney injury. Caveolin-1 (Cav1), a multifunctional membrane protein, is the main component of caveolae on the plasma membrane. Caveolae serve as a platform to regulate stress responses, cellular endocytosis, and signal transduction. Previous studies have shown that the expression of Cav1 was increased in AKI models induced by ischemia-reperfusion and gentamicin. However, the crucial role of Prdx1 in AKI remains unclear.

Methods: Cav1-deficient mice were used to determine its function and potential mechanisms in AKI.

Results: In ischemic-reperfusion-induced AKI mice, a significant increase in the expression of Cav1 in kidney tissue was observed. Similar observations were also obtained in the lipopolysaccharide (LPS)-induced AKI mouse model. Likely, the expression of Cav-1 was increased in patients with AKI. Cav1 deficiency worsened renal function and caused more tubular injury in AKI induced by ischemia-reperfusion and LPS. Furthermore, i.p. injection of Cav1 peptide in *Cav1*$^{-/-}$ mice improves kidney function and attenuates kidney tubular injury in ischemic-reperfusion and LPS-induced AKI mice. Additionally, knockout of Cav1 aggravated endoplasmic reticulum stress and apoptosis in primary renal tubular epithelial cells.

Conclusions: Our results revealed that Cav1 may play a protective role in AKI by regulating ER stress, thereby identifying a novel and important therapeutic target for AKI.

Clathrin-Mediated HMGB1 Endocytosis Promotes Acute Kidney Ischemia-Reperfusion-Induced Lung Injury

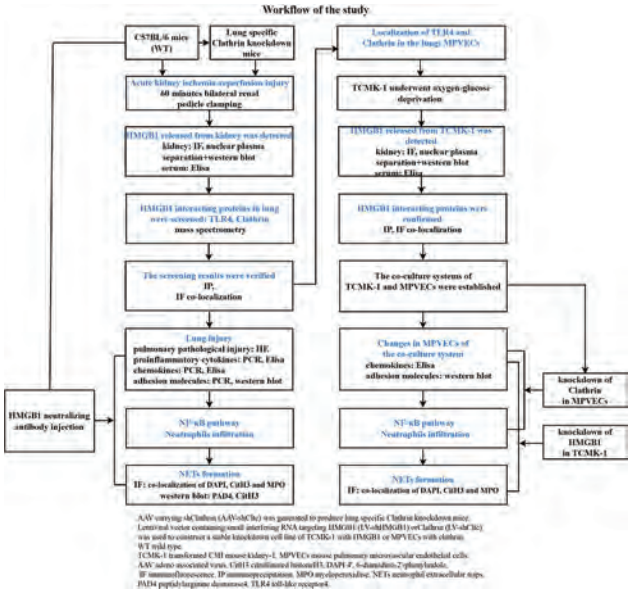
Yuxian Kuai, Yanhong Li. *Children's Hospital of Soochow University, Suzhou, China.*

Background: Acute kidney injury (AKI) further increases mortality when combined with acute lung injury (ALI). Blockade of high mobility group box1 (HMGB1) may reduce AKI induced ALI. However, the potential molecular mechanisms in kidney-lung crosstalk after AKI remain elusive. We hypothesized that circulating HMGB1, released form ischemia-reperfusion (I/R) injured kidney, enters the lung cells and promotes AKI induced ALI by modulating neutrophil extracellular traps (NETs) formation.

Methods: Workflow of the study is shown in Fig.

Results: Analysis of cytokines and chemokines and lung histology revealed increased lung inflammation and injury following kidney I/R. Serum HMGB1 level increased gradually with the continued extracellular release of HMGB1 from kidney cells following the extension of I/R time. The interaction of clathrin, screened by mass spectrometry, with HMGB1 and its receptor TLR4 in lung endothelial cells was confirmed by co-IP and IF co-localization, and the lung specific knockdown of clathrin decreased lung inflammation and injury induced by kidney I/R in mice. Increased expression of PAD4 and CitH3 and the co-localization of CitH3 and MPO suggested that kidney I/R induced NETs formation in lung. Blockade of HMGB1 by neutralizing antibody in vivo and knockdown of HMGB1 in vitro inhibited NETs formation and ameliorated AKI induced ALI.

Conclusions: HMGB1 released from I/R kidney promotes AKI-induced ALI in mice by modulating NETs, and clathrin-mediated endocytosis is required for HMGB1-TLR4 to enter lung endothelial cells and regulate neutrophils infiltration. Induced NETs formation leads to lung injury that could be rescued by HMGB1 neutralizing antibody, suggesting that targeting NETs and the HMGB1 pathway might extend effective therapeutic strategies to minimize AKI-induced ALI.



AAV carrying shClathrin (AAV-shClic) was generated to produce lung specific Clathrin knockdown mice.
Lentiviral vector containing small interfering RNA targeting HMGB1 (LV-shHMGB1) or Clathrin (LV-shClic) was used to construct a stable knockdown cell line of TCMK-1 with HMGB1 or MPVECs with clathrin.
WT wild type.
TCMK-1 transformed CMI mouse kidney-1. MPVECs mouse pulmonary microvascular endothelial cells.
AAV adeno-associated virus. CitH3 citrullinated histone H3. DAPI 4', 6-diamidino-2'-phenylindole.
IP immunoprecipitation. MPO myeloperoxidase. NETs neutrophil extracellular traps.
PAD4 peptidylarginine deiminase4. TLR4 toll-like receptor4.

Endothelial Cells Regulate Post-Ischemic Kidney Repair Through PHD/HIF-Dependent Hyperglycolysis

Ratnakar Tiwari, Si Young An, Rajni Sharma, Gabriella Borkowski, James O'Sullivan, Susan E. Quaggin, Pinelopi P. Kapitsinou. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Recently, we showed that inhibiting the oxygen-sensing molecule prolyl hydroxylases (PHDs) controls human endothelial cell (EC) metabolism and angiogenic ability. However, in the context of acute kidney injury (AKI), little is known about the functions of endothelial PHDs. Here, we used a genetic approach in conjunction with scRNA-seq to investigate the roles of endothelial PHDs in post-ischemic kidney repair.

Methods: To delete PHD1, PHD2, and PHD3 in ECs, VECadherin (Cdh5)-CreER transgenic mice were crossed to mice carrying conditional PHD1, PHD2, and PHD3 alleles, generating *PHD* ^{TiEC} mice. For our loss of function studies, we generated mice that lack the constitutive HIF-1β (*ARNT*) in ECs (*ARNT* ^{iEC}). Ischemia-reperfusion injury (IRI) was induced by uni-/bilateral renal artery clamping, and tamoxifen treatment was started at day 1 post IRI, followed by analysis at day 14.

Results: Compared to *Cre*$^{-}$ controls, day 14 post IRI kidneys of *PHD* ^{TiEC} showed significant upregulation of profibrotic genes *Loxl2, Tgfβ1,* and *Acta2,* increased collagen deposition (n=6-8, p≤0.05), higher tubular injury, and reduced capillary density. Further, *PHD* ^{TiEC} showed a 26% reduction in glomerular filtration rate than *Cre*$^{-}$ controls (n=7, p≤0.01). Suppression of post-ischemic EC-HIF signaling in *ARNT* ^{iEC} mice ameliorated kidney injury and fibrosis assessed by similar analyses as indicated above (n=6-7, P≤0.5). scRNA-seq analysis of the day 14 post-IRI kidney revealed a hyperglycolysis signature in the medullary EC of *PHD* ^{TiEC} mice compared to *Cre*$^{-}$ mice. Among the significantly upregulated glycolytic genes was *Slc16a3,* a HIF target gene that encodes the lactate transporter MCT4, known to mediate lactate efflux. Notably, post-ischemic administration of the dual MCT4/MCT1 inhibitor Syrosingopine (Syro) attenuated kidney injury in *PHD* ^{TiEC} mice (n=4, P≤0.5). In vitro, Syro or MCT4 siRNA suppressed the hypoxia/reoxygenation+IL1-β (1ng/ml) induction of EC-adhesion molecules VCAM1 and ICAM1, leading to reduced monocyte adhesion to human EC (n=3, P≤0.5).

Conclusions: In summary, endothelial PHDs regulate post-ischemic kidney repair through HIF-dependent mechanisms. Furthermore, our studies identify the endothelial MCT4 as a potential target for renoprotective therapies.

Hedgehog Interacting Protein (Hhip) Deficiency in Endothelial Cells Prevents Ischemia Reperfusion-Induced Renal Tubular Cell Injury Through Inhibition of NF-KB Signaling

Yuchao Pang,[1] Junzheng Peng,[1] Xin-Ping Zhao,[1] Shiao-Ying Chang,[1] Min-Chun Liao,[1] Alain Rivard,[1] Julie R. Ingelfinger,[2] John S. Chan,[1] Shao-Ling Zhang.[1] *[1]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [2]Massachusetts General Hospital, Boston, MA.*

Background: Acute kidney injury (AKI) caused by renal ischemia reperfusion (R I/R) is a major clinical issue that is lacking viable therapies, and its underlying mechanisms are poorly understood. Given the important role of hedgehog interacting protein in chronic kidney disease-related renal fibrosis, we investigated whether Hhip knockout in endothelial cells (EC) (Hhip^{EC} KO) could prevent R I/R-induced kidney injury in vivo and in vitro.

Methods: Male Hhip^{EC} KO and control Hhip$^{fl/fl}$ mice at 10-weeks old were subjected to 45 minutes of the unilateral R I/R or sham surgery, both with contralateral nephrectomy. The AKI time-course was examined at Day1, Day 3, Day7 and Day 21. In vitro, naïve renal proximal tubular cells (IRPTCs) exposed to the conditioned media harvested from mouse endothelial cell (mECs) with or without Hhip (siRNA) ± gentamicin treatment, were studied.

Results: Compared to the respective controls, R I/R mice (Hhip$^{fl/fl}$ and Hhip^{EC} KO) body weight loss (BW, g) occurred from Day 1 until Day 21, regardless of Hhip deficiency. In line with the AKI time course, Hhip$^{fl/fl}$-R I/R mice displayed kidney dysfunction marked by increased urinary albumin-to-creatinine ratio; tubular/endothelial cell injury and fibrosis as assessed by kidney morphological staining (Periodic Acid-Schiff, Masson's trichrome and Sirius Red) with enhanced cystatin C-, kidney-induced molecular 1-and TGFβ1- immunoexpression in their kidneys. Maladaptive and inadequate renal tubular damage repair was observed by enhanced vascular cell adhesion protein 1 and NF/kB (p50/p65) expression. In contrast, these changes were significantly ameliorated in the kidneys of Hhip^{EC} KO -R I/R mice. In vitro, naïve IRPTCs exposed to the conditioned media harvested from mECs treated with gentamicin (2.5mg/ml) had lower wound healing ability/capacity, higher cellular senescent activity and increased NF/kB expression. Those changes were largely prevented in naïve IRPTCs exposed to conditioned media harvested from Hhip KO mECs treated with gentamicin.

Conclusions: Our data suggest that Hhip knockout in endothelial cells prevented AKI-induced renal tubular injury. This action might be mediated, at least, in part, by inhibition of NF-KB signaling.

VEGF-R2 Signaling in Renal Stroma Exacerbates Post-AKI CKD Progression

Takuto Chiba, Akira Oda, Sunder Sims-Lucas. *University of Pittsburgh, Pittsburgh, PA.*

Background: A dire consequence of AKI is progression to CKD. AKI patients are at more than twice the increased risk of progressive CKD that leads to excessive morbidity and mortality. Understanding the mechanisms by which AKI progresses to CKD is essential for establishing a new therapeutic target since no established therapy to date is available for. Renal microvasculature, including pericytes and endothelial cells, are damaged in AKI, leading to recruitment of inflammatory cells which contributes to progression to CKD. It was recently shown that Platelet-derived growth factors (PDGFs) are predicted to signal via VEGF-R2, particularly in disease conditions. However, the functional implications of VEGF-R2 in the renal stroma, which gives rise to renal pericytes, in CKD remain poorly understood. This informed us an overarching hypothesis that renal stroma specific VEGF-R2 signaling dysregulates microvascular recovery and exacerbates post-AKI progression to CKD.

Methods: We generated genetic mouse models for renal stromal cells (RSCs)-specific loss-of-function of *VegfR2* with constitutively expressed Foxd1-Cre (*VegfR2*$^{RSC-/-}$) as well as tamoxifen inducible Foxd1-Cre (*iVEGF-R2*$^{RSC-/-}$) to interrogate timing specific role of *VegfR2* in renal stroma in AKI-to-CKD. CKD models induced either by a renal ischemia/reperfusion injury (IRI) or by low/dose repeated treatment of cisplatin were performed. Mice were monitored for the development of AKI and post-AKI CKD using serum chemistries and tissue analysis.

Results: We found that *VegfR2*$^{RSC-/-}$ mice have reduced inflammation and vascular injury after renal IRI and have reduced renal intertitial fibrosis after renal IRI as well as reduced interstitial lipid deposition. Consistently, *VegfR2*$^{RSC-/-}$ are protected against progression to CKD in a cisplatin CKD model. Mechanistically, *VegfR2*$^{RSC-/-}$ kidneys

have reduced expression of a pro-inflammatory signaling axis of Thrombospondin-1 (TSP1)/ CD148 and have increased expression of fatty acid metabolism associated genes contributing to the enhanced protection. Furthermore, *iVegfR2*$^{RSC-/-}$ mice are significantly protected against renal IRI.

Conclusions: These data suggest that VEGF-R2 signaling in renal stroma exacerbates renal IRI and its CKD progression as well as cisplatin CKD.

Protective Mechanisms of Lymphangiogenesis During Kidney Injury

Michael D. Donnan, Dilip K. Deb, Yalu Zhou, Susan E. Quaggin. *Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Lymphangiogenesis is demonstrated to be a protective response in multiple etiologies of kidney injury. As injury-related lymphangiogenesis is driven by the release of the growth factor VEGF-C by tubular epithelial cells, this signaling pathway is a candidate for future kidney therapeutics. However, the mechanisms by which kidney lymphangiogenesis protects the kidney against injury remain uncertain. Recent investigations in other organ systems have revealed lymphatic endothelial cells (LECs) secrete factors termed "lymphoangiocrine" molecules which directly promote protection against injury in surrounding tissues. Our hypothesis is that lymphangiocrine factors are also released by kidney LECs and convey protection against kidney injury.

Methods: We generated a conditional mouse model to promote lymphangiogenesis (*VegfcGOF*) through overexpressing VEGF-C in the kidney tubules using the Pax8-rtTA-TetOcre driver strain. The ischemia-reperfusion mouse model of acute kidney injury (IR-AKI) was performed on *VegfcGOF* mice and littermate controls and kidneys were collected 7 days post-injury. Kidneys were processed for standard histology, tissue clearing with 3D light-sheet imaging of the vasculature, and single-cell RNA sequencing.

Results: *VegfcGOF* mice demonstrate an expansion of lymphatic capillaries throughout the kidney cortex, which is further potentiated by IR-AKI. There is no baseline difference in BUN, creatinine, or blood pressure between *VegfcGOF* mice and littermate controls. At 7 days post-injury, kidneys demonstrate a similar level of peritubular capillary rarefaction, and expression of the injury marker *Kim-1*, however, *Vegfc*GOF mice have a reduction in a distinct set of previously identified genes (*Dcd2a, Sema5a,* and *Vcam1)* that signify proximal tubule epithelial cells (PTECs) which have failed to repair after injury. Additionally, the known cardiac lymphangiocrine factor Reelin (RELN) is expressed by kidney LECs during injury with its receptor integrinß1 (ITGB1) expressed in tubule epithelial and stromal cells.

Conclusions: Kidney lymphangiogenesis is robustly induced in the *VegfcGOF* mice without overt consequence to kidney function at baseline. In the setting of kidney injury, kidney LECs may promote successful repair of PTECs with RELN-ITGB1 signaling being a potential mechanism of this protective effect.

Renalase Ameliorates AKI by Altering Mitochondrial Function to Induce Cellular Repair Mechanisms

Xiaojia Guo,[1] Rongmin Chen,[1] Tian-Min Chen,[1] Robert L. Safirstein,[1,2] Elizabeth A. Jonas,[1] Gary V. Desir.[1,2] *[1]Yale School of Medicine, New Haven, CT; [2]VA Connecticut Healthcare System West Haven VA Medical Center, West Haven, CT.*

Background: Renalase (RNLS) is a protein that activates kinases linked to survival and attenuates acute ischemic and cisplatin (CP)-induced kidney injury. We now study RNLS role in inducing changes in mitochondrial function to assist in survival and repair of injured tissue.

Methods: RNLS knockout (KO) and wild type (WT) mice were given CP at 15 mg/kg or vehicle control. Kidney mitochondrial structure was analyzed by electron microscopy (EM), and mitochondrial proteins were analyzed by immunoblotting, co-immunoprecipitation and patch clamp recording. The activities of complex I and II were evaluated in mitochondria isolated from kidneys of WT and KO with and without CP.

Results: Both RNLS and its receptor PMCA4b were detected in WT mitochondria by immunofluorescence and RNLS was localized to the inner mitochondrial membrane or matrix by pan-Expansion Microscopy. CP induced severe renal damage in RNLS deficient animals as evidenced by a 7.8-fold increase in plasma creatinine (KO 1.18 ± 0.29 mg/dL, n=13 vs WT 0.15 ± 0.03 mg/dL, n=14, $p<0.005$). By EM, WT kidney demonstrated decreased mitochondrial area (suggesting fission) and osmotic changes; in contrast mitochondria in RNLS KO were deficient in these activities. Cisplatin induced increased markers of mitophagy and stress in KO vs. WT; Parkin, p-AMPKα and p-AMPKβ were increased, OPA-1 expression was decreased. RNLS KO mouse kidneys exhibited reduced mitochondrial complex I and II activities as compared to WT ($p<0.005$ and $p<0.05$, respectively, n=5); recombinant RNLS rescued these activities in RNLS KO kidneys (n=3, $p<0.001$). Physiological recording of mitochondrial inner membranes of KO and WT animals showed that RNLS addition increased the conductance of the mitochondrial inner membrane.

Conclusions: RNLS alters mitochondrial morphology and function in response to renal injury. The absence of RNLS increases mitophagy, possibly *in lieu* of metabolic repair mechanisms during CP-AKI. These data suggest that RNLS modifies renal injury by encouraging metabolic repair mechanisms as opposed to mitochondrial removal via mitophagy.

MAVS Modulates Inflammation and Apoptosis in Renal Ischemia-Reperfusion Injury

Taichiro Minami, Yasunori Iwata, Shinji Kitajima, Tadashi Toyama, Akinori Hara, Norihiko Sakai, Miho Shimizu, Takashi Wada. *Kanazawa Daigaku, Kanazawa, Japan.*

Background: Mitochondria have a central role not only in the initiation of ischemia-reperfusion injury (IRI) but also are involved in recovery processes. Mitochondrial antiviral-signaling protein (MAVS) is a component of innate immunity, leading to cytokines production upon activation. Here, we characterize the role of MAVS in tubular epithelial cells during the various phases of IRI-induced AKI, and their relative importance to renal fibrogenesis.

Methods: We performed unilateral renal artery clamping for 50 minutes in wild-type mice (C57BL/6) and MAVS knockout mice and assessed the pathology at the acute kidney injury phase (Day2, Day5) and chronic phase (Day20).

Results: Compared with their wild-type counterparts, MAVS knockout mice showed less urine protein and tubular injury scores, tubular epithelial cell apoptosis in the acute stage of AKI, and attenuated fibrosis in the late stage. Immunostaining revealed that MAVS is mainly expressed in the renal tubules in the physiological state, and strongly expressed in the injured proximal tubules after renal ischemia-reperfusion. Transient transfection of MAVS in HEK293T cells increased TRAF6 expression, nuclear translocation of NFκB, and phosphorylation of MAPK (p38, ERK, JNK), suggesting that it activates inflammation and apoptosis. Moreover, MAVS inhibition resulted in less mitochondrial reactive oxygen species and pro-inflammatory cytokines production after hypoxia.

Conclusions: Collectively, we identify MAVS as a pro-inflammatory contributor to renal tubules in the early phase of AKI and it might be a therapeutic target.

TH-PO101

Inhibition of Retinoic Acid Signaling in Proximal Tubules Protects Against AKI by Enhancing Kim1-Dependent Efferocytosis

Min Yang,[1] Haichun Yang,[1] Leslie S. Gewin,[2] Craig R. Brooks,[1] Mark P. de Caestecker.[1] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]Washington University in St Louis, St Louis, MO.*

Background: Retinoic acid receptor (RAR) signaling is activated in proximal tubules (PTs) and macrophages (Møs) after IRI-AKI, and systemic inhibition of RARs increases Mø-dependent injury after IRI-AKI. It is unknown whether RARs are activated in other forms of AKI, and the functional role of PT RAR signaling after AKI remains unknown.

Methods: GSEA for RAR targets enriched in a snRNA seq database from patients with sepsis-associated AKI (SA-AKI) (Hinze, 2022). RARE-LacZ (RAR reporter mice); PEPCK-CRE; R26R-dominant negative RAR (PT-DN RAR), bilateral IRI- or rhabdomyolysis-AKI (rhabdo-AKI). Injury and RARE-LacZ localization evaluated by BUN, QRT-PCR, LacZ staining, and IF. Renal Møs by RNA seq and FACS; PT proliferation, metabolic activity, and Kim-1 function in primary PTs. Efferocytosis by quantifying PT apoptosis +/- a lysosome inhibitor, Bafilomycin, after IRI-AKI.

Results: These is enrichment for RAR targets in PTs from patients with SA-AKI. The same gene set was upregulated in mouse kidneys after rhabdo-AKI. In contrast to IRI-AKI where reporter activation was transient, there was prolonged activation of RARE-LacZ in PTs throughout the kidney after rhabdo-AKI. Inhibition of PT RAR signaling in PT-DN RAR mice protected against acute tubular injury (ATI) in rhabdo-, and to a lesser extent, IRI-AKI. This was unexpectedly associated with increased Kim-1 expression; PT de-differentiation, proliferation, and metabolic reprogramming (increased glycolysis and ox phos), in PT-DN RAR kidneys and cultured PTs. Kim-1-dependent uptake of oxidized LDL was increased in PT-DN RAR PTs, and there was reduced PT apoptosis after IRI- and rhabdo-AKI. This was reversed by Bafilomycin treatment, indicating that decreased apoptosis is dependent on PT efferocytosis. Consistent with increased efferocytosis as a protective mechanism in AKI, there was also a reduction in pro-inflammatory renal Møs after IRI-AKI in PT DN RAR mice.

Conclusions: These findings indicate that there is extensive activation of PT RAR signaling in experimental and human AKI, and that inhibition of RAR signaling in PTs protects from AKI by promoting PT de-differentiation and enhancing Kim-1 dependent efferocytosis. This suggests that activation of RAR signaling in PTs after AKI is a compensatory response that reestablishes PT differentiation and function after ATI.

Indoxyl Sulfate Influences Susceptibility of Proximal Tubule Epithelial Cells to Gentamicin Cytotoxicity

Joseph Alge.[1,2] *[1]Baylor College of Medicine, Houston, TX; [2]Texas Children's Hospital, Houston, TX.*

Background: Patients with chronic kidney disease (CKD) are at increased risk of acute kidney injury (AKI) following exposure to nephrotoxic medications, and there is a critical need to understand the molecular pathogenesis of acute-on-chronic kidney disease. CKD leads to systemic bioaccumulation of uremic solutes, such as the tryptophan metabolite indoxyl sulfate (IS), which have direct effects on the kidneys that promote CKD progression. The objective of this study was to the determine the effect of IS on proximal tubule epithelial cell (PTEC) and test the hypothesis that IS exposure increases susceptibility to gentamicin-induced cytotoxicity.

Methods: Cultured immortalized PTECs (HK-2 cells) were treated with IS and gentamicin at varying concentrations, and cell viability was assessed using the Trypan blue and MTT assays. TMT proteomic profiling with IBAQ quantitation and gene set enrichment analysis was used to identify differentially abundant proteins and pathways that are dysregulated by IS exposure and could mediate the cytotoxic effects of IS influence susceptibility to gentamicin cytotoxicity.

Results: Treatment with 100 μM IS had a modest cytotoxic effect (15-20% cell death after 24 hours). Proteomic profiling identified 10,030 proteins, and IS treatment induced changes in the abundance of 60 proteins, including increased expression of kidney injury molecule-1 and VCAM-1 and down regulated mitochondrial complex V ATPase subunits and mitochondrial ribosomal proteins. GSEA found that there was a decrease in mitochondrial translation following IS exposure. These results suggest that IS is directly cytotoxic to PTECs and negatively impacts mitochondrial dynamics and cellular respiration. Pretreatment with IS increased susceptibility of HK-2 cells to 10 mM gentamicin cytotoxicity as assessed by Trypan blue staining (30.1% +/- 6.4% cells stained positive without IS pretreatment vs 46.1 +/- 3.1% with IS pretreatment, $p < 0.001$), and this effect was confirmed using the MTT assay.

Conclusions: IS induces modest cytotoxicity to PTECs and increases their susceptibility to gentamicin cytotoxicity. These effects are associated with downregulation of mitochondrial gene translation that could reflect broad perturbations in mitochondrial dynamics and impaired cellular respiration.

TH-PO103

Comparative Effects of Cyclosporine and Voclosporin on Primary Human Proximal Tubular Epithelial Cell (PTEC) Gene Expression

Theresa Aliwarga,[1] Linda M. Rehaume,[3] Catherine K. Yeung,[1,2] Jonathan Himmelfarb,[1,2] Edward J. Kelly.[1,2] *[1]University of Washington, Seattle, WA; [2]Kidney Research Institute, Seattle, WA; [3]Aurinia Pharmaceuticals Inc, Edmonton, AB, Canada.*

Background: The development of calcineurin inhibitors (CNIs) dramatically changed the face of transplantation, with the majority of solid organ transplant patients prescribed CNI-based therapeutics. Cyclosporine, a CNI that complexes with cyclophilin to competitively inhibit calcineurin phosphatase activity, has significant side effects with chronic nephrotoxicity the primary clinical concern. Cyclosporine related toxic effects include glomerulosclerosis, thrombotic microangiopathy and tubular vacuolization. Voclosporin, a recently approved CNI for treating adults with active lupus nephritis on a background of immunosuppression, is structurally similar to cyclosporine, with improved binding to calcineurin, higher potency and better tolerability.

Methods: To compare the tubular effects of these two CNIs, we exposed cultures of primary human PTEC in either standard 2D tissue culture or when grown in a 3D kidney microphysiological system (MPS).

Results: Exposure to increasing concentrations (0-10 μM) of cyclosporine or voclosporin [HJ1] revealed only minimal toxicity after 48 hr. in 2D culture. Similarly, exposure of MPS to 10 μM voclosporin or cyclosporine for 48 hr. did not significantly increase KIM-1, a urinary biomarker of acute kidney injury, in MPS effluents. To further differentiate these two CNIs, we performed bulk RNAseq analysis from the MPS studies and observed 443 differentially-expressed genes in the cyclosporine-treated MPS versus 45 genes in the voclosporin cohort. Biological process gene ontology analysis revealed 26 significant pathways in the cyclosporine group and none in the voclosporin group with the majority related to cell cycle processes. PTEC were labeled with a GFP-cytochrome C biosensor to monitor mitochondrial responses. Treatment with either CNI at 1 μM for 48 hr. revealed no changes whereas treatment with 10 μM of either CNI resulted in modest changes in mitochondria as measured by signal intensity and complexity of the network.

Conclusions: Ongoing studies include longer term CNI exposures and effects of CYP3A5 genotype as this enzyme is polymorphic, expressed in the kidney and produces isozyme-specific metabolites of cyclosporine. Our results to date support differential effects of voclosporin versus cyclosporine on PTEC gene expression.

TH-PO104

Role of KIM-1 and TBX1 in AKI to CKD Transition

Elena Tutunea-Fatan,[1] Shabitha Arumugarajah,[2] Lakshman Gunaratnam.[2,1] *[1]Lawson Health Research Institute, London, ON, Canada; [2]Western University Schulich School of Medicine & Dentistry, London, ON, Canada.*

Background: Acute kidney injury (AKI) affects 20% of hospitalized patients. The most common cause is renal ischemia-reperfusion injury (IRI). Patients who survive mild-to-moderate AKI often have complete renal recovery, but severe AKI can progress to the development of chronic kidney disease (CKD). Kidney Injury Molecule-1 (KIM-1) is a transmembrane receptor expressed by proximal tubular epithelial cells (PTECs) during injury. Notwithstanding that, severe AKI leads to persistent KIM-1 expression and drives renal fibrosis. Using microarray analysis, we identified T Box-1/TBX1 as a potential KIM-1 regulated gene that may mediate its maladaptive effects during severe AKI.

Methods: KIM-$1^{+/+}$ and KIM-$1^{-/-}$ C57BL/6 mice were subjected to sevre unilateral ischemia reperfusion injury (UIRI) by clamping the renal artery for 55 minutes. Kidneys were isolated after 7 and 42 days of reperfusion to assess histology and, markers of injury and fibrosis. RNA sequencing of kidneys from the KIM-$1^{+/+}$ and KIM-$1^{-/-}$ mice after 55 min UIRI was performed. In order to assess the fibrogenic potential of TBX1 *in vivo*, Tamoxifen-inducible PTEC-specific TBX1 knockout ($TBX1^{pKO}$) mice were generated. *In vitro* model for gain of TBX1 function was created by using primary PTECs isolated from murine cortical kidney subjected to biochemical and functional assays.

Results: Compared to the ipsilateral kidneys from KIM-$1^{-/-}$ mice, the kidneys from KIM-$1^{+/+}$ mice were markedly shrunken and fibrotic at 42 days after UIRI. We also observed a significant upregulation of mRNA encoding a panel of pro-inflammatory cytokines and growth factors at both 7 and 42 days after UIRI in KIM-$1^{+/+}$ kidney compared to KIM-$1^{-/-}$ kidneys. Primary PTECs isolated only from KIM-$1^{+/+}$ kidneys significantly increased the chemotaxis of Raw macrophages whereas KIM-$1^{+/+}$ PTECs became arrested at the G2/M phase of the cell cycle, and adopted a senescent phenotype. Conditional silencing of KIM-1 was associated with a significant reduction in TBX1 expression at both mRNA and protein levels. TBX1 expression profile positively correlated with fibrosis in KIM-$1^{+/+}$ mice exposed to severe IRI. TBX1 enhanced PTEC migration, acquisition of a senescence phenotype, production of extracellular matrix and profibrotic factors.

Conclusions: Our results suggest that sustained KIM-1 expression following severe AKI may drive murine kidney fibrosis due to activation of TBX1.

Mass Spectrometry Imaging Reveals Metabolic Switch to Glycolysis in Proximal Tubules During AKI

Guanshi Zhang,[1] Ian M. Tamayo,[1] Li Liu,[1] Dusan Velickovic,[2] Brittney L. Gorman,[2] Christopher R. Anderton,[2] Theodore Alexandrov,[3,4] Manjeri A. Venkatachalam,[1] William B. Reeves,[1] Kumar Sharma.[1] For the KPMP Consortium. *[1]The University of Texas Health Science Center at San Antonio, San Antonio, TX; [2]Pacific Northwest National Laboratory, Richland, WA; [3]European Molecular Biology Laboratory, Heidelberg, Germany; [4]BioInnovation Institute, Copenhagen, Denmark.*

Background: Aberrant glucose metabolism has been reported in the pathogenesis of acute kidney injury (AKI). *In vitro* studies of proximal tubular cells showed damaged cells that were unable to fully recover underwent a metabolic switch to glycolysis during the AKI to CKD transition. Additionally, *In vivo* data of AKI murine models also demonstrated upregulated expression of rate-limiting enzymes of glycolysis in mice with AKI. However, changes in energy metabolism under AKI in human patients remain an enigma. We performed a comprehensive analysis of metabolites in proximal tubules of kidney biopsies from AKI patients vs healthy reference tissues (HRT).

Methods: A matrix-assisted laser desorption/ionization (MALDI)-mass spectrometry imaging (MSI) platform was employed to characterize the metabolic profile in kidney biopsies from AKI patients (n = 6) and HRT (n = 6) *in situ* (spatial resolution: 20 μm). SCiLS Lab was used for raw data processing. METASPACE was applied for metabolite annotations at 20% FDR. Univariate (*t*-test) and multivariate (e.g., PCA and PLS-DA) analyses were performed to compare metabolic profiles in kidney biopsies between AKI and HRT.

Results: In total, 1797 *m/z*'s were annotated as different metabolite species in human kidney biopsies. Specifically, seven metabolites from the tricarboxylic acid cycle and 10 intermediates from glycolysis were measured. Multivariate analyses showed clearly separated clusters between AKI and HRT biopsies, suggesting aberrant metabolic changes in AKI kidneys. Univariate analysis revealed that 361 metabolites were significantly different in proximal tubules of AKI compared to HRT. Particularly, several glycolytic intermediates including lactic acid ($P = 0.0251$), 2-phosphoglycerate ($P=0.0152$), and fructose-6-phosphate ($P=0.0013$) were found to accumulate in proximal tubules of AKI renal biopsies, suggesting the potential role of metabolic switch to glycolysis in the kidney with AKI.

Conclusions: These findings demonstrate an accumulation of glycolytic intermediates in proximal tubules of AKI kidney biopsies which may play an important role in the pathogenesis of AKI. Our human kidney biopsy data reveal a potential metabolic switch to glycolysis in damaged proximal tubular cells during the AKI to CKD transition.

Mouse Model of Local Iron Homeostasis Disruption in AKI

Abdul A. Soofi, Vivie Li, Jeffrey A. Beamish, Greg R. Dressler. *University of Michigan Michigan Medicine, Ann Arbor, MI.*

Background: Iron plays an essential role in many critical biological processes including oxygen transport, cell proliferation, and regeneration. However, when iron is present in excess, it is toxic to the kidneys. Acute kidney injury (AKI) and iron-related disorders are associated with significant morbidity and mortality. Dysregulation of iron homeostasis plays an important pathogenic role in kidney disease, but limited data are available on successful iron targeting therapies in AKI. Ferroportin (FPN) is expressed in the kidney and is known as the iron exporter and central regulator of iron metabolism, but its function in the pathogenesis of AKI still unclear. Through this work, we will determine whether the disruption of local iron homeostasis by selective depletion of FPN in renal proximal tubules cells (PTCs) alters the response to AKI.

Methods: We are testing this hypothesis by generating conditional knockout mice to target iron trafficking proteins and determine their roles in AKI and the molecular and genetic mechanisms regenerating of PTCs. We selectively expressed Cre in PTCs with a Pepck promoter (PepcK-Cre) and confirmed deletion with a red-green reporter (mT/mG) to produce FPNf/f; Pepck-cre; mT/mG (FPN-KO) mice.

Results: FPN-KO mice were generated and deletion of FPN was confirmed. Mutant mice showed no gross morphology or renal phenotype. FPN-OK and controls mice were subjected to either folic acid or renal ischemia-reperfusion models. Blood and tissue

samples were collected at 0, 2, 7, and 28 days after injury. Kidney function and iron deposition were measured. Histology, immunohistochemistry, RNA isolation, and immunoblot analysis and qualification were performed. Data indicate that FPN-KO mice subjected to AKI models developed pronounced iron deposition in PTCs. Damaged tubules lead to worsening interstitial fibrosis, ferroptosis, and failure to recover and regenerate injured tubules compared to controls.

Conclusions: Despite the essential role in life, excessive iron is toxic due to its ability to generate reactive oxygen species. Disrupting iron trafficking in PTCs by manipulating the expression of FPN increases AKI severity and impairs recovery. Understanding the molecular mechanisms underlying the regulation of local iron homeostasis and ferroptosis may provide therapeutic strategies for progressive kidney disease and ferroptosis-associated disorders.

Proximal Tubular-Specific Cell Cycle Arrest Ameliorates AKI in Mice

Vera C. Wulfmeyer,[1] Inga Soerensen-Zender,[1] Vanessa Voß,[1] Song Rong,[1] Arnaud Marlier,[2] Kai M. Schmidt-Ott,[1] Anette Melk,[1] Roland Schmitt.[1] Roland Schmitt Lab. *[1]Medizinische Hochschule Hannover, Hannover, Germany; [2]Altos Labs Inc, Redwood City, CA.*

Background: Acute kidney injury (AKI) is a major medical and economic burden. Renal tubular epithelial cells are normally arrested in the G0 phase of the cell cycle (CC), but are rapidly entering the CC after AKI. Recent studies indicate that regulated CC is required for optimal regeneration following AKI. Cyclin D1 (Ccnd1) is essential for CC progression from G1- to S-phase. We characterized a proximal tubular (PT)-specific Ccnd1 knock-out (KO) and a siRNA-based Ccnd1 knock-down (KD) in a murine ischemia-reperfusion (IRI) model.

Methods: Tamoxifen (tam)-inducible proximal tubular Ccnd1 KO mice (Ccnd1flox/flox::Slc34a1CreERT2) underwent IRI surgery following vehicle (veh) or tam treatment. Serum creatinine/urea, histology, leukocyte infiltration, cell cycle phases, and fibrosis were assessed (2h, 1d, 3d, 7d, 14d, 28d after IRI; n=8 per group). A Ccnd1-siRNA KD was established in vitro (primary tubular epithelial cells) and in vivo (1nmol siRNA/g mouse; 24h before and at reperfusion) and evaluated by the abovementioned parameters on day 14 after IRI. To evaluate the underlying mechanism, RNAseq analysis of isolated PT (n=3) and MALDI-TOF-MSI of kidneys 1d after IRI (n=5) were performed.

Results: PT-specific Ccnd1 KO attenuated the functional decline of AKI (S-crea 312±74% vs. 142±11% (3d relative to 0d); p=0.036). KD mice showed a comparable outcome. At day 1 and 3 after IRI, KO kidneys had reduced histological damage (AKI score maximal 4; 1d: 2.26±0.13 vs. 1.84±0.11; p=0.028; 3d: 2.68±0.12 vs. 2.06±0.16; p=0.009). KO kidneys showed a 15-fold reduction in leukocyte infiltration (3d: 12.8±0.75% leukocytes/all cells vs. 0.81±0.14%; p<0.0001). At later time points after IRI (28d), KO mice showed no damage/regeneration benefit (histology and brush border staining). RNAseq analysis revealed a decreased expression of CC-associated genes in KO proximal tubules. Moreover, depletion of adenosine monophosphate was strongest in the cortex of WT kidneys.

Conclusions: Specific ablation of Ccnd1 in the proximal tubule or systemic antagonism of Ccnd1 reduced proliferation in the kidney after IRI. This was associated with reduced AKI injury at early time points after IRI in KO and KD models. Our data suggest a cell cycle-associated, energy-dependent mechanism of protection.

Autophagy Inhibition Aggravates Renal Microvascular Injury Secondary to Ischemia-Reperfusion

Hyunyun Kim,[1,2] Francis Migneault,[2] Shanshan Lan,[2] Imane Kaci,[1,2] Julie Turgeon,[2] Annie Karakeussian Rimbaud,[2] Shijie Qi,[1,2] Natalie Patey,[1,4] Mélanie Dieudé,[1,3] Marie-Josee Hebert.[1,3] *[1]Universite de Montreal, Montreal, QC, Canada; [2]Centre de Recherche du Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [3]Centre Hospitalier de l'Universite de Montreal, Montreal, QC, Canada; [4]Centre Hospitalier Universitaire Sainte-Justine, Montreal, QC, Canada.*

Background: Ischemia-reperfusion injury (IRI) is an integral component of kidney transplantation. Programmed cell death (PCD) of endothelial cells (EC) in peritubular capillaries (PTCs) post-IRI is a major predictor of long-term loss of renal function. We have shown that caspase-3-deficient mice show reduced PTC apoptosis post-IRI and preserved long-term renal function. Autophagy is a cellular stress response that protects against PCD. However, the precise role of PTC autophagy post-IRI remains unclear. Here, we characterize the dynamics of PCD activation and the effect of autophagy inhibition on the renal microvasculature post-IRI.

Methods: Transgenic GFP-LC3 mice were subjected to unilateral renal artery clamping for 30 minutes with contralateral nephrectomy. Mice were injected intraperitoneally with PBS or chloroquine (CHQ), an autophagy inhibitor, on the day of surgery and every day post-surgery until sacrifice. Mice were sacrificed 1, 2, 7, or 21 days post-IRI. Kidney function was assessed by measuring serum creatinine levels. Activation of Caspase-3-dependent apoptosis and necroptosis (pRIPK3) were measured by immunohistochemistry (IHC). Autophagy activation was evaluated by confocal immunofluorescence microscopy for GFP-LC3 puncta. PTC rarefaction, myofibroblast accumulation, and collagen deposition were assessed.

Results: IRI induced a specific pattern of apoptosis, necroptosis, and autophagy in PTCs. PTCs showed sustained apoptosis from day 1 to day 21 post-IRI, whereas necroptosis showed an early increase at days 1 and 2 with a rapid return to basal level at day 7. GFP-LC3+ autophagy puncta increased steadily until day 21 in PTCs. CHQ inhibited autophagic flux in PTC and worsened renal function with higher serum creatinine levels post-IRI 1 day. In the long term (21 days), microvascular rarefaction was significantly increased in the CHQ-injected group compared to the vehicle-treated group. This was associated with increased renal fibrosis, increased α-SMA, and collagen deposition within the PTC.

Conclusions: The results indicate that IRI induces progressive autophagy activation in PTC EC. Inhibition of autophagy aggravates renal dysfunction and increases microvascular injury, myofibroblast differentiation, and collagen deposition post-IRI.

Effect of Peroxidase Reductase 5 and Ferroptosis in Contrast-Induced AKI (CI-AKI)

Fangfang Zhou, Lailiang Wang, Youjun Xu, Sheng Qilin, Shuzhen Zhang, Xingyue Zheng, Qun Luo. *Ningbo NO.2 Hospital, Ningbo, China.*

Background: Our previous study found the expression of urinary peroxidase reductase 5 (PRDX5) decreased significantly in CI-AKI patients by proteomics,and ferroptosis was involved in CI-AKI. The aim was to identify PRDX5 involved in the mechanism of ferroptosis in CI-AKI.

Methods: Human renal tubule epithelial cells (HK-2) were cultured and divided into control group, CI-AKI group (HK-2 cells were added 200 mg I/ml iodohexol for 12h), CI-AKI+ FeI group (HK-2 cells were added 200 mg I/ml iodohexol and ferroptosis inhibitor, 10μmol/L for 12h), PRDX5 overexpression group (PRDX5 overexpression plasmid was constructed), PRDX5 overexpression +CI-AKI group (PRDX5 overexpression HK-2 cells were added 200 mg I/ml iodohexol for 12h). The cell activity was determined by MTT assay. The expressions of ferroptosis related protein GPX4, SLC7A11 and ACSL4 were detected by western blot. Iron Assay Kit was used to measure intracellular iron. Mitochondrial ROS levels were detected by DCFDA/H2DCFDA fluorescent probe.

Results: Compared with control group, the cell proliferation rate of CI-AKI group slowed down significantly, while that of CI-AKI+ FeI group was increased, compared with CI-AKI group, (P<0.05). In terms of ferroptosis mechanism, compared with control group, the protein content of ACSL4, GPX4 and SLC7A11 in HK-2 cells in CI-AKI group was significantly increased (p<0.05), the protein contents of GPx4 and SLC7A11 were significantly decreased (p<0.05), the iron content was significantly increased (p<0.05), and the mitochondrial ROS level was significantly increased (p<0.05). After adding ferroptosis inhibitor, the above indexes were relieved (p<0.05). The expression of PRDX5 mRNA and protein in CI-AKI group was significantly decreased compared with control group (p<0.05), and that in PRDX5 overexpression group was significantly increased (p<0.05). Compared with CI-AKI group, PRDX5 overexpression+CI-AKI group increased cell proliferation rate (P<0.05). Compared with CI-AKI group, the expression of ferroptosis related protein ACSL4, GPX4 and SLC7A11 were significantly decreased (p<0.05), iron content was significantly decreased (p<0.05), and mitochondrial ROS level was significantly decreased (p<0.05) after overexpression of PRDX5.

Conclusions: Ferroptosis is involved in CI-AKI. PRDX5 has a protective effect on the mechanism of ferroptosis in CI-AKI.

SIRT2 Regulates Cisplatin-Induced Endoplasmic Reticulum Stress Through Heat Shock Factor 1 Deacetylation

Woong Park,[1] Yujin Jung,[1] Hyeongwan Kim,[1,2] Jihyun Yeom,[2] Soo jin Lee,[2] Yujin Shin,[2] Won Kim.[1,2] *[1]Jeonbuk National University Medical School, Jeonju, Jeollabuk-do, Republic of Korea; [2]Jeonbuk National University Hospital, Jeonju, Jeollabuk-do, Republic of Korea.*

Background: Nephrotoxicity is an important cisplatin-induced adverse reaction and restricts the use of cisplatin to treat malignant tumors. Endoplasmic reticulum (ER) stress is caused by the accumulation of misfolded proteins, and can be induced by cisplatin in the kidney. SIRT2, a nicotinamide adenine dinucleotide (NAD^+)-dependent deacetylase, is a member of the sirtuin family. In this study, we evaluated role of SIRT2 in cisplatin-induced ER stress.

Methods: To investigate the effect of SIRT2 on cisplatin-induced ER stress, we used SIRT2 knockout mice and human proximal tubular epithelial cells (HK-2 cells). We treated HK-2 cells with cisplatin (20 μg/mL) and administered cisplatin (20 mg/kg, i.p.) to mice to induce acute kidney injury. We evaluated the changes of ER stress and its signal mechanism.

Results: *In vivo* experiment, cisplatin administration was found to significantly increase the expressions of PRKR-like ER kinase (PERK), phosphorylation of eukaryotic translation initiation factor 2α (eIF2α), and the C/EBP homologous protein (CHOP) and caspase-12 in the kidneys of SIRT2-wild type mice. However, cisplatin-induced increases in the expressions of p-PERK, p-eIF2α, CHOP and, caspase-12 were diminished in kidneys of SIRT2 knockout mice. *In vitro*, cisplatin significantly increased the expressions of p-PERK, p-eIF2α, CHOP, and caspase-12 in HK-2 cells. When the effect of SIRT2 on cisplatin-induced ER stress was evaluated using SIRT2-siRNA (ON-TARGET plus human SIRT2 siRNA) or the SIRT2 inhibitors, AGK2 and AK1, knockdown or inhibition of SIRT2 significantly attenuated the cisplatin-induced protein expression of p-PERK, p-eIF2α, CHOP, and caspase-12. Immunoprecipitation studies showed SIRT2 bound physically to heat shock factor (HSF)1 and that HSF1 acetylation was significantly increased by cisplatin. In addition, knockdown of SIRT2 increased cisplatin-induced HSF1 acetylation and increased the expression of heat shock protein (HSP)70.

Conclusions: These observations suggest that suppression of SIRT2 ameliorates cisplatin-induced ER stress by increasing HSF1 acetylation and HSP expression.

Kinetics of the De Novo NAD/NADH Pathway from AKI to CKD

Justine Serre,[1,2] Alexandre Bras,[1] Pierre Galichon,[1,3] Juliette Hadchouel.[1] CoRaKiD UMRS_1155. *[1]INSERM UMRS 1155, Paris, France; [2]Hopital Tenon, Paris, France; [3]Sorbonne Universite, Paris, France.*

Background: Energy metabolism deficiency is part of the acute kidney injury (AKI) pathophysiology. Recent studies highlighted the role of nicotinamide adenine dinucleotide (NAD) production in the pathogenesis of AKI. NAD is an electron carrier for mitochondria and a cofactor for cytoplasmic redox reactions. Its production is decreased during AKI following a decrease of the expression of PGC1α (Peroxisome proliferator activated receptor gamma co-activator-1-α) and an alteration of its *de novo* synthesis pathway: with a reduction in the expression of the Quinolinate PhosphoRibosylTransferase (QPRT). The modulation of this *de novo* pathway has been studied mainly in the acute phase immediately after AKI. However, its correlation with the severity of the ischemic insult and its evolution during the transition from AKI to CKD have not been described yet.

Methods: Renal ischemia-reperfusion was performed in C57Bl6/J male mice after nephrectomy of the contralateral kidney. For the 'severity' study, a 5-30 minutes ischemia was performed. Renal function was assessed 24h after ischemia. For the 'AKI to CKD' study, renal ischemia was performed during 10 minutes. Mice were sacrificed 1, 2, 3, 6 and 28 days after ischemia. PGC1α and QPRT mRNA expression was measured by RT-qPCR.

Results: We induced AKI in mice by unilateral ischemia reperfusion injury of increasing time to induce several degrees of AKI severity. PGC1α and QPRT mRNA expression decreased progressively with ischemia severity until reaching a plateau at 15 minutes of ischemia for PGC1α, like plasma creatinine and urea, whereas QPRT decrease is linear until 30 min of ischemia. PGC1α mRNA decrease is also inversely correlated to kidney dysfunction ($p<0.001$). A 10-minute ischemia led to the development of Chronic Kidney Disease (CKD), as evidenced by an incomplete recovery of the kidney function at 28 days. QPRT and PGC1α mRNA expression showed a progressive but incomplete recovery during the transition from AKI to CKD compared to sham mice.

Conclusions: In addition to confirming the decrease of PGCα and QPRT mRNA expression during AKI, we show that it is correlated to the severity of the ischemic AKI. Furthermore, we describe the recovery during renal repair and transition to CKD.

Funding: Government Support - Non-U.S.

TH-PO112

Targeting Oxidative Stress to Prevent Cardiorenal Syndrome in Right Ventricular Failure

Firoozeh Farahmand. *Saint Louis University, Saint Louis, MO.*

Background: Renal dysfunction remains an independent risk predictor of death and hospitalization in right ventricular failure (RVF) and RV function plays a pivotal role in preventing CRS. However, the pathophysiology of RV failure induced CRS remains poorly understood. The heart and the kidney have complex bidirectional interlinks and there is a growing body of evidence that oxidative stress is a major bidirecional crosstalk mediator of the Heart-kdiney in left ventricualr dusfunction. Clinically driven experimental modeling is crucial to investigate pathophysiology based therapy.

Methods: This study on RVF- Induced CRS investigated changes in antioxidants and oxidative stress in compensated CRS and if antioxidant prevents the pathophysiological heart-kidney cross talk. RVF-Induced CRS in rats was produced by alkaloid (ALK) injection. Rats were treated with antioxidant-LOS, 1 wk. pre & post-ALK injection. At 1 and 2 weeks post-ALK injection, echocardiography was performed to monitor cardiac function. RV systolic pressure (RVSP), RV hypertrophy (RVH), RV function, kidney and RV levels of superoxide dismutase (SOD), catalase, glutathione peroxidase (GSHPx) and lipid peroxidation (LPX). were measured. After sacrificing animals, hearts and kidneys were removed for histopathology and wet /dry weight ratios measurement.

Results: At 1 week, ALK-induced CRS resulted in RVSP, RV hypertrophy and LPX in RV myocardium as well as the kidney. There was a mild increase in antioxidant enzymes activities including SOD and GSHPx in RV and the kidney with no histopathological finding of kidney injury. At 2 weeks post-ALK injection there was RV failure and a significant increase in oxidative stress and antioxidant enzymes in RV and the kidney. Kidney histopathology with Periodic acid-Schiff (PAS) staining demonstrated ATN. Antioxidant-LOS treatment prevents ALK-induced CRS and decreased oxidative in the RV myocardium and the kidney. no change in RV and kidney wet/dry weight ratio between CRS and control animals were obsreved that suggest there was no renal or RV congestion at 2 weeks post ALK-indced CRS.

Conclusions: Since RVF-induced CRS was associated with oxidative stress and antioxidant was able to inhibit these pathophysiological heart-kindey cross talk it is proposed that antixodant modulates cardiac remodelling and ATN in CRS. Therefore, targetting of oxidative stress as an adjunt therapy is suggested.

TH-PO113

Renal Mitochondria Exhibit Cell Type-Specific Heterogeneity and Are Functionally Dynamic

Kyle C. Feola,[1] Andrea H. Venable,[1] Lauren Elizabeth Lee,[1,2] Sarah C. Huen.[1] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]University of Pennsylvania, Philadelphia, PA.*

Background: Mitochondrial dysfunction is a key component of both acute and chronic kidney disease. Across tissues, mitochondria differ in composition and substrate utilization. As the kidney contains many different cell types, we hypothesize that there is intra-renal mitochondrial heterogeneity contributing to cell-specific mitochondrial function. To interrogate this, we utilized a novel mitochondrial tagging technique to isolate mitochondria in a cell-type specific manner. Here, we investigate the proteomes, metabolomes, and mitochondrial functional capacities of the early and late proximal tubule (PT) and distal convoluted tubule (DCT).

Methods: We generated three lines of mutant mice: early PT (*Slc34a1-CreERT2;MITO-Tag*); late PT (*Ggt1-Cre;MITO-Tag*); and DCT (*PvAlb-Cre;MITO-Tag*), capable of cell-specific isolation of hemagglutinin (HA)-tagged mitochondria. Mice were either fed ad libitum or fasted for 24 hours before kidneys were harvested. Cell-specific mitochondria were isolated using anti-HA magnetic beads and processed for proteomics, metabolomics, or functional analyses. Mitochondrial fatty acid oxidation (FAO) functional capacity was assessed using palmitoyl-CoA/carnitine (CPT1-dependent) or palmitoylcarnitine (CPT1-independent) as substrates and measured by Seahorse (Agilent).

Results: Using these MITO-Tag models, we demonstrated the ability to isolate renal mitochondria in a cell-specific manner. We observed differential mitochondrial protein and metabolite profiles of these cell types at both baseline and in fasting conditions. Pathway analysis revealed FAO as a key differentially regulated process, including CPT1A and CPT1B. CPT1A expression significantly increased with fasting in the late PT, and CPT1B expression was significantly higher in the DCT as compared to the PT cell types. Compared to the fed state, CPT1-dependent mitochondrial FAO capacity significantly increased in both the late PT and DCT in the fasted state. Surprisingly, when mitochondrial FAO capacity was assayed independent of CPT1, DCT mitochondria had significantly lower FAO capacity compared to late PT mitochondria in both baseline and fasting conditions.

Conclusions: We demonstrated the successful use of a system to study cell type-specific mitochondria in the mouse kidney. Our data suggest that FAO is differentially regulated in the renal PT and DCT.

Renal Tubular CD24 Upregulation Aggravates Folic Acid-Induced AKI Through Inhibition of T-Regulatory Cells in Mice

Doron Schwartz,[1,2] Moshe Shashar,[3,4] Idit F. Schwartz.[1,2] *[1]Tel Aviv University, Tel Aviv, Israel; [2]Tel Aviv Medical Center, Tel Aviv, Israel; [3]Laniado Medical Center, Natania, Israel; [4]Boston University School of Medicine, Boston, MA.*

Background: Acute kidney injury (AKI) is characterized by cell death and inflammation. CD24 is a protein which is induced during tissue damage and is not expressed in matured renal tissue. We explored the role of CD24 in the pathogenesis of folic acid induced AKI (FA-AKI) in mice.

Methods: A single i.p. injection of folic acid induced AKI in WT and $CD24^{-/-}$ mice. Renal function tests, histological analysis, immunohistochemistry, Western blot analysis, and ELISA were performed to assess the severity of renal damage and the intensity of the inflammatory response.

Results: FA-AKI induced CD24 in the distal tubular epithelial cells. Compared to WT mice, FA-AKI $CD24^{-/-}$ mice exhibited an attenuated reduction in renal function and histological injury, lower serum IL-10 and interferon γ, and decreased expression of renal TNFα. In contrast, renal and systemic IL-33 upregulation were augmented. $CD24^{-/-}$ FA-AKI animals exhibited increased splenic margination and renal infiltration of regulatory T cells (Tregs). At day 7, FA-AKI $CD24^{-/-}$ mice exhibited increased expression of tubular pro-apoptotic and decreased anti-apoptotic proteins compared to WT animals. Anti CD24 antibody administration to FA-AKI mice attenuated the decrease in renal function and attenuated histological injury. Renal biopsies from patients with ATN stained strongly for CD24 in the distal tubules.

Conclusions: During AKI, upregulation of CD24 promotes renal inflammation through inhibition of Tregs infiltration and diversion of cell death towards necrosis rather than apoptosis. Neutralization of CD24 may prove as a target for future therapies in AKI.

TH-PO115

Stress-Inducible p53 Isoform in the Kidney

Shin-ichi Makino, Amy Zollman, Pierre C. Dagher, Takashi Hato. *Indiana University School of Medicine, Indianapolis, IN.*

Background: The need for understanding p53 biology and controlling p53 expression in the setting of AKI is compelling. Beyond its role as a tumor suppressor, p53 acts as a crucial stress-response gene involved in a variety of pathophysiological conditions. The basic functions of p53 include cell cycle arrest, apoptosis, and DNA repair. p53 has many other nuanced properties and the role of p53 under various circumstances remains elusive. Here, using a murine model of endotoxemia, we report a distinct p53 isoform that emerges during the recovery phase of AKI.

Methods: C57BL/6 male mice were injected with endotoxin 4 mg/kg and kidney tissues were harvested at various time points. Full-length cDNA sequencing was done

using the direct cDNA Nanopore protocol on MinION Flow Cells (total n = 40). DEXseq was used to identify differentially expressed isoforms across the time course. Based on the mouse data, we generated two p53 mutant human cell lines in which 1) cryptic exon splicing signals were abolished by sequentially applying the CRISPR knock-in strategy, or 2) the entire cryptic exon was excised by using the dual-sgRNA strategy.

Results: We found that RNA isoform switching is prevalent during the recovery phase of endotoxemia in the kidney. The isoform switching was observed in a distinct set of stress-responsive genes including p53. The alternative p53 isoform involves a cryptic exon that is repressed under basal condition and appears exclusively in the late phases of endotoxemia. To investigate the role of the alternative p53 isoform, we generated human cell lines that cannot express the alternative isoform. We found that these mutant cell lines (lacking the cryptic exon or its splicing signals) exhibit increased expression of the canonical p53 transcript as well as its downstream target genes such as p21. As a result, the proliferation rate decreased in these mutant cell lines.

Conclusions: The alternative p53 isoform encodes no protein and emerges during the recovery phase of endotoxemia at the expense of canonical p53 expression. Such reciprocal isoform switching could serve as an endogenous downregulation mechanism for canonical p53, enabling cells to exit cell cycle arrest and promote tissue recovery. We envision that controlling the balance between canonical p53 and its non-coding isoform could provide a route for rescuing cells from a maladaptive state or extending a beneficial adaptive state.

Prioritizing Pathways Shared Between Humans and Mice in AKI-to-CKD Transition

Kathrien Abdank,[1] Sena Z. Cetin,[1] Amin Abedini,[3] Katalin Susztak,[3] Kai-Uwe Eckardt,[1] Michael S. Balzer.[1,2] *[1]Charite Universitatsmedizin Berlin, Berlin, Germany; [2]Berlin Institute of Health at Charite, Berlin, Germany; [3]University of Pennsylvania, Philadelphia, PA.*

Background: Gaps in our understanding of the transition from acute kidney injury (AKI) to chronic kidney disease (CKD) remain a major unmet medical need due to lack of effective therapeutics for CKD in >850 million people worldwide. Pathways with important roles in AKI-to-CKD transition have not been prioritized on a cross-species level, potentially impairing the development of new target approaches and drugs for human kidney disease.

Methods: Here, we analyzed recent single-cell datasets from humans with AKI and CKD as well as several mouse models along the AKI-to-CKD spectrum. Using 3 human and 3 mouse datasets generated by different research groups, we performed differential gene expression analysis between disease and physiological conditions. Differentially expressed genes (DEGs) were mapped to orthologous human genes, if necessary, and fed into pathway enrichment analysis, allowing for a standardized, unified comparison of datasets and disease conditions on the pathway level. Finally, we validated our results on 2 separate human and mouse proximal tubule trajectory datasets.

Results: Despite an unexpectedly low overlap among top DEGs of clinically similar models/conditions along the AKI-to-CKD axis (suggesting high disease state specificity), biological processes and pathways along this continuum were well-conserved: processes already enriched during mild AKI, such as hypoxia, TNFα/NFκB signaling, immune processes, epithelial-to-mesenchymal transition, and IL18 signaling, were sustained and increasingly enriched as AKI severity increased and AKI transitioned to CKD. Conversely, cell matrix and adhesion pathways were enriched specifically in milder AKI, whereas solute carrier-mediated ion transport predominated in successfully repaired and healthy control states. Our studies inform on commonalities of human and murine renal pathophysiology after AKI. Nonetheless, our analysis called out inconsistencies and considerable inter-dataset variability, which is important when considering future research prioritizing potential drug targets for people with AKI.

Conclusions: Our studies inform on the consensus of human and murine renal pathophysiology after AKI, call out inconsistencies between single-cell datasets, and are meant to serve as a primer to prioritize efforts for future research in the AKI-to-CKD community.

Acrolein Promotes Tubular Cell Death in Ischemia Reperfusion-Induced AKI

Seishi Aihara, Yutaro Hirashima, Kumiko Torisu, Takanari Kitazono, Toshiaki Nakano. *Department of Medicine and Clinical Science, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan.*

Background: We previously showed that ischemia–reperfusion injury in the kidney was attenuated in arginase 2 knockout (KO) mice or arginase inhibitor-treated mice. Arginase 2 is an enzyme involved in arginine metabolism and one of its metabolites is polyamine. Polyamines, essential for cell growth and proliferation, are known to inhibit cardiovascular disease. However, under conditions of cellular damage, toxic acrolein is produced from polyamines by the enzyme spermine oxidase (SMOX).

Methods: We used a mouse renal ischemia-reperfusion model to investigate changes in the amount and localization of acrolein due to injury. We also used human proximal tubule cells (HK-2) to study whether acrolein induces renal tubular cell death. To inhibit acrolein-induced cell death, an acrolein scavenger cysteamine, or spermine oxidase (SMOX) siRNA was added to HK-2 cells. Acrolein was detected with acrolein antibody in the kidney. In HK-2 cells, acrolein was visualized with acroleinRED. To expose cells to hypoxia-reoxygenation, HK-2 cells were cultured under 1% oxygen for 24 hours, then switched to 21% oxygen for 24 hours. Mitochondrial membrane potential was determined by MitoTrackerCMXRos. Cell viability was measured by WST-8.

Results: Acrolein was accumulated in ischemia-reperfusion kidneys, particularly in tubular cells. When HK-2 cells were hypoxia-reoxygenated, acrolein accumulated and SMOX mRNA and protein levels were increased. Acrolein induced cell death and fibrosis-related TGFβ1 mRNA in HK-2 cells. Administration of cysteamine suppressed the acrolein-induced upregulation of TGFβ1 mRNA. Cysteamine also inhibited a decrease in the mitochondrial membrane potential, and cell death induced by hypoxia-reoxygenation. The siRNA-mediated knockdown of SMOX also suppressed hypoxia reoxygenation-induced acrolein accumulation and cell death.

Conclusions: Acrolein promotes tubular cell death. Accumulated acrolein in the kidney during ischemia-reperfusion injury suggested that acrolein may be directly involved in tubular cell death. Treatment to control the accumulation of acrolein might be an effective therapeutic option for renal ischemia-reperfusion injury.

Polyploid Tubular Cells Promote Tubulointerstitial Fibrosis After AKI via TGF-β1 Activation

Letizia De Chiara,[1] Elena Lazzeri,[1] Paola Romagnani.[1,2] *[1]Universita degli Studi di Firenze, Firenze, Italy; [2]Azienda Ospedaliero Universitaria Meyer, Firenze, Italy.*

Background: We recently showed that tubular cell (TC) polyploidy is triggered by Acute Kidney Injury (AKI). Polyploid TC are required to promote survival in the early phase after AKI, but promote fibrosis and chronic kidney disease (CKD) progression in the long term. However, the molecular mechanism governing the link between polyploid TC and kidney fibrosis remains to be clarified.

Methods: We employed transgenic mouse models based on the FUCCI2aR reporter and *in vivo* single cell RNA-sequencing (scRNA-seq) to identify polyploid TC. *In vitro* scRNA-seq followed by sorting of polyploid TC was employed to characterize the expression profile of pro-fibrotic polyploid TC.

Results: Immediately after AKI, the expression of cell cycle markers identifies a population of DNA damaged polyploid TC. Polyploid TC accumulate DNA damage and survive, eventually resting in G1 phase of the cell cycle, while diploid TC die. *In vivo* and *in vitro* scRNA-seq along with sorting of polyploid TC show that these cells with DNA damage acquire a pro-fibrotic phenotype culminating in TGF-β1 expression. *In vitro* stimulation proved that TGF-β1 directly promotes TC polyploidization. *In vivo* interactome analysis revealed that TGF-β1 signaling fosters a reciprocal activation loop among polyploid TC, macrophages and fibroblasts to sustain kidney fibrosis and promote CKD progression.

Conclusions: Collectively, this study contributes to the ongoing revision of the paradigm of kidney tubule response to AKI, supporting the existence of a tubulointerstitial crosstalk mediated by TGF-β1 signaling produced by polyploid TC with DNA damage. Finally, these results further demonstrate that TC polyploidization is a self-sustained mechanism.

TH-PO119

PPP1R3G Promotes Necroptosis in Ischemia Reperfusion-Induced AKI by RIPK1 Dephosphorylation

Minh H. Tran, Lei Wang. *University of South Florida, Tampa, FL.*

Background: Recent discoveries have revealed necroptosis as a major contributor to the pathogenesis of acute kidney injury (AKI). Protein phosphatase 1 regulatory subunit 3G (PPP1R3G) has been linked to the essentiality of RIPK1-dependent apoptosis and type I necroptosis. Nonetheless, the involvement of PPP1R3G in the regulation of necroptosis during ischemia reperfusion-induced acute kidney injury (IR-AKI) has yet to be elucidated.

Methods: Here, we investigated the role of PPP1R3G in the regulation of necroptosis in IR using an *in vitro* cellular I/R model and *in vivo* IRI-AKI mouse model. Primary proximal tubular cells (PTCs) from C57BL/6 and Ppp1r3g$^{-/-}$ mice were cultured and cell I/R was induced through hypoxia/reoxygenation. Cell viability and necroptosis were analyzed using a LUNA-II cell counter and flow cytometry, respectively. The expression levels of necroptosis, oxidative stress, and inflammation factors were determined by real-time PCR, western blotting, immunofluorescence staining, and ELISA. In the *in vivo* IRI-AKI model, the kidney injury and function were evaluated by plasma creatine, BUN, and KIM-1 levels and GFR values, respectively. Morphological evidence of kidney injury was assessed by PAS staining and cell death by immunofluorescent staining.

Results: We found that knockout of PPP1R3G significantly decreased (by 35-50%) hypoxia-inducible factor-1α (HIF-1α), as well as the levels of necroptosis factors (RIP1, RIP3, and Sirtuin-2), and inflammatory factors (IL-6, IL-10 and TNF-α) in I/R injury cells and IR-AKI mice. Deletion of PPP1R3G attenuated the I/R induced kidney injury indicated by 54% decrease in the plasma creatine (2.28±0.12mg/dL vs. 1.09±0.07mg/dL, $p<0.0001$) and 45% higher GFR values than WT mice at day 3 after reperfusion. Histology showed less diffuse renal tubular necrosis, casts, and debris in Ppp1r3g$^{-/-}$ mice, as well as 60% less cell death compared to WT mice. Moreover, the application of chemical compounds to prevent inhibitory phosphorylations of RIPK1 significantly reinstated cell death in Ppp1r3g$^{-/-}$ cells.

Conclusions: In conclusion, our findings demonstrate, for the first time, that Ppp1r3g-mediated necroptosis significantly promotes IRI-AKI. Therefore, targeting Ppp1r3g to reduce necroptosis in the kidney holds promising potential for significant clinical benefits.

The AMPK Activator ATX-304 Reprograms Tubular Cell Metabolism to Protect Against Cisplatin-Induced AKI

Peter F. Mount,[1,2] Marina Katerelos,[1] Kurt Gleich,[1] Geoffrey Harley,[1] Mardiana Lee,[1] Kim Loh,[3] Jonathan S. Oakhill,[3] Vinod K. Narayana,[4] David P. De Souza,[4] Adrienne Laskowski,[5] Melinda T. Coughlan,[5] Bruce E. Kemp,[3] David A. Power.[1,2] *[1]Austin Health, Heidelberg, VIC, Australia; [2]The University of Melbourne Austin Clinical School, Heidelberg, VIC, Australia; [3]St Vincent's Institute of Medical Research, Fitzroy, VIC, Australia; [4]The University of Melbourne Bio21 Molecular Science and Biotechnology Institute, Parkville, VIC, Australia; [5]Monash University Central Clinical School, Melbourne, VIC, Australia.*

Background: Acute kidney injury (AKI) is characterized by widespread disruption of energy metabolism pathways. Targeting the metabolic regulator AMP-activated protein kinase (AMPK) is a potential strategy for addressing the problem of AKI. ATX-304 is a novel PAN-AMPK activator with reported benefits in models of diabetes, obesity and aging.

Methods: C57Bl/6 mice were fed chow containing ATX-304 (1mg/gm) versus control chow for 7-days prior to cisplatin-induced AKI (CI-AKI). Primary cultures of tubular epithelial cells (TECs) were pre-treated with ATX-304 (20 μM, 4-hrs), prior to exposure to cisplatin (20 μM, 23-hours).

Results: ATX-304 protected against CI-AKI as measured by serum creatinine at 48-hours (control 0.05±0.03 mM vs ATX-304 0.02+0.01 mM, P=0.004), western blot for neutrophil gelatinase-associated lipocalin (NGAL) (control 3.3±1.8-fold vs ATX-304 1.2±0.55-fold, P=0.002), RT-PCR for NGAL (control 99.6±22.8-fold vs ATX-304 35.2±5.9-fold, P=0.006), monocyte chemoattractant protein-1 (control 18.7±5.1-fold vs ATX-304 10.4±1.3-fold, P=0.048) and receptor-interating protein kinase 3 (CI-AKI control 6.9±2.4-fold vs CI-AKI ATX-304 4.9±1.3-fold, P=0.02), and histological injury score (control 3.5±0.59 vs ATX-304 2.7±0.74, P=0.03). In TECs, pre-treatment with ATX-304 protected from cisplatin mediated cell death, measured by lactate dehydrogenase release assay (control 27.1±4.2% lysis vs ATX304 -0.6±2.5% lysis, p<0.0001), and maintained cell viability in the presence of cisplatin, as measured by MTS assay. ATX-304 protection against cisplatin was lost in AMPK-null murine embryonic fibroblasts. In TECs metabolomic analysis revealed that ATX-304 (20 μM, 4-hrs) altered the level of 66/126 detected metabolites, including changes in fatty acids, tricarboxylic acid cycle metabolites, and amino acids. Energy metabolism studies of live TECs using the XFe96 Seahorse analyser found ATX-304 increased basal oxygen consumption rate by 38%, whereas maximal respiration was unchanged.

Conclusions: The mechanism of ATX-304 protection against cisplatin injury is AMPK- dependent and involves widespread metabolic reprogramming. AMPK activation by ATX-304 is a promising therapeutic strategy for AKI.

Unveiling the Role of Lactate Dehydrogenase A (LDHA) in AKI: Insights from a Transgenic Mouse Model Study

Yan Lu, Anna A. Zmijewska, Matthew D. Cheung, Yanlin Jiang, Amie Traylor, Gunars Osis, Anupam Agarwal. *The University of Alabama at Birmingham, Birmingham, AL.*

Background: Acute kidney injury (AKI) is a pressing global health concern, affecting millions of individuals worldwide. Despite its high prevalence, the prognosis of AKI remains poor, and effective biomarkers, prevention strategies, and treatment options are limited. Accumulating evidence from clinical, animal, and in vitro studies supports a close association between AKI, inflammation, and metabolic dysregulation. Notably, proximal tubule cells (PTCs) within the kidney play a vital role in AKI, as they possess numerous mitochondria with high metabolic activity, serving as both early sensors and major effectors in this condition. Additionally, under hypoxia and LPS-induced inflammation, lactate dehydrogenase A (LDHA), an enzyme involved in fermentative glycolysis, is upregulated in PTCs. However, the specific role of LDHA in AKI remains unexplored.

Methods: To generate kidney proximal tubule-specific LDHA knockout mice, we used PEPCK Cre crossbreeding with LDHA floxed mice. To confirmed the deletion of LDHA, we use western blot and immunostaining for characterization To induce AKI in both the LDHA knockout (KO) mice and wild-type (WT) mice, we administered a single dose of cisplatin (20mg/kg, IP) To assess the severity of AKI, we utilized various measurements, including serum creatinine levels, survival rates, and glomerular filtration rate (GFR). GFR was evaluated by employing transdermal measurement of excretion kinetics FITC.

Results: In our preliminary study, baseline observations did not reveal any phenotype changes in LDHA KO mice within the proximal tubules. However, when subjected to cisplatin-induced AKI through a single dose injection, LDHA KO mice exhibited more severe injury compared to wild-type (WT) mice. This phenotype was confirmed by increased serum creatinine levels at day 3 post-injection in KO mice (KO: 0.689 mg/dl vs WT: 0.338 mg/dl; p=0.0062), a lower 5-day survival rate in KO mice (KO: 70% vs WT: 90%), and reduced glomerular filtration rate (GFR) in KO mice (KO: 82.6 ml/min/100g b.w. vs WT: 256.6 ml/min/100g b.w. ; p= 0.022).

Conclusions: Overall, our findings suggest that LDHA may play a significant role in exacerbating AKI may through the facilitation of glycolytic switch within the proximal tubule.

TH-PO122

Lactate Dehydrogenase (LDH): Not Just a Marker of Kidney Injury

William B. Reeves, Weiwei Wang, Kang Li, Muniswamy Madesh. *The University of Texas Health Science Center at San Antonio, San Antonio, TX.*

Background: Lactate dehydrogenase (LDH) catalyzes the final step in glycolysis, the conversion of pyruvate to lactate. The release of LDH into extracellular fluids has been used for decades as a clinical and experimental marker of cell injury. However, the role of LDH as a mediator of cell injury has not been examined. Glycolysis is increased in AKI leading to the accumulation of lactate. Here we show that LDH and lactate are, in fact, not just markers but potent mediators of AKI.

Methods: C57BL6 male mice were subjected to bilateral ischemia reperfusion injury (IRI). Mice received LDH inhibitors (oxamate 300 mg/kg or NCATS SM1441 10 mg/kg), lactate (2g/kg), the Mrs2 inhibitor CPACC (10 mg/kg/d) or vehicle. Renal function and structure were assessed 24 hr after reperfusion.

Results: Oxamate-treated mice developed substantially less structural damage and kidney dysfunction (BUN 38±7 mg/dl, Cr 0.37±0.06 mg/dl) than vehicle-treated mice (BUN 148±25, Cr 0.93±0.12, P<0.0001). NCATS SM1441 also prevented ischemic AKI (NCATS BUN 31±6, Cr 0.23±0.06 vs saline BUN 111±10, Cr 1.59±0.3, P<0.0001). Administration of NCATS up to 6 hours after reperfusion also reduced IRI. LDH inhibitors also reduced hypoxic and cisplatin-induced cell death in renal epithelial cells *in vitro*. Moreover, the administration of L-lactate (but not D-Lactate) sensitized mice to a subsequent mild (22 min) ischemic insult (BUN L-lactate 95±8 vs D-lactate 22±6, P<0.0001) and also abrogated the protective effects of LDH inhibitors. In prior work, we showed that lactate stimulates mitochondrial Mg^{2+} uptake via Mrs2 and that Mrs2 mediates ischemic AKI. Here, we found that lactate did not exacerbate AKI in the absence of Mrs2. Finally, inhibition of LDH or Mrs2 starting 3 days after IRI, when injury is established, preserved kidney function and reduced fibrosis and atrophy measured at day 28.

Conclusions: These results indicate that the production of lactate via LDH is an important mediator of ischemic AKI and support the view that lactate-triggered mitochondrial Mg^{2+} uptake mediates AKI. These results also support the view that a sustained increase in glycolysis contributes mechanistically to the AKI-CKD transition. Finally, we provide preclinical evidence that LDH inhibitors may be highly effective in preventing ischemic AKI when administered before or shortly after injury and in preventing the development of CKD when administered after AKI.

TH-PO123

Proximal Tubule-Specific Transcriptomic Changes Mediate Sex Differences in Susceptibility to Aristolochic Acid I-Induced AKI in Mice

Tej Bahadur,[1] Jiakang Wang,[1] Robert Bronstein,[1] Yiqing Guo,[1] Nehaben A. Gujarati,[1] Monica P. Revelo Penafiel,[2] Sian Piret,[1] Sandeep K. Mallipattu.[1] *[1]Stony Brook University Renaissance School of Medicine, Stony Brook, NY; [2]University of Utah Health, Salt Lake City, UT.*

Background: Previous studies have demonstrated the role of sex differences in susceptibility to human and murine models of AKI. However, proximal tubule (PT)-specific transcriptomic changes that mediate these differences have not been previously described. Here, we aim to investigate the sex-specific transcriptomic differences that mediate the susceptibility to AKI in Aristolochic Acid I (AAI)-induced injury model.

Methods: Age-matched male and female mice were administered DMSO (vehicle) or AAI (2mg/kg) every 72 hours for a total of 4 doses. FITC-sinistrin was used to measure GFR. Histological analysis and immunostaining were performed to determine extent of tubular injury and interstitial fibrosis. In addition, single nuclear multiome (RNA and ATAC) sequencing using 10X Genomics to assess changes to the transcriptome and chromatin accessibility.

Results: Immunostaining for AAI DNA adducts showed no significant differences between male and female mice. However, AAI-treated male mice demonstrated an increase in tubular injury and interstitial fibrosis based on H&E, PAS, and immunostaining (Cytokeratin 20) with a decrease in GFR. Single-nuclear multiome data showed all PT segments clustered distinctly between male and female mice (DMSO or AAI) with 2 unique PT clusters only present in the AAI-treated male as compared to all other groups. Key TF motifs were enriched in these 2 unique PT clusters were (cluster 1: *Elf4, Ets1, Irf1, Klf2, Stat2*) and (cluster 2: *Ebf1, Hivep2, Nfkb1, Pax8* and *Relb).* Pathway enrichment analysis showed enrichment in ribosome, ubiquitin mediated proteolysis and mitophagy-related pathways in these injured PT clusters. In comparison, key TF motifs were enriched in the female PT clusters such as *Atp5a1, Ndufa11, Ndufb10* (oxidative phosphorylation) and *Aldoa, Dld, Eno1, G6pc, Gapdh* (glycolysis and gluconeogenesis). Conversely, key TF motifs enriched in the male PT clusters were *Ank3, Atp2b1, Cadm, Cask, Cdh2, Agrn, Cask, Dab1, Epb41, Gphn (*splicing factor NOVA regulated synaptic proteins).

Conclusions: To date, this is the first study to demonstrate PT-specific changes to the transcriptome and chromatin accessibility that might mediate sex differences in susceptibility to AKI post-AAI treatment.

Sexual Dimorphism and Epigenetic Control of the Kidney Disease Marker Klotho

Jakub Jankowski,[1] Hye kyung Lee,[1] Julia Wilflingseder,[2] Lothar Hennighausen.[1] [1]*National Institute of Diabetes and Digestive and Kidney Diseases, Bethesda, MD;* [2]*Veterinarmedizinische Universitat Wien, Wien, Austria.*

Background: Preclinical studies investigating physiological and pathophysiological processes in the kidney are mainly performed in males. This is due to a higher susceptibility to kidney injury and faster subsequent disease progression in male rodents. In consequence, sexual dimorphism of kidney injury markers like Klotho is often overlooked. *Klotho* is well-linked to renal health and its deletion in mice results in severe phenotype and premature death. Here, we identified putative *Klotho* enhancers and investigated their functions in males and females using mice with deletions in the *Klotho* associated enhancers.

Methods: We generated mutant mice carrying deletion of putative *Klotho* enhancers using CRISPR/Cas9 gene editing. Warm ischemia-reperfusion surgery was performed bilaterally to induce acute kidney injury and unilaterally in a fibrosis model. Using ChIP-seq and RNA-seq, we analyzed chromatin features and gene expression in mouse kidney. ELISA assay was utilized to measure serum FGF23 levels.

Results: We detected *Klotho* gene expression being twice as high in males compared to females at baseline. Enhancer deletion decreased *Klotho* mRNA levels more effectively in female than in male mice (90 vs. 50%). ChIP-seq data suggest additional regulatory elements present only in male mice, as promoter marks remain more pronounced in males even after deletion. Weight, lifespan and fertility of the knockout mice was not impacted. Baseline serum FGF23 level was significantly higher only in female enhancer knockouts (192.4 vs. 599.6pg/ml, p=0.0003). Severe bilateral ischemia resulted in similar creatinine increase in male and female WT and knockout mice, but only male knockout mice displayed higher *Havcr1* expression after injury than controls (1048 vs. 231.4, p=0.0016). 28 days after unilateral renal ischemia, fibrosis as measured by *Acta2* and *Tgfb* expression and Masson Trichrome staining was not significantly changed regardless of genotype.

Conclusions: Our results demonstrate sexual dimorphism of *Klotho* gene expression and its enhancer regulation. Despite having a larger effect in female mice, including changes in baseline FGF23 levels, only male knockout mice are more susceptible to acute injury and the deletion has no impact on the fibrosis model. Further dissection of the mechanisms of *Klotho* regulation is necessary to reexamine its efficacy as a kidney injury marker.

Development of an Analytical Approach to Quantify Ammonium Flux in Tissue and Biofluids

Oliver Hahn,[1] Johannes Jaegers,[1] Markus M. Rinschen.[1,2] Kidney Omics Lab. [1]*Aarhus Universitet Institut for Biomedicin, Aarhus, Denmark;* [2]*III Department of Medicine, University Medical Center Hamburg Eppendorf, Germany, Hamburg, Germany.*

Background: Ammonia is a waste product of amino acids and other nitrogen-containing compounds, and its accumulation in the body can be toxic. The detection of abundance and flux is challenging because of its volatile nature, its conversion to ammonium and its fixation and excretion in other metabolic cycles such as the urea cycle. Here, we aimed to develop a method for quantifying changes in ammonia metabolism in multiple organs, urine, and plasma.

Methods: We modified the Berthelot method to derivatize ammonium into a measurable molecule called indophenol. Using ultra-high pressure liquid chromatography – triple quadrupole tandem mass spectrometry, this allows for quantifying both normal (^{14}N) and heavy (^{15}N) labeled ammonia through indophenol derivatization. The method was validated by measuring the pure indophenol and replicating the same peak when analyzing different dilutions of derivatized ammonium chloride standards.

Results: Standard curves correlated with initial concentrations of the standards. We then used a porcine kidney injury model with unilateral IRI and infused heavy labeled 15N-ammonium chloride to trace the handling of ammonia in different organs. The ^{15}N to ^{14}N ratio was used to observe changes in the handling of the infused heavy ammonia in different organs during kidney injury, revealing strong alterations in the inner medulla.

Conclusions: The data also allowed for calculation of fluxes, revealing altered detoxification into urea. This method will be used in future studies to determine changes in waste product metabolism during kidney injury.

TH-PO126

Mechanistic Representation of NAG Release in Renal Proximal Tubular Cellular Injury

Nader Hamzavi,[1] Pallavi Bhargava,[1] Simone H. Stahl,[2] Jeffrey Woodhead.[1] [1]*Simulations Plus Inc, Lancaster, CA;* [2]*Clinical Pharmacology and Safety Sciences, AstraZeneca, Cambridge, United Kingdom.*

Background: N-acetyl-beta-D-glucosaminidase (NAG) is a novel biomarker for early detection of tubular injury in the event of acute kidney injury (AKI). While elevated levels of NAG in urine have been associated with renal tubular cell breakdown, the mechanistic underpinnings of NAG release remain poorly understood. In this study, we investigated the relationship between NAG release and potential mechanisms of proximal tubular injury.

Methods: We developed a mathematical model of NAG release from proximal tubule cells (PTCs) within the framework of RENAsym, a quantitative systems toxicology model of drug-induced AKI. The model was designed to represent urinary NAG increase as a result of cellular necrosis and brush border loss. In RENAsym, ATP decline results in various forms of cellular injury including microfilament disruption and cellular necrosis. NAG release was simulated using a driving signal from either necrosis or microfilament disruption and parameterized using observed urinary NAG in rats treated with cisplatin [1] and cyclosporine A (CsA) [2]. [1] Weichert-Jacobsen, K J et al. Cancer research vol. 59,14 (1999): 3451-3. [2] Nephrotoxicity biomarker evaluation after repeat dose oral administration of cyclosporine A in male rats. AstraZeneca, 2007.

Results: The results of our mathematical model of the NAG response indicate that the kinetics of urinary NAG in rats treated with cisplatin and CsA can be predicted using cellular necrosis. The model correctly predicted the peak time of urinary NAG in rats after single dose of 5 mg/kg cisplatin with time to resolution of ~48 hours. Furthermore, the model could recapitulate the dose-dependent response of NAG release in rats treated daily with CsA for two weeks. Specifically, NAG peak time occurred on day 5 or 6 and levels remained elevated until day 14. Simulated urinary NAG was shown to saturate at CsA doses of 30 mg/kg and higher, in line with observed data.

Conclusions: We developed a mechanistic model of NAG release in connection with cellular necrosis. The model predicts NAG kinetics for CsA- and cisplatin-mediated AKI as a useful biomarker for monitoring tubular injury in (pre)clinical settings.

Funding: Commercial Support - RENAsym development is funded by the RENAsym Consortium, which includes Janssen, AstraZeneca, AbbVie, Servier, Merck KGA, Gilead, and GSK as current members.

Multi-Trait Genome-Wide Association Study (GWAS) and Functional Genomics Identifies Novel Genetic Traits and Dynamic Networks for FGF23

Farzana Perwad,[1] Nicholas Vartanian,[2] Elvis A. Akwo,[2] Cassianne Robinson-Cohen.[2] [1]*University of California San Francisco, San Francisco, CA;* [2]*Vanderbilt University Medical Center, Nashville, TN.*

Background: Multi-trait analysis of Genome-wide association (MTAG) is a novel method to explore overlapping genetic architecture between traits. In this study, we investigated genetic traits common to mineral metabolism (MM) to identify novel genetic associations for fibroblast growth factor 23 (FGF23).

Methods: We applied MTAG to genetic variants common to 5 genetically correlated mineral metabolism markers (phosphorus, FGF23, calcium, 25(OH)D and PTH) in European-ancestry subjects from UKBioBank GWAS for phosphate and calcium (n=366,484), and two GWAS from the CHARGE consortium for PTH (n=29,155) and FGF23 (n=16,624). We used a functional genomics approach to model interactive and dynamic networks to identify novel associations between MM and FGF23.

Results: MTAG identified independent genome-wide significant SNPs for all traits, including 47 novel and known loci for FGF23. Using gene ontology and pathway analysis, we identified 9 overlapping networks including canonical pathways associated with cardiac hypertrophy and hematopoiesis. VDR and TGFβR2 signaling pathways were identified as the top regulator effect networks and MAPK signaling molecules were common to the top 5 causal networks (Figure 1 and 2). In addition, Coordinated Lysosomal Expression and Regulation (CLEAR) signaling pathway that regulates lysosomal function, autophagy and cellular response to nutrient sensing had the highest predicted activation z-score.

Conclusions: Novel genetic traits for FGF23 were identified with MTAG. Functional genomics revealed networks that inform unique biologic processes and cellular functions that could be targeted to develop therapeutics for mineral disorders.

The Association Between Fibroblast Growth Factor 23 and Blood Pressure in a Hemodialysis Cohort

Mireille M. Mbah,[1] Jyothsna Gattineni,[1] Peter N. Van Buren.[1,2] *[1]The University of Texas Southwestern Medical Center, Dallas, TX; [2]VA North Texas Health Care System, Dallas, TX.*

Background: Mineral bone disease (MBD) is associated with mortality in hemodialysis (HD) patients, and we recently found associations between hyperphosphatemia and vasoconstriction/endothelial cell dysfunction in a small HD cohort. We hypothesized that fibroblast growth factor 23 (FGF23), the earliest MBD marker, would be independently associated with blood pressure in this cohort.

Methods: In a cohort of hypertensive HD patients, we measured plasma FGF23 from remaining frozen samples using ELISA. We conducted correlation and linear regression analysis to determine the association between FGF23 and peridialytic BP metrics and other lab parameters.

Results: There were 34 participants (53% women, 59% Black, 45% with diabetes) with a mean age of 46.8 years, mean pre-HD systolic BP of 160 (19) mmHg, mean serum phosphate of 6.5 (2.3) mg/dL and median FGF23 of 3264 (1042-6817) ng/mL. LogFGF23 did not differ based on diabetes status or sex, but it was higher in Black vs. White participants (p=.003). FGF23 correlated with phosphate (r=0.5, p=.001), but not PTH. Table 1 shows that logFGF23 was associated with almost all peridialytic BP metrics in univariate analysis that remained independent after controlling for phosphate, but were no longer significant after controlling for race.

Conclusions: FGF23 was associated with phosphate in hypertensive HD patients, and it was higher in Black vs. White participants. Associations between FGF23 and BP were independent of phosphate, but race was a confounding variable in this small cohort. Further larger studies are required better understand mechanisms by which FGF23 and MBD in general impact BP and CV health as well as to determine the generalizability of the race-based differences found in this study.

Funding: NIDDK Support, Veterans Affairs Support

Interactive Simulator for Model-Based Predictions of Parathyroid Hormone (PTH) Levels in Hemodialysis Patients

Gudrun Schappacher-Tilp,[1] Nicoletta Kaehling,[1] Egon Teiniker,[1] Peter Kotanko.[2,3] *[1]FH Joanneum GmbH, Graz, Austria; [2]Renal Research Institute, New York, NY; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Secondary hyperparathyroidism is a prevalent condition among hemodialysis (HD) patients and a significant contributor to chronic kidney disease-mineral bone disorder (CKD-MBD). CKD-MBD poses a considerable risk of vascular calcification and cardiovascular events. The KDIGO guidelines strongly emphasize the importance of managing parathyroid hormone (PTH) levels in hemodialysis patients (Kidney Int Suppl 2017). Considering this, we have built an interactive simulator to predict PTH levels based on interventions targeting phosphate and calcitriol levels tailored to exemplary patients.

Methods: We utilized a comprehensive physiology-based mathematical model of parathyroid gland biology (Schappacher-Tilp, Physiol Rep, 2019) which has been employed successfully to predict individual PTH levels in HD patients (Pirklbauer, Front Med, 2021). The simulator follows a client-server architecture (**Fig 1A**) and features a user-friendly graphical user interface (GUI) allowing the user to select various parameters for the simulation (**Fig 1B**). Within the simulator, users can set treatment targets for serum phosphate and calcitriol levels, along with specifying the target time horizon.

Results: The interactive simulator provides users with the ability to select specific treatment targets and track the response of intact parathyroid hormone (iPTH) over time, as depicted in **Fig 1C.**

Conclusions: Our simulator predicts iPTH levels for various patient groups based on user-specified treatment targets for phosphate and calcitriol, serving as an effective educational tool to illustrate the effect of phosphate and calcitriol on iPTH levels.

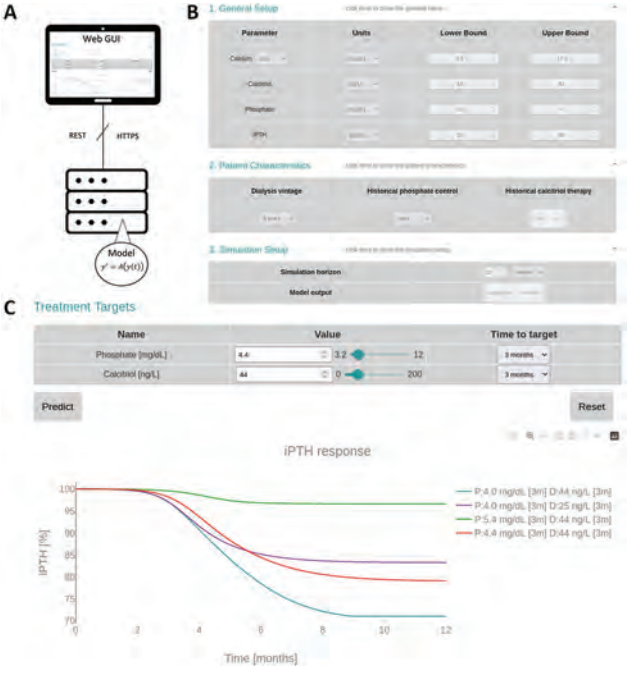

Fig 1: A The client-server architecture and **B** GUI. **C** iPTH level predictions for an exemplary patient (5 years HD, poor historic phosphate control, no calcitriol therapy history)

Risk Factors Associated with Hip and Vertebral Fractures in CKD: The Chronic Renal Insufficiency Cohort (CRIC) Study

Simon Hsu,[1] Leila R. Zelnick,[1] Nisha Bansal,[1] Michelle Denburg,[2,3] Charles Ginsberg,[4] Andrew N. Hoofnagle,[1] Tamara Isakova,[5] Joachim H. Ix,[4] Bryan R. Kestenbaum,[1] Cassianne Robinson-Cohen,[6] Myles Wolf,[7] Ian H. de Boer.[1] *[1]University of Washington, Seattle, WA; [2]The Children's Hospital of Philadelphia, Philadelphia, PA; [3]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [4]University of California San Diego, La Jolla, CA; [5]Northwestern University Feinberg School of Medicine, Chicago, IL; [6]Vanderbilt University Medical Center, Nashville, TN; [7]Duke University School of Medicine, Durham, NC.*

Background: Fracture risk is substantially higher in patients with chronic kidney disease (CKD) than those without CKD and may have different pathophysiology, yet risk factors for fracture in CKD have largely been generalized from studies in non-CKD populations.

Methods: We used Cox regression to test associations of putative demographic and clinical risk factors with the composite hip and vertebral fracture assessed using hospital discharge diagnosis codes in 3,939 participants from the Chronic Renal Insufficiency Cohort (CRIC). Estimated glomerular filtration rate (eGFR) and proteinuria assessed by 24-hour urine collection were time-updated exposures. Serum 25-hydroxyvitamin D, 1,25-dihydroxyvitamin D, and 24,25-dihydroxyvitamin D_3 were measured in a subset of 1,786 participants by liquid chromatography-tandem mass spectrometry.

Results: Mean cohort age was 58 years, 45% were female, 42% were Black, and 13% were Hispanic. Mean (standard deviation [SD]) eGFR was 44.4 (15.2). There were 82 hip and 24 vertebral fractures over a mean (SD) follow-up of 11.1 (4.8) years (incidence rate 2.4 events per 1000 person-years [95% CI: 2.0, 2.9]). Black race was associated with lower fracture risk after adjusting for demographics, comorbidity, medication use,

and eGFR and proteinuria. Older age, lower body mass index, and lower eGFR were associated with higher fracture risk after full covariate adjustment. Neither proteinuria, parathyroid hormone, nor other biomarkers of mineral metabolism were associated with fracture risk after full covariate adjustment.

Conclusions: Older age, non-Black race, and lower body mass index and eGFR were associated with fracture risk. None of the biomarkers of mineral metabolism tested in this study were associated with elevated risk of fracture experienced by patients with CKD.

Funding: NIDDK Support

Table 1. Associations of demographic and clinical risk factors with hip and vertebral fractures in the Chronic Renal Insufficiency Cohort (CRIC).

	N at risk (N events)	Incidence rate (events/1000 person-years)	Hazard Ratio (95% CI)	
			Model 1	Model 2
Age, per decade higher:			1.92 (1.51, 2.42)*	1.96 (1.51, 2.54)*

TH-PO131

Lower Parathyroid Hormone Levels Are Associated with Lower Risk of Fractures in Japanese Hemodialysis Patients: A Nationwide Cohort Study

Hirotaka Komaba,[1,2] Takahiro Imaizumi,[3] Takayuki Hamano,[4] Naohiko Fujii,[5] Masanori Abe,[1,6] Norio Hanafusa,[1,7] Masafumi Fukagawa.[2] *[1]Committee of Renal Data Registry, Japanese Society for Dialysis Therapy, Tokyo, Japan; [2]Tokai University School of Medicine, Isehara, Japan; [3]Nagoya University Hospital, Nagoya, Japan; [4]Nagoya City University Graduate School of Medical Sciences, Nagoya, Japan; [5]Hyogo Prefectural Nishinomiya Hospital, Nishinomiya, Japan; [6]Nihon University School of Medicine, Tokyo, Japan; [7]Tokyo Women's Medical University, Tokyo, Japan.*

Background: Secondary hyperparathyroidism is associated with high-turnover bone disease in hemodialysis patients. However, conflicting evidence exists as to whether parathyroid hormone (PTH) levels are associated with fracture risk and whether the relationship is linear or U-shaped.

Methods: Using data from the Japanese Society for Dialysis Therapy Renal Data Registry, we analyzed 180,333 adult hemodialysis patients with data on serum albumin, calcium, phosphorus, and intact or whole PTH at the end of 2016 and data on hospitalization in 2017. The primary outcome was the composite of hospitalizations due to hip, vertebral, and other fractures. The secondary outcomes included hospitalization due to site-specific fracture. Fracture risk was assessed using Cox proportional hazards models, adjusted for potential confounders. We also examined the association between percent change in PTH levels during a 1-year baseline period and subsequent risk of fractures.

Results: At baseline, the median intact PTH level was 141 pg/mL (interquartile range, 78–226 pg/mL). During the 1-year follow-up, there were a total of 3,762 fractures requiring hospitalization (1,361 hip, 551 vertebral, and 1,850 others). In adjusted analyses, increasing PTH levels were associated with a monotonically increasing risk of fractures (odds ratio per doubling of intact PTH, 1.06; 95% CI, 1.03–1.09). When analyzed in deciles, the risk of fracture was lowest in the lowest decile of intact PTH levels (<39 pg/mL). The relationship between PTH levels and fracture risk was more pronounced for hip fractures, whereas there was no association between PTH levels and vertebral fractures. Changes in PTH levels were also associated with fracture risk: the adjusted odds ratio of fractures per 30% reduction in PTH during a 1-year baseline period was 0.97 (95% CI, 0.95–0.99).

Conclusions: Lower PTH levels are associated with a monotonically decreasing risk of fractures. Further studies are needed to determine whether intensive control of PTH decreases fracture risk.

TH-PO132

Improving Treatment of CKD-Mineral Bone Disorder (CKD-MBD) Through the Incorporation of Agatston Scores

Adam E. Gaweda,[1] Michael E. Brier,[1,2] Eleanor D. Lederer.[3,4] *[1]University of Louisville School of Medicine, Louisville, KY; [2]VA Robley Rex Medical Center, Louisville, KY; [3]VA North Texas Health Care System, Dallas, TX; [4]The University of Texas Southwestern Medical Center Medical School, Dallas, TX.*

Background: KDIGO targets for CKD-MBD for Ca, P, and PTH are surrogates for the real damage that takes place in bone and the cardiovascular (CV) system. Vascular calcification (VC) correlates strongly with CV disease and death in individuals with CKD. We have modeled CKD-MBD through a series of mass balance equations describing movement of mineral between bone and soft tissue. We hypothesize that incorporation of measures and biomarkers of VC into a quantitative systems pharmacology model optimized using reinforcement learning will improve therapy by identifying alternative targets.

Methods: Data were abstracted from the Chronic Renal Insufficiency Cohort (CRIC) consisting of 5499 individual subjects with a mean CKD EPI eGFR of 47.7 ml/min/1.73m2 and a range between 3.0 and 126. Total and site specific Agatston scores were calculated and used for analysis. A total of 3230 Agatston scores were reported with a mean of 350 ± 767 and a range of 0 to 8247. A Cox Proportional hazard analysis was performed on CV death comparing Agatston score, site specific scores, and measured markers of inflammation (CaxP, Neutrophil/Lymphocyte Ratio (NLR), Fatty Acid Binding Protein (FABP), N-Acetyl-Beta-Glucosamide (NABG), Beta-2 Microglobulin (B2M), Beta-Trace Protein (BTP), Kidney Injury Molecule 1 (KIM1).

Results: The effects of inflammation markers on Total Agatston score and site-specific scores were not different, so only Total Agatston score will be reported. The results of the Cox model are shown in Table 1 following modeling with backwards elimination. All factors entered the model as an increased risk of CV death except for Beta-Trace Protein.

Conclusions: Substituting Agatston score for Ca net balance and modeling inflammatory intermediates NLR, B2M, BTP and FABP will optimize the CKD-MBD model. Leveraging artificial intelligence in the form of reinforcement learning will yield new pathways for treatment by targeting more proximal surrogates of disease.

TH-PO133

Association Among Bone Mass, Muscle Mass and Strength, Mortality, and CKD Progression in Older Adults

Yuta Nakano, Shintaro Mandai, Shotaro Naito, Tamami Fujiki, Yutaro Mori, Fumiaki Ando, Takayasu Mori, Koichiro Susa, Soichiro Iimori, Eisei Sohara, Shinichi Uchida. *Tokyo Ika Shika Daigaku, Bunkyo-ku, Japan.*

Background: Chronic kidney disease (CKD) causes a progressive loss of muscle and bone mass. However, the impact of sarcopenia, low bone mineral density (BMD), and osteosarcopenia on CKD progression is yet to be determined.

Methods: This longitudinal prospective cohort study included 251 (median age 76 years; 35% women) outpatients aged ≥65 years with nondialysis-dependent CKD (NDD-CKD). Sarcopenia was defined according to the 2014 criteria of the Asian Working Group for Sarcopenia (AWGS), and low BMD was defined as a T-score of ≤−1.0. The patients were divided into four groups: normal (no sarcopenia/normal BMD), only low BMD (no sarcopenia/low BMD), only sarcopenia (sarcopenia/normal BMD), and osteosarcopenia (sarcopenia/low BMD). The primary outcome was a composite of all-cause deaths, end-stage kidney disease (ESKD), and admissions owing to major cardiovascular events (MACEs). The secondary outcome was a kidney composite outcome that included a 30% estimated glomerular filtration rate (eGFR) reduction and ESKD. The outcome risk was determined using stratified Cox models adjusted for potential confounders.

Results: During a median follow-up period of 5.2 years, there were 22 deaths, 117 30% eGFR reductions, 48 ESKDs, and 18 admissions owing to MACEs. The osteosarcopenia group rather than the only low BMD or only sarcopenia groups exhibited a higher risk of the primary (hazard ratio [HR]: 2.81, 95% confidence interval [CI]: 1.32–5.99) and kidney composite (HR: 1.90, 95% CI: 1.01–3.57) outcomes. Low handgrip strength (HGS) was associated with a high risk of primary and kidney composite outcomes (HR: 2.38, 95% CI: 1.40–4.05; HR: 1.55, 95% CI: 1.01–2.37, respectively). The increase in HGS but not the body mass index, skeletal muscle mass index, or BMD was associated with a lower risk of primary and kidney composite outcomes (HR: 0.67, 95% CI: 0.52–0.87; HR: 0.76, 95% CI: 0.63–0.93 per 5 kg, respectively).

Conclusions: Osteosarcopenia was associated with poor survival and kidney outcomes. Low HGS was associated with increased mortality risk and kidney function decline. These findings bring insights into the pathogenesis of the kidney–bone–muscle axis and improving muscle strength may mitigate CKD progression.

The Vitamin D Metabolite Ratio Is Associated with Volumetric Bone Density in Older Men

Charles Ginsberg,[1] Terri L. Blackwell,[2] Jonathan Cheng,[1] O. Alison Potok,[1] Jane Cauley,[3] Kristine E. Ensrud,[4] Simon Hsu,[5] Deborah M. Kado,[6] Eric Orwoll,[7] Peggy M. Cawthon,[2] Joachim H. Ix.[1] *[1]University of California San Diego, La Jolla, CA; [2]California Pacific Medical Center Research Institute, San Francisco, CA; [3]University of Pittsburgh, Pittsburgh, PA; [4]Minneapolis Veterans Affairs Healthcare System, Minneapolis, MN; [5]University of Washington, Seattle, WA; [6]Stanford University School of Medicine, Stanford, CA; [7]Oregon Health & Science University School of Medicine, Portland, OR.*

Background: The ratio of the vitamin D catabolic product (24,25-dihydroxyvitamin D) to 25(OH)D (vitamin D metabolite ratio or VMR) has been suggested as a superior marker of vitamin D status than 25(OH)D. High-resolution peripheral quantitative computed tomography (HR-pQCT) provides information on bone health beyond bone mineral density (BMD), providing volumetric BMD (vBMD) and bone strength data. We evaluate the associations of the VMR and 25(OH)D_3 with vBMD and bone strength, in the distal radius and tibia in 545 participants in the Osteoporotic Fractures in Men (MrOS) Study.

Methods: We used multivariable linear regression in models adjusted for demographics, season, study site, physical activity, BMI, smoking status, diabetes, blood pressure and estimated glomerular filtration rate (eGFR) among 545 men aged ≥ 65 years who participated in MrOS and provided HR-pQCT data in visit 4 (Year 14 of the study). Our primary outcome was vBMD and secondary outcome was estimated failure load (EFL) at both the distal radius and tibia.

Results: Mean age was 84± 4 years, 88.3% were White, and 32% had an estimated glomerular filtration rate (eGFR) <60ml/min/1.73m^2. In fully adjusted models, each two-fold higher VMR was associated with 9% (3%, 16%) and 6% (0.4%, 11%) higher vBMD at the distal radius and tibia, respectively (**Table**). In contrast, we found no association of 25(OH)D_3, with vBMD at either anatomic site. Similarly, each two-fold higher VMR was associated with 13% (5%, 21%) and 10% (4%, 16%) EFL at the distal radius and tibia, respectively (**Table**). In contrast, we found no association of 25(OH)D_3, with EFL at either anatomic site.

Conclusions: Among community-living older men, a higher VMR is associated with higher vBMD and EFL while 25(OH)D_3 was not. The VMR may serve as a valuable predictor of skeletal health in older men at risk for osteoporosis and fractures.

Serum Bicarbonate Is Associated with Bone Density Among Adults with Type 2 Diabetes: Results from the African American Diabetes Heart Study

Kishan Rao,[1] Jean H. Ancion,[1,2] Meredith Akerman,[1,3] Barry I. Freedman,[4,5] Jasmin Divers,[1,3] Minesh Khatri.[1,2] *[1]New York University Long Island School of Medicine, Mineola, NY; [2]Division of Nephrology, Mineola, NY; [3]Center for Population and Health Services Research, Mineola, NY; [4]Wake Forest University School of Medicine, Winston-Salem, NC; [5]Section on Nephrology, Winston-Salem, NC.*

Background: Osteoporosis is a significant cause of morbidity and mortality in the aging population. Individuals with type 2 diabetes (T2D) typically have higher bone density but also a higher rate of fractures. Serum bicarbonate may be a risk factor for bone loss, but studies are conflicting, and little is known about this relationship in T2D, especially in African Americans.

Methods: We examined the longitudinal relationship between serum bicarbonate and change in bone density in 300 participants with T2D in the African American - Diabetes Heart Study (AA-DHS). Serum bicarbonate was measured at baseline, and bone density was assessed using CT volumetric bone mineral density (vBMD) scans of the thoracic and lumbar spines at baseline and after an average of five years of follow up. Multivariate linear regression models assessed associations between baseline serum bicarbonate and longitudinal change in vBMD.

Results: At baseline, the cohort was 50% female, with a mean age of 55.1 years and a mean duration of diabetes of 10.2 years. The mean baseline serum bicarbonate was 26.6 (SD 3.3) mEq/L; the median baseline lumbar spine vBMD was 179.3 (IQR 148.2, 208.9) mg/cm3, and the median baseline thoracic spine vBMD was 204.9 (IQR 171.6, 231.9) mg/cm3. In adjusted analyses, every 1 mEq/L increase in baseline serum bicarbonate was significantly associated with a relative improvement in lumbar vBMD (1.04 (0.73, 1.36) mg/cm3, p < 0.01), as well as thoracic vBMD (1.36 (0.77, 1.94) mg/cm3, p < 0.01).

Conclusions: In this cohort of African-Americans with T2D, higher baseline serum bicarbonate levels associated with improved changes in bone density over time. Further studies are needed to determine if treatment of metabolic acidosis would lessen bone loss and fractures in this population.

Funding: Other NIH Support - Funding: 2R01DK071891

Effect of Citrate-Buffered, Magnesium-Enriched Dialysate on Calcification Propensity in Hemodialysis Patients: Results of a Randomized Controlled Trial (CitMag Study)

Daniel Cejka,[1] Ursula Thiem,[1] Eric Blinzler,[1] Jennifer D. Machacek,[1] Jakob Voelkl,[4] Edward R. Smith,[2] Andreas Pasch,[3,4] Maria C. Haller.[1] *[1]Ordensklinikum Linz GmbH, Linz, Austria; [2]The Royal Melbourne Hospital, Parkville, VIC, Australia; [3]Calciscon AG, Biel, Switzerland; [4]Johannes Kepler Universitat Linz, Linz, Austria.*

Background: Accelerated serum calcification propensity (lower T50 time) is directly associated with increased risk of cardiovascular events and mortality in dialysis patients. Several solitary interventions have been reported to improve T50 but whether a combination of these interventions yields further increases T50 is unknown. Therefore, the effect of substituting acetate for citrate buffer in combination with increases in magnesium concentration in dialysate on T50 was investigated.

Methods: In a randomized, controlled trial, 60 chronic hemodialysis patients were allocated to either continue on standard (S) dialysate (3 mmol/l acetate, 0.5 mmol/l magnesium) or a sequence of magnesium-enriched ($Mg_{0.75}$) dialysate (3 mmol/l acetate, 0.75 mmol/l magnesium) for 2 weeks followed by citrate-buffered, magnesium-enriched (Cit+$Mg_{0.75}$) dialysate (1 mmol/l citrate, 0.75 mmol/l magnesium) for 3 weeks. The primary endpoint was the difference in T50 times between the S group and the Cit+$Mg_{0.75}$ group at 5 weeks.

Results: There was no significant difference in T50 time between the S group compared to the Cit+$Mg_{0.75}$ group (236 ± 77 vs. 265 ± 97 minutes, p=0.23). The size of secondary calciprotein particles (CPP-2_{Rh}) did not differ between the S group and the Cit+$Mg_{0.75}$ group (294 ± 95 vs. 309 ± 91 nm, p=0.55). In longitudinal analyses, serum magnesium concentrations increased from 1.07 ± 0.17 to 1.24 ± 0.17 mmol/l with the $Mg_{0.75}$ dialysate (p<0.0001) but decreased again to 1.19 ± 0.16 mmol/l with the Cit+$Mg_{0.75}$ dialysate (p<0.0001). Serum bicarbonate levels did not change significantly throughout the study.

Conclusions: The combination of citrate-buffer with increased magnesium concentration in dialysate does not improve T50 and may even be antagonistic when administered concurrently.

Histologic Specificity in Calciphylaxis

W. Charles O'Neill,[1] Justin T. Cheeley,[1] Carla L. Ellis,[1,2] Geetha Jagannathan.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]Northwestern University Feinberg School of Medicine, Chicago, IL.*

Background: Skin biopsy is often used to support the diagnosis of calciphylaxis, otherwise termed calcific uremic arteriolopathy (CUA), but the specificity is unknown. We previously showed that many of the findings ascribed to CUA were also present in amputation specimens of patients without CUA. To better understand the specificity of histology in CUA and thus the underlying pathophysiology, we prospectively compared involved and uninvolved tissue from 18 subjects with a clinical diagnosis of CUA.

Methods: 16 patients undergoing skin biopsies for CUA consented for a biopsy of uninvolved skin, usually on the contralateral extremity. In an additional 2 cases, skin samples were obtained at autopsy. Sections were stained with hematoxylin and

eosin and von Kossa calcium stain. The clinical diagnosis was made by the consulting dermatologist, who also performed the punch biopsies. The biopsies were reviewed by one of two pathologists and scored for the following: calcification, thrombosis, or intimal hyperplasia of small arteries or arterioles, and extravascular calcification.

Results: The characteristics of the subjects were as follow: age, 58 +/- 3 years; gender, 67% female; end-stage renal disease, 89%; warfarin use, 50%. Locations of the biopsies were thigh (11), lower leg (4), arm (1), abdominal wall (1), and mons pubis (1). Small vessel calcification was seen in half of the lesional samples and 44% of control samples. Extravascular calcification was seen in 44% of lesional samples and 22% of control samples. In contrast, thrombosis (50%) and intimal hyperplasia (33%) of small vessels were observed only in lesional samples. Of the lesional biopsies with thrombosis or intimal hyperplasia, small vessel calcification was present in 78% and 83% respectively. There were nondiagnostic histologic findings in 6 lesional biopsies and 7 control biopsies.

Conclusions: The similar proportions of small vessel calcification in lesional and control biopsies indicate a lack of any specificity and suggest that this is not sufficient to cause of CUA. Thrombosis or intimal hyperplasia were specific to lesional biopsies, suggesting a pathogenic role and consistent with the ischemic nature of the lesions. While not a specific finding, calcification was present in most of the lesional biopsies with thrombosis or intimal hyperplasia, suggesting a contributory role.

Patients' Experience of Calciphylaxis: Living with a Disease of Uncertain Etiology and Management

Olivia Durant,[1,2] Carmel Salhi,[2] Sagar U. Nigwekar.[1] Kidney Research Center. *[1]Massachusetts General Hospital, Boston, MA; [2]Northeastern University Bouve College of Health Sciences, Boston, MA.*

Background: Calciphylaxis is a condition with sudden, unpredictable onset that predominantly affects people with end-stage renal disease (ESRD). Caused by the calcium-based occlusion of the microvasculature, calciphylaxis results in large, extremely painful non-healing skin ulcers. Calciphylaxis has no cure and a one-year mortality between 40 and 80% for patients who have ESRD. Prior research has focused on identifying the biological mechanisms of the disease with the goal of developing treatment. Little is known about how patients currently living with calciphylaxis manage their illness and care, especially regarding the treatment options and severe, often debilitating, symptoms.

Methods: Using purposive sampling, we recruited participants (n=15) who had contact with a calciphylaxis clinical practice in the Northeast United States. This qualitative study utilized semi-structured phenomenological interviews to investigate the lived experience of patients with calciphylaxis. These 1-hour interviews focused on specific domains of patients' experience: process to diagnosis, treatment process, and social and emotional support.

Results: There were 5 major findings of this study: 1) unpredictability resulting from acuity of disease and uncertain clinical diagnosis and treatment options; 2) severity of pain affecting basic functioning and access to clinical care; 3) central role of social support due to the debilitating nature of pain; 4) coping and challenges of the disease; 5) becoming a self-advocate in the clinical setting in order to navigate clinical care. Two issues tie these findings together. A lack of clinical attention to pain management affected both daily functioning and patients' ability to access other aspects of calciphylaxis care. Patients' experiences of uncertainty were exacerbated by limited communication and lack of coherent calciphylaxis clinical knowledge.

Conclusions: Our findings are the first to describe, in depth, patients' experiences with calciphylaxis. They inform various clinical recommendations, for both calciphylaxis and other conditions with acute, unpredictable onset and potentially debilitating symptoms. In particular, inclusion of pain management specialists as core members of a care team could improve the quality of life of calciphylaxis patients and help communicate the challenges patients face to other members of the care team.

Decision Tree Model Simulating the Burden of Hyperphosphatemia in US Adult Patients with ESKD on Dialysis

Sandeepkumar Balabbigari,[1] Michael Gargano,[2] Darrin W. Benjumea,[2] Quan Doan,[2] Bryce Foote.[1] *[1]Akebia Therapeutics Inc, Cambridge, MA; [2]Genesis Research LLC, Hoboken, NJ.*

Background: Hyperphosphatemia is a common complication in patients with end-stage kidney disease (ESKD) on dialysis. It can lead to vascular calcification, secondary hyperparathyroidism, increased risk for fractures, and other poor health outcomes. It is important to understand the extent of serum phosphate control benefit in this population.

Methods: A decision tree model was built to simulate the population-level effect of reducing serum phosphate levels in US adult patients with ESKD on in-center hemodialysis (n=480,516) over a 5-year time horizon. Patients were assigned an initial serum phosphate level derived from the US Renal Data System's 2022 Annual Data Report, after which a reduction of 2.0 mg/dL was applied. Changes in hospitalization (all-cause, cardiovascular, and fracture), parathyroidectomies, mortality, and healthcare costs were calculated by the model based on published literature and Medicare cost data. The model does not specify how patients' serum phosphate levels are reduced; thus, direct drug costs are not assessed.

Results: The greatest benefit observed with modeled serum phosphate reduction is reduced mortality, with 16,565 fewer deaths occurring over the 5-year period in the simulated population compared with a population that maintained the initial serum phosphate level. There were 46,308 additional all-cause hospitalizations in the simulated population over the same time period, which comprised the majority of an additional $165.9M in Medicare costs. Key limitations of the model are that simulated serum phosphate levels did not fluctuate as they would in the real world, and that the data were derived from older retrospective studies that may not represent the present-day ESKD population.

Conclusions: Simulated reduction of serum phosphate levels in patients with ESKD on dialysis decreased mortality. This pronounced effect in mortality leads to an increase in all-cause hospitalization, resulting in additional Medicare costs. However, serum phosphate control is only one component of managing patients with ESKD on dialysis; there are numerous contending comorbidities and extenuating factors. These results highlight the need to continue exploring how management of patients with ESKD can provide the best patient outcomes.

Impact of Accessibility to Non-Calcium-Based Phosphate Binders and Calcimimetics on Mineral Outcomes in Maintenance Hemodialysis

Sinee Disthabanchong. *Faculty of Medicine, Ramathibodi Hospital, Mahidol University, Krung Thep (Bangkok), Thailand.*

Background: Traditional management of CKD-MBD with calcium and active vitamin D results in hypercalcemia and calcification. Newer drugs including non-calcium-based phosphate binders (NCBPBs) and calcimimetics may help achieving the treatment targets with less hypercalcemia and calcification. In our country, NCBPBs and calcimimetics are not covered in social security and universal coverage reimbursement schemes (SS/UC), whereas they are covered in civil servant and state enterprise reimbursement schemes (CS/SE). Our institution serves both groups of patients providing a unique opportunity to study the differences in mineral outcomes.

Methods: This is a retrospective cohort study that included maintenance hemodialysis (MHD) patients between 2015–2022. Patients were categorized into two groups according to their reimbursement schemes (SS/UC or CS/SE). Differences in mineral parameters were compared using linear mixed models. The composite endpoint of parathyroidectomy and severe hyperparathyroidism (HPT) (PTH ≥1500 pg/mL) was analyzed by multivariate Cox-Proportional Hazard regression.

Results: A total of 714 patients were included. The average serum calcium and phosphate and proportions of patients with hypercalcemia and hyperphosphatemia were substantially higher in SS/UC group compared with CS/SE group. Parathyroid hormone levels were comparable but the proportion of patients with HPT was significantly higher in SS/UC group. The composite endpoint of parathyroidectomy and severe HPT was also significantly higher in SS/UC group. A sensitivity analysis in 563 patients who were prescribed at least 1 type of CKD-MBD medications yielded similar findings.

Conclusions: MHD patients who did not have access to NCBPBs and calcimimetics showed poorer mineral outcomes compared with those who had access to the drugs.

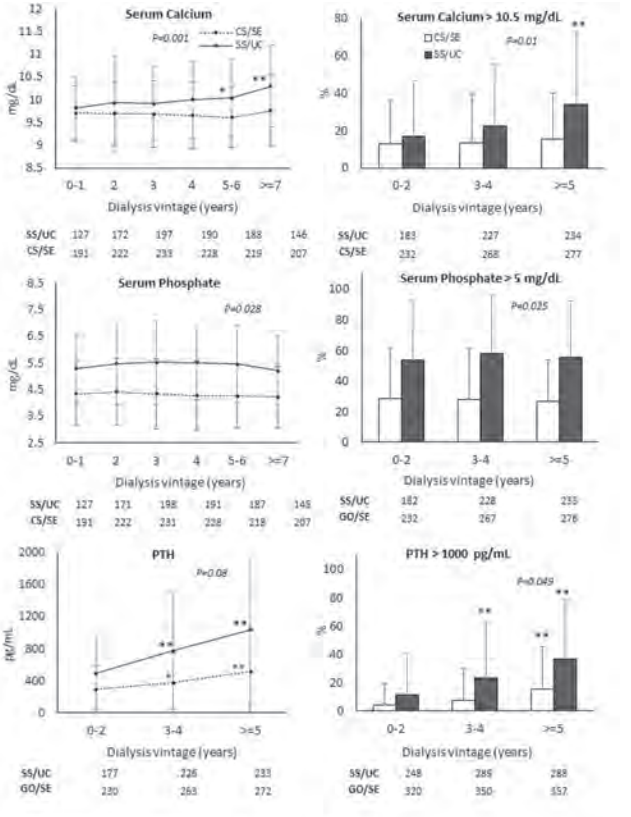

Figure 2 Mineral parameters according to dialysis vintage

Number of available laboratory data are shown below each graph. CS/SE, government/state enterprise; SS/UC, social security/universal coverage. P-values in the graphs represent between group differences over the study period. *P<0.05 and **P<0.001 vs. 0-1 years or 0-2 years of the same group

TH-PO141

Effects of a Low Phosphorus Diet on Phosphorus and Calcium Whole-Body Balance and Intestinal Absorption: Results of a Pilot Study in Adults with Moderate CKD

Kathleen M. Hill Gallant,[1,2] Meryl E. Wastney,[3] Xinyuan Zheng,[1] Sharon M. Moe,[2] Patrick H. Nachman,[1] Dennis Cladis,[1,4] Annabel Biruete,[3,2] Ranjani N. Moorthi.[2] *[1]University of Minnesota Twin Cities, Minneapolis, MN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Purdue University, West Lafayette, IN; [4]Virginia Polytechnic Institute and State University, Blacksburg, VA.*

Background: Dietary P restriction is often used as a management strategy to prevent and treat hyperphosphatemia and CKD-MBD progression. It is presumed that a low P diet results in lower P balance or retention, but this has not been determined, nor the effects on Ca absorption and balance.

Methods: This pilot two-phase crossover, controlled feeding, metabolic balance study investigated the effects of dietary P level (low P [LP], 800 mg/d; high P [HP], 1500 mg/d) on P and Ca balance and absorption in N=3 adults with moderate CKD. Nutrient content was similar, including low Ca (500 mg/d). Each phase consisted of 1wk run-in on the diet, 1wk inpatient metabolic balance, and 3wk washout between phases. Complete timed urine and feces were collected inpatient. Oral and IV Ca and P isotopes were administered and serial serum and urine samples analyzed for their concentrations to determine fractional intestinal absorption by kinetic modeling. Balance was calculated as intake minus urine and fecal excretion. Serum iPTH, iFGF, and 1,25D were measured at baseline and end of each phase.

Results: Intestinal fractional P absorption varied widely among participants (51-95%) but appeared unaffected by dietary P level in all participants. Thus, absolute intestinal P absorption (mg/d) was approximately doubled in the HP compared to the LP. 24h urine P was lower in all participants with the LP diet. The response in P balance to dietary P level varied among subjects. The response in fractional intestinal Ca absorption and Ca balance also varied. 24h urine Ca was very low in all subjects (6-20 mg/d) and did not change with the LP diet. Serum 1,25D was not associated with intestinal fractional P or Ca absorption nor in response to dietary P. iPTH and iFGF23 were lower with LP in two participants who had moderately elevated levels at baseline and with HP.

Conclusions: In adults with moderate CKD, Ca and P balance and intestinal absorption are variable in response to different controlled dietary P intakes. In this pilot study, fractional P absorption did not change with dietary P level and was not associated with 1,25D. Further studies are needed to identify explanatory factors for the observed variation in whole-body Ca and P physiology in adults with CKD.

TH-PO142

Management of Serum Phosphorus over a Six-Month Follow-Up in Home Hemodialysis Patients Prescribed Sucroferric Oxyhydroxide as Part of Routine Clinical Care

Meijiao Zhou,[1] Linda Ficociello,[1] Michael S. Anger,[1] Christopher Kwoh.[2] *[1]Fresenius Medical Care Global Medical Office, Waltham, MA; [2]The Kidney Institute, Houston, TX.*

Background: With the growing use of home hemodialysis (HHD) and the increasing trend of physicians prescribing sucroferric oxyhydroxide (SO) in recent years, this real-world data analysis examines the serum phosphorus (sP) management with SO in HHD patients (pts) over 6 months.

Methods: Eligible HHD pts (n=713) were adults from Fresenius Kidney Care first prescribed SO monotherapy during 9/2016-12/2020 and had sP measured the month (mo) before SO start (-1M). sP was assessed up to 3 months (mos) before (baseline, BL; -3M to -1M) and 6 mos following SO initiation (follow up, FU; M1 to M6). Pts were censored from the analysis upon transplant (n=53), discharge (n=94), and discontinuation of SO (n=177 including n=80 prescribed another phosphate binder (PB) after SO stop). Comparisons of parameters were made between -1M and other mos.

Results: Pts (n=713) were on average 53 years, 42 mos vintage, and 34% female. The PB distribution in pts with PB recorded at BL (78%): sevelamer 51%, calcium acetate 21%, lanthanum carbonate 3%, ferric citrate 8% and >1 PB 16%. sP increased over the BL, from 6.1 mg/dL at -3M to 6.6 mg/dL at -1M but declined after SO start (5.9 to 6.1 mg/dL during FU; p<.0001). Accordingly, the % of pts with sP≤ 5.5 mg/dL increased from 22% at -1M to 43% at M6 (p<.0001), and the % with sP≤ 4.5 mg/dL increased from 9% at -1M to 19% at M6 (p<.0001), with pill burden decreasing from 8.3 to 4.7 pills/day (p<.0001). Serum calcium showed a significant decline from -1M to M6 (9.15 to 9.03 mg/dL, p<.001). No significant changes (p=0.3) were observed in iPTH following SO prescription (518 pg/mL at -1M and 525 to 553 pg/mL during FU).

Conclusions: HHD pts prescribed SO as part of routine clinical care experienced improvements in sP control and reductions in PB pill burden over a 6-month FU, compared to BL.

TH-PO143

Optimal Initiation of Tenapanor Treatment Analyzed by Baseline Phosphate Binder Dose: A Subanalysis of the OPTIMIZE Study

Stuart M. Sprague,[1] Jill M. Meyer,[2] David P. Rosenbaum,[3] Yang Yang,[3] Suling Zhao,[3] David M. Spiegel.[3] *[1]NorthShore University HealthSystem, Evanston, IL; [2]Balboa Nephrology Group, San Diego, CA; [3]Ardelyx, Inc., Waltham, MA.*

Background: Tenapanor (TEN) is a novel phosphate absorption inhibitor that blocks paracellular phosphate absorption by local inhibition of the intestinal sodium hydrogen exchanger isoform 3 (NHE3). TEN is being evaluated for control of serum phosphate (sP) in adult patients (pts) with chronic kidney disease (CKD) on maintenance dialysis. Real world data shows that nearly 80% of pts are unable to consistently maintain adequate control of sP over a 6-month period with the use of phosphate binders (PBs) alone. OPTIMIZE (NCT04549597) was an open-label study of TEN initiation in pts on dialysis that evaluated sP control, pill burden, and quality of life (QOL).

Methods: OPTIMIZE study design was previously described. In Cohort 1 (C1; n=151) pts stopped PBs and initiated TEN 30 mg bid. In Cohort 2 (C2; n=152) pts reduced PB dose by ≥50% and added TEN 30 mg bid. The PB/TEN dose could be adjusted to achieve sP ≤5.5 mg/dL. Dose up-titration for PBs was not allowed until week (wk) 2. Pts in C1 and C2 were categorized into two groups: low PB (LPB) dose (≤6 pills/day at baseline) and high PB (HPB) dose (>6 pills/day at baseline). We evaluated sP response (sP reduction ≥1.2 mg/dL at ≥2 of 3 measurements) at wks 1–4 and wks 6–10 of treatment. A QOL survey was administered at the end of wk 10.

Results: Overall, 87 and 93 HPB pts and 60 and 55 LPB pts were randomized to C1 and C2, respectively. For HPB pts, sP response was achieved at wk 4 by 24.1% (C1) and 47.3% (C2) of pts. Median sP-lowering pill burden (including TEN) reduction at wk 4 was 7 (C1) and 4 (C2) pills/day. For LPB pts, sP response was achieved at wk 4 by 38.3% (C1) and 47.3% (C2) of pts. Median sP-lowering pill burden reduction was 2.5 (C1) and 1 (C2) pills/day. Overall, 60–80% of those who achieved a sP response at wk 4 continued to have a sP response later. Both cohorts achieved consistent sP control throughout the entire study by adding TEN, independent of how TEN was initiated.

Conclusions: Both cohorts experienced improved sP control, self-assessed QOL, and reduction in PB pill burden. HPB pts may have better early sP control by initiating TEN with a 50% reduction in PB dose, while LPB appeared to have a similar early response regardless of TEN initiation method.

TH-PO144

Tenapanor Effect on Decrease in Phosphate Binder Pill Burden for Hyperphosphatemia in Japanese Patients Undergoing Hemodialysis: A Phase 3 Long-Term Study

Keitaro Yokoyama,[1,2] Yu Sato,[3] Meiko Ohara,[3] Kaoru Nakanishi,[3] Masafumi Fukagawa,[4] Tadao Akizawa.[5] *[1]The Jikei University School of Medicine, Tokyo, Japan; [2]Harumi Toriton Clinic of The Jikei University Hospital, Tokyo, Japan; [3]Kyowa Kirin Co., Ltd., Tokyo, Japan; [4]Tokai University School of Medicine, Isehara, Japan; [5]Showa University School of Medicine, Tokyo, Japan.*

Background: Phosphate binders (PBs) are commonly prescribed for treating hyperphosphatemia. However, management with PBs often requires a high pill burden which is a significant issue in hemodialysis (HD) patients. Tenapanor (TEN) is a novel drug that reduces paracellular phosphorus absorption via the selective inhibition of sodium/hydrogen exchanger isoform 3, and the dose consists of one small tablet taken twice daily. We aimed to evaluate the ability of TEN to decrease PB pill burden for hyperphosphatemia in Japanese HD patients in the long-term safety study.

Methods: This was a multicenter, open-label, single-arm, phase 3 study. HD patients whose serum phosphorus level was 3.5–7.0 mg/dL at baseline received TEN 5 mg BID added to their PB regimen. The TEN dose was titrated in a stepwise manner within the range of 5, 10, 20 and 30 mg BID. The dose of TEN and PBs was adjusted based on serum phosphorus levels from Week 2, while controlling serum phosphorus levels and switching

from PBs to TEN. While the primary endpoint was safety of the 52-week TEN treatment, the key secondary endpoint was a ≥30% reduction in the total pill number of daily PBs and TEN from baseline.

Results: Overall, 212 patients started treatment, and 154 patients completed the study. At Week 52 or the time of discontinuation, 158 patients (77.5%) achieved a ≥30% reduction in the total daily pill number of PBs and TEN. Complete switching from PBs to TEN was achieved in 93 patients (45.6%). From Week 0 to Week 52, the mean (SD) daily pill number of PBs decreased from 11.4 (7.62) to 3.1 (5.48). Mean (SD) serum phosphorus levels were well controlled, 5.24 (0.96), 4.01 (1.14), and 5.11 (1.17) mg/dL at baseline, Week 2, and Week 52, respectively. The major drug-related adverse event was diarrhea (56.6%), and most events were mild in severity. Nine patients (4.2%) discontinued because of diarrhea. There were no clinically relevant changes other than serum phosphorus level for study period.

Conclusions: TEN demonstrated its ability to significantly decrease the pill number of PBs and was well tolerated in the long-term administration. These results suggest that TEN could achieve the dual targets of decreasing PB pill burden and controlling serum phosphorus levels.

Efficacy and Safety of Tenapanor in Japanese Peritoneal Dialysis Patients with Hyperphosphatemia: Results of a Phase 3 Study

Minoru Kubota,[1] Kazuaki Ikejiri,[2] Miho Kusakabe,[2] Kaoru Nakanishi,[2] Masafumi Fukagawa,[3] Tadao Akizawa.[4] *[1]Hakuhoukai Ouji Hospital, Tokyo, Japan; [2]Kyowa Kirin Co., Ltd., Tokyo, Japan; [3]Tokai University School of Medicine, Kanagawa, Japan; [4]Showa University School of Medicine, Tokyo, Japan.*

Background: Hyperphosphatemia develops in most peritoneal dialysis (PD) patients and is treated with diet and phosphorus binders (PBs), however some patients do not respond adequately to these treatments. Tenapanor is a novel drug for hyperphosphatemia that blocks intercellular influx of phosphorus from intestinal tract by binding the sodium/hydrogen exchanger 3 transporter (NHE3) expressed on the apical membrane of intestinal epithelial cells. This is the first study to evaluate the efficacy and safety of tenapanor in Japanese PD patients with hyperphosphatemia.

Methods: This was a multicenter, open-label, single-arm, phase 3 study in Japanese PD patients with hyperphosphatemia. The study consisted of a screening period, PB-washout period, and treatment period. Patients were enrolled if serum phosphorus level was 3.5–7.0 mg/dL at screening and elevated to 6.1–9.9 mg/dL after PB-washout. Tenapanor dose was started at 5 mg and titrated to a maximum of 30 mg for 16 weeks to manage serum phosphorus levels within the target range of 3.5–6.0 mg/dL. After week 8, use of only one PB was allowed when serum phosphorus levels were not in the target range. The primary endpoint was the mean change in serum phosphorus at week 8 from baseline. The data for the change in serum phosphorus levels from baseline were carried forward for missing changes using the last observation carried forward method.

Results: A total of 54 subjects received tenapanor. Serum phosphorus levels decreased from a baseline of 7.65 mg/dL to 6.14 mg/dL in week 8 and 5.44 mg/dL in week 16. The change in serum phosphorus at week 8 (primary endpoint) and at week 16 from baseline was −1.18 mg/dL (95% confidence interval −1.54 mg/dL, −0.81 mg/dL) and −1.65 mg/dL, respectively. The proportion of patients who achieved the target levels at week 8 and at week 16 was 46.3% (19/41) and 76.5% (26/34), respectively. The most common adverse event was diarrhea (74.1%, 40/54). All were mild or moderate in severity and only three subjects (5.6%) discontinued due to diarrhea. These results were comparable to those of the phase 3 study in Japanese hemodialysis (HD) patients.

Conclusions: Tenapanor could be a new treatment option for PD patients with hyperphosphatemia as well as HD patients.

Funding: Commercial Support - Kyowa Kirin Co., Ltd.

TH-PO146

Safety Analysis of Tenapanor Monotherapy vs. Sevelamer Carbonate in Patients on Maintenance Dialysis with Hyperphosphatemia

Arnold L. Silva,[1] German T. Hernandez,[2] David M. Spiegel,[3] David P. Rosenbaum,[3] Susan A. Edelstein,[3] Yang Yang,[3] Suling Zhao,[3] Laura Williams.[3] *[1]Boise Kidney & Hypertension Institute, Nampa, IN; [2]El Paso Kidney Specialists, El Paso, TX; [3]Ardelyx, Inc., Waltham, MA.*

Background: Tenapanor (TEN) is a novel phosphate absorption inhibitor that blocks paracellular phosphate absorption by local inhibition of the intestinal sodium hydrogen exchanger isoform 3 (NHE3). TEN is being evaluated for the control of serum phosphate (sP) in adult patients (pts) with chronic kidney disease on maintenance dialysis. PHREEDOM (NCT03427125) was a phase 3 trial that evaluated TEN in pts on dialysis with HP. The phosphate binder (PB) sevelamer (SEV) was used as a safety control. Here we evaluate overall safety from PHREEDOM and present exposure-adjusted safety analyses.

Methods: The study design has been previously described. The trial enrolled pts on maintenance dialysis with sP ≤10.0 mg/dL and an sP increase ≥1.5 mg/dL after PB washout. The first 26 weeks was an open-label randomized treatment period (RTP) with pts randomized 3:1 to TEN 30 mg bid or SEV per package insert. Safety data collected during the RTP were from pts who received ≥1 dose of study drug. We calculated the exposure-adjusted incidence rates per 100 pt-years.

Results: Safety data is shown in the **Table**. 63.5% of pts randomized to the SEV arm (n=137) had received SEV prior to study entry. During the RTP, one death occurred in the TEN arm (n=419) due to a treatment-emergent adverse event (AE) unrelated to TEN. While the incidence of AEs leading to study drug discontinuation was higher in the TEN arm, the incidence of serious AEs (SAEs) and AEs leading to hospitalization was lower in the TEN arm than the SEV arm. The exposure-adjusted rates of SAEs were similar in both arms.

Conclusions: Incidence of AEs leading to hospitalization was lower in the TEN arm than the SEV arm. The analysis confirmed TEN has an acceptable safety profile.

Funding: Commercial Support - Ardelyx, Inc.

	TEN (n=419)	SEV (n=137)
Pt-years	157.4	64.3
Pts with any treatment-emergent AE (TEAE), n (%)*	337 (80.4%)	88 (64.2%)
Exposure-adjusted incidence rate of AEs per 100 pt-years	214.1	136.9
Pts with any serious TEAE, n (%)	73 (17.4%)	32 (23.4%)
Exposure-adjusted incidence rate of serious AEs per 100 pt-years	46.4	49.8
Pts with any TEAE leading to death, n (%)	1 (0.2%)	0
Pts with any TEAE leading to study drug discontinuation, n (%)	102 (24.3%)	2 (1.5%)
Pts with any TEAE leading to hospitalization, n (%)	73 (17.4%)	32 (23.4%)

*63.5% of pts in the SEV arm had received SEV prior to study entry, potentially confounding the interpretation of AEs in favor of SEV, as demonstrated by the lower AE incidence than reported in its label. Serious AEs should have been largely unaffected by prior exposure.

TH-PO147

Patient Education Improves Tenapanor Tolerability in OPTIMIZE Study

Stephen Z. Fadem,[1] David P. Tietjen,[2] David M. Spiegel,[3] Susan A. Edelstein,[3] Yang Yang,[3] David P. Rosenbaum.[3] *[1]Kidney Associates, Houston, TX; [2]Nephrology Consultants, Huntsville, AL; [3]Ardelyx, Inc., Waltham, MA.*

Background: Tenapanor (TEN) is a novel phosphate absorption inhibitor that blocks paracellular phosphate absorption by local inhibition of the intestinal sodium hydrogen exchanger isoform 3 (NHE3). TEN is being evaluated for the control of serum phosphate (sP) in adult patients (pts) with chronic kidney disease (CKD) on maintenance dialysis. TEN has demonstrated efficacy and acceptable safety in two pivotal monotherapy hyperphosphatemia clinical studies, BLOCK (NCT02675998) and PHREEDOM (NCT03427125). Diarrhea was the most common adverse event, observed in >5% of pts. Here, we evaluate the benefit of pt education on gastrointestinal tolerability during the OPTIMIZE (NCT04549597) study.

Methods: Methods for the trials have been previously described. The majority of patients were started on TEN at 30 mg bid. We assessed data from the analysis period in BLOCK (8-week treatment period [TP]), PHREEDOM (first 8 weeks of TP), and OPTIMIZE (10-week TP). In OPTIMIZE, pts were educated at study start about TEN, how to take TEN, what they may experience on TEN, medications to be discontinued before starting TEN, and how best to mitigate the potential onset of loose stools or diarrhea.

Results: As expected, given the mechanism of action and data from past trials, most diarrhea events (75.7%–79.6%) occurred within the first 2 weeks of treatment in all three studies and the majority of cases were mild to moderate. Overall, the diarrhea incidence was lower during the analysis period in OPTIMIZE (39.3%) than in BLOCK and PHREEDOM (47.9% and 47.7%, respectively), and was also lower during the first two weeks of study treatment in OPTIMIZE (33.6%) vs BLOCK and PHREEDOM (38.0% and 39.4%). Discontinuation rates due to diarrhea were lower during the 10-week analysis period of OPTIMIZE (6.0%) than the 8-week analysis periods of BLOCK or PHREEDOM (7.0% and 13.4%).

Conclusions: Pt education may help ameliorate TEN-related diarrhea in dialysis pts. Specifically, since many pts on dialysis take medications to alleviate constipation, advising pts to discontinue these medications prior to starting TEN may also help reduce the occurrence of diarrhea.

Association Between Sevelamer Use and Risk of Gastrointestinal Bleeding in Patients with Kidney Failure

Dustin Le,[1] Deidra C. Crews,[1] Morgan Grams,[2] Josef Coresh,[3] Jung-Im Shin.[3] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]New York University Grossman School of Medicine, New York, NY; [3]Johns Hopkins University Welch Center for Prevention Epidemiology and Clinical Research, Baltimore, MD.*

Background: Phosphate binders are used to manage hyperphosphatemia in patients with kidney failure requiring replacement therapy. There have been multiple case reports postulating an association between sevelamer use and risk of gastrointestinal bleeding (GIB).

Methods: Using the US Renal Data System and Medicare Parts A, B, and D claims data from 2015 to 2019, we compared the risk of incident GIB hospitalization and death between sevelamer initiation and non-sevelamer phosphate binder initiation among patients on incident hemodialysis (new user, active comparator). We fit Cox regression models with inverse probability of treatment weights to estimate the adjusted hazard ratios (HR) and repeated across relevant subgroups.

Results: We identified 19,939 sevelamer and 19,166 non-sevelamer containing phosphate binder users (mean age 69 years, 52% females, 70% White, 24% Black, and mean dialysis vintage 8.2 months). There were 5,904 GIB hospitalizations and 12,591 deaths after an average of 1.8 years of follow-up. Compared with initiation of

non-sevelamer binders, sevelamer was not associated with an increased risk of GIB hospitalization (HR 1.02, 95% CI 0.97 – 1.07) or all-cause mortality (HR 1.01 95% CI 0.98 – 1.05). Findings were similar across key subgroups, including those defined by diabetes, smoking, anticoagulation, sodium polystyrene, and cholestyramine status.

Conclusions: The initiation of sevelamer versus non-sevelamer containing phosphate binders was not associated with an increased risk of GIB hospitalization in patients on hemodialysis.

Table. IPTW-HR of Incident Gastrointestinal Bleed (GIB) After Phosphate Binder Initiation in Patients on Hemodialysis using an Intention-To-Treat Analysis

	Unweighted No. of Events/N		IPTW-IR (95% CI), per 1000 PYs		
Intention to Treat	Sevelamer	Non-Sevelamer	Sevelamer	Non-Sevelamer	IPTW-HR
Total GIB[a]	3,021/19,939	2883/19,166	86 (81, 90)	84 (81, 87)	1.02 (0.97 - 1.07)
Upper	1,631 (54%)	1,511 (52%)	49 (46, 53)	46 (44, 49)	1.06 (0.99 - 1.13)
Lower	422 (14%)	412 (14%)	13 (11, 15)	13 (12, 15)	0.98 (0.85 - 1.12)
NOS	968 (32%)	960 (33%)	30 (27, 32)	30 (29, 32)	0.97 (0.89 - 1.07)

Calcimimetic Reimbursement Changes in 2021: Impact of Etelcalcetide Discontinuation on Parathyroid Hormone (PTH) Levels in US Hemodialysis Patients

Angelo Karaboyas,[1] Junhui Zhao,[1] Junjie Ma,[2] Carol Moore,[2] Najma Saleem,[2] Kevin J. Martin,[3] Stuart M. Sprague,[4] Ronald L. Pisoni.[1] *[1]Arbor Research Collaborative for Health, Ann Arbor, MI; [2]Amgen, Thousand Oaks, CA; [3]Saint Louis University School of Medicine, Saint Louis, MO; [4]NorthShore University HealthSystem, Evanston, IL.*

Background: Calcimimetics, including etelcalcetide and cinacalcet, are often prescribed to hemodialysis (HD) patients to prevent complications of elevated parathyroid hormone (PTH) levels. In January 2021, US reimbursement policy switched from the transitional drug add-on payment adjustment (TDAPA) to an increased bundled payment, with $10.09 per session added for all patients to cover the expense for calcimimetics, whether patients are taking etelcalcetide or not. The impact on calcimimetic prescription practices and mineral and bone disorder (MBD) markers is unknown.

Methods: Data from 23,359 US in-center HD patients were extracted from the prospective Dialysis Outcomes and Practice Patterns Study (DOPPS). Within-patient changes in PTH and other MBD markers in the 6 months before (pre) vs. 6 months after (post) etelcalcetide discontinuation were compared using linear regression among patients who discontinued etelcalcetide between December 2020 to April 2021 – when discontinuation was more likely driven by policy change than patient indication.

Results: From July 2020 to July 2021, etelcalcetide use decreased from 12% to 5%. Among 713 patients who discontinued etelcalcetide between December 2020 and April 2021, the prevalence of PTH >600 pg/mL increased from 28% to 43% overall and from 32% to 50% among Black patients. Mean serum calcium and phosphorus levels increased by 0.42 and 0.16 mg/dL, respectively. Adjusted model results were consistent (Figure).

Conclusions: In the US HD setting, etelcalcetide use decreased substantially following the end of TDAPA designation in January 2021 in spite of the increased bundle payment. We observed a swift and sustained impact on PTH levels, especially among Black patients, raising concerns about disparities and potential downstream impact on clinical outcomes.

Etelcalcetide and Long-Term Control of Parathyroid Hormone Levels

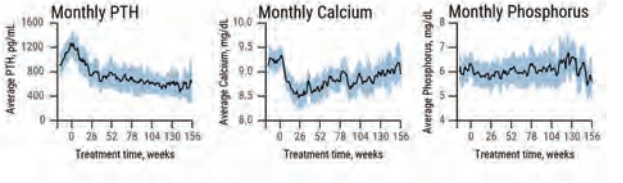
Jose E. Navarrete,[1] Vanessa L. Hunt,[2] Olivia Haeberle,[2] Jason Cobb,[1] Tahsin Masud,[1] Anees Quyyumi.[1] *[1]Emory University School of Medicine, Atlanta, GA; [2]HSM Medical Services, Atlanta, GA.*

Background: Secondary hyperparathyroidism is a common situation in end stage kidney disease patients receiving hemodialysis. Elevated PTH levels have correlated with vascular complications, accelerated vascular calcification and abnormal bone metabolism, and in clinical practice is used as a surrogate of bone health. Etelcalcetide was approved by the FDA in 2017 for control of moderate to severe hyperparathyroidism in hemodialysis patients. Original studies evaluated the efficacy and safety for a period of up to 26 weeks. The long-term efficacy in controlling PTH levels as well as calcium and phosphorus has not been described.

Methods: All hemodialysis patients treated with Etelcalcetide at Emory hemodialysis centers for at least 3 months were identified and their medical records reviewed. Patients were followed while on treatment if Etelcaetide. Basic demographic information and laboratory data were extracted from the medical record. Median values with IQR are presented unless stated otherwise.

Results: Since 2018, 209 hemodialysis patients were treated with Etelcalcetide and 185 of them received the drug for at least 3 months and represent the study cohort described here. 50% were female. Age was 58 (48-68) years, predominantly Black (96%) and the time on renal replacement therapy before initiation of Etelcalcetide was 4.6 (2.5-7.9) years. Figure 1 shows average PTH, calcium and phosphorus levels during treatment with Etelcalcetide. Median (IQR) PTH levels decreased from 1050pg/mL (861-1396) at time zero to 550pg/mL (351-890) at 6 months and the proportion of patients with PTH below 600 pg/mL was 58.4% compared to 0% at the beginning of treatment. Use of Etelcalcetide was associated with significant reductions of serum calcium specially during the first 6 months of treatment. Phosphorus levels were not significantly affected by the use of Etelcalcetide.

Conclusions: Etelcalcetide was effective lowering serum PTH in a sample of predominantly black patients. The effects of the drug were sustained over a period of 3 years. Treatment with Etelcalcetide was associated with significant decrease in serum calcium during the first 6 months of treatment.



TH-PO151

Predictors of Post-Parathyroidectomy Hypocalcemia in ESRD Patients with Resistant Renal Hyperparathyroidism

Fangxia Chen, Wan Limm Looi, Zi Kheng Tan, See Cheng Yeo, Manohar Bairy.
Tan Tock Seng Hospital, Singapore, Singapore.

Background: Post-operative hypocalcemia following parathyroidectomy (PTX) for resistant renal hyperparathyroidism(rRHPT) is a major complication that is preventable yet highly prevalent despite protocolized perioperative management. We aimed to determine the predictors of post operative hypocalcemia in our centre from patient characteristics and routine biochemical parameters in order to aid our review of the current centre protocol.

Methods: 75 ESKD patients who underwent parathyroidectomy for rRHPT between May 2016 and October 2022 were enrolled in the study. We collected patients' demographic data, serum levels of albumin, calcium, phosphate, intact parathyroid hormone (iPTH), alkaline phosphatase (ALP), doses of phosphate binders (calcium based and non-calcium based), vitamin D and cinacalcet before and for up to seven days after parathyroidectomy.ROC curves with AUC for iPTH and ALP levels against hypocalcemia were used to determine cutoffs. Multivariable logistic regression model was used to determine the odds ratio and as the incidence rate of the outcome was high, generalized linear models using Poisson regression with robust error variance were used to estimate relative risk.

Results: 37 men and 38 women with mean age of 53.8 ± 11.4 years at the time of surgery were enrolled. The median serum iPTH and ALP levels were 169.8 pmol/L (IQR 113.7, 266.7) and 272U/L (IQR 169, 463) respectively. The mean dialysis vintage was 73.4 months. 43(57%) patients developed severe hypocalcaemia (< 2mmol/L). Patients with severe hypocalcaemia had higher median pre-operative serum iPTH and ALP levels (216pmol/L vs.129.75pmol/L, 380U/L vs. 220.5U/L respectively) and significantly longer mean post operative hospitalization (10.5 vs 4.3 days). Preoperative iPTH level was the only significant predictor of hypocalcemia. iPTH level of >166 pmol/L had 72% sensitivity and 73% specificity for predicting post-operative hypocalcaemia with a relative risk of 2.00 [95% CI 1.27-3.33], p=0.003.

Conclusions: Pre-operative iPTH levels >166 pmol/L can predict post PTX hypocalcemia in ESRD patients. A clinical protocol utilising this iPTH level for risk stratification to determine frequency of calcium level monitoring and calcium and vitamin D supplementation in the peri operative period may help reduce the risk of hypocalcemia.

TH-PO152

The Importance of Parathormone Control in Kidney Transplant Candidates to Avoid Persistent Hyperparathyroidism and Graft Dysfunction

Lorena C. Mainardes,[1] Rosilene M. Elias,[1] Eduardo J. Duque,[1] Vanda Jorgetti,[1] Thomas Nickolas,[2] Elias David-Neto,[1] Rosa M. Moyses.[1]
[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Columbia University, New York, NY.

Background: Persistent hyperparathyroidism (PHPT) after kidney transplantation (KTX) has been associated with poor graft outcome, bone loss, increased risk of fracture, and cardiovascular morbidity. In Brazil, there is a high prevalence of secondary hyperparathyroidism (SHPT) among patients on hemodialysis. We hypothesized that SHPT would increase the incidence of PHPT, which, in turn, would be associated with graft dysfunction.

Methods: We analyzed data from a retrospective cohort of 3,492 patients enrolled in a kidney transplant waiting list at a tertiary Hospital from Jan/2011 to Dec/2020. Parathormone (PTH) was measured in 2,910 individuals, and 870 patients were submitted to KTX during the study. PHPT was defined as calcium > 10.2 mg/dl and/or PTH > 100 pg/ml. Poor graft function was defined as eGFR < 30 ml/min 1 year after KTX.

Results: In the entire cohort, median PTH was 287 (142-544) pg/ml; 1,396 (47.9%) had PTH > 300 pg/ml; 654 (22.4%) had PTH > 9 times the upper limit of the reference range and 399 (13.7%) had > 800 pg/ml, which should be indicative of parathyroidectomy (PTX). However, only 58 (1.9%) were previously submitted to PTX. In those who were submitted to KTX, 428 (49.1%) had PTH > 100 pg/ml, 133 (16.4%) had total calcium > 10.2 mg/dl, and 460 (52.8%) had PHPT after 12 months. PHPT was independently associated with pre-KTX calcium (each 1 mg/dl of Ca increased the risk by 51.6%), PTH (each 100 pg/ml increased the risk by 20%) and graft function (each 1 ml/min increase in eGFR was associated with a decrease in the risk of PHPT by 2.1%). PTX was performed only in 17 patients (2%) during the first year after KTX. PHPT increased the risk of poor graft function by 2.3 times (P<0.001), in a model adjusted for age, sex, race, and donor type.

Conclusions: The high prevalence of SHPT in patients waiting for a kidney transplant is associated with an increased proportion of KTX recipients with PHTP. The consequent impact of PHPT on graft function highlights that CKD-MBD management must be a priority for all CKD patients, even KTX candidates.

Long-Term Effects of Hypercalcemia in Kidney Transplant Recipients with Persistent Hyperparathyroidism

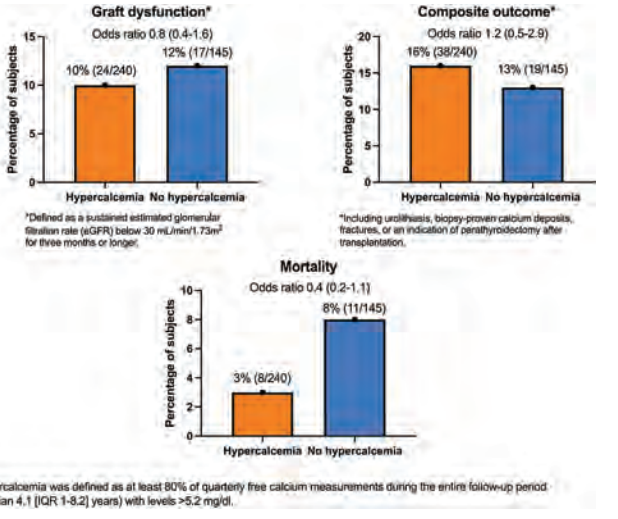
Gabriel Cojuc,[1,2] Lluvia A. Marino-Vazquez,[1] Nathalie D. Pichardo,[1] Cristino Cruz Rivera,[1] Alfredo A. Reza-Albarrán,[1] Ricardo Correa-Rotter,[1] Luis E. Morales-Buenrostro,[1] Juan Carlos Ramirez-Sandoval.[1] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Red de Universidades Anahuac, Naucalpan de Juarez, Mexico.*

Background: Hypercalcemia is prevalent in kidney transplant recipients (KTRs) with hyperparathyroidism. However, its long-term impact on graft function is uncertain.

Methods: Prospective cohort study investigating adverse graft outcomes associated with persistent hypercalcemia (free calcium >5.2 mg/dL in ≥80% of measures) and inappropriately elevated PTH (>30 pg/mL) in KTRs. Asymptomatic mild hypercalcemia was observed unless complications developed.

Results: We included 385 KTRs. During a 4-year (IQR 1-8.2) median follow-up, 62% of KTRs presented persistent hypercalcemia. Compared to KTRs without hypercalcemia, there were no significant differences in graft dysfunction (10% Vs. 12%, p=0.61), symptomatic urolithiasis (5% Vs. 3%, p=0.43), biopsy-proven calcium deposits (6% Vs. 5%, p=1.0), fractures (6% Vs. 4%, p=0.64), and a composite outcome of urolithiasis, calcium deposits, fractures, and parathyroidectomy indication (10% Vs. 5%, p=0.55) in subjects with persistent hypercalcemia. In a subset of 76 KTRs, those with persistent hypercalcemia had higher urinary calcium (median 84 [43-170] Vs. 38 [24-64] mg/day, p=0.03) and iFGF23 (median 36 [24-54] Vs. 27 [19-40] pg/mL, p=0.04) levels, and lower 25D levels (11.3±1.2 Vs. 16.3±1.4 ng/mL, p<0.001). An iPTH level <300 pg/mL was associated with a reduced risk of post-transplant hypercalcemia in a multivariate analysis (OR 0.51, 95% CI 0.32-0.80).

Conclusions: Long-term persistent mild hypercalcemia, with inappropriately elevated iPTH, was frequent in KTRs after transplantation. This condition closely resembled a mild form of primary hyperparathyroidism, with hypophosphatemia and hypovitaminosis D as well as increased urinary calcium and iFGF23 levels. Despite these symptoms, the risk of adverse graft outcomes was low.



Outcomes associated with hypercalcemia

How Do We Treat Mineral Bone Disease After Transplantation? A Single-Centre Experience

Thomas B. Coupe,[1] Francisco Montero,[1] Rouven Calayag,[1] Rosa M. Montero.[1,2] *[1]St George's University Hospitals NHS Foundation Trust, London, United Kingdom; [2]King's College London, London, United Kingdom.*

Background: Mineral bone disease (MBD) causes increased morbidity and mortality. Previous studies report resolution of hyperparathyroidism in 30% of kidney transplant recipients (KTR) after 1 year and 57% 2 years post transplantation. Current guidelines recommend different strategies of treating hyperparathyroidism without guidance on de-escalation of therapy post transplant. Some centres stop all MBD treatment at the time of transplantation. We looked to determine what medical treatments our KTR were taking for management of MBD.

Methods: A cross-sectional retrospective observational study of all KTR at our centre between 2021-2022 were included. Clinical outcome data was collected from electronic patient records including medications were grouped into; Cinacalcet, Alfacalcidol, Vitamin D3(VitD3) and/or combinations of these for treatment of MBD. The length of time KTR were on these medications and biochemical data was collected. Paired t-tests and ANOVA were used to perform statistical analysis with a $p<0.05$ significant level.

Results: There were 509 KTR between 2021-2022. 9 were excluded due to missing data. 275 male, 225 female with a median age 56yrs (21-87yrs). 500 KTR; 2% were on Cinacalcet, 4% Cinacalcet+Alfacalcidol, 1% Cinacalcet+Alfacalcidol+VitD3, 30% Alfacalcidol, 15% Alfacalcidol+VitD3, 21% VitD3 and 27% on none. Mean time after transplantation was; 8.1yrs, 6.4yrs, 7.1yrs, 7.7yrs, 10.6yrs, 10.7yrs and 10.6yrs, respectively. Mean Creatinine was significantly different between the 2021 and 2022 in the different treatment groups ($p<0.04$) with no significant changes in mean GFR. Mean Creatinine in all the groups except the cinacalcet alone decreased. Those on Cinacalcet+Alfacalcidol or Cinacalcet+Alfacalcidol+VitD3 had the highest creatinine's that decreased from 2021 to 2022. Mean PTH (pmol/L) levels decreased from 2021-2022 in all of the groups (11.7-10.7, 36-14.2, 71.8-61.3, 16.2-13.1, 12-8, 10-9, 9.2-8.7, respectively, $p<0.05$). Calcium adjusted (CA) levels were lower in the Alfacalcidol+VitD3 and VitD3 groups alone (2.0mmol/L). Mean Phosphate levels remain unchanged. Phosphate binders were used in all groups except Cinacalcet and VitaminD3.

Conclusions: A range of combination therapies are used for MBD management. We propose a de-escalation of therapy post transplantation guidance will reduce polypharmacy. Limitation is a single centre experience.

TH-PO155

Bone Disease in Kidney Transplantation: How Are the Bones of Long-Term Kidney Transplant Recipients?

Italo R. Alves, Ana Paula Gueiros, Jose E. Gueiros. *Hospital das Clinicas, Recife, Brazil.*

Background: Kidney transplant (KT) recipients may present persistent chronic kidney disease mineral and bone metabolism disorder (CKD-MBD), changes in bone turnover secondary to immunosuppression, de-novo MBD, and age-related bone loss. The aim of this study was to assess the osteometabolic profile and factors associated with loss of bone mass in long-term transplant patients.

Methods: This was a cross-sectional, retrospective study. Clinical parameters assessed were: age, sex, CKD etiology, dialysis time, KT time, donor type, and immunosuppression. Laboratory tests: intact parathyroid hormone (iPTH pg/dL), calcium, phosphorus, total alkaline phosphatase, 25OH vit D, creatinine and glomerular filtration rate (GFR). Bone mineral density was assessed using densitometry. According to the T-score, patients were divided into two groups: osteoporosis (T-score ≤ -2.5) and non-osteoporosis (T-score > -2.5). A comparative analysis between groups was performed; univariate and multivariate analyzes were undertaken to determine the risk factors for osteoporosis.

Results: We studied 38 patients (60.5% female), with a median age of 57 years, 74% with CKD of undetermined etiology, the median time of dialysis 71 months. Seventy-one percent of KT were from deceased donors and the median time of KT was 181 months. The median GFR was 54 mL/min. The median T-score in the femoral neck and lumbar spine were -1.9 and -2.5, respectively. Twenty patients (52.6%) presented osteoporosis. Patients with and without osteoporosis were distinguished by: age (62 x 50; p=0.002), KT time (252 x 95; p=0.009), iPTH (131 x 234; p=0.034) and use of tacrolimus (35% x 72%; p=0.025). Univariate analysis revealed that age (OR: 1.13; p=0.004), KT time (OR: 1.01; p=0.01) and use of tacrolimus (OR: 0.21; p=0.025) were associated with osteoporosis. In the multivariate analysis, only age (OR: 1.12; p=0.025) was an independent risk for osteoporosis. We observed a positive correlation between iPTH and the T-score, in the lumbar spine (R 0.25; p=0.028) and in the femoral neck (R 0.35; p=0.003).

Conclusions: In long-term kidney transplant recipients, we observed a high prevalence of osteoporosis and confirmed that the loss of bone mass is determined by aging. In the late phase of KT, lower iPTH levels seem to be more associated with loss of bone mass.

TH-PO156

Efficacy of Cinacalcet in the Treatment of Persistent Hyperparathyroidism in Late Kidney Transplantation

Italo R. Alves, Ana Paula Gueiros, Jose E. Gueiros. *Hospital das Clinicas, Recife, Brazil.*

Background: Despite the recovery of renal function after a successful kidney transplant (KT), 20 to 50% of patients present with persistent hyperparathyroidism (PHPT) at the end of the first year, with a low chance of spontaneous remission over time. Permanently high levels of parathyroid hormone (PTH) causes hypercalcemia, hypophosphatemia and loss of bone mass. Most studies that assess the effectiveness of cinacalcet in PHPT have included patients with less than 5 years of KT. The aim of this study was to assess the response to cinacalcet in patients with PHPT with a long duration of KT.

Methods: This was a retrospective observational study. The definition of PHPT was: intact PTH (iPTH)>100 pg/dL and calcium (Ca)>10.5 mg/dL, in patients with glomerular filtration rate (GFR CKD-EPI)>30mL/min/1.73m^2. Ca control (Ca≤10.5) was considered as a response to cinacalcet. According to the response, patients were divided into two groups: responder (RG) and non-responder (NRG). The clinical parameters assessed were: age, sex, etiology of chronic kidney disease (CKD), time on dialysis, time on KT, type of donor and immunosuppression. The laboratory parameters were: iPTH, Ca, phosphorus (mg/dL), total alkaline phosphatase (U/L), creatinine (mg/dL) and GFR. The observation period was one year. A comparative analysis was performed between the groups, as well as an analysis of how the exam results evolved over time.

Results: Twenty patients were included in the study, with a median GFR of 63 mL/min/1.73m^2, (60% female), a median age of 57 years, most with CKD of undetermined etiology, a median time on dialysis of 59 months and a median time of KT of 108 months (70 % deceased donors). A response to cinacalcet was observed in 75% of patients. At baseline, there was no difference between the RG and NRG, except for the iPTH which tended to be lower in the RG (216 x 494; p=0.06). Over the course of a year, Ca in the RG decreased from 10.7 to 9.4 (p=0.003), the same occurred with iPTH, from 216 to 88 (p=0.02). No changes were observed in the Ca and iPTH of the NRG group. The GFR remained stable throughout the observation period in both groups.

Conclusions: Cinacalcet proved to be effective and safe in the treatment of PHPT, even after almost a decade of KT. Our results suggest that the initial iPTH levels seem to influence the response to cinacalcet.

TH-PO157

Dietary Vitamin K Is Inversely Associated with Parathyroid Hormone (PTH) in People with CKD: The PROGREDIR Cohort Study

Alisson D. Machado,[1] Dirce Marchioni,[1] Isabela M. Bensenor,[2] Paulo Lotufo,[2] Rosa M. Moyses,[2] Silvia Titan.[3] *[1]Universidade de Sao Paulo Faculdade de Saude Publica, Sao Paulo, Brazil; [2]Universidade de Sao Paulo Faculdade de Medicina, Sao Paulo, Brazil; [3]Mayo Clinic Minnesota, Rochester, MN.*

Background: Dietary intake has a relevant role in mineral and bone disorder in chronic kidney disease (CKD-MBD), being an important part of the treatment of this condition. However, most studies have focused on intake of phosphorus and calcium, and there is limited literature on possible nutritional determinants of parathyroid hormone (PTH) and fibroblast growth factor 23 (FGF23). In this study, we evaluated the association of macro and micronutrients from dietary intake with intact PTH (iPTH), 1-84 PTH, and FGF23 in a cohort of people with CKD.

Methods: We included 441 participants from the Progredir Study, a cohort of people with CKD based in São Paulo, Brazil. Food and nutrient intakes were estimated by a food frequency questionnaire. We evaluated the association of these variables with iPTH, 1-84 PTH, and FGF23 by linear regression using SPSS software (version 21).

Results: The median age and 2021 CKD-EPI eGFR were 68 years old and 40 mL/min/1.73 m2, respectively. The median iPTH was 92 pg/mL (IQR 63, 140), 1-84 PTH was 36 pg/mL (IQR 28, 51), and FGF23 was 93 pg/mL (IQR 69, 128). In the univariate linear regression, vitamin K was associated with log iPTH and 1-84 PTH. No associations were observed for FGF-23 and macro or micronutrients. After adjusting for age, sex, eGFR, skin color, diabetes, nutritional status, energy intake, serum calcium, calcium carbonate use, and warfarin use, vitamin K intake remained associated with iPTH (β = -0.13, 95% CI -0.21, -0.04, p = 0.003). Similar result was seen for 1-84 PTH (β = -0.08, 95% CI -0.14, -0.02, p = 0.02).

Conclusions: In these analyses, dietary vitamin K intake was inversely associated with iPTH and 1-84 PTH, even after adjustments for possible confouding variables. To our best knowledge, this is the first study to show this association. Future studies are needed to replicate this finding, investigate mechanisms underlying this association, as well as determine whether interventions in vitamin K lead to changes in PTH levels.

TH-PO158

Association of Parathyroid Hormone Concentration with Incident Atrial Fibrillation in Older Persons with Kidney Failure Initiating Dialysis

Pascale Khairallah,[1] Sai Liu,[2] Maria E. Montez-Rath,[2] Tara I. Chang,[2] Wolfgang C. Winkelmayer.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Stanford University School of Medicine, Stanford, CA.*

Background: Atrial fibrillaton (AF) is common in persons with kidney failure on hemodialysis (KF-HD). In the general population, higher intact parathyroid hormone (iPTH) levels were found to be associated with presence of AF. Whether iPTH associates with AF in patients with KF-HD is unknown.

Methods: Using merged USRDS-DaVita data (2006-2011) we selected persons aged 67+ years who initiated HD and survived 120 days. Eligible persons had continuous Medicare A+B coverage from 2 years prior to KF and no diagnosis of AF. Sociodemographic, comorbidity, and clinical information was abstracted from Medicare forms, billing claims, and electronic health records. iPTH was categorized consistent with work by Block et al (JASN 2004). Patients were followed for incident (ie, newly-diagnosed) AF as reflected in inpatient and outpatient claims. Unadjusted and multivariable Cox regression was used to estimate the associations of time-updated iPTH category (ref: 150-<300 pg/mL) with incident AF.

Results: Of 15,225 patients initiating HD, surviving 120 days, and without a prior diagnosis of AF, iPTH (in pg/mL) at baseline was <150 in 4479, 150-<300 in 5964, 300-<600 in 3479, and ≥600 in 1064 persons. During 21,845 patient-years 2857 patients had incident AF (rate, 13.1/100 person-years). Hazard ratios with increasing levels of adjustment are shown in the Figure. After multivariable adjustment, patients with iPTH<150 pg/mL had 13% (95% CI, 3-25%) higher AF incidence compared with the 150-<300 pg/mL group, but no association was found for those with iPTH 300-<600 or iPTH ≥600 pg/mL.

Conclusions: Among persons with incident KF-HD, compared with those whose iPTH was between 150 and <300 pg/mL, lower iPTH was independently associated with higher AF incidence; however, no association with AF was identified for higher iPTH levels.

TH-PO159

Is the Discordance Between Spine and Hip Bone Mineral Density in Patients on Dialysis by Vascular Calcification?

Donghyuk Kang,[1,2] Young-Joo Kwon.[3] *[1]Catholic University of Korea Bucheon Saint Mary's Hospital, Bucheon, Gyeonggi-do, Republic of Korea; [2]The Catholic University of Korea School of Medicine, Seoul, Republic of Korea; [3]Korea University College of Medicine, Seoul, Republic of Korea.*

Background: End-stage kidney disease (ESKD) patients with long-standing maintenance dialysis had at greater risk of developing vascular calcification, osteoporosis and cardiovascular disease. In general population, many studies had undergone to identify the association between vascular calcification and bone mineral density (BMD). However, the pathophysiology of vascular calcification in dialysis patients is different from general population, and the study evaluating relationship of vascular calcification with bone mineral density is scarce. In addition, it is not well-known that which bone is more affected to vascular calcification. Therefore, we aimed to evaluate the association between BMD and vascular calcification in patients with maintenance dialysis

Methods: In this multicenter, prospective, observational study of ESKD patient, 576 patients with older than 50 years old or menopausal state of women were analyzed. Vascular calcification was measured by Kaupplia score and BMD of lumbar spine and hip was measured by dual-energy X-ray absorptiometry. Using T-scores, association of vascular calcification with each site of BMD (femur, spine, and lowest score of either femur or spine) was evaluated. Additional analysis with discordance between hip and spine BMD was also performed.

Results: Among 268 (46.5%) women patients, 242 (90.3%) were menopausal state. Median age of study participants was 63.0 (57.0-70.0) years. Spine BMD showed negative correlation with vascular calcification (R=0.1, P=0.014), but hip and lowest score of both BMD were not significant (R=-0.051, P=0.02; R=-0.029, P=0.49, respectively). 282 (52%) patients were concordance between hip and spine BMD, and correlation was not significant in all the hip, spine, and lowest score of both BMD (R=0.0034, P=0.95; R=0.073, P=0.22; R=0.0037, P=0.95, respectively). In discordance group, spine BMD was also negatively correlated (R=0.19, P=0.0023) and hip BMD was positively correlated (R=-0.12, P=0.053), with more prominent in low BMD of less than -2.5 (R=-0.22, P=0.048).

Conclusions: In dialysis patients with discordance BMD, vascular calcification is positively associated with hip BMD (especially in low BMD of less than -2.5) and negatively associated with spine BMD.

TH-PO160

Efficacy and Side Effects of Denosumab for Stage 3b-4 CKD Patients with Osteoporosis: An Open-Label, Prospective Pilot Clinical Study

So-young Lee. *Eulji University College of Medicine, Seoul, Nowon, Republic of Korea.*

Background: We sought to evaluate the efficacy and safety of denosumab, including denosumab-induced hypoglycemia, in patients with chronic kidney disease (CKD) stage 3b-4 and osteoporosis. We also aimed to evaluate whether denosumab affects coronary artery calcium score (CAC) in these patients.

Methods: A total of 27 female patients with CKD stage 3b-4 and osteoporosis were enrolled. Twenty patients received denosumab plus calcium carbonate and vitamin D, and 7 control patients received calcium carbonate and vitamin D for 1 year. Osteoporosis was confirmed by using dual-energy X-ray absorptiometry (DXA). Coronary multi-detector CT was performed to calculate the coronary calcium score.

Results: No significant differences were found in medication history, demographics, eGFR, BMI, lumbar and hip BMD, bone turnover markers, 25(OH)D, homocysteine, CAC between the two groups at baseline. There was significant improvement of BMD in the denosumab treatment group. Lumbar spine, femur neck, total hip T score increased by 5.6±5.9%, 3.6±3.2%, 3.4±3.8% respectively, from baseline in the denosumab-treated group, while, 2.7±3.9%, -0.7±4.4%, -1.9±2.1% changes were observed in the control group. (Lumbar; *P*=0.273, femur neck; *P*=0.033, total hip; *P*=0.001). Among bone turnover markers, the percent change in bone ALP and CTX was -31.1±30.0% and -49.2±29.9% in the denosumab treatment group and -4.5±32.0% and -17.7±28.0% in the control group (ALP; *P*=0.027 and CTX; *P*=0.025). PTH level change were not different between two groups (denosumab; 9.0±81.7% vs. control; -0.7±79.4%, p=0.580). There were no significant changes in calcium, ionized calcium, phosphorus, and PTH levels throughout the study. CAC, and homocysteine percent change did not differ between groups (CAC; *P*=0.563 and homocysteine; *P*=0.143)

Conclusions: Denosumab has provided significant benefits without hypocalcemia for 1 year in patients with stage 3b-4 CKD when used judiciously. However, denosumab treatment did not affect homocysteine and CAC in these patients.

International Variations in Serum PTH and Calcium Levels and Their Mortality Associations in Peritoneal Dialysis Patients: Results from PDOPPS

Kosaku Nitta,[1] Brian Bieber,[2] Angelo Karaboyas,[2] David W. Johnson,[3] Talerngsak Kanjanabuch,[4] Yong-Lim Kim,[5] Mark Lambie,[6] Jenny I. Shen,[7] Mihran V. Naljayan,[8] Roberto Pecoits-Filho,[2] Bruce M. Robinson,[9] Ronald L. Pisoni,[2] Jeffrey Perl,[10] Hideki Kawanishi.[11] *[1]Tokyo Joshi Ika Daigaku Igakubu Daigakuin Igaku Kenkyuka, Shinjuku-ku, Japan; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]Princess Alexandra Hospital, Brisbane, QLD, Australia; [4]Chulalongkorn University, Bangkok, Thailand; [5]Kyungpook National University School of Medicine, Daegu, Republic of Korea; [6]Keele University, Keele, United Kingdom; [7]The Lundquist Institute, Torrance, CA; [8]DaVita Inc, Denver, CO; [9]University of Michigan Michigan Medicine, Ann Arbor, MI; [10]University of Toronto, Toronto, ON, Canada; [11]Tsuchiya Sogo Byoin, Hiroshima, Japan.*

Background: Mineral bone disorder (MBD) in chronic kidney disease (CKD) is associated with high symptom burden, fractures, vascular calcification, cardiovascular disease, and increased morbidity and mortality. CKD-MBD studies have been limited in peritoneal dialysis (PD) patients. Here, we describe calcium and parathyroid hormone (PTH) control, and mortality associations in PD patients.

Methods: We used data from 8 countries [Australia and New Zealand (A/NZ), Canada, Japan, Thailand, South Korea, United Kingdom, United States (US)] participating in the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS; 2014-2022) among patients receiving PD for >3 months. We analyzed the association of baseline PTH and albumin-adjusted calcium ($calcium^{Alb}$) with all-cause mortality using Cox regression, adjusted for potential confounders.

Results: Mean age ranged from 54.6 yrs in South Korea to 63.5 yrs in Japan. PTH and serum $calcium^{Alb}$ were measured at baseline in 12,642 and 14,244 patients, respectively. Median PTH ranged from 161 (Japan) to 363 pg/mL (US); mean $calcium^{Alb}$ ranged from 9.1 (South Korea, US) to 9.8 mg/dL (A/NZ). The PTH/mortality relationship was U-shaped with lowest risk at PTH 300-599 pg/mL. Mortality was nearly 20% higher at serum $calcium^{Alb}$ 9.6+ mg/dL vs 8.4-<9.6 mg/dL.

Conclusions: A large proportion of PD patients in this multi-national study have Ca and/or PTH levels in ranges associated with substantially higher mortality. These observations point to the need to substantially improve MBD management in PD to optimize patient outcomes.

Serum Parathormone Trajectory During the First Year of Hemodialysis: A Roadmap to Severe Hyperparathyroidism

Eduardo J. Duque,[1] Maria Eugenia F. Canziani,[3] Ana Beatriz L. Barra,[2] Maria Dalboni,[4] Jorge P. Strogoff-de-Matos,[2] Rosilene M. Elias,[1,4] Rosa M. Moyses.[1] *[1]Universidade de Sao Paulo, Sao Paulo, Brazil; [2]Universidade Federal Fluminense, Niteroi, Brazil; [3]Universidade Federal de Sao Paulo, Sao Paulo, Brazil; [4]Universidade Nove de Julho, Sao Paulo, Brazil.*

Background: Previous studies have shown that uncontrolled hyperparathyroidism is more common in patients that initiate dialysis therapy with high parathormone (PTH). In Brazil, optimal control of PTH is challenging and many patients are in waiting lists for parathyroidectomy (PTX). However, data on PTH levels during dialysis initiation and its behaviour during the first year of therapy is still scarce. We hypothesized that high PTH

levels at beginning of therapy, as well as poor control of CKD-MBD parameters would contribute to the high percentage of severe forms of hyperparathyroidism in prevalent patients on hemodialysis.

Methods: We included 1,973 individuals starting therapy between Feb 1, 2012, and Dec 31, 2016, who completed 1 year of dialysis. Data evaluated included age, sex, race, diabetes mellitus, body mass index (BMI), paying source (Public Health System or private), place of first dialysis (clinic or hospital), calcium, phosphorus, albumin, urea, alkaline phosphatase and PTH. Patients were divided into 3 groups according to baseline and 12-months PTH values (<150, 150-600 and >600 pg/mL).

Results: The percentage of patients with PTH <150, 150-600 and >600 pg/mL was 28.1%, 53.5% and 18.4%, respectively at the study entry and 30.7%, 52.5% and 16.8% after 1 year of follow-up. From patients with a baseline PTH >600 pg/mL, 44.9 % and 10.2% reached 150-600 and <150 pg/mL, respectively, but 44.9% remained with high serum PTH. Patients with PTH >600 pg/mL at 12 months were younger, mostly non-white and financed by Public Health System, less likely to have diabetes. In addition, they had higher PTH, phosphate, alkaline phosphatase, and albumin serum levels at baseline. Multivariate analysis confirmed that age [CI 0.981 (0.973-0.990)], diabetes [CI 0.595 (0.445-0.795)], baseline alkaline phosphatase [CI 1.003 (1.001-1.004)], and baseline PTH >600 [CI 4.003 (3.055-5.325)] were independently associated with uncontrolled PTH after 1 year of therapy.

Conclusions: A considerable proportion of dialysis patients in Brazil initiate therapy with high PTH levels, indicating a poor control during conservative management. Also, the inadequate management of medically therapy during the first year of dialysis might expose high number of individuals to a risk of future need of PTX.

TH-PO163

Serum Magnesium Levels and Cognitive Function in Hemodialysis Patients: A Cross-Sectional Study

Kazuhiko Kato,[1,2] Akio Nakashima,[1] Arisa Kobayashi,[1,3] Ichiro Ohkido,[1] Takashi Yokoo.[1] *[1]Tokyo Jikeikai Ika Daigaku Igakubu Igakuka Jinzo Koketsuatsu Naikagaku, Minato-ku, Japan; [2]Division of Molecular Epidemiology, The Jikei University School of Medicine, Tokyo, Japan; [3]Human Health Sciences, Kyoto University Graduate School of Medicine, Kyoto, Japan.*

Background: Dementia is a global challenge for geriatric care and social welfare, including for aging dialysis patients. Previous studies have suggested a potential association between cognitive function and chronic kidney disease-mineral and bone disorder (CKD-MBD). The present study aims to evaluate this association among patients with hemodialysis.

Methods: We conducted a cross-sectional study of patients with hemodialysis to examine the association between cognitive functions, as assessed by the Montreal Cognitive Assessment (MoCA) and the Mini-Mental State Examination (MMSE), and serum magnesium, intact parathyroid hormone (PTH), 25-hydroxyvitamin D(OHD), Fibroblast Growth Factor(FGF)-23, and soluble α-Klotho.

Results: This study involved 390 patients whose median age was 74 (70-80) years and who had been receiving hemodialysis for an average of 87 (36-168) months. The mean serum magnesium level was 2.4 ±0.3 mg/dL, and the median intact PTH and 25-OHD levels were 157 (94-238) pg/mL and 14.1 (10-19.6) ng/mL. The median intact FGF-23 and soluble α-Klotho levels were 1921 (602-4840) pg/mL and 381 (300-517) pg/mL. The median MoCA and MMSE scores were 25 (22-26) and 28 (26-29). The MoCA and MMSE score were significantly higher (cognitive function is preserved) in patients with higher magnesium levels than lower magnesium after adjusted multivariate analysis (β coefficient [95% confidence interval], 0.91 [0.03, 1.78]; P=0.043 for MoCA, and 0.82 [0.13, 1.5]; P=0.019 for MMSE). There were no significant associations between cognitive functions and serum intact PTH, 25OHD, FGF-23, and soluble α-Klotho levels.

Conclusions: Higher serum magnesium levels were associated with preserved cognitive function in hemodialysis patients, and avoiding hypomagnesemia may be recommended to protect cognitive function. On the other hand, no significant associations were observed between cognitive functions and serum intact PTH, 25OHD, FGF-23, and soluble α-Klotho levels.

TH-PO164

Marrow Adipocytes Do Not Suppress Mineralization by Osteocytes in Hemodialysis Patients

Aiji Yajima,[1,2] Norio Hanafusa,[1] Takatoshi Kakuta,[3] Ken Tsuchiya,[1] Kosaku Nitta.[1] *[1]Tokyo Joshi Ika Daigaku, Shinjuku-ku, Japan; [2]Indiana University School of Medicine, Indianapolis, IN; [3]Tokai Daigaku Igakubu Fuzoku Hachioji Byoin, Hachioji, Japan.*

Background: Increased marrow adipocytes induce low bone turnover in non-CKD and CKD subjects (Bone Rep. 21, Endocr Rev. 19). And bone marrow adiposity is increased in CKD subjects (Osteoporos Int. 15). It was revealed recently that the osteocyte plays the important roles which affect bone turnover and osteocytic perilacunar/canalicular turnover in dialysis patients (Bone. 18, Kidney Int. 18, JBMR Plus. 19). In this research, the relationship between marrow adiposity and mineralization by osteocytes after parathyroidectomy for secondary hyperparathyroidism (IIHPT) was investigated in hemodialysis (HD) patients.

Methods: Thirty one HD patients with IIHPT, including Group I (n = 15, Age; 56.1 ± 6.5 yr, duration of HD; 17.7 ± 5.9 yr, serum intact PTH (iPTH); 1482.5 ± 860.7 pg/mL) and Group II (n = 16, Age; 56.7 ± 9.1 yr, duration of HD; 13.4 ± 8.2 yr, serum iPTH; 1330.4 ± 659.2 pg/mL) were investigated. These patients were treated with total parathyroidectomy with immediate autotransplantation (PTX) and received 2.0μg/day of alfacalcidol for four weeks after PTX. The patients underwent transiliac bone biopsies before and 1 week (Group I) and 4 weeks (Group II) after PTX. Oc.S/BS (%), Ob.S/BS (%), BFR/BS ($mm^3/mm^2/yr$), hypomineralized bone area (HM.B.Ar/B.Ar; %) and marrow adipocyte area (Ad.Ar/Ma.Ar; %) were measured in cancellous bone.

Results: In Group I, serum iPTH decreased from 1482.5 ± 860.7 to 43.2 ± 81.6 pg/mL. Oc.S/BS significantly decreased and Ob.S/BS increased after PTX. And Ad.Ar/Ma. Ar increased from 13.6 ± 8.2 to 25.8 ± 12.4 % (p = 0.002) after PTX. In Group II, serum iPTH decreased from 1330.4 ± 659.2 to 20.6 ± 24.8 pg/mL. Oc.S/BS decreased from 4.4 ± 3.7 to 0.1 ± 0.5 % (p < 0.001) and Ob.S/BS also decreased from 22.3 ± 11.4 to 15.0 ± 17.2 % (p = 0.004) after PTX. BFR/BS was significantly lower than that of the other HD patients with IIHPT (n = 14, iPTH = 755.7 ± 341.5 pg/mL) (0.022 ± 0.014 vs. 0.051 ± 0.027 $mm^3/mm^2/yr$, p = 0.003). HM.B.Ar/B.Ar decreased from 17.0 ± 13.5 to 2.8 ± 3.4 % (p < 0.001) although Ad.Ar/Ma. Ar increased from 16.7 ± 11.2 to 26.6 ± 8.3 % (p = 0.030) after PTX in Group II.

Conclusions: Increased marrow adiposity was closely associated with low bone turnover, however, mineralization by osteocytes was not suppressed after PTX.

Effect of Gastrointestinal Factors on Bone Turnover Markers in ESRD

Morten B. Jørgensen,[1] Maria L. Mace,[1] Filip K. Knop,[2] Thomas Idorn,[3] Niklas R. Jørgensen,[4] Bolette Hartmann,[5] Jens J. Holst,[5] Mads Hornum,[1] Bo Feldt-Rasmussen.[1] *[1]Rigshospitalet, Department of Nephrology, Copenhagen, Denmark; [2]Gentofte Hospital, Center for Clinical Metabolic Research, Gentofte, Denmark; [3]Novo Nordisk A/S, Søborg, Denmark; [4]Rigshospitalet, Department of Clinical Biochemistry, Glostrup, Denmark; [5]University of Copenhagen, Department of Biomedical Sciences, Copenhagen, Denmark.*

Background: Chronic kidney disease - mineral and bone disorder (CKD-MBD) is a serious but not yet fully understood complication to CKD. Recent studies show that an oral glucose challenge affects bone resorption to a larger extent than intravenously administered glucose – the so-called gut-bone axis. Here, we investigated the effect of gastrointestinal factors on bone-turnover in end-stage renal disease.

Methods: Plasma samples from a previously published study involving 10 patients receiving chronic hemodialysis treatment (ESRD) and 11 healthy controls (CTRL) with normal glucose tolerance were analyzed post hoc. On two separate examination days, participants were studied in a fasted state with a 3h oral glucose tolerance test (OGTT) and an isoglycemic intravenous glucose infusion (IIGI) mimicking the plasma glucose excursions on the OGTT day. Carboxy-terminal collagen type 1 crosslinks (CTX), procollagen type I N-terminal propeptide (PINP), bone-specific alkaline phosphatase (BAP) and intact parathyroid hormone (PTH) were measured at baseline and every 30 minutes during OGTT and IIGI. All bone-turnover marker concentrations were evaluated relative to baseline levels and average excursions calculated using baseline-subtracted area under the curve (AUC). Values are expressed as median [IQR] or mean (95% CI).

Results: Median baseline concentrations of CTX (2.3 [1.9;4.9] (ESRD) vs. 0.4 [0.4;0.8] ng/ml (CTRL), P = 0.014) and PTH (292 [146;500] (ESRD) vs. 44 [32;73] pg/ml (CTRL), P = 0.003) were significantly elevated in patients compared to controls while PINP (142 [54;274] (ESRD) vs. 67 [60;78] ng/ml (CTRL)) and BAP (13.4 [10.8;20.5] (ESRD) vs. 15.3 [11.4;17.1] μg/l (CTRL)) were comparable. CTX was significantly suppressed during OGTT in both groups but to a significantly lesser extent in ESRD compared to CTRL (-15 (-20;-9)%) vs. (-43 (-50;-36)%; P < 0.001). During IIGI, CTX was significantly suppressed in CTRL (-15 (-21;-9)%) but not in ESRD (-1 (-6; 4)%). Neither P1NP nor BAP changed from baseline in response to OGTT or IIGI whereas PTH showed significant suppression in response to OGTT (but not to IIGI) in CTRL (-9 (-15;-4)%).

Conclusions: Suppression of the bone resorption marker CTX in response to OGTT is impaired in ESRD indicating that gastrointestinal factors may play a role in CKD-MBD.

TH-PO166

Impact of an EHR Alert on SGLT2 Inhibitor Use in Patients with Type 2 Diabetes (DM2) and CKD

Ken J. Park,[1] Maria Carren R. Cruz,[2] Lisa J. Nakashimada,[2] Eric S. Albright.[1] *[1]Kaiser Permanente Northwest, Portland, OR; [2]Kaiser Permanente, Oakland, CA.*

Background: SGLT2-inhibitors have been shown to reduce the risk of progression to ESRD in patients with CKD. Both KDIGO and ADA strongly recommend that all patients with CKD and DM2 should be prescribed an SGLT2-inhibitor. However, SGLT2-inhibitors remain under prescribed, especailly amongst non-nephrologists. We implemented a quality improvement project to increase SGLT2-inhibitor prescribing and to narrow the gap between nephrologists and non-nephrologists by developing an EHR alert recommending SGLT2-inhibitors at time of patient visit.

Methods: This was a quality improvement project in which an EHR alert targeting patients with DM2 with last eGFR between 30 and 60 ml/min and last ACR > 300 was rolled out on 6/22/2022. Inclusion criteria for the EHR alert were age 18-85, CKD G3

with last eGFR between 30-59 ml/min, most recent ACR > 300 mg/gm or PCR > 0.5 within past 12 months, and on ACEi or ARB or intolerance. Data was deidentified and collected cross sectionally monthly from a diabetes registry and reviewed quarterly. We tracked SGLT2 inhibitor use within 1 year of index date. SGLT2-inhibitor use was compared to patients with eGFR > 60 ml/min with ACR > 300 mg/gm who were not included in the EHR alert.

Results: Prior to the EHR alert, SGLT2 inhibitor was prescribed at a higher rate in patients managed by nephrology vs. patient not managed by nephrology (28.5% vs. 10.7%). By 8 months after its rollout, this gap had increased further (44.5% vs. 16.3%). Prior to EHR alert, SGLT2 inhibitors were prescribed in 18.6% of patients with eGFR between 30 to 60 ml/min and ACR > 300 mg/gm vs. 10.2% in patients with eGFR ≥ 60 ml/min and ACR > 300 mg/gm. By 8 months afterwards, this had increased to 32% and 15.7% respectively. Amongst patients not followed by nephrology, SGLT2 inhibitor was prescribed in 13% of patients with eGFR between 30 to 60 ml/min and ACR > 300 mg/gm vs. 9.4% in patients with eGFR ≥ 60 ml/min and ACR > 300 mg/gm prior and 23.6% vs. 13.3% by 8 months after the EHR alert.

Conclusions: We saw a greater increase in SGLT2 inhibitor prescribing in patients with CKD targeted by an EHR alert compared to patients not targeted by an EHR alert. However, overall SGLT2 prescribing remained low and we were unable to close the gap between patients managed and not managed with nephrology.

TH-PO167

Trajectory of Glomerular Filtration Rate Decline and Fluctuation in Albuminuria Leading to ESKD: An Observational Cohort Study of Biopsy-Confirmed Diabetic Kidney Disease

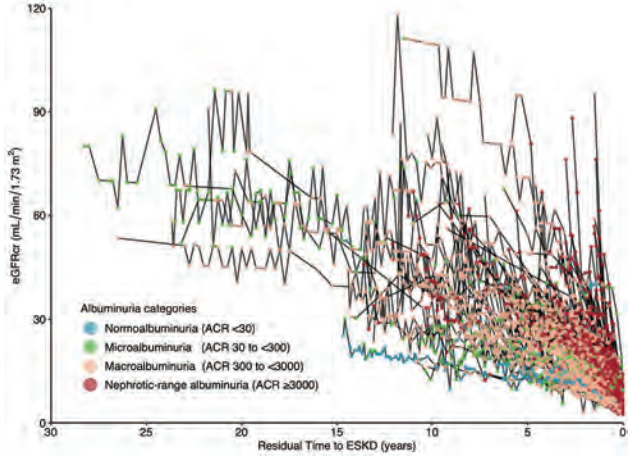
Masayuki Yamanouchi. *Toranomon Byoin, Minato-ku, Japan.*

Background: Data on trajectory of kidney function decline and fluctuation in albuminuria leading to end-stage kidney disease (ESKD) is sparse in patients with type 2 diabetes.

Methods: Using data from an observational study of biopsy-confirmed diabetic kidney disease (DKD), panel data analyses were performed to quantify patterns of trajectory of estimated glomerular filtration rate (eGFR) decline to ESKD associated with repeated measures of urine albumin-to-creatinine ratio (ACR).

Results: During a median follow-up of 3.25 years, 156 out of 312 developed ESKD. Among them, 84.0% showed a curvilinear pattern of eGFR trajectory, 62.2% moved into a different albuminuria status from that at baseline, and 84.6% of patients developed nephrotic-range albuminuria, many of whom remained nephrotic. Mixed-effects models for repeated measures showed that speed of eGFR decline for normo- [ACR <30 mg/g], micro- [ACR 30 to <300 mg/g], macro- (non-nephrotic range albuminuria) [ACR 300 to <3000 mg/g] and nephrotic-range albuminuria [ACR ≥3000 mg/g] were -2.50 (95% CI, -8.62 to 3.62; P =0.423), -4.76 (95% CI, -8.94 to -0.57; P =0.026), -6.39 (95% CI, -8.31 to -4.48; P <0.001) and -9.51 (95% CI, -11.75 to -7.28; P <0.001) mL/min/1.73 m^2/year, respectively.

Conclusions: Majority of patients with biopsy-confirmed DKD who developed ESKD showed a curvilinear eGFR trajectory with fluctuation in ACR. Although there were high inter- and intra-individual variability in changes in eGFR and ACR, ACR were inversely associated with eGFR decline, which suggests that close monitoring of ACR fluctuation over time instead of a single assessment of ACR may be necessary to detect eGFR decline to ESKD.



TH-PO168

AWARD-7 Post Hoc Analysis: Circulating Proteins Measured by Joslin Kidney Panel Identify Dulaglutide Responders

Brandon E. McFarlin,[1] Sok Cin Tye,[2] Eiichiro Satake,[2] Zaipul Md Dom,[2] Joseph Ricca,[2] Afton V. Kechter,[1] Jonathan M. Wilson,[1] Kevin L. Duffin,[1] Andrzej S. Krolewski.[2] *[1]Eli Lilly and Company, Indianapolis, IN; [2]Joslin Diabetes Center, Boston, MA.*

Background: The AWARD-7 trial demonstrated that the glucagon-like peptide-1 receptor agonist (GLP1-RA) dulaglutide (DULA) can slow the decline in estimated glomerular filtration rate (eGFR) in diabetic patients with chronic kidney disease (CKD). Previously we've identified 21 circulating proteins (Joslin Kidney panel – JKP) that are associated with progression to end-stage kidney disease (Kobayashi et al. 2022). We aimed to investigate whether we could leverage the JKP to discern between patients for whom DULA is associated with reduced odds of rapid eGFR decline from those with no impact.

Methods: Plasma samples were obtained from AWARD-7 patients who received DULA 1.5 mg (n=124) or insulin glargine (n=125) for 52 weeks. The 21 JKP was measured using Olink custom-made platform. Proportion of fast decliners (eGFR loss >5.0 ml/min/yr) was evaluated according to plasma concentration of the 21 JKP proteins at baseline, 26- and 52- weeks of the trial.

Results: Concentration of 21 JKP proteins at baseline and 52 weeks did not provide information to predict effectiveness of DULA on reduction of fast decliners. Among patients with above median change in protein concentration from baseline to 26 weeks (26 DELTA), DULA was associated with lower odds of rapid eGFR decline compared with glargine. Specifically, 26 DELTA above median for EHNA4, SYND1, TNF-R1A, -R1B, GFRa1, or DLL1 was associated with significantly lower odds of fast eGFR decline in DULA arm. There was no difference between treatments in patients with below median change in protein concentration.

Conclusions: DULA arm was associated with lower odds of rapid eGFR decline in patients with the greatest change in 6 circulating risk proteins. Further studies are necessary to validate the use of these JKP proteins as effective biomarkers of treatment responders.

Funding: Commercial Support - Eli Lilly and Company

Associations of rapid eGFR decline with change in protein concentration from baseline to 26 weeks (26 DELTA)

Protein	Treatment	Below median		Above median		$P_{interaction}$

Below median defines patients within quartile 1 and 2 or pateints with lowest change from baseline. Above median defines pateints within quartile 3 and 4 or patients with highest change from baseline. Rapid eGFR decline is defined as >5 ml/min/1.73m^2/year loss of eGFR. The number of rapid decline cases (n) per patient population (N) and frequency (%) are displayed. OR (CI) defines the risk of eGFR decline >5 ml/min/1.73m^2/year. P value for interaction represents the statistical comparisons between the two odds ratios. TNF-R3, -R4, -R6B, -R7, -R10A, R19L, R27, WFDC2, PI3, CD160, EPHA2, LAYN, KIM1, IL1RT1, and PVRL4 were also measured but did not reach statistical significance.

TH-PO169

Renal Autologous Cell Therapy (REACT) to Delay Dialysis in Advanced CKD

Joseph Stavas,[1] Bijin Thajudeen,[2] Steven G. Coca,[3] Randal K. Detwiler,[4] Arnold L. Silva,[5] Johnna D. Anderson,[1] Anna M. Burgner.[6] *[1]ProKidney, Raleigh, NC; [2]Banner University Medical Center Tucson, Tucson, AZ; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [5]Boise Kidney and Hypertension, Boise, ID; [6]Vanderbilt University Medical Center, Nashville, TN.*

Background: Few treatments delay CKD progression. Cell-based options may offer destination therapy to preserve kidney function and avoid/delay renal replacement therapy (RRT).

Methods: Adults with Type 2 diabetes (T2DKD) and eGFRs 14-20 ml/min/1.73m^2 participated in a multisite, FDA-approved phase 2 open label single arm trial (NCT03270956). After a kidney biopsy and *ex vivo* cell expansion, 2 percutaneous injections of REACT into the renal cortex were performed ~6 months apart. Patients were followed for up to 24 months to end of study (EOS) after the last injection. Outcomes

included estimated glomerular filtration rate (eGFR) slope change (mixed linear effects analysis), time to dialysis, and adverse events (AEs).

Results: Ten patients were enrolled: 8 White race, 3 Hispanics, 5 Women. The cohort's mean age was 58.3 ±5.0 years and BMI 35.20 ±8.4 kg/m^2. Nine patients had two injections and selected parameters are displayed in Table 1. Median time to dialysis was 19.4 months (IQR 13.3-27.9) and two patients were alive and dialysis free at EOS. Pre-injection eGFR slope improved 2.9 and 3.5 ml/min/1.73m^2/year post 1st and 2nd injections. AEs: Six patients progressed to sustained RRT, two deaths occurred without RRT due to COVID-19 pneumonia and diabetes complications with COVID-19. Biopsy-related AEs: 1 each hematoma (no transfusion) and AVF. Injection-related AEs: 6 small-moderate hematomas (no transfusions), 1 each: hematuria, perinephric fluid, anemia, fatigue, and pain. REACT-related AEs: none.

Conclusions: REACT was tolerated and preserved function to decelerate eGFR decline, suggesting a non-dialytic treatment option for T2DKD progressing to RRT. Phase 3 randomized controlled trials and safety monitoring are underway.

Funding: Commercial Support - ProKidney

Table 1. Trial parameters

Parameter	Baseline n=10	12 months n=5	EOS n=2
Serum Cr mg/dL	3.62±0.7	4.46±1.0	4.33±1.9
eGFR ml/min/1.73m^2	15.5±2.7	12.6±3.3	14.8±7.7
Phosphate mg/dL	4.75±0.9	4.18±0.6	5.3±2.0
Potassium mEq/L	5.19±0.5	4.65±0.3	4.7±0.7
Bicarbonate mEq/L	19.24±2.5	19.22±2.3	18.50±5.9
Calcium mg/dL	8.95±0.6	9.06±0.7	9.0±0.4

Canagliflozin Treatment Impact on Collagen Type III Turnover Is Associated with a Reduced Mortality Risk in CANVAS

Federica Genovese,[1] Daniel Guldager Kring Rasmussen,[1] Bruce Neal,[2,4] Morten A. Karsdal,[1] Michael K. Hansen.[3] *[1]Nordic Bioscience, Herlev, Denmark; [2]The George Institute for Global Health, Sydney, NSW, Australia; [3]Janssen Research and Development LLC, Spring House, PA; [4]Imperial College London, London, United Kingdom.*

Background: The precise mechanism underlying the beneficial effects of SGLT2 inhibition remains uncertain; however, it has been suggested that it may be related to a decrease in inflammation and tissue fibrosis. Collagen type III (COL III) is one of the major constituents of the extracellular matrix in different organs and is markedly upregulated in fibrotic conditions. In this study, we examined the effect of canagliflozin treatment on biomarkers of COL III turnover in the CANVAS trial.

Methods: Fragments reflecting COL III formation (PRO-C3) and degradation fragments of both cross-linked (CTX-III) or non-cross-linked COL III (C3M) were assessed with ELISA in plasma (n=2141, 1549, 2155, respectively). The change in biomarker levels from baseline to year 3 were investigated in plasma samples from both placebo (PBO)- and canagliflozin (CANA)-treated patients using a linear model. Investigated outcomes included all-cause mortality (n=116). Hazard ratios (HR) with 95% CI represent a comparison of the 75th percentile versus 25th percentile. The p-values presented are derived from a Wald test.

Results: At follow-up,PRO-C3 was significantly lower (p<0.0001; **Figure 1A**) and CTX-III was significantly higher in CANA-treated patients compared to PBO-treated patients (p=0.0002; **Figure 1B**). There was no impact on C3M (p=0.06, not shown). In the entire cohort, an increase in PRO-C3 was significantly associated with all-cause mortality (HR [95% CI] = 1.07 [1.05-1.10], p<0.0001). The prognostic ability of an increase in PRO-C3 to predict all-cause mortalitywas significantly higher in the PBO-treated patients than in the CANA-treated patients (1.28 [1.11-1.47] vs 1.07 [1.04-1.10], p=0.04).

Conclusions: The observed decrease in fragments reflecting COL III formation, as well as the increase in cross-linked COL III degradation fragments following canagliflozin treatment may reflect the anticipated potential anti-fibrotic effect of the treatment. An increase in COL III formation was associated to an increase in the risk of all-cause mortality.

Circulating Proteins Protect Against Fast Kidney Function Decline and ESKD in Early Diabetic Kidney Disease

Zaipul Md Dom,[1,2] Helen C. Looker,[3] Eiichiro Satake,[1,2] Robert G. Nelson,[3] Andrzej S. Krolewski.[1,2] *[1]Joslin Diabetes Center, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ.*

Background: We recently identified circulating protective proteins against ESKD and kidney function decline in advanced diabetic kidney disease (DKD) (Md Dom *et al.* Sci Transl Med 2021). Proteins that protect against kidney failure/decline in early stages of DKD will further complement and offer valuable insights into underlying mechanisms.

Methods: We followed 294 subjects (45% female) with T1D from Joslin Proteinuria Cohort (median uACR 491 mg/g) with normal baseline kidney function (median eGFR 100 ml/min). We conducted a replication study in an independent cohort of 162 Pima Indians with T2D and very early stage of DKD (median GFR 149 ml/min); 105 subjects had research kidney biopsies obtained in close proximity to baseline examination. We quantified 550 proteins in baseline plasma samples using the SOMAscan platform.

Results: In the Joslin cohort, 39% subjects reached the composite outcome of ESKD or 40% GFR loss within 10 years. Sixty-two (38%) of Pima subjects developed the composite outcome. In univariable logistic model, 54 proteins were significantly associated (Bonferroni-corrected) with protection against kidney failure/decline in the Joslin T1D cohort. Ten proteins were replicated in the Pima T2D cohort. Odds ratios remained significant after adjustment for key confounders. Proteins were clustered into 3 groups. A three-marker panel (FGF17, BMP10, PRLR) was derived and this panel, with added clinical parameters, significantly improved prediction of the composite outcome (c=0.852, p=0.026). BMP10 had significant positive correlations with podocyte density (r=0.30) and filtration slit frequency (r=0.21), and inverse correlations with global glomerular sclerosis (r=-0.28), mesangial fractional volume (r=-0.21) and podocyte foot process width (r=-0.20). Kidney transcriptomic profiles suggest a non-kidney source of circulating protective proteins.

Conclusions: In two independent cohorts with different types of diabetes and racial groups, we identified ten plasma proteins in early DKD associated with no/slow progression to ESKD, which may be therapeutic targets for delaying or preventing the onset of ESKD.

Evaluation of Extracellular Matrix Turnover Proteins as Risk Markers in Persons with Type 2 Diabetes and Microalbuminuria

Victor Wasehuus,[1] Anne-Cathrine Skriver-Møller,[1] Alexandra L. Møller,[2] Daniel Guldager Kring Rasmussen,[2] Federica Genovese,[2] Henrik Reinhard,[1] Bernt Johan Von Scholten,[1,4] Peter K. Jacobsen,[5] Hans-Henrik Parving,[6] Morten A. Karsdal,[2] Tine Hansen,[1] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Nordic Bioscience, Herlev, Denmark; [3]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark; [4]Novo Nordisk A/S, Bagsvaerd, Denmark; [5]Department of Cardiology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [6]Department of Endocrinology, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark.*

Background: Increased turnover of extracellular matrix (ECM) proteins has been demonstrated in many diseases and is an underlying and driving feature of pathogenesis. We investigated whether biomarkers of ECM turnover were risk markers for occurrence of cardiovascular disease (CVD), mortality and progression of chronic kidney disease (CKD) in persons with type 2 diabetes (T2D) and microalbuminuria. Altered levels of the biomarkers were hypothesized to be detrimental.

Methods: Serum concentration of TUM (tumstatin, a matrikine of collagen type IV), TGF-β (a pro-fibrotic cytokine), C1M (a degradation product of collagen type I), CTX-III (a degradation product of cross-linked collagen type III), PRO-C7 (a pro-peptide of collagen type VII) and PRO-C28 (a C-terminal of collagen type XXVIII) was measured in 192 participants with T2D and microalbuminuria included in an observational, prospective study at Steno Diabetes Center Copenhagen in Denmark from 2007-2008. Endpoints were CVD, mortality and CKD progression (>30% decline in estimated glomerular filtration rate (eGFR)) with mortality as competing risk.

Results: Mean (SD) age was 59 (9) years, eGFR was 89 (17) ml/min/1.73m^2, median (IQR) urine albumin excretion rate (UAE) was 102 (39–229) mg/24-h and 75 % were males. Median follow-up ranged from 4.9 to 6.3 years, and 38 CVD events, 24 deaths and 40 CKD events were recorded. Higher C1M was associated with higher risk of CKD progression in the crude model (hazard ratio (per doubling): 1.62 (95% CI: 1.01-2.61), p=0.047), but not after adjustment for sex, age, body mass index, LDL cholesterol,

smoking, HbA1c, plasma creatinine, systolic blood pressure and UAE (p=0.15). None of the other markers were associated with CKD progression (p≥0.20), and none of the markers were associated with mortality (p≥0.11) or CVD (p≥0.19).

Conclusions: In this cohort of individuals with T2D and microalbuminuria, higher level of a degradation product of collagen type I (C1M) was associated with CKD progression, but not independent of other risk factors. None of the extracellular matrix turnover proteins were associated with risk of CVD or mortality.

Plasma Biomarkers and Mortality Among REGARDS Participants with Diabetes and CKD

Teresa K. Chen,[1,2] Michelle M. Estrella,[1,2] Ronit Katz,[3] Mark J. Sarnak,[4] Morgan Grams,[5] Mary Cushman,[9] Chirag R. Parikh,[6] Orlando M. Gutierrez,[7] Joachim H. Ix,[8] Michael Shlipak.[1,2] CKD Biomarkers Consortium.
[1]University of California San Francisco, San Francisco, CA; [2]San Francisco VA Health Care System, San Francisco, CA; [3]University of Washington, Seattle, WA; [4]Tufts Medical Center, Boston, MA; [5]New York University, New York, NY; [6]Johns Hopkins University, Baltimore, MD; [7]The University of Alabama at Birmingham, Birmingham, AL; [8]University of California San Diego, La Jolla, CA; [9]University of Vermont, Burlington, VT.

Background: Individuals with diabetes and chronic kidney disease (CKD) are at increased risk of death but their clinical course varies. We aimed to determine whether six plasma biomarkers of kidney injury, inflammation, and repair further captured mortality risk.

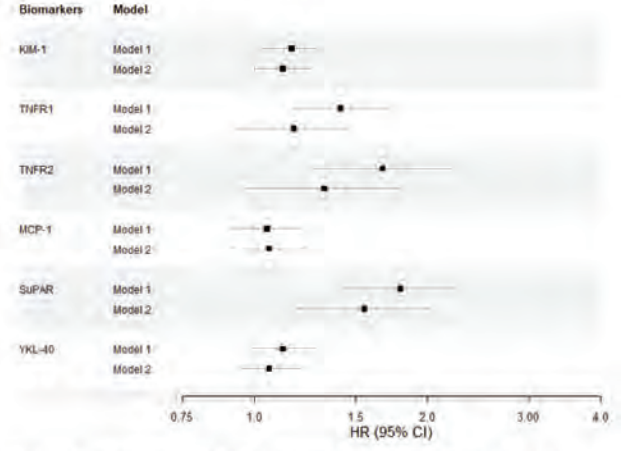
Methods: Among a cohort of REGARDS participants with diabetes and creatinine-based eGFR (eGFRcr) <60 ml/min/1.73 m^2 (n=594), we used Cox proportional hazards regression to evaluate associations of plasma KIM-1, TNFR1, TNFR2, MCP-1, suPAR, and YKL-40 concentrations with all-cause mortality. Covariates included sociodemographic and clinical factors, UACR, and eGFRcr or cystatin C-based eGFR (eGFRcys).

Results: At baseline, mean age was 70 years, 47% were men, 53% were Black, mean eGFRcr and eGFRcys were 44 and 38 ml/min/1.73 m^2, and median UACR was 32 mg/g. TNFR1, TNFR2, and suPAR strongly correlated with cystatin C (r=0.73-0.79). Over a mean follow-up of 6.2 years, 332 participants died. Higher baseline levels of KIM-1, TNFR1, TNFR2, and suPAR were associated with higher mortality risk in fully adjusted models that included eGFRcr (**Figure 1**). When accounting for eGFRcys rather than eGFRcr, however, only the association of suPAR with mortality persisted.

Conclusions: Among adults with diabetes and CKD, higher plasma KIM-1, TNFR1, TNFR2, and suPAR are associated with mortality, independent of baseline eGFRcr and albuminuria. However, the attenuation by eGFRcys suggests that the associations of KIM-1, TNFR1, and TNFR2 with mortality may, in part, reflect residual confounding by GFR.

Funding: NIDDK Support, Other NIH Support - NINDS and NIA, Other U.S. Government Support

Figure 1: Forest plot of plasma biomarker associations with all-cause mortality among REGARDS participants with diabetes and CKD



Hazard ratios are per two-fold higher baseline level. Model 1 adjusted for age, sex, race, education, systolic blood pressure, use of hypertension medications, body mass index, smoking, coronary heart disease, stroke, C-reactive protein, eGFRcr, and urine albumin-to-creatinine ratio. Model 2 replaces eGFRcr with eGFRcys.

TH-PO174

Identification of Circulating Metabolites to Predict Cardiorenal Outcomes in Patients with Type 2 Diabetes (T2D)

Michael K. Hansen,[1] Manjula Darshi,[2] Kristen Kohler,[3] Owen Tang,[4] Gemma Figtree.[4] *[1]Janssen Research & Development, Spring House, PA; [2]Janssen Research & Development, Boston, MA; [3]Janssen Research & Development, La Jolla, CA; [4]Charles Perkins Centre, The University of Sydney; Department of Cardiology, Royal North Shore Hospital; Cardiovascular Discovery Group, Kolling Institute of Medical Research, The University of Sydney; Faculty of Medicine and Health, The University of Sydney, Sydney, NSW, Australia.*

Background: Individuals with type 2 diabetes mellitus (T2D) are at elevated risk of adverse cardiorenal outcomes. Additional biomarkers are needed to better identify patients at highest risk of adverse outcomes and to better understand pathways associated with risk. We examined if baseline plasma metabolites predict renal and cardiovascular (CV) outcomes in the Canagliflozin Cardiovascular Assessment Study (CANVAS) participants with T2D at high cardiovascular risk.

Methods: Plasma metabolites were assayed from a subset of the CANVAS study participants by HPLC (HILIC & AMIDE)-mass spectrometry using targeted assays. Cox proportional hazard regression analysis was used to examine the association of 105 baseline metabolites with the renal outcome (40% eGFR decline, end-stage kidney disease, or renal death), and CV outcomes including heart failure, heart failure and CV death, and MACE. The predicted hazard ratio (HR) for a 1-unit increase in the log metabolite values, 95% confidence intervals, and p-values were calculated. Results were calculated overall and broken out by treatment when a significant treatment interaction was observed.

Results: We included 934 (22%) of the 4,330 CANVAS participants. The Figure below shows a summary of the metabolites across the renal and CV outcomes where a 1-unit increase in the log metabolite was associated with either increased or decreased risk in a fully adjusted model, (age, gender, race, BMI, HbA1C, cholesterol, blood pressure, history of heart failure, baseline ACR and eGFR).

Conclusions: A number of metabolites were identified and associated with higher or lower risk of cardiorenal outcomes. Further research is required to better understand and validate these findings.

Global Proteomic Search for Circulating Proteins Associated with Albuminuria in Patients with Diabetic Kidney Disease

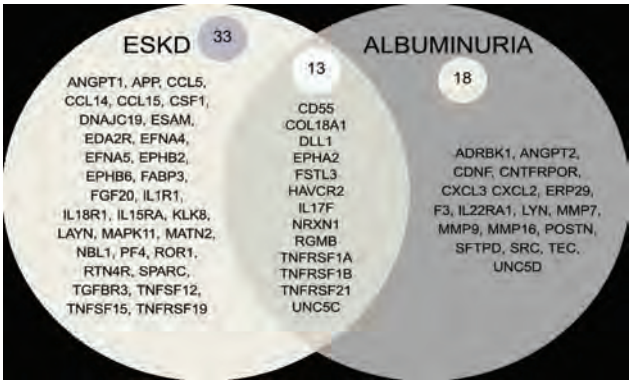
Sok Cin Tye,[1] Helen C. Looker,[2] Zaipul Md Dom,[1] Eiichiro Satake,[1] Joseph Ricca,[1] Robert G. Nelson,[2] Andrzej S. Krolewski.[1] Section of Genetics and Epidemiology, Joslin Diabetes Center. *[1]Joslin Diabetes Center, Boston, MA; [2]Chronic Kidney Disease Section, National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ.*

Background: Fast kidney function decline and the presence of albuminuria are traditional predictors of progression to end-stage kidney disease (ESKD) in patients with diabetic kidney disease (DKD). In this study, we aim to identify circulating proteins associated with albuminuria in patients with DKD and to compare them with 46 novel proteins associated with fast kidney function decline previously reported by us [1].

Methods: Using the SOMAscan proteomics platform, we measured the baseline concentration of 550 circulating proteins in participants with type 1 diabetes from the Joslin Kidney Cohort (JKC, N=294), and with type 2 diabetes from the Pima Indian cohort (N=162). Spearman rank correlation was used in an untargeted analysis to assess the association between measured proteins and albuminuria in both cohorts. We used a Venn diagram to describe proteins contributing to the development of albuminuria and/or ESKD.

Results: In the JKC and Pima Indian cohorts, 196 proteins (P<0.00001) and 55 proteins (P<0.001), respectively, were associated with albuminuria; 31 of them were common to both cohorts. Comparing these 31 proteins to the 46 proteins associated with the risk of progression to ESKD, we identified 13 proteins associated with both outcomes (Figure 1).

Conclusions: Our findings indicate that the underlying disease processes for albuminuria and progressive kidney function decline are very different. Only a few circulating proteins are common indicators for both processes. **References:** 1. Kobayashi, H., et al., Results of untargeted analysis using the SOMAscan proteomics platform indicates novel associations of circulating proteins with risk of progression to kidney failure in diabetes. Kidney Int, 2022. 102(2): p. 370-381.



TH-PO176

Baseline and Short-Term Change of Concentration of Plasma Proteins Measured by Joslin Kidney Panel and Progression to ESKD in the Chronic Renal Insufficiency Cohort (CRIC)

Hiroki Kobayashi,[1,3] Zaipul Md Dom,[1] Eiichiro Satake,[1] James P. Lash,[2] Andrzej S. Krolewski.[1] *[1]Joslin Diabetes Center, Boston, MA; [2]University of Illinois Chicago, Chicago, IL; [3]Nihon University School of Medicine, Tokyo, Japan.*

Background: The Joslin Kidney Panel (JKP) of 21 circulating proteins is associated with increased risk of ESKD in patients with diabetes (Kobayashi *et al.* KI 2022). We evaluated the JKP as a tool for assessing prognosis in Chronic Renal Insufficiency Cohort (CRIC).

Methods: We conducted a case-cohort study involving 218 participants with diabetes and impaired renal function at baseline. Using assays developed by OLINK inc. to measure JKP 21 proteins we quantified concentration of the proteins at Baseline and at follow-up (interval 2 years apart) in study groups; cases were those who progress to ESKD within 10-years (n=89), and controls were those who did not progress to ESKD within 10-years (n=129). We employed logistic regression models to determine the association of baseline concentration, longitudinal change (DELTA), and INDEX (Baseline and DELTA) for each biomarker with progression to ESKD.

Results: Higher levels of 19 of 21 proteins at baseline and 20 of 21 DELTAs and INDEXs were statistically and significantly associated with an increased risk of progression to ESKD within 10 years. Among the 20 INDEXs, 5 including TNF-R7, WFDC2, SYND1, KIM-1, and PVRL4 remained statistically significant after adjusting for GFR-INDEX and baseline 24-hour urinary protein (24h-UP).

Conclusions: Higher levels of most proteins at baseline, DELTAs, and INDEXs in JKP were significantly associated with increased ESKD risk within 10 years. INDEXs for the 5 proteins were better in prediction of risk of ESKD than GFR-INDEX. Further studies are needed to validate the utility of measuring INDEXs for prediction of ESKD and monitoring the effectiveness of reno-protective therapies. CRIC data was provided by NIDDK CR, a program of the National Institute of Diabetes and Digestive and Kidney Diseases, and this study was supported by a grant from Renalityx Inc.

Serum Sphingolipids as Indicators of ESRD Risk in Diabetic Patients

Vismaya J. Kharkar,[1] Marcus G. Pezzolesi.[2] Pezzolesi Lab. *[1]The University of Utah School of Medicine, Salt Lake City, UT; [2]The University of Utah Department of Human Genetics, Salt Lake City, UT.*

Background: Chronic kidney disease (CKD) is a complication of diabetes that affects one-third of diabetic patients; 15% of CKD patients with diabetes develop end-stage renal disease (ESRD). Underlying genetic, environmental, and biological factors contribute significantly to CKD risk. Sphingolipids are a class of lipids that have been associated with increased insulin resistance and hepatic steatosis. Through analysis of longitudinal data from participants in Chronic Renal Insufficiency Cohort (CRIC) study and newly generated lipidomic data, this project investigates the potential use of longitudinal serum sphingolipid measurements as an indicator for risk of progression to ESRD.

Methods: We analyzed ESRD outcomes in participants of CRIC with type II diabetes and CKD (n = 1054). We performed targeted lipidomics measuring 55 sphingolipids in patient serum samples from their fifth CRIC visit. Data from this visit served as the baseline for evaluating time to progression to ESRD and change in serum sphingolipids over time. Additionally, patients' health variables available through the CRIC dataset were investigated for correlation with all sphingolipids at baseline for a larger cohort of 1618 patients with diabetes and CKD. Each variable was analyzed for correlation with each sphingolipid using a standardized linear regression model; variables were then grouped using hierarchical clustering according to both p-value and adjusted R-squared value.

Results: At baseline, 506 patients had early stage CKD (CKD stages 1-3) and 546 patients had late stage CKD (CKD stages 4-5). 257 of 1054 patients developed ESRD in the range of 517 to 5048 days after the first CRIC visit, with a mean of 2619 days. Seven of 55 serum sphingolipids were significantly ($p < 0.05$) associated with time to ESRD; none explained greater than 0.01% of variability. Additionally, we identified 3 clusters of patient health variables that were significantly ($p < 0.05$) associated with the same sphingolipids and with each other. These clustered health variables included lipid measurements, indicators of kidney function, and quality of life evaluation.

Conclusions: Our analysis indicates that serum sphingolipids measured at baseline are correlated with progression to ESRD. As we continue our analysis, we further investigate the relationship between average sphingolipid measurements over time and rate of progression through CKD stages to ESRD.

TH-PO178

High High-Density Lipoprotein Cholesterol (HDL-C) Levels May Indicate a Higher Risk of ESRD and All-Cause Mortality in Patients with Type 2 Diabetes Mellitus (T2DM) and CKD

Yutong Zou. *West China Hospital of Sichuan University, Chengdu, China.*

Background: To investigate the relationship between high-density lipoprotein cholesterol (HDL-C) and end-stage renal disease (ESRD) and all-cause mortality in patients with both diabetes mellitus (DM) and chronic kidney disease (CKD).

Methods: We enrolled 375 participants with confirmed diabetic kidney disease (DKD) via renal biopsy between January 2008 and September 2020 in our longitudinal observational study. Additionally, a total of 3,267 participants with DM and CKD from the National Health and Nutrition Examination Survey (NHANES) spanning 1999-2018 were included to examine the association between HDL-C concentration and all-cause mortality.

Results: Patients were divided into Group 1 (HDL-C<1.03mmol/L), Group 2 (1.55mmol/L>HDL-C≥1.03mmol/L), and Group 3 (HDL-C≥1.55mmol/L). Overall, of the 375 patients, after a median follow-up of 36 months, 165 participants (44%) developed ESRD. The Kaplan-Meier curves revealed a higher risk for ESRD among patients in Group 3 (p<0.001). After adjusting for potential confounders, patients in Group 3 were still found to have a significantly higher risk of ESRD compared to patients in Group 1, with an adjusted HR (95%CI) of 1.68(1.03, 2.71) (p=0.036). Higher levels of HDL3 and lower levels of HDL2 were associated with a higher risk for ESRD. Moreover, a total of 3,262 individuals with both DM and CKD in NHANES 1999-2018 were analyzed. After a median follow-up of 75 months, 1,369 participants (42%) had died. The weighted Kaplan-Meier curves reveal that higher HDL-C levels are associated with a higher risk of all-cause mortality (p=0.02). Notably, in patients with CKD stage 1-2, multivariate Cox regression analysis suggests that patients in Group 3 had a significantly higher HR of 1.61 (95%CI: 1.19, 2.19) (p=0.002).

Conclusions: This study identified a significant positive association of high concentration of HDL-C with incident ESRD and all-cause mortality in DKD patients. These findings may be different from previous beliefs about the role of HDL-C as "good cholesterol".

TH-PO179

PRO-C3 as a Risk Marker for Kidney Disease Progression and Mortality in Type 1 Diabetes

Marte Opseth Rygg,[1] Alexandra L. Møller,[2] Viktor Rotbain Curovic,[1] Daniel Guldager Kring Rasmussen,[2] Simone Theilade,[1,3] Nete Tofte,[1] Signe A. Winther,[1] Federica Genovese,[2] Morten A. Karsdal,[2] Tine Hansen,[1] Peter Rossing.[1,3] *[1]Steno Diabetes Center Copenhagen, Herlev, Denmark; [2]Nordic Bioscience, Herlev, Denmark; [3]Kobenhavns Universitet, Copenhagen, Denmark.*

Background: Kidney fibrosis, a hallmark of diabetic kidney disease, is characterized by impaired extracellular matrix remodeling, causing excessive collagen deposition. We investigated if biomarkers of collagen type III (PRO-C3), VII (PRO-C7) and XXVIII (PRO-C28) formation, and a fragment of degraded crosslinked collagen type III (CTX-III), were related to kidney disease progression and mortality in people with type 1 diabetes (T1D).

Methods: The biomarkers were measured in serum by ELISA. Endpoints were 1) a composite kidney endpoint including ≥30% decline in estimated glomerular filtration rate (eGFR), onset of kidney failure (eGFR ≤15 ml/min/1.73m^2, dialysis, or transplantation) and all-cause mortality; and 2) all-cause mortality. Associations with baseline biomarker levels were tested using Cox proportional hazard models after log2 transformation. Hazard ratios (HRs) are reported per doubling and adjusted for age, sex, HbA_{1c}, eGFR, systolic blood pressure, body mass index, smoking, urinary albumin excretion rate, diabetes duration and treatment with a renin-angiotensin-aldosterone system inhibitor.

Results: We enrolled 667 individuals with T1D, 311 with normal (<30 mg/24h), 166 with moderately (30-299 mg/24h), and 190 with severely increased (≥300 mg/24h) urinary albumin excretion. Median follow-up was 5.2-6.2 years. Higher PRO-C3 was associated with development of the composite kidney endpoint (events: 125) and

all-cause mortality (events: 58); adjusted HR: 1.51 (95% CI: 1.08-2.11, p=0.017) and 1.65 (1.05-2.61, p=0.031), respectively. Higher PRO-C7 was associated with a higher risk of the composite kidney endpoint (1.56 (1.16-2.09), p=0.003), but not after adjustment (p=0.40), and not associated with mortality. PRO-C28 and CTX-III were not associated with the endpoints (p≥0.13).

Conclusions: PRO-C3, a marker of collagen type III formation, was associated with kidney disease progression and death, highlighting PRO-C3 as a potential risk marker of severe complications in T1D.

The Influence of Bone on Kidney Disease Progression in Persons with Type 1 Diabetes

Sabina C. Hauge,[1] Henrik Øder Hjortkjær,[2] Frederik Persson,[2] Peter Rossing,[2,3] Ditte Hansen.[1,3] *[1]Department of Nephrology, Copenhagen University Hospital – Herlev and Gentofte, Herlev, Denmark; [2]Steno Diabetes Center Copenhagen, Herlev, Denmark; [3]Department of Clinical Medicine, University of Copenhagen, Copenhagen, Denmark.*

Background: The number of patients with chronic kidney disease (CKD) and diabetes is expected to increase. Identification of mechanisms influencing the progression of CKD is of great importance. In CKD, a bone-vascular cross-talk has been described, but if bone influences on kidney function has been sparsely investigated. The aim of this study was to explore the influence of bone-derived factors (sclerostin, Dickkopf-1 (DKK1), and osteoprotegerin (OPG)) on the progression of kidney disease in persons with type 1 diabetes (T1D).

Methods: This was a prospective cohort study. Blood samples from persons with T1D were collected between 2009-2011. Outcomes were: 1) End-stage kidney disease (ESKD) defined as estimated glomerular filtration rate (eGFR) <15 mL/min/1.73m^2, initiation of dialysis, or kidney transplantation; 2) Progression of albuminuria (from 0-30 mg/day to 30-300 mg/day or from 30-300 mg/day to >300 mg/day); 3) An eGFR decline ≥30%; 4) A composite kidney endpoint consisting of all three endpoints. Kaplan-Meier curves and Cox proportional hazard regression models were used.

Results: Among the 318 persons, the mean age was 56 years, 50% were men, and the median eGFR was 79 mL/min/1.73m^2. During a median follow-up of 5.5 years, 3.5% met the ESKD endpoint, 6.3% progressed in albuminuria, 14.2% had a decline in eGFR ≥30%, and 21.1% met the composite kidney endpoint. The Kaplan-Meier curves showed no association between sclerostin or DKK1 and kidney disease progression, whereas OPG above median had a lower survival for all endpoints except for albuminuria progression (Figure 1). In unadjusted Cox regression models, sclerostin and DKK1 were significantly associated with ESKD, while OPG was significantly associated with all kidney endpoints except for eGFR decline ≥30%. After adjustment for age, gender, systolic blood pressure, diabetes duration, eGFR, and UACR, only OPG was significantly associated with the composite kidney endpoint (p=0.047).

Conclusions: In this prospective cohort study, OPG, but not sclerostin or DKK1, was associated with progression of CKD, and could have prognostic importance in patients with T1D.

Utility of Serum β2-Microglobulin for Prediction of Kidney Outcome Among Patients with Biopsy-Proven Diabetic Nephropathy

Takayuki Uemura,[1] Masatoshi Nishimoto,[1] Masahiro Eriguchi,[1] Hiroyuki Tamaki,[1] Hikari Tasaki,[1] Riri Furuyama,[1] Fumihiro Fukata,[2] Takaaki Kosugi,[1] Katsuhiko Morimoto,[3] Masaru Matsui,[4] Ken-ichi Samejima,[1] Kazuhiko Tsuruya.[1] *[1]Nara Kenritsu Ika Daigaku, Kashihara, Japan; [2]Yamatotakada Shiritsu Byoin, Yamato Takada, Japan; [3]Nara Prefecture Seiwa Medical Center, Ikoma-gun, Japan; [4]Nara-ken Sogo Iryo Center, Nara, Japan.*

Background: Little is known regarding the importance of serum β2-microglobulin (β2-MG) on subsequent decline in kidney function among patients with diabetic nephropathy (DN). Here, we aimed to examine whether the addition of serum β2-MG to known predictors could improve the prediction performance for incident kidney failure with replacement therapy (KFRT) among patients with biopsy-proven DN.

Methods: A retrospective observational study consists of patients with biopsy-proven DN between June 1981 and December 2014. Patients complicated with other kidney diseases were excluded. Exposure of interest was log-transformed serum β2-MG levels measured at the time of kidney biopsy. The outcome variables were KFRT. Multivariable Cox regression models and competing-risk regression models, with all-cause mortality as a competing event, were performed with adjustments for previously known risk factors. Model fit by adding serum β2-MG levels was calculated using the Akaike information criterion (AIC). The net reclassification improvement (NRI) and integrated discrimination improvement (IDI) indexes were examined based on the 5-year cumulative incidence of KFRT, and the improvement of predictive performance for KFRT by serum β2-MG levels was evaluated.

Results: Among 408 patients, 99 developed KFRT during a median follow-up period of 6.7 years. A higher serum β2-MG level (1-unit increase in log-transformed serum β2-MG level) was associated with a higher incidence of KFRT, even after adjustments for previously known clinical and histological risk factors (hazard ratio [95% confidence interval (CI)]: 3.30 [1.57–6.94] and subdistribution hazard ratio [95% CI]: 3.07 [1.55–6.06]). Subgroup analyses revealed no effect modification by creatinine-based estimated glomerular filtration rate or kidney histological findings. The addition of log-transformed serum β2-MG level reduced AIC, and improved the prediction of KFRT (NRI and IDI: 0.32 [0.09–0.54] and 0.03 [0.01–0.56], respectively).

Conclusions: Among patients with biopsy-proven DN, serum β2-MG was an independent predictor of KFRT and improved prediction performance. In addition to serum creatinine, serum β2-MG could be also evaluated for DN.

TH-PO182

Levels of Oxidative Stress and Inflammation in Different Degrees of Diabetic Kidney Disease Caused by Diabetes Mellitus Type 2

José J. Gutiérrez Hernandez, Luis A. Salazar Soltero, Javier Soto-Vargas, Juan O. Romero Tafoya, Hugo B. Espinoza, Roxana Villanueva Macedo, Paulina De Niz Hernández, Renato Parra Michel. *Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico.*

Background: Chronic inflammation is related to its progression and cardiovascular and infectious complications, alterations in the immune response, which translates into a greater risk of morbidity and mortality. Oxidative stress is considered a non-traditional risk factor for all causes of mortality, considering it a prognostic factor and a target for the prevention and treatment of CKD.

Methods: Retrospective observational descriptive study in adult patients >18 years of age, with type 2 Diabetes Mellitus (DM2) and CKD grades 1 5 according to the KDIGO, who attended the Nephrology clinic at the IMSS HGR46. We evaluate the levels of oxidative stress and inflammation in the different degrees of diabetic kidney disease in patients with DM2.

Results: We included 80 patients diagnosed with diabetic CKD were included and the serum levels of Superoxide dismutase SOD and Malondialdehyde MDA were determined. We classified according to the severity of the disease using KDIGO based on eGFR into three groups: patients with mild, moderate and severe. Plasma SOD levels were determined in patients with CKD; the average SOD was 2.07 ± 0.64. According to the severity of the CKD, no significant differences were identified p=0.46, although there were numerical differences with a tendency to lower levels in patients with severe CKD. Regarding MDA, a significant difference was observed in the levels according to the severity of the CKD. With higher levels in patients with mild CKD, and with lower levels according to the severity of the disease p=0.003.

Conclusions: Serum levels of SOD and MDA seem to reduce as eGFR decreases, being higher in the mild disease group, which may be related to greater inflammation at the onset of CKD.

Correlation Between Serum suPAR and Severity of Renal Injury and Renal Function Progression in Diabetic Kidney Disease

Yue Gu,[1,2] Jing Zhou,[1,2] Ren Y. Ying,[1,2] Fengmin Shao.[1,2] *[1]Henan Provincial People's Hospital, Zhengzhou, China; [2]Zhengzhou University People's Hospital, Zhengzhou, China.*

Background: To analyze the correlation between serum soluble urokinase Plasminogen Activator Receptor (suPAR) and renal function in diabetic kidney disease(DKD).

Methods: 152 DKD patients and 105 T2DM patients were recruited. The patients with DKD were divided into microalbuminuria group (30mg/g≤UACR < 300mg/g), macroalbuminuria group (UACR≥300mg/g). Spearman correlation and partial correlation analysis were conducted to compare the correlation between suPAR and various clinical indicators. End events were defined as Estimated glomerular filtration rate (eGFR) decrease of ≥30%, urinary protein advancement, progress to end-stage renal disease (ESRD) or receive renal replacement therapy. According to the median serum suPAR level, all patients were divided into low-level suPAR group (suPAR < 5.76ng/ml) and high-level suPAR group (suPAR≥5.76ng/ml). Survival curves were plotted by Kaplan-Meier method, and differences in renal cumulative survival at different serum suPAR levels were measured by Log-rank test. Cox regression analysis was used to analyze the influence factors for renal progression in DKD. The predictive value of suPAR in renal function progression was evaluated by Receiver operating characteristic curve (ROC).

Results: The mean age was 60.30±11.89 years old. SuPAR level in T2DM group was significantly lower than that in microalbuminuria group and macroalbuminuria group ($P < 0.05$). Serum suPAR in DKD patients was positively correlated with UACR, BUN, Scr, SUA, RBP and CysC (all $P < 0.05$), and negatively correlated with Hb, ALB, TBIL and eGFR (all $P < 0.05$). Kaplan-Meier survival analysis showed that the cumulative survival rate of kidney in the high-level suPAR group was significantly lower than that in the low-level suPAR group (P =0.001). The results showed that higher levels of RBP and suPAR, lower levels of ALB were independent risk factors for renal function progression in DKD patients (P < 0.05). The area under ROC curve of suPAR level to predict renal function progression was 0.791, the critical value was 8.15ng/ml, the sensitivity was 66.7%, and the specificity was 84.9%.

Conclusions: Serum suPAR level increased in DKD patients, which was positively correlated with the severity of renal impairment. High level of suPAR is an independent risk factor for renal progression in patients with DKD.

Autoantibodies to Erythropoietin Receptor and Clinical Outcomes in Patients with Type 2 Diabetes and CKD: A Post Hoc Analysis of the CREDENCE Trial

Akihiko Koshino,[1,2] Brendon L. Neuen,[3] Megumi Oshima,[2] Tadashi Toyama,[2] Akinori Hara,[2] Clare G. Arnott,[3,4] Bruce Neal,[3] Meg Jardine,[3,5] Sunil Badve,[3,6] Kenneth W. Mahaffey,[7] Carol A. Pollock,[8,9] Michael K. Hansen,[10] Takashi Wada,[2] Hiddo J. Heerspink.[1,3] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Kanazawa University, Kanazawa, Japan; [3]The George Institute for Global Health, Newtown, NSW, Australia; [4]Royal Prince Alfred Hospital, Camperdown, NSW, Australia; [5]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [6]University of New South Wales, Sydney, NSW, Australia; [7]Stanford Center for Clinical Research, Stanford University School of Medicine, Stanford, CA; [8]Kolling Institute of Medical Research, St Leonards, NSW, Australia; [9]Royal North Shore Hospital, St Leonards, NSW, Australia; [10]Janssen Research and Development LLC, Spring House, PA.*

Background: Anti-erythropoietin receptor (EPOR) antibodies have been identified in patients with various kidney diseases. This study aimed to assess the association of anti-EPOR antibodies with kidney, cardiovascular and mortality outcomes in the CREDENCE trial, and to determine whether the effects of canagliflozin on hemoglobin and hematocrit were modified by anti-EPOR antibodies.

Methods: Patients with type 2 diabetes (T2D) and CKD were randomly assigned to receive canagliflozin 100mg daily or a matching placebo. Serum anti-EPOR antibodies at baseline were measured using an indirect enzyme-linked immunosorbent assay. The primary composite outcome consisted of a doubling of serum creatinine, end-stage kidney disease, or death from kidney or cardiovascular reasons. The secondary outcome was death from any cause. Multivariable adjusted Cox proportional hazard regression was used to estimate associations between anti-EPOR antibodies and outcomes. The effects of canagliflozin on hemoglobin and hematocrit over time were assessed with a repeated measures mixed effect model.

Results: Of 2600 (59.1%) CREDENCE participants with available samples, 191 (7.3%) were positive for anti-EPOR antibodies. During a median follow-up of 2.8 years, the primary composite outcome and all-cause death occurred in 348 (13.4%) and 227 (8.7%) individuals, respectively. Higher baseline levels of anti-EPOR antibodies were independently associated with increased risk of the primary outcome (HR per 1-SD increase 1.12 [95%CI 1.01, 1.24], p=0.04) and all-cause death (HR 1.27 [95%CI 1.08, 1.48], p<0.01). Canagliflozin, compared to placebo, increased hemoglobin and hematocrit by 7.0 g/L (95%CI 6.2, 7.9, p<0.01) and 2.4% (95%CI 2.2, 2.7, p<0.01), respectively. These effects were consistent in patients with and without anti-EPOR antibodies (p-interaction=0.39 and 0.70).

Conclusions: In patients with T2D and CKD, anti-EPOR antibodies were associated with the composite kidney and cardiovascular outcome and all-cause mortality. Canagliflozin increased hemoglobin and hematocrit regardless of the presence of anti-EPOR antibodies.

Iron Biomarkers and Effects of Canagliflozin in Patients with Type 2 Diabetes and CKD: A Post Hoc Analysis of the CREDENCE Trial

Akihiko Koshino,[1,2] Brendon L. Neuen,[3] Clare G. Arnott,[3,4] Bruce Neal,[3] Meg Jardine,[3,5] Sunil Badve,[3,6] Kenneth W. Mahaffey,[7] Carol A. Pollock,[8,9] Michael K. Hansen,[10] Takashi Wada,[2] Hiddo J. Heerspink.[1,3] *[1]University Medical Center Groningen, Groningen, Netherlands; [2]Kanazawa University, Kanazawa, Japan; [3]The George Institute for Global Health, Newtown, NSW, Australia; [4]Royal Prince Alfred Hospital, Camperdown, NSW, Australia; [5]NHMRC Clinical Trials Centre, Camperdown, NSW, Australia; [6]University of New South Wales, Sydney, NSW, Australia; [7]Stanford Center for Clinical Research, Stanford University School of Medicine, Stanford, CA; [8]Kolling Institute of Medical Research, St Leonards, NSW, Australia; [9]Royal North Shore Hospital, St Leonards, NSW, Australia; [10]Janssen Research and Development LLC, Spring House, PA.*

Background: Disturbed iron homeostasis occurs commonly in patients with chronic kidney disease (CKD) and is implicated in the development of anemia and adverse clinical events. This study aimed to determine the effects of canagliflozin on iron parameters in the CREDENCE trial and to assess whether the effects of canagliflozin on anemia and clinical outcomes were modified by iron deficiency (ID).

Methods: Patients with type 2 diabetes (T2D) and CKD were randomized to canagliflozin 100mg or placebo. We measured serum iron, total iron binding capacity (TIBC), transferrin saturation (TSAT) and ferritin at baseline and year 1. The effects of canagliflozin, relative to placebo, on iron markers were assessed with analysis of covariance. Interactions between baseline ID, defined as TSAT<20%, and the effects of canagliflozin on hemoglobin and clinical outcomes were evaluated with mixed effect models and Cox regression models, respectively.

Results: 2414/4401 (54.9%) participants had available serum samples. Canagliflozin, compared to placebo, increased TIBC by 2.1% (95% CI 0.4, 3.8; p=0.01) and decreased ferritin by 11.3% (95% CI 3.1, 15.4; p<0.001) with no clear effect on iron and TSAT (Figure). At baseline, 924 (38.3%) participants had ID. Canagliflozin increased hemoglobin over time by 7.3 g/L (95% CI 6.2, 8.5; p<0.001) and 6.7 g/L (95% CI 5.2, 8.2; p<0.001) in patients with and without ID, respectively (p-interaction=0.38). Canagliflozin reduced CKD progression (HR 0.70, 95% CI 0.56-0.87) regardless of ID (p-interaction=0.83).

Conclusions: One-year treatment with canagliflozin increased TIBC and decreased ferritin in patients with T2D and CKD, suggesting improvement in iron use.

Distal Tubule Urinary Biomarkers in Diabetic Kidney Disease: Results from the VA NEPHRON-D Trial

Christina L. Tamargo,[1] David Hu,[1] Heather Thiessen Philbrook,[1] Joseph V. Bonventre,[4] Linda F. Fried,[2] Steven G. Coca,[3] Chirag R. Parikh.[1] *[1]The Johns Hopkins University School of Medicine, Baltimore, MD; [2]UPMC, Pittsburgh, PA; [3]Icahn School of Medicine at Mount Sinai, New York, NY; [4]Brigham and Women's Hospital, Boston, MA.*

Background: Urinary biomarkers of proximal renal tubule injury (KIM-1, NGAL, L-FABP) have demonstrated associations with DKD progression, but investigations of biomarkers of distal tubular health in DKD have been limited.

Methods: We evaluated associations between two distal tubular urinary biomarkers, epidermal growth factor (EGF) and uromodulin (UMOD), and DKD progression among 1135 participants in the Veterans Affairs Diabetes iN Nephropathy (VA NEPHRON-D) study. EGF and UMOD were measured by electrochemiluminescence assay in a single batch in urine samples collected at randomization.

Results: At baseline, the mean age was 64.9 years, the mean eGFR was 56.2 (18.9) ml/min/1.73 m^2, and the median urine albumin-to-creatinine ratio was 840 (IQR 423-1761) mg/g. One hundred forty-eight patients (13.0%) had DKD progression over a median of 2.2 years of follow-up. Higher levels of EGF and UMOD were both independently associated with a lower risk of DKD progression in continuous models after adjustment for several covariates (adjusted HR 0.58 (0.34, 0.98) and 0.80 (0.66, 0.97); Figure 1).

In categorical models, patients with the highest tertiles of both biomarkers had the lowest risk of DKD progression. However, associations were attenuated in models that adjusted for albuminuria, particularly for EGF (adjusted HR 0.70 (0.42, 1.15) and 0.55 (0.34, 0.89) for UMOD).

Conclusions: Among veterans with DKD, higher levels of distal tubular health markers were independently prognostic for a lower risk of DKD progression. Distal tubular health deserves further investigation in DKD cohorts and clinical trials.

Funding: NIDDK Support

Figure 1. Baseline Urinary EGF and UMOD associations with DKD progression

Urinary Biomarker		Event rate per 1000 person-years (95% CI)	Hazard ratio (95% CI) for DKD progression[a]	
			Model 1[b]	Model 2[c]
EGF (pg/mL)	Continuous	63 (53, 74)	**0.41 (0.27, 0.64)**	**0.58 (0.34, 0.98)**
	T1: <786	91 (71, 115)	1.0 (referent)	
	T2: 786-1061	54 (40, 73)	**0.56 (0.38, 0.83)**	0.68 (0.45, 1.04)
	T3: >1061	44 (32, 62)	**0.51 (0.33, 0.80)**	0.70 (0.42, 1.15)
UMOD (µg/mL)	Continuous	63 (53, 74)	**0.65 (0.55, 0.78)**	**0.80 (0.66, 0.97)**
	T1: <21.78	100 (79, 126)	1.0 (referent)	
	T2: 21.78-48.47	57 (43, 77)	**0.59 (0.40, 0.87)**	0.79 (0.53, 1.17)

[a]DKD progression was defined as eGFR decline (≥30 ml/min/1.73 m^2 if eGFR at randomization was ≥60 ml/min/1.73 m^2, or ≥50% if eGFR at randomization was <60 ml/min/1.73 m^2) or incident end-stage kidney disease. [b]Model 1: Adjusted for urine creatinine concentration, age, sex, race, ethnicity, BMI, systolic blood pressure, hemoglobin A1c, and treatment assignment at baseline. [c]Model 2: Model 1 + natural log-transformed UACR at 0 months + eGFR at 0 months.
Bolded values indicate statistical significance. T, tertile.

Figure 1. Baseline Urinary EGF and UMOD associations with DKD progression

TH-PO187

Tubular Biomarker Trajectories in Type 1 Diabetes

Christine P. Limonte,[1] David K. Prince,[1] Andrew N. Hoofnagle,[1] Irl B. Hirsch,[1] Michael Mauer,[4] Alessandro Doria,[2,3] Bryan R. Kestenbaum,[1] Ian H. de Boer.[1] *[1]University of Washington, Seattle, WA; [2]Joslin Diabetes and Endocrinology Research Center, Boston, MA; [3]Harvard Medical School, Boston, MA; [4]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Evaluation of kidney tubular biomarker trajectories over the course of type 1 diabetes (T1D) may provide insight into how tubulointerstitial disease progresses over time.

Methods: We assessed biomarkers of tubular injury and function over time in two prospective T1D cohorts: the Renin Angiotensin System Study (RASS; n=283, 5 year follow-up) of adults with early T1D and no clinical evidence of kidney disease, and the Preventing Early Renal Loss in Diabetes Study (PERL; n=530, 3 year follow-up) of adults with longstanding T1D and CKD or risk for kidney disease progression. We measured the following at baseline, mid-study, and study end: KIM-1, sTNFR1, arginine-citrulline ratio in plasma; UMOD, EGF excretion in timed urine; urinary clearances of 8 secretory solutes summarized as a composite tubular secretion score.

Results: At baseline, RASS participants had mean age 30 years, diabetes duration 11 years, iohexol-GFR (iGFR) 129 ml/min/1.73m^2, AER 6 µg/min, and HbA1c 8.6%; PERL participants had mean age 51 years, diabetes duration 35 years, iGFR 68 ml/min/1.73m^2, AER 285 µg/min, and HbA1c 8.2%. Overall, KIM-1, sTNFR1, and UMOD were higher and arginine-citrulline ratio, EGF, and tubular secretion score were lower in PERL versus RASS (**Table**). Tubular biomarkers changed significantly over time at rates similar to and sometimes faster than iGFR and AER. Baseline HbA1c was associated with tubular marker changes in multivariate models (% change/year per 1% higher HbA1c [95% CI]): in RASS, KIM-1 0.8% (0,1.6), sTNFR1 0.4% (0.1,0.7), EGF -1.1% (-2.1,0), arginine-citrulline ratio 1.1% (0.4,1.7); in PERL, sTNFR1 1.0% (0.6,1.4), tubular secretion score 0.7% (0.2,1.2). Neither ACEi/ARB versus placebo in RASS nor allopurinol versus placebo in PERL affected tubular biomarker trajectories.

Conclusions: Plasma KIM-1 and sTNFR1 significantly increase over the course of T1D, suggesting early onset of tubulointerstitial pathology and progression over time. Higher HbA1c is associated with faster rise in sTNFR1.

Funding: NIDDK Support

Table. Tubular biomarker median values and changes over time

	Median (Q1 median, Q3 median)		Absolute change per year (95% CI)		Percent change per year (95% CI)	
	RASS	PERL	RASS	PERL	RASS	PERL
KIM-1, plasma (pg/mL)	38.0 (28.8, 56.0)	114.3 (69.8, 204.9)	5.7 (1.6, 9.8)	7.5 (3.3, 11.8)	5.4 (4.0, 6.7)	2.9 (1.6, 4.1)
sTNFR1, plasma (pg/mL)	894.5 (794.4, 1023.6)	1587.1 (1254.0, 2079.9)	14.2 (3.6, 24.8)	75.0 (64.6, 85.4)	1.3 (0.8, 1.8)	3.4 (2.9, 3.9)
Arginine-citrulline ratio, plasma	1.9 (1.6, 2.2)	1.5 (1.2, 1.9)	-0.03 (-0.05, -0.01)	0.01 (-0.02, 0.03)	-1.7 (-2.7, -0.8)	0.1 (-1.0, 1.3)
UMOD urinary excretion (mg/day)	52.9 (24.2, 108.4)	65.7 (34.6, 111.0)	0.6 (-1.6, 2.7)	-3.7 (-6.4, -1.0)	0.7 (-2.3, 3.8)	-5.8 (-9.3, -2.2)
EGF urinary excretion (µg/day)	25.7 (20.2, 33.7)	10.5 (6.7, 15.7)	-0.2 (-0.5, 0.1)	-0.3 (-0.7, -0.008)	-1.5 (-3.0, 0.1)	-4.6 (-6.3, -2.8)
Tubular secretion score	68.9 (66.1, 71.0)	64.9 (60.5, 68.6)	0.1 (-0.1, 0.3)	-0.6 (-0.8, -0.3)	0.1 (-0.4, 0.6)	-1.2 (-1.7, -0.6)
iGFR (ml/min/1.73m^2)	126.0 (113.0, 136.8)	65.0 (51.8, 77.5)	-1.4 (-1.7, -1.1)	-1.8 (-2.2, -1.5)	-1.2 (-1.6, -0.7)	-3.4 (-3.8, -2.9)
AER (µg/min)	4.7 (3.6, 6.2)	56.8 (10.5, 257.8)	0.6 (-17.0, 18.2)	52.6 (34.1, 71.1)	-2.7 (-5.5, 0.1)	7.3 (4.5, 10.3)

Biomarkers represent various aspects of tubular health: tubular injury (KIM-1), inflammation (sTNFR1), synthesis (arginine-citrulline ratio; UMOD), viability (EGF), and secretion (clearance of secretory solutes). Tubular secretion scores were calculated from the clearances of 8 secretory solutes (cinnamoylglycine, indoxyl sulfate, isovalerylglycine, kynurenic acid, p-cresol sulfate, pyridoxic acid, tiglylglycine, xanthosine). Clearances for each solute were log-transformed then min-max scaled. Afterwards, scaled values for all solutes were averaged to generate a summary tubular secretion score.

Association of Urinary DNlite IVD-103 with CKD and Coronary Artery Disease in Diabetic Nephropathy

Varun Kumar Bandi, Harsha Nnss, Sindhu Chaganti. *Dr Pinnamaneni Siddhartha Institute of Medical Sciences & Research Foundation, Vijayawada, India.*

Background: Fetuin-A is associated with inflammation and vascular complications in diabetes. We evaluated association of urinary post-translationally modified fetuin-A (DNlite IVD-103) in diabetics with chronic kidney disease (CKD) and coronary artery disease (CAD).

Methods: A cross-sectional study was conducted in patients with diabetic nephropathy. Patients and divided into those having only albuminuria, CKD or CAD. eGFR (Glomerular Filtration Rate) was calculated using CKD-EPI equation, and an eGFR <60ml/min/1.73m2 was considered CKD. Severity of CAD was assessed using SYNTAX score. Spot urine was tested for urine albumin to creatinine ratio (UACR), and DNlite-IVD103 (Fetuin) was measured using ELISA test kit. Urinary Fetuin:creatinine ratio (UFCR) was calculated. Statistical analysis was carried out using SPSS v23.0. A p value of <0.05 was considered significant.

Results: 137 patients were included, with 61% being men. The mean age, eGFR, UACR, and FCR were 56.4±11.8 years, 64.5±36.4 ml/min/1.73m^2, 1359±2030.6 mg/g, and 175±268.9 ng/g, respectively. Of these, 20.4% of patients had CAD, 39.4% had albuminuria, and 40.1% had CKD. There was a significant difference in UACR and UFCR between the groups. UACR had significant positive correlation with age and negative correlation with eGFR (p<0.05). UFCR had significant negative correlation with eGFR. UFCR was also significantly higher in patients with CKD compared to CAD (p<0.05). Compared to albuminuria patients, UACR, and UFCR were significantly increased in patients with CAD (p<0.05) and CKD (p<0.01). In patients with CAD, SYNTAX II score had significant negative correlation with UFCR (p<0.05) but not UACR (p=0.58)

Conclusions: DNlite IVD-103 is significantly associated with worsening renal function, and is not influenced by age. It was also significantly different between CAD & CKD, and also had significant correlation with severity of CAD. UFCR could be used to stratify patients with micro- or macrovascular disease (albuminuria, CAD, CKD).

Relationship Between Urinary DcR2/Cr Levels and Poor Prognosis of Diabetic Nephropathy

Weidong Wang, Jia Chen, Yani He, Kehong Chen. *Department of Nephrology, Daping Hospital, Army Specialized Medical Center, Chongqing, China.*

Background: Urinary decoy receptor 2 is closely associated with interstitial injury in diabetic kidney disease, and the aim of this paper was to investigate whether urinary DcR2/Cr levels could be used as a biomarker to predict poor prognosis in diabetic kidney disease.

Methods: A total of 96 patients diagnosed with diabetic kidney disease by pathological biopsy and with urine specimens retained were included. Basic data, laboratory findings, and pathological information were collected for retrospective analysis, and patients were followed up, and the follow-up time and endpoint events were recorded. The follow-up (composite) endpoint was defined as a doubling of the patient's serum creatinine level or entry into ESRD. ESRD was defined as a patient's eGFR <15 ml/(min-1.73 m2) or initiation of renal replacement therapy. According to the urinary DcR2/Cr levels, they were divided into three groups, group 1: DcR2/Cr <287ng/mmol, group 2: 287≤DcR2/Cr≤544ng/mmol, group 3: DcR2/Cr>544ng/mmol. Analyzed using Kaplan–Meier and Cox regression analyses.

Results: With the increase of DcR2/Cr levels, urinary protein quantification, urinary albumin creatinine ratio (ACR), cystatin C (CYC), blood creatinine, total cholesterol, triglycerides, and LDL levels tended to increase, while the estimated glomerular filtration rate (eGFR), hemoglobin, and serum albumin levels gradually decreased (P<0.05). Correlation analysis revealed that DcR2/Cr levels were positively correlated with ACR (P<0.01), CYC (P<0.01), and blood creatinine (P<0.05) and negatively correlated with eGFR (P<0.05); DcR2/Cr levels were positively correlated with IFTA score (P<0.01) and renal atherosclerosis score (P<0.05). COX regression analysis revealed that The Kaplan-Meier survival curves showed that the risk of adverse prognosis was 5.213 times higher

in the DcR2/Cr3 group than in the DcR2/Cr1 group. The higher the DcR2/Cr level, the worse the prognosis of the patients.

Conclusions: Urinary DcR2/Cr is closely associated with DKD interstitial injury and is a valid biomarker for predicting poor prognosis in DKD.

Urinary Podocyte Stress Marker as a Prognostic Indicator for Diabetic Kidney Disease

Lingfeng Zeng.[1,2] *[1]The Chinese University of Hong Kong Faculty of Medicine, Hong Kong, Hong Kong; [2]Prince of Wales Hospital, Hong Kong, Hong Kong.*

Background: Diabetic kidney diseases (DKD) is a the most common cause of end-stage kidney disease (ESKD) around the world. Previous studies suggest that urinary podocyte stress biomarker, e.g. podocin:nephrin mRNA ratio, is a surrogate marker of podocyte injury in non-diabetic kidney diseases.

Methods: We studied 118 patients with biopsy-proved DKD and 13 non-diabetic controls. Their urinary mRNA levels of nephrin, podocin, and aquaporin-2 (AQP2) were quantified. Renal events, defined as death, dialysis, or 40% reduction in glomerular filtration rate, were determined at 12 months.

Results: Urinary podocin:nephrin mRNA ratio of DKD was significantly higher than the control group (p=0.0019), while urinary nephrin:AQP2 or podocin:AQP2 ratios were not different between groups. In DKD, urinary podocin:nephrin mRNA ratio correlated with the severity of tubulointerstitial fibrosis (r = 0.254, p = 0.006). and was associated with the renal event-free survival in 12 months (unadjusted hazard ratio [HR], 1.523; 95% confidence interval [CI] 1.157-2.006; p = 0.003). After adjusting for clinical and pathological factors, urinary podocin:nephrin mRNA ratio have a trend to predict renal event-free survival (adjusted HR, 1.327; 95%CI 0.980-1.797; p = 0.067), but the result did not reach statistical significance.

Conclusions: Urinary podocin:nephrin mRNA ratio has a marginal prognostic value in biopsy-proven DKD. Further validation is required for DKD patients without kidney biopsy.

A Second Dose of Allogeneic Neo-Islets (NIs) Further Reduces Insulin Need and HbA1c and Preserves Renal Function Long Term in Autoimmune T1DM Pet Dogs (INAD 012-776)

Anna Gooch, Christof Westenfelder. *SymbioCellTech, Salt Lake City, UT.*

Background: Spontaneously T1D dogs, like T1D humans, never spontaneously revert to a non-diabetic state. Their insulin needs remain stable or increase. They experience progressive CKD, hyperlipidemia, hepatic steatosis, diabetic neuropathy and retinopathy, malignancies, hypoglycemic events, and other complications, making them an ideal translational model for T1DM. We reported (n=8 dogs) that one dose of Neo-Islets (NIs), organoids of Mesenchymal Stromal Cells (MSCs) and culture expanded Islet Cells, when administered i.p. engraft in the omentum where they physiologically secrete insulin and other islet hormones, thereby reducing the need for insulin in autoimmune, spontaneously T1DM pet dogs by up to 50% for up to 3 years. As the MSC component is immune-modulatory, NIs require no antirejection drugs. Here we demonstrate that NIs' beneficial effects are enhanced through administration of a 2nd dose.

Methods: 4 of the original 8 NI-treated, autoimmune diabetic dogs were administered a second dose of 2x10e5 NIs/kg bw i.p. at various times post the first dose. Dogs were assessed for antibodies to NIs, changes in serum glucose, HbA1c, insulin need, liver and renal function, blood counts, adverse and serious adverse events and their relation to administration of the study drug.

Results: A dog who had been unresponsive to the first dose of NIs received a 2nd dose 4 years post the 1st dose. 1 year later, she has a 25% reduced need for insulin, and a 17% reduction in serum glucose. Of the 3 dogs re-dosed within a year of the first administration, insulin need has decreased 25- 50%, and serum glucose levels decreased 40-59%. HbA1c levels are ~4 percentage points reduced, and within normal range. No significant changes in renal function, serum chemistries or blood counts have been observed in the 2-12 months since redose. No dog has developed antibodies to NIs subsequent to either dose. No AEs or SAEs have been attributed to NI therapy.

Conclusions: Allogeneic-NI therapy, which delivers insulin physiologically, is safe durably effective, requires no anti-rejection drugs, can be safely re-administered, and preserves renal function long term. As with human islet transplants, redosing potentiates therapeutic efficacy, and several doses may be required to achieve insulin independence.

Identification and Validation of Neutrophil Extracellular Traps-Associated Genes in Diabetic Kidney Disease: Integration Data from Bulk RNA and Single-Nucleus RNA Sequencing Analyses

Ruiyan Xie, Sin Yu Cindy Tang, Ka Ho Jason Sher, Danting Zhang, Yat Hin Desmond Yap. Dr. Yap, Yat Hin Desmond Team. *Department of Medicine, The University of Hong Kong, Queen Mary Hospital, Hong Kong, China.*

Background: Accumulating data shows that immune response has crucial pathogenic contributions in diabetic kidney disease (DKD), but the contribution of Neutrophil Extracellular Traps (NETs) is limited.

Methods: The differentially expressed genes of NETs in human DKD were selected using the bulk RNA-seq of kidney biopsy from DKD patients (GSE30528 and GSE30529). The characteristic NETs-associated genes were further identified by machine learning algorithms. The DKD bulk RNA sequencing (GSE30122) and single-nucleus RNA-seq (GSE195460) were used to validate the genes expression.

Results: Three candidate genes (ITGAM, ITGB2 and TLR7) were all significantly upregulated in human DKD using machine learning approach. Single-cell analysis indicated that the three transcriptional expressions were mostly increased in leucocytes. GSEA further suggested that hub genes play key roles in IL-2/STAT5 signaling pathway (p=0.029). Good diagnostic performance for DKD were also shown. Our polit data validated ITGAM and ITGB2 expressions in the peripheral active neutrophils isolated from DKD patients.

Conclusions: Dysregulation of ITGAM and ITGB2 may play pathogenic roles for DKD, and drugs that target these genes in neutrophil may have therapeutic potential for DKD.

The Search for Liquid Biopsies: Serum Biomarkers and Kidney Structure in Early Diabetic Kidney Disease

Helen C. Looker,[1] Zaipul Md Dom,[2] Robert G. Nelson,[1] Andrzej S. Krolewski.[2] *[1]National Institute of Diabetes and Digestive and Kidney Diseases, Phoenix, AZ; [2]Joslin Diabetes and Endocrinology Research Center, Boston, MA.*

Background: The Joslin Kidney Panel (JKP) of 21 circulating proteins biomarkers linked to inflammation, axon guidance, fibrosis, and tubular damage is associated with kidney failure in Caucasians with type 1 diabetes from the Joslin Kidney Study and in American Indians with type 2 diabetes. We examined the association of these proteins with early kidney structural lesions in a subset of the American Indians who also underwent a research kidney biopsy.

Methods: GFR was measured by the urinary clearance of iothalamate and serum samples collected at these visits were measured on an OLINK platform using a proximity extension assay. Research kidney biopsies were obtained a median of 1.3 years from the clearance study. Kidney structure was assessed using standard morphometric techniques. Regression models with Lasso selection and k-fold cross-validation were used to assess best biomarkers for each measure.

Results: Mean age of the 107 participants (78 women) was 45.5 (SD 9.6) years, blood pressure 123 (13) / 77 (9) mmHg, HbA1c 9.2 (2.3)%, GFR 150 (47) ml/min, and median diabetes duration was 12.8 (IQR 11.0-19.4) years. All participants had GFR >60 ml/min; 40 (37%) had moderate albuminuria and 21 (20%) had severe albuminuria. Biomarker concentrations correlated positively with global glomerular sclerosis, glomerular basement membrane width, mesangial fractional volume, cortical interstitial fractional volume, and podocyte foot process width and negatively with glomerular filtration surface density, total filtration surface density, podocyte density, and percentage of endothelial fenestrations (Figure). KIM1 was the leading biomarker for most morphometric parameters based on regression models (Figure).

Conclusions: The JKP of biomarkers that includes proteins linked to multiple diabetic kidney disease (DKD) pathways demonstrated associations with a broad range of early structural lesions associated with DKD progression.

Funding: NIDDK Support

Significance of Non-B Cell-Derived Immunoglobulin G in the Renal Tubulointerstitium of Chinese Patients with Type 2 Diabetic Kidney Disease

Xinyao Wang, Zhenling Deng, Yue Wang. *Peking University Third Hospital, Beijing, China.*

Background: Epithelial-mesenchymal transition (EMT) is critical in the progression of DKD. Studies have reported that positive IgG staining in renal tubules in patients with DKD, but the significance is unknown. Studies have demonstrated that renal intrinsic cells, including renal tubular epithelial cells, can produce IgG (non-B IgG). Therefore, we clarified the non-B IgG in the tubulointerstitium of patients with DKD and its clinicopathological features, and may contribute to renal tubule EMT.

Methods: A total of sixty patients with type 2 diabetes mellitus and biopsy-proven DKD was studied retrospectively. The monoclonal antibody RP215 can screen out human non-B IgG rather than B-IgG. The clinicopathological features of non-B IgG deposition in the renal tubulointerstitium were compared with and without. The risk factors for poor renal function and interstitial lesions were evaluated using logistic regression analysis. In addition, the relationship between tubulointerstitial non-B IgG deposition and EMT was assessed in 30 patients with DKD.

Results: The non-B IgG positive patients showed decreased eGFR (p=0.038) and more severe anemia(p=0.002). Multivariate logistic regression analysis showed that tubulointerstitial non-B IgG deposition was an independent risk factor for poor renal function(p=0.037) and interstitial lesions(p=0.030). The positive area of non-B IgG in DKD renal tubulointerstitium and α-SMA showed a positive correlation (p=0.034).

Conclusions: Renal tubulointerstitial non-B IgG deposition in patients with DKD showed poorer renal function and severe interstitial lesions. The renal tubule EMT was more sever in positive tubulointerstitial non-B IgG staining, suggesting that non-B IgG may be involved in DKD kidney injury by promoting EMT.

Funding: Government Support - Non-U.S.

Cardiovascular Benefits and Safety of Sacubitril-Valsartan in ESKD: A Systematic Review and Meta-Analysis

Mariam Charkviani, Pajaree Krisanapan, Charat Thongprayoon, Iasmina Craici, Wisit Cheungpasitporn. *Mayo Clinic Minnesota, Rochester, MN.*

Background: End-stage kidney disease (ESKD) patients often experience heart failure, which significantly contributes to their high mortality rates. Despite the crucial role of sacubitril-valsartan in heart failure management, limited data exists on its cardiovascular benefits and safety in ESKD patients. This systematic review aims to assess the efficacy and safety of sacubitril-valsartan compared to standard care in ESKD patients on dialysis, addressing this critical knowledge gap.

Methods: A comprehensive search of was conducted in Embase, MEDLINE, and Cochrane databases though February 2022 to identify studies assessing cardiovascular and/or safety outcomes of sacubitril-valsartan in ESKD patients on dialysis. Effect estimates were derived and consolidated using a random-effect model and the generic inverse variance approach.

Results: Analysis of 12 studies involving 799 eligible ESKD patients demonstrated notable improvements in left ventricular ejection fraction (LVEF) with sacubitril-valsartan compared to the control group, resulting in a pooled mean difference (MD) of 6.58 (95% CI 1.86, 11.29). Subgroup analysis revealed significant differences between heart failure patients with reduced ejection fraction (HFrEF) or moderately reduced ejection fraction (HFmrEF) versus preserved ejection fraction (HFpEF) (p<0.0001). LVEF significantly improved in patients with LVEF <50% (HFrEF and HFmrEF) with an MD of 12.42 (95% CI 9.39, 15.45). However, patients with LVEF >50% (HFpEF) did not show a statistically significant effect, reporting an MD of 2.6 (95% CI 1.15, 6.35). Notably, sacubitril-valsartan significantly enhanced LVEF in HFrEF patients, with a pooled MD of 13.8 (95% CI 12.04, 15.82). Safety analysis revealed no significant differences in the incidence of hyperkalemia (pooled odds ratio [OR] 0.72; 95% CI 0.38, 1.36) or hypertension (pooled risk ratio [RR] 1.03; 95% CI 0.36, 2.98) between sacubitril-valsartan and standard care groups. No cases of angioedema were reported.

Conclusions: Our systematic review suggests that sacubitril-valsartan, compared to standard care, provides benefits to ESKD patients with HFrEF and HFmrEF by improving LVEF, without increasing the risk of hyperkalemia, hypotension, or angioedema.

Nocturnal Systolic Blood Pressure Dipping and Progression of CKD

Jun Hye Seo,[1] Hyojin Ahn,[1] Cheol Ho Park,[1] Boyoung Nam,[2,1] Jaejin Ryu,[2,1] Gyu R. Kim,[2,1] Tae-Hyun Yoo,[1] Hyung Woo Kim,[1] Seung Hyeok Han,[1] Shin-Wook Kang.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]Yonsei University Institute of Kidney Disease, Seodaemun-gu, Seoul, Republic of Korea.*

Background: The relationship between declining nocturnal blood pressure (BP) and adverse cardiovascular outcomes is well-recognized. However, the relationship between diurnal BP profile and the risk of chronic kidney disease (CKD) progression is unclear.

Methods: We analyzed 1,061 participants from Cardiovascular and Metabolic Disease Etiology Research Center-High Risk (CMERC-HI). The main exposure was diurnal systolic BP (SBP) profile and diurnal SBP difference ([nighttime SBP-daytime SBP]×100/daytime SBP). The primary outcome was CKD progression, defined as a composite of ≥ a 50% decline in the estimated glomerular filtration rate from baseline or the initiation of kidney replacement therapy.

Results: During 4,749 person-years of follow-up (median, 4.8 years), the composite outcome occurred in 380 (35.8%) participants. Compared to dippers, the hazard ratios (HRs) for the risk of adverse kidney outcomes were 1.02 (95% confidence interval [CI], 0.64–1.62), 1.30 (95% CI, 1.02–1.66), and 1.40 (95% CI, 1.03–1.90) for extreme dipper, non-dipper, and reverse dipper, respectively. In a continuous modeling, a 10% increase in diurnal SBP difference was associated with a 1.21-fold (95% CI, 1.07–1.37) higher risk of CKD progression.

Conclusions: Decreased nocturnal SBP decline was associated with adverse kidney outcomes in patients with CKD. Particularly, patients with non-dipping and reverse dipping patterns were at higher risk for CKD progression than those with a dipping pattern.

TH-PO197

The 2021 KDIGO Blood Pressure Target and the Progression of CKD: Findings from KNOW-CKD

Jun Hye Seo,[1] Hyojin Ahn,[1] Cheol Ho Park,[1] Hyung Woo Kim,[1] Jung Tak Park,[1] Tae ik Chang,[2] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Seung Hyeok Han.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: The 2021 KDIGO clinical practice guideline for management of blood pressure (BP) in chronic kidney disease (CKD) recommends a target systolic BP of remains unknown.

Methods: We examined the association of the 2021 KDIGO BP target with CKD progression compared with the 2012 KDIGO BP target among 1724 participants from the Korean Cohort Study for Outcomes in Patients With CKD. The main exposure was BP status categorized according to the 2012 or 2021 KDIGO guideline: 1) controlled within 2021 target; 2) controlled within 2012 target only; and 3) above both targets. The primary outcome was a composite kidney outcome of ≥50% decline in estimated glomerular filtration rate from baseline or the initiation of kidney replacement therapy during the follow-up.

Results: During 8,078 person-years of follow-up (median, 4.9 years), the composite kidney outcome occurred in 650 (37.7%) participants. The incidence rates of this outcome were 55, 66.5, and 116.4 per 1,000 person-years in BP controlled within the 2021 and 2012 KDIGO targets, and BP above both targets, respectively. In the multivariable cause-specific hazard model, hazard ratios for the composite outcome were 0.76 (95% confidence interval, 0.60-0.95) for BP controlled within the 2021 target and 1.36 (95% confidence interval, 1.13-1.64) for BP above both targets, compared with BP controlled within 2012 target only.

Conclusions: The newly lowered BP target by the 2021 KDIGO guideline was associated with improved kidney outcome compared with BP target by the 2012 KDIGO guideline.

TH-PO198

Early Decline in GFR Predicts Long-Term Renal Events in Hypertensive CKD Patients Using Renin-Angiotensin System (RAS) Blockers

Giae Yun,[1] Ho Jun Chin.[1,2] *[1]Seoul National University Bundang Hospital Department of Internal Medicine, Seongnam, Gyeonggi-do, Republic of Korea; [2]Seoul National University College of Medicine Department of Internal Medicine, Seoul, Republic of Korea.*

Background: Renin-angiotensin-aldosterone inhibitors (RASIs) are essential in treating chronic kidney disease (CKD), but their initiation can lead to a decline in glomerular filtration rate (GFR). Limited research exists on the impact of RASI-induced GFR changes on long-term GFR variations and albuminuria.

Methods: This observational cohort study extends an open-label, case-controlled randomized clinical trial (NCT01552954) with hypertensive CKD patients(estimated GFR (eGFR) ≥30ml/min/1.73m^2, random urine albumin-to-creatinine ratio (UACR) ≥30mg/g creatinine). After an 8-week screening phase (0-week) after discontinuing RASIs, participants were prescribed an angiotensin receptor blocker (ARB: Olmesartan 40mg/day) and underwent a second visit at 8 weeks with randomization into intensive or conventional low-salt diet education. Third visit was conducted at 16 weeks. We recruited participants for cohort observation and completed at 38 months(29-48) after a 0-week visit. Patients were grouped into tertiles based on percent change in initial GFR during the first 8 weeks (**pcGFRi**).

Results: We analyzed data from 174 people finished 38-month observation among 235 participants enrolled for the trial phase. Groups 1, 2, and 3 (first, second, and third tertiles) showed percent changes in GFR of -16.0(-41.5~-8.1), -2.8(-7.3~-1.6), and 8.3(1.8~28.4)%, respectively. At the 0-week visit, there were no differences in the tertile groups' age, gender, GFR, 24hr UACR, or 24hr sodium excretion. These factors positively correlated with the percent change in GFR during the study period (factor B=8.180, p<0.001 for the group; factor B=0.801, p<0.001 for pcGFRi). The GFR slopes during a study peroid were, in order, -2.9(-4.0~-1.8), -1.3(-2.4~-0.3), and 0.1 (-1.0~1.2)ml/min/1.73 m^2/year (p=0.001 by the ANCOVA test). The relative risks to eGFR decrease ≥30% in groups 2 and 3 compared to 1 were 0.237 (0.07~0.798, p=0.020) and 0.035 (0.004~0.302, p=0.035). The pcGFRi's AUC to eGFR decrease ≥30% was 0.787 (0.685–0.889, p0.001). The cut-off value for pcGFRi eGFR decline ≥30% is 7.25% (71.4 % sensitivity, 70.9% specificity).

Conclusions: The decline of GFR by initiation of RASI predicts long-term renal event of GFR decline ≥30% in users of RASI, strongly. Further research comparing renal outcomes between RASI users with initial decrease in GFR and non-users is needed to guide RASI usage based on initial change in GFR.

TH-PO199

Association of Tricuspid Regurgitant Jet Velocity with Kidney Function in Patients with Heart Failure with Preserved Ejection Fraction in TOPCAT

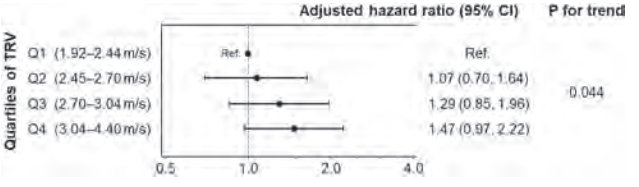
Tatsufumi Oka,[1] Hocine Tighiouart,[1] Wendy I. McCallum,[1] Marcelle Tuttle,[1] Jeffrey M. Testani,[2] Mark J. Sarnak.[1] *[1]Tufts Medical Center, Boston, MA; [2]Yale School of Medicine, New Haven, CT.*

Background: Pulmonary hypertension is common and associated with higher mortality in heart failure with preserved ejection fraction (HFpEF). While increasing evidence suggests that venous congestion can cause worsening kidney function, the association of pulmonary artery systolic pressure (PASP) with kidney function remains uncertain in patients with HFpEF.

Methods: This post-hoc analysis of the Treatment of Preserved Cardiac Function Heart Failure with an Aldosterone Antagonist (TOPCAT) trial analyzed patients with HFpEF who had an echocardiogram at baseline. The exposure variable was tricuspid regurgitant jet velocity (TRV), a surrogate of PASP. In a cross-sectional analysis, the association of TRV with eGFR at baseline was assessed using linear regression. In a longitudinal analysis, the association of quartiles of TRV with time to eGFR decline of ≥30% was assessed using a Cox proportional hazards regression. Covariates, including patient demographics, comorbidities, laboratory data, medications, and randomized group, were adjusted in the multivariable models.

Results: Among 450 patients, median age, TRV, and eGFR at baseline were 73 years, 2.7 m/s, and 61 mL/min/1.73 m^2, respectively. In a multivariable analysis, each 1.0 m/s higher TRV was significantly associated with a 3.9 (95% confidence interval, 0.2–7.6) ml/min/1.73 m^2 lower eGFR at baseline. Over a median follow-up of 94 weeks, 52 patients died and 203 had an eGFR decline of ≥30%. Patients with a higher quartile of TRV had a higher risk of eGFR decline of ≥30% (Figure). There was no interaction by randomized group ($P_{interaction}$ =0.45). An analysis using all-cause death as a competing event did not substantially change the results.

Conclusions: A higher TRV was associated with a higher risk of kidney function decline among patients with HFpEF in TOPCAT.



TH-PO200

Association of Pulmonary Arterial Pulsatility Index (PAPi) with Kidney Outcomes Among Patients Admitted for Acute Decompensated Heart Failure

Marcelle Tuttle,[1] Hocine Tighiouart,[1] Jeffrey M. Testani,[2] Run Banlengchit,[1] Amanda I. Moises,[1] Hannah L. Sarnak,[1] Tatsufumi Oka,[1] Michael S. Kiernan,[1] Mark J. Sarnak,[1] Wendy I. McCallum.[1] *[1]Tufts Medical Center, Boston, MA; [2]Yale University, New Haven, CT.*

Background: Pulmonary arterial pulsatility index (PAPi), defined as (pulmonary artery (PA) systolic pressure - PA diastolic pressure)/right atrial pressure, has emerged as a novel marker to capture right ventricular failure. Lower PAPi is associated with increased risk of death but has not been studied in association with renal outcomes.

Methods: Records for patients requiring a PA catheter for acute decompensated heart failure (ADHF) admissions to a single quaternary center between 2015-2021 were reviewed. PAPi was calculated based on the initial measurements; values were log-transformed given their skewed distribution. Linear regression models were used to examine the cross-sectional association of PAPi with baseline estimated glomerular filtration rate (eGFR) and in-hospital eGFR slope. Patient records were linked to the US Renal Data System to capture dialysis outcomes. We used multivariable Cox proportional hazards regression models to examine the association of PAPi with dialysis and the composite endpoint of death or heart transplant (HT). Covariates included demographics, measures of cardiac disease severity and medications.

Results: Among 753 patients with mean age 62 (SD 14) years, median PAPi was 2.0 (IQR 1.4, 3.2), mean eGFR of 58 (SD 27) ml/min/1.73m^2 and mean eGFR slope was 1.2 (SD 6.2) ml/min/1.73m^2/week. For every doubling of PAPi, there was a 3.3 ml/min/1.73m^2 (95% CI 1.5, 5.2) higher baseline eGFR, and 0.7 (95% CI 0.3, 1.2) ml/min/1.73m^2/week higher in-hospital eGFR slope. Over median follow-up of 23 (IQR 8, 47) months, 62 (8%) reached dialysis and 365 (48%) reached the composite endpoint. Higher PAPi was associated with significantly lower risk of requiring dialysis both in unadjusted and adjusted models (Table). Higher PAPi also trended toward decreased risk for the composite outcome (Table).

Conclusions: Higher PAPi is associated with higher baseline eGFR, higher in-hospital eGFR slope and lower risk of progression to dialysis in patients admitted for ADHF.

Funding: NIDDK Support

Table. Hazard ratios for risk of composite outcome of death or heart transplant and need for dialysis per doubling of PAPi.

Outcome	Need for Dialysis	Death/Heart Transplant
N	753	753
Number of Events	62	365
Unadjusted HR (95% CI)	0.64 (0.49, 0.83)	0.92 (0.83, 1.03)
Adjusted HR (95% CI) *	0.70 (0.51, 0.96)	0.92 (0.82, 1.04)

*Adjusted for age, sex, ejection fraction, diabetes, estimated glomerular filtration rate and use of renin angiotensin aldosterone system blockade, mineralocorticoid receptor antagonists, angiotensin receptor/neprilysin inhibitors, and inotropes.

TH-PO201

Is the Increased Risk of Heart Failure with Preserved Ejection Fraction (HFpEF) and Heart Failure with Reduced Ejection Fraction (HFrEF) in CKD in Type 2 Diabetes (T2D) explained by Hypertension (HTN)?

Sydney E. Hartsell,[1,2] Amara Sarwal,[1,2] Guo Wei,[1,2] Mckenna R. Nevers,[1,2] Brad Adams,[1,2] Ravinder Singh,[1,2] Robert E. Boucher,[1,2] Azeem M. Mohammed,[2] Tom Greene,[1,2] Srinivasan Beddhu.[1,2] *[1]VA Salt Lake City Health Care System, Salt Lake City, UT; [2]University of Utah Health, Salt Lake City, UT.*

Background: CKD is a clear risk factor for HFpEF and HFrEF but the degree to which HTN it plays a role in the pathogenesis of these disorders in CKD is unknown.

Methods: We used the VA Informatics and Computing Infrastructure to create a national cohort of veterans with T2D but without HF (using ICD9/10 codes) who had at least 2 outpatient CKD-EPI eGFR measured from 1/1/2000 to 12/31/2021 (n=2,462,350). Incident HF through 12/31/2021 were identified using ICD 9/10 codes. Using ejection fraction (EF) data extracted with natural language processing from echocardiograms done within 180 days of HF diagnosis, HFpEF (EF ≥ 50%) and HFpEF (< 50%) were defined. We related CKD stages at baseline with time to HFpEF or HFrEF incidence while adjusting for demographics, baseline comorbidities, BMI, duration of T2D, diabetic retinopathy, T2D meds, statins and A1C in separate Cox regression models. We then adjusted for baseline hypertension, blood pressure (BP) and BP-modulating medications.

Results: Out of 410,783 (16.7%) patients who developed HF over 1.78 million patient-years of follow up, 289,508 (70.5%) had an echocardiogram within 180 days of diagnosis (median days for the closet echo with diagnosis 1 with IQR 0 to 13). Mean EF was 45±15%. Overall, 168,079 (6.8%) patients developed HFpEF and 121,421 (4.9%) HFrEF. As shown in the Figure, adjusted for demographics, comorbidity and other factors, more advanced CKD was associated with higher risk of HFpEF and HFrEF. Adjusting for baseline hypertension, SBP and DBP and BP meds resulted in modest to moderate attenuation of the associations of CKD stages with HFpEF or HFrEF.

Conclusions: HTN appears to play a role in both HFpEF and HFrEF, particularly in CKD stages 3a and 3b to 4. Intensive BP control might reduce the risk of HFpEF and HFrEF in these stages of CKD than in stage V/ ESRD.

TH-PO202

Is Pulmonary Hypertension (PH) Associated with the Type of Hemodialysis Access and Is PH a Barrier to Kidney Transplant?

Muhammad U. Jahngir, Christine De Antonis, Avrum Gillespie. *Temple University, Philadelphia, PA.*

Background: In hemodialysis (HD) patients, PH is multifactorial. Surgically created arterio-venous (AV) fistulas/grafts may contribute to PH by increasing right ventricular preload. We compared the prevalence of PH among patients with AV accesses to those with hemodialysis central venous catheters (CVC). We then examined whether PH was a contraindication to kidney transplantation.

Methods: A single-center 10-year retrospective cross-sectional study of right heart catheterizations (RHC) in randomly selected HD patients, were identified with the CPT codes: 93451 and ICD10 Z99.2. Patients with a previous solid organ transplantation or advanced heart failure requiring inotropic or mechanical support were excluded. Categorical variables were compared with Fisher's exact tests and continuous variables were compared with t-tests.

Results: 3834 charts were extracted, 257 were reviewed, and 107 were included. 65% were male and 63% had diabetic renal disease. The median dialysis vintage was 26 months (IQR:61.8months). 64.5% patients had mean pulmonary arterial pressure of >20mmHg, 43% had pulmonary capillary wedge pressure ≥15mmHg, and 22% had pulmonary vascular resistance of ≥3.00. The type of HD access was not associated with PH (47%CVC vs 41%AV, p=0.65). Among 26% patients with vascular duplex, there was no difference between AV access flow rates in those with and without PH (median(IQR):1483(2139) vs 1267(2092), p=0.29). 86% survived after 1-year of RH and mortality was not associated with prevalance of PH. There was no difference in transplant candidacy between those with and without PH (81% vs 75%, p=0.47).

Conclusions: PH was common in HD patients (42%), and the type of vascular access was not associated with PH between. Diagnosis of PH had no direct effect on transplant candidacy.

Assessing Heart Rate Variability in Patients with CKD: Association with Vascular Dysfunction

Obed O. Nyarko, Cortney Steele, Ester Oh, Heather Farmer-Bailey, Mallory Britz, Michel Chonchol, Kristen L. Nowak. *University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Background: Autonomic dysfunction (AD) has been recognized as an important contributor to poor outcomes in patients with chronic kidney disease (CKD) characterized by adrenergic overdrive and/or loss of parasympathetic activity. Heart rate variability (HRV) is a measure of the exact changes between successive R-R intervals in a heartbeat and reflects the balance between sympathetic and parasympathetic tone. HRV has been associated with all-cause mortality and vascular dysfunction in patients with cardiovascular diseases, but very few studies have assessed its association with vascular disease and dysfunction in CKD. Thus, this study examined HRV in patients with CKD and how it associates with vascular dysfunction.

Methods: This study cross-sectionally pooled baseline data from three clinical studies conducted in patients with stage 3-4 CKD. Five-minute electrocardiogram readings at rest with paced breathing were analyzed using an automated HRV analysis tool in the LabChart software. HRV parameters were compared to age-matched healthy controls. Regression models were used to evaluate associations of low HRV with other vascular parameters: endothelial dysfunction (brachial artery flow-mediated dilation [FMD_B%]), central arterial stiffness (carotid-femoral pulse-wave velocity [CFPWV]), local arterial compliance (carotid artery compliance), cerebrovascular stiffness (resting middle cerebral artery pulsatility index), and cerebrovascular reactivity (middle cerebral artery blood flow-velocity response to hypercapnia) in the CKD group.

Results: Forty-four participants with CKD (33/11 M/F; mean age (years) ± s.d 68±7, eGFR 44±11 ml/min/1.73m^2) were compared to nine age-matched controls (4/5 M/F;

65±8 years, eGFR 97±18 ml/min/1.73m^2). Patients with CKD had lower HRV (pRR50; Percent of adjacent R-R intervals with a difference greater than 50 ms) compared to controls (CKD: 7.7±4.2; control: 25.0±16.5; P=0.0001). Low pRR50 was inversely associated with endothelial dysfunction (FMD_B%) (r = -0.4320, P<0.05), but not with other vascular parameters.

Conclusions: Patients with CKD had lower HRV (autonomic dysfunction) than age-matched healthy controls. Low HRV associates with endothelial dysfunction. This observation should be explored in a larger cohort with further covariate adjustment.

TH-PO204

Phenotyping of Heart Failure (HF) Risk in CKD Using 12-Lead ECG

Qandeel H. Soomro,[1] Jasmin Divers,[2] David M. Charytan.[1] *[1]New York University Grossman School of Medicine, New York, NY; [2]New York University, New York, NY.*

Background: H in CKD is associated with high rates of mortality and recurrent hospitalizations. Early identification of individuals at increased risk for HF in CKD would facilitate improved risk stratification and modification of treatment strategies. Current tools to predict de novo HF in CKD are lacking. We aimed to analyze associations of standard ECG features and the risk of incident HF in CKD.

Methods: We assembled a dataset of clinical and ECG data on individuals at NYU with at least two eGFR measurements <60 mL/min/1.73m^2 ≥90 days apart and an ECGs done at NYU between 2012-2021. The index ECG was the first ECG after an eGFR measurement. We excluded individuals with existing history of HF or HF admission within 30 days of index ECG. HF event was defined as primary inpatient discharge diagnosis identified using validated ICD codes. Univariate associations were analyzed using KM curves, multivariable associations of ECG features and incidence HF event were analyzed using Cox proportional hazards adjusting for relevant covariates.

Results: Among 14,503 individuals included, HF event rate was 6.2% with median time to event of 672 days (340,1625). eGFR stages and sex were similar among those with and without HF. Standard ECG features such as PR, QRS, QT, QTc, P and T axis as well as HRV parameters derived from ECG such as SDNN, RMSSD, PRR50% differed significantly between the two groups on univariate analyses (Figure). The concentrations of potassium, albumin, and calcium were significantly different in those with and without HF. In the best fit model standard ECG but not HRV parameters were independent predictors of HF (Table).

Conclusions: Standard ECG features when combined with demographic and comorbidities data can predict incident HF in CKD.

Liver Elasticity in Heart Failure Patient: The Role of Kidney in Cardio-Hepatic Interaction

Hirohito Sugawara.[1,2] *[1]Showa Daigaku Yokohama-shi Hokubu Byoin, Yokohama, Japan; [2]Bokoi Tenshi Byoin, Sapporo, Japan.*

Background: Liver elastography is a novel ultrasound technique assessing elasticity of liver tissue. Previously, it had been reported that the more elevated liver stiffness, the poorer the prognosis in heart failure indicating cardio-hepatic interaction. However, clinical indication of liver elastography remains unrevealed. Moreover, reports about relationship between liver stiffness and heart failure subtypes haven't well been published. Therefore, we have investigated the cardio-hepatic interaction using liver elastography in heart failure subtypes.

Methods: We prospectively enrolled 58 consecutive patients with heart failure admission from April 2022 to March 2023. Liver elastography, transthoracic echocardiography and blood sampling were done at the time of discharge from heart failure treatment.

Results: Patients were divided into two groups according to the left ventricular ejection fraction (LVEF) of echocardiography: heart failure with reduced ejection fraction (HFrEF) group (EF ≦40%, n = 11) and non-HFrEF group (EF >40%, n = 31). The mean age of all patients was 83 ± 11 years. The mean age and the prevalence of hypertension and diabetes mellitus was higher in non-HFrEF group than in HFrEF group. The prevalence of taking SGLT2 inhibitors was lower in non-HFrEF group than in HFrEF group. LV end-diastolic diameter, LV end-systolic diameter was larger in HFrEF group than in non-HFrEF group. Tricuspid regurgitation pressure gradient (TRPG) was higher in non-HFrEF group than in HFrEF group. Inferior vena cava diameter was not different between two groups. The mean values of almost liver function tests of all patients were within the normal range. eGFR was lower in non-HFrEF group than in HFrEF group. Liver elasticity was higher in non-HFrEF group than in HFrEF group (7.1 ± 2.7 vs. 5.1 ± 1.5 hPa; P=0.008) indicating liver stiffness. Pearson's correlation coefficient showed that liver elasticity was positively correlated with the prevalence of diabetes mellitus, LVEF, TRPG, serum creatinine, AST, GGT and was negatively correlated with LV end-diastolic diameter, LV end-systolic diameter.

Conclusions: Liver stiffness was elevated and renal function was decreased in EF-preserved heart failure patients. Liver elasticity was correlated with the parameter of congestion (TRPG) and useful for the assessment of congestion. Renal function was also correlated with liver elasticity.

TH-PO206

Role of Dual-Energy Computed Tomography (DECT) in Detection of Carotid Artery Monosodium Urate Deposition (MSU) in Patients with CKD

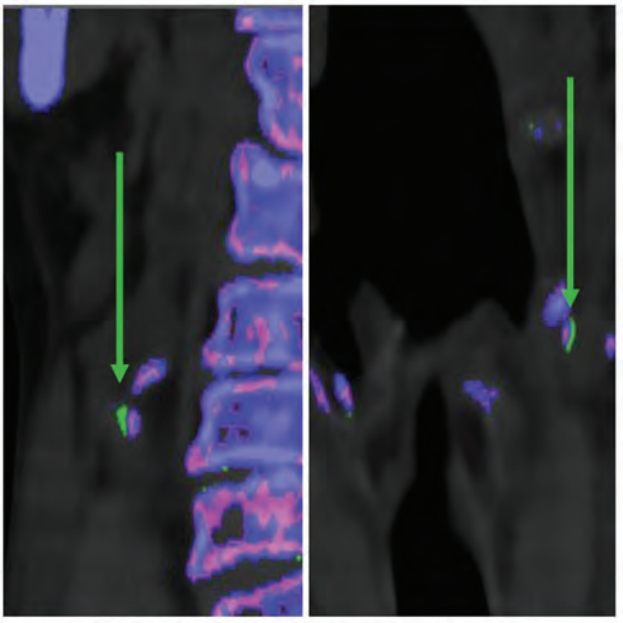
Muhammad Danish Sarfraz, Lee Treanor, Savvas Nicolaou, Adnan M. Sheikh. *The University of British Columbia, Vancouver, BC, Canada.*

Background: To find out if a Dual energy CT can detect MSU deposition in carotid arteries in patients with CKD and whether the presence of monosodium urate crystals has any effect on atherosclerotic disease in terms of plaque volume.

Methods: This is a retrospective study. All patients with CKD who underwent Dual energy neck imaging (like carotid angiogram, neck soft tissues or cervical spine) from January 2015 to December 2022 were included. Charts were reviewed to find CKD patients and potential confounding variables like isolated gout or smoking which can add to atherosclerotic disease. Same number of healthy controls were included which were then age (within 5 years), sex and confounders-matched to CKD patients using MedCalc. DECT datasets were post-processed using Syngo.ViaVB30 with MSU application and Calcium scoring application for volumetric analysis of atherosclerotic plaque.

Results: Out of total 2157 patients who underwent dual energy neck imaging during study period, 85 were established CKD cases with confirmed clinical and laboratory evidence. Of 85 CKD cases, 2 were excluded due to presence of artefacts from dentures, n=83. Out of 83, MSU was detected in carotid arteries of 10 patients (12%). None of the matched control patient demonstrated MSU deposition. Volumetric analysis of atherosclerotic plaque demonstrated larger plaque volumes in CKD patients with MSU (n=10) than matched CKD patients without MSU (n=10) and matched control/non-CKD patients (n=10) (p value of 0.03).

Conclusions: 1. Dual energy CT is an effective tool to detect MSU deposition in carotid arteries of patients with CKD. 2. MSU deposition increases atherosclerosis which can lead to increased TIA/strokes and hence has significant role in patient's morbidity.



Positive MSU carotid plaque in patient with CKD

Outcomes with Inpatient Use of Midodrine in Patients on Maintenance Hemodialysis with Heart Failure

Neev Patel,[1] Bruno Alvarez Concejo,[1] Meenakshi Mishra,[4] Kevin Bryan Lo,[3] Adrian P. Sequeira,[1] Ayeesha Kattubadi,[1] Janani Rangaswami.[2] *[1]LSU Health Shreveport, Shreveport, LA; [2]The George Washington University School of Medicine and Health Sciences, Washington, DC; [3]Albert Einstein Medical Center, Philadelphia, PA; [4]Ochsner Center for Academic Excellence, New Orleans, LA.*

Background: Midodrine, a peripheral vasoconstrictor, is commonly used in kidney failure patients for predialytic and intradialytic hypotension. However, in patients with systolic and/or right heart failure (HF), midodrine is potentially harmful. No known studies examine the safety of midodrine in hospitalized patients with kidney failure and HF.

Methods: We queried TriNetX database for inpatients with kidney failure and systolic and/or right HF who had at least an event of hypotension (SBP < 110 mm Hg or MAP < 70 mm Hg). Patients requiring critical care, inotropes or vasopressors were excluded. Cohorts were separated based on midodrine use. Temporality was established between hypotension, midodrine use, and hemodialysis, as shown in figure. Cohorts were matched for relevant comorbidities.

Results: In patients receiving midodrine, 6-month mortality risk ratio (RR) was significantly higher than no midodrine use (RR 1.53, 95% CI 1.037 to 2.246). Kaplan Meier survival analysis log-rank test at 6 months revealed a Hazard Ratio of 1.54 (95% CI 1.022 to 2.317).

Conclusions: In patients with systolic and/or right HF and kidney failure, hypotension is a limiting factor for decongestion and guideline directed therapy implementation, making midodrine a tool used in real world practice for stabilization. Our exploratory results in noncritically ill inpatients show an association between use of midodrine and higher 6-month mortality. This may reflect deleterious effects from vasoconstriction and/or unmeasured confounders in sicker patients with HF and kidney failure that increase mortality risk. This study has multiple limitations. Given its observational nature, it cannot establish a cause-effect relationship. Other limitations include the lack of data regarding dosage and duration of midodrine, and severity and etiology of heart failure. Our study demonstrates increased mortality associated with midodrine use for hypotension, warranting further research and consideration of alternative strategies.

The Characteristics of Myocardial Fibrosis and Analysis on Related Influencing Factors in Hemodialysis Patients

Bing Zhuang, Yuan Luo, Guiling Wei, Hong Ye, Junwei Yang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: This study aimed to analyze the characteristics of myocardial fibrosis and related influencing factors in hemodialysis patients, and to explore whether cardiovascular magnetic resonance (CMR) based on T1 mapping technique has prognostic value in predicting cardiovascular events.

Methods: This was a prospective observational study. The clinical data and dialysis parameters were collected, and laboratory tests were conducted. All patients underwent CMR, T1 mapping technique was used to identify myocardial interstitial fibrosis and LGE positive was used to identify alternative myocardial.

Results: A total of 42 hemodialysis patients were enrolled, the mean native T1 value of the entire heart was 1277.34±54.95ms. The native T1 value was positively correlated with heart rate and the ratio of transmitral Doppler early filling velocity to tissue Doppler early diastolic mitral annular velocity (E/e') (r=0.366, P=0.017; r=0.386, P=0.014), and negatively correlated with six-minute walk distance (r=-0.474, P=0.002). E/e' was found to be a risk factor for the mean native T1 value of the entire heart in hemodialysis patients (OR=1.508, 95% CI: 1.008-2.258, P=0.046). LGE scans were completed in 39 patients, of whom 12 (30.8%) were LGE positive and 27 (69.2%) were LGE negative. Compared with the LGE negative group, the LGE positive group had a shorter six-minute walk distance (P=0.029), larger left ventricular end-systolic volume (LVESV) and left ventricular mass (LVM) (P=0.023 and P=0.025, respectively). Left ventricular mass was found to be a factor influencing LGE positivity (OR=1.045, 95% CI: 1.003-1.088, P=0.035). Logistic regression analysis showed that the higher the native T1 value, the greater the probability of cardiovascular events occurring within six months (OR=1.1, 95% CI: 1.003-1.206, P=0.043).

Conclusions: E/e' is a factor influencing interstitial fibrosis in hemodialysis patients and the left ventricular mass is a factor influencing alternative fibrosis. The native T1 value has predictive value for cardiovascular events within six months.

Large Artery Stiffness and New-Onset Diabetes in the Chronic Renal Insufficiency Cohort

Harini Sarathy,[1] Raymond R. Townsend,[2] Mahboob Rahman,[3] Julio A. Chirinos,[2] Jordana B. Cohen.[2] *[1]University of California San Francisco School of Medicine, San Francisco, CA; [2]University of Pennsylvania Perelman School of Medicine, Philadelphia, PA; [3]UH Cleveland Medical Center, Cleveland, OH.*

Background: Chronic kidney disease (CKD) accelerates large artery stiffness (LASt), which can cause damage to low-resistance high-flow microvascular beds in the liver, skeletal muscle, and pancreas, and which may affect insulin sensitivity. Our goal was to explore the relationship of LASt with new-onset diabetes in adults with CKD.

Methods: Carotid femoral pulse wave velocity (CFPWV) was performed in 1,512 participants of the Chronic Renal Insufficiency Cohort (CRIC) Study without diabetes. We used Cox regression and generalized estimating equations to evaluate baseline and time-updated CFPWV and incident diabetes, adjusting for age, sex, race, BMI, MAP, heart rate, eGFR, UPCR, smoking, total cholesterol, HDL, antihypertensives, and family history of diabetes. We assessed for effect modification by age, sex, prediabetes, and proteinuria.

Results: Participants in the highest tertile of CFPWV (median 10.8 m/s) were older (66 vs 53 years), had higher MAP (90 vs 84 mmHg) and lower eGFR (41 vs 50 mL/min/1.73m^2) compared to the lowest tertile (median 6.5 m/s). Over a median of 9 years, CFPWV was associated with new-onset diabetes (unadjusted HR 1.25, 95% CI 1.07-1.46 per standard deviation increase in CFPWV [sHR]; Figure), which dissipated after multivariable adjustment (sHR 1.15, 95% CI 0.95-1.38) but persisted in multivariable-adjusted models incorporating time-updated CFPWV (sOR 1.18, 95% CI 1.04-1.33).

There was significant effect modification by proteinuria. Higher CFPWV was associated with new-onset diabetes among participants with UPCR <1g/g (sHR 1.27, 95% CI 1.03-1.56) but not ≥1 g/g.

Conclusions: Among adults with CKD, LASt was associated with new-onset diabetes, particularly in those without significant proteinuria. LASt may have a key mechanistic role in abnormal glucose metabolism and could be a helpful marker of diabetes risk among patients with non-proteinuric CKD.

Relationship Between Pulse Wave Velocity and Nocturnal Blood Pressure in Hypertensive Subjects: A Retrospective Study

Marwa Abdalla,[1] Arvin Daneshmand,[2] Negiin Pourafshar.[1] *[1]MedStar Georgetown University Hospital, Washington, DC; [2]University of Florida, Gainesville, FL.*

Background: Tonometric pulse wave velocity (PWV) has been established as a non-invasive method for assessment of arterial stiffness[1]. Arterial stiffness as measured by PWV is an emerging tool for Cardiovascular risk evaluation and stratification[2]; as in hypertensive patients, elevated PWV could be associated with an increased risk of cardiovascular death[3]. The purpose of this study was to assess the relationship between nocturnal blood pressure (BP) decline and PWV in the hypertensive subjects.

Methods: This is a retrospective study of patients who underwent ambulatory blood pressure monitoring between April 2021 and June 2022 at Medstar Georgetown University Hospital. Fifty-two subjects with essential hypertension were included. BP was measured by ambulatory monitoring every 30 min between 06:00 am and 22:00 pm and every 30 min at night, throughout 48 hours with a Mobil-o-graph device. Carotid-femoral PWV was also measured as an index of aortic stiffness, by using the Mobil-o-graph which uses a validated transfer function.

Results: Among the 52 subjects, 42% were female, 58% were male, and the average age range was 64 years old. Forty-eight hour systolic/diastolic BP were 127.9 (± 13.1)/77.8 (± 10.7) mmHg, mean nocturnal BP was 119.1 (± 15.1)/ 70.3 (± 11.9) mmHg and nocturnal BP changes was -8.5 (± 10.2)/-12.2 (± 11.3) mmHg. Among subjects, 40.3% of were dipper, 9.6% were extreme dipper, and 50% were non-dipper. Mean PWV was 8.2 m/sec. Nocturnal systolic BP had a significant correlation with PWV (r=0.72; p=0.000). No significant correlation was observed between PWV and diurnal BP.

Conclusions: Nocturnal blood pressure may assist physicians in identifying hypertensive subjects with higher arterial stiffness, who are at higher cardiovascular risk. Further studies are needed to assess advantages of lowering nocturnal blood pressure. Ambulatory blood pressure monitoring could be useful to appropriately evaluate cardiovascular risk in hypertensive subjects.

TH-PO211

Associations Between Urine Sodium and Potassium Level, Elevated Arterial Stiffness, and Hypertension in a Population-Based Study: A Mediation Analysis

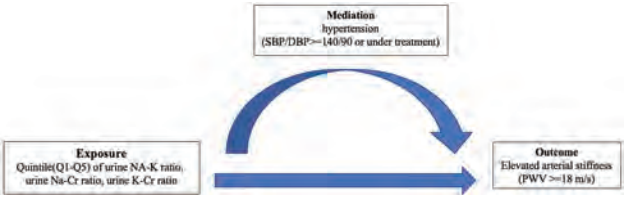
Xiaohong Fan, Jie Ma. *Peking Union Medical College Hospital, Dongcheng-qu, China.*

Background: The urinary sodium-potassium ratio (Na-K ratio) has recently been regarded as another hypertension indicator. The current study aims to assess the association of urine sodium and potassium level with elevated arterial stiffness and investigate how this association is mediated via blood pressure.

Methods: We performed a cross-sectional study of 10,281 participants in rural China. First void morning urine was collected to detect urine creatinine(Cr), sodium(Na), and potassium(K) levels. All subjects underwent brachial-ankle pulse wave velocity (baPWV) measurement to estimate arterial stiffness. *Hypertension* was defined as a systolic BP≥140mmHg or diastolic BP≥90mmHg, a self-reported history of hypertension, or the use of antihypertensive medications in the past three months. We analyzed the direct and indirect effects of urine Na-K ratio, Na-Cr ratio, and K-Cr ratio on elevated arterial stiffness (baPWV>=18 m/s) by hypertension in a mediation framework. Analyses were performed with SAS 9.4 (SAS Institute Inc, Cary, NC) and R version 4.0.2.

Results: The mean age of the study population was 55.4±10.0 years; 47.1% were males. Study findings indicated a significant direct association between urine Na-K ratio and elevated baPWV(OR= 1.07; 95% CI, 1.02–1.11). A significant indirect association was also observed between urine Na-K ratio and elevated baPWV (OR= 1.04; 95% CI, 1.03–1.05), indicating that 59.2% of the association of urine Na-K ratio with elevated baPWV was mediated by hypertension. Hypertension accounted for 30.3% of the association between urine Na-Cr ratio and elevated baPWV(direct association: OR= 1.09; 95% CI, 1.05–1.14; indirect association: OR= 1.03; 95% CI, 1.02–1.04). Though, we found a significant direct association between urine K-Cr ratio and elevated baPWV(OR= 1.05; 95% CI, 1.00–1.09), which was not mediated by hypertension (indirect association: OR= 0.98; 95% CI, 0.97–0.99).

Conclusions: Three-fifth of the association of urine Na-K ratio with elevated arterial stiffness may be accounted for hypertension. The urine Na-K ratio is a valuable marker of hypertension and high arterial stiffness risk.



TH-PO212

Association Between Systolic Blood Pressure Time in Target Range and Progression of CKD: Findings from KNOW-CKD Study

Cheol Ho Park,[1] Hyung Woo Kim,[1] Jung Tak Park,[1] Tae ik Chang,[2] Tae-Hyun Yoo,[1] Shin-Wook Kang,[1] Seung Hyeok Han.[1] *[1]Yonsei University College of Medicine, Seodaemun-gu, Seoul, Republic of Korea; [2]National Health Insurance Service Ilsan Hospital, Goyang, Gyeonggi-do, Republic of Korea.*

Background: Time-in-target range (TTR) is determined by the proportion of time during which the systolic blood pressure (SBP) remains within a defined range. It has emerged as a good metric for assessing SBP control over time. However, whether TTR of SBP can predict progression of chronic kidney disease (CKD) is uncertain.

Methods: We investigated the association between SBP-TTR during the first year of enrollment and CKD progression among 1,758 participants from KNOW-CKD (Korean Cohort Study for Outcomes in Patients With Chronic Kidney Disease). Participants were categorized into 4 groups according to SBP-TTR (0%, 1–50%, 51–99%, and 100%). The primary outcome was a composite kidney outcome of a ≥50% decline in eGFR from baseline measurement or the initiation of kidney replacement therapy.

Results: During a follow-up period of 9,212 person-years (median, 5.4 years), the composite outcome occurred 710 (40.4%) participants. In multivariable cause-specific hazard model, a 1-SD increase in SBP-TTR was associated with an 11% lower risk of the composite outcome (hazard ratio [HR], 0.89; 95% confidence interval [CI], 0.82–0.97). Additionally, compared to the patients with SBP-TTR 0%, the HRs (95% CIs) for the SBP-TTR 1–50%, 51–99%, and 100% were 0.86 (0.68–1.08), 0.77 (0.61–0.97), and 0.73 (0.56–0.95), respectively. Moreover, the corresponding slopes of eGFR decline were -2.71 (-3.13 to -2.30), -2.52 (-2.80 to -2.23), -2.25 (-2.50 to -2.01), and -2.06 (-2.34 to -1.78) ml/min/1.73m^2, respectively.

Conclusions: Higher SBP-TTR was associated with a decreased risk of CKD progression in patients with CKD.

Uncovering the Added Benefits of Lowering Resting Heart Rate by Physical Activity in Reducing the Incidence and Mortality Risks of CKD and Proteinuria

Chi Pang Wen, Min Kuang Tsai. *National Health Research Institutes, Zhunan, Taiwan.*

Background: Physical activity (PA) is known to be able to reduce Chronic Kidney Disease (CKD) mortality, but the effect was perceived as too little, too late to motivate exercisers. However, smart types of exercise could be employed to double the effect by simultaneously lowering resting heart rate (RHR). The added role of RHR in enlarging the benefits of physical activity to prevent or to reduce CKD has not been reported.

Methods: A medical screening cohort of 680,277 adults in Taiwan was successively recruited during 1996-2017, and 64,577 deaths were identified by National Death File and 5,671 cases of ESRD after a medium follow up of 18 years. CKD was analyzed by 5 component stages, eGFR values and proteinuria tested by dipstick. RHR came from electrocardiogram taken after rest in a supine position, with 80-99/min considered as elevated but within normal limits. Physical activity was expressed as MET-h/week, which was a product of exercise intensity and duration. Exercise status was classified as inactive, low, medium high or very high active. The association of RHR with CKD at entry points or with various CKD associated all-cause mortality risks during follow up was both calculated by Cox model.

Results: A triangular interactive relationship existed among PA, RHR and CKD, with PA able to reduce both RHR and CKD and with RHR associated with less CKD when slowed down by PA. Increasing RHR per 10 beats from 60/min up was associated with 30% increase in CKD, 39% increase in proteinuria and 30% increase in GFR<45. Physical activity, as officially recommended, was associated with 18% reduction of CKD, with the more vigorous intensity, the larger the reduction. It was also inversely associated with RHR, and vigorous intensity exercise for 3 months was associated with a lowering of RHR by 11 beats/min. Not all PA could slow RHR, mostly by those with vigorous intensity. Most CKD people were inactive (>80%) and could benefit from engaging in all types of PA recommended. When participants exercised, majority (60%) lowered RHR and small minority (9%) increased RHR, with remaining unchanged.

Conclusions: The incidence and mortality of CKD and proteinuria could be maximally reduced by vigorous physical activity when RHR was simultaneously lowered. Promoting the kind of exercise that reduced RHR may double the reduction of CKD or proteinuria.

TH-PO214

The Association Between Subclinical Reductions in Kidney Function and Major Adverse Cardiovascular Events in Young Adults: A Population-Based Retrospective Cohort Study

Manish M. Sood,[1] Junayd Hussain,[1] Mark Canney,[1] Meghan J. Elliott,[3] Gregory L. Hundemer,[1] Navdeep Tangri.[2] *[1]University of Ottawa School of Epidemiology and Public Health, Ottawa, ON, Canada; [2]University of Manitoba Max Rady College of Medicine, Winnipeg, MB, Canada; [3]University of Calgary Cumming School of Medicine, Calgary, AB, Canada.*

Background: Cardiovascular risk factors and disease in young adults (18-39 years) are on the rise. Whether early reductions in kidney function (i.e., estimated glomerular filtration rate [eGFR] above the current accepted threshold for chronic kidney disease [>60 mL/min/1.73m^2], but below age-expected values) are associated with elevated risk is unknown. We aim to examine age-specific associations of subclinical eGFR reductions in young adults with major adverse cardiovascular events (MACE).

Methods: We conducted a retrospective cohort study of 8.7 million individuals (3.6 million aged 18-39 years) using linked provincial healthcare datasets from Ontario, Canada from January 2008-March 2021. Cox models examined the association of categorized eGFR (50-120 mL/min/1.73m^2) with MACE (first of cardiovascular mortality, acute coronary syndrome, ischemic stroke) and MACE-plus-heart failure (MACE+), stratified by age (18-39, 40-49, 50-65 years).

Results: In our cohort (mean age 41.3, mean eGFR 104.2, median follow-up 9.2 years), a stepwise increase in the relative risk of MACE and MACE+ was observed as early as eGFR<90 in young adults (e.g., for MACE, at eGFR 70-80, ages 18-30: 2.37 events per 1000 person-years(p-y), HR 1.31(1.27-1.40); ages 40-49: 6.26/1000p-y, HR 1.09(1.06-1.12); ages 50-65: 14.9/1000p-y, HR 1.07(1.05-1.08)). Elevations in relative risk occurred for 18-39-year-olds at higher eGFR levels than ages 40-49 and 50-65. This persisted when examining each component individually and in additional analyses (stratified by past CV disease, accounting for index albuminuria, defining index eGFR from repeated measures).

Conclusions: In young adults, eGFR levels above the current threshold for chronic kidney disease associated with an elevated risk for MACE and MACE+, warranting age-appropriate risk stratification, proactive monitoring, and timely intervention.

TH-PO215

Seize the Night: A Retrospective Cohort Analysis on the Timing of Antihypertensive Agents on Nocturnal Blood Pressure

Sean Michael, Hammad I. Huda, Monicka Felix. *HCA Florida Oak Hill Hospital, Brooksville, FL.*

Background: Hypertension is a long standing modifiable risk factor in cardiovascular disease. Blood pressure follows a circadian rhythm in response to hormonal and environmental factors. However, when this balance is disrupted it may lead to an elevated nighttime blood pressure which is a more significant predictor of cardiovascular mortality than daytime hypertension. This study aims to see if the timing of antihypertensive agents among those with hypertension and chronic kidney disease may reduce night-time blood pressure.

Methods: In this retrospective cohort analysis, 8814 patients (3975 female/4839 male, 65+/-9 years of age) with hypertension or chronic kidney disease who were admitted to HCA healthcare in 2021 and 2022 were categorized based on receiving blood pressure medication in the morning (n=2142), evening (n=176), or morning and evening (n=6209). In response, patients blood pressure at night time were measured to see if there was a normal blood pressure lowering pattern of 10-20% at night-time.

Results: The results showed patients who had evening only blood pressure medicaiton were 1.842 times as a likely to have a night-time drop in blood pressure compared to patients whom had medication administered in the morning only(p=0.001, 95% CI [1.253-2.710] when all other variables were held constant.

Conclusions: Patients who administer an evening dose blood pressure medication are more likely to have an appropriate drop in night-time blood pressure. Clinicians can therefore consider switching antihypertensive agents to evening among patient with nocturnal hypertension. Furthermore, this study raises awareness regarding nocturnal hypertension, an often overlooked aspect in the treatment of hypertension.

A Systematic Review and Meta-Analysis of Myocardial Fibrosis in CKD and ESKD Assessed by Cardiac MRI T1 Mapping

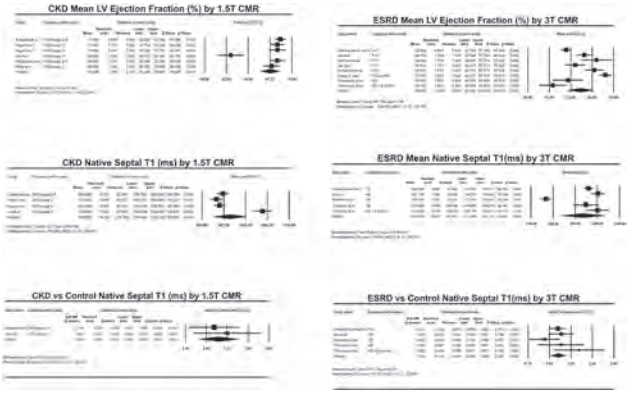
Deepak Chandramohan,[1] Rhoshini Rajasekaran,[1] Raghunandan Konda,[1] Ashwini S. Pujari,[1] Sreekant Avula.[2] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]University of Minnesota Twin Cities, Minneapolis, MN.*

Background: Non-atherosclerotic fibrotic changes to the cardiac myocardium occur early in Chronic Kidney Disease (CKD) and End Stage Kidney Disease (ESKD) patients. Uremic myocardial fibrosis can lead to arrhythmias and heart failure. T1 mapping technique in Cardiac MRI (CMR) estimates myocardial fibrosis and offers a non-invasive way to characterize the severity of cardiac remodeling.

Methods: A systematic search was done in PubMed, Google Scholar, Embase, and Web of Science from inception to February 2023. Studies were divided according to scanner field strength (1.5 or 3 Tesla). The random effects model was used to calculate pooled mean, 95% confidence interval, standard error (SE), and standardized mean difference (SMD). The heterogeneity between study-specific estimates was assessed by the I^2 statistic.

Results: The initial search retrieved 765 studies. From these, 25 studies met the inclusion criteria that had 697 CKD (mean age of 55.5 years; 65.5% males; mean eGFR of 41 mL/min/1.73m2) and 658 ESKD patients on dialysis (mean age of 55.6 years; 63.3% males; mean dialysis duration of 5 years). The mean native septal T1 is 998.2ms (970-1026.3) for CKD and 1267.4ms (1217.8-1317.1) in ESKD patients. The SMD of native T1 measurements in CKD vs. controls is 1.09 (0.73-1.46), and SMD for ESKD vs. controls is 1.12 (0.85-1.38).

Conclusions: CKD and ESKD patients with preserved LVEF have increased T1 values indicating an increased fibrosis burden. T1 mapping can be used in the early detection of cardiomyopathy and as a risk-stratification tool. Large, randomized trials are needed to confirm these findings and find long-term effects of dialysis on cardiac fibrosis.



Forest plots of LVEF, Native T1 measurements in CKD and ESKD

CMR sequence	Method	Assessment
Cine Imaging	Usually done by a method called balanced steady-state free precession (SSFP) that produces bright signals from stationary tissues and suppresses signals from moving tissues and blood.	LV Volume and mass
T1 Mapping	When done without a contrast agent is called 'Native T1 mapping'. It measures the longitudinal magnetization recovery time after being disturbed by a magnetic field. Mapping is done by combining a series of T1 relaxation times.	Myocardial fibrosis, scar

TH-PO217

Health Care Resource Use and Costs in the Year Following a Major Bleeding Event in Patients with and Without ESKD

Alejandro Victores,[1] Lori D. Bash,[1] Nicholas S. Roetker,[2] Dena Rosen R. Ramey,[1] James B. Wetmore,[2] Marc P. Bonaca.[3] *[1]Merck & Co Inc, Rahway, NJ; [2]Hennepin Healthcare Research Institute Chronic Disease Research Group, Minneapolis, MN; [3]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Background: Patients with end-stage kidney disease (ESKD) are at an elevated risk of major bleeding events which may result in substantial healthcare resource use(HCRU). There is limited information on HCRU following a major bleeding event in those with ESKD.

Methods: Retrospective cohorts of patients ≥66 years were created using the US Renal Data System (USRDS) for ESKD patients receiving in-center hemodialysis (HD) and 20% sample general Medicare database for non-ESKD patients. The index date was the date of hospital admission for an incident major bleeding event between 2015 and 2019. Only those enrolled in Medicare Part D were included in follow-up analysis. All-cause HCRU and costs were calculated (including the index event) for up to 1 year. HCRU is expressed as a percent or rate per 100 person-years. Per person per year adjusted costs are expressed in 2019 dollars.

Results: A total of 68,608 non-ESKD patients and 11,881 ESKD patients with incident major bleeding were included in the follow-up analysis. Patients with ESKD had significantly more admissions, inpatient days, and emergency visits than those without. Use of outpatient (OP) cardiac rehabilitation was significantly lower among ESKD patients. Post-index OP encounters had the largest magnitude difference, with 460.8 more OP encounters per 100 person-years among those with ESKD. Total costs for inpatient encounters, observation unit visits, ED visits, and OP encounters were statistically significantly higher for ESKD patients compared with non-ESKD patients.

Conclusions: In the year following an incident major bleed, Medicare beneficiaries with ESKD have significantly higher all-cause HCRU and total healthcare costs than patients without ESKD who experienced the same event; these differences persist after adjustment.

Funding: Commercial Support - Merck Sharp & Dohme Corp., a subsidiary of Merck & Co., Inc., Rahway, NJ, USA

Table 1. HCRU in the year following incident major bleeding event in patients with and without ESKD, adjusted for age, sex, and race*

	Non-ESKD	ESKD (In-center HD)	Difference (95% CI)
Number of patients in follow-up analysis	68,608	11,881	
30-day readmission (%)	18.2	29.6	11.4 (10.5, 12.2)
90-day readmission (%)	30.8	50.2	19.4 (18.4, 20.4)
Number of inpatient hospital admissions	125.9 (0.554)	289.3 (2.922)	163.5 (157.2, 169.3)
Number of inpatient hospital ICU admissions	44.4 (0.288)	113.2 (1.647)	68.8 (65.8, 71.9)
Number of days in inpatient hospital	9.3 (0.053)	22.2 (0.285)	12.9 (12.3, 13.5)
Number of observation unit encounters	18.0 (0.156)	38.1 (0.768)	20.1 (18.5, 21.7)
Number of emergency department encounters	76.6 (0.438)	147.1 (1.947)	70.5 (66.6, 74.5)
Number of outpatient encounters	1061.9 (3.600)	1522.7 (13.061)	460.8 (433.8, 486.9)
Number of other institutional care visits	305.0 (1.154)	402.7 (4.107)	97.8 (89.9, 106.2)
Number of outpatient cardiac rehabilitation encounters	35.5 (1.081)	12.5 (1.596)	-23.0 (-26.8, -19.1)
Number of physician encounters (all specialties)	3752.2 (7.937)	6417.3 (33.380)	2665.1 (2594.6, 2734.2)
Number of cardiology/vascular physician encounters	644.3 (2.434)	1137.1 (10.486)	492.8 (471.6, 513.1)
Number of neurology/neurosurgery physician encounters	156.0 (1.104)	143.5 (3.024)	-12.5 (-18.6, -6.1)
Number of physiatry physician encounters	122.3 (1.282)	133.3 (4.827)	11.0 (0.9, 20.1)
Number of hematology physician encounters	176.7 (1.929)	114.9 (3.852)	-61.8 (-70.0, -53.2)
Number of gastroenterology physician encounters	303.4 (1.119)	485.2 (4.991)	181.8 (171.4, 191.6)
Number of primary care physician encounters	1575.8 (4.517)	2491.5 (21.787)	915.6 (868.6, 959.8)
Number of blood transfusion events	154.7 (0.274)	202.1 (1.488)	47.4 (44.4, 50.5)

*Frequency of 30-day and 90-day readmission expressed as percentage. All other post-index encounter types expressed as rate (SE) per 100 person-years.

Survival Benefit of Anticoagulation in Patients with ESKD and Atrial Fibrillation

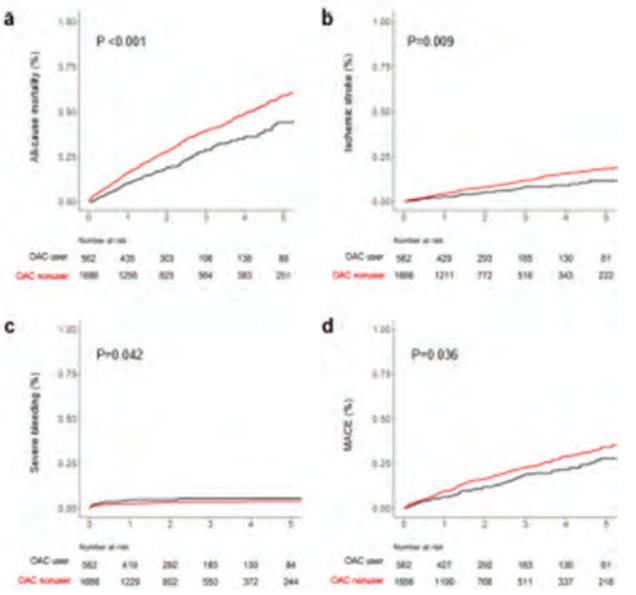
Soo yeon Choi, Jun Young Lee, Donghui Shin, Jae seok Kim, Byoung Geun Han. *Yonsei University Wonju College of Medicine, Wonju, Republic of Korea.*

Background: Prevalence of atrial fibrillation (AF) in patients with end stage kidney disease (ESKD) is high and increasing, however, current evidence is insufficient and conflicting regarding oral anticoagulant (OAC) use in patients with ESKD and AF.

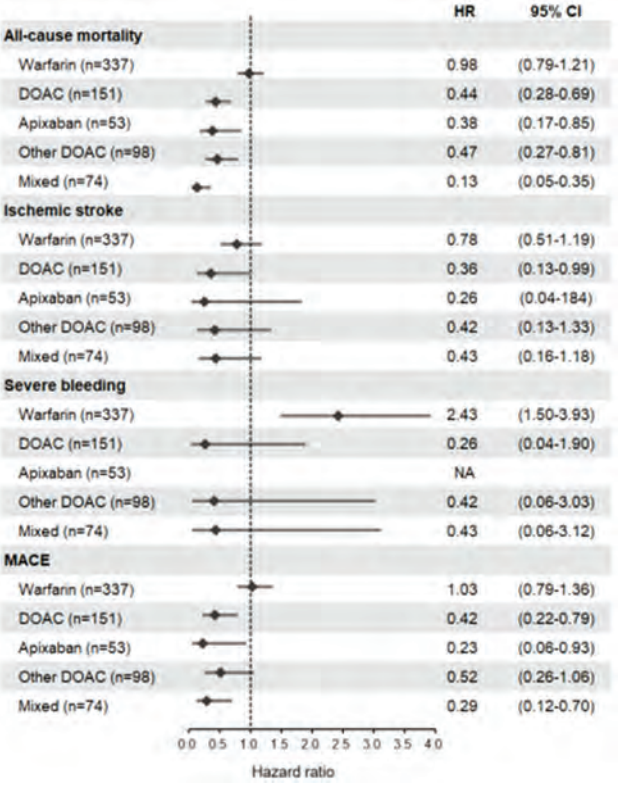
Methods: A retrospective cohort study of patients diagnosed with AF after ESKD was conducted using the Korea National Health Insurance System Database from January 2007 to December 2017.

Results: Compared with OAC nonuser OAC user were associated with lower risk of all-cause death (hazard ratios (HR) 0.71; 95% confidence interval (CI) 0.58-86), ischemic stroke (HR 0.63; 95% CI 0.43-92), and MACE (HR 0.76; 95% CI 0.59-0.98) without increased risk of severe bleeding (HR 1.58; 95% CI 0.99-2.52). Patients used direct OAC showed significantly lower risk of all-cause death (HR 0.44; 95% CI 0.28-0.69), ischemic stroke (HR 0.36; 95% CI 0.13-0.99), and MACE (HR 0.42; 95% CI 0.22-0.79) than those of OAC-nonuser, but no association with severe bleeding (HR 0.26; 95% CI 0.04-1.90).

Conclusions: In patients with ESKD and AF, OACs were associated with reduced all-cause death, ischemic stroke, and MACE risks.



Kaplan–Meier curve analyses for each outcome. a. All-cause mortality, b. ischemic stroke, c. severe bleeding, and d. MACE.



Subgroup analysis for all-cause mortality, ischemic stroke, severe bleeding, and MACE according to type of oral anticoagulant.

National Rates of Primary Aldosteronism Screening in Patients with CKD

Jordana B. Cohen, Maria Bonanni, Jesse Passman, Heather Wachtel, Debbie L. Cohen. *University of Pennsylvania Perelman School of Medicine, Philadelphia, PA.*

Background: Primary aldosteronism (PA) is a common, treatable cause of resistant hypertension and kidney fibrosis but is vastly underdiagnosed. Limited evidence exists regarding screening rates and outcomes of screening for PA among patients with chronic kidney disease (CKD).

Methods: In a national cohort of US Veterans diagnosed with incident hypertension and followed from January 2000 to December 2021, we identified patients with new indications for PA screening (i.e., hypertension with hypokalemia or resistant hypertension). We evaluated rates of PA screening and results of screening among those with and without CKD (eGFR <60 vs. ≥60 mL/min/1.73m^2) using Cox regression, adjusted for age, sex, race, systolic blood pressure, heart rate, insurance status, smoking, substance abuse, homelessness, cardiovascular disease, obstructive sleep apnea, and diabetes.

Results: A total of 457,395 patients met inclusion criteria, among whom 73,747 (16%) had CKD at the time of developing a new indication for PA screening. Those with CKD were older (mean 72 vs. 61 years) and had higher serum potassium levels (4.2 vs. 4.0 mEq/L) and higher prevalence of diabetes (42% vs. 30%) and cardiovascular disease (25% vs. 18%) compared to those without CKD. In the overall cohort, 7,427 (1.5%) patients underwent PA screening, among whom 1,068 (14%) had biochemical evidence of PA. Patients with CKD were 55% more likely to undergo PA screening than those without CKD (adjusted HR 1.55, 95% CI 1.44-1.67), which was similar across all CKD stages. Among those who underwent PA screening, biochemical evidence of PA was similar in patients with and without CKD (adjusted HR 0.92, 95% CI 0.75-1.12). Patients with CKD had similar rates of adrenalectomy but were less likely than those without CKD to be appropriately treated with a mineralocorticoid receptor antagonist (adjusted HR 0.86, 95% CI 0.78-0.94), excluding patients with serum potassium >4.5 mEq/L.

Conclusions: In a national cohort of Veterans with indications to undergo PA screening, those with CKD were more likely to undergo PA screening and had similar rates of PA compared to those without CKD, but were less likely to receive appropriate treatment with a mineralocorticoid receptor antagonist. Overall, rates of PA screening among all groups were exceptionally low.

Salt Sensitivity and Hypertensive Nephropathy: A Link to Be Discovered

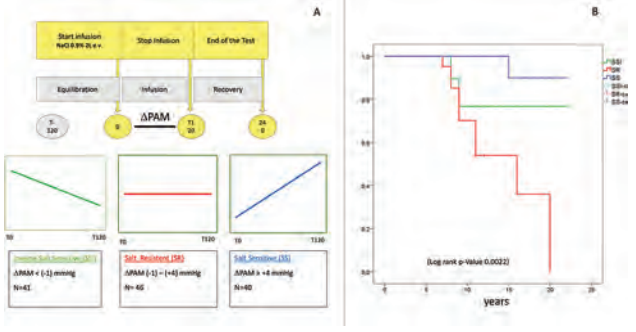
Francesca Tunesi, Luca D'Urbano, Marco Simonini, Lorena Citterio, Laura Zagato, Paolo Manunta, Chiara Lanzani. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: Sodium sensitivity (SS) is a change in blood pressure (BP) depending on Na^+ intake, 30% of population has it. Either a salt load test or a sodium dietary protocol can be used to stratify the population into 3 groups based on BP variation: sodium sensitive (SS), sodium resistant (SR), inverse sodium sensitivity (ISS), based on an increase, a non-significant variation or a decrease in BP following the administration of Na^+. SNPs located in genes related with Na^+ metabolism, aldosterone synthesis and kidney tubular Na^+ reabsorption are related to this phenotype.

Methods: We analyzed data collected from the follow-up (FUP) of 127 subjects with a new diagnosis of hypertension, categorized by their profile through acute salt load test. We analyzed the kidney damage by annual decline of eGFR and development of microalbuminuria. Genetic polymorphism analysis has been executed.

Results: No differences in the decline of eGFR are observed among the groups (-1.3084 ml/min ± 0.16 p= 0.372). SR subjects seem to be more prone to develop earlier microalbuminuria (χ 2 10.682, p= 0.005) even with an adequate BP control (P-Anova SBP 0.766; P-Anova DBP 0.856). An inverse correlation exists between pressure-natriuresis ratio and decline in eGFR (R -0.194 p= 0.016). Polymorphism in CYP11B2 (0.72 OR p= 0.045) and NEDD4L (0.74 OR p=0.027) are protective against eGFR decline. ADD3 polymorphism (3.73 OR p= 0.049) is a risk factor for development of microalbuminuria. KL (0.15 OR p= 0.034), PKD and TRPC6 (p-Value 0.037, p-Value 0.009) polymorphism are protective factor against microalbuminuria.

Conclusions: SR patients are more at risk of developing hypertensive nephropathy earlier than other groups; steeper pressure natriuresis ratio is involved in quicker decline in renal function possibly accelerating development of hypertensive nephropathy. Further studies with larger sample and standardization in salt sensitivity test are needed to translate this knowledges into clinical setting.



A) salt load test; B) microalbuminuria

TH-PO221

Clinical Impact of Diastolic Dysfunction in ESKD

Hojin Jeon, Kyungho Lee, Junseok Jeon, Jung eun Lee, Wooseong Huh, Yoon-Goo Kim, Hye Ryoun Jang. *Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.*

Background: Diastolic dysfunction with left ventricular hypertrophy and myocardial fibrosis is an important characteristic of uremic cardiomyopathy (UCM) in end-stage kidney disease (ESKD). We investigated clinical courses and risk factors of mortality and major adverse cardiac event (MACE) in ESKD patients starting kidney replacement therapy (KRT) according to the grade of diastolic dysfunction.

Methods: A total of 1038 patients who underwent surgery for vascular or peritoneal access and started KRT between 2010 and 2020 were enrolled. We classified patients according to the diastolic dysfunction grade (DDG) evaluated by echocardiography. Patients with atrial fibrillation (AF) were classified separately. The primary outcome was a composite outcome of all-cause mortality and MACE.

Results: The median age was 62 years, and 662 patients (63.78%) were male. Patients were divided into six groups based on the pre-KRT echocardiography: normal (n=280), DDG 1 (n=149), DDG 2 (n=192), DDG 3 (n=23), DDG undetermined (n=338), and AF (n=56). All-cause mortality and the incidence of MACE were significantly higher in pre-KRT DDG 1 and AF groups (P<0.01). However, after adjusting for age and underlying ischemic heart disease (IHD) at the initiation of KRT, pre-KRT diastolic dysfunction or AF did not affect to mortality and MACE (P=0.75). Furthermore, post-KRT echocardiography was performed at least 6 months after starting KRT, and the patients were regrouped: post-KRT normal (n=132), DDG 1 (n=311), DDG 2 (n=168), DDG 3 (n=23), DDG undetermined (n=303), and AF (n=101). Patients with post-KRT normal diastolic function showed better survival compared to patients with diastolic dysfunction or AF (P<0.01). In a multivariable analysis including post-KRT echocardiographic parameters, post-KRT DDG 2 (HR 2.61, 95% CI 1.08 – 6.30, P=0.03) and post-KRT AF (HR 3.20, 95% CI 1.26 – 8.12, P=0.01) were identified as significant risk factors for all-cause mortality and MACE. Low left ventricle ejection fraction after KRT was associated with increased risk of mortality and MACE (HR 0.98, 95% CI 0.97 – 0.99, P<0.01).

Conclusions: Age and IHD were more important prognostic factors compared to pre-KRT diastolic dysfunction. However, post-KRT echocardiographic findings, including diastolic dysfunction, and AF could be considered as prognostic markers in ESKD patients.

TH-PO222

Nocturnal Hypertension in Patients with Controlled Daytime Blood Pressure

Nandini M. Biyani,[1] Marcel Ruzicka,[1,2] Manish M. Sood,[1,2] Gregory L. Hundemer,[1,2] Ayub Akbari.[1,2] *[1]University of Ottawa, Ottawa, ON, Canada; [2]Ottawa Hospital Research Institute, Ottawa, ON, Canada.*

Background: 24-hour ambulatory blood pressure monitoring (ABPM) is the modality of choice for the diagnosis of hypertension (HTN). Besides assessment of blood pressure (BP) and its variability while awake, it also provides BP readings during sleep. Sleep BP is the single most important factor for adverse HTN related cardiovascular outcomes. 24-hour ABPM is underutilized, misclassifying many patients as 'treated or controlled' based solely on awake BP while in fact they have persistent nocturnal hypertension.

Methods: The study was carried out at the Renal hypertension program of The Ottawa Hospital which is a tertiary care hospital based HTN program serving catchment area of approximately 1.2 million people. We extracted data from completed and technically satisfactory 24-hour ABPMs from incident patients treated in our clinic from January 01, 2019 to March 31, 2023. For each patient who underwent 24-hour ABPM, only the first report was considered for this study. We defined daytime HTN as mean systolic BP >=140 mmHg and/or mean diastolic BP>=90 mmHg and nocturnal HTN as mean nighttime systolic BP >= 125 mmHg and/or mean diastolic BP >=75 mmHg.

Results: Our cohort included 1024 patients. Mean (SD) age was 60.6 (16.3) years, females 486 (46.7%), mean BMI (SD) 30.0 (7.9) kg/m^2. 388 (37.2%) patients had uncontrolled HTN during daytime, and out of these, 272 (26.1%) also had nocturnal HTN. More importantly though, in patients with controlled day time HTN (n= 654, 62.8%), 21.5% (n=141) had nocturnal HTN with mean (SD) nocturnal BP of 132/75 (6.3/10.4).

Conclusions: Our data show that a significant segment of patients with controlled daytime HTN (documented by ABPM) still have nocturnal HTN. As nocturnal BP is an important factor for adverse HTN related cardiovascular outcomes, one could certainly consider low utilization of 24-hour ABPM among patients with HTN as a missed treatment opportunity contributing to unnecessary and potentially preventable adverse cardiovascular events. We advocate for a broader utilization of 24-hour ABPM in patients with HTN.

Statewide Burden of CKD due to Hypertension (HTN) from 1990 to 2019 in the United States: Analysis for the Global Burden of Disease Study

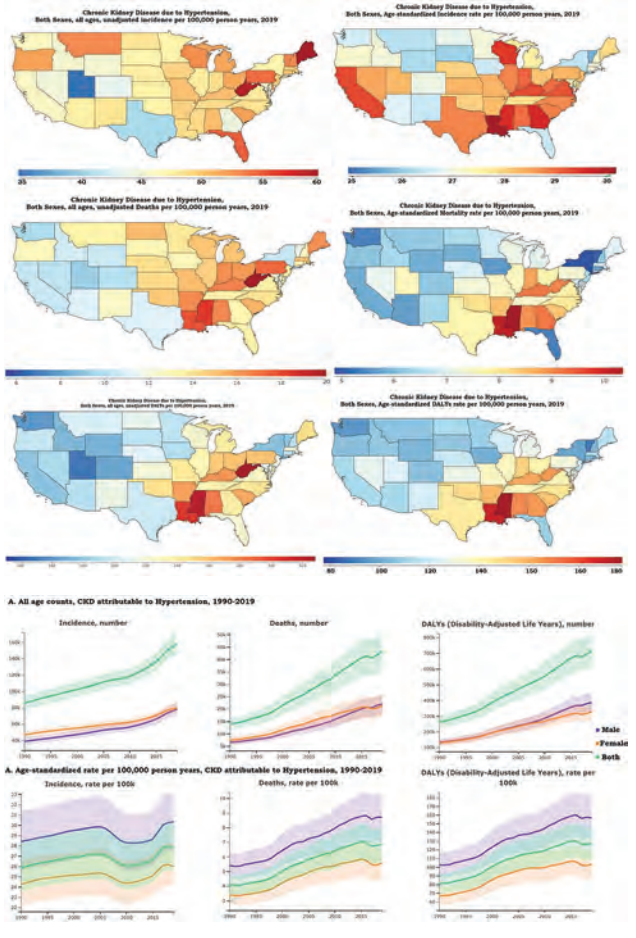
Rohan Gajjar,[1] Hardik Desai,[2] Bijin Thajudeen,[3] Sahas Reddy Jitta,[4] Shasank Rachapudi,[5] Jobby John,[6] Abhiraj Patel,[7] Viswaja Koppana.[8] *[1]John H Stroger Jr Hospital of Cook County, Chicago, IL; [2]Gujarat Adani Institute of Medical Science, Bhuj, India; [3]Banner University Medical Center Tucson, Tucson, AZ; [4]Mercy Hospital St Louis Area, Saint Louis, MO; [5]Kurnool Medical College, Kurnool, India; [6]Dr Somervell Memorial CSI Medical College and Hospital, Thiruvananthapuram, India; [7]Our Lady of Fatima University College of Medicine, Valenzuela City, Philippines; [8]Mayo Clinic Minnesota, Rochester, MN.*

Background: CKD due to HTN ranks as the 2nd leading cause of death among all causes of CKD in United States (US). We sought to assess the burden of CKD due to HTN within the US.

Methods: Using Global Burden of Disease methodology, prevalence, incidence, death, and disability-adjusted life year (DALYs) of CKD due to HTN assessed by age, sex, year from 1990-2019 for all resident in US.

Results: The prevalence has shown a steady increase over the years, with the total number of cases rising from 1.5 million (95% uncertainty interval [UI]:1.4-1.7million) in 1990 to 2.8 million (95%UI:2.6-3.1million) in 2019. Simultaneously, the number of deaths has tripled, from 13,960 in 1990 to 43,329 in 2019. The highest Annual Percentage of Change (APC) in the age-standardized mortality rate (ASMR) was found in West Virginia(101%), Iowa(95%) and Minnesota(93%). For the ASIR, the highest rates were observed in Utah and California, both at 11%, with Iowa at 10%. The ASDR revealed West Virginia(87%), Iowa(81%), and Kentucky(80%) as the areas with the highest burdens. These conditions are more prevalent in older populations, significantly impacting that group.

Conclusions: CKD attributed to HTN has shown a rapid increase across the US, given the substantial APC in prevalence rose by 86%. From 1990-2019, the DALY numbers and the age standardized DALYs per 100,000 population caused by CKD due to HTN increased by 171% and 57%, respectively.



TH-PO224

Representation of Real-World Adults with CKD in Clinical Trials Supporting Blood Pressure Treatment Targets

June Li,[1,2] Jaejin An,[3,4] Mengjiao Huang,[1] Matt M. Zhou,[3] Maria E. Montez-Rath,[2] Fang Niu,[5] John J. Sim,[4,6] Alan C. Pao,[2,7] Vivek Charu,[2,8] Michelle Odden,[1,2] Manjula Tamura.[1,2] *[1]VA Palo Alto Geriatric Research Education and Clinical Center, Palo Alto, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]Kaiser Permanente Southern California Department of Research & Evaluation, Pasadena, CA; [4]Kaiser Permanente Bernard J Tyson School of Medicine, Pasadena, CA; [5]Kaiser Permanente Southern California, Pasadena, CA; [6]Kaiser Permanente Los Angeles Medical Center, Los Angeles, CA; [7]VA Palo Alto Health Care System, Palo Alto, CA; [8]Stanford University Department of Pathology, Stanford, CA.*

Background: Little is known about how well trial participants with CKD represent real-world adults with CKD. We assessed the population representativeness of clinical trials supporting the 2021 Kidney Disease: Improving Global Outcomes blood pressure (BP) guidelines in real-world adults with CKD.

Methods: We identified two real-world population of patients with CKD who met the guideline definition of hypertension based on use of antihypertensive medications or a sustained systolic BP ≥120 mm Hg in 2019 in the Veterans Health Administration (VA) and Kaiser Permanente of Southern California (KPSC). We applied the inclusion and exclusion criteria from three BP target trials, the Systolic Pressure Intervention Trial, the Action to Control Cardiovascular Risk in Diabetes trial, and the African American Study of Kidney disease, to estimate the proportion of adults with a systolic BP above the guideline recommended target of <120 mm Hg and the proportion who met eligibility criteria for ≥1 trial.

Results: We identified 503,480 adults in VA and 73,412 adults in KPSC with CKD and hypertension in 2019. We estimated 79.7% in the VA population and 87.3% in the KPSC population had a systolic BP ≥120 mm Hg; only 23.8% (95% CI: 23.7% - 24.0%) in the VA and 20.8% (95% CI: 20.5% - 21.1%) in KPSC were trial-eligible. BP trials were representative of <15% of adults with CKD and diabetes, age <50 years, or stage 4 CKD. More than 50% of trial-ineligible adults met ≥1exclusion criteria.

Conclusions: Fewer than one in four real-world adults with CKD and hypertension were represented in major BP target trials. A large proportion of adults who are at risk for cardiovascular morbidity from hypertension and susceptible to potential adverse treatment effects still lack relevant treatment information.

Funding: NIDDK Support

Table 2. Percentage of real-world adults with chronic kidney disease and hypertension in the VA and KPSC cohorts in 2019 with BP above the 2021 KDIGO guideline recommended target, and percentage who meet eligibility criteria of blood pressure trials.

Characteristic	All adults with CKD		CKD without Diabetes		CKD with Diabetes

Blood Pressure Control Before and After the Updated 2017 Guidelines in Patients with Proteinuric Kidney Disease

Donald J. Weaver,[1] Nathaniel Putnam,[2] Bruce M. Robinson,[2] Eloise Salmon,[2] Elaine S. Kamil,[5] Sharon G. Adler,[3] Richard A. Lafayette,[4] Susan F. Massengill,[1] Zubin J. Modi.[2] Kidney Research Network. *[1]Levine Children's Hospital, Charlotte, NC; [2]University of Michigan, Ann Arbor, MI; [3]University of California Los Angeles, Los Angeles, CA; [4]Stanford Medicine, Stanford, CA; [5]Cedars-Sinai Medical Center, Los Angeles, CA.*

Background: We hypothesized that the stricter 2017 ACC/AHA Task Force hypertension (HTN) guidelines led to improved blood pressure control (BPC) in patients with proteinuric renal disease after 2017.

Methods: Data from existing electronic health record documentation for each patient up to May 1, 2022 was extracted on adult patients (≥18) from the Kidney Research Network multi-center electronic health record registry of patients with glomerular disease. Baseline diagnosis of HTN was defined using blood pressure measurements, ICD-9/10 codes, and medication records. BPC was defined as BP < 120/80 for ≥75% of follow-up recordings following hypertension diagnosis. Follow-up was split into two eras,

pre-2017 and post-2017. We used generalized linear models with a log odds outcome and an unstructured correlation matrix to evaluate the adjusted association between era and BPC.

Results: In this analysis, 725 patients were included of which 55% were male and median eGFR was 62. Only 6% had normal BP at diagnosis. In the pre-2017 era 10% of patients demonstrated BPC compared to 14% in the post-2017 era. In adjusted analysis, patients were more likely to achieve BPC after 2017, however not statistically significant (OR 1.7; CI 0.96-3.02) (Figure 1). More severe prior HTN and higher medication burden were associated with worse BPC.

Conclusions: In adjusted analyses, BPC improved modestly after 2017. However, BPC in patients with proteinuric CKD remains poor, especially when compared to more recent stricter recommendations. Future analysis with greater follow-up time, and using the most contemporary data possible, are needed to understand opportunities to do more to achieve greater BPC in this population.

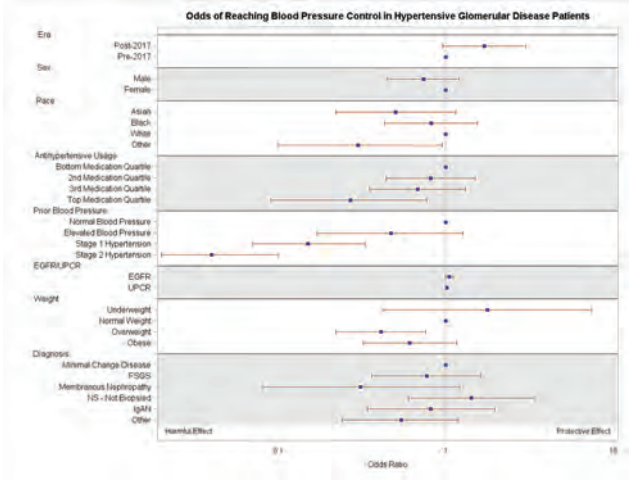

Figure 2. Odds of reaching blood pressure control in hypertensive glomerular disease patients

TH-PO226

A Multicentre Audit of Standardised Office Blood Pressure Measurement in Ireland

Eithne M. Nic an Riogh,[1,2] Anees Anees,[1] Lynn Redahan,[1] Yvonne M. O'Meara,[1] Frank Ward,[2] Denise M. Sadlier.[1] *[1]Mater Misericordiae University Hospital, Dublin, Ireland; [2]Tallaght University Hospital, Dublin, Ireland.*

Background: Hypertension is a common comorbidity of chronic kidney disease (CKD) and increases the risk of cardiovascular disease, end-stage kidney disease and death. The KDIGO 2021 Clinical Practice Guideline on the Management of Blood Pressure in CKD recommends a target systolic blood pressure (BP) target <120 mmHg in adults with CKD. Importantly, the guideline distinguishes between routine and standardised office BP measurement with the latter more likely to be an accurate measure of BP. In this study, adherence to standardised office BP measurement was assessed in busy nephrology outpatient clinics in two hospitals.

Methods: The KDIGO guidelines describe eighteen criteria to achieve standardised office BP measurement (e.g. patient sitting relaxed >5 mins, avoidance of caffeine/tobacco in 30 minutes prior to BP measurement, position of BP cuff). Adherence to these criteria was prospectively assessed by direct observation of BP measurements. Basic demographics and BP data from patients attending nephrology outpatient departments in two Dublin teaching hospitals were collected electronically. Adherence to 18 criteria was assessed using descriptive statistics. This audit is now expanding to include cardiology clinics as well as a questionnaire to assess patient awareness of hypertension.

Results: From January 2022–2023, 308 patients were recruited. Of the 18 criteria assessed, 6 had an adherence of > 90% and 5 criteria had an adherence of <10%. Areas with poorest compliance included supporting the arm during BP measurement 18.2% (n=56), averaging >/= 2 readings 0.3% (n=1) and noting the time antihypertensive medication was last taken 2.3 % (n=7). Measurement of BP in both arms at the initial visit was not carried out for any patients. The mean BP was 136/72 mmHg and Systolic BP <20 mmHg was achieved in 22% (n=33) patients. Clinical practice was similar across both sites other than a statistically significant difference in practice: informing patients of their BP verbally (99.3% vs 12%, P <0.001) and in writing (100% vs 1.9%, p <0.001).

Conclusions: Current clinic BP measurement does not meet the definition of standardised office BP measurement as outlined by KDIGO. However, simple changes to clinical practice could be implemented through education to significantly improve BP measurement as a more accurate measure of treatment response.

TH-PO227

Exploring the Spectrum of Blood Pressure Associations with CKD: The International 24-Hour Aortic Blood Pressure Consortium (i24ABC)

Sola Aoun Bahous,[1] Thomas Weber,[2] Chadia S. Haddad,[1] Pascale Salameh,[1] Alejandro De La Sierra,[4] Antonios A. Argyris,[3] Bernhard Hametner,[14] Christopher C. Mayer,[14] Daniel L. Background: Chronic kidney disease (CKD) has emerged as a significant public health concern. The kidneys are primarily exposed to pulsatile rather than steady hemodynamics, which complicates the bidirectional relationship between CKD and hypertension. We aimed to explore relationships between blood pressure (BP) parameters and renal function in a pooled dataset from 21 centers worldwide.

Methods: The dataset included clinical and hemodynamic information. All participants underwent office BP measurements, in addition to 24-hour ambulatory BP monitoring (ABPM) with the same validated automated brachial oscillometric device (Mobil-O-Graph, I.E.M., Germany) using a transfer function for central pressure, and mean/diastolic pressure calibration. Renal function was estimated using the CKD-EPI equation and subjects classified into the 6 eGFR categories following the KDIGO 2021 guideline.

Results: We included 5204 subjects, 46.1% females, with a mean age of 60.8 ± 13.9 years. Diabetes was noted in 14.7% and hypertension in 70.3% of subjects, 76% of whom were on antihypertensive therapy. The mean eGFR was 88.5 ± 19.9 mL/min/1.73 m^2. More than half of the participants (56.5%) had a normal or high eGFR (G1) and only 1.9% had a severely decreased eGFR (G5). The prevalence of hypertension increased progressively across GFR categories with 95.7% of subjects in G5 vs. 67.7% in G1 (p<0.001) with hypertension. Diastolic BP tended to decrease (p<0.001) and SBP to increase (p<0.001) with decreasing eGFR. These associations were consistent for both brachial and central values, and for office and ABPM measurement techniques. Systolic reverse dipping status was independently associated with decreased eGFR after adjustment for gender and age, and irrespective of hypertension status (β=-1.74, p=0.004).

Conclusions: CKD is associated with adverse hemodynamic changes, both at the brachial and the aortic level, and in office and out-of-office measurements, indicative of arterial stiffening.

TH-PO228

Risk Factors for Progressive Cardiorenal Syndrome in CKD Patients

Jing Chen,[1] L. Lee Hamm,[1] Bernard G. Jaar,[2] Hua He,[3] Cong Zhao,[3] Siyi Geng,[3] Amanda H. Anderson,[3] Vecihi Batuman,[1] Joshua D. Bundy,[3] Jonathan J. Taliercio,[4] Panduranga S. Rao,[5] Sarah J. Schrauben,[6] Milica Djokic,[3] Joel Merriman,[6] Giselle M. Rodriguez Mendez de Sosa,[9] Alan S. Go,[7] James P. Lash,[8] Jiang He.[3] *[1]Tulane University School of Medicine, New Orleans, LA; [2]Johns Hopkins University, Baltimore, MD; [3]Tulane University, New Orleans, LA; [4]Cleveland Clinic, Cleveland, OH; [5]University of Michigan Michigan Medicine, Ann Arbor, MI; [6]University of Pennsylvania, Philadelphia, PA; [7]The Permanente Medical Group Inc, Oakland, CA; [8]University of Illinois Chicago, Chicago, IL; [9]University of New Mexico Health Sciences Center, Albuquerque, NM.*

Background: Cardiorenal syndrome (CRS) is linked with poor outcomes. We studied the incidence and risk factors for progressive CRS (pCRS) in CKD patients.

Methods: 3,557 CKD patients in the Chronic Renal Insufficiency Cohort (CRIC) Study were included in this analysis after excluding those with heart failure (HF) at baseline. The mean follow-up was 10.5 years. pCRS was defined as development of both HF and renal failure (RF) (ESKD) within 12 months of each other. Cox proportional hazards models were used to examine the association of risk factors and pCRS. Risk factors for CRS type 2 (HF preceded RF) and CRS type 4 (RF preceded HF) were also analyzed.

Results: The average age was 59 years for those with pCRS and 57 years for those without. Age-adjusted incidence was 4.5/1000 person years, and was 5.0 in Men and 5.9 in Black. Traditional risk factors [multivariable-adjusted hazard ratios (95% CI)] for

pCRS were less than high school education [1.82 (1.21, 2.73)], history of CVD [1.48 (1.03, 2.12)], lower eGFR [per 1SD,1.83 (1.40, 2.39)], and higher uACR [per 1SD, 2.26 (1.78, 2.86)]. The significant multivariable-adjusted HRs associated with novel risk factors are presented in **Table**. The risk factor associated with both CRS type 2 and 4 were kidney dysfunction, albuminuria, and mineral bone disorder (higher alkaline phosphatase and FGF23), inflammation (TNF-α), and fibrotic factor (GDF-15).

Conclusions: This study indicates that education level, history of CVD, kidney dysfunction, albuminuria, mineral bone disorder, diabetes control, anemia, volume overload, inflammation, and fibrotic factor are associated with pCRS. Further studies are warranted to assess the benefits of specific interventions to improve CRS outcomes.

TH-PO229

The Association Between Food Insecurity and Hypertension in the Context of CKD: Reviewing the Literature

Judy A. Ukrainetz,[1,2] Branko Braam.[1,2] *[1]University of Alberta, Dept. Medicine, Div. Nephrology, Edmonton, AB, Canada; [2]Alberta Health Services, Alberta Kidney Care North, Edmonton, AB, Canada.*

Background: Hypertension (HTN) and dietary choices are closely related. HTN is a leading cause of CKD and a poor diet contributes to about 80% of HTN. Food insecurity (FI) is defined as the lack of secure access to sufficient amounts of safe and nutritious food for normal growth and development of an active and healthy life and is prevalent and determines dietary choices. The prevalence of FI for adults has increased by 84% in the last 20 years and the mortality rate from CKD has also increased by over 40% in the same time frame making this a relevant issue to address. We wanted to explore the relationship between the modifiable risk factors of FI and HTN in the context of CKD.

Methods: A narrative review was performed using a systematic search in PubMed. Search terms were food insecurity, chronic disease, hypertension, social determinants of health and for years 2004-2023. After manual appraisal of each study, findings were narrowed down to exclude other literature or systematic reviews. Data synthesis was conducted according to a thematic synthesis approach.

Results: Out of a total of 147 articles, 26 studies were included in the final review. The thematic synthesis enabled the construction of 4 themes: "Low income negatively affects diet and is associated with food insecurity and HTN"; "Education and health literacy affect diet and the correlation between food insecurity and HTN"; "Access to healthy food feeds into the association between food insecurity and HTN"; and "Poor diet aggravates other adverse health conditions and is correlated to food insecurity and HTN".

Conclusions: FI is correlated to poor nutrition and HTN. Both FI and HTN together are an increasing global public health concern. The literature indicated how diet and health behavior are modifiable by addressing low income, limited access to healthy food and poor education thereby making it relevant to mitigate the negative dietary consequences of food insecurity on HTN and cardiovascular disease at a local and global scale. This is a threat also for the development of CKD. Relevance Statement: Globally, HTN is a leading non-communicable risk factor for cardiovascular morbidity and mortality. Hypertension is one of the leading causes of CKD. FI is associated with HTN, and these global health threats beg for urgent attention to improve health outcomes on a worldwide scale.

TH-PO230

Cardiovascular Health and CKD Progression Among US Hispanic/Latino Adults of the Hispanic Community Health Study/Study of Latinos, 2008-2017

Amit K. Chakrabarti,[1] Lesley A. Inker,[2] Yelena Drexler,[1] Samuel L. Swift,[3] James P. Lash,[4] Martha L. Daviglus,[5] Amber Pirzada,[5] Daniela Sotres-Alvarez,[6] Tanya S. Johns,[7] Tali Elfassy.[1] *[1]University of Miami School of Medicine, Miami, FL; [2]Tufts Medical Center, Boston, MA; [3]University of New Mexico Health Sciences Center, Albuquerque, NM; [4]University of Illinois Chicago College of Medicine, Chicago, IL; [5]University of Illinois Chicago, Chicago, IL; [6]The University of North Carolina at Chapel Hill, Chapel Hill, NC; [7]Albert Einstein College of Medicine, Bronx, NY.*

Background: The primary cause of death in chronic kidney disease (CKD) is cardiovascular (CV) disease. "Life's Essential 8" (LE8) is an established measure of CV health. Our objective was to examine the relationship between CV health (LE8) and CKD progression among US Hispanic/Latino adults, an understudied but growing population.

Methods: The Hispanic Community Health Study/Study of Latinos (HCHS/SOL) is a longitudinal cohort of Hispanic/Latino adults 18-74 years old from four US cities, examined at visit 1 (V1) (2008-2011) and V2 (2014-2017). At V1, participants underwent a comprehensive assessment of health behaviors (diet, smoking status, physical activity, sleep duration) and clinical measurements (body mass index, blood pressure, cholesterol, fasting glucose, medication use) used to estimate a LE8 score (range: 0 to 100). Estimated glomerular filtration rate (eGFR) was calculated from serum creatinine and cystatin C using the 2021 CKD-Epi equation and albumin to creatinine ratio (ACR) was measured from urine. CKD was defined as eGFR < 60 ml/min/1.73m^2 or ACR ≥ 30mg/g. Change in eGFR and log ACR were defined as the difference in each measure between V1 and V2. To estimate the association between LE8 score with change in eGFR and log ACR, we used linear regression models adjusted for follow-up time, demographic, socio-economic, and clinical factors. All analyses accounted for HCHS/SOL complex survey design.

Results: Among 1,284 Hispanic/Latino participants with CKD at V1, mean age was 48.6, 57.2% were women, and mean LE8 was 61.1 (SE: 0.7). Over an average of six years of follow-up, eGFR declined by 5.8 ml/min/1.73m^2 and log ACR declined by 0.60. From multivariable adjusted models, for each 10-unit increment (improvement) in LE8 score, eGFR declined by 0.99 less (95% CI: -1.97, -.02) and log ACR declined an additional 0.15 (95% CI: 0.06, 0.28) between V1 and V2.

Conclusions: Among diverse US Hispanics/Latino adults with CKD, greater LE8 score (better CV health) was associated with modest but statistically significantly lower declines in eGFR and greater improvements in log ACR over six years.

Ideal Cardiovascular Health and CKD Progression in Hispanic Adults

Magdalena Madero,[1] Ana C. Ricardo,[2] Ana K. Fernandez Yepez,[1] Eunice Carmona,[2] Karen Sacal Saba,[1] Jose M. Alvarez Vallejo,[1] Sara Cabrera Castelán,[1] Ana L. Ramírez Santamaria,[1] Natalie Meza,[2] Claire T. Larkin,[2] Celestin Missikpode,[2] James P. Lash.[2] *[1]Instituto Nacional de Cardiologia Ignacio Chavez, Mexico, Mexico; [2]University of Illinois Chicago, Chicago, IL.*

Background: The American Heart Association developed the Life's Simple 7 metric to promote cardiovascular health. We evaluated the association of this metric with chronic kidney disease (CKD) progression among Hispanic individuals with CKD.

Methods: We conducted a prospective observational cohort study of 663 adults with CKD enrolled in the Mexico and Hispanic Chronic Renal Insufficiency Cohorts (HCRIC and MCRIC), with entry estimated glomerular filtration rate (eGFR) 20-70 ml/min/1.73 m^2. Ideal levels of Life's Simple 7 (score range 0-14) were the following: nonsmoker; body mass index <25 kg/m^2; ≥150 minutes/week of physical activity; healthy dietary pattern (high in fruits and vegetables, fish, and fiber-rich whole grains; low in sodium and sugar-sweetened beverages); total cholesterol <200 mg/dL; blood pressure <120/80 mm Hg; and fasting blood glucose <100 mg/dL). The primary outcome was CKD progression defined as 30% and 40% decline in eGFR from baseline. Cox proportional hazards regression analyses were used.

Results: At study entry, mean (SD) age was 56 (12) years, 238 (36%) were female, and 408 (62%) had diabetes. Mean (SD) baseline eGFR was 45 (17) ml/min/1.73m^2, and median (IQR) urine protein excretion was 0.6 (0.1-2.6) g/24 hours. The median (IQR) Life's Simple 7 score was 7 (6-9) points, and 47% of participants had ideal or intermediate cardiovascular health (score 8-14 points). During a median follow-up of 3.4 years, there were 415 (63%) and 341 (51%) CKD progression events for 30 and 40% eGFR decline, respectively. In analyses adjusted for age, sex, education, and baseline eGFR and proteinuria, each point higher Life's Simple 7 score was associated with 10-12% lower risk of 30% and 40% eGFR decline (HR, 95% CI, 0.90,0.85-0.94 and 0.88, 0.84-0.93), respectively.

Conclusions: In this cohort of Hispanic adults with CKD, the prevalence of ideal cardiovascular health was low. Higher Life simple 7 score was associated with reduced risk for CKD progression.

TH-PO232

Cardionephrology Clinic for Comprehensive Care of Patients with CKD and Cardiovascular Disease: A Promising Opportunity

Sebastian Consuegra-Flores,[1,2] Fernando A. Cuellar-Gonzalez,[1,2] Mauricio Arvizu Hernández.[1,2] *[1]Instituto Nacional de Ciencias Medicas y Nutricion Salvador Zubiran, Ciudad de Mexico, Mexico; [2]Tecnologico de Monterrey - Campus Ciudad de Mexico, Ciudad de Mexico, Mexico.*

Background: The coexistence of CKD and CV disease poses significant challenges in patient management, CV disease is the leading cause of mortality among CKD patients. This study aims to describe the establishment of a specialized cardio-nephrology clinic and report the initial and follow up results.

Methods: Since 2022, the cardio-nephrology clinic has been established, involving the participation of a nephrologist, cardiologist, nephrology fellows, medical students, and a nutritionist. Together, we conduct simultaneous clinical evaluations of patients using ultrasound (VEXUs) and bioimpedance. The clinic aims to enhance care, optimize pharmacological and non-pharmacological management, reduce hospitalizations, slow disease progression, and ultimately improve patient outcomes.

Results: 50 patients completed one year follow-up, 30 (60%) being male, mean age of 43.8±13.5 yrs. The baseline and outcomes of the patients are presented in Table 1.

Conclusions: The establishment of a specialized cardio-nephrology clinic offers comprehensive management and care for pts. living with CKD and CVD. The clinic aims to reduce the risk of complications and improve long-term prognosis for these patients. In addition, nearly all of these patients have experienced successful outcomes, including effective management of their comorbidities and the utilization of appropriate medications and overall clinical improvement. As a result, patients experience an enhanced quality of life.

Influence of Baseline Depressive Symptoms on the Effect of Blood Pressure (BP) Intervention on Cognitive Outcomes in the SPRINT Trial

George Bissada, Augustine Takyi, Sydney E. Hartsell, Robert E. Boucher, Guo Wei, Ravinder Singh, Amara Sarwal, Srinivasan Beddhu. *University of Utah Health, Salt Lake City, UT.*

Background: We examined the hypothesis that baseline depressive symptoms might modify the effects of BP control on cognitive outcomes.

Methods: We used data from SPRINT, an RCT that tested the effects of SBP goal <120 vs <140 mmHg on cardiovascular and cognitive outcomes. Based on Patient Health Questionnaire (PHQ)-9, we defined 3 groups: no (score 0), minimal/mild (score 1-9), moderate/ severe (Scores 10-27) depressive symtpoms. We examined interactions of baseline PHQ9 groups and SBP intervention on adjuducated cognitive outcomes of mild cognitive impairment (MCI) or probable dementia (PD).

Results: Among 8487 SPRINT participants included in the analysis, the three baseline PHQ9 groups were 34.6, 57.9, 7.3 respectively. There were 1243 MCI events and 322 PD events. As shown in Table 1, BP intervention lowered the risk of MCI/PD composite whereas higher baseline PHQ 9 scores were assoicated with higher risk of MCI/PD. Interaction p-values for BP intervention X PHQ 9 groups for MCI/PD, MCI alone and PD alone were 0.94, 0.73 and 0.56, repsectively.

Conclusions: Intensive SBP control resulted in decreased hazard of develpoing MCI/PD and presence of baseline moderate/severe depression was assiocated with significant increase in hazard of developing PD and PD/MCI. Nonetheless, there was no evidence that the effects of BP intervention on cognitive outcomes were modified by baseline depressive symptoms.

Depressive Symptoms and Achieving Blood Pressure (BP) Goals in the Systolic Blood Pressure Intervention Trial (SPRINT)

Augustine Takyi, George Bissada, Sydney E. Hartsell, Robert E. Boucher, Guo Wei, Ravinder Singh, Amara Sarwal, Srinivasan Beddhu. *University of Utah Health, Salt Lake City, UT.*

Background: We examined the hypothesis that depressive symptoms might result in lower adherence to systolic BP intervention (SBP goal < 120 vs. < 140 mmHg) in a post-hoc analysis of SPRINT data.

Methods: Based on baseline depressive symptoms assessed by the Patient Health Questionnaire (PHQ) - 9 scores, we defined depressive symptom groups as no (score = 0), minimal/mild (score =1-9), moderate/severe (score = 10-27) depressive symptoms. We used mixed effects models to relate baseline PHQ9 groups to post-randomization delta SBP (achieved standard arm SBP -achieved intensive arm SBP and delta number of antihypertensives).

Results: In the 9340 included SPRINT participants, achieved SBP by baseline PHQ9 groups in standard and intensive arms are presented in Fig 1. Delta SBP and delta antihypertensives are presented in Table 1.

Conclusions: Moderate/severe depressive symptoms were associated with less separation of achieved SBP in SPRINT. Addressing depressive symptoms might be important to achieve adherence to interventions.

Funding: NIDDK Support

Table 1

Depressive symptoms	Delta SBP	Delta # antihypertensives
Absent	14.8 (14.4, 15.3)	-0.8 (-0.8,-0.7)
Mild	14.0(13.4,14.6)	-0.7 (-0.7,-0.6)
Moderate/Severe	9.0(5.6,12.4)	-0.8(-1.0,-0.5)

Population Trends in the Incidence, Treatment, and Outcomes of Myocardial Infarction and Stroke in Patients with Kidney Failure: A National Data-Linkage Study

Peter J. Gallacher, Neeraj Dhaun. *The University of Edinburgh Centre for Cardiovascular Science, Edinburgh, United Kingdom.*

Background: Temporal trends of myocardial infarction and stroke are declining in the general population, but have not been evaluated in patients with kidney failure (ie. on dialysis/with a kidney transplant). We describe national trends in the incidence, treatment and outcomes of myocardial infarction and stroke in patients with kidney failure over a 20-year period, stratified by age and sex.

Methods: In this retrospective national data-linkage study, all patients with kidney failure in Scotland (UK) experiencing an incident myocardial infarction or stroke between 01/01/1996 and 12/31/2016 were linked to national hospitalization, prescribing and death records. The primary outcome was 1-year cardiovascular death. Generalized additive models were constructed to estimate age-standardized, sex-stratified incidence rates and trends in mortality.

Results: Amongst 16,050 patients with kidney failure (52±15 years;41.5% women), there were 1,992 (66±12 years;34.8% women) and 996 (65±13 years;45.1% women) incident myocardial infarctions and strokes between 01/01/1996 and 12/31/2016. The age-standardized incidence of myocardial infarction per 100,000 decreased in men (from 4,376 [95% confidence interval [CI] 3,998-4,785] to 1,835 [95%CI 1,692-1,988]) and women (from 3,268 [95%CI 2,982-3,593] to 1,369 [95%CI 1,257-1,491]). The age-standardized incidence of stroke per 100,000 also decreased in men (from 1,978 [95%CI 1,795-2,175] to 799 [95%CI 729-875]) and women (from 2,234 [95%CI 2,031-2,468] to 903 [95%CI 824-990]). Compared to the general population, the incidence of myocardial infarction was 4-8-fold higher in patients with kidney failure, whilst for stroke it was 2-4-fold higher. The use of evidence-based cardioprotective treatment increased and the predicted probability of 1-year cardiovascular death following myocardial infarction for a 66-year-old patient with kidney failure (mean age of cohort) fell in men (76.6% to 38.6%) and women (76.8% to 38.8%), and also decreased in both sexes following stroke (men: 63.5% to 41.4%; women: 67.6% to 45.8%).

Conclusions: The incidence of myocardial infarction and stroke has halved in patients with kidney failure over the past 20 years but remains significantly higher than in the general population. Despite improvements in treatment, the prognosis of these high-risk patients remains poor.

TH-PO236

Trends of Blood Pressure Control in CKD Among US Adults: Findings from the National Health and Nutrition Examination Survey 2011-2020

Sadaf Akbari,[1] Patrick Ten Eyck,[1] Masaaki Yamada,[1,2] Linder Wendt,[1] Robert E. Boucher,[4] Srinivasan Beddhu,[3] Diana I. Jalal.[1,2] *[1]University of Iowa Carver College of Medicine, Iowa City, IA; [2]Iowa City VA Medical Center, Iowa City, IA; [3]University of Utah Health, Salt Lake City, UT; [4]University of Utah Hospital, Salt Lake City, UT.*

Background: Hypertension contributes to kidney disease progression, cardiovascular disease, and death in patients with chronic kidney disease (CKD). The evidence and clinical guidelines support lowering blood pressure (BP) goals in this patient population. We evaluated if BP control improved among US adults with CKD.

Methods: In the National Health and Nutrition Examination Survey (NHANES) for the periods 2011-2014, 2015-2016, and 2017-2020, we identified individuals with CKD defined as estimated glomerular filtration rate 20-59 mL/min/1.73 m² or urinary albumin/creatinine ratio ≥30 mg/g. The following systolic BP categories were evaluated: <120, 120-129, 130-139, and ≥140 mm Hg. All measures were tested for differences between year groups accounting for sample strata, clusters, and weights.

Results: During the periods of 2011-2014, 2015-2016, and 2017-2020, the prevalence of CKD was stable at 14, 13, and 13%, respectively (p value=0.4) and among those with CKD, the % of individuals with self-reported hypertension or taking BP medications was 66, 69, and 86%, respectively (p value<.0001). Although the number of BP medications prescribed increased significantly across time (**Table**), a significant % of individuals with CKD and hypertension had systolic BP 130-139 mm Hg (17%) or ≥140 mm Hg (37%) during the period 2017-2020 (**Figure**).

Conclusions: The number of individuals with CKD noted to have hypertension has increased significantly over time. Although there has been a significant increase in the number of BP medications prescribed, a considerable number of individuals with CKD still did not meet their BP goal.

Funding: Other NIH Support - NHLBI

Table: Number of individuals with CKD receiving BP medications

Number of BP medications	2011-2014	2015-2016	2017-2020	p value
0	13,240,309 (45)	13,283,274 (45)	6,974,905 (18)	<.0001

An Interesting Presentation of Unilateral Renal Artery Stenosis

Swee Ping Teh,[1] Ivan Wei Zhen Lee,[2] Jia Min Chua.[1] *[1]Sengkang General Hospital, Singapore, Singapore; [2]Ministry of Health Holdings Pte Ltd, Singapore, Singapore.*

Introduction: Renal artery stenosis is uncommon, however, the prevalence increase in the presence of hypokalaemia and severe hypertension. We report a spontaneous dissection of the renal artery resulting in unilateral ischaemic nephropathy and secondary hyperaldosteronism.

Case Description: A 52-year-old Chinese Male was referred for the evaluation of hypertension and symptomatic hypokalemia (2.4mmol/L). 24-hour urine potassium (K+) was 74mmol/day suggestive of urinary loss. There was no history of diuretic use. Cortisol post 1mg ONDST was 25nmol/L, excluding Cushing's syndrome. Serum aldosterone was elevated (29 ng/dL (<21)) and plasma renin activity was not suppressed (5.4 ng/ml/h (2.9-10.8)), suggesting secondary hyperaldosteronism. Doppler ultrasonography of the renal arteries showed an atrophied left kidney with poor visualization of the proximal segment of the left renal artery with tardus parvus waveform. CT angiography showed near complete occlusion at the origin of the dominant left renal artery with significantly reduced opacification distally and an atrophic left kidney suggesting chronic dissection with thrombosis. The right renal artery was normal. DMSA scan showed left kidney contributes to 5% and the right kidney contributes to 95% of the total kidney function. He was started on Valsartan 40mg OD and spironolactone 12.5mg OD later. His blood pressure is well controlled. Potassium supplementation was reduced from 3.6g/day to 0.6g/day while maintaining normal K+, stable serum creatinine of 119umol/L, eGFR 58ml/min/1.73m² and urine albumin/creatinine ratio of 2.7mg/mmol.

Discussion: We present an interesting case of unilateral RAS, likely from a chronic dissection of the left renal artery causing secondary hyperaldosteronism. Common etiologies of renovascular hypertension include atherosclerosis or fibromuscular dysplasia. Upon reviewing his medical history, we noted that he presented with left flank pain a year ago, and was treated for pyelonephritis. CT KUB then revealed normal-sized kidneys. We postulate that the spontaneous dissection could have happened then, resulting in left renal artery stenosis and secondary hyperaldosteronism. Initiation of RAAS blockade resulted in the reversal of the effects of hyperaldosteronism and glomerular hyperfiltration, as evidenced by the reduction in potassium supplementation, albuminuria, and BP control.

TH-PO238

Resistant Hypertension with Recurrent Flash Pulmonary Edema in the Setting of Bilateral Renal Artery Occlusion

Korin Karabulut. *Boston University, Boston, MA.*

Introduction: Resistant hypertension is defined as elevated blood pressure despite three different classes of anti-hypertensives and warrants thorough investigation to rule out underlying secondary causes. Renal artery occlusion is an uncommon pathology, which can lead to severe kidney damage and can present with non-specific symptoms such as hematuria, acute kidney injury, uncontrolled hypertension.

Case Description: 49-year-old male with past medical history of unprovoked pulmonary embolism, recurrent flash pulmonary edema, hypertension, stage 4 chronic kidney disease with nephrotic range proteinuria who presented with shortness of breath, back pain and claudication symptoms. On presentation, he was found to have hypertensive emergency with flash pulmonary edema, requiring nicardipine infusion and mechanical ventilation. Initial laboratory tests were remarkable for hypokalemia, elevated creatinine, 4 g/g proteinuria on dipstick and microscopic hematuria. Anti-PLA2r, ANA, serum and urine electrophoresis, ANCA, serum and urine metanephrines were unrevealing. Patient had prior renal biopsy showing collapsing glomerulopathy with chronic renal thrombotic angiopathy. As the patient was hemodynamically stabilized, secondary causes for hypertension were investigated. Renal doppler ultrasound was performed, showing abdominal aorta thrombosis at the level of juxtarenal to infrarenal segments with bilateral occlusion of renal arteries. These findings furthermore confirmed with MR-Angiogram and renal nuclear scans. Given the life debilitating claudication symptoms, the patient underwent right axillobifemoral bypass.

Discussion: Recurrent flash pulmonary edema and resistant hypertension should raise suspect for renovascular hypertension and potentially renal artery occlusion. Renal artery occlusion is a rare finding and can be seen in patients with trauma, endovascular interventions, atherosclerosis, thromboembolic events and possibly underlying hypercoagulability. After ruling out lupus anticoagulants, antiphospholipid panel, Factor Leiden V, homocysteine, trauma and we concluded that the renal artery occlusion was due to atherosclerotic plaque proved by pathology. While the treatment is on case-on-case basis, revascularization was pursued for our patient with resolution of claudication symptoms but no significant improvement of kidney functions.

TH-PO239

Primary Hyperaldosteronism Secondary to Right Adrenal Hyperplasia with Nonfunctioning Left Adrenal Adenoma Elucidated by Adrenal Vein Sampling

Adam Tuchinsky,[1] Sundus Sardar,[2,3] Abdel-Rauof M. Akkari,[2,3] Umar Farooq,[2,3] Nasrollah Ghahramani.[2,3] *[1]UPMC Pinnacle Lititz, Lititz, PA; [2]Penn State Health Milton S Hershey Medical Center, Hershey, PA; [3]Penn State College of Medicine, Hershey, PA.*

Introduction: Primary hyperaldosteronism includes two main subtypes namely idiopathic hyperaldosteronism(also termed bilateral adrenal hyperplasia) and unilateral aldosterone-producing adenoma, managed with aldosterone antagonists or adrenalectomy, respectively. Aldosterone renin ratio (ARR) has emerged as a significant parameter as compared to plasma aldosterone concentration (PAC), thus identifying need for adrenal vein sampling (AVS) or further exclusionary tests including imaging, the solitary utility of which without AVS may result in unwarranted adrenalectomy. Our case demonstrates the importance of AVS and elaborates the context that needs to be applied to plasma renin and aldosterone levels.

Case Description: A 68-year-old male with history of type 2 diabetes, coronary artery disease status post stenting 15 years ago, hyperlipidemia, and GERD, was referred for refractory hypertension, requiring carvedilol 25mg twice a day, doxazosin 2mg twice a day, hydrochlorothiazide 50mg daily, isosorbide mononitrate 30mg daily, losartan 100mg daily and spironolactone 50mg daily. Workup revealed microalbuminuria, normal serum potassium, bicarbonate, free metanephrines, renin, elevated aldosterone level of 40.1ng/dL, and elevated ARR of 44.6. Renal duplex ultrasound negative for renal artery stenosis. Noncontrast CT revealed 13x11mm left adrenal adenoma and bilateral adrenal gland thickening likely secondary to hyperplasia; adrenal vein sampling confirmed right adrenal vein aldosterone of 4880ng/dL, cortisol of 1158nmol/L(ratio 4.2), with left aldosterone 146ng/dL, cortisol 495nmol/L(ratio 0.3), and cortisol-corrected PAC laterization ratio of 14. He underwent laparoscopic right adrenalectomy with pathology confirming adrenocortical adenoma. Postoperative followup showed significant improvement in hypertension on fewer agents, decreased aldosterone of 7.8ng/dL, and ARR of 15.6.

Discussion: PAC may be challenging to interpret due to many influencing factors, hence, ARR is emerging as a beneficial parameter to delineate the initial diagnosis of primary hyperaldosteronism. Our case also emphasizes the utility of cortisol corrected PAC laterization ratio in these cases. While adrenal vein sampling may appear counterintuitive, it is prudent to consider AVS for confirmation prior to adrenalectomy.

TH-PO240

Lessons Learned in Determining Unilateral vs. Bilateral Intervention in Bilateral Renal Artery Stenosis

Amanda Abi Doumet, Ruchir D. Trivedi. *UConn Health, Farmington, CT.*

Introduction: Renal artery stenosis (RAS) is defined as a narrowing of one or both renal arteries. It is most frequently caused by atherosclerosis and less frequently by Fibromuscular Dysplasia (FMD) and other vascular abnormalities. Although RAS due to FMD is successfully treated with balloon angioplasty, such intervention is not as promising in atherosclerotic RAS. We present a case of a patient with bilateral RAS with successful balloon angioplasty of only the Left renal artery.

Case Description: A 46-year-old male with a history of hypertension and CKD stage IIIb presented with headaches and blurry vision. His BP was severely elevated at 209/153. His creatinine was elevated at 2.1 (baseline of 1.7). He was admitted for hypertensive emergency and underwent a workup for secondary causes of hypertension. Aldosterone/Renin ratio was 11.8/8.5 (1.4). Renal ultrasound duplex revealed a right kidney of 8.5 cm and left kidney of 11.4 cm, ostium of the right kidney was unable to be visualized and left renal artery systolic velocities were elevated. Renal angiography revealed critical mid-segment left RAS and right ostial RAS. A stent was placed in the left renal artery and the patient was started on Aspirin and Clopidogrel. Kidney function and blood pressure improved thereafter.

Discussion: RAS has many cardiovascular implications including resistant hypertension, CKD, and cardiac destabilization syndromes to name a few. Although the mainstay of treatment is medical therapy, some patients do benefit from stenting, such as those with hemodynamically significant atherosclerotic RAS and recurrent heart failure, refractory ACS, refractory hypertension, or progressive CKD due to bilateral or solitary ARAS. Although our patient had evidence of bilateral RAS, we concluded that the hemodynamically significant stenosis was that of the left renal artery. Since the left kidney was larger, we theorized that the primary stenosis was in the right kidney which led to compensatory hypertrophy of the left kidney and points to the relatively acute development of left RAS, explaining the patient's acute presentation. Improvement in kidney function and BP after stenting the left renal artery further supports that conclusion. More studies are needed to identify which patients will benefit most from stenting, based on clinical presentation and assessment of hemodynamic significance of RAS.

TH-PO241

Preeclampsia Superimposed on Secondary Hypertension in the Setting of Fibromuscular Dysplasia

Alejandro Valdesuso,[1] Eric S. Kerns.[2] *[1]Landmark Medical Center, Woonsocket, RI; [2]Rhode Island Hospital, Providence, RI.*

Introduction: Fibromuscular dysplasia (FMD) is a noninflammatory, nonatherosclerotic disorder of medium-sized vessels that leads to arterial stenosis. Most affected vessels are the renal and internal carotid arteries. When to pursue endovascular treatment is not always clear.

Case Description: The patient is an 18-year-old female who had recently given birth presented to the nephrology clinic for evaluation of uncontrolled hypertension possibly related to fibromuscular dysplasia. The patient was first seen to have hypertension at an emergency department when she was 10 weeks 4 days pregnant. At that time, her blood pressure was 176/82 mmHg. She was discharged home on labetalol 100 mg three times a day and referred for obstetric evaluation. At the obstetric clinic, work-up for secondary causes of hypertension was initiated. Renal ultrasound only showed involvement of the right renal artery with 60% stenosis. At 32 weeks 3 days, protein was detected for the first time in the urine and protein-creatinine ratio was 19.4, which represents at least 5000 mg of protein/day. As her blood pressure continued to be difficult to control, nifedipine was added to labetalol. At 32 weeks 5 days, labor had to be induced due to preeclampsia with severe features that included systolic blood pressures raging from 180-200 mmHg and fetal growth restriction. Creatinine remained within normal range throughout the entire pregnancy and afterwards. After leaving the hospital post-delivery, CT angiogram of abdomen/pelvis with and without contrast demonstrated left renal artery stenosis possibly related to FMD. At that time, protein-creatinine ratio had dropped to 0.22. Since then, losartan was added to the previous 2 antihypertensive and her blood pressure is still not well controlled.

Discussion: This patient had hypertension before 20 weeks gestation and proteinuria was first detected at 32 weeks 3 days, making this case one of chronic hypertension that progressed to preeclampsia with severe features. This patient meets criteria for angioplasty since she appears to have bilateral FMD and her blood pressure is not well controlled on as many as 3 antihypertensives. Cure rate of endovascular treatment appears to fall markedly with age. Curing hypertension in her case is preferable in view of her history of preeclampsia with severe features and the patient's desire to become pregnant again.

TH-PO242

Sex Differences in the Risk of Uncontrolled Hypertension: Variation over the Life Course

Wan-Jin Yeo,[1] Aditya L. Surapaneni,[1] Josef Coresh,[2] Shoshana Ballew,[2] Bige Ozkan,[2] Pascal Schlosser,[2] Morgan Grams.[1] *[1]NYU Langone Health, New York, NY; [2]Johns Hopkins University, Baltimore, MD.*

Background: Recent studies suggest that sex differences in uncontrolled hypertension (HTN) may vary by age.

Methods: We evaluated the prevalence of HTN and uncontrolled HTN in middle-aged (visit 2) and older-aged (visit 5) men and women of the Atherosclerosis Risk in Communities (ARIC) Study, assessing the associated risk of death and kidney function decline (defined as a 40% decline in eGFR). We looked at whether sex differences in older age could be explained by differences in chronic kidney disease (CKD), coronary heart disease (CHD), obesity, or by anti-HTN medication prescription patterns or adherence.

Results: Among 14,261 participants attending visit 2 (mean age 57), the prevalence of hypertension was 36% in both men and women. Among those with hypertension, the prevalence of uncontrolled hypertension (defined as systolic blood pressure ≥ 140 mmHg or diastolic blood pressure ≥ 90 mmHg) was higher in men (51%) than in women (44%). Among 6398 participants attending visit 5 (mean age 76), the prevalence of hypertension was similar in both men and women (76% and 74% respectively). Among those with hypertension, the prevalence of uncontrolled hypertension was higher in women (41%) than in men (33%). Both controlled HTN and uncontrolled HTN were risk factors for mortality for visit 2 participants (HR 1.3, 95% CI [0.08, 1.3] and HR 1.5 [1.3, 1.6], respectively), with higher risk associated with uncontrolled HTN in women compared with men (p=6.8E-03). Both controlled HTN and uncontrolled HTN were risk factors for kidney function decline (HR 1.2 [1.0, 1.5] and HR 1.6 [1.4, 1.9], respectively), with no difference by sex. Among visit 5 participants, controlled HTN and uncontrolled HTN were not significantly associated with mortality, but were strong risk factors for kidney function decline (HR 2.1 [1.2, 4.0] and HR 3.4 [1.8, 6.5], respectively) with no sex difference. Differences in uncontrolled HTN by sex at visit 5 was not explained by differences in CKD prevalence, CHD, obesity, anti-HTN medication prescription patterns (prescription, classes, and number), or anti-HTN medication adherence (defined as having at least one detectable anti-HTN medication metabolite in urine).

Conclusions: Uncontrolled HTN shows sex differences which vary by age, with implications for mortality and kidney function decline.

Trends in Hypertension Recognition, Treatment, and Control Between 2011 and 2019 Among Adults with CKD in the Veterans Health Administration

Joshua D. Martinez,[1] I-Chun Thomas,[2] Maria E. Montez-Rath,[2,1] Alan C. Pao,[2,1] Enrica Fung,[1] Vivek Charu,[1] John J. Sim,[3] Jaejin An,[3] Michelle Odden,[1,2] Manjula Tamura.[2,1] *[1]Stanford University, Stanford, CA; [2]VA Palo Alto Health Care System, Palo Alto, CA; [3]Kaiser Permanente Southern California, Pasadena, CA.*

Background: Hypertension frequently accompanies chronic kidney disease (CKD) as etiology and sequela. We examined contemporary trends in hypertension treatment and control in a national sample of adults with CKD.

Methods: We evaluated serial 5% cross-sectional samples of adults with CKD between 2011 and 2019 in the Veterans Health Administration (VA). We defined CKD as a sustained estimated glomerular filtration rate (eGFR) value <60 ml/min/1.73m² or a urine albumin-creatinine ratio (UACR) ≥30 mg/g.

Results: We examined 238,748 adults with a mean age of 72 years, 96% of whom were male. The age-adjusted proportion of adults with controlled BP declined from 78.0% in 2011 to 72.9% in 2019 (p-value for linear trend <0.001). Between 2011 and 2019, among adults with BP above goal, the age-adjusted proportion with a diagnosis of hypertension declined from 97.1% to 94.3% (p-value for linear trend <0.001), the age-adjusted proportion who did not receive antihypertensive treatment increased from 18.8% to 21.6% (p-value for linear trend <0.001), while the age-adjusted proportion who received three or more antihypertensive medications decreased from 41.8% to 36.3% (p-value for linear trend <0.001). The age-adjusted proportion of adults who received angiotensin converting enzyme inhibitors or angiotensin receptor blockers declined from 65.0% to 59.7% (p-value for linear trend <0.001); the age-adjusted proportion of adults who received thiazide-type diuretics declined from 24.1% to 20.0% (p-value for linear trend <0.001).

Conclusions: Among adults with CKD treated in the VA, the proportion with controlled BP has declined over time, coinciding with fewer prescriptions for antihypertensive medications.

Proteomics of Myocardial Fibrosis in Advanced CKD

Chenyu Liu,[1] Liangliang Zhang,[1] Scott E. Janus,[2] Robert J. Gaivin,[1] Sudha K. Iyengar,[1] Aparna Padiyar,[2] Mahboob Rahman,[1] Sanjay Rajagopalan,[1] Sadeer Al-Kindi,[2] Anne M. Huml,[3] Jeffrey R. Schelling,[1] Mirela A. Dobre.[1] *[1]Case Western Reserve University, Cleveland, OH; [2]University Hospitals, Cleveland, OH; [3]Cleveland Clinic, Cleveland, OH.*

Background: We used a large-scale, high-throughput DNA aptamer-based discovery proteomic platform to identify circulating biomarkers of myocardial fibrosis (MF) in advanced chronic kidney disease (CKD).

Methods: We evaluated 26 living kidney transplant (KT) recipients (age 53±16 years, 44% women, dialysis vintage 24.3±20 months) and 21 KT waitlisted participants (age 55±13 years, 38% women, dialysis vintage 23.2±17 months) who underwent proteomic profiling (SomaScan v.4.1) at study baseline. Living KT group had MF assessed by non-contrast cardiac magnetic resonance T1 maps prior to and 9 months post KT. Waitlisted group had T1 maps at baseline and 9 months follow-up. Plasma levels of 6472 proteins were related to baseline and change in T1 maps using DESeq2, adjusted linear regression, spike and slab regression, and Firth's bias-reduced logistic regression models. PathfindR and STRING-db v11.5 enrichment analyses were used to explore pathways.

Results: Among 126 proteins associated with baseline T1 maps, 43 remained significant after adjusting for clinical covariates (false discovery rate [FDR] adjusted p<0.05). Of these, 10 proteins were consistently selected across a large proportion of resampling iterations (>60%), with macrophage colony stimulating factor-1 (M-CSF1), displaying the greatest retest reproducibility (80%). Compared to waitlisted, KT recipients had a significant reduction in T1 maps at 9 months (79.2% vs 38.9% participants, p=0.003). Though FDR adjustment attenuated the association, greater baseline M-CSF1 was associated with decreased T1 maps in KT recipients (OR 2.53, 95%CI: 0.85, 14.11) and lower baseline M-CSF1 associated with increased T1 maps in waitlisted participants (OR 0.35, 95%CI: 0.07, 1.08). Plasma M-CSF1 levels by ELISA highly correlated with SomaScan values, and confirmed the inverse correlation with T1 maps.

Conclusions: Kidney transplantion was associated with a reduction in myocardial fibrosis measured by T1 maps. Plasma M-CSF1 was inversely associated with T1 maps and may serve as prognostic, and potentially mechanistic biomarker, conferring a protective effect against myocardial fibrosis in advanced CKD.

Relative Blood Volume Monitoring Using Crit-Line and Hospital Admissions: A Retrospective Analysis of over 25,000 Patients Across 330 Dialysis Clinics

Linda Ficociello, Meijiao Zhou, Hao Han, Michael S. Anger, Jeffrey L. Hymes. *Fresenius Medical Care, Global Medical Office, Waltham, MA.*

Background: Relative blood volume (RBV) monitoring may help guide fluid management, but real-world data on its use and potential impact on hospital admissions in chronic hemodialysis is limited. We aimed to compare hospital admissions among Fresenius Kidney Care (FKC) clinics with high utilization of RBV and propensity score matched (PSM) clinics not using RBV.

Methods: All data was retrospective, de-identified, and collected as part of routine clinical care and spanned 7/1/22-12/31/2022. RBV was conducted using Crit-Line (CLiC; Crit-Line in a Clip) devices integrated into 2008T dialysis machines. 165 FKC clinics with high utilization of RBV (HI-RBV; >90% of HD treatments used RBV) were PSM to 165 clinics not using RBV (NO-RBV) based on the following: pt census, age, gender, race, primary insurance, diabetes, catheter use, and ESRD network. Hospital admission rates (all-cause and fluid-related), hospital days, and 30-day readmissions were calculated and compared as rate ratios (RR), rate differences (RD), and proportions along with 95% confidence intervals and p-values.

Results: Outcomes for HI-RBV clinic pts (n=11,845) compared to NO-RBV clinic pts (n=13,238) are shown in Table. We observed an 8% lower rate of hospital admissions (p<0.0001) and 14% lower rate of fluid-related hospital admissions (p=0.0002) comparing HI-RBV to NO-RBV. There were 13 and 4 fewer hospital admissions per 100 person years (py) for all-cause and fluid related, respectively, along with 113 fewer hospital days per 100 py comparing HI-RBV to NO-RBV (p<0.0001). We can estimate an additional 48 missed treatments per 100 py in NO-RBV clinics due to these excess hospital days. There was a trend toward lower 30-day readmissions among HI-RBV vs NO-RBV (25.5% vs 27.3%, p=0.049).

Conclusions: Clinics with high utilization of RBV experienced fewer all-cause (8%) and fluid-related (14%) hospital admissions and hospital days (113 days per 100 py) when compared to PSM clinics without RBV.

Funding: Commercial Support - Fresenius Medical Care

	Incident Rate ppy		Rate Ratio	Rate difference ppy	p-value
	HI-RBV	NO-RBV	HI-RBV vs NO-RBV	HI-RBV vs NO-RBV	HI-RBV vs NO-RBV
All-cause hospital admissions	1.55 (1.51,1.59)	1.68 (1.64,1.72)	0.92 (0.89,0.95)	-0.13 (-0.18,-0.08)	<0.0001
Hospital days	9.75 (9.66,9.85)	10.89 (10.79,10.98)	0.90 (0.88,0.91)	-1.13 (-1.27,-1.00)	<0.0001
Fluid- related hospital admissions	0.27 (0.26,0.29)	0.32 (0.30,0.33)	0.86 (0.80,0.93)	-0.04 (-0.07,-0.02)	0.0002

TH-PO246

New Approach for Intradialytic Estimation of Absolute Blood Volume During Ultrafiltration

Rammah M. Abohtyra,[1] Daniel Schneditz,[2] Tyrone Vincent.[3] *[1]The University of Texas Permian Basin, Odessa, TX; [2]Medizinische Universitat Graz, Graz, Austria; [3]Colorado School of Mines, Golden, CO.*

Background: Managing blood and fluid volumes in chronic kidney disease (CKD) patients plays an essential role in dialysis therapy to replace kidney function. The study aims to develop an estimation approach to provide predictable information on blood and fluid volumes during a regular dialysis routine.

Methods: The method utilizes a nonlinear fluid volume model, a mathematical optimization technique, and the Unscented Kalman Filter (UKF). The method relies on anthropometric patient information (pre-dialysis weight, assumed dry weight), bounded parameter assumptions, and actual, on-line treatment information (UF-rate and hematocrit (H) or related measures of hemoconcentration). The method does not require a specific UF-rate or volume infusion protocols. Data collected were used where UF was varied to examine intravascular volume dynamics.

Results: The method was applied to 20 data sets of ten patients and provided comparable results compared to a previous method. Average blood volumes of 5.3±0.55L, plasma volumes of 4.1±0.64L, interstitial fluid volumes of 17.3±3.3L, and red blood cell volumes of 1.2±0.14L were estimated. We show that by implementing the estimated parameters, the measured H can be precisely predicted.

Conclusions: The method is comparable with a previous method and uses a short data segment for estimation.

Funding: Government Support - Non-U.S.

TH-PO247

Estimation of Absolute Blood Volume in Hemodialysis Patients Using Bioimpedance Spectroscopy

Fansan Zhu,[1] Jochen G. Raimann,[1] Ulrich Moissl,[2] Samer R. Abbas,[1] Paul W. Chamney,[3] Stephan Thijssen,[1] Peter Kotanko.[1,4] *[1]Renal Research Institute, New York, NY; [2]Fresenius SE & Co KGaA, Bad Homburg, Germany; [3]Fresenius Medical Care (UK) Ltd, Huthwaite, United Kingdom; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Measurement of absolute blood volume (ABV) during hemodialysis is essential to understand the relationship between the rates of vascular refilling and ultrafiltration. However, ABV is usually measured with dilution methods that are impractical in clinical routine. We evaluated whole body bioimpedance spectroscopy (wBIS) as an alternative approach.

Methods: Extracellular (ECV) and intracellular (ICV) volume were estimated using published equations (Moissl, Physiol Meas 27:921-933, 2006) based on wBIS measurements (Hydra 4200). Lean tissue mass (LTM) and adipose tissue mass (ATM) were calculated by a body composition model (BCM) (Chamney, Am J Clin Nutr 85:80 –89,2007). Reference blood volume (ABV_Dax) was measured by tracer dilution (Daxor BVA-100 analyzer, Daxor Corp., New York, NY, USA). Multiple regression and Bland-Altman analyses were used to determine the relationship of ABV with BCM and wBIS models, respectively.

Results: Data from 12 subjects (3 females, 53.8±15.2 years, pre-HD weight 85.6±19.7 kg) were analyzed. Pre-HD ECV (19.01±3.62L), ICV (23.02±5.96L), LTM (46.78±13.97kg) and ATM (36.86±18.53 kg) were calculated, while ABV_Dax (5.58±1.20 L) was measured before HD. The BCM model (ABV_BCM=1.028+0.023*ATM+0.079*LTM) comprised LTM and ATM as independent variables (Fig. 1). The wBIS model (ABV_wBIS=0.711+0.141*ICV+0.085*ECV) comprised ECV and ICV as independent variables (Fig.2). ABV_Dax correlated with ABV_BCM (R^2=0.84, p<0.0001; bias = -0.01±0.5 L) and with ABV_wBIS (R^2=0.84, p<0.0001; bias=0.00±0.49 L). Since the head and parts of the feet and hands had not been measured by wBIS, the y-intercept in both regression models conceptually represents an estimate of the blood in these body parts.

Conclusions: Estimation of ABV by both ABV_BCM and ABV_wBIS models correlate with the reference method. Despite the small sample size, utilizing such simple models may provide an approach using wBIS to estimate ABV and, in conjunction with relative blood volume measurements, to monitor ABV during HD.

TH-PO248

Estimation of Fluid Overload in Hemodialysis Patients Using Leg Bioimpedance

Fansan Zhu,[1] Peter Kotanko.[1,2] *[1]Renal Research Institute, New York, NY; [2]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: While 8-point bioimpedance provides a simple and convenient technique to measure segmental and whole body extracellular (ECV) and intracellular volume (ICV), it cannot quantitate fluid overload (FO). The aim of this study was to evaluate whether FO in hemodialysis patients can be estimated with a leg bioimpedance model.

Methods: Leg resistances were measured with four metal electrodes built into the footplate (Fig.1). Leg extracellular resistance (R_L; at 1 kHz frequency) and volume (ECV_L) were measured. ECV_{2L} represents ECV of both legs combined. Body height (H), pre-HD weight (Wt) and ultrafiltration volume (UFV) were recorded. Leg hydration index (α, Ω/cm) was defined as R_L/H in healthy subjects (HS; $\alpha_{HS}= R_{LHS}/H_{HS}$) and patients ($\alpha_P= R_{LP}/H_P$), respectively. The difference between average α_{HS} (α'_{HS}) in the HS and patients ($\Delta\alpha=\alpha'_{HS} - \alpha_P$) reflects the degree of leg FO. $\Delta\alpha*ECV_{2L}$ and body mass index ($BMI=Wt/H^2$) were considered as independent variables in a regression model that was built to explore the relationship between UFV and FO.

Results: Sixteen HS (age 34.8±7.6 years, H 168.7±9.5 cm, Wt 72.7±17.3 kg) and thirteen HD patients (age 47±16 years, H 169.5±4.5 cm, Wt 83.9±5.4 kg) were studied pre-HD. Leg resistance (R_L) was 217.3±55.3 Ω pre-HD, UFV was 3862±1320 mL. Average α_{HS} (α'_{HS}), defined as the standard index of leg normal hydration, was 1.8±0.3 Ω/cm. Δα was 0.24±0.37 Ω/cm in the HD patients. FO [in mL] was estimated as 534 + $0.36*\Delta\alpha*ECV_{2L}$ + 70.24*BMI. UFV was highly correlated with estimated FO (R^2= 0.82, p<0.0001). Bland-Altman analysis showed a bias of 0.15±394 mL (Fig.2).

Conclusions: Estimated leg hydration correlates well with FO in hemodialysis patients. A model with leg resistance and BMI as independent variables can predict FO in HD patients.

Pulmonary Congestion Management Guided by Lung Echography in Hemodialysis: When and How?

Saleh Kaysi,[1,2] Bakhtar Pacha,[1,2] Frederic Collart,[1,2] Marie-Helene Antoine,[2,3] Joelle L. Nortier.[1,2] *[1]UVC Brugmann - Site Victor Horta, Laken, Belgium; [2]Universite Libre de Bruxelles, Bruxelles, Belgium; [3]Laboratoire de Néphrologie expérimentale, Bruxelles, Belgium.*

Background: Assessment of pulmonary congestion (PC) by lung ultrasound (LUS) may help its management in hemodialysis (HD) patients, and better defining the dry weight (DW). We inspected the best moment to perform LUS in HD, and then applied a LUS guided DW adjustment approach.

Methods: Prospective randomized study: 18 HD patients, preceded by an observational phase: B-lines score (BLS: 8-sites method) and echocardiography were obtained before and after the first 2 HD sessions of the week. Total body volume using Bio-electrical Impedance Analysis (BIA) was measured besides serum NT-pro BNP levels. Circulating markers of inflammation (soluble urokinase Plasminogen Activator Receptor [suPAR] and soluble Suppression of Tumorigenicity 2 [sST2]) were measured. Patients were then randomized into: an active group where DW was reduced by 500 g in case of BLS > 0.54/zone measured after HD2 (every 2 weeks), and a control group where DW was modified only according to standard of care. Same measurements were repeated a month later.

Results: BLS pre-HD1 (16 ± 5.53) and post-HD1 (15.3 ± 6.63) were elevated as pre-HD2 (16.2 ± 5.26) and post-HD2 (13.6 ± 5.83). BLS was not affected by inter-dialysis interval (68h vs 44h). BIA was correlated to BLS only before HD2 (P= 0.007). BLS and the systolic cardiac function (left ventricular ejection fraction) were correlated only after HD2 (P=0.046). NT-ProBNP levels and BLS were correlated before both sessions (P=0.004, P=0.001). Cardiac diastolic function was correlated to BLS before HD1 (P=0.002) and after HD2 (P=0.034). Mean levels (± SD, ng/ml) of suPAR (7.88 ± 3.07 and 7.78 ± 3.02) remained high (N< 4 ng/ml), while sST2 levels reached 2-fold the upper normal value (27.4 ± 17.8). At day 30, a significant reduction in BLS was obtained before (17.4 *vs* 8.5, P <0.0001) and after (13.3 *vs* 5.0, P<0.001) HD in the active group, whereas no difference was found in controls.

Conclusions: Pulmonary congestion is common in HD patients even after reaching their dry weightand is not systematically correlated to volume status or cardiac function. Chronic inflammation may be involved in PC pathophysiology. The best moment to estimate pulmonary congestion degree by lung ultrasound is after the 2nd HD session of the week, and a step by step DW adjustment guided by LUS may significantly and safely reduce PC.

Funding: Government Support - Non-U.S.

TH-PO250

Legacy Effect of a Lung-Ultrasound Intervention on the Risk for Death and Cardiovascular Events in Dialysis Patients

Carmine Zoccali,[1,2] Claudia Torino,[3] Rocco Tripepi,[3] Giovanni Tripepi,[3] Francesca Mallamaci.[4] On Behalf of the LUST Workgroup. *[1]Renal Research Institute, New York, NY; [2]Associazione Ipertensione Nefrologia e Trapianto Renale (IPNET), Reggio Calabria, Italy; [3]Istituto di Fisiologia Clinica Consiglio Nazionale delle Ricerche Sezione di Reggio Calabria, Reggio Calabria, Italy; [4]Grande Ospedale Metropolitano (GOM), Reggio Calabria, Italy.*

Background: In the "LUng water by Ultra-Sound Guided Treatment (LUST) to Prevent Death and Cardiovascular Complications in High Risk ESRD Patients with Cardiomyopathy" trial (NCT02310061)", this treatment strategy was not more effective than a usual care strategy in improving the primary end point of the study over two years. Since robust long-term effects of intensive haemodialsyis in the frequent haemodialysis trial, we designed a post-trial, observational analysis extended up to 4.4 years.

Methods: We included in this analysis 315 HD patients. In patients in the active arm of the trial (n=157) ultrafiltration prescription was guided by lung US, while in the control arm (n=158) ultrafiltration was prescribed on the basis of standard clinical criteria. After the trial, patients were followed-up for 2 additional years, but no intervention was applied (observational phase). Since fluid volume is higher in men than in women, by protocol we tested the effect modification of male sex on the response to the lung-US intervention.

Results: Among the 315 HD patients, 223 (71%) were males. During the long-term observation (up to 4.4 years), the combined event occurred in 88 patients (56%) in the active arm and 100 (63%) in the control arm. Like in the LUST trial, the 16% risk reduction registered in the observational extension of the trial failed to achieve significance (HR: 0.84, 95% CI: 0.63-1.12, P=0.23). Sex emerged as a robust modifier [P for effect modification 0.02] of the effect of the lung US intervention on the combined end-point. Indeed, the intervention produced a 35% risk reduction in men [HRmen: 0.65, 95%CI: 0.46-0.93, P=0.02] but not in women [HRwomen: 1.40, 95%CI: 0.84-2.34, P=0.20].

Conclusions: In an observational extension to 4.4 years of the LUST trial, the treatment strategy guided by lung-US was associated with a 35% reduction of the risk of the combined end-point of the trial in men while no such an effect emerged in women. These results are in keeping with biological knowledge indicating that in the hemodialysis population, men have higher fluid volume and cardiovascular risk than women.

TH-PO251

Volume Status Assessed by Physical Examination Correlates with Lung Ultrasound Findings in Patients with CKD

Orit Kliuk Ben Bassat,[1,2] Michal A. Raz,[1] Ayelet Grupper.[1,2] *[1]Tel Aviv Sourasky Medical Center, Tel Aviv, Israel; [2]Tel Aviv University Sackler Faculty of Medicine, Tel Aviv, Israel.*

Background: Volume overload is common in patients with chronic kidney disease (CKD), predominantly in dialysis patients. Volume assessment by physical examination (PE) may be subjective, therefore more accurate methods are necessary. Lung ultrasound (LUS) is one method used to accurately diagnose dry weight in dialysis patients. We aimed to assess LUS accuracy compared to PE in the range of CKD stages.

Methods: A prospective single center study. Hemodialysis (HD), peritoneal dialysis (PD) and CKD 1-5 patients were enrolled. PE was performed prior to LUS to evaluate signs of volume overload. Lung findings (crackles, pleural effusion) were reported as present or not, peripheral edema was graded 0-4[1]. HD patients were examined twice, pre and post dialysis. LUS was performed by inspection of 12-zones. Each zone was assigned 0 points for less than 2 separated B-lines, 1 point if more than 3 B-lines were observed, 2 points when multiple B-lines with coalescing lines were documented and 3 points in cases of pulmonary consolidation. Accordingly, exam scores could range from 0, indicating a normal exam, to 36, indicating worst congestion possible. Results of PE and LUS were compared.

Results: Among 175 participants, 112 were HD patients, 18 PD and 45 CKD 1-5ND patients. Higher LUS scores correlated with presence of lung crackles (OR=1.16 (1.10-1.23) p<0.01) and pleural effusion (OR=1.17 (1.11-1.23) p<0.01). There was a significant correlation between LUS score and peripheral edema (Figure 1), and an inverse correlation between room air saturation and LUS score (r=-0.143, p=0.017). In HD patients weight differences before and after dialysis (delta weight) were compared with LUS score difference before and after dialysis (delta score). There was a linear correlation between delta weight and delta score (r=0.225, p=0.013).

Conclusions: LUS correlates significantly with PE findings in volume overload assessment in a broad spectrum of CKD patients.

TH-PO252

Temporal Trend of Direct Oral Anticoagulant vs. Vitamin K Antagonist Usage in Dialysis Patients

Tariq A. Shaheed, Douglas A. Stram, Aida Shirazi, Sumie Iwasaki, Sijie Zheng. The Permanente Medical Group, Kaiser Oakland Hospital, Kaiser San Francisco Hospital, and the Division of Research, California. *The Permanente Medical Group, Berkeley, CA.*

Background: Many dialysis patients take anticoagulation for various indications such as stroke prevention in atrial fibrillation, DVT and/or PE. Vitamin K antagonist (VKA) has been used for decades and Direct Oral Anticoagulants (DOAC) have gradually replaced VKA in the general population due to its ease of use. However, due to its safety issue in dialysis patients, the adoption of DOAC has been slow, until the approval of Apixaban by FDA in advanced CKD patients. In this study, we examined the temporal trend of anticoagulant usage in dialysis patients in an integrated health care system.

Methods: This is a retrospective cohort study performed within Kaiser Permanente Northern California (KPNC) from 2013-2021. Pharmacy records and ICD codes identified patients on dialysis (hemodialysis or peritoneal dialysis) who are taking oral anticoagulants to determine the percentage of dialysis patients on anticoagulants. Next, we determined the percent of patients on VKA and a DOAC. The percentage of patients on these two anticoagulants were determined every year.

Results: We identified 1688 dialysis patients on anticoagulants in the study period, representing 16.5% of dialysis populations (10242). In this population, mean age was 68.3 (SD 12.7), 40% female, 41% white, 21% Asian, 18% Hispanic, 15% Black and 6% others. There is an increase in the prescribing trends of DOAC with concurrent decrease in prescribing of VKAs (apixaban increased from 0 % in 2013 to 5.4 % in 2021 while warfarin decreased from 14.5% in 2013 to 9.8% in 2021 (figure). If a patient was to be switched off anticoagulation, they were more likely to be switched off VKA rather than apixaban.

Conclusions: This study revealed a diverging trend in the prescribing of VKA and DOAC over the past 9 years. Prescribers were more likely to switch from VKA to DOAC. Study is ongoing comparing the efficacy, safety, and cost.

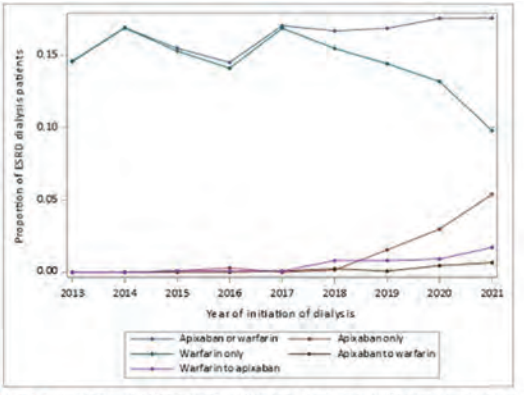

Figure 2. Illustrates prescribing trends of Warfarin, Apixaban over the course of 8 years. The top line is either Warfarin or Apixaban (blue), the second from top line is warfarin only (green), 3rd from top in red is Apixaban only (red). Then the 4th from top in magenta id the trend of switching warfarin to apixaban and bottom line in brown is trend from switching Apixaban to warfarin which occurred the least over the course of the study period.

Absolute Iron Deficiency, Coronary Artery Calcification, and Mortality in Dialysis Patients

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Toshiki Doi,[1,3] Aiko Okubo,[1,3] Kenichi Morii,[1,3] Kazuomi Yamashita,[1] Koji Usui,[2] Kenichiro Shigemoto,[1] Takao Masaki.[3] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Iryohojin Ichiyokai Ichiyokai Clinic, Hiroshima, Japan; [3]Hiroshima Daigaku Byoin, Hiroshima, Japan.*

Background: It is reported that iron-deficiency is associated with hypercoagulability and stroke by upregulating transferrin (Tang X. Circ Res. 2020;127:651). We studied the associations among iron deficiency, coronary artery calcification and mortality in patients on dialysis.

Methods: We included 230 patients with predilution online hemodiafiltration and 76 on hemodialysis. The Agatston coronary artery calcium score (CACS) and clinical data, such as transferrin saturation (TSAT), ferritin, hemoglobin, mean corpuscular hemoglobin (MCH), serum albumin and C-reactive protein (CRP) at baseline, were assessed. Kaplan–Meier survival analyses and Cox proportional hazard models were used to assess patients' survival. Logistic regression analyses were used to determine related factors for absolute iron deficiency (TSAT ≤20% and ferritin concentrations ≤100 ng/mL).

Results: In all patients (n=306), age, dialysis duration and diabetes prevalence were 65±12 years, 76 (38–142) months and 42.5%, respectively. During 3 years, 52 all-cause deaths and 34 cardiovascular (CV) deaths occurred. Patients with absolute iron deficiency (n=102) showed significantly lower TSAT (13%±4% vs 30%±10%) and ferritin (34±23 vs 109±96 ng/mL) and MCH (28±3 vs 32±2 pg) concentrations, but significantly higher CRP concentrations than patients without absolute iron deficiency (n=204) (P<0.05). Age, sex, dialysis duration, prevalence of diabetes and serum albumin concentrations were not significantly different according to the presence of absolute iron deficiency. Absolute iron deficiency was significantly related to the CACS (P<0.05). Patients with absolute iron deficiency had a significantly lower Kaplan–Meier survival rate for 3-year CV death than patients without absolute iron deficiency (82.2% vs 90.9%; log-rank test, *P*<0.05). However, there was no significant difference in survival for 3-year all-cause death between the two groups. After adjusting for age, sex, diabetes, dialysis duration, serum albumin, C-reactive protein and hemoglobin, absolute iron deficiency was a significant predictor for 3-year CV mortality (hazard ratio: 2.08, P<0.05), but not for 3-year all-cause mortality.

Conclusions: Absolute iron deficiency is a significant predictor for the CACS and CV mortality, but not for all-cause mortality in patients on dialysis.

Coronary Artery Calcification Is Associated with Low Kt/Vurea and Extracellular Fluid Excess in Patients on Hemodialysis

Sonoo Mizuiri,[1] Yoshiko Nishizawa,[1] Toshiki Doi,[1,2] Aiko Okubo,[1,2] Kenichi Morii,[1,2] Kazuomi Yamashita,[1] Kazuyoshi Karasuda,[1] Koji Usui,[3] Kenichiro Shigemoto,[1] Takao Masaki.[2] *[1]Iryo Hojin Ichiyokai Harada Byoin, Hiroshima, Japan; [2]Hiroshima University Hospital, Hiroshima, Japan; [3]Iryo Hojin Ichiyokai Ichiyokai Clinic, Hiroshima, Japan.*

Background: An insufficient dialysis dose and extracellular fluid excess are independent predictors of cardiovascular morbidity in patients on hemodialysis. We studied the associations among coronary artery calcification, Kt/Vurea, and body composition in patients on hemodialysis.

Methods: The Agatston coronary artery calcium score (CACS), postdialysis body composition using bioelectrical impedance device, and clinical data including Kt/Vurea and predialysis β2-microglobulin (β2M) at enrollment, were assessed in patients on hemodialysis. The patients were classified into two groups according to a CACS ≥400 or a CACS <400, and intergroup differences were analyzed using the Wilcoxon test or the x^2 test, as appropriate. Linear regression analyses were performed to identify the risk factors for CACS.

Results: In all patients (n=324), age, the dialysis duration, the diabetes prevalence, and the CACS were 69±12 years, 116±105 months, 133/324 (41.0%), and 763 (155–2491), respectively. Patients with a CACS ≥400 (n=208) were older (72±11 vs. 66±14 years), had a longer dialysis duration (123±109 vs. 104±98 months), had a higher diabetes prevalence (46.6 vs. 31.0 %), serum phosphate concentrations (5.5±1.5 vs. 5.1±1.3 mg/dL), extracellular water/total body water (ECW/TBW) (0.49±0.03 vs. 0.47±0.03), and overhydration (OH) (1.2±1.5 vs. 0.7±1.1 L), and had lower Kt/Vurea (1.43±0.24 vs. 1.64±0.54) than patients with a CACS <400 (n=116), (*P*<0.05). Serum albumin, magnesium, C-reactive protein, and albumin-adjusted calcium levels were not significantly different between the two groups. In simple linear regression analyses, age, dialysis duration, diabetes, smoking, serum phosphate, ECW/TBW, and OH were significantly associated with the CACS (all *P*<0.05), and β2M showed marginal significance (*P*=0.06). Multiple linear regression analysis adjusted for age, dialysis duration, and diabetes showed that Kt/Vurea, β2M, and ECW/TBW were risk factors for CACS (all *P*<0.05). After additional adjustment for serum phosphate and smoking, only Kt/Vurea (β: −0.16) and ECW/TBW (β: 0.12) were significant predictors for CACS (both *P*<0.05).

Conclusions: Lower Kt/Vurea and extracellular fluid excess are independently associated with coronary artery calcification in patients on hemodialysis.

Association Between Magnesium, Erythropoietin Resistance, and Mortality: The Japanese Dialysis Outcome and Practice Pattern Study (J-DOPPS) Study

Sawako Kato,[1] Jui Wang,[2,3] Yoshihiro Onishi,[2] Masaomi Nangaku.[4] *[1]Nagoya Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Nagoya, Japan; [2]Institute for Health Outcomes and Process Evaluation Research, Tokyo, Japan; [3]National Taiwan University, Taipei, Taiwan; [4]Tokyo Daigaku Daigakuin Igakukei Kenkyuka Igakubu, Bunkyo-ku, Japan.*

Background: Limited data are now available to evaluate the relationship between serum magnesium level, anemia, and mortality in the dialysis population.

Methods: Using data from the Japanese Dialysis Outcomes and Practice Patterns Study (J-DOPPS) phases 5 and 6, we analyzed the association between serum magnesium (s-Mg) levels and the erythropoietin resistance index (ERI) as the primary outcome. To estimate the longitudinal relationship, a mixed-effect model was used with ERI at each 4-month period as the dependent variable, quintiles of s-Mg at the previous 4-month period as the independent variable. We also examined the all-cause and cardiovascular disease (CVD)-related deaths as secondary outcomes by Cox regression with quintiles of s-Mg at baseline.

Results: Of the 4776 participants in J-DOPPS, 1650 were included in the analysis. The median of s-Mg at baseline was 2.5 mg/dL. A significant linear association of s-Mg with ERI (p for trend < 0.001) was revealed (Figure). The highest quintile of s-Mg was significantly associated with lower incidence of all-cause mortality (Table) and deaths due to CVD events compared to the middle (reference) quintile.

Conclusions: We observed that lower s-Mg levels subsequently induced higher ERI and that mild higher s-Mg levels predicted good rather than poor outcomes in Japanese hemodialysis patients. Adjustment of s-Mg levels may be proposed as a new strategy at low cost and risk to reduce the risk of premature mortality.

Anticoagulant and Antiplatelet Use and Risk of Serious Bleeding Events Among PDOPPS and DOPPS Patients Receiving Peritoneal or Hemodialysis, 2009-2022

Catelyn Coyle,[1] Lori D. Bash,[1] Dena Rosen R. Ramey,[1] Brandon Atkins,[1] Irina Barash,[1] Murilo H. Guedes,[2] Junhui Zhao,[2] Angelo Karaboyas,[2] Roberto Pecoits-Filho,[2] Marc P. Bonaca.[3] *[1]Merck & Co Inc, Rahway, NJ; [2]Arbor Research Collaborative for Health, Ann Arbor, MI; [3]University of Colorado Anschutz Medical Campus School of Medicine, Aurora, CO.*

Background: Risk of serious bleeds among patients receiving dialysis is higher than the general population and may increase with the use of oral anticoagulant (OAC) and antiplatelet therapies (APT). The rate of bleeding in patients on OAC and APT between dialysis modalities are not well reported.

Methods: Using data from the Dialysis Outcomes and Practice Patterns Study (DOPPS; 2009-2022) and Peritoneal DOPPS (PDOPPS; 2014-2022), we describe OAC and APT use among patients receiving hemodialysis (HD) or peritoneal dialysis (PD) and present event rates of bleeding events that led to death or inpatient hospitalization, per 100 person-years, stratified by dialysis type, and use of OAC or APT.

Results: Overall, 27,612 received HD and 5,288 PD. OAC (9% vs. 4%) and APT (10% vs. 7%) use was higher among patients receiving HD vs. PD, and >99% of all OAC use was warfarin. In both modalities, the rates of non-fatal, fatal bleeding events and hospitalizations due to any bleed or GI bleed were higher for patients prescribed (vs. not) OAC and APT (Table). First hospitalization bleeding rates occurred 2 and 3 times more often among HD patients and PD patients using OACs (compared to not), respectively. Those using APTs were observed to have a 25% (HD) and 40% (PD) increase (compared to not) in first hospitalization rate. The same trend was observed for recurrent hospitalizations due to any bleed and fatal bleeds.

Conclusions: OAC and APT use was ≤10% in both populations. Serious bleeding rates were higher among patients prescribed OAC and APT regardless of dialysis modality and differences in bleeding rates between treatment groups were larger among PD patients. Results underscore the need for strategies to reduce bleeding in patients on dialysis requiring anticoagulation, including novel agents with improved safety profiles.

Funding: Commercial Support - Merck and Co., Inc.

Rate of serious bleeding event types by anticoagulant or antiplatelet use among patients with ESKD receiving peritoneal or hemodialysis in DOPPS (2009-2022) and PDOPPS (2014-2020)

Bleeding Event Rate (per 100 person-years)	Hemodialysis		Peritoneal Dialysis		Hemodialysis		Peritoneal Dialysis	
	Anticoagulant Use				Antiplatelet Use

Hemoglobin (Hgb) Variability and Target Range in Hemodialysis (HD) Patients

Ariella E. Mermelstein,[1] Tomislav Kovacevic,[2] Jeffrey L. Hymes,[3] Peter Kotanko,[1,4] Jochen G. Raimann.[1] *[1]Renal Research Institute, New York, NY; [2]Vifor Pharma Management Ltd, Glattbrugg, Switzerland; [3]Fresenius Medical Care Holdings Inc, Waltham, MA; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: Based on randomized controlled trials in CKD patients (pts), in the US, a hgb target range between 10 to 11 g/dL is the mandated. Retrospective studies have shown lower hospitalization and death rates with higher hgb, and a higher risk of death with increased hgb variability. We investigated in this retrospective cohort study of incident HD pts receiving erythropoietin stimulating agent (ESA), the association between all-cause mortality hazard ratio (HR), hgb variability and level.

Methods: We studied a cohort of incident HD pts initiated with a long-acting ESA (Mircera; Vifor) within the first 90 days. In pts with at least twelve hgb values over the 6-months baseline period we quantified mean hgb and variability, as either standard deviation (sd) or slope of a linear model, as metrices. We built proportional hazard models including both mean and variability metrices to predict HR over the following 18 months, adjusted for race, sex, age, diabetes, serum albumin and phosphorus. We then built spline functions to depict HR in a bivariate fashion as a function of baseline mean hgb level and variability.

Results: We studied 64,042 pts out of 517,860 pts in Fresenius Kidney Care clinics. A range between 10.5 and 12.5 g/dL associated with the lowest HR when accounting for variability of hgb during the baseline period (**Figure 1** and **2**). An increasing slope and increased variability seem to associate with improved survival at low hgb levels.

Conclusions: A wider and upwards shifted hgb target range is associated with favorable mortality outcomes, independent of variability or systematic trends. Hgb variability, possibly a resultant of responsiveness to therapy, confers a survival advantage at lower and higher levels of mean hgb Limitations of retrospective research apply. Adequately powered and designed experimental studies are needed.

Using Machine Learning to Construct a Predictive Model for Hemoglobin in Maintenance Hemodialysis Patients

Mingzhu Li, Daqing Hong, Guisen Li, Li Wang. *Sichuan Academy of Medical Sciences and Sichuan People's Hospital, Chengdu, China.*

Background: Constructing prediction models of hemoglobin concentration by machine learning method, to assist clinicians to make clinical decisions in order to achieve individualized and precise treatment for maintenance hemodialysis (MHD) patients with renal anemia.

Methods: The medical records of maintenance hemodialysis patients from January 1, 2021 to January 1, 2023 in Sichuan Provincial People's Hospital were included. Demographic characteristics, test results, medication orders were included to constructed the prediction models. Selection of characteristic variables were mainly based on previous published articles, and all medical data were derived after desensitization. Data were randomly divided into training set (80%) and test set (20%) after desensitization, filling, deletion and other preprocessing. Ten machine learning methods (Linear Regression, K Neighbors Regressor, Support Vactor Regression, Ridge Regression, Lasso Regression, eXtreme Gradient Boosting Regressor, Random Forest Regressor, AdaBoost Regressor, Gradient Boosting Regressor, Bagging Regressor) were used to construct prediction models. Model performance was assessed by assessing the difference between predicted and true values and by fitting with internal validation.

Results: The medical records of 495 patients were finally included. The study included 56% male with a median age of 60 years old. The patients' dry weight was 58.7±11.3 kg and their weight before dialysis was 61.3±11.6 kg. In terms of laboratory results, the patients had a hemoglobin level of 109(96~118) g/L, serum albumin level of 40.8 (38.1~43.9)g/L, serum ferritin of 210.3(130.0~359.4)ng/mL and an average transferrin saturation level of 26.2±17.3 %. The patients' median dose of intravenous iron supplements was 500 mg/month, and their median dose of erythropoiesis-stimulating agents was 5 (4 to 6.25)×10^4 U/month. Ten machine learning models were used for modeling, Random Forest showed better prediction performance compared with other models, with an RMSE of 9.41 and a coefficient of determination R^2 of 0.65 for the training set.

Conclusions: The machine learning-based hemoglobin prediction model of MHD patients can be used to predict hemoglobin concentration to a certain extent, which can contribute to the individualized and precise management of anemia in maintenance hemodialysis patients.

Dynamic Predictions of All-Cause Mortality in Incident Hemodialysis Patients with Extended Joint Models Adjusting for Albumin Trajectory and Competing Risks

Ivan Damgov,[1,2] Meinhard Kieser,[2] Peter Rutherford,[3] Muh Geot Wong,[4] Carol A. Pollock,[5] David W. Johnson,[6,7] Claus Peter Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, University of Heidelberg, Heidelberg, Germany; [2]Institute of Medical Biometry, University of Heidelberg, Heidelberg, Germany; [3]Baxter Healthcare Corporation, Zurich, Switzerland; [4]Department of Renal Medicine, Royal North Shore Hospital, St Leonards, NSW, Australia; [5]Kolling Institute, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; [6]Australasian Kidney Trials Network, University of Queensland, Brisbane, QLD, Australia; [7]Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia.*

Background: Joint models (JM) provide individual patient dynamic risk predictions based on the association between longitudinal biomarkers and mortality. We explore extensions to JM methodology performed for the first time with hemodialysis (HD) clinical trial data.

Methods: We evaluated the association of albumin with all-cause mortality in incident HD patients followed over 8 years in the Initiating Dialysis Early And Late trial. To account for skewness/outliers in albumin, novel JM with mixed effects sub-model with skew-normal, *t* and skew-*t* errors were compared with conventional JM under normal distribution. Furthermore, we adjusted for the competing event of transplantation using Weibull cause-specific hazards. The dataset (N=315 patients) was randomly split into training dataset (3/4, N=236) for model fitting and validation dataset (1/4, N=78) to infer predictive performance. We obtained 12-month individual patient survival predictions from all JM at cut-offs 1, 1.5 and 2 years utilizing albumin trajectory and baseline risk factors.

Results: A median of 12 albumin records per patient with 24% and 19% event rates for death and transplantation ensured convergence of all 12 joint models. Albumin hazard ratio of death remained robust (0.89 to 0.90), suggesting significant inverse relationship between albumin and death adjusted for baseline confounders and the competing event of transplantation. JM presented excellent survival prediction accuracy in the validation dataset which improved with longer follow-up. JM with competing event outperformed JM with survival only (area under the curve (AUC) ranges at 1, 1.5 and 2 years: 0.80-0.84 vs 0.79-0.83, 0.86-0.90 vs 0.84-0.88, 0.96-0.97 vs 0.96-0.97), across all distributional models for albumin. Prediction performance of all JM surpassed classical Cox model with baseline albumin (AUC = 0.71, 0.77, 0.93). Results were confirmed by a simulation study.

Conclusions: Our first comprehensive study of JM extensions in incident HD patients indicates its great potential for dynamic personalized survival prediction. Robustness of estimates to deviations from normality and higher predictive accuracy when adjusting competing events contribute to JM superiority over the classical Cox approach.

Real-Time Dual Prediction of Intradialytic Hypotension and Hypertension Using an Explainable Deep Learning Model

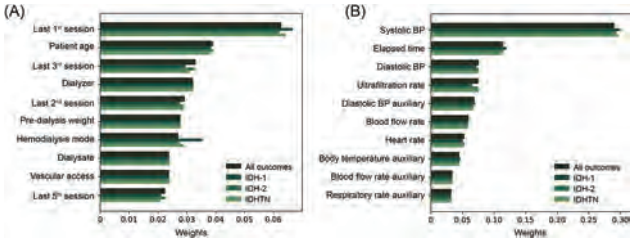
Donghwan Yun,[1,2] Dong Ki Kim,[1,2] Kook-Hwan Oh,[1,2] Seung Seok Han.[1,2]
[1]*Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea;*
[2]*Seoul National University College of Medicine, Seoul, Jongno-gu, Republic of Korea.*

Background: Intradialytic hypotension (IDH) and hypertension (IDHTN) are associated with poor outcomes in hemodialysis patients. However, there is currently no real-time predictive model for dual outcomes. This study aims to develop an explainable deep learning model using a sequence-to-sequence-based attention network to simultaneously predict IDH and IDHTN.

Methods: Electronic health records of 11,110 hemodialysis patients were utilized, comprising 302,774 sessions. The data was divided into training (70%), validation (10%), and test (20%) sets using randomization. IDH-1 was defined as nadir systolic blood pressure (BP) <90 mmHg, IDH-2 as a decrease in systolic BP ≥20 mmHg and/or a decrease in mean arterial pressure ≥10 mmHg, and IDHTN as an increase in systolic BP ≥10 mmHg within 1 hour. The temporal fusion transformer (TFT)-based model was developed and compared with other machine learning models, including recurrent neural network, light gradient boosting machine, random forest, and logistic regression, in terms of model performance measured by receiver operating characteristic curve (AUROC) and area under the precision-recall curves (AUPRC).

Results: The TFT-based model outperformed other models with AUROCs of 0.953 (0.952–0.954), 0.892 (0.891–0.893), and 0.889 (0.888–0.890) for predicting IDH-1, IDH-2, and IDHTN, respectively. The AUPRCs of the TFT-based model for the outcomes were higher compared to other models. Key predictors included age, previous session, systolic BP, and elapsed time.

Conclusions: The developed TFT-based model enables real-time prediction of both IDH and IDHTN while providing explainable variable importance.



Mean weights of time-invariant and time-varying features from the attention module in the model. (A), Weights of time-invariant features. (B), Weights of time-varying features. BP, blood pressure.

Effect of Antioxidants on Oxidative Stress, Endothelial Dysfunction, Inflammatory Markers, and Carotid Intima Media Thickness in Maintenance Hemodialysis and Renal Transplant Patients

Himanish Goswami, Mitul Bora. *Apollo Hospitals Guwahati, Guwahati, India.*

Background: Cardiovascular disease (CVD) is a major cause of morbidity and mortality in dialysis patients. Various non-traditional factors have been proposed for the increased incidence of CVD. N-acetylcysteine (NAC) serves as an antioxidant, acts on atherosclerosis and also improves the endothelial functions. This study was designed to assess the effects of three months of NAC therapy on oxidative stress, endothelial dysfunction, inflammatory markers and carotid intima media thickness in maintenance hemodialysis and renal transplant patients.

Methods: Doppler was done to assess endothelial function by flow mediated dilatation (FMD) of the brachial artery and carotid arterial intima media thickness (CIMT). Brachial artery was imaged during reactive hyperemia (endothelium-dependent, flow-mediated dilatation, FMD) and during nitroglycerine-mediated dilatation (NMD, endothelium-independent). Oxidants (Melondialdehyde, MDA) and antioxidants (Total Antioxidant Status) were measured. NAC 1200 mg was given in two divided doses for three months. Parameters were repeated after three months of NAC therapy.

Results: 220 hemodialysis, 135 renal transplant patients were enrolled. Hemodialysis patients had higher serum homocysteine level which was significantly reduced after three months of NAC (25.7±3.86 vs 13.9±3.01 µmol/L after NAC, p<0.001). At baseline they had a high hsCRP (05.6±1.01 mg/dl) which reduced significantly (02.1±0.43 mg/dl, p<0.001) after NAC. CIMT was significantly reduced after three months of NAC (0.49±0.12mm). FMD of brachial artery endothelium was impaired at baseline (0.34±0.07mm, 0.69±2.11%), significant improvement after 3 months of NAC (0.41±0.11mm, 10.12±2.86%, p<0.001). Elevated baseline oxidative stress markers (MDA) compared to levels after NAC (16.21±10.34 vs 09.31±4.34 nmol/ml, p<0.001). Antioxidant status was significantly low at baseline (1.03±0.21 mmol/l) compared to antioxidant status after NAC (1.41±0.24 mmol/l, p=0.01). Similar findings were seen in the post renal transplant patients.

Conclusions: CKD patients have endothelial dysfunction and oxidative stress which begins early, progresses during dialysis and persists after renal transplantation. With three months of therapy, NAC significantly reduces the oxidative stress, inflammatory markers and improves the endothelial function.

TH-PO262

Experience Comparing the Use of Citric Acid Solution (CD) with L-Ascorbic Acid (Vitamin C) to Simple Citric Solution in Patients with ESRD Under Hemodialysis (HD)

Ioannis Griveas. *Noseleutiko Idryma Metochikou Tameiou Stratou, Athens, Greece.*

Background: The purpose of the study is to record the experience of comparing the use of CD solution with Vitamin-C in relation to the use of pure CD solution in patients with ESRD under HD.

Methods: 45 patients with ESRD under HD (40 new entrants) receiving CD solution with vitamin-C (2g/lt) for a period of 12 months were compared with 26 patients (18 new entrants) of the same weight who received plain CD solution. Changes in heparin dose as well as the anemia profile of the patients were recorded.

Results: In the vitamin C solution the initial cumulative dose of heparin 1818±659.28 iu (24 iu/kgrBW) to 3323.52±1467.79 iu (44 iu/kgr/BW) at 12 months. With no observed thrombotic events or bleeding tendency, the heparin dose was significantly reduced from classically recommended doses (loading dose 30-50 IU/kgBW and then 10 IU/kgBW/hour). A corresponding observation was also noted in pure CD (29 iu/kgrBW beginning-39 iu/kgrBW end). Hb and Hct increased significantly (10.63±1.55 start-11.79±0.91 end, p<0.05, 32.25±4.45 start-36.5±2.92 end, p<0.05) with constant weekly dose of erythropoietin (14000±9500 iu start-14000±10000 iu end, p=NS) and constant ferritin levels (526.73±498.72 iu start-690.44±470.32 iu end, p=NS). The above notice was combined with a significant reduction in monthly iron administration (200 mg monthly final dose). In CD without Vitamin-C we had corresponding observations with a consistently significantly higher dose of monthly iron administration (400-500 mg final dose).

Conclusions: Our findings suggest that the use of both solutions provides anticoagulation with a significant decrease in heparin while simultaneously increasing hemoglobin with a fixed dose of erythropoietin. The addition of vitamin C is associated with reduced monthly iron intake.

TH-PO263

Comparison of Citrate Dialysate in Pre- and Post-Dilution Online Hemodiafiltration: Effect on Clot Formation and Adequacy of Dialysis in Hemodialysis Patients

Thananda Trakarnvanich. *Faculty of Medicine, Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand.*

Background: Citrate dialysate (CD) has been used successfully in conventional hemodialysis and continuous renal replacement therapy but has never been compared between pre- and post-dilution online hemodiafiltration (oL-HDF). Therefore, we investigated the efficacy, metabolic changes, and quality of life of citrate anticoagulation for oL-HDF in the maintenance of hemodialysis patients in both modes.

Methods: Eight dialysis patients were treated with CD for 4 weeks in each phase. The visual clotting scores were investigated as the primary endpoints. The adequacy of dialysis, laboratory parameters, and quality of life were measured as secondary objectives.

Results: The mean clotting scores in the pre-dilution mode were significantly lower than in the post-dilution and all phases except in the heparin-free phase ($P < 0.001$ in baseline phase, $P = 0.001$ in phase 1, and $P = 0.023$ in phase 2). The quality of life related to physical in the post-dilution mode was significantly higher than in the pre-dilution mode in baseline and phase 1 ($P = 0.014$ and 0.004 at baseline and phase 1, respectively). The metabolic changes were not different in both modes.

Conclusions: Citrate dialysate allows decrease or discontinuation of anticoagulation in both the pre- and post-dilution mode of oL-HDF without significant side effects.

Citrate-Acidified Dialysate Requires Less Heparin Use Without Affecting Mineral Metabolism Negatively

Rainer P. Woitas,[1,2] Mathias Haarhaus,[2] Dario Capin,[1] Fernando Jose Gordinho R. Macario.[2] *[1]Diaverum Germany, Munich, Germany; [2]Diaverum Renal Services Group, Malmö, Sweden.*

Background: Heparin is used to prevent clotting in hemodialysis, but may cause bleeding, thrombocytopenia, and skeletal complications. Citrate-acidified dialysate (CAD) compared to acetate-acidified dialysate (AAD) may improve hemodynamic stability and reduce inflammation. Citrate has calcium complexing properties in regional anticoagulation, yet its use may affect mineral metabolism negatively. We studied the effect of a dialysis bath with low concentrations of citrate on heparin use and mineral metabolism.

Methods: 207 prevalent ESRD pts. (182 with high flux dialysis (HD), 25 with post dilution hemodiafiltration (HDF)) were followed for 48 weeks after switching from AAD (3mmol/l acetate) to CAD (0.8 mmol/l citrate, 0.3 mmol/l acetate; MTN, Germany). We monitored heparin consumption, KT/V, CRP, iPTH, phosphate, magnesium, and calcium as well as side effects.

Results: The cohort comprised 127 males and 81 females, mean age 71.6 years (range 25 – 95). Mean treatment time was 254 minutes per session (range 180– 00) and mean blood flow at baseline 360 mL/min (range 250 -420) vs. 254 minutes (range 180–300) and 370 ml/min (range 240-420) at 48 weeks. Mean initial heparin dosing per session was 5171 IU (95%CI 4836-5507) in HD and 6720 IU (95%CI 5920-7520) in HDF. This could be reduced step by step to a mean of 2985 IU (95%CI 2723-3246) in HD and 3375 IU 95%CI 2867-3883) in HDF (after 48 weeks ($p \leq 0.05$) in HD pts. than in HDF pts. at start. It increased during the observation in HD (8.0 vs. 15.0, n.s. after 48 weeks), but not in HDF (CRP start 2.7mg/l vs. 4.2mg/l after 48 weeks, n.s.). In neither group magnesium, calcium, phosphate, iPTH nor KT/V changed significantly. During the observation period 7 pts. (3.4%) were intolerable to CAD, 11 withdraw for unknown reasons (5.3%), 11 pts. (5.3%) left the clinic, 1 patient switched to CAPD (0.5%), 3 (1.4%) were transplanted and 32 died (15.38%).

Conclusions: Under CAD heparin-dosing could be reduced markedly. This may be beneficial for the patient and reduce treatment costs. Long-term treatment with a low-concentration CAD was well tolerated and did not exacerbate secondary hyperparathyroidism. Further long-term studies are ongoing to assess effects on calcification, morbidity, and mortality.

TH-PO265

To Study the Clinical and Biochemical Outcomes of Citrate-Based Dialysate in Hemodialysis Compared with Bicarbonate-Based Dialysate in a Tertiary Care Hospital

Mohit M. Kurundwadkar, Rajesh Aggarwal, Blessy S. Bhalla, Vikas K. Bohra. *Sri Balaji Action Medical Institute, New Delhi, India.*

Background: The study to compare the effects of Citrate-based dialysate with Bicarbonate-based dialysate on systemic haemodynamics, dialysis efficiency, serum calcium, phosphate and bicarbonate levels.

Methods: The study was conducted in 25 ESRD patients undergoing HD with bicarbonate dialysate initially for period of 3 months followed by citrate dialysate for 3 months. Parameters were recorded at start, 3 months of HD with bicarbonate dialysate and HD with citrate dialysate at 6 months. Predialytic, intradialytic and postdialytic BP was recorded at each HD session. The mean of all BP readings was calculated for both groups. The clinical and lab parameters Kt/v, calcium, phosphate and bicarbonate levels were compared among both groups

Results: The mean Predialytic SBP in bicarbonate is 153.84 ± 16.80 mmhg, in Citrate dialysate is 140.24 ± 16.63 mmhg($p<0.001$), mean Predialytic DBP in bicarbonate is 87.16 ± 10.75 mmhg, in citrate dialysate is 79.96± 8.63 mmhg ($p<0.001$). The Intradialytic SBP and DBP were lower in pts.undergoing citrate vs bicarbonate. The mean Intradialytic SBP in bicarbonate is 148.56 ± 15.50 mmhg vs 135.92 ± 15.29 in citrate($p=0.0053$). The mean Intradialytic DBP in bicarbonate is 84.12 ± 12.02 mmhg vs 75.92 ± 8.94 mmhg in citrate($p=0.0086$). The mean Postdialytic SBP in bicarbonate is 143.56 ± 17.50 mmhg vs 129.24 ± 15.46 in citrate($p=0.0035$). The mean Postdialytic DBP in bicarbonate is 82.40 ± 10.07 mmhg vs74.20 ± 7.04 mmhg in citrate(p value=0.0016). The mean Kt/v in bicarbonate is 1.2 ± 0.06 vs 1.33± 0.06 in citrate (p value<0.001). The mean calcium level in bicarbonate is 9.03 ± 1.03 mg/dl vs 8.51 ± 0.97 mg/dl in citrate($p=0.07$), the phosphate in bicarbonate dialysate is 5.53 ± 1.04 vs 4.76 ± 1.72 in citrate (p value=0.06). The mean HCO3 level in bicarbonate dialysate is 16.08 ± 1.39 vs 17.75 ± 1.34 in citrate group(p value<0.001)

Conclusions: Citrate dialysate can be good alternative for the standard bicarbonate based dialysate as it provides significant advantages in improvement in Pre, Intra And Postdialytic BP, better dialysis efficiency, improved acid base balance and lower phosphate levels.

TH-PO266

The Association of Dialysate Bicarbonate with Cardiac Arrhythmia in the Monitoring in Dialysis (MiD) Study

Katherine S. Ravi,[1,2] James A. Tumlin,[3] Prabir Roy-Chaudhury,[5] David M. Charytan,[4] Finnian R. McCausland.[1,2] Monitoring in Dialysis Study Group. *[1]Brigham and Women's Hospital, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]NephroNet Clinical Research Consortium, Atlanta, GA; [4]New York University School of Medicine and NYU Langone Medical Center, New York, NY; [5]UNC Kidney Center, Chapel Hill, NC and WG (Bill) Hefner VA Medical Center, Salisbury, NC.*

Background: Sudden death accounts for half of all cardiovascular-related mortality among patients receiving maintenance hemodialysis (HD) and occurs more frequently on days that patients undergo HD. Higher dialysate bicarbonate (D_{BIC}) may predispose to alkalemia and arrhythmogenesis. We tested if higher D_{BIC} is associated with cardiac arrhythmia, and if this is modified by serum bicarbonate (S_{BIC}).

Methods: Using data from the Monitoring in Dialysis study, we analyzed session-level data over a 12-month period from 66 patients with implantable loop recorders (ILR). We fit logistic regression and negative binomial mixed effects regression models to assess the association of D_{BIC} with the presence and frequency of reviewer confirmed arrhythmia (RCA) events (ILR identified or patient marked event in which a manual review of the stored ECG tracing confirmed the presence of atrial fibrillation, supraventricular tachycardia, sinus tachycardia with rate >130 beats per minute, ventricular tachycardia, asystole, or bradycardia) in the intra- and inter-dialytic period.

Results: Mean age was 56 ± 12 years, 70% were male, 53% were Black, and 35% were Asian. There were 9,718 RCA events over 3,655 HD sessions. There were fewer RCA episodes associated with D_{BIC} >35 compared to 35 mEq/L in unadjusted and adjusted models (IRR 0.45 (0.27, 0.75) and aIRR 0.54 (0.30, 0.97), respectively). Otherwise no associations between D_{BIC} and arrhythmia were identified. No results were modified by the inclusion of S_{BIC} in the model.

Conclusions: We observed a lower frequency of RCA with higher D_{BIC}, contrary to our original hypothesis. Within RCA, a majority of events were atrial arrhythmia. Validation of these findings in larger studies is required, with further need for interventional studies to explore the optimal D_{BIC} level.

Funding: NIDDK Support

Table: Association of dialysate bicarbonate with arrhythmia – session to session models (repeated measures negative binomial regression). Adjusted for age, sex, race, dialysis vintage, vascular access, and pre-dialysis serum bicarbonate.

Dialysate Buffer in Hemodialysis: Effect of Practice Patterns on Serum PTH

Pablo A. Urena Torres, Pascal Seris, Anne Kolko-Labadens, Charles Chazot. *Aura Paris, Paris, France.*

Background: We report the analysis of 3 dialysate (D) acidic buffers on serum PTH in 4 dialysis units in Paris (France) area.

Methods: Data from prevalent hemodialysis (HD) patients (pts) treated in 4 units were collected in the 4th quarter 2022 and analyzed with Kruskal-Wallis and stepwise logistic regression tests. The biology lab is common to the 4 units. PTH was assessed using the Architect Intact PTH assay®.

Results: The 529 pts were 64 y.o. with 35% females, dialysis vintage: 47 months, Charlson index: 10. The acidic buffers were acetate (30.7%), hydrochloric acid (HCl) (35.7%) and citric acid (citrate) (33.6%). Pts on acetate were significantly younger (59 years) versus 67.5 and 66 years on HCl and citrate ($p=0.001$), with a lower Charlson index (9 versus 10 (0.001). Pts on HCl had significantly lower serum PTH levels; serum magnesium was significantly lower in citrate group; calcium, phosphate, native vitamin D were not different (Table 1). Muscle cramps during the dialysis were found in 10.2% (citrate), 8.5% (HCl) and 6.2% (acetate, $p=0.027$). The D calcium is reported in Table 1. The proportion of pts on calcimimetics and active vitamin D did not differ between groups. Factors associated with a PTH >612 pg/ml were age (-0.012, $p<0.04$), acetate buffer (0.065, $p<0.001$) and calcimimetic prescription (0.76; $p<0.001$). Conversely, only dialysis vintage was associated with a PTH < 130pg/ml (0.07; $p=0.0066$).

Conclusions: The use of citrate D in this cohort was not associated with a higher PTH compared to pts on acetate or HCl. The large prescription of D calcium at 1,65 mmoles/l in the citrate group may have helped to avoid low ionized calcium. Higher muscle cramps and lower magnesium were findings already reported with the use of citrate D and confirmed in this cohort. Dialysis with citrate or HCl are possible alternatives when avoiding acetate buffer is wanted. Increasing D magnesium to avoid cramps remains to be studied.

TH-PO268

Asymptomatic Heartbeat Irregularities (AHbI) During Hemodialysis (HD) Are Associated with Decreased Short-Term Survival

Dan Sapoznikov, Rebecca Backenroth, Michal Dranitzki Elhalel, Dvora Rubinger. *Hadassah University Medical Center, Jerusalem, Israel.*

Background: Intradialytic AHbI are not well defined and are of unknown significance.

Methods: Beat-to-beat systolic blood pressure (SBP) and interbeat interval (IBI) were monitored during regular HD sessions in 83 age-matched patients (Pt). AHbI were defined as ≥10 irregular beats on a 4hr recording. Hemodynamic variability indices were assessed using Finometer device and Beatscope software.

Results: AHbI were detected in 25 Pt (AHbI (+)). The representative clinical, laboratory and hemodynamic data in AHbI (+) and in Pt with regular beats (AHbI(-)) are listed in Table 1. There were no statistically significant differences between groups regarding the proportion of diabetes, hypertension, ischemic heart disease, SBP, intradialytic hypotension, PTH level or ultrafiltration rate. Kaplan-Meier analysis showed a significnant decreased survival at 2y in AHbI(+) (Figure 1).

Conclusions: 1.Intradialytic AHbI are associated with cardiovascular risk factors and a higher plasma phosphate level, suggesting a link between mineral metabolism and heart disease. 2. In AHbI (+), diminished post HD plasma potassium change combined with decreased IBI and increased sdCO suggest a tendency to hemodynamic instability leading to higher mortality. The nature and the long term effects of the AHbI remain to be further explored.

Table 1.

Platelet Count Has a U-Shaped Association with Mortality in Hemodialysis Patients: A Multinational Analysis of DOPPS

Xinju Zhao,[1] Li Zuo,[1] Angelo Karaboyas,[3] Roberto Pecoits-Filho.[2] [1]*Peking University People's Hospital, Beijing, China;* [2]*Arbor Research Collaborative for Health, Ann Arbor, MI;* [3]*Arbor Research Collaborative for Health, Ann Arbor, MI.*

Background: Based on the role of platelets in coagulation, clot formation, and systemic inflammation, we utilized data from a very large international cohort study to explore the association of platelet counts with mortality and cardiovascular (CV) death in hemodialysis (HD) patients.

Methods: International data from 13,631 patients enrolled in the Dialysis Outcomes and Practice Patterns Study (DOPPS) phase 5 (2012-2015) were analyzed. Participants were divided into 3 groups according to their platelet counts (low: <100, normal: 100-300, high: >300*10^9). Associations between platelet counts and all-cause and CV mortality were analyzed using Cox regression, adjusted for confounders.

Results: Mean platelet count was 205*10^9/L overall and ranged from 173 *10^9/L in China to 227 *10^9/L in Sweden (figure 1). Overall, 2,463 (18 %) patients died and 948 (7%) died from CV disease. Both low (HR=1.5, 95% CI: 1.2, 1.8) and high (HR=1.2; 95% CI: 1.0, 1.4) platelet counts were associated with higher all-cause mortality after adjustment for covariates (Figure 2); results for CV death were consistent.

Conclusions: Platelet count has a U-shaped association with all-cause and CV mortality in HD patients, and thus may be used as an outcome predictor that is readily available among HD patients.

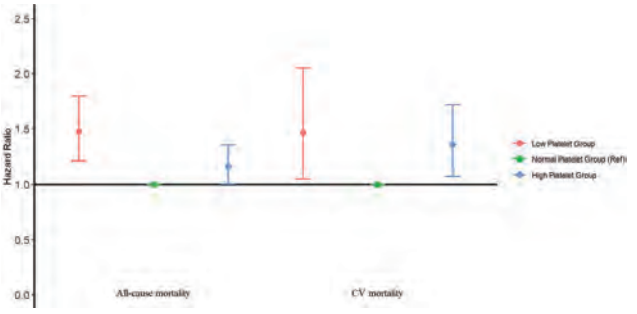

Figure 1. Patients in normal, low, and high platelet groups from 15 countries and areas, A/NZ is for Australia and New Zealand; GCC is for Gulf Cooperation Council (6 countries)

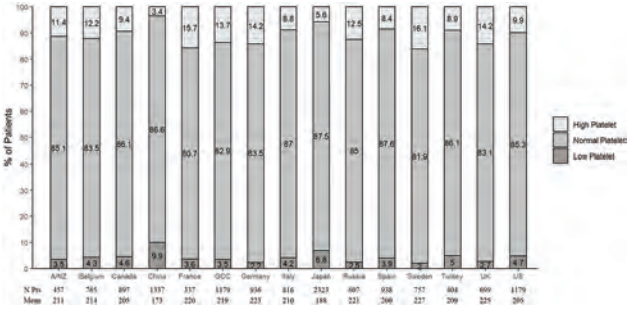

Figure 2. Associations between the platelet counts and all-cause/CV mortality in COX regression model (adjusted for age, gender, BMI, vintage, comorbidities, lab data, Intradialytic weight loss, fistula, primary kidney disease, standard kt/v, urine output < 200 ml/d)

TH-PO270

Clinical Burden and Management of Hyperkalemia in Hemodialysis Centers in China: A Multicenter Retrospective Study (Visualize-HD)

Xinju Zhao, Li Zuo. For the Visualize-HD Study Group. *Peking University People's Hospital, Beijing, China.*

Background: Hyperkalemia (HK) is associated with sudden cardiac death in patients on maintenance hemodialysis (mHD). We aimed to examine HK prevalence, serum potassium (sK) management practices, and mortality data in Chinese HD centers.

Methods: Visualize-HD (NCT05020717) was a retrospective survey conducted in 31 Chinese administrative divisions. Patients aged ≥18 years who were on mHD for ≥3 months were eligible. HD centers were grouped as having high or low HK (sK >5.0 mmol/L) prevalence based on median values. Outcomes were analyzed over 3 years. The primary outcome was risk factors associated with HK prevalence. Secondary outcomes included HK prevalence, sK management practices, and risk factors associated with mortality.

Results: A total of 50,983 patients from 231 centers were included. The age groups 18–44, 45–64, 65–74, and ≥75 years accounted for 18.7%, 46.5%, 23.0%, and 11.8% of patients, respectively; 59.2% were male. Most patients had a dialysis vintage of <5 years (62.2%), used 2.0 mmol/L dialysate potassium (91.8%), were on three times weekly dialysis (68.0%), and had a sK test once every three months (53.9%). Over half of the cohort (55.2%) received renin-angiotensin-aldosterone system inhibitors and 7.7% received potassium-binding drugs. HK occurred in 40.8% of patients; 20.4%, 8.7%, and 3.2% had sK >5.5, >6.0, and >6.5 mmol/L, respectively. Higher HK prevalence was associated with a higher proportion of patients with hyperphosphatemia and lower proportions of elderly patients and those with hypoalbuminemia at the HD center level (all P < 0.05). The 3-year cumulative mortality rate was 21.3%. Over one-third of deceased patients (36.7%) had HK based on their last sK tests. Centers with high vs low HK prevalence had higher mortalities (all-cause: 21.9% vs 20.7%; cardiovascular: 13.5% vs 11.5%, both P < 0.05).

Conclusions: HK is prevalent in Chinese HD centers and is associated with risk factors. Chinese HD centers with higher HK prevalence had increased mortality rates. Long-term sK control is important for improving survival in patients on mHD. Yet, potassium-binding drugs are underused.

Readmission After Gastrointestinal Bleeding Hospitalization in Dialysis Patients

Yue Jiao,[1] Belen Alejos,[2] Melanie Wolf,[2] John W. Larkin,[1] Anke Winter,[2] Sheetal Chaudhuri,[1] Manuela Stauss-Grabo,[2] Len A. Usvyat,[1] Jeffrey L. Hymes,[1] Franklin W. Maddux,[6] David C. Wheeler,[3] Peter Stenvinkel,[4] Jürgen Floege.[5] On Behalf of the INSPIRE Core Group. *[1]Fresenius Medical Care, Waltham, MA; [2]Fresenius Medical Care, Bad Homburg, Germany; [3]University College London, London, United Kingdom; [4]Dept of Renal Medicine Karolinska University Hospital, Karolinska Institutet, Stockholm, Sweden; [5]University Hospital RWTH Aachen, Division of Nephrology and Clinical Immunology, Aachen, Germany; [6]Fresenius Medical Care AG & Co KGaA, Bad Homburg, Germany*.

Background: Gastrointestinal bleeding (GIB) is the most common bleeding event in patients on chronic dialysis, and oftentimes leads to hospitalization. The outcomes associated with hospitalization for a GIB are unknown. The INSPIRE collaborative group assessed all-cause hospital readmission rates after a GIB hospitalization among a nationally representative sample of dialysis patients in the United States.

Methods: We used data from adult dialysis patients who had a GIB hospitalization between Jan-2018 to Mar-2021. GIB hospitalizations were defined from primary, secondary, or tertiary discharge diagnosis codes (Zhao et al., AHRQ 2006). All-cause readmission rate considered hospitalizations within 30 days from an index GIB hospitalization.

Results: Among a population of 405,530 patients, there were 19,663 GIB hospitalizations during follow up and 5,196 all-cause readmissions (26.4%) within 30 days of the index GIB hospitalization. On average readmissions occurred within 16.3 days of the index GIB hospitalization. Patients with a GIB hospitalization typically had one readmission event (n=4,365), yet a small proportion of patients had multiple readmissions during follow-up. Readmission rates after a GIB hospitalization were highest for younger patients between 18-44 years old, and those with an unknown or black race (**Figure 1**).

Conclusions: The 30-day all-cause readmission rate after a GIB hospitalization was 26%, and appeared to be highest among younger patients of a black race or those who were missing data on race. These findings act as a benchmark for the nephrology community. Future adjusted analyses are warranted to confirm the results and should consider modality and competing events of death within 30 days of an index GIB hospitalization.

TH-PO272

Left Ventricular Global Longitudinal Strain in Stable Stage 5 CKD Patients with Preserved Ejection Fraction Predicts Cardiovascular Events and Mortality After Dialysis Commencement

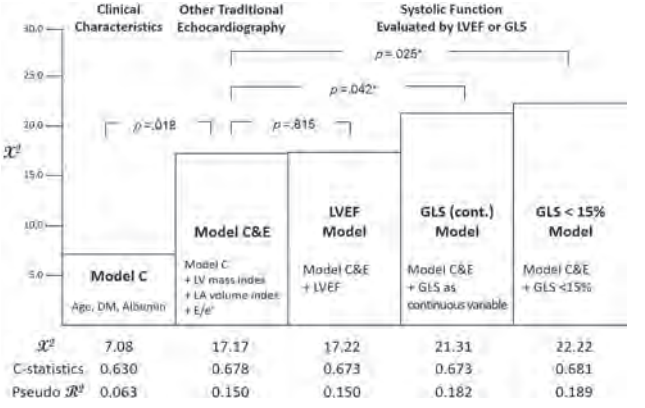
Chih-Hen Yu, Li Wenhuang, Yen-wen Liu, Junne-Ming Sung. *National Cheng Kung University College of Medicine, Tainan, Taiwan*.

Background: Early detection of subclinical cardiac dysfunction offers opportunity of timely intervention, especially before vulnerable transition from advanced CKD to ESKD. We previously found absolute left ventricular global longitudinal strain (GLS) <15% is predictive to mortality in dialysis patients with preserved ejection fraction (EF), while it's still inconclusive whether the systolic function evaluated by GLS before hemodialysis commencement (HDC) is applicable to predict post-dialysis outcome in clincial stable CKD5 patients.

Methods: In this longitudinal prospective observation across HDC, we aimed to predict the post-dialysis cardiovascular outcome with pre-dialysis GLS. The CKD5 patients who had long-term HDC before 2020 were enrolled to post-dialysis outcome follow-up. Inclusions were EF>50% and eligible GLS within 2 years before HDC; main exclusion was frequent admission. The primary outcomes were post-dialysis major adverse cardiovascular cerebral events(MACCE), and secondary outcome was all-cause mortality(ACM).

Results: 201 among 242 stable CKD5 patients reached HDC, and 108 with eligible GLS were enrolled. Median duration from examination to HDC was 5.39 months. Median follow-up was 1458 days. GLS<15% is independent predictor of MACCE (HR 2.34[1.11-4.91]p=.025*) and ACM(HR 2.97[1.18-7.49]p=.021*). GLS as continuous variable is independent predictor of MACCE(HR 0.90[0.82-1.00]p=.040*) and ACM(HR 0.84[0.73-0.95]p=.007**). The incremental diagnostic values contributed from GLS<15%(p=.025*) or GLS(p=.042*) were significant in nested Cox models but LVEF (Figure).

Conclusions: LV subclinical systolic dysfunction, assessed by GLS<15% within previous 2 years before HDC, predictedpost-dialysis MACCE and ACM in clinically stable patients having their HDC.



GLS and GLS<15% increase predicting value of Cox models of MACCE; colums represent chi-square value in -2 log likelihood test

TH-PO273

Effectiveness of Heart Rate Variability for Predicting Intradialytic Hypotension in Chronic Hemodialysis Patients

Ji won Lee, Se-Hee Yoon, Sung-Ro Yun, Won Min Hwang, Yohan Park. *Konyang University Hospital, Daejeon, Republic of Korea*.

Background: Intradialytic hypotension(IDH) is a common complication during hemodialysis reported to occur in 20–30% of hemodialysis sessions. According to a recent meta-analysis, IDH based on nadir 90 criterion was reported to have the highest association with the patient survival rates. The heart rate variability(HRV) test is a non-invasive and simple method to measure autonomic nervous system activity. To date, no studies have demonstrated the usefulness of the HRV test in predicting IDH based on nadir 90 criterion. This study was aimed to elucidate the usefulness of the HRV test in predicting the occurrence of IDH.

Methods: This study was a multi-center prospective observational study. A total of 70 patients were enrolled in this study. Blood tests, echocardiography, and body composition measurement results were collected, and HRV test was performed for 24 hours during non-hemodialysis period. And then, a total 12 hemodialysis sessions were monitored. The patients were divided into the IDH group and non-IDH group. HRV index model was developed by a multivariate logistic regression analysis. The predictive value of IDH occurrence was analyzed through area under the receiver operating characteristic curve(AuROC) value.

Results: According to the nadir 90 criterion, 37 patients were placed in the IDH group, and 33 patients in the non-IDH group. Considering that the HRV test is affected by the lifestyle, data of night-time(00:00~04:00) was used. Standard deviation of normal-to-normal interval(SDNN), root-mean-square of successive differences(RMSSD), normal-to-normal interval>50ms(NN50) count, percentage of NN50 count(pNN50), total power(TP), very low frequency(VLF), low frequency(LF), high frequency(HF), and LF/HF ratio, which are parameters of the HRV test, were analyzed to develop a HRV index model. The AuROC value for IDH occurrence (even in one session) of the developed HRV index model was 0.776. The AuROC value for frequent IDH occurrence (in more than 10% of sessions) was 0.803. A high HRV index(>0.544) was observed as an independent risk factor after adjusting for several other confounding factors(odds ratio 6.137, P=0.011).

Conclusions: The HRV test can be used as a useful tool to predict IDH. This is the first study to demonstrate the usefulness of the HRV test in prediction of the IDH occurrence according to the nadir 90 criterion.

TH-PO274

Changes of Hemodynamic Parameters over a Single Treatment Week in Patients Undergoing Chronic Intermittent Hemodialysis

Bernhard N. Bohnert, David König, Ferruh Artunc. *Eberhard-Karls-Universitat Tubingen Medizinische Fakultat, Tubingen, Germany*.

Background: Using ultrasound dilution, hemodynamic parameters such as access flow or cardiac output can be measured non-invasively and repeatedly during hemodialysis (HD). No data are available on the changes of these parameters within one week of treatment with long and short dialysis intervals.

Methods: In a prospective cohort study, various hemodynamic parameters were determined in n=44 prevalent HD patients during a 4-hour HD using the HD03 monitor (Transonic). Measurements were taken hourly on the first HD day of the week, on the

second and third day at the beginning and end of HD. Access flow (AF, L/min), cardiac index (CI, L/min/m2 body surface area), central blood volume index (CBVI, mL/kg body weight), total cardiac ejection fraction (TEF, %) and total cardiac end-diastolic volume index (TEDVI, mL/kg) were recorded.

Results: The median AF was 1.1 L/min (interquartile range 0.8-1.7) at the beginning of the first HD of the week and did not change during HD. The values were unchanged on the following HD days. The median CI was 3.2 (2.7-3.9) L/min/m2 body surface area at the beginning of the first HD and CI continuously decreased to 85% of the baseline value during the HD ($p<0.001$). The CI recovered to baseline by the second HD and decreased to a median of 83% of baseline at the end of the second HD ($p<0.001$). The same pattern was found at the third HD. Median TEF was 53% (46-64) at the start of the first HD of the week and remained constant across all HD treatments. Medians of the central hydration parameters CBVI and TEDVI were 19 (16-25) and 10 (8-12) ml/kg body weight, respectively, at the beginning of the first HD and were lowered significant by 13% and 9%, respectively, at the end of the first HD. The course was similar to that of the CI, with a re-increase until the beginning and a reduction at the end of the second and third HD, respectively. The TEDVI and the CBVI were significantly lower before the beginning of the third HD than before the first HD. Systolic and diastolic blood pressure as well as heart rate showed a course parallel to that of the CI.

Conclusions: HD treatment compromises cardiac index that recurs regularly and reversibly within the treatment week. Central overhydration is highest after the long interval and decreases as the week progresses.

TH-PO275

Risk Factors for Inpatient Mortality in Patients with CKD Hospitalized with Infections due to Multidrug-Resistant Organisms: A Nationally Representative Study

Sae Morita,[1] Akshay Agrawal,[1] Priya Nori,[2] Ibironke W. Apata,[3] Michal L. Melamed,[2] Tanya S. Johns.[2] *[1]SBH Health System, Bronx, NY; [2]Montefiore Health System, Bronx, NY; [3]Emory University School of Medicine, Atlanta, GA.*

Background: The CKD population, especially those with end-stage kidney disease (ESKD) on hemodialysis (HD), has higher rates of infections and more exposure to multidrug-resistant organisms (MDRO). However, few studies have evaluated the risk factors for mortality among CKD patients hospitalized with MDRO infections.

Methods: We extracted data from the 2020 national inpatient sample, the largest nationwide inpatient database in the US, for adults (age ≥18 years) with diagnosis of CKD (non-dialysis dependent CKD) and ESKD (on HD) with MDRO infections (methicillin-resistant *Staphylococcus aureus*, vancomycin-resistant *Enterococcus*, multidrug-resistant gram-negative bacilli and *Clostridioides difficile*) by ICD 10 codes. The primary outcome was inpatient mortality. We compared the baseline characteristics and constructed multivariable logistic regression models adjusted for socio-demographics, comorbidities, and hospital characteristics to determine the risk factors for inpatient mortality.

Results: There were 49,624 and 15,075 admissions with MDRO infections among patients with CKD and ESKD, respectively. The mean age was 72.5 vs. 63.3 years, females 49.1% vs 47.2%, and White patient accounted for 73.0% vs. 48.9% in CKD vs ESKD group, respectively. Inpatient mortality was higher in ESKD patients compared to CKD patients (9.5% vs.12.1%). Older age and worse comorbidity scores were associated with increased risk of death in both groups. Black patients had higher risk of inpatient mortality compared to White patients (OR 1.40; 95% CI 1.14-1.71) in the CKD but not ESKD group. In the CKD group, hospital characteristics including large bed size, Northeast location, and government ownership were associated with higher risk of death; while in ESRD group, private-investor hospitals had higher mortality.

Conclusions: Inpatient mortality is higher in ESKD compared to CKD patients hospitalized with MDROs. Risk factors for mortality were older age, more comorbidities, and among those with CKD, Black race. Hospital-level risk factors include size, region, and ownership. Further studies should investigate structural, social, and dialysis-related factors on risk of inpatient mortality in CKD and ESKD patients hospitalized with MDRO infections.

TH-PO276

Factors Influencing Pre- and Post-Dialysis Central and Peripheral Blood Pressure in Dialysis-Dependent Veterans: A Single-Center Study

Abdul Hannan A. Rasheed,[1,2] Anuradha Wadhwa,[1,2] Holly J. Kramer,[1,2] Kavitha Vellanki.[1,2] *[1]Edward Hines Junior VA Hospital, Hines, IL; [2]Loyola University Health System, Maywood, IL.*

Background: Central aortic blood pressure (BP) is more reflective of cardiovascular health than peripheral BP. While it is hypothesized, central BP monitoring which detects minute changes in vessels is not suitable for dialysis patients due to stiff vessels, data on pre and post dialysis variations between central and peripheral BP is non-existent. We aimed to study the differences between pre and post dialysis central and brachial BP in patients and identify factors influencing any differences.

Methods: All patients receiving hemodialysis at Hines VA Hospital were approached between December 2021 and March 2022. Pre and post dialysis central aortic and brachial BP were obtained using ACTOR technology. Data collected included demographic characteristics, prescribed dialysis time and achieved ultrafiltration (UF). Mixed effects model was used for statistical analysis.

Results: A total of 51 patients participated in the study. Baseline characteristics are shown in Fig 1. Average difference of 2.6 mmHg is noted between pre and post dialysis brachial and central aortic systolic BP readings, post dialysis readings being higher than pre dialysis readings (Fig 2) after controlling for age, BMI, ethnicity, history of smoking, diabetes, peripheral vascular disease and coronary artery disease. Every 1 liter increase in UF is associated with a 1.35 mmHg difference in brachial vs. central aortic systolic BP.

Conclusions: In our single center study of veteran male dialysis population, for every liter of UF achieved, a 1.35 mmHg difference is noted in post dialysis brachial and central aortic systolic BP.

Variable	Mean	S.D	Min	Max
Age (Years)	69.3	10.2	50	89
Weight (kg)	93.6	23.2	54	164
BMI	29.5	6.7	18.3	47.9
Brachial Systolic (mmHg)	142.5	27.5	69	201
Brachial Diastolic (mmHg)	70.7	14.3	43	111
Central Systolic (mmHg)	128.6	24.8	65	189
Central Diastolic (mmHg)	72.5	14.5	45	115
Ultrafiltrate (Liter)	2.3	1.1	-0.4	4.4

Exposure to Elevated Temperature Is Associated with Elevated Risk for Cardiovascular Disease (CVD) Outcomes and Mortality Among Hemodialysis Patients in the United States

Yuzhi Xi,[1,2] Zachary S. Wettstein,[3] Abhijit V. Kshirsagar,[4] Yang Liu,[1] Danlu Zhang,[1] Yun Hang,[1] Ana G. Rappold.[5] *[1]Emory University, Atlanta, GA; [2]ORISE Fellow at US EPA, Chapel Hill, NC; [3]University of Washington, Seattle, WA; [4]The University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, NC; [5]United States Environmental Protection Agency, Washington, DC.*

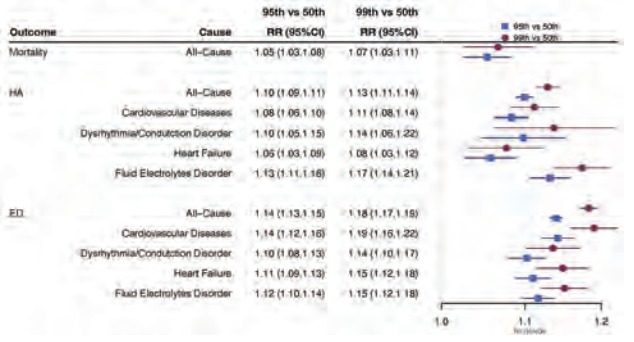
Background: Ambient temperatures have increased due to climate change in many parts of the world. Adaptation and resilience to changing conditions is particularly concerning among individuals with chronic kidney disease, due to loss of renal function which impacts regulation of thermoregulatory mechanisms. The aim of this study is to assess the effect of heat on mortality and health care utilization among US hemodialysis patients.

Methods: We conducted a retrospective time-series analysis (2011-2016) of daily mortality, hospital admission, and emergency department visits identified in the United States Renal Data System. Daily ambient temperature was estimated on a 1 km grid and assigned to ZIP-code. Conditional-Poisson models were used to assess the risk of developing adverse health outcomes associated with temperature exposure.

Results: Overall, daily ambient temperature increase is associated with elevated risk for both mortality and health care utilization among hemodialysis patients. The rate ratios for all-cause mortality and daily temperature was 1.07 (95% CI: 1.03-1.11), 1.17 (1.14-1.21) for fluid disorder-related hospital admissions, and 1.19 (1.16-1.22) for cardiovascular event-related emergency department visits, comparing 99th percentile vs. 50th percentile daily temperatures. Larger effects were observed for cumulative lagged exposure three-days prior to the outcome and for Southwest and Northwest climate regions.

Conclusions: Heat exposure is associated with elevated risk for mortality and health care utilization among this vulnerable population. Furthermore, the effect appears to be potentially cumulative in the short-term, and varies geographically. Disclammer: this abstract does not represent EPA policy nor USRDS position.

Figure 1. Same day effect (Rate Ratios (RR) and 95% Confidence Interval) of exposure to daily ambient temperature on mortality and health care utilization among hemodialysis patients in the contiguous United States 2011-2016



TH-PO278

Predictors of Hospitalization in Adolescents and Young Adults with ESKD

Rebecca V. Levy,[1] Michal L. Melamed,[2] Vagish Hemmige.[2] *[1]University of Rochester Medical Center, Rochester, NY; [2]Albert Einstein College of Medicine, Bronx, NY.*

Background: Treatments for end-stage kidney disease (ESKD) include in-center dialysis, home dialysis, and transplant. Adolescents and young adults (AYA) are at increased risk for difficult disease course. Identification of risk factors for hospitalization may lead to changes in management.

Methods: We performed a secondary analysis of data in the US Renal Data System (USRDS). Included subjects were 16-24 years old at dialysis start 2010-2015 and had no previous history of kidney transplant. The combined outcome is time to first hospitalization. Analysis was by Cox proportional hazard modeling.

Results: Of the 4658 eligible subjects, 57% were male, 65% were white, and they had a mean age of 20.7 years (Table 1). Participants were followed for a median of 2.7 (2.6, 2.9) years during which there were 1963 hospitalizations. Multivariable Cox proportional hazards showed female sex, non-Hispanic ethnicity, dialysis catheter use, diabetic kidney disease, and lack of insurance were associated with increased risk of first hospitalization (Table 2).

Conclusions: Both demographic and potentially modifiable dialysis-related factors are associated with increased risk of hospitalization in AYA with ESKD.

Optimal Caloric Requirements of Critically Ill Patients on Chronic Hemodialysis (CHD)

Pir Shehzad, Daniel L. Landry, Mark A. Tidswell, Spencer Hodgins, Gregory L. Braden. *UMASS Chan Med School-Baystate, Springfield, MA*.

Background: The KDOQI 2020 nutrition guidelines do not address the energy requirements of critically ill CHD patients (pts). This study determined the actual caloric needs of critically ill CHD pts.

Methods: This was a single-center, single-blinded, randomized control trial of 11 critically ill intubated pts admitted to the ICU. A Puritan Bennet Indirect calorimeter was used for the data collection on nondialysis days or before starting hemodialysis while NPO or on enteral feeding or TPN matched for protein, fat & carbohydrates after reaching a steady state. All pts were randomized to either a 28 kcal/kg/day or a 38 kcal/kg/day after baseline NPO data was obtained the prior day. The data collected by the calorimeter were 8 hr machine averages and included VO2, VCO2, respiratory quotient, and energy expenditure. In addition, time-averaged glucose obtained every 4 hours was calculated. Finally, statistics were performed utilizing the Student's T-test & ANOVA for paired data.

Results: A total of 11 pts were included, seven males & four females. The pts had a mean age of 39 ± 7 years. 8 out of the 11 patients completed all three days of the study. Four patients were under 60 years, two males and two females. two females and five males comprised the over-60 age group. The baseline REE for patients <60 years was 26.0 ± 4 kcal/kg/day, and for patients >60 years was 22.0 ± 2 kcal/kg/day despite sepsis in two patients in each group. REE for all NPO patients was 23.5 ± 4 kcal/kg/day and only 24.5 ± 4 kcal/kg/day, and 26.0 ± 3 kcal/kg/day for TPN days with 28 or 38 kcal/kg/day ($p>0.05$). Time-averaged glucose increased to a clinically significant level with both diets; 162 ± 30 mg/dL ($p<0.05$) for pts receiving a 28 kcal/kg/day diet and 159 ± 25 mg/dL($p<0.05$) for a 38 kcal/kg/day diet.(Table1)

Conclusions: Current KDOQI nutrition recommendations overestimate the energy expenditure of critically ill HD patients. Critically ill CHD pts should be fed 24-26 kcal/kg/day or have their EE measured by indirect calorimetry to receive proper nutrition and avoid overfeeding.

Funding: Clinical Revenue Support

Table 1

	V02 (ml/min)	VCO2 (ml/min)	RQ	REE	Glucose
NPO	208±19	155±12	0.8	1426.5±125.2	106±15
28 kcal/kg/day	204±20	192±13*	0.95*	1454.9±131.8	162±30*
38 kcal/kg/day	214±24*	214±24*	0.95*	1676±214.3	159±25*

* $p<0.05$ compared to NPO. Increase in VCO2, RQ and glucose levels suggest CHO overfeeding and increased lipogenesis in the TPN, enteral feeding groups. No statistically significant difference was found between 28 kcal/kg/day and 38 kcal/kg/day groups in studied parameters.

TH-PO280

Mortality of Elderly Patients with AKI Undergoing Continuous Renal Replacement Therapy: Is Age a Risk Factor?

Jeeyoung Yoon,[1,2] Ji Won Min,[3,1] Eun Sil Koh,[4,1] Eun jeong Ko,[3,1] Hyung Duk Kim,[5,1] Byung ha Chung,[6,1] Seok Joon Shin,[2,1] Hye Eun Yoon,[2,1] Sang Hun Eum.[2,1] *[1]The Catholic University of Korea, College of Medicine, Seoul, Republic of Korea; [2]Incheon St. Mary's Hospital, Incheon, Republic of Korea; [3]Bucheon St. Mary's Hospital, Bucheon, Republic of Korea; [4]Yeouido St. Mary's Hospital, Seoul, Republic of Korea; [5]Eunpyeong St. Mary's Hospital, Seoul, Republic of Korea; [6]Seoul St. Mary's Hospital, Seoul, Republic of Korea*.

Background: The incidence of elderly patients with acute kidney injury (AKI) requiring continuous renal replacement therapy (CRRT) is increasing. There is little evidence on the difference of mortality rates according to age in elderly patients. This study aimed to evaluate the age effect and predictors for mortality in elderly patients with AKI requiring CRRT.

Methods: A retrospective analysis was performed in elderly patients with AKI who underwent CRRT. A total of 480 patients aged ≥65 years were stratified into three groups according to age: youngest-old (age 65-74 years, n=205), middle-old (age 75-84 years, n=217), and oldest-old (age ≥85 years, n=58). The 28-day and 90-day survival rates were compared between three groups and predictors for mortality were analysed.

Results: The 28-day and 90-day survival rates were not different between three age groups (P=0.156 and P=0.189, respectively). The oldest-old group did not show an inferior survival rate to other two groups. For 28-day mortality, prothrombin time [hazard ratio (HR) = 1.37, 95% confidence interval (CI) = 1.01 – 1.88, P = 0.046] and urine output at the start of CRRT (HR = 0.999, 95% CI = 0.998 – 1.000, P=0.012) and CRRT duration (HR = 0.89, 95% CI = 0.83 – 0.95, P=0.001) were predictors. For 90-day mortality, mean arterial pressure (HR = 1.02, 95% CI = 1.00 – 1.05, P=0.019), admission duration (HR = 0.97, 95% CI = 0.95 – 0.99, P<0.001) and CRRT duration (HR = 0.96, 95% CI = 0.91 – 0.99, P=0.036) were predictors. The middle-old group or the oldest-old group did not exhibit higher risk compared to the youngest-old group for 28-day and 90-day mortality.

Conclusions: An older age was not a risk factor for mortality in elderly patients with AKI undergoing CRRT. This implicates the importance of active management and application of CRRT in critically ill elderly patients with AKI.

TH-PO281

Intradialytic Hypotension and Worse Outcome in Patients with AKI Requiring Intermittent Hemodialysis

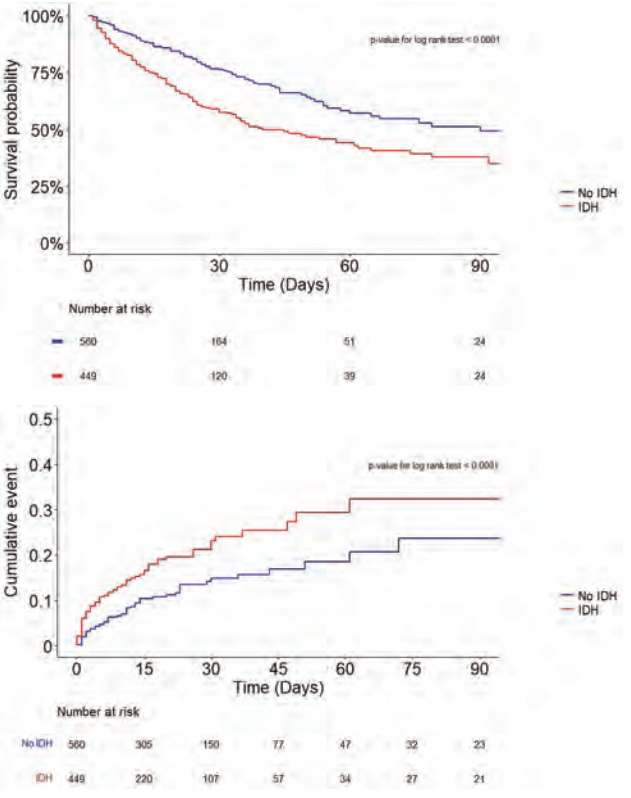
Yeongwon Park, Sehoon Park, Seong Geun Kim, Seung Seok Han. *Seoul National University Hospital, Jongno-gu, Seoul, Republic of Korea*.

Background: Intradialytic hypotension (IDH) is a critical complication related with worse outcomes in patients undergoing maintenance hemodialysis. Herein, we addressed impact of IDH on death and other outcomes in patients with severe acute kidney injury (AKI) requiring intermittent hemodialysis.

Methods: We retrospectively reviewed 1,009 patients who underwent intermittent hemodialysis due to severe AKI. IDH was defined as a decrease in systolic blood pressure (SBP) of ≥30 mmHg, with or without a nadir SBP of <90 mmHg during the first session. The primary outcome was all-cause death, and transfer to the intensive care unit due to unstable status was additionally analyzed. Hazard ratios (HRs) of outcomes were calculated using a Cox regression model after adjusting for multiple variables. Risk factor of IDH was evaluated using a logistic regression model.

Results: IDH occurred in 449 (44%) patients during the first hemodialysis session. Patients with IDH had higher death rate (39.6%) than those without IDH (23%) (HR, 1.39 [1.09–1.78]). The rate of ICU transfer was higher in patients experiencing IDH (17%) than those without IDH (11%) (HR 1.46 [1.02–2.09]). Factors, such as old age, high SBP, high pulse rate, active cancer, cirrhosis, anemia, and hypoalbuminemia, were associated with an increased risk of IDH episode.

Conclusions: The occurrence of IDH is associated with worse outcomes in patients with AKI requiring intermittent hemodialysis. Therefore, careful monitoring of IDH is necessary in this patient subset.



TH-PO282

Antibiotics Dosing in Four-Hour Sustained Low-Efficiency Dialysis: A Retrospective Data Review

Husien Almarawi, Alaa Rahhal, Amer Aljundi, Mohamed M. Kasem, Ahmed S. Mahfouz, Khaled M. Mahmoud. *Hamad Medical Corporation, Doha, Qatar*.

Background: Sustained Low-Efficiency Dialysis (SLED) is characterized by a slower blood flow rate than intermittent hemodialysis (IHD). SLED is usually done over 6-12 hours and a shorter duration of 4-hour might spare more time for procedures in critical care units (ICU). However, antibiotics dosing is not well established in 4-hour SLED, and clinicians might prescribe antibiotics using IHD dosing in view of the shorter duration.

Methods: In this single-center study, we assessed the dosing practices and clinical outcomes of antibiotics among recipients of 4-hour SLED. In-hospital mortality and recovery from sepsis were compared between those who received SLED dosing versus IHD dosing, using Cox regression and Kaplan-Meier curves. P-value <0.05 was set to represent statistical significance.

Results: A total of 107 patients who underwent 4-hour SLED and received at least one broad-spectrum antibiotic were identified between 1/06/2016 to 1/06/2020. Among them, 68% were male with a mean age of 68 ± 12 years. The majority of patients were from the Middle East (81%). Around 20% had positive urine cultures, 19% had positive blood cultures, and 10% had positive sputum cultures. The majority of 4-hour SLED recipients (84%) were prescribed antibiotics according to IHD dosing, while only 16% were prescribed SLED dosing regimens. The use of SLED-based recommended dosing in 4-hour SLED resulted in significantly higher sepsis recovery [76% vs. 42%, HR= 2.02, 95 CI (1.07-3.82), p=0.030]. Interestingly, the in-hospital mortality didn't differ between the two groups.

Conclusions: Our findings suggest that patients undergoing 4-hour SLED are more likely to get prescribed antibiotics using IHD-recommended dosing, which resulted in worse clinical outcomes. These findings would encourage using SLED-recommended dosing for 4-hour SLED and might serve as the basis for future larger studies.

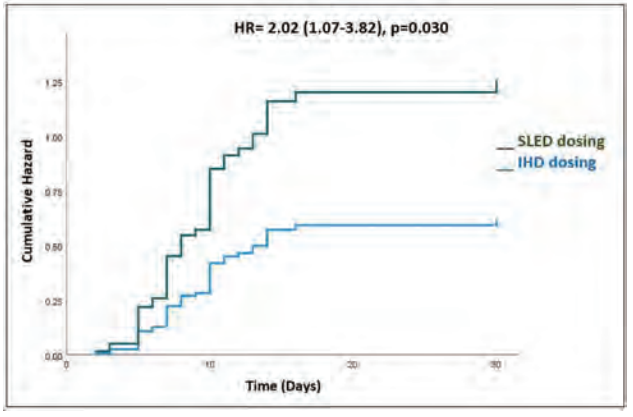


Figure 1. Kaplan-Meier curve of recovery from sepsis

TH-PO283

Clinical Factors Affecting Continuous Renal Replacement Therapy Circuit Survival

Soo yeon Choi, Donghui Shin, Jun Young Lee, Jae Won Yang, Byoung Geun Han, Seung-Ok Choi, Jae seok Kim. *Wonju Severance Christian Hospital, Wonju, Gangwon-do, Republic of Korea.*

Background: Continuous renal replacement therapy (CRRT) is an effective treatment for critically ill patients with acute kidney injury (AKI). However, CRRT circuit is frequently clotted despite anticoagulation resulting in blood loss and reduced dialysis efficacy. We aim to investigate the clinical factors affecting CRRT circuit survival.

Methods: A total of 117 CRRT circuit cases from 102 patients were reviewed retrospectively. We collected clinical data and investigated the factors affecting (1) the time from CRRT start to first dialysis circuit clotting or (2) frequency of circuit exchange during CRRT operation.

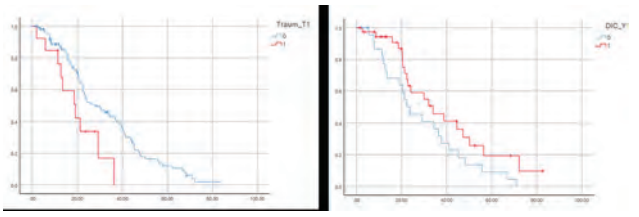
Results: The average time to 1st clotting was 26.1 hours. In Kaplan-Meier estimation, AKI due to trauma was related to shorter CRRT circuit survival (p=0.016), while DIC condition was related to longer survival (p=0.061) (Figure 1). In multivariate Cox-regression analysis, it was confirmed that the higher filtration fraction (FF) is associated with the shorter circuit lifespan, while the higher DIC score or corrected calcium level were associated with the longer circuit survival (Table 1). The average number of circuit exchange was 1.46. In multivariate linear regression test adjusted for age, FF, DIC score and RBC transfusion, it was shown that FF had the positive correlation with frequent circuit exchanges (β=0.272, p=0.026), while DIC score had the negative correlation (β= - 0.287, p=0.019).

Conclusions: The study indicates CRRT circuit survival depends on factors related to intra-dialyzer condition such as FF or clotting tendency rather than clinical severity of patients. Interestingly, our results suggest that consumptive coagulopathy due to DIC rather prevents circuit clotting. Low corrected calcium is also thought to be due to consumption as a clotting factor and therefore predict early CRRT circuit clotting.

Table 1. Clinical factors contributing to early CRRT circuit clotting

Variable	Adjusted HR (95% CI)*	*P* value
FF	1.16 (1.04, 1.28)	0.005
DIC score	0.68 (0.52, 0.89)	0.005
Corrected Ca	0.72 (0.55, 0.93)	0.011

HR: Hazard ratio; CI: confidence interval; DIC: diffuse intravascular coagulation; FF: filtration fraction; Ca: calcium
*Adjusted for age, hemodialysis catheter access, SOFA score.



TH-PO284

Continuous Renal Replacement Therapy vs. Intermittent Hemodialysis: Outcomes of Critically Ill Patients with AKI

Abdel-Rauof M. Akkari, Sundus Sardar, Mohammad Gul Yousaf Khan, Nasrollah Ghahramani. Dept of Medicine-Division of Nephrology, Pennsylvania State University College of Medicine - Hershey Medical Center. *Penn State College of Medicine, Hershey, PA.*

Background: Acute kidney injury (AKI) is a commonly diagnosed condition in critically ill patients, which poses a significant risk of chronic kidney disease, end-stage renal disease, and dialysis dependence (DD). Renal replacement therapies, including continuous renal replacement therapy (CRRT) and intermittent hemodialysis (iHD), are often used to support AKI patients. Although each modality has benefits, results from studies of outcomes associated with each modality remain inconclusive.

Methods: This retrospective multicenter cohort study utilized the TriNetX, a global federated health research network, to access deidentified electronic medical records from multiple large healthcare organizations. The primary objective was to investigate the outcomes of critically ill patients with AKI who received either CRRT or iHD after propensity score matching. The study identified and compared a total of 1024 propensity score-matched AKI patients in each group from Jan 2012, assessing them for 30-day mortality and DD using odds ratio (OR), 95% confidence interval (CI), hazard ratio (HR), log-rank test, and Kaplan-Meier survival analysis. Additionally, the study identified and compared a propensity-matched subgroup of 195 patients on mechanical ventilation in each group, with platelet count < 100/mL and bilirubin > 6 mg/dL and assessed these outcomes.

Results: The study was conducted on two groups, CRRT versus iHD, each consisting of 1024 patients. The 30-day mortality rate was 537 patients in the iHD group, and 672 patients in the CRRT group [OR: 0.578; 95% CI: 0.743-0.860; HR: 0.692; 95% CI: 0.617-0.775; p=0.637]. DD was observed in 114 and 93 patients in the iHD and CRRT groups, respectively [OR:1.254; 95% CI: 0.940-1.674; HR:1.125; 95% CI: 0.855-1.480; p=0.150]. In subgroup analysis 30-day mortality was reported in 100 and 110 patients and survival probability of 47.61% and 41.76% in the iHD and CRRT groups respectively, [HR: 0.851; 95% CI: 0.649-1.115; p=0.790]. DD was observed in 25 patients in both cohorts.

Conclusions: In the cohort of critically ill patients with acute kidney injury who were admitted to the intensive care unit and required renal replacement therapy, the choice of renal replacement therapy modality did not have a significant impact on either 30-day mortality or the development of dialysis dependence.

TH-PO285

Timing of Continuous Renal Replacement Therapy in Critically Ill Patients on Extracorporeal Membrane Oxygenation

Jing Zhou,[1,2] Yue Gu,[1,2] Mei Gao,[1,2] Fengmin Shao.[1,2] *[1]Henan Provincial People's Hospital, Zhengzhou, China; [2]Zhengzhou University People's Hospital, Zhengzhou, China.*

Background: To investigate the timing for continuous renal replacement therapy (CRRT) in critically ill patients undergoing extracorporeal membrane oxygenation (ECMO).

Methods: Clinical data were collected of critically ill patients who received ECMO combined with CRRT in the Intensive Care Unit (ICU) of Henan Provincial People's Hospital from January 2017 to June 2021. According to the time to start CRRT after ECMO application, they were divided into early CRRT group or late CRRT group. The differences in baseline clinical data and mortality between the two groups were compared. Kaplan-Meier curves obtained with the Log-rank test were plotted to demonstrate the differences in patients' survival between the two groups. Cox regression analysis was used to explore the risk factors of death.

Results: A total of 122 patients were enrolled, while 96 patients (78.69%) died. The early CRRT group and late CRRT group included 100 cases (81.97%),22 cases (18.03%),respectively. Compared with the late CRRT group, the early CRRT group had higher proportion of receiving ECMO treatment due to respiratory and cardiac arrest, proportion of ECMO with venous-arterial mode, APACHEII score, and SOFA score (all $P<0.05$). In contrast, ICU stay time, The mechanical ventilation time and ECMO application time were shorter (all $P<0.05$). Kaplan-Meier curve showed that there was no significant difference in cumulative survival between the two group ($\chi 2=3.397$, $P=0.065$). Time-Dependent Cox Regression Model showed that Early CRRT was a risk influencing factor for patient death {HR=Exp[3.642+1.177×ln(t)], 95% CI 3.225~451.394, $P=0.004$}. Multivariate Cox regression analysis showed that early CRRT {HR=Exp[3.499+1.162×ln(t)], 95% CI 2.123~516.029, $P=0.013$}, ECMO weaning failed (HR=3.470, 95%CI 1.986~6.061, $P<0.001$), high APACHEII score (HR=1.042, 95% CI 1.001~1.085, $P=0.044$) were risk factors for in-hospital death.

Conclusions: Early CRRT after ECMO treatment may have a greater effect on mortality in critically ill patients than the late CRRT. Failure of ECMO weaning and high APACHEII score were risk factors for in-hospital death.

TH-PO286

The Timing of Renal Replacement Therapy in Patients with Venoarterial Extracorporeal Membrane Oxygenation (VA-ECMO): A Nationwide Observational Cohort Study in Japan

Tomonori Takeuchi,[1,2] Toshihiro Kubo,[2] Norihiko Inoue,[2] Ashita J. Tolwani,[1] Keith M. Wille,[1] Kenji Wakabayashi,[2] Javier A. Neyra,[1] Kiyohide Fushimi.[2] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]Tokyo Ika Shika Daigaku Daigakin Ishigaku Sogo Kenkyuka, Bunkyo-ku, Japan.*

Background: Acute kidney injury is a common complication in patients on VA ECMO, thus fluid management plays a crucial role during VA ECMO. Renal replacement therapy (RRT) enables precise fluid management, but early initiation of RRT has not shown benefits in general critically ill populations. We hypothesized that early initiation of tight fluid control with RRT would be beneficial for VA ECMO patients. In this study, we aimed to determine the association of early initiation of RRT with clinical outcomes in patients on VA ECMO, using the Diagnosis Procedure Combination database, a nationwide claims database in Japan.

Methods: This is a cohort study of adult patients who underwent VA ECMO during hospitalization between 4/2018 and 3/2022. We excluded patients who initiated RRT before starting VA ECMO and patients with end-stage kidney disease. We used propensity-score-based inverse probability weighting (IPW) to balance the baseline factors and to compare outcomes between two groups: patients who initiated RRT within 48h of VA ECMO initiation (Early RRT group) and those who did not (Late RRT group). The primary outcome was in-hospital mortality and the secondary outcome was RRT dependence at discharge in survivors.

Results: Of 1,181 VA ECMO patients, 336 were in the Early and 845 were in the Late RRT groups. After IPW, the clinical factors between the groups were well balanced, including the prevalence of cardiovascular disease (96.7 vs 97.8%), the total SOFA scores on the day of VA ECMO initiation (10.4 vs 10.4), and its renal component (0.9 vs 0.9). The median time to initiate RRT from the start of VA ECMO was 0 (IQR 0–1) days in the Early and 5 (IQR 2–11) days in the Late RRT groups. Early RRT initiation was associated with increased in-hospital mortality (66.5 vs 53.6%; OR 1.7, 95%CI 1.3 – 2.3) and increased RRT dependence at discharge in survivors (12.7 vs 2.0%; OR 5.6, 95%CI 2.2 – 14.0).

Conclusions: In adult patients with VA ECMO, early RRT initiation was associated with increased in-hospital mortality and RRT dependence at discharge in survivors, suggesting that early RRT initiation may not provide advantages for this population. Further investigation is needed to explore causal inference and identify specific subpopulations that may benefit from early initiation of RRT.

TH-PO287

Treatment Time Loss and Its Association with Fluid Balance Gap and Hospital Mortality in Critically Ill Adult Patients Receiving Continuous Renal Replacement Therapy

Chloe G. Braun,[1] Tomonori Takeuchi,[1] Lucas J. Liu,[2] Stuart M. Carter,[1] Sarah A. Roberts,[1] Ashita J. Tolwani,[1] Javier A. Neyra.[1] *[1]The University of Alabama at Birmingham, Birmingham, AL; [2]University of Kentucky, Lexington, KY.*

Background: Even with CRRT, fluid balance goals are not always achieved. Recent studies showed that fluid balance gap (prescribed vs. achieved) is independently associated with hospital mortality. It has also been suggested that CRRT downtime can impair fluid management. Herein, we aimed to examine patient-related risk factors for treatment time loss and its association with hospital mortality and fluid balance gap.

Methods: Retrospective cohort study of critically ill adults receiving CRRT. Percent fluid balance gap (%FBgap) was calculated as the percentage difference between fluid balance goal and fluid balance achieved, divided by fluid balance goal. Percent treatment time loss (%TTL) was defined as the percentage of CRRT downtime in relation to the total CRRT time. We performed a linear regression model with %TTL as the dependent variable and age, sex, SOFA score at ICU admission and start of CRRT, Charlson comorbidity index, and %FBgap as independent variables. Adjusting for these clinical parameters, we further conducted a logistic regression model to determine the independent association of %TTL with hospital mortality. The correlation and interaction between %FBgap and %TTL were also examined.

Results: We included 591 patients with a median age of 60 years [IQR 50-68] and median SOFA score of 11 [IQR 7-14] at ICU admission and 13 [IQR 10-15] at start of CRRT. The median CRRT duration was 72.3h [IQR 30.7–141.4] (total of 61,718h). On average, treatment downtime per patient was 4.7h, accounting for 4.5% of total CRRT. There was no significant correlation between %FBgap and %TTL (r= -0.011, p=0.78). The multivariable model did not identify any patient-specific clinical parameters associated with %TTL. In the adjusted model, %TTL was not independently associated with hospital mortality (OR 1.02, 95%CI: 0.99–1.04) and there was no interaction between %FBgap and %TTL with hospital mortality (p interaction =0.92).

Conclusions: In this cohort of critically ill adult patients undergoing CRRT, treatment downtime only accounted for 4.5% of total CRRT time. %TTL was not independently associated with hospital mortality or significantly correlated with %FBgap. Other factors beyond %TTL need to be investigated to optimize fluid management with CRRT.

Interactions Between Intradialytic Central Venous Oxygen Saturation, Ultrafiltration Rate, and All-Cause Mortality in Maintenance Hemodialysis Patients

Hanjie Zhang,[1] Priscila Preciado,[1] Laura Rosales M.,[1] Jeroen Kooman,[2] Frank van der Sande,[2] Peter Kotanko.[1,3] *[1]Renal Research Institute, New York, NY; [2]Maastricht University Medical Center, Maastricht, Netherlands; [3]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: In hemodialysis patients, low central venous oxygen saturation ($ScvO_2$) and high ultrafiltration rate (UFR) have been associated with adverse outcomes. Here we explore the interactions between $ScvO_2$ and UFR in relation to all-cause mortality.

Methods: We conducted a retrospective study in maintenance hemodialysis patients with central venous catheters as vascular access. During a 6-month baseline period, Crit-Line (Fresenius Medical Care, Waltham, MA) was used to measure continuously intradialytic $ScvO_2$. We defined four groups by median $ScvO_2$ and median UFR. The follow-up period was 3 years. We constructed a Cox proportional hazards model with adjustment for age, diabetes, and dialysis vintage to assess the association between $ScvO_2$ and UFR and all-cause mortality during follow-up.

Results: Baseline comprised 5,231 dialysis sessions in 216 patients. The median $ScvO_2$ was 58.8% and median UFR was 6.8 mL/kg/h. During follow-up, 44 patients (20.4%) died. Kaplan-Meier analysis (**Figure 1A)** showed that worst survival was observed in patients with lower ScvO2 combined with higher UFR (group 4). The same result was observed in univariate Cox analysis. In multivariate analysis with adjustment for age, diabetes, and vintage, this association was mitigated (**Figure 1 B**).

Conclusions: Intradialytic $ScvO_2$ is an important effect modifier that should be considered when interpreting the relationship between UFR and outcomes. In patients with higher intradialytic $ScvO_2$, high UFR may be better tolerated, and fluid overload can be prevented easier while imposing high UFR in patients with low intradialytic $ScvO_2$ may lead to worse outcomes.

Funding: Commercial Support - Renal Research Institute

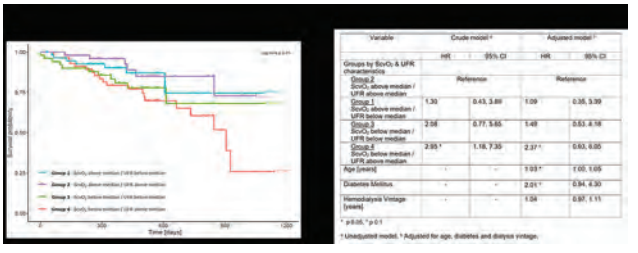

Figure 1A. Kaplan-Meier analysis of survival probabilities in the four subgroups of patients based on the level of $ScvO_2$ and UFR above and below the median of 58.8% and 6.8 mL/kg/h, respectively.

Figure 1B. Crude and adjusted hazard ratios (HR) for all-cause mortality associated with $ScvO_2$ and UFR levels below or above the median population. CI, confidence interval.

TH-PO289

Parathyroid Hormone Decrease During Sepsis Predicts Re-Hospitalization in Hemodialysis Patients

Etty Kruzel Davila,[1,2] Majd Kananeh,[1] Orly Yakir.[1] *[1]Galilee Medical Center, Nahariya, Israel; [2]Bar-Ilan University The Azrieli Faculty of Medicine, Ramat Gan, Israel.*

Background: Hemodialysis patients are at significant risk for infections. Given our clinical observation of decreased Parathyroid hormone (PTH) levels during sepsis among hemodialysis patients suffering from secondary hyperparathyroidism, we aim to characterize PTH levels before and during infection and explore its clinical significance.

Methods: A retrospective observational study conducted in the nephrology department at the Galilee Medical Center, Israel, between 2020-2022. Hemodialysis patients suffering from sepsis were included. PTH levels at different time points were analyzed using Wilcoxon signed rank test. Multivariable logistic regression analyses were conducted to identify risk factors for rehospitalization and mortality (median follow-up: 12.3 months, range:1.9-35.5). Model 1 included Age≥65 years, gender, dialysis vintage≥4 years and diabetes. Model 2: Similar to model 1 plus C reactive Protein (CRP), neutrophil/lymphocyte ratio (NLR) and albumin during hospitalization. Model 3: Similar to model 2 plus partial PTH decrease compared to baseline PTH.

Results: 72 hemodialysis patients were included in this study. The median duration of hospitalization was 9 days (IQR 7-15). 74% were re-hospitalized after discharge while 50% were re-hospitalized within 1.8 months (IQR 0.5-5.8). Infection was the most common rehospitalization diagnosis. The mortality rate during follow-up period was 17% (median survival time: 7.7 months (IQR 3.7-11.9). As hypothesized, PTH levels significantly decreased during sepsis compared to baseline (p<0.001), with partial decrease of 29% (IQR 8%-49%). In the final model of the multivariable logistic regression analyses, several traditional risk factors were associated with re-hospitalization risk: Age≥65 years: OR 5.3, p=0.034 and dialysis vintage≥4 years: OR 5.5, p=0.045. Interestingly, partial PTH decrease during infection was the most significant risk factor for re-hospitalization (OR 12.6, p=0.013). In the final model of the multivariable logistic regression analyses for mortality, only diabetes had a borderline significance (OR 8.6, p=0.065).

Conclusions: In this hemodialysis cohort a significant decrease in PTH levels during infection had the highest OR for re-hospitalization. Further multicenter, prospective studies are needed to validate and explore this association, mechanism, and clinical implications.

TH-PO290

Association Between Sleep Quality and Cardiovascular Disease in Maintenance Hemodialysis Patients

Han Tian, Lulu Wang, Junwei Yang, Hong Ye, Lei Jiang. *The Second Affiliated Hospital of Nanjing Medical University, Nanjing, China.*

Background: Most patients on maintenance hemodialysis (MHD) have sleep disorders. Studies have shown that poor sleep quality is associated with a variety of diseases, such as diabetes, cardiovascular disease (CVD), and depression. However, few studies have investigated sleep quality in the population of Chinese patients on hemodialysis. This study aimed to analyze sleep quality in patients on maintenance hemodialysis (MHD), and assess the impact of sleep quality on their prognosis.

Methods: A total of 601 patients on MHD were prospectively included in this cohort study. Pittsburgh sleep quality index (PSQI) was used to evaluate the sleep quality of patients. The global PSQI score > 7 indicates that a person with poor sleep quality. Follow-up was conducted until December 31 2022, with all-cause death and major adverse cardiovascular events (MACEs) as the endpoint events. Correlations between sleep quality and incidences of endpoint events were analyzed using Cox risk regression models.

Results: Of the 601 patients, 595 completed the PSQI assessment, with 278 (46.7%) having poor sleep quality. Patients in the PSQI>7 group were older (p<0.001) and had a higher proportion of comorbid cardiovascular disease (CVD, p<0.001) and diabetes (p=0.002). Years of education (p=0.028), diastolic blood pressure (p=0.002), and heart rate (p=0.005) were lower in the PSQI>7 group than in the PSQI≤7 group. The 595 patients were followed up for 3 (2.5-3.7) years, during which 116 (19.4%) died, 415 (69.8%) survived, 64 (10.8%) were lost to follow-up, and 115 (19.3%) experienced MACEs. After adjusting for confounding factors such as age, gender, dialysis age, and previous cardiovascular disease, the risk of MACE in patients with poor sleep quality was twice that of patients with good sleep quality (HR=2.037 (1.339, 3.097), p=0.001). There was no significant difference in the risk of all-cause death between the two groups (HR=0.851 (0.584,1.240), p=0.4).

Conclusions: The prevalence of poor sleep quality in patients on MHD was 46.7%. Poor sleep quality was independent risk factor for MACEs in patients on MHD.

TH-PO291

Comparison of Utilities Consumption Between Different Modalities of In-Center Haemodialysis

Sam Henderson, Nicolas Goux, Mohamed Mahsoub, Omneya E. Mohamed, Ayman Karkar. *Baxter AG, Dubai, United Arab Emirates.*

Background: Water is scarce in different parts of the world, including the Kingdom of Saudi Arabia (KSA). Water consumption during hemodialysis (HD) is about 360 liters/patient/week. Online hemodiafiltration (HDF) requires more water consumption (dialysate and replacement fluid) than HD/patient/week. Electricity production is interconnected with water usage. In KSA, Dialysis incidence is expected to increase on average by 5% yearly. This study quantifies local KSA utilities costs associated with in-center HD (ICHD; including High-Flux HD [HF-HD], Expanded HD [HDx], & online HDF).

Methods: Under laboratory conditions and a set treatment protocol, consumptions were recorded for power (Watt-hours, Wh) & water (Liters, L). We gathered cost data from available resources; KSA National Water Company (NWC) & Saudi Electricity Company (SEC). The results were tabulated in Microsoft Excel comparing HD modalities (HF-HD, HDF & HDx). We used single & double-pump dialysis machines (Baxter, Deerfield, IL, USA). Protocols for HF-HD, HDx, & HDF were derived from local expert opinion based on local practice. The cost of consumables & session provision per modality is assumed the same. The analysis considered the perspective of a single center with 30 dialysis beds running two shifts/day over 6 days/week at 100% capacity, caring for 120 patients/year.

Results: HDx water consumption is 3 million (m) liters and electricity consumption is 50.4m Wh/ center/year (same results for HF-HD). The total for HDF is 4.1m L & 60.2m Wh/year, respectively. HF-HD and HDx will reduce the consumption of water and electricity by 1.1m L and 9.8m Wh/year, respectively. For HF-HD and for HDx, the total cost of water & electricity consumption in US Dollars $ (USD)/center/year was $16,002.33 (USD $1 = 3.75 Saudi Riyal [SAR]). When providing HDF, water and electricity cost/center/year was $21,297.20.

Conclusions: In a typical dialysis center in Saudi Arabia, choosing to provide HDx may reduce water and electricity consumptions by $5,294.87 /year versus HDF. This significant cost savings together with the clinical benefits and ease of delivery of the HDx modality may help in favoring this therapeutic modality and strengthening economic data available to policymakers and providers.

TH-PO292

Does Online Hemodiafiltration Improve Clinical Outcomes and Quality of Life in Dialysis Patients Compared to Conventional Hemodialysis?

Dinesh Khullar, Sudip Patil, Rahul Grover, Gagan Chhabra, Sahil Bagai, Prof Narinder P. Singh, Anish K. Gupta. *Max Super Speciality Hospital, Dehli, India.*

Background: The field of dialytic renal replacement modalities has seen advancements; however, interventional studies have produced dismal outcomes. The debate regarding the most beneficial outcome between hemodiafiltration (OL-HDF) and hemodialysis (HD) for dialysis patients remains open. This study aimed to compare clinical, biochemical, and quality of life (QoL) data between patients receiving HD and OL-HDF over a six-month follow-up period.

Methods: A prospective observational study was conducted involving 70 dialysis patients. The inclusion criteria included stable patients with a dialysis Kt/Vurea greater than 1.2 who had received either HDF or HD three times per week for at least three months. Patients who had undergone renal transplantation, exhibited severe noncompliance, or had a life expectancy of less than three months due to conditions unrelated to kidney illness were excluded. QoL was assessed using the dialysis symptom score over the six-month period, along with clinical and biochemical parameters. Both modalities had an intended HD treatment duration of 240 minutes, with a blood flow rate between 250-400 mL/min and a dialysate flow rate of 500 mL/min for both groups.

Results: Out of the 70 dialysis patients, 35 (19 males) were in the HD group, with an average age of 50.05±15.31 (range 41-60) years, and 35 (19 males) were in the OL-HDF group, with an average age of 50.31±11.44 years. Compared to the HD group, the HDF group showed significantly lower levels of inflammatory markers such as Beta 2-microglobulin ($p < 0.001$) and hs-CRP ($p < 0.002$), lower levels of phosphorus ($p < 0.001$), and higher hemoglobin ($p < 0.001$) over the six-month follow-up period. Patients in the HD group had higher mean symptom severity scores compared to those in the HDF group (40.97±12.24 vs. 24.11±5.03, $p < 0.001$). Single pool dialysis Kt/V, calcium, blood pressure control, and the amount of anti-hypertensive drugs required were similar in both groups.

Conclusions: Online hemodiafiltration may be a preferable option over conventional HD due to reduced inflammation, improved anemia control, better phosphorus control, and improved dialysis tolerance with fewer symptoms. Further research is needed to determine the long-term effects of mortality and morbidity in dialysis.

TH-PO293

Predialysis Serum Albumin and Hemoglobin and the Risk of Intradialytic Hypotension

Katherine Curtis,[1,2] Sushrut S. Waikar,[3] Finnian R. McCausland.[1,4] McCausland Lab. *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]The George Washington University Milken Institute of Public Health, Washington, DC; [3]Boston Medical Center, Boston, MA; [4]Harvard Medical School, Boston, MA.*

Background: Intravascular hypovolemia may predispose to intra-dialytic hypotension (IDH), a common occurrence among patients receiving maintenance hemodialysis (HD), which is associated with adverse outcomes. Whether higher pre-HD serum albumin and hemoglobin (Hb), which may reflect hemoconcentration, could serve as biomarkers to predict IDH during an HD session warrants further investigation.

Methods: We analyzed data from a prospective cohort study of patients included in the DaVita Biorepository (N=950). Pre-HD serum albumin, hemoglobin, and complete blood pressure (BP) data were available for n=938 patients and n=11,460 sessions. Random-effects Poisson regression models (adjusting for age, sex, race, access type, pre-HD systolic BP (SBP), session length, ultrafiltration, post-HD weight, diabetes mellitus, heart failure, ischemic heart disease, peripheral vascular disease, lung disease) were fit to examine the association of serum albumin and hemoglobin with IDH (defined as minimum SBP <100 if pre-SBP ≥160 or minimum SBP <90 if pre-SBP<160 mmHg).

Results: At baseline, mean age was 58 ±14 years and 44% were female. The mean pre-HD albumin and hemoglobin were 3.5 ±0.5 g/dL and 10.8 ±1.6 g/dL, respectively. A total of 1,606 (14%) sessions were complicated by IDH. Higher pre-HD serum albumin was associated with a 17% higher adjusted risk of IDH (IRR 1.17; 95%CI 1.00, 1.37). Higher Hb (per g/dL) was associated with 6% higher risk of IDH (IRR 1.06; 95%CI 1.02,1.11). When both were considered in the same model, only hemoglobin retained significance (IRR 1.05; 95%CI 1.01, 1.10).

Conclusions: Higher pre-HD serum albumin and hemoglobin were each independently associated with IDH, but only hemoglobin retained significance in a joint-model. Higher hemoglobin may thus serve as a widely-available biomarker to predict IDH at an individual HD-session level.

TH-PO294

Impact of Dialysate Calcium Concentration on Bone Metabolism in Relation to Different Calcimimetics

Jyunichiro Hashiguchi,[1] Tomoya Nishino,[2] Satoshi Funakoshi.[1] *[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Daigaku Byoin, Nagasaki, Japan.*

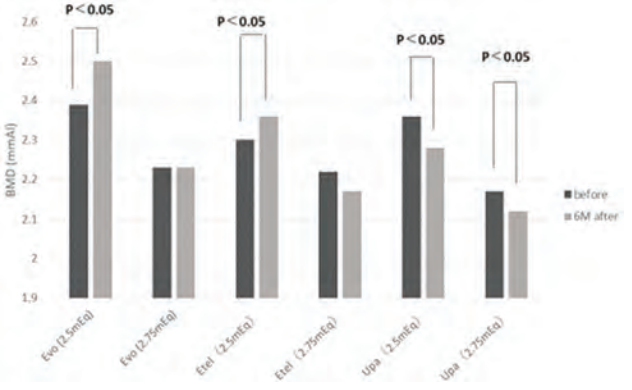
Background: In Japan, three types of calcimimetics are currently approved to treat secondary hyperparathyroidism. However, the specific impact of these drugs on bone metabolism remains unknown. Furthermore, limited research is available on the potential influence of different dialysate calcium concentrations used during hemodialysis on the

bone-related effects of these calcimimetics. This study aimed to examine the influence of dialysate calcium concentration on bone metabolism associated with different calcimimetics.

Methods: Ninety patients undergoing hemodialysis with a dialysate containing either a calcium concentration of 2.75 mEq/mL or 2.5 mEq/mL and having secondary hyperparathyroidism with an intact parathyroid hormone (i-PTH) level ranging from 50–400 pg/mL were included in the study. These participants had been taking calcimimetics for more than a year. Six groups were established by combining two dialysate calcium concentrations and three types of calcimimetic preparations. Changes in bone mineral density were assessed over six months using the Dual-Energy X-ray Absorptiometry (DEXA) Imaging Protocol.

Results: In patients with a calcium concentration of 2.5 mEq/L dialysate, evocalcet and etelcalcetide resulted in an increase in bone mineral density by 4.4% and 1.3%, respectively. Conversely, upacicalcet showed a decrease in bone mineral content by 3.3%. Among patients receiving dialysate with a calcium concentration of 2.75 mEq/L, only upacicalcet resulted in a significant reduction of 2.3% in bone mineral density when comparing pre- and post-medication measurements. (Figure)

Conclusions: Calcimimetics exert significant effects on bone metabolism in addition to their ability to lower iPTH levels. However, this effect may vary depending on the concentration of calcium in the dialysate.



TH-PO295

Loss of Residual Kidney Function at One Year in Diabetic and Non-Diabetic Incident Patients Treated with Incremental Hemodialysis

Patrick Saudan,[1] David A. Jaques,[1] Belen Ponte,[1] Anne Dufey Teso,[1] Fadi Haidar,[1] Sebastian Carballo,[2] Sophie M. De Seigneux.[1] [1]*Service of Nephrology, Geneva University Hospitals, Geneva, Switzerland;* [2]*Service of General Internal Medicine, Geneva University Hospitals, Geneva, Switzerland.*

Background: Residual kidney function (RKF) is better preserved with incremental haemodialysis (I-HD) as compared to conventional thrice-weekly HD (TW-HD). Presence of diabetes is associated with a faster decline of RKF in TW-HD. We aimed to analyze the RKF decline at one-year in diabetic versus non-diabetic patients initiating dialysis with I-HD.

Methods: We conducted an analysis of a prospectively assembled cohort in a single university centre including all adults initiating I-HD from January 2013 to December 2021. Outcomes were maintenance of incremental dialysis at one year and RKF decline at one year (or transition to TW-HD) according to the presence of diabetes.

Results: Of 264 patients who started hemodialysis, 93 initiated dialysis with I-HD of whom 30 were diabetics. At dialysis initiation, age, eGFR, comorbidity score, daily diuresis and urea clearance (KrU) were similar between non-diabetic and diabetic patients. Transition to TW-HD occurred after a mean duration of 16 +/- 15 months and 11+/- 10 months in non-diabetic and diabetic patients respectively (p= 0.07). At one year, the percentages of non-diabetic patients and diabetic patients still on I-HD were 51% and 37% respectively. At one-year, non-diabetic and diabetic patients had a daily diuresis decline of 32 and 37 % (p= 0.07) and a KrU decline of 34 and 46 % (p< 0.01) respectively.

Conclusions: RKF decline is more rapid in incident diabetic patients versus non-diabetic patients treated with I-HD and its duration before transition to TW-HD is shorter in patients with diabetes. Nephrologists should be aware that transition to TW-HD could be faster in diabetic patients.

TH-PO296

Patiromer Efficacy to Reduce Episodic Hyperkalemia in ESRD Patients: The PEARL-HD Study

John P. Middleton,[1] Shifeng Sun,[2] Clemontina A. Davenport,[2] James P. Daubert.[1] [1]*Duke University, Durham, NC;* [2]*Duke University Department of Biostatistics and Bioinformatics, Durham, NC.*

Background: Patients who have end-stage kidney disease (ESKD) maintained on hemodialysis (HD) are exposed to a high risk of cardiac arrhythmias, and this risk is augmented by periodic exposures to hyperkalemia (HK). Use of dialysate with a low potassium concentration may increase the risk of sudden cardiac death. Furthermore, HD patients carry a high pill burden, and it is unclear if prescription of an additional oral medication will reduce the frequency of episodic HK. The purpose of the study is to determine whether patiromer (P) administered daily will effectively reduce episodes of HK in ESKD patients who receive HD, and to explore whether P administration reduces the number of significant arrhythmia events.

Methods: This is a prospective, randomized, open-label trial. Eligible ESKD patients who were on thrice-weekly HD were screened from health records. A total of 33 patients were randomized 1:1 to P vs usual care. Patients randomized to P were administered the medication daily with breakfast or lunch in place of their prescribed phosphate binder, and the dose was titrated based on pre-HD serum potassium concentrations at start of weeks 1, 2, and 3. All participants received 7-day continuous cardiac monitors (CCM) at baseline and at week 4. A Mann-Whitney test was used to compare median number of HK episodes across groups. Fisher's exact test was used to compare the probability of at least 1 HK episode.

Results: Of those randomized, one withdrew due to adverse symptoms, and one withdrew due to pregnancy. The mean age of randomized patients was 57 y, 50% were male, 79% were Black, 11% were Hispanic/Latino, and mean HD vintage was 6 y. The P group had significantly lower median HK episodes compared to the control group (0 vs 3, p=0.002). Those in the P group were significantly less likely to have at least one HK episode compared to the control group (21% vs 71%; p=0.021). On the week 4 CCMs, 5 participants had > 1000/24 hr premature ventricular contractions, 4 had ventricular tachycardia events, 3 had atrial fibrillation, and 0 had bradycardia events, with no differences between the groups.

Conclusions: Patiromer administered orally once a day effectively reduces frequency of HK in ESKD patients who receive thrice-weekly HD. Larger studies are needed to determine whether patiromer reduces significant cardiac events.

Incidence and Concurrence of Hyperkalemia and Hyperphosphatemia in a Single Outpatient Dialysis Setting: Long vs. Short Interdialytic Interval

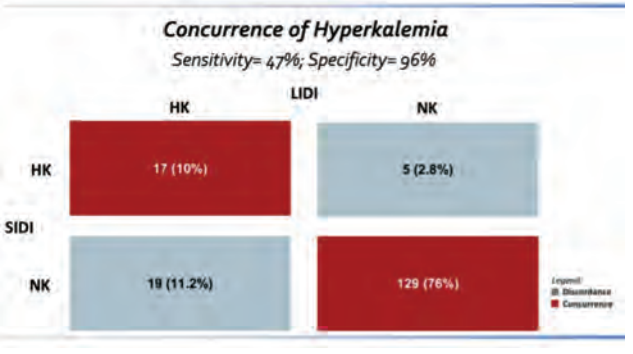
Bruce S. Spinowitz, Danielle Freitas Serafim, Rayen Kuo, Muhammad Shoaib, Sheng F. Kuo. *New York Presbyterian Queens, Queens, NY.*

Background: Predialysis hyperkalemia is a common finding in patients receiving intermittent hemodialysis, more common following the long interdialytic interval (LIDI). Monthly laboratory assessments are most often done mid-week, following a short interdialytic interval (SIDI). We examined the occurrence and concurrence of hyperkalemia and hyperphosphatemia in individual patients, SIDI vs. LIDI to determine the sensitivity and specificity of detecting these electrolyte abnormalities following short vs. long intervals.

Methods: Serum potassium and phosphorus were measured predialysis after a LIDI which followed a previous mid-week SIDI. We performed a retrospective observational cohort study in this single outpatient dialysis center treating 174 patients aged ≥ 18 receiving dialysis 3 times weekly for at least 3 months. Hypokalemic patients were excluded. Patients were categorized into two groups depending on severity of serum potassium: NK=Normal and mild (3.5-5.4 mEq/L) and HK=Moderate and Severe (≥ 5.5mEq/L). Phosphorus levels were grouped: NP= 2.4-6.5 mg/dL and HP ≥ 6.6 mg/dl. The incidence of these two electrolyte abnormalities and concurrence, with calculations of sensitivity and specificity for elevations noted in SIDI vs LIDI were evaluated.

Results: HK group was noted in 13% of patients (22/170) at SIDI and 21% (36/170) at LIDI, 1.6 times more likely. Only 17 of the 36 patients in the HK group were hyperkalemic at both SIDI and LIDI, 47% sensitivity. Similarly, the sensitivity for detection of hyperphosphatemia SIDI vs LIDI in the HP group was only 50%.

Conclusions: A clinically significant number of patients with predialysis hyperkalemia will go undiagnosed if routine monthly testing is only performed following a SIDI. In view of new, safe and effective potassium binders approved for treatment in adults with chronic hyperkalemia, monitoring of potassium following LIDI should be evaluated on a periodic basis.



TH-PO298

Favorable Outcome of Combined Antihypertensive Agents for Patients Undergoing Hemodialysis

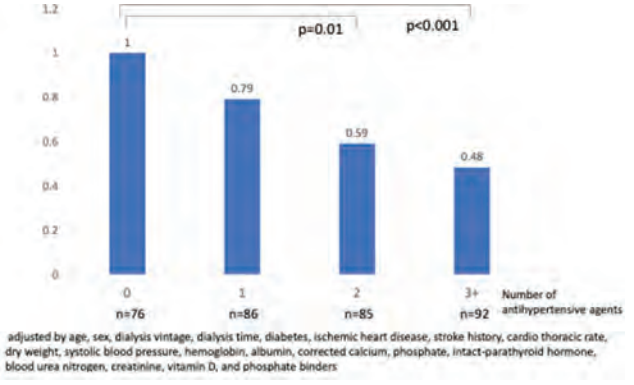
Emiko Otsuka,[1,2] Mineaki Kitamura,[2] Maiko Nakamura,[1] Hiro Inoue,[1] Satoshi Funakoshi,[1] Tomoya Nishino.[2] *[1]Nagasaki Renal Center, Nagasaki, Japan; [2]Nagasaki Daigaku, Nagasaki, Japan.*

Background: Various antihypertensive agents are currently available. Some of them, including angiotensin receptor blockers, not only lower blood pressure but also have a favorable effect on life prognosis. However, the pleiotropic effects of anti-hypertensive agents in patients undergoing hemodialysis remain unknown.

Methods: Patients undergoing hemodialysis during 2011 and 2012 at Nagasaki Renal Center were followed up until June 2021. Multivariate Cox regression analyses were conducted, including patients' demographic data, such as blood pressure and the number of antihypertensive agents received.

Results: A total of 339 patients (mean age: 67.3 years, 57% men, median dialysis vintage: 4.7 years) were included. The prescription ratios of angiotensin receptor blockers, beta-blockers, and calcium blockers were 41%, 19%, and 50%, respectively. According to the multivariable Cox regression analysis, angiotensin receptor blockers (Hazard ratio [HR]: 0.69, 95% confidential interval: 0.51–0.95, P=0.02) and calcium channel blockers (HR: 0.58, 95% confidential interval: 0.43–0.77, P<0.001] were associated with a better prognosis. Compared with patients who did not receive antihypertensive agents, patients who were prescribed one, two, and three or more antihypertensive agents showed an adjusted relative risks of death of 0.79, 0.59 (p=0.01), and 0.48 (p<0.001), respectively.

Conclusions: Our study showed that the number of antihypertensive agents received was negatively correlated with prognosis, indicating their pleiotropic effect. Therefore, physicians should combine antihypertensive agents to lower the blood pressure of patients undergoing hemodialysis to improve the prognosis.



TH-PO299

Association of Erythropoiesis-Stimulating Agents with Peri-Dialytic Blood Pressure Parameters

Anika T. Singh,[1,2] Timothy E. Yen,[3] Suraj Sarvode Mothi,[4] Sushrut S. Waikar,[5,6] Finnian R. McCausland.[1,2] *[1]Brigham and Women's Hospital Department of Medicine, Boston, MA; [2]Harvard Medical School, Boston, MA; [3]The University of Mississippi Medical Center, Jackson, MS; [4]St Jude Children's Research Hospital, Memphis, TN; [5]Boston Medical Center, Boston, MA; [6]Boston University School of Medicine, Boston, MA.*

Background: Anemia is a common comorbid condition among patients with end-stage kidney disease (ESKD) requiring maintenance hemodialysis and is associated with morbidity and mortality. While recombinant human erythropoietin (rHuEPO) revolutionized anemia correction, concerns existed about the development or worsening of hypertension. This study aims to understand practice patterns of erythropoiesis-stimulating agent (ESA) use in outpatient hemodialysis and associations of ESA use with Hyper0 (any increase in systolic BP from pre- to post-HD) and peri-HD BP parameters.

Methods: ESA administration at individual HD sessions was assessed from the DaVita Biorepository (n=950), a prospective cohort study consisting of clinical data and biospecimen collection. Unadjusted and multivariable Poisson and linear random effects models adjusted for age, sex, race, access, pre-HD SBP, HD vintage, UFR, diabetes, heart failure, ischemic heart disease, peripheral vascular disease, and lung disease were fit. Exploratory models were fit including the prior variables with additional adjustment for hemoglobin (Hb) and endothelin-1 (ET-1).

Results: Mean age was 53 ±22 years, 44% were females, and 38% were Black. Mean pre-HD SBP was 152 ±28 mmHg. ESAs were administered at 97,172 of the 135,892 sessions (71.5%) sessions. Those with ESAs administered were younger, had higher UF volume and rate, longer HD sessions, higher pre-HD SBP, diabetes, PVD, and higher Hb and ET-1. In fully adjusted models, we observed a 9% higher rate of Hyper0 (IRR 1.09; 95%CI 1.06–1.12 mmHg.) In exploratory models adjusted for Hb + ET-1, this association was mildly attenuated (IRR 1.06; 95%CI 1.01–1.1 mmHg.) In fully adjusted models of peri-HD parameters, ESAs were associated with a higher nadir SBP (IRR 1.3; 95%CI 1.1–1.6 mmHg) with similar patterns of association noted for ESAs and post-HD SBP.

Conclusions: We observed an independent association between ESA administration and higher risk of Hyper0, and higher intradialytic SBP parameters. Future studies are warranted to better understand the mechanisms underlying these findings.

TH-PO300

Hypotension at the Start of Dialysis Is a Risk Factor of Cardiovascular Mortality

Shota Suzuki, Akira Fujiwara, Rina Kawano, Aiko Haruna, Tatsuya Haze, Nobuhito Hirawa. *Yokohama Shiritsu Daigaku Fuzoku Shimin Sogo Iryo Center, Yokohama, Japan.*

Background: In recent studies on hemodialysis (HD) patients, The association of Blood pressure at the start of dialysis and cardiovascular disease (CVD) morbidity is controversial. In a retrospective study, we aimed to investigate whether the pre-hemodialysis blood pressure levels predict CVD-related death.

Methods: The patients were followed up for up to 4 years. At baseline, demographic data, comorbidity data, physical examination results, and laboratory data were recorded for each patient. Pre-dialysis fasting blood samples were collected from arterial blood lines at the beginning of a week. We divided the study patients into 4 groups according to their systolic blood pressure at the start of dialysis in an ascending order: from the bottom 25th percentile (Q 1) to the top 25th percentile (Q 4). The Cox proportional hazards model was used to assess the association between blood pressure and the risk of CVD related death.

Results: A total of 132 outpatients treated at the Kohsaikai Kamiooka Jinsei Clinic in Yokohama and the Soubudai Nieren Clinic in Kanagawa, Japan between December 2008 and July 2009 were enrolled. At the baseline, blood pressure at the start of dialysis was 147 ± 20 / 51 ± 5 mmHg. Among the 132 patients, there were 11 lethal events due to CVD. The risk of CVD death was significantly higher in the lowest systolic blood pressure patients (Q 1) than in highest blood pressure patients (Q 4) for 4 -years (Kaplan-Meier curve, log rank $P = 0.035$). In the multivariate Cox regression analysis, low systolic blood pressure was found to be independent risk factors for CVD mortality.

Conclusions: Hypotension at the start of dialysis is an independent risk factor of cardiovascular mortality.

TH-PO301

A Single-Center Study of the Appropriate Timing of Chest X-Rays in Hemodialysis Patients

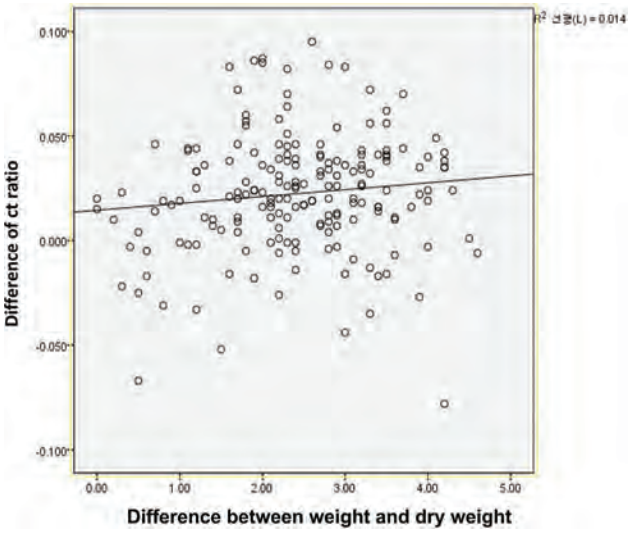
Jeongmyung Ahn, A. R. Lee, Kim Nam Sik, Yanghyeon Kim, Hee yeoun Kim, Joon Seok Oh, Joong Kyung Kim. *BongSeng Memorial Hospital, Busan, Republic of Korea.*

Background: To determine dry weight, the most commonly method is bioimpedance and relative plasma volume(RPV) monitoring. However the cardiothoracic ratio(ct ratio) of chest PA is still a common method of setting the dry weight. It is not clear when to perform chest PA. So chest PA is conducted at the convenience of patients and medical staff regardless of dialysis. We hypothesis that the ct ratio before dialysis would be different from that when the appropriate dry weight was reached.

Methods: We analyzed 211 hemodialysis patients at our hospital from December 1 to 10, 2022. We took chest PA in patients before hemodialysis on Monday or Tuesday, the beginning of the week(Pre-HD ct ratio). When our patients had been considered euvolemia and reached dry weight after hemodialysis during the week, we additionally performed a chest PA test and evaluated the ct ratio(Post-HD ct ratio). Using SPSS ver. 18, we compared the ct ratio of chest PA before and after dialysis. We analyzed the correlation between the difference in the ct ratio of chest PA and the difference between weight and dry weight at the time of the test.

Results: There was a significant difference between the Pre-HD ct ratio(0.513 ± 0.058) and the Post-HD ct ratio(0.491 ± 0.060, $P < 0.05$). The difference in the ct ratio of the chest PA was correlated with the difference between weight and dry weight. However, differences in ct ratio were not related to gender, age, primary disease, dialysis period, and previous RRT methods.

Conclusions: There was a difference in the ct ratio of chest PA before and after dialysis. As the patient's weight approached the dry weight, the ct raito of the chest PA decreased. We concluded that the appropriate time to administer chest PA was after the patient's weight reached dry weight.



TH-PO302

Transcatheter Aortic Valve Implantation Is Effective for Severe Aortic Valve Stenosis in Hemodialysis Patients

Kenji Harada. *Kokura Kinen Byoin, Kitakyushu, Japan.*

Background: In Japan, of the >340,000 chronic dialysis patients, approximately 60% have lifestyle-related diseases including diabetes and nephrosclerosis. Two-thirds of maintenance dialysis patients (age, ≥65 years) often develop aortic stenosis (AS) and other serious and complex systemic cardiovascular disease complications associated with chronic kidney disease mineral and bone disorder (CKD-MBD). Furthermore, renal function loss and a prolonged state of renal failure are observed requiring renal replacement therapy (RRT). AS in dialysis patients progresses quickly, and the frequency of hospitalized treatment for heart failure increases with the worsening condition, leading to ADL deterioration, which may subsequently cause dialysis hypotension/interruption. At our hospital, of the 420 maintenance dialysis patients who died during hospitalization in 5 years before 2020 (420/2,637=16%), 32 cases (8%) developed AS complications, which became their direct cause of death in 12 cases (3%), and aortic valve replacement (AVR) was performed in 5 cases (1%). Maintenance hemodialysis patients (HD) are at high risk group and have a poor prognosis for life. Previously, transcatheter aortic valve implantation (TAVI) was not indicated, but recently TAVI has been approved in Japan. Efficacy of TAVI for HD patients remains unclear, here we investigated several outcomes.

Methods: A total of 123 maintenance dialysis patients with severe AS were included in 2019-2021. We examined TAVI group and AVR group for length of hospital stay, hospitalization costs, life expectancy, and rates of complications such as occurrence of arrhythmias.

Results: Over a 3-year period, we performed TAVI for 58 maintenance dialysis patients (mean age, 81 years); their median duration of hospitalization was 14 days for a median cost of 6,259,350 JPY. The mean age was older than that of 66 patients who underwent open-heart AVR during the same period (mean age, 73 years; 35 days for 7,192,570 JPY); therefore, the cost was less, and the rate of complications, including vital prognosis and arrhythmia, was not inferior in hospitalization period.

Conclusions: In conclusion, TAVI is effective for elderly maintenance dialysis patients with severe AS and has a positive health care economics, ADL maintenance.

TH-PO303

Apollo DB: Characteristics of a Global Dialysis Database Across Major World Regions

Melanie Wolf,[1] Yue Jiao,[2] Kaitlyn Croft,[1] Maria Ines Diaz Bessone,[3] Marco Rancati,[4] Anke Winter,[1] Paola Carioni,[4] Sheetal Chaudhuri,[2] Luca Neri,[4] Kanti Singh,[2] Milind Nikam,[5] Stefano Stuard,[1] Adrian M. Guinsburg,[2] Jeffrey L. Hymes,[2] Len A. Usvyat,[2] John W. Larkin,[2] Franklin W. Maddux.[2] Apollo DB Team. *[1]Fresenius Medical Care, Bad Homburg, Germany; [2]Fresenius Medical Care, Waltham, MA; [3]Fresenius Medical Care, Buenos Aires, Argentina; [4]Fresenius Medical Care, Crema, Italy; [5]Fresenius Medical Care, Singapore, Singapore.*

Background: Large amounts of data are captured during dialysis. This data can be used for secondary purposes to understand and advance care models, yet data is often not available on a multinational level. Apollo DB is an anonymized dialysis database that combines and harmonizes data from a global provider for research and quality improvement activities.

Methods: Apollo DB captures data from 40 countries on demographics, laboratories, treatments, and outcomes. Data from different electronic systems is harmonized and anonymized based on logic established in a re-identification risk assessment. Data is consolidated and stored in a central cloud environment. The database contains data on 363 variables from Jan 2018-Mar 2021 and will be updated periodically.

Results: Apollo DB includes 543,169 patients, 4.6% Asia-Pacific (AP), 13.9% Europe, Middle East, & Africa (EMEA), 7.0% Latin America (LA), and 74.5% North America (NA). Select characteristics are shown by world region in **Figure 1**. Most patients are 45-64 years old (yo), yet more are 18-44 yo in AP & LA, while more are 65-74 & ≥75 yo in EMEA & NA. Hemodialysis is the most used modality, but peritoneal dialysis is common in LA (17.3%) and NA (13.2%). There were regional differences, such as higher urea removal in EMEA that commonly uses hemodiafiltration. The mean treatment time tends to be lower in NA and patients have a higher weight and are taller versus other regions.

Conclusions: In a first descriptive analysis, several regional differences were observed. These patient characteristics act as benchmarks for the nephrology community. Apollo DB offers opportunities for investigators to conduct global analytics and advance the state of the art.

Characteristics of Global Dialysis Data from Multiple Providers in the New MONitoring Dialysis Outcomes (MONDO) Dataset

Vladimir Rigodon,[1,2] Murilo H. Guedes,[1] Sophanny Tiv,[3] Vincent Peters,[4,5] Yue Jiao,[2] Anke Winter,[6] Melanie Wolf,[6] Kaitlyn Croft,[6] Paola Carioni,[7] Sheetal Chaudhuri,[2] Marco Rancati,[7] Maria Ines Diaz Bessone,[8] Xiaoling Ye,[9] John W. Larkin,[2] Milind Nikam,[10] Edwin B. Toffelmire,[11] Constantijn Konings,[4] Stefano Stuard,[6] Adrian M. Guinsburg,[8] Jeffrey L. Hymes,[2] Roberto Pecoits-Filho,[1] Thyago P. Moraes,[1] Rasha H. Hussein,[12] Marcello Tonelli,[3] Peter Kotanko.[9,13] From the MONDO Investigators. *[1]Pontificia Universidade Catolica do Parana, Curitiba, Brazil; [2]Fresenius Medical Care, Waltham, MA; [3]University of Calgary, Calgary, AB, Canada; [4]Catharina Ziekenhuis, Eindhoven, Netherlands; [5]Tilburg University, Tilburg, Netherlands; [6]Fresenius Medical Care, Bad Homburg, Germany; [7]Fresenius Medical Care, Cremona, Italy; [8]Fresenius Medical Care LatAm, Buenos Aires, Argentina; [9]Renal Research Institute, New York, NY; [10]Fresenius Medical Care, Singapore, Singapore; [11]Fresenius Medical Care, Richmond Hill, ON, Canada; [12]University of Khartoum, Khartoum, Sudan; [13]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: The **MON**itoring **D**ialysis **O**utcomes (**MONDO**) initiative is an academia-industry collaboration whereby providers can contribute data to an anonymized dataset used for joint research purposes. We present the characteristics of 20 years of longitudinal patient data contributed to the new MONDO dataset, which is now the most robust global dialysis dataset in the world.

Methods: Data from Jan 2000-Dec 2019 on 382 fields was captured longitudinally on a per patient per observation level (e.g., each lab, treatment, value) with a universal data structure. Detailed distribution statistics were used for re-identification risk assessment and confirmed the anonymization logic for providers to apply and provide acceptably low risk, consistent with international data privacy standards (e.g., GDPR, HIPAA). Final datasets were consolidated and hosted by the Renal Research Institute.

Results: Nine providers from 41 countries across six continents contributed to MONDO (289,715 patients across 20 years). Hemodialysis was the most used modality globally (**Table 1**). In Europe, Middle East & Africa, 63.2% of patients used hemodiafiltration (HDF) for ≥1 treatment. Peritoneal dialysis (PD) was used in 20% of patients in Latin America (LA) (20%) and 15% in North America (NA), yet ambulatory PD was more frequent in LA, while cycling PD was more frequent in NA. 11% of patients received a transplant. 42.5% died or stopped dialysis with some regional variability.

Conclusions: MONDO developed a new global research dataset to study dialysis outcomes, pathophysiology, and risk prediction. MONDO is open to collaboration and contributions without geographic restrictions.

Funding: Commercial Support - Fresenius Medical Care

TH-PO305

Volumetric Accuracy Testing (VAT) of a Novel Patient-Centric Gravity-Based Automated Peritoneal Dialysis Cycler (GBC) vs. Conventional Pump-Based Cyclers (PBC)

James A. Sloand,[1,2] Steve J. Lindo,[2] Rick Pendergraft.[2] *[1]The George Washington University Milken Institute of Public Health, Washington, DC; [2]Simergent, Oklahoma City, OK.*

Background: Safe and effective APD cycler function requires volumetric accuracy of fill and drain (F/D) volumes to accurately calculate achieved ultrafiltration (UF) critical to clinical outcomes in PD. PD fluid volume measurement in most contemporary APD cyclers is now pump, rather than gravity-based, partly due to unreliability of GBC load cells. However, PBCs contribute to device noise/sleep disruption and drain pain (in up to 47% of patients) from high suction pressures. VAT of a low cost, novel, newly engineered GBC designed to provide reliable F/D volumes was performed and values compared with reported F/D accuracy of conventional PBCs and another recently marketed GBC. In a recent blinded study, features of the novel GBC were rated far more favorably by PD patients & RNs than those of conventional PBCs.

Methods: VAT was performed collecting volume from both a Sartorius laboratory scale ("actual") and the new GBC ("measured"). VAT was performed on 3 tubing sets with a patient bag at 2 bed heights (36" & 20") and 2 F/D volumes (500ml & 3000ml). For both Fill & Drain, 5 cycles of 500ml (total 30 F/D cycles) and 3 cycles of 3000ml (total 18 F/D cycles) were tested. VAT was calculated as (measured-actual/actual) x 100%.

Results: Figures 1 & 2 show VAT results for Fill and Drain for 500ml & 3000ml F/D cycles at described bed heights. All 500ml Fills were within the required accuracy bounds of ±2%; all Drains were within the required accuracy bounds of ±3%. VAT for 3000mL volumes for both F/D was within ±1% volumetric error at both bed heights. Published F/D accuracy for FMC Liberty, Baxter HomeChoice, and FMC Silencia (GBC) are ±2%/±3%, ±2/±2%, and <±5%, respectively.

Conclusions: The novel low cost GBC with enhanced load cell technology & features previously demonstrated to be preferred by PD patients & RNs achieved F/D volumetric accuracy comparable to conventional PBCs and better than that of another recently marketed GBC. The new GBC has potential to significantly reduce drain pain, device noise & cost while maintaining UF accuracy.

A Feasibility Study to Establish Dialysate Flow Characteristics in Peritoneal Dialysis to Associate Outflow Dysfunction

Nupur Gupta, Kathleen A. Lane, Yang Li, Brent W. Miller. *Indiana University School of Medicine, Indianapolis, IN.*

Background: Peritoneal dialysis (PD) catheter dysfunction is the second leading cause of technique failure in PD after peritonitis. Failure to recognize this complication early result in techinique failure. Dialysate flow characteristics have been measured in the past for modeling automated PD dwell and drain time for clearance of solute rather than catheter dysfunction. We hypothesize dialysate flow characteristics are associated with outflow dysfunction.

Methods: The study was a prospective observational study measuring dialysate flow characteristics in incident PD patients. Dialysate flow rates were measured by standardized method weighing the drained volumes every 5 minutes up to maximum of 30 min or complete drainage of fluid up to 3 times during Training. The catheter-related complications were recorded during the study visits and then monthly up to 6 months. Patient characteristics at study entry were summarized by mean ± SD and proportions. Repeated-measure Poisson regression was performed to analyze incidences rates during and after training.

Results: 21 patients were consented; 3 withdrew. 17/21 patients had completed flow records. The mean age at study entry was 53.3 ± 16.9 years, and 58.8% were men. Two out of three training visits were used for analysis. The mean drain time for training visits (both sitting and reclined) was 17.9 ±8.1 min. 52.9% and 64.7 % of patients reported catheter related complications in training and follow up visits respectively. Drain pain was the most reported complication during training while catheter dysfunction was most common during follow up visits. SThe sitting total time ≥ 10 minutes from first training visit was associated with 83% lower odd risk incidents rates of complications in training (incidents rates ratio (IRR) - 0.17, CI - 0.050-0.581, P= 0.005). Catheter dysfunction in training was associated with complications during monthly visits (IRR -1.66, CI-1.01-2.73, P= 0.0477).

Conclusions: Our study established feasibility of measuring dialysate flow characteristics and reports PD catheter complication rate. The drain time ≥ 10 min is associated with reduced catheter related complications in training due to early intervention by the clinical staff. Catheter dysfunction in training increases the odds of complications during monthly visits.

Dynamical Monitoring of "Intraperitoneal" Pressures by a Sensor Integrated into a Peritoneal Dialysis (PD) Cycler: Proof-of-Principle Bench Studies

Fansan Zhu,[1] Laura Rosales M.,[1] Lela Tisdale,[1] Jun Yi,[2] Karsten Fischer,[2] Kulwinder Plahey,[2] Paul W. Chamney,[3] Brigitte Schiller,[2] Peter Kotanko.[1,4] *[1]Renal Research Institute, New York, NY; [2]Fresenius Medical Care, Waltham, MA; [3]Fresenius Medical Care (UK) Ltd, Huthwaite, United Kingdom; [4]Icahn School of Medicine at Mount Sinai, New York, NY.*

Background: We performed two bench studies utilizing a PD simulator. One evaluated the accuracy and precision of IPP measurements by a pressure sensor integrated in a PD cycler; the second assessed the relationship between IPP and intraperitoneal volume (IPV) during volume exchanges.

Methods: The first study was performed using a PD simulator filled with 2 liters of 2.5% dextrose dialysate (Fig.1). The IPP was monitored every 15 seconds by the Liberty Cycler (Fresenius Medical Care North America, Waltham, MA). The height (h) of the PD simulator was adjusted to increase in 6 steps and decrease in 5 steps. The height increment (Δh) was 5.08 cm; each step was maintained for 10 minutes. The change in pressure (ΔP) is calculated as ΔP=ρ*g*Δh, where ρ (density of dialysate) and g (acceleration of gravity) were kept constant. The coefficient of variation (CV% = 100*Mean/SD) of the IPP was obtained at each step. The second bench study kept the PD simulator at a constant height and IPP measurements were repeated 8 times. Regression analysis and Bland-Altman plots were performed to determine the relationship between calculated and measured IPP.

Results: Fig.2 shows the change in height (a) of the simulator and the concurrent increased and decreased in IPP (b) with the steps up and down. ΔIPP correlated (R^2=0.98, p<0.0001) with ΔP in each step (c). IPPs were accurately and precisely measured with a smaller bias (0.34±0.87 cmH_2O) and CV (2.5±1.9 %). IPP correlated with IPV (Fig.3) during filling (R^2=0.99, p<0.0001) and draining (R^2=0.86, p<0.0003) respectively.

Conclusions: This bench study shows that ΔIPP can be measured accurately and precisely by the pressure sensor integrated in the Liberty Cycler and that IPP measurements should be feasibly, non-invasively and automatically performed using a PD cycler equipped with a pressure sensor. Given the importance of IPP changes during a PD treatment, the technique could be a valuable tool to dynamically assess IPP.

TH-PO308

A Prospective, Multi-Center, Open-Label Assessment of Efficacy and Safety of the Quanta Dialysis System for Home Hemodialysis

Paul Komenda,[1] Wael F. Hussein,[2] Naveen K. Atray,[3] Doreen W. Bett,[4] Christopher T. Chan,[5] Matthew J. Diamond,[6] Gopa B. Green,[2] Nupur Gupta,[7] Bethany E. Karl,[8] Andrea G. Kattah,[9] Melvin Seek,[10] Suzanne Watnick,[11,12] Eric D. Weinhandl,[2,13] Reid Whitlock,[14] Lisa Bismarck,[1] Kelley L. Gorbe.[1]
[1]Quanta Dialysis Technologies Ltd, Alcester, United Kingdom; [2]Satellite Healthcare, San Jose, CA; [3]Capital Nephrology Group, Sacramento, CA; [4]DaVita Manheim Pike At Home, Lancaster, PA; [5]Toronto General Hospital, Toronto, ON, Canada; [6]Southeastern Clinical Research Institute, Chattanooga, TN; [7]Indiana University School of Medicine, Indianapolis, IN; [8]University of California San Diego, La Jolla, CA; [9]Mayo Clinic College of Medicine and Science, Rochester, MN; [10]DaVita Ocala Rkchd At Home, Ocala, FL; [11]Northwest Kidney Centers, Portland, OR; [12]University of Washington, Seattle, WA; [13]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN; [14]Seven Oaks General Hospital, Winnipeg, MB, Canada.

Background: Hemodialysis (HD) treatments in the United States (US) are typically delivered in a dialysis center. Home hemodialysis (HHD) reduces costs to healthcare payors while providing more flexibility to patients with kidney failure. The Quanta™ Dialysis System (Quanta Dialysis System) is a modern, user-friendly HD device. Whether it is equally safe and effective when operated by patients and caregivers in the US at home vs. healthcare professionals at a center is unknown. The purpose of this study is to determine non-inferiority of efficacy and safety of the Quanta Dialysis System in self-care HHD vs. in-center HD.

Methods: This is a prospective study set in 12 sites in the US. Adult patients with kidney failure currently undergoing dialysis for ≥90 days were eligible. Enrollment began November 2021 and continued during the Omicron wave of the COVID-19 pandemic. Participants received HD at their respective HHD training centers for 4-8-weeks. While dialyzing, participants and caregivers trained to use the device at home. Once deemed competent by a nephrology care team, participants performed supervised HHD during a transition week, then performed HHD with a care partner for 8 weeks. The primary efficacy outcome is dialysis adequacy measured by mean standardized weekly Kt/V. The primary safety outcome is a composite of adverse events.

Results: As of April 2023, 23 patients were enrolled. The mean age was 55.5 ± 13.1 years, mean weight was 95.6 ± 20.4 kg, 10 (43.5%) participants were female, and 17 (73.9%) had a fistula or a graft for dialysis access. Only 4 (17.4%) participants have previously dialyzed with an HHD device. To date, 15 patients have transitioned from in-center HD to HHD, including 11 (73%) who achieved competency by the 5th week of training. Eight patients have completed the study.

Conclusions: Data on successful completion of training suggests the Quanta Dialysis System is easy to use for patients with kidney failure in the US. As the final participants are projected to complete the study by August 2023, complete safety and efficacy comparisons between use of the Quanta Dialysis System in HHD vs. in-center HD will be reported at the time of presentation.

TH-PO309

Patient Reported Outcomes (PRO) Among Patients Receiving Home Hemodialysis (HHD) with the Tablo® Hemodialysis System

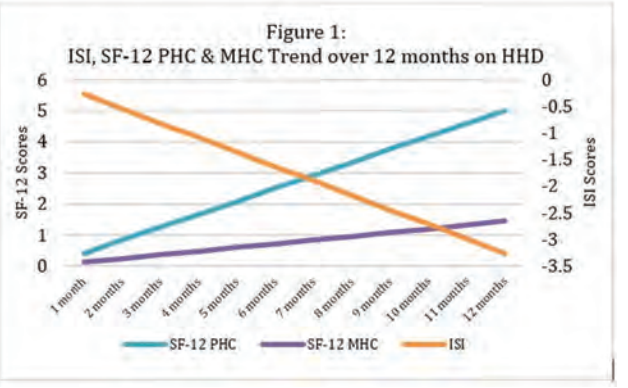
Jarnet H. Wazny,[1] Christie D. Holmes,[1] Cynthia J. D'Alessandri-Silva,[1] Glenn Chertow.[2] *[1]Outset Medical, San Jose, CA; [2]Stanford University School of Medicine, Stanford, CA.*

Background: The HOME Registry is an ongoing observational ("real world") study of patients with kidney failure utilizing the Tablo® Hemodialysis System (Tablo) for home hemodialysis (HHD). To date, relatively few studies have evaluated patient-reported outcomes among patients receiving HHD.

Methods: We evaluated the first 55 patients on Tablo HHD using an ePRO software at 1-, 3-, 6- and 12-month visits using: 1) Physical Health Composite (PHC) and 2) Mental Health Composite (MHC) scores from the Medical Outcomes Study Short Form 12 (SF-12) along with the 3) insomnia total score from the Insomnia Severity Index (ISI). We employed mixed effects regression for repeated measurements, using specific covariance matrix structures to allow for model convergence and to optimize model fit. We analyzed time (visit) as a fixed effect and age, designated race, education, employment, and care partner type as random effects.

Results: The mean patient age was 57.4 years old. The demographic composition was 76% men, 5.5% Black, 9% Hispanic/Latino, 39% with less than college degree attainment, 69% AV fistula, and 45% having transitioned from in-center HD. The SF-12 PHC and ISI had positive correlations with time, at p=0.046 and p=0.0035, respectively. Every 1 month increase in time was associated with a 0.417 increase in the SF-12 PHC and a 0.272 decrease in ISI score. There was no significant relation between time and the SF-12 MHC (p=0.19). Figure 1 shows modeled results for ISI and SF-12 PHC and MHC.

Conclusions: Preliminary results show favorable effects of Tablo-enabled HHD on self-reported physical health and symptoms of insomnia. Longer term follow-up in a larger patient sample will further elucidate the benefits of Tablo-enabled HHD on functional capacity, symptoms, and well-being.



TH-PO310

Characteristics of Tablo Home Hemodialysis Users in Medicare Fee-for-Service

Stephan C. Dunning,[1] Michael A. Aragon,[1] Cynthia J. D'Alessandri-Silva,[1] Eric D. Weinhandl.[2,3] *[1]Outset Medical, San Jose, CA; [2]University of Minnesota Twin Cities, Minneapolis, MN; [3]Satellite Healthcare, San Jose, CA.*

Background: The Tablo® Hemodialysis System was cleared for home hemodialysis (HHD) use in March 2020, offering dialysis patients the first novel technology for HHD since 2005. In the 2022 ESRD PPS Final Rule, the Centers for Medicare and Medicaid Services (CMS) designated Tablo a "substantial clinical improvement" over the incumbent technology based on increased treatment flexibility, higher treatment adherence, higher modality retention and improvement in patient quality of life. This designation made it eligible for Capital-Related Assets Transitional add-on Payment for Innovative Equipment and Supplies (CRA TPNIES).

Methods: Using CMS Medicare FFS Limited Data Sets, we identified Tablo HHD claims between Jan 1 and June 30, 2022, using HCPCS E1629, which was designated for billing the CRA TPNIES reimbursement. Importantly, TPNIES billing is not validated, so may under capture the true Tablo HHD population in Medicare FFS. We then summarized user characteristics, including age, sex, race/ethnicity, and concurrent Medicaid enrollment, as well as treatment characteristics.

Results: Between Jan 1 and June 30, 2022, there were 53 patients who collectively had 1,830 billed Tablo HHD treatments (Mean treatments per patient: 34.5, SD: 25.2). The mean (SD) age was 60.6 (15.5), with 51% age ≥65. Racial distribution was 28.3% Black, 49.1% White and 22.6% Other, and 34.4% of users had concurrent Medicaid enrollment. A summary of the billed treatments shows a mean (SD) weight of 82.9 (20.8) kg, and a mean (SD) hemoglobin of 9.8 (1.4) g/dL. Vascular access type in use was 42% Catheter, 58% Fistula. Based on billed Tablo HHD treatment volume, the total TPNIES add-on payments (assuming $25 per treatment) in the first half of 2022 are estimated to be $45,750.

Conclusions: This is a novel and early window into Tablo HHD users and treatments in the Medicare FFS population and a first estimate of the TPNIES add-on payment. Thus far, the population appears to be more elderly and diverse, and with greater catheter dependence than the broader HHD population. Additional research into Tablo HHD adoption, utilization and outcomes in the Medicare population will be important for understanding and advancing home dialysis growth overall.

TH-PO311

Characteristics of the First 500 Tablo Home Hemodialysis Users

Stephan C. Dunning, Hunter Kirk, Cynthia J. D'Alessandri-Silva, Michael A. Aragon. *Outset Medical, San Jose, CA.*

Background: The Tablo® Hemodialysis System was cleared for home hemodialysis (HHD) use in March 2020, offering dialysis patients the first novel technology for HHD since 2005. In the 2022 ESRD PPS Final Rule, the Centers for Medicare and Medicaid Services (CMS) designated Tablo a "substantial clinical improvement" over the incumbent technology based on increased treatment flexibility, higher treatment adherence, higher modality retention and improvement in patient quality of life. As adoption continues to grow, we sought to characterize the first 500 users in the Tablo HHD population.

Methods: We collected user-reported demographics and geographic information among the first 500 Tablo HHD users. Data include age, sex, race/ethnicity, employment status and Zip Code. Using Zip Code, we evaluated neighborhood characteristics such as Social Deprivation Index (SDI) and Rural status using RUCA 4+. Population characteristics are compared to similar data from the 2022 USRDS Annual Data Report, where feasible. The results are descriptive only using MS Excel. No statistical significance tests were performed.

Results: Across the basic demographics of age sex and race/ethnicity, the Tablo HHD population and USRDS HHD appear to have similar characteristics with several favorable trends. The first 500 Tablo HHD users versus USRDS HHD are: ● Slightly older: 35.2% vs 29.0%, Age 65+ respectively. ● Slightly more racially/ethnically diverse: 45.6% vs 52.8% White, 19.5% vs 30.6% Black, 11.5% vs 3.0% Asian and 18.1% vs 11.1% Hispanic, respectively. ● More unemployed, fewer retired: 33.5% vs 18.6% Unemployed,

38.8% vs 54.3% Retired, respectively. Socio-economic data show equitable adoption across strata, with SDI 1-33 (37.2%), SDI 34-66 (32.2%) and SDI 67-100 (30.6%). Rural and Urban status are 14.4% and 85.6%, respectively.

Conclusions: Continued improvement in equity across ethnic, racial and socio-economic status among all HHD patients is critical to successful expansion of home adoption in the US. The first 500 Tablo Home Hemodialysis users have similar characteristics to the overall HHD population reported by the USRDS with early favorable trends toward diverse and equitable adoption across racial and socio-economic groups.

TH-PO312

Utilization of Extended Training Decay Periods to Evaluate Training Effectiveness in Home Dialysis Devices

Brittany Lim, Keertana Sureshbabu, Elise Edson, Jarnet H. Wazny, Cynthia J. D'Alessandri-Silva, Michael A. Aragon. *Outset Medical, San Jose, CA.*

Background: When conducting medical device usability testing, users perform tasks under representative use conditions. A "training decay" in the study is a defined time period between user training and user testing to allow for representative memory decay. FDA 2016 guidance emphasizes the training provided to test participants should approximate the training that actual users would receive including training decay. In practice, medical device manufacturers typically utilize a 1-hour training decay to simplify scheduling logistics. Real-world training decay for home hemodialysis (HHD) patients ranges from several hours up to nine days before their first-time independent use. Here we present the results of a usability validation study evaluating extended training decay on the safe and effective use of the Tablo Hemodialysis System.

Methods: A human factors (HF) protocol was implemented with recruitment of 16 patient/care partner pairs (PCP) and 17 health care professionals (HCP). The PCP arm included 10 pairs without any prior HHD experience, and the HCP arm was composed of dialysis nurses and technicians. Each participant completed standard Tablo training, after which they experienced extended training decay periods ranging from 1 to 4 weeks. All participants then performed a simulated dialysis treatment (treatment setup, monitoring, and tear down) on Tablo. Task performance (use errors, close calls, and difficulties), subjective interviews and knowledge task assessments were recorded.

Results: The training decay averaged 16 days (min = 9 days, max = 28 days) for HCPs and 13 days (min = 6 days, max = 25 days) for patient/care partner pairs. Participants were able to complete all necessary tasks with minimal use error rates (0.32% and 0.65%), for HCPs and PCPs, respectively. Post testing, 100% of participants reported confidence in being able to use Tablo safely and effectively.

Conclusions: Objective evidence of effective training through HF validation is critical to ensuring safe use of home dialysis devices. Task performance from this study demonstrates the effectiveness of standard Tablo training in scenarios of extended training decay including and beyond actual use (up to 28 days). These results extend prior data on the usability and ease of learning Tablo for patients performing home hemodialysis.

TH-PO313

Hybrid Dialysis in Peritoneal Dialysis Patients with Low Solute Clearance or Volume Overload: Two Years' Experience

Mohammed E. Hussain, Musab Elgaali, Mohamad M. Alkadi, Ahlam B. Ali, Sahar Aly, Hanaa Ahmed, Abdullah I. Hamad, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar.*

Background: ESRD patients on PD prefer this modality because it allows them greater flexibility related to timing, a better lifestyle, and fewer dietary restrictions compared to HD. With the reduction in residual renal functions, the largest applicable PD regimen might not be enough to achieve adequate solute clearance or fluid removal. In such circumstances, convincing some patients to shift completely to hemodialysis is usually difficult. We started a Hybrid Dialysis (HyD) prescription for these patients by keeping them on PD 6 days per week and an HD session once per week. The safety and efficacy of HyD were evaluated.

Methods: Identified all PD patients with either low solute clearance or inadequate ultrafiltration despite using the maximum applicable PD regimen. They were referred to vascular surgeons for hemodialysis access then arranged HD slots. We enrolled eighteen patients from May 2021 till April 2023. All of them were kept on once-weekly hemodialysis for 3-4 hours plus PD 6 days per week. We evaluated volume status clinically, Pre-HD urea, potassium, phosphorus, and bicarbonate as indicators of solute clearance, and Albumin level as an indicator of nutritional state. In addition, dialysis-related Emergency Department visits and dialysis access-related infection rates after starting hybrid dialysis were also observed.

Results: Volume status significantly improved associated with a reduction in mean systolic blood pressure, (169 ± 32 Vs 135± 15 mmHg, $p < 0.0001$) and around a 5 % drop in mean dry weight. All solute clearance indicators showed significant improvement with HyD, reductions in mean urea by 36.7% (27.5 ± 8 vs 18.4 ± 7 mmol/L) p-value < 0.001, mean potassium by 23.52% p-value <0.0001 and mean phosphorus reduction of 26.5 % p-value <0.01. The rise in mean bicarbonate was by 15.6 % p-value <0 .001. Improvement of mean serum albumin from 26 ± 6 gm/L to 30 ± 7 gm/L p-value < 0.05. No ED visits or dialysis access-related infections were reported.

Conclusions: Hybrid dialysis is a safe, effective, and reasonable dialysis modality in PD patients with either volume-overloaded or low solute clearance. associated with an improved nutritional state & better control of BP.

TH-PO314

Urgent Start Peritoneal Dialysis (PD) as a Safe and Effective Dialysis Modality to Reduce the Dropout of Patients on Peritoneal Dialysis

Mohammed E. Hussain, Mohamad M. Alkadi, Tarek A. Ghonimi, Nahid I. Ali, Hanaa Ahmed, Abdullah I. Hamad, Hassan A. Al-Malki. *Hamad Medical Corporation, Doha, Qatar.*

Background: PD dropout became a major factor affecting the unitized PD program and created a new burden in the setting of limited HD slots. Our registry shows that almost 35-50 % yearly for the last 3 years of patients who choose PD as a permanent dialysis modality and started temporary HD through Permcath till the maturation of the PD catheter will change their mind and request to be kept on HD and removal of PD catheter even before starting PD training. Urgent start PD program started by keeping CKD 5 patients eligible to start PD on one vascular access (PD catheter) without Permcath insertion and start Peritoneal dialysis 48hrs post PD catheter insertion. The safety and efficacy of the program were evaluated through monitor any mechanical complications and patient satisfaction besides our regular parameters such as volume status and electrolytes.

Methods: Identified CKD-5 patients during ED visits with eithe an earlier plan for PD as a dialysis modality or having no plan. We evaluated the emergency and urgent need to start Renal replacement therapy. We created an Urgent Start PD pathway for those patients without the emergency need to start or who had an emergency need and became stable after starting HD through a temporary dialysis catheter. They were referred to vascular surgeons for PD catheter insertion after checking suitability and liability to Peritoneal dialysis. PD will start 48 hrs. after insertion. We enrolled sixteen patients from October 2022 till April 2023, all of them were started on APD but the final PD model is decided after completing both APD and CAPD training. Body surface area was the main factor that affected APD Prescription. Frequent PD clinic visits were arranged to readjust the PD regimen and monitor mechanical complications, patient satisfaction, volume status, and electrolytes.

Results: Almost all patients were discharged with satisfactory conditions & accepted electrolytes without any mechanical complications and with fewer dates of admission after starting the new program.

Conclusions: Urgent start PD seems to be a safe, effective, and reasonable way to reduce PD dropout in addition to reducing cost and total days of hospitalization. We need a larger number of patients and a longer duration to generalize the findings of these observations.

TH-PO315

Prevalence of Frailty and Symptom Burden in Patients on Staff-Assisted Peritoneal Dialysis

Wael F. Hussein,[1,2] Eric D. Weinhandl,[1,3] Graham E. Abra.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN.*

Background: Peritoneal dialysis (PD) is a preferred modality for patients with clinical or psychosocial consideration, but self-care can be challenging for some individuals. Staff-assisted PD offers support for patients to start or remain on PD. This study aims to evaluate the physical, cognitive, and emotional status of patients receiving staff-assisted PD.

Methods: Patients who received staff-assisted PD by April 2023 were included. Physical function was evaluated by the Clinical Frailty Scale (CFS; score >=5 indicating frailty), and the Katz Activities of Daily Living (ADL) surveys. Symptom burden (physical and emotional), cognition, and patient activation were evaluated using the Integrated Palliative Outcome Score (IPOS)-Renal survey, the Quick Mild Cognitive Impairment Screen (QMCI), and the Patient Activation Measures (PAM)-13-item survey, respectively. Surveys were completed after initiation of assistance. Descriptive analysis was performed on completed surveys.

Results: A total of 72 patients received staff-assisted PD. CFS, ADL, IPOS-Renal, QMCI, and PAM were completed by 72 (100%), 51(71%), 68(94%), 42 (58%), and 46 (64%) patients respectively. Frailty was identified by the CFS survey in 28% of patients, and 29% of ADL respondents were dependent in at least one activity. Of those who completed the IPOS-Renal survey, physical symptoms of moderate or worse severity were reported by 79% of patients, with weakness and poor mobility being the most common physical symptoms, while anxiety and depression at a moderate or worse severity was reported by 40% and 28% of the patients respectively. Mild cognitive impairment and dementia were identified in 15% and 28% respectively of those who completed the QMCI survey. Low activation (levels 1 and 2) was observed in 37% of patients.

Conclusions: Patients referred to staff-assisted PD experience significant physical and psychosocial challenges, underscoring the need for these programs to support home dialysis.

TH-PO316

Outcomes of Incident Peritoneal Dialysis Patients with Depressive Symptoms

Wael F. Hussein,[1,2] Eric D. Weinhandl,[1,3] Emily Watson,[1] Gopa B. Green,[1,2] Graham E. Abra.[1,2] *[1]Satellite Healthcare, San Jose, CA; [2]Stanford University School of Medicine, Stanford, CA; [3]University of Minnesota Twin Cities College of Pharmacy, Minneapolis, MN.*

Background: In 2016, CMS introduced annual depression screening as a reporting measure under the QIP. For incident dialysis patients, screening surveys are typically administered by social workers in the fourth month of modality initiation. This study aimed to explore the outcomes related to depressive symptoms in a contemporary cohort of incident peritoneal dialysis (PD) patients.

Methods: A retrospective observational study was conducted on patients starting PD for the first time between January 2017 and December 2022 at dialysis units managed by a mid-sized U.S. non-profit dialysis provider. Those who completed the PHQ2 survey within 150 days after starting PD were followed for 365 days from the date of survey completion. A PHQ2 score equal to or greater than 3 was considered positive. Univariate and age- and sex-adjusted Fine-Gray models were used to examine the association between time to transfer to hemodialysis (HD) or death, and time to first hospitalization, while Poisson regression was used for rate ratios.

Results: A total of 2,215 patients were included. Mean age was 58.7 ± 15.9 years, with 38% being female. PHQ2 surveys were positive in 75 (3.4%) patients. During the follow-up period, 16.3% transferred to HD, 3.7% died, and 6.5% received a kidney transplant. Patients with a positive PHQ2 survey were found more likely to experience transfer to HD or death (hazard ratios (HR): 1.99; 95% CI: 1.33 – 2.97, and 2.02; 95% CI: 1.35 – 3.03 in the unadjusted and adjusted models respectively). The hospitalization event rate was 1.45 and 0.75 events per patient-year for those with positive and negative PHQ2 results, respectively (Rate Ratio (RR) 1.95, 95% CI: 1.53 – 2.45). Similarly, hospital days per year were 11.06 and 5.44 days per patient-year for the PHQ2 positive and negative patients, respectively (RR: 2.03, 95% CI: 1.87 – 2.20). Lastly, a higher hazard for time to first hospitalization was observed in those with a positive PHQ2 survey (HR 1.62, 95% CI: 1.14 – 2.31, and 1.62, 95% CI: 1.14 – 2.30).

Conclusions: Among incident peritoneal dialysis patients, depression symptoms are associated with increased risk of transfer to HD or death and of hospitalization. This represents a potentially addressable risk factor for poor clinical outcomes that may be amenable to intervention.

TH-PO317

Nurse-Assisted Home Hemodialysis with NxStage System One Portable Machine: An Experience in the Gulf Cooperation Council (GCC)

Satarupa Gogoi. *HHD Home Healthcare LLC, Dubai, United Arab Emirates.*

Background: Home hemodialysis (HHD) is a renal replacement therapy applied to treat active, autonomous, and relatively, healthy dialysis patients. NxStage System One, portable dialysis machine suitable for home setting. NAHHD is an innovative modality for patients providing freedom choice in dialysis therapy. Indications for NAHHD in the GCC is due to Limited Mobility, CVA, Fractures, Morbid Obesity, Intolerance to conventional HD, Infections, Mental Retardation, Psychiatric disorder. Here, at NAHHD treating mostly debilitated and frail patients with comorbidities at home and long term care facilities. Presenting clinical outcomes of Home Hemodialysis treatment, at HHD, service provider in the GCC.

Methods: The study includes 566 patients undergoing HHD treatment, for atleast more than 3 months and thus one year report of the health outcomes with portable HD machine at home was done. Estimated the HD adequacy and key performance indicators. The frequency and length of session, fluid volume calculated by dose calculator by NxStage, with target standardised KT/V ≥2.1.

Results: The total number of 566 patients (X) on NxStage machine at home and at long term care facility were included in the study. Study group selected based on duration i.e., (X >3 months). Female- 52.65% and Male- 47.35%. The mean average age of the patients, 69.06 ± 14.63. The average comorbidities: 6.114 ± 3.45 (Min-2, Max-16). The vascular access: AVF- 25.27%, AVG- 3.53%, PC- 70.67%, AVF/PC- 0.53%. The yearly average of the biological parameters with HD adequacy are shown in Table 1. The annual mortality rate is 18.02%, as shown in Graph 1.

Conclusions: The results as shown states efficient and remarkable health outcomes. Moreover, the mortality rate of the HHD patients as comapred to the US Renal Data System, shows better quality of therapy and retention in patients.

TABLE 1: HD ADEQUACY & BIOLOGICAL OUTCOMES

HD ADEQUACY	YEARLY AVERAGE
Session Length (minutes)	222.75
Number of Sessions/Week	3.90
Filtration/Flow Fraction (FF%)	49.58
Dialysate Volume (L)	31.35
Post weight (Kg)	67.40
UF Volume (L)	1.96
HB (g/L)	107.39
Albumin (g/L)	36.77
Serum Calcium (mmol/L)	2.28
PO4 (mmol/L)	1.47
K (mmol/L)	4.98
PTH (pg/mL)	440.88
Std Kt/V	2.19

TH-PO318

Assisted Home Hemodialysis: A Game-Changer for Patients and Providers

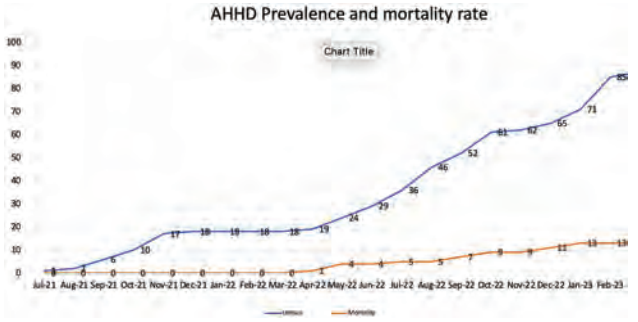
Abdullah I. Hamad, Mohamed Mohamed, Mostafa Elshirbeny, Mossab Filali, Dina N. Alkhayyat, Ahmed Adel H. Abd El Wahed, Ismail Alzalma, Mohamad M. Alkadi, Hassan A. Al-Malki. *Hamad General Hospital, Doha, Qatar.*

Background: Home hemodialysis HD (HHD) offers autonomy, cost benefits, and better quality of life. Uptake of HHD is limited by patient motivation and cognitive and physical barriers. Assisted HHD (AHHD) is a new concept where dialysis team provides HD at home but it is limited due to financial and logistics restriction. We are reporting success and outcomes of our AHHD program in the State of Qatar.

Methods: A Retrospective study of all HD patients who are enrolled in AHHD program between 7/2021 to 2/2023. Inclusion mainly for elderly patients requiring ambulance transportation to the dialysis center. Primary objective was effectiveness and safety of AHHD and secondary objectives were cost effectiveness and quality of life.

Results: 85 patients enrolled in our AHHD program during study period with a mean follow up of 7 months (total 5968 HD treatments). Age was 71+/-10 years with 45% males. 13 patients died and 2 patients returned to dialysis center. We had 8 incidents of HD catheter malfunction and 20 technical incidents resolved without affecting program flow. No reported significant access bleeding, falls or hypotension episodes. We found a significant decrease of 43% in hospitalization rates compared to 6-month pre-study period. The program proved to be cost-effective, resulting in a reduction of costs by 27%, primarily attributed to savings in ambulance transport expenses. Key performance indicators, including adequacy, anemia, and mineral and bone management were maintained. In a survey, patients and families expressed an extraordinary level of satisfaction, with rates exceeding 98% in all assessed categories.

Conclusions: We present our program for AHHD, designed for frailed dialysis population. This initiative has yielded exceptional outcomes, substantial cost savings, exemplary safety measures, remarkable enhancements in quality of life, and an extraordinary level of patient satisfaction.



AHHD prevalence and mortality rate

TH-PO319

Medication Management with Antihypertensive Agents and Associations with Peritoneal Dialysis Technique Failure in a Large, Retrospective Incident Cohort

Billy Kim,[1] Gennady Kutovoy,[1] Joseph Warzyn,[1] Marissa A. Lee,[1] Rachel A. Lasky,[2] Linda Ficociello,[2] Dinesh K. Chatoth.[2] *[1]FreseniusRx, Franklin, TN; [2]Fresenius Medical Care, Global Medical Office, Waltham, MA.*

Background: The first 90 days of peritoneal dialysis (PD) have high rates of PD technique failure (TF). Although many factors determine patients' (pts) longevity on PD, only some are potentially modifiable. Proper management of antihypertensive medications (AH-M) is one modifiable factor that may help to control blood pressure and fluid balance. We aimed to assess the association between AH-M and PD TF at 90 days.

Methods: Adult, ESKD pts first prescribed PD at Fresenius Kidney Care (FKC) facilities between 2017-2019 were included. Deidentified data were extracted from the clinical data warehouse. Medication classification was conducted by clinical pharmacists. Case-mix adjusted Cox regression models were used to evaluate the associations between AH-M and PD TF. Subanalyses were conducted based on residual renal function (RRF).

Results: Pts included (n=22,908) were often treated with AH-M (91%). There was a trend toward any AH-M being protective of PD TF (HR: 0.85, p=0.06). However, certain AH-M subclasses had stronger associations than others (Table). Treatment with any diuretic (54% of pts) was associated with 17% lower technique failure rate (p=0.001) compared to no diuretic. Subclasses of diuretics were associated with lower TF (15% for loop diuretics and 18% for other diuretics). ACEi were associated with lower rates of PD TF (19%, p=0.0047), whereas remaining subclasses showed no association. There was no association with diuretics in the pts without RRF (Table).

Conclusions: In a large population of incident PD pts, we observed that several AH-M subclasses were associated with reduced rates of PD TF after controlling for many non-modifiable case-mix variables/confounders.

The Effect of Implementing a Dialysis Start Unit on Modality Decision Among Patients with Urgent Start Kidney Replacement Therapy

Shira Goldman,[1,2] Joanne M. Bargman,[1,3] Charmaine E. Lok,[1,3] Anna M. Gozdzik,[1,3] Jeffrey Perl,[1,4] Christopher T. Chan.[1,3] *[1]University of Toronto, Toronto, ON, Canada; [2]Rabin Medical Center, Petah Tikva, Israel; [3]Toronto General Hospital, Toronto, ON, Canada; [4]Division of Nephrology, St. Michael's Hospital, Toronto, ON, Canada.*

Background: Many individuals start dialysis in an acute setting with suboptimal pre-dialysis education. The dialysis start unit (DSU) is a program performing in-center hemodialysis (HD) in a separate space while providing support and education on chronic kidney disease and treatment options in the initial weeks of kidney replacement therapy. We aimed to assess the uptake of home dialysis therapies between 2013-2021 among patients who started acute inpatient HD at University Health Network, Toronto and underwent dialysis at the DSU.

Methods: This is a retrospective observational cohort study based on prospectively collected data. Patients' demographics were obtained from electronic charts. In the DSU, all patients received dialysis modality education by a nurse educator, dedicated home dialysis nurses, and the allied health care team.

Results: During 2013-2021, 122 patients were dialyzed in the DSU and included in the study. Among those patients, 68 patients ultimately chose home dialysis (57 peritoneal dialysis and 11 home HD). Fifty-four patients continued in-center HD. Patients adopting home dialysis were less likely to have diabetes and hypertension as the etiology of kidney failure and more likely to have glomerulonephritis or vasculitis.

Conclusions: Dialysis modality education is implementable in advanced chronic kidney disease. Individualized education and care after urgent start dialysis can potentially enhance home dialysis choice and utilization.

	Home dialysis (n= 68)	In center hemodialysis (n=54)

Participation in a CKD Navigator Program Is Associated with Improved Quality of Dialysis Starts

Jeffrey M. Rimmer. *University of Vermont, Burlington, VT.*

Background: Initiation of chronic dialysis is frequently accompanied by the use of central venous catheters, hospitalisation and need for in-center hemodialysis. Optimal start dialysis with a permanent access, in an oupatient setting and with the patient's choice of modality is suggested to improve patient quality of life as well as reduce complications and cost. Education, coaching and monitoring of patients as they approach End-Stage Kidney Disease (ESKD) are proposed to increase the probability of optimal starts.

Methods: The University of Vermont Medical Center (UVMMC) began enrolloing persons with an eGFR $\leq$ 20 ml/min/1.73m^2 in a CKD navigator program in November 2020. The program provides education, assessment, planning, coaching and monitoring. From November 2020 through April 2023, 270 patients were approached to participate, 180 agreed (67% engagement rate) and 127 had completed a plan for ESKD and were being monitored. During this same period, 141 UVMMC patients started dialysis, 33 of whom were followed in the navigator program. The 141 starts were assessed for a permanent access (PermAcc), outpatient location (OP) and whether they were in a home program (HOME) then grouped according to participation in the program (NAV) or not (NoNAV). Starts with the combinationof PermACC+OP and PermAcc+OP+Home were also compared. The significance of differences between groups was assessed by Chi Square analysis with Yates correction when appropriate.

Results: For numerical results see findings in Table. Patients participating in the navigator program were statisically more likely to start with a permanent access and in a home program. Combinations of these characteristics with an outpatient start also were statistically more common in navigator participants. Starting dialysis in an outpatient setting as a single finding was not different between groups.

Conclusions: Although lacking radomization, this observational study supports the proposal that patient participation in a CKD navigator program improves the quality of dialysis starts.

Experience with Remote Monitoring of Automated Peritoneal Dialysis: The First 50 Patients in a Private Peritoneal Dialysis Program in Mexico

Ismael A. Gómez Ruiz. *Médica Santa Carmen, Mexico City, Mexico.*

Background: The benefits of remote monitoring (RM) of automated peritoneal dialysis (APD) have been established, the aim of this study is to describe the characteristics and outcome of the first 50 patients who were mantained in APD with RM, from November 2019 to February 2022 in a private peritoneal dialysis program in Mexico City. Also, we analyzed time and distance traveled savings for patients.

Methods: Retrospective cohort study. This was an observational study, describing the main clinical outcomes in our patients maintained in APD with RM.

Results: A total of 50 patients were admitted to the study. Their mean age was 62.5 years. Most patients lived in an urban setting. 2 patients were lost to follow-up. The main causes of end stage renal disease were diabetes mellitus (60%) and hypertension (20%). The basal frequency of clinic visits was 1 per month; During the study, 92% of the prescribed PD sessions were completed. Just 2% of prescribed sessions were interrupted, and 6% were missed treatments. The median lost dwelling time was 78 minutes per patient-month (range 0-366), the mean number of prescription changes was 3 (range 0-8). Among patients who had a change in prescription during the study, the main adjustment was an increase in infusion volume and time spent on treatment (57%). Icodextrin 7.5% was prescribed, 16% of the prescribed PD sessions. The leak rate was only 5%. Peritonitis rate was 0.36 episodes/patient-year, both episodes were caused by gram positive microorganisms. 1-year PD catheter migration rate was 30%, most catheters were placed by a variety of surgical techniques (65%). 1-year PD catheter patency rate was 75%. Weekly Kt/V mean was 1.60 (± 0.28). 1-year PD technique survival was 60 %, the main causes of PD technique failure were mechanical failure (35%) and infections (35%). Twelve patients died during the study, the main cause was infections 50% (COVID-19 25%). The distance traveled by patients was reduced by 534 km with a time saving of 804 min for patients.

Conclusions: APD with RM allows a better use of healthcare resources, helping to improve patients follow up and remote early prescription modification. The main outcomes rates were similar than previously reported in similars countries. It is important to consider the COVID-19 pandemic impact on these results.

TH-PO323

Machine Learning for Identification of Near-Term All-Cause and Cardiovascular Death Among Patients Undergoing Peritoneal Dialysis

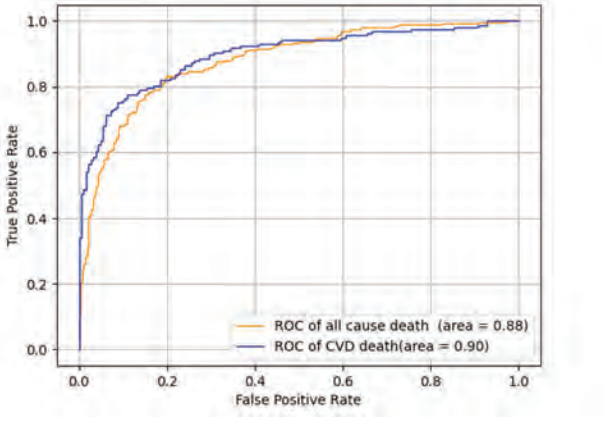
Xiao Xu, Jie Dong. *Peking University First Hospital Department of Nephrology, Beijing, China.*

Background: Although more and more cardiovascular risk factors have been verified in peritoneal dialysis (PD) populations in different countries and regions, it is still difficult for clinicians to accurately predict who will have cardiovascular events and when the cardiovascular events will occur and cause death. We developed and validated machine learning-based models to predict near-term all-cause and cardiovascular death.

Methods: Machine learning models were developed on the Peritoneal Dialysis Telemedicine-assisted Platform Cohort (PDTAP) of 7539 PD patients enrolled between June 2016 and April 2019, which was randomly divided into a training set and an internal test set by 5 random shuffles of 5-fold cross-validation, to predict of 3-month cardiovascular death and all-cause death. We chose objectively collected markers such as patient demographics, clinical characteristics, and laboratory, and dialysis-related variables to inform the models and assessed the predictive performance using a range of common performance metrics, such as precision, accuracy, and area under the curve (AUC).

Results: CVDformer model was used to predict 3-month cardiovascular death of PD patients. In the test set, CVDformer model had a precision of 87.96% - 89.45% and an accuracy of 86.10% - 88.74%. best than the LSTM model had 78.78% - 80.45% for precision and 76.53% - 79.12% for accuracy. The AUC was 0.88-0.90 in identifying the presence of near-term all-cause death and cardiovascular death using the CVDformer model.

Conclusions: We developed and used a novel combination of machine learning methods to assess the all-cause mortality risk and cardiovascular death risk in 3 months. The ability to identify the potential risks of all-cause and cardiovascular death with an inexpensive, widely available, and automatic procedure has important practical implications, particularly for the management of dialysis patients.



TH-PO324

Computational Models of Peritoneal Dialysis

Sangita Swapnasrita,[1] Joost C. de Vries,[2] Carl M. Öberg,[3] Karin G. Gerritsen,[2] Aurélie Carlier.[1] *[1]Universiteit Maastricht, Maastricht, Netherlands; [2]Universitair Medisch Centrum Utrecht, Utrecht, Netherlands; [3]Lunds Universitet, Lund, Sweden.*

Background: *In silico* models may play a vital role in improving patient-specific kidney replacement therapies. Recent advances in mathematical modeling include models of kidney physiology (e.g. regarding sex-specific differences, solute, drug and toxin transport and their interactions). Various models have been generated for peritoneal dialysis (PD) as well, but what lacks is a benchmarking of the different models on the same (pre-) clinical dataset. Here, we look at previously published models of PD and benchmark the efficiency of the models in predicting time-dependent evolution dialysate concentrations of six solutes.

Methods: Two mechanistic models (Graff, Öberg (modified for static dwells; this model is also modular and has been applied to automated PD and continuous flow PD)) and two analytical models used in clinical practice and research (Garred, Waniewski) were chosen. The four models, in combination, encompass various mechanisms that are essential to PD (diffusion, convection, lymphatics). The dataset consisted of data from multiple static dwells (n = 16) in uremic pigs. Each model was trained by fitting the dialysate solute concentrations (in a subset of the dwells) to predict the mass transfer area coefficient (MTAC) of each solute. With the fitted MTAC, we predicted the dialysate solute concentrations in the remaining dwells.

Results: The (modified) model by Öberg appears to be the optimal model in terms of low error in solute concentration predictions, applicability of the model to multiple datasets (with different initial dialysate concentration), physiological MTAC values and reasonable ultrafiltration values in pigs. Applying the modified Öberg model to the data obtained in the uremic pig experiments showed a good predictive accuracy (Figure 1). Notably, this model accurately predicted the effects of sodium sieving, whereas other models did not.

Conclusions: The modified Öberg model provided an accurate prediction of solute concentrations throughout a static dwell in uremic pigs.

Robust Joint Models of Albumin and All-Cause Mortality in Incident Peritoneal Dialysis Patients: A Dynamic Predictions Perspective Adjusting for Competing Risks

Ivan Damgov,[1,2] Meinhard Kieser,[2] Peter Rutherford,[9] Mark Lambie,[3,4] Simon J. Davies,[3,4] Muh Geot Wong,[7] Carol A. Pollock,[8] David W. Johnson,[5,6] Claus Peter Schmitt.[1] *[1]Center for Pediatric and Adolescent Medicine, University of Heidelberg, Heidelberg, Germany; [2]Institute of Medical Biometry, University of Heidelberg, Heidelberg, Germany; [3]Faculty of Medicine and Health Sciences, Keele University, Stoke-on-Trent, United Kingdom; [4]Renal Unit, Royal Stoke University Hospital, University Hospitals of North Midlands NHS Trust, Stoke-on-Trent, United Kingdom; [5]Australasian Kidney Trials Network, University of Queensland, Birsbane, QLD, Australia; [6]Department of Nephrology, Princess Alexandra Hospital, Brisbane, QLD, Australia; [7]Department of Renal Medicine, Royal North Shore Hospital, St Leonards, NSW, Australia; [8]Kolling Institute, Sydney Medical School, University of Sydney, Royal North Shore Hospital, St Leonards, NSW, Australia; [9]Baxter Healthcare Corporation, Zurich, Switzerland.*

Background: Joint models (JM) allow investigation of association between longitudinal biomarkers and mortality in patients on peritoneal dialysis (PD) and provide individual patient dynamic risk predictions. Yet, deviations from JM assumptions in dialysis trial data and consideration of competing events remain unexplored.

Methods: We evaluated the association of albumin with all-cause mortality in incident PD patients followed over 8 years in the Initiating Dialysis Early And Late trial. To account for skewness/outliers in albumin, novel JM with mixed effects sub-model with skew-normal, t and skew-t errors were compared with conventional JM under normal distribution. Furthermore, we adjusted for the competing events of transfer to hemodialysis and transplantation using Weibull cause-specific hazards. The dataset (N=314 patients) was randomly split into training dataset (3/4, N=236) for model fitting and validation dataset (1/4, N=78) to infer predictive performance. We obtained 6-month individual patient survival predictions from all JM at cut-offs 1, 1.5 and 2 years utilizing albumin trajectory and baseline risk factors.

Results: A median of 9 albumin records per patient and a 35% death rate with median time-to-event of 4.5 years ensured convergence of all 16 joint models. Albumin hazard ratio of death remained robust (0.78 to 0.81), suggesting significant inverse relationship between albumin and death across all models. Longer follow-up improved the prediction accuracy of all JM in the validation dataset. JM with competing events outperformed JM with survival only (area under the curve (AUC) ranges at 1, 1.5 and 2-years: 0.53-0.57 vs 0.52-0.55, 0.75-0.80 vs 0.75-0.77, 0.84-0.90 vs 0.82-0.88), regardless of the distribution assumption for albumin. Prediction performance of all JM surpassed classical Cox model with baseline albumin (AUC = 0.46, 0.70, 0.75). Results were confirmed by two simulation studies.

Conclusions: This first comprehensive JM in dialysis patients demonstrates utility for dynamic personalized survival prediction, with robustness of estimates to deviations from normality and higher predictive accuracy when adjusting for competing risks, and marked superiority to the classical Cox approach.

TH-PO326

Random Forest Can Accurately Predict the Technique Failure of Peritoneal Dialysis-Associated Peritonitis Patients

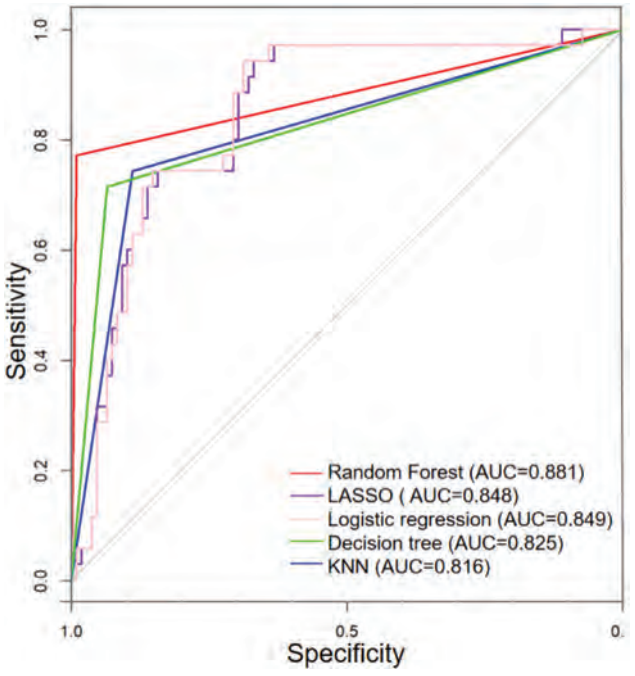
Zi Li, Zhiyun Zang. *Institute of Nephrology, West China Hospital of Sichuan University, Chengdu, China.*

Background: Peritoneal dialysis associated peritonitis (PDAP) is a major cause of technique failure in peritoneal dialysis (PD) patients globally. The purpose of this study is to construct a risk prediction model which could accurately predict the technique failure in PDAP patients.

Methods: This retrospective cohort study included maintenance PD patients in our center from January 1, 2010 to December 31, 2021. Technique failure was defined as catheter removal, transfer to hemodialysis (HD) or peritonitis-related death. The risk prediction models for technique failure in PDAP patients were constructed based on five machine learning algorithms: random forest (RF), the least absolute shrinkage and selection operator (LASSO), decision tree, k nearest neighbor (KNN), and logistic regression (LR). And the internal validation was conducted in the test cohort.

Results: A total of 574 episodes of peritonitis during the 12 years were included in this study. The technique failure accounted for 23.69%, and the mortality rate was 4.00%. There were significant statistical differences between the technique failure group and the technique survival group in multiple baseline characteristics. The RF prediction model is the best able to predict the technique failure in PDAP patients, with the accuracy of 93.75% and AUC of 0.881. And the model had sensitivity and specificity of 77.14% and 99.08%, respectively.

Conclusions: RF prediction model could accurately predict the technique failure of PDAP patients, which demonstrated excellent predictive performance and assist in clinical decision making.



ROC curves of prediction models based on machine learning algorithms

TH-PO327

Modifiable Physical Factors that Influence Physical Function for People Receiving Peritoneal Dialysis

Brett Tarca,[1] Shilpa Jesudason,[2] Paul N. Bennett,[1] Thomas Wycherley,[1] Katia Ferrar.[1] *[1]University of South Australia Allied Health & Human Performance Academic Unit, Adelaide, SA, Australia; [2]Central Adelaide Local Health Network, Adelaide, SA, Australia.*

Background: People receiving peritoneal dialysis experience physical function decline, impairing their ability to complete everyday activities, leading to poorer quality of life. Physical factors including cardiorespiratory fitness, muscle strength, physical activity and sedentary behaviour are associated with physical function, and considered modifiable, as they can be altered through intervention. However, little is known about the interrelationship between the factors and physical function or how these factors change over time in this cohort. This study aimed to explore modifiable physical factors that are associated with physical function, identifying which has the strongest influence, and explore temporal changes.

Methods: Adults receiving peritoneal dialysis underwent assessments for objective (Short Physical Performance Battery) and self-report (Short Form-36 Physical Function) physical function, cardiorespiratory fitness (six-minute walk), muscle strength (quadricep, bicep, abdominal, hand-grip strength), physical activity (accelerometry) and sedentary behaviour (inclinometery) on three occasions over a 12-month period (baseline, 6-months, 12-months).

Results: Eighty-two participants (mean age 61.4 years) underwent assessments. All modifiable physical factors were predominantly moderate to strongly associated with physical function at baseline. Through the observation period, cardiorespiratory fitness had the strongest and most consistent influence with every metre conferring a 0.08-unit ($p < 0.01$) and 0.01-unit ($p < 0.05$) increase in self-report and objective physical function score, respectively. Temporal changes were observed for modifiable physical factors with significant mean changes in cardiorespiratory fitness (-9.8%), quadricep strength (-5%), moderate-vigorous (-25.9%) and total (-16.2%) physical activity, and sedentary behaviour (+7.1%).

Conclusions: The results of this study indicate that cardiorespiratory fitness could be routinely monitored to detect risk of physical function decline and targeted through intervention to enhance physical function for people receiving peritoneal dialysis. Nevertheless, all factors should be considered when designing interventions to mitigate temporal changes and induce the numerous health benefits offered.

TH-PO328

Home Therapy New Patient Experience Survey Assessment for New Home Dialysis Patients

Derek M. Blankenship,[1] Namrata Wadhwa,[2] Judy Green,[2] Aakash M. Dharmadhikari,[2] Joanna Willetts,[1] Len A. Usvyat,[1] Franklin W. Maddux.[1] *[1]Global Medical Office, Fresenius Medical Care, Waltham, MA; [2]Care Delivery, Fresenius Medical Care, Waltham, MA.*

Background: Home hemodialysis (HHD) and peritoneal dialysis (PD) patients with an email receive a Home Therapy New Patient Experience Survey (PES) 21 days after initiating treatment. Feedback gathered from the survey is used to identify and address problems early and patients are referred for clinical support as needed. The aim is to listen and respond to patient feedback early in their journey, improve experience and clinical and health outcomes, thereby increasing home dialysis retention rates. The purpose of this study is to assess these aims.

Methods: 11,793 PD and 2,156 HHD patients who received a PES between 5/1/19 and 2/28/21 are compared to matched patients of the same modality who did not receive a survey. Controls were chosen using propensity score matching with confounders including month of first order occurrence, age, gender, race, ethnicity, state, urban/rural, BMI, residual kidney function, vintage, vascular access type, comorbidities, and primary insurance. Outcomes include 1 year follow-up status (maintained modality, in-center HD [ICHD], other home modality, transfer, transplant, or death), and hospitalizations. Analysis included Cox proportional hazards model and bootstrap methods with =0.05.

Results: PD: Compared to controls, PES patients were 15% less likely to switch to ICHD, 25% more likely to have a transplant, and had fewer hospitalizations. Not statistically significant but directionally positive, survey patients were 21% more likely to switch to HHD, 16% less likely to transfer to a non-Fresenius clinic, and had fewer days hospitalized. **HHD:** Compared to controls, survey patients were 49% less likely to switch to ICHD, 71% less likely to switch to PD, 48% less likely to transfer to a non-Fresenius clinic and had fewer frequency and duration of hospitalizations. Not statistically significant but directionally positive, survey patients were 34% more likely to have a transplant.

Conclusions: This study provided evidence that proactively and consistently listening to patients to understand their experience on home dialysis and taking action based on their feedback, often in real-time, can help prevent issues escalating, improve patients' overall health outcomes, increase patient retention on home and their overall loyalty to Fresenius Kidney Care as a dialysis provider.

TH-PO329

Patient-Reported Experience Measure of Home Haemodialysis Dialysis at Imperial College Renal and Transplant Centre

Oshini Shivakumar,[1,2] Emily Davenport,[2] Neill D. Duncan,[2] Eden Jeanne Cacal,[2] Sally Punzalan,[2] Normandy L. Coloma.[2] *[1]Imperial College London Institute of Global Health Innovation, London, United Kingdom; [2]Hammersmith Hospital, London, United Kingdom.*

Background: There is a drive to expand home dialysis in the United Kingdom. Instruments to explore patient reported experience measures (PREM) are vital to identifying barriers to home dialysis. In 2021, Rivera et al developed the first English language instrument which incorporates aspects of service widely recognised as key components of high-quality home dialysis care.

Methods: An observation study of patient experience of home haemodialysis (HHD) in West London Renal and Transplant Centre. In June 2022, with permission from Rivera et al, we approached all patients on HHD with an adapted questionnaire.

Results: 29 of 37 patients responded. Table 1 lists demographics. 20 patients had been on HHD for 1 to 5 years, and 4 patients for more than 5 years. One patient had been on HHD for ≤ 3 months, hence excluded in further analysis. 24 patients rated their overall mental or emotional health as either 'Good', 'Very good' or 'Excellent'. 9 reported of difficulty doing errands alone, such as visiting a doctor's office or shopping. 24 patients reported 'Usually' or 'Always' staff spent enough time with them. 21 patients felt the staff were 'Usually' or 'Always' able to help with problems encountered during HHD. 26 patients felt involved in treatment decision and 27 reported their HHD team made sure their dialysis plan worked for them. All 28 patients reported confidence in caring for their dialysis access and performing their dialysis safely at home.

Conclusions: This is a diverse cohort with bias towards patients with higher educational attainment, functional independence and reduced burden of comorbidities. Approachability of staff, structured guidance and an individualised treatment plan aid sustainability of HHD. To reassess in June 2023, for continuing development.

Patient and Care Partner Perspectives of Psychosocial Issues While on Home Dialysis

Ayesha Anwaar,[1,2] Wael F. Hussein,[2,1] Karine E. Manera,[3] Nicole J. Scholes-Robertson,[3,5] Jenny I. Shen.[4] *[1]Stanford University, Stanford, CA; [2]Satellite Healthcare, San Jose, CA; [3]The University of Sydney, Sydney, NSW, Australia; [4]Harbor-UCLA Medical Center, Torrance, CA; [5]Flinders University, Adelaide, SA, Australia*.

Background: Home dialysis has many advantages but requires initiative from patients and care partners. Without proper support, patients run the risk of burning out. We sought to explore patients' and care partners' perspectives and experiences of the psychosocial factors that make home dialysis challenging, contribute to burnout, and ultimately lead to transfer to in-center hemodialysis (ICHD).

Methods: We conducted 5 focus groups and 3 semi-structured interviews of 18 adult English-speaking patients and 11 care partners with experience with home dialysis, 16 who had transferred to ICHD, and 13 who were identified as high risk for transfer to ICHD. Transcripts were thematically analyzed.

Results: We identified three themes: 1) being overwhelmed by the reality of dialysis, 2) the exhausting monotony of treatment, and 3) ongoing psychosocial impacts. Participants found it overwhelming to depend on a lifesaving therapy, manage comorbid conditions and deal with machine issues. The exhausting monotony of treatment entailed the burden of time and responsibility required for home dialysis and continually planning/storing dialysis equipment and supplies. Psychosocial impacts included feeling isolated, fear of making a fatal mistake, feeling dependent on others, dealing with body disfigurement issues, and negatively impacting relationships.

Conclusions: Performing home dialysis can be a daunting task for patients and care partners. Care teams need to identify and understand the psychosocial struggles to implement effective support strategies for patients and care partners.

Illustrative Quotes

Theme	Subtheme	Quotes
Overwhelmed by reality of dialysis	Concurrent management of co-morbidities	"Yeah because of her diabetes and the fact that the dextrose in the [dialysis] bags makes her sugars worse."
	Frustration at ongoing machine issues	"It started out pretty rough and that was due to equipment failure. It's a complicated machine, but those failures are draining on me."
	Burden of time required	"The first phrase that comes to my mind, I think about dialysis is that it takes time."
Exhausting monotony of treatment	Drowning in responsibility	"It's just a hell of a responsibility with everything or even just with a partner. It's just a lot, a lot to do."
	Continual Logistics and storage management	"I guess it really didn't hit me until all of the supplies started showing up the machine. Just all these little fine details that you really don't think of."
	Feelings of isolation	"You feel like you're on an island by yourself, like you just don't have anywhere to turn."
Ongoing psychosocial impacts	Negatively impacting relationships	"To be honest, we would take it at each other a lot of times, like his stress would be taken out on me and vice versa."
	Fear of making a fatal error	"You know, like the horror stories you would hear about if air got in so he would panic."
	Crippling dependence on others	"First of all, if they were by themselves, I don't know how you do it."

TH-PO331

A Survey on the Prevalence of Burnout Among Peritoneal Dialysis Patients and Caregivers in Performing Peritoneal Dialysis

Yung An Chen, Yi-Ting Chen, Yu-hsiang Chou, Shuei-Liong Lin. *National Taiwan University Hospital, Taipei, Taiwan.*

Background: PD patients or their caregivers should regularly perform PD fluids exchanges 1-4 times per day. Some PD patients are still unable to accept their kidney damage and require dialysis to keep their lives. Previous studies have shown that emotional and social deficits are the major causes of burnout of PD patients. The study's aim is to survey the prevalence and risk factor of burnout in PD patients and their caregivers in performing PD.

Methods: We used two questionnaires the Maslach Burnout Inventory (MBI) and the State-Trait Anxiety Inventory (STAI) to investigate PD patients and caregivers who were the primary operator performing PD. The MBI questionnaire includes three main dimensions (emotional exhaustion, depersonalization, and reduced sense of personal accomplishment), 22 items, and a scale of 0-6 to indicate the severity of symptoms. The definition of burnout in MBI is high emotional exhaustion(cutoff score=7.78) and high depersonalization (cutoff score=22.36). The STAI questionnaire consists of state anxiety and trait anxiety, each containing 20 items, and each item is rated on a scale of 1-4.

Results: A total of 107 PD operators including PD patients and their caregivers, were enrolled for our study from April 2023. One of them withdrew due to peritonitis in the past 3 months, and 5 refused to participate due to lack of interest. In the final sample of 101 patients, mean age was 54 years old, and 49.5% were female. Ninety (89%) participants were patients and the remainder were caregivers. Median PD vintage were 3.5 years. In the MBI questionnaire survey, 22 patients (21.8%) had a high exhaustion score; 9 cases (8.9%) had a high score of cynicism (>22.36); 63 patients (62.4%) had a high Professional Efficacy (>28.2). On the STAI questionnaire, the mean score for state anxiety was 35.5, and 24 patients (23.8%) reported severe anxiety; the average score for trait anxiety was 38.3, and 31 cases (30.7%) met severe anxiety.

Conclusions: In our PD patients, there was a high incidence of emotional exhaustion and severe anxiety but a high personal efficacy. However, after adjusting for PD operators, age, PD vintage, there was no significant correlation between these parameters and the scores in each questionnaire.

TH-PO332

The Effects of Negotiation on Discordant Home Hemodialysis Patients

Ana Sanchez Escuredo,[1,2] Naeim G. Salah,[1] Rose Faratro,[1] Celine D'Gama,[1] Christopher T. Chan.[1] *[1]UHN, Toronto, ON, Canada; [2]Hospital Moises Broggi, Barcelona, Spain.*

Background: Home hemodialysis (HHD) has demonstrated superior clinical outcomes, improved quality of life and enhanced treatment flexibility in comparison to 3days/week incenter HDs.Nonetheless, some patients are discordant to their dialysis prescription and require a negotiation program to maintain their normal lifestyle and ameliorate their illness behavior.

Methods: Retrospective single center observational study of all prevalent HHD patients at UHN (2018-2022). Demographic and clinical data were extracted from clinical charts. Negotiation was defined as weekly contact between nurses and patients by phone, email or clinical visit to discuss the importance of being concordant to treatment and adapting the length and schedule of dialysis to avoid clinical complications. Patients were defined as concordant, concordant with agreement with at least 75%of dialysis prescription and discordant for those skipping/shortening HHD sessions without prior agreement with the clinical team.

Results: From 94patients, 33(35%) required negotiation:15(16%) were concordant patients with agreement and 18(19%) discordant patient. There were no demographic differences between groups. Patients requiring negotiation presents higher median time on HHD (7.6years vs 4.3years for concordant patients). Discordant patients tended to be younger and were less likely to be listed for kidney transplant(figure 1). There were no differences in hospitalisation/technique complications amongst the 3groups.

Conclusions: A third of HHD patients require negotiation to maintain their lifestyle and safety. Those patients requiring negotiation did not present with more hospitalisation or technique complications than concordant patients. We speculate that a negotiation

program should be implemented in HHD centers to ameliorate patient concordance and mitigate attrition.

	Total (n = 94)	Concordant (n= 61)	Concordant with agreement at least 75% of dialysis prescription (n = 15)	Discordant (n = 18)	p value

TH-PO333

Measuring Mindset: Validation of the Health Mindset Scale (HMS) in Peritoneal Dialysis (PD) Patients

Rachel B. Fissell,[1] Sagar Patel,[1] Nupur Gupta,[2] Elizabeth Taber-Hight,[2] Shweta Bansal,[3] Devika Nair,[1] Ebele M. Umeukeje,[1] Andrew Guide,[4] Marcus G. Wild,[4] Claudia Mueller,[5] Robert Greevy,[4] Kerri L. Cavanaugh.[1]
[1]Vanderbilt University Medical Center, Nashville, TN; [2]Indiana University School of Medicine, Indianapolis, IN; [3]University of Texas Health Sciences Center, San Antonio, TX; [4]Vanderbilt University, Nashville, TN; [5]Stanford University School of Medicine, Stanford, CA.

Background: Many patients who start peritoneal dialysis (PD) transition to hemodialysis after complications. Patient psychological factors may influence long-term PD success. Fixed mindset is the belief that ability cannot change, and growth mindset is the belief that knowledge and ability can grow and improve. Patient mindset may influence PD training, patient dialysis task execution at home, patient response to peritonitis, and modality persistence. The purpose of this study is to examine validity of the Health Mindset Scale (HMS) among adult PD patients.

Methods: Home dialysis units at two academic medical centers in the US are participating. The Health Mindset Scale (HMS), a 3-item Likert-based survey [scored 3-18, higher number indicates greater growth mindset], was administered at baseline, and then repeated for test-retest reliability. Instruments for resilience, depression, and health mindset specific to peritonitis were also administered at baseline. Spearman's rank correlation coefficients assessed correlations, and Cronbach's alpha assessed internal consistency.

Results: Mean age of 52 enrolled participants was 52yo [SD 16], with 48% male, 28% black, 40% with diabetes, and 87% with hypertension. Mean vintage was 628 days [SD 631]. Mean albumin was 3.9 gm/dL [SD 0.44]. Mean HMS score was 11.8 [SD 4.9] at baseline, and 13.7 [SD 3.5] at follow-up. HMS test-retest correlation was 0.43 [95% CI 0.05, 0.70]. Correlations between HMS and peritonitis mindset score, resilience, and depression were 0.64 [95% CI 0.41, 0.79], 0.26 [95% CI -0.03, 0.50], and 0.13 [95% CI -0.16, 0.40], respectively. Cronbach's alphas for baseline HMS, peritonitis mindset, depression, and resilience were 0.88, 0.83, 0.69, and 0.93, respectively.

Conclusions: Results results suggest good internal consistency of instruments for health mindset and peritonitis mindset, depression, and resilience in this sample of adult PD patients. Mindset variation suggests that an intervention to support growth mindset may be an important target to maintain PD as the ESKD treatment option.

Time Trends and Causes of Infectious Mortality Among Patients Starting Dialysis in Finland

Patrik Finne,[1,2] Susanna Kinnunen,[4] Jaakko Helve,[1,3] Auni Juutilainen,[5] Wisam Bitar,[6] Ilkka Helantera.[7] *[1]HUS-yhtyma, Helsinki, Finland; [2]Helsingin yliopisto, Helsinki, Finland; [3]Finnish Registry for Kidney Diseases, Helsinki, Finland; [4]Kuopion yliopistollinen sairaala, Kuopio, Finland; [5]Kuopion yliopistollinen sairaala, Kuopio, Finland; [6]HUS-yhtyma, Helsinki, Finland; [7]HUS-yhtyma, Helsinki, Finland.*

Background: Infections are the second most common cause of death among dialysis patients. Still, there is very scarce information on recent trends and causes of infectious mortality among dialysis patients. Our aim was to evaluate the development of mortality caused by infectious diseases during the past decades in the dialysis population in Finland.

Methods: All adult patients who started chronic dialysis treatment in Finland during 2000–2019 were included. The patients were identified from the Finnish Registry for Kidney Diseases, and followed until kidney transplantation, death, five years from start of dialysis or end of 2019. Cumulative incidence of death caused by infections was calculated and deaths due to other causes were accounted for as competing risk events. Hazard ratios of infectious death were calculated according to time periods of dialysis start using Cox regression with adjustment for age, sex, primary kidney disease, and comorbidities.

Results: Altogether 9671 patients started dialysis of whom 75% commenced hemodialysis and 25% peritoneal dialysis. During the 5-year follow-up, 2956 (31%) patients received a kidney transplant, and 3692 (38%) dialysis patients died of whom 866 (23%) due to infections. The crude cumulative incidence of infectious death decreased steadily over five-year time periods during 2000–2019 (Figure). The hazard ratio of infectious death decreased continuously and was 0.50 (95% CI 0.39–0.61) for patients who started dialysis in 2015–2019 compared to 2000–2004. The most common causes of infectious death were septicemia (38%), pulmonary infection (36%), and peritonitis (8%). Invasive fungal, viral, or opportunistic infections rarely caused death.

Conclusions: Dialysis patients' risk of dying due to infections has dropped by half since the beginning of the millennia. The reason for this development will need further studies.

Impact of Glycemic Control on Technique Failure in Incident Peritoneal Dialysis with Diabetes: Focusing on Volume Overload

Dong Eon Kim,[1] Hyo Jin Kim,[1,2] Eun Young Seong,[1,2] Sang Heon Song.[1,2]
[1]Pusan National University Hospital, Busan, Republic of Korea; [2]Pusan National University Yangsan Hospital, Yangsan, Republic of Korea.

Background: To date, diabetes mellitus (DM) has been regarded as a risk factor for ultrafiltration failure in peritoneal dialysis (PD). This study is aim to delineate whether glycemic control could contribute to the technique failure in PD patients with DM, especially in terms of volume overload.

Methods: We retrospectively analyzed data from 84 incident PD patients with DM. The study population consisted of 71 males and 13 females, with mean age 51.1 ±1.3 years. Median follow-up duration was 34.5 ± 2.4 months. We divided the patients into two groups based on the time-average HbA1c values : HbA1c 8.0%≤ (n=17) and HbA1c 8.0%>(n=67). We used multivariate Cox proportional regression models to assess the relationship between the degree of glycemic control and the occurrence of volume overload-associated technique failure.

Results: Multivariate Cox regression analysis revealed that patients with a HbA1c level 8.0≤ had a significantly higher risk of volume overload associated technique failure (HR 3.741, 95%CI 1.166-11.908, P=0.026) compared to counterparts particularly within the first 2-years (HR 6.760, 95%CI 1.413-32.331, P=0.017). Additionally, hypertension was found to be significantly associated with an increased risk of volume overload-associated technique failure (HR 10.021, 95%CI 1.236-81.260, P=0.033).

Conclusions: Inadequate glycemic control (HbA1c 8.0≤) particularly during the first 2-years, and hypertension were found to be related with a volume overload-associated technique failure in DM patients undergoing PD.

Funding: Veterans Affairs Support

TH-PO336

Impact of Hypokalemia on Peritonitis in Peritoneal Dialysis Patients: A Multicenter Study

Jing L. Choe,[1] Xian Pei Cheong,[1] Lay Meng Tan,[1] Zainal Abidin Nur Nadzifah Hanim,[2] Agni N. Kumar,[3] Xue Qi Tan,[1] Leng S. Lee,[1] Mei Sian Fu,[1] Lik Wee Ee,[1] Hon shen Png,[3] Zher lin Go,[2] Nuzaimin H. Ahmad,[2] Wen J. Liu.[1] *[1]Hospital Sultanah Aminah, Johor Bahru, Malaysia; [2]Hospital Pakar Sultanah Fatimah, Muar, Malaysia; [3]Hospital Sultanah Nora Ismail Batu Pahat, Batu Pahat, Malaysia.*

Background: The association between peritoneal dialysis (PD) related peritonitis and hypokalemia is not well recognized. We examined their relationship and outcome of peritonitis in three PD centres of the southern region of Malaysia.

Methods: A total of 99 adult patients in Johor state who had undergone Tenchkoff catheter insertion for PD from 1st January 2017 to 31st December 2019 were analysed. Demography, lab results and medical data were obtained from medical records. Serial outpatient readings of serum potassium levels were analysed to define into two groups: hypokalemia (HK) and normokalemia (NK). Subjects with peritonitis will only have preceding 6 months of potassium readings analysed while subjects without peritonitis, have a maximum of 24 months study period. HK was defined as an average serum potassium level <3.5mmol/l, while NK ≥3.5mmol/L. Demographic factors are analysed using chi-square test. Association of potassium status and other related factors with peritonitis were analysed using univariate and multivariate logistic regression.

Results: Among 99 eligible PD patients, mean age (±SD) was 52.68 (±27.99) years old. 59.6% were females and 50.5% were diabetes mellitus. 17 (17.2%) belonged to HK group. Univariate and multivariate logistic regression (table 1) showed only hypokalemia status positively associated with peritonitis: unadjusted odds ratio 3.452 (CI 95% 1.176-10.132, p=0.024) versus adjusted odds ratio 3.224 (CI 95% 1.000–10.395, p=0.050). Among patients who developed peritonitis, HK subjects had lower mean serum albumin level (g/L) than those with NK (25.50±4.06 vs 29.16±5.94). HK subjects had higher CRP levels (mg/L) as compared to those with NK (151.47±94.91 vs 138.29±99.63). Peritonitis-associated catheter removal rate was higher in NK group compared to HK group (45.8% vs 10%, p=0.046).

Conclusions: PD patients with hypokalemia is positively associated with occurrence of peritonitis. Larger sample size and further studies are needed to understand its mechanisms. Correction of hypokalemia is therefore important to prevent such events.

TH-PO337

Peritoneal Dialysis Outcomes in Severely Obese Patients: Single-Center Experience

Akwe Nyabera, Omar A. Ayah, Gabriela Dande, Alexis Lorio, Shweta Bansal. *The University of Texas at San Antonio, San Antonio, TX.*

Background: Peritoneal dialysis (PD) has been increasingly performed in obese end stage kidney disease patients (ESKD) with the rising prevalence of obesity. However, PD is still viewed as a relative contraindication in severe obesity and experience in this group is sparse.

Methods: In a retrospective study, we identified patients with body mass index (BMI)>40 kg/m^2 from patients who initiated PD between 2014 and 2020 (n=99) at the University Hospital Home Dialysis Center. Charts were reviewed for clinical and laboratory variables to assess PD adequacy, technique, and patient survival. Date of last evaluation was March 2023.

Results: A total of nine patients (9%) had severe obesity with mean BMI 43.2±2.9 kg/m^2, age 47.8±12.6 years, and 44% were female. The cause of ESKD was Diabetes Mellitus in eight and IgA nephropathy in one patient. PD catheter was placed percutaneously in six and surgically in three patients. None of the patients had pericatheter leak or poor healing. PD training was initiated within 7.4±11.4 days after catheter placement. The initial prescription involved on average 4±0.5 cycles over 8.7±1.1 hr at night, total volume 9.0±1.2 lt and three patients had a last fill of 1.67±0.24 lt. Adequacy (both clinical and weekly kt/v>1.7 using actual/adjusted weight) was achieved in every patient using incremental PD. After an average of 17.7±6.8 months on PD, three patients transferred to hemodialysis (1 burnout, 1 prolonged hospitalization after cardiac surgery, 1 peritonitis with leak in the tunnel) and one moved to another PD facility. The remaining five patients continue to be on PD with a mean duration of 27.8±4.5 months. The latest prescription was 4.3±0.7 cycles over 9.2±1.2 hr at night, total volume of 11.1±2.6 lt and six had a last fill of 1.9±0.08 lt. Seven patients maintained the residual kidney function by the end of follow up. Peritonitis rate was 0.28 episode/pt-yr. Two patients had issues with slow drain and one with omental wrapping. Mean HbA1c was 7.8±2.3% and 7.1±1.3% at PD initiation and end of follow up, respectively.

Conclusions: Our experience demonstrates that PD is a viable option for long term therapy in patients with severe obesity. Further studies in a large population are needed to confirm our findings.

TH-PO338

Association Between Prediabetes and Cardiovascular Mortality in Patients Treated with Peritoneal Dialysis: A Retrospective Study from Southern China

Hu Qinghua, Qimei Luo, Xianrui Dou. *Shunde Hospital of Southern Medical University, Foshan, China.*

Background: The term prediabetes is used for individuals who have impaired glucose metabolism but the levels of glucose or HbA1c are not yet high enough to be diagnosed as diabetes. Prediabetes may already be associated with an increased risk of chronic diabetes-related complications in the general population. The present study was aimed to investigate the clinical impact of prediabetes on cardiovascular mortality in a population from southern of China who received peritoneal dialysis(PD) treatment.

Methods: Patients who received PD treatment above 3 months between January 2004 and December 2021 from four center were enrolled. The clinical record from last time before PD treatment were collected as baseline data. Prediabetes was defined as impaired fasting plasm glucose (FPG) according to the definition of the World Health Organization (WHO-prediabetes:6.1-6.9mmol/L). The association of baseline prediabets with cardiovascular mortality was evalued with multivariable Cox proportiona hazard analyses. We further performed subgroup analysis stratified by baseline characteristics including age(<47,≥47year), sex, smoking, hypertension status, PD vintage(<42,≥42months), hemoglobin(<83,≥83g/L), albumin(<36,≥36g/L), serum potassium(<2.0,≥2.0mmol/L).

Results: A total of 2045 PD patients were enrolled in this study. Of them, 545 were (26.7%) diagnosed as diabetes, 165(8.1%) were diagnosed as prediabetes according to IFG-WHO. During a median follow-up period of 42months, 178(8.7%) patients occurred cardiovascular mortality, of which 95 of1335(7.1%) patients in the non-prediabetes group and 20 of 165(12.1%) patients in the WHO-prediabetes group. Adjusted Cox regression models showed that compared with non-prediabetes, patients diagnosed as WHO-prediabetes was associated with an increased risk of cardiovascular mortality(HR 1.80,95% CI,1.12-2.88) after adjusted for age, sex, smoking, hypertension status, PD vintage, hemoglobin, albumin etc. The inverse association between the prediabetes with cardiovascular mortality was stronger in patients without hypertension (P for interaction=0.013).

Conclusions: WHO-prediabetes is an independent risk factor for cardiovascular mortality in patients receiving PD treatment.

TH-PO339

Clinical Outcomes of Peritoneal Dialysis in Patients with Chronic Liver and Kidney Failure: A Single-Center Experience

Oluwatitomi A. Tedunjaiye, Sefia Khan, Litty Thomas, Ramesh Saxena. *The University of Texas Southwestern Medical Center Department of Internal Medicine, Dallas, TX.*

Background: Patients with Chronic Liver and Kidney Failure (CLKF) face severe complications and high mortality. Simultaneous Liver-Kidney Transplant (SLKT) is the ideal therapeutic option, but the dearth of organs leaves most patients dialysis-dependent. PD is often overlooked due to concern for elevated peritonitis risk, hypoalbuminemia, and poor transplant candidacy. However, HD is often poorly tolerated due to exacerbation of pre-existing hemodynamic problems. We present a single-center experience to provide evidence that PD should be recommended in CLKF patients.

Methods: In this retrospective observational study, we included all patients with CLKF who initiated PD from 01/2006 to 03/2023. Medical charts were reviewed, and demographic/clinical data was retrieved. The primary clinical outcomes included mortality, PD complications, hospitalization rates, change in serum albumin from baseline, and SLKT candidacy. Censoring events were study period end, death, transfer to HD or to a different PD center, and SLKT.

Results: Twenty-six patients with CLKF and mean age of 58 years initiated PD during the study period. The mean time on PD was 38.3 months. There were 18 episodes of peritonitis with a rate of 0.2 episodes per year. Nine patients died with annualized mortality of 10.9%. Hospitalization rate was 0.95 per patient per year. Six patients received SLKT, 5 remain active on the waitlist. Four patients had technique failure with a permanent switch to HD. Mean serum albumin at the end of the observation period was 2.8g/dL, a 12% decline from baseline ($p=0.06$). No patient needed therapeutic paracentesis for ascites while on PD.

Conclusions: To our knowledge, this is the largest single-center study on PD with CLKF patients. Our patients had mortality, hospitalization, and peritonitis rates lower than the general PD population. Peritonitis episodes were more commonly from non-enteric pathogens suggesting a failure of aseptic PD technique rather than cirrhosis-related spontaneous bacterial peritonitis. The decline in serum albumin from baseline was not statistically significant. Six patients received SLKT and 5 are active on the list, demonstrating PD can be a successful bridge to SLKT. Given excellent outcomes and effectiveness in ascites management, we propose PD as a first-line kidney replacement therapy option in patients with CLKF.

TH-PO340

The Effects of Objective Structured Clinical Examination on Home Hemodialysis Transition

Xin Bo (Justin) Cheng,[1,2] Ibrahim M. Alrowiyti,[1] Christopher T. Chan.[1,3]
[1]University Health Network, Toronto, ON, Canada; [2]Vancouver General Hospital, Vancouver, BC, Canada; [3]University of Toronto, Toronto, ON, Canada.

Background: Home hemodialysis (HHD) augments quality of life and improves several clinical outcomes in patients with end-stage kidney disease. However, patients are required to learn a complex medical task and are obligated to demonstrate competency of training. We hypothesize that Objective Structured Clinical Examination (OSCE) is a feasible strategy to enhance training and improve patient and provider confidence.

Methods: From 2017 to 2021, 58 patients completed HHD training at University Health Network. Each patient completed an OSCE for formative assessment and a final OSCE for summative evaluation. The OSCE comprised of 94 or 85 items, depending on vascular access. Targeted training was provided after the first OSCE on identified areas of improvement. 25 of 58 consented and completed an optional Likert Scale survey (1 to 10) assessing confidence in seven categories, as seen in Figure 1. These include three routine practices of ultrafiltration (UF) target, HHD access, and machine set up followed by three advanced actions of alarm and complication management, and safety. A final item, readiness to go home, served as a global assessment. Patients and training nurses completed the surveys, scoring from 1 to 10, before and after each OSCE. Within subject differences were assessed by paired Student t test.

Results: The mean OSCE score increased from 96.2 (+/- 5.7) after the first OSCE to 98.2 (+/- 3.1) % after the second OSCE ($p > 0.05$). The patient mean score for home readiness increased from 8.0 (+/- 1.8) after the first OSCE to 9.5 (+/- 1.0) after the final OSCE ($p < 0.05$). Similar trends were observed from the nurse trainers, with their mean home readiness score increased from 6.6 (+/- 1.8) to 8.9 (+/- 1.1) ($p < 0.05$) after the OSCE process. Individually, there was an increase in patient confidence in all categories. Confidence in ultrafiltration target, dialysis access, and machine setup improved by 0.68, 0.40, and 0.36 respectively ($p < 0.05$). Confidence in advanced components including alarm troubleshooting, complication management, and safety increased by 0.84, 1.04, and 0.72 respectively ($p < 0.05$).

Conclusions: We demonstrated that OSCE is an implementable training strategy, which is associated with augmented home readiness and confidence scores in our patients and nurse trainers. We speculate that assurance of training may reduce patient burnout.

	Patient		Nurse	
	After OSCE 1	After OSCE 2	After OSCE 1	After OSCE 2
Ultrafiltration Target	9.2	9.9	8.4	9.0
Dialysis Access	9.3	9.7	8.4	9.0
Machine Setup	9.6	9.9	8.7	9.2
Alarm Troubleshooting	8.3	9.1	7.4	8.4
Complications Management	8.0	9.1	7.3	8.4
Safety	8.8	9.6	7.3	8.7
Readiness for Home	8.0	9.5	6.6	8.9

TH-PO341

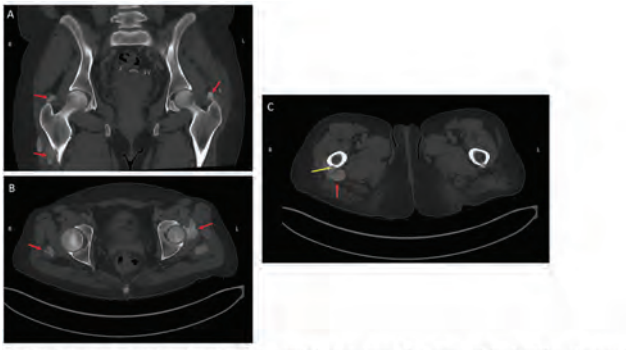
Tumoral Calcinosis in a Patient with ESKD on Peritoneal Dialysis: A Diagnostic Dilemma

Kartik Kalra, Lakshna Sankar, Evan Norfolk. *Geisinger Health, Danville, PA.*

Introduction: Tumoral calcinosis is an uncommon complication of secondary hyperparathyroidism related to end-stage kidney disease (ESKD) with calcium and phosphate deposition in soft tissues, which is different from calciphylaxis characterized by microvascular calcification resulting in painful skin ulcers.

Case Description: A 42-year-old woman with history of ESKD on peritoneal dialysis (PD) for 6 years presented with severe multiple joint pains for 2-week duration. Home medications included losartan, cinacalcet and calcium acetate. Labs revealed phosphorus of 11 mg/dl (2.5 - 4.8 mg/dl); parathyroid hormone (PTH) of 1061 pg/ml (15-65 pg/ml). She was anuric and her most recent Kt/V was 2.3. On examination, she had tenderness in multiple proximal and distal interphalangeal joints on her hands, bilateral hip, and knee joints. Computed tomography (CT) pelvis with contrast showed calcified masses in soft tissue and periarticular region in bilateral hip consistent with tumoral calcinosis (Figure A, B and C – red arrows); direct extrinsic erosion of the right posterior proximal femoral diaphyseal cortex (Figure C – yellow arrow) and left hip acetabulum. Given the severity of symptoms, she was transitioned to intermittent hemodialysis and received sodium thiosulfate infusions. Calcium acetate was switched to sevalamer. She received a kidney transplant 3 months later. On 10 month follow up, her symptoms resolved.

Discussion: The timeline for tumoral calcinosis can range from 17 - 84 months in PD patients. Treatment includes low phosphorus diet, noncalcium-based phosphorus binders, calcimimetics, sodium thiosulfate and surgical options are parathyroidectomy for secondary or tertiary hyperparathyroidism. Nephrologists should be aware of this rare entity to provide appropriate care including patient education on medication adherence, if needed switching dialysis modalities to intensive hemodialysis (5 times per week) and surgical management. Studies have shown complete resolution of tumoral calcinosis after kidney transplant.



CT pelvis with contrast: A – Coronal view shows bilateral hip tumoral calcinosis (red arrow); B - Cross sectional view shows bilateral hip tumoral calcinosis (arrows); C – Cross sectional view shows tumoral calcinosis (red arrow) causing erosion of right posterior proximal femoral diaphyseal cortex (yellow arrow)

TH-PO342

Pantoea dispersa Peritonitis in a Patient on Peritoneal Dialysis

Yoshitsugu Obi, Mohamed Hassanein, Prakhar Vijayvargiya, Khaled Obeidat, Zackary Knott, Neville R. Dossabhoy. *The University of Mississippi Medical Center, Jackson, MS.*

Introduction: *Pantoea dispersa*, a gram-negative bacterium belonging to the genus Pantoea, is commonly found in natural environments, including plants, soil, and water. While traditionally regarded as a plant pathogen, certain species have emerged as significant pathogens in humans, particularly in immunocompromised individuals. Here, we report a rare occurrence of *Pantoea dispersa* peritonitis in a patient on peritoneal dialysis (PD).

Case Description: A male in his mid-60s with end-stage kidney disease on PD presented with a two-day history of progressively worsening diffuse abdominal pain and cloudy dialysis effluent. Additional symptoms included chills, nausea, emesis, and diarrhea. Analysis of PD fluid revealed an elevated WBC (9749 cells/mm^3) with neutrophil predominance (98%). We initiated empirical intraperitoneal (IP) antibiotic therapy using vancomycin and cefepime. PD fluid culture grew *Pantoea dispersa* from tow separate samples. Susceptibility testing showed low minimum inhibitory concentrations (MIC) to all tested antibiotics including aminoglycosides, trimethoprim/sulfamethoxazole, fluoroquinolones, and cephalosporins (cefoxitin was intermediate). Hence, the IP antibiotic regimen was changed to ceftazidime monotherapy. The patient reported significant improvement in abdominal pain by day 3, and repeat analysis of PD fluid on day 4 confirmed an excellent response to antibiotic therapy (WBC 113 cells/mm^3). He was discharged with a plan to complete a 3-week course of IP ceftriaxone as outpatient.

Discussion: This case sheds light on the emerging significance of *Pantoea dispersa* as a pathogen in human infections, particularly in immunocompromised hosts including patients with end-stage kidney disease. *Pantoea dispersa* often exhibits multidrug resistance, emphasizing the importance of susceptibility testing for optimal management. Notably, *Pantoea agglomerans*, a related species, has been reported as a rare cause of peritonitis in PD patients, with documented complications including ultrafiltration failure and encapsulating peritoneal sclerosis. However, the consequences of *Pantoea dispersa* peritonitis remain unclear. By presenting this case, we hope to enhance clinicians' understanding and awareness of the potential pathogenicity of *Pantoea dispersa*, facilitating the establishment of effective management in similar clinical scenarios.

Comprehensive Approach to Renal Education and Support: Methods and Outcomes

Sana F. Khan, Danielle Wentworth. UVA CARES - Comprehensive Approach to Renal Education and Support. *UVA Health, Charlottesville, VA.*

Introduction: The 2019 Advancing American Kidney Health Initiative aims to increase home dialysis utilization and improve access to kidney transplantation. In our approach to achieve these goals, we designed a quality initiative to provide comprehensive, patient-centered nephrology care for patients with high risk of disease progression.

Case Description: This QI project started January 2021. High risk patients were identified via EMR registry. Inclusion criteria was GFR < 30 ml/min or KFRE score > 20% at 2 years. Patients were contacted and offered enhanced education and support regarding modality choices & CKD progression. Patients were sequentially scheduled with an experienced nephrology NP, Social Worker, dietician and home dialysis nurse, with an additional NP follow up visit to determine further education, resource needs, ESRD decision plan and tracking. Patient modality choices were subsequently relayed to primary nephrologists and documented in the EMR. Patient progress and gaps in coordination were discussed during quarterly list management meetings.

Discussion: Our cohort included 42 patients (Average age; 65 years, GFR 16 ml/min, KFRE 53%).35% patients completed all 5 comprehensive visits.78% made decisions on preferred modality (33% iHD, 40% PD, 21% undecided). 20 patients (47%) progressed to ESRD, with incident rates of PD 25% and iHD 75%. 7% patients died prior to ESRD progression. 9 patients (45% of ESRD group) initiated hemodialysis as in-hospital starts. 36% (n=8) of patients without progression to ESRD are with AVF/AVG placement, awaiting RRT initiation. Transplant status include 2 patients on the active, 10 inactive transplant lists. 23 referrals were closed due to patient ineligibility whereas 1 patient received a pre-emptive transplant. Development of a multidisciplinary high-risk nephrology care clinic at our institution resulted in attainment of improved rates of incident PD utilization, which surpassed rnational benchmarks. Significant number of our patietns without ESRD progression are expected to have optimal start RRT with functioning AV access. Despite advanced care planning, 45% of our ESRD starts initiated RRT in hospital, demonstrating high complexity of care/disease burden of advanced CKD patients. Adoption of comprehensive care models for patients at increased risk for development of ESRD may lead to improved patient outcomes while also meeting national quality metrics.

TH-PO344

Mycobacterium Exit Site Infection in a Peritoneal Dialysis Patient

Kristi Dodbiba, Rachel Hilburg. *University of Pennsylvania, Philadelphia, PA.*

Introduction: Mycobacterium Fortuitum (*M.Fortuitum*) is a rare form of nontuberculous infection that uncommonly affects peritoneal dialysis (PD) patients. Mycobacterial peritonitis has a high rate of morbidity and mortality. We present a case of a patient with Mycobacterium exit site infection which led to PD catheter removal, transition to intermittent hemodialysis, eradication of infection and reinsertion of PD catheter to successfully reinitiate PD.

Case Description: A 41-year-old man with end stage kidney disease on PD (catheter placed 2021), hypertension, and diabetes mellitus, presented to outpatient PD clinic in July 2022 with purulent drainage from the PD catheter exit site. Prior to this in April 2022 he was treated for coagulase negative staphylococcus peritonitis with intraperitoneal cefazolin and fungal prophylaxis. In July 2022, exit site culture was positive for AFB with speciation to *M. Fortuitum*. Peritoneal fluid cultures were negative. He was initiated on ciprofloxacin, clarithromycin and fungal prophylaxis. Due to ongoing purulent drainage, he underwent surgical evaluation with PD catheter revision and exit site debridement. He was also referred to Infectious Disease. Exit site culture again grew *M. Fortuitum* that was macrolide resistant. He was switched to doxycycline and ciprofloxacin. CAT scan showed no drainable fluid collection. Due to sustained exit site infection, he underwent PD catheter removal and transitioned to intermittent hemodialysis via tunneled dialysis catheter. After 4 months of antibiotic therapy post-PD catheter removal, CAT scan confirmed no evidence of fluid collection, at which time antibiotics were concluded. A month after he was infection free, he underwent new PD catheter placement and transitioned back to PD, with plan for re-activation on the transplant list.

Discussion: Our patient had resolution of exit site infection and restarted PD after a long course of antibiotics and removal of the initial PD catheter. This case not only advocates for early removal of PD catheter and foregoing exit site revision, but also illustrates the importance of dual therapy for mycobacterial infection treatment. Fortunately, this patient never progressed to mycobacterial peritonitis. Lastly, this case demonstrates the importance of multidisciplinary collaboration between nephrology, infectious disease, and surgery to safely and quickly eradicate infection.

TH-PO345

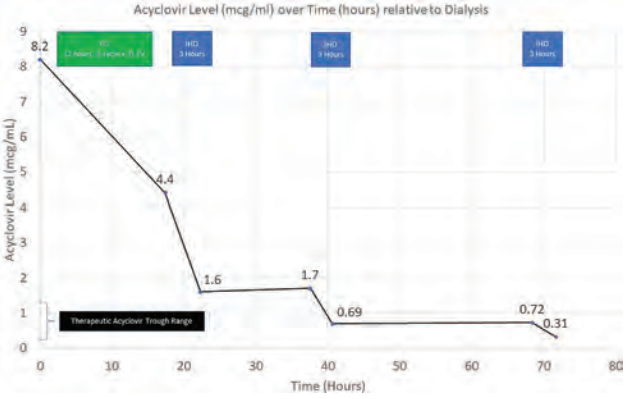
Valacyclovir Neurotoxicity: A Case Comparison of Peritoneal Dialysis and Hemodialysis

Briahni M. Walker, Alaa'i E. Ahamed, Keerat Dhatt, Tram Dao, Brian Y. Young. *UC Davis Health, Sacramento, CA.*

Introduction: The standard treatment for acyclovir neurotoxicity in ESRD is hemodialysis (HD) as it eliminates roughly one-third of acyclovir per session. However, there are various reports of success with peritoneal dialysis (PD) intensification. We report an ESRD patient with acyclovir neurotoxicity given both PD and, after persistent symptoms, HD. This offers the unique opportunity to compare therapeutic effects.

Case Description: An 87-year-old man with ESRD on PD was hospitalized with confusion, ataxia, and visual hallucinations. Prior to admit, the patient had shingles and got valacyclovir 1gm q8 hours (ESRD max recommended dose = 500mg q24-48 hours). Neurologic symptoms began after his 3rd dose. He was adherent to home PD. Total KT/V 1 month prior was 2.09 with little residual GFR (KT/Vr = 0.06). On admit, he was afebrile with left flank vesicular rash, slurred speech, slow motor skills, and imbalance. BMP had BUN 60 mg/dl, creatinine 11.7 mg/dl. CBC, cultures, toxicology, and CT head were negative. Acyclovir neurotoxicity was diagnosed. Dialysis was performed and acyclovir levels were drawn (Figure). Patient declined initial recommendation of temporary HD. Yet, after no clinical change with 12 hours intense PD, he had HD, improving after each HD, and eventual neurotoxic resolution.

Discussion: Valacyclovir, a prodrug of acyclovir, is efficacious in treating herpes zoster. We have a unique neurotoxic acyclovir overdose treated with PD and HD sequentially. Despite 12 hours of intervening PD, our patient's acyclovir level took ~18 hours to reduce in half. In normal renal function, the elimination half-life of acyclovir is ~3 hours, yet in ESRD this increases to ~14 hours. Based on ESRD half-life, this suggests intense PD was not effective for acyclovir toxicity. In contrast, the acyclovir level dropped rapidly with each HD along with clinical improvement. In our patient, HD was the superior modality and should be considered first to avoid potential long-term neurotoxic injury in patients with minimal residual kidney function.



TH-PO346

A Case of Hyperprolactinemia in a Dialysis Patient

Adnan Faruqui, Nupur Gupta. *Indiana University School of Medicine, Indianapolis, IN.*

Introduction: The prolactin levels are elevated in the CKD population, up to nearly 65% in the ESKD population, but symptoms like galactorrhea may not be present generally. We present a case of hyperprolactinemia in a CKD patient significant enough to cause symptom

Case Description: A 23-year-old female with a history of obesity, Caroli's disease, BPD, ESKD secondary to nephronophthisis, currently on Home hemodialysis, history of deceased donor kidney transplant 2008 with graft failure 2022, presented with bilateral breast enlargement, pain, and milky discharge for a year, associated with oligomenorrhea. She denied any visual disturbances. Labs notably showed elevated prolactin levels of 92.7; TSH, ACTH, IGF, FSH, LH, and testosterone levels were within normal limits. Head CT with and without contrast were done which showed no masses or lesions, and an unremarkable sella turcica. Initially, she had been on Abilify for BPD, and despite a lowered dosage symptoms persisted. Subsequently despite being off Abilify for two months symptoms persisted. She has been started on cabergoline with the improvement of symptoms.

Discussion: Hyperprolactinemia in CKD is thought to be secondary to a reduction in metabolism and reduced availability of dopamine-stimulating prolactin. While the patient was on Abilify, which may cause elevated prolactin levels, being off of it, the symptoms persisted, therefore was unlikely the cause. CT head was unremarkable, suggesting against prolactinoma, and the hyperprolactinemia attributed to ESKD. Hyperprolactinemia is common, but galactorrhea is rarely seen and could be appropriately treated with cabergoline.

TH-PO347

Dialysis-Associated Ascites: Leave No Stone Unturned

Prerna Sharma, Alan Segal. *Maine Medical Center, Portland, ME.*

Introduction: Dialysis-associated ascites (DAA) is a rare complication of ESRD, with a pathogenesis that is poorly understood. Here, we present a case of DAA that developed in a patient after starting home hemodialysis.

Case Description: A 54-year-old man with a rare genetic renal-limited neoplasm eventually had all kidney tissue removed and went on HHD using NxStage via an AVF. Shortly thereafter, he developed large ascites that required paracentesis (~8 L) every 6-8 weeks, and also developed sexual dysfunction and restless leg syndrome (RLS). Cardiac function and hepatic synthetic function remained normal and he had no edema. The ascites was exudative with a serum:ascites albumin gradient less than 1.1. Cytology was always negative. After 4 years on HHD, he received a kidney transplant that had to have a ureteral stone removed just prior to transplant. Within 48 hours of transplant, his DAA completely resolved and over the next 6 weeks his sexual dysfunction and RLS also resolved. In the 8 years since his transplant, he has never developed nephrolithiasis and continues to enjoy essentially normal kidney function.

Discussion: DAA is said to carry a poor prognosis with a mortality rate of 45% over 15 months. The pathogenesis is unclear, but hypoalbuminemia is thought to be a contributing factor. Patients usually present with severe, worsening and recurrent ascites, and cachexia. It is considered generally refractory to the usual treatment modalities and remains largely a diagnosis of exclusion. Kidney transplantation is the only definitive treatment with resolution of the ascites usually occurring over 6 weeks. In our patient, who was anephric due to a very rare renal-limited neoplasm, the ascites was mobilized immediately and resolved in 48 hours, and his other symptoms resolved within 6 weeks.

Although his transplant kidney came from a stone-former, he is not a stone former and has never had nephrolithiasis. We conclude that although being anephric may increase the risk of DAA, it can rapidly resolve with transplantation so the prognosis may not be as grave if transplant can be expedited.

TH-PO348

A Case of Cellulosimicrobium Peritonitis Associated with Peritoneal Dialysis

Kevin Bodker. *Medical University of South Carolina, Charleston, SC.*

Introduction: While peritoneal dialysis (PD) associated peritonitis is common, isolation of an uncommon organism can pose a clinical challenge. We present a case of PD peritonitis caused by the organism *Cellulosimicrobium*. A review from 2019 by Rivero et al found only 43 described cases of infection due to *Cellulosimicrobium*. Two-thirds of described cases were associated with an indwelling medical foreign body, and only 5 cases described associated with PD.[1]

Case Description: A 71-year-old male presented with acute coronary syndrome and hypervolemia. Nephrology was consulted for PD management. During evaluation for coronary artery bypass graft (CABG) patient was transitioned from PD to Continuous Hemodiafiltration, requiring aggressive ultrafiltration. CABG was complicated by protracted cardiogenic shock. Unresolving shock and leukocytosis raised concern for concurrent sepsis, broad-spectrum antibiotics (vancomycin and cefepime IV) and infectious workup were pursued. PD fluids were consistent with peritonitis and cultures were positive for *Cellulosimicrobium*. Despite 10 days of vancomycin cultures remained positive. Persistent clinical instability delayed removal of PD catheter, which was removed on day 20. Patient was successfully transitioned to hemodialysis and remained without evidence of persistent infection at discharge.

Discussion: Despite vancomycin sensitivity in all previously described cases of infection attributed to this organism, two weeks of IV administration failed to clear the infection in our case.[1] This is consistent with the five published cases of *Cellulosimicrobium* described in the literature (fig 1), where three out of five cases were considered antibiotic failure and required PD catheter removal. Depending on the clinical context, removal of PD catheter should be considered early in the treatment course of *Cellulosimicrobium* peritonitis given high rate of treatment failure.

Year Author	Patient Demographics	Antibiotics Regimen	Required PD catheter removal?
1990 Rihs et al.[2]	71-year-old Female	Vanc (IP) +Genta (IM and IP)	Yes
1996 Borra and Kleinfeld[3]	59-year-old Female	Vanco (IP)+ tobra (IM)→ Doxycycline (PO)	No
1999 Lujan-Zilberman et al[4]	13-year-old Female	Vancomycin (IP)	No

TH-PO349

Delayed "Sweet" Hydrothorax Associated with Peritoneal Dialysis

Hariharasudan Natarajan, Bibi Maryam, Zahid B. Ahmad. *OU Health, Oklahoma City, OK.*

Introduction: Hydrothorax in Peritoneal Dialysis (PD) patients is diagnostically challenging, often attributed to volume overload, uremic effusion, or parapneumonic effusion. A pleuro-peritoneal leak is a rare complication, usually presenting within 30 days of PD initiation, predominantly in females. We present a case of delayed pleuro-peritoneal leak three years after PD initiation.

Case Description: A 48-year-old man with end-stage renal disease from PLA2R-associated membranous nephropathy on automated peritoneal dialysis for 3 years presented with progressive dyspnea over 2 weeks. He had a recent admission for PD peritonitis 3 months ago. Examination revealed decreased breath sounds on the right side, crackles on the left lower lung fields, and pitting edema in both legs. A chest radiograph indicated a large right pleural effusion. Labs showed glucose of 69 mg/dL, elevated creatinine (21 mg/dL), elevated blood urea nitrogen (81 mg/dL), and elevated B-natriuretic peptide (1101 pg/mL), suggesting possible non-compliance with PD or PD failure. However, analysis of the pleural fluid sample revealed a protein concentration of 2.6 g/dL, creatinine of 22.1 mg/dL, glucose of 80 mg/dL, and lactate dehydrogenase of 162 IU/L, similar in composition to the dialysate fluid, consistent with a pleuro-peritoneal leak. Symptoms resolved upon discontinuing PD and switching to hemodialysis.

Discussion: Pleuro-peritoneal leak, also known as "sweet hydrothorax," is a rare complication of PD and classically occurs within a month of initiating PD due to increased intra-abdominal pressure during PD fluid administration in patients with diaphragmatic defects. Our patient's delayed presentation is unique and may be linked to prior peritonitis and weakened diaphragmatic tissue. Prompt identification is crucial, as treating other causes of hydrothorax can worsen the leak. A pleural fluid to serum glucose ratio >1.0 and elevated creatinine levels close to dialysate composition indicate a leak, confirmable with Peritoneal Scintigraphy or CT/MR Peritoneography. Temporary transfer to hemodialysis often promotes healing, while chemical pleurodesis, surgical repair, or permanent transfer to hemodialysis are options if conservative measures fail. Our case highlights the possibility of delayed presentation after peritonitis and underscores the importance of timely identification.

TH-PO350

Diagnosing Scrotal Wall Edema in a Patient Undergoing Peritoneal Dialysis

Dhruv Bakshi, Deep Phachu. *Saint Vincent Hospital, Worcester, MA.*

Introduction: Acute genital edema is a well-documented complication of peritoneal dialysis (PD) and is seen in 4-10 % of patients. While most incidents occur via obvious defects in the peritoneal membrane, we present a case of acute scrotal wall edema thought to be due to microtears in the peritoneal membrane.

Case Description: A 46 year old male on PD for the past 20 months presented with complaints of acute scrotal swelling. Shortly after his first dwell via continuous cycling peritoneal dialysis (CCPD), he suffered a severe coughing bout while supine. He awoke the following day with diffuse, bilateral, nonreducible and nontender scrotal swelling. CCDP was temporarily held and swelling improved, but immediately re-occurred after resumption of CCPD. CT of the abdomen and pelvis did not show a patent processus vaginalis, inguinal hernia or other obvious peritoneal membrane defect. Scrotal ultrasound did not show a fluid collection but showed diffuse scrotal wall edema. To confirm that this edema was of PD origin, we added 30 mL of gastrograffin into 1 liter of PD fluid and let this dwell for 3 hours after which repeat CT abdomen and pelvis showed a contrast-enhanced scrotum (Figure 1). CCPD was discontinued and patient was transitioned to intermittent hemodialysis with complete resolution of his edema within 7 days.

Discussion: While scrotal edema is not uncommon in patients on PD, the mechanism for development is usually related to an obvious defect, such as an inguinal hernia or patent processus vaginalis. In our patient however, we hypothesize that microtears in his peritoneal membrane caused by the acute coughing episode may have been the culprit. To our knowledge, there is no gold-standard test for diagnosing peritoneal microtears in PD, however our method of instilling 30 mL of gastrograffin in 1 liter of peritoneal dialysis fluid may be beneficial in aiding diagnosis. Moreover, we hypothesize that serial imaging done at one, two and three hour intervals may provide additional information regarding the location of such microtears.

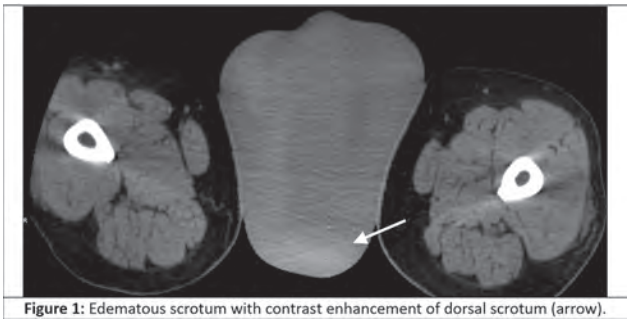

Figure 1: Edematous scrotum with contrast enhancement of dorsal scrotum (arrow).

TH-PO351

Neisseria zoodegmatis: An Interesting Cause of Peritoneal Dialysis (PD)-Related Peritonitis

Amara Sarwal, Nirupama Ramkumar, Josephine Abraham. *University of Utah Health, Salt Lake City, UT.*

Introduction: Neisseria zoodegmatis is a zoonotic pathogen that has typically been associated with cats and dogs. In humans, infection with this organism is usually through cat or dog bites. It was originally termed Eugonic Fermenter(EF)-4b by the Centers for Disease Control, however has since been renamed as Neisseria zoodegmatis [1]. To the best of our knowledge, we present the second reported case of PD-related peritonitis due to Neisseria zoodegmatis [2].

Case Description: A 35 year old female with ESRD due to ADPKD, on peritoneal dialysis (PD) presented to our Emergency Department for abdominal pain. She had recently started on PD three months ago, and had not had any issues with her dialysis. She denied any cloudy effluent or peritonitis in the past. Preliminary workup revealed a potassium of 3.3 mmol/L, BUN of 48 mg/dL, serum creatinine of 6.98 mg/dL, calcium of 8.0 mg/dL, phosphorus of 4.4 mg/dL and albumin of 3.8g/dL. Contrasted imaging of the abdomen revealed enlarged kidneys with numerous cysts due to ADPKD as well as pneumoperitoneum likely due to the PD catheter. Upon further discussion, the patient mentioned that her cat chewed her PD tubing two weeks prior to presentation. Peritoneal fluid analysis revealed turbid yellow fluid along with 300 RBCs/uL, 14625 total nucleated cells/uL with 92% polymorphonuclear neutrophils and 2% lymphocytes. Anaerobic culture was negative however aerobic culture was significant for Neisseria zoodegmatis (formerly CDC group EF-4b). The infectious disease service was consulted, who recommended intraperitoneal (IP) ceftriaxone. As ceftriaxone dosing >2 grams in

PD patients has not been well tested, we planned for ceftriaxone 1 gram during a long, daytime dwell. Patient was discharged on a course of IP ceftriaxone with resolution of her symptoms.

Discussion: In this case, the patient's history was key to raising a high clinical suspicion for an unusual pathogen. Neisseria zoodegmatis is often misidentified as Pasteurella, dismissed as skin contaminant or not recognized at all [3]. We were able to identify this microbe and promptly treat with appropriate antibiotic with resolution of infection. Neisseria zoodegmatis is a pathogen that can cause peritonitis, especially in patients with household pets. Patient education regarding maintenance of PD equipment and exercising extreme caution when pets are near should be of utmost importance.

TH-PO352

The Phantom of the Peritoneum

Christopher El Mouhayyar,[1,2] Pui Susan W. Cheung.[1] *[1]Massachusetts General Hospital, Boston, MA; [2]Brigham and Women's Hospital, Boston, MA.*

Introduction: Patients in urgent need of dialysis are commonly started on hemodialysis (HD) via a central venous catheter. More recently, acute to urgent start peritoneal dialysis (PD) is becoming an alternative. Studies have shown that the incidence of acute and chronic pancreatitis in PD patients was higher compared to HD patients and the general population. Most studies looked at patients on chronic PD. Here, we present a case of urgent start PD complicated by acute pancreatitis.

Case Description: A 58-year-old woman with a past medical history pertinent for ischemic stroke and CKD stage V with loss to follow up for months, and a one-week-old PD catheter presented to the emergency department with tonic-clonic seizures. She was given lorazepam with no response, so she was transferred to a tertiary care hospital. Labs showed a BUN of 117 mg/dL, similar to her BUN for the past month (94-112mg/dL), Cr 15.2 mg/dL, eGFR of 2 mL/min/1.73 m2, potassium of 5.5, lactic acid of 0.6 mmol/L, bicarbonate 15 mg/dL, creatinine kinase 347. CT head was unremarkable. EEG showed no evidence of seizure activity. She was started on PD with low volume runs of 500ml, which she tolerated and gradually increased to 1L. She was eventually extubated successfully. However, while into her fourth run, she started complaining of severe abdominal pain, nausea and vomiting. The PD was stopped. Lipase level came back elevated at 3000. CT abdomen pelvis showed pancreatic and peripancreatic edema with surrounding fluid consistent with acute pancreatitis. PD was held, and the patient was switched to HD. She improved and was discharged home with an outpatient dialysis unit. Her seizure was thought to be due to her old stroke per neurology. She was transitioned back to PD 8 weeks later and has tolerated it well.

Discussion: The majority of ESKD patients are started on in-center HD via a central venous catheter. The use of PD has been increasing in the last decade. Unplanned hemodialysis via a CVC is associated with higher rates of infection and reduced rates of survival compared to PD. Ideally, all patients with CKD should start dialysis in a planned elective manner rather than urgently. The evidence with regard to pancreatitis while on PD is controversial. Some studies report a higher incidence, while others do not. This case is the first to report acute pancreatitis in an urgent start of PD.

TH-PO353

A Peculiar Case of Pica in Peritoneal Dialysis (PD) Peritonitis

Pushpa Devulapalli, Jared G. Imber, Dia R. Waguespack, Jade M. Teakell. *The University of Texas Health Science Center at Houston John P and Katherine G McGovern Medical School, Houston, TX.*

Introduction: Anemia is found in majority of patients with CKD. It is associated with an increased risk of cardiovascular disease, morbidity and mortality in patients dependent on dialysis. Iron supplementation is usually advised to help improve symptoms and quality of life as well as reduce cardiovascular risk.

Case Description: Our patient is a 30 year old woman with history of ESRD secondary to anti-GBM disease on peritoneal dialysis with history of recurrent PD related peritonitis who presented to the emergency room due to abdominal pain, fevers, chills, nausea, and vomiting. She was hemodynamically stable with no leukocytosis but borderline left shift. CT of abdomen showed small bowel wall thickening. PD effluent samples were collected for gram stain and culture. Analysis showed turbidity and a WBC count of 58k with 80% neutrophils. She was started on broad spectrum antibiotics. Culture eventually grew *Acinetobacter pitti*. On further investigation, she reported eating dirt and clay for weeks. Bacteria of the genus *Acinetobacter* are ubiquitously distributed in nature, found in various types of soils. Iron panel showed low iron, low TIBC, and low ferritin. Iron was not given during admission due to active infection. Acinetobacter has a tendency to form biofilms which can cause recurrence of infection. The decision was made to keep the PD catheter in and she was sent home on a course of PO Cipro. Weeks later, she presented again with similar symptoms. During this admission, PD catheter was removed and she was transitioned to HD.

Discussion: Our case is a reminder of the surprising prevalence of pica in the ESRD population. Pica can go unrecognized until metabolic abnormalities or complications arise. Physicians do not routinely investigate pica due to underreporting and lack of information as well as guilt and fear of judgement from patients. CKD is a key player for major stress and can trigger pica. A common co-morbid condition associated with pica is anemia. Patients can have metabolic derangements such as alkalosis, hypoalbuminemia, ascorbic acid deficiency and zinc deficiency. Soil pica can affect certain electrolytes (potassium, phosphate and calcium) depending on soil composition and these electrolytes are further exacerbated in ESRD patients. Pica has extreme significance in the nutritional status of patients with kidney disease and should not be neglected in its implications on these patients.

TH-PO354

Alternatives to Daytime In-Center Hemodialysis and Employment in Patients with Kidney Failure

Kevin F. Erickson,[1] Kerri L. Cavanaugh,[2] Wolfgang C. Winkelmayer,[1] Monique R. Pappadis,[3] Jose J. Perez.[1] *[1]Baylor College of Medicine, Houston, TX; [2]Vanderbilt University, Nashville, TN; [3]The University of Texas Medical Branch at Galveston Development Office, Galveston, TX.*

Background: Maintaining employment is a priority for many patients with kidney failure. Yet, many working aged patients in the U.S. stop working with the onset of kidney failure. Access to a dialysis treatment schedule outside of working hours may help patients to remain employed.

Methods: We analyzed data from the US National Dialysis Registry to determine whether access to nearby facilities offering evening dialysis shifts and home dialysis increases the likelihood that patients are able to continue working after they start dialysis. Our cross-sectional analysis included working-aged patients (ages 18-54) receiving dialysis in US facilities in 2016. In a negative binomial regression model, we examined the associations among exposures of interest (the presence of facilities offering home dialysis or evening dialysis shifts in a patient's locality) and the number of employed working-aged adults at each dialysis facility. The multivariable model adjusted for observed patient, dialysis facility, and geographic characteristics, including information about individual patient employment at the onset of dialysis.

Results: We identified 4,860 US dialysis facilities with information about patient employment in 2016. Median employment among working-aged adults at these facilities was 17.9% (interquartile range 8.8% to 28.6%). In fully adjusted regression models, the presence of at least one facility offering an evening dialysis shift in a county was associated with a 5% increase in the relative rate of maintaining employment among working-aged patients receiving dialysis in the county (risk ratio (rr) 1.05; 95% Confidence Interval (CI) 1.01 to 1.09; p=0.02). The presence of at least one facility offering home dialysis in a county was associated with a 26% increase in the relative rate of maintaining employment (rr 1.26; 95% CI 1.18 to 1.34; p<0.001). The likelihood of employment did not increase with additional facilities in a county offering home dialysis.

Conclusions: Access to dialysis schedules outside of regular working hours – evening dialysis shifts and home dialysis – is associated with increased employment among patients with kidney failure. Efforts to increase access to these alternative dialysis treatments could help patients to continue working.

TH-PO355

REVOLUTIONIZE III: Consequences of Recurrent Hyperkalemia on Healthcare Resource Utilization and Cost

George L. Bakris,[1] Abiy Agiro,[2] Alexandra Greatsinger,[3] Manasvi Sundar,[4] Helen Guo,[4] Elaine M. Louden,[5] Erin Cook,[5] Ellen Colman,[6] Fan Mu,[5] Pooja N. Desai.[6] *[1]Department of Medicine, University of Chicago, Chicago, IL; [2]US Evidence, US Medical Affairs, AstraZeneca, Wilmington, DE; [3]Analysis Group, New York, NY; [4]Analysis Group, Los Angeles, CA; [5]Analysis Group, Boston, MA; [6]US Renal, US Medical Affairs, AstraZeneca, Wilmington, DE.*

Background: Hyperkalemia (HK) is associated with increased healthcare resource utilization (HRU) and costs, but there are limited data on the impact of HK recurrence on these in patients (pts) with chronic kidney disease (CKD). This real-world study describes all-cause medical costs and HRU in pts with recurrent HK (rHK), non-recurrent HK (nrHK) and normokalemia (NK).

Methods: Pts aged ≥18 years with stage 3/4 CKD were identified from Optum's de-identified Market Clarity data; HK was classified as rHK or nrHK by a claims-based algorithm. Pts with rHK were 1:1 exact and propensity-score matched with separate cohorts of pts with NK and nrHK. Index dates were the date of the first event of the index pair of HK diagnosis with ≥1 serum K^+ value >5.0 mEq within 7 days (rHK and nrHK cohorts) or a randomly-selected serum K^+ lab value of 3.5–5.0 mmol/L (NK cohort). Continuous insurance was required for 12 months before and after the index date. Study outcomes were all-cause medical costs and HRU over 12 months.

Results: There were 4549 matched pairs in the rHK vs NK analysis and 1599 matched pairs in the rHK vs nrHK analysis. The rHK cohorts had significantly higher mean per-pt all-cause medical costs than the NK cohort ($34,163 vs $15,175) and nrHK cohort ($52,290 vs $38,233) over 12 months (**Table**); HRU rates were also significantly higher for the rHK cohorts. The increased costs were driven by increased inpatient medical costs with rHK vs NK and rHK vs nrHK.

Conclusions: Large increases in all-cause medical costs and HRU after HK recurrence illustrate the unmet need for chronic management of HK in pts with stage 3/4 CKD, such as through long-term novel potassium binder therapies.

Baseline Characteristics of Early Enrollees in TRACK, a Prospective Study of Hyperkalemia Management Decision-Making

Judith Hsia,[1,2] Nitin Shivappa,[3] Ameet Bakhai,[4] Jordi Bover,[5] Javed Butler,[6,7] Pietro Manuel Ferraro,[8] Linda F. Fried,[9] Markus P. Schneider,[10] Navdeep Tangri,[11] Wolfgang C. Winkelmayer,[12] Meredith S. Bishop,[3] Hungta (tony) Chen,[3] Krister Järbrink,[13] Anna-Karin Sundin,[13] Marc P. Bonaca.[1,2] *[1]University of Colorado, Denver, CO; [2]CPC Clinical Research, Aurora, CO; [3]Biopharmaceuticals Medical, AstraZeneca, Gaithersburg, MD; [4]Royal Free London NHS Foundation Trust, London, United Kingdom; [5]Hospital Universitari Germans Trias i Pujol, Badalona, Spain; [6]Baylor Scott and White Research Institute, Dallas, TX; [7]University of Mississippi School of Medicine, Jackson, MS; [8]Universita Cattolica del Sacro Cuore, Milano, Italy; [9]University of Pittsburgh, Pittsburgh, PA; [10]University of Erlangen-Nürnberg, Erlangen, Germany; [11]University of Manitoba, Winnipeg, MB, Canada; [12]Baylor College of Medicine, Houston, TX; [13]Biopharmaceuticals Medical, AstraZeneca, Gothenburg, Sweden.*

Background: The TRACK study is a prospective, observational, implementation science study designed to address the evidence gap regarding healthcare provider decision-making and management of patients with hyperkalemia (HK).

Methods: The study will enroll 1250 patients with HK in the US and Europe and record management decisions, treatment objectives and outcomes, HK recurrence and attainment of target renin-angiotensin-aldosterone system inhibitor (RAASi) dose during 12 months following an index episode of HK. The planned sample size provides a margin of error <3% to estimate endpoints of interest such as attainment of target doses of RAASi therapies at month 12. Eligible participants are adults with serum K^+ >5.0 mmol/L collected during standard of care within 14 days prior to informed consent. Baseline characteristics of early enrollees are presented descriptively.

Results: Baseline characteristics and initial HK management approach are shown for the first 62 enrollees. Chronic kidney disease (CKD) and/or heart failure was present in 90%. Mineralocorticoid receptor antagonist use was reported by 7% and other RAASi by 53%. RAASi downtitration and discontinuation during the qualifying HK episode was reported for (18%). Median K^+ was 5.4 mmol/L (IQR 5.2-5.6); eGFR 26 mL/min/1.73m^2 (IQR 15, 35). The most common initial management strategies for the index episode of HK, apart from monitoring serum K^+, were prescription of a low K^+ diet and use of K^+ binders (Table). We anticipate enrolling approximately half of the planned 1250 participants for presentation at Kidney Week.

Conclusions: TRACK will characterize contemporary provider decision-making in patients with HK and its impact on HK recurrence across a broad range of patient types in a variety of practice settings in the US and Europe.

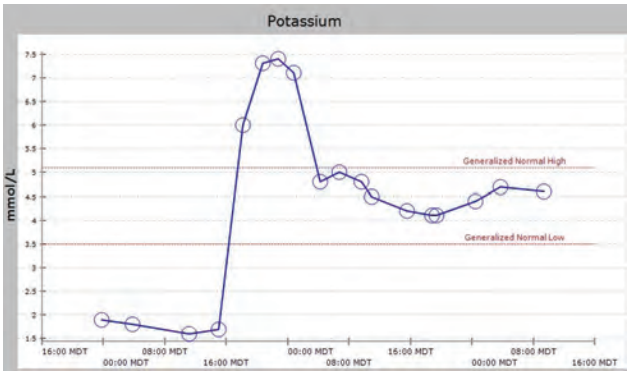
Thyrotoxic Periodic Paralysis Complicated by Severe Rebound Hyperkalemia

Raja Ravender, Zan Shareef, Pablo Garcia, J. Pedro Teixeira. UNM Nephrology. *The University of New Mexico, Albuquerque, NM.*

Introduction: Thyrotoxic periodic paralysis (TPP) is a rare, acquired subtype of periodic paralysis in which muscle weakness develops from profound hypokalemia in the setting of hyperthyroidism. We present a case of TPP complicated by severe rebound hyperkalemia.

Case Description: A 31-year-old Hispanic man without medical history presented with severe generalized weakness. His physical exam was notable for proptosis and tremor. Initial labs included hypokalemia (serum potassium 1.6 mEq/L), undetectable thyroid-stimulating hormone (TSH), free T4 2.3 ng/dL, and urine potassium 5 mEq/L. He was admitted to intensive care with a diagnosis of TPP and treated with methimazole, propranolol, and aggressive potassium replacement (100 mEq IV + 220 mEq PO in 24 hours). His weakness improved, but he subsequently developed severe hyperkalemia with peak serum potassium of 7.4 mEq/L (Figure 1). His hyperkalemia resolved with medical therapy. He was diagnosed with Graves' disease based on a positive TSH receptor antibody, and he was discharged home on methimazole and propranolol.

Discussion: TPP is a potentially fatal complication of hyperthyroidism characterized by episodes of sudden paralysis and hypokalemia, classically triggered by carbohydrate intake or exercise and often predating overt clinical hyperthyroidism. Though common in East Asian men, other non-white minorities, including Hispanics, appear to be at increased risk. Rather than potassium depletion, the primary cause of acute hypokalemia in TPP is transcellular shift caused by a hyperadrenergic state. As such, aggressive potassium repletion — particularly as the underlying hyperthyroidism abates with treatment — carries a risk of rebound hyperkalemia which can be lethal. Thus, initial treatment for TPP must focus on the underlying hyperthyroidism with antithyroid therapy and non-selective beta-blockade, with recommended potassium replacement limited to ≤90 mEq PO in 24 hours.



TH-PO358

Contemporary Use of Guideline-Directed Medical Therapy and Associated Outcomes in Cardiorenal Patients with Hyperkalemia: An Observational Multi-Country Study

Anjay Rastogi,[1] Charles Pollack,[2] Ignacio J Sanchez-Lazaro,[3] Eva Lesén,[4] Matthew Arnold,[5] Stefan Franzén,[6] Alaster Allum,[7] Toyoaki Murohara,[8] Eiichiro Kanda.[9] *[1]David Geffen School of Medicine at the University of California Los Angeles, Los Angeles, CA; [2]University of Mississippi School of Medicine, Jackson, MS; [3]Hospital Universitari i Politecnic La Fe, Valencia, Spain; [4]CVRM Evidence, AstraZeneca, Gothenburg, Sweden; [5]Real World Science and Digital, AstraZeneca, Cambridge, United Kingdom; [6]Medical & Payer Evidence Statistics, AstraZeneca, Gothenburg, Sweden; [7]BioPharmaceuticals Medical CVRM, AstraZeneca, Cambridge, United Kingdom; [8]Nagoya University Graduate School of Medicine, Nagoya, Japan; [9]Kawasaki Medical School, Okayama, Japan.*

Background: International guidelines recommend renin-angiotensin-aldosterone system inhibitor (RAASi) therapy at the maximal tolerated dose to optimize treatment benefits in chronic kidney disease (CKD) and heart failure (HF). However, RAASi therapy increases the risk of hyperkalemia (HK), which is a barrier to achieving guideline-directed RAASi therapy. Novel oral anti-HK treatments, e.g., sodium zirconium cyclosilicate (SZC), are recommended to manage HK and allow the maintenance of RAASi therapy. This ongoing observational study investigates contemporary use of guideline-concordant RAASi and SZC therapy and associated outcomes in cardiorenal patients (pts) with HK in 3 geographic regions.

Methods: This analysis includes data from hospital records and claims from the US (Optum Clinformatics Data Mart), Japan (Medical Data Vision) and Spain (Big-Pac), and evaluates adults with CKD and/or HF who have an HK episode (ICD-10 code E87.5) or initiate outpatient SZC therapy while treated with RAASi. The observation period started when SZC became available in the respective country (July 2019 [US], May 2020 [Japan], June 2021 [Spain]). Across countries, use of guideline-directed medical therapy (GDMT) and associated outcomes will be assessed in terms of maintained/reduced RAASi therapy, SZC treatment, and HK- and cardiorenal-related hospitalizations.

Results: The US dataset includes 125,632 cardiorenal pts (mean age, 74 years; 50% male) who had an HK episode. CKD was present in 83% of pts and HF in 56%. The 3648 pts who initiated SZC were younger (72 years), more often male (54%), and more often had CKD (96%) compared with the overall HK cohort. Data from Japan and Spain will be available for analyses during Q2 2023. Results from analyses of RAASi therapy and SZC treatment patterns and associated outcomes across countries will be presented at the ASN congress.

Conclusions: This study provides contemporary insights into the characteristics of cardiorenal pts with HK and use of GDMT in clinical practice across 3 geographic regions which, together with the associated outcomes, may guide treatment optimization and improve patient prognosis.

Evaluation of Efficacy, Safety, and Treatment Patterns of Sodium Zirconium Cyclosilicate in Management of Hyperkalemia in China: An Interim Analysis (Actualize)

Hong L. Lin,[1] Nan Shen,[1] Qingyang Meng,[1] Lihong Zhang,[2] Jing Yang,[3] Yong Qiang Lin,[4] Xinyu Liu,[5] Xudong Cai,[6] Juan Cao,[7] Qiang Zhu,[8] Xun Luo,[9] Xin Wan,[10] Henglan Wu,[11] Jianming Ye,[12] Chunyan Shan,[13] Hua Xie,[14] Yifan Wu,[15] Yanping Cao,[16] Jianmin Wang,[17] Xiaoyong Yu,[18] Huimin Wang,[19] Jingdong He,[20] Shaojiang Tian,[21] Wu F. Lei,[22] Yifan Shi.[23] Actualize Study Group. *[1]The First Affiliated Hospital of Dalian Medical University, Dalian, China; [2]The First Hospital of Hebei Medical University, Shijiazhuang, China; [3]Hefei First People's Hospital, Hefei, China; [4]Wenzhou Integrated Chinese and Western Medicine Hospital, Wenzhou, China; [5]Nanyang Central Hospital, Nanyang, China; [6]Ningbo Traditional Chinese Medicine Hospital, Ningbo, China; [7]Taixing People's Hospital, Taizhou, China; [8]Xinghua People's Hospital, Xinghua, China; [9]Hunan Provincial People's Hospital, Changsha, China; [10]The First Hospital of Nanjing, Nanjing, China; [11]The First Hospital of Jiaxing, Jiaxing, China; [12]The First People's Hospital of Kunshan, Kunshan, China; [13]Chu Hsien-I Memorial Hospital of Tianjin Medical University, Tianjin, China; [14]Dalian Ruikaer Renal Disease Hospital, Dalian, China; [15]Guangdong Provincial Hospital of Traditional Chinese Medicine, Guangzhou, China; [16]Handan First Hospital, Handan, China; [17]Linfen Central Hospital, Linfen, China; [18]Shanxi Provincial Hospital of Chinese Medicine, Xi'an, China; [19]Liaoning Health Industry Group Bensteel General Hospital, Liaoning, China; [20]Nuclear Industry 416 Hospital, Chengdu, China; [21]Shiyan People's Hospital, Shiyan, China; [22]Qidong People's Hospital, Qidong, China; [23]AstraZeneca Investment China Co, Medical Affairs, Shanghai, China.*

Background: Sodium zirconium cyclosilicate (SZC), a novel highly selective potassium binder is approved in China for the treatment of hyperkalemia (HK), a potential life-threatening electrolyte imbalance condition. This interim analysis from an ongoing multi-center, prospective, non-interventional study evaluated the efficacy, safety and treatment patterns of SZC in Chinese HK patients under real-world settings (NCT05271266).

Methods: This study included patients ≥18 years with documented HK from 40 sites in China, taking/willing to take SZC treatment. The interim analysis included patients who have completed 1 month follow-up. As per Chinese label, SZC treatment was categorized into correction phase (FAS-P1) and maintenance phase (FAS-P2); the treatment was discontinued as per HK threshold (5.3/5.5 mmol/L in most sites under real-world settings). The study evaluated changes in serum K^+ (sK^+) levels and incidence of adverse events (AEs).

Results: A total of 193 patients and 354 patients were enrolled in FAS-P1 and FAS-P2, respectively. With an SZC mean daily dose of 11.5g in FAS-P1, the sK+ levels reduced significantly from baseline, 5.9 mmol/L to 5.0 mmol/L (ΔsK^+ -0.9 mmol/L), after correction phase, 51.3% and 77.8% patients showed sK+ levels between 3.5-5.0 mmol/L and 3.5-5.5 mmol/L. With an SZC median daily dose of 5g in FAS-P2, the mean sK^+ levels were 5.1 mmol/L during the maintenance treatment. SZC was well tolerated with only 1.5% and 0.5% patients in FAS-P1 and FAS-P2, respectively reporting AEs with rarely severe AEs and treatment discontinuations (Table 1).

Conclusions: From the interim analysis, SZC was effective and safe in treating HK. Hence, SZC can be considered a standard treatment for acute and chronic HK in China.

Funding: Commercial Support - AstraZeneca Investment China, Shanghai, China

Table 1 Summary of AE with SZC

Association Between Hyperkalemia and Cardiovascular Outcomes in Patients with Stage 3b/4 CKD: REVOLUTIONIZE II Study

Abiy Agiro,[1] Ellen Colman,[2] Alexandra Greatsinger,[3] Jingyi Chen,[4] Angela Zhao,[4] Elaine M. Louden,[4] Erin Cook,[4] Fan Mu,[4] Pooja N. Desai,[2] Glenn Chertow.[5] *[1]US Evidence, US Medical Affairs, AstraZeneca, Wilmington, DE; [2]US Renal, US Medical Affairs, AstraZeneca, Wilmington, DE; [3]Analysis Group, New York City, NY; [4]Analysis Group, Boston, MA; [5]Stanford University School of Medicine, Stanford, CA.*

Background: Hyperkalemia (HK) is a common complication of moderate to advanced chronic kidney disease (CKD). The impact of HK (defined here as serum K+ >5.0 mEq and diagnosis code in any setting) on the time to cardiovascular (CV) outcomes among patients (pts) with CKD has not been well studied. Here we report cardiovascular (CV) outcome analyses from the REVOLUTIONIZE II study.

Methods: This observational study compared propensity score matched adult pts with stage 3b/4 CKD, with and without HK (HK and non-HK cohorts), in Optum's de-identified Market Clarity database. Index dates were the first CKD stage 3b/4 diagnosis date after ≥1 HK diagnosis in the 12 months (mo) prior (HK cohort) and a randomly selected CKD stage 3b/4 diagnosis date (non-HK cohort). Continuous insurance coverage was required for 12 mo before the index date. CV outcomes were major adverse CV events (MACE; all-cause mortality or inpatient [IP] admission with myocardial infarction or stroke), MACE+ (MACE or IP admission with heart failure), and IP admission with arrhythmia, analyzed in 3 matched subsets.

Results: Of 6619 matched pairs overall, CV analysis subsets included 5949 pairs for MACE, 5301 for MACE+, and 5564 for IP arrhythmia. Baseline variables were balanced between the two cohorts in all subsets. In each subset, the HK cohort had significantly higher rates of CV outcomes than the non-HK cohort during follow-up (P<0.001 for each CV subset; **Table**).

Conclusions: Among pts with stage 3b/4 CKD, rates of MACE, MACE+, and IP arrhythmia are significantly higher for pts with HK than those without HK. This reveals an unmet need for long-term outpatient treatment of HK.

Rates of Emergency Temporary Central Venous Access and Emergency Haemodialysis in the Advent of Lokelma: A Retrospective Case Series in a Tertiary Renal Unit

Will Marshall,[1] Gabriel A. Curran,[2] Jamie P. Traynor,[1] Patrick B. Mark,[2] Jennifer S. Lees.[2] *[1]NHS Greater Glasgow and Clyde, Glasgow, United Kingdom; [2]University of Glasgow, Glasgow, United Kingdom.*

Background: The value of Lokelma (sodium zirconium cyclosilicate) in the emergency treatment of hyperkalaemia is yet to be proven. We hypothesised that its use would be associated with a reduction in emergency temporary central venous access (CVC) and emergency haemodialysis (HD).

Methods: We conducted a retrospective case series of patients admitted to our unit with hyperkalaemia, comparing before (Jan 2018 – Dec 2019) and after (Apr 2021 – Sept 2022) Lokelma was available. All patients with a potassium >5.5 mmol/L treated with at least one ≥10g dose of Lokelma were analysed (post-Lokelma period). Patients treated with alternative potassium binders in the post-Lokelma period were excluded. A random number generator selected a comparator group of patients admitted with a serum potassium >5.5 mmol/L (pre-Lokelma period). Multivariable-adjusted logistic regression models determined likelihood of emergency temporary CVC and emergency HD.

Results: Of the 1668 patients admitted in the post-Lokelma period, 271 were suitable for analysis. 265 patients were selected from the pre-Lokelma period. Participants in both periods were well matched (Figure 1). In the post-Lokelma period, patients were 69% less likely to require emergency temporary CVC (OR 0.31; CI 0.21 – 0.47) and 73% less likely to need emergency HD (OR 0.27; CI 0.18 to 0.40). These results were consistent after sequential adjustment for potential explanatory variables (Figure 2).

Conclusions: Lokelma was associated with a signification reduction in emergency temporary CVC and emergency HD in patients presenting to a tertiary renal unit with hyperkalaemia.

The Beneficial Effect of Sodium Zirconium Cyclosilicate on the Continuity of Renin-Angiotensin-Aldosterone System Inhibitors in the Management of Hyperkalemia: A Retrospective Observational Study

Shun Minatoguchi,[1] Wakana Kimura,[1] Tomohiro Mizuno,[1] Shigehisa Koide,[1] Hiroki Hayashi,[1] Midori Hasegawa,[1] Daijo Inaguma,[2] Naotake Tsuboi.[1]
[1]Fujita Ika Daigaku, Toyoake, Japan; [2]Fujita Ika Daigaku Banbuntane Byoin, Nagoya, Japan.

Background: Sodium zirconium cyclosilicate (SZC), a non-absorbed non-polymer zirconium silicate, is a new potassium binder for hyperkalemia. A previous report showed that the administration of SZC in patients with hyperkalemia allows a higher continuation rate of renin-angiotensin-aldosterone system inhibitors (RAASi). However, few comparative studies have focused on the clinical utility between SZC and existing potassium binders. The purpose of this study was to evaluate the effect of SZC on the continuation of angiotensin-converting enzyme inhibitors (ACEIs)/angiotensin receptor blockers (ARBs) in patients with hyperkalemia compared to that of calcium polystyrene sulfonate (CPS).

Methods: Patients treated with ACEIs/ARBs, who were newly prescribed SZC or CPS for hyperkalemia at a tertiary referral hospital between August 2020 and April 2022, were enrolled in this single-center, retrospective observational study. The primary outcome measure was ACEIs/ARBs prescription three months after the initiation of potassium binders.

Results: A total of 174 patients on ACEIs/ARBs who were newly administered SZC (n=62) or CPS (n=112) were analyzed. The prescription rate of ACEIs/ARBs at three months was significantly higher in the SZC group than in the CPS group (89% vs. 72%). Multivariate logistic regression models showed that SZC was independently associated with the primary outcome (odds ratio 2.66, 95% confidence interval 1.05-7.43). The propensity score-matched comparison also showed a significant association between SZC and the primary outcome.

Conclusions: The current study demonstrated that the administration of SZC in patients with hyperkalemia allows for a higher continuation rate of ACEIs/ARBs than CPS. These findings suggest that SZC have potential benefits for patients with hyperkalemia receiving RAASi.

TH-PO363

A Paralyzing Consequence: Succinylcholine-Induced Hyperkalemia, A Rare but Dangerous Side Effect

Hannah Kruger, Ryan Mullane, Kathleen Borghoff. *University of Nebraska Medical Center, Omaha, NE.*

Introduction: Succinylcholine is a depolarizing neuromuscular blockade agent used during general anesthesia. Succinylcholine use can cause hyperkalemia and cardiovascular instability in certain susceptible patients. Here we describe a case of succinylcholine-induced hyperkalemia with cardiac arrest.

Case Description: A 27-year-old male with a medical history of alcohol use disorder was admitted to the ICU for rhabdomyolysis and septic shock due to MRSA pneumonia requiring mechanical ventilation. Following successful extubation, the patient had immobility due to profound weakness with an EMG demonstrating subacute sensory motor axonal polyneuropathy. He had also developed post-intubation dysphonia and laryngoscopy was recommended. Prior to laryngoscopy, his serum potassium level was 3.9 mEq/L. Upon administration of succinylcholine for intubation, he had a cardiac arrest. Immediate repeat labs revealed a serum potassium level of 9.2 mEq/L. Nephrology was contacted for emergent dialysis. In the interim, temporizing measures were given, including insulin with dextrose and calcium gluconate. A repeat serum potassium level was then 6.4 mEq/L with another level 30 minutes later being 3.3 mEq/L. The patient recovered without needing dialysis and was eventually discharged to an acute rehabilitation facility.

Discussion: Succinylcholine causes intracellular potassium efflux when binding to acetylcholine receptors. Several pathologic states cause an upregulation of acetylcholine receptors and predispose patients to a higher risk of critical hyperkalemia. These states include severe infections, rhabdomyolysis, diffuse atrophy, immobilization, denervation injury or diseases, and trauma. Identifying these conditions prior to using succinylcholine is vital. If succinylcholine use is required, close monitoring of the potassium level and cardiac status are necessary. The optimal treatment for patients with succinylcholine-induced hyperkalemia includes those treatments that redistribute potassium back inside cells. Dialysis has a limited role in treatment and poses a greater risk and delayed time to treatment. Succinylcholine-induced hyperkalemia is a rare, life-threatening condition, and practitioners should be aware of predisposing factors and appropriate treatment.

TH-PO364

Impact of Sodium Zirconium Cyclosilicate on Serum Potassium and Bicarbonate in Patients with Hyperkalemia and Metabolic Acidosis Associated with CKD: NEUTRALIZE Study

Stephen R. Ash,[1] Daniel Batlle,[2] Jessica B. Kendrick,[3] Yemisi Oluwatosin,[4] Laura Kooienga,[5] James M. Eudicone,[4] Anna-Karin Sundin,[6] Emily Guerrieri,[7] Linda F. Fried.[8] *[1]Nephrology Department, Indiana University Health Arnett, Lafayette, IN; [2]Division of Nephrology and Hypertension, Department of Medicine, The Feinberg School of Medicine, Chicago, IL; [3]Division of Renal Diseases and Hypertension, Department of Medicine, University of Colorado Anschutz Medical Campus, Aurora, CO; [4]Renal CVRM (US Medical), AstraZeneca, Wilmington, DE; [5]Colorado Kidney Care, Denver, CO; [6]BioPharmaceuticals Medical (Evidence), AstraZeneca, Mölndal, Sweden; [7]Renal CVRM, AstraZeneca, Gaithersburg, MD; [8]Division of Renal-Electrolyte, Veterans Affairs Pittsburgh Healthcare System and University of Pittsburgh, Pittsburgh, PA.*

Background: Acidosis and hyperkalemia are common in CKD. The dual effect of sodium zirconium cyclosilicate (SZC), a selective binder of potassium (K^+) and ammonium, on serum K^+ (sK^+) and serum bicarbonate ($sHCO3^-$) was evaluated in CKD patients with hyperkalemia (HK) and metabolic acidosis.

Methods: In the NEUTRALIZE study (NCT04727528), patients with CKD (Stage 3–5) not on dialysis with HK (sK^+ >5.1 to ≤5.9 mmol/L) and metabolic acidosis ($sHCO3^-$ 16–20 mmol/L) received open-label SZC 10 g TID for ≤48 h. Patients achieving normokalemia (NK; sK^+ 3.5–5.0 mmol/L) were randomized 1:1 to SZC 10 g QD or placebo (PBO) for 4 weeks. Primary endpoint was patients (%) maintaining NK at end of treatment (EOT) without rescue. Key secondary endpoints were patients (%) with NK with ≥3 mmol/L increase in $sHCO3^-$ without rescue, and change in $sHCO3^-$ from baseline (BL) to EOT.

Results: Patients (n=229) were screened and 37 were randomized and received treatment (SZC n=17; PBO n=20: high screen failure rate and slow enrolment led to early study termination). Mean age was 63.3y, 68% male, and 87% White. Mean sK^+ (mmol/L) at BL was 5.4 (SZC) and 5.5 (PBO) and for $sHCO3^-$ (mmol/L) 16.1 (SZC) and 15.6 (PBO). At EOT, patients maintaining NK was 88.2% for SZC and 20.0% for PBO (OR, SZC vs PBO, 56.2; P=0.001). Due to small patient number, P-values for secondary endpoints are nominal. $sHCO3^-$ (mmol/L) at EOT was 18.2 for SZC vs 16.5 for PBO (P=0.050). Patients maintaining NK and ≥3 mmol/L increase in $sHCO3^-$ without rescue was 35.3% (SZC) and 5.0% (PBO; P<0.05). For SZC, trends were seen towards a decrease in sK^+ and an increase in $sHCO3^-$ (**Figure**). No safety concerns were reported.

Conclusions: SZC effectively lowered sK^+ and maintained NK during treatment. Despite low patient number, trends towards significance were seen for the increase in $sHCO3^-$ with SZC.

Prevalence, Recurrence, and Prognosis of Hyperkalemia in Real-World Patients in China

Haijiao Jin, Yang Fan, Renhua Lu, Qin Wang, Minfang Zhang, Xiajing Che, Zanzhe Yu, Yijun Zhou, Leyi Gu, Zhaohui Ni. *Shanghai Jiao Tong University School of Medicine Affiliated Renji Hospital, Shanghai, China.*

Background: Hyperkalemia is a common and life-threatening electrolyte disorder. However, data on hyperkalemia burden in China especially its relationship to clinical outcome in real-world patients remain limited. We conducted a retrospective cohort study to investigate the prevalence, recurrence and prognosis of hyperkalemia in a large tetertiary hospital in China.

Methods: Patients aged ≥18 years who had at least one serum potassium measurement from January 2018 to December 2021 in a large tetertiary hospital in China were enrolled and followed up until April 2022. The primary endpoint was the proportion of patients who experienced a hyperkalemia event (serum potassium [sK] >5.0 mmol/L). Secondary endpoints included the proportion of patients who experienced hyperkalemia recurrence and all-cause mortality rate in patients with hyperkalemia. Risk factors associated with all-cause death in patients with hyperkalemia were analyzed using logistic regression (exploratory).

Results: A total of 55,288 patients were enrolled (median age: 54.0 years; 44.0% were male). Overall, 1131 patients(2.1%) experienced hyperkalemia (428 [0.8%] had sK >5.5 mmol/L and 167 [0.3%] had sK >6.0 mmol/L). 73.2% of patients with hyperkalemia were first diagnosed in the emergency department. Besides, hyperkalemia recurrence occurred in 12.4% patients during the 30 days follow-up, among them 6.6% patients recurred in 7 days. The 1-, 2-, 3- and 4-year all-cause mortality rates in patients with hyperkalemia were 18.5%, 19.5%, 19.9% and 20.2%. Risk factors for all-cause death were serum potassium level(per 1 mmol/L increase) [HR: 1.328, 95%CI:1.033-1.078,p=0.027] and hemoglobin lever(per 1g/dL) [HR:2.027, 95%CI: 1.460-2.815,p<0.01].

Conclusions: Hyperkalemia was common in real-world patients in China with relatively high recurrence and poor prognosis. In fact, hyperkalemia is not only considered as an occasional one-time critical event, but also affects long-term outcome and required continuous management.

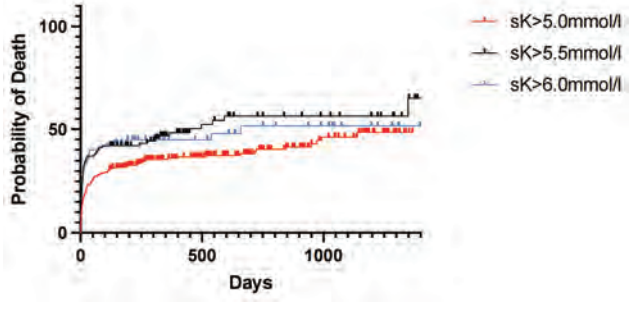

Figure 1. The all-cause mortality rates in patients with hyperkalemia.

Predictors of EKG Changes in Hyperkalemia

Jai Behgal, Salina Kalik, Michael Kwark, Tanvi Lather, Nnedindu Asogwa, Joanne Ling, Gennifer Wahbah Makhoul, Radu C. Grovu, Suzanne E. El Sayegh. *Staten Island University Hospital, Staten Island, NY.*

Background: Hyperkalemia can be potentially life-threatening in patients and calls for urgent intervention in a hospitalized setting. Typically, hyperkalemia is defined as serum potassium greater than 5 to 5.5 mEq/L. The incidence of hyperkalemia in hospitalized patients ranges from 1% to 10%. Studies have shown that the probability of electrocardiogram (ECG) changes increases with increasing serum potassium levels. ECG changes are also more common with acute, rapid changes of serum potassium and the concomitant presence of hypocalcemia and/or acidemia. In experimental settings, there appears to be a clear association between hyperkalemia and typical ECG abnormalities. However, in actual clinical practice, the relationship between potassium levels and ECG manifestations is less clear.

Methods: A partial database search and retrospective review of medical charts at Staten Island University Hospital between the years 2019-2022 was performed evaluating patients with hyperkalemia with potassium levels > 6.5 mEq/L. ECGs were reviewed to identify changes related to hyperkalemia. The presence or absence of certain variables, including demographics, electrolyte abnormalities, medications, and other co-morbidities were compared between the patients that had ECG changes and those that did not. We excluded patients with hemolyzed potassium samples and patients with baseline ECG changes. Univariate chi-square analysis and multivariate analysis were performed.

Results: One hundred forty-nine patients were identified that had admissions for non-hemolyzed hyperkalemia with serum potassium levels greater than 6.5 mEq/L, of which only 38 patients presented with EKG changes. There was no significant difference between patients with the presence or absence of CKD, ESRD, CHF, diabetes potassium-sparing diuretics, ACEs or ARBS, or patients admitted for rhabdomyolysis or acute coronary syndrome.

Conclusions: No significant predictors of ECG changes were identified in patients that had presented with hyperkalemia greater than 6.5 mEq/L between 2019-2022 at SIUH. The study may have been limited by the patient population. A larger patient population size may help identify predictors of ECG changes when hospitalized patients are admitted with hyperkalemia. Identifying these factors may potentially guide future treatment of hyperkalemia in the clinical setting.

TH-PO367

Real-World Experience with Sodium Zirconium Cyclosilicate for Hyperkalemia in the Acute Inpatient Setting

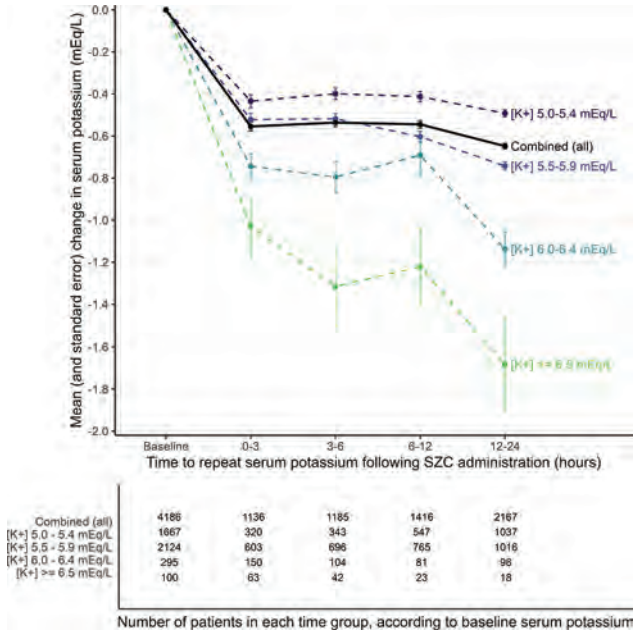
Jamie S. Hirsch,[1,2] Kenar D. Jhaveri,[1,2] Steven Fishbane,[1,2] Jia Hwei Ng.[1,2]
[1]*Donald and Barbara Zucker School of Medicine at Hofstra/Northwell, Hempstead, NY;* [2]*Northwell Health, New Hyde Park, NY.*

Background: The potassium binder sodium zirconium cyclosilicate (SZC) is often used for hyperkalemia treatment in the hospital. Its utility in this setting remains unknown, having been studied largely among outpatients and patients on dialysis. We sought to evaluate the real-world efficacy of SZC monotherapy for acute hyperkalemia in a large health system with a diverse patient population.

Methods: We included all adult (≥18) patients admitted to emergency departments or hospitals of Northwell Health in 2021-22; who received SZC due to a serum potassium (K) ≥5 mEq/L; and received no concomitant K-lowering therapy (loop diuretics, bicarbonate, insulin, albuterol, potassium binders, dialysis). Only the first SZC dose per patient was analyzed, and K was evaluated for up to 24 hours. We examined the mean reduction in K overall and by predefined hyperkalemia severity stratifications.

Results: Among 4186 patients, mean (SD) age was 71.3 (15.3) years with 55.3% men. Mean (SD) K was 5.6 (0.35) mEq/L. The proportion of patients with K 5-5.4, 5.5-5.9, 6-6.4, and ≥6.5 mEq/L were 39.8%, 50.7%, 7.0%, and 2.4%, respectively. SZC resulted in mean (SD) K decrease 0.56 (0.71) mEq/L within 3 hours, with greater reductions at higher baseline K levels (Figure). By 24 hours, 58.9% of patients had a decline in K of ≥0.5 mEq/L and 77.4% had K <5.5 mEq/L.

Conclusions: In the largest real-world study of SZC monotherapy in the acute setting, we found SZC to be effective for moderately severe acute hyperkalemia. Treatment efficacy was achieved after administration, and most patients had a clinically meaningful response. Further studies could help define the role of SZC with more severe hyperkalemia and when used with other therapeutic agents.



Mean (SE) change in K at intervals by baseline K and overall, and number of patients

TH-PO368

Minimizing Hypoglycemia Associated with Insulin Use for the Treatment of Hyperkalemia in the Inpatient Setting

Ruchika Batwara,[1] Ciaran A. Twomey Brenner,[2] Janet M. Shapiro.[1] *[1]Icahn School of Medicine at Mount Sinai, New York, NY; [2]King's College London, London, United Kingdom.*

Background: Insulin use for hyperkalemia has been linked to hypoglycemia, especially with the commonly used 10 Units of Regular Insulin. However, studies have shown that a lower insulin dose of 5 units is just as effective in reducing potassium levels, with fewer incidences of hypoglycemia. Our Quality Improvement Project aims to establish a standardized Insulin protocol for hyperkalemia treatment across our Health System.

Methods: We searched our hospital's Electronic Health Record database to assess uses of the inbuilt "Hyperkalemia Order Set" within 30 days before and after the intervention. Our analysis considered lab data, Insulin usage, and finger stick glucose (FSG) after Insulin administration. The intervention involved: (A) educating the providers and (B) modifying the Hyperkalemia Order Set to default to 5 Units of Insulin, with up to 10 Units allowed at the provider's discretion. An alert was included with the Insulin order, reminding the provider to adjust the dose for renal impairment.

Results: During the 30-day observation phase, 48 orders were identified for intravenous (IV) Regular Insulin (with IV Dextrose 25 grams, per protocol) in patients with a mean pre-treatment serum potassium of 6.0 Meq/L. Among these orders, 69% prescribed 10 Units of Insulin while 31% prescribed 5-8 units of Insulin. We found 6 documented cases of hypoglycemia (FSG < 60) accounting for 12.5% of all orders. These patients were more likely to have received a higher dose of Insulin (mean Insulin dose = 10.2 Units) and have impaired renal function. In the post-intervention analysis, 37 orders were identified for IV Regular Insulin over a 30-day period. The mean pre-treatment potassium level was 6.5 Meq/L. Of these orders, 15.7% prescribed 10 Units of Insulin while the remaining 84.3% prescribed 5 units of insulin or less. Notably, three cases of severe hyperkalemia (mean potassium = 7.3 Meq/L) were successfully treated stepwise with 5 Units of Insulin followed by an additional 5 units given after repeating the potassium and glucose level. No cases of hypoglycemia were identified in the post-intervention phase.

Conclusions: Institutions need to have consistent protocols in place for managing hyperkalemia. Lower doses of insulin can effectively treat hyperkalemia while minimizing the risk of hypoglycemia.

TH-PO369

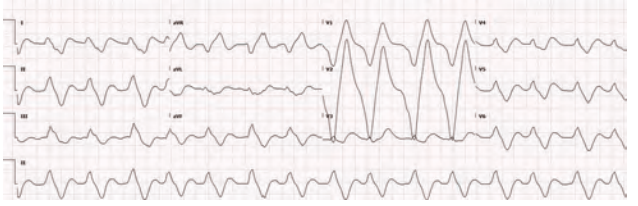
A Case of Severe Hyperkalemia: How High Can You Go?

Golriz Jafari, Masoud Haghi, Phuong-Chi T. Pham, Anita Kamarzarian. *UCLA Medical Center Olive View, Sylmar, CA.*

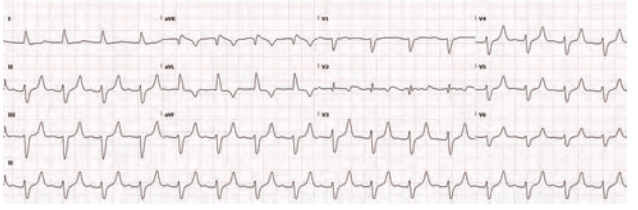
Introduction: Hyperkalemia is a common complication of both acute kidney injury (AKI) as well as chronic kidney disease (CKD). In severe cases, it can result in fatal arrhythmias and cardiovascular complications. Extremely elevated values may be mistaken for lab error due to hemolysis which can delay treatment and lead to preventable complications.

Case Description: A 46-year-old female with HTN and DM who presents to the emergency room with abdominal pain and found to have AKI with creatinine 8.9 mg/dl, BUN 75 mg/dl, CO2 9 mmol/L and severe hyperkalemia K 10 meq/L. There was no available baseline creatinine or history of prior CKD. Initial ECG at 22:07 showed QRS widening which was near a sinusoidal wave pattern. Patient was temporized with calcium gluconate, insulin/D50, fluids and received loop diuretic and zirconium. Dialysis access was quickly obtained, and dialysis initiated with 2K bath for the first hour followed by 1K bath for the second hour. Follow up ECG at 22:25 showed improvement of QRS after temporization and ECG had complete resolution with normal sinus rhythm and narrow QRS complex post dialysis. Etiology of AKI was presumed due to severe hypovolemia from poor oral intake in setting of Covid infection. There was no evidence of rhabdomyolysis, hemolysis, or urinary obstruction. Patient only required 1 dialysis session and creatinine improved to 3.4 on discharge 3 days later and 1.9 mg// dl 10 days after.

Discussion: Patients with advanced CKD and especially those on dialysis can usually tolerate higher levels of serum potassium due to higher intracellular stores and consequently a lower degree of membrane potential differential. In contrast patients with AKI usually do not have that buffer and have a higher likelihood of morbidity and mortality with severe hyperkalemia. ECG is a valuable tool to assess, confirm and monitor hyperkalemia in order to avoid delays in treatment and prevent cardiac arrest.



ECG at 22:07



ECG at 22:25

TH-PO370

Life-Threatening Hypokalemia: Incidence, Risk Factors, and Clinical Outcomes

Alaeldin Abdalla,[1] Sultan Fathi,[1,2] Ruaa A. Mansi,[1,2] Ciara De Buitleir,[1] Yusuf E. Abdalla,[1] Shari Srinivasan,[1] Peter J. Conlon.[1,2] *[1]Beaumont Hospital, Dublin, Ireland; [2]Royal College of Surgeons in Ireland, Dublin, Ireland.*

Background: Hypokalemia is one of the most common electrolyte disturbances encountered in clinical practice, and it can be fatal. Extremely low potassium levels (less than 2.5 mmol/L) can cause muscle necrosis, paralysis, cardiac arrhythmias, respiratory failure, and sudden death. In addition to decreased intake and trans-cellular shifts, the most common etiological factors in clinical practice are medication use, renal and gastrointestinal losses. To prevent serious complications, it is essential to conduct a thorough evaluation to determine the cause, correct it rapidly and closely monitor the patient's serum potassium levels.

Methods: In this retrospective analysis, we aimed to determine the incidence, risk factors, clinical manifestations, and outcomes of life-threatening hypokalemia in patients admitted to Beaumont Hospital between January 2018 and December 2023. A serum potassium concentration of less than 2.0 mmol/L was defined as life-threatening hypokalemia. The information was extracted from the laboratory information system, electronic patient records and medical charts.

Results: A total of 2,058,608 samples were analyzed for potassium during the study period. Among these, 208 (<0.01%) instances demonstrated life-threatening hypokalemia in an aggregate of 53 patients. Mean age at presentation (+SD) was 63 ± 21 years, with the majority (35/53, 66.3%) being females. Non-surgical causes were the most prevalent primary diagnosis, in which gastrointestinal and renal losses accounted for 35% of the cases in the setting of sepsis as a prevalent precipitating etiology in 18.9%. Long-standing gastrointestinal conditions such as Ulcerative colitis, Crohn's disease, and Gastritis [23% (n=12)], chronic alcohol use [21%], and chronic kidney diseases [9% (n=5)] are important risk factors. In approximately 2% of the cases, hypokalemia was caused by medication. Majority of patients required intravenous potassium replacement to a maximum of 560mmols, under close monitoring in ICU or CCU. In 4% of patients, life-threatening hypokalemia precipitated cardiac arrest. Over all, in-hospital mortality was observed in 17% of patients.

Conclusions: Severe life-threatening hypokalemia is uncommon, but associated with significant morbidity, and can be fatal. Gastrointestinal and renal losses are significant contributors.

TH-PO371

Hypokalemia: An Enigma

Gaayathri Krishnan,[1] Cason Murdoch,[2] Alexa Morrow,[2] Kemi Falope,[1] Fernando M. Abanilla.[1] *[1]AdventHealth, Sebring, FL; [2]Lake Erie College of Osteopathic Medicine, Bradenton, FL.*

Introduction: Hypokalemia is common, but *severe hypokalemia* (K < 2.5 mmol/L) is rare, with a narrower differential. This unique case presents a patient whose interminable hypokalemia was an enigma and whose labs were significantly discordant with presentation.

Case Description: A 47y/o man with diabetic CKD II presented to the ER with global weakness and paresthesias for two days. He denied diarrhea, nausea, or vomiting, but admitted to taking homeopathic OTC supplements from his home country with unknown contents. P/E including vitals was benign except for diminished strength across all muscle groups. Labs showed severe hypokalemia <1.5mEq/L, AKI, hypocalcemia, and combined HAGMA and NAGMA. Other electrolytes were normal. EKG revealed sinus rhythm. He was admitted to the ICU and started on oral and parenteral potassium supplementation. HAGMA resolved on day 2, but NAGMA persisted. After investigation, all causes of HAGMA proved negative and its origin remained unclear. Due to resolute NAGMA and hypokalemia, RTA was considered due to a negative diarrhea workup. Urine studies revealed a mixed picture - negative urine anion gap but high pH consistent during hospitalization. His family brought his OTC medications on the day of discharge, which contained phenolphthalein (PH), which was discontinued. Despite dramatic corrective measures, potassium levels improved marginally; it took five days of hospitalization to normalize.

Discussion: PH, a stimulant-laxative and OTC weight loss supplement, is banned in most countries due to carcinogenic effects, but still available in developing countries, and studies show harmful impact on kidneys due to toxicity and electrolyte imbalances. Although the patient did not experience diarrhea, PH, mainly eliminated by his kidneys, led to his lab anomalies. Persistent NAGMA, hypokalemia, and no diarrhea suggested RTA, but urinary studies indicated neither proximal nor distal RTA. Studies relay urinary pH is less reliable than anion gap as an indicator of RTA type. Chronic diarrhea mimics proximal RTA with a negative anion gap but variable pH which depends on hydration, and thus the urine sodium delivered to the collecting duct. Several cases of PH-induced hypokalemia were reported, having similarly mild symptoms relative to the degree of hypokalemia, likely due to the chronicity of use as in this patient. Thus, chronic PH use may result in milder symptoms for severe hypokalemia than expected.

TH-PO372

Hypokalemic Rhabdomyolysis as an Unusual Consequence of Cryptosporidium-Associated Diarrhea in an Immunocompromised Host: A Case Report

Marc Lawrence S. Soco, Rey Jaime M. Tan. *Philippine General Hospital, Manila, Philippines.*

Introduction: Hypokalemic rhabdomyolysis is rare and frequently overlooked. While most case reports associate it with renal potassium wasting, gastrointestinal losses leading to rhabdomyolysis have been sparsely reported. We report a case of an immunocompromised individual with cryptosporidium-associated diarrhea resulting to hypokalemic rhabdomyolysis.

Case Description: A 38-year-old Filipino male with a two-month history of anorexia, weight loss, and diarrhea presented to our institution with bilateral lower extremity weakness. Pertinent findings include hypotonia, decreased muscle strength in both lower extremities, and diminished deep tendon reflexes. Workup revealed a positive HIV test, serum creatinine 1.38 mg/dL (eGFR 64.40 mL/min/1.73m^2), blood urea nitrogen 21.07 mg/dL, and potassium 1.4 mmol/L. The complete blood count, electrocardiogram, thyroid function tests, and other serum electrolytes were unremarkable. The calculated urine potassium-creatinine ratio of 0.9, transtubular potassium gradient of 3.1, normal anion gap metabolic acidosis, and a negative urine anion gap were all consistent with lower gastrointestinal potassium loss. Rhabdomyolysis was confirmed with positive urine myoglobin and elevated serum creatinine kinase (15,573 U/L). Upon further investigation into the diarrhea, he was diagnosed with cryptosporidiosis. He received potassium supplementation and adequate hydration and eventually started on anti-retroviral drugs with the eventual resolution of symptoms.

Discussion: Potassium release into the interstitial fluid is crucial in regulating muscle blood flow during skeletal muscle contraction. Severe hypokalemia, whether renal or extrarenal in origin, attenuates this physiologic vasodilation resulting in relative ischemia and muscle necrosis. Hypokalemia caused by lower gastrointestinal losses only occurs if the diarrhea is persistent, as observed in this patient with cryptosporidiosis, or if accompanied by significant volume loss. This case underscores the significance of excluding rhabdomyolysis in patients with profound symptomatic hypokalemia. Thorough evaluation and clinical suspicion can aid in accurate diagnosis and prompt treatment.

TH-PO373

An Unusual Electrolyte Disturbance in Iron Man Athlete

Connor J. Grantham,[1] Hunter K. Huston.[2] *[1]Vanderbilt University Medical Center, Nashville, TN; [2]UPMC, Pittsburgh, PA.*

Introduction: Endurance athletes are at risk for developing numerous electrolyte disorders during competition, famously hyponatremia. The incidence ranges from 0 to 18% in marathoners and triathletes and may be as high as 51% in longer endurance events. Other disturbances with potassium and acid base balance may also be present. The healthcare and performance industries continue to try optimize this balance.

Case Description: A 38 year old male participating in the Ironman World Championship developed exhaustion, tingling in his extremities and swelling. Unable to finish the race, initial medical evaluation revealed a venous pH of 7.64, PCO2 of 57.7, HCO3 level of 62.2. Sodium of 128, potassium of 2.3, chloride less than 65. He received two liters of normal saline and 40mEq of potassium chloride with rapid improvement in his symptoms. Due to prior episodes of hyponatremia and nausea while training, this patient had sought consultation with a company focused on sweat and solute replacement. Testing illustrated a sweat rate of 2.5 L per hour and over 2 g of sodium per liter. He noted improvement in his performance with a concentrated electrolyte mix of sodium and potassium, as well as a dedicated water replacement strategy. However, for this race he used a strictly sodium citrate solution, delivering 25 grams of sodium citrate.

Discussion: The case represents a unique presentation of citrate toxicity in a high endurance athlete. The patient had been supplementing his electrolytes during this race, using sodium citrate alone with a focus on mitigating sodium loss. He consumed 25 g of sodium citrate over four hours and developed citrate toxicity which contributed to his metabolic alkalosis and hypokalemia. The case demonstrates the importance of maintaining a high index of suspicion for electrolyte abnormalities in athletes. It highlights the role of Nephrology in optimizing fluids and electrolytes for high performance athletes, thereby avoiding hazard and improving performance. Finally, it serves as a reminder to monitor the contents and concentrations of supplements for our patients, itself a burgeoning industry.

TH-PO374

Urinary Potassium Excretion Rate in Hypokalemic Periodic Paralysis: Spot vs. 24-Hour Urine

Chih-Chien Sung,[1] Chien-Chou Chen,[1] Chin Lin,[2] Yu-Juei Hsu,[1] Chien-Ming Lin,[3] Shih-Hua P. Lin.[1] *[1]Division of Nephrology, Department of Medicine, Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan; [2]School of Medicine, National Defense Medical Center, Taipei, Taiwan; [3]Tri-Service General Hospital, National Defense Medical Center, Taipei, Taiwan.*

Background: Hypokalemic periodic paralysis (HypoKPP) with acute hypokalemia and muscle paralysis is a potentially life-threatening emergency requiring rapid diagnosis and management. The role of timely spot versus 24 hour urine for urine K^+ excretion rate in the diagnostic and therapeutic value of HypoKPP have not well evaluated.

Methods: HypoKPP patients with the exclusion of other non-HypoKPP causes and incomplete urine collection were consecutively enrolled over 5 years. Spot and 24 hour urine collection for urine K^+ and other electrolytes excretion rate, and clinical characteristics including K^+ supplementation to achieve recovery were examined. Spot urine K^+ excretion was calculated by transtubular potassium concentration gradient (TTKG) and potassium-creatinine ratio (K^+/Cr). Balanced K^+ was defined as (supplemental K^+-24 hour urine K^+ excretion). Patients with K^+ deficit was defined as positive balanced K^+.

Results: Sixty-two HypoKPP patients (age 35.5 ± 10.4 year-old) including thyrotoxic periodic paralysis (TPP) (n=50), sporadic periodic paralysis (SPP) (n=9), and others (n=3) had hypokalemia (serum K^+ 2.2 ± 0.5 mmol/L) and received K^+ supplementation (77.0±45.3 mmol) to achieve recovery. All of them had a higher 24 hour urine K^+ excretion (61.7 ± 34.2 mmol/day > 20 mmol/day), but their TTKG (< 3, 64% of them) or K^+/Cr (< 0.18 mmol/L/mg/dl, 84% of them) were often lower. Despite acute hypokalemia without K^+ deficit, thirty-eight patients (61%) with a positive balanced K^+ balance had significantly lower serum K^+ (2.1±0.5 vs 2.4±0.4 mmol/dL, p=0.013), needed more supplemental K^+ (96.1±43.6 vs 46.7±28.8 mEq, p<0.001), and exhibited a slower increase in serum K^+ concentration during K^+ supplementation than those without K^+ deficit (n=24).

Conclusions: To evaluate urine K^+ excretion rate, timely spot urine is superior to 24 hour urine, which helps reveal the underlying subclinical K^+ deficit in HypoKPP patients.

TH-PO375

Newly Diagnosed Graves Disease in a Young Patient with Lower Extremity Weakness

Trey H. Richardson, Russell Leong, Connor J. Grantham, Osama El Shamy. Vanderbilt Nephrology. *Vanderbilt University Medical Center, Nashville, TN.*

Introduction: The differential diagnosis for myositis and myopathy is broad and includes medication side effects, auto-immune myositis, infectious myositis, neuromuscular junction disease, metabolic diseases, and electrolyte abnormalities.

Case Description: A 32-year-old male with osteoarthritis presents to the emergency department with acute lower extremity weakness that developed over the course of the day. He had a similar episode 3 months ago that self-resolved, however on this occasion, the weakness progressed to lower extremity paralysis, prompting his presentation. His labs were notable for a potassium of 2.2 mEq/dL, an undetectable TSH, total T3 of 311 (high), and a T4 of 1.6 (high). Thyroid receptor antibodies were elevated to 21.3. He was diagnosed with thyrotoxic periodic paralysis (TPP) due to Graves disease. His potassium was repleted, and he was started on methimazole with rapid improvement in his symptoms.

Discussion: TPP is a skeletal muscle channelopathy associated with hyperthyroidism - most often secondary to Graves disease. Besides hypokalemia, differentiating factors from other forms of periodic paralysis include elevated T4, low T3, hypophosphatemia, hypomagnesemia, and often presents after the second decade of life. Thyrotoxicosis increases the activity and transcription of the Na-K ATPase, enhances sensitivity to catecholamines, and inhibits potassium leak channels leading to intracellular potassium

shifts. This leads to cellular hyperpolarization and subsequent paralysis. Treatment of TPP should be directed at correcting hypokalemia. Those treated with intravenous potassium tend to recover more quickly than those receiving oral supplementation. Lifestyle modifications such as avoiding heavy exercise, high-carbohydrate meals, and alcohol are crucial. Definitive treatment is achieved by restoring euthyroidism either through medications, radioactive iodine ablation, or surgery. It is vital to maintain a high index of suspicion of TPP in patients presenting with hypokalemia and abrupt paralysis.

TH-PO376

An Unexpected Cause of Hypokalemia and Metabolic Alkalosis

Kanza Haq,[1] Carmen E. Cervantes,[1] Tareq Hanouneh,[3] Mohamad A. Hanouneh.[1,2] *[1]Johns Hopkins University, Baltimore, MD; [2]Nephrology Center of Maryland, Baltimore, MD; [3]Mayo Clinic in Florida, Jacksonville, FL.*

Introduction: Ectopic ACTH syndrome (EAS) is a rare cause of Cushing's syndrome and is often linked with cancer, particularly neuroendocrine tumors, among which bronchial carcinoids are the most common. ACTH-secreting pulmonary carcinoids are often small and pose diagnostic/therapeutic challenges.

Case Description: A 21-year-old man presented to the hospital with psychosis symptoms. His BP was 140/90 mmHg. Laboratory test results are listed in Figure 1A. Further workup revealed low serum levels of renin < 0.1 ng/ml/hour and aldosterone 3.1 ng/dL. AM serum cortisol, 24-hour urine cortisol, and ACTH levels were elevated at 49.5 mcg/dL, 5,904 ug/g Cr, and 258 pg/ml, respectively. Brain MRI showed a 5mm pituitary adenoma (Fig 1B). High-dose dexamethasone suppression test resulted in less than 50% suppression of serum cortisol, indicating a potential source of ectopic ACTH secretion. Inferior petrosal sinus sampling resulted in non-functional pituitary adenoma. A CT scan of the chest/abdomen/pelvis was performed but failed to identify the source of ACTH secretion. Eventually, a PET radiotracer (Gallium-68 dotatate) scan showed a left lung perihilar nodule with somatostatin receptor positivity (Fig 2A). Lung nodule resection confirmed a carcinoid tumor labeled immunohistochemically with ACTH and resulted in the resolution of hypokalemia and hypertension.

Discussion: 11β-HSD2 enzyme inactivates cortisol to cortisone. High levels of circulating cortisol oversaturate the activity of 11β-HSD2, leading to a mineralocorticoid effect on the collecting ducts, causing sodium resorption and potassium excretion (fig 2B). Clinical manifestations of hypercortisolism include hypertension, hypokalemia, metabolic alkalosis, low serum renin, and low aldosterone levels.

Figure 1A

Tests	Results	Normal range
Sodium	143 mmol/L	132-148 mmol/L

TH-PO377

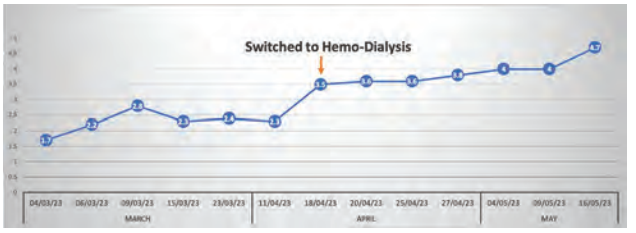
Severe, Symptomatic, and Resistant Hypokalemia in Peritoneal Dialysis

Mahendra L. Agraharkar,[1,2] Abinay S. Vanteru,[4] Krishna Vani Nemalidinne.[3] *[1]The University of Texas Medical Branch at Galveston School of Medicine, Galveston, TX; [2]Baylor College of Medicine, Houston, TX; [3]Max Hospital Gurgaon, Gurgaon, India; [4]Max Healthcare Institute Limited, New Delhi, India.*

Introduction: Hypokalemia is common in peritoneal dialysis (PD) patients and it affects a third of all PD patients. According to the Peritoneal Dialysis Outcomes and Practice Patterns Study (PDOPPS), the prevalence of hypokalemia in PD patients ranges from 3% to 47%. The reason can be poor intake, increased losses from sweat, urine, stool or dialysis and intracellular shift. Hypokalemia is associated with an increased risk of arrythmia and cardiovascular mortality.

Case Description: A 53-year-old female ESRD patient with a history of diabetes, hypertension and dyslipidemia on peritoneal dialysis presented with bilateral leg weakness. She had hypokalemia that was resistent to potassium chloride, ACE inhibitors and spironolactone. Magnessium level was low and was replaced. Her medication list included potassium chloride 80 mg BID, lantus insulin, lisinopril and spironolactone. Her aldosterone level was 5 ng/dl (4 - 31). Dialysate effluent potassium was only 1.7 mmol/L. The patient was discharged home hypokalemic but symptom free. A month later, she was readmitted with persistent bilateral leg weakness and pain. She had severe hypokalemia despite high dose oral potassium, ACE inhibitors and spironolactone. She was switched to hemodialysis and insulin dose decreased. Her potassium levels normalized on a standard bath of 2K (2 mEq/L). She is off potassium and spironolactone. Her symptoms improved dramatically.

Discussion: Hypokalemia is very common in peritoneal dialysis patients and can leed to fatal cardiac arrhythmia. In most cases it is amenable to treatment with potassium supplements or addition of ACE inhibitors or spironolactone. In our patient, we failed to treat her hypokalemia while on PD. The normal distribution of potassium between cells and the extracellular fluid is maintained by the Na-K-ATPase pump in the cell membrane. In our case, we believe that it was disrupted due to presence of insulin resulting in hypokalemia from increased potassium entry into cells. We are not aware of any other means to maintain normokalemia and have not encountered any case that needed a change in modality due to hypokalemia.



Persistent Hypokalemia in Peritoneal Dialysis

TH-PO378

Flaccid Paralysis due to Nafcillin-Induced Pseudo-Gitelman Syndrome

Hassan H. Allahrakha, Hector L. Santiago-Gonzalez, Roberto L. Collazo-Maldonado. *Methodist Dallas Medical Center, Dallas, TX.*

Introduction: Mild hypokalemia is a known side effect of the penicillin antibiotic Nafcillin. However, severe hypokalemia (i.e., serum potassium of <2.5 mmol/L) after starting penicillin-type antimicrobials is rare. Severe hypokalemia can be associated with weakness, cramps, arrythmias, and increased risk of mortality. Hypomagnesemia is a well-known cause of hypokalemia. In hospitalized patients, most cases of hypokalemia are asymptomatic or mild.

Case Description: We present the case of a 69-year-old woman with a history of methicillin-sensitive *Staphylococcus aureus* bacteremia. She was started on Nafcillin 12 g/day during a prior hospitalization, which was continued as an outpatient. The patient had intermittent hypokalemia at that time. However, her magnesium and potassium levels were normal at discharge. She was readmitted to the hospital 10 days later with chief complaints of nausea, diarrhea, body aches, weakness, flaccid paralysis, muscle spasms, and numbness. Upon arrival to the emergency department, she was noted to have low potassium (1.6 mEq/L) and magnesium (1.0 mEq/L) levels. Her vital signs were stable and physical exam was unremarkable besides diffuse flaccid paralysis. She received IV and oral potassium chloride with aggressive magnesium replacement. Despite attempts at repleting both electrolytes, her hypokalemia and hypomagnesemia persisted. Her urinary fractional excretion of potassium and magnesium were elevated, suggesting renal potassium and magnesium wasting. Nafcillin was replaced with daptomycin after consultation with Infectious Disease, and her potassium level and magnesium levels normalized within 24 hours. Her potassium at discharge was 4.3 mEq/L and magnesium was 2.0 mEq/L.

Discussion: Nafcillin-induced hypokalemia is rare. Nafcillin is a non-reabsorbable anion that causes increased sodium absorption in the collecting duct and makes the urinary lumen more negative, which facilitates potassium excretion. In this case, Nafcillin also contributed to hypomagnesemia, resulting in renal magnesium wasting.

TH-PO379

Too Much of a Good Thing Can Be Deadly

David M. Brooker, Sheahahn V. Soundranayagam, Brandon T. Dunmyre, Patricia Khalil. *Allegheny Health Network, Pittsburgh, PA.*

Introduction: The treatment of megaloblastic anemia from vitamin B12 deficiency results in an increase in hematopoietic cell production leading to potassium uptake into the cells. This has been reported to cause hypokalemia. It is rare for this to cause arrhythmias leading to cardiac arrest. We present a case of hypokalemia following vitamin B12 administration which resulted in cardiac arrest.

Case Description: A 29 y/o G1P0 female was found to have anemia with workup revealing low vitamin B12 level. She was started on oral B12 which was escalated to IM injections at 33 weeks gestation. She received weekly doses of IM B12 1,000mcg x 4 doses. Serum potassium 4 months prior was 3.9 mmol/L and was not repeated. Ten days after her final dose, at 37 weeks gestation she suffered a cardiac arrest with achievement of ROSC. Workup at the hospital revealed a serum potassium of 2.1 mmol/L which required intensive IV potassium repletion. Along with that she had features of pre-eclampsia. Blood pressure ranged from systolic readings of 110 to 150 mmHg, with serum creatinine ranging from 0.3-0.7 mg/dL, and spot UPCR of 350mg/g. She had spontaneous vaginal birth at 37 weeks gestation. Cardiac workup showed no coronary disease and no evident etiology for the cardiac arrest. Workup for hypokalemia was initiated and no other cause was identified including no endocrinology or genetic conditions. Discharged in stable condition

on potassium supplementation with external defibrillator. She was taken off potassium supplementation as outpatient with stable potassium levels and no other cardiac event.

Discussion: In normal pregnancy, vitamin B12 levels can decline by as much as 30% by the third trimester. Typically recommendations are to replete if symptomatic or with macrocytic anemia. Dangerously low levels of potassium leading to cardiac arrest are possible following vitamin B12 replacement therapy. This is mentioned by the manufacturer. No cases were described in pregnancy. However in a more recent experience, this was found not to be clinically significant. Potassium levels are not routinely checked during parenteral vitamin B12 administration. This raises the question if we should check potassium levels in certain circumstances. Ordering providers should be aware of hypokalemia after vitamin B12 supplementation with consideration of following potassium level after administration especially in pregnancy.

TH-PO380

Refractory Hypokalemia in a Patient with Ectopic Adrenocorticotropic Hormone (ACTH) Secretion

Massiel P. Cruz Peralta,[1] Blaise W. Abramovitz.[1,2] *[1]UPMC, Pittsburgh, PA; [2]University of Pittsburgh School of Medicine, Pittsburgh, PA.*

Introduction: Due to similarities in structure, aldosterone and cortisol bind to mineralocorticoid receptors with similar affinity. The enzyme 11ß-hydroxysteroid dehydrogenase (11ß-HSD) limits the effect of cortisol at this receptor by converting cortisol to cortisone which is inactive at this site. Deficiency in 11ß-HSD allows for unopposed cortisol stimulation at this receptor which mimics a state of mineralocorticoid excess. This condition manifests clinically with hypertension, hypokalemia, and metabolic alkalosis. We report a case of mineralocorticoid excess from ectopic production of ACTH leading to profound, refractory hypokalemia.

Case Description: A 56-year-old female with a history of COPD and large cell neuroendocrine carcinoma presented with one day of dyspnea, chills, and bilateral lower extremity edema. Lab work was remarkable for creatinine 1.4 mg/dL (baseline creatinine 0.7), tCO_2 > 40 mmol/L, potassium of 2.2 mEq/L, and WBC 11.3 x 10^9/L with 87% neutrophils. CT angiography chest showed LLL subsegmental PE and multifocal pneumonia. The patient was admitted for management of pneumonia and started on IV fluids, broad-spectrum antibiotics, subcutaneous enoxaparin, and oral and IV potassium supplementation. She was noted to have worsening hypokalemia to 1.6 mEq/L despite aggressive repletion. A comprehensive chart review revealed nine months of intermittent episodes of moderate to severe hypokalemia and metabolic alkalosis starting one month after her neuroendocrine lung cancer diagnosis. A VBG showed pH 7.48, CO_2 77 mmHg, and HCO_3 56 mmol/L, suggestive of a primary metabolic alkalosis. 24-hour urine potassium was 68 mEq which confirmed inappropriately elevated urine potassium losses in the setting of severe hypokalemia. ACTH was elevated at 183 pg/mL (normal: 9-46), suggesting ectopic production of this hormone. 24-hour urine cortisol was 2086 mcg (normal: 4-50), confirming the suspicion of ectopic secretion of ACTH causing an apparent mineraloid corticoid excess picture. The patient was started on spironolactone and standing oral potassium replacement with subsequent improvement of her hypokalemia.

Discussion: This case emphasizes the importance of thoroughly working up persistent hypokalemia. Ectopic ACTH production leading to mineralocorticoid excess in patients with malignancy is a rare occurrence. Without establishing a diagnosis, appropriate management cannot be sought.

TH-PO381

The Dual Diagnosis: Hypokalemic Rhabdomyolysis Unveils an Adrenal Nodule

Ahana Bhan, Mohamed Taher, Kartik Kalra. *Geisinger Medical Center, Danville, PA.*

Introduction: The occurrence of rhabdomyolysis as the initial manifestation of primary hyperaldosteronism (PHA), accompanied by severe hypokalemia is uncommon. We present a distinctive case where a patient with hypertension experiences myalgia, revealing severe hypokalemia causing rhabdomyolysis, ultimately leading to the identification of adrenal nodule.

Case Description: 61 year old female with past medical history of hypertension presented to the hospital evaluation of weakness and myalgias ongoing for 2 weeks. She denied drug abuse, diuretics or liquorice use. No significant family history. Blood pressure (BP) 165/102 mm Hg and tenderness to palpation of thighs bilaterally. Labwork (table 1) revealed Hypokalemia and elevated CK levels. EKG demonstrated elongated QT interval and U wave. Rhabdomyolysis and severe Hypokalemia were established as first diagnosis. She was treated with supplemental IV/oral potassium and fluids. Labs (Table 1) suggested low plasma renin activity (PRA) and elevated Aldosterone/PRA ratio raising suspicion for PHA. Patient was started on amlodipine, telmisartan, aldactone with oral potassium. A CT adrenal protocol revealed 2 cm right adrenal nodule, possibly an aldosteronoma. Patient was referred for lapraroscopic adrenelectomy.

Discussion: Severe hypokalemia (potassium < 2.0 mmol/L), can lead to decreased blood flow and muscle perfusion, triggering rhabdomyolysis. While there are limited documented cases in the literature, PHA has been identified as a potential cause of hypokalemia-induced rhabdomyolysis. Other factors associated with this condition include licorice ingestion, laxative abuse, and diuretic use. Diagnosing PHA can be challenging when rhabdomyolysis and severe hypokalemia manifest as initial symptoms. A high level of suspicion is crucial in hypertensive patients, where the occurrence of rhabdomyolysis and hypokalemia necessitates considering primary hyperaldosteronism as a potential cause.

TH-PO382

Renal Replacement Therapy in Treatment of Adult-Onset Ornithine Transcarbamylase Deficiency

Leanna V. Ritchie, Benjamin J. Mccormick, Ivan E. Porter. *Mayo Foundation for Medical Education and Research, Jacksonville, FL.*

Introduction: Hyperammonemia is a relatively common disorder that has a spectrum of presentations ranging from confusion to coma. The less common etiology of hyperammonemia is related to urea cycle disorders such as ornithine transcarbamoylase deficiency (OTCD). This X-linked enzymatic disorder results in an accumulation of ornithine, orotic acid and urea with incomplete penetrance. The majority of cases occur as congenital enzyme disorders that may present with severe, development effects and high mortality in the pediatric population. However, the enzyme deficiency may also be inherited with incomplete penetrance such that the disorder is triggered by high protein catabolism states at later life stages.

Case Description: Here presented is a case of a 61 year old female without prior medical history who presented with somnolence after initiation of corticosteroids for acute back pain. No evidence of infection, hemodynamically stable and serum ammonia was 233 mcg/dL. The patient had no hepatic dysfunction and was evaluated for urea cycle disorder. Intermittent hemodialysis (IHD) was used for rapid lowering of serum ammonia levels. Following IHD ammonia improved to 118 mcg/dL. However, within 24h ammonia increased to 223 mcg/dL. The patient received a second session of IHD followed by initiation of CVVH to prevent rebound accumulation. CVVH was continued for approximately 24h to allow for administration of nitrogen scavengers (benzoate and phenylacetate). The patient was initiated on intravenous nitrogen scavengers, low protein/high glucose/high fat diet until mental status improved. Genetic testing identified X-linked hemizygous variant for OTCD.

Discussion: This case report explores the tandem use of large surface area dialyzer via IHD and continuous veno-venous hemofiltration (CVVH) for rapid ammonia filtration. Rapid withdrawal of IHD prior to maintenance therapy with nitrogen scavengers has been associated with rapid reaccumulation of ammonia if the urea cycle co-factors are not replaced. This is a method that has been previously studied in the pediatric population with limited application to the adult population due to its rarity (1 in 56000 births). However, we applied these principles to an adult with success and improvement in clinical outcome.

TH-PO383

Urinary Response to Consumption of Plant-Based Meat Alternatives: Secondary Analysis of the SWAP-MEAT Trial

Catherine Ward,[1] Matthew J. Landry,[1] Kalani L. Raphael,[2] Christopher D. Gardner,[1] Alan C. Pao.[1] *[1]Stanford University School of Medicine, Stanford, CA; [2]University of Utah Health, Salt Lake City, UT.*

Background: Consumption of excess animal meat can exacerbate kidney disorders such as urinary stone disease and chronic kidney disease. Plant-based meat alternatives, "plant-meat", have entered the commercial market. It is not known whether plant-meat confers the same health benefits as whole vegetables because plant-meat is highly processed food. We hypothesized that consumption of plant-meat reduces dietary load of acid, phosphorus, and nitrogen compared with consumption of animal-meat.

Methods: SWAP-MEAT was a randomized crossover trial in which participants consumed ≥2 servings/day of either plant-meat or animal-meat for 8 weeks each, while keeping all other foods and beverages similar. We analyzed fasting spot urine samples from participants at baseline and after each phase of plant-meat or animal-meat. We used a linear mixed-effects model to investigate if the change in urine indices was different between baseline and at the end of each phase, adjusting for urine creatinine

concentration, the fixed effect of diet order, phase, and the random effect of correlated observations. Primary outcomes included differences between baseline and after plant-meat or animal-meat phase for urine sulfate, urine ammonium, urine phosphorus, urine urea nitrogen, and urine pH.

Results: Differences in mean concentration for urine sulfate, urine ammonium, urine phosphorus, and urine urea nitrogen were significantly lower after plant-meat compared with animal-meat. Difference in mean urine pH was significantly higher after plant-meat compared with animal-meat.

Conclusions: Consumption of plant-meat was associated with lower dietary load of acid, phosphorus, and nitrogen compared with consumption of animal-meat. Plant-based meat products could support persons who wish to reduce dietary acid load in a manner that does not increase dietary phosphorus or nitrogen, which may benefit patients with urinary stone disease or chronic kidney disease.

Funding: NIDDK Support

Mixed Effects Linear Regression Model: adjusted for urine creatinine (mg/dL)

Plant-meat	Estimate	95% Confidence Interval
Urine sulfate (mEq/L)	-6.68	-10.96, -2.4
Urine ammonium (mmol/L)	-4.15	-8.2, -0.07
Urine phosphorus (mg/dL)	-9.01	-17.5, -0.5
Urine urea nitrogen (mg/dL)	-124.8	-226.9, -22.6
Urine pH	+0.32	+0.18, +0.46

Reference: Animal-meat

TH-PO384

SGLT2 Inhibitors as a Treatment for Fanconi-Bickel Syndrome: A Case Report

Viola D'Ambrosio,[1,2] Elizabeth R. Wan,[1] Keith Siew,[1] Stephen B. Walsh.[1] London Tubular Centre. *[1]University College London, London, United Kingdom; [2]Universita Cattolica del Sacro Cuore, Rome, Italy.*

Introduction: Fanconi-Bickel syndrome is an ultra-rare genetic disease characterized by SLC2A2 mutation encoding for the basolateral glucose transporter (GLUT2) in the proximal tubule of the nephron. This defective transport ultimately leads to accumulation of glycogen and dysfunction of proximal tubule cells. This manifests clinically as the renal Fanconi syndrome and eventually kidney failure. Systemic complications of proximal tubule injury include metabolic acidosis, bone demineralization and, for some not completely elucidated reasons, dysglycemia.

Case Description: We present the case of a 43-year-old man who was diagnosed with Fanconi-Bickel syndrome (homozygous splice site mutation in SLC2A2). He had a history of infantile-onset renal Fanconi syndrome, hypercalciuria and bilateral nephrolithiasis, osteoporosis, bilateral sensorineural deafness and non-insulin dependent type 2 diabetes. At referral the patient presented with CKD G2, non-anion gap metabolic acidosis, slightly elevated serum calcium, decreased serum phosphate, supressed PTH and hypercalciuria, despite oral supplementation of phosphate, bicarbonate and vitamin D. We hypothesized that SGLT2i in this patient may halt the progressive proximal tubule injury by preventive glucose uptake and help the management of diabetes. Fractional excretion of phosphate (FE_{PO4}) and urinary retinol-binding protein (RBP)-creatinine ratio, two markers of proximal tubular injury, were stable after 2 months of SGLT2i therapy.

Discussion: To date, Fanconi-Bickel syndrome does not have a specific treatment. Standard of care includes supplements of fluids and electrolytes to counterbalance proximal tubular injury and management of complications such as diabetes. SGLT2i use has been described in a mouse model of another glycogen storage disease (GSD1b), whose underlying defect is different from that of Fanconi-Bickel but presents with a similar phenotype. Data showed that gliflozins prevents glycogen accumulation and restores proximal tubule cells' function. Using the same rationale, the administration of SGLT2i in adult patients with Fanconi-Bickel syndrome may prevent further proximal damage and slow the progression towards end-stage kidney disease. In conclusion, we hypothesize a potential benefit of SGLT2i in adult patients affected by Fanconi-Bickel syndrome.

TH-PO385

A Hidden Challenge: Metabolic Acidosis After Neobladder Surgery

Paola M. Vazquez-Fernandez,[1] Ileana E. Ocasio Melendez,[2] Jeaneishka M. Rivera Rios,[2] Caleb S. Pacheco-Molina,[2] Krystahl Z. Andujar-Rivera.[2] *[1]Hospital Damas, Ponce, Puerto Rico; [2]Universidad de Puerto Rico Escuela de Medicina, San Juan, Puerto Rico.*

Introduction: Neobladder construction is a surgical procedure involving the creation of a new bladder using intestinal segments. One complication is hyperchloremic metabolic acidosis, which occurs due to the continued exchange of electrolytes by the neobladder lumen. This complication is uncommon and may not be promptly identified by primary physicians.

Case Description: A 70-year-old man with urothelial cancer who underwent transurethral resection of bladder tumor, radical cystoprostatectomy, and neobladder construction. The patient experienced postoperative complications, including pneumonia and fungemia. One month later, he presented with weakness and a humming sensation in his ears. His medical history included hypertension and type 2 diabetes mellitus, and he was taking metformin and losartan. He denied experiencing diarrhea, using non-steroidal anti-inflammatory drugs, or having a prior history of renal disease. Vital signs showed blood pressure of 115/75 mmHg, heart rate 100 beats per minute, respiratory rate 19, oxygen saturation 98% at room air, and temperature 37°C. Physical examination revealed an acutely ill male in no distress, with dry oral mucosa and decreased skin turgor. Initial laboratory results revealed creatinine level 1.76 mg/dL (baseline creatinine 0.8 mg/dL), BUN level 62.0 mg/dL, chloride level 116 mmol/L, bicarbonate level 8.1 mmol/L, potassium level 5.54 mmol/L. Arterial blood gas values of pH 7.255, pCO2 14 mmHg, and pO2 100 mmHg. Normal anion gap metabolic acidosis with an anion gap of 9. The urinary anion gap was +23. The patient was initially treated with a bicarbonate drip, which was later transitioned to oral bicarbonate. Renal function improved, and the metabolic acidosis resolved. The patient was discharged with oral buffer therapy and scheduled for follow-up at the clinics.

Discussion: Hyperchloremic metabolic acidosis is a rare complication of neobladder reconstruction. The apical Cl-/HCO3- exchanger plays a key role in the development of acidosis. Although this can be transient, delayed diagnosis can lead to significant morbidity. Early identification allows for effective treatment with sodium bicarbonate. It is crucial to provide detailed and clear post-operative discharge documentation to ensure early recognition of such complications.

TH-PO386

Nonsteroidal Anti-Inflammatory Drug-Induced Type I (Distal) Renal Tubular Acidosis

Branavan V. Ragunanthan, Clay A. Block, Brian D. Remillard, Charles W. Hopley. *Dartmouth Hitchcock Medical Center, Lebanon, NH.*

Introduction: Acute kidney injury (AKI) is the most recognized kidney toxicity of non-steroidal anti-inflammatory drugs (NSAID), but NSAIDs have also been linked to the development of acid-base disorders. Here, we present a patient with a history of frequent ibuprofen consumption resulting in the manifestation of a type I renal tubular acidosis (RTA).

Case Description: A 38-year-old man with a history of C6-C7 spinal injury due to a snow-boarding accident causing spastic paraplegia presented to an emergency department with new-onset agitation and confusion. His medications included ibuprofen 800mg every 6-8 hours and oxycodone. Brain imaging and blood and urine cultures were unremarkable. Urine toxicology was positive for his prescribed agent. Laboratory investigations were notable for an ammonia of 74 mcmol/L (normal range: 16 – 60), albumin of 4.4 g/dL (3.2 - 5.2), potassium of 2.8 mmol/L (3.5 – 5.0), venous pH of 7.22 (7.32 – 7.42), venous pCO2 of 36 mmHg (41 – 51), serum bicarbonate of 15 mmol/L (22 – 31), anion gap (AG) of 16, creatinine of 0.97 mg/dL (0.80 – 1.50) correlating to eGFR or 102 mL/min/1.73m2 via CKD-EPI, and glucose of 58 mg/dL (65 – 199). He was administered Dextrose 10% @100 mL/h and lactulose enema with improvement in encephalopathy. Post treatment labs demonstrated a venous pH of 7.26, venous pCO2 of 30 mmHg, serum bicarbonate of 13 mmol/L, AG of 12, urine pH of 7.5, and a urine anion gap at 29 (Urine Na(97mmol/L) + Urine K(32mmol/L) - Urine Cl(100mmol/L)). Acetaminophen, salicylate, ethanol, creatinine-kinase and lactate were all normal/negative. Ibuprofen was discontinued and sodium citrate-citric acid 30mL twice daily was provided. At outpatient follow up, his acid-base disorder had resolved and his mentation normalized.

Discussion: This case adds to several reports illustrating the association of ibuprofen with type I RTA in setting of preserved renal function. Ibuprofen is postulated to inhibit carbonic anhydrase (CA) II yielding impaired urinary acidification and luminal retention of bicarbonate. Hypokalemia is associated with type I RTA and are potent stimulators of ammoniagenesis. Although impairment of CA is usually associated with proximal (type 2) RTA, impairment of CAII can cause a distal RTA.

TH-PO387

Unveiling the Enigma: Hypokalemic Paralysis in Sjögren-Associated Renal Tubular Acidosis

Shrirang D. Pathak, Avani Kulkarni, Vaibhav Ingle. *All India Institute of Medical Science - Bhopal, Bhopal, India.*

Introduction: Hypokalemic Paralysis (HP) is a rare life-threatening disorder presenting as muscle weakness and low serum potassium levels. This case series focuses on two female patients with Sjögren's syndrome-associated renal tubular acidosis (SS-RTA) who developed HP. SS-RTA is a form of distal renal tubular acidosis where the kidneys are unable to adequately acidify urine and reabsorb bicarbonate, resulting in an acid-base imbalance. The SS-RTA is thought to occur due to inflammation caused by Sjögren's syndrome-associated autoantibodies. Although distal renal tubular acidosis causes hypokalemia, HP is rare. The important differential diagnoses include Hypokalemic Periodic Paralysis and Thyrotoxic Periodic Paralysis. The cases illustrate the association between SS-RTA and HP.

Case Description: Case 1: A 26-year-old female with intellectual impairment presented with vomiting, weakness, altered sensorium, and hypercapnic respiratory failure requiring intubation and mechanical ventilation. Investigations confirmed hypokalemia, normal anion gap metabolic acidosis (NAGMA), and SS-RTA. Treatment included intravenous (IV) potassium and sodium bicarbonate. Follow-up was done on an outpatient basis for correction of hypokalemia and NAGMA. Case 2: A 47-year-old female had progressive limb weakness, slurred speech, reduced muscle power and absent reflexes. On investigations low serum potassium and positive serology for Primary Sjögren syndrome (PSS) were found, and renal biopsy findings of Membranoproliferative glomerulonephritis with chronic tubulointerstitial inflammation. Treatment involved IV potassium and IV fluids. She was readmitted for recurrence of hypokalemia.

Discussion: Hypokalemic Paralysis is characterized by muscle weakness and low serum potassium levels. SS-RTA leads to hypokalemia, triggering HP. Low magnesium and potassium levels and high creatine kinase levels are risk factors for severe paralysis in HP. The diagnosis is based on clinical, laboratory, and imaging findings. Management involves correcting acidosis, normalizing potassium, and addressing the underlying cause. Recognizing SS-RTA as a possible cause of hypokalemia in periodic paralysis,

especially in Sjögren's syndrome, is essential. Early diagnosis and treatment are crucial for better outcomes. Further research is needed for delineating genotypes and phenotypes of PSS predisposing to HP.

TH-PO388

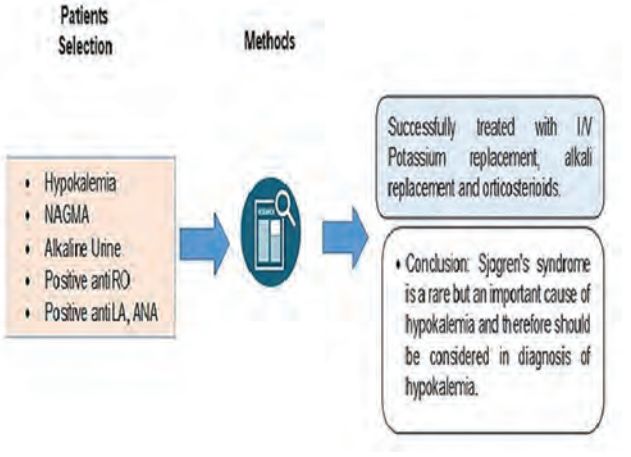
Rare Presentation of Primary Sjögren Syndrome, Hypokalemic Paralysis: A Case Report

Nosheen Anjum, Zahid Nabi. *KRL Hospital, Islamabad, Pakistan.*

Introduction: Sjogren's Syndrome is a multisystem autoimmune disorder characterized by chronic inflammation of exocrine glands, sicca syndrome. Among extra glandular manifestations renal involvement occurs as tubulointerstitial nephritis (TIN) and glomerular damage. Distal renal tubular acidosis (dRTA) is the most common presentation of TIN. However, dRTA may rarely be severe enough to present as hypokalemic paralysis. Also, Sjogren's syndrome presenting for the first time with hypokalemic paralysis secondary to dRTA without other glandular manifestations is also very rare. Our patient had severe hypokalemic paralysis secondary to dRTA as the first manifestation of primary Sjogren's syndrome.

Case Description: Methodology: We report a case of 45 years old lady, recently diagnosed as depressive illness with no other pre-morbid, who presented to us with acute onset of severe weakness in all four limbs for last 4 days. There was no other complaint. Clinical examination revealed hyporeflexia in four limbs with no other positive findings. Laboratory workup revealed severe hypokalemia, normal anion gap metabolic acidosis, alkaline urine and strongly positive serological markers of Sjogren's syndrome, (anti-RO, anti-LA, ANA). Results: We treated that patient by intravascular replacement of potassium, oral, alkali, replacement and corticosteroids. Patient showed an excellent response to this treatment. She will be followed up for the recurrence of tubular dysfunction and other systemic manifestations of Sjogren's syndrome.

Discussion: This report highlights that Sjogren's syndrome is a rare but an important cause of hypokalemia and therefore should be considered in diagnosis of hypokalemia.



TH-PO389

Distal Renal Tubular Acidosis as the Initial Manifestation of Hashimoto Thyroiditis

Renan G. Diniz, Irma B. Sousa Pontes, Liudmila G. de Menezes, José Guilherme R. Gonçalves, Diogo Campos, Tassila G. Maia, Marilia Rodovalho Guimaraes, Marcia Fernanda Arantes de Oliveira, Igor Smolentzov, Jose M. Vieira Jr., Victor F. Seabra, Lucia Andrade. *Hospital das Clinicas - University of Sao Paulo School of Medicine, Sao Paulo, Brazil.*

Introduction: Distal renal tubular acidosis (dRTA) is a rare disorder, characterized by inadequate proton secretion in the distal tubule and collecting duct in the presence of metabolic acidosis. In adults, the most common cause of dRTA is autoimmune disease, and the association with Hashimoto thyroiditis (HT) has rarely been studied.

Case Description: A 25-year-old female diagnosed with nephrolithiasis 2 years prior presented to the emergency room complaining of weakness, loss of coordination and strength, pain and paresthesias. On examination, her arms showed decreases in speed, range of motion and deep tendon reflexes. Labs revealed severe hypokalemia (2.0 mEq/L), together with increase in CPK (3412 U/L), hyperchloremic metabolic acidosis (anion gap 9) and urinary pH of 8.5. Intravenous potassium and bicarbonate were started in the with gradual symptom improvement. On day 4 she was discharged on oral potassium citrate (40 mEq/d) and sodium bicarbonate (6 g/d). On follow-up, there was complete symptom resolution, normalization of potassium (4.3 mEq/L) and improved bicarbonate (20 mEq/L), but thyroid hormones were altered (TSH = 73.58, T4 < 0.42). We started levothyroxine at 25 μg/d. The patient tested positive for anti-TSH receptor antibody (1.95 IU/L) and anti-thyroid peroxidase antibody (> 900 IU/ml), thus confirming the diagnosis of HT. The levothyroxine dose was increased to 100 μg/d due to persistence of the hormonal alteration (TSH = 51, T4 = 0.48).

Discussion: In this case, the dRTA might have been due to a reduction in the number or function of H^+- and H^+/K^+-ATPases. To our knowledge, this is the sixth reported case of dRTA secondary to HT, which may be underdiagnosed.

Variable	Normal range	Admission (01/31/23)	Follow-up (08/02/23)
pH	(7.35-7.45)	7.24	7.3
Bicarbonate (mEq/L)	(22-28)	11.1	20.0
Base excess	(10 ± 2)	−14.7	−4.2
Anion gap	(8-12)	9	6
Sodium (mEq/L)	(135-145)	141	140
Potassium (mEq/L)	(3.5-5.0)	2.4	4.3
Chloride (mEq/L)	(98-106)	121	114
Ionized calcium (mmol/L)	(4.49-5.29)	5.41	4.68
Magnesium (mg/dl)	(1.6-2.6)	3.1	2.5

TH-PO390

A Varied Presentation of Fanconi Syndrome Following AKI in COVID-19 Infection

Thabuna Sivaprakasam, Deepan Panneerselvam. *University of South Dakota, Sioux Falls, SD.*

Introduction: Renal pathology in COVID-19 may manifest as glomerulopathies, tubular injuries, acute kidney injury (AKI), and CKD. One such pathology is generalized proximal convoluted tubular (PCT) dysfunction, referred to as Fanconi's syndrome. We present a case of COVID-19 infection associated with AKI followed by Fanconi syndrome, characterized by persistent electrolyte abnormalities and metabolic acidosis. Incomplete Fanconi's syndrome in COVID has occurred before the onset of AKI, but here our patient develops it after the resolution of the AKI.

Case Description: A 60-year-old female was admitted for severe COVID-19 infection and intubated due to respiratory failure. She eventually developed AKI which resolved quickly with fluids. Labs showed persistent normal anion gap metabolic acidosis (NAGMA) even after AKI resolution, along with hyponatremia, hypokalemia, hypophosphatemia, hypocalcemia, and hypomagnesemia. Nephrology was consulted for the persistent electrolyte disturbances despite adequate replacement and hyperchloremic NAGMA. Urine studies showed mild renal tubular acidosis but negative for proteinuria and glycosuria. Post-COVID Fanconi syndrome was suspected, and electrolyte monitoring with replacement was continued. Eventually, she was extubated and with the recovery of her respiratory status - electrolyte disturbances, and metabolic acidosis also slowly normalized. The patient was discharged on electrolyte supplements and had stable renal function and electrolytes at the follow-up.

Discussion: Tubulopathies can be explained by the direct toxic effect of the virus via the ACE2 ligand, expressed on proximal and distal tubular cells. Incomplete Fanconi's in COVID-19 infection has been described based on 4 specific PCT abnormalities (proteinuria, renal phosphate wasting, hyperuricosuria, and glycosuria). But this case presented differently with varied electrolyte disturbances and acidosis. Fanconi's in COVID usually precedes AKI, possibly acting as a predictor of AKI or can occur alone. But here, it evolved after the resolution of AKI, questioning its utility as such a predictor. It is important to acknowledge this significant association between COVID-19 and tubulopathies to explain some persistent electrolyte and acid-base abnormalities in such patients. This case also emphasizes that there might be more unique ramifications of COVID-19 to be expected in every organ system.

TH-PO391

Is Diabetic Ketoacidosis Synonymous with Death in Patients on Enfortumab Vedotin for Urothelial Carcinoma?

Francis N. Atemnkeng, Fatima Aguilar, Savneek S. Chugh, Sanjeev Gupta, Michael D. Klein. *Westchester Medical Center, Valhalla, NY.*

Introduction: Enfortumab vedotin (EV), is a novel breakthrough therapy which received accelerated FDA approval in 2019 for the treatment of metastatic urothelial carcinoma in patients who have failed other lines of treatment. The characteristics of its adverse effects especially diabetic ketoacidosis (DKA) are not well understood.

Case Description: A 57-year-old male with no history of diabetes, diagnosed with urothelial carcinoma two years prior, failed several lines of treatment including platinum-based chemotherapy and immune checkpoint inhibitors. He developed metastasis and was started on EV. After his second dose of EV, he was admitted to the ICU for diabetic ketoacidosis (DKA) with a high anion gap metabolic acidosis, serum bicarbonate of 12 mEq/L, blood Ph 7.2, hyperglycemia to 450 mg/dL, positive ketones in urine, an elevated C-peptide, with an initial hemoglobin A1C of 7.7%. He was in shock requiring multiple pressors and developed oliguric AKI (serum creatinine 1.5 mg/dL, baseline 0.7 mg/dL). He was intubated for airway protection and started on continuous renal replacement therapy. Despite aggressive treatment, the patient died on hospital day 2.

Discussion: EV is an antibody-drug conjugate which joins an antibody directed against the cell adhesion molecule, nectin-4, which is highly expressed in urothelial carcinoma, with monomethyl auristatin E, an inducer of cell cycle arrest and apoptosis. Just 2 cases of DKA due to EV have been reported since its approval for use in metastatic urothelial carcinoma (One at the 2020 American Thoracic Society Conference and the other at the 2021 American Society of Nephrology Conference). The precise mechanism for the development of DKA is yet unidentified. An elevated C-peptide, noted in one of the reported cases, suggests insulin resistance, but the very rapid progression of the acidosis and death within three days in all the cases suggests some other effects of the drug on glucose metabolism still to be elucidated. There is an FDA warning on its use in patients with glucose over 250 mg/dl, but this was insufficient to prevent DKA in the

reported patients. Our patient had an elevated A1C on admission. Therefore, we strongly suggest screening for diabetes in every patient considered for EV, and to avoid it if A1C is greater than 7%.

TH-PO392

Continuous Renal Replacement Therapy (CRRT) Worsening Acidosis

Sandeep R. Sasidharan, Omar N. Elhawary, Fausto R. Cabezas, Tahir A. Jatoi, Mohammad W. Abushawer, Mary C. Mallappallil, Sonalika Agarwal, Isha Puri. *SUNY Downstate Health Sciences University, New York City, NY.*

Introduction: Euglycemic ketoacidosis (EDKA) is an uncommon cause of high anion gap metabolic acidosis (HAGMA) and should be suspected in diabetics with normal blood glucose (BG) who develop HAGMA. EDKA can complicate continuous renal replacement therapy (CRRT) when poor intake is accompanied by dialysate caloric losses. We describe a patient with EDKA on CRRT following peritonitis from perforated diverticulitis.

Case Description: A 52-year-old AA male with a history of HTN, T2DM, obesity and ESRD on HD presented with diarrhea, left lower quadrant (LLQ) pain and 2 episodes of emesis. On exam, he had LLQ tenderness and leukocytosis with left shift. Imaging showed diverticulitis with multiple fistulas and organizing collection suspicious of abscess. Initially, managed conservatively, but later had signs of peritonitis with free fluid and pneumoperitoneum on imaging, requiring sigmoidectomy. Post-op he was in septic shock, requiring vasopressor support and switched to CRRT from HD. He remained NPO, first awaiting ostomy creation and later due to poor mentation. He continued CVVHDF with Phoxillium and Primasol solutions (both glucose-free dialysate and replacement fluid), however had worsening HAGMA without diarrhea or hyperlactatemia. His BG remained <200 mg/dL. Starvation ketoacidosis was suspected and confirmed with serum Beta hydroxy butyrate (BHB) levels of 7.6. He was started on TPN and transitioned to tube feeds with subsequent resolution of acidosis. Within 2 days of feeding his Hco3 levels normalized in parallel with a decrease BHB levels.

Discussion: Euglycemic ketosis is driven by insulin deficiency and insulin resistance, starvation, and an excess of counter-regulatory hormones. In absence of external nutrition, glucose content of replacement fluid, especially phosphate-containing fluid can cause negative caloric balance with glucose loss of > 80g in the effluent which is more than SGLT2, a known cause of EDKA. In our patient, the day of ketonemia detection, metabolic acidosis had worsened despite appropriately dosed CRRT with minimal lactatemia, while not on insulin and the use of phosphate-containing replacement fluid providing a perfect storm to develop euglycemic ketoacidosis while being on CRRT. This case highlights the need to consider EDKA in the differential diagnosis of high anion gap metabolic acidosis in patients on CRRT.

TH-PO393

Unraveling the Enigma: Deciphering Recurrent Metabolic Acidosis and the Elusive Kabadi Syndrome

Samira M. Samant, Camilo Cortesi. *The Permanente Medical Group Inc, Santa Clara, CA.*

Introduction: This case report explores the diagnostic challenges posed by rare metabolic acidosis conditions. It focuses on Kabadi syndrome (KBS), accompanied by carnitine deficiency. Understanding and managing KBS remains difficult due to its rarity and limited knowledge of the condition. In highlighting the complexity of such cases, we emphasize the need for thorough investigation into rare etiologies.

Case Description: A 65-year-old female with idiopathic chronic pancreatitis with recurrent life-threatening severe anion gap metabolic acidosis (AGMA) over three years, requiring frequent admissions to the intensive care unit. She presented with respiratory distress, altered mental status, and abdominal pain. Laboratory findings consistently showed severe acidemia, low bicarbonate, and elevated anion gap. Glucose levels were normal, with positive ketones. Workup revealed consistently elevated lipase levels with normal liver function tests. Genetic testing was inconclusive, except for low carnitine levels. Imaging indicated chronic pancreatitis. Management involved insulin therapy, hydration, correction of acidosis, pancreatic enzymes, and carnitine supplementation, leading to resolution; ultimately, medication non-compliance led to readmissions.

Discussion: KBS, or pancreatic ketoacidosis, is a rare condition characterized by euglycemic ketoacidosis. It is triggered by elevated pancreatic lipase levels, resulting in fat necrosis and ketone production. The pathophysiology involves the release of free fatty acids, converting them into ketone bodies and causing metabolic acidosis. Carnitine deficiency further impairs ketone clearance and contributes to acidemia. In this patient, the combination of KBS and carnitine deficiency adds complexity. Carnitine supplementation may protect against recurrence; especially as cognitive impairments associated with carnitine deficiency may explain medication non-compliance. This case underscores the importance of comprehensive investigations, genetic testing, and innovative thinking in unraveling rare etiologies. The multidimensional treatment approach includes fluid management, acidosis correction, pain management, pancreatic enzyme replacement therapy, nutritional support, and carnitine supplementation. This report highlights the complexity of rare AGMA etiologies, emphasizing perseverance, innovative investigations, and personalized approaches.

TH-PO394

An Unusual Case of Metabolic Acidosis

Theresa T. Le, Tammy N. Do, Norman Wall, Rajesh Mohandas. *LSU Health New Orleans, New Orleans, LA.*

Introduction: Metabolic acidosis is common in hospitalized patients, and more than half the patients admitted to intensive care units have metabolic acidosis. The cause of acidosis is usually apparent from the clinical setting, but in rare instances, a methodical workup is needed to decipher the underlying cause. We present an unusual cause of metabolic acidosis.

Case Description: A 40 yr. woman with Mitochondrial Encephalomyopathy with Lactic Acidosis and Stroke-like episodes (MELAS), presented with sudden worsening of chronic right-sided weakness. An initial work up ruled out acute stroke, and patient was started on intravenous L-Arginine for MELAS. On day five, she developed acute encephalopathy and severe acidosis (Figure-1). The severe non-gap metabolic acidosis was thought to be from L-arginine. Following discontinuation of IV L-arginine and initiation of bicarbonate supplementation, the patient's acidosis improved rapidly.

Discussion: Metabolic acidosis has been reported with prolonged use of L-arginine, particularly in high doses. The mechanisms by which L-arginine causes metabolic acidosis remains unclear. While arginine is administered as arginine hydrochloride, the number of protons added is not significant enough to cause severe acidosis. Although the urine anion gap was negative in our patient, possibly due to exogenous bicarbonate, the urine osmolar gap indicated a renal tubular acidosis. This was confirmed by generalized aminoaciduria and low levels of directly measured ammonia. There was no evidence of phosphaturia or hypophosphatemia. Interestingly, in the isolated perfused tubule exposure to L-arginine causes inhibition of bicarbonate reabsorption in the proximal tubules. Metabolic acidosis could augment L-arginine absorption in the intestine worsening acidosis. Our case highlights that L-arginine can be an unusual cause of severe metabolic acidosis. The physiology underlying this clinical observation requires further studies.

Lab	On admission	Day 1 of IV Arginine	IV Arginine discontinued (s/p day 5)	Prior to discharge
Sodium	134	132	129	138
Potassium	3.8	6.0	5.9	3.8
Chloride	100	108	107	101

TH-PO395

Factitious Lactate Elevation: A Clue for Ethylene Glycol Poisoning

Reshub R. Pendyala,[1] Anjana Chepur,[3] Prashant Pendyala.[2] [1]*Nichols School, Buffalo, NY;* [2]*Buffalo General Medical Center, Buffalo, NY;* [3]*Uplift North Hills Preparatory School, Irving, TX.*

Introduction: Ethylene glycol poisoning is a medical emergency, and an early diagnosis is imperative for proper treatment. In most of the institutions the turnaround time for a direct measurement takes a few hours. Severe metabolic acidosis with an elevated osmolar gap can give a clue in the appropriate clinical setting. We describe a case of factitious lactic acid elevation using blood gas analyzers (point of care) in this group of patients. This could be an additional indicator to support a diagnosis of ethylene glycol poisoning.

Case Description: 50 yr old lady was found by family in bed, unresponsive, and with labored respirations. She was intubated in the field for airway protection given her poor GCS, and transported to the emergency department. She was afebrile but hypertensive and initially needed nicardipine drip for BP control. Labs were significant for leucocytosis of 34000, anion gap 30, serum bicarbonate 5, lactate 15 (obtained on blood gas analyzer), pH 6.90. Sodium 148, Chloride 113, blood glucose 185. Creatine Kinase 47. Initial Creatinine 2.4 and Blood Urea Nitrogen 16. Measured osmolarity was 357 with osmolal gap of 44. Simultaneous lactic acid done in the central laboratory was normal at 0.9. Ethylene Glycol level was significantly increased and was 46. Patient started on sodium bicarb, fomepizole, thiamine and folinic acid and pyridoxine, monitoring BMP and VBG every 4 hours. Patient underwent hemodialysis. Eventually her acidosis improved, and she was extubated.

Discussion: Ethylene glycol gets metabolized in liver and form glycolic acid and glyoxylic acid. These compounds cross react with L-lactate oxidase used in point of care blood gas analyzers and release hydrogen peroxide that is measured as a surrogate for the level of lactate. This results in a false elevation of lactate. A concurrent lactate level performed in the central laboratory using ion selective electrodes was normal. There is usually a very good correlation between point of care analyzers and the central laboratory in measuring lactic acid in various clinical situations. This discrepancy and a factitious elevation of lactic acid can be an important clue for the diagnosis of ethylene glycol poisoning.

TH-PO396

Patent Foramen Ovale Causing Lactic Acidosis

Prathap Simhadri,[1] Pradeep Vaitla,[2] Sriram Sriperumbuduri,[2] Ujjwala Murari.[3] *[1]AdventHealth, Daytona Beach, FL; [2]The University of Mississippi Medical Center, Jackson, MS; [3]West Virginia University, Morgantown, WV.*

Introduction: Lactic acidosis is secondary to the accumulation of protons and lactate in body fluids and is associated with poor clinical outcomes and increased mortality. Hypoxemia leads to increased anaerobic glycolysis causing excess generation of lactate. Congenital cyanotic heart diseases are associated with an increased risk for lactic acidosis, which is also rarely seen in acyanotic heart disease. Here we present a case of a patient with patent foramen ovale (PFO) causing lactic acidosis, which resolved after its closure.

Case Description: A 70-year-old white male with a history of hypertension, and remote smoking presented with worsening shortness of breath for a few hours. He had hypoxemia with oxygen saturation between 83% to 88%; his heart rate ranged from 100 to 110 beats per minute, and his respiratory rate ranged from 22 to 30 breaths per minute. Initial blood gas showed a pH of 7.53, pCO2 of 24.8 mm Hg, and PO2 of 48.7 mm Hg on room air. His initial chemistry showed a sodium level of 139 mmol/l, potassium of 4.0 mmol/l, bicarb level of 12 mmol/l, chloride level of 101 mmol/l, anion gap of 26 mmol/l, BUN of 34 mg/dl, creatinine of 0.98 mg/dl, serum albumin level was 4.1 gr/dl. He had normal pro-BNP and lactic acid of 4.8 mmol/l. Chest X-ray was negative for any signs of volume overload or infiltrate. Common etiologies of lactic acidosis were considered and ruled out. The patient never had hypotension, and pan cultures were negative. The lactic acid level remained elevated even after tachypnea had improved. Pulmonary / Cardiac shunting was suspected, and the patient underwent an echocardiogram with an agitated saline contrast study, which showed a right-to-left shunt. The patient underwent transesophageal echocardiography, which was suggestive of mild-to-moderate pulmonary hypertension, right ventricular systolic pressure was 40 mmHg, and 6 mm PFO with a right-to-left shunt. The patient underwent percutaneous closure of the PFO, leading to the resolution of hypoxemia and normalization of the lactic acid and anion gap. Significant right to left shunting through the PFO contributed to his hypoxemia, which likely worsened recently, contributing to Type A lactic acidosis.

Discussion: After excluding common etiologies, nephrologists should consider cardiac and pulmonary shunts in the differential diagnosis when evaluating patients with elevated anion gap metabolic acidosis with lactic acidosis.

TH-PO397

Mind the Gap: Pyroglutamic Acidosis as a Not-so-Rare Cause of High Anion Gap Metabolic Acidosis (HAGMA)

Sam Beavin, Sadiq Ahmed. *University of Kentucky Medical Center, Lexington, KY.*

Introduction: In addition to the common causes of high-anion gap metabolic acdiosis (such as lactic acidosis, ketoacidosis, and toxic alcohol ingestion), pyroglutamic acidosis can also result in HAGMA. This case report illustrates a patient in which otherwise unexplained metabolic acidosis was attributed to 5-oxoproline accumulation in the setting of chronic acetaminophen exposure and malnutrition.

Case Description: A 39-year-old man with a history of paraplegia, malnutrition, and prior PEG tube placement was admitted for management of a gastro-cutaneous fistula involving abdominal wall takedown and partial omentectomy. His post-operative course was complicated by pneumonia, septic shock, and AKI-D requiring two sessions of iHD on hospital days 8 and 10. Following HD treatments, he recovered renal function with appropriate urine output and stable electrolytes. During this period, he was started on scheduled acetaminophen 4 g daily for pain control. Over the course of subsequent hospital days 11–13, he developed worsening AGMA with a peak anion gap of 26. After initial respiratory compensation, he ultimately required intubation for tachypnea and worsening hypercarbia. The workup for common causes of AGMA was non-revealing with normal lactate, D-lactate, alcohol, and beta-hydroxybuterate levels. Organic acid analysis of urine showed significantly elevated levels of 5-oxoproline excretion (6797 mmol/mol Cr., reference range: <62). Acetaminophen was discontinued, with subsequent resolution of metabolic acidosis over the next 3 days.

Discussion: This case demonstrates the development of HAGMA in a malnourished patient after several days of acetaminophen ingestion where the workup for common causes of HAGMA was non-revealing. In these situations, the accumulation of 5-oxoproline (pyroglutamic acid) is an important consideration. This rare condition can occur due to chronic acetaminophen exposure and subsequent glutathione depletion, particularly in the setting of poor nutritional status and a malfunctioning intestine.

Acidosis Trend

Hospital Day	HCO3-	Anion Gap
Day 10 (last iHD)	21	18
Day 11	18	22
Day 12	15	23
Day 13 (Acetaminophen stopped)	10	26
Day 14	15	21
Day 15	21	14

TH-PO398

Severe ICU-Acquired Metabolic Acidosis due to Pyroglutamic Acidosis (5-Oxoprolinuria)

Daniel D. Mai, Chaitanya A. Pal, J. Pedro Teixeira. *University of New Mexico Health Sciences Center, Albuquerque, NM.*

Introduction: Anion gap metabolic acidosis (AGMA) is an acid-base disturbance frequently encountered in the intensive care unit (ICU). However, pyroglutamic acidosis (PGA) is a rare cause of ICU-acquired metabolic acidosis.

Case Description: A 56-year-old woman with a recent large stroke requiring craniectomy with abdominal bone flap was readmitted for septic shock from an abdominal abscess. Her course was complicated by new intracranial hemorrhage, persistent encephalopathy requiring prolonged mechanical ventilation via tracheostomy, malnutrition requiring tube feeds, and multiple episodes of acute kidney injury (AKI). A month after readmission, she developed AGMA of unclear etiology, with arterial pH 7.31, arterial PCO_2 16 mmHg, bicarbonate 9 mEq/L (down from 21-31), anion gap 17 mEq/L (up from <6-8), albumin 1.2 g/dL, creatinine 1.5 mg/dL, lactic acid 2.5 mmol/L, and beta-hydroxybutyrate 0.1 mmol/L. Notably, since admit she had received scheduled acetaminophen 500-650 mg four times daily, which was stopped upon nephrology consult. She received N-acetylcysteine 600 mg twice daily for five days. She required continuous renal replacement therapy (CRRT) for one day for transient oliguria and worsening AKI (peak SCr 1.9 mg/dL) from recurrent septic shock, with sustained resolution of her acid-base disturbance. However, a urine sample sent for organic acids prior to CRRT initiation ultimately revealed elevated pyroglutamic acid.

Discussion: Acetaminophen normally undergoes cytochrome metabolism to N-acetyl-p-benzoquinone imine (NAPQI), a highly reactive oxidation product that is detoxified by glutathione. In glutathione deficiency, a buildup of the organic anion pyroglutamic acid (5-oxoproline) can occur. In predisposed patients – classically older malnourished women – chronic therapeutic acetaminophen use can induce acquired glutathione deficiency and PGA, which likely explains the severe AGMA out of proportion to renal dysfunction in our case. As most labs do not measure 5-oxoproline locally, PGA is likely underrecognized and underreported, though it features in the modern GOLDMARK mnemonic for AGMA (glycols, 5-oxoproline, L- and D-lactate, methanol, aspirin, renal failure, ketosis). Moreover, though this is one of only a few prior published cases of ICU-acquired PGA, this case illustrates that PGA must be considered on the differential diagnosis of unexplained ICU-acquired AGMA.

TH-PO399

Amiloride vs. Furosemide for the Treatment of Edema in Nephrotic Syndrome (AMILOR): A Pilot Study

Ferruh Artunc, Elisabeth Vogel, Bernhard N. Bohnert, Daniel Essigke, Anja Schork. *Eberhard-Karls-Universitat Tubingen Medizinische Fakultat, Tubingen, Germany.*

Background: According to findings from nephrotic mouse models, edema formation in nephrotic syndrome (NS) is caused by sodium retention through activation of the epithelial sodium channel ENaC. In these models, edema formation could be prevented by ENaC blockade with amiloride. The monocentric randomized controlled AMILOR study investigated the anti-edematous effect of the ENaC blocker amiloride in nephrotic patients in comparison to standard therapy with the loop diuretic furosemide.

Methods: Patients with acute NS (n=10 per arm, etiology MCD n=6, MN n=8, FSGS n=2, amyloidosis n=1, IgAN n=1, other n=2; age 53 [interquartile range 38–61], male/female 13/7) and eGFR (CKD-EPI)>30 ml/min/1,73m2 were randomized to treatment with amiloride (start 5mg/d, max.15mg/d) or furosemide (40mg/d, max.120mg/d) over 16 days. Overhydration (OH) was measured by bioimpedance spectroscopy (Body Composition Monitor, Fresenius). Depending on the course of OH, the dose was adjusted on days 2,5,8,12 and 16 and, if necessary, HCT was added on d8 (start 12.5mg/d, max. 25mg/d). The primary endpoint was the decrease in OH on d8. The study was terminated prematurely due to insufficient recruitment and low statistical power due to a low actual effect size.

Results: Median baseline OH was 5.3 L /1.73m2 (26 [18-34]% of extracellular water [ECW]) in the amiloride arm and 6.2 L/1.73m2 (28 [24-29]% ECW) in the furosemide arm. On d8, OH decreased to 3.7 L/1.73m2 (19 [16-27]% ECW) in the amiloride arm and to 4.5L/1.73m2 (21 [13-28]% ECW) in the furosemide arm. Till d16, OH decreased significantly to 60 [29-93]% or 2.2 L/1.73m2 (12 [9-24]% ECW) in the amiloride arm and to 69 [57-85]% or 3.4 L/1.73m2 (17 [14-27]% ECW) in the furosemide arm. The decrease in OH on d8 and d16 was not significantly different between both arms. Hyperkalemia>5.3 mM (max. 5.7 mM) occurred in n=3 patients taking amiloride (all GFR according to CKD-EPI-Cys <40mL/min/1.73m2).

Conclusions: The AMILOR study is the first randomized controlled pilot study on the use of diuretics in NS demonstrating an antiedematous effect of the ENaC blocker amiloride without a significant difference to furosemide. Thus, amiloride emerges as an alternative to the standard therapy with furosemide. The knowledge gained lays the foundation for the design of a larger multi-centre study with greater statistical power.

TH-PO400

Correlation Between Conventional Ultrasound and Microchip Technology Ultrasound in Evaluating Pulmonary and Inferior Vena Cava in AKI Patients Undergoing Renal Replacement Therapy

Renata D. Mendes,[1,2] Jose H. Suassuna,[1] Debora M. Soares.[1] [1]*Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil;* [2]*Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.*

Background: Point of care ultrasonography is an essential tool in nephrologists physical examination. Ultraportable ultrasound with microchip technology-Butterfly IQ is a recent technological advance and should be compared with the traditional piezoelectric. So the study aims to compare both technologies, in the analysis of two extravascular volume parameters: B-lines and Inferior venous collapsibility index (IVCi) in patients with acute kidney injury (AKI) in the ICU receiving renal replacement therapy (RRT).

Methods: We conducted a study on fifty sedated, mechanically ventilated patients with AKI requiring RRT in two hospitals. Exclusions included individuals under 18 years, pregnant women, cancer patients with no further treatment options, and patients receiving high-dose norepinephrine or any dose of vasopressin. We evaluated B lines and IVCi using both technologies at two-time points. Correlation tests were performed.

Results: A total of 200 exams were done with a mean age of 73.5±13, including 20 male patients (39%). Conventional HD was performed in 27.5% of cases, with a mean prescribed ultrafiltration of 1.6 ± 0.8 L. The correlation between the piezoelectric and microchip technologies for evaluating pulmonary B-lines was strongly positive, with correlation coefficients 0.96 and 0.93 at the beginning and 1st hour, respectively (P=0.001). Similarly, the correlation coefficients of tIVCi were 0.70 and 0.87 at the beginning and 1st hour, respectively (P=0.001), indicating a moderate correlation.

Conclusions: On AKI patients under RRT USG by Butterfly IQ microchip has an excellent correlation with traditional piezoeletric technology and combines advantages related to portability, easy handling and low cost with reliability in obtaining parameters for volume assessment obtained at the bedside.

Chronology of Cyst Epithelium Transformation to Renal Cell Carcinoma Through scRNA-seq

Sara Clerici, Daniel Spies, Alessandra Boletta. *IRCCS Ospedale San Raffaele, Milano, Italy.*

Background: We have described a mouse model suitable for studying the progression of renal cell carcinoma (RCC). Upon deletion of a single gene (*Tsc1*) by a kidney-specific Cre (*KspCre*) in specific segments of the nephron, the mTORC1-dependent downregulation of polycystin-1 initially triggers the establishment of an overt cystic phenotype. Mutated epithelial cells then transform into cancerous lesions. The slow progression of the phenotype allows to dissect between mechanisms driving cyst formation, and the ones supporting epithelium malignant transformation. However, mutant cells lose epithelial markers, making it difficult to follow the next steps of transformation.

Methods: Our RCC model (*Tsc1;kKO*) was crossed with *mTmG* strain, ubiquitously expressing membrane Tomato (mT) marker that recombines to mGFP (mG) upon KspCre expression, allowing to discriminate mutated cells over time. Mutant kidneys were characterized by histological and immunofluorescence analysis. Kidney single cell suspension was characterized by flow cytometry. Chromium 10x single cell RNA sequencing (scRNA-seq) was performed on 20 000 cells from P80 mutant and ctrl kidneys.

Results: *mTmG;Tsc1;kKO* mutants were comparable to our previous RCC model, with the epithelium lining the cysts progressively transforming to papillae (P20), cystadenomas (P50), and carcinomas (P80). All the structures identified were mG^+, allowing following the mutated cells during transformation. Indeed, flow cytometric analysis confirmed the expansion of the mG^+ population at P80, consistent with the reported prominent proliferation of *Tsc1* KO cells. scRNA-seq identified clusters of cells from all the segments of the nephron, both in mutant and ctrl kidneys. Cells deriving from the distal tubule and collecting duct were identified by *Egfp* transcript. This uniquely defined the *Tsc1* KO cells and their expansion in the mutated kidney. Interestingly, we identified sub-clusters of mG^+ cells with a proliferative and de-differentiated profile, and we observed the expansion of different immune populations in mutated kidneys, potentially supporting the RCC progression.

Conclusions: We generated a model of RCC through which we can dissect between driving events of cystogenesis and mechanisms supporting epithelial transformation to cancerous lesions. scRNA-seq represents a valuable approach to deciphering key mechanisms and new populations in RCC.

Selective V2 Vasopressin Receptor Blockade Increases Urinary Exosome Pendrin Expression in Patients with Autosomal Dominant Polycystic Kidney Disease

Matteo Bargagli,[1,2] Giuseppe Albano,[1] Daniel G. Fuster,[1] Pietro Manuel Ferraro.[2] [1]*Department of Nephrology and Hypertension, Inselspital, Bern University Hospital, University of Bern, Bern, Switzerland;* [2]*U.O.S. Terapia Conservativa della Malattia Renale Cronica, Fondazione Policlinico Universitario A. Gemelli IRCCS, Rome, Italy.*

Background: Tolvaptan, a selective V2 vasopressin receptor (V2R) antagonist, has shown to improve kidney function and acid retention biomarkers in ADPKD-treated patients. However, the underlying mechanisms of this association remain unclear. Here we investigated the effect of Tolvaptan on renal acid-base handling in ADPKD by analyzing the abundance in urinary exosomes of Pendrin and the B1 subunit of V-ATPase, which regulate HCO_3^- and H^+ transport in the collecting ducts.

Methods: In this prospective study, 24 ADPKD patients were enrolled from the Bern ADPKD registry. Patients were allocated with a 1:1 ratio in the Tolvaptan and no-Tolvaptan groups. All patients performed baseline and 2-year follow-up visits. Net acid excretion (NAE) and net gastrointestinal alkali absorption (NGIA), markers of acid and alkali intake, were calculated from 24h urines. Second morning spot urine samples with freshly added protease inhibitors and immediately frozen at –80 °C were used to isolate urinary exosome proteins with an already established differential centrifugation method. Primary polyclonal anti-rabbit antibodies for Pendrin and the B1 subunit of V-ATPase were used for immunoblotting. Changes in urinary exosome abundance were normalized by Alix (exosome housekeeping protein).

Results: 19 patients (9 with and 10 without Tolvaptan) were included in the final analysis. 5 patients were excluded because Alix was not detectable. Compared to baseline, urinary exosome Pendrin abundance increased by 134.4% only in Tolvaptan-treated patients ($p < 0.01$) after two years. Pendrin abundance strongly and directly correlated with NGIA (rho 0.75, $p < 0.01$) at baseline, and inversely with NAE (rho –0.51, $p = 0.03$) during follow-up. Urinary HCO_3^- excretion was associated with Pendrin expression over time (rho 0.73, $p < 0.01$). Ultimately, changes in urinary exosomal Pendrin were inversely associated with plasma potassium (rho –0.71, $p = 0.03$) only in the Tolvaptan group.

Conclusions: Urinary exosome Pendrin expression is sensitive to subtle changes in the acid-base status of ADPKD patients. Tolvaptan increases the expression of Pendrin in urinary exosomes, supporting the hypothesis that selective V2R blockade exerts an effect on systemic acid-base status of ADPKD patients.

TH-PO403

Automated Detection and Quantification of Individual Collagen Fibers Indicates Collagen Dynamics Underlying Increased Fibrotic Index in ADPKD

Caroline R. Sussman, Heather L. Holmes, Peter C. Harris, Michael F. Romero. *Mayo Foundation for Medical Education and Research, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the fourth leading cause of kidney failure. While cysts are the most obvious phenotype, accumulating evidence indicates the involvement of the extracellular matrix in in the kidney and other organs. The most abundant protein in this matrix is collagen, which is encoded by 44 genes comprising supramolecular assemblies making up 28 collagen types. As such, histological methods to assess overall collagen are valuable and routinely used in ADPKD research, yet they are limited by variability and insensitivity. We used CT-FIRE software that automatically detects individual collagen fibers to determine fiber density in glomeruli and tubules in an ADPKD mouse model.

Methods: Four-month-old *Pkd1*$^{RC/RC}$ mice were compared to WT. All mice were F1 progeny from a 129/C57BL6J cross. Kidneys were fixed, cryosectioned, and stained with Sirius red. Tissue area and fibrotic index were determined using ImageJ and collagen fibers were automatically detected using CT-FIRE fiber detection software (LOCI; Madison, WI). Statistical measurements were obtained using PRISM (GraphPad Software, Inc.).

Results: Standard brightfield imaging trended toward a higher fibrotic index in *Pkd1*$^{RC/RC}$ than WT, and individual fibers showed an increase in fiber density overall in *Pkd1*$^{RC/RC}$. Comparison of glomeruli vs tubules showed a higher density of fibers in glomeruli for both *Pkd1*$^{RC/RC}$ and WT. Fiber density did not differ in glomeruli of *Pkd1*$^{RC/RC}$ vs WT but was higher in *Pkd1*$^{RC/RC}$ tubules (see figure). There were no differences in fiber width, length, or straightness in either glomeruli or tubules between *Pkd1*$^{RC/RC}$ and WT.

Conclusions: These data demonstrate the potential of CT-FIRE software to provide more objective, higher resolution information about collagen in ADPKD. Mice used here had already developed cysts, but additional studies are needed to determine whether this approach can provide new insight into earlier-stage ADPKD.

TH-PO404

Correction of PKD by Gene Transfer into Pkd1-Null Mouse Model

Marie Trudel, Almira Kurbegovic. *Institut de Recherches Cliniques de Montreal, Montreal, QC, Canada.*

Background: Autosomal dominant polycystic kidney disease(ADPKD) causes renal cysts and insufficiency due mainly to PKD1 mutations. Since microscopic cysts in ADPKD kidneys are likely formed *in utero,* we re-expressed wild-type *Pkd1*/*Pc1* protein in *Pkd1*$^{-/-}$ mouse via germ line by series of complementary gene transfer to assess for long-term cure of severe cystogenesis and neonatal death.

Methods: Pc1 re-expression in the most severe mouse model *Pkd1*$^{-/-}$ was assessed by 3 strategies using genomic *Pkd1* under its own regulatory elements (*Pkd1*^{wt}), driven by kidney specific regulatory elements (900nt SB, ^{SB}*Pkd1*) or *Pkd1*^{Minigene}. Renal molecular (qPCR, IB), tubular (stainings, IF, RNAscope) and functional (BUN, hct) analyses were performed.

Results: *Pkd1*$^{-/-}$ mice targeted with 2 distinct *Pkd1*^{wt} gene transfers, of ~8-fold overexpression and intense RNAscope signal over all tubular segments and glomeruli similarly to endogenous cell profile, fully rescued PKD phenotype. ^{SB}*Pkd1* one- and high-copy gene transfers conveyed 0.6- or 7-fold *Pkd1* endogenous levels respectively. One-copy ^{SB}*Pkd1* transfer initiates cysts after birth ~P3 and confer sufficient *Pkd1* expression during maturation to correct proximal tubules and glomeruli, to minimize distal cyst and to postpone but not prevent cyst in collecting ducts. This transfer extended *Pkd1*$^{-/-}$ life survival by 4-fold. High-copy ^{SB}*Pkd1* transfer provide proper targeting and expression levels for complete rescue during renal maturation, and significantly retard cyst in proximal and collecting tubules at post-maturation but is insufficient to prevent distal cysts. This transfer increased lifespan by 25-fold. ^{SB}*Pkd1* transfers show that collecting tubules require higher *Pkd1* expression during maturation and that SB regulatory elements appreciably overlap with those of the endogenous promoter. High-copy renal *Pkd1*^{Mini} transfer resulted in similar expression to endogenous *Pkd1* with widespread and homogeneous weak *Pkd1* cellular signal, partially rescuing glomeruli and all cystic tubular segments during maturation and attained therapeutic levels with increased lifespan by 4-fold.

Conclusions: Our study determined that *Pkd1* intragenic sequences not only control levels of expression but alike the upstream sequences, also regulate spatio-temporal expression pattern. One-copy ^{SB}*Pkd1* is sufficient to substantially delay cystogenesis. Pc1 re-expression can considerably extend lifespan or eliminate PKD.

TH-PO405

Delivering Nucleic Acids to ADPKD Cystic Cells via a Nucleic Acid Binding and Cell-Penetrating Antibody

Laura Onuchic, Elias Quijano, Marcela A. Reyna-Neyra, Victoria Rai, Peter M. Glazer, Michael J. Caplan. *Yale School of Medicine, New Haven, CT.*

Background: Mutations in *PKD1*, which encodes polycystin-1 (PC1), cause ~78% of autosomal dominant polycystic kidney disease (ADPKD) cases. We have shown that transgenic expression of the 200-aa PC1 C-terminal tail (CTT) in the Pkd1$^{fl/fl}$;Pax8^{rtTA};TetO-Cre (*Pkd1*-KO) mouse model of ADPKD suppresses cystic phenotype and preserves renal function. To overcome the challenge of delivering CTT-encoding cDNA or mRNA to cystic epithelia we used the lupus-derived antibody 3E10-D31N and its humanized version, V66. These cell-penetrating antibodies non-covalently bind and deliver nucleic acids to tumors by targeting the nucleoside transporter ENT2. Specific targeting of tumors occurs due to increased ENT2 expression in proliferative tissues.

Methods: Trial #1: one 200μg dose of 3E10-D31N labeled with fluorochrome IR700, administered to 11-week *Pkd1*-KO mice. Trial #2: 3 doses of V66 (100μg/dose) combined with mRNA encoding GFP (20μg/dose), administered 24 hours apart to 13-week *Pkd1*-KO mice. In vivo imaging system (IVIS) and immunofluorescence microscopy (IF) were used to assess treatment results.

Results: IVIS imaging of Trial #1 kidneys revealed absence of fluorescently labeled 3E10-D31N in untreated controls, suggesting specificity of the total radiant efficiency (TRE) observed in treated WT and pre-cystic mice. Interestingly, treated pre-cystic mice showed an ~ 50% increase in TRE relative to treated WT, suggesting that this approach can successfully target highly proliferative ADPKD tissue. IVIS imaging of kidneys from Trial #2 revealed GFP fluorescence only in cystic kidneys from mice that were treated with V66/GFP mRNA, and not in cystic tissue from mice that received GFP mRNA alone or untreated mice. Interestingly, a positive correlation was observed between kidney size and TRE levels. Finally, IF studies revealed GFP present in a punctate cytoplasmic pattern in cystic epithelial cells of animals that received V66/GFP mRNA and not in controls.

Conclusions: 3E10-D31N/V66 targets cystic epithelia and delivers GFP mRNA that drives protein expression *in vivo.* We will next deliver CTT mRNA and assess protein expression and potential impacts of this intervention on the development of cystic phenotype. This strategy could support the delivery of other potentially therapeutic mRNAs or cDNAs in the context of other renal diseases.

Obesity and PKD: Mechanistic Studies Using the Pkd1RC/RC Model

Marie-Louise T. Monaghan, Dustin Nguyen, Michael D. Berger, Angelo D'Alessandro, Francesca I. Cendali, Berenice Y. Gitomer, Michel Chonchol, Katharina Hopp. *University of Colorado Anschutz Medical Campus, Aurora, CO.*

Background: Obesity is a covariate of more rapid kidney cyst growth in patients with Autosomal Dominant Polycystic Kidney Disease (ADPKD). Murine studies suggest that immune cell function and metabolic defects influence disease progression; both of which are altered in obesity. Caloric restriction (CR), in turn, slows PKD progression in mice.

Methods: Using the C57Bl/6J *Pkd1* p.R3277C (*Pkd1*$^{RC/RC}$) mouse, we established a diet-induced obesity model of ADPKD by *ad libitum* feeding a high fat diet (HFD, 42% calories from fat) from 4 weeks to 7 months of age; control diet (CD, 13% calories from fat, matched composition). PKD severity, fat mass (quantitative magnetic resonance), and kidney immune- (flow cytometry) and metabolic- (LC-MS/MS) state were assessed at study end.

Results: Compared to consumption of CD, HFD caused a 1.2-fold ($p<0.01$) increase in body weight in males (M)/females (F) and a 2.4-fold in M ($p<0.05$) and 1.8-fold in F ($p<0.05$) increase in fat mass. Interestingly, PKD severity only significantly worsened in females on HFD vs CD not males: increased kidney weight/femur length (1.4-fold, $p<0.01$), cyst- (1.98-fold, $p<0.01$) and fibrotic- volume (2-fold, $p<0.05$). Kidney metabolomics revealed significant dysregulation of the kynurenine pathway, which we recently identified as key modifier of PKD progression and immunosuppression, e.g., kynurenic acid (KA) increased by 3.1-fold (F) ($p<0.001$) and 1.28-fold (M) in mice on HFD vs CD. Of note, CR resulted in a 3-fold reduction in KA ($p<0.05$) in a separate age/sex matched study of *Pkd1*$^{RC/RC}$ mice. Correlatively, the kidney immune landscape of *Pkd1*$^{RC/RC}$ mice on HFD significantly shifted towards immunosuppression with increased numbers of M2-like infiltrating macrophages (1.45-fold, <0.01), $CD4^+$ T_{Regs} (1.96-fold, $p<0.05$), and T cell PD-1 expression (1.8-fold, <0.01).

Conclusions: We established a model of ADPKD that mimics clinical findings of patients with ADPKD and high adiposity, although the sex dimorphism needs further investigation. We also outline kynurenines/immunosuppression as a potential mechanistic link. The model will allow evaluation of novel therapeutic/nutritional avenues to reduce adiposity and slow PKD progression as well as adiposity-linked mechanisms driving kidney cyst growth.

TH-PO407

A Novel Kidney-Selective AMPK Activator Slows Renal Cystic Disease and Fibrosis in PKD Mice

Yan Zhang,[1,2] Emily A. Daniel,[1] Yuqiao Dai,[1] Gail Reif,[1] Ken W. Batchelor,[3] Darren P. Wallace.[1] [1]*University of Kansas Medical Center Department of Internal Medicine, Kansas City, KS;* [2]*Michigan Technological University, Houghton, MI;* [3]*Pano Therapeutics, Inc, Haleiwa, HI.*

Background: ADPKD is characterized by progressive enlargement of fluid-filled cysts, leading to inflammation and fibrosis, and a decline in kidney function. Metformin, the only FDA-approved AMPK activator and most commonly used drug for the treatment of type 2 diabetes, reduced mTOR-mediated cell proliferation and CFTR-mediated ion transport in *Pkd1* mutant cells and inhibited cyst growth of rapid PKD models. However, metformin-associated lactic acidosis, a potentially lethal side effect, raises concerns about its application for long-term treatment of ADPKD. Metformin is a biguanide that requires an organic cation transporter (OCT) to be taken up by cells and is transported into the kidneys *via* OCT2; however, it is not a substract for OCTN1/2 and is eliminated in urine. In collaboration with Pano Therapeutics, we tested biguanides with improved potency for AMPK, OCT2, and OCTN1/2. PAN1021 was 38× more potent for OCT2 and >100× more potent of OCTN1/2 than metformin, thus reducing renal elimination. Previously, PAN1021 decreased mTOR signaling, proliferation, anion secretion, and *in vitro* cyst formation of human ADPKD cells. Here, we compared effects of PAN1021 and metformin on cyst disease, inflammation, and fibrosis in an orthologous PKD mouse model.

Methods: PAN1021 (100mg/kg) or metformin (300mg/kg) was delivered to *Pkd1*$^{RC/RC}$*;Pkd2*$^{+/-}$ mice, an early onset PKD model, by daily gavage from 5 to 20 wk. Mice were killed 3 h after the last treatment, and blood and kidneys were collected for analysis.

Results: PAN1021 had no effect on body weight, appearance, or behavior of the PKD mice, indicating that the drug was safe, and it caused a significant decrease in kidney weight (%body weight; KW/BW). By contrast, the metformin response was variable and half of the mice showed an increase in KW/BW. Both drugs reduced renal fibrosis and BUN. PAN1021 reduced P-S6/S6, a component of mTOR signaling, and PCNA, a proliferation marker. It potently reduced TNF-α and F480, inflammation markers, and α-SMA and collagen 1A1, fibrosis markers, and restored the levels of PPARα, a regulator of fatty acid oxidation.

Conclusions: A novel kidney-selective AMPK activator PAN1021 inhibits renal mTOR, cell proliferation, cyst growth, tissue inflammation, and fibrosis in PKD mice. PAN1021 has an OCT profile anticipated to reduce the risk of lactic acidosis in ADPKD patients.

TH-PO408

The Effect of Lowering Uric Acid with a Xanthine Oxidase Inhibitor on PKD in Mice

Anjana Chaudhary, Zhibin He, Daniel Atwood, Allen Davidoff, Charles L. Edelstein. *Univ of Colorado, Aurora, CO.*

Background: In rodents uricase converts uric acid (UA) to allantoin and uricase inhibition with oxonic acid (OXO) raises serum UA. The aim of the study was to determine the effects of lowering UA with the xanthine oxidase inhibitor, oxypurinol (Oxy), in a mouse model of PKD.

Methods: Pkd1$^{RC/RC}$ (RC) mice, a hypomorphic Pkd1 gene model. OXO (300 mg/kg) or Oxy (24 mg/kg) +L-arginine (increases solubility of Oxy) treatment from day 50 to 120 of age. UA measured by LC/MS-MS. Males+females analyzed together. Caspase-1 protein measured by immunoblot. Cyst index (% of kidney cystic) cyst number and cyst area determined on cross sections by a computerized algorithm.

Results: See Table. Pharmacokinetic studies in normal rodents showed a 5 -fold increase in serum UA 2 hrs after OXO dosing. Oxy did not affect PKD in mice likely because baseline UA levels were low in rodents (0.35 mg/dL) due to uricase. So, the effect of OXO that increases UA in mice was determined. In RC mice, OXO resulted in a significant increase in serum UA, 2 kidney/body weight ratio (2K/BW) (%) and cyst indices. Mechanisms of increased PKD caused by UA were investigated: OXO resulted in a 50% increase in serum UA and an increase in pro-inflammatory cytokines/chemokines in the kidney: IL-5, IL-6, CXCL1. On polarized light UA crystals were not seen and caspase-1, a marker of the inflammasome, was not increased in OXO-treated kidneys. Oxy resulted in a 300% decrease in serum UA and significantly decreased the increase in 2K/BW and cyst indices caused by increasing UA with OXO.

Conclusions: Increasing serum UA by inhibiting uricase with OXO results in an increase in kidney weight and cyst indices. The combination of OXO + Oxy decreased the increase in kidney weight and cyst indices induced by OXO. A potential mechanisms of how OXO causes increased cyst growth in RC mice is induction of a pro-inflammatory cytokine storm in the PKD kidney in the absence of UA crystalluria or inflammasome activation.

Funding: Commercial Support - XORTX Pharmaceuticals

TH-PO409

Therapeutic Blocking of IL-17A Binding to IL-17RA Diminishes PD-L1 Expression Is a Novel Therapeutic Approach for ADPKD

Snigdha Samarpita,[1,2] Xiaoyan Li,[1,2] Ewud Agborbesong,[1,2] Xia Zhou,[1,2] Vicente E. Torres,[1,2] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN.*

Background: Interleukin (IL) - 17A is a critical pro-inflammatory determinant that has been demonstrated to expedite cell proliferation and inflammatory responses in the disease microenvironment. Howbeit, its role in ADPKD has not yet been reported.

Methods: To verify the role of IL-17A in ADPKD, we administered cyanidin, a small molecule flavonoid that disrupts IL-17A/IL-17RA interaction, to *Pkd1* mutant mouse models. To determine the molecular basis of IL-17A/IL-17RA signaling inhibition, we performed western blotting, qRT-PCR and knockdown studies in *Pkd1* mutant renal epithelial cells and tissues. We also determined the relationship of IL-17A/IL-17RA signaling with PD-L1 immune-checkpoint molecule via co-IP and siRNA knockdown studies. Flow cytometry analysis was carried out to determine CD8 and CD4 Th17 cell population.

Results: We found that disruption of IL-17A/IL-17RA interaction by cyanidin significantly impeded cyst growth as well as the recruitment of macrophages via decreased levels of MCP-1 secretion into the cystic microenvironment in *Pkd1* mutant mouse kidneys. Mechanistically, ablation of IL-17A/IL-17RA signaling blunted the activation of PKD associated signaling pathways (AKT, MAPK, NF-κB) to reduce cyst growth and inflammatory responses in *Pkd1* mutant cells and kidneys. In essence, the therapeutic utility of IL-17A signaling blockade in inhibiting cyst proliferation was mediated via decrease in mitochondrial fragmentation in *Pkd1* mutant cells. Interruption of IL-17A binding to IL-17RA also reduced the expression of TGF-β and then abrogated renal fibrosis and collagen deposition in *Pkd1* mutant kidneys. We further found that - 1) disruption the interaction of IL-17A/IL-17RA with cyanidin and knockdown of IL-17RA decreased the expression of PD-L1 immune checkpoint molecule, and 2) IL-17RA interacted with PD-L1 to alter its activity. As a result, the adaptive immune response was tempered via dramatic rise in CD8+ T cells infiltration and reduction in the CD4+ Th17 population due to lowering of the levels of CCL-20.

Conclusions: This study elucidates the roles of IL-17A/IL-17RA signaling and its novel relationship with PD-L1 in ADPKD, suggesting that disruption of IL-17 signaling either alone or in combination with anti-PD-L1 immunotherapy can be a viable powerful strategy in ADPKD treatment.

TH-PO410

Targeting ALDH1A1 with Nanoparticle-Based Immunotherapy on Kidney PD-L1 Synergistically Delays Cyst Growth

Shasha Cheng,[1,2] Xiaoyan Li,[1,2] Xia Zhou,[1,2] James P. Calvet,[3] Xiaogang Li.[1,2] *[1]Mayo Clinic Department of Internal Medicine, Rochester, MN; [2]Mayo Clinic Department of Biochemistry and Molecular Biology, Rochester, MN; [3]Department of Biochemistry and Molecular Biology, University of Kansas Medical Center, Kansas, MO.*

Background: ALDH1A1 is responsible for oxidation of acetaldehyde in mammals, which is upregulated in various cancers to drive cancer growth. ALDH1A1 is associated with tumor immunity by regulating the ratio of effector T cells to Treg cells within tumor tissues. However, the role of ALDH1A1 and its relationship with PD-L1 as well as the PD-L1 mediated immune response in ADPKD remains elusive.

Methods: To investigate the role of ALDH1A1 and its relationship with PD-L1 in ADPKD, we treated Pkd1 mutant mouse models with the ALDH1A1 inhibitor DSF either alone or together with nanoparticles carrying PD-L1 antibody and evaluated their effect on cyst growth, immune response and fibrosis as well as on specific PKD associated signaling pathways by immunostaining, Western blot, qRT-PCR and flow cytometry analysis. To increase kidney specificity, nanoparticles were conjugated with PD-L1 and kidney specific cadherin-16 (CDH16) antibodies.

Results: ALDH1A1 was upregulated in cyst lining epithelial cells in *Pkd1* mutant kidneys. Targeting ALDH1A1 with its specific inhibitor DSF decreased cyst growth as seen by the decrease of cystic index, KW/BW ratio and BUN levels in *Pkd1$^{RC/RC}$* kidneys as well as cyst lining epithelial cell proliferation by the decrease of the activation of AURKA, AKT, S6 and STAT3. In addition, treatment with DSF decreased the expression of PD-L1 and activated the immune response characterized by the increase of CD8+ T cells as examined by flow cytometry analysis, and decrease the recruitment of macrophages. Our CHIP assay indicated that ALDH1A1 bound with the promoter of *PD-L1* to regulate its transcription. Treatment with DSF induced cystic renal epithelial cell death which should be mediated by the downregulation of PD-L1 and the activation of CD8+ T cells in *Pkd1$^{RC/RC}$* kidneys. ALDH1A1 can also bind with the promoter of *CCL2* to regulate its transcription, which is responsible for the recruitment of macrophages. Treatment with DSF and mesoporous silica nanoparticles (MSN) conjugated with PD-L1 and CDH16 antibodies has a synergistic effect on cyst growth.

Conclusions: ALDH1A1 is a novel transcription factor which binds the promoters of specific genes, such as *PD-L1*, *CCL2* and fibrotic genes. Targeting ALDH1A1 with its inhibitor either alone or in combination with nanoparticle-mediated PD-L1 antibody is a novel therapeutic strategy for ADPKD.

TH-PO411

New Therapy for Early-Stage Polycystic Kidney Disease: Combination of Difelikefalin and Tolvaptan

Juan Gao,[1] Kara Johnson,[1] Madison G. Haggard,[1] Ian B. Denys,[1] Mihran V. Naljayan,[1,2] Daniel R. Kapusta.[1] *[1]LSU Health New Orleans, New Orleans, LA; [2]DaVita Inc, Denver, CO.*

Background: We have reported that difelikefalin, a partial agonist of kappa opioid receptors, produces a centrally mediated water diuresis presumably by inhibiting the central release of vasopressin (AVP). Since plasma AVP is elevated and participates in mediating polycystic kidney disease (PKD), we tested the hypothesis that difelikefalin would be superior to the V2 AVP antagonist, tolvaptan, in slowing progression of early-stage PKD.

Methods: Three-month old PKD mice were divided into 4 groups and were treated daily (dose titrated to decrease urine osmolality) for 3-months with either difelikefalin, tolvaptan, combination of difelikefalin and tolvaptan (D+T), or vehicle. Glomeruli filtration rate (GFR; beginning, midterm, endpoint) and total kidney volume (TKV, calculated as length, width, and depth of kidneys after mice were sacrificed) were measured in each group. Metabolic studies were also performed to measure 24-hour urine output and water intake.

Results: The results demonstrated that in contrast to vehicle treatment, difelikefalin, tolvaptan, and D+T each prevented a significant decline in GFR during the 3-month PKD disease progression. However, at the termination of study only D+T markedly reduced TKV compared with vehicle treated PKD mice (188 ± 12 vs 228 ±10 mm^3, resp.). In other studies, it was shown that the same age PKD mice treated for 3-months with difelikefalin combined with a half dose of tolvaptan (D+1/2T) was as efficacious in preventing a decline in GFR and suppressing an increase in TKV as D+T. Compared to baseline levels, water intake and urine output were significantly elevated in PKD mice treated with tolvaptan and D+T. Importantly, PKD mice treated with D+1/2T had significantly reduced urine output and water intake than PKD mice treated with tolvaptan alone or D+T.

Conclusions: Together, these findings suggest that difelikefalin not only potentiates the effect of tolvaptan but also allows a reduced dose of tolvaptan to achieve the same protection of renal function and kidney size, but with less polyuria and polydipsia. Thus, the combination of half-dose tolvaptan and difelikefalin is superior to tolvaptan alone in maintaining GFR and TKV and causes fewer side effects. (Funding DoD W81XWH-22-1-0046)

First-in-Human Study of an mTORC1-Selective Inhibitor for the Treatment of ADPKD

Alex Dinh, Victor Dishy, Jason R. Waggoner, Dénes Csonka, Yifan Shi, Romer A. Gonzalez-Villalobos, Nikolay O. Bukanov, Maria Chiara Magnone, Matthew D. Breyer, James F. Tobin, Susan C. Wendel, Hideo Makimura. *Janssen Research and Development LLC, Raritan, NJ.*

Background: There are no disease modifying therapies currently available for patients with autosomal dominant polycystic kidney disease (ADPKD). The mechanistic target of rapamycin complex 1 (mTORC1) is a protein kinase complex and key regulator of cellular metabolism and proliferation that promotes cyst formation and growth. We are developing a mTORC1-selective inhibitor to slow kidney disease progression in patients with ADPKD while reducing the incidence of mTORC2-associated toxicities that have limited other rapalogs in ADPKD clinical trials. In addition to demonstrating selectivity for mTORC1 inhibition over mTORC2 inhibition, our compound has previously been demonstrated to reduce disease burden in ADPKD animal models. The objective of this first-in-human study was to assess the safety, tolerability and pharmacokinetics of single ascending doses of our compound in healthy adult volunteers.

Methods: In this double-blind, single ascending dose (SAD) study, we enrolled healthy adult volunteers into 4 sequential ascending dose cohorts. Subjects were randomized to receive our compound or placebo. Safety, tolerability and pharmacokinetics were assessed at baseline and at multiple timepoints after dosing.

Results: In this SAD study, our compound was safe and well tolerated at all dose levels examined. All adverse events related to our compound were mild. Concentrations of our compound increased with increasing doses.

Conclusions: Our compound was safe and well tolerated after a single dose in healthy volunteers. A planned phase 1b, multiple ascending dose study in patients with ADPKD will evaluate the safety, tolerability, pharmacokinetics, and pharmacodynamics with repeated doses of our compound.

Hypoxia-Inducible Factor-Prolyl Hydroxylase (HIF-PHD) Inhibitor Accelerates Liver Cyst Growth in Autosomal Dominant Polycystic Kidney Disease

Shun Takenaka, Saori Nishio. *Hokkaido Daigaku Daigakuin Igaku Kenkyuin, Sapporo, Japan.*

Background: It has been reported that hypoxia-inducible factor prolyl hydroxylase (HIF-PHD) inhibitor promotes renal cyst formation due to activation of HIF. However, the effect on liver cysts is unclear. In this study, we will analyze the effects of HIF-PHD inhibitor on liver cysts and their mechanisms.

Methods: We used *Pkd1* conditional knockout mice (*Pkd1*$^{flox/flox}$ *Mx-1-Cre* mice). Mice were injected with polyinosinic-polycytidylic acid for 6 consecutive days at 5 days of age to inactivate *Pkd1*. Both cystic and non-cystic mice were randomly assigned to vehicle-only and enarodustat-treated groups (non-Cystic (CT), non-Cystic (Ena), Cystic (CT) and Cystic (Ena) group). Enarodustat was mixed in feed. Mice were sacrificed at 8 weeks of age. We analyzed the phenotype of cystic livers by liver/body weight ratio (LV/BW), and cystic index (CI) which was defined as the percentage of areas occupied by cysts. For evaluation of cell proliferation, immunohistochemical staining for proliferating cell nuclear antigen (PCNA) was performed. We also performed western blotting of signaling pathway of cyst growth by using whole liver.

Results: There was no significant difference in body weight among 4 groups. Mice treated with enarodustat exhibited a significant high level of hematocrit in both non-Cystic (CT) and Cystic (Ena) groups ($p<0.01$). There was no significant difference in LW/BW, but the Cystic Index (CI) of liver was significantly elevated in Cystic (Ena) group (30.8±8.5%) than in Cystic (CT) group (18.0±5.9%; $p<0.05$). Masson-Trichrome staining showed accelerated liver fibrosis in the Cystic (Ena) group. PCNA positive cells in the cystic epithelial cells was higher in the Cystic (Ena) group than in the Cystic (CT) group ($p=0.02$). In immunohistochemical staining of glucose transporter 1, the positive area rate was significantly higher in the Cystic group than in the non-Cystic group and was significantly expressed in the Cystic (Ena) group. Western blotting showed that phosphorylated Erk and phosphorylated p70S6K tended to be upregulated in the Cystic (Ena) group.

Conclusions: HIF-PHD inhibitor accelerated liver cyst formation via proliferation of cyst lining cells by activating the MAPK pathway and mTOR pathway.

Time-Restricted Feeding and Autosomal Dominant Polycystic Kidney Disease: A Pilot, Randomized Clinical Trial

Cortney Steele,[1] Erin R. Coleman,[1] Diana George,[1] Heather Farmer-Bailey,[1] Sumana Ramanathan,[2] Adriana Gregory,[2] Wei Wang,[1] Berenice Y. Gitomer,[1] Michel Chonchol,[1] Elizabeth Thomas,[1] Timothy L. Kline,[2] Kristen L. Nowak.[1] *[1]University of Colorado Anschutz Medical Campus, Aurora, CO; [2]Mayo Clinic Minnesota, Rochester, MN.*

Background: Autosomal dominant polycystic kidney disease (ADPKD) is the most commonly inherited progressive kidney disease leading to cyst growth. Time-restricted feeding (TRF) is a novel fasting regimen that restricts eating to a particular window (typically 8 hrs/day) which could slow cyst growth based on preclinical models.

Methods: A 12-month, randomized controlled, single-blind, behavioral dietary intervention was utilized to compare TRF vs. a healthy eating advice without TRF control group (HE). Participants underwent baseline and 12-month measurements, including adherence via meal logging (primary outcome), anthropometric measures, blood/urine sampling, and magnetic resonance imaging (MRI) to determine height adjusted total kidney volume (htTKV) and abdominal adiposity (exploratory outcomes). The behavioral intervention sessions were taught by a registered dietician via zoom with classes held weekly for the 1st month and then monthly. Independent t-tests and Pearson's bivariate correlations were performed.

Results: Twenty-nine participants were randomized (TRF n=14, HE n=15) including (23 females (F) 48±9 yrs of age (mean±s.d.), body mass index (BMI) 32.0 ±5 kg/m^2, estimated glomerular filtration rate 75±24 ml/min/1.73m^{2,} and htTKV 710 [334,1018] ml/m (median [IQR]). 71% (n=10) of TRF and 87% (n=13) of HE participants completed the intervention. The eating window was 9.5±0.2 hours for TRF (60% achieving the 8-hour window) and 12.1±0.1(mean±s.d.) for HE groups ($p=0.07$). Likelihood to adhere to TRF at 12 months was 8±2 points (10-point likert scale). Both groups lost weight: -3.7 [-8.1,2.6] % and -3.6 [-8.1,-0.4] % (median[IQR]) in the TRF and HE group, respectively. Annual percent change in htTKV was 2.8 [0.8,4.3] % and 4.0 [-2.4,11.5] % in the TRF and HE groups, respectively. Both change in weight ($r=0.674$, $p=0.0002$) and change in visceral adipose volume ($r=0.54$, $p=0.009$) were positively correlated with change in htTKV.

Conclusions: Both TRF and HE groups lost modest weight after the 12-month intervention. The 8-hour eating window appeared to be difficult to adhere to in the TRF group, although satisfaction of adherence was high. Weight and adiposity loss may be more important drivers of kidney growth than timing of eating.

Development of a Clinical Trial Enrichment (CTE) Tool for Autosomal Dominant Polycystic Kidney Disease

Varun Aggarwal,[1] Susana Zaph,[4] Randolph J. Leiser,[4] Lauren E. Quinlan,[1] Zihan Cui,[1] Juan F. Morales,[1] Christine E. Miller,[1] Pronabesh Dasmahapatra,[4] Wendy Vanasco,[1,2] Klaus Romero,[1] Ronald D. Perrone,[3] Sorin V. Fedeles.[1,2] *[1]Critical Path Institute, Tucson, AZ; [2]Polycystic Kidney Disease Outcomes Consortium, Tucson, AZ; [3]Tufts Medical Center, Boston, MA; [4]Sanofi, Boston, MA.*

Background: Despite the regulatory advances in ADPKD including the qualification of total kidney volume (TKV) as a prognostic enrichment biomarker and its designation by the FDA as a reasonably likely surrogate endpoint, the clinical development paradigms for PKD remain challenging.

Methods: Registry (Mayo, Emory, Colorado), longitudinal (CRISP), and RCT data (HALT) were curated and mapped to Clinical Data Interchange Standards Consortium Study Data Tabulation Model (CDISC SDTM) standards. Model-Informed Drug Development (MIDD) approaches to predict time to end-stage renal disease (ESRD) were employed with estimated glomerular filtration rate (eGFR) decline and total kidney volume (TKV) as longitudinal markers. The data was divided with 80% for training and 20% for validation. To build the joint model, we identified the appropriate longitudinal progression model, the appropriate time to event ESRD model, and incorporated the impact of longitudinal markers on event hazard.
